# **Contents**

About This Book.		ix
CHAPTER 1	Introduction	
	What Is the Full-Text Search Specialty Data Store?	
	Capabilities of the Full-Text Search Engine	1
	High Availablility	3
CHAPTER 2	Understanding the Full-Text Search Engine	5
	Components of the Full-Text Search Engine	
	The Source Table	
	The Verity Collections	6
	Filters	6
	The text_db Database	6
	The Index Table	7
	The text_events Table	
	Relationships Between the Components	8
	How a Full-Text Search Works	9
CHAPTER 3	Configuring Adaptive Server for Full-Text Searches	13
	Configuring Adaptive Server for a Full-Text Search Engine	13
	Enabling Configuration Parameters	14
	Running the installtextserver Script	14
	Running the installmessages Script	16
	Running the installevent Script	
	Name the local server	
	Creating and Maintaining the Text Indexes	
	Setting Up Source Tables for Indexing	
	Creating the Text Index and Index Table	
	Bringing the Database Online for Full-Text Searches	
	Propagating Changes to the Text Index	
	Replicating Text Indexes	
	Example: Enabling a New Database for Text Searches	24

CHAPTER 4	Setting Up Verity Functions	27
	Enabling Query-By-Example, Summarization, and Clustering	
	Editing the Master style.prm File	28
	Editing Individual style.prm Files	
	Setting Up a Column to Use As a Sort Specification	30
	Using Filters on Text That Contains Tags	
	Creating a Custom Thesaurus (Enhanced Version Only)	
	Examining the Default Thesaurus (Optional)	
	Creating the Control File	
	Creating the Thesaurus	
	Replacing the Default Thesaurus with the Custom Thesaurus	
	Creating Topics (Enhanced Version Only)	
	Creating an Outline File	
	Creating a Topic Set Directory	
	Creating a Knowledge Base Map	
	Defining the Location of the Knowledge Base Map	
	Executing Queries Against Defined Topics	
	Troubleshooting Topics	
	Troubleshooting Topics	. 42
CHAPTER 5	Writing Full-Text Search Queries	43
Oliva 1210	Components of a Full-Text Search Query	
	Default Behaviour	
	Pseudo Columns in the Index Table	
	Using the score Column to Relevance-Rank Search Results	
	Using the sort_by Column to Specify a Sort Order	
	Using the summary Column to Summarize Documents	
	Using Pseudo Columns to Request Clustered Result Sets	
	Full-Text Search Operators	
	Considerations When Using Verity Operators	
	Using the Verity Operators	
	Operator Modifiers	
	Operator iviouniers	. 60
CHAPTER 6	System Administration	63
Olina Tela	Starting the Full-Text Search Engine on UNIX	
	Creating the Runserver File	
	Starting the Full-Text Search Engine on Windows NT	
	Starting the Full-Text Search Engine As a Service	
	Shutting Down the Full-Text Search Engine	. 66
	Modifying the Configuration Parameters	
	Modifying Values in the Enhanced Version	
	Available Configuration Parameters	
	Setting the Default Language	
	Setting the Default Character Set	
	.Setting the Delauit Character Set	. / [

	Setting the Default Sort Order Setting Trace Flags Setting Open Server Trace Flags Setting Case Sensitivity  Backup and Recovery for the Enhanced Full-Text Search Engine Customizable Backup and Restore Backing Up Verity Collections Restoring Collections and Text Indexes from Backup	72 74 74 75 76 76
CHAPTER 7	Performance and Tuning	79
· · · · · · · · · · · · · · · · · · ·	Updating Existing Indexes	
	Increasing Query Performance	
	Limiting the Number of Rows	
	Ensuring the Correct Join Order for Queries	
	Reconfiguring Adaptive Server	
	cis cursor rows	
	cis packet size	
	Reconfiguring the Full-Text Search Engine	
	batch_size	
	min_sessions and max_sessions	
	Using sp_text_notify	
	Configuring Multiple Full-Text Search Engines	
	Creating Multiple Full-Text Search Engines at Start-Up	
	Adding Full-Text Search Engines	
	Configuring Additional Full-Text Search Engines	
	Multiple Users	
CHAPTER 8	Verity Topics	87
OHAI TERO	What are Topics?	
	Topic Organization	
	Weight Assignments	
	Using a Topic Outline File	
	Making Topics Available	
	Setup Process	
	Knowledge Bases of Topics	
	Combining Topics into a Knowledge Base	
	Structure of Topics	
	Top-Level Topics	
	Subtopics	
	Evidence Topics	
	Topic and Subtopic Relationships	
	Maximum Number of Topics	
	Topic Naming Issues	

Verity Query Language	95

## **About This Book**

This book explains how to use the Full-Text Search Specialty Data Store product with Sybase® Adaptive Server<sup>TM</sup> Enterprise.

This book describes the features and functionality of the enhanced version which is a separately priced product.

## **Audience**

This book is for System Administrators who are configuring Adaptive Server for a Full-Text Search Specialty Data Store and for users who are performing full-text searches on Adaptive Server data.

## How to Use This Book

This book includes the following chapters:

- Chapter 1, "Introduction," provides an overview of Full-Text Search Specialty Data Store.
- Chapter 2, "Understanding the Full-Text Search Engine," describes the components of the Full-Text Search Specialty Data Store and how it works.
- Chapter 3, "Configuring Adaptive Server for Full-Text Searches," describes how to configure Adaptive Server so that Full-Text Search Specialty Data Store can perform full-text searches on the databases.
- Chapter 4, "Setting Up Verity Functions," describes the setup you need to do before issuing full-text search queries.
- Chapter 5, "Writing Full-Text Search Queries," describes the components you use to write full-text search queries.

- Chapter 6, "System Administration," provides information about system administration issues.
- Chapter 7, "Performance and Tuning," provides information about performance and tuning issues.
- Chapter 8, "Verity Topics," provides information about configuring the Verity engine.
- Appendix A, "System Procedures," describes Full-Text Search Specialty Data Store system procedures.
- Appendix B, "Sample Files," contains the text of the textsvr.cfg file, describes the sample files included with Full-Text Search Specialty Data Store, and discusses issues regarding the sample\_text\_main.sql script.
- Appendix C, "Unicode Support," describes how to configure Full-Text Search Specialty Data Store to use Unicode.

# **Adaptive Server Enterprise Documents**

The following documents comprise the Sybase Adaptive Server Enterprise documentation:

- The release bulletin for your platform contains last-minute information that was too late to be included in the books.
  - A more recent version of the release bulletin may be available on the World Wide Web. To check for critical product or document information that was added after the release of the product CD, use the Sybase Technical Library.
- The *Installation Guide* for your platform describes installation, upgrade, and configuration procedures for all Adaptive Server and related Sybase products.
- Configuring Adaptive Server Enterprise for your platform provides instructions for performing specific configuration tasks for Adaptive Server.
- What's New in Adaptive Server Enterprise? describes the new features in Adaptive Server version 12.5, the system changes added to support those features, and the changes that may affect your existing applications.

- Transact-SQL User's Guide documents Transact-SQL, Sybase's
  enhanced version of the relational database language. This manual
  serves as a textbook for beginning users of the database management
  system. This manual also contains descriptions of the pubs2 and
  pubs3 sample databases.
- System Administration Guide provides in-depth information about administering servers and databases. This manual includes instructions and guidelines for managing physical resources, security, user and system databases, and specifying character conversion, international language, and sort order settings.
- Reference Manual contains detailed information about all Transact-SQL commands, functions, procedures, and datatypes. This manual also contains a list of the Transact-SQL reserved words and definitions of system tables.
- Performance and Tuning Guide explains how to tune Adaptive
  Server for maximum performance. This manual includes information
  about database design issues that affect performance, query
  optimization, how to tune Adaptive Server for very large databases,
  disk and cache issues, and the effects of locking and cursors on
  performance.
- The *Utility Guide* documents the Adaptive Server utility programs, such as isql and bcp, which are executed at the operating system level.
- The *Quick Reference Guide* provides a comprehensive listing of the names and syntax for commands, functions, system procedures, extended system procedures, datatypes, and utilities in a pocket-sized book. Available only in print version.
- The *System Tables Diagram* illustrates system tables and their entity relationships in a poster format. Available only in print version.
- Error Messages and Troubleshooting Guide explains how to resolve frequently occurring error messages and describes solutions to system problems frequently encountered by users.
- Component Integration Services User's Guide explains how to use the Adaptive Server Component Integration Services feature to connect remote Sybase and non-Sybase databases.
- Java in Adaptive Server Enterprise describes how to install and use Java classes as datatypes, functions, and stored procedures in the Adaptive Server database.

- Using Sybase Failover in a High Availability System provides instructions for using Sybase's Failover to configure an Adaptive Server as a companion server in a high availability system.
- Using Adaptive Server Distributed Transaction Management Features explains how to configure, use, and troubleshoot Adaptive Server DTM features in distributed transaction processing environments.
- *EJB Server User's Guide* explains how to use EJB Server to deploy and execute Enterprise JavaBeans in Adaptive Server.
- XA Interface Integration Guide for CICS, Encina, and TUXEDO –
  provides instructions for using Sybase's DTM XA interface with
  X/Open XA transaction managers.
- Glossary defines technical terms used in the Adaptive Server documentation.
- Sybase jConnect for JDBC Programmer's Reference describes the jConnect for JDBC product and explains how to use it to access data stored in relational database management systems.
- Full-Text Search Specialty Data Store User's Guide describes how to use the Full-Text Search feature with Verity to search Adaptive Server Enterprise data.
- Historical Server User's Guide –describes how to use Historical Server to obtain performance information for SQL Server and Adaptive Server.
- Monitor Server User's Guide describes how to use Monitor Server to obtain performance statistics from SQL Server and Adaptive Server.
- Monitor Client Library Programmer's Guide describes how to write Monitor Client Library applications that access Adaptive Server performance data.

#### Other Sources of Information

Use the Sybase Technical Library CD and the Technical Library Web site to learn more about your product:

- Technical Library CD contains product manuals and technical documents and is included with your software. The DynaText browser (included on the Technical Library CD) allows you to access technical information about your product in an easy-to-use format.
  - Refer to the *Technical Library Installation Guide* in your documentation package for instructions on installing and starting Technical Library.
- Technical Library Web site is an HTML version of the Technical Library CD that you can access using a standard Web browser.

To use the Technical Library Web site, go to www.sybase.com and choose Documentation, choose Technical Library, then choose Product Manuals.

## **Conventions**

## **Directory Paths**

For readability, directory paths in this manual are in UNIX format. On Windows NT, substitute \$SYBASE with %SYBASE% and replace slashes (/) with backslashes (\). For example, replace this user input:

```
$SYBASE/$SYBASE_FTS/scripts
```

with:

%SYBASE%\%SYBASE\_FTS%\scripts

## Formatting SQL Statements

SQL is a free-form language: there are no rules about the number of words you can put on a line or where you must break a line. However, for readability, all examples and syntax statements in this manual are formatted so that each clause of a statement begins on a new line. Clauses that have more than one part extend to additional lines, which are indented.

## **SQL Syntax Conventions**

The conventions for syntax statements in this manual are as follows:

Table 1: Syntax statement conventions

Key	Definition
command	Command names, command option names, utility names, utility flags, and other keywords are in
	bold Courier
	in syntax statements and in bold Helvetica in paragraph text.
variable	Variables, or words that stand for values that you fill in, are in <i>italics</i> .
{ }	Curly braces indicate that you choose at least one of the enclosed options. Do not include braces in your option.
[ ]	Brackets mean choosing one or more of the enclosed options is optional. Do not include brackets in your option.
( )	Parentheses are to be typed as part of the command.
	The vertical bar means you may select only one of the options shown.
,	The comma means you may choose as many of the options shown as you like, separating your choices with commas to be typed as part of the command.

• Syntax statements (displaying the syntax and all options for a command) are printed like this:

sp\_dropdevice [device\_name]

or, for a command with more options:

select column\_name from table\_name where search\_conditions

In syntax statements, keywords (commands) are in normal font and identifiers are in lowercase: normal font for keywords, italics for user-supplied words.

 Examples showing the use of Transact-SQL commands are printed like this:

select \* from publishers

• Examples of output from the computer are printed like this:

pub_id	pub_name	city	state
0736	New Age Books	Boston	MA

0877	Binnet & Hardley	Washington	DC
1389	Algodata Infosystems	Berkeley	CA

(3 rows affected)

#### Case

In this manual, most of the examples are in lowercase. However, you can disregard case when typing Transact-SQL keywords. For example, SELECT, Select, and select are the same.

Adaptive Server's sensitivity to the case of database objects, such as table names, depends on the sort order installed on Adaptive Server. You can change case sensitivity for single-byte character sets by reconfiguring the Adaptive Server sort order. See "Changing the Default Character Set, Sort Order, or Language" in Chapter 19 of the *System Administration Guide* for more information.

#### **Obligatory Options (You Must Choose At Least One)**

• Curly Braces and Vertical Bars: Choose one and only one option.

```
{die_on_your_feet | live_on_your_knees | live_on_your_feet}
```

• *Curly Braces and Commas*: Choose one or more options. If you choose more than one, separate your choices with commas.

```
{cash, check, credit}
```

#### Optional Options [You Don't Have to Choose Any]

• One Item in Square Brackets: You don't have to choose it.

```
[anchovies]
```

• *Square Brackets and Vertical Bars:* Choose none or only one.

```
[beans | rice | sweet_potatoes]
```

 Square Brackets and Commas: Choose none, one, or more than one option. If you choose more than one, separate your choices with commas.

```
[extra_cheese, avocados, sour_cream]
```

#### Ellipsis: Do It Again (and Again)...

An ellipsis (...) means that you can *repeat* the last unit as many times as you like. In this syntax statement, buy is a required keyword:

```
buy thing = price [cash | check | credit]
   [, thing = price [cash | check | credit]]...
```

You must buy at least one thing and give its price. You may choose a method of payment: one of the items enclosed in square brackets. You may also choose to buy additional things: as many of them as you like. For each thing you buy, give its name, its price, and (optionally) a method of payment.

# If You Need Help

Each Sybase installation that has purchased a support contract has one or more designated people who are authorized to contact Sybase Technical Support. If you cannot resolve a problem using the manuals or online help, please have the designated person contact Sybase Technical Support or the Sybase subsidiary in your area.

## CHAPTER 1 Introduction

# What Is the Full-Text Search Specialty Data Store?

Full-Text Search Specialty Data Store (referred to in this book as the Full-Text Search engine) is an Open Server<sup>TM</sup> application built on Verity® technology available in the Verity Developer's Kit. Adaptive Server connects to the Full-Text Search engine through Component Integration Services (CIS), allowing queries written in the Verity query language to perform full-text searches on Adaptive Server data.

This book describes the features and functionality of the enhanced Full-Text Search Specialty Data Store.

# Capabilities of the Full-Text Search Engine

The Full-Text Search Specialty Data Store product performs powerful, full-text searches on Adaptive Server data. In Adaptive Server, without the Full-Text Search engine, you can search text columns only for data that matches what you specify in a select statement. For example, if a table contains documents about dog breeds, and you perform a search on the words "Saint Bernard," the query produces only the rows that include "Saint Bernard" in the text column.

With the Full-Text Search engine, you can expand queries on text columns to do the following:

- Rank the results by order of how often a searched item appears in the selected document. For example, you can obtain a list of document titles that reference the words "Saint Bernard" five or more times.
- Select documents in which the words you search for appear within n number of words of each other. For example, you can search only for the documents that include the words "Saint Bernard" and "Swiss Alps" and that appear within 10 words of each other.

- Select documents that include all the search elements you specify within a single paragraph or sentence. For example, you can query the documents that include the words "Saint Bernard" in the same paragraph or sentence as the words "Swiss Alps."
- Select documents that contain one or more synonyms of the word you specify. For example, you can select documents that discuss "dogs," and it returns documents that contain the words "dogs," "canine," "pooch," "pup," and so on.
- Create your own custom thesaurus. For example, you can create a custom thesaurus that includes "working dogs," "St. Bernard," "large dogs," and "European Breeds" as synonyms for "Saint Bernard."
- Create topics that specify the search criteria for a query. For example, you can create a topic that returns documents that include the phrase "Saint Bernard" or "St. Bernard," followed by documents that include the phrase "working dogs," "large dogs," or "European Breeds."
- Return documents grouped in clusters to give you a sense of the major topics covered in the documents.
- Select a section of relevant text in a document and search for other, similar documents.
- Index many different document types, such as Microsoft Word, and FrameMaker.
- Sort documents using up to 16 sort orders.
- Integrated backup and restore capabilities
- Ability to change the value of a configuration parameter using a system procedure
- Ability to optimize indexes for text searches when your server is inactive, to enhance performance
- Additional system management reports for viewing setup information
- Ability to bring databases online automatically for text searches

## **High Availablility**

The Full-Text Search product now supports the High Availability feature of Adaptive Server Enterprise. If an Adaptive Server Enterprise fails, the Full-Text Search will accept connections from the companion server. Additionally, if the Adaptive Server has proxy database support enabled, then both the primary and companion servers can use the Full-Text Search at the same time.

# CHAPTER 2 Understanding the Full-Text Search Engine

This chapter describes how a Full-Text Search engine works.

Topics include:

Topic	Page
Components of the Full-Text Search Engine	5
How a Full-Text Search Works	9

# **Components of the Full-Text Search Engine**

The Full-Text Search engine uses the following components to provide full-text search capabilities:

- Source table
- Verity collections (text index)
- Filters for a variety of document types
- text\_db database
- Index table
- text\_events table

#### The Source Table

The **source table** is a user table maintained by Adaptive Server. It contains one or more columns using the text, image, char, varchar, datetime, or small datetime datatype, which holds the data to be searched. With the Enhanced Full-Text Search engine, the source table can also have int, smallint, and tinyint columns, which holds the data to be searched. The source table must have an IDENTITY column, which is used to join the source table with the id column of an index table during text searches.

The source table can be a local table, which holds the actual data, or it can be a proxy table that is mapped to remote data using CIS.

## The Verity Collections

The Full-Text Search engine uses the Verity collections, which are located in \$SYBASE/\$SYBASE\_FTS/collections. When you create the text indexes, as described in "Creating the Text Index and Index Table" on page 20, Verity creates a **collection**, which is a directory that implements a text index. This collection is queried by the Full-Text Search engine. For more information about Verity collections, see the Verity Web site at http://www.verity.com.

#### **Filters**

The text index uses a filter to strip out the tags in a document that is not ASCII text. The Enhanced Full-Text Search engine provides filters for a variety of document types (Microsoft Word, FrameMaker, WordPerfect, SGML, and HTML).

## The text\_db Database

During the installation of the Full-Text Search engine, a database named text\_db is added to Adaptive Server using the installation script installtextserver, as described in "Running the installtextserver Script" on page 14. The database does not contain any user data, but contains two support tables: vesaux and vesauxcol. These tables contain the metadata used by the Full-Text Search engine to maintain integrity between the Adaptive Server source tables and the Verity collections.

When updating the collections after an insert, update, or delete is made to an indexed column, the Full-Text Search engine queries the vesaux and vesauxcol tables. These tables determine which collections contain the modified columns so that all affected collections are updated. The Full-Text Search engine also uses these tables when it is brought online, to make sure that all necessary collections exist.

#### The vesaux Table

The columns in the vesaux table are described in Table 2-1.

Table 2-1: Columns in the vesaux table

Column Name	Description	
id	IDENTITY column	
object_name	Name of the source table on which the external index is being created	
option_string	Text index creation options	
collection_id	Name of the Verity collection	
key_column	Name of the IDENTITY column in the source table	
svrid	Server ID of the Full-Text Search engine maintaining the collection	

#### The vesauxcol Table

The columns in the vesauxcol table are described in Table 2-2.

Table 2-2: Columns in the vesauxcol table

Column Name	Description	
id	ID of the referenced row in the vesaux table	
col_name	Name of the column for which you are searching	
col_type	Column type (text, image, char, varchar, datetime, smalldatetime; with the Enhanced Full-Text Search engine, also int, smallint, and tinyint)	

#### The Index Table

The **index table** provides a means of locating and searching documents stored in the source table. The index table is maintained by the Full-Text Search engine and has an id column that maps to the IDENTITY column of the corresponding source table. The IDENTITY value from the row in the source table is stored with the data in the Verity collections, which allows the source and index tables to be joined. Although the index table is stored and maintained by the Full-Text Search engine, it functions as a proxy table to Adaptive Server through the Component Integration Services feature.

The index table contains special columns, called *pseudo columns*, that are used by the Full-Text Search engine to determine the parameters of the search and the location of the text data in the source table. Pseudo columns have no associated physical storage—the values of a pseudo column are valid only for the duration of the query and are removed immediately after the query finishes running.

For example, when you use the score pseudo column in a query, to rank each document according to how well the document matches the query, you may have to use a *score* of 15 to find references to the phrase "small Saint Bernards" in the text database. This phrase does not occur very often, and a low score value broadens the search to include documents that have a small number of occurrences of the search criteria. However, if you are searching for a phrase that is common, like "large Saint Bernards," you could use a *score* of 90, which would limit the search to those documents that have many occurrences of the search criteria.

You use the score column and the other pseudo columns, id, index\_any, sort\_by, summary, and max\_docs, to specify the parameters to include in your search. For a description of the pseudo columns, see "Pseudo Columns in the Index Table" on page 44.

#### The text\_events Table

Each database containing tables for which there is a text index must contain an **events table**, which logs inserts, updates, and deletes to indexed columns. The name of this table is text\_events. It is used to propagate updated data to the Verity collections.

The columns in the text\_events table are described in Table 2-3.

Column Name	Description
event_id	IDENTITY column.
id	ID of the row that was updated, inserted, or deleted.
tableid	Name of the table that contains the row that was updated, inserted, or deleted.
columnid	Name of the column that the text index was created on.
event_date	Date and time of the update, insert, or delete.
event_type	Type of update (update, insert, or delete).
event_status	Indicates whether the update, insert, or delete has been propagated to the collections. Event Unread = 0. Event Read = 1. Event Succeeded = 2. Event Failed = 3.
srvid	Server ID of the Full-Text Search engine maintaining the collection.

Table 2-3: Columns in the text\_events table

## **Relationships Between the Components**

The relationships between the Full-Text Search engine components are shown in Figure 2-1.

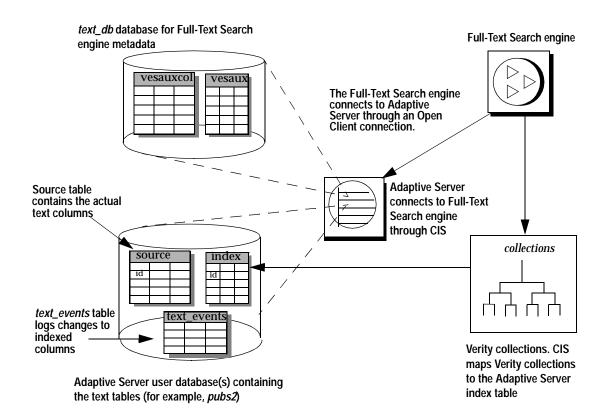

Figure 2-1: Components of the Full-Text Search engine

## How a Full-Text Search Works

To perform a full-text search, you enter a select statement that joins the IDENTITY column from the source table with the id column of the index table, using pseudo columns as needed to define the search. For example, the following query searches for documents in the blurbs table of the pubs2 database in which the word "Greek" appears near the word "Gustibus" (the i\_blurbs table is the index table):

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
```

```
where t1.id=t2.id and t1.score > 20
and t1.max_docs = 10
and t1.index_any = "<near>(Greek, Gustibus)"
```

Adaptive Server and the Full-Text Search engine split the query processing, as follows:

1 The Full-Text Search engine processes the query:

```
select t1.score, t1.id
from i_blurbs t1
where t1.score > 20
and t1.max_docs = 10
and t1.index_any = "<near>(Greek, Gustibus)"
```

The select statement includes the Verity operator near and the pseudo columns score, max\_docs, and index\_any. The operator and pseudo columns provide the parameters for the search on the Verity collections—they narrow the result set from the entire copy column to the 10 documents in which the words "Greek" and "Gustibus" appear closest to each other.

Adaptive Server processes the following select statement on the result set that is returned by the Full-Text Search engine in step 1:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id
```

This joins the blurbs and i\_blurbs tables (the source table and the index table, respectively) on the IDENTITY column of the blurbs table and the id column of the i\_blurbs table.

Figure 2-2 describes how Adaptive Server and the Full-Text Search engine process the query.

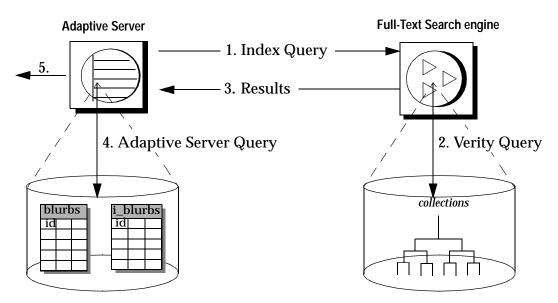

Figure 2-2: Processing a full-text search query

- 1. Adaptive Server sends the index guery to the Full-Text Search engine.
- 2. The Full-Text Search engine processes the Verity operators in the query and produces a result set from the collections.
- 3. The Full-Text Search engine returns the result set to Adaptive Server. 4. Adaptive Server processes the select statement on the local table.
- 5. Adaptive Server displays the results of the query.

# CHAPTER 3 Configuring Adaptive Server for Full-Text Searches

This chapter describes how to configure Adaptive Server to perform full-text searches.

Topics include:

Topic	Page
Configuring Adaptive Server for a Full-Text Search Engine	13
Creating and Maintaining the Text Indexes	18

# **Configuring Adaptive Server for a Full-Text Search Engine**

The Full-Text Search engine is a remote server that Adaptive Server connects to through Component Integration Services (CIS). Before you can use the Full-Text Search engine, you must configure Adaptive Server for the Full-Text Search engine as follows:

- Enable the enable cis, cis rpc handling and full-text search configuration parameters if you have not done so. You will need a license to enable full-text search.
- Run the installtextserver script to define one or more Full-Text Search engines.
- Run the installmessages script to install messages for the Full-Text Search engine's system procedures.
- Run the installevent script to create the text\_events table in each user database which will contain text indexes.
- Name the local server and reboot.

## **Enabling Configuration Parameters**

To connect to the Full-Text Search engine, Adaptive Server must be running with the enable cis and cis rpc handling configuration parameters enabled. If those parameters are not enabled, log in to Adaptive Server using isql and use sp\_configure to enable them. For example:

```
exec sp_configure "enable cis", 1
exec sp_configure "cis rpc handling", 1
exec sp_configure "enable full-text search", 1
```

Adaptive Server displays a series of messages stating that you have altered a configuration parameter and that Adaptive Server must be rebooted for the new configuration parameters to take effect.

## Running the installtextserver Script

The installtextserver script:

- Defines the Full-Text Search engine as a remote server of server class sds to Adaptive Server.
- Creates a database for storing text index metadata. For more information about this database, see "The text\_db Database" on page 6.
- Installs the system procedures required by the Full-Text Search engine.

Run the installtextserver script only once (see "Running the installtextserver Script" on page 16). To add Full-Text Search engines at a later time, use sp\_addserver. See "Configuring Multiple Full-Text Search Engines" on page 84 for more information about sp\_addserver.

All Full-Text Search engines use the same database for storing text index metadata. This database is referred to in this book as the text\_db database, the default name.

For a list and description of the system procedures added with the installtextserver script, see Appendix A, "System Procedures."

#### Editing the installtextserver Script

The installtextserver script is located in the \$SYBASE/\$SYBASE\_FTS/scripts directory. Use a text editor (such as vi or emacs) to open the script, and make your edits. The edits you can make are as follows:

• Changing the name of the text\_db database. If you use a different name, replace all occurrences of text\_db with the appropriate name.

**Note** If you change the name of the *text\_db* database, you must change the name in the defaultDb configuration parameter (see "Modifying the Configuration Parameters" on page 67).

- Changing the name of the Full-Text Search engine. By default, the installtextserver script defines a Full-Text Search engine named "textsvr." If your Full-Text Search engine is named differently, edit this script so that it defines the correct server name.
- Adding multiple Full-Text Search engines (for information on how
  this can enhance performance, see "Configuring Multiple Full-Text
  Search Engines" on page 84). If you are initially defining more than
  one Full-Text Search engine, edit the installtextserver script so that it
  includes all the Full-Text Search engine definitions. installtextserver
  includes the following section for naming the Full-Text Search engine
  you are configuring ("textsvr" by default):

```
/*
** Add the text server
*/
exec sp_addserver textsvr,sds,textsvr
go
```

Add an entry for each Full-Text Search engine you are configuring. For example, if you are configuring three Full-Text Search engines named KRAZYKAT, OFFICAPUP, and MOUSE, replace the default "textsvr" line with the following lines:

```
exec sp_addserver KRAZYKAT, sds, KRAZYKAT exec sp_addserver OFFICAPUP, sds, OFFICAPUP exec sp_addserver MOUSE, sds, MOUSE go
```

If you use OmniConnect to communicate with the Full-Text Search
engine, change the server name specification in the sp\_addobjectdef
calls for the vesaux and vesauxcol tables to a valid remote server. For
example, if your remote server is named REMOTE, change the lines:

```
exec sp_addobjectdef
  "vesaux", "SYBASE.master.dbo.vesaux", "table"
  exec sp_addobjectdef
  "vesauxcol", "SYBASE.master.dbo.vesauxcol",
    "table"

to:
    exec sp_addobjectdef
    "vesaux", "REMOTE.master.dbo.vesaux", "table"
    exec sp_addobjectdef
    "vesauxcol", "REMOTE.master.dbo.vesauxcol",
    "table"
```

#### Running the installtextserver Script

Use isql to run the installtextserver script. For example, to run the installtextserver script in an Adaptive Server named MYSVR, enter:

```
isql -Usa -P -SMYSVR -i
$SYBASE/$SYBASE_FTS/scripts/installtextserver
```

## Running the installmessages Script

The Full-Text Search engine has its own set of system procedure messages that you must install in Adaptive Server. Use the installmessages script to install the messages. You run the installmessages script only once, even if you have multiple Full-Text Search engines.

For example, to run the installmessages script in a server named MYSVR, enter:

```
isql -Usa -P -SMYSVR -i
$SYBASE/$SYBASE_FTS/scripts/installmessages
```

## Running the installevent Script

Each database containing tables referenced by a text index must contain a text\_events table, which logs inserts, updates, and deletes to indexed columns. It is used to propagate updated data to the Verity collections.

Run the installevent script, as described below, to create the text\_events table and associated system procedures in a database. Use the installevent script as follows:

- If all databases require text indexes, run the installevent script to create
  a text\_events table in the model database. Each newly created database
  will then have a text\_events table. To add a text\_events table to
  existing databases, edit the script as described below to create the
  text\_events table in the existing user database.
- If not all databases have text indexes, use the installevent script as a sample. For each existing database and each new database that includes tables that require text indexing, run the installevent script. You must edit the script as described below, to create the text\_events table in the correct user database.

**Note** If a text\_events table does not exist in a database that includes source tables that require text indexing, changes to the source table will not be propagated to the Verity collections.

## Editing the installevent Script

The installevent script is located in the \$SYBASE\_\$SYBASE\_FTS/scripts directory. Use a text editor (such as vi or emacs) to open the script, and make the edits. The edits you can make are:

Changing the user database name. The installevent script creates an
events table (named text\_events) and associated system procedures in
the model database. The model database is the default database. To
install the text\_events table in an existing user database, edit the script
and replace all references to model with the user database name.

 Changing the text\_db database name. If your database for storing text index metadata is named something other than text\_db, replace all references to text\_db with the appropriate name.

**Note** The name of the *text\_db* database must be the same as the name in the defaultDb configuration parameter (see "Modifying the Configuration Parameters" on page 67).

#### Running the installevent Script

Using isql, run the installevent script to install the text\_events table and related system procedures in Adaptive Server. For example, to run the installevent script in a server named MYSVR, enter:

```
isql -Usa -P -SMYSVR -i
$SYBASE/$SYBASE_FTS/scripts/installevent
```

**Note** The text\_db database must exist before you run the installevent script. If it does not exist, run the installtextserver script first.

#### Name the local server

When using the full-Text Search engine with ASE 12.0, you must name the local ASE server using the stored procedure, sp\_addserver <servername>, local. After issuing sp\_addserver, the local server must be rebooted. Do not install any system stored procedures in the model database. They should be installed in sybsystemprocs. If they are installed in model, every new database that is created will inherit a copy.

# **Creating and Maintaining the Text Indexes**

Before the Full-Text Search engine can process full-text searches, you must create text indexes for the source tables in the user database. After the text indexes are created, you must update them when the source data changes to keep the text indexes current. To create and maintain the text indexes:

- Set up the source table for indexing (see "Setting Up Source Tables for Indexing" on page 19).
- Create the text indexes and index tables (see "Creating the Text Index and Index Table" on page 20).
- Bring the databases online for full-text searches (see "Bringing the Database Online for Full-Text Searches" on page 22).
- Propagate changes in the user data to the text indexes (see "Propagating Changes to the Text Index" on page 22).
- If you are replicating text indexes, set up text indexing in the destination database (see "Replicating Text Indexes" on page 23).

For an example of setting up a text index, see the sample script sample\_text\_main.sql in the \$SYBASE/\$SYBASE\_FTS/sample/scripts directory.

## **Setting Up Source Tables for Indexing**

The source table contains the data on which you perform searches (for example, the blurbs table in the pubs2 database). For more information on source tables, see "The Source Table" on page 5.

Before you can create text indexes on a source table, you must:

- Verify that the source table has an IDENTITY column
- Create a unique index on the IDENTITY column (optional)

#### Adding an IDENTITY Column to a Source Table

Every source table must contain an IDENTITY column to uniquely identify each row and provide a means of joining the index table and the source table. When you create a text index, the IDENTITY column is passed with the indexed columns to the Full-Text Search engine. The IDENTITY column value is stored in the text index and is mapped to the id column in the index table.

For example, to create an IDENTITY column in a table named composers, define the table as follows:

```
create table composers (
   id      numeric(m,n)      identity,
   comp_fname char(30)      not null,
```

```
comp_lname char(30) not null,
  text_col text
)
```

where m = <38 and n always =0

To add an IDENTITY column to an existing table, enter:

```
alter table table_name add id numeric(10,0) identity
```

#### Adding a Unique Index to an IDENTITY Column

For optimum performance, Sybase recommends creating a unique index on the IDENTITY column. For example, to create a unique index named comp\_id on the IDENTITY column created above, enter:

```
create unique index comp_id
on composers(id)
```

For more information about creating a unique index, see Chapter 11, "Creating Indexes on Tables," of the *Transact-SQL User's Guide*.

## **Creating the Text Index and Index Table**

Use the sp\_create\_text\_index system procedure to create the text indexes. sp\_create\_text\_index does the following:

- Updates the vesaux and vesauxcol tables in the text\_db database
- Creates the text index (Verity collections)
- Populates the Verity collections
- Creates the index table in the user database where the source table is located

The text index can contain up to 16 columns. Columns of the following datatypes can be indexed:

char, varchar, nchar, nvarchar, text, image, datetime, smalldatetime, int, smallint, tinyint, unichar, and univarchar.

For example, to create a text index and an index table named i\_blurbs for the copy column in the blurbs table in pubs2 on KRAZYKAT, enter:

- KRAZYKAT is the name of the Full-Text Search engine
- i\_blurbs is the name of the index table and text index you are creating
- blurbs is the source table on which you are creating the text indexes
- " " is a placeholder for text index creation options
- copy is the column in the blurbs table that you are indexing

See sp\_create\_text\_index on page 140 for more information.

**Note** Make sure the text\_db database name in the configuration file (listed after the defaultDb parameter) matches the database name in Adaptive Server. If they do not match, the text index cannot be created. Also, verify that the text\_events table exists in the user database. If it does not exist, run the installevent script for that database (refer to "Running the installevent Script" on page 17).

Populating the Verity collections can take a few minutes or several hours, depending on the amount of data you are indexing. You may want to perform this step when the server is not being heavily used. Increasing the batch\_size configuration parameter will also expedite the process. See "batch\_size" on page 82 for more information.

**Note** Do not rename an index because the Verity collection will not be renamed.

## **Specifying Multiple Columns When Creating a Text Index**

When you create a text index on two or more columns, each column in the text index is placed into its own document zone. The name of the zone is the name of the column. For example, to create a text index and an index table named i\_blurbs for both the copy column and the au\_id column in the blurbs table in pubs2 on KRAZYKAT, enter:

```
sp_create_text_index "KRAZYKAT", "i_blurbs", "blurbs", " ", "copy", "au_id"
```

sp\_create\_text\_index creates two zones in the text index named "copy" and "au\_id." When you issue a query against the i\_blurbs text index, the search includes the copy and au\_id columns. However, you can limit your search to a particular column by using the in operator to specify a document zone (for more information, see "in" on page 54).

## **Bringing the Database Online for Full-Text Searches**

With the Enhanced Full-Text Search engine, the database is automatically brought online when the auto\_online configuration parameter is set to 1.

When you bring a database online, the Full-Text Search engine initializes the internal Verity structures and confirms that the Verity collections exist.

Use the sp\_text\_online system procedure to bring a database online for full-text searches if it is not automatically brought online. For example, to bring the pubs2 database online before issuing full-text searches on the blurbs table in a Full-Text Search engine named KRAZYKAT, enter:

```
sp_text_online KRAZYKAT, pubs2
```

This message appears:

```
Database 'pubs2' is now online
```

The pubs2 database is now available for performing full-text searches.

See sp\_text\_online on page 157 for more information.

## **Propagating Changes to the Text Index**

When you insert, update, or delete data in your source table, the text indexes are not updated automatically. After you update data, run the sp\_refresh\_text\_index system procedure to log the changes to the text\_events table. Then, run the sp\_text\_notify system procedure to notify the Full-Text Search engine that changes need to be processed. The Full-Text Search engine then connects to Adaptive Server, reads the entries in the text\_events table, determines which indexes, tables, and rows are affected, and updates the appropriate collections.

See sp\_refresh\_text\_index on page 146 and sp\_text\_notify on page 156 for more information on these system procedures.

To have sp\_refresh\_text\_index run automatically after each insert, update, or delete, you can create triggers on your source tables, as follows:

- Create a trigger that runs sp\_refresh\_text\_index after a delete operation.
- Create a trigger that runs sp\_refresh\_text\_index after an insert operation.
- Create a trigger that runs sp\_refresh\_text\_index after an update operation to an indexed column.

Triggers are not fired when you use writetext to update a text column. To have sp\_refresh\_text\_index automatically run after a writetext:

- Set up a non-text column and update that column after each writetext.
- Create a trigger on the non-text column to run sp\_refresh\_text\_index.
   Since the Full-Text Search engine reinserts the entire row when you issue sp\_text\_notify, the update to the text column gets propagated to the text index.

For examples of each of these triggers, see the sample script sample\_text\_main.sql in the \$SYBASE/\$SYBASE\_FTS/sample/scripts directory.

## **Replicating Text Indexes**

To replicate tables that have text indexes, follow these guidelines:

- Create the table definition in the destination database.
- Run the installevent script to create the text\_events table in the destination database, if the text\_events table does not already exist (see "Running the installevent Script" on page 17).
- Run sp\_create\_text\_index to create the text index on the empty table in the destination database (see "Creating the Text Index and Index Table" on page 20).
- Create triggers for running sp\_refresh\_text\_index to insert entries into
  the text\_events table whenever you insert, update, or delete data into
  the table (see "Propagating Changes to the Text Index" on page 22).
- Create the replication definition in the Replication Server. This replicates all the data in the source table to the destination table. Refer to the "Replication Server Administration Guide" for more details.

Run sp\_text\_notify to update the text index; run sp\_text\_notify
periodically to process changes to the destination table (see
"Propagating Changes to the Text Index" on page 22).

**Note** You must issue an update against a non-text column whenever a writetext command is performed. This ensures that the trigger that inserts data into the text events table is fired.

## **Example: Enabling a New Database for Text Searches**

This example describes the steps for creating a text index on the plot column of the reviews table in the movies database. This process assumes that:

- You have created a reviews table in a new database named movies on the MYSVR server
- The reviews table has a column named plot that you are going to index
- Adaptive Server and the Full-Text Search engine named MYTXTSVR have been configured to connect to each other

#### Step 1. Verify that the text\_events Table Exists

Each database containing tables referenced by a text index must contain a text\_events table, which logs inserts, updates, and deletes to indexed columns.

If a text\_events table is in your model database, it will be in all new databases. If a text\_events table is not in your model database, run the installevent script to install the text\_events table in the new database. For example, to install the text\_events table in the movies database:

- Save the installevent script as installeventmovies.
- Edit the script to replace all references to the word model with the word movies.
- Run the script as follows:

```
isql -Usa -P -SMYSVR -i
$SYBASE/$SYBASE_FTS/scripts/installeventmovies
```

See "Running the installevent Script" on page 17 for information on installing the text\_events table.

#### Step 2. Check for an IDENTITY Column

Every source table must contain an IDENTITY column, which uniquely identifies each row and provides a means of joining the index table and the source table.

For example, to add an IDENTITY column to the reviews table, enter:

```
alter table reviews add id numeric(10,0) identity
```

See "Adding an IDENTITY Column to a Source Table" on page 19 for more information on creating an IDENTITY column.

#### Step 3. Create a Unique Index on the IDENTITY Column

This step is optional. To enhance performance, Sybase recommends creating a unique index that contains only the IDENTITY column. For example, to create a unique index named reviews\_id on the IDENTITY column created in step 2, issue the command:

```
create unique index reviews_id on reviews(id)
```

For more information about creating a unique index, see Chapter 11, "Creating Indexes on Tables," of the *Transact-SQL User's Guide*.

#### Step 4. Create the Text Index and Index Table

The source tables in the user database need to be indexed so that you can perform full-text searches. For example, to create a text index and an index table named reviews\_idx for the plot column in the reviews table, enter:

```
sp_create_text_index "MYTXTSVR", "reviews_idx",
"reviews", " ", "plot"
```

The reviews table is now available for running full-text searches.

See sp create text index on page 140 for more information.

## Step 5. Bring the Database Online for a Full-Text Search

To bring the movies database online for the Full-Text Search engine named MYTXTSVR, enter:

sp\_text\_online MYTXTSVR, movies

**Note** Omit this step if you have Enhanced Full-Text Search engine and your auto\_online configuration parameter is set to "1".

See sp\_text\_online on page 157 for more information.

# CHAPTER 4 Setting Up Verity Functions

This chapter describes the setup required before you can write queries with certain Verity functionality.

#### Topics includes:

Topic	Page
Enabling Query-By-Example, Summarization, and Clustering	27
Setting Up a Column to Use As a Sort Specification	30
Using Filters on Text That Contains Tags	32
Creating a Custom Thesaurus (Enhanced Version Only)	34
Creating Topics (Enhanced Version Only)	38

# **Enabling Query-By-Example, Summarization, and Clustering**

The *style.prm* file specifies additional data to include in the text indexes to support the following functionality:

• Query-by-example – Retrieves documents that are similar to a phrase (see "like" on page 55 for more information).

**Note** The text indexes only need additional data to support phrases in the query-by-example specification of the like operator. If you use a document in the query-by-example specification, additional data is not required.

- Summarization returns summaries of documents rather than entire documents (see "Using the summary Column to Summarize Documents" on page 48 for more information).
- Clustering groups documents in result sets by subtopic (see "Using Pseudo Columns to Request Clustered Result Sets" on page 48 for more information). Clustering is available only with the Enhanced Full-Text Search engine.

You can enable these features for all text indexes by editing the master *style.prm* file, or you can enable them for an individual text index by editing its *style.prm* file. Both methods are describe below.

# Query-By-Example and Clustering

To use phrases in a query-by-example specification and to use clustering, you must enable the generation of document feature vectors at indexing time. To do this, uncomment the following line in the *style.prm* file:

```
$define DOC-FEATURES "TF"
```

#### Summarization

To configure the Full-Text Search engine for summarization, uncomment one of the following lines that starts with "#\$define" in the *style.prm* file:

```
# The example below stores the best three sentences of
# the document, but not more than 255 bytes.
#$define DOC-SUMMARIES "XS MaxSents 3 MaxBytes 255"
# The example below stores the first four sentences of
# the document, but not more than 255 bytes.
#$define DOC-SUMMARIES "LS MaxSents 4 MaxBytes 255"
# The example below stores the first 150 bytes of
# the document, with whitespace compressed.
#$define DOC-SUMMARIES "LB MaxBytes 150"
```

Each of those lines reflects a different level of summarization. You can specify how many bytes of data you want the Full-Text Search engine to display, by altering the numbers at the ends of these lines. For example, if you want only the first 233 bytes of data summarized, edit the script to read:

```
$define DOC-SUMMARIES "LS MaxSents 4 MaxBytes 233"
```

The maximum number of bytes displayed is 255. Any number greater than that is truncated to 255.

## Editing the Master style.prm File

The master *style.prm* file is located in:

\$SYBASE/\$SYBASE\_FTS/verity/common/style

It contains the default Full-Text Search engine style parameters. Edit this file to configure the Full-Text Search engine so that all tables on which you create text indexes allow clustering and literal text in your query-by-example specifications, or summarization. Uncomment the applicable lines as described above.

**Note** If you have existing text indexes, you must re-create the text index with these features enabled as described in Editing Individual style.prm Files below.

## Editing Individual style.prm Files

Perform the following steps to configure the Full-Text Search engine so that the individual text index allows clustering and literal text in your query-by-example specifications, or summarization:

1 Create the text index using sp\_create\_text\_index. Use the word "empty" in the *option\_string* parameter so that the *style.prm* file is created for the text index, but the Verity collections are not populated with data. For example, if you are enabling clustering for the copy column of the blurbs table, use the following syntax:

```
sp_create_text_index "KRAZYKAT", "i_blurbs", "blurbs", "empty", "copy"
```

**Note** If the text index already exists, omit this step. You do not need to create the text index again.

2 Use sp\_drop\_text\_index to drop the text index associated with the style.prm file you are editing.

For example, to drop the text index created in step 1, enter:

```
sp_drop_text_index "blurbs.i_blurbs"
```

3 Edit the *style.prm* file that exists for the text index. The *style.prm* file for an existing collection is located in:

\$SYBASE\\$SYBASE\_FTS\collections\db.owner.index\style

where *db.owner.index* is the database, the database owner, and the index created with sp\_create\_text\_index. For example, if you create a text index called i\_blurbs on the pubs2 database, the full path to these files is:

\$SYBASE\\$SYBASE\_FTS\collections\pubs2.dbo.i\_blurbs\style

4 Uncomment the applicable lines as described above.

For example, to enable clustering, uncomment the following line:

```
$define DOC-FEATURES "TF"
```

5 Re-create the text index you dropped in step 2. For example, to recreate the *i blurbs* text index, enter:

```
sp_create_text_index "KRAZYKAT", "i_blurbs",
"blurbs", "", "copy"
```

# Setting Up a Column to Use As a Sort Specification

Before you can sort by specific columns, you must modify the *style.vgw* and *style.ufl* files. (For information on including a column in a sort specification, see "Using the sort\_by Column to Specify a Sort Order" on page 47.) Both files are in the directory:

\$SYBASE/\$SYBASE\_FTS/collections/db.owner.index/style

where *db.owner.index* is the database, the database owner, and the index created using sp\_create\_text\_index. For example, if you created a text index called i\_blurbs on the pubs2 database, the full path to those files would be similar to:

\$SYBASE\\$SYBASE\_FTS\collections\pubs2.dbo.i\_blurbs\style

To edit the *style.vgw* and *style.ufl* files, follow these steps:

1 Drop the text index that contains the columns for which you are adding definitions. (Dropping the text index does not drop the collection directory.)

For example, to add definitions for the copy column in the blurbs table, use the following command to drop the text index:

```
sp_drop_text_index i_blurbs
```

2 Edit the *style.vgw* file. Following this line:

```
dda "SybaseTextServer"
```

add an entry for the column you are defining. The syntax is:

where *column\_number* is the number of the column you are defining. Column numbers start with 0; if you want the first column to be sorted, specify "f0"; to sort the second column, specify "f1"; to sort the third column, specify "f2", and so on.

For example, to define the first column in a table, the syntax is:

Then, your *style.vgw* file will be similar to this:

```
#
# Sybase Text Server Gateway
#
$control: 1
gateway:
{
    dda: "SybaseTextServer"
{
    copy: f0 copy_f0
}
}
```

Edit the *style.ufl* file, by adding the column definition for a data table named fts. The syntax is:

```
data-table: fts
{
    fixwidth: copy_fcolumn_number precision datatype
}
```

Column numbers start with 0; if you want the first column to be sorted, specify "f0"; to sort the second column, specify "f1"; to sort the third column, specify "f2", and so on. For example, to add a definition for the first column of a table, with a precision of 4, and a datatype of date, enter:

```
data-table: fts
{
     fixwidth: copy_f0 4 date
}
```

Similarly, to add a definition for the second column of a table with a precision of 10, and a datatype of character, enter:

```
data-table: fts
{
    fixwidth: copy_f1 10 text
}
```

4 Re-create the index, using sp\_create\_text\_index.

# **Using Filters on Text That Contains Tags**

To perform accurate searches on documents that contain tags (such as HTML or postscript), the text index must use a filter to strip out the tags. The Enhanced Full-Text Search engine provides filters for a variety of document types (Microsoft Word, FrameMaker, WordPerfect, SGML, HTML, and others).

When you create the text index to use a filter, the data for each type of tag in the document is placed into its own document zone. For example, if you have a tag called "chapter," all chapter names are placed into one document zone. You can issue a query that searches the entire document, or that searches only for data in the "chapter" zone (for more information, see "in" on page 54).

To create a text index that uses a filter, modify the *style.dft* file for that text index. To edit the *style.dft* file, follow these steps:

1 Create the text index using sp\_create\_text\_index. Use the word "empty" in the *option\_string* parameter so that the *style.dft* file is created for the text index, but the Verity collections are not populated with data. For example, to create a text index for the copy column of the blurbs table, use the following syntax:

```
sp_create_text_index "KRAZYKAT", "i_blurbs", "blurbs", "empty", "copy"
```

2 Drop the text index that you create in step 1. This drops the text index, but not the *style.dft* file. For example, use the following command to drop the i\_blurbs text index:

```
sp_drop_text_index i_blurbs
```

3 Edit the *style.dft* file. The *style.dft* file is in the directory:

\$SYBASE/\$SYBASE\_FTS/collections/db.owner.index/style

where *db.owner.index* is the database, the database owner, and the index created using sp\_create\_text\_index. For example, if you created a text index called i\_blurbs on the pubs2 database, the full path to the *style.dft* file would be similar to:

\$SYBASE\_\$SYBASE\_FTS/collections/pubs2.dbo.i\_blurbs/style

Following this line:

```
field: f0
```

add syntax to use a filter.

Use the following syntax:

• For SGML documents, use:

/filter="zone -nocharmap"

• For HTML documents, use:

```
/filter="zone -html -nocharmap"
```

With Enhanced Full-Text Search engine, use the following syntax for all document types:

```
/filter="universal"
```

For example, your *style.dft* file for an SGML document in the will look like this:

Your *style.dft* file for an SGML document in the Enhanced version will look like this:

```
$control: 1
dft:
{
    field: f0
        /filter="universal"
    field: f1
```

```
field: f2
.
.
field: f15
```

**Note** Use getsend to load the database with document data. getsend takes the following arguments: database, table, column and row id. Insert a null value for the rowid for each row of text you wish to insert. getsend must insert into an image column for filtering to work. For more information on getsend, refer to the *README.TXT* file and *getsend.c* file in \$SYBASE/\$SYBASE\_FTS/sample/source directory.

4 Re-create the index, using sp\_create\_text\_index. For example:

```
sp_create_text_index "KRAZYKAT", "i_blurbs", "blurbs", "", "copy"
```

# **Creating a Custom Thesaurus (Enhanced Version Only)**

The Verity thesaurus operator expands a search to include the specified word and its synonyms (for information on using the thesaurus operator, see "thesaurus" on page 58). In the Enhanced version of the Full-Text Search engine, you can create a custom thesaurus that contains application-specific synonyms to use in place of the default thesaurus.

For example, the default English language thesaurus contains these words as synonyms for "money": "cash," "currency," "lucre," "wampum," and "greenbacks." You can create a custom thesaurus that contains a different set of synonyms for "money"; for example, such as: "bid," "tokens," "credit," "asset," and "verbal offer."

To create a custom thesaurus, follow these steps:

- 1 Make a list of the synonyms that you will use with your application. It may help to examine the default thesaurus (see "Examining the Default Thesaurus (Optional)" on page 35).
- 2 Create a control file that contains the synonyms you are defining for your custom thesaurus (see "Creating the Control File" on page 36).

- 3 Create the custom thesaurus using the mksyd utility (see "Creating the Thesaurus" on page 37). This uses the control file as input.
- 4 Replace the default thesaurus with your custom thesaurus (see "Replacing the Default Thesaurus with the Custom Thesaurus" on page 38).

For more information on "Custom Thesaurus Support" and the mksyd utility, see the Verity Web site at http://www.verity.com.

In the Enhanced version of Full-Text Search engine, two sample files illustrate how to set up and use a custom thesaurus:

- *sample\_text\_thesaurus.ctl* is a sample control file
- sample\_text\_thesaurus.sql issues queries against the custom thesaurus defined in the sample control file

These files are in the \$SYBASE/\$SYBASE\_FTS/sample/scripts directory.

## **Examining the Default Thesaurus (Optional)**

A control file contains all the synonym definitions for a thesaurus. To examine the default thesaurus, create its control file using the mksyd utility. Use the syntax:

```
mksyd -dump -syd
$SYBASE_$SYBASE_FTS/verity/common/vdkLanguage/vdk20
.syd -f work_location/control_file.ctl
```

#### where:

- *vdkLanguage* is the value of the vdkLanguage configuration parameter (for example, "english")
- work\_location is the directory where you want to place the control file
- *control\_file* is the name of the control file you are creating from the default thesaurus

Examine the control file (*control\_file.ctl*) that it creates to view the default synonym lists.

## **Creating the Control File**

Create a control file that contains the new synonyms for your custom thesaurus. The control file is an ASCII text file in a structured format. Using a text editor (such as vi or emacs), either:

- Edit the control file from the default thesaurus and add new synonyms to the existing thesaurus (see "Examining the Default Thesaurus (Optional)" on page 35), or
- Create a new control file that includes only your synonyms

#### **Control File Syntax**

The control file contains synonym list definitions in a synonyms: statement. For example, the following is a control file named *colors.ctl*:

```
$control: 1
synonyms:
{
list: "red, ruby, scarlet, fuchsia,\
magenta"
list: "electric blue <or> azure"
/keys = "lapis"
}
$$
```

The synonyms: statement includes:

• list: keywords that specify the start of a synonym list. The synonyms in the list are either in query form or in a list of words or phrases separated by commas.

• Each list: can optionally have a /keys modifier that specifies one or more keys separated by commas. In the example above, no keys are specified in the first "list". This means the list is found when the thesaurus is queried for the word "red," "ruby," "scarlet," "fuchsia," or "magenta." The second "list" uses the /keys modifier to specify one key. This means the words or phrases in the list will satisfy a query only when you specify <thesaurus>lapis.

**Note** If you use emacs to build a synonym list and any of your lists go beyond one line, turn off auto-fill mode. If you separate your list into multiple lines, include a backslash (\) at the end of each line so that the lines are treated as one list.

For more complex examples of control files, see the Verity Web site.

## **Creating the Thesaurus**

The mksyd utility creates the custom thesaurus using a control file as input. It is located in:

\$SYBASE/\$SYBASE\_FTS/verity/bin

Run, or define an alias to run, mksyd from this *bin* directory. Create your custom thesaurus in any work directory.

The mksyd syntax for creating a custom thesaurus is:

```
mksyd -f control_file.ctl -syd custom_thesaurus.syd
```

#### where:

- control\_file is the name of the control file you create in Creating the Control File above
- custom\_thesaurus is the name of the custom thesaurus you are creating

For example, to execute the mksyd utility reading the sample control file defined above, and directing output to a work directory, use the syntax:

```
mksyd -f /usr/u/sybase/dba/thesaurus/colors.ctl -
syd /usr/u/sybase/dba/thesaurus/custom.syd
```

## Replacing the Default Thesaurus with the Custom Thesaurus

The default thesaurus named *vdk20.syd* is located in:

\$SYBASE/\$SYBASE\_FTS/verity/common/vdkLanguage

where *vdkLanguage* is the value of the vdkLanguage configuration parameter (for example, the English directory is \$SYBASE/\$SYBASE\_FTS/verity/common/english). Each application and user reading from this location at runtime uses this thesaurus. To replace it with your custom thesaurus, follow these steps:

Back up the default thesaurus before replacing it with the custom thesaurus. For example:

mv /\$SYBASE\_FTS/verity/common/english/vdk20.syd default.syd

2 Replace the *vdk20.syd* file with your custom thesaurus. For example:

cp custom.syd /\$SYBASE/\$SYBASE\_FTS/verity/common/english/vdk20.syd

3 Restart your Full-Text Search engine; no configuration file changes are required. The thesaurus is read from this location when the Full-Text Search engine is started, not when a query is executed.

Queries using the thesaurus operator will now use the custom thesaurus.

# **Creating Topics (Enhanced Version Only)**

The section provides a condensed overview of Verity Topics. Topics are discussed in detail in Chapter 8, "Verity Topics."

A TOPIC® is a grouping of information related to a concept or subject area. With topic definitions in place, a user can perform searches on the topic instead of having to write queries with complex syntax.

The user creates topics which can be combinations of words and phrases, Verity operators and modifiers, and weight values. Then, any user can query the topic.

Before you create topics, determine your application requirements, and establish standards for naming conventions and for the location of the following:

 Outline files – contains the topic definitions. Each topic has its own outline file.

- Topic set directories contains the compiled topic. Each topic has its own topic set directory.
- Knowledge base map file contains pointers to the topic set directories.

To implement topics, perform the following steps:

- 1 Create one or more outline input files to define your topics (see "Creating an Outline File" on page 39). Each outline file is used to populate one topic set.
- 2 Create and populate a topic set directory, using the mktopics utility (see "Creating a Topic Set Directory" on page 40). Each topic set directory is populated based on one topic outline input file.
- 3 Create a *knowledge base map*, specifying the locations of one or more topic set directories (see "Creating a Knowledge Base Map" on page 41)
- 4 Set the knowledge\_base configuration parameter to point to the location of the knowledge base map (see "Defining the Location of the Knowledge Base Map" on page 41)
- 5 Execute queries against defined topics.

The following sample files illustrate the topics feature:

- *sample\_text\_topics.otl* is a sample outline file
- sample text topics.kbm is a sample knowledge base map
- sample\_text\_topics.sql issues queries using defined topics

These files are in the \$SYBASE/\$SYBASE FTS/sample/scripts directory.

#### **Creating an Outline File**

A topic outline file specifies all the combinations of words and phrases, Verity operators and modifiers, and weight values that the search engine uses when you issue a query using the topic. The outline file is an ASCII text file in a structured format.

For example, the following outline file defines the topic "saint-bernard":

```
$control: 1
saint-bernard <accrue>
*0.80 "Saint Bernard"
```

```
*0.80 "St. Bernard"

* "working dogs"

* "large dogs"

* "European breeds"

$$
```

When you issue a query specifying the topic "saint-bernard", the Full-Text Search engine:

- Returns documents that contain one or more of the following phrases: "Saint Bernard," "St. Bernard," "working dogs," "large dogs," and "European breeds"
- Scores documents that contain the phrase "Saint Bernard" or "St. Bernard" higher than documents that contain the phrase "working dogs, "large dogs," or "European breeds"

This example is a very basic topic definition. An outline can introduce more complex relationships by using:

- Multiple levels of subtopics
- Combinations of Verity operators (this example uses accrue)
- Verity modifiers

**Note** In Windows NT, you can use the graphical user interface of the Verity Intelligent Classifier product to create topic outlines. It is available from Verity. If you use Intelligent Classifier, it automatically creates a topic set directory, and you can go to "Creating a Knowledge Base Map" on page 41 to continue setting up your topics.

## **Creating a Topic Set Directory**

Use the mktopics utility to create and populate a topic set directory. It is located in:

\$SYBASE/\$SYBASE FTS/verity/bin

Run, or define an alias to run, mktopics from this *bin* directory. You can create a topic set directory or directories in any work directory.

The mktopics syntax is:

```
mktopics -outline outline_file.otl -topicset topic_set_directory
```

where:

- *outline\_file* is the name of the outline file you create in "Creating an Outline File" on page 39
- *topic\_set\_directory* —is the name of the topic set directory you are creating

For example, to execute the mktopics utility reading the *saint-bernard.otl* file defined above, and directing output to a work directory, use the syntax:

```
mktopics -outline
/usr/u/sybase/topic_outlines/saint-bernard.otl -
topicset /usr/u/sybase/topic_sets/saint-
bernard_topic
```

## **Creating a Knowledge Base Map**

A *knowledge base map* specifies the locations of one or more topic set directories. Create an ASCII knowledge base map file that defines the fully-qualified directory paths to your topic sets.

For example, the following knowledge base map file illustrates how you can list multiple knowledge bases in the map. The first entry identifies the topic set directory created with mktopics above.

```
$control:1
kbases:
{
kb:
/kb-path = /usr/u/sybase/topic_sets/saint-bernard_topic
kb:
/kb-path = /usr/u/sybase/topic_sets/another_topic
}
```

## **Defining the Location of the Knowledge Base Map**

Set the knowledge\_base configuration parameter to point to the location of the knowledge base map. For example:

```
sp_text_configure KRAZYKAT, 'knowledge_base',
'/usr/u/sybase/topic_sets/sample_text_topics.kbm'
```

The knowledge\_base configuration parameter is static, and you must restart the Full-Text Search engine for the definition to take effect.

## **Executing Queries Against Defined Topics**

You can now execute queries using the defined topic instead of a complex query. For example, before you create the "saint-bernard" topic, you would have to use the following syntax:

...where i.index\_any = "<accrue> ([80]Saint Bernard, [80]St. Bernard, working dogs, large dogs, European breeds)"

#### to find documents that:

- Contain one or more of the following phrases: "Saint Bernard," "St. Bernard," "working dogs," "large dogs," and "European breeds"
- Score documents containing the phrase "Saint Bernard" or "St. Bernard" higher than documents containing the phrase "working dogs," "large dogs," or "European breeds"

After you create the topic "saint-bernard", you can use this syntax:

```
...where i.index_any = "<topic>saint-bernard"
or:
...where i.index_any = "saint bernard"
```

**Note** If you enter a word in a query expression, the Full-Text Search engine tries to match it with a topic name. If you enter a phrase in a query expression, the Full-Text Search engine replaces spaces with hyphens (-), and then tries to match it with a topic name. For example, the Full-Text Search engine matches "saint bernard" with the topic "saint-bernard".

See the *sample\_text\_topics.sql* file for examples of using topics in queries.

## **Troubleshooting Topics**

If the knowledge\_base configuration parameter specifies a knowledge base map file that does not exist, the Full-Text Search engine will not be able to start a session with Verity, and the server will not start. If the map file exists but contains invalid entries, Verity issues warning messages at start-up time. You can correct errors by editing the *<textserver>.cfg* file in the *\$SYBASE* directory. You can correct path information and change the line beginning: "knowledge\_base=".

# CHAPTER 5 Writing Full-Text Search Queries

This chapter describes the pseudo columns, search operators, and modifiers that you can include in a full-text search.

#### Topics include:

Topic	Page
Components of a Full-Text Search Query	43
Pseudo Columns in the Index Table	44
Full-Text Search Operators	50
Operator Modifiers	60

# Components of a Full-Text Search Query

To write a full-text search query, you enter the search parameters as part of an Adaptive Server select statement. Then the Full-Text Search engine processes the search. The select statement requires:

- A where clause that assigns a Verity language query to the index\_any pseudo column
- Pseudo columns to further define the parameters of the search (optional)
- A join between the IDENTITY column from the source table and the id column from the index table

For example, to return the 10 documents from the copy column of the blurbs table that have the most occurrences of the word "software," enter:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id
and t1.index_any = "<many> <word> software"
and t1.max_docs = 10
```

Adaptive Server passes the Verity query to the Full-Text Search engine to process the search. For more information on how Adaptive Server processes the query, see "How a Full-Text Search Works" on page 9.

#### **Default Behaviour**

The default or simple syntax of a query to the full-Text Search engine is treated broadly:

- Searches are case sensitive.
- 2 The STEM operator applies to search words.
- 3 The MANY modifier is applied.
- 4 The ACCRUE operator is activated at the parent level.

## **Pseudo Columns in the Index Table**

*Pseudo columns* are columns in the index table that define the parameters of the search and provide access to the results data. (For more information about index tables, see "The Index Table" on page 7.) These columns are valid only in the context of a query; that is, the information in the columns is valid only for the duration of the query. If the query that follows contains a different set of parameters, the pseudo columns contain a different set of values.

Each pseudo column in an index table describes a different search attribute. For example, if you indicate the score column, the query displays only the result set that falls within the parameters you define. For example, the following query displays only the results that have a score value greater than 90:

```
index_table_name.score > 90
```

Other pseudo columns are used to retrieve data generated by Verity for a particular document. Table 5-1 describes the pseudo columns that are maintained by the Full-Text Search engine.

Table 5-1: Full-Text Search engine pseudo columns

Pseudo Column Name	Description	Datatype	Length (in Bytes)
cluster_number	Enhanced Full-Text Search engine only. Contains the cluster that the row is part of. Clusters are numbered starting with 1. You can use the cluster_number column only in the select clause of a query.	int	4
cluster_keywords	Enhanced Full-Text Search engine only. Contains the keywords that Verity uses to build the cluster. You can use cluster_keywords only in the select clause of a query.	varchar	255
id	Uniquely identifies a document within a collection. Used to join with the IDENTITY column of the source table. You can use id in the select clause or where clause of a query.	numeric	6
index_any	Provides a Verity language query to the Full-Text Search engine. You can use index_any only in a where clause.	varchar	255
max_docs	Limits results to the first <i>n</i> documents, based on the default sort order. In a clustered result set, limits results to the first <i>n</i> documents in each cluster. You can use max_docs only in a where clause.	int	4
score	The normalized measure of correlation between search strings and indexed columns. The score associated with a specific document has meaning only in reference to the query used to retrieve the document. You can use score in a select clause or a where clause.	int	4
sort_by	Specifies the sort order in which to return the result set.  The Enhanced Full-Text Search engine allows up to 16 sort specifications in the sort_by column.  You can use sort_by only in a where clause.	varchar	35
summary	Selects summarization data. You can use the summary column only in the select clause of a query.	varchar	255

The following sections describe the functionality of the pseudo columns.

## Using the score Column to Relevance-Rank Search Results

Relevance ranking is the ability of the Full-Text Search engine to assign the score parameter a value that indicates how well a document satisfies the query. The score calculation depends on the search operator used in the query (for more information, see "Using the Verity Operators" on page 53). The closer the document satisfies the query, the higher the score value is for that document.

For example, if you search for documents that contain the word "rain," a document with 12 occurrences of "rain" receives a higher score value than a document with 6 occurrences of "rain."

If you set *score* to a high value (such as 90) in your query, you limit the result set to documents that have a *score* value greater than that number.

**Note** Verity uses decimals for score values; Sybase uses whole numbers. For example, if Verity reports a score value of .85, Sybase reports the same value as 85.

For example, the following query searches for documents that contain the word "raconteur" or "Paris," or both, and that have a score of 90 or greater:

The query does not find any documents that contain the word "raconteur" or "Paris" and that have a score greater than 90. However, if the *score* value in the query is lowered to 39, you find that one document in the *blurbs* table mentions the word "raconteur" or "Paris":

## Using the sort\_by Column to Specify a Sort Order

The sort order specifies the collating sequence used to order the data in the result set. The default sort order is set by the sort\_order configuration parameter (for more information, see "Setting the Default Sort Order" on page 72). Case insensitive sort order is supported in the Enhanced version.

Use the sort\_by pseudo column to return a result set with a sort order other than the default. With the Enhanced Full-Text Search engine, you can specify up to 16 sort specifications in the sort\_by pseudo column.

Table 5-2 lists the values for the sort\_by pseudo column.

Table 5-2: Values for the sort\_by pseudo column

Value	Description
fts_score desc	Returns a result set sorted by score in descending order.
fts_score asc	Returns a result set sorted by score in ascending order.
fts_timestamp desc	Returns a result set sorted by a timestamp in descending order.
fts_timestamp asc	Returns a result set sorted by a timestamp in ascending order.
column_name desc	Returns a result set sorted according to the descending order of a column. <i>column_name</i> is the name of the source table's column.
column_name asc	Returns a result set sorted according to the ascending order of a column. <i>column_name</i> is the name of the source table's column.
fts_cluster asc	Returns a clustered result set. Only available with the Enhanced Full-Text Search engine. (See "Using Pseudo Columns to Request Clustered Result Sets" on page 48 for more information.)

**Note** Before you can sort by specific columns, you must modify the *style.vgw* and *style.ufl* files (see "Setting Up a Column to Use As a Sort Specification" on page 30).

For example, the following query sorts the documents by timestamp in ascending order:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 90
and t1.index_any = "<accrue>(raconteur, Paris)"
and t1.sort_by = "fts_timestamp asc"
```

## Using the *summary* Column to Summarize Documents

Use the summary pseudo column to have queries return only summaries of the documents that meet the search criteria, rather than returning entire documents. The summary column is not available by default; you must edit the *style.prm* file prior to creating the text index to enable summarization. See "Enabling Query-By-Example, Summarization, and Clustering" on page 27 for information about enabling the summary column.

For example, the following query returns only summaries of documents that include the words "Iranian" and "book" (in this example, the *style.prm* file is configured to display 255 characters):

The Full-Text Search engine supports summaries of up to 255 bytes.

For additional examples of queries using summarization, see the sample script *sample\_text\_queries.sql* in the \$SYBASE/\$SYBASE FTS/sample/scripts directory.

## Using Pseudo Columns to Request Clustered Result Sets

The clustering function analyzes a result set and groups rows into clusters so that the rows in each cluster are semantically more similar to each other, on average, than they are to other rows in other clusters. Ordering rows by subtopics can help you get a sense of the major subject areas covered in the result set. Clustering is only available with the Enhanced Full-Text Search Specialty Data Store.

Returning a clustered result set can be significantly slower than returning a nonclustered result set. If the response time of a query is critical, use a nonclustered result set.

#### **Preparing to Use Clustering**

Before you request a clustered result set, you must build the text index with the clustering function enabled (see "Enabling Query-By-Example, Summarization, and Clustering" on page 27).

The Verity clustering algorithm attempts to group similar rows together, based on the values of the following configuration parameters:

- cluster\_style
- cluster max
- cluster\_effort
- cluster\_order

Use the sp\_text\_cluster system procedure to have a query use values that are different from the default values of these configuration parameters. (For values and how to set them for a query, see sp\_text\_cluster on page 148.)

#### Writing Queries Requesting a Clustered Result Set

To obtain a clustered result set, specify "fts\_cluster asc" as the sort specification in the sort\_by pseudo column of the query. For example:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id
and t1.index_any = "<many> <word> software"
and t1.max_docs = 10
and t1.sort_by = "fts_cluster asc"
```

Include any of the following pseudo columns in your query to return additional clustering information:

- cluster\_number contains the number of the cluster the row belongs to. Clusters are numbered starting with 1.
- cluster\_keywords contains the most common words found in the cluster. The cluster\_keywords column contains a null value for each row that does not fit into any cluster.
- max\_docs limits the number of rows returned for each cluster. (In a nonclustered query, the max\_docs column limits the total number of rows that are returned in a result set.)

• score – contains a value of 0 to 10000. The higher the score, the closer the row is to the cluster center. A score of 0 indicates the row does not fit into any cluster. (In a nonclustered query, the score column can contain a value of 0 to 100.) The search engine does not return results with a score of 0. Logically a score of 0 represents "no match" but the user never sees a score of 0.

See the sample script named *sample\_text\_queries.sql* in the \$SYBASE/\$SYBASE\_FTS/sample/scripts directory for examples of SQL statements using clustering.

# **Full-Text Search Operators**

The special search operators that you use to perform full-text searches are part of the Verity search engine. Table 5-3 describes the Verity search operators provided by the Full-Text Search engine.

Table 5-3: Verity search operators

Operator Name	Description	
accrue	Selects documents that contain at least one of the search elements specified in a query. The more search elements there are, the higher the score will be.	
and	Selects documents that contain all the search elements specified in a query.	
complement	Returns the complement of the score value (the score value subtracted from 100).	
in	Selects documents that contain the search criteria in the document zone specified.	
like	Selects documents that are similar to the sample documents or passages specified in a query.	
near	Selects documents containing the specified search elements, where the closer the search terms are to each other in a document, the higher the document's score.	
near/n	Selects documents containing two or more search terms within $n$ number of words of each other, where $n$ is an integer up to 1000. The closer the search terms are to each other in a document, the higher the document's score.	
or	Selects documents that contain at least one of the search elements specified in a query.	
paragraph	Selects documents that include all the search elements you specify within the same paragraph.	
phrase	Selects documents that include a particular phrase. A phrase is a grouping of two or more words that occur in a specific order.	
product	Multiplies the score values for each of the items of the search criteria.	
sentence	Selects documents that include all the specified words in the same sentence.	

Operator Name	Description
stem	Expands the search to include the specified word and its variations.
sum	Adds the score values for all items in the search criteria.
thesaurus	Expands the search to include the specified word and its synonyms.
topic	Specifies that the search term you enter is a topic.
wildcard	Matches wildcard characters included in search strings. Certain characters indicate a wildcard specification automatically.
word	Performs a basic word search, selecting documents that include one or more instances of the specified word.
yesno	Converts all nonzero score values to 100.

## **Considerations When Using Verity Operators**

Consider the following when you write full-text search queries:

• You *must* enclose the operators in angle brackets (<>) in the query. If they are not enclosed in angle brackets, the Full-Text Search engine issues error messages similar to the following:

```
Msg 20200, Level 15, State 0:
Server 'KRAZYKAT', Line 1:
       E1-0111 (Query Builder): Syntax error in query string near
Error
character 5
Msg 20200, Level 15, State 0:
Server 'KRAZYKAT', Line 1:
       E1-0114 (Query Builder): Error parsing query: word(tasmanian)
Msg 20101, Level 15, State 0:
Server 'KRAZYKAT', Line 1:
VdkSearchNew failed with vdk error (-40).
Msg 20101, Level 15, State 0:
Server 'KRAZYKAT', Line 1:
VdkSearchGetInfo failed with vdk error (-11).
score
____
(0 rows affected) score
```

 You must enclose the Verity language query in single quotes (') or double quotes ("). The Full-Text Search engine strips off the outermost quotes before it sends the query to Verity. For example, when you enter the query:

```
...where index_any = "'?own'"
```

the Full-Text Search engine sends the following query to Verity:

'?own'

 A query may be comprised of several "index\_any" clauses anded together in SQL. The right and value strings can be prefixed with "<snnn>". All such strings will be concatenated in Full-Text Search in the order determined by the "nnn" values. The "<snnn>" is removed. For instance:

```
where index_any="<s001>hello" and index_any="<s002> world"
```

is the same as:

```
where index_any = "hello world"
```

This is a handy work-around for search strings that are greater than 255 characters.

- Search terms entered in mixed case automatically become case sensitive. Search terms entered in all uppercase or all lowercase are not automatically case sensitive. For example, a query on "Server" finds only the string "Server". A query on "server" or "SERVER" finds the strings "Server", "server", and "SERVER".
- You can use alternative syntax for the query expressions shown in Table 5-4.

Table 5-4: Alternative Verity syntax

Standard Query Expression	Alternative Syntax
<many><word>string</word></many>	"string"
<many><stem>string</stem></many>	'string'

When using the alternative syntax, remember that the Full-Text Search engine strips off the outermost quotes before it sends the query to Verity. For example, when you enter the query:

```
...where index_any = "'play'"
```

the Full-Text Search engine sends the following query to Verity:

```
'play'
```

This is the same as:

```
<MANY><STEM>play
```

## **Using the Verity Operators**

The following sections describe how to use the Verity operators shown in Table 5-3 on page 50.

#### accrue

The accrue operator selects documents that contain at least one of the search items specified in the query. There must be two or more search elements. Each result is relevance-ranked. For example, the following query searches for the word "restaurant" or "deli" or both in the copy column of the blurbs table:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 35
and t1.index_any = "<accrue>(restaurant, deli)"
```

#### and, or

The and and or operators select documents that contain the specified search elements. Each result is relevance-ranked. The and operator selects documents that contain all the elements specified in the query. For example, the following query selects documents that contain both "Iranian" and "business":

```
select t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id
and t1.index_any = "(Iranian <and> business)"
```

The or operator selects the documents that contain any of the search elements. For example, if the preceding query is rewritten to use the or operator, the query selects documents that contain the word "Iranian" or "business":

```
select t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id
and t1.index_any = "(Iranian <or> business)"
```

#### complement

The complement operator returns the complement of the score value for a document; that is, it subtracts the value of score from 100 and returns the result as the score value for the document.

#### in

The in operator selects documents that contain the specified search element in one or more document zones. Document zones are created for a text index in the following two scenarios:

• When you create an index on two or more columns using sp\_create\_text\_index, a document zone is created for each column in the text index (for more information, refer to "Specifying Multiple Columns When Creating a Text Index" on page 21). A document zone is not created when you create a text index on a single column. For example, if you specify the au\_id and copy columns of the blurbs table when you create the text index, you can issue the following query:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 35
and t1.index_any = "gorilla <in> copy"
```

This returns rows that contain the word "gorilla" in the copy column. However, if you specify only the copy column of the blurbs table when you create the text index, this query does not return any rows.

• When you create an index that uses a filter, a document zone is created for each tag in the document (for more information, see "Using Filters on Text That Contains Tags" on page 32). You can limit your search to a particular tag by specifying the tag name after the in operator. For example, to search for the word "automotive" in a "title" tag in an HTML document, specify:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 35
and t1.index_any = "automotive <in> title"
```

Text indexes utilizing filters can contain only one column.

like

The like operator selects documents that are similar to the document(s) or passages you provide. The search engine analyzes the text to find the most important terms to use. If you specify multiple samples, the search engine selects important terms that are common across the samples. Each result is relevance-ranked.

The like operator accepts a single operand, called the query-by-example (QBE) specification. The QBE specification can be either literal text or document IDs. The document IDs are from the IDENTITY column in the source table. For example, to select documents that are similar to the document in the copy column in the row with an IDENTITY of "2", enter:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 35
and t1.index_any = '<like> ( "{2}" )'
```

Before using literal text in the QBE specification, you must uncomment the following line in the *style.prm* file:

```
$define DOC-FEATURES "TF"
```

For more information, see "Enabling Query-By-Example, Summarization, and Clustering" on page 27.

See the sample script named *sample\_text\_queries.sql* in the \$SYBASE/\$SYBASE\_FTS/sample/scripts directory for examples of SQL statements using QBE.

#### near, near/n

The near operator selects documents that contain the items specified in the query and are near each other ("near" being a relative term). The documents in which the search words appear closest to each other receive the highest relevance-ranking.

The near/n operator specifies how far apart the items can be (n has a maximum value of 1000). The following example selects documents in which the words "raconteur" and "home" appear within 10 words of each other:

```
select t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id
and t1.index_any = "<near/10>(raconteur, home)"
```

or

See "and, or" on page 53.

#### phrase

The phrase operator selects documents that contain a particular phrase (a group of two or more items that occur in a specific order). Each result is relevance-ranked. The following example selects the documents that contain the phrase "gorilla's head":

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 50
and t1.index_any = "<phrase>(gorilla's head)"
```

#### paragraph

The paragraph operator selects documents in which the specified search elements appear in the same paragraph. The closer the words are to each other in a paragraph, the higher the score the document receives in relevance-ranking. The following example searches for documents in which the words "text" and "search" occur within the same paragraph:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 50
and t1.index_any = "<many><paragraph>(text, search)"
```

## product

The product operator multiplies the score value for the documents for each of the search elements. To arrive at a document's score, the Full-Text Search engine calculates a score for each search element and multiplies the scores. For example:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 50
and t1.index_any = "product>(cat, created)"
```

The score value for each search element is 78; however, because the score values for the items are multiplied, the document has a score value of 61  $(.78 \times .78 = .61(100) = 61)$ .

#### sentence

The sentence operator selects documents in which the specified search elements appear in the same sentence. The closer the words are to each other in a sentence, the higher the score the document receives in relevance-ranking. The following example searches for documents in which the words "tax" and "service" occur within the same sentence:

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 50
and t1.index_any = "<many><sentence>(tax, service)"
```

#### stem

The stem operator searches for documents containing the specified word and its variations. For example, if you specify the word "cook," the Full-Text Search engine produces documents that contain "cooked," "cooking," "cooks," and so on. To relevance-rank the result set, include the many modifier in the query (see "Operator Modifiers" on page 60).

The following query uses the stem operator to find documents that contain variations of the word "create," that is, words that contain the word "create" as a stem. Notice that even though the first document contains a word in which "create" is not a perfect stem ("creative"), the document is still selected:

#### sum

The sum operator totals the score values for each search element, up to a maximum of 100. To arrive at a document's score, the Full-Text Search engine calculates a score for each search element and totals those scores.

#### thesaurus

The thesaurus operator searches for documents containing a synonym for a search element. For example, you might perform a search using the word "dog," looking for documents that use any of its synonyms ("canine," "pooch," "pup," "watchdog," and so on). Each result is relevance-ranked.

The Full-Text Search engine supplies a default thesaurus. With the Enhanced Full-Text Search engine, you can create a custom thesaurus. For more information, see "Creating a Custom Thesaurus (Enhanced Version Only)" on page 34.

The following example uses the thesaurus operator to find a result set that contains synonyms for the word "crave." The first document is selected because it contains the word "want"; the second, because it contains the word "hunger":

#### topic (Enhanced Version Only)

The topic operator selects documents that meet the search criteria defined by the specified topic. For more information, see "Creating Topics (Enhanced Version Only)" on page 38. For example, use the following syntax to find documents that meet the criteria defined by the topic "engineering":

```
select t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id
and t1.index_any = "<topic>(engineering)"
```

#### wildcard

The wildcard operator allows you to substitute wildcard characters for part of the item for which you are searching. Table 5-5 describes the wildcard characters and their attributes.

Table 5-5: Full-Text Search engine wildcard characters

Character	Function	Syntax	Locates
?	Specifies one alphanumeric character. You do not need to include the wildcard operator when you include the question mark in your query. The question mark is ignored in a set ([]) or in an alternative pattern ({}).	'?an'	"ran,""pan,""can," and "ban"
*	Specifies zero or more of any alphanumeric character. You do not need to include the wildcard operator when you include the asterisk in your query; you should not use the asterisk to specify the first character of a wildcard-character string. The asterisk is ignored in a set ([]) or in an alternative pattern ({}).	'corp*'	"corporate," "corporation," "corporal," and "corpulent"
[]	Specifies any single character in a set. If a word includes a set, you must enclose the word in backquotes ("). Also, there can be no spaces in a set.	<wildcard> 'c[auo]t'</wildcard>	"cat," "cut," and "cot"
{}	Specifies one of each pattern separated by a comma. If a word includes a pattern, you must enclose the word in backquotes ("). Also, there can be no spaces in a set.	<wildcard> 'bank{s,er,ing}'</wildcard>	"banks," "banker," and "banking"
^	Specifies one of any character not included in a set. The caret (^) must be the first character after the left bracket ([) that introduces a set.	<wildcard> 'st[^oa]ck'</wildcard>	Excludes "stock" and "stack," but locates "stick" and "stuck"
-	Specifies a range of characters in a set.	<wildcard> 'c[a-r]t'</wildcard>	Includes every three-letter word from "cat" to "crt"

To relevance-rank the result set, include the many modifier in the query (see "Operator Modifiers" on page 60).

For example, the following query searches for documents that include variations of the word "slingshot":

```
select t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id
```

```
and t1.index_any = '"slingshot*"'
score copy
----
100 Albert Ringer was born in a trunk to circus parents, but
another kind of circus trunk played a more important role
. . .
gorilla. "Slingshotting" himself from the ring ropes,
. . . .
```

#### word

The word operator searches for documents containing the specified word. To relevance-rank the result set, include the many operator in the query. The following example searches the blurbs table for documents containing the word "palates":

```
select t1.score, t2.copy
from i_blurbs t1, blurbs t2
where t1.id=t2.id and t1.score > 50
and t1.index_any = "<many><word>(palates)"
```

#### yesno

The yesno operator converts all nonzero score values to 100. For example, if the score values for five documents are 86, 45, 89, 89, and 100, each of those documents is returned with a score value of 100. score values of 0 are not changed. The yesno operator is helpful for ensuring that all documents containing the search criteria are returned in the result set, regardless of the sort order.

# **Operator Modifiers**

The Verity query language includes modifiers that you can use with the operators to refine a search. The modifiers are described in Table 5-6.

Table 5-6: Verity operator modifiers

Modifier Name	Description	Works with These Operators	Example
case	Performs case- sensitive searches. If you enter search terms in mixed case, the search is automatically case sensitive.	wildcard word	<case><word>(Net)</word></case>
many	Counts the number of times that a word, stemmed word, or phrase occurs in a document. Relevanceranks the document according to its density.	paragraph phrase sentence stem word wildcard	<many><stem>(write)</stem></many>
not	Excludes documents that contain the items for which the query is searching.	and or	cat <and><not>elephant</not></and>
order	Specifies that the items in the documents occur in the same order in which they appear in the query.  Always place the order modifier just before the operator	near/n paragraph sentence	Simple syntax:  tidbits <order><paragraph>king  Explicit syntax:  <order><paragraph>(tidbits,king)</paragraph></order></paragraph></order>

# CHAPTER 6 System Administration

This chapter describes system administration issues for the Enhanced version of the Full-Text Search engine.

#### Topics include:

Topic	Page
Starting the Full-Text Search Engine on UNIX	63
Starting the Full-Text Search Engine on Windows NT	65
Shutting Down the Full-Text Search Engine	66
Modifying the Configuration Parameters	67
Backup and Recovery for the Enhanced Full-Text Search Engine	75

# Starting the Full-Text Search Engine on UNIX

Use the startserver utility to start the Full-Text Search engine on UNIX. The startserver utility is included in the *install* directory of Adaptive Server. For example, to start a Full-Text Search engine named KRAZYKAT, enter:

```
startserver -f
$SYBASE/$SYBASE_FTS/install/RUN_KRAZYKAT
```

where the -f flag specifies the relative path to the runserver file. After you issue the command, the Full-Text Search engine issues a series of messages describing the settings of the configuration parameters.

# **Creating the Runserver File**

The runserver file contains start-up commands for the Full-Text Search engine. The runserver file can include the flags shown in Table 6-1

Flag	Definition
-Sserver_name	Specifies the name of the Full-Text Search engine and is used to locate the configuration file and the network connection information in the interfaces file.
-t	Causes the Full-Text Search engine to write start- up messages to standard error.
-lerrorlog_path	Specifies the path to the error log file.
-iinterfaces_file_path	Specifies the path to the interfaces file.

A sample runserver file is copied to the \$SYBASE\_\$SYBASE\_FTS/install directory during installation. Make a copy of this file, renaming it RUN\_server\_name, where server\_name is the name of the Full-Text Search engine. You must include the correct path environment variable for your platform in the runserver file. Table 6-2 shows the path environment variable to use for each platform.

Table 6-2: Path environment variable for the runserver file

Platform	Environment Variable
RS/6000 AIX	LIBPATH
Sun Solaris	LD_LIBRARY_PATH
HP 9000(800)	SHLIB_PATH
Digital UNIX	LD_LIBRARY_PATH

For example, the runserver file on Sun Solaris for a Full-Text Search engine named KRAZYKAT would be *RUN\_KRAZYKAT* and would be similar to:

```
#!/bin/sh
#

LD_LIBRARY_PATH="$SYBASE/$SYBASE_FTS/lib:$LD_LIBRAR
Y_PATH"
export LD_LIBRARY_PATH
$SYBASE/bin/txtsvr -SKRAZYKAT
```

The start-up command in the runserver file must consist of a single line and cannot include a return. If you have to carry the contents of the file over to a second or third line, include a backslash (\) for a line break.

# Starting the Full-Text Search Engine on Windows NT

You can start the Full-Text Search engine from Sybase Central<sup>TM</sup>, as a service, or from the command line:

- From Sybase Central see your Sybase Central documentation for information about starting servers.
- As a service see Starting the Full-Text Search Engine As a Service below.
- From the command line use the following syntax:

```
%SYBASE%\%SYBASE_FTS%\bin\txtsvr.exe -Sserver_name
[-t] [-i%SYBASE%path_to_sql.ini_file] [-
l%SYBASE%path_to_errorlog]
```

#### where:

- -S is the name of the Full-Text Search engine you are starting
- t directs start-up messages to standard error
- -i is the path to the *sql.ini* file
- -l is the path to the error log

For example, to start a Full-Text Search engine named KRAZYKAT on NT using the default *sql.ini* and error log files, and using -t to trace start-up messages, enter:

```
%SYBASE%\%SYBASE_FTS%\bin\txtsvr.exe -SKRAZYKAT -t
```

The Full-Text Search engine is up and running when you see the start-up complete message.

# Starting the Full-Text Search Engine As a Service

Use the instsvr utility in Sybase Central to add the Full-Text Search engine to the list of items you can start and stop with the Services utility. instsvr is located in the %SYBASE%\%SYBASE\_FTS%\bin directory.

The instsvr utility uses the following syntax:

instsvr.exe service\_name %SYBASE%\%SYBASE\_FTS%\bin\txtsvr.exe
"startup\_parameters"

where:

- service\_name is the name of the Full-Text Search engine you are
  adding as a service. With Sybase Central, Sybase recommends you
  use a server name with the extension "\_TS" (for example,
  KRAZYKAT TS).
- startup\_parameters are any parameters you want used at start-up.

For example, to install a Full-Text Search engine named KRAZYKAT\_TS as a service, enter:

instsvr.exe KRAZYKAT\_TS %SYBASE%\sds\text\bin\txtsvr.exe
"-SKRAZYKAT\_TS -t"

**Note** If you need to include more than one parameter (for example, -i), you must include all the parameters in one set of double quotes.

To configure Sybase Central to start and stop your Full-Text Search engine, you must provide a service name that begins with "SYBTXT\_server\_name", where server\_name is the name of the Full-Text Search engine listed in the interfaces file. For example, if the name in the interfaces file is KRAZYKAT\_TS, run the following instsvr command to create a service that can be managed by Sybase Central:

instsvr SYBTXT\_KRAZYKAT\_TS %SYBASE%\%SYBASE\_FTS%\bin\txtsvr.exe
"-SKRAZYKAT\_TS -t"

# **Shutting Down the Full-Text Search Engine**

Use the following command to shut down the Full-Text Search engine from Adaptive Server:

```
server_name...sp_shutdown
```

where *server\_name* is the name of the Full-Text Search engine you are shutting down.

For example, to shutdown a Full-Text Search engine named KRAZYKAT, enter:

KRAZYKAT...sp\_shutdown

# **Modifying the Configuration Parameters**

Each Full-Text Search engine has configuration parameters with default values, as shown in Table 6-3.

Table 6-3: Configuration parameters

Parameter	Description	Default Value
batch_size	Determines the size of the batches sent to the Full-Text Search engine.	500
batch_blocksize	When enabled, the text server reads data in smaller chunks. This parameter instructs the text server to retrieve <i>n</i> number of rows at a time. Should be set to 0 (disabled) to 65535.	0
max_indexes	The maximum number of text indexes that will be created in the Full-Text Search engine.	126
max_stacksize	Size (in kilobytes) of the stack allocated for client threads.	34,816
max_threads	Maximum number of threads available for the Full-Text Search engine.	50
max_packetsize	Packet size sent between the Full-Text Search engine and the Adaptive Server.	2048
max_sessions	Maximum number of sessions for the Full-Text Search engine.	100
min_sessions	Minimum number of sessions for the Full-Text Search engine.	10
language	Language used by the Full-Text Search engine.	us_english
charset	Character set used by the Full-Text Search engine.	iso_1
vdkCharset	Character set used by Verity search engine.	850
vdkLanguage	Language used by Verity search engine.	english
vdkHome	Verity directory.	UNIX:
		\$SYBASE/\$SYBASE_FTS/verity
		Windows NT:
		%SYBASE%\%SYBASE_FTS%\verity
collDir	Storage location of the Full-Text Search engine's	UNIX:
	collection.	\$SYBASE/\$SYBASE_FTS/collections
		Windows NT:
		%SYBASE%\%SYBASE_FTS%\collections
defaultDb	Name of the Full-Text Search engine database that stores text index metadata.	text_db

Parameter	Description	Default Value
interfaces Full path to the directory in which the interfaces		UNIX:
	file used by the Full-Text Search engine is	\$SYBASE/interfaces
	located.	Windows NT:
		%SYBASE%\ini\sql.ini
sort_order	Default sort order.	0
errorLog	Full path name to the error log file.	The directory in which you start Full-Text Search engine
traceflags	String containing numeric identifiers used to generate diagnostic information.	0
srv_traceflags	String containing numeric flag identifiers used to generate Open Server diagnostic information.	0

The Enhanced Full-Text Search engine has additional configuration parameters as shown in Table 6-4:

Table 6-4: Configuration parameters for Enhanced version only

Parameter	Description	Default Value
cluster_style	Clustering style to use.	Fixed
cluster_max	Maximum number of clusters to generate when cluster_style is set to Fixed.	0
cluster_effort	Amount of effort the Full-Text Search engine should expend on finding a good cluster.	Default
cluster_order	The order to return clusters and rows within a cluster.	0
auto_online	Specifies whether to bring indexes online automatically when the Full-Text Search engine is started. 0 indicates online is not automatic; 1 indicates automatic.	0
backDir	The default location for the placement of text index backup files.	UNIX: \$SYBASE/\$SYBASE_FTS/backup Windows NT: %SYBASE%\%SYBASE_FTS%\backup
knowledge_base	The location of a knowledge base map for implementing the Verity topics feature.	null
nocase	Sets the case-sensitivity of the Full-Text Search engine. If you are using a case-sensitive sort order in Adaptive Server, set to 0. If you are using a case-insensitive sort order, set to 1.	0

A sample configuration file that includes all of these parameters is copied to your installation directory during installation. The sample configuration file is named *textsvr.cfg*. The entire sample configuration file is listed in Appendix B, "Sample Files."

### **Modifying Values in the Enhanced Version**

With Enhanced Full-Text Search Specialty Data Store, you can use the sp\_text\_configure system procedure to change the value of a configuration parameter. The syntax is:

sp\_text\_configure server\_name, config\_name, config\_value where:

- server\_name is the name of the Full-Text Search engine
- *config\_name* is the name of the configuration parameter
- *config\_value* is the value you assign to the configuration parameter

For more information, see sp\_text\_configure on page 150.

# **Available Configuration Parameters**

The following table provides a list of available configuration parameters with valid limits:

Table 6-5: Limits to Configuration parameters

Parameter	Values	Static/Dynamic
batch_size	0 - MAX_INT	Dynamic
batch_blocksize	0 - 65535	Dynamic
max_indexes	0 - MAX_INT	Static
max_stacksize	0 - MAX_INT	Static
max_threads	0 - MAX_INT	Static
max_packetsize	0 - MAX_INT	Static
max_sessions	0 - MAX_INT	Static
min_sessions	0 - max_sessions	Static
language	french, spanish german, us_english	Static
charset	ascii_8, cp037, cp1047, cp437, cp500, cp850, deckanji, eucjis, iso_1, mac, roman8, sjis, utf8	Static
vdkCharset	850, 437, 1252, mac1 (Just the ones listed in the manual)	Static

Parameter	Values	Static/Dynamic
vdkLanguage	frenchx, spanishx, germanx, english, englishx, bokmalx, dutchx, finnishx, nynorskx, swedishx, portugx, italianx, danishx	Static
vdkHome	A string < 255 chars	Static
collDir	A string < 255 chars	Static
default_Db	A string < 32 chars	Static
interfaces	A string < 255 chars	Static
sort_order	0, 1, 2, 3	Dynamic
errorLog	A string < 255 chars	Static
traceflags	A string with comma delimited numbers ranging anywhere from 1 to 15.	Static
srv_traceflags	A string with comma delimited numbers ranging anywhere from 1 to 8	Static
cluster_style	Coarse, Medium, Fine, Fixed	Dynamic
cluster_max	0 - MAX_INT	Dynamic
cluster_effort	Low, Medium, High, Default	Dynamic
cluster_order	0 or 1	Dynamic
auto_online	0 or 1	Static
backCmd	A string < 255 chars	Dynamic
restoreCmd	A string < 255 chars	Dynamic
backDir	A string < 255 chars	Static
knowledge_base	A string < 255 chars	Static
nocase	0 or 1	Dynamic

# **Setting the Default Language**

The default language for Verity is set with the vdkLanguage configuration parameter. By default, vdkLanguage is set to "english". You can configure Verity to use a different default language. Table 6-6 lists the locales supported by Sybase.

Table 6-6: vdkLanguage configuration parameters

Language	Default Locale Name
English	english
German	german
French	french

Additional language adapters are available in the \$SYBASE/\$SYBASE\_FTS/verity/common directory; however, the Full-Text Search engine displays messages only in the languages shown in Table 6-6.

The language parameter is the language the Full-Text Search engine displays its error messages and Open Server and Open Client error messages. Set the language parameter to the Adaptive Server language.

With the Enhanced Full-Text Search engine, run the following:

sp\_text\_configure KRAZYKAT, 'vdkLanguage', 'spanish'

For more information about the Verity languages, see the Verity Web site at http://www.verity.com.

# .Setting the Default Character Set

The default character set for Verity is set with the vdkCharset parameter in the configuration file. The files used for the Verity character sets are in \$SYBASE\_\$SYBASE\_FTS/verity/common. Table 6-7 describes the character sets you can use with Verity.

Table 6-7: Verity character sets

Character Set	Description
850	Default
437	IBM PC character set
1252	Windows code page for Western European languages
mac1	Macintosh roman

The default character set for the Full-Text Search engine is set with the charset parameter. Set the charset parameter to the Adaptive Server character set.

For example, with the Enhanced Full-Text Search engine, run the following:

sp\_text\_configure KRAZYKAT, 'vdkCharset', '437'

### **Setting the Default Sort Order**

By default, the Full-Text Search engine sorts the result set by the score pseudo column in descending order (the higher scores appear first). To change the default sort order, set the sort\_order configuration parameter to one of the values in Table 6-8.

Table 6-8: Sort order values for the configuration file

Value	Description
0	Returns result sets sorted by the score pseudo column in descending order. The default value.
1	Returns result sets sorted by the score pseudo column in ascending order.
2	Returns result sets sorted by a timestamp in descending order.
3	Returns result sets sorted by a timestamp in ascending order.

For example, with the Enhanced Full-Text Search engine, enter:

```
sp_text_configure KRAZYKAT, 'sort_order', '2'
```

When you sort a result set by descending timestamp (value 2 in Table 6-8), the Full-Text Search engine returns the newest documents first. The newest documents are those that were inserted or updated most recently. When results are sorted by ascending timestamp (value 3 in Table 6-8), the Full-Text Search engine returns the oldest documents first.

Setting the default sort order is especially important if your query uses the max\_docs pseudo column. The max\_docs pseudo column limits the number of rows of the result set to the first *n* rows, ordered by the sort order. If you set max\_docs to a number smaller than the size of the result set, the sort order you select could exclude the rows that contain the information for which you are searching.

For example, if you sort by ascending timestamp, the latest document added to the table appears last in the result set. If the entire result set consists of 11 documents, and you set max\_docs to 10, the latest document does not appear in the result set. However, if you sort by descending timestamp, the latest document appears first in the result set.

### **Setting Trace Flags**

The traceflags parameter enable the logging of certain events when they occur within the Full-Text Search engine. Each trace flag is uniquely identified by a number. Trace flags are described in Table 6-9.

Table 6-9: Full-Text Search engine trace flags

Trace Flag	Description
1	Traces connects, disconnects, and attention events from Adaptive Server.
2	Traces language events. Traces the SQL statement that Adaptive Server sent to the Full-Text Search engine.
3	Traces RPC events.
4	Traces cursor events. Traces the SQL statement sent to the Full-Text Search engine by Adaptive Server.
5	Writes the errors that display to the log.
6	Traces information about text indexes. Writes the search string being passed to Verity to the log, and writes the number of records that the search returns to the log.
7	Traces done packets.
8	Traces calls to the interface between the Full-Text Search engine and the Verity API.
9	Traces SQL parsing.
10	Traces Verity processing.
11	Disables Verity collection optimization.
12	Disables sp_statistics from returning information.
13	Traces backup operations. Available only with Enhanced Full-Text Search Specialty Data Store.
14	Logs Verity status and timing information.
15	Generates ngram index information for collections. ngrams increase the speed of wildcard searches. This trace flag is required for wildcard searches against data in unicode format.
30	This traceflag enables the Verity MaxClean feature that removes out of date collection files. It should only be used during maintenance since it could take extra time and interfere with normal usage. It is enabled in conjuntion with sp_optimize_text_index.

You can enable and disable trace flags interactively, using the remote procedure calls (RPCs) sp\_traceon and sp\_traceoff in the Full-Text Search engine.

To execute sp\_traceon, use the following syntax:

textserver...sp\_traceon 1,2,3,4

where textserver is the name of the Full-Text Search engine.

The traceflags will stay active until the session is terminated or until the sp\_traceoff RPC is executed using the specific traceflag. To set a traceflag permanently, either set it in the config file or use the sp\_text\_configure command.

### **Setting Open Server Trace Flags**

Use the srv\_traceflags parameter to turn on trace flags to log Open Server diagnostic information. Open Server trace flags are described in Table 6-10.

Table 6-10: Open Server trace flags

Trace	<u> </u>
Flag	Description
1	Traces TDS headers.
2	Traces TDS data.
3	Traces attention events.
4	Traces message queues.
5	Traces TDS tokens.
6	Traces Open Server events.
7	Traces deferred event queues.
8	Traces network requests.

For example, with the Enhanced Full-Text Search engine, run the following:

```
sp_text_configure KRAZYKAT, 'srv_traceflags', '3'
```

### **Setting Case Sensitivity**

By default, the Full-Text Search engine is case sensitive. This means you must enter identifiers in the same case or they are not recognized. For example, if you have a table named blurbs (lowercase), you cannot issue an sp\_create\_text\_index command that specifies the table name BLURBS. You must issue a command that uses the same case for the table name argument:

```
sp_create_text_index "KRAZYKAT", "i_blurbs", "blurbs", "", "copy"
```

With Enhanced Full-Text Search engine, use the nocase parameter to set the case sensitivity of the Full-Text Search engine. 0 indicates case sensitive; 1 indicates case insensitive. Set the nocase parameter to the sort order case sensitivity in Adaptive Server.

#### For example:

```
sp_text_configure KRAZYKAT, 'nocase', '1'
changes the KRAZYKAT server to case insensitive.
```

**Note** The nocase parameter does not affect the case sensitivity of the Verity query. For information on Verity case sensitivity, see "Considerations When Using Verity Operators" on page 51.

# Backup and Recovery for the Enhanced Full-Text Search Engine

Backup and recovery for the Enhanced Full-Text Search Specialty Data Store is automated with the sp\_text\_dump\_database and sp\_text\_load\_index system procedures. These system procedures provide a seamless interface for maintaining data and text index integrity.

The Adaptive Server user database and the Verity collections are physically separate. Backing up your user database does *not* back up the Verity collections, and restoring your database from a backup does *not* restore your Verity collections. The backup and recovery procedures described in Chapter 21, "Backing Up and Restoring User Databases," of the *System Administration Guide* apply only to the user database and the text\_db database in Adaptive Server.

Follow the recommended schedule for backing up your databases, as described in Chapter 20, "Developing a Backup and Recovery Plan," of the *System Administration Guide*. Sybase recommends that when you back up a user database with text indexes, you also back up:

The text\_db database

The text indexes

**Note** You do not have to back up the user database and text indexes at the same time to recover the text indexes. However, you must restore the user database before you restore the text index. This restores the text\_events table, which the sp\_text\_load\_index system procedure uses to bring the text indexes in sync with the user database.

A regular backup schedule ensures the integrity of the text indexes, the Adaptive Server data, and the text\_events table, all of which are integral to recovering your text indexes without having to drop and re-create them.

### **Customizable Backup and Restore**

backCmd and restoreCmd allow customizable backup and restore commands to be used instead of tar or zip commands when backing up collection files. If these two parameters are blank, the default commands are used, otherwise the specified command is executed. String substitution is performed before execution to allow specification of input and output directories and collection identification. The string substitution is defined as follows:

- \${backDir} is replaced by the *backup* directory specified as the "backDir" configuration parameter.
- \${collDir} is replaced by the full path name for the collection
- \${colID} is replaced by the collection ID which is the full name of the backup file.

# **Backing Up Verity Collections**

The sp\_text\_dump\_database system procedure backs up collections and (optionally) the user and text\_db databases. sp\_text\_dump\_database also maintains the text\_events table by deleting entries that are no longer needed for recovery. It is available only with the Enhanced Full-Text Search engine.

During a backup, the Full-Text Search engine processes queries, but defers any update requests until the backup is complete. This eliminates the need to shut down and restart the Full-Text Search engine.

Run sp\_text\_dump\_database from the database containing the text indexes you are backing up. Make sure all the required servers are running when issuing the sp\_text\_dump\_database command. sp\_text\_dump\_database unconditionally backs up all indexes of all enhanced text servers. The backup of the text indexes is placed in the directory specified in the backDir configuration parameter. The output of the dump database command is written to the Full-Text Search error log. Sybase recommends dumping the current database and the text\_db database at the time the text indexes are backed up. However, this is optional.

For example, to back up the text indexes, the sample\_colors\_db database to the /work2/sybase/colorsbackup directory, and the text\_db database to the /work2/sybase/textdbbackup directory, enter:

```
sp_text_dump_database @backupdbs =
INDEXES_AND_DATABASES, @current_to = "to
'/work2/sybase/colorsbackup'", @textdb_to="to
'/work2/sybase/textdbbackkup'"
```

**Note** It is important to back up the text\_db database whenever text indexes are backed up, since that database contains the metadata for all text indexes.

sp\_text\_dump\_database may fail on Solaris if the required file size is greater than 2GB.

For more information, see sp\_text\_dump\_database on page 151.

### Restoring Collections and Text Indexes from Backup

The sp\_text\_load\_index system procedure restores text indexes that have been backed up with the sp\_text\_dump\_database system procedure.

As Database Administrator, perform the following procedures to restore your Verity collections:

- 1 Restore your Adaptive Server user database and text\_db database. This returns the source tables, metadata, and text\_events table to a consistent and predictable state. Follow the procedures described in Chapter 21, "Backing Up and Restoring User Databases," in the System Administration Guide, to restore user and text\_db databases.
- 2 Run sp\_text\_load\_index to restore the Verity collection from the most recent index dump. The procedure resets the status of all text\_events table entries made since the last index dump to "unprocessed" and notifies the Full-Text Search engine to process those events.

#### Example:

To restore the sample\_colors\_db database and all of its text indexes:

1 Restore the text\_db database:

```
1> use master
2> go
1> load database text_db from '/work2/sybase/textdbbackkup'
2> go
```

2 Restore the sample\_colors\_db database:

```
1> load database sample_colors_db from '/work2/sybase/colorsbackup'
2> go
```

3 Bring the text\_db and sample\_colors\_db databases online:

```
1> online database text_db
2> online database sample_colors_db
3> go
```

4 Restore the text index:

```
1> use sample_colors_db
2> go
1> sp_text_load_index
2> go
```

For more information, see sp\_text\_load\_index on page 155.

# CHAPTER 7 Performance and Tuning

The Full-Text Search engine is shipped with a default configuration. You can optimize the performance of the Full-Text Search engine by altering the default configuration so that it better reflects the needs of your site. This chapter describes ways in which you can enhance performance.

#### Topics include:

Topic	Page
Updating Existing Indexes	
Increasing Query Performance	80
Reconfiguring Adaptive Server	81
Reconfiguring the Full-Text Search Engine	
Using sp_text_notify	83
Configuring Multiple Full-Text Search Engines	84

# **Updating Existing Indexes**

The amount of time it takes to update records in a text index can be reduced by enabling (turning on) trace flag 11 or trace flag 12, or both:

Enabling trace flag 11 disables Verity collection optimization. This
means that Verity does not optimize the text index after you issue
sp\_text\_notify, which is a performance gain. If trace flag 11 is turned
off (the default), the Full-Text Search engine calls Verity to optimize
the text index at the end of sp\_text\_notify processing, which can delay
the completion of sp\_text\_notify.

With Enhanced Full-Text Search Specialty Data Store, you can use the sp\_optimize\_text\_index system procedure to optimize a text index at a later time if trace flag 11 is enabled. (For more information, see sp\_optimize\_text\_index on page 144.)  Enabling trace flag 12 disables the Full-Text Search engine from returning sp\_statistics information. If trace flag 12 is turned off (the default), an update statistics command is issued to the Full-Text Search engine, which can delay the completion of sp\_text\_notify.

If updates to the text index occur as often as every few seconds, you may improve performance by disabling the update statistics processing and the Verity optimization, or both, for most of the updates.

Trace flags 11 and 12 can be enabled and disabled interactively using the remote procedure calls sp\_traceon and sp\_traceoff in the Full-Text Search engine.

# **Increasing Query Performance**

Two issues can significantly improve query performance:

- Limiting the number of rows returned by the Full-Text Search engine
- Ensuring the correct join order for queries

### **Limiting the Number of Rows**

Use the max\_docs pseudo column to limit the number of rows returned by the Full-Text Search engine. The fewer the number of rows returned by the Full-Text Search engine, the faster Adaptive Server can process the join between the source table and the index table.

### **Ensuring the Correct Join Order for Queries**

The more tables and text indexes that are listed in a join, the greater the chance that the query will run slowly because of incorrect join order. Queries run fastest when the text index is queried first during a join between the text index and one or more tables.

To ensure correct join order:

 Make sure that a unique clustered or nonclustered index is created on the IDENTITY column of the table being indexed Limit joins to one base table and one text index

If a query is running slowly, use showplan or enable trace flag 11205, and examine the join order. Trace flag 11205 dumps remote queries to the Adaptive Server error log file. The fastest queries contain an index\_any search condition in the where clause and query the text index first.

The slowest queries contain the id column in the text index where clause and query the indexed table first. In this case, rewrite the query or use forceplan to force the join order that is listed in your query. For more information about forceplan, see Chapter 10, "Advanced Optimizing Techniques," in the *Performance and Tuning Guide*.

# **Reconfiguring Adaptive Server**

You can improve the performance of the Full-Text Search engine by resetting the following Adaptive Server configuration parameters. (For information about setting configuration parameters with sp\_configure, see Chapter 11,"Setting Configuration Parameters," in the *System Administration Guide*.)

#### cis cursor rows

The cis cursor rows parameter specifies the number of rows received by Adaptive Server during a single fetch operation. The default number for cis cursor rows is 50. Increasing this number increases the number of rows received by Adaptive Server from the Full-Text Search engine during a fetch operation. However, keep in mind that the larger the number you set for cis cursor rows, the more memory Adaptive Server will dynamically allocate to return the result set.

### cis packet size

The cis packet size parameter determines the number of bytes contained in a single network packet. The default for cis packet size is 512. You must specify values for this parameter in multiples of 512. Increasing this parameter improves the performance of the Full-Text Search engine because, with a larger packet size, it returns fewer packets for each query. However, keep in mind that the larger the number you set for cis packet size, the more memory Adaptive Server will allocate for that parameter.

The cis packet size parameter is dynamic; you do not need to reboot Adaptive Server for this parameter to take effect.

**Note** If you change the cis packet size, you must also change the max\_packetsize parameter in the Full-Text Search engine configuration file to the same value. If CIS is used to access other remote servers, the max network packet size on those servers must be increased as well.

You need to reboot the Full-Text Search engine for the max\_packetsize parameter to take effect.

# **Reconfiguring the Full-Text Search Engine**

You can improve the performance of the Full-Text Search engine by reconfiguring the following Full-Text Search engine configuration parameters (see "Modifying the Configuration Parameters" on page 67):

### batch\_size

The batch\_size configuration parameter determines the number of rows per batch the Full-Text Search engine indexes. batch\_size has a default of 500 (that is, 500 rows of data indexed per batch). Performance improves if you increase the size of the batches that are indexed. However, the larger the batch size, the more memory the Full-Text Search engine allocates for this parameter.

When considering how large to set batch\_size, consider the size of the data on which you are creating a text index. When creating the text index, the Full-Text Search engine allocates memory equal to (in bytes):

(amount of space needed for data) x (batch\_size) = memory used

For example, if the data you are indexing is 10,000 bytes per row, and batch\_size is set to 500, then the Full-Text Search engine will need to allocate almost 5MB of memory when creating the text index.

Base the batch size you choose on the typical size of your data and the amount of memory available on your machine.

#### min sessions and max sessions

min\_sessions and max\_sessions determine the minimum and maximum number of user connections allowed for the Full-Text Search engine. Each user connection requires about 5MB of memory. Do not set max\_sessions to an amount that exceeds your available memory. Also, because the memory for min\_sessions is allocated at start-up, if you set the number for min\_sessions extremely high (to allow for a large number of user connections), a large percentage of your memory will be dedicated to user connections for the Full-Text Search engine.

You may improve the performance of the Full-Text Search engine by setting min\_sessions equal to the average number of user sessions that will be used. Doing so prevents the Full-Text Search engine from having to allocate memory at the start of the user session.

# Using sp\_text\_notify

Review the needs of your site before you decide how often to issue sp\_text\_notify.

Using the sp\_text\_notify system procedure produces a load on the Full-Text Search engine as the system procedure reads the data and updates the text collections. Depending on the size of this load, the performance hit for issuing sp\_text\_notify can be substantial. Because of the performance implications, you must determine how up to date the indexes need to be. If they need to be current (close to real-time), then you will have to issue sp\_text\_notify frequently (as often as every 5 seconds). However, if your indexes do not need to be that current, it may be prudent to wait until the system is not active before you issue sp\_text\_notify.

**Note** You cannot issue sp\_text\_notify from within a transaction.

# **Configuring Multiple Full-Text Search Engines**

For tables that are used frequently, you can improve performance by placing the text indexes for these tables on separate Full-Text Search engines. Performance improves because users can spread their queries over a number of Full-Text Search engines, instead of sending all queries to a single engine. Each Adaptive Server can connect to multiple Full-Text Search engines, but each Full-Text Search engine can connect to only one Adaptive Server.

### Creating Multiple Full-Text Search Engines at Start-Up

If you are initially creating multiple Full-Text Search engines, you can edit the installtextserver script so that it includes all of those Full-Text Search engines. For more information, see "Editing the installtextserver Script" on page 15.

### **Adding Full-Text Search Engines**

You can add Full-Text Search engines at a later date by issuing the sp\_addserver command from isql. The sp\_addserver command has the following syntax:

```
sp_addserver server_name [, server_class [,
```

```
physical_name]]
```

#### where:

- *server\_name* is the name used to address the server on your system (in this case, the Full-Text Search engine).
- *server\_class* identifies the category of server being added. For the Full-Text Search engine, the value is "sds".
- physical\_name is the name in the interfaces file used by the server server name.

For more information, see sp\_addserver in the *Adaptive Server Reference Manual*.

For example, to add a Full-Text Search engine named BLUE, enter:

```
sp_addserver BLUE, sds, BLUE
```

After you configure and start the Full-Text Search engine, you can use the following syntax to see if you can connect to the Full-Text Search engine from the Adaptive Server:

```
server_name...sp_show_text_online
```

For example, to connect to a server named BLUE, enter:

```
BLUE...sp_show_text_online
```

# **Configuring Additional Full-Text Search Engines**

Follow the steps described in "Configuring the Full-Text Search Engine" in the *Installation and Release Bulletin* for your platform, to configure additional Full-Text Search engines. Each Full-Text Search engine requires its own:

- Interfaces file entry
- Configuration file

All Full-Text Search engines use the same database (named text\_db by default) for storing text index metadata and the same vesaux and vesauxcol tables.

# **Multiple Users**

The following tips will help avoid deadlocks with multiple users:

1 Make sure the ASE is using the same number of connections as the Full-Text Search. 100 is the default.

```
sp_configure "user connections", 100
```

2 Make sure the vesaux, vesauxcol and text\_events tables (in the model, or in each of your new databases) are using row level locking.

For existing tables: alter table table\_name lock datarows

For new tables: create table ... lock datarows

- 3 For large batches of commands, try to break them into smaller transactions.
- 4 If deadlocks still occur, increase the number of locks available to the ASE, and tweak the row lock promotion settings. See the ASE System Administration Guide to assist with setting locks.

# CHAPTER 8 Verity Topics

This chapter is reproduced with permission from Verity. It is a section of Verity documentation provided to give Full-Text Search users insight into the complex issue of Verity Topics.

# What are Topics?

A topic is a grouping of information related to a concept, or a subject area. Topics provide a convenient means by which you can encapsulate knowledge, and make it available to end users as a shared resource. By adding topics to your Verity application, users can more easily perform searches over the subject matter which the topics represent.

Topics are combined to form knowledge bases that represent a catalogue of knowledge that users can tap into when performing searches. Knowledge bases offer users the ability to find the information they want without having to compose sophisticated queries using complex syntax.

### **Topic Organization**

Topics organize groups of related search criteria in a format similar to that of an outline. Operators and modifiers act as the glue that joins related groups of search criteria. You can create topics as independent units, or as units with relationships to other topics in a hierarchical structure.

### **Weight Assignments**

You can even give some groups of search criteria more weight than other groups of search criteria in a topic's structure. Assigning weight to search criteria affects the importance of documents selected in a search; the closer a document is to the top of the results list, the more important, or relevant, the document is to the search criteria. A search criteria weight is a number between 0.01 and 1.00. The position of a selected document in the results list can help you determine at a glance how relevant the document is compared to the search criteria.

# **Using a Topic Outline File**

You can compose topics by creating a topic outline file.

A topic outline file is an ASCII text file in a structured format that contains topic definitions. A topic outline file might appear as follows:

```
$Control:1
art <Accrue>
*performing-arts <Accrue>
**0.80 "ballet"
**0.50 "drama"
**0.50 'dance'
**0.80 "opera"
**0.80 "symphony"
**0.90 "chamber music"
**"Isaac Stern"
*film <Accrue>
**directors <Filter>
/definition="title CONTAINS Truffaut"
*visual-arts <Accrue>
literature <Accrue>
philosophy <Accrue>
language <Accrue>
history <Accrue>
$$
```

You can create a topic outline file with any text editor.

# **Making Topics Available**

The topics you make available to users must exist within a topic set that is generated using the mktopics utility. Verity topic sets generated by mktopics can be used by any Verity application. A single topic set supports a maximum of 20,000 topic definitions, and the exact number of topics allowed for one topic set depends on the Verity query language used to define them.

### **Setup Process**

Making topics available to users is a three-step process, as outlined below.

- 1 Create topic definitions using a topic outline file.
- 2 Generate a topic set. You can create a topic set using the mktopics utility. The mktopics utility creates the topic set and can also index the topics over a specific collection.
- 3 Import the topic set to the Full-Text Search engine.

# **Knowledge Bases of Topics**

This section discusses the principle features of knowledge bases, and the organization format used to define topics for them.

The following aspects of topic knowledge bases are covered:

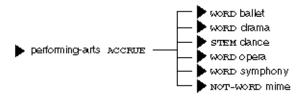

- Combining topics into a knowledge base
- The structure of topics
- The relationship between topics and subtopics
- Topic types
- Naming topics

### **Combining Topics into a Knowledge Base**

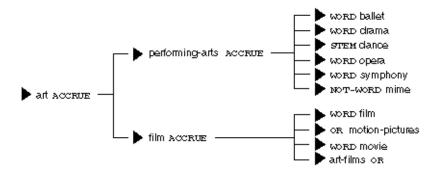

A topic is simply a grouping of information related to a concept, or a subject area. A knowledge base is a grouping of these concepts called topics. Combining topics into a knowledge base provides users with the ability to look up concepts saved as topics in a convenient fashion.

The subject area of a topic is typically identified by the topic's name. In the example below, the subject of the topic is *performing-arts*. This topic is composed of two structural elements, its name, *performing-arts*, and its evidence topics, *ballet*, *musical*, *dance*, *opera*, *symphony*, and *drama*.

Operators and modifiers act as the glue that joins related evidence topics. Operators represent logic to be applied to evidence topics. This logic defines the qualifications of the kinds of documents you want to find. Modifiers apply further logic to evidence topics. For example, a modifier can specify that documents containing an evidence topic not be included in the list of results.

A topic's structure becomes more sophisticated as topics are added to it. In the next example, the topic film has been added to the structure to form what is now the top-level topic, art. In this structure, performing-arts and film are subtopics of the topic art.

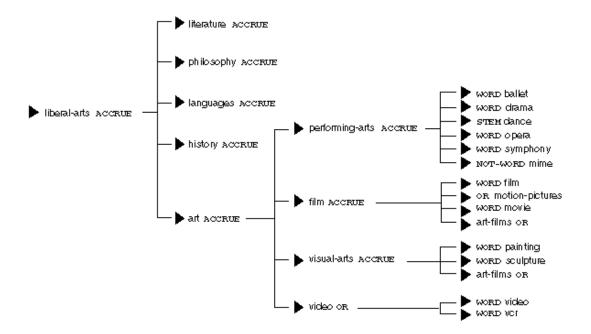

Sophisticated topics are composed of top-level topics, subtopics, and evidence topics. These elements determine the related subject areas of a topic. Typically, a knowledge base consists of several top-level topics. Note that subtopics and evidence topics can be used by multiple top-level topics.

# **Structure of Topics**

The structure of topics affects how the topic is interpreted during search processing. Designing topics so that they accurately express a concept involves defining a topic structure with the components described below.

### **Top-Level Topics**

Top-level topics are the highest topics defined in a topic structure. Top-level topics represent the subject areas you want a Verity search agent to find. In the example below you could think of, literature, philosophy, languages, history, and art as top-level subtopics that comprise the top-level topic, liberal-arts.

### **Subtopics**

Subtopics form the levels between top-level topics and evidence topics. The name of a subtopic should identify the subject area that its subtopics or evidence topics combine to describe. For example, the subtopic visual-arts includes several related words, or evidence topics, as shown below:

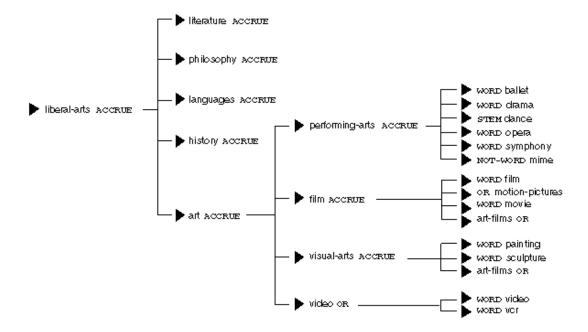

### **Evidence Topics**

Evidence topics are the lowest units of a topic structure. Evidence topics are strings, made up of combinations of alphanumeric characters. An evidence topic can contain up to 128 alphanumeric characters.

## **Topic and Subtopic Relationships**

Each topic and its associated subtopics form a hierarchical parent and child relationship. In the example below, the subtopics performing-arts, film, visual-arts, and video are children of the art topic. The art topic itself is a child of the liberal-arts topic. The liberal-arts topic could in turn be a child of successively higher parent topics within the structure.

When you use a topic to perform a search, the subject area defined by the topic includes its subtopics, their subtopics, and so on, down to the evidence topics of the structure. Topics that are not direct descendants of the topic you use are not included in the search.

In the example above, for instance, a search using the film topic would cause the Verity search engine to find documents containing information on film, motion pictures, movies, and art films. In this example, the search would not find documents related to the performing-arts, visual-arts, or video topics since these topics are not children, of the film topic. However, if the art topic was used, the search would find documents related to all the art topic's children, which includes performing-arts, film, visual-arts, and video.

# **Maximum Number of Topics**

A single topic set representing a knowledge base can consist of as many as 20,000 topics. This includes top-level topics, subtopics, and evidence topics. Topics containing as many as 1,000 subtopics may exceed memory limitations when used in a search.

# **Topic Naming Issues**

Note the following issues surrounding the naming of topics.

#### **Topic Name Length**

A topic name can contain up to 128 alphanumeric characters, including hyphens and underscores.

#### **Case Sensitivity**

Topic names and evidence topics are normally case-insensitive. You can name a evidence topic using all caps, as in APPLE, initial caps, as in Apple, or all lower-case, as in apple. Case is not considered when a search is performed. Thus, if your evidence topic is entered as APPLE, the Verity search engine will select documents containing "APPLE", "Apple", or "apple".

You can, however, use the CASE modifier to specify that case match the entry of a evidence topic.

# **Verity Query Language**

This section describes the Verity Query Language, consisting of operators and modifiers that you can use to create topics. Operators represent logic to be applied to search elements which can be combined to create a topic. This logic defines the qualifications of the kinds of documents you want to find. Modifiers apply further logic to search elements. For example, a modifier can specify that a search element be case-sensitive.

The information in this section includes the following:

- Query Language Summary
- Operator Precedence Rules
- Sample Topic Outlines
- Operator Reference
- Modifier Reference

# **Query Language Summary**

The Verity Query Language consists of operators and modifiers. Both operators and modifiers represent logic to be applied to a search element. This logic defines the qualifications a document must meet to be retrieved. Operators are classified by their type, as follows:

- Evidence operators
- Proximity operators
- Relational operators
- Concept operators
- Boolean operators

Modifiers extend the logic applied by operators and are used in combination with operators.

#### **Evidence Operators**

Evidence operators expand a search word into a list of related words which are then searched for as well. When you perform a search using an evidence operator, documents containing one or more occurrences of the words in the expanded word list are documents containing the word specified, as well as its synonyms. Documents retrieved using evidence operators are not relevance-ranked unless you use the MANY modifier. See "MANY Modifier" in this section for information. The following table describes each evidence operator.

Table 8-1: Evidence Operators

Operator Name	Description
WORD	Selects documents that include one or more instances of a word you specify.
STEM	Selects documents that include one or more variations of the search word you specify.
THESAURUS	Selects documents that contain one or more synonyms of the word you specify.
WILDCARD	Selects documents that contain matches to a character string containing variables.
SOUNDEX	Selects documents that include one or more words that "sound like," or whose letter pattern is similar to, the word specified.
NEAR/N	Expands the search to include the word you enter plus words that are similar to the query term. This operator performs "approximate pattern matching" to identify similar words.

### **Proximity Operators**

Proximity operators specify the relative location of specific words in the document; that is, specified words must be in the same phrase, paragraph, or sentence for a document to be retrieved. In the case of the NEAR and NEAR/N operators, retrieved documents are relevance-ranked based on the proximity of the specified words. When proximity operators are nested, the ones with the broadest scope should be used first; that is, phrases or individual words can appear within SENTENCE or PARAGRAPH operators, and SENTENCE operators can appear within PARAGRAPH operators. The following table describes each proximity operator.

Table 8-2: Proximity Operators

Operator Name Description		
IN	Selects documents that contain specified values in one or more document zones. A document zone represents a region of a document, such as the document's summary, date, or body text.	
PHRASE	Selects documents that include a phrase you specify. A phrase is a grouping of two or more words that occur in a specific order.	
SENTENCE	Selects documents that include all of the words you specify within a sentence.	
PARAGRAPH	Selects documents that include all of the search elements you specify within a paragraph.	
NEAR	Selects documents containing specified search terms within close proximity to each other.	
NEAR/N	Selects documents containing two or more words within N number of words of each other, where N is an integer.	

#### **Relational Operators**

Relational operators search document fields (such as AUTHOR) that have been defined in the collection. These operators perform a filtering function by selecting documents that contain specified field values. The fields that are used with relational operators can contain alphanumeric characters. Documents retrieved using relational operators are not relevance-ranked, and you cannot use the MANY modifier with relational operators.

When creating topics, relational operators are always used in conjunction with the special FILTER operator. See the example under the topic "visual-arts" in "Sample Topic Outlines" later in this section for the proper syntax.

A number of relational operators are available for numeric and date comparisons, including the following: = (equals), > (greater than), >= (greater than or equal to), < (less than), <= (less than or equal to).

A number of relational operators are available for text comparisons, including the following.

Table 8-3: Relational Operators

Operator Name	Description
CONTAINS	Selects documents by matching the word or phrase you specify with values stored in a specific document field.
MATCHES	Selects documents by matching the character string you specify with values stored in a specific document field.
STARTS	Selects documents by matching the character string you specify with the starting characters of the values stored in a specific document field.
ENDS	Selects documents by matching the character string you specify with the ending characters of the values stored in a specific document field.
SUBSTRING	Selects documents by matching the character string you specify with a portion of the strings of the values stored in a specific document field.

#### **Concept Operators**

Concept operators combine the meaning of search elements to identify a concept in a document. Documents retrieved using concept operators are relevance-ranked. The following table describes each concept operator.

Table 8-4: Concept Operators

Operator Name	Description Selects documents that contain all of the search elements you specify.	
AND		
OR	Selects documents that show evidence of at least one of your search elements.	
ACCRUE	Selects documents that include at least one of the search elements you specify.	

### **Boolean Operators**

Boolean operators can be assigned to topics to retrieve documents containing any or all of the children of that topic. Unlike topics created using the concept operators, Boolean operators do not accept weights. The following table describes each Boolean operator..

Table 8-5: Boolean Operators

Operator Name	Description
ALL	Selects documents that contain all children of a topic.
ANY	Selects documents that contain at least one of the children of a topic.

#### **Modifiers**

Modifiers affect the behavior of operators. The following table describes each modifier..

Table 8-6: Modifiers

Operator Name	Description
CASE	Performs a case-sensitive search.
MANY	Counts the density of words or phrases in a document and produces a relevance-ranked score for the retrieved documents.
NOT	Excludes documents that show evidence of the specified word or phrase.
ORDER	Specifies the order in which search elements must occur.

# **Operator Precedence Rules**

The Verity search engine uses precedence rules to determine how operators can be assigned. These rules state that some operators rank higher than others when assigned to topics, and affect how document selections are performed.

The following table describes how precedence rules apply to operators.

Table 8-7: Precedence rules

Operator	Precedence	How Precedence is Determined		
AND	Highest	The concept operators take the highest		
OR	precedence	precedence over the other operators.		
ACCRUE		Thus, subtopics of topics using these operators can be assigned any of the		
		operators listed below under		
		"incremental precedence" or "lowest precedence."		
ALL	Incremental	The proximity operators refer to		
PARAGRAPH	precedence	incremental ranges which exist within		
SENTENCE	(in descending	a document. Subtopics of topics using these operators can be assigned their		
NEAR	order)	next lowest operator in the precedence		
NEAR/N		order. Thus, a phrase takes precedence		
PHRASE		over a word; a sentence takes		
ANY		precedence over a phrase or a word; and a paragraph takes precedence over		
		a sentence, a phrase, or a word.		
WORD	Lowest	The evidence operators reside at the		
STEM	precedence	lowest level in a topic structure.		
SOUNDEX		Because evidence operators are used with words contained in documents,		
WILDCARD		these operators all have the same		
THESAURUS		precedence.		

To avoid a precedence violation, do not use ANY or ALL in a parent topic whose child topic includes a concept operator (AND, OR, ACCRUE). Topics that use ANY or ALL cannot have variable weights assigned to them, so you cannot use these operators in a parent topic with any child topic that allows variable weights (such as AND, OR, ACCRUE). Topics using ANY and ALL limit evaluation to present or not present (a score of 0.00 or 1.00). If the criteria are met, the children of these topics get an automatic score of 1.00; if the criteria are not met, the children of these topics get an automatic score of 0.00; so it is not meaningful to assign these children variable weights such as 0.80.

# **Sample Topic Outlines**

The following are the same topics as you would create them in a topic outline file:

```
$Control:1
art <Accrue>
*performing-arts <Or>
**0.80 "drama"
**0.50 "theater"
**0.80 'dance'
*film <And>
**0.90 "cinema"
**0.90 "documentary"
**newsreel <Filter>
/definition="DATE >= 05/01/96"
*film-makers <Accrue>
**"Woody Allen"
*film-making <Paragraph>
**"direct"
**"produce"
*visual-arts <Accrue>
**sculpture <In>
/zonespec="title"
**painters <Filter>
/definition="Title MATCHES Famous Painters"
**<Thesaurus>
/wordtext="paint"
literature <Accrue>
*novels <Near>
**0.80 "Proust"
**0.80 "Remembrance" <Case>
*american-novel <Sentence>
**"American"
**"novel"
history <Accrue>
*<Wildcard>
/wordtext="histor*"
music <Accrue>
*jazz
**"bebop"
**<Not> "fusion"
*classical
**"Italian opera"
$$
```

# **Operator Reference**

Each operator is listed below alphabetically. Examples for many of these operators can be found in the topic outline in the previous section.

# **ACCRUE Operator**

Selects documents that include at least one of the search elements you specify. Valid search elements are two or more words or phrases. Selected documents are relevance-ranked.

The ACCRUE operator scores selected documents according to the presence of each search element in the document using a "the more, the better" approach: the more search elements found in the document, the better the document's score. Several examples of the ACCRUE operator appear in the sample outline file in the previous section, "Sample Topic Outlines."

# **ALL Operator**

Selects documents that include all of the search elements you specify. Unlike the ACCRUE operator, you cannot assign weights when you use the ALL operator.

# **AND Operator**

Selects documents that contain all of the search elements you specify. Documents selected using the AND operator are relevance-ranked. The example in "Sample Topic Outlines" shows how the AND operator might be used with the topic "film." In the example, only those documents that contain both search words and a date greater than or equal to 05/01/96 are selected and ranked according to their score.

# **ANY Operator**

Selects documents include at least one of the search elements you specify. Unlike the ACCRUE operator, you cannot assign weights when you use the ANY operator.

### **CONTAINS Operator**

Selects documents by matching the word or phrase you specify with values stored in a specific document field. When you use the CONTAINS operator, you specify the field name to search, and the word or phrase to search for.

With the CONTAINS operator, the words stored in a document field are interpreted as individual, sequential units. You may specify one or more of these units as search criteria. To specify multiple words, each word must be sequential and contiguous, and must be separated by a blank space. Use CONTAINS with the FILTER operator.

The syntax for CONTAINS is the same as that for MATCHES. See the example for MATCHES under the topic "visual arts" in "Sample Topic Outlines." The example assumes that the field TITLE has been created for the collection.

The CONTAINS operator does not recognize non-alphanumeric characters. The CONTAINS operator interprets non-alphanumeric characters as a space and treats the separated values as individual units. For example, if you have defined a slash (/) as a valid character, and you enter search criteria that include this character, as in OS/2, "OS" and "2" are treated as individual units.

Note that the CONTAINS operator does not refer to the *style.lex* file for the definition of which characters are included in a word.

### **ENDS Operator**

Selects documents by matching the character string you specify. Use ENDS with the FILTER operator. The syntax for ENDS is the same as that for MATCHES. See the example for MATCHES under the topic "visual arts" in "Sample Topic Outlines." The example assumes that the field TITLE has been created for the collection.

# = (EQUALS) Operator

Selects documents whose document field values are exactly the same as the search string you specify. Use EQUALS with the FILTER operator. The syntax for EQUALS is the same as that for GREATER THAN OR EQUAL TO. See the example for GREATER THAN OR EQUAL TO under the topic "film" in "Sample Topic Outlines." The example assumes that the field DATE has been created for the collection.

# **FILTER Operator**

The special FILTER operator is used in conjunction with the relational operators to do field searches. See the example under the topic "visual-arts" in "Sample Topic Outlines" for the proper syntax.

# > (GREATER THAN) Operator

Selects documents whose document field values are greater than the search string you specify. Use GREATER THAN with the FILTER operator. The syntax for GREATER THAN is the same as that for GREATER THAN OR EQUAL TO. See the example for GREATER THAN OR EQUAL TO under the topic "film" in "Sample Topic Outlines." The example assumes that the field DATE has been created for the collection.

# >= (GREATER THAN OR EQUAL TO) Operator

Selects documents whose document field values are greater than or equal to the search string you specify. Use GREATER THAN OR EQUAL TO with the FILTER operator. See the example under the topic "film" in "Sample Topic Outlines." The example assumes that the field DATE has been created for the collection.

# < (LESS THAN) Operator

Selects documents whose document field values are less than the search string you specify. Use LESS THAN with the FILTER operator. The syntax for LESS THAN is the same as that for GREATER THAN OR EQUAL TO. See the example for GREATER THAN OR EQUAL TO under the topic "film" on "Sample Topic Outlines." The example assumes that the field DATE has been created for the collection.

### <= (LESS THAN OR EQUAL TO) Operator

Selects documents whose document field values are less than or equal to the search string you specify. Use LESS THAN OR EQUAL TO with the FILTER operator. The syntax for LESS THAN OR EQUAL TO is the same as that for GREATER THAN OR EQUAL TO. See the example for GREATER THAN OR EQUAL TO under the topic "film" on "Sample Topic Outlines." The example assumes that the field DATE has been created for the collection.

#### **IN Operator**

Selects documents that contain specified values in one or more document zones. A document zone represents a region of a document, such as the document's summary, date, or body text. The IN operator only works if document zones have been defined in your collections. If you use the IN operator to search collections for which zones are not defined, no documents will be selected. In addition, the zone name you specify must match the zone names defined in your collections. Consult your collection administrator to determine which zones have been defined for specific collections. The example in "Sample Topic Outlines" shows how IN might be used with the word "sculpture" and the TITLE zone.

### **MATCHES Operator**

Selects documents by matching the character string you specify with values stored in a specific document field. When you use the MATCHES operator, you specify the field name to search, and the word, phrase, or number to search for.

Unlike the CONTAINS operator, the search criteria you specify with a MATCHES operator must match the field value exactly for a document to be selected. With the MATCHES operator, any occurrence of a search string that appears as a portion of a value is not selected; only values matching the entire search string are selected.

You can use question marks (?) to represent individual variable characters within a string, and asterisks (\*) to match multiple variable characters within a string.

Use MATCHES with the FILTER operator. The example in "Sample Topic Outlines" shows how MATCHES might be used with the phrase "famous painters" and the TITLE field. The example assumes that the field TITLE has been created for the collection.

# **NEAR Operator**

Selects documents containing specified search terms within close proximity to each other. Document scores are calculated based on the relative number of words between search terms. For example, if the search expression includes two words, and those words occur next to each other in a document (so that the region size is two words long), then the score assigned to that document is 1.00. Thus, the document with the smallest region containing all search terms always receives the highest score. Documents whose search terms are not within 1000 words of each other are not selected, since the search terms are probably too far apart to be meaningful within the context of the document.

The NEAR operator is similar to the other proximity operators in the sense that the search words you enter must be found within close proximity of one another. However, unlike other proximity operators, the NEAR operator calculates relative proximity and assigns scores based on its calculations.

The example in "Sample Topic Outlines" shows how NEAR might be used with the topic "novels."

# **NEAR/N Operator**

Selects documents containing two or more words within N number of words of each other, where N is an integer. Document scores are calculated based on the relative distance of the specified words when they are separated by N words or less. Documents containing the specified words separated by more than N words are not selected. For example, if the search expression NEAR/5 is used to find two words within five words of each other, a document that has the specified words within three words of each other is scored higher than a document that has the specified words within five words of each other.

The N variable can be an integer between 1 and 1,024, where NEAR/1 searches for two words that are next to each other. Note that if N is 1,000 or above, you must specify its value without commas, as in NEAR/1000.

The NEAR/N operator is similar to the other proximity operators in the sense that the search words you enter must be found within a close proximity of one another. However, unlike other proximity operators, the NEAR/N operator assigns scores based on relative proximity.

# **OR Operator**

Selects documents that show evidence of at least one of your search elements. Documents selected using the OR operator are relevance-ranked. The example in "Sample Topic Outlines" shows how you might use OR with the topic "performing-arts."

### **PARAGRAPH Operator**

Selects documents that include all of the search elements you specify within a paragraph. Valid search elements are two or more words or phrases. You can specify search elements in a sequential or a random order. Documents are retrieved as long as search elements appear in the same paragraph. The example in "Sample Topic Outlines" shows you how you might use PARAGRAPH with the topic "film-making."

### **PHRASE Operator**

Selects documents that include a phrase you specify. A phrase is a grouping of two or more words that occur in a specific order. You must use the PHRASE operator when you enter more than one word in the evidence field. Words with the PHRASE operator are displayed in double quotes. The example in "Sample Topic Outlines" shows "Woody Allen" and "Italian opera" as uses of the PHRASE operator.

### **SENTENCE Operator**

Selects documents that include all of the words you specify within a sentence. You can specify search elements in a sequential or a random order. Documents are retrieved as long as search elements appear in the same sentence. The example in "Sample Topic Outlines" shows how you how you might use SENTENCE with the topic "american-novel."

# **SOUNDEX Operator**

Selects documents that include one or more words that "sound like," or whose letter pattern is similar to, the word specified. Words have to start with the same letter as the word you specify to be selected. For example, when you use SOUNDEX with "sale," the documents selected will include words such as "sale," "sell," "seal," "shell," "soul," and "scale." Documents are not relevance-ranked unless the MANY modifier is used.

### STARTS Operator

Selects documents by matching the character string you specify with the starting characters of the values stored in a specific document field. Use STARTS with the FILTER operator. The syntax for STARTS is the same as that for MATCHES. See the example for MATCHES under the topic "visual arts" in "Sample Topic Outlines." The example assumes that the field TITLE has been created for the collection.

### **STEM Operator**

Selects documents that include one or more variations of the search word you specify. Words with the STEM operator are displayed in single quotes. In the example in "Sample Topic Outlines," the word "dance" is used with the STEM operator. Documents selected will therefore include words such as "dances," "danced," "and "dancing," as well as "dance."

# **SUBSTRING Operator**

Selects documents by matching the character string you specify with a portion of the strings of the values stored in a specific document field. The characters that comprise the string can occur at the beginning of a field value, within a field value, or at the end of a field value. The syntax for SUBSTRING is the same as that for MATCHES. See the example for MATCHES under the topic "visual arts" in "Sample Topic Outlines." The example assumes that the field TITLE has been created for the collection.

# **THESAURUS Operator**

Selects documents that contain one or more synonyms of the word you specify. For example, when you use the word "altitude" with the THESARUS operator, the documents selected will include words such as "height" and "elevation." Documents are not relevance-ranked unless the MANY modifier is used.

### WILDCARD Operator

Selects documents that contain matches to a character string containing variables. The WILDCARD operator lets you define a search string with variables, which can be used to locate related word matches in documents. The example in "Sample Topic Outlines" shows how you might use the string "histor\*" to search for words such as "history," "historical," and "historian." Documents are not relevance-ranked unless the MANY modifier is used.

# **Using Wildcard Special Characters**

You can use the following wildcard characters to represent variable portions of search strings with the WILDCARD operator.

Table 8-8: Wildcard Special Characters

Character	Function			
?	Specifies one of any alphanumeric character, as in ?an, which locates "ran," "pan," "can," and "ban." Note that it is not necessary to specify the WILDCARD operator when you use the question mark. The question mark is ignored in a set ([]) or in an alternative pattern ({}).			
*	Specifies zero or more of any alphanumeric character, as in corp*, which locates "corporate," "corporation," "corporal," and "corpulent." Note that it is not necessary to specify the WILDCARD operator when you use the asterisk, and you should not use the asterisk to specify the first character of a wildcard string. The asterisk is ignored in a set ([]) or in an alternative pattern ({}).			
[]	Specifies one of any character in a set, as in <wildcard> 'c[auo]t', which locates "cat," "cut," and "cot." Note that you must enclose the word which includes a set in backquotes ('), and there can be no spaces in a set.</wildcard>			
{}	Specifies one of each pattern separated by a comma, as in <wildcard> 'bank{s,er,ing}', which locates "banks," "banker," and "banking." Note that you must enclose the word which includes a pattern in backquotes ('), and there can be no spaces in a set.</wildcard>			
۸	Specifies one of any character not in the set, as in <wildcard> 'st[^oa]ck', which excludes "stock" and "stack" but locates "stick" and "stuck." Note that the caret (^) must be the first character after the left bracket ([) that introduces a set.</wildcard>			
-	Specifies a range of characters in a set, as in <wildcard> 'c[a-r]t', which locates every three-letter word from "cat" to "crt."</wildcard>			

# **Searching for Non-alphanumeric Characters**

Remember that you can only search for non-alphanumeric characters if the style.lex file used to create the collections you are searching is set up to recognize the characters you want to search for. Consult your collection administrator for information.

## **Searching for Wildcard Characters as Literals**

The wildcard characters listed above are interpreted as wildcard characters, not literal characters, unless they are delimited by a backslash (\). If you want a wildcard character to be interpreted as a literal in a wildcard string, you must precede the character with a backslash. For example, to match the literal asterisk (\*) in a wildcard string, you delimit the character as follows:

#### <WILDCARD> a\\*

#### **Searching for Special Characters as Literals**

The following non-alphanumeric characters perform special, internal functions, and by default are not treated as literals in a wildcard string:

- comma,
- left and right parentheses ()
- double quotation mark "
- backslash \
- at sign @
- left curly brace {
- left bracket [
- less than sign <</li>
- · backquote`

To interpret special characters as literals, you must surround the whole wildcard string in backquotes (`). For example, to search for the wildcard string "a{b", you surround the string with backquotes, as follows:

```
<WILDCARD> 'a{b'
```

To search for a wildcard string that includes the literal backquote character (`), you must use two backquotes together and surround the whole wildcard string in backquotes (`), as follows:

```
<WILDCARD> '*n''t'
```

Note that you can only search on backquotes if the style.lex file used to create the collections you are searching is set up to recognize the backquote character. Consult your collection administrator for information.

## **WORD Operator**

Selects documents that include one or more instances of a word you specify. Words with the WORD operator are displayed in double quotes. The example in "Sample Topic Outlines" displays many instances of the WORD operator.

### **Modifier Reference**

Modifiers further specify the behavior of operators. For example, you can use the CASE modifier with an operator to specify that the case of the search word you enter be considered a search element as well. Modifiers include CASE, MANY, NOT, and ORDER, which are described below.

#### **CASE Modifier**

Use the CASE modifier with the WORD or WILDCARD operator to perform a case-sensitive search, based on the case of the word or phrase specified.

By default, documents containing any occurrences of a search word or phrase are retrieved regardless of case. To use the CASE modifier, you simply enter the search word or phrase as you wish it to appear in retrieved documents - in all uppercase letters, in mixed uppercase and lowercase letters, or in all lowercase letters. The example in "Sample Topic Outlines" shows how you might use the word "Remembrance" with the CASE modifier in order to refer to the first word of Proust's novel, Remembrance of Things Past.

#### **MANY Modifier**

Counts the density of words, stemmed variations, or phrases in a document, and produces a relevance-ranked score for retrieved documents. The more occurrences of a word, stem, or phrase proportional to the amount of document text, the higher the score of that document when retrieved. Because the MANY modifier considers density in proportion to document text, a longer document that contains more occurrences of a word may score lower than a shorter document that contains fewer occurrences.

The MANY modifier can be used with the following operators: WORD, WILDCARD, STEM, SOUNDEX, PHRASE, SENTENCE, PARAGRAPH and THESAURUS.

Note that the MANY modifier cannot be used with AND, OR, ACCRUE, or relational operators.

#### **NOT Modifier**

Use the NOT modifier with a word or phrase to exclude documents that show evidence of that word or phrase. The example in "Sample Topic Outlines" shows how you might use the NOT modifier to retrieve documents that mention "bebop" but not "fusion."

#### **ORDER Modifier**

Use the ORDER modifier to express the order in which search elements must occur. If search values do not occur in the specified order in a document, the document is not selected. Always place the ORDER modifier just before the operator.

Note that you can only use the ORDER modifier with the operators ALL, PARAGRAPH, SENTENCE, and NEAR/N.

# Weights and Document Importance

This section describes assigning weights to search criteria in topics, and the affect of weights on selected documents. The specific information covered includes the following:

- Which operators accept weights
- How weights affect importance
- Assigning weights
- Topic scoring and document importance

# **Topic Weights**

When processing a search agent, the Verity search engine calculates a score for each selected document behind the scenes. A document score can be in the range from 1.0 to 0.01. The higher a document's score, the more relevant it is. Using the score assignments for documents selected by a search agent, Verity applications can present relevance-ranked results in descending order to application users.

The ranking of documents is determined by the elements which comprise your search criteria. Document ranking can be affected depending on whether the search criteria includes topics, and whether topics include weights.

When creating topics, you can assign weights to the topic structure to indicate the relative importance of specific aspects of the topic definition. For example, you may be interested in two related subjects, but one subject is more important than another. Note that you do not have to assign weights when you compose topics because default weights are assigned as appropriate when a topic set is indexed. However, by assigning weights you can fine-tune the importance of things you are looking for.

# **Which Operators Accept Weights**

Weights are used in conjunction with operators to compute scores for parent and child topics during a search. The weight you assign to a topic child can be a number between 0.01 and 1.00. A child's weight indicates its importance relative to the other children that have been defined for its parent. The higher a child's weight, the more important that child is considered to be with respect to its siblings.

Weights can only be assigned to the children of topics which use the concept operators, as follows:

- AND
- OR
- ACCRUE

Topics which use the proximity operators SENTENCE and PARAGRAPH, cannot be assigned a weight. These operators assume a simple "yes" or "no" presence for their children.

Note that if a topic assigned a proximity operator is, in turn, the child of a topic which has been assigned a concept operator, such as the AND operator, that child can be assigned a weight.

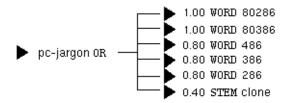

It is not mandatory that you assign weights to the children of a topic just because the operator can accept weighted children. When weights are not assigned, the child has an automatic weight assignment based on its operator. Children of topics using AND and OR operators assume a weight of 1.00, and children of topics using the ACCRUE operator assume a weight of 0.50. If these operators are changed-for example, if an OR operator is changed to an ACCRUE operator-the weights of children which have not been specifically assigned a weight change accordingly. Thus, if an unweighted child of an AND topic has an assumed weight of 1.00, this assumed weight changes to 0.50 if the operator is changed to ACCRUE.

If you assign a variable weight to a topic child, then change the operator used with the parent to one which does not accept weighted children, such as the SENTENCE operator. The Verity search engine will automatically assume a weight of 1.00 while this operator is in effect. If the operator is subsequently changed to one which accepts variable-weighted children, the previously-assigned variable weights will become effective once again.

# **How Weights Affect Importance**

When you assign a weight to the child of a topic which uses a concept operator, you specify the relative contribution of that child to the overall score produced by a topic. The higher the weight you assign to the child, the higher selected documents which contain that child will appear in the list of results. Thus, weights directly affect the importance, or ranking, of selected documents.

For example, assume you have the following topic:

The evidence topics 80286 and 80386 (which describe the microprocessors used in PC products) have an automatic weight assignment of 1.00. The evidence topics 486, 386, and 286 have a relatively high probability of referring to their parent topic, so these evidence topics are assigned weights of 0.80. The evidence topic clone may or may not refer to PC clones at all; therefore, this evidence topic is assigned a weight of 0.40.

A search agent using this topic and its assigned weights might produce the following scores for the matched documents:

```
SCOTES

1.00 01-0ct-90 New Toshiba Portable Desktop Computers Offer a Serious Alternative for Desktop Users
1.00 14-Feb-90 Technology: 'Chip Set' Unveiled for Use in Making Faster Computers
0.80 13-Feb-91 CMS Enhancements Inc. Unveils New Products
0.80 01-0ct-90 Top Selling Microsoft Windows Applications How Available in One Convenient Package
0.80 01-0ct-90 KeyCorp Successful Bidder to Acquire New York State Divisions of Empire of America Federal
0.80 15-Feb-90 Health: U.S. Birth Control Lags
```

If you change the weights of each evidence topic, the importance of your selection results are affected, as well. In this example, if you change the weights of the evidence topic 486 to 0.60, the evidence topic 386 to 0.45, the evidence topic 286 to 0.35, and the evidence topic clone to 0.20, your selected document scores will change as follows:

```
SCOYES

1.00 01-0ct-90 New Toshiba Portable Desktop Computers Offer a Serious Alternative for Desktop Users
1.00 14-Feb-90 Technology: 'Chip Set' Unveiled for Use in Making Faster Computers
0.60 13-Feb-91 CM5 Enhancements Inc. Unveils New Products
0.60 01-0ct-90 KeyCorp Successful Bidder to Acquire New York State Divisions of Empire of America Federal
0.60 15-Feb-90 Health: U.S. Birth Control Lags
0.45 01-0ct-90 Top Selling Microsoft Windows Applications Now Available in One Convenient Package
```

### **Assigning Weights**

When you assign a weight to a child, keep in mind that the weight you use reflects the importance of a child to its parent topic. The matched documents will be ranked by importance to the search; thus, your selection results are directly affected by the weights you assign. If you change a weight, your selection results will be changed, as well.

#### Example:

The topic boeing-people includes three weighted children, binder, shrontz, and woodard, as shown below.

These subtopics are assigned various weights, as follows: the child binder is assigned a weight of 0.80, since this child is considered to be the most important of the three. The subtopic hitsman is assigned a "median" weight of 0.50, since this child is reasonably important with respect to the other two children. The subtopic johnson is assigned a low weight of 0.30, since this child is considered to be the least important with respect to the other children.

When the topic boeing-people is used for a search, the Verity search engine assumes that if the phrase "Paul Binder" is located within a document, there is a high probability that the document will be relevant to a search which uses the topic boeing-people. Documents which contain the phrase "Frank Shrontz" will be reasonably relevant to this search; documents which contain the phrase "Ron Woodard" will be the least relevant.

Because the topic boeing-people has been assigned the ACCRUE operator, the documents displayed at the top of the results list will be those which contain the greatest number of children; therefore all documents with references to all three people will be given the most importance. Documents which contain just one name will be selected in an order that reflects the weights of each child. Thus, because the binder child has the highest weight, documents which include only one individual will be ranked by those which refer to Paul Binder first, followed by Frank Shrontz, and finally Ron Woodard.

# **Automatic Weight Assignments**

When you create a child, the Verity search engine automatically assigns a default weight of 0.50 for children of topics which use the ACCRUE operator. A weight of 1.00 is assigned automatically to children of topics which use the AND or OR operators. These default weights can be manually adjusted up or down, as described in "Changing Weights" in this section. When you create a evidence topic off of a topic which uses a proximity operator, default weight of 1.00 is assigned, and it cannot be changed.

# **Tips for Assigning Weights**

When initially assigning weights, start with a weight of 0.50 for children of ACCRUE topics, and 1.00 for children of all other topics.

When assigning weights to children of topics which use the ACCRUE operator, you may select more relevant results if the children do not have overly high weights. For example, assigning all of the children of an ACCRUE topic weights of 1.00 will cause all documents to have equal importance, regardless of how many of the children are present within the documents. The Verity search engine will assign equal importance to all documents containing only one child as well as for documents which contain all children, so you will not be able to distinguish between these documents when you view the selection results.

Assign weights between 0.80 and 0.20 for the best selection results.

# **Changing Weights**

Once you have assigned weights to children, you can test these weights by running a search using the parent topics to see if the documents you want are selected. If you find that you need to change the weights, you can edit the existing weight assigned to that subtopic or evidence topic. Note that when you edit topic definitions in the topic outline file, you must rebuild the topic set using mktopics. For complete information about using mktopics, refer to your Verity application's administration guide.

# **Topic Scoring and Document Importance**

When you use a topic to perform a search, the search agent starts its analysis by considering the evidence topics for that topic. If the evidence topic is present, it is given 1.00 score and is considered relevant to the search. If the evidence topic is absent, it is given a 0.00 score and is considered irrelevant to the search. If the evidence topics are weighted, the scores of the evidence topics are multiplied by the weights, then combines the resulting products in a manner specified by the operator of the parent topic. If this parent topic is, in turn, the child of another topic which is being searched, its score is multiplied by its assigned weight, and the resulting product is combined with the products of its siblings in a manner specified by the operator assigned to the parent topic. This process continues until the parent topic is reached.

The operators you use determine how parent and child scores contribute to the importance of a selected document. As each child in the topic is given an importance score, the following calculations are performed:

- If a topic uses an ACCRUE operator, the highest ranking result is taken from the products of each child's weight and score, then adds a little to the score for each child which is present in the document.
- If a topic uses an AND operator, the products of each child's own weight and score are compared, and the lowest product (the minimum) is taken as the score.
- If a child uses an OR operator, the products of each child's weight and score are compared, and highest product (the maximum) is taken as the score.

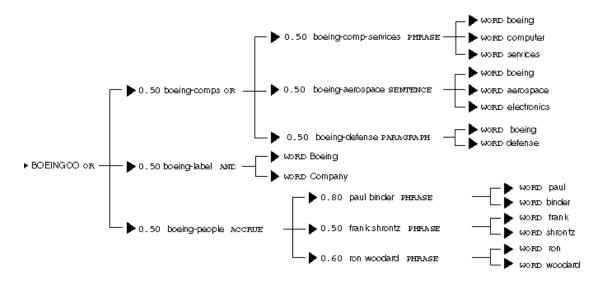

- If a child uses a proximity operator (PHRASE, SENTENCE, or PARAGRAPH), or a relational operator, the child receives a score of 1.00 if the topic is present, and a score of 0.00 if the topic is not present.
- An evidence topic receives a score of 1.00 if it is present, and no score of 0.00 if it is not present.

Once the final calculations for the parent topic have been performed, a matched document becomes available to the Verity application so that users can view it with its highlights.

#### Example:

The following example provides a breakdown of how evidence topics and subtopics are calculated to illustrate the process by which importance is assigned to selected documents.

In the following illustration, the parent topic BOEINGCO is being used in a search.

The evidence topics of each subtopic are first checked against the documents to determine if they are present. Evidence topics that are present are assigned scores of 1.00; evidence topics that are absent are assigned a score of 0.00.

The operators at the next level of a topic structure are used to combine the scores of the evidence topics. Because the operators

at this level are all proximity operators (thus, no weights assigned), they all produce scores that are either 0.00 or 1.00.

For example, assume that the following evidence topics appear within a given document:

- The evidence topic "Boeing Computer Services" appears within a phrase
- The evidence topic "Boeing Defense" appears within a paragraph The evidence topic "Boeing Company" appears within the document
- The evidence topic "Ron Woodard" appears within a phrase

The other evidence topics are only partially present, or are absent. The following table shows how the presence or absence of these evidence topics affect topic scores. Note that the score for each topic reflects the presence of all related evidence topics, based on the operators which have been assigned to the parent topics.

Table 8-9: Evidence Topics and Scores

Evidence topic	Evidence topic Present	Evidence topic Absent	Topic Score
<u> </u>	1		1
	1		
	1		
boeing aerospace electronics	1		0
		1	
		1	
boeing defense	1		1
	1		
boeing company	1		1
	1		
paul binder		1	0
		1	
frank shrontz		1	0
		1	
ron woodard	1		1
	1		
	boeing defense  boeing company  paul binder  frank shrontz	boeing computer services  1 1 1 boeing aerospace electronics  1 boeing defense 1 boeing company 1 paul binder  frank shrontz	Evidence topic         Present         Absent           boeing computer services         1           1         1           boeing aerospace electronics         1           1         1           boeing defense         1           1         1           boeing company         1           paul binder         1           frank shrontz         1           1         1

Given the above topic scores, the operators at the next level of topics in the structure are calculated as follows:

- The subtopic boeing-comps, which uses the AND operator, has a score of 0.50.
- The subtopic boeing-people, which uses the ACCRUE operator, has a score of 0.50.

Finally, the topic BOEINGCO, which uses the OR operator, compares the products of each child's weight and score, and takes the highest product (the maximum) as its score. The selected document is thus scored as 0.50.

This process is repeated for each document. The documents are sorted by the scores of the BOEINGCO topic, and displayed in ranked order.

# **Designing Topics**

This section discusses methodologies you can use to design effective topics. You can apply the methodologies and strategies described here whether you plan to compose topics using a topic outline file or one of the Verity clients. The information in this section includes the following:

- Preparing your topic design
- Topic design strategies
- Designing the initial topic

# **Preparing Your Topic Design**

As you prepare your topic design, consider the naming conventions you will use. Your topic names should help identify the subject matter of the kinds documents you want to find.

To ensure the best search performance, use alphanumeric characters (A through Z, and 0 through 9) for topic names. You can also use foreign characters whose ASCII value is greater than or equal to 128, as well as these symbols: \$ (dollar sign), % (percentage sign), ^ (circumflex), + (plus sign), - (dash), and \_ (underscore). Using other non-alphanumeric characters, could cause misinterpretation of the topic name and affect results.

# **Understanding Your Information Needs**

You should have an understanding of the subject areas to be addressed by your topic design and be familiar with the search requirements of users at your site. The next step is to understand your informational needs, as well as the document types to be searched.

In planning your initial topic design, keep in mind that you are developing a strategy, and the topics you define are the tactics you will use to implement that strategy.

As you develop your strategy, try to answer the following questions:

- What do you wish to gain by using a Verity search agents?
- What issues are to be solved by Verity search agents?
- Who will use search agents?
- What kind(s) of source material will be used?
- What kinds of searches will be performed?
- How are searches currently being performed?

Consider the topics you define as questions to be asked. Just as you might ask a reference librarian at your local library for information relating to a subject area, the topics you create should pose questions when creating Verity search agents.

When considering your strategy, and how Verity search applications will be implemented to provide a solution, keep in mind that a topic you design performs several roles, as follows:

- A librarian
- A research assistant
- An information repository

A knowledge base

# **Understanding Your Documents**

To build effective topics, you must have a good understanding of the types of documents being used as information sources. For example, your documents may consist of one or more of the following types of information:

- Letters
- Memos
- Reports
- Articles

Collect representative samples of the types of documents to be searched. Note common characteristics you will need to apply to the topics you design. For example, if your documents contain important terms, acronyms, or jargon, highlight them so you can create topics that search for this text.

As you collect your document samples, identify their sources-whether they are internal sources, such as internal auditing reports; or external sources, such as electronic mail messages from outside organizations. This information will enable you to define the subtopics for top-level topics.

# **Using Scanned Data**

If your documents are scanned into electronic files using an OCR facility, determine whether the document files will be reviewed for accuracy prior to indexing. If scanned files are reviewed, consult with reviewers to ensure that standards are applied to terms, acronyms, and jargon. If scanned files are not reviewed, note possible variations that may occur. You can develop a topic that uses an OR operator to include variations.

### **Categorizing Document Samples**

Once you have collected your representative document samples and have performed an initial analysis of their contents, you may want to categorize them further. The categorization process can help you to define the top-level topics and children contained in your topic design, and help determine the operators and weights to assign.

Following are categorization examples:

- Geographic location
- Sit
- Project
- Subject area
- Date

The categorization process can help you understand the common, meaningful elements which exist in your information sources. For example, if you categorize your information by date (such as a month), it makes sense to create topics that use relational operators, such as EQUALS.

# **Topic Design Strategies**

Once you have an understanding of your documents, you are ready to choose a topic design strategy. There are two topic design strategies

- The "top-down" strategy considers the major subject classifications first, followed by classifications of increasing detail.
- The "bottom-up" strategy considers the detailed areas first, followed by classifications which group each detailed area by a more generalized subject.

### **Top-Down Design**

A top-down strategy assumes you are designing a topic from the top-level topics down through the individual evidence topics of each subtopic. To design from the top down, you must adopt a taxonomy, or scientific classification approach, to creating a topic, as follows:

- Top-level topics: use general headings to identify the subject area
- Subtopics: use more specific headings to identify the primary groupings within the subject area, as well as topics which are increasingly more specific.
- Evidence topics: use important terms, acronyms, or jargon, to define the subject.

A top-down design works best when you have clearly-defined requirements. This approach is also ideal if your set of searchable documents is constantly growing or changing. With this strategy, for example, you are likely to define subjects which may not yet be evident in your information sources. Keep in mind that you can always add new topics, if you find that a number of new documents contain information which are not identified in your topic design.

If your information sources (that is your set of indexed documents) changes constantly, specific subjects within documents may be missed, especially at the lowest levels. So, you should periodically analyze the information being selected by your topics to ensure that topics critical to your application are current, and the appropriate information is being found.

# **Bottom-Up Design**

A bottom-up strategy assumes you are designing a topic from the individual evidence topics up through the top-level topics which will be defined. With this strategy, your topic design objective is to select documents containing information similar to your lower-level topics.

When you use a bottom-up design, you can start with a document which contains a good representative sample of the words or phrases you want to search for. Then you can group these words by successively higher classifications.

A bottom-up design works best when you have documents which are representative of many other documents that contain similar information. This approach is also useful when your information sources are not subject to many changes or additions.

Keep in mind that topic designs based on the contents of specific documents may miss related subject areas in other documents. For example, if a name is used in the sample document and that name changes in other documents, the new name may be missed in searches.

In addition, the bottom-up strategy implies that your topic design is tuned to the specific document set being used to develop

your topics. These documents may not be representative of all documents contained in your information sources. So, you should

periodically review the effectiveness of your searches.

# **Designing the Initial Topic**

When you have decided whether to use the top-down approach or the bottom-up approach for your initial topic design, it can be helpful to create a topic outline to identify the topic levels to be defined.

# **Outlining a Topic**

Making a topic outline can help you determine how information will be categorized at the various levels within a topic. You can use a topic outline with the top-down or the bottom-up design approach, but it is particularly useful for the top-down approach. We recommend that every topic you build be developed as an outline first, so that you can understand the relationships between topics and subtopics, and organize them to be the most useful.

A topic outline helps you understand how information might be searched for by the people who use Verity search agents at your site. You can use a topic outline to fine-tune the information specified by topics and subtopics to pinpoint document selection. Try to do the following as you develop a topic outline:

- Identify the specific areas of information people will use when performing searches.
- Identify any related subtopics which may be grouped as children under a parent topic.
- Consider the initial level of detail to be covered by your topic design.

Keep the scope of your topic outline relatively small to begin with. A smaller, simpler topic outline is easier to define, and you can always add additional information later. As you develop your topic outline, determine how many levels your topic design will include.

### **Top-Down Topic Outline Example**

Developing a top-down topic outline involves three steps.

- Establishing an information hierarchy
- Establishing individual search categories
- Establishing the topics to be built

As you work through these steps, you should meet with the people who use Verity search agents at your site to develop a topic outline that best meets their search needs, as described below.

#### Step One: Establishing an Information Hierarchy

Talk to the people at your site to learn what types of documents contain the information they need.

For example, assume you are developing a topic design for people in the medical industry to find information relating to current drug testing. Based on discussions with the people who will use Verity search agents at your site, you learn that the following types of documents are prime sources of current drug testing information:

- Research reports
- Product literature

These documents form the information sources to be searched by Verity search agents.

#### Step Two: Establishing Individual Search Categories

Review the documents that will form the information sources at your site. Look for ways to categorize documents.

In our example, a review of the medical research reports and product literature shows information contained in these documents is divided into several categories. You determine that the following categories will be used to define the top-level topics in your topic design:

- Lab reports
- Clinical trials, data, or research
- Product literature

#### Step Three: Establishing the Topics to be Built

Discuss categories you define with the people who create Verity search agents at your site to determine the most important concepts that selected documents should contain, and to determine the top-level topics you need to develop for each category.

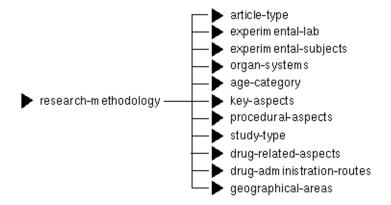

For example, you determine that the category "clinical trials" includes the following top-level topics:

product-testing

research-methodology

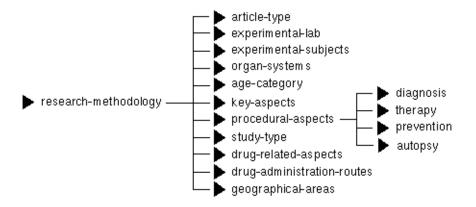

Within these top-level topics, for example, the following subtopics are identified by subject-area experts:

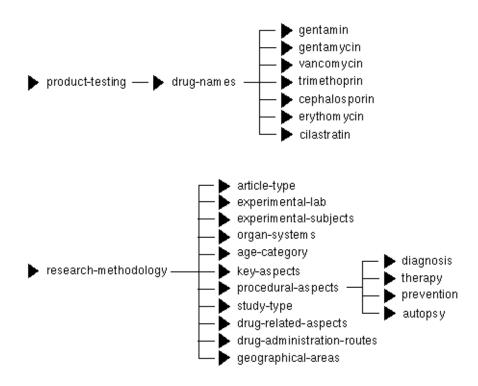

Once these topics are classified, you consult the people who use Verity search agents at your site to determine subtopics. Following is an example of subtopics classified as children for the topic procedural-aspects:

product-testing — b drug-names

As the topic outline is defined, you consult the people who use Verity search agents at your site to ensure the topics select meaningful documents. In the next example, a topic called drug-names enables the users at your site to search clinical trials data for drugs, based on their names.

### **Bottom-Up Topic Outline Example**

Developing a bottom-up topic outline involves three steps.

- Identifying the subtopics which will form the lowest levels of the topic design
- Categorizing related subtopics into higher-level topics
- Establishing the top-level topic classifications

As you work through these steps, meet with the people who create Verity search agents at your site to develop a topic outline that best meets your search needs, as described below.

#### **Step One: Identifying Low-level Topics**

Find a document you can use as a model whose information is representative of other documents you want to find.

For example, assume you are developing a topic design to find information on the computer industry. As a start, you build a topic that searches for documents related to Apple Computer and related products.

You use the following sample as a model document whose information is representative of other documents you want to find:

A system developed specifically for networked Apple Computer, Inc. Macintosh computers has been announced by Human Designs, Inc.

Dubbed Chorus, the floor-standing unit reportedly can contain up to 16 floating-point processors and connects to networked Macintoshes to create a multiuser desktop environment.

The product offers performance of eight million to 32 million floating-point operations per second and was designed to accommodate software development, according to the vendor. Options include an Ethernet I/O upgrade and a software simulator.

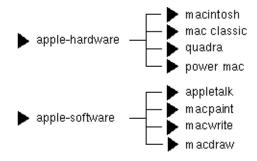

A Chorus 1 single floating-point processor entry-level system costs \$9,700. A Chorus 4 configuration with four floating point processors is available at \$25,000, which includes a dedicated I/O processor with an Apple Appletalk port and system software. Both systems are upgradable.

Human Designs, 322 W. 71st St., New York, N.Y. 10023. 212-580-0257.

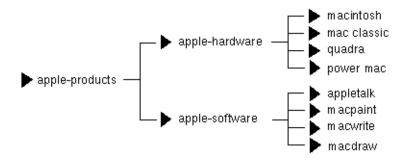

This document makes you decide you want to locate other documents which refer to "Appletalk" and "Macintosh," so you define two parent topic names, apple-software and apple-hardware.

You decide you want to add additional evidence topics to select documents containing related information, such as "Macintosh,"

"Mac Classic," "Quadra," and "Power Mac." In addition, you decide you want to include the evidence topics "AppleTalk" "MacPaint," "MacWrite," and "MacDraw," as related software products. You assign these evidence topics to your apple-hardware and apple-software topics, as follows:

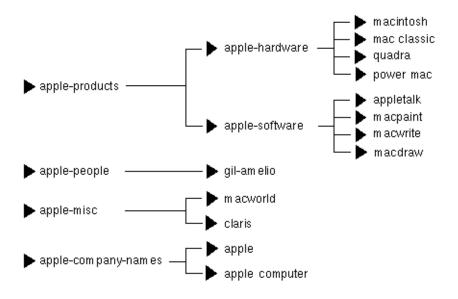

Finally, you want to combine these topics into the topic apple-products, as follows:

### **Step Two: Categorizing Related Subtopics**

Discuss subtopics with the people who use Verity search agents at your site to determine if other subtopics exist that can be logically grouped in a category.

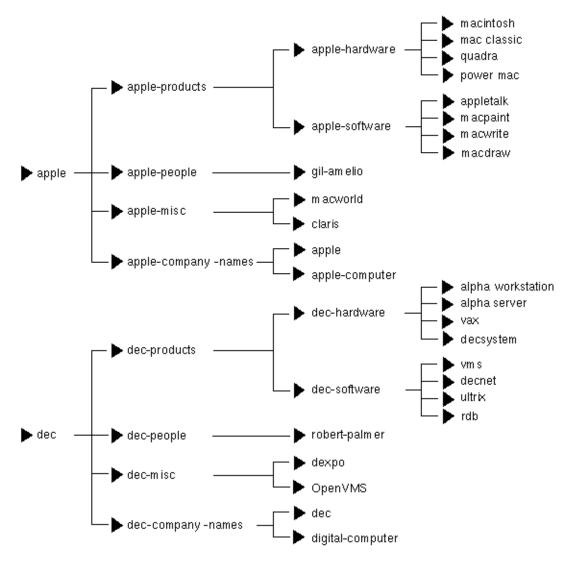

In our example, some of the people who use Verity search agents are interested in finding information on personnel at Apple Computer, and others are interested in finding any documents which refer to Apple Computer. In the example below, a logical group of topics addresses several aspects of Apple Computer:

### **Step Three: Establishing Top-Level Topics**

Determine whether other top-level topics are necessary to find related information.

In the following example, a new topic, dec, is developed for another computer company, Digital Equipment Corporation. This topic was assigned a top-level topic and contains subtopics similar to those defined for the apple topic, as shown below.

Verity® and TOPIC® are registered trademarks of Verity, Inc.

### APPENDIX A System Procedures

This appendix describes the Sybase-supplied system procedures used for updating and getting reports from system tables. Table A-1 lists the system procedures included with the Full-Text Search engine.

Table A-1: System procedures

	• •	
Procedure	Description	
sp_check_text_index	Reports or fixes consistency problems in FTS index and source tables	
sp_clean_text_events	Removes processed entries from the text_events table.	
sp_clean_text_indexes	Removes text indexes which are note associated with a table.	
sp_create_text_index	Creates an external text index.	
sp_drop_text_index	Drops text indexes.	
sp_help_text_index	Enhanced version only. Displays text indexes.	
sp_optimize_text_index	Enhanced version only. Runs the Verity optimization routines.	
sp_redo_text_events	Changes the status of entries in the text_events table and forces reindexing of the modified table.	
sp_refresh_text_index	Adds an entry to the text_events table reflecting updates to the corresponding source table.	
sp_show_text_online	Displays information about databases or indexes that are currently online.	
sp_text_cluster	Enhanced version only. Displays or modifies clustering options.	
sp_text_configure	Enhanced version only. Displays or modifies Full-Text Search engine configuration parameters.	
sp_text_dump_database	Enhanced version only. Makes a backup copy of the text indexes in a database and optionally dumps the text_db and current databases.	
sp_text_kill	Enhanced version only. Terminates all connections to a specific text index.	
sp_text_load_index	Enhanced version only. Restores text indexes from a backup.	
sp_text_notify	Notifies the Full-Text Search engine that the text_events table has been modified.	
sp_text_online	Makes a database available to Adaptive Server.	

### sp\_check\_text\_index

Description Reports or fixes consistency problems in the FTS index and source tables.

Syntax sp\_check\_text\_index server, "index\_name", "id\_column", "fixit"

Parameters server

the name of the text server.

index name

- the name of the text server.

id column

- the source identity column name.

fixit

– if FALSE, just reports problems. If TRUE, doesn't report but repairs problems.

sp\_check\_text\_index "textsvr", "text.i\_text", "id",
"false"

Lists problems on the server named textsvr with the column name text.i\_text.

- Before using sp\_check\_text\_index you must issue sp\_dboption "select into", true
- This procedure addresses three problems:

It generates an sp\_refresh\_text\_index insert for entries in the source table that do not have a matching entry in the index.

It generates an sp\_refresh\_text\_index delete for entries in the index table that have no source table entry.

It generates an sp\_refresh\_text\_index delete for each extra entry where duplicate index entries exist.

• In order to determine the index duplicates, it is necessary to select all of the ID values from the index table into a temporary table. If the collection has more than 64K ID values, it will be necessary to change the "batch\_blocksize configuration parameter from its default of 0 to 65536 to enable blocked reading of the returned Verity information. If this is not done, FTS will attempt to real all ID values in one read and fail with a Verity error of "-27."

Messages None

Permissions Any user can execute sp\_check\_text\_index.

Examples

Usage

### sp\_clean\_text\_events

Description Removes processed entries from the text\_events table.

Syntax sp\_clean\_text\_events [up\_to\_date]

Parameters up\_to\_date

– the date and time through which all processed entries will be deleted.

Examples sp\_clean\_text\_events "01/15/98:17:00"

Removes data entered on or before January 15, 1998 at 5:00 p.m.

• If the *up to date* parameter is specified, all entries having a date

 If the up\_to\_date parameter is specified, all entries having a date less than or equal to up\_to\_date and whose status is set to processed is deleted.

 If up\_to\_date is omitted, all entries whose status is set to processed is deleted.

 Remove entries from the text\_events table only after you have backed up the collection associated with the text index.

 With the Enhanced Full-Text Search engine, the sp\_text\_dump\_database system procedure automatically runs this.

Messages None

Permissions Any user can execute sp\_clean\_text\_events.

See also sp\_text\_dump\_database

### sp\_clean\_text\_indexes

Description Removes indexes from the vesaux table that are not associated with a

table.

Syntax sp\_clean\_text\_indexes

Parameters None.

Examples sp\_clean\_text\_indexes

• This procedure reads entries from the vesaux and vesauxcol tables,

verifying that both the source table and the corresponding index table

exist. If either is missing, the index is dropped.

Messages • Fetch resulted in an error

• Unable to drop object definition for *index\_name*!

Permissions

Any user can execute sp\_clean\_text\_indexes.

### sp\_create\_text\_index

Description

Creates a text index.

Syntax

sp\_create\_text\_index server\_name, index\_table\_name,
 table\_name, "batch", column\_name
[, column\_name ... ]

Parameters

server name

– is the name of the Full-Text Search engine.

index\_table\_name

- is the name of the index table. *index\_table\_name* has the form [dbname.[owner.]]table, where:
- dbname is the name of the database containing the index table.
- owner is the name of the owner of the index table.
- table is the name of the index table.

table\_name

– is the name of the source table containing the text being indexed. *table\_name* has the form [dbname.[owner.]]table.

batch

- The "batch" operator (must be in quotes) tells the Full-Text Search to reallocate every session after each batch sent to the VDK.

column\_name

– is the name of the column indexed by the text index.

Examples

```
sp_create_text_index "blue", "i_blurbs", "blurbs", "
", "copy"
```

Creates a text index and an index table named i\_blurbs on the copy column of the blurbs table.

Usage

- Up to 16 columns can be indexed in a single text index.
- Columns of the following datatypes can be indexed: char, varchar, nchar, nvarchar, text, image, datetime, and smalldatetimeint, smallint, and tinyint

- The content of *option\_string* is not case sensitive.
- option\_string uses a null string (" ") to specify "No Options".
- Assign the value "empty" to option\_string to create a text index that you will immediately drop. This creates the Verity collection directory and the style files, but does not populate the collections. For example, when you configure an individual table for clustering, you create the text index and immediately drop it. After you edit the style.prm file, you re-create the text index. For more information, see "Editing Individual style.prm Files" on page 29.
- sp\_create\_text\_index writes entries to the vesaux table and tells the Full-Text Search engine to create the text index.
- Execution of sp\_create\_text\_index is synchronous. The Adaptive Server process executing this system procedure remains blocked until the index is created. The time required to index large amounts of data may be take as long as several hours to complete.
- When you create a text index on two or more columns, each column in the text index is placed into its own document zone. The name of the zone is the name of the column. The zones can be used to limit your search to a particular column. For more information, see "in" on page 54.
- Do not rename an index after creating.
- Can't run sp\_create\_text\_index from within a transaction
- 'column name' cannot be NULL.
- Column 'column name' does not exist in table 'table name'
- Index table mapping failed Text Index creation aborted
- Invalid text index name 'index name' already exists
- 'parameter' is not in the current database
- Server name 'server\_name' does not exist in sysservers.
- 'table name' does not exist
- 'table name' is not a valid object name
- Table 'table\_name' does not have an identity column text index creation aborted
- Text index creation failed
- User 'user name' is not a valid user in the database

Messages

Permissions

Any user can execute sp\_create\_text\_index.

### sp\_drop\_text\_index

Description

Drops the index table and text indexes.

Syntax

sp\_drop\_text\_index "table\_name.index\_table\_name"
[,"table\_name.index\_table\_name"...]

**Parameters** 

table name

- is the name of the table associated with the text indexes you are dropping. table\_name has the form [dbname.[owner.]]table, where:
- dbname is the name of the database containing the table.
- owner is the name of the owner of the table.
- table is the name of the table.

index\_table\_name

is the name of the index table and text index you are dropping.index\_table\_name has the form [dbname.[owner.]]index.

Drops the index table and text index associated with the blurbs table.

Examples

sp\_drop\_text\_index "blurbs.i\_blurbs"

Usage

- First, the sp\_drop\_text\_index system procedure issues a remote
  procedure call (RPC) to the Full-Text Search engine to delete the
  Verity collection. Then, it removes the associated entries from the
  vesaux and vesauxcol tables, drops the index table, and removes the
  index table object definition.
- Up to 255 indexes can be specified in a single sp\_drop\_text\_index request.
- If database and owner are not specified, the current owner and database are used.

Messages

- Can't run sp\_drop\_text\_index from within a transaction.
- Index 'index name' is not a Text Index
- 'parameter\_name' is not a valid name
- Server name 'server\_name' does not exist in sysservers

- Unable to drop index table 'table\_name'. This table must be dropped manually
- User 'user\_name' is not a valid user in the 'database\_name' database

• vs\_drop\_index failed with code 'code\_name'.

Permissions

Any user can execute sp\_drop\_text\_index.

### sp\_help\_text\_index

Description (Enhanced version only)

Displays a list of text indexes for the current database.

Syntax sp\_help\_text\_index [index\_table\_name]

Parameters index\_table\_name

– is the name of the text index you want to display.

Examples Example 1

sp\_help\_text\_index

Displays all indexes.

Example 2

sp\_help\_text\_index "i\_blurbs"

Displays information about the text index i\_blurbs.

Usage

- sp\_help\_text\_index is available only with Enhanced Full-Text Search Specialty Data Store.
- If the *index\_table\_name* parameter is specified, information about that text index is displayed. This information includes the name of the text index, the name of the Verity collection for the index, the name of the source table, the name of the IDENTITY column, and the name of the Full-Text Search engine that created the index.
- If *index\_table\_name* is omitted, a list of all text indexes in the current database is displayed

Messages • No text indexes found in database 'database\_name'

- Text index 'index name' does not exist in database 'database name'
- Object must be in the current database

### the exament detabase

#### 143

Permissions

Any user can execute sp\_help\_text\_index.

### sp\_optimize\_text\_index

(Enhanced version only) Description

Performs optimization on a text index.

Syntax sp\_optimize\_text\_index index\_table\_name

**Parameters** index table name

> - is the name of the text index you want to optimize. *index\_table\_name* has the form [dbname.[owner.]]table, where:

- dbname is the name of the database containing the index table. If present, the owner or a placeholder is required.
- owner is the name of the owner of the index table.
- table is the name of the index table.

sp optimize text index "i blurbs"

Optimizes the text index i\_blurbs to improve query performance.

- sp\_optimize\_text\_index is available only with Enhanced Full-Text Search Specialty Data Store.
- This system procedure causes the Full-Text Search engine to run the specified text index through the Verity optimization routines.
- sp\_optimize\_text\_index is useful for optimizing a text index that has been updated with Verity optimization disabled (trace flag 11 turned on).
- To enable MaxClean optimization turn on traceflag 30. This traceflag should only be used during maintenance since it could take extra time and interfere with normal usage. MaxClean is a Verity optimization feature that removes out-of-date collection files.
- 'index table name' is not in the current database
- 'index table name' does not exist
- Index 'index table name' is not a Text Index
- This procedure is not supported against remote server 'server name'

Permissions Any user can execute sp\_optimize\_text\_index.

Examples

Usage

"Updating Existing Indexes" on page 79

### sp\_redo\_text\_events

Description Changes the status of entries in the text\_events table and forces the re-

indexing of the modified columns.

Syntax sp\_redo\_text\_events [from\_date [,to\_date]]

Parameters from\_date

– is the starting date and time in a date range of entries to be modified.

to\_date

– is the ending date and time in the specified date range of the entries

to be modified.

Examples sp\_redo\_text\_events "01/05/98:17:00",

"02/12/98:08:30"

Re-indexes columns that were modified between January 5, 1998 at 5:00 p.m. and February 12, 1998 at 8:30 a.m.

p.m. and February 12, 1998 at 8:30 a.m

• Resets the status to "unprocessed" for all entries in the text\_events table that currently have a status of "processed." The Full-Text Search engine is notified that a re-index operation is required.

- Useful for synchronizing a text index after a recovery of the Verity collection from a backup. When you use the Enhanced Full-Text Search engine, this procedure is run automatically during sp\_text\_load\_index.
- If *to\_date* is omitted, all entries between *from\_date* and the current date with a status of "processed" are reset to "unprocessed."
- If both from\_date and to\_date are omitted, all entries in the text\_events table with a status of "processed" are reset to "unprocessed."

• *to\_date* cannot be specified without *from\_date* 

You have not specified the full range.

Any user can execute sp\_redo\_text\_events.

Usage

Messages

Permissions

### sp\_refresh\_text\_index

Description

Records modifications in the text\_events table when you change the text index's source table data.

Syntax

sp\_refresh\_text\_index table\_name, column\_name, rowid, mod\_type

**Parameters** 

table\_name

- is the name of the source table being updated. table\_name has the form [dbname.[owner.]]table, where:
- dbname is the name of the database containing the table.
- owner is the name of the owner of the table.
- table is the name of the table.

column\_name

- is the name of the column being updated.

rowid

- is the IDENTITY column value of the changed row.

mod type

– specifies the type of the change. Must be insert, update, or delete.

sp\_refresh\_text\_index "blurbs", "copy", 2.000000,

"update"

Usage

Examples

- Records in the text\_events table that you have updated the copy column of the blurbs table. The row you have updated has an id of 2.000000.
- The user maintains the consistency of the text index. You must run sp\_refresh\_text\_index anytime you update source data that has been indexed so that the text\_events table reflects the change. This keeps the collections in sync with your source data. The collections are not updated until you run sp\_text\_notify.
- You can create triggers that issue sp\_refresh\_text\_index for non-text and non-image columns. For more information on creating triggers, see "Propagating Changes to the Text Index" on page 22.
- Column 'column\_name' does not exist in table 'table\_name'
- Invalid mod\_type specified ('mod\_type'). Correct values: INSERT, UPDATE, DELETE
- Owner 'owner name' does not exist
- Table 'table\_name' does not exist
- 'table\_name' is not a valid name.

Messages

Text event table not found

Permissions Any user can execute sp\_refresh\_text\_index.

See also sp\_text\_notify

### sp\_show\_text\_online

Description Displays information about databases or text indexes that are currently

online.

Syntax sp\_show\_text\_online server\_name [,{INDEXES | DATABASES}]

Parameters server\_name

– is the name of the Full-Text Search engine to which the request is

sent.

INDEXES | DATABASES

- specifies whether the request should contain data about online

indexes or online databases. The default is INDEXES.

Examples Example 1

exec sp\_show\_text\_online KRAZYKAT

Displays all indexes that are currently online in the KRAZYKAT Full-Text

Search engine.

Example 2

exec sp\_show\_text\_online KRAZYKAT, DATABASES

Displays all databases that are currently online in the KRAZYKAT Full-

Text Search engine.

• sp\_show\_text\_online issues a remote procedure call (RPC) to the Full-Text Search engine to retrieve information about the indexes or the databases that are currently online.

 If the results of this procedure do not list a database, use sp\_text\_online to bring the desired database online.

• sp show text online failed for server server name.

• The parameter value 'value' is invalid

• The RPC sent to the server returned a failure return code

The second parameter must be INDEXES or DATABASES

Usage

Messages

Permissions Any user can execute sp\_show\_text\_online.

See also sp\_text\_online

### sp\_text\_cluster

Description (Enhanced version only)

Displays or changes clustering parameters for the active thread.

Syntax sp\_text\_cluster server\_name, cluster\_parameter [, cluster\_value]

**Parameters** server\_name – is the name of the Full-Text Search engine.

cluster\_parameter

– is the name of the clustering parameter. Values are shown in Table A-2.

cluster\_value

– is the value you assign to the clustering parameter for the active thread. Values are shown in Table A-2.

Table A-2: Clustering configuration parameters

Values for	
cluster_parameter	Values for cluster_value
cluster_style	Specifies the type of clustering to use. Valid values are:
	<ul> <li>fixed – generates a fixed number of clusters. The number is set by the cluster_max parameter.</li> </ul>
	• coarse – automatically determines the number of clusters to generate, based on fewer, coarse grained clusters.
	<ul> <li>medium – automatically determines the number of clusters to generate, based on medium sized clusters.</li> </ul>
	<ul> <li>fine – automatically determines the number of clusters to generate, based on smaller, finer grained clusters.</li> </ul>
cluster_max	Specifies the maximum number of clusters to generate when cluster_style is set to fixed. A value of 0 means that the search engine determines the number of clusters to generate.

Values for cluster_parameter	Values for cluster_value
cluster_effort	Specifies the amount of effort (time) that the search engine should expend on finding a good clustering. Valid values are:
	• effort_default – the search engine spends the default amount of time. You can also use the Verity term "default" if you enclose it in double quotes (" ").
	• high – the search engine spends the longest time.
	<ul> <li>medium – the search engine spends less time.</li> </ul>
	• low – the search engine spends the least amount of time.
cluster_order	Specifies the order in which to return the rows within the clusters. Valid values are
	<ul> <li>"0" – indicates rows are returned in order of similarity to the cluster center. This means the first row returned for a cluster is the one that is most prototypical of the rows in the cluster.</li> </ul>
	<ul> <li>"1" – indicates that rows are returned in the same relative order in which they were submitted for clustering. For example, if cluster 1 contains the first, third and seventh rows found for the query, they will be returned in that relative order within the cluster.</li> </ul>
Examples	Example 1
	sp_text_cluster KRAZYKAT, cluster_order, "1"
	Changes the cluster_order parameter to 1 for the active thread.
	Example 2
	sp_text_cluster KRAZYKAT, cluster_style
	Displays the current value of the <i>cluster_style</i> parameter.
Usage	<ul> <li>The Verity clustering algorithm attempts to group similar rows together, based on the values of the clustering parameters.</li> </ul>
	<ul> <li>If the cluster_parameter parameter is specified, but the cluster_value parameter is omitted, sp_text_cluster displays the value of the clustering parameter that is specified.</li> </ul>
	<ul> <li>sp_text_cluster does not modify the value of the clustering configuration parameter. The <i>cluster_value</i> is valid only for the thread that is currently executing. To modify the default values, use the sp_text_configure system procedure.</li> </ul>
	<ul> <li>For information on how to request a clustered result set, see "Using Pseudo Columns to Request Clustered Result Sets" on page 48.</li> </ul>
Messages	• This procedure is not supported against remote server 'server_name
	• The parameter value 'value' is invalid

• sp\_text\_cluster failed (status = *status*)

Permissions Any user can execute sp\_text\_cluster.

See also sp\_text\_configure

### sp\_text\_configure

Description (Enhanced version only)

Displays or changes Full-Text Search engine configuration parameters.

Syntax sp\_text\_configure server\_name [, config\_name [, config\_value]]

Parameters server\_name

– is the name of the Full-Text Search engine.

config\_name

– is the name of the configuration parameter to be displayed or

modified.

config\_value

– is the value you assign to the configuration parameter.

Examples Example 1

sp\_text\_configure KRAZYCAT, backdir, "/data/backup"

Changes the backup destination directory to /data/backup.

Example 2

sp\_text\_configure KRAZYCAT, backdir

Displays the backup destination directory.

When you execute sp\_text\_configure to modify a dynamic parameter:

• The configuration and run values are updated

The configuration file is updated

• The change takes effect immediately

• When you execute sp\_text\_configure to modify a static parameter:

The configuration value is updated

The configuration file is updated

Usage

- The change takes effect only when you restart the Full-Text Search engine
- When issued with no parameters, sp\_text\_configure displays a report of all Full-Text Search engine configuration parameters and their current values.
- If the *config\_name* parameter is specified, but the *config\_value* parameter is omitted, sp\_text\_configure displays the report for the configuration parameter specified.
- For information on the individual configuration parameters, see "Modifying the Configuration Parameters" on page 67.

Messages

- Configuration value cannot be specified without a configuration option
- This procedure is not supported against remote server 'server\_name'
- sp\_text\_configure failed possible invalid configuration option ('config\_name')

Permissions

Any user can execute sp\_text\_configure.

### sp\_text\_dump\_database

Description (Enhanced version only)

Makes a backup copy of a text index.

Syntax sp\_text\_dump\_database backupdbs [, current\_to] [,

current\_with] [, current\_stripe01 [, ... [,

current\_stripe31]]] [, textdb\_to] [, textdb\_with] [,

textdb\_stripe01 [, ... [, textdb\_stripe31]]]

Parameters backupdbs

 specifies whether the current database and the text\_db database are backed up before the text index is backed up. Valid values are shown in Table A-3.

Table A-3: Values for backupdbs

# Value Description CURRENT\_DB\_AND\_INDEXES Indicates that the current database is backed up before the text indexes are backed up.

Value	Description
CURRENT_DB_AND_CURRENT_INDEXES	Indicates that the current database is backed up before the text indexes are backed up, and only the indexes associated with the current database are dumped.
TEXT_DB_AND_INDEXES	Indicates that the text_db database is backed up before the text indexes are backed up.
INDEXES_AND_DATABASES	Indicates that the current and text_db databases are backed up before the text indexes are backed up.
ONLY_INDEXES	Indicates that only the text indexes are backed up.

#### current\_to

 is the to clause of the dump database command for dumping the current database. Use this only if you specify
 CURRENT\_DB\_AND\_INDEXES or INDEXES\_AND\_DATABASES for the backupdbs parameter.

#### current\_with

 is the with clause of the dump database command for dumping the current database. Use this only if you specify
 CURRENT\_DB\_AND\_INDEXES or INDEXES\_AND\_DATABASES for the backupdbs parameter.

#### current\_stripe

 is the stripe clause of the dump database command for dumping the current database. Use this only if you specify
 CURRENT\_DB\_AND\_INDEXES or INDEXES\_AND\_DATABASES for the backupdbs parameter.

#### textdb\_to

is the to clause of the dump database command for dumping the text\_db database. Use this only if you specify
 INDEXES\_AND\_DATABASES for the *backupdbs* parameter. Use this only if you specify TEXT\_DB\_AND\_INDEXES or
 INDEXES\_AND\_DATABASES for the *backupdbs* parameter.

#### textdb\_with

 is the with clause of the dump database command for dumping the text\_db database. Use this only if you specify TEXT\_DB\_AND\_INDEXES or INDEXES\_AND\_DATABASES for the backupdbs parameter. textdb\_stripe

- is the stripe clause of the dump database command for dumping the text\_db database. Use this only if you specify

TEXT\_DB\_AND\_INDEXES or INDEXES\_AND\_DATABASES for the *backupdbs* parameter.

#### Examples

#### **Example 1**

sp\_text\_dump\_database ONLY\_INDEXES

Only text indexes are backed up.

#### Example 2

sp\_text\_dump\_database CURRENT\_DB\_AND\_INDEXES, "to '/data/db1backup'"

The current database is dumped to /data/db1backup before the text indexes are backed up.

#### Example 3

sp\_text\_dump\_database @backkupdbs = "TEXT\_DB\_AND\_INDEXES", @textdb\_to = "to
'/data/textdbbackup'"

The *text\_db* database is dumped to */data/textdbbackup* before the text indexes are backed up.

#### Example 4

```
sp_text_dump_database @backupdbs = "INDEXES_AND_DATABASES", @current_to =
"to '/data/db1backup'",
@textdb_to = "to '/data/textdbbackup'"
```

The current database is dumped to /data/db1backup and the text\_db database is dumped to /data/textdbbackup before the text indexes are backed up.

#### Usage

- The Full-Text Search engine concatenates the values of *current\_to*, *current\_with*, and *current\_stripe01* to *current\_stripe31* to dump database *currentdbname* and then executes the dump database command. The output from the execution of the dump database command is sent to the Full-Text Search error log.
- The Full-Text Search engine concatenates the values of *textdb\_to*, *textdb\_with*, and *textdb\_stripe01* to *textdb\_stripe31* to the string "dump database *currentdbname*" and then executes the dump database command. The output from the execution of the dump database command is sent to the Full-Text Search error log.
- All entries in the text\_events table that have a "processed" status in the current database are deleted when all indexes have been backed up.

- The backup files for the Verity collections are stored in the directory specified in the backDir configuration parameter.
- See references to the configuration paramter backCmd for customizing backups.

Messages

- The parameter value 'value' is invalid
- Server name 'server' does not exist in sysservers
- Attempt to dump database 'database\_name' failed use the 'dump database' command
- Attempt to backup text indexes on server 'server\_name' failed
- Attempt to clean text\_events in database 'database\_name' failed (date = 'date')
- Parameter 'parameter\_name' is required when dumping database 'database\_name'
- Dumping database 'database\_name' check Full Text Search SDS error log for status

Permissions

Any user can execute sp\_text\_dump\_database.

See also

dump\_database in the Adaptive Server Reference Manual.

### sp\_text\_kill

Description

(Enhanced version only)

Terminates all connections to a specific text index.

Syntax

sp\_text\_kill index\_table\_name

**Parameters** 

index table name

- is the name of the text index from which all connections will be terminated. *index\_table\_name* has the form [dbname.[owner.]]table, where:
- dbname is the name of the database containing the index table. If present, the owner or a placeholder is required.
- owner is the name of the owner of the index table.
- table is the name of the index table.

Examples

sp\_text\_kill "i\_blurbs"

Terminates all existing connections to the text index i\_blurbs.

Usage

- sp\_text\_kill is available only with Enhanced Full-Text Search Specialty Data Store.
- This system procedure causes the Full-Text Search engine to terminate all connections to the specified index, except for the connection that initiated the request.
- Attempts to drop a text index that is currently in use will fail.
   sp\_text\_kill can be used to terminate all existing connections so that the index can be successfully dropped.

Messages

- Index 'index table name' is not a text index
- This procedure is not supported against remote server 'server name'
- 'index\_table\_name' does not exist
- Only the System Administrator (SA) may execute this procedure

Permissions Only user "sa" can execute sp\_text\_kill.

See also sp\_drop\_text\_index

### sp\_text\_load\_index

Description (Enhanced version only)

Restores a text index backup.

Syntax sp\_text\_load\_index

Parameters None.

Examples sp\_text\_load\_index

Restores all text indexes in the current database.

Usage

- Run sp\_text\_load\_index after the text\_db database and the current database have been fully recovered.
- sp\_text\_load\_index restores the Verity collections from the most recent backup. The Full-Text Search engine then runs sp\_redo\_text\_events and sp\_text\_notify to reapply all entries in the text\_events table since the date and time the index was backed up.

• See references to the configuration paramter restoreCmd for customizing backups.

• Server name 'server\_name' does not exist in sysservers

• Unable to restore text indexes for server 'server\_name'

• This procedure is not supported against remote server 'server\_name'

• Update to text\_events table in database *database\_name* failed for server 'server name' - text events not rolled forward

Permissions Any user can execute sp\_text\_load\_index.

See also sp\_redo\_text\_events; sp\_text\_notify

### sp\_text\_notify

Description Notifies the Full-Text Search engine that the text\_events table has been

modified.

Syntax sp\_text\_notify [{true | false}] [, server\_name]

Parameters true

– causes the procedure to run synchronously.

false

– causes the procedure to run asynchronously.

server\_name

– is the name of the Full-Text Search engine you are notifying.

Examples sp\_text\_notify true

 You must run sp\_text\_notify after you issue sp\_refresh\_text\_index to inform the Full-Text Search engine that the source tables have been

modified.

If you do not specify true or false, sp\_text\_notify runs synchronously.

• If no server name is specified, all Full-Text Search engines are

notified.

• Can't run sp\_text\_notify from within a transaction

Notification failed, server = 'server\_name'

Server name 'server\_name' does not exist in sysservers

Messages

Usage

156

The parameter value 'value' is invalid

Permissions Any user can execute sp\_text\_notify.

See also sp refresh text index

### sp text online

Description Makes a database available for full-text searches to Adaptive Server.

Syntax sp\_text\_online [server\_name], [database\_name]

**Parameters** server name

– is the name of the Full-Text Search engine.

database name

- is the name of the database that you are bringing online.

Examples sp\_text\_online @database\_name = pubs2

> Makes the pubs2 database available for full-text searches using the Full-Text Search engine.

If a database is not specified, all databases are brought online for fulltext searches.

- If a server name is not specified, all Full-Text Search engines listed in the vesaux table are notified.
- With the Enhanced Full-Text Search engine, databases are brought online automatically if the auto\_online configuration parameter is set to 1.
- All Databases using text indexes are now online
- Databases containing text indexes on server 'database names' are now online
- Server name 'server name' is now online"
- Server name 'server name' does not exist in sysservers.
- The parameter value 'value' is invalid
- The specified database does not exist
- vs online failed for server 'server name'

Any user can execute sp\_text\_online.

#### Permissions

### APPENDIX B Sample Files

This appendix contains the following:

- The text of the default configuration file (textsvr.cfg)
- An overview of the sample\_text\_main.sql sample script
- A list of all the sample files provided by the Full-Text Search engine
- An overview of the getsend program

### Default textsvr.cfg Configuration File

```
@(#) File: textsvr.cfg 1.17 07/26/99
 Full Text Search Specialty Data Store
          Sample Configuration File
 The installation procedure places this file in the
 "SYBASE" directory.
 Lines with a semi-colon in column 1 are comment lines.
 Modification History:
  11-21-97
          Create file for Full Text Search SDS
 03-02-98
          Add trace flags and config values for
            Enhanced Full Text Search SDS
; 05-26-99
           remove references to sds/text
 07-09-99
           added batch block size
 08-24-99 remove version string and correct copyright
copyright (c) 1997, 1999
          Sybase, Inc. Emeryville, CA
```

```
;
            All rights reserved.
DIRECTIONS
;
;
  Modifying the textsvr.cfg file:
  An installation can run the Text Search SDS product
  as supplied, with no modifications to configuration
  parameters. Default values from the executable program
  are in effect.
;
  The "textsvr.cfg" file is supplied with all configuration
;
;
  parameters commented out.
ï
;
  The hierarchy for setting configuration values is:
;
   default value internal to the executable program (lowest)
;
   configuration file value (overrides default value)
;
   command line argument (overrides default value and *.cfg file)
;
;
  Command line arguments are available to override
  settings for these options:
;
ï
;
     -i<file specification for interfaces file>
     -l<file specification for log file>
;
     -t (no arg) directs text server to write start-up
        information to stderr (default is DO NOT write start-up information)
;
  To set configuration file parameters, follow these steps:
;
;
  (1) If changing the server name to other than "textsvr":
      (1A) Copy "textsvr.cfg" to "your_server_name.cfg"
;
           Example: text_server.cfg
           Modify the [textsvr] line to [your_server_name]
;
      (1B)
           Example: [text_server]
      The maximum length of "your_server_name" is 30 characters.
  (2) Set any configuration values in the CONFIG VALUES SECTION below.
      Remove the semi-colon from column 1.
;
                  DEFINITIONS OF TRACE FLAG AND SORT ORDER VALUES
```

```
; "traceflags" parameter, for text server
; Available "traceflags" values: 1,2,3,4,5,6,7,8,9,10,11,12,13
 1 trace connect/disconnect/attention events
;
  2 trace language events
  3 trace rpc events
  4 trace cursor events
  5 log error messages returned to the client
  6 trace information about indexes
;
  7 trace senddone packets
  8 write text server/Verity api interface records to the log
; 9 trace sql parser
; 10 trace Verity processing
; 11 disable Verity collection optimization
; 12 disable returning of sp_statistics information
; 13 trace backup operations (Enhanced Full Text Search only)
; "srv_traceflags" parameter, for Open Server component of text server
; Available "srv_traceflags" values: 1,2,3,4,5,6,7,8
 1 trace TDS headers
 2 trace TDS data
  3 trace attention events
  4 trace message queues
 5 trace TDS tokens
;
 6 trace open server events
 7 trace deferred event queue
 8 trace network requests
; "sort_order" parameter
; Available "sort_order" values: 0,1,2,3
 0 order by score, descending (default)
; 1 order by score, ascending
 2 order by timestamp, descending
  3 order by timestamp, ascending
CONFIG VALUES SECTION
; The "textsvr.cfg" file is supplied with the values commented out.
; To override value(s) in the executable program:
    - Set required value(s) below
    - Remove the semicolon from column 1
[textsvr]
```

```
; min\_sessions = 10
; max\_sessions = 100
;batch_size = 500
;sort_order = 0
;defaultDb = text_db
;errorLog = textsvr.log
; language = english
;charset = iso 1
; vdkLanguage =
;vdkCharset = 850
;traceflags = 0
;srv_traceflags = 0
;max_indexes = 126
;max_packetsize = 2048
;max_stacksize = 34816
; max\_threads = 50

;cluster effort = Default
;batch blocksize = 0
```

### The sample\_text\_main.sql Script

The installation of the Full-Text Search engine copies the sample\_text\_main.sql script to the \$\$SYBASE\_\$\$SYBASE\_FTS/sample/scripts directory. This script illustrates the following operations:

- Setting up a text index.
- Modifying data and propagating changes to the collections. This
  includes inserts, updates, and deletes.
- Dropping a text index.

Execution of this script is not required for installation or configuration; Sybase supplies the script as a sample.

Before you run the sample\_text\_main.sql script:

- Your Adaptive Server and Full-Text Search engine must be configured and running.
- Use a text editor to edit the sample\_text\_main.sql script. Change
  "YOUR\_TEXT\_SERVER" to the name of your Full-Text Search
  engine in Step 4 in the sample\_text\_main.sql script.
- Verify that your model database contains a text\_events table. If your model database is not configured this way, you need to:
  - Modify the sample\_text\_main.sql script to exit after creating the database
  - Apply the installevent script to the new database (see "Running the installevent Script" on page 17)
  - Execute the remainder of the sample script

Direct the script as input to your Adaptive Server. For example, to run the sample\_text\_main.sql script on an Adaptive Server named MYSVR:

```
isql -Ulogin -Ppassword -SMYSVR
-i
$SYBASE/$SYBASE_FTS/sample/scripts/sample_text_main
.sql -omain.out
```

When you finish with this sample environment, log in to your Adaptive Server and drop the sample database. For example:

```
1> use master
2> go
1> drop database sample_colors_db
```

2> go

The sample\_text\_main.sql script can be rerun.

## Sample Files Illustrating Full-Text Search Engine Features

The Full-Text Search engine supplies a set of sample files for illustrating text server operations. The files are located in the \$\$SYBASE\_\$SYBASE\_FTS/sample/scripts directory. Execution of the sample files is not required for installation, configuration, or operation of a Full-Text Search engine.

#### **Custom Thesaurus**

The following files illustrate how to set up and use a custom thesaurus:

- *sample\_text\_thesaurus.ctl* is a sample control file.
- *sample\_text\_thesaurus.sql* provides sample queries using the custom thesaurus created by the sample control file.

You can create a custom thesaurus only with the Enhanced Full-Text Search engine. The scripts can be rerun.

### **Topics**

The following files illustrate how to set up and use topics:

- *sample\_text\_topics.otl* is a sample outline file.
- *sample\_text\_topics.kbm* is a sample knowledge base map.
- *sample\_text\_topics.sql* provides sample queries using the defined topics.

Topics is available only with the Enhanced Full-Text Search engine. The scripts can be rerun.

## Clustering, Summarization, and Query-by-Example

The following files illustrate how to set up and use clustering, summarization and query-by example:

- *sample\_text\_setup.sql* creates a sample environment.
- *sample\_text\_queries.sql* issues queries against the environment and drops the environment.

You can use these scripts only with the Enhanced Full-Text Search engine. These scripts can be rerun as a pair.

## getsend Sample Program

The Enhanced Full-Text Search engine supplies a program named getsend to load text or image data from a file into a column defined in Adaptive Server.

The required source and header files, a makefile, and directions for building and running the program are included in the directory:

\$SYBASE\\$SYBASE\_FTS\sample\source

Refer to the *README.TXT* file and *getsend.c* file for information on how to use the program.

## APPENDIX C Unicode Support

The Unicode standard, a subset of the International Standards Organization's ISO 10646 standard, is an international character set. Unicode is identical to the Basic Multilingual Plane (BMP) of ISO 10646, which supports all the major scripts and languages in the world. Therefore, it is a superset of all existing character sets.

The major advantages of Unicode are:

- Provides single-source development. This means you develop an
  application once and it can then be localized for multiple locales and
  in multiple languages. By using a single unified character set, you do
  not have to modify your applications to take into account differences
  between character sets, thus reducing development, testing, and
  support costs.
- Allows you to mix different languages in the same database. An all-Unicode system does not require that you design your database to keep track of the character set of your data.

The Enhanced Full-Text Search engine supports Unicode. To use this feature, you need to obtain and install the Unicode Developer's Kit (also known as UDK). This contains everything you need to set up a Unicode-enabled client/server database system.

To configure the Full-Text Search engine to store data in Unicode format, set the charset configuration value to utf8 (see "Modifying the Configuration Parameters" on page 67).

**Note** If you issue wildcard searches against data in Unicode format, turn on trace flag 15. For more information, refer to "Setting Trace Flags" on page 72,
