- Number of Observations, which is the total number of observations used in the analysis, excluding observations with missing values
- Sum of Weights, if you specify a WEIGHT statement
- Mean of the dependent variable in the MODEL statement, or Weighted Mean if you specify a WEIGHT statement
- Sum of the dependent variable in the MODEL statement, or Weighted Sum if you specify a WEIGHT statement

Design Summary

When you specify a CLUSTER statement or a STRATA statement, the procedure displays a “Design Summary” table, which provides the following sample design information:

- Number of Strata, if you specify a STRATA statement
- Number of Strata Collapsed, if the procedure collapses strata
- Number of Clusters, if you specify a CLUSTER statement
- Overall Sampling Rate used to calculate the design effect, if you specify the DEFF option in the MODEL statement

Fit Statistics

By default, PROC SURVEYREG displays the following regression statistics in the “Fit Statistics” table:

- R-square for the regression
- Root MSE, which is the square root of the mean square error
- Denominator DF, which is the denominator degrees of freedom for the F tests and also the degrees of freedom for the t tests produced by the procedure

Stratum Information

When you specify the LIST option in the STRATA statement, PROC SURVEYREG displays a “Stratum Information” table, which provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Population Total, if you specify the TOTAL= option
- Sampling Rate, if you specify the TOTAL= option or the RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of nonmissing observations in the stratum.
- N Obs, which is the number of observations
- number of Clusters, if you specify a CLUSTER statement
- Collapsed, which has the value ‘Yes’ if the stratum is collapsed with another stratum before analysis

If PROC SURVEYREG collapses strata, the “Stratum Information” table also displays stratum information for the new, collapsed stratum. The new stratum has a Stratum Index of 0 and is labeled ‘Pooled’.

Class Level Information

If you use a CLASS statement to name classification variables, PROC SURVEYREG displays a “Class Level Information” table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

X'X Matrix

If you specify the XPX option in the MODEL statement, PROC SURVEYREG displays the $X'X$ matrix, or the $X'WX$ matrix when there is a WEIGHT variable. This option also displays the crossproducts vector $X'y$ or $X'Wy$, where y is the response vector (dependent variable).

Inverse Matrix of X'X

If you specify the INV option in the MODEL statement, PROC SURVEYREG displays the inverse or the generalized inverse of the $X'X$ matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the $X'WX$ matrix.

ANOVA for Dependent Variable

If you specify the ANOVA option in the model statement, PROC SURVEYREG displays an analysis of variance table for the dependent variable. This table is identical to the ANOVA table displayed by the GLM procedure.

Tests of Model Effects

By default, PROC SURVEYREG displays a “Tests of Model Effects” table, which provides Wald’s F test for each effect in the model. The table contains the following information for each effect:

- Effect, which is the effect name
- Num DF, which is the numerator degrees of freedom for Wald’s F test
- F Value, which is Wald’s F statistic
- Pr > F, which is the significance probability corresponding to the F Value

A footnote displays the denominator degrees of freedom, which is the same for all effects.

Estimated Regression Coefficients

PROC SURVEYREG displays the “Estimated Regression Coefficients” table by default when there is no CLASS statement. Also, the procedure displays this table when you specify a CLASS statement and also specify the SOLUTIONS option in the MODEL statement. This table contains the following information for each regression parameter:

- Parameter, which identifies the effect or regressor variable
- Estimate, which is the estimate of the regression coefficient
- Standard Error, which is the standard error of the estimate
- t Value, which is the t statistic for testing $H_0: \text{Parameter} = 0$
- $\text{Pr} > |t|$, which is the two-sided significance probability corresponding to the t Value

Covariance of Estimated Regression Coefficients

When you specify the COVB option in the MODEL statement, PROC SURVEYREG displays the “Covariance of Estimated Regression Coefficients” matrix.

Coefficients of Contrast

When you specify the E option in a CONTRAST statement, PROC SURVEYREG displays a “Coefficients of Contrast” table for the contrast. You can use this table to check the coefficients you specified in the CONTRAST statement. Also, this table gives a note for a nonestimable contrast.

Analysis of Contrasts

If you specify a CONTRAST statement, PROC SURVEYREG produces an “Analysis of Contrasts” table, which displays Wald’s F test for the contrast. If you use more than one CONTRAST statement, the procedure displays all results in the same table. The “Analysis of Contrasts” table contains the following information for each contrast:

- Contrast, which is the label of the contrast
- Num DF, which is the numerator degrees of freedom for Wald’s F test
- F Value, which is Wald’s F statistic for testing $H_0: \text{Contrast} = 0$
- Pr > F, which is the significance probability corresponding to the F Value

Coefficients of Estimate

When you specify the E option in an ESTIMATE statement, PROC SURVEYREG displays a “Coefficients of Estimate” table for the linear function of the regression parameters in the ESTIMATE statement. You can use this table to check the coefficients you specified in the ESTIMATE statement. Also, this table gives a note for a nonestimable function.

Analysis of Estimable Functions

If you specify an ESTIMATE statement, PROC SURVEYREG checks the function for estimability. If the function is estimable, PROC SURVEYREG produces an “Analysis of Estimable Functions” table, which displays the estimate and the corresponding t test. If you use more than one ESTIMATE statement, the procedure displays all results in the same table. The table contains the following information for each estimable function:

- Parameter, which is the label of the function
- Estimate, which is the estimate of the estimable liner function
- Standard Error, which is the standard error of the estimate
- t Value, which is the t statistic for testing $H_0: \text{Estimable Function} = 0$
- Pr > | t |, which is the two-sided significance probability corresponding to the t Value

Output Data Sets

Output data sets from PROC SURVEYREG are produced using ODS (Output Delivery System). ODS encompasses more than just the production of output data sets. For example, you can use ODS to manipulate the format of your output, the headers and titles of the tables, the order of the columns in a table. For a more detailed description on using ODS, see Chapter 14, “Using the Output Delivery System.”

ODS Table Names

PROC SURVEYREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 71.2. ODS Tables Produced in PROC SURVEYREG

ODS Table Name	Description	Statement	Option
ANOVA	ANOVA for dependent variable	MODEL	ANOVA
ClassVarInfo	Class level information	CLASS	default
ContrastCoef	Coefficients of contrast	CONTRAST	E
Contrasts	Analysis of contrasts	CONTRAST	default
CovB	Covariance of estimated regression coefficients	MODEL	COVB
DataSummary	Data summary	MODEL	default
DesignSummary	Design summary	STRATA CLUSTER	default
Effects	Tests of model effects	MODEL	
EstimateCoef	Coefficients of estimate	ESTIMATE	E
Estimates	Analysis of estimable functions	ESTIMATE	default
FitStatistics	Fit Statistics	MODEL	default
InvXPX	Inverse matrix of $X'X$	MODEL	INV
ParameterEstimates	Estimated regression coefficients	MODEL	default
StrataInfo	Stratum information	STRATA	LIST
XPX	$X'X$ matrix	MODEL	XPX

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set named `MyStrata`, which contains the “StrataInfo” table, an output data set named `MyParmEst`, which contains the “ParameterEstimates” table, and an output data set named `Cov`, which contains the “CovB” table for the ice cream study discussed in the section “[Stratified Sampling](#)” on page 4368:

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
  strata Grade /list;
  class Kids;
  model Spending = Income Kids / solution covb;
  weight Weight;
  ods output StrataInfo = MyStrata
             ParameterEstimates = MyParmEst
             CovB = Cov;
run;

```

Note that the option CovB is specified in the MODEL statement in order to produce the covariance matrix table.

Examples

Example 71.1. Simple Random Sampling

This example investigates the relationship between the labor force participation rate (LFPR) of women in 1968 and 1972 in large cities in the United States. A simple random sample of 19 cities is drawn from a total of 200 cities. For each selected city, the LFPRs are recorded and saved in a SAS data set named `Labor`. The LFPR in 1972 is contained in the variable `LFPR1972`, and the LFPR in 1968 is identified by the variable `LFPR1968`:

```
data Labor;
  input City $ 1-16 LFPR1972 LFPR1968;
  datalines;
New York      .45      .42
Los Angeles   .50      .50
Chicago       .52      .52
Philadelphia  .45      .45
Detroit       .46      .43
San Francisco .55      .55
Boston        .60      .45
Pittsburgh    .49      .34
St. Louis     .35      .45
Connecticut   .55      .54
Washington D.C. .52      .42
Cincinnati    .53      .51
Baltimore     .57      .49
Newark        .53      .54
Minn/St. Paul .59      .50
Buffalo       .64      .58
Houston       .50      .49
Patterson     .57      .56
Dallas        .64      .63
;
```

Assume that the LFPRs in 1968 and 1972 have a linear relationship, as shown in the following model:

$$\text{LFPR1972} = \beta_0 + \beta_1 * \text{LFPR1968} + \text{error}$$

You can use PROC SURVEYREG to obtain the estimated regression coefficients and estimated standard errors of the regression coefficients. The following statements perform the regression analysis:

```
title 'Study of Labor Force Participation Rates of Women';
proc surveyreg data=Labor total=200;
  model LFPR1972 = LFPR1968;
run;
```

Here, the TOTAL=200 option specifies the finite population total from which the simple random sample of 19 cities is drawn. You can specify the same information by using the sampling rate option RATE=0.095 (19/200=.095).

Output 71.1.1. Summary of Regression Using Simple Random Sampling

```

Study of Labor Force Participation Rates of Women

The SURVEYREG Procedure

Regression Analysis for Dependent Variable LFPR1972

Data Summary

Number of Observations           19
Mean of LFPR1972                 0.52684
Sum of LFPR1972                 10.01000

Fit Statistics

R-square                          0.3970
Root MSE                          0.05657
Denominator DF                    18

```

Output 71.1.1 summarizes the data information, the fit information.

Output 71.1.2. Regression Coefficient Estimates

```

Study of Labor Force Participation Rates of Women

The SURVEYREG Procedure

Regression Analysis for Dependent Variable LFPR1972

Tests of Model Effects

Effect          Num DF    F Value    Pr > F
-----
Model              1      13.84    0.0016
Intercept          1       4.63    0.0452
LFPR1968           1      13.84    0.0016

NOTE: The denominator degrees of freedom for the F tests is 18.

Estimated Regression Coefficients

Parameter      Estimate      Standard
              Error      t Value    Pr > |t|
-----
Intercept      0.20331056   0.09444296    2.15    0.0452
LFPR1968      0.65604048   0.17635810    3.72    0.0016

NOTE: The denominator degrees of freedom for the t tests is 18.

```

Output 71.1.2 presents the significance tests for the model effects and estimated regression coefficients. The F tests and t tests for the effects in the model are also presented in these tables.

From the regression performed by PROC SURVEYREG, you obtain a positive estimated slope for the linear relationship between the LFPR in 1968 and the LFPR in 1972. The regression coefficients are all significant at the 5% level. Effects Intercept and LFPR1968 are significant in the model at the 5% level. In this example, the F test for the overall model without intercept is the same as the effect LFPR1968.

Example 71.2. Simple Random Cluster Sampling

This example illustrates the use of regression analysis in a simple random cluster sample design. The data are from Särndal, Swenson, and Wretman (1992, p. 652).

A total of 284 Swedish municipalities are grouped into 50 clusters of neighboring municipalities. Five clusters with a total of 32 municipalities are randomly selected. The results from the regression analysis in which clusters are used in the sample design are compared to the results of a regression analysis that ignores the clusters. The linear relationship between the population in 1975 and in 1985 is investigated.

The 32 selected municipalities in the sample are saved in the data set Municipalities:

```

data Municipalities;
  input Municipality Cluster Population85 Population75;
datalines;
205 37 5 5
206 37 11 11
207 37 13 13
208 37 8 8
209 37 17 19
6 2 16 15
7 2 70 62
8 2 66 54
9 2 12 12
10 2 60 50
94 17 7 7
95 17 16 16
96 17 13 11
97 17 12 11
98 17 70 67
99 17 20 20
100 17 31 28
101 17 49 48
276 50 6 7
277 50 9 10
278 50 24 26
279 50 10 9
280 50 67 64
281 50 39 35
282 50 29 27
283 50 10 9
284 50 27 31

```

```

52  10   7   6
53  10   9   8
54  10  28  27
55  10  12  11
56  10 107 108

```

```
;
```

The variable Municipality identifies the municipalities in the sample; the variable Cluster indicates the cluster to which a municipality belongs; and the variables Population85 and Population75 contain the municipality populations in 1985 and in 1975 (in thousands), respectively. A regression analysis is performed by PROC SURVEYREG with a CLUSTER statement:

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Cluster Simple Random Sampling';
proc surveyreg data=Municipalities total=50;
  cluster Cluster;
  model Population85=Population75;
run;

```

The TOTAL=50 option specifies the total number of clusters in the sampling frame.

Output 71.2.1. Regression Analysis for Simple Random Cluster Sampling

Regression Analysis for Swedish Municipalities				
Cluster Simple Random Sampling				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable Population85				
Data Summary				
Number of Observations				32
Mean of Population85				27.50000
Sum of Population85				880.00000
Design Summary				
Number of Clusters				5
Fit Statistics				
R-square				0.9860
Root MSE				3.0488
Denominator DF				4
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	-0.0191292	0.89204053	-0.02	0.9839
Population75	1.0546253	0.05167565	20.41	<.0001
NOTE: The denominator degrees of freedom for the t tests is 4.				

Output 71.2.1 displays the data summary, design summary, fit statistics, and regression coefficient estimates. Since the sample design includes clusters, the procedure displays the total number of clusters in the sample in the “Design Summary” table. In the “Estimated Regression Coefficients” table, the estimated slope for the linear relationship is 1.05, which is significant at the 5% level; but the intercept is not significant. This suggests that a regression line crossing the original can be established between populations in 1975 and in 1985.

The CLUSTER statement is necessary in PROC SURVEYREG in order to incorporate the sample design. If you do not specify a CLUSTER statement in the regression analysis, the standard deviation of the regression coefficients will be incorrectly estimated:

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Simple Random Sampling';
proc surveyreg data=Municipalities total=284;
  model Population85=Population75;
run;

```

The analysis ignores the clusters in the sample, assuming that the sample design is a simple random sampling. Therefore, the TOTAL= option specifies the total number of municipalities, which is 284.

Output 71.2.2. Regression Analysis for Simple Random Sampling

Regression Analysis for Swedish Municipalities				
Simple Random Sampling				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable Population85				
Data Summary				
Number of Observations			32	
Mean of Population85			27.50000	
Sum of Population85			880.00000	
Fit Statistics				
R-square			0.9860	
Root MSE			3.0488	
Denominator DF			31	
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	-0.0191292	0.67417606	-0.03	0.9775
Population75	1.0546253	0.03668414	28.75	<.0001
NOTE: The denominator degrees of freedom for the t tests is 31.				

Output 71.2.2 displays the regression results ignoring the clusters. Compared to the results in Output 71.2.1 on page 4398, the regression coefficient estimates are the same. However, without using clusters, the regression coefficients have a smaller variance estimate in Output 71.2.2. Using clusters in the analysis, the estimated regression coefficient for effect Population75 is 1.05, with the estimated standard error 0.05, as displayed in Output 71.2.1; without using the clusters, the estimate is 1.05, but with the estimated standard error 0.04, as displayed in Output 71.2.2. To estimate the variance of the regression coefficients correctly, you should include the clustering information in the regression analysis.

Example 71.3. Regression Estimator for Simple Random Sample

Using auxiliary information, you can construct the regression estimators to provide more accurate estimates of the population characteristics that are of interest. With ESTIMATE statements in PROC SURVEYREG, you can specify a regression estimator as a linear function of the regression parameters to estimate the population total. This example illustrates this application, using the data in the previous example.

In this sample, a linear model between the Swedish populations in 1975 and in 1985 is established:

$$\text{Population85} = \alpha + \beta * \text{Population75} + \text{error}$$

Assuming that the total population in 1975 is known to be 8200 (in thousands), you can use the ESTIMATE statement to predict the 1985 total population using the following statements:

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Estimate Total Population';
proc surveyreg data=Municipalities total=50;
  cluster Cluster;
  model Population85=Population75;
  estimate '1985 population' Intercept 284 Population75 8200;
run;

```

Since each observation in the sample is a municipality, and there is a total of 284 municipalities in Sweden, the coefficient for Intercept (α) in the ESTIMATE statement is 284, and the coefficient for Population75 (β) is the total population in 1975 (8.2 million).

Output 71.3.1. Use the Regression Estimator to Estimate the Population Total

```

Regression Analysis for Swedish Municipalities
Estimate Total Population

The SURVEYREG Procedure

Regression Analysis for Dependent Variable Population85

Analysis of Estimable Functions

Parameter              Estimate          Standard
                        Error              t Value      Pr > |t|
1985 population      8642.49485      258.558613    33.43        <.0001

NOTE: The denominator degrees of freedom for the t tests is 4.
```

Output 71.3.1 displays the regression results and the estimation of the total population. Using the linear model, you can predict the total population in 1985 to be 8.64 million, with a standard error of 0.26 million.

Example 71.4. Stratified Sampling

This example illustrates using the SURVEYREG procedure to perform a regression in a stratified sample design. Consider a population of 235 farms producing corn in Nebraska and Iowa. You are interested in the relationship between corn yield (CornYield) and the total farm size (FarmArea).

Each state is divided into several regions, and each region is used as a stratum. Within each stratum, a simple random sample with replacement is drawn. A total of 19 farms is selected using a stratified simple random sample. The sample size and population size within each stratum are displayed in Table 71.3.

Table 71.3. Number of Farms in Each Stratum

Stratum	State	Region	Number of Farms	
			Population	Sample
1	Iowa	1	100	3
2		2	50	5
3		3	15	3
4	Nebraska	1	30	6
5		2	40	2
	Total		235	19

Three models for the data are considered:

- Model I — Common intercept and slope:

$$\text{Corn Yield} = \alpha + \beta * \text{Farm Area}$$

- Model II — Common intercept, different slope:

$$\text{Corn Yield} = \begin{cases} \alpha + \beta_{\text{Iowa}} * \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha + \beta_{\text{Nebraska}} * \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases}$$

- Model III — Different intercept and different slope:

$$\text{Corn Yield} = \begin{cases} \alpha_{\text{Iowa}} + \beta_{\text{Iowa}} * \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha_{\text{Nebraska}} + \beta_{\text{Nebraska}} * \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases}$$

Data from the stratified sample are saved in the SAS data set `Farms`. In the data set `Farms`, the variable `Weight` represents the sampling weight. In this example, the sampling weights are reciprocal of selection probabilities:

```
data Farms;
  input State $ Region FarmArea CornYield Weight;
  datalines;
Iowa      1 100   54 33.333
Iowa      1  83   25 33.333
Iowa      1  25   10 33.333
Iowa      2 120   83 10.000
Iowa      2  50   35 10.000
Iowa      2 110   65 10.000
Iowa      2  60   35 10.000
Iowa      2  45   20 10.000
Iowa      3  23    5  5.000
Iowa      3  10    8  5.000
Iowa      3 350 125  5.000
Nebraska  1 130   20  5.000
Nebraska  1 245   25  5.000
Nebraska  1 150   33  5.000
Nebraska  1 263   50  5.000
Nebraska  1 320   47  5.000
Nebraska  1 204   25  5.000
Nebraska  2  80   11 20.000
Nebraska  2  48    8 20.000
;
```

The information on population size in each stratum is saved in the SAS data set `StratumTotals`:

```
data StratumTotals;
  input State $ Region _TOTAL_;
  datalines;
Iowa      1 100
Iowa      2  50
Iowa      3  15
Nebraska  1  30
Nebraska  2  40
;
```

Using the sample data from the data set `Farms` and the control information data from the data set `StratumTotals`, you can fit Model I using PROC SURVEYREG with the following statements:

```

title1 'Analysis of Farm Area and Corn Yield';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
  strata State Region / list;
  model CornYield = FarmArea;
  weight Weight;
run;

```

Output 71.4.1. Data Summary and Stratum Information Fitting Model I

Analysis of Farm Area and Corn Yield					
Model I: Same Intercept and Slope					
The SURVEYREG Procedure					
Regression Analysis for Dependent Variable CornYield					
Data Summary					
Number of Observations					19
Sum of Weights				234.99900	
Weighted Mean of CornYield				31.56029	
Weighted Sum of CornYield				7416.6	
Design Summary					
Number of Strata					5
Fit Statistics					
R-square				0.3882	
Root MSE				20.6422	
Denominator DF				14	
Stratum Information					
Stratum Index	State	Region	N Obs	Population Total	Sampling Rate
1	Iowa	1	3	100	3.00%
2		2	5	50	10.0%
3		3	3	15	20.0%
4	Nebraska	1	6	30	20.0%
5		2	2	40	5.00%

Output 71.4.1 displays the data summary and stratification information fitting Model I. The sampling rates are automatically computed by the procedure based on the sample sizes and the population totals in strata.

Output 71.4.2. Estimated Regression Coefficients and the Estimated Covariance Matrix

Analysis of Farm Area and Corn Yield				
Model I: Same Intercept and Slope				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable CornYield				
Tests of Model Effects				
Effect	Num DF	F Value	Pr > F	
Model	1	21.74	0.0004	
Intercept	1	4.93	0.0433	
FarmArea	1	21.74	0.0004	
NOTE: The denominator degrees of freedom for the F tests is 14.				
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	11.8162978	5.31981027	2.22	0.0433
FarmArea	0.2126576	0.04560949	4.66	0.0004
NOTE: The denominator degrees of freedom for the t tests is 14.				

Output 71.4.2 displays tests of model effects and the estimated regression coefficients.

Alternatively, you can assume that the linear relationship between corn yield (CornYield) and farm area (FarmArea) is different among the states (Model II). In order to analyze the data using this model, you create auxiliary variables FarmAreaNE and FarmAreaIA to represent farm area in different states:

$$\text{FarmAreaNE} = \begin{cases} 0 & \text{if the farm is in Iowa} \\ \text{FarmArea} & \text{if the farm is in Nebraska} \end{cases}$$

$$\text{FarmAreaIA} = \begin{cases} \text{FarmArea} & \text{if the farm is in Iowa} \\ 0 & \text{if the farm is in Nebraska} \end{cases}$$

The following statements create these variables in a new data set called FarmsByState and use PROC SURVEYREG to fit Model II:

```

title1 'Analysis of Farm Area and Corn Yield';
title2 'Model II: Same Intercept, Different Slopes';
data FarmsByState; set Farms;
  if State='Iowa' then do;
    FarmAreaIA=FarmArea ; FarmAreaNE=0; end;
  else do;
    FarmAreaIA=0 ; FarmAreaNE=FarmArea; end;
run;

```

The following statements perform the regression using the new data set FarmsByState. The analysis uses the auxiliary variables FarmAreaIA and FarmAreaNE as the regressors:

```
proc SURVEYREG data=FarmsByState total=StratumTotals;
  strata State Region;
  model CornYield = FarmAreaIA FarmAreaNE;
  weight Weight;
run;
```

Output 71.4.3. Regression Results from Fitting Model II

Analysis of Farm Area and Corn Yield				
Model II: Same Intercept, Different Slopes				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable CornYield				
Data Summary				
Number of Observations				19
Sum of Weights				234.99900
Weighted Mean of CornYield				31.56029
Weighted Sum of CornYield				7416.6
Design Summary				
Number of Strata				5
Fit Statistics				
R-square				0.8158
Root MSE				11.6759
Denominator DF				14
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	4.04234816	3.80934848	1.06	0.3066
FarmAreaIA	0.41696069	0.05971129	6.98	<.0001
FarmAreaNE	0.12851012	0.02495495	5.15	0.0001
NOTE: The denominator degrees of freedom for the t tests is 14.				

Output 71.4.3 displays the data summary, design information, fit statistics, and parameter estimates. The estimated slope parameters for each state are quite different from the estimated slope in Model I. The results from the regression show that Model II fits these data better than Model I.

For Model III, different intercepts are used for the linear relationship in two states. The following statements illustrate the use of the NOINT option in the MODEL statement associated with the CLASS statement to fit Model III:

```

title2 'Model III: Different Intercepts and Slopes';
proc SURVEYREG data=FarmsByState total=StratumTotals;
  strata State Region;
  class State;
  model CornYield = State FarmAreaIA FarmAreaNE / noint covb solution;
  weight Weight;
run;

```

The model statement includes the classification effect `State` as a regressor. Therefore, the parameter estimates for effect `State` will presents the intercepts in two states.

Output 71.4.4. Regression Results for Fitting Model III

Analysis of Farm Area and Corn Yield				
Model III: Different Intercepts and Slopes

FarmAreaIA	-0.205517205	0	0.0041711265	0
FarmAreaNE	0	-0.027354011	0	0.0003988349

Output 71.4.4 displays the regression results for fitting Model III, including the data summary, parameter estimates, and covariance matrix of the regression coefficients. The estimated covariance matrix shows a lack of correlation between the regression coefficients from different states. This suggests that Model III might be the best choice for building a model for farm area and corn yield in these two states.

However, some statistics remain the same under different regression models, for example, Weighted Mean of CornYield. These estimators do not rely on the particular model you use.

Example 71.5. Regression Estimator for Stratified Sample

This example uses the corn yield data from the previous example to illustrate how to construct a regression estimator for a stratified sample design.

Similar to Example 71.3 on page 4400, by incorporating auxiliary information into a regression estimator, the procedure can produce more accurate estimates of the population characteristics that are of interest. In this example, the sample design is a stratified sample design. The auxiliary information is the total farm areas in regions of each state, as displayed in Table 71.4. You want to estimate the total corn yield using this information under the three linear models given in Example 71.4.

Table 71.4. Information for Each Stratum

Stratum	State	Region	Number of Farms in		Total Farm Area
			Population	Sample	
1	Iowa	1	100	3	13,200
2		2	50	5	
3		3	15	3	
4	Nebraska	1	30	6	8,750
5		2	40	2	
	Total		235	19	21,950

The regression estimator to estimate the total corn yield under Model I can be obtained by using PROC SURVEYREG with an ESTIMATE statement:

```

title1 'Estimate Corn Yield from Farm Size';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
  strata State Region / list;
  class State Region;
  model CornYield = FarmArea State*Region /solution;
  weight Weight;
  estimate 'Estimate of CornYield under Model I'
          INTERCEPT 235 FarmArea 21950
          State*Region 100 50 15 30 40 /e;
run;

```

To apply the constraint in each stratum that the weighted total number of farms equals to the total number of farms in the stratum, you can include the strata as an effect in the MODEL statement, effect State*Region. Thus, the CLASS statement must list the STRATA variables, State and Region, as classification variables. The following

ESTIMATE statement specifies the regression estimator, which is a linear function of the regression parameters:

```
estimate 'Estimate of CornYield under Model I'
        INTERCEPT 235 FarmArea 21950
        State*Region 100 50 15 30 40 /e;
```

This linear function contains the total for each explanatory variable in the model. Because the sampling units are farms in this example, the coefficient for Intercept in the ESTIMATE statement is the total number of farms (235); the coefficient for FarmArea is the total farm area listed in [Table 71.4](#) (21950); and the coefficients for effect State*Region are the total number of farms in each strata (as displayed in [Table 71.4](#)).

Output 71.5.1. Regression Estimator for the Total of CornYield under Model I

Estimate Corn Yield from Farm Size				
Model I: Same Intercept and Slope				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable CornYield				
Analysis of Estimable Functions				
Parameter	Estimate	Standard Error	t Value	Pr > t
Estimate of CornYield under Model I	7463.52329	926.841541	8.05	<.0001

NOTE: The denominator degrees of freedom for the t tests is 14.

[Output 71.5.1](#) displays the results of the ESTIMATE statement. The regression estimator for the total of CornYield in Iowa and Nebraska is 7464 under Model I, with a standard error of 927.

Under Model II, a regression estimator for totals can be obtained using the following statements:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model II: Same Intercept, Different Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
  strata State Region;
  class State Region;
  model CornYield = FarmAreaIA FarmAreaNE
              state*region /solution;
  weight Weight;
  estimate 'Total of CornYield under Model II'
          INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
          State*Region 100 50 15 30 40 /e;
run;
```

In this model, you also need to include strata as a fixed effect in the MODEL statement. Other regressors are the auxiliary variables FarmAreaIA and FarmAreaNE (defined in Example 71.4). In the following ESTIMATE statement, the coefficient for Intercept is still the total number of farms; and the coefficients for FarmAreaIA and FarmAreaNE are the total farm area in Iowa and Nebraska, respectively, as displayed in Table 71.4. The total number of farms in each strata are the coefficients for the strata effect:

```
estimate 'Total of CornYield under Model II'
        INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
        State*Region 100 50 15 30 40 /e;
```

Output 71.5.2. Regression Estimator for the Total of CornYield under Model II

Estimate Corn Yield from Farm Size				
Model II: Same Intercept, Different Slopes				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable CornYield				
Analysis of Estimable Functions				
Parameter	Estimate	Standard Error	t Value	Pr > t
Total of CornYield under Model II	7580.48657	859.180439	8.82	<.0001
NOTE: The denominator degrees of freedom for the t tests is 14.				

Output 71.5.2 displays that the results of the regression estimator for the total of corn yield in two states under Model II is 7580 with a standard error of 859. The regression estimator under Model II has a slightly smaller standard error than under Model I.

Finally, you can apply Model III to the data and estimate the total corn yield. Under Model III, you can also obtain the regression estimators for the total corn yield for each state. Three ESTIMATE statements are used in the following statements to create the three regression estimators:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model III: Different Intercepts and Slopes';
proc SURVEYREG data=FarmsByState total=StratumTotals;
  strata State Region;
  class State Region;
  model CornYield = state FarmAreaIA FarmAreaNE
        State*Region /noint solution;
  weight Weight;
  estimate 'Total CornYield in Iowa under Model III'
        State 165 0 FarmAreaIA 13200 FarmAreaNE 0
        State*region 100 50 15 0 0 /e;
  estimate 'Total CornYield in Nebraska under Model III'
```

```

State 0 70 FarmAreaIA 0 FarmAreaNE 8750
State*Region 0 0 0 30 40 /e;
estimate 'Total CornYield in both states under Model III'
State 165 70 FarmAreaIA 13200 FarmAreaNE 8750
State*Region 100 50 15 30 40 /e;
run;

```

The fixed effect `State` is added to the `MODEL` statement to obtain different intercepts in different states, using the `NOINT` option. Among the `ESTIMATE` statements, the coefficients for explanatory variables are different depending on which regression estimator is estimated. For example, in the `ESTIMATE` statement

```

estimate 'Total CornYield in Iowa under Model III'
State 165 0 FarmAreaIA 13200 FarmAreaNE 0
State*region 100 50 15 0 0 /e;

```

the coefficients for the effect `State` are 165 and 0, respectively. This indicates that the total number of farms in Iowa is 165 and the total number of farms in Nebraska is 0, because the estimation is the total corn yield in Iowa only. Similarly, the total numbers of farms in three regions in Iowa are used for the coefficients of the strata effect `State*Region`, as displayed in [Table 71.4](#).

Output 71.5.3. Regression Estimator for the Total of CornYield under Model III

Estimate Corn Yield from Farm Size Model III: Different Intercepts and Slopes			
The SURVEYREG Procedure			
Regression Analysis for Dependent Variable CornYield			
Analysis of Estimable Functions			
Parameter	Estimate	Standard Error	t Value
Total CornYield in Iowa under Model III	6246.10697	851.272372	7.34
Total CornYield in Nebraska under Model III	1334.37961	116.302948	11.47
Total CornYield in both states under Model III	7580.48657	859.180439	8.82
Analysis of Estimable Functions			
Parameter	Pr > t		
Total CornYield in Iowa under Model III	<.0001		
Total CornYield in Nebraska under Model III	<.0001		
Total CornYield in both states under Model III	<.0001		
NOTE: The denominator degrees of freedom for the t tests is 14.			

[Output 71.5.3](#) displays the results from the three regression estimators using Model III. Since the estimations are independent in each state, the total corn yield from both states is equal to the sum of the estimated total of corn yield in Iowa and Nebraska,

$6246 + 1334 = 7580$. This regression estimator is the same as the one under Model II. The variance of regression estimator of the total corn yield in both states is the sum of variances of regression estimators for total corn yield in each state. Therefore, it is not necessary to use Model III to obtain the regression estimator for the total corn yield unless you need to estimate the total corn yield for each individual state.

Example 71.6. Stratum Collapse

In a stratified sample, it is possible that some strata will have only one sampling unit. When this happens, PROC SURVEYREG collapses the strata that contain a single sampling unit into a pooled stratum. For more detailed information on stratum collapse, see the section “[Stratum Collapse](#)” on page 4388.

Suppose that you have the following data:

```
data Sample;
  input Stratum X Y W;
  datalines;
10 0 0 5
10 1 1 5
11 1 1 10
11 1 2 10
12 3 3 16
33 4 4 45
14 6 7 50
12 3 4 16
;
```

The variable `Stratum` is again the stratification variable, the variable `X` is the independent variable, and the variable `Y` is the dependent variable. You want to regress `Y` on `X`. In the data set `Sample`, both `Stratum=33` and `Stratum=14` contain one observation. By default, PROC SURVEYREG collapses these strata into one pooled stratum in the regression analysis.

To input the finite population correction information, you create the SAS data set `StratumTotals`:

```
data StratumTotals;
  input Stratum _TOTAL_;
  datalines;
10 10
11 20
12 32
33 40
33 45
14 50
15 .
66 70
;
```

The variable `Stratum` is the stratification variable, and the variable `_TOTAL_` contains the stratum totals. The data set `StratumTotals` contains more strata than the data set `Sample`. Also in the data set `StratumTotals`, more than one observation contains the stratum totals for `Stratum=33`:

```
33 40
33 45
```

PROC SURVEYREG allows this type of input. The procedure simply ignores strata that are not present in the data set `Sample`; for the multiple entries of a stratum, the procedure uses the first observation. In this example, `Stratum=33` has the stratum total `_TOTAL_=40`.

The following SAS statements perform the regression analysis:

```
title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'With Stratum Collapse';
proc SURVEYREG data=Sample total=StratumTotals;
  strata Stratum/list;
  model Y=X;
  weight W;
run;
```

Output 71.6.1. Summary of Data and Regression

Stratified Sample with Single Sampling Unit in Strata With Stratum Collapse	
The SURVEYREG Procedure	
Regression Analysis for Dependent Variable Y	
Data Summary	
Number of Observations	8
Sum of Weights	157.00000
Weighted Mean of Y	4.31210
Weighted Sum of Y	677.00000
Design Summary	
Number of Strata	5
Number of Strata Collapsed	2
Fit Statistics	
R-square	0.9564
Root MSE	0.5111
Denominator DF	4

Output 71.6.1 displays that there are a total of five strata in the input data set, and two strata are collapsed into a pooled stratum. The denominator degrees of freedom

is 4, due to the collapse (see the section “Denominator Degrees of Freedom” on page 4386).

Output 71.6.2. Stratification Information

Stratified Sample with Single Sampling Unit in Strata With Stratum Collapse						
The SURVEYREG Procedure						
Regression Analysis for Dependent Variable Y						
Stratum Information						
Stratum Index	Collapsed	Stratum	N Obs	Population Total	Sampling Rate	
1		10	2	10	20.0%	
2		11	2	20	10.0%	
3		12	2	32	6.25%	
4	Yes	14	1	50	2.00%	
5	Yes	33	1	40	2.50%	
0	Pooled		2	90	2.22%	

NOTE: Strata with only one observation are collapsed into the stratum with Stratum Index "0".

Output 71.6.2 displays the stratification information, including stratum collapse. Under the column Collapsed, the fourth stratum (Stratum=14) and the fifth (Stratum=33) are marked as ‘Yes’, which indicates that these two strata are collapsed into the pooled stratum (Stratum Index=0). The sampling rate for the pooled stratum is 2% (see the section “Sampling Rate of the Pooled Stratum from Collapse” on page 4389).

Output 71.6.3. Parameter Estimates and Effect Tests

Stratified Sample with Single Sampling Unit in Strata With Stratum Collapse				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable Y				
Tests of Model Effects				
Effect	Num DF	F Value	Pr > F	
Model	1	173.01	0.0002	
Intercept	1	0.00	0.9961	
X	1	173.01	0.0002	
NOTE: The denominator degrees of freedom for the F tests is 4.				
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	0.00179469	0.34306373	0.01	0.9961
X	1.12598708	0.08560466	13.15	0.0002
NOTE: The denominator degrees of freedom for the t tests is 4.				

Output 71.6.3 displays the parameter estimates and the tests of the significance of the model effects.

Alternatively, if you prefer not to collapse strata with a single sampling unit, you can specify the NOCOLLAPSE option in the STRATA statement:

```

title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'Without Stratum Collapse';
proc SURVEYREG data=Sample total=StratumTotals;
  strata Stratum/list nocollapse;
model Y = X;
weight W;
run;

```

Output 71.6.4. Summary of Data and Regression

```

Stratified Sample with Single Sampling Unit in Strata
Without Stratum Collapse

The SURVEYREG Procedure

Regression Analysis for Dependent Variable Y

Data Summary

Number of Observations      8
Sum of Weights              157.00000
Weighted Mean of Y          4.31210
Weighted Sum of Y           677.00000

Design Summary

Number of Strata            5

Fit Statistics

R-square                    0.9564
Root MSE                    0.5111
Denominator DF              3
    
```

Output 71.6.4 does not contain the stratum collapse information displayed in Output 71.6.1, and the denominator degrees of freedom is 3 instead of 4.

Output 71.6.5. Stratification Information

```

Stratified Sample with Single Sampling Unit in Strata
Without Stratum Collapse

The SURVEYREG Procedure

Regression Analysis for Dependent Variable Y

Stratum Information

Stratum Index   Stratum   N Obs   Population Total   Sampling Rate
1               10         2       10                20.0%
2               11         2       20                10.0%
3               12         2       32                 6.25%
4               14         1       50                 2.00%
5               33         1       40                 2.50%
    
```

In Output 71.6.5, although the fourth stratum and the fifth stratum contain only one observation, no stratum collapse occurs.

Output 71.6.6. Parameter Estimates and Effect Tests

```

Stratified Sample with Single Sampling Unit in Strata
Without Stratum Collapse

The SURVEYREG Procedure

Regression Analysis for Dependent Variable Y

Tests of Model Effects

Effect          Num DF      F Value      Pr > F
Model              1        347.27      0.0003
Intercept          1           0.00      0.9962
X                  1        347.27      0.0003

NOTE: The denominator degrees of freedom for the F tests is 3.

Estimated Regression Coefficients

Parameter      Estimate      Standard
                Error      t Value      Pr > |t|
Intercept      0.00179469   0.34302581    0.01      0.9962
X              1.12598708   0.06042241   18.64     0.0003

NOTE: The denominator degrees of freedom for the t tests is 3.

```

As a result of not collapsing strata, the standard error estimates of the parameters are different from those in [Output 71.6.3](#), as are the tests of the significance of model effects are.

Chapter 72

The SURVEYSELECT Procedure

Overview

The SURVEYSELECT procedure provides a variety of methods for selecting probability-based random samples. The procedure can select a simple random sample or can sample according to a complex multistage sample design that includes stratification, clustering, and unequal probabilities of selection. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population.

To select a sample with PROC SURVEYSELECT, you input a SAS data set that contains the sampling frame or list of units from which the sample is to be selected. You also specify the selection method, the desired sample size or sampling rate, and other selection parameters. The SURVEYSELECT procedure selects the sample, producing an output data set that contains the selected units, their selection probabilities, and sampling weights. When you are selecting a sample in multiple stages, you invoke the procedure separately for each stage of selection, inputting the frame and selection parameters for each current stage.

The SURVEYSELECT procedure provides methods for both equal probability sampling and probability proportional to size (PPS) sampling. In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. In PPS sampling, a unit's selection probability is proportional to its size measure. For details on probability sampling methods, refer to Lohr (1999), Kish (1965, 1987), Kalton (1983), and Cochran (1977).

The SURVEYSELECT procedure provides the following equal probability sampling methods:

- simple random sampling
- unrestricted random sampling (with replacement)
- systematic random sampling
- sequential random sampling

This procedure also provides the following probability proportional to size (PPS) methods:

- PPS sampling without replacement
- PPS sampling with replacement
- PPS systematic sampling
- PPS algorithms for selecting two units per stratum
- sequential PPS sampling with minimum replacement

The procedure uses fast, efficient algorithms for these sample selection methods. Thus, it performs well even for large input data sets or sampling frames, which may occur in practice for large-scale sample surveys.

The SURVEYSELECT procedure can perform stratified sampling, selecting samples independently within the specified strata, or nonoverlapping subgroups of the survey population. Stratification controls the distribution of the sample size in the strata. It is widely used in practice toward meeting a variety of survey objectives. For example, with stratification you can ensure adequate sample sizes for subgroups of interest, including small subgroups, or you can use stratification toward improving the precision of the overall estimates. When you are using a systematic or sequential selection method, the SURVEYSELECT procedure also can sort by control variables within strata for the additional control of implicit stratification.

The SURVEYSELECT procedure provides replicated sampling, where the total sample is composed of a set of replicates, each selected in the same way. You can use replicated sampling to study variable nonsampling errors, such as variability in the results obtained by different interviewers. You can also use replication to compute standard errors for the combined sample estimates.

Getting Started

In this example, an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company's current subscribers. The company plans to select a sample of customers from this population, interview the selected customers, and then make inferences about the entire survey population from the sample data.

The SAS data set `Customers` contains the sampling frame, which is the list of units in the survey population. The sample of customers will be selected from this sampling frame. The data set `Customers` is constructed from the company's customer database. It contains one observation for each customer, with a total of 13,471 observations. [Figure 72.1](#) displays the first 10 observations of the data set `Customers`.

Internet Service Provider Customers (First 10 Observations)				
Obs	CustomerID	State	Type	Usage
1	416-87-4322	AL	New	839
2	288-13-9763	GA	Old	224
3	339-00-8654	GA	Old	2451
4	118-98-0542	GA	New	349
5	421-67-0342	FL	New	562
6	623-18-9201	SC	New	68
7	324-55-0324	FL	Old	137
8	832-90-2397	AL	Old	1563
9	586-45-0178	GA	New	615
10	801-24-5317	SC	New	728

Figure 72.1. Customers Data Set (First 10 Observations)

In the SAS data set `Customers`, the variable `CustomerID` uniquely identifies each customer. The variable `State` contains the state of the customer's address. The company has customers in the following four states: Georgia (GA), Alabama (AL), Florida (FL), and South Carolina (SC). The variable `Type` equals 'Old' if the customer has subscribed to the service for more than one year; otherwise, the variable `Type` equals 'New'. The variable `Usage` contains the customer's average monthly service usage, in minutes.

The following sections illustrate the use of PROC SURVEYSELECT for probability sampling with three different designs for the customer satisfaction survey. All three designs are one stage, with customers as the sampling units. The first design is simple random sampling without stratification. In the second design, customers are stratified by state and type, and the sample is selected by simple random sampling within strata. In the third design, customers are sorted within strata by usage, and the sample is selected by systematic random sampling within strata.

Simple Random Sampling

The following PROC SURVEYSELECT statements select a probability sample of customers from the `Customers` data set using simple random sampling:

```

title 'Customer Satisfaction Survey';
proc surveyselect data=Customers
    method=srs n=100
    out=SampleSRS;
run;

```

The PROC SURVEYSELECT statement invokes the procedure. The `DATA=` option names the SAS data set `Customers` as the input data set from which to select the sample. The `METHOD=SRS` option specifies simple random sampling as the sample selection method. In simple random sampling, each unit has an equal probability of selection, and sampling is without replacement. Without-replacement sampling means that a unit cannot be selected more than once. The `N=100` option specifies a sample size of 100 customers. The `OUT=` option stores the sample in the SAS data set named `SampleSRS`.

[Figure 72.2](#) displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 100 customers is selected from the data set `Customers` by simple random sampling. With simple random sampling and no stratification in the sample design, the selection probability is the same for all units in the sample. In this sample, the selection probability for each customer equals 0.007423, which is the sample size (100) divided by the population size (13,471). The sampling weight equals 134.71 for each customer in the sample, where the weight is the inverse of the selection probability. If you specify the `STATS` option, PROC SURVEYSELECT includes the selection probabilities and sampling weights in the output data set. (This information is always included in the output data set for more complex designs.)

The random number seed is 39647. PROC SURVEYSELECT uses this number as the initial seed for random number generation. Since the SEED= option is not specified in the PROC SURVEYSELECT statement, the seed value is obtained using the time of day from the computer's clock. You can specify SEED=39647 to reproduce this sample.

Customer Satisfaction Survey	
The SURVEYSELECT Procedure	
Selection Method	Simple Random Sampling
Input Data Set	CUSTOMERS
Random Number Seed	39647
Sample Size	100
Selection Probability	0.007423
Sampling Weight	134.71
Output Data Set	SAMPLESRS

Figure 72.2. Sample Selection Summary

The sample of 100 customers is stored in the SAS data set `SampleSRS`. PROC SURVEYSELECT does not display this output data set. The following PROC PRINT statements display the first 20 observations of `SampleSRS`:

```

title1 'Customer Satisfaction Survey';
title2 'Sample of 100 Customers, Selected by SRS';
title3 '(First 20 Observations)';
proc print data=SampleSRS(obs=20);
run;

```

Figure 72.3 displays the first 20 observations of the output data set `SampleSRS`, which contains the sample of customers. This data set includes all the variables from the `DATA=` input data set `Customers`. If you do not want to include all variables, you can use the `ID` statement to specify which variables to copy from the input data set to the output (sample) data set.

Figure 72.3. Customer Sample (First 20 Observations)

Stratified Sampling

In this section, stratification is added to the sample design for the customer satisfaction survey. The sampling frame, or list of all customers, is stratified by **State** and **Type**. This divides the sampling frame into nonoverlapping subgroups formed from the values of the **State** and **Type** variables. Samples are then selected independently within the strata.

PROC SURVEYSELECT requires that the input data set be sorted by the STRATA variables. The following PROC SORT statements sort the Customers data set by the stratification variables **State** and **Type**:

```
proc sort data=Customers;
  by State Type;
run;
```

The following PROC FREQ statements display the crosstabulation of the Customers data set by **State** and **Type**:

```
proc freq data=Customers;
  tables State*Type;
run;
```

The FREQ Procedure

Table of State by Type

State	Type		
Frequency			
Percent			
Row Pct			
Col Pct	New	Old	Total
AL	1238	706	1944
	9.19	5.24	14.43
	63.68	36.32	
	14.43	14.43

	16.11	10.17	26.28
	61.30	38.70	
	25.29	28.01	
GA	3488	1940	5428
	25.89	14.40	40.29
	64.26	35.74	
	40.65	39.66	
SC	1684	875	2559
	12.50	6.50	19.00
	65.81	34.19	
	19.63	17.89	
Total	8580	4891	13471
	63.69	36.31	100.00

Figure 72.4. Stratification of Customers by State and Type

Figure 72.4 presents the table of State by Type for the 13,471 customers. There are four states and two levels of Type, forming a total of eight strata.

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set according to the stratified sample design:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers
    method=srs n=15
    seed=1953 out=SampleStrata;
    strata State Type;
run;

```

The STRATA statement names the stratification variables State and Type. In the PROC SURVEYSELECT statement, the METHOD=SRS option specifies simple random sampling. The N=15 option specifies a sample size of 15 customers for each stratum. If you want to specify different sample sizes for different strata, you can use the N=SAS-data-set option to name a secondary data set that contains the stratum sample sizes. The SEED=1953 option specifies '1953' as the initial seed for random number generation.

Customer Satisfaction Survey	
Stratified Sampling	
The SURVEYSELECT Procedure	
Selection Method	Simple Random Sampling
Strata Variables	State Type
Input Data Set	CUSTOMERS

Stratum Sample Size	15
Number of Strata	8
Total Sample Size	120
Output Data Set	SAMPLESTRATA

Figure 72.5. Sample Selection Summary

Figure 72.5 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 120 customers are selected.

The following PROC PRINT statements display the first 30 observations of the output data set SampleStrata:

```

title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Stratified Design';
title3 '(First 30 Observations)';
proc print data=SampleStrata(obs=30);
run;

```

Figure 72.6 displays the first 30 observations of the output data set SampleStrata, which contains the sample of 120 customers, 15 customers from each of the eight strata. The variable SelectionProb contains the selection probability for each customer in the sample. Since customers are selected with equal probability within strata in this design, the selection probability equals the stratum sample size (15) divided by the stratum population size. The selection probabilities differ from stratum to stratum since the population sizes differ. The selection probability for each customer in the first stratum (State='AL' and Type='New') is 0.012116, and the selection probability is 0.021246 for customers in the second stratum. The variable SamplingWeight contains the sampling weights, which are computed as inverse selection probabilities.

Customer Satisfaction Survey Sample Selected by Stratified Design (First 30 Observations)

Figure 72.6. Customer Sample (First 30 Observations)

Stratified Sampling with Control Sorting

The next sample design for the customer satisfaction survey uses stratification by **State**. The sampling frame is also sorted by **Type** and **Usage** before sample selection, to provide additional control over the distribution of the sample. Customers are then selected by systematic random sampling within strata. Selection by systematic sampling, together with control sorting, spreads the sample uniformly over the range of type and usage values within each stratum or state. The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set using this design:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling with Control Sorting';
proc surveyselect data=Customers
    method=sys rate=.02
    seed=1234 out=SampleControl;
    strata State;
    control Type Usage;
run;

```

The STRATA statement names the stratification variable **State**. The CONTROL statement names the control variables **Type** and **Usage**. In the PROC SURVEYSELECT statement, the METHOD=SYS option requests systematic random sampling. The RATE=.02 option specifies a sampling rate of 2% for each stratum. The SEED=1234 option specifies the initial seed for random number generation.

Figure 72.7 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 271 customers is selected, using systematic random sampling within strata determined by **State**. The sampling frame **Customers** is sorted by control variables **Type** and **Usage** within strata. The type of sorting is serpentine, which is used by default since SORT=NEST is not specified. See the section “[Sorting by CONTROL Variables](#)” on page 4445 for a description of serpentine sorting. The sorted data set replaces the input data set. (To store the sorted input data in another data set, leaving the input data set unsorted, use the OUTSORT= option.) The output data set **SampleControl** contains the sample of customers.

Figure 72.7. Sample Selection Summary

Syntax

The following statements are available in PROC SURVEYSELECT:

```
PROC SURVEYSELECT options ;  
  STRATA variables ;  
  CONTROL variables ;  
  SIZE variable ;  
  ID variables ;
```

The PROC SURVEYSELECT statement invokes the procedure and optionally identifies input and output data sets. It also specifies the selection method, the sample size, and other sample design parameters. The SURVEYSELECT statement is required.

The SIZE statement identifies the variable that contains the size measures. It is required for any selection method that is probability proportional to size (PPS).

The remaining statements are optional. The STRATA statement identifies a variable or set of variables that stratify the input data set. When you specify a STRATA statement, PROC SURVEYSELECT selects samples independently from the strata formed by the STRATA variables. The CONTROL statement identifies variables for ordering units within strata. It can be used for systematic and sequential sampling methods. The ID statement identifies variables to copy from the input data set to the output data set of selected units.

The rest of this section gives detailed syntax information for the CONTROL, ID, SIZE, and STRATA statements in alphabetical order after the description of the PROC SURVEYSELECT statement.

PROC SURVEYSELECT Statement

```
PROC SURVEYSELECT options ;
```

The PROC SURVEYSELECT statement invokes the procedure and optionally identifies input and output data sets. If you do not name a DATA= input data set, the procedure selects the sample from the most recently created SAS data set. If you do not name an OUT= output data set to contain the sample of selected units, the procedure still creates an output data set and names it according to the DATA n convention.

The PROC SURVEYSELECT statement also specifies the sample selection method, the sample size, and other sample design parameters. If you do not specify a selection method, PROC SURVEYSELECT uses simple random sampling (METHOD=SRS) if there is no SIZE statement. If you specify a SIZE statement but do not specify a selection method, PROC SURVEYSELECT uses probability proportional to size selection without replacement (METHOD=PPS). You must specify the sample size or sampling rate unless you request a method that selects two units from each stratum (METHOD=PPS_BREWER or METHOD=PPS_MURTHY).

You can use the SAMPSIZE= n option to specify the sample size, or you can use the SAMPSIZE=SAS-*data-set* option to name a secondary input data set that contains

stratum sample sizes. You can also specify stratum sampling rates, minimum size measures, maximum size measures, and certainty size measures in the secondary input data set. See the descriptions of the `SAMPSIZE=`, `SAMPRATE=`, `MINSIZE=`, `MAXSIZE=`, and `CERTSIZE=` options. You can name only one secondary input data set in each invocation of the procedure.

The following table lists the options available with the PROC SURVEYSELECT statement. Descriptions follow in alphabetical order.

Table 72.1. PROC SURVEYSELECT Statement Options

Task	Options
Specify the input data set	DATA=
Specify output data sets	OUT= OUTSORT=
Suppress displayed output	NOPRINT
Specify selection method	METHOD=
Specify sample size	SAMPSIZE= SELECTALL
Specify sampling rate	SAMPRATE= NMIN= NMAX=
Specify number of replicates	REP=
Adjust size measures	MINSIZE= MAXSIZE=
Specify certainty size measures	CERTSIZE=
Specify sorting type	SORT=
Specify random number seed	SEED=
Control OUT= contents	JTPROBS OUTALL OUTHITS OUTSEED OUTSIZE STATS

You can specify the following options in the PROC SURVEYSELECT statement:

CERTSIZE

requests automatic selection of those units with size measures greater than or equal to the stratum certainty size measure. You provide sampling unit size measures in the `DATA=` input data set variable named in the `SIZE` statement. And you provide the stratum certainty size measures in the secondary input data set variable `_CERTSIZE_`. Use the `CERTSIZE` option when you have already named the secondary input data set in another option, such as `SAMPSIZE=SAS-data-set`, `SAMPRATE=SAS-data-set`, `MAXSIZE=SAS-data-set`, or `MINSIZE=SAS-data-set`. You can name only one secondary input data set in each invocation of the procedure.

If any unit's size measure is greater than or equal to the certainty size measure for its stratum, then PROC SURVEYSELECT selects this unit with certainty. Each certainty size measure must be a positive number. The CERTSIZE option is available for [METHOD=PPS](#) and [METHOD=PPS_SAMPFORD](#).

If you want to specify a single certainty size measure in the PROC SURVEYSELECT statement, use the [CERTSIZE=*certain*](#) option.

CERTSIZE=*certain*

specifies the certainty size measure. PROC SURVEYSELECT selects with certainty any unit with size measure greater than or equal to the value *certain*, which must be a positive number. You provide size measures in the DATA= input data set variable named in the [SIZE](#) statement. This option is available for [METHOD=PPS](#) and [METHOD=PPS_SAMPFORD](#).

If you request a stratified sample design with a [STRATA](#) statement and specify the CERTSIZE= option, PROC SURVEYSELECT uses the certainty size *certain* for all strata. If you do not want to use the same certainty size for all strata, use the [CERTSIZE=*SAS-data-set*](#) option to specify a certainty size for each stratum.

CERTSIZE=*SAS-data-set*

names a SAS data set that contains the certainty size measures for the strata. PROC SURVEYSELECT selects with certainty any unit with size measure greater than or equal to the certainty size measure for its stratum. You provide sampling unit size measures in the DATA= input data set variable named in the [SIZE](#) statement. And you provide the stratum certainty size measures in the CERTSIZE= input data set variable `_CERTSIZE_`. Each certainty size measure must be a positive number. This option is available for [METHOD=PPS](#) and [METHOD=PPS_SAMPFORD](#).

The CERTSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the CERTSIZE= data set as in the DATA= data set. The CERTSIZE= data set must include a variable named `_CERTSIZE_` that contains the certainty size measure for each stratum.

CERTSIZE=*P=p*

specifies the certainty proportion. PROC SURVEYSELECT selects with certainty any unit with size measure greater than or equal to the proportion p of the total size for all units in the stratum. The procedure repeats this process with the remaining units until no more certainty units are selected. You provide size measures in the DATA= input data set variable named in the [SIZE](#) statement. This option is available for [METHOD=PPS](#) and [METHOD=PPS_SAMPFORD](#).

The certainty proportion must be a positive number. You can specify p as a number between 0 and 1. Or you can specify p in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you request a stratified sample design with a [STRATA](#) statement and specify the CERTSIZE=P= option, PROC SURVEYSELECT uses the same certainty proportion p for all strata.

DATA=SAS-data-set

names the SAS data set from which PROC SURVEYSELECT selects the sample. If you omit the DATA= option, the procedure uses the most recently created SAS data set. In sampling terminology, the input data set is the *sampling frame*, or list of units from which the sample is selected.

JTPROBS

includes joint probabilities of selection in the OUT= output data set. This option is available for the following probability proportional to size selection methods: [METHOD=PPS](#), [METHOD=PPS_SAMPFORD](#), and [METHOD=PPS_WR](#). By default, PROC SURVEYSELECT outputs joint selection probabilities for [METHOD=PPS_BREWER](#) and [METHOD=PPS_MURTHY](#), which select two units per stratum.

For details on computation of joint selection probabilities for a particular sampling method, see the method description in the section “[Sample Selection Methods](#)” on page 4446. For more information on the contents of the output data set, see the section “[Output Data Set](#)” on page 4456.

MAXSIZE

requests that sampling unit size measures be adjusted according to the stratum maximum size measures in the secondary input data set. You provide sampling unit size measures in the DATA= input data set variable named in the [SIZE](#) statement. And you provide the stratum maximum size measures in the secondary input data set variable `_MAXSIZE_`. Use the MAXSIZE option when you have already named the secondary input data set in another option, such as [SAMPSIZE=SAS-data-set](#), [SAMPRATE=SAS-data-set](#), [MINSIZE=SAS-data-set](#), or [CERTSIZE=SAS-data-set](#). You can name only one secondary input data set in each invocation of the procedure.

If any size measure exceeds the maximum size measure for its stratum, then PROC SURVEYSELECT adjusts this size measure downward to equal the maximum size measure. Each maximum size measure must be a positive number. The MAXSIZE option is available whenever you specify a [SIZE](#) statement for probability proportional to size selection and a [STRATA](#) statement for stratification.

If you want to specify a single maximum size value in the PROC SURVEYSELECT statement, use the [MAXSIZE=max](#) option.

MAXSIZE=max

specifies the maximum size measure allowed. If any size measure exceeds the value *max*, then PROC SURVEYSELECT adjusts this size measure to equal *max*, which must be a positive number. You provide size measures in the DATA= input data set variable named in the [SIZE](#) statement. This option is available whenever you specify a [SIZE](#) statement for selection with probability proportional to size.

If you request a stratified sample design with a [STRATA](#) statement and specify the MAXSIZE= option, PROC SURVEYSELECT uses the maximum size *max* for all strata. If you do not want to use the same maximum size for all strata, use the [MAXSIZE=SAS-data-set](#) option to specify a maximum size for each stratum.

MAXSIZE=SAS-data-set

names a SAS data set that contains the maximum size measures allowed for the strata. If any size measure exceeds the maximum size measure for its stratum, then PROC SURVEYSELECT adjusts this size measure downward to equal the maximum size measure. You provide sampling unit size measures in the DATA= input data set variable named in the [SIZE](#) statement. And you provide the stratum maximum size measures in the MAXSIZE= input data set variable `_MAXSIZE_`. Each maximum size measure must be a positive number. This option is available whenever you specify a [SIZE](#) statement for probability proportional to size selection and a [STRATA](#) statement for stratified selection.

The MAXSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the MAXSIZE= data set as in the DATA= data set. The MAXSIZE= data set must include a variable named `_MAXSIZE_` that contains the maximum size measure for each stratum.

METHOD=name**M=name**

specifies the method for sample selection. If you do not specify the METHOD= option, by default, PROC SURVEYSELECT uses simple random sampling ([METHOD=SRS](#)) if there is no [SIZE](#) statement. If you specify a [SIZE](#) statement, the default selection method is probability proportional to size without replacement ([METHOD=PPS](#)). Valid values for *name* are as follows:

- PPS** requests selection with probability proportional to size and without replacement. See the section [“PPS Sampling without Replacement”](#) on page 4449 for details. If you specify METHOD=PPS, you must name the size measure variable in the [SIZE](#) statement.
- PPS_BREWER** | **BREWER** requests selection according to Brewer’s method. Brewer’s method selects two units from each stratum with probability proportional to size and without replacement. See the section [“Brewer’s PPS Method”](#) on page 4453 for details. If you specify METHOD=PPS_BREWER, you must name the size measure variable in the [SIZE](#) statement. You do not need to specify the sample size with the [SAMPSIZE=](#) option, since Brewer’s method selects two units from each stratum.
- PPS_MURTHY** | **MURTHY** requests selection according to Murthy’s method. Murthy’s method selects two units from each stratum with probability proportional to size and without replacement. See the section [“Murthy’s PPS Method”](#) on page 4454 for details. If you specify METHOD=PPS_MURTHY, you must name the size measure variable in the [SIZE](#) statement. You do not need to specify the sample size with the [SAMPSIZE=](#) option, since Murthy’s method selects two units from each stratum.

- PPS_SAMPFORD | SAMPFORD requests selection according to Sampford's method. Sampford's method selects units with probability proportional to size and without replacement. See the section [“Sampford's PPS Method”](#) on page 4455 for details. If you specify METHOD=PPS_SAMPFORD, you must name the size measure variable in the SIZE statement.
- PPS_SEQ | CHROMY requests sequential selection with probability proportional to size and with minimum replacement. This method is also known as Chromy's method. See the section [“PPS Sequential Sampling”](#) on page 4452 for details. If you specify METHOD=PPS_SEQ, you must name the size measure variable in the SIZE statement.
- PPS_SYS requests systematic selection with probability proportional to size. See the section [“PPS Systematic Sampling”](#) on page 4451 for details on this method. If you specify METHOD=PPS_SYS, you must name the size measure variable in the SIZE statement.
- PPS_WR requests selection with probability proportional to size and with replacement. See the section [“PPS Sampling with Replacement”](#) on page 4451 for details on this method. If you specify METHOD=PPS_WR, you must name the size measure variable in the SIZE statement.
- SEQ requests sequential selection according to Chromy's method. If you specify METHOD=SEQ and do not specify a size measure variable with the SIZE statement, PROC SURVEYSELECT uses sequential zoned selection with equal probability and without replacement. See the section [“Sequential Random Sampling”](#) on page 4448 for details on this method. If you specify METHOD=SEQ and also name a size measure variable in the SIZE statement, PROC SURVEYSELECT uses METHOD=PPS_SEQ, which is sequential selection with probability proportional to size and with minimum replacement. See the section [“PPS Sequential Sampling”](#) on page 4452 for details on this method.
- SRS requests simple random sampling, which is selection with equal probability and without replacement. See the section [“Simple Random Sampling”](#) on page 4447 for details. This method is the default if you do not specify the METHOD= option and also do not specify a SIZE statement.
- SYS requests systematic random sampling. If you specify METHOD=SYS and do not specify a size measure variable with the SIZE statement, PROC SURVEYSELECT uses systematic selection with equal probability. See the section [“Systematic Random Sampling”](#) on page 4448 for details on this method. If you specify METHOD=SYS and also name a size measure variable in the SIZE statement, PROC SURVEYSELECT uses METHOD=PPS_SYS, which is systematic selection with probability proportional to size. See the section [“PPS Systematic Sampling”](#) on page 4451 for details.

URS requests unrestricted random sampling, which is selection with equal probability and with replacement. See the section “Unrestricted Random Sampling” on page 4447 for details.

MINSIZE

requests that sampling unit size measures be adjusted according to the stratum minimum size measures in the secondary input data set. You provide sampling unit size measures in the DATA= input data set variable named in the [SIZE](#) statement. And you provide the stratum minimum size measures in the secondary input data set variable `_MINSIZE_`. Use the MINSIZE option when you have already named the secondary input data set in another option, such as [SAMPSIZE=SAS-data-set](#), [SAMPRATE=SAS-data-set](#), [MAXSIZE=SAS-data-set](#), or [CERTSIZE=SAS-data-set](#). You can name only one secondary input data set in each invocation of the procedure.

If any size measure is less than the minimum size measure for its stratum, then PROC SURVEYSELECT adjusts this size measure upward to equal the minimum size measure. Each minimum size measure must be a positive number. The MINSIZE option is available whenever you specify a SIZE statement for probability proportional to size selection and a [STRATA](#) statement for stratification.

If you want to specify a single minimum size value in the PROC SURVEYSELECT statement, use the [MINSIZE=min](#) option.

MINSIZE=min

specifies the minimum size measure allowed. If any size measure is less than the value *min*, then PROC SURVEYSELECT adjusts this size measure upward to equal *min*, which must be a positive number. You provide size measures in the DATA= input data set variable named in the [SIZE](#) statement. This option is available whenever you specify a SIZE statement for selection with probability proportional to size.

If you request a stratified sample design with a [STRATA](#) statement and specify the MINSIZE= option, PROC SURVEYSELECT uses the minimum size *min* for all strata. If you do not want to use the same minimum size for all strata, use the [MINSIZE=SAS-data-set](#) option to specify a minimum size for each stratum.

MINSIZE=SAS-data-set

names a SAS data set that contains the minimum size measures allowed for the strata. If any size measure is less than the minimum size measure for its stratum, then PROC SURVEYSELECT adjusts this size measure upward to equal the minimum size measure. You provide sampling unit size measures in the DATA= input data set variable named in the [SIZE](#) statement. And you provide the stratum minimum size measures in the MINSIZE= input data set variable `_MINSIZE_`. Each minimum size measure must be a positive number. This option is available whenever you specify a SIZE statement for probability proportional to size selection and a [STRATA](#) statement for stratified selection.

The MINSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the MINSIZE= data set as in the DATA= data set. The MINSIZE= data set must include a variable named `_MINSIZE_` that contains the minimum size measure for each stratum.

NMAX=*n*

specifies the maximum stratum sample size *n* for the [SAMPRATE=](#) option. When you specify the [SAMPRATE=](#) option, PROC SURVEYSELECT calculates the desired stratum sample size from the specified sampling rate and the total number of units in the stratum. If this sample size is greater than the value [NMAX=*n*](#), then PROC SURVEYSELECT selects the maximum of *n* units.

The maximum sample size *n* must be a positive integer. The [NMAX=](#) option is available only with the [SAMPRATE=](#) option, which may be used with equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), and [METHOD=SEQ](#)).

NMIN=*n*

specifies the minimum stratum sample size *n* for the [SAMPRATE=](#) option. When you specify the [SAMPRATE=](#) option, PROC SURVEYSELECT calculates the desired stratum sample size from the specified sampling rate and the total number of units in the stratum. If this sample size is less than the value [NMIN=*n*](#), then PROC SURVEYSELECT selects the minimum of *n* units.

The minimum sample size *n* must be a positive integer. The [NMIN=](#) option is available only with the [SAMPRATE=](#) option, which may be used with equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), and [METHOD=SEQ](#)).

NOPRINT

suppresses the display of all output. You can use the [NOPRINT](#) option when you want only to create an output data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see [Chapter 14](#), “Using the Output Delivery System.”

OUT=*SAS-data-set*

names the output data set that contains the sample. If you omit the [OUT=](#) option, the data set is named [DATA*n*](#), where *n* is the smallest integer that makes the name unique.

The output data set contains the units selected for the sample, as well as design information and selection statistics, depending on the selection method and output options you specify. See the descriptions for the options [JTPROBS](#), [OUTHITS](#), [OUTSEED](#), [OUTSIZE](#), and [STATS](#). For information on the contents of the output data set, see the section “[Output Data Set](#)” on page 4456.

By default, the output data set contains only those units selected for the sample. To include all observations from the input data set in the output data set, use the [OUTALL](#) option.

OUTALL

includes all observations from the input data set in the output data set. By default, the output data set includes only those observations selected for the sample. When you specify the [OUTALL](#) option, the output data set includes all observations from [DATA=](#) and also contains a variable to indicate each observation’s selection status. The variable [Selected](#) equals 1 for an observation selected for the sample, and equals

0 for an observation not selected. For information on the contents of the output data set, see the section “[Output Data Set](#)” on page 4456.

The OUTALL option is available only for equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), and [METHOD=SEQ](#)).

OUTHITS

includes a separate observation in the output data set for each selection when the same unit is selected more than once. By default, the output data set contains only one observation for each selected unit, even if it is selected more than once, and the variable `NumberHits` contains the number of hits or selections for that unit. The OUTHITS option is available for selection methods that select with replacement or with minimum replacement ([METHOD=URS](#), [METHOD=PPS_WR](#), [METHOD=PPS_SYS](#), and [METHOD=PPS_SEQ](#)).

OUTSEED

includes the initial seed for each stratum in the output data set. The variable `InitialSeed` contains the stratum initial seed. See the section “[Sample Selection Methods](#)” on page 4446 for information on initial seeds and random number generation in PROC SURVEYSELECT.

To reproduce the same sample for any stratum in a subsequent execution of PROC SURVEYSELECT, you can specify the same stratum initial seed with the [SEED=SAS-data-set](#) option, along with the same sample selection parameters.

OUTSIZE

includes additional design and sampling frame parameters in the output data set. If you specify the OUTSIZE option, PROC SURVEYSELECT includes the sample size or sampling rate in the output data set. When you request the OUTSIZE option and also specify the [SIZE](#) statement, the procedure outputs the size measure total for the sampling frame. If you do not specify the [SIZE](#) statement, the procedure outputs the total number of sampling units in the frame. Also, PROC SURVEYSELECT includes the minimum size measure if you specify the [MINSIZE=](#) option, the maximum size measure if you specify the [MAXSIZE=](#) option, and the certainty size measure if you specify the [CERTSIZE=](#) option.

If you have a stratified design, the output data set includes the stratum-level values of these parameters. Otherwise, the output data set includes the overall population-level values.

For information on the contents of the output data set, see the section “[Output Data Set](#)” on page 4456.

OUTSORT=SAS-data-set

names an output data set that contains the sorted input data set. This option is available when you specify a [CONTROL](#) statement for systematic or sequential selection methods ([METHOD=SYS](#), [METHOD=PPS_SYS](#), [METHOD=SEQ](#), and [METHOD=PPS_SEQ](#)). PROC SURVEYSELECT sorts the input data set by the [CONTROL](#) variables within strata before selecting the sample.

If you specify [CONTROL](#) variables but do not name an output data set with the [OUTSORT=](#) option, then the sorted data set replaces the input data set.

REP=*nrep*

specifies the number of sample replicates. If you specify the REP= option, PROC SURVEYSELECT selects *nrep* independent samples, each with the same specified sample size or sampling rate and the same sample design.

You can use replicated sampling to provide a simple method of variance estimation for any form of statistic, as well as to evaluate variable nonsampling errors such as interviewer differences. Refer to Lohr (1999), Kish (1965, 1987), and Kalton (1983) for information on replicated sampling.

SAMPRATE=*r***RATE=*r***

specifies the sampling rate, which is the proportion of units selected for the sample. The sampling rate *r* must be a positive number. You can specify *r* as a number between 0 and 1. Or you can specify *r* in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The SAMPRATE= option is available only for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ). For systematic random sampling (METHOD=SYS), PROC SURVEYSELECT uses the inverse of the sampling rate *r* as the interval. See the section “[Systematic Random Sampling](#)” on page 4448 for details. For other selection methods, PROC SURVEYSELECT converts the sampling rate *r* to the sample size before selection, multiplying the rate by the number of units in the stratum or frame and rounding up to the nearest integer.

If you request a stratified sample design with a STRATA statement and specify the SAMPRATE=*r* option, PROC SURVEYSELECT uses the sampling rate *r* for each stratum. If you do not want to use the same sampling rate for each stratum, use the SAMPRATE=(*values*) option or the SAMPRATE=SAS-data-set option to specify a sampling rate for each stratum.

SAMPRATE=(*values*)**RATE=(*values*)**

specifies sampling rates for the strata. You can separate *values* with blanks or commas. The number of SAMPRATE= values must equal the number of strata in the input data set.

List the stratum sampling rate values in the order in which the strata appear in the input data set. If you use the SAMPRATE=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED options in the STRATA statement.

Each stratum sampling rate value must be a positive number. You can specify each value as a number between 0 and 1. Or you can specify a value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The `SAMPRATE=` option is available only for equal probability selection methods (`METHOD=SRS`, `METHOD=URS`, `METHOD=SYS`, and `METHOD=SEQ`). For systematic random sampling (`METHOD=SYS`), PROC SURVEYSELECT uses the inverse of the stratum sampling rate as the interval for the stratum. See the section “Systematic Random Sampling” on page 4448 for details on systematic sampling. For other selection methods, PROC SURVEYSELECT converts the stratum sampling rate to a stratum sample size before selection, multiplying the rate by the number of units in the stratum and rounding up to the nearest integer.

SAMPRATE=SAS-data-set

RATE=SAS-data-set

names a SAS data set that contains sampling rates for the strata. This input data set should contain all the `STRATA` variables, with the same type and length as in the `DATA=` data set. The `STRATA` groups should appear in the same order in the `SAMPSIZE=` data set as in the `DATA=` data set. The `SAMPRATE=` data set should have a variable `_RATE_` that contains the sampling rate for each stratum.

Each sampling rate value must be a positive number. You can specify each value as a number between 0 and 1. Or you can specify a value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The `SAMPRATE=` option is available only for equal probability selection methods (`METHOD=SRS`, `METHOD=URS`, `METHOD=SYS`, and `METHOD=SEQ`). For systematic random sampling (`METHOD=SYS`), PROC SURVEYSELECT uses the inverse of the stratum sampling rate as the interval for the stratum. See the section “Systematic Random Sampling” on page 4448 for details. For other selection methods, PROC SURVEYSELECT converts the stratum sampling rate to the stratum sample size before selection, multiplying the rate by the number of units in the stratum and rounding up to the nearest integer.

SAMPSIZE=*n*

N=*n*

specifies the sample size, which is the number of units selected for the sample. The sample size *n* must be a positive integer. For methods that select without replacement, the sample size *n* must not exceed the number of units in the input data set.

If you request a stratified sample design with a `STRATA` statement and specify the `SAMPSIZE=n` option, PROC SURVEYSELECT selects *n* units from each stratum. For methods that select without replacement, the sample size *n* must not exceed the number of units in any stratum. If you do not want to select the same number of units from each stratum, use the `SAMPSIZE=(values)` option or the `SAMPSIZE=SAS-data-set` option to specify different sample sizes for the strata.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum. However, you can change this default by specifying the `SELECTALL` option. With the `SELECTALL` option, PROC SURVEYSELECT selects all stratum units whenever the stratum sample size exceeds the number of units in the stratum.

SAMPSIZE=(values)**N=(values)**

specifies sample sizes for the strata. You can separate *values* with blanks or commas. The number of SAMPSIZE= values must equal the number of strata in the input data set.

List the stratum sample size values in the order in which the strata appear in the input data set. If you use the SAMPSIZE=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED options in the STRATA statement.

Each stratum sample size value must be a positive integer. For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum. However, you can change this default by specifying the [SELECTALL](#) option. With the SELECTALL option, PROC SURVEYSELECT selects all stratum units whenever the stratum sample size exceeds the number of units in the stratum.

SAMPSIZE=SAS-data-set**N=SAS-data-set**

names a SAS data set that contains the sample sizes for the strata. This input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPSIZE= data set as in the DATA= data set. The SAMPSIZE= data set should have a variable `_NSIZE_` that contains the sample size for each stratum.

Each stratum sample size value must be a positive integer. For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum. However, you can change this default by specifying the [SELECTALL](#) option. With the SELECTALL option, PROC SURVEYSELECT selects all stratum units whenever the stratum sample size exceeds the number of units in the stratum.

SEED=number

specifies the initial seed for random number generation. The value of the SEED= option must be an integer. If you do not specify the SEED= option, or if the SEED= value is negative or zero, PROC SURVEYSELECT uses the time of day from the computer's clock to obtain the initial seed. See the section [“Sample Selection Methods”](#) on page 4446 for more information.

Whether or not you specify the SEED= option, PROC SURVEYSELECT displays the value of the initial seed in the “Sample Selection Summary” table. If you need to reproduce the same sample in a subsequent execution of PROC SURVEYSELECT, you can specify this same seed value with the SEED= option, along with the same sample selection parameters, and PROC SURVEYSELECT will reproduce the sample.

If you request a stratified sample design with a [STRATA](#) statement, you can use the [SEED=SAS-data-set](#) option to specify an initial seed for each stratum. Otherwise, PROC SURVEYSELECT generates random numbers continuously across strata from

the random number stream initialized by the SEED= value, as described in the section “[Sample Selection Methods](#)” on page 4446.

To include the stratum initial seeds in the output data set, use the [OUTSEED](#) option.

SEED=SAS-data-set

names a SAS data set that contains initial seeds for the strata. This input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPSIZE= data set as in the DATA= data set. The SEED= data set should have a variable `_SEED_` that contains the initial seed for each stratum.

Each stratum initial seed value should be an integer. If the initial seed value for the first stratum is not a positive integer, PROC SURVEYSELECT uses the time of day from the computer’s clock to obtain the initial seed. If the initial seed value for a subsequent stratum is not a positive integer, PROC SURVEYSELECT continues to use the random number stream already initialized by the seed for the previous stratum. See the section “[Sample Selection Methods](#)” on page 4446 for more information.

To include the stratum initial seeds in the output data set, specify the [OUTSEED](#) option.

If you specified initial seeds by strata with the SEED=SAS-data-set option, you can reproduce the same sample in a subsequent execution of PROC SURVEYSELECT by specifying these same stratum initial seeds, along with the same sample selection parameters. If you need to reproduce the same sample for only a subset of the strata, you can use the same initial seeds for those strata in the subset.

SELECTALL

requests that PROC SURVEYSELECT select all stratum units whenever the stratum sample size exceeds the total number of units in the stratum, for without-replacement selection methods. By default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum, for methods that select without replacement.

The SELECTALL option is available for without-replacement selection methods, which include [METHOD=SRS](#), [METHOD=SYS](#), [METHOD=SEQ](#), [METHOD=PPS](#), and [METHOD=PPS_SAMPFORD](#). The SELECTALL option is not available for with-replacement selection methods, with-minimum-replacement methods, or for those PPS methods that select two units per stratum.

SORT=NEST | SERP

specifies the type of sorting by CONTROL variables. The option SORT=NEST requests nested sorting, and SORT=SERP requests hierarchic serpentine sorting. The default is SORT=SERP. See the section “[Sorting by CONTROL Variables](#)” on page 4445 for descriptions of serpentine and nested sorting. Where there is only one CONTROL variable, the two types of sorting are equivalent.

This option is available when you specify a [CONTROL](#) statement for systematic or sequential selection methods ([METHOD=SYS](#), [METHOD=PPS_SYS](#), [METHOD=SEQ](#), and [METHOD=PPS_SEQ](#)). When you specify a CONTROL

statement, PROC SURVEYSELECT sorts the input data set by the CONTROL variables within strata before selecting the sample.

With sorting by CONTROL variables, you can also use the **OUTSORT=** option to name an output data set that contains the sorted input data set. Otherwise, if you do not specify the **OUTSORT=** option, then the sorted data set replaces the input data set.

STATS

includes selection probabilities and sampling weights in the **OUT=** output data set for equal probability selection methods when you do not specify a STRATA statement. This option is available for the following equal probability selection methods: **METHOD=SRS**, **METHOD=URS**, **METHOD=SYS**, and **METHOD=SEQ**. For PPS selection methods and stratified designs, the output data set contains selection probabilities and sampling weights by default. For more information on the contents of the output data set, see the section “[Output Data Set](#)” on page 4456.

CONTROL Statement

CONTROL *variables* ;

The CONTROL statement names variables for sorting the input data set. The CONTROL variables can be character or numeric.

PROC SURVEYSELECT sorts the input data set by the CONTROL variables before selecting the sample. If you also specify a STRATA statement, PROC SURVEYSELECT sorts by CONTROL variables within strata. Control sorting is available for systematic and sequential selection methods (**METHOD=SYS**, **METHOD=PPS_SYS**, **METHOD=SEQ**, and **METHOD=PPS_SEQ**).

By default, PROC SURVEYSELECT uses hierarchic serpentine sorting by the CONTROL variables. If you specify the **SORT=NEST** option, the procedure uses nested sorting. See the description for the **SORT=** option. For more information on serpentine and nested sorting, see the section “[Sorting by CONTROL Variables](#)” on page 4445.

You can use the **OUTSORT=** option to name an output data set that contains the sorted input data set. If you do not specify the **OUTSORT=** option when you use the CONTROL statement, then the sorted data set replaces the input data set.

ID Statement

ID *variables* ;

The ID statement names variables from the **DATA=** input data set to be included in the **OUT=** data set of selected units. If there is no ID statement, PROC SURVEYSELECT includes all variables from the **DATA=** data set in the **OUT=** data set. The ID variables can be character or numeric.

SIZE Statement

SIZE *variable* ;

The SIZE statement names one and only one size measure variable, which contains the size measures to be used when sampling with probability proportional to size. The SIZE variable must be numeric. When the value of an observation's SIZE variable is missing or nonpositive, that observation has no chance of being selected for the sample.

The SIZE statement is required for all PPS selection methods, which include `METHOD=PPS`, `METHOD=PPS_BREWER`, `METHOD=PPS_MURTHY`, `METHOD=PPS_SAMPFORD`, `METHOD=PPS_SEQ`, `METHOD=PPS_SYS`, and `METHOD=PPS_WR`. For details on how size measures are used, see the descriptions of PPS methods in the section “Sample Selection Methods” on page 4446.

Note that a unit's size measure, specified in the SIZE statement and used for PPS selection, is not the same as the sample size. The sample size is the number of units selected for the sample, and you can specify this with the `SAMPSIZE=` option.

STRATA Statement

STRATA *variables* ;

You can specify a STRATA statement with PROC SURVEYSELECT to partition the input data set into nonoverlapping groups defined by the STRATA variables. PROC SURVEYSELECT then selects independent samples from these strata, according to the selection method and design parameters specified in the PROC SURVEYSELECT statement. For information on the use of stratification in sample design, refer to Lohr (1999), Kalton (1983), Kish (1965, 1987), and Cochran (1977).

The *variables* are one or more variables in the input data set. The STRATA variables function much like BY variables, and PROC SURVEYSELECT expects the input data set to be sorted in order of the STRATA variables.

If you specify a `CONTROL` statement, or if you specify `METHOD=PPS`, the input data set must be sorted in ascending order of the STRATA variables. This means you cannot use the STRATA option `NOTSORTED` or `DESCENDING` when you specify a `CONTROL` statement or `METHOD=PPS`.

If your input data set is not sorted by the STRATA variables in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with the STRATA variables in a BY statement.
- Specify the option `NOTSORTED` or `DESCENDING` in the STRATA statement for the SURVEYSELECT procedure (when you do not specify a `CONTROL` statement or `METHOD=PPS`). The `NOTSORTED` option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the STRATA variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the STRATA variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

Details

Missing Values

If an observation has a missing or nonpositive value for the **SIZE** variable, PROC SURVEYSELECT excludes that observation from the sample selection. The procedure writes a note to the log giving the number of observations omitted due to missing or nonpositive size measures.

PROC SURVEYSELECT treats missing **STRATA** variable values like any other STRATA variable value. The missing values form a separate stratum.

If a value of **_NSIZE_** is missing in the **SAMPSIZE=** input data set, then PROC SURVEYSELECT writes an error message to the log and does not select a sample from that stratum. The procedure treats missing values of **_NRATE_**, **_MINSIZE_**, **_MAXSIZE_**, and **_CERTSIZE_** similarly.

Sorting by CONTROL Variables

If you specify a **CONTROL** statement, PROC SURVEYSELECT sorts the input data set by the CONTROL variables before selecting the sample. If you also specify a **STRATA** statement, the procedure sorts by CONTROL variables within strata. Sorting by CONTROL variables is available for systematic and sequential selection methods, which include **METHOD=SYS**, **METHOD=PPS_SYS**, **METHOD=SEQ**, and **METHOD=PPS_SEQ**. Sorting provides additional control over the distribution of the sample, giving some benefits of proportionate stratification.

By default, the sorted data set replaces the input data set. Or you can use the **OUTSORT=** option to name an output data set that contains the sorted input data set.

PROC SURVEYSELECT provides two types of sorting: nested sorting and hierarchic serpentine sorting. If you specify the **SORT=NEST** option, then the procedure sorts by the CONTROL variables according to nested sorting. If you do not specify the **SORT=NEST** option, the procedure uses serpentine sorting by default. These two types of sorting are equivalent when there is only one CONTROL variable.

If you request nested sorting, PROC SURVEYSELECT sorts observations in the same order as PROC SORT does for an ascending sort by the CONTROL variables. Refer to the chapter on the SORT procedure in the *SAS Procedures Guide*. PROC SURVEYSELECT sorts within strata if you also specify a STRATA statement. The procedure first arranges the input observations in ascending order of the first CONTROL variable. Then within each level of the first control variable, the procedure arranges the observations in ascending order of the second CONTROL variable. This continues for all CONTROL variables specified.

In hierarchic serpentine sorting, PROC SURVEYSELECT sorts by the first CONTROL variable in ascending order. Then within the first level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in ascending order. Within the second level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in descending order. Sorting by the second CONTROL variable continues to alternate between ascending and descending sorting throughout all levels of the first CONTROL variable. If there is a third CONTROL variable, the procedure sorts by that variable within levels formed from the first two CONTROL variables, again alternating between ascending and descending sorting. This continues for all CONTROL variables specified. This sorting algorithm minimizes the change from one observation to the next with respect to the CONTROL variable values, thus making nearby observations more similar. For more information on serpentine sorting, refer to Chromy (1979) and Williams and Chromy (1980).

Sample Selection Methods

PROC SURVEYSELECT provides a variety of methods for selecting probability-based random samples. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population. Refer to Lohr (1999), Kish (1965, 1987), Kalton (1983), and Cochran (1977) for more information on probability sampling.

In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. PROC SURVEYSELECT provides the following methods that select units with equal probability: simple random sampling, unrestricted random sampling, systematic random sampling, and sequential random sampling. In simple random sampling, units are selected *without replacement*, which means that a unit cannot be selected more than once. Both systematic and sequential equal probability sampling are also without replacement. In unrestricted random sampling, units are selected *with replacement*, which means that a unit can be selected more than once. In with-replacement sampling, the *number of hits* refers to the number of times a unit is selected.

In probability proportional to size (PPS) sampling, a unit's selection probability is proportional to its size measure. PROC SURVEYSELECT provides the following methods that select units with probability proportional to size (PPS): PPS sampling without replacement, PPS sampling with replacement, PPS systematic sampling, PPS sequential sampling, Brewer's method, Murthy's method, and Sampford's method. PPS sampling is often used in cluster sampling, where you select clusters (or groups of sampling units) of varying size in the first stage of selection. For example, clusters may be schools, hospitals, or geographical areas, and the final sampling units may be students, patients, or citizens. Cluster sampling can provide efficiencies in frame construction and other survey operations. Refer to Lohr (1999), Kalton (1983), Kish (1965), and the other references cited in the following sections for more information.

All the probability sampling methods provided by PROC SURVEYSELECT use random numbers in their selection algorithms, as described in the following sections

and in the references cited. PROC SURVEYSELECT uses a uniform random number function to generate streams of pseudo-random numbers from an initial starting point, or *seed*. You can use the **SEED=** option to specify the initial seed. If you do not specify the **SEED=** option, PROC SURVEYSELECT uses the time of day from the computer's clock to obtain the initial seed. PROC SURVEYSELECT generates uniform random numbers according to the method of Fishman and Moore (1982), using a prime modulus multiplicative generator with modulus 2^{31} and multiplier 397204094. PROC SURVEYSELECT uses the same uniform random number generator as the RANUNI function. For more information on the RANUNI function, see the *SAS Language Reference: Dictionary*

The following sections give detailed descriptions of the sample selection methods available in PROC SURVEYSELECT. In these sections, n_h denotes the sample size (the number of units in the sample) for stratum h , and N_h denotes the population size (number of units in the population) for stratum h , for $h = 1, 2, \dots, H$. When the sample design is not stratified, n denotes the sample size, and N denotes the population size. For PPS sampling, M_{hi} represents the size measure for unit i in stratum h , M_h is the total of all size measures for the population of stratum h , and $Z_{hi} = M_{hi}/M_h$ is the relative size of unit i in stratum h .

Simple Random Sampling

The method of simple random sampling (**METHOD=SRS**) selects units with equal probability and without replacement. Each possible sample of n different units out of N has the same probability of being selected. The selection probability for each individual unit equals n/N . When you request stratified sampling with a **STRATA** statement, PROC SURVEYSELECT selects samples independently within strata. The selection probability for a unit in stratum h equals n_h/N_h for stratified simple random sampling.

By default, PROC SURVEYSELECT uses Floyd's ordered hash table algorithm for simple random sampling. This algorithm is fast, efficient, and appropriate for large data sets. Refer to Bentley and Floyd (1987) and Bentley and Knuth (1986).

If there is not enough memory available for Floyd's algorithm, PROC SURVEYSELECT switches to the sequential algorithm of Fann, Muller, and Rezucha (1962), which requires less memory but may require more time to select the sample. When SURVEYSELECT uses the alternative sequential algorithm, it writes a note to the log. To request the sequential algorithm, even if enough memory is available for Floyd's algorithm, you can specify **METHOD=SRS2** in the PROC SURVEYSELECT statement.

Unrestricted Random Sampling

The method of unrestricted random sampling (**METHOD=URS**) selects units with equal probability and with replacement. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of selections or hits for each unit equals n/N when sampling without stratification. For stratified sampling, the expected number of hits for a unit in stratum h equals n_h/N_h . Note that the expected number of hits exceeds one when the sample size n is greater than the population size N .

For unrestricted random sampling, by default, the output data set contains one observation for each distinct unit selected for the sample, together with a variable `NumberHits` that gives the number of times the observation was selected. But if you specify the `OUTHITS` option, then the output data set contains a separate observation for each selection, so that a unit selected three times, e.g., is represented by three observations in the output data set. For information on the contents of the output data set, see the section “[Output Data Set](#)” on page 4456.

Systematic Random Sampling

The method of systematic random sampling (`METHOD=SYS`) selects units at a fixed interval throughout the sampling frame or stratum after a random start. If you specify the sample size (or the stratum sample sizes) with the `SAMPsize=` option, PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals N/n , or N_h/n_h for stratified sampling. The selection probability for each unit equals n/N , or n_h/N_h for stratified sampling. If you specify the sampling rate (or the stratum sampling rates) with the `SAMPrate=` option, PROC SURVEYSELECT uses the inverse of the rate as the interval for systematic selection. The selection probability for each unit equals the specified rate.

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the `CONTROL` statement to order the input data set by the `CONTROL` variables before sample selection. If you also use a `STRATA` statement, PROC SURVEYSELECT sorts by the `CONTROL` variables within strata. If you do not specify a `CONTROL` statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

Sequential Random Sampling

If you specify the option `METHOD=SEQ` and do not include a `SIZE` statement, PROC SURVEYSELECT uses the equal probability version of Chromy’s method for sequential random sampling. This method selects units sequentially with equal probability and without replacement. Refer to Chromy (1979) and Williams and Chromy (1980). See the section “[PPS Sequential Sampling](#)” on page 4452 for a description of Chromy’s PPS selection method.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the `CONTROL` statement to sort the input data set by the `CONTROL` variables before sample selection. If you also use a `STRATA` statement, PROC SURVEYSELECT sorts by the `CONTROL` variables within strata. By default, the procedure uses hierarchic serpentine ordering for sorting. If you specify the `SORT=NEST` option, the procedure uses nested sorting. See the section “[Sorting by CONTROL Variables](#)” on page 4445 for descriptions of serpentine and nested sorting. If you do not specify a `CONTROL` statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

Following Chromy’s method of sequential selection, PROC SURVEYSELECT randomly chooses a starting unit from the entire stratum (or frame, if the design is not

stratified). Using this unit as the first one, the procedure treats the stratum units as a closed loop. This is done so that all pairwise (joint) selection probabilities are positive and an unbiased variance estimator can be obtained. The procedure numbers units sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, PROC SURVEYSELECT accumulates the expected number of selections or hits, where the expected number of selections ES_{hi} equals n_h/N_h for all units i in stratum h . The procedure computes

$$I_{hi} = \text{Int} \left(\sum_{j=1}^i ES_{hj} \right) = \text{Int} (i n_h/N_h)$$

$$F_{hi} = \text{Frac} \left(\sum_{j=1}^i ES_{hj} \right) = \text{Frac} (i n_h/N_h)$$

where Int denotes the integer part of the number, and Frac denotes the fractional part.

Considering each unit sequentially, Chromy's method determines whether unit i is selected by comparing the total number of selections for the first $i - 1$ units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of $I_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)}$, Chromy's method determines whether or not unit i is selected as follows. If $F_{hi} = 0$ or $F_{h(i-1)} > F_{hi}$, then unit i is selected with certainty. Otherwise, unit i is selected with probability

$$(F_{hi} - F_{h(i-1)}) / (1 - F_{h(i-1)})$$

If $T_{h(i-1)} = I_{h(i-1)} + 1$, Chromy's method determines whether or not unit i is selected as follows. If $F_{hi} = 0$ or $F_{hi} > F_{h(i-1)}$, then the unit is not selected. Otherwise, unit i is selected with probability

$$F_{hi} / F_{h(i-1)}$$

PPS Sampling without Replacement

If you specify the option `METHOD=PPS`, PROC SURVEYSELECT selects units with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals $n_h Z_{hi}$. The procedure uses the Hanurav-Vijayan algorithm for PPS selection without replacement. Hanurav (1967) introduced this algorithm for the selection of two units per stratum, and Vijayan (1968) generalized it for the selection of more than two units. The algorithm enables computation of joint

selection probabilities and provides joint selection probability values that usually ensure nonnegativity and stability of the Sen-Yates-Grundy variance estimator. Refer to Fox (1989), Golmant (1990), and Watts (1991) for details.

Notation in the remainder of this section drops the stratum subscript h for simplicity, but selection is still done independently within strata if you specify a stratified design. For a stratified design, n now denotes the sample size for the current stratum, N denotes the stratum population size, and M_i denotes the size measure for unit i in the stratum. If the design is not stratified, this notation applies to the entire sampling frame.

According to the Hanurav-Vijayan algorithm, PROC SURVEYSELECT first orders units within the stratum in ascending order by size measure, so that $M_1 \leq M_2 \leq \dots \leq M_N$. Then the procedure selects the PPS sample of n observations as follows:

1. The procedure randomly chooses one of the integers $1, 2, \dots, n$ with probability $\theta_1, \theta_2, \dots, \theta_n$, where

$$\theta_i = n (Z_{N-n+i+1} - Z_{N-n+i}) (T + i Z_{N-n+1}) / T$$

$Z_j = M_j/M$, $T = \sum_{j=1}^{N-n} Z_j$, and, by definition, $Z_{N+1} = 1/n$ to ensure that $\sum_{i=1}^n \theta_i = 1$.

2. If i is the integer selected in step 1, the procedure includes the last $(n-i)$ units of the stratum in the sample, where the units are ordered by size measure as described previously. The procedure then selects the remaining i units according to steps 3 through 6 below.
3. The procedure defines new normed size measures for the remaining $(N-n+i)$ stratum units that were not selected in steps 1 and 2:

$$\begin{aligned} Z_j^* &= Z_j / (T + i Z_{N-n+1}) && \text{for } j = 1, \dots, N - n + 1 \\ Z_j^* &= Z_{N-n+1} / (T + i Z_{N-n+1}) && \text{for } j = N - n + 2, \dots, N - n + i \end{aligned}$$

4. The procedure selects the next unit from the first $(N-n+1)$ stratum units with probability proportional to $a_j(1)$, where

$$\begin{aligned} a_1(1) &= i Z_1^* \\ a_j(1) &= i Z_j^* \prod_{k=1}^{j-1} [1 - (i-1) P_k] && \text{for } j = 2, \dots, N - n + 1 \end{aligned}$$

and $P_k = M_k / (M_{k+1} + M_{k+2} + \dots + M_{N-n+i})$.

5. If stratum unit j_1 is the unit selected in step 4, then the procedure selects the next unit from units $j_1 + 1$ through $N - n + 2$ with probability proportional to $a_j(2, j_1)$, where

$$\begin{aligned} a_{j_1+1}(2, j_1) &= (i-1) Z_{j_1+1}^* \\ a_j(2, j_1) &= (i-1) Z_j^* \prod_{k=j_1+1}^{j-1} [1 - (i-2) P_k] && \text{for } j = j_1 + 2, \dots, N - n + 2 \end{aligned}$$

6. The procedure repeats step 5 until all n sample units are selected.

If you request the **JTPROBS** option, PROC SURVEYSELECT computes the joint selection probabilities for all pairs of selected units in each stratum. The joint selection probability for units i and j in the stratum equals

$$P_{(ij)} = \sum_{r=1}^n \theta_r K_{ij}^{(r)}$$

where

$$\begin{aligned} K_{ij}^{(r)} &= 1 && N - n + r < i \leq N - 1 \\ &= r Z_{N-n+1} / (T + r Z_{N-n+1}) && N - n < i \leq N - n + r, \quad j > N - n + r \\ &= r Z_i / (T + r Z_{N-n+1}) && 1 \leq i \leq N - n, \quad j > N - n + r \\ &= \pi_{ij}^{(r)} && j \leq N - n + r \end{aligned}$$

and

$$\pi_{ij}^{(r)} = \frac{r(r-1)}{2} P_i Z_j \prod_{k=1}^{i-1} (1 - P_k)$$

where $P_k = M_k / (M_{k+1} + M_{k+2} + \cdots + M_{N-n+r})$.

PPS Sampling with Replacement

If you specify the option **METHOD=PPS_WR**, PROC SURVEYSELECT selects units with probability proportional to size and with replacement. The procedure makes n_h independent random selections from the stratum of N_h units, selecting with probability $Z_{hi} = M_{hi} / M_h$. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of selections or hits for unit i in stratum h equals $n_h Z_{hi}$. If you request the **JTPROBS** option, PROC SURVEYSELECT computes the joint expected number of hits for all pairs of selected units in each stratum. The joint expected number of hits for units i and j in stratum h equals

$$\begin{aligned} P_{h(ij)} &= n_h(n_h - 1) Z_{hi} Z_{hj} && \text{for } j \neq i \\ &= n_h(n_h - 1) Z_{hi} Z_{hi} / 2 && \text{for } j = i \end{aligned}$$

PPS Systematic Sampling

If you specify the option **METHOD=PPS_SYS**, PROC SURVEYSELECT selects units by systematic random sampling with probability proportional to size. Systematic sampling selects units at a fixed interval throughout the stratum or sampling frame after a random start. PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals M_h / n_h for stratified sampling and M/n for sampling without stratification. Depending on the sample size and the values of the size measures, it may be possible for a unit to be selected more

than once. The expected number of selections or hits for unit i in stratum h equals $n_h M_{hi} / M_h = n_h Z_{hi}$. Refer to Cochran (1977, pp. 265–266) and Madow (1949).

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the **CONTROL** statement to order the input data set by the CONTROL variables before sample selection. If you also use a **STRATA** statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

PPS Sequential Sampling

If you specify the option **METHOD=PPS_SEQ**, PROC SURVEYSELECT uses Chromy’s method of sequential random sampling. Refer to Chromy (1979) and Williams and Chromy (1980). Chromy’s method selects units sequentially with probability proportional to size and with minimum replacement. Selection *with minimum replacement* means that the actual number of hits for a unit can equal the integer part of the expected number of hits for that unit, or the next largest integer. This can be compared to selection *without replacement*, where each unit can be selected only once, so the number of hits can equal 0 or one. The other alternative is selection *with replacement*, where there is no restriction on the number of hits for each unit, so the number of hits can equal $0, 1, \dots, n_h$, where n_h is the stratum sample size.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the **CONTROL** statement to sort the input data set by the CONTROL variables before sample selection. If you also use a **STRATA** statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. By default, the procedure uses hierarchic serpentine ordering to sort the sampling frame by the CONTROL variables within strata. If you specify the **SORT=NEST** option, the procedure uses nested sorting. See the section “**Sorting by CONTROL Variables**” on page 4445 for descriptions of serpentine and nested sorting. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

According to Chromy’s method of sequential selection, PROC SURVEYSELECT first chooses a starting unit randomly from the entire stratum, with probability proportional to size. The procedure uses this unit as the first one and treats the stratum observations as a closed loop. This is done so that all pairwise (joint) expected number of hits are positive and an unbiased variance estimator can be obtained. The procedure numbers observations sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, Chromy’s method partitions the ordered stratum sampling frame into n_h zones of equal size. There is one selection from each zone and a total of n_h selections or hits, although fewer than n_h distinct

units may be selected. Beginning with the random start, the procedure accumulates the expected number of hits and computes

$$ES_{hi} = n_h Z_{hi}$$

$$I_{hi} = \text{Int} \left(\sum_{j=1}^i ES_{hj} \right)$$

$$F_{hi} = \text{Frac} \left(\sum_{j=1}^i ES_{hj} \right)$$

where ES_{hi} represents the expected number of hits for unit i in stratum h ; Int denotes the integer part of the number; and Frac denotes the fractional part.

Considering each unit sequentially, Chromy's method determines the actual number of hits for unit i by comparing the total number of hits for the first $i - 1$ units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of $I_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)}$, Chromy's method determines the total number of hits for the first i units as follows. If $F_{hi} = 0$ or $F_{h(i-1)} > F_{hi}$, then $T_{hi} = I_{hi}$. Otherwise, $T_{hi} = I_{hi} + 1$ with probability

$$(F_{hi} - F_{h(i-1)}) / (1 - F_{h(i-1)})$$

And the number of hits for unit i equals $T_{hi} - T_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)} + 1$, Chromy's method determines the total number of hits for the first i units as follows. If $F_{hi} = 0$, then $T_{hi} = I_{hi}$. If $F_{hi} > F_{h(i-1)}$, then $T_{hi} = I_{hi} + 1$. Otherwise, $T_{hi} = I_{hi} + 1$ with probability

$$F_{hi} / F_{h(i-1)}$$

Brewer's PPS Method

Brewer's method (**METHOD=PPS_BREWER**) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals $2M_{hi}/M_h = 2Z_{hi}$.

Brewer's algorithm first selects a unit with probability

$$\frac{Z_{hi} (1 - Z_{hi})}{D_h (1 - 2Z_{hi})}$$

where

$$D_h = \sum_{i=1}^{N_h} \frac{Z_{hi} (1 - Z_{hi})}{1 - 2Z_{hi}}$$

Then a second unit is selected from the remaining units with probability

$$\frac{Z_{hj}}{1 - Z_{hi}}$$

where unit i is the first unit selected. The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = \frac{2 Z_{hi} Z_{hj}}{D_h} \left(\frac{1 - Z_{hi} - Z_{hj}}{(1 - 2Z_{hi})(1 - 2Z_{hj})} \right)$$

Brewer's method requires that the relative size Z_{hi} be less than 0.5 for all units. Refer to Cochran (1977, pp. 261–263) and Brewer (1963). Brewer's method yields the same selection probabilities and joint selection probabilities as Durbin's method. Refer to Cochran (1977) and Durbin (1967).

Murthy's PPS Method

Murthy's method (`METHOD=PPS_MURTHY`) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals

$$P_{hi} = Z_{hi} [1 + K - (Z_{hi}/(1 - Z_{hi}))]$$

where $Z_{hi} = M_{hi}/M_h$. and

$$K = \sum_{j=1}^N [Z_{hj}/(1 - Z_{hj})]$$

Murthy's algorithm first selects a unit with probability Z_{hi} . Then a second unit is selected from the remaining units with probability $Z_{hj}/(1 - Z_{hi})$, where unit i is the first unit selected. The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = Z_{hi} Z_{hj} \frac{2 - Z_{hi} - Z_{hj}}{(1 - Z_{hi})(1 - Z_{hj})}$$

Refer to Cochran (1977, pp. 263–265) and Murthy (1957).

Sampford's PPS Method

Sampford's method (METHOD=PPS_SAMPFORD) is an extension of Brewer's method that selects more than two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals

$$P_{hi} = n_h \frac{M_{hi}}{M_h} = n_h Z_{hi}$$

Sampford's method first selects a unit from stratum h with probability Z_{hi} . Then subsequent units are selected with probability proportional to

$$\frac{Z_{hi}}{1 - n_h Z_{hi}}$$

and with replacement. If the same unit appears more than once in the sample of size n_h , then Sampford's algorithm rejects that sample and selects a new sample. The sample is accepted if it contains n_h distinct units.

The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = K_h \lambda_i \lambda_j \sum_{t=2}^{n_h} \left[t - n_h (P_{hi} + P_{hj}) L_{n_h-t}(ij) \right] / n_h^{t-2}$$

where

$$\lambda_i = \frac{Z_{hi}}{1 - n_h Z_{hi}}$$

$$L_m = \sum_{S(m)} \lambda_{i_1} \lambda_{i_2} \cdots \lambda_{i_m}$$

where $S(m)$ denotes all possible samples of size m , for $m = 1, 2, \dots, N_h$. The sum $L_m(ij)$ is defined similarly to L_m but sums over all possible samples of size m that do not include units i and j , and

$$K_h = \left(\sum_{t=1}^{n_h} t L_{n_h-t} / n_h^t \right)^{-1}$$

Sampford's method requires that the relative size Z_{hi} be less than $1/n_h$ for all units. Refer to Cochran (1977, pp. 262–263) and Sampford (1967).

Output Data Set

PROC SURVEYSELECT creates a SAS data set that contains the sample of selected units. You can specify the name of this output data set with the **OUT=** option in the PROC SURVEYSELECT statement. If you omit the **OUT=** option, the data set is named **DATA n** , where n is the smallest integer that makes the name unique.

By default, the output data set contains one observation for each unit selected for the sample. But if you specify the **OUTALL** option, the output data set includes all observations from the input data set. With **OUTALL**, the output data set also contains a variable to indicate each observation's selection status. The variable **Selected** equals 1 for an observation selected for the sample, and equals 0 for an observation not selected. The **OUTALL** option is available only for equal probability selection methods.

If you specify the **OUTHITS** option for methods that may select the same unit more than once (that is, methods that select with replacement or with minimum replacement), the output data set contains a separate observation for each selection. If you do not specify the **OUTHITS** option, the output data set contains only one observation for each selected unit, even if the unit is selected more than once, and the variable **NumberHits** contains the number of hits or selections for that unit.

The output data set contains design information and selection statistics, depending on the selection method and output options you specify. The output data set can include the following variables:

- **Selected**, which indicates whether or not the observation is selected for the sample. This variable is included if you specify the **OUTALL** option. It equals 1 for an observation selected for the sample, and it equals 0 for an observation not selected.
- **STRATA** variables, which you specify in the **STRATA** statement
- **Replicate**, which is the sample replicate number. This variable is included when you request replicated sampling with the **REP=** option.
- **ID** variables, which you name in the **ID** statement
- **CONTROL** variables, which you specify in the **CONTROL** statement
- **Zone**, which is the selection zone. This variable is included for **METHOD=PPS_SEQ**.
- **SIZE** variable, which you specify in the **SIZE** statement
- **AdjustedSize**, which is the adjusted size measure. This variable is included if you request adjusted sizes with the **MINSIZE=** option or the **MAXSIZE=** option.
- **Certain**, which indicates certainty selection. This variable is included if you specify the **CERTSIZE=** option. It equals 1 for units included with certainty because their size measures exceed the certainty size measure. Otherwise, it equals 0.

- **NumberHits**, which is the number of hits or selections. This variable is included for selection methods that are with replacement or with minimum replacement (**METHOD=URS**, **METHOD=PPS_WR**, **METHOD=PPS_SYS**, and **METHOD=PPS_SEQ**).

The output data set includes the following variables if you request a PPS selection method or if you specify the **STATS** option for other methods:

- **ExpectedHits**, which is the expected number of hits or selections. This variable is included for selection methods that are with replacement or with minimum replacement, and so may select the same unit more than once (**METHOD=URS**, **METHOD=PPS_WR**, **METHOD=PPS_SYS**, and **METHOD=PPS_SEQ**).
- **SelectionProb**, which is the probability of selection. This variable is included for selection methods that are without replacement.
- **SamplingWeight**, which is the sampling weight. This variable equals the inverse of **ExpectedHits** or **SelectionProb**.

For **METHOD=PPS_BREWER** and **METHOD=PPS_MURTHY**, which select two units from each stratum with probability proportional to size, the output data set contains the following variable:

- **JtSelectionProb**, which is the joint probability of selection for the two units selected from the stratum

If you request the **JTPROBS** option to compute joint probabilities of selection for **METHOD=PPS** or **METHOD=PPS_SAMPFORD**, then the output data set contains the following variables:

- **Unit**, which is an identification variable that numbers the selected units sequentially within each stratum
- **JtProb_1**, **JtProb_2**, **JtProb_3**, ..., where the variable **JtProb_1** contains the joint probability of selection for the current unit and unit 1. Similarly, **JtProb_2** contains the joint probability of selection for the current unit and unit 2, and so on.

If you request the **JTPROBS** option for **METHOD=PPS_WR**, then the output data set contains the following variables:

- **Unit**, which is an identification variable that numbers the selected units sequentially within each stratum
- **JtHits_1**, **JtHits_2**, **JtHits_3**, ..., where the variable **JtHits_1** contains the joint expected number of hits for the current unit and unit 1. Similarly, **JtHits_2** contains the joint expected number of hits for the current unit and unit 2, and so on.

If you request the **OUTSIZE** option, the output data set contains the following variables. If you specify a **STRATA** statement, the output data set includes stratum-level values of these variables. Otherwise, the output data set contains population-level values of these variables.

- **MinimumSize**, which is the minimum size measure specified with the **MINSIZE=** option. This variable is included if you request the **MINSIZE=** option.
- **MaximumSize**, which is the maximum size measure specified with the **MAXSIZE=** option. This variable is included if you request the **MAXSIZE=** option.
- **CertaintySize**, which is the certainty size measure specified with the **CERTSIZE=** option. This variable is included if you request the **CERTSIZE=** option.
- **Total**, which is the total number of sampling units in the stratum. This variable is included if there is no **SIZE** statement.
- **TotalSize**, which is the total of size measures in the stratum. This variable is included if there is a **SIZE** statement.
- **TotalAdjSize**, which is the total of adjusted size measures in the stratum. This variable is included if there is a **SIZE** statement and if you request adjusted sizes with the **MAXSIZE=** option or the **MINSIZE=** option.
- **SamplingRate**, which is the sampling rate. This variable is included if you specify the **SAMPRATE=** option.
- **SampleSize**, which is the sample size. This variable is included if you specify the **SAMPSIZE=** option, or if you specify **METHOD=PPS_BREWER** or **METHOD=PPS_MURTHY**, which select two units from each stratum.

If you request the **OUTSEED** option, the output data set contains the following variable:

- **InitialSeed**, which is the initial seed for the stratum.

Displayed Output

By default, PROC SURVEYSELECT displays two tables that summarize the sample selection. You can suppress display of these tables by using the **NOPRINT** option.

PROC SURVEYSELECT creates an output data set that contains the units selected for the sample. The procedure does not display this output data set. Use PROC PRINT, PROC REPORT, or any other SAS reporting tool to display the output data set.

PROC SURVEYSELECT displays the following information in the “Sample Selection Method” table:

- Selection Method
- Size Measure variable, if you specify a [SIZE](#) statement
- Minimum Size Measure, if you specify the [MINSIZE=](#) option
- Maximum Size Measure, if you specify the [MAXSIZE=](#) option
- Certainty Size Measure, if you specify the [CERTSIZE=](#) option
- Strata Variables, if you specify a [STRATA](#) statement
- Control Variables, if you specify a [CONTROL](#) statement
- type of Control Sorting, Serpentine or Nested, if you specify a [CONTROL](#) statement

PROC SURVEYSELECT displays the following information in the “Sample Selection Summary” table:

- Input Data Set name
- Sorted Data Set name, if you specify the [OUTSORT=](#) option
- Random Number Seed
- Sample Size or Stratum Sample Size, if you specify the [SAMPSIZE=*n*](#) option
- Sample Size Data Set, if you specify the [SAMPSIZE=*SAS-data-set*](#) option
- Sampling Rate or Stratum Sampling Rate, if you specify the [SAMPRATE=*r*](#) option
- Sampling Rate Data Set, if you specify the [SAMPRATE=*SAS-data-set*](#) option
- Minimum Sample Size or Stratum Minimum Sample Size, if you specify the [NMIN=](#) option with the [SAMPRATE=](#) option
- Maximum Sample Size or Stratum Maximum Sample Size, if you specify the [NMAX=](#) option with the [SAMPRATE=](#) option
- Selection Probability, if you specify [METHOD=SRS](#), [METHOD=SYS](#), or [METHOD=SEQ](#) and do not specify a [STRATA](#) statement

- Output Data Set name

ODS Table Names

PROC SURVEYSELECT assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 72.2. ODS Tables Produced in PROC SURVEYSELECT

ODS Table Name	Description	Statement	Option
Method	Sample selection method	PROC	default
Summary	Sample selection summary	PROC	default

Examples

Example 72.1. Replicated Sampling

This example uses the `Customers` data set from the section “Getting Started” on page 4422. The data set `Customers` contains an Internet service provider’s current subscribers, and the service provider wants to select a sample from this population for a customer satisfaction survey.

This example illustrates replicated sampling, which selects multiple samples from the survey population according to the same design. You can use replicated sampling to provide a simple method of variance estimation, or to evaluate variable nonsampling errors such as interviewer differences. Refer to Lohr (1999), Kish (1965, 1987), and Kalton (1983) for information on replicated sampling.

This design includes four replicates, each with a sample size of 50 customers. The sampling frame is stratified by `State` and sorted by `Type` and `Usage` within strata. Customers are selected by sequential random sampling with equal probability within strata. The following PROC SURVEYSELECT statements select a probability sample of customers from the `Customers` data set using this design.

```

title1 'Customer Satisfaction Survey';
title2 'Replicated Sampling';
proc surveyselect data=Customers
    method=seq n=(8 12 20 10)
    rep=4
    seed=40070 out=SampleRep;
    strata State;
    control Type Usage;
run;

```

The STRATA statement names the stratification variable `State`. The CONTROL statement names the control variables `Type` and `Usage`. In the PROC SURVEYSELECT statement, the METHOD=SEQ option requests sequential random sampling. The REP=4 option specifies four replicates of this sample. The N=(8 12 20 10) option specifies the stratum sample sizes for each replicate. The

N= option lists the stratum sample sizes in the same order as the strata appear in the **Customers** data set, which has been sorted by **State**. The sample size of eight customers corresponds to the first stratum, **State = 'AL'**. The sample size 12 corresponds to the next stratum, **State = 'FL'**, and so on. The **SEED=40070** option specifies '40070' as the initial seed for random number generation.

Output 72.1.1 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 200 customers is selected in four replicates. PROC SURVEYSELECT selects each replicate using sequential random sampling within strata determined by **State**. The sampling frame **Customers** is sorted by control variables **Type** and **Usage** within strata, according to hierarchic serpentine sorting. The output data set **SampleRep** contains the sample.

Output 72.1.1. Sample Selection Summary

Customer Satisfaction Survey Replicated Sampling	
The SURVEYSELECT Procedure	
Selection Method	Sequential Random Sampling With Equal Probability
Strata Variable	State
Control Variables	Type Usage
Control Sorting	Serpentine
Input Data Set	CUSTOMERS
Random Number Seed	40070
Number of Strata	4
Number of Replicates	4
Total Sample Size	200
Output Data Set	SAMPLEREP

The following PROC PRINT statements display the selected customers for the first stratum, **State = 'AL'**, from the output data set **SampleRep**.

```

title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Replicated Design';
title3 '(First Stratum)';
proc print data=SampleRep;
  where State = 'AL';
run;

```

Output 72.1.2. Customer Sample (First Stratum)

Customer Satisfaction Survey Sample Selected by Replicated Design (First Stratum)

Output 72.1.2 displays the 32 sample customers of the first stratum (State = 'AL') from the output data set `SampleRep`, which includes the entire sample of 200 customers. The variable `SelectionProb` contains the selection probability, and `SamplingWeight` contains the sampling weight. Since customers are selected with equal probability within strata in this design, all customers in the same stratum have the same selection probability. These selection probabilities and sampling weights apply to a single replicate, and the variable `Replicate` contains the sample replicate number.

Example 72.2. PPS Selection of Two Units Per Stratum

A state health agency plans to conduct a state-wide survey of a variety of different hospital services. The agency plans to select a probability sample of individual discharge records within hospitals using a two-stage sample design. First stage units are hospitals, and second stage units are patient discharges during the study time period. Hospitals are stratified first according to geographic region and then by rural/urban type and size of hospital. Two hospitals are selected from each stratum with probability proportional to size. This example describes hospital selection for this survey using PROC SURVEYSELECT.

The data set `HospitalFrame` contains all hospitals in the first geographical region of this state.

```
data HospitalFrame;
  input Hospital$ Type$ SizeMeasure @@;
  if (SizeMeasure < 20) then Size='Small ';
  else if (SizeMeasure < 50) then Size='Medium';
  else Size='Large ';
  datalines;
034 Rural  0.870   107 Rural  1.316
079 Rural  2.127   223 Rural  3.960
236 Rural  5.279   165 Rural  5.893
086 Rural  0.501   141 Rural 11.528
042 Urban  3.104   124 Urban  4.033
006 Urban  4.249   261 Urban  4.376
195 Urban  5.024   190 Urban 10.373
038 Urban 17.125   083 Urban 40.382
259 Urban 44.942   129 Urban 46.702
133 Urban 46.992   218 Urban 48.231
026 Urban 61.460   058 Urban 65.931
119 Urban 66.352
;
```

In the SAS data set `HospitalFrame`, the variable `Hospital` identifies the hospital. The variable `Type` equals 'Urban' if the hospital is located in an urbanized area, and 'Rural' otherwise. The variable `SizeMeasure` contains the hospital's size measure, which is constructed from past data on service utilization for the hospital together with the desired sampling rates for each service. This size measure reflects the amount of relevant survey information expected from the hospital. Refer to Drummond et al. (1982) for details on this type of size measure. The variable `Size` equals 'Small', 'Medium', or 'Large', depending on the value of the hospital's size measure.

The following PROC PRINT statements display the data set `Hospital Frame`.

```
title1 'Hospital Utilization Survey';
title2 'Sampling Frame, Region 1';
proc print data=HospitalFrame;
run;
```

Output 72.2.1. Sampling Frame

Hospital Utilization Survey Sampling Frame, Region 1				
Obs	Hospital	Type	Size Measure	Size
1	034	Rural	0.870	Small
2	107	Rural	1.316	Small
3	079	Rural	2.127	Small
4	223	Rural	3.960	Small
5	236	Rural	5.279	Small
6	165	Rural	5.893	Small
7	086	Rural	0.501	Small
8	141	Rural	11.528	Small
9	042	Urban	3.104	Small
10	124	Urban	4.033	Small
11	006	Urban	4.249	Small
12	261	Urban	4.376	Small
13	195	Urban	5.024	Small
14	190	Urban	10.373	Small
15	038	Urban	17.125	Small
16	083	Urban	40.382	Medium
17	259	Urban	44.942	Medium
18	129	Urban	46.702	Medium
19	133	Urban	46.992	Medium
20	218	Urban	48.231	Medium
21	026	Urban	61.460	Large
22	058	Urban	65.931	Large
23	119	Urban	66.352	Large

The following PROC SURVEYSELECT statements select a probability sample of hospitals from the HospitalFrame data set, using a stratified design with PPS selection of two units from each stratum.

```

title1 'Hospital Utilization Survey';
proc surveyselect data=HospitalFrame
  method=pps_brewer
  seed=48702 out=SampleHospitals;
  size SizeMeasure;
  strata Type Size notsorted;
run;

```

The STRATA statement names the stratification variables Type and Size. The NOTSORTED option specifies that observations with the same STRATA variable values are grouped together but are not necessarily sorted in alphabetical or increasing numerical order. In the HospitalFrame data set, Size = 'Small' precedes Size = 'Medium'.

In the PROC SURVEYSELECT statement, the METHOD=PPS_BREWER option requests sample selection by Brewer's method, which selects two units per stratum with probability proportional to size. The SEED=48702 option specifies '48702' as the initial seed for random number generation. The SIZE statement specifies the size measure variable. It is not necessary to specify the sample size with the N= option, since Brewer's method always selects two units from each stratum.

Output 72.2.2 displays the output from PROC SURVEYSELECT. A total of 8 hospitals were selected from the 4 strata. The data set SampleHospitals contains the selected hospitals.

Output 72.2.2. Sample Selection Summary

Hospital Utilization Survey	
The SURVEYSELECT Procedure	
Selection Method	Brewer's PPS Method
Size Measure	SizeMeasure
Strata Variables	Type
	Size

Random Number Seed	48702
Stratum Sample Size	2
Number of Strata	4
Total Sample Size	8
Output Data Set	SAMPLEHOSPITALS

The following PROC PRINT statements display the sample hospitals.

```

title1 'Hospital Utilization Survey';
title2 'Sample Selected by Stratified PPS Design';
proc print data=SampleHospitals;
run;

```

Output 72.2.3. Sample Hospitals

Hospital Utilization Survey							
Sample Selected by Stratified PPS Design							
Obs	Type	Size	Hospital	Size Measure	Selection Prob	Sampling Weight	Jt Selection Prob
1	Rural	Small	079	2.127	0.13516	7.39868	0.01851
2	Rural	Small	236	5.279	0.33545	2.98106	0.01851
3	Urban	Small	006	4.249	0.17600	5.68181	0.01454
4	Urban	Small	195	5.024	0.20810	4.80533	0.01454
5	Urban	Medium	133	46.992	0.41357	2.41795	0.11305
6	Urban	Medium	218	48.231	0.42448	2.35584	0.11305
7	Urban	Large	026	61.460	0.63445	1.57617	0.31505
8	Urban	Large	058	65.931	0.68060	1.46929	0.31505

The variable SelectionProb contains the selection probability for each hospital in the sample. The variable JtSelectionProb contains the joint probability of selection for the two sample hospitals in the same stratum. The variable SamplingWeight contains the sampling weight component for this first stage of the design. The final-stage weight components, which correspond to patient record selection within hospitals, can be multiplied by the hospital weight components to obtain the overall sampling weights.

Example 72.3. PPS (Dollar-Unit) Sampling

A small company wants to audit employee travel expenses in an effort to improve the expense reporting procedure and possibly reduce expenses. The company does not have resources to examine all expense reports and wants to use statistical sampling to objectively select expense reports for audit.

The data set `TravelExpense` contains the dollar amount of all employee travel expense transactions during the past month.

```

data TravelExpense;
  input ID$ Amount @@;
  if (Amount < 500) then Level='1_Low ';
  else if (Amount > 1500) then Level='3_High';
  else Level='2_Avg ';
  datalines;
110 237.18 002 567.89 234 118.50
743 74.38 411 1287.23 782 258.10
216 325.36 174 218.38 568 1670.80
302 134.71 285 2020.70 314 47.80
139 1183.45 775 330.54 425 780.10
506 895.80 239 620.10 011 420.18
672 979.66 142 810.25 738 670.85
192 314.58 243 87.50 263 1893.40
496 753.30 332 540.65 486 2580.35
614 230.56 654 185.60 308 688.43
784 505.14 017 205.48 162 650.42
289 1348.34 691 30.50 545 2214.80
517 940.35 382 217.85 024 142.90
478 806.90 107 560.72
;

```

In the SAS data set `TravelExpense`, the variable `ID` identifies the travel expense report. The variable `Amount` contains the dollar amount of the reported expense. The variable `Level` equals '1_Low', '2_Avg', or '3_High', depending on the value of `Amount`.

In the sample design for this audit, expense reports are stratified by `Level`. This ensures that each of these expense levels is included in the sample and also permits a disproportionate allocation of the sample, selecting proportionately more of the expense reports from the higher levels. Within strata, the sample of expense reports is selected with probability proportional to the amount of the expense, thus giving a greater chance of selection to larger expenses. In auditing terms, this is known as monetary-unit sampling. Refer to Wilburn (1984).

PROC SURVEYSELECT requires that the input data set be sorted by the STRATA variables. The following PROC SORT statements sort the `TravelExpense` data set by the stratification variable `Level`.

```

proc sort data=TravelExpense;
  by Level;
run;

```

The following PROC PRINT statements display the sampling frame data set TravelExpense, which contains 41 observations.

```

title1 'Travel Expense Audit';
proc print data=TravelExpense;
run;

```

Output 72.3.1. Sampling Frame

The following PROC SURVEYSELECT statements select a probability sample of expense reports from the `TravelExpense` data set using the stratified design with PPS selection within strata.

```

title1 'Travel Expense Audit';
proc surveyselect data=TravelExpense
  method=pps n=(6 10 4)
  seed=47279 out=AuditSample;
  size Amount;
  strata Level;
run;

```

The STRATA statement names the stratification variable `Level`. The SIZE statement specifies the size measure variable `Amount`. In the PROC SURVEYSELECT statement, the METHOD=PPS option requests sample selection with probability proportional to size and without replacement. The N=(6 10 4) option specifies the stratum sample sizes, listing the sample sizes in the same order that the strata appear in the `TravelExpense` data set. The sample size of 6 corresponds to the first stratum, `Level = '1_Low'`, the sample size of 10 corresponds to the second stratum, `Level = '2_Avg'`, and 4 corresponds to the last stratum, `Level = '3_High'`. The SEED=47279 option specifies '47279' as the initial seed for random number generation.

[Output 72.3.2](#) displays the output from PROC SURVEYSELECT. A total of 20 expense reports is selected for audit. The data set `AuditSample` contains the sample of travel expense reports.

Output 72.3.2. Sample Selection Summary

Chapter 73

The TPHREG Procedure

(Experimental)

Overview

The TPHREG procedure, experimental in this release, includes most of the functionality of the PHREG procedure (see [Chapter 54, “The PHREG Procedure”](#)) with the additional benefits of the CLASS statement. The CLASS statement enables you to specify categorical variables (also known as factors or CLASS variables) to be used in the analysis. Model effects, including covariates, main effects (CLASS variables), crossed effects (interactions), and nested effects, can be specified in the same way as in the GLM procedure. The CLASS statement supports the less-than-full-rank parameterization as in the GLM procedure as well as various full-rank parameterization methods such as reference coding, effect coding, and orthogonal polynomial coding. For some of the full-rank coding schemes, you can designate a specific value (category or level) of the CLASS variable as the reference level. The CLASS statement also enables you to specify the ordering of the categories of CLASS variables, to reverse the ordering of the categories, and to treat categories with missing values as valid categories.

With the TPHREG procedure, you can control how to move model effects in and out of a model with various model-building strategies such as forward selection, backward elimination, or stepwise selection. When there are no interaction terms, a main effect can enter or leave a model in a single step based on the p -value of the score or Wald statistic, respectively. When there are crossed or nested effects, the selection process also depends on whether you want to preserve model hierarchy. The HIERARCHY= option in the MODEL statement enables you to specify whether model hierarchy is to be preserved, how model hierarchy is applied, and whether a single effect or multiple effects can be moved in a single step.

The TPHREG procedure also enables you to specify CONTRAST statements for testing customized hypotheses concerning the regression parameters. Each CONTRAST statement also provides estimation of individual rows of contrasts, which is particularly useful in comparing the hazards between the categories of a CLASS variable.

Syntax

The PROC TPHREG statement invokes the TPHREG procedure. All the other statements in the PHREG procedure (with the exception of the experimental ASSESS statement) are available in the TPHREG procedure. The MODEL statement in the TPHREG procedure enables you to specify explanatory effects, not just individual continuous variables, and has additional options specifically for having CLASS variables. In addition, you can specify the CLASS statement and the CONTRAST statement as follows:

```
CLASS variable <(options)> <variable <(options)>... >
      < / options >;
```

```
CONTRAST 'label' effect values <,... effect values>< / options >;
```

The PROC TPHREG statement and the MODEL statement are required. The CLASS statement (if used) must precede the MODEL statement, and CONTRAST statements (if used) must follow the MODEL statement. The CLASS statement specifies the categorical variables to be used as explanatory variables. Variables specified in the CLASS statement have to exist in the input data. You cannot use programming statements to modify their values. The CONTRAST statement tests customized hypotheses concerning the regression parameters and estimates the parameters for the corresponding rows of contrasts.

PROC TPHREG Statement

```
PROC TPHREG < options > ;
```

All PROC PHREG statement options can be used in the PROC TPHREG statement. In addition, you can specify the following option:

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

MODEL Statement

```
MODEL time < *censor ( list ) > = effects < /options > ;
```

```
MODEL (t1, t2) < *censor(list) > = effects < /options > ;
```

The specifications of the time variables, the censoring indicator, and censored values are same as those in the PHREG procedure. The model *effects*, which follow the equal sign, include continuous or CLASS variables as the main effects. Categorical variables, which can be character or numeric, must be declared in the CLASS statement. Crossed and nested effects can be specified in the same fashion as in the GLM procedure (see the section “Specification of Effects” on page 1784 of Chapter 32, “The GLM Procedure,” for more information).

Any MODEL statement options in the PHREG procedure can be used in the TPHREG procedure. To accommodate the broader specification of model effects, the variable-selection options INCLUDE=, START=, and STOP= have been modified.

INCLUDE=*n*

includes the first *n* effects in the MODEL statement in every model. By default, INCLUDE=0. The INCLUDE= option has no effect when SELECTION=NONE.

START=*n*

begins the FORWARD, BACKWARD, or STEPWISE selection process with the first *n* effects listed in the MODEL statement. The value of *n* ranges from 0 to *s*, where *s* is the total number of effects in the MODEL statement. The default value of *n* is *s* for the BACKWARD method and 0 for the FORWARD and STEPWISE methods. Note that START=*n* specifies only that the first *n* effects appear in the first model, while INCLUDE=*n* requires that the first *n* effects be included in every model. For the SCORE method, START=*n* specifies that the smallest models contain *n* effects, where *n* ranges from 1 to *s*; the default value is 1. The START= option has no effect when SELECTION=NONE.

STOP=*n*

specifies the maximum (FORWARD method) or minimum (BACKWARD method) number of effects to be included in the final model. The effect selection process is stopped when *n* effects are found. The value of *n* ranges from 0 to *s*, where *s* is the total number of effects in the MODEL statement. The default value of *n* is *s* for the FORWARD method and 0 for the BACKWARD method. For the SCORE method, STOP=*n* specifies that the smallest models contain *n* effects, where *n* ranges from 1 to *s*; the default value of *n* is *s*. The STOP= option has no effect when SELECTION=NONE or STEPWISE.

Two new options are added to the MODEL statement in the TPHREG procedure.

HIERARCHY=*keyword*

HIER=*keyword*

specifies whether and how the model hierarchy requirement is applied and whether a single effect or multiple effects are allowed to enter or leave the model in one step. You can specify that only CLASS variable effects, or both CLASS and continuous variable effects, be subject to the hierarchy requirement. The HIERARCHY= option is ignored unless you also specify the FORWARD, BACKWARD, or STEPWISE selection method.

Model hierarchy refers to the requirement that, for any term to be in the model, all effects contained in the term must be present in the model. For example, in order for the interaction A*B to enter the model, the main effects A and B must be in the model. Likewise, neither effect A nor B can leave the model while the interaction A*B is in the model.

The keywords you can specify in the HIERARCHY= option are described as follows:

NONE

Model hierarchy is not maintained. Any single effect can enter or leave the model at any given step of the selection process.

SINGLE

Only one effect can enter or leave the model at one time, subject to the model hierarchy requirement. For example, suppose that you specify the main effects A and B and the interaction of A*B in the model. In the first step of the selection process, either A or B can enter the model. In the second step, the other main effect can enter the model. The interaction effect can enter the model only when both main effects have already been entered. Also, before A or B can be removed from the model, the A*B interaction must first be removed. All effects (CLASS and continuous variables) are subject to the hierarchy requirement.

SINGLECLASS

This is the same as HIERARCHY=SINGLE except that only CLASS effects are subject to the hierarchy requirement.

MULTIPLE

More than one effect can enter or leave the model at one time, subject to the model hierarchy requirement. In a forward selection step, a single main effect can enter the model, or an interaction can enter the model together with all the effects that are contained in the interaction. In a backward elimination step, an interaction itself, or the interaction together with all the effects that the interaction contains, can be removed. All effects (CLASS and continuous variable) are subject to the hierarchy requirement.

MULTIPLECLASS

This is the same as HIERARCHY=MULTIPLE except that only CLASS effects are subject to the hierarchy requirement.

The default value is HIERARCHY=SINGLE, which means that model hierarchy is to be maintained for all effects (that is, both CLASS and continuous variable effects) and that only a single effect can enter or leave the model at each step.

NODUMMYPRINT

NODESIGNPRINT

NODP

suppresses the “Class Level Information” table, which shows how the design matrix columns for the CLASS variables are coded.

CLASS Statement

```
CLASS variable <(options)> <variable <(options)>... >
      < / options >;
```

The CLASS statement names the categorical variables to be used in the analysis. The CLASS statement must precede the MODEL statement. You can specify various *options* for each variable by enclosing them in parentheses after the variable name. You can also specify global *options* for the CLASS statement by placing them after a slash (/). Global *options* are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the global *options* specified on any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the global *options*.

CPREFIX= *n*

specifies that, at most, the first *n* characters of a CLASS variable name be used in creating names for the corresponding dummy variables. The default is $32 - \min(32, \max(2, f))$, where *f* is the formatted length of the CLASS variable.

DESCENDING

DESC

reverses the sorting order of the categorical variable.

LPREFIX= *n*

specifies that, at most, the first *n* characters of a CLASS variable label be used in creating labels for the corresponding dummy variables.

MISSING

allows missing value (for example, '.' for a numeric variable and blanks for a character variable) as a valid value for the CLASS variable.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the categories of categorical variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option may be useful when you use the CONTRAST statement. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values. The following table shows how PROC TPHREG interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, see the chapter on the SORT procedure in the *SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

PARAM=keyword

specifies the parameterization method for the categorical variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes. The default is PARAM=REF. If PARAM=ORTHPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used. See the “CLASS Variable Parameterization” section on page 4482 for further details.

EFFECT	specifies effect coding
GLM	specifies less-than-full-rank, reference-cell coding; this option can only be used as a global option
ORDINAL	specifies the cumulative parameterization for an ordinal CLASS variable.
POLYNOMIAL	
POLY	specifies polynomial coding
REFERENCE	
REF	specifies reference cell coding
ORTHEFFECT	orthogonalizes PARAM=EFFECT
ORTHORDINAL	orthogonalizes PARAM=ORDINAL
ORTHPOLY	orthogonalizes PARAM=POLYNOMIAL
ORTHREF	orthogonalizes PARAM=REFERENCE

The EFFECT, POLYNOMIAL, REFERENCE, ORDINAL, and their orthogonal parameterizations are full rank parameterization. The REF= option in the CLASS statement determines the reference level for the EFFECT, REFERENCE, and their orthogonal parameterizations.

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization.

REF='level' | keyword

specifies the reference level for PARAM=EFFECT or PARAM=REF. For an individual variable, you can specify a specific *level* of the variable in the REF= option. For a global or individual variable REF= *option*, you can use one of the following *keywords*. The default is REF=LAST.

FIRST	designates the first ordered level as reference
LAST	designates the last ordered level as reference

TRUNCATE

specifies that class levels should be determined using no more than the first 16 characters of the formatted values of CLASS variables. This is a global option, not an individual CLASS variable option.

CONTRAST Statement

CONTRAST *'label'* *row-description* <,... *row-description*>< /*options*> ;

where a *row-description* is: *effect values* <,...*effect values*>

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST statement in PROC GLM and PROC CATMOD, depending on the coding schemes used with any categorical variables involved.

The CONTRAST statement enables you to specify a matrix, \mathbf{L} , for testing the hypothesis $\mathbf{L}\beta = 0$. You must be familiar with the details of the model parameterization that PROC TPHREG uses (for more information, see the PARAM= option in the “CLASS Statement” section on page 4477). Optionally, the CONTRAST statement enables you to estimate each row, $\mathbf{l}'_i\beta$, of $\mathbf{L}\beta$ and test the hypothesis $\mathbf{l}'_i\beta = 0$. Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the MODEL statement.

The following parameters are specified in the CONTRAST statement:

- label* identifies the contrast on the output. A label is required for every contrast specified, and it must be enclosed in quotes.
- effect* identifies an effect that appears in the MODEL statement. You do not need to include all effects that are included in the MODEL statement.
- values* are constants that are elements of the \mathbf{L} matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The “Class Level Information” table shows the ordering of levels within variables. The E option, described later in this section, enables you to verify the proper correspondence of *values* to parameters.

The rows of \mathbf{L} are specified in order and are separated by commas. Multiple degree-of-freedom hypotheses can be tested by specifying multiple *row-descriptions*. For any of the full-rank parameterizations, if an effect is not specified in the CONTRAST statement, all of its coefficients in the \mathbf{L} matrix are set to 0. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.

When you use effect coding (by specifying `PARAM=EFFECT` in the `CLASS` statement), all parameters are directly estimable (involve no other parameters). For example, suppose an effect coded `CLASS` variable `A` has four levels. Then there are three parameters ($\alpha_1, \alpha_2, \alpha_3$) representing the first three levels, and the fourth parameter is represented by

$$-\alpha_1 - \alpha_2 - \alpha_3$$

To test the first versus the fourth level of `A`, you would test

$$\alpha_1 = -\alpha_1 - \alpha_2 - \alpha_3$$

or, equivalently,

$$2\alpha_1 + \alpha_2 + \alpha_3 = 0$$

which, in the form $L\beta = 0$, is

$$\begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = 0$$

Therefore, you would use the following `CONTRAST` statement:

```
contrast '1 vs. 4' A 2 1 1;
```

To contrast the third level with the average of the first two levels, you would test

$$\frac{\alpha_1 + \alpha_2}{2} = \alpha_3$$

or, equivalently,

$$\alpha_1 + \alpha_2 - 2\alpha_3 = 0$$

Therefore, you would use the following `CONTRAST` statement:

```
contrast '1&2 vs. 3' A 1 1 -2;
```

Other `CONTRAST` statements are constructed similarly. For example,

```
contrast '1 vs. 2' A 1 -1 0;
contrast '1&2 vs. 4' A 3 3 2;
contrast '1&2 vs. 3&4' A 2 2 0;
contrast 'Main Effect' A 1 0 0,
A 0 1 0,
A 0 0 1;
```

When you use the less-than-full-rank parameterization (by specifying PARAM=GLM in the CLASS statement), each row is checked for estimability. If PROC TPHREG finds a contrast to be nonestimable, it displays missing values in corresponding rows in the results. PROC TPHREG handles missing level combinations of categorical variables in the same manner as PROC GLM. Parameters corresponding to missing level combinations are not included in the model. This convention can affect the way in which you specify the **L** matrix in your CONTRAST statement. If the elements of **L** are not specified for an effect that contains a specified effect, then the elements of the specified effect are distributed over the levels of the higher-order effect just as the GLM procedure does for its CONTRAST and ESTIMATE statements. For example, suppose that the model contains effects A and B and their interaction A*B. If you specify a CONTRAST statement involving A alone, the **L** matrix contains nonzero terms for both A and A*B, since A*B contains A.

The degrees of freedom is the number of linearly independent constraints implied by the CONTRAST statement, that is, the rank of **L**.

You can specify the following options after a slash (/).

ALPHA= *p*

specifies the level of significance *p* for the $100(1 - p)\%$ confidence interval for each contrast when the ESTIMATE option is specified. The value *p* must be between 0 and 1. By default, *p* is equal to the value of the ALPHA= option in the PROC TPHREG statement, or 0.05 if that option is not specified.

E

requests that the **L** matrix be displayed.

ESTIMATE=*keyword*

requests that each individual contrast (that is, each row, $l'_i\beta$, of $\mathbf{L}\beta$) or exponentiated contrast ($e^{l'_i\beta}$) be estimated and tested. PROC TPHREG displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test for each contrast. The significance level of the confidence interval is controlled by the ALPHA= option. You can estimate the contrast or the exponentiated contrast ($e^{l'_i\beta}$), or both, by specifying one of the following *keywords*:

PARM	specifies that the contrast itself be estimated
EXP	specifies that the exponentiated contrast be estimated
BOTH	specifies that both the contrast and the exponentiated contrast be estimated

SINGULAR = *number*

tunes the estimability check. This option is ignored when the full-rank parameterization is used. If \mathbf{v} is a vector, define $\text{ABS}(\mathbf{v})$ to be the largest absolute value of the elements of \mathbf{v} . For a row vector l' of the contrast matrix **L**, define *c* to be equal to $\text{ABS}(l)$ if $\text{ABS}(l)$ is greater than 0; otherwise, *c* equals 1. If $\text{ABS}(l' - l'T)$ is greater than $c * \text{number}$, then *l* is declared nonestimable. The **T** matrix is the Hermite form matrix $\mathbf{I}_0^- \mathbf{I}_0$, where \mathbf{I}_0^- represents a generalized inverse of the information matrix \mathbf{I}_0 .

of the null model. The value for *number* must be between 0 and 1; the default value is 1E-4.

Details

CLASS Variable Parameterization

Consider a model with one CLASS variable *A* with four levels, 1, 2, 5, and 7. Details of the possible choices for the PARAM= option follow.

EFFECT Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of -1. For instance, if the reference level is 7 (REF=7), the design matrix columns for *A* are as follows.

Effect Coding			
A	Design Matrix		
	A1	A2	A5
1	1	0	0
2	0	1	0
5	0	0	1
7	-1	-1	-1

Parameter estimates of CLASS main effects using the effect coding scheme estimate the difference in the effect of each nonreference level compared to the average effect over all four levels.

GLM As in PROC GLM, four columns are created to indicate group membership. The design matrix columns for *A* are as follows.

GLM Coding				
A	Design Matrix			
	A1	A2	A5	A7
1	1	0	0	0
2	0	1	0	0
5	0	0	1	0
7	0	0	0	1

Parameter estimates of CLASS main effects using the GLM coding scheme estimate the difference in the effects of each level compared to the last level.

ORDINAL

Three columns are created to indicate group membership of the higher levels of the effect. For the first level of the effect (which for A is 1), all three dummy variables have a value of 0. The design matrix columns for A are as follows.

Ordinal Coding			
	Design Matrix		
A	A2	A5	A7
1	0	0	0
2	1	0	0
5	1	1	0
7	1	1	1

The first level of the effect is a control or baseline level. Parameter estimates of CLASS main effects using the ORDINAL coding scheme estimate the effect on the response as the ordinal factor is set to each succeeding level. When the parameters for an ordinal main effect have the same sign, the response effect is monotonic across the levels.

POLYNOMIAL**POLY**

Three columns are created. The first represents the linear term (x), the second represents the quadratic term (x^2), and the third represents the cubic term (x^3), where x is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, . . . according to their sorting order. The design matrix columns for A are as follows.

Polynomial Coding			
	Design Matrix		
A	APOLY1	APOLY2	APOLY3
1	1	1	1
2	2	4	8
5	5	25	125
7	7	49	343

REFERENCE

REF Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of 0. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

Reference Coding			
	Design Matrix		
A	A1	A2	A5
1	1	0	0
2	0	1	0
5	0	0	1
7	0	0	0

Parameter estimates of CLASS main effects using the reference coding scheme estimate the difference in the effect of each nonreference level compared to the effect of the reference level.

ORTHEFFECT The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=EFFECT. The design matrix columns for A are as follows.

Orthogonal Effect Coding			
	Design Matrix		
A	AOEFF1	AOEFF2	AOEFF3
1	1.41421	-0.81650	-0.57735
2	0.00000	1.63299	-0.57735
5	0.00000	0.00000	1.73205
7	-1.41421	-0.81649	-0.57735

ORTHORDINAL The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=ORDINAL. The design matrix columns for A are as follows.

Orthogonal Ordinal Coding			
	Design Matrix		
A	AOORD1	AOORD2	AOORD3
1	-1.73205	0.00000	0.00000
2	0.57735	-1.63299	0.00000
5	0.57735	0.81650	-1.41421
7	0.57735	0.81650	1.41421

ORTHPOLY The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=POLY. The design matrix columns for A are as follows.

Orthogonal Polynomial Coding			
A	Design Matrix		
	AOPOLY1	AOPOLY2	AOPOLY5
1	-1.153	0.907	-0.921
2	-0.734	-0.540	1.473
5	0.524	-1.370	-0.921
7	1.363	1.004	0.368

ORTHREF The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=REFERENCE. The design matrix columns for A are as follows.

Orthogonal Reference Coding			
A	Design Matrix		
	AOREF1	AOREF2	AOREF3
1	1.73205	0.00000	0.00000
2	-0.57735	1.63299	0.00000
5	-0.57735	-0.81650	1.41421
7	-0.57735	-0.81650	-1.41421

Miscellaneous Changes from PROC PHREG

The default method of computing the survivor function estimate is METHOD=CH which is based on the empirical cumulative hazard function estimate rather than the product-limit estimate (METHOD=PL) as in PROC PHREG. This applies to both the OUTPUT and BASELINE statements.

The OUT= data set in the OUTPUT statement contains the entire input data set along with statistics you request using the *keyword=name* options. Observations in the OUT= data set follow the same order as the input data set. The ORDER=SORTED option in the OUTPUT statement of PROC PHREG (see the “OUTPUT Statement” section (page 3233) in Chapter 54, “The PHREG Procedure,”) is no longer available.

The BASELINE statement in PROC PHREG enables you to predict the cumulative mean function (CMF) and the cumulative hazard function (CUMHAZ) for recurrent events models. However, such features are not yet available in the BASELINE statement of PROC TPHREG.

Displayed Output

If you use the NOPRINT option in the PROC TPHREG statement, the procedure does not display any output. Otherwise, the displayed output of the TPHREG procedure includes the following:

- the “Model Information” table, which contains
 - the two-level name of the input data set
 - the name and label of the failure-time variable
 - if you specify the censoring variable,
 - the name and label of the censoring variable
 - the values that the censoring variable assumes to indicate censored times
 - if you use the OFFSET= option in the MODEL statement, the name and label of the offset variable
 - if you specify the FREQ statement, the name and label of the frequency variable
 - if you specify the WEIGHT statement, the name and label of the weight variable
 - the method of handling ties in the failure time
- the “Class Level Information” table, which shows the levels and the corresponding design variables for each CLASS explanatory variable
- the “Summary of the Number of Event and Censored Values” table, which gives, for each stratum, the breakdown of the number of events and censored values. This table is not produced if the NOSUMMARY option is specified.
- if you specify the SIMPLE option in the PROC TPHREG statement, the “Descriptive Statistics for Continuous Explanatory Variables” table for continuous explanatory variables, and the “Frequency Distribution of CLASS Variables” table. The “Descriptive Statistics for Continuous Explanatory Variables” table contains the mean, standard deviation, maximum and minimum of each continuous variable specified in the MODEL statement. If the WEIGHT statement is specified, the “Frequency Distribution of Class Variables” table also contains the weight distributions of the CLASS variables.
- if you specify the ITPRINT option in the MODEL statement, the “Iteration History” table, which displays the iteration number, step size, log likelihood, and parameter estimates at each iteration. The last evaluation of the gradient vector is also displayed.
- the “Model Fit Statistics” table, which gives the values of -2 log likelihood for fitting a model with no explanatory variable and for fitting a model with all the explanatory variables. The AIC and SBC are also given in this table.
- the “Testing Global Null Hypothesis: BETA=0” table, which displays results of the likelihood ratio test, the score test, and the Wald test

- if the model contains an effect involving a CLASS variable, the “Type 3 Tests” table, which gives the Wald chi-square statistic, the degrees of freedom, and the p -value for each effect in the model
- the “Analysis of Maximum Likelihood Estimates” table, which contains the following:
 - the maximum likelihood estimate of the parameter
 - the estimated standard error of the parameter estimate, computed as the square root of the corresponding diagonal element of the estimated covariance matrix
 - if you specify the COVS option in the PROC statement, the ratio of the robust standard error estimate to the model-based standard error estimate
 - the Wald Chi-Square statistic, computed as the square of the parameter estimate divided by its standard error estimate
 - the degrees of freedom of the Wald chi-square statistic. It has a value of 1 unless the corresponding parameter is redundant or infinite, in which case the value is 0.
 - the p -value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom
 - the hazards ratio estimate computed by exponentiating the parameter estimate
 - if you specified the RISKLIMITS option in the MODEL statement, the confidence limits for the hazards ratio
- if you specify SELECTION=SCORE in the MODEL statement, the “Regression Models Selected by Score Criterion” table, which gives the number of explanatory variables in each model, the score chi-square statistic, and the names of the variables included in the model
- if you use the FORWARD or STEPWISE selection method and specify the DETAILS option in the MODEL statement, the “Effects to Enter” table, which gives the score chi-square statistic for testing the significance of each candidate effect for entry (after adjusting for the effects already in the model), the degrees of freedom of the score chi-square statistic, and the corresponding p -value. This table is produced before an effect is selected for entry.
- if you use the BACKWARD or STEPWISE selection method and specify the DETAILS option in the MODEL statement, the “Effects to Remove” table, which gives the Wald chi-square statistic for testing the significance of each candidate effect for removal, the degrees of freedom of the Wald chi-square, and the corresponding p -value. This table is produced before an effect is selected for removal.
- if you use the BACKWARD, FORWARD, or STEPWISE selection method, a table summarizing the model-building process, which gives the step number, the effect entered or removed at each step, the chi-square statistic, and the corresponding p -value on which the selection is based
- if you use the COVB option in the MODEL statement, the estimated covariance matrix of the parameter estimates

- if you use the CORRB option in the MODEL statement, the estimated correlation matrix of the parameter estimates
- if you specify a CONTRAST statement, the “Contrast Test Results” table, which gives the result of the Wald test for each CONTRAST specified. If you specify the E option in the CONTRAST statement, then the contrast matrix is displayed. If you specify the ESTIMATE= option in the CONTRAST statement, the “Contrast Rows Estimation and Testing Results” table is produced, which includes the point estimate and confidence interval for each row of the contrast matrix, and the corresponding Wald test as well.
- if you specify a TEST statement,
 - the “Linear Coefficients” table, which gives the coefficients and constants of the linear hypothesis (if the E option is specified)
 - the printing of the intermediate calculations of the Wald test (if the option PRINT is specified)
 - the “Test Results” table, which gives the Wald chi-square statistic, the degrees of freedom, and the p -value
 - the “Average Effect” table, which gives the weighted average of the parameter estimates for the variables in the TEST statement, the estimated standard error, the z -score, and the p -value (if the AVERAGE option is specified)

ODS Table Names

PROC TPHREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 73.1. ODS Tables Produced in PROC TPHREG

ODS Table Name	Description	Statement	Option
BestSubsets	Best subset selection	MODEL	SELECTION=SCORE
CensoredSummary	Summary of event and censored observations	MODEL	default
ClassLevelFreq	Frequency breakdown of CLASS variables	PROC	SIMPLE (with CLASS vars)
ClassLevelInfo	CLASS variable levels and design variables	MODEL	default (with CLASS vars)
ClassWgt	Weight breakdown of CLASS variables	WEIGHT	SIMPLE (with CLASS vars)
ContrastCoeff	L matrix for contrasts	CONTRAST	E
ContrastEstimate	Individual contrast estimates	CONTRAST	ESTIMATE=
ContrastTest	Wald test for contrasts	CONTRAST	default
ConvergenceStatus	Convergence status	MODEL	default
CorrB	Estimated correlation matrix of parameter estimators	MODEL	CORRB
CovB	Estimated covariance matrix of parameter estimators	MODEL	COVB

Table 73.1. (continued)

ODS Table Name	Description	Statement	Option
EffectsToEnter	Eligible effects for entry to model	MODEL	SELECTION=F/S
EffectsToRemove	Eligible effects for removal from model	MODEL	SELECTION=B/S
FitStatistics	Model fit statistics	MODEL	default
GlobalScore	Global chi-square test	MODEL	NOFIT
GlobalTests	Tests of the global null hypothesis	MODEL	default
IterHistory	Iteration history	MODEL	ITPRINT
LastGradient	Last evaluation of gradient	MODEL	ITPRINT
ModelBuildingSummary	Summary of model building	MODEL	SELECTION=B/F/S
ModelInfo	Model information	PROC	default
NObs	Number of observations		default
ParameterEstimates	Maximum likelihood estimates of model parameters	MODEL	default
ResidualChiSq	Residual chi-square	MODEL	SELECTION=F/B
SimpleStatistics	Summary statistics for continuous explanatory variables	PROC	SIMPLE
TestAverage	Average Effect for test	TEST	AVERAGE
TestCoeff	coefficients for linear hypotheses	TEST	E
TestPrint1	$L[\text{cov}(\mathbf{b})]L'$ and $L\mathbf{b}-\mathbf{c}$	TEST	PRINT
TestPrint2	$G\text{inv}(L[\text{cov}(\mathbf{b})]L')$ and $G\text{inv}(L[\text{cov}(\mathbf{b})]L')(L\mathbf{b}-\mathbf{c})$	TEST	PRINT
TestStmts	Linear Hypotheses Test Results	TEST	default
Type3	Type 3 tests of effects	MODEL	default (with CLASS vars)

Example

Example 73.1. Analysis of the VA Lung Cancer Data

This example uses the Veteran’s Administration lung cancer data presented in Appendix 1 of Kalbfleisch and Prentice (1980). In this trial, males with advanced inoperable lung cancer were randomized to a standard therapy and a test chemotherapy. The primary end point for the therapy comparison was time to death in days, represented by the variable **Time**. Negative values of **Time** are censored values. The data include information on a number of explanatory variables: **Therapy** (type of therapy: standard or test), **Cell** (type of tumor cell: adeno, large, small, or squamous), **Prior** (prior therapy: 0=no, 1=yes), **Age** (age in years), **Duration** (months from diagnosis to randomization), and **Kps** (Karnofsky performance scale). A censoring indicator variable **Censor** is created from the data, with value 1 indicating a censored time and value 0 an event time.

```

PROC TPHREG is invoked to fit the Cox proportional hazards model to these data. Variables `Prior`, `Cell`, and `Therapy`, which are categorical variables, are declared in the `CLASS` statement. By default, PROC TPHREG parameterizes the `CLASS` variables using the reference coding with the last category as the reference category. However, you can explicitly specify the reference category of your choice. Here, `Prior=no` is chosen as the reference category for prior therapy, `Cell=large` is chosen as the reference category for type of tumor cell, and `Therapy=standard` is chosen as the reference category for the type of therapy. Both the continuous explanatory variables (`Kps`, `Duration`, and `Age`) and the `CLASS` explanatory variables (`Prior`, `Cell`, and `Therapy`) are specified in the `MODEL` statement. Knowing how the `Cell` variable is parameterized, the hazards ratios of all pairs of cell-type groups can be estimated using the `ESTIMATE=EXP` option in a `CONTRAST` statement.

```

proc tphreg data=VALung;
  class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
  model Time*censor(1) = Kps Duration Age Prior Cell Therapy;
  contrast 'Pairwise' cell 1 0 0, /* adeno vs large */
              cell 0 1 0, /* small vs large */
              cell 0 0 1, /* squamous vs large */
              cell 1 -1 0, /* adeno vs small */
              cell 1 0 -1, /* adeno vs squamous */
              cell 0 1 -1 /* small vs squamous */
              / estimate=exp;
run;

```

The output of PROC TPHREG is very similar to that of PROC PHREG, with additional tables for displaying the parameterization of the `CLASS` variables, the multiparameter tests for the model effects, and the analysis results of the specified contrasts.

Output 73.1.1. Reference Coding of CLASS Variables

The TPHREG Procedure				
Class Level Information				
Class	Value	Design Variables		
Prior	no	0		
	yes	1		
Cell	adeno	1	0	0
	large	0	0	0
	small	0	1	0
	squamous	0	0	1
Therapy	standard	0		
	test	1		

Coding of the CLASS variables is displayed in [Output 73.1.1](#). There is one dummy variable for **Prior** and one for **Therapy**, since both variables are binary. The dummy variable has a value of 0 for the reference category (**Prior**=no, **Therapy**=standard). The CLASS variable **Cell** has four categories and are represented by three dummy variables. Note that the reference category, **Cell**=large, has a value of 0 for all three dummy variables.

Output 73.1.2. Wald Tests for Individual Model Effects

Type 3 Tests			
Effect	DF	Wald Chi-Square	Pr > ChiSq
Kps	1	35.1124	<.0001
Duration	1	0.0001	0.9920
Age	1	0.8443	0.3582
Prior	1	0.0971	0.7554
Cell	3	17.9164	0.0005
Therapy	1	1.9579	0.1617

The test results of individual model effects are shown in [Output 73.1.2](#). There is a strong prognostic effect of the Karnofsky performance status on patient survival ($p < 0.0001$), and the survival times in the various cell-type groups differ significantly ($p = 0.0005$). However, there is a lack of evidence that the test chemotherapy differs from the standard therapy ($p = 0.1617$) after accounting for the prognostic effects of other variables.

Output 73.1.3. Inference about the Regression Parameters

Analysis of Maximum Likelihood Estimates					
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq
Kps	1	-0.03262	0.00551	35.1124	<.0001
Duration	1	-0.0000916	0.00913	0.0001	0.9920
Age	1	-0.00855	0.00930	0.8443	0.3582
Prior	yes	0.07232	0.23213	0.0971	0.7554
Cell	adeno	0.78867	0.30267	6.7899	0.0092
Cell	small	0.45686	0.26627	2.9438	0.0862
Cell	squamous	-0.39963	0.28266	1.9988	0.1574
Therapy	test	0.28994	0.20721	1.9579	0.1617

Analysis of Maximum Likelihood Estimates		
Parameter	Hazard Ratio	Variable Label
Kps	0.968	Karnofsky performance scale
Duration	1.000	months from diagnosis to randomization
Age	0.991	age in years
Prior	yes	prior therapy yes
Cell	adeno	cell type adeno
Cell	small	cell type small
Cell	squamous	cell type squamous
Therapy	test	type of treatment test

In the Cox proportional hazards model, the effects of the covariates are to act multiplicatively on the hazard of the survival time, and therefore it is a little easier to interpret the corresponding hazards ratios than the regression parameters. For a parameter that corresponds to an continuous variable, the hazard ratio is the ratio of hazard rates for a increase of one unit of the variable. From [Output 73.1.3](#), the hazard ratio estimate for Kps is 0.968, meaning that an increase of 10 units in Karnofsky performance scale will shrink the hazard rate by $1 - (0.968)^{10} = 28\%$. For a CLASS variable parameter, the hazard ratio is the ratio of the hazard rates between the given category and the reference category. The hazard rate of Cell=adeno is 220% that of Cell=large, the hazard rate of Cell=small is 158% that of Cell=large, and the hazard rate of Cell=squamous is only 67% that of Cell=large.

Output 73.1.4. Overall Test for All Paired Cell-type Groups

Contrast Test Results			
Contrast	DF	Wald Chi-Square	Pr > ChiSq
Pairwise	3	17.9164	0.0005

Although there are six pairwise comparisons for the four types of tumor cells in the CONTRAST statement, the overall test has only 3 degrees of freedom ([Output](#)

73.1.4). In fact this is the very same testing of no prognostics effect between the cell-type groups as shown in [Output 73.1.2](#).

Output 73.1.5. Hazards Ratios for All Paired Cell-type Groups

Contrast Rows Estimation and Testing Results							
Contrast	Type	Row	Estimate	Standard Error	Alpha	Confidence Limits	
Pairwise	EXP	1	2.2005	0.6660	0.05	1.2159	3.9824
Pairwise	EXP	2	1.5791	0.4205	0.05	0.9370	2.6611
Pairwise	EXP	3	0.6706	0.1895	0.05	0.3853	1.1669
Pairwise	EXP	4	1.3935	0.3840	0.05	0.8119	2.3916
Pairwise	EXP	5	3.2815	0.9870	0.05	1.8200	5.9167
Pairwise	EXP	6	2.3549	0.6480	0.05	1.3732	4.0384

Contrast Rows Estimation and Testing Results				
Contrast	Type	Row	Wald Chi-Square	Pr > ChiSq
Pairwise	EXP	1	6.7899	0.0092
Pairwise	EXP	2	2.9438	0.0862
Pairwise	EXP	3	1.9988	0.1574
Pairwise	EXP	4	1.4497	0.2286
Pairwise	EXP	5	15.6101	<.0001
Pairwise	EXP	6	9.6866	0.0019

[Output 73.1.5](#) is generated by the ESTIMATE=EXP option in the CONTRAST statement. Values of the Estimate column are the estimated hazard ratios: 2.200 for ‘adeno’ vs ‘large’, 1.579 for ‘small’ versus ‘large’, 0.671 for ‘squamous’ versus ‘large’, 1.394 for ‘adeno’ versus ‘small’, 3.282 for ‘adeno’ versus ‘squamous’, and 2.355 for ‘small’ versus ‘squamous’. Note that the first three hazard ratio estimates are already given in the parameter estimate table ([Output 73.1.3](#)), and therefore there is no need to specify those first three rows in the CONTRAST statement.

Chapter 74

The TPSPLINE Procedure

Overview

The TPSPLINE procedure uses the penalized least squares method to fit a nonparametric regression model. It computes thin-plate smoothing splines to approximate smooth multivariate functions observed with noise. The TPSPLINE procedure allows great flexibility in the possible form of the regression surface. In particular, PROC TPSPLINE makes no assumptions of a parametric form for the model. The generalized cross validation (GCV) function may be used to select the amount of smoothing.

The TPSPLINE procedure complements the methods provided by the standard SAS regression procedures such as the GLM, REG and NLIN procedures. These procedures can handle most situations in which you specify the regression model and the model is known up to a fixed number of parameters. However, when you have no prior knowledge about the model, or when you know that the data cannot be represented by a model with a fixed number of parameters, you can use the TPSPLINE procedure to model the data.

The TPSPLINE procedure uses the penalized least squares method to fit the data with a flexible model in which the number of effective parameters can be as large as the number of unique design points. Hence, as the sample size increases, the model space increases as well, enabling the thin-plate smoothing spline to fit more complicated situations.

The main features of the TPSPLINE procedure are as follows:

- provides penalized least squares estimates
- supports the use of multidimensional data
- supports multiple SCORE statements
- fits both semiparametric models and nonparametric models
- provides options for handling large data sets
- supports multiple dependent variables
- enables you to choose a particular model by specifying the model degrees of freedom or smoothing parameter

The Penalized Least Squares Estimate

Penalized least squares estimates provide a way to balance fitting the data closely and avoiding excessive roughness or rapid variation. A penalized least squares estimate

is a surface that minimizes the penalized least squares over the class of all surfaces satisfying sufficient regularity conditions.

Define \mathbf{x}_i as a d -dimensional covariate vector, \mathbf{z}_i as a p -dimensional covariate vector, and y_i as the observation associated with $(\mathbf{x}_i, \mathbf{z}_i)$. Assuming that the relation between \mathbf{z}_i and y_i is linear but the relation between \mathbf{x}_i and y_i is unknown, you can fit the data using a semiparametric model as follows:

$$y_i = f(\mathbf{x}_i) + \mathbf{z}_i\beta + \epsilon_i$$

where f is an unknown function that is assumed to be reasonably smooth, $\epsilon_i, i = 1, \dots, n$ are independent, zero-mean random errors, and β is a p -dimensional unknown parametric vector.

This model consists of two parts. The $\mathbf{z}_i\beta$ is the parametric part of the model, and the \mathbf{z}_i are the regression variables. The $f(\mathbf{x}_i)$ is the nonparametric part of the model, and the \mathbf{x}_i are the smoothing variables.

The ordinary least squares method estimates $f(x_i)$ and β by minimizing the quantity:

$$\frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i\beta)^2$$

However, the functional space of $f(\mathbf{x})$ is so large that you can always find a function f that interpolates the data points. In order to obtain an estimate that fits the data well and has some degree of smoothness, you can use the penalized least squares method.

The penalized least squares function is defined as

$$S_\lambda(f) = \frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i\beta)^2 + \lambda J_2(f)$$

where $J_2(f)$ is the penalty on the roughness of f and is defined, in most cases, as the integral of the square of the second derivative of f .

The first term measures the goodness of fit and the second term measures the smoothness associated with f . The λ term is the smoothing parameter, which governs the tradeoff between smoothness and goodness of fit. When λ is large, it more heavily penalizes rougher fits. Conversely, a small value of λ puts more emphasis on the goodness of fit.

The estimate f_λ is selected from a reproducing kernel Hilbert space, and it can be represented as a linear combination of a sequence of basis functions. Hence, the final estimates of f can be written as

$$f_\lambda(\mathbf{x}_i) = \theta_0 + \sum_{j=1}^d \theta_j x_{ij} + \sum_{j=1}^n \delta_j B_j(\mathbf{x}_i)$$

where B_j is the basis function, which depends on where the data \mathbf{x}_j is located, and θ_j and δ_j are the coefficients that need to be estimated.

For a fixed λ , the coefficients (θ, δ, β) can be estimated by solving an $n \times n$ system.

The smoothing parameter can be chosen by minimizing the generalized cross validation (GCV) function.

If you write

$$\hat{\mathbf{y}} = \mathbf{A}(\lambda)\mathbf{y}$$

then $\mathbf{A}(\lambda)$ is referred to as the *hat* or *smoothing* matrix, and the GCV function $V(\lambda)$ is defined as

$$V(\lambda) = \frac{(1/n)\|(\mathbf{I} - \mathbf{A}(\lambda))\mathbf{y}\|^2}{[(1/n)\text{tr}(\mathbf{I} - \mathbf{A}(\lambda))]^2}$$

PROC TPSPLINE with Large Data Sets

The calculation of the penalized least squares estimate is computationally intensive. The amount of memory and CPU time needed for the analysis depend on the number of unique design points, which corresponds to the number of unknown parameters to be estimated.

You can specify the *D= value* option in the MODEL statement to reduce the number of unknown parameters. The option groups design points by the specified range (see the [D= option](#) on page 4509).

PROC TPSPLINE selects one design point from the group and treats all observations in the group as replicates of that design point. Calculation of the thin-plate smoothing spline estimates are based on the reprocessed data. The way to choose the design point from a group depends on the order of the data. Therefore, different orders of input data may result in different estimates.

This option, by combining several design points into one, reduces the number of unique design points, thereby approximating the original data. The *D= value* you specify determines the width of the range used to group the data.

Getting Started

The following example demonstrates how you can use the TPSPLINE procedure to fit a semiparametric model.

Suppose that y is a continuous variable and x_1 and x_2 are two explanatory variables of interest. To fit a smoothing spline model, you can use a MODEL statement similar to that used in many regression procedures in the SAS System.

```
proc tpspline;
  model y = (x1 x2);
run;
```

The TPSPLINE procedure can fit semiparametric models; the parentheses in the preceding MODEL statement separates the smoothing variables from the regression variables. The following statements illustrates this syntax.

```
proc tpspline;
  model y = x3 (x1 x2);
run;
```

This model assumes a linear relation with x3 and an unknown functional relation with x1 and x2.

If you want to fit several responses using the same explanatory variables, you can save computation time by using the multiple responses feature in the MODEL statement. For example, if y1 and y2 are two response variables, the following MODEL statement can be used to fit two models. Separate analyses are then performed for each response variable.

```
proc tpspline;
  model y1 y2 = (x1 x2);
run;
```

The following example illustrates the use of PROC TPSPLINE. The data are from Bates, Lindstrom, Wahba, and Yandell (1987).

```

The data set `Measure` contains three variables `x1`, `x2`, and `y`. Suppose that you want to fit a surface by using the variables `x1` and `x2` to model the response `y`. The variables `x1` and `x2` are spaced evenly on a $[-1 \times 1] \times [-1 \times 1]$ square, and the response `y` is generated by adding a random error to a function $f(x_1, x_2)$. The raw data are plotted using the `G3D` procedure. In order to plot those replicates, the data are jittered a little bit.

```

data Measure1;
  set Measure;
run;

proc sort data=Measure1;
  by x2 x1;
run;

data measure1;
  set measure1; by x1;
  if last.x1 then x1=x1+0.00001;
run;

proc g3d data=Measure1;
  scatter x2*x1=y /size=.5
          zmin=9 zmax=21
          zticknum=4;
  title "Raw Data";
run;

```

Figure 74.1 displays the raw data.

Figure 74.1. Plot of Data Set MEASURE

The following statements invoke the TPSPLINE procedure, using the `Measure` data set as input. In the `MODEL` statement, the `x1` and `x2` variables are listed as smoothing variables. The `LOGNLAMBDA=` option returns a list of GCV values with $\log_{10}(n\lambda)$ ranging from -4 to -2 . The `OUTPUT` statement creates the data set `estimate` to contain the predicted values and the 95% upper and lower confidence limits.

```
proc tpspline data=Measure;
    model y=(x1 x2) /lognlambda=(-4 to -2 by 0.1);
    output out=estimate pred uclm lclm;
run;

proc print data=estimate;
run;
```

The results of this analysis are displayed in the following figures. [Figure 74.2](#) shows that the data set `Measure` contains 50 observations with 25 unique design points. The GCV values are listed along with the \log_{10} of $n\lambda$. The value of $\log_{10}(n\lambda)$ that minimizes the GCV function is around -3.5 . The final thin-plate smoothing spline estimate is based on `LOGNLAMBDA` = -3.4762 . The residual sum of squares is 0.246110, and the degrees of freedom is 24.593203. The standard deviation, defined as $\text{RSS}/(\text{Tr}(\mathbf{I}-\mathbf{A}))$, is 0.098421. The predictions and 95% confidence limits are displayed in [Figure 74.3](#).

Figure 74.3. Data Set ESTIMATE

The fitted surface is plotted with PROC G3D as follows.

```
proc g3d data=estimate;
  plot x2*x1=p_y/grid
      zmin=9 zmax=21 zticknum=4;
title 'Plot of Fitted Surface';
run;
```

The resulting plot is displayed in [Figure 74.4](#).

Figure 74.4. Plot of TPSPLINE Fit of Data Set Measure

Because the data in data set `Measure` are very sparse, the fitted surface is not smooth. To produce a smoother surface, the following statements generate the data set `Pred` in order to obtain a finer grid. The `SCORE` statement evaluates the fitted surface at those new design points.

```
data pred;
  do x1=-1 to 1 by 0.1;
    do x2=-1 to 1 by 0.1;
      output;
    end;
  end;
run;

proc tpspline data=measure;
  model y=(x1 x2)/lognlambda=(-4 to -2 by 0.1);
  score data=pred out=predy;
run;

proc g3d data=predy;
  plot x2*x1=p_y/grid
      zmin=9 zmax=21 zticknum=4;
  title 'Plot of Fitted Surface on a Fine Grid';
run;
```

The surface plot based on the finer grid is displayed in [Figure 74.5](#). The plot shows

that a parametric model with quadratic terms of x_1 and x_2 provides a reasonable fit to the data.

Figure 74.5. Plot of TPSPLINE fit

Syntax

```

PROC TPSPLINE < option > ;
  MODEL dependents = < variables > (variables) < /options > ;
  SCORE data=SAS-data-set out=SAS-data-set ;
  OUTPUT < out=SAS-data-set > keyword < ... keyword > ;
  BY variables ;
  FREQ variable ;
  ID variables ;

```

The syntax in PROC TPSPLINE is similar to that of other regression procedures in the SAS System. The PROC TPSPLINE and MODEL statements are required. The SCORE statement can appear multiple times; all other statements appear only once.

The syntax for PROC TPSPLINE is described in the following sections in alphabetical order after the description of the PROC TPSPLINE statement.

PROC TPSPLINE Statement

PROC TPSPLINE < *option* > ;

The PROC TPSPLINE statement invokes the procedure. You can specify the following option.

DATA=SAS-data-set

specifies the SAS data set to be read by PROC TPSPLINE. The default value is the most recently created data set.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC TPSPLINE to obtain separate analysis on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TPSPLINE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If one variable in your input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TPSPLINE treats the data as if each observation appears n times, where n is the value of the FREQ variable for the observation. If the value of the FREQ variable is less than one, the observation is not used in the analysis. Only the integer portion of the value is used.

ID Statement

ID *variables* ;

The variables in the ID statement are copied from the input data set to the OUT= data set. If you omit the ID statement, only the variables used in the MODEL statement and requested statistics are included in the output data set.

MODEL Statement

MODEL *dependents* = < *regression variables* > (*smoothing variables*) < /*options* > ;

The MODEL statement specifies the dependent variables, the independent regression variables, which are listed with no parentheses, and the independent smoothing variables, which are listed inside parentheses.

The regression variables are optional. At least one smoothing variable is required, and it must be listed after the regression variables. No variables can be listed in both the regression variable list and the smoothing variable list.

If you specify more than one dependent variable, PROC TPSPLINE calculates a thin-plate smoothing spline estimate for each dependent variable, using the regression variables and smoothing variables specified on the right-hand side.

If you specify regression variables, PROC TPSPLINE fits a semiparametric model using the regression variables as the linear part of the model.

You can specify the following options in the MODEL statement.

ALPHA=*number*

specifies the significance level α of the confidence limits on the final thin-plate smoothing spline estimate when you request confidence limits to be included in the output data set. Specify *number* as a value between 0 and 1. The default value is 0.05. See the “[OUTPUT Statement](#)” section on page 4510 for more information on the OUTPUT statement.

DF=*number*

specifies the degrees of freedom of the thin-plate smoothing spline estimate, defined as

$$df = \text{trace}(\mathbf{A}(\lambda))$$

where $\mathbf{A}(\lambda)$ is the *hat* matrix. Specify *number* as a value between zero and the number of unique design points.

DISTANCE=*number*

D=*number*

defines a range such that if two data points $(\mathbf{x}_i, \mathbf{z}_i)$ and $(\mathbf{x}_j, \mathbf{z}_j)$ satisfy

$$\max_k |x_{ik} - x_{jk}| \leq D/2$$

then these data points are treated as replicates, where \mathbf{x}_i are the smoothing variables and \mathbf{z}_i are the regression variables.

You can use the DISTANCE= option to reduce the number of unique design points by treating nearby data as replicates. This can be useful when you have a large data set. The default value is 0.

LAMBDA0=*number*

specifies the smoothing parameter, λ_0 , to be used in the thin-plate smoothing spline estimate. By default, PROC TPSPLINE uses the λ parameter that minimizes the GCV function for the final fit. The LAMBDA0= value must be positive.

LAMBDA=*list-of-values*

specifies a set of values for the λ parameter. PROC TPSPLINE returns a GCV value for each λ point that you specify. You can use the LAMBDA= option to study the GCV function curve for a set of values for λ . All values listed in the LAMBDA= option must be positive.

LOGNLAMBDA0=*number*

LOGNL0=*number*

specifies the smoothing parameter λ_0 on the $\log_{10}(n\lambda)$ scale. If you specify both the LOGNL0= and LAMBDA0= options, only the value provided by the LOGNL0= option is used. By default, PROC TPSPLINE uses the λ parameter that minimizes the GCV function for the estimate.

LOGNLAMBDA=*list-of-values*

LOGNL=*list-of-values*

specifies a set of values for the λ parameter on the $\log_{10}(n\lambda)$ scale. PROC TPSPLINE returns a GCV value for each λ point that you specify. You can use the LOGNLAMBDA= option to study the GCV function curve for a set of λ values. If you specify both the LOGNL= and LAMBDA= options, only the list of values provided by LOGNL= option is used.

In some cases, the LOGNL= option may be preferred over the LAMBDA= option. Because the LAMBDA= value must be positive, a small change in that value can result in a major change in the GCV value. If you instead specify λ on the \log_{10} scale, the allowable range is enlarged to include negative values. Thus, the GCV function is less sensitive to changes in LOGNLAMBDA.

M=*number*

specifies the order of the derivative in the penalty term. The M= value must be a positive integer. The default value is the $\max(2, \text{INT}(d/2) + 1)$, where d is the number of smoothing variables.

SCORE Statement

SCORE *DATA=SAS-data-set OUT=SAS-data-set* ;

The SCORE statement calculates predicted values for a new data set. If you have multiple data sets to predict, you can specify multiple SCORE statements. You must use a SCORE statement for each data set.

The following keywords must be specified in the SCORE statement.

DATA=SAS-data-set

specifies the input SAS data set containing the smoothing variables *x* and regression variables *z*. The predicted response (*y*) value is computed for each (*x*, *z*) pair. The data set must include all independent variables specified in the MODEL statement.

OUT=SAS-data-set

specifies the name of the SAS data set to contain the predictions.

OUTPUT Statement

OUTPUT *OUT=SAS-data-set < keyword... keyword >* ;

The OUTPUT statement creates a new SAS data set containing diagnostic measures calculated after fitting the model.

You can request a variety of diagnostic measures that are calculated for each observation in the data set. The new data set contains the variables specified in the MODEL statement in addition to the requested variables. If no *keyword* is present, the data set contains only the predicted values.

Details on the specifications in the OUTPUT statement are as follows.

OUT=SAS-data-set

specifies the name of the new data set to contain the diagnostic measures. This specification is required.

keyword

specifies the statistics to include in the output data set. The names of the new variables that contain the statistics are formed by using a prefix of one or more characters that identify the statistic, followed by an underscore (_), followed by the dependent variable name.

For example, suppose that you have two dependent variables, say *y1* and *y2*, and you specify the keywords PRED, ADIAG, and UCLM. The output SAS data set will contain the following variables:

- P_y1 and P_y2
- ADIAG_y1 and ADIAG_y2
- UCLM_y1 and UCLM_y2

The keywords and the statistics they represent are as follows:

RESID R	residual values, calculated as ACTUAL - PREDICTED
PRED	predicted values
STD	standard error of the mean predicted value
UCLM	upper limit of the confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits.
LCLM	lower limit of the confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits.
ADIAG	diagonal element of the hat matrix associated with the observation
COEF	coefficients arranged in the order of $(\theta_0, \theta_1, \dots, \theta_d, \delta_1, \dots, \delta_{nUnique})$ where $nUnique$ is the number of unique data points. This option can only be used when there is only one dependent variable in the model.

Details

Computational Formulas

The theoretical foundations for the thin-plate smoothing spline are described in Duchon (1976, 1977) and Meinguet (1979). Further results and applications are given in Wahba and Wendelberger (1980), Hutchinson and Bischof (1983), and Seaman and Hutchinson (1985).

Suppose that \mathcal{H}_m is a space of functions whose partial derivatives of total order m are in $L_2(E^d)$ where E^d is the domain of \mathbf{x} .

Now, consider the data model

$$y_i = f(x_1(i), \dots, x_d(i)) + \epsilon_i, i = 1, \dots, n$$

where $f \in \mathcal{H}_m$.

Using the notation from the section “[The Penalized Least Squares Estimate](#)” on page 4497, for a fixed λ , estimate f by minimizing the penalized least squares function

$$\frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i \beta)^2 + \lambda J_m(f)$$

There are several ways to define $J_m(f)$. For the thin-plate smoothing spline, with x of dimension d , define $J_m(f)$ as

$$J_m(f) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \sum \frac{m!}{\alpha_1! \cdots \alpha_d!} \left[\frac{\partial^m f}{\partial x_1^{\alpha_1} \cdots \partial x_d^{\alpha_d}} \right]^2 dx_1 \cdots dx_d$$

where $\sum_i \alpha_i = m$.

When $d = 2$ and $m = 2$, $J_m(f)$ is as follows:

$$J_2(f) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left(\left[\frac{\partial^2 f}{\partial x_1^2} \right]^2 + 2 \left[\frac{\partial^2 f}{\partial x_1 \partial x_2} \right]^2 + \left[\frac{\partial^2 f}{\partial x_2^2} \right]^2 \right) dx_1 dx_2$$

In general, m and d must satisfy the condition that $2m - d > 0$. For the sake of simplicity, the formulas and equations that follow assume $m = 2$. Refer to Wahba (1990) and Bates et al. (1987) for more details.

Duchon (1976) showed that f_λ can be represented as

$$f_\lambda(\mathbf{x}_i) = \theta_0 + \sum_{j=1}^d \theta_j \mathbf{x}_{ij} + \sum_{j=1}^n \delta_j \mathbf{E}_2(\mathbf{x}_i - \mathbf{x}_j)$$

where $E_2(\mathbf{s}) = \frac{1}{2^3 \pi} \|\mathbf{s}\|^2 \ln(\|\mathbf{s}\|)$.

If you define $\mathbf{K} = (\mathbf{K})_{ij} = E_2(\mathbf{x}_i - \mathbf{x}_j)$ and $\mathbf{T} = (\mathbf{T})_{ij} = (\mathbf{x}_{ij})$, the goal is to find coefficients β , θ , and δ that minimize

$$S_\lambda(\beta, \theta, \delta) = \frac{1}{n} \|\mathbf{y} - \mathbf{T}\theta - \mathbf{K}\delta - \mathbf{Z}\beta\|^2 + \lambda \delta^T \mathbf{K} \delta$$

A unique solution is guaranteed if the matrix \mathbf{T} is of full rank and $\delta^T \mathbf{K} \delta \geq 0$.

If $\alpha = \begin{pmatrix} \theta \\ \beta \end{pmatrix}$ and $\mathbf{X} = (\mathbf{T} : \mathbf{Z})$, the expression for S_λ becomes

$$\frac{1}{n} \|\mathbf{y} - \mathbf{X}\alpha - \mathbf{K}\delta\|^2 + \lambda \delta^T \mathbf{K} \delta$$

The coefficients α and δ can be obtained by solving

$$\begin{aligned} (\mathbf{K} + n\lambda \mathbf{I}_n) \delta + \mathbf{X}\alpha &= \mathbf{y} \\ \mathbf{X}^T \delta &= \mathbf{0} \end{aligned}$$

To compute α and δ , let the QR decomposition of \mathbf{X} be

$$\mathbf{X} = (\mathbf{Q}_1 : \mathbf{Q}_2) \begin{pmatrix} \mathbf{R} \\ \mathbf{0} \end{pmatrix}$$

where $(\mathbf{Q}_1 : \mathbf{Q}_2)$ is an orthogonal matrix and \mathbf{R} is upper triangular, with $\mathbf{X}^T \mathbf{Q}_2 = \mathbf{0}$ (Dongarra et al. 1979).

Since $\mathbf{X}^T \delta = \mathbf{0}$, δ must be in the column space of \mathbf{Q}_2 . Therefore, δ can be expressed as $\delta = \mathbf{Q}_2 \gamma$ for a vector γ . Substituting $\delta = \mathbf{Q}_2 \gamma$ into the preceding equation and multiplying through by \mathbf{Q}_2^T gives

$$\mathbf{Q}_2^T (\mathbf{K} + n\lambda \mathbf{I}_n) \mathbf{Q}_2 \gamma = \mathbf{Q}_2^T \mathbf{y}$$

or

$$\delta = \mathbf{Q}_2 \gamma = \mathbf{Q}_2 [\mathbf{Q}_2^T (\mathbf{K} + n\lambda \mathbf{I}_n) \mathbf{Q}_2]^{-1} \mathbf{Q}_2^T \mathbf{y}$$

The coefficient α can be obtained by solving

$$\mathbf{R}\alpha = \mathbf{Q}_1^T [\mathbf{y} - (\mathbf{K} + n\lambda \mathbf{I}_n) \delta]$$

The influence matrix $\mathbf{A}(\lambda)$ is defined as

$$\hat{\mathbf{y}} = \mathbf{A}(\lambda) \mathbf{y}$$

and has the form

$$\mathbf{A}(\lambda) = \mathbf{I} - n\lambda \mathbf{Q}_2 [\mathbf{Q}_2^T (\mathbf{K} + n\lambda \mathbf{I}_n) \mathbf{Q}_2]^{-1} \mathbf{Q}_2^T$$

Similar to the regression case, and if you consider the trace of $\mathbf{A}(\lambda)$ as the degrees of freedom for the information signal and the trace of $(\mathbf{I}_n - \mathbf{A}(\lambda))$ as the degrees of freedom for the noise component, the estimate σ^2 can be represented as

$$\hat{\sigma}^2 = \frac{RSS(\lambda)}{Trace(\mathbf{I}_n - \mathbf{A}(\lambda))}$$

where $RSS(\lambda)$ is the residual sum of squares. Theoretical properties of these estimates have not yet been published. However, good numerical results in simulation studies have been described by several authors. For more information, refer to O'Sullivan and Wong (1987), Nychka (1986a, 1986b, and 1988), and Hall and Titterton (1987).

Confidence Intervals

Viewing the spline model as a Bayesian model, Wahba (1983) proposed Bayesian confidence intervals for smoothing spline estimates as follows:

$$\hat{f}_\lambda(x_i) \pm z_{\alpha/2} \sqrt{\hat{\sigma}^2 a_{ii}(\lambda)}$$

where $a_{ii}(\lambda)$ is the i th diagonal element of the $\mathbf{A}(\lambda)$ matrix and $z_{\alpha/2}$ is the $\alpha/2$ point of the normal distribution. The confidence intervals are interpreted as intervals “across the function” as opposed to point-wise intervals.

Suppose that you fit a spline estimate to experimental data that consists of a true function f and a random error term, ϵ_i . In repeated experiments, it is likely that about $100(1 - \alpha)\%$ of the confidence intervals cover the corresponding true values, although some values are covered every time and other values are not covered by the confidence intervals most of the time. This effect is more pronounced when the true surface or surface has small regions of particularly rapid change.

Smoothing Parameter

The quantity λ is called the smoothing parameter, which controls the balance between the goodness of fit and the smoothness of the final estimate.

A large λ heavily penalizes the m th derivative of the function, thus forcing $f^{(m)}$ close to 0. A small λ places less of a penalty on rapid change in $f^{(m)}(x)$, resulting in an estimate that tends to interpolate the data points.

The smoothing parameter greatly affects the analysis, and it should be selected with care. One method is to perform several analyses with different values for λ and compare the resulting final estimates.

A more objective way to select the smoothing parameter λ is to use the “leave-out-one” cross validation function, which is an approximation of the predicted mean squares error. A generalized version of the leave-out-one cross validation function is proposed by Wahba (1990) and is easy to calculate. This Generalized Cross Validation (GCV) function ($V(\lambda)$) is defined as

$$V(\lambda) = \frac{(1/n) \|(\mathbf{I} - \mathbf{A}(\lambda))\mathbf{y}\|^2}{[(1/n)\text{tr}(\mathbf{I} - \mathbf{A}(\lambda))]^2}$$

The justification for using the GCV function to select λ relies on asymptotic theory. Thus, you cannot expect good results for very small sample sizes or when there is not enough information in the data to separate the information signal from the noise component. Simulation studies suggest that for independent and identically distributed Gaussian noise, you can obtain reliable estimates of λ for n greater than 25 or 30. Note that, even for large values of n (say $n \geq 50$), in extreme Monte Carlo simulations there may be a small percentage of unwarranted extreme estimates in which $\hat{\lambda} = 0$ or $\hat{\lambda} = \infty$ (Wahba 1983). Generally, if σ^2 is known to within an order of magnitude, the occasional extreme case can be readily identified. As n gets larger, the effect becomes weaker.

The GCV function is fairly robust against nonhomogeneity of variances and non-Gaussian errors (Villalobos and Wahba 1987). Andrews (1988) has provided favorable theoretical results when variances are unequal. However, this selection method is likely to give unsatisfactory results when the errors are highly correlated.

The GCV value may be suspect when λ is extremely small because computed values may become indistinguishable from zero. In practice, calculations with $\lambda = 0$

or λ near 0 can cause numerical instabilities resulting in an unsatisfactory solution. Simulation studies have shown that a λ with $\log_{10}(n\lambda) > -8$ is small enough that the final estimate based on this λ almost interpolates the data points. A GCV value based on a $\lambda \leq 10^{-8}$ may not be accurate.

ODS Tables Produced by PROC TPSPLINE

PROC TPSPLINE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 74.1. ODS Tables Produced by PROC TPSPLINE

ODS Table Name	Description	Statement	Option
DataSummary	Data summary	PROC	default
FitSummary	Fit parameters and fit summary	PROC	default
FitStatistics	Model fit statistics	PROC	default
GCVFunction	GCV table	MODEL	LOGNLAMBDA, LAMBDA

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set named `FitStats` containing the `FitStatistics` table, an output data set named `DataInfo` containing the `DataSummary` table, an output data set named `ModelInfo` containing the `FitSummary` and an output data set named `GCVFunc` containing the `GCVFunction`.

```
proc tpspline data=Melanoma;
  model Incidences=Year /LOGNLAMBDA=(-4 to 0 by 0.2);
  ods output FitStatistics = FitStats
             DataSummary   = DataInfo
             FitSummary     = ModelInfo
             GCVFunction    = GCVFunc;
run;
```

Examples

Example 74.1. Partial Spline Model Fit

The following example analyzes the data set `Measure` that was introduced in the “Getting Started” section on page 4499. That analysis determined that the final estimated surface can be represented by a quadratic function for one or both of the independent variables. This example illustrates how you can use PROC TPSPLINE to fit a partial spline model. The data set `Measure` is fit using the following model:

$$f(x_1, x_2) = 1 + x_1 + x_1^2 + h(x_2)$$

The model has a parametric component (associated with the x_1 variable) and a non-parametric component (associated with the x_2 variable). The following statements fit a partial spline model.

```

data Measure;
  set Measure;
  xlsq = x1*x1;
run;

data pred;
  do x1=-1 to 1 by 0.1;
    do x2=-1 to 1 by 0.1;
      xlsq = x1*x1;
      output;
    end;
  end;
run;

proc tpspline data= measure;
  model y = x1 xlsq (x2);
  score data = pred
        out = predy;
run;

```

Output 74.1.1 displays the results from these statements.

Output 74.1.1. Output from PROC TPSPLINE

The TPSPLINE Procedure	
Dependent Variable: y	
Summary of Input Data Set	
Number of Non-Missing Observations	50
Number of Missing Observations	0
Unique Smoothing Design Points	5
Summary of Final Model	
Number of Regression Variables	2
Number of Smoothing Variables	1
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	4
Summary Statistics of Final Estimation	
log10(n*Lambda)	-2.2374
Smoothing Penalty	205.3461
Residual SS	8.5821
Tr(I-A)	43.1534
Model DF	6.8466
Standard Deviation	0.4460

As displayed in [Output 74.1.1](#), there are five unique design points for the smoothing variable x_2 and two regression variables in the model (x_1, x_1^2). The dimension of the null space (polynomial space) is 4. The standard deviation of the estimate is much larger than the one based on the model with both x_1 and x_2 as smoothing variables (0.445954 compared to 0.098421). One of the many possible explanations may be that the number of unique design points of the smoothing variable is too small to warrant an accurate estimate for $h(x_2)$.

The following statements produce a surface plot for the partial spline model:

```

title 'Plot of Fitted Surface on a Fine Grid';

proc g3d data=preddy;
  plot x2*x1=p_y/grid
      zmin=9
      zmax=21
      zticknum=4;
run;

```

The surface displayed in [Output 74.1.2](#) is similar to the one estimated by using the full nonparametric model (displayed in [Figure 74.5](#)).

Output 74.1.2. Plot of TPSPLINE Fit from the Partial Spline Model

Example 74.2. Spline Model With Higher-Order Penalty

The following example continues the analysis of the data set `Measure` to illustrate how you can use PROC TPSPLINE to fit a spline model with a higher-order penalty term. Spline models with high-order penalty terms move low-order polynomial terms into the null space. Hence, there is no penalty for these terms, and they can vary without constraint.

As shown in the previous analyses, the final model for the data set `Measure` must include quadratic terms for both `x1` and `x2`. This example fits the following model:

$$f(x_1, x_2) = \theta_0 + \theta_1 x_1 + \theta_2 x_1^2 + \theta_3 x_2 + \theta_4 x_2^2 + \theta_5 x_1 * x_2 + g(x_1, x_2)$$

The model includes quadratic terms for both variables, although it differs from the usual linear model. The nonparametric term $g(x_1, x_2)$ explains the variation of the data unaccounted for by a simple quadratic surface.

To modify the order of the derivative in the penalty term, specify the `M=` option. The following statements specify the option `M=3` in order to include the quadratic terms in the null space:

```
data measure;
  set measure;
  x1sq = x1*x1;
  x2sq = x2*x2;
  x1x2 = x1*x2;
;

proc tpspline data= measure;
  model y = (x1 x2) / m=3;
  score data = pred
          out = predy;
run;
```

The output resulting from these statements is displayed in [Output 74.2.1](#).

Output 74.2.1. Output from PROC TPSPLINE with M=3

The TPSPLINE Procedure	
Dependent Variable: y	
Summary of Input Data Set	
Number of Non-Missing Observations	50
Number of Missing Observations	0
Unique Smoothing Design Points	25
Summary of Final Model	
Number of Regression Variables	0
Number of Smoothing Variables	2
Order of Derivative in the Penalty	3
Dimension of Polynomial Space	6
Summary Statistics of Final Estimation	
log10(n*Lambda)	-3.7831
Smoothing Penalty	2092.4495
Residual SS	0.2731
Tr(I-A)	29.1716
Model DF	20.8284
Standard Deviation	0.0968

The model contains six terms in the null space. Compare [Output 74.2.1](#) with [Figure 74.2](#): the LOGNLAMBDA value and the smoothing penalty differ significantly. Note that, in general, these terms are not directly comparable for different models. The final estimate based on this model is close to the estimate based on the model using the default, M=2.

In the following statements, the REG procedure fits a quadratic surface model to the data set Measure.

```
proc reg data= measure;
  model y = x1 x1sq x2 x2sq x1x2;
run;
```

The results are displayed in [Output 74.2.2](#).

Output 74.2.2. Quadratic Surface Model: The REG Procedure

The REG Procedure					
Model: MODEL1					
Dependent Variable: y					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	5	443.20502	88.64100	436.33	<.0001
Error	44	8.93874	0.20315		
Corrected Total	49	452.14376			
Root MSE		0.45073	R-Square	0.9802	
Dependent Mean		15.08548	Adj R-Sq	0.9780	
Coeff Var		2.98781			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	14.90834	0.12519	119.09	<.0001
x1	1	0.01292	0.09015	0.14	0.8867
x1sq	1	-4.85194	0.15237	-31.84	<.0001
x2	1	0.02618	0.09015	0.29	0.7729
x2sq	1	5.20624	0.15237	34.17	<.0001
x1x2	1	-0.04814	0.12748	-0.38	0.7076

The REG procedure produces slightly different results. To fit a similar model with PROC TPSPLINE, you can use a MODEL statement specifying the degrees of freedom with the DF= option. You can also use a large value for the LOGNLAMBDA0= option to force a parametric model fit.

Because there is one degree of freedom for each of the following terms, Intercept, x1, x2, x1sq, x2sq, and x1x2, the DF=6 option is used.

```
proc tpspline data=measure;
  model y=(x1 x2) /m=3 df=6 lognlambda=(-4 to 1 by 0.2);
  score data = pred
        out = predy;
run;
```

The results are displayed in [Output 74.2.3](#). PROC TPSPLINE displays the list of GCV values for comparison.

Output 74.2.3. Output from PROC TPSPLINE Using M=3 and DF=6

```

```

The TPSPLINE Procedure	
Dependent Variable: y	
Summary Statistics of Final Estimation	
log10(n*Lambda)	2.3830
Smoothing Penalty	0.0000
Residual SS	8.9384
Tr(I-A)	43.9997
Model DF	6.0003
Standard Deviation	0.4507

The final estimate is based on 6.000330 degrees of freedom because there are already 6 degrees of freedom in the null space and the search range for lambda is not large enough (in this case, setting DF=6 is equivalent to setting $\lambda = \infty$).

The standard deviation and RSS ([Output 74.2.3](#)) are close to the sum of squares for the error term and the root MSE from the the linear regression model ([Output 74.2.2](#)), respectively.

For this model, the optimal LOGNLAMBDA is around -3.8 , which produces a standard deviation estimate of 0.096765 (see [Output 74.2.1](#)) and a GCV value of 0.016051, while the model specifying DF=6 results in a LOGNLAMBDA larger than 1 and a GCV value larger than 0.23074. The nonparametric model, based on the GCV, should provide better prediction, but the linear regression model can be more easily interpreted.

Example 74.3. Multiple Minima of the GCV Function

The following data represent the deposition of sulfate (SO_4) at 179 sites in 48 contiguous states of the United States in 1990. Each observation records the latitude and longitude of the site as well as the SO_4 deposition at the site measured in gram per square meter (g/m^2).

You can use PROC TPSPLINE to fit a surface that reflects the general trend and that reveals underlying features of the data.

data pred;
  do latitude = 25 to 47 by 1;
    do longitude = 68 to 124 by 1;
      output;
    end;
  end;
run;

```

The preceding statements create the SAS data set `so4` and the data set `pred` in order to make predictions on a regular grid. The following statements fit a surface for SO_4 deposition. The ODS OUTPUT statement creates a data set called `GCV` to contain the GCV values for `LOGNLAMBDA` in the range from -6 to 1 .

```

proc tpspline data=so4;
  ods output GCVFunction=gcv;
  model so4 = (latitude longitude) /lognlambda=(-6 to 1 by 0.1);
  score data=pred out=prediction1;
run;

```

Partial output from these statements is displayed in [Output 74.3.1](#).

Output 74.3.1. Partial Output from PROC TPSPLINE for Data Set SO4

The TPSPLINE Procedure	
Dependent Variable: so4	
Summary of Input Data Set	
Number of Non-Missing Observations	179
Number of Missing Observations	0
Unique Smoothing Design Points	179
Summary of Final Model	
Number of Regression Variables	0
Number of Smoothing Variables	2
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	3
Summary Statistics of Final Estimation	
log10(n*Lambda)	0.2770
Smoothing Penalty	2.4588
Residual SS	12.4450
Tr(I-A)	140.2750
Model DF	38.7250
Standard Deviation	0.2979

The following statements produce [Output 74.3.2](#):

```

symbol1 interpol=join value=none;
title "GCV Function";

proc gplot data=gcv;
  plot gcv*lognlambda/frame cframe=ligr
      vaxis=axis1 haxis=axis2;
run;

```

[Output 74.3.2](#) displays the plot of the GCV function versus `nlambda` in \log_{10} scale. The GCV function has two minima. PROC TPSPLINE locates the minimum at 0.277005. The figure also displays a local minimum located around -2.56 . Note that the TPSPLINE procedure may not always find the global minimum, although it did in this case.

Output 74.3.2. GCV Function of SO4 Data Set

The following analysis specifies the option `LOGNLAMBDA0=-2.56`. The output is displayed in [Output 74.3.3](#).

```

proc tpspline data=so4;
  model so4 = (latitude longitude) /lognlambda0=-2.56;
  score data=pred out=prediction2;
run;

```

Output 74.3.3. Output from PROC TPSPLINE for Data Set SO4 with LOGNLAMBDA=-2.56

The TPSPLINE Procedure	
Dependent Variable: so4	
Summary of Input Data Set	
Number of Non-Missing Observations	179
Number of Missing Observations	0
Unique Smoothing Design Points	179
Summary of Final Model	
Number of Regression Variables	0
Number of Smoothing Variables	2
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	3
Summary Statistics of Final Estimation	
log10(n*Lambda)	-2.5600
Smoothing Penalty	177.2144
Residual SS	0.0438
Tr(I-A)	7.2086
Model DF	171.7914
Standard Deviation	0.0779

The smoothing penalty is much larger in [Output 74.3.3](#) than that displayed in [Output 74.3.1](#). The estimate in [Output 74.3.1](#) uses a large lambda value and, therefore, the surface is smoother than the estimate using LOGNLAMBDA=-2.56 ([Output 74.3.3](#)).

The estimate based on LOGNLAMBDA=-2.56 has a larger value for the degrees of freedom, and it has a much smaller standard deviation.

However, a smaller standard deviation in nonparametric regression does not necessarily mean that the estimate is good: a small λ value always produces an estimate closer to the data and, therefore, a smaller standard deviation.

The following statements produce two contour plots of the estimates using the GCONTOUR procedure. In the final step, the plots are placed into a single graphic with the GREPLAY procedure.

```

title "TPSPLINE fit with lognlambda=0.277";
proc gcontour data=prediction1 gout=grafcat;
  plot latitude*longitude = P_so4/
        name="tpscon1" legend=legend1
        vaxis=axis1 haxis=axis2 cframe=ligr hreverse;
run;

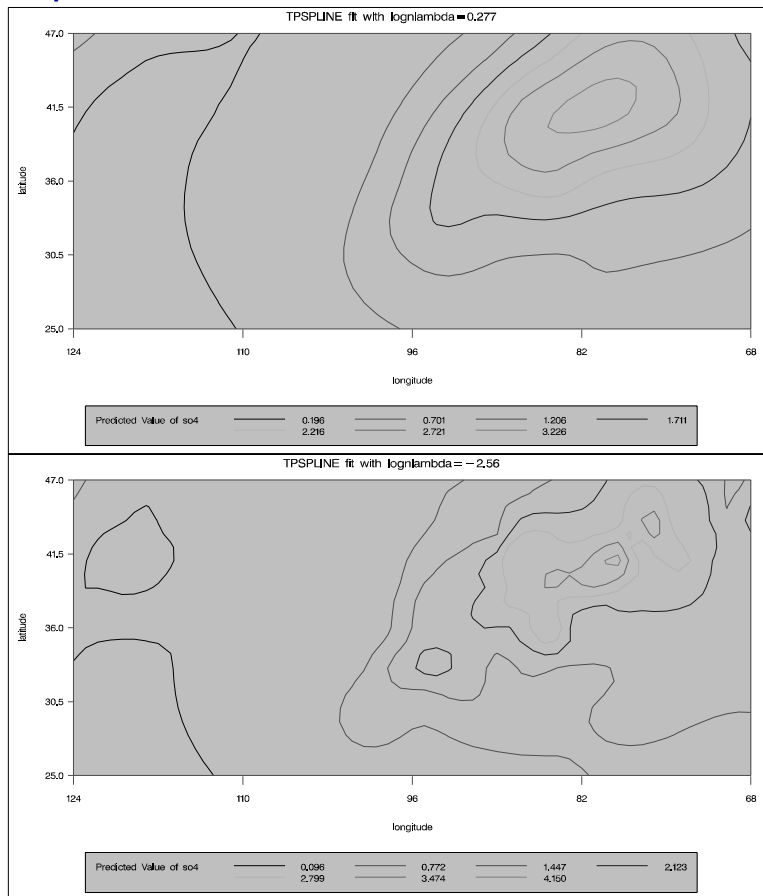

title "TPSPLINE fit with lognlambda=-2.56";
proc gcontour data=prediction2 gout=grafcat;
  plot latitude*longitude = P_so4/
        name="tpscon2" legend=legend1
        vaxis=axis1 haxis=axis2 cframe=ligr hreverse;
run;

title;
proc greplay igout=grafcat tc=sashelp.templt template=v2 nofs;
  treplay 1:tpscon1 2:tpscon2;
quit;

```

Compare the two estimates by examining the contour plots of both estimates ([Output 74.3.4](#)).

Output 74.3.4. Contour Plot of TPSPLINE Estimates with Different Lambdas

As the contour plots show, the estimate with LOGNLAMBDA=0.277 may repre-

sent the underlying trend, while the estimate with the LOGNLAMBDA=-2.56 is very rough and may be modeling the noise component.

Example 74.4. Large Data Set Application

The following example illustrates how you can use the D= option to decrease the computation time needed by the TPSPLINE procedure. Note that, while the D= option can be helpful in decreasing computation time for large data sets, it may produce unexpected results when used with small data sets.

The following statements generate the data set large:

```
data large;
  do x=-5 to 5 by 0.02;
    y=5*sin(3*x)+1*rannor(57391);
    output;
  end;
run;
```

The data set large contains 501 observations with one independent variable x and one dependent variable y. The following statements invoke PROC TPSPLINE to produce a thin-plate smoothing spline estimate and the associated 99% confidence interval. The output statistics are saved in the data set fit1.

```
proc tpspline data=large;
  model y =(x) /lambda=(-5 to -1 by 0.2) alpha=0.01;
  output out=fit1 pred lclm uclm;
run;
```

The results from this MODEL statement are displayed in [Output 74.4.1](#).

Output 74.4.1. Output from PROC TPSPLINE without the D= Option

```

Output 74.4.3. Comparison of Two Fits with and without the D= Option

Example 74.5. Computing a Bootstrap Confidence Interval

The following example illustrates how you can construct a bootstrap confidence interval by using the multiple responses feature in PROC TPSPLINE.

Numerous epidemiological observations have indicated that exposure to solar radiation is an important factor in the etiology of melanoma. The following data present age-adjusted melanoma incidences for 37 years from the Connecticut Tumor Registry (Houghton, Flannery, and Viola 1980). The data are analyzed by Ramsay and Silverman (1997).

```

data melanoma;
  input year incidences @@;
  datalines;
1936    0.9    1937    0.8    1938    0.8    1939    1.3
1940    1.4    1941    1.2    1942    1.7    1943    1.8
1944    1.6    1945    1.5    1946    1.5    1947    2.0
1948    2.5    1949    2.7    1950    2.9    1951    2.5
1952    3.1    1953    2.4    1954    2.2    1955    2.9
1956    2.5    1957    2.6    1958    3.2    1959    3.8
1960    4.2    1961    3.9    1962    3.7    1963    3.3
1964    3.7    1965    3.9    1966    4.1    1967    3.8
1968    4.7    1969    4.4    1970    4.8    1971    4.8
1972    4.8
  ;
run;

```

The variable incidences records the number of melanoma cases per 100,000 people for the years 1936 to 1972. The following model fits the data and requests a 90% Bayesian confidence interval along with the estimate.

```

proc tpspline data=melanoma;
  model incidences = (year) /alpha = 0.1;
  output out = result pred uclm lclm;
run;

```

The output is displayed in [Output 74.5.1](#)

Output 74.5.1. Output from PROC TPSPLINE for the Melanoma Data Set

The TPSPLINE Procedure	
Dependent Variable: incidences	
Summary of Input Data Set	
Number of Non-Missing Observations	37
Number of Missing Observations	0
Unique Smoothing Design Points	37
Summary of Final Model	
Number of Regression Variables	0
Number of Smoothing Variables	1
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	2
Summary Statistics of Final Estimation	
log10(n*Lambda)	-0.0607
Smoothing Penalty	0.5171
Residual SS	1.2243
Tr(I-A)	22.5852
Model DF	14.4148
Standard Deviation	0.2328

The following statements produce a plot of the estimated curve:

```

symbol1 h=1pct ;
symbol2 i=join v=none;
symbol3 i=join v=none;
symbol4 i=join v=none c=cyan;

legend1 frame cframe=ligr cborder=black
        label=none position=center;
axis1 label=(angle=90 rotate=0) minor=none;
axis2 minor=none;

title1 'Age-adjusted Melanoma Incidences for 37 years';

proc gplot data=result;
  plot incidences*year=1
       p_incidences*year=2
       lclm_incidences*year=3
       uclm_incidences*year=4 /overlay legend=legend1
                               vaxis=axis1 haxis=axis2
                               frame cframe=ligr;
run;

```

The estimated curve is displayed with 90% confidence interval bands in [Output 74.5.2](#). The number of melanoma incidences exhibits a periodic pattern and increases over the years. The periodic pattern is related to sunspot activity and the accompanying fluctuations in solar radiation.

Output 74.5.2. TPSPLINE Estimate and 90% Confidence Interval of Melanoma Data

Wang and Wahba (1995) compared several bootstrap confidence intervals to Bayesian confidence intervals for smoothing splines. Both bootstrap and Bayesian confidence intervals are across-the-curve intervals, not point-wise intervals. They concluded that bootstrap confidence intervals work as well as Bayesian intervals concerning average coverage probability. Additionally, bootstrap confidence intervals appear to be better for small sample sizes. Based on their simulation, the “percentile- t interval” bootstrap interval performs better than the other types of bootstrap intervals.

Suppose that \hat{f}_λ and $\hat{\sigma}$ are the estimates of f and σ from the data. Assume that \hat{f}_λ is the “true” f , and generate the bootstrap sample as follows:

$$y_i^* = \hat{f}_\lambda(x_i) + \epsilon_i^*, \quad i = 1, \dots, n$$

where $\epsilon^* = (\epsilon_1^*, \dots, \epsilon_n^*)^T \approx \mathbf{N}(\mathbf{0}, \hat{\sigma} \mathbf{I}_{n \times n})$. Denote $f_\lambda^*(x_i)$ as the random variable of the bootstrap estimate at x_i . Repeat this process K times, so that at each point x_i , you have K bootstrap estimates $f_\lambda^*(x_i)$ or K realizations of $f_\lambda^*(x_i)$. For each fixed x_i , consider the following statistic D_i^* , which is similar to a Student’s t statistic:

$$D_i^* = (f_\lambda^*(x_i) - \hat{f}_\lambda(x_i)) / \hat{\sigma}_i^*$$

where $\hat{\sigma}_i^*$ is the estimate of $\hat{\sigma}$ based on the i th bootstrap sample.

Suppose $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$ are the lower and upper $\alpha/2$ points of the empirical distribution of D_i^* . The $(1 - \alpha)100\%$ bootstrap confidence interval is defined as

$$(\hat{f}_{\hat{\lambda}}(x_i) - \chi_{1-\alpha/2}\hat{\sigma}, \hat{f}_{\hat{\lambda}}(x_i) - \chi_{\alpha/2}\hat{\sigma})$$

Bootstrap confidence intervals are easy to interpret and can be used with any distribution. However, because they require K model fits, their construction is computationally intensive.

The multiple dependent variables feature in PROC TPSPLINE enables you to fit multiple models with the same independent variables. The procedure calculates the matrix decomposition part of the calculations only once regardless of the number of dependent variables in the model. These calculations are responsible for most of the computing time used by the TPSPLINE procedure. This feature is particularly useful when you need to generate a bootstrap confidence interval.

To construct a bootstrap confidence interval, perform the following tasks:

- Fit the data using PROC TPSPLINE and obtain estimates $\hat{f}_{\hat{\lambda}}(x_i)$ and $\hat{\sigma}$.
- Generate K bootstrap samples based on $\hat{f}_{\hat{\lambda}}(x_i)$ and $\hat{\sigma}$.
- Fit the K bootstrap samples with the TPSPLINE procedure to obtain estimates of $\hat{f}_{\hat{\lambda}}^*(x_i)$ and $\hat{\sigma}_i^*$.
- Compute D_i^* and the values $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$.

The following statements illustrate this process:

```
proc tpspline data=melanoma;
  model incidences = (year) /alpha = 0.05;
  output out = result pred uclm lclm;
run;
```

The output from the initial PROC TPSPLINE analysis is displayed in [Output 74.5.3](#). The data set `result` contains the predicted values and confidence limits from the analysis.

Output 74.5.3. Output from PROC TPSPLINE for the Melanoma Data Set

The TPSPLINE Procedure	
Dependent Variable: incidences	
Summary of Input Data Set	
Number of Non-Missing Observations	37
Number of Missing Observations	0
Unique Smoothing Design Points	37
Summary of Final Model	
Number of Regression Variables	0
Number of Smoothing Variables	1
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	2
Summary Statistics of Final Estimation	
log10(n*Lambda)	-0.0607
Smoothing Penalty	0.5171
Residual SS	1.2243
Tr(I-A)	22.5852
Model DF	14.4148
Standard Deviation	0.2328

The following statements illustrate how you can obtain a bootstrap confidence interval for the Melanoma data. The following statements create the data set `bootstrap`. The observations are created with information from the preceding PROC TPSPLINE execution; as displayed in [Output 74.5.3](#), $\hat{\sigma} = 0.232823$. The values of $\hat{f}_{\hat{\lambda}}(x_i)$ are stored in the data set `result` in the variable `P_incidence`.

```
data bootstrap;
  set result;
  array y{1070} y1-y1070;
  do i=1 to 1070;
    y{i} = p_incidences + 0.232823*rannor(123456789);
  end;
  keep y1-y1070 p_incidences year;
run;

ods listing close;

proc tpspline data=bootstrap;
  ods output FitStatistics=FitResult;
  id p_incidences;
  model y1-y1070 = (year);
  output out=result2;
run;
ods listing;
```

The DATA step generates 1,070 bootstrap samples based on the previous estimate from PROC TPSPLINE. For this data set, some of the bootstrap samples result in λ s

(selected by the GCV function) that cause problematic behavior. Thus, an additional 70 bootstrap samples are generated.

The ODS listing destination is closed before PROC TPSPLINE is invoked. The model fits all the y_1 – y_{1070} variables as dependent variables, and the models are fit for all bootstrap samples simultaneously. The output data set `result2` contains the variables `year`, y_1 – y_{1070} , p_{y_1} – $p_{y_{1070}}$, and `P_incidences`.

The ODS OUTPUT statement writes the FitStatistics table to the data set `FitResult`. The data set `FitResult` contains the two variables. They are `Parameter` and `Value`. The `FitResult` data set is used in subsequent calculations for D_i^* .

In the data set `FitResult`, there are 63 estimates with a standard deviation of zero, suggesting that the estimates provide perfect fits of the data and are caused by $\hat{\lambda}$ s that are approximately equal to zero. For small sample sizes, there is a positive probability that the λ chosen by the GCV function will be zero (refer to Wang and Wahba 1995).

In the following steps, these cases are removed from the bootstrap samples as “bad” samples: they represent failure of the GCV function.

The following SAS statements manipulate the data set `FitResult`, retaining the standard deviations for all bootstrap samples and merging `FitResult` with the data set `result2`, which contains the estimates for bootstrap samples. In the final data set `boot`, the D_i^* statistics are calculated.

```

data FitResult; set FitResult;
    if Parameter="Standard Deviation";
    keep Value;
run;

proc transpose data=FitResult out=sd prefix=sd;

data result2;
    if _N_ = 1 then set sd;
    set result2;

data boot;
    set result2;
    array y{1070} p_y1-p_y1070;
    array sd{1070} sd1-sd1070;
    do i=1 to 1070;
        if sd{i} > 0 then do;
            d = (y{i} - P_incidences)/sd{i};
            obs = _N_;
            output;
        end;
    end;
    keep d obs P_incidences year;
run;

```

The following SAS statements retain the first 1000 bootstrap samples and calculate the values $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$ with $\alpha = 0.1$.

```

proc sort data=boot;
  by obs;
run;

data boot;
  set boot;
  by obs;
  retain n;

  if first.obs then n=1;
  else n=n+1;
  if n > 1000 then delete;
run;

proc sort data=boot;
  by obs d;
run;

data chi1 chi2 ;
  set boot;
  if (_N_ = (obs-1)*1000+50) then output chi1;
  if (_N_ = (obs-1)*1000+950) then output chi2;
run;

proc sort data=result;
  by year;
run;

proc sort data=chi1;
  by year;
run;

proc sort data=chi2;
  by year;
run;

data result;
  merge result
    chi1(rename=(d=chi05))
    chi2(rename=(d=chi95));
  keep year incidences P_incidences lower upper
    LCLM_incidences UCLM_incidences;

  lower = -chi95*0.232823 + P_incidences;
  upper = -chi05*0.232823 + P_incidences;

  label  lower="Lower 90% CL (Bootstrap)"
         upper="Upper 90% CL (Bootstrap)"
         lclm_incidences="Lower 90% CL (Bayesian)"
         uclm_incidences="Upper 90% CL (Bayesian)";
run;

```

The data set `result` contains the variables `year`, `incidences`, the TPSPLINE estimate

P_incidences, and the 90% Bayesian and 90% bootstrap confidence intervals.

The following statements produce [Output 74.5.4](#):

```

symbol1  v=dot  h=1pct  ;
symbol2  i=join v=none l=1;
symbol3  i=join v=none l=33;
symbol4  i=join v=none l=33;
symbol5  i=join v=none l=43 c=green;
symbol6  i=join v=none l=43 c=green;

title1 'Age-adjusted Melanoma Incidences for 37 years';
proc gplot data=result;
  plot      incidences * year=1
           p_incidences * year=2
           lclm_incidences * year=3
           uclm_incidences * year=3
           lower * year=4
           upper * year=4
  /overlay  legend=legend1
  vaxis=axis1  haxis=axis2
  frame      cframe=ligr;
run;

```

[Output 74.5.4](#) displays the plot of the variable incidences, the predicted values, and the Bayesian and bootstrap confidence intervals.

The plot shows that the bootstrap confidence interval is similar to the Bayesian confidence interval. However, the Bayesian confidence interval is symmetric around the estimates, while the bootstrap confidence interval is not.

Output 74.5.4. Comparison of Bayesian and Bootstrap Confidence Interval for Melanoma Data

The TRANSREG Procedure

Overview

The TRANSREG (transformation regression) procedure fits linear models, optionally with spline and other nonlinear transformations, and it can be used to code experimental designs prior to their use in other analyses.

The TRANSREG procedure fits many types of linear models, including

- ordinary regression and ANOVA
- metric and nonmetric conjoint analysis (Green and Wind 1975; de Leeuw, Young, and Takane 1976)
- metric and nonmetric vector and ideal point preference mapping (Carroll 1972)
- simple, multiple, and multivariate regression with variable transformations (Young, de Leeuw, and Takane 1976; Winsberg and Ramsay 1980; Breiman and Friedman 1985)
- redundancy analysis (Stewart and Love 1968) with variable transformations (Israels 1984)
- canonical correlation analysis with variable transformations (van der Burg and de Leeuw 1983)
- response surface regression (Meyers 1976; Khuri and Cornell 1987) with variable transformations
- linear models with Box-Cox (1964) transformations of the dependent variables

The data set can contain variables measured on nominal, ordinal, interval, and ratio scales (Siegel 1956). Any mix of these variable types is allowed for the dependent and independent variables. The TRANSREG procedure can transform

- nominal variables by scoring the categories to minimize squared error (Fisher 1938), or they can be expanded into dummy variables
- ordinal variables by monotonically scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and squared error is minimized. Ties can be optimally untied or left tied (Kruskal 1964). Ordinal variables can also be transformed to ranks.
- interval and ratio scale of measurement variables linearly or nonlinearly with spline (de Boor 1978; van Rijckevorsel 1982) or monotone spline (Winsberg and Ramsay 1980) transformations. In addition, smooth, logarithmic, exponential, power, logit, and inverse trigonometric sine transformations are available.

Transformations produced by the PROC TRANSREG multiple regression algorithm, requesting spline transformations, are often similar to transformations produced by the ACE smooth regression method of Breiman and Friedman (1985). However, ACE does not explicitly optimize a loss function (de Leeuw 1986), while PROC TRANSREG always explicitly optimizes a squared-error loss function.

PROC TRANSREG extends the ordinary general linear model by providing optimal variable transformations that are iteratively derived using the method of alternating least squares (Young 1981). PROC TRANSREG iterates until convergence, alternating

- finding least-squares estimates of the parameters of the model given the current scoring of the data (that is, the current vectors)
- finding least-squares estimates of the scoring parameters given the current set of model parameters

For more background on alternating least-squares optimal scaling methods and transformation regression methods, refer to Young, de Leeuw, and Takane (1976), Winsberg and Ramsay (1980), Young (1981), Gifi (1990), Schiffman, Reynolds, and Young (1981), van der Burg and de Leeuw (1983), Israels (1984), Breiman and Friedman (1985), and Hastie and Tibshirani (1986). (These are just a few of the many relevant sources.)

Getting Started

This section provides several examples that illustrate features of the TRANSREG procedure.

Main-Effects ANOVA

This example shows how to use the TRANSREG procedure to code and fit a main-effects ANOVA model. The input data set contains the dependent variables Y, factors X1 and X2, and 11 observations. The following statements perform a main-effects ANOVA:

```

title 'Introductory Main-Effects ANOVA Example';

data A;
  input Y X1 $ X2 $;
  datalines;
8 a a
7 a a
4 a b
3 a b
5 b a
4 b a
2 b b
1 b b
8 c a

```

```
7 c a
5 c b
2 c b
;

*---Fit a Main-Effects ANOVA model with 1, 0, -1 coding. ---;
proc transreg ss2;
  model identity(Y) = class(X1 X2 / effects);
  output coefficients replace;
run;

*---Print TRANSREG output data set---;
proc print label;
  format Intercept -- X2a 5.2;
run;
```

```

Figure 75.1. ANOVA Example Output from PROC TRANSREG

The iteration history in [Figure 75.1](#) shows that the final R-Square of 0.88144 is reached on the first iteration.

This is followed by ANOVA, fit statistics, and regression tables. PROC TRANSREG uses an effects (also called deviations from means or 0, 1, -1) coding in this example. For more information on using PROC TRANSREG for ANOVA and other codings, see the “ANOVA Codings” section on page 4662.

The TRANSREG procedure produces the data set displayed in [Figure 75.2](#).

Introductory Main-Effects ANOVA Example									
Obs	_TYPE_	_NAME_	Y	Intercept	X1 a	X1 b	X2 a	X1	X2
1	SCORE	ROW1	8	1.00	1.00	0.00	1.00	a	a
2	SCORE	ROW2	7	1.00	1.00	0.00	1.00	a	a
3	SCORE	ROW3	4	1.00	1.00	0.00	-1.00	a	b
4	SCORE	ROW4	3	1.00	1.00	0.00	-1.00	a	b
5	SCORE	ROW5	5	1.00	0.00	1.00	1.00	b	a
6	SCORE	ROW6	4	1.00	0.00	1.00	1.00	b	a
7	SCORE	ROW7	2	1.00	0.00	1.00	-1.00	b	b
8	SCORE	ROW8	1	1.00	0.00	1.00	-1.00	b	b

10	SCORE	ROW10	7	1.00	-1.00	-1.00	1.00	c	a
11	SCORE	ROW11	5	1.00	-1.00	-1.00	-1.00	c	b
12	SCORE	ROW12	2	1.00	-1.00	-1.00	-1.00	c	b
13	M COEFFI	Y	.	4.67	0.83	-1.67	1.83		
14	MEAN	Y	.	.	5.50	3.00	6.50		

Figure 75.2. Output Data Set from PROC TRANSREG

The output data set has three kinds of observations, identified by values of `_TYPE_`.

- When `_TYPE_='SCORE'`, the observation contains information on the dependent and independent variables as follows:
 - Y is the original dependent variable.
 - X1 and X2 are the independent classification variables, and the Intercept through X2 a columns contain the main effects design matrix that PROC TRANSREG creates. The variable names are Intercept, X1a, X1b, and X2a. Their labels are shown in the listing.
- When `_TYPE_='M COEFFI'`, the observation contains coefficients of the final linear model.
- When `_TYPE_='MEAN'`, the observation contains the marginal means.

The observations with `_TYPE_='SCORE'` form the score partition of the data set, and the observations with `_TYPE_='M COEFFI'` and `_TYPE_='MEAN'` form the coefficient partition of the data set.

Detecting Nonlinear Relationships

The TRANSREG procedure can detect nonlinear relationships among variables. For example, suppose 400 observations are generated from the following function

$$t = \frac{x}{4} + \sin(x)$$

and data are created as follows

$$y = t + \epsilon$$

where ϵ is random normal error.

The following statements find a cubic spline transformation of X with four knots. For information on using splines and knots, see the “[Smoothing Splines](#)” section on page 4596, the “[Solving Standard Least-Squares Problems](#)” section on page 4628, [Example 75.1](#), and [Example 75.4](#).

The following statements produce [Figure 75.3](#) through [Figure 75.4](#):

```

title 'Curve Fitting Example';

*---Create An Artificial Nonlinear Scatter Plot---;
data Curve;
  Pi=constant('pi');
  Pi4=4*Pi;
  Increment=Pi4/400;
  do X=Increment to Pi4 by Increment;
    T=X/4 + sin(X);
    Y=T + normal(7);
    output;
  end;
run;

*---Request a Spline Transformation of X---;
proc transreg data=Curve dummy;
  model identity(Y)=spline(X / nknots=4);
  output predicted;
  id T;
run;

*---Plot the Results---;
goptions goutmode=replace nodisplay;
%let opts = haxis=axis2 vaxis=axis1 frame cframe=ligr;
* Depending on your goptions, these plot options may work better:
* %let opts = haxis=axis2 vaxis=axis1 frame;

proc gplot;
  title;
  axis1 minor=none label=(angle=90 rotate=0);

```

```

axis2 minor=none;
plot T*X=2                / &opts name='tregin1';
plot Y*X=1                / &opts name='tregin2';
plot Y*X=1 T*X=2 PY*X=3 / &opts name='tregin3' overlay ;
symbol1 color=blue      v=star i=none;

symbol2 color=yellow v=none i=join line=1;
symbol3 color=red      v=none i=join line=2;
run; quit;

goptions display;
proc greplay nofs tc=sashelp.templt template=l2r2;
  igout gseg;
  treplay 1:tregin1 2:tregin3 3:tregin2;
run; quit;

```

PROC TRANSREG increases the squared multiple correlation from the original value of 0.19945 to 0.47062. The plot of T by X shows the original function, the plot of Y by X shows the error-perturbed data, and the third plot shows the data, the true function as a solid curve, and the regression function as the dashed curve. The regression function closely approximates the true function.

Figure 75.3. Curve Fitting Example Output

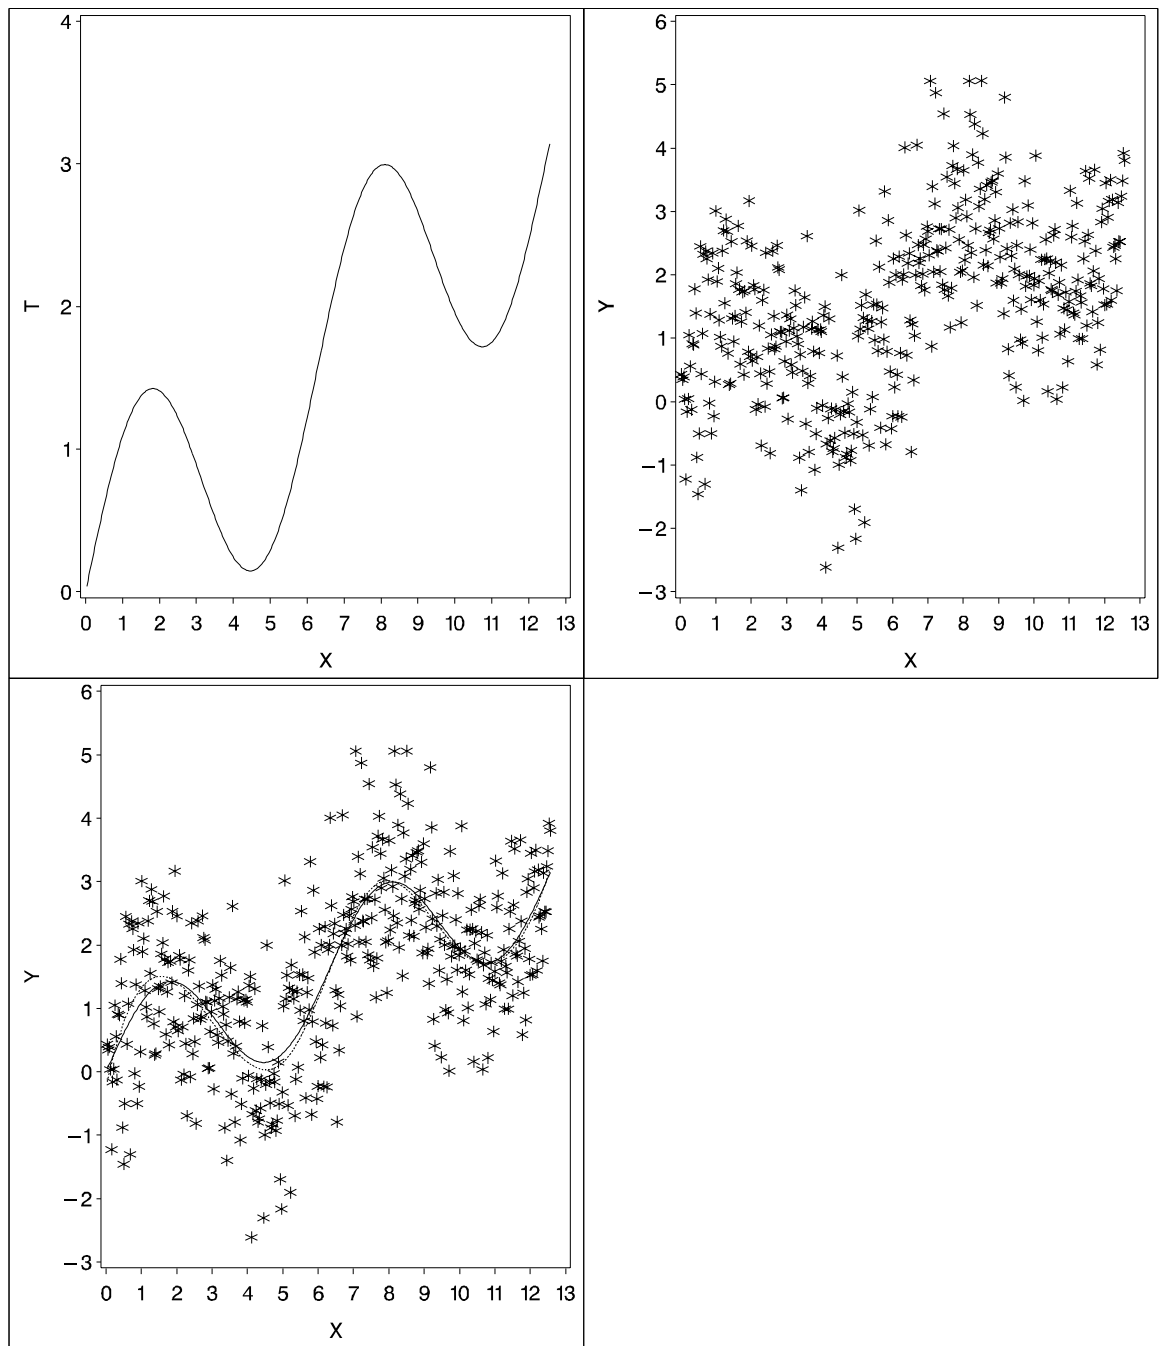

Figure 75.4. Plots for the Curve Fitting Example

Syntax

The following statements are available in PROC TRANSREG.

```

PROC TRANSREG < DATA=SAS-data-set >
    < OUTTEST=SAS-data-set >< a-options >< o-options > ;
MODEL < transform(dependents < / t-options >)
    < transform(dependents < / t-options >)...> = >
    transform(independents < / t-options >)
    < transform(independents < / t-options >)...>< / a-options > ;
OUTPUT < OUT=SAS-data-set >< o-options > ;
ID variables ;
FREQ variable ;
WEIGHT variable ;
BY variables ;

```

To use the TRANSREG procedure, you need the PROC TRANSREG and MODEL statements. To produce an OUT= output data set, the OUTPUT statement is required. PROC TRANSREG enables you to specify the same options in more than one statement. All of the MODEL statement *a-options* (algorithm options) and all of the OUTPUT statement *o-options* (output options) can also be specified in the PROC TRANSREG statement. You can abbreviate all *a-options*, *o-options*, and *t-options* (transformation options) to their first three letters. This is a special feature of the TRANSREG procedure and is not generally true of other SAS/STAT procedures. See [Table 75.1](#) on page 4554.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC TRANSREG statement. The remaining statements are described in alphabetical order.

PROC TRANSREG Statement

```

PROC TRANSREG < DATA=SAS-data-set >
    < OUTTEST=SAS-data-set >< a-options
    >< o-options > ;

```

The PROC TRANSREG statement starts the TRANSREG procedure. Optionally, this statement identifies an input and an OUTTEST= data set, specifies the algorithm and other computational details, requests displayed output, and controls the contents of the OUT= data set (which is created with the OUTPUT statement). The DATA= and OUTTEST= options can appear only in the PROC TRANSREG statement.

The following table summarizes options available in the PROC TRANSREG statement. All *a-options* and *o-options* are described in the sections on either the MODEL or OUTPUT statement, in which these options can also be specified.

Table 75.1. Options Available in the TRANSREG Procedure

DATA=SAS-data-set

specifies the SAS data set to be analyzed. If you do not specify the DATA= option, PROC TRANSREG uses the most recently created SAS data set. The data set must be an ordinary SAS data set; it cannot be a special TYPE= data set.

OUTTEST=SAS-data-set

specifies an output data set to contain hypothesis tests results. When you specify the OUTTEST= option, the data set contains ANOVA results. When you specify the SS2 *a-option*, regression tables are also output. When you specify the UTILITIES *o-option*, conjoint analysis part-worth utilities are also output. For more information on the OUTTEST= data set, see the “OUTTEST= Output Data Set” section on page 4626.

BY Statement

BY variables ;

You can specify a BY statement with PROC TRANSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TRANSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TRANSREG then treats the data set as if each observation appeared n times, where n is the value of the FREQ variable for the observation. Noninteger values of the FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

ID Statement

ID *variables* ;

The ID statement includes additional character or numeric variables in the OUT= data set. The variables must be contained in the input data set.

MODEL Statement

MODEL < *transform*(*dependents* < / *t-options* >)
 < *transform*(*dependents* < / *t-options* >)...> = >
transform(*independents* < / *t-options* >)
 < *transform*(*independents* < / *t-options* >)...> < / *a-options* > ;

The MODEL statement specifies the dependent and independent variables (*dependents* and *independents*, respectively) and specifies the transformation (*transform*) to apply to each variable. Only one MODEL statement can appear in the TRANSREG procedure. The *t-options* are transformation options, and the *a-options* are the algorithm options. The *t-options* provide details for the transformation; these depend on the *transform* chosen. The *t-options* are listed after a slash in the parentheses that enclose the variable list (either *dependents* or *independents*). The *a-options* control the algorithm used, details of iteration, details of how the intercept and dummy variables are generated, and displayed output details. The *a-options* are listed after the entire model specification (the *dependents*, *independents*, transformations, and *t-options*) and after a slash. You can also specify the algorithm options in the PROC TRANSREG statement. When you specify the DESIGN *o-option*, *dependents* and an equal sign are not required. The operators “*”, “|”, and “@” from the GLM procedure are available for interactions with the CLASS expansion and the IDENTITY transformation.

```

Class(a * b ...
      c | d ...
      e | f ... @ n)
Identity(a * b ...
         c | d ...
         e | f ... @ n)

```

In addition, transformations and spline expansions can be crossed with classification variables:

```
transform(var) * class(group)
transform(var) | class(group)
```

See the “Types of Effects” section on page 1784 in Chapter 32, “The GLM Procedure,” for a description of the @, *, and | operators and see the “Model Statement Usage” section on page 4592 for information on how to use these operators in PROC TRANSREG. Note that nesting is not allowed in PROC TRANSREG.

The next three sections discuss the transformations available (*transforms*) (see the “Families of Transformations” section on page 4558), the transformation options (*t-options*) (see the “Transformation Options (t-options)” section on page 4564), and the algorithm options (*a-options*) (see the “Algorithm Options (a-options)” section on page 4573).

Families of Transformations

In the MODEL statement, *transform* specifies a transformation in one of four families.

Variable expansions	preprocess the specified variables, replacing them with more variables.
Nonoptimal transformations	preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.
Optimal transformations	replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except for contrived cases where the transformation fits the model exactly as well as the original variable).
Other transformations	are the IDENTITY and SSPLINE transformations. These do not fit into the preceding categories.

The following table summarizes the transformations in each family.

Family	Members of Family
Variable expansions	
B-spline basis	BSPLINE
set of dummy variables	CLASS
elliptical response surface	EPOINT
circular response surface	POINT
piecewise polynomial basis	PSPLINE
quadratic response surface	QPOINT
Nonoptimal transformations	
inverse trigonometric sine	ARSIN
Box-Cox	BOXCOX
exponential	EXP
logarithm	LOG
logit	LOGIT
raises variables to specified power	POWER
transforms to ranks	RANK
noniterative smoothing spline	SMOOTH
Optimal transformations	
linear	LINEAR
monotonic, ties preserved	MONOTONE
monotonic B-spline	MSPLINE
optimal scoring	OPSCORE
B-spline	SPLINE
monotonic, ties not preserved	UNTIE
Other transformations	
identity, no transformation	IDENTITY
iterative smoothing spline	SSPLINE

You can use any transformation with either dependent or independent variables (except the SMOOTH transformation, which can be used only with independent variables, and BOXCOX, which can be used only with dependent variables). However, the variable expansions are usually more appropriate for independent variables.

The *transform* is followed by a variable (or list of variables) enclosed in parentheses. Optionally, depending on the *transform*, the parentheses can also contain *t-options*, which follow the variables and a slash. For example,

```
model log(y)=class(x);
```

finds a LOG transformation of Y and performs a CLASS expansion of X.

```
model identity(y) = spline(x1 x2 / nknots=3);
```

The preceding statement finds SPLINE transformations of X1 and X2. The NKNOTS=*t-option* used with the SPLINE transformation specifies three knots. The IDENTITY(Y) transformation specifies that Y is not to be transformed.

The rest of this section provides syntax details for members of the four families of transformations. The *t-options* are discussed in the “Transformation Options (*t-options*)” section on page 4564.

Variable Expansions

The TRANSREG procedure performs variable expansions before iteration begins. Variable expansions expand the original variables into a typically larger set of new variables. The original variables are those that are listed in parentheses after *transform*, and they are sometimes referred to by the name of the *transform*. For example, in CLASS(X1 X2), X1 and X2 are sometimes referred to as CLASS expansion variables or simply CLASS variables, and the expanded variables are referred to as dummy variables. Similarly, in POINT(Dim1 Dim2), Dim1 and Dim2 are sometimes referred to as POINT variables.

The resulting variables are not transformed by the iterative algorithms after the initial preprocessing. Observations with missing values for these types of variables are excluded from the analysis.

The POINT, EPOINT, and QPOINT variable expansions are used in preference mapping analyses (also called PREFMAP, external unfolding, ideal point regression) (Carroll 1972) and for response surface regressions. These three expansions create circular, elliptical, and quadratic response or preference surfaces (see the “Point Models” section on page 4605 and Example 75.5). The CLASS variable expansion is used for main effects ANOVA.

The following list provides syntax and details for the variable expansion *transforms*.

BSPLINE

BSP

expands each variable to a B-spline basis. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with the BSPLINE expansion. When DEGREE=*n* (3 by default) with *k* knots (0 by default), $n + k + 1$ variables are created. In addition, the original variable appears in the OUT= data set before the ID variables. For example, BSPLINE(X) expands X into X_0 X_1 X_2 X_3 and outputs X as well. The X_: variables contain the B-spline (which are the same basis vectors that the SPLINE and MSPLINE transformations use internally). The columns of the BSPLINE expansion sum to a column of ones, so an implicit intercept model is fit when the BSPLINE expansion is specified. If you specify the BSPLINE expansion for more than one variable, the model is less than full rank. See the section “SPLINE, BSPLINE, and PSPLINE Comparisons” on page 4614. Variables following BSPLINE must be numeric, and they are typically continuous.

CLASS

CLA

expands the variables to a set of dummy variables. For example, CLASS(X1 X2) is used for a simple main-effects model, CLASS(X1 | X2) fits a main-effects and interactions model, and CLASS(X1|X2|X3|X4@2 X1*X2*X3) creates all main effects,

all two-way interactions, and one three-way interaction. See the “[Model Statement Usage](#)” section on page 4592 for information on how to use the operators @, *, and | in PROC TRANSREG. To determine class membership, PROC TRANSREG uses the values of the formatted variables. Variables following CLASS can be either character or numeric; numeric variables should be discrete.

EPOINT

EPO

expands the variables for an elliptical response surface regression or for an elliptical ideal point regression. Specify the COORDINATES *o-option* to output PREFMAP ideal elliptical point model coordinates to the OUT= data set. Each axis of the ellipse (or ellipsoid) is oriented in the same direction as one of the variables. The EPOINT expansion creates a new variable for each original variable. The value of each new variable is the square of each observed value for the corresponding parenthesized variable. The regression analysis then uses both sets of variables (original and squared). Variables following EPOINT must be numeric, and they are typically continuous.

POINT

POI

expands the variables for a circular response surface regression or for a circular ideal point regression. Specify the COORDINATES *o-option* to output PREFMAP ideal point model coordinates to the OUT= data set. The POINT expansion creates a new variable having a value for each observation that is the sums of squares of all the POINT variables. This new variable is added to the set of variables and is used in the regression analysis. For more on ideal point regression, refer to Carroll (1972). Variables following POINT must be numeric, and they are typically continuous.

PSPLINE

PSP

expands each variable to a piecewise polynomial basis. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with PSPLINE. When DEGREE= n (3 by default) with k knots (0 by default), $n + k$ variables are created. In addition, the original variable appears in the OUT= data set before the ID variables. For example, PSPLINE(X / NKNOTS=1) expands X into X_1 X_2 X_3 X_4 and outputs X as well. Unlike BSPLINE, an intercept is not implicit in the columns of PSPLINE. Refer to Smith (1979) for a good introduction to piecewise polynomial splines. Also see the section “[SPLINE, BSPLINE, and PSPLINE Comparisons](#)” on page 4614. Variables following PSPLINE must be numeric, and they are typically continuous.

QPOINT

QPO

expands the variables for a quadratic response surface regression or for a quadratic ideal point regression. Specify the COORDINATES *o-option* to output PREFMAP quadratic ideal point model coordinates to the OUT= data set. For m QPOINT variables, $m(m+1)/2$ new variables are created containing the squares and crossproducts of the original variables. The regression analysis uses both sets (original and crossed). Variables following QPOINT must be numeric, and they are typically continuous.

Nonoptimal Transformations

Like variable expansions, nonoptimal transformations are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation with missing value estimation).

The following list provides syntax and details for nonoptimal variable transformations.

ARSIN

ARS

finds an inverse trigonometric sine transformation. Variables following ARSIN must be numeric, in the interval $(-1.0 \leq X \leq 1.0)$, and they are typically continuous.

BOXCOX

BOX

finds a Box-Cox transformation of the specified variables (see the “[Box-Cox Transformations](#)” section on page 4595 and [Example 75.6](#)). The BOXCOX transformation can be used only with dependent variables. The ALPHA=, CLL=, CONVENIENT, GEOMETRICMEAN, LAMBDA=, and PARAMETER= *t-options* can be used with the BOXCOX transformation. Variables following BOXCOX must be numeric, and they are typically continuous.

EXP

exponentiates variables (the variable X is transformed to a^X). To specify the value of a , use the PARAMETER= *t-option*. By default, a is the mathematical constant $e = 2.718\dots$. Variables following EXP must be numeric, and they are typically continuous.

LOG

transforms variables to logarithms (the variable X is transformed to $\log_a(X)$). To specify the base of the logarithm, use the PARAMETER= *t-option*. The default is a natural logarithm with base $e = 2.718\dots$. Variables following LOG must be numeric and positive, and they are typically continuous.

LOGIT

finds a logit transformation on the variables. The logit of X is $\log(X/(1-X))$. Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables following LOGIT must be numeric, in the interval $(0.0 < X < 1.0)$, and they are typically continuous.

POWER

POW

raises variables to a specified power (the variable X is transformed to X^a). You must specify the power parameter a by specifying the PARAMETER= *t-option* following the variables:

```
power(variable / parameter=number)
```

You can use POWER for squaring variables (PARAMETER=2), reciprocal transformations (PARAMETER=-1), square roots (PARAMETER=0.5), and so on. Variables following POWER must be numeric, and they are typically continuous.

RANK

RAN

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables following RANK must be numeric.

SMOOTH

SMO

is a noniterative smoothing spline transformation. You can specify the smoothing parameter with either the SM= or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. Variables following SMOOTH must be numeric, and they are typically continuous. The SMOOTH transformation can be used only with independent variables. For more information, see the “[Smoothing Splines](#)” section on page 4596.

Optimal Transformations

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the “[Missing Values](#)” section on page 4599).

The following list provides syntax and details for optimal transformations.

LINEAR

LIN

finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables following LINEAR must be numeric.

MONOTONE

MON

finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least-squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables following MONOTONE must be numeric, and they are typically discrete.

MSPLINE

MSP

finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with MSPLINE. By default, PROC TRANSREG uses a quadratic spline. Variables following MSPLINE must be numeric, and they are typically continuous.

OPSCORE

OPS

finds an optimal scoring of each variable. The OPSCORE transformation assigns scores to each class (level) of the variable. Fisher’s (1938) optimal scoring method

is used. Variables following OPSCORE can be either character or numeric; numeric variables should be discrete.

SPLINE

SPL

finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC TRANSREG uses a cubic polynomial transformation. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with SPLINE. Variables following SPLINE must be numeric, and they are typically continuous.

UNTIE

UNT

finds a monotonic transformation of each variable without the restriction that ties are preserved. The TRANSREG procedure uses the Kruskal (1964) primary least-squares monotonic transformation method. This transformation weakly preserves order but not category membership (it may untie some previously tied values). Variables following UNTIE must be numeric, and they are typically discrete.

Other Transformations

IDENTITY

IDE

specifies variables that are not changed by the iterations. Typically, the IDENTITY transformation is used with a simple variable list, such as IDENTITY(X1-X5). However, you can also specify interaction terms. For example, IDENTITY(X1 | X2) creates X1, X2, and the product X1*X2; and IDENTITY(X1 | X2 | X3) creates X1, X2, X1*X2, X3, X1*X3, X2*X3, and X1*X2*X3. See the “[Model Statement Usage](#)” section on page 4592 for information on how to use the operators @, *, and | in PROC TRANSREG.

The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT *t-option*, the ADDITIVE *a-option*, and the TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables. Variables following IDENTITY must be numeric.

SSPLINE

SSP

finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= *t-option* or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. Variables following SSPLINE must be numeric, and they are typically continuous.

Transformation Options (*t-options*)

If you use a nonoptimal, optimal, or other transformation, you can use *t-options*, which specify additional details of the transformation. The *t-options* are specified within the parentheses that enclose variables and are listed after a slash. You can use *t-options* with both dependent and independent variables. For example,

```
proc transreg;
  model identity(y)=spline(x / nknots=3);
  output;
run;
```

The preceding statements find an optimal variable transformation (SPLINE) of the independent variable, and they use a *t-option* to specify the number of knots (NKNOTS=). The following is a more complex example:

```
proc transreg;
  model mspline(y / nknots=3)=class(x1 x2 / effects);
  output;
run;
```

These statements find a monotone spline transformation (MSPLINE with three knots) of the dependent variable and perform a CLASS expansion with effects coding of the independents.

The following sections discuss the *t-options* available for nonoptimal, optimal, and other transformations.

The following table summarizes the *t-options*.

Table 75.2. *t-options* Available in the MODEL Statement

Task	Option
Nonoptimal transformation t-options	
uses original mean and variance	ORIGINAL
Parameter t-options	
specifies miscellaneous parameters	PARAMETER=
specifies smoothing parameter	SM=
Spline t-options	
specifies the degree of the spline	DEGREE=
spaces the knots evenly	EVENLY
exterior knots	EXKNOTS=
specifies the interior knots or break points	KNOTS=
creates <i>n</i> knots	NKNOTS=
CLASS Variable t-options	
CLASS dummy variable name prefix	CPREFIX=
requests a deviations-from-means coding	DEVIATIONS
requests a deviations-from-means coding	EFFECTS
CLASS dummy variable label prefix	LPREFIX=
order of class variable levels	ORDER=
CLASS dummy variable label separators	SEPARATORS=
controls reference levels	ZERO=
BOXCOX t-options	
confidence interval alpha	ALPHA=
convenient lambda list	CLL=

Table 75.2. (continued)

Task	Option
use a convenient lambda	CONVENIENT
scale the transformation using geometric mean	GEOMETRICMEAN
power parameter list	LAMBDA=
Other t-options	
operations occur after the expansion	AFTER
centers before the analysis begins	CENTER
renames variables	NAME=
reflects the variable around the mean	REFLECT
specifies transformation standardization	TSTANDARD=
standardizes before the analysis begins	Z

Nonoptimal Transformation t-options

ORIGINAL

ORI

matches the variable's final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL *t-option* is available for all of the nonoptimal transformations.

Parameter t-options

PARAMETER=*number*

PAR=*number*

specifies the transformation parameter. The PARAMETER= *t-option* is available for the BOXCOX, EXP, LOG, POWER, SMOOTH, and SSPLINE transformations. For BOXCOX, the parameter is the value to add to each value of the BOXCOX variable before a Box-Cox transformation. For EXP, the parameter is the value to be exponentiated; for LOG, the parameter is the base value; and for POWER, the parameter is the power. For SMOOTH and SSPLINE, the parameter is the raw smoothing parameter. (You can specify a SAS/GRAPH-style smoothing parameter with the SM= *t-option*.) The default for the PARAMETER= *t-option* for the BOXCOX transformation is 0 and for the LOG and EXP transformations is $e = 2.718\dots$. The default parameter for SMOOTH and SSPLINE is computed from SM=0. For the POWER transformation, you must specify the PARAMETER= *t-option*; there is no default.

SM=*n*

specifies a SAS/GRAPH-style smoothing parameter in the range 0 to 100. You can specify the SM= *t-option* only with the SMOOTH and SSPLINE transformations. The smoothness of the function increases as the value of the smoothing parameter increases. By default, SM=0.

Spline t-options

The following *t-options* are available with the SPLINE and MSPLINE optimal transformations and the PSPLINE and BSPLINE expansions.

DEGREE=*n***DEG=*n***

specifies the degree of the spline transformation. The degree must be a nonnegative integer. The defaults are DEGREE=3 for SPLINE, PSPLINE, and BSPLINE variables and DEGREE=2 for MSPLINE variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

EVENLY**EVE**

is used with the NKNOTS= *t-option* to space the knots evenly. The differences between adjacent knots are constant.

If you specify NKNOTS=*k*, *k* knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum})/(k + 1))$$

for $i = 1, \dots, k$. For example, if you specify

```
spline(X / knots=2 evenly)
```

and the variable X has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the EVENLY *t-option*, the NKNOTS= *t-option* places knots at percentiles, so the knots are not evenly spaced.

EXKNOTS=*number-list* | *n* TO *m* BY *p***EXK=*number-list* | *n* TO *m* BY *p***

specifies exterior knots for SPLINE and MSPLINE transformations and BSPLINE expansions. Usually, this option is not needed; PROC TRANSREG automatically picks suitable exterior knots. The only time you need to use this option is when you want to ensure that the exact same basis is used for different splines, for example when applying coefficients from one spline transformation to a variable in a different data set (see “Scoring Spline Variables” at the end of [Example 75.1](#)).

Specify one or two values. If the minimum EXKNOTS= value is less than the minimum data value, it is used as the exterior knot. If the maximum EXKNOTS= value is greater than the maximum data value, it is used as the exterior knot. Otherwise these values are ignored. When EXKNOTS= is specified with the CENTER or Z *t-options*, the knots apply to the original variable, not to the centered or standardized variable.

The B-spline transformations and expansions use a knot list consisting of exterior knots (values just smaller than the minimum), the specified (interior) knots, and exterior knots (values just larger than the minimum). You can use the DETAILS option to see all of these knots. Using different external knots gives different but equivalent B-spline bases. You can specify exterior knots on either the KNOTS= or EXKNOTS= *t-options*, however for the BSPLINE expansion, the KNOTS= *t-option* creates extra all-zero basis columns, whereas the EXKNOTS= *t-option* will give you the correct basis.

KNOTS=*number-list* | *n TO m BY p*

KNO=*number-list* | *n TO m BY p*

specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the n th (from $\text{DEGREE}=n$) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the $(n - 1)$ th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the **KNOTS=** *t-option* with the **NKNOTS=** *t-option*. You should keep the number of knots small (see the section “[Specifying the Number of Knots](#)” on page 4613).

NKNOTS=*n*

NKN=*n*

creates n knots, the first at the $100/(n + 1)$ percentile, the second at the $200/(n + 1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if **NKNOTS=**3, knots are placed at the twenty-fifth percentile, the median, and the seventy-fifth percentile. By default, **NKNOTS=**0. The **NKNOTS=** *t-option* must be ≥ 0 .

You cannot use the **NKNOTS=** *t-option* with the **KNOTS=** *t-option*.

You should keep the number of knots small (see the section “[Specifying the Number of Knots](#)” on page 4613).

CLASS Variable t-options

CPREFIX=*n* | *number-list*

CPR=*n* | *number-list*

specifies the number of first characters of a CLASS expansion variable’s name to use in constructing names for dummy variables. When **CPREFIX=** is specified as an *a-option* (see the description of the **CPREFIX=** *a-option* on page 4575) or an *o-option*, it specifies the default for all CLASS variables. When you specify **CPREFIX=** as a *t-option*, it overrides the default only for selected variables. A different **CPREFIX=** value can be specified for each CLASS variable by specifying the **CPREFIX=***number-list t-option*, like the **ZERO=***formatted-value-list t-option*.

DEVIATIONS

DEV

EFFECTS

EFF

requests a deviations-from-means coding of CLASS variables. The coded design matrix has values of 0, 1, and -1 for reference levels. This coding is referred to as “deviations-from-means,” “effects,” “center-point,” or “full-rank” coding.

LPREFIX=*n* | *number-list*

LPR=*n* | *number-list*

specifies the number of first characters of a CLASS expansion variable’s label (or name if no label is specified) to use in constructing labels for dummy variables. When **LPREFIX=** is specified as an *a-option* (see the description of the **LPREFIX=** *a-option*

on page 4576) or an *o-option*, it specifies the default for all CLASS variables. When you specify LPREFIX= as a *t-option*, it overrides the default only for selected variables. A different LPREFIX= value can be specified for each CLASS variable by specifying the LPREFIX=number-list *t-option*, like the ZERO=formatted-value-list *t-option*.

ORDER=DATA | FREQ | FORMATTED | INTERNAL

ORD=DAT | FRE | FOR | INT

specifies the order in which the CLASS variable levels are to be reported. The default is ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine dependent. When ORDER= is specified as an *a-option* (see the description of the [ORDER= a-option](#) on page 4578) or as an *o-option*, it specifies the default ordering for all CLASS variables. When you specify ORDER= as a *t-option*, it overrides the default ordering only for selected variables. You can specify a different ORDER= value for each CLASS specification.

SEPARATORS='string-1' <'string-2' >

SEP='string-1' <'string-2' >

specifies separators for creating CLASS expansion variable labels. By default, SEPARATORS=' ' * ' ("blank" and "blank asterisk blank"). When SEPARATORS= is specified as an *a-option* (see the description of the [SEPARATORS= a-option](#) on page 4579) or an *o-option*, it specifies the default separators for all CLASS variables. When you specify SEPARATORS= as a *t-option*, it overrides the default only for selected variables. You can specify a different SEPARATORS= value for each CLASS specification.

ZERO=FIRST | LAST | NONE | SUM

ZER=FIR | LAS | NON | SUM

ZERO='formatted-value' <'formatted-value' ...>

is used with CLASS variables. The default is ZERO=LAST.

The specification CLASS(variable / ZERO=FIRST) sets to missing the dummy variable for the first of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO=LAST) sets to missing the dummy variable for the last of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO='formatted-value') sets to missing the dummy variable for the category with a formatted value that matches 'formatted-value', implying a zero coefficient for that category. With ZERO=formatted-value-list, the first formatted value applies to the first variable in the specification, the second formatted value applies to the next variable that was not previously mentioned and so on. For example, CLASS(A A*B B*B*C C / ZERO='x' 'y' 'z') specifies that the reference level for A is 'x', for B is 'y', and for C is 'z'. With ZERO='formatted-value', the procedure first looks for exact matches between the formatted values and the specified value. If none are found, leading blanks are stripped from both and the values are compared again. If zero or two or more matches are found, warnings are issued.

The specifications ZERO=FIRST, ZERO=LAST, and ZERO='formatted-value' are used for reference cell models. The Intercept parameter estimate is the marginal

mean for the reference cell, and the other marginal means are obtained by adding the intercept to the dummy variable coefficients.

The specification CLASS(variable / ZERO=NONE) sets to missing none of the dummy variables. The columns of the expansion sum to a column of ones, so an implicit intercept model is fit. If you specify ZERO=NONE for more than one variable, the model is less than full rank. In the model MODEL IDENTITY(Y) = CLASS(X / ZERO=NONE), the coefficients are cell means.

The specification CLASS(variable / ZERO=SUM) sets to missing none of the dummy variables, and the coefficients for the dummy variables created from the variable sum to 0. This creates a less-than-full-rank model, but the coefficients are uniquely determined due to the sum-to-zero constraint.

In the presence of iterative transformations, hypothesis tests for ZERO=NONE and ZERO=SUM levels are not exact; they are liberal because a model with an explicit intercept is fit inside the iterations. There is no provision for adjusting the transformations while setting to 0 a parameter that is redundant given the explicit intercept and the other parameters.

Box-Cox t-options

The following *t-options* are available only with the BOXCOX transformation of the dependent variable (see the “[Box-Cox Transformations](#)” section on page 4595 and [Example 75.6](#)).

ALPHA= ρ

ALP= ρ

specifies the Box-Cox alpha for the confidence interval for the power parameter. By default, ALPHA=0.05.

CLL=*number-list*

specifies the Box-Cox convenient lambda list. When the confidence interval for the power parameter includes one of the values in this list, PROC TRANSREG reports it and can optionally use the convenient power parameter instead of the more optimal power parameter. The default is CLL=1.0 0.0 0.5 -1.0 -0.5 2.0 -2.0 3.0 -3.0. By default, a linear transformation is preferred over log, square root, inverse, inverse square root, quadratic, inverse quadratic, cubic, and inverse cubic. If you specify the CONVENIENT *t-option*, then PROC TRANSREG uses the first convenient power parameter in the list that is in the confidence interval. For example, if the optimal power parameter is 0.25 and 0.0 is in the confidence interval but not 1.0, then the convenient power parameter is 0.0.

CONVENIENT

CON

specifies that a power parameter from the CLL= *t-option* list is to be used for the final transformation instead of the LAMBDA= *t-option* value if a CLL= value is in the confidence interval. See the CLL= *t-option* for more information on its usage.

GEOMETRICMEAN**GEO**

divides the Box-Cox transformation by $\hat{y}^{\lambda-1}$ where \hat{y} is the geometric mean of the variable to be transformed. This form of the Box-Cox transformation essentially converts the transformation back to original units and hence allows direct comparison of the residual sums of squares for models with different power parameters.

LAMBDA=number-list

LAM=number-list

specifies a list of Box-Cox power parameters. The default is LAMBDA=-3 TO 3 BY 0.25. PROC TRANSREG tries each power parameter in the list and picks the best one. However, when the CONVENIENT *t-option* value is in the confidence interval. See the CLL= *t-option* for more information on its usage.

Other t-options**AFTER****AFT**

requests that certain operations occur after the expansion. This *t-option* affects the NKNOTS= *t-option* when the SPLINE or MSPLINE transformation is crossed with a CLASS specification. For example, if the original spline variable (1 2 3 4 5 6 7 8 9) is expanded into the three variables (1 2 3 0 0 0 0 0 0), (0 0 0 4 5 6 0 0 0), and (0 0 0 0 0 7 8 9), then, by default, NKNOTS=1 would use the overall median of 5 as the knot for all three variables. When you specify the AFTER *t-option*, the knots for the three variables are 2, 5, and 8. Note that the structural zeros are ignored when the internal knot list is created, but they are not ignored for the external knots.

You can also specify the AFTER *t-option* with the RANK and SMOOTH transformations. The following specifications compute ranks and smooth within groups, after crossing, ignoring the structural zeros.

```
class(x / zero=none) | rank(z / after)
class(x / zero=none) | smooth(z / after)
```

CENTER**CEN**

centers the variables before the analysis begins (in contrast to the TSTANDARD=CENTER option which centers after the analysis ends). The CENTER *t-option* can be used instead of running PROC STANDARD before PROC TRANSREG (see the “Centering” section on page 4675). When the KNOTS= *t-option* is specified with CENTER, the knots apply to the original variable, not to the centered variable. PROC TRANSREG will center the knots.

NAME=(variable-list)

NAM=(variable-list)

renames variables as they are used in the MODEL statement. This *t-option* allows a variable to be used more than once.

For example, if X is a character variable, then the following step stores both the original character variable X and a numeric variable XC that contains category numbers in the OUT= data set.

```
proc transreg data=a;
  model identity(y) = opscore(x / name=(xc));
  output;
  id x;
run;
```

With the CLASS and IDENTITY transformations, which allow interaction effects, the first name applies to the first variable in the specification, the second name applies to the next variable that was not previously mentioned, and so on. For example, IDENTITY(A A*B B*B*C C / NAME=(G H I)) specifies that the new name for A is G, for B is H, and for C is I. The same assignment is used for the (not useful) specification IDENTITY(A A B B C C / NAME=(G H I)). For all *transforms* other than CLASS and IDENTITY (all those in which interactions are not supported), repeated variables are not handled specially. For example, SPLINE(A A B B C C / NAME=(A G B H C I)) creates six variables, a copy of A named A, another copy of A named G, a copy of B named B, another copy of B named H, a copy of C named C, and another copy of C named I.

REFLECT**REF**

reflects the transformation

$$y = -(y - \bar{y}) + \bar{y}$$

after the iterations are completed and before the final standardization and results calculations. This *t-option* is particularly useful with the dependent variable in a conjoint analysis. When the dependent variable consists of ranks with the most preferred combination assigned 1.0, the REFLECT *t-option* reflects the transformation so that positive utilities mean high preference. (See [Example 75.2.](#))

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z**TST=CEN | NOM | ORI | Z**

specifies the standardization of the transformed variables for the hypothesis tests and in the OUT= data set (see the “[Centering](#)” section on page 4675). By default, TSTANDARD=ORIGINAL. When TSTANDARD= is specified as an *a-option* (see the description of the [TSTANDARD= a-option](#) on page 4580) or an *o-option*, it determines the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables. You can specify a different TSTANDARD= value for each transformation. For example, to perform a redundancy analysis with standardized dependent variables, specify

```
model identity(y1-y4 / tstandard=z) = identity(x1-x10);
```

Z

centers and standardizes the variables to variance one before the analysis begins (in contrast to the TSTANDARD=Z option, which standardizes after the analysis ends). The Z *t-option* can be used instead of running PROC STANDARD before PROC

TRANSREG (see the “Centering” section on page 4675). When the KNOTS= *t-option* is specified with Z, the knots apply to the original variable, not to the centered variable. PROC TRANSREG will standardize the knots.

Algorithm Options (*a-options*)

This section discusses the options that can appear in the PROC TRANSREG or MODEL statements as *a-options*. They are listed after the entire model specification and after a slash.

For example,

```
proc transreg;
  model spline(y / nknots=3)=log(x1 x2 / parameter=2)
    / nomiss maxiter=50;
  output;
run;
```

In the preceding statements, NOMISS and MAXITER= are *a-options*. (SPLINE and LOG are *transforms*, and NKNOTS= and PARAMETER= are *t-options*.) The statements find a spline transformation with 3 knots on Y and a base 2 logarithmic transformation on X1 and X2. The NOMISS *a-option* excludes all observations with missing values, and the MAXITER= *a-option* specifies the maximum number of iterations.

Table 75.3. Options Available in the PROC TRANSREG or MODEL Statements

Task	Option
Input data set	
specifies input observation type	TYPE=
restarts iterations	REITERATE
Specify method and control iterations	
specifies minimum criterion change	CCONVERGE=
specifies minimum data change	CONVERGE=
specifies canonical dummy-variable initialization	DUMMY
specifies maximum number of iterations	MAXITER=
specifies iterative algorithm	METHOD=
specifies number of canonical variables	NCAN=
specifies singularity criterion	SINGULAR=
Control missing data handling	
METHOD=MORALS fits each model individually	INDIVIDUAL
includes monotone special missing values	MONOTONE=
excludes observations with missing values	NOMISS
unties special missing values	UNTIE=
Control intercept and CLASS variables	
CLASS dummy variable name prefix	CPREFIX=
CLASS dummy variable label prefix	LPREFIX=
no intercept or centering	NOINT
order of class variable levels	ORDER=
controls output of reference levels	REFERENCE=

Table 75.3. (continued)

Task	Option
CLASS dummy variable label separators	SEPARATORS=
Control displayed output	
confidence limits alpha	ALPHA=
displays parameter estimate confidence limits	CL
displays model specification details	DETAIL
displays iteration histories	HISTORY
suppresses displayed output	NOPRINT
suppresses the iteration histories	SHORT
displays regression results	SS2
displays ANOVA table	TEST
displays conjoint part-worth utilities	UTILITIES
Control standardization	
fits additive model	ADDITIVE
do not zero constant variables	NOZEROCONSTANT
specifies transformation standardization	TSTANDARD=

The following list provides details on these *a-options*.

ADDITIVE**ADD**

creates an additive model by multiplying the values of each independent variable (after the TSTANDARD= standardization) by that variable's corresponding multiple regression coefficient. This process scales the independent variables so that the predicted-values variable for the final dependent variable is simply the sum of the final independent variables. An additive model is a univariate multiple regression model. As a result, the ADDITIVE *a-option* is not valid if METHOD=CANALS, or if METHOD=REDUNDANCY or METHOD=UNIVARIATE with more than one dependent variable.

ALPHA=number

ALP=number

specifies the level of significance for all of the confidence limits. By default, ALPHA=0.05.

CCONVERGE=n

CCO=n

specifies the minimum change in the criterion being optimized (squared multiple correlation for METHOD=MORALS and METHOD=UNIVARIATE, average squared multiple correlation for METHOD=REDUNDANCY, average squared canonical correlation for METHOD=CANALS) that is required to continue iterating. By default, CCONVERGE=0.0.

CL

requests confidence limits on the parameter estimates in the displayed output.

CONVERGE=*n***CON=*n***

specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations; that is, all LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE variables and nonoptimal transformation variables with missing values.

CPREFIX=*n***CPR=*n***

specifies the number of first characters of a CLASS expansion variable's name to use in constructing names for dummy variables. Dummy variable names are constructed from the first *n* characters of the CLASS expansion variable's name and the first 32 – *n* characters of the formatted CLASS expansion variable's value. For example, if the variable ClassVariable has values 1, 2, and 3, then, by default, the dummy variables are named ClassVariable1, ClassVariable2, and ClassVariable3. However, with CPREFIX=5, the dummy variables are named Class1, Class2, and Class3. When CPREFIX=0, dummy variable names are created entirely from the CLASS expansion variable's formatted values. Valid values range from -1 to 31, where -1 indicates the default calculation and 0 to 31 are the number of prefix characters to use. The default, -1, sets *n* to $32 - \min(32, \max(2, fl))$, where *fl* is the format length. When CPREFIX= is specified as an *a-option* or an *o-option*, it specifies the default for all CLASS variables. When you specify CPREFIX= as a *t-option*, it overrides the default only for selected variables.

DETAIL**DET**

reports on details of the model specification. For example, it reports the knots and coefficients for splines, reference levels for CLASS variables, Box-Cox results, and so on.

DUMMY**DUM**

provides a canonical dummy variable initialization. When there are no monotonicity constraints and there is only one canonical variable in each set, PROC TRANSREG (with the DUMMY *a-option*) can usually find the optimal solution in only one iteration. The initialization iteration is number 0, which is slower and uses more memory than other iterations. However, when there are no monotonicity constraints, when there is only one canonical variable in each set, and when there is enough available memory, specifying the DUMMY *a-option* can greatly decrease the amount of time required to find the optimal transformations. Furthermore, by solving for the transformations directly instead of iteratively, PROC TRANSREG avoids certain nonoptimal solutions.

HISTORY**HIS**

displays the iteration histories even when the NOPRINT *a-option* is specified.

INDIVIDUAL**IND**

fits each model for each dependent variable individually. This means, for example, that when INDIVIDUAL is specified, missing values in one dependent variable will not cause that observation to be deleted for the other models with the other dependent variables. In contrast, by default, missing values in any variable in any model can cause the observation to be deleted for all models. The INDIVIDUAL option can only be specified with METHOD=MORALS.

This option also affects the order of the output. By default, the number of observations table is printed once at the beginning of the output. With INDIVIDUAL, a number of observations table appears for each model.

LPREFIX=*n***LPR=*n***

specifies the number of first characters of a CLASS expansion variable's label (or name if no label is specified) to use in constructing labels for dummy variables. Dummy variable labels are constructed from the first *n* characters of the CLASS expansion variable's name and the first 127 – *n* characters of the formatted CLASS expansion variable's value. Valid values range from -1 to 127. Values of 0 to 127 specify the number of name or label characters to use. The default is -1, which specifies that PROC TRANSREG should pick a value depending on the length of the prefix and the formatted class value. When LPREFIX= is specified as an *a-option* or an *o-option*, it determines the default for all CLASS variables. When you specify LPREFIX= as a *t-option*, it overrides the default only for selected variables.

MAXITER=*n***MAX=*n***

specifies the maximum number of iterations (see the [“Controlling the Number of Iterations”](#) section on page 4601). By default, MAXITER=30. A specification of MAXITER=0 is allowed to save time when no transformations are requested.

METHOD=CANALS | MORALS | REDUNDANCY | UNIVARIATE**MET=CAN | MOR | RED | UNI**

specifies the iterative algorithm. By default, METHOD=UNIVARIATE, unless you specify options that cannot be handled by the UNIVARIATE algorithm. Specifically, the default is METHOD=MORALS for the following situations:

- if you specify LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, or SSPLINE transformations for the independent variables
- if you specify the ADDITIVE *a-option* with more than one dependent variable
- if you specify the IAPPROXIMATIONS *o-option*

- CANALS** specifies canonical correlation with alternating least squares. This jointly transforms all dependent and independent variables to maximize the average of the first n squared canonical correlations, where n is the value of the `NCAN=` *a-option*.
- MORALS** specifies multiple optimal regression with alternating least squares. This transforms each dependent variable, along with the set of independent variables, to maximize the squared multiple correlation.
- REDUNDANCY** jointly transforms all dependent and independent variables to maximize the average of the squared multiple correlations (see the “[Redundancy Analysis](#)” section on page 4606).
- UNIVARIATE** transforms each dependent variable to maximize the squared multiple correlation, while the independent variables are not transformed.

MONOTONE=*two-letters***MON=***two-letters*

specifies the first and last special missing value in the list of those special missing values to be estimated using within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The *two-letters* value must consist of two letters in alphabetical order. For example, `MONOTONE=DF` means that the estimate of `.D` must be less than or equal to the estimate of `.E`, which must be less than or equal to the estimate of `.F`; no order constraints are placed on estimates of `._`, `.A` through `.C`, and `.G` through `.Z`. For details, see the “[Missing Values](#)” section on page 4599.

NCAN= n **NCA=** n

specifies the number of canonical variables to use in the `METHOD=CANALS` algorithm. By default, `NCAN=1`. The value of the `NCAN=` *a-option* must be ≥ 1 .

When canonical coefficients and coordinates are included in the `OUT=` data set, the `NCAN=` *a-option* also controls the number of rows of the canonical coefficient matrices in the data set. If you specify an `NCAN=` value larger than the minimum of the number of dependent variables and the number of independent variables, `PROC TRANSREG` displays a warning and sets the `NCAN=` *a-option* to the maximum allowable value.

NOINT**NOI**

omits the intercept from the `OUT=` data set and suppresses centering of data. The `NOINT` *a-option* is not allowed with iterative transformations since there is no provision for optimal scaling without an intercept. The `NOINT` *a-option* is allowed only when there is no implicit intercept and when all of the data in a `BY` group absolutely will not change during the iterations.

NOMISS**NOM**

excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS *a-option*, PROC TRANSREG simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error. For details, see the “[Missing Values](#)” section on page 4599.

Casewise deletion of observations with missing values occurs when the NOMISS *a-option* is specified, when there are missing values in expansions, when there are missing values in METHOD=UNIVARIATE independent variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the _TYPE_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as *supplementary* or *passive* observations.

See the “[Passive Observations](#)” section on page 4605 for more information on excluded observations.

NOPRINT**NOP**

suppresses the display of all output unless you specify the HISTORY *a-option*. The NOPRINT *a-option* without the HISTORY *a-option* temporarily disables the Output Delivery System (ODS). For more information, see [Chapter 14](#), “[Using the Output Delivery System](#).”

NOZEROCONSTANT**NOZERO****NOZ**

specifies that constant variables are expected and should not be zeroed. By default, constant variables are zeroed. This option is useful when PROC TRANSREG is used to code experimental designs for discrete choice models (see the “[Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO](#)” section on page 4660). When these designs are very large, it may be more efficient to use the DESIGN=*n* option. It may be that attributes are constant within a block of *n* observations, so you need to specify the NOZEROCONSTANT option to get the correct results. You can specify this option in the PROC TRANSREG, MODEL, and OUTPUT statements.

ORDER=DATA | FREQ | FORMATTED | INTERNAL**ORD=DAT | FRE | FOR | INT**

specifies the order in which the CLASS variable levels are to be reported. The default is ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine dependent. When ORDER= is specified as an *a-option* or an *o-option*, it determines the default ordering for all CLASS variables. When you specify ORDER= as a *t-option*, it overrides the default ordering only for selected variables.

DATA sorts by order of appearance in the input data set.

FORMATTED sorts by formatted value.

FREQ	sorts by descending frequency count; levels with the most observations appear first.
INTERNAL	sorts by unformatted value.

REFERENCE=NONE | MISSING | ZERO**REF=NON | MIS | ZER**

specifies how reference levels of CLASS variables are to be treated. The options are REFERENCE=NONE, the default, in which reference levels are suppressed; REFERENCE=MISSING, in which reference levels are displayed and output with missing values; and REFERENCE=ZERO, in which reference levels are displayed and output with zeros. The REFERENCE= option can be specified in the PROC TRANSREG, MODEL, or OUTPUT statement, and it can be independently specified for the OUT= data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the OUT= data set.

REITERATE**REI**

enables the TRANSREG procedure to use previous transformations as starting points. The REITERATE *a-option* affects only variables that are iteratively transformed (specified as LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE). For iterative transformations, the REITERATE *a-option* requests a search in the input data set for a variable that consists of the value of the TDPREFIX= or TIPREFIX= *o-option* followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the section [“Using the REITERATE Algorithm Option”](#) on page 4602.

SEPARATORS='string-1' <'string-2' >**SEP='string-1' <'string-2' >**

specifies separators for creating CLASS expansion variable labels. By default, SEPARATORS=' ' * ' (“blank” and “blank asterisk blank”). The first value is used to separate variable names and values in interactions. The second value is used to separate interaction components. For example, the label for the dummy variable for the A=1 and B=2 cell is, by default, 'A 1 * B 2'. If SEPARATORS=' ' 'x' is specified, then the label is 'A=1xB=2'. When SEPARATORS= is specified as an *a-option* or an *o-option*, it determines the default separators for all CLASS variables. When you specify SEPARATORS= as a *t-option*, it overrides the default only for selected variables.

SHORT**SHO**

suppresses the iteration histories.

SINGULAR=*n***SIN=*n***

specifies the largest value within rounding error of zero. By default, SINGULAR=1E-12. The TRANSREG procedure uses the value of the SINGULAR= *a-option* for checking $1 - R^2$ when constructing full-rank ma-

trices of predictor variables, checking denominators before dividing, and so on. PROC TRANSREG computes the regression coefficients by sweeping with rational pivoting.

SS2

produces a regression table based on Type II sums of squares. Tests of the contribution of each transformation to the overall model are displayed and output to the OUTTEST= data set when you specify the OUTTEST= option. When you specify the SS2 *a-option*, the TEST *a-option* is implied. See the section “[Hypothesis Tests](#)” on page 4615. You can suppress the variable labels in the regression tables by specifying the NOLABEL option in the OPTIONS statement.

TEST**TES**

generates an ANOVA table. PROC TRANSREG tests the null hypothesis that the vector of scoring coefficients for all of the transformations is zero. See the section “[Hypothesis Tests](#)” on page 4615.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z**TST=CEN | NOM | ORI | Z**

specifies the standardization of the transformed variables for the hypothesis tests and in the OUT= data set. By default, TSTANDARD=ORIGINAL. When TSTANDARD= is specified as an *a-option* or an *o-option*, it determines the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables.

CENTER	centers the output variables to mean zero, but the variances are the same as the variances of the input variables.
NOMISS	sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.
ORIGINAL	sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.
Z	standardizes the variables to mean zero, variance one.

The final standardization is affected by other options. If you also specify the ADDITIVE *a-option*, the TSTANDARD= option specifies an intermediate step in computing the final means and variances. The final independent variables, along with their means and standard deviations, are scaled by the regression coefficients, creating an additive model with all coefficients equal to one.

For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the ORIGINAL nonoptimal *t-option* in the MODEL statement. For example, if a variable X with no missing values is specified as LOG, then, by default, the final transformation of X is simply LOG(X), not LOG(X) standardized to the mean of X and variance of X.

TYPE=*'text'* | *name*

TYP=*'text'* | *name*

specifies the valid value for the `_TYPE_` variable in the input data set. If PROC TRANSREG finds an input `_TYPE_` variable, it uses only observations with a `_TYPE_` value that matches the TYPE= value. This enables a PROC TRANSREG OUT= data set containing coefficients to be used as input to PROC TRANSREG without requiring a WHERE statement to exclude the coefficients. If a `_TYPE_` variable is not in the data set, all observations are used. The default is TYPE='SCORE', so if you do not specify the TYPE= *a-option*, only observations with `_TYPE_='SCORE'` are used. Do not confuse this option with the data set TYPE= option. The DATA= data set must be an ordinary SAS data set.

PROC TRANSREG displays a note when it reads observations with blank values of `_TYPE_`, but it does not automatically exclude those observations. Data sets created by the TRANSREG and PRINQUAL procedures have blank `_TYPE_` values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their `_TYPE_` value is blank.

UNTIE=*two-letters*

UNT=*two-letters*

specifies the first and last special missing value in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The *two-letters* value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the “Missing Values” section on page 4599 and the “Optimal Scaling” section on page 4609.

UTILITIES

UTI

produces a table of the part-worth utilities from a conjoint analysis. Utilities, their standard errors, and the relative importance of each factor are displayed and output to the OUTTEST= data set when you specify the OUTTEST= option. When you specify the UTILITIES *a-option*, the TEST *a-option* is implied. Refer to SAS Technical Report R-109, *Conjoint Analysis Examples*, for more information on conjoint analysis.

OUTPUT Statement

OUTPUT **OUT=SAS-data-set** < *o-options* > ;

The OUTPUT statement creates a new SAS data set that contains coefficients, marginal means, and information on original and transformed variables. The information on original and transformed variables composes the score partition of the data set; observations have `_TYPE_='SCORE'`. The coefficients and marginal means compose the coefficient partition of the data set; observations have `_TYPE_='M COEFFI'` or `_TYPE_='MEAN'`. Other values of `_TYPE_` are possible; for details, see “`_TYPE_` and `_NAME_` Variables” later in this chapter. For details on data set structure, see the “[Output Data Set](#)” section on page 4617.

To specify the data set, use the `OUT=` specification.

OUT=SAS-data-set

specifies the output data set for the data, transformed data, predicted values, residuals, scores, coefficients, and so on. When you use an OUTPUT statement but do not use the `OUT=` specification, PROC TRANSREG creates a data set and uses the DATAN convention. If you want to create a permanent SAS data set, you must specify a two-level name (refer to “SAS Files” in *SAS Language Reference: Concepts* and “Introduction to DATA Step Processing” in the *SAS Procedures Guide* for details).

To control the contents of the data set and variable names, use one or more of the *o-options*. You can also specify these options in the PROC TRANSREG statement.

Output Options (o-options)

The following table provides a summary of options in the OUTPUT statement. These options include the `OUT=` option and all of the *o-options*.

Table 75.4. Options Available in the OUTPUT Statement

Task	Option
Identify output data set	
output data set	OUT=
Predicted values, residuals, scores	
outputs canonical scores	CANONICAL
outputs individual confidence limits	CLI
outputs mean confidence limits	CLM
specifies design matrix coding	DESIGN=
outputs leverage	LEVERAGE
does not restore missings	NORESTOREMISSING
suppresses output of scores	NOSCORES
outputs predicted values	PREDICTED
outputs redundancy variables	REDUNDANCY=
outputs residuals	RESIDUALS
Output data set replacement	
replaces dependent variables	DREPLACE
replaces independent variables	IREPLACE

Table 75.4. (continued)

Task	Option
replaces all variables	REPLACE
Output data set coefficients	
outputs coefficients	COEFFICIENTS
outputs ideal point coordinates	COORDINATES
outputs marginal means	MEANS
outputs redundancy analysis coefficients	MREDUNDANCY
Output data set variable name prefixes	
dependent variable approximations	ADPREFIX=
independent variable approximations	AIPREFIX=
canonical dependent variables	CDPREFIX=
conservative individual lower CL	CILPREFIX=
canonical independent variables	CIPREFIX=
conservative-individual-upper CL	CIUPREFIX=
conservative-mean-lower CL	CMLPREFIX=
conservative-mean-upper CL	CMUPREFIX=

approximations to transformed dependents	DAPPROXIMATIONS
approximations to transformed independents	IAPPROXIMATIONS
elliptical point coordinates	MEC
point coordinates	MPC
quadratic point coordinates	MQC
multiple regression coefficients	MRC

For the coefficients partition, the COEFFICIENTS, COORDINATES, and MEANS *o-options* provide the coefficients that are appropriate for your model. For more explicit control of the coefficient partition, use the options that control details and prefixes.

The following list provides details on these options.

ADPREFIX=*name*

ADP=*name*

specifies a prefix for naming the dependent variable predicted values. The default is ADPREFIX=P when you specify the PREDICTED *o-option*; otherwise, it is ADPREFIX=A. Specifying the ADPREFIX= *o-option* also implies the PREDICTED *o-option*, and the ADPREFIX= *o-option* is the same as the PPREFIX= *o-option*.

AIPREFIX=*name*

AIP=*name*

specifies a prefix for naming the independent variable approximations. The default is AIPREFIX=A. Specifying the AIPREFIX= *o-option* also implies the IAPPROXIMATIONS *o-option*.

APPROXIMATIONS

APPROX

APP

is equivalent to specifying both the DAPPROXIMATIONS and the IAPPROXIMATIONS *o-options*. If METHOD=UNIVARIATE, then the APPROXIMATIONS *o-option* implies only the DAPPROXIMATIONS *o-option*.

CANONICAL

CAN

outputs canonical variables to the OUT= data set. When METHOD=CANALS, the CANONICAL *o-option* is implied. The CDPREFIX= *o-option* specifies a prefix for naming the dependent canonical variables (default Cand), and the CIPREFIX= *o-option* specifies a prefix for naming the independent canonical variables (default Cani).

CCC

outputs canonical correlation coefficients to the OUT= data set.

CDPREFIX=*name*

CDP=*name*

provides a prefix for naming the canonical dependent variables. The default is CDPREFIX=Cand. Specifying the CDPREFIX= *o-option* also implies the CANONICAL *o-option*.

CEC

outputs canonical elliptical point model coordinates to the OUT= data set.

CILPREFIX=*name*

CIL=*name*

specifies a prefix for naming the conservative-individual-lower confidence limits. The default prefix is CIL. Specifying the CILPREFIX= *o-option* also implies the CLI *o-option*.

CIPREFIX=name**CIP=name**

provides a prefix for naming the canonical independent variables. The default is CIPREFIX=Cani. Specifying the CIPREFIX= *o-option* also implies the CANONICAL *o-option*.

CIUPREFIX=name**CIU=name**

specifies a prefix for naming the conservative-individual-upper confidence limits. The default prefix is CIU. Specifying the CIUPREFIX= *o-option* also implies the CLI *o-option*.

CLI

outputs individual confidence limits to the OUT= data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following *o-options*: LILPREFIX= (default LIL for liberal individual lower), CILPREFIX= (default CIL for conservative individual lower), LIUPREFIX= (default LIU for liberal individual upper), and CIUPREFIX= (default CIU for conservative individual upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

CLM

outputs mean confidence limits to the OUT= data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following *o-options*: LMLPREFIX= (default LML for liberal mean lower), CMLPREFIX= (default CML for conservative mean lower), LMUPREFIX= (default LMU for liberal mean upper), and CMUPREFIX= (default CMU for conservative mean upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

CMLPREFIX=name**CML=name**

specifies a prefix for naming the conservative-mean-lower confidence limits. The default prefix is CML. Specifying the CMLPREFIX= *o-option* also implies the CLM *o-option*.

CMUPREFIX=name**CMU=name**

specifies a prefix for naming the conservative-mean-upper confidence limits. The default prefix is CMU. Specifying the CMUPREFIX= *o-option* also implies the CLM *o-option*.

COEFFICIENTS**COE**

outputs either multiple regression coefficients or raw canonical coefficients to the OUT= data set. If you specify METHOD=CANALS (in the MODEL or PROC TRANSREG statement), then the COEFFICIENTS *o-option* outputs the first *n* canonical variables, where *n* is the value of the NCAN= *a-option* (specified in the MODEL or PROC TRANSREG statement). Otherwise, the COEFFICIENTS *o-option* includes multiple regression coefficients in the OUT= data set. In ad-

dition, when you specify the CLASS expansion for any independent variable, the COEFFICIENTS *o-option* also outputs marginal means.

COORDINATES

COO

outputs either ideal point or vector model coordinates for preference mapping to the OUT= data set. When METHOD=CANALS, these coordinates are computed from canonical coefficients; otherwise, the coordinates are computed from multiple regression coefficients. For details, see the “[Point Models](#)” section on page 4605.

CPC

outputs canonical point model coordinates to the OUT= data set.

CQC

outputs canonical quadratic point model coordinates to the OUT= data set.

DAPPROXIMATIONS

DAP

outputs the approximations of the transformed dependent variables to the OUT= data set. These are the target values for the optimal transformations. With METHOD=UNIVARIATE and METHOD=MORALS, the dependent variable approximations are the ordinary predicted values from the linear model. The names of the approximation variables are constructed from the ADPREFIX= *o-option* (default A) and the original dependent variable names. For ordinary predicted values, use the PREDICTED *o-option* instead of the DAPPROXIMATIONS *o-option*, since the PREDICTED *o-option* uses a more relevant prefix (“P” instead of “A”) and a more relevant variable label suffix (“Predicted Values” instead of “Approximations”).

DESIGN<=n>

DES<=n>

specifies that your primary goal is design matrix coding, not analysis. Specifying the DESIGN *o-option* makes the procedure run faster. The DESIGN *o-option* sets the default method to UNIVARIATE and the default MAXITER= value to zero. It suppresses computing the regression coefficients, unless they are needed for some other option. Furthermore, when the DESIGN *o-option* is specified, the MODEL statement is not required to have an equal sign. When no MODEL statement equal sign is specified, all variables are considered independent variables, all options that require dependent variables are ignored, and the IREPLACE *o-option* is implied.

You can use DESIGN=*n* for coding very large data sets, where *n* is the number of observations to code at one time. For example, to code a data set with a large number of observations, you can specify DESIGN=100 or DESIGN=1000 to process the data set in blocks of 100 or 1000 observations. If you specify the DESIGN *o-option* rather than DESIGN=*n*, PROC TRANSREG tries to process all observations at once, which will not work with very large data sets. Specify the NOZEROCONSTANT *o-option* with DESIGN=*n* to ensure that constant variables within blocks are not zeroed. See the section “[Using the DESIGN Output Option](#)” on page 4654 and the section “[Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO](#)” on page 4660.

DEPENDENT=*name*

DEP=*name*

specifies the untransformed dependent variable for OUT= data sets with METHOD=MORALS when there is more than one dependent variable. The default is DEPENDENT=_DEPEND_.

DREPLACE

DRE

replaces the original dependent variables with the transformed dependent variables in the OUT= data set. The names of the transformed variables in the OUT= data set correspond to the names of the original dependent variables in the input data set. By default, both the original dependent variables and transformed dependent variables (with names constructed from the TDPREFIX= (default T) *o-option* and the original dependent variable names) are included in the OUT= data set.

IAPPROXIMATIONS

IAP

outputs the approximations of the transformed independent variables to the OUT= data set. These are the target values for the optimal transformations. The names of the approximation variables are constructed from the AIPREFIX= *o-option* (default A) and the original independent variable names. Specifying the AIPREFIX= *o-option* also implies the IAPPROXIMATIONS *o-option*. The IAPPROXIMATIONS *o-option* is not valid when METHOD=UNIVARIATE.

IREPLACE

IRE

replaces the original independent variables with the transformed independent variables in the OUT= data set. The names of the transformed variables in the OUT= data set correspond to the names of the original independent variables in the input data set. By default, both the original independent variables and transformed independent variables (with names constructed from the TIPREFIX= *o-option* (default T) and the original independent variable names) are included in the OUT= data set.

LEVERAGE<=*name*>

LEV<=*name*>

creates a variable with the specified name in the OUT= data set that contains leverages. Specifying the LEVERAGE *o-option* is equivalent to specifying LEVERAGE=Leverage.

LILPREFIX=*name*

LIL=*name*

specifies a prefix for naming the liberal-individual-lower confidence limits. The default prefix is LIL. Specifying the LILPREFIX= *o-option* also implies the CLI *o-option*.

LIUPREFIX=*name*

LIU=*name*

specifies a prefix for naming the liberal-individual-upper confidence limits. The default prefix is LIU. Specifying the LIUPREFIX= *o-option* also implies the CLI *o-option*.

LMLPREFIX=*name***LML=***name*

specifies a prefix for naming the liberal-mean-lower confidence limits. The default prefix is LML. Specifying the LMLPREFIX= *o-option* also implies the CLM *o-option*.

LMUPREFIX=*name***LMU=***name*

specifies a prefix for naming the liberal-mean-upper confidence limits. The default prefix is LMU. Specifying the LMUPREFIX= *o-option* also implies the CLM *o-option*.

MACRO(*keyword=name...*)**MAC**(*keyword=name...*)

creates macro variables. Most of the options available within the MACRO *o-option* are rarely needed. By default, the TRANSREG procedure creates a macro variable named `_TRGIND` with a complete list of independent variables created by the procedure. When the TRANSREG procedure is being used for design matrix creation prior to running a procedure without a CLASS statement, this macro provides a convenient way to use the results from PROC TRANSREG. For example, a PROC LOGISTIC step that uses a design matrix coded by PROC TRANSREG could use the following MODEL statement:

```
model y=&_trgind;
```

The TRANSREG procedure, also by default, creates a macro variable named `_TRGINDN`, which contains the number of variables in the `_TRGIND` list. This macro variable could be used in an ARRAY statement as follows:

```
array indvars[&_trgindn] &_trgind;
```

See the section “Using the DESIGN Output Option” on page 4654 and the section “Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO” on page 4660 for examples of using the default macro variables.

The available *keywords* are as follows.

DN=*name* specifies the name of a macro variable that contains the number of dependent variables. By default, a macro variable named `_TRGDEPN` is created. This is the number of variables in the DL= list and the number of macro variables created by the DV= and DE= specifications.

IN=*name* specifies the name of a macro variable that contains the number of independent variables. By default, a macro variable named `_TRGINDN` is created. This is the number of variables in the IL= list and the number of macro variables created by the IV= and IE= specifications.

- DL=name** specifies the name of a macro variable that contains the list of the dependent variables. By default, a macro variable named `_TRGDEP` is created. These are the variable names of the final transformed variables in the `OUT=` data set. For example, if there are three dependent variables, `Y1–Y3`, then `_TRGDEP` contains, by default, `TY1 TY2 TY3` (or `Y1 Y2 Y3` if you specify the `REPLACE o-option`).
- IL=name** specifies the name of a macro variable that contains the list of the independent variables. By default, a macro variable named `_TRGIND` is created. These are the variable names of the final transformed variables in the `OUT=` data set. For example, if there are three independent variables, `X1–X3`, then `_TRGIND` contains, by default, `TX1 TX2 TX3` (or `X1 X2 X3` if you specify the `REPLACE o-option`).
- DV=prefix** specifies a prefix for creating a list of macro variables, each of which contains one dependent variable name. For example, if there are three dependent variables, `Y1–Y3`, and you specify `MACRO(DV=DEP)`, then three macro variables, `DEP1`, `DEP2`, and `DEP3`, are created, containing `TY1`, `TY2`, and `TY3`, respectively (or `Y1`, `Y2`, and `Y3` if you specify the `REPLACE o-option`). By default, no list is created.
- IV=prefix** specifies a prefix for creating a list of macro variables, each of which contains one independent variable name. For example, if there are three independent variables, `X1–X3`, and you specify `MACRO(IV=IND)`, then three macro variables, `IND1`, `IND2`, and `IND3`, are created, containing `TX1`, `TX2`, and `TX3`, respectively (or `X1`, `X2`, and `X3` if you specify the `REPLACE o-option`). By default, no list is created.
- DE=prefix** specifies a prefix for creating a list of macro variables, each of which contains one dependent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify `MACRO(DE=D)`, then a macro variable `D1` is created for `IDENTITY(Y)`. The `D1` macro variable is shown next, wrapped onto two lines.

```

      4                                TY
IDENTITY                             Y

```

The first part is the number of parts (4), the second part is the transformed variable name, the third part is the transformation, and the last part is the input variable name. By default, no list is created.

- IE=prefix** specifies a prefix for creating a list of macro variables, each of which contains one independent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify `MACRO(IE=I)`, then three

macro variables, I1, I2, and I3, are created for CLASS(X1 | X2) when both X1 and X2 have values of 1 and 2. These macro variables are shown next, but with extra white space removed.

```

5      Tx11      CLASS      x1      1
5      Tx21      CLASS      x2      1
8      Tx11x21  CLASS      x1      1      CLASS      x2      1

```

For CLASS variables, the formatted level appears after the variable name. The first two effects are the main effects, and the last is the interaction term. By default, no list is created.

MEANS**MEA**

outputs marginal means for CLASS variable expansions to the OUT= data set.

MEC

outputs multiple regression elliptical point model coordinates to the OUT= data set.

MPC

outputs multiple regression point model coordinates to the OUT= data set.

MQC

outputs multiple regression quadratic point model coordinates to the OUT= data set.

MRC

outputs multiple regression coefficients to the OUT= data set.

MREDUNDANCY**MRE**

outputs multiple redundancy analysis coefficients to the OUT= data set.

NORESTOREMISSING**NORESTORE****NOR**

specifies that missing values should not be restored when the OUT= data set is created. By default, the coded CLASS variable contains a row of missing values for observations in which the CLASS variable is missing. When you specify the NORESTOREMISSING *o-option*, these observations contain a row of zeros instead. This is useful when the TRANSREG procedure is used to code experimental designs for discrete choice models and there is a constant alternative indicated by a missing value.

NOSCORES**NOS**

excludes original variables, transformed variables, predicted values, residuals, and scores from the OUT= data set. You can use the NOSCORES *o-option* with various other options to create an OUT= data set that contains only a coefficient partition (for example, a data set consisting entirely of coefficients and coordinates).

PREDICTED**PRE****P**

outputs predicted values, which for METHOD=UNIVARIATE and METHOD=MORALS are the ordinary predicted values from the linear model, to the OUT= data set. The names of the predicted values' variables are constructed from the PPREFIX= *o-option* (default P) and the original dependent variable names. Specifying the PPREFIX= *o-option* also implies the PREDICTED *o-option*.

PPREFIX=name**PDPREFIX=name****PDP=name**

specifies a prefix for naming the dependent variable predicted values. The default is PPREFIX=P when you specify the PREDICTED *o-option*; otherwise, it is PPREFIX=A. Specifying the PPREFIX= *o-option* also implies the PREDICTED *o-option*, and the PPREFIX= *o-option* is the same as the ADPREFIX= *o-option*.

RDPREFIX=name**RDP=name**

specifies a prefix for naming the residual (dependent) variables to the OUT= data set. The default is RDPREFIX=R. Specifying the RDPREFIX= *o-option* also implies the RESIDUALS *o-option*.

REDUNDANCY<=STANDARDIZE | UNSTANDARDIZE>**RED<=STA | UNS>**

outputs redundancy variables to the OUT= data set, either standardized or unstandardized. Specifying the REDUNDANCY *o-option* is the same as specifying REDUNDANCY=STANDARDIZE. The results of the REDUNDANCY *o-option* depends on the TSTANDARD= option. You must specify TSTANDARD=Z to get results based on standardized data. The TSTANDARD= option controls how the data that go into the redundancy analysis are scaled, and REDUNDANCY=STANDARDIZE|UNSTANDARDIZE controls how the redundancy variables are scaled. The REDUNDANCY *o-option* is implied by METHOD=REDUNDANCY. The RPREFIX= *o-option* specifies a prefix (default Red) for naming the redundancy variables.

REFERENCE=NONE | MISSING | ZERO**REF=NON | MIS | ZER**

specifies how reference levels of CLASS variables are to be treated. The options are REFERENCE=NONE, the default, in which reference levels are suppressed; REFERENCE=MISSING, in which reference levels are displayed and output with missing values; and REFERENCE=ZERO, in which reference levels are displayed and output with zeros. The REFERENCE= option can be specified in the PROC TRANSREG, MODEL, or OUTPUT statement, and it can be independently specified for the OUT= data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the OUT= data set.

REPLACE**REP**

is equivalent to specifying both the DREPLACE and the IREPLACE *o-options*.

RESIDUALS**RES****R**

outputs the differences between the transformed dependent variables and their predicted values. The names of the residual variables are constructed from the RDPREFIX= *o-option* (default R) and the original dependent variable names.

RPREFIX=name**RPR=name**

provides a prefix for naming the redundancy variables. The default is RPREFIX=Red. Specifying the RPREFIX= *o-option* also implies the REDUNDANCY *o-option*.

TDPREFIX=name**TDP=name**

specifies a prefix for naming the transformed dependent variables. By default, TDPREFIX=T. The TDPREFIX= *o-option* is ignored when you specify the DREPLACE *o-option*.

TIPREFIX=name**TIP=name**

specifies a prefix for naming the transformed independent variables. By default, TIPREFIX=T. The TIPREFIX= *o-option* is ignored when you specify the IREPLACE *o-option*.

WEIGHT Statement

WEIGHT *variable* ;

When you use a WEIGHT statement, a weighted residual sum of squares is minimized. The WEIGHT statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than 0.

Details

Model Statement Usage

```
MODEL < transform(dependents < / t-options >)
      < transform(dependents < / t-options >)...> = >
      transform(independents < / t-options >)
      < transform(independents < / t-options >)...>< / a-options > ;
```

Here are some examples of model statements:

- linear regression

```
model identity(y) = identity(x);
```

- a linear model with a nonlinear regression function

```
model identity(y) = spline(x / nknots=5);
```

- multiple regression

```
model identity(y) = identity(x1-x5);
```

- multiple regression with nonlinear transformations

```
model spline(y / nknots=3) = spline(x1-x5 / nknots=3);
```

- multiple regression with nonlinear but monotone transformations

```
model mspline(y / nknots=3) = mspline(x1-x5 / nknots=3);
```

- multivariate multiple regression

```
model identity(y1-y4) = identity(x1-x5);
```

- canonical correlation

```
model identity(y1-y4) = identity(x1-x5) / method=canals;
```

- redundancy analysis

```
model identity(y1-y4) = identity(x1-x5) / method=redundancy;
```

- preference mapping, vector model (Carroll 1972)

```
model identity(Attrib1-Attrib3) = identity(Dim1-Dim2);
```

- preference mapping, ideal point model (Carroll 1972)

```
model identity(Attrib1-Attrib3) = point(Dim1-Dim2);
```

- preference mapping, ideal point model, elliptical (Carroll 1972)

```
model identity(Attrib1-Attrib3) = epoint(Dim1-Dim2);
```

- preference mapping, ideal point model, quadratic (Carroll 1972)

```
model identity(Attrib1-Attrib3) = qpoint(Dim1-Dim2);
```

- metric conjoint analysis

```
model identity(Subj1-Subj50) = class(a b c d e f / zero=sum);
```

- nonmetric conjoint analysis

```
model monotone(Subj1-Subj50) = class(a b c d e f / zero=sum);
```

- main effects, two-way interaction

```
model identity(y) = class(a|b);
```

- less-than-full-rank model—main effects and two-way interaction are constrained to sum to zero

```
model identity(y) = class(a|b / zero=sum);
```

- main effects and all two-way interactions

```
model identity(y) = class(a|b|c@2);
```

- main effects and all two- and three-way interactions

```
model identity(y) = class(a|b|c);
```

- main effects and just B*C two-way interaction

```
model identity(y) = class(a b c b*c);
```

- seven main effects, three two-way interactions

```
model identity(y) = class(a b c d e f g a*b a*c a*d);
```

- deviations-from-means (effects or (1, 0, -1)) coding, with an A reference level of '1' and a B reference level of '2'

```
model identity(y) = class(a|b / deviations zero='1' '2');
```

- cell-means coding (implicit intercept)

```
model identity(y) = class(a*b / zero=none);
```

- reference cell model

```
model identity(y) = class(a|b / zero='1' '1');
```

- reference line with change in line parameters

```
model identity(y) = class(a) | identity(x);
```

- reference curve with change in curve parameters

```
model identity(y) = class(a) | spline(x);
```

- separate curves and intercepts

```
model identity(y) = class(a / zero=none) | spline(x);
```

- quantitative effects with interaction

```
model identity(y) = identity(x1 | x2);
```

- separate quantitative effects with interaction within each cell

```
model identity(y) = class(a * b / zero=none) | identity(x1 | x2);
```

Box-Cox Transformations

The Box-Cox (1964) transformation has the form

$$\begin{array}{ll} (y^\lambda - 1)/\lambda & \lambda \neq 0 \\ \log(y) & \lambda = 0 \end{array}$$

This family of transformations of the positive dependent variable y is controlled by the parameter λ . Transformations linearly related to square root, inverse, quadratic, cubic, and so on are all special cases. The limit as λ approaches 0 is the log transformation. More generally, Box-Cox transformations of the following form can be fit:

$$\begin{array}{ll} ((y + c)^\lambda - 1)/(\lambda g) & \lambda \neq 0 \\ \log(y + c)/g & \lambda = 0 \end{array}$$

By default, $c = 0$. The parameter c can be used to rescale y so that it is strictly positive. By default, $g = 1$. Alternatively, g can be $\bar{y}^{\lambda-1}$ where \bar{y} is the geometric mean of y .

The BOXCOX transformation in PROC TRANSREG can be used to perform a Box-Cox transformation of the dependent variable. You can specify a list of power parameters using the LAMBDA= transformation option. By default, LAMBDA=-3 TO 3 BY 0.25. The procedure chooses the optimal power parameter using a maximum likelihood criterion (Draper and Smith 1981, pp. 225-226). You can specify the PARAMETER= c transformation option when you want to shift the values of y , usually to avoid negatives. To divide by $\bar{y}^{\lambda-1}$, specify the GEOMETRICMEAN transformation option.

Here are some examples of usage of the LAMBDA= option:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
model BoxCox(y) = identity(x1-x5);
```

In the first example

```
model BoxCox(y / lambda=0) = identity(x1-x5);
```

LAMBDA=0 specifies a Box-Cox transformation with a power parameter of 0. Since a single value of 0 was specified for LAMBDA=, there is no difference between the following models:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
model log(y) = identity(x1-x5);
```

In the second example

```
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
```

there is a list of power parameters specified. This tells PROC TRANSREG to find a Box-Cox transformation before the usual iterations begin. PROC TRANSREG tries each power parameter in the list and picks the best transformation. A maximum likelihood approach (Draper and Smith 1981, pp. 225-226) is used. Note that this is quite different from TRANSREG's usual approach of iteratively finding optimal transformations. It is analogous to SMOOTH, RANK, and the other nonoptimal transformations that are performed before the iterations begin.

In the third example

```
model BoxCox(y) = identity(x1-x5);
```

the default list of -3 TO 3 BY 0.25 is used.

The procedure prints the optimal power parameter, a confidence interval on the power parameter (using the ALPHA= transformation option), a “convenient” power parameter (selected from the CLL= option list), and the log likelihood for each power parameter tried (see [Example 75.6](#)).

Smoothing Splines

You can use PROC TRANSREG to output to a SAS data set the same smoothing splines that the GPLOT procedure creates. The SMOOTH transformation is a noniterative transformation for smoothing splines. The smoothing parameter can be specified with either the SM= or the PARAMETER= *o-option*. The independent variable transformation (Tx in this case) contains the results. The GPLOT request $y*x=2$ with I=SM50 creates the same curve as Tx*x.

```
title 'Smoothing Splines';

data x;
  do x = 1 to 100 by 2;
    do rep = 1 to 3;
      y = log(x) + sin(x / 10) + normal(7);
      output;
    end;
  end;
run;

proc transreg;
  model identity(y) = smooth(x / sm=50);
  output;
run;

%let opts = haxis=axis2 vaxis=axis1 frame cframe=ligr;
proc gplot;
  axis1 minor=none label=(angle=90 rotate=0);
  axis2 minor=none;
```

```

plot y*x=1 y*x=2 tx*x=3 / &opts overlay;
symbol1 color=blue v=star i=none;
symbol2 color=yellow v=none i=sm50;
symbol3 color=cyan v=dot i=none;
run; quit;

```

Figure 75.5. Smoothing Spline Example 1

When you cross a `SMOOTH` variable with a `CLASS` variable, specify `ZERO=NONE` with the `CLASS` expansion and the `AFTER t-option` with the `SMOOTH` transformation so that separate functions are found within each group.

```

title2 'Two Groups';

data x;
  do x = 1 to 100;
    group = 1;
    do rep = 1 to 3;
      y = log(x) + sin(x / 10) + normal(7);
      output;
    end;
    group = 2;
    do rep = 1 to 3;
      y = -log(x) + cos(x / 10) + normal(7);
      output;
    end;
  end;
run;

```

```

proc transreg;
  model identity(y) = class(group / zero=none) |
                    smooth(x / after sm=50);
  output out=curves;
run;

data curves2;
  set curves;
  if group1 = 0 then tgroup1x = .;
  if group2 = 0 then tgroup2x = .;
run;

%let opts = haxis=axis2 vaxis=axis1 frame cframe=ligr;
proc gplot;
  axis1 minor=none label=(angle=90 rotate=0);
  axis2 minor=none;
  plot y*x=1 tgroup1x*x=2 tgroup2x*x=2 / &opts overlay;
  symbol1 color=blue v=star i=none;
  symbol2 color=yellow v=none i=join;
run; quit;

```

Figure 75.6. Smoothing Spline Example 2

The SMOOTH transformation is valid only with independent variables; typically, it is used in models with a single independent and a single dependent variable. When there are multiple independent variables designated as SMOOTH, the TRANSREG procedure tries to smooth the i th independent variable using the i th dependent variable as a target. When there are more independent variables than dependent variables, the last dependent variable is reused as often as is necessary. For example, for the model

```
model identity(y1-y3) = smooth(x1-x5);
```

smoothing is based on the pairs (y1, x1), (y2, x2), (y3, x3), (y3, x4), and (y3, x5).

The SMOOTH transformation is a noniterative transformation; smoothing occurs once per variable before the iterations begin. In contrast, SSPLINE provides an iterative smoothing spline transformation. It does not generally minimize squared error; hence, divergence is possible with SSPLINE.

Missing Values

PROC TRANSREG can estimate missing values, with or without category or monotonicity constraints, so that the regression model fit is optimized. Several approaches to missing data handling are provided. All observations with missing values in IDENTITY, CLASS, POINT, EPOINT, QPOINT, SMOOTH, PSPLINE, and BSPLINE variables are excluded from the analysis. When METHOD=UNIVARIATE (specified in the PROC TRANSREG or MODEL statement), observations with missing values in any of the independent variables are excluded from the analysis. When you specify the NOMISS *a-option*, observations with missing values in the other analysis variables are excluded. Otherwise, missing data are estimated, using variable means as initial estimates.

You can specify the LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, SSPLINE, LOG, LOGIT, POWER, ARSIN, BOXCOX, RANK, and EXP transformations in any combination with nonmissing values, ordinary missing values, and special missing values, as long as the nonmissing values in each variable have positive variance. No category or order restrictions are placed on the estimates of ordinary missing values. You can force missing value estimates within a variable to be identical by using special missing values (refer to “DATA Step Processing” in *SAS Language Reference: Concepts*). You can specify up to 27 categories of missing values, in which within-category estimates must be the same, by coding the missing values using `._` and `.A` through `.Z`.

You can also specify an ordering of some missing value estimates. You can use the MONOTONE=*a-option* in the PROC TRANSREG or MODEL statement to indicate a range of special missing values (a subset of the list from `.A` to `.Z`) with estimates that must be weakly ordered within each variable in which they appear. For example, if MONOTONE=AI, the nine classes, `.A`, `.B`, . . . , `.I`, are monotonically scored and optimally scaled just as MONOTONE transformation values are scored. In this case, category but not order restrictions are placed on the missing values `._` and `.J` through `.Z`. You can also use the UNTIE=*a-option* (in the PROC TRANSREG or MODEL statement) to indicate a range of special missing values with estimates that must be weakly ordered within each variable in which they appear but can be untied.

The missing value estimation facilities allow for partitioned or mixed-type variables. For example, a variable can be considered part nominal and part ordinal. Nominal classes of otherwise ordinal variables are coded with special missing values. This feature can be useful with survey research. The class “unfamiliar with the product” in the variable “Rate your preference for ‘Brand X’ on a 1 to 9 scale, or if you are unfamiliar with the product, check ‘unfamiliar with the product’” is an example. You

can code “unfamiliar with the product” as a special missing value, such as .A. The 1s to 9s can be monotonically transformed, while no monotonic restrictions are placed on the quantification of the “unfamiliar with the product” class.

A variable specified for a LINEAR transformation, with special missing values and ordered categorical missing values, can be part interval, part ordinal, and part nominal. A variable specified for a MONOTONE transformation can have two independent ordinal parts. A variable specified for an UNTIE transformation can have an

ordered categorical part and an ordered part without category restrictions. Many other mixes are possible.

Missing Values, UNTIE, and Hypothesis Tests

The TRANSREG procedure has the ability to estimate missing data and monotonically transform variables while untying tied values. Estimates of ordinary missing values (.) may all be different. Analyses with UNTIE transformations, the UNTIE=*a-option*, and ordinary missing data estimation are all prone to degeneracy problems. Consider the following example. A perfect fit is found by collapsing all observations except the one with two missing values into a single value in Y and X1.

```
data x;

Figure 75.7. Missing Values Example

Generally, the use of ordinary missing data estimation, the UNTIE transformation, and the UNTIE=*a-option* should be avoided, particularly with hypothesis tests. With these options, parameters are estimated based on only a single observation, and they can exert tremendous influence over the results. Each of these parameters has one model degree of freedom associated with it, so small or zero error degrees of freedom can also be a problem.

Controlling the Number of Iterations

Several *a-options* in the PROC TRANSREG or MODEL statement control the number of iterations performed. Iteration terminates when any one of the following conditions is satisfied:

- The number of iterations equals the value of the MAXITER=*a-option*.
- The average absolute change in variable scores from one iteration to the next is less than the value of the CONVERGE=*a-option*.
- The criterion change is less than the value of the CCONVERGE=*a-option*.

You can specify negative values for either convergence option if you wish to define convergence only in terms of the other option. The criterion change can become negative when the data have converged so that it is numerically impossible, within machine precision, to increase the criterion. Usually, a negative criterion change is the result of very small amounts of rounding error since the algorithms are (usually) convergent. However, there are other cases where a negative criterion change is a sign of divergence, which is not necessarily an error. When you specify an SSPLINE transformation or the REITERATE or DUMMY *a-option*, divergence may be perfectly normal.

When there are no monotonicity constraints and there is only one canonical variable in each set, PROC TRANSREG (with the DUMMY *a-option*) can usually find the optimal solution in only one iteration. (There are no monotonicity constraints when the MONOTONE, MSPLINE, or UNTIE transformations and the UNTIE= and MONOTONE=*a-options* are not specified. There is only one canonical variable in each set when METHOD=MORALS or METHOD=UNIVARIATE, or when METHOD=REDUNDANCY with only one dependent variable, or when METHOD=CANALS and NCAN=1.)

The initialization iteration is number 0. When there are no monotonicity constraints and there is only one canonical variable in each set, the next iteration shows no change and iteration stops. At least two iterations (0 and 1) are performed with the DUMMY *a-option* even if nothing changes in iteration 0. The MONOTONE, MSPLINE, and UNTIE variables are not transformed by the dummy variable initialization. Note that divergence with the DUMMY *a-option*, particularly in the second iteration, is not an error. The initialization iteration is slower and uses more memory than other iterations. However, for many models, specifying the DUMMY *a-option* can greatly decrease the amount of time required to find the optimal transformations. Furthermore, by solving for the transformations directly instead of iteratively, PROC TRANSREG avoids certain nonoptimal solutions.

You can increase the number of iterations to ensure convergence by increasing the value of the `MAXITER=` *a-option* and decreasing the value of the `CONVERGE=` *a-option*. Since the average absolute change in standardized variable scores seldom decreases below $1E-11$, you should not specify a value for the `CONVERGE=` *a-option* less than $1E-8$ or $1E-10$. Most of the data changes occur during the first few iterations, but the data can still change after 50 or even 100 iterations. You can try different combinations of values for the `CONVERGE=` and `MAXITER=` *a-options* to ensure convergence without extreme overiteration. If the data do not converge with the default specifications, try `CONVERGE=1E-8` and `MAXITER=50`, or `CONVERGE=1E-10` and `MAXITER=200`. Note that you can specify the `REITERATE` *a-option* to start iterating where the previous analysis stopped.

Using the REITERATE Algorithm Option

You can use the `REITERATE` *a-option* to perform additional iterations when PROC TRANSREG stops before the data have adequately converged. For example, suppose that you execute the following code:

```
proc transreg data=a;
  model mspline(y) = mspline(x1-x5);
  output out=b coefficients;
run;
```

If the transformations do not converge in the default 30 iterations, you can perform more iterations without repeating the first 30 iterations.

```
proc transreg data=b reiterate;
  model mspline(y) = mspline(x1-x5);
  output out=b coefficients;
run;
```

Note that a `WHERE` statement is not necessary to exclude the coefficient observations. They are automatically excluded because their `_TYPE_` value is not `SCORE`.

You can also use the `REITERATE` *a-option* to specify starting values other than the original values for the transformations. Providing alternate starting points may avoid local optima. Here are two examples.

```
proc transreg data=a;
  model rank(y) = rank(x1-x5);
  output out=b;
run;

proc transreg data=b reiterate;
  /* Use ranks as the starting point. */
  model mspline(y) = mspline(x1-x5);
  output out=c coefficients;
run;
```

```

data b;
  set a;
  array tx[6] ty tx1-tx5;
  do j = 1 to 6;
    tx[j] = normal(7);
  end;
run;

proc transreg data=b reiterate;
  /* Use a random starting point. */
  model mspline(y) = mspline(x1-x5);
  output out=c coefficients;
run;

```

Note that divergence with the REITERATE *a-option*, particularly in the second iteration, is not an error since the initial transformation is not required to be a valid member of the transformation family. When you specify the REITERATE *a-option*, the iteration does not terminate when the criterion change is negative during the first 10 iterations.

Avoiding Constant Transformations

There are times when the optimal scaling produces a constant transformed variable. This can happen with the MONOTONE, UNTIE, and MSPLINE transformations when the target is negatively correlated with the original input variable. It can happen with all transformations when the target is uncorrelated with the original input variable. When this happens, the procedure modifies the target to avoid a constant transformation. This strategy avoids certain nonoptimal solutions.

If the transformation is monotonic and a constant transformed variable results, the procedure multiplies the target by -1 and tries the optimal scaling again. If the transformation is not monotonic or if the multiplication by -1 did not help, the procedure tries using a random target. If the transformation is still constant, the previous non-constant transformation is retained. When a constant transformation is avoided by any strategy, a message is displayed: “A constant transformation was avoided for *name*.”

With extreme collinearity, small amounts of rounding error might interact with the instability of the coefficients to produce target vectors that are not positively correlated with the original scaling. If a regression coefficient for a variable is zero, the formula for the target for that variable contains a zero divide. In a multiple regression model, after many iterations, one independent variable can be scaled the same way as the current scaling of the dependent variable, so the other independent variables have coefficients of zero. When the constant transformation warning appears, you should interpret your results with extreme caution, and recheck your model.

Constant Variables

Constant and almost constant variables are zeroed and ignored. As long as the dependent variable is not constant, PROC TRANSREG produces an iteration history table for all models, not just models in which the variables can change. When constant variables are expected and should not be zeroed, specify the NOZEROCONSTANT option.

Character OPSCORE Variables

Character OPSCORE variables are replaced by a numeric variable containing category numbers before the iterations, and the character values are discarded. Only the first eight characters are considered when determining category membership. If you want the original character variable in the output data set, give it a different name in the OPSCORE specification (OPSCORE(x / name=(x2)) and name the original variable on the ID statement (ID x;).

Convergence and Degeneracies

When you specify the SSPLINE transformation, divergence is normal. The rest of this section assumes that you did not specify SSPLINE. For all the methods available in PROC TRANSREG, the algorithms are convergent, both in terms of the criterion being optimized and the parameters being estimated. The value of the criterion being maximized (squared multiple correlation, average squared multiple correlation, or average squared canonical correlation) can, theoretically, never decrease from one iteration to the next. The values of the parameters being solved for (the scores and weights of the transformed variables) become stable after sufficient iteration.

In practice, the criterion being maximized can decrease with overiteration. When the statistic has very nearly reached its maximum, further iterations might report a decrease in the criterion in the last few decimal places. This is a normal result of very small amounts of rounding error. By default, iteration terminates when this occurs because, by default, CCONVERGE=0.0. Specifying CCONVERGE=-1, an impossible change, turns off this check for convergence.

Even though the algorithms are convergent, they might not converge to a global optimum. Also, under extreme circumstances, the solution might degenerate. Because two points always form a straight line, the algorithms sometimes try to reach this degenerate optimum. This sometimes occurs when one observation is an ordinal outlier (when one observation has the extreme rank on all variables). The algorithm can reach an optimal solution that ties all other categories producing two points. Similar results can occur when there are many missing values. More generally, whenever there are very few constraints on the scoring of one or more points, degeneracies can be a problem. In a well-behaved analysis, the maximum data change, average data change, and criterion change all decrease at a rapid rate with each iteration. When the rate of change increases for several iterations, the solution might be degenerating.

Implicit and Explicit Intercepts

Depending on several options, the model intercept is nonzero, zero, or implicit, or there is no intercept. Ordinarily, the model contains an explicit nonzero intercept, and the Intercept variable in the OUT= data set contains ones. When TSTANDARD=CENTER or TSTANDARD=Z is specified, the model contains an explicit, zero intercept and the Intercept variable contains zeros. When METHOD=CANALS, the model is fit with centered variables and the Intercept variable is set to missing.

If you specify CLASS with ZERO=NONE or BSPLINE for one or more independent variables, and TSTANDARD=NOMISS or TSTANDARD=ORIGINAL (the default), an implicit intercept model is fit. The intercept is implicit in a set of the independent variables since there exists a set of independent variables the sum of which is a column of ones. All statistics are mean corrected. The implicit intercept is not an option; it is implied by the model.

With METHOD=CANALS, the Intercept variable contains the *canonical intercept* for canonical coefficients observations: $\hat{\beta}_0 = \bar{y}'\hat{\alpha} - \bar{x}'\hat{\beta}$ where $\mathbf{Y}\hat{\alpha} \approx \mathbf{X}\hat{\beta}$.

Passive Observations

Observations may be excluded from the analysis for several reasons; these include zero weight; zero frequency; missing values in variables designated IDENTITY, CLASS, POINT, EPOINT, QPOINT, SMOOTH, PSPLINE, or BSPLINE; and missing values with the NOMISS *a-option* specified. These observations are passive in that they do not contribute to determining transformations, R^2 , sums of squares, degrees of freedom, and so on. However, some information can be computed for them. For example, if no independent variable values are missing, predicted values and redundancy variable values can both be computed. Residuals can be computed for observations with a nonmissing dependent and nonmissing predicted value. Canonical variables for dependent variables can be computed when no dependent variables are missing; canonical variables for independent variables can be computed when no independent variables are missing, and so on. Passive observations in the OUT= data set have a blank value for _TYPE_.

Point Models

The expanded set of independent variables generated from the POINT, EPOINT, and QPOINT expansions can be used to perform ideal point regressions (Carroll 1972) and compute ideal point coordinates for plotting in a biplot (Gabriel 1981). The three types of ideal point coordinates can all be described as transformed coefficients. Assume that m independent variables are specified in one of the three point expansions. Let \mathbf{b}' be a $1 \times m$ row vector of coefficients for these variables and one of the dependent variables. Let \mathbf{R} be a matrix created from the coefficients of the extra variables. When coordinates are requested with the MPC, MEC, or MQC *o-options*, \mathbf{b}' and \mathbf{R} are created from multiple regression coefficients. When coordinates are requested with the CPC, CEC, or CQC *o-options*, \mathbf{b}' and \mathbf{R} are created from canonical coefficients.

If you specify the POINT expansion in the MODEL statement, \mathbf{R} is an $m \times m$ identity matrix times the coefficient for the sums of squares (`_ISSQ_`) variable. If you specify the EPOINT expansion, \mathbf{R} is an $m \times m$ diagonal matrix of coefficients from the squared variables. If you specify the QPOINT expansion, \mathbf{R} is an $m \times m$ symmetric matrix of coefficients from the squared variables on the diagonal and crossproduct variables off the diagonal. The MPC, MEC, MQC, CPC, CEC, and CQC ideal point coordinates are defined as $-0.5\mathbf{b}'\mathbf{R}^{-1}$. When \mathbf{R} is singular, the ideal point coordinates are infinitely far away and are set to missing, so you should try a simpler version of the model. The version that is simpler than the POINT model is the vector model where no extra variables are created. In the vector model, designate all independent variables as `IDENTITY`. Then draw vectors from the origin to the `COEFFICIENTS` points.

Typically, when you request ideal point coordinates, the MODEL statement should consist of a single transformation for the dependent variables (usually `IDENTITY`, `MONOTONE`, or `MSPLINE`) and a single expansion for the independent variables (one of `POINT`, `EPOINT`, or `QPOINT`).

Redundancy Analysis

Redundancy analysis (Stewart and Love 1968) is a principal component analysis of multivariate regression predicted values. These first steps show the redundancy analysis results produced by PROC TRANSREG. The specification `TSTANDARD=Z` standardizes all variables to mean zero and variance one. `METHOD=REDUNDANCY` specifies redundancy analysis and outputs the redundancy variables to the `OUT=` data set. The `MREDUNDANCY` *o-option* outputs two sets of redundancy analysis coefficients to the `OUT=` data set.

Figure 75.8. Redundancy Analysis Example

The `_TYPE_='SCORE'` observations of the `Red1–Red3` variables contain the redundancy variables. The nonmissing “M REDUND” values are coefficients for predicting the redundancy variables from the independent variables. The nonmissing “R REDUND” values are coefficients for predicting the independent variables from the redundancy variables.

These following steps show how to generate the same results manually. The data set is standardized, predicted values are computed, and principal components of the predicted values are computed. The following statements produce the redundancy variables, shown in [Figure 75.9](#):

Optimal Scaling

An alternating least-squares optimal scaling algorithm can be divided into two major stages. The first stage estimates the parameters of the linear model. These parameters are used to create the predicted values or target for each variable that can be transformed. Each target minimizes squared error (as explained in the discussion of the algorithms in *SAS Technical Report R-108*. The definition of the target depends on many factors, such as whether a variable is independent or dependent, which algorithm is used (for example, regression, redundancy, CANALS, principal components), and so on. The definition of the target is independent of the transformation family you specify for the variable. However, the target values for a variable typically do not fit the prescribed transformation family for the variable. They might not have the right category structure; they might not have the right order; they might not be a linear combination of the columns of a B-spline basis; and so on.

The second major stage is optimal scaling. Optimal scaling can be defined as a possibly constrained, least-squares regression problem. When you specify an optimal transformation, or when missing data are estimated for any variable, the full representation of the variable is not simply a vector; it is a matrix with more than one column. The optimal scaling phase finds the vector that is a linear combination of the columns of this matrix, that is closest to the target (in terms of minimum squared error), among those that do not violate any of the constraints imposed by the transformation family. Optimal scaling methods are independent of the data analysis method that generated the target. In all cases, optimal scaling can be accomplished by creating a design matrix based on the original scaling of the variable and the transformation family specified for that variable. The optimally scaled variable is a linear combination of the columns of the design matrix. The coefficients of the linear combination are found using (possibly constrained) least squares. Many optimal scaling problems are solved without actually constructing design and projection matrices. The following two sections describe the algorithms used by PROC TRANSREG for optimal scaling. The first section discusses optimal scaling for OPSCORE, MONOTONE, UNTIE, and LINEAR transformations, including how missing values are handled. The second section addresses SPLINE and MSPLINE transformations.

OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations

Two vectors of information are needed to produce the optimally scaled variable: the initial variable scaling vector \mathbf{x} and the target vector \mathbf{y} . For convenience, both vectors are first sorted on the values of the initial scaling vector. If you request an UNTIE transformation, the target vector is sorted within ties in the initial scaling vector. The normal SAS System collating sequence for missing and nonmissing values is used. Sorting simply allows constraints to be specified in terms of relations among adjoining coefficients. The sorting process partitions \mathbf{x} and \mathbf{y} into missing and nonmissing parts $(\mathbf{x}'_m \mathbf{x}'_n)'$, and $(\mathbf{y}'_m \mathbf{y}'_n)'$.

Next, PROC TRANSREG determines category membership. Every ordinary missing value (.) forms a separate category. (Three ordinary missing values form three categories.) Every special missing value within the range specified in the UNTIE=*a-option* forms a separate category. (If UNTIE= BC and there are three .B and two .C missing values, five categories are formed from them.) For all other special missing values, a separate category is formed for each different value. (If there are four .A missing values, one category is formed from them.)

Each distinct nonmissing value forms a separate category for OPSCORE and MONOTONE transformations (1 1 1 2 2 3 form three categories). Each nonmissing datum forms a separate category for all other transformations (1 1 1 2 2 3 form six categories). Once category membership is determined, category means are computed. Here is an example:

x:	(. . .A .A .B 1 1 1 2 2 3 3 3 4)'
y:	(5 6 2 4 2 1 2 3 4 6 4 5 6 7)'
OPSCORE and MONOTONE means:	(5 6 3 2 2 5 5 7)'
other means:	(5 6 3 2 1 2 3 4 6 4 5 6 7)'

The category means are the coefficients of a category indicator design matrix. The category means are the Fisher (1938) optimal scores. For MONOTONE and UNTIE transformations, order constraints are imposed on the category means for the nonmissing partition by merging categories that are out of order. The algorithm checks upward until an order violation is found, then averages downward until the order violation is averaged away. (The average of \bar{x}_1 computed from n_1 observations and \bar{x}_2 computed from n_2 observations is $(n_1\bar{x}_1 + n_2\bar{x}_2)/(n_1 + n_2)$.) The MONOTONE algorithm (Kruskal 1964, secondary approach to ties) for this example with means for the nonmissing values (2 5 5 7)' would do the following checks: 2 < 5:OK, 5 = 5:OK, 5 < 7:OK. The means are in the proper order, so no work is needed.

The UNTIE transformation (Kruskal 1964, primary approach to ties) uses the same algorithm on the means of the nonmissing values (1 2 3 4 6 4 5 6 7)' but with different results for this example: 1 < 2:OK, 2 < 3:OK, 3 < 4:OK, 4 < 6:OK, 6 > 4:average

6 and 4 and replace 6 and 4 by the average. The new means of the nonmissing values are (1 2 3 4 5 5 5 6 7)'. The check resumes: 4 < 5:OK, 5 = 5:OK, 5 = 5:OK, 5 < 6:OK, 6 < 7:OK. If some of the special missing values are ordered, the upward checking, downward averaging method is applied to them also, independently of the other missing and nonmissing partitions. Once the means conform to any required category or order constraints, an optimally scaled vector is produced from the means. The following example results from a MONOTONE transformation.

```

x:      (. . .A .A .B 1 1 1 2 2 3 3 3 4)'
y:      (5 6 2 4 2 1 2 3 4 6 4 5 6 7)'
result: (5 6 3 3 2 2 2 2 5 5 5 5 5 7)'

```

The upward checking, downward averaging algorithm is equivalent to creating a category indicator design matrix, solving for least-squares coefficients with order constraints, then computing the linear combination of design matrix columns.

For the optimal transformation LINEAR and for nonoptimal transformations, missing values are handled as just described. The nonmissing target values are regressed onto the matrix defined by the nonmissing initial scaling values and an intercept. In this example, the target vector $y_n = (1\ 2\ 3\ 4\ 6\ 4\ 5\ 6\ 7)'$ is regressed onto the design matrix

$$\begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 2 & 2 & 3 & 3 & 3 & 4 \end{bmatrix}'$$

Although only a linear transformation is performed, the effect of a linear regression optimal scaling is not eliminated by the later standardization step (unless the variable has no missing values). In the presence of missing values, the linear regression is necessary to minimize squared error.

SPLINE and MSPLINE Transformations

The missing portions of variables subjected to SPLINE or MSPLINE transformations are handled the same way as for OPSCORE, MONOTONE, UNTIE, and LINEAR transformations (see the previous section). The nonmissing partition is handled by first creating a B-spline basis of the specified degree with the specified knots for the nonmissing partition of the initial scaling vector and then regressing the target onto the basis. The optimally scaled vector is a linear combination of the B-spline basis vectors using least-squares regression coefficients. An algorithm for generating the B-spline basis is given in de Boor (1978, pp. 134–135). B-splines are both a computationally accurate and efficient way of constructing a basis for piecewise polynomials; however, they are not the most natural method of describing splines.

Consider an initial scaling vector $x = (1\ 2\ 3\ 4\ 5\ 6\ 7\ 8\ 9)'$ and a degree three spline with interior knots at 3.5 and 6.5. The B-spline basis for the transformation is the left matrix in Table 75.5, and the natural piecewise polynomial spline basis is the

right matrix. The two matrices span the same column space. The natural basis has an intercept, a linear term, a quadratic term, a cubic term, and two more terms since there are two interior knots. These terms are generated (for knot k and x element x) by the formula $(x - k)^3 \times I_{(x>k)}$. The indicator variable $I_{(x>k)}$ evaluates to 1.0 if x is greater than k and to 0.0 otherwise. If knot k had been repeated, there would be a $(x - k)^2 \times I_{(x>k)}$ term also. Notice that the fifth column makes no contribution to the curve before 3.5, makes zero contribution at 3.5 (the transformation is continuous), and makes an increasing contribution beyond 3.5. The same pattern of results holds for the last term with knot 6.5. The coefficient of the fifth column represents the change in the cubic portion of the curve after 3.5. The coefficient of the sixth column represents the change in the cubic portion of the curve after 6.5.

Table 75.5. Spline Bases

B-Spline Basis						Piecewise Polynomial Splines					
1.000	0.000	0.000	0.000	0	0	1	1	1	1	0	0

0	0	0.000	0.000	0.000	1.000	1	9	81	729	166.375	15.625

The numbers in the B-spline basis do not have a simple interpretation like the numbers in the natural piecewise polynomial basis. The B-spline basis has a diagonally banded structure. The band shifts one column to the right after every knot. The number of entries in each row that may potentially be nonzero is one greater than the degree. The elements within a row always sum to one. The B-spline basis is accurate because of the smallness of the numbers and the lack of extreme collinearity inherent in the natural polynomials. B-splines are efficient because PROC TRANSREG can take advantage of the sparseness of the B-spline basis when it accumulates crossproducts. The number of required multiplications and additions to accumulate the crossproduct matrix does not increase with the number of knots but does increase with the degree of the spline, so it is much more computationally efficient to increase the number of knots than to increase the degree of the polynomial.

MSPLINE transformations are handled like SPLINE transformations except that constraints are placed on the coefficients to ensure monotonicity. When the coefficients of the B-spline basis are monotonically increasing, the transformation is monotonically increasing. When the polynomial degree is two or less, monotone coefficient splines, integrated splines (Winsberg and Ramsay 1980), and the general class of all monotone splines are equivalent.

Specifying the Number of Knots

Keep the number of knots small (usually less than ten, although you can specify more). A degree three spline with nine knots, one at each decile, can closely follow a large variety of curves. Each spline transformation of degree p with q knots fits a model with $p + q$ parameters. The total number of parameters should be much less than the number of observations. Usually in regression analyses, it is recommended that there be at least five or ten observations for each parameter in order to get stable results. For example, when spline transformations of degree three with nine knots are requested for six variables, the number of observations in the data set should be at least five or ten times 72 (since $6 \times (3 + 9)$ is the total number of parameters). The overall model can also have a parameter for the intercept and one or more parameters for each nonspline variable in the model.

Increasing the number of knots gives the spline more freedom to bend and follow the data. Increasing the degree also gives the spline more freedom, but to a lesser extent. Specifying a large number of knots is much better than increasing the degree beyond three.

When you specify `NKNOTS= q` for a variable with n observations, then each of the $q + 1$ segments of the spline contains $n/(q + 1)$ observations on the average. When you specify `KNOTS=number-list`, make sure that there is a reasonable number of observations in each interval.

The following statements find a cubic polynomial transformation of X and no transformation of Y :

```
proc transreg;
  model identity(Y)=spline(X);
  output;
run;
```

The following statements find a cubic spline transformation curve for X that consists of the weighted sum of a single constant, a single straight line, a quadratic curve for the portion of the variable less than 3.0, a different quadratic curve for the portion greater than 3.0 (since the 3.0 knot is repeated), and a different cubic curve for each of the intervals: (minimum to 1.5), (1.5 to 2.4), (2.4 to 3.0), (3.0 to 4.0), and (4.0 to maximum). The transformation is continuous everywhere, its first derivative is continuous everywhere, its second derivative is continuous everywhere except at 3.0, and its third derivative is continuous everywhere except at 1.5, 2.4, 3.0, and 4.0.

```
proc transreg;
  model identity(Y)=spline(X / knots=1.5 2.4 3.0 3.0 4.0);
  output;
run;
```

The following statements find a quadratic spline transformation that consists of a polynomial $X_{-t} = b_0 + b_1X + b_2X^2$ for the range ($X < 3.0$) and a completely different polynomial $X_{-t} = b_3 + b_4X + b_5X^2$ for the range ($X > 3.0$). The two curves are not required to be continuous at 3.0.

```
proc transreg;
  model identity(y)=spline(x / knots=3 3 3 degree=2);
  output;
run;
```

The following statements categorize Y into 10 intervals and find a step-function transformation. One aspect of this transformation family is unlike all other optimal transformation families. The initial scaling of the data does not fit the restrictions imposed by the transformation family. This is because the initial variable can be continuous, but a discrete step function transformation is sought. Zero degree spline variables are categorized before the first iteration.

```
proc transreg;
  model identity(Y)=spline(X / degree=0 nknots=9);
  output;
run;
```

The following statements find a continuous, piecewise linear transformation of X :

```
proc transreg;
  model identity(Y)=spline(X / degree=1 nknots=8);
  output;
run;
```

SPLINE, BSPLINE, and PSPLINE Comparisons

SPLINE is a transformation. It takes a variable as input and produces a transformed variable as output. Internally, with SPLINE, a B-spline basis is used to find the transformation, which is a linear combination of the columns of the B-spline basis. However, with SPLINE, the basis is not made available in any output.

BSPLINE is an expansion. It takes a variable as input and produces more than one variable as output. The output variables comprise the B-spline basis that is used internally by SPLINE.

PSPLINE is an expansion. It takes a variable as input and produces more than one variable as output. The difference between PSPLINE and BSPLINE is that PSPLINE produces a piecewise polynomial, whereas BSPLINE produces a B-spline. A matrix consisting of a piecewise polynomial basis and an intercept spans the same space as the B-spline matrix, but the basis vectors are quite different. The numbers in the piecewise polynomials can get quite large; the numbers in the B-spline basis range between 0 and 1. There are many more zeros in the B-spline basis.

Interchanging SPLINE, BSPLINE, and PSPLINE should have no effect on the fit of the overall model except for the fact that PSPLINE is much more prone to numerical problems. Similarly, interchanging a CLASS expansion and an OPSCORE transformation should have no effect on the fit of the overall model.

Hypothesis Tests

The TRANSREG procedure has a set of options for testing hypotheses in models with a single dependent variable. The TEST *a-option* produces an ANOVA table. It tests the null hypothesis that the vector of coefficients for all of the transformations is zero. The SS2 *a-option* produces a regression table with Type II tests of the contribution of each transformation to the overall model. In some cases, exact tests are provided; in other cases, the tests are approximate, liberal, or conservative.

For two reasons it is typically not appropriate to test hypotheses by using the output from PROC TRANSREG as input to other procedures such as the REG procedure. First, PROC REG has no way of determining how many degrees of freedom were used for each transformation. Second, the Type II sums of squares for the tests of the individual regression coefficients are not correct for the transformation regression model since PROC REG, as it evaluates the effect of each variable, cannot change the transformations of the other variables. PROC TRANSREG uses the correct degrees of freedom and sums of squares.

In an ordinary univariate linear model, there is one parameter for each independent variable, including the intercept. In the transformation regression model, many of the “variables” are used internally in the bases for the transformations. Each basis column has one parameter or *scoring* coefficient, and each linearly independent column has one model degree of freedom associated with it. Coefficients applied to transformed variables, *model coefficients*, do not enter into the degrees of freedom calculations. They are by-products of the standardizations and can be absorbed into the transformations by specifying the ADDITIVE *a-option*. The word *parameter* is reserved for model and scoring coefficients that have a degree of freedom associated with them.

For expansions, there is one model parameter for each variable created by the expansion (except for all missing CLASS columns and expansions that have an implicit intercept). Each IDENTITY variable has one model parameter. If there are m POINT variables, they expand to $m + 1$ variables and, hence, have $m + 1$ model parameters. For m EPOINT variables, there are $2m$ model parameters. For m QPOINT variables, there are $m(m + 3)/2$ model parameters. If a variable with m categories is designated CLASS, there are $m - 1$ parameters. For BSPLINE and PSPLINE variables of DEGREE= n with NKNOTS= k , there are $n + k$ parameters. Note that one of the $n + k + 1$ BSPLINE columns and one of the m CLASS(variable / ZERO=NONE) columns are not counted due to the implicit intercept.

There are scoring parameters for missing values in nonexcluded observations. Each ordinary missing value (.) has one scoring parameter. Each different special missing value (._ and .A through .Z) within each variable has one scoring parameter. Missing values specified in the UNTIE= and MONOTONE= options follow the rules for UNTIE and MONOTONE transformations, which are described later in this chapter.

For all nonoptimal transformations (LOG, LOGIT, ARSIN, POWER, EXP, RANK, BOXCOX), there is one parameter per variable in addition to any missing value scoring parameters.

For SPLINE, OPSCORE, and LINEAR transformations, the number of scoring parameters is the number of basis columns that are used internally to find the transformations minus 1 for the intercept. The number of scoring parameters for SPLINE variables is the same as the number of model parameters for BSPLINE and PSPLINE variables. If $\text{DEGREE}=n$ and $\text{NKNOTS}=k$, there are $n + k$ scoring parameters. The number of scoring parameters for OPSCORE, SMOOTH, and SSPLINE variables is the same as the number of model parameters for CLASS variables. If there are m categories, there are $m - 1$ scoring parameters. There is one parameter for each LINEAR variable. For SPLINE, OPSCORE, LINEAR, MONOTONE, UNTIE, and MSPLINE transformations, missing value scoring parameters are computed as described previously with the nonoptimal transformations.

The number of scoring parameters for MONOTONE, UNTIE, and MSPLINE transformations is less precise than for SPLINE, OPSCORE, and LINEAR transformations. One way of handling a MONOTONE transformation is to treat it as if it were the same as an OPSCORE transformation. If there are m categories, there are $m - 1$ potential scoring parameters. However, there are typically fewer than $m - 1$ unique parameter estimates since some of those $m - 1$ scoring parameter estimates may be tied during the optimal scaling to impose the order constraints. Imposing ties on the scoring parameter estimates is equivalent to fitting a model with fewer parameters. So there are two available scoring parameter counts: $m - 1$ and a smaller number that is determined during the analysis. Using $m - 1$ as the model degrees of freedom for MONOTONE variables (treating OPSCORE and MONOTONE transformations the same way) is *conservative*, since the MONOTONE scoring parameter estimates are more restricted than the OPSCORE scoring parameter estimates. Using the smaller count (the number of scoring parameter estimates that are different minus 1 for the intercept) in the model degrees of freedom is *liberal*, since the data and the model together are being used to determine the number of parameters. PROC TRANSREG reports tests using both liberal and conservative degrees of freedom to provide lower and upper bounds on the “true” p -values.

For the UNTIE transformation, the conservative scoring parameter count is the number of distinct observations, whereas the liberal scoring parameter count is the number of scoring parameter estimates that are different minus 1 for the intercept. Hence, when you specify UNTIE, conservative tests have zero error degrees of freedom unless there are replicated observations.

For MSPLINE variables of $\text{DEGREE}=n$ and $\text{NKNOTS}=k$, the conservative scoring parameter count is $n + k$, whereas the liberal parameter count is the number of scoring parameter estimates that are different, minus 1 for the intercept. A liberal degrees of freedom of 1 does not necessarily imply a linear transformation. It just implies that n plus k minus the number of ties imposed equals 1. An example of a one degree-of-freedom nonlinear transformation is a two-piece linear transformation in which the slope of one piece is 0.

The number of scoring parameters is determined during each iteration. After the last iteration, enough information is available for the TEST *a-option* to produce an ANOVA table that reports the overall fit of the model. If you specify the SS2 *a-option*, further iterations are necessary to test the contribution of each transformation

to the overall model.

The liberal tests do not compensate for over-parameterization. For example, requesting a spline transformation with k knots when a linear transformation will suffice results in “liberal” tests that are actually conservative because too many degrees of freedom are being used for the transformations. Use as few knots as possible to avoid this problem.

In ordinary multiple regression, an F test of the null hypothesis that the coefficient for variable x_j is zero can be constructed by comparing two linear models. One model is the full model with all parameters, and the other is a reduced model that has all parameters except the parameter for variable x_j . The difference between the model sum of squares for the full model and the model sum of squares for the reduced model is the Type II sum of squares for the test of the null hypothesis that the coefficient for variable x_j is 0. The numerator of the F test has one degree of freedom. The mean square error for the full model is the denominator of the F test of variable x_j . Note that the estimates of the coefficients for the two models are not usually the same. When variable x_j is removed, the coefficients for the other variables change to compensate for the removal of x_j . In a transformation regression model, the transformations of the other variables must be allowed to change and the numerator degrees of freedom are not always ones. It is not correct to simply let the model coefficients for the transformed variables change and apply the new model coefficients to the old transformations computed with the old scoring parameter estimates. In a transformation regression model, further iteration is needed to test each transformation because all the scoring parameter estimates for other variables must be allowed to change to test the effect of variable x_j . This can be quite time consuming for a large model if the DUMMY *a-option* cannot be used to solve directly for the transformations.

Output Data Set

The OUT= output data set can contain a great deal of information; however, in most cases, the output data set contains a small portion of the entire range of available information and is organized for direct input into the %PLOTIT macro or graphical or analysis procedures. For information on the %PLOTIT macro, see [Appendix B](#), “Using the %PLOTIT Macro.”

Output Data Set Examples

The next section provides a complete list of the contents of the OUT= data set. However, before presenting complete details, this section provides three brief examples, illustrating some typical output data sets.

The first example shows the output data set from a two-way ANOVA model. The following statements produce [Figure 75.12](#):

The `_TYPE_` variable indicates observation type: score, multiple regression coefficient (parameter estimates), and marginal means. The `_NAME_` variable contains the default observation labels, “ROW1”, “ROW2”, and so on, and contains the dependent variable name (Y) for the remaining observations. If you specify an ID statement, `_NAME_` contains the values of the first ID variable for score observations. The Y variable is the dependent variable, PY contains the predicted values, RY contains the residuals, and the variables Intercept through X1aX2a contain the design matrix. The X1 and X2 variables are the original CLASS variables.

The next example shows the contents of the output data set from fitting a curve through a scatter plot.

Figure 75.13. Predicted Values Example Output Data Set Contents

The OUT= data set contains `_TYPE_` and `_NAME_` variables. Since no coefficients or coordinates are requested, all observations are `_TYPE_='SCORE'`. The Y variable is the original dependent variable, TY is the transformed dependent variable, PY contains the predicted values, X is the original independent variable, and TX is the transformed independent variable. The data set also contains an Intercept and transformed intercept TIntercept variable. (In this case, the transformed intercept is the same as the intercept. However, if you specify the TSTANDARD= and ADDITIVE options, these are not always the same.)

The next example shows the results from specifying METHOD=MORALS when there is more than one dependent variable.

Figure 75.14. (continued)

If you specify METHOD=MORALS with multiple dependent variables, PROC TRANSREG performs separate univariate analyses and stacks the results in the OUT= data set. For this example, the results of the first analysis are in the partition designated by _DEPVAR_='Spline(Y1)' and the results of the first analysis are in the partition designated by _DEPVAR_='Spline(Y2)', which are the transformation and dependent variable names. Each partition has _TYPE_='SCORE' observations for the variables and a _TYPE_='M COEFFI' observation for the coefficients. In this example, an ID variable is specified, so the _NAME_ variable contains the formatted values of the first ID variable. Since both dependent variables have to go into the same column, the dependent variable is given a new name, _DEPEND_. The dependent variable transformation is named T_DEPEND_, the predicted values variable is named P_DEPEND_, and the residuals variable is named R_DEPEND_.

The independent variables are character OPSCORE variables. By default, PROC TRANSREG replaces character OPSCORE variables with category numbers and discards the original character variables. To avoid this, the input variables are renamed from X1 and X2 to N1 and N2 and the original X1 and X2 are added to the data set as ID variables. The N1 and N2 variables contain the initial values for the OPSCORE transformations, and the TN1 and TN2 variables contain optimal scores. The data set also contains an Intercept and transformed intercept TIntercept variable. The regression coefficients are in the transformation columns, which also contain the variables to which they apply.

Output Data Set Contents

This section presents the various matrices that can result from PROC TRANSREG processing and that appear in the OUT= data set. The exact contents of an OUT= data set depends on many options.

Table 75.6. PROC TRANSREG OUT= Data Set Contents

TYPE	Contents	Options, Default Prefix
SCORE	dependent variables	DREPLACE not specified
SCORE	independent variables	IREPLACE not specified
SCORE	transformed dependent variables	default, TDPREFIX=T
SCORE	transformed independent variables	default, TIPREFIX=T
SCORE	predicted values	PREDICTED, PPREFIX=P
SCORE	residuals	RESIDUALS, RDPREFIX=R
SCORE	leverage	LEVERAGE, LEVERAGE=Leverage
SCORE	lower individual confidence limits	CLI, LILPREFIX=LIL, CILPREFIX=CIL
SCORE	upper individual confidence limits	CLI, LIUPREFIX=LIU, CIUPREFIX=CIU
SCORE	lower mean confidence limits	CLM, LMLPREFIX=LML, CMLPREFIX=CML
SCORE	upper mean confidence limits	CLM, LMUPREFIX=LMU, CMUPREFIX=CMU
SCORE	dependent canonical variables	CANONICAL, CDPREFIX=Cand
SCORE	independent canonical variables	CANONICAL, CIPREFIX=Cani
SCORE	redundancy variables	REDUNDANCY, RPREFIX=Red
SCORE	ID, CLASS, BSPLINE variables	ID, CLASS, BSPLINE,
SCORE	independent variables approximations	IAPPROXIMATIONS, IAPREFIX=A
M COEFFI	multiple regression coefficients	COEFFICIENTS, MRC
C COEFFI	canonical coefficients	COEFFICIENTS, CCC
MEAN	marginal means	COEFFICIENTS, MEANS
M REDUND	multiple redundancy coefficients	MREDUNDANCY
R REDUND	multiple redundancy coefficients	MREDUNDANCY
M POINT	point coordinates	COORDINATES or MPC, POINT
M EPOINT	elliptical point coordinates	COORDINATES or MEC, EPOINT
M QPOINT	quadratic point coordinates	COORDINATES or MQC, QPOINT
C POINT	canonical point coordinates	COORDINATES or CPC, POINT
C EPOINT	canonical elliptical point coordinates	COORDINATES or CEC, EPOINT
C QPOINT	canonical quadratic point coordinates	COORDINATES or CQC, QPOINT

The independent and dependent variables are created from the original input data. Several potential differences exist between these variables and the actual input data. An intercept variable can be added, new variables can be added for POINT, EPOINT, QPOINT, CLASS, IDENTITY, PSPLINE, and BSPLINE variables, and category numbers are substituted for character OPSCORE variables. These matrices are not always what is input to the first iteration. After the expanded data set is stored for inclusion in the output data set, several things happen to the data before they are input to the first iteration: column means are substituted for missing values; zero degree SPLINE and MSPLINE variables are transformed so that the iterative algorithms get

step function data as input, which conform to the zero degree transformation family restrictions; and the nonoptimal transformations are performed.

Details for the UNIVARIATE Method

When you specify METHOD=UNIVARIATE (in the MODEL or PROC TRANSREG statement), PROC TRANSREG can perform several analyses, one for each dependent variable. While each dependent variable can be transformed, their independent variables are not transformed. The OUT= data set optionally contains all of the _TYPE_='SCORE' observations, optionally followed by coefficients or coordinates.

Details for the MORALS Method

When you specify METHOD=MORALS (in the MODEL or PROC TRANSREG statement), successive analyses are performed, one for each dependent variable. Each analysis transforms one dependent variable and the entire set of the independent variables. All information for the first dependent variable (scores then, optionally, coefficients) appear first. Then all information for the second dependent variable (scores then, optionally, coefficients) appear next. This arrangement is repeated for all dependent variables.

Details for the CANALS and REDUNDANCY Methods

For METHOD=CANALS and METHOD=REDUNDANCY (specified in either the MODEL or PROC TRANSREG statement), one analysis is performed that simultaneously transforms all dependent and independent variables. The OUT= data set optionally contains all of the _TYPE_='SCORE' observations, optionally followed by coefficients or coordinates.

Variable Names

As shown in the preceding examples, some variables in the output data set directly correspond to input variables and some are created. All original optimal and nonoptimal transformation variable names are unchanged.

The names of the POINT, QPOINT, and EPOINT expansion variables are also left unchanged, but new variables are created. When independent POINT variables are present, the sum-of-squares variable _ISSQ_ is added to the output data set. For each EPOINT and QPOINT variable, a new squared variable is created by appending “_2”. For example, Dim1 and Dim2 are expanded into Dim1, Dim2, Dim1_2, and Dim2_2. In addition, for each pair of QPOINT variables, a new crossproduct variable is created by combining the two names, for example, Dim1Dim2.

The names of the CLASS variables are constructed from original variable names and levels. Lengths are controlled by the CPREFIX= *a-option*. For example, when X1 and X2 both have values of 'a' and 'b', CLASS(X1 | X2 / ZERO=NONE) creates X1 main effect variable names X1a X1b, X2 main effect variable names X2a X2b, and interaction variable names X1aX2a X1aX2b X1bX2a X1bX2b.

PROC TRANSREG then uses these variable names when creating the transformed, predicted, and residual variable names by affixing the relevant prefix and possibly dropping extra characters.

METHOD=MORALS Variable Names

When you specify METHOD=MORALS and only one dependent variable is present, the output data set is structured exactly as if METHOD=REDUNDANCY (see the section “[Details for the CANALS and REDUNDANCY Methods](#)” on page 4625). When more than one dependent variable is present, the dependent variables are output in the variable `_DEPEND_`, transformed dependent variables are output in the variable `T_DEPEND_`, predicted values are output in the variable `P_DEPEND_`, and residuals are output in the variable `R_DEPEND_`. You can partition the data set into BY groups, one per dependent variable, by referring to the character variable `_DEPVAR_`, which contains the original dependent variable names and transformations.

Duplicate Variable Names

When the same name is generated from multiple variables in the OUT= data set, new names are created by appending '2', '3', or '4', and so on, until a unique name is created. For 32-character names, the last character is replaced with a numeric suffix until a unique name is created. For example, if there are two output variables that otherwise would be named X, then X and X2 are created instead. If there are two output variables that otherwise would be named ThisIsAThirtyTwoCharacterVarName, then ThisIsAThirtyTwoCharacterVarName and ThisIsAThirtyTwoCharacterVarNam2 are created instead.

OUTTEST= Output Data Set

The OUTTEST= data set contains hypothesis test results. The OUTTEST= data set always contains ANOVA results. When you specify the *SS2 a-option*, regression tables are also output. When you specify the *UTILITIES a-option*, conjoint analysis part-worth utilities are also output. The OUTTEST= data set has the following variables:

<code>_DEPVAR_</code>	is a 42-character variable that contains the dependent variable transformation and name.
<code>_TYPE_</code>	is an 8-character variable that contains the table type. The first character is “U” for univariate or “M” for multivariate. The second character is blank. The third character is “A” for ANOVA, “2” for Type II sum of squares, or “U” for UTILITIES. The fourth character is blank. The fifth character is “L” for liberal tests, “C” for conservative tests, or “U” for the usual tests.
Title	is an 80-character variable that contains the table title.
Variable	is a 42-character variable that contains the independent variable transformations and names for regression tables and blanks for ANOVA tables.
Coefficient	contains the multiple regression coefficients for regression tables and underscore special missing values for ANOVA tables.
Statistic	is a 24-character variable that contains the names for statistics in other variables, such as Value.

Value	contains multivariate test statistics and all other information that does not fit in one of the other columns including R-Square, Dependent Mean, Adj R-Sq, and Coeff Var. Whenever Value is not an underscore special missing value, Statistic describes the contents of Value.
NumDF	contains numerator degrees of freedom for F tests.
DenDF	contains denominator degrees of freedom for F tests.
SSq	contains sums of squares.
MeanSquare	contains mean squares.
F	contains F statistics.
NumericP	contains the p -value for the F statistic, stored in a numeric variable.
P	is a 9-character variable that contains the formatted p -value for the F statistic, including the appropriate \sim , \leq , \geq , or blank symbols.
LowerLimit	contains lower confidence limits on the parameter estimates.
UpperLimit	contains upper confidence limits on the parameter estimates.
StdError	contains standard errors. For SS2 and UTILITIES tables, standard errors are output for each coefficient with one degree of freedom.
Importance	contains the relative importance of each factor for UTILITIES tables.
Label	is a 256-character variable that contains variable labels.

There are several possible tables in the OUTTEST= data set corresponding to combinations of univariate and multivariate tests; ANOVA and regression results; and liberal, conservative, and the usual tests. Each table is composed of only a subset of the variables. Numeric variables contain underscore special missing values when they are not a column in a table. Ordinary missing values (.) appear in variables that are part of a table when a nonmissing value cannot be produced. For example, the F is missing for a test with zero degrees of freedom.

Computational Resources

This section provides information on the computational resources required to use PROC TRANSREG.

Let

- n = number of observations
- q = number of expanded independent variables
- r = number of expanded dependent variables
- k = maximum spline degree
- p = maximum number of knots

- More than $56(q + r)$ plus the maximum of the data matrix size, the optimal scaling work space, and the covariance matrix size bytes of array space are required. The data matrix size is $8n(q + r)$ bytes. The optimal scaling work space requires less than $8(6n + (p + k + 2)(p + k + 11))$ bytes. The covariance matrix size is $4(q + r)(q + r + 1)$ bytes.
- PROC TRANSREG tries to store the original and transformed data in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time. The amount of memory for the preceding data formulas is an underestimate of the amount of memory needed to handle most problems. These formulas give the absolute minimum amount of memory required. If a utility data set is used, and if memory can be used with perfect efficiency, then roughly the amount of memory stated previously is needed. In reality, most problems require at least two or three times the minimum.
- PROC TRANSREG sorts the data once. The sort time is roughly proportional to $(q + r)n^{3/2}$.
- One regression analysis per iteration is required to compute model parameters (or two canonical correlation analyses per iteration for METHOD=CANALS). The time required for accumulating the crossproducts matrix is roughly proportional to $n(q + r)^2$. The time required to compute the regression coefficients is roughly proportional to q^3 .
- Each optimal scaling is a multiple regression problem, although some transformations are handled with faster special-case algorithms. The number of regressors for the optimal scaling problems depends on the original values of the variable and the type of transformation. For each monotone spline transformation, an unknown number of multiple regressions is required to find a set of coefficients that satisfies the constraints. The B-spline basis is generated twice for each SPLINE and MSPLINE transformation for each iteration. The time required to generate the B-spline basis is roughly proportional to nk^2 .

Solving Standard Least-Squares Problems

This section illustrates how to solve some ordinary least-squares problems and generalizations of those problems by formulating them as transformation regression problems. One problem involves finding linear and nonlinear regression functions in a scatter plot. The next problem involves simultaneously fitting two lines or curves through a scatter plot. The last problem involves finding the overall fit of a multi-way main-effects and interactions analysis-of-variance model.

Nonlinear Regression Functions

This example uses PROC TRANSREG in simple regression to find the optimal regression line, a nonlinear but monotone regression function, and a nonlinear non-monotone regression function. A regression line can be found by specifying

```
proc transreg;
  model identity(y) = identity(x);
  output predicted;
run;
```

A monotone regression function (in this case, a monotonically decreasing regression function, since the correlation coefficient is negative) can be found by requesting an MSPLINE transformation of the independent variable, as follows.

```
proc transreg;
  model identity(y) = mspline(x / nknots=9);
  output predicted;
run;
```

The monotonicity restriction can be relaxed by requesting a SPLINE transformation of the independent variable, as shown next.

```
proc transreg;
  model identity(y) = spline(x / nknots=9);
  output predicted;
run;
```

In this example, it is not useful to plot the transformation TX, since TX is just an intermediate result used in finding a regression function through the original X and Y scatter plot.

The following statements provide a specific example of using the TRANSREG procedure for fitting nonlinear regression functions. These statements produce [Figure 75.15](#) through [Figure 75.18](#).

Figure 75.17. A Nonmonotone Regression Function

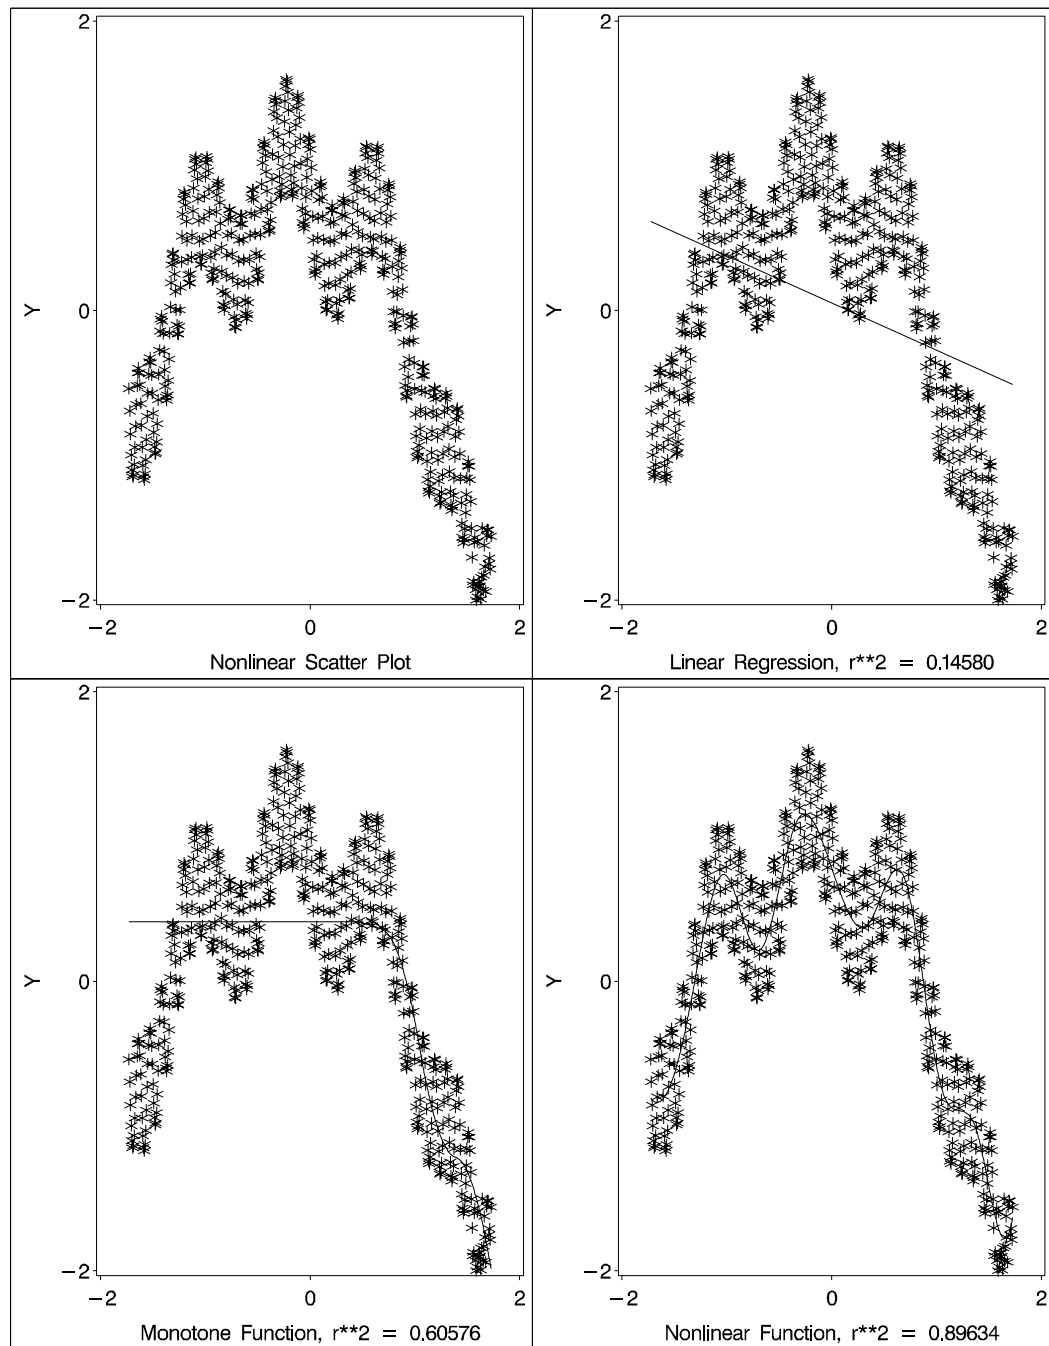

Figure 75.18. Linear, Monotone, and Nonmonotone Regression Functions

The squared correlation is only 0.15 for the linear regression, showing that a simple linear regression model is not appropriate for these data. By relaxing the constraints placed on the regression line, the proportion of variance accounted for increases from 0.15 (linear) to 0.61 (monotone) to 0.90 (nonmonotone). Relaxing the linearity constraint allows the regression function to bend and more closely follow the right portion of the scatter plot. Relaxing the monotonicity constraint allows the regression

function to follow the periodic portion of the left side of the plot more closely. The nonlinear MSPLINE transformation is a quadratic spline with knots at the deciles. The nonlinear nonmonotonic SPLINE transformation is a cubic spline with knots at the deciles.

Different knots and different degrees would produce slightly different results. The two nonlinear regression functions could be closely approximated by simpler piecewise linear regression functions. The monotone function could be approximated by a two-piece line with a single knot at the elbow. The nonmonotone function could be approximated by a six-piece function with knots at the five elbows.

With this type of problem (one dependent variable with no missing values that is not transformed and one independent variable that is nonlinearly transformed), PROC TRANSREG always iterates exactly twice (although only one iteration is necessary). The first iteration reports the R^2 for the linear regression line and finds the optimal transformation of X . Since the data change in the first iteration, a second iteration is performed, which reports the R^2 for the final nonlinear regression function, and zero data change. The predicted values, which are a linear function of the optimal transformation of X , contain the y -coordinates for the nonlinear regression function. The variance of the predicted values divided by the variance of Y is the R^2 for the fit of the nonlinear regression function. When X is monotonically transformed, the transformation of X is always monotonically increasing, but the predicted values increase if the correlation is positive and decrease for negative correlations.

Simultaneously Fitting Two Regression Functions

One application of ordinary multiple regression is fitting two or more regression lines through a single scatter plot. With PROC TRANSREG, this application can easily be generalized to fit separate or parallel curves. To illustrate, consider a data set with two groups. The data set has a continuous independent variable X , a continuous dependent variable Y , and a group membership variable G that has the value 1 for one group and 2 for the other group. The following code shows how PROC TRANSREG can be used to fit two lines, curves, and monotone curves simultaneously through a scatter plot. You can use this code with an appropriate number-list for the `KNOTS=` *t-option*.

```
proc transreg data=A dummy;
  title 'Parallel Lines, Separate Intercepts';
  model identity(Y)=class(G) identity(X);
  output predicted;
run;

proc transreg data=A;
  title 'Parallel Monotone Curves, Separate Intercepts';
  model identity(Y)=class(G) mspline(X / knots=-1.5 to 2.5 by 0.5);
  output predicted;
run;

proc transreg data=A dummy;
  title 'Parallel Curves, Separate Intercepts';
  model identity(Y)=class(G) spline(X / knots=-1.5 to 2.5 by 0.5);
```

```

        output predicted;
run;

proc transreg data=A;
    title 'Separate Slopes, Same Intercept';
    model identity(Y)=class(G / zero=none) * identity(X);
    output predicted;
run;

proc transreg data=A;
    title 'Separate Monotone Curves, Same Intercept';
    model identity(Y) = class(G / zero=none) *
                        mspline(X / knots=-1.5 to 2.5 by 0.5);
    output predicted;
run;

proc transreg data=A dummy;
    title 'Separate Curves, Same Intercept';
    model identity(Y) = class(G / zero=none) *
                        spline(X / knots=-1.5 to 2.5 by 0.5);
    output predicted;
run;

proc transreg data=A;
    title 'Separate Slopes, Separate Intercepts';
    model identity(Y) = class(G / zero=none) | identity(X);
    output predicted;
run;

proc transreg data=A;
    title 'Separate Monotone Curves, Separate Intercepts';
    model identity(Y) = class(G / zero=none) |
                        mspline(X / knots=-1.5 to 2.5 by 0.5);
    output predicted;
run;

proc transreg data=A dummy;
    title 'Separate Curves, Separate Intercepts';
    model identity(Y) = class(G / zero=none) |
                        spline(X / knots=-1.5 to 2.5 by 0.5);
    output predicted;
run;

```

Since the variables X1 and X2 both have a large partition of zeros, the `KNOTS=` *t-option* is specified instead of the `NKNOTS=` *t-option*. The following example generates an artificial data set with two curves. In the interest of space, only the preceding separate curves, separate intercepts example is run.

```

title 'Separate Curves, Separate Intercepts';

data A;
  do X = -2 to 3 by 0.025;
    G = 1;
    Y = 8*(X*X + 2*cos(X*6)) + 15*normal(7654321);
    output;
    G = 2;
    Y = 4*(-X*X + 4*sin(X*4)) - 40 + 15*normal(7654321);
    output;
  end;
run;

proc transreg data=A dummy;
  model identity(Y) = class(G / zero=none) |
                    spline(X / knots=-1.5 to 2.5 by 0.5);
  output predicted;
run;

proc gplot;
  axis1 minor=none;
  axis2 minor=none label=(angle=90 rotate=0);
  symbol1 color=blue v=star i=none;
  symbol2 color=yellow v=dot i=none;
  plot Y*X=1 PY*X=2 /overlay frame cframe=ligr haxis=axis1
      vaxis=axis2 href=0 vref=0;
run; quit;

```

The previous statements produce [Figure 75.19](#) through [Figure 75.20](#).

Figure 75.20. Plot for the Separate Curves, Separate Intercepts Example

Unbalanced ANOVA without Dummy Variables

This example illustrates that an analysis of variance model can be formulated as a simple regression model with optimal scoring. The purpose of the example is to explain one aspect of how PROC TRANSREG works, not to propose an alternative way of performing an analysis of variance.

Finding the overall fit of a large, unbalanced analysis of variance model can be handled as an optimal scoring problem without creating large, sparse design matrices. For example, consider an unbalanced full main-effects and interactions ANOVA model with six factors. Assume that a SAS data set is created with factor level indicator variables C1 through C6 and dependent variable Y. If each factor level consists of nonblank single characters, you can create a cell indicator in a DATA step with the statement

```
x=compress(c1||c2||c3||c4||c5||c6);
```

The following statements optimally score X (using the OPSCORE transformation) and do not transform Y. The final R^2 reported is the R^2 for the full analysis of variance model.

```
proc transreg;
  model identity(y)=opscore(x);
  output;
run;
```

The R^2 displayed by the preceding statements is the same as the R^2 that would be reported by both of the following PROC GLM runs.

```
proc glm;
  class x;
  model y=x;
run;

proc glm;
  class c1-c6;
  model y=c1|c2|c3|c4|c5|c6;
run;
```

PROC TRANSREG optimally scores the classes of X , within the space of a single variable with values linearly related to the cell means, so the full ANOVA problem is reduced to a simple regression problem with an optimal independent variable. PROC TRANSREG requires only one iteration to find the optimal scoring of X but, by default, performs a second iteration, which reports no data changes.

Hypothesis Tests for Simple Univariate Models

If the dependent variable has one parameter (IDENTITY, LINEAR with no missing values, and so on) and if there are no monotonicity constraints, PROC TRANSREG fits univariate models, which can also be fit with a DATA step and PROC REG. This is illustrated with an artificial data set.

```
data htex;
  do i = 0.5 to 10 by 0.5;
    x1 = log(i);
    x2 = sqrt(i) + sin(i);
    x3 = 0.05 * i * i + cos(i);
    y = x1 - x2 + x3 + 3 * normal(7);
    x1 = x1 + normal(7);
    x2 = x2 + normal(7);
    x3 = x3 + normal(7);
    output;
  end;
run;
```

Both PROC TRANSREG and PROC REG are run to fit the same polynomial regression model. The ANOVA and regression tables from PROC TRANSREG are displayed in [Figure 75.21](#). The ANOVA and regression tables from PROC REG are displayed in [Figure 75.22](#). The SHORT *a-option* is specified to suppress the iteration history.

```
proc transreg data=htex ss2 short;
  title 'Fit a Polynomial Regression Model with PROC TRANSREG';
  model identity(y) = spline(x1);
run;
```

Figure 75.22. ANOVA and Regression Output from PROC REG

The PROC TRANSREG regression table differs in several important ways from the parameter estimate table produced by PROC REG. The REG procedure displays standard errors and *ts*. PROC TRANSREG displays Type II sums of squares, mean squares, and *F*s. The difference is because the numerator degrees of freedom are not always 1, so *t*-tests are not uniformly appropriate. When the degrees of freedom for variable x_j is 1, the following relationships hold between the standard errors (s_{β_j}) and the Type II sums of squares (SS_j):

$$s_{\beta_j} = (\hat{\beta}_j^2 / F_j)^{1/2}$$

and

$$SS_j = \hat{\beta}_j^2 \times MSE / s_{\beta_j}^2$$

PROC TRANSREG does not provide tests of the individual terms that go into the transformation. (However it could if BSPLINE or PSPLINE had been specified instead of SPLINE.) The test of SPLINE(X1) is the same as the test of the overall

model. The intercepts are different due to the different numbers of variables and their standardizations.

In the next example, both X1 and X2 are transformed in the first PROC TRANSREG step, and PROC TRANSREG is used instead of a DATA step to create the polynomials for PROC REG. Both PROC TRANSREG and PROC REG fit the same polynomial regression model. The output from PROC TRANSREG and PROC REG is in [Figure 75.23](#).

```
proc transreg data=htex ss2 dummy;
  title 'Two-Variable Polynomial Regression';
  model identity(y) = spline(x1 x2);
run;

proc transreg noprint data=htex maxiter=0;
  /* Use PROC TRANSREG to prepare input to PROC REG */
  model identity(y) = pspline(x1 x2);
  output out=htex2;
run;

proc reg;
  model y = x1_1-x1_3 x2_1-x2_3;
  test x1_1, x1_2, x1_3;
  test x2_1, x2_2, x2_3;
run;
```

Figure 75.23. (continued)

There are three iteration histories: one for the overall model and two for the two independent variables. The first PROC TRANSREG iteration history shows the R^2 of 0.17287 for the fit of the overall model. The second is for

```
model identity(y) = spline(x2);
```

which excludes SPLINE(X1). The third is for

```
model identity(y) = spline(x1);
```

which excludes SPLINE(X2). The difference between the first and second R^2 times the total sum of squares is the model sum of squares for SPLINE(X1)

$$(0.17287 - 0.15249) \times 224.143800 = 4.568165$$

The difference between the first and third R^2 times the total sum of squares is the model sum of squares for SPLINE(X2)

$$(0.17287 - 0.02604) \times 224.143800 = 32.911247$$

The TEST statement in PROC REG tests the null hypothesis that the vector of parameters for X1_1 X1_2 X1_3 is zero. This is the same test as the SPLINE(X1)

test used by PROC TRANSREG. Similarly, the PROC REG test that the vector of parameters for X2_1 X2_2 X2_3 is zero is the same as the PROC TRANSREG SPLINE(X2) test. So for models with no monotonicity constraints and no dependent variable transformations, PROC TRANSREG provides little more than a different packaging of standard least-squares methodology.

Hypothesis Tests with Monotonicity Constraints

Now consider a model with monotonicity constraints. This model has no counterpart in PROC REG.

```
proc transreg data=htex ss2 short;
  title 'Monotone Splines';
  model identity(y) = mspline(x1-x3 / nknots=3);
run;
```

The SHORT *a-option* is specified to suppress the iteration histories. Two ANOVA tables are displayed—one using liberal degrees of freedom and one using conservative degrees of freedom. All sums of squares and the R^2 s are the same for both tables. What differs are the degrees of freedom and statistics that are computed using degrees of freedom. The liberal test has 8 model degrees of freedom and 11 error degrees of freedom, whereas the conservative test has 15 model degrees of freedom and only 4 error degrees of freedom. The “true” p -value is between 0.8462 and 0.9997, so clearly you would fail to reject the null hypothesis. Unfortunately, results are not always this clear. See [Figure 75.24](#).

Figure 75.24. (continued)

Hypothesis Tests with Dependent Variable Transformations

PROC TRANSREG can also provide approximate tests of hypotheses when the dependent variable is transformed, but the output is more complicated. When a dependent variable has more than one degree of freedom, the problem becomes multivariate. Hypothesis tests are performed in the context of a multivariate linear model with the number of dependent variables equal to the number of scoring parameters for the dependent variable transformation. The transformation regression model with a dependent variable transformation differs from the usual multivariate linear model in two important ways. First, the usual assumption of multivariate normality is always violated. This fact is simply ignored. This is one reason that all hypothesis tests in the presence of a dependent variable transformation should be considered approximate at best. Multivariate normality is assumed even though it is known that the assumption is violated.

The second difference concerns the usual multivariate test statistics: Pillai's Trace, Wilks' Lambda, Hotelling-Lawley Trace, and Roy's Greatest Root. The first three statistics are defined in terms of all the squared canonical correlations. Here, there is only one linear combination (the transformation) and, hence, only one squared canonical correlation of interest, which is equal to the R^2 . It may seem that Roy's Greatest Root, which uses only the largest squared canonical correlation, is the only statistic of interest. Unfortunately, Roy's Greatest Root is very liberal and provides only a lower bound on the p -value. Approximate upper bounds are provided by adjusting the other three statistics for the one linear combination case. The Wilks' Lambda,

Pillai's Trace, and Hotelling-Lawley Trace statistics are a conservative adjustment of the usual statistics.

These statistics are normally defined in terms of the squared canonical correlations, which are the eigenvalues of the matrix $\mathbf{H}(\mathbf{H} + \mathbf{E})^{-1}$, where \mathbf{H} is the hypothesis sum-of-squares matrix and \mathbf{E} is the error sum-of-squares matrix. Here the R^2 is used for the first eigenvalue, and all other eigenvalues are set to 0 since only one linear combination is used. Degrees of freedom are computed assuming that all linear combinations contribute to the Lambda and Trace statistics, so the F tests for those statistics are conservative. The p -values for the liberal and conservative statistics provide approximate lower and upper bounds on p . In practice, the adjusted Pillai's Trace is very conservative—perhaps too conservative to be useful. Wilks' Lambda is less conservative, and the Hotelling-Lawley Trace seems to be the least conservative. The conservative statistics and the liberal Roy's Greatest Root provide a bound on the true p -value. Unfortunately, they sometimes report a bound of 0.0001 and 1.0000.

Here is an example with a dependent variable transformation.

```
proc transreg data=htex ss2 dummy short;  
  title 'Transform Dependent and Independent Variables';  
  model spline(y) = spline(x1-x3);  
run;
```

The univariate results match Roy's Greatest Root results. Clearly, the proper action is to fail to reject the null hypothesis. However, as stated previously, results are not always this clear. See [Figure 75.25](#).

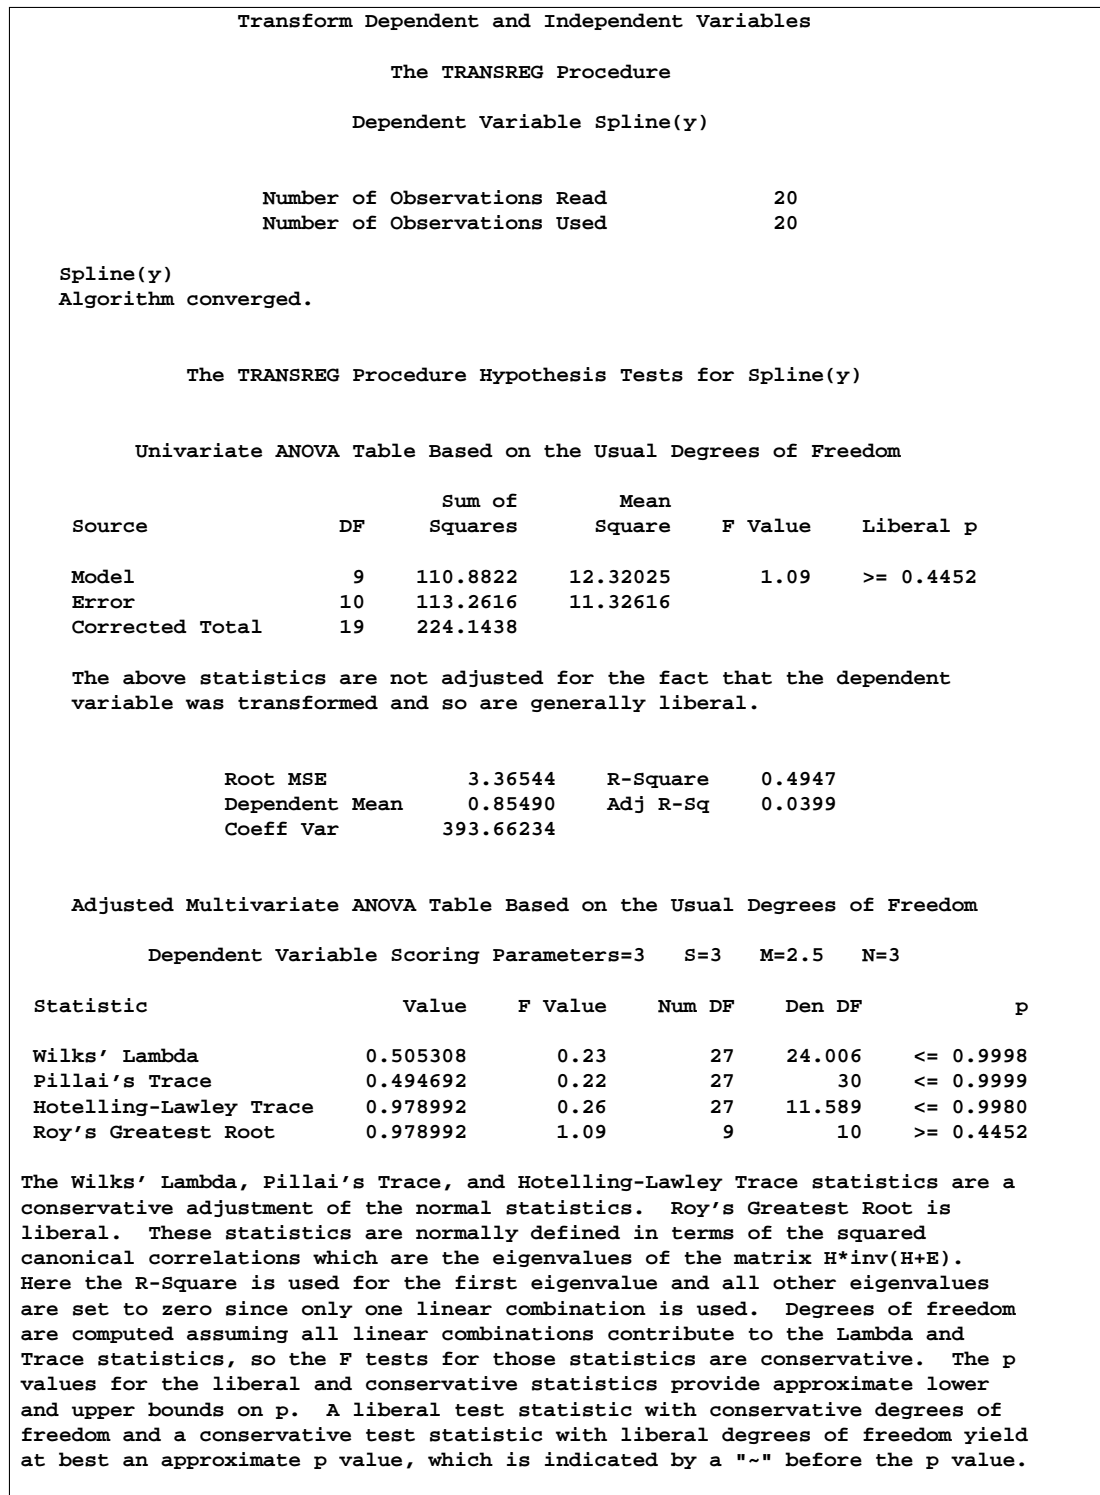

Figure 75.25. Transform Dependent and Independent Variables

Transform Dependent and Independent Variables						
The TRANSREG Procedure						
Univariate Regression Table Based on the Usual Degrees of Freedom						
Variable	DF	Coefficient	Type II Sum of Squares	Mean Square	F Value	Liberal p
Intercept	1	6.9089087	117.452	117.452	10.37	>= 0.0092
Spline(x1)	3	-1.0832321	32.493	10.831	0.96	>= 0.4504
Spline(x2)	3	-2.1539191	45.251	15.084	1.33	>= 0.3184
Spline(x3)	3	0.4779207	10.139	3.380	0.30	>= 0.8259

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Adjusted Multivariate Regression Table Based on the Usual Degrees of Freedom							
Variable	Coefficient	Statistic	Value	F Value	Num DF	Den DF	p
Intercept	6.9089087	Wilks' Lambda	0.49092	2.77	3	8	0.1112
		Pillai's Trace	0.50908	2.77	3	8	0.1112
		Hotelling-Lawley Trace	1.036993	2.77	3	8	0.1112
		Roy's Greatest Root	1.036993	2.77	3	8	0.1112
Spline(x1)	-1.0832321	Wilks' Lambda	0.777072	0.24	9	19.621	<= 0.9840
		Pillai's Trace	0.222928	0.27	9	30	<= 0.9787
		Hotelling-Lawley Trace	0.286883	0.24	9	9.8113	<= 0.9784
		Roy's Greatest Root	0.286883	0.96	3	10	>= 0.4504
Spline(x2)	-2.1539191	Wilks' Lambda	0.714529	0.32	9	19.621	<= 0.9572
		Pillai's Trace	0.285471	0.35	9	30	<= 0.9494
		Hotelling-Lawley Trace	0.399524	0.33	9	9.8113	<= 0.9424
		Roy's Greatest Root	0.399524	1.33	3	10	>= 0.3184
Spline(x3)	0.4779207	Wilks' Lambda	0.917838	0.08	9	19.621	<= 0.9998
		Pillai's Trace	0.082162	0.09	9	30	<= 0.9996
		Hotelling-Lawley Trace	0.089517	0.07	9	9.8113	<= 0.9997
		Roy's Greatest Root	0.089517	0.30	3	10	>= 0.8259

These statistics are adjusted in the same way as the multivariate statistics above.

Figure 75.25. (continued)

Hypothesis Tests with One-Way ANOVA

One-way ANOVA models are fit with either an explicit or implicit intercept. In implicit intercept models, the ANOVA table of PROC TRANSREG is the correct table for a model with an intercept, and the regression table is the correct table for a model

that does not have a separate explicit intercept. The PROC TRANSREG implicit intercept ANOVA table matches the PROC REG table when the NOINT *a-option* is not specified, and the PROC TRANSREG implicit intercept regression table matches the PROC REG table when the NOINT *a-option* is specified. The following code illustrates this relationship. See [Figure 75.26](#) through [Figure 75.27](#) for the results.

Figure 75.27. (continued)

Using the DESIGN Output Option

This example uses PROC TRANSREG and the DESIGN *o-option* to prepare an input data set with classification variables for the LOGISTIC procedure. The DESIGN *o-option* specifies that the goal is design matrix creation, not analysis. When you specify DESIGN, dependent variables are not required. The DEVIATIONS (or EFFECTS) *t-option* requests a deviations-from-means (1, 0, -1) coding of the classification variables, which is the same coding the CATMOD procedure uses. See Figure 75.28. PROC TRANSREG automatically creates a macro variable `&_trgind` that contains the list of independent variables created. This macro is used in the PROC LOGISTIC MODEL statement. See Figure 75.29. For comparison, the same analysis is also performed with PROC CATMOD. See Figure 75.30.

```

Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO

A discrete choice experiment is constructed consisting of four product brands, each available at three different prices, \$1.49, \$1.99, \$2.49. In addition, each choice set contains a constant “other” alternative available at \$1.49. In the fifth choice set, price is constant. PROC TRANSREG is used to code the design and the PHREG procedure fits the multinomial logit choice model (not shown). See http://www.sas.com/service/techsup/tnote/tnote_stat.html for more information on discrete choice modeling and the multinomial logit model. Look for the latest “Multinomial Logit, Discrete Choice Modeling” report.

```

```

In the interest of space, only the fifth choice set is displayed in [Figure 75.31](#).

Choice Model Coding							
Obs	set	brand	brand1	brand2	brand3	brand4	price
21	5	1	1	0	0	0	1.49
22	5	2	0	1	0	0	1.49
23	5	3	0	0	1	0	1.49
24	5	4	0	0	0	1	1.49
25	5	.	0	0	0	0	1.49

Figure 75.31. The Fifth Choice Set

For the constant alternative (BRAND = .), the brand coding is a row of zeros due to the NORESTOREMISSING *o-option*, and PRICE is a constant \$1.49 (instead of 0) due to the NOZEROCONSTANT *a-option*.

The data set was coded by choice set (BY set;). This is a small problem, but with very large problems, it may be necessary to restrict the number of observations that are coded at one time so that the procedure uses less time and memory. Coding by choice set is one option. When coding is performed after the data are merged in, coding by subject and choice set combinations is another option. Alternatively, you can specify DESIGN=*n*, where *n* is the number of observations to code at one time. For example, you can specify DESIGN=100 or DESIGN=1000 to process the data set in blocks of 100 or 1000 observations. Specify the NOZEROCONSTANT option to ensure that constant variables within blocks are not zeroed. When you specify DESIGN=*n*, or perform coding after the data are merged in, specify the dependent variable and any other variables needed for analysis as ID variables.

ANOVA Codings

This set of examples illustrates several different ways to code the same two-way ANOVA model. [Figure 75.32](#) displays the input data set.

Figure 75.44. Less-Than-Full-Rank Model, Design Matrix

Centering

You can use transformation options to center and standardize the variables in several ways. For example, this MODEL statement creates three independent variables, x , x^2 , and x^3 .

```
model identity(y) = pspline(x);
```

The variables are not centered.

When the CENTER *t-option* is specified, the three independent variables are $x - \bar{x}$, $(x - \bar{x})^2$, and $(x - \bar{x})^3$.

```
model identity(y) = pspline(x / center);
```

Since operations such as squaring occur after the centering, the resulting variables will not always be centered. The CENTER *t-option* is particularly useful with polynomials since centering before squaring and cubing can help reduce collinearity and

numerical problems. For example, if one of your variables is year, with values all greater than 1900. Squaring and cubing without centering first will create variables that are all essentially perfectly correlated.

When the TSTANDARD=CENTER *t-option* is specified, the three independent variables are $x - \bar{x}$, $x^2 - \overline{x^2}$, and $x^3 - \overline{x^3}$.

```
model identity(y) = pspline(x / tstandard=center);
```

In this case, the variables are squared and cubed and then centered.

Displayed Output

The display options control the amount of displayed output. The displayed output can contain

- an iteration history and convergence status table, by default
- an ANOVA table when the TEST, SS2, or UTILITIES *a-option* is specified
- a regression table when the SS2 *a-option* is specified
- conjoint analysis part-worth utilities when the UTILITIES *a-option* is specified
- model details when the DETAIL *a-option* is specified
- a multivariate ANOVA table when the dependent variable is transformed and the TEST or SS2 *a-option* is specified
- a multivariate regression table when the dependent variable is transformed and it is specified
- liberal and conservative ANOVA, multivariate ANOVA, regression, and multivariate regression tables when there are MONOTONE, UNTIE, or MSPLINE transformations and the TEST or SS2 *a-option* is specified

ODS Table Names

PROC TRANSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 75.7. ODS Tables Produced in PROC TRANSREG

*1. Liberal and conservative test tables are produced when a MONOTONE, UNTIE, or MSPLINE, transformation is requested.

*2. Multivariate tables are produced when the dependent variable is iteratively transformed.

Examples

Example 75.1. Using Splines and Knots

This example illustrates some properties of splines. *Splines* are curves, which are usually required to be continuous and smooth. Splines are usually defined as piecewise polynomials of degree n with function values and first $n - 1$ derivatives that agree at the points where they join. The abscissa values of the join points are called *knots*. The term “spline” is also used for polynomials (splines with no knots) and piecewise polynomials with more than one discontinuous derivative. Splines with no knots are generally smoother than splines with knots, which are generally smoother than splines with multiple discontinuous derivatives. Splines with few knots are generally smoother than splines with many knots; however, increasing the number of knots usually increases the fit of the spline function to the data. Knots give the curve freedom to bend to more closely follow the data. Refer to Smith (1979) for an excellent introduction to splines.

In this example, an artificial data set is created with a variable Y that is a discontinuous function of X . See the first plot in [Output 75.1.7](#). Notice that the function has four unconnected parts, each of which is a curve. Notice too that there is an overall quadratic trend, that is, ignoring the shapes of the individual curves, at first the Y values tend to decrease as X increases, then Y values tend to increase.

The first PROC TRANSREG analysis fits a linear regression model. The predicted values of Y given X are output and plotted to form the linear regression line. The R^2 for the linear regression is 0.10061, and it can be seen from the second plot in [Output 75.1.7](#) that the linear regression model is not appropriate for these data. The following statements create the data set and perform the first PROC TRANSREG analysis. These statements produce [Output 75.1.1](#).

```

title 'An Illustration of Splines and Knots';

* Create in Y a discontinuous function of X.
*
* Store copies of X in V1-V7 for use in PROC GPLOT.
* These variables are only necessary so that each
* plot can have its own x-axis label while putting
* four plots on a page.;

data A;
  array V[7] V1-V7;
  X=-0.000001;
  do I=0 to 199;
    if mod(I,50)=0 then do;
      C=((X/2)-5)**2;
      if I=150 then C=C+5;
      Y=C;
    end;
    X=X+0.1;
    Y=Y-sin(X-C);
  end;

```

```

do J=1 to 7;
  V[J]=X;
end;
output;
end;
run;

* Each of the PROC TRANSREG steps fits a
* different spline model to the data set created
* previously. The TRANSREG steps build up a data set with
* various regression functions. All of the functions
* are then plotted with the final PROC GPLOT step.
*
* The OUTPUT statements add new predicted values
* variables to the data set, while the ID statements
* save all of the previously created variables that
* are needed for the plots.;

proc transreg data=A;
  model identity(Y) = identity(X);
  title2 'A Linear Regression Function';
  output out=A pprefix=Linear;
  id V1-V7;
run;

```

1	0.00000	0.00000	0.10061		Converged
Algorithm converged.					

The second PROC TRANSREG analysis finds a degree two spline transformation with no knots, which is a quadratic polynomial. The spline is a weighted sum of a single constant, a single straight line, and a single quadratic curve. The R^2 increases from 0.10061, which is the linear fit value from before, to 0.40720. It can be seen from the third plot in [Output 75.1.7](#) that the quadratic regression function does not fit any of the individual curves well, but it does follow the overall trend in the data. Since the overall trend is quadratic, a degree three spline with no knots (not shown) increases R^2 by only a small amount. The following statements perform the quadratic analysis and produce [Output 75.1.2](#).

```
proc transreg data=A;
```

```

model identity(Y)=spline(X / degree=2);
title2 'A Quadratic Polynomial Regression Function';
output out=A pprefix=Quad;
id V1-V7 LinearY;
run;

```

Output 75.1.2. Fitting a Quadratic Polynomial

An Illustration of Splines and Knots A Quadratic Polynomial Regression Function					
The TRANSREG Procedure					
TRANSREG MORALS Algorithm Iteration History for Identity(Y)					
Iteration Number	Average Change	Maximum Change	R-Square	Criterion Change	Note
1	0.82127	2.77121	0.10061		
2	0.00000	0.00000	0.40720	0.30659	Converged

Algorithm converged.

The next step uses the default degree of three, for a piecewise cubic polynomial, and requests knots at the known break points, $X=5$, 10, and 15. This requests a spline that is continuous, has continuous first and second derivatives, and has a third derivative that is discontinuous at 5, 10, and 15. The spline is a weighted sum of a single constant, a single straight line, a single quadratic curve, a cubic curve for the portion of X less than 5, a different cubic curve for the portion of X between 5 and 10, a different cubic curve for the portion of X between 10 and 15, and another cubic curve for the portion of X greater than 15. The new R^2 is 0.61730, and it can be seen from the fourth plot (in [Output 75.1.7](#)) that the spline is less smooth than the quadratic polynomial and it follows the data more closely than the quadratic polynomial. The following statements perform this analysis and produce [Output 75.1.3](#):

```

proc transreg data=A;
model identity(Y) = spline(X / knots=5 10 15);
title2 'A Cubic Spline Regression Function';
title3 'The Third Derivative is Discontinuous at X=5, 10, 15';
output out=A pprefix=Cub1;
id V1-V7 LinearY QuadY;
run;

```

Output 75.1.3. Fitting a Piecewise Cubic Polynomial

An Illustration of Splines and Knots					
A Cubic Spline Regression Function					
The Third Derivative is Discontinuous at X=5, 10, 15					
The TRANSREG Procedure					
TRANSREG MORALS Algorithm Iteration History for Identity(Y)

2	0.00000	0.00000	0.61730	0.51670	Converged

Algorithm converged.

The same model could be fit with a DATA step and PROC REG, as follows. (The output from the following code is not displayed.)

```

data B;          /* A is the data set used for transreg */
  set a(keep=X Y);
  X1=X;          /* X */
  X2=X**2;      /* X squared */
  X3=X**3;      /* X cubed */
  X4=(X> 5)*((X-5)**3); /* change in X**3 after 5 */
  X5=(X>10)*((X-10)**3); /* change in X**3 after 10 */
  X6=(X>15)*((X-15)**3); /* change in X**3 after 15 */
run;

proc reg;
  model Y=X1-X6;
run;

```

In the next step each knot is repeated three times, so the first, second, and third derivatives are discontinuous at $X=5$, 10, and 15, but the spline is required to be continuous at the knots. The spline is a weighted sum of the following.

- a single constant
- a line for the portion of X less than 5
- a quadratic curve for the portion of X less than 5
- a cubic curve for the portion of X less than 5
- a different line for the portion of X between 5 and 10
- a different quadratic curve for the portion of X between 5 and 10
- a different cubic curve for the portion of X between 5 and 10
- a different line for the portion of X between 10 and 15
- a different quadratic curve for the portion of X between 10 and 15
- a different cubic curve for the portion of X between 10 and 15

- another line for the portion of X greater than 15
- another quadratic curve for the portion of X greater than 15
- and another cubic curve for the portion of X greater than 15

The spline is continuous since there is not a separate constant in the formula for the spline for each knot. Now the R^2 is 0.95542, and the spline closely follows the data, except at the knots. The following statements perform this analysis and produce [Output 75.1.4](#):

```
proc transreg data=A;
  model identity(y) = spline(x / knots=5 5 5 10 10 10 15 15 15);
  title3 'First - Third Derivatives Discontinuous at X=5, 10, 15';
  output out=A pprefix=Cub3;

Algorithm converged.

The same model could be fit with a DATA step and PROC REG, as follows. (The output from the following code is not displayed.)

```
data B;
  set a(keep=X Y);
  X1=X; /* X */
  X2=X**2; /* X squared */
  X3=X**3; /* X cubed */
  X4=(X>5) * (X- 5); /* change in X after 5 */
  X5=(X>10) * (X-10); /* change in X after 10 */
  X6=(X>15) * (X-15); /* change in X after 15 */
  X7=(X>5) * ((X-5)**2); /* change in X**2 after 5 */
  X8=(X>10) * ((X-10)**2); /* change in X**2 after 10 */
  X9=(X>15) * ((X-15)**2); /* change in X**2 after 15 */
  X10=(X>5) * ((X-5)**3); /* change in X**3 after 5 */
  X11=(X>10) * ((X-10)**3); /* change in X**3 after 10 */
```

```

X12=(X>15) * ((X-15)**3);    /* change in X**3 after 15 */
run;

proc reg;
  model Y=X1-X12;
run;

```

When the knots are repeated four times in the next step, the spline function is discontinuous at the knots and follows the data even more closely, with an R^2 of 0.99254. In this step, each separate curve is approximated by a cubic polynomial (with no knots within the separate polynomials). The following statements perform this analysis and produce [Output 75.1.5](#):

```

proc transreg data=A;
  model identity(Y) = spline(X / knots=5 5 5 5 10 10 10 10 15 15 15 15);
  title3 'Discontinuous Function and Derivatives';
  output out=A pprefix=Cub4;
  id V1-V7 LinearY QuadY Cub1Y Cub3Y;
run;

Algorithm converged.

To solve this problem with a DATA step and PROC REG, you would need to create all of the variables in the preceding DATA step (the B data set for the piecewise polynomial with discontinuous third derivatives), plus the following three variables.

```

X13=(X > 5);    /* intercept change after 5 */
X14=(X > 10);   /* intercept change after 10 */
X15=(X > 15);   /* intercept change after 15 */

```

The last two steps use the NKNOTS= *t*-option to specify the number of knots but not their location. NKNOTS=4 places knots at the quintiles while NKNOTS=9 places knots at the deciles. The spline and its first two derivatives are continuous. The R^2 values are 0.74450 and 0.95256. Even though the knots are placed in the wrong

places, the spline can closely follow the data with NKNOTS=9. The following statements produce [Output 75.1.6](#).

```
proc transreg data=A;
  model identity(Y) = spline(X / nknots=4);
  title3 'Four Knots';
  output out=A pprefix=Cub4k;

run; quit;

```

Output 75.1.7. Plots Summarizing Analysis for Spline Example

Output 75.1.7. (continued)

These next steps show how to find optimal spline transformations of variables in one data set and apply the same transformations to variables in another data set. These steps produce two artificial data sets, in which the variable Y is a linear function of nonlinear transformations of the variables X, W, and Z.

```

title2 'Scoring Spline Variables';

data x;
  do i = 1 to 5000;
    w = normal(7);
    x = normal(7);
    z = normal(7);
    y = w * w + log(5 + x) + sin(z) + normal(7);
    output;
  end;
run;

data z;
  do i = 1 to 5000;
    w = normal(1);
    x = normal(1);
    z = normal(1);
    y = w * w + log(5 + x) + sin(z) + normal(1);
    output;
  end;
run;

```

First, you run PROC TRANSREG asking for spline transformations of the three independent variables. You must use the EXKNOTS= *t-option*, because you need to use the same knots, both interior and exterior, with both data sets. By default the exterior knots will be different if the minima and maxima are different in the two data sets, so you will get the wrong results if you do not specify the EXKNOTS= *t-option* with values less than the minima and greater than the maxima of the two Y variables.

```

ods output splinecoef=c;
proc transreg data=x dum det ss2;
  model ide(y) = spl(w x z / knots=-1.5 to 1.5 by 0.5 exknots=-5 5);
  output out=d;
run;

```

The nonprinting “SplineCoef” table is output to a SAS data set. This data set contains the coefficients used to get the spline transformations and can be used to transform variables in other data sets. These coefficients are also in the details table. However, in the “SplineCoef” table they are in a form directly suitable for use with PROC SCORE.

This next step reads a different input data set and generates an output data set with the B-spline basis for each of the variables. Note that the same interior and exterior knots are used in both the previous and the next steps.

```
proc transreg data=z design;
  model bspl(w x z / knots=-1.5 to 1.5 by 0.5 exknots=-5 5);
  output out=b;
run;
```

These next three steps score the B-spline bases created in the previous step using the coefficients generated in the first PROC TRANSREG step. PROC SCORE is run once for each SPLINE variable.

```
proc score data=b score=c out=o1(rename=(spline=bw w=nw));
  var w;;
run;

proc score data=b score=c out=o2(rename=(spline=bx x=nx));
  var x;;
run;

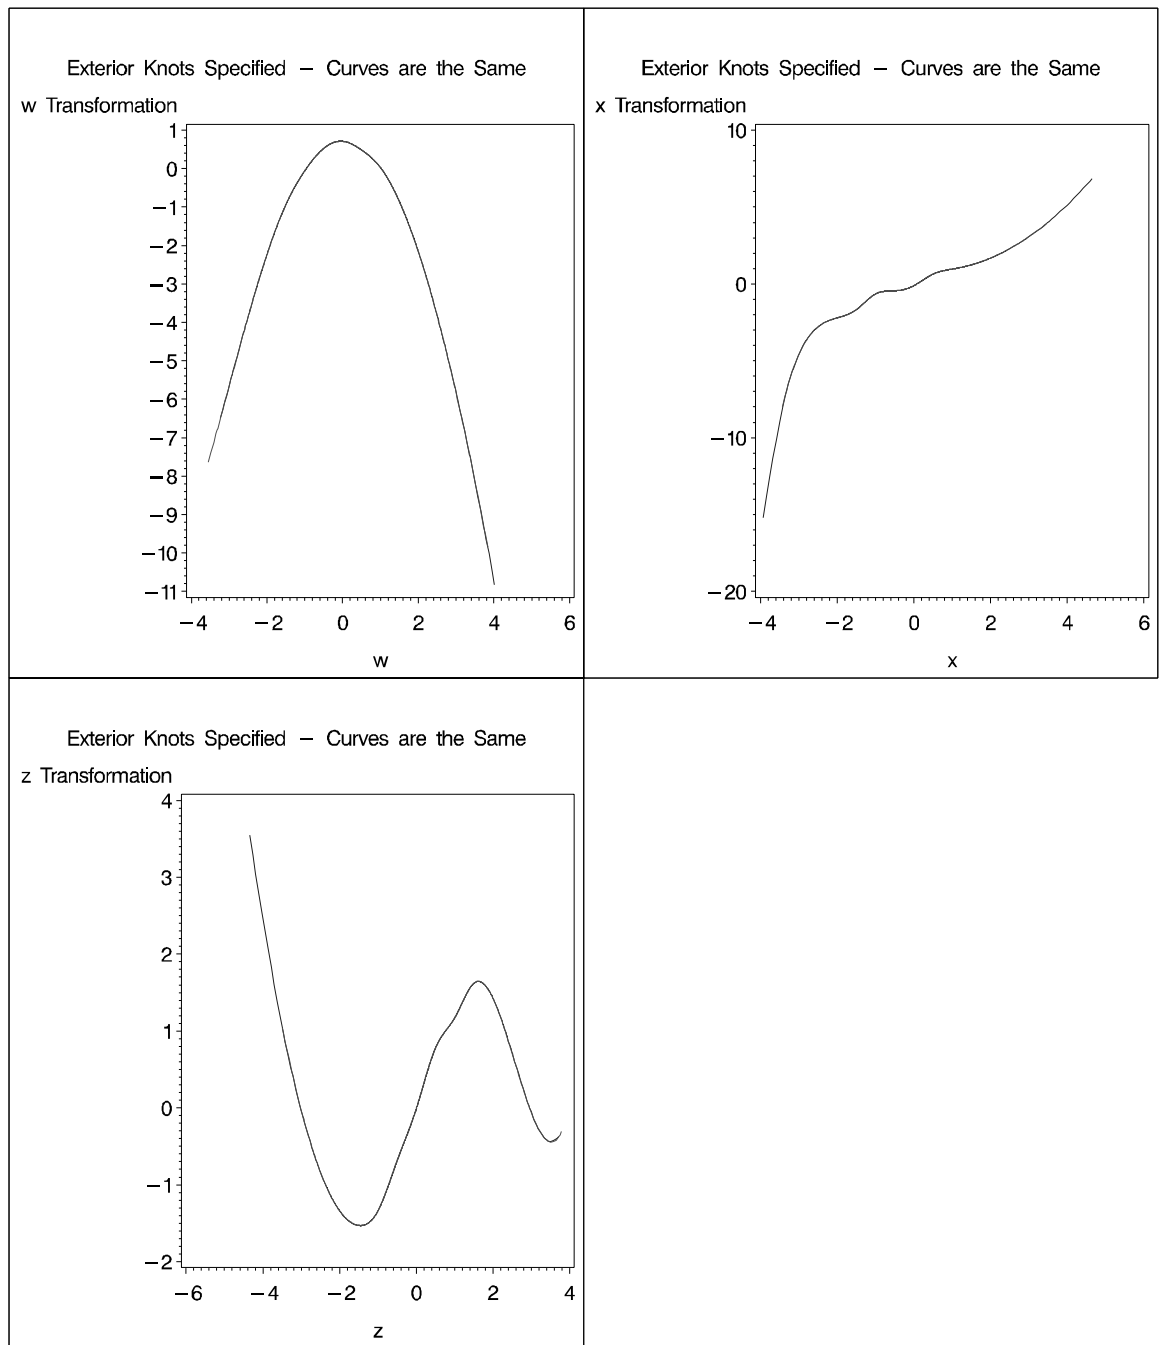

proc score data=b score=c out=o3(rename=(spline=bz z=nz));
  var z;;
run;
```

The next steps merge the three transformations with the original data and plot the results. The plots in [Output 75.1.8](#) show that in fact the two transformations for each variable, original and scored, are the same function. Furthermore, PROC TRANSREG found the functional forms that were used to generate the data: quadratic for W, log for X, and sine for Z.

```
goptions goutmode=replace nodisplay;
data all;
  merge d(keep=w x z tw tx tz) o1(keep=nw bw)
        o2(keep=nx bx) o3(keep=nz bz);
run;

proc gplot data=all;
  title3 'Exterior Knots Specified - Curves are the Same';
  symbol1 color=blue v=none i=smooths;
  symbol2 color=red v=none i=smooths;
  plot tw * w = 1 bw * nw = 2 / overlay name='tregspl1';
  plot tx * x = 1 bx * nx = 2 / overlay name='tregspl2';
  plot tz * z = 1 bz * nz = 2 / overlay name='tregspl3';
run; quit;

goptions display;
proc greplay nofs tc=sashelp.templt template=l2r2;
  igout gseg;
  treplay 1:tregspl1 2:tregspl3 3:tregspl2;
run; quit;
```

Output 75.1.8. Scoring Spline Variables Example

Example 75.2. Nonmetric Conjoint Analysis of Tire Data

This example uses PROC TRANSREG to perform a nonmetric conjoint analysis of tire preference data. Conjoint analysis decomposes rank ordered evaluation judgments of products or services into components based on qualitative product attributes.

For each level of each attribute of interest, a numerical “part-worth utility” value is computed. The sum of the part-worth utilities for each product is an estimate of the utility for that product. The goal is to compute part-worth utilities such that the product utilities are as similar as possible to the original rank ordering. (This example is a greatly simplified introductory example.)

The stimuli for the experiment are 18 hypothetical tires. The stimuli represent different brands (Goodstone, Pirogi, Machismo),* prices (\$69.99, \$74.99, \$79.99), expected tread life (50,000, 60,000, 70,000), and road hazard insurance plans (Yes, No). There are $3 \times 3 \times 3 \times 2 = 54$ possible combinations. From these, 18 combinations are selected that form an efficient experimental design for a main effects model. The combinations are then ranked from 1 (most preferred) to 18 (least preferred). In this simple example, there is one set of rankings. A real conjoint study would have many more.

First, the FORMAT procedure is used to specify the meanings of the factor levels, which are entered as numbers in the DATA step along with the ranks. PROC TRANSREG is used to perform the conjoint analysis. A maximum of 50 iterations is requested. The specification Monotone(Rank / Reflect) in the MODEL statement requests that the dependent variable Rank should be monotonically transformed and reflected so that positive utilities mean high preference. The variables Brand, Price, Life, and Hazard are designated as CLASS variables, and the part-worth utilities are constrained by ZERO=SUM to sum to zero within each factor. The UTILITIES *a-option* displays the conjoint analysis results.

The Importance column of the Utilities Table shows that price is the most important attribute in determining preference (57%), followed by expected tread life (18%), brand (15%), and road hazard insurance (10%). Looking at the Utilities Table for the maximum part-worth utility within each attribute, you see from the results that the most preferred combination is Pirogi brand tires, at \$69.99, with a 70,000 mile expected tread life, and road hazard insurance. This product is not actually in the data set. The sum of the part-worth utilities for this combination is

$$20.64 = 9.50 + 1.90 + 5.87 + 2.41 + 0.96$$

The following statements produce [Output 75.2.1](#):

Example 75.3. Metric Conjoint Analysis of Tire Data

This example, which is more detailed than the previous one, uses PROC TRANSREG to perform a metric conjoint analysis of tire preference data. Conjoint analysis can be used to decompose preference ratings of products or services into components based on qualitative product attributes. For each level of each attribute of interest, a numerical “part-worth utility” value is computed. The sum of the part-worth utilities for each product is an estimate of the utility for that product. The goal is to compute part-worth utilities such that the product utilities are as similar as possible to the original ratings. Metric conjoint analysis, as shown in this example, fits an ordinary linear model directly to data assumed to be measured on an interval scale. Nonmetric conjoint analysis, as shown in [Example 75.2](#), finds an optimal monotonic transformation of original data before fitting an ordinary linear model to the transformed data.

This example has three parts. In the first part, an experimental design is created. In the second part, a DATA step creates descriptions of the stimuli for the experiment. The third part of the example performs the conjoint analyses.

The stimuli for the experiment are 18 hypothetical tires. The stimuli represent different brands (Goodstone, Pirogi, Machismo),* prices (\$69.99, \$74.99, \$79.99), expected tread life (50,000, 60,000, 70,000), and road hazard insurance plans (Yes, No).

For a conjoint study such as this, you need to create an experimental design with 3 three-level factors, 1 two-level factor, and 18 combinations or *runs*. The easiest way to get this design is with the %MktEx autocall macro. The %MktEx macro requires

*In real conjoint experiments, real brand names would be used

you to specify the number of levels of each of the four factors, followed by N=18, the number of runs. Specifying a random number seed, while not strictly necessary, helps ensure that the design is reproducible. The %MktLab macro assigns the actual factor names instead of the default names X1, X2, and so on, and it assigns formats to the factor levels. The %MktEval macro helps you evaluate the design. It shows how correlated or independent the factors are, how often each factor level appears in the design, how often each pair occurs for every factor pair, and how often each product profile or run occurs in the design. See Kuhfeld (2003) for more information on these tools and their use in conjoint and choice modeling.

%mkteval;

proc print data=sasuser.TireDesign;
run;

```

The %MktEx macro output displayed in [Output 75.3.1](#) shows you that the design is 100% efficient, which means it is orthogonal and balanced. The %MktEval macro output displayed in [Output 75.3.2](#) shows you that all of the factors are uncorrelated or orthogonal, the design is balanced (each level occurs once), and every pair of factor levels occurs equally often (again showing that the design is orthogonal). The *n*-way frequencies show that each product profile occurs once (there are no duplicates). The design is shown in [Output 75.3.3](#). The design is automatically randomized (the profiles were sorted into a random order and the original levels are randomly reassigned). Orthogonality, balance, randomization, and other design concepts are discussed in detail in Kuhfeld (2003).

Next, the questionnaires are printed, and subjects are given the questionnaires and are asked to rate the tires.

The following statements produce [Output 75.3.4](#). This output is abbreviated; the statements produce stimuli for all combinations.

```

data _null_;
  title;
  set sasuser.TireDesign;
  file print;
  if mod(_n_,4) eq 1 then do;
    put _page_;
    put +55 'Subject _____';
  end;
  length hazardstring $ 7.;
  if put(hazard, hazardf3.) = 'Yes'
    then hazardstring = 'with';
    else hazardstring = 'without';

  s = 3 + (_n_ >= 10);
  put // _n_ +(-1) ' ) For your next tire purchase, '
      'how likely are you to buy this product?'
      // +s Brand 'brand tires at ' Price +(-1) ', '
      / +s 'with a ' Life 'tread life guarantee, '
      / +s 'and ' hazardstring 'road hazard insurance.'
      // +s 'Definitely Would          Definitely Would'
      / +s 'Not Purchase                Purchase'

Definitely Would Not Purchase					Definitely Would Purchase				
1	2	3	4	5	6	7	8	9	

The third part of the example performs the conjoint analyses. The DATA step reads the data. Only the ratings are entered, one row per subject. Real conjoint studies have many more subjects than five. The TRANSPOSE procedure transposes this (5 × 18) data set into an (18 × 5) data set that can be merged with the factor level data set sasuser.TireDesign. The next DATA step does the merge. The PRINT procedure displays the input data set.

PROC TRANSREG fits the five individual conjoint models, one for each subject. The UTILITIES *a-option* displays the conjoint analysis results. The SHORT *a-option*

suppresses the iteration histories, OUTTEST=Utils creates an output data set with all of the conjoint results, and the SEPARATORS= option requests that the labels constructed for each category contain two blanks between the variable name and the level value. The ODS select statement is used to limit the displayed output. The MODEL statement specifies IDENTITY for the ratings, which specifies a metric conjoint analysis—the ratings are not transformed. The variables Brand, Price, Life, and Hazard are designated as CLASS variables, and the part-worth utilities are constrained to sum to zero within each factor.

The following statements produce [Output 75.3.5](#):

```

title 'Tire Study, Data Entry, Preprocessing';

data Results;
  input (c1-c18) (1.);

These following statements summarize the results. Three tables are displayed: all of the importance values, the average importance, and the part-worth utilities. The first DATA step selects the importance information from the Utils data set. The final assignment statement stores just the variable name from the label relying on the fact that the separator is two blanks. PROC TRANSPOSE creates the data set of importances, one row per subject, and PROC PRINT displays the results. The MEANS procedure displays the average importance of each attribute across the subjects. The next DATA step selects the part-worth utilities information from the Utils data set. PROC TRANSPOSE creates the data set of utilities, one row per subject, and PROC PRINT displays the results.

Based on the importance values, price is the most important attribute for some of the respondents, but expected tread life is most important for others. On the average, price is most important followed closely by expected tread life. Brand and road hazard insurance are less important. Both Goodstone and Pirogi are the most preferred brands by some of the respondents. All respondents preferred a lower price over a higher price, a longer tread life, and road hazard insurance.

Example 75.4. Transformation Regression of Exhaust Emissions Data

In this example, the MORALS algorithm is applied to data from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel, compression ratio, and equivalence ratio. The data are provided by Brinkman (1981).

The equivalence ratio and nitrogen oxide variables are continuous and numeric, so spline transformations of these variables are requested. Each spline is degree three with nine knots (one at each decile) in order to allow PROC TRANSREG a great deal of freedom in finding transformations. The compression ratio variable has only five discrete values, so an optimal scoring is requested. The character variable `Fuel` is nominal, so it is designated as a classification variable. No monotonicity constraints are placed on any of the transformations. Observations with missing values are excluded with the NOMISS *a-option*.

The squared multiple correlation for the initial model is less than 0.25. PROC TRANSREG increases the R^2 to over 0.95 by transforming the variables. The transformation plots show how each variable is transformed. The transformation of compression ratio (`TCpRatio`) is nearly linear. The transformation of equivalence ratio (`TEqRatio`) is nearly parabolic. It can be seen from this plot that the optimal transformation of equivalence ratio is nearly uncorrelated with the original scoring. This suggests that the large increase in R^2 is due to this transformation. The transformation of nitrogen oxide (`TNOx`) is something like a log transformation.

These results suggest the parametric model

$$\begin{aligned} \log(\text{NOx}) = & b_0 + b_1 \times \text{EqRatio} + b_2 \times \text{EqRatio}^2 + b_3 \times \text{CpRatio} \\ & + \sum_j b_j \text{class}_j(\text{Fuel}) + \text{error} . \end{aligned}$$

You can perform this analysis with PROC TRANSREG using the following MODEL statement:

```
model log(NOx)= psp(EqRatio / deg=2) identity(CpRatio)
               class(Fuel / zero=first);
```

The LOG transformation computes the natural log. The PSPLINE expansion expands `EqRatio` into a linear term, `EqRatio`, and a squared term, `EqRatio`². A linear transformation of `CpRatio` and a dummy variable expansion of `Fuel` is requested with the first level as the reference level. These should provide a good parametric operationalization of the optimal transformations. The final model has an R^2 of 0.91 (smaller than before since the model uses fewer degrees of freedom, but still quite good).

The following statements produce [Output 75.4.1](#) through [Output 75.4.2](#):

```

Gasoline Example					
Iteratively Estimate NOx, CPRATIO and EQRATIO					
The TRANSREG Procedure					
Adjusted Multivariate ANOVA Table Based on the Usual Degrees of Freedom					
Dependent Variable Scoring Parameters=12 S=12 M=4 N=67					
Statistic	Value	F Value	Num DF	Den DF	p
Wilks' Lambda	0.041355	2.05	252	1455	<= <.0001
Pillai's Trace	0.958645	0.61	252	1764	<= 1.0000
Hotelling-Lawley Trace	23.18089	12.35	252	945.01	<= <.0001
Roy's Greatest Root	23.18089	162.27	21	147	>= <.0001

The Wilks' Lambda, Pillai's Trace, and Hotelling-Lawley Trace statistics are a conservative adjustment of the normal statistics. Roy's Greatest Root is liberal. These statistics are normally defined in terms of the squared canonical correlations which are the eigenvalues of the matrix $H \cdot \text{inv}(H+E)$. Here the R-Square is used for the first eigenvalue and all other eigenvalues are set to zero since only one linear combination is used. Degrees of freedom are computed assuming all linear combinations contribute to the Lambda and Trace statistics, so the F tests for those statistics are conservative. The p values for the liberal and conservative statistics provide approximate lower and upper bounds on p. A liberal test statistic with conservative degrees of freedom and a conservative test statistic with liberal degrees of freedom yield at best an approximate p value, which is indicated by a "~" before the p value.

Example 75.5. Preference Mapping of Cars Data

This example uses PROC TRANSREG to perform a preference mapping (PREFMAP) analysis (Carroll 1972) of car preference data after a PROC PRINQUAL principal component analysis. The PREFMAP analysis is a response surface regression that locates ideal points for each dependent variable in a space defined by the independent variables.

The data are ratings obtained from 25 judges of their preference for each of 17 automobiles. The ratings were made on a zero (very weak preference) to nine (very strong preference) scale. These judgments were made in 1980 about that year's products. There are two character variables that indicate the manufacturer and model of the automobile. The data set also contains three ratings: miles per gallon (MPG), projected reliability (Reliability), and quality of the ride (Ride). These ratings are on a one (bad) to five (good) scale. PROC PRINQUAL creates an OUT= data set containing standardized principal component scores (Prin1 and Prin2), along with the ID variables MODEL, MPG, Reliability, and Ride.

The first PROC TRANSREG step fits univariate regression models for MPG and Reliability. All variables are designated IDENTITY. A vector drawn in the plot of Prin1 and Prin2 from the origin to the point defined by an attribute's regression coefficients approximately shows how the cars differ on that attribute. Refer to Carroll (1972) for more information. The Prin1 and Prin2 columns of the TResult1 OUT= data set contain the car coordinates (_Type_='SCORE' observations) and endpoints of the MPG and Reliability vectors (_Type_='M COEFFI' observations).

The second PROC TRANSREG step fits a univariate regression model with Ride designated IDENTITY, and Prin1 and Prin2 designated POINT. The POINT expansion creates an additional independent variable _ISSQ_, which contains the sum of Prin1 squared and Prin2 squared. The OUT= data set TResult2 contains no _Type_='SCORE' observations, only ideal point (_Type_='M POINT') coordinates for Ride. The coordinates of both the vectors and the ideal points are output by specifying COORDINATES in the OUTPUT statement in PROC TRANSREG.

A vector model is used for MPG and Reliability because perfectly efficient and reliable cars do not exist in the data set. The ideal points for MPG and Reliability are far removed from the plot of the cars. It is more likely that an ideal point for quality of the ride is in the plot, so an ideal point model is used for the ride variable. Refer to Carroll (1972) and Schiffman, Reynolds, and Young (1981) for discussions of the vector model and point models (including the EPOINT and QPOINT versions of the point model that are not used in this example).

The final DATA step combines the two output data sets and creates a data set suitable for the %PLOTIT macro. (For information on the %PLOTIT macro, see [Appendix B](#), "Using the %PLOTIT Macro.") The plot contains one point per car and one point for each of the three ratings. The %PLOTIT macro options specify the input data set, how to handle anti-ideal points (described later), and where to draw horizontal and vertical reference lines. The DATATYPE= option specifies that the input data set contains results of a PREFMAP vector model and a PREFMAP ideal point model.

This instructs the macro to draw vectors to `_Type_='M COEFFI'` observations and circles around `_Type_='M POINT'` observations.

An unreliable to reliable direction extends from the left and slightly below the origin to the right and slightly above the origin. The Japanese and European Cars are rated, on the average, as more reliable. A low MPG to good MPG direction extends from the top left of the plot to the bottom right. The smaller cars, on the average, get better gas mileage. The ideal point for `Ride` is in the top, just right of the center of the plot. Cars near the `Ride` ideal point tend to have a better ride than cars far away. It can be seen from the iteration history tables that none of these ratings perfectly fits the model, so all of the interpretations are approximate.

The `Ride` point is a “negative-negative” ideal point. The point models assume that small ratings mean the object (car) is similar to the rating name and large ratings imply dissimilarity to the rating name. Because the opposite scoring is used, the interpretation of the `Ride` point must be reversed to a negative ideal point (bad ride). However, the coefficient for the `_ISSQ_` variable is negative, so the interpretation is reversed again, back to the original interpretation. Anti-ideal points are taken care of in the `%PLOTIT` macro. Specify `ANTIIDEA=1` when large values are positive or ideal and `ANTIIDEA=-1` when small values are positive or ideal.

The following statements produce [Output 75.5.1](#) through [Output 75.5.2](#):

Example 75.6. Box Cox

This example illustrates finding a Box-Cox transformation (see the “[Box-Cox Transformations](#)” section on page 4595) of some artificial data. Data were generated from the model

$$y = e^{x+\epsilon}$$

where $\epsilon \sim N(0, 1)$. The transformed data can be fit with a linear model

$$\log(y) = x + \epsilon$$

These statements produce [Output 75.6.1](#).

```

< - Best Lambda
* - Confidence Interval
+ - Convenient Lambda

PROC TRANSREG correctly selects the log transformation $\lambda = 0$, with a narrow confidence interval. The maximum of the log likelihood function is flagged with the less-than sign (<), and the convenient power parameter of $\lambda = 0$ in the confidence interval is flagged by the plus sign (+). The rest of the output is shown next in [Output 75.6.2](#).

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.						

This next example uses several options. The LAMBDA= option specifies power parameters sparsely from -2 to -0.5 and 0.5 to 2 just to get the general shape of the log likelihood function in that region. Between -0.5 and 0.5, more power parameters are tried. The CONVENIENT option is specified so that if a power parameter like $\lambda = 1$ or $\lambda = 0$ is found in the confidence interval, it will be used instead of the optimal power parameter. PARAMETER=2 is specified to add 2 to each y before performing the transformations. ALPHA=0.00001 specifies a wide confidence interval.

These statements produce [Output 75.6.3](#).

```
proc transreg data=x ss2 details;

The next part of this example shows how to make graphical displays of the Box-Cox transformation results. Plots include the log likelihood function with the confidence interval, root mean squared error as a function of the power parameter, R^2 as a function of the power parameter, the Box-Cox transformation of the variable y , the original scatter plot based on the untransformed data, and the new scatter plot based on the transformed data. Also, a condensed version of the log likelihood table with the confidence interval is printed. Here are the data.

The TRANSREG procedure is run to find the Box-Cox transformation. The lambda list is -2 TO 2 BY 0.01, which produces 401 lambdas. This many power parameters makes a nice graphical display with plenty of detail around the confidence interval. However, 401 values is a lot to print, so for this reason, the usual Box-Cox transformation information table is excluded from the printed output. Instead, it is output to a SAS data set using ODS so a sample of it can be printed. Just the confidence interval and the rows corresponding to power parameters that are multiples of 0.5 are printed. Null labels are provided for the columns that need to be printed without headers. The details table is also output to a SAS data set using ODS, since it contains information that will be incorporated into some of the plots. These statements produce [Output 75.6.5](#).

```

* Fit Box-Cox model, output results to output data sets;
ods output boxcox=b details=d;
ods exclude boxcox;
proc transreg details data=x;
  model boxcox(y / convenient lambda=-2 to 2 by 0.01) = identity(x);
  output out=trans;
run;

proc print noobs label data=b(drop=rmse);
  title2 'Confidence Interval';
  where ci ne ' ' or abs(lambda - round(lambda, 0.5)) < 1e-6;
  label convenient = '00'x ci = '00'x;
run;

```

BoxCox(y)	2.00	0.70	-435.01		

These next steps extract information from the Box-Cox transformation and details tables and store the information in macro variables. The confidence interval limit from the details table provides a vertical axis reference line for the log likelihood plot. The convenient power parameter ('Lambda Used') is extracted from the footnote. The confidence interval is extracted from the confidence interval observations of the Box-Cox transformation table and will be used in the footnote and for horizontal axis reference lines in the log likelihood plot.

```

* Store values for reference lines;
data _null_;
  set d;
  if description = 'CI Limit'
    then call symput('vref', formattedvalue);
  if description = 'Lambda Used'
    then call symput('lambda', formattedvalue);
run;

data _null_;
  set b end=eof;
  where ci ne ' ';
  if _n_ = 1
    then call symput('href1', compress(put(lambda, best12.)));
  if ci = '<'
    then call symput('href2', compress(put(lambda, best12.)));
  if eof
    then call symput('href3', compress(put(lambda, best12.)));
run;

```

These steps plot the log likelihood, root mean square error and R^2 . The input data set is the Box-Cox transformation table, which was output using ODS. These statements produce [Output 75.6.6](#).

```

Chapter 76

The TREE Procedure

Overview

The TREE procedure produces a tree diagram, also known as a *dendrogram* or *phenogram*, using a data set created by the CLUSTER or VARCLUS procedure. The CLUSTER and VARCLUS procedures create output data sets that contain the results of hierarchical clustering as a tree structure. The TREE procedure uses the output data set to produce a diagram of the tree structure in the style of Johnson(1967), with the root at the top. Alternatively, the diagram can be oriented horizontally, with the root at the left. Any numeric variable in the output data set can be used to specify the heights of the clusters. PROC TREE can also create an output data set containing a variable to indicate the disjoint clusters at a specified level in the tree.

Tree diagrams are discussed in the context of cluster analysis by Duran and Odell (1974), Hartigan (1975), and Everitt (1980). Knuth (1973) provides a general treatment of tree diagrams in computer programming.

The literature on tree diagrams contains a mixture of botanical and genealogical terminology. The objects that are clustered are *leaves*. The cluster containing all objects is the *root*. A cluster containing at least two objects but not all of them is a *branch*. The general term for leaves, branches, and roots is *node*. If a cluster A is the union of clusters B and C, then A is the *parent* of B and C, and B and C are *children* of A. A leaf is thus a node with no children, and a root is a node with no parent. If every cluster has at most two children, the tree diagram is a *binary tree*. The CLUSTER procedure always produces binary trees. The VARCLUS procedure can produce tree diagrams with clusters that have many children.

Getting Started

The TREE procedure creates tree diagrams from a SAS data set containing the tree structure. You can create this type of data set with the CLUSTER or VARCLUS procedure.

In the following example, the VARCLUS procedure is used to divide a set of variables into hierarchical clusters and to create the SAS data set containing the tree structure. The TREE procedure then generates the tree diagrams.

The following data, from Hand, et al. (1994), represent the amount of protein consumed from nine food groups for each of 25 European countries. The nine food groups are red meat (RedMeat), white meat (WhiteMeat), eggs (Eggs), milk (Milk), fish (Fish), cereal (Cereal), starch (Starch), nuts (Nuts), and fruits and vegetables (FruVeg).

The following SAS statements create the data set Protein:

```

data Protein;
  input Country $15. RedMeat WhiteMeat Eggs Milk
        Fish Cereal Starch Nuts FruVeg;
  datalines;
Albania      10.1  1.4  0.5   8.9  0.2  42.3  0.6  5.5  1.7
Austria      8.9 14.0  4.3  19.9  2.1  28.0  3.6  1.3  4.3
Belgium     13.5  9.3  4.1  17.5  4.5  26.6  5.7  2.1  4.0
Bulgaria     7.8  6.0  1.6   8.3  1.2  56.7  1.1  3.7  4.2

Yugoslavia  4.4  5.0  1.2   9.5  0.6  55.9  3.0  5.7  3.2
;
run;

```

The data set `Protein` contains the character variable `Country` and the nine numeric variables representing the food groups. The `$15.` in the `INPUT` statement specifies that the variable `Country` is a character variable with a length of 15.

The following statements cluster the variables in the data set `Protein`. The `OUTTREE=` option creates an output SAS data set named `Tree` to contain the tree structure. The `CENTROID` option specifies the centroid clustering method, and the `MAXCLUSTERS=` option specifies that the largest number of clusters desired is four. The `NOPRINT` option suppresses the display of the output. The `VAR` statement specifies that all numeric variables (`RedMeat`—`FruVeg`) are used by the procedure.

```

proc varclus data=Protein outtree=Tree
  centroid maxclusters=4 noprint;
  var RedMeat--FruVeg;
run;

```

The output data set `Tree`, created by the `OUTTREE=` option in the previous statements, contains the following variables:

<code>_NAME_</code>	the name of the cluster
<code>_PARENT_</code>	the parent of the cluster
<code>_NCL_</code>	the number of clusters
<code>_VAREXP_</code>	the amount of variance explained by the cluster
<code>_PROPOR_</code>	the proportion of variance explained by the clusters at the current level of the tree diagram
<code>_MINPRO_</code>	the minimum proportion of variance explained by a cluster
<code>_MAXEIGEN_</code>	the maximum second eigenvalue of a cluster

The following statements produce a tree diagram of the clusters created by PROC VARCLUS:

```
proc tree data=tree ;
proc tree data=tree lineprinter;
```

PROC TREE is invoked twice. In the first invocation, the tree diagram is presented using the default high resolution graphical output. In the second invocation, the LINEPRINTER option specifies line printer output.

Figure 76.1 displays the default high resolution graphics version of the tree diagram.

Figure 76.1. High Resolution Tree Diagram from PROC TREE

Figure 76.2 displays the same information as Figure 76.1, using line printer output.

Figure 76.2. Line Printer Graphics Version of the Tree Diagram

In both figures, the name of the cluster is displayed on the horizontal axis and the number of clusters is displayed on the vertical or height axis.

As you look up from the bottom of the figures, clusters are progressively joined until a single, all-encompassing cluster is formed at the top (or root) of the diagram. Clusters exist at each level of the diagram. For example, at the level where the diagram indicates three clusters, the clusters are as follows:

- Cluster 1: RedMeat WhiteMeat Eggs Milk
- Cluster 2: Fish Starch
- Cluster 3: Cereal Nuts FruVeg

As you proceed up the diagram one level, the number of clusters is two. The clusters are

- Cluster 1: RedMeat WhiteMeat Eggs Milk Fish Starch
- Cluster 2: Cereal Nuts FruVeg

The following statements illustrate how you can specify the numeric variable defining the height of each node (cluster) in the tree. First, the `AXIS1` statement is defined. The `ORDER=` option specifies the data values in the order in which they are to appear on the axis.

Next, the `TREE` procedure is invoked. The `HORIZONTAL` option orients the tree diagram horizontally. The `HAXIS` option specifies that the `AXIS1` statement be used to customize the appearance of the horizontal axis. The `HEIGHT` statement specifies the variable `_PROPOR_` (the proportion of variance explained) as the height variable.

```
axis1 order=(0 to 1 by 0.2);
proc tree data=Tree horizontal haxis=axis1;
  height _PROPOR_;
run;
```

Figure 76.3. Horizontal Tree Diagram Using `_PROPOR_` as the HEIGHT Variable

Figure 76.3 displays the tree diagram oriented horizontally, using the variable `_PROPOR_` as the height variable. As you look from left to right in the diagram,

objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the diagram.

Clusters exist at each level of the diagram, represented by horizontal line segments. Each vertical line segment represents a point where leaves and branches are connected into progressively larger clusters.

For example, three clusters are formed at the left-most point along the axis where three horizontal line segments exist. At that point, where a vertical line segment connects the Cereal-Nuts and FruVeg clusters, the proportion of variance explained is about 0.6 (`_PROPOR_ = 0.6`). At the next clustering level the variables Fish and Starch are clustered with variables RedMeat through Milk, resulting in a total of two clusters. The proportion of variance explained is about 0.45 at that point.

Syntax

The TREE procedure is invoked by the following statements:

```
PROC TREE < options > ;
  NAME variables ;
  HEIGHT variable ;
  PARENT variables ;
  BY variables ;
  COPY variables ;
  FREQ variable ;
  ID variable ;
```

If the input data set has been created by CLUSTER or VARCLUS, the only statement required is the PROC TREE statement. The BY, COPY, FREQ, HEIGHT, ID, NAME, and PARENT statements are described after the PROC TREE statement.

PROC TREE Statement

```
PROC TREE < options > ;
```

The PROC TREE statement starts the TREE procedure.

The options that can appear in the PROC TREE statement are summarized in the following table.

Table 76.1. PROC TREE Statement Options

Task	Options	Effect
Specify data sets	DATA=	specifies the input data set
	DOCK=	does not count small clusters in OUT= data set
	LEVEL=	defines disjoint cluster in OUT= data set
	NCLUSTERS=	specifies the number of clusters in OUT= data set
	OUT=	specifies the output data set

Table 76.1. (continued)

Task	Options	Effect
Specify cluster heights	ROOT=	displays the root of a subtree
	HEIGHT= DISSIMILAR SIMILAR	specifies the variable for the height axis specifies that large values are far apart specifies that small values are close together
Display horizontal trees	HORIZONTAL	specifies that the height axis is horizontal
Control sort order	DESCENDING SORT	reverses SORT order sorts children by HEIGHT variable
Control displayed output	LIST NOPRINT	displays all nodes in the tree suppresses display of the tree
High resolution graphics	LINEPRINTER	displays tree using line printer style graphics
	INC=	specifies the increment between tick values
	MAXHEIGHT=	specifies the maximum value on axis
	MINHEIGHT=	specifies the minimum value on axis
	NTICK=	specifies the number of tick intervals
	CFRAME=	specifies the color of the frame
	DESCRIPTION=	specifies the catalog description
	GOUT=	specifies the catalog name
	HAXIS=	customizes horizontal axis
	HORDISPLAY=	displays a horizontal tree with leaves on the right
	HPAGES=	specifies the number of pages to expand tree horizontally
	LINES=	specifies the line color and thickness, dots at the nodes
	NAME=	specifies the name of graph in the catalog
VAXIS=	customizes vertical axis	
VPAGES=	specifies the number of pages to expand tree vertically	
Line printer graphics	INC=	specifies the increment between tick values
	MAXHEIGHT=	specifies the maximum value on axis
	MINHEIGHT=	specifies the minimum value on axis
	NTICK=	specifies the number of tick intervals
	PAGES=	specifies the number of pages
	POS=	specifies the number of column positions
	SPACES=	specifies the number of spaces between objects
	TICKPOS=	specifies the number of column positions between ticks
	FILLCHAR=	specifies the fill character between unjoined leaves
	JOINCHAR=	specifies the character to display between joined leaves

Table 76.1. (continued)

Task	Options	Effect
	LEAFCHAR=	specifies the character to represent clusters with no children
	TREECHAR=	specifies the character to represent clusters with children

CFRAME=*color*

specifies a color for the frame, which is the rectangle bounded by the axes.

DATA=*SAS-data-set*

specifies the input data set defining the tree. If you omit the DATA= option, the most recently created SAS data set is used.

DESCENDING**DES**

reverses the sorting order for the SORT option.

DESCRIPTION=*entry-description*

specifies a description for the graph in the GOUT= catalog. The default is “Proc Tree Graph Output.”

DISSIMILAR**DIS**

implies that the values of the HEIGHT variable are dissimilarities; that is, a large height value means that the clusters are very dissimilar or far apart.

If neither the SIMILAR nor the DISSIMILAR option is specified, PROC TREE attempts to infer from the data whether the height values are similarities or dissimilarities. If PROC TREE cannot tell this from the data, it issues an error message and does not display a tree diagram.

DOCK=*n*

causes observations in the OUT= data set assigned to output clusters with a frequency of *n* or less to be given missing values for the output variables CLUSTER and CLUSNAME. If the NCLUSTERS= option is also specified, DOCK= also prevents clusters with a frequency of *n* or less from being counted toward the number of clusters requested by the NCLUSTERS= option. By default, DOCK=0.

FILLCHAR=*'c'***FC=***'c'*

specifies the character to display between leaves that are not joined into a cluster. The character should be enclosed in single quotes. The default is a blank. The LINEPRINTER option must also be specified.

GOUT=*<libref.>member-name*

specifies the catalog in which the generated graph is stored. The default is WORK.GSEG.

HAXIS=AXIS n

specifies the `AXIS n` statement used to customize the appearance of the horizontal axis.

HEIGHT=*name***H=*name***

specifies certain conventional variables to be used for the height axis of the tree diagram. For many situations, the only option you need is the `HEIGHT=` option. Valid values for *name* and their meanings are as follows:

<code>HEIGHT H</code>	specifies the <code>_HEIGHT_</code> variable.
<code>LENGTH L</code>	defines the height of each node as its path length from the root. This can also be interpreted as the number of ancestors of the node.
<code>MODE M</code>	specifies the <code>_MODE_</code> variable.
<code>NCL N</code>	specifies the <code>_NCL_</code> (number of clusters) variable.
<code>RSQ R</code>	specifies the <code>_RSQ_</code> variable.

See also the “[HEIGHT Statement](#)” section on page 4755, which can specify any variable in the input data set to be used for the height axis. In rare cases, you may need to specify either the `DISSIMILAR` option or the `SIMILAR` option.

HORDISPLAY=RIGHT

specifies that the graph is to be oriented horizontally, with the leaf nodes on the right side, when the `HORIZONTAL` option is also specified. By default, the leaf nodes are on the left side.

HORIZONTAL**HOR**

orients the tree diagram with the height axis horizontal and the root at the left. The leaf nodes are on the side specified in the `HORDISPLAY=` option. If you do not specify the `HORIZONTAL` option, the height axis is vertical, with the root at the top. When the tree takes up more than one page and is viewed on a screen, horizontal orientation can make the tree diagram considerably easier to read.

HPAGES= $n1$

specifies that the original graph is to be enlarged to cover $n1$ pages. If you also specify the `VPAGES= $n2$` option, the original graph is enlarged to cover $n1 \times n2$ graphs. For example, if `HPAGES=2` and `VPAGES=3`, then the original graph is generated followed by $2 \times 3 = 6$ more graphs. In these six graphs, the original is enlarged by a factor of 2 in the horizontal direction and by a factor of 3 in the vertical direction. The graphs are generated in left-to-right and top-to-bottom order.

INC= n

specifies the increment between tick values on the height axis. If the `HEIGHT` variable is `_NCL_`, the default is usually 1, although a different value can be specified for consistency with other options. For any other `HEIGHT` variable, the default is some power of 10 times 1, 2, 2.5, or 5.

JOINCHAR='c'**JC='c'**

specifies the character to display between leaves that are joined into a cluster. The character should be enclosed in single quotes. The default is X. The LINEPRINTER option must also be specified.

LEAFCHAR='c'**LC='c'**

specifies a character to represent clusters having no children. The character should be enclosed in single quotes. The default is a period. The LINEPRINTER option must also be specified.

LEVEL=*n*

specifies the level of the tree defining disjoint clusters for the OUT= data set. The LEVEL= option also causes only clusters between the root and a height of *n* to be displayed. The clusters in the output data set are those that exist at a height of *n* on the tree diagram. For example, if the HEIGHT variable is _NCL_ (number of clusters) and LEVEL=5 is specified, then the OUT= data set contains five disjoint clusters. If the HEIGHT variable is _RSQ_ (R^2) and LEVEL=0.9 is specified, then the OUT= data set contains the smallest number of clusters that yields an R^2 of at least 0.9.

LINEPRINTER

specifies that the generated report is to be displayed using line printer graphics.

LINES=(*<COLOR=color><WIDTH=n><DOTS>*)

enables you to specify both the color and the thickness of the lines. In addition, a dot can be drawn at each leaf node. Note that if the frame and the lines are specified to be the same color, PROC TREE selects a different color for the lines.

LIST

lists all the nodes in the tree, displaying the height, parent, and children of each node.

MAXHEIGHT=*n***MAXH=*n***

specifies the maximum value displayed on the height axis.

MINHEIGHT=*n***MINH=*n***

specifies the minimum value displayed on the height axis.

NAME=*name*

specifies the entry name for the generated graph in the GOUT= catalog. Note that each time another graph is generated with the same name, the name is modified by appending a number to make it unique.

NCLUSTERS=*n***NCL=*n*****N=*n***

specifies the number of clusters desired in the OUT= data set. The number of clusters obtained may not equal the number specified if (1) there are fewer than *n* leaves in the tree, (2) there are more than *n* unconnected trees in the data set, (3) a multi-way

tree does not contain a level with the specified number of clusters, or (4) the DOCK= option eliminates too many clusters.

The NCLUSTERS= option uses the `_NCL_` variable to determine the order in which the clusters are formed. If there is no `_NCL_` variable, the height variable (as determined by the HEIGHT statement or HEIGHT= option) is used instead.

NTICK=*n*

specifies the number of tick intervals on the height axis. The default depends on the values of other options.

NOPRINT

suppresses the display of the tree. Specify the NOPRINT option if you want only to create an OUT= data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see [Chapter 14, “Using the Output Delivery System.”](#)

OUT=SAS-*data-set*

creates an output data set that contains one observation for each object in the tree or subtree being processed and variables called CLUSTER and CLUSNAME showing cluster membership at any specified level in the tree. If you specify the OUT= option, you must also specify either the NCLUSTERS= or LEVEL= option in order to define the output partition level. If you want to create a permanent SAS data set, you must specify a two-level name (refer to “SAS Data Files” in *SAS Language Reference: Concepts*).

PAGES=*n*

specifies the number of pages over which the tree diagram (from root to leaves) is to extend. The default is 1. The LINEPRINTER option must also be specified.

POS=*n*

specifies the number of column positions on the height axis. The default depends on the value of the PAGES= option, the orientation of the tree diagram, and the values specified by the PAGESIZE= and LINESIZE= options. The LINEPRINTER option must also be specified.

ROOT='*name*'

specifies the value of the NAME variable for the root of a subtree to be displayed if you do not want to display the entire tree. If you also specify the OUT= option, the output data set contains only objects belonging to the subtree specified by the ROOT= option.

SIMILAR

SIM

implies that the values of the HEIGHT variable are similarities; that is, a large height value means that the clusters are very similar or close together.

If neither the SIMILAR nor the DISSIMILAR option is specified, PROC TREE attempts to infer from the data whether the height values are similarities or dissimilarities. If PROC TREE cannot tell this from the data, it issues an error message and does not display a tree diagram.

SORT

sorts the children of each node by the HEIGHT variable, in the order of cluster formation. See the [DESCENDING option](#) on page 4750.

SPACES=s**S=s**

specifies the number of spaces between objects on the output. The default depends on the number of objects, the orientation of the tree diagram, and the values specified by the PAGESIZE= and LINESIZE= options. The LINEPRINTER option must also be specified.

TICKPOS=n

specifies the number of column positions per tick interval on the height axis. The default value is usually between 5 and 10, although a different value can be specified for consistency with other options.

TREECHAR='c'**TC='c'**

specifies a character to represent clusters with children. The character should be enclosed in single quotes. The default is X. The LINEPRINTER option must also be specified.

VAXIS=AXISn

specifies that the AXISn statement be used to customize the appearance of the vertical axis.

VPAGES=n2

specifies that the original graph is to be enlarged to cover $n2$ pages. If you also specify the HPAGES= $n1$ option, the original graph is enlarged to cover $n1 \times n2$ pages. For example, if HPAGES=2 and VPAGES=3, then the original graph is generated followed by $2 \times 3 = 6$ more graphs. In these six graphs, the original is enlarged by a factor of 2 in the horizontal direction and by a factor of 3 in the vertical direction. The graphs are generated in left-to-right and top-to-bottom order.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC TREE to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TREE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

COPY Statement

COPY *variables* ;

The COPY statement specifies one or more character or numeric variables to be copied to the OUT= data set.

FREQ Statement

FREQ *variables* ;

The FREQ statement specifies one numeric variable that tells how many clustering observations belong to the cluster. If the FREQ statement is omitted, PROC TREE looks for a variable called `_FREQ_` to specify the number of observations per cluster. If neither the FREQ statement nor the `_FREQ_` variable is present, each leaf is assumed to represent one clustering observation, and the frequency for each internal node is found by summing the frequencies of its children.

HEIGHT Statement

HEIGHT *variable* ;

The HEIGHT statement specifies the name of a numeric variable to define the height of each node (cluster) in the tree. The height variable can also be specified by the HEIGHT= option in the PROC TREE statement. If both the HEIGHT statement and the HEIGHT= option are omitted, PROC TREE looks for a variable called `_HEIGHT_`. If the data set does not contain `_HEIGHT_`, PROC TREE looks for a variable called `_NCL_`. If `_NCL_` is not found either, the height of each node is defined to be its path length from the root.

ID Statement

ID *variables* ;

The ID variable is used to identify the objects (leaves) in the tree on the output. The ID variable can be a character or numeric variable of any length. If the ID statement is omitted, the variable in the NAME statement is used instead. If both the ID and NAME statements are omitted, PROC TREE looks for a variable called `_NAME_`. If the `_NAME_` variable is not found in the data set, PROC TREE issues an error message and stops. The ID variable is copied to the OUT= data set.

NAME Statement

NAME *variables* ;

The NAME statement specifies a character or numeric variable identifying the node represented by each observation. The NAME variable and the PARENT variable jointly define the tree structure. If the NAME statement is omitted, PROC TREE looks for a variable called `_NAME_`. If the `_NAME_` variable is not found in the data set, PROC TREE issues an error message and stops.

PARENT Statement

PARENT *variables* ;

The PARENT statement specifies a character or numeric variable identifying the node in the tree that is the parent of each observation. The PARENT variable must have the same formatted length as the NAME variable. If the PARENT statement is omitted, PROC TREE looks for a variable called `_PARENT_`. If the `_PARENT_` variable is not found in the data set, PROC TREE issues an error message and stops.

Details

Missing Values

An observation with a missing value for the NAME variable is omitted from processing. If the PARENT variable has a missing value but the NAME variable is present, the observation is treated as the root of a tree. A data set can contain several roots and, hence, several trees.

Missing values of the HEIGHT variable are set to upper or lower bounds determined from the nonmissing values under the assumption that the heights are monotonic with respect to the tree structure.

Missing values of the FREQ variable are inferred from nonmissing values where possible; otherwise, they are treated as zero.

Output Data Set

The `OUT=` data set contains one observation for each leaf in the tree or subtree being processed. The variables are as follows:

- the BY variables, if any
- the ID variable, or the NAME variable if the ID statement is not used
- the COPY variables
- a numeric variable `CLUSTER` taking values from 1 to c , where c is the number of disjoint clusters. The cluster to which the first observation belongs is given the number 1, the cluster to which the next observation belongs that does not belong to cluster 1 is given the number 2, and so on.

- a character variable **CLUSNAME** giving the value of the **NAME** variable of the cluster to which the observation belongs

The **CLUSTER** and **CLUSNAME** variables are missing if the corresponding leaf has a nonpositive frequency.

Displayed Output

The displayed output from the **TREE** procedure includes the following:

- the names of the objects in the tree
- the height axis
- the tree diagram. A high-resolution graphics tree diagram is produced on the graphics device. The leaves are displayed at the bottom of the graph. Horizontal lines connect the leaves into branches, while the topmost horizontal line indicates the root.

If the **LINEPRINTER** option is specified, the root (the cluster containing all the objects) is indicated by a solid line of the character specified by the **TREECHAR=** option (the default character is 'X'). At each level of the tree, clusters are shown by unbroken lines of the **TREECHAR=** symbol with the **FILLCHAR=** symbol (the default is a blank) separating the clusters. The **LEAFCHAR=** symbol (the default character is a period) represents single-member clusters.

By default, the tree diagram is oriented with the height axis vertical and the object names at the top of the diagram. If the **HORIZONTAL** option is specified, then the height axis is horizontal and the object names are on the left.

ODS Table Names

PROC TREE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see [Chapter 14, “Using the Output Delivery System.”](#)

Table 76.2. ODS Tables Produced in **PROC TREE**

ODS Table Name	Description	Statement	Option
Tree	Line-printer plot of the tree	PROC	LINEPRINTER
TreeListing	Line-printer listing of all nodes in the tree	PROC	LIST

Examples

Example 76.1. Mammals' Teeth

The following data give the numbers of different kinds of teeth for a variety of mammals. The mammals are clustered by average linkage using the CLUSTER procedure (Output 76.1.1). The PROC TREE statement uses the average-linkage distance as the height axis, which is the default, and creates a horizontal high-resolution graphics tree (Output 76.1.2).

Output 76.1.2. PROC TREE High-Resolution Graphics

As you look from left-to-right in the diagram in [Output 76.1.2](#), objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the diagram. Clusters exist at each level of the diagram, and every vertical line connects leaves and branches into progressively larger clusters. For example, the five bats form a cluster at the 0.6 level, while the next cluster consists only of the mole. The observations Reindeer, Elk, Deer, and Moose form the next cluster at the 0.6 level, the mammals Pika through House Mouse are in the fourth cluster, The observations Wolf, Bear, and Raccoon form the fifth cluster, while the last cluster contains the observations Marten through Elephant Seal.

The following statements create the same tree with line printer graphics in a vertical orientation; the tree is displayed in [Output 76.1.3](#).

```
proc tree lineprinter;
run;
```

Output 76.1.3. PROC TREE with the LINEPRINTER Option

As you look up from the bottom of the diagram, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the top (or root) of the diagram. Clusters exist at each level of the diagram. For example, the unbroken line of Xs at the left-most side of the 0.6 level indicates that the five bats have formed a cluster. The next cluster is represented by a period because it contains only one mammal, Mole. Reindeer, Elk, Deer, and Moose form the next cluster, indicated by Xs again. The mammals Pika through House Mouse are in the fourth cluster. The observations Wolf, Bear, and Raccoon form the fifth cluster, while the last cluster contains the observations Marten through Elephant Seal.

The next statement sorts the clusters at each branch in order of formation and uses the number of clusters as the height axis. The resulting tree is displayed in [Output 76.1.4](#).

```
proc tree sort height=n horizontal;
run;
```

Output 76.1.4. PROC TREE with SORT and HEIGHT= Options

Because the CLUSTER procedure always produces binary trees, the number of internal (root and branch) nodes in the tree is one less than the number of leaves. Therefore 31 clusters are formed from the 32 mammals in the input data set. These are represented by the 31 vertical line segments in the tree diagram, each at a different value along the horizontal axis.

As you examine the tree from left to right, the first vertical line segment is where Beaver and Groundhog are clustered and the number of clusters is 31. The next cluster is formed from Gray Squirrel and Porcupine. The third contains Wolf and Bear. Note how the tree graphically displays the clustering order information that was presented in tabular form by the CLUSTER procedure in [Output 76.1.1](#).

The same clusters as in [Output 76.1.2](#) and [Output 76.1.3](#) can be seen at the six-cluster level of the tree diagram in [Output 76.1.4](#), although the SORT and HEIGHT= options make them appear in a different order.

The following statements create these six clusters and display them in [Output 76.1.5](#). The PROC TREE statement produces no output but creates an output data set indicating the cluster to which each observation belongs at the six-cluster level in the tree.

```

proc tree noprint out=part nclusters=6;
  id mammal;
  copy v1-v8;
proc sort;
  by cluster;
proc print label uniform;
  id mammal;
  var v1-v8;
  format v1-v8 1.;
  by cluster;
run;

```

Example 76.2. Iris Data

Fisher's (1936) iris data gives sepal and petal dimensions for three different species of iris. The data are clustered by k th-nearest-neighbor density linkage using the CLUSTER procedure with $K=8$. Observations are identified by species (Setosa, Versicolor or Virginica) in the tree diagram, which is oriented with the height axis horizontal. The following statements produce [Output 76.2.1](#) and [Output 76.2.2](#).

```
proc format;
  value specname
    1='Setosa      '
    2='Versicolor'
    3='Virginica  ';
run;

data iris;
  title 'Fisher (1936) Iris Data';
  input SepalLength SepalWidth PetalLength PetalWidth
        Species @@;
  format Species specname.;
  label SepalLength='Sepal Length in mm.'
        SepalWidth  ='Sepal Width in mm.'
        PetalLength='Petal Length in mm.'
        PetalWidth  ='Petal Width in mm.';
  symbol = put(species, specname10.);

The PAGES=1 option specifies that the tree diagram extends over one page from tree to root. Since the HORIZONTAL option is also specified, the horizontal extent of the diagram is one page. The number of vertical pages required for the diagram is dictated by the number of leaves in the tree.

The MAXH=10 limits the values displayed on the height axis to a maximum of 10. This prunes the tree diagram so that only the portion from the leaves to level 10 is displayed. You can see this pruning effect in [Output 76.2.2](#).

Chapter 77

The TTEST Procedure

Overview

The TTEST procedure performs t tests for one sample, two samples, and paired observations. The one-sample t test compares the mean of the sample to a given number. The two-sample t test compares the mean of the first sample minus the mean of the second sample to a given number. The paired observations t test compares the mean of the differences in the observations to a given number.

For one-sample tests, PROC TTEST computes the sample mean of the variable and compares it with a given number. Paired comparisons use the one sample process on the differences between the observations. Paired comparisons can be made between many pairs of variables with one call to PROC TTEST. For group comparisons, PROC TTEST computes sample means for each of two groups of observations and tests the hypothesis that the population means differ by a given amount. This latter analysis can be considered a special case of a one-way analysis of variance with two levels of classification.

The underlying assumption of the t test in all three cases is that the observations are random samples drawn from normally distributed populations. This assumption can be checked using the UNIVARIATE procedure; if the normality assumptions for the t test are not satisfied, you should analyze your data using the NPAR1WAY procedure. The two populations of a group comparison must also be independent. If they are not independent, you should question the validity of a paired comparison.

PROC TTEST computes the group comparison t statistic based on the assumption that the variances of the two groups are equal. It also computes an approximate t based on the assumption that the variances are unequal (the Behrens-Fisher problem). The degrees of freedom and probability level are given for each; Satterthwaite's (1946) approximation is used to compute the degrees of freedom associated with the approximate t . In addition, you can request the Cochran and Cox (1950) approximation of the probability level for the approximate t . The folded form of the F statistic is computed to test for equality of the two variances (Steel and Torrie 1980).

FREQ and WEIGHT statements are available. Data can be input in the form of observations or summary statistics. Summary statistics and their confidence intervals, and differences of means are output. For two-sample tests, the pooled-variance and a test for equality of variances are also produced.

Getting Started

One-Sample *t* Test

A one-sample *t* test can be used to compare a sample mean to a given value. This example, taken from Huntsberger and Billingsley (1989, p. 290), tests whether the mean length of a certain type of court case is 80 days using 20 randomly chosen cases. The data are read by the following DATA step:

```

title 'One-Sample t Test';
data time;
  input time @@;
  datalines;
  43  90  84  87  116  95  86  99  93  92
  121 71  66  98  79  102 60  112 105 98
  ;
run;

```

The only variable in the data set, `time`, is assumed to be normally distributed. The trailing at signs (`@@`) indicate that there is more than one observation on a line. The following code invokes PROC TTEST for a one-sample *t* test:

```

proc ttest h0=80 alpha=0.1;
  var time;
run;

```

The VAR statement indicates that the `time` variable is being studied, while the `H0=` option specifies that the mean of the `time` variable should be compared to the value 80 rather than the default null hypothesis of 0. This `ALPHA=` option requests 10% confidence intervals rather than the default 5% confidence intervals. The output is displayed in Figure 77.1.

One-Sample t Test										
The TTEST Procedure										
Statistics										
Variable	N	Lower CL Mean	Upper CL Mean	Lower CL Std Dev	Upper CL Std Dev	Std Dev	Std Err	Minimum	Maximum	
time	20	82.447	89.85	97.253	15.2	19.146	26.237	4.2811	43	121
T-Tests										
Variable	DF	t Value	Pr > t							
time	19	2.30	0.0329							

Figure 77.1. One-Sample *t* Test Results

Summary statistics appear at the top of the output. The sample size (*N*), the mean and its confidence bounds (Lower CL Mean and Upper CL Mean), the standard deviation

and its confidence bounds (Lower CL Std Dev and Upper CL Std Dev), and the standard error are displayed with the minimum and maximum values of the time variable. The test statistic, the degrees of freedom, and the p -value for the t test are displayed next; at the 10% α -level, this test indicates that the mean length of the court cases are significantly different from 80 days ($t = 2.30, p = 0.0329$).

Comparing Group Means

If you want to compare values obtained from two different groups, and if the groups are independent of each other and the data are normally distributed in each group, then a group t test can be used. Examples of such group comparisons include

- test scores for two third-grade classes, where one of the classes receives tutoring
- fuel efficiency readings of two automobile nameplates, where each nameplate uses the same fuel
- sunburn scores for two sunblock lotions, each applied to a different group of people
- political attitude scores of males and females

In the following example, the golf scores for males and females in a physical education class are compared. The sample sizes from each population are equal, but this is not required for further analysis. The data are read by the following statements:

```

title 'Comparing Group Means';
data scores;
  input Gender $ Score @@;
  datalines;
f 75 f 76 f 80 f 77 f 80 f 77 f 73
m 82 m 80 m 85 m 85 m 78 m 87 m 82
;
run;

```

The dollar sign (\$) following **Gender** in the **INPUT** statement indicates that **Gender** is a character variable. The trailing at signs (@@) enable the procedure to read more than one observation per line.

You can use a group t test to determine if the mean golf score for the men in the class differs significantly from the mean score for the women. If you also suspect that the distributions of the golf scores of males and females have unequal variances, then submitting the following statements invokes **PROC TTEST** with options to deal with the unequal variance case.

```

proc ttest cochrans ci=equal umpu;
  class Gender;
  var Score;
run;

```

The CLASS statement contains the variable that distinguishes the groups being compared, and the VAR statement specifies the response variable to be used in calculations. The COCHRAN option produces p -values for the unequal variance situation using the Cochran and Cox(1950) approximation. Equal tailed and uniformly most powerful unbiased (UMPU) confidence intervals for σ are requested by the CI= option. Output from these statements is displayed in Figure 77.2 through Figure 77.4.

Comparing Group Means								
The TTEST Procedure								
Statistics								
Variable	Gender	N	Lower CL	Mean	Upper CL	Lower CL	UMPU	Std Dev
			Mean		Mean	Std Dev	Lower CL	
Score	f	7	74.504	76.857	79.211	1.6399	1.5634	2.5448
Score	m	7	79.804	82.714	85.625	2.028	1.9335	3.1472
Score	Diff (1-2)		-9.19	-5.857	-2.524	2.0522	2.0019	2.8619

Statistics						
Variable	Gender	UMPU	Upper CL	Std Err	Minimum	Maximum
		Upper CL	Std Dev			
Score	f	5.2219	5.6039	0.9619	73	80
Score	m	6.4579	6.9303	1.1895	78	87
Score	Diff (1-2)	4.5727	4.7242	1.5298		

Figure 77.2. Simple Statistics

Simple statistics for the two populations being compared, as well as for the difference of the means between the populations, are displayed in Figure 77.2. The Variable column denotes the response variable, while the Class column indicates the population corresponding to the statistics in that row. The sample size (N) for each population, the sample means (Mean), and lower and upper confidence bounds for the means (Lower CL Mean and Upper CL Mean) are displayed next. The standard deviations (Std Dev) are displayed as well, with equal tailed confidence bounds in the Lower CL Std Dev and Upper CL Std Dev columns and UMPU confidence bounds in the UMPU Upper CL Std Dev and UMPU Lower CL Std Dev columns. In addition, standard error of the mean and the minimum and maximum data values are displayed.

T-Tests					
Variable	Method	Variances	DF	t Value	Pr > t
Score	Pooled	Equal	12	-3.83	0.0024
Score	Satterthwaite	Unequal	11.5	-3.83	0.0026
Score	Cochran	Unequal	6	-3.83	0.0087

Figure 77.3. t Tests

The test statistics, associated degrees of freedom, and p -values are displayed in [Figure 77.3](#). The Method column denotes which t test is being used for that row, and the Variances column indicates what assumption about variances is being made. The pooled test assumes that the two populations have equal variances and uses degrees of freedom $n_1 + n_2 - 2$, where n_1 and n_2 are the sample sizes for the two populations. The remaining two tests do not assume that the populations have equal variances. The Satterthwaite test uses the Satterthwaite approximation for degrees of freedom, while the Cochran test uses the Cochran and Cox approximation for the p -value.

Equality of Variances					
Variable	Method	Num DF	Den DF	F Value	Pr > F
Score	Folded F	6	6	1.53	0.6189

Figure 77.4. Tests of Equality of Variances

Examine the output in [Figure 77.4](#) to determine which t test is appropriate. The “Equality of Variances” test results show that the assumption of equal variances is reasonable for these data (the Folded F statistic $F' = 1.53$, with $p = 0.6189$). If the assumption of normality is also reasonable, the appropriate test is the usual pooled t test, which shows that the average golf scores for men and women are significantly different ($t = -3.83$, $p = 0.0024$). If the assumption of equality of variances is not reasonable, then either the Satterthwaite or the Cochran test should be used.

The assumption of normality can be checked using PROC UNIVARIATE; if the assumption of normality is not reasonable, you should analyze the data with the non-parametric Wilcoxon Rank Sum test using PROC NPAR1WAY.

Syntax

The following statements are available in PROC TTEST.

```

PROC TTEST < options > ;
  CLASS variable ;
  PAIRED variables ;
  BY variables ;
  VAR variables ;
  FREQ variable ;
  WEIGHT variable ;

```

No statement can be used more than once. There is no restriction on the order of the statements after the PROC statement.

PROC TTEST Statement

PROC TTEST < options > ;

The following options can appear in the PROC TTEST statement.

ALPHA=*p*

specifies that confidence intervals are to be $100(1 - p)\%$ confidence intervals, where $0 < p < 1$. By default, PROC TTEST uses ALPHA=0.05. If *p* is 0 or less, or 1 or more, an error message is printed.

CI=EQUAL

CI=UMPU

CI=NONE

specifies whether a confidence interval is displayed for σ and, if so, what kind. The CI=EQUAL option specifies an equal tailed confidence interval, and it is the default. The CI=UMPU option specifies an interval based on the uniformly most powerful unbiased test of $H_0: \sigma = \sigma_0$. The CI=NONE option requests that no confidence interval be displayed for σ . The values EQUAL and UMPU together request that both types of confidence intervals be displayed. If the value NONE is specified with one or both of the values EQUAL and UMPU, NONE takes precedence. For more information, see the “[Confidence Interval Estimation](#)” section on page 4785.

COCHRAN

requests the Cochran and Cox (1950) approximation of the probability level of the approximate *t* statistic for the unequal variances situation.

DATA=SAS-*data-set*

names the SAS data set for the procedure to use. By default, PROC TTEST uses the most recently created SAS data set. The input data set can contain summary statistics of the observations instead of the observations themselves. The number, mean, and standard deviation of the observations are required for each BY group (one sample and paired differences) or for each class within each BY group (two samples). For more information on the DATA= option, see the “[Input Data Set of Statistics](#)” section on page 4783.

H0=*m*

requests tests against *m* instead of 0 in all three situations (one-sample, two-sample, and paired observation *t* tests). By default, PROC TTEST uses H0=0.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC TTEST to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.

- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TTEST procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the *SAS Procedures Guide*.

CLASS Statement

CLASS *variable* ;

A CLASS statement giving the name of the classification (or grouping) variable must accompany the PROC TTEST statement in the two independent sample cases. It should be omitted for the one sample or paired comparison situations. If it is used without the VAR statement, all numeric variables in the input data set (except those appearing in the CLASS, BY, FREQ, or WEIGHT statement) are included in the analysis.

The class variable must have two, and only two, levels. PROC TTEST divides the observations into the two groups for the t test using the levels of this variable. You can use either a numeric or a character variable in the CLASS statement.

Class levels are determined from the formatted values of the CLASS variable. Thus, you can use formats to define group levels. Refer to the discussions of the FORMAT procedure, the FORMAT statement, formats, and informats in *SAS Language Reference: Dictionary*.

FREQ Statement

FREQ *variable* ;

The *variable* in the FREQ statement identifies a variable that contains the frequency of occurrence of each observation. PROC TTEST treats each observation as if it appears n times, where n is the value of the FREQ variable for the observation. If the value is not an integer, only the integer portion is used. If the frequency value is less than 1 or is missing, the observation is not used in the analysis. When the FREQ statement is not specified, each observation is assigned a frequency of 1. The FREQ statement cannot be used if the DATA= data set contains statistics instead of the original observations.

PAIRED Statement

PAIRED *PairLists* ;

The *PairLists* in the PAIRED statement identifies the variables to be compared in paired comparisons. You can use one or more *PairLists*. Variables or lists of variables are separated by an asterisk (*) or a colon (:). The asterisk requests comparisons between each variable on the left with each variable on the right. The colon requests comparisons between the first variable on the left and the first on the right, the second on the left and the second on the right, and so forth. The number of variables on the left must equal the number on the right when the colon is used. The differences are calculated by taking the variable on the left minus the variable on the right for both the asterisk and colon. A pair formed by a variable with itself is ignored. Use the PAIRED statement only for paired comparisons. The CLASS and VAR statements cannot be used with the PAIRED statement.

Examples of the use of the asterisk and the colon are shown in the following table.

These PAIRED statements...	yield these comparisons
PAIRED A*B ;	A-B
PAIRED A*B C*D ;	A-B and C-D
PAIRED (A B)*(C D) ;	A-C, A-D, B-C, and B-D
PAIRED (A B)*(C B) ;	A-C, A-B, and B-C
PAIRED (A1-A2)*(B1-B2) ;	A1-B1, A1-B2, A2-B1, and A2-B2
PAIRED (A1-A2):(B1-B2) ;	A1-B1 and A2-B2

VAR Statement

VAR *variables* ;

The VAR statement names the variables to be used in the analyses. One-sample comparisons are conducted when the VAR statement is used without the CLASS statement, while group comparisons are conducted when the VAR statement is used with a CLASS statement. If the VAR statement is omitted, all numeric variables in the input data set (except a numeric variable appearing in the BY, CLASS, FREQ, or WEIGHT statement) are included in the analysis. The VAR statement can be used with one- and two-sample *t* tests and cannot be used with the PAIRED statement.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement weights each observation in the input data set by the value of the WEIGHT variable. The values of the WEIGHT variable can be nonintegral, and they are not truncated. Observations with negative, zero, or missing values for the WEIGHT variable are not used in the analyses. Each observation is assigned a weight of 1 when the WEIGHT statement is not used. The WEIGHT statement cannot be used with an input data set of summary statistics.

Details

Input Data Set of Statistics

PROC TTEST accepts data containing either observation values or summary statistics. It assumes that the DATA= data set contains statistics if it contains a character variable with name `_TYPE_` or `_STAT_`. The TTEST procedure expects this character variable to contain the names of statistics. If both `_TYPE_` and `_STAT_` variables exist and are of type character, PROC TTEST expects `_TYPE_` to contain the names of statistics including 'N', 'MEAN', and 'STD' for each BY group (or for each class within each BY group for two-sample *t* tests). If no 'N', 'MEAN', or 'STD' statistics exist, an error message is printed.

FREQ, WEIGHT, and PAIRED statements cannot be used with input data sets of statistics. BY, CLASS, and VAR statements are the same regardless of data set type. For paired comparisons, see the `_DIF_` values for the `_TYPE_=T` observations in output produced by the OUTSTATS= option in the PROC COMPARE statement (refer to the *SAS Procedures Guide*).

Missing Values

An observation is omitted from the calculations if it has a missing value for either the CLASS variable, a PAIRED variable, or the variable to be tested. If more than one variable is listed in the VAR statement, a missing value in one variable does not eliminate the observation from the analysis of other nonmissing variables.

Computational Methods

The *t* Statistic

The form of the *t* statistic used varies with the type of test being performed.

- To compare an individual mean with a sample of size *n* to a value *m*, use

$$t = \frac{\bar{x} - m}{s/\sqrt{n}}$$

where \bar{x} is the sample mean of the observations and s^2 is the sample variance of the observations.

- To compare n paired differences to a value m , use

$$t = \frac{\bar{d} - m}{s_d / \sqrt{n}}$$

where \bar{d} is the sample mean of the paired differences and s_d^2 is the sample variance of the paired differences.

- To compare means from two independent samples with n_1 and n_2 observations to a value m , use

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - m}{s \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

where s^2 is the pooled variance

$$s^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}$$

and s_1^2 and s_2^2 are the sample variances of the two groups. The use of this t statistic depends on the assumption that $\sigma_1^2 = \sigma_2^2$, where σ_1^2 and σ_2^2 are the population variances of the two groups.

The Folded Form F Statistic

The folded form of the F statistic, F' , tests the hypothesis that the variances are equal, where

$$F' = \frac{\max(s_1^2, s_2^2)}{\min(s_1^2, s_2^2)}$$

A test of F' is a two-tailed F test because you do not specify which variance you expect to be larger. The p -value gives the probability of a greater F value under the null hypothesis that $\sigma_1^2 = \sigma_2^2$.

The Approximate t Statistic

Under the assumption of unequal variances, the approximate t statistic is computed as

$$t' = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{w_1 + w_2}}$$

where

$$w_1 = \frac{s_1^2}{n_1}, \quad w_2 = \frac{s_2^2}{n_2}$$

The Cochran and Cox Approximation

The Cochran and Cox (1950) approximation of the probability level of the approximate t statistic is the value of p such that

$$t' = \frac{w_1 t_1 + w_2 t_2}{w_1 + w_2}$$

where t_1 and t_2 are the critical values of the t distribution corresponding to a significance level of p and sample sizes of n_1 and n_2 , respectively. The number of degrees of freedom is undefined when $n_1 \neq n_2$. In general, the Cochran and Cox test tends to be conservative (Lee and Gurland 1975).

Satterthwaite's Approximation

The formula for Satterthwaite's (1946) approximation for the degrees of freedom for the approximate t statistic is:

$$df = \frac{(w_1 + w_2)^2}{\left(\frac{w_1^2}{n_1 - 1} + \frac{w_2^2}{n_2 - 1}\right)}$$

Refer to Steel and Torrie (1980) or Freund, Littell, and Spector (1986) for more information.

Confidence Interval Estimation

The form of the confidence interval varies with the statistic for which it is computed. In the following confidence intervals involving means, $t_{1-\frac{\alpha}{2}, n-1}$ is the $100(1 - \frac{\alpha}{2})\%$ quantile of the t distribution with $n - 1$ degrees of freedom. The confidence interval for

- an individual mean from a sample of size n compared to a value m is given by

$$(\bar{x} - m) \pm t_{1-\frac{\alpha}{2}, n-1} \frac{s}{\sqrt{n}}$$

where \bar{x} is the sample mean of the observations and s^2 is the sample variance of the observations

- paired differences with a sample of size n differences compared to a value m is given by

$$(\bar{d} - m) \pm t_{1-\frac{\alpha}{2}, n-1} \frac{s_d}{\sqrt{n}}$$

where \bar{d} and s_d^2 are the sample mean and sample variance of the paired differences, respectively

- the difference of two means from independent samples with n_1 and n_2 observations compared to a value m is given by

$$((\bar{x}_1 - \bar{x}_2) - m) \pm t_{1-\frac{\alpha}{2}, n_1+n_2-2} s \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$$

where s^2 is the pooled variance

$$s^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}$$

and where s_1^2 and s_2^2 are the sample variances of the two groups. The use of this confidence interval depends on the assumption that $\sigma_1^2 = \sigma_2^2$, where σ_1^2 and σ_2^2 are the population variances of the two groups.

The distribution of the estimated standard deviation of a mean is not symmetric, so alternative methods of estimating confidence intervals are possible. PROC TTEST computes two estimates. For both methods, the data are assumed to have a normal distribution with mean μ and variance σ^2 , both unknown. The methods are as follows:

- The default method, an equal-tails confidence interval, puts an equal amount of area ($\frac{\alpha}{2}$) in each tail of the chi-square distribution. An equal tails test of $H_0: \sigma = \sigma_0$ has acceptance region

$$\left\{ \chi_{\frac{\alpha}{2}, n-1}^2 \leq \frac{(n-1)S^2}{\sigma_0^2} \leq \chi_{\frac{1-\alpha}{2}, n-1}^2 \right\}$$

which can be algebraically manipulated to give the following $100(1 - \alpha)\%$ confidence interval for σ^2 :

$$\left(\frac{(n-1)S^2}{\chi_{1-\frac{\alpha}{2}, n-1}^2}, \frac{(n-1)S^2}{\chi_{\frac{\alpha}{2}, n-1}^2} \right)$$

In order to obtain a confidence interval for σ , the square root of each side is taken, leading to the following $100(1 - \alpha)\%$ confidence interval:

$$\left(\sqrt{\frac{(n-1)S^2}{\chi_{1-\frac{\alpha}{2}, n-1}^2}}, \sqrt{\frac{(n-1)S^2}{\chi_{\frac{\alpha}{2}, n-1}^2}} \right)$$

- The second method yields a confidence interval derived from the uniformly most powerful unbiased test of $H_0: \sigma = \sigma_0$ (Lehmann 1986). This test has acceptance region

$$\left\{ c_1 \leq \frac{(n-1)S^2}{\sigma_0^2} \leq c_2 \right\}$$

where the critical values c_1 and c_2 satisfy

$$\int_{c_1}^{c_2} f_n(y) dy = 1 - \alpha$$

and

$$\int_{c_1}^{c_2} y f_n(y) dy = n(1 - \alpha)$$

where $f_n(y)$ is the chi-squared distribution with n degrees of freedom. This acceptance region can be algebraically manipulated to arrive at

$$P \left\{ \frac{(n-1)S^2}{c_2} \leq \sigma^2 \leq \frac{(n-1)S^2}{c_1} \right\} = 1 - \alpha$$

where c_1 and c_2 solve the preceding two integrals. To find the area in each tail of the chi-square distribution to which these two critical values correspond, solve $c_1 = \chi_{1-\alpha_2, n-1}^2$ and $c_2 = \chi_{\alpha_1, n-1}^2$ for α_1 and α_2 ; the resulting α_1 and α_2 sum to α . Hence, a $100(1 - \alpha)\%$ confidence interval for σ^2 is given by

$$\left(\frac{(n-1)S^2}{\chi_{1-\alpha_2, n-1}^2}, \frac{(n-1)S^2}{\chi_{\alpha_1, n-1}^2} \right)$$

In order to obtain a $100(1 - \alpha)\%$ confidence interval for σ , the square root is taken of both terms, yielding

$$\left(\sqrt{\frac{(n-1)S^2}{\chi_{1-\alpha_2, n-1}^2}}, \sqrt{\frac{(n-1)S^2}{\chi_{\alpha_1, n-1}^2}} \right)$$

Displayed Output

For each variable in the analysis, the TTEST procedure displays the following summary statistics for each group:

- the name of the dependent variable
- the levels of the classification variable
- N, the number of nonmissing values
- Lower CL Mean, the lower confidence bound for the mean
- the Mean or average
- Upper CL Mean, the upper confidence bound for the mean
- Lower CL Std Dev, the lower confidence bound for the standard deviation
- Std Dev, the standard deviation
- Upper CL Std Dev, the upper confidence bound for the standard deviation
- Std Err, the standard error of the mean
- the Minimum value, if the line size allows
- the Maximum value, if the line size allows
- upper and lower UMPU confidence bounds for the standard deviation, displayed if the CI=UMPU option is specified in the PROC TTEST statement

Next, the results of several t tests are given. For one-sample and paired observations t tests, the TTEST procedure displays

- t Value, the t statistic for testing the null hypothesis that the mean of the group is zero
- DF, the degrees of freedom
- $\text{Pr} > |t|$, the probability of a greater absolute value of t under the null hypothesis. This is the two-tailed significance probability.

To compute the one-tailed significance probability, first determine whether large values of t are significant or small values are. Let p denote the significance probability for the two-tailed test. If large values of t are significant, then the one-tailed probability is $p/2$ if $t \geq 0$, and is $1 - p/2$ if $t < 0$. If small values of t are significant, then the one-tailed probability is $1 - p/2$ if $t \geq 0$, and is $p/2$ if $t < 0$.

For two-sample t tests, the TTEST procedure displays all the items in the following list. You need to decide whether equal or unequal variances are appropriate for your data.

- Under the assumption of unequal variances, the TTEST procedure displays results using Satterthwaite's method. If the COCHRAN option is specified, the results for the Cochran and Cox approximation are also displayed.
 - t Value, an approximate t statistic for testing the null hypothesis that the means of the two groups are equal
 - DF, the approximate degrees of freedom
 - $\text{Pr} > |t|$, the probability of a greater absolute value of t under the null hypothesis. This is the two-tailed significance probability. The one-tailed probability is computed the same way as in a one-sample t test.
- Under the assumption of equal variances, the TTEST procedure displays results obtained by pooling the group variances.
 - t Value, the t statistic for testing the null hypothesis that the means of the two groups are equal
 - DF, the degrees of freedom
 - $\text{Pr} > |t|$, the probability of a greater absolute value of t under the null hypothesis. This is the two-tailed significance probability. The one-tailed probability is computed the same way as in a one-sample t test.
- PROC TTEST then gives the results of the test of equality of variances:
 - the F' (folded) statistic (see the “[The Folded Form F Statistic](#)” section on page 4784)
 - Num DF and Den DF, the numerator and denominator degrees of freedom in each group
 - $\text{Pr} > F$, the probability of a greater F' value. This is the two-tailed significance probability.

ODS Table Names

PROC TTEST assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 77.1. ODS Tables Produced in PROC TTEST

ODS Table Name	Description	Statement
Equality	Tests for equality of variance	CLASS statement
Statistics	Univariate summary statistics	by default
TTests	<i>t</i> -tests	by default

Examples

Example 77.1. Comparing Group Means Using Input Data Set of Summary Statistics

The following example, taken from Huntsberger and Billingsley (1989), compares two grazing methods using 32 steer. Half of the steer are allowed to graze continuously while the other half are subjected to controlled grazing time. The researchers want to know if these two grazing methods impact weight gain differently. The data are read by the following DATA step.

```

title 'Group Comparison Using Input Data Set of Summary Statistics';
data graze;
  length GrazeType $ 10;
  input GrazeType $ WtGain @@;
  datalines;
controlled 45   controlled 62
controlled 96   controlled 128
controlled 120  controlled 99
controlled 28   controlled 50
controlled 109  controlled 115
controlled 39   controlled 96
controlled 87   controlled 100
controlled 76   controlled 80
continuous 94   continuous 12
continuous 26   continuous 89
continuous 88   continuous 96
continuous 85   continuous 130
continuous 75   continuous 54
continuous 112  continuous 69
continuous 104  continuous 95
continuous 53   continuous 21
;
run;

```

The variable `GrazeType` denotes the grazing method: ‘controlled’ is controlled grazing and ‘continuous’ is continuous grazing. The dollar sign (\$) following `GrazeType` makes it a character variable, and the trailing at signs (@@) tell the procedure that

there is more than one observation per line. The MEANS procedure is invoked to create a data set of summary statistics with the following statements:

```
proc sort;
  by GrazeType;
proc means data=graze noprint;
  var WtGain;
  by GrazeType;
  output out=newgraze;
run;
```

The NOPRINT option eliminates all output from the MEANS procedure. The VAR statement tells PROC MEANS to compute summary statistics for the WtGain variable, and the BY statement requests a separate set of summary statistics for each level of GrazeType. The OUTPUT OUT= statement tells PROC MEANS to put the summary statistics into a data set called newgraze so that it may be used in subsequent procedures. This new data set is displayed in [Output 77.1.1](#) by using PROC PRINT as follows:

```
proc print data=newgraze;
run;
```

The _STAT_ variable contains the names of the statistics, and the GrazeType variable indicates which group the statistic is from.

Output 77.1.1. Output Data Set of Summary Statistics

Group Comparison Using Input Data Set of Summary Statistics					
Obs	GrazeType	_TYPE_	_FREQ_	_STAT_	WtGain
1	continuous	0	16	N	16.000
2	continuous	0	16	MIN	12.000
3	continuous	0	16	MAX	130.000
4	continuous	0	16	MEAN	75.188
5	continuous	0	16	STD	33.812
6	controlled	0	16	N	16.000
7	controlled	0	16	MIN	28.000
8	controlled	0	16	MAX	128.000
9	controlled	0	16	MEAN	83.125
10	controlled	0	16	STD	30.535

The following code invokes PROC TTEST using the newgraze data set, as denoted by the DATA= option.

```
proc ttest data=newgraze;
  class GrazeType;
  var WtGain;
run;
```

The CLASS statement contains the variable that distinguishes between the groups being compared, in this case `GrazeType`. The summary statistics and confidence intervals are displayed first, as shown in [Output 77.1.2](#).

Output 77.1.2. Summary Statistics

The TTEST Procedure							
Statistics							
Variable	GrazeType	N	Lower CL		Upper CL	Lower CL	
			Mean	Mean	Mean	Std Dev	Std Dev
WtGain	continuous	16	57.171	75.188	93.204	.	33.812
WtGain	controlled	16	66.854	83.125	99.396	.	30.535
WtGain	Diff (1-2)		-31.2	-7.938	15.323	25.743	32.215

Statistics					
Variable	GrazeType	Upper CL		Minimum	Maximum
		Std Dev	Std Err		
WtGain	continuous	.	8.4529	12	130
WtGain	controlled	.	7.6337	28	128
WtGain	Diff (1-2)	43.061	11.39		

In [Output 77.1.2](#), the Variable column states the variable used in computations and the Class column specifies the group for which the statistics are computed. For each class, the sample size, mean, standard deviation and standard error, and maximum and minimum values are displayed. The confidence bounds for the mean are also displayed; however, since summary statistics are used as input, the confidence bounds for the standard deviation of the groups are not calculated.

Output 77.1.3. t Tests

T-Tests					
Variable	Method	VariANCES	DF	t Value	Pr > t
WtGain	Pooled	Equal	30	-0.70	0.4912
WtGain	Satterthwaite	Unequal	29.7	-0.70	0.4913

Equality of Variances					
Variable	Method	Num DF	Den DF	F Value	Pr > F
WtGain	Folded F	15	15	1.23	0.6981

[Output 77.1.3](#) shows the results of tests for equal group means and equal variances. A group test statistic for the equality of means is reported for equal and unequal variances. Before deciding which test is appropriate, you should look at the test for equality of variances; this test does not indicate a significant difference in the two variances ($F' = 1.23, p = 0.6981$), so the pooled t statistic should be used. Based

on the pooled statistic, the two grazing methods are not significantly different ($t = 0.70, p = 0.4912$). Note that this test assumes that the observations in both data sets are normally distributed; this assumption can be checked in PROC UNIVARIATE using the raw data.

Example 77.2. One-Sample Comparison Using the FREQ Statement

This example examines children's reading skills. The data consist of Degree of Reading Power (DRP) test scores from 44 third-grade children and are taken from Moore (1995, p. 337). Their scores are given in the following DATA step.

```

title 'One-Mean Comparison Using FREQ Statement';
data read;
  input score count @@;
  datalines;
40 2   47 2   52 2   26 1   19 2
25 2   35 4   39 1   26 1   48 1
14 2   22 1   42 1   34 2   33 2
18 1   15 1   29 1   41 2   44 1
51 1   43 1   27 2   46 2   28 1
49 1   31 1   28 1   54 1   45 1
;
run;

```

The following statements invoke the TTEST procedure to test if the mean test score is equal to 30. The COUNT variable contains the frequency of occurrence of each test score; this is specified in the FREQ statement.

```

proc ttest data=read h0=30;
  var score;
  freq count;
run;

```

The output, shown in [Output 77.2.1](#), contains the results.

Output 77.2.1. TTEST Results

One-Mean Comparison Using FREQ Statement										
The TTEST Procedure										
Statistics										
Variable	N	Lower CL Mean	Upper CL Mean	Lower CL Mean	Upper CL Mean	Lower CL Std Dev	Upper CL Std Dev	Std Err	Minimum	Maximum
score	44	31.449	34.864	38.278	9.2788	11.23	14.229	1.693	14	54
T-Tests										
Variable	DF	t Value	Pr > t							
score	43	2.87	0.0063							

The SAS log states that 30 observations and two variables have been read. However, the sample size given in the TTEST output is N=44. This is due to specifying the count variable in the FREQ statement. The test is significant ($t = 2.87$, $p = 0.0063$) at the 5% level, thus you can conclude that the mean test score is different from 30.

Example 77.3. Paired Comparisons

When it is not feasible to assume that two groups of data are independent, and a natural pairing of the data exists, it is advantageous to use an analysis that takes the correlation into account. Utilizing this correlation results in higher power to detect existing differences between the means. The differences between paired observations are assumed to be normally distributed. Some examples of this natural pairing are

- pre- and post-test scores for a student receiving tutoring
- fuel efficiency readings of two fuel types observed on the same automobile
- sunburn scores for two sunblock lotions, one applied to the individual's right arm, one to the left arm
- political attitude scores of husbands and wives

In this example, taken from *SUGI Supplemental Library User's Guide, Version 5 Edition*, a stimulus is being examined to determine its effect on systolic blood pressure. Twelve men participate in the study. Their systolic blood pressure is measured both before and after the stimulus is applied. The following statements input the data:

```

title 'Paired Comparison';
data pressure;
    input SBPbefore SBPafter @@;
    datalines;
120 128   124 131   130 131   118 127
140 132   128 125   140 141   135 137
126 118   130 132   126 129   127 135
;
run;

```

The variables SBPbefore and SBPafter denote the systolic blood pressure before and after the stimulus, respectively.

The statements to perform the test follow.

```

proc ttest;
    paired SBPbefore*SBPafter;
run;

```

The PAIRED statement is used to test whether the mean change in systolic blood pressure is significantly different from zero. The output is displayed in [Output 77.3.1](#).

Output 77.3.1. TTEST Results

Paired Comparison										
The TTEST Procedure										
Statistics										
Difference	N	Lower CL Mean	Mean	Upper CL Mean	Lower CL Std Dev	Std Dev	Upper CL Std Dev	Std Err	Minimum	Maximum
SBPbefore - SBPafter	12	-5.536	-1.833	1.8698	4.1288	5.8284	9.8958	1.6825	-9	8
T-Tests										
Difference	DF	t Value	Pr > t							
SBPbefore - SBPafter	11	-1.09	0.2992							

The variables SBPbefore and SBPafter are the paired variables with a sample size of 12. The summary statistics of the difference are displayed (mean, standard deviation, and standard error) along with their confidence limits. The minimum and maximum differences are also displayed. The t test is not significant ($t = -1.09$, $p = 0.2992$), indicating that the stimuli did not significantly affect systolic blood pressure.

Note that this test of hypothesis assumes that the differences are normally distributed. This assumption can be investigated using PROC UNIVARIATE with the NORMAL option. If the assumption is not satisfied, PROC NPAR1WAY should be used.

Chapter 78

The VARCLUS Procedure

Overview

The VARCLUS procedure divides a set of numeric variables into disjoint or hierarchical clusters. Associated with each cluster is a linear combination of the variables in the cluster. This linear combination can be either the first principal component (the default) or the centroid component (if you specify the CENTROID option). The first principal component is a weighted average of the variables that explains as much variance as possible. See [Chapter 58, “The PRINCOMP Procedure,”](#) for further details. Centroid components are unweighted averages of either the standardized variables (the default) or the raw variables (if you specify the COVARIANCE option). PROC VARCLUS tries to maximize the variance that is explained by the cluster components, summed over all the clusters.

The cluster components are oblique, not orthogonal, even when the cluster components are first principal components. In an ordinary principal component analysis, all components are computed from the same variables, and the first principal component is orthogonal to the second principal component and to each other principal component. In PROC VARCLUS, each cluster component is computed from a different set of variables than all the other cluster components. The first principal component of one cluster may be correlated with the first principal component of another cluster. Hence, PROC VARCLUS is a type of oblique component analysis.

As in principal component analysis, either the correlation or the covariance matrix can be analyzed. If correlations are used, all variables are treated as equally important. If covariances are used, variables with larger variances have more importance in the analysis.

PROC VARCLUS creates an output data set that can be used with the SCORE procedure to compute component scores for each cluster. A second output data set can be used by the TREE procedure to draw a tree diagram of hierarchical clusters.

The VARCLUS procedure can be used as a variable-reduction method. A large set of variables can often be replaced by the set of cluster components with little loss of information. A given number of cluster components does not generally explain as much variance as the same number of principal components on the full set of variables, but the cluster components are usually easier to interpret than the principal components, even if the latter are rotated.

For example, an educational test might contain fifty items. PROC VARCLUS can be used to divide the items into, say, five clusters. Each cluster can then be treated as a subtest, with the subtest scores given by the cluster components. If the cluster components are centroid components of the covariance matrix, each subtest score is simply the sum of the item scores for that cluster.

The VARCLUS algorithm is both divisive and iterative. By default, PROC VARCLUS begins with all variables in a single cluster. It then repeats the following steps:

1. A cluster is chosen for splitting. Depending on the options specified, the selected cluster has either the smallest percentage of variation explained by its cluster component (using the PROPORTION= option) or the largest eigenvalue associated with the second principal component (using the MAXEIGEN= option).
2. The chosen cluster is split into two clusters by finding the first two principal components, performing an orthoblique rotation (raw quartimax rotation on the eigenvectors; Harris and Kaiser, 1964), and assigning each variable to the rotated component with which it has the higher squared correlation.
3. Variables are iteratively reassigned to clusters to try to maximize the variance accounted for by the cluster components. You can require the reassignment algorithms to maintain a hierarchical structure for the clusters.

The procedure stops splitting when either:

- the maximum number of clusters as specified by the MAXCLUSTERS= option is reached, or
- each cluster satisfies the stopping criteria specified by the PROPORTION= (percentage of variation explained) and/or the MAXEIGEN= (second eigenvalue) options.

By default, VARCLUS stops splitting when each cluster has only one eigenvalue greater than one, thus satisfying the most popular criterion for determining the sufficiency of a single underlying dimension.

The iterative reassignment of variables to clusters proceeds in two phases. The first is a nearest component sorting (NCS) phase, similar in principle to the nearest centroid sorting algorithms described by Anderberg (1973). In each iteration, the cluster components are computed, and each variable is assigned to the component with which it has the highest squared correlation. The second phase involves a search algorithm in which each variable is tested to see if assigning it to a different cluster increases the amount of variance explained. If a variable is reassigned during the search phase, the components of the two clusters involved are recomputed before the next variable is tested. The NCS phase is much faster than the search phase but is more likely to be trapped by a local optimum.

If principal components are used, the NCS phase is an alternating least-squares method and converges rapidly. The search phase can be very time consuming for a large number of variables. But if the default initialization method is used, the search phase is rarely able to substantially improve the results of the NCS phase, so the search takes few iterations. If random initialization is used, the NCS phase may be trapped by a local optimum from which the search phase can escape.

If centroid components are used, the NCS phase is not an alternating least-squares method and may not increase the amount of variance explained; therefore, it is limited, by default, to one iteration.

You can have VARCLUS do the clustering hierarchically by restricting the reassignment of variables such that the clusters maintain a tree structure. In this case, when a cluster is split, a variable in one of the two resulting clusters can be reassigned to the other cluster resulting from the split but not to a cluster that is not part of the original cluster (the one that is split).

Getting Started

This example demonstrates how you can use the VARCLUS procedure to create hierarchical, unidimensional clusters of variables.

The following data, from Hand, et al. (1994), represent amounts of protein consumed from nine food groups for each of 25 European countries. The nine food groups are red meat (RedMeat), white meat (WhiteMeat), eggs (Eggs), milk (Milk), fish (Fish), cereal (Cereal), starch (Starch), nuts (Nuts), and fruits and vegetables (FruitVeg).

Suppose you want to simplify interpretation of the data by reducing the number of variables to a smaller set of variable cluster components. You can use the VARCLUS procedure for this type of variable reduction.

The following DATA step creates the SAS data set Protein:

```

data Protein;
  input Country $18. RedMeat WhiteMeat Eggs Milk
         Fish Cereal Starch Nuts FruitVeg;
  datalines;
Albania      10.1  1.4  0.5   8.9  0.2  42.3  0.6  5.5  1.7
Austria      8.9 14.0  4.3  19.9  2.1  28.0  3.6  1.3  4.3
Belgium     13.5  9.3  4.1  17.5  4.5  26.6  5.7  2.1  4.0
Bulgaria     7.8  6.0  1.6   8.3  1.2  56.7  1.1  3.7  4.2
Czechoslovakia 9.7 11.4  2.8  12.5  2.0  34.3  5.0  1.1  4.0

;

```

The data set `Protein` contains the character variable `Country` and the nine numeric variables representing the food groups. The `$18.` in the `INPUT` statement specifies that the variable `Country` is a character variable with a length of 18.

The following statements create the variable clusters.

```

proc varclus data=Protein outtree=tree centroid maxclusters=4;
  var RedMeat--FruitVeg;
run;

```

The `DATA=` option specifies the SAS data set `Protein` as input. The `OUTTREE=` option creates the output SAS data set `Tree` to contain the tree structure information. When you specify this option, you are implicitly requiring the clusters to be hierarchical rather than disjoint.

The `CENTROID` option specifies the centroid method of clustering. This means that the calculated cluster components are the unweighted averages of the standardized variables. The `MAXCLUSTERS=4` option specifies that no more than four clusters be computed.

The `VAR` statement lists the numeric variables (`RedMeat–FruitVeg`) to be used in the analysis.

The results of this analysis are displayed in the following figures.

Although `PROC VARCLUS` displays output for each step in the clustering process, the following figures display only the final analysis for four clusters. [Figure 78.1](#) displays the final cluster summary.

Oblique Centroid Component Cluster Analysis					
Cluster Summary for 4 Clusters					
Cluster	Members	Cluster Variation	Variation Explained	Proportion Explained	
1	4	4	2.173024	0.5433	
2	2	2	1.650997	0.8255	
3	2	2	1.403853	0.7019	
4	1	1	1	1.0000	
Total variation explained = 6.227874 Proportion = 0.6920					

Figure 78.1. Final Cluster Summary from the VARCLUS Procedure

For each cluster, [Figure 78.1](#) displays the number of variables in the cluster, the cluster variation, the total explained variation, and the proportion of the total variance

explained by the variables in the cluster. The variance explained by the variables in a cluster is similar to the variance explained by a factor in common factor analysis, but it includes contributions only from the variables in the cluster rather than from all variables.

The line labeled “Total variation explained” in Figure 78.1 gives the sum of the explained variation over all clusters. The final “Proportion” represents the total explained variation divided by the sum of cluster variation. This value, 0.6920, indicates that about 69% of the total variation in the data can be accounted for by the four cluster components.

Figure 78.2 shows how the variables are clustered. The first cluster represents animal protein (RedMeat, WhiteMeat, Eggs, and Milk), the second cluster contains the variables Cereal and Nuts, the third cluster is composed of the variables Fish and Starch, and the last cluster contains the single variable representing fruits and vegetables (FruitVeg).

Oblique Centroid Component Cluster Analysis				
4 Clusters		R-squared with		
Cluster	Variable	Own Cluster	Next Closest	1-R**2 Ratio
Cluster 1	RedMeat	0.4375	0.1518	0.6631
	WhiteMeat	0.6302	0.3331	0.5545
	Eggs	0.7024	0.4902	0.5837
	Milk	0.4288	0.2721	0.7847
Cluster 2	Cereal	0.8255	0.3983	0.2900
	Nuts	0.8255	0.5901	0.4257
Cluster 3	Fish	0.7019	0.1365	0.3452
	Starch	0.7019	0.3075	0.4304
Cluster 4	FruitVeg	1.0000	0.0578	0.0000

Figure 78.2. R-square Values from the VARCLUS Procedure

Figure 78.2 also displays the R^2 value of each variable with its own cluster and the R^2 value with its nearest cluster. The R^2 value for a variable with the nearest cluster should be low if the clusters are well separated. The last column displays the ratio of $(1 - R_{own}^2)/(1 - R_{nearest}^2)$ for each variable. Small values of this ratio indicate good clustering.

Figure 78.3 displays the cluster structure and the intercluster correlations. The structure table displays the correlation of each variable with each cluster component. The table of intercorrelations contains the correlations between the cluster components.

Oblique Centroid Component Cluster Analysis				
Cluster Structure				
Cluster	1	2	3	4
RedMeat	0.66145	-0.38959	0.06450	-0.34109
WhiteMeat	0.79385	-0.57715	0.04760	-0.06132
Eggs	0.83811	-0.70012	0.30902	-0.04552
Milk	0.65483	-0.52163	0.16805	-0.26096
Fish	-0.08108	-0.36947	0.83781	0.26614
Cereal	-0.58070	0.90857	-0.63111	0.04655
Starch	0.41593	-0.55448	0.83781	0.08441
Nuts	-0.76817	0.90857	-0.37089	0.37497
FruitVeg	-0.24045	0.23197	0.20920	1.00000

Inter-Cluster Correlations				
Cluster	1	2	3	4
1	1.00000	-0.74230	0.19984	-0.24045
2	-0.74230	1.00000	-0.55141	0.23197
3	0.19984	-0.55141	1.00000	0.20920
4	-0.24045	0.23197	0.20920	1.00000

Figure 78.3. Cluster Correlations and Intercorrelations

PROC VARCLUS next displays the summary table of statistics for the cluster history (Figure 78.4). The first three columns give the number of clusters, the total variation explained by clusters, and the proportion of variation explained by clusters.

As displayed in Figure 78.4, when the number of allowable clusters is two, the total variation explained is 3.9607, and the cumulative proportion of variation explained by two clusters is 0.4401. When the number of clusters increases to three, the proportion of explained variance increases to 0.5880. When four clusters are computed, the explained variation is 0.6920.

Oblique Centroid Component Cluster Analysis					
Number of Clusters	Total Variation Explained by Clusters	Proportion of Variation Explained by Clusters	Minimum Proportion Explained by a Cluster	Minimum R-squared for a Variable	Maximum 1-R**2 Ratio for a Variable
1	0.732343	0.0814	0.0814	0.0875	
2	3.960717	0.4401	0.3743	0.1007	1.0213
3	5.291887	0.5880	0.5433	0.3928	0.7978
4	6.227874	0.6920	0.5433	0.4288	0.7847

Figure 78.4. Final Cluster Summary Table from the VARCLUS Procedure

Figure 78.4 also displays the minimum proportion of variance explained by a cluster, the minimum R^2 for a variable, and the maximum $(1 - R^2)$ ratio for a variable. The last quantity is the ratio of the value $1 - R^2$ for a variable's own cluster to the value $1 - R^2$ for its nearest cluster.

The following statements produce a tree diagram of the cluster structure created by PROC VARCLUS. The AXIS1 statement suppresses the label for the vertical axis, which would otherwise be “Name of Variable or Cluster”.

```
axis1 label=none;
proc tree data=tree horizontal vaxis=axis1;
height _propor_;
run;
```

Next, the TREE procedure is invoked using the SAS data set TREE, created by the OUTTREE= option in the preceding PROC VARCLUS statement. The HORIZONTAL option orients the tree diagram horizontally. The VAXIS option associates the vertical axis with the the AXIS1 statement. The HEIGHT statement specifies the use of the variable `_PROPOR_` (the proportion of variance explained) as the height variable.

Figure 78.5 shows how the clusters are created. The ordered variable names are displayed on the vertical axis. The horizontal axis displays the proportion of variance explained at each clustering level.

Figure 78.5. Horizontal Tree Diagram from PROC TREE

As you look from left to right in the diagram, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the diagram. Clusters exist at each level of the diagram, and every vertical line connects leaves and branches into progressively larger clusters.

For example, when the variables are formed into three clusters, one cluster contains the variables RedMeat, WhiteMeat, Eggs, and Milk; the second cluster contains the

variables Fish and Starch; the third cluster contains the variables Cereal, Nuts, and FruitVeg. The proportion of variance explained at that level is 0.5880 (from Figure 78.4). At the next stage of clustering, the third cluster is split as the variable FruitVeg forms the fourth cluster; the proportion of variance explained is 0.6920.

Syntax

The following statements are available in PROC VARCLUS.

```
PROC VARCLUS < options > ;
  VAR variables ;
  SEED variables ;
  PARTIAL variables ;
  WEIGHT variables ;
  FREQ variables ;
  BY variables ;
```

Usually you need only the VAR statement in addition to the PROC VARCLUS statement. The following sections give detailed syntax information for each of the statements, beginning with the PROC VARCLUS statement. The remaining statements are listed in alphabetical order.

PROC VARCLUS Statement

```
PROC VARCLUS < options >;
```

The PROC VARCLUS statement starts the VARCLUS procedure. By default, VARCLUS clusters the numeric variables in the most recently created SAS data set, starting with one cluster and splitting clusters until all clusters have at most one eigenvalue greater than one.

VARCLUS chooses a cluster to split based on two options: MAXEIGEN=, and PROPORTION=.

1. If you specify *either* or *both* of these two options, then *only* the specified options affect the choice of the cluster to split.
2. If you specify *neither* of these options, the criterion for choice of cluster to split depends on the CENTROID option:
 - (a) If you specify CENTROID, VARCLUS splits the cluster with the smallest percentage of variation explained by its cluster component, as if you had specified the PROPORTION= option.
 - (b) If you do not specify CENTROID, VARCLUS splits the cluster with the largest eigenvalue associated with the second principal component, as if you had specified the MAXEIGEN= option.

The final number of clusters is controlled by three options: MAXCLUSTERS=, MAXEIGEN=, and PROPORTION=.

1. If you specify *any* of these three options, then *only* the options you specify affect the final number of clusters.
2. If you specify *none* of these options, VARCLUS continues to split clusters until the default splitting criterion is satisfied. The default splitting criterion depends on the CENTROID option:
 - (a) If you specify CENTROID, the default splitting criterion is PROPORTION=0.75.
 - (b) If you do not specify CENTROID, splitting is based on the MAXEIGEN= criterion, with a default depending on the COVARIANCE option:
 - i. for analyzing a correlation matrix (no COVARIANCE option), the default value for MAXEIGEN= is one.
 - ii. for analyzing a covariance matrix (using the COVARIANCE option), the default value for MAXEIGEN= is the average variance of the variables being clustered.

VARCLUS continues to split clusters until any of the following conditions holds:

- the number of cluster equals the value specified for MAXCLUSTERS=.
- no cluster qualifies for splitting according to the MAXEIGEN= or PROPORTION= criteria.
- a cluster was chosen for splitting, but after iteratively reassigning variables to clusters, one of the cluster has no members.

Table 78.1 summarizes some of the options available in the PROC VARCLUS statement.

Table 78.1. Options Available in the PROC VARCLUS Statement

Task	Options
Specify data sets	DATA= OUTSTAT= OUTTREE=
Determine the number of clusters	MAXCLUSTERS= MINCLUSTERS= MAXEIGEN= PROPORTION=
Specify cluster formation	CENTROID COVARIANCE HIERARCHY INITIAL= MAXITER= MAXSEARCH= MULTIPLEGROUP RANDOM=
Control output	CORR NOPRINT SHORT SIMPLE SUMMARY TRACE
Omit intercept	NOINT
Specify divisor for variances	VARDEF=

The following list gives details on these options. The list is in alphabetical order.

CENTROID

uses centroid components rather than principal components. You should specify centroid components if you want the cluster components to be unweighted averages of the standardized variables (the default) or the unstandardized variables (if you specify the COVARIANCE option). It is possible to obtain locally optimal clusterings in which a variable is not assigned to the cluster component with which it has the highest squared correlation. You cannot specify both the CENTROID and MAXEIGEN= options.

CORR

C

displays the correlation matrix.

COVARIANCE**COV**

analyzes the covariance matrix instead of the correlation matrix. The COVARIANCE option causes variables with a large variance to have more effect on the cluster components than variables with a small variance.

DATA=SAS-data-set

specifies the input data set to be analyzed. The data set can be an ordinary SAS data set or TYPE=CORR, UCORR, COV, UCOV, FACTOR, or SSCP. If you do not specify the DATA= option, the most recently created SAS data set is used. See [Appendix A, “Special SAS Data Sets,”](#) for more information on types of SAS data sets.

HIERARCHY**HI**

requires the clusters at different levels to maintain a hierarchical structure. To draw a tree diagram, use the OUTTREE= option and the TREE procedure.

INITIAL=GROUP**INITIAL=INPUT****INITIAL=RANDOM****INITIAL=SEED**

specifies the method for initializing the clusters. If the INITIAL= option is omitted and the MINCLUSTERS= option is greater than 1, the initial cluster components are obtained by extracting the required number of principal components and performing an orthoblique rotation (raw quartimax rotation on the eigenvectors; Harris and Kaiser, 1964). The following list describes the values for the INITIAL= option:

GROUP	obtains the cluster membership of each variable from an observation in the DATA= data set where the <code>_TYPE_</code> variable has a value of “GROUP”. In this observation, the variables to be clustered must each have an integer value ranging from one to the number of clusters. You can use this option only if the DATA= data set is a TYPE=CORR, UCORR, COV, UCOV, or FACTOR data set. You can use a data set created either by a previous run of PROC VARCLUS or in a DATA step.
INPUT	obtains scoring coefficients for the cluster components from observations in the DATA= data set where the <code>_TYPE_</code> variable has a value of “SCORE”. You can use this option only if the DATA= data set is a TYPE=CORR, UCORR, COV, UCOV, or FACTOR data set. You can use scoring coefficients from the FACTOR procedure or a previous run of PROC VARCLUS, or you can enter other coefficients in a DATA step.
RANDOM	assigns variables randomly to clusters.
SEED	initializes each cluster component to be one of the variables named in the SEED statement. Each variable listed in the SEED statement becomes the sole member of a cluster, and the other variables are initially unassigned. If you do not specify the SEED statement, the

first MINCLUSTERS= variables in the VAR statement are used as seeds.

MAXCLUSTERS=*n*

MAXC=*n*

specifies the largest number of clusters desired. The default value is the number of variables. VARCLUS stops splitting clusters after the number of clusters reaches the value of the MAXCLUSTERS= option, regardless of what other splitting options are specified.

MAXEIGEN=*n*

specifies that when choosing a cluster to split, VARCLUS should choose the cluster with the largest second eigenvalue, provided that its second eigenvalue is greater than the MAXEIGEN= value. The MAXEIGEN= option cannot be used with the CENTROID or MULTIPLEGROUP options.

If you do not specify MAXEIGEN=, then:

- If you specify PROPORTION=, CENTROID, or MULTIPLEGROUP, cluster splitting does not depend on the second eigenvalue.
- Otherwise, if you specify MAXCLUSTERS=, the default value for MAXEIGEN= is zero.
- Otherwise, the default value for MAXEIGEN= is either 1.0 if the correlation matrix is analyzed, or the average variance if the COVARIANCE option is specified.

If you specify both MAXEIGEN= and MAXCLUSTERS=, the number of clusters will never exceed the value of the MAXCLUSTERS= option.

If you specify both MAXEIGEN= and PROPORTION=, VARCLUS first looks for a cluster to split based on the MAXEIGEN= criterion. If no cluster meets that criterion, VARCLUS then looks for a cluster to split based on the PROPORTION= criterion.

MAXITER=*n*

specifies the maximum number of iterations during the NCS phase. The default value is 1 if you specify the CENTROID option; the default is 10 otherwise.

MAXSEARCH=*n*

specifies the maximum number of iterations during the search phase. The default is 1000 divide by the number of variables.

MINCLUSTERS=*n*

MINC=*n*

specifies the smallest number of clusters desired. The default value is 2 for INITIAL=RANDOM or INITIAL=SEED; otherwise, VARCLUS begins with one cluster and tries to split it in accordance with the PROPORTION= or MAXEIGEN= options.

MULTIPLEGROUP**MG**

performs a multiple group component analysis (Harman 1976). You specify which variables belong to which clusters. No clusters are split, and no variables are reassigned to a different cluster. The input data set must be TYPE=CORR, UCORR, COV, UCOV, FACTOR or SSCP and must contain an observation with `_TYPE_="GROUP"` defining the variable groups. Specifying the MULTIPLEGROUP option is equivalent to specifying all of the following options: INITIAL=GROUP, MINC=1, MAXITER=0, MAXSEARCH=0, PROPORTION=0, and MAXEIGEN=large number.

NOINT

requests that no intercept be used; covariances or correlations are not corrected for the mean. If you specify the NOINT option, the OUTSTAT= data set is TYPE=UCORR.

NOPRINT

suppresses displayed output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see [Chapter 14, "Using the Output Delivery System."](#)

OUTSTAT=SAS-data-set

creates an output data set to contain statistics including means, standard deviations, correlations, cluster scoring coefficients, and the cluster structure. If you want to create a permanent SAS data set, you must specify a two-level name. The OUTSTAT= data set is TYPE=UCORR if the NOINT option is specified. For more information on permanent SAS data sets, refer to "SAS Files" and "DATA Step Concepts" in *SAS Language Reference: Concepts*. For information on types of SAS data sets, see [Appendix A, "Special SAS Data Sets,"](#).

OUTTREE=SAS-data-set

creates an output data set to contain information on the tree structure that can be used by the TREE procedure to display a tree diagram. The OUTTREE= option implies the HIERARCHY option. See [Example 78.1](#) for use of the OUTTREE= option. If you want to create a permanent SAS data set, you must specify a two-level name. For more information on permanent SAS data sets, refer to "SAS Files" and "DATA Step Concepts" in *SAS Language Reference: Concepts*.

PROPORTION=*n***PERCENT=*n***

specifies that when choosing a cluster to split, VARCLUS should choose the cluster with the smallest proportion of variation explained, provided that its proportion of variation explained is less than the PROPORTION= value. Values greater than 1.0 are considered to be percentages, so PROPORTION=0.75 and PERCENT=75 are equivalent.

However, if you specify both MAXEIGEN= and PROPORTION=, VARCLUS first looks for a cluster to split based on the MAXEIGEN= criterion. If no cluster meets that criterion, VARCLUS then looks for a cluster to split based on the PROPORTION= criterion.

If you do not specify PROPORTION= then:

- If you specify MAXEIGEN=, cluster splitting does not depend on the proportion of variation explained.
- Otherwise, if you specify CENTROID and MAXCLUSTERS=, the default value for PROPORTION= is one.
- Otherwise, if you specify CENTROID, without MAXCLUSTERS=, the default value is PROPORTION=0.75 or PERCENT=75.
- Otherwise, cluster splitting does not depend on the proportion of variation explained.

If you specify both PROPORTION= and MAXCLUSTERS=, the number of clusters will never exceed the value of the MAXCLUSTERS= option.

RANDOM=*n*

specifies a positive integer as a starting value for use with REPLACE=RANDOM. If you do not specify the RANDOM= option, the time of day is used to initialize the pseudo-random number sequence.

SHORT

suppresses display of the cluster structure, scoring coefficient, and intercluster correlation matrices.

SIMPLE

S

displays means and standard deviations.

SUMMARY

suppresses all default displayed output except the final summary table.

TRACE

lists the cluster to which each variable is assigned during the iterations.

VARDEF=DF

VARDEF=N

VARDEF=WDF

VARDEF=WEIGHT | WGT

specifies the divisor to be used in the calculation of variances and covariances. The default value is VARDEF=DF. The values and associated divisors are displayed in the following table.

Value	Divisor	Formula
DF	degrees of freedom	$n - i$
N	number of observations	n
WDF	sum of weights minus one	$(\sum_j w_j) - 1$
WEIGHT WGT	sum of weights	$\sum_j w_j$

In the preceding table, $i = 0$ if the NOINT option is specified, and $i = 1$ otherwise.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC VARCLUS to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the VARCLUS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If a variable in your data set represents the frequency of occurrence for the other values in the observation, include the variable's name in a FREQ statement. The procedure then treats the data set as if each observation appears n times, where n is the value of the FREQ variable for the observation. If the value of the FREQ variable is less than 1, the observation is not used in the analysis. Only the integer portion of the value is used. The total number of observations is considered equal to the sum of the FREQ variable.

PARTIAL Statement

PARTIAL *variable* ;

If you want to base the clustering on partial correlations, list the variables to be partialled out in the PARTIAL statement.

SEED Statement

SEED *variables* ;

The SEED statement specifies variables to be used as seeds to initialize the clusters. It is not necessary to use INITIAL=SEED if the SEED statement is present, but if any other INITIAL= option is specified, the SEED statement is ignored.

VAR Statement

VAR *variables* ;

The VAR statement specifies the variables to be clustered. If you do not specify the VAR statement and do not specify TYPE=SSCP, all numeric variables not listed in other statements (except the SEED statement) are processed. The default VAR variable list does not include the variable INTERCEPT if the DATA= data set is TYPE=SSCP. If the variable INTERCEPT is explicitly specified in the VAR statement with a TYPE=SSCP data set, the NOINT option is enabled.

WEIGHT Statement

WEIGHT *variables* ;

If you want to specify relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances. The WEIGHT variable can take nonintegral values. An observation is used in the analysis only if the value of the WEIGHT variable is greater than zero.

Details

Missing Values

Observations containing missing values are omitted from the analysis.

Using PROC VARCLUS

Default options for PROC VARCLUS often provide satisfactory results. If you want to change the final number of clusters, use the MAXCLUSTERS=, MAXEIGEN=, or PROPORTION= options. The MAXEIGEN= and PROPORTION= options usually produce similar results but occasionally cause different clusters to be selected for splitting. The MAXEIGEN= option tends to choose clusters with a large number of variables, while the PROPORTION= option is more likely to select a cluster with a small number of variables.

Execution time

PROC VARCLUS usually requires more computer time than principal factor analysis, but it can be faster than some of the iterative factoring methods. If you have more than 30 variables, you may want to reduce execution time by one or more of the following methods:

- Specify the MINCLUSTERS= and MAXCLUSTERS= options if you know how many clusters you want.
- Specify the HIERARCHY option.
- Specify the SEED statement if you have some prior knowledge of what clusters to expect.

If computer time is not a limiting factor, you may want to try one of the following methods to obtain a better solution:

- If the clustering algorithm has not converged, specify larger values for MAXITER= and MAXSEARCH=.
- Try several factoring and rotation methods with PROC FACTOR to use as input to PROC VARCLUS.
- Run PROC VARCLUS several times, specifying INITIAL=RANDOM.

Output Data Sets

OUTSTAT= Data Set

The OUTSTAT= data set is TYPE=CORR, and it can be used as input to the SCORE procedure or a subsequent run of PROC VARCLUS. The variables it contains are

- BY variables
- `_NCL_`, a numeric variable giving the number of clusters
- `_TYPE_`, a character variable indicating the type of statistic the observation contains
- `_NAME_`, a character variable containing a variable name or a cluster name, which is of the form `CLUS n` where n is the number of the cluster
- the variables that are clustered

The values of the `_TYPE_` variable are listed in the following table.

Table 78.2. `_TYPE_` Value and Statistic

<code>_TYPE_</code>	Contents
MEAN	means
STD	standard deviations
USTD	uncorrected standard deviations, produced when the NOINT option is specified
N	number of observations
CORR	correlations
UCORR	uncorrected correlation matrix, produced when the NOINT option is specified
MEMBERS	number of members in each cluster
VAREXP	variance explained by each cluster
PROPOR	proportion of variance explained by each cluster
GROUP	number of the cluster to which each variable belongs
RSQUARED	squared multiple correlation of each variable with its cluster component
SCORE	standardized scoring coefficients
USCORE	scoring coefficients to be applied without subtracting the mean from the raw variables, produced when the NOINT option is specified
STRUCTUR	cluster structure
CCORR	correlations between cluster components

The observations with `_TYPE_`="MEAN", "STD", "N", and "CORR" have missing values for the `_NCL_` variable. All other values of the `_TYPE_` variable are repeated for each cluster solution, with different solutions distinguished by the value of the `_NCL_` variable. If you want to specify the OUTSTAT= data set with the SCORE procedure, you can use a DATA step to select observations with the `_NCL_` variable missing or equal to the desired number of clusters.

```

data Coef2;
  set Coef;
  if _ncl_ = . or _ncl_ = 3;
  drop _ncl_;
run;

proc score data=NewScore score=Coef2; run;

```

PROC SCORE standardizes the new data by subtracting the original variable means that are stored in the `_TYPE_='MEAN'` observations, and dividing by the original variable standard deviations from the `_TYPE_='STD'` observations. Then PROC SCORE multiplies the standardized variables by the coefficients from the `_TYPE_='SCORE'` observations to get the cluster scores.

OUTTREE= Data Set

The OUTTREE= data set contains one observation for each variable clustered plus one observation for each cluster of two or more variables, that is, one observation for each node of the cluster tree. The total number of output observations is between n and $2n - 1$, where n is the number of variables clustered.

The variables in the OUTTREE= data set are

- BY variables, if any
- `_NAME_`, a character variable giving the name of the node. If the node is a cluster, the name is `CLUS n` where n is the number of the cluster. If the node is a single variable, the variable name is used.
- `_PARENT_`, a character variable giving the value of `_NAME_` of the parent of the node. If the node is the root of the tree, `_PARENT_` is blank.
- `_LABEL_`, a character variable giving the label of the node. If the node is a cluster, the label is `CLUS n` where n is the number of the cluster. If the node is a single variable, the variable label is used.
- `_NCL_`, the number of clusters.
- `_VAREXP_`, the total variance explained by the clusters at the current level of the tree.
- `_PROPOR_`, the total proportion of variance explained by the clusters at the current level of the tree.
- `_MINPRO_`, the minimum proportion of variance explained by a cluster component.
- `_MAXEIG_`, the maximum second eigenvalue of a cluster.

Computational Resources

Let

n = number of observations

v = number of variables

c = number of clusters

It is assumed that, at each stage of clustering, the clusters all contain the same number of variables.

Time

The time required for PROC VARCLUS to analyze a given data set varies greatly depending on the number of clusters requested, the number of iterations in both the alternating least-squares and search phases, and whether centroid or principal components are used.

The time required to compute the correlation matrix is roughly proportional to nv^2 .

Default cluster initialization requires time roughly proportional to v^3 . Any other method of initialization requires time roughly proportional to cv^2 .

In the alternating least-squares phase, each iteration requires time roughly proportional to cv^2 if centroid components are used or

$$\left(c + 5\frac{v}{c^2}\right)v^2$$

if principal components are used.

In the search phase, each iteration requires time roughly proportional to v^3/c if centroid components are used or v^4/c^2 if principal components are used. The HIERARCHY option speeds up each iteration after the first split by as much as $c/2$.

Memory

The amount of memory, in bytes, needed by PROC VARCLUS is approximately

$$v^2 + 2vc + 20v + 15c$$

Interpreting VARCLUS Procedure Output

Because PROC VARCLUS is a type of oblique component analysis, its output is similar to the output from the FACTOR procedure for oblique rotations. The scoring coefficients have the same meaning in both PROC VARCLUS and PROC FACTOR; they are coefficients applied to the standardized variables to compute component scores. The cluster structure is analogous to the factor structure containing the correlations between each variable and each cluster component. A cluster pattern is not displayed because it would be the same as the cluster structure, except that zeros would appear

in the same places in which zeros appear in the scoring coefficients. The intercluster correlations are analogous to interfactor correlations; they are the correlations among cluster components.

PROC VARCLUS also displays a cluster summary and a cluster listing. The cluster summary gives the number of variables in each cluster and the variation explained by the cluster component. The latter is similar to the variation explained by a factor but includes contributions from only the variables in that cluster rather than from all variables, as in PROC FACTOR. The proportion of variance explained is obtained by dividing the variance explained by the total variance of variables in the cluster. If the cluster contains two or more variables and the CENTROID option is not used, the second largest eigenvalue of the cluster is also displayed.

The cluster listing gives the variables in each cluster. Two squared correlations are calculated for each cluster. The column labeled “Own Cluster” gives the squared correlation of the variable with its own cluster component. This value should be higher than the squared correlation with any other cluster unless an iteration limit has been exceeded or the CENTROID option has been used. The larger the squared correlation is, the better. The column labeled “Next Closest” contains the next highest squared correlation of the variable with a cluster component. This value is low if the clusters are well separated. The column headed “1-R**2 Ratio” gives the ratio of one minus the “Own Cluster” R^2 to one minus the “Next Closest” R^2 . A small “1-R**2 Ratio” indicates a good clustering.

Displayed Output

The following items are displayed for each cluster solution unless the NOPRINT or SUMMARY option is specified. The CLUSTER SUMMARY table includes

- the Cluster number
- Members, the number of members in the cluster
- Cluster Variation of the variables in the cluster
- Variation Explained by the cluster component. This statistic is based only on the variables in the cluster rather than on all variables.
- Proportion Explained, the result of dividing the variation explained by the cluster variation
- Second Eigenvalue, the second largest eigenvalue of the cluster. This is displayed if the cluster contains more than one variable and the CENTROID option is not specified

PROC VARCLUS also displays

- Total variation explained, the sum across clusters of the variation explained by each cluster
- Proportion, the total explained variation divided by the total variation of all the variables

The cluster listing includes

- Variable, the variables in each cluster
- R-squared with Own Cluster, the squared correlation of the variable with its own cluster component; and R-squared with Next Closest, the next highest squared correlation of the variable with a cluster component. Own Cluster values should be higher than the R^2 with any other cluster unless an iteration limit is exceeded or you specify the CENTROID option. Next Closest should be a low value if the clusters are well separated.
- $1-R^{*2}$ Ratio, the ratio of one minus the value in the Own Cluster column to one minus the value in the Next Closest column. The occurrence of low ratios indicates well-separated clusters.

If the SHORT option is not specified, PROC VARCLUS also displays

- Standardized Scoring Coefficients, standardized regression coefficients for predicting cluster components from variables
- Cluster Structure, the correlations between each variable and each cluster component
- Inter-Cluster Correlations, the correlations between the cluster components

If the analysis includes partitions for two or more numbers of clusters, a final summary table is displayed. Each row of the table corresponds to one partition. The columns include

- Number of Clusters
- Total Variation Explained by Clusters
- Proportion of Variation Explained by Clusters
- Minimum Proportion (of variation) Explained by a Cluster
- Maximum Second Eigenvalue in a Cluster
- Minimum R-squared for a Variable
- Maximum $1-R^{*2}$ Ratio for a Variable

ODS Table Names

PROC VARCLUS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see [Chapter 14, “Using the Output Delivery System.”](#)

Table 78.3. ODS Tables Produced in PROC VARCLUS

ODS Table Name	Description	Option
ClusterQuality	Cluster quality	default
ClusterStructure	Cluster structure	default
ClusterSummary	Cluster Summary	default
ConvergenceStatus	Convergence status	default
Corr	Correlations	CORR
DataOptSummary	Data and options summary table	default
InterClusterCorr	Inter-cluster correlations	default
IterHistory	Iteration history	TRACE
RSquare	Cluster Rsq	default
SimpleStatistics	Simple statistics	SIMPLE
StdScoreCoef	Standardized scoring coefficients	default

Example

Example 78.1. Correlations among Physical Variables

The following data are correlations among eight physical variables as given by Harman (1976). The first PROC VARCLUS run clusters on the basis of principal components, the second run clusters on the basis of centroid components. The third analysis is hierarchical, and the TREE procedure is used to display a tree diagram. The results of the analyses follow.

```

data phys8(type=corr);
  title 'Eight Physical Measurements on 305 School Girls';
  title2 'Harman: Modern Factor Analysis, 3rd Ed, p22';
  label height='Height'      arm_span='Arm Span'
        forearm='Length of Forearm'
        low_leg='Length of Lower Leg'
        weight='Weight'      bit_diam='Bitrochanteric Diameter'
        girth='Chest Girth'  width='Chest Width';
  input _name_ $ 1-8
        (height arm_span forearm low_leg weight bit_diam
         girth width)(7.);
  _type_='corr';
  datalines;
height 1.0      .846  .805  .859  .473  .398  .301  .382
arm_span .846  1.0    .881  .826  .376  .326  .277  .415
forearm .805  .881  1.0    .801  .380  .319  .237  .345
low_leg .859  .826  .801  1.0    .436  .329  .327  .365
weight .473  .376  .380  .436  1.0    .762  .730  .629
bit_diam .398  .326  .319  .329  .762  1.0    .583  .577
girth .301  .277  .237  .327  .730  .583  1.0    .539
width .382  .415  .345  .365  .629  .577  .539  1.0
;

proc varclus data=phys8;
run;

```

The PROC VARCLUS statement invokes the procedure. By default, PROC VARCLUS clusters on the basis of principal components.

Output 78.1.1. Principal Cluster Components: Cluster Summary

```

      Eight Physical Measurements on 305 School Girls
      Harman: Modern Factor Analysis, 3rd Ed, p22

      Oblique Principal Component Cluster Analysis

      Cluster Summary for 1 Cluster

                   arm_span      0.9002      0.1658      0.1196      Arm Span
                   forearm      0.8661      0.1413      0.1560      Length of Forearm
                   low_leg      0.8652      0.1829      0.1650      Length of Lower Leg
      Cluster 2      weight      0.8477      0.1974      0.1898      Weight
                   bit_diam      0.7386      0.1341      0.3019      Bitrochanteric Diameter
                   girth      0.6981      0.0929      0.3328      Chest Girth
                   width      0.6329      0.1619      0.4380      Chest Width

No cluster meets the criterion for splitting.

```

As displayed in [Output 78.1.1](#), the cluster component (by default, the first principal component) explains 58.41% of the total variation in the 8 variables.

The cluster is split because the second eigenvalue is greater than 1 (the default value of the MAXEIGEN option).

The two resulting cluster components explain 80.33% of the variation in the original variables. The cluster summary table shows that the variables `height`, `arm_span`, `forearm`, and `low_leg` have been assigned to the first cluster; and that the variables `weight`, `bit_diam`, `girth`, and `width` have been assigned to the second cluster.

Output 78.1.2. Standard Scoring Coefficients and Cluster Structure Table

Oblique Principal Component Cluster Analysis			
Standardized Scoring Coefficients			
Cluster		1	2
height	Height	0.266977	0.000000
arm_span	Arm Span	0.270377	0.000000
forearm	Length of Forearm	0.265194	0.000000
low_leg	Length of Lower Leg	0.265057	0.000000
weight	Weight	0.000000	0.315597
bit_diam	Bitrochanteric Diameter	0.000000	0.294591
girth	Chest Girth	0.000000	0.286407
width	Chest Width	0.000000	0.272710

Cluster Structure			
Cluster		1	2
height	Height	0.936881	0.456908
arm_span	Arm Span	0.948813	0.407210
forearm	Length of Forearm	0.930624	0.375865
low_leg	Length of Lower Leg	0.930142	0.427715
weight	Weight	0.444281	0.920686
bit_diam	Bitrochanteric Diameter	0.366201	0.859404
girth	Chest Girth	0.304779	0.835529
width	Chest Width	0.402430	0.795572

The standardized scoring coefficients in [Output 78.1.2](#) show that each cluster component has similar scores for each of its associated variables. This suggests that the principal cluster component solution should be similar to the centroid cluster component solution, which follows in the next PROC VARCLUS run.

The cluster structure table displays high correlations between the variables and their own cluster component. The correlations between the variables and the opposite cluster component are all moderate.

Output 78.1.3. Inter-Cluster Correlations

Oblique Principal Component Cluster Analysis			
Inter-Cluster Correlations			
Cluster		1	2
1		1.00000	0.44513
2		0.44513	1.00000

The intercluster correlation table shows that the cluster components are moderately correlated with $\rho = 0.44513$.

In the following statements, the CENTROID option in the PROC VARCLUS statement specifies that cluster centroids be used as the basis for clustering.

```
proc varclus data=phys8 centroid;
run;
```

Output 78.1.4. Centroid Cluster Components: Cluster Summary

Oblique Centroid Component Cluster Analysis					
Cluster Summary for 1 Cluster					
Cluster	Members	Cluster Variation	Variation Explained	Proportion Explained	
1	8	8	4.631	0.5789	
Total variation explained = 4.631 Proportion = 0.5789					
Cluster Summary for 2 Clusters					
Cluster	Members	Cluster Variation	Variation Explained	Proportion Explained	
1	4	4	3.509	0.8773	
2	4	4	2.91	0.7275	
Total variation explained = 6.419 Proportion = 0.8024					
2 Clusters					
Cluster	Variable	R-squared with			Variable Label
		Own Cluster	Next Closest	1-R**2 Ratio	
Cluster 1	height	0.8778	0.2075	0.1543	Height
	arm_span	0.8994	0.1669	0.1208	Arm Span
	forearm	0.8663	0.1410	0.1557	Length of Forearm
	low_leg	0.8658	0.1824	0.1641	Length of Lower Leg
Cluster 2	weight	0.8368	0.1975	0.2033	Weight
	bit_diam	0.7335	0.1341	0.3078	Bitrochanteric Diameter
	girth	0.6988	0.0929	0.3321	Chest Girth
	width	0.6473	0.1618	0.4207	Chest Width

The first cluster component, which, in the centroid method, is an unweighted sum of the standardized variables, explains 57.89% of the variation in the data. This value is near the maximum possible variance explained, 58.41%, which is attained by the first principal component ([Output 78.1.1](#)).

The centroid clustering algorithm splits the variables into the same two clusters created in the principal component method. Recall that this outcome was suggested by the similar standardized scoring coefficients in the principal cluster component solution.

The default behavior in the centroid method is to split any cluster with less than 75% of the total cluster variance explained by the centroid component. In the next step, the second cluster, with a component that explains only 72.75% of the total variation of the cluster, is split.

In the R-squared table for two clusters, the `width` variable has a weaker relation to its cluster than any other variable; in the three cluster solution this variable is in a cluster of its own.

Output 78.1.5. Standardized Scoring Coefficients

Oblique Centroid Component Cluster Analysis			
Standardized Scoring Coefficients			
Cluster		1	2
height	Height	0.266918	0.000000
arm_span	Arm Span	0.266918	0.000000
forearm	Length of Forearm	0.266918	0.000000
low_leg	Length of Lower Leg	0.266918	0.000000
weight	Weight	0.000000	0.293105
bit_diam	Bitrochanteric Diameter	0.000000	0.293105
girth	Chest Girth	0.000000	0.293105
width	Chest Width	0.000000	0.293105

Each cluster component ([Output 78.1.5](#)) is an unweighted average of the cluster’s standardized variables. Thus, the coefficients for each of the cluster’s associated variables are identical in the centroid cluster component solution.

Output 78.1.6. Cluster Summary for Three Clusters

Oblique Centroid Component Cluster Analysis					
Cluster Summary for 3 Clusters					
Cluster	Members	Cluster Variation	Variation Explained	Proportion Explained	
1	4	4	3.509	0.8773	
2	3	3	2.383333	0.7944	
3	1	1	1	1.0000	
Total variation explained = 6.892333 Proportion = 0.8615					
R-squared with					
Cluster	Variable	Own Cluster	Next Closest	1-R**2 Ratio	Variable Label
Cluster 1	height	0.8778	0.1921	0.1513	Height
	arm_span	0.8994	0.1722	0.1215	Arm Span
	forearm	0.8663	0.1225	0.1524	Length of Forearm
	low_leg	0.8658	0.1668	0.1611	Length of Lower Leg
Cluster 2	weight	0.8685	0.3956	0.2175	Weight
	bit_diam	0.7691	0.3329	0.3461	Bitrochanteric Diameter
	girth	0.7482	0.2905	0.3548	Chest Girth
Cluster 3	width	1.0000	0.4259	0.0000	Chest Width

The centroid method stops at the three cluster solution. As displayed in [Output 78.1.6](#) and [Output 78.1.7](#), the three centroid components account for 86.15% of the variability in the eight variables, and all cluster components account for at least 79.44% of the total variation in the corresponding cluster. Additionally, the smallest squared correlation between the variables and their own cluster component is 0.7482.

Output 78.1.7. Cluster Quality Table

Oblique Centroid Component Cluster Analysis						
Number of Clusters	Total Variation Explained by Clusters	Proportion of Variation Explained by Clusters	Minimum Proportion Explained by a Cluster	Minimum R-squared for a Variable	Maximum 1-R**2 Ratio for a Variable	Maximum Ratio for a Variable
1	4.631000	0.5789	0.5789	0.4306		
2	6.419000	0.8024	0.7275	0.6473	0.4207	
3	6.892333	0.8615	0.7944	0.7482	0.3548	

Note that, if the proportion option were set to a value between 0.5789 (the proportion of variance explained in the 1-cluster solution) and 0.7275 (the minimum proportion of variance explained in the 2-cluster solution), PROC VARCLUS would stop at a two cluster solution, and the centroid solution would find the same clusters as the principal components solution.

In the following statements, the MAXC= option computes all clustering solutions, from one to eight clusters. The SUMMARY option suppresses all output except the final cluster quality table, and the OUTTREE= option saves the results of the analysis to an output data set and forces the clusters to be hierarchical. The TREE procedure is invoked to produce a graphical display of the clusters.

```
proc varclus data=phys8 maxc=8 summary outtree=tree;
run;

goptions ftext=swiss;
axis2 label=(justify=left);
axis1 order=(0.5 to 1.0 by 0.1);
proc tree horizontal vaxis=axis2 haxis=axis1 lines=(width=2);
  height _propor_;
  id _label_;
run;
```

Output 78.1.8. Hierarchical Clusters and the SUMMARY Option

Oblique Principal Component Cluster Analysis						
Number of Clusters	Total Variation Explained by Clusters	Proportion of Variation Explained by Clusters	Minimum Proportion Explained by a Cluster	Maximum Second Eigenvalue in a Cluster	Minimum R-squared for a Variable	Maximum 1-R**2 Ratio for a Variable
1	4.672880	0.5841	0.5841	1.770983	0.3810	
2	6.426502	0.8033	0.7293	0.476418	0.6329	0.4380
3	6.895347	0.8619	0.7954	0.418369	0.7421	0.3634
4	7.271218	0.9089	0.8773	0.238000	0.8652	0.2548
5	7.509218	0.9387	0.8773	0.236135	0.8652	0.1665
6	7.740000	0.9675	0.9295	0.141000	0.9295	0.2560
7	7.881000	0.9851	0.9405	0.119000	0.9405	0.2093
8	8.000000	1.0000	1.0000	0.000000	1.0000	0.0000

The principal component method first separates the variables into the same two clusters that were created in the first PROC VARCLUS run. Note that, in creating the third cluster, the principal component method identifies the variable width. This is

the same variable that is put into its own cluster in the preceding centroid method example.

Output 78.1.9. TREE Diagram from PROC TREE

The tree diagram in [Output 78.1.9](#) displays the cluster hierarchy. It is clear from the diagram that there are two, or possibly three, clusters present. However, the MAXC=8 option forces PROC VARCLUS to split the clusters until each variable is in its own cluster.

Chapter 79

The VARCOMP Procedure

Overview

The VARCOMP procedure handles general linear models that have random effects. Random effects are classification effects with levels that are assumed to be randomly selected from an infinite population of possible levels. PROC VARCOMP estimates the contribution of each of the random effects to the variance of the dependent variable.

A single MODEL statement specifies the dependent variables and the effects: main effects, interactions, and nested effects. The effects must be composed of class variables; no continuous variables are allowed on the right side of the equal sign.

You can specify certain effects as fixed (nonrandom) by putting them first in the MODEL statement and indicating the number of fixed effects with the FIXED= option. An intercept is always fitted and assumed fixed. Except for the effects specified as fixed, all other effects are assumed to be random, and their contribution to the model can be thought of as an observation from a distribution that is normally and independently distributed.

The dependent variables are grouped based on the similarity of their missing values. Each group of dependent variables is then analyzed separately. The columns of the design matrix \mathbf{X} are formed in the same order in which the effects are specified in the MODEL statement. No reparameterization is done. Thus, the columns of \mathbf{X} contain only 0s and 1s.

You can specify four methods of estimation in the PROC VARCOMP statement using the METHOD= option. They are TYPE1 (based on computation of Type I sum of squares for each effect), MIVQUE0, Maximum Likelihood (METHOD=ML), and Restricted Maximum Likelihood (METHOD=REML).

Getting Started

Analyzing the Cure Rate of Rubber

This example, using data from Hicks (1973), concerns an experiment to determine the sources of variability in cure rates of rubber. The goal of the experiment was to find out if the different laboratories contributed more to the variance of cure rates than did the different batches of raw materials. This information would be useful in trying to control the cure rate of the final product because it would provide insights into the sources of the variability in cure rates. The rubber used was cured at three temperatures, which were taken to be fixed. Three laboratories were chosen at random, and three different batches of raw material were tested at each combination of temperature and laboratory. The following statements read the data into the SAS data set Cure.

```

;

```

The variables Lab, Temp, and Batch contain levels of laboratory, temperature, and batch, respectively. The Cure variable contains the response values.

The following SAS statements perform a restricted maximum-likelihood variance component analysis.

```
proc varcomp method=reml;
  class Temp Lab Batch;
  model Cure=Temp|Lab Batch(Lab Temp) / fixed=1;
run;
```

The FIXED=1 option indicates that the first factor, Temp, is fixed. The effect specification Temp|Lab is equivalent to putting the three terms Temp, Lab, and Temp*Lab in the model. Batch(Lab Temp) is equivalent to putting Batch(Temp*Lab) in the MODEL statement. The results of this analysis are displayed in Figure 79.1 through Figure 79.4.

Var(Batch(Temp*Lab))	-0.04998	0	0.45042	-0.0022417
Var(Error)	1.0259E-12	0	-0.0022417	0.0089668

Figure 79.4. Covariance Matrix for REML Estimates

The “Asymptotic Covariance Matrix of Estimates” table in [Figure 79.4](#) displays the asymptotic covariance matrix of the REML estimates.

The results of the analysis show that the variance attributable to **Batch(Temp*Lab)** (with a variance component of 2.0739) is considerably larger than the variance attributable to **Lab** (0.3176). Therefore, attempts to reduce the variability of cure rates should concentrate on improving the homogeneity of the batches of raw material used rather than standardizing the practices or equipment within the laboratories. Also, note that since the **Batch(Temp*Lab)** variance is considerably larger than the experimental error ($\text{Var}(\text{Error})=0.6026$), the **Batch(Temp*Lab)** variability plays an important part in the overall variability of the cure rates.

Syntax

The following statements are available in PROC VARCOMP.

```
PROC VARCOMP < options > ;
  CLASS variables ;
  MODEL dependent = < effects > < / options > ;
  BY variables ;
```

Only one MODEL statement is allowed. The BY, CLASS, and MODEL statements are described after the PROC VARCOMP statement.

PROC VARCOMP Statement

```
PROC VARCOMP < options >;
```

This statement invokes the VARCOMP procedure. You can specify the following options in the PROC VARCOMP statement.

DATA=SAS-data-set

specifies the input SAS data set to use. If this option is omitted, the most recently created SAS data set is used.

EPSILON=number

specifies the convergence value of the objective function for METHOD=ML or METHOD=REML. By default, EPSILON=1E-8.

MAXITER=number

specifies the maximum number of iterations for METHOD=ML or METHOD=REML. By default, MAXITER=50.

METHOD=TYPE1 | MIVQUE0 | ML | REML

specifies which of the four methods (TYPE1, MIVQUE0, ML, or REML) you want to use. By default, METHOD= MIVQUE0. For more information see the “Computational Methods” section on page 4838.

BY Statement

```
BY variables ;
```

You can specify a BY statement with PROC VARCOMP to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The *variables* are one or more variables in the input data set.

If your input data set is not sorted in ascending order, use one of the following alternatives.

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the VARCOMP procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, see the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, see the discussion in the *SAS Procedures Guide*.

CLASS Statement

CLASS *variables* ;

The CLASS statement specifies the classification variables to be used in the analysis. All effects in the MODEL statement must be composed of effects that appear in the CLASS statement. Class variables can be either numeric or character; if they are character, only the first 16 characters are used.

Numeric class variables are not restricted to integers since a variable's format determines the levels. For more information, see the discussion of the FORMAT statement in *SAS Language Reference: Dictionary*.

MODEL Statement

MODEL *dependent* = < *effects* > < / *option* > ;

The MODEL statement gives the dependent variables and independent effects. If you specify more than one dependent variable, a separate analysis is performed for each one. The independent effects are limited to main effects, interactions, and nested effects; no continuous effects are allowed. All independent effects must be composed of effects that appear in the CLASS statement. [Effects](#) are specified in the VARCOMP procedure in the same way as described for the ANOVA procedure. Only one MODEL statement is allowed.

Only one option is available in the MODEL statement.

FIXED=*n*

tells the VARCOMP procedure that the first *n* effects in the MODEL statement are fixed effects. The remaining effects are assumed to be random. By default, PROC VARCOMP assumes that all effects are random in the model. Keep in mind that if you use bar notation and, for example, specify Y=A|B / FIXED=2, then A*B is considered a random effect.

Details

Missing Values

If an observation has a missing value for any variable used in the independent effects, then the analyses of all dependent variables omit this observation. An observation is deleted from the analysis of a given dependent variable if the observation's value for that dependent variable is missing. Note that a missing value in one dependent variable does not eliminate an observation from the analysis of the other dependent variables.

During processing, PROC VARCOMP groups the dependent variables on their missing values across observations so that sums of squares and cross products can be computed in the most efficient manner.

Fixed and Random Effects

Central to the idea of variance components models is the idea of fixed and random effects. Each effect in a variance components model must be classified as either a fixed or a random effect. Fixed effects arise when the levels of an effect constitute the entire population about which you are interested. For example, if a plant scientist is comparing the yields of three varieties of soybeans, then **Variety** would be a fixed effect, providing that the scientist was concerned about making inferences on only these three varieties of soybeans. Similarly, if an industrial experiment focused on the effectiveness of two brands of a machine, **Machine** would be a fixed effect only if the experimenter's interest did not go beyond the two machine brands.

On the other hand, an effect is classified as a random effect when you want to make inferences on an entire population, and the levels in your experiment represent only a sample from that population. Psychologists comparing test results between different groups of subjects would consider **Subject** as a random effect. Depending on the psychologists' particular interest, the **Group** effect might be either fixed or random. For example, if the groups are based on the sex of the subject, then **Sex** would be a fixed effect. But if the psychologists are interested in the variability in test scores due to different teachers, then they might choose a random sample of teachers as being representative of the total population of teachers, and **Teacher** would be a random effect. Note that, in the soybean example presented earlier, if the scientists are interested in making inferences on the entire population of soybean varieties and randomly choose three varieties for testing, then **Variety** would be a random effect.

If all the effects in a model (except for the intercept) are considered random effects, then the model is called a *random effects model*; likewise, a model with only fixed effects is called a *fixed-effects model*. The more common case, where some factors are fixed and others are random, is called a *mixed model*. In PROC VARCOMP, by default, effects are assumed to be random. You specify which effects are fixed by using the **FIXED=** option in the **MODEL** statement. In general, if an interaction or nested effect contains any effect that is random, then the interaction or nested effect should be considered as a random effect as well.

In the linear model, each level of a fixed effect contributes a fixed amount to the expected value of the dependent variable. What makes a random effect different is that each level of a random effect contributes an amount that is viewed as a sample from a population of normally distributed variables, each with mean 0, and an unknown variance, much like the usual random error term that is a part of all linear models. The estimate of the variance associated with the random effect is known as the *variance component* because it is measuring the part of the overall variance contributed by that effect. Thus, PROC VARCOMP estimates the variance of the random variables that are associated with the random effects in your model, and the variance components tell you how much each of the random factors contributes to the overall variability in the dependent variable.

Negative Variance Component Estimates

The variance components estimated by PROC VARCOMP should theoretically be nonnegative because they are assumed to represent the variance of a random variable. Nevertheless, when you are using METHOD=MIVQUE0 (the default) or METHOD=TYPE1, some estimates of variance components may become negative. (Due to the nature of the algorithms used for METHOD=ML and METHOD=REML, negative estimates are constrained to zero.) These negative estimates may arise for a variety of reasons:

- The variability in your data may be large enough to produce a negative estimate, even though the true value of the variance component is positive.
- Your data may contain outliers. Refer to Hocking (1983) for a graphical technique for detecting outliers in variance components models using the SAS System.
- A different model for interpreting your data may be appropriate. Under some statistical models for variance components analysis, negative estimates are an indication that observations in your data are negatively correlated. Refer to Hocking (1984) for further information about these models.

Assuming that you are satisfied that the model PROC VARCOMP is using is appropriate for your data, it is common practice to treat negative variance components as if they are zero.

Computational Methods

Four methods of estimation can be specified in the PROC VARCOMP statement using the METHOD= option. They are described in the following sections.

The Type I Method

This method (METHOD=TYPE1) computes the Type I sum of squares for each effect, equates each mean square involving only random effects to its expected value, and solves the resulting system of equations (Gaylor, Lucas, and Anderson 1970). The $X'X \mid X'Y$ matrix is computed and adjusted in segments whenever memory is not sufficient to hold the entire matrix.

The MIVQUE0 Method

Based on the technique suggested by Hartley, Rao, and LaMotte (1978), the MIVQUE0 method (METHOD=MIVQUE0) produces unbiased estimates that are invariant with respect to the fixed effects of the model and that are locally best quadratic unbiased estimates given that the true ratio of each component to the residual error component is zero. The technique is similar to TYPE1 except that the random effects are adjusted only for the fixed effects. This affords a considerable timing advantage over the TYPE1 method; thus, MIVQUE0 is the default method used in PROC VARCOMP. The $\mathbf{X}'\mathbf{X}|\mathbf{X}'\mathbf{Y}$ matrix is computed and adjusted in segments whenever memory is not sufficient to hold the entire matrix. Each element (i, j) of the form

$$\text{SSQ}(\mathbf{X}_i' \mathbf{M} \mathbf{X}_j)$$

is computed, where

$$\mathbf{M} = \mathbf{I} - \mathbf{X}_0(\mathbf{X}_0' \mathbf{X}_0)^{-1} \mathbf{X}_0'$$

and where \mathbf{X}_0 is part of the design matrix for the fixed effects, \mathbf{X}_i is part of the design matrix for one of the random effects, and SSQ is an operator that takes the sum of squares of the elements. For more information refer to Rao (1971, 1972) and Goodnight (1978).

The Maximum Likelihood Method

The Maximum Likelihood method (METHOD=ML) computes maximum-likelihood estimates of the variance components; refer to Searle, Casella, and McCulloch (1992). The computing algorithm makes use of the W-transformation developed by Hemmerle and Hartley (1973). The procedure uses a Newton-Raphson algorithm, iterating until the log-likelihood objective function converges.

The objective function for METHOD=ML is $\ln(|\mathbf{V}|) + \mathbf{r}'\mathbf{V}^{-1}\mathbf{r}$, where

$$\mathbf{V} = \sigma_0^2 \mathbf{I} + \sum_{i=1}^{n_r} \sigma_i^2 \mathbf{X}_i \mathbf{X}_i'$$

and where σ_0^2 is the residual variance, n_r is the number of random effects in the model, σ_i^2 represents the variance components, \mathbf{X}_i is part of the design matrix for one of the random effects, and

$$\mathbf{r} = \mathbf{y} - \mathbf{X}_0(\mathbf{X}_0' \mathbf{V}^{-1} \mathbf{X}_0)^{-1} \mathbf{X}_0' \mathbf{V}^{-1} \mathbf{y}$$

is the vector of residuals.

The Restricted Maximum Likelihood Method

The Restricted Maximum Likelihood Method (METHOD=REML) is similar to the maximum likelihood method, but it first separates the likelihood into two parts: one that contains the fixed effects and one that does not (Patterson and Thompson 1971). The procedure uses a Newton-Raphson algorithm, iterating until convergence is reached for the log-likelihood objective function of the portion of the likelihood that does not contain the fixed effects. Using notation from earlier methods, the objective function for METHOD=REML is $\ln(|\mathbf{V}|) + \mathbf{r}'\mathbf{V}^{-1}\mathbf{r} + \ln(|\mathbf{X}'_0\mathbf{V}^{-1}\mathbf{X}_0|)$. Refer to Searle, Casella, and McCulloch (1992) for additional details.

Displayed Output

PROC VARCOMP displays the following items:

- Class Level Information for verifying the levels in your data
- Number of observations read from the data set and number of observations used in the analysis
- for METHOD=TYPE1, an analysis-of-variance table with Source, DF, Type I Sum of Squares, Type I Mean Square, and Expected Mean Square, and a table of Type I variance component estimates
- for METHOD=MIVQUE0, the SSQ Matrix containing sums of squares of partitions of the $\mathbf{X}'\mathbf{X}$ crossproducts matrix adjusted for the fixed effects
- for METHOD=ML and METHOD=REML, the iteration history, including the objective function, as well as variance component estimates
- for METHOD=ML and METHOD=REML, the estimated Asymptotic Covariance Matrix of the variance components
- a table of variance component estimates

ODS Table Names

PROC VARCOMP assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 79.1. ODS Tables Produced in PROC VARCOMP

ODS Table Name	Description	Statement
ANOVA	Type I analysis of variance	METHOD=TYPE1
AsyCov	Asymptotic covariance matrix of estimates	METHOD=ML or REML
ClassLevels	Class level information	default
ConvergenceStatus	Convergence status	METHOD=ML or REML
DepVar	Dependent variable	METHOD=TYPE1, REML, or ML
DependentInfo	Dependent variable info (multiple variables)	
Estimates	Variance component estimates	default
IterHistory	Iteration history	METHOD=ML or REML
NObs	Number of observations	default
SSCP	Sum of squares matrix	METHOD=MIVQUE0

In situations where multiple dependent variables are analyzed that differ in their missing value pattern, separate names for ANOVAn, AsyCovn, Estimatesn, IterHistoryn, and SSCPn tables are no longer required. The results are combined into a single output data set. For METHOD=TYPE1, ML, or REML, variable `Dependent` in the output data set identifies the dependent variable. For METHOD=MIVQUE0, a variable is added to the output data set for each dependent variable.

Relationship to PROC MIXED

The MIXED procedure effectively performs the same analyses as PROC VARCOMP and many others, including Type I, Type II, and Type III tests of fixed effects, confidence limits, customized contrasts, and least-squares means. Furthermore, continuous variables are permitted as both fixed and random effects in PROC MIXED, and numerous other covariance structures besides variance components are available.

To translate PROC VARCOMP code into PROC MIXED code, move all random effects to the RANDOM statement in PROC MIXED. For example, the syntax for the example in the “Getting Started” section on page 4832 is as follows:

```
proc mixed;
  class Temp Lab Batch;
  model Cure = Temp;
  random Lab Temp*Lab Batch(Lab Temp);
run;
```

REML is the default estimation method in PROC MIXED, and you can specify other methods using the METHOD= option.

Example

Example 79.1. Using the Four Estimation Methods

In this example, *a* and *b* are classification variables and *y* is the dependent variable. *a* is declared fixed, and *b* and *a*b* are random. Note that this design is unbalanced because the cell sizes are not all the same. PROC VARCOMP is invoked four times, once for each of the estimation methods. The data are from Hemmerle and Hartley (1973). The following statements produce [Output 79.1.1](#).

```

data a;
  input a b y @@;
  datalines;
1 1 237   1 1 254   1 1 246   1 2 178   1 2 179
2 1 208   2 1 178   2 1 187   2 2 146   2 2 145   2 2 141
3 1 186   3 1 183   3 2 142   3 2 125   3 2 136
;

proc varcomp method=type1;
  class a b;
  model y=a|b / fixed=1;
run;

proc varcomp method=mivque0;
  class a b;
  model y=a|b / fixed=1;
run;

proc varcomp method=ml;
  class a b;
  model y=a|b / fixed=1;
run;

proc varcomp method=reml;
  class a b;
  model y=a|b / fixed=1;
run;

```

Output 79.1.1. VARCOMP Procedure: Method=TYPE1

Variance Components Estimation Procedure		
Class Level Information		
Class	Levels	Values
a	3	1 2 3
b	2	1 2
Number of Observations Read		16
Number of Observations Used		16
Dependent Variable:		y

The “Class Level Information” table displays the levels of each variable specified in the CLASS statement. You can check this table to make sure the data are input correctly.

Variance Components Estimation Procedure				
Type 1 Analysis of Variance				
Source	DF	Sum of Squares	Mean Square	Expected Mean Square
a	2	11736	5868.218750	Var(Error) + 2.725 Var(a*b) + 0.1 Var(b) + Q(a)
b	1	11448	11448	Var(Error) + 2.6308 Var(a*b) + 7.8 Var(b)
a*b	2	299.041026	149.520513	Var(Error) + 2.5846 Var(a*b)
Error	10	786.333333	78.633333	Var(Error)
Corrected Total	15	24270	.	.

The Type I analysis of variance consists of sequentially partitioning the total sum of squares. The mean square is the sum of squares divided by the degrees of freedom, and the expected mean square is the expected value of the mean square under the mixed model. The “Q” notation in the expected mean squares refers to a quadratic form in parameters of the parenthesized effect.

Variance Components Estimation Procedure	
Type 1 Estimates	
Variance Component	Estimate
Var(b)	1448.4
Var(a*b)	27.42659
Var(Error)	78.63333

The Type I estimates of the variance components result from solving the linear system of equations established by equating the observed mean squares to their expected values.

Output 79.1.2. VARCOMP Procedure: Method=MIVQUE0

Variance Components Estimation Procedure		
Class Level Information		
Class	Levels	Values
a	3	1 2 3
b	2	1 2
Number of Observations Read		16
Number of Observations Used		16

The “Class Level Information” is the same as before.

Variance Components Estimation Procedure				
MIVQUE(0) SSQ Matrix				
Source	b	a*b	Error	y
b	60.84000	20.52000	7.80000	89295.4
a*b	20.52000	20.52000	7.80000	30181.3
Error	7.80000	7.80000	13.00000	12533.5

The MIVQUE0 sums-of-squares matrix is displayed in the previous table.

Variance Components Estimation Procedure	
MIVQUE(0) Estimates	
Variance Component	y
Var(b)	1466.1
Var(a*b)	-35.49170
Var(Error)	105.73660

The MIVQUE0 estimates result from solving the equations established by the MIVQUE0 SSQ matrix. Note that the estimate of the variance component for the interaction effect, Var(a*b), is negative for this example.

Output 79.1.3. VARCOMP Procedure: Method=ML

Variance Components Estimation Procedure		
Class Level Information		
Class	Levels	Values
a	3	1 2 3
b	2	1 2
Number of Observations Read		16
Number of Observations Used		16
Dependent Variable:		y

The “Class Level Information” is the same as before.

Variance Components Estimation Procedure				
Maximum Likelihood Iterations				
Iteration	Objective	Var(b)	Var(a*b)	Var(Error)
0	78.3850371200	1031.49070	0	74.3909717935
1	78.2637043807	732.3606453636	0	77.4011688154
2	78.2635471161	723.6867470850	0	77.5301774839
3	78.2635471152	723.6658365289	0	77.5304926877

Convergence criteria met.

The Newton-Raphson algorithm used by PROC VARCOMP requires three iterations to converge to the maximum likelihood estimates.

Variance Components Estimation Procedure	
Maximum Likelihood Estimates	
Variance Component	Estimate
Var(b)	723.66584
Var(a*b)	0
Var(Error)	77.53049

The ML estimate of Var(a*b) is zero for this example, and the other two estimates are smaller than their Type I and MIVQUE0 counterparts.

Variance Components Estimation Procedure			
Asymptotic Covariance Matrix of Estimates			
	Var(b)	Var(a*b)	Var(Error)
Var(b)	537826.1	0	-107.33905
Var(a*b)	0	0	0
Var(Error)	-107.33905	0	858.71104

One benefit of using likelihood-based methods is that an approximate covariance matrix is available from the matrix of second derivatives evaluated at the ML solution. This covariance matrix is valid asymptotically and can be unreliable in small samples.

Here the variance component estimates for B and the Error are negatively correlated and the elements for Var(a*b) are set to zero because the estimate equals zero. Also, the very large variance for Var(b) indicates a lot of uncertainty about the estimate for Var(b), and one contributing explanation is that B has only two levels in this data set.

Output 79.1.4. VARCOMP Procedure: Method=REML

Variance Components Estimation Procedure			
Class Level Information			
Class	Levels	Values	
a	3	1	2 3
b	2	1	2
Number of Observations Read		16	
Number of Observations Used		16	
Dependent Variable:		y	

The “Class Level Information” is the same as before.

Variance Components Estimation Procedure				
REML Iterations				
Iteration	Objective	Var(b)	Var(a*b)	Var(Error)
0	63.4134144942	1269.52701	0	91.5581191305
1	63.0446869787	1601.84199	32.7632417174	76.9355562461
2	63.0311530508	1468.82932	27.2258186561	78.7548276319
3	63.0311265148	1464.33646	26.9564053003	78.8431476502
4	63.0311265127	1464.36727	26.9588525177	78.8423898761
Convergence criteria met.				

The REML optimization requires four iterations to converge.

Variance Components Estimation Procedure	
REML Estimates	
Variance Component	Estimate
Var(b)	1464.4
Var(a*b)	26.95885
Var(Error)	78.84239

The REML estimates are all larger than the corresponding ML estimates (adjusting for potential downward bias) and are fairly similar to the Type I estimates.

Variance Components Estimation Procedure			
Asymptotic Covariance Matrix of Estimates			
	Var(b)	Var(a*b)	Var(Error)
Var(b)	4401703.8	1.29359	-273.39651
Var(a*b)	1.29359	3559.1	-502.85157
Var(Error)	-273.39651	-502.85157	1249.7

The Error variance component estimate is negatively correlated with the other two variance component estimates, and the estimated variances are all larger than their ML counterparts.

The VARIOGRAM Procedure

Overview

The VARIOGRAM procedure computes sample or empirical measures of spatial continuity for two-dimensional spatial data. These continuity measures are the regular semivariogram, a robust version of the semivariogram, and the covariance. The continuity measures are written to an output data set, allowing plotting or parameter estimation for theoretical semivariogram or covariance models. Both isotropic and anisotropic measures are available.

The VARIOGRAM procedure produces two additional output data sets that are useful in the analysis of pairwise distances in the original data. The OUTPAIR= data set contains one observation for each pair of points. The coordinates, distance, angle, and values of the analysis variables are written to this data set. The OUTDISTANCE= data set contains histogram information on the count of pairs within distance intervals, which is useful for determining unit lag distances.

Introduction to Spatial Prediction

Spatial prediction, in general, is any prediction method that incorporates spatial dependence. A simple and popular spatial prediction method is ordinary kriging.

Ordinary kriging requires a model of the spatial continuity, or dependence. This is typically in the form of a covariance or semivariogram.

Spatial prediction, then, involves two steps. First, you model the covariance or semivariogram of the spatial process. This involves choosing both a mathematical form and the values of the associated parameters. Second, you use this dependence model in solving the kriging system at a specified set of spatial points, resulting in predicted values and associated standard errors.

SAS/STAT software has two procedures corresponding to these steps for spatial prediction of two-dimensional data. The VARIOGRAM procedure is used in the first step. By computing a sample estimate of the variogram or covariance, you can choose a theoretical model based on graphical or other means.

Getting Started

In activities such as reservoir estimation in mining, petroleum exploration, and environmental modeling of air and water pollution, it often happens that data on one or more quantities are available at given spatial locations, and the goal is to predict the measured quantities at unsampled locations. Often, these unsampled locations are on a regular grid, and the predictions are used to produce surface plots or contour maps.

A popular method of spatial prediction is ordinary kriging, which produces both predicted values and associated standard errors. Ordinary kriging requires the complete specification (the form and parameter values) of the spatial dependence of the spatial process in terms of a covariance or semivariogram model.

Typically the semivariogram model is not known in advance and must be estimated, either visually or by some estimation method.

PROC VARIOGRAM computes the sample semivariogram, from which you can find a suitable theoretical semivariogram by visual methods.

The following example goes through a typical problem to show how you can compute a sample variogram and determine an appropriate theoretical model.

Preliminary Spatial Data Analysis

The simulated data consist of coal seam thickness measurements (in feet) taken over an approximately square area. The coordinates are offsets from a point in the southwest corner of the measurement area, with the north and east distances in units of thousands of feet.

First, the data are input.

;

```

It is instructive to see the locations of the measured points in the area where you want to perform spatial prediction. It is desirable to have these locations scattered evenly around the prediction area. If this is not the case, the prediction error might be unacceptably large where measurements are sparse. The following GPLOT procedure is useful in determining potential problems:

```

proc gplot data=thick;
  title 'Scatter Plot of Measurement Locations';
  plot north*east / frame cframe=ligr haxis=axis1
                vaxis=axis2;
  symbol1 v=dot color=blue;
  axis1 minor=none;
  axis2 minor=none label=(angle=90 rotate=0);
  label east   = 'East'
        north  = 'North'
;
run;

```

Figure 80.1. Scatter Plot of Measurement Locations

As Figure 80.1 indicates, while the locations are not ideally spread around the prediction area, there are not any large areas lacking measurements. You now can look at a surface plot of the measured variable, the thickness of coal seam, using the G3D procedure. This is a crucial step. Any obvious surface trend has to be removed before you compute and estimate the model of spatial dependence (the semivariogram model).

```
proc g3d data=thick;
  title 'Surface Plot of Coal Seam Thickness';
  scatter east*north=thick / xticknum=5 yticknum=5
    grid zmin=20 zmax=65;
  label east = 'East'
        north = 'North'
        thick = 'Thickness'
;
run;
```

Figure 80.2. Surface Plot of Coal Seam Thickness

Figure 80.2 shows the small-scale variation typical of spatial data, but there does not appear to be any surface trend. Hence, you can work with the original thickness data rather than residuals from a trend surface fit.

Preliminary Variogram Analysis

Recall that the goal of this example is spatial prediction. In particular, you would like to produce a contour map or surface plot on a regular grid of predicted values based on ordinary kriging. Ordinary kriging requires the complete specification of the spatial covariance or semivariogram.

You can use PROC VARIOGRAM, along with a DATA step and PROC GPLOT, to estimate visually a reasonable semivariogram model (both the form and associated parameters) for the thickness data.

Before proceeding with this estimation, consider the formula for the empirical or experimental semivariogram $\gamma_z(h)$. Denote the coal seam thickness process by $\{Z(r), r \in D \subset \mathcal{R}^2\}$. You have measurements $(Z(r_i), i = 1, \dots, 75)$. The standard formula for $\gamma_z(h)$ (isotropic case) is

$$2\gamma_z(h) = \frac{1}{|N(h)|} \sum_{N(h)} (Z(r_i) - Z(r_j))^2$$

where $N(h)$ is given by

$$N(h) = \{i, j : |r_i - r_j| = h\}$$

and $|N(h)|$ is the number of such pairs (i, j) .

For actual data, it is unlikely that any pair (i, j) would exactly satisfy $|r_i - r_j| = h$, so typically a range of pairwise distances, $|r_i - r_j| \in [h - \delta h, h + \delta h)$, is used to group pairs (r_i, r_j) for a single term in the expression for $\gamma_z(h)$. Using this range, $N(h)$ is modified by

$$N(h, \delta h) = \{i, j : |r_i - r_j| \in [h - \delta h, h + \delta h)\}$$

PROC VARIOGRAM performs this grouping with two required options for variogram computation: the LAGDISTANCE= and MAXLAGS= options.

The meaning of the required LAGDISTANCE= option is as follows. Classify all pairs of points into intervals according to their pairwise distance. The width of the distance interval is the LAGDISTANCE= value. The meaning of the required MAXLAGS= option is simply the number of intervals.

The problem is that a surface plot of the original data, or the scatter plot of the measurement locations, is not very helpful in determining the distribution of these pairwise distances; it is not clear what values to give to the LAGDISTANCE= and MAXLAGS= options.

You use PROC VARIOGRAM with the OUTDISTANCE= option to produce a modified histogram of the pairwise distances in order to find reasonable values for the LAGDISTANCE= and MAXLAGS= options. In the following analysis, you use the

NOVARIOGRAM option in the COMPUTE statement and the OUTDISTANCE= option in the PROC VARIOGRAM statement. You need the NOVARIOGRAM option to keep an error message from being issued due to the absence of the LAGDISTANCE= and MAXLAGS= options.

The DATA step after the PROC VARIOGRAM statement computes the midpoint of each distance interval. This midpoint is then used in the GCHART procedure. Since the number of distance intervals is not specified by using the NHCLASSES= option in the COMPUTE statement, the default of 10 is used.

```
proc variogram data=thick outdistance=outd;
  compute novariogram;
  coordinates xc=east yc=north;
  var thick;
run;

title 'OUTDISTANCE= Data Set Showing Distance Intervals';
proc print data=outd;
run;

data outd; set outd;
  mdpt=round((lb+ub)/2,.1);
  label mdpt = 'Midpoint of Interval';
run;

Figure 80.3. OUTDISTANCE= Data Set Showing Distance Intervals

Figure 80.4. Distribution of Pairwise Distances

For plotting and estimations purposes, it is desirable to have as many points as possible for the plot of $\gamma_z(h)$ against h . This corresponds to having as many distance intervals as possible, that is, having a small value for the LAGDISTANCE= option.

However, a rule of thumb used in computing sample semivariograms is to use at least 30 point pairs in computing a single value of the empirical or experimental semivariogram.

If the LAGDISTANCE= value is set too small, there may be too few points in one or more of the intervals. On the other hand, if the LAGDISTANCE= value is set to a large value, the number of point pairs in the distance intervals may be much greater than that needed for estimation precision, thereby “wasting” point pairs at the expense of variogram points.

Hence, there is a tradeoff between the number of distance intervals and the number of point pairs within each interval.

As discussed in the section “OUTDIST=SAS-data-set” on page 4878 the first few distance intervals, corresponding to lag 0 and lag 1, are typically the limiting intervals. This is particularly true for lag 0 since it is half the width of the remaining intervals. For the default of NHCLASSES=10, the lag 0 class contains 45 points, which is reasonably close to 30, but the lag 1 class contains 263 points.

If you rerun PROC VARIOGRAM with NHCLASSES=20, these numbers become 8 and 83 for lags 0 and 1, respectively. Because of the asymmetrical nature of lag 0, you are willing to violate the rule of thumb for the 0th lag. You will, however, have sufficient numbers in lag 1 and above.

```
proc variogram data=thick outdistance=outd;
  compute nhc=20 novariogram;
  coordinates xc=east yc=north;
  var thick;
run;

title 'OUTDISTANCE= Data Set Showing Distance Intervals';

Figure 80.5. OUTDISTANCE= Data Set Showing Distance Intervals

Figure 80.6. Distribution of Pairwise Distances

The length of the lag 1 class (3.484, 10.453) is 6.969. You round off and use LAGDISTANCE=7.0 in the COMPUTE statement.

The use of the MAXLAGS= option is more difficult. From Figure 80.5, note that up to a pairwise distance of 101, you have a sufficient number of pairs. With your choice of LAGDISTANCE=7.0, this yields a maximum number of lags $\frac{101}{7} \approx 14$.

The problem with using the maximum lag value is that it includes pairs of points so far apart that they are likely to be independent. Using pairs of points that are independent adds nothing to the empirical semivariogram plot; they are essentially added noise.

If there is an estimate of correlation length, perhaps from a prior geologic study of a similar site, you can specify the MAXLAGS= value so that the maximum pairwise distance does not exceed two or three correlation lengths. If there is no estimate of correlation length, you can use the following rule of thumb: use $\frac{1}{2}$ to $\frac{3}{4}$ of the “diameter” of the region containing the data. A MAXLAGS= value of 10 is within this range.

You now rerun PROC VARIOGRAM with these values.

Sample Variogram Computation and Plots

Using the values of LAGDISTANCE=7.0 and MAXLAGS=10 computed previously, rerun PROC VARIOGRAM without the NOVARIogram option. Also, request a robust version of the semivariogram; then, plot both results against the pairwise distance of each class.

```
proc variogram data=thick outv=outv;
    compute lagd=7 maxlag=10 robust;
    coordinates xc=east yc=north;
    var thick;
run;

title 'OUTVAR= Data Set Showing Sample Variogram Results';

Figure 80.7. OUTVAR= Data Set Showing Sample Variogram Results

Figure 80.8. Standard and Robust Semivariogram for Coal Seam Thickness Data

Figure 80.8 shows first a slow, then a rapid rise from the origin, suggesting a Gaussian type form:

$$\gamma_z(h) = c_0 \left[1 - \exp\left(-\frac{h^2}{a_0^2}\right) \right]$$

See the section “Theoretical and Computational Details of the Semivariogram” on page 4872 for graphs of the standard semivariogram forms.

By experimentation, you find that a scale of $c_0 = 7.5$ and a range of $a_0 = 30$ fits reasonably well for both the robust and standard semivariogram

The following statements plot the sample and theoretical variograms:

```

data outv3; set outv;
  c0=7.5; a0=30;
  vari = c0*(1-exp(-distance*distance/(a0*a0)));
  type = 'Gaussian'; output;
  vari = variog; type = 'regular'; output;
  vari = rvario; type = 'robust'; output;
run;

title 'Theoretical and Sample Semivariogram for Coal Seam
      Thickness Data';
proc gplot data=outv3;
  plot vari*distance=type / frame cframe=ligr vaxis=axis2
                        haxis=axis1;
  symbol1 i=join l=1 c=blue /* v=star */;
  symbol2 i=join l=1 c=yellow /* v=square */;
  symbol3 i=join l=1 c=cyan /* v=diamond */;
  axis1 minor=none
        label=(c=black 'Lag Distance') /* offset=(3,3) */;
  axis2 order=(0 to 9 by 1) minor=none
        label=(angle=90 rotate=0 c=black 'Variogram')
        /* offset=(3,3) */;
run;

```

Figure 80.9. Theoretical and Sample Semivariogram for Coal Seam Thickness Data

Figure 80.9 shows that the choice of a semivariogram model is adequate. You can use this Gaussian form and these particular parameters in PROC KRIGE2D to produce a contour plot of the kriging estimates and the associated standard errors.

Syntax

The following statements are available in PROC VARIOGRAM.

```

PROC VARIOGRAM options ;
  COMPUTE computation-options ;
  COORDINATES coordinate-variables ;
  DIRECTIONS directions-list ;
  VAR analysis-variables-list ;

```

The COMPUTE and COORDINATES statements are required.

The following table outlines the options available in PROC VARIOGRAM classified by function.

Table 80.1. Options Available in the VARIOGRAM Procedure

PROC VARIOGRAM Statement

PROC VARIOGRAM *options* ;

You can specify the following options in the PROC VARIOGRAM statement.

DATA=SAS-data-set

specifies a SAS data set containing the x and y coordinate variables and the VAR statement variables.

OUTDISTANCE=SAS-data-set

OUTDIST=SAS-data-set

OUTD=SAS-data-set

specifies a SAS data set in which to store summary distance information. This data set contains a count of all pairs of data points within a given distance interval. The number of distance intervals is controlled by the NHCLASSES= option in the COMPUTE statement. The OUTDISTANCE= data set is useful for plotting mod-

ified histograms of the count data for determining appropriate lag distances. See the section “[OUTDIST=SAS-data-set](#)” on page 4878 for details.

OUTPAIR=SAS-data-set

OUTP=SAS-data-set

specifies a SAS data set in which to store distance and angle information for each pair of points in the DATA= data set. This option should be used with caution when the DATA= data set is large. If n denotes the number of observations in the DATA= data set, the OUTPAIR= data set contains $\frac{n(n-1)}{2}$ observations unless you restrict it with the OUTPDISTANCE= option in the COMPUTE statement. The OUTPDISTANCE= option in the COMPUTE statement excludes pairs of points when the distance between the pairs exceeds the OUTPDISTANCE= value. See the section “[OUTPAIR=SAS-data-set](#)” on page 4881 for details.

OUTVAR=SAS-data-set

OUTVR=SAS-data-set

specifies a SAS data set in which to store the continuity measures. See the section “[OUTVAR=SAS-data-set](#)” on page 4877 for details.

COMPUTE Statement

COMPUTE *computation-options* ;

The COMPUTE statement provides a number of options that control the computation of the semivariogram, the robust semivariogram, and the covariance.

ANGLETOLERANCE=*angle tolerance*

ANGLETOL=*angle tolerance*

ATOL=*angle tolerance*

specifies the tolerance, in degrees, around the angles determined by the NDIRECTIONS= specification. The default is $\frac{180^\circ}{2 \times n_d}$, where n_d is the NDIRECTIONS= specification.

See the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 4872 for more detailed information.

BANDWIDTH=*bandwidth distance*

BANDW=*bandwidth distance*

specifies the bandwidth, or perpendicular distance cutoff for determining the angle class for a given pair of points. The distance classes define a series of cylindrically shaped areas, while the angle classes radially cut these cylindrically shaped areas. For a given angle class $(\theta_1 - \delta\theta_1, \theta_1 + \delta\theta_1)$, as you proceed out radially, the area encompassed by this angle class becomes larger. The BANDWIDTH= option restricts this area by excluding all points with a perpendicular distance from the line $\theta = \theta_1$ that is greater than the BANDWIDTH= value.

If you do not specify the BANDWIDTH= option, no restriction occurs. See [Figure 80.15](#) on page 4876 for more detailed information.

DEPSILON=*distance value*

DEPS=*distance value*

specifies the distance value for declaring that two distinct points are zero distance apart. Such pairs, if they occur, cause numeric problems. If you specify **DEPSILON**= ε , then pairs of points P_1 and P_2 for which the distance between them $|P_1P_2| < \varepsilon$ are excluded from the continuity measure calculations. The default value of the **DEPSILON**= option is 100 times machine epsilon; this product is approximately 1E-10 on most computers.

LAGDISTANCE=*distance unit*

LAGDIST=*distance unit*

LAGD=*distance unit*

specifies the basic distance unit defining the lags. For example, a specification of **LAGDISTANCE**= x results in lag distance classes that are multiples of x . For a given pair of points P_1 and P_2 , the distance between them, denoted $|P_1P_2|$, is calculated. If $|P_1P_2| = x$, then this pair is in the first lag class. If $|P_1P_2| = 2x$, then this pair is in the second lag class, and so on.

For irregularly spaced data, the pairwise distances are unlikely to fall exactly on multiples of the **LAGDISTANCE**= value. A distance tolerance of δx is used to accommodate a spread of distances around multiples of x (the **LAGTOLERANCE**= option specifies the distance tolerance). For example, if $|P_1P_2|$ is within $x \pm \delta x$, you would place this pair in the first lag class; if $|P_1P_2|$ is within $2x \pm \delta x$, you would place this pair in the second lag class, and so on.

You can determine the candidate values for the **LAGDISTANCE**= option by plotting or displaying the **OUTDISTANCE**= data set.

A **LAGDISTANCE**= value is required unless you specify the **NOVARIOGRAM** option.

See the section [“Theoretical and Computational Details of the Semivariogram”](#) on page 4872 for more details.

LAGTOLERANCE=*tolerance number*

LAGTOL=*tolerance number*

LAGT=*tolerance number*

specifies the tolerance around the **LAGDISTANCE**= value for grouping distance pairs into lag classes. See the preceding description of the **LAGDISTANCE**= option for information on the use of the **LAGTOLERANCE**= option, and see the section [“Theoretical and Computational Details of the Semivariogram”](#) on page 4872 for more details.

If you do not specify the **LAGTOLERANCE**= option, a default value of $(1/2)$ times the **LAGDISTANCE**= value is used.

MAXLAGS=*number of lags*

MAXLAG=*number of lags*

MAXL=*number of lags*

specifies the maximum number of lag classes used in constructing the continuity measures. This option excludes any pair of points P_1 and P_2 for which the distance

between them, $|P_1P_2|$, exceeds the MAXLAGS= value times the LAGDISTANCE= value.

You can determine candidate values for the MAXLAGS= option by plotting or displaying the OUTDISTANCE= data set.

A MAXLAGS= value is required unless you specify the NOVARIOGRAM option.

NDIRECTIONS=*number of directions*

NDIR=*number of directions*

ND=*number of directions*

specifies the number of angle classes to use in computing the continuity measures. This option is useful when there is potential anisotropy in the spatial continuity measures. Anisotropy occurs when the spatial continuity or dependence between a pair of points depends on the orientation or angle between the pair. Isotropy is the absence of this effect: the spatial continuity or dependence between a pair of points depends only on the distance between the points, not the angle.

The angle classes formed from the NDIRECTIONS= option start from N–S and proceed clockwise. For example, NDIRECTIONS=3 produces three angle classes. In terms of compass points, these classes are centered at 0° (or its reciprocal 180°), 60° (or its reciprocal 240°), and 120° (or its reciprocal 300°). For irregularly spaced data, the angles between pairs are unlikely to fall exactly in these directions, so an angle tolerance of $\delta\theta$ is used (the ANGLETOLERANCE= option specifies the angle tolerance). If NDIRECTIONS= n_d , the base angle is $\theta = \frac{180^\circ}{n_d}$, and the angle classes are

$$(k\theta - \delta\theta, k\theta + \delta\theta) \quad k = 0, \dots, n_d - 1$$

If you do not specify the NDIRECTIONS= option, no angles are formed, and the spatial continuity measures are assumed to be isotropic.

The NDIRECTIONS= option is useful for exploring possible anisotropy. The DIRECTIONS statement, described in the “[DIRECTIONS Statement](#)” section on page 4870, provides greater control over the angle classes. See the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 4872 for more detailed information.

NHCLASSES=*number of histogram classes*

NHCLASS=*number of histogram classes*

NHC=*number of histogram classes*

specifies the number of distance or histogram classes to write to the OUTDISTANCE= data set. The actual number of classes is one more than the NHCLASSES= value since a special lag 0 class is also computed. See the [OUTDISTANCE= option](#) on page 4865 and the section “[OUTDIST=SAS-data-set](#)” on page 4878 for details.

The default value of the NHCLASSES= option is 10. This option is ignored if you do not specify an OUTDISTANCE= data set.

NOVARIOGRAM

prevents the computation of the continuity measures. This option is useful for preliminary analysis when you require only the OUTDISTANCE= or OUTPAIR= data sets.

OUTPDISTANCE=*distance limit*

OUTPDIST=*distance limit*

OUTPD=*distance limit*

specifies the cutoff distance for writing observations to the OUTPAIR= data set. If you specify OUTPDISTANCE= d_{max} , the distance $|P_1P_2|$ between each pair of points P_1 and P_2 is checked against d_{max} . If $|P_1P_2| > d_{max}$, the observation for this pair is not written to the OUTPAIR= data set. If you do not specify the OUTPDISTANCE= option, all distinct pairs are written. This option is ignored if you do not specify an OUTPAIR= data set.

ROBUST

requests that a robust version of the semivariogram be calculated in addition to the regular semivariogram and covariance.

COORDINATES Statement

COORDINATES *coordinate-variables* ;

The following two options give the names of the variables in the DATA= data set containing the values of the x and y coordinates of the data.

Only one COORDINATES statement is allowed, and it is applied to all the analysis variables. In other words, it is assumed that all the VAR variables have the same x and y coordinates.

XCOORD= (*variable-name*)

XC= (*variable-name*)

gives the name of the variable containing the x coordinate of the data in the DATA= data set.

YCOORD= (*variable-name*)

YC= (*variable-name*)

gives the name of the variable containing the y coordinate of the data in the DATA= data set.

DIRECTIONS Statement

DIRECTIONS *directions-list* ;

You use the DIRECTIONS statement to define angle classes. You can specify angle classes as a list of angles, separated by commas, with optional angle tolerances and bandwidths within parentheses following the angle. You must specify at least one angle.

If you do not specify the optional angle tolerance, the default value of 45° is used. If you do not specify the optional bandwidth, no bandwidth is checked. If you specify a bandwidth, you must also specify an angle tolerance.

For example, suppose you want to compute three separate semivariograms at angles $\theta_1 = 0^\circ$, $\theta_2 = 60^\circ$, and $\theta_3 = 120^\circ$, with corresponding angle tolerance $\delta\theta_1 = 22.5^\circ$, $\delta\theta_2 = 12.5^\circ$, and $\delta\theta_3 = 22.5^\circ$, with bandwidths 50 and 40 distance units on the first two angle classes and no bandwidth check on the last angle class.

The appropriate DIRECTIONS statement is

```
directions 0.0(22.5,50), 60.0(12.5,40),120(22.5);
```

VAR Statement

VAR *analysis-variables-list* ;

Use the VAR statement to specify the analysis variables. You can specify only numeric variables. If you do not specify a VAR statement, all numeric variables in the DATA= data set that are not in the COORDINATES statement are used.

Details

Theoretical Semivariogram Models

The VARIOGRAM procedure computes the sample, or experimental semivariogram. Prediction of the spatial process at unsampled locations by techniques such as ordinary kriging requires a theoretical semivariogram or covariance.

It is necessary, then, to decide on a theoretical variogram based on the sample variogram. While there are methods of fitting semivariogram models, such as least squares, maximum likelihood, and robust methods (Cressie 1993, section 2.6), these techniques are not appropriate for data sets resulting in a small number of variogram points. Instead, a visual fit of the variogram points to a few standard models is often satisfactory. Even when there are sufficient variogram points, a visual check against a fitted theoretical model is appropriate (Hohn 1988, p. 25ff).

In some cases, a plot of the experimental semivariogram suggests that a single theoretical model is inadequate. Nested models, anisotropic models, and the nugget effect increase the scope of theoretical models available. All of these concepts are discussed in this section. The specification of the final theoretical model is provided by the syntax of PROC KRIGE2D.

Note the general flow of investigation. After a suitable choice is made of the LAGDIST= and MAXLAGS= options and, possibly, the NDIR= option (or a DIRECTIONS statement), the experimental semivariogram is computed. Potential theoretical models, possibly incorporating nesting, anisotropy, and the nugget effect, are computed by a DATA step, then they are plotted against the experimental semivariogram and evaluated. A suitable theoretical model is thus found visually, and the specification of the model is used in PROC KRIGE2D. This flow is illustrated in Figure 80.10; also see the “Getting Started” section on page 4852 for an illustration in a simple case.

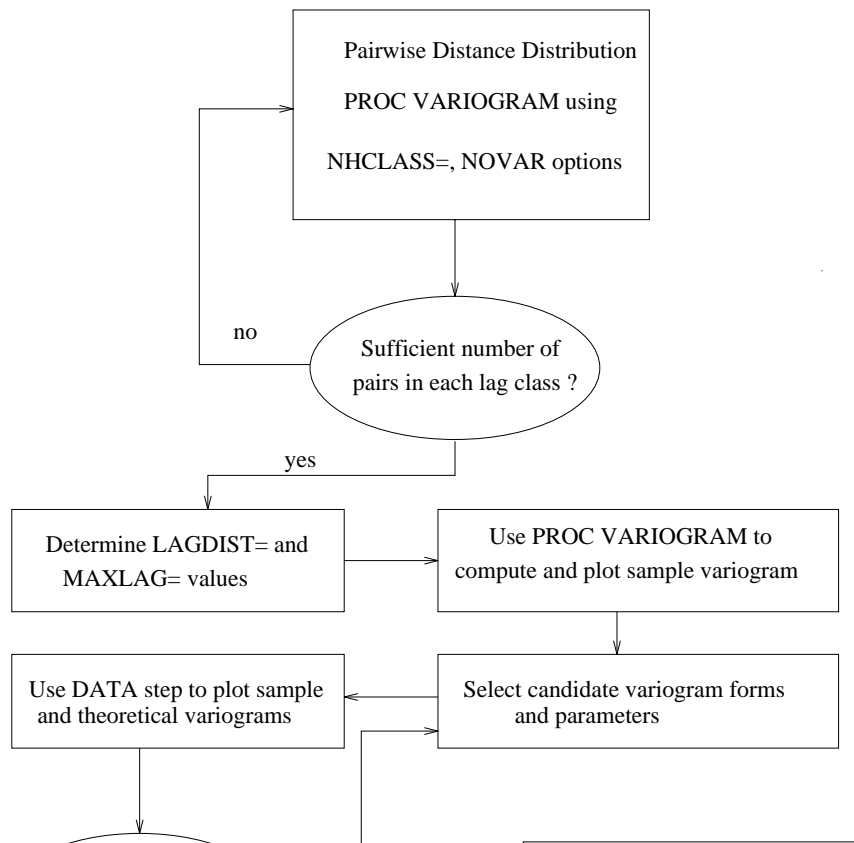

Figure 80.10. Flowchart for Variogram Selection

Theoretical and Computational Details of the Semivariogram

The basic starting point in computing the semivariogram is the enumeration of pairs of points for the spatial data. Figure 80.11 shows a spatial domain in which a set of measurements are made at the indicated locations. Two points P_1 and P_2 , with coordinates (x_1, y_1) , (x_2, y_2) , are selected for illustration. A vector, or directed line segment, is drawn between these points. This pair is then categorized first by orientation of this directed line segment and then by its length. That is, the pair P_1P_2 is placed into an angle and distance class.

Figure 80.11. Selection of Points P_1 and P_2 in Spatial Domain

Angle Classification

Suppose you specify $NDIR=3$ in the COMPUTE statement in PROC VARIOGRAM. This results in three angle classes defined by midpoint angles between 0° and 180° : $0^\circ \pm \delta\theta$, $60^\circ \pm \delta\theta$, and $120^\circ \pm \delta\theta$, where $\delta\theta$ is the angle tolerance. If you do not specify an angle tolerance using the ATOL= option in the COMPUTE statement, the following default value is used.

$$\delta\theta = \frac{180^\circ}{2 \times NDIR}$$

For three classes, $\delta\theta = 30^\circ$. When the example directed line segment P_1P_2 is superimposed on the coordinate system showing the angle classes, its angle, measured clockwise from north, is approximately 45° . In particular, it falls within $[60^\circ - \delta\theta, 60^\circ + \delta\theta] = [30^\circ, 90^\circ]$, the second angle class. See [Figure 80.12](#).

Figure 80.12. Selected Pair P_1P_2 Falls within the Second Angle Class

Note that if the designated points P_1 and P_2 are labeled in the opposite order, the orientation is in a reciprocal direction, that is, approximately 225° for the point pair instead of approximately 45° . This does not affect angle class selection; the angle classes $[60^\circ - \delta\theta, 60^\circ + \delta\theta]$ and $[240^\circ - \delta\theta, 240^\circ + \delta\theta]$ are the same.

If you specify an angle tolerance less than the default, for example, $ATOL = 15^\circ$, some point pairs might be excluded. For example, the selected point pair P_1P_2 in [Figure 80.12](#), while closest to the 60° axis, might lie outside $[60 - \delta\theta, 60 + \delta\theta] = [45^\circ, 75^\circ]$. In this case, the point pair P_1P_2 would be excluded from the variogram computation.

On the other hand, you can specify an angle tolerance *greater* than the default. This can result in a point pair being counted in more than one angle class. This has a smoothing effect on the variogram and is useful when there is a small amount of data available.

An alternative way to specify angle classes and angle tolerances is with the DIRECTIONS statement. The DIRECTIONS statement is useful when angle classes are not equally spaced. When you specify the DIRECTIONS statement, you should also specify the angle tolerance. The default value of the angle tolerance is 45°

when a DIRECTIONS statement is used instead of the NDIRECTIONS= option in the COMPUTE statement. This may not be appropriate for a particular set of angle classes. See the “DIRECTIONS Statement” section on page 4870 for more details on the DIRECTIONS statement.

Distance Classification

Next, the distance class for the point pair P_1P_2 is determined. The directed line segment P_1P_2 is superimposed on the coordinate system showing the distance or lag classes. These classes are determined by the LAGD= specification in the COMPUTE statement. Denoting the length of the line segment by $|P_1P_2|$ and the LAGD value by Δ , the lag class L is determined by

$$L(P_1P_2) = \left\lfloor \frac{|P_1P_2| + .5}{\Delta} \right\rfloor$$

where $\lfloor x \rfloor$ denotes the largest integer $\leq x$.

When the directed line segment P_1P_2 is superimposed on the coordinate system showing the distance classes, it is seen to fall in the first lag class; see Figure 80.13 for an illustration for $\Delta = 1$.

Figure 80.13. Selected Pair P_1P_2 Falls within the First Lag Class

Because pairwise distances are positive, lag class zero is smaller than lag classes $1, \dots, MAXLAG - 1$. For example, if you specify LAGD=1.0 and MAXLAG=10,

and you do not specify a LAGTOL= value in the COMPUTE statement in PROC VARIOGRAM, the ten lag classes generated by the preceding equation are

$$[0, .5), [.5, 1.5), [1.5, 2.5), \dots, [8.5, 9.5)$$

This is because the default lag tolerance is one-half the LAGD= value, resulting in no gaps between the distance class intervals. This is shown in Figure 80.14.

Figure 80.14. Lag Distance Axis Showing Lag Classes

On the other hand, if you do specify a distance tolerance with the DTOL= option in the COMPUTE statement, a further check is performed to see if the point pair falls within this tolerance of the nearest lag. In the preceding example, if you specify LAGD=1.0 and MAXLAG=10 (as before) and also specify LAGTOL=0.25, the intervals become

$$[0, 0.25), [0.75, 1.25), [1.75, 2.25), \dots, [8.75, 9.25)$$

Note that this specification results in gaps in the lag classes; a point pair P_1P_2 might fall, for example, in the interval

$$| P_1P_2 | \in [1.25, 1.75)$$

and hence be excluded from the semivariogram calculation. The maximum LAGTOL= value allowed is half the LAGD= value; no overlap of the distance classes is allowed.

Bandwidth Restriction

Because the areal segments generated from the angle and distance classes increase in area as the lag distance increases, it is sometimes desirable to restrict this area (Duetsch and Journel 1992, p. 45). If you specify the BANDW= option in the COMPUTE statement, the lateral, or perpendicular, distance from the axis defining the angle classes is fixed.

For example, suppose two points P_3, P_4 are picked from the domain in Figure 80.11 and are superimposed on the grid defining distance and angle classes, as shown in Figure 80.15.

Figure 80.15. Selected Pair P_3P_4 Falls Outside Bandwidth Limit

The endpoint of vector P_3P_4 falls within the angle class around 60° and the 5th lag class; however, it falls outside the restricted area defined by the bandwidth. Hence, it is excluded from the semivariogram calculation.

Finally, a pair P_iP_j that falls in a lag class larger than the value of the MAXLAG= option is excluded from the semivariogram calculation.

From this description, it is clear that the number of pairs within each angle/distance class is strongly affected by the angle and lag tolerances. Since it is desirable to have the maximum number of point pairs within each class, the angle tolerance and the distance tolerance should usually be the default values.

Semivariogram Computation

With the classification of a point pair P_iP_j into an angle/distance class, as shown in the preceding section, the semivariogram computation proceeds as follows.

Denote all pairs P_iP_j belonging to angle class $[\theta_k - \delta\theta_k, \theta_k + \delta\theta_k)$ and distance class $L = L(P_iP_j)$ by $N(\theta_k, L)$. For example, in the preceding illustration, P_1P_2 belongs to $N(60^\circ, 1)$.

Let $|N(\theta_k, L)|$ denote the *number* of such pairs. Let V_i, V_j be the measured values at points P_i, P_j . The component of the standard (or method of moments) semivariogram

corresponding to angle/distance class $N(\theta_k, L)$ is given by

$$2\gamma(h_k) = \frac{1}{|N(\theta_k, L)|} \sum_{P_i P_j \in N(\theta_k, L)} (V_i - V_j)^2$$

where h_k is the average distance in class $N(\theta_k, L)$; that is,

$$h_k = \frac{1}{|N(\theta_k, L)|} \sum_{P_i P_j \in N(\theta_k, L)} |P_i P_j|$$

The robust version of the semivariogram, as suggested by Cressie (1993), is given by

$$2\bar{\gamma}(h_k) = \frac{\Psi^4(h_k)}{0.457 + 0.494/N(\theta_k, L)}$$

where

$$\Psi(h_k) = \frac{1}{N(\theta_k, L)} \sum_{P_i P_j \in N(\theta_k, L)} (V_i - V_j)^{\frac{1}{2}}$$

This robust version of the semivariogram is computed when you specify the **ROBUST** option in the **COMPUTE** statement in **PROC VARIOGRAM**.

PROC VARIOGRAM computes and writes to the **OUTVAR=** data set the quantities h_k , θ_k , L , $N(\theta_k, L)$, $\gamma(h)$, and $\bar{\gamma}(h)$.

Output Data Sets

The **VARIOGRAM** procedure produces three data sets: the **OUTVAR=SAS-data-set**, the **OUTPAIR=SAS-data-set**, and the **OUTDIST=SAS-data-set**. These data sets are described in the following sections.

OUTVAR=SAS-data-set

The **OUTVAR=** data set contains the standard and robust versions of the sample semivariogram, the covariance, and other information at each lag class.

The details of the computation of the variogram, the robust variogram, and the covariance is described in the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 4872.

The **OUTVAR=** data set contains the following variables:

- **ANGLE**, which is the angle class value (clockwise from N-S)
- **ATOL**, which is the angle tolerance for the lag/angle class
- **AVERAGE**, which is the average variable value for the lag/angle class

- BANDW, which is the band width for the lag/angle class
- COUNT, which is the number of pairs in the lag/angle class
- COVAR, which is the covariance value for the lag/angle class
- DISTANCE, which is the average lag distance for the lag/angle class
- LAG, which is lag class value (in LAGDISTANCE= units)
- RVARIO, which is the sample robust variogram value for the lag/angle class
- VARIOG, which is the sample variogram value for the lag/angle class
- VARNAME, which is the name of the current VAR= variable

The bandwidth variable, BANDW, is not included in the data set if no bandwidth specification is given in the COMPUTE statement or in a DIRECTIONS statement.

OUTDIST=SAS-data-set

The OUTDIST= data set contains counts for a modified histogram showing the distribution of pairwise distances. The purpose of this data set is to enable you to make choices for the value of the LAGDISTANCE= option in the COMPUTE statement in subsequent runs of PROC VARIOGRAM.

For plotting and estimation purposes, it is desirable to have as many points as possible for a variogram plot. However, a rule of thumb used in computing sample semivariograms is to use at least 30 points in each interval whenever possible. Hence, there is a lower limit to the value of the LAGDISTANCE= option.

Since the distribution of pairwise distances is seldom known in advance, the information contained in the OUTDIST= data set enables you to choose, in an iterative fashion, a value for the LAGDISTANCE= parameter. The value you choose is a compromise between the number of pairs making up each variogram point and the number of variogram points.

In some cases, the pattern of measured points may result in some lag or distance classes having a small number of pairs, while the remaining classes have a large number of pairs. By adjusting the value of the LAGDISTANCE= option to honor the rule of thumb (at least 30 pairs), you are “wasting” pairs in the other distance classes.

One strategy for solving this problem is to use less than 30 pairs for these distance classes. Then, either delete the corresponding variogram points or use them and accept the increased uncertainty. Unfortunately, the deficient distance classes are usually those close to the origin ($h = 0$). This is the crucial portion of the experimental variogram curve for determining the form of the theoretical variogram and for detecting the presence of a nugget effect.

Another alternative is to force distance classes to contain approximately the same number of pairs. This results in distance classes of unequal widths.

While PROC VARIOGRAM does not produce such distance classes directly, the OUTPAIR= data set, described in the section “OUTPAIR=SAS-data-set” on page 4881, contains information on all distinct pairs of points. You can use this data set,

along with the RANK procedure, to produce experimental variogram-based equal numbers of pairs in each distance class.

To request an OUTDIST= data set, you specify the OUTDIST= data set in the PROC VARIOGRAM statement and the NOVARIOGRAM option in the COMPUTE statement. The NOVARIOGRAM option prevents any variogram or covariance computation from being performed.

Computation of the Distribution Distance Classes

The simplest way of determining the distribution of pairwise distances is to determine the maximum distance h_{max} between pairs and divide this distance by some number N of intervals to produce distance classes of length $\delta = \frac{h_{max}}{N}$. The distance between each pair of points P_1, P_2 , denoted $|P_1P_2|$, is computed, and the pair P_1P_2 is counted in the k th distance class if $|P_1P_2| \in [(k-1)\delta, k\delta)$ for $k = 1, \dots, N$.

The actual computation is a slight variation of this. A bound, rather than the actual maximum distance, is computed. This bound is the length of the diagonal of a bounding rectangle for the data points. This bounding rectangle is found by using the maximum and minimum x and y coordinates, $x_{max}, x_{min}, y_{max}, y_{min}$, and forming the rectangle determined by the points

$$(x_{max}, y_{max}), (x_{max}, y_{min}), (x_{min}, y_{min}), (x_{min}, y_{max})$$

See Figure 80.16 for an illustration of the bounding rectangle.

Figure 80.16. Bounding Rectangle to Determine Maximum Pairwise Distance

The pairwise distance bound, denoted by h_b , is given by

$$h_b^2 = (x_{max} - x_{min})^2 + (y_{max} - y_{min})^2$$

Using h_b , the interval $(0, h_b]$ is divided into $N + 1$ subintervals, where N is the value of the `NHCLASSES=` option specified in the `COMPUTE` statement, or $N = 10$ if the `NHCLASSES=` option is not specified. The basic distance unit is $h_0 = \frac{h_b}{N}$; the distance intervals are centered on $h_0, 2h_0, \dots, Nh_0$, with a distance tolerance of $\pm \frac{h_0}{2}$. The extra subinterval is $(0, h_0/2)$, corresponding to the 0th lag. It is half the length of the remaining subintervals, and it often contains the smallest number of pairs.

This method of partitioning the interval $(0, h_b]$ is identical to what is done when you actually compute the sample variogram.

The lag classes corresponding to $h_0=1$ are shown in [Figure 80.17](#).

Figure 80.17. Lag Classes Corresponding to $h_0 = 1$

By increasing or decreasing the value of the `NHCLASSES=` option, you can adjust the lag or distance class with the smallest count so that this count is around 30 or some other value that you judge appropriate.

Once you determine an appropriate value for the `NHCLASSES=` option, you can use the width of the lag classes as a candidate value for the `LAGDIST=` option in the `COMPUTE` statement. The width of the lag classes is determined by the upper bound (`UB`) and lower bound (`LB`) variables.

For example, read the observation from the `OUTDIST=` data set corresponding to lag 1 and compute the quantity `UB-LB`. Use this value for the `LAGDIST=` option in the `COMPUTE` statement.

Note: Do not use the 0th lag class; it is half the length of the other intervals. Use lag 1 instead.

Variables in the `OUTDIST=` data set

The following variables are written to the `OUTDIST=` data set:

- `COUNT`, which is the number of pairs falling into this lag class
- `LAG`, which is the lag class value
- `LB`, which is the lower bound of the lag class interval
- `UB`, which is the upper bound of the lag class interval
- `PER`, which is the percent of all pairs falling in this lag class
- `VARNAME`, which is the name of the current `VAR=` variable

OUTPAIR=SAS-data-set

The OUTPAIR= data set contains one observation for each distinct pair of points P_1, P_2 in the original data set, unless you specify the OUTPDISTANCE= option in the COMPUTE statement.

If you specify OUTPDISTANCE= D_{max} in the COMPUTE statement, all pairs P_1, P_2 in the original data set that satisfy the relation $|P_1 P_2| \leq D_{max}$ are written to the OUTPAIR= data set.

Note that the OUTPAIR= data set can be very large even for a moderately sized DATA= data set. For example, if the DATA= data set has NOBS=500, the OUTPAIR= data set has $\text{NOBS}(\text{NOBS} - 1)/2 = 124,750$ if no OUTPDISTANCE= restriction is given in the COMPUTE statement.

The OUTPAIR= data set contains information on the distance and orientation for each point pair, and you can use it for specialized continuity measure calculations.

The OUTPAIR= data set contains the following variables:

- AC, which is the angle class value
- COS, which is the cosine of the angle between pairs
- DC, which is the distance (lag) class
- DISTANCE, which is the distance between pairs
- V1, which is the variable value for the first point in the pair
- V2, which is the variable value for the second point in the pair
- VARNAME, which is the variable name for the current VAR variable
- X1, which is the x coordinate of the first point in the pair
- X2, which is the x coordinate of the second point in the pair
- Y1, which is the y coordinate of the first point in the pair
- Y2, which is the y coordinate of the second point in the pair

Computational Resources

The computations of the VARIOGRAM procedure are basically binning: for each pair of observations in the input data set, a distance and angle class is determined and recorded. Let N_d denote the number of distance classes, N_a denote the number of angle classes, and N_v denote the number of VAR variables. The memory requirements for these operations are proportional to $N_d \times N_a \times N_v$. This is typically small.

The CPU time required for the computations is proportional to the number of pairs of observations, or to $N^2 \times N_v$, where N is the number of observations in the input data set.

Example

Example 80.1. A Box Plot of the Square Root Difference Cloud

The Gaussian form chosen for the variogram in the “Getting Started” section on page 4852 is based on the consideration of the plots of the sample variogram. For the coal thickness data, the Gaussian form appears to be a reasonable choice.

It can often happen, however, that a plot of the sample variogram shows so much scatter that no particular form is evident. The cause of this scatter can be one or more outliers in the pairwise differences of the measured quantities.

A method of identifying potential outliers is discussed in Cressie (1993, section 2.2.2). This example illustrates how to use the OUTPAIR= data set from PROC VARIOGRAM to produce a square root difference cloud, which is useful in detecting outliers.

For the spatial process $Z(s)$, $s \in \mathcal{R}^2$, the square root difference cloud for a particular direction \mathbf{e} is given by

$$|Z(s_i + h\mathbf{e}) - Z(s_i)|^{\frac{1}{2}}$$

for a given lag distance h . In the actual computation, all pairs of points P_1, P_2 within a distance tolerance around h and an angle tolerance around the direction \mathbf{e} are used. This generates a number of point pairs for each lag class h . The spread of these values gives an indication of outliers.

Following the example in the “Getting Started” section on page 4852, this example uses a basic lag distance of 7 units, with a distance tolerance of 3.5, and a direction of N–S, with a 30° angle tolerance.

First, input the data, then use PROC VARIOGRAM to produce an OUTPAIR= data set. Then use a DATA step to subset this data by choosing pairs within 30° of N–S. In addition, compute lag class and square root difference variables. Next, summarize the results using the MEANS procedure and present them in a box plot using the SHEWHART procedure. The box plot facilitates the detection of outliers.

You can conclude from this example that there does not appear to be any outliers in the N–S direction for the coal seam thickness data.

Special SAS Data Sets

Introduction to Special SAS Data Sets

All SAS/STAT procedures create SAS data sets. Any table generated by a procedure can be saved to a data set by using the Output Delivery System (ODS), and many procedures also have syntax to enable you to save other statistics to data sets. Some of these data sets are organized according to certain conventions that allow them to be read by a SAS/STAT procedure for further analysis. Such specially organized data sets are recognized by the TYPE= attribute of the data set.

For example, the CORR procedure (refer to the *SAS Procedures Guide*) can create a data set with the attribute TYPE=CORR containing a correlation matrix. This TYPE=CORR data set can be read by the REG or FACTOR procedure, among others. If the original data set is large, using a special SAS data set in this way can save a great deal of computer time by avoiding the recomputation of the correlation matrix in each of several analyses.

As another example, the REG procedure can create a TYPE=EST data set containing estimated regression coefficients. If you need to make predictions for new observations, you can have the SCORE procedure read both the TYPE=EST data set and a data set containing the new observations. PROC SCORE can then compute predicted values or residuals without repeating the entire regression analysis. See [Chapter 64](#), “The SCORE Procedure,” for an example.

A special SAS data set may contain different kinds of statistics. A special variable called _TYPE_ is used to distinguish the various statistics. For example, in a TYPE=CORR data set, an observation in which _TYPE_='MEAN' contains the means of the variables in the analysis, and an observation in which _TYPE_='STD' contains the standard deviations. Correlations appear in observations with _TYPE_='CORR'. Another special variable, _NAME_, is needed to identify the row of the correlation matrix. Thus, the correlation between variables X and Y would be given by the value of the variable X in the observation for which _TYPE_='CORR' and _NAME_='Y', or by the value of the variable Y in the observation for which _TYPE_='CORR' and _NAME_='X'.

You can create special SAS data steps directly in a DATA step by specifying the TYPE= option in parentheses after the data set name in the DATA statement. See [Example A.2](#) on page 4896 for an example.

The special data sets created by SAS/STAT procedures can generally be used directly by other procedures without modification. However, if you create an output data set with PROC CORR and use the NOCORR option to omit the correlation matrix from the OUT= data set, you need to set the TYPE= option either in parentheses following the OUT= data set name in the PROC CORR statement or in parentheses following

the DATA= option in any other procedure that recognizes the special TYPE= attribute. In either case, the TYPE= option should be set to COV, CSSCP, or SSCP according to what type of matrix is stored in the data set and what data set types are accepted as input by the other procedures you plan to use. If you do not follow these steps and you use the TYPE=CORR data set with no correlation matrix as input to another procedure, the procedure may issue an error message indicating that the correlation matrix is missing from the data set.

If you use a DATA step with a SET statement to modify a special SAS data set, you must specify the TYPE= option in the DATA statement. The TYPE= attribute of the data set in the SET statement is *not* automatically copied to the data set being created.

You can determine the TYPE= attribute of a data set by using the CONTENTS procedure (see [Example A.1](#) on page 4895 and refer to the *SAS Procedures Guide* for details).

[Table A.1](#) summarizes the TYPE= data sets that can be used as input to SAS/STAT procedures and the TYPE= data sets that are created by SAS/STAT procedures. The essential parts of the statements each procedure uses to create its output data set or data sets are shown.

Formulas useful for illustrating differences between corrected and uncorrected matrices in some special SAS data sets are shown in the “[Definitional Formulas](#)” section on page 4902.

Special SAS Data Sets

TYPE=CORR Data Sets

A TYPE=CORR data set usually contains a correlation matrix and possibly other statistics including means, standard deviations, and the number of observations in the original SAS data set from which the correlation matrix was computed.

Using PROC CORR with an output data set option (OUTP=, OUTS=, OUTK=, OUTH=, or OUT=) produces a TYPE=CORR data set. (For a complete description of the CORR procedure, refer to the *SAS Procedures Guide*). The CALIS, CANCECORR, CANDISC, DISCRIM, PRINCOMP, and VARCLUS procedures can also create a TYPE=CORR data set with additional statistics.

A TYPE=CORR data set containing a correlation matrix can be used as input for the ACECLUS, CALIS, CANCECORR, CANDISC, DISCRIM, FACTOR, PRINCOMP, REG, SCORE, STEPPDISC, and VARCLUS procedures.

The variables in a TYPE=CORR data set are

- the BY variable or variables, if a BY statement is used with the procedure
- `_TYPE_`, a character variable of length eight with values identifying the type of statistic in each observation, such as 'MEAN', 'STD', 'N', and 'CORR'
- `_NAME_`, a character variable with values identifying the variable with which a given row of the correlation matrix is associated
- other variables that were analyzed by the CORR procedure or other procedures

The usual values of the `_TYPE_` variable are as follows.

<code>_TYPE_</code>	Contents
MEAN	mean of each variable analyzed
STD	standard deviation of each variable
N	number of observations used in the analysis. PROC CORR records the number of nonmissing values for each variable unless the NOMISS option is used. If the NOMISS option is specified, or if the CALIS, CANCECORR, CANDISC, PRINCOMP, or VARCLUS procedure is used to create the data set, observations with one or more missing values are omitted from the analysis, so this value is the same for each variable and provides the number of observations with no missing values. If a FREQ statement is used with the procedure that creates the data set, the number of observations is the sum of the relevant values of the variable in the FREQ statement. Procedures that read a TYPE=CORR data set use the smallest value in the observation with <code>_TYPE_='N'</code> as the number of observations in the analysis.
SUMWGT	sum of the observation weights if a WEIGHT statement is used with the procedure that creates the data set. The values are determined analogously to those of the <code>_TYPE_='N'</code> observation.
CORR	correlations with the variable named by the <code>_NAME_</code> variable

There may be additional observations in a TYPE=CORR data set depending on the particular procedure and options used.

If you create a TYPE=CORR data set yourself, the data set need not contain the observations with `_TYPE_='MEAN'`, 'STD', 'N', or 'SUMWGT', unless you intend to use one of the discriminant procedures. Procedures assume that all of the means are 0.0 and that the standard deviations are 1.0 if this information is not in the TYPE=CORR data set. If `_TYPE_='N'` does not appear, most procedures assume that the number of observations is 10,000; significance tests and other statistics that depend on the number of observations are, of course, meaningless. In the CALIS and CANCECORR procedures, you can use the EDF= option instead of including a `_TYPE_='N'` observation.

A correlation matrix is symmetric; that is, the correlation between X and Y is the same as the correlation between Y and X. The CALIS, CANCELL, CANDISC, CORR, DISCRIM, PRINCOMP, and VARCLUS procedures output the entire correlation matrix. If you create the data set yourself, you need to include only one of the two occurrences of the correlation between two variables; the other may be given a missing value.

If you create a TYPE=CORR data set yourself, the `_TYPE_` and `_NAME_` variables are not necessary except for use with the discriminant procedures and PROC SCORE. If there is no `_TYPE_` variable, then all observations are assumed to contain correlations. If there is no `_NAME_` variable, the first observation is assumed to correspond to the first variable in the analysis, the second observation to the second variable, and so on. However, if you omit the `_NAME_` variable, you will not be able to analyze arbitrary subsets of the variables or list the variables in a VAR or MODEL statement in a different order.

Example A.1: A TYPE=CORR Data Set Produced by PROC CORR

See [Output A.1.1](#) for an example of a TYPE=CORR data set produced by the following SAS statements. [Output A.1.2](#) displays partial output from the CONTENTS procedure, which indicates that the “Data Set Type” is ‘CORR’.

Output A.2.2. A TYPE=CORR Data Set Created by a DATA Step

Five Socioeconomic Variables							
Obs	type_	_name_	pop	school	employ	services	house
1	corr	POP	1.00000
2	corr	SCHOOL	0.00975	1.00000	.	.	.
3	corr	EMPLOY	0.97245	0.15428	1.00000	.	.
4	corr	SERVICES	0.43887	0.69141	0.51472	1.00000	.
5	corr	HOUSE	0.02241	0.86307	0.12193	0.77765	1

TYPE=UCORR Data Sets

A TYPE=UCORR data set is almost identical to a TYPE=CORR data set, except that the correlations are uncorrected for the mean. The corresponding value of the `_TYPE_` variable is 'UCORR' instead of 'CORR'. Uncorrected standard deviations are in observations with `_TYPE_='USTD'`.

A TYPE=UCORR data set can be used as input for every SAS/STAT procedure that uses a TYPE=CORR data set, except for the CANDISC, DISCRIM, and STEPDISC procedures. TYPE=UCORR data sets can be created by the CALIS, CANCECORR, PRINCOMP, and VARCLUS procedures.

TYPE=COV Data Sets

A TYPE=COV data set is similar to a TYPE=CORR data set except that it has `_TYPE_='COV'` observations containing covariances instead of or in addition to `_TYPE_='CORR'` observations containing correlations. The CALIS and PRINCOMP procedures create a TYPE=COV data set if the COV option is used. You can also create a TYPE=COV data set by using PROC CORR with the COV and NOCORR options and specifying the data set option TYPE=COV in parentheses following the name of the output data set. You can use only the OUTP= or OUT= options to create a TYPE=COV data set with PROC CORR.

Another way to create a TYPE=COV data set is to read a covariance matrix in a data set, in the same manner as shown in [Example A.2](#) on page 4896 for a TYPE=CORR data set.

TYPE=COV data sets are used by the same procedures that use TYPE=CORR data sets.

TYPE=UCOV Data Sets

A TYPE=UCOV data set is similar to a TYPE=COV data set, except that the covariances are uncorrected for the mean. Also, the corresponding value of the `_TYPE_` variable is 'UCOV' instead of 'COV'.

A TYPE=UCOV data set can be used as input for every SAS/STAT procedure that uses a TYPE=COV data set, except for the CANDISC, DISCRIM, and STEPDISC procedures. TYPE=UCOV data sets can be created by the CALIS and PRINCOMP procedures.

TYPE=SSCP Data Sets

A TYPE=SSCP data set contains an uncorrected sum of squares and crossproducts (SSCP) matrix. TYPE=SSCP data sets are produced by PROC REG when the OUTSSCP= option is specified in the PROC REG statement. You can also create a TYPE=SSCP data set by using PROC CORR with the SSCP option and specifying the data set option TYPE=SSCP in parentheses following the name of the OUTP= or OUT= data set. You can also create TYPE=SSCP data sets in a DATA step; in this case, TYPE=SSCP must be specified as a data set option.

The variables in a TYPE=SSCP data set include those found in a TYPE=CORR data set. In addition, there is a variable called `Intercept` that contains crossproducts for the intercept (sums of the variables). The SSCP matrix is stored in observations with `_TYPE_='SSCP'`, including a row with `_NAME_='Intercept'`. PROC REG also outputs an observation with `_TYPE_='N'`. PROC CORR includes observations with `_TYPE_='MEAN'` and `_TYPE_='STD'` as well.

TYPE=SSCP data sets are used by the same procedures that use TYPE=CORR data sets.

Example A.3: A TYPE=SSCP Data Set Produced by PROC REG

Output A.3.1 shows a TYPE=SSCP data set produced by PROC REG from the SocEcon data set created in Example A.1 on page 4895.

```
proc reg data=SocEcon outsscp=regsscp;
    model house=pop school employ services / noprint;
run;

proc print data=regsscp;
run;
```

Output A.3.1. A TYPE=SSCP Data Set Produced by PROC REG

Obs	_TYPE_	_NAME_	Intercept	pop	school	employ	services	house
1	SSCP	Intercept	12.0	74900	137.30	28000	1450	204000
2	SSCP	pop	74900.0	597670000	857640.00	220440000	10959000	1278700000
3	SSCP	school	137.3	857640	1606.05	324130	18152	2442100
4	SSCP	employ	28000.0	220440000	324130.00	82280000	4191000	486600000

7	N		12.0	12	12.00	12	12	12

TYPE=CSSCP Data Sets

A TYPE=CSSCP data set contains a corrected sum of squares and crossproducts (CSSCP) matrix. TYPE=CSSCP data sets are created by using the CORR procedure with the CSSCP option and specifying the data set option TYPE=CSSCP in parentheses following the name of the OUTP= or OUT= data set. You can also create TYPE=CSSCP data sets in a DATA step; in this case, TYPE=CSSCP must be specified as a data set option.

The variables in a TYPE=CSSCP data set are the same as those found in a TYPE=SSCP data set, except that there is not a variable called Intercept or a row with _NAME_='Intercept'.

TYPE=CSSCP data sets are read by only the CANDISC, DISCRIM, and STEPDISC procedures.

TYPE=EST Data Sets

A TYPE=EST data set contains parameter estimates. The CALIS, CATMOD, LIFEREG, LOGISTIC, NLIN, ORTHOREG, PHREG, PROBIT, and REG procedures create TYPE=EST data sets when the OUTEST= option is specified. A TYPE=EST data set produced by PROC LIFEREG, PROC ORTHOREG, or PROC REG can be used with PROC SCORE to compute residuals or predicted values.

The variables in a TYPE=EST data set include

- the BY variables, if a BY statement is used
- _TYPE_, a character variable of length eight, that indicates the type of estimate. The values depend on which procedure created the data set. Usually a value of 'PARM' or 'PARMS' indicates estimated regression coefficients, and a value of 'COV' or 'COVB' indicates estimated covariances of the parameter estimates. Some procedures, such as PROC NLIN, have other values of _TYPE_ for special purposes.
- _NAME_, a character variable that contains the values of the names of the rows of the covariance matrix when the procedure outputs the covariance matrix of the parameter estimates.
- variables that contain the parameter estimates, usually the same variables that appear in the VAR statement or in any MODEL statement. See Chapter

19, “The CALIS Procedure,” Chapter 22, “The CATMOD Procedure,” and Chapter 50, “The NLIN Procedure,” for details on the variable names used in output data sets created by those procedures.

Other variables can be included depending on the particular procedure and options used.

Example A.4: A TYPE=EST Data Set Produced by PROC REG

Output A.4.1 shows the TYPE=EST data set produced by the following statements:

```
proc reg data=SocEcon outest=regest covout;
  full:  model house=pop school employ services / noprint;
  empser: model house=employ services / noprint;
run;
proc print data=regest;
run;
```

Output A.4.1. A TYPE=EST Data Set Produced by PROC REG

Obs	MODEL	TYPE	NAME	DEPVAR	RMSE	Intercept

10	.	.	-6.41	134.49	.

TYPE=ACE Data Sets

A TYPE=ACE data set is created by the ACECLUS procedure, and it contains the approximate within-cluster covariance estimate, as well as eigenvalues and eigenvectors from a canonical analysis, among other statistics. It can be used as input to the ACECLUS procedure to initialize another execution of PROC ACECLUS. It can also be used to compute canonical variable scores with the SCORE procedure and as input to the FACTOR procedure, specifying METHOD=SCORE, to rotate the canonical variables. See Chapter 16, “The ACECLUS Procedure,” for details.

TYPE=DISTANCE Data Sets

You can create a TYPE=DISTANCE data set containing distance or dissimilarity measures using the DISTANCE procedure. The proximity measures are stored as a lower triangular matrix or a square matrix in the OUT= data set (depending on the SHAPE= option). See Chapter 26, “The DISTANCE Procedure,” for details. You can also create a TYPE=DISTANCE data set in a DATA step by reading or computing a lower triangular or symmetric matrix of dissimilarity values, such as a chart of mileage between cities. The number of observations must be equal to the number of variables used in the analysis. This type of data set is used as input by the CLUSTER and MODECLUS procedures. PROC CLUSTER ignores the upper triangular portion of a TYPE=DISTANCE data set and assumes that all main diagonal values are zero, even if they are missing. PROC MODECLUS uses the entire distance matrix and does not require the matrix to be symmetric. See Chapter 23, “The CLUSTER Procedure,” and Chapter 47, “The MODECLUS Procedure,” for examples and details.

TYPE=FACTOR Data Sets

A TYPE=FACTOR data set is created by PROC FACTOR when the OUTSTAT= option is specified. The CALIS, CANCECORR, FACTOR, PRINCOMP, SCORE, and VARCLUS procedures can use TYPE=FACTOR data sets as input. The variables are the same as in a TYPE=CORR data set. The statistics include means, standard deviations, sample size, correlations, eigenvalues, eigenvectors, factor patterns, residual correlations, scoring coefficients, and others depending on the options specified. See Chapter 27, “The FACTOR Procedure,” for details.

When the NOINT option is used with the OUTSTAT= option in PROC FACTOR, the value of the `_TYPE_` variable is set to 'USCORE' instead of 'SCORE' to indicate that the scoring coefficients have not been corrected for the mean. If this data set is used with the SCORE procedure, the value of the `_TYPE_` variable tells PROC SCORE whether or not to subtract the mean from the scoring coefficients.

TYPE=RAM Data Sets

The CALIS procedure creates and accepts as input a TYPE=RAM data set. This data set contains the model specification and the computed parameter estimates. A TYPE=RAM data set is intended to be reused as an input data set to specify good initial values in subsequent analyses by PROC CALIS. See Chapter 19, “The CALIS Procedure,” for details.

TYPE=WEIGHT Data Sets

The CALIS procedure creates and accepts as input a TYPE=WEIGHT data set. This data set contains the weight matrix used in generalized, weighted, or diagonally weighted least-squares estimation. See Chapter 19, “The CALIS Procedure,” for details.

TYPE=LINEAR Data Sets

A TYPE=LINEAR data set contains the coefficients of a linear function of the variables in observations with `_TYPE_='LINEAR'`.

The DISCRIM procedure stores linear discriminant function coefficients in a TYPE=LINEAR data set when you specify METHOD=NORMAL (the default method), POOL=YES, and an OUTSTAT= data set; the data set can be used in a subsequent invocation of PROC DISCRIM to classify additional observations. Many other statistics can be included depending on the options used. See Chapter 25, “The DISCRIM Procedure,” for details.

TYPE=QUAD Data Sets

A TYPE=QUAD data set contains the coefficients of a quadratic function of the variables in observations with `_TYPE_='QUAD'`.

The DISCRIM procedure stores quadratic discriminant function coefficients in a TYPE=QUAD data set when you specify METHOD=NORMAL (the default method), POOL=NO, and an OUTSTAT= data set; the data set can be used in a subsequent invocation of PROC DISCRIM to classify additional observations. Many other statistics can be included depending on the options used. See Chapter 25, “The DISCRIM Procedure,” for details.

TYPE=MIXED Data Sets

A TYPE=MIXED data set contains coefficients of either a linear or a quadratic function, or both if there are BY groups.

The DISCRIM procedure produces a TYPE=MIXED data set when you specify METHOD=NORMAL (the default method), POOL=TEST, and an OUTSTAT= data set. See Chapter 25, “The DISCRIM Procedure,” for details.

Definitional Formulas

This section contrasts corrected and uncorrected SSCP, COV, and CORR matrices by showing how these matrices can be computed.

In the following formulas, assume that the data consist of two variables, X and Y, with n observations.

$$\text{SSCP} = \begin{bmatrix} n & \sum X & \sum Y \\ \sum X & \sum X^2 & \sum XY \\ \sum Y & \sum XY & \sum Y^2 \end{bmatrix}$$

$$\text{CSSCP} = \begin{bmatrix} \sum (X - \bar{X})^2 & \sum (X - \bar{X})(Y - \bar{Y}) \\ \sum (X - \bar{X})(Y - \bar{Y}) & \sum (Y - \bar{Y})^2 \end{bmatrix}$$

$$\text{COV} = \frac{\text{CSSCP}}{n-1} = \frac{1}{n-1} \left[\begin{array}{cc} \sum(X - \bar{X})^2 & \sum(X - \bar{X})(Y - \bar{Y}) \\ \sum(X - \bar{X})(Y - \bar{Y}) & \sum(Y - \bar{Y})^2 \end{array} \right]$$

$$\text{UCOV} = \frac{1}{n} \left[\begin{array}{cc} \sum X^2 & \sum XY \\ \sum XY & \sum Y^2 \end{array} \right]$$

$$\text{CORR} = \left[\begin{array}{cc} 1 & \frac{\sum(X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum(X - \bar{X})^2 \sum(Y - \bar{Y})^2}} \\ \frac{\sum(X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum(X - \bar{X})^2 \sum(Y - \bar{Y})^2}} & 1 \end{array} \right]$$

$$\text{UCORR} = \left[\begin{array}{cc} 1 & \frac{\sum XY}{\sqrt{\sum X^2 \sum Y^2}} \\ \frac{\sum XY}{\sqrt{\sum X^2 \sum Y^2}} & 1 \end{array} \right]$$

OVERVIEW	4907
%PLOTIT MACRO OPTIONS USED IN THIS BOOK	4907

Appendix B

Using the %PLOTIT Macro

Overview

You can use the PLOT procedure to create low-resolution printer plots of labeled points. Alternatively, you can use the %PLOTIT macro to create high-resolution graphical scatter plots of labeled points.

The %PLOTIT macro is designed to make it easy to display raw data, regression results, and results from the CORRESP, MDS, PRINCOMP, PRINQUAL, and TRANSREG procedures. You can use this macro to position labels, draw curves, vectors, and circles, and shade to show density or a third variable. You can also use the %PLOTIT macro to control the colors, sizes, fonts, and general appearance of the plots and to create contour plots for discriminant analysis.

The %PLOTIT macro is a part of the SAS autocall library. If your site has installed the autocall libraries supplied by SAS Institute and uses the standard configuration of SAS software supplied by the Institute, you need only to ensure that the SAS system option MAUTOSOURCE is in effect to begin using the autocall macros.

For more information about autocall libraries, refer to *SAS Macro Language: Reference, First Edition*, 1997. The %PLOTIT macro can also be found at SAS Institute's Web site [<http://www.sas.com>]. Refer to "Experimental Design and Choice Modeling Macros" and "Graphical Scatter Plots of Labeled Points" at [http://support.sas.com/techsup/tnote/tnote_stat.html#market].

%PLOTIT Macro Options Used in This Book

Most of the examples in this book that invoke the %PLOTIT macro are created with a specific set of options. The graphics are generated by using a special macro variable called plotitop.

The code you see in the examples creates the color graphics that appear in the online (CD) version of the manual. A slightly different set of options and statements are used to create the black-and-white graphics that appear in the printed version of the book.

To create the online (color) version of the graphic output, the plotitop variable is defined as follows.

```
%let plotitop = gopts = gsfmode = replace
                gaccess = gsasfile device = gif
                hsize = 5.63 vsize = 3.5
                cback = white,
                cframe = ligr,
                color = black,
                colors = red blue white,
                options = noclip expand, post=myplot.gif;
```

To create the black-and-white version of the graphic output, which appears in the printed version of the manual, the plotitop variable is defined as follows:

```
%let plotitop = gopts = gsfmode = replace
                gaccess = gsasfile device = pslepsf
                hsize = 5.63 vsize = 3.5
                cback = white,
                color = black,
                colors = black,
                options = noclip border expand, post=myplot.ps;
```

For information on graphics options used in other examples, see [Chapter 1](#), “Introduction.”
