To reduce the computing time associated with algorithms to solve (4.7) or (4.8), we wish to keep N as small as possible. After each complete iteration of [18, Algorithm 5.2], we will drop those constraints that appear to be nonbinding and we will add constraints where the inequality $f(x, y) \leq \rho$ seems to be violated significantly. Let us now explain more precisely when to delete or add constraints. Given a finite set $S \subset Y$ and a multiplier λ with support in S , the augmented Lagrangian introduced in § 3 is

$$(4.9) \quad L(\lambda, S, x) = \text{minimum} \{L(\lambda, S, x, \rho) : \rho \in R\}$$

where

$$L(\lambda, S, x, \rho) = \rho + \sum_{y \in S_+} \{\lambda_y(f(x, y) - \rho) + r(f(x, y) - \rho)^2\} - \frac{1}{4r} \sum_{y \in S_-} \lambda_y^2.$$

As usual, the limits for the summations above are

$$(4.10) \quad \begin{aligned} S_+ &= \{y \in S : 2r(f(x, y) - \rho) + \lambda_y \geq 0\} \quad \text{and} \\ S_- &= \{y \in S : 2r(f(x, y) - \rho) + \lambda_y < 0\}. \end{aligned}$$

PROPOSITION 4.1. *For fixed r, λ, S , and x , suppose that $\rho = \rho^*$ attains the minimum in (4.9), and let S_+ be the corresponding set given in (4.10). Then we have*

$$L(\lambda, S, x) = L(\lambda_+, S_+, x) - \frac{1}{4r} \sum_{y \in S_-} \lambda_y^2$$

where λ_+ denotes the vector formed from λ by extracting those components λ_y corresponding to $y \in S_+$.

Proof. The identity

$$0 = \frac{d}{d\rho} L(\lambda, S, x, \rho^*) = \frac{d}{d\rho} L(\lambda_+, S_+, x, \rho^*)$$

implies that ρ^* also minimizes $L(\lambda_+, S_+, x, \cdot)$. \square

Since $L(\lambda, S, x)$ just differs from $L(\lambda_+, S_+, x)$ by a constant, Proposition 4.1 implies that, at least locally, the constraints $f(x, y) \leq \rho$ corresponding to $y \in S_-$ can be dropped. Consequently, our rule for deleting elements from Y^N can be stated:

CONSTRAINT DELETION

Let λ_k and x_k denote the approximations generated by one complete iteration of say [18, Algorithm 5.2]. Delete from Y^N those elements corresponding to $y \in Y_-^N$.

Now consider the addition of constraints. Again, the augmented Lagrangian helps us decide when the N in (4.8) must be increased. Suppose that η is not an element of S and $f(x, \eta) < \rho^*$ where $\rho = \rho^*$ attains the minimum in (4.9). Letting S_η denote $S \cup \{\eta\}$, we now show that $L(\lambda, S_\eta, x)$ is locally equal to $L(\lambda, S, x)$ if f is continuous and λ_η is zero. By the definition of the augmented Lagrangian, we have the inequality $L(\lambda, S_\eta, x) \geq L(\lambda, S, x)$ whenever $\lambda_\eta = 0$. Since $L(\lambda, S_\eta, x, \rho^*) = L(\lambda, S, x, \rho^*)$, it follows that $L(\lambda, S_\eta, x) = L(\lambda, S, x)$ whenever $\lambda_\eta = 0$. Since the inequality $f(x, \eta) < \rho^*$ is preserved for small perturbations in x when f is continuous, we conclude that $L(\lambda, S_\eta, x)$ is locally equal to $L(\lambda, S, x)$. Conversely, suppose that $f(x, \eta) > \rho^*$ and $\lambda_\eta = 0$. Since $L(\lambda, S_\eta, x, \rho) \geq L(\lambda, S, x, \rho)$ for every ρ when $\lambda_\eta = 0$ and since $L(\lambda, S_\eta, x, \rho^*) > L(\lambda, S, x, \rho^*)$, it follows from the uniqueness result Lemma 3.2 that $L(\lambda, S_\eta, x) > L(\lambda, S, x)$. To summarize, if $f(x, \eta) > \rho^*$, then $L(\lambda, S_\eta, x)$ is larger than $L(\lambda, S, x)$ and the gap between the value of the primal problem (4.1) and the value of the dual problem

$$\max_{\lambda, S} \min_{x \in X} L(\lambda, S, x)$$

may be reduced by inserting η into S . These observations lead us to the following rule for adding constraints in phase one:

CONSTRAINT ADDITION IN PHASE ONE

Let λ_k and x_k denote the approximations generated by one complete iteration of say [18, Algorithm 5.2] and let $\rho = \rho^*$ minimize $L(\lambda_k, Y^N, x_k, \rho)$ over ρ . Insert $y_i(x_k)$ into Y^N if $f(x_k, y_i(x_k)) > \rho^*$ and the distance between $y_i(x_k)$ and Y^N is greater than some fixed predetermined constant Δ .

Since phase one approximates the solution to the minimax problem, the local maximizer $y_i(x_k)$ appearing in the constraint addition step of phase one does not need to be computed very accurately. The positive parameter Δ introduced above prevents points in Y^N from clustering together. As the number of points in Y^N increases, the time to evaluate L increases and the Hessian of L becomes ill conditioned. Since it helps to keep the number of points in Y^N small, we exclude those local maxima which are already near elements of Y^N . In numerical experiments, the convergence speed is not very sensitive to the choice of Δ . In phase two, the elements of Y^N are local

maxima instead of fixed elements in Y . Hence, the analogous rule for adding constraints in phase two can be stated:

CONSTRAINT ADDITION IN PHASE TWO

Let λ_k and x_k denote the approximations generated by one complete iteration of say [18, Algorithm 5.2] and let $\rho = \rho^*$ minimize $L(\lambda_k, Y^N, x_k, \rho)$ over ρ . Insert $y_i(\cdot)$ into Y^N if $f(x_k, y_i(x_k)) > \rho^*$.

Up to here, we have explained how to initialize a mathematical programming algorithm to solve either (4.7) or (4.8) and we have explained how to add or delete constraints at the end of each iteration in the algorithm. Now let us consider the details of an iteration. In formulation (4.7) and (4.8), a parameter ρ is introduced and the number of independent variables is increased by one. For many algorithms, the artificial variable ρ can be eliminated and the iterations can be expressed in terms of x and λ . For notational convenience, we assume X is R^n . Let x_k be the k th approximation to a solution to the minimax problem and suppose that after deleting and adding constraints at the end of iteration k , we have $Y^N = \{y_1, \dots, y_N\}$. In [18, Algorithm 5.2], we estimate the multipliers corresponding to the constraints of (4.7) or (4.8) by computing the least squares solution λ to the system of equations

$$(4.11) \quad \sum_{i=1}^N \lambda_i = 1, \quad \sum_{i=1}^N \lambda_i \nabla f(x_k, y_i) = 0.$$

Computing the least squares solution to this system of $n+1$ equations in N unknowns is equivalent to computing the pseudoinverse of a $(n+1) \times N$ matrix. As an alternative to this procedure, we suggest the following: Solve the first equation in (4.11) for λ_1 in terms of λ_2 through λ_N and substitute into the second relation to obtain n equations in $N-1$ unknowns:

$$\sum_{i=2}^N \lambda_i (\nabla_x f(x_k, y_i) - \nabla_x f(x_k, y_1)) = -\nabla_x f(x_k, y_1).$$

The least squares solution to this system gives us an estimate for λ_2 through λ_N while λ_1 is determined from the relation $\lambda_1 = 1 - \lambda_2 - \lambda_3 - \dots - \lambda_N$.

The procedure outlined above to estimate the multipliers is quite effective in phase two. On the other hand, in phase one a simpler strategy involving the gradient approximation to the multipliers (see [2]) is often just as effective. Let λ_k be the k th approximation to the multipliers and let x_k be the corresponding approximation to a minimizer of the augmented Lagrangian $L(\lambda_k, Y^N, \cdot)$. Set $\lambda_{k+1,i} = \lambda_{ki} + 2r(f(x_k, y_{ki}) - \rho_k)$ for $i \in Y_+^N$ and set $\lambda_{k+1,i} = 0$ for $i \in Y_-^N$ if this rule generates a λ_{k+1} with the property that (λ_{k+1}, x_k) is a better approximation to a Kuhn-Tucker point for (4.7) than (λ_k, x_k) . Otherwise, set $\lambda_{k+1} = \lambda_k$. Here ρ_k denotes the minimizer in (4.9) corresponding to $\lambda = \lambda_k$, $S = Y^N$, and $x = x_k$. A technique for measuring the distance to a Kuhn-Tucker point is developed in [18].

In [18, Algorithm 5.2], the restoration step is essentially a Newton iteration applied to the system of N equations

$$(4.12) \quad f(x, y_i) = \rho \quad \text{for } i = 1 \text{ to } N$$

where the starting guess is x_k and the corresponding ρ_k generated the previous iteration. Since the N equations (4.12) are equivalent to the $N-1$ equations

$$(4.13) \quad f(x, y_i) - f(x, y_1) = 0 \quad \text{for } i = 2 \text{ to } N,$$

an alternative procedure is to apply one Newton iteration to the system (4.13). Observe that this Newton iteration involves computing the pseudoinverse of the same matrix used in the multiplier estimate.

In the minimization step of [18, Algorithm 5.2], we use a preconditioned conjugate gradient method to minimize $L(\lambda_k, Y^N, x)$ over x . (Here, λ_k denotes the multiplier associated with iteration k .) Near the optimum, the preconditioner is chosen to project the gradients into the null space of the binding constraints. Therefore, near the optimum, the preconditioner projects the gradients into the null space of the $(N-1) \times n$ matrix with rows

$$\nabla_x f(x_k, y_i) - \nabla_x f(x_k, y_1) \quad \text{for } i = 2 \text{ to } N.$$

Far from the optimum, the preconditioner is chosen to mitigate the ill conditioning due to penalty terms in the augmented Lagrangian. At the start of iteration $k+1$, the inequalities $f(x, y_i) \leq \rho$ are viewed as equalities and it follows from (4.9) that for x near x_k ,

$$L(\lambda_k, Y^N, x) = \sum_{i=1}^N \lambda_{ki} f(x, y_i) + r \sum_{i=1}^N f(x, y_i)^2 - \frac{r}{N} \left(\sum_{i=1}^N f(x, y_i) \right)^2.$$

The identity

$$\sum_{i=1}^N f(x, y_i)^2 - \frac{1}{N} \left(\sum_{i=1}^N f(x, y_i) \right)^2 = \sum_{i=1}^N \left(f(x, y_i) - \frac{1}{N} \sum_{j=1}^N f(x, y_j) \right)^2,$$

combined with the preconditioning theory developed in [18, § 4], tells us that a natural preconditioner for the minimax problem is the matrix $H = (I + B^T B)^{-1}$, where B is the $N \times n$ matrix with i th row

$$\nabla_x f(x_k, y_i) - \frac{1}{N} \sum_{j=1}^N \nabla_x f(x_k, y_j).$$

Observe that the rows of B are linearly dependent since their sum is zero. Let V denote the matrix $I - vv^T$, where

$$v = \frac{1}{\sqrt{\sqrt{N}(1+\sqrt{N})}} \begin{bmatrix} 1 + \sqrt{N} \\ 1 \\ \vdots \\ 1 \end{bmatrix}.$$

Since the first row of V is a multiple of $\mathbf{1}$, the first row of VB is zero. Let W be the matrix obtained by deleting the first row of VB . Since V is orthogonal, we have

$$B^T B = (VB)^T VB = W^T W.$$

Applying the Woodbury formula [15, p. 3], the preconditioner H can be written

$$H = (I + rW^T W)^{-1} = I - W^T (r^{-1}I + WW^T)^{-1} W.$$

When using any gradient technique to minimize $L(\lambda_k, Y^N, \cdot)$, we must compute the gradient of the augmented Lagrangian with respect of x . By [10, Thm. 2.1] this gradient can be expressed

$$\nabla_x L(\lambda, S, x) = \sum_{y \in S_+} (\lambda_y + 2r(f(x, y) - \rho^*)) \nabla_x f(x, y)$$

where ρ^* attains the minimum in (4.9). This formula for the gradient is also valid when the elements of S depend on x (as in (4.8)) provided these elements are local

extreme points of $f(x, \cdot)$ on Y and (for example) $\nabla_x f(x, y)$ is a continuous function of x and y .

Comparing our approach to the minimax problem to the approach of Murray and Overton [26], some similarities are that we both reformulate the minimax problem as a mathematical program with an extra unknown and we both estimate simultaneously the primal solution and the Lagrange multipliers. Some differences in our methods are the following: (i) In [26] Y is finite. (ii) We utilize an augmented Lagrangian while [26] considers the ordinary Lagrangian. (iii) Our strategy for adding and deleting constraints is different from [26]—our strategy ties in with the augmented Lagrangian. (iv) With our approach, nonlinear constraints contained in X can be incorporated in the augmented Lagrangian just as easily as the constraints $f(x, y) \leq \rho$.

5. Reducible minimax problems. So far we have viewed the minimax problem as an optimization problem with inequality constraints and we have applied a constrained optimization algorithm. Now let us develop an algorithm that is specially tailored to reducible minimax problems. That is, we assume that there exists a finite set $Y^* \subset Y$ and a x^* in X such that

$$\min_{x \in X} \max_{y \in Y^*} f(x, y) = \max_{y \in Y^*} f(x^*, y) = \max_{y \in Y} f(x^*, y) = \Phi(x^*),$$

and we search for the set Y^* . It is also assumed that there exists a real number r and a multiplier λ^* with support in Y^* such that $L(\lambda^*, Y^*) = \Phi(x^*)$ where $L(\cdot, \cdot)$ denotes the dual functional defined by

$$L(\lambda, S) = \inf \{L(\lambda, S, x) : x \in X\}.$$

Given an approximation $Y_k = \{y_{k1}, \dots, y_{kN}\}$ to Y^* and given an approximation λ_k to λ^* , the rules for computing Y_{k+1} and λ_{k+1} are the following:

PEAK CHASING ALGORITHM

(a) If x_k minimizes $L(\lambda_k, Y_k, x)$ over $x \in X$, then set $\lambda_{k+1,i} = \lambda_{ki} + 2r(f(x_k, y_{ki}) - \rho_k)$ for $i \in S_+$ and $\lambda_{k+1,i} = 0$ for $i \in S_-$ where ρ_k attains the minimum in (4.9) corresponding to $\lambda = \lambda_k$ and $S = Y_k$.

(b) If x_{k+1} minimizes $L(\lambda_{k+1}, Y_k, \cdot)$ over X and if $Z_k = \{z_1, \dots, z_N\}$ denotes a collection of local maxima for $f(x_{k+1}, \cdot)$ on Y where z_i is the closest local maximizer to y_{ki} , then we set $Y_{k+1} = \beta Y_k + (1 - \beta)Z_k$ where

$$\beta = \arg \max_{0 \leq \alpha \leq 1} L(\lambda_{k+1}, \alpha Y_k + (1 - \alpha)Z_k).$$

Step (a) is the usual gradient step for an augmented Lagrangian (see [2]). Since this algorithm is linearly convergent, the parameter β of step (b) can be imprecise. In practice, we find that the maximizer of the interpolating quadratic that agrees with $L(\lambda_{k+1}, \alpha Z_k + (1 - \alpha)Y_k)$ at $\alpha = 0$, at $\alpha = \frac{1}{2}$, and at $\alpha = 1$ works well. To show that the peak chasing algorithm is locally convergent, we verify that each iteration increases the value of the dual functional. That is, $L(\lambda_{k+1}, Y_{k+1}) \geq L(\lambda_k, Y_k)$ with equality only possible at $\lambda_k = \lambda^*$ and at $Y_k = Y^*$. In order to show that step (a) is an ascent step, let us first consider the equality constrained problem

$$(5.1) \quad \begin{aligned} &\text{minimize } f(x) \\ &\text{subject to } h(x) = 0, \quad x \in R^n \end{aligned}$$

where f is quadratic: $f(x) = x^T A x + a^T x$ and h is linear: $h(x) = Bx - b$. Here A is an $n \times n$ matrix, B is an $m \times n$ matrix, and a and b are vectors in R^n and R^m , respectively. The augmented Lagrangian corresponding to (5.1) is

$$L(\lambda, x) = f(x) + \lambda^T h(x) + r|h(x)|^2.$$

LEMMA 5.1. *Suppose that the rows of B are linearly independent and A is positive definite in the null space of B . Then there exist positive parameters α and s such that $A + rB^T B \geq \alpha I$ for every $r \geq s$. If $\lambda \in R^n$ and z minimizes $L(\lambda, \cdot)$ over R^n , then we have*

$$(5.2) \quad L(\lambda + 2rh(z), y) \geq L(\lambda, z) + \frac{1}{2}r|h(z)|^2 + \alpha|y - z|^2$$

for every $r \geq 3s$ and for every $y \in R^n$.

(If M_1 and M_2 are symmetric matrices of the same dimension, then the notation $M_1 > M_2$ means that $M_1 - M_2$ is positive definite.)

Proof. In [16, Lemma 2.6] we determine a parameter $s < \infty$ with the property that $A + rB^T B$ is positive definite for $r \geq s$. Let μ denote $\lambda + 2rh(z)$. Expanding the Lagrangian in a Taylor series, we have

$$(5.3) \quad L(\mu, y) = L(\mu, z) + \nabla_x L(\mu, z)(y - z) + \frac{1}{2}\nabla_x^2 L(\mu, \xi)(y - z)^2$$

where ξ lies on the line segment connecting y and z . The relation $\mu = \lambda + 2rh(z)$ implies that

$$(5.4) \quad L(\mu, z) = L(\lambda, z) + 2r|h(z)|^2$$

and

$$(5.5) \quad \nabla_x L(\mu, z)(y - z) = \nabla_x L(\lambda, z)(y - z) + 2rh(z)^T \nabla h(z)(y - z).$$

(Note that $\nabla_x L(\mu, z)$ is not equal to the gradient of the right side of (5.4) since μ is treated as a constant when computing $\nabla_x L(\mu, z)$.) If z minimizes $L(\lambda, \cdot)$, then $\nabla_x L(\lambda, z)$ is zero and by (5.5), we have

$$(5.6) \quad \nabla_x L(\mu, z)(y - z) = 2rh(z)^T \nabla h(z)(y - z).$$

By the definition of f and h , it follows that $\nabla h = B$ and $\nabla_x^2 L = 2(A + rB^T B)$. Combining (5.3), (5.4), and (5.6) gives us

$$L(\mu, y) = L(\lambda, z) + 2r|h(z)|^2 + 2rh(z)^T B(y - z) + (y - z)^T (A + rB^T B)(y - z).$$

Utilizing the inequality

$$ab \leq \frac{3}{4}a^2 + \frac{1}{3}b^2$$

where we identify a with $|h(z)|$ and b with $|B(y - z)|$ yields

$$(5.7) \quad L(\mu, y) \geq L(\lambda, z) + \frac{1}{2}r|h(z)|^2 + (y - z)^T (A + \frac{1}{3}rB^T B)(y - z).$$

Hence, (5.2) holds for $r \geq 3s$. \square

For a general f and h , the same argument employed in the proof of Lemma 5.1 can also be applied to a neighborhood of a local optimum. Removing the restriction that f is quadratic and h is linear, we have the following.

THEOREM 5.2. *Suppose that x^* and λ^* satisfy the hypotheses of Theorem 3.1. Then there exists a neighborhood N_x of x^* , a neighborhood N_λ of λ^* , and positive parameters α and s such that*

$$(5.8) \quad \nabla_x^2 l(\lambda, x) + 2r\nabla h(x)^T \nabla h(x) > \alpha I$$

whenever $r \geq s$, $\lambda \in N_\lambda$, and $x \in N_x$. Moreover, for s sufficiently large, a parameter c can be chosen so that $L(\lambda, \cdot)$ has a unique local minimizer $x(\lambda)$ inside N_x whenever $|\lambda - \lambda^*| \leq cr$ and $r \geq s$. And if λ and μ lie in N_λ , $y \in N_x$ with $|y - x^*| \leq c|\lambda - \lambda^*|/r$, and $r \geq s$, then we have

$$(5.9) \quad L(\mu, y) \geq L(\lambda, z) + \frac{1}{2}(r|h(z)|^2 + (\alpha - \delta|\lambda - \lambda^*|)|y - z|^2)$$

where $z = x(\lambda)$, $\mu = \lambda + 2rh(z)$, and δ is a constant that is independent of λ and y .

Proof. By [16, Lemma 2.6], $\nabla_x^2 L(\lambda^*, x^*)$ is positive definite for r sufficiently large, and by [16, Lemma 6.5], there exists a neighborhood of (λ^*, x^*) where (5.8) holds for α sufficiently small and r sufficiently large. The statement concerning the existence of a locally unique minimizer $x(\lambda)$ for $L(\lambda, \cdot)$ is established (for example) in [2]. To prove (5.9), we expand L in a Taylor series giving us the following analogue of (5.7):

$$(5.10) \quad L(\mu, y) \geq L(\lambda, z) + \frac{1}{2}r|h(z)|^2 + \frac{1}{2}(y - z)^T \nabla_x^2 L(\mu, \xi)(y - z) - \frac{2}{3}r|\nabla h(z)(y - z)|^2$$

where ξ lies between y and z . Utilizing the inequality

$$|x|^2 \leq (|x - y| + |y|)^2 \leq 5|x - y|^2 + \frac{5}{4}|y|^2$$

where x is identified with $\nabla h(z)(y - z)$ and y is identified with $\nabla h(\xi)(y - z)$, the last two terms in (5.10) satisfy the relation

$$(5.11) \quad \begin{aligned} & \frac{1}{2}(y - z)^T \nabla_x^2 L(\mu, \xi)(y - z) - \frac{2}{3}r|\nabla h(z)(y - z)|^2 \\ & \geq \frac{1}{2}(y - z)^T \nabla_x^2 L(\mu, \xi)(y - z) + \frac{1}{6}r|\nabla h(\xi)(y - z)|^2 \\ & \quad - \frac{10}{3}r|(\nabla h(\xi) - \nabla h(z))(y - z)|^2 \\ & \quad + r(y - z)^T \left(\sum_{i=1}^m h_i(\xi) \nabla^2 h_i(\xi) \right) (y - z). \end{aligned}$$

By (5.8), we have

$$(5.12) \quad \frac{1}{2}(y - z)^T \nabla_x^2 L(\mu, \xi)(y - z) + \frac{1}{6}r|\nabla h(\xi)(y - z)|^2 \geq \frac{1}{2}\alpha|y - z|^2$$

provided r is sufficiently large, $\mu \in N_\lambda$, and $\xi \in N_x$. By Theorem 3.1, $|z - x^*|$ is bound by a constant times $|\lambda - \lambda^*|/r$ and by assumption, $|y - x^*|$ is bound by a constant times $|\lambda - \lambda^*|/r$. Since $h(x^*)$ is zero, there exists a constant δ such that

$$(5.13) \quad \begin{aligned} & \frac{10}{3}r|(\nabla h(\xi) - \nabla h(z))(y - z)|^2 + r(y - z)^T \left(\sum_{i=1}^m h_i(\xi) \nabla^2 h_i(\xi) \right) (y - z) \\ & \leq \delta|\lambda - \lambda^*| |y - z|^2 \end{aligned}$$

for λ near λ^* . Combining (5.10)–(5.13), the proof is complete. \square

Theorem 5.2 implies that if λ is near λ^* , then for $\mu = \lambda + 2rh(x(\lambda))$, $L(\mu, x(\mu))$ is equal to $L(\lambda, x(\lambda))$ only if $h(x(\lambda)) = 0$. Since $x(\lambda)$ minimizes $L(\lambda, \cdot)$ over N_x , we conclude that if $L(\mu, x(\mu)) = L(\lambda, x(\lambda))$, then $x = x(\lambda)$ is a solution to the problem: minimize $f(x)$ subject to $x \in N_x$ and $h(x) = 0$. Therefore, $x(\lambda) = x^*$, the local minimizer corresponding to λ^* . Theorem 5.2 also applies to problems of the form

$$(5.14) \quad \begin{aligned} & \text{minimize } f(x) \\ & \text{subject to } h(x) = 0, \quad x \in X \end{aligned}$$

where X is a convex set. The proof of Theorem 5.2 in this more general setting involves an analogue of Theorem 3.1 that applied to (5.14). See Bertsekas [2] for the extension of Theorem 3.1 to problems with the constraint $x \in X$. Furthermore, referring to the

proof of Lemma 5.1, the constraint $x \in X$ alters the treatment of the term $\nabla_x \mathbf{L}(\lambda, z)(y - z)$. When X is R^n , $\nabla_x \mathbf{L}(\lambda, z)$ is zero and the term $\nabla_x \mathbf{L}(\lambda, z)(y - z)$ can be dropped. But for an arbitrary convex set, the corresponding relation is

$$\nabla_x \mathbf{L}(\lambda, z)(y - z) \geq 0.$$

This inequality has the right direction so that the term $\nabla_x \mathbf{L}(\lambda, z)(y - z)$ can still be dropped without affecting (5.7).

Although Theorem 5.2 is established for an equality constraint, it also applies to the inequality constraint $g(x) \leq 0$ provided λ_i^* is positive whenever $g_i(x^*)$ is zero. This follows from [31, Thm. 5.1] where Rockafellar proves that near λ^* , minimizing $\mathbf{L}(\lambda, \cdot)$ is equivalent to minimizing the augmented Lagrangian corresponding to an equality constraint $h(x) = 0$ —the components h_i of h are the components g_i of g for which $\lambda_i^* > 0$. Hence, by Theorem 5.2, step (a) of the peak chasing algorithm is an ascent step under appropriate assumptions. That is, $\mathbf{L}(\lambda_{k+1}, Y_k) \geq \mathbf{L}(\lambda_k, Y_k)$ with equality only possible when the x_k which locally minimizes $\mathbf{L}(\lambda_k, Y_k, \cdot)$ on X is a local minimizer for the problem

$$\underset{x \in X}{\text{minimize}} \quad \underset{y \in Y_k}{\text{maximum}} \quad f(x, y).$$

Now consider step (b) of the peak chasing algorithm. As noted above, in a neighborhood of an optimum, the augmented Lagrangian corresponding to an inequality constrained problem is the same as the augmented Lagrangian corresponding to an equality constrained problem. For this reason, we focus attention on the augmented Lagrangian

$$\mathbf{L}(\lambda, S, x) = \sum_{y \in S} \lambda_y f(x, y) + r \sum_{y \in S} f(x, y)^2 - \frac{r}{N} \left(\sum_{y \in S} f(x, y) \right)^2$$

which corresponds to the equality constrained problem

$$\text{minimize } \rho$$

$$\text{subject to } x \in X, \quad \rho \in R, \quad f(x, y) = \rho \quad \text{for every } y \in S.$$

And we establish the following property for the dual functional:

LEMMA 5.3. *Let λ be a fixed vector in R^N with nonnegative components, let $S_0 = \{y_1, \dots, y_N\}$ and let $S_1 = \{z_1, \dots, z_N\}$ be subsets of Y , and suppose that for $i = 0$ and for $i = 1$, x_i minimizes $\mathbf{L}(\lambda, S_i, x)$ over x in X . Then we have*

$$(5.15) \quad \mathbf{L}(\lambda, S_1) \geq \mathbf{L}(\lambda, S_0) + \sum_{i=1}^N (\lambda_i + 2r(f(x_1, y_i) - \rho_1))(f(x_1, z_i) - f(x_1, y_i))$$

where

$$\rho_1 = \frac{1}{N} \sum_{i=1}^N f(x_1, y_i).$$

Proof. Let $Q: R^N \rightarrow R$ be the quadratic defined by

$$Q(p) = \sum_{i=1}^N \lambda_i p_i + r p_i^2 - \frac{r}{N} \left(\sum_{i=1}^N p_i \right)^2.$$

The Hessian of Q is

$$\nabla^2 Q = 2r \left(I - \frac{1}{N} \mathbf{1} \mathbf{1}^T \right),$$

which is positive semidefinite by Gerschgorin's theorem. Hence, Q is a convex function which satisfies the standard inequality [29, p. 242]:

$$(5.16) \quad Q(p) - Q(q) \geq \nabla Q(q)(p - q) = \sum_{i=1}^N (\lambda_i + 2r(q_i - \rho))(p_i - q_i)$$

where

$$\rho = \frac{1}{N} \sum_{i=1}^N q_i.$$

Since x_0 minimizes $L(\lambda, S_0, x)$ over $x \in X$, it follows that $L(\lambda, S_0) \leq L(\lambda, S_0, x_1)$, or equivalently,

$$(5.17) \quad L(\lambda, S_1) - L(\lambda, S_0) \geq L(\lambda, S_1, x_1) - L(\lambda, S_0, x_1).$$

Applying (5.16) to the right side of (5.17) where $p_i = f(x_1, z_i)$ and $q_i = f(x_1, y_i)$ yields (5.15). \square

Lemma 5.3 can be used to show that under appropriate assumptions, step (b) of the peak chasing algorithm is an ascent step. Let S_α denote $\alpha S_1 + (1 - \alpha)S_0$. Suppose that for α between zero and one, the minimum of $L(\lambda, S_\alpha, x)$ over $x \in X$ is attained at a point labeled x_α which is a continuous function of α . Let λ^* maximize $L(\lambda, S_0)$ over λ . Typically the components of λ^* are positive. By Theorem 3.1, the vector μ_0 with components

$$\mu_{0i} = \lambda_i + 2r(f(x_0, y_i) - \rho_0), \quad \rho_0 = \frac{1}{N} \sum_{i=1}^N f(x_0, y_i)$$

satisfies the inequality $|\mu_0 - \lambda^*| \leq c|\lambda - \lambda^*|/r$ for some constant c . Hence, the components of μ_0 are positive for r sufficiently large. Letting μ_α be the vector defined by

$$\mu_{\alpha i} = \lambda_i + 2r(f(x_\alpha, y_i) - \rho_\alpha), \quad \rho_\alpha = \frac{1}{N} \sum_{i=1}^N f(x_\alpha, y_i),$$

it follows that the components of μ_α are positive for α sufficiently small. If z_i is a local maximizer of $f(x_0, \cdot)$, then we expect that $f(x_0, \cdot)$ is locally concave near z_i . Assuming that $f(z_\alpha, \cdot)$ is concave for α near zero on the line segment connecting y_i and z_i , we have

$$(5.18) \quad f(x_\alpha, \alpha z_i + (1 - \alpha)y_i) \geq \alpha f(x_\alpha, z_i) + (1 - \alpha)f(x_\alpha, y_i).$$

Combining (5.15) and (5.18) gives us

$$(5.19) \quad L(\lambda, S_\alpha) \geq L(\lambda, S_0) + \alpha \left\{ \sum_{i=1}^N \mu_{\alpha i} (f(x_\alpha, z_i) - f(x_\alpha, y_i)) \right\}.$$

Hence, for α sufficiently small, $L(\lambda, S_\alpha)$ is strictly larger than $L(\lambda, S_0)$ unless the y_i are equal to the z_i . Now let us state a more precise convergence result.

THEOREM 5.4. *We make the following assumptions:*

- I. X is R^n , Y is a convex, compact subset of a vector space, and $f(x, y)$ is a concave function of y for each fixed x . There exists x^* in X , a finite set $Y^* = \{y_1^*, \dots, y_N^*\}$ contained in Y , and a multiplier λ^* with support equal to Y^* such that

$$L(\lambda^*, Y^*) = \max_{y \in Y^*} f(x^*, y) = \max_{y \in Y} f(x^*, y).$$

II. The Hessian $\nabla_x^2 f(x, y)$ exists and depends continuously on x near x^* and on y near y_i^* for each i between 1 and N . Moreover, the mathematical program

minimize ρ

subject to $x \in R^n$, $f(x, y_i^*) - \rho = 0$ for $i = 1, \dots, N$

satisfies the assumptions of Theorem 3.1 at the optimum $x = x^*$ and $\rho = f(x, y_i^*)$ and if N is the neighborhood of x^* introduced in Theorem 3.1, then we have

$$L(\lambda, S) = \inf \{L(\lambda, S, x) : x \in N\}$$

for λ and S in some neighborhood W of (λ^*, Y^*) .

III. For $x \in N$ there exist local maxima $y_i(x)$ of $f(x, \cdot)$ on Y such that $y_i(x)$ approaches y_i^* as x approaches x^* for $i = 1, \dots, N$. Furthermore, $y_i(x)$ is the locally unique maximizer of $f(x, \cdot)$ for x near x^* and for x near x^* , we have

$$\max_{1 \leq i \leq N} f(x, y_i(x)) = \max_{y \in Y} f(x, y).$$

IV. $L(\lambda, S) < L(\lambda^*, Y^*)$ whenever $(\lambda, S) \in W$, $\lambda \neq \lambda^*$, and $S \neq Y^*$.

Under assumptions I-IV and for r large enough, the peak chasing algorithm converges to λ^* and Y^* starting from any point sufficiently close to λ^* and Y^* .

Proof. We just sketch the proof. For λ near λ^* and for S near Y^* , assumption II implies that there exists $x(\lambda, S)$ which minimizes $L(\lambda, S, x)$ over x in a neighborhood of x^* and $x(\lambda, S)$ depends continuously on λ and S . By Theorem 5.2, step (a) of the peak chasing algorithm is an ascent step for r sufficiently large. Since step (b) of the peak chasing algorithm does not decrease the value of the dual functional, assumption IV implies that if the iterations start near λ^* and Y^* , then the iterations remain near λ^* and Y^* . Since λ_k , Y_k , and x_k lie in compact sets, we can extract subsequences converging to limits λ_∞ , Y_∞ , and x_∞ , respectively. For convenience, these subsequences are also denoted λ_k , Y_k , and x_k . Since x_k minimizes $L(\lambda_k, Y_k, x)$ over $x \in X$, we conclude that x_∞ minimizes $L(\lambda_\infty, Y_\infty, x)$ over $x \in X$. Since $L(\lambda_k, Y_k)$ is bound above by $L(\lambda^*, Y^*)$, the difference $L(\lambda_{k+1}, Y_{k+1}) - L(\lambda_k, Y_k)$ approaches zero as k increases. Hence, Theorem 5.2 implies that $f(x_\infty, y_{\infty i}) - \rho_\infty$ is zero for each i . Also, it follows from (5.19) that the elements of Y_∞ are local maxima of $f(x_\infty, \cdot)$ on Y . Combining these relations, we conclude that

$$(5.20) \quad L(\lambda_\infty, Y_\infty) = \max_{y \in Y_\infty} f(x_\infty, y) = \max_{y \in Y} f(x_\infty, y).$$

The first equality in (5.20) implies through duality that x_∞ is the solution to the discrete minimax problem

minimize ρ

subject to $x \in R^n$, $f(x, y_{\infty i}) \leq \rho$ for $i = 1, \dots, N$.

And the second equality in (5.20) implies that x_∞ is a solution to the continuous minimax problem

$$\min_{x \in R^n} \max_{y \in Y} f(x, y).$$

By assumption IV, λ^* and Y^* are locally unique maxima of L . Consequently, $\lambda_\infty = \lambda^*$,

$Y_\infty = Y^*$, and $x_\infty = x^*$. It then follows from the ascent property that the original sequence (not just the extracted subsequence) converges to λ^* , Y^* , and x^* . \square

Acknowledgment. We wish to thank the referee for a suggestion that led to a shorter proof for Lemma 3.2 and a more direct treatment of the algorithm to minimize $L(\lambda, x, \rho)$ over ρ .

ON THE H^∞ -OPTIMAL SENSITIVITY PROBLEM FOR SYSTEMS WITH DELAYS*

CIPRIAN FOIAS†, ALLEN TANNENBAUM‡ AND GEORGE ZAMES§

Abstract. In this paper we extend some of the results of [IEEE Trans. Automat. Control, AC-31 (1986), pp. 763–766] to more general delay systems. In particular, we analyze the effect of the interaction of delays and nonminimum phase zeros on the H^∞ -optimal weighted sensitivity.

Key words. sensitivity minimization, delay, contraction, defect operator, distributed system

AMS(MOS) subject classifications. 93B35, 93C05

Notation and Terminology.

D = open unit disc

\bar{D} = closed unit disc

∂D = unit circle

H = open right half plane

\bar{H} = closed right half plane

$\hat{H} = \bar{H} \cup \{\infty\}$

$H^p(X)$ = the standard Hardy p -space ($1 \leq p \leq \infty$) on X where $X = D$ or H . See Duren [6] or Rudin [19] for details. We will also use some elementary facts about L^p -spaces and Hilbert spaces. Again see [6] or [19] for details.

$H^2(X) \ominus uH^2(X)$ = orthogonal complement of $uH^2(X)$ in $H^2(X)$ where $u \in H^\infty(X)$ is an inner function.

Let S denote an arbitrary Hilbert space with inner product $\langle \cdot, \cdot \rangle$. Then for $x, y \in S$, $x \otimes y$ denotes the operator defined by $(x \otimes y)w := \langle w, y \rangle x$ for $w \in S$.

On the unit circle ∂D we identify \bar{z} and $1/z$ in the usual way.

Finally we use all the standard notation from Hilbert space theory. See, e.g., [6], [19], [24].

Introduction. This paper is the sequel to [9]. We recall that in [9], the authors solved the weighted H^∞ -minimization problem for a plant consisting of a pure delay and arbitrary stable (with stable inverse) real rational proper weighting function. We saw that in contrast to the unweighted problem, which reduces to a simple classical Nevanlinna–Pick interpolation problem for a large class of distributed systems [7], [16], even for the simplest weighting function ($W(s) = 1/(as + 1)$, $a > 0$), the weighted problem reflects the distributed nature of systems with delays.

In this paper, we give a general procedure for computing the optimal weighted sensitivity for an arbitrary real rational stable (with stable inverse) weight, and for plants of the form $e^{-hs}P_0(s)$ where $P_0(s)$ is a proper real rational function with no poles or zeros on the $j\omega$ -axis.

In point of fact, we give a general procedure for solving the following kind of problem: Let $P(s)$ be a plant (perhaps distributed) and suppose that we have a

factorization $P(s) = P_1(s)P_2(s)$. Then for given weight, we can write down an expression for the H^∞ -optimal sensitivity of $P(s)$ in terms of data determined by $P_1(s)$ and $P_2(s)$. Moreover in this expression (see (3.2) below for a more precise statement) the data given by $P_1(s)$ is *decoupled* from the data given by $P_2(s)$. So for example when $P(s) = e^{-hs}P_0(s)$ as above, we can apply our procedure to $P_1(s) = e^{-hs}$ and $P_2(s) = P_0(s)$, a proper real rational function for which the optimal sensitivity problem is easy to solve.

Our methods are in a certain sense a generalization in the rational weighting case of the one-step extension technique of Adamjan, Arov and Krein [1], [2] and actually give new proofs to certain of their results (see Theorem 3.2, § 3.4 and Theorem 3.9 below for details). Basically what we have solved is an “ n -step” or even an “ ∞ -step” extension problem Theorem 3.2. Thus our techniques even give a new viewpoint to certain problems in Nevanlinna–Pick interpolation theory [14].

As in [9], our methods are heavily influenced by the results of Sarason [20] and Sz. Nagy and Foias [23], [24]. Consequently, we will be working in $H^2(D)$ where D is the unit disc. Moreover, the techniques we use have a strong complex-analytic flavor.

Finally in § 4, we will apply our procedure to the case

$$P(s) = e^{-hs} \left(\frac{s-b}{s+b} \right), \quad W(s) = \frac{1}{as+1},$$

$a, b, h > 0$. This will allow us to understand the coupling and effect of the three fundamental parameters a (the inverse of the bandwidth), b (the nonminimum phase zero), and h (the delay) on the optimal sensitivity. As expected for $b \rightarrow \infty$, our formula approaches that of [9] (see also § 1), and so our method here actually gives an alternative route to some of the results of [9].

1. Preliminaries. In this section we would like to briefly review some of the material from our paper [9], and set up some of the notation connected with the weighted sensitivity H^∞ -minimization problem posed by Zames [26]. We should note that independently David Flamm in his thesis [8] (done while at M.I.T.) has derived some results very similar to the ones that we will describe in this section. Israel Gohberg more recently discussed with the authors an approach to derive (1) below, similar to that of Flamm’s using the Hankel operator.

We begin by recalling the general weighted sensitivity H^∞ -minimization problem for SISO, LTI plants (see [11] for an excellent survey on all of this). We are given a SISO, LTI plant $P(s)$, and a stable (with stable inverse) proper real rational weight $W(s)$. Let $C(s)$ denote an internally stabilizing LTI controller for $P(s)$ in the feedback system of Fig. 1.

Then following [26], we define the *weighted sensitivity*:

$$S_W(s) := W(s)(1 + P(s)C(s))^{-1}.$$

The problem in which we are interested is in determining the existence of and computing

$$\inf \{ \|S_W(s)\|_\infty : C \text{ stabilizing} \}$$

where $\| \cdot \|_\infty$ denotes the H^∞ -norm in the right half plane H .

FIG. 1. Standard feedback configuration.

In the finite-dimensional case, this problem is discussed and solved in [13], [12], [15]. In our previous paper [9], we considered the case in which $P(s) = e^{-hs}$, and $W(s)$ a stable strictly proper real rational weighting function with stable inverse. Basically we showed that the problem of the computation of the optimal sensitivity could be reduced to computing the eigenvalues of a certain linear ordinary differential operator with constant coefficients of order $2n$ subject to $2n$ boundary conditions, where n = number of poles of $W(s)$. From the associated Wronskian determinant of the problem, we could then find the required minimal sensitivity (actually all of the singular values of the associated Hankel operator).

To see how this goes, let us briefly sketch the argument from [9]. (See [9] for all the rigorous details.) First of all using the results of [26], one can show that the computation of the optimal sensitivity amounts to finding:

$$\mu := \inf_{q \in H^\infty} \|W(s) - e^{-hs}q(s)\|_\infty.$$

(Throughout this section $H^2 := H^2(H)$, $H^\infty := H^\infty(H)$.) Let $\Pi: H^2 \rightarrow H^2 \ominus e^{-hs}H^2$ denote orthogonal projection. Moreover, we denote by M_W the operator $H^2 \rightarrow H^2$ defined by multiplication by W . Then by [1], [20], [23],

$$\mu = \|\Pi M_W|_{H^2 \ominus e^{-hs}H^2}\|.$$

Computing this norm is not difficult. Indeed we can show via the Fourier or Laplace transform (see [20]) that there exists an isometric isomorphism

$$\phi: H^2 \ominus e^{-hs}H^2 \xrightarrow{\sim} L^2[0, h].$$

Setting

$$\Gamma := \phi \circ (\Pi M_W|_{H^2 \ominus e^{-hs}H^2}) \circ \phi^{-1}$$

we are reduced to computing $\|\Gamma\|$. (Notice $\Gamma: L^2[0, h] \rightarrow L^2[0, h]$.) But again from [20] it follows that we can identify the operator “ $1/s$ ” on $H^2 \ominus e^{-hs}H^2$ with the Volterra operator

$$V: L^2[0, h] \rightarrow L^2[0, h]$$

$Vf(x) := \int_0^x f(t) dt$ via ϕ . The inverse operator (of course unbounded) of V is the derivative operator $Df = f'$ with domain consisting of

$$\{f \in L^2[0, h]: f' \in L^2[0, h], f(0) = 0\}$$

(i.e. the operator D corresponds to “ s ”).

Now to compute $\|\Gamma\|$, we need to compute the largest eigenvalue of $\Gamma^*\Gamma$ (since Γ is compact), or equivalently the smallest positive eigenvalue of $(\Gamma^*\Gamma)^{-1}$. To do this we clearly only need identify the adjoint D^* of D . But it is easy to compute (using integration by parts) that $D^* = -D$ with domain

$$\{f \in L^2[0, h]: f' \in L^2[0, h], f(h) = 0\}.$$

With these remarks one can derive the eigenvalue problem alluded to above [9].

In the particular case in which

$$W(s) = \frac{1}{as+1}, \quad a > 0,$$

we get $\Gamma \equiv (aD+1)^{-1}$ and one derives the eigenvalue problem of finding the largest positive ρ (it is straightforward to check $\rho < 1$) such that

$$(-a^2 D^2 + 1)f = \frac{1}{\rho^2} f, \quad f(h) = 0, \quad -af'(0) + f(0) = 0.$$

From the associated Wronskian, one is reduced to finding the largest $\rho \in (0, 1)$, say ρ_1 , that satisfies

$$(1) \quad \left(\sqrt{\frac{1}{\rho^2} - 1} \right) + \tan \left(\frac{h\sqrt{(1/\rho^2) - 1}}{a} \right) = 0.$$

Then ρ_1 is the required norm (and the first singular value of the associated Hankel operator).

Note that if $\rho_2 \in (0, 1)$, $\rho_2 < \rho_1$, is the next largest root of (1), then ρ_2 will be the second singular value of the associated Hankel, and so on. In other words we have an explicit procedure for computing all of the singular values of the associated Hankel from the Wronskian of a certain elementary eigenvalue problem. Moreover we can clearly even write down the Schmidt vectors using this procedure. (See [18] for the relevant definitions.)

In §§ 3 and 4 below, we will offer another procedure for computing the optimal sensitivity applicable to more general delay systems. Our new method only makes use of elementary properties of $H^2(D)$ and $H^\infty(D)$ and reduces the optimal sensitivity problem to an algebraic one. We will generalize (1) in § 4 to the case of a plant with a delay and a nonminimum phase zero.

2. Triangular operators. In this section we collect some standard facts about certain types of lower block triangular operators. Our basic references are [22], [23].

Let H_1, H_2 denote (complex) Hilbert spaces, and set $H := H_1 \oplus H_2$. Let $S: H \rightarrow H$ be a bounded linear operator such that H_2 is S -invariant subspace of H , i.e., $S|_{H_2}: H_2 \rightarrow H_2$. Then clearly we can write

$$S = \begin{bmatrix} S_1 & 0 \\ Y & S_2 \end{bmatrix}$$

where $S_1 := (S^*|_{H_1})^*$, $S_2 := S|_{H_2}$, and $Y: H_1 \rightarrow H_2$ is the *coupling operator*.

Next let $A: H \rightarrow H$ be an arbitrary contraction, i.e., $\|A\| \leq 1$. Then in the usual way [24] we can define the associated *defect operators* and *defect spaces*:

$$D_A := (I - A^*A)^{1/2}, \quad D_{A^*} := (I - AA^*)^{1/2},$$

$$\mathcal{D}_A := \overline{D_A H}, \quad \mathcal{D}_{A^*} := \overline{D_{A^*} H}.$$

We can now state one of the key results of [22].

THEOREM 2.1. *With the above notation, $\|S\| \leq \rho$ if and only if $\|S_i\| \leq \rho$ ($i = 1, 2$) and $Y = D_{S_2/\rho} L D_{S_1/\rho}$ for some $L: \mathcal{D}_{S_1/\rho} \rightarrow \mathcal{D}_{S_2/\rho}$ such that $\|L\| \leq \rho$. Moreover, if we set $\theta := \max\{\|S_1\|, \|S_2\|\}$, and assume $\rho > \theta$, then $\|S\| = \rho$ if and only if $\|L\| = \rho$.*

Proof. The first statement is Theorem 1 of [22]. The second statement is standard, but since we do not know a convenient reference, we will include the proof. By scaling we can assume $\rho = 1$. Therefore under the hypothesis that $1 > \theta$, we want to show $\|S\| = 1$ if and only if $\|L\| = 1$.

Suppose first $\|S\| = 1$. Then following [22, pp. 205–207], one can define an isometry $\sigma: \mathcal{D}_S \rightarrow \mathcal{D}_L \oplus \mathcal{D}_{S_2}$ such that

$$\sigma D_S h = \begin{bmatrix} D_L D_{S_1} & 0 \\ -S_2^* L D_{S_1} & D_{S_2} \end{bmatrix} \begin{bmatrix} h_1 \\ h_2 \end{bmatrix}.$$

Now $\|S\| = 1$ if and only if there exists a sequence

$$h^{(n)} = \begin{bmatrix} h_1^{(n)} \\ h_2^{(n)} \end{bmatrix},$$

$\|h^{(n)}\| = 1$ such that $D_S h^{(n)} \rightarrow 0$, which in turn is equivalent to

$$(*) \quad \|D_{S_2} h_2^{(n)} - S_2^* L D_{S_1} h_1^{(n)}\|^2 + \|D_L D_{S_1} h_1^{(n)}\|^2 \rightarrow 0.$$

We claim now that

$$\limsup_{n \rightarrow \infty} \|D_{S_1} h_1^{(n)}\| =: q > 0.$$

Indeed, suppose not. Then $\|h_1^{(n)}\| \rightarrow 0$ since D_{S_1} is invertible (S_1 by hypothesis is a strict contraction), and therefore by (*) $\|D_{S_2} h_2^{(n)}\| \rightarrow 0$, and so $\|h_2^{(n)}\| \rightarrow 0$ since D_{S_2} is invertible (S_2 is a strict contraction). But this contradicts our hypothesis that $\|h^{(n)}\| = 1$.

Choose a subsequence $\{h_1^{(n)}\}$ such that $\|D_{S_1} h_1^{(n)}\| > 0$, and $\|D_{S_1} h_1^{(n)}\| \rightarrow q$. Since by (*) $\|D_L D_{S_1} h_1^{(n)}\| \rightarrow 0$, we get that $\|D_L(D_{S_1} h_1^{(n)} / \|D_{S_1} h_1^{(n)}\|)\| \rightarrow 0$ which implies $\|L\| = 1$.

Conversely suppose $\|L\| = 1$ (and $1 > \theta$). By hypothesis $D_{S_1}^{-1}$ exists. Then we can choose a sequence $\{h_1^{(n)}\}$ such that $\|D_{S_1} h_1^{(n)}\| = 1$, and $\|D_L D_{S_1} h_1^{(n)}\| \rightarrow 0$. Set $h_2^{(n)} := D_{S_2}^{-1} S_2^* L D_{S_1} h_1^{(n)}$ (note $D_{S_2}^{-1}$ exists). Then clearly

$$\|D_{S_2} h_2^{(n)} - S_2^* L D_{S_1} h_1^{(n)}\|^2 + \|D_L D_{S_1} h_1^{(n)}\|^2 \rightarrow 0$$

and hence $D_S h^{(n)} \rightarrow 0$ where

$$h^{(n)} = \begin{bmatrix} h_1^{(n)} \\ h_2^{(n)} \end{bmatrix}.$$

To complete the proof therefore we need only show $\|h^{(n)}\| \geq M > 0$ for fixed positive constant M for all n . But clearly

$$\|h^{(n)}\| \geq \|h_1^{(n)}\| \geq \frac{1}{\|D_{S_1}\|}. \quad \square$$

Remark 2.2. For results related to (2.1) see [5] in which arbitrary block 2×2 matrices are considered.

So far we have been considering results about general contractions. In point of fact however, for our purposes the contractions we will need have a special form.

More precisely, let $m_1, m_2 \in H^\infty(D)$ be inner functions. Let $H_i := H^2 \ominus m_i H^2$ $i = 1, 2$ and set $H := H^2 \ominus m_1 m_2 H^2$ (where throughout this section $H^2 := H^2(D)$). We denote by T the *compression* (i.e. projection) of the unilateral shift on H^2 (defined by multiplication by z) to H . (Recall $T := \Pi M_z|_H$ where $M_z: H^2 \rightarrow H^2$ denotes multiplication by z and $\Pi: H^2 \rightarrow H$ is the orthogonal projection.)

Next we have that

$$\begin{aligned} H^2 \ominus m_1 m_2 H^2 &= (H^2 \ominus m_1 H^2) \oplus (m_1 H^2 \ominus m_1 m_2 H^2) \\ &\cong H_1 \oplus H_2. \end{aligned}$$

Note that by abuse of notation, the direct sum symbol in $H_1 \oplus m_1 H_2$ stands for “orthogonal direct sum,” while the direct sum symbol in $H_1 \oplus H_2$ stands for “external direct sum.” (See [19] for the relevant definitions.)

Moreover, we have the following.

LEMMA 2.3. $m_1 H^2 \ominus m_1 m_2 H^2$ is an invariant subspace of $H^2 \ominus m_1 m_2 H^2$ with respect to T .

Proof. Let $v \in m_1 H^2 \ominus m_1 m_2 H^2$. Set $m = m_1 m_2$. Clearly $\bar{m}v \perp H^2$. Let $v_{-1} = \langle \bar{m}v, \bar{z} \rangle$. Then it is easy to compute that

$$Tv = zv - v_{-1}m.$$

But then Tv is divisible by m_1 , i.e., $Tv \in m_1 H^2 \ominus m_1 m_2 H^2$. \square

Lemma 2.3 means that if we identify $H_2 \cong m_1 H^2 \ominus m_1 m_2 H^2$, then we can regard H_2 as an invariant subspace of H with respect to T . Thus with these identifications, we can write

$$T = \begin{bmatrix} T_1 & 0 \\ X & T_2 \end{bmatrix}$$

where the T_i are defined as above. Clearly T_1, T_2, T are contractions.

Now in this case it is well known [24] that $D_{T_1}, D_{T_2^*}$ are of rank 1. Indeed we can compute that

$$I - T_1^* T_1 = \mu_1 \otimes \mu_1, \quad I - T_2 T_2^* = \mu_{2*} \otimes \mu_{2*}$$

where

$$\mu_1 := \bar{z}(m_1(z) - m_1(0)); \quad \mu_{2*} := 1 - m_2(z) \overline{m_2(0)}$$

and where $(x \otimes y)w := \langle w, y \rangle x$.

For such T_1 and T_2 , it is easy to compute X .

PROPOSITION 2.4. $X = \mu_{2*} \otimes \mu_1$.

Proof. Since T is a contraction, by (2.1) we can write $X = D_{T_2^*} L D_{T_1}$ where $L: \mathcal{D}_{T_1} \rightarrow \mathcal{D}_{T_2^*}$ is a contraction between the corresponding defect spaces. Set

$$\hat{\mu}_1 := \frac{\mu_1}{\|\mu_1\|} \quad \text{and} \quad \hat{\mu}_{2*} := \frac{\mu_{2*}}{\|\mu_{2*}\|}$$

(note that $\|\mu_1\|^2 = 1 - |m_1(0)|^2$ and $\|\mu_{2*}\|^2 = 1 - |m_2(0)|^2$). Then $L: \mathcal{D}_{T_1} \rightarrow \mathcal{D}_{T_2^*}$ is such that $L\hat{\mu}_1 = \lambda\hat{\mu}_{2*}$ for some constant λ (since the defect spaces are one-dimensional). Hence, using the facts that $D_{T_1} = \|\mu_1\|(\hat{\mu}_1 \otimes \hat{\mu}_1)$, $D_{T_2^*} = \|\mu_{2*}\|(\hat{\mu}_{2*} \otimes \hat{\mu}_{2*})$, and $X = D_{T_2^*} L D_{T_1}$, we get that $X = \lambda \mu_{2*} \otimes \mu_1$. Note that since T is a contraction $|\lambda| \leq 1$. We have still not used the fact that T is the compression to $H^2 \ominus m_1 m_2 H^2$ of the shift. We do this now.

Indeed we can apply T to μ_1 . It is easy to compute that

$$\begin{aligned} T\mu_1 &= z\mu_1 - \overline{m_2(0)}(1 - |m_1(0)|^2)m_1 m_2 \\ &= z\mu_1 - (1 - |m_1(0)|^2)m_1 \\ &\quad + (1 - |m_1(0)|^2)m_1 + \overline{m_2(0)}(1 - |m_1(0)|^2)m_1 m_2. \end{aligned}$$

Under our isomorphisms,

$$\begin{aligned} H^2 \ominus m_1 m_2 H^2 &= (H^2 \ominus m_1 H^2) \oplus (m_1 H^2 \ominus m_1 m_2 H^2) \\ &\cong (H^2 \ominus m_1 H^2) \oplus (H^2 \ominus m_2 H^2), \end{aligned}$$

we can write

$$T\mu_1 = \begin{bmatrix} z\mu_1 - (1 - |m_1(0)|^2)m_1(z) \\ (1 - |m_1(0)|^2)(1 - \overline{m_2(0)}m_2(z)) \end{bmatrix}.$$

Finally it is easy to compute that

$$\begin{bmatrix} T_1 & 0 \\ \lambda\mu_{2*} \otimes \mu_1 & T_2 \end{bmatrix} \begin{bmatrix} \mu_1 \\ 0 \end{bmatrix} = \begin{bmatrix} z\mu_1 - (1 - |m_1(0)|^2)m_1(z) \\ \lambda(1 - |m_1(0)|^2)(1 - \overline{m_2(0)}m_2(z)) \end{bmatrix}.$$

Thus $\lambda = 1$ as required. \square

3. Weighted sensitivity minimization. In this section we explicitly solve the weighted sensitivity minimization problem for L^∞ -plants of the form $e^{-hs}P_0(s)$, where $P_0(s)$ is a real rational proper function with no poles or zeros on the $j\omega$ -axis. Actually our procedure does much more. Basically for given weight $W(s)$ (with the hypotheses discussed in § 1), we give a technique for solving the weighted H^∞ -minimization problem for a plant $P(s) = P_1(s)P_2(s)$ in terms of data determined independently by $P_1(s)$, and independently by $P_2(s)$. Our method only depends on one knowing the maximum of the optimal sensitivities of $P_1(s)$ and $P_2(s)$, and from this one can find the optimal sensitivity for $P(s)$.

As in [9], for simplicity we initially will take a weight of the form

$$W(s) = \frac{qs + r}{ms + n}$$

stable with stable inverse, and such that $\|W(s)\|_\infty \leq 1$. In § 3.8 we will explain how our method immediately applies to general real rational weights. Moreover we will assume that $P(s)$ is proper and stable with no zeros on the $j\omega$ -axis. Again in Remarks 3.10 we show how to extend our method to unstable plants. The example to keep in mind is $P(s) = e^{-hs}P_0(s)$ where $P_0(s)$ is a stable proper plant with no zeros on the $j\omega$ -axis. However, the technique we give applies much more generally.

Let $\phi: H \rightarrow D$ be a fixed conformal equivalence. Set

$$\hat{W}(z) = W(\phi^{-1}(z)), \quad \hat{P}(z) = P(\phi^{-1}(z)).$$

Let $\hat{P}_i(z)$ be the inner part of $\hat{P}(z)$. Then we assume $\hat{P}_i(z) = m_1(z)m_2(z)$ where the $m_i(z)$ are inner functions. As in § 2, set ($H^2 := H^2(D)$):

$$H := H^2 \ominus m_1 m_2 H^2,$$

$$H_i := H^2 \ominus m_i H^2, \quad i = 1, 2,$$

$$T := \text{compression of the unilateral shift on } H^2(D) \text{ to } H.$$

Then if we make the identifications

$$\begin{aligned} H &= H^2 \ominus m_1 m_2 H^2 \\ &= (H^2 \ominus m_1 H^2) \oplus (m_1 H^2 \ominus m_1 m_2 H^2) \\ &\cong H_1 \oplus H_2 \end{aligned}$$

we can regard H_2 as an invariant subspace of H with respect to T .

When $P(s) = e^{-hs}P_0(s)$ as above, we can take $m_1(z)$ to be the Blaschke product in D whose zeros consist of the images under ϕ of the nonminimum phase zeros of $P_0(s)$, and $m_2(z) = e^{-h\phi^{-1}(z)}$.

Then following the notation of § 1 and the constructions of [26], [13], [12] the problem of computing the optimal sensitivity

$$\inf_{C \text{ stabilizing}} \|W(1+PC)^{-1}\|_\infty$$

can be reduced to computing

$$\mu := \inf_{q \in H^\infty(D)} \|\hat{W}(z) - m_1(z)m_2(z)q(z)\|_\infty.$$

Remark 3.1. We should note that the existence of a $q(z)$, achieving the infimum μ for the given $m(z) = m_1(z)m_2(z)$ inner as above, only depends on the hypothesis that $\hat{W}(z) \in H^\infty(D)$. See [14], [20].

Now as in § 2, we have

$$T = \begin{bmatrix} T_1 & 0 \\ X & T_2 \end{bmatrix}$$

relative to the decomposition $H \cong H_1 \oplus H_2$. If we write

$$\hat{W}(z) = \frac{\alpha z + \beta}{\gamma z + \delta}$$

where $\Delta := \alpha\delta - \beta\gamma \neq 0$, then $\|\hat{W}(z)\|_\infty \leq 1$ since we assumed $\|W(s)\|_\infty \leq 1$. Moreover without loss of generality we may clearly assume $\|\hat{W}(z)\|_\infty = 1$. (Indeed, if necessary, we can always replace $\hat{W}(z)$ by $\hat{W}(z)/\|\hat{W}(z)\|_\infty$.) Thus

$$\|\hat{W}(T)\| \leq 1, \quad \|\hat{W}(T_1)\| \leq 1, \quad \|\hat{W}(T_2)\| \leq 1.$$

Moreover it is easy to compute that

$$\hat{W}(T) = \begin{bmatrix} \hat{W}(T_1) & 0 \\ \Delta(\gamma T_2 + \delta)^{-1}X(\gamma T_1 + \delta)^{-1} & \hat{W}(T_2) \end{bmatrix}.$$

Now it is well known (see [20], [23], [24]) that the infimum

$$\inf_{q \in H^\infty(D)} \|\hat{W}(z) - m_1(z)m_2(z)q(z)\|_\infty = \|\hat{W}(T)\|,$$

and what we will do now is give an explicit procedure for computing the latter norm in terms of data determined separately by the $\hat{W}(T_1)$ and $\hat{W}(T_2)$ parts of $\hat{W}(T)$. In effect we will decouple these in order to compute $\|\hat{W}(T)\|$. First note, however, that

$$\begin{aligned} \|\hat{W}(T)\| &\leq \|\hat{W}(z)\|_\infty = 1, \\ \|\hat{W}(T)\| &\geq \theta := \max \{\|\hat{W}(T_1)\|, \|\hat{W}(T_2)\|\} \end{aligned}$$

and so $\theta = 1$ implies that $\|\hat{W}(T)\| = 1$. Therefore we can clearly assume $\theta < 1$.

Using the defect operator notation of § 2 (as well as the functions μ_1 and μ_{2*}), define for $j = 1, 2$ and $\rho \in (0, 1]$ such that $\rho > \theta$

$$\begin{aligned} \mu_1^{(j)} &= D_{\hat{W}(T_1)/\rho}^{-j}(\bar{\gamma}T_1^* + \bar{\delta})^{-1}\mu_1, \\ \mu_{2*}^{(j)} &= D_{\hat{W}(T_2)^*/\rho}^{-j}(\gamma T_2 + \delta)^{-1}\mu_{2*}. \end{aligned}$$

We can now state (finally!) the following key result.

THEOREM 3.2. *With the above notation $\|\hat{W}(T)\| \leq \rho$ if and only if*

$$(2) \quad \langle (\bar{\gamma}T_2^* + \bar{\delta})^{-1}\mu_{2*}^{(2)}, \mu_{2*} \rangle \cdot \langle (\gamma T_1 + \delta)^{-1}\mu_1^{(2)}, \mu_1 \rangle \leq \rho^2 \Delta^{-2}.$$

Moreover $\|\hat{W}(T)\| = \rho$ if and only if (2) is an equality. (Note we are assuming $\rho \in (0, 1]$ is such that $\rho > \theta$.)

Proof by Theorem 2.1. $\|\hat{W}(T)\| \leq \rho$ if and only if

$$\frac{1}{\rho} \Delta(\gamma T_2 + \delta)^{-1} X(\gamma T_1 + \delta)^{-1} = D_{\hat{W}(T_2)^*/\rho} L_\rho D_{\hat{W}(T_1)/\rho}$$

where

$$L_\rho : \mathcal{D}_{\hat{W}(T_1)/\rho} \rightarrow \mathcal{D}_{\hat{W}(T_2)^*/\rho}$$

defines a contraction of the corresponding defect spaces. But then it is easy to compute that

$$L_\rho = \frac{1}{\rho} \Delta \mu_{2*}^{(1)} \otimes \mu_1^{(1)}.$$

Indeed this follows immediately from the definition of the $\mu_{2*}^{(1)}$ and $\mu_1^{(1)}$ once we show that

$$\mu_{2*}^{(1)} \otimes \mu_1(\gamma T_1 + \delta)^{-1} D_{\hat{W}(T_1)/\rho}^{-1} = \mu_{2*}^{(1)} \otimes D_{\hat{W}(T_1)/\rho}^{-1}(\bar{\gamma} T_1^* + \bar{\delta})^{-1} \mu_1.$$

But to see this just apply the first operator to an element ψ . We get

$$\begin{aligned} \mu_{2*}^{(1)} \otimes \mu_1(\gamma T_1 + \delta)^{-1} D_{\hat{W}(T_1)/\rho}^{-1} \psi &= \langle (\gamma T_1 + \delta)^{-1} D_{\hat{W}(T_1)/\rho}^{-1} \psi, \mu_1 \rangle \mu_{2*}^{(1)} \\ &= \langle \psi, D_{\hat{W}(T_1)/\rho}^{-1}(\bar{\gamma} T_1^* + \bar{\delta})^{-1} \mu_1 \rangle \mu_{2*}^{(1)} \end{aligned}$$

since $D_{\hat{W}(T_1)/\rho}^{-1}$ is self-adjoint.

Therefore

$$\|L_\rho\| \leq 1 \Leftrightarrow \|\mu_{2*}^{(1)}\| \|\mu_1^{(1)}\| \leq \rho \Delta^{-1}$$

\Leftrightarrow the inequality (2) holds.

Finally, under the assumption that $\rho > \theta$, by (2.1) $\|\hat{W}(T)\| = \rho$ if and only if $\|L_\rho\| = 1$ if and only if (2) is an equality. \square

Remarks 3.3. (i) In case $m_1(z) = (z - a)/(1 - \bar{a}z)$, $|a| < 1$, (2) is equivalent to certain inequalities derived by Adamjan, Arov and Krein [1], [2] in connection with the one-step extension problem. Hence what we have derived here is an expression for the norm of an “ n -step extension” (in case m_1 is a finite Blaschke product), or even an “ ∞ -step extension” (e.g., when m_1 is an infinite Blaschke product).

(ii) We will assume from now on that $\rho \geq \|\hat{W}(T)\|$, and $\rho > \theta$. Note that in our procedure below, we can compute $\|\hat{W}(T)\|$ explicitly once we know θ . Thus if we can find the optimal sensitivity for plants $P_1(s)$, $P_2(s)$ we can find it for $P(s) = P_1(s)P_2(s)$.

We now come to the crucial question of how to compute the inner products of (2). Again we can give an explicit procedure.

3.4. Computation of inner products. We will start with the computation of

$$\langle (\bar{\gamma} T_2^* + \bar{\delta})^{-1} \mu_{2*}^{(2)}, \mu_{2*} \rangle.$$

Set $\nu_* := (\bar{\gamma} T_2^* + \bar{\delta})^{-1} \mu_{2*}^{(2)}$. Since $\mu_{2*} = 1 - m_2(z) \overline{m_2(0)}$, and since $\nu_* \in H^2 \ominus m_2 H^2$, we have that $\langle \nu_*, \mu_{2*} \rangle = \nu_*(0)$. Thus we must show how to find $\nu_*(0)$. We give a simple algebraic procedure for doing this.

First note that

$$(\gamma T_2 + \delta)^{-1} \mu_{2*} = \left(1 - \frac{1}{\rho^2} \hat{W}(T_2) \hat{W}(T_2)^*\right) \mu_{2*}^{(2)}.$$

Therefore

$$(3) \quad \begin{aligned} \mu_{2*} &= \left[(\gamma T_2 + \delta)(\bar{\gamma} T_2^* + \bar{\delta}) - \frac{1}{\rho^2} (\alpha T_2 + \beta)(\bar{\alpha} T_2^* + \bar{\beta}) \right] \nu_* \\ &= (A + B T_2 + \bar{B} T_2^* + C T_2 T_2^*) \nu_* \end{aligned}$$

where

$$\begin{aligned} A &:= |\delta|^2 - \left(\frac{1}{\rho^2} \right) |\beta|^2, \\ B &:= \left(\gamma \bar{\delta} - \left(\frac{1}{\rho^2} \right) \alpha \bar{\beta} \right), \\ C &:= \left(|\gamma|^2 - \left(\frac{1}{\rho^2} \right) |\alpha|^2 \right). \end{aligned}$$

Now $(1 - T_2 T_2^*) \nu_* = \langle \nu_*, \mu_{2*} \rangle \mu_{2*} = \nu_*(0) \mu_{2*}$. Therefore, from (3) we see that

$$(4) \quad (1 + C \nu_*(0)) \mu_{2*} = (F + B T_2 + \bar{B} T_2^*) \nu_*$$

where $F := A + C$. But $\bar{m}_2 \nu_* \perp H^2$ so we can write $\bar{m}_2 \nu_* = \nu_{-1} \bar{z} + \nu_{-2} \bar{z}^2 + \dots$. Then

$$T_2^* \nu_* = \bar{z}(\nu_* - \nu_*(0)), \quad T_2 \nu_* = z \nu_* - m_2 \nu_{-1}.$$

Consequently, from (4) we see that

$$(5) \quad (1 + C \nu_*(0)) \mu_{2*} + \bar{B} \bar{z} \nu_*(0) + B m_2 \nu_{-1} = (F + B z + \bar{B} \bar{z}) \nu_*.$$

Finally, multiplying both sides of (4) by z and rearranging terms, we derive the following key relationship:

$$(6) \quad (C \mu_{2*} z + \bar{B}) \nu_*(0) + B m_2 z \nu_{-1} = (B z^2 + F z + \bar{B}) \nu_* - \mu_{2*} z.$$

(Note that even though this relationship has been derived on the boundary on D , since all the functions are in $H^2(D)$, they can be analytically continued to D .)

We are almost done! Indeed it is easy to see that the roots z_1, z_2 of $B z^2 + F z + \bar{B}$ are such that $|z_1 z_2| = 1$. If $B = \bar{B}$ is real (which always occurs in cases of interest in engineering) $z_1 z_2 = 1$. We can always assume $|z_1| \leq 1$. We have three cases.

CASE (i). $|F| > 2|B|$. Then $z_1 \in D, z_2 = 1/\bar{z}_1$. Now multiply (5) by \bar{m}_2 to get

$$(7) \quad (C \bar{m}_2 \mu_{2*} z + \bar{B} \bar{m}_2) \nu_*(0) + B z \nu_{-1} = (B z^2 + F z + \bar{B}) \bar{m}_2 \nu_* - \bar{m}_2 \mu_{2*} z.$$

Note that $\bar{m}_2 \mu_{2*}$ and $\bar{m}_2 \nu_*$ can be continued analytically in the complement of the unit disc and are 0 at ∞ . (On the boundary of D we identify \bar{z} and $1/z$.)

Then plugging z_1 into (6) and z_2 into (7) we get

$$(8) \quad (C \mu_{2*}(z_1) z_1 + \bar{B}) \nu_*(0) + B m_2(z_1) z_1 \nu_{-1} = -\mu_{2*}(z_1) z_1,$$

$$(9) \quad (C(\bar{m}_2 \mu_{2*})(z_2) \cdot z_2 + \bar{B} m_2(z_2)) \nu_*(0) + B z_2 \nu_{-1} = -(\bar{m}_2 \mu_{2*})(z_2) \cdot z_2.$$

Using the fact that $z_2 = 1/\bar{z}_1$, one can solve these equations for $\nu_*(0)$ and show

$$(10) \quad \frac{1}{|\nu_*(0)|} = \left| \frac{A - C}{2} + \frac{1}{2} \sqrt{F^2 - 4|B|^2} \frac{1 + |m_2(z_1)|^2}{1 - |m_2(z_1)|^2} \right|.$$

Note that the case in which $B=0$ is a limiting case of Case (i) in which $z_1=0$, $z_2=\infty$. When this occurs one can compute

$$(11) \quad \frac{1}{|\nu_*(0)|} = \left| \frac{A + C|m_2(0)|^2}{1 - |m_2(0)|^2} \right|.$$

Before stating Cases (ii) and (iii) we will need the following lemma.

LEMMA 3.5. *Let z_1 be such that $Bz_1^2 + Fz_1 + \bar{B} = 0$, and such that $|z_1| = 1$. Then $m_2(z)$ admits an analytic extension to a neighborhood of z_1 , and $|m_2(\zeta)| = 1$ for all ζ in an arc neighborhood of z_1 on the unit circle.*

Proof. First we claim $z_1 \notin \sigma(T_2)$ (where $\sigma(T_2)$ denotes the spectrum of the contraction T_2). Indeed if to the contrary $z_1 \in \sigma(T_2)$, then $\hat{W}(z_1) \in \sigma(\hat{W}(T_2))$. But by definition, since $Bz_1^2 + Fz_1 + \bar{B} = 0$, we have that $(1 - (|\hat{W}(z_1)|^2/\rho^2)) = 0$, that is $|\hat{W}(z_1)| = \rho$. But this would imply that $\|\hat{W}(T_2)\| \geq \rho$, which contradicts our assumption in Remark 3.3(ii) that $\|\hat{W}(T_2)\| < \rho$.

But since $z_1 \notin \sigma(T_2)$ we get the required result from [24, Chap. III, Thm. (5.1)]. \square

Remark 3.6. With the notation of (3.5), note that since $m_2(z)$ is analytic in a neighborhood of z_1 , μ_{2*} must be analytic in this neighborhood of z_1 , and ν_* can have at most a pole at z_1 . But since $\nu_* \in H^2(D)$, in point of fact ν_* must be analytic at z_1 as well. Moreover the derivatives of these functions will also be analytic in a neighborhood of z_1 , since the derivative of an analytic function is itself analytic.

We can now state Cases (ii) and (iii) (z_1 and z_2 are the roots of $Bz^2 + Fz + \bar{B}$).

CASE (ii). $|F| < 2|B|$ i.e. $|z_1| = |z_2| = 1$, $z_1 \neq z_2$. In this case plug the z_i $i = 1, 2$ into (6) to get two linear equations (one of which will be (7), and the other (7) with z_2 substituted for z_1) in the two unknowns $\nu_*(0)$, ν_{-1} and solve for $\nu_*(0)$. By (3.5) and (3.6) this is valid since the functions m_2 , μ_{2*} , ν_* are analytic in neighborhoods of z_1 and z_2 .

We can then compute that

$$(12) \quad \frac{1}{|\nu_*(0)|} = \left| \frac{A - C}{2} + \frac{j\sqrt{4|B|^2 - F^2}}{2} \cdot \frac{1 + m_2(z_1)\overline{m_2(z_2)}}{1 - m_2(z_1)\overline{m_2(z_2)}} \right|.$$

(When $m_2(z_1) = m_2(z_2)$, $z_1 \neq z_2$, it is easy to show that $\nu_*(0) = 0$.)

CASE (iii). $|F| = 2|B|$, i.e. $z_1 = z_2$. Then plug z_1 into (6), and z_2 into the derivative of (6). Once more by (3.5) and (3.6) this makes sense, and we can solve the two resulting equations in the two unknowns $\nu_*(0)$, ν_{-1} for $\nu_*(0)$.

Making the computation, we get that

$$(13) \quad \frac{1}{|\nu_*(0)|} = \left| -C + \varepsilon|B| - B \frac{m_2(z_1)}{m_2'(z_1)} \right|$$

where

$$\varepsilon = \begin{cases} 1 & \text{if } F > 0, \\ -1 & \text{if } F < 0, \end{cases}$$

for $m_2'(z_1) \neq 0$. When $m_2'(z_1) = 0$, it is easy to show that $\nu_*(0) = 0$.

In short from (6), using simple linear algebra, we can find $\nu_*(0)$, the value of the first inner product. Notice that Cases (i) and (ii) are generic, while Case (iii) is the nongeneric case in this situation.

Next we come to the computation of the second inner product of (2), namely

$$\langle (\gamma T_1 + \delta)^{-1} \mu_1^{(2)}, \mu_1 \rangle.$$

We will propose two methods for doing this. The first works for any inner function $m_1(z)$, and the second for a finite Blaschke product.

The first method is simply to imitate the procedure that we used previously in evaluating $\langle \nu_*, \mu_{2*} \rangle$. Indeed, set

$$\nu := (\gamma T_1 + \delta)^{-1} \mu_1^{(2)}.$$

Then we want to evaluate $\langle \nu, \mu_1 \rangle$. But

$$\begin{aligned} \langle \nu, \mu_1 \rangle &= \langle \nu, \bar{z}(m_1(z) - m_1(0)) \rangle \\ &= \langle \bar{m}_1 \nu, \bar{z} \rangle. \end{aligned}$$

Since $\bar{m}_1 \nu \perp H^2$, we may write $\bar{m}_1 \nu = \hat{\nu}_{-1} \bar{z} + (\text{higher order terms in } \bar{z})$ and so $\langle \nu, \mu_1 \rangle = \hat{\nu}_{-1}$. Playing the same game as above we end up with the following analogue of equation (6):

$$(14) \quad (C\mu_1 z + Bm_1 z) \hat{\nu}_{-1} + \bar{B}\nu(0) = (Bz^2 + Fz + \bar{B})\nu - \mu_1 z.$$

We again divide the analysis of (14) into the identical Cases (i), (ii) and (iii) depending upon the roots of $Bz^2 + Fz + \bar{B}$ from which we derive analogous formulae for $\hat{\nu}_{-1}$ (the required value of $\langle \nu, \mu_1 \rangle$) to those we found above for $\nu_*(0)$.

We should note that a deeper explanation of the analogy between (6) and (14) can be given via a beautiful result from [21]. In point of fact using this result it is possible to write down (14) immediately from (6) and the analogous formulae to those of (10)–(13) for $\hat{\nu}_{-1}$ just by inspection. However since these formulae may be derived by elementary linear algebra as above, we will leave it to the interested reader to consult [21].

The second method for finding $\hat{\nu}_{-1}$ works when $m_1(z)$ is a finite Blaschke product. In this case, $H^2 \ominus m_1 H^2$ is finite dimensional and it is easy to compute a basis for this space (see e.g. [21], [17]). Therefore the computation of the second inner product of (2) amounts to finite matrix operations once a suitable basis is chosen. For example, if

$$m_1(z) = \prod_{i=1}^n \left(\frac{z - a_i}{1 - \bar{a}_i z} \right)$$

with $a_i \neq a_j$ for $i \neq j$, then the elements

$$v_k := \frac{(1 - |a_k|^2)^{1/2}}{1 - \bar{a}_k z} \prod_{i=1}^{k-1} \left(\frac{z - a_i}{1 - \bar{a}_i z} \right)$$

for $k = 1, \dots, n$ form a unitary basis for $H^2 \ominus m_1 H^2$ relative to which all the relevant linear operators may be given a finite matrix form. For Blaschke products (in the unit disc) which have roots with multiplicities, it is again easy and standard to write down a similar unitary basis (see [20], [10], [17]).

We thus have an explicit procedure for computing the inner products (3.2). We now give an explicit algorithm for the computation of the optimal sensitivity.

3.7. Computation of optimal sensitivity. We will use the notation of (3.4). Note moreover that the computation of $\nu_*(0)$ and $\hat{\nu}_{-1}$ as functions of ρ divide into the identical Cases (i), (ii) and (iii) depending on the roots $Bz^2 + Fz + \bar{B}$.

To make the dependence of ρ explicit, let us set

$$\nu_1(\rho) := \nu_*(0), \quad \nu_2(\rho) := \hat{\nu}_{-1}.$$

Then (3.2) reads

$$(15) \quad \nu_1(\rho) \nu_2(\rho) \leq \rho^2 \Delta^{-2}.$$

Let us now recall some of our assumptions:

(a) $\hat{W}(z) = (\alpha z + \beta)/(\gamma z + \delta) \in H^\infty(D)$, $\hat{W}^{-1}(z)$ has no poles in D , the open unit disc. (This follows since we assumed $W(s) \in H^\infty(H)$ with stable inverse.) We should note that our methods immediately go through without the hypothesis that $\hat{W}^{-1}(z)$ has no poles in D , but we retain it since it will be easier to explain our algorithm this way.

(b) $\hat{W}(z)$ is normalized so that $\|\hat{W}(z)\|_\infty = 1$. (Again this can be done without loss of generality, by replacing if necessary $\hat{W}(z)$ by $\hat{W}(z)/\|\hat{W}(z)\|_\infty$. We make this normalization since it will be a bit easier to state our algorithm this way. Of course, one can easily write down a similar algorithm without such a normalization.)

(c) $\rho \in (0, 1]$ is such that $\rho \geq \|\hat{W}(T)\|$, and $\rho > \theta := \max\{\|\hat{W}(T_1)\|, \|\hat{W}(T_2)\|\}$. Note that for the algorithm to work we must know θ .

Here then is our algorithmic procedure for the computation of $\|\hat{W}(T)\|$ and hence the optimal sensitivity. We consider two cases.

(A) $|\beta/\alpha| = 1$. Then the algorithm is as follows:

- (i) We first consider Case (iii) of (3.4), i.e. $|F|^2 = 4|B|^2$. Regarding this as an equation in $\rho \in (0, 1]$, it is easy to see that the unique solution will be $\rho = 1$. (Just consider the locus

$$\{z: \rho^2 - |W(z)|^2 = 0\}$$

and notice that there exists $z_0 \in \partial D$ such that $\hat{W}(z_0) = 0$. See Fig. 2.)

We now check if $\rho = 1$ gives equality for (15) using the Case (iii) formulae of (3.4) ((13) and the analogous formula for $\nu_2(\rho)$). If we do get equality, then by Theorems 2.1 and 3.2, $\|\hat{W}(T)\| = 1$, and the algorithm terminates. If not, i.e. if we get strict inequality, we go to step (ii).

- (ii) If $\rho < 1$, then it is easy to check we are in Case (ii) of (3.4). (See Fig. 2.) Using the formulae we derived for Case (ii) ((12) and the analogous formula for $\nu_2(\rho)$), we check if there exists $\rho \in (0, 1)$ with $\rho > \theta$ which gives equality in (15). If there exists such a solution, say ρ_1 , then by Theorems 2.1 and 3.2 it is unique and $\|\hat{W}(T)\| = \rho_1$, i.e. the algorithm terminates. If not, i.e. if we get strict inequality for all $\rho \in (0, 1)$ with $\rho > \theta$, we go to step (iii).

FIG. 2. Representation of the case $|\beta/\alpha| = 1$. Both solid circles are centered at 0, the larger being ∂D , the unit circle. The dashed circle represents the locus $\hat{W}(\partial D)$. Since $\|\hat{W}(z)\|_\infty = 1$, $\hat{W}^{-1}(z)$ has no poles in D , and $|\beta/\alpha| = 1$, $\hat{W}(\partial D)$ passes through the origin 0 and is tangent to ∂D . Note that the circle of radius ρ' intersects $\hat{W}(\partial D)$ in two points, i.e. for any $0 < \rho' < 1$ we are in Case (ii). When $\rho' = 1$, we are in Case (iii).

- (iii) If steps (ii) and (iii) fail to find the norm, then from our hypotheses and Theorems 2.1 and 3.2, we have

$$\|\hat{W}(T)\| = \theta = \max \{\|\hat{W}(T_1)\|, \|\hat{W}(T_2)\|\}$$

and once more we are done.

This completes the analysis of case (A).

- (B) $|\beta/\alpha| \neq 1$. Then the algorithmic procedure for finding $\|\hat{W}(T)\|$ is as follows:

- (i) As in (A), we first consider Case (iii) of (3.4), that is $|F|^2 = 4|B|^2$. Regarding this as an equation in $\rho \in (0, 1]$ and with the above hypotheses (a), (b), (c) one can easily show that we get precisely two solutions, namely $\rho = 1$, and a unique $0 < \rho_0 < 1$. (Again to see this, just consider the locus $\{\rho^2 - |\hat{W}(z)|^2 = 0\}$ and examine the cases $|\beta/\alpha| < 1$, $|\beta/\alpha| > 1$. See Figs. 3 and 4 below.)

FIG. 3. Representation of the case $|\beta/\alpha| < 1$. All three solid circles are centered at 0, the largest being ∂D , the unit circle. The dashed circle represents the locus $\hat{W}(\partial D)$. Since $\|\hat{W}(z)\|_\infty = 1$, and $\hat{W}^{-1}(z)$ has no poles in D , $\hat{W}(\partial D)$ is tangent to ∂D . ρ_0 is the distance of 0 to the closest point on $\hat{W}(\partial D)$. Note that the circle of radius ρ' intersects $\hat{W}(\partial D)$ in two points, i.e. for $\rho_0 < \rho' < 1$ we are in Case (ii). For $0 < \rho' < \rho_0$ we are in Case (i). For $\rho' = 1$, or $\rho' = \rho_0$, we are in Case (iii).

FIG. 4. Representation of the case $|\beta/\alpha| > 1$. Same explanation as for Fig. 3, except here the origin 0 lies to the exterior of $\hat{W}(\partial D)$ (which is represented by the dashed circle).

We now check if $\rho = 1$ gives equality for (15) using the Case (iii) formulae of (3.4) and if it does, then as before $\|\hat{W}(T)\| = 1$. If we get strictly inequality, we consider ρ_0 . If $\rho_0 > \theta$, and if it gives equality when substituted in (15) (using the Case (iii) formulae), then by Theorems 2.1 and 3.2, $\|\hat{W}(T)\| = \rho_0$. If not, we go to step (ii).

- (ii) If from step (i) we have failed to find the required norm, we consider now ρ such that $\rho > \theta$ and $\rho_0 < \rho < 1$. Then it is easy to check that we will be in Case (ii) of (3.4) (see Figs. 3 and 4). If we can find such a ρ , say ρ_2 , which gives equality in (15) (using the Case (ii) formulae of (3.4)), then by Theorems 2.1 and 3.2 ρ_2 will be unique and $\|\hat{W}(T)\| = \rho_2$, and so the algorithm terminates. If all such ρ with $\rho > \theta$ and $\rho_0 < \rho < 1$ give strict inequality, we go to step (iii).
- (iii) We consider ρ such that $\rho > \theta$ and $0 < \rho < \rho_0$. (Of course we need $\rho_0 > \theta$ in this step. If not, just go to step (iv).) Then one can easily check that we will be in Case (i) of (3.4) (see Figs. 3 and 4). If we can find such a ρ , say ρ_3 , which gives equality in (15) (using the Case (i) formulae of (3.4)), then by Theorems 2.1 and 3.2 ρ_3 will be unique and $\|\hat{W}(T)\| = \rho_3$, i.e., we are done. If all such ρ with $\rho > \theta$ and $0 < \rho < \rho_0$ give strict inequality, we go to step (iv).
- (iv) If in all three steps above we have failed to find the norm, then by Theorems 2.1 and 3.2 and the above hypotheses

$$\|\hat{W}(T)\| = \theta = \max \{ \|\hat{W}(T_1)\|, \|\hat{W}(T_2)\| \}$$

and once again the algorithm terminates.

In short, (3.7) gives an easily computable algorithm for finding $\|\hat{W}(T)\|$ once we know θ . Thus we have a technique for computing the H^∞ -optimal sensitivity for distributed systems like $e^{-hs}P_0(s)$, $P_0(s)$ rational stable, since we know the optimal sensitivities for e^{-hs} and $P_0(s)$ already. We now will discuss what occurs for more general weights.

3.8. General weights and one-step extensions. The above analysis was made for linear weights. Still keeping our assumptions on $P(s)$ (i.e. $P(s)$ is stable, proper, with no zeros on the $j\omega$ -axis), we would like to explicitly show how our methods carry over for a general real rational weight $W(s)$, $W(s) \in H^\infty$ with stable inverse, $\|W(s)\|_\infty \leq 1$. Using the above conformal equivalence $\phi: H \rightarrow D$ we set as before

$$\hat{W}(z) := W(\phi^{-1}(z))$$

and we write $\hat{W}(z) = p(z)/q(z)$ a ratio of relatively prime polynomials in z .

Then given as above that

$$T = \begin{bmatrix} T_1 & 0 \\ X & T_2 \end{bmatrix}$$

it is easy to compute that

$$\hat{W}(T) = \begin{bmatrix} \hat{W}(T_1) & 0 \\ q^{-1}(T_2)r(X)q^{-1}(T_1) & \hat{W}(T_2) \end{bmatrix}$$

where $r(X)$ has the form

$$(16) \quad r(X) = \sum_{0 \leq j, k \leq n-1} a_{jk} T_2^j \mu_{2*} \otimes T_1^{*k} \mu_1$$

for some constants a_{jk} , and where $n = \max \{ \text{degree } p(z), \text{degree } q(z) \}$.

Indeed (16) may be derived as follows: Set for $k \in \mathbb{N}$

$$X^{(k)} := \sum_{\substack{0 \leq i, j \leq k-1 \\ i+j=k-1}} T_2^i X T_1^j.$$

Given a polynomial

$$b(z) = \sum_{k=0}^s b_k z^k,$$

set

$$\hat{b}(X) = \sum_{k=1}^s b_k X^{(k)}.$$

Notice in $\hat{b}(X)$ we have dropped the constant term. Then by direct computation, one gets that

$$r(X) = q(T_2) \hat{p}(X) - p(T_2) \hat{q}(X).$$

Equation (16) now follows from the facts that $X = \mu_{2*} \otimes \mu_1$, and that

$$T_2^j X T_1^k = T_2^j \mu_{2*} \otimes T_1^{*k} \mu_1.$$

In short, $r(X)$ is a *finite rank operator*, and is composed of tensor products of the $T_2^j \mu_{2*}$ and $T_1^{*k} \mu_1$ all of which may be explicitly computed. Hence as in the linear weight case, the computation of $\|\hat{W}(T)\|$ may be reduced to an analogous (but of course messier) algebraic problem using the procedures discussed in Theorem 3.2 and (3.4).

In the most important (from a practical point of view) special case, in which $m_1(z)$ is a finite Blaschke product, we can even get simple closed form formulae as we did above. We will do this now.

Indeed first note that when $m_1(z)$ is a finite Blaschke product, we can in point of fact always reduce ourselves to the case in which $m_1(z) = (z - a)/(1 - \bar{a}z)$ for some $a \in D$. To see this let us suppose that

$$m_1(z) = \prod \left(\frac{z - a_i}{1 - \bar{a}_i z} \right).$$

Suppose moreover that we give a procedure for solving the optimal sensitivity problem for $((z - a_1)/(1 - \bar{a}_1 z))m_2(z)$ in terms of (decoupled) data determined by $m_2(z)$ and $(z - a_1)/(1 - \bar{a}_1 z)$ as we did in Theorem 3.2. Then we can take $\hat{m}_2(z) := ((z - a_1)/(1 - \bar{a}_1 z))m_2(z)$ as our new “ $m_2(z)$ ”, and $(z - a_2)/(1 - \bar{a}_2 z)$ as our new “ $m_1(z)$,” and solve the resulting problem for $((z - a_2)/(1 - \bar{a}_2 z))\hat{m}_2(z)$ in terms of $\hat{m}_2(z)$ and $(z - a_2)/(1 - \bar{a}_2 z)$, and so on. In other words, when $m_1(z)$ is a finite Blaschke product in order to solve the optimal sensitivity problem, it is enough to describe the solution to the problem when we add the zeros of $m_1(z)$ one at a time. This is, of course, the basic idea behind the classical recursive procedure of Nevanlinna–Pick interpolation [14], and the one-step extension procedure of Adamjan, Arov and Krein [1], [2].

Consequently, we will give an explicit solution now of the kind we gave for a linear weight, for a general real rational weight, $\hat{W}(z) = p(z)/q(z)$, $\|\hat{W}(z)\|_\infty \leq 1$, such that \hat{W}^{-1} has no poles in the unit disc, and an inner function $m(z) = m_1(z)m_2(z)$ where $m_1(z) = (z - a)/(1 - \bar{a}z)$, $a \in D$. Then with this notation, $\mu_1 = (1 - |a|^2)/(1 - \bar{a}z)$, and $T_1 \mu_1 = a \mu_1$.

From (16), we can write that

$$\begin{aligned} r(X) &= \sum_{0 \leq j, k \leq n-1} a_{jk} T_2^j \mu_{2*} \otimes \bar{a}^k \mu_1 \\ &= \sum_{j=0}^{n-1} b_j T_2^j \mu_{2*} \otimes \mu_1 \end{aligned}$$

(where $n = \max \{\text{degree } p(z), \text{degree } q(z)\}$), for some (explicitly computable) constants b_j .

Set

$$\mu_* = \sum_{j=0}^{n-1} b_j T_2^j \mu_{2*}.$$

Then

$$r(X) = \mu_* \otimes \mu_1.$$

Therefore we have

$$\hat{W}(T) = \begin{bmatrix} \hat{W}(T_1) & 0 \\ q(T_2)^{-1}(\mu_* \otimes \mu_1)q(T_1)^{-1} & \hat{W}(T_2) \end{bmatrix}.$$

We can now play precisely the same game that we did in the linear weight case. Once more without loss of generality we can assume that

$$\theta := \max \{\|\hat{W}(T_1)\|, \|\hat{W}(T_2)\|\} < 1.$$

Let $\rho \in (0, 1]$ and suppose $\rho > \theta$. Then we set for $j = 1, 2$

$$\begin{aligned} \mu_*^{(j)} &:= D_{\hat{W}(T_2)^*/\rho}^{-j}(q(T_2)^{-1})\mu_*, \\ \mu_1^{(j)} &:= D_{\hat{W}(a)/\rho}^{-j}(\overline{q(a)})^{-1}\mu_1 \end{aligned}$$

(since T_1 is multiplication by a).

Then the analogue of Theorem 3.2 in this case is the next theorem.

THEOREM 3.9. $\|\hat{W}(T)\| \leq \rho$ if and only if

$$(17) \quad \langle \bar{q}(T_2^*)^{-1}\mu_*^{(2)}, \mu_* \rangle \cdot \left\langle \frac{\mu_1^{(2)}}{q(a)}, \mu_1 \right\rangle \leq \rho^2.$$

Moreover $\|\hat{W}(T)\| = \rho$ if and only if equality holds in (17). (We are assuming $\rho > \theta$.)

Proof. As in Theorem 3.2, $\|\hat{W}(T)\| \leq \rho$ if and only if

$$\frac{1}{\rho} q(T_2)^{-1} r(X) q(T_1)^{-1} = D_{(1/\rho)\hat{W}(T_2)^*} L_\rho D_{(1/\rho)\hat{W}(T_1)}$$

for some contraction L_ρ . But it is easy to compute that

$$L_\rho = \frac{1}{\rho} (\mu_*^{(1)} \otimes \mu_2^{(1)}).$$

Therefore $\|\hat{W}(T)\| \leq 1$ if and only if we have the inequality (17). The second part of the theorem follows immediately from Theorem 2.1. \square

Remarks 3.10. (i) Clearly in this case the second inner product of (17) is trivial to compute. As for the first inner product, it is clear that one can use the same algebraic technique that we discussed in (3.4). Here from the roots of a polynomial of degree $2n$ one gets $2n$ linear equations in $2n$ unknowns from which one can solve for the

required value of the inner product, where $n := \max \{p(z), q(z)\}$. Depending upon the multiplicities of the roots and where they lie in relation to D , one can derive a procedure analogous to that of (3.7). We did this by hand for a simple quadratic weight ($W(s) = 1/(as + 1)^2$) and admittedly the computation becomes very messy. However, our procedure can certainly be programmed on computer for the kind of rational weights we have considered above.

(ii) Now we finally come to the case in which $P(s) \in L^\infty$ is not stable (but has no zeros on the $j\omega$ -axis). This poses no problem (at least theoretically). Indeed using the arguments of [13], [27] one may reduce the sensitivity minimization problem to the problem of computing

$$\inf_{q \in H^\infty} \|V - Bq\|_\infty$$

where $B(s) = \text{inner part of } P(s)$, $V \in H^\infty$.

Now from (3.1), with these hypotheses, the minimization problem will have a solution. If we then assume that the outer part of $P(s)$ is rational (of course we always consider rational weights that are in H^∞), V will be rational, and we can apply our techniques to the solution of the minimization problem. More explicitly, if $P(s) = P_1(s)P_2(s)$ and we could compute the minimal sensitivities of $P_1(s)$, $P_2(s)$, then we could use our preceding procedure in order to solve the problem for $P(s)$. This occurs for example when $P(s) = e^{-hs}P_0(s)$, $P_0(s)$ real rational and proper, $P_0 \in L^\infty$ with no zeros on the $j\omega$ -axis.

4. An explicit example. Given the general procedures of § 3, an illustrative non-trivial example is certainly called for. We will take

$$W(s) = \frac{1}{as + 1}, \quad a > 0$$

$$P(s) = e^{-hs} \left(\frac{s - b}{s + b} \right), \quad h, b > 0.$$

The minimum sensitivity in this case will allow us to understand the relationship among the quantities a , b , h .

So, let us plug these parameters into our machine and compute. First we choose $\phi: H \rightarrow D$ to be

$$z = \phi(s) := \frac{s - b}{s + b}.$$

Then

$$\hat{W}(z) = W(\phi^{-1}(z)) = \frac{1 - z}{(ab - 1)z + (ab + 1)},$$

$$e^{h\phi^{-1}(z)} = e^{hb((z+1)/(z-1))}$$

We now use the notation of (3.4). Note that $m_1(z) = z$, $m_2(z) = e^{hb((z+1)/(z-1))}$,

$$A = (ab + 1)^2 - \frac{1}{\rho^2}, \quad B = \bar{B} = ((ab)^2 - 1) + \frac{1}{\rho^2},$$

$$C = (ab - 1)^2 - \frac{1}{\rho^2}, \quad F = 2 \left((ab)^2 + 1 - \frac{1}{\rho^2} \right).$$

Then in this case, the two roots of the quadratic equation $Bz^2 + Fz + \bar{B}$ are

$$z_1 = \frac{-((ab)^2 + 1 - (1/\rho^2)) + 2abj\sqrt{(1/\rho^2) - 1}}{((ab)^2 - 1) + (1/\rho^2)}$$

and $z_2 = \bar{z}_1$. It is clear for our plant $P(s)$ that for $a, b, h > 0$ and finite, that the optimal sensitivity will always be strictly less than 1. Hence we can immediately remove Case (iii) of (3.4) from our considerations. (Note $|\beta/\alpha| = 1$ here. See (3.7) (A) above.)

Therefore since $|z_1| = |z_2| = 1$, we are in Case (ii) of the procedure (3.4) and (3.7). Then solving the corresponding linear equations (or using the formulae of (3.4)) we get

$$\nu_*(0) = \frac{\sin\left(\frac{h\sqrt{(1/\rho^2) - 1}}{a}\right)}{2ab \sin\left(\frac{h\sqrt{(1/\rho^2) - 1}}{a}\right) + 2ab\sqrt{(1/\rho^2) - 1} \cos\left(\frac{h\sqrt{(1/\rho^2) - 1}}{a}\right)}.$$

The second inner product is trivial to compute and turns out to be

$$\hat{\nu}_{-1} := \frac{\rho^2}{(\rho^2(ab+1)^2 - 1)}.$$

Next it is trivial to compute that $\Delta = -2ab$, and therefore from (2) we see

$$\nu_*(0)\hat{\nu}_{-1} \leq \frac{\rho^2}{4a^2b^2}.$$

Hence we get that

$$(18) \quad \frac{\sin\left(\frac{h\sqrt{(1/\rho^2) - 1}}{a}\right)}{\sin\left(\frac{h\sqrt{(1/\rho^2) - 1}}{a}\right) + \sqrt{(1/\rho^2) - 1} \cos\left(\frac{h\sqrt{(1/\rho^2) - 1}}{a}\right)} \leq \frac{\rho^2(ab+1)^2 - 1}{ab}.$$

Using our above notation set

$$\theta := \max \{ \|\hat{W}(T_1)\|, \|\hat{W}(T_2)\| \}$$

where T_1 is the compressed shift corresponding to $m_1(z) = z$, and T_2 is the compressed shift corresponding to $m_2(z) = e^{hb((z+1)/(z-1))}$. It is easy to compute that $\|\hat{W}(T_1)\| = 1/(ab+1)$, and $\|\hat{W}(T_2)\| = \rho_1$, the largest root of (1) (of § 1), $\rho_1 \in (0, 1)$.

Then if we algebraically manipulate (18) and invoke Theorems 2.1 and 3.2, (3.7) (A) we see that we are required to find ρ_{opt} , the unique root contained in $(\theta, 1)$ of the following equation (it is easy to check ρ_{opt} exists for $a, b, h \in (0, \infty)$):

$$(19) \quad \left(1 - \frac{2ab}{\rho^2(ab+1)^2 - 1}\right) \tan\left(\frac{h\sqrt{(1/\rho^2) - 1}}{a}\right) + \sqrt{\frac{1}{\rho^2} - 1} = 0.$$

By our above theory, $\|\hat{W}(T)\| = \rho_{\text{opt}}$. Equation (19) has a number of interesting properties a few of which we discuss here. For example, as $b \rightarrow \infty$, (19) approaches (1) of § 1; this just relates the a and the h . Hence in this sense (19) generalizes (1). As $b \rightarrow 0$, it is simple to check $\rho_{\text{opt}} \rightarrow 1$. In short, (19) gives the exact relationship among the fundamental parameters a, b, h in optimal sensitivity theory.

5. Conclusions. Once again we have seen the utility of the complex and functional-analytical methods of [21], [24] in dealing with systems with delays. In this paper we have solved (or at least given an implementable procedure to solve) the weighted H^∞ -minimization problem for an interesting class of delay systems. From our techniques, we have derived a precise picture of the interaction of a delay, nonminimum

phase zero, and given weight in an H^∞ -optimal sensitivity problem. Our work in a certain sense gives mathematically rigorous justification to results that one would hope to be true from just purely engineering considerations.

Finally, we have generalized some of the one-step extension results of Adamjan, Arov and Krein [1], [2], and perhaps given a new perspective to certain kinds of (generalized) interpolation problems. It should be interesting to try to push through the techniques we have given here for broader classes of distributed systems, for example those considered in [3], or even in [7].

SYNTHESIS OF OPTIMAL CONTROL FOR AN INFINITE DIMENSIONAL PERIODIC PROBLEM*

G. DA PRATO†

Abstract. We prove an existence and uniqueness result on periodic solutions of an infinite dimensional Riccati equation.

Key words. optimal control, periodic control, dynamic programming

AMS(MOS) subject classifications. 93C, 49B

1. Introduction. Consider the following optimal control problem: minimize

$$(1.1) \quad J(u) = \frac{1}{2} \int_0^\tau [\langle M(t)y(t), y(t) \rangle + \langle N(t)u(t), u(t) \rangle] dt$$

over all $u \in L^2(0, \tau; U)$ subject to

$$(1.2) \quad y'(t) = A(t)y(t) + B(t)u(t) + f(t), \quad y(0) = y(\tau).$$

Here $A(t)$ is a linear operator in a Hilbert space H , U is the Hilbert space of the controls, $M(t)$ is a linear operator in H , $N(t)$ is a linear operator in U , $B(t)$ is a linear operator from U into H and $f \in L^2(0, \tau, H)$. We give precise notations and assumptions in § 2. In § 3 we study existence and uniqueness of periodic solutions of the infinite dimensional Riccati equation

$$(1.3) \quad Q' + A^*Q + QA - QBB^*Q + M = 0$$

and in § 4 we prove that the optimal control for problem (1.1), (1.2) is a feedback control. We shall use an argument of dynamic programming, which follows closely [2] where a similar problem was studied in a finite dimensional space.

2. Notation and hypotheses. Let U and H be Hilbert spaces (scalar product $\langle \cdot, \cdot \rangle$). We shall denote by $L(H)$ the Banach algebra of all linear bounded operators in H . We set

$$(2.1) \quad \Sigma(H) = \{T \in L(H); T = T^*\}, \quad \Sigma^+(H) = \{T \in \Sigma(H); T \geq 0\}$$

where T^* represents the adjoint of T .

Given any interval $[a, b]$ we shall denote by $C_s([a, b]; L(H))$ the set of all the mappings $[a, b] \rightarrow L(H)$, $t \rightarrow T(t)$ such that $T(\cdot)x$ is continuous for any $x \in H$. If a and b are finite, then $C_s([a, b]; L(H))$, endowed with the norm

$$(2.2) \quad \|T\| = \sup \{\|T(t)\|; t \in [a, b]\},$$

is a Banach space (by the uniform boundedness theorem). We set moreover

$$(2.3) \quad C_s([a, b]; \Sigma(H)) = \{T \in C_s([a, b]; L(H)); T(t) \in \Sigma(H)\},$$

$$(2.4) \quad C_s([a, b]; \Sigma^+(H)) = \{T \in C_s([a, b]; L(H)); T(t) \in \Sigma^+(H)\}.$$

* Received by the editors November 12, 1984; accepted for publication (in revised form) April 14, 1986.

† Scuola Normale Superiore, 56100 Pisa, Italy.

$C_s([a, b]; L(U))$ and $C_s([a, b]; L(U, H))$ are defined analogously. Concerning the operators $A(t)$, $t \in \mathbb{R}$, we shall assume:

- (2.5) (i) $A(t) = A(t + \tau)$, $t \in \mathbb{R}$.
 (ii) There exists an evolution operator $U(t, s)$, $0 \leq s \leq t$ such that the initial value problem

$$z'(t) = A(t)z(t) + g(t), \quad z(0) = x$$

with $g \in L^2(0, \tau; H)$ and $x \in H$ has a unique mild solution z given by

$$z(t) = U(t, 0)x + \int_0^t U(t, s)g(s) ds.$$

- (iii) $A_n(t) = n^2(n - A(t))^{-1} - nI$ is defined for n sufficiently large. Moreover we have $z_n \rightarrow z$ in $C([0, \tau]; H)$, where z_n is the strict solution of the approximating problem

$$z'_n(t) = A_n(t)z_n(t) + g(t), \quad z_n(0) = x.$$

We shall denote by $U_n(t, s)$ the evolution operator relative to $A_n(t)$. We remark that (2.5) are fulfilled under the usual hypotheses of Tanabe and Kato-Tanabe (see for instance [3], [6], [8]).

Concerning M , N , B and f we shall assume:

- (2.6) (i) $f: \mathbb{R} \rightarrow H$ is τ -periodic and $f \in L^2(0, \tau; H)$,
 (ii) $B \in C_s(\mathbb{R}, L(U, H))$ and it is τ -periodic,
 (iii) $M \in C_s(\mathbb{R}; \Sigma^+(H))$ and it is τ -periodic,
 (iv) $N \in C_s(\mathbb{R}, \Sigma^+(U))$, it is τ -periodic and there exists $\varepsilon > 0$ such that $N(t) \geq \varepsilon I$, $t \leq 0$.

Finally, in order to solve uniquely problem (1.2), we need the following assumption:

- (2.7) 1 belongs to the resolvent set $\rho(U(\tau, 0))$ of $U(\tau, 0)$.

Under hypotheses (2.5)–(2.7) it is easy to prove that problem (1.2) has a unique mild solution y given by

$$(2.8) \quad y(t) = U(t, 0)(I - U(\tau, 0))^{-1} \int_0^\tau U(\tau, s)(f(s) + B(s)u(s)) ds \\ + \int_0^t U(t, s)(f(s) + B(s)u(s)) ds.$$

Returning now to the control problem (1.1), (1.2), we remark that the functional $J: L^2(0, \tau; U) \rightarrow \mathbb{R}$ has a unique minimum u^* (since it is a coercive quadratic form); u^* is called the *optimal control* and the corresponding solution of (1.2) the *optimal state*. Finally $J(u^*)$ is the *optimal cost*.

The optimality conditions are also easily derived. Namely if u is the optimal control and y the optimal state, we have:

$$(2.9) \quad \begin{aligned} y' &= Ay + Bu + f, & y(0) &= y(\tau), \\ p' &= -A^*p - My, & p(0) &= p(\tau), \\ u &= -N^{-1}B^*p. \end{aligned}$$

Concerning the synthesis problem we shall look for a linear operator Q such that

$$(2.10) \quad p = Qy + r.$$

As easily seen, Q and r must satisfy the equations

$$(2.11) \quad Q' + A^*Q + QA - QBN^{-1}B^*Q + M = 0,$$

$$(2.12) \quad r' + (A^* - QBN^{-1}B^*)r + Qf = 0$$

with the periodic conditions

$$(2.13) \quad Q(0) = Q(\tau), \quad r(0) = r(\tau).$$

The differential equations in (2.9), (2.12) are intended in the mild sense, whereas the precise meaning of a solution of (2.11) will be stated in the next section.

In § 4 we will prove that the optimal control u is given by the formula

$$(2.14) \quad u = -N^{-1}B^*(Qy + r)$$

where y (the optimal state) is the solution of the closed loop equation

$$(2.15) \quad y' = Ay - BN^{-1}B^*Qy - BN^{-1}B^*r + f$$

with the condition

$$(2.16) \quad y(0) = y(\tau).$$

We remark that if the following hypothesis holds:

$$(2.17) \quad 1 \text{ belongs to the resolvent sets of the evolution operators relative to } A - BN^{-1}B^*Q \text{ and } A^* - QBN^{-1}B^*,$$

then (2.12) and (2.15) have a unique τ -periodic solution.

3. Periodic solutions of the Riccati equation. We are here concerned with periodic solutions of the Riccati equation

$$(3.1) \quad Q' + A^*Q + QA - QBN^{-1}B^*Q + M = 0.$$

We first recall some result on the final value problem

$$(3.2) \quad Q' + A^*Q + QA - QBN^{-1}B^*Q + M = 0, \quad Q(\tau) = L \in \Sigma^+(H),$$

which we write in the following integral form:

$$(3.3) \quad \begin{aligned} Q(t)x &= U^*(\tau, t)LU(\tau, t)x \\ &- \int_t^\tau U^*(s, t)(Q(s)B(s)N^{-1}(s)B^*(s)Q(s) - M(s))U(s, t)x \, ds, \quad x \in H. \end{aligned}$$

Under suitable hypotheses (see Proposition 3.1 below) (3.3) has a unique solution $Q(t) = \Lambda(t, L)$.

We say that $Q \in C_s([0, \tau]; \Sigma^+(H))$ is a τ -periodic solution of (3.1) if it is a solution of (3.3) with $Q(\tau) = Q(0)$; this is equivalent to

$$(3.4) \quad Q(\tau) = \Lambda(0, Q(\tau)).$$

We shall consider also the approximating problem

$$(3.5) \quad Q'_n + A_n^*Q_n + Q_nA_n - Q_nBN^{-1}B^*Q_n + M = 0, \quad Q_n(\tau) = L$$

where $A_n(t) = n^2(n - A(t))^{-1} - nI$. Problem (3.5) has clearly a unique solution that we denote by $Q_n(t) = \Lambda_n(t, L)$.

PROPOSITION 3.1. Assume (2.5), (2.6) and let L belong to $\Sigma^+(H)$. Then

$$(3.6) \quad (i) \text{ There exists a unique solution } Q \text{ (resp. } Q_n \text{) of (3.3) (resp. (3.5)). Moreover } Q_n \rightarrow Q \text{ in } C_s([0, \tau]; \Sigma^+(H)).$$

(ii) If $L \leq \bar{L}$ we have:

$$\Lambda(t, L) \leq \Lambda(t; \bar{L}).$$

(iii) If $\{L_k\}$ is an increasing sequence in $\Sigma^+(H)$ that converges strongly to L , then $\Lambda(\cdot, L_k)$ converges to $\Lambda(\cdot, \bar{L})$ in $C_s([0, \tau]; \Sigma^+(H))$.

Proof. Statement (i) is essentially proved in [4] (see also [1, Thm. 1, p. 64]). The proof of (ii) is completely similar to that of [1, Lemma 16, p. 83]. Let us prove (iii). Setting $Q(t) = \Lambda(t, L)$, $Q_k(t) = \Lambda(t, L_k)$ we have

$$(3.7) \quad \begin{aligned} Q_k(t)x &= U^*(\tau, t)L_k U(\tau, t)x \\ &\quad - \int_t^\tau U^*(s, t)(Q_k(s)B(s)N^{-1}(s)B^*(s)Q_k(s) - M(s))U(s, t)x ds, \end{aligned} \quad x \in H.$$

By (3.6), $\{Q_k(t)\}$ is increasing for any t and $Q_k(t) \leq Q(t)$. It follows that there exists $\bar{Q}(t) \leq Q(t)$ such that $Q_k(t) \rightarrow \bar{Q}(t)x$ for any $x \in H$. By the dominated convergence theorem, taking the limit, as $k \rightarrow \infty$ in (3.7), we obtain

$$(3.8) \quad \begin{aligned} \bar{Q}(r)x &= U^*(\tau, t)L U(\tau, t)x \\ &\quad - \int_t^\tau U^*(s, t)(\bar{Q}(s)B(s)N^{-1}(s)B^*(s)\bar{Q}(s) - M(s))U(s, t)x ds, \end{aligned} \quad x \in H.$$

From (3.8) it follows that $\bar{Q} \in C_s([0, \tau]; \Sigma^+(H))$ so that, by uniqueness, we have $\bar{Q} = Q$. \square

In order to prove the existence of a periodic solution of (3.1), we need a stabilizability assumption:

(3.9) There exists a τ -periodic function $K \in C_s(\mathbb{R}; L(H, U))$ and two numbers, $\omega > 0$, $\mu > 0$ such that $\|U_{A-BK}(t, s)\| \leq \mu e^{-\omega(t-s)}$, $t > s$, where U_{A-BK} is the evolution operator relative to $A(t) - B(t)K(t)$, $t \in [0, \tau]$.

This hypothesis reduces to the usual one for the algebraic Riccati equation when A , B and M are time-independent (see [7]).

Remark 3.2. Hypothesis (3.9) is fulfilled if either $\|U(t, s)\| \leq a e^{-b(t-s)}$ with $b > 0$ or $B(t) \geq \sigma > 0$ and $a = 1$. \square

We are ready now to prove the following theorem:

THEOREM 3.3. Assume (2.5), (2.6) and (3.9). Then there exists a τ -periodic solution of (3.1).

Proof. We first recall a well-known identity (see for instance [1]). Let $u \in L^2(0, T; U)$, $T > 0$ and let y be the mild solution of the problem

$$(3.10) \quad y' = Ay + Bu, \quad y(0) = x, \quad x \in H.$$

Let W be the solution of the final value problem

$$(3.11) \quad W' + A^*W + WA - WB N^{-1} B^* W + M = 0, \quad W(T) = 0;$$

then we have:

$$(3.12) \quad \langle W(0)x, x \rangle + \int_0^T \|N^{-1/2} B^* W y + N^{1/2} u\|^2 ds = \int_0^T [\langle M y, y \rangle + \langle N u, u \rangle] ds.$$

We prove now the existence of a τ -periodic solution of (3.1). Set

$$(3.13) \quad S_0 = 0, \quad S_{n+1}(t) = \Lambda(t, S_n(0)), \quad n \in \mathbb{N}.$$

By (3.6) $\{S_n\}$ is increasing. For any $k \in \mathbb{N}$ we set

$$(3.14) \quad \begin{aligned} W_k(t) &= S_h(t - (k-h-1)\tau), \\ t &\in [(k-h-1)\tau, (k-h)\tau], \quad h = 1, \dots, k. \end{aligned}$$

As easily checked, W_k is a solution of the problem

$$(3.15) \quad \begin{aligned} W'_k + A^* W_k + W_k A - W_k B N^{-1} B^* W_k + M &= 0, \\ W_k(k\tau) &= 0, \quad 0 \leq t \leq k\tau. \end{aligned}$$

We now resort to (3.9) and (3.12) with u and y given by

$$(3.16) \quad u(t) = -K(t)U_{A-BK}(t, 0)x, \quad y(t) = U_{A-BK}(t, 0)x, \quad x \in H$$

and we get

$$(3.17) \quad \langle W_k(0)x, x \rangle \leq \frac{\mu^2}{2\eta} (\|M\| + \|N\| \|K\|) \|x\|^2,$$

which implies that the sequence $\{S_n(0)\}$ is bounded in $\Sigma^+(H)$. By a well-known result on the monotone sequences of linear operators it follows that there exists $\bar{S} \in \Sigma^+(H)$ such that $S_n(0)x \rightarrow \bar{S}x$ for any $x \in H$. Now, by Proposition 3.1(iii) and by (3.13) we have, as $n \rightarrow \infty$ $\bar{S} = \Lambda(0, \bar{S})$ so that $\Lambda(t, \bar{S})$ is the required periodic solution. \square

Remark 3.4. Theorem 3.3 generalizes a result in [9].

We consider now uniqueness and to this purpose we introduce a detectability assumption which reduces to the usual one for the algebraic Riccati equation (see [7]). We assume:

$$(3.18) \quad \text{There exists a } \tau\text{-periodic function } K_1 \in C_s(\mathbb{R}, L(H)) \text{ and two numbers } \omega_1 > 0, \mu_1 > 0 \text{ such that}$$

$$\|U_{A-K_1\sqrt{M}}(t, s)\| \leq \mu_1 e^{-\omega_1(t-s)}, \quad t \geq s$$

where $U_{A-K_1\sqrt{M}}$ is the evolution operator relative to

$$A(t) - K_1(t)\sqrt{M(t)}, \quad t \in [0, \tau].$$

We remark that (3.18) implies (2.17).

We first prove two lemmas as follows.

LEMMA 3.5. Assume (2.5), (2.6) and (3.18) and set $L = A - BN^{-1}B^*Q$ where Q is a τ -periodic solution of (3.1). Then there exists $c > 0$ such that

$$(3.19) \quad \int_s^\infty \|U_L(t, s)x\|^2 dt \leq c \|x\|^2.$$

Proof. Let Q be a τ -periodic solution of (3.1), fix $k \in \mathbb{N}$. Then we have

$$(3.20) \quad Q' + L^*Q + QL + QBN^{-1}B^*Q + M = 0, \quad Q(k\tau) = Q(0), \quad t \in [0, k\tau].$$

Let Q_n be the solution of the approximating problem

$$(3.21) \quad Q'_n + L_n^*Q_n + Q_nL_n + Q_nBN^{-1}B^*Q_n + M = 0, \quad Q_n(k\tau) = Q(0)$$

where $L_n = A_n - BN^{-1}B^*Q_n$. We remark that Q_n is not necessarily periodic. For any $x \in H$ we have

$$(3.22) \quad \begin{aligned} \frac{d}{dt} &< Q_n(t)U_{L_n}(t, s)x, U_{L_n}(t, s)x \rangle \\ &= -\|N^{1/2}BQ_nU_{L_n}(t, s)x\|^2 - \|\sqrt{M}U_{L_n}(t, s)x\|^2. \end{aligned}$$

By integrating in $[s, t]$ and letting n go to infinity we find

$$(3.23) \quad \begin{aligned} \langle Q(s)x, x \rangle &= \langle Q(k\tau)U_L(k\tau, s)x, U_L(k\tau, s)x \rangle \\ &+ \int_0^{k\tau} [\|N^{-1/2}Q(\sigma)U_L(\sigma, s)x\|^2 + \|\sqrt{M(\sigma)}U_L(\sigma, s)x\|^2] d\sigma. \end{aligned}$$

Then functions $N^{-1/2}QU_L(\cdot, s)x$ and $\sqrt{M}U_L(\cdot, s)x$ belong to $L^2(s, \infty; H)$. Let now Π be defined by

$$(3.24) \quad L = \Pi + (K_1\sqrt{M} - BN^{-1}B^*Q)$$

and remark that, by (2.18),

$$(3.25) \quad \|U_\Pi(t, s)\| \leq \mu_1 e^{-\omega_1(t-s)}.$$

By (3.24) it follows

$$(3.26) \quad \begin{aligned} U_L(t, s)x &= U_\Pi(t, s)x \\ &+ \int_s^t U_\Pi(t, \sigma)(K_1(\sigma)\sqrt{M(\sigma)} - B(\sigma)N^{-1}(\sigma)B^*(\sigma)Q(\sigma))U_L(\sigma, s)x d\sigma; \end{aligned}$$

now, by the Young inequality $U_L(\cdot, s)x$ belongs to $L^2(s, \infty; H)$ as required. \square

LEMMA 3.6. *Under the same hypotheses of Lemma 3.5 there exists a constant $c_1 > 0$ such that*

$$(3.27) \quad \|U_L(t, s)\| \leq \frac{c_1}{(t-s)}, \quad t \geq s.$$

Proof. Since L is τ -periodic, there exist $\mu_2 > 0$ and $\xi \in \mathbb{R}$ such that

$$(3.28) \quad \|U_L(t, s)\| \leq \mu_2 e^{\xi(t-s)}, \quad t > s.$$

For any $x \in H$ we have

$$\begin{aligned} \frac{1}{2\xi}(e^{2\xi(t-s)} - 1)\|U_L(t, s)x\| &= \int_s^t e^{2\xi(\sigma-s)}\|U_L(t, s)x\|^2 d\sigma \\ &\leq \int_s^t e^{2\xi(\sigma-s)}\|U_L(\sigma, s)x\|^2\|U_L(t, \sigma)\|^2 d\sigma \\ &\leq c\mu_2^2 e^{2\xi(t-s)}\|x\|^2 \end{aligned}$$

by (3.19); thus there exists $\gamma > 0$ such that

$$(3.29) \quad \|U_L(t, s)\| \leq \gamma, \quad t \geq s.$$

We have finally

$$\begin{aligned} (t-s)\|U_L(t, s)x\|^2 &= \int_s^t \|U_L(t, s)x\|^2 d\sigma \\ &\leq \int_s^t \|U_L(\sigma, s)x\|^2\|U_L(t, \sigma)\|^2 d\sigma \leq \gamma^2 c\|x\|^2 \end{aligned}$$

and the conclusion follows. \square

Remark 3.7. The above proof is inspired by the proof of the Datko theorem given in [7].

We are now ready to prove uniqueness.

THEOREM 3.8. *Assume (2.5), (2.6) and (3.18). Then (3.1) has at most one τ -periodic solution.*

Proof. Let Q, Q_1 be τ -periodic solutions of (3.1); set $R = Q - Q_1$. Then R verifies the equation

$$(3.30) \quad R' + L^*R + RL + RBN^{-1}B^*R = 0, \quad t \in [0, k\tau]$$

for any $k \in \mathbb{N}$. Let R_n be the solution of the final value problem

$$(3.31) \quad R'_n + L_n^*R_n + R_nL_n + R_nBN^{-1}B^*R_n = 0, \quad R_n(k\tau) = R(k\tau).$$

It follows that

$$(3.32) \quad \begin{aligned} & \frac{d}{dt} \langle R_n(t)U_{L_n}(t, s)x, U_{L_n}(t, s)x \rangle \\ &= -\|N^{-1/2}B^*(t)R_n(t)U_{L_n}(t, s)x\|^2 \leq 0, \quad x \in H, \end{aligned}$$

which implies

$$(3.33) \quad \langle R(0)U_L(k\tau, s)x, U_L(k\tau, s)x \rangle \leq \langle R(s)x, x \rangle.$$

Letting k go to infinity and using (3.27), we get $\langle R(s)x, x \rangle \geq 0$, that is, $Q(s) \geq Q_1(s)$; by interchanging Q and Q_1 we find $Q(s) \leq Q_1(s)$ and finally that $Q = Q_1$. \square

Remark 3.9. Stability. Assume the hypotheses of Theorems 3.3 and 3.8; let Q be the unique periodic solution of (3.1) and S a solution of the final value problem

$$S' + A^*S + SA - SBN^{-1}B^*S + M = 0, \quad S(0) = S_0 \in \Sigma^+(H), \quad -\infty < t \leq 0.$$

Setting $Z = Q - S$, $L = A - BN^{-1}B^*Q$, we have

$$Z' + L^*Z + ZL + ZBN^{-1}B^*Z = 0.$$

Thus, by (3.27), it follows that

$$\lim_{\|S_0\| \rightarrow 0} \|Q(t) - S(t)\| = 0 \quad \text{uniformly in } t$$

and the periodic solution Q is stable.

4. Dynamic programming. The Hamilton–Jacobi–Bellman equation corresponding to the control problem (1.1)–(1.2) is

$$(4.1) \quad \begin{aligned} & \psi_t(t, x) - \frac{1}{2} \|N(t)^{-1/2}B^*(t)\psi_x(t, x)\|^2 \\ & + \langle Ax + f(t), \psi_x(t, x) \rangle + \frac{1}{2} \langle M(t)x, x \rangle = 0. \end{aligned}$$

The following result is easily proved.

PROPOSITION 4.1. Assume (2.5)–(2.7), (2.17) and (3.9). Let Q be a τ -periodic solution of (3.1) and r the periodic solution of (2.12). Then the function

$$(4.2) \quad \psi(t, x) = \frac{1}{2} \langle Q(t)x, x \rangle + \langle r(t), x \rangle + s(t)$$

is a solution of (4.1) if and only if we have

$$(4.3) \quad s' - \frac{1}{2} \|N^{-1}B^*r\|^2 + \langle f(t), r(t) \rangle = 0.$$

LEMMA 4.2. Assume the hypotheses of Proposition 4.1. Let ψ be given by (4.2), $u \in L^2(0, \tau; U)$, y be defined by (1.2) and J by (1.1). Then the following identity holds:

$$(4.4) \quad \begin{aligned} J(u) &= \int_0^\tau \|N^{-1/2}B^*(Qy + r) + N^{1/2}u\|^2 dt \\ &+ \int_0^\tau [\langle f, r \rangle - \frac{1}{2} \|B^*r\|^2] dt. \end{aligned}$$

Proof. Let $Q_n(t) = \Lambda_n(t, Q(\tau))$, let r_n be the solution of the problem

$$(4.5) \quad r'_n + (A_n^* - Q_n B N^{-1} B^*) r_n + Q_n f = 0, \quad r_n(\tau) = r(\tau).$$

Let s_n be such that

$$(4.6) \quad s'_n - \frac{1}{2} \|N^{-1/2} B^* r_n\|^2 + \langle f, r_n \rangle = 0$$

and, finally, let y_n be the solution of the problem

$$(4.7) \quad y'_n = A_n y_n + B u + f, \quad y_n(0) = y(0).$$

Setting

$$(4.8) \quad \psi_n(t, y) = \frac{1}{2} \langle Q_n(t) y, y \rangle + \langle r_n(t), y \rangle + s_n(t)$$

we have

$$(4.9) \quad \frac{d}{dt} \psi_n(t, y_n) = \frac{1}{2} \|N^{-1/2} B^* (Q_n y_n + r_n)\|^2 - \frac{1}{2} [\langle M y_n + y_n \rangle + \langle N u, u \rangle].$$

Now the conclusion follows by integrating (4.9) in $[0, \tau]$ and by letting n go to infinity. \square

THEOREM 4.3. Assume (2.5)–(2.7), (2.17) and (3.9). Let Q be a τ -periodic solution of (3.1), let r be the corresponding τ -periodic solution of (2.12) and y the solution of the closed loop equation (2.15) with $y(0) = y(\tau)$. Then the optimal control u^* is given by

$$(4.10) \quad u^* = -N^{-1} B^* (Q y + r)$$

and the optimal cost results from

$$(4.11) \quad J(u^*) = \int_0^\tau \left[\langle f, r \rangle - \frac{1}{2} \|B^* r\|^2 \right] dt.$$

Proof. By (4.4) it follows that

$$(4.12) \quad J(u) \geq \int_0^\tau \left[\langle f, r \rangle - \frac{1}{2} \|B^* r\|^2 \right] dt = \Gamma;$$

now, if u is given by (4.10) we have $J(u^*) = \Gamma$ so that u is optimal. \square

Example 4.4. Let Ω be a bounded subset of R^n with smooth boundary $\partial\Omega$. Consider the following problem:

Minimize

$$(4.13) \quad J(u) = \frac{1}{2} \int_0^\tau dt \int_\Omega d\xi [|y(t, \xi)|^2 + |u(t, \xi)|^2]$$

over all $u \in L^2([0, \tau] \times \Omega)$

subject to

$$\frac{d}{dt} y(t, \xi) = \Delta_\xi y(t, \xi) - \phi(t) y(t, \xi) + u(t, \xi) + f(t, \xi),$$

$$(4.14) \quad y(t, \xi) = 0, \quad t \in [0, \tau], \quad \xi \in \partial\Omega,$$

$$y(0, \xi) = y(t, \xi)$$

where f and ϕ are continuous, τ -periodic in t and ϕ is nonnegative. Δ_ξ is the Laplace operator acting in the variable ξ .

Set $H = U = L^2(\Omega)$, $M(t) = N(t) = B = I$ and

$$(4.15) \quad A(t) = \Delta_\xi - \phi(t), \quad D(A(t)) = H^2(\Omega) \cap H_0^1(\Omega).$$

As easily seen, hypotheses (2.5) and (2.6) hold; moreover

$$(4.16) \quad U(t, s) = \exp \left(C(t-s) - \int_s^t \phi(\sigma) d\sigma \right)$$

where $Cy = \Delta_\xi y$ and $D(C) = D(A(t))$. By the maximum principle we have

$$(4.17) \quad \|U(t, s)\| \leq 1$$

so that $1 \in \rho(U(\tau, 0))$ and (2.7) is fulfilled. Moreover, (2.17) also holds because $A - BN^{-1}B^*Q = A - Q$ and Q is positive. Finally (3.9) holds by virtue of Remark 3.2. \square

CONTROLLABILITY OF SEMILINEAR CONTROL SYSTEMS DOMINATED BY THE LINEAR PART*

KOICHIRO NAITO†

Abstract. While various equivalent conditions for controllability have been obtained in the case of linear control systems, controllability problems of semilinear control systems usually require some complicated and limited assumptions. In this paper we show the approximate controllability of an abstract semilinear control system under the assumption, which has a simple form and can be easily checked in many examples.

Key words. semilinear control system, approximate controllability

AMS(MOS) subject classification. 93B

1. Introduction. In this paper we study the approximate controllability (a.c.) of the following semilinear control system.

$$(1.1) \quad \begin{aligned} \frac{dy}{dt} + Ay(t) &= F(y(t)) + (Bv)(t), & 0 < t < T, \\ y(0) &= 0. \end{aligned}$$

Let the state space X and the control space V be Hilbert spaces and the state function $y(t)$, $0 \leq t \leq T$, takes values in X and the control function $v(\cdot)$ is given in $L^2(0, T; V)$. Assume that the operator $-A$ generates a C_0 -semigroup $S(t)$ on X and B is a bounded linear mapping from $L^2(0, T; V)$ to $L^2(0, T; X)$. $F(\cdot)$ is a nonlinear operator on X . When $F \equiv 0$, system (1.1) is called the corresponding linear system, denoted by $(1.1)_1$.

The controllability theory for abstract linear control systems has been established; the necessary and sufficient conditions for the various types of controllability are well known (cf. [1], [7]). On the other hand, in the case of semilinear control systems, we need some complicated and restrictive conditions, which are of two classes, in the approximate controllability problem with dense reachable sets and in the local controllability problem with limited reachable sets. In either problem the restrictions are placed on the system components, such as range of B , continuity of F , regularity of $S(t)$ and control time T . For instance, in [11] Zhou showed a.c. of an abstract semilinear control system by assuming some inequality conditions, which are dependent on the properties of the system components, and also Quinn and Carmichael in [6] showed the diameters of the reachable sets by using the system constants determined restrictively.

Our purpose is to show a.c. of (1.1) under simple and fundamental assumptions on the system components. In particular, the range conditions of the operator B are most essential. We assume hypothesis (B1), which implies a.c. of $(1.1)_1$, and also, which is described as a geometrical relation in $L^2(0, T; X)$ between the range of the operator B and the subspace N^\perp related with the semigroup $S(t)$ (§ 2). On this space N^\perp , exactly, on an equivalent quotient space, we use the Schauder's degree theorem to show a.c. of (1.1). Furthermore, if the operator B is invertible (hypothesis (B2)), we can show an inclusive relation between the reachable sets of $(1.1)_1$ and those of (1.1) by determining the diameters of their control sets (§ 3). Because of its simple form, hypothesis (B1) can be easily checked in many examples (§ 4).

2. Notation and hypotheses. For system (1.1) we further assume

(F1) The nonlinear operator F on X is Lipschitz continuous; there exists a constant $K > 0$ such that

$$\|F(x_1) - F(x_2)\|_X \leq K \|x_1 - x_2\|_X, \quad x_1, x_2 \in X.$$

Then, we can consider a unique mild solution $y(t; v)$ for each $v \in L^2(0, T; V)$,

$$(2.1) \quad y(t; v) = \int_0^t S(t-s) \{F(y(s; v)) + (Bv)(s)\} ds, \quad 0 \leq t \leq T,$$

and we define the solution mapping W from $L^2(0, T; V)$ to $C(0, T; X)$ by

$$(Wv)(t) = y(t; v), \quad v \in L^2(0, T; V).$$

(See [5] for mild solutions of semilinear systems.) We also assume

(W) The solution mapping W is compact.

Remark 1. If A generates a compact semigroup, (W) is satisfied (cf. [4]). Recently, Seidman [8] shows the various sufficient conditions for the compactness of the solution mapping.

We introduce some definitions and notation. We define the linear operator \tilde{S} from $L^2(0, T; X)$ to X by

$$\tilde{S}p = \int_0^T S(T-s)p(s) ds \quad \text{for } p \in L^2(0, T; X).$$

Denote the kernel of the operator \tilde{S} by N , which is a closed subspace in $L^2(0, T; X)$, and its orthogonal space in $L^2(0, T; X)$ by N^\perp . Let P_J be the projection on $L^2(0, T; X)$ with the range N^\perp . Denote the range of the operator B by X_B and its closure by \bar{X}_B . We need the following hypothesis:

(B1) For each $p \in L^2(0, T; X)$ there exists a function $q \in \bar{X}_B$: $\tilde{S}p = \tilde{S}q$.

Remark 2. It is easily known that (B1) is equivalent to the following conditions: $L^2(0, T; X) = \bar{X}_B + N$ or $P_J \bar{X}_B = N^\perp$. We see later in Lemma 2 that (B1) implies a.c. of (1.1)₁. On the other hand, a.c. of (1.1)₁ is equivalent to the density condition $L^2(0, T; X) = \overline{X_B + N}$. Therefore, if the closedness of the product space is assumed (cf. Kato [2]), (B1) is equivalent to a.c. of (1.1)₁.

Under hypothesis (B1) we can define the mapping P from N^\perp to \bar{X}_B as follows: let $u_m \in N^\perp$ and define Pu_m as the unique minimum norm element u_X in $\{u_m + N\} \cap \bar{X}_B$:

$$\|Pu_m\| = \|u_X\| = \min \{\|u\| : u \in \{u_m + N\} \cap \bar{X}_B\}.$$

From hypothesis (B1) it follows that for each u_m in N^\perp $\{u_m + N\} \cap \bar{X}_B \neq \emptyset$. Thus the operator P is well defined.

LEMMA 1. *The operator P from N^\perp to \bar{X}_B is linear and continuous.*

Proof. Denote the range space of the mapping P by $R(P)$. Since $R(P)$ is identified with the quotient space $\bar{X}_B/(\bar{X}_B \cap N)$, $R(P)$ is a closed subspace in $L^2(0, T; X)$. Restrict the domain of the projection P_J to $R(P)$ and consider hypothesis (B1); then it is easily known that $P_J|_{R(P)}$ is an injective and surjective mapping from $R(P)$ to N^\perp . Since $(P_J|_{R(P)})^{-1} = P$, it follows from the open mapping theorem that P is linear and continuous.

In (2.1), consider the case in which $V = X$ and $B = I$. For each $u \in L^2(0, T; X)$, there exists a unique mild solution $y_u \in C(0, T; X)$ which satisfies

$$y_u(t) = \int_0^t S(t-s) \{F(y_u(s)) + u(s)\} ds.$$

So we can define the nonlinear operator \mathcal{F} on $L^2(0, T; X)$ by

$$(\mathcal{F}u)(t) = F(y_u(t)), \quad u \in L^2(0, T; X).$$

Since the solution mapping W is compact, hypothesis (F1) implies the compactness of the operator \mathcal{F} .

Let \tilde{Y} denote the quotient space; $\tilde{Y} = L^2(0, T; X)/N$ and define the norm of a coset $\tilde{y} = y + N$ in \tilde{Y} by $\|\tilde{y}\| = \inf \{\|y + f\| : f \in N\}$. Then we denote the isometric isomorphism from \tilde{Y} onto N^\perp by G . We will treat the controllability problem by using the degree theorem in \tilde{Y} . We define the operator $\tilde{\mathcal{F}}$ on \tilde{Y} by

$$\tilde{\mathcal{F}}\tilde{u} = \mathcal{F}(PG\tilde{u}) + N, \quad \tilde{u} \in \tilde{Y}.$$

From the previous argument we note that $\tilde{\mathcal{F}}$ is compact.

3. Approximate controllability. We denote the reachable set of system (1.1) by $K_T(F)$;

$$K_T(F) = \{y(T; v) : v \in L^2(0, T; V)\}$$

where $y(T; v)$ is the T -time value of the state function $y(t; v)$ which satisfies (2.1) with a given control function v in $L^2(0, T; V)$. If the reachable set is dense in X ; $\overline{K_T(F)} = X$, then the system is called approximately controllable. We also define the reachable set $K'_T(F)$ by

$$K'_T(F) = \{y(T; v) : v \in V_r\}$$

where V_r is an open ball in $L^2(0, T; V)$ with its radius $r > 0$. Similarly, as for the corresponding linear system (1.1)₁, we can define $K_T(0)$, $K'_T(0)$ and the approximate controllability.

For a.c. of (1.1)₁ we know the following.

LEMMA 2. Assume hypothesis (B1); then we have $\overline{K_T(0)} = X$.

Proof. Let $\xi \in D(A)$, then there exists a function $p \in C^1(0, T; X)$ such that

$$\xi = \int_0^T S(T-s)p(s) ds,$$

for instance, put $p(s) = (\xi + sA\xi)/T$. From (B1), there exists a function $q \in \bar{X}_B$ such that $p - q \in N$, that is,

$$\xi = \int_0^T S(T-s)p(s) ds = \int_0^T S(T-s)q(s) ds.$$

For every $\varepsilon > 0$ there exists a control function v_ε in $L^2(0, T; V)$ such that

$$\|Bv_\varepsilon - q\| < (MT)^{-1}\varepsilon$$

where M is a positive constant: $\|S(t)\| \leq M, 0 \leq t \leq T$. Put

$$\xi_\varepsilon = \int_0^T S(T-s)Bv_\varepsilon(s) ds;$$

then we have

$$\|\xi - \xi_\varepsilon\|_X \leq MT\|Bv_\varepsilon - q\| < \varepsilon.$$

Since ε is given arbitrarily, the density of the domain $D(A)$ in X implies a.c. of (1.1)₁.

To prove the controllability without the density condition for the range of the operator B and without any restrictions to the control time T , we need some additional

assumptions on the nonlinear function F . Here we consider the following case (cf. [3], [12]).

(F2) F is uniformly bounded; there exists a constant $M_F > 0$ such that

$$\|F(x)\|_X \leq M_F \quad \text{for all } x \in X.$$

Remark 3. As for the boundedness of the function \mathcal{F} on $L^2(0, T; X)$ and $\tilde{\mathcal{F}}$ on \tilde{Y} , it is easily known that

$$\|\tilde{\mathcal{F}}\tilde{u}\| \leq \|\mathcal{F}u\| \leq M_F\sqrt{T} \quad \text{for all } u \in L^2(0, T; X), \quad \tilde{u} \in \tilde{Y}.$$

THEOREM 1. *We assume the hypotheses (B1), (F1) and (F2); then we have*

$$K_T(0) \subset \overline{K_T(F)}.$$

Therefore, since $K_T(0)$ is dense in X , system (1.1) is approximately controllable.

Proof. We use the following open balls:

$$U_d = \{x \in L^2(0, T; X) : \|x\| < d\},$$

$$\tilde{U}_d = \{\tilde{x} \in \tilde{Y} : \tilde{x} = x + N, x \in U_d\},$$

$$\theta_d = \{\tilde{x} \in \tilde{Y} : \|\tilde{x}\|_{\tilde{Y}} < d\};$$

then we know that $\tilde{U}_d \subset \theta_d$. If $\eta \in K_T(0)$, then there exists a constant $r > 0$ and $v \in V_r$ such that $\eta \in K'_T(0)$ and

$$\eta = \int_0^T S(T-s)Bv(s) \, ds.$$

Put $z = Bv$ and $r_1 = \|B\|r$, then we have

$$\tilde{z} = z + N \in \tilde{U}_{r_1}.$$

Take a constant $R_1 > 0$ such that

$$R_1 > M_F\sqrt{T} + r_1.$$

We will apply the degree theorem on θ_{R_1} .

For the element $\tilde{z} \in \tilde{U}_{r_1}$, consider the equation

$$(3.1) \quad \tilde{z} = \lambda \tilde{\mathcal{F}}\tilde{u}_\lambda + \tilde{u}_\lambda, \quad 0 \leq \lambda \leq 1.$$

Since $\tilde{z} \in \theta_{R_1}$, (3.1) has a solution in θ_{R_1} when $\lambda = 0$. Let \tilde{u}_λ , $0 \leq \lambda \leq 1$ be a solution of (3.1); then we have

$$(3.2) \quad \begin{aligned} \|\tilde{u}_\lambda\| &\leq \|\tilde{z}\| + \|\tilde{\mathcal{F}}\tilde{u}_\lambda\| \\ &\leq r_1 + M_F\sqrt{T} < R_1. \end{aligned}$$

Thus, $\tilde{u}_\lambda \notin \partial\theta_{R_1}$, $0 \leq \lambda \leq 1$. It follows from the compactness of $\tilde{\mathcal{F}}$ that there exists a solution $\tilde{u} \in \theta_{R_1}$ which satisfies the equation

$$(3.3) \quad \tilde{z} = \tilde{\mathcal{F}}\tilde{u} + \tilde{u}.$$

Since

$$P(G\tilde{u}) \in P_J^{-1}(G\tilde{u}) \cap \bar{X}_B,$$

we have

$$P(G\tilde{u}) + N = \tilde{u}.$$

Put $u_B = P(G\tilde{u})$, then (3.3) is described by

$$\tilde{z} = \mathcal{F}(u_B) + u_B + N.$$

It follows that

$$\eta = \int_0^T S(T-s)z(s) ds = y_{u_B}(T) = \int_0^T S(T-s)\{F(y_{u_B}(s)) + u_B(s)\} ds.$$

Since the mapping P takes values in \bar{X}_B , for every $\varepsilon > 0$ there exists a function v_ε in $L^2(0, T; V)$ such that

$$\|PG\tilde{u} - Bv_\varepsilon\| < \varepsilon_0$$

where $\varepsilon_0 = \{M\sqrt{T} \exp(MKT)\}^{-1}\varepsilon$ and M is a positive constant such that $\|S(t)\| \leq M, 0 \leq t \leq T$. Consider the mild solution $y(t; v_\varepsilon) \in C(0, T; X)$;

$$y(t; v_\varepsilon) = \int_0^t S(t-s)\{F(y(s; v_\varepsilon)) + (Bv_\varepsilon)(s)\} ds.$$

Since the operator F is Lipschitz continuous, by using Hölder's inequality we have

$$\begin{aligned} \|y_{u_B}(t) - y(t; v_\varepsilon)\| &\leq \int_0^t \|S(t-s)\| \{\|F(y_{u_B}(s)) - F(y(s; v_\varepsilon))\| + \|u_B(s) - Bv_\varepsilon(s)\|\} ds \\ &\leq M\sqrt{T}\varepsilon_0 + KM \int_0^t \|y_{u_B}(s) - y(s; v_\varepsilon)\| ds, \quad 0 \leq t \leq T. \end{aligned}$$

By using Gronwall's lemma it follows that

$$\|y_{u_B}(t) - y(t; v_\varepsilon)\| \leq M\sqrt{T}\varepsilon_0 \exp(MKt), \quad 0 \leq t \leq T.$$

Thus for every $\varepsilon > 0$ there exists a control function v_ε in $L^2(0, T; V)$ such that

$$\|y_{u_B}(T) - y(T; v_\varepsilon)\| \leq \varepsilon.$$

It follows that

$$y_{u_B}(T) \in K_T(F) + S_\varepsilon$$

where $S_\varepsilon = \{x \in X : \|x\| \leq \varepsilon\}$. Since ε can be given arbitrarily, we have

$$\eta = y_{u_B}(T) \in \overline{K_T(F)},$$

which completes the proof.

Next we estimate the diameters of the admissible control sets, which implies the inclusive relation between the reachable set of system (1.1) and that of its corresponding linear system. We need the following hypothesis.

(B2) There exists a constant $k_B > 0$ such that

$$\|v\| \leq k_B \|Bv\|, \quad v \in L^2(0, T; V).$$

From the hypothesis (B2) it follows that X_B is a closed subspace in $L^2(0, T; X)$. We can see many examples which satisfy (B2) (cf. [12]).

THEOREM 2. *Under hypotheses (F1), (F2), (B1) and (B2), we have the following inclusive relation; for every $r > 0$, there exists $R > 0$ such that*

$$K_T^r(0) \subset K_T^R(F)$$

where R is a positive constant that satisfies

$$R > (r\|B\| + M_F\sqrt{T})\|P\|k_B.$$

Proof. We can use the same argument and the same notations in the proof of Theorem 1. Let $\eta \in K_T^r(0)$ and $z \in U_{r_1}$ such that

$$\eta = \int_0^T S(T-s)z(s) ds;$$

then we have $\tilde{z} = \tilde{\mathcal{F}}\tilde{u} + \tilde{u}$. By the definition of the operator P and hypothesis (B2) there exists a control function v in $L^2(0, T; V)$ such that $PG\tilde{u} = Bv$. Without the approximation argument in the proof of Theorem 1 we have

$$\eta = \int_0^T S(T-s)\{F(y(s; v)) + Bv(s)\} ds.$$

We also have

$$\begin{aligned} \|v\| &\leq k_B\|Bv\| = k_B\|PG\tilde{u}\| \\ &\leq k_B\|P\|\|\tilde{u}\| \\ &< k_B\|P\|(r\|B\| + M_F\sqrt{T}). \end{aligned}$$

Take a constant $R > k_B\|P\|(r\|B\| + M_F\sqrt{T})$; then we have

$$\eta \in K_T^R(F).$$

Remark 4. The hypotheses (F1) and (F2) can be weakened to the following hypothesis (F'):

$$\|F(x)\| \leq K'(1 + \|x\|^\alpha), \quad x \in X$$

where K' is a positive constant and $0 < \alpha < 1$. (See Seidman [9].) In fact, using an elementary inequality: $r^\alpha \leq 1 + r$ ($r \geq 0$) and Gronwall's lemma, we have

$$\|y_u\| \leq C'(1 + \|u\|), \quad u \in L^2(0, T; X)$$

and it follows that

$$\|\mathcal{F}u\| \leq C''(1 + \|u\|)^\alpha$$

where C' and C'' are positive constants dependent on K' , T , M . Dividing both sides of (2.3) by $\|\tilde{u}_\lambda\|^\alpha$ if $\|\tilde{u}_\lambda\|^\alpha \geq k$ for an arbitrarily given constant $k > 0$, we can obtain the similar estimation and use the same argument as that in the proof of Theorem 1.

4. Examples.

Example 1. In this section we consider the heat control system studied by Zhou [10]. Let $X = L^2(0, \pi)$ and $A = -d^2/dx^2$ with $D(A)$ consisting of all $y \in X$ with $d^2y/dx^2 \in X$ and $y(0) = y(\pi) = 0$. Put $\phi_n(x) = (2/\pi)^{1/2} \sin nx$, $0 \leq x \leq \pi$, $n = 1, 2, \dots$, then $\{\phi_n, n = 1, 2, \dots\}$ is an orthonormal base for X and ϕ_n is the eigenfunction corresponding to the eigenvalue $\lambda_n = -n^2$ of the operator $-A$, $n = 1, 2, \dots$. Define an infinite-dimensional space V by

$$V = \left\{ \sum_{n=2}^{\infty} u_n \phi_n, \text{ with } \sum_{n=2}^{\infty} u_n^2 < +\infty \right\}.$$

The norm in V is defined by $\|u\|_V = (\sum_{n=2}^{\infty} u_n^2)^{1/2}$. Define a continuous linear mapping from V to X as follows:

$$(4.1) \quad Bu = 2u_2\phi_1 + \sum_{n=2}^{\infty} u_n\phi_n \quad \text{for } u = \sum_{n=2}^{\infty} u_n\phi_n \in V.$$

Consider a control system governed by the semilinear heat equation

$$(4.2) \quad \begin{aligned} \frac{\partial y(t, x)}{\partial t} &= \frac{\partial^2 y(t, x)}{\partial x^2} + F(x, y(t, x)) + Bu(t, x), \quad 0 < t < T, \quad 0 < x < \pi, \\ y(t, 0) &= y(t, \pi) = 0, \quad 0 \leq t \leq T, \\ y(0, x) &= 0, \quad 0 \leq x \leq \pi. \end{aligned}$$

Now we can define the bounded linear operator \tilde{B} from $L^2(0, T; V)$ to $L^2(0, T; X)$ by $(\tilde{B}u)(t) = Bu(t)$, $u \in L^2(0, T; V)$. And the nonlinear operator F on X is assumed to satisfy hypotheses (F1) and (F2).

In [10] Zhou showed that this heat control system satisfied his inequality conditions and proved the approximate controllability of this system. Here we examine our condition (B1) and (B2) for this control system. By using Theorems 1 and 2 we show the approximate controllability without checking Zhou's inequality conditions.

It is well known that $-A$ generates a compact semigroup $S(t)$ and that

$$S(t)\phi_n = e^{-\lambda_n t}\phi_n, \quad n = 1, 2, \dots$$

Let $a \in N \subset L^2(0, T; X)$ and $a(s) = \sum_1^{\infty} a_n(s)\phi_n$, where $a_n(s) = (a(s), \phi_n)_X$. Since $S(t)a(s) = \sum_1^{\infty} a_n(s)e^{-\lambda_n t}\phi_n$, we have

$$\begin{aligned} \int_0^T S(T-s)a(s) ds &= \int_0^T \sum_1^{\infty} a_n(s) e^{-\lambda_n(T-s)} \phi_n ds \\ &= \sum_1^{\infty} \int_0^T a_n(s) e^{-\lambda_n(T-s)} ds \phi_n = 0. \end{aligned}$$

Thus we have

$$\int_0^T a_n(s) e^{-\lambda_n(T-s)} ds = 0, \quad n = 1, 2, \dots$$

Therefore, we know that $a \in N$ if and only if

$$a \in L^2(0, T; X) \quad \text{and} \quad \int_0^T a_n(s) e^{\lambda_n s} ds = 0, \quad n = 1, 2, \dots$$

We show the following claim which corresponds to hypothesis (B1): let $h \in L^2(0, T; X)$ and $h = \sum_1^{\infty} h_n(s)\phi_n$, then there exists a function u in $L^2(0, T; V)$ and a function a in N such that $h = a + \tilde{B}u$, that is, $h_1 = a_1 + 2u_2$, and $h_n = a_n + u_n$, $n = 2, 3, \dots$.

In Hilbert space $L^2(0, T)$ we easily know that

$$L^2(0, T) = \{e^s\}^{\perp} + \{e^{4s}\}^{\perp}.$$

So, for $h_1, h_2 \in L^2(0, T)$, there exists functions $a_1 \in \{e^s\}^{\perp}$, $a_2 \in \{e^{4s}\}^{\perp}$ which satisfy $h_1 - 2h_2 = a_1 - 2a_2$. Put $u_2 = h_2 - a_2$, then we have $h_1 = a_1 + 2u_2$ and $h_2 = a_2 + u_2$. And also, put $u_n = h_n$, $a_n = 0$, $n = 3, 4, \dots$, then we know that hypothesis (B1) is satisfied.

It is easily known that the operator \tilde{B} from $L^2(0, T; V)$ to $L^2(0, T; X)$ is one to one and the range of \tilde{B} is closed. It follows that the operator \tilde{B} satisfies hypothesis (B2).

Example 2. We introduce a simple example of the control operator B which satisfies hypothesis (B1). Consider the case $X = V$ and define the intercept operator $B_{(\alpha, T)}$, $0 < \alpha < T$, on $L^2(0, T; X)$ by

$$(B_{(\alpha, T)}v)(t) = \begin{cases} 0, & 0 \leq t < \alpha, \\ v(t), & \alpha \leq t \leq T, \end{cases} \quad v \in L^2(0, T; X).$$

We will show that for a given function $p \in L^2(0, T; X)$, there exists a control $v \in L^2(0, T; X)$: $\tilde{S}p = \tilde{S}B_{(\alpha, T)}v$. By using the semigroup property and the change of variation we obtain the following:

$$\begin{aligned} \int_0^T S(T-s)p(s) ds &= \int_0^\alpha S(T-s)p(s) ds + \int_\alpha^T S(T-s)p(s) ds \\ &= \int_\alpha^T S(T-s)S\left(s - \frac{\alpha}{T-\alpha}(s-\alpha)\right) \frac{\alpha}{T-\alpha} p\left(\frac{\alpha}{T-\alpha}(s-\alpha)\right) ds \\ &\quad + \int_\alpha^T S(T-s)p(s) ds. \end{aligned}$$

Thus, we can find a required control function $v(t)$:

$$v(t) = \begin{cases} 0, & 0 \leq t < \alpha, \\ p(t) + \frac{\alpha}{T-\alpha} S\left(t - \frac{\alpha}{T-\alpha}(t-\alpha)\right) p\left(\frac{\alpha}{T-\alpha}(t-\alpha)\right), & \alpha \leq t \leq T. \end{cases}$$

Furthermore, by using the similar calculations, we can see that if $-A$ generates a group $S(t)$, the intercept operator $B_{(0, \alpha)}$ and the impulsive operator $B_{(\alpha, \alpha+\varepsilon)}$, $0 < \varepsilon \ll 1$ also satisfy (B1).

Acknowledgments. The author wishes to express his deep appreciation to Professor T. I. Seidman for his many helpful suggestions and to Professor W. Takahashi for many stimulating conversations.

STABILIZABILITY AND STABLE-PROPER FACTORIZATIONS FOR LINEAR TIME-VARYING SYSTEMS*

KAMESHWAR POOLLA[†] AND PRAMOD KHARGONEKAR[‡]

Abstract. The objective of this paper is to study in detail stabilizability and stable-proper factorizations for linear *time-varying* discrete-time systems. Our main results are:

(i) If a linear-time-varying system can be stabilized by *dynamic* state feedback, then it can also be stabilized by *memoryless* state feedback.

(ii) A complete characterization of the *existence* of stable-proper factorizations for linear time-varying input/output operators. This characterization is nontrivial; there exist input/output operators that *do not* admit stable-proper factorizations.

Key words. time-varying systems, transfer-functions, stabilizability, skew-rings

AMS(MOS) subject classifications. 93D15, 93C50

1. Introduction. The aim of this paper is to study in detail stabilizability and stable-proper factorizations for linear *time-varying* discrete-time systems.

Many frequency-domain based synthesis methods used to design controllers for linear time-invariant plants begin with left- and/or right-stable proper coprime factorizations of the plant transfer-function matrix (see, for example, Zames and Francis [1983]). Given the power and utility of these representations, it seems natural and desirable to develop corresponding results for *time-varying* systems. In order to realize this objective we need to incorporate time-variance in a natural way into a transform type description of the system behavior. Attempts have been made to develop such a theory (e.g., the system function of Zadeh [1950]), but until recently, there has been no theory that has met with much success.

In § 2 of this paper, we establish some notation, and we outline the basic elements of a transfer-function approach to linear time-varying systems based on skew (noncommutative) rings developed by Kamen, Khargonekar and Poolla [1985]. For more detailed exposition, the reader is referred to the dissertation of Poolla [1984].

Following this, in § 3, we briefly review some well-known concepts related to the stability of linear time-varying systems. Then, in § 4, we introduce the key notion of *asycontrollability* of a linear-time-varying system Σ which is equivalent to being able to stabilize Σ via *dynamic* state feedback. Anderson and Moore [1981] have defined a notion of stabilizability for linear-time-varying systems, which is equivalent to being able to stabilize Σ via *memoryless* state feedback. One of the deepest results of this paper (Theorem 4.4) is the equivalence of asycontrollability and stabilizability. This result in particular implies that *dynamics* in state feedback buy nothing extra as far as the problem of stabilization is concerned.

Finally, in § 5 we introduce stable-proper factorizations for linear-time-varying systems. In glaring contrast to time-invariant systems, *not* all time-varying input/output maps admit stable-proper factorizations (see Example 5.8). Hence we first characterize the existence of stable-proper factorizations (see Theorem 5.2). Following this one can

systematically employ the axiomatic theory of Desoer et al. [1980] to study feedback control problems, for instance by obtaining a complete parametrization of all controllers that internally stabilize a linear-time-varying plant. The results in this paper are a natural extension of our earlier work on a polynomial theory for linear-time-varying systems; the interested reader may consult Khargonekar and Poolla [1986].

2. The basic framework. With \mathbb{Z} = set of integers and \mathbb{R} = field of real numbers, let A denote \mathbb{R} -linear space of all functions from \mathbb{Z} into \mathbb{R} . With the operations of pointwise addition and pointwise multiplication, it is easy to see that A is a commutative ring with identity 1, where $1(k) = 1$ for all $k \in \mathbb{Z}$. Let σ denote the *right-shift operator* on A defined by

$$(\sigma\alpha)(k) = \alpha(k-1) \quad \text{all } k \in \mathbb{Z}.$$

Let A_+ denote the subring of A consisting of all functions with support bounded on the left; that is, for any $\alpha \in A_+$ there is an integer k_α (depending on α in general) such that $\alpha(k) = 0$ for all $k \leq k_\alpha$. Let $l^\infty(\mathbb{Z})$ denote the set of all bounded time-functions. Clearly, $l^\infty(\mathbb{Z})$ is a difference subring of A .

DEFINITION 2.1. Let m and p be positive integers. An m -input p -output linear time-varying causal input/output map f is an \mathbb{R} linear map

$$f: A_+^m \rightarrow A_+^p$$

such that $\{u(k) = 0, k \leq k_u\} \Rightarrow \{f(u)(k) = 0, k \leq k_u\}$.

It is well known that for any input/output map f as defined above, there exists a $p \times m$ matrix function $W_f(i, j)$ such that for any $u \in A_+^m$,

$$f(u)(i) = \sum_{j=-\infty}^i W_f(i, j)u(j).$$

The matrix function W_f is the *unit-pulse response function* associated with the input/output map f . Note that by causality, $W_f(i, j)$ is not defined for $i < j$.

Our next concept is the notion of a system.

DEFINITION 2.2. An m -input p -output n -dimensional linear time-varying system Σ over A is a quadruple $\Sigma = (F, G, H, J)$ of matrices over A where F is $n \times n$, G is $n \times m$, H is $p \times n$, and J is $p \times m$.

With a system $\Sigma = (F, G, H, J)$, we shall associate the dynamical equations

$$x(j+1) = F(j)x(j) + G(j)u(j),$$

$$y(j) = H(j)x(j) + J(j)u(j)$$

where $u(j)$, $x(j)$, $y(j)$ have the usual interpretations.

A system $\Sigma = (F, G, H, J)$ or the pair (F, G) over A is said to be *reachable in N steps* if for any $j \in \mathbb{Z}$ and any $x \in \mathbb{R}^n$ there exists an input sequence $u(j-N), u(n-N+1), \dots, u(j-1)$ which drives Σ from the zero state at time $j-N$ to the state x at time j . The dual notion of *observability in N steps* has the obvious system-theoretic interpretation.

Let \mathbb{R}_N denote the N -step reachability matrix

$$\mathbb{R}_N := [G|F(\sigma G)|\dots|F(\sigma F)\dots(\sigma^{N-2}F)(\sigma_{N-1}G)].$$

Weiss [1972] has shown that $\Sigma = (F, G, H, J)$ is reachable in N steps if and only if $\text{rank } \mathbb{R}_N(j) = n$, for all j in \mathbb{Z} . Dual criteria for observability also exist.

As is easy to see, the unit-pulse response function W_Σ associated with the system $\Sigma = (F, G, H, J)$ is given by

$$W_\Sigma(i, j) = \begin{cases} H(i)F(i-1)F(i-2) \cdots F(j+1)G(j), & i > j, \\ J(j), & i = j, \\ \text{not defined,} & i < j. \end{cases}$$

The input/output behavior of a system Σ is described by its input/output map f_Σ , where

$$f_\Sigma(u)(i) = \sum_{j=-\infty}^i W_\Sigma(i, j)u(j), \quad u \in A_+^m.$$

Given an input/output map $f: A_+^m \rightarrow A_+^p$, a *realization of f* is a system $\Sigma = (F, G, H, J)$ over A such that $f_\Sigma = f$. For results on realizability, we refer the reader to Weiss [1972].

The commutative rings of polynomials, power series and formal Laurent series all with coefficients in the reals \mathbb{R} , play a central role in the transfer-function theory of linear time-invariant systems. For *time-varying* systems the analogous objects are skew (noncommutative) rings with coefficients in the ring of time functions.

More precisely, with z equal to an indeterminate, let $A((z^{-1}))$ denote the set of all formal Laurent series of the form

$$\sum_{r=-N}^{\infty} z^{-r}\alpha_r, \quad \alpha_r \text{ in } A.$$

With the usual addition and multiplication defined by

$$z^r z^t = z^{r+t}, \quad \alpha z = z(\sigma\alpha), \quad \alpha \text{ in } A,$$

where $(\sigma\alpha)(k) = \alpha(k-1)$, $A((z^{-1}))$ is a noncommutative ring with identity, called the *skew ring of formal Laurent series* over A . There are two important subrings of $A((z^{-1}))$: The skew ring of polynomials $A[z]$ and the skew ring of formal power series $A[[z^{-1}]]$. These have the obvious definitions.

We now describe our transfer function approach to linear time-varying systems. All proofs are omitted; they can be found in Kamen, Khargonekar and Poolla [1985].

Again, let A_+ denote the subring of A consisting of all functions $\alpha: \mathbb{Z} \rightarrow \mathbb{R}$ with support bounded on the left. Let Δ denote the unit-impulse at the origin, i.e., $\Delta(k) = 1$ if $k = 0$, and $\Delta(k) = 0$ otherwise. Given any b in A_+ , the (generalized) *z-transform* of b written $B(z)$ is defined to be the skew Laurent series

$$B(z) = \sum_r z^{-r}b(r)\Delta.$$

Let f be an input/output map, and let W_f denote the unit-pulse response function associated with f . For each integer $r \geq 0$, define a $p \times m$ matrix W_r over A by

$$W_r(j) = W_f(r+j, j), \quad j \text{ in } \mathbb{Z}.$$

DEFINITION 2.3. The (formal) transfer-function matrix $\hat{W}_f(z)$ associated with the input/output map f is the $p \times m$ matrix over $A[[z^{-1}]]$ defined by

$$\hat{W}_f(z) = \sum_{r=0}^{\infty} z^{-r}W_r.$$

We would like to point out that $\hat{W}_f(z)$ is the same as the frequency-response function of Arveson [1975]. The input/output difference equation $y = f(u)$ can now be characterized in terms of the transfer-function matrix $\hat{W}_f(z)$ as follows.

PROPOSITION 2.4. *Let f be an input/output map. Let y be the output resulting from the input u in A_+^m . Let $Y(z)$ and $U(z)$ denote the (generalized) z -transforms of y and u . Then,*

$$(2.5) \quad Y(z) = \hat{W}_f(z)U(z).$$

Note the close resemblance of (2.5) to the time-invariant transfer function theory. This analogy to the time-invariant theory is further illustrated by the following proposition.

PROPOSITION 2.6. *Let $\Sigma = (F, G, H, J)$ be a linear time-varying system with input/output map f_Σ . Then the transfer-function matrix \hat{W}_Σ associated with f_Σ is given by*

$$(2.7) \quad \hat{W}_\Sigma(z) = H(zI - F)^{-1}G + J.$$

Despite the close resemblance these two results bear to the time-invariant theory, it must be emphasized that (2.5) and (2.7) are computed via the skew (noncommutative) multiplication defined earlier.

3. Stability. In this section we briefly review some well-known concepts dealing with the stability of linear time-varying systems, and we relate these concepts to the transfer-function theory based on skew-rings described in § 2. There is extensive literature available on the stability of linear time-varying systems (see, for example, Anderson and Moore [1981], Willems [1970], Cesari [1963], Freedman and Zames [1968], etc.).

For any vector x in \mathbb{R}^n let $\|x\|$ denote the Euclidean norm of x . For an $m \times m$ matrix M over \mathbb{R} , let $\|M\| := \sup_{x \neq 0} \|Mx\|/\|x\|$. For an $m \times m$ matrix N over A , define the norm of N to be $\|N\| := \sup_t \|N(t)\|$.

Let $f: A_+^m \rightarrow A_+^p$ be an input/output map. We shall say that f is *bounded input-bounded output (BIBO) stable* if for any bounded input sequence, i.e., for any u in $l^\infty(\mathbb{Z})_+$, the corresponding output sequence $y = f(u)$ is bounded. Let $\Sigma = (F, G, H, J)$ be any (fixed) realization of f . Consider the free behavior of the system Σ described by the vector difference equation

$$(3.1) \quad x(k+1) = F(k)x(k).$$

The system Σ is said to be *internally uniformly asymptotically stable*, henceforth *stable*, if for every number $\varepsilon > 0$, there exists a positive integer N_ε such that for any initial time t_0 in \mathbb{Z} and any initial state $x(t_0)$ with $\|x(t_0)\| \leq 1$, we have that $\|x(t_0+i)\| \leq \varepsilon$ for all $i \geq N_\varepsilon$. Here, $x(t_0+i)$ is the solution of (3.1) at time t_0+i starting from initial state $x(t_0)$.

Let $P(z)$ be an $n \times m$ matrix over the skew ring $A((z^{-1}))$, i.e., $P(z)$ is of the form

$$P(z) = \sum_{i=-N}^{\infty} z^{-i}P_i, \quad P_i \in A^{n \times m}.$$

DEFINITION 3.2. The matrix Laurent series $P(z)$ is said to be *stable* if $\lim_{i \rightarrow \infty} \|P_i\| \rightarrow 0$.

In terms of this notion, we can characterize internal stability as follows (see Green and Kamen [1984] and Kamen, Khargonekar and Poolla [1985, Prop. (4.4)]).

PROPOSITION 3.3. *Let $\Sigma = (F, G, H)$ be a linear time-varying system over A . Then, Σ is internally u.a.s. if and only if $(zI - F)^{-1}$ is a stable matrix power series.*

Note the similarity this result bears to the time-invariant theory. Let f be an input/output map, and let $\Sigma = (F, G, H, J)$ over A be any (fixed) realization of f . In contrast with the time-invariant case, internal stability of Σ does *not* in general imply

BIBO stability of f . However, for the class of *bounded* linear time-varying systems, we have the following result (the proof is omitted on account of its relative ease).

PROPOSITION 3.4. *Let f be an input/output map and let $\Sigma = (F, G, H, J)$ over $l^\infty(\mathbb{Z})$ be any (fixed) realization of f . Suppose Σ is internally u.a.s. Then f is BIBO stable.*

In subsequent sections, we shall deal only with linear time-varying systems with *bounded* coefficients, i.e., defined over the difference subring $l^\infty(\mathbb{Z}) \subset A$. We shall also require that any controller we design be over $l^\infty(\mathbb{Z})$. These are physically reasonable constraints since most time-varying plants that arise in practice have bounded time variation, and implementation of controllers with unbounded coefficients would be numerically ill-conditioned. (Technically, these constraints substantially complicate proofs and make results harder to obtain.)

4. Stabilizability and asycontrollability. In this section, we introduce the key notion of *asycontrollability*, which is closely related to being able to stabilize a linear time-varying system by *dynamic* state feedback. Anderson and Moore [1981] have defined the notion of *stabilizability*, which is equivalent to being able to stabilize a linear time-varying system by *nondynamic* (i.e., memoryless) state feedback. The central result in this paper, Theorem 4.4, shows the equivalence of stabilizability and asycontrollability. A striking conclusion of this theorem is that *dynamics* in state feedback buy nothing extra as far as the problem of stabilization is concerned.

We begin with the following key definition.

DEFINITION 4.1. A system $\Sigma = (F, G, H)$ over $l^\infty(\mathbb{Z})$ is said to be asycontrollable if for every $\varepsilon > 0$ there exists a real number \hat{M} and an integer N such that for any initial time t_0 in \mathbb{Z} and any initial state ξ in \mathbb{R}^n with $\|\xi\| = 1$, there exists an input sequence $u(t_0), u(t_0+1), \dots, u(t_0+N-1)$ which results in the state trajectory $\xi = x(t_0), x(t_0+1), \dots, x(t_0+N)$ and such that

$$\|x(t_0+N)\| < \varepsilon, \quad \|x(t_0+k)\|, \|u(t_0+k)\| < \hat{M} \quad \text{for all } k.$$

This technical definition has a precise system-theoretic interpretation in terms of stabilizing Σ via an open-loop control law. Roughly speaking, a system is asycontrollable if and only if it can be driven near zero “final” state asymptotically, using *uniformly* bounded input sequences along *uniformly* bounded state trajectories. The phrase asycontrollability (from *asymptotically controllable*) is borrowed from Khargonekar and Sontag [1982] for time-invariant systems over rings.

Remark 4.2. It can be shown (see Khargonekar and Poolla [1986]) that asycontrollability is equivalent to the existence of *stable* Laurent series Y_1 and Y_2 over $l^\infty(\mathbb{Z})((z^{-1}))$ such that $(zI - F)Y_1 + GY_2 = I$. In particular, this means that if Σ can be stabilized using a *dynamic* state-feedback controller, then Σ is asycontrollable.

Let $\Sigma = (F, G, H)$ be a linear time-varying system over $l^\infty(\mathbb{Z})$. Anderson and Moore [1981] have defined a notion of *stabilizability* which intuitively corresponds to requiring that unstable modes be controllable. The authors then show that this notion is equivalent to the existence of a stabilizing *memoryless* state feedback law $u(k) = -L(k)x(k)$. We shall take this to be the definition of stabilizability. In terms of our skew-ring framework, we phrase this as follows.

DEFINITION 4.3. Let $\Sigma = (F, G, H)$ over $l^\infty(\mathbb{Z})$ be a linear time-varying system. Then Σ is said to be stabilizable if there exists an $m \times n$ matrix L over $l^\infty(\mathbb{Z})$ such that $(zI - F + GL)^{-1}$ is a stable matrix power series.

One can similarly define the dual notion of *detectability*.

Let $\Sigma = (F, G, H)$ over $l^\infty(\mathbb{Z})$ be a stabilizable linear time-varying system. Let L be an $m \times n$ feedback matrix as in Definition 4.3. Notice that we can write

$$(zI - F)Y_1 + GY_2 = I,$$

where $Y_1 = (zI - F + GL)^{-1}$ and $Y_2 = LY_1$. Since Y_1 and Y_2 are *stable* Laurent series, it follows from Remark 4.2 that Σ is asycontrollable. Thus, stabilizability *implies* asycontrollability. The much more difficult converse is also true.

THEOREM 4.4. *Let $\Sigma = (F, G, H, J)$ be a linear time-varying system over $l^\infty(\mathbb{Z})$. Then, Σ is asycontrollable if and only if Σ is stabilizable.*

Proof. See Appendix A. We would like to remark that the essential technical difficulty in the proof is ensuring that the feedback matrix L is over $l^\infty(\mathbb{Z})$. \square

Recall (see Remark 4.2) that if a linear time-varying system Σ can be stabilized by a dynamic state-feedback controller, then Σ is asycontrollable. This observation of stabilizability, together with Definition 4.3, immediately offers the following surprising conclusion.

COROLLARY 4.5. *If a linear time-varying system Σ over $l^\infty(\mathbb{Z})$ can be stabilized using dynamic state-feedback, then Σ can also be stabilized using memoryless state-feedback.*

Remark 4.6. Indeed the above corollary is not (necessarily) *expected*, because there are classes of systems (for example, delay systems (see Kamen [1982, Ex. 3, p. 371])) for which it is *not* true. For time-invariant systems over a field, it is a well-known fact that dynamic state feedback is equivalent to memoryless state feedback as far as the problem of stabilization is concerned. The proof of this fact relies heavily on the Kalman canonical decomposition. No such decomposition exists for time-varying systems because the “dimension” of the reachable space could depend on time.

Since stabilizability and asycontrollability are equivalent notions, we shall henceforth only speak of stabilizability.

It is important to find “nice” necessary and sufficient tests for stabilizability. This problem appears to be quite formidable unless one specializes to particular classes (e.g., periodic) of time-varying systems. We do have, however, the following sufficient condition.

THEOREM 4.7. *Let $\Sigma = (F, G, H, J)$ over $l^\infty(\mathbb{Z})$ be a linear time-varying system. Suppose there exist integers N and K and a real number $\varepsilon > 0$ with the following property: For any integer t_0 , there exists some t_1 with $t_0 \leq t_1 \leq t_0 + K$ such that*

$$(4.8) \quad \det [R_N R'_N](t_1) \geq \varepsilon > 0$$

where R_N is the N step reachability matrix. Then, Σ is stabilizable.

Proof. Essentially condition (4.8) corresponds to the system being $l^\infty(\mathbb{Z})$ -reachable in N steps but *not* at all times.

Given any initial state ξ in \mathbb{R}^n and any initial time t_0 , we construct an open-loop stabilizing control law as follows: we apply zero control (i.e. $u(t) = 0$) for the time $t_0 \leq t < t_1$. Then, we drive the system to zero state in N steps. This can be done because from (4.8) Σ is reachable at time t_1 . Moreover, the input sequences applied are uniformly (in t_1) bounded in norm. Having brought the system to zero state we apply no further inputs. We can thus stabilize Σ by an open-loop control law. This implies that Σ is asycontrollable, which by Theorem 4.4 implies that Σ is stabilizable. \square

5. Stable-proper factorizations. Of late, the use of stable-proper factorizations for control system design has become increasingly popular. See, for example, Vidyasagar [1978], Desoer et al. [1980], Feintuch and Francis [1984], Khargonekar and Sontag [1982], etc. In this section we investigate in detail stable-proper factorizations for time-varying systems.

Define the set RP (for Rational and Proper) to be

$$RP := \{\phi \text{ in } l^\infty(\mathbb{Z})[[z^{-1}]]: \text{there exist } \alpha, \beta, \gamma, \delta \text{ such that } \phi = \alpha(zI - \beta)^{-1}\gamma + \delta\},$$

where α, β, γ , and δ are matrices of compatible dimensions over $l^\infty(\mathbb{Z})$. It is easy to

verify that RP forms a ring with the usual skew-multiplication and addition defined in $l^\infty(\mathbb{Z})[[z^{-1}]]$. Also, define the subring RP_s by

$$RP_s := \{\phi = \alpha(zI - \beta)^{-1}\gamma + \delta \text{ in } RP: (zI - \beta)^{-1} \text{ is stable}\}.$$

We shall call RP_s the *ring of stable, proper, rational functions* (the subscript s denotes stable). We shall abandon rigorous nomenclature and loosely refer to elements in RP_s or matrices over RP_s as being *stable-proper*.

Let $D(z)$ be an $n \times n$ matrix over RP . We shall say that $D(z)$ is *bicausal* if D has an inverse $D^{-1}(z)$ also over RP . Let f be an input/output map and let $\hat{W}_f(z)$ be its associated transfer-function matrix. Then, $\hat{W}_f(z)$ is said to admit a *right-Bezout stable-proper factorization* if there exist stable-proper matrices (i.e., over RP_s) N , D , X , and Y with D bicausal and such that

$$(5.1) \quad \hat{W}_f(z) = ND^{-1}, \quad XN + YD = I.$$

One can also similarly define *left-Bezout stable-proper factorization*. Such factorizations have been found to be extremely useful in tackling many control-theoretic problems (for example, H^∞ -optimal controller design, see Zames and Francis [1983], Francis and Zames [1984], Francis, Helton and Zames [1984]). We first characterize input/output maps whose transfer functions admit left- and/or right-Bezout stable-proper factorizations. We have the following central result.

THEOREM 5.2. *Let f be an input/output map and let $W_f(z)$ be its $p \times m$ associated transfer function matrix over $l^\infty(\mathbb{Z})[[z^{-1}]]$. Then, the following are equivalent:*

- (a) $\hat{W}_f(z)$ admits a right-Bezout stable-proper factorization;
- (b) $\hat{W}_f(z)$ admits a left-Bezout stable-proper factorization;
- (c) f admits a stabilizable and detectable realization.

Proof. (c) \rightarrow (a). Let $\Sigma = (F, G, H, J)$ be a stabilizable and detectable realization of f . Consequently, by definition, there exist matrices L and K over $l^\infty(\mathbb{Z})$ that $(zI - F + GL)^{-1}$ and $(zI - F + KH)^{-1}$ are stable matrix power series. Define the stable-proper (i.e., over RP_s) matrices N , D , X , and Y by

$$(5.3) \quad \begin{aligned} N &= (H - JL)(zI - F + GL)^{-1}G + J, & D &= I - L(zI - F + GL)^{-1}G, \\ X &= L(zI - F + KH)^{-1}K, & Y &= I + L(zI - F + KH)^{-1}(G - KJ). \end{aligned}$$

Clearly D is bicausal, and it can be mechanically verified that with these definitions

$$\hat{W}_f(z) := H(zI - F)^{-1}G + J = ND^{-1}, \quad XN + YD = I.$$

Thus, $\hat{W}_f(z)$ admits a right-Bezout stable-proper factorization. We would like to point out that formulae (5.3) have been available in the system theory literature for a number of years (see Khargonekar and Sontag [1982, pp. 635–636]; Nett, Jacobsen and Balas [1984]; and Vidyasagar [1985]). The difficulty, however, is in showing the *existence* of stabilizable and detectable realizations (i.e., (a) \rightarrow (c)) as this critically involves Theorem 4.4. We proceed to do this.

(a) \rightarrow (c). Now suppose that $\hat{W}_f(z)$ admits a right-Bezout stable-proper factorization, i.e., there exist stable-proper matrices N , D , X , and Y with D bicausal and such that $\hat{W}_f(z) = ND^{-1}$, $XN + YD = I$. From the definitions of a stable-proper function (i.e., the ring RP_s), it follows that we can write

$$N = N_1(zI - N_2)^{-1}N_3 + N_4, \quad D = D_1(zI - D_2)^{-1}D_3 + D_4$$

where $N_1, \dots, N_4, D_1, \dots, D_4$ are matrices of appropriate sizes over $l^\infty(\mathbb{Z})$, with $(zI - N_2)^{-1}$ and $(zI - D_2)^{-1}$ being *stable* matrix power series. Since D is bicausal,

without loss of generality, $D_4 = I$. Define the linear time-varying system (over $l^\infty(\mathbb{Z})$) $\Sigma = (F, G, H, J)$ by

$$(5.4) \quad \begin{aligned} F &= \begin{bmatrix} N_2 & -N_3 D_1 \\ 0 & D_2 - D_3 D_1 \end{bmatrix}, & G &= \begin{bmatrix} N_3 \\ D_3 \end{bmatrix}, \\ H &= [N_1 \quad -N_4 D_1], & J &= N_4. \end{aligned}$$

The system Σ is stabilizable because with $L = [0 \quad -D_1]$ (which is over $l^\infty(\mathbb{Z})$),

$$(zI - F + GL)^{-1} = \begin{bmatrix} (zI - N_2)^{-1} & 0 \\ 0 & (zI - D_2)^{-1} \end{bmatrix},$$

which is *stable*. We now show that Σ , defined by (5.4), is detectable.

Define the stable-proper matrix Q by

$$Q = \begin{bmatrix} (zI - N_2)^{-1} N_3 \\ (zI - D_2)^{-1} D_3 \end{bmatrix}.$$

It is easy to verify that $(zI - F)Q - GD = 0$ and $HQ + JD = N$. Combining these equations with $XN + YD = 1$, we can write

$$(5.5) \quad \begin{bmatrix} zI - F & G \\ XH & -(Y + XJ) \end{bmatrix} \begin{bmatrix} (zI - F + GL)^{-1} & Q \\ L(zI - F + GL)^{-1} & -D \end{bmatrix} = \phi\psi = \begin{bmatrix} I & O \\ V & I \end{bmatrix}$$

where V is some stable-proper matrix whose exact formula is not critical to our needs. It is clear from (5.5) that ϕ is *right-invertible* with ϕ_R^{-1} (the subscript R denotes right) a *stable-proper matrix*. We now show that ϕ is also left-invertible (and thus its inverse $\phi_R^{-1} = \phi_L^{-1} = \phi^{-1}$ is unique). Notice that

$$(5.6) \quad \phi = \begin{bmatrix} zI - F & O \\ O & I \end{bmatrix} \begin{bmatrix} I & (zI - F)^{-1} G \\ XH & -(Y + XJ) \end{bmatrix} := \phi_1 \phi_2.$$

The matrix ϕ_1 is clearly both left- and right-invertible. Also, $(Y + XJ)$ must be of the form $(Y + XJ) = I + \text{terms in } z^{-1}, z^{-2}, \dots$ since $XN + YD = 1$. Thus, the leading (z^0) coefficient ϕ_2 is invertible (over $l^\infty(\mathbb{Z})$). Consequently, ϕ_2 is both left- and right-invertible. Thus, from (5.6), ϕ must be both left- and right-invertible, proving our claim. Recalling that ϕ^{-1} is a stable-proper matrix, we can write

$$\phi^{-1}\phi = \begin{bmatrix} W_1 & W_2 \\ * & * \end{bmatrix} \begin{bmatrix} (zI - F) & G \\ XH & -(Y + XJ) \end{bmatrix}.$$

One component of the above equality is

$$W_1(zI - F) + (W_2 X)H = I.$$

Thus the dual of the pair (F, H) is asycontrollable, which by Theorem 4.4 implies that Σ is detectable. This completes the proof of (a) \rightarrow (c).

(b) \rightarrow (c) and (c) \rightarrow (b) follow from a dual argument. \square

Remark 5.7. In proving the above result, we have made critical use of Theorem 4.4, the fundamental result of the previous section. Recall that Theorem 4.4 states that asycontrollability is equivalent to stabilizability. There appears to be no way to circumvent Theorem 4.4 in studying the existence of stable-proper factorizations. We would further like to remark that (5.3) enables one to compute stable-proper factorizations once the stabilizing feedback matrices L and K are determined.

Theorem 5.2 essentially states that a time-varying system admits stable-proper factorizations if and only if it admits a stabilizable and detectable realization. This characterization is nontrivial because (in glaring contrast with time-invariant systems), *not all time-varying systems admit stabilizable realizations* (and therefore by Theorem 5.2, stable-proper factorizations). We illustrate this with the following example.

Example 5.8. Consider the linear time-varying system $\Sigma = (F, G, H)$ over $l^\infty(\mathbb{Z})$, where $F(k) = H(k) = 1$ for all k in \mathbb{Z} and $G = \Delta$ = the unit pulse concentrated at the origin. Let f_Σ be the input/output map associated with Σ . Suppose f_Σ admits a stabilizable realization $\bar{\Sigma} = (\bar{F}, \bar{G}, \bar{H})$. This would imply that for any initial state ξ at time $t = 1$, there exists an open loop control law that drives $\bar{\Sigma}$ from $\bar{x}(1) = \xi$ to zero final state (and therefore zero final output) asymptotically. However, from the unit-pulse response function of f_Σ , it is evident that application of inputs after $t = 1$ has no effect on the output. Thus, it must be that

$$(5.9) \quad \lim_{k \rightarrow \infty} \|\bar{H}(k)\bar{F}(k-1)\bar{F}(k-1) \cdots \bar{F}(1)\| = 0.$$

However,

$$W_\Sigma(z) := H(zI - F)^{-1}G = z^{-1}\Delta + z^{-2}\Delta + \cdots = \bar{H}(zI - \bar{F})^{-2}\bar{G}.$$

Consequently, for all integers $k \geq 1$

$$\bar{H}(k)\bar{F}(k-1) \cdots \bar{F}(1)\bar{G}(0) = 1.$$

This, together with the fact that \bar{G} is over $l^\infty(\mathbb{Z})$, renders (5.9) impossible. Therefore, f_Σ does *not* admit a stabilizable realization which implies (by Theorem 5.2) that $\hat{W}_{f_\Sigma}(z)$ does not admit a stable-proper factorization.

Armed with the powerful tool of stable-proper factorizations, we can systematically apply the axiomatic theory of Desoer et al. [1980] to study feedback control problems for linear time-varying plants. For instance we can readily obtain a complete parameterization of all stabilizing controllers as follows.

THEOREM 5.10. *Let $\Sigma = (F, G, H, J)$ be a stabilizable and detectable plant. Let*

$$\hat{W}_\Sigma(z) = ND^{-1} = D_1^{-1}N_1,$$

$$XN + YD = I = N_1X_1 + D_1Y_1$$

be any left- and right-stable-proper factorizations of W_Σ . Then, a controller Σ_c internally stabilizes Σ if and only if the controller transfer-function $\hat{W}_{\Sigma_c}(z)$ is of the form

$$(5.11) \quad \hat{W}_{\Sigma_c}(z) = (MN_1 + Y)^{-1}(-MD_1 + X)$$

for some matrix M over RP_s .

Appendix A: Proof of Theorem 4.4. We shall require several intermediate results before we are in a position to prove Theorem 4.4. We proceed to derive these:

Let $X = \{x_1, x_2, \dots, x_k\}$ be an ordered set of vectors in \mathbb{R}^n . Define $r(X) = r$ = the number of linearly independent vectors in X . The set X will be called *well ordered* if and only if the following conditions are satisfied:

- (a) $\{x_1, x_2, \dots, x_r\}$ are linearly independent;
- (b) For $i = r+1, \dots, k$, we can write

$$x_i = \sum_{j=1}^r \alpha_{i,j}x_j \quad \text{with } |\alpha_{i,j}| \leq 1;$$

- (c) On applying the Gram-Schmidt orthogonalization procedure to $\{x_1, x_2, \dots, x_r\}$ as

$$\begin{aligned}
x_1 &= b_1, \\
x_2 &= \alpha_{2,1}b_1 + b_2, \\
&\vdots \\
x_r &= \alpha_{r,1}b_1 + \alpha_{r,2}b_2 + \cdots + \alpha_{r,r-1}b_{r-1} + b_r
\end{aligned}$$

with $\{b_1, b_2, \dots, b_r\}$ orthogonal, we have

$$|\alpha_{i,j}| \leq 1, \quad \|b_1\| \geq \|b_2\| \geq \cdots \geq \|b_r\|.$$

We first have the following result (see Poolla [1984, Appendix C]):

PROPOSITION A.1. *Every ordered set $X = \{x_1, x_2, \dots, x_k\}$ of vectors in \mathbb{R}^n has a well-ordered rearrangement*

$$\hat{X} = \{\hat{x}_1, \hat{x}_2, \dots, \hat{x}_k\}.$$

We shall adopt the following notation through the remainder of this appendix: Let F and G be $n \times n$ and $n \times m$ matrices over $l^\infty(\mathbb{Z})$, with

$$\sup_t \|F(t)\|, \quad \sup_t \|G(t)\| < M.$$

If for some t in \mathbb{Z} an $m \times n$ matrix $L(t)$ is defined, then,

$$\tilde{F}(t) := F(t) + G(t)L(t).$$

Also define, for $t_1 > t_0$, the state-transition matrix

$$\phi(t_1, t_0) := F(t_1 - 1) \cdots F(t_0 + 1)F(t_0).$$

Let $N > 0$ be a (fixed) integer and let $\varepsilon > 0$ be a (fixed) real number. For a well-ordered set X , define

$$\lambda(X) := i \quad \text{such that} \quad \|b_i\| \geq \frac{\varepsilon}{M^N} > \|b_{i+1}\|.$$

Clearly, $\lambda \leq r \leq k$. We are now in a position to prove the key.

PROPOSITION A.2. *Let t be a (fixed) integer $0 \leq t \leq N$. Let $X_t = \{x_1(t), x_2(t), \dots, x_k(t)\}$ be a set of vectors in \mathbb{R}^n . Suppose that there exist $u_i(t)$, $i = 1, 2, \dots, k$ such that*

$$(A.3) \quad \|u_i(t)\| < \hat{M}, \quad \|\phi(N, t+1)x_i(t+1)\| < \varepsilon$$

where $x_i(t+1) := F(t)x_i(t) + G(t)u_i(t)$. Then there exists an $m \times n$ matrix $L(t)$ with

$$(A.4) \quad \|L(t)\| < \frac{n^2 \hat{M} M^N}{\varepsilon}$$

and such that

$$(A.5) \quad \|\phi(N, t+1)\tilde{F}(t)x_i(t)\| < \begin{cases} \varepsilon & \text{if } \lambda(X_t) = k, \\ \varepsilon n^4 & \text{otherwise.} \end{cases}$$

Proof. Without loss of generality, assume that X_t is well ordered. Let $b_i, \alpha_{i,j}$ be as in the definition of well-ordered sets. Let $\lambda = \lambda(X_t)$. Extend $\{x_1(t), x_2(t), \dots, x_\lambda(t), b_{\lambda+1}(t), \dots, b_k(t)\}$ orthogonally by $\{b_{k+1}(t), \dots, b_n(t)\}$ to form a basis for \mathbb{R}^n . Define $L(t)$ by

$$(A.6) \quad \begin{aligned} L(t): x_i(t) &\rightarrow u_i(t), & i &= 1, 2, \dots, \lambda, \\ L(t): b_i(t) &\rightarrow 0, & i &= \lambda + 1, \lambda + 2, \dots, n. \end{aligned}$$

We first prove (A.4). Notice that

$$(A.7) \quad \left\| \sum_{i=1}^{\lambda} \beta_i b(t) \right\|^2 = \sum_{i=1}^{\lambda} \beta_i^2 \|b_i(t)\|^2 \leq \frac{\varepsilon^2}{M^{2N}} \sum_{i=1}^{\lambda} \beta_i^2.$$

We now show inductively that for $i = 1, 2, \dots, \lambda$

$$(A.8) \quad \|L(t)b_i(t)\| < 2^{i-1}\hat{M} \leq 2^n\hat{M}.$$

For $i = 1$,

$$\|L(t)b_1(t)\| = \|L(t)x_1(t)\| = \|u_1(t)\| < \hat{M},$$

and the assertion is clearly true. Assume that the assertion holds for $i = 1, 2, \dots, s$. We then have

$$\begin{aligned} \|L(t)b_{s+1}(t)\| &\leq \|L(t)x_{s+1}(t)\| + \sum_{j=1}^s |\alpha_{s+1,j}| \cdot \|L(t)b_j(t)\| \\ &\leq \|u_{s+1}(t)\| + \sum_{j=1}^s |\alpha_{s+1,j}| 2^{j-1} \hat{M}. \end{aligned}$$

But $|\alpha_{s+1,j}| \leq 1$ and $\|u_{s+1}(t)\| \leq \hat{M}$ by (A.3). The above equation then becomes

$$\|L(t)b_{s+1}(t)\| \leq \hat{M} \left(1 + \sum_{j=1}^s 2^{j-1} \right) \leq \hat{M} 2^s,$$

completing the induction.

Combining (A.7) and (A.8) we see that

$$\begin{aligned} \|L(t)\|^2 &= \sup_{\beta_1 \cdots \beta_\lambda} \frac{\left\| \sum_{i=1}^{\lambda} \beta_i L(t)b_i(t) \right\|^2}{\left\| \sum_{i=1}^{\lambda} \beta_i b_i(t) \right\|^2} \leq \sup_{\beta_1 \cdots \beta_\lambda} \frac{(\sum_{i=1}^{\lambda} |\beta_i| 2^n \hat{M})^2}{\sum_{i=1}^{\lambda} \beta_i^2} \cdot \frac{M^{2N}}{\varepsilon^2} \\ &\leq \sup_{\beta_1 \cdots \beta_\lambda} \left(\frac{2^n \hat{M} M^N}{\varepsilon} \right)^2 \frac{(\sum_{i=1}^{\lambda} |\beta_i|)^2}{\sum_{i=1}^{\lambda} \beta_i^2} \leq \left(\frac{n 2^n \hat{M} M^N}{\varepsilon^2} \right), \end{aligned}$$

proving (A.4).

We now prove (A.5). Notice first that for $i = 1, 2, \dots, \lambda$

$$\tilde{F}(t)x_i(t) = F(t)x_i(t) + G(t)L(t)x_i(t) = x_i(t+1).$$

Therefore, from (A.3),

$$(A.9) \quad \|\phi(N, t+1)\tilde{F}(t)x_i(t)\| < \varepsilon \quad \text{for } i = 1, 2, \dots, \lambda.$$

Also, for $i = \lambda + 1, \dots, r$ from (A.7),

$$x_i(t) = \alpha_{i,1}b_1(t) + \alpha_{i,2}b_2(t) + \dots + \alpha_{i,\lambda}b_\lambda(t) + c(t)$$

where $\|c(t)\| < \varepsilon/M^N$. Using (c), we can rewrite the above equation as

$$x_i(t) = \gamma_{i,1}x_1(t) + \gamma_{i,2}x_2(t) + \dots + \gamma_{i,\lambda}x_\lambda(t) + c(t),$$

where $|\gamma_{i,j}| < n$. Consequently, for $i = \lambda + 1, \dots, r$,

$$(A.10) \quad \|\phi(N, t+1)\tilde{F}(t)x_i(t)\| < \lambda n \varepsilon + \varepsilon = (\lambda n + 1)\varepsilon.$$

For $i = r+1, r+2, \dots, k$, it follows from the definition of well-ordered sets that we can write

$$x_i(t) = \sum_{j=1}^r \alpha_{i,j} n_j(t), \quad |\alpha_{i,j}| \leq 1.$$

Therefore, for $i = r+1, \dots, k$,

$$(A.11) \quad \|\phi(N, t+1) \tilde{F}(t) x_i(t)\| < \lambda \varepsilon + (r - \lambda)(\lambda n + 1) \varepsilon < n^4 \varepsilon.$$

Summarizing (A.9)–(A.11), we see that for $i = 1, 2, \dots, k$,

$$\|\phi(N, t+1) \tilde{F}(t) n_i(t)\| < \begin{cases} \varepsilon & \text{if } \lambda = k, \\ n^4 \varepsilon & \text{otherwise.} \end{cases}$$

PROPOSITION A.12. *Suppose that there exist $u_i(t)$, $i = 1, 2, \dots, n$, $t = 0, 1, \dots, N-1$ with*

$$\|u_i(t)\| < \hat{M}$$

and such that

$$\|x_i(N)\| < \varepsilon$$

where $x_i(N)$ is defined recursively by $x_i(0) = e_i$ (the i th unit vector in \mathbb{R}^n), $x_i(t+1) = F(t)x_i(t) + G(t)u_i(t)$. Then, there exist $m \times n$ matrices $L(t)$, $t = 0, 1, \dots, N-1$ and a real number Δ with

$$\|L(t)\| < \Delta$$

and such that

$$\|\tilde{F}(N-1)\tilde{F}(N-2) \cdots \tilde{F}(1)\tilde{F}(0)\| < \varepsilon n^6.$$

Proof. We first set up some notation. For a set of vectors $X = \{x_1, x_2, \dots, x_k\}$ in \mathbb{R}^n , let $\hat{X} = \{\hat{x}_1, \hat{x}_2, \dots, \hat{x}_k\}$ be any well-ordered rearrangement of X . Recall that

$$\lambda = \lambda(X) := i \quad \text{such that } \|\hat{b}_i\| \geq \frac{\varepsilon}{M^N} > \|\hat{b}_{i+1}\|,$$

and that $k = k(X)$ = the number of vectors in X . Define a set of integers

$$I_X := \{j: x_j \in \{\hat{x}_1, \hat{x}_2, \dots, \hat{x}_\lambda\}\}.$$

For $t = 0, 1, 2, \dots, N-1$ define X_t and λ_t recursively by

$$\begin{aligned} \lambda_0 &= n, & X_0 &= \{x_1(0), x_2(0), \dots, x_2(0)\}, \\ X_{t+1} &= \{x_i(t+1): i \in I_{X_t}\}, & \lambda_{t+1} &= \lambda(X_{t+1}). \end{aligned}$$

From the above definition it is clear that

$$(A.13) \quad n = \lambda_0 = k_1 \geq \lambda_1 = k_2 \geq \lambda_2 \cdots \lambda_t = k_{t+1} \geq \lambda_{t+1} \cdots \geq \lambda_{N-1} \geq 0.$$

Define f_t , $t = 0, 1, \dots, N-1$ by

$$f_t := \begin{cases} 1 & \text{if } \lambda_t = k_t, \\ n^4 & \text{otherwise.} \end{cases}$$

It is clear from (A.13) that (and this is the *key step*)

$$(A.14) \quad f_{N-1} f_{N-2} \cdots f_0 \leq n^5.$$

We now apply Proposition A.2 to X_{N-1} to conclude that there exists an $m \times n$ matrix $L(N-1)$ with $\|(N-1)\| \leq CM^N$ where $C = n2^n(\hat{M}/\varepsilon)$ and such that

$$\|\tilde{F}(N-1)x_i(N-1)\| < \varepsilon f_{N-1}, \quad x_i(N-1) \in X_{N-1}.$$

Notice that

$$\|\tilde{F}(N-1)\| \leq \|F(N-1)\| + \|G(N-1)L(N-1)\| < M + M(CM^N) \leq CM^{N+2}.$$

We can again apply Proposition A.2 to X_{N-2} (with M being replaced by CM^{N+2} and ε being replaced by εf_{N-1}) to conclude that there exists an $m \times n$ matrix $L(N-2)$ with

$$\|L(N-2)\| < (CM)^{N^2}$$

and such that

$$\|\tilde{F}(N-1)\tilde{F}(N-2)x_i(N-2)\| < \varepsilon f_{N-1}f_{N-2}, \quad x_i(N-2) \in X_{N-2}.$$

Repeating this argument N times, we conclude that there exist $m \times n$ matrices $L(0), L(1), \dots, L(N-1)$ with

$$\|L(t)\| < (CM)^{N^N} =: \Delta$$

and such that for $i = 1, 2, \dots, n$,

$$\|\tilde{F}(N-1)\tilde{F}(N-2) \cdots \tilde{F}(0)e_i\| < \varepsilon f_{N-1}f_{N-2} \cdots f_0.$$

The above equation, along with (A.14), gives us

$$\|\tilde{F}(N-1)\tilde{F}(N-2) \cdots \tilde{F}(0)\| < n^6 \varepsilon,$$

completing the proof. \square

We are finally in a position to prove Theorem 4.4, which is restated below for convenience.

THEOREM 4.4. *Let $\Sigma = (F, G, H)$ be a linear time-varying system over $l^\infty(\mathbb{Z})$. Then Σ is asycontrollable if and only if Σ is stabilizable.*

Proof. We have already shown (see discussion preceding Theorem 4.4) that stabilizability implies asycontrollability. We now prove the converse.

Suppose Σ is asycontrollable. Choose in the Definition 4.1 of asycontrollability, $\varepsilon = \frac{1}{2}n^{-6}$. Then, by Proposition A.12, there exist matrices $L(t)$, $t = 0, 1, \dots, N-1$ such that

$$\|L(t)\| < \Delta, \quad \|\tilde{F}(N-1)\tilde{F}(N-2) \cdots \tilde{F}(1)\tilde{F}(0)\| < \frac{1}{2}$$

where $\tilde{F}(t) = F(t) + G(t)L(t)$. Recall that here N is the number of steps required to drive all states to energy $< \varepsilon$ as in Definition 4.1 of asycontrollability. Since all our arguments are independent of initial time, we can (again by Proposition A.12) find matrices $L(t)$ for all t in \mathbb{Z} such that $\|L(t)\| < 2\Delta n^6$ and

$$\|\tilde{F}(kN-1)\tilde{F}(kN-2) \cdots \tilde{F}(kN-N+1)\tilde{F}(kN-N)\| < \frac{1}{2}$$

for all k in \mathbb{Z} . Thus the matrix $L(t)$ viewed as being over A is bounded (i.e., in $l^\infty(\mathbb{Z})$), and $(zI - F - GL)^{-1}$ is a stable power series. This completes the proof. \square

DIFFUSION FOR GLOBAL OPTIMIZATION IN \mathbb{R}^n *

TZUU-SHUH CHIANG†, CHII-RUEY HWANG† AND SHUENN-JYI SHEU†

Abstract. We seek a global minimum of $U: \mathbb{R}^n \rightarrow \mathbb{R}$. The solution to $(*) (d/dt)X(t) = -\nabla U(X(t))$ will find local minima. Using the idea of simulated annealing, we consider the diffusion process, $dX(t) = -\nabla U(X(t)) dt + \sigma(t) dW(t)$, $X(0) = x$, where $W(\cdot)$ is the n -dimensional standard Brownian motion and $\frac{1}{2}\sigma^2(t)$ is the annealing rate which decreases to zero as t goes to ∞ . Under suitable condition on $U(x)$, we prove that $X(t)$ converges weakly to a probability measure π if for large t , $\sigma^2(t) = c/\log t$ with $c > c_0$, where c_0 has a simple expression involving the action function of the dynamical system $(*)$, π concentrates on the global minima of U and is the weak limit of the Gibbs densities $\pi_t(x) \propto \exp(-2U(x)/\sigma^2(t))$.

The above result can also be formulated as follows: consider the Fokker-Planck equation (forward equation)

$$\frac{\partial}{\partial t} V(t, y) = \frac{1}{2} \sigma^2(t) \Delta V(t, y) + \nabla \cdot (V(t, y) \nabla U(y))$$

with $V(0, y) = \delta_x(y)$.

If $\sigma^2(t) = c/\log t$ for large t and $c > c_0$, then $V(t, y) \rightarrow \pi$ weakly.

Key words. diffusion, global optimization, simulated annealing, perturbed dynamical system, large deviation, action functional

AMS(MOS) subject classifications. GOH10, GOJ70

1. Introduction. For a fixed $U: \mathbb{R}^n \rightarrow [0, \infty)$, we give suitable conditions on U such that by choosing

$$\sigma^2(t) = \frac{c}{\log t} \quad \text{for large } t \text{ with } c > c_0 \quad \text{as } t \rightarrow \infty$$

$p(s, x, t, \cdot)$ converges weakly to a probability measure π concentrating on the global minima of U , $p(s, x, t, \cdot)$ is the transition probability of the diffusion process defined by

$$(1.1) \quad dZ(t) = -\nabla U(Z(t)) dt + \sigma(t) dW(t),$$

where $\frac{1}{2}\sigma^2(t)$ corresponding to the "temperature" is the annealing rate, $W(t)$ is a standard Brownian motion in \mathbb{R}^n . The probability π is the weak limit of the Gibbs density

$$(1.2) \quad \pi_t(x) \propto \exp\left(-\frac{2U(x)}{\sigma^2(t)}\right) \quad \text{as } t \rightarrow \infty.$$

The constant c_0 , which will be defined in § 2, has a simple expression involving the action function of the dynamical system

$$(1.3) \quad \frac{dY(t)}{dt} = -\nabla U(Y(t)).$$

The idea of our approach is as follows: Heuristically if we hold the temperature at time s for a *fairly large* amount of time, then $Z(t)$ defined by (1.1) and the fixed temperature process behaves almost the same at the end of that time interval. Hence, instead of (1.1) we may consider

$$(1.4) \quad \begin{aligned} dX(t) &= -\nabla U(X(t)) dt + \sigma(s) dW(t), \\ X(0) &= x. \end{aligned}$$

Note that the weak limit π depends only on the local property of U near the minima [9]. If we modify U for large $|x|$, π remains unchanged. One may consider a modified version with $U(X) = |x|^4$ for large $|x|$. In this case $X(t)$ comes back from “infinity” to a fixed finite ball in a finite time which is independent of $\sigma(s)$. It is almost as in the compact situation. Some of the ideas used in [4], which dealt with a reflected version of (1.1), can be used again in here. Furthermore, results and ideas in [13], [14] are available when we consider (1.4).

Independently, Gidas and Kushner also consider (1.1) in their recent works [6], [11], respectively.

Our work was inspired by the “simulated annealing” [1], [10] which deals mainly with the discrete state space. A lot of research has been going on in this aspect, see e.g. [3], [5], [8].

The use of (1.1) as a global minimization algorithm is motivated by problems in imaging processing [4], [7] as well as in studying lattice gauge theory [12].

We think that the constant c_0 obtained here is not the best possible. One may argue heuristically as follows. For the fixed temperature process (1.4) with $\varepsilon = \sigma(s)$, Lemma 3 in § 3 describes a distance between p_t and π^ε . Let $L_\varepsilon = \frac{1}{2}\varepsilon^2\Delta - \nabla U \cdot \nabla$ and $\lambda_2(\varepsilon)$ denote the second eigenvalue of L_ε . Let $\|\cdot\|_{\pi^\varepsilon}$ denote the norm of $L^2(\pi^\varepsilon)$; then clearly

$$\|p_t^\varepsilon(x, f) - \pi^\varepsilon(f)\|_{\pi^\varepsilon} \leq \exp(t\lambda_2(\varepsilon))\|f\|_{\pi^\varepsilon}.$$

If $\lim_{\varepsilon \rightarrow 0} \varepsilon^2 \log(-\lambda_2(\varepsilon)) = -c_1$, then for $c > c_1$ such that $c > c_1 + a$ we have $-\lambda_2(\varepsilon) \geq \exp(-(c_1 + a)/\varepsilon^2)$ for small ε . For $\varepsilon^2 \approx c/\log t$

$$\|p_t^\varepsilon(x, f) - \pi^\varepsilon(f)\|_{\pi^\varepsilon} \leq \exp(-t^{1-((c_1+a)/c)}) \rightarrow 0 \quad \text{as } t \rightarrow \infty.$$

One would expect c_1 here is the critical constant.

Another heuristic approach is to consider the function

$$N(t) = \int \left| \frac{p(0, x, t, y)}{\pi_t(y)} - 1 \right|^2 \pi_t(y) dy, \quad t > 1,$$

which was discussed previously in [4]. If $N(t) \rightarrow 0$ as $t \rightarrow \infty$, then it is easy to see that $p(0, x, t, \cdot) \rightarrow \pi(\cdot)$ weakly. For simplicity, let us write $\sigma^2(t) = 2T(t)$ and heuristically one has

$$\begin{aligned} \frac{dN(t)}{dt} &= \left(\frac{d}{dt} \frac{1}{T(t)} \right) \int \frac{1}{\pi_t(y)} (U(y) - \pi_t(U)) p(0, x, t, y)^2 dy \\ &\quad - 2T(t) \int \left| \nabla_y \left(\frac{p(0, x, t, y)}{\pi_t(y)} \right) \right|^2 \pi_t(y) dy \\ &\leq \frac{c_2}{t} (N(t) + 1) - 2(-\lambda_2(\sigma(t))) N(t) \\ &= \frac{c_2}{t} + N(t) \left(\frac{c_2}{t} - 2t^{-(c_1+a)/c} \right) \end{aligned}$$

by

$$\int |f(y) - \pi_t(f)|^2 \pi_t(y) dy \leq \frac{T(t)}{-\lambda_2(\sigma(t))} \int |\nabla f(y)|^2 \pi_t(y) dy.$$

Then one can establish $N(t) \rightarrow 0$ from this differential inequality.

2. Statement of result. Let U be a twice continuously differentiable function from \mathbb{R}^n to $[0, \infty)$ such that the following assumptions hold:

- $$\min_{x \in \mathbb{R}^n} U(x) = 0,$$
- (A1) $U(x) \rightarrow \infty$ and $|\nabla U(x)| \rightarrow \infty$ as $|x| \rightarrow \infty$,
- $$\lim_{|x| \rightarrow \infty} |\nabla U(x)|^2 - \Delta U(x) > -\infty.$$
- For $0 < \varepsilon < 1$,
- (A2) $\pi^\varepsilon(x) := \frac{1}{c(\varepsilon)} \exp\left(-\frac{2U(x)}{\varepsilon^2}\right),$
- where $c(\varepsilon) = \int_{\mathbb{R}^n} \exp\left(-\frac{2U(x)}{\varepsilon^2}\right) dx < \infty.$
- (A3) π^ε has a unique weak limit π as $\varepsilon \downarrow 0$.

Clearly π concentrates on the global minima of U . The detailed discussion for the existence of π and its characterization in terms of the Hessian of U can be found in [9].

For simplicity we shall assume $\sigma^2(t) < 1$, $\sigma^2(t) = c/\log t$ for large t and the process $Z(t)$ starts at $Z(0) = x$.

Let S denote the set of all stationary points of U , i.e., $S = \{x | \nabla U(x) = 0\}$.

For any $\eta > 0$, $\xi > 0$, we define the following:

$$S(\eta) := \{x | d(x, S) < \eta\},$$

$$K(\eta) := \text{the set containing all the solutions of the dynamical system (1.3) with starting points in } S(\eta),$$

$$K(\eta, \xi) := \{x | d(x, K(\eta)) \leq \xi\},$$

$$I(t, x, y) := \inf_{\substack{\psi(0)=x \\ \psi(t)=y}} \frac{1}{2} \int_0^t |\dot{\psi}(s) + \nabla U(\psi(s))|^2 ds,$$

$$J(t, \eta, \xi) := \sup_{x, y \in K(\eta, \xi)} (I(t, x, y) - 2U(y)),$$

$$J(\eta, \xi) := \overline{\lim}_{t \rightarrow \infty} J(t, \eta, \xi),$$

$$c_0 := \frac{3}{2} \inf_{\eta} (\inf_{\xi} J(\eta, \xi)).$$

For a measure μ , $\mu(f) := \int f d\mu$.

THEOREM. Assume (A1), (A2) and (A3) and $c > c_0$; then for any bounded continuous function f

$$p(0, x, t, f) \rightarrow \pi(f) \quad \text{as } t \rightarrow \infty$$

and the convergence is uniform for x in a compact set. $p(s, x, t, \cdot)$ here is the transition probability of (1.1).

Remark 1. Without going into detail, we note that $J(\eta, \xi)$ is independent of η, ξ and

$$\begin{aligned} c_* &= J(\eta, \xi) = \sup_{x, y \in K(\eta, \xi)} (V(x, y) - 2U(y)) \\ &= \sup_{x, y \in S} (V(x, y) - 2U(y)), \end{aligned}$$

where $V(x, y) = \lim_{t \rightarrow \infty} I(t, x, y)$. This $V(x, y)$ is the same function used by Freidlin and Wentzell for describing the long time behavior of perturbed dynamical systems $dX(t) = -\nabla U(X(t)) dt + \varepsilon dw(t)$.

Remark 2. We suspect that $c > c_* = \frac{2}{3} c_0$ is enough for the result of the theorem to hold.

3. Proof of theorem. The proof of the main theorem is based on the following three lemmas.

LEMMA 1. $\lim_{t \rightarrow \infty} p(s, x, t, K(\eta, \xi)) = 1$. The convergence is uniform for x in a compact set.

LEMMA 2. Consider a family of processes defined by

$$\begin{aligned} (3.1) \quad dY(s, t) &= -\nabla U(Y(s, t)) dt + \sigma(s) dW(t), \\ Y(s, 0) &= y. \end{aligned}$$

Then for $h(s) \leq s^{2/3}$ and $h(s)$ increasing to ∞ ,

$$\lim_{s \rightarrow \infty} E_{0,y}(f(Y(s, h(s)))) - E_{s,y}(f(Z(\beta(s)))) = 0,$$

where $\beta(\cdot)$ is defined by

$$\int_s^{\beta(s)} \frac{\log s}{\log u} du = h(s).$$

And the convergence is uniform for y in a compact set.

LEMMA 3. Consider the following process

$$\begin{aligned} (3.2) \quad dX(t) &= -\nabla U(X(t)) + \varepsilon dW(t), \\ X(0) &= x. \end{aligned}$$

Then there exist $T_0 > 0 \ni \forall M > 0, \forall T > 2T_0, \forall \alpha > 0$

$$\overline{\lim}_{\varepsilon \rightarrow 0} |E_x^\varepsilon f(X(mT)) - \pi^\varepsilon(f)| \leq 4e^{-M} \|f\|,$$

where

$$m = M \exp\left(\frac{1}{\varepsilon^2}(J(t, \eta, \xi) + \alpha)\right), \quad t = T - 2T_0,$$

α is an arbitrary fixed positive constant. The convergence is uniform for x in a compact set.

Assuming the validity of these, we establish the theorem as follows: For a fixed $c > c_0$, there exists an $\alpha > 0$ such that for sufficiently large time t , sufficiently small η and ξ ,

$$(3.3) \quad c > \frac{3}{2}(J(t, \eta, \xi) + \alpha).$$

Choose a fixed large T such that (3.3) holds for time $T - 2T_0$, where T_0 is the constant in Lemma 3.

Choose $h(s)$ in Lemma 2 as

$$\begin{aligned} h(s) &= MT \exp \left(\frac{1}{\sigma^2(s)} (J(T - 2T_0, \eta, \xi) + \alpha) \right) \\ (3.4) \quad &= MT s^{(J(T - 2T_0, \eta, \xi) + \alpha)/c} \\ &< s^{2/3} \quad \text{for large } s. \end{aligned}$$

Note that h and β are strictly increasing functions and $s + h(s) \leq \beta(s) \leq s + 2h(s)$. Hence for $t \gg 1$, one can choose s such that $t = \beta(s)$. Clearly $s < t$ and $s \rightarrow \infty$.

$$\begin{aligned} p(0, x, t, f) - \pi_s(f) &= \int p(0, x, s, y) p(s, y, t, f) dy - \pi_s(f) \\ &= \int_{y \in K(\eta, \xi)} p(0, x, s, y) (p(s, y, t, f) - \pi_s(f)) dy \\ &\quad + \int_{y \notin K(\eta, \xi)} p(0, x, s, y) (p(s, y, t, f) - \pi_s(f)) dy. \end{aligned}$$

The second term is bounded by

$$2\|f\|(1 - p(0, x, s, K(\eta, \xi))),$$

which goes to zero uniformly over x in a compact set as $s \rightarrow \infty$ by Lemma 1. Note that $\pi_s(f) \rightarrow \pi(f)$.

By Lemma 2,

$$\begin{aligned} E_{0,y}(f(Y(s, h(s)))) - p(s, y, \beta(s), f) &\rightarrow 0, \\ E_{0,y}(f(Y(s, h(s)))) &= E_y^{\sigma(s)}(f(X(h(s)))) \\ &= E_y^{\sigma(s)}(f(X(mT))) \end{aligned}$$

by identifying $h(s)$ with mT and $\sigma(s)$ with ε .

Now by Lemma 3, we have the theorem.

4. Proof of Lemma 1. Let us first assume the validity of the following two lemmas.

LEMMA 4.1. For any compact set K in \mathbb{R}^n , the family of probability measures

$$\{p(s, x, t, \cdot) | s < t, x \in K\}$$

is tight.

LEMMA 4.2. For any compact set K , there exists T such that for any $t > T$, $Y(t) \in K(\eta)$, where

$$\frac{dY(t)}{dt} = -\nabla U(Y(t)), \quad Y(0) = y \in K.$$

The proof of Lemma 1 is as follows: By Lemma 4.1, for any $\delta > 0$ and for any given compact set J , there exists a compact set K such that

$$p(s, x, t, K) > 1 - \delta/2 \quad \text{for all } s < t, x \in J.$$

Choose T as in Lemma 4.2, then

$$\begin{aligned} p(s, x, t, K(\eta, \xi)) &= \int p(s, x, t - T, dy) p(t - T, y, t, K(\eta, \xi)) \\ &> \int_K p(s, x, t - T, dy) p(t - T, y, t, K(\eta, \xi)). \end{aligned}$$

It remains to show that there exists t_0 such that

$$p(t-T, y, t, K(\eta, \xi)) > 1 - \delta/2, \quad y \in K, \quad t > t_0.$$

Let $Y(\cdot)$ be the solution of (4.1) with $Y(t-T) = y$. Then by Lemma 4.2,

$$\begin{aligned} p(t-T, y, t, K(\eta, \xi)) &= E_{t-T, y} \{Z(t) \in K(\eta, \xi)\} \\ &= E_{t-T, y} \{|Z(t) - Y(t)| \leq \xi\} \\ &\quad + E_{t-T, y} \{|Z(t) - Y(t)| > \xi, Z(t) \in K(\eta, \xi)\} \\ &\geq E_{t-T, y} \{|Z(t) - Y(t)| \leq \xi\} \\ &\geq 1 - E_{t-T, y} \{\tau \leq t\}, \end{aligned}$$

where $\tau := \inf \{s > t-T, |Z(s) - Y(s)| > \xi\}$.

Now consider the process $Z(t)$ starting at $Z(t-T) = y$. Compare $Z(t)$ and $Y(t)$ up to τ . For $u \leq \tau$,

$$Z(u) - Y(u) = \int_{t-T}^u (-\nabla U(Z(s)) + \nabla U(Y(s))) ds + H(u),$$

where $H(u) = \int_{t-T}^u \sigma(s) dW(s)$. Note that for $t-T \leq s \leq \tau$, $Z(s)$ and $Y(s)$ are in a compact set in which U is Lipschitz with constant d , and we have

$$|Z(u) - Y(u)| \leq d \int_{t-T}^u |Z(s) - Y(s)| ds + |H(u)|.$$

By Gronwall inequality,

$$|Z(u) - Y(u)| \leq \exp(d(u - (t-T))) \sup_{t-T \leq s \leq u} |H(s)|.$$

For $\tau \leq t$,

$$\begin{aligned} \xi = |Z(\tau) - Y(\tau)| &\leq e^{dT} \sup_{t-T \leq s \leq t} |H(s)|, \\ p\{\tau \leq t\} &\leq p\left\{\sup_{t-T \leq s \leq t} |H(s)| \geq e^{-dT} \xi\right\} \\ &\leq 2n \exp\left\{\frac{-\xi^2 \log t}{2cnT} e^{-2dT}\right\} \\ &\leq \frac{\delta}{2} \quad \text{if } t \geq t_0 \text{ for a fixed large } t_0 \end{aligned}$$

[15, p. 87]. Hence,

$$p(t-T, y, t, K(\eta, \xi)) \geq 1 - \frac{\delta}{2}.$$

This completes the proof.

Proof of Lemma 4.1.

$$\begin{aligned} de^{U(Z(t))} e^{\lambda t} &= \left(\frac{\sigma^2(t)}{2} \Delta U(Z(t)) - \left(1 - \frac{\sigma^2(t)}{2}\right) |\nabla U(Z(t))|^2 + \lambda\right) e^{\lambda t} e^{U(Z(t))} dt \\ &\quad + e^{\lambda t} dM(t), \end{aligned}$$

where $M(t) = \int_0^t \sigma(s) \nabla U(Z(s)) e^{U(Z(s))} dW(s)$ is a local martingale.

For any $\lambda > 0$, there exists constant $A = A(\lambda) > 0$ such that

$$\begin{aligned} & \left(\frac{\sigma^2(t)}{2} \Delta U(z) - \left(1 - \frac{\sigma^2(t)}{2} \right) |\nabla U(z)|^2 + \lambda \right) e^{U(z)} \\ &= \left[\frac{\sigma^2(t)}{2} (\Delta U(z) - |\nabla U(z)|^2) - (1 - \sigma^2(t)) |\nabla U(z)|^2 + \lambda \right] e^{U(z)} \\ &\leq A \quad \forall t \text{ and } z \in \mathbb{R}^n, \end{aligned}$$

since for large $|z|$, the term in the bracket parentheses is negative for all t .

Let $\tau_m := \inf \{t; |Z(t)| > m\}$ and $\tau = \lim_{m \rightarrow \infty} \tau_m$ is the explosion time.

Then

$$E_{s,x} \{ e^{U(Z(t\wedge\tau_m))} e^{\lambda(t\wedge\tau_m)} \} \leq A E_{s,x} \left\{ \int_s^{t\wedge\tau_m} e^{\lambda u} du + e^{U(x)} e^{\lambda s} \right\}.$$

Let $m \rightarrow \infty$,

$$E_{s,x} \{ e^{U(Z(t\wedge\tau))} e^{\lambda(t\wedge\tau)} \} \leq \frac{A}{\lambda} (e^{\lambda t} - e^{\lambda s}) + e^{U(x)} e^{\lambda s}.$$

If $p\{\tau \leq \infty\} > 0$, then there exists t such that $E_{s,x} e^{U(Z(t\wedge\tau))} e^{\lambda(t\wedge\tau)} = \infty$. Hence we conclude that $p\{\tau = \infty\} = 1$.

Now we have

$$\begin{aligned} E_{s,x} e^{U(Z(t))} &\leq \frac{A}{\lambda} + e^{U(x)} e^{-\lambda(t-s)} \\ &\leq \frac{A}{\lambda} + e^{U(x)}. \end{aligned}$$

From this, it is easy to show that $\{p(s, x, t, \cdot), s < t, x \in K\}$ is tight.

Proof of Lemma 4.2.

$$(4.1) \quad U(Y(t)) - U(y) = - \int_0^t |\nabla U(Y(s))|^2 ds.$$

For $z \notin S(\eta)$, there exists $\nu > 0$ independent of z such that $U(z) > \nu$ and $|\nabla U(z)| > \nu$. Hence by (4.1) and the compactness of K , there exists T such that $Y(t) \in S(\eta)$ for some $t \leq T$. But by the definition of $K(\eta)$, once $Y(t) \in S(\eta) \subseteq K(\eta)$, then $Y(t') \in K(\eta)$ if $t' > t$. Therefore, $Y(t) \in K(\eta)$ if $t \geq T$.

5. Proof of Lemma 2. For simplicity, we shall write $b = -\nabla U$. Define $\beta(s, t)$ by

$$\int_s^{\beta(s,t)} \frac{\sigma^2(u)}{\sigma^2(s)} du = t.$$

Note that $\beta(s)$ defined in the statement is $\beta(s, h(s))$. For any fixed s , define $\tilde{Z}(s, t) = Z(\beta(s, t))$; then

$$\tilde{Z}(s, t) = x + \int_0^t b(\tilde{Z}(s, u)) \frac{\log \beta(s, u)}{\log s} du + \sigma(s) W(t).^1$$

¹ The Wiener process $W(t)$ may not be the same at each occurrence. This does not matter because we are only interested in the probability distributions.

Now compare $\tilde{Z}(s, \cdot)$ with $Y(s, \cdot)$,

$$Y(s, t) = x + \int_0^t b(Y(s, u)) du + \sigma(s) W(t).$$

Let us first consider $|b(x)| \leq M < \infty$. By the Girsanov theorem,

$$Ef(\tilde{Z}(s, t)) = E(f(Y(s, t)) \exp(A(t) - \frac{1}{2}B(t))),$$

where

$$\begin{aligned} A(t) &= \int_0^t b(Y(s, u)) \left(\frac{\log \beta(s, u)}{\log s} - 1 \right) \frac{1}{\sigma(s)} dW(u), \\ B(t) &= \int_0^t |b(Y(s, u))|^2 \left(\frac{\log \beta(s, u)}{\log s} - 1 \right)^2 \frac{1}{\sigma^2(s)} du, \\ Ef(\tilde{Z}(s, t)) &= Ef(Y(s, t)) + E \left\{ f(Y(s, t)) \left(\exp \left(A(t) - \frac{1}{2}B(t) \right) - 1 \right) \right\}. \end{aligned}$$

We shall show that the second term tends to zero for $t = h(s) \leq s^{2/3}$ as $s \rightarrow \infty$.

$$\begin{aligned} E(\exp(A(t) - \frac{1}{2}B(t)) - 1)^2 &= E(\exp(2A(t) - B(t)) - 1) \\ (5.1) \qquad \qquad \qquad &= E(\exp(2A(t) - 2B(t))(\exp B(t) - 1)), \end{aligned}$$

since $\exp(A(t) - \frac{1}{2}B(t))$ and $\exp(2A(t) - 2B(t))$ are martingales with expectation 1.

$$\begin{aligned} B(t) &= \int_0^t |b(Y(s, u))|^2 \left(\frac{\log \beta(s, u)}{\log s} - 1 \right)^2 \frac{1}{\sigma^2(s)} du \\ &\leq \frac{M^2}{c} \log s \int_0^t \left(\frac{\log \beta(s, u)}{\log s} - 1 \right)^2 du \\ &= \frac{M^2}{c} \log s \int_s^{\beta(s, t)} \left(\frac{\log u}{\log s} - 1 \right)^2 \frac{\log s}{\log u} du \\ &\leq \text{constant} \frac{1}{\log s} \int_s^{\beta(s, t)} \left(\frac{u}{s} - 1 \right)^2 du \\ &= \text{constant} \frac{1}{\log s} \frac{(\beta(s, t) - s)^3}{s^2} \\ &\leq \text{constant} \frac{1}{\log s} \rightarrow 0, \end{aligned}$$

since $s + 2t \geq \beta(s, t) \geq s + t$ and we choose $t = h(s) \leq s^{2/3}$. Then (5.1) is bounded by

$$\text{constant} \frac{1}{\log s} E(\exp(2A(t) - 2B(t))) = \text{constant} \frac{1}{\log s} \rightarrow 0.$$

Therefore for bounded $b(x)$, we have proved

$$(5.2) \qquad E_{s,x} f(Z(\beta(s))) - E_{0,x} f(Y(s, h(s))) \rightarrow 0.$$

Now let us prove the lemma for the general case. Let

$$\begin{aligned} \tau_r &= \inf \{t: U(Z(t)) > r\}, \\ \tau_r(s) &= \inf \{t: U(Y(s, t)) > r\}. \end{aligned}$$

Using the same argument as before by taking f an indicator function and noticing that b is bounded on the compact set $\{U(x) \leq r\}$, we can show that as $s \rightarrow \infty$,

$$(5.3) \quad E_{s,x}\{\tau_r > \beta(s)\} - E_{0,x}\{\tau_r(s) > h(s)\} \rightarrow 0.$$

If there exists r such that

$$(5.4) \quad E_{0,x}\{\tau_r(s) > h(s)\} \rightarrow 1 \text{ uniformly over } x \text{ in a compact set,}$$

then by combining (5.2) for bounded b and (5.3), one gets Lemma 2.

As for (5.4), it is an easy consequence of Lemma 6.4.

6. Proof of Lemma 3.

Super normal case. Let us first prove Lemma 3 for the following particular super normal case: there is a large fixed R_0 , such that

$$(6.1) \quad \begin{aligned} U(x) &= |x|^4 \quad \text{for } |x| > R_0; \quad \text{then} \\ |\nabla U(x)| &= 4|x|^3, \quad \Delta U(x) = (4n+8)|x|^2, \end{aligned}$$

and $K(\eta, \xi) \subseteq \{|x| < R_0\}$.

$$(6.2) \quad \begin{aligned} dX(t) &= -\nabla U(X(t)) dt + \varepsilon dW(t), \\ X(0) &= x. \end{aligned}$$

Let $\tau = \inf\{t \mid |X(t)| = 2R_0\}$.

CLAIM. There exists a constant c_1 such that for any $|x| > 2R_0$, for any $0 < \varepsilon < 1$, $E_x^\varepsilon(\tau) \leq c_1$.

Proof. For $|x| > 2R_0$, $\tau_0 := \inf\{t \mid |X(t)| = \frac{1}{2}|x|\}$, then

$$\begin{aligned} E_x^\varepsilon U(X(\tau_0)) - U(x) &= E_x^\varepsilon \int_0^{\tau_0} \left(-|\nabla U(X(s))|^2 + \frac{\varepsilon^2}{2} \Delta U(X(s)) \right) ds. \\ \left| \frac{1}{2}x \right|^4 - |x|^4 &= E_x^\varepsilon \int_0^{\tau_0} \left(-16|X(s)|^6 + \frac{\varepsilon^2}{2n+4} |X(s)|^2 \right) ds \\ &\leq -c_3 |x|^6 E_x^\varepsilon \tau_0. \end{aligned}$$

Therefore,

$$E_x^\varepsilon \tau_0 \leq c_4 |x|^{-2}.$$

Now let us define the following stopping times:

$$\begin{aligned} \tau_1 &= \inf\{t \mid |X(t)| = \frac{1}{2}|x|\}, \\ \tau_2 &= \inf\{t > \tau_1 \mid |X(t)| = \frac{1}{2}|X(\tau_1)|\}, \\ &\vdots \\ \tau_{i+1} &= \inf\{t > \tau_i \mid |X(t)| = \frac{1}{2}|X(\tau_i)|\}. \end{aligned}$$

Let m be a positive integer such that

$$2^m R_0 < |x| \leq 2^{m+1} R_0.$$

Then, $\tau \leq \tau_m$ and

$$\begin{aligned}
 E_x^\varepsilon(\tau) &\leq \sum_{k=2}^m E_x^\varepsilon(\tau_k - \tau_{k-1}) + E_x^\varepsilon(\tau_1) \\
 &= \sum_{k=2}^m E_x^\varepsilon E_{x(\tau_{k-1})}^\varepsilon(\tau_0) + E_x^\varepsilon(\tau_1) \\
 &\leq c_4 \sum_{k=2}^m E_x^\varepsilon |X(\tau_{k-1})|^{-2} + c_4 |x|^{-2} \\
 &\leq c_4 R_0^{-2} \sum_{k=1}^m (2^{m-k+1})^{-2} \leq \frac{1}{3} c_4 R_0^{-2} = c_1.
 \end{aligned}$$

CLAIM. For any $\delta > 0$ there exist T_0 and ε_0 such that

$$(6.3) \quad E_x^\varepsilon\{X(T_0) \in K(\eta, \xi)\} \geq 1 - \delta \quad \text{for all } x \in \mathbb{R}^n \text{ and } \varepsilon \leq \varepsilon_0.$$

Proof. First choose T_2 such that $c_1/T_2 < \delta/2$.

$$B(2R_0) = \{|x| \leq 2R_0\} \supset K(\eta, \xi).$$

T_1 is the time in Lemma 4.2 such that with initial point in $B(2R_0)$ the solution of the dynamic system will be contained in $K(\eta)$ after time T_1 . Now let $T_0 = T_1 + T_2$.

As in the proof of Lemma 1, we can choose an ε_0 such that

$$E_x^\varepsilon\{X(t) \in K(\eta, \xi)\} > 1 - (\delta/2) \quad \forall x \in B(2R_0), \quad \forall T_1 \leq t \leq T_0, \quad \forall \varepsilon \leq \varepsilon_0.$$

Now for any $x \in \mathbb{R}^n$,

$$\begin{aligned}
 E_x^\varepsilon\{X(T_0) \in K(\eta, \xi)\} &\geq E_x^\varepsilon\{E_{X(\tau)}^\varepsilon\{X(T_0 - \tau) \in K(\eta, \xi)\}, \tau \leq T_2\} \\
 &\quad (\text{for } \tau \leq T_2, T_1 \leq T_0 - \tau \leq T_0, \text{ and } X(\tau) \in B(2R_0)) \\
 &\geq \left(1 - \frac{\delta}{2}\right) E_x^\varepsilon\{\tau \leq T_2\} \\
 &\geq \left(1 - \frac{\delta}{2}\right) \left(1 - \frac{c_1}{T_2}\right) > 1 - \delta.
 \end{aligned}$$

LEMMA 6.1. Let $p_t^\varepsilon(x, y)$ denote the transition density of (6.2) and define

$$q_t^\varepsilon(x, y) \pi^\varepsilon(y) = p_t^\varepsilon(x, y).$$

Then for any x_0, y_0 in \mathbb{R}^n , $\varepsilon \leq \varepsilon_0$, $t > 0$,

$$q_{t+2T_0}^\varepsilon(x_0, y_0) \geq \inf_{x, y \in K(\eta, \xi)} q_t^\varepsilon(x, y) (1 - \delta)^2,$$

the relation between δ , T_0 , ε_0 is the same as in (6.3). And one may take any fixed δ , say $\delta = \frac{1}{2}$.

Proof. For $\varepsilon < 1$, by a similar argument as in Lemma 4.1, $X(t)$ has no explosion. By the Girsanov theorem it is obvious that $X(t)$ has transition densities.

Since the infinitesimal generator $(\varepsilon^2/2)\Delta - \nabla U \cdot \nabla$ is self-adjoint in the weighted space $L^2(\mathbb{R}^n, \pi^\varepsilon)$, it is not hard to show that

$$(6.4) \quad q_t^\varepsilon(x, y) = q_t^\varepsilon(y, x),$$

$$\begin{aligned}
 q_{t+2T_0}^\varepsilon(x_0, y_0) &= \int p_{T_0}^\varepsilon(x_0, x) p_t^\varepsilon(x, y) q_{T_0}^\varepsilon(y, y_0) dx dy \\
 &\geq \int_{x, y \in K(\eta, \xi)} p_{T_0}^\varepsilon(x_0, x) q_t^\varepsilon(x, y) \pi^\varepsilon(y) q_{T_0}^\varepsilon(y, y_0) dx dy \\
 &\geq \inf_{x, y \in K(\eta, \xi)} q_t^\varepsilon(x, y) p_{T_0}^\varepsilon(x_0, K(\eta, \xi)) \\
 &\quad \cdot \int_{K(\eta, \xi)} q_{T_0}^\varepsilon(y, y_0) \pi^\varepsilon(y) dy \quad (\text{by 6.4}) \\
 &= \inf_{x, y \in K(\eta, \xi)} q_t^\varepsilon(x, y) p_{T_0}^\varepsilon(x_0, K(\eta, \xi)) p_{T_0}^\varepsilon(y_0, K(\eta, \xi)) \\
 &\geq (1 - \delta)^2 \inf_{x, y \in K(\eta, \xi)} q_t^\varepsilon(x, y), \quad \varepsilon \leq \varepsilon_0.
 \end{aligned}$$

This completes the proof.

LEMMA 6.2 (Sheu [13, Cor. 2.5]).

$$\lim_{\varepsilon \rightarrow 0} \varepsilon^2 \log p_t^\varepsilon(x, y) \geq -I(t, x, y)$$

uniformly for x, y in a compact set.

COROLLARY 6.1. For any $t > 0, \alpha > 0$, there is $\varepsilon_0 > 0$ such that for $\varepsilon \leq \varepsilon_0, x_0, y_0 \in \mathbb{R}^n$

$$q_{t+2T_0}^\varepsilon(x_0, y_0) \geq \exp\left(-\frac{1}{\varepsilon^2}(J(t, \eta, \xi) + \alpha)\right).$$

LEMMA 6.3 (Super normal case.) For a fixed $t > 0$, let $T = t + 2T_0$. Then $\forall \alpha > 0, \forall M > 0$ there is $\varepsilon_0 > 0$ such that for $\varepsilon \leq \varepsilon_0$

$$|p_{mT}^\varepsilon(x, f) - \pi^\varepsilon(f)| < 4\|f\|\exp(-M),$$

where

$$m = M \exp\left(\frac{1}{\varepsilon^2}(J(t, \eta, \xi) + \alpha)\right).$$

Proof. Let $\beta = \exp(-1/\varepsilon^2(J(t, \eta, \xi) + \alpha))$.

$$\begin{aligned}
 &p_{mT}^\varepsilon(x_1, f) - p_{mT}^\varepsilon(x_2, f) \\
 &= \int p_T^\varepsilon(x_1, z) p_{(m-1)T}^\varepsilon(z, f) dz - \int p_T^\varepsilon(x_2, z) p_{(m-1)T}^\varepsilon(z, f) dz \\
 &= \int q_T(x_1, z) \pi^\varepsilon(z) p_{(m-1)T}^\varepsilon(z, f) dz \\
 &\quad - \int q_T(x_2, z) \pi^\varepsilon(z) p_{(m-1)T}^\varepsilon(z, f) dz \\
 &= \int (q_T(x_1, z) - \beta) \pi^\varepsilon(z) p_{(m-1)T}^\varepsilon(z, f) dz \\
 &\quad - \int (q_T(x_2, z) - \beta) \pi^\varepsilon(z) p_{(m-1)T}^\varepsilon(z, f) dz \\
 &\leq (1 - \beta) (\max_z p_{(m-1)T}^\varepsilon(z, f) - \min_x p_{(m-1)T}^\varepsilon(x, f)) \\
 &= (1 - \beta) \sup_{x_1, x_2 \in \mathbb{R}^n} |p_{(m-1)T}^\varepsilon(x_1, f) - p_{(m-1)T}^\varepsilon(x_2, f)|.
 \end{aligned}$$

By induction,

$$\sup_{x_1, x_2 \in \mathbb{R}^n} |p_{mT}^\varepsilon(x_1, f) - p_{mT}^\varepsilon(x_2, f)| \leq 2\|f\|(1-\beta)^{[m]}.$$

Since π^ε is the invariant measure of $p_t^\varepsilon(x, y)$ [16, p. 243],

$$\begin{aligned} |\pi^\varepsilon(f) - p_{mT}^\varepsilon(x, f)| &\leq \left| \int \pi^\varepsilon(z) (p_{mT}^\varepsilon(z, f) - p_{mT}^\varepsilon(x, f)) dz \right| \\ &\leq 2(1-\beta)^{[m]}\|f\|. \end{aligned}$$

General case. In order to compare the general case with the super normal case, we need the following lemma.

LEMMA 6.4. Let $B(r) = \{x | U(x) \leq r\}$ and $\tau_r = \inf \{t | X(t) \notin B(r)\}$. Then there exists $c(r)$ for large r

$$(i) \quad c(r) \rightarrow \infty \quad \text{as } r \rightarrow \infty,$$

$$(ii) \quad \lim p_x^\varepsilon \left\{ \tau_r > \exp \left(\frac{1}{\varepsilon^2} c(r) \right) \right\} = 1 \quad \text{uniformly for } x \in K(\eta, \xi) \subseteq B(r).$$

Suppose that Lemma 6.4 holds. Choose r large enough such that

$$c(r) > J(t, \eta, \xi) + 1, \quad K(\eta, \xi) \subset B(r).$$

Let \hat{U} satisfy (6.1) for $R_0 > r$ and $\hat{U} = U$ on $B(r)$. Let $\hat{\pi}^\varepsilon$ denote the modified version.

$$\begin{aligned} |p_{mT}^\varepsilon(x, f) - \pi^\varepsilon(f)| &\leq |p_{mT}^\varepsilon(x, f) - \hat{p}_{mT}^\varepsilon(x, f)| \\ &\quad + |\hat{p}_{mT}^\varepsilon(x, f) - \hat{\pi}^\varepsilon(f)| + |\hat{\pi}^\varepsilon(f) - \pi^\varepsilon(f)|. \end{aligned}$$

The second term goes to zero by Lemma 6.3. Since $\hat{\pi}^\varepsilon$ and π^ε have the same weak limit, the third term also tends to zero.

$$|p_{mT}^\varepsilon(x, f) - \hat{p}_{mT}^\varepsilon(x, f)| \leq 2\|f\| E_x^\varepsilon \{ \tau_r \leq mT \} \rightarrow 0 \quad \text{as } \varepsilon \rightarrow 0$$

by Lemma 6.4.

Proof of Lemma 6.4. Choose r_0 such that $K(\eta, \xi) \subseteq B(r_0) =: \Omega_1$ and $\Omega_2 := B(r_0 + 1) \subseteq B(r) =: \Omega_3$. Define

$$\begin{aligned} \sigma_1 &= \inf \{t | X(t) \in \Omega_1\}, \\ \theta_1 &= \inf \{t > \sigma_1 | X(t) \notin \Omega_2\}, \\ &\vdots \\ \sigma_m &= \inf \{t > \theta_{m-1} | X(t) \in \Omega_1\}, \\ \theta_m &= \inf \{t > \sigma_m | X(t) \notin \Omega_2\}. \end{aligned}$$

If one can prove that before exit from Ω_3 , the path spends a lot of time jumping between Ω_1 and Ω_2 , then τ_r will have a good lower estimate.

Let $U(x) = r_0 + 1$ and Q_x^ε denote the measure of the zero drift process, then

$$\begin{aligned} p_x^\varepsilon \{ \tau_r < \sigma_1 \} &= Q_x^\varepsilon \left\{ \tau_r < \sigma_1, \exp \left(\frac{1}{\varepsilon^2} \int_0^{\tau_r} (-\nabla U(X(s)) \cdot dX(s) \right. \right. \\ &\quad \left. \left. - \frac{1}{2\varepsilon^2} \int_0^{\tau_r} |\nabla U(X(s))|^2 ds \right) \right\} \\ &= Q_x^\varepsilon \left\{ \tau_r < \sigma_1, \exp \left(-\frac{1}{\varepsilon^2} \{ U(X(\tau_r)) - U(x) \} \right. \right. \\ &\quad \left. \left. - \frac{1}{2\varepsilon^2} \int_0^{\tau_r} (|\nabla U(X(s))|^2 - \varepsilon^2 \Delta U(X(s))) ds \right) \right\}. \end{aligned}$$

For $s \leq \tau_r < \sigma_1$, $U(X(s)) > r_0$, then there exist $M_1 > 0$ and $M_2 > 0$ such that

$$\begin{aligned} & |\nabla U(X(s))|^2 - \varepsilon^2 \Delta U(X(s)) \\ &= \varepsilon^2 (|\nabla U(X(s))|^2 - \Delta U(X(s))) + (1 - \varepsilon^2) |\nabla U(X(s))|^2 \\ &\geq -\varepsilon^2 M_1 + (1 - \varepsilon^2) M_2 > 0 \quad \text{for small } \varepsilon. \end{aligned}$$

Hence,

$$\begin{aligned} p_x^\varepsilon\{\tau_r < \sigma_1\} &\leq Q_x^\varepsilon\left\{\tau_r < \sigma_1, \exp\left(-\frac{1}{\varepsilon^2}(r - r_0 - 1)\right)\right\} \\ &\leq \exp\left(-\frac{1}{\varepsilon^2}(r - r_0 - 1)\right), \\ p_x^\varepsilon(\tau_r < \sigma_m) &= \sum_{k=1}^m p_x^\varepsilon(\tau_r < \sigma_k, \tau_r \geq \sigma_{k-1}) \\ &= \sum_{k=1}^m p_x^\varepsilon\left\{E_{X(\sigma_{k-1})}\{\tau_r < \sigma_1\}, \tau_r \geq \sigma_{k-1}\right\} \\ &\leq m \exp\left(-\frac{1}{\varepsilon^2}(r - r_0 - 1)\right). \end{aligned}$$

Now we shall show that σ_1 is not too small. Let

$$T^* = \inf_{U(x)=r_0+1} \inf\{t \mid Y(0) = x, Y(t) \in \Omega_1, Y(s) \text{ satisfies (1.3) for } 0 \leq s \leq t\}.$$

Let

$$0 < \delta_0 < d \left(\Omega_1, \left\{ Y(T^*/2) \mid Y(0) = x, U(x) = r_0 + 1, \right. \right. \\ \left. \left. Y(s) \text{ satisfies (1.3) for } 0 \leq s \leq T^*/2 \right\} \right).$$

Let $T_0 \leq T^*/2$; then by a similar method as in the end of the proof of Lemma 1,

$$\begin{aligned} p_x^\varepsilon\{\sigma_1 < T_0\} &\leq p\{\tau < T_0\} \leq (2n) \exp(-e^{-2dT_0}\delta_0^2/(2nT_0\varepsilon^2)) \\ &\leq 2n \exp(-e^{-2dT_0}\delta/(T_0\varepsilon^2)) \end{aligned}$$

(n is the dimension and $\delta = \delta_0^2/2n$, $\tau = \inf\{t \mid |X(t) - Y(t)| > \delta_0\}$, d is the corresponding Lipschitz constant of ∇U in a compact set).

Then, it is obvious that

$$\begin{aligned} p_x^\varepsilon\{\sigma_m < mT_0\} &\leq 2nm \exp\left(-e^{-2dT_0}\frac{\delta}{T_0\varepsilon^2}\right), \\ p_x^\varepsilon\{\tau_r < mT_0\} &\leq p_x^\varepsilon\{\tau_r < \sigma_m\} + p_x^\varepsilon\{\sigma_m < mT_0\} \\ &\leq m \exp\left(-\frac{1}{\varepsilon^2}(r - r_0 - 1)\right) + 2nm \exp\left(-\frac{1}{\varepsilon^2}\frac{e^{-2dT_0}\delta}{T_0}\right). \end{aligned}$$

Choose T_0 such that

$$\frac{e^{-2dT_0}\delta}{T_0} > (r - r_0 - 1).$$

And choose $m-1 = [\exp(1/\varepsilon^2(r-r_0-1-v))]$, where v is an arbitrary fixed small positive number

$$\begin{aligned} p_x^\varepsilon \left\{ \tau_r \geq \exp \left(\frac{1}{\varepsilon^2} (r-r_0-1-v) \right) T_0 \right\} \\ > 1 - (2n+3) \exp \left(-\frac{v}{\varepsilon^2} \right) \rightarrow 1 \quad \text{as } \varepsilon \rightarrow 0. \end{aligned}$$

Hence we may choose $c(r) = r-r_0-1-v$ for any fixed $v > 0$.

For $x \in K(\eta, \xi)$,

$$\begin{aligned} p_x^\varepsilon \{ \tau_r < \exp(c(r)/\varepsilon^2) \} &= p_x^\varepsilon \{ E_{X(\theta)} \{ \tau_r < \exp(c(r)/\varepsilon^2) \}, \theta < \exp(c(r)/\varepsilon^2) \} \\ &\rightarrow 0 \quad \text{as } \varepsilon \rightarrow 0, \end{aligned}$$

where $\theta = \inf \{ t | U(X(t)) = r_0 + 1 \}$.

7. Appendix.

(1) Properties of $I(t, x, y)$ can be found in [2] and [14].

(2) $c_0 < \infty$ is obvious. In fact if we consider

$$\begin{aligned} \phi(u) &= x + u(z-x) \quad \text{for } 0 \leq u \leq 1, \\ &= z \quad \text{for } 1 \leq u \leq t-1, \\ &= z + (u-(t-1))(y-z) \quad \text{for } t-1 \leq u \leq t, \end{aligned}$$

where z is a stationary point, then it is easy to see why $c_0 < \infty$.

(3) Suppose that the set S of all stationary points has only finitely many, say l , connected components. We also assume that points in each component can be connected by smooth curves. Choose ε small enough such that $S(\varepsilon)$ has l disjoint components S_1, \dots, S_l . For x, y belong to the same S_i ,

$$I(t, x, y) = O(1/t) + O(\varepsilon).$$

Indeed, connect x to a stationary point v in S_i with $|x-v| < 2\varepsilon$ by straight line for time interval $[0, 1]$. Connect y to a stationary point w in S_i with $|y-w| < 2\varepsilon$ by straight line for time interval $[t-1, t]$. Connect v, w by a fixed smooth curve ψ with all the curve stationary points. Rescale the parameter of the curve to the interval $[1, t-1]$ and denote it by ϕ , then

$$\begin{aligned} \int_1^{t-1} |\dot{\phi}(u) + \nabla U(\phi(u))|^2 du &= \int_1^{t-1} |\dot{\phi}(u)|^2 du \\ &= \frac{1}{t-2} \int_0^1 |\dot{\psi}(u)|^2 du. \end{aligned}$$

If $\phi(t-u)$, $0 \leq u \leq t$, is a solution, then

$$\int_0^t |\dot{\phi}(u) + \nabla U(\phi(u))|^2 du = 0.$$

For any starting point x , and end point y , since U is a Lyapunov function for the dynamical system (1.4), within a fixed finite time x will reach some S_i via a solution of (1.4) and y some S_j via a solution. If ϕ is a solution, then

$$\frac{1}{4} \int_0^t |\dot{\phi}(u) + \nabla U(\phi(u))|^2 du = U(\phi(t)) - U(\phi(0)).$$

(4) A good upper bound for $I(t, x, y)$ is a curve $\phi(0) = x$, $\phi(t) = y$ and ϕ spends most of its time at a stationary point. From (3), we only have to count the contribution from connecting different components. Consider $\{S_i\}_{i=1, \dots, l}$ as nodes of a graph, and define S_i and S_j as neighboring nodes if there is a trajectory of (1.4) connecting S_i and S_j . Suppose S_1, S_2, \dots, S_m , $m \leq l$, are in the same connected component, and assume there exist points $x_1, \bar{x}_2, x_2, \bar{x}_3, x_3, \dots, \bar{x}_{m-1}, x_{m-1}, \bar{x}_m$ in S_1, \dots, S_m , respectively, such that a trajectory connects x_i to \bar{x}_{i+1} (see Fig. 1). If $U(\bar{x}_{i+1}) > U(x_i)$, then the contribution

FIG. 1

is $2(U(\bar{x}_{i+1}) - U(x_i))$. Otherwise, it is a free ride. Of course, there are other paths to connect S_1, \dots, S_m . Note that $U(x_j)$, $U(\bar{x}_j)$ and $U(z_j)$ are almost of the same value, where z_i is a stationary point in S_j . Two consecutive increasing trajectories contribute

$$2(U(\bar{x}_{i+2}) - U(x_{i+1}) + U(\bar{x}_{i+1}) - U(x_i)) \sim 2(U(\bar{z}_{i+2}) - U(z_i)).$$

Hence, $2([m/2] \max_{1 \leq j \leq m} U(z_j))$ is a bound.

(5) Suppose the graph $\{S_j\}_{1 \leq j \leq l}$ has, say, G_1, \dots, G_k components. Let K be any bounded connected set containing all S_j 's. For any $x \in K$ either x in some G_i or there exists a unique G_i such that x is connected to G_i by a trajectory. Now we have partitioned K into K_1, \dots, K_k disjoint sets. Define K_i, K_j are neighbors if $d(K_i, K_j) = 0$. If we regard $\{K_j\}_{j=1, \dots, k}$ as nodes of a graph, then we can show it is a connected graph since K is connected. In other words we can connect G_i to G_j via trajectories of (1.4) and at most $k-1$ line segments of arbitrary small length. The same argument as in 4 yields that the contribution to connect different components is less than

$$2\left(\left[\frac{k}{2}\right] \max_{1 \leq i \leq l} U(z_i)\right).$$

(6) One may use $3([l/2] + [k/2]) \max_{1 \leq i \leq l} U(z_i)$ as a rough bound for c_0 .

(7) We give some examples (see Figs. 2-5) to calculate c_* for the one-dimensional case.

FIG. 2. $c_* = (U(x_2) - U(x_1)) + (U(x_4) - U(x_3)) = (U(x_2) - U(x_3)) + (U(x_4) - U(x_5))$.

FIG. 3. $c_* = (U(x_2) - U(x_1)) + (U(x_4) - U(x_3)) - U(x_5) = (U(x_4) - U(x_5)) + (U(x_2) - U(x_3))$, ($U(x_1) = 0$).

FIG. 4. $c_* = (U(x_2) - U(x_1)) + (U(x_4) - U(x_3)) = (U(x_4) - U(x_5)) + (U(x_2) - U(x_3))$.

FIG. 5. $c_* = (U(x_2) - U(x_1)) + (U(x_4) - U(x_3)) - U(x_5) = (U(x_4) - U(x_5)) + (U(x_2) - U(x_3)) - U(x_1)$.

Acknowledgment. The authors would like to thank Professor Daniel Stroock for very helpful suggestions and discussions.

SPECTRAL FACTORIZATION AND NEVANLINNA-PICK INTERPOLATION*

TRYPHON T. GEORGIOU† AND PRAMOD P. KHARGONEKAR‡

Abstract. We develop a spectral factorization algorithm based on linear fractional transformations and on the Nevanlinna-Pick interpolation theory. The algorithm is recursive and depends on a choice of points $(z_k, k = 1, 2, \dots)$ inside the unit disk. Under a mild condition on the distribution of the z_k 's, the convergence of the algorithm is established. The algorithm is flexible and convergence can be influenced by the selection of z_k 's.

Key words. spectral factorization, interpolation theory, positive-real functions, Nevanlinna-Pick interpolation

AMS(MOS) subject classifications. 93C05, 30E05, 30D50

1. Introduction. Interpolation theory for complex analytic functions has a long history in mathematics and engineering. The origin of the subject can be traced back at least to the work of Caratheodory, Schur, Nevanlinna and Pick (see [7]) and continues with the recent works of Adamjan, Arov and Krein [1], Sarason [24], Sz. Nagy and Foias [20], and Ball and Helton [3] which have extended the theory to a general operator theoretic setting. In engineering, interpolation theory has been used in a variety of problem areas. Passive circuit synthesis, optimal control, stability theory, representation and prediction theory for stochastic processes, and control theory are some of the engineering disciplines where interpolation theory of complex analytic functions has played a significant role. For these, see for example [10], [11], [18], [19], [25], [26] and the references therein.

In the present work we use interpolation theoretic ideas and, in particular, linear fractional transformations to develop a general scheme for spectral factorization. Spectral factorization is a key problem in a variety of engineering fields, and has been investigated extensively. In particular, see [2], [5], [6], [11], [12], [15], [21], [23]. The approach we have taken leads to a connection with ideas from interpolation theory and in particular to the use of linear fractional transformations. *Our main contribution in this paper is a new and versatile theoretical algorithm for spectral factorization.* However, numerical properties of this algorithm are not addressed here and will be pursued elsewhere.

We denote by \mathbb{U} the unit ball in H^∞ ; i.e., $\mathbb{U} := \{f(z) \text{ analytic in } \mathbb{D} \text{ such that } |f(z)| \leq 1 \text{ for all } z \in \mathbb{D}\}$, where \mathbb{D} denotes the *open unit disc* in the complex plane. The classical Nevanlinna-Pick interpolation problem requires finding a function f in \mathbb{U} that satisfies the following interpolation conditions:

$$f^{(m)}(z_k) = w_{m,k}, \quad m = 0, 1, \dots, N_k, \quad \text{for } k = 1, 2, \dots, N.$$

(The case $N = 1$ is known as Caratheodory–Schur interpolation.) The *Nevanlinna–Pick recursion* allows the solution, i.e., existence and characterization of all solutions, of this problem by iteratively reducing it to an equivalent one with fewer interpolation constraints. The general form of the solutions is then presented in terms of a linear fractional transformation

$$(1.1) \quad f(z) = [A(z) + B(z)h(z)] \times [C(z) + D(z)h(z)]^{-1},$$

where A, B, C and D are functions depending on the data of the problem and $h(z)$ is an arbitrary function in \mathbb{U} that parametrizes the set of solutions.

With every function f in \mathbb{U} , such that

$$\ln [1 - |f(e^{i\theta})|^2] \text{ is in } L^1 := L^1[-\pi, \pi],$$

there is associated a unique outer function (see [22])

$$g_f(z) := \exp \left\{ (4\pi)^{-1} \int_{-\pi}^{\pi} [e^{i\theta} + z][e^{i\theta} - z]^{-1} \ln [1 - |f(e^{i\theta})|^2] d\theta \right\}$$

such that $|g_f(e^{i\theta})|^2 = 1 - |f(e^{i\theta})|^2$ a.e. on $[-\pi, \pi]$. The function g_f is known as the **canonical spectral factor** of f and plays an important role in several problem areas such as representation of stochastic processes, optimal control, network synthesis, etc. Under fairly general conditions g_f can in fact be defined as a meromorphic function on the whole complex plane (see [8]). This is certainly true for the important case where f is also a rational function, and this is precisely the case we consider in the present paper.

If g_f and g_h denote the spectral factors of f and h respectively that are related as in (1.1), then it can be shown that g_f and g_h under certain conditions have the same zeros. (The general problem of describing invariants of the action of the semigroup of linear fractional transformations has been considered by Helton [17].) Utilizing the invariance of the so-called spectral zeros (or transmission zeros) under linear fractional transformations, we developed a spectral factorization algorithm along the lines of Caratheodory–Schur interpolation [14], [15]. The present work extends our earlier results to the Nevanlinna–Pick setting and gives rise to a general spectral factorization algorithm.

2. The Nevanlinna–Pick recursion. We begin with the following well-known lemma, which is simply an invariant formulation of Schwarz’s lemma. This has provided an important tool in the theory of interpolation with complex analytic functions and was utilized in a masterful way in that context by Nevanlinna (see Garnett [13]).

LEMMA 2.1. *Let f_1 be in \mathbb{U} , and consider a sequence of points $(z_k \in \mathbb{D}, k = 1, 2, \dots)$ and a sequence of parameters $(c_k \in \mathbb{D}, k = 1, 2, \dots)$. Define*

$$(2.2a) \quad w_k := f_k(z_k),$$

$$(2.2b) \quad \tilde{f}_{k+1} := \frac{1 - \bar{z}_k z}{z - z_k} \frac{f_k - w_k}{1 - \bar{w}_k f_k},$$

$$(2.2c) \quad f_{k+1} := \frac{\tilde{f}_{k+1} - c_k}{1 - \bar{c}_k \tilde{f}_{k+1}},$$

for $k = 1, 2, \dots$. Then, $f_k, k = 2, 3, \dots$, is a sequence of \mathbb{U} -functions. In case $|w_n| = 1$ for a value $k = n$, then the above sequence terminates to a function $f_n \equiv w_n$. This last case

occurs only if f_1 is a finite Blaschke product; i.e., f_1 is of the form

$$f_1(z) = e^{i\varphi} \prod_{k=1}^n \frac{(z - \xi_k)}{(1 - \bar{\xi}_k z)},$$

and consequently has modulus equal to one on the boundary of the disk.

The case where f_1 is a finite Blaschke product is of no interest to us because in this case the spectral factor of f_1 is the zero function, and the spectral factorization problem becomes trivial. Hence, in the sequel, even when not explicitly stated, we tacitly assume that this is not the case.

The sequence of the parameters c_k in the Nevanlinna recursion can be taken to be arbitrary constants in \mathbb{D} . However, we follow a standard and convenient normalization (see [4], [8]) described in the lemma below.

LEMMA 2.3. *Let $f_1 \in \mathbb{U}$ (but not a finite Blaschke product), and let $f_1(0) = 0$. Given a sequence of points $(z_k \in \mathbb{D}, k = 1, 2, \dots)$, and letting*

$$(2.4) \quad c_k := \tilde{f}_{k+1}(0) = \begin{cases} \frac{w_k}{z_k} & \text{whenever } z_k \neq 0, \\ \lim_{z \rightarrow 0} \frac{f_k(z)}{z} & \text{whenever } z_k = 0, \end{cases}$$

the Nevanlinna recursion (2.2a-c) produces a sequence $f_k, k = 2, 3, \dots$, of \mathbb{U} -functions that satisfy $f_k(0) = 0$, for all k .

The Nevanlinna recursion in Lemma 2.1 can be used to provide a constructive approach to the Nevanlinna-Pick problem (see Garnett [13, p. 166]). It can also be used to generate, from a known function f_1 in \mathbb{U} , the associated sequence of the so-called Schur parameters/reflection coefficients w_k . This is the way we apply the Nevanlinna recursion. In fact, our objective in the next section is to study the limiting behavior of the “by-product” f_k as k tends to ∞ .

3. Some convergence results. Let f_1 (different from a finite Blaschke product) be in \mathbb{U} and assume that $f_1(0) = 0$. This causes no loss of generality from our standpoint because the functions f in \mathbb{U} , and zf which is also in \mathbb{U} , have the same spectral factor. The assumption $f_1(0) = 0$ simplifies the computations required in the sequel.

Compute now the sequence $f_k, k = 2, 3, \dots$, of \mathbb{U} -functions from f_1 and the sequence of points $(z_k \in \mathbb{D}, k = 1, 2, \dots)$ via the Nevanlinna recursion (2.2) and (2.4). Recall that the choice (2.4) for the constants c_k readily implies that $f_k(0) = 0$ for $k = 2, 3, \dots$. This is very convenient as we will see shortly.

Using (2.2b) and (2.2c) it easily follows that

$$\frac{(1 - |w_k|^2)(1 - |f_k|^2)}{|1 - \bar{w}_k f_k|^2} = \frac{(1 - |c_k|^2)(1 - |f_{k+1}|^2)}{|1 + \bar{c}_k f_{k+1}|^2} \quad \text{for } z \text{ on } \mathbb{T},$$

and $k = 1, 2, \dots, n-1$. Applying $\ln(\cdot)$ to both sides of the above equation, we obtain that

$$(3.1) \quad \begin{aligned} & \ln(1 - |w_k|^2) + \ln(1 - |f_k|^2) - \ln|1 - \bar{w}_k f_k|^2 \\ & = \ln(1 - |c_k|^2) + \ln(1 - |f_{k+1}|^2) - \ln|1 + \bar{c}_k f_{k+1}|^2 \end{aligned}$$

for $z \in \mathbb{T}$. Note that $|\bar{w}_k f_k| < 1$ in \mathbb{D} . Hence $1 - \bar{w}_k f_k$ is an analytic function with no roots in \mathbb{D} . Therefore, (see Rudin [22, Thm. 13.12]) $u(z) := \ln|1 - \bar{w}_k f_k|^2$ is a harmonic function

in \mathbb{D} . Also, since $f_k(0) = 0$, it follows that $u(0) = 0$. Consequently, using the well-known mean value property of harmonic functions (see [22])

$$\int_{-\pi}^{\pi} \ln |1 - \bar{w}_k f_k(e^{i\theta})|^2 d\theta = u(0) = 0.$$

A similar argument applies to $\ln |1 + \bar{c}_k f_{k+1}|^2$ and yields

$$\int_{-\pi}^{\pi} \ln |1 + \bar{c}_k f_{k+1}(e^{i\theta})|^2 d\theta = 0.$$

Now, from (3.1), we integrate over the interval $[-\pi, \pi]$ and exponentiate both sides to obtain that

$$\begin{aligned} \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln (1 - |f_k(e^{i\theta})|^2) d\theta \right\} \\ = \left(\frac{1 - |c_k|^2}{1 - |w_k|^2} \right) \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln (1 - |f_{k+1}|^2) d\theta \right\} \end{aligned}$$

for all k . Finally by induction we conclude that

$$\begin{aligned} \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln (1 - |f_1(e^{i\theta})|^2) d\theta \right\} \\ (3.2) \quad = \left(\prod_{k=1}^n \frac{1 - |c_k|^2}{1 - |w_k|^2} \right) \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln (1 - |f_{k+1}|^2) d\theta \right\}. \end{aligned}$$

We are interested in the case where f_1 is a rational function in \mathbb{U} but different from a finite Blaschke product. In this case the above integrals are different from zero and we can obtain the following theorem.

THEOREM 3.3. *Let f_1 be a rational function in \mathbb{U} such that $\ln (1 - |f_1(e^{i\theta})|^2)$ is in L^1 (hence not a Blaschke product), and $f_1(0) = 0$. Let $(z_k, k = 1, 2, \dots)$ be a sequence of points in \mathbb{D} satisfying the property*

$$(3.4) \quad \sum_{k=1}^{\infty} (1 - |z_k|) = \infty,$$

and obtain the corresponding sequence of w_k 's and c_k 's from (2.2) and (2.4). Then

$$\exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln (1 - |f_1(e^{i\theta})|^2) d\theta \right\} = \lim_{n \rightarrow \infty} \prod_{k=1}^n \left(\frac{1 - |c_k|^2}{1 - |w_k|^2} \right).$$

The proof of the above theorem is based on certain classical facts in function theory and some results obtained by Dewilde and Dym [8], [9] and Bulteel and Dewilde [4], and is given in § 6. Below we give an immediate corollary of Theorem 3.3 and relation (3.2).

COROLLARY 3.5. *Under the conditions of Theorem 3.3,*

$$\lim_{k \rightarrow \infty} \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln (1 - |f_{k+1}|^2) d\theta \right\} = 1$$

and

$$\lim_{k \rightarrow \infty} f_{k+1}(z) = 0 \text{ a.e. on } \mathbb{T}.$$

4. Invariance of spectral zeros–spectral factorization. Let f be a rational \mathbb{U} -function (but not a finite Blaschke product) and let it be represented as the ratio of two coprime polynomials $a(z)/b(z)$. Since f is in \mathbb{U} ,

$$1 - |f(z)|^2 = \frac{|b(z)|^2 - |a(z)|^2}{|b(z)|^2} \geq 0 \quad \text{on } \mathbb{T},$$

and it admits a factorization

$$(4.1) \quad 1 - |f(z)|^2 = \frac{|\mu\eta(z)|^2}{|b(z)|^2} \quad \text{for } z = e^{i\theta},$$

where $\eta(z)$ is a polynomial that *can be taken to have no root inside \mathbb{D} with $\eta(0) = 1$, and μ a positive constant*. Under this normalization $\eta(z)$ is uniquely defined by f and will be called the **spectral numerator of f** . The canonical spectral factor of f is then given by

$$g(z) = \mu \frac{\eta(z)}{b(z)},$$

and is defined on the whole complex plane. Moreover, (4.1) extends to an equality of meromorphic functions

$$(4.2) \quad 1 - f(z)f(z^{-1}) = \mu^2 \frac{\eta(z)}{b(z)} \frac{\bar{\eta}(z^{-1})}{\bar{b}(z^{-1})}$$

valid throughout the complex plane.

Let now f_1 be a rational \mathbb{U} -function and $f_k, k = 2, 3, \dots$, be the sequence of \mathbb{U} -functions obtained from f_1 and from a sequence of points $(z_k, k = 1, 2, \dots)$ via the Nevanlinna recursion. In view of (2.2), it is clear that f_{k+1} is also a rational function. Thus, the Nevanlinna recursion produces a sequence of rational functions $f_k, k = 2, 3, \dots$.

We now express the recurrence formulas (2.2, 2.4) in terms of fractional representations a_k/b_k for the functions $f_k, k = 1, 2, \dots$. First

$$(4.3) \quad w_k := \frac{a_k(z_k)}{b_k(z_k)}.$$

By solving (2.2) for f_{k+1} in terms of f_k we obtain (see also Garnett [13, p. 167])

$$(4.4) \quad f_{k+1} = \frac{\alpha_k - \gamma_k f_k}{-\beta_k + \delta_k f_k},$$

where

$$(4.5) \quad \begin{aligned} \alpha_k(z) &= w_k(1 - \bar{z}_k z) + c_k(z - z_k), \\ \beta_k(z) &= \bar{c}_k w_k(1 - \bar{z}_k z) + (z - z_k), \\ \gamma_k(z) &= (1 - \bar{z}_k z) + c_k \bar{w}_k(z - z_k), \\ \delta_k(z) &= \bar{c}_k(1 - \bar{z}_k z) + \bar{w}_k(z - z_k) \end{aligned}$$

and we use (2.4), which becomes

$$(4.6) \quad c_k = \begin{cases} \frac{w_k}{z_k} & \text{when } z_k \neq 0, \\ \lim_{z \rightarrow 0} \frac{a_k(z)}{zb_k(z)} & \text{when } z_k = 0. \end{cases}$$

Starting from a coprime fraction for $f_1 = a_1/b_1$, i.e., a_1 and b_1 are polynomials with no common factor, define a sequence of pairs of functions (that will turn out to be polynomials) (a_k, b_k) , for $k = 2, 3, \dots$, via the following:

$$(4.7) \quad \begin{bmatrix} a_{kf1} \\ b_{k+1} \end{bmatrix} = \frac{1}{(z - z_k)(1 - |c_k|^2)} \begin{bmatrix} \gamma_k & -\alpha_k \\ -\delta_k & \beta_k \end{bmatrix} \begin{bmatrix} a_k \\ b_k \end{bmatrix}$$

for $k = 2, 3, \dots$. We can now state the following proposition:

PROPOSITION 4.8. *Let f_1 be a rational \mathbb{U} -function that is not a finite Blaschke product, a_1/b_1 be a polynomial coprime fraction for f_1 , and generate the sequence of (a_k, b_k) and of f_k via (4.3)–(4.7). Then the following hold.*

$$(4.8a) \quad f_k = a_k/b_k \quad \text{for all } k.$$

$$(4.8b) \quad (a_k, b_k) \quad \text{for } k = 2, 3, \dots, \text{ are polynomials in } z.$$

$$(4.8c) \quad \text{The maximum degree of the polynomials } (a_k, b_k) \text{ never exceeds the maximum degree of the polynomials } (a_1, b_1).$$

$$(4.8d) \quad \text{If } f_1(0) = 0, \text{ and the polynomials } a_1, b_1 \text{ have been normalized to satisfy } a_1(0) = 0, \text{ and } b_1(0) = 1, \text{ then}$$

$$a_k(0) = 0 \quad \text{and} \quad b_k(0) = 1 \quad \text{for all } k.$$

Proof.

$$(4.8a) \quad \text{It follows immediately by comparison of (4.4) with (4.7).}$$

$$(4.8b) \quad \text{For } z = z_k, \text{ the expressions } (\gamma_k a_k - \alpha_k b_k) \text{ and } (\delta_k a_k - \beta_k b_k) \text{ become equal to } [(1 - \bar{z}_k z_k) a_k(z_k) - w_k(1 - \bar{z}_k z_k) b_k(z_k)], \text{ and } [\bar{c}_k(1 - \bar{z}_k z_k) a_k(z_k) - \bar{c}_k w_k(1 - \bar{z}_k z_k) b_k(z_k)], \text{ respectively. But } a_k(z_k) = w_k b(z_k). \text{ Hence, both expressions become equal to zero. Therefore, } (\gamma_k a_k - \alpha_k b_k) \text{ and } (\delta_k a_k - \beta_k b_k) \text{ are polynomial expressions divisible by } (z - z_k). \text{ From (4.7) we now conclude that } (a_k, b_k), \text{ for } k = 2, 3, \dots \text{ are polynomials in } z.$$

$$(4.8c) \quad \text{The polynomials } \alpha, \beta, \gamma \text{ and } \delta, \text{ have degree equal to one. Hence the maximum degree of } \{(\gamma_k a_k - \alpha_k b_k)/(z - z_k), (\delta_k a_k - \beta_k b_k)/(z - z_k)\} \text{ does not exceed the maximum degree of } (a_k, b_k).$$

$$(4.8d) \quad \text{It follows by straightforward computation. } \square$$

However, $a_k(z)$ and $b_k(z)$ might have a common factor. The determinant of the transformation matrix in (4.7) is computed directly and is given below

$$(4.9) \quad \gamma_k \beta_k - \alpha_k \delta_k = (1 - |c_k|^2)(1 - |w_k|^2)(z - z_k)(1 - \bar{z}_k z)$$

for $k = 1, 2, \dots$. (Note that $(z - z_k)$ cannot be a factor of a_{k+1} or b_{k+1} since it has been divided out in (4.7).) Thus, the only possible common factor of a_{k+1} and b_{k+1} , in addition to common factors of a_k and b_k , is $(1 - \bar{z}_k z)$. In fact a_{k+1} and b_{k+1} will have $(1 - \bar{z}_k z)$ as a common factor precisely when it is also a factor in $\eta_k(z)$. (Then, this becomes a common factor of every pair (a_{k+l}, b_{k+l}) for $l = 1, 2, \dots$.) The following theorem addresses exactly this point.

THEOREM 4.10. *Let f_1 be a rational \mathbb{U} -function (different from a finite Blaschke product) and a_k/b_k be a coprime polynomial fraction description of f_1 satisfying (4.8d). Let (a_k, b_k) , $k = 2, 3, \dots$, be obtained from (4.3), (4.5)–(4.7) and a sequence of points $(z_k$ in \mathbb{D} , for $k = 1, 2, \dots$). Define d_k to be the greatest common divisor of (a_k, b_k)*

normalized by $d_k(0) = 1$, and let η_k denote the spectral numerator of the \mathbb{U} -function $f_k := a_k/b_k$. Then the following hold:

(i) If for $k = n$, $(1 - \bar{z}_n z)$ is a factor of $\eta_n(z)$, then

$$d_{n+1} = (1 - \bar{z}_n z) d_n, \text{ whereas}$$

$$\eta_n = (1 - \bar{z}_n z) \eta_{n+1};$$

(ii) If for $k = n$, $(1 - \bar{z}_n z)$ is not a factor of $\eta_n(z)$, then

$$d_{n+1} = d_n, \text{ and } \eta_n = \eta_{n+1}.$$

Proof. We begin by recalling first a certain well-known property of the transformation matrix

$$M_k(z) := \frac{1}{(z - z_k)(1 - |c_k|^2)} \begin{bmatrix} \gamma_k(z) & -\alpha_k(z) \\ -\delta_k(z) & \beta_k(z) \end{bmatrix}$$

used in (4.7). Define by

$$M_k(z)_* := M_k^*(z^{-1}),$$

where $(\)^*$ denotes complex conjugation of the coefficients and transposition of the matrix. Then,

$$(4.11) \quad M_k(z)_* \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} M_k(z) = \frac{(1 - |w_k|^2)}{(1 - |c_k|^2)} \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}.$$

This property is known as *J-unitarity*; e.g., see [9]. (It follows directly by algebraic manipulations and the use of (4.5) and (4.9).)

We now compute

$$\begin{aligned} & \bar{b}_{k+1}(z^{-1})b_{k+1}(z) - \bar{a}_{k+1}(z^{-1})a_{k+1}(z) \\ &= [\bar{a}_{k+1}(z^{-1})\bar{b}_{k+1}(z^{-1})] \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} a_{k+1}(z) \\ b_{k+1}(z) \end{bmatrix}, \end{aligned}$$

which because of (4.11)

$$\begin{aligned} &= \frac{(1 - |w_k|^2)}{(1 - |c_k|^2)} [\bar{a}_k(z^{-1})\bar{b}_k(z^{-1})] \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} a_k(z^{-1}) \\ b_k(z^{-1}) \end{bmatrix} \\ &= \frac{(1 - |w_k|^2)}{(1 - |c_k|^2)} (\bar{b}_k(z^{-1})b_k(z) - \bar{a}_k(z^{-1})a_k(z)). \end{aligned}$$

This last equality implies that

$$(4.12) \quad |d_{k+1}(z)\eta_{k+1}(z)|^2 = |d_k(z)\eta_k(z)|^2, \quad z = e^{i\theta},$$

where μ_k is a nonzero constant that can be taken to be positive. Also note that, as it was argued before on the basis of (4.9) and (4.7),

$$(4.13) \quad d_{k+1}(z) \text{ is either equal to } d_k(z) \text{ or equal to } (1 - \bar{z}_k z)d_k(z)$$

for all values of k . Consequently, $d_k(z)$ has no roots in \mathbb{D} . Since the same applies to $\eta_k(z)$, we now conclude from (4.12) that

$$(4.14) \quad d_{k+1}(z)\eta_{k+1}(z) = d_k(z)\eta_k(z) \quad \text{for } k = 1, 2, \dots$$

Now, if $(1 - \bar{z}_k z)$ is not a factor of $\eta_k(z)$, then we conclude from (4.13) and (4.14) that

$$d_{k+1}(z) = d_k(z) \quad \text{and} \quad \eta_{k+1}(z) = \eta_k(z).$$

If $(1 - \bar{z}_k z)$ is a factor of $\eta_k(z)$, we only need to consider the case where $z_k \neq 0$. In this case

$$\eta_k(\bar{z}_k^{-1})\bar{\eta}_k(\bar{z}_k) = 0,$$

which implies that

$$(4.15) \quad 1 - f_k(\bar{z}_k^{-1})\bar{f}_k(\bar{z}_k) = 0.$$

But $\bar{f}_k(\bar{z}_k) = \overline{a_k(z_k)/b_k(z_k)} = \bar{w}_k$; therefore (4.15) implies that

$$(4.16) \quad b_k(\bar{z}_k^{-1}) = \bar{w}_k a_k(\bar{z}_k^{-1}).$$

From (4.5) we now have that

$$\begin{aligned} a_{k+1}(\bar{z}_k^{-1}) &= \frac{1}{(\bar{z}_k^{-1} - z_k)(1 - |c_k|^2)} [\gamma_k(\bar{z}_k^{-1})a_k(\bar{z}_k^{-1}) - \alpha_k(\bar{z}_k^{-1})b_k(\bar{z}_k^{-1})] \\ &= \frac{1}{(\bar{z}_k^{-1} - z_k)(1 - |c_k|^2)} [c_k \bar{w}_k(\bar{z}_k^{-1} - z_k)a_k(\bar{z}_k^{-1}) - c_k(\bar{z}_k^{-1} - z_k)b_k(\bar{z}_k^{-1})]. \end{aligned}$$

Because of (4.16), the above expression is equal to zero, hence

$$a_{k+1}(\bar{z}_k^{-1}) = 0,$$

and in fact $(1 - \bar{z}_k z)$ is a factor of $a_{k+1}(z)$. Clearly, even if $(1 - \bar{z}_k z)$ is already a factor of $d_k(z)$, the above can be used to show that $a_{k+1}(z)$ is divisible by $(1 - \bar{z}_k z)d_k(z)$. In a similar way we conclude that $(1 - \bar{z}_k z)d_k(z)$ divides $b_{k+1}(z)$. Therefore,

$$d_{k+1}(z) = (1 - \bar{z}_k z)d_k(z),$$

and from (4.14) we deduce that

$$\eta_{k+1}(z)(1 - \bar{z}_k z) = \eta_k(z).$$

This concludes the proof. \square

An immediate consequence of the above is that *if for no point in the sequence $(z_k, k = 1, 2, \dots)$ we have $(1 - \bar{z}_k z)$ as a factor of $\eta_1(z)$, then*

$$\eta_k(z) = \eta_1(z) \quad \text{for } k = 1, 2, \dots,$$

and also $d_k(z) \equiv 1$ for all values of k . Alternatively, *if all roots of $\eta_1(z)$, including multiplicities, have inverse complex conjugate values belonging to $(z_k, k = 1, 2, \dots)$, then after a finite number of steps we will have that*

$$d_n(z) = d_{n+l}(z) = \eta_1(z) \quad \text{for } l = 1, 2, \dots,$$

while $\eta_{n+l}(z) = 1$.

However, regardless of how the points $z_k, k = 1, 2, \dots$, are chosen (provided a mild condition on their distribution is met), the polynomials $a_k(z)$ and $b_k(z)$ as $k \rightarrow \infty$, tend to the zero polynomial and $\eta_1(z)$ respectively. This is the content of the next theorem.

THEOREM 4.17. *Let $f_1(z)$ be a rational \mathbb{U} -function (with $f_1(0) = 0$), $\eta_1(z)$ be the associated spectral numerator, and $f_1(z) = a_1(z)/b_1(z)$ a representation of f_1 as the ratio of two coprime polynomials satisfying $a_1(0) = 0$ and $b_1(0) = 1$. Let $z_k, k = 1, 2, \dots$, be a sequence of points in \mathbb{D} satisfying*

$$(3.4) \quad \sum_{k=1}^{\infty} (1 - |z_k|) = \infty,$$

and $(a_k, b_k), k = 2, 3, \dots$, be obtained from (4.3), (4.5)–(4.7). Then as $k \rightarrow \infty$,

$$b_k(z) \rightarrow \eta_1(z), \quad a_k(z) \rightarrow 0$$

coefficientwise.

Proof. Let

$$(4.18) \quad \frac{a_k(z)}{b_k(z)} = \rho_1 z + \rho_2 z^2 + \cdots + \rho_m z^m + \cdots$$

be a Taylor series for $f_k(z)$ around the origin. Since $f_k(z)$ is a rational function in \mathbb{U} , it is analytic in \mathbb{D} and also continuous on the boundary (because of the rationality). Corollary 3.5 now implies that $f_k(z)$ tends uniformly to zero on compact subsets of \mathbb{D} and in particular that $\rho_m \rightarrow 0$, for all m , as $k \rightarrow \infty$.

From Proposition 4.8, the polynomial $b_k(z)$ satisfies $b_k(0) = 1$ for all values of k and has no root in \mathbb{D} (because f_k is in \mathbb{U} and $d_k(z)$ has no root in \mathbb{D} as discussed earlier). Therefore, the coefficients of b_k are all bounded by one. Also $\rho_m \rightarrow 0$, uniformly in m for $m = 1, \dots, l$, when $k \rightarrow \infty$, and l being any finite integer. We conclude that $a_k(z) \rightarrow 0$ as a polynomial; i.e., its coefficients tend to zero.

From the proof of Theorem 4.10 we now have that

$$\begin{aligned} |b_k(z)|^2 - |a_k(z)|^2 &= |\mu_k|^2 |d_k(z) \eta_k(z)|^2 \\ &= |\mu_k \eta_1(z)|^2 \quad \text{on } \mathbb{T}. \end{aligned}$$

But $a_k(z) \rightarrow 0$, whereas $b_k(z)$ and $\eta_1(z)$ are polynomials that have no root in \mathbb{D} and have value one at the origin. Therefore

$$b_k(z) \rightarrow \eta_1(z),$$

and $\mu_k \rightarrow 1$, when $k \rightarrow \infty$. \square

Theorem 4.17 provides a general recursive scheme in the form of relations (4.3), (4.5)–(4.7), for obtaining the spectral factor of a rational \mathbb{U} -function $f_1(z) = a_1(z)/b_1(z)$ as summarized below:

1. Select a sequence of points $(z_k$ in \mathbb{D} : $k = 1, 2, \dots$) satisfying (3.4).

Iterate step 2 for $k = 1, 2, 3, \dots$:

2. Given $(a_k(z), b_k(z))$ compute $(a_{k+1}(z), b_{k+1}(z))$ using (4.7), and λ_{k+1} using

$$\lambda_{k+1} = \frac{1 - |c_k|^2}{1 - |w_k|^2} \lambda_k,$$

with $\lambda_1 = 1$, and the parameters w_k and c_k obtained from (4.3) and (4.6) respectively.

3. Then as $k \rightarrow \infty$, $b_k(z)$ approaches the spectral numerator of $f_1(z)$ and $\lambda_k b_k(z)/b_1(z)$ approaches the canonical spectral factor of $f_1(z)$.

The choice of the sequence $(z_k, k = 1, 2, \dots)$ is arbitrary provided they do not converge too fast towards the boundary; i.e., condition (3.4) of the theorem is met. However, the choice of this sequence influences the speed of the convergence $b_k(z) \rightarrow \eta_1(z)$. But the convergence itself is guaranteed by the theorem. It appears that the choice of the z_k 's in the vicinity of the roots of η_1 results in a relatively fast convergence. This may potentially be useful when η_1 has roots on or very near the boundary of \mathbb{D} . However, a thorough analysis of the numerical properties and speed of convergence will be pursued elsewhere.

5. Proof of Theorem 3.3. Define $\mathbb{C} := \{F(z) \text{ analytic and with positive real part in } \mathbb{D}\}$. (\mathbb{C} for Caratheodory; also the class of positive real functions.) With any function f in \mathbb{U} we associate the function

$$(5.1) \quad F(z) = \frac{1 - f(z)}{1 + f(z)} \quad \text{for } z \in \mathbb{D}.$$

It is well known that F is a \mathbb{C} -function. (In fact (5.1) sets up a bijective correspondence between \mathbb{U} and \mathbb{C} .) Also, the condition $f(0) = 0$, which appeared earlier, translates into $F(0) = 1$.

The real part of $F(z)$ is defined almost everywhere on \mathbb{T} and is equal to

$$(5.2) \quad \tau(\theta) := \operatorname{Re} \{F(e^{i\theta})\} = \frac{1 - |f(e^{i\theta})|^2}{|1 + f(e^{i\theta})|^2} \quad \text{a.e. on } \mathbb{T}.$$

The function $1 + f$ has no root in \mathbb{D} . Hence, $\ln |1 + f|$ is a harmonic function in \mathbb{D} . Provided $f(0) = 0$, $\ln |1 + f(z)|$ has value at the origin equal to zero. Therefore, the integral of $\ln |1 + f(e^{i\theta})|$ in the interval $[-\pi, \pi]$ is equal to zero. Then, by applying $\ln(\cdot)$ to both sides in (5.2) and integrating we derive that

$$(5.3) \quad \int_{-\pi}^{\pi} \ln [\tau(\theta)] d\theta = \int_{-\pi}^{\pi} \ln [1 - |f(e^{i\theta})|^2] d\theta.$$

The above integral plays a key role in an approximation problem for analytic functions (Szegő's Theorem—see Grenander and Szegő [16]):

$$\begin{aligned} & \inf \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} |p(e^{i\theta})|^2 \tau(\theta) d\theta : p(z) \text{ polynomial with } p(0) = 1 \right\} \\ &= \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln [\tau(\theta)] d\theta \right\}. \end{aligned}$$

(The left-hand side of the above equality can be seen as the error of approximating 1 with polynomials vanishing at the origin, in $L^2[\tau(\theta)d\theta]$.) In general *the infimum is attained for a function $p_0(z)$ in H^2* —the subspace of L^2 functions with analytic continuation inside \mathbb{D} . (This in general is not a polynomial and turns out to be a scalar multiple of the inverse of the canonical spectral factor corresponding to $\tau(\theta)$.) Hence,

$$(5.4) \quad (2\pi)^{-1} \int_{-\pi}^{\pi} |p_0(e^{i\theta})|^2 \tau(\theta) d\theta = \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln [\tau(\theta)] d\theta \right\},$$

where $p_0(0) = 1$.

Let now $(z_k, k = 1, 2, \dots)$ be a sequence of points in \mathbb{D} . Define $K_n := (zB_n(z)H^2)^\perp$, where $B_n(z)$ denotes the Blaschke product corresponding to the first n “interpolation” points

$$B_n(z) := \prod_{k=1}^n \frac{(z - z_k)}{(1 - \bar{z}_k z)},$$

and “ $^\perp$ ” denotes the “orthogonal complement of.” K_n is a finite dimensional linear space. Let $\tau(\theta)$ be the real part of a \mathbb{C} -function $F(z)$ for $z = e^{i\theta}$. Then $\tau(\theta)$ is defined a.e. in $[-\pi, \pi]$ and it is a nonnegative valued function. K_n can be endowed with an inner product defined by

$$\langle f, g \rangle_\tau := (2\pi)^{-1} \int_{-\pi}^{\pi} f(e^{i\theta}) \overline{g(e^{i\theta})} \tau(\theta) d\theta,$$

and then we will use the obvious notation $\|p(z)\|_{\tau(\theta)}^2$. Bultheel and Dewilde [4, Cor. 1] and Dewilde and Dym [8, Lemma 4.3] have considered approximation with functions in K_n and have shown that

$$(5.5) \quad \inf \{ \|p(z)\|_{\tau(\theta)}^2 : p(z) \text{ in } K_n \text{ and } p(0) = 1 \} = \prod_{k=1}^n \left(\frac{1 - |c_k|^2}{1 - |w_k|^2} \right).$$

Clearly,

$$\begin{aligned} \inf \{ \|p(z)\|_{\tau(\theta)}^2 : p(z) \text{ in } K_n \text{ and } p(0) = 1 \} &\geq \|p_0(z)\|_{\tau(\theta)}^2 \\ &= \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln [\tau(\theta)] d\theta \right\} = \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln [1 - |f(e^{i\theta})|^2] d\theta \right\}. \end{aligned}$$

In order to prove the theorem, we need to establish that the above holds with equality. To show this it suffices to show that

$$K := \bigcup_{n=1}^{\infty} K_n \text{ is dense in } H^2$$

with respect to $\langle \cdot, \cdot \rangle_{\tau(\theta)}$.

We now briefly indicate that it is sufficient to show that the aforementioned space is dense in H^2 with respect to the standard norm. Since f is a rational function, it can be readily shown that $\tau(\theta) = |g(e^{i\theta})|^2$ where $g(z)$ is a rational function with no poles on the unit circle (since $g(z)$ is an outer function). This implies that $\tau(\theta)$ is bounded from above for all $\theta \in [-\pi, \pi]$. Consequently, convergence in the standard norm implies convergence in $\|\cdot\|_{\tau(\theta)}^2$ and this establishes our claim.

Now we shall use a classical result of Blaschke, which states that

$$(5.6) \quad \sum_{k=1}^{\infty} (1 - |z_k|) = \infty,$$

holds if and only if $B_n(z)$ tends to zero at every point in \mathbb{D} as $n \rightarrow \infty$. Any function q in H^2 that is orthogonal to K belongs to $zB_n H^2$, for all n . Therefore, q must be the zero function. Hence the closure of K is in fact the whole of H^2 . Therefore (5.6) implies that

$$(5.7) \quad \liminf_{n \rightarrow \infty} \{ \|p(z)\|_{\tau(\theta)}^2 : p \in K_n \text{ and } p(0) = 1 \} = \|p_0(z)\|_{\tau(\theta)}^2$$

and consequently that

$$\lim_{n \rightarrow \infty} \prod_{k=1}^n \left(\frac{1 - |c_k|^2}{1 - |w_k|^2} \right) = \exp \left\{ (2\pi)^{-1} \int_{-\pi}^{\pi} \ln [1 - |f(e^{i\theta})|^2] d\theta \right\}.$$

This completes the proof of the theorem. \square

6. Remarks on spectral factorization of \mathbb{C} -functions. So far we have considered spectral factorization of rational \mathbb{U} -functions. In many cases one is given a \mathbb{C} -function $F(z)$ instead. So let

$$F(z) = \frac{\pi(z)}{\chi(z)} \quad \text{be in } \mathbb{C},$$

where $\pi(z)$ and $\chi(z)$ are polynomials in z . Then

$$\operatorname{Re} \{ F(e^{i\theta}) \} = \frac{\pi(z)\bar{\chi}(z^{-1}) + \chi(z)\bar{\pi}(z^{-1})}{\chi(z)\bar{\chi}(z^{-1})} \geq 0 \quad \text{for } z = e^{i\theta},$$

and assumes a factorization

$$\operatorname{Re} \{ F(e^{i\theta}) \} = \frac{|\kappa\eta(z)|^2}{|\chi(z)|^2} \quad \text{for } z = e^{i\theta}, \quad \theta \in [-\pi, \pi],$$

where κ is a positive constant and $\eta(z)$ can be assumed to have no root in \mathbb{D} and to have value equal to one at the origin. Then $\kappa\eta(z)/\chi(z)$ is called the *canonical spectral factor* of $F(z)$, and $\eta(z)$ will be said to be the *spectral numerator* of $F(z)$.

With no loss in generality we may assume that $F(0) = 1$. From (6.1) we can obtain an associated function

$$f(z) = \frac{1 - F(z)}{1 + F(z)} = \frac{a(z)}{b(z)}$$

of class \mathbb{U} . Then $a(z) := \chi(z) - \pi(z)$ and $b(z) := \chi(z) + \pi(z)$ are also polynomials. Let $\eta(z)$ be the spectral numerator of $f(z)$, and

$$g_f(z) = \frac{\kappa\eta(z)}{b(z)}$$

be the canonical spectral factor of f . Then, from (6.1)–(6.2) we obtain that

$$\operatorname{Re}\{F(e^{i\theta})\} = \frac{|\kappa\eta(z)|^2}{|b(z) + a(z)|^2} = \frac{|\kappa\eta(z)|^2}{|\chi(z)|^2} \quad \text{for } z = e^{i\theta}, \quad \theta \in [-\pi, \pi],$$

and the spectral factor of $F(z)$ is $\kappa\eta(z)/\chi(z)$. Thus, the spectral numerator of both $F(z)$ and $f(z)$ is the same. Therefore, when looking for the spectral factor of F , we may consider the corresponding \mathbb{U} -function $f(z)$. Then take

$$a(z) = \chi(z) - \pi(z) \quad \text{and} \quad b(z) = \chi(z) + \pi(z),$$

and apply the algorithm of Theorem 4.17 given by (4.3), (4.5)–(4.7) and an appropriate choice of points $(z_k \in \mathbb{D}, k = 1, 2, \dots)$ to obtain the spectral numerator $\eta(z)$. The algorithm expressed by (4.3), (4.5)–(4.7) can be written directly in terms of polynomial fractions of \mathbb{C} -functions. However, this offers no advantage over (4.3), (4.5)–(4.7), which seem to be simpler and thus preferable.

AVERAGING AND DETERMINISTIC OPTIMAL CONTROL*

F. CHAPLAIS†

Abstract. Averaging is often used in ordinary differential equations when dealing with fast periodic phenomena. It is shown here that it can be used efficiently in optimal control. As the period tends to zero, a limit or “averaged” problem is defined. The open loop optimal control of the limit problem induces a cost which is optimal up to the second order when evaluated through the original dynamics. The definition of the averaged problem is then generalized to the nonperiodic case. It is shown that the Bellman function of the original “fast” problem tends uniformly on any compact set to that of the averaged problem.

Key words. averaging, optimal control, time scales, perturbations in control, Hamilton–Jacobi equations

AMS(MOS) subject classifications. 34C29, 41A60, 4900, 49C20

Introduction: A perturbation approach. Averaging can be seen as part of the perturbation theory of differential equations. Consider

$$(1) \quad \frac{dx}{dt} = f^\varepsilon(x, t), \quad x(0) = x_0, \quad x(t) \in \mathbf{R}^n, \quad t \in [0, T].$$

Regular perturbations correspond to the situation when f^ε has a limit in $C^0(\mathbf{R}^n \times [0, T], \mathbf{R}^n)$ as ε tends to zero. Singular perturbations [6] can be seen as f^ε having a limit in $L^2(\mathbf{R}^n \times [0, T], \mathbf{R}^n)$. Roughly speaking, averaging is the case when f^ε has a limit in $L^2(\mathbf{R}^n \times [0, T], \mathbf{R}^n)$ in the weak topology. As an example, consider

$$(2) \quad \frac{dx}{dt} = f\left(x, t, \frac{t}{\varepsilon}\right)$$

where f is periodic in the last variable. Define $f^\varepsilon(x, t) = f(x, t, t/\varepsilon)$; clearly f^ε has no limit either pointwise or in L^2 ; yet f^ε tends to f^0 defined by $f^0(x, t) = 1/\omega \int_0^\omega f(x, t, \theta) d\theta$, weakly in L^2 .

It is well known [1] that the solution of (2) can be approximated by the solution of

$$(3) \quad \frac{dy}{dt} = f^0(y, t), \quad y(0) = x_0$$

with an error of order $\varepsilon\omega$, provided that f be regular enough. Solving (3) instead of (2) is known as “averaging”.

What is good for differential equations is often good for optimal control. Regular and singular perturbations have been extensively studied ([2], [6]). As far as averaging is concerned, it has been studied in the context of partial differential equations [3] or stochastic optimal control [5]. We present here some approximation results in deterministic optimal control.

1. The periodic case.

1.1. The averaged problem. Let

$$f: \mathbf{R}^n \times \mathbf{R}^p \times [0, T] \times \mathbf{R} \rightarrow \mathbf{R}^n, \\ (x, u, t, \theta) \rightarrow f(x, u, t, \theta),$$

* Received by the editors February 3, 1986; accepted for publication (in revised form) May 5, 1986.

† Centre d'Automatique et Informatique de l'Ecole Nationale Supérieure des Mines de Paris, 35, rue Saint-Honoré, 77305 Fontainebleau Cedex, France.

$$L: \mathbf{R}^n \times \mathbf{R}^p \times [0, T] \times \mathbf{R} \rightarrow \mathbf{R},$$

$$(x, u, t, \theta) \rightarrow L(x, u, t, \theta),$$

with f and L periodic in θ with a period ω independent of x, u and t (regularity will be considered in § 1.2). Let U^{ad} be a constraint domain and $W^{ad} = \{u \in L^2([0, T], \mathbf{R}^p), u(t) \in U^{ad} \text{ for almost every } t\}$ the set of admissible controls. We define the problem (P^ε) as:

$$(4) \quad \left. \begin{aligned} \frac{dx}{dt} &= f\left(x(t), u(t), t, \frac{t}{\varepsilon}\right), \quad x(0) = x_0, \\ \text{Minimize } \int_0^T L\left(x(t), u(t), t, \frac{t}{\varepsilon}\right) dt &\text{ in } W^{ad}, \end{aligned} \right\} (P^\varepsilon).$$

We define the associated problem \bar{P} as follows:

$$(5) \quad \left. \begin{aligned} V^{ad} &= \{v \in L^2([0, T] \times [0, \omega], \mathbf{R}^p), v(t, \theta) \in U^{ad} \text{ a.e. } (t, \theta)\}, \\ \frac{dy}{dt} &= \frac{1}{\omega} \int_0^\omega f(y(t), v(t, \theta), t, \theta) d\theta, \quad y(0) = x_0, \\ \text{Minimize } \int_0^T \frac{dt}{\omega} \int_0^\omega L(y(t), v(t, \theta), t, \theta) d\theta &\text{ in } V^{ad}, \end{aligned} \right\} (\bar{P}).$$

Problem (4) can be seen as the perturbation of (5) by a fast oscillating input of null average. Notice that if f is Lipschitz in x and measurable in u, t, θ , then, for v in V^{ad} , the average \bar{f} of f as defined in (5) is Lipschitz in x and measurable in t . Hence, both (4) and (5) have a unique solution over $[0, T]$.

Remark 1. At first sight, it would seem reasonable to consider in (5) the averages of f and L in θ *independently* of u , that is, u being a constant vector in \mathbf{R}^p and not a function in $L^2([0, \omega], \mathbf{R}^p)$. This amounts to restricting V^{ad} to controls which are constant over $[0, \omega]$ at time t . As we shall see, this may lead to a severe loss of optimality when ε tends to 0. In short, it is necessary to have a feedback on the fast time θ . Consider for instance the following problem: $n = p = 1$, $U^{ad} = \mathbf{R}$, $f(x, u, t, \theta) = -x + u \sin(\theta)$ and $L(x, u, t, \theta) = x^2 + (u^2/6)$. If u is independent of θ , the average of f is equal to $-x$, which is itself independent of u . Within this class of functions, the optimal cost for (P^ε) is asymptotically equal to $\bar{J}(0)$, if $\bar{J}(u)$ denotes the cost of u in (\bar{P}) . $\bar{J}(0)$ is equal to $x_0^2(1 - e^{-2T})/2$.

Now use our definition of the averaged problem to compute a better control. Let q be the solution of the Riccati equation of the averaged problem: $dq/dt = 3q^2 + 2q - 1$, $q(T) = 0$; then $q(0) = (1 - e^{-4T})/(3 + e^{-4T})$. Define z by $dz/dt = -z(1 + 3q)$, $z(0) = x(0)$; z is the optimal trajectory for the averaged problem. Now use the open-loop control $u^\varepsilon(t) = -6q(t)z(t) \sin(t/\varepsilon)$ in problem (P^ε) . Then it is easy to see that x^ε driven by u^ε in (4) is asymptotic to z . Hence the cost of u^ε in (P^ε) is asymptotic to $\int_0^T z^2(t) \times (1 + 3q^2(t)) dt$. Thanks to the Riccati equation, the latter quantity is equal to $q(0)x^2$, which is smaller than $\bar{J}(0)$; thus for ε small enough, u^ε is better than any "slow" control.

Notice that the same phenomenon can be observed in stochastic optimal control, where it is well known that open-loop controls alone are not enough to ensure optimality. In both cases this is due to the presence of averages w.r.t. the events or fast time in the problem (the same can be said of the "ordinary," "slow" time, of course).

Remark 2. Even though the controls of problem (\bar{P}) are in an infinite dimensional state, the minimum principle and dynamic programming apply; the important fact is that the state is finite-dimensional. One also checks that the Bellman function is the viscosity solution of the Hamilton-Jacobi-Bellman equation [7].

Let $\bar{f}(x, v, t)$ denote the average of f and \bar{L} the average of L . The adjoint state equations for the problem (\bar{P}) are:

$$\frac{dp}{dt} = -\frac{\partial \bar{f}^T}{\partial x} p - \frac{\partial \bar{L}}{\partial x}, \quad p(T) = 0$$

and if v^* is an optimal control for the problem (\bar{P}) , the minimum principle says that $v^*(t, \cdot)$ minimizes the Hamiltonian of (\bar{P}) , that is, $p(t)^T \bar{f}(x, v, t) + \bar{L}(x, v, t)$, with respect to v in V^{ad} . This is equivalent to: $v^*(t, \theta)$ minimizes $p(t)^T f(x, v, t, \theta) + L(x, v, t, \theta)$ with respect to v in U^{ad} , this for almost every θ . We see that the control appears naturally as a feedback on the fast time (cf. Remark 1).

Remark 3. (\bar{P}) is better conditioned numerically than (P^ε) , since (P^ε) involves a time grid of order $\delta t/\varepsilon$, while (\bar{P}) involves only a grid of order δt , at least in the simulation part. A time grid in $\delta t/\varepsilon$ is still needed to compute the averages and to minimize the Hamiltonian.

1.2. An approximation theorem. The averaged problem is used here to compute a near optimal control for the problem (P^ε) , with an error of order ε^2 . The proof and assumptions are close to those used in [2].

Assumptions.

- (H1) $U^{ad} = \mathbf{R}^p$; no constraint.
- (H2) L does not depend on θ ; f and L are C^0 , of class C^2 in x , and u ; the first- and second-order derivatives of f are bounded, and Lipschitz; the second-order derivatives of L are bounded, and Lipschitz.
- (H3) (\bar{P}) has a solution, with optimal control u_0 , trajectory y and adjoint state q .
- (H4) Let $H(p, x, u, t, \theta) = p^T f(x, u, t, \theta) + L(x, u, t, \theta)$. There exists $\beta > 0$ such that, for all (x, u, t, θ) , $\partial^2 H / \partial v^2$ is greater than β Identity at point $(q(t), x, u, t, \theta)$, in the sense of the cone of positive semidefinite matrices.
- (H5) One has

$$\left[\frac{\partial^2 H}{\partial x^2} - \frac{\partial^2 H}{\partial x \partial v} \left(\frac{\partial^2 H}{\partial v^2} \right)^{-1} \frac{\partial^2 H}{\partial v \partial x} \right] \geq 0 \quad \text{at } (q(t), x, u, t, \theta) \text{ for all } (x, u, t, \theta).$$

- (H6) $f(y(t), u_0(t, \theta), t, \theta)$ and $\frac{\partial H}{\partial x}(q(t), y(t), u_0(t, \theta), t, \theta)$ are C^1 in t with a Lipschitz derivative.

Assumptions (H4) and (H5) ensure sufficient regularity of the control with respect to the cost. Assumption (H6) is specific to averaging: if it did not hold, there would not be a true separation of time scales.

THEOREM 1. *Let f and L meet Assumptions (H1)–(H6). Define u^ε by $u^\varepsilon(t) = u_0(t, t/\varepsilon)$. Then u^ε is near optimal for the problem (P^ε) with an error on the cost of order ε^2 .*

Sketch of proof. (A detailed proof can be found in [4].) We will proceed in two stages. First, we will exhibit a lower bound of the cost for any control u . We will then show that the control u^ε induces a cost which approximates this lower bound with an error of order ε^2 . It is then easy to conclude that u^ε is near optimal for the problem (P^ε) .

Remark 4. Unless otherwise stated, all partial derivatives will be taken at time t , with x being $y(t)$, u being $u_0(t, t/\varepsilon) = u^\varepsilon(t)$, θ being t/ε and the adjoint state being $q(t)$. We will make use of the following conventions: if $g(\sigma, \theta)$ is a periodic function

of θ , we will denote by $\bar{g}(\sigma)$ or $\bar{g}(\sigma, \cdot)$ or $\text{av}(g(\sigma, \cdot))$ the average of g in θ . We then define the operator Π on periodic functions g , by $\Pi(g(\sigma, \cdot))$ being the only primitive in θ of $g - \bar{g}$ with a null average. Π plays a key role in all developments of integrals or solutions of differential equations involving a periodicity in fast time. Finally, the superscript T denotes transposition.

LEMMA 1. Let $x_2(t, \theta) = \Pi(f(y(t), u_0(t, \cdot), t, \cdot)(\theta))$. There exists $\varepsilon_0 > 0$, $k \geq 0$, such that, for any control u and any $\varepsilon \in]0, \varepsilon_0[$, x being the trajectory driven by u in (4), the following estimation holds:

$$\begin{aligned} \int_0^T L(x(t), u(t), t) dt &\geq \int_0^T L\left(y(t), u_0\left(t, \frac{t}{\varepsilon}\right), t\right) dt \\ &\quad + \varepsilon \int_0^T \text{av} \left[\frac{\partial H}{\partial x}(y(t), q(t), u_0(t, \cdot), t, \cdot) x_2(t, \cdot) \right] dt \\ &\quad - \varepsilon q(0)^T x_2(0, 0) - k\varepsilon^2. \end{aligned}$$

Proof of Lemma 1. We will denote by \tilde{x} and \tilde{u} the following errors:

$$\tilde{x}(t) = x(t) - y(t) - \varepsilon x_2\left(t, \frac{t}{\varepsilon}\right), \quad \tilde{u}(t) = u(t) - u_0\left(t, \frac{t}{\varepsilon}\right).$$

It should be noticed that, if x_1 is defined by

$$(6) \quad \frac{dx_1}{dt} = \frac{\partial \tilde{f}}{\partial x} x_1 + \frac{\partial \tilde{f}}{\partial x} x_2, \quad x_1(0) + x_2(0, 0) = 0$$

and if $\tilde{u} = 0$ (that is, x is the trajectory driven by u^ε), then $y + \varepsilon x_1 + \varepsilon x_2(t, t/\varepsilon)$ is a uniform approximation of x with an ε^2 error.

We will use developments of functions with integral remains. To this end, we will use the following notation: for λ in $[0, 1]$, μ in $[0, 1]$, $F_t(\lambda, \mu)$ will denote the Hessian symmetric operator associated with the second-order derivatives of f in x and u , at point $(y(t), \lambda \mu(\varepsilon x_2(t, t/\varepsilon) + \tilde{x}(t)), u_0(t, t/\varepsilon) + \lambda \mu \tilde{u}(t), t, t/\varepsilon)$. $L_t(\lambda, \mu)$ will denote the analogue for L and $H_t(\lambda, \mu) = q^T(t) F_t(\lambda, \mu) + L_t(\lambda, \mu)$ will denote the Hessian of H at the same point.

We will also make use of the following linear quadratic oscillatory “tangent” problem:

$$(7) \quad \left. \begin{aligned} \frac{dz}{dt} &= \frac{\partial f}{\partial x} \left(z + x_2\left(t, \frac{t}{\varepsilon}\right) \right) + \frac{\partial f}{\partial u} v, \quad z(0) + x_2(0, 0) = 0, \\ \text{Min}_v \int_0^T &\left[\frac{1}{2} (z^T, v^T) H_t(0, 0) (z^T, v^T)^T + p_2^T \left(t, \frac{t}{\varepsilon} \right) \left(\frac{\partial f}{\partial x} z + \frac{\partial f}{\partial u} v \right) \right] dt, \end{aligned} \right\} (TP^\varepsilon)$$

where $p_2 = -\Pi(\partial H^T / \partial x)$. p_2 is the analogue of x_2 for the adjoint state.

Thanks to (H4) and (H5), (TP^ε) has a unique solution with trajectory y_1 , optimal control v_1 and adjoint state q_1 . Moreover, $\|y_1\|_\infty$ and $\|v_1\|_\infty$ are bounded when ε ranges within a neighbourhood of zero. Finally estimates will bear on the quantity

$$z_\varepsilon^2 = \int_0^1 \lambda d\lambda \int_0^1 d\mu \|Z_\varepsilon(\lambda, \mu)\|_{L^2}^2$$

where

$$\begin{aligned} Z_\varepsilon(\lambda, \mu)(t) &= v(t) + \left[\left(\frac{\partial^2 H}{\partial v^2} v \right)^{-1} \frac{\partial^2 H}{\partial v \partial x} \right] \left(r(t) + \varepsilon x_2\left(t, \frac{t}{\varepsilon}\right) \right), \\ r &= \tilde{x} - \varepsilon y_1, \quad v = \tilde{u} - \varepsilon v_1, \end{aligned}$$

the derivatives being taken at the same interpolation points as for $F_t(\lambda, \mu)$, $L_t(\lambda, \mu)$ and $H_t(\lambda, \mu)$.

At last, \approx will denote an approximation with an ε^2 error.

LEMMA 1.1.

$$\begin{aligned} \int_0^T L(x, u, t) dt &\approx \int_0^T L(y, u^\varepsilon, t) dt + \varepsilon \int_0^T \frac{\partial \bar{H}}{\partial x} x_2 dt - \varepsilon q(0)^T x_2(0, 0) \\ &\quad + \int_0^T \left[\frac{\partial H}{\partial x} - \frac{\partial \bar{H}}{\partial x} \right] \tilde{x} dt \\ &\quad + \int_0^T dt \int_0^1 \lambda d\lambda \int_0^1 d\mu \left(\tilde{x}^T + \varepsilon x_2^T \left(t, \frac{t}{\varepsilon} \right), \tilde{u}^T \right) H_t(\lambda, \mu) \\ &\quad \times \begin{pmatrix} \tilde{x} + \varepsilon x_2(t, t/\varepsilon) \\ \tilde{u} \end{pmatrix}. \end{aligned}$$

Proof of Lemma 1.1. The cost is expanded at the second order using an integral remain. Since there is no constraint, $q^T(\partial f/\partial u) + (\partial L/\partial u) = 0$; the Hamiltonian appears after a classical integration by parts. We then neglect all integrals depending on fast time when of order larger than or equal to ε^2 .

LEMMA 1.2. *There exists $k \geq 0$ such that*

$$\|r\|_\infty^2 \leq k(\varepsilon^2 + z_\varepsilon^2) \quad \text{and} \quad \|v\|_{L^2}^2 \leq k(\varepsilon^2 + z_\varepsilon^2).$$

Proof of Lemma 1.2.

$$\begin{aligned} \frac{dr}{dt} &= \frac{dx}{dt} - \frac{dy}{dt} - \varepsilon \frac{d}{dt} \left(x_2 \left(t, \frac{t}{\varepsilon} \right) \right) - \varepsilon \frac{dy_1}{dt} \\ (8) \quad &= f \left(r + y + \varepsilon x_2 + \varepsilon y_1, v + u_0 + \varepsilon v_1, t, \frac{t}{\varepsilon} \right) - f \left(y, u_0 \left(t, \frac{t}{\varepsilon} \right), t, \frac{t}{\varepsilon} \right) - \varepsilon \frac{\partial f}{\partial x} (y_1 + x_2) \\ &\quad - \varepsilon \frac{\partial f}{\partial u} v_1 - \varepsilon \Pi \left[\frac{\partial}{\partial t} (f(y, u_0(t, \cdot), t, \cdot)) \right] \left(\frac{t}{\varepsilon} \right), \end{aligned}$$

since $\partial/\partial\theta[\Pi(f)] = f - \bar{f}$. The second expression is equal to

$$\begin{aligned} &f \left(r + y + \varepsilon x_2 + \varepsilon y_1, v + u_0 + \varepsilon v_1, t, \frac{t}{\varepsilon} \right) - f \left(y + \varepsilon x_2 + \varepsilon y_1, u_0 + \varepsilon v_1, t, \frac{t}{\varepsilon} \right) \\ &\quad + \varepsilon^2 \int_0^1 \lambda d\lambda \int_0^1 d\mu (x_2^T + y_1^T, v_1^T) F_t(\lambda, \mu) \begin{pmatrix} x_2 + y_1 \\ v_1 \end{pmatrix} - \varepsilon \Pi \left[\frac{\partial}{\partial t} (f) \right] \left(\frac{t}{\varepsilon} \right). \end{aligned}$$

v then appears as a difference in the controls and is replaced by

$$Z_\varepsilon(\lambda, \mu) - \left[\left(\frac{\partial^2 H}{\partial v^2} \right)^{-1} \frac{\partial^2 H}{\partial v \partial x} \right] (r + \varepsilon x_2).$$

Using the Gronwall lemma, and neglecting the integrals of fast periodic functions at the second order, we get the estimate on $\|r\|_\infty$. The estimation on $\|v\|_{L^2}$ is obtained through the definition of Z_ε .

LEMMA 1.3. *r can be approximated uniformly with an error of order ε^2 by r_1 , with*

$$\begin{aligned} (9) \quad \frac{dr_1}{dt} &= f \left(r_1 + y + \varepsilon x_2 + \varepsilon y_1, v + u_0 + \varepsilon v_1, t, \frac{t}{\varepsilon} \right) - f \left(y + \varepsilon x_2 + \varepsilon y_1, u_0 + \varepsilon v_1, t, \frac{t}{\varepsilon} \right), \\ r_1(0) &= 0. \end{aligned}$$

In particular, one has $\|r_1\|_\infty^2 \leq 2k(\varepsilon^2 + z_\varepsilon^2)$.

Proof of Lemma 1.3. Note that (9) is close to (8). We then get the result by using the Gronwall lemma. We will now use r_1 rather than r .

LEMMA 1.4. *There exists $k \geq 0$ such that, for $\varepsilon \in]0, 1]$:*

$$\int_0^T \left(\frac{\partial H}{\partial x} - \frac{\partial \bar{H}}{\partial x} \right) \tilde{x} dt \geq \varepsilon \int_0^T p_2^T \left(t, \frac{t}{\varepsilon} \right) \left[\frac{\partial f}{\partial x} r_1 + \frac{\partial f}{\partial u} v \right] dt - k\varepsilon^2 - k\varepsilon z_\varepsilon^2.$$

Proof of Lemma 1.4.

$$-\varepsilon \frac{d}{dt} \left(p_2^T \left(t, \frac{t}{\varepsilon} \right) \right) = \varepsilon \Pi \left[\frac{\partial}{\partial t} \left(\frac{\partial H}{\partial x} (q(t), y(t), u_0(t, \cdot), t, \cdot) \right) \right] \left(\frac{t}{\varepsilon} \right) + \frac{\partial H}{\partial x} - \frac{\partial \bar{H}}{\partial x}$$

and $\tilde{x} \approx r_1 + \varepsilon y_1$. Hence, integrating by parts, and neglecting second order terms,

$$\begin{aligned} \int_0^T \left(\frac{\partial H}{\partial x} - \frac{\partial \bar{H}}{\partial x} \right) \tilde{x} dt &\approx -\varepsilon \int_0^T \Pi \left[\frac{\partial}{\partial t} \left(\frac{\partial H}{\partial x} (q, y, u_0(t, \cdot), t, \cdot) \right) \right] \left(\frac{t}{\varepsilon} \right) r_1 dt \\ &\quad + \varepsilon \int_0^T p_2^T \left(t, \frac{t}{\varepsilon} \right) \left[f \left(x, u, t, \frac{t}{\varepsilon} \right) - f \left(x - r_1, u - v, t, \frac{t}{\varepsilon} \right) \right] dt. \end{aligned}$$

But

$$\begin{aligned} &\varepsilon \int_0^T p_2^T \left(t, \frac{t}{\varepsilon} \right) \left[f \left(x, u, t, \frac{t}{\varepsilon} \right) - f \left(x - r_1, u - v, t, \frac{t}{\varepsilon} \right) \right] dt \\ &\quad \geq \varepsilon \int_0^T p_2^T \left(t, \frac{t}{\varepsilon} \right) \left[\frac{\partial f}{\partial x} r_1 + \frac{\partial f}{\partial u} v \right] dt - k\varepsilon \int_0^T \left| p_2^T \left(t, \frac{t}{\varepsilon} \right) \right| (|r_1|^2 + |v|^2) dt \\ &\quad \geq \varepsilon \int_0^T p_2^T \left(t, \frac{t}{\varepsilon} \right) \left[\frac{\partial f}{\partial x} r_1 + \frac{\partial f}{\partial u} v \right] dt - k\varepsilon (\varepsilon^2 + z_\varepsilon^2) \end{aligned}$$

by Lemma 1.2. On the other hand,

$$\begin{aligned} &\varepsilon \int_0^T \Pi \left[\frac{\partial}{\partial t} \left(\frac{\partial H}{\partial x} (q, y, u_0(t, \cdot), t, \cdot) \right) \right] \left(\frac{t}{\varepsilon} \right) r_1 dt \\ &\quad = \varepsilon \left\{ \int_0^T \Pi \left[\frac{\partial}{\partial t} \left(\frac{\partial H}{\partial x} (q, y, u_0(t, \cdot), t, \cdot) \right) \right] \left(\frac{t}{\varepsilon} \right) dt \right\} r_1(T) \\ &\quad \quad - \varepsilon \int_0^T \left\{ \int_0^t \Pi \left[\frac{\partial}{\partial t} \left(\frac{\partial H}{\partial x} (q, y, u_0(s, \cdot), s, \cdot) \right) \right] \left(\frac{s}{\varepsilon} \right) ds \right\} \frac{dr_1}{dt} dt \\ &\quad \geq -k\varepsilon^2 \left(\|r_1\|_\infty + \left\| \frac{dr_1}{dt} \right\|_{L^1} \right), \end{aligned}$$

by averaging estimations. But, from (9) and Lemmas 1.2 and 1.3, one sees that there exists $k > 0$ such that $\|dr_1/dt\|_{L^1} \leq k(1 + z_\varepsilon^2)$; this completes the proof.

We are now going to study the second order term with $H_t(\lambda, \mu)$ in Lemma 1.1.

LEMMA 1.5. *There exists $k > 0$ such that:*

$$\begin{aligned} &\int_0^1 dt \int_0^1 \lambda d\lambda \int_0^1 d\mu (\tilde{x}^T + \varepsilon x_2^T, \tilde{u}^T) H_t(\lambda, \mu) \begin{pmatrix} \tilde{x} + \varepsilon x_2 \\ v \end{pmatrix} \\ &\quad \geq 2\varepsilon \int_0^1 dt \int_0^1 \lambda d\lambda \int_0^1 d\mu (y_1 + v_1^T) H_t(\lambda, \mu) \begin{pmatrix} r + \varepsilon x_2 \\ v \end{pmatrix} - k\varepsilon^2 + \beta z_\varepsilon^2. \end{aligned}$$

Proof of Lemma 1.5. By substituting $Z_\varepsilon - [(\partial^2 H / \partial v^2)^{-1} \partial H / \partial v \partial x](r + \varepsilon x_2)$ to v in the integral and using Assumptions (H4) and (H5), one shows that the expression on the left-hand side is greater than $\int_0^1 dt \int_0^1 \lambda d\lambda \int_0^1 d\mu \beta |Z_\varepsilon(\lambda, \mu)(t)|^2$, that is, βz_ε^2 .

This will be the only positive term in z_ε^2 ; the others will be of the form $-k\varepsilon z_\varepsilon^2$.

Note that Lemma 1.4 already displays one part of the cost to be minimized in problem (TP^ε) . The other part will appear by replacing $H_t(\lambda, \mu)$ by $H_t(0, 0)$ in the estimates of Lemma 1.5.

LEMMA 1.6. *There exists $k \geq 0$ such that:*

$$\begin{aligned} 2\varepsilon \int_0^T dt \int_0^1 \lambda d\lambda \int_0^1 d\mu (y_1^T, v_1^T) H_t(\lambda, \mu) \begin{pmatrix} r + \varepsilon x_2 \\ v \end{pmatrix} \\ \geq \varepsilon \int_0^T (y_1^T, v_1^T) H_t(0, 0) \begin{pmatrix} r + \varepsilon x_2 \\ v \end{pmatrix} dt - k\varepsilon^2 - k\varepsilon z_\varepsilon^2. \end{aligned}$$

Proof of Lemma 1.6. Since the second derivatives of f and L are Lipschitz,

$$\|H_t(\lambda, \mu) - H_t(0, 0)\| \leq K\lambda\mu(|x - y|^2 + |u - u_0|^2)^{1/2} = K\lambda\mu(|r + \varepsilon x_2 + \varepsilon y_1|^2 + |v - \varepsilon v_1|^2)^{1/2}.$$

As x_2, y_1 and v_1 are bounded, there exists $k > 0$ such that:

$$\begin{aligned} \varepsilon \left| \int_0^T dt \int_0^1 \lambda d\lambda \int_0^1 d\mu (y_1 + v_1^T) [H_t(\lambda, \mu) - H_t(0, 0)] \begin{pmatrix} r + \varepsilon x_2 \\ v \end{pmatrix} \right| \\ \leq k\varepsilon(\varepsilon^2 + \|r\|_\infty^2 + \|v\|_{L^2}^2). \end{aligned}$$

We get the result from Lemma 2.

LEMMA 1.7. *There exists $k \geq 0$ such that:*

$$\begin{aligned} \int_0^T L(x, u, t) dt &\geq \int_0^T L(x, u^\varepsilon, t) dt + \varepsilon \int_0^T \overline{\frac{\partial H}{\partial x}} x_2 dt - \varepsilon q(0)^T x_2(0, 0) \\ &\quad + \varepsilon \int_0^T p_2^T \left(t, \frac{t}{\varepsilon} \right) \left[\frac{\partial f}{\partial x} r_1 + \frac{\partial f}{\partial u} v \right] dt \\ &\quad + \varepsilon \int_0^T (y_1^T, v_1^T) H_t(0, 0) \begin{pmatrix} r + \varepsilon x_2 \\ v \end{pmatrix} dt + z_\varepsilon^2(\beta - k\varepsilon) - k\varepsilon^2. \end{aligned}$$

Proof of Lemma 1.7. Combine the results of Lemmas 1.1, 1.4, 1.5 and 1.6.

We are going now to complete the estimate by using the problem (TP^ε) .

LEMMA 1.8. *There exists $k \geq 0$ such that:*

$$\varepsilon \int_0^T p_2^T \left(t, \frac{t}{\varepsilon} \right) \left[\frac{\partial f}{\partial x} r_1 + \frac{\partial f}{\partial v} v \right] dt + \varepsilon \int_0^T (y_1^T, v_1^T) H_t(0, 0) \begin{pmatrix} r + \varepsilon x_2 \\ v \end{pmatrix} dt \geq -k\varepsilon(\varepsilon^2 + z_\varepsilon^2).$$

Proof of Lemma 1.8. Transformations using the adjoint equations of (TP^ε) and the explicit value of v_1 as a feedback yield the following estimate for the expression on the left-hand side:

$$\varepsilon \int_0^T q_1^T \left[f \left(x, u, t, \frac{t}{\varepsilon} \right) - f \left(x - r_1, u - v, t, \frac{t}{\varepsilon} \right) - \frac{\partial f}{\partial x} r_1 - \frac{\partial f}{\partial u} v \right] dt$$

which is clearly of second order in $(\|r_1\|^2 + \|v\|_{L^2}^2)^{1/2}$; from Lemmas 1.2 and 1.3 we get the result.

From Lemmas 1.8 and 1.7 the estimation proposed in Lemma 1 is proved for ε sufficiently small to make βz_ε^2 dominant against $-k\varepsilon$. This completes the proof of Lemma 1.

LEMMA 2. *We are going to estimate the cost induced by U^ε .*

Let now $u = u^\varepsilon$, that is $\tilde{u} = 0$. Then:

$$\int_0^T L(x, u^\varepsilon, t) dt \approx \int_0^T L(y, u^\varepsilon, t) dt - \varepsilon q^T(0)x_2(0, 0) + \varepsilon \int_0^t \overline{\frac{\partial H}{\partial x}} x_2 dt.$$

Proof of Lemma 2. We can use Lemma 1.1 to get a first estimate:

$$\begin{aligned} \int_0^T L(x, u^\varepsilon, t) dt &\approx \int_0^T L(x, u^\varepsilon, t) dt - \varepsilon q^T(0)x_2(0, 0) + \varepsilon \int_0^t \overline{\frac{\partial H}{\partial x}} x_2 dt \\ &\quad + \int_0^T \left(\frac{\partial H}{\partial x} - \frac{\partial \bar{H}}{\partial x} \right) \tilde{x} dt \\ &\quad + \int_0^T dt \int_0^1 \lambda d\lambda \int_0^1 d\mu (\tilde{x}^T + \varepsilon x_2^T) \frac{\partial^2 H}{\partial x^2}(\lambda, \mu) (\tilde{x} + \varepsilon x_2) \end{aligned}$$

where $\partial^2 H / \partial x^2$ is computed at the same point as for $H_t(\lambda, \mu)$. Since \tilde{x} is of order one in ε , the last integral is of order two. Proceeding as in Lemma 1.4, we also show that the integral before that one is of order two. This completes the proof of Lemma 2. Theorem 1 follows from Lemmas 1 and 2.

COROLLARY 1. *If u is a "better" control than u^ε for the problem (P^ε) , then:*

$$\|x - y\|_\infty \leq k\varepsilon \left(1 + \frac{1}{\sqrt{\beta}} \right) \quad \text{and} \quad \|u - u_0\|_{L^2} \leq k\varepsilon \left(1 + \frac{1}{\sqrt{\beta}} \right).$$

Proof of Corollary 1. Denote by $J^\varepsilon(u)$ the cost in problem (P^ε) . For $\varepsilon \in]0, 1]$, one has $J^\varepsilon(u) \geq J^\varepsilon(u^\varepsilon) - k\varepsilon^2 + (\beta - k\varepsilon)z_\varepsilon^2$, with $k \geq 0$. If u is better than u^ε , then $(\beta - k\varepsilon)z_\varepsilon^2 \leq k\varepsilon^2$. Take $\varepsilon < \beta/2k$; then $z_\varepsilon^2 \leq 2k/\beta\varepsilon^2$. The result follows from Lemma 1.2.

2. The nonperiodic case.

2.1. An ergodic theorem on O.D.E. Let

$$f: \begin{cases} \mathbf{R}^n \times [0, T] \times \mathbf{R}_+ \rightarrow \mathbf{R}^n \\ (x, t, \theta) \rightarrow f(x, t, \theta) \end{cases}$$

meeting the following assumptions:

(H7) f is Lipschitz in (x, t) with Lipschitz constant Λ , and integrable in θ .

(H8) f has an average \bar{f} in the sense that, for any bound B , one has:

$$\sup_{\substack{|x| \leq B \\ t \in [0, T] \\ \hat{t} \geq 0}} \left| \frac{1}{\tau} \int_{\hat{t}}^{\hat{t}+\tau} f(x, t, \theta) d\theta - \bar{f}(x, t) \right| \xrightarrow{\tau \rightarrow +\infty} 0.$$

As before, (H7) ensures that one has a true separation of time scales.

Let x^ε and y be defined by:

$$(10) \quad \frac{dx^\varepsilon}{dt} = f\left(x^\varepsilon, t, \frac{t}{\varepsilon}\right), \quad x^\varepsilon(0) = x_0, \quad t \in [0, T],$$

$$(11) \quad \frac{dy}{dt} = \bar{f}(y, t), \quad y(0) = x_0, \quad t \in [0, T].$$

Then

$$\sup_{t \in [0, T]} |x^\varepsilon(t) - y(t)| \xrightarrow{\varepsilon \rightarrow 0} 0.$$

Proof. At a fast time scale, the slow time t can be considered as constant, as well as $x^\varepsilon(t)$ and $y(t)$. Hence the dynamics f can be approximated by \bar{f} ; integration yields the result.

More precisely, let $D \in \mathbf{N}^*$ and, for $t \in [0, T]$, let $t_k = kt/D$. Then:

$$\begin{aligned} |x^\varepsilon(t) - y(t)| &\leq \Lambda \int_0^t |x^\varepsilon(s) - y(s)| ds + \sum_{k=0}^{D-1} \int_{t_k}^{t_{k+1}} \left| f\left(y(s), s, \frac{s}{\varepsilon}\right) - f\left(y(t_k), t_k, \frac{s}{\varepsilon}\right) \right| ds \\ &\quad + \sum_{k=0}^{D-1} \int_{t_k}^{t_{k+1}} |\bar{f}(y(s), s) - \bar{f}(y(t_k), t_k)| ds \\ &\quad + \sum_{k=0}^{D-1} \int_{t_k}^{t_{k+1}} \left| f\left(y(t_k), t_k, \frac{s}{\varepsilon}\right) - \bar{f}(y(t_k), t_k) \right| ds \\ &\leq \Lambda \int_0^t |x^\varepsilon(s) - y(s)| ds + \Lambda_1 \frac{t^2}{D} + t \sup_{\substack{|x| \leq \|y\|_\infty \\ t \in [0, T] \\ \hat{t} \geq 0}} \left| \frac{D\varepsilon}{t} \int_{\hat{t}}^{\hat{t}+\tau} f(x, t, \theta) d\theta \right. \\ &\quad \left. - \bar{f}(x, t) \right| \xrightarrow{\tau \rightarrow +\infty} 0. \end{aligned}$$

Choose $D = D(\varepsilon)$ such that $D(\varepsilon) \rightarrow_{\varepsilon \rightarrow 0} \infty$ and $\varepsilon D(\varepsilon) \rightarrow_{\varepsilon \rightarrow 0} 0$; use of the Gronwall lemma yields the result.

2.2. The averaged problem. Section 2.1 can be viewed as a generalization of averaging techniques to the nonperiodic case. We are now going to use it to define the averaged problem in the nonperiodic case.

Let f and L be as in § 1.1, except that now they need not be periodic in θ , and define problem (P^ε) accordingly. The important point in the definition of the averaged problem is that of the set W^{ad} of admissible controls. W^{ad} will be the set of functions u from $[0, T] \times \mathbf{R}_+$ to \mathbf{R}^p , with values in U^{ad} for almost every (t, θ) , and such that $f(x, u(t, \theta), t, \theta)$ and $L(x, u(t, \theta), t, \theta)$ have an average in θ for every (x, t) .

Note that W^{ad} may be empty. However, we will show that, if averaging can reasonably be expected to be used (i.e., the minimized Hamiltonian has an average), then W^{ad} is nonempty (see § 2.3).

For u in W^{ad} we define the averaged problem:

$$\left. \begin{aligned} \frac{dy}{dt} &= \bar{f}(y, u(t, \cdot), t, \cdot), \quad y(0) = x_0, \quad t \in [0, T], \\ \text{Minimize } \int_0^T \bar{L}(y, u(t, \cdot), t, \cdot) dt, \end{aligned} \right\} (\bar{P}).$$

If f and L are periodic, we find the same definition as in § 1.1.

2.3. The Hamiltonian of the averaged problem. In this section, we will omit the mention x and t . All assumptions made will be supposed to hold for every x and t .

Define the pseudo-Hamiltonian $h(p, u, \theta)$ by $h(p, u, \theta) = p^T f(u, \theta) + L(u, \theta)$ and let $H(p, \theta) = \min_{u \in U^{ad}} h(p, u, \theta)$ when it exists.

We are going to show that if H has an average for any p , then its average is the minimum of the Hamiltonian of the averaged problem. We will use the following assumptions:

- (H9) For any bounded part B of \mathbf{R}^p , f and L are bounded and uniformly continuous on $B \times \mathbf{R}_+$ (i.e., f and L are in $\text{BUC}(B, \mathbf{R}_+)$).
- (H10) For any (p, θ) , $h(p, u, \theta)$ has a minimum on U^{ad} . Moreover, for any bounded domain B in \mathbf{R}^p there exists a compact set K in U^{ad} such that the minimum can be reached in K for any (p, θ) in $B \times \mathbf{R}_+$.
- (H11) H has an average \bar{H} , i.e.,

$$\frac{1}{\tau} \int_0^\tau H(p, \theta) d\theta \xrightarrow{\tau \rightarrow +\infty} \bar{H}(p) \quad \text{for all } p \text{ in } \mathbf{R}^n.$$

THEOREM 2. *Let f and L meeting (H9), (H10) and (H11). Then W^{ad} is nonempty and $\bar{H}(p) = \text{Min}_{v \in W^{ad}} p^T \bar{f}(v) + \bar{L}(v)$.*

Proof. Denote $p^T \bar{f}(v) + \bar{L}(v)$ by $\bar{h}(p, v)$ for v in W^{ad} and let $E = \{p \in \mathbf{R}^n \mid \exists v \in W^{ad}, \bar{H}(p) = \bar{h}(p, v)\}$. As obviously $\bar{h}(p, v) \geq \bar{H}(p)$ for any v in W^{ad} , Theorem 2 is equivalent to $E = \mathbf{R}^n$. We are going to show that E is closed and that $\mathbf{R}^n - E$ is of null measure (Lebesgue).

(i) E is closed.

If $E = \emptyset$, this is true. If $E \neq \emptyset$, let p_n be a sequence in E , converging in \mathbf{R}^n , with $\bar{H}(p_n) = \bar{h}(p_n, v_n)$. Thanks to (H9) and (H10), $\bar{f}(v_n)$ and $\bar{L}(v_n)$ are bounded; let \bar{f} and \bar{L} be two cluster points, and w_n a subsequence such that $\bar{f}(w_n) \rightarrow_{n \rightarrow \infty} \bar{f}$ and $\bar{L}(w_n) \rightarrow_{n \rightarrow \infty} \bar{L}$. We are going to exhibit a control v such that $p^T \bar{f} + \bar{L} = p^T \bar{f}(v) + \bar{L}(v)$.

Let τ_n be an increasing sequence in \mathbf{R}_+ such that $\tau_n \geq n!$ and such that, for $\tau \geq \tau_n$:

$$\left| \frac{1}{\tau} \int_0^\tau f(w_n(\theta), \theta) d\theta - \bar{f}(w_n) \right| < \frac{1}{n}.$$

τ_n exists since w_n is in W^{ad} . Define v by $v(\theta) = w_n(\theta)$ for θ in $[\tau_n, \tau_{n+1}[$; it is then easy to check that v is in W^{ad} and that $p^T \bar{f} + \bar{L} = \bar{h}(p, v)$.

(ii) $\mathbf{R}^n - E$ is of null measure.

\bar{H} is locally Lipschitz, thanks to Assumptions (H9) and (H10), and thus, if F denotes the set of differentiability points of \bar{H} , $\mathbf{R}^n - F$ is of null measure. We are going to show that $F \subset E$.

Notice that, thanks to (H9) and (H10), there exists a measurable function u from $\mathbf{R}^n \times \mathbf{R}_+$ to U^{ad} such that $H(p, \theta) = h(p, u(p, \theta), \theta)$. Let ρ be a small positive number, p in F and q a direction in \mathbf{R}^n . Then:

$$\frac{H(p + \rho q) - H(p, \theta)}{\rho} \leq q^T f(p, u(p, \theta), \theta) \leq \frac{H(p, \theta) - H(p - \rho q, \theta)}{\rho}.$$

Let l be a cluster point of $1/\tau \int_0^\tau q^T f(p, u(p, \theta), \theta) d\theta$ as $\tau \rightarrow +\infty$; l exists thanks to (H9) and (H10). Then let $\tau \rightarrow \infty$ first, then $\rho \rightarrow 0$ in the above inequalities. We conclude that $l = \partial \bar{H} / \partial p$ in the direction q .

As this is true for any cluster point and any direction q , we have

$$\lim_{\tau \rightarrow \infty} \frac{1}{\tau} \int_0^\tau f(p, u(p, \theta), \theta) d\theta = \frac{\partial \bar{H}^T}{\partial p}.$$

Since f and H have an average, L has an average and $u(p, \theta)$ is in W^{ad} , with $\bar{H}(p) = p^T \bar{f}(u) + \bar{L}(u)$.

Remark 5. The concavity of H in p is essential. Let $H(p, \theta) = \sin(p, \theta)$. $\bar{H} = 0$, yet $\partial H / \partial p$ has no average.

2.4. A limit theorem on the Bellman function. Assumption (H11) has given sense to the averaged problem by ensuring that W^{ad} is nonempty. It also yields a limit theorem on the Bellman function. We will consider the latter as the unique viscosity solution of the Hamilton–Jacobi–Bellman equation (see [7]).

Assumptions. Let

$$H: \begin{cases} \mathbf{R}^n \times \mathbf{R}^n \times [0, T] \times \mathbf{R}_+ \rightarrow \mathbf{R}, \\ (p, x, t, \theta) \rightarrow H(p, x, t, \theta). \end{cases}$$

H may represent, for instance, the minimized Hamiltonian of § 2.3. The assumptions are the following:

$$(H12) \quad H \in \text{BUC}(B \times \mathbf{R}^n \times [0, T] \times \mathbf{R}_+) \text{ for any bounded part } B \text{ of } \mathbf{R}^n, \text{ and } |H(p, x, t, \theta) - H(p, y, t, \theta)| \leq C(1 + |p|)(|x - y|).$$

$$(H13) \quad H \text{ has an average } \bar{H} \text{ such that, for any } p, x, t,$$

$$\sup_{\hat{t} \geq 0} \left| \frac{1}{\tau} \int_{\hat{t}}^{\hat{t} + \tau} H(p, x, t, \theta) d\theta - \bar{H}(p, x, t) \right| \xrightarrow{\tau \rightarrow +\infty} 0.$$

THEOREM 3. *Let V be the viscosity solution of:*

$$(12) \quad \frac{\partial V}{\partial t} + \bar{H}\left(\frac{\partial V}{\partial x}, x, t\right) = 0, \quad V(x, T) \equiv 0, \quad x \in \mathbf{R}^n, \quad t \in [0, T].$$

Let V^ε be the viscosity solution of:

$$(13) \quad \frac{\partial V^\varepsilon}{\partial t} + H\left(\frac{\partial V^\varepsilon}{\partial x}, x, t, \frac{t}{\varepsilon}\right) = 0, \quad V^\varepsilon(x, T) \equiv 0, \quad x \in \mathbf{R}^n, \quad t \in [0, T].$$

Then V^ε converges to V as ε tends to zero, uniformly on any compact subset of $\mathbf{R}^n \times [0, T]$.

Proof. We will make use of the following notation:

$$L^p_{\text{unif}}(\mathbf{R}^n \times [0, T]) = \left\{ \phi \in L^p_{\text{loc}}(\mathbf{R}^n \times [0, T], \mathbf{R}), \sup_{y \in \mathbf{R}^n} \int_{t \in [0, T]} \int_{|x-y| < 1} |\phi(x, t)|^p dx dt < \infty \right\}.$$

$W^{2,1,p}_{\text{unif}}(\mathbf{R}^n \times [0, T])$ is the set of functions ϕ in $L^p_{\text{unif}}(\mathbf{R}^n \times [0, T])$ such that $\partial \phi / \partial t$, $\partial \phi / \partial x$ and $\partial^2 \phi / \partial x^2$ exist and are in L^p_{unif} . $W^{2,1,p}_{\text{unif}}$ is the analogue of $W^{2,1,p}$ except that L^p is replaced by L^p_{unif} . We can use the norm on $W^{2,1,p}_{\text{unif}}$ defined by the sup of $W^{2,1,p}$ norms over all $\bar{B}(y, 1) \times [0, T]$, where $\bar{B}(y, 1)$ is the closed ball of center y and radius 1.

We will denote, for $\alpha > 0$, by V^ε_α the unique solution in $\cap_{p \geq 0} W^{2,1,p}_{\text{unif}}$ of

$$(14) \quad \frac{\partial V^\varepsilon_\alpha}{\partial t} + \alpha \Delta V^\varepsilon_\alpha + H\left(\frac{\partial V^\varepsilon_\alpha}{\partial x}, x, t, \frac{t}{\varepsilon}\right) = 0, \quad V^\varepsilon_\alpha(x, T) \equiv 0$$

and V_α the analogue for

$$(15) \quad \frac{\partial V_\alpha}{\partial t} + \alpha \Delta V_\alpha + \bar{H}\left(\frac{\partial V_\alpha}{\partial x}, x, t\right) = 0, \quad V_\alpha(x, T) \equiv 0.$$

It is well known [7] that

$$\|V^\varepsilon_\alpha - V^\varepsilon\|_\infty \leq k\sqrt{\alpha} \quad \text{and} \quad \|V_\alpha - V\|_\infty \leq k_2\sqrt{\alpha}.$$

Moreover, k does not depend on the behaviour of H in time, that is, in particular k does not depend on ε . Hence, the theorem will be proved if, α being fixed, V_α^ε converges to V_α for ε in $]0, 1]$. Estimates on the derivatives of V_α^ε ensure that the V_α^ε are bounded in (and thus form a weakly relatively compact subset of) $W_{\text{unif}}^{2,1,p}$ for any $p > 0$. Thus, the $(V_\alpha^\varepsilon, \partial V_\alpha^\varepsilon / \partial x)$ are relatively compact in $C^0(K \times [0, T], \mathbf{R})$, K being any compact subset of \mathbf{R}^n . Let $(\bar{V}_\alpha, \partial \bar{V}_\alpha / \partial x)$ a cluster point and $(V_{\alpha^n}^\varepsilon, \partial V_{\alpha^n}^\varepsilon / \partial x)$ a sequence converging to $(\bar{V}_\alpha, \partial \bar{V}_\alpha / \partial x)$ uniformly on any compact, with $V_{\alpha^n}^\varepsilon \rightarrow_{n \rightarrow \infty} \bar{V}_\alpha$ in $W_{\text{unif}}^{2,1,p}$ weakly.

Proving the theorem thus amounts to showing that \bar{V}_α is a solution of (15) in the weak sense. Let ϕ a function in $C^\infty(\mathbf{R}^n \times [0, T])$ with a compact domain.

$$\begin{aligned} \int_{t_k}^{t_{k+1}} dt \int_{\mathbf{R}^n} dx \left[\frac{\partial \bar{V}_\alpha}{\partial t} + \alpha \Delta \bar{V}_\alpha + \bar{H} \left(\frac{\partial \bar{V}_\alpha}{\partial x}, x, t \right) \right] \phi(x, t) \\ = \int_{t_k}^{t_{k+1}} dt \int_{\mathbf{R}^n} dx \left[\frac{\partial \bar{V}_\alpha}{\partial t} - \frac{\partial V_\alpha^\varepsilon}{\partial t} + \alpha \Delta \bar{V}_\alpha - \alpha \Delta V_\alpha^\varepsilon \right] \phi(x, t) \\ + \int_{t_k}^{t_{k+1}} dt \int_{\mathbf{R}^n} dx \left[H \left(\frac{\partial \bar{V}_\alpha}{\partial x}, x, t, \frac{t}{\varepsilon} \right) - H \left(\frac{\partial V_\alpha^\varepsilon}{\partial x}, x, t, \frac{t}{\varepsilon} \right) \right] \phi(x, t) \\ + \int_{t_k}^{t_{k+1}} dt \int_{\mathbf{R}^n} dx \left[\bar{H} \left(\frac{\partial \bar{V}_\alpha}{\partial x}, x, t \right) - H \left(\frac{\partial \bar{V}_\alpha}{\partial x}, x, t, \frac{t}{\varepsilon} \right) \right] \phi(x, t). \end{aligned}$$

As ε tends to zero, the first expression has limit zero by weak convergence in $W_{\text{unif}}^{2,1,2}$. The second one tends to zero thanks to the Lebesgue dominated convergence theorem. A discretization scheme similar to that used in § 2.1 ensures that the third one has limit zero, thanks to Assumption (H13).

Remark 6. It can be proved [4] that, if H is locally Lipschitz in p and if the convergence in Assumption (H13) is uniform for x in \mathbf{R}^n , then the convergence of V^ε to V is uniform on $\mathbf{R}^n \times [0, T]$.

One may wonder when (H12) is true with $H = p^T f + L$. It is true if, for instance, f and L are BUC and Lipschitz in x . However, this can be extended to the case where f is uniformly continuous, Lipschitz in x with $|f| \leq k(1 + |x| + |u|)$; and L is uniformly continuous, locally Lipschitz in x , $|\partial L / \partial x| \leq k(1 + |x| + |u|)$ and $|L| \leq k(1 + |x|^2 + |u|^2)$, $L \geq k_1(-1 + |u|^2)$.

This includes the linear quadratic case; actually, we might call this the “sublinear quadratic case.” With a suitable truncation of f and L on the phase domain, we may keep V^ε and V unchanged on a portion of $\mathbf{R}^n \times [0, T]$, while retrieving Assumption (H12). The convergence is still uniform on any compact.

3. Perspectives. We have proven here, at least in the periodic case, that averaging can be used as an efficient tool in deterministic optimal control. It is efficient for two reasons.

First, the averaged problem (\bar{P}) is easier to solve numerically than the original problem (P^ε) , since a “fast” time grid is no longer needed in the simulation part. Gains should also be expected on the state space grid, since it is often related to the former one; it is an important point if one thinks, for instance, of dynamic programming.

Second, and thanks to Theorem 1, the solution of (\bar{P}) is known to be near optimal for (P^ε) ; hence, we do not lose much by solving the averaged problem instead of the original one.

We have shown that use of the averaged problem can also be expected to be efficient in the nonperiodic case, as the optimal cost of (P^ε) is close to that of (\bar{P}) when ε is small (Theorem 3).

However, practical problems are seldom under the form (P^ε) , be it in the periodic or nonperiodic case. Most of the time, there is, for instance, no explicit separation of the time scales under the form (t, θ) , with θ ranging from 0 to $+\infty$; in particular, periodicity or averaging assumptions cannot be checked directly. Nevertheless, the results presented here provide an important theoretical background for developments of both theoretical and practical interest.

From the theoretical point of view, it is reasonable to expect problem (TP^ε) in Lemma 1 to provide further expansions of the cost (J^ε) , as similar methods have already been used with success in the case of regular and singular perturbations [2]. A complete expansion of the Bellman function in the linear quadratic periodic case has already been obtained [4]. In particular, the terms of order higher than two are in the form $V(x, t, t/\varepsilon, (T - t/\varepsilon))$, with periodicity in both the forward and backward fast times. This is probably related to the existence of the terms x_2 and p_2 in the expansion of the primal and dual trajectories. The same phenomenon exists in singular perturbations with boundary layers instead of phase terms.

We have seen that x_2 and p_2 are defined through the operator Π . In fact, Π appears in any expansion of an integral with an integrand periodic in fast time. A generalization of Π would be welcome if we hope to find some results equivalent to Theorem 1 in the nonperiodic case.

At last, links should be developed with singular perturbations. From the practical point of view, we have seen that the assumptions in Theorems 1 and 3 cannot be checked directly. It should be noticed (especially in the nonperiodic case) that the question is not so much that the assumptions might not hold, as it is rather to immerse the optimization problem in the "right" family of problems (P^ε) . Moreover, the ideas are sufficiently simple and general to be used in heuristics. One can think, for instance, of separating the time scales through the use of "moving averages." Heuristics can also be developed to generalize the operator Π to the nonperiodic case and use it to improve performances. We are going to experiment numerically on these ideas.

Conversely, averaging has been often used empirically by engineers in practical problems. The results and notions presented here may provide them some guidelines in further applications.

We have discussed *how* averaging could be used practically. We shall discuss now *when* it could be used. Heuristically, averaging can be expected to yield good results and performances when the dynamics of a system depend on a fast "erratic" exogenous phenomenon. A good example is given by weather disturbances.

However, these phenomena are often modeled by stochastic processes. As we mentioned before, both approaches are similar in the sense that they make use of averages; their theoretical background is, however, quite different. Moreover, averaging has also been used in stochastic control ([5], for instance). In all cases, the original data consists often of a finite number of physical measures, in no way probabilistic or two-time scaled in nature. Thus, neither approach is justified a priori. Therefore, it should prove quite interesting to experiment all methods on various sets of data. We plan to conduct such experiments.

LINEAR-QUADRATIC PROGRAMMING AND OPTIMAL CONTROL*

R.T. ROCKAFELLAR†

Abstract. A generalized approach is taken to linear and quadratic programming in which dual as well as primal variables may be subjected to bounds, and constraints may be represented through penalties. Corresponding problem models in optimal control related to continuous-time programming are then set up and theorems on duality and the existence of solutions are derived. Optimality conditions are obtained in the form of a global saddle point property which decomposes into an instantaneous saddle point condition on the primal and dual control vectors at each time, along with an endpoint condition.

Key words. Linear-quadratic programming, dual control problems, intertemporal programming, continuous-time programming, penalty representation of constraints

AMS(MOS) subject classifications. 49B10, 90C20, 90C05

1. Introduction. In finite-dimensional optimization a great importance is attached to problems of linear and quadratic programming. Such problems serve as mathematical models for a large number of applications. They are relatively easy to work with and possess duality properties that yield valuable insights and are the basis for many special algorithms. They are useful in methods of solving more general problems, for instance, in connection with sequential approximation or direction-finding subroutines. For such purposes they can be extended beyond traditional formulations to admit piecewise linear-quadratic objectives and penalty representations of constraints, although this possibility has not yet fully been utilized.

In optimal control there has not been a comparable emphasis on a "linear-quadratic" class of problems. The linear-quadratic regulator problem fits the picture to some degree but is virtually unconstrained. The continuous-time linear programming problems first introduced as "bottleneck" problems by Bellman [1] include certain types of control problems with constraints on states and controls (possibly mixed), but they carry no provision for quadratic terms in the objective and are very narrow in their treatment of initial and terminal conditions. Continuous-time linear programming problems do enjoy a strong duality theory, thanks to efforts of Tyndall [2], [3], Levinson [4], Grinold [5], [6], Schecter [7], Reiland [8], Meidan and Perold [9], and others. Continuous-time nonlinear programming has also been investigated, chiefly for duality; cf. Hanson [10], Hanson and Mond [11], Grinold [12], Farr and Hanson [13], Reiland and Hanson [14], Reiland [15]. This nonlinear literature covers certain classes of optimal control problems with quadratic terms, subject to the same limitations on the treatment of initial and terminal states. However, the quadratic case has not been worked out to take advantage of its special nature, and, in any case, the results are based on a Lagrange multiplier approach that does not yield even in finite dimensions a duality theory as broad and flexible as may currently be needed.

Our goal in this paper is to develop a theory of linear-quadratic programming-type problems specifically adapted to the optimal control setting and capable eventually of being used in new computational schemes, as well as directly.

Some of the motivation comes from mathematical modeling. Linear-quadratic models do not appear to have been used so far to their full potential. An obstacle may lie in the format in which finite-dimensional problems in linear programming and quadratic programming are ordinarily presented. In this format it is hard to deal with piecewise linear or piecewise quadratic functions, such as often are important in penalty representations, except by reformulations that disrupt the fundamental relationships, especially duality.

An alternative approach in finite dimensions, which we have followed recently in work on algorithms in stochastic programming [16], [17], [18], is to give primacy to an underlying saddle point problem (minimax problem). Thus we think of finite-dimensional linear-quadratic programming in a more general sense than usual as corresponding to finding a saddle point of a convex-concave quadratic (or linear) function on a product of polyhedral convex sets. Any such saddle point problem generates a primal problem of minimization and a dual problem of maximization. The classical case of linear and quadratic programming duality is the one where the polyhedral convex sets are orthants.

The problems in the general case could be reduced individually to the classical case, but by working directly in the broader format one gains several advantages. The most significant is the perception that bounds can reasonably be introduced for dual variables as well as primal variables, and moreover that this amounts to passing from exact representations of certain constraints to penalty representations.

We begin in §2 and §3 by explaining this unconventional approach to finite-dimensional linear-quadratic programming and the kinds of problem forms it handles. A particular aim is the elucidation of circumstances under which a model involving bounds on both primal and dual variables is appropriate, at least for computation. Then in §4 and §5 we introduce corresponding problems in optimal control, of a sort we call *intertemporal linear-quadratic programming*. The main results are obtained in §6. They consist of theorems on existence, duality, and the characterization of optimal controls. They are tied to an infinite-dimensional saddle point representation in terms of a convex-concave quadratic functional on a product of generalized polyhedral sets.

Our problems in optimal control have dynamics that are essentially linear, although “polyhedral differential inclusions” are also encompassed by the formulation. The expression of the objective and constraints involves, in general, terms that may be piecewise linear-quadratic. To clarify the nature of such terms in this introduction would take us too far. A brief description of one of the basic *linear* models covered by our theory is feasible, however, and may help to put the approach and results in perspective.

Over a fixed time interval $[t_0, t_1]$ we consider a dynamical system

$$(1.1) \quad \dot{x}(t) = A(t)x(t) + B(t)u(t) + b(t), \quad x(t_0) = B_e u_e + b_e,$$

where $x(t) \in \mathbb{R}^n$ is the state, $u(t) \in \mathbb{R}^k$ is the instantaneous control and $u_e \in \mathbb{R}^{k_e}$ is an additional vector to be chosen, an “endpoint control.” The incorporation of such a vector u_e may seem odd relative to the customary patterns in control theory, but it greatly aids in dualizing various conditions. Of course u_e could be trivialized by taking the dimension k_e to be 0 (then $x(t_0) = b_e$ in (1.1)). Another case to note is the one of a free initial point: $B_e = I$, $b_e = 0$ (then $x(t_0) = u_e$ in (1.1)). The subscript e will consistently be used in our notation for elements connected with endpoints.

For the basic linear case in question, the problem we associate with the system (1.1) takes the form

$$\begin{aligned}
 & \text{minimize} && \int_{t_0}^{t_1} [p(t) \cdot u(t) - c(t) \cdot x(t)] dt + [p_e \cdot u_e - c_e \cdot x(t_1)] \\
 (\mathcal{P}_1) \quad & \text{subject to} && (1.1) \text{ with} \quad C(t)x(t) + D(t)u(t) \geq q(t), \quad u(t) \geq 0, \\
 & && C_e x(t_1) + D_e u_e \geq q_e, \quad u_e \geq 0.
 \end{aligned}$$

Discussion of the exact technical assumptions is postponed until §4. Observe, however, that the formulation allows for constraints only on the controls (rows of $C(t)$ consisting of 0's), constraints only on the states (rows of $D(t)$ consisting of 0's), and mixed constraints. The endpoint conditions allow for any system of finitely many linear equations or inequalities to be imposed on the pair $x(t_0), x(t_1)$ (as explained in detail in Examples 5.1 and 5.2 in §5).

In dualizing (\mathcal{P}_1) we pass to the dynamical system

$$(1.2) \quad -\dot{y}(t) = A^*(t)y(t) + C^*(t)v(t) + c(t), \quad y(t_1) = C_e^* v_e + c_e,$$

where $y(t) \in \mathbb{R}^n$ is the state, $v(t) \in \mathbb{R}^\ell$ is the instantaneous control, and $v_e \in \mathbb{R}^{\ell_e}$ is the endpoint control; the asterisk $*$ denotes the transpose of a matrix. The dual problem over the system (1.2) is

$$\begin{aligned}
 & \text{maximize} && \int_{t_0}^{t_1} [q(t) \cdot v(t) - b(t) \cdot y(t)] dt + [q_e \cdot v_e - b_e \cdot y(t_0)] \\
 (\mathcal{Q}_1) \quad & \text{subject to} && (1.2) \text{ with} \quad B_e^*(t)y(t) + D^*(t)v(t) \leq p(t), \quad v(t) \geq 0, \\
 & && B_e y(t_0) + D_e^* v_e \leq p_e, \quad v_e \geq 0.
 \end{aligned}$$

Although (\mathcal{P}_1) and (\mathcal{Q}_1) have been written with inequality constraints only, there is no difficulty about extending the formulation to include equations in the manner familiar in linear programming. Thus, for example, the condition $C(t)x(t) + D(t)u(t) \geq q(t)$ in (\mathcal{P}_1) can be converted to $C(t)x(t) + D(t)u(t) = q(t)$ by dropping the condition $v(t) \geq 0$ in (\mathcal{Q}_1) .

In contrast to (\mathcal{P}_1) and (\mathcal{Q}_1) the continuous-time linear programming problems mentioned earlier take the primal form

$$\begin{aligned}
 & \text{minimize} && \int_{t_0}^{t_1} p(t) \cdot u(t) dt \\
 & \text{subject to} && \int_{t_0}^t K(t, \tau) u(\tau) d\tau + D(t)u(t) \geq q(t), \quad u(t) \geq 0,
 \end{aligned}$$

and the dual form

$$\begin{aligned}
 & \text{maximize} && \int_{t_0}^{t_1} q(t) \cdot v(t) dt \\
 & \text{subject to} && \int_t^{t_1} K^*(\tau, t) v(\tau) d\tau + D^*(t)v(t) \leq p(t), \quad v(t) \geq 0,
 \end{aligned}$$

where the matrix $K(t, \tau)$ is some "kernel" with transpose $K^*(t, \tau)$. These are not necessarily problems of optimal control but become so in choosing

$$K(t, \tau) = C(t)A(t)A(\tau)^{-1}B(\tau)$$

with $A(t)$ the fundamental matrix corresponding to the differential equation (1.1) (i.e., $A(t)x_0$ is the unique solution to $\dot{x}(t) = A(t)x(t)$, $x(t_0) = x_0$), and setting

$$x(t) = A(t) \int_{t_0}^t A(\tau)^{-1} B(\tau) u(\tau) d\tau, \quad y(t) = A^*(t)^{-1} \int_t^{t_0} A^*(\tau) C^*(\tau) v(\tau) d\tau.$$

Then one gets the case of (P_1) and (Q_1) where $b(t) = 0$, $c(t) = 0$, and all the e terms trivialize: the primal has $x(t_0) = 0$ but $x(t_1)$ free, whereas the dual has $y(t_1) = 0$ but $y(t_0)$ free.

In the work that has been done on special computational methods in continuous-time linear programming, e.g. Perold [19], [20], Anstreicher [21], attention has typically been limited further to the case where the kernel K is a *constant* matrix. In optimal control this corresponds not merely to having $A(t)$, $B(t)$ and $C(t)$ constant, but $A(t) \equiv 0$, a severe restriction.

Because of these distinctions and the desirability of being able to treat discrete-time analogues under the same heading, we shall refer to (P_1) and (Q_1) as problems of "intertemporal linear programming" (in continuous time) rather than "continuous-time linear programming."

The possibility of mixed constraints on states and controls is important in accommodating many applications of an economic nature, involving planned activities with cumulative effects. But it also puts problems like (P_1) and (Q_1) beyond the range of the Pontryagin maximum principle. Mixed constraints can be readily handled, however, in the versions of optimal control and variational calculus that have been developed over the years in the conceptual framework of convex analysis and, more recently, nonsmooth analysis in the sense of Clarke [22].

The theory of convex problems of Bolza type, developed by the author in [23]–[29], is specifically applicable to problems (P_1) , (Q_1) and their quadratic programming counterparts after a transformation which expresses everything through the trajectories x and y , as outlined in [30]. By this route it would be possible, with a degree of technical elaboration, to derive sharp duality theorems that characterize solutions and the circumstances in which they exist. Full justice to constraints involving states would, however, require us in the context of such duality to pass beyond the formulation of our primal and dual problems in terms of control *functions* u and v to one in which "impulse controls" may occur. An extension along those lines is indeed appropriate, and for the basic linear programming case in (P_1) , (Q_1) , it has been carried out by Murray [31] under a somewhat different choice of endpoint expressions.

For the present purpose we are able to postpone working with such an extension. We follow a different path and sidestep the difficulties posed by state constraints by appealing instead to alternative problem formulations where the constraints may be enforced by linear or piecewise linear-quadratic penalty expressions. We argue that as a practical matter of mathematical modeling and computation this is an often reasonable tactic which can be served by a much simpler theory where solutions always exist and strong duality always holds. The supporting results in finite-dimensional linear-quadratic programming provided in §§2 and 3 are critical in understanding this.

The saddle point representation furnished in §6 for the duality between our two infinite-dimensional problems of intertemporal linear-quadratic programming is of a kind not previously seen in optimal control. Moreover the representation has a separate decomposition property in each argument that may open the way to new saddle point techniques for computation such as extensions of the finite generation method

devised by R.J.-B. Wets and the author in a similar setting in stochastic programming [17]. Decomposition of the intertemporal saddle point condition leads to a characterization of optimality in terms of a “instantaneous” saddle point condition satisfied at each time t and an “endpoint” saddle point condition. This is a sort of “minimax principle” which has some precedent in continuous-time linear programming (Grinold [5, p. 46]) and the theory of Bolza problems (Rockafellar [23, Thm. 6]) but is new in this context of optimal control.

2. Linear-quadratic programming in finite dimensions. The infinite-dimensional control problems that are the subject of this paper, and our approach to them, will better be understood after a brief treatment of the formulation and duality properties of finite-dimensional linear-quadratic programming problems in the generalized sense. Such a treatment will also introduce facts and concepts that will be needed in later sections.

A simple foundation for almost all kinds of duality theory in optimization starts with a function $J(u, v)$ on a product set $U \times V$, where J is real-valued or possibly extended-real-valued. Regardless of the nature of J and the sets U and V (as long as the latter are nonempty), there is an associated *primal* problem

$$(\mathcal{P}_0) \quad \text{minimize } f(u) \text{ over } U \quad \text{where } f(u) = \sup_{v \in V} J(u, v),$$

and a *dual* problem

$$(\mathcal{Q}_0) \quad \text{maximize } g(v) \text{ over } V \quad \text{where } g(v) = \inf_{u \in U} J(u, v).$$

The relationship between these problems is tied to the *saddle point*, or *minimax* problem for J on $U \times V$, a saddle point being by definition a pair $(\bar{u}, \bar{v}) \in U \times V$ such that

$$(2.1) \quad J(u, \bar{v}) \geq J(\bar{u}, \bar{v}) \geq J(\bar{u}, v) \quad \text{for all } u \in U, v \in V.$$

The following facts are well known (cf. [32, Thm. 2], for example).

PROPOSITION 2.1. *It is always true that $\inf(\mathcal{P}_0) \geq \sup(\mathcal{Q}_0)$. Furthermore a pair (\bar{u}, \bar{v}) is a saddlepoint of J on $U \times V$ if and only if \bar{u} solves (\mathcal{P}_0) , \bar{v} solves (\mathcal{Q}_0) , and $\min(\mathcal{P}_0) = \max(\mathcal{Q}_0)$.*

Here we use the notation that $\inf(\mathcal{P}_0)$ is the optimal value in (\mathcal{P}_0) , namely the infimum of f over U . We allow ourselves to write $\min(\mathcal{P}_0)$ in place of $\inf(\mathcal{P}_0)$ if the infimum is actually attained at some \bar{u} . Similarly for $\sup(\mathcal{Q}_0)$, $\max(\mathcal{Q}_0)$.

By finite-dimensional (*piecewise*) *linear-quadratic programming* in the general sense we shall mean the case of problems (\mathcal{P}_0) and (\mathcal{Q}_0) where U is a nonempty convex polyhedron in a space \mathbb{R}^k , V is a nonempty convex polyhedron in space \mathbb{R}^ℓ , and J is a convex-concave function of the form

$$(2.2) \quad J(u, v) = p \cdot u + v \cdot q + \frac{1}{2}u \cdot Pu - \frac{1}{2}v \cdot Qv - v \cdot Du,$$

where $p \in \mathbb{R}^k$, $q \in \mathbb{R}^\ell$, $P \in \mathbb{R}^{k \times k}$, $Q \in \mathbb{R}^{\ell \times \ell}$ and $D \in \mathbb{R}^{\ell \times k}$, with P and Q symmetric and positive *semidefinite*. When $P = 0$ and $Q = 0$, we speak of (*piecewise*) *linear programming* in the general sense. This includes classical linear programming, of course (cf. Example 3.1 below).

In the linear-quadratic programming case the objective functions in (\mathcal{P}_0) and (\mathcal{Q}_0) take the form

$$(2.3) \quad f(u) = p \cdot u + \frac{1}{2}u \cdot Pu + \rho_{V, Q}(q - Du),$$

$$(2.4) \quad g(v) = q \cdot v - \frac{1}{2}v \cdot Qv - \rho_{U,P}(D^*v - p),$$

where

$$(2.5) \quad \rho_{V,Q}(s) = \sup_{v \in V} \{s \cdot v - \frac{1}{2}v \cdot Qv\},$$

$$(2.6) \quad \rho_{U,P}(r) = \sup_{u \in U} \{r \cdot u - \frac{1}{2}u \cdot Pu\}.$$

When $P = 0$ and $Q = 0$, the functions $\rho_{V,Q}$ and $\rho_{U,P}$ reduce to the *support functions*

$$(2.7) \quad \sigma_V(s) = \sup_{v \in V} s \cdot v, \quad \sigma_U(r) = \sup_{u \in U} r \cdot u.$$

The specific nature of these various expressions will be explored in the examples in §3. The central fact is that strong duality always holds for such problems.

THEOREM 2.2. *In the case where (P_0) and (Q_0) are finite-dimensional linear-quadratic programming problems in the general sense just described, one has*

$$\infty > \min(P_0) = \max(Q_0) > -\infty,$$

unless the optimal values $\inf(P_0)$ and $\sup(Q_0)$ are both infinite. In particular, any finite-dimensional linear-quadratic programming problem with finite optimal value has an optimal solution.

Theorem 2.2 can easily be derived from known results about quadratic programming in the standard sense, specifically the duality theorem of Dorn [33] and Cottle [34] and the existence criterion of Frank and Wolfe [35]. We have given the argument in full in [17, Thm. 2].

Incidentally, the suprema in (2.5) and (2.6) must be attained also, when finite. Indeed, these formulas give the optimal values in certain quadratic programming problems and are covered by the result just cited.

The sense in which the terminology "linear-quadratic programming in the general sense" is appropriate for the problems in Theorem 2.2 is elucidated by our next result.

PROPOSITION 2.3. *The function $\rho_{V,Q}$ is lower semicontinuous, convex, and piecewise linear-quadratic: its effective domain*

$$(2.8) \quad L = \{s \in \mathbb{R}^\ell \mid \rho_{V,Q}(s) < \infty\}$$

is a nonempty convex polyhedron that can be decomposed into finitely many polyhedral convex sets, on each of which $\rho_{V,Q}$ is quadratic (or linear).

The same holds of course for $\rho_{U,P}$ and its effective domain

$$(2.9) \quad K = \{r \in \mathbb{R}^k \mid \rho_{U,P}(r) < \infty\}.$$

Proof. Define

$$(2.10) \quad \begin{aligned} \varphi(v) &= \begin{cases} \frac{1}{2}v \cdot Qv & \text{when } v \in V, \\ \infty & \text{when } v \notin V \end{cases} \\ &= j_Q(v) + \delta_V(v), \end{aligned}$$

where j_Q is the quadratic convex function corresponding to the positive definite form Q , and δ_V is the indicator of the convex polyhedron V :

$$(2.11) \quad \delta_V(v) = \begin{cases} 0 & \text{when } v \in V, \\ \infty & \text{when } v \notin V. \end{cases}$$

Clearly φ is convex, and its conjugate

$$(2.12) \quad \varphi^*(s) = \sup_{v \in \mathbb{R}^\ell} \{s \cdot v - \varphi(s)\}$$

is given by

$$(2.13) \quad \varphi^*(s) = \rho_{V,Q}(s).$$

The latter is therefore lower semicontinuous and convex in s , and its effective domain L is a nonempty convex set (these properties being true for the conjugate of any proper convex function [36, §12]).

For each $s \in L$, the supremum in (2.12) (equivalently (2.5)) must actually be attained, as noted above. On the other hand we know from convex analysis [36, Thm. 23.5] that the supremum in (2.12) is attained at v if and only if $v \in \partial\varphi^*(s)$, which is equivalent to $s \in \partial\varphi(v)$. Thus L coincides with the effective domain of the subdifferential multifunction $\partial\varphi^*$, which is also the range of $\partial\varphi$. We shall use this fact to demonstrate that L is polyhedral and has the decomposition claimed.

Because $\varphi = j_Q + \delta_V$ and j_Q is finite everywhere on \mathbb{R}^ℓ , we have by [36, Thm. 23.8] that

$$(2.14) \quad \partial\varphi(v) = \partial j_Q(v) + \partial\delta_V(v) = Qv + N_V(v),$$

where $N_V(v)$ is the normal cone to V at v [36, p. 215]. This normal cone is polyhedral, because V is polyhedral, and it depends only on the face of V to which v belongs. There are only finitely many faces of V , so it follows from (2.14) that $\partial\varphi$ is a polyhedral multifunction in the sense of Robinson [37], namely its graph in $\mathbb{R}^\ell \times \mathbb{R}^\ell$ is the union of finitely many polyhedral convex sets (one for each face of V). The same is then true for the multifunction $\partial\varphi^* = \partial\varphi^{-1}$, whose domain, already identified with L , must therefore be the projection of the union of finitely many polyhedral convex sets. We may conclude that the convex set L is actually polyhedral and can be decomposed into finitely many polyhedral convex sets L_i , over each of which the graph of $\partial\varphi^*$ is a polyhedral convex set. In the case of such a subset L_i having $\text{int } L_i \neq \emptyset$, $\partial\varphi^*$ must by this reduce to a single-valued affine mapping on $\text{int } L_i$, inasmuch as $\partial\varphi^*$ is single-valued almost everywhere on $\text{int } L$ (a fact true of the subdifferential of any proper convex function on the interior of its effective domain [36, Thm. 24.5]). Therefore φ^* is quadratic (or linear) on $\text{int } L_i$ by the lower semicontinuity of φ^* . For L_i with $\text{int } L_i = \emptyset$, a slightly more general argument based on relative interiors of convex sets leads to the same conclusion. Thus the function $\varphi^* = \rho_{V,Q}$ is piecewise linear-quadratic as claimed. \square

The terminology “linear programming in the general sense” in the case where $P = 0$ and $Q = 0$ is justified similarly. The functions $\rho_{V,Q}$ and $\rho_{U,P}$ reduce then to the support functions σ_V and σ_U in (2.7), which are polyhedral convex (piecewise linear) because U and V are polyhedral [36, Cor. 19.2.1].

Because $\rho_{V,Q}$ and $\rho_{U,P}$ can take ∞ as a value in some cases, the linear-quadratic programming problems (P_0) and (Q_0) may have implicit constraints. Thus in minimizing the function f given by (2.3) we are really interested only in the choices of u that satisfy

$$(2.15) \quad q - Du \in L \quad \text{as well as } u \in U.$$

Likewise in maximizing the function g in (2.4) we focus on v satisfying

$$(2.16) \quad D^*v - p \in K \quad \text{as well as } v \in V.$$

The polyhedral convexity of L and K in Proposition 2.3 together with that of U and V means that these constraint systems can be represented in principle by finitely many linear equations and inequalities.

A closer analysis of the sets L and K reveals additional structure that will be of use to us. Here we denote the *null space* of Q by

$$\text{nl } Q = \{w \in \mathbb{R}^\ell \mid Qw = 0\}$$

and the *recession cone* [36, §8] of V by

$$\text{rc } V = \{w \in \mathbb{R}^\ell \mid v + \lambda w \in V, \forall \lambda \geq 0\} \quad \text{for } v \in V.$$

The latter is the same regardless of the choice of $v \in V$. It is a polyhedral convex cone (always containing 0), because V is a polyhedral convex set [36, Thm. 19.5]. Indeed, if $V = \{v \mid Mv \leq m\}$, one has $\text{rc } V = \{w \mid Mw \leq 0\}$. We denote the *polar* of a cone G as usual by

$$(2.17) \quad G^\circ = \{z \mid z \cdot w \leq 0, \forall w \in G\}.$$

PROPOSITION 2.4. *The effective domains L and K in Proposition 2.3 are the polar cones*

$$(2.18) \quad L = [\text{rc } V \cap \text{nl } Q]^\circ \quad \text{and} \quad K = [\text{rc } U \cap \text{nl } P]^\circ.$$

Thus

$$(2.19) \quad L = \mathbb{R}^\ell \iff [\text{the only } w \in \text{rc } V \text{ with } Qw = 0 \text{ is } w = 0],$$

$$(2.20) \quad K = \mathbb{R}^k \iff [\text{the only } z \in \text{rc } U \text{ with } Pz = 0 \text{ is } z = 0].$$

In particular $L = \mathbb{R}^\ell$ if V is bounded or if Q is positive definite, whereas $K = \mathbb{R}^k$ if U is bounded or if P is positive definite.

Proof. Let φ be given again by (2.10), so that $\varphi^* = \rho_{V,Q}$ as in (2.13). Since $L = \text{dom } \varphi^*$ and L is closed, we have by [36, Thm. 13.3] that the indicator δ_L is conjugate to the recession function

$$(\text{rc } \varphi)(w) = \lim_{\lambda \rightarrow \infty} \varphi(v + \lambda w)/\lambda,$$

where $v \in \text{dom } \varphi = V$ (the limit being independent of the particular choice of v [36, Thm. 8.5]). The limit works out to

$$(\text{rc } \varphi)(w) = \begin{cases} 0 & \text{if } w \in \text{rc } V \text{ and } Qw = 0, \\ \infty & \text{otherwise.} \end{cases}$$

Thus $\text{rc } \varphi = \delta_G$ for $G = \text{rc } V \cap \text{nl } Q$. The indicators δ_G and δ_L being conjugate to each other, we conclude that G and L are cones polar to each other [36, §14]. \square

An important question of mathematical modeling and computation in applications both finite and infinite-dimensional is whether a problem (\mathcal{P}_0) , associated with a certain choice of J, U , and V , can reasonably be replaced by a more amenable problem $(\hat{\mathcal{P}}_0)$ obtained in substituting for U and V a pair of smaller sets \hat{U} and \hat{V} , e.g. bounded sets. The theorem we state next provides the answers for finite-dimensional linear-quadratic programming, although its full import will not be clear until the end of §3. It will be the basis for an infinite-dimensional generalization at the end of §6.

THEOREM 2.5. *Let (\mathcal{P}_0) and (\mathcal{Q}_0) be a pair of finite-dimensional linear-quadratic programming problems in the general sense. Consider also an auxiliary pair of such problems $(\hat{\mathcal{P}}_0)$ and $(\hat{\mathcal{Q}}_0)$ which corresponds to the same function J but subsets $\hat{U} \subset U$ and $\hat{V} \subset V$.*

(a) If \bar{u} and \bar{v} are solutions to (\mathcal{P}_0) and (\mathcal{Q}_0) such that actually $\bar{u} \in \hat{U}$ and $\bar{v} \in \hat{V}$, then \bar{u} and \bar{v} are also solutions to $(\hat{\mathcal{P}}_0)$ and $(\hat{\mathcal{Q}}_0)$.

(b) Conversely, if \bar{u} and \bar{v} are solutions to $(\hat{\mathcal{P}}_0)$ and $(\hat{\mathcal{Q}}_0)$, and if U coincides with \hat{U} around \bar{u} (i.e. $U \cap N = \hat{U} \cap N$ for some neighborhood N of \bar{u}) and V coincides with \hat{V} around \bar{v} , then \bar{u} and \bar{v} are actually solutions to (\mathcal{P}_0) and (\mathcal{Q}_0) .

Proof. From Proposition 2.1 and Theorem 2.2 we know that \bar{u} and \bar{v} solve (\mathcal{P}_0) and (\mathcal{Q}_0) if and only if (\bar{u}, \bar{v}) is a saddle point of J relative to $U \times V$. Likewise, \bar{u} and \bar{v} solve $(\hat{\mathcal{P}}_0)$ and $(\hat{\mathcal{Q}}_0)$ if and only if (\bar{u}, \bar{v}) is a saddle point of J relative to $\hat{U} \times \hat{V}$. The former trivially implies the latter when $\hat{U} = U$ and $\hat{V} = V$, and this establishes (a). Under the assumptions in (b), (\bar{u}, \bar{v}) is a saddle point relative to certain neighborhoods of \bar{u} in U and \bar{v} in V , i.e. it is a *local* saddle point relative to $U \times V$. But any local saddle point must be a global saddle point by the convexity-concavity of J . \square

3. Basic models in linear-quadratic programming. The nature of the ρ functions appearing in the finite-dimensional linear-quadratic programming problems in §2 is revealed more clearly in the examples that follow. These examples illustrate various possibilities in formulation that one needs to appreciate in order to see the broad scope of the optimal control problems which will be introduced in §4.

Example 3.1. (Classical linear programming.) Let $P = 0$, $Q = 0$, $U = \mathbb{R}_+^k$, $V = \mathbb{R}_+^\ell$. Then

$$(3.1) \quad \rho_{V,Q}(s) = \sigma_{\mathbb{R}_+^\ell}(s) = \begin{cases} 0 & \text{if } s \leq 0, \\ \infty & \text{if } s \not\leq 0, \end{cases}$$

$$(3.2) \quad \rho_{U,P}(r) = \sigma_{\mathbb{R}_+^k}(r) = \begin{cases} 0 & \text{if } r \leq 0, \\ \infty & \text{if } r \not\leq 0. \end{cases}$$

It follows that in (\mathcal{P}_0) we

$$\begin{aligned} & \text{minimize} && p \cdot u \\ & \text{subject to} && Du \geq q, \quad u \geq 0, \end{aligned}$$

whereas in (\mathcal{Q}_0) we

$$\begin{aligned} & \text{maximize} && q \cdot v \\ & \text{subject to} && D^*v \leq p, \quad v \geq 0. \end{aligned}$$

Note the role of ∞ in (3.1) and (3.2) in representing constraints in these problems as discussed in connection with the sets L and K in Proposition 2.3.

Versions of linear programming that involve equality constraints or variables not restricted to be nonnegative correspond to other choices of U and V as polyhedral convex cones.

Example 3.2. (Standard quadratic programming.) Let $Q = 0$ (but $P \neq 0$) and take $U = \mathbb{R}^k$, $V = \mathbb{R}_+^\ell$. Then (2.8) holds, and in (\mathcal{P}_0) we

$$\begin{aligned} & \text{minimize} && p \cdot u + \frac{1}{2} u \cdot Pu \\ & \text{subject to} && Du \geq q. \end{aligned}$$

This is quadratic programming in the traditional sense. To see what the dual is we must determine

$$(3.3) \quad \rho_{\mathbb{R}^k, P}(r) = \sup_{u \in \mathbb{R}^k} \{r \cdot u - \frac{1}{2} u \cdot Pu\}.$$

If P is positive definite, we easily calculate the supremum to be $\frac{1}{2}r \cdot P^{-1}r$, so that in (\mathcal{Q}_0) we

$$\begin{aligned} & \text{maximize} && q \cdot v - \frac{1}{2}[D^*v - p] \cdot P^{-1}[D^*v - p] \\ & \text{subject to} && v \geq 0. \end{aligned}$$

If P is only positive semidefinite, the dualization is more subtle and is facilitated by an algebraic normalization. First we can decompose $U = \mathbb{R}^k$ into $U_1 \times U_2$, where $U_1 = \{u \mid Pu = 0\}$ and $U_2 = U_1^\perp$. Then by a change of coordinates if necessary we can actually suppose that $U_1 \times U_2 = \mathbb{R}^{k_1} \times \mathbb{R}^{k_2}$ for some $k_1 + k_2 = k$, so that $P = \text{diag}(P_1, 0)$ for an positive definite matrix $P_1 \in \mathbb{R}^{k_1 \times k_1}$. Writing $u = (u_1, u_2)$ with $u_1 \in \mathbb{R}^{k_1}$, $u_2 \in \mathbb{R}^{k_2}$, and correspondingly $r = (r_1, r_2)$ in (3.4), we calculate

$$\begin{aligned} \rho_{U,P}(r_1, r_2) &= \sup_{u_1, u_2} \{r_1 \cdot u_1 + r_2 \cdot u_2 - \frac{1}{2}u_1 \cdot P_1 u_1\} \\ (3.4) \qquad &= \begin{cases} \frac{1}{2}r_1 \cdot P_1^{-1}r_1 & \text{if } r_2 = 0, \\ \infty & \text{if } r_2 \neq 0. \end{cases} \end{aligned}$$

Also writing $p = (p_1, p_2)$ and $D = (D_1, D_2)$, we see that in (\mathcal{P}_0) we

$$\begin{aligned} & \text{minimize} && p_1 \cdot u_1 + p_2 \cdot u_2 + \frac{1}{2}u_1 \cdot P_1 u_1 \\ & \text{subject to} && D_1 u_1 + D_2 u_2 \geq q \end{aligned}$$

whereas in (\mathcal{Q}_0) we

$$\begin{aligned} & \text{maximize} && q \cdot v - \frac{1}{2}[D_1^*v - p_1] \cdot P_1^{-1}[D_1^*v - p_1] \\ & \text{subject to} && D_2^*v = p_2, \quad v \geq 0. \end{aligned}$$

Mixed systems of equality and inequality constraints can be handled by choosing $V = \mathbb{R}_+^{\ell_1} \times \mathbb{R}^{\ell_2}$ for some $\ell_1 + \ell_2 = \ell$.

With further algebra transformations it is possible actually to normalize the study of quadratic programming to the case where the matrix P is always *diagonal*. All one has to do is provide a factorization

$$(3.5) \qquad P = M^*M \quad \text{with} \quad M \in \mathbb{R}^{m \times k} \text{ for some dimension } m.$$

Then the problem (\mathcal{P}_0) at the beginning of this example can be written as:

$$\begin{aligned} & \text{minimize} && p \cdot u + 0 \cdot u' + \frac{1}{2}u' \cdot u' \quad \text{over all } (u, u') \in \mathbb{R}^k \times \mathbb{R}^m \\ & \text{satisfying} && Du + 0u' \geq q, \quad Mu - Iu' = 0. \end{aligned}$$

This can be identified as a quadratic programming problem which can be written in terms of the enlarged vector (u, u') in the same format as the original (\mathcal{P}_0) , but with mixed equality and inequality constraints and a diagonalized quadratic form (actually with diagonal entries that are 0 for the components of u and 1 for the components of u').

Incidentally, some quadratic programming models can be set up more easily by taking advantage of the matrix Q instead of P . For example, the problem

$$\begin{aligned} & \text{minimize} && \frac{1}{2}|Du - q|^2 \\ & \text{subject to} && u \geq 0, \end{aligned}$$

where $|\cdot|$ is the Euclidean norm, can be regarded as the case of (\mathcal{P}_0) where $p = 0$, $P = 0$, $Q = I$, $U = \mathbb{R}_+^k$, $V = \mathbb{R}^\ell$, inasmuch as

$$(3.6) \qquad \rho_{\mathbb{R}^\ell, I}(s) = \frac{1}{2}|s|^2.$$

The corresponding dual problem (\mathcal{Q}_0) is:

$$\begin{aligned} & \text{maximize} && q \cdot v - \frac{1}{2}|v|^2 \\ & \text{subject to} && D^*v \leq 0. \end{aligned}$$

Example 3.3. (Basic piecewise linear programming.) Suppose $P = 0$, $Q = 0$. Let U be any convex polyhedron in \mathbf{R}^k (expressible by some system of linear constraints which, for now, does not need to be specified), and let V be the unit simplex in \mathbf{R}^ℓ :

$$(3.7) \quad V = \{v \in \mathbf{R}_+^\ell \mid v \cdot \mathbf{1} = 1\} \quad \text{where } \mathbf{1} = (1, 1, \dots, 1).$$

Then

$$(3.8) \quad \rho_{V,Q}(r) = \sigma_V(r) = \max_{i=1, \dots, \ell} r_i \quad \text{for } r = (r_1, \dots, r_\ell).$$

It follows that in (\mathcal{P}_0) we

$$\text{minimize} \quad p \cdot u + \max_{i=1, \dots, \ell} \{q_i - d_i \cdot u\} \quad \text{over } u \in U,$$

where q_i is the i th component of q and d_i the i th row of D . The “max” expression in the objective in (\mathcal{P}_0) is the pointwise maximum of a finite collection of affine functions of u and represents a general piecewise linear (i.e. polyhedral convex) function of u in the sense of [36, §19]. In the corresponding dual problem (\mathcal{Q}_0) we

$$\begin{aligned} & \text{maximize} && q \cdot v - \sigma_U(p - D^*v) \\ & \text{subject to} && v \geq 0, \quad v \cdot \mathbf{1} = 1, \end{aligned}$$

where σ_U is the support function of U as in (2.7).

The constraint structure represented so far by the set U can be handled more directly under a different choice of notation. Still with $P = 0$ and $Q = 0$, simply take $U = \mathbf{R}^k$ but

$$V = \left\{ v \in \mathbf{R}_+^\ell \mid \sum_{i=1}^m v_i = 1 \right\} \quad \text{for an index } m \text{ satisfying } 1 < m < \ell,$$

where v_i is the i th component of v . This time

$$(3.9) \quad \rho_{V,Q}(r) = \sigma_V(r) = \begin{cases} \max_{i=1, \dots, m} r_i & \text{if } r_{m+1} \geq 0, \dots, r_\ell \geq 0, \\ \infty & \text{otherwise.} \end{cases}$$

Then in (\mathcal{P}_0) we

$$\begin{aligned} & \text{minimize} && p \cdot u + \max_{i=1, \dots, m} \{q_i - d_i \cdot u\} \\ & \text{subject to} && d_i \cdot u \geq q_i \quad \text{for } i = m+1, \dots, \ell, \end{aligned}$$

whereas in (\mathcal{Q}_0) we

$$\begin{aligned} & \text{maximize} && \sum_{i=1}^{\ell} q_i v_i \\ & \text{subject to} && v_i \geq 0 \quad \text{for } i = 1, \dots, \ell, \quad \sum_{i=1}^m v_i = 1, \quad \sum_{i=1}^{\ell} v_i d_i = p. \end{aligned}$$

Example 3.4. (Bounded linear programming.) The linear programming problems in Example 3.1 are stated in terms of unbounded variables, but in practice this may not always be wise or convenient. Many linear programming codes ask the user to specify

both upper and lower bounds for the vector u in the primal problem, say $\hat{u}^- \leq u \leq \hat{u}^+$. The effects on duality, however, are not widely appreciated. In fact there is reason impose upper and lower bounds on the dual variables too, say $\hat{v}^- \leq v \leq \hat{v}^+$. What this corresponds to is a representation of constraints in terms of *linear penalties*, like those in the currently popular ℓ_1 penalty function approach to nonlinear programming (cf. Fletcher [38]).

To be specific, suppose $P = 0$, $Q = 0$, and let U and V be vectorial intervals ("boxes") defined by upper and lower bounds:

$$U = [\hat{u}^-, \hat{u}^+], \quad V = [\hat{v}^-, \hat{v}^+].$$

Adopting the notation

$$(3.10) \quad [s]_+ = \max\{0, s\}, \quad [s]_- = \min\{0, s\}$$

in the vectorial sense, where the max is taken component by component (so that $s = [s]_+ + [s]_-$), we get

$$(3.11) \quad \rho_{V,Q}(s) = \sigma_V(s) = \max_{\hat{v}^- \leq v \leq \hat{v}^+} v \cdot s = \hat{v}^+ \cdot [s]_+ + \hat{v}^- \cdot [s]_-,$$

$$(3.12) \quad \rho_{U,P}(r) = \sigma_U(r) = \max_{\hat{u}^- \leq u \leq \hat{u}^+} u \cdot r = \hat{u}^+ \cdot [r]_+ + \hat{u}^- \cdot [r]_-.$$

It follows that in (\mathcal{P}_0) we

$$\begin{aligned} &\text{minimize} && p \cdot u + \hat{v}^+ \cdot [q - Du]_+ + \hat{v}^- \cdot [q - Du]_- \\ &\text{subject to} && \hat{u}^- \leq u \leq \hat{u}^+, \end{aligned}$$

whereas in (\mathcal{Q}_0) we

$$\begin{aligned} &\text{maximize} && q \cdot v + \hat{u}^+ \cdot [D^*v - p]_+ + \hat{u}^- \cdot [D^*v - p]_- \\ &\text{subject to} && \hat{v}^- \leq v \leq \hat{v}^+. \end{aligned}$$

Observe that these problems have piecewise linear objectives of a special kind. The optimal values are always finite, so optimal solutions always exist (Theorem 2.2).

Bounded linear programming in this sense may be a more natural vehicle in some applications than standard linear programming. Furthermore, problems in such a format can be solved directly, without reformulating them in the traditional way. Versions of the simplex method developed by Fourer [39] and the author [40, Chap. 11] can be used instead, for example.

Example 3.5. (Bounded quadratic programming.) This is an extension of the preceding example to allow for quadratic terms. Let

$$U = [\hat{u}^-, \hat{u}^+] \quad \text{and} \quad V = [\hat{v}^-, \hat{v}^+]$$

again, and take

$$P = \text{diag} [\beta_1, \dots, \beta_k], \quad Q = \text{diag} [\gamma_1, \dots, \gamma_\ell],$$

where $\beta_j \geq 0$, $\gamma_i \geq 0$. (The assumption of a diagonal form for P and Q does not entail the loss of generality that might be imagined; cf. Example 3.2.) The calculation of the ρ functions (2.5) and (2.6) decomposes into one-dimensional calculations of the form

$$(3.13) \quad \max_{\alpha \in [\alpha^-, \alpha^+]} \left\{ \tau \alpha - \frac{1}{2} \lambda \alpha^2 \right\}$$

for various intervals $[\alpha^-, \alpha^+]$ and constants $\lambda \geq 0$. The maximum value in (3.13) is a function of $\tau \in \mathbb{R}$ that depends on the parameters α^-, α^+ and λ , and it is given by

$$(3.14) \quad \theta(\tau; \alpha^-, \alpha^+, \lambda) = \begin{cases} (2\tau - \lambda\alpha^+)(\alpha^+/2) & \text{when } \tau \geq \lambda\alpha^+, \\ (1/2\lambda)\tau^2 & \text{when } \lambda\alpha^- < \tau < \lambda\alpha^+, \\ (2\tau - \lambda\alpha^-)(\alpha^-/2) & \text{when } \tau \leq \lambda\alpha^-. \end{cases}$$

Despite its formula, this function of τ has a simple form and a natural meaning. In the case where $\lambda = 0$, it vanishes at $\tau = 0$, is linear with slope α_+ for $\tau > 0$ and linear with slope α_- for $\tau < 0$. In the case where $\lambda > 0$, it has a similar structure but with a quadratic interpolation instead of a “corner.” Indeed, it is the unique *smooth* function whose values are given by $\alpha^+\tau + \text{const.}$ for τ sufficiently high, by $\alpha^-\tau + \text{const.}$ for τ sufficiently low, and by $(1/2\lambda)\tau^2$ on the interval between.

With this notation, and denoting the components of p, q , and D by p_j, q_i, d_{ij} , and so forth, we can express the primal and dual problems as follows. In (\mathcal{P}_0) we

$$\begin{aligned} &\text{minimize} && \sum_{j=1}^k [p_j u_j + \tfrac{1}{2} \beta_j u_j^2] + \sum_{i=1}^{\ell} \theta \left(q_i - \sum_{j=1}^k d_{ij} u_j; \hat{v}_i^-, \hat{v}_i^+, \gamma_i \right) \\ &\text{subject to} && \hat{u}_j^- \leq u_j \leq \hat{u}_j^+ \quad \text{for } j = 1, \dots, k, \end{aligned}$$

whereas in (\mathcal{Q}_0) we

$$\begin{aligned} &\text{maximize} && \sum_{i=1}^{\ell} [q_i v_i - \tfrac{1}{2} \gamma_i v_i^2] - \sum_{j=1}^k \theta \left(\sum_{i=1}^{\ell} v_i d_{ij} - p_j; \hat{u}_j^-, \hat{u}_j^+, \beta_j \right) \\ &\text{subject to} && \hat{v}_i^- \leq v_i \leq \hat{v}_i^+ \quad \text{for } i = 1, \dots, \ell. \end{aligned}$$

When $\beta_j = 0, \gamma_i = 0$, these problems reduce to the bounded linear case in Example 3.4. They are useful in modeling situations where constraints are not necessarily sharp, as in stochastic programming (see Rockafellar and Wets [18] and King et al. [41]). Thus for instance if $[\hat{v}_i^-, \hat{v}_i^+] = [0, \alpha_i^+]$ the corresponding θ term in (\mathcal{P}_0) imposes no penalty if the putative constraint $\sum_{j=1}^k d_{ij} u_j \geq q_i$ is satisfied, a slight penalty at a marginal cost that grows linearly (at the rate $1/\gamma_i$) from 0 as this constraint begins to be violated, and eventually for large violations a penalty with constant marginal cost α_i^+ .

Of course it is also possible to get versions of these problems in which the penalty expressions do not eventually become linear but stay quadratic for arbitrarily large violations. These correspond to limiting cases of $\theta(\tau; \alpha^-, \alpha^+, \lambda)$ where $\alpha^- = -\infty$ or $\alpha^+ = \infty$, or both. They can be obtained by taking U and V not to be “boxes” but orthants or products of orthants and subspaces, as in Example 2.3. \square

In understanding the relationship between penalty models such as Examples 3.4 and 3.5 and the more traditional models without penalties, such as Examples 3.1 and 3.2, the facts in Theorem 2.5 are essential. As an illustration of the way Theorem 2.5 can be employed, let us look again at the standard linear programming problems in Example 3.1. Suppose we know that an optimal solution \bar{u} to (\mathcal{P}_0) will exist within certain upper bounds, say $\bar{u} \leq \hat{u}$, and also that a dual optimal solution \bar{v} to (\mathcal{Q}_0) will exist within certain upper bounds, say $\bar{v} \leq \hat{v}$. Then according to Theorem 2.5(a), \bar{u} and \bar{v} can be found by solving, instead of the given problems, the bounded linear programming problems in Example 3.4 with

$$(3.15) \quad U = [\hat{u}^-, \hat{u}^+] = [0, \hat{u}], \quad V = [\hat{v}^-, \hat{v}^+] = [0, \hat{v}].$$

The idea here that dual bounds can be given along with primal bounds is not so far-fetched as it might seem. The components of a dual optimal solution \bar{v} often have interpretation as marginal prices, or as rates of change with respect to certain perturbations of constraints. Economic limitations or experience may dictate appropriate bounds. Anyway, there is no great harm in going ahead with solving the bounded versions of the problems in terms of *estimated* bounds \hat{u} and \hat{v} . If solutions \bar{u} and \bar{v} are obtained for which the upper bounds are not tight, then \bar{u} and \bar{v} actually solve the original problems, according to Theorem 2.5(b). If the upper bounds are tight in some components, they can be loosened and the procedure repeated.

4. Intertemporal linear-quadratic programming. The general problems of optimal control that are the main object of our study can now be formulated. The time interval $[t_0, t_1]$ is fixed. The primal problem is:

(P) Over the dynamical system

$$\dot{x}(t) = A(t)x(t) + B(t)u(t) + b(t) \quad \text{a.e.}, \quad x(t_0) = B_e u_e + b_e,$$

with control space

$$\mathcal{U} = \{(u, u_e) \mid u \in \mathcal{L}^1, u(t) \in U(t) \text{ a.e.}, u_e \in U_e\}$$

minimize the functional

$$\begin{aligned} \mathcal{F}(u, u_e) = & \int_{t_0}^{t_1} [p(t) \cdot u(t) + \frac{1}{2}u(t) \cdot P(t)u(t) - c(t) \cdot x(t)]dt + [p_e \cdot u_e + \frac{1}{2}u_e \cdot P_e u_e - c_e \cdot x(t_1)] \\ & + \int_{t_0}^{t_1} \rho_{V(t), Q(t)}(q(t) - C(t)x(t) - D(t)u(t)) + \rho_{V_e, Q_e}(q_e - C_e x(t_1) - D_e u_e). \end{aligned}$$

The dual problem is:

(Q) Over the dynamical system

$$-\dot{y}(t) = A^*(t)y(t) + C^*(t)v(t) + c(t) \quad \text{a.e.}, \quad y(t_1) = C_e^* v_e + c_e,$$

with control space

$$\mathcal{V} = \{(v, v_e) \mid v \in \mathcal{L}^1, v(t) \in V(t) \text{ a.e.}, v_e \in V_e\},$$

maximize the functional

$$\begin{aligned} \mathcal{G}(v, v_e) = & \int_{t_0}^{t_1} [q(t) \cdot v(t) - \frac{1}{2}v(t) \cdot Q(t)v(t) - b(t) \cdot y(t)]dt + [q_e \cdot v_e - \frac{1}{2}v_e \cdot Q_e v_e - b_e \cdot y(t_0)] \\ & - \int_{t_0}^{t_1} \rho_{U(t), P(t)}(B^*(t)y(t) + D^*(t)v(t) - p(t))dt - \rho_{V_e, P_e}(B_e^* y(t_0) + D_e^* v_e - p_e). \end{aligned}$$

Here

$$u(t) \in \mathbf{R}^k, \quad u_e \in \mathbf{R}^{k_e}, \quad x(t) \in \mathbf{R}^n, \quad v(t) \in \mathbf{R}^\ell, \quad v_e \in \mathbf{R}^{\ell_e}, \quad y(t) \in \mathbf{R}^n,$$

and dimensions of the other elements are determined accordingly. The matrices $P(t)$, P_e , $Q(t)$ and Q_e are assumed to be symmetric and positive *semidefinite* (possibly 0). The sets $U(t) = \mathbf{R}^k$, $U_e = \mathbf{R}^{k_e}$, $V(t) \subset \mathbf{R}^\ell$ and $V_e \subset \mathbf{R}^{\ell_e}$ are assumed to be polyhedral

convex. The ρ terms are defined by (2.5) and (2.6). In general they are piecewise linear-quadratic convex functions that may take on the value ∞ ; cf. Proposition 2.3. Various cases based in part on the finite-dimensional models in §3 will be viewed in §5. First we must clarify our technical foundations.

All the data elements in problems (\mathcal{P}) and (\mathcal{Q}) , namely

$$A(t), B(t), C(t), D(t), b(t), c(t), P(t), Q(t), p(t), q(t), U(t), V(t),$$

are assumed to depend *continuously* on t . For the sets $U(t)$ and $V(t)$ this means continuity with respect to the usual notions of convergence of subsets of Euclidean space that are not necessarily bounded; see Salinetti and Wets [42] for an exposition of the convex case. Thus the multifunctions $t \mapsto U(t)$ and $t \mapsto V(t)$ should be lower semicontinuous and of closed graph. Lower semicontinuity of $t \mapsto U(t)$ implies that the multifunction $t \mapsto \text{int } U(t)$ is of open graph; indeed, by virtue of the convexity of $U(t)$, lower semicontinuity is equivalent to the latter property if $\text{int } U(t) \neq \emptyset$ for all $t \in [t_0, t_1]$ (Rockafellar [43, p. 458]). A special case of continuous dependence, of course, is the one where $U(t)$ and $V(t)$ are constant with respect to t .

Under these assumptions the dynamical systems in (\mathcal{P}) and (\mathcal{Q}) are well defined with respect to the control spaces \mathcal{U} and \mathcal{V} . They determine unique absolutely continuous functions x and y from $[t_0, t_1]$ to \mathbb{R}^n .

In showing that the integrals in the objective functionals in (\mathcal{P}) and (\mathcal{Q}) are well defined too, we shall make use of the following.

PROPOSITION 4.1. *The expression $\rho_{V(t), Q(t)}(s)$ is lower semicontinuous jointly in t and s , in fact continuous relative to $\{(t, s) \mid s \in \text{int } L(t)\}$, where*

$$(4.1) \quad L(t) = \{s \in \mathbb{R}^\ell \mid \rho_{V(t), Q(t)}(s) < \infty\}.$$

Moreover $L(t)$ depends lower semicontinuously on t .

The same holds for the expression $\rho_{U(t), P(t)}(r)$ and the effective domain

$$(4.2) \quad K(t) = \{r \in \mathbb{R}^k \mid \rho_{U(t), P(t)}(r) < \infty\}.$$

Proof. Our argument is based on showing that the function $\rho_{V(t), Q(t)}$ depends *epicontinuously* on t , i.e. its epigraph set

$$(4.3) \quad E(t) = \{(s, \alpha) \in \mathbb{R}^\ell \times \mathbb{R} \mid \rho_{V(t), Q(t)}(s) \leq \alpha\},$$

which is convex, depends continuously on t . Epicontinuity corresponds to a notion of function convergence first considered by Wijsman [44] and subsequently developed by others; see Wets [45]. It yields all the properties claimed. Indeed, if the multifunction $t \mapsto E(t)$ is continuous, then by definition it is lower semicontinuous and of closed graph. The closed graph property is equivalent to the lower semicontinuity of the function

$$(4.4) \quad (t, s) \mapsto \rho_{V(t), Q(t)}(s).$$

The lower semicontinuity of $t \mapsto E(t)$ implies from its definition the lower semicontinuity of the domain multifunction $t \mapsto L(t)$, since $L(t)$ is the projection in \mathbb{R}^ℓ of the epigraph (4.3). (Recall from Proposition 2.3 that $L(t)$ is a *closed* convex set, since it is polyhedral.) The multifunction $t \mapsto \text{int } L(t)$ is then of open graph, as cited above, i.e. the set $\{(t, s) \mid s \in \text{int } L(t)\}$ is open in the space $[t_0, t_1] \times \mathbb{R}^\ell$. The upper semicontinuity of $\rho_{V(t), Q(t)}(s)$ on this open set follows then from the lower semicontinuity of $t \mapsto E(t)$ again and the corresponding openness of $\{(t, s, \alpha) \mid (s, \alpha) \in \text{int } E(t)\}$, and with the lower semicontinuity noted earlier for (4.4) one gets continuity.

To prove that $\rho_{V(t), Q(t)}$ depends epicontinuously on t , we resort to the notation of Proposition 2.3, where now, however, everything depends on t . We identify $\rho_{V(t), Q(t)}$ with the conjugate φ_t^* of the convex function $\varphi_t = j_{Q(t)} + \delta_{V(t)}$, where $\delta_{V(t)}$ is the indicator of $V(t)$ and

$$(4.5) \quad j_{Q(t)}(v) = \frac{1}{2}v \cdot Q(t)v.$$

Trivially $\delta_{V(t)}$ depends epicontinuously on t , since its epigraph is just $V(t) \times \mathbb{R}_+$. Furthermore the convex function $j_{Q(t)}$ is finite everywhere on \mathbb{R}^ℓ , and its values depend continuously on t because $Q(t)$ depends continuously on t . This implies by Wets [45, p. 392] that $j_{Q(t)}$ depends epicontinuously on t and by McLinden and Bergstrom [46, Thm. 6] that the sum $\varphi_t = j_{Q(t)} + \delta_{V(t)}$ depends epicontinuously on t . The operation of passing to the conjugate of a convex function is known to preserve epicontinuity (Wijsman [44]), so we may conclude that the function $\rho_{V(t), Q(t)} = \varphi_t^*$ does depend epicontinuously on t , as claimed. \square

THEOREM 4.2. *In problem (P) the control space \mathcal{U} is a nonempty closed convex subset of $\mathcal{L}^1([t_0, t_1], \mathbb{R}^k) \times \mathbb{R}^{k_e}$, and the objective functional \mathcal{F} is well defined, lower semicontinuous and convex, with values that are finite or ∞ .*

Likewise, in problem (Q) the control space \mathcal{V} is a nonempty closed convex subset of $\mathcal{L}^1([t_0, t_1], \mathbb{R}^\ell) \times \mathbb{R}^{\ell_e}$, and the objective functional \mathcal{G} is well defined, upper semicontinuous and concave, with values that are finite or $-\infty$.

Proof. Only the first half has to be argued; the second half is parallel. The convexity and closedness of \mathcal{U} is obvious from the convexity and closedness of the sets $U(t)$ and U_e . The nonemptiness of \mathcal{U} comes from the nonemptiness of $U(t)$ and U_e and the continuity of $t \mapsto U(t)$: the selection theorem of Michael [47] asserts that any lower semicontinuous multifunction from $[t_0, t_1]$ to \mathbb{R}^k with nonempty closed convex values has a continuous selection. Thus there actually exist pairs (u, u_e) in \mathcal{U} with u continuous rather than just \mathcal{L}^1 .

The mapping $(u, u_e) \mapsto x$ from $\mathcal{L}^1([t_0, t_1], \mathbb{R}^k) \times \mathbb{R}^{k_e}$ into $\mathcal{C}([t_0, t_1], \mathbb{R}^n)$ is affine and continuous, even compact:

$$(4.6) \quad x(t) = M(t) \left(B_e u_e + b_e + \int_{t_0}^t M(\tau)^{-1} [B(\tau)u(\tau) + b(\tau)] d\tau \right),$$

where $M(t)$ is the matrix with the property that $\xi(t) = M(t)x_0$ is the solution to $\dot{\xi}(t) = A(t)\xi(t)$, $\xi(t_0) = x_0$. The terms

$$\int_{t_0}^{t_1} [p(t) \cdot u(t) - c(t) \cdot x(t)] dt + [p_e \cdot u_e - c_e \cdot x(t_1)]$$

in $\mathcal{F}(u, u_e)$ therefore give a continuous, affine functional of (u, u_e) . The mapping that takes a pair (u, u_e) in $\mathcal{L}^1([t_0, t_1], \mathbb{R}^k) \times \mathbb{R}^{k_e}$ into the pair (s, s_e) in $\mathcal{L}^1([t_0, t_1], \mathbb{R}^\ell) \times \mathbb{R}^{\ell_e}$ given by

$$(4.7) \quad s(t) = q(t) - C(t)x(t) - D(t)u(t), \quad s_e = q_e - C_e x(t_1) - D_e u_e,$$

is affine and continuous too.

It remains only to show that the expressions

$$\begin{aligned} I_1(u, u_e) &= \int_{t_0}^{t_1} u(t) \cdot P(t)u(t) dt + u_e \cdot P_e u_e, \\ I_2(s, s_e) &= \int_{t_0}^{t_1} \rho_{V(t), Q(t)}(s(t)) dt + \rho_{V_e, Q_e}(s_e) \end{aligned}$$

give well defined, lower semicontinuous, convex functionals on $\mathcal{L}^1([t_0, t_1], \mathbf{R}^k) \times \mathbf{R}^{k_e}$ and $\mathcal{L}^1([t_0, t_1], \mathbf{R}^\ell) \times \mathbf{R}^{\ell_e}$ respectively, with values that are finite or ∞ . Certainly the continuity of $P(t)$ in t and the lower semicontinuity of $\rho_{V(t), Q(t)}(s)$ jointly in t and s (proved in Proposition 4.1) ensure that the integrands for I_1 and I_2 are measurable in t .

All the terms in the formula for I_1 are nonnegative and convex, because $P(t)$ and P_e are positive semidefinite. Therefore I_1 is a well defined convex functional with values in $[0, \infty]$. Its lower semicontinuity follows from Fatou's lemma, since every norm-convergent sequence in $\mathcal{L}^1([t_0, t_1], \mathbf{R}^k)$ has a subsequence that converges pointwise almost everywhere.

The argument for I_2 is the same, after a normalization. We showed at the outset of this proof that \mathcal{U} contains a pair (u, u_e) with u actually continuous. The same applies to \mathcal{V} . Taking (v, v_e) to be such a pair in \mathcal{V} and observing from the definition of the ρ functions that then

$$\rho_{V(t), Q(t)}(s) \geq s(t) \cdot v(t), \quad \rho_{V_e, Q_e}(s_e) \geq s_e \cdot v_e,$$

we can write

$$I_2(s, s_e) = I_3(s, s_e) + \int_{t_0}^{t_1} s(t) \cdot v(t) dt + s_e \cdot v_e,$$

where

$$I_3(s, s_e) = \int_{t_0}^{t_1} [\rho_{V(t), Q(t)}(s(t)) - s(t) \cdot v(t)] dt + [\rho_{V_e, Q_e}(s_e) - s_e \cdot v_e].$$

Thus I_2 differs by only a continuous linear functional from a functional I_3 whose terms are all convex and nonnegative. As with I_1 we can see that I_3 is well defined with values in $[0, \infty]$ and is convex and lower semicontinuous. Therefore I_2 has these required properties, except that its values will generally be in $(-\infty, \infty]$. \square

It is evident that in the minimization in (\mathcal{P}) we are really interested only in the controls $(u, u_e) \in \mathcal{U}$ yielding $\mathcal{F}(u, u_e) < \infty$. Such controls have to satisfy

$$(4.8) \quad q(t) - C(t)x(t) - D(t)u(t) \in L(t) \text{ a.e. and } q_e - C_e x(t_1) - D_e u_e \in L_e,$$

where $L(t)$ and L_e are the effective domains of $\rho_{V(t), Q(t)}$ and ρ_{V_e, Q_e} (cf. Proposition 2.3). Similarly, in the maximization in (\mathcal{Q}) we are really interested only in the controls (v, v_e) yielding $\mathcal{G}(v, v_e) > -\infty$, and these have to satisfy

$$(4.9) \quad B^*(t)y(t) + D^*(t)v(t) - p(t) \in K(t) \text{ a.e. and } B_e^* y(t_0) + D_e^* v_e - p_e \in K_e,$$

where $K(t)$ and K_e are the effective domains of $\rho_{U(t), P(t)}$ and ρ_{U_e, P_e} . These implicit constraints can be regarded as "linear," incidentally, since the sets $L(t)$, L_e , $K(t)$ and K_e are polyhedral convex cones (Propositions 2.3 and 2.4).

As stated in §1, our approach in this paper to such implicit constraints involving the states $x(t)$ and $y(t)$ is to skirt them when convenient by adopting alternative problem formulations where they have no force, specifically because $L(t)$ and L_e are all of \mathbf{R}^ℓ and \mathbf{R}^{ℓ_e} , or $K(t)$ and K_e are all of \mathbf{R}^k and \mathbf{R}^{k_e} . Accordingly the following type of assumption will sometimes be of importance to us.

We shall say that the *primal finiteness condition* is satisfied if the functions $\rho_{V(t), Q(t)}$ and ρ_{V_e, Q_e} are finite everywhere (i.e. $L(t) = \mathbf{R}^\ell$ and $L_e = \mathbf{R}^{\ell_e}$). Likewise, the *dual finiteness condition* is satisfied if the functions $\rho_{U(t), P(t)}$ and ρ_{U_e, P_e} are finite everywhere (i.e. $K(t) = \mathbf{R}^k$ and $K_e = \mathbf{R}^{k_e}$). Criteria for this are furnished by Proposition 2.4.

PROPOSITION 4.3. *If the primal finiteness condition is satisfied, then $\mathcal{F}(u, u_e)$ in (\mathcal{P}) is finite for all $(u, u_e) \in \mathcal{U}$ with $u \in \mathcal{L}^\infty$.*

Likewise, if the dual finiteness condition is satisfied, then $\mathcal{G}(v, v_e)$ in (\mathcal{Q}) is finite for all $(v, v_e) \in \mathcal{V}$ with $v \in \mathcal{L}^\infty$.

Proof. Under the primal finiteness condition the convex functions $\rho_{V(t), Q(t)}$ and ρ_{V_e, Q_e} are finite on \mathbb{R}^ℓ and \mathbb{R}^{ℓ_e} and therefore continuous on these spaces, inasmuch as a convex function on a finite-dimensional space is continuous on any open set where it is finite [36, §10]. Moreover $\rho_{V(t), Q(t)}(s)$ is continuous jointly in t and s by Proposition 4.1 and consequently is bounded above and below on $[t_0, t_1] \times S$ for any bounded subset $S \subset \mathbb{R}^\ell$. For the function $s(t)$ in (4.7), then, the expression $\rho_{V(t), Q(t)}(s(t))$ is \mathcal{L}^∞ in t when $u(t)$ is \mathcal{L}^∞ in t , as is the expression $u(t) \cdot P(t)u(t)$. All the integrals in the formula for $\mathcal{F}(u, u_e)$ are therefore finite when $u \in \mathcal{L}^\infty$. The argument for $\mathcal{G}(v, v_e)$ under the dual finiteness condition runs the same way. \square

The reader may wonder why we have formulated problems (\mathcal{P}) and (\mathcal{Q}) with control spaces involving \mathcal{L}^1 rather than \mathcal{L}^∞ . Matters would be simpler in some respects with \mathcal{L}^∞ , and for applications \mathcal{L}^∞ is apparently more natural. The work done in continuous-time programming uses \mathcal{L}^∞ too. Of course, our problems include the \mathcal{L}^∞ case by simple restriction. The real reason for taking \mathcal{L}^1 , however, is not extra generality but the need for allowing ample controls in order to close a possible duality gap between (\mathcal{P}) and (\mathcal{Q}) . The payoff will come in our result on strong duality, Theorem 6.3.

5. Special cases of the optimal control models. Our task now is to illuminate the scope of the problems (\mathcal{P}) and (\mathcal{Q}) introduced in §4. We explain how they cover the linear programming models (\mathcal{P}_1) and (\mathcal{Q}_1) in §1 and much more.

The treatment of endpoints $x(t_0)$ and $x(t_1)$ in (\mathcal{P}) and $y(t_0)$ and $y(t_1)$ in (\mathcal{Q}) departs from the traditional patterns in the literature on optimal control. We therefore begin by considering various important cases embedded in our formulation and the way they come to be dualized.

Example 5.1. (Problems with fixed endpoints.) How can one represent in terms of the endpoint provisions in the structure of (\mathcal{P}) a problem in which an integral

(5.1)

$$\int_{t_0}^{t_1} [p(t) \cdot u(t) + \frac{1}{2} u(t) \cdot P(t)u(t) - c(t) \cdot x(t) + \rho_{V(t), Q(t)}(q(t) - C(t)x(t) - D(t)u(t))] dt$$

is minimized over all pairs x, u , satisfying $u(t) \in U(t)$ a.e., $u \in \mathcal{L}^1$,

$$(5.2) \quad \dot{x}(t) = A(t)x(t) + B(t)u(t) + b(t) \quad \text{a.e.}, \quad x(t_0) = a_0, \quad x(t_1) = a_1,$$

where a_0 and a_1 are fixed points in \mathbb{R}^n ? The requirement $x(t_0) = a_0$ can be handled by setting $b_e = a_0$ and trivializing the u_e vector by taking \mathbb{R}^{k_e} to be *zero-dimensional* (so $U_e = \{0\}$, $B_e = 0$, $D_e = 0$, $p_e = 0$, $P_e = 0$). Only the term

$$(5.3) \quad \rho_{V_e, Q_e}(q_e - C_e x(t_1)) - c_e \cdot x(t_1)$$

remains then in the endpoint expression for (\mathcal{P}) . This can be made to represent the requirement $x(t_1) = a_1$ as follows. First choose $V_e = \mathbb{R}^n$ and $Q_e = 0$, so that

$$(5.4) \quad \rho_{V_e, Q_e}(s_e) = \sigma_{\mathbb{R}^n}(s_e) = \begin{cases} 0 & \text{if } s_e = 0, \\ \infty & \text{if } s_e \neq 0. \end{cases}$$

Then

$$(5.5) \quad \rho_{V_e, Q_e}(q_e - C_e x(t_1)) = \begin{cases} 0 & \text{if } C_e x(t_1) = q_e, \\ \infty & \text{if } C_e x(t_1) \neq q_e. \end{cases}$$

Now all one has to do is take $C_e = I$, $q_e = a_1$, $c_e = 0$.

Note that the dual problem (Q) in this case has as its endpoint term

$$(5.6) \quad q_e \cdot v_e - \frac{1}{2} v_e \cdot Q_e v_e - b_e \cdot y(t_0) - \rho_{V_e, P_e}(B_e^* y(t_0) + D_e^* v_e - p_e) = a_1 \cdot y(t_1) - a_0 \cdot y(t_0).$$

In (Q) , therefore, one maximizes

$$(5.7) \quad \int_{t_0}^{t_1} [q(t) \cdot v(t) - \frac{1}{2} v(t) \cdot Q(t) v(t) - b(t) \cdot y(t) - \rho_{U(t), P(t)}(B^*(t) y(t) + D^*(t) v(t) - p(t))] dt \\ + a_1 \cdot y(t_1) - a_0 \cdot y(t_0)$$

over all pairs y, v , such that $v(t) \in V(t)$ a.e., $v \in \mathcal{L}^1$, and

$$(5.8) \quad -\dot{y}(t) = A^*(t) y(t) + C^*(t) v(t) + c(t) \quad \text{a.e.}$$

(with no restriction on the endpoints $y(t_0)$ and $y(t_1)$).

Of course one can stop with (5.4), (5.5), and have in place of $x(t_1) = a_1$ the more general constraint $C_e x(t_1) = q_e$ for some matrix C_e and vector q_e . In (Q) this would correspond to replacing the term $a_1 \cdot y(t_1)$ in (5.7) by $q_e \cdot v_e$, where v_e is unrestricted but $y(t_1) = C_e^* v_e$ in (5.8) (if $c_e = 0$ still).

If we only want $x(t_0) = a_0$ in (5.2), so that $x(t_1)$ is a free endpoint in (P) , and correspondingly want to incorporate a term $-d_1 \cdot x(t_1)$ in the objective (5.1), we can represent this by trivializing the vector v_e too, i.e. by taking \mathbb{R}^{l_e} to be zero-dimensional (so that $V_e = \{0\}$, $C_e = 0$, $q_e = 0$, $Q_e = 0$), and setting $c_e = d_1$. Then the term (5.3) reduces to $-d_1 \cdot x(t_1)$. In the corresponding version of (Q) the term $a_1 \cdot y(t_1)$ drops from (5.7) but $y(t_1) = d_1$ is added to (5.8). Thus (Q) is a problem of the same type but with $y(t_1)$ fixed and $y(t_0)$ free.

Example 5.2. (General linear constraints on endpoints.) Instead of fixed endpoints let us consider a much more general case where the functional (5.1) is to be minimized over all pairs x, u , satisfying $u(t) \in U(t)$ a.e., $u \in \mathcal{L}^1$,

$$\dot{x}(t) = A(t)x(t) + B(t)u(t) + b(t) \quad \text{a.e.}$$

and a constraint system of the form

$$(5.9) \quad A_0 x(t_0) + A_1 x(t_1) \geq a$$

on the endpoints, with $a \in \mathbb{R}^d$. This can be placed in the form of (P) by choosing $B_e = I$ and $b_e = 0$ (so that $x(t_0) = u_e$ in (P)) and then setting $U_e = \mathbb{R}^n$, $D_e = A_0$, $C_e = A_1$, $q_e = a$, $V_e = \mathbb{R}_+^d$, $Q_e = 0$. Then

$$(5.10) \quad \rho_{V_e, Q_e}(q_e - C_e x(t_1) - D_e u_e) = \begin{cases} 0 & \text{if (5.9) holds,} \\ \infty & \text{otherwise.} \end{cases}$$

Taking $p_e = 0$, $P_e = 0$, $c_e = 0$, we get all the endpoint terms other than (5.9) to drop out, and (P) then represents the problem as specified.

The corresponding dual problem (Q) maximizes

$$\int_{t_0}^{t_1} [q(t) \cdot v(t) - \frac{1}{2} v(t) \cdot Q(t) v(t) - b(t) \cdot y(t) - \rho_{U(t), P(t)}(B^*(t) y(t) + D^*(t) v(t) - p(t))] dt + a \cdot v_e$$

over all y, v, v_e satisfying $v(t) \in V(t)$ a.e., $v \in \mathcal{L}^\infty$, $v_e \in \mathbb{R}_+^d$,

$$(5.11) \quad -\dot{y}(t) = A^*(t)y(t) + C^*(t)v(t) + c(t) \text{ a.e.}, \quad y(t_0) = -A_0^*v_e, \quad y(t_1) = A_1^*v_e.$$

Obviously the inequality in (5.9) can be converted to an equation by taking $V_e = \mathbb{R}^d$ instead of \mathbb{R}_+^d . For a particularly interesting case of this, let $A_0 = -I$, $A_1 = I$, $a = 0$. Then (5.9) reduces to the requirement that $x(t_0) = x(t_1)$, and the endpoint conditions in (5.11) reduce correspondingly to $y(t_0) = y(t_1)$ ("periodic" boundary conditions).

Example 5.3. (Basic intertemporal linear programming.) Problems (\mathcal{P}) and (\mathcal{Q}) turn into the basic linear programming models (\mathcal{P}_1) and (\mathcal{Q}_1) described in §1 when $P(t), P_e, Q(t)$ and Q_e are zero matrices and

$$(5.12) \quad U(t) = \mathbb{R}_+^k, \quad U_e = \mathbb{R}_+^{k_e}, \quad V(t) = \mathbb{R}_+^\ell, \quad V_e = \mathbb{R}_+^{\ell_e}$$

in the pattern of Example 3.1. By choosing products of orthants and subspaces in (5.12) instead of merely orthants, one obtains the versions of these problems having a mixture of equality and inequality constraints. Neither the primal nor the dual finiteness condition (as defined in the last section, before Proposition 4.3) is satisfied in any such formulation, however.

The endpoint conditions in Examples 5.1 and 5.2 all fit into the mold of this example, since only linear constraints are involved.

Example 5.4. (Bounded intertemporal linear programming.) With $P(t), P_e, Q(t)$ and Q_e still taken to be zero matrices as in the preceding example, replace (4.8) by a choice of vectorial intervals giving upper and lower bounds on the various control vectors:

$$(5.13)$$

$$U(t) = [\hat{u}^-(t), \hat{u}^+(t)], \quad U_e = [\hat{u}_e^-, \hat{u}_e^+], \quad V(t) = [\hat{v}^-(t), \hat{v}^+(t)], \quad V_e = [\hat{v}_e^-, \hat{v}_e^+].$$

The assumption of continuous dependence of $U(t)$ and $V(t)$ on t is satisfied if the vectors $\hat{u}^-(t)$, $\hat{u}^+(t)$, $\hat{v}^-(t)$ and $\hat{v}^+(t)$ depend continuously on t . In this case *the primal and dual finiteness conditions are both satisfied*. In the notation introduced in Example 3.4 the objective in (\mathcal{P}) is to minimize

$$\begin{aligned} \mathcal{F}(u, u_e) = & \int_{t_0}^{t_1} [p(t) \cdot u(t) - c(t) \cdot x(t)] dt + [p_e \cdot u_e - c_e \cdot x(t_1)] \\ & + \int_{t_0}^{t_1} \hat{v}^-(t) \cdot [q(t) - C(t)x(t) - D(t)u(t)]_- dt + \hat{v}_e^- \cdot [q_e - C_e x(t_1) - D_e u_e]_- \\ & + \int_{t_0}^{t_1} \hat{v}^+(t) \cdot [q(t) - C(t)x(t) - D(t)u(t)]_+ dt + \hat{v}_e^+ \cdot [q_e - C_e x(t_1) - D_e u_e]_+, \end{aligned}$$

while the objective in (\mathcal{Q}) is to maximize

$$\begin{aligned} \mathcal{G}(v, v_e) = & \int_{t_0}^{t_1} [q(t) \cdot v(t) - b(t) \cdot y(t)] dt + [q_e \cdot v_e - b_e \cdot y(t_0)] \\ & - \int_{t_0}^{t_1} \hat{u}^-(t) \cdot [B^*(t)y(t) + D^*(t)v(t) - p(t)]_- dt - \hat{u}_e^- \cdot [B_e^* y(t_0) + D_e^* v_e - p_e]_- \\ & - \int_{t_0}^{t_1} \hat{u}^+(t) \cdot [B^*(t)y(t) + D^*(t)v(t) - p(t)]_+ dt - \hat{u}_e^+ \cdot [B_e^* y(t_0) + D_e^* v_e - p_e]_+. \end{aligned}$$

For instance, by taking

$$(5.14) \quad V(t) = [-\lambda \mathbf{1}, \lambda \mathbf{1}], \quad V_e = [-\lambda_e \mathbf{1}, \lambda_e \mathbf{1}],$$

where $\mathbf{1}$ denotes a vector $(1, 1, \dots, 1)$ of appropriate dimension, we obtain in (\mathcal{P}) the objective

$$(5.15) \quad \begin{aligned} \mathcal{F}(u, u_e) = & \int_{t_0}^{t_1} [p(t) \cdot u(t) - c(t) \cdot x(t)] dt + [p_e \cdot u_e - c_e \cdot x(t_1)] \\ & + \lambda \int_{t_0}^{t_1} \|q(t) - C(t)x(t) - D(t)u(t)\|_1 dt + \lambda_e \|q_e - C_e x(t_1) - D_e u_e\|_1, \end{aligned}$$

where

$$(5.16) \quad \|s\|_1 = \|(s_1, \dots, s_\ell)\|_1 = |s_1| + \dots + |s_\ell|.$$

This corresponds to a mathematical model in which constraints of the form

$$(5.17) \quad C(t)x(t) + D(t)u(t) = q(t) \quad \text{a.e.}, \quad C_e x(t_1) + D_e u_e = q_e,$$

are to be enforced by linear penalties with parameter values $\lambda > 0$ and $\lambda_e > 0$ sufficiently high.

These ideas are useful in particular in penalty representations of endpoint constraints like the ones discussed in Examples 5.1 and 5.2. Thus a condition $x(t_1) = a_1$ can be modeled by a term $\lambda \|(x(t_1) - a_1)\|_1$ in the objective (the case of $C_e = I$, $D_e = 0$ and $q_e = a_1$ in (5.15) and (5.17)). A condition $x(t_0) = a_0$ corresponds of course to a trivial interval $U_e = [0, 0]$ and needs no penalty representation.

Example 5.5. (Intertemporal piecewise linear programming.) In the general case where $P(t) = 0$, $P_e = 0$, $Q(t) = 0$ and $Q_e = 0$, one minimizes in (\mathcal{P}) the objective

$$\begin{aligned} \mathcal{F}(u, u_e) = & \int_{t_0}^{t_1} [p(t) \cdot u(t) - c(t) \cdot x(t)] dt + [p_e \cdot u_e - c_e \cdot x(t_1)] \\ & + \int_{t_0}^{t_1} \sigma_{V(t)}(q(t) - C(t)x(t) - D(t)u(t)) dt + \sigma_{V_e}(q_e - C_e x(t_1) - D_e u_e) \end{aligned}$$

and one maximizes in (\mathcal{Q}) the objective

$$\begin{aligned} \mathcal{G}(v, v_e) = & \int_{t_0}^{t_1} [q(t) \cdot v(t) - b(t) \cdot y(t)] dt + [q_e \cdot v_e - b_e \cdot y(t_0)] \\ & - \int_{t_0}^{t_1} \sigma_{U(t)}(B^*(t)y(t) + D^*(t)v(t) - p(t)) dt - \sigma_{U_e}(B_e^* y(t_0) + D_e^* v_e - p_e), \end{aligned}$$

where the σ terms are support functions defined by (2.7) and are polyhedral convex (piecewise linear).

There are two different ways of using this general piecewise linear model, beyond those already covered in Examples 5.3 and 5.4, that deserve emphasis here. The first is in problems where the objective directly involves piecewise linear terms expressed as the pointwise maximum of finite collections of affine functions. This case corresponds to the patterns in Example 3.3 and need not be written out in detail. One has

$$V(t) = [\text{simplex in } \mathbf{R}^{\ell_1}] \times [\text{orthant or interval in } \mathbf{R}^{\ell_2}],$$

and similarly for V_e . Note that in taking in an interval for the second term in each product one has a case where $V(t)$ and V_e are both bounded, so *the primal finiteness condition is satisfied*.

The other way of using this model is less obvious but important in reaching formulations of intertemporal linear programming problems that satisfy the primal and dual finiteness conditions. As already noted in Example 5.3, those conditions are never fulfilled in the basic case of (\mathcal{P}_1) and (\mathcal{Q}_1) , but they can be brought to bear by passing to a bounded linear programming formulation as in Example 5.4. A more subtle approach is possible, however, in which only *some* of the constraints receive a linear penalty representation, namely those that definitely involve the state $x(t)$ (or $y(t)$). This might turn out to be a valuable consideration in the application of numerical methods for finding solutions.

For example, suppose we are dealing with a problem initially in the (\mathcal{P}_1) format but with constraints partitioned to clarify the involvement of $x(t)$:

minimize

$$\int_{t_0}^{t_1} [p(t) \cdot u(t) - c(t) \cdot x(t)] dt + [p_e \cdot u_e - c_e \cdot x(t_1)]$$

subject to

$$C_1(t)x(t) + D_1(t)u(t) \geq q_1(t),$$

$$D_2(t)u(t) \geq q_2(t), \quad u(t) \geq 0,$$

$$C_{e1}x(t_1) + D_{e1}u_e \geq q_{e1},$$

$$D_{e2}u_e \geq q_{e2}, \quad u_e \geq 0,$$

where $q_1(t) \in \mathbb{R}^{\ell_1}$, $q_2(t) \in \mathbb{R}^{\ell_2}$, $q_{e1} \in \mathbb{R}^{\ell_{e1}}$, $q_{e2} \in \mathbb{R}^{\ell_{e2}}$. The (\mathcal{P}_1) format corresponds to choosing

$$C(t) = \begin{bmatrix} C_1(t) \\ 0 \end{bmatrix}, \quad D(t) = \begin{bmatrix} D_1(t) \\ D_2(t) \end{bmatrix}, \quad C_e = \begin{bmatrix} C_{e1} \\ 0 \end{bmatrix}, \quad D_e = \begin{bmatrix} D_{e1} \\ D_{e2} \end{bmatrix},$$

$$U(t) = \mathbb{R}_+^k, \quad U_e = \mathbb{R}_+^{\ell_e}, \quad V(t) = \mathbb{R}_+^{\ell}, \quad V_e = \mathbb{R}_+^{\ell_e}$$

(with $\ell = \ell_1 + \ell_2$ and $\ell_e = \ell_{e1} + \ell_{e2}$). An alternative formulation, however, is to take

$$C(t) = C_1(t), \quad D(t) = D_1(t), \quad q(t) = q_1(t),$$

$$U(t) = \{u \geq 0 \mid D_2(t)u \geq q_2(t)\}, \quad V(t) = \mathbb{R}_+^{\ell_1},$$

$$C_e = C_{e1}, \quad D_e = D_{e1}, \quad q_e = q_{e1},$$

$$U_e = \{u_e \geq 0 \mid D_{e2}u_e \geq q_{e2}\}, \quad V_e = \mathbb{R}_+^{\ell_{e1}}.$$

If $U(t)$ and U_e happen to be bounded sets, we *have the dual boundedness condition satisfied* in this formulation even though it was not satisfied in the formulation as (\mathcal{P}_1) .

What effect does this alternative have on the nature of the dual problem? One maximizes the expression

$$\begin{aligned} & \int_{t_0}^{t_1} [q_1(t) \cdot v_1(t) - b(t) \cdot y(t)] dt + [q_{e1} \cdot v_{e1} - b_e \cdot y(t_0)] \\ & - \int_{t_0}^{t_1} \sigma_{U(t)}(B^*(t)y(t) + D_1^*(t)v_1(t) - p(t)) dt - \sigma_{U_e}(B_e^*y(t_0) + D_{e1}^*v_{e1} - p_e) \end{aligned}$$

subject to $v_1(t) \in \mathbb{R}_+^{k_1}$ and $v_{e1} \in \mathbb{R}_+^{\ell_{e1}}$. One has

$$\begin{aligned} -\sigma_{U(t)}(r) &:= -\sup\{r \cdot u \mid u \geq 0, D_2(t)u \geq q_2(t)\} \\ &= \inf\{-r \cdot u \mid u \geq 0, D_2(t)u \geq q_2(t)\} \\ &= \sup\{q_2(t) \cdot v_2 \mid v_2 \geq 0, D_2^*(t)v_2 \leq -r\} \end{aligned}$$

by finite-dimensional linear programming duality, so that

$$\begin{aligned} & -\sigma_{U(t)}(B^*(t)y(t) + D_1^*(t)v_1(t) - p(t)) \\ & = \sup\{q_2(t) \cdot v_2 \mid v_2 \geq 0, B^*(t)y(t_0) + D_1^*(t)v_1(t) + D_2^*(t)v_2 \leq p(t)\}. \end{aligned}$$

Similarly

$$\begin{aligned} & -\sigma_{U_e}(B_e^*y(t_0) + D_{e1}^*v_{e1} - p_e) \\ & = \sup\{q_{e2} \cdot v_{e2} \mid v_{e2} \geq 0, B_e^*y(t) + D_{e1}^*v_{e1} + D_{e2}^*v_{e2} \leq p_e\}. \end{aligned}$$

The dual problem for the alternative approach is therefore essentially the same as (\mathcal{Q}_1) , except that the v_2 and v_{e2} components in \mathbf{R}^{ℓ_2} and $\mathbf{R}^{\ell_{e2}}$ have been “maximized out.” These components can ultimately be recovered if necessary, but in the meantime we do not need to worry about them in connection with theorems about optimality conditions, existence and duality, in particular the \mathcal{L}^∞ requirement on $v(t)$ in (\mathcal{Q}) .

Of course, in order for this approach to work, we must also be able to verify the assumption of continuous dependence of $U(t)$ on t . When $U(t) = \{u \geq 0 \mid D_2(t)u \geq q_2(t)\}$, this is satisfied for instance if $D_2(t)$ and $q_2(t)$ do not actually depend on t , or if there is a *continuous* function u such that $u(t) \geq 0$ and $D_2(t)u(t) > q_2(t)$ (strict inequality in every component). For the latter and also more general cases involving a possible mixture of equality and inequality constraints, see Rockafellar [48, Cor. 3.3].

Similar ideas can be applied to a partitioning of the constraints of a problem (\mathcal{Q}_1) into those that affect $y(t)$ and those that do not. In (\mathcal{P}_1) this would correspond to dynamics $\dot{x} = Ax + Bu + b$, $x(t_0) = B_e u_e + b_e$, where $B = [B_1, 0]$ and $B_e = [B_{e1}, 0]$, i.e. not all components of u and u_e are directly active in the dynamics.

Example 5.6. (Linear-quadratic regulator problem and generalizations.) Consider now a classical type of problem having the form

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} \int_{t_0}^{t_1} [u(t) \cdot P(t)u(t) + (x(t) - \hat{x}(t)) \cdot R(t)(x(t) - \hat{x}(t))] dt \\ & \quad + \frac{1}{2} (x(t_1) - a_1) \cdot R_e(x(t_1) - a_1) \\ & \text{subject to} \quad u \in \mathcal{L}^\infty([t_0, t_1], \mathbf{R}^k), \\ & \quad \dot{x}(t) = A(t)x(t) + B(t)u(t) + b(t) \text{ a.e.}, \quad x(t_0) = a_0, \end{aligned} \tag{5.18}$$

where a_0 and a_1 are given points, \hat{x} is a given function (continuous), $P(t)$ is positive *definite*, and $R(t)$ and R_e are positive *semidefinite*. This can be formulated as a problem (\mathcal{P}) by introducing factorizations

$$R(t) = C^*(t)Q(t)^{-1}C(t) \quad \text{and} \quad R_e = C_e^*Q_e^{-1}C_e, \tag{5.19}$$

where $Q(t)$ and Q_e are positive *definite*. (If $R(t)$ and R_e themselves are positive definite, one can of course take $C(t) = I$, $Q(t) = R(t)^{-1}$, $C_e = I$, $Q_e = R_e^{-1}$, in (5.19).) Set

$$p(t) = 0, \quad c(t) = 0, \quad D(t) = 0, \quad q(t) = C(t)\hat{x}(t), \quad U(t) = \mathbf{R}^k, \quad V(t) = \mathbf{R}^\ell.$$

Then in the general format of (\mathcal{P}) the terms

$$p(t) \cdot u(t) \cdot P(t)u(t) - c(t) \cdot x(t) + \rho_{V(t), Q(t)}(q(t) - C(t)x(t) - D(t)u(t))$$

reduce to

$$\frac{1}{2}u(t) \cdot P(t)u(t) + \frac{1}{2}(x(t) - \hat{x}(t)) \cdot R(t)(x(t) - \hat{x}(t)).$$

For the endpoints, trivialize u_e by taking \mathbf{R}^{k_e} to be zero-dimensional (so $U_e = \{0\}$, $p_e = 0$, $P_e = 0$, $B_e = 0$, $D_e = 0$) and let $b_e = a_0$, $q_e = C_e a_1$, $c_e = 0$. The terms

$$p_e \cdot u_e + \frac{1}{2} u_e \cdot P_e u_e - c_e \cdot x(t_1) + \rho_{v_e, Q_e}(q_e - C_e x(t_1) - D_e u_e)$$

in (\mathcal{P}) then reduce to

$$\frac{1}{2}(x(t_1) - a_1) \cdot R_e(x(t_1) - a_1),$$

and we get the desired problem (5.18) as a special case of (\mathcal{P}) . The corresponding dual (\mathcal{Q}) has the form

$$\begin{aligned} (5.20) \quad & \text{minimize} \quad \int_{t_0}^{t_1} [\hat{x}(t) \cdot C^*(t)v(t) - b(t) \cdot y(t)]dt + [a_1 \cdot C_e^* v_e - a_0 \cdot y(t_0)] \\ & \quad - \frac{1}{2} \int_{t_0}^{t_1} [v(t) \cdot Q(t)v(t) + y(t) \cdot S(t)y(t)]dt - \frac{1}{2} v_e \cdot Q_e v_e \\ & \text{subject to} \quad v \in \mathcal{L}^\infty([t_0, t_1], \mathbf{R}^\ell), \quad v_e \in \mathbf{R}^{\ell_e}, \\ & \quad -\dot{y}(t) = A^*(t)y(t) + C^*(t)v(t) \text{ a.e.}, \quad y(t_1) = C_e^* v_e, \end{aligned}$$

where

$$(5.21) \quad S(t) = B(t)P(t)^{-1}B^*(t).$$

Note that in this example *the primal and dual boundedness conditions are both satisfied*.

Generalizations of the linear-quadratic regulator problem can be made in several directions without going beyond the format of our problem (\mathcal{P}) . For instance, instead of letting $u(t)$ be a free vector in \mathbf{R}^k one can insist on bounds $\hat{u}^-(t) \leq u(t) \leq \hat{u}^+(t)$. Dually one can introduce bounds

$$-\lambda \mathbf{1} \leq v(t) \leq \lambda \mathbf{1} \quad \text{and} \quad -\lambda_e \mathbf{1} \leq v_e \leq \lambda_e \mathbf{1}$$

for parameter values $\lambda > 0$, $\lambda_e > 0$. The effect of this on the formulation of the original problem (5.18) is to replace the purely quadratic penalty expressions by terms that are quadratic near the origin but eventually grow at a linear rate. Thus for example if

$$R(t) = \mu I \quad \text{and} \quad R_e = \mu_e I \quad \text{for} \quad \mu > 0, \mu_e > 0$$

(corresponding in (5.19) to $C(t) = I$, $Q(t) = \mu^{-1}I$, $C_e = I$, $Q_e = \mu_e^{-1}I$) one has terms

$$(\mu/2) \int_{t_0}^{t_1} |x(t) - \hat{x}(t)|^2 dt + (\mu_e/2) |x(t_1) - a_1|^2$$

in (5.18) that are replaced by

$$\sum_{i=1}^n \left[\int_{t_0}^{t_1} \psi(|x_i(t) - \hat{x}_i(t)|) dt + \psi_e(|x_i(t_1) - a_{1i}|) \right],$$

where $x_i(t)$ and a_{1i} are the i th components of $x(t)$ and a_1 and ψ is the growth function defined by

$$\psi(\tau) = \begin{cases} (\mu/2)\tau^2 & \text{when } 0 \leq \tau \leq \lambda/\mu, \\ \lambda(\tau - (\lambda/\mu)) + (\lambda^2/2\mu) & \text{when } \tau \geq \lambda/\mu, \end{cases}$$

and similarly ψ_e in terms of λ_e and μ_e .

Still other generalizations of the linear-quadratic regulator problem are covered by the patterns in the next example.

Example 5.7. (Bounded intertemporal quadratic programming.) This corresponds to the finite-dimensional bounded quadratic programming models in Example 3.5 in the same way that Example 5.4 corresponds to the finite-dimensional bounded linear programming models in Example 3.4. Due to all the notation involved, we shall not write these problems out in full. The point is, however, that these are formulations of considerable versatility which allow for quadratic terms without damaging the explicit, symmetric nature of the dualization.

Example 5.8. (Problems whose duals are essentially finite-dimensional.) Suppose in problem (\mathcal{P}) that $C(t) \equiv 0$. Then in (\mathcal{Q}) the trajectory y is uniquely determined from v_e alone. Although $v(t)$ still appears in the objective in (\mathcal{Q}) , it does so in a very simple way: the value chosen for $v(t)$ has no connection to past or future. At each time t one can just take $v(t)$ to maximize the expression

$$q(t) \cdot v(t) - \frac{1}{2}v(t) \cdot Q(t)v(t) - b(t) \cdot y(t) - \rho_{V(t), Q(t)}(B^*(t)y(t) + D^*(t)v(t) - p(t))$$

over $V(t)$, where $y(t)$ is already fixed. In this sense (\mathcal{Q}) is really a problem in v_e alone and is therefore finite-dimensional. (Of course $v(t)$ must ultimately be an \mathcal{L}^1 function of t .)

6. Saddle points and optimality. The duality between problems (\mathcal{P}) and (\mathcal{Q}) will be established by associating them with an infinite-dimensional saddle point problem. This will lead to the principal results of this paper, which concern the existence and optimality properties of solutions to (\mathcal{P}) and (\mathcal{Q}) .

The saddle point representation we aim at follows the general guidelines at the beginning of §2. We take the control spaces \mathcal{U} and \mathcal{V} already introduced in §4 (which are nonempty by Theorem 4.2) and define on $\mathcal{U} \times \mathcal{V}$ a certain functional J , namely

$$(6.1) \quad J(u, u_e; v, v_e) = \int_{t_0}^{t_1} J(t, u(t), v(t))dt + J_e(u_e, v_e) - [(u, u_e), (v, v_e)]$$

under the convention $\infty - \infty = \infty$ (see below), where

$$(6.2) \quad J(t, u, v) = p(t) \cdot u + q(t) \cdot v + \frac{1}{2}u \cdot P(t)u - \frac{1}{2}v \cdot Q(t)v - v \cdot D(t)u,$$

$$(6.3) \quad J_e(u_e, v_e) = p_e \cdot u_e + q_e \cdot v_e + \frac{1}{2}u_e \cdot P_e u_e - \frac{1}{2}v_e \cdot Q_e v_e - v_e \cdot D_e u_e,$$

and

$$(6.4) \quad \begin{aligned} [(u, u_e), (v, v_e)] &= \int_{t_0}^{t_1} y(t) \cdot [B(t)u(t) + b(t)]dt + y(t_0) \cdot [B_e u_e + b_e] \\ &= \int_{t_0}^{t_1} x(t) \cdot [C^*(t)v(t) + c(t)]dt + x(t_1) \cdot [C_e^* v_e + c_e]. \end{aligned}$$

The common value of the two expressions for $[(u, u_e), (v, v_e)]$ in (6.4) stems from the integration-by-parts formula

$$\int_{t_0}^{t_1} y(t) \cdot \dot{x}(t)dt + y(t_0) \cdot x(t_0) = - \int_{t_0}^{t_1} x(t) \cdot \dot{y}(t)dt + x(t_1) \cdot y(t_1).$$

The term $[(u, u_e), (v, v_e)]$, which is affine in (u, u_e) for fixed (v, v_e) and affine in (v, v_e) for fixed (u, u_e) , as well as continuous with respect to all arguments, embodies the fundamental connection between the control systems in (\mathcal{P}) and (\mathcal{Q}) .

The convention $\infty - \infty = \infty$ mentioned in the definition (6.1) of J refers to possible ambiguities in the value of the integral of $J(t, u(t), v(t))$. In general, since

$u(t)$ and $v(t)$ are only \mathcal{L}^1 in t , the integral of the term $u(t) \cdot P(t)u(t)$ might be ∞ , the integral of $v(t) \cdot Q(t)v(t)$ might be $-\infty$, and the integral of $v(t) \cdot D(t)u(t)$ might be either. We use $\infty - \infty = \infty$ to resolve any dilemmas in extended arithmetic that might arise. This amounts to taking the integral term in (6.1) to be ∞ if $J(t, u(t), v(t))$ is not majorized by any \mathcal{L}^1 function of t . Of course if $J(t, u(t), v(t)) \leq \alpha(t)$ for an \mathcal{L}^1 function α , then the integral has an unambiguous value which is finite or $-\infty$, whereas if $J(t, u(t), v(t)) \geq \beta(t)$ for an \mathcal{L}^1 function β , it is finite or ∞ . Actually there is no difficulty at all if $u \in \mathcal{L}^\infty$ or $v \in \mathcal{L}^\infty$: one has

$$(6.5) \quad J(u, u_e; v, v_e) < \infty \quad \text{when} \quad u \in \mathcal{L}^\infty,$$

$$(6.6) \quad J(u, u_e; v, v_e) > -\infty \quad \text{when} \quad v \in \mathcal{L}^\infty,$$

and therefore $J(u, u_e; v, v_e)$ finite when both $u \in \mathcal{L}^\infty$ and $v \in \mathcal{L}^\infty$.

Anyway, under the specified convention J is a well-defined functional on $\mathcal{U} \times \mathcal{V}$ which is quadratic convex in (u, u_e) and quadratic concave in (v, v_e) . The convention $\infty - \infty = -\infty$ could have been used instead and would have led to a functional \tilde{J} that would serve our purposes in equivalent fashion; we shall occasionally make use of \tilde{J} in our proofs. Obviously from (6.5) and (6.6), J and \tilde{J} agree whenever $u \in \mathcal{L}^\infty$ or $v \in \mathcal{L}^\infty$.

THEOREM 6.1. *Problems (\mathcal{P}) and (\mathcal{Q}) are the primal and dual optimization problems associated with the saddle point problem for J on $\mathcal{U} \times \mathcal{V}$. Thus the functional \mathcal{F} which in (\mathcal{P}) is minimized over \mathcal{U} is given by*

$$(6.7) \quad \mathcal{F}(u, u_e) = \sup_{(v, v_e) \in \mathcal{V}} J(u, u_e; v, v_e),$$

whereas the functional \mathcal{G} which in (\mathcal{Q}) is maximized over \mathcal{V} is given by

$$(6.8) \quad \mathcal{G}(v, v_e) = \inf_{(u, u_e) \in \mathcal{U}} J(u, u_e; v, v_e).$$

Proof. In establishing (6.7) we take the second of the expressions in (6.4) for the term $[(u, u_e), (v, v_e)]$ in the definition (6.1) of J , so that

$$(6.9) \quad \begin{aligned} J(u, u_e; v, v_e) = & \int_{t_0}^{t_1} [p(t) \cdot u(t) + \tfrac{1}{2}u(t) \cdot P(t)u(t) - c(t) \cdot x(t)]dt \\ & + \int_{t_0}^{t_1} (v(t) \cdot [q(t) - C(t)x(t) - D(t)u(t)] - \tfrac{1}{2}v(t) \cdot Q(t)v(t))dt \\ & + [p_e \cdot u_e + \tfrac{1}{2}u_e \cdot P_e u_e - c_e \cdot x(t_1)] \\ & + v_e \cdot [q_e - C_e x(t_1) - D_e u_e] - \tfrac{1}{2}v_e \cdot Q_e v_e. \end{aligned}$$

From the definition (2.5) of the functions $\rho_{V(t), Q(t)}$ and ρ_{V_e, Q_e} it is clear that

$$(6.10) \quad \mathcal{F}(u, u_e) \geq J(u, u_e; v, v_e) \quad \text{for all } (u, u_e) \in \mathcal{U}, (v, v_e) \in \mathcal{V},$$

and that the desired equation (6.7) can be verified by showing that the equation

$$(6.11) \quad \sup_{\substack{v \in \mathcal{L}^\infty \\ v(t) \in V(t)}} \int_{t_0}^{t_1} [v(t) \cdot s(t) - \tfrac{1}{2}v(t) \cdot Q(t)v(t)]dt = \int_{t_0}^{t_1} \rho_{V(t), Q(t)}(s(t))dt$$

holds for arbitrary $s \in \mathcal{L}^1$. This equation can be written as

$$(6.12) \quad \sup_{v \in \mathcal{L}^\infty} \int_{t_0}^{t_1} [v(t) \cdot s(t) - \varphi_t(v(t))]dt = \int_{t_0}^{t_1} \varphi_t^*(s(t))dt$$

for the convex function $\varphi_t(v) = j_{Q(t)}(v) + \delta_{V(t)}(v)$ utilized in the proofs of Proposition 2.3, 2.4, and 4.1. It holds by [49, Thm. 2] (or [50, Thm. 3C]) if $\varphi(t, v) = \varphi_t(v)$ is a so-called *normal integrand* and the left side of (6.12) is not $-\infty$. Actually $\varphi(t, v)$ is lower semicontinuous jointly in t and v , inasmuch as $Q(t)$ and $V(t)$ depend continuously on t , whereas normality merely requires $\varphi(t, v)$ to be lower semicontinuous in v for fixed t and measurable in (t, v) with respect to the σ -algebra in $[t_0, t_1] \times \mathbb{R}^\ell$ generated by the Lebesgue sets in $[t_0, t_1]$ and the Borel sets in \mathbb{R}^ℓ [50, Thm. 24]. Thus φ is normal. Furthermore the left side of (6.12), or equivalently of (6.11), cannot be $-\infty$, because the integral is finite when $v \in \mathcal{L}^\infty$, and we do know (from the proof of Theorem 4.2) that \mathcal{V} contains at least one pair (v, v_e) with v actually continuous.

Our argument has not only verified (6.7) but shown that the same would be true if J were replaced by the alternative functional \tilde{J} using $\infty - \infty = -\infty$ instead of $\infty - \infty = \infty$. Indeed, (6.10) still holds for \tilde{J} , since $J \geq \tilde{J}$. Everything else is unchanged, because we relied only on $v \in \mathcal{L}^\infty$, and for such v the values of J and \tilde{J} agree. This symmetry is all we need to conclude that (6.8) is valid too. \square

THEOREM 6.2 (Weak Duality). *For the optimal control problems (\mathcal{P}) and (\mathcal{Q}) it is always true that*

$$\inf(\mathcal{P}) \geq \sup(\mathcal{Q}).$$

Furthermore a pair $((\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e))$ is a saddle point of J on $\mathcal{U} \times \mathcal{V}$ if and only if (\bar{u}, \bar{u}_e) solves (\mathcal{P}) , (\bar{v}, \bar{v}_e) solves (\mathcal{Q}) , and $\min(\mathcal{P}) = \max(\mathcal{Q})$ (finite).

Proof. This is just a repeat of the general facts in Proposition 2.1 for the specific case in Theorem 6.1. \square

A stronger result is obtained by appealing to the *finiteness conditions* for (\mathcal{P}) and (\mathcal{Q}) that were introduced at the end of §4. We wish to emphasize again, as in §1, that this is by no means the most general result on strong duality. Rather, it is presented as a relatively simple result which is easy to work with and already capable of covering many important cases, especially in view of the modeling possibilities explained in §5.

THEOREM 6.3 (Strong Duality). *If the primal finiteness condition is satisfied, then*

$$(6.13) \quad \inf(\mathcal{P}) = \max(\mathcal{Q}) < \infty,$$

and moreover the dual objective \mathcal{G} is weakly sup-compact relative to \mathcal{V} , i.e. all level sets of the form

$$(6.14) \quad \{(v, v_e) \in \mathcal{V} \mid \mathcal{G}(v, v_e) \geq \alpha\} \quad \text{for } \alpha \in \mathbb{R}$$

are weakly compact in $\mathcal{L}^1([t_0, t_1], \mathbb{R}^\ell) \times \mathbb{R}^{\ell_e}$.

Likewise, if the dual finiteness condition is satisfied, then

$$(6.15) \quad \min(\mathcal{P}) = \sup(\mathcal{Q}) > -\infty,$$

and moreover the primal objective (\mathcal{P}) is weakly inf-compact relative to \mathcal{U} , i.e. all level sets of the form

$$(6.16) \quad \{(u, u_e) \in \mathcal{U} \mid \mathcal{F}(u, u_e) \leq \alpha\} \quad \text{for } \alpha \in \mathbb{R}$$

are weakly compact in $\mathcal{L}^1([t_0, t_1], \mathbb{R}^k) \times \mathbb{R}^{k_e}$.

Thus if both finiteness conditions are satisfied, solutions exist to both (\mathcal{P}) and (\mathcal{Q}) , and

$$(6.17) \quad \min(\mathcal{P}) = \max(\mathcal{Q}) \quad (\text{finite}).$$

Proof. Our proof of the formulas (6.7) and (6.8) in Theorem 6.1 gave something slightly stronger that will now be of use: if we denote by \mathcal{U}^∞ and \mathcal{V}^∞ the subsets of \mathcal{U} and \mathcal{V} having $u \in \mathcal{L}^\infty$ and $v \in \mathcal{L}^\infty$, then

$$(6.18) \quad \mathcal{F}(u, u_e) = \sup_{(v, v_e) \in \mathcal{V}^\infty} J(u, u_e; v, v_e) \quad \text{for all } (u, u_e),$$

$$(6.19) \quad \mathcal{G}(v, v_e) = \inf_{(u, u_e) \in \mathcal{U}^\infty} J(u, u_e; v, v_e) \quad \text{for all } (v, v_e).$$

In order to obtain (6.13) it will be enough by this to demonstrate

$$(6.20) \quad \inf_{\mathcal{U}^\infty} \sup_{\mathcal{V}} J = \max_{\mathcal{V}} \inf_{\mathcal{U}^\infty} J,$$

since the inequalities

$$\inf_{\mathcal{U}^\infty} \sup_{\mathcal{V}} J \geq \inf_{\mathcal{U}} \sup_{\mathcal{V}} J \geq \sup_{\mathcal{V}} \inf_{\mathcal{U}} J$$

hold trivially. The one-sided minimax theorem of Moreau [51] will justify (6.20) provided we can show that under the primal finiteness condition $J(u, u_e; v, v_e)$ is weakly sup-compact in (v, v_e) relative to \mathcal{V} when $(u, u_e) \in \mathcal{U}^\infty$. The latter will also give us the claimed sup-compactness of \mathcal{G} via (6.19).

Fix $(u, u_e) \in \mathcal{U}^\infty$. Taking J as expressed in (6.9) and introducing $s(t)$ and s_e as in (4.5), we have

$$(6.21) \quad J(u, u_e; v, v_e) = \int_{t_0}^{t_1} [v(t) \cdot s(t) - \frac{1}{2} v(t) \cdot Q(t) v(t)] dt + [v_e \cdot s_e - \frac{1}{2} v_e \cdot Q_e v_e] + \text{const.}$$

for all $(v, v_e) \in \mathcal{V}$, where $s(t)$ is \mathcal{L}^∞ in t . The required sup-compactness property of J is the weak compactness of the level sets

$$\{(v, v_e) \in \mathcal{V} \mid J(u, u_e; v, v_e) \geq \alpha\} \quad \text{for } \alpha \in \mathbb{R}.$$

We recognize now that this is the same as the weak compactness of the level sets

$$(6.22) \quad \{(v, v_e) \in \mathcal{V} \mid \frac{1}{2} \int_{t_0}^{t_1} v(t) \cdot Q(t) v(t) dt + \frac{1}{2} v_e \cdot Q_e v_e - \langle (v, v_e), (s, s_e) \rangle \leq \beta\}$$

for $\beta \in \mathbb{R}$, where

$$(6.23) \quad \langle (v, v_e), (s, s_e) \rangle = \int_{t_0}^{t_1} v(t) \cdot s(t) dt + v_e \cdot s_e.$$

Once again the convex function

$$\varphi_t(v) = j_{Q(t)}(v) + \delta_{V(t)}(v) = \begin{cases} \frac{1}{2} v \cdot Q(t) v & \text{if } v \in V(t), \\ \infty & \text{if } v \notin V(t) \end{cases}$$

will be useful, together with

$$\varphi_e(v_e) = j_{Q_e}(v_e) + \delta_{V_e}(v_e) = \begin{cases} \frac{1}{2} v_e \cdot Q_e v_e & \text{if } v_e \in V_e, \\ \infty & \text{if } v_e \notin V_e. \end{cases}$$

The convex functional

$$I(v, v_e) = \int_{t_0}^{t_1} \varphi_t(v(t)) dt + \varphi_e(v_e)$$

is well defined on $\mathcal{L}^1([t_0, t_1], \mathbb{R}^\ell) \times \mathbb{R}^{\ell_e}$ with values in $[0, \infty)$, and in terms of it the set (6.22) can be written as

$$(6.24) \quad \{(v, v_e) \in \mathcal{L}^1([t_0, t_1], \mathbb{R}^\ell) \times \mathbb{R}^{\ell_e} \mid I(v, v_e) - \langle (v, v_e), (s, s_e) \rangle \leq \beta\}.$$

We shall be able to establish the weak compactness of this set for arbitrary $(s, s_e) \in \mathcal{L}^\infty([t_0, t_1], \mathbf{R}^\ell) \times \mathbf{R}^{\ell_e}$ and $\beta \in R$ by means of the theory of integral functional conjugate to each other [49], [50].

Let us think of the spaces $\mathcal{L}^1([t_0, t_1], \mathbf{R}^\ell) \times \mathbf{R}^{\ell_e}$ and $\mathcal{L}^\infty([t_0, t_1], \mathbf{R}^\ell) \times \mathbf{R}^{\ell_e}$ as dual to each other under the pairing (6.23). The pairing formula and the formula for I can actually be viewed as integrals over a measure space that is the union of $[t_0, t_1]$ and an atom $\{e\}$ of measure 1. In this sense I is an integral functional, pure and simple. The functional

$$I^*(s, s_e) = \int_{t_0}^{t_1} \varphi_t^*(s(t)) dt + \varphi_e^*(s_e)$$

on $\mathcal{L}^\infty([t_0, t_1], \mathbf{R}^\ell) \times \mathbf{R}^{\ell_e}$, where φ_t^* and φ_e^* are conjugate to φ_t and φ_e , is an integral functional too, and I and I^* are conjugate to each other by [49, Thm. 2] (or [50, Thm. 3C]) with respect to the pairing (6.23). Indeed $\varphi_t^* = \rho_{V(t), Q(t)}$ and $\varphi_e^* = \rho_{V_e, Q_e}$, so φ_t^* and φ_e^* are finite convex functions on \mathbf{R}^ℓ under the primal finiteness condition we are assuming. Furthermore $\varphi_t^*(s)$ is for each $s \in \mathbf{R}^\ell$ continuous in t by Proposition 4.1, hence integrable over $[t_0, t_1]$. These properties for I^* plug into the weak inf-compactness criterion of [49, p. 538] for integral functional on \mathcal{L}^1 -type spaces and prove the required weak compactness of all level sets of the form (6.24) for the conjugate functional $I = (I^*)^*$.

The proof of (6.15) and the weak compactness of the sets (6.16) follows now by symmetry. \square

COROLLARY 6.4. *Suppose the primal and dual finiteness conditions both hold. Then in order that (\bar{u}, \bar{u}_e) solve (\mathcal{P}) and (\bar{v}, \bar{v}_e) solve (\mathcal{Q}) , it is both necessary and sufficient that $(\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e)$ be a saddle point of J on $\mathcal{U} \times \mathcal{V}$.*

Proof. According to Theorem 6.2 the saddle point condition is always sufficient, and if $\min(\mathcal{P}) = \max(\mathcal{Q})$ it is also necessary. Necessity therefore follows from the primal and dual finiteness conditions by the result just proved in Theorem 6.3. \square

The saddle point condition in Corollary 6.4 means that $(\bar{u}, \bar{u}_e) \in \mathcal{U}, (\bar{v}, \bar{v}_e) \in \mathcal{V}$, and

$$(6.25) \quad J(\bar{u}, \bar{u}_e; v, v_e) \leq J(\bar{u}, \bar{u}_e; \bar{v}, \bar{v}_e) \leq J(u, u_e; \bar{v}, \bar{v}_e)$$

for all $(u, u_e) \in \mathcal{U}$ and $(v, v_e) \in \mathcal{V}$. This “global” condition actually decomposes, as we show next, into an “instantaneous” saddle point condition at each time t and an “endpoint” saddle point condition.

THEOREM 6.5 (Minimaximum Principle). *For $((\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e))$ to be a saddle point of J on $\mathcal{U} \times \mathcal{V}$, it is necessary and sufficient that the following conditions hold (in addition to $\bar{u}(t)$ and $\bar{v}(t)$ being \mathcal{L}^1 in t). For almost every $t \in [t_0, t_1]$*

$$(6.26) \quad (\bar{u}(t), \bar{v}(t)) \text{ is a saddlepoint relative to } U(t) \times V(t) \text{ for } J(t, u, v) - u \cdot B^*(t)\bar{y}(t) - v \cdot C(t)\bar{x}(t),$$

and also

$$(6.27) \quad (\bar{u}_e, \bar{v}_e) \text{ is a saddlepoint relative to } U_e \times V_e \text{ for } J_e(u_e, v_e) - u_e \cdot B_e^*\bar{y}(t_0) - v_e \cdot C_e\bar{x}(t_1),$$

where \bar{x} and \bar{y} are the primal and dual state functions corresponding to (\bar{u}, \bar{u}_e) and (\bar{v}, \bar{v}_e) .

Proof. The saddle point condition (6.25) for J on $\mathcal{U} \times \mathcal{V}$ is equivalent by Theorem 6.1 to the condition

$$(6.28) \quad \mathcal{F}(\bar{u}, \bar{u}_e) = J(\bar{u}, \bar{u}_e; \bar{v}, \bar{v}_e) = \mathcal{G}(\bar{v}, \bar{v}_e).$$

Let us write this as

$$(6.29) \quad \mathcal{F}(\bar{u}, \bar{u}_e) + \bar{\alpha} = J(\bar{u}, \bar{u}_e; \bar{v}, \bar{v}_e) + \bar{\alpha} = \mathcal{G}(\bar{v}, \bar{v}_e) + \bar{\alpha},$$

where

$$\bar{\alpha} = \int_{t_0}^{t_1} [c(t) \cdot \bar{x}(t) + b(t) \cdot \bar{y}(t)] dt + c_e \cdot \bar{x}(t_1) + b_e \cdot \bar{y}(t_0) - [(\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e)].$$

The alternative expressions for $[(\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e)]$ in (6.4) give

$$\begin{aligned} \bar{\alpha} &= \int_{t_0}^{t_1} [c(t) \cdot \bar{x}(t) - \bar{u}(t) \cdot B^*(t) \bar{y}(t)] dt + [c_e \cdot \bar{x}(t_1) - \bar{u}_e \cdot B_e^* \bar{y}(t_0)] \\ &= \int_{t_0}^{t_1} [b(t) \cdot \bar{y}(t) - \bar{v}(t) \cdot C(t) \bar{x}(t)] dt + [b_e \cdot \bar{y}(t_0) - \bar{v}_e \cdot C_e \bar{x}(t_1)]. \end{aligned}$$

Using these along with the formulas defining \mathcal{F}, \mathcal{G} , and J , we get expressions of the form

$$\begin{aligned} \mathcal{F}(\bar{u}, \bar{u}_e) &= \int_{t_0}^{t_1} \bar{f}_t(\bar{u}(t)) dt + \bar{f}_e(\bar{u}_e), \\ \mathcal{G}(\bar{v}, \bar{v}_e) + \bar{\alpha} &= \int_{t_0}^{t_1} \bar{g}_t(\bar{v}(t)) dt + \bar{g}_e(\bar{v}_e), \\ J(\bar{u}, \bar{u}_e; \bar{v}, \bar{v}_e) + \alpha &= \int_{t_0}^{t_1} \bar{J}_t(\bar{u}(t), \bar{v}(t)) dt + \bar{J}_e(u_e, v_e), \end{aligned}$$

where

$$(6.30) \quad \bar{f}_t(u) = [p(t) - B^*(t) \bar{y}(t)] \cdot u + \frac{1}{2} u \cdot P(t) u + \rho_{V(t), Q(t)}(q(t) - C(t) \bar{x}(t) - D(t) u),$$

$$(6.31) \quad \bar{f}_e(u_e) = [p_e - B_e^* \bar{y}(t_0)] \cdot u + \frac{1}{2} u_e \cdot P_e u_e + \rho_{V_e, Q_e}(q_e - C_e \bar{x}(t_1) - D_e u_e),$$

$$(6.32) \quad \bar{g}_t(v) = [q(t) - C(t) \bar{x}(t)] \cdot v - \frac{1}{2} v \cdot Q(t) v - \rho_{V(t), P(t)}(B^*(t) \bar{y}(t) + D^*(t) v - p(t)),$$

$$(6.33) \quad \bar{g}_e(v_e) = [q_e - C_e \bar{x}(t_1)] \cdot v_e - \frac{1}{2} v_e \cdot Q_e v_e - \rho_{V_e, P_e}(B_e^* \bar{y}(t_0) + D_e^* v_e - p_e),$$

$$(6.34) \quad \bar{J}_t(u, v) = J(t, u, v) - u \cdot B^*(t) \bar{y}(t) - v \cdot C(t) \bar{x}(t),$$

$$(6.35) \quad \bar{J}_e(u_e, v_e) = J_e(u_e, v_e) - u_e \cdot B_e^* \bar{y}(t_0) - v_e \cdot C_e \bar{x}(t_1).$$

The saddle point condition on $((\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e))$, written as (6.27), is equivalent under this formulation to

$$\begin{aligned} (6.36) \quad \int_{t_0}^{t_1} \bar{f}_t(\bar{u}(t)) dt + \bar{f}_e(\bar{u}_e) &= \int_{t_0}^{t_1} \bar{J}_t(\bar{u}(t), \bar{v}(t)) dt + \bar{J}_e(\bar{u}_e, \bar{v}_e) \\ &= \int_{t_0}^{t_1} \bar{g}_t(\bar{v}(t)) dt + \bar{g}_e(\bar{v}_e). \end{aligned}$$

But

$$(6.37a) \quad \bar{f}_t(u) = \sup_{v \in V(t)} \bar{J}_t(u, v), \quad \bar{g}_t(v) = \inf_{u \in U(t)} \bar{J}_t(u, v),$$

$$(6.37b) \quad \bar{f}_e(u_e) = \inf_{v \in V_e} \bar{J}_e(u_e, v_e), \quad \bar{g}_e(v_e) = \sup_{u \in U_e} \bar{J}_e(u_e, v_e),$$

by the definition of the ρ terms in (6.30) – (6.33), so

$$\begin{aligned} f_t(u) &\geq J_t(u, v) \geq g_t(v) \quad \text{for all } u \in U(t), v \in V(t), \\ f_e(u_e) &\geq J_e(u_e, v_e) \geq g_e(v_e) \quad \text{for all } u_e \in U_e, v_e \in V_e. \end{aligned}$$

Since the left side of (6.36) cannot be $-\infty$, whereas the right side cannot be ∞ (from the corresponding facts about $\mathcal{F}(u, u_e)$ and $\mathcal{G}(v, v_e)$ in Theorem 6.1), condition (6.36) holds if and only if

$$\bar{f}_t(\bar{u}(t)) = \bar{J}_t(\bar{u}(t), \bar{v}(t)) = \bar{g}_t(\bar{v}(t)) \quad \text{a.e.,} \quad f_e(\bar{u}_e) = \bar{J}_e(\bar{u}_e, \bar{v}_e) = \bar{g}_e(\bar{v}_e).$$

In view of (6.37a) and (6.37b) these are precisely the “instantaneous” and “endpoint” saddle point conditions asserted in the theorem. \square

Theorem 6.5 has an interesting interpretation in the context of the finite-dimensional linear-quadratic programming problems in §2, as revealed by its proof. We shall formulate this as a corollary.

Corresponding to the trajectories \bar{x} and \bar{y} , consider the “instantaneous” primal and dual problems associated with the linear-quadratic form $\bar{J}_t(u, v)$ on $U(t) \times V(t)$, where \bar{J}_t is given by (6.34), namely:

$$\begin{aligned} (\mathcal{P}_t(\bar{x}, \bar{y})) \quad & \text{minimize } \bar{f}_t(u) \text{ over } u \in V(t) \quad \text{where } \bar{f}_t \text{ is given by (6.30),} \\ (\mathcal{Q}_t(\bar{x}, \bar{y})) \quad & \text{maximize } \bar{g}_t(v) \text{ over } v \in V(t) \quad \text{where } \bar{g}_t \text{ is given by (6.31).} \end{aligned}$$

Consider too the “endpoint” primal and dual problems associated with the linear-quadratic form $\bar{J}_e(u_e, v_e)$ on $U_e \times V_e$, where \bar{J}_e is given by (6.35), namely:

$$\begin{aligned} (\mathcal{P}_e(\bar{x}, \bar{y})) \quad & \text{minimize } \bar{f}_e(u_e) \text{ over } u_e \in U_e \quad \text{where } \bar{f}_e \text{ is given by (6.32),} \\ (\mathcal{Q}_e(\bar{x}, \bar{y})) \quad & \text{maximize } \bar{g}_e(v_e) \text{ over } v_e \in V_e \quad \text{where } \bar{g}_e \text{ is given by (6.33).} \end{aligned}$$

COROLLARY 6.6. *For $((\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e))$ to be a saddle point of J on $\mathcal{U} \times \mathcal{V}$, it is necessary and sufficient that the following conditions hold (in addition to $u(t)$ and $v(t)$ being \mathcal{L}^1 in t). For almost every $t \in [t_0, t_1]$*

$$(6.38) \quad \begin{aligned} \bar{u}(t) &\text{ solves the instantaneous primal } (\mathcal{P}_t(\bar{x}, \bar{y})), \text{ and} \\ \bar{v}(t) &\text{ solves the instantaneous dual } (\mathcal{Q}_t(\bar{x}, \bar{y})), \end{aligned}$$

and furthermore

$$(6.39) \quad \begin{aligned} \bar{u}_e &\text{ solves the endpoint primal } (\mathcal{P}_e(\bar{x}, \bar{y})), \text{ and} \\ \bar{v}_e &\text{ solves the endpoint dual } (\mathcal{Q}_e(\bar{x}, \bar{y})). \end{aligned}$$

Proof. Because the instantaneous and endpoint problems fall in the category of finite-dimensional linear-quadratic programming, we can apply Theorem 2.2 to them and see that (6.38) entails

$$\min(\mathcal{P}_t(\bar{x}, \bar{y})) = \max(\mathcal{Q}_t(\bar{x}, \bar{y})),$$

and (6.39) entails

$$\min(\mathcal{P}_e(\bar{x}, \bar{y})) = \max(\mathcal{Q}_e(\bar{x}, \bar{y})).$$

It follows then from Proposition 2.1 that (6.38) is equivalent to (6.26), whereas (6.39) is equivalent to (6.27). \square

Our final result extends Theorem 2.5 to the infinite-dimensional case. It provides a basis for the idea that in intertemporal linear-quadratic programming as well as in finite-dimensional linear-quadratic programming, a given pair of problems (\mathcal{P}) and (\mathcal{Q}) can often be remodeled, at least for computational purposes, by a more tractable pair $(\hat{\mathcal{P}})$ and $(\hat{\mathcal{Q}})$ in the pattern of *bounded* linear or quadratic programming as in Examples 5.4 and 5.7.

THEOREM 6.7. Consider along with (\mathcal{P}) and (\mathcal{Q}) an auxiliary pair of problems $(\hat{\mathcal{P}})$ and $(\hat{\mathcal{Q}})$ under the same assumptions and defined by the same data, except with the control sets $U(t)$, U_e , $V(t)$, and V_e replaced by sets

$$(6.40) \quad \hat{U}(t) \subset U(t), \quad \hat{U}_e \subset U_e, \quad \hat{V}(t) \subset V(t), \quad \hat{V}_e \subset V_e.$$

Suppose $\min(\hat{\mathcal{P}}) = \max(\hat{\mathcal{Q}})$, as would be true in particular by Theorem 6.3 if the sets $\hat{U}(t)$, \hat{U}_e , $\hat{V}(t)$ and \hat{V}_e are all bounded.

(a) If (\bar{u}, \bar{u}_e) and (\bar{v}, \bar{v}_e) satisfy the instantaneous and endpoint conditions in Theorem 6.5 (or Corollary 6.6) and also are such that

$$\bar{u}(t) \in \hat{U}(t) \text{ a.e.}, \quad \bar{u}_e \in \hat{U}_e, \quad \bar{v}(t) \in \hat{V}(t) \text{ a.e.}, \quad \bar{v}_e \in \hat{V}_e,$$

then (\bar{u}, \bar{u}_e) solves not only (\mathcal{P}) but $(\hat{\mathcal{P}})$, and (\bar{v}, \bar{v}_e) solves not only (\mathcal{Q}) but $(\hat{\mathcal{Q}})$.

(b) If (\bar{u}, \bar{u}_e) solves $(\hat{\mathcal{P}})$ and (\bar{v}, \bar{v}_e) solves $(\hat{\mathcal{Q}})$, and if $U(t)$ and $V(t)$ coincide with $\hat{U}(t)$ and $\hat{V}(t)$ around $\bar{u}(t)$ and $\bar{v}(t)$ for almost every t , while \hat{U}_e and \hat{V}_e coincide with U_e and V_e around \bar{u}_e and \bar{v}_e , then actually (\bar{u}, \bar{u}_e) solves (\mathcal{P}) and (\bar{v}, \bar{v}_e) solves (\mathcal{Q}) .

(The terminology about "coinciding" is defined in the statement of Theorem 2.5.)

Proof. Under the assumptions in (a), (\bar{u}, \bar{u}_e) and (\bar{v}, \bar{v}_e) give a saddle point of J on $\mathcal{U} \times \mathcal{V}$ (by Theorem 6.5, or as the case may be, Corollary 6.6), and this saddle point happens to lie in $\hat{\mathcal{U}} \times \hat{\mathcal{V}}$ (where $\hat{\mathcal{U}}$ and $\hat{\mathcal{V}}$ are the control spaces corresponding to $(\hat{\mathcal{P}})$ and $(\hat{\mathcal{Q}})$). Then $((\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e))$ is also a saddle point for J relative to $\hat{\mathcal{U}} \times \hat{\mathcal{V}}$. Theorem 6.2, applied to both pairs of problems, yields the conclusions.

Under the assumptions in (b) we know by Theorem 6.2, as applied to $(\hat{\mathcal{P}})$ and $(\hat{\mathcal{Q}})$, that $((\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e))$ is a saddle point of J relative to $\hat{\mathcal{U}} \times \hat{\mathcal{V}}$. The instantaneous conditions and endpoint conditions in Theorem 6.5 must therefore be satisfied relative to $\hat{U}(t) \times \hat{V}(t)$ and $\hat{U}_e \times \hat{V}_e$. But by Theorem 2.5 and our hypothesis about the sets coinciding locally, the same conditions are then satisfied relative to $U(t) \times V(t)$ and $U_e \times V_e$. Theorem 6.5 tells us now that $((\bar{u}, \bar{u}_e), (\bar{v}, \bar{v}_e))$ is a saddle point also for J relative to $\mathcal{U} \times \mathcal{V}$. Then (\bar{u}, \bar{u}_e) and (\bar{v}, \bar{v}_e) are optimal for (\mathcal{P}) and (\mathcal{Q}) by Theorem 6.2. \square

To make the best use of Theorem 6.7 in the manner outlined at the end of §3 for the finite-dimensional case, it would be helpful to have criteria under which (\mathcal{P}) and (\mathcal{Q}) have solutions (\bar{u}, \bar{u}_e) and (\bar{v}, \bar{v}_e) with \bar{u} and \bar{v} actually in \mathcal{L}^∞ . Then, for example, Theorem 6.7 can be applied with the subsets (6.40) taken to be intervals adequately large. Such criteria can be developed, but we shall not address the issue here. Results of this nature for the cases covered by continuous-time programming may be gleaned from Grinold [5], [6] and Reiland [8], [15].

LINEAR CONTROL THEORY WITH AN H_∞ OPTIMALITY CRITERION*

BRUCE A. FRANCIS† AND JOHN C. DOYLE‡

Abstract. This expository paper sets out the principal results in H_∞ control theory in the context of continuous-time linear systems. The focus is on the mathematical theory rather than computational methods.

Key words. H_∞ control theory, linear systems

AMS(MOS) subject classification. 93

1. Introduction. The subject of this paper is a general regulator problem: a controller is to be designed to regulate the output of a plant subjected to exogenous inputs, such as disturbances, sensor noises and reference signals. A theory for the regulator problem begins by specifying a model of the plant (the model may be a set, to reflect uncertainty), a model of the exogenous inputs, the performance requirements of the controlled system and the allowable class of controllers. For example, two typical regulator theories are the algebraic approach of Pernebo [70] and the Wiener-Hopf approach of Youla, Jabr and Bongiorno [93]. In both these theories the plant is a known time-invariant finite-dimensional linear system and the controller is required to be of this type too. In the algebraic approach the exogenous signal is (after prefiltering) an unknown initial condition, or equivalently a signal of the form $\delta(t)x$, where x is an unknown vector, and the performance requirements are internal stability and asymptotic regulation. In the Wiener-Hopf approach the exogenous signal is (again, after prefiltering) standard white noise, and the performance requirements are internal stability and minimization of the mean-square value of some signal.

In a seminal paper [96], [97], Zames introduced a new theory for the regulator problem. To describe this theory we need a few preliminary mathematical concepts [25], [82]. The Hardy space H_∞ is the class of matrix-valued functions which are analytic and bounded in the open right half-plane, the H_∞ -norm of such a function, say $F(s)$, being defined as

$$\|F\|_\infty := \sup \sigma_{\max}[F(s)].$$

Here σ_{\max} denotes maximum singular value and the supremum is over all s in the open right half-plane, $\operatorname{Re} s > 0$. For such a function the boundary value

$$F(j\omega) := \lim_{\xi \downarrow 0} F(\xi + j\omega)$$

exists for almost all ω and the boundary function is of class L_∞ (Fatou's theorem). As a consequence of the maximum modulus principle the H_∞ -norm of $F(s)$ equals the L_∞ -norm of the boundary function, i.e.,

$$\|F\|_\infty = \operatorname{ess\,sup}_\omega \sigma_{\max}[F(j\omega)].$$

For example, suppose $F(s)$ is scalar-valued, analytic and bounded in $\operatorname{Re} s > 0$, and continuous on the imaginary axis. Then $\|F\|_\infty$ equals the distance in the complex plane from the origin to the farthest point on the Nyquist plot of F .

A fundamental fact is that the $L_2[0, \infty)$ -gain of a causal time-invariant linear system equals the H_∞ -norm of its transfer function. To state this more precisely introduce the space $L_2[0, \infty)$ of vector-valued square-integrable functions. The norm on $L_2[0, \infty)$ is

$$\|x\|_2 := \left[\int_0^\infty x(t)^* x(t) dt \right]^{1/2},$$

where $*$ denotes complex-conjugate transpose. The Laplace transform of $x(t)$ in $L_2[0, \infty)$, denoted with abuse of notation by $x(s)$, belongs to the Hardy space H_2 of functions analytic in $\operatorname{Re} s > 0$ and satisfying the condition

$$\sup_{\xi > 0} \int_{-\infty}^{\infty} x(\xi + j\omega)^* x(\xi + j\omega) d\omega < \infty.$$

Such functions also have boundary values almost everywhere and the H_2 -norm is

$$\|x\|_2 := \left[(2\pi)^{-1} \int_{-\infty}^{\infty} x(j\omega)^* x(j\omega) d\omega \right]^{1/2}.$$

The Laplace transform is a Hilbert space isomorphism from $L_2[0, \infty)$ onto H_2 (the Paley-Wiener theorem). Now consider a causal time-invariant linear system having a transfer matrix $F(s)$. Suppose $F \in H_\infty$. Then $Fx \in H_2$ whenever $x \in H_2$, and moreover,

$$(1) \quad \|F\|_\infty = \sup\{\|Fx\|_2 : x \in H_2, \|x\|_2 = 1\}.$$

The H_∞ -norm arises in the regulator problem primarily under two circumstances: when there are sets of exogenous signals and when there is plant uncertainty.

Consider first an example of a tracking problem in which a plant output is to track a reference signal. Suppose, for simplicity, that these two signals are scalar-valued, and let $F(s)$ denote the transfer function from the reference input to the tracking error (reference minus output). Assume the system is stable in the sense that $F \in H_\infty$. Control designs are often based on test inputs, sinusoids being the natural ones in the frequency domain. Suppose the reference signal is allowed to be any sinusoid of amplitude no greater than 1 and of frequency belonging to some interval Ω . An appropriate performance measure might then be

$$\operatorname{ess\,sup}_{\omega \in \Omega} |F(j\omega)|,$$

this equaling the maximum amplitude of the tracking error. Let $W(s)$ be an H_∞ -function such that

$$|W(j\omega)| = 1, \quad \omega \in \Omega, \quad |W(j\omega)| = \varepsilon, \quad \omega \notin \Omega.$$

For small ε the performance measure is approximated by the H_∞ -norm $\|WF\|_\infty$. (For a nontrivial function to be analytic in the right half-plane, its magnitude cannot be zero on a subset of the imaginary axis of positive measure (F. and M. Riesz' theorem); hence the necessity of introducing ε .)

The previous example shows how an H_∞ -norm performance measure can arise from consideration of a set of exogenous inputs, namely sinusoids. Another way to arrive at the same performance measure is with inputs belonging to $L_2[0, \infty)$. Continuing with scalar-valued signals, suppose the reference input is allowed to be any function in the class

$$\{x : x = Wv \text{ for some } v \in H_2, \|v\|_2 \leq 1\},$$

where $W, W^{-1} \in H_\infty$; that is, the reference signal class consists of all x in H_2 such that

$$(2) \quad (2\pi)^{-1} \int_{-\infty}^{\infty} |x(j\omega)|^2 |W(j\omega)|^{-2} d\omega \leq 1.$$

This inequality can be interpreted as a constraint on the weighted energy of x : the energy-density spectrum $|x(j\omega)|^2$ is weighted by the factor $|W(j\omega)|^{-2}$. For example, if $|W(j\omega)|$ were relatively large on a certain frequency band and relatively small off it, then (2) would generate a class of signals having their energy concentrated on that band. This could be useful in representing, for example, a class of narrowband signals whose spectra are confined to a common frequency band. If $F(s)$ again denotes the transfer function from x to the tracking error, then by virtue of (1), $\|WF\|_\infty$ equals the maximum H_2 -norm of the tracking error (i.e., the square root of its energy).

The problem of robust stabilization can also lead to an H_∞ criterion. In this introductory section we consider a simplified version of the problem; a fuller account is given in § 2. The block diagram in Fig. 1(a) shows a plant and a controller with transfer matrices $P(s) + \Delta P(s)$ and $K(s)$ respectively; P represents the nominal plant and ΔP an unknown perturbation, usually caused by unmodeled dynamics or parameter variations. Suppose, for simplicity, that P , ΔP , and K are rational, P and ΔP are strictly proper, K is proper, and P and ΔP are analytic in $\text{Re } s \geq 0$. Suppose also that the system is internally stable for $\Delta P = 0$. How large can ΔP be so that internal stability is maintained?

One method which is used to obtain a transfer function model of a physical system is a frequency response experiment. This yields gain and phase estimates at several frequencies, which in turn provide an upper bound for the norm of $\Delta P(j\omega)$ at several values of ω . Suppose r is a scalar-valued H_∞ -function such that

$$\sigma_{\max}[\Delta P(j\omega)] < |r(j\omega)| \quad \text{for all } \omega,$$

or equivalently

$$(3) \quad \|r^{-1}\Delta P\|_\infty < 1.$$

How large can r be so that internal stability is maintained?

Simple loop transformations lead from Fig. 1(a) to Fig. 1(b) to Fig. 1(c). Since the nominal feedback system is internally stable, $K(I - PK)^{-1} \in H_\infty$. The small gain theorem [78], [95] says that the system in Fig. 1(c) will be internally stable provided the loop gain is less than unity, i.e.,

$$(4) \quad \|\Delta PK(I - PK)^{-1}\|_\infty < 1.$$

FIG. 1(a). Feedback system with perturbed plant.

FIG. 1(b). Loop transformation.

FIG. 1(c). Loop transformation.

In view of (3) a sufficient condition for (4) is

$$(5) \quad \|rK(I - PK)^{-1}\|_{\infty} \leq 1.$$

We conclude that an H_{∞} -norm bounded on a weighted closed-loop transfer matrix is sufficient for robust stability. (Condition (5) is actually necessary for internal stability for all perturbations satisfying (3) ([10], [19]).)

The problem treated in this paper concerns the system in Fig. 2. The signals w , u , z and y are vector-valued and denote, respectively, the exogenous signal (disturbances, sensor noises, reference inputs, etc.), the control signal, the signal to be regulated (tracking errors, plant outputs to be attenuated, weighted actuator outputs, etc.) and the measured signal. The transfer matrices G and K represent the plant and controller respectively. It is assumed that G is real-rational, proper and given; a real-rational proper K is sought to minimize the H_{∞} -norm of the transfer matrix from w to z under the constraint of internal stability.

For ease of reference let us call the problem just stated the *standard (H_{∞}) problem*. It must be emphasized that a controller is designed for a given nominal G ; uncertainty in G is not a consideration. (However, it may already be evident, and will be shown in § 2, that the robust stabilization problem can be recast as a standard problem.) There now exists a reasonably complete solution to the standard problem. The purpose of this paper is to set out the principal results in the context of continuous-time linear systems. The focus is on the mathematical theory rather than computational methods. For the latter the reader may consult [21], [50].

Inclusion of plant uncertainty into the H_{∞} problem increases its difficulty considerably. Let us suppose that uncertainty is introduced in the following general way: G can be any element in a family \mathbf{G} . We could then try to find a controller to minimize the maximum H_{∞} -norm of the transfer matrix from w to z , the maximum taken over all G in \mathbf{G} . For this problem Zames [97] has obtained qualitative results for a simple feedback configuration, showing how performance degrades as uncertainty increases, and Doyle [20] has introduced the concept of structured uncertainty, where the elements of \mathbf{G} have specified structures as well as norm constraints; the H_{∞} problem with structured uncertainty can be reduced to a family of standard problems, thus providing further motivation for the latter.

This introductory section concludes with a brief survey of the literature. The first papers on the subject of H_{∞} -norm optimization of systems are those of Helton [47],

FIG. 2. The standard configuration.

Tannenbaum [83] and Zames [96]. The important papers of Sarason [79] and Adamjan, Arov and Krein [1] established connections between operator theory and complex function theory, in particular, H_∞-functions; Helton [47] showed that these two mathematical subjects have useful applications in electrical engineering, namely, in broadband matching. Tannenbaum [83], [84] used (Nevanlinna–Pick) interpolation theory to attack the problem of stabilizing a plant with an unknown gain. And Zames [96] formulated the problem of sensitivity reduction by feedback as an optimization problem with an operator norm, in particular, an H_∞-norm. The latter paper was amplified in the seminal paper [97].

The fact that the L₂-gain of a system equals the H_∞-norm of its transfer function (i.e. (1)) was used by Zames [94] in his pioneering work on nonlinear system theory. This fact is also central in L₂-stability theory, such as the circle criterion (see e.g. [17]).

Motivation for the H_∞ approach with regard to modeling the exogenous signals is discussed in [20], [21], [24], [90], [97], [98] and with regard to plant uncertainty in [21], [62], [73], [97]. Classical frequency-domain performance specifications also lead to an H_∞ criterion as shown in [48], [75]. The robust stabilization problem discussed above is treated in [22], [24], [44], [54], [58], [73], [84], [85], [88]–[90]. Various versions of the standard problem for finite-dimensional time-invariant systems are covered in [35], [41], [56], [62], [86], [90], [98] in the single-input/single-output case and in [8], [9], [12], [13], [20]–[24], [32]–[34], [36], [37], [48], [49], [60], [61], [71], [74], [77], [87], [90]–[92], [97], [99] in the multivariable case. The mathematical tools primarily used in these references are Nevanlinna–Pick interpolation theory [16], the operator theory of Sarason [79] and Adamjan, Arov and Krein [1], [2] and the geometric theory of Ball and Helton [4]. The standard problem is extended beyond the finite-dimensional time-invariant case in [14], [15], [26]–[31], [42], [54], [55], [57]. References [7], [23], [35], [38]–[40], [51], [66]–[69] present performance bounds for systems designed according to an H_∞ criterion. Algorithms for computing optimal controllers are contained in [21], [50], [76], [80]. Part of the computation in [21] involves solving a special model-reduction problem, for which state-space algorithms are presented in [5], [6], [43], [59], [81]. Finally, the H_∞ approach is compared with the Wiener–Hopf approach in [21], [45], [97], [98].

2. The standard problem. The standard problem pertains to Fig. 2. It is *assumed* that G is real-rational and proper (analytic at $s = \infty$). Partition it as

$$G = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix},$$

so that the equations corresponding to Fig. 2 are

$$z = G_{11}w + G_{12}u, \quad y = G_{21}w + G_{22}u, \quad u = Ky.$$

Now eliminate u and y to get that the transfer matrix from w to z is a linear fractional transformation of K :

$$z = [G_{11} + G_{12}K(I - G_{22}K)^{-1}G_{21}]w.$$

It simplifies the theory to guarantee that the rational matrix $I - G_{22}K$ is invertible for every proper real-rational K . A simple sufficient condition for this is that G_{22} be strictly proper (equal to zero at $s = \infty$). Accordingly, this will be *assumed* hereafter.

To define what it means for K to stabilize G , introduce two fictitious inputs v_1 and v_2 as in Fig. 3. It is easy to show that the nine transfer matrices from the three

FIG. 3. System for definition of stability.

inputs w , v_1 , v_2 to the three signals z , u , y exist and are proper; if they belong to \mathbf{H}_∞ , then K stabilizes G . This is the usual notion of internal stability. An equivalent definition in terms of state-space models is as follows. Take minimal state-space realizations of G and K and in Fig. 2 set the input w to zero. Then K stabilizes G if and only if the state vectors of G and K tend to zero from every initial condition.

The *standard problem* is this: find a real-rational proper K to minimize the \mathbf{H}_∞ -norm of the transfer matrix from w to z under the constraint that K stabilize G .

Following are three examples of the standard problem.

2.1. A model-matching problem. In Fig. 4 the transfer matrix T_1 represents a “model” which is to be matched by the cascade T_2QT_3 of three transfer matrices T_2 , T_3 and Q . Here, T_i ($i = 1-3$) are given and the “controller” Q is to be designed. Let \mathbf{RH}_∞ denote the space of real-rational matrices in \mathbf{H}_∞ , that is, the space of real-rational proper matrices which are stable, i.e., analytic in $\text{Re } s \geq 0$. It is assumed that $T_i \in \mathbf{RH}_\infty$ ($i = 1-3$) and it is required that $Q \in \mathbf{RH}_\infty$. Thus the four blocks in Fig. 4 represent stable linear systems.

For our purposes the *model-matching criterion* is

$$\sup \{\|z\|_2 : w \in \mathbf{H}_2, \|w\|_2 \leq 1\} = \text{minimum.}$$

Thus the energy of the error z is to be minimized for the worst input w of unit energy. In view of (1) an equivalent criterion is

$$\|T_1 - T_2QT_3\|_\infty = \text{minimum.}$$

This model-matching problem can be cast as a standard problem by defining

$$G := \begin{bmatrix} T_1 & T_2 \\ T_3 & 0 \end{bmatrix}, \quad K := -Q,$$

so that Fig. 4 becomes equivalent to Fig. 2. The constraint that K stabilize G is then equivalent to the constraint that $Q \in \mathbf{RH}_\infty$.

This version of the model-matching problem is not very important per se; its significance in the context of this paper arises from the fact that the standard problem can be transformed to the model-matching problem (§ 3), which is simpler.

FIG. 4. Model-matching.

2.2. A tracking problem [90], [91]. Figure 5 shows a plant P whose output, v , is to track a reference signal r . The plant input, u , is generated by passing r and v through controllers C_1 and C_2 respectively. It is postulated that r is not a known fixed signal, but, as in the introduction, may be modeled as belonging to the class

$$\{r: r = Ww \text{ for some } w \in \mathbf{H}_2, \|w\|_2 \leq 1\}.$$

Here P and W are given and C_1 and C_2 are to be designed. These four transfer matrices are assumed to be real-rational and proper.

The tracking error signal is $r - v$. Let us take the cost function to be

$$(6) \quad (\|r - v\|_2^2 + \|\rho u\|_2^2)^{1/2},$$

where ρ is a positive scalar weighting factor. The reason for including ρu in (6) is to ensure the existence of an optimal proper controller; for $\rho = 0$ "optimal" controllers tend to be improper. Note that (6) equals the \mathbf{H}_2 -norm of

$$z := \begin{bmatrix} r - v \\ \rho u \end{bmatrix}.$$

Thus the *tracking criterion* is taken to be

$$\sup \{\|z\|_2: w \in \mathbf{H}_2, \|w\|_2 \leq 1\} = \text{minimum}.$$

The equivalent standard problem is obtained by defining

$$(7a) \quad y := \begin{bmatrix} r \\ v \end{bmatrix}, \quad K := \begin{bmatrix} C_1 & C_2 \end{bmatrix},$$

$$G := \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix},$$

$$(7b) \quad G_{11} := \begin{bmatrix} W \\ 0 \end{bmatrix}, \quad G_{12} := \begin{bmatrix} -P \\ \rho I \end{bmatrix},$$

$$(7c) \quad G_{21} := \begin{bmatrix} W \\ 0 \end{bmatrix}, \quad G_{22} := \begin{bmatrix} 0 \\ P \end{bmatrix}.$$

2.3. A robust stabilization problem [58], [73], [88]. This example has already been discussed in the Introduction. The system under consideration is shown in Fig. 1(a). Assume P is a strictly proper nominal plant and let r be a scalar-valued (radius) function in \mathbf{RH}_∞ . Now define a family \mathbf{P} of neighboring plants to be the set of all strictly proper real-rational matrices $P + \Delta P$ having the same number (in terms of McMillan degree) of poles in $\text{Re } s \geq 0$ as P has, where the perturbation ΔP satisfies the bound

$$\sigma_{\max}[\Delta P(j\omega)] < |r(j\omega)| \quad \text{for all } \omega.$$

For a real-rational proper K the *robust stability criterion* is that K stabilize all plants in \mathbf{P} . Stability means internal stability, that the four transfer matrices in Fig. 1(a) from v_1, v_2 to u, y all belong to \mathbf{RH}_∞ .

FIG. 5. Tracking.

We saw in the Introduction that robust stability is guaranteed by a small gain condition.

LEMMA 2.1 [10], [19]. *A real-rational proper K stabilizes all plants in \mathbf{P} if and only if K stabilizes the nominal plant P and*

$$\|rK(I - PK)^{-1}\|_{\infty} \leq 1.$$

We can convert to the set-up of the standard problem by defining G so that in Fig. 2 the transfer matrix from w to z equals $rK(I - PK)^{-1}$. This is accomplished by

$$G := \begin{bmatrix} 0 & rI \\ I & P \end{bmatrix}.$$

Then Lemma 2.1 implies that the following two conditions are equivalent: K achieves robust stability for the original system (Fig. 1(a)); in Fig. 2 K stabilizes G and puts the transfer matrix from w to z inside the closed unit ball of \mathbf{H}_{∞} .

There are several other examples of the standard problem and several other problems which are equivalent to the standard problem [21].

3. From the standard problem to a model-matching problem. In this section it is shown that the standard problem can be reduced to the model-matching problem of the first example. The procedure is to parametrize, via a parameter matrix Q in \mathbf{RH}_{∞} , all K 's which stabilize G . Then Fig. 2 can be transformed into Fig. 4, where the T_i 's depend only on G . The parametrization employed in this section is due to Youla et al. [93] as modified by Desoer et al. [18]. Previous work on stability theory for the system in Fig. 2 was carried out by Pernebo [70], Cheng and Pearson [11], and Antoulas [3]; Nett [65] treated a more general setup (K has an additional input and output).

When K stabilizes G can be characterized in terms of coprime factorizations over the ring \mathbf{RH}_{∞} of stable proper real-rational functions. Factor G and K as

$$G = NM^{-1} = \tilde{M}^{-1}\tilde{N}, \quad K = UV^{-1} = \tilde{V}^{-1}\tilde{U}.$$

The matrices N and M belong to \mathbf{RH}_{∞} and are *right-coprime*. This means that, if X is a square matrix in \mathbf{RH}_{∞} which is a right divisor of both N and M , i.e.,

$$N = YX, \quad M = ZX \quad \text{for some } Y, Z \text{ in } \mathbf{RH}_{\infty},$$

then X is a unit of \mathbf{RH}_{∞} , i.e. $X^{-1} \in \mathbf{RH}_{\infty}$. Such N and M constitute a *right-coprime factorization* (rcf) of G . Analogously, \tilde{N} and \tilde{M} are left-coprime and constitute a left-coprime factorization (lcf) of G . Similar remarks apply to the factorization of K . Such factorizations are known to exist [90].

PROPOSITION 3.1. *The following are equivalent statements about the proper transfer matrix K :*

(i) K stabilizes G ,

(ii) $\begin{bmatrix} M & \begin{bmatrix} 0 \\ I \end{bmatrix} U \\ [0 \ I] N & V \end{bmatrix}$ is a unit of \mathbf{RH}_{∞} ,

(iii) $\begin{bmatrix} \tilde{M} & \tilde{N} \begin{bmatrix} 0 \\ I \end{bmatrix} \\ \tilde{U} [0 \ I] & \tilde{V} \end{bmatrix}$ is a unit of \mathbf{RH}_{∞} .

The idea underlying the equivalence of (i) and (ii) is simply that the determinant of the matrix in (ii) is the least common denominator (in \mathbf{RH}_∞) of all the transfer functions from w, v_1, v_2 to z, u, y ; hence the determinant must be a unit for all these transfer functions to belong to \mathbf{RH}_∞ , and conversely.

The transfer matrix G is *stabilizable* if there exists a K which stabilizes it. Not every G is stabilizable; an obvious nonstabilizable G is $G_{12}=0, G_{21}=0, G_{22}=0, G_{11}$ unstable. Proposition 3.1 provides a test for stabilizability. For example, in terms of N and M, G is stabilizable if and only if suitable U and V exist satisfying condition (ii). Such a consideration readily leads to the following.

PROPOSITION 3.2. *The following are equivalent:*

- (i) G is stabilizable;
- (ii) $M, [0 \ I]N$ are right-coprime and $M, \begin{bmatrix} 0 \\ I \end{bmatrix}$ are left-coprime;
- (iii) $\tilde{M}, \tilde{N} \begin{bmatrix} 0 \\ I \end{bmatrix}$ are left-coprime and $M, [0 \ I]$ are right-coprime.

In terms of a state-space model G is stabilizable if and only if, roughly speaking, its unstable modes are controllable from u and observable from y (Fig. 2). For example, right-coprimeness of $M, [0 \ I]N$ can be interpreted as a frequency-domain stabilizability condition.

Hereafter, G will be *assumed* to be stabilizable. To recap, G is assumed so far to be real-rational, proper with G_{22} strictly proper, and stabilizable. Intuitively, stabilizability of G implies that G and G_{22} share the same unstable modes, so that to stabilize G it is enough to stabilize G_{22} . The controller K stabilizes G_{22} if, in Fig. 6, the four transfer matrices from v_1, v_2 to u, y are stable.

PROPOSITION 3.3. *K stabilizes G if and only if K stabilizes G_{22} .*

The next step is to parametrize all K 's stabilizing G_{22} . For this it is convenient to introduce a special rcf and lcf of G_{22} :

$$(8) \quad G_{22} = N_2 M_2^{-1} = \tilde{M}_2^{-1} \tilde{N}_2,$$

$$(9) \quad \begin{bmatrix} \tilde{X}_2 & -\tilde{Y}_2 \\ -\tilde{N}_2 & \tilde{M}_2 \end{bmatrix} \begin{bmatrix} M_2 & Y_2 \\ N_2 & X_2 \end{bmatrix} = I.$$

The eight matrices introduced in (8) and (9) all belong to \mathbf{RH}_∞ ; their existence is proved in § 4. Equation (9) is known as a generalized Bezout identity; its satisfaction guarantees that N_2, M_2 are right-coprime and \tilde{N}_2, \tilde{M}_2 are left-coprime. Equations (8) and (9) constitute a generalization of the usual polynomial matrix-fraction description [18], [53], [90].

FIG. 6. Part of standard configuration.

THEOREM 3.1 [18], [90], [93]. *The following formulas parametrize all proper K 's which stabilize G_{22} :*

$$(10) \quad K = (Y_2 - M_2 Q)(X_2 - N_2 Q)^{-1}$$

$$(11) \quad = (\tilde{X}_2 - Q \tilde{N}_2)^{-1} (\tilde{Y}_2 - Q \tilde{M}_2), \quad Q \in \mathbf{RH}_\infty.$$

The right-hand sides of (10) and (11) constitute an rcf and lcf of K respectively; the inverses exist for every Q in \mathbf{RH}_∞ (because G_{22} is strictly proper). As Q varies over all stable proper matrices, the formulas generate all possible stabilizing K 's.

The final step is to determine the transfer matrix from w to z in Fig. 2 when K is given by formulas (10) and (11). Define

$$(12a) \quad T_1 := G_{11} + G_{12} Y_2 \tilde{M}_2 G_{21},$$

$$(12b) \quad T_2 := G_{12} M_2,$$

$$(12c) \quad T_3 := \tilde{M}_2 G_{21}.$$

It can be proved that $T_i \in \mathbf{RH}_\infty$ ($i = 1-3$).

THEOREM 3.2 [21]. *With K as in (10), (11), the transfer matrix from w to z equals $T_1 - T_2 Q T_3$.*

We conclude from this theorem that *the standard problem reduces to the model-matching problem* of finding matrices Q in \mathbf{RH}_∞ to minimize $\|T_1 - T_2 Q T_3\|_\infty$. A solution Q to the model-matching problem yields a solution K to the standard problem via formulas (10) and (11).

A special case is when G is itself stable. In (8) and (9) we may then take

$$N_2 = \tilde{N}_2 = G_{22},$$

$$M_2, \tilde{M}_2, X_2, \tilde{X}_2 \text{ all} = I,$$

$$Y_2 = 0, \quad \tilde{Y}_2 = 0,$$

in which case (10) and (11) become [97]

$$\begin{aligned} K &= -Q(I - G_{22}Q)^{-1} \\ &= -(I - QG_{22})^{-1}Q \end{aligned}$$

and (12) produces

$$T_1 = G_{11}, \quad T_2 = G_{12}, \quad T_3 = G_{21}.$$

4. State-space computations. The reduction in the previous section was developed using transfer matrix models. However, as a practical matter the computations are quite easily and reliably performed using state-space models. This section describes how to obtain state-space realizations of the matrices T_i ($i = 1-3$) starting from a state-space realization of G . The formulas are very simple and they provide a fundamental link (Theorem 4.1) between the stability result of Theorem 3.1 and observer-based stability theory. Some of the results of this section are contained in [64].

We begin with a minimal realization of $G(s)$,

$$G(s) = D + C(s - A)^{-1}B, \quad A, B, C, D \text{ real matrices.}$$

It is convenient to introduce a new data structure:

$$[A, B, C, D] := D + C(s - A)^{-1}B.$$

Since the input and output of G are partitioned as

$$\begin{bmatrix} w \\ u \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} z \\ y \end{bmatrix},$$

the matrices B , C , and D have corresponding partitions,

$$B = [B_1 \quad B_2], \quad C = \begin{bmatrix} C_1 \\ C_2 \end{bmatrix}, \quad D = \begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix}.$$

Thus

$$G_{ij}(s) = [A, B_j, C_i, D_{ij}], \quad i, j = 1, 2.$$

Note that $D_{22} = 0$ because G_{22} is strictly proper. It follows from the stabilizability of G that the pair (A, B_2) is stabilizable and the pair (C_2, A) is detectable.

The objective now is to specify state-space realizations of transfer matrices N_2 , M_2 , etc. belonging to \mathbf{RH}_∞ and satisfying (8) and (9). Denote the state, input and output vectors of G_{22} by x , u and y respectively, so that $y = G_{22}u$ and

$$(13a) \quad \dot{x} = Ax + B_2u,$$

$$(13b) \quad y = C_2x.$$

Next, choose a real matrix F so that $A_F := A + B_2F$ is stable (all eigenvalues in $\text{Re } s < 0$) and define the vector $v := u - Fx$. Then from (13) we get

$$\dot{x} = A_Fx + B_2v, \quad u = Fx + v, \quad y = C_2x.$$

The transfer matrix from v to u is

$$(14) \quad M_2(s) := [A_F, B_2, F, I]$$

and that from v to y is

$$(15) \quad N_2(s) := [A_F, B_2, C_2, 0].$$

Therefore $G_{22} = N_2M_2^{-1}$. Similarly, by choosing a real matrix H so that $A_H := A + HC_2$ is stable and defining

$$\tilde{M}_2(s) := [A_H, H, C_2, I], \quad \tilde{N}_2(s) := [A_H, B_2, C_2, 0],$$

we obtain $G_{22} = \tilde{M}_2^{-1}\tilde{N}_2$. Thus (8) is satisfied.

Now introduce an observer-based controller, denoted by $K_o(s)$, to stabilize G_{22} . The familiar equations for K_o are

$$\dot{\hat{x}} = A\hat{x} + B_2u + H(C_2\hat{x} - y), \quad u = F\hat{x},$$

or equivalently,

$$\dot{\hat{x}} = (A + B_2F + HC_2)\hat{x} - Hy, \quad u = F\hat{x}.$$

Thus

$$K_o(s) = [A + B_2F + HC_2, -H, F, 0].$$

Obtaining factorizations of K_o analogous to those just obtained for G_{22} , we arrive at the equations

$$(16) \quad K_o = Y_2X_2^{-1} = \tilde{X}_2^{-1}\tilde{Y}_2,$$

where

$$(17) \quad X_2(s) := [A_F, -H, C_2, I],$$

$$(18) \quad Y_2(s) := [A_F, -H, F, 0],$$

$$\tilde{X}_2(s) := [A_H, -B_2, F, I], \quad \tilde{Y}_2(s) := [A_H, -H, F, 0].$$

Routine algebra verifies (9).

Formula (16) provides just one controller which stabilizes G_{22} , whereas formulas (10) and (11) in Theorem 3.1, having the additional stable matrix Q , generate all stabilizing controllers. These two results can be used to show that every stabilization procedure amounts to adding stable dynamics to the plant and then using an observer-based controller to stabilize the result. The precise statement is as follows.

THEOREM 4.1 [21]. *Suppose K stabilizes*

$$G_{22}(s) = [A, B_2, C_2, 0].$$

Then G_{22} can be embedded in a system $[A_e, B_e, C_e, 0]$, where

$$A_e := \begin{bmatrix} A & 0 \\ 0 & A_a \end{bmatrix}, \quad B_e := \begin{bmatrix} B_2 \\ 0 \end{bmatrix}, \quad C_e := [C_2 \ 0]$$

and A_a is stable, such that K has the form

$$K(s) = [A_e + B_e F_e + H_e C_e, -H_e, F_e, 0],$$

where $A_e + B_e F_e$ and $A_e + H_e C_e$ are stable.

Now consider the transfer matrices T_i defined in (12). We have obtained realizations of all the matrices on the right-hand sides of (12). Algebraic manipulations lead to the realizations

$$\begin{aligned} (19a) \quad T_1(s) &= [A_1, \underline{B}_1, \underline{C}_1, D_{11}], \\ A_1 &= \begin{bmatrix} A_F & -B_2 F \\ 0 & A_H \end{bmatrix}, \quad \underline{B}_1 = \begin{bmatrix} B_1 \\ B_1 + H D_{21} \end{bmatrix}, \\ \underline{C}_1 &= [C_1 + D_{12} F \quad -D_{12} F], \\ (19b) \quad T_2(s) &= [A_F, B_2, C_1 + D_{12} F, D_{12}], \\ (19c) \quad T_3(s) &= [A_H, B_1 + H D_{21}, C_2, D_{21}]. \end{aligned}$$

5. Model-matching theory. This section treats the model-matching problem finding matrices Q in \mathbf{RH}_∞ to minimize the model-matching error $\|T_1 - T_2 Q T_3\|_\infty$ where $T_i \in \mathbf{RH}_\infty$ ($i = 1-3$).

5.1. Existence of a solution. Define the *infimal model-matching error*

$$(20) \quad \alpha := \inf \{ \|T_1 - T_2 Q T_3\|_\infty : Q \in \mathbf{RH}_\infty \}.$$

The natural question to answer first is when is this infimum achieved. The following provides a mild sufficient condition.

THEOREM 5.1 (e.g. [33]). *The infimum in (20) is achieved if the ranks of the two matrices $T_2(j\omega)$ and $T_3(j\omega)$ are constant for all $0 \leq \omega \leq \infty$.*

These rank conditions will be *assumed* to hold for the remainder of § 5. (In applications they do hold for well-defined problems.) In general there is a family of optimal Q 's, i.e., Q 's achieving the infimum. Moreover, the model-matching error cannot be reduced by a nonrational Q , i.e.,

$$\min \{ \|T_1 - T_2 Q T_3\|_\infty : Q \in \mathbf{RH}_\infty \} = \min \{ \|T_1 - T_2 Q T_3\|_\infty : Q \in \mathbf{H}_\infty \}.$$

The latter minimum equals the distance in \mathbf{H}_∞ from T_1 to the subspace

$$T_2 \mathbf{H}_\infty T_3 := \{ T_2 Q T_3 : Q \in \mathbf{H}_\infty \}.$$

Hence

$$(21) \quad \alpha = \text{dist}(T_1, T_2 \mathbf{H}_\infty T_3).$$

The rank conditions in Theorem 5.1 suffice to make $T_2\mathbf{H}_\infty T_3$ closed in the weak-star topology of \mathbf{H}_∞ , and this in turn guarantees the existence of a matrix in $T_2\mathbf{H}_\infty T_3$ closest to an arbitrary T_1 .

The model-matching problem is relatively easy when the T_i 's are scalar-valued. The main results can be summarized as follows. A function $f(s)$ in \mathbf{RH}_∞ is said to be an *inner function* if $f(s)f(-s) = 1$. The zeros of such a function all lie in $\text{Re } s > 0$; the number of its zeros will be called its *degree*.

PROPOSITION 5.1 [98] (Scalar-valued case). *The infimum in (20) is achieved if $T_2 T_3$ has no zeros on the extended imaginary axis. In this case the optimal Q is unique and is uniquely determined by the following property: $T_1 - T_2 Q T_3$ is a scalar multiple of an inner function of degree less than the number of zeros of $T_2 T_3$ in $\text{Re } s > 0$.*

5.2. A formula for the minimal model-matching error. This subsection shows that α equals the norm of a certain operator, a Hankel operator in a special case. First, it will be shown that α can be expressed in the form

$$\alpha = \text{dist} \left(R, \begin{bmatrix} I \\ 0 \end{bmatrix} \mathbf{H}_\infty \begin{bmatrix} I & 0 \end{bmatrix} \right)$$

where the matrix R belongs to \mathbf{RL}_∞ (the space of real-rational \mathbf{L}_∞ -matrices) and depends only on the T_i 's. For this maneuver we need the concepts of inner and outer matrices [82].

Introduce the notation $F^\sim(s) := F(-s)'$ for a matrix-valued function $F(s)$, where prime denotes transpose. A matrix F in \mathbf{RH}_∞ is an *inner matrix* if $F^\sim F = I$ and an *outer matrix* if it has full row rank in $\text{Re } s > 0$; it is termed *co-inner* or *co-outer* if its transpose is inner or outer, respectively.

LEMMA 5.1. *For each matrix F in \mathbf{RH}_∞ there exist inner, outer, co-inner and co-outer matrices F_i, F_o, F_{ci}, F_{co} respectively, such that*

$$F = F_i F_o = F_{co} F_{ci}.$$

If F has constant rank on the extended imaginary axis, then F_o has a right-inverse in \mathbf{RH}_∞ and F_{co} has a left-inverse in \mathbf{RH}_∞ .

Returning to the model-matching problem, introduce inner, outer, co-inner and co-outer matrices as follows:

$$T_2 = (T_2)_i (T_2)_o, \quad T_3 = (T_3)_{co} (T_3)_{ci}.$$

(In going from the standard problem to the model-matching problem, it is possible to arrange that T_2 is automatically inner and T_3 is automatically co-inner [21].) Lemma 5.1, together with the assumptions on T_2 and T_3 , implies that $(T_2)_o$ is right-invertible over \mathbf{RH}_∞ and $(T_3)_{co}$ is left-invertible over \mathbf{RH}_∞ . Thus the mapping

$$Q \rightarrow (T_2)_o Q (T_3)_{co}$$

on \mathbf{H}_∞ is surjective. Hence from (21) we get the expression

$$\alpha = \text{dist} (T_1, (T_2)_i \mathbf{H}_\infty (T_3)_{ci}).$$

To simplify notation define

$$U_i := (T_2)_i, \quad U_{ci} := (T_3)_{ci}$$

so that

$$(22) \quad \alpha = \text{dist} (T_1, U_i \mathbf{H}_\infty U_{ci}).$$

Being inner, U_i has the property that $U_i^\sim U_i = I$. This in turn implies that

$$(23) \quad E^\sim E = I,$$

where

$$E := \begin{bmatrix} U_i^\sim \\ I - U_i U_i^\sim \end{bmatrix}.$$

It is a consequence of (23) that the norm of an \mathbf{L}_∞ -matrix is unchanged if the matrix is pre-multiplied by E . Similarly, $L^\sim L = I$, where

$$L := \begin{bmatrix} U_{ci} \\ I - U_{ci}^\sim U_{ci} \end{bmatrix},$$

and post-multiplication by L^\sim preserves the \mathbf{L}_∞ -norm. Hence (22) yields

$$\alpha = \text{dist}(ET_1 L^\sim, EU_i \mathbf{H}_\infty U_{ci} L^\sim).$$

But

$$EU_i = \begin{bmatrix} I \\ 0 \end{bmatrix}, \quad U_{ci} L^\sim = [I \quad 0].$$

Defining

$$(24) \quad R := ET_1 L^\sim,$$

we conclude that

$$(25) \quad \alpha = \text{dist}\left(R, \begin{bmatrix} I \\ 0 \end{bmatrix} \mathbf{H}_\infty [I \quad 0]\right).$$

An interesting special case occurs when T_2 has full row rank and T_3 has full column rank over the field of rational functions. Then U_i and U_{ci} are both square, so that

$$U_i^\sim = U_i^{-1}, \quad U_{ci}^\sim = U_{ci}^{-1},$$

and R has the form

$$R = \begin{bmatrix} R_1 & 0 \\ 0 & 0 \end{bmatrix}$$

where $R_1 := U_i^{-1} T_1 U_{ci}^{-1}$. Then (25) simplifies to the expression

$$\alpha = \text{dist}(R_1, \mathbf{H}_\infty).$$

In this case α equals the distance in \mathbf{L}_∞ from R_1 to the nearest \mathbf{H}_∞ -matrix.

Let us concentrate on this simpler problem of finding the distance from an \mathbf{L}_∞ -matrix R to the nearest \mathbf{H}_∞ -matrix. (The subscript on R_1 has been temporarily dropped.) Let \mathbf{L}_2 denote the Hilbert space of vector-valued square-integrable functions on the imaginary axis. The Hardy space \mathbf{H}_2 is a closed subspace of \mathbf{L}_2 ; let \mathbf{H}_2^\perp denote its orthogonal complement. The \mathbf{L}_∞ -norm of R equals the norm of the corresponding Laurent operator on \mathbf{L}_2 (cf. (1)); denote this operator by M_R :

$$M_R f = Rf, \quad f \in \mathbf{L}_2.$$

For an H_∞ -matrix X the Laurent operator M_X leaves the subspace H_2 of L_2 invariant, i.e.,

$$(26) \quad \text{if } f \in H_2 \quad \text{then } M_X f = Xf \in H_2.$$

If $\Pi: L_2 \rightarrow H_2^\perp$ denotes the *orthogonal projection*, then (26) is equivalent to the condition that

$$\Pi M_X|_{H_2} = 0.$$

Thus we have that

$$(27) \quad \begin{aligned} \text{dist}(R, H_\infty) &= \min \{\|R - X\|_\infty: X \in H_\infty\} \\ &= \min \{\|M_R - M_X\|: X \in H_\infty\} \\ &\geq \min \{\|\Pi(M_R - M_X)|_{H_2}\|: X \in H_\infty\} \\ &= \|\Pi M_R|_{H_2}\|. \end{aligned}$$

In fact, equality holds in (27).

THEOREM 5.2. *The distance from a matrix R in L_∞ to the nearest matrix in H_∞ equals the norm of the operator $\Pi M_R|_{H_2}$ from H_2 to H_2^\perp .*

This result is generally known as Nehari's theorem [63] and the operator $\Pi M_R|_{H_2}$ is called the *Hankel operator with symbol R* [72]. As a concrete example, consider the scalar-valued function $R(s) = (s-1)^{-1}$. For g in H_2 we have

$$R(s)g(s) = (s-1)^{-1}g(1) + (s-1)^{-1}[g(s) - g(1)].$$

The first function on the right-hand side belongs to H_2^\perp and the second to H_2 . Hence the Hankel operator maps $g(s)$ in H_2 into $(s-1)^{-1}g(1)$ in H_2^\perp .

The Hankel operator has a time-domain version (e.g. [43]). Suppose $R(s)$ is analytic in a strip containing the imaginary axis; such would be the case if $R(s)$ were rational, for example. Taking the region of convergence to be this strip, let $r(t)$ denote the inverse bilateral Laplace transform of $R(s)$. The linear system with impulse response $r(t)$ is therefore $L_2(-\infty, \infty)$ -stable, but noncausal in general. The Hankel operator in the time-domain maps a function u in $L_2[0, \infty)$ into a function y in $L_2(-\infty, 0]$ according to the convolution equation

$$y(t) = \int_0^\infty r(t-\tau)u(\tau) d\tau, \quad t \leq 0.$$

Since the bilateral Laplace transformation is an isomorphism from $L_2[0, \infty)$ onto H_2 and from $L_2(-\infty, 0]$ onto H_2^\perp , the Hankel operators in the two domains have equal norms. A causal system leaves $L_2[0, \infty)$ invariant, so its Hankel operator equals zero. Interpreted in the time-domain, Theorem 5.2 states that the distance from the noncausal system with impulse response $r(t)$ to the nearest causal system equals the norm of the Hankel operator; in other words, the Hankel operator's norm is a measure of noncausality. Here the distance is the norm of the error system considered as a mapping on $L_2(-\infty, \infty)$.

It is a useful fact that the norm of a Hankel operator with a rational symbol can be computed by state-space methods. Let R be a matrix in \mathbf{RL}_∞ and let $C(s-A)^{-1}B$ be a minimal realization of its antistable part, i.e.,

$$(28) \quad R(s) = C(s-A)^{-1}B + (\text{a matrix in } \mathbf{RH}_\infty),$$

and the eigenvalues of A lie in $\operatorname{Re} s > 0$. Introduce the controllability and observability gramians

$$(29) \quad L_c := \int_{-\infty}^0 e^{At} B B' e^{A't} dt,$$

$$(30) \quad L_o := \int_{-\infty}^0 e^{A't} C' C e^{At} dt.$$

Thus L_c and L_o are the unique solutions of the Lyapunov equations

$$(31) \quad A L_c + L_c A' = B B',$$

$$(32) \quad A' L_o + L_o A = C' C.$$

It can be proved [81] that $L_c L_o$ has only real, nonnegative eigenvalues.

LEMMA 5.2 (e.g. [43]). *The Hankel operator $\Gamma := \Pi M_R|_{\mathbf{H}_2}$ with rational symbol R has finite rank. The operator $\Gamma^* \Gamma$ and the matrix $L_c L_o$ share the same nonzero eigenvalues. In particular, the norm of Γ equals the square-root of the largest eigenvalue of $L_c L_o$.*

Now let us return to the general case. From (25) α equals the distance in \mathbf{L}_∞ from R to the subspace

$$\begin{bmatrix} I \\ 0 \end{bmatrix} \mathbf{H}_\infty [I \ 0].$$

A matrix in this subspace has the form

$$(33) \quad \begin{bmatrix} I \\ 0 \end{bmatrix} X [I \ 0] = \begin{bmatrix} X & 0 \\ 0 & 0 \end{bmatrix} =: X$$

for some X in \mathbf{H}_∞ , and the corresponding Laurent operator is M_X . This operator acts on \mathbf{L}_2 -vectors partitioned conformably with the partitioning in (33):

$$M_X \begin{bmatrix} f \\ g \end{bmatrix} = X \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} Xf \\ 0 \end{bmatrix}.$$

Hence the domain of this operator is the product space (external direct sum) $\mathbf{L}_2 \times \mathbf{L}_2$. Moreover, since $X \in \mathbf{H}_\infty$, the subspace $\mathbf{H}_2 \times \mathbf{L}_2$ is invariant under this operator, or equivalently

$$\Pi M_X |_{(\mathbf{H}_2 \times \mathbf{L}_2)} = 0,$$

where Π denotes the orthogonal projection from $\mathbf{L}_2 \times \mathbf{L}_2$ onto $\mathbf{H}_2^\perp \times \mathbf{L}_2$. As in (27) we conclude that

$$\operatorname{dist} \left(R, \begin{bmatrix} I \\ 0 \end{bmatrix} \mathbf{H}_\infty [I \ 0] \right) \cong \|\Pi M_R |_{(\mathbf{H}_2 \times \mathbf{L}_2)}\|.$$

Again, equality holds.

To recap, let R be defined as in (24), let M_R denote the Laurent operator on $\mathbf{L}_2 \times \mathbf{L}_2$ of multiplication by R , and let Π denote the orthogonal projection from $\mathbf{L}_2 \times \mathbf{L}_2$ onto $\mathbf{H}_2^\perp \times \mathbf{L}_2$.

THEOREM 5.3 [29]. *The minimal model-matching error α equals the norm of the operator*

$$(34) \quad \Pi M_R |_{(\mathbf{H}_2 \times \mathbf{L}_2)}$$

from $\mathbf{H}_2 \times \mathbf{L}_2$ to $\mathbf{H}_2^\perp \times \mathbf{L}_2$.

Operator (34) is not a Hankel operator (by definition) and at present there is unfortunately no direct procedure for computing its norm. It is easy to get crude bounds for its norm: an upper bound is $\|R\|_\infty$ and a lower bound is the maximum of

$$\|[0 \ I]R\|_\infty, \quad \left\| R \begin{bmatrix} 0 \\ I \end{bmatrix} \right\|_\infty.$$

5.3. Nearly optimal solutions. The value of α cannot be computed directly, as we just noted, but it is possible to compute, by iteration, an upper bound which is as close to α as desired. To do this, let α_1 and α_2 be, respectively, any lower and upper bounds for α , for example, those given at the end of the previous subsection. A number γ satisfies the inequality $\alpha < \gamma$ if and only if (see (21))

$$(35) \quad \text{dist}(T_1, T_2 H_\infty T_3) < \gamma.$$

Thus testing if (35) holds for several values of γ in the interval $[\alpha_1, \alpha_2]$ serves to locate α for any desired accuracy. A bisection search could be used.

This subsection treats the problem of checking if (35) is true for a prespecified γ and, when it is true, of finding all Q 's in \mathbf{RH}_∞ which achieve the inequality

$$\|T_1 - T_2 Q T_3\|_\infty < \gamma;$$

when γ is a bit larger than α , such Q 's are nearly optimal. It will be shown that (35) is equivalent to the following three conditions:

$$\|Y\|_\infty < \gamma, \quad \|Z\|_\infty < 1, \quad \text{dist}(R, H_\infty) < 1.$$

Here¹ R , Y and Z are \mathbf{RL}_∞ -matrices which are computed from T_i ($i = 1-3$) and γ (Theorem 5.4 below). Notice that the distance from R to H_∞ can be readily computed (Theorem 5.2, Lemma 5.2).

We require two definitions. Let F be an \mathbf{RL}_∞ -matrix and let η be a positive number. The inequality

$$(36) \quad \eta > \|F\|_\infty$$

is equivalent to the condition

$$\eta^2 I - F(j\omega)^* F(j\omega) > 0 \quad \text{for all } 0 \leq \omega \leq \infty.$$

This latter condition implies that the matrix $\eta^2 I - F^* F$ has a spectral factorization:

$$\eta^2 I - F^* F = F_o^* F_o, \quad F_o, F_o^{-1} \in \mathbf{RH}_\infty.$$

Such a matrix F_o will be called a *spectral factor* of $\eta^2 I - F^* F$. (It is outer, hence the subscript o .) The same inequality, (36), implies that

$$\eta^2 I - F F^* = F_{co} F_{co}^*$$

for some $F_{co}, F_{co}^{-1} \in \mathbf{RH}_\infty$; F_{co} will be called a *co-spectral factor* of $\eta^2 I - F F^*$.

Let us consider, first, condition (35) under the simplifying assumption that $T_3 = I$. Write $T_2 = U_i U_o$ where U_i is inner and U_o is outer, and let $Q \in \mathbf{RH}_\infty$. Then, as in the previous subsection, the matrices $T_1 - T_2 Q$ and

$$\begin{bmatrix} U_i^* \\ I - U_i U_i^* \end{bmatrix} (T_1 - T_2 Q) = \begin{bmatrix} U_i^* T_1 - U_o Q \\ (I - U_i U_i^*) T_1 \end{bmatrix}$$

¹ The matrix R in this subsection is defined somewhat differently from that in the previous one.

have equal norms. Defining

$$Y := (I - U_i U_i^\sim) T_1,$$

we obtain that

$$\|T_1 - T_2 Q\|_\infty < \gamma$$

if and only if

$$(37) \quad \left\| \begin{bmatrix} U_i^\sim T_1 - U_o Q \\ Y \end{bmatrix} \right\|_\infty < \gamma.$$

It can be shown that (37) holds if and only if $\|Y\|_\infty < \gamma$ and

$$\|(U_i^\sim T_1 - U_o Q) Y_o^{-1}\|_\infty < 1,$$

where Y_o is a spectral factor of $\gamma^2 I - Y^\sim Y$. We conclude that

$$\text{dist}(T_1, T_2 \mathbf{H}_\infty) < \gamma$$

if and only if $\|Y\|_\infty < \gamma$ and

$$\text{dist}(U_i^\sim T_1 Y_o^{-1}, \mathbf{H}_\infty) < 1.$$

The general result is as follows.

THEOREM 5.4 [20], [21]. *Let $Q \in \mathbf{RH}_\infty$ and $\gamma > 0$. Then*

$$\|T_1 - T_2 Q T_3\|_\infty < \gamma$$

if and only if

$$(38) \quad \|Y\|_\infty < \gamma, \quad \|Z\|_\infty < 1, \quad \|R - X\|_\infty < 1,$$

where R, Y, Z are \mathbf{RL}_∞ -matrices and X is an \mathbf{RH}_∞ -matrix defined as follows:

$$(39) \quad T_2 = U_i U_o, \quad U_i \text{ inner}, \quad U_o \text{ outer},$$

$$(40) \quad Y := (I - U_i U_i^\sim) T_1,$$

$$Y_o = \text{spectral factor of } \gamma^2 I - Y^\sim Y,$$

$$(41) \quad T_3 Y_o^{-1} = V_{co} V_{ci}, \quad V_{co} \text{ co-outer}, \quad V_{ci} \text{ co-inner},$$

$$(42) \quad Z := U_i^\sim T_1 Y_o^{-1} (I - V_{ci}^\sim V_{ci}),$$

$$(43) \quad Z_{co} = \text{co-spectral factor of } I - Z Z^\sim,$$

$$(44) \quad R := Z_{co}^{-1} U_i^\sim T_1 Y_o^{-1} V_{ci}^\sim,$$

$$(45) \quad X := Z_{co}^{-1} U_o Q V_{co}.$$

Observe that $Z_{co}^{-1} U_o$ is right-invertible over \mathbf{RH}_∞ and V_{co} is left-invertible over \mathbf{RH}_∞ . Thus (45) provides a linear relation between Q 's satisfying (35) and X 's satisfying (38).

Let us recap. Suppose the objective is to compute an upper bound γ for α such that $\gamma - \alpha$ is less than a prespecified number, and then to determine a Q in \mathbf{RH}_∞ satisfying

$$\|T_1 - T_2 Q T_3\|_\infty < \gamma.$$

To accomplish this, first determine lower and upper bounds α_1 and α_2 for α . Then, select a trial value for γ in the interval $[\alpha_1, \alpha_2]$. Next, test to see if the following conditions hold:

$$\|Y\|_\infty < \gamma, \quad \|Z\|_\infty < 1, \quad \text{dist}(R, \mathbf{H}_\infty) < 1.$$

If so, reduce the value of γ ; if not, increase it. When a sufficiently accurate upper bound is obtained, find an X in \mathbf{RH}_∞ such that $\|R - X\|_\infty < 1$. Finally, solve (45) for a Q in \mathbf{RH}_∞ .

The part of the procedure which remains to be described is how to find such an X . This is the next topic.

5.4. Best approximation. Let R be an \mathbf{RL}_∞ -matrix. The problem of best approximation is that of finding one, some, or all matrices X in \mathbf{RH}_∞ such that

$$\|R - X\|_\infty = \text{dist}(R, \mathbf{RH}_\infty).$$

Such X 's will be termed *optimal*. This problem has an extensive theory, involving several different approaches. In this paper there is space to describe only two of them.

The first approach, due to Adamjan, Arov and Krein [1], is applicable only to the special case where R and X are scalar-valued; then the optimal X is unique and $R - X$ is a scalar times an inner function (cf. Prop. 5.1). As in Lemma 5.2 let Γ denote the Hankel operator with symbol R , and consider the self-adjoint operator

$$\Gamma\Gamma^*: \mathbf{H}_2^\perp \rightarrow \mathbf{H}_2^\perp.$$

Let λ^2 denote the maximum eigenvalue of $\Gamma\Gamma^*$, let f be a corresponding eigenvector, and define $g := \lambda^{-1}\Gamma^*f$. Observe that f and g satisfy the equations

$$\Gamma g = \lambda f, \quad \Gamma^* f = \lambda g;$$

such vectors form what is called a Schmidt pair for Γ .

THEOREM 5.5 [1]. *The optimal X equals $R - \lambda f/g$.*

Silverman and Bettayeb [81] employed this formula together with state-space realizations to get a simple way to compute the optimal X . As in (28)–(30) let $C(s - A)^{-1}B$ be a minimal realization of the antistable part of $R(s)$ and let L_c and L_o denote the controllability and observability gramians. By Lemma 5.2 λ^2 (defined above) equals the maximum eigenvalue of $L_c L_o$; let w be a corresponding eigenvector and define $v := \lambda^{-1}L_o w$.

COROLLARY 5.1 [81]. *The optimal X is given*

$$X(s) = R(s) - \lambda[A, w, C, 0]/[-A', v, B', 0].$$

The second approach, due to Ball and Helton [4], applies to the general matrix-valued problem. The theory of suboptimal X 's is simpler than the theory of optimal ones, so a characterization will be presented of all X 's in \mathbf{RH}_∞ such that

$$\|R - X\|_\infty \leq \beta,$$

where β can be any positive number greater than $\text{dist}(R, \mathbf{RH}_\infty)$. To simplify notation slightly, scale R and X by the factor β^{-1} ; now $\text{dist}(R, \mathbf{RH}_\infty) < 1$ and the problem is to find all X 's in \mathbf{RH}_∞ such that $\|R - X\|_\infty \leq 1$. Or, in terms of $S := R - X$, the problem is to find all S 's in \mathbf{RL}_∞ such that $R - S \in \mathbf{RH}_\infty$ and $\|S\|_\infty \leq 1$.

An outline of the Ball-Helton theory takes three steps. First, instead of looking at \mathbf{RL}_∞ -matrices, we look at graphs of operators. Consider the restriction to \mathbf{H}_2 of the Laurent operator induced by R :

$$M_R|_{\mathbf{H}_2}: \mathbf{H}_2 \rightarrow \mathbf{L}_2, \quad f \rightarrow Rf.$$

The graph of this operator, which we shall call the *graph* of R , is the set of ordered pairs (Rf, f) in $\mathbf{L}_2 \times \mathbf{H}_2$. Let us write these ordered pairs as 2-vectors $\begin{pmatrix} Rf \\ f \end{pmatrix}$, so that the graph has the representation

$$\mathbf{G}_R := \begin{bmatrix} R \\ I \end{bmatrix} \mathbf{H}_2.$$

If $R - S \in \mathbf{RH}_\infty$ and $\|S\|_\infty \leq 1$, what properties does the graph of S have? First, the condition $R - S \in \mathbf{RH}_\infty$ restricts the graph to being contained in a certain subspace of $\mathbf{L}_2 \times \mathbf{H}_2$, namely

$$\mathbf{W} := \begin{bmatrix} I & R \\ 0 & I \end{bmatrix} (\mathbf{H}_2 \times \mathbf{H}_2).$$

This is easily seen as follows:

$$\begin{aligned} \mathbf{G}_S &= \begin{bmatrix} S \\ I \end{bmatrix} \mathbf{H}_2 \\ &= \begin{bmatrix} I & R \\ 0 & I \end{bmatrix} \begin{bmatrix} S - R \\ I \end{bmatrix} \mathbf{H}_2 \\ &\subset \mathbf{W}. \end{aligned}$$

Second, the graph of S is *steep*, meaning that

$$(46) \quad \text{if } \begin{pmatrix} f \\ g \end{pmatrix} \in \mathbf{G}_S, \quad \text{then } \|f\|_2 \leq \|g\|_2.$$

(The slope of the line in the plane through the origin and the point $(\|f\|_2, \|g\|_2)$ is at least 45 degrees.) Fact (46) follows immediately from the condition $\|S\|_\infty \leq 1$. These two properties characterize the graph.

LEMMA 5.3 [4]. *Let S be an \mathbf{RL}_∞ -matrix (of the same dimensions as R). Then $\|S\|_\infty \leq 1$ and $R - S \in \mathbf{RH}_\infty$ if and only if the graph of S is steep and is contained in \mathbf{W} .*

The second step in the theory is to represent \mathbf{W} in a way which is useful for characterizing steep graphs. For this representation introduce the matrix

$$J := \begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix}.$$

(The dimension of the upper left unit matrix equals the number of rows of R ; the dimension of the lower right, the number of columns.) A square matrix L in \mathbf{RL}_∞ (of appropriate dimensions) is *J-unitary* if $L^* J L = J$.

LEMMA 5.4 [4]. *There exists a J-unitary matrix L such that $L(\mathbf{H}_2 \times \mathbf{H}_2) = \mathbf{W}$.*

Lemma 5.4 is a generalization of Beurling's theorem [46]. The useful fact about L is that, because it is *J-unitary*, it maps a steep subspace of $\mathbf{H}_2 \times \mathbf{H}_2$ into a steep subspace of \mathbf{W} (in fact, it is a one-to-one correspondence between such subspaces). Thus, if $Y \in \mathbf{RH}_\infty$ and $\|Y\|_\infty \leq 1$, then LG_Y is a steep subspace of \mathbf{W} .

The third step in the theory is to combine Lemmas 5.3 and 5.4 to obtain the main result, which is stated in terms of X .

THEOREM 5.6 [4]. *The set of all X 's in \mathbf{RH}_∞ such that $\|R - X\|_\infty \leq 1$ is parametrized by the formula*

$$\begin{aligned} X &= R - X_1 X_2^{-1}, & \begin{bmatrix} X_1 \\ X_2 \end{bmatrix} &= L \begin{bmatrix} Y \\ I \end{bmatrix}, \\ Y &\in \mathbf{RH}_\infty, & \|Y\|_\infty &\leq 1. \end{aligned}$$

Ball and Ran [5], [6] showed how to obtain a state-space realization of L . A summary of their procedure is as follows. As above, let $[A, B, C, 0]$ be a minimal realization of the antistable part of $R(s)$ and let L_c and L_o denote the controllability and observability gramians. (Recall that R has been scaled so that its distance to \mathbf{RH}_∞ is less than 1.) Then a realization of L is

$$L(s) = [A, B, \underline{C}, I],$$

where

$$\begin{aligned} \underline{A} &:= \begin{bmatrix} A & 0 \\ 0 & -A' \end{bmatrix}, \\ \underline{B} &:= \begin{bmatrix} -L_c & I \\ I & -L_o \end{bmatrix} \begin{bmatrix} I - L_o L_c & 0 \\ 0 & I - L_c L_o \end{bmatrix}^{-1} \begin{bmatrix} C' & 0 \\ 0 & B \end{bmatrix}, \\ \underline{C} &:= \begin{bmatrix} C & 0 \\ 0 & -B' \end{bmatrix}. \end{aligned}$$

Other approaches to the best approximation problem are those of Glover [43] (based on [2]) and Chang and Pearson [8] (based on [16]).

6. A numerical example. The purpose of this section is to elucidate the theory of §§ 3–5 by carrying out a numerical example of the tracking problem of § 2. With reference to Fig. 5 we take the unstable nonminimum phase plant

$$P(s) = \frac{s-1}{s(s-2)}.$$

The weighting factor ρ in (6) and the weighting filter W in Fig. 5 are as follows:

$$\rho = 1, \quad W(s) = \frac{s+1}{10s+1}.$$

The Bode magnitude plot of W is nearly 0 db up to the frequency .1, so this choice of W reflects a family of reference signals having their energy concentrated in the frequency band $[0, .1]$. With this choice of P , W and ρ , the transfer matrix G in Fig. 2 is determined from (7) to be

$$\begin{aligned} G(s) &= \begin{bmatrix} G_{11}(s) & G_{12}(s) \\ G_{21}(s) & G_{22}(s) \end{bmatrix} \\ &= \left[\begin{array}{c|c} \frac{s+1}{10s+1} & -\frac{s-1}{s(s-2)} \\ 0 & 1 \\ \hline \frac{s+1}{10s+1} & 0 \\ 0 & \frac{s-1}{s(s-2)} \end{array} \right]. \end{aligned}$$

The first step in computing a controller is to obtain the matrices T_i ($i = 1-3$) in the equivalent model-matching problem. We shall use the state-space method of § 4

(although this is not the easiest way for this simple example). We begin with a minimal realization of G :

$$G(s) = [A, B, C, D],$$

$$A = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 2 \end{bmatrix}, \quad B = [B_1 \ B_2] = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 1 \end{bmatrix},$$

$$C = \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} = \begin{bmatrix} .09 & -.5 & -.5 \\ 0 & 0 & 0 \\ .09 & 0 & 0 \\ 0 & .5 & .5 \end{bmatrix}, \quad D = \begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix} = \begin{bmatrix} .1 & 0 \\ 0 & 1 \\ .1 & 0 \\ 0 & 0 \end{bmatrix}.$$

Now F and H are chosen so that the matrices

$$A_F := A + B_2 F, \quad A_H := A + H C_2$$

are stable. The exact locations of the eigenvalues are not important for the purpose at hand; the choice

$$F = [0 \ .5 \ -4.5], \quad H = \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 0 & -9 \end{bmatrix}$$

yields

$$A_F = \begin{bmatrix} -1 & 0 & 0 \\ 0 & .5 & -4.5 \\ 0 & .5 & -2.5 \end{bmatrix}, \quad A_H = \begin{bmatrix} -1 & 0 & 0 \\ 0 & .5 & .5 \\ 0 & -4.5 & -2.5 \end{bmatrix},$$

which both have spectrum $\{-1, -1, -1\}$. Then (19) produces

$$T_1(s) = T_3(s) = \begin{bmatrix} \frac{s+1}{10s+1} \\ 0 \end{bmatrix}, \quad T_2(s) = \begin{bmatrix} -\frac{s-1}{(s+1)^2} \\ \frac{s(s-2)}{(s+1)^2} \end{bmatrix}.$$

Theorem 5.1 can now be used to show that there does indeed exist an optimal proper controller: $T_2(j\omega)$ and $T_3(j\omega)$ both have rank 1 for all $0 \leq \omega \leq \infty$.

The second step is to compute an upper bound γ for the infimal model-matching error α defined in (20). Recall from Theorem 5.4 that $\gamma > \alpha$ if and only if the following three conditions hold:

$$(47) \quad \|Y\|_\infty < \gamma, \quad \|Z\|_\infty < 1, \quad \text{dist}(R, H_\infty) < 1.$$

The matrices Y , Z and R are computed as in Theorem 5.4. A simple way to do the inner-outer factorization (39) of T_2 is first to get

$$\tilde{T}_2(s) T_2(s) = \frac{s^4 - 5s^2 + 1}{(-s+1)^2(s+1)^2}.$$

Solving $\tilde{T}_2 T_2 = U_o^\sim U_o$ for an outer function U_o gives

$$U_o(s) = \frac{s^2 + \sqrt{7}s + 1}{(s+1)^2}.$$

Then the inner factor U_i is

$$U_i = T_2 U_o^{-1}, \quad U_i(s) = \frac{1}{s^2 + \sqrt{7}s + 1} \begin{bmatrix} -s + 1 \\ s(s-2) \end{bmatrix}.$$

The matrix Y defined in (40) is determined next:

$$(48) \quad Y(s) = \frac{s+1}{(10s+1)(s^4-5s^2+1)} \begin{bmatrix} s^2(s^2-4) \\ -s(s+1)(s-2) \end{bmatrix}.$$

From (47) the value of γ must be at least $\|Y\|_\infty$. From (48) we get

$$Y^\sim(s) Y(s) = \frac{s^2(s^2-4)(s^2-1)}{(100s^2-1)(s^4-5s^2+1)}.$$

The spectral factor of $Y^\sim Y$ is

$$(49) \quad \frac{s(s+2)(s+1)}{(10s+1)(s^2+\sqrt{7}s+1)}.$$

Thus $\|Y\|_\infty$ equals the H_∞ -norm of the function (49), which can be read off its Bode magnitude plot. This yields $\|Y\|_\infty = .1683$. Thus γ must be at least .1683. It turns out that for $\gamma = .2$ the distance from R to H_∞ is greater than 1, violating (47). We shall show that (47) holds for $\gamma = .3$.

The spectral factor of $\gamma^2 - Y^\sim Y$ is

$$Y_o(s) = \frac{2.828s^3 + 7.615s^2 + 3.165s + .3}{(10s+1)(s^2+\sqrt{7}s+1)}.$$

Since $T_3 Y_o^{-1}$ is already co-outer, in (41) we can take $V_{co} = T_3 Y_o^{-1}$ and $V_{ci} = 1$. Then from (42) $Z = 0$, and from (43) $Z_{co} = 1$. Finally, from (44) we get

$$R(s) = \frac{(s+1)^2(s^2+\sqrt{7}s+1)}{(s^2-\sqrt{7}s+1)(2.828s^3 + 7.615s^2 + 3.165s + .3)}.$$

We shall compute the distance from R to H_∞ using Theorem 5.2 and Lemma 5.2. The antistable part of R is

$$\frac{.9267}{s-2.189} - \frac{.8217}{s-.4569},$$

which has the realization

$$A = \begin{bmatrix} 2.189 & 0 \\ 0 & .4569 \end{bmatrix}, \quad B = \begin{bmatrix} .9267 \\ -.8217 \end{bmatrix}, \quad C = [1 \quad 1].$$

The Lyapunov equations (31) and (32) are readily solved, giving

$$L_c = \begin{bmatrix} .1962 & -.2878 \\ -.2878 & .7389 \end{bmatrix}, \quad L_o = \begin{bmatrix} .2284 & .3780 \\ .3780 & 1.094 \end{bmatrix}.$$

The distance equals the square root of the largest eigenvalue of $L_c L_o$:

$$\text{dist}(R, H_\infty) = .7907.$$

Thus (47) is satisfied for $\gamma = .3$ and we conclude that $.2 < \alpha < .3$. We could at this point find a better estimate for α by reducing γ and checking (47) again, but we shall instead complete the computation with $\gamma = .3$.

The third step is to find the closest H_∞ -function X to R . Since these functions are scalar-valued, we can use Proposition 5.2. We already have that $\lambda^2 (= .7907^2)$ equals the maximum eigenvalue of $L_c L_o$; a corresponding eigenvector is

$$w = [1 \quad -2.862]'$$

Then $v := \lambda^{-1} L_o w$ equals

$$[-1.079 \quad -3.483]'$$

The formula in Proposition 5.2 yields

$$X(s) = \frac{(s^2 + \sqrt{7}s + 1)(.7170s^2 + 1.912s + .7628)}{(.3206s + 1)(2.828s^3 + 7.615s^2 + 3.165s + .3)}$$

The fourth step is to solve (45) for a Q in \mathbf{RH}_∞ . The matrix Q has dimensions 1×2 :

$$Q = [Q_1 \quad Q_2].$$

Equation (45) determines Q_1 uniquely:

$$Q_1(s) = \frac{(s+1)(.7170s^2 + 1.912s + .7628)}{(.3206s + 1)(s^2 + \sqrt{7}s + 1)},$$

whereas Q_2 is unconstrained, and hence may be taken to be zero.

Finally, the controller K is computed using Theorem 3.1. We can determine M_2 , N_2 , X_2 and Y_2 from (14), (15), (17), (18) and then get K from (10):

$$K = [C_1 \quad C_2],$$

$$C_1(s) = -\frac{(s+1)^3(.7170s^2 + 1.912s + .7628)}{(.3206s + 1)(s^2 + \sqrt{7}s + 1)(s^2 + 6s - 23)},$$

$$C_2(s) = -\frac{41s - 1}{s^2 + 6s - 23}.$$

(The reader will have noticed that C_1 is unstable, so the controller cannot be implemented as shown in Fig. 5. However, the theory guarantees that C_2 contains the unstable factor of C_1 . This common unstable factor would be moved past the summing junction into the loop.)

The properties of this design are illustrated in the Bode magnitude plots of Fig. 7. The transfer function, say H_1 , from reference r to tracking error $r - v$ has magnitude less than -10 db over the frequency band $[0, .1]$ of r (smaller tracking error could be obtained by reducing the weighting ρ on control energy), it peaks to about 4 db outside the operating band, and it rolls off to 0 db at high frequency, as it must for a proper controller. This sort of shape is characteristic of H_∞ designs. The transfer function, say H_2 , from r to u has a zero at $s = 0$ because P has a pole there. The actual quantity being minimized in this example is the H_∞ -norm of the transfer matrix

$$\begin{bmatrix} H_1 W \\ H_2 W \end{bmatrix}$$

from w to $(r - v, u)'$. This norm equals the supremum of

$$(50) \quad (|H_1(j\omega)|^2 + |H_2(j\omega)|^2)^{1/2} |W(j\omega)|$$

over all ω . For our design the function (50) is very nearly flat at -12 db (the supremum of (50) must be greater than -14 db corresponding to the bound $\alpha > .2$).

FIG. 7. Bode magnitude plots.

7. Achievable performance. For some simple examples of the standard problem it is possible to obtain useful bounds on achievable performance, sometimes even to characterize achievable performance exactly. Such results can shed light on what properties of a system affect its performance. This section presents three illustrative examples.

Figure 8 shows a feedback system with a disturbance signal w referred to the output of the plant P . As usual, P is strictly proper and K is proper. The transfer matrix from w to y is the *sensitivity matrix* $S := (I - PK)^{-1}$.

Suppose first that the spectrum of w is confined to a prespecified interval of frequencies $[-\omega_1, \omega_1]$, $\omega_1 > 0$. Then the problem of attenuating the effect of w on the output y of the plant is equivalent to the problem of making $\sigma_{\max}[S(j\omega)]$ uniformly small on the interval $[-\omega_1, \omega_1]$. Let χ denote the characteristic function of this interval, i.e.,

$$\chi(j\omega) = 1, \quad |\omega| \leq \omega_1, \quad \chi(j\omega) = 0, \quad |\omega| > \omega_1.$$

Then the maximum value of $\sigma_{\max}[S(j\omega)]$ over the interval $[-\omega_1, \omega_1]$ equals the L_∞ -norm $\|\chi S\|_\infty$. It may happen that as we try to make $\|\chi S\|_\infty$ smaller and smaller, the global bound $\|S\|_\infty$ becomes larger and larger. This is unpleasant because a large value of $\|S\|_\infty$ means the system has poor stability margin. (Think of the scalar-valued case: if $\|S\|_\infty$ is large, then the Nyquist plot of PK passes near the critical point.)

The first result says that if P is minimum phase, then $\|\chi S\|_\infty$ can be made as small as desired while $\|S\|_\infty$ is simultaneously maintained less than any bound δ . Of course δ must be greater than unity since $\|S\|_\infty \geq 1$ for every stabilizing K .

FIG. 8. Disturbance attenuation.

THEOREM 7.1 [67], [99]. *If P has a right-inverse which is analytic in $\operatorname{Re} s \geq 0$, then for every $\varepsilon > 0$ and $\delta > 1$ there exists a stabilizing K such that*

$$\|\chi S\|_\infty < \varepsilon, \quad \|S\|_\infty < \delta.$$

On the other hand, if P has a zero in the right half-plane, then $\|S\|_\infty$ must necessarily increase without limit if $\|\chi S\|_\infty$ tends to zero. This might be described as the “waterbed effect.”

THEOREM 7.2 [33], [35], [39]. *If at some point in $\operatorname{Re} s > 0$ the rank of P is less than the number of its rows, then there exists a positive real number a such that for every stabilizing K*

$$\|\chi S\|_\infty \|S\|_\infty^a > 1.$$

For the third result consider, with regard to Fig. 8 again, the problem of attenuating the effect of w (no longer restricted to be bandlimited) on the control signal u ; that is, the problem is to achieve feedback stability by a controller which limits as much as possible the control effort. The transfer matrix from w to u equals KS , so the objective is to minimize $\|KS\|_\infty$. The case where P is stable is trivial: an optimal K is $K = 0$. So we suppose P is not stable. For technical reasons it is assumed that P has no poles on the imaginary axis; thus P belongs to \mathbf{RL}_∞ but not \mathbf{RH}_∞ . Let Γ denote the Hankel operator with symbol P and let $\sigma_{\min}(\Gamma)$ denote the smallest (nonzero) singular value of Γ .

THEOREM 7.3 [44], [87]. *If P belongs to \mathbf{RL}_∞ but not \mathbf{RH}_∞ , then the minimum value of $\|KS\|_\infty$ over all stabilizing K 's equals the reciprocal of $\sigma_{\min}(\Gamma)$.*

8. Comparison with the Wiener–Hopf approach. In the model-matching problem posed in § 2 and solved in § 5, the criterion is to minimize the \mathbf{H}_∞ -norm of the error transfer matrix $T_1 - T_2 Q T_3$. It is evident from § 5 that, at least in the matrix case, optimal Q 's are not very easy to compute. By way of contrast the Wiener–Hopf approach to the model-matching problem is to minimize the \mathbf{H}_2 -norm of the error transfer matrix. (In Fig. 4, if w is standard white noise, then the root-mean-square value of z equals the \mathbf{H}_2 -norm of the transfer matrix from w to z .) It is relatively easy to compute optimal Q 's for the \mathbf{H}_2 -criterion. Therefore it is perhaps legitimate to ask if the computational effort required for the \mathbf{H}_∞ approach is worthwhile. How much better is the \mathbf{H}_∞ solution than the \mathbf{H}_2 solution?

To give one possible answer to this question we consider for simplicity the case where T_i ($i = 1-3$) are scalar-valued, in which case we may assume that $T_3 = 1$ by redefining T_2 . The function T_2 is assumed not to be zero anywhere on the extended imaginary axis (so that the following two optima exist). Let Q_2 denote the optimal solution for the \mathbf{H}_2 criterion

$$\|T_1 - T_2 Q\|_2 = \text{minimum},$$

and let Q_∞ denote the optimal solution for the \mathbf{H}_∞ criterion

$$\|T_1 - T_2 Q\|_\infty = \text{minimum}.$$

If we were to use the \mathbf{H}_2 solution, the supremal value of $\|z\|_2$ over all $\|w\|_2 \leq 1$ would equal $\|T_1 - T_2 Q_2\|_\infty$. Thus the above question can be rephrased as follows: How large can the ratio

$$(51) \quad \|T_1 - T_2 Q_2\|_\infty / \|T_1 - T_2 Q_\infty\|_\infty$$

be?

Let k denote the number of zeros of T_2 in the right half-plane.

PROPOSITION 8.1. *The supremum of the ratio (51) equals $2k$.*

Here the supremum is over all T_i 's in \mathbf{RH}_∞ such that T_2 has k zeros in $\operatorname{Re} s > 0$ (and no zeros on the extended imaginary axis). The idea of the proof of Proposition 8.1 is as follows. We may suppose without loss of generality that T_2 is an inner function: just absorb the outer factor into Q . Then for Q in \mathbf{H}_2 the \mathbf{H}_2 -norm of $T_1 - T_2 Q$ equals the \mathbf{L}_2 -norm of $T_1 T_2^{-1} - Q$. Hence Q_2 equals the projection of $T_1 T_2^{-1}$ onto \mathbf{H}_2^\perp . Denote this projection by T . Thus the \mathbf{H}_∞ -norm of $T_1 - T_2 Q_2$ equals the \mathbf{L}_∞ -norm of T . Similarly, the \mathbf{H}_∞ -norm of $T_1 - T_2 Q_\infty$ equals the norm of the Hankel operator with symbol T . Denote this operator by Γ_T . The function T has at most k poles in $\operatorname{Re} s > 0$. Glover proved ([43, Cor. 9.3]) that

$$\|T\|_\infty / \|\Gamma_T\| \leq 2k,$$

and Jonckheere et al. [52] showed that this bound could be approached as closely as desired by suitable choice of T .

We conclude that the improvement in the \mathbf{H}_∞ solution over the \mathbf{H}_2 solution, for the \mathbf{H}_∞ criterion, can be arbitrarily great.

9. Summary. The standard problem, which includes the robust stabilization problem, is to minimize the \mathbf{H}_∞ -norm of the closed-loop transfer function for a fixed known plant. Under parametrization of the controller, the standard problem reduces to one of model-matching: minimize the \mathbf{H}_∞ -norm of an affine function. The model-matching problem reduces in turn to a sequence of best approximation problems: approximate in \mathbf{L}_∞ -norm an unstable transfer function by a stable one.

10. Conclusion. The standard problem is well understood and software exists for its solution [12], [21]; the software uses standard routines (such as singular-value decompositions and solving Lyapunov equations). The \mathbf{H}_∞ problem with plant uncertainty, how to achieve frequency-domain performance specifications in the face of plant uncertainty, is a current area of research.

OPTIMAL ADAPTIVE CONTROL AND CONSISTENT PARAMETER ESTIMATES FOR ARMAX MODEL WITH QUADRATIC COST*

HAN-FU CHEN† AND LEI GUO†

Abstract. We consider the multidimensional ARMAX model

$$A(z)y_n = B(z)u_n + C(z)w_n$$

with loss function

$$J(u) = \overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n (y_i^T Q_1 y_i + u_i^T Q_2 u_i)$$

where the coefficients in the matrix polynomials $A(z)$, $B(z)$ and $C(z)$ are unknown. Conditions used here are: 1) stability of $A(z)$ and full rank of A_p ; 2) strictly positive realness of $C(z) - \frac{1}{2}I$, and 3) controllability and observability of a matrix triple consisting of coefficients in $A(z)$, $B(z)$ and Q_1 . On the basis of the estimates given by the stochastic gradient algorithm for unknown parameters an adaptive control law is recursively defined. It is proved that the parameter estimates are strongly consistent and the quadratic loss function reaches its minimum. This paper also includes some general theorems on parameter estimation, on which the results about adaptive control are essentially based.

Key words. stochastic systems, ARMAX model, stochastic adaptive control, quadratic cost, parameter estimation

AMS(MOS) subject classification. 93C40

1. Introduction and statement of problem. In recent years there has been considerable research effort on the parameter estimation and adaptive control problem for linear stochastic systems (see e.g. Goodwin et al. (1984)). Ljung (1977), Solo (1979), Chen (1981), (1982) and Lai and Wei (1982) showed various conditions guaranteeing strong consistency of parameter estimates given by different algorithms for stochastic systems without monitoring, while Goodwin et al. (1981) and Sin and Goodwin (1982) gave adaptive control making the system global stable and the tracking error minimal, but the parameter estimates given there in general, as shown by Becker et al. (1985), are inconsistent. The first step towards getting both consistency of estimates and asymptotic minimality of tracking errors was made by Caines and Lafortune (1984), Chen (1984) and Chen and Caines (1985). In their results the parameter estimates are proved strongly consistent but the tracking error is no longer minimal because of the disturbance artificially introduced to the reference signal. Recently, Chen and Guo (1985a), (1985b) have given an adaptive control under which not only the parameter estimates are strongly consistent, but also the long run average of tracking error reaches its minimum.

For stochastic adaptive control when a general quadratic loss function is considered, Kumar (1983), Hijab (1983) and Caines and Chen (1985) are concerned with the case where the unknown parameters are valued in a finite set, Chen and Caines (1984) and Chen (1985) deal with systems for which the consistent parameter estimates are available, and Samson (1983) considers bounded disturbance case. Recently for systems in state space representation with state completely observed, Chen and Guo

* Received by the editors July 1, 1985; accepted for publication (in revised form) March 20, 1986. This work was supported by the Science Fund of the Chinese Academy of Sciences.

† Institute of Systems Science, Academia Sinica, Beijing, People's Republic of China.

(1986) have given the optimal stochastic LQ control based on the least squares estimates for unknown parameters which may take arbitrary values in the Euclidean spaces of compatible dimensions.

In this paper we consider the general stochastic MIMO system (ARMAX model):

$$(1) \quad A(z)y_n = B(z)u_n + C(z)w_n$$

with quadratic loss function

$$(2) \quad J(u) = \overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=0}^{n-1} (y_i^T Q_1 y_i + u_i^T Q_2 u_i),$$

where $Q_1 \geq 0$, $Q_2 > 0$ and the matrix polynomials in shift-back operator z

$$(3) \quad A(z) = I + A_1 z + \cdots + A_p z^p, \quad p \geq 0,$$

$$(4) \quad B(z) = B_1 z + B_2 z^2 + \cdots + B_q z^q, \quad q \geq 1,$$

$$(5) \quad C(z) = I + C_1 z + \cdots + C_r z^r, \quad r \geq 0$$

are of known orders p , q and r , respectively, and with unknown parameter θ denoting

$$(6) \quad \theta^T = [-A_1 \cdots -A_p \ B_1 \cdots B_q \ C_1 \cdots C_r]$$

by definition. We emphasize that A_i , B_j , C_k ($i = 1 \cdots p$, $j = 1 \cdots q$, $k = 1 \cdots r$) may be any matrices of compatible dimensions.

Let dimensions for y_n , u_n and w_n be m , l and m , respectively, $y_i = 0$, $u_i = 0$, $w_i = 0$ for $i < 0$, and let $\{w_n\}$ be a martingale difference sequence with respect to a family $\{\mathcal{F}_n\}$ of increasing σ -algebras, i.e., w_n is \mathcal{F}_n -measurable and $E(w_n | \mathcal{F}_{n-1}) = 0$. In addition, we assume that

$$(7) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n w_i w_i^T = Q > 0$$

and

$$(8) \quad \sup_n E[\|w_n\|^2 | \mathcal{F}_{n-1}] < \infty \quad \text{a.s.}$$

where and hereafter $\|X\|$ denotes the maximum singular value of X .

At any time n , by use of the past input-output data $\{u_i, y_j, 0 \leq i \leq n-1, 0 \leq j \leq n\}$ we want 1) to estimate the unknown parameter θ and 2) to define adaptive control u_n^a minimizing the loss function (2). In this paper, for the case where $A(z)$ is stable, we give a complete solution of this problem in the sense that the consistency of parameter estimates and minimality of the loss function are achieved simultaneously. Although the results are established for adaptive control based on parameter estimates given by the stochastic gradient algorithm, the same results also hold for the case where the extended least squares algorithm is applied.

In § 2 we describe the optimal control for system (1) and (2) with known parameters, and in § 3 we define the algorithm for both parameter estimation and adaptive control and formulate the main theorem of this paper. For its proof we start with some general theorems on strong consistency of parameter estimates for systems without monitoring (§ 4). Then in § 5 we prove that they can be applied to the adaptive control system defined in § 3, and show that the loss function is really minimized.

2. Optimal control for systems with known parameters. The adaptive control law given later on is inspired by the optimal control for system (1), (2) with known parameters. So we first rewrite (1) in the state space form

$$(9) \quad x_{k+1} = Ax_k + Bu_k + Cw_{k+1},$$

$$(10) \quad y_k = Hx_k, \quad x_0^T = [y_0^T 0 \cdots 0]$$

and give a solution of optimal control, where

$$(11) \quad A = \begin{bmatrix} -A_1 & I & 0 & \cdots & 0 \\ & 0 & \ddots & & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ -A_s & 0 & \cdots & & I \end{bmatrix}, \quad B = \begin{bmatrix} B_1 \\ \vdots \\ B_s \end{bmatrix},$$

$$(12) \quad C^T = [I \ C_1^T \ \cdots \ C_{s-1}^T], \quad H = \underbrace{[I \ 0 \ \cdots \ 0]}_{ms} m$$

with $s = p \vee q \vee (r+1)$ and $A_i = 0, B_j = 0, C_k = 0$ for $i > p, j > q, k > r$.

We note at once that the nonzero eigenvalues of A coincide with the reciprocals of zeros of $\det A(z)$ (Chen (1985)).

All conditions used in this paper are listed here.

(a) A_p is of full rank ($A_0 = I$ by definition) and $A(z)$ is stable, i.e. all zeros of $\det A(z)$ lie outside the closed unit disk.

(b) $C(z) - \frac{1}{2}I$ is strictly positive real, i.e.

$$C(e^{i\varphi}) + C^T(e^{-i\varphi}) - I > 0 \quad \forall \varphi \in [0, 2\pi].$$

(c) (A, B, D) is controllable and observable, where D is any matrix such that $D^T D = H^T Q_1 H$.

We first explain these conditions.

(1) The full rank of A_p is used to ensure $\deg(\det A(z)) = mp$ for identifiability.

(2) For the uncorrelated noise case $r = 0, C(z) = I$, condition (b) is automatically satisfied.

(3) Condition (c) implies that $A(z)$ and $B(z)$ have no common left factor, i.e. there are matrix polynomials $M(z)$ and $N(z)$ such that

$$(13) \quad A(z)M(z) + B(z)N(z) = I;$$

this is a consequence of Theorem 6.2-6 of Kailath (1980, p. 366). Also, condition (c) implies either A_s or B_s is not zero, which implies $r+1 \leq \max(p, q)$. So under condition (c) $s = p \vee q$.

(4) If condition (c) is fulfilled (stability of $A(z)$ is not required here), then there is a unique positive definite matrix solution S in the class of nonnegative definite matrices for the Riccati algebraic equation

$$(14) \quad S = A^T S A - A^T S B (Q_2 + B^T S B)^{-1} B^T S A + H^T Q_1 H,$$

and the matrix $A + BL$ is stable with

$$(15) \quad L = -(Q_2 + B^T S B)^{-1} B^T S A$$

(see, e.g. Anderson and Moore (1971)).

(5) Instead of condition (c), which is rather restrictive, we can directly assume (14), (15) for which the weaker conditions are sufficient and assume that $A(z), B(z)$ and $C(z)$ have no common left factor which is a natural condition for identifiability of the system.

The following lemma is not concerned with adaptive control but it shows the minimal value of the loss function and hints the form of adaptive control.

Throughout the paper, the relationship between two random quantities may have an exceptional set with probability 0, but sometimes we omit to write "a.s."

LEMMA 1. *If conditions (a) and (c) hold, then*

$$(16) \quad J(u) = \text{tr } SCQC^\tau + \overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=0}^{n-1} (u_i - Lx_i)^\tau (Q_2 + B^\tau SB)(u_i - Lx_i) \quad \text{a.s.}$$

whenever u_i is \mathcal{F}_i -measurable and $\{u_i\} \in U$ with

$$(17) \quad U = \left\{ u: \sum_{i=1}^n \|u_i\|^2 = O(n), \quad \|u_n\|^2 = o(n), \text{ as } n \rightarrow \infty \quad \text{a.s.} \right\}.$$

The proof is given in Appendix 1.

This lemma tells us that the optimal control is $u_n = Lx_n$ and that the lower bound to the loss is

$$\min_{u \in U} J(u) = \text{tr } SCQC^\tau.$$

We now give a multidimensional version of a result from Lai and Wei (1982) which is used in the proof of Lemma 1 and will be repeatedly used in the sequel.

LEMMA 2. *Let f_i be \mathcal{F}_i -measurable random vectors and let $\{w_i, \mathcal{F}_i\}$ be a martingale difference sequence satisfying (8). Then as $n \rightarrow \infty$*

$$\sum_{i=1}^n f_i w_{i+1}^\tau = O(s_n^{1/2} \log^{(1/2)+\eta}(s_n + e)) \quad \forall \eta > 0 \quad \text{with } s_n \triangleq \sum_{i=1}^n \|f_i\|^2.$$

The proof is given in Appendix 1.

3. Main theorem. For estimating the unknown parameter θ we use the stochastic gradient algorithm defined by

$$(18) \quad \theta_{n+1} = \theta_n + \frac{\varphi_n}{r_n} (y_{n+1}^\tau - \varphi_n^\tau \theta_n),$$

$$(19) \quad \varphi_n^\tau = [y_n^\tau, \dots, y_{n-p+1}^\tau, u_n^\tau, \dots, u_{n-q+1}^\tau, y_n^\tau - \varphi_{n-1}^\tau \theta_{n-1}, \dots, y_{n-r+1}^\tau - \varphi_{n-r}^\tau \theta_{n-r}],$$

$$(20) \quad r_n = 1 + \sum_{i=1}^n \|\varphi_i\|^2, \quad r_0 = 1.$$

Denote by A_{in}, B_{jn}, C_{kn} the estimates given by θ_n for A_i, B_j, C_k , respectively, $i = 1 \dots p, j = 1 \dots q, k = 1 \dots r$. The state x_n is estimated by the adaptive filter

$$(21) \quad \begin{aligned} \hat{x}_{n+1} &= \hat{A}_n \hat{x}_n + \hat{B}_n u_n + \hat{C}_n (y_{n+1} - H \hat{A}_n \hat{x}_n - H \hat{B}_n u_n), \\ \hat{x}_0 &= [y_0^\tau 0 \dots 0]^\tau \end{aligned}$$

where \hat{A}_n, \hat{B}_n and \hat{C}_n are defined by (11) and (12) with A_i, B_j, C_k replaced by their estimates A_{in}, B_{jn}, C_{kn} , respectively, $i = 1 \dots p, j = 1 \dots q, k = 1 \dots r$.

Set

$$(22) \quad L_n = -(\hat{B}_n^\tau S_n \hat{B}_n + Q_2)^{-1} \hat{B}_n^\tau S_n \hat{A}_n,$$

where S_n is recursively defined by

$$(23) \quad S_n = \hat{A}_n^\tau S_{n-1} \hat{A}_n - \hat{A}_n^\tau S_{n-1} \hat{B}_n (Q_2 + \hat{B}_n^\tau S_{n-1} \hat{B}_n)^{-1} \hat{B}_n^\tau S_{n-1} \hat{A}_n + H^\tau Q_1 H,$$

with an arbitrary initial value $S_0 \geq 0$.

It is natural to guess that $L_n \hat{x}_n$ is something we should take as adaptive control, but, in fact, it may lead to an inconsistent estimate for θ . To avoid this trouble we use the randomly varying truncation technique and the attenuating excitation technique similar to those used in Chen and Guo (1986).

Take an arbitrary l -dimensional i.i.d. sequence $\{\varepsilon_n\}$ independent of $\{w_n\}$ and with properties

$$(24) \quad E\varepsilon_1 = 0, \quad E\varepsilon_1 \varepsilon_1^\tau = I, \quad E\|\varepsilon_1\|^3 < \infty.$$

Without loss of generality we assume $\mathcal{F}_n = \sigma\{w_i, i \leq n, \varepsilon_j, j \leq n\}$.

Then the random sequence $\{v_n\}$ will serve as the source of attenuating excitation, where by definition

$$(25) \quad v_1 = 0, \quad v_n = \frac{\varepsilon_n}{\log^{\varepsilon/2} n} \quad \forall n \geq 2, \quad \varepsilon \in \left(0, \frac{1}{4s(m+2)}\right).$$

From Theorem 3, which is stated later on, we shall see that for strong consistency of parameter estimates besides conditions on system structure there is a growth rate requirement for system input when the attenuating excitation is applied to the control. But $L_n \hat{x}_n$ may not meet this requirement. This is the motivation to truncate the control at randomly varying bounds which we describe right now.

We partition the time axis by a sequence of stopping times

$$1 = \tau_1 < \sigma_1 < \tau_2 < \sigma_2 < \dots$$

at which the control is truncated in order to keep the required growth rate.

From the random time τ_k we define adaptive control u_n^a as $L_n \hat{x}_n$ excited by v_n as far as $n < \sigma_k$, where σ_k is the first time when the growth rate of $1/(j-1) \sum_{i=\tau_k}^{j-1} \|L_i \hat{x}_i\|^2$ is greater, roughly speaking, than $\log^\delta(j-1)$; and from the random time σ_k we define adaptive control as a pure disturbance v_n until $n < \tau_{k+1}$ where τ_{k+1} indicates the time when $(1/n) \sum_{j=1}^n \|\hat{x}_j\|^2$ is less than $\log^{\delta/2} n$ and when some other technical conditions are satisfied. To be precise, we define

$$(26) \quad \sigma_k = \sup \left\{ t > \tau_k : \sum_{i=\tau_k}^{j-1} \|L_i \hat{x}_i\|^2 \leq (j-1) \log^\delta(j-1) + \|L_{\tau_k} \hat{x}_{\tau_k}\|^2, \quad \forall j \in (\tau_k, t] \right\},$$

$$(27) \quad \tau_{k+1} = \inf \left\{ t > \sigma_k : \sum_{i=\tau_k}^{\sigma_k-1} \|L_i \hat{x}_i\|^2 \leq \frac{t \log^\delta t}{2^k}; \sum_{j=1}^t \|\hat{x}_j\|^2 \leq t \log^{\delta/2} t; \frac{\|L_t \hat{x}_t\|^2}{t \log^\delta t} \leq 1 \right\}$$

with any but fixed δ such that

$$(28) \quad \delta \in \left(0, \frac{\frac{1}{4} - (m+2)s\varepsilon}{2 + (m+1)s}\right).$$

Clearly, for any $\varepsilon \in (0, 1/(4s(m+2)))$ the interval for δ is not empty and the upper bound for δ is chosen to ensure an important inequality, which will be used later on:

$$(29) \quad \frac{1}{4} - 2\delta - \varepsilon - (mp + s)(\varepsilon + \delta) > 0.$$

On the right-hand side of the inequality in definition (26) the term $\|L_{\tau_k} \hat{x}_{\tau_k}\|^2$ is added to ensure the existence of σ_k , while in definition (27) the first and the last inequalities are rather technical and are used in the proof of Lemma 4 for considering case (3).

The adaptive control is defined by

$$(30) \quad u_n^a = L_n^0 \hat{x}_n + v_n$$

with

$$(31) \quad L_n^0 = \begin{cases} L_1 & \text{if } n \text{ belongs to some } [\tau_k, \sigma_k), \\ 0 & \text{if } n \text{ belongs to some } [\sigma_k, \tau_{k+1}). \end{cases}$$

We note at once that u_n^a can be recursively computed in real time and this makes the results developed here practically applicable. It is not difficult to see that u_n^a is indeed \mathcal{F}_n -measurable, and it will be shown in § 5 that $\{u_n^a\} \in U$ defined by (17).

We now formulate our main result.

THEOREM 1. *If conditions (a)–(c) are satisfied, then the adaptive control $u^a = \{u_n^a\}$ given by (30) is optimal in the following sense: that for system (1) with $\{u_n^a\}$ applied the parameter estimate θ_n given by (18) is strongly consistent and the loss function (2) attains its minimum, i.e.,*

$$\theta_n \xrightarrow[n \rightarrow \infty]{} \theta \quad \text{a.s.}$$

and

$$J(u^a) = \text{tr } SCQC^\tau \quad \text{a.s.}$$

The proof of Theorem 1 is given in § 5.

Obviously, the optimal adaptive control is not unique; it may differ first by a different choice of excitation source $\{v_n\}$, second by various estimation schemes applied to θ . For example, we can use the least squares algorithm. In this case, instead of (18)–(20) we take

$$(32) \quad \theta_{n+1} = \theta_n + a_n P_n \varphi_n (y_{n+1}^\tau - \varphi_n^\tau \theta_n),$$

$$(33) \quad P_{n+1} = P_n - a_n P_n \varphi_n \varphi_n^\tau P_n, \quad a_n = (1 + \varphi_n^\tau P_n \varphi_n)^{-1},$$

$$(34) \quad \varphi_n^\tau = [y_n^\tau \cdots y_{n-p+1}^\tau, u_n^\tau \cdots u_{n-q+1}^\tau, y_n^\tau - \varphi_{n-1}^\tau \theta_n, \cdots, y_{n-r+1}^\tau - \varphi_{n-r}^\tau \theta_{n-r+1}],$$

and we change $\log^{\varepsilon/2} n$ in (25) to $n^{\varepsilon/2}$, $\log^\delta(j-1)$ in (26) to $(j-1)^\delta$ and finally $\log^\delta t$ and $\log^{\delta/2} t$ in (27) to t^δ and $t^{\delta/2}$, respectively, then Theorem 1 can be modified to the following.

THEOREM 1'. *Assume that conditions (a) and (c) are satisfied and $C^{-1}(z) - \frac{1}{2}I$ is strictly positive real. If the parameter estimates are given by (32)–(34) and in the definition of adaptive control (25)–(31) $\log i$ is replaced by i for all i , then*

$$\theta_n \xrightarrow[n \rightarrow \infty]{} \theta \quad \text{and} \quad J(u^a) = \text{tr } SCQC^\tau \quad \text{a.s.}$$

The proof of this theorem can be carried out along the lines of that of Theorem 1. In the sequel by θ_n we always mean the estimate given by (18)–(20).

4. Consistency theorems. In this section we give some theorems on the strong consistency of parameter estimates.

In the sequel we always denote, respectively, by $\lambda_{\max}(X)$ and $\lambda_{\min}(X)$ the maximum and the minimum eigenvalues of a matrix X . We first give a result on matrix production; it plays a crucial role in the proof of Theorem 2.

LEMMA 3. *Let $\{f_i\}$ be a sequence of deterministic vectors of dimension d and let $F(n+1, i)$ be recursively defined by,*

$$(35) \quad F(n+1, i) = \left(I - \frac{f_n f_n^\tau}{r_n^f} \right) F(n, i), \quad F(i, i) = I,$$

$$(36) \quad r_n^f = 1 + \sum_{i=1}^n \|f_i\|^2, \quad r_0^f = 1.$$

If $r_n^f \xrightarrow{m \rightarrow \infty} \infty$ and for some $a \in [0, \frac{1}{4}]$ there are constants N_0 and M such that for all $n \geq N_0$

$$r_{n+1}^f / r_n^f \leq M(\log r_n^f)^a,$$

and

$$\frac{\lambda_{\max}\left(\sum_{i=1}^n f_i f_i^\tau + \frac{1}{d} I\right)}{\lambda_{\min}\left(\sum_{i=1}^n f_i f_i^\tau + \frac{1}{d} I\right)} \leq M(\log r_n^f)^{(1/4)-a}$$

then

$$F(n, 0) \xrightarrow{n \rightarrow \infty} 0.$$

The proof of Lemma 3 is given in Appendix 1.

Set

$$(37) \quad r_n^0 = 1 + \sum_{i=1}^n \|\varphi_i^0\|^2, \quad r_0^0 = 1,$$

$$(38) \quad \varphi_n^{0\tau} = [y_n^\tau, \dots, y_{n-p+1}^\tau, u_n^\tau, \dots, u_{n-q+1}^\tau, w_n^\tau, \dots, w_{n-r+1}^\tau],$$

which is obtained from φ_n with $y_i^\tau - \varphi_{i-1}^\tau \theta_{i-1}$ replaced by w_i^τ , $i = n \cdots n-r+1$.

THEOREM 2. If condition (b) holds, $r_n^0 \rightarrow \infty$ and if there are $a \in [0, \frac{1}{4}]$, N_0 and M possibly depending upon ω such that for any $n \geq N_0 - 1$

$$(39) \quad r_{n+1}^0 / r_n^0 \leq M(\log r_n^0)^a \quad \text{a.s.},$$

$$(40) \quad \frac{\lambda_{\max}\left(\sum_{i=1}^n \varphi_i^0 \varphi_i^{0\tau} + \frac{1}{d} I\right)}{\lambda_{\min}\left(\sum_{i=1}^n \varphi_i^0 \varphi_i^{0\tau} + \frac{1}{d} I\right)} \leq M(\log r_n^0)^{1/4-a} \quad \text{a.s.},$$

with $d = mp + lq + mr$, then

$$\theta_n \xrightarrow{n \rightarrow \infty} \theta \quad \text{a.s.}$$

The theorem holds true if in its conditions φ_i^0 and r_i^0 are replaced by φ_i and r_i respectively.

Proof. We rewrite $F(n, i)$ defined in Lemma 3 to $\Phi(n, i)$ and $\Phi^0(n, i)$ if f_i is replaced by φ_i and φ_i^0 respectively. We know that $\Phi(n, 0) \rightarrow 0$ is equivalent to $\Phi^0(n, 0) \rightarrow 0$ if condition (b) holds (Chen and Guo (1985a), (1985b)). Then by Lemma 3 under the conditions of the theorem we have $\Phi^0(n, 0) \rightarrow 0$; hence $\theta_n \rightarrow \theta$ as shown in Chen and Guo (1985a), (1985b), (1987).

For consistency of parameter estimates we now give a theorem that translates conditions on φ_n and φ_n^0 to conditions on u_n alone. This is a basic step for proving our main result and is interesting by itself.

THEOREM 3. Suppose that for system (1) $A(z)$, $B(z)$ and $C(z)$ have no common left factor and conditions (a) and (b) are satisfied and that

$$(41) \quad u_n = u_n^s + v_n$$

and

$$(42) \quad \frac{1}{n} \sum_{i=1}^n \|u_i^s\|^2 = O(\log^\delta n)$$

for some δ satisfying (28), where v_n is given by (25) and u_n^s is any \mathcal{F}'_{n-1} -measurable random vector with \mathcal{F}'_{n-1} being σ -algebra generated by $\{w_i, i \leq n, v_j, j \leq n-1\}$, $\forall n \geq 1$. Then θ_n is strongly consistent:

$$\theta_n \xrightarrow[n \rightarrow \infty]{} \theta \quad a.s.$$

The proof is given in Appendix 2.

5. Proof of the main theorem. The proof of Theorem 1 is separated into several lemmas.

LEMMA 4. Under conditions of Theorem 1 the estimate θ_n is strongly consistent:

$$\theta_n \xrightarrow[n \rightarrow \infty]{} \theta \quad a.s.$$

and

$$L_n \xrightarrow[n \rightarrow \infty]{} L \quad a.s.,$$

where L and L_n are defined by (15) and (22) respectively.

Proof. We first prove consistency of θ_n .

(1) If $\tau_k < \infty$, $\sigma_k = \infty$ for some k , then $L_i^0 = L_i$ for $i \geq \tau_k$ and by definition (26) for σ_k we have

$$\frac{1}{n} \sum_{i=1}^n \|L_i \hat{x}_i\|^2 = O(\log^\delta n).$$

Then by (30) and (31) we see that Theorem 3 can be applied, since $L_i^0 \hat{x}_i$ is obviously \mathcal{F}'_{i-1} -measurable. Hence $\theta_n \xrightarrow[n \rightarrow \infty]{} \theta$ a.s.

(2) If $\sigma_k < \infty$, $\tau_{k+1} = \infty$ for some k , then by (30) and (31) $u_n^a = v_n$ for $n \geq \sigma_k$, and again Theorem 3 leads to the conclusion of the lemma.

(3) If $\sigma_k < \infty$, $\tau_k < \infty$, for all k , then by (26), (27) and (31) we have for all $k \geq 1$

$$\begin{aligned} & \sup_{\tau_k \leq n < \tau_{k+1}} \frac{1}{n \log^\delta n} \sum_{i=1}^n \|L_i^0 \hat{x}_i\|^2 \\ &= \sup_{\tau_k \leq n \leq \sigma_{k-1}} \frac{1}{n \log^\delta n} \sum_{i=\tau_1}^n \|L_i^0 \hat{x}_i\|^2 \\ &= \sup_{\tau_k \leq n \leq \sigma_{k-1}} \frac{1}{n \log^\delta n} \left[\left(\sum_{i=\tau_1}^{\sigma_1-1} + \sum_{i=\tau_2}^{\sigma_2-1} + \cdots + \sum_{i=\tau_{k-1}}^{\sigma_{k-1}-1} + \sum_{i=\tau_k}^n \right) \|L_i^0 \hat{x}_i\|^2 \right] \\ &\leq \frac{1}{\tau_2 \log^\delta \tau_2} \sum_{i=\tau_1}^{\sigma_1-1} \|L_i \hat{x}_i\|^2 + \cdots + \frac{1}{\tau_k \log^\delta \tau_k} \sum_{i=\tau_{k-1}}^{\sigma_{k-1}-1} \|L_i \hat{x}_i\|^2 \\ &\quad + \sup_{\tau_k \leq n \leq \sigma_{k-1}} \frac{1}{n \log^\delta n} \sum_{i=\tau_k}^n \|L_i \hat{x}_i\|^2 \\ &\leq \sum_{i=1}^{k-1} \frac{1}{2^i} + \sup_{\tau_k \leq n \leq \sigma_{k-1}} \frac{1}{n \log^\delta n} (n \log^\delta n + \|L_{\tau_k} \hat{x}_{\tau_k}\|^2) \leq 3 \quad \forall k \geq 1. \end{aligned}$$

Hence in this case Theorem 3 can also be applied. Thus we have established the strong consistency of θ_n . The second assertion follows from Lemma 5.

In the proof of Lemmas 5, 6 and 7 we need the following fact; If matrices Ω_n converge to a stable matrix, then there are constants $0 < \mu < 1$ and c_2 such that (Chen (1985, p. 191))

$$(43) \quad \|\Omega_k \Omega_{k-1} \cdots \Omega_{i+1}\| \leq c_2 \mu^{k-i} \quad \forall k > i, \quad \forall i \geq 0.$$

LEMMA 5. If $\theta_n \xrightarrow{n \rightarrow \infty} \theta$ and condition (c) holds, then S_n defined by (23) tends to the solution S of (14) as $n \rightarrow \infty$.

The proof is given in Appendix 1.

We now write x_n given by (9) and \hat{x}_n given by (21) in the vector component forms

$$(44) \quad x_n = [x_n^{1\tau}, \cdots, x_n^{s\tau}]^\tau, \quad \hat{x}_n = [\hat{x}_n^{1\tau}, \cdots, \hat{x}_n^{s\tau}]^\tau,$$

where x_n^i and \hat{x}_n^i are m -dimensional, $i = 1 \cdots s$.

Set

$$(45) \quad z_n = [x_n^{2\tau} \cdots x_n^{s\tau}]^\tau, \quad \hat{z}_n = [\hat{x}_n^{2\tau} \cdots \hat{x}_n^{s\tau}]^\tau.$$

From (21) we have

$$(46) \quad \begin{aligned} \hat{x}_{n+1}^1 &= A_{1n} \hat{x}_n^1 + \hat{x}_n^2 + B_{1n} u_n + (H A x_n + H B u_n + w_{n+1} - H \hat{A}_n \hat{x}_n - H \hat{B}_n u_n) \\ &= A_1 x_n^1 + x_n^2 + B_1 u_n + w_{n+1} = x_{n+1}^1. \end{aligned}$$

Then

$$(47) \quad \begin{aligned} &\hat{C}_n (y_{n+1} - H \hat{A}_n \hat{x}_n - H \hat{B}_n u_n) \\ &= \hat{C}_n H A (x_n - \hat{x}_n) + \hat{C}_n H (A - \hat{A}_n) \hat{x}_n + \hat{C}_n H (B - \hat{B}_n) u_n + \hat{C}_n w_{n+1} \\ &= \hat{C}_n^0 (z_n - \hat{z}_n) + \hat{C}_n H (A - \hat{A}_n) \hat{x}_n + \hat{C}_n H (B - \hat{B}_n) u_n + \hat{C}_n w_{n+1}, \end{aligned}$$

with

$$\hat{C}_n^0 = [\underbrace{\hat{C}_n, 0}_{(s-1)m}] sm.$$

Consequently, by taking $u_n = u_n^a$ we can write (21) in the following form:

$$(48) \quad \begin{aligned} \hat{x}_{n+1} &= (\hat{A}_n + \hat{B}_n L_n^0) \hat{x}_n + \hat{B}_n v_n + \hat{C}_n^0 (z_n - \hat{z}_n) + \hat{C}_n H (A - \hat{A}_n) \hat{x}_n \\ &\quad + \hat{C}_n H (B - \hat{B}_n) L_n^0 \hat{x}_n + \hat{C}_n H (B - \hat{B}_n) v_n + \hat{C}_n w_{n+1} \\ &= [\hat{A}_n + \hat{B}_n L_n^0 + \hat{C}_n H (A - \hat{A}_n) + \hat{C}_n H (B - \hat{B}_n) L_n^0] \hat{x}_n \\ &\quad + \hat{C}_n^0 (z_n - \hat{z}_n) + [\hat{B}_n + \hat{C}_n H (B - \hat{B}_n)] v_n + \hat{C}_n w_{n+1}. \end{aligned}$$

From (9), (21) and (47) we obtain

$$\begin{aligned} x_{n+1} - \hat{x}_{n+1} &= A (x_n - \hat{x}_n) + (A - \hat{A}_n) \hat{x}_n + (B - \hat{B}_n) u_n^a + (C - \hat{C}_n) w_{n+1} \\ &\quad - \hat{C}_n^0 (z_n - \hat{z}_n) - \hat{C}_n H (A - \hat{A}_n) \hat{x}_n - \hat{C}_n H (B - \hat{B}_n) u_n^a, \end{aligned}$$

and from here and (46)

$$(49) \quad \begin{aligned} z_{n+1} - \hat{z}_{n+1} &= G_n (z_n - \hat{z}_n) + (A' - \hat{A}'_n) \hat{x}_n + (B' - \hat{B}'_n) u_n^a + (C' - \hat{C}'_n) w_{n+1} \\ &\quad - \hat{C}'_n H (A - \hat{A}_n) \hat{x}_n - C'_n H (B - \hat{B}_n) u_n^a \\ &= G_n (z_n - \hat{z}_n) + [A' - \hat{A}'_n + (B' - \hat{B}'_n) L_n^0 - \hat{C}'_n H (A - \hat{A}_n) \\ &\quad - \hat{C}'_n H (B - \hat{B}_n) L_n^0] \hat{x}_n \\ &\quad + [B' - \hat{B}'_n - \hat{C}'_n H (B - \hat{B}_n)] v_n + (C' - \hat{C}'_n) w_{n+1}, \end{aligned}$$

where

$$G_n = \begin{bmatrix} -\hat{C}'_n & I \\ 0 & 0 \end{bmatrix} \begin{matrix} (s-2)m \\ m \end{matrix}$$

and X' denotes the matrix obtained from X by deleting its first m rows, for example, $B' = [B'_2 \cdots B'_s]^T$.

Finally, (48) and (49) give us a useful representation:

$$(50) \quad \begin{pmatrix} \hat{x}_{n+1} \\ z_{n+1} - \hat{z}_{n+1} \end{pmatrix} = \Phi_n \begin{pmatrix} \hat{x}_n \\ z_n - \hat{z}_n \end{pmatrix} + \begin{pmatrix} \hat{B}_n + \hat{C}_n H(B - \hat{B}_n) \\ B' - \hat{B}'_n - \hat{C}'_n H(B - \hat{B}_n) \end{pmatrix} v_n + \begin{pmatrix} \hat{C}_n \\ C - \hat{C}_n \end{pmatrix} w_{n+1},$$

where

$$(51) \quad \Phi_n = \begin{pmatrix} \hat{A}_n + \hat{B}_n L_n^0 + \hat{C}_n H(A - \hat{A}_n) + \hat{C}_n H(B - \hat{B}_n) L_n^0 & \hat{C}_n^0 \\ A' - \hat{A}'_n + (B' - \hat{B}'_n) L_n^0 - \hat{C}'_n H(A - \hat{A}_n) - \hat{C}'_n H(B - \hat{B}_n) L_n^0 & G_n \end{pmatrix}.$$

LEMMA 6. *If conditions of Theorem 1 hold then there is a k such that*

$$\tau_k < \infty, \quad \sigma_k = \infty.$$

Proof. Since $1 = \tau_1 < \sigma_1 < \tau_2 < \sigma_2 < \cdots$, we only need to prove the impossibility of the following two cases:

- (1) $\sigma_k < \infty, \tau_{k+1} = \infty$ for some k ;
- (2) $\tau_k < \infty, \sigma_k < \infty$ for all k .

By (50) we have for $n \geq \sigma_k$

$$(52) \quad \begin{pmatrix} \hat{x}_{n+1} \\ z_{n+1} - \hat{z}_{n+1} \end{pmatrix} = \prod_{j=\sigma_k}^n \Phi_j \begin{pmatrix} \hat{x}_{\sigma_k} \\ z_{\sigma_k} - \hat{z}_{\sigma_k} \end{pmatrix} + \sum_{i=\sigma_k}^n \prod_{j=i+1}^n \Phi_j \left\{ \begin{pmatrix} \hat{B}_i + \hat{C}_i H(B - \hat{B}_i) \\ B' - \hat{B}'_i - \hat{C}'_i H(B - \hat{B}_i) \end{pmatrix} v_i + \begin{pmatrix} \hat{C}_i \\ C - \hat{C}_i \end{pmatrix} w_{i+1} \right\}$$

where by definition

$$\prod_{j=i+1}^n \Phi_j = \begin{cases} \Phi_n \cdots \Phi_{i+1} & \text{for } n > i, \\ I & \text{for } n = i. \end{cases}$$

In case (1) $L_n^0 = 0$ for $n \geq \sigma_k$ by (32); then by Lemma 4 we have

$$(53) \quad \Phi_n \xrightarrow{n \rightarrow \infty} \begin{pmatrix} A & C^0 \\ 0 & G \end{pmatrix} \triangleq \Phi \quad \text{with } C^0 = [C, 0] sm, \quad G = \begin{pmatrix} -C' & I \\ 0 & 0 \end{pmatrix}.$$

Notice that $A(z)$ is stable by condition (a), and $C(z)$ is also stable since $C(z)$ is strictly positive real by condition (b), so Φ is a stable matrix.

From (43), (52) and Lemma 4 we obtain for all $n \geq \sigma_k$

$$\begin{aligned} & \frac{1}{n} \sum_{i=\sigma_k}^n (\|\hat{x}_{i+1}\|^2 + \|z_{i+1} - \hat{z}_{i+1}\|^2) \\ &= O\left(\frac{1}{n} \sum_{i=\sigma_k}^n \mu^{i-\sigma_k}\right) + O\left(\frac{1}{n} \sum_{i=\sigma_k}^n \sum_{j=\sigma_k}^i \mu^{i-j} (\|w_{j+1}\|^2 + \|v_j\|^2)\right) = O(1). \end{aligned}$$

Then

$$\sum_{k=1}^n \|\hat{x}_k\|^2 = O(n) \quad \text{as } n \rightarrow \infty.$$

This means that τ_{k+1} must be finite by its definition (27) since $L_n \xrightarrow{n \rightarrow \infty} L$ by Lemma 4. Therefore case (1) cannot occur.

Now assume that $\tau_k < \infty$, $\sigma_k < \infty$ for all k . By definition τ_k is a sequence of monotonically increasing integers; then $\tau_k \xrightarrow{k \rightarrow \infty} \infty$.

By (31) $L_n^0 = L_n$ for $n \in [\tau_k, \sigma_k)$, and then by (51) and Lemma 4 we have

$$(54) \quad \Phi_n \xrightarrow[n \in [\tau_k, \sigma_k), k \rightarrow \infty]{} \begin{bmatrix} A + BL & C^0 \\ 0 & G \end{bmatrix},$$

where C^0 and G are defined in (53).

Since $A + BL$ is stable then for $n \in (\tau_k, \sigma_k - 1]$ by (43), (54) and Lemma 4 it immediately follows from (50) that

$$(55) \quad \sum_{i=\tau_k}^n \|\hat{x}_{i+1}\|^2 \leq c_3(\|\hat{x}_{\tau_k}\|^2 + \|z_{\tau_k} - \hat{z}_{\tau_k}\|^2) + c_4\sigma_k,$$

where here and hereafter c_i , $i = 3, 4, \dots$, denote constants free of k .

Similarly, from (49) we know that

$$(56) \quad \begin{aligned} \|z_{\tau_k} - \hat{z}_{\tau_k}\|^2 &= O(1) + O\left(\sum_{i=0}^{\tau_k} \|\hat{x}_i\|^2\right) + \left(\sum_{i=0}^{\tau_k} (\|w_{i+1}\|^2 + \|v_i\|^2)\right) \\ &\leq c_5\tau_k + c_6\tau_k \log^{\delta/2} \tau_k, \end{aligned}$$

where for the last inequality (27) is invoked.

Putting (56) into (55) and noticing the boundedness of L_i , we conclude that for sufficiently large k

$$\sum_{i=\tau_k}^{\sigma_k} \|L_i \hat{x}_i\|^2 \leq c_7\tau_k \log^{\delta/2} \tau_k + c_8\sigma_k \leq c_9\sigma_k \log^{\delta/2} \sigma_k < \sigma_k \log^{\delta} \sigma_k + \|L_{\tau_k} \hat{x}_{\tau_k}\|^2.$$

On the other hand, by definition (26) we have the converse inequality

$$\sum_{i=\tau_k}^{\sigma_k} \|L_i \hat{x}_i\|^2 > \sigma_k \log^{\delta} \sigma_k + \|L_{\tau_k} \hat{x}_{\tau_k}\|^2$$

since $\sigma_k < \infty$.

The obtained contradiction shows that case (2) cannot take place as well.

To finish the proof of Theorem 1 it remains to show that the loss function reaches its minimum when u_n^a given by (30) is applied. It is done in the next lemma.

LEMMA 7. *If conditions of Theorem 1 hold, then $\{u_n^a\} \in U$ defined by (17) and*

$$J(u_n^a) = \text{tr } SCQC^T.$$

Proof. By Lemma 6 and (31) there exists some k_0 such that

$$L_n^0 = L_n \quad \forall n \geq \tau_{k_0}.$$

By Lemma 4 we know that $\{\Phi_n\}$ converges to the matrix stated at the right-hand side of (54). Then by (43) from (50) it is easy to see that

$$(57) \quad \|\hat{x}_{k+1}\|^2 + \|z_{k+1} - \hat{z}_{k+1}\|^2 = O(1) + O\left(\sum_{i=1}^k \mu^{k-i} (\|w_{i+1}\|^2 + \|v_i\|^2)\right),$$

and

$$(58) \quad \begin{aligned} & \frac{1}{n} \sum_{k=1}^n (\|\hat{x}_{k+1}\|^2 + \|z_{k+1} - \hat{z}_{k+1}\|^2) \\ &= O\left(\frac{1}{n} \sum_{k=1}^n \mu^k\right) + O\left(\frac{1}{n} \sum_{k=1}^n \sum_{i=1}^k \mu^{k-i} (\|w_{i+1}\|^2 + \|v_i\|^2)\right) = O(1). \end{aligned}$$

Then by (A2), (25), (57) and (58) it follows that

$$(59) \quad \|\hat{x}_n\|^2 = o(n) \quad \text{and} \quad \sum_{k=1}^n \|\hat{x}_k\|^2 = O(n) \quad \text{a.s.}$$

Hence $\sum_{i=1}^n \|u_i^a\|^2 = O(n)$, $\|u_n^a\|^2 = o(n)$, and thus $\{u^a\} \in U$.

Using (59) and the consistency of θ_n and noticing that G_n in (49) converges to a stable matrix, then from (49) we are easily convinced of

$$(60) \quad \frac{1}{n} \sum_{k=1}^n \|z_{k+1} - \hat{z}_{k+1}\|^2 = o(1) \quad \text{a.s.,}$$

which together with (46) yields

$$(61) \quad \frac{1}{n} \sum_{i=1}^n \|x_i - \hat{x}_i\|^2 \xrightarrow{n \rightarrow \infty} 0.$$

From (59) and (61) we see

$$(62) \quad \frac{1}{n} \sum_{i=1}^n \|x_i\|^2 = O(1).$$

Finally, putting u_n^a into (16) and using (25), (61), (62) and the fact $L_n^0 \xrightarrow{n \rightarrow \infty} L$ we conclude that

$$\begin{aligned} J(u^a) &= \text{tr } SCQC^\tau + \overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=0}^{n-1} [(L_i^0 - L)x_i + L_i^0(\hat{x}_i - x_i) + v_i]^\tau (Q_2 + B^\tau SB) \\ &\quad \cdot [(L_i^0 - L)x_i + L_i^0(\hat{x}_i - x_i) + v_i] \\ &= \text{tr } SCQC^\tau. \end{aligned}$$

This completes the proof for Lemma 7 as well as for Theorem 1.

6. Conclusion remark. 1) In Chen and Guo (1987) the authors have given the optimal stochastic control minimizing the tracking error and leading to consistency of estimates given by the stochastic gradient algorithm. It is natural to ask: Is it possible to give a unified adaptive control applicable to both problems of tracking and quadratic cost. This requires further consideration.

2) The stability condition on $A(z)$ is rather restrictive. It is desirable to weaken it.

Appendix 1.

Proof of Lemma 1. By a standard treatment (see e.g. Chen (1985)) from (9), (10), (14) and (15) we have

$$(A.1) \quad \begin{aligned} \sum_{i=0}^{n-1} (y_i^\tau Q_1 y_i + u_i^\tau Q_2 u_i) &= x_0^\tau S x_0 - x_n^\tau S x_n + \sum_{i=0}^{n-1} w_{i+1}^\tau C^\tau S C w_{i+1} \\ &\quad + 2 \sum_{i=0}^{n-1} (A x_i + B u_i)^\tau S C w_{i+1} \\ &\quad + \sum_{i=0}^{n-1} (u_i - L x_i)^\tau (Q_2 + B^\tau S B) (u_i - L x_i). \end{aligned}$$

From (7) it is clear that

$$(A.2) \quad \frac{\|w_n\|^2}{n} = \text{tr} \frac{w_n w_n^\tau}{n} = \text{tr} \left(\frac{\sum_{i=1}^n w_i w_i^\tau}{n} - \frac{\sum_{i=1}^{n-1} w_i w_i^\tau}{n} \right) \xrightarrow{n \rightarrow \infty} 0.$$

By stability of A there are constants c_0 and $\rho \in (0, 1)$ such that

$$(A.3) \quad \|A^k\| \leq c_0 \rho^k \quad \forall k \geq 0.$$

Then by (9) and (A.3) it follows that

$$\|x_n\|^2 \leq 3c_0^2 \rho^{2n} \|x_0\|^2 + 3c_0^2 \frac{\|B\|^2 + \|C\|^2}{1 - \rho} \sum_{j=0}^{n-1} \rho^{n-j} (\|u_j\|^2 + \|w_j\|^2).$$

Therefore by (7), (17) and (A.2) from here it is concluded that

$$(A.4) \quad \frac{\|x_n\|^2}{n} = o(1), \quad \sum_{i=1}^n \|x_i\|^2 = O(n) \quad \text{a.s.}$$

From (17), (A.1) and (A.4) the conclusion of the lemma will follow immediately if we can show that

$$\sum_{i=0}^{n-1} (Ax_i + Bu_i)^\tau SCw_{i+1} = O \left(\left[\sum_{i=1}^{n-1} (\|x_i\|^2 + \|u_i\|^2) \right]^{1/2} \log^{1/2+\eta} \left(\sum_{i=1}^{n-1} (\|x_i\|^2 + \|u_i\|^2) + e \right) \right) \\ \forall \eta > 0.$$

But this is a direct consequence of Lemma 2.

Proof of Lemma 2. By the martingale convergence theorem (Chow (1965)) $\sum_{i=1}^n f_i w_{i+1}^\tau$ is convergent on the set $V = \{\omega: s_\infty < \infty\}$; hence Lemma 2 obviously holds on V .

Further, for $\omega \in V^c$, without loss of generality we assume $f_1 \neq 0$; then we have

$$\begin{aligned} \sum_{i=2}^{\infty} E \left[\left\| \frac{f_i w_{i+1}^\tau}{s_i^{1/2} \log^{1/2+\eta} (s_i + e)} \right\|^2 \middle| \mathcal{F}_i \right] &\leq \sigma^2 \sum_{i=2}^{\infty} \frac{\|f_i\|^2}{s_i \log^{1+2\eta} (s_i + e)} \\ &\leq \sigma^2 \sum_{i=2}^{\infty} \left(\int_{s_{i-1}}^{s_i} dx \right) / s_i \log^{1+2\eta} (s_i + e) \\ &\leq \sigma^2 \sum_{i=2}^{\infty} \left(\int_{s_{i-1}}^{s_i} \frac{dx}{x \log^{1+2\eta} (x + e)} \right) \\ &= \sigma^2 \int_{s_1}^{\infty} \frac{dx}{x \log^{1+2\eta} (x + e)} \\ &< \infty, \end{aligned}$$

where $\sigma^2 = \sup_n E[\|w_{n+1}\|^2 | \mathcal{F}_n]$ by definition. Again by the martingale convergence theorem we see that

$$\sum_{i=2}^{\infty} f_i w_{i+1}^\tau / s_i^{1/2} \log^{1/2+\eta} (s_i + e)$$

is convergent on V^c . Then the Kronecker Lemma guarantees validity of Lemma 2 on V^c .

Proof of Lemma 3. Set

$$(A.5) \quad m(t) = \max [n: t_n \leq t],$$

$$(A.6) \quad t_n \triangleq \sum_{i=N_0}^{n-1} \frac{\|f_i\|^2}{r_i^f (\log r_{i-1}^f)^{1/4}}.$$

We note that $m(t)$ is nothing but the inverse function of t_n , which is defined such that it diverges in an appropriate rate.

It is easy to see that

$$\begin{aligned} t_n &\geq \frac{1}{M} \sum_{i=N_0}^{n-1} \frac{\|f_i\|^2}{r_{i-1}^f (\log r_{i-1}^f)^{1/4+a}} \geq \frac{1}{M} \sum_{i=N_0}^{n-1} \int_{r_{i-1}^f}^{r_i^f} \frac{dt}{t (\log t)^{1/4+a}} \\ &= \frac{4}{(3-4a)M} (\log^{3/4-a} r_{n-1}^f - \log^{3/4-a} r_{N_0-1}^f), \end{aligned}$$

which via (A.5) implies $t_n \rightarrow \infty$, $m(t) < \infty$ for all t , and

$$(A.7) \quad \log r_{m(N+k\alpha)-1}^f \leq \left[\frac{(3-4a)M}{4} (N+k\alpha) + \log^{3/4-a} r_{N_0-1}^f \right]^{4/(3-4a)} \quad \forall N \geq 1.$$

For sufficiently large N_0 we have

$$(A.8) \quad \log r_i^f \leq \log r_{i-1}^f + \log M + a \log \log r_{i-1}^f \leq 2 \log r_{i-1}^f \quad \forall i \geq N_0.$$

then

$$t_n \leq 2 \sum_{i=N_0}^{n-1} \frac{\|f_i\|^2}{r_i^f (\log r_i^f)^{1/4}} \leq \frac{8}{3} (\log^{3/4} r_{n-1}^f - \log^{3/4} r_{N_0-1}^f)$$

and hence

$$t \leq t_{m(t)+1} \leq \frac{8}{3} (\log^{3/4} r_{m(t)}^f - \log^{3/4} r_{N_0-1}^f)$$

or

$$(A.9) \quad \log^a r_{m(N+(k-1)\alpha)}^f \geq \left[\frac{3}{8} (N+(k-1)\alpha) + \log^{3/4} r_{N_0-1}^f \right]^{4a/3}.$$

Since $m(t) < \infty$ for all t , there exists N such that $m(N) \geq N_0$ and

$$(A.10) \quad \frac{(\log r_i^f)^{1/4-a}}{r_i^f} \leq \frac{1}{2M} \quad \forall i \geq m(N).$$

For any $k \geq 1$ by summation by parts and using (A.9) we obtain

$$\begin{aligned} \sum_{i=m(N+(k-1)\alpha)}^{m(N+k\alpha)-1} \frac{f_i f_i^T}{r_i^f} &\geq \sum_{i=m(N+(k-1)\alpha)}^{m(N+k\alpha)} \frac{1}{r_i^f} \left(\sum_{j=1}^i f_j f_j^T - \sum_{j=1}^{i-1} f_j f_j^T \right) - I \\ &\geq \sum_{i=m(N+(k-1)\alpha)+1}^{m(N+k\alpha)} \sum_{j=1}^{i-1} f_j f_j^T \frac{\|f_i\|^2}{r_{i-1}^f r_i^f} - 2I \\ &\geq \sum_{i=m(N+(k-1)\alpha)+1}^{m(N+k\alpha)} \left[\frac{\lambda_{\max}(\sum_{j=1}^{i-1} f_j f_j^T + (1/d)I)}{M(\log r_{i-1}^f)^{1/4-a}} - \frac{1}{d} \right] \frac{\|f_i\|^2}{r_i^f r_{i-1}^f} I - 2I \\ &\geq \frac{1}{d} (\log r_{m(N+(k-1)\alpha)}^f)^a \cdot \sum_{i=m(N+(k-1)\alpha)+1}^{m(N+k\alpha)} \\ &\quad \cdot \left(\frac{1}{M} - \frac{(\log r_{i-1}^f)^{1/4-a}}{r_{i-1}^f} \right) \frac{\|f_i\|^2}{r_i^f (\log r_{i-1}^f)^{1/4}} I - 2I \\ &\geq \frac{1}{2Md} \log^a r_{m(N+(k-1)\alpha)}^f (t_{m(N+k\alpha)+1} - t_{m(N+(k-1)\alpha)+1}) I - 2I \\ &\geq \left[\frac{\alpha-1}{2Md} \log^a r_{m(N+(k-1)\alpha)}^f - 2 \right] I \\ &\geq \left[\frac{\alpha-1}{2Md} \left(\frac{3}{8} (N-\alpha) + \frac{3\alpha}{8} k + \log^{3/4} r_{N-1}^f \right)^{4a/3} - 2 \right] I. \end{aligned}$$

We take N, α large enough so that $N > \alpha$ and

$$b = \frac{\alpha - 1}{2Md} \left(\frac{3\alpha}{8} \right)^{4a/3} - 2 > 0;$$

then

$$(A.11) \quad \sum_{i=m(N+(k-1)\alpha)}^{m(N+k\alpha)-1} \frac{f_i f_i^\tau}{r_i^f} \geq b(k^{4a/3})I \quad \forall k \geq 1.$$

Let ρ_k be the maximum eigenvalue of the matrix

$$F^\tau(m(N+k\alpha), m(N+(k-1)\alpha))F(m(N+k\alpha), m(N+(k-1)\alpha))$$

and let $x_{m(N+(k-1)\alpha)}$ be the corresponding normalized eigenvector. For $i \in [m(N+(k-1)\alpha), m(N+k\alpha)-1]$ recursively define x_i

$$(A.12) \quad x_{i+1} = \left(I - \frac{f_i f_i^\tau}{r_i^f} \right) x_i.$$

Then we have

$$(A.13) \quad \begin{aligned} x_{m(N+k\alpha)}^\tau x_{m(N+k\alpha)} &= x_{m(N+(k-1)\alpha)}^\tau F^\tau(m(N+k\alpha), m(N+(k-1)\alpha)) \\ &\quad \cdot F(m(N+k\alpha), m(N+(k-1)\alpha)) x_{m(N+(k-1)\alpha)} \\ &= x_{m(N+(k-1)\alpha)}^\tau \rho_k x_{m(N+(k-1)\alpha)} \end{aligned}$$

and

$$(A.14) \quad x_{i+1}^\tau x_{i+1} \leq x_i^\tau x_i - x_i^\tau \frac{f_i f_i^\tau}{r_i^f} x_i.$$

Summing up both sides of (A.14) we obtain that

$$(A.15) \quad \sum_{i=m(N+(k-1)\alpha)}^{m(N+k\alpha)-1} \frac{\|f_i^\tau x_i\|^2}{r_i^f} \leq \|x_{m(N+(k-1)\alpha}\|^2 - \|x_{m(N+k\alpha)}\|^2 = 1 - \rho_k.$$

For $i \in [m(N+(k-1)\alpha), m(N+k\alpha)-1]$ from (A.12) by Schwarz inequality and (A.6), (A.15) we see that

$$(A.16) \quad \begin{aligned} \|x_i - x_{m(N+(k-1)\alpha}\| &= \left\| \sum_{j=m(N+(k-1)\alpha)}^{i-1} \frac{f_j f_j^\tau}{r_j^f} x_j \right\| \\ &\leq \{\log r_{m(N+k\alpha)-1}^f\}^{1/8} \sum_{j=m(N+(k-1)\alpha)}^{m(N+k\alpha)-1} \frac{\|f_j\|}{(r_j^f)^{1/2} (\log r_{j-1}^f)^{1/8}} \cdot \frac{\|f_j^\tau x_j\|}{(r_j^f)^{1/2}} \\ &\leq \{\log r_{m(N+k\alpha)-1}^f\}^{1/8} \sqrt{1+\alpha} \cdot \sqrt{1-\rho_k}. \end{aligned}$$

Finally, by (A.7), (A.11), (A.15) and (A.16) we conclude that

$$\begin{aligned} bk^{4a/3} &\leq x_{m(N+(k-1)\alpha)}^\tau \sum_{i=m(N+(k-1)\alpha)}^{m(N+k\alpha)-1} \frac{f_i f_i^\tau}{r_i^f} (x_{m(N+(k-1)\alpha)} - x_i + x_i) \\ &\leq (\log r_{m(N+k\alpha)-1}^f)^{1/4} \sum_{i=m(N+(k-1)\alpha)}^{m(N+k\alpha)-1} \frac{\|f_i\|^2}{r_i^f (\log r_{i-1}^f)^{1/4}} \|x_{m(N+(k-1)\alpha)} - x_i\| \\ &\quad + \{\log r_{m(N+k\alpha)-1}^f\}^{1/8} \sum_{i=m(N+(k-1)\alpha)}^{m(N+k\alpha)-1} \frac{\|f_i\|}{(r_i^f)^{1/2} (\log r_{i-1}^f)^{1/8}} \cdot \frac{\|f_i^\tau x_i\|}{(r_i^f)^{1/2}} \\ &\leq \{(\log r_{m(N+k\alpha)-1}^f)^{3/8} (\alpha+1)^{3/2} + (\log r_{m(N+k\alpha)-1}^f)^{1/8} (\alpha+1)^{1/2}\} \sqrt{1-\rho_k} \end{aligned}$$

$$\leq \left\{ (\alpha+1)^{3/2} + (\alpha+1)^{1/2} \left[\frac{(3-4a)M}{4} (N+k\alpha) + \log^{3/4-a} r_{N_0-1}^f \right]^{-1/(3-4a)} \right\} \\ \times \left\{ \frac{(3-4a)M}{4} (N+k\alpha) + \log^{3/4-a} r_{N_0-1}^f \right\}^{3/2(3-4a)} \cdot \sqrt{1-\rho_k}.$$

It is clear that there is a constant $c_1 > 0$ such that

$$bk^{4a/3} \leq c_1 k^{3/2(3-4a)} (1-\rho_k)^{1/2} \quad \forall k \geq 1,$$

or

$$\rho_k \leq 1 - \frac{b^2}{c_1^2} \cdot \frac{1}{k^{3/(3-4a)-(8a/3)}}.$$

Then

$$\|F(m(N+k\alpha), 0)\| \leq \prod_{i=1}^k \|F(m(N+i\alpha), m(N+(i-1)\alpha))\| \cdot \|F(m(N), 0)\| \\ \leq \prod_{i=1}^k \sqrt{\rho_i} \xrightarrow[k \rightarrow \infty]{} 0$$

since

$$\frac{5}{6} \leq \frac{3}{3-4a} - \frac{8}{3}a \leq 1 \quad \text{for } a \in [0, \frac{1}{4}].$$

Notice that $\|F(n, 0)\|$ is nonincreasing; then the lemma follows immediately.

Proof of Lemma 5. For simplicity we denote by $P(A, B, S)$ the right-hand side of (14). By Theorem 14.3 of Lipster and Shirayev (1978) equation (14) can be solved recursively

$$(A.17) \quad \Gamma_{n+1} = P(A, B, \Gamma_n)$$

and $\Gamma_n \rightarrow S$ for any $\Gamma_0 \geq 0$. Γ_n with initial value $\Gamma_0 = 0$ is denoted by Γ_n^0 . In this theorem it is proved that for any vector x of compatible dimension

$$(A.18) \quad x^T \Gamma_n^0 x \leq x^T \Gamma_n x \leq x^T S x + \bar{x}_n^T (\Gamma_0 - S) \bar{x}_n,$$

or equivalently,

$$x^T (\Gamma_n^0 - S) x \leq x^T (\Gamma_n - S) x \leq \bar{x}_n^T (\Gamma_0 - S) \bar{x}_n,$$

where $\bar{x}_n \xrightarrow[n \rightarrow \infty]{} 0$ and $\Gamma_n^0 \rightarrow S$ and both \bar{x}_n and Γ_n^0 are independent of Γ_0 . Hence from (A.18) we see that the convergence $\Gamma_n \rightarrow S$ is uniform in Γ_0 for $\|\Gamma_0\| \leq c$ with c being any fixed constant.

From (23) we know that

$$S_n \leq \hat{A}_n^T S_{n-1} \hat{A}_n + H^T Q_1 H \quad \forall n \geq 1.$$

Then, taking into account (43) we have the boundedness of S_n :

$$(A.19) \quad \|S_n\| \leq \|\hat{A}_n^T S_{n-1} \hat{A}_n + H^T Q_1 H\| \leq \dots \\ \leq \left\| \sum_{i=2}^n (\hat{A}_i \hat{A}_{i+1} \cdots \hat{A}_n)^T H^T Q_1 H (\hat{A}_i \hat{A}_{i+1} \cdots \hat{A}_n) \right. \\ \left. + (\hat{A}_1 \cdots \hat{A}_n)^T S_0 (\hat{A}_1 \cdots \hat{A}_n) + H^T Q_1 H \right\| \\ \leq \|H^T Q_1 H\| + c_2^2 (\|H^T Q_1 H\| + \|S_0\|) \frac{1}{1-\mu} \triangleq c \quad \forall n \geq 1.$$

By strong consistency of θ_n and by boundedness of S_n it is easy to see

$$P(A, B, S_n) - P(\hat{A}_{n+1}, \hat{B}_{n+1}, S_n) \xrightarrow{n \rightarrow \infty} 0.$$

Hence for any $\varepsilon > 0$ we can find $N > 0$ such that

$$(A.20) \quad \|\Delta S_{n+k}\| \leq \varepsilon \quad \forall k \geq 0, \quad \forall n \geq N,$$

where

$$(A.21) \quad \Delta S_{n+k} = S_{n+k} - P(A, B, S_{n+k-1}).$$

For simplicity we set

$$P_1(\Gamma) \triangleq P(A, B, \Gamma), \quad P_n(\Gamma) \triangleq P_1(P_{n-1}(\Gamma)).$$

It is easy to show that there is a constant ζ such that

$$(A.22) \quad P_1(\Gamma + \Delta\Gamma) = P_1(\Gamma) + \overline{\Delta\Gamma}, \quad \|\overline{\Delta\Gamma}\| \leq \zeta\varepsilon$$

for matrices $\Gamma \geq 0$ with $\|\Gamma\| \leq c$ and $\Delta\Gamma$ with $\|\Delta\Gamma\| \leq \varepsilon$.

We now by induction prove that for any $n \geq N$ and $k \geq 1$

$$(A.23) \quad S_{n+k} = P_k(S_n) + Z_{nk}(\varepsilon) \quad \text{with} \quad \|Z_{nk}(\varepsilon)\| \leq c_k\varepsilon,$$

where c_k is a real number independent of n .

By (A.20), (A.21), we see that (A.23) is true for $k = 1$. Now assume (A.23) holds for k . By boundedness of $\|S_n\| \leq c$ for all n , the same argument as that used in (A.19) leads to the conclusion that $P_k(S_n)$ is uniformly bounded in $n \geq 0$ and $k \geq 1$. Then by (A.21)–(A.23) it follows that

$$\begin{aligned} S_{n+k+1} &= P_1(S_{n+k}) + \Delta S_{n+k+1} = P_1(P_k(S_n) + Z_{nk}(\varepsilon)) + \Delta S_{n+k+1} \\ &= P_{k+1}(S_n) + \overline{Z_{nk}}(\varepsilon) + \Delta S_{n+k+1} = P_{k+1}(S_n) + Z_{n,k+1}(\varepsilon), \end{aligned}$$

where, obviously, $\|Z_{n,k+1}(\varepsilon)\| \leq c_{k+1} \cdot \varepsilon$ with $c_{k+1} = \zeta c_k + 1$. Hence (A.23) holds for $k + 1$.

In the present notation

$$\Gamma_n = P_n(\Gamma_0)$$

where Γ_n is defined by (A.17). By the uniform convergence of Γ_n for any $\delta > 0$ we can take k_0 large enough such that

$$(A.24) \quad \|P_{k_0}(\Gamma_0) - S\| \leq \delta \quad \forall \Gamma_0: \|\Gamma_0\| \leq c.$$

For $\varepsilon \triangleq \delta / c_{k_0}$ take N such that

$$(A.25) \quad \|\Delta S_{n+k_0}\| \leq \varepsilon \quad \forall n \geq N.$$

Then from (A.23) we have

$$S_{n+k_0} = P_{k_0}(S_n) + Z_{nk_0}(\varepsilon), \quad \|Z_{nk_0}(\varepsilon)\| \leq c_{k_0}\varepsilon = \delta$$

and by (A.24) for all $n \geq N$

$$\|S_{n+k_0} - S\| \leq \|P_{k_0}(S_n) - S\| + \|Z_{nk_0}(\varepsilon)\| \leq 2\delta,$$

which yields the conclusion of the lemma.

Appendix 2.

Proof of Theorem 3. First we note that $\{v_n, \mathcal{F}_n\}$ is a martingale difference sequence. Then by Lemma 2 we have

$$(A.26) \quad \sum_{i=1}^n u_i^s v_i^t = O\left(\left(\sum_{i=1}^n \|u_i^s\|^2\right)^{1/2} \log^{1/2+\eta}\left(\sum_{i=1}^n \|u_i^s\|^2 + e\right)\right).$$

Further, by (24), (25) we know that for $\gamma \in (\frac{2}{3}, 1)$

$$\sum_{i=1}^{\infty} E \left[\left| \frac{\|v_i v_i^t - I / \log^{\epsilon} i\|^{3/2}}{i^{3\gamma/2}} \right| \middle| \mathcal{F}_{i-1}' \right] < \infty.$$

Hence $\sum_{i=1}^{\infty} [v_i v_i^t - (1/\log^{\epsilon} i)I] / i^{\gamma}$ is convergent by the martingale convergence theorem. Then from the Kronecker lemma it follows that

$$(A.27) \quad \lim_{n \rightarrow \infty} \frac{1}{n^{\gamma}} \sum_{i=1}^n \left(v_i v_i^t - \frac{1}{\log^{\epsilon} i} I \right) = 0 \quad \forall \gamma \in (\frac{2}{3}, 1).$$

It is clear that

$$\int_2^{n+1} \frac{dx}{\log^{\epsilon} x} \leq \sum_{i=2}^n \frac{1}{\log^{\epsilon} i} \leq \frac{1}{\log^{\epsilon} 2} + \int_2^n \frac{dx}{\log^{\epsilon} x}$$

and the l'Hôpital rule shows

$$(A.28) \quad \frac{\log^{\epsilon} n}{n} \sum_{i=2}^n \frac{1}{\log^{\epsilon} i} \xrightarrow{n \rightarrow \infty} 1;$$

hence by (A.27)

$$(A.29) \quad \frac{\log^{\epsilon} n}{n} \sum_{i=1}^n v_i v_i^t \xrightarrow{n \rightarrow \infty} I \quad \text{a.s.}$$

From (42), (A.26) and (A.29) we see

$$(A.30) \quad \frac{1}{n} \sum_{i=1}^n \|u_i\|^2 = O(\log^{\delta} n).$$

Then by condition (a)

$$(A.31) \quad \frac{1}{n} \sum_{i=1}^n \|y_i\|^2 = O(\log^{\delta} n);$$

hence

$$(A.32) \quad r_n^0 = O(n \log^{\delta} n),$$

which means

$$(A.33) \quad \lambda_{\max} \left(\sum_{i=1}^n \varphi_i^0 \varphi_i^{0\tau} + \frac{1}{d} I \right) = O(n \log^{\delta} n).$$

Again by (41), (42), (A.26), (A.29), and noting that $q \geq 1$, we have for all sufficiently large n

$$(A.34) \quad r_n^0 \geq \sum_{i=1}^n \|u_i\|^2 \geq \frac{1}{2} \sum_{i=1}^n \|v_i\|^2 \geq \frac{l}{4} \frac{n}{\log^{\epsilon} n}.$$

Then $r_n^0 \xrightarrow{n \rightarrow \infty} \infty$ a.s. and

$$\frac{r_{n+1}^0}{r_n^0} = O\left(\frac{(n+1) \log^{\delta} (n+1)}{n / \log^{\epsilon} n}\right) = O(\log^{\delta+\epsilon} n) = O((\log r_n^0)^{\delta+\epsilon}).$$

Comparing with conditions in Theorem 2 we find that $a = \delta + \varepsilon$ and by (A.33) and (A.34) for (40) to hold we only need to verify

$$(A.35) \quad \lim_{n \rightarrow \infty} \frac{(\log n)^{1/4-2\delta-\varepsilon}}{n} \lambda_{\min} \left(\sum_{i=1}^n \varphi_i^0 \varphi_i^{0\tau} + \frac{1}{d} I \right) \neq 0.$$

By condition (a) it is easy to see that

$$\begin{aligned} y_{n-i} &= A^{-1}(z)B(z)z^i u_n + A^{-1}(z)C(z)z^i w_n \\ &= z^i A^{-1}(z)[B(z), C(z)] \cdot \begin{bmatrix} u_n \\ w_n \end{bmatrix}. \end{aligned}$$

Then φ_n^0 can be written as

$$(A.36) \quad \varphi_n^0 = \begin{bmatrix} F_{n1}(z) \\ F_{n2}(z) \\ F_{n3}(z) \end{bmatrix} \cdot \begin{bmatrix} u_n \\ w_n \end{bmatrix},$$

where by definition

$$\begin{aligned} F_{n1}(z) &= \begin{bmatrix} A^{-1}(z)[B(z), C(z)] \\ zA^{-1}(z)[B(z), C(z)] \\ \vdots \\ z^{p-1}A^{-1}(z)[B(z), C(z)] \end{bmatrix}, & F_{n2}(z) &= \begin{bmatrix} [I_l, 0] \\ z[I_l, 0] \\ \vdots \\ z^{q-1}[I_l, 0] \end{bmatrix}, \\ F_{n3}(z) &= \begin{bmatrix} [0, I_m] \\ z[0, I_m] \\ \vdots \\ z^{r-1}[0, I_m] \end{bmatrix}, \end{aligned}$$

where I_x denotes the identity matrix of dimension x .

Set

$$(A.37) \quad \psi_n = [\det A(z)] \varphi_n^0$$

and notice that A_p is of full rank, then $\deg A(z) = p$, $\deg [\det A(z)] = mp$, and $\deg [\text{Adj } A(z)] = mp - p$, since $A(z)[\text{Adj } A(z)] = [\det A(z)] \cdot I$.

Let

$$\det A(z) = a_0 + a_1 z + \cdots + a_{mp} z^{mp}.$$

Since $\varphi_i^0 = 0$ for $i < 0$ we have

$$\begin{aligned} \lambda_{\min} \left(\sum_{i=1}^n \psi_i \psi_i^\tau \right) &= \inf_{\|x\|=1} \sum_{i=1}^n (x^\tau \psi_i)^2 \\ &= \inf_{\|x\|=1} \sum_{i=1}^n \left(\sum_{j=0}^{mp} a_j x^\tau \varphi_{i-j}^0 \right)^2 \\ &\leq \sum_{j=0}^{mp} a_j^2 \inf_{\|x\|=1} \sum_{i=1}^n \sum_{j=0}^{mp} (x^\tau \varphi_{i-j}^0)^2 \\ &\leq (mp+1) \sum_{j=0}^{mp} a_j^2 \inf_{\|x\|=1} \sum_{i=1}^n (x^\tau \varphi_i^0)^2 \\ &= (mp+1) \sum_{j=0}^{mp} a_j^2 \lambda_{\min} \left(\sum_{i=1}^n \varphi_i^0 \varphi_i^{0\tau} \right). \end{aligned}$$

Hence for (A.35) it is sufficient to prove

$$(A.38) \quad \lim_{n \rightarrow \infty} \frac{(\log n)^\lambda}{n} \lambda_{\min} \left(\sum_{i=1}^n \psi_i \psi_i^\tau \right) \neq 0 \quad \text{a.s.},$$

where for simplicity we set $\lambda = \frac{1}{4} - 2\delta - \varepsilon$.

Let D be the set on which (A.38) is not satisfied. Suppose that $P(D) > 0$. Then for any $\omega \in D$ there exist vectors

$$\eta_{n_k} = (\alpha_{n_k}^{0\tau} \cdots \alpha_{n_k}^{(p-1)\tau} \beta_{n_k}^{0\tau} \cdots \beta_{n_k}^{(q-1)\tau} \gamma_{n_k}^{0\tau} \cdots \gamma_{n_k}^{(r-1)\tau})^\tau \in \mathbb{R}^d,$$

where $\|\eta_{n_k}\| = 1$ such that

$$(A.39) \quad \frac{(\log n_k)^\lambda}{n_k} \sum_{i=1}^{n_k} (\eta_{n_k}^\tau \psi_i)^2 \xrightarrow[k \rightarrow \infty]{} 0.$$

Set

$$(A.40) \quad H_{n_k}(z) \triangleq \sum_{i=0}^{p-1} \alpha_{n_k}^{i\tau} z^i (\text{Adj } A(z)) [B(z), C(z)] + \sum_{i=0}^{q-1} \beta_{n_k}^{i\tau} z^i [\det A(z) I_l, 0]$$

$$+ \sum_{i=0}^{r-1} \gamma_{n_k}^{i\tau} z^i [0, \det A(z) I_m]$$

$$(A.41) \quad \triangleq \sum_{i=0}^t [h_{n_k}^{i\tau}, g_{n_k}^{i\tau}] z^i,$$

where $t = mp + s - 1$, and $h_{n_k}^i$ and $g_{n_k}^i$ are l - and m -dimensional vectors, respectively.

Since $\|\alpha_{n_k}^i\| \leq 1$, $\|\beta_{n_k}^i\| \leq 1$, $\|\gamma_{n_k}^i\| \leq 1$, for any $k \geq 1$, $i = 0 \cdots p-1$, $j = 0 \cdots q-1$, and $\nu = 0 \cdots r-1$, there exists a constant $c_1 > 0$ independent of k and i such that

$$(A.42) \quad \|h_{n_k}^i\| \leq c_1, \quad \|g_{n_k}^i\| \leq c_1 \quad \forall k \geq 1, \quad i = 0, \dots, t.$$

By (A.36), (A.37) and (A.41) we can rewrite (A.39) as

$$(A.43) \quad \frac{(\log n_k)^\lambda}{n_k} \sum_{i=1}^{n_k} (h_{n_k}^{0\tau} u_i + \cdots + h_{n_k}^{t\tau} u_{i-t} + g_{n_k}^{0\tau} w_i + \cdots + g_{n_k}^{t\tau} w_{i-t})^2 \xrightarrow[k \rightarrow \infty]{} 0,$$

or equivalently,

$$(A.44) \quad \frac{(\log n_k)^\lambda}{n_k} \left\{ \sum_{i=1}^{n_k} [(h_{n_k}^{0\tau} v_i)^2 + (h_{n_k}^{0\tau} u_i^s + h_{n_k}^{1\tau} u_{i-1} + \cdots + h_{n_k}^{t\tau} u_{i-t} + g_{n_k}^{0\tau} w_i + \cdots + g_{n_k}^{t\tau} w_{i-t})^2] \right. \\ \left. + 2h_{n_k}^{0\tau} \left(\sum_{i=1}^{n_k} u_i^s v_i^\tau \right) h_{n_k}^0 + 2 \sum_{j=1}^{n_k} h_{n_k}^{j\tau} \left(\sum_{i=1}^{n_k} u_{i-j} v_i^\tau \right) h_{n_k}^0 \right. \\ \left. + 2 \sum_{j=0}^t g_{n_k}^{j\tau} \left(\sum_{i=1}^{n_k} w_{i-j} v_i^\tau \right) h_{n_k}^0 \right\} \xrightarrow[k \rightarrow \infty]{} 0.$$

We now show that (A.44) implies

$$(A.45) \quad \|h_{n_k}^i\| \xrightarrow[k \rightarrow \infty]{} 0, \quad \|g_{n_k}^i\| \xrightarrow[k \rightarrow \infty]{} 0 \quad \forall i: 0 \leq i \leq t.$$

Applying Lemma 2 to $\sum_{i=1}^{n_k} w_{i-j} v_i^\tau$ and noticing (7), (A.42), we find that

$$\lim_{n \rightarrow \infty} \frac{\log^\lambda n_k}{n_k} \sum_{j=0}^t g_{n_k}^{j\tau} \left(\sum_{i=1}^{n_k} w_{i-j} v_i^\tau \right) h_{n_k}^0 \leq (1+t) c_1^2 \lim_{k \rightarrow \infty} \frac{\log^\lambda n_k}{n_k} O(n_k^{1/2} \log^{1/2+\eta}(n_k + e)) = 0$$

for any $\omega \in D$ with a possible exception set of probability zero. In the following discussion such a possible exception is always assumed. We note that no measurability of $h_{n_k}^i$ and $g_{n_k}^i$ is required.

Similarly, by applying Lemma 2 to $\sum_{i=1}^{n_k} u_i^s v_i^\tau$ and $\sum_{i=1}^{n_k} u_{i-j} v_i^\tau$ ($j \geq 1$) and by use of (41), (42) and (A.42) we conclude that for $\omega \in D$

$$\lim_{k \rightarrow \infty} \frac{\log^\lambda n_k}{n_k} \left[h_{n_k}^{0\tau} \left(\sum_{i=1}^{n_k} u_i^s v_i^\tau \right) h_{n_k}^0 + \sum_{j=1}^t h_{n_k}^{j\tau} \left(\sum_{i=1}^{n_k} u_{i-j} v_i^\tau \right) h_{n_k}^0 \right] = 0.$$

Hence from (A.44) we have

$$(A.46) \quad \frac{(\log n_k)^\lambda}{n_k} \sum_{i=1}^{n_k} (h_{n_k}^{0\tau} u_i^s + h_{n_k}^{1\tau} u_{i-1} + \cdots + h_{n_k}^{t\tau} u_{i-t} + g_{n_k}^{0\tau} w_i + \cdots + g_{n_k}^{t\tau} w_{i-t})^2 \xrightarrow[k \rightarrow \infty]{} 0,$$

and

$$(A.47) \quad \frac{(\log n_k)^\lambda}{n_k} \sum_{i=1}^{n_k} (h_{n_k}^{0\tau} v_i)^2 \xrightarrow[k \rightarrow \infty]{} 0 \quad \text{for } \omega \in D.$$

By (A.29) and (A.47) it is clear that

$$(A.48) \quad \|h_{n_k}^0\|^2 = o((\log n_k)^{-\lambda+\varepsilon}), \quad \omega \in D;$$

hence by (42)

$$\frac{(\log n_k)^{\lambda-(\varepsilon+\delta)}}{n_k} \sum_{i=1}^{n_k} (h_{n_k}^{0\tau} u_i^s)^2 = o(1), \quad \omega \in D.$$

Then from here and (A.46) we have for $\omega \in D$

$$(A.49) \quad \frac{(\log n_k)^{\lambda-(\varepsilon+\delta)}}{n_k} \sum_{i=1}^{n_k} (h_{n_k}^{1\tau} u_{i-1} + \cdots + h_{n_k}^{t\tau} u_{i-t} + g_{n_k}^{0\tau} w_i + \cdots + g_{n_k}^{t\tau} w_{i-t})^2 \xrightarrow[k \rightarrow \infty]{} 0.$$

Comparing (A.49) with (A.43) we see that in (A.49) we have deleted u_i by changing the order of $\log n_k$ from λ to $\lambda - (\varepsilon + \delta)$.

Generally, using the same treatment as described above we conclude that

$$(A.50) \quad \|h_{n_k}^i\|^2 = o((\log n_k)^{-\lambda+i(\varepsilon+\delta)+\varepsilon}), \quad 0 \leq i \leq t, \quad \omega \in D$$

and

$$(A.51) \quad \frac{(\log n_k)^{\lambda-(t+1)(\varepsilon+\delta)}}{n_k} \sum_{i=1}^{n_k} (g_{n_k}^{0\tau} w_i + \cdots + g_{n_k}^{t\tau} w_{i-t})^2 \xrightarrow[k \rightarrow \infty]{} 0, \quad \omega \in D.$$

The same argument applied to (A.51) by using (7) and (A.42) leads to

$$(A.52) \quad \|g_{n_k}^i\|^2 = o((\log n_k)^{-\lambda+(t+1)(\varepsilon+\delta)}) \quad \forall i: 0 \leq i \leq t.$$

Since $t = mp + s - 1$ and $\lambda = \frac{1}{4} - 2\delta - \varepsilon$, then by (29), (A.50) and (A.52) imply (A.45); hence we have

$$(A.53) \quad H_{n_k}(z) \xrightarrow[k \rightarrow \infty]{} 0, \quad \omega \in D.$$

Let $\{\eta_{m_k}\}$ be a convergent subsequence of $\{\eta_{n_k}\}$: $\eta_{m_k} \xrightarrow[k \rightarrow \infty]{} \eta$ with

$$(A.54) \quad \|\eta\| = 1, \quad \omega \in D, \\ \eta = (\alpha^{0\tau} \cdots \alpha^{(p-1)\tau}, \beta^{0\tau} \cdots \beta^{(q-1)\tau}, \gamma^{0\tau} \cdots \gamma^{(\gamma-1)\tau}).$$

Then by (A.40) and (A.53) we have

$$(A.55) \quad \sum_{i=0}^{p-1} \alpha^{ir} z^i (\text{Adj } A(z)) [B(z), C(z)] \\ = - \sum_{i=0}^{q-1} \beta^{ir} z^i [\det A(z) I_l, 0] - \sum_{i=0}^{r-1} \gamma^{ir} z^i [0, \det A(z) I_m].$$

Since $A(z)$, $B(z)$ and $C(z)$ have no common left factor, there are matrix polynomials $M(z)$, $N(z)$ and $L(z)$ such that

$$A(z)M(z) + B(z)N(z) + C(z)L(z) = I.$$

Then by (A.55) we see

$$(A.56) \quad \sum_{i=0}^{p-1} \alpha^{ir} z^i \text{Adj } A(z) \\ = \sum_{i=0}^{p-1} \alpha^{ir} z^i \text{Adj } A(z) \left(A(z)M(z) + [B(z), C(z)] \begin{bmatrix} N(z) \\ L(z) \end{bmatrix} \right) \\ = \det A(z) \left[\sum_{i=0}^{p-1} \alpha^{ir} z^i M(z) - \sum_{i=0}^{q-1} \beta^{ir} z^i N(z) - \sum_{i=0}^{r-1} \gamma^{ir} z^i L(z) \right], \quad \omega \in D.$$

But

$$\deg \left(\sum_{i=0}^{p-1} \alpha^{ir} z^i \text{Adj } A(z) \right) \leq p-1 + \deg (\text{Adj } A(z)) \\ = p-1 + mp - p < mp = \deg (\det A(z)),$$

so (A.56) implies

$$\sum_{i=0}^{p-1} \alpha^{ir} z^i \text{Adj } A(z) = 0, \quad \omega \in D.$$

Hence $\alpha^i = 0$, $i = 0, \dots, p-1$, and by (A.55) $\beta^i = 0$, $i = 0 \cdots q-1$, and $\gamma^j = 0$, $j = 1 \cdots r-1$ for $\omega \in D$. This conclusion contradicts with $\|\eta\| = 1$; therefore, $P(D) = 0$ and (A.38) is verified.

THE STRUCTURE OF TIME-OPTIMAL TRAJECTORIES FOR SINGLE-INPUT SYSTEMS IN THE PLANE: THE GENERAL REAL ANALYTIC CASE*

H. J. SUSSMANN†

Abstract. For arbitrary single-input real analytic systems in the plane, in which the control enters linearly, we prove that the time-optimal trajectories are finite concatenations of “bang-bang” and singular arcs, with local bounds on the number of switchings. No “nondegeneracy” assumption is made other than real-analyticity. The analysis proceeds by applying our previous results on nondegenerate C^∞ systems to study the behavior of the trajectories on a neighborhood of every point, except for the points in a discrete set of “branch points.” The branch points are then handled by a combination of control-theoretic arguments and the use of subanalytic set theory.

Key words. time-optimal control, two-dimensional systems, regular synthesis

AMS(MOS) subject classifications. 93C10, 93B15, 93B20

1. Introduction. This paper continues the analysis, begun in [A], of the time-optimal trajectories for systems

$$(1.1) \quad \dot{x} = F(x) + uG(x), \quad |u| \leq 1,$$

where x belongs to an open subset of the plane, and F and G are C^∞ vector fields. In [A] we proved theorems about the structure of the trajectories in regions where the system is sufficiently nonsingular. Here we will limit ourselves to real-analytic systems, but we will make no extra assumptions. It then turns out, as shown in § 2, that the analysis of [A] applies in a neighborhood of every point x of the state space, except for (a) certain “branch points,” that constitute a discrete set, and (b) systems which are so degenerate that, locally, *every* trajectory is time-optimal. The main part of the paper is § 3, where we analyse the structure of the trajectories in a neighborhood of a branch point. In § 4 we dispose of the other exceptional case mentioned above, and the analysis is complete. The main conclusion of our analysis is then stated in § 5.

We will be using all the definitions and notations introduced in [A].

Our work makes heavy use of the theory of subanalytic sets. It is a remarkable fact that this theory is not only used in the way mentioned earlier (i.e., to go from the local bounds on the number of switchings to the existence of regular synthesis) but also in the trajectory analysis itself. We provide an Appendix which gives all the definitions and results about analytic, semianalytic, and subanalytic sets which are used in the paper.

Our work partially overlaps with Baytman’s book [Ba]. Baytman proved existence of a regular synthesis for a class of smooth systems, without using the theory of subanalytic sets. However, he has to make various nondegeneracy assumptions which, in particular, fail to be satisfied for arbitrary analytic systems.

2. The analytic case. In [A] we studied the time-optimal trajectories in the neighborhood of near-ordinary points p , for an arbitrary smooth system Σ . We now consider the case when Σ is *analytic*, i.e., we assume that

$$(2.1) \quad F \text{ and } G \text{ are real analytic vector fields on } M.$$

Moreover, we will assume that

(2.II) M is connected.

A system Σ for which (2.I) and (2.II) hold will be called a *connected analytic system* (C.A.S.). If Σ is a C.A.S., then the functions $\Delta_A: M \rightarrow \mathbb{R}$ and $\Delta_B: M \rightarrow \mathbb{R}$ are real analytic and, therefore, each of these functions either vanishes everywhere on M or its set of zeros has an empty interior in M .

We let $L(F, G)$ denote the Lie algebra of vector fields on M which is generated by F and G , and we let $L_0(F, G)$ denote the ideal of $L(F, G)$ generated by G . Then $L_0(F, G)$ is spanned by $G, [F, G], [F, [F, G]], [G, [F, G]],$ etc. If \mathcal{S} is any set of vector fields on M , and $p \in M$, we write

$$(2.1) \quad \mathcal{S}(p) = \{V(p): V \in \mathcal{S}\}.$$

We say that Σ has *the accessibility property* (AP) at a point $p \in M$ if

$$(2.2) \quad \dim L(F, G)(p) = 2$$

and we say that Σ has *the strong accessibility property* (SAP) at p if

$$(2.3) \quad \dim L_0(F, G)(p) = 2.$$

It is well known (cf. [SuJ]) that Σ has the AP at p if and only if the set of points that can be reached from p by Σ -trajectories has a nonempty interior. Also, Σ has the SAP from p if and only if there is a $t > 0$ such that $A_t^\Sigma(p)$ has a nonempty interior, where $A_t^\Sigma(p)$ is the set of points that can be reached in time t by Σ -trajectories from p . If Σ has the SAP from p , then $A_t^\Sigma(p)$ has a nonempty interior for every $t > 0$.

We say that Σ has *the accessibility property* (AP) if Σ has the AP at p for all $p \in M$, and that Σ has *the dense accessibility property* (DAP) if it has the AP from p for all p in some dense subset of M . The definitions of the *strong accessibility property* (SAP), and of the *dense strong accessibility property* (DSAP) are similar.

LEMMA 2.1. *Let Σ be a C.A.S. on M . Then the following conditions are equivalent:*

- (a) Σ has the DAP,
- (b) Σ has the AP at some $p \in M$,
- (c) Δ_A does not vanish identically on M .

Proof. If $G \equiv 0$ on M , then it is clear that (a), (b) and (c) are all false, and so the equivalence holds. Therefore we may assume that G is not $\equiv 0$ on M . So there is an open dense subset M' of M such that $G(p) \neq 0$ for $p \in M'$ (because M is connected, and G is analytic). If $\Delta_A \equiv 0$, then there is a function $\alpha_F: M' \rightarrow \mathbb{R}$ such that $F = \alpha_F G$ on M' . Then it is easy to see, that, if L' is the set of all $E \in L(F, G)$ such that $E \upharpoonright M'$ is equal to $G \upharpoonright M'$ times some scalar function $\alpha_E: M' \rightarrow \mathbb{R}$, then L' is a Lie algebra. Since $F \in L'$ and $G \in L'$, we see that $L' = L(F, G)$. So, if $E \in L(F, G)$, then $E = \alpha_E G$ on M' , for some $\alpha_E: M' \rightarrow \mathbb{R}$. Therefore, if $p \in M'$, the space $L(F, G)(p)$ is the linear span of $G(p)$. Hence $L(F, G)(p)$ is one-dimensional, and so the AP fails to hold at p . If $q \in M$ and if the AP holds at q , then there are E_1, E_2 in $L(F, G)$ such that $E_1(q)$ and $E_2(q)$ are linearly independent. But then $E_1(q')$ and $E_2(q')$ must be independent for all q' in some neighborhood of q . Since M' is dense, there must be a $q' \in M'$ such that $E_1(q')$ and $E_2(q')$ are independent, and therefore $\dim L(F, G)(q') = 2$. But this contradicts the fact that the AP fails at all $q' \in M'$. So the AP fails at all $q \in M$. Therefore the negation of (c) implies the negation of (b), and so (b) \Rightarrow (c). That (a) \Rightarrow (b) is obvious. Finally, if (c) holds, then there is a dense $M' \subseteq M$ such that $F(p)$ and $G(p)$ are independent for every $p \in M'$. But then the AP holds at every $p \in M'$, and so (a) holds. So (c) \Rightarrow (a). \square

LEMMA 2.2. *Let Σ be a C.A.S. on M . Then the following are equivalent:*

- (a) Σ has the DSAP,
- (b) Σ has the SAP at some $p \in M$,
- (c) Δ_B does not vanish identically on M .

Proof. The proof that (c) \Rightarrow (a) is exactly like that of the analogous statement for Lemma 2.1. The implication (a) \Rightarrow (b) is also trivial. The proof that (b) \Rightarrow (c) is almost identical to the corresponding proof for Lemma 2.1. We may assume that $G \neq 0$ on a dense open $M' \subseteq M$. If $\Delta_B \equiv 0$, then $H = \alpha_H G$ for some $\alpha_H: M' \rightarrow \mathbb{R}$. We define L' exactly as in the proof of Lemma 2.1. Then it is easy to see that, if $E \in L'$, then $[F, E]$ and $[G, E]$ are in L' . So L' is an ideal in $L(F, G)$. Since $G \in L'$, we conclude that $L_0(F, G) \subseteq L'$, and so $L_0(F, G)(q)$ is one-dimensional for all $q \in M'$. Therefore the SAP fails at all $q \in M'$. Exactly as in the proof of Lemma 2.1, this implies that SAP fails at every $q \in M$. So (b) \Rightarrow (c). \square

We now consider a C.A.S. Σ that has the DSAP, and hence the DAP as well. Then the functions Δ_A and Δ_B both fail to vanish identically. We let $\text{NO}(\Sigma)$ denote the set of nonordinary points of Σ . Then $\text{NO}(\Sigma)$ is the set of zeros of the real analytic function $\Delta_A \Delta_B$, and so $\text{NO}(\Sigma)$ is an *analytic subset* of M . Moreover, since $\Delta_A \Delta_B$ does not vanish identically on M , and M is connected, the set $\text{NO}(\Sigma)$ is of dimension ≤ 1 . It follows from the general structure theory of analytic sets that $\text{NO}(\Sigma)$ is a locally finite union of arcs and points. More precisely, there is a locally finite partition \mathcal{P} of M into connected analytic embedded submanifolds of M that are semianalytic sets, such that $\text{NO}(\Sigma)$ is a union of members of \mathcal{P} , and that, if $S \in \mathcal{P}$, then $\text{Clos}(S) - S$ is also a union of members of \mathcal{P} , whose dimension is smaller than that of S . If $S \in \mathcal{P}$, and $S \subseteq \text{NO}(\Sigma)$, then S is either a point or an analytic arc. In the latter case, the function $\Delta_A \upharpoonright S$ either vanishes identically, or has a set of zeros S_1 which is discrete relative to S . Since S_1 is semianalytic, it follows that S_1 is locally finite (i.e., discrete) in M (so that S_1 has no accumulation points in $M - S$ either). Let $S'_1 = S_1$ if $\Delta_A \upharpoonright S$ does not vanish identically, and let $S'_1 = \emptyset$ if $\Delta_A \equiv 0$ on S . Define S_2, S'_2 similarly, using the function Δ_B instead of Δ_A . Also, define $S_3, S'_3, S_4, S'_4, S_5, S'_5$ using the vector-valued functions X, Y and G , respectively. Define S_6 to be the set of points $p \in S$ such that $X(p)$ is tangent to S . If X is not everywhere tangent to S , then S_6 is a discrete subset of S , and it is easy to show that S_6 is semianalytic in M , and so S_6 is discrete in M . (Indeed, suppose first that the functions $X^k(\Delta_A \Delta_B)$ vanish identically on S for all integers $k > 0$. Then it follows easily that $(\Delta_A \Delta_B)(\Phi_t^X(p)) = 0$ for all $p \in S$ and all $t \in \mathbb{R}$ for which $\Phi_t^X(p)$ is defined. If $p \in S$, then we claim that $\text{NO}(\Sigma) \cap U = S \cap U$ for some neighborhood U of p . To see this, suppose there were no such U . Then there would be a sequence $\{q_n\}$ such that $q_n \in \text{NO}(\Sigma)$, $q_n \notin S$, and $q_n \rightarrow p$ as $n \rightarrow \infty$. Since \mathcal{P} is locally finite, we may assume that all the q_n are in some $\tilde{S} \in \mathcal{P}$, which is necessarily one-dimensional and disjoint from S . But then $p \in \text{Clos}(\tilde{S}) - \tilde{S}$, and so $\{p\} \in \mathcal{P}$, contradicting the fact that $p \in S \in \mathcal{P}$, $\dim S = 1$. So U exists, and therefore there is an $\varepsilon > 0$ such that, if $|t| < \varepsilon$ and $\Phi_t^X(p) \in \text{NO}(\Sigma)$, it follows that $\Phi_t^X(p) \in S$. Since $(\Delta_A \Delta_B)(\Phi_t^X(p)) = 0$ for all t , it follows that $\Phi_t^X(p) \in \text{NO}(\Sigma)$ for all t , and then that $\Phi_t^X(p) \in S$ for small t . So $X(p)$ is tangent to S . But this is true for all p , which is a contradiction, since we are assuming that $S_6 \neq S$. So there is a smallest $k > 0$ with the property that $X^k(\Delta_A \Delta_B) \upharpoonright S$ is not identically zero. If we let $\eta = X^{k-1}(\Delta_A \Delta_B)$, then η is an analytic function on M , and $\eta \upharpoonright S \neq 0$. Let Q be the set of zeros of $X\eta$. Then Q is an analytic subset of M . So $Q \cap S$ is semianalytic in M . Since $Q \cap S$ is discrete in M , because $X\eta$ does not vanish identically on S , we conclude that $Q \cap S$ is discrete in M . If $p \in S_6$, then $(X\eta)(p) = 0$, because $\eta \upharpoonright S \neq 0$, and $X(p)$ is tangent to S . So $p \in Q \cap S$. Therefore $S_6 \subseteq Q \cap S$, and so S_6 is discrete in M .) We now define $S'_6 = S_6$ if $S_6 \neq S$, $S'_6 = \emptyset$ if

$S_6 = S$. We define S_7 and S'_7 similarly, using Y instead of X . If X is not everywhere tangent to S , then there is a $k \geq 0$ such that $X^k \Delta_B$ does not vanish identically on S , but that $X^i \Delta_B = 0$ on S for $0 \leq i < k$. (Indeed, if $X^k \Delta_B = 0$ for all k , then $X^k (\Delta_A \Delta_B) = 0$ for all k , and so X would be everywhere tangent to S , as shown above during the discussion of S_6 .) We let S'_8 be the set of zeros of $X^k \Delta_B$ on S , so that S'_8 is semianalytic in M . If X is everywhere tangent to S , let $S'_8 = \emptyset$. Define S'_9 similarly, using Y instead of X . Finally, let

$$(2.4) \quad S' = \bigcup_{i=1}^9 S'_i.$$

Then S' is discrete in M , for each $S \in \mathcal{P}$ such that $\dim S = 1$, $S \subseteq \text{NO}(\Sigma)$. Form a new partition \mathcal{P}' by letting \mathcal{P}' consist of: (a) all the connected components of $M - \text{NO}(\Sigma)$, (b) all the connected components of $S - S'$, for all the $S \in \mathcal{P}$ such that $S \subseteq \text{NO}(\Sigma)$, $\dim S = 1$, and (c) all the sets $\{p\}$, where $p \in S'$ for some $S \in \mathcal{P}$, $S \subseteq \text{NO}(\Sigma)$, $\dim S = 1$, or $\{p\} \in \mathcal{P}$, $p \in \text{NO}(\Sigma)$. Then \mathcal{P}' satisfies:

- (2.II.i) \mathcal{P}' is a locally finite partition of M , whose elements are embedded connected analytic submanifolds of M , which are also semianalytic subsets of M ;
- (2.II.ii) $\text{NO}(\Sigma)$ is the union of all the members of \mathcal{P}' which have dimension zero or one;
- (2.II.iii) If $P \in \mathcal{P}'$, then $(\text{Clos } P) - P$ is a union of members of \mathcal{P}' , of dimension strictly smaller than $\dim P$;
- (2.II.iv) Every one-dimensional $P \in \mathcal{P}'$ is a regular INOA, which is nondegenerate if it is of the antiturnpike type.

It follows from the preceding considerations that, with the exception of a discrete set, all the nonordinary points of Σ belong to regular INOA's which, if they are of the antiturnpike type, actually are nondegenerate. Precisely, let us say that a point $p \in \text{NO}(\Sigma)$ is *good* if $p \in S$ for some S such that: (a) S is a regular INOA, and (b) if S is of the antiturnpike type, then S is nondegenerate.

Let us say that p is *bad* if it is not good. Let us write $\text{NO}_g(\Sigma)$, $\text{NO}_b(\Sigma)$ for the sets of good and bad points $p \in \text{NO}(\Sigma)$, respectively. Then

$$(2.5) \quad \text{NO}(\Sigma) = \text{NO}_g(\Sigma) \cup \text{NO}_b(\Sigma)$$

and

$$(2.6) \quad \text{NO}_g(\Sigma) \cap \text{NO}_b(\Sigma) = \emptyset.$$

Moreover, the preceding remarks prove the following.

COROLLARY 2.3. *If Σ is a C.A.S. that has the DSAP, then the set $\text{NO}_b(\Sigma)$ consists of isolated points.*

In the terminology of § 6 of [A], $\text{NO}_b(\Sigma)$ is the complement of the set of near-ordinary points. Using Corollary 6.5 of [A], we conclude the following.

COROLLARY 2.4. *Let $p \in M$ be such that $p \notin \text{NO}_b(\Sigma)$, and suppose that Σ is a C.A.S. that has the DSAP. Then p has a neighborhood U such that*

$$\text{Opt}^1(\Sigma|U) \subseteq [\text{Traj}(X \vee Y \vee Z)]^5.$$

In order to complete the description of the local behavior of time-optimal trajectories, at least for systems which have the DSAP, we must study what happens in the neighborhood of each point in $\text{NO}_b(\Sigma)$. This will be done in § 3.

3. Bad nonordinary points. We now study the time-optimal trajectories in the neighborhood of a point $p \in \text{NO}_b(\Sigma)$, for a system Σ which is analytic and has the DSAP. As will be shown later (cf. Appendix A2), the case when $X(p) = Y(p) = 0$ (i.e., when $F(p) = G(p) = 0$) is fundamentally different. In this section we shall exclude this possibility, and we shall assume that $X(p) \neq 0$ or $Y(p) \neq 0$.

Precisely, here is a list of our assumptions for this section:

- (3.I.i) At least one of the vectors $X(p)$, $Y(p)$ is nonzero,
- (3.I.ii) X and Y are real analytic in a neighborhood of p ,
- (3.I.iii) The function $\Delta_A \Delta_B$ does not vanish identically in any neighborhood of p .

We shall distinguish three cases, namely

- (3.II.a) $X(p) = Y(p)$,
- (3.II.b) $X(p) \neq 0$, and $Y(p)$ is not of the form $rX(p)$ with $r \geq 1$, and
- (3.II.c) $Y(p) = rX(p)$, $r > 1$ or $X(p) = 0$.

If (3.II.c) holds, then we may interchange X and Y , and the resulting system satisfies (3.II.b). So, without loss of generality, we may assume that either (3.II.a) or (3.II.b) holds.

Our discussion of the two cases (3.II.a), (3.II.b) will be parallel, but there will be some significant differences. We begin by choosing an analytic coordinate chart $(U_0, (\xi, \eta))$, centred at p , such that U_0 is mapped by (ξ, η) onto a square $\text{Sq}(\varepsilon_0)$, that $\text{Clos}(U_0) \subseteq M$, that X and Y are analytic on U_0 , and that, relative to this chart, X has components $(1, 0)$. (This is possible because, if either (3.II.a) or (3.II.b) hold, then $X(p) \neq 0$.) If $X(p)$ and $Y(p)$ are linearly independent, we impose the additional requirement that $Y(p)$ have components $(0, 1)$.

Let α, β be the components of Y . If (3.II.a) holds, then $\alpha(p) = 1$, and so we may assume, by making ε_0 smaller, that $\alpha > 0$ throughout U_0 . If (3.II.b) holds, then either $X(p)$ and $Y(p)$ are linearly independent, in which case $\alpha(p) = 0$, or they are dependent, in which case $Y(p) = rX(p)$ for some constant $r < 1$. (Note that r may be negative or zero.) In that case, $\alpha(p) < 1$. In either case, we may assume, by making ε_0 smaller, that $\alpha < 1$ throughout U_0 .

We may also assume that $(\Delta_A \Delta_B)(p) = 0$. (Otherwise, p would be an ordinary point, in which case we already know that $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient on some neighborhood of p .)

We now identify U_0 with $\text{Sq}(\varepsilon_0)$, and we list the assumptions made so far:

- (3.III.i) $U_0 = \text{Sq}(\varepsilon_0)$, $p = (0, 0)$, and $\text{Clos } U_0 \subseteq M$;
- (3.III.ii) $X = \partial_x$;
- (3.III.iii) $Y = \alpha \partial_x + \beta \partial_y$, where α and β are analytic functions on U_0 ;
- (3.III.iv) either $\alpha(0, 0) = 1$ and $\beta(0, 0) = 0$, in which case $\alpha(x, y) > 0$ for all $(x, y) \in U_0$, or $\alpha(x, y) < 1$ for all $(x, y) \in U_0$. The former situation occurs if (3.II.a) holds, and the latter if (3.II.b) holds;
- (3.III.v) $(\Delta_A \Delta_B)(p) = 0$, but $\Delta_A \Delta_B$ does not vanish identically on U_0 .

Our goal is to find an ε such that $0 < \varepsilon < \varepsilon_0$, and that $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient on $\text{Sq}(\varepsilon)$. This will require that we construct an appropriate CASA stratification \mathcal{S} of $\text{Sq}(\varepsilon_0)$, and that we then restrict \mathcal{S} to $\text{Sq}(\varepsilon)$ in an appropriate sense.

We let $\text{Strat}_p(\varepsilon)$ denote the set of all CASA stratifications \mathcal{S} of $\text{Sq}(\varepsilon)$ such that $\{p\} \in \mathcal{S}$. We are interested in the subset $\text{Strat}_p^*(\varepsilon)$ that consists of those $\mathcal{S} \in \text{Strat}_p(\varepsilon)$

that are compatible with the vector fields X , Y , and ∂_y . Also, we are interested in the collection $\mathcal{A}(\varepsilon)$ of all subsets S of $\text{Sq}(\varepsilon)$ that satisfy

- (3.IV.i) S is a one-dimensional CASA subset of $\text{Sq}(\varepsilon)$,
- (3.IV.ii) S is a set of the form $\{(\psi(y), y) : a < y < b\}$ where $-\varepsilon \leq a < b \leq \varepsilon$, and $\psi :]a, b[\rightarrow]-\varepsilon, \varepsilon[$ is a real analytic function which is either constant or strictly monotonic.

Also, we let $\mathcal{A}'(\varepsilon)$ denote the set of all horizontal segments $\{(x, y) : a < x < b, y = y_0\}$, such that $-\varepsilon \leq a < b \leq \varepsilon$, $-\varepsilon < y_0 < \varepsilon$.

If $\mathcal{S} \in \text{Strat}_p(\varepsilon)$, and $i = 0, 1, 2$, we let \mathcal{S}_i denote the set of i -dimensional strata of \mathcal{S} other than $\{p\}$.

LEMMA 3.1. *If $\mathcal{S} \in \text{Strat}_p^*(\varepsilon)$, then*

$$(3.1) \quad \mathcal{S}_1 \subseteq \mathcal{A}(\varepsilon) \cup \mathcal{A}'(\varepsilon).$$

Proof. Let $S \in \mathcal{S}_1$. Since \mathcal{S}_1 is compatible with X , the vector field X is either everywhere tangent to S , or nowhere tangent to S . In the former case, $S \in \mathcal{A}'(\varepsilon)$. In the latter case, the function $(x, y) \rightarrow y$ has a nonzero directional derivative in the direction tangential to S , at every point of S . So S can be parametrized by the y -coordinate. Therefore S is of the form $\{(\psi(y), y) : a < y < b\}$, where $\psi :]a, b[\rightarrow \mathbb{R}$ is real analytic. Since $S \subseteq \text{Sq}(\varepsilon)$, it is clear that $-\varepsilon \leq a < b \leq \varepsilon$, and that ψ takes values in $]-\varepsilon, \varepsilon[$. Since \mathcal{S} is compatible with ∂_y , the derivative $d\psi/dy$ either vanishes for all y or for no y . In the former case, ψ is constant. In the latter case, it is strictly monotonic. \square

If $S \in \mathcal{A}(\varepsilon)$, and if $0 < \delta < \varepsilon$, we let $S^\delta = S \cap \text{Sq}(\delta)$. If S is the graph of $\psi :]a, b[\rightarrow]-\varepsilon, \varepsilon[$ as in (3.IV.ii), then S^δ is the graph of $\psi^\delta :]a^\delta, b^\delta[\rightarrow]-\delta, \delta[$, where $]a^\delta, b^\delta[$ is the intersection of the intervals $]-\delta, \delta[$ and $\{y : a < y < b, -\delta < \psi(y) < \delta\}$, and $\psi^\delta = \psi|_{]a^\delta, b^\delta[}$. So we have the following.

LEMMA 3.2. *If $S \in \mathcal{A}(\varepsilon)$, and $0 < \delta < \varepsilon$, then $S^\delta \in \mathcal{A}(\delta)$. \square*

Now suppose $\mathcal{S} \in \text{Strat}_p^*(\varepsilon_0)$. We say that ε is *good* for \mathcal{S} if

- (3.V.i) $0 < \varepsilon < \varepsilon_0$,
- (3.V.ii) the only zero-dimensional stratum of \mathcal{S} that is contained in $\text{Sq}(\varepsilon)$ is $\{p\}$,
- (3.V.iii) if $S \in \mathcal{S}_1$, and $S \cap \text{Sq}(\varepsilon) \neq \emptyset$, then $p \in \text{Clos } S$.

We then have (cf. Fig. 1) the following.

LEMMA 3.3. *For every $\mathcal{S} \in \text{Strat}_p^*(\varepsilon_0)$ there exists a good ε .*

Proof. Pick ε_1 such that $0 < \varepsilon_1 < \varepsilon_0$. Since $\text{Sq}(\varepsilon_1)$ is relatively compact in $\text{Sq}(\varepsilon_0)$, only a finite number of strata of \mathcal{S} meet $\text{Sq}(\varepsilon_1)$. Let P be the union of all the zero-dimensional strata $\{q\}$ of \mathcal{S} such that $q \neq p$, $q \in \text{Sq}(\varepsilon_0)$, and of the closures of all the one-dimensional strata $S \in \mathcal{S}$ such that $p \notin \text{Clos } S$. Then P is closed, and $p \notin P$. If $0 < \varepsilon < \varepsilon_1$, and $P \cap \text{Sq}(\varepsilon) = \emptyset$, then ε is good. \square

If $\mathcal{S} \in \text{Strat}_p^*(\varepsilon_0)$, and ε is good for \mathcal{S} , we let $\mathcal{S}_1(\varepsilon)$ denote the set of all sets S^ε , as S ranges over all the one-dimensional strata of \mathcal{S} such that $p \in \text{Clos } S$. If $T \in \mathcal{S}_1(\varepsilon)$, then T is of the form $\{(\psi(y), y) : a < y < b\}$ for some strictly monotonic or constant analytic ψ , or T is a horizontal segment (because, if $T = S^\varepsilon$, $S \in \mathcal{S}_1$, then $S \in \mathcal{A}(\varepsilon_0) \cup \mathcal{A}'(\varepsilon_0)$ by Lemma 3.1; if $S \in \mathcal{A}(\varepsilon_0)$ then $T \in \mathcal{A}(\varepsilon)$, and if $S \in \mathcal{A}'(\varepsilon_0)$ then $T \in \mathcal{A}'(\varepsilon)$). In the former case, the fact that $p \in \text{Clos } T$ but $p \notin T$ implies that either $a = 0$ or $b = 0$. (If $a < 0 < b$, $\psi(0) \neq 0$, then $p \notin \text{Clos } T$; if $a < 0 < b$, $\psi(0) = 0$, then $p \in T$, and if either $0 < a < b$ or $a < b < 0$, then $p \notin \text{Clos } T$.) If $a = 0$, then $\psi(y)$ must converge to zero as $y \rightarrow 0+$. If we let $L = \lim_{y \rightarrow b-} \psi(y)$, then the point (b, L) belongs to the closure of T

FIG. 1. A stratification in $\text{Strat}_p^*(\epsilon_0)$ and a good ϵ .

(in $\text{Sq}(\epsilon_0)$). If $T = S^\epsilon$, $S \in \mathcal{S}_1$, we either have $(b, L) \in S$ or $(b, L) \in (\text{Clos } S) - S$. In the former case, (b, L) cannot be in $\text{Sq}(\epsilon)$ (otherwise (b, L) would be in T). In the latter case, $\{(b, L)\}$ is a zero-dimensional stratum of \mathcal{S} , and $(b, L) \neq (0, 0)$, so that, again, $(b, L) \notin \text{Sq}(\epsilon)$. Therefore b must equal ϵ , or $|L|$ must be ϵ . In any case, we see that T disconnects $\text{Sq}(\epsilon)^+$, where

$$(3.2a) \quad \text{Sq}(\epsilon)^+ = \{(x, y): |x| < \epsilon, 0 < y < \epsilon\}.$$

If $b = 0$, a similar reasoning shows that $\psi(b-) = 0$, and that either $\psi(a+) = \pm\epsilon$, or $a = -\epsilon$. Also, if we let

$$(3.2b) \quad \text{Sq}(\epsilon)^- = \{(x, y): |x| < \epsilon, -\epsilon < y < 0\},$$

we see that T disconnects $\text{Sq}(\epsilon)^-$.

Finally, there is the possibility that T is a segment $\{(x, y): a < x < b, y = y_0\}$. Since $p \in \text{Clos } T$, we necessarily have $y_0 = 0$. Also, a or b must equal 0 and, if $a = 0$, b must equal ϵ whereas, if $b = 0$, then $a = -\epsilon$. So $T = \Gamma_\epsilon^+$ or $T = \Gamma_\epsilon^-$, where

$$(3.3a) \quad \Gamma_\epsilon^+ = \{(x, y): 0 < x < \epsilon, y = 0\},$$

$$(3.3b) \quad \Gamma_\epsilon^- = \{(x, y): -\epsilon < x < 0, y = 0\}.$$

Let us define $\mathcal{A}_p^+(\epsilon)$ to be the set of all CASA subsets of $\text{Sq}(\epsilon_0)$ that are of the form $\{(\psi(y), y): 0 < y < b\}$, where $0 < b \leq \epsilon$, and where ψ is an analytic function on

$]0, b[$, which is either constant or strictly monotonic, and satisfies $\psi(0+) = 0$, and either $\psi(b-) = \pm \varepsilon$ or $b = \varepsilon$. We define $\mathcal{A}_p^-(\varepsilon)$ similarly, except that, instead of an interval $]0, b[$, the domain of ψ is an interval of the form $]a, 0[$, and the behavior of ψ at the endpoints is given by $\psi(0-) = 0$, and $\psi(a+) = \pm \varepsilon$ or $a = -\varepsilon$. Then we can summarize our preceding remarks in the following.

LEMMA 3.4. *Let $\mathcal{S} \in \text{Strat}_p^*(\varepsilon_0)$, and let ε be good for \mathcal{S} . Then every $T \in \mathcal{S}_1(\varepsilon)$ is either one of the segments Γ_ε^\pm , or $T \in \mathcal{A}_p^+(\varepsilon)$, or $T \in \mathcal{A}_p^-(\varepsilon)$. If $T \in \mathcal{A}_p^+(\varepsilon)$, then T disconnects $\text{Sq}(\varepsilon)^+$ and, similarly, if $T \in \mathcal{A}_p^-(\varepsilon)$, then T disconnects $\text{Sq}(\varepsilon)^-$. \square*

Suppose that $T = S^\varepsilon$ for $S \in \mathcal{S}_1$, $\mathcal{S} \in \text{Strat}_p^*(\varepsilon_0)$, that ε is good for \mathcal{S} , and that $T \neq \Gamma_\varepsilon^+$, $T \neq \Gamma_\varepsilon^-$. Then $T \in \mathcal{A}_p^+(\varepsilon) \cup \mathcal{A}_p^-(\varepsilon)$, and T splits the half-square $\text{Sq}(\varepsilon)^+$ (or $\text{Sq}(\varepsilon)^-$) into two connected components, T_L and T_R , where T_R is the component into which X points, and T_L is the other one. We refer to T_R and T_L as the “right” and “left” sides of T , but a word of caution is needed: a vector v , at a point $q \in T$, may very well “point right” (i.e., have a positive x -component) and point to the “left” of T (i.e., to T_L). (This will happen if v has a larger slope than T at q .) Since \mathcal{S} is compatible with Y , the vector $Y(q)$ points to T_R for all q , or to T_L for all q , or is tangent to T for all q . In particular, we have the following.

LEMMA 3.5. *Let $\mathcal{S} \in \text{Strat}_p^*(\varepsilon_0)$, let ε be good for \mathcal{S} , and let $T = S^\varepsilon$ for some $S \in \mathcal{S}_1$. Suppose that $T \neq \Gamma_\varepsilon^+$ and $T \neq \Gamma_\varepsilon^-$. Let $U^T = \text{Sq}(\varepsilon)^+$ if $T \in \mathcal{A}_p^+(\varepsilon)$, $U^T = \text{Sq}(\varepsilon)^-$ if $T \in \mathcal{A}_p^-(\varepsilon)$. Then either (a) $Y(q)$ points towards T_L for all $q \in T$, or (b) T is a barrier in U^T . \square*

We now construct a particular stratification $\mathcal{S} \in \text{Strat}_p^*(\varepsilon_0)$. We let $E(\varepsilon)$ denote, for $0 < \varepsilon \leq \varepsilon_0$, the set of zeros of $\Delta_A \Delta_B$ in $\text{Sq}(\varepsilon)$ (i.e., $E(\varepsilon) = \text{Sq}(\varepsilon) \cap \text{NO}(\Sigma)$). Then $E(\varepsilon_0)$ is an analytic subset of $\text{Sq}(\varepsilon_0)$. Moreover, for $0 < \varepsilon \leq \varepsilon_0$:

$$E(\varepsilon) = E_1(\varepsilon) \cup E_2(\varepsilon) \cup E_3(\varepsilon),$$

where the (possibly overlapping) sets $E_i(\varepsilon)$ are defined by

$$(3.4a) \quad E_1(\varepsilon) = \{(x, y) \in \text{Sq}(\varepsilon) : \Delta_A(x, y) = 0\},$$

$$(3.4b) \quad E_2(\varepsilon) = \{(x, y) \in \text{Sq}(\varepsilon) : \Delta_B(x, y) = 0\},$$

$$(3.4c) \quad E_3(\varepsilon) = \{(x, y) \in \text{Sq}(\varepsilon) : G(x, y) = 0\}.$$

(Notice that, since

$$(3.5) \quad G = \frac{1}{2}((\alpha - 1)\partial_x + \beta\partial_y),$$

the set $E_3(\varepsilon_0)$ is necessarily empty if (3.II.b) holds.)

We let $E = E(\varepsilon_0)$, $E_i = E_i(\varepsilon_0)$. The sets E_i are analytic and have dimension zero or one. We pick a CASA stratification $\hat{\mathcal{S}}$ of $\text{Sq}(\varepsilon_0)$ which is compatible with the sets E_i , $i = 1, 2, 3$, with $\{p\}$, with $\text{Sq}(\varepsilon_1)$ (where ε_1 is some number such that $0 < \varepsilon_1 < \varepsilon_0$) and with the vector fields X , Y , and ∂_y . We then define \mathcal{S} by modifying $\hat{\mathcal{S}}$ as follows.

For each $S \in \hat{\mathcal{S}}_1$ which meets $\text{Sq}(\varepsilon_1)$, let $k^X(S)$ (resp. $k^Y(S)$) be the smallest nonnegative integer k such that $X^k \Delta_B$ (resp. $Y^k \Delta_B$) is not identically zero on S . (If no such k exists let $k^X(S)$ (resp. $k^Y(S)$) be $+\infty$.) Then let S_X (resp. S_Y) be the intersection of S with the zero set of $X^{k^X}(S) \Delta_B$ (resp. $Y^{k^Y}(S) \Delta_B$). If $k^X(S)$ (resp. $k^Y(S)$) is infinite, let S_X (resp. S_Y) be empty. Then S_X and S_Y are subanalytic subsets of $\text{Sq}(\varepsilon_0)$, and they are clearly discrete. If $S \in \hat{\mathcal{S}}_1$, and S meets $\text{Sq}(\varepsilon_1)$, the set $\check{S} = (S_X \cup S_Y) \cap \text{Sq}(\varepsilon_1)$ is therefore finite. Form a new collection S^* of sets whose elements are the connected components of $S - \check{S}$, and the sets $\{q\}$, $q \in \check{S}$. Then S^* is a partition of S . Form \mathcal{S} by replacing each $S \in \hat{\mathcal{S}}_1$ which meets $\text{Sq}(\varepsilon_1)$ by the collection

of all members of S^* . The stratification \mathcal{S} obtained in this fashion has the following properties:

- (3.VI.i) \mathcal{S} is a CASA stratification of $\text{Sq}(\varepsilon_0)$, compatible with the sets E_i , with $\{p\}$, and with the vector fields X , Y , and ∂_y .
- (3.VI.ii) If $S \in \mathcal{S}_1$, $p \in \text{Clos } S$, and if V is either X or Y , then either V is everywhere tangent to S or, if it is not, and if k is the first nonnegative integer j for which $V^j \Delta_B$ is not $\equiv 0$ on S , then $V^k \Delta_B$ never vanishes on S .

A stratification \mathcal{S} with properties (3.VI.i, ii) above will be called an *appropriate stratification* of $\text{Sq}(\varepsilon_0)$. The following trivial observation will be useful later.

LEMMA 3.6. *If \mathcal{S} is an appropriate stratification of $\text{Sq}(\varepsilon_0)$, and if \mathcal{S}' is a CASA stratification of $\text{Sq}(\varepsilon_0)$ which is a refinement of \mathcal{S} , then \mathcal{S}' is also appropriate.* \square

The remarks preceding the definition of an appropriate stratification prove that such stratifications exist. From now on, we let \mathcal{S} be a fixed appropriate stratification of $\text{Sq}(\varepsilon_0)$.

We now return to our search for an $\varepsilon > 0$ such that $\text{Traj}(X \vee Y \vee Z)^\infty$ is boundedly sufficient for $\text{Sq}(\varepsilon)$. We begin by proving some lemmas that reduce the problem to that of finding bounds for the number of switchings for some special families of trajectories in the half-squares $\text{Sq}(\varepsilon)^\pm$.

LEMMA 3.7. *Let ε be good for \mathcal{S} . Suppose that $\nu > 0$ is such that*

$$(3.6) \quad \text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon)^+) \cup \text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon)^-) \subseteq \text{Traj}(X \vee Y \vee Z)^\nu.$$

Then

$$(3.7) \quad \text{Opt}^1(\Sigma \upharpoonright (\text{Sq}(\varepsilon) - \{p\})) \subseteq \text{Traj}(X \vee Y \vee Z)^{3\nu+2}.$$

Proof. We first prove that, if $Q = \Gamma_\varepsilon^+$ or $Q = \Gamma_\varepsilon^-$, then Y is either everywhere tangent to Q or nowhere tangent to Q . It is clear that Y is tangent to Q at a point $q \in Q$ if and only if $\beta(q) = 0$, i.e. iff $\Delta_A(q) = 0$ (since $\Delta_A = \beta$). If Y is tangent to Q at some point $q \in Q$, then $\Delta_A(q) = 0$ and so $q \in E_1$. So $q \in S$ for an $S \in \mathcal{S}$ such that $S \subseteq E_1$. Therefore $\dim S = 0$ or 1 . Since ε is good, $\dim S \neq 0$. So $S \in \mathcal{S}_1$, and $q \in S^\varepsilon$. Since $q \in \Gamma_\varepsilon^- \cup \Gamma_\varepsilon^+$, the set S^ε cannot belong to $\mathcal{A}_p^+(\varepsilon) \cup \mathcal{A}_p^-(\varepsilon)$. So Lemma 3.4 implies that $S^\varepsilon = \Gamma_\varepsilon^-$ or $S^\varepsilon = \Gamma_\varepsilon^+$. Therefore $S^\varepsilon = Q$. We conclude that $\Delta_A \equiv 0$ on Q , i.e., that Y is everywhere tangent to Q .

Since X is everywhere tangent to Γ_ε^- and to Γ_ε^+ , we conclude that Γ_ε^- is a barrier in $\text{Sq}(\varepsilon) - (\{p\} \cup \Gamma_\varepsilon^+)$, and that Γ_ε^+ is a barrier in $\text{Sq}(\varepsilon) - (\{p\} \cup \Gamma_\varepsilon^-)$.

So, by Lemma 4.1 of [A], if γ is a trajectory in $\text{Sq}(\varepsilon) - (p)$, then γ cannot leave one of the segments Γ_ε^- , Γ_ε^+ and return to it unless it crosses the other one first.

Now suppose that (3.II.a) holds. Then $\alpha > 0$ throughout U_0 , and therefore every trajectory of Σ in U_0 goes from left to right. If a trajectory $\gamma \in \text{Traj}(\Sigma \upharpoonright (\text{Sq}(\varepsilon) - \{p\}))$ starts, say, at a point in $\text{Sq}(\varepsilon)^-$, then γ either stays in $\text{Sq}(\varepsilon)^-$ forever, in which case it is in $\text{Traj}(X \vee Y \vee Z)^\nu$, or it crosses into $\text{Sq}(\varepsilon)^+$ through Γ_ε^- or Γ_ε^+ (possibly after staying in Γ_ε^- or Γ_ε^+ for some time interval). If γ crosses through Γ_ε^+ , then it cannot cross again into $\text{Sq}(\varepsilon)^-$ unless it goes through Γ_ε^- . But this is impossible because γ goes from left to right. If γ crosses through Γ_ε^- , then it may cross again into $\text{Sq}(\varepsilon)^-$ through Γ_ε^+ , but once this crossing has taken place then no more crossings are possible. Therefore $\gamma \in \text{Traj}(X \vee Y \vee Z)^{3\nu+2}$. So, if (3.II.a) holds, we have proved that

$$\text{Opt}^1(\Sigma \upharpoonright (\text{Sq}(\varepsilon) - \{p\})) \subseteq \text{Traj}(X \vee Y \vee Z)^{3\nu+2}.$$

The case when (3.II.b) holds is slightly more difficult. The main observation for this case is that no trajectory $\gamma \in \text{Traj}(\Sigma \setminus (\text{Sq}(\varepsilon) - \{p\}))$ that goes from a $q_- \in \Gamma_\varepsilon^-$ to a $q_+ \in \Gamma_\varepsilon^+$ can belong to $\text{Opt}^1(\Sigma \setminus \text{Sq}(\varepsilon) - \{p\})$.

To prove this, we first show that $T(\gamma) > T(\gamma')$, where γ' is the X -trajectory from q_- to q_+ . Let $q_- = (x_-, 0)$, $q_+ = (x_+, 0)$ (so that $x_- < 0 < x_+$). Let $\gamma: [a, b] \rightarrow \text{Sq}(\varepsilon) - \{p\}$ have the form $t \rightarrow (x(t), y(t))$, and let γ correspond to the control $u(\cdot): [a, b] \rightarrow [-1, 1]$. Then

$$(3.8) \quad \dot{x}(t) = \frac{1}{2}[(1 - u(t)) + \alpha(x(t), y(t))(1 + u(t))]$$

for almost all t . Since $\alpha < 1$ throughout $\text{Sq}(\varepsilon)$, (3.8) gives

$$(3.9) \quad \dot{x}(t) \leq 1 \quad \text{for almost all } t.$$

Therefore

$$(3.10) \quad x_+ - x_- = \int_a^b \dot{x}(t) dt \leq b - a,$$

i.e., $T(\gamma') \leq T(\gamma)$. Moreover, equality is only possible if $\dot{x}(t) = 1$ for almost all t , i.e., if $u(t) = -1$ for almost all t . But in this case γ would be an X -trajectory, and then γ would go through p , contradicting the fact that γ is a trajectory in $\text{Sq}(\varepsilon) - \{p\}$. So $T(\gamma') < T(\gamma)$.

The inequality $T(\gamma') < T(\gamma)$ does not yet prove that γ is not in $\text{Opt}^1(\Sigma \setminus (\text{Sq}(\varepsilon) - \{p\}))$, because $\gamma' \notin \text{Traj}(\Sigma \setminus (\text{Sq}(\varepsilon) - \{p\}))$ (since γ' goes through p). However, it is clear that Y cannot be everywhere tangent to $\Gamma_\varepsilon^- \cup \Gamma_\varepsilon^+ \cup \{p\}$, and that Y cannot always point to the same side of this segment either. (Otherwise $\Gamma_\varepsilon^- \cup \Gamma_\varepsilon^+ \cup \{p\}$ would be a barrier in $\text{Sq}(\varepsilon)$, contradicting the fact that γ leaves it and later returns.) So Y points to one side of $\Gamma_\varepsilon^- \cup \Gamma_\varepsilon^+ \cup \{p\}$ for $q \in \Gamma_\varepsilon^-$, and to the other side for $q \in \Gamma_\varepsilon^+$. If $\rho > 0$ is very small, then we can form a trajectory γ'_ρ from q_- to q_+ by following first a Y -trajectory until we get to the line $y = +\rho$ or $y = -\rho$ (depending on whether $Y(q_-)$ points up or down), then an X -trajectory until we get to a point in the Y -trajectory through q_+ , and finally this Y -trajectory to q_+ . The curves γ'_ρ are in $\text{Traj}(\Sigma \setminus (\text{Sq}(\varepsilon) - \{p\}))$, and they converge to γ' as $\rho \rightarrow 0$. So, for sufficiently small ρ , $T(\gamma'_\rho) < T(\gamma)$, proving that $\gamma \notin \text{Opt}^1(\Sigma \setminus (\text{Sq}(\varepsilon) - \{p\}))$.

Now let $\gamma \in \text{Opt}^1(\Sigma \setminus (\text{Sq}(\varepsilon) - \{p\}))$. Then, once γ crosses Γ_ε^- , it cannot cross Γ_ε^- again unless it crosses Γ_ε^+ first, and it cannot cross Γ_ε^+ because then it would not be optimal. So the worst that can happen is that γ starts in $\text{Sq}(\varepsilon)^-$, or in $\text{Sq}(\varepsilon)^+$, then crosses Γ_ε^+ (possibly after staying in Γ_ε^+ for some time), then crosses Γ_ε^- (again, after staying there for some time) back to the region where it started, and then it stays in this region forever. So, again, γ must belong to $\text{Traj}(X \vee Y \vee Z)^{3\nu+2}$. \square

LEMMA 3.8. *If ε is good for \mathcal{S} , then there is an integer $\nu > 0$ such that every $\gamma \in \text{Opt}^1(\Sigma \setminus \text{Sq}(\varepsilon)^-) \cap \text{Traj}(Y \vee Z)^\infty$ or $\text{Opt}^1(\Sigma \setminus \text{Sq}(\varepsilon)^+) \cap \text{Traj}(Y \vee Z)^\infty$ is actually in $\text{Traj}(Y \vee Z)^\nu$.*

Proof. If $\gamma \in \text{Opt}^1(\Sigma \setminus \text{Sq}(\varepsilon)^+)$, and γ is a trajectory in $\text{Traj}(Y \vee Z)^\infty$, then γ is a concatenation of finitely many pieces which either are Y -trajectories or are entirely contained in some S^ε that is a turnpike, for some $S \in \mathcal{S}_1$. Then $S^\varepsilon \in \mathcal{A}_p^+(\varepsilon)$. For any given S^ε which is a turnpike, the complement of S^ε in $\text{Sq}(\varepsilon)^+$ has two connected components, and Y points into one of them. Therefore γ can never return to S^ε after it has left it. So γ cannot have more than μ Z -pieces, where μ is the number of sets S^ε , $S \in \mathcal{S}_1$, that are turnpikes. So $\gamma \in \text{Traj}(Y \vee Z)^\nu$, where $\nu = 2\mu + 1$.

A similar reasoning shows that, if $\gamma \in \text{Traj}(Y \vee Z)^\infty$ is an optimal trajectory in $\text{Sq}(\varepsilon)^-$, then $\gamma \in \text{Traj}(Y \vee Z)^\nu$. \square

A similar proof shows the following.

LEMMA 3.9. *If ε is good for \mathcal{S} , then there is an integer $\nu > 0$ such that*

$$[\text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon)^-) \cup \text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon)^+)] \cap \text{Traj}(X \vee Z)^\infty \subseteq \text{Traj}(X \vee Z)^\nu. \quad \square$$

If $\gamma \in \text{Traj}(X \vee Y \vee Z)^\infty$, let $\hat{I}_0(\gamma)$ denote the collection of all intervals J such that

- (3.VII.i) $J \subseteq \text{Dom}(\gamma)$;
- (3.VII.ii) J contains some interval J' , with nonempty interior, such that $\gamma \upharpoonright J' \in \text{Traj}(X)$;
- (3.VII.iii) $\gamma \upharpoonright J \in \text{Traj}(X \vee Z)^\infty$.

We let $\hat{I}(\gamma)$ denote the set of all maximal elements of $\hat{I}_0(\gamma)$, and we let $I(\gamma)$ denote the set of those $J \in \hat{I}(\gamma)$ that do not contain any of the endpoints of $\text{Dom}(\gamma)$. Then, if $\text{Dom}(\gamma) = [a, b]$, an interval J belongs to $I(\gamma)$ if and only if

- (3.VIII.i) $J = [t_0, t_1]$ for some t_0, t_1 such that $a < t_0 < t_1 < b$;
- (3.VIII.ii) $\gamma \upharpoonright J \in \text{Traj}(X \vee Z)^\infty$;
- (3.VIII.iii) there exist t'_0, t'_1 such that $t_0 \leq t'_0 < t'_1 \leq t_1$ and $\gamma \upharpoonright [t'_0, t'_1] \in \text{Traj}(X)$;
- (3.VIII.iv) there exists $\delta > 0$ such that $a \leq t_0 - \delta$, $b \geq t_1 + \delta$, and that $\gamma \upharpoonright [t_0 - \delta, t_0]$ and $\gamma \upharpoonright [t_1, t_1 + \delta]$ are Y -trajectories.

For each $\gamma \in \text{Traj}(X \vee Y \vee Z)^\infty$, let $m(\gamma)$ denote the number of intervals $J \in I(\gamma)$. For $0 < \varepsilon \leq \varepsilon_0$, let

$$(3.11a) \quad m_\varepsilon^+ = \sup \{m(\gamma) : \gamma \in \text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon)^+) \cap \text{Traj}(X \vee Y \vee Z)^\infty\};$$

$$(3.11b) \quad m_\varepsilon^- = \sup \{m(\gamma) : \gamma \in \text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon)^-) \cap \text{Traj}(X \vee Y \vee Z)^\infty\}.$$

The main fact to be proved is the following.

LEMMA 3.10. *If ε is sufficiently small, then m_ε^+ and m_ε^- are finite.*

Before we prove Lemma 3.10, let us show that this lemma solves our problem, i.e. let us prove the following.

LEMMA 3.11. *Suppose that ε is good for \mathcal{S} , and that m_ε^+ and m_ε^- are finite. Then $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient for $\text{Sq}(\varepsilon)$.*

Proof. If $\gamma \in \text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon))$, then γ cannot have a loop. So γ goes through p at most once. Therefore γ is the concatenation of at most two trajectories, each of which is entirely contained in $\text{Sq}(\varepsilon) - \{p\}$ (except possibly for one of its endpoints). So our conclusion will follow if we prove that $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient for $\text{Sq}(\varepsilon) - \{p\}$.

In view of Lemma 3.7, it is sufficient to prove that $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient for $\text{Sq}(\varepsilon)^+$ and for $\text{Sq}(\varepsilon)^-$.

If ε is good for \mathcal{S} , then Lemmas 3.8 and 3.9 tell us that there is an integer ν such that, whenever γ is an optimal trajectory in $\text{Sq}(\varepsilon)^+$, or in $\text{Sq}(\varepsilon)^-$, such that $\gamma \in \text{Traj}(X \vee Z)^\infty$ or that $\gamma \in \text{Traj}(Y \vee Z)^\infty$, then $\gamma \in \text{Traj}(X \vee Y \vee Z)^\nu$. If γ is an arbitrary optimal trajectory in $\text{Sq}(\varepsilon)^+$ or in $\text{Sq}(\varepsilon)^-$, then γ must be in $\text{Traj}(X \vee Y \vee Z)^\infty$, because every point of $\text{Sq}(\varepsilon)^+ \cup \text{Sq}(\varepsilon)^-$ is either an ordinary point or a member of a regular, nondegenerate INOA. So γ is a concatenation of at most $m(\gamma) + 2$ pieces that are in $\text{Traj}(X \vee Z)^\infty$, and of at most $m(\gamma) + 1$ pieces that belong to $\text{Traj}(Y \vee Z)^\infty$. Each of these pieces belongs to $\text{Traj}(X \vee Y \vee Z)^\nu$, and so

$$\gamma \in \text{Traj}(X \vee Y \vee Z)^{\mu(\gamma)},$$

where $\mu(\gamma) = (2m(\gamma) + 3)\nu$.

If the numbers m_ε^+ , m_ε^- are finite, then $\mu < \infty$, where

$$\mu = \sup \{\mu(\gamma) : \gamma \in \text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon)^+) \cup \text{Opt}^1(\Sigma \upharpoonright \text{Sq}(\varepsilon)^-)\}.$$

Also, $\gamma \in \text{Traj}(X \vee Y \vee Z)^\mu$. Therefore $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient for $\text{Sq}(\varepsilon)^+$ and for $\text{Sq}(\varepsilon)^-$. As explained before, our desired conclusion follows. \square

We now must prove Lemma 3.10. We let \mathcal{H} denote the set of all trajectories $\gamma \in \text{Traj}(X \vee Y \vee Z)^\infty$ such that, for some $a, b, t_0, t_1, t'_0, t'_1$, the following hold:

- (3.IX.i) $\text{Dom}(\gamma) = [a, b]$;
- (3.IX.ii) $a < t_0 \leq t'_0 < t'_1 \leq t_1 < b$;
- (3.IX.iii) $\gamma|_{[a, t_0]}$ and $\gamma|_{[t_1, b]}$ are Y -trajectories;
- (3.IX.iv) $\gamma|_{[t_0, t_1]} \in \text{Traj}(X \vee Z)$;
- (3.IX.v) $\gamma|_{[t'_0, t'_1]} \in \text{Traj}(X)$.

Lemma 3.10 will follow from the following.

LEMMA 3.12. *If ε is sufficiently small, then there exist finite sets $\mathcal{B}^+, \mathcal{B}^-$, such that*

- (3.X.a) *If $B \in \mathcal{B}^+$ then B is a barrier in $\text{Sq}(\varepsilon)^+$, and if $B \in \mathcal{B}^-$ then B is a barrier in \mathcal{B}^- ;*
- (3.X.b) *If $B_1 \neq B_2$ and both B_1 and B_2 are in $\mathcal{B}^+ \cup \mathcal{B}^-$, then $B_1 \cap B_2 = \emptyset$;*
- (3.X.c) *If $q \in B \in \mathcal{B}^+ \cup \mathcal{B}^-$, then $X(q)$ is not tangent to B at q , and*
- (3.X.d) *If $\gamma \in \mathcal{H}$, and γ is an optimal trajectory in $\text{Sq}(\varepsilon)^+$ or in $\text{Sq}(\varepsilon)^-$, then γ goes through some point of some $B \in \mathcal{B}^+ \cup \mathcal{B}^-$.*

Before we prove Lemma 3.12, let us show that this lemma implies Lemma 3.10. Let γ be an arbitrary optimal trajectory in $\text{Sq}(\varepsilon)^+$, or in $\text{Sq}(\varepsilon)^-$, such that $\gamma \in \text{Traj}(X \vee Y \vee Z)^\infty$. Let $J_1(\gamma), \dots, J_m(\gamma)(\gamma)$ be the members of $I(\gamma)$, ordered from left to right. Each $J_i(\gamma)$ is immediately preceded by a maximal interval $J_i(\gamma)_-$ such that $\gamma|_{J_i(\gamma)_-}$ is a Y -trajectory, and it is followed by another maximal interval $J_i(\gamma)_+$ such that $\gamma|_{J_i(\gamma)_+}$ is a Y -trajectory.

We let $J_i^*(\gamma) = J_i(\gamma)_- \cup J_i(\gamma) \cup J_i(\gamma)_+$. Then we define $\gamma_i = \gamma|_{J_i^*(\gamma)}$. The trajectories γ_i are in \mathcal{H} , and they are optimal. So each γ_i meets some $B \in \mathcal{B}^+ \cup \mathcal{B}^-$.

For each $B \in \mathcal{B}^+ \cup \mathcal{B}^-$, let $N(B)$ denote the set of indices $i \in \{1, 2, \dots, m(\gamma)\}$ such that γ_i meets B . We claim that $N(B)$ consists of at most two indices. Indeed, suppose there are three different indices i, j, k that belong to $N(B)$. Order them so that $i < j < k$. Then there are times t_i, t_k such that $t_i \in J_i^*(\gamma), t_k \in J_k^*(\gamma)$ and that $\gamma(t_i) \in B, \gamma(t_k) \in B$. Since γ is entirely contained in $\text{Sq}(\varepsilon)^+$ (or in $\text{Sq}(\varepsilon)^-$) and B is a barrier in $\text{Sq}(\varepsilon)^+$ (or in $\text{Sq}(\varepsilon)^-$), Lemma 4.1 of [A] implies that $\gamma|_{[t_i, t_k]}$ is entirely contained in B . On the other hand,

$$J_j(\gamma) \subseteq [t_i, t_k],$$

and therefore $\gamma|_{J_j(\gamma)}$ is entirely contained in B . However, the fact that $J_j(\gamma) \in I(\gamma)$ implies that $J_j(\gamma)$ contains some interval J' such that $\gamma|_{J'} \in \text{Traj}(X)$. But $\gamma|_{J'}$ must be contained in B . Since X is nowhere tangent to B , we have reached a contradiction.

So $N(B)$ has at most two elements for each $B \in \mathcal{B}^+ \cup \mathcal{B}^-$. Since every $i \in \{1, 2, \dots, m(\gamma)\}$ is in $N(B)$ for some B , it follows that $m(\gamma) \leq 2\nu$, where ν is the cardinality of $\mathcal{B}^+ \cup \mathcal{B}^-$. Therefore m_ε^+ and m_ε^- are finite. This concludes the proof that Lemma 3.10 follows from Lemma 3.12.

We now proceed to the rather long proof of Lemma 3.12. The main step of the proof is the construction of a stratification \mathcal{T} with some special properties. In order to construct \mathcal{T} , we must first study some properties of conjugate points. If q_1, q_2 are two points of $\text{Sq}(\varepsilon_0)$, we write $q_1 \sim q_2$ if q_1 and q_2 lie on the same X -trajectory and are conjugate along it. In coordinates, if $q_i = (x_i, y_i)$, the relation $q_1 \sim q_2$ holds if and only if

$$(3.12a) \quad y_1 = y_2$$

and

$$(3.12b) \quad \sigma(x_1, y_1; x_2, y_2) = 0,$$

where $\sigma(x_1, y_1; x_2, y_2)$ is equal to four times the determinant of the vectors $G(q_1)$, $G(q_2)$, i.e.

$$(3.13) \quad \sigma(x_1, y_1; x_2, y_2) = [\alpha(x_1, y_1) - 1]\beta(x_2, y_2) - [\alpha(x_2, y_2) - 1]\beta(x_1, y_1).$$

We define, for $0 < \varepsilon \leq \varepsilon_0$

$$(3.14) \quad Q(\varepsilon) = \{(q_1, q_2) \in \text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon) : q_1 \sim q_2\}.$$

Then $Q(\varepsilon_0)$ is an analytic subset of $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$, because it is the set of solutions of the pair of equations (3.12a), (3.12b). If $0 < \varepsilon < \varepsilon_0$, then $Q(\varepsilon)$ is a semianalytic, relatively compact subset of $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$.

We now pick an ε_1 such that $0 < \varepsilon_1 < \varepsilon_0$ and that ε_1 is good for \mathcal{S} . From now on, and until the end of this section, ε_1 will be kept fixed. We consider the set \mathcal{P} of those strata $S \in \mathcal{S}$ such that: (a) S is one-dimensional, (b) S meets $\text{Sq}(\varepsilon_1)$ and (c) G does not vanish identically on S . Then \mathcal{P} is finite. For each $S \in \mathcal{P}$, we let S^\sim denote the set of all $q_2 \in \text{Sq}(\varepsilon_1)$ such that $q_2 \sim q_1$ for some $q_1 \in S \cap \text{Sq}(\varepsilon_1)$. If

$$\pi: \text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0) \rightarrow \text{Sq}(\varepsilon_0)$$

denotes the projection $(q_1, q_2) \rightarrow q_1$, then

$$(3.15) \quad S^\sim = \pi(Q(\varepsilon_1) \cap (\text{Sq}(\varepsilon_1) \times S)).$$

So S^\sim is the image, under the analytic map π , of the relatively compact semianalytic subset $Q(\varepsilon_1) \cap (\text{Sq}(\varepsilon_1) \times S)$ of $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$. Therefore S^\sim is a subanalytic subset of $\text{Sq}(\varepsilon_0)$, and $S^\sim \subseteq \text{Sq}(\varepsilon_1)$, so that S^\sim is relatively compact in $\text{Sq}(\varepsilon_0)$. (Actually, S^\sim is semianalytic, because every subanalytic subset of \mathbb{R}^2 is semianalytic; but we will not need to use this fact.)

It will be important later to know that, if $S \in \mathcal{P}$, then S^\sim cannot be two-dimensional. In order to prove this, we need the results of a calculation that will be useful for other reasons as well.

We have

$$(3.16) \quad [X, Y] = (\partial_x \alpha) \partial_x + (\partial_x \beta) \partial_y.$$

On the other hand,

$$(3.17) \quad (\partial_{x_2} \sigma)(x_1, y_1; x_2, y_2) = [\alpha(x_1, y_1) - 1](\partial_x \beta)(x_2, y_2) - (\partial_x \alpha)(x_2, y_2)\beta(x_1, y_1),$$

i.e.

$$(3.18) \quad (\partial_{x_2} \sigma)(x_1, y_1; x_2, y_2) = 2 \det(G(x_1, y_1), [X, Y](x_2, y_2)).$$

Now suppose S^\sim were two-dimensional for some $S \in \mathcal{P}$. Pick a q_2 in the interior of S^\sim , and let $W \subseteq \text{Sq}(\varepsilon_1)$ be open, and such that $q_2 \in W$, $W \subseteq S^\sim$. For each $q'_2 \in W$, there is a $q'_1 \in S \cap \text{Sq}(\varepsilon_1)$ such that $q'_1 \sim q'_2$. In particular, q'_1 must have the same y -coordinate as q'_2 , and so $S \cap \text{Sq}(\varepsilon_1)$ must contain points not on the x -axis. In view of Lemma 3.4, together with the fact that ε_1 is good for \mathcal{S} , the set $S \cap \text{Sq}(\varepsilon_1)$ is entirely contained in $\text{Sq}(\varepsilon_1)^+$ or in $\text{Sq}(\varepsilon_1)^-$. Pick a $q_1 \in S$ for which $q_2 \sim q_1$ and $q_1 \in \text{Sq}(\varepsilon_1)$. Let L denote the open segment $\{(x, y_1) : |x| < \varepsilon_1\}$, where we let $q_i = (x_i, y_i)$, $i = 1, 2$ (so that, in particular, $y_1 = y_2$). Since W is open, $W \cap L$ contains a nonempty open segment L' . Each $q' \in L'$ must satisfy $q' \sim q$ for some $q \in S \cap \text{Sq}(\varepsilon_1)$. In principle, the point q might depend on q' , but it is easy to see that it does not. Indeed, since $S \cap \text{Sq}(\varepsilon_1)$ is

in $\mathcal{A}_p^+(\varepsilon_1) \cup \mathcal{A}_p^-(\varepsilon_1)$, $S \cap L$ consists of at most one point, and so $S \cap L = \{q_1\}$. So $q' \sim q$ for all $q' \in L'$. Therefore the function

$$(3.19) \quad x \rightarrow \sigma(x_1, y_1; x, y_1)$$

vanishes for all x in some neighborhood of x_2 . Because the function (3.19) is analytic, we can conclude that

$$(3.20) \quad \sigma(x_1, y_1; x, y_1) = 0 \quad \text{for } |x| < \varepsilon_1.$$

So

$$(3.21) \quad (\partial_x \sigma)(x_1, y_1; x, y_1) = 0 \quad \text{for } |x| < \varepsilon_1,$$

and then, using (3.18), we get

$$(3.22) \quad \det(G(x_1, y_1), [X, Y](x, y_1)) = 0 \quad \text{for } |x| < \varepsilon_1.$$

Now recall that $S \in \mathcal{P}$, and therefore G does not vanish identically on S . Since $S \in \mathcal{S}$, which is compatible with E_3 , we see that G vanishes nowhere on S . So $G(x_1, y_1) \neq 0$. If $|x| < \varepsilon_1$, (3.20) shows that $G(x_1, y_1)$ and $G(x, y_1)$ are linearly dependent, and so $G(x, y_1) = \rho G(x_1, y_1)$ for some number ρ . Therefore

$$\begin{aligned} \Delta_B(x, y_1) &= \frac{1}{2} \det(G(x, y_1), [X, Y](x, y_1)) \\ &= \frac{\rho}{2} \det(G(x_1, y_1), [X, Y](x, y_1)) \\ &= 0. \end{aligned}$$

So Δ_B vanishes identically on L , and $L \subseteq E_2$. Since ε_1 is good for \mathcal{S} , and $y_1 \neq 0$, only a finite number of one-dimensional strata of \mathcal{S} meet L , and no zero-dimensional stratum of L meets L . So some point of L must belong to a two-dimensional stratum of \mathcal{S} . Since $L \subseteq E_2$ and \mathcal{S} is compatible with E_2 , it follows that E_2 must contain an open set, and so Δ_B vanishes identically, contradicting (3.III.v).

The contradiction arose from assuming that S^\sim was two-dimensional. So, we have proved the following.

LEMMA 3.13. *If $S \in \mathcal{P}$, then $\dim S^\sim \leq 1$. \square*

We now let $Q_0(\varepsilon)$ denote, for $0 < \varepsilon \leq \varepsilon_0$, the set of all pairs $(q_1, q_2) \in Q(\varepsilon)$ such that $q_1 \neq q_2$, that both q_1 and q_2 are ordinary points, and that $f(q_1)$ and $f(q_2)$ have opposite signs. Then $Q_0(\varepsilon)$ is the subset of $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$ defined by the conditions $(q_1, q_2) \in Q(\varepsilon)$ and $(\Delta_A \Delta_B)(q_1) \cdot (\Delta_A \Delta_B)(q_2) < 0$. So $Q_0(\varepsilon)$ is semianalytic in $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$. Moreover, $Q_0(\varepsilon)$ is relatively compact if $\varepsilon < \varepsilon_0$.

LEMMA 3.14. *For $0 < \varepsilon \leq \varepsilon_0$, the set $Q_0(\varepsilon)$ is an embedded two-dimensional submanifold of $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$, and the projection $\pi: Q_0(\varepsilon) \rightarrow \text{Sq}(\varepsilon_0)$ is nonsingular at each point $(q_1, q_2) \in Q_0(\varepsilon)$.*

Proof. Pick $(\bar{q}_1, \bar{q}_2) \in Q_0(\varepsilon)$, and let $\bar{q}_i = (\bar{x}_i, \bar{y}_i)$, for $i = 1, 2$. Then $\bar{y}_1 = \bar{y}_2$, and $\sigma(\bar{x}_1, \bar{y}_1; \bar{x}_2, \bar{y}_2) = 0$. On the other hand, $\Delta_B(\bar{q}_2) \neq 0$, and so

$$(3.23) \quad \det(G(\bar{x}_2, \bar{y}_2), [X, Y](\bar{x}_2, \bar{y}_2)) \neq 0.$$

Since $\bar{q}_1 \sim \bar{q}_2$, the vectors $G(\bar{x}_1, \bar{y}_1)$ and $G(\bar{x}_2, \bar{y}_2)$ are linearly dependent. Since \bar{q}_1 and \bar{q}_2 are ordinary points, both $G(\bar{x}_1, \bar{y}_1)$ and $G(\bar{x}_2, \bar{y}_2)$ are nonzero. So (3.23) implies

$$(3.24) \quad \det(G(\bar{x}_1, \bar{y}_1), [X, Y](\bar{x}_2, \bar{y}_2)) \neq 0.$$

In view of (3.18), we get

$$(3.25) \quad \frac{\partial \sigma}{\partial x_2}(\bar{x}_1, \bar{y}_1; \bar{x}_2, \bar{y}_2) \neq 0.$$

Pick $\delta > 0$ such that, whenever $q_i = (x_i, y_i)$, $i = 1, 2$, and $|x_i - \bar{x}_i| < \delta$, $|y_i - \bar{y}_i| < \delta$, for $i = 1, 2$, it follows that $(\Delta_A \Delta_B)(q_1) \cdot (\Delta_A \Delta_B)(q_2) < 0$, and that $q_1 \in \text{Sq}(\varepsilon)$, $q_2 \in \text{Sq}(\varepsilon)$.

In view of (3.25), and of the fact that $\bar{y}_1 = \bar{y}_2$, we can apply the Implicit Function Theorem to find δ_1, δ_2 such that $0 < \delta_1 < \delta$, $0 < \delta_2 < \delta$, and a real analytic function k , defined for $|x_1 - \bar{x}_1| < \delta_1$, $|y_1 - \bar{y}_1| < \delta_1$, with the property that $|k(x_1, y_1) - \bar{x}_2| < \delta_2$ for $(x_1 - \bar{x}_1, y_1 - \bar{y}_1) \in \text{Sq}(\delta_1)$, and that, if $(x_1 - \bar{x}_1, y_1 - \bar{y}_1) \in \text{Sq}(\delta_1)$ and $|x - \bar{x}_2| < \delta_2$, then $\sigma(x_1, y_1; x, y_1) = 0$ if and only if $x = k(x_1, y_1)$.

Now let W denote the set

$$(3.26) \quad \{(x_1, y_1; x_2, y_2) : |x_1 - \bar{x}_1| < \delta_1, |y_1 - \bar{y}_1| < \delta_1, |x_2 - \bar{x}_2| < \delta_2, |y_2 - \bar{y}_2| < \delta_2\}.$$

Then $W \cap Q_0(\varepsilon)$ is the set of those $(x_1, y_1; x_2, y_2) \in W$ that satisfy $y_2 = y_1$, $x_2 = k(x_1, y_1)$. So $W \cap Q_0(\varepsilon)$ is an embedded submanifold of W . Since every $(\bar{q}_1, \bar{q}_2) \in Q_0(\varepsilon)$ has such a neighborhood W , it follows that $Q_0(\varepsilon)$ is an embedded manifold. Moreover, the map $(x_1, y_1) \rightarrow (x_1, y_1; k(x_1, y_1), y_1)$ is an inverse of $\pi|_{(Q_0(\varepsilon) \cap W)}$. So $\pi|_{Q_0(\varepsilon)}$ has rank two at every point of $Q_0(\varepsilon)$. \square

Suppose that V is a smooth vector field on $\text{Sq}(\varepsilon_0)$. Since $\pi : Q_0(\varepsilon_0) \rightarrow \pi(Q_0(\varepsilon_0))$ is a local diffeomorphism, there exists a unique vector field V^* on $Q_0(\varepsilon_0)$ such that

$$(3.27) \quad \pi_*(V^*(q_1, q_2)) = V(q_1)$$

for all $(q_1, q_2) \in Q_0(\varepsilon_0)$. (Here π_* is the differential of π .)

If $t \rightarrow \zeta(t)$ denotes the integral curve of V^* such that $\zeta(0) = (q_1, q_2)$, then $\zeta(t) = (\zeta_1(t), \zeta_2(t))$, where $\zeta_1(t) = \pi(\zeta(t))$, and therefore $\zeta_1(t) = \Phi_t^V(q_1)$. So $\zeta_1(0) = V(q_1)$. This shows that V^* is of the form

$$(3.28) \quad V^*(q_1, q_2) = (V(q_1), V^{\sim}(q_1, q_2))$$

for some vector-valued $V^{\sim} : Q_0(\varepsilon_0) \rightarrow \mathbb{R}^2$.

We now compute V^{\sim} . Pick $(\bar{q}_1, \bar{q}_2) \in Q_0(\varepsilon_0)$, and then pick $\delta, \delta_1, \delta_2, k(\cdot, \cdot)$ as in the proof of Lemma 3.14. Let K denote the map $(x_1, y_1) \rightarrow (k(x_1, y_1), y_1)$. Then it is clear that

$$(3.29) \quad \Phi_t^{V^*}(\bar{q}_1, \bar{q}_2) = (\Phi_t^V(\bar{q}_1), K(\Phi_t^V(\bar{q}_1)))$$

and therefore

$$(3.30) \quad V^{\sim}(\bar{q}_1, \bar{q}_2) = K_*(\bar{q}_1) V(\bar{q}_1),$$

where $K_*(\bar{q}_1)$ is the Jacobian matrix of K at \bar{q}_1 . An easy computation gives

$$(3.31) \quad K_*(\bar{q}_1) = \begin{bmatrix} (\partial_{x_1} k)(\bar{x}_1, \bar{y}_1) & \partial_{y_1} k(\bar{x}_1, \bar{y}_1) \\ 0 & 1 \end{bmatrix}.$$

On the other hand, the partial derivatives of k can be computed by implicit differentiation of

$$(3.32) \quad \sigma(x_1, y_1; k(x_1, y_1), y_1) = 0.$$

The result is

$$(3.33) \quad \partial_{x_1} k(x_1, y_1) = -\frac{\partial_{x_1} \sigma}{\partial_{x_2} \sigma}(x_1, y_1; k(x_1, y_1), y_1),$$

$$(3.34) \quad \partial_{y_1} k(x_1, y_1) = -\frac{\partial_{y_1} \sigma + \partial_{y_2} \sigma}{\partial_{x_2} \sigma}(x_1, y_1; k(x_1, y_1), y_1).$$

So

$$(3.35) \quad K_*(\bar{q}_1) = \frac{1}{\partial_{x_2}\sigma} \begin{bmatrix} -\partial_{x_1}\sigma & -(\partial_{y_1}\sigma + \partial_{y_2}\sigma) \\ 0 & \partial_{x_2}\sigma \end{bmatrix} (\bar{q}_1, \bar{q}_2).$$

In particular, if V is given by

$$(3.36) \quad V = v_1\partial_x + v_2\partial_y$$

we find that

$$(3.37) \quad V^\sim(q_1, q_2) = v_1^\sim(q_1, q_2)\partial_x + v_2^\sim(q_1, q_2)\partial_y,$$

where

$$(3.38) \quad v_1^\sim(q_1, q_2) = -\left(\frac{\partial_{x_1}\sigma}{\partial_{x_2}\sigma}\right)(q_1, q_2)v_1(q_1) - \left(\frac{\partial_{y_1}\sigma + \partial_{y_2}\sigma}{\partial_{x_2}\sigma}\right)(q_1, q_2)v_2(q_1)$$

and

$$(3.39) \quad v_2^\sim(q_1, q_2) = v_2(q_1).$$

Of particular interest to us are the vector fields X^* and Y^* . We have

$$(3.40) \quad X^\sim(q_1, q_2) = -\left(\frac{\partial_{x_1}\sigma}{\partial_{x_2}\sigma}\right)(q_1, q_2)\partial_x$$

and

$$(3.41) \quad Y^\sim(q_1, q_2) = \alpha^\sim(q_1, q_2)\partial_x + \beta^\sim(q_1, q_2)\partial_y$$

where

$$(3.42) \quad \alpha^\sim(q_1, q_2) = -\left(\frac{\partial_{x_1}\sigma}{\partial_{x_2}\sigma}\right)(q_1, q_2)\alpha(q_1) - \left(\frac{\partial_{y_1}\sigma + \partial_{y_2}\sigma}{\partial_{x_2}\sigma}\right)(q_1, q_2)\beta(q_2)$$

and

$$(3.43) \quad \beta^\sim(q_1, q_2) = \beta(q_1).$$

It will be important to know the direction of $X^\sim(q_1, q_2)$. The following lemma tells us all we need to know.

LEMMA 3.15. *Suppose that $(q_1, q_2) \in Q_0(\varepsilon_0)$ and that $\Delta_A(q_1)\Delta_A(q_2) > 0$. Then the vector $X^\sim(q_1, q_2)$ points to the left, i.e.,*

$$(3.44) \quad -\frac{\partial_{x_1}\sigma}{\partial_{x_2}\sigma}(q_1, q_2) < 0.$$

Proof. Suppose that $(q_1, q_2) \in Q_0(\varepsilon_0)$, and that $\Delta_A(q_1)\Delta_A(q_2) > 0$. Then $G(q_1) \neq 0$, $G(q_2) \neq 0$, and $G(q_1)$ is linearly independent from $G(q_2)$, so that

$$G(q_1) = \rho G(q_2)$$

for some nonzero number ρ . Formula (3.18) then implies that

$$(\partial_{x_2}\sigma)(q_1, q_2) = 2\rho \det(G(q_2), [X, Y](q_2)),$$

i.e., that

$$(\partial_{x_2}\sigma)(q_1, q_2) = 4\rho\Delta_B(q_2).$$

A similar calculation yields

$$\begin{aligned}(\partial_{x_1}\sigma)(q_1, q_2) &= -2 \det(G(q_2), [X, Y](q_1)) \\ &= -4\rho^{-1}\Delta_B(q_1).\end{aligned}$$

Therefore

$$-\frac{\partial_{x_1}\sigma}{\partial_{x_2}\sigma}(q_1, q_2) = \rho^{-2} \frac{\Delta_B(q_1)}{\Delta_B(q_2)}.$$

Since $\Delta_A(q_1)\Delta_B(q_1)$ and $\Delta_A(q_2)\Delta_B(q_2)$ have opposite signs (because $(q_1, q_2) \in Q_0(\varepsilon_0)$), but we are assuming that $\Delta_A(q_1)$ and $\Delta_A(q_2)$ have the same sign, it follows that $\Delta_B(q_1)$ and $\Delta_B(q_2)$ have opposite signs. So (3.44) follows. \square

We now single out, for $0 < \varepsilon \leq \varepsilon_0$, subsets $\hat{Q}_1(\varepsilon)$, $Q_1(\varepsilon)$ of $Q_0(\varepsilon)$ as follows. We let $(q_1, q_2) \in \hat{Q}_1(\varepsilon)$ if and only if (a) $(q_1, q_2) \in Q_0(\varepsilon_0)$ and (b) the vectors $Y(q_2)$ and $Y^\sim(q_1, q_2)$ are linearly dependent. We let $(q_1, q_2) \in Q_1(\varepsilon)$ iff (a) $(q_1, q_2) \in \hat{Q}_1(\varepsilon)$ but (b) there does not exist a $\delta > 0$ such that $\Phi_t^{X^*}(q_1, q_2) \in \hat{Q}_1(\varepsilon)$ for all $t \in]-\delta, \delta[$.

LEMMA 3.16. (a) $\hat{Q}_1(\varepsilon_0)$ is a semianalytic subset of $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$, (b) $Q_1(\varepsilon)$ is a subanalytic subset of $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$, of dimension not greater than one, if $0 < \varepsilon < \varepsilon_0$.

Proof. If $(q_1, q_2) \in \text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$, then $(q_1, q_2) \in \hat{Q}_1(\varepsilon_0)$ if and only if $(q_1, q_2) \in Q_0(\varepsilon_0)$ and $\tau(q_1, q_2) = 0$, where τ is the determinant of $Y^\sim(q_1, q_2)$ and $Y(q_2)$. Formulas (3.41)–(3.43) imply that τ is a quotient τ_1/τ_2 , where τ_1 and τ_2 are analytic functions on $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$, and τ_2 never vanishes on $Q_0(\varepsilon_0)$. Therefore $(q_1, q_2) \in \hat{Q}_1(\varepsilon_0)$ if and only if $(q_1, q_2) \in Q_0(\varepsilon_0)$ and $\tau_1(q_1, q_2) = 0$. So $\hat{Q}_1(\varepsilon_0)$ is the intersection of $Q_0(\varepsilon_0)$ with an analytic set, and is therefore semianalytic.

Now let $0 < \varepsilon < \varepsilon_0$. Define a new vector field X^* by

$$(3.45) \quad X^*(q_1, q_2) = \partial_{x_2}\sigma(q_1, q_2)X^*(q_1, q_2).$$

Then X^* is a well defined analytic vector field on the whole cube $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0) \subseteq \mathbb{R}^4$, which is tangent to the submanifold $Q_0(\varepsilon_0)$ and which, restricted to this submanifold, is equal to a nonzero scalar multiple of X^* . If $(q_1, q_2) \in Q_0(\varepsilon_0)$, then the integral curve of X^* through (q_1, q_2) coincides with that of X^* , after a suitable reparametrization. Therefore the definition of $Q_1(\varepsilon)$ can be rephrased as follows:

- (3.XI) (q_1, q_2) belongs to $Q_1(\varepsilon)$ iff
 (3.XI.a) $(q_1, q_2) \in \hat{Q}_1(\varepsilon)$, and
 (3.XI.b) For every $\delta > 0$ there exists a t such that $|t| < \delta$ and that $\Phi_t^{X^*}(q_1, q_2) \notin \hat{Q}_1(\varepsilon)$.

Since X^* is an analytic vector field on $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$, and $0 < \varepsilon < \varepsilon_0$, we can pick $\bar{\varepsilon}$, $\bar{\delta}$ such that $0 < \bar{\delta}$, that $\varepsilon < \bar{\varepsilon} < \varepsilon_0$, and that $\Phi_t^{X^*}(q_1, q_2)$ is defined and belongs to $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$ for all $(t, q_1, q_2) \in W$, where

$$W =]-\bar{\delta}, \bar{\delta}[\times \text{Sq}(\bar{\varepsilon}) \times \text{Sq}(\bar{\varepsilon}).$$

Now let $\tilde{W} \subseteq \mathbb{R}^9$ be the open set $W \times \text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$, and let $\tilde{\Phi} \subseteq \tilde{W}$ be the graph of the restriction to W of the flow of X , that is

$$(3.46) \quad \tilde{\Phi} = \{(t, q_1, q_2, q'_1, q'_2) \in \tilde{W} : (q'_1, q'_2) = \Phi_t^{X^*}(q_1, q_2)\}.$$

Then $\tilde{\Phi}$ is the set of zeros in \tilde{W} of four analytic real-valued functions defined on all of \tilde{W} , so that $\tilde{\Phi}$ is an analytic subset of \tilde{W} . Let $\tilde{\Phi}_1$ denote the set of those $(t, q_1, q_2, q'_1, q'_2) \in \tilde{\Phi}$ such that (q'_1, q'_2) does not belong to $\hat{Q}_1(\varepsilon)$. Then $\tilde{\Phi}_1$ is the

intersection of $\tilde{\Phi}$ with $\psi^{-1}([\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)] - \hat{Q}_1(\varepsilon))$, where ψ is the projection $(t, q_1, q_2, q'_1, q'_2) \rightarrow (q'_1, q'_2)$. So $\tilde{\Phi}_1$ is a semianalytic subset of \tilde{W} . Now let $\tilde{W} \subseteq \mathbb{R}^{10}$ be the set $] -\bar{\delta}, \bar{\delta}[\times \tilde{W}$, and consider the subset $\tilde{\Phi}_1$ of those $(\delta, t, q_1, q_2, q'_1, q'_2)$ that satisfy $|t| < \delta$, $(t, q_1, q_2, q'_1, q'_2) \in \tilde{\Phi}_1$. Let $0 < \delta^* < \bar{\delta}$, and let $\tilde{\Phi}_1^*$ be the set of those $(\delta, t, q_1, q_2, q'_1, q'_2) \in \tilde{\Phi}_1$ such that $\delta < \delta^*$, $(q_1, q_2) \in \text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$, and $(q'_1, q'_2) \in \text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$. Then $\tilde{\Phi}_1$ is semianalytic in \tilde{W} , and $\tilde{\Phi}_1^*$ is semianalytic and relatively compact in \tilde{W} . Let $\nu: \tilde{W} \rightarrow]0, \bar{\delta}^*[\times \text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$ be the map $(\delta, t, q_1, q_2, q'_1, q'_2) \rightarrow (\delta, q_1, q_2)$. Then (δ, q_1, q_2) is in $\nu(\tilde{\Phi}_1^*)$ if and only if

- (3.XII.a) $0 < \delta < \delta^*$;
- (3.XII.b) $(q_1, q_2) \in \text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$;
- (3.XII.c) There is a t such that $|t| < \delta$ and that $\Phi_t^{X^*}(q_1, q_2)$ does not belong to $\hat{Q}_1(\varepsilon)$, but belongs to $\text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$.

Therefore, a point

$$(\delta, q_1, q_2) \in]0, \delta^*[\times \text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$$

will fail to belong to $\nu(\tilde{\Phi}_1^*)$ if and only if, for every t such that $|t| < \delta$, the point $\Phi_t^{X^*}(q_1, q_2)$ either belongs to $\hat{Q}_1(\varepsilon)$ or fails to belong to $\text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$.

Let D denote the set of those $(\delta, q_1, q_2) \in]0, \delta^*[\times \text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$ such that $(\delta, q_1, q_2) \notin \nu(\tilde{\Phi}_1^*)$, but $(q_1, q_2) \in Q_0(\varepsilon)$. Then D is relatively compact in W . Moreover, D is the intersection of the semianalytic subset $\hat{\psi}^{-1}(Q_0(\varepsilon))$ of W with the set $W - \nu(\tilde{\Phi}_1^*)$. (Here $\hat{\psi}$ is the projection $(\delta, q_1, q_2) \rightarrow (q_1, q_2)$.) Since $\tilde{\Phi}_1^*$ is semianalytic and relatively compact in \tilde{W} , the set $\nu(\tilde{\Phi}_1^*)$ is subanalytic in W . So D is a subanalytic subset of W , and it is clearly relatively compact in W . Moreover, D is the set of those (δ, q_1, q_2) such that $0 < \delta < \delta^*$, $(q_1, q_2) \in Q_0(\varepsilon)$, and $\Phi_t^{X^*}(q_1, q_2) \in \hat{Q}_1(\varepsilon)$ or $\Phi_t^{X^*}(q_1, q_2) \notin \text{Sq}(\varepsilon) \times \text{Sq}(\varepsilon)$ for $|t| < \delta$. Therefore $\hat{\psi}(D)$ is the set of those $(q_1, q_2) \in Q_0(\varepsilon)$ such that $\Phi_t^{X^*}(q_1, q_2) \in \hat{Q}_1(\varepsilon)$ for all sufficiently small t . So

$$Q_1(\varepsilon) = \hat{Q}_1(\varepsilon) - \hat{\psi}(D).$$

Since $\hat{\psi}(D)$ is subanalytic, it follows that $Q_1(\varepsilon)$ is subanalytic.

Finally, to prove that $\dim Q_1(\varepsilon) \leq 1$, observe that, if $\dim Q_1(\varepsilon)$ were equal to two, this would imply that $Q_1(\varepsilon)$ contains a subset S which is open in $Q_0(\varepsilon)$. If $(q_1, q_2) \in S$, then $\Phi_t^{X^*}(q_1, q_2) \in Q_1(\varepsilon)$ for small t , and so $\Phi_t^{X^*}(q_1, q_2) \in \hat{Q}_1(\varepsilon)$ for small t . But then $(q_1, q_2) \notin Q_1(\varepsilon)$, and we have reached a contradiction. \square

We now let $\pi_2: \text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0) \rightarrow \text{Sq}(\varepsilon_0)$ denote the projection $(q_1, q_2) \rightarrow q_2$. The set $\pi_2(Q_1(\varepsilon_1))$ is therefore a subanalytic subset of $\text{Sq}(\varepsilon_0)$.

We choose a pair \mathcal{V}, \mathcal{T} of CASA stratifications of $\text{Sq}(\varepsilon_0) \times \text{Sq}(\varepsilon_0)$ and $\text{Sq}(\varepsilon_0)$, respectively, such that

- (3.XIII.i) \mathcal{V} is compatible with $\text{Sq}(\varepsilon_1) \times \text{Sq}(\varepsilon_1)$, with $Q_0(\varepsilon_0)$, with $Q_1(\varepsilon_1)$, and with $\{(p, p)\}$;
- (3.XIII.ii) \mathcal{T} is compatible with $\pi_2(Q_1(\varepsilon_1))$, with all the members of \mathcal{S} , and with all the sets S^- , for $S \in \mathcal{P}$;
- (3.XIII.iii) $(\mathcal{V}, \mathcal{T})$ is compatible with π over $\text{Sq}(\varepsilon_1) \times \text{Sq}(\varepsilon_1)$.

Since \mathcal{T} is a refinement of \mathcal{S} , it follows from Lemma 3.6 that \mathcal{T} is appropriate.

We now take $\varepsilon > 0$ so small that $0 < \varepsilon < \varepsilon_1$ and that ε is good for \mathcal{T} . We define \mathcal{B}_0 to be the set of all $T^\varepsilon = T \cap \text{Sq}(\varepsilon)$, as T ranges over all one-dimensional strata of \mathcal{T} that meet $\text{Sq}(\varepsilon)$ (i.e., equivalently, over all one-dimensional $T \in \mathcal{T}$ such that

$p \in \text{Clos } T$). By Lemma 3.4, every element of \mathcal{B}_0 is in $\mathcal{A}_p^+(\varepsilon)$, or in $\mathcal{A}_p^-(\varepsilon)$, or is one of the segments Γ_ε^+ , Γ_ε^- . We define

$$(3.47) \quad \mathcal{B}_0^+ = \mathcal{B}_0 \cap \mathcal{A}_p^+(\varepsilon),$$

$$(3.48) \quad \mathcal{B}_0^- = \mathcal{B}_0 \cap \mathcal{A}_p^-(\varepsilon).$$

We let \mathcal{B}_1^+ be the set obtained by adding to \mathcal{B}_0^+ the segment $\{0\} \times]0, \varepsilon[$. Similarly, we let

$$\mathcal{B}_1^- = \mathcal{B}_0^- \cup \{\{0\} \times]-\varepsilon, 0[\}.$$

Finally, we let \mathcal{B}^+ denote the set of all $B \in \mathcal{B}_1^+$ that are barriers in $\text{Sq}(\varepsilon)^+$, and we define \mathcal{B}^- similarly. It is clear that \mathcal{B}^+ and \mathcal{B}^- are finite sets, and that the members of \mathcal{B}^+ (resp. \mathcal{B}^-) are barriers in $\text{Sq}(\varepsilon)^+$ (resp. $\text{Sq}(\varepsilon)^-$). Moreover, the members of $\mathcal{B}^+ \cup \mathcal{B}^-$ are clearly pairwise disjoint. (Indeed, if B_1, B_2 are in $\mathcal{B}^+ \cup \mathcal{B}^-$, then $B_1 \cap B_2 = \emptyset$ if one of the B_i is in \mathcal{B}^+ and the other one in \mathcal{B}^- . If, say, both B_i are in \mathcal{B}^+ , then it is clear that $B_1 \cap B_2 = \emptyset$ if both B_i are in \mathcal{B}_0^+ . If, say, $B_1 \in \mathcal{B}_0^+$ and $B_2 = \{0\} \times]0, \varepsilon[$, then B_1 is the graph $\{(\psi(y), y)\}$ of a function ψ which is defined on some interval $]0, \delta[$, and $\psi(0+) = 0$. Moreover, ψ is either constant (in which case $\psi \equiv 0$) or strictly monotonic. In the latter case, ψ never takes the value zero, so that $B_1 \cap B_2 = \emptyset$. In the former case we necessarily have $\delta = \varepsilon$ and $B_1 = B_2$.) Finally, it is clear that, if $B \in \mathcal{B}^+ \cup \mathcal{B}^-$, then X is never tangent to B , because B is a graph $\{(\psi(y), y)\}$.

So \mathcal{B}^+ and \mathcal{B}^- satisfy all the conditions (3.X) of Lemma 3.12, except, possibly, for (3.X.d) (which is, naturally, the most important one). The rest of this section is devoted to the proof that \mathcal{B}^+ and \mathcal{B}^- satisfy (3.X.d) as well.

We consider a trajectory γ which belongs to \mathcal{K} , and which is time-optimal and entirely contained in $\text{Sq}(\varepsilon)^+$. We let $a, t_0, t'_0, t'_1, t_1, b$ be such that (3.XI.i, \dots, v) hold. It is clear that we can choose $[t'_0, t'_1]$ to be a maximal subinterval J of $[t_0, t_1]$ such that $\gamma|_J$ is an X -trajectory. Also, if there are several such maximal intervals, we can choose $[t'_0, t'_1]$ to be the one farthest to the left. With this choice, we may, and will, assume that

(3.XIV.a) Either $t'_0 = t_0$, or $\gamma|_{[t_0, t'_0]}$ is a Z -trajectory;

(3.XIV.b) Either $t'_1 = t_1$, or there is a $\delta > 0$ such that $\gamma|_{[t'_1, t'_1 + \delta]}$ is a Z -trajectory.

Finally, let us write

$$q_0 = \gamma(t_0), \quad q_1 = \gamma(t_1), \quad q'_0 = \gamma(t'_0), \quad q'_1 = \gamma(t'_1).$$

Our goal is to prove that γ necessarily meets one of the members of \mathcal{B}^+ . We will do it by considering several different possible cases.

CASE 1. $t_0 = t'_0, t'_1 = t_1$, and both q_0 and q_1 are ordinary points.

In this case, γ is a strict $Y * X * Y$ -trajectory. Moreover, the points q_0 and q_1 are conjugate along $\gamma|_{[t_0, t_1]}$, because γ is optimal. Since both q_0 and q_1 are ordinary, the quantities $\Delta_A(q_0), \Delta_A(q_1), \Delta_B(q_0), \Delta_B(q_1)$ are all nonzero. In particular (since $\Delta_A = \frac{1}{2}\beta$) we see that $\beta(q_0)$ and $\beta(q_1)$ are both nonzero.

We distinguish two subcases:

SUBCASE 1a. $\beta(q_0)\beta(q_1) < 0$,

SUBCASE 1b. $\beta(q_0)\beta(q_1) > 0$.

Subcase 1a can only occur if (3.II.a) holds. Indeed, if (3.II.b) holds, then $\alpha < 1$ throughout U_0 , and therefore the equality

$$(3.49) \quad (\alpha(q_0) - 1)\beta(q_1) - (\alpha(q_1) - 1)\beta(q_0) = 0$$

implies that $\beta(q_0)\beta(q_1) > 0$.

So, if we are in Subcase 1a, it follows that $\alpha > 0$ throughout U_0 . Since $\beta(\gamma(t_0))$ and $\beta(\gamma(t_1))$ have opposite signs, there is a point $t_2 \in [t_0, t_1]$ such that $\beta(\gamma(t_2)) = 0$. Let $q_2 = \gamma(t_2)$. Then $\Delta_A(q_2) = 0$, so that $q_2 \in E_1(\varepsilon)$. Therefore $q_2 \in S^\varepsilon$ for some stratum $S \in \mathcal{T}$ such that $S \subseteq E_1$. Since ε is good for \mathcal{T} , it follows that S^ε is in $\mathcal{A}_p^+(\varepsilon)$. (Clearly, S^ε cannot lie in $\mathcal{A}_p^-(\varepsilon) \cup \{\Gamma_\varepsilon^+\} \cup \{\Gamma_\varepsilon^-\}$, because $q_2 \in S \cap \text{Sq}(\varepsilon)^+$.) To show that S^ε is a barrier, it suffices to show that both X and Y point to the same side of S^ε . But this is trivial since, along S^ε , X has components $(1, 0)$, whereas Y has components $(\alpha, 0)$, and $\alpha > 0$. So S is a barrier. Since $S \in \mathcal{T}$, we conclude that $S^\varepsilon \in \mathcal{B}^+$.

We now turn to Subcase 1b. The facts that q_0 and q_1 are ordinary points, and that optimal switchings occur at q_0, q_1 , in opposite senses (i.e. from $Y-$ to $X-$ at q_0 , and from $X-$ to $Y-$ at q_1) imply that $f(q_0)$ and $f(q_1)$ have opposite signs, so that $(q_0, q_1) \in Q_0(\varepsilon)$. Moreover, $\Delta_A(q_0)$ and $\Delta_A(q_1)$ have the same sign, and so Lemma 3.15 applies, and we can conclude that the vector $X^\sim(q_0, q_1)$ points to the left.

Now let $\zeta(\cdot)$ be the maximal integral curve of X^* such that $\zeta(0) = (q_0, q_1)$. (We emphasize that X^* is, by definition, a vector field on $Q_0(\varepsilon_0)$, so that, if $\lim_{s \rightarrow \bar{s}-} \zeta(s) \notin Q_0(\varepsilon_0)$, then $\zeta(\bar{s})$ is not defined.) The curve $\zeta(\cdot)$ is defined on an interval $[0, s_{\max}[$, where s_{\max} is finite. (To see that $s_{\max} < \infty$, notice that, if

$$(3.50) \quad \zeta(s) = (\zeta_0(s), \zeta_1(s)),$$

then $\zeta_0(\cdot)$ is an X -trajectory, so that the point $\zeta_0(s)$ moves to the right as s increases. On the other hand, as long as $\zeta(s)$ stays in $Q_0(\varepsilon_0)$, the number $\Delta_A(\zeta_0(s))\Delta_A(\zeta_1(s))$ must remain strictly positive, because it is positive for $s = 0$, and it can never vanish, since $\zeta_0(s)$ and $\zeta_1(s)$ are ordinary points. So $X^\sim(\zeta_0(s), \zeta_1(s))$ points left. Therefore the point $\zeta_1(s)$ moves to the left. Since $\zeta_0(s)$ moves right with velocity 1, the points $\zeta_0(s)$ and $\zeta_1(s)$ would have to coincide for some finite s , if $s_{\max} = \infty$. But, if $\zeta_0(s) = \zeta_1(s)$, then $\zeta(s)$ would not be in $Q_0(\varepsilon_0)$, which is a contradiction. So $s_{\max} < \infty$.)

The preceding remarks also show that $\zeta(s_{\max}-) = (\hat{q}_0, \hat{q}_1)$ is well defined, that $s_{\max} < t_1 - t_0$, and that $\hat{q}_0 = \gamma(\hat{t}_0)$, $\hat{q}_1 = \gamma(\hat{t}_1)$ for some \hat{t}_0, \hat{t}_1 such that $t_0 < \hat{t}_0 \leq \hat{t}_1 < t_1$ (and that, moreover, $\hat{t}_0 = t_0 + s_{\max}$). It is clear that $\zeta_0(s) \sim \zeta_1(s)$ for all $s \in [0, s_{\max}[$, and so $\hat{q}_0 \sim \hat{q}_1$. On the other hand, the point (\hat{q}_0, \hat{q}_1) is not in $Q_0(\varepsilon_0)$. Therefore one of the equalities $\Delta_A(\hat{q}_0) = 0$, $\Delta_A(\hat{q}_1) = 0$, $\Delta_B(\hat{q}_0) = 0$, $\Delta_B(\hat{q}_1) = 0$ must hold. (Otherwise, if $(\Delta_A\Delta_B)(\hat{q}_0)$ and $(\Delta_A\Delta_B)(\hat{q}_1)$ were $\neq 0$, it would follow from the inequality $(\Delta_A\Delta_B)(\zeta_0(s)) \cdot (\Delta_A\Delta_B)(\zeta_1(s)) < 0$ that $(\Delta_A\Delta_B)(\hat{q}_0)$ and $(\Delta_A\Delta_B)(\hat{q}_1)$ have opposite signs, so that $(\hat{q}_0, \hat{q}_1) \in Q_0(\varepsilon_0)$.)

We now observe that

$$(3.XV) \quad \text{The vector } Y^\sim(q_0, q_1) \text{ is not a linear combination of } X(q_1) \text{ and } Y(q_1) \text{ with strictly positive coefficients.}$$

Indeed, suppose $Y^\sim(q_0, q_1)$ were a combination $\mu X(q_1) + \nu Y(q_1)$, with $\mu > 0$, $\nu > 0$. Let $\lambda(\cdot): [t_0 - \delta, t_0] \rightarrow Q_0(\varepsilon_0)$ be an integral curve of Y^* such that $\lambda(t_0) = (q_0, q_1)$. If $\lambda(t) = (\lambda_1(t), \lambda_2(t))$, then $\lambda_1(\cdot)$ is a Y -trajectory, and $\lambda_2(\cdot)$ satisfies

$$(3.51) \quad \dot{\lambda}_2(t) = Y^\sim(\lambda_1(t), \lambda_2(t)).$$

Therefore λ_2 is, after a suitable reparametrization, a trajectory of Σ . Notice that both $Y(\lambda_1(t))$ and $Y^\sim(\lambda_1(t), \lambda_2(t))$ have the same y component. Therefore, either both $\lambda_1(\cdot)$ and $\lambda_2(\cdot)$ go up, or both go down.

By choosing δ smaller, if necessary, we may assume that $\lambda_2(t)$ lies to the right of $\lambda_1(t)$ for all $t \in [t_0 - \delta, t_0]$.

Let λ_2^* be the result of reparametrizing λ_2 so that it becomes a trajectory of Σ . Let γ_2 be the concatenation of the piece of X -trajectory going from $\gamma(t_0 - \delta)$ to

$\lambda_2(t_0 - \delta)$, and of λ_2^* . Let $\gamma_1 = \gamma \upharpoonright [t_0 - \delta, t_1]$. Then both γ_1 and γ_2 go from the same initial point to the same terminal point. It is clear that γ_1 and γ_2 satisfy the hypotheses of Lemma 3.6 of [A], so that $T(\gamma_1) = T(\gamma_2)$. Since γ is time-optimal, it follows that γ_1 is time-optimal, and so γ_2 is time-optimal. Therefore λ_2^* is time-optimal. On the other hand, λ_2^* consists entirely of ordinary points. Since λ_2^* is not bang-bang, it cannot be time-optimal. This contradiction proves that (3.XV) holds.

Let us subdivide Subcase 1b into three sub-subcases.

SUB-SUBCASE 1b.i. $\zeta(s) \in Q_1(\varepsilon)$ for some $s \in [0, s_{\max}]$;

SUB-SUBCASE 1b.ii. $\zeta(s) \notin Q_1(\varepsilon)$ for all $s \in [0, s_{\max}]$;

SUB-SUBCASE 1b.iii. $\zeta(s) \in \bar{Q}_1(\varepsilon) - Q_1(\varepsilon)$ for some $s \in [0, s_{\max}]$.

We consider Sub-subcase 1b.i first.

It is clear from the definition of $Q_1(\varepsilon)$ that the set of those s for which $\zeta(s) \in Q_1(\varepsilon)$ is discrete. Let \bar{s} be the smallest element of this set. Let $\bar{q} = (\bar{q}_0, \bar{q}_1) = \zeta(\bar{s})$. Then $\bar{q} \in Q_1(\varepsilon)$, and therefore $\bar{q} \in Q_1(\varepsilon_1)$, so that \bar{q} belongs to a stratum V of \mathcal{V} . Moreover, V is entirely contained in $Q_1(\varepsilon_1)$, so that $\dim V \leq 1$. Since $(\mathcal{V}, \mathcal{T})$ is compatible with π over $\text{Sq}(\varepsilon_1) \times \text{Sq}(\varepsilon_1)$, it follows that $\pi(V) \in \mathcal{T}$. On the other hand, $\bar{q}_1 \in \pi(V) \cap \text{Sq}(\varepsilon)$, so that $\pi(V)$ meets $\text{Sq}(\varepsilon)$, and therefore $\pi(V)$ is one-dimensional, and $\pi(V) \cap \text{Sq}(\varepsilon) \in \mathcal{A}_p^+(\varepsilon)$ (because ε is good for \mathcal{T}).

Since \mathcal{T} is compatible with the subanalytic set $\pi_2(Q_1(\varepsilon_1))$, the point \bar{q}_1 must belong to a stratum W of \mathcal{T} , such that $W \subseteq \pi_2(Q_1(\varepsilon_1))$. Since W meets $\text{Sq}(\varepsilon)$, and ε is good for \mathcal{T} , we see that W is one-dimensional, and that $W \in \mathcal{A}_p^+(\varepsilon)$. The point \bar{q}_1 cannot belong to the closure of any set $T \cap \text{Sq}(\varepsilon)$, for $T \in \mathcal{T}_1$. So there is a neighborhood U of \bar{q}_1 such that $U \cap \pi_2(Q_1(\varepsilon_1)) = U \cap W$.

Now pick an open arc V_0 of V , such that $\bar{q} \in V_0$ and that $\pi_2(V_0) \subseteq U$. The map $\pi \upharpoonright V_0$ is a diffeomorphism from V_0 onto $\pi(V_0)$. Since $\pi(V_0) \subseteq \pi(V)$, the set $\pi(V_0)$ is of the form $\{(\psi(y), y) : w < y < w'\}$, where $w < \bar{y} < w'$ and $\psi :]w, w'[\rightarrow \mathbb{R}$ is analytic. (Here we let \bar{y} be the y -coordinate of \bar{q}_0 and of \bar{q}_1 .) Moreover, we can use the y -coordinate, for $y \in]w, w'[$, to parametrize V_0 . Then V_0 is the set of all points $(\psi(y), y, \psi'(y), \psi''(y))$, where ψ' , ψ'' are analytic functions on $]w, w'[$. Since $(\psi'(y), \psi''(y)) \sim (\psi(y), y)$ (because $V_0 \subseteq Q_1(\varepsilon_1) \subseteq Q_0(\varepsilon_0)$), we necessarily have $\psi''(y) = y$. On the other hand, the point $(\psi'(y), y)$ belongs to $\pi_2(V_0) \cap U$, and therefore to $\pi_2(Q_1(\varepsilon_1)) \cap U$. So $(\psi'(y), y) \in W$. Therefore, if $W = \{(\psi^*(y), y) : w^* < y < w^{*'}\}$, we see that $\psi' = \psi \upharpoonright]w, w'[$.

We now prove that one of the sets $\pi(V) \cap \text{Sq}(\varepsilon)$, $W \cap \text{Sq}(\varepsilon)$ is necessarily a barrier in $\text{Sq}(\varepsilon)^+$. It is clear that X points to the right of both sets. Since \mathcal{T} is compatible with Y , if $Y(\bar{q}_0)$ points to the right of $\pi(V) \cap \text{Sq}(\varepsilon)$, or is tangent to it, then the same will be true for $Y(q)$, for all $q \in \pi(V) \cap \text{Sq}(\varepsilon)$, proving that $\pi(V) \cap \text{Sq}(\varepsilon)$ is a barrier. A similar conclusion works for W . So, all we need is to prove that $Y(\bar{q}_0)$ and $Y(\bar{q}_1)$ cannot both point to the "left" side of $\pi(V) \cap \text{Sq}(\varepsilon)$, $W \cap \text{Sq}(\varepsilon)$, respectively. Suppose they do. The numbers $\beta(\bar{q}_0)$, $\beta(\bar{q}_1)$ both have the same sign. (Recall that we are in Subcase 1b, so that $\beta(q_0)\beta(q_1) > 0$. Moreover, as long as $s \in [0, s_{\max}]$, $\zeta_0(s)$ and $\zeta_1(s)$ are ordinary points, and so $\beta(\zeta_0(s))$ and $\beta(\zeta_1(s))$ cannot change sign.) So $Y(\bar{q}_0)$ and $Y(\bar{q}_1)$ both point up, or both point down. In the former case, let v be the tangent vector v_1 at \bar{q} to the curve $y \mapsto (\psi(y), y, \psi'(y), y)$. If both $Y(\bar{q}_0)$ and $Y(\bar{q}_1)$ point down, let $v = -v_1$. In either case, v is tangent to V , and therefore $\pi_*(v)$, $\pi_2^*(v)$ are tangent to $\pi(V) \cap \text{Sq}(\varepsilon)$, $W \cap \text{Sq}(\varepsilon)$, respectively. Moreover, we have $\pi_*(v) = \theta_1 Y(\bar{q}_0) + \theta_2 X(\bar{q}_0)$, and $\pi_2^*(v) = \theta_3 Y(\bar{q}_1) + \theta_4 X(\bar{q}_1)$, where the coefficients θ_i are strictly positive. On the other hand, using the fact that π is a local diffeomorphism on $Q_0(\varepsilon_0)$, we get $v = \theta_1 Y^*(\bar{q}) + \theta_2 X^*(\bar{q})$ and, projecting via π_2 , we get $\pi_2^*(v) = \theta_1 Y^{\sim}(\bar{q}) + \theta_2 X^{\sim}(\bar{q})$. Because $\bar{q} \in Q_1(\varepsilon_1)$, the vectors $Y(\bar{q}_1)$ and $Y^{\sim}(\bar{q})$ are linearly dependent. Since both

have the same y -component, we see that $Y^{\sim}(\bar{q}) = \theta_5 Y(\bar{q}_1)$ for some $\theta_5 > 0$. Also, since $\bar{q} \in Q_0(\varepsilon_0)$ and $\Delta_A(\bar{q}_0)\Delta_A(\bar{q}_1) > 0$, we see from Lemma 3.15 that $X^{\sim}(\bar{q}) = -\theta_6 X(\bar{q}_1)$, where $\theta_6 > 0$. So

$$(3.52) \quad \pi_{2*}(v) = \theta_1 \theta_5 Y(\bar{q}_1) - \theta_2 \theta_6 X(\bar{q}_1).$$

If we equate coefficients for the two expressions of $\pi_{2*}(v)$ as a linear combination of $Y(\bar{q}_1)$ and $X(\bar{q}_1)$, we get $\theta_3 = -\theta_2 \theta_6$, which contradicts the fact that all the θ_i are strictly positive.

This contradiction shows that one of the sets $\pi(V) \cap \text{Sq}(\varepsilon)$, $W \cap \text{Sq}(\varepsilon)$ is a barrier in $\text{Sq}(\varepsilon)^+$. Since both $\pi(V)$ and W are in \mathcal{T} , we see that $\pi(V) \cap \text{Sq}(\varepsilon) \in \mathcal{B}^+$ or that $W \cap \text{Sq}(\varepsilon) \in \mathcal{B}^+$. On the other hand, it is clear that all the points $\zeta_0(s)$, $\zeta_1(s)$, $0 \leq s < s_{\max}$, lie on γ . So γ meets a member of \mathcal{B}^+ . This concludes the discussion of Sub-subcase 1b.i.

We now consider Sub-subcases 1b.ii and 1b.iii. (cf. Fig. 2). We may have $\hat{q}_0 = \hat{q}_1$ or $\hat{q}_0 \neq \hat{q}_1$. If $\hat{q}_0 \neq \hat{q}_1$, then, as observed earlier, one of the equalities $\Delta_A(\hat{q}_0) = 0$, $\Delta_A(\hat{q}_1) = 0$, $\Delta_B(\hat{q}_0) = 0$, $\Delta_B(\hat{q}_1) = 0$ must hold, so that at least one of the \hat{q}_i is in E . If, say, $\hat{q}_0 \in E$, then $\hat{q}_0 \in S$ for an $S \in \mathcal{S}_1$, so that $\hat{q}_0 \in S$ for an $S \in \mathcal{P}$. Therefore $\hat{q}_1 \in S^{\sim}$, and so the stratum $T \in \mathcal{T}$ to which \hat{q}_1 belongs is one-dimensional. If $\hat{q}_0 = \hat{q}_1$ then, again, \hat{q}_0 cannot be an ordinary point, and so \hat{q}_0 belongs to an $S \in \mathcal{S}_1$. In either case, we see that the points \hat{q}_0 , \hat{q}_1 belong to one-dimensional strata S_0 , S_1 of \mathcal{T} . Moreover, these strata have the property that, whenever r_0 , r_1 are points in S_0 , S_1 which lie on the same horizontal line, then $r_0 \sim r_1$. (Reason: suppose, e.g., that $S_0 \subseteq S \in \mathcal{S}_1$. Since $\hat{q}_1 \in S^{\sim} \cap S_1$, it follows that $S_1 \subseteq S^{\sim}$. Therefore $r_1 \sim r'_0$ for some $r'_0 \in S$ which, of necessity, must lie on the same horizontal line as r_1 and r_0 . Since S intersects each horizontal line at most once, it follows that $r'_0 = r_0$.)

FIG. 2. (The situation depicted here is proved to be impossible, because $Y(\hat{q}_1)$ has to point to the right of μ_1 .)

We now prove that at least one of the sets $S_i \cap \text{Sq}(\varepsilon)$ is a barrier in $\text{Sq}(\varepsilon)^+$. As before, it is sufficient to prove that it is impossible for $Y(\hat{q}_i)$ to point to the “left” of S_i for $i = 0, 1$.

Suppose $Y(\hat{q}_0)$, $Y(\hat{q}_1)$ point to the “left” of S_0 , S_1 . Let $\hat{q}_i = (\hat{x}_i, \hat{y}_i)$ (so that $\hat{y}_0 = \hat{y}_1 = \hat{y}$). Pick rectangular neighborhoods \tilde{U}_i ($i = 0, 1$) of \hat{q}_i , of the form

$$(3.53) \quad \tilde{U}_i =]\hat{x}_i - \delta, \hat{x}_i + \delta[\times]\hat{y} - \delta', \hat{y} + \delta'[$$

such that

$$(3.54) \quad \tilde{U}_i \cap S_i = \{(\psi_i(y), y) : \hat{y} - \delta' < y < \hat{y} + \delta\},$$

where the ψ_i are analytic functions on $] \hat{y} - \delta, \hat{y} + \delta[$, and that \tilde{U}_i intersects no other one-dimensional stratum \mathcal{T} . Then each set $\tilde{U}_i - S_i$ is partitioned into two disjoint connected open sets $(\tilde{U}_i)_L, (\tilde{U}_i)_R$ (the “left” and right sides of S_i in U_i) defined by

$$(3.55a) \quad (x, y) \in (\tilde{U}_i)_L \Leftrightarrow (x, y) \in \tilde{U}_i \quad \text{and} \quad x < \psi_i(y),$$

$$(3.55b) \quad (x, y) \in (\tilde{U}_i)_R \Leftrightarrow (x, y) \in \tilde{U}_i \quad \text{and} \quad x > \psi_i(y).$$

The vectors $G(\hat{q}_0), G(\hat{q}_1)$ are both nonzero (otherwise we would have $Y(\hat{q}_i) = X(\hat{q}_i)$ for one of the i 's, and so $Y(\hat{q}_i)$ would point to the “right” of S_i). Since they are linearly dependent (because $\hat{q}_0 \sim \hat{q}_1$), it follows that either $\beta(\hat{q}_0) \neq 0$ and $\beta(\hat{q}_1) \neq 0$, or $\beta(\hat{q}_0) = \beta(\hat{q}_1) = 0$, in which case

$$\alpha(\hat{q}_0) - 1 \neq 0 \quad \text{and} \quad \alpha(\hat{q}_1) - 1 \neq 0.$$

By making δ and δ' smaller, if needed, we may assume that either

$$(3.XVI.1) \quad \beta \text{ never vanishes on } \tilde{U}_0 \cup \tilde{U}_1, \text{ or}$$

$$(3.XVI.2) \quad \alpha - 1 \text{ never vanishes on } \tilde{U}_0 \cup \tilde{U}_1.$$

Notice that, if $\hat{q}_0 = \hat{q}_1$, then $S_0 = S_1$ and $\tilde{U}_0 = \tilde{U}_1$. If $\hat{q}_0 \neq \hat{q}_1$, we shall assume that δ, δ' are so small that $\tilde{U}_0 \cap \tilde{U}_1 = \emptyset$.

Define $\tau: \tilde{U}_0 \cup \tilde{U}_1 \rightarrow \mathbb{R}$ by

$$(3.56a) \quad \tau = \frac{1 - \alpha}{\beta} \quad \text{if (3.XVI.1) holds,}$$

$$(3.56b) \quad \tau = \frac{\beta}{\alpha - 1} \quad \text{if (3.XVI.2) holds.}$$

(If both (3.XVI.1) and (3.XVI.2) hold, we may define τ either way.) In either case, τ is a well-defined analytic function on $\tilde{U}_0 \cup \tilde{U}_1$, and two points $(x_0, y) \in \tilde{U}_0, (x_1, y) \in \tilde{U}_1$ satisfy $(x_0, y) \sim (x_1, y)$ if and only if

$$\tau(x_0, y) = \tau(x_1, y).$$

In particular, this implies that

$$(3.57) \quad \tau(\psi_0(y), y) = \tau(\psi_1(y), y) \quad \text{for } |y - \hat{y}| < \delta'.$$

The x -derivative of τ is given by

$$(3.58) \quad \partial_x \tau = \frac{(\alpha - 1)\beta_x - \alpha_x \beta}{D},$$

where the denominator D equals β^2 or $(\alpha - 1)^2$, according to whether (3.XVI.1) or (3.XVI.2) holds. In any case, we see that $\partial_x \tau$ equals Δ_B times a strictly positive number, so that

$$(3.59) \quad (\partial_x \tau) \Delta_B > 0 \quad \text{wherever } \Delta_B \neq 0.$$

In particular, Δ_B never vanishes on $(\tilde{U}_0)_L$ or on $(\tilde{U}_1)_R$, and therefore

$$(3.60) \quad (\partial_x \tau) \Delta_B > 0 \quad \text{on } (\tilde{U}_0)_L \cup (\tilde{U}_1)_R.$$

On the other hand, the point $\zeta_0(s)$ is in $(\tilde{U}_0)_L$ for s near s_{\max} , while $\zeta_1(s) \in (\tilde{U}_1)_R$. Since $\Delta_A(\zeta_0(s))$ and $\Delta_A(\zeta_1(s))$ have the same sign for all $s \in [0, s_{\max}]$, and $(\Delta_A \Delta_B)(\zeta_0(s)) \cdot (\Delta_A \Delta_B)(\zeta_1(s)) < 0$ (because $\zeta(s) \in Q_0(\varepsilon_0)$), it follows that $\Delta_B(\zeta_0(s)) \cdot \Delta_B(\zeta_1(s)) < 0$ and so Δ_B has opposite signs on $(\tilde{U}_0)_L$ and on $(\tilde{U}_1)_R$. Therefore $\partial_x \tau$ has opposite signs on $(\tilde{U}_0)_L$ and on $(\tilde{U}_1)_R$.

Let $\tilde{\delta}$ be so small that $\zeta_i(s) \in \tilde{U}_i$ for $i = 0, 1$, $s > s_{\max} - \tilde{\delta}$. Let L be an open vertical segment, of height $2\delta^* \leq 2\delta'$, whose center is the point $\zeta_0(\bar{s})$, where \bar{s} is a number such that $s_{\max} - \tilde{\delta} < \bar{s} < s_{\max}$. Make δ^* smaller, if needed, and assume that $L \subseteq (\tilde{U}_0)_L$. Since $\zeta(\bar{s}) \in Q_0(\varepsilon_0)$, and π is a local diffeomorphism on $Q_0(\varepsilon_0)$, we may assume, by making δ^* smaller if necessary, that $L = \pi(L')$, where L' is a smooth arc contained in $Q_0(\varepsilon_0)$, such that $\zeta(\bar{s}) \in L'$. Let $L'' = \pi_2(L')$. Then

$$(3.61) \quad L'' = \{(\theta(y), y) : \hat{y} - \delta^* < y < \hat{y} + \delta^*\},$$

where $\theta :]\hat{y} - \delta^*, \hat{y} + \delta^*] \rightarrow \mathbb{R}$ is analytic. Now replace δ' by δ^* (i.e. shrink both \tilde{U}_i in the vertical direction, if needed). Then L is a vertical segment which goes from the lower to the upper edge of \tilde{U}_0 , and is entirely contained in $(\tilde{U}_0)_L$. Also, L'' is an arc which goes from the lower to the upper edge of \tilde{U}_1 . Moreover, L'' is never horizontal, because it is of the form $\{(\theta(y), y) : \hat{y} - \delta' < y < \hat{y} + \delta'\}$. Let $\theta_1 = \theta$, and let θ_0 be the function such that $L = \{(\theta_0(y), y) : |y - \hat{y}| < \delta'\}$ (so that θ_0 is actually a constant). Let τ' denote τ , if $\partial_x \tau < 0$ on $(\tilde{U}_0)_L$, and let τ' be $-\tau$ if $\partial_x \tau > 0$ on $(\tilde{U}_0)_L$. Then τ' is strictly decreasing as a function of x on $(\tilde{U}_0)_L$, and it is therefore strictly increasing as a function of x on $(\tilde{U}_1)_R$. Therefore $\tau'(\theta_0(y), y) > \tau'(\psi_0(y), y)$ for $|y - \hat{y}| < \delta'$. Since, by construction, $(\theta_0(y), y) \sim (\theta_1(y), y)$, we see that $\tau'(\theta_1(y), y) > \tau'(\psi_1(y), y)$. This implies, in particular, that L'' never meets $S_1 \cap \tilde{U}_1$. Since $\zeta_1(\bar{s}) \in L'' \cap (\tilde{U}_1)_R$, we see that $L'' \subseteq (\tilde{U}_1)_R$. If r is any point (x, y) such that $|y - \hat{y}| < \delta'$, $\theta_0(y) \leq x \leq \psi_0(y)$, it follows that there exists a unique point $K(r) = (k(x, y), y)$ such that $K(r) \sim r$ and that $\psi_1(y) \leq k(x, y) \leq \theta_1(y)$. If, in addition, $x < \psi_0(y)$, then it follows that $k(x, y) > \psi_1(y)$. In this case, both r and $K(r)$ are ordinary points. Moreover, we already know that Δ_A has the same sign on $(\tilde{U}_0)_L$ as on $(\tilde{U}_1)_R$, whereas Δ_B has opposite signs. So $(\Delta_A \Delta_B)(r)$ and $(\Delta_A \Delta_B)(K(r))$ have opposite signs, and therefore $(r, K(r)) \in Q_0(\varepsilon_0)$. Since $\pi(r, K(r)) = r$, and K is clearly continuous, the fact that π is a local diffeomorphism on $Q_0(\varepsilon_0)$ implies that K is analytic on $\{(x, y) : \theta_0(y) \leq x < \psi_0(y), |y - \hat{y}| < \delta'\}$. Now let $\mu_0(\cdot)$ denote the integral curve of Y which goes through \hat{q}_0 at time 0. Let t_{\max} be the largest t such that $\mu_0([0, t])$ is entirely contained in $\tilde{U}_0 \cap \{(x, y) : x > \theta_0(y)\}$. Then $\mu_0(t_{\max})$ is well defined, and belongs to L , or to the boundary of \tilde{U}_0 . Since we are assuming that Y points to the left of S_0 , the curve $\mu_0 \upharpoonright]0, t_{\max}[$ is entirely contained in $(\tilde{U}_0)_L$.

Now let $\mu_1(t) = K(\mu_0(t))$. We see that $\mu_1(0) = \hat{q}_1$, that $\mu_1 \upharpoonright]0, t_{\max}[$ is entirely contained in $(\tilde{U}_1)_R$, and that $(\mu_0(t), \mu_1(t)) \in Q_0(\varepsilon_0)$ for $0 < t < t_{\max}$. Let $\mu(t) = (\mu_0(t), \mu_1(t))$. Then $\mu \upharpoonright]0, t_{\max}[$ is a curve in $Q_0(\varepsilon_0)$, and $\pi \circ \mu = \mu_0$, which is a Y -trajectory. So $\mu \upharpoonright]0, t_{\max}[$ is a Y -trajectory, and therefore

$$(3.62) \quad \dot{\mu}_1(t) = Y^-(\mu_0(t), \mu_1(t)) \quad \text{for } 0 < t < t_{\max}.$$

As observed before, the vector $Y^-(q_0, q_1)$ is not a linear combination of $Y(q_1)$ and $X(q_1)$ with strictly positive coefficients. We claim that the same conclusion then follows for $Y^-(\mu_0(t), \mu_1(t))$, for $t \in]0, t_{\max}[$. To see this, let us consider, for a particular t , the curve ν_0 obtained by following ζ_0 from q_0 to $\zeta_0(\bar{s})$, and then some continuous curve $\tilde{\nu}$ in $(\tilde{U}_0)_L \cap \{(x, y) : x \geq \theta_0(y)\}$ up to $\mu_0(t)$. Then there is a continuous curve ν_1 (obtained by following ζ_1 from q_1 to $\zeta_1(\bar{s})$, and then $K \circ \tilde{\nu}$ to $\mu_1(t)$) such that, if

$\nu(s) = (\nu_0(s), \nu_1(s))$, then ν is a curve in $Q_0(\varepsilon_0)$, such that $\pi \circ \nu = \nu_0$. For each $s \in \text{Dom}(\nu)$, we can express $Y^-(\nu(s))$ in a unique way as a combination

$$(3.63) \quad \tilde{Y}(\nu(s)) = \theta_1(s)Y(\nu_1(s)) + \theta_2(s)X(\nu_1(s)).$$

The coefficients θ_1, θ_2 are continuous functions of s . We know that, initially, θ_1 and θ_2 are not both positive. We will use this to show that

$$(3.XVII) \quad \text{For every } s \in \text{Dom}(\nu) \text{ either } \theta_1(s) \leq 0 \text{ or } \theta_2(s) \leq 0.$$

In view of (3.XV), the desired conclusion holds when s is the left endpoint of $\text{Dom}(\nu)$.

We also know that $Y^-(r_0, r_1)$ has the same y -component as $Y(r_0)$ for all $(r_0, r_1) \in Q_0(\varepsilon_0)$. Since $\nu_0(s)$ and $\nu_1(s)$ are ordinary points for all $s \in \text{Dom}(\nu)$ (because ν is a curve in $Q_0(\varepsilon_0)$), the function $s \rightarrow \beta(\nu_0(s))\beta(\nu_1(s))$ cannot vanish for $s \in \text{Dom}(\nu)$. Since $\beta(q_0)\beta(q_1) > 0$ (because we are in Subcase 1b), we conclude that

$$(3.64) \quad \beta(\nu_0(s))\beta(\nu_1(s)) > 0 \quad \text{for all } s \in \text{Dom}(\nu).$$

So $Y^-(\nu_0(s), \nu_1(s))$ and $Y(\nu_1(s))$ have y -components of the same sign, for each $s \in \text{Dom}(\nu)$. In particular, this implies that

$$(3.XVIII) \quad \theta_1(s) > 0 \text{ whenever } \theta_2(s) = 0.$$

We now prove (3.XVII). We treat Sub-subcases 1b.ii and 1b.iii separately. Let us begin with Sub-subcase 1b.iii. If s^* is such that $s^* \in [0, s_{\max}[$, and $\zeta(s^*) \in \hat{Q}_1(\varepsilon) - Q_1(\varepsilon)$, then the definition of $Q_1(\varepsilon)$ implies that $\zeta(s) \in \hat{Q}_1(\varepsilon)$ for s near s^* and so, by analyticity, that $Y(\zeta(s))$ and $Y^-(\zeta_0(s), \zeta_1(s))$ are linearly dependent for all $s \in [0, s_{\max}[$. So, either

$$(3.XIX.a) \quad \nu(s) \in \hat{Q}_1(\varepsilon) \quad \text{for all } s \in \text{Dom}(\nu), \text{ or}$$

$$(3.XIX.b) \quad \nu(s) \notin \hat{Q}_1(\varepsilon) \quad \text{for some } s \text{ such that } \nu_0(s) \in (\tilde{U}_0)_L.$$

If (3.XIX.a) holds, then $\theta_2(s) = 0$ for all $s \in \text{Dom}(\nu)$, and so (3.XVII) holds. If (3.XIX.b) holds, then $\nu(s^*)$ must belong to the frontier of $\hat{Q}_1(\varepsilon_1)$ for some s such that $\nu_0(s^*) \in (\tilde{U}_0)_L$ (because $\zeta(\bar{s}) \in \hat{Q}_1(\varepsilon_1)$). So $\nu(s^*) \in V^*$, where V^* is a stratum of \mathcal{V} such that $\dim V^* \leq 1$. But then $\nu_0(s^*) \in \pi(V^*)$, which is a stratum of \mathcal{T} such that $\dim \pi(V^*) \leq 1$. But this contradicts the fact that $(U_0)_L$ does not meet any low-dimensional strata of \mathcal{T} . This contradiction proves that (3.XVII) holds, if we are in Sub-subcase 1b.iii.

We now prove (3.XVII) in Sub-subcase 1b.ii. If (3.XVII) were not true, there would have to be an $s^* \in \text{Dom}(\nu)$ such that either $\theta_1(s^*) = 0$ or $\theta_2(s^*) = 0$. The possibility that $\theta_1(s^*) = 0$ is excluded, because the y -component of $Y^-(\nu(x))$ is nonzero for all s . So $\theta_2(s^*) = 0$, and $\nu(s^*) \in \hat{Q}_1(\varepsilon_1)$. Since we are in Sub-subcase 1b.ii, so that $\zeta(s) \notin \hat{Q}_1(\varepsilon_1)$ for $s \in [0, s_{\max}[$, we necessarily have $\nu(s^*) \in (\tilde{U}_0)_L \times (\tilde{U}_1)_R$. Let V^* be the stratum of \mathcal{V} to which $\nu(s^*)$ belongs. Then $\nu_0(s^*) \in \pi(V^*)$, which is a stratum of \mathcal{T} . If $\dim V^* \leq 1$, then $\dim \pi(V^*) \leq 1$, and so $\nu_0(s^*)$ is in a stratum of \mathcal{T} of dimension < 2 , which contradicts the fact that $\nu_0(s^*) \in (\tilde{U}_0)_L$, and that $(\tilde{U}_0)_L$ does not meet any low-dimensional strata of \mathcal{T} . So $\dim V^* = 2$. Since \mathcal{V} is compatible with $\hat{Q}_1(\varepsilon_1)$ and with $Q_1(\varepsilon_1)$, and $\dim Q_1(\varepsilon_1) \leq 1$, we necessarily have $V^* \subseteq \hat{Q}_1(\varepsilon_1) - Q_1(\varepsilon_1)$. Since $\pi: Q_0(\varepsilon_0) \rightarrow \text{Sq}(\varepsilon_0)$ is a local diffeomorphism, and $\hat{Q}_1(\varepsilon_1) \subseteq Q_0(\varepsilon_0)$, we see that $\pi(V^*)$ is open in $\text{Sq}(\varepsilon_0)$. But then $\nu(s^*)$ has a neighborhood W with the property that $(r, K(r)) \in \hat{Q}_1(\varepsilon_1)$ for all $r \in W$. Therefore the vectors $Y(K(r))$ and $Y^-(r, K(r))$ are linearly dependent for all $r \in W$. By analyticity, it follows that $Y(K(r))$ and $Y^-(r, K(r))$ are dependent for all $r \in (U_0)_L$, i.e., that $(r, K(r)) \in \hat{Q}_1(\varepsilon_1)$ for all $r \in (U_0)_L$. But then, in particular, $\zeta(\bar{s}) \in \hat{Q}_1(\varepsilon_1)$, which contradicts the hypothesis that we are in Sub-subcase 1b.ii.

So (3.XVII) holds in Sub-subcase 1b.ii as well.

Having proved (3.XVII) we can conclude, in particular, that $\theta_1(s) \leq 0$ or $\theta_2(s) \leq 0$ if s is the right endpoint of $\text{Dom}(\nu)$. So, for each $t \in \text{Dom}(\mu)$

(3.XX) The vector $Y^-(\mu(t))$ is not a linear combination of $X(\mu_1(t))$ and $Y(\mu_1(t))$ with strictly positive coefficients.

Since the y -components of $Y(\mu_1(t))$ and $Y^-(\mu(t))$ have the same sign, (3.XX) implies that:

(3.XXI) $Y(\mu_1(t))$ is a linear combination of $X(\mu_1(t))$ and $\tilde{Y}(\mu(t))$ with nonnegative coefficients.

From (3.XXI) we conclude that, at each point $\mu_1(t)$, both $Y(\mu_1(t))$ and $X(\mu_1(t))$ point to the same side of μ_1 . Also, we know that β is either >0 throughout $(\tilde{U}_0)_L \cup (\tilde{U}_1)_R$, or that it is <0 throughout $(\tilde{U}_0)_L \cup (\tilde{U}_1)_R$. Consider the former case. (The other one is similar.) Then $Y^-(\mu_0(t), \mu_1(t))$ has a positive y -component for $t \in]0, t_{\max}[$. So the curve μ_1 starts off at $\hat{q}_1 \in S_1$, and then goes to the right and up, into $(\tilde{U}_1)_R$. On the other hand, the integral curve of Y through \hat{q}_1 goes up but enters $(\tilde{U}_1)_L$. So, for \hat{q}'_1 near \hat{q}_1 and to the right of it, the integral curve of Y through \hat{q}'_1 also enters $(\tilde{U}_1)_L$ after a while. Therefore this curve has to cross μ_1 from "right" to "left". At the crossing, Y and X must point to opposite sides of μ_1 , which is a contradiction. This contradiction completes the proof that either S_0^ε or S_1^ε is a barrier in $\text{Sq}(\varepsilon)^+$. This completes the analysis of Sub-subcase 1b.ii, which was the only missing sub-subcase of Subcase 1b, which was the only missing subcase of Case 1. So our analysis of Case 1 is complete.

We now proceed to Case 2.

CASE 2. $t_0 = t'_0$ and $t'_1 = t_1$, but at least one of q_0, q_1 is not an ordinary point.

We consider first the easiest subcase.

SUBCASE 2a. $\Delta_A(q_0)\Delta_A(q_1) = 0$.

If $\Delta_A(q_0) = 0$, then $q_0 \in S$ for some stratum $S \in \mathcal{S}_1$ such that Δ_A vanishes on S . We claim that $S \cap \text{Sq}(\varepsilon)$ is a barrier in $\text{Sq}(\varepsilon)^+$. To prove this, it suffices to exclude the possibility that $Y(q_0)$ points to the left of S . Since $Y(q_0)$ and $X(q_0)$ are linearly dependent, this possibility can only occur if $Y(q_0) = -\rho X(q_0)$ for some $\rho > 0$. On the other hand, it is clear that the X - and Y -curves through q_0 have a finite-order tangency at q_0 . So we can apply Lemma 5.1 of [A], and conclude that γ is not optimal. This contradiction shows that S^ε is indeed a barrier in $\text{Sq}(\varepsilon)^+$.

If $\Delta_A(q_0) \neq 0$, but $\Delta_A(q_1) = 0$, a similar reasoning shows that $q_1 \in S$ for some $S \in \mathcal{S}_1$, and that S^ε is a barrier in $\text{Sq}(\varepsilon)^+$. This concludes the analysis of Subcase 2a.

We now analyze the following.

SUBCASE 2b. $\Delta_A(q_0) \neq 0 \neq \Delta_A(q_1)$.

In this subcase, at least one of the numbers $\Delta_B(q_0), \Delta_B(q_1)$ must vanish. Therefore one of q_0, q_1 belongs to an $S \in \mathcal{S}_1$. This S is necessarily in \mathcal{P} , and so the other q_i is in S^- , and therefore in a one-dimensional stratum of \mathcal{T} . In either case, the points q_0, q_1 belong to one-dimensional strata S_0, S_1 of \mathcal{T} , with the property that, whenever $r_0 \in S_0, r_1 \in S_1$, and r_0 lies in the same horizontal line as r_1 , then $r_0 \sim r_1$. We distinguish two sub-subcases.

SUB-SUBCASE 2b.i. $\beta(q_0)\beta(q_1) < 0$,

SUB-SUBCASE 2b.ii. $\beta(q_0)\beta(q_1) > 0$.

Sub-subcase 2b.i is handled exactly like Sub-subcase 1b.i. Since $q_0 \sim q_1$, this sub-subcase can only occur if (3.II.a) holds, in which case $\alpha > 0$ throughout $\text{Sq}(\varepsilon_0)$. On the other hand, there must be a $t \in [t_0, t_1]$ such that $\beta(\gamma(t)) = 0$. Therefore $\gamma(t) \in E_1$, and so $\gamma(t) \in S$, where $S \in \mathcal{S}_1$ and $\Delta_A \equiv 0$ on S . Since $\alpha > 0$ on $\text{Sq}(\varepsilon_0)$, we see that $Y(q)$ is a positive multiple of $X(q)$ for each $q \in S$. Therefore S^ε is a barrier in $\text{Sq}(\varepsilon)$.

We now turn to Sub-subcase 2b.ii. In this sub-subcase, Δ_A never vanishes on $S_0 \cup S_1$, and so β is either positive throughout $S_0 \cup S_1$, or negative throughout $S_0 \cup S_1$. We consider the case when $\beta > 0$ on $S_0 \cup S_1$. (The other case is similar.)

Suppose that both S_0 and S_1 fail to be barriers. Then Y points to the “left” of both S_0 and S_1 . Therefore both S_0 and S_1 , if suitably reparametrized, are trajectories of Σ . Now pick a point \bar{p} in γ , of the form $\gamma(t)$ for some $t < t_0$, but close to t_0 . Let p_0, p_1 be the points where the horizontal line through \bar{p} meets S_0, S_1 . Then we can apply Lemma 3.6 of [A] and conclude that

(3.65)

$$T(p_0, p_1 q_1) = T(p_0 m_0 q_0 q_1)$$

(where, for any points r_1, r_2, \dots, r_m , we use $T(r_1 r_2 \dots r_m)$ to denote the time along the trajectory from r_1 to r_m which goes through $r_2 \dots r_{m-1}$ as shown in Fig. 3). On the other hand, we claim that

(3.66)

$$T(p_0 m_0 q_0) < T(p_0 \bar{p} q_0).$$

To see this, notice first that f never vanishes in the open region \mathcal{R} bounded by the arcs $p_0 \bar{p}$, $\bar{p} m_2$, $m_2 q_1$ and $q_0 p_0$. Since γ is time-optimal, $T(\bar{p} q_0 m_2) \leq T(\bar{p} m_1 m_2)$, and therefore Lemma 3.11 of [A] excludes the possibility that $f > 0$ on \mathcal{R} . Then $f < 0$ on \mathcal{R} , and therefore (3.66) holds.

If we add $T(q_0 q_1)$ to both sides, we find that

(3.67)

$$T(p_0 m_0 q_0 q_1) < T(p_0 \bar{p} q_0 q_1).$$

In view of (3.65), we have

(3.68)

$$T(p_0 \bar{p} p_1 q_1) < T(p_0 \bar{p} q_0 q_1).$$

Subtracting $T(p_0 \bar{p})$ from both sides, we get

(3.69)

$$T(\bar{p} p_1 q_1) < T(\bar{p} q_0 q_1).$$

Therefore the arc $\bar{p} q_0 q_1$ is not optimal. Since this arc is a piece of γ , we conclude that γ is not optimal. This contradiction establishes that S_0^e or S_1^e is a barrier. This completes the analysis of Sub-subcase 2b.ii, which concludes the analysis of Case 2.

We now consider Case 3.

CASE 3. $t_0 = t'_0$ but $t'_1 < t_1$.

In this case, the switching at q'_1 is necessarily from an X - to a Z -trajectory. Therefore $q'_1 \in E_2$, so that q'_1 belongs to a stratum $S \in \mathcal{S}_1$ such that $\Delta_B \equiv 0$ on S . (Actually,

FIG. 3

S must be a turnpike.) So $q_0 \in S^\sim$, and therefore both q_0 and q_1 belong to one-dimensional strata S_0, S_1 of \mathcal{T} . If $\Delta_A(q_0) = 0$, then we prove that S_0^ε must be a barrier in $Sq(\varepsilon)^+$, using exactly the same reasoning as in Subcase 2a. The possibility that $\Delta_A(q'_1) = 0$ is excluded because S_1 is a turnpike.

Now suppose that $\Delta_A(q_0)$ and $\Delta_A(q'_1)$ are nonzero. Then we distinguish the subcases when $\Delta_A(q_0)\Delta_A(q'_1) < 0$, and when $\Delta_A(q_0)\Delta_A(q'_1) > 0$. The first case is handled exactly like Sub-subcase 2b.i, by showing that some point of γ , lying between q_0 and q'_1 , must belong to a one-dimensional $S \in \mathcal{T}$ such that S^ε is a barrier. Finally, if $\Delta_A(q_0)\Delta_A(q'_1) > 0$, then we proceed exactly as in Sub-subcase 2b.ii. We assume that $\beta > 0$ throughout $S_0 \cup S_1$ (the other case being similar). Then we are exactly in the same situation as in Fig. 3, except that now q_1 is replaced by q'_1 and that, after q'_1 , γ continues along S_1 , rather than along a Y -trajectory. Since the reasoning of Sub-subcase 2b.ii did not in any way depend on the nature of γ after it went through q'_1 , this reasoning applies here as well, and we reach again the conclusion that γ is not optimal. This concludes the analysis of Case 3.

Next, we consider Case 4.

CASE 4. $t_0 < t'_0$ but $t'_1 = t_1$.

This case is identical to Case 3. Both q'_0 and q_1 must belong to one-dimensional strata S_0, S_1 of \mathcal{T} . Since S_0 is a turnpike, we necessarily have $\Delta_A(q'_0) = 0$. If $\Delta_A(q_1)$ vanishes, we see that S_1^ε must be a barrier in $Sq(\varepsilon)^+$. If both $\Delta_A(q'_0)$ and $\Delta_A(q_1)$ are nonzero, but they have opposite signs, then there has to be an $S \in \mathcal{T}_1$ which crosses γ between q'_0 and q_1 , and is a barrier in $Sq(\varepsilon)^+$. Finally, if $\Delta_A(q'_0)\Delta_A(q_1) > 0$, then we may assume that $\beta > 0$ on $S_0 \cup S_1$. (The other case is similar.) Suppose that neither S_0^ε nor S_1^ε are barriers. Then we are in the situation shown in Fig. 4. Using exactly the same reasoning as in the study of Sub-subcase 2b.ii, we show that $T(q'_0 p_0 \bar{p}) < T(q'_0 q_1 \bar{p})$, so that γ is not time-optimal. This completes the analysis of Case 4.

Finally, we consider Case 5.

CASE 5. $t_0 < t'_0 < t'_1 < t_1$.

Here, again, the points q'_0, q'_1 must belong to one-dimensional strata S_0, S_1 of \mathcal{T}_1 , such that Δ_B vanishes identically on $S_0 \cup S_1$. On the other hand, Δ_A can never vanish on S_0 or on S_1 , because both S_0 and S_1 are turnpikes. If we have $\Delta_A(q'_0)\Delta_A(q'_1) < 0$,

FIG. 4

then the reasoning of Sub-subcase 2b.i gives us a stratum $S \in \mathcal{T}_1$ that crosses γ somewhere between q'_0 and q'_1 , and is such that S^ε is a barrier in $Sq(\varepsilon)^+$.

If $\Delta_A(q'_0)\Delta_A(q'_1) > 0$, then we distinguish the subcases.

SUBCASE 5.i. $\beta(q'_0) > 0$ and $\beta(q'_1) > 0$.

SUBCASE 5.ii. $\beta(q'_0) < 0$ and $\beta(q'_1) < 0$.

(As we shall see below, there is a very minor technical reason why these subcases are slightly different, so that we cannot just limit ourselves to dealing with one of them.)

Consider Subcase 5.i, and suppose that both S_0^ε and S_1^ε fail to be barriers. Then we are in the situation shown in Fig. 5. (Recall that $[t'_0, t'_1]$ was the *leftmost* maximal subinterval of $[t_0, t_1]$ on which γ is an X -trajectory.) Since $(x, y) \sim (x', y)$ whenever $(x, y) \in S_0$ and $(x', y) \in S_1$, we can apply Lemma 3.6 of [A], and conclude that $T(q_0 p_1 q'_1) = T(q_0 q'_0 q'_1)$. So, if we modify γ by replacing the arc from q_0 to q'_0 to q'_1 by the arc from q_0 to p_0 to q'_1 , we see that the new trajectory $\tilde{\gamma}$ is also time-optimal. However, the reasoning of Sub-subcase 2b.i can be applied to $\tilde{\gamma}$, to conclude that $T(\bar{p} r p_1) < T(\bar{p} q_0 p_1)$, and therefore $\tilde{\gamma}$ is not optimal. This contradiction settles Subcase 5.i.

FIG. 5

Note that the preceding reasoning depends strongly on the fact that, for each point m_0 in S_0 , lying between q_0 and q'_0 , the horizontal line through m_0 actually meets S_1 . If we are in Subcase 5.ii, then γ might be as shown in Fig. 6, so that the horizontal line through q_0 does not meet S_1 , because S_1 leaves $Sq(\varepsilon)^+$ through its right vertical edge, at a height below that of q_0 . So, in this subcase, the reasoning has to be modified slightly. Let $[t'_1, t'^*_1]$ be the maximal subinterval of $[t_0, t_1]$ that contains t'_1 and is such that $\gamma|_{[t'_1, t'^*_1]} \in \text{Traj}(Z)$. Let $q'^*_1 = \gamma(t'^*_1)$. Then Lemma 3.6 of [A] implies that $T(q'_0 p_1 q'^*_1) = T(q'_0 q'_1 q'^*_1)$. Therefore we can form a new trajectory γ_2 by substituting the arc $q'_0 \rightarrow p_1 \rightarrow q'^*_1$ for the arc $q'_0 \rightarrow q'_1 \rightarrow q'^*_1$. The new trajectory γ_2 is also optimal. If there is another singular piece to the right of t'^*_1 , let t'_2, t'^*_2 be the endpoints of the

FIG. 6

leftmost such piece, and let S_2 be the stratum containing it. If $\Delta_A > 0$ on S_2 then there would have to be a barrier of the form S^ε , $S \in \mathcal{T}_1$, lying between S_1 and S_2 (by the reasoning of Sub-subcase 2b.i). If $\Delta_A < 0$ on S_2 , then $\gamma \upharpoonright [t'_2, t_2^*]$ goes downwards along S_2 . Let $q'_2 = \gamma(t'_2)$, $q_2^* = \gamma(t_2^*)$. Then Lemma 3.6 of [A] shows that $T(p_1 p_2 q'_2) = T(p_1 q'_2 q_2^*)$. So we may replace the arc $p_1 q'_2 q_2^*$ of γ_2 by the arc $p_1 p_2 q'_2$, and obtain a new optimal trajectory γ_3 . This procedure can be continued until all the singular pieces to the right of $[t'_0, t'_1]$ have been eliminated. The resulting trajectory γ_m is still time-optimal. However, γ_m is a strict $Y * X * Z * Y$ trajectory, and so γ_m is of the type studied in Case 4. So γ_m cannot be time-optimal, as shown in the study of Case 4. This contradiction concludes the study of Case 5, which was the last missing case.

The proof of Lemma 3.12 is now complete. As explained before, we have proved the following.

THEOREM 3.17. *Let $p \in M$ be any point such that (3.I.i, ii, iii) hold. Then p has a neighborhood U such that $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient for U . \square*

This result, together with Corollary 2.4, gives the following.

THEOREM 3.18. *Let Σ be a C.A.S. that has the DSAP. Let $p \in M$ be such that either $X(p) \neq 0$ or $Y(p) \neq 0$. Then there exists a neighborhood U of p such that $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient for U . \square*

4. The degenerate cases. In this section, we prove the analogues of Theorem 3.17 for analytic systems that do not have the DSAP. First, we consider a C.A.S. that does not have the DAP, i.e., a system for which Δ_A vanishes identically.

LEMMA 4.1. *Suppose that Σ is a C.A.S. for which $\Delta_A \equiv 0$. Let $p \in M$ be such that either $X(p) \neq 0$ or $Y(p) \neq 0$. Then p has a neighborhood U such that $\text{Traj}(X \vee Y)$ is boundedly sufficient for U .*

Proof. Assume that $X(p) \neq 0$. (The case when $Y(p) \neq 0$ is similar.) Then we can choose a square coordinate chart $(U, (\xi, \eta))$, centered at p , by means of which U becomes identified with a square $S_q(\varepsilon)$, and having the property that

$$(4.1) \quad X = \partial_x.$$

Then $Y = \alpha \partial_x + \beta \partial_y$, for some analytic functions α, β on U . The hypothesis that $\Delta_A \equiv 0$ implies that $\beta \equiv 0$, so that

$$(4.2) \quad Y = \alpha \partial_x.$$

From this it is clear that every trajectory γ of $\Sigma \downarrow U$ is contained in a horizontal line. If γ is time-optimal, then clearly γ cannot go twice through the same point. Therefore γ either goes from right to left or from left to right. The former can only happen if $\alpha(\gamma(t)) < 0$ for all $t \in \text{Dom}(\gamma)$. Then the t -derivative of the x -coordinate of $\gamma(t)$ is a convex combination of $\alpha(\gamma(t))$ (which is < 0) and of 1. Clearly, if the coefficient of 1 is nonzero, then one could achieve greater speed leftwards by making it zero, so γ would not be time-optimal. Therefore, any time-optimal trajectory in U which goes from right to left is necessarily in $\text{Traj}(Y)$.

Now suppose that γ is a time-optimal trajectory in U that goes from left to right. It is clear that $\gamma \upharpoonright J \in \text{Traj}(X)$, if J is any interval such that $\alpha(\gamma(t)) < 1$ for $t \in J$, and that $\gamma \upharpoonright J \in \text{Traj}(Y)$ if $\alpha(\gamma(t)) > 1$ for $t \in J$. Therefore, γ is regular bang-bang, and it can only switch at points q such that $\alpha(q) = 1$. (This is because the set of zeros of $\alpha - 1$ on any horizontal segment S is discrete, unless $\alpha \equiv 1$ on S . But, in the latter case, if γ is contained in S , then γ is an X -trajectory.) The fact that $\gamma \in \text{Traj}(X \vee Y)^\nu$ for some fixed ν , independent of γ , now follows easily, if ε is small enough, from well-known properties of analytic functions. (For instance, take a CASA stratification of $\text{Sq}(\varepsilon)$ which is compatible with X and ∂_y , and with the set of zeros of $\alpha - 1$. As shown in Lemma 3.1, every one-dimensional stratum of \mathcal{S} is either a horizontal segment or a set of the form $\{(\psi(y), y) : a < y < b\}$ for some function ψ . So, if S is a horizontal segment in $\text{Sq}(\varepsilon)$, then S meets each one- or zero-dimensional stratum of \mathcal{S} at most once, unless $\alpha \equiv 1$ on S . If $0 < \varepsilon' < \varepsilon$, and if S is a horizontal segment in $\text{Sq}(\varepsilon')$ such that $\alpha - 1$ does not vanish identically on S , then $\alpha - 1$ cannot have more than ν zeros on S , where ν is the number of strata of \mathcal{S} that meet $\text{Sq}(\varepsilon')$ and have dimension zero or one.) \square

We now study the case of systems which have the DAP but fail to have the DSAP. It can be proved that, for such a system, there is a good *weakly sufficient* family of optimal trajectories in a neighborhood of any point p such that $X(p) \neq 0$ or $Y(p) \neq 0$. However, it turns out that the proof is simpler if we make the extra hypothesis that the accessibility property holds at p , and that this case is the only one which is actually needed for the proof of the existence of a regular synthesis. So we will limit ourselves to the simpler case.

The reason why we will only obtain weakly sufficient families, rather than sufficient families, is as follows. If the DSAP fails, then $\Delta_B \equiv 0$ (cf. Lemma 2.2). Then Lemma 3.10 of [A], together with Formula (3.43) of [A], imply that any two trajectories from a point p to a point q take the same time, at least if Δ_A never vanishes. So there are many optimal trajectories. In fact, in a neighborhood of a point where $\Delta_A \neq 0$, every trajectory will be optimal, and so there is no hope of proving that every optimal trajectory is of a particularly simple type. However, one can prove that, whenever a point q can be reached from a point p , then q can be reached from p by a particularly simple trajectory, which then turns out to be optimal.

THEOREM 4.2. *Let Σ be a C.A.S. such that $\Delta_B \equiv 0$. Let $p \in M$ be such that the AP holds at p . Then p has a neighborhood U with the property that $\text{Traj}(X \vee Y)$ is weakly boundedly sufficient for U (i.e. there exists an $N > 0$ such that, whenever $q_1 \in U$ can be reached from $q_0 \in U$ by means of a time-optimal trajectory in U , then q_1 can be reached from q_0 by means of a time-optimal $\gamma \in \text{Traj}(\Sigma \downarrow U)$ such that $\gamma \in [\text{Traj}(X \vee Y)]^N$.)*

Proof. First assume that $X(p)$ and $Y(p)$ are linearly independent. In this case we can use Lemma 3.12 of [A], and find a neighborhood U which is the domain of a square coordinate chart centered at p , relative to which X and Y have components $(\alpha, 0)$, $(0, \beta)$, where α, β are analytic on U , and > 0 . Then it is clear that, whenever a point $q_1 \in U$ can be reached from a point $q_0 \in U$ by means of a trajectory in U , then

q_1 can be reached from q_0 by means of a γ in $\text{Traj}(\Sigma \upharpoonright U) \cap \text{Traj}(X * Y)$. We now show that every trajectory in U is time-optimal. (This will establish that $\text{Traj}(X \vee Y)$ is weakly sufficient for U .)

A simple computation shows that

$$(4.3) \quad [X, Y] = -\beta(\partial_y \alpha) \partial_x + \alpha(\partial_x \beta) \partial_y.$$

Therefore

$$(4.4) \quad \Delta_B = \frac{1}{4}(-\alpha^2(\partial_x \beta) + \beta^2(\partial_y \alpha)).$$

Since $\Delta_B \equiv 0$, we get

$$(4.5) \quad \frac{\partial_x \beta}{\beta^2} = \frac{\partial_y \alpha}{\alpha^2}.$$

Therefore

$$(4.6) \quad \partial_x \left(\frac{1}{\beta} \right) = \partial_y \left(\frac{1}{\alpha} \right).$$

Since U is simply connected, there is an analytic function $\psi: U \rightarrow \mathbb{R}$ such that

$$(4.7) \quad \partial_x \psi = \frac{1}{\alpha}, \quad \partial_y \psi = \frac{1}{\beta}.$$

Therefore

$$(4.8) \quad \langle d\psi, X \rangle \equiv \langle d\psi, Y \rangle \equiv 1.$$

From this it follows easily that, if $\gamma \in \text{Traj}(\Sigma \upharpoonright U)$, and $\text{Dom}(\gamma) = [a, b]$, then

$$(4.9) \quad \int_{\gamma} \psi = b - a,$$

i.e.,

$$(4.10) \quad \psi(\gamma(b)) - \psi(\gamma(a)) = T(\gamma).$$

If $\gamma(a) = q_0$, $\gamma(b) = q_1$, we see that $T(\gamma) = \psi(q_1) - \psi(q_0)$, so that $T(\gamma)$ is independent of γ . Therefore all trajectories from q_0 to q_1 in U take exactly the same time.

We now consider the case when $X(p)$ and $Y(p)$ are linearly dependent. The accessibility hypothesis implies, first of all, that $X(p)$ and $Y(p)$ cannot both vanish. Assume, without loss of generality, that $X(p) \neq 0$. Choose a square coordinate chart, centered at p , with domain U_0 , by means of which U_0 is identified with a square $\text{Sq}(\varepsilon_0)$, and which is such that, on U_0 ,

$$(4.11) \quad X = \partial_x.$$

Let Y have components α, β . Then a simple computation shows that

$$(4.12) \quad \Delta_B = \frac{1}{4}((\alpha - 1)(\partial_x \beta) - (\partial_x \alpha)\beta).$$

So, $\Delta_B \equiv 0$ implies that

$$(4.13) \quad (\partial_x \alpha)\beta \equiv (\alpha - 1)(\partial_x \beta).$$

If $\alpha(0, 0) \neq 1$, then the function $\phi: x \rightarrow \beta(x, 0)$ is a solution of

$$(4.14) \quad \dot{\phi} = \phi\mu,$$

where

$$(4.15) \quad \mu(x) = \frac{(\partial_x \alpha)(x, 0)}{\alpha(x, 0) - 1}$$

for x in some interval $]-\delta, \delta[$. Since $X(p)$ and $Y(p)$ are dependent, we have $\beta(0, 0) = 0$, and so $\beta(x, 0) = 0$ for $|x| < \delta$. Therefore, by analyticity, $\beta(x, 0) = 0$ for $|x| < \varepsilon$. This shows that Y is everywhere tangent, on U_0 , to the integral curve of X through p , and therefore the accessibility property does not hold. This contradiction arose from assuming that $\alpha(0, 0) \neq 1$. So $\alpha(0, 0) = 1$. Since $\beta(0, 0) = 0$, we conclude that

$$(4.16) \quad X(p) = Y(p).$$

By making ε smaller we may assume that the accessibility property holds at every point of U_0 , and that $\alpha > 0$, throughout U_0 . Then the proof that $\beta(p) = 0$ implies $\alpha(p) = 1$ also works at all other points $q \in U_0$, and we conclude that

$$\alpha(q) = 1 \quad \text{whenever } q \in U_0, \quad \beta(q) = 0.$$

We now let \mathcal{S} be a CASA stratification of U_0 which is compatible with $\{p\}$, with the set of zeros of $\beta \upharpoonright U_0$, and with the vector fields X , Y , and ∂_y . Let $0 < \varepsilon < \varepsilon_0$ be such that ε is good for \mathcal{S} (cf. the definition of a "good" ε , before Lemma 3.3). We now let $\mathcal{S}_1(\varepsilon)$ be the set of all intersections $S \cap \text{Sq}(\varepsilon)$, as S ranges over all one-dimensional strata of \mathcal{S} that meet $\text{Sq}(\varepsilon)$. Then $\mathcal{S}_1(\varepsilon)$ is finite, and the zero set of $\beta \upharpoonright \text{Sq}(\varepsilon)$ is exactly the union of $\{p\}$ and of the members of $\mathcal{S}_1(\varepsilon)$. Lemma 3.4 implies that, if $S \in \mathcal{S}_1(\varepsilon)$, then $S \in \mathcal{A}_p^+(\varepsilon) \cup \mathcal{A}_p^-(\varepsilon)$. (The remaining possibility, that $S = \Gamma_\varepsilon^+$ or $S = \Gamma_\varepsilon^-$, cannot arise. Indeed, if $S = \Gamma_\varepsilon^+$ or $S = \Gamma_\varepsilon^-$, it would follow that $\beta(x, 0) = 0$ for $|x| < \varepsilon$, contradicting the accessibility assumption.)

It is easy to see that the open set $\{q: q \in \text{Sq}(\varepsilon), \beta(q) \neq 0\}$ is partitioned into a finite number W_1, \dots, W_m of connected components, which have the following properties:

- (4.I.1) W_i is simply connected;
- (4.I.2) W_i is a union of horizontal segments;
- (4.I.3) The right boundary $\partial_R W_i$ of W_i (i.e. the set of all right endpoints of all the segments whose union is W_i) is either
 - (a) a set $S \in \mathcal{S}_1(\varepsilon)$, of the form $\{(\psi(y), y): 0 < y < \varepsilon\}$, or
 - (b) a union $S_1 \cup S_2$, where $S_1 = \{(\psi(y), y): 0 < y < b\}$, $b < \varepsilon$, and $\psi(b-) = \varepsilon$, and $S_2 = \{(\varepsilon, y): b \leq y < \varepsilon\}$, or
 - (c) a set $S \in \mathcal{S}_1(\varepsilon)$ of the form $\{(\psi(y), y): -\varepsilon < y < 0\}$ or
 - (d) a union $S_1 \cup S_2$, where $S_1 = \{(\psi(y), y): a < y < 0\}$, $-\varepsilon < a$, and $\psi(a+) = \varepsilon$, and $S_2 = \{(\varepsilon, y): -\varepsilon < y \leq a\}$, or
 - (e) the union of $\{p\}$, of a set of the type described in (a) or (b), and of a set of the type described in (c) or (d). In all cases, ψ is a real analytic function which is either constant or strictly monotonic.
- (4.I.4) $\beta \neq 0$ throughout W_i .

The *left boundary* of W_i is defined similarly, and it satisfies a property similar to (4.I.3), which we shall not state explicitly.

Let $B_i^* = (\partial_R W_i) \cap \text{Sq}(\varepsilon)$. If $\partial_R W_i$ satisfies (a) or (b) of (4.I.3), let B_i be the union of B_i^* and of the vertical segment $\{(0, y): -\varepsilon < y \leq 0\}$. If $\partial_R W_i$ satisfies (c) or (d), let B_i^* be the union of B_i and of the vertical segment $\{(0, y): 0 < y < \varepsilon\}$. Finally, if $\partial_R W_i$ satisfies (e), let $B_i = B_i^*$. Then B_i is a barrier in $\text{Sq}(\varepsilon)$. If $\gamma \in \text{Traj}(\Sigma \upharpoonright \text{Sq}(\varepsilon))$, and if γ contains some point in W_i , but eventually leaves W_i , then it must leave through a

point in B_i . Therefore γ never re-enters W_i . So every trajectory of $\Sigma \upharpoonright \text{Sq}(\varepsilon)$ is a concatenation of at most m pieces, each of which is contained in one of the sets $\text{Clos } W_i$. Therefore, our conclusion will be proved if we show that, whenever γ is a time-optimal trajectory which is contained in $\text{Clos } W_i$ for some i , and goes from q_0 to q_1 , then there is a time-optimal $\gamma' \in \text{Traj}(\Sigma \upharpoonright \text{Clos } W_i)$, that goes from q_0 to q_1 , and is in $\text{Traj}(X * Y)$. We will establish this by proving that:

(4.II.a) Whenever γ_1, γ_2 are trajectories in $\text{Clos } W_i$, such that $\text{In}(\gamma_1) = \text{In}(\gamma_2)$ and $\text{Term}(\gamma_1) = \text{Term}(\gamma_2)$, then $T(\gamma_1) = T(\gamma_2)$

and

(4.II.b) Whenever $q_1 \in \text{Clos } W_i$ can be reached from $q_0 \in \text{Clos } W_i$ by means of a trajectory in $\text{Clos } W_i$, then q_1 can be reached from q_0 by means of a $\gamma \in \text{Traj}(\Sigma \upharpoonright U) \cap \text{Traj}(X * Y)$.

To prove (4.II.a), it is clearly sufficient to assume that γ_1 and γ_2 are entirely contained in W_i . Since β never vanishes on W_i , we can define an analytic function ψ and W_i by

$$(4.17) \quad \psi = \frac{1 - \alpha}{\beta}.$$

Then

$$(4.18) \quad \partial_x \psi = \frac{-(\partial_x \alpha)\beta - (1 - \alpha)(\partial_x \beta)}{\beta^2}.$$

So (4.13) implies that $\partial_x \psi \equiv 0$ on W_i . Since $\partial_y 1 \equiv 0$, and W_i is simply connected, there exists an analytic $\phi: W_i \rightarrow \mathbb{R}$ such that

$$\partial_x \phi = 1, \quad \partial_y \phi = \psi.$$

Therefore

$$\langle d\phi, X \rangle = \partial_x \phi \equiv 1$$

and

$$\langle d\phi, Y \rangle = \alpha(\partial_x \phi) + \beta(\partial_y \phi) \equiv 1.$$

Then, if γ is any trajectory of $\Sigma \upharpoonright W_i$, we have

$$T(\gamma) = \int_{\gamma} d\phi = \phi(\text{Term}(\gamma)) - \phi(\text{In}(\gamma)).$$

So $T(\gamma)$ only depends on the endpoints of γ , and (4.II.a) is proved.

We now prove (4.II.b). Assume that $\beta > 0$ on W_i . (The case when $\beta < 0$ on W_i is identical.) Then the Y -trajectories in $\text{Clos } W_i$ go to the right and up. Suppose that $\gamma: [a, b] \rightarrow \text{Clos } W_i$ is a trajectory of Σ , such that $\gamma(a) = q_0$, $\gamma(b) = q_1$. Then q_1 is to the right of and above q_0 . Let $\gamma'(t) = \Phi_t^Y(q_0)$. Then there are t_1, t_2 such that $\gamma'(t_1) \in \partial_L W_i$, $\gamma'(t_2) \in \partial_R W_i$, and $t_1 \leq 0 < t_2$. Since $\gamma' \upharpoonright]t_1, t_2[$ goes up and to the right, and $X = \partial_x$, the curve $\gamma' \upharpoonright]t_1, t_2[$ is a barrier in W_i . The connected components of $W_i - \gamma'$ are W_i^L, W_i^R , where W_i^R is the union of all the segments $(\mathbb{R} \times \{y\}) \cap W_i$, for $y \leq \bar{y}$ (where \bar{y} is the y -coordinate of q_0), and of all the segments $(]x(t), \infty[\times \{y(t)\}) \cap W_i$, where $\gamma'(t) = (x(t), y(t))$, $t \in]t_1, t_2[$. Since $\gamma' \upharpoonright]t_1, t_2[$ is a barrier in W_i , and q_1 is reachable from q_0 in $\text{Clos } W_i$, it follows that $q_1 \in \text{Clos}(W_i^R)$. Since q_1 has a larger y -coordinate than q_0 , we necessarily have $q_1 \in (]x(t), \infty[\times \{y(t)\}) \cap W_i$ for some t , and so q_1 is reachable from q_0 by an $X * Y$ -trajectory in $\text{Clos } W_i$. \square

5. Conclusion. If we combine the results of Theorem 3.18, Lemma 4.1 and Theorem 4.2, we obtain the following conclusions (for which the connectedness of Σ is no longer needed):

THEOREM 5.1. *Let Σ be a real analytic system*

$$(5.1) \quad \dot{x} = f(x) + ug(x), \quad |u| \leq 1$$

on a two-dimensional real-analytic manifold M . Let $p \in M$ be such that at least one of the vectors $f(p)$, $g(p)$ does not vanish. Assume that either (i) Σ has the DSAP, or (ii) Σ has the AP at p , or (iii) Δ_A vanishes identically near 0. Let $X = f - g$, $Y = f + g$, and let Z denote the singular vector field. Then p has a neighborhood U such that, for the minimum time problem, $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient for U .

THEOREM 5.2. *Let Σ , M , f , g , X , Y , Z be as in Theorem 5.1. Let $\gamma: [a, b] \rightarrow M$ be a time-optimal trajectory of Σ . Then there exists a time-optimal trajectory $\gamma': [a, b] \rightarrow M$ of Σ such that $\gamma'(a) = \gamma(a)$, $\gamma'(b) = \gamma(b)$, and γ' is a finite concatenation of X -, Y - and Z -trajectories.*

Proof. If γ goes through a point p where both f and g vanish, then necessarily $b = a$ and we can take $\gamma' = \gamma$. Otherwise γ is a finite concatenation of trajectories γ_i that are contained in open sets U_i for which $\text{Traj}(X \vee Y \vee Z)$ is boundedly sufficient, and the desired conclusion follows. \square

Appendix.

A1. Semianalytic and subanalytic sets. We list here the main facts about semianalytic and subanalytic sets. For details, see Hardt [Ha], Lojasiewicz [Loj], Sussmann [Su6], and Tamm [Ta].

A subset S of a C^ω manifold M is *analytic* if every $p \in M$ has a neighborhood U such that $S \cap U$ is the set of zeros of a C^ω function $f: U \rightarrow \mathbb{R}$. We say that S is *semianalytic* if every $p \in M$ has a neighborhood U such that

$$S \cap U = \bigcup_{j=1}^m \bigcup_{i=1}^{n(j)} S_{ij}$$

where each S_{ij} is a subset of U of the form $\{x: f_{ij}(x) = 0\}$ or $\{x: f_{ij}(x) > 0\}$, and $f_{ij}: U \rightarrow \mathbb{R}$ is real analytic.

We shall not repeat the actual definition of the class of subanalytic sets (cf. [Ha], where they are called “semianalytic shadows”, or [Hi1], or [Ta], or [Su]). The main facts are:

- (A.I) Every semianalytic subset of M is subanalytic;
- (A.II) Every locally finite union or intersection of subanalytic sets is subanalytic;
- (A.III) The complement and the closure of a subanalytic set is subanalytic.

Moreover, subanalyticity is local, i.e.:

- (A.IV) If $S \subseteq M$, then S is a subanalytic subset of M if and only if every $p \in M$ has a neighborhood U such that $S \cap U$ is subanalytic in U .

Also:

- (A.V) If $f: M \rightarrow N$ is a C^ω map, and S is subanalytic in N , then $f^{-1}(S)$ is subanalytic in M .

Finally, we have the most important property of all, namely, that one can take proper images. Precisely, if $f: M \rightarrow N$ is a map, and $A \subseteq M$, we say that f is *proper on A* if $f^{-1}(K) \cap A$ is compact for each compact $K \subseteq N$. Then we have:

(A.VI) If $f: M \rightarrow N$ is analytic, S is a subanalytic subset of M , and f is proper on $\text{Clos } S$, then $f(S)$ is a subanalytic subset of N .

The preceding properties make it possible to prove easily that many sets are subanalytic. Consider formulas $F(x_1, \dots, x_n)$ with free variables x_1, \dots, x_n ranging over analytic manifolds M_1, \dots, M_n . If F_1, \dots, F_m are formulas which define subanalytic sets, then any formula obtained from them by taking conjunctions, disjunctions and negations also has this property. Moreover, we can also allow existential quantifications, provided that they are bounded. (In $(\exists x)F(x, y)$, we say that the quantifier $(\exists x)$ is bounded if for every compact $K \subseteq N$ there is a compact $J \subseteq M$ such that, for each $y \in K$, $(\exists x)F(x, y)$ is equivalent to $(\exists x)(x \in J \wedge F(x, y))$.) Finally, since a universal quantifier can be expressed in terms of existential quantifiers and negations, we can also allow universal quantifiers, provided that they are bounded. (The definition of a bounded universal quantifier \forall is the same as that for \exists , except that $(\exists x)(x \in J \wedge F(x, y))$ must be replaced by $(\forall x)(x \in J \Rightarrow F(x, y))$.)

A C^k stratification of a manifold M is a locally finite partition \mathcal{S} of M into connected, embedded submanifolds of M , of class C^k , such that, if $S \in \mathcal{S}$, then the frontier $\text{Fron } S (= (\text{Clos } S) - S)$ is a union of members of \mathcal{S} , all of them of dimension smaller than $\dim S$. A CASA stratification of M is a stratification whose members are analytic submanifolds and subanalytic sets. A stratification \mathcal{S} is *compatible* with a set A if A is a union of members of \mathcal{S} . If \mathcal{A} is a family of sets, then \mathcal{S} is *compatible with* \mathcal{A} if it is compatible with each $A \in \mathcal{A}$. If X is an analytic vector field on M , we say that \mathcal{S} is *compatible with* X if, for each $S \in \mathcal{S}$, X is either everywhere tangent to S or nowhere tangent to S .

(A.VII) If \mathcal{A} is an arbitrary locally finite family of subanalytic subsets of M , and \mathcal{F} a finite family of analytic vector fields on M , then there is a CASA stratification \mathcal{S} of M which is compatible with all the $A \in \mathcal{A}$ and all the $X \in \mathcal{F}$.

If $f: M \rightarrow N$ is a map, L is a subset of M , and \mathcal{S}, \mathcal{T} are stratifications of M, N , we say that $(\mathcal{S}, \mathcal{T})$ is *compatible with f over L* if \mathcal{S} is compatible with L and, for every $S \in \mathcal{S}$, $S \subseteq L$, the image $f(S)$ is in \mathcal{T} , and $f|_S: S \rightarrow f(S)$ is a submersion. We say that $(\mathcal{S}, \mathcal{T})$ is *one-one compatible with f over L* if, in addition, the map $f|_S$ is one-to-one for every $S \in \mathcal{S}$, $S \subseteq L$, such that $\dim S = \dim f(S)$.

(A.VIII) If $f: M \rightarrow N$ is an analytic map, L is a subanalytic subset of M such that f is proper on $\text{Clos } L$, and \mathcal{A}, \mathcal{B} are locally finite families of subanalytic subsets of M, N , respectively, then there exist CASA stratifications \mathcal{S}, \mathcal{T} of M, N , which are compatible with \mathcal{A}, \mathcal{B} , and are such that $(\mathcal{S}, \mathcal{T})$ is one-one compatible with f over L .

It follows from (A.VII) that, if A is a subanalytic subset of M , then A is a union of members S of a stratification \mathcal{S} . In particular, if A is relatively compact, then A only meets finitely many members of \mathcal{S} , and therefore:

(A.IX) A relatively compact subanalytic subset of M has finitely many components.

Finally, we quote a fact from [Loj]:

(A.X) A subanalytic subset of the plane is necessarily semianalytic.

A2. A counterexample. We show that, in the neighborhood of a point p where X and Y both vanish, there need not be bounds on the number of switchings. Let X be an analytic vector field whose trajectories spiral about 0, and converge to 0 as $t \rightarrow \infty$. Let $Y = \phi X$, where ϕ is a positive function which is < 1 above the x axis, and > 1 below the x axis. If U is an arbitrary neighborhood of 0, one can pick $q_1 \in U$, $q_2 \in U$ such that $q_2 = \Phi_t^X(q_1)$ for a $t > 0$, and that the number of times that the X -trajectory γ from q_1 to q_2 winds around the origin is arbitrarily large. To make γ time-optimal, we must reparametrize γ , so that γ is an X -trajectory above the x -axis, but a Y -trajectory below the x -axis. So U contains time-optimal trajectories with an arbitrarily large number of switchings.

With a little bit of work, one can modify the preceding example so as to get X and Y to have the strong accessibility property everywhere, except at 0.

In these examples, the unboundedness in the number of switchings arises as the time becomes unbounded. We do not know whether there are examples where the number of switchings is unbounded even when the time remains bounded.

A NONQUADRATIC BOLZA PROBLEM AND A QUASI-RICCATI EQUATION FOR DISTRIBUTED PARAMETER SYSTEMS*

YOU YUN-CHENG†

Abstract. Closed-loop optimal control of a nonquadratic Bolza problem for linear distributed parameter systems and normal solution of an associated quasi-Riccati operator equation are studied by the approach of a nonlinear integral equation.

Key words. Bolza problem, nonquadratic cost function, quasi-Riccati equation, closed-loop optimal control, nonlinear integral equation, distributed parameter system

AMS(MOS) subject classification. 49A27

1. Introduction. In this paper, we consider an optimal control problem for a linear evolution system,

$$(1.1) \quad \frac{dx}{dt} = Ax(t) + Bu(t), \quad x(0) = x_0,$$

$$(1.2) \quad \min_{u \in L^2(0, T; U)} \left\{ J(u) = M(x(T)) + \int_0^T (Q(x(t)) + \frac{1}{2} \langle Ru(t), u(t) \rangle) dt \right\}.$$

Assume that $T > 0$ is finite and fixed, X and U are real Hilbert spaces, $x(t)$ and x_0 take values in X , and the admissible set of control functions is $\mathcal{U} = L^2(0, T; U)$. In (1.1), $A: D(A) (\subset X) \rightarrow X$ is an infinitesimal generator of C_0 -semigroup of bounded linear operators $e^{At} (t \geq 0) \in \mathcal{L}(X)$, and $B \in \mathcal{L}(U; X)$. In (1.2), we assume that

$$(1.3) \quad \begin{aligned} &M(\cdot) \text{ and } Q(\cdot) \text{ are } C^2 \text{ convex mappings from } X \text{ to } \mathbb{R} \\ &\quad \text{(nonquadratic in general),} \\ &R \in \mathcal{L}(U) \text{ is self-adjoint and coercively positive.} \end{aligned}$$

We take the mild solution of (1.1) to be state function, i.e.,

$$(1.4) \quad x(t) = e^{At}x_0 + \int_0^t e^{A(t-s)}Bu(s) ds, \quad t \in [0, T],$$

where the integration is in the Bochner sense.

This optimal control problem will be referred to as (NQBP). The results in this paper generalize the well-known quadratic optimal control [1].

In [2] and [3], the author proved the closed-loop optimal control and global normal solution of the associated quasi-Riccati equations in the cases $Q(\cdot) = 0$ and $M(\cdot) = 0$ respectively. In these two cases, the optimal nonlinear feedbacks are given by

$$(1.5) \quad u(t) = -R^{-1}B^*e^{A^*(T-t)}M'(H(T-t, x(t))) \quad (\text{see [2]}),$$

$$(1.6) \quad u(t) = -R^{-1}B^* \int_t^T e^{A^*(s-t)}Q'(G(s, t, x(t))) ds \quad (\text{see [3]})$$

respectively, where $H(T-t, x)$ and $G(s, t, x)$ are solution operators of following nonlinear algebraic equation [2]

$$(1.7) \quad y + \left\{ \int_0^{T-t} e^{As} B R^{-1} B^* e^{A^*s} ds \right\} M'(y) = e^{A(T-t)} x$$

for any given $(t, x) \in [0, T] \times X$,

and nonlinear Fredholm integral equation

$$(1.8) \quad y(s) + \int_t^T \left\{ \int_t^{\min(s, \sigma)} e^{A(s-\eta)} B R^{-1} B^* e^{A^*(\sigma-\eta)} d\eta \right\} Q'(y(\sigma)) d\sigma = e^{A(s-t)} x,$$

$s \in [t, T]$ for any given $(t, x) \in [0, T] \times X$,

respectively. However, these two approaches are not applicable to the more general case of (NQBP) we consider here.

In [4], more general convex control problems for linear evolutionary processes had been studied. By means of subdifferentials and adjoint equations, those authors established a set of optimality conditions which amounts to the open-loop relations of the optimal control process.

In connection with closed-loop syntheses of the related problems, [5] developed a series of results on local and global existence of solution to Hamilton-Jacobi equations mainly by the constructive approximation approach.

Here in this paper, we consider the $\{x(T), x(\cdot), u(\cdot)\}$ -separate nonquadratic criteria with the C^2 -assumption. The obtained results will provide

- (i) A simpler open-loop formula of the optimal control;
- (ii) A new proof of the global existence of the solution of the quasi-Riccati equation as well as the improved regularity of the solution;
- (iii) A new variational formula, which directly leads to the closed-loop relation;
- (iv) A class of nonlinear integral equations whose solution mappings yield both the optimal feedback operators and normal solutions of the quasi-Riccati equations;
- (v) A generalization to closed-loop optimal strategies of nonquadratic differential games.

The contents of this paper are outlined as follows. In § 2, the existence of the optimal control and an open-loop relation are proved. In § 3, we show that a normal solution of quasi-Riccati equation will provide optimal feedback for the closed-loop solution. Section 4 is devoted to the investigation of solution mapping $K(s, t, x)$ of a nonlinear integral equation. We prove in § 5 that $K(t, t, x) = P(t, x)$ turns out to be a normal solution of quasi-Riccati equation. Hence the closed-loop solution to (NQBP) is given. In § 6 we give some remarks.

Here we list some notations. We shall denote a scalar product by $\langle \cdot, \cdot \rangle$. Let E , E_1 and E_2 be Banach spaces; then $\mathcal{L}(E_1; E_2)$ and $\mathcal{L}(E)$ stand for the Banach spaces of bounded linear operators from E_1 to E_2 and from E to itself respectively. Superscript $*$ will be attached to adjoint operators. $e^{A^*t} \in \mathcal{L}(X)$ is the dual semigroup of e^{At} and is generated by A^* , the adjoint of the densely defined and closed operator A . For a self-adjoint operator S , then $S \geq 0$ (resp. $S > 0$) means nonnegative (resp. coercively positive).

If E is a Banach space, $[a, b] \subset \mathbb{R}$, then we shall denote by $L^2(a, b; E)$ the Hilbert space of strongly measurable functions $g(\cdot): [a, b] \rightarrow X$, such that

$$\int_a^b \|g(t)\|_E^2 dt < +\infty.$$

We shall denote by $C([a, b]; E)$ the Banach space of all strongly continuous functions from $[a, b]$ to E .

For a mapping f from a Banach space E_1 to another E_2 , we shall denote its Fréchet derivative by f' or Df . Subscripts will be used to represent partial Fréchet derivatives or related parameters of mappings according to the context.

All the concepts and facts of nonlinear analysis used later appear in [6]. In particular, we shall make use of the following relation of a differentiable mapping f , i.e.,

$$(1.9) \quad f(x+h) - f(x) = \int_0^1 Df(x+\lambda h)h \, d\lambda.$$

2. Existence and open-loop equality.

THEOREM 1. *For any given $x_0 \in X$, there exists a unique optimal control of (NQBP).*

Proof. First we assert that for a C^1 convex mapping $\varphi(\cdot)$ from a Hilbert space E to \mathbb{R} there exist an element $e \in E$ and a constant $\gamma \in \mathbb{R}$ such that

$$(2.1) \quad \varphi(x) \geq \langle e, x \rangle_E + \gamma \quad \forall x \in E.$$

This is a consequence of the monotonicity of $\varphi'(\cdot)$ and (1.9).

From (1.3) and (2.1), there must be constants $\delta > 0$, $\beta > 0$, and $\alpha(x_0) \in \mathbb{R}$ which depends continuously on x_0 , such that

$$(2.2) \quad \begin{aligned} \delta \|u\|_{\mathcal{U}}^2 &\leq \frac{1}{2} \int_0^T \langle Ru(t), u(t) \rangle \, dt \\ &= J(u; x_0) - M \left(e^{AT} x_0 + \int_0^T e^{A(T-s)} Bu(s) \, ds \right) \\ &\quad - \int_0^T Q \left(e^{At} x_0 + \int_0^t e^{A(t-s)} Bu(s) \, ds \right) \, dt \\ &\leq J(u; x_0) + \alpha(x_0) + \beta \|u\|_{\mathcal{U}}, \end{aligned}$$

where we write (1.2) as $J(u; x_0)$ to indicate its dependence on $u(\cdot)$ and x_0 . Thus we have

$$(2.3) \quad 0 \leq \delta \left(\|u\|_{\mathcal{U}} - \frac{\beta}{2\delta} \right)^2 \leq J(u; x_0) + \left(\alpha(x_0) + \frac{\beta^2}{4\delta} \right) \quad \forall u(\cdot) \in \mathcal{U}.$$

It follows from (2.3) that for a given $x_0 \in X$,

$$(2.4) \quad -\infty < J(u; x_0) < +\infty,$$

and that a minimizing sequence is uniformly bounded in \mathcal{U} so that there is a weakly convergent subsequence in \mathcal{U} .

From (1.3) we can deduce that for any $0 \leq \lambda \leq 1$, $u(\cdot)$ and $v(\cdot)$ in \mathcal{U} ,

$$(2.5) \quad \lambda J(u) + (1-\lambda)J(v) \geq J(\lambda u + (1-\lambda)v) + \frac{1}{2}\lambda(1-\lambda) \int_0^T \langle R(u-v), u-v \rangle \, dt.$$

Hence, $J(u)$ is a strictly convex and (easy to see) strongly continuous functional on \mathcal{U} , so that it is weakly lower semi-continuous.

The above facts imply the existence and uniqueness of optimal control of (NQBP). QED.

COROLLARY 1. Let $t_0 \in [0, T]$, the following optimal control problem $(\text{NQBP})_{t_0}$:

$$(2.6) \quad x(t) = e^{A(t-t_0)}x_0 + \int_{t_0}^t e^{A(t-s)}Bu(s) ds,$$

$$(2.7) \quad \min_{u \in L^2(t_0, T; U)} \left\{ J_{t_0}(u) = M(x(T)) + \int_{t_0}^T (Q(x(t)) + \frac{1}{2}\langle Ru(t), u(t) \rangle) dt \right\}$$

has a unique optimal control for any given $x_0 \in X$.

COROLLARY 2. Let Σ be an arbitrarily fixed bounded subset in X , and $u_{(t_0, x_0)}(\cdot)$ be the optimal control of $(\text{NQBP})_{t_0}$ corresponding to the initial state $x_0 \in \Sigma$. Then,

$$1^\circ) \quad \sup_{(t_0, x_0) \in [0, T] \times \Sigma} \{J_{(t_0, x_0)}^* = \inf_{u \in L^2(t_0, T; U)} J_{t_0}(u; x_0)\} < +\infty,$$

$$2^\circ) \quad \sup_{(t_0, x_0) \in [0, T] \times \Sigma} \|u_{(t_0, x_0)}(\cdot)\|_{L^2(t_0, T; U)} < +\infty.$$

Proof. Similar to (2.3), with appropriate choice of constants $\tilde{\alpha}(x_0)$ only depending continuously on x_0 , and $\tilde{\beta}$, we have the following inequality:

$$(2.8) \quad 0 \leq \delta \left(\|u\|_{L^2(t_0, T; U)} - \frac{\tilde{\beta}}{2\delta} \right)^2 \leq J_{t_0}(u; x_0) + \left(\tilde{\alpha}(x_0) + \frac{\tilde{\beta}^2}{4\delta} \right) \quad \forall u \in L^2(t_0, T; U), t_0 \in [0, T], x_0 \in X.$$

Obviously,

$$(2.9) \quad J_{(t_0, x_0)}^* \leq M(e^{A(T-t_0)}x_0) + \int_{t_0}^T Q(e^{A(t-t_0)}x_0) dt \leq \text{const}(\Sigma).$$

From (2.8) and the continuous dependence of $\tilde{\alpha}(x_0)$ on $x_0 \in \Sigma$, we have

$$(2.10) \quad J_{(t_0, x_0)}^* \geq - \left(\tilde{\alpha}(x_0) + \frac{\tilde{\beta}^2}{4\delta} \right) \geq \text{const}(\Sigma).$$

Hence 1° is valid. Moreover 1° and (2.8) show that 2° is valid. QED.

THEOREM 2. For any given $t_0 \in [0, T]$ and $x_0 \in X$, if $u(\cdot)$ is the optimal control and $x(\cdot)$ is the corresponding optimal trajectory of $(\text{NQBP})_{t_0}$, then the following open-loop equality must be satisfied:

$$(2.11) \quad u(t) = -R^{-1}B^*(e^{A^*(T-t)}M'(x(T)) + \int_t^T e^{A^*(\sigma-t)}Q'(x(\sigma)) d\sigma),$$

$$(2.12) \quad x(t) = e^{A(t-t_0)}x_0 - \int_{t_0}^t e^{A(t-s)}BR^{-1}B^* \cdot \left(e^{A^*(T-s)}M'(x(T)) + \int_s^T e^{A^*(\sigma-s)}Q'(x(\sigma)) d\sigma \right) ds, \quad t \in [t_0, T].$$

Proof. For each fixed $v(\cdot) \in \mathcal{U}$, let $\psi(\lambda; v) = J_{t_0}(u + \lambda v; x_0)$, $\lambda \in \mathbb{R}$. As $\psi(0; v) = \min_{\lambda \in \mathbb{R}} \psi(\lambda; v)$, it must be $\psi'_\lambda(0; v) = 0$, $\forall v(\cdot) \in \mathcal{U}$. We can write (2.6) as

$$(2.13) \quad x(\cdot) = h_{t_0}(\cdot) + (\Gamma_{t_0}u)(\cdot), \quad x(T) = h_{t_0}(T) + \Lambda_{t_0}u,$$

where $h_{t_0}(t) = e^{A(t-t_0)}x_0$, $\Gamma_{t_0} \in \mathcal{L}(L^2(t_0, T; U); L^2(t_0, T; X))$ and $\Lambda_{t_0} \in \mathcal{L}(L^2(t_0, T; U); X)$ are defined to be

$$(2.14) \quad \begin{aligned} (\Gamma_{t_0}v)(t) &= \int_{t_0}^t e^{A(t-s)}Bv(s) ds, \quad v \in L^2(t_0, T; U), \\ \Lambda_{t_0}v &= \int_{t_0}^T e^{A(T-s)}Bu(s) ds, \quad v \in L^2(t_0, T; U). \end{aligned}$$

Substitute (2.13) into (2.7) for $u + \lambda v$; it follows that

$$\begin{aligned}
 \psi'_\lambda(0; v) &= \langle M'(h_0(T) + \Lambda_0 u), \Lambda_0 v \rangle_X + \langle Q'(h_0 + \Gamma_0 u), \Gamma_0 v \rangle_{L^2(t_0, T; X)} \\
 &\quad + \langle Ru, v \rangle_{L^2(t_0, T; U)} \\
 (2.15) \quad &= \langle Ru + \Lambda_0^* M'(h_0(T) + \Lambda_0 u) + \Gamma_0^* Q'(h_0 + \Gamma_0 u), v \rangle_{L^2(t_0, T; U)} = 0 \\
 &\quad \forall v(\cdot) \in L^2(t_0, T; U).
 \end{aligned}$$

Thus we obtain (2.11):

$$\begin{aligned}
 u(t) &= -R^{-1} \{ \Lambda_0^* M'(h_0(T) + \Lambda_0 u) + \Gamma_0^* Q'(h_0 + \Gamma_0 u) \} \\
 &= -R^{-1} B^* (e^{A^*(T-t)} M'(x(T)) + \int_t^T e^{A^*(\sigma-t)} Q'(x(\sigma)) d\sigma), \quad t \in [t_0, T].
 \end{aligned}$$

Substitution of (2.11) into (2.6) leads to (2.12). QED.

3. Quasi-Riccati operator equation and normal solution. We consider a quasi-Riccati operator equation associated with (NQBP),

$$\begin{aligned}
 (3.1) \quad &\frac{d}{dt} \langle P(t, x), y \rangle + \langle P_x(t, x) Ax, y \rangle + \langle P(t, x), Ay \rangle + \langle Q'(x), y \rangle \\
 &- \langle P_x(t, x) BR^{-1} B^* P(t, x), y \rangle = 0, \quad (t, x, y) \in [0, T] \times D(A) \times D(A), \\
 &P(T, x) = M'(x), \quad x \in X.
 \end{aligned}$$

DEFINITION 1. If a nonlinear mapping $P(t, x): [0, T] \times X \rightarrow X$ satisfies the following conditions, then it is called a normal solution of the quasi-Riccati equation (3.1),

- 1° $P(t, x): [0, T] \times X \rightarrow X$ is strongly continuous in (t, x) ;
- 2° $\langle P(t, x), y \rangle$ is continuously differentiable in $t \in [0, T]$, for each x and y in $D(A)$;
- 3° $P(t, x)$ is Fréchet differentiable in $x \in X$, for each $t \in [0, T]$;
 - (i) $P_x(t, x): [0, T] \times X \rightarrow \mathcal{L}(X)$ is strongly continuous in (t, x) , i.e., $(t, x) \rightarrow (\hat{t}, \hat{x})$ in $[0, T] \times X$ implies $P_x(t, x)\xi \rightarrow P_x(\hat{t}, \hat{x})\xi$ in X , $\forall \xi \in X$;
 - (ii) $P_x(t, x)$ is bounded in $\mathcal{L}(x)$ -norm for (t, x) in any given bounded subset of $[0, T] \times X$;
- 4° $P(t, x)$ satisfies (3.1);
- 5° $P(t, \cdot): X \rightarrow X$ is a gradient operator, for each $t \in [0, T]$;
- 6° Cauchy problem

$$(3.2) \quad \frac{dx}{dt} = Ax - BR^{-1} B^* P(t, x), \quad x(0) = x_0$$

has a global mild solution [7] $x(\cdot) \in C([0, T]; X)$ for each given $x_0 \in X$.

Assume that $P(t, x)$ is a normal solution of (3.1). By definition of gradient operators [6], for each $t \in [0, T]$, there are anti-derivatives $\Phi(t, x): x \rightarrow \mathbb{R}$ such that

$$(3.3) \quad \Phi_x(t, x) = P(t, x), \quad x \in X.$$

Those $\Phi(t, x)$ satisfying (3.3) may well be different from each other by a constant $c(t)$. We set, without loss of generality, a definition as follows.

DEFINITION 2. The anti-derivative $\Phi(t, x)$ of a normal solution $P(t, x)$ of (3.1) is called canonical, if $\Phi(t, x)$ is such that

$$(3.4) \quad \Phi(t, 0) = M(0), \quad 0 \leq t \leq T.$$

LEMMA 1. Assume that $P(t, x)$ is a normal solution of (3.1) and $\Phi(t, x)$ is the canonical anti-derivative of $P(t, x)$. Then, for each $\{x_0, u(\cdot)\} \in D(A) \times C^1([0, T]; U)$ and corresponding trajectory $x(\cdot)$, the function $\Phi(t, x(t))$ is absolutely continuous on $[0, T]$.

The proof of Lemma 1 is similar to that of [5, Lemma 2], by means of properties 1°–3° of Definition 1, and the following equality, which is obtained from (1.9), (3.3) and (3.4),

$$(3.5) \quad \Phi(t, x(t)) = \int_0^1 \langle P(t, sx(t)), x(t) \rangle ds + M(0), \quad t \in [0, T].$$

The detail is omitted here.

LEMMA 2. The assumptions are the same as in Lemma 1. Then, for each $\{x_0, u(\cdot)\} \in D(A) \times C^1([0, T]; U)$ and corresponding trajectory $x(\cdot)$, the following relation holds:

$$(3.6) \quad \begin{aligned} \frac{d}{dt} \Phi(t, x(t)) &= Q(0) - Q(x(t)) + \langle Bu(t), P(t, x(t)) \rangle \\ &+ \int_0^1 \langle P_x(t, sx(t)) BR^{-1} B^* P(t, sx(t)), x(t) \rangle ds. \end{aligned}$$

The proof of Lemma 2 is straight from (3.5) and similar to that of [5, Lemma 3], so is omitted here.

LEMMA 3. For each $\{x_0, u(\cdot)\} \in X \times \mathcal{U}$ and corresponding trajectory $x(\cdot)$ given by (1.4), there exists a sequence $\{x_n^0, u_n(\cdot)\}_1^\infty \subset D(A) \times C^1([0, T]; U)$ such that

$$\begin{aligned} x_n^0 &\rightarrow x_0 \quad \text{in } X, \\ u_n(\cdot) &\rightarrow u(\cdot) \quad \text{in } \mathcal{U} = L^2(0, T; U), \\ x_n(\cdot) &\rightarrow x(\cdot) \quad \text{in } C([0, T]; X), \end{aligned}$$

where $x_n(\cdot)$ is the trajectory corresponding to x_n^0 and $u_n(\cdot)$.

Proof. This is simply a consequence of the density of $D(A)$ in X , the mollification of L^2 -Bochner integrable functions, and the Hölder inequality.

THEOREM 3. Assume that the quasi-Riccati equation (3.1) has a normal solution $P(t, x)$. Then, for any given $x_0 \in X$, there exists a closed-loop optimal control of (NQBP), given by

$$(3.7) \quad u(t) = -R^{-1} B^* P(t, x(t)), \quad t \in [0, T],$$

where $x(\cdot)$ is the corresponding optimal trajectory.

Proof. Let $\mu(t, x) = \frac{1}{2} \langle R^{-1} B^* P(t, x), B^* P(t, x) \rangle$. It is easy to see that

$$(3.8) \quad \mu'_x(t, x) = P_x(t, x) BR^{-1} B^* P(t, x).$$

For each $\{x_0, u(\cdot)\} \in D(A) \times C^1([0, T]; U)$ and corresponding $x(\cdot)$, by (3.6), (3.8) and (1.9), we have

$$(3.9) \quad \begin{aligned} \frac{d}{dt} \Phi(t, x(t)) &+ Q(x(t)) + \frac{1}{2} \langle Ru(t), u(t) \rangle \\ &= \frac{1}{2} \langle R(u(t) + R^{-1} B^* P(t, x(t))), u(t) + R^{-1} B^* P(t, x(t)) \rangle \\ &+ Q(0) - \mu(t, 0), \end{aligned}$$

where $\Phi(t, x)$ is the canonical anti-derivative of $P(t, x)$.

Integrate (3.9) for $t \in [0, T]$, by Lemma 1, $\Phi_x(T, x) = P(T, x) = M'(x)$ and $\Phi(T, 0) = M(0)$, and it follows that $\Phi(T, x) = M(x)$, $\forall x \in X$, and

$$\begin{aligned}
 J(u) &= M(x(T)) + \int_0^T (Q(x(t)) + \frac{1}{2} \langle Ru(t), u(t) \rangle) dt \\
 &= \left\{ \Phi(0, x_0) + Q(0)T - \int_0^T \mu(t, 0) dt \right\} \\
 &\quad + \frac{1}{2} \int_0^T \langle R(u(t) + R^{-1}B^*P(t, x(t))), u(t) + R^{-1}B^*P(t, x(t)) \rangle dt \\
 &\cong \Phi(0, x_0) + Q(0)T - \int_0^T \mu(t, 0) dt \equiv \rho(x_0),
 \end{aligned}
 \tag{3.10}$$

where $\rho(x_0)$ is a constant determined by x_0 . In view of Lemma 3, (1.3), the continuity of $\Phi(t, x)$ in x , and the property 1° of normal solution $P(t, x)$, we know that (3.10) is also valid for each $\{x_0, u(\cdot)\} \in X \times \mathcal{U}$ and corresponding $x(\cdot)$.

On the other hand, the property 6° of $P(t, x)$ shows that the feedback control (3.7) is admissible, i.e., in \mathcal{U} . Therefore, (3.10) indicates that (3.7) must be optimal, and

$$\min_{u(\cdot) \in \mathcal{U}} J(u; x_0) = \rho(x_0) \quad \forall x_0 \in X.
 \tag{3.11}$$

Thus we have completed the proof. QED.

4. Solution mapping $K(s, t, x)$ of a nonlinear integral equation. In order to explore the existence and possible expression of normal solution of the quasi-Riccati equation (3.1), we consider a nonlinear integral equation:

$$\begin{aligned}
 y(s) &= e^{A^*(T-s)} M' \left(e^{A(T-t)} x - \int_t^T e^{A(T-\eta)} B R^{-1} B^* y(\eta) d\eta \right) \\
 &\quad + \int_s^T e^{A^*(\sigma-s)} Q' \left(e^{A(\sigma-t)} x - \int_t^\sigma e^{A(\sigma-\eta)} B R^{-1} B^* y(\eta) d\eta \right) d\sigma,
 \end{aligned}
 \tag{4.1}$$

$(s, t, x) \in \Omega$,

where

$$\Omega = \{(s, t, x) | 0 \leq t \leq s \leq T, x \in X\}.
 \tag{4.2}$$

LEMMA 4. Let $G_t \in \mathcal{L}(L^2(t, T; X))$ and $H_t \in \mathcal{L}(L^2(t, T; X); X)$ be defined as

$$(G_t \varphi)(s) = \int_t^s e^{A(s-\sigma)} \varphi(\sigma) d\sigma, \quad s \in [t, T], \quad \varphi \in L^2(t, T; X),
 \tag{4.3}$$

$$H_t \varphi = \int_t^T e^{A(T-\sigma)} \varphi(\sigma) d\sigma, \quad \varphi \in L^2(t, T; X).
 \tag{4.4}$$

Suppose that $W \in \mathcal{L}(X)$ and $N \in \mathcal{L}(L^2(t, T; X))$ are nonnegative self-adjoint operators. Then, the following assertions are valid.

1°) The operator

$$V_t = I + (H_t^* W H_t + G_t^* N G_t) B R^{-1} B^* \in \mathcal{L}(L^2(t, T; X))
 \tag{4.5}$$

is bijective and its inverse operator is given by

$$\begin{aligned}
 V_t^{-1} &= I - (H_t^* W H_t + G_t^* N G_t) \sqrt{B R^{-1} B^*} \\
 &\quad \cdot (I + \sqrt{B R^{-1} B^*} (H_t^* W H_t + G_t^* N G_t) \sqrt{B R^{-1} B^*})^{-1} \sqrt{B R^{-1} B^*}.
 \end{aligned}
 \tag{4.6}$$

2°) If $N \in \mathcal{L}(L^2(t, T; X))$ is defined to be

$$(N\varphi)(s) = Y(s)\varphi(s), \quad s \in [t, T],$$

where $Y(\cdot): [t, T] \rightarrow \mathcal{L}(X)$ is a nonnegative self-adjoint operator function and strongly continuous in $s \in [t, T]$, then the above 1° holds and $V_t \in \mathcal{L}(C([t, T]; X))$ has bounded inverse operator $V_t^{-1} \in \mathcal{L}(C([t, T]; X))$ given by (4.6) too.

Proof. Assertion 1° can be verified directly. We see, by transposition,

$$(4.7) \quad \begin{aligned} (G_t^* \varphi)(s) &= \int_s^T e^{A^*(\sigma-s)} \varphi(\sigma) d\sigma, \quad s \in [t, T], \quad \varphi \in L^2(t, T; X), \\ (H_t^* \xi)(s) &= e^{A^*(T-s)} \xi, \quad s \in [t, T], \quad \xi \in X. \end{aligned}$$

By virtue of the facts that both V_t and V_t^{-1} , given by (4.5) and (4.6) with N described as above, map $C([t, T]; X)$ into itself, we obtain 2°. QED.

THEOREM 4. For any given $(t, x) \in [0, T] \times X$, there exists a unique solution $y(\cdot) \in C([t, T]; X)$ of (4.1).

Proof. (1) Existence: According to Corollary 1 and Theorem 2, there exists a unique optimal process $\{\hat{u}_{(t,x)}(\cdot), \hat{x}_{(t,x)}(\cdot)\}$ of (NQB P) $_t$, for the given initial state value x , which satisfies (2.11) and (2.12). Let

$$(4.8) \quad y(s; t, x) = e^{A^*(T-s)} M'(\hat{x}_{(t,x)}(T)) + \int_s^T e^{A^*(\sigma-s)} Q'(\hat{x}_{(t,x)}(\sigma)) d\sigma, \quad s \in [t, T].$$

From (4.8) and (2.12) we can directly verify that $y(\cdot; t, x)$ given by (4.8) is exactly a solution (4.1).

(2) Uniqueness: Let $F: C([t, T]; X) \times [0, T] \times X \rightarrow C([t, T]; X)$ be

$$(4.9) \quad \begin{aligned} F(y(\cdot), t, x)(s) &= y(s) - e^{A^*(T-s)} M' \left(e^{A(T-t)} x - \int_t^T e^{A(T-\eta)} B R^{-1} B^* y(\eta) d\eta \right) \\ &\quad - \int_s^T e^{A^*(\sigma-s)} Q' \left(e^{A(\sigma-t)} x - \int_t^\sigma e^{A(\sigma-\eta)} B R^{-1} B^* y(\eta) d\eta \right) d\sigma, \end{aligned} \quad s \in [t, T].$$

In order to prove the uniqueness, according to the implicit function theorem in Banach spaces (see [6, p. 115]), we only need to show that $D_y F(y(\cdot), t, x) \in \mathcal{L}(C([t, T]; X))$ is boundedly invertible for each $(y(\cdot), x) \in C([t, T]; X) \times X$ and fixed $t \in [0, T]$. In fact,

$$(4.10) \quad \begin{aligned} (D_y F(y(\cdot), t, x) z(\cdot))(s) &= z(s) + \int_t^T \Pi_t(s, \eta) B R^{-1} B^* z(\eta) d\eta \\ &= \{[I + (H_t^* W_t(y, x) H_t + G_t^* N_t(y, x) G_t) B R^{-1} B^*] z(\cdot)\}(s), \quad s \in [t, T] \\ &\quad \forall z(\cdot) \in C([t, T]; X) \end{aligned}$$

where G_t , H_t and their adjoint operators are given by (4.3), (4.4) and (4.7),

$$(4.11) \quad \begin{aligned} \Pi_t(s, \eta) &= e^{A^*(T-s)} M'' \left(e^{A(T-t)} x - \int_t^T e^{A(T-\xi)} B R^{-1} B^* y(\xi) d\xi \right) e^{A(T-\eta)} \\ &\quad + \int_{\max(s, \eta)}^T e^{A^*(\sigma-s)} Q'' \\ &\quad \cdot \left(e^{A(\sigma-t)} x - \int_t^\sigma e^{A(\sigma-\xi)} B R^{-1} B^* y(\xi) d\xi \right) e^{A(\sigma-\eta)} d\sigma, \end{aligned}$$

$$(4.12) \quad W_t(y, x) = M'' \left(e^{A(T-t)} x - \int_t^T e^{A(T-\xi)} B R^{-1} B^* y(\xi) d\xi \right),$$

$$(4.13) \quad (N_t(y, x)\varphi)(s) = Q'' \left(e^{A(s-t)} x - \int_t^s e^{A(s-\xi)} B R^{-1} B^* y(\xi) d\xi \right) \varphi(s),$$

$$s \in [t, T] \quad \forall \varphi \in L^2(t, T; X).$$

The convexity of $M(\cdot)$ and $Q(\cdot)$ implies that $M''(x)$ and $Q''(x) \in \mathcal{L}(X)$ are nonnegative self-adjoint, so that $W_t(y, x) \in \mathcal{L}(X)$ and $N_t(y, x) \in \mathcal{L}(L^2(t, T; X))$ are also non-negative. According to Lemma 4-2° and (4.10), $D_y F(y(\cdot), t, x) \in \mathcal{L}(C([t, T]; X))$ is boundedly invertible. QED.

We denote the solution mapping of (4.1) by

$$(4.14) \quad y(s) = K(s, t, x), \quad (s, t, x) \in \Omega.$$

Let $E(s, t, x)$ be defined as

$$(4.15) \quad E(s, t, x) = e^{A(s-t)} x - \int_t^s e^{A(s-\eta)} B R^{-1} B^* K(\eta, t, x) d\eta.$$

LEMMA 5. For any bounded subset $\Sigma \subset X$, let $\Omega_\Sigma = \{(s, t, x) | 0 \leq t \leq s \leq T, x \in \Sigma\}$. Then,

$$(4.16) \quad \sup_{(s, t, x) \in \Omega_\Sigma} \|K(s, t, x)\| = \text{const}(\Sigma) < +\infty,$$

$$(4.17) \quad \sup_{(s, t, x) \in \Omega_\Sigma} \|E(s, t, x)\| = \text{const}(\Sigma) < +\infty.$$

Proof. These two conclusions are consequences of (4.8), (1.3), 2° of Corollary 2 and (4.15). QED.

LEMMA 6. For any given $x \in X$, the following limit relation is equiconvergent with respect to $t \in [0, T]$,

$$(4.18) \quad \lim_{\delta x \rightarrow 0} \|K(\cdot, t, x + \delta x) - K(\cdot, t, x)\|_{C([t, T]; X)} = 0.$$

Proof. Let $\Delta K(s) = K(s, t, x + \delta x) - K(s, t, x)$ and

$$(4.19) \quad E_{\delta x}(s, t, x) = e^{A(s-t)} \delta x - \int_t^s e^{A(s-\eta)} B R^{-1} B^* \Delta K(\eta) d\eta.$$

By calculation we see that $\Delta K(\cdot)$ satisfies the following equation:

$$(4.20) \quad \begin{aligned} & (1 + (H_t^* \tilde{W}_{\delta x} H_t + G_t^* \tilde{N}_{\delta x} G_t) B R^{-1} B^*) \Delta K(\cdot) \\ & = H_t^* \tilde{W}_{\delta x} e^{A(T-t)} \delta x + G_t^* \tilde{N}_{\delta x} e^{A(\cdot-t)} \delta x, \end{aligned}$$

where G_t , H_t and their adjoint operators are given by (4.3), (4.4) and (4.7),

$$(4.21) \quad \tilde{W}_{\delta x} = \int_0^1 M''(E(T, t, x) + \lambda E_{\delta x}(T, t, x)) d\lambda \in \mathcal{L}(X),$$

and $\tilde{N}_{\delta x} \in \mathcal{L}(L^2(t, T; X)) \cap \mathcal{L}(C([t, T]; X))$ is a multiplication operator:

$$(4.22) \quad (\tilde{N}_{\delta x} \varphi)(s) = \int_0^1 Q''(E(s, t, x) + \lambda E_{\delta x}(s, t, x)) d\lambda \cdot \varphi(s), \quad s \in [t, T].$$

By Lemma 4-2° and (4.6), on account of the following facts,

$$\begin{aligned}
 & \sup_{0 \leq t \leq s \leq T} \|E(s, t, x)\| < +\infty, \quad \sup_{\substack{0 \leq t \leq s \leq T \\ \|\delta x\| \leq 1}} \|E_{\delta x}(s, t, x)\| < +\infty \quad (\text{by Lemma 5}), \\
 & \sup_{t \in [0, T]} \|G_t\|_{\mathcal{L}(L^2(t, T; X); C([t, T]; X))} < +\infty, \quad \sup_{t \in [0, T]} \|G_t^*\|_{\mathcal{L}(C([t, T]; X))} < +\infty \\
 (4.23) \quad & \hspace{15em} (\text{by (4.3) and (4.7)}), \\
 & \sup_{t \in [0, T]} \|H_t\|_{\mathcal{L}(L^2(t, T; X); X)} < +\infty, \quad \sup_{t \in [0, T]} \|H_t^*\|_{\mathcal{L}(X; C(t, T; X))} < +\infty \\
 & \hspace{15em} (\text{by (4.4) and (4.7)}),
 \end{aligned}$$

and for sufficiently small $\|\delta x\|$ (e.g. $\|\delta x\| \leq 1$) and all $t \in [0, T]$,

$$\begin{aligned}
 & \|\tilde{W}_{\delta x}\|_{\mathcal{L}(X)} \leq \text{const}, \quad \|\tilde{N}_{\delta x}\|_{\mathcal{L}(L^2(t, T; X))} \leq \text{const}, \quad \|\tilde{N}_{\delta x}\|_{\mathcal{L}(C([t, T]; X))} \leq \text{const} \\
 (4.24) \quad & \hspace{10em} (\text{from the } C^2 \text{ continuity of } M(\cdot) \text{ and } Q(\cdot)),
 \end{aligned}$$

we obtain, by inversion of (4.20), that

$$(4.25) \quad \|\Delta K(\cdot)\|_{C([t, T]; X)} \leq \text{const} \|\delta x\|,$$

where the constant is independent of $t \in [0, T]$ and δx such that $\|\delta x\| \leq 1$. This amounts to the equiconvergence of (4.18). QED.

THEOREM 5. *The solution mapping $K(s, t, x)$ of (4.1) possesses the following properties:*

1°) $K(s, t, x)$ is strongly continuous in $(s, t, x) \in \Omega$.

2°) $\langle K(s, t, x), y \rangle$ is differentiable in $s \in [t, T]$, for each x and y in $D(A)$, and

$$(4.26) \quad \frac{d}{ds} \langle K(s, t, x), y \rangle = -\langle K(s, t, x), Ay \rangle - \langle Q'(E(s, t, x)), y \rangle,$$

which is continuous in (s, t) such that $0 \leq t \leq s \leq T$.

3°) $K(s, t, x)$ is strongly differentiable in $t \in [0, T]$, for each $s \in [t, T]$ and $x \in D(A)$, and

$$\begin{aligned}
 K_t(s, t, x) = & \left\{ (D_y F(K(\cdot, t, x), t, x))^{-1} \left[e^{A^*(T-\cdot)} M''(E(T, t, x)) e^{A(T-t)} \right. \right. \\
 (4.27) \quad & \left. \left. + \int_t^T e^{A^*(\sigma-\cdot)} Q''(E(\sigma, t, x)) e^{A(\sigma-t)} d\sigma \right] \right\} (s) \\
 & \cdot [-Ax + BR^{-1}B^*K(t, t, x)].
 \end{aligned}$$

Moreover, $K_t(s, t, x)$ is strongly continuous in (s, t) such that $0 \leq t \leq s \leq T$, for each $x \in D(A)$.

4°) $K(s, t, x)$ is Fréchet differentiable in $x \in X$, for each (s, t) such that $0 \leq t \leq s \leq T$, and

$$\begin{aligned}
 K_x(s, t, x) = & \left\{ [D_y F(K(\cdot, t, x), t, x)]^{-1} \left[e^{A^*(T-\cdot)} M''(E(T, t, x)) e^{A(T-t)} \right. \right. \\
 (4.28) \quad & \left. \left. + \int_t^T e^{A^*(\sigma-\cdot)} Q''(E(\sigma, t, x)) e^{A(\sigma-t)} d\sigma \right] \right\} (s)
 \end{aligned}$$

Moreover,

(i) $K_x(s, t, x)\xi$ is strongly continuous in $(s, t, x) \in \Omega$, for each $\xi \in X$;

(ii) $K_x(s, t, x)$ is bounded in $\mathcal{L}(X)$ -norm for $0 \leq t \leq s \leq T$ and $x \in \Sigma$, where $\Sigma \subset X$ is any bounded subset.

We divide the proof of Theorem 5 into following three lemmas.

LEMMA 7. Assertions 1° and 2° of Theorem 5 are valid.

Proof. Assertion 1°: Because the associated space $C([t, T]; X)$ of the mapping F in (4.9) is t -variant, we cannot simply use the abstract implicit function theorem here. Let $\Delta s \rightarrow +0$, $\Delta t \rightarrow +0$ (similarly for other cases), and $\delta x \rightarrow 0$; we have

$$K(s + \Delta s, t + \Delta t, x + \delta x) - K(s, t, x) = I_1 + I_2 + I_3 \rightarrow 0,$$

because of

$$I_1 = K(s + \Delta s, t + \Delta t, x + \delta x) - K(s + \Delta s, t + \Delta t, x) \rightarrow 0 \quad (\text{by Lemma 6}),$$

$$I_2 = K(s + \Delta s, t + \Delta t, x) - K(s + \Delta s, t, x)$$

$$= K(s + \Delta s, t + \Delta t, x) - K(s + \Delta s, t + \Delta t, \hat{x}_{(t,x)}(t + \Delta t)) \rightarrow 0$$

$$(\text{by (4.8), (2.12), Lemma 6 and } \hat{x}_{(t,x)}(t + \Delta t) \rightarrow x \text{ when } \Delta t \rightarrow 0),$$

$$I_3 = K(s + \Delta s, t, x) - K(s, t, x) \rightarrow 0.$$

Assertion 2°: By (4.1), for $x, y \in D(A)$, we can differentiate $\langle K(s, t, x), y \rangle$ straight to achieve (4.26) and the assertion 2°. QED.

LEMMA 8. Assertion 3° of Theorem 5 is valid.

Proof. Let $\Delta > 0$ be sufficiently small and

$$\delta K(s, t, x, \Delta) = \frac{1}{\Delta} (K(s, t + \Delta, x) - K(s, t, x)), \quad s \in [t + \Delta, T].$$

By calculation we see that $\delta K(\cdot, t, x, \Delta)$ satisfies the following equation:

$$\begin{aligned} & (I + (H_{t+\Delta}^* \hat{W}_{t+\Delta} H_{t+\Delta} + G_{t+\Delta}^* \hat{N}_{t+\Delta} G_{t+\Delta}) BR^{-1} B^*) \delta K(\cdot, t, x, \Delta) \\ (4.29) \quad & = [H_{t+\Delta}^* \hat{W}_{t+\Delta} e^{A(T-(t+\Delta))} + G_{t+\Delta}^* \hat{N}_{t+\Delta} e^{A(-(t+\Delta))}] \\ & \quad \cdot \left\{ \frac{1}{\Delta} (I - e^{A\Delta}) x + \frac{1}{\Delta} \int_t^{t+\Delta} e^{A(t+\Delta-\eta)} BR^{-1} B^* K(\eta, t, x) d\eta \right\}, \end{aligned}$$

where G_t , H_t and their adjoint operators are given by (4.3), (4.4) and (4.7),

$$(4.30) \quad \hat{W}_{t+\Delta} = \int_0^1 M''(E(T, t, x) + \lambda E^\Delta(T, t, x)) d\lambda \in \mathcal{L}(X),$$

$$(4.31) \quad (\hat{N}_{t+\Delta} \varphi)(s) = \int_0^1 Q''(E(s, t, x) + \lambda E^\Delta(s, t, x)) d\lambda \cdot \varphi(s), \quad s \in [t + \Delta, T]$$

(a multiplication operator on $L^2(t + \Delta, T; X)$)

in which $E(s, t, x)$ given by (4.15), and

$$\begin{aligned} E^\Delta(s, t, x) &= (e^{A(s-(t+\Delta))} - e^{A(s-t)})x + \int_t^{t+\Delta} e^{A(s-\eta)} BR^{-1} B^* K(\eta, t, x) d\eta \\ (4.32) \quad & - \int_{t+\Delta}^s e^{A(s-\eta)} BR^{-1} B^* (K(\eta, t + \Delta, x) - K(\eta, t, x)) d\eta. \end{aligned}$$

For $0 \leq t \leq s \leq T$ and $x \in D(A)$, in view of (4.3), (4.4), (4.6), (4.7), (4.29)–(4.32), (4.23) and (4.10), we obtain

(4.33)

$$\lim_{\Delta \rightarrow +0} \delta K(s, t, x, \Delta) = \{[D_y F(K(\cdot, t, x), t, x)]^{-1} [H_t^* \hat{W}_t e^{A(T-t)} + G_t^* \hat{N}_t e^{A(\cdot-t)}]\}(s) \\ \cdot (-Ax + BR^{-1}B^*K(t, t, x)).$$

Hence (4.27) holds for the right derivative $K_t^+(s, t, x)$, $0 \leq t < s \leq T$, $x \in D(A)$. Similarly it holds for $K_t^-(s, t, x)$, $0 \leq t \leq s \leq T$, $x \in D(A)$.

The remains can be deduced from (4.27), (4.10), (4.6), (1.3) and Lemmas 6 and 7. QED.

LEMMA 9. *The assertion 4° of Theorem 5 is valid.*

Proof. Now we can fix $t \in [0, T]$ arbitrarily. Apply the abstract implicit function theorem to the mapping F of (4.9); then we have the Fréchet differentiability of $K(s, t, x)$ in $x \in X$; moreover,

$$K_x(\cdot, t, x) = -(D_y F(K(\cdot, t, x), t, x))^{-1} D_x F(K(\cdot, t, x), t, x) \\ = -(D_y F(K(\cdot, t, x), t, x))^{-1} (-e^{A^*(T-\cdot)} M''(E(T, t, x)) e^{A(T-t)} \\ - \int_{\cdot}^T e^{A^*(\sigma-\cdot)} Q''(E(\sigma, t, x)) e^{A(\sigma-t)} d\sigma).$$

Thus (4.28) is true. The remains can be deduced from (4.28), (4.10), (4.6), (1.3) and Lemmas 6 and 7. QED.

Thus we complete the proof of Theorem 5.

5. Feedback operator $P(t, x)$ and closed-loop solution. $K(s, t, x): \Omega \rightarrow X$ is the solution mapping (4.14) of (4.1). Let

$$(5.1) \quad P(t, x) = K(t, t, x): [0, T] \times X \rightarrow X.$$

We shall prove that $P(t, x)$ given by (5.1) is a normal solution of the quasi-Riccati equation (3.1), so that by Theorem 3 it is a feedback operator of closed-loop optimal control of (NQBP).

LEMMA 10. *$P(t, x)$ given by (5.1) possesses the properties 1°, 2° and 3° of Definition 1.*

Proof. By Theorem 5 and (4.26)–(4.28) we have

$$(5.2) \quad \frac{d}{dt} \langle P(t, x), y \rangle = \left\{ \frac{d}{ds} \langle K(s, t, x), y \rangle + \frac{d}{dt} \langle K(s, t, x), y \rangle \right\} \Big|_{s=t} \\ = -\langle P(t, x), Ay \rangle - \langle Q'(x), y \rangle \\ + \left\{ (D_y F(K, t, x))^{-1} \left[e^{A^*(T-\cdot)} M''(E(T, t, x)) e^{A(T-t)} \right. \right. \\ \left. \left. + \int_{\cdot}^T e^{A^*(\sigma-\cdot)} Q''(E(\sigma, t, x)) e^{A(\sigma-t)} d\sigma \right] \right\}(t) \\ \cdot (-Ax + BR^{-1}B^*P(t, x)), \quad (t, x, y) \in [0, T] \times D(A) \times D(A),$$

and

$$(5.3) \quad P_x(t, x) = \left\{ (D_y F(K, t, x))^{-1} \left[e^{A^*(T-\cdot)} M''(E(T, t, x)) e^{A(T-t)} + \int_t^T e^{A^*(\sigma-\cdot)} Q''(E(\sigma, t, x)) e^{A(\sigma-t)} d\sigma \right] \right\} (t),$$

$$(t, x) \in [0, T] \times X.$$

The mentioned properties 1°, 2° and 3° can be verified by means of (5.1)–(5.3) and those properties of $K(s, t, x)$ described in Theorem 5. QED.

LEMMA 11. For each $t \in [0, T]$, $P(t, \cdot): X \rightarrow X$ given by (5.1) is gradient operator.

Proof. According to Theorem 2.5.2 of [6], it is equivalent to show that $P_x(t, x) \in \mathcal{L}(X)$ is self-adjoint for each $t \in [0, T]$ and $x \in X$. In fact, by (5.3), (4.10) and (4.6), we have

$$(5.4) \quad P_x(t, x) = \left\{ e^{A^*(T-t)} M''(E(T, t, x)) e^{A(T-t)} + \int_t^T e^{A^*(\sigma-t)} Q''(E(\sigma, t, x)) e^{A(\sigma-t)} d\sigma \right\} \\ - Z_t(t) \sqrt{BR^{-1}B^*} (I + \sqrt{BR^{-1}B^*} Z_t \sqrt{BR^{-1}B^*})^{-1} \sqrt{BR^{-1}B^*} \\ \cdot \left\{ e^{A^*(T-\cdot)} M''(E(T, t, x)) e^{A(T-t)} + \int_t^T e^{A^*(\sigma-\cdot)} Q''(E(\sigma, t, x)) e^{A(\sigma-t)} d\sigma \right\},$$

where

$$(5.5) \quad Z_t = H_t^* W_E H_t + G_t^* N_E G_t, \\ Z_t(t) \varphi = (Z_t \varphi)(t) \quad \forall \varphi \in L^2(t, T; X),$$

and

$$(5.6) \quad W_E = M''(E(T, t, x)), \\ (N_E \varphi)(\sigma) = Q''(E(\sigma, t, x)) \varphi(\sigma), \quad \sigma \in [t, T], \quad \varphi \in L^2(t, T; X).$$

Note that $Z_t(t) \in \mathcal{L}(L^2(t, T; X); X)$; we can verify that its adjoint operator $Z_t(t)^* \in \mathcal{L}(X; L^2(t, T; X))$ is given by

$$(5.7) \quad Z_t(t)^* = e^{A^*(T-\cdot)} M''(E(T, t, x)) e^{A(T-t)} + \int_t^T e^{A^*(\sigma-\cdot)} Q''(E(\sigma, t, x)) e^{A(\sigma-t)} d\sigma.$$

Substitute (5.7) for the last bracket of (5.4). We see that $P_x(t, x) \in \mathcal{L}(X)$ is self-adjoint for $(t, x) \in [0, T] \times X$. QED.

LEMMA 12. The Cauchy problem (3.2) with $P(t, x)$ given by (5.1) admits a global mild solution $x(\cdot) \in C([0, T]; X)$ for any given $x_0 \in X$.

Proof. We show that (see (4.15))

$$(5.8) \quad x(t) = E(t, 0, x_0), \quad t \in [0, T]$$

is a desired mild solution of (3.2), i.e., it is a strongly continuous solution of following equation:

$$(5.9) \quad x(t) = e^{At} x_0 - \int_0^t e^{A(t-s)} BR^{-1} B^* P(s, x(s)) ds, \quad t \in [0, T].$$

Obviously, $E(\cdot, 0, x_0) \in C([0, T]; X)$. We only need to prove

$$(5.10) \quad K(t, 0, x_0) = K(t, t, E(t, 0, x_0)), \quad t \in [0, T], \quad x_0 \in X,$$

for then (5.9) is satisfied by (5.8):

$$\begin{aligned} E(t, 0, x_0) &= e^{At}x_0 - \int_0^t e^{A(t-s)}BR^{-1}B^*K(s, 0, x_0) ds \\ &= e^{At}x_0 - \int_0^t e^{A(t-s)}BR^{-1}B^*K(s, s, E(s, 0, x_0)) ds \quad (\text{by (5.10)}) \\ &= e^{At}x_0 - \int_0^t e^{A(t-s)}BR^{-1}B^*P(s, E(s, 0, x_0)) ds \quad (\text{by (5.1)}). \end{aligned}$$

Now we prove (5.10). Let $\Delta K_{(t, x_0)}(s) = K(s, t, E(t, 0, x_0)) - K(s, 0, x_0)$, $s \in [t, T]$. By calculation we obtain that $\Delta K_{(t, x_0)}(\cdot)$ satisfies the following equation:

$$(5.11) \quad (I + (H_t^*W_{\Delta K}H_t + G_t^*N_{\Delta K}G_t)BR^{-1}B^*)\Delta K_{(t, x_0)}(\cdot) = 0,$$

where

$$(5.12) \quad W_{\Delta K} = \int_0^1 M'' \left(E(T, 0, x_0) - \lambda \int_t^T e^{A(T-\eta)}BR^{-1}B^*\Delta K_{(t, x_0)}(\eta) d\eta \right) d\lambda,$$

$$(5.13) \quad (N_{\Delta K}\varphi)(s) = \int_0^1 Q'' \left(E(s, 0, x_0) - \lambda \int_t^s e^{A(s-\eta)}BR^{-1}B^*\Delta K_{(t, x_0)}(\eta) d\eta \right) d\lambda \cdot \varphi(s),$$

$s \in [t, T], \quad \varphi \in L^2(t, T; X).$

By Lemma 4, we conclude that $\Delta K_{(t, x_0)}(\cdot) = 0$ in $C([t, T]; X)$. Therefore (5.10) is valid. Besides, the well properties of $P(t, x)$ imply that the strongly continuous solution of (5.9) is unique. QED.

THEOREM 6. $P(t, x)$ given by (5.1) is a normal solution of the quasi-Riccati operator equation (3.1).

Proof. Obviously this $P(t, x)$ is such that (by (4.1))

$$(5.14) \quad P(T, x) = K(T, T, x) = M'(x), \quad x \in X.$$

From (5.2) and (5.3) we can verify directly that (3.1) is satisfied by this $P(t, x)$:

$$\begin{aligned} &\frac{d}{dt} \langle P(t, x), y \rangle + \langle P_x(t, x)Ax, y \rangle + \langle P(t, x), Ay \rangle + \langle Q'(x), y \rangle - \langle P_x(t, x)BR^{-1}B^*P(t, x), y \rangle \\ &= \{ -\langle P(t, x), Ay \rangle - \langle Q'(x), y \rangle + \langle P_x(t, x)(-Ax + BR^{-1}B^*P(t, x)), y \rangle \\ &\quad + \langle P_x(t, x)Ax, y \rangle + \langle P(t, x), Ay \rangle + \langle Q'(x), y \rangle - \langle P_x(t, x)BR^{-1}B^*P(t, x), y \rangle \} = 0. \end{aligned}$$

By Lemmas 10–12 we know that all the properties described in Definition 1 are possessed by this $P(t, x)$. Thus it is a normal solution of (3.1). QED.

THEOREM 7 (Closed-loop theorem). *For any given $x_0 \in X$, there exists a closed-loop optimal control of (NQBP), given by the following state feedback:*

$$(5.15) \quad u(t) = -R^{-1}B^*P(t, x(t)) = -R^{-1}B^*K(t, t, x(t)), \quad t \in [0, T],$$

where $K(s, t, x)$ is the solution operator (4.14) of the nonlinear integral equation (4.1) and $P(t, x)$ is given by (5.1).

Proof. This closed-loop result is obtained by combination of Theorem 3 with Theorem 6. QED.

6. Remarks. We have two remarks about the relation between the closed-loop result of (NQBP) and that of quadratic optimal control, and that of the nonquadratic differential game problem.

Remark 1. If $M(\cdot)$ and $Q(\cdot)$ in (1.2) reduce to quadratic forms, $M(x) = \frac{1}{2}\langle \hat{M}x, x \rangle$ and $Q(x) = \frac{1}{2}\langle \hat{Q}x, x \rangle$, where $\hat{M} \in \mathcal{L}(X)$ and $\hat{Q} \in \mathcal{L}(X)$ are nonnegative self-adjoint, then we can verify that (4.1) becomes following integral equation of Fredholm type [8]:

$$y(s) + \int_t^T \Psi_t(s, \eta) B R^{-1} B^* y(\eta) d\eta = \left[e^{A^*(T-s)} \hat{M} e^{A(T-t)} + \int_s^T e^{A^*(\sigma-s)} \hat{Q} e^{A(\sigma-t)} d\sigma \right] x, \quad (6.1)$$

$(s, t, x) \in \Omega$

where

$$\Psi_t(s, \eta) = e^{A^*(T-s)} \hat{M} e^{A(T-\eta)} + \int_{\max(s, \eta)}^T e^{A^*(\sigma-s)} \hat{Q} e^{A(\sigma-\eta)} d\sigma, \quad (6.2)$$

$(s, \eta) \in [t, T] \times [t, T]$.

The solution operator $K(s, t, x)$ of (6.1) turns out to be a bounded linear operator in x , $K(s, t, x) = \hat{K}(s, t)x$. As a result, (5.1) gives $P(t, x) = \hat{P}(t)x$ where $\hat{P}(t) = \hat{K}(t, t) \in \mathcal{L}(X)$ is the strongly continuous and self-adjoint solution of following Riccati operator equation:

$$\begin{aligned} \frac{d}{dt} \langle \hat{P}(t)x, y \rangle + \langle Ax, \hat{P}(t)y \rangle + \langle \hat{P}(t)x, Ay \rangle \\ + \langle \hat{Q}x, y \rangle - \langle \hat{P}(t) B R^{-1} B^* \hat{P}(t)x, y \rangle = 0, \quad (t, x, y) \in [0, T] \times D(A) \times D(A), \\ \hat{P}(T) = \hat{M}. \end{aligned} \quad (6.3)$$

Thus in this case, the closed-loop result (5.15) coincides with the well-known linear state feedback [1], [9]

$$u(t) = -R^{-1} B^* \hat{P}(t)x(t), \quad t \in [0, T]. \quad (6.4)$$

Remark 2. The method in this paper can be applied to deal with nonquadratic differential game problem of Bolza type on Hilbert spaces:

$$\begin{aligned} \frac{dx}{dt} = Ax(t) + Bu(t) + Cv(t), \quad x(0) = x_0, \\ J(u, v) = M(x(T)) + \int_0^T (Q(x(t)) + \frac{1}{2}\langle R_1 u(t), u(t) \rangle + \frac{1}{2}\langle R_2 v(t), v(t) \rangle) dt, \end{aligned} \quad (6.5)$$

where $C \in \mathcal{L}(V; X)$, $R_1 > 0$ and $R_2 < 0$ coercively, and it is desired to find an optimal closed-loop strategy $\{\hat{u}(\cdot), \hat{v}(\cdot)\} \in L^2(0, T; U) \times L^2(0, T; V)$ such that

$$J(\hat{u}, v) \leq J(\hat{u}, \hat{v}) \leq J(u, \hat{v}) \quad (6.6)$$

for arbitrary admissible feedback control $u(\cdot)$ and $v(\cdot)$. We give a synthesis result whose proof is similar to Theorem 3 and omitted here.

THEOREM 8. *If the following quasi-Riccati operator equation*

$$\begin{aligned} \frac{d}{dt} \langle P(t, x), y \rangle + \langle P_x(t, x) Ax, y \rangle + \langle P(t, x), Ay \rangle + \langle Q'(x), y \rangle \\ - \langle P_x(t, x) (B R_1^{-1} B^* + C R_2^{-1} C^*) P(t, x), y \rangle = 0, \\ P(T, x) = M'(x), \quad x \in X \end{aligned} \quad (6.7)$$

$(t, x, y) \in [0, T] \times D(A) \times D(A)$,

has a normal solution $P(t, x): [0, T] \times X \rightarrow X$ (as in Definition 1), then, for any given $x_0 \in X$, there exists a closed-loop optimal strategy

$$(6.8) \quad \begin{aligned} u(t) &= -R_1^{-1} B^* P(t, x(t)), \\ v(t) &= -R_2^{-1} C^* P(t, x(t)), \end{aligned} \quad t \in [0, T].$$

This result is a generalization of the quadratic differential game [10].

OPTIMIZATION OF "log x" ENTROPY OVER LINEAR EQUALITY CONSTRAINTS*

YAIR CENSOR† AND ARNOLD LENT‡

Abstract. In this paper we develop a special-purpose iterative algorithm, of the row-action type, for solving the problem of maximizing the "log x" entropy functional over linear equality constraints. The algorithm employs "projections" onto hyperplanes which we call "log x" entropy projections. A complete proof of convergence is given.

Key words. entropy optimization, row-action algorithm, linear equality

AMS(MOS) subject classifications. 49D20, 65K05, 90C25, 94A17

1. Introduction. The " $x \log x$ " entropy functional, $\text{ent } x$, maps the nonnegative orthant \mathbb{R}_+^n of the n -dimensional Euclidean space \mathbb{R}^n into \mathbb{R} according to

$$(1) \quad \text{ent } x := - \sum_{j=1}^n x_j \log x_j,$$

where, by definition, $0 \log 0 := 0$.

Entropy optimization problems which seek to maximize $\text{ent } x$ over linear constraints sets (equality, inequality or interval constraints) arise in various fields of applications. These include (i) *transportation planning* (the gravity model) see, e.g., [31], (ii) *statistics* (adjustment of contingency tables, maximum-likelihood estimation) see, e.g., [12], (iii) *linear numerical analysis* (preconditioning of a matrix prior to calculation of eigenvalues and eigenvectors) see, e.g. [15], (iv) *chemistry* (the chemical equilibrium problem) see, e.g., the remark and references mentioned in [16], (v) *geometric programming* (the dual problem) see, e.g., [40], (vi) *image processing* (image reconstruction from projections, image restoration) see, e.g., [6], [18], [22]. For further general information we mention here [28], [30], [19].

The use of entropy is rigorously founded in several areas, see, e.g., [1], [28], [34], while in other situations entropy optimization is used on a more empirical basis. In image reconstruction from projections (from where our own motivation to study entropy optimization comes), arguments in favor of maximum entropy imaging have been given, typically expressing a conviction that the maximum entropy approach yields the most probable solution agreeing with the available data, i.e., a solution which is most objective or maximally uncommitted with respect to missing information.

Another measure of entropy is the "log x" entropy functional defined on the positive orthant by

$$(2) \quad h(x) := \sum_{j=1}^n \log x_j.$$

This entropy was first proposed by Burg in [3], see [17, §§ 5.17, 5.18] and [28], and has since then provoked a controversy regarding the question of which entropy functional should be used in different situations. This question was discussed in [11], [17], [39], [19, § 10.4.14], and recently in [29].

We do not enter the argument of “ $x \log x$ ” entropy versus “ $\log x$ ” entropy at all but are rather interested in the mathematical question of the construction and study of useful algorithms for solving computationally linearly constrained entropy optimization problems.

Several recent publications discuss algorithms for optimization of the “ $x \log x$ ” entropy functional over various linear constraints. These include [32], where the convergence of the algorithm called “MART” (Multiplicative Algebraic Reconstruction Technique), first proposed in [20], was proved, and [37], where a maximum entropy algorithm called “MENT” was proposed, studied and experimented with. References [23], [24] contain further results about the practical performance of “ $x \log x$ ” entropy optimization algorithms in image reconstruction from projections.

The algorithms presented in [10] are applicable to “ $x \log x$ ” (but *not* to “ $\log x$ ”) entropy optimization over equality, inequality and interval linear constraints. They are based on the method of Bregman [2], see also [5], [8], [31].

In spite of the extensive work done on algorithms for “ $x \log x$ ” entropy optimization problems, little attention has been given to the development of special-purpose algorithms for “ $\log x$ ” entropy optimization. In this paper we develop and study such an algorithm.

Special-purpose algorithms for solving optimization problems with a specific objective function have demonstrated their effectiveness in several fields of applications. For example, in image reconstruction from projections several special-purpose algorithms were proposed, studied and tested [7], [14], [21], [25]. The method of Hildreth [26], further studied in [33], is a special-purpose method for norm minimization over linear inequalities. Reference [4] is a recent review of various such special algorithms.

The algorithm we study here is a special-purpose algorithm, of the row-action type (in the sense of [4]), for solving the “ $\log x$ ” entropy optimization problem over linear equality constraints. We have first proposed this algorithm on a heuristic basis and without mathematical analysis in [9]. It was implemented by Jain and Ranganath [27], who applied it to a problem of two-dimensional spectral estimation. The present paper is, to our knowledge, the first presentation of a thorough study including a proof of convergence of this algorithm. This paper is statedly a mathematical, not an experimental, study and therefore we make no claims whatsoever about the efficacy of the algorithm presented here in practical application. However, the row-action nature of the algorithm (discussed later) points to its potential advantages for handling very large and sparse problems.

Bregman’s theory [2], as applied and extended in [10] is not *immediately* applicable to the case of “ $\log x$ ” entropy because of the singularity of this function at the boundary of its domain. However, by showing that the iterates produced by the algorithm we study “stay away” from that boundary, we are able to analyze convergence along the lines of Bregman’s original theory.

2. Problem formulation and algorithm development. Consider the following “ $\log x$ ” entropy optimization problem:

$$(3) \quad \begin{array}{ll} \text{Max } h(x) \\ \text{subject to } Ax = b \quad \text{and} \quad x > 0 \end{array}$$

where $h(x)$ is given by (2), A is a given real $m \times n$ matrix, $b \in \mathbb{R}^m$ is a given vector and $x > 0$ means $x_j > 0$, $j = 1, 2, \dots, n$. The system $Ax = b$ is alternatively written as $\langle a^i, x \rangle = b_i$, $i = 1, 2, \dots, m$, where $\langle \cdot, \cdot \rangle$ is the (usual) inner product in \mathbb{R}^n and a^i (all vectors are columns) is the i th column of A^T (T stands for transpose).

Define the feasible set of (3) by $F := \{x \in \mathbb{R}^n \mid Ax = b\} \cap \text{int } \mathbb{R}_+^n$ and the null space of A by $N(A) = \{x \in \mathbb{R}^n \mid Ax = 0\}$.

The function $[-h(x)]$ is strictly convex over $\text{int } \mathbb{R}_+^n$ and, for convenience, we rewrite (3) as

$$(4) \quad \begin{aligned} &\text{Min } [-h(x)] \\ &\text{subject to } x \in F. \end{aligned}$$

Introducing dual variables for the equality constraints, we form the Lagrangian associated with (4),

$$(5) \quad L(x, u) = -\sum_{j=1}^n \log x_j + \sum_{i=1}^m u_i (\langle a^i, x \rangle - b_i).$$

Duality (see, e.g., [35, p. 316] permits us to define the dual function

$$(6) \quad \phi(u) = \text{Inf } \{L(x, u) \mid x \in \text{int } \mathbb{R}_+^n\}.$$

The next proposition gives a necessary and sufficient condition for the solvability of (4).

PROPOSITION 1. *If $F \neq \emptyset$ and $A \neq 0$, then a necessary and sufficient condition for the solution of (4) to exist is*

$$(7) \quad N(A) \cap \mathbb{R}_+^n = \{0\}.$$

Proof. Sufficiency. Assume that $\text{Inf } \{-h(x) \mid x \in F\} = -\infty$ and take a sequence $\{x^k\}_{k=0}^\infty$ such that $x^k \in F$ and $-h(x^k) = -k$ for all $k \geq 0$. Such a sequence exists since $\{h(x) \mid x \in F\}$ is an interval. This sequence must be unbounded because

$$\exp h(x) = \prod_{j=1}^n x_j \leq \left(\max_{1 \leq j \leq n} x_j \right)^n$$

and, therefore,

$$\max_{1 \leq j \leq n} x_j^k \geq \exp(k/n) \quad \text{for all } k \geq 0.$$

Take a subsequence of $\{x^k / \|x^k\|\}$ which converges to a $v \in \mathbb{R}^n$. This limit must have the properties $v \geq 0$ and $\|v\| = 1$. However, since $Ax^k = b$, $Ax^k / \|x^k\| = b / \|x^k\|$ and the unboundedness of $\{x^k\}$ implies that $\|x^k\| \rightarrow \infty$, thus, $Av = 0$ which shows that (7) does not hold.

Necessity. Suppose that x^* solves (4) and that there exists

$$v \geq 0, \quad v \neq 0 \quad \text{with } Av = 0.$$

Then, $x^* + tv \in F$ for $t \geq 0$, and $-h(x + tv) \searrow -\infty$, as t gets arbitrarily large, which is a contradiction. \square

In view of Proposition 1, we henceforth make the following assumptions on problem (4)

$$(A1) \quad a^i \neq 0 \text{ for all } i = 1, 2, \dots, m,$$

$$(A2) \quad F \neq \emptyset, \text{ and}$$

$$(A3) \quad N(A) \cap \mathbb{R}_+^n = \{0\}.$$

Next we derive our algorithm for solving (4). The underlying principle is the construction of a primal-dual algorithm, i.e., one in which both primal variables $\{x^k\}$

and dual variables $\{u^k\}$ are iteratively changed in such a way as to increase the dual function $\phi(u)$. However, as sometimes happens with primal-dual algorithms for linear equality constrained problems, the algorithm in its final form does not require that a dual sequence $\{u^k\}$ be actually updated (see, e.g., [32]).

The necessary conditions for the minimization of the Lagrangian (5) are

$$(8) \quad 0 = \frac{\partial L}{\partial x_j} = \frac{-1}{x_j} + \sum_{i=1}^m u_i a_j^i, \quad j = 1, 2, \dots, n.$$

Therefore, we impose the relation

$$(9) \quad x_j^k = \frac{1}{(A^T u^k)_j}, \quad j = 1, 2, \dots, n$$

on the primal and the dual iterates. We use cyclic coordinate ascent for the dual vectors, changing only one coordinate of u^k during each iteration, i.e.

$$(10) \quad u_i^{k+1} = \begin{cases} u_i^k, & i \neq i_k, \\ u_{i_k}^{k+1}, & i = i_k, \end{cases}$$

where $\{i_k\}_{k=0}^\infty$ is the *control sequence* of the algorithm. This is a sequence of indices according to which the algorithm works. In the k th iterative step, when u^{k+1} and x^{k+1} are calculated from u^k and x^k , the index i_k determines which coordinate of u^k will be changed, and which equation $\langle a^{i_k}, x \rangle = b_{i_k}$ will be used to update x^k .

The *cyclic control*, according to which our algorithm is controlled, is given by the sequence

$$(11) \quad i_k = k(\bmod m) + 1,$$

where m is the number of rows in A .

In view of (9) and (10) we write

$$(12) \quad x_j^{k+1} = \frac{1}{\sum_{i=1}^m u_i^{k+1} a_j^i} = \frac{x_j^k \cdot \sum_{i=1}^m u_i^k a_j^i}{\sum_{i=1}^m u_i^k a_j^i - B_k a_j^{i_k}},$$

where B_k is defined by

$$(13) \quad B_k := u_{i_k}^k - u_{i_k}^{k+1}.$$

Thus,

$$x_j^{k+1} = \frac{x_j^k}{1 - B_k a_j^{i_k} x_j^k},$$

or

$$(14) \quad \frac{1}{x_j^{k+1}} = \frac{1}{x_j^k} - B_k a_j^{i_k}, \quad j = 1, 2, \dots, n,$$

which is the final form of the iterative step for the primal iterates.

Equation (13) may be rewritten as

$$(15) \quad u^{k+1} = u^k - B_k e^{i_k}$$

where e^i stands for the i th standard basis-vector in \mathbb{R}^m with 1 in its i th coordinate and zeros elsewhere.

To complete the definition of our algorithm we define B_k by imposing the condition that

$$(16) \quad \langle a^{i_k}, x^{k+1} \rangle = b_{i_k}$$

which means that x^{k+1} has to fulfill the i_k th constraint equation. This leads to the notion of the "log x" *entropy projection* which is studied in the next section.

3. "log x" entropy projections onto hyperplanes. We define the concept of "log x" *entropy projection* as follows. Let $H = \{x \in \mathbb{R}^n \mid \langle a, x \rangle = \beta\}$ be a given hyperplane with $a = (a_j) \neq 0$. Denote

$$(17) \quad H^+ := H \cap \text{int } \mathbb{R}_+^n$$

and assume that $H^+ \neq \emptyset$. Let $y \in \text{int } \mathbb{R}_+^n$ be a given vector, and define, for every $j = 1, 2, \dots, n$,

$$(18) \quad \alpha_j := a_j y_j.$$

Assume that all $\alpha_j \neq 0$. This does not restrict the generality because, as seen below, if $\alpha_j = 0$ it can be deleted beforehand without affecting what we do.

Next define

$$(19) \quad r := \text{Max } \{1/\alpha_j \mid 1 \leq j \leq n, a_j < 0\};$$

if $a_j \geq 0$ for all j , set $r \equiv -\infty$, and

$$(20) \quad t := \text{Min } \{1/\alpha_j \mid 1 \leq j \leq n, a_j > 0\};$$

if $a_j \leq 0$ for all j , set $t \equiv \infty$.

DEFINITION 1. The "log x" *entropy projection* of y onto H^+ is defined as the vector y' obtained from the system

$$(21) \quad y'_j = \frac{y_j}{1 - B y_j a_j}, \quad j = 1, 2, \dots, n,$$

$$(22) \quad \langle a, y' \rangle = \beta,$$

where B obeys the additional restriction

$$(23) \quad r < B < t.$$

PROPOSITION 2. Given $H^+ \neq \emptyset$ as in (17) with $a \neq 0$ and a vector $y > 0$, the system (21)–(23) determines uniquely the vector $y' > 0$, which is the "log x" *entropy projection* of y onto H^+ , and the real number B which is called the projection parameter associated with the "log x" *entropy projection* of y onto H^+ .

Proof. The system (21), (22) gives rise to

$$(24) \quad \sum_{j=1}^n a_j \frac{y_j}{1 - B y_j a_j} = \beta$$

which leads us to consider the behavior of the real-valued function

$$(25) \quad g(s) := \sum_{j=1}^n \frac{\alpha_j}{(1 - s \alpha_j)} = \sum_{j=1}^n \left(\frac{1}{\alpha_j} - s \right)^{-1}$$

of the single variable s , $r < s < t$. Here we see that we may assume $\alpha_j \neq 0$ since $\alpha_j = 0$ contributes nothing to the first sum in (25) anyway. The derivative

$$(26) \quad g'(s) = \sum_{j=1}^n \left(\frac{1}{\alpha_j} - s \right)^{-2}$$

is always nonnegative, thus $g(s)$ is monotonically increasing. At the points $s_j = 1/\alpha_j$, $j = 1, 2, \dots, n$, $g(s)$ is discontinuous in such a manner that

$$(27) \quad g(s) = \beta$$

has exactly one solution s_j^* between each two consecutive s_j 's.

We verify the existence of a solution to (27). There are three cases:

Case (i). $-\infty < r < t < \infty$. In this case $\lim_{s \rightarrow r^+} g(s) = -\infty$ and $\lim_{s \rightarrow t^-} g(s) = +\infty$. Hence, by continuity of g over the open interval (r, t) , there is a solution to (27).

Case (ii). $-\infty = r < t < \infty$. In this case $a_j \geq 0$ for all j , $\lim_{s \rightarrow r^+} g(s) = 0$ and $\lim_{s \rightarrow t^-} g(s) = \infty$. But, by assumption, $H^+ \neq \emptyset$, so β in the definition of H must be positive, hence (27) has a (finite) solution.

Case (iii). $-\infty < r < t = \infty$. This case is handled in the same way as Case (ii) but with $\beta < 0$.

According to (23) we pick precisely that solution s^* such that $r < s^* < t$ and set

$$(28) \quad B = s^*.$$

To conclude the proof we verify that y' which is uniquely determined from (21) and (28) belongs to $\text{int } \mathbb{R}_+^n$. Indeed, if $a_j = 0$ then $y'_j = y_j > 0$. If $a_j > 0$ then, from (18), (20) and (28),

$$(29) \quad 1 - B y_j a_j > 0,$$

which shows, by (21), that $y'_j > 0$. If $a_j < 0$, then from (18), (19) and (28), again (29) holds. \square

4. Convergence of the algorithm. Based on the considerations set forth in the previous sections we study the following algorithm for the solution of the "log x " entropy optimization problem (4).

ALGORITHM.

Initialization: $x^0 > 0$ is a positive vector for which there exists a $u^0 \in \mathbb{R}^m$ such that

$$(30) \quad x_j^0 \cdot (A^T u^0)_j = 1, \quad j = 1, 2, \dots, n.$$

Iterative Step:

$$(31) \quad \frac{1}{x_j^{k+1}} = \frac{1}{x_j^k} - B_k a_j^{i_k}, \quad j = 1, 2, \dots, n$$

where B_k is the projection parameter associated with the "log x " entropy projection of x^k onto the set $H_{i_k}^+$ where

$$(32) \quad H_{i_k} = \{x \in \mathbb{R}^n \mid \langle a^{i_k}, x \rangle = b_{i_k}\},$$

i.e., B_k is the number which is uniquely determined from (31), (16) and

$$(33) \quad r_k < B_k < t_k$$

where

$$(34) \quad r_k := \text{Max} \left\{ \frac{1}{a_j^{i_k} x_j^k} \mid 1 \leq j \leq n, a_j^{i_k} < 0 \right\}$$

or $r_k = -\infty$ if $a_j^{i_k} \geq 0$ for all j , and

$$(35) \quad t_k := \text{Min} \left\{ \frac{1}{a_j^{i_k} x_j^k} \mid 1 \leq j \leq n, a_j^{i_k} > 0 \right\},$$

or $t_k = \infty$ if $a_j^{i_k} \leq 0$ for all j .

Control Sequence: The algorithm is controlled by a cyclic control sequence (11).

Remark 1. The initialization step of this algorithm requires that

$$(36) \quad \{u \in \mathbb{R}^m \mid A^T u > 0\} \neq \emptyset.$$

This follows from assumption (A3) by Gordan's transposition theorem. See, e.g., [36].

The following propositions lead to the conclusion about the convergence of this algorithm to the desired limit.

PROPOSITION 3. *A sequence $\{x^k\}$ produced by the algorithm has, for all $k \geq 0$, the properties (i) $x^k > 0$ and (ii) $x_j^k \cdot (A^T u^k)_j = 1, j = 1, 2, \dots, n$, where u^{k+1} is determined from (15).*

Proof. (i) Follows from Proposition 2. The conditions $H_i^+ \neq \emptyset$ and $a^i \neq 0, i = 1, 2, \dots, m$, necessary for the application of Proposition 2 follow from assumptions (A1) and (A2).

(ii) By induction. Initialization takes care of $k = 0$. Assume the claim is true up to k , then

$$\frac{1}{x_j^{k+1}} = (A^T u^k)_j - B_k a_j^{i_k} = [A^T (u^k - B_k e^{i_k})]_j = (A^T u^{k+1})_j. \quad \square$$

PROPOSITION 4. *The limit*

$$(37) \quad \lim_{k \rightarrow \infty} L(x^k, u^k),$$

where L is the Lagrangian defined in (5), $\{x^k\}$ is any sequence generated by the algorithm, and $\{u^k\}$ is its dual sequence determined from (15), exists and is finite.

Proof. Abbreviating

$$(38) \quad L_k := L(x^k, u^k) \quad \text{and} \quad d_k := L_{k+1} - L_k,$$

we have

$$(39) \quad d_k = -h(x^{k+1}) + \langle u^{k+1}, Ax^{k+1} - b \rangle + h(x^k) - \langle u^k, Ax^k - b \rangle.$$

From Proposition 3(ii) we see that (∇ stands for gradient),

$$(40) \quad A^T u^k = \nabla h(x^k)$$

for all $k \geq 0$. Therefore,

$$(41) \quad d_k = -h(x^{k+1}) + h(x^k) + \langle \nabla h(x^{k+1}), x^{k+1} \rangle - \langle \nabla h(x^k), x^k \rangle - \langle u^{k+1} - u^k, b \rangle.$$

Now, by (31),

$$(42) \quad \begin{aligned} & \langle \nabla h(x^{k+1}), x^{k+1} \rangle - \langle \nabla h(x^k), x^k \rangle \\ &= \langle \nabla h(x^{k+1}) - \nabla h(x^k), x^{k+1} \rangle + \langle \nabla h(x^k), x^{k+1} - x^k \rangle \\ &= -B_k \langle a^{i_k}, x^{k+1} \rangle + \langle \nabla h(x^k), x^{k+1} - x^k \rangle, \end{aligned}$$

and, by (15),

$$(43) \quad \langle u^{k+1} - u^k, b \rangle = \langle -B_k e^{i_k}, b \rangle.$$

Therefore, using also (16), we obtain

$$(44) \quad d_k = -h(x^{k+1}) + h(x^k) + \langle \nabla h(x^k), x^{k+1} - x^k \rangle$$

which is always nonnegative by Theorem 3.4.4 of [38], because $-h(x)$ is a convex function on the open convex set $\text{int } \mathbb{R}_+^n$. This proves that $\{L_k\}$ is monotonically increasing. To conclude the proof we show that it is also bounded from above. Take some fixed $z \in F$, then

$$(45) \quad \langle A^T u^k, z - x^k \rangle = \langle u^k, Az - Ax^k \rangle = \langle u^k, b - Ax^k \rangle.$$

By the same Theorem 3.4.4 of [38],

$$(46) \quad \Gamma := -h(z) + h(x^k) + \langle \nabla h(x^k), z - x^k \rangle \geq 0$$

for all $k \geq 0$. But, by (45), (40), (38) and (5),

$$(47) \quad \Gamma = -h(z) + h(x^k) + \langle u^k, b - Ax^k \rangle = -h(z) - L_k,$$

which proves that, for all $k \geq 0$,

$$(48) \quad L_k \leq -h(z). \quad \square$$

COROLLARY 1. $\lim_{k \rightarrow \infty} d_k = 0$.

Proof. We have the proof by (38) and Proposition 4. \square

Next we show that any sequence $\{x^k\}$ generated by the algorithm is both bounded and bounded away from zero.

DEFINITION 2. A set $S, S \subseteq \text{int } \mathbb{R}_+^n$, is called *bounded away from zero* if there exists a positive vector $q > 0$ such that

$$(49) \quad x \in S \Rightarrow x \geq q.$$

PROPOSITION 5. For any fixed $z \in \text{int } \mathbb{R}_+^n$ and any real α the set

$$(50) \quad \Omega(z, \alpha) := \left\{ x > 0 \left| \sum_{j=1}^n [\log x_j + (z_j/x_j)] \leq \alpha \right. \right\}$$

is (i) *bounded*, and (ii) *bounded away from zero*.

Proof. We prove (i) and (ii) together. Suppose (i) (respectively (ii)) was not true. Then for some α and some $z > 0$ we could have produced a sequence

$$(51) \quad \{x^k\}_{k=0}^\infty \subseteq \Omega(z, \alpha)$$

such that, for at least one component $l, 1 \leq l \leq n, \lim_{k \rightarrow \infty} x_l^k = +\infty$ (respectively, $\lim_{k \rightarrow \infty} x_l^k = 0^+$) would hold. But this would immediately contradict (50) because, for any fixed real positive γ and δ , the following limits hold:

$$(52) \quad \lim_{\xi \rightarrow +\infty} \left(\log \xi + \frac{\gamma}{\xi} \right) = +\infty$$

and

$$(53) \quad \lim_{\eta \rightarrow 0^+} \left(\log \eta + \frac{\delta}{\eta} \right) = +\infty. \quad \square$$

PROPOSITION 6. Any sequence $\{x^k\}$ generated by the algorithm is bounded and bounded away from zero.

Proof. Take a fixed $z \in F$. Then Γ (defined in (46)) may be written in the form

$$(54) \quad \Gamma = \sum_{j=1}^n \left[\log x_j^k + \frac{z_j}{x_j^k} \right] - h(z) - n.$$

On the other hand, by (47) and the monotonicity of $\{L_k\}$, proven in Proposition 4,

$$(55) \quad \Gamma = -h(z) - L_k \leq -h(z) - L_{k-1} \leq \dots \leq -h(z) - L_0.$$

Therefore, for any sequence $\{x^k\}$ generated by the algorithm,

$$(56) \quad \sum_{j=1}^n \left[\log x_j^k + \frac{z_j}{x_j^k} \right] \leq n - L_0 = \alpha,$$

and the proof is complete by Proposition 5. \square

Our next goal is to show that every cluster point x^* of any sequence $\{x^k\}$ generated by the algorithm is feasible for (4).

First, another property of "log x" entropy has to be checked. (It is similar, but not identical, to property (vi) in the definition of Bregman functions in [10, Def. 2.1].)

PROPOSITION 7. *Let $\{y^k\}_{k=0}^\infty$ be a convergent sequence in $\text{int } \mathbb{R}_+^n$ whose limit is $y^* > 0$ and let $\{x^k\}_{k=0}^\infty$ be a bounded sequence in $\text{int } \mathbb{R}_+^n$ which is bounded away from zero. If*

$$(57) \quad \lim_{k \rightarrow \infty} \left[\sum_{j=1}^n \left(\log y_j^k - \log x_j^k + \frac{x_j^k}{y_j^k} - 1 \right) \right] = 0,$$

then

$$(58) \quad \lim_{k \rightarrow \infty} x^k = y^*.$$

Proof. Take a convergent subsequence $x^{k_l} \rightarrow z$, as $l \rightarrow \infty$, $z > 0$. Then the limit in (57) is equal to

$$(59) \quad \sum_{j=1}^n \left[\log \frac{y_j^*}{z_j} + \frac{z_j}{y_j^*} - 1 \right],$$

in which each summand is nonnegative, because $\log x$ is convex, and therefore equal to zero, implying that $z_j = y_j^*$, $j = 1, 2, \dots, n$. \square

PROPOSITION 8. *If x^* is a cluster point of $\{x^k\}$ which is generated by the algorithm then $x^* \in F$.*

Proof. Let $x^{k_l} \rightarrow x^*$ as $l \rightarrow \infty$. By Proposition 6, $x^* > 0$. Use (44) to write

$$(60) \quad d_{k_l} = -h(x^{k_l+1}) + h(x^{k_l}) + \langle \nabla h(x^{k_l}), x^{k_l+1} - x^{k_l} \rangle.$$

Proposition 6 guarantees that $\{x^{k_l+1}\}$ is bounded and Corollary 1 ensures that $\lim_{l \rightarrow \infty} d_{k_l} = 0$. Now use Proposition 7 to deduce that $x^{k_l+1} \rightarrow x^*$. Repeating this argument leads to

$$(61) \quad x^{k_l+i} \xrightarrow{l \rightarrow \infty} x^* \quad \text{for every } i = 0, 1, 2, \dots, m.$$

The remainder of the proof is similar to the proof of [10, Step 5]. Consider the semi-infinite array which has $m+1$ rows, with $\{x^{k_l+i}\}_{l=1}^\infty$ in its i th row. We show that for each i , $1 \leq i \leq m$, some row of the array contains an infinite number of elements belonging to $H_i = \{x \in \mathbb{R}^n \mid \langle a^i, x \rangle = b_i\}$. For each i , at least one element in each column of the array must belong to H_i because $x^{k_l+1} \in H_{i_k}$ and the control sequence is cyclic.

It follows that there must be some row in the array, infinitely many elements of which belong to H_i because otherwise there would be only a finite number of such elements in the whole array. Thus, we can extract from the rows of the array subsequences, all of which converge to x^* , which belong to each of the H_i 's. Therefore, $x^* \in \bigcap_{i=1}^m H_i$ which, together with $x^* > 0$, proves that $x^* \in F$. \square

The convergence theorem now follows.

THEOREM 1. *If assumptions (A1), (A2) and (A3) hold then any sequence $\{x^k\}_{k=0}^\infty$ generated by the algorithm converges to the solution x^* of problem (4).*

Proof. Let x^* be a cluster point of $\{x^k\}$

$$(62) \quad x^{k_l} \xrightarrow{l \rightarrow \infty} x^*,$$

and, by Proposition 8, $x^* \in F$. Using Proposition 3(ii) write

$$(63) \quad \langle u^{k_l}, Ax^{k_l} - b \rangle = \sum_{j=1}^n \frac{1}{x_j^{k_l}} (x_j^{k_l} - x_j^*),$$

therefore, and since $\{x^{k_l}\}$ is bounded away from zero,

$$(64) \quad \lim_{l \rightarrow \infty} \langle u^{k_l}, Ax^{k_l} - b \rangle = 0.$$

This shows, using (62) and continuity of $h(x)$, that

$$(65) \quad \lim_{l \rightarrow \infty} L(x^{k_l}, u^{k_l}) = -h(x^*).$$

From (48), $L_{k_l} \leq -h(z)$ for any $z \in F$; thus, by (65),

$$(66) \quad -h(x^*) \leq -h(z),$$

which shows that x^* is optimal for problem (4). Since $[-h(x)]$ is strictly convex over $\text{int } \mathbb{R}_+^n$, x^* must be unique, which proves that $x^k \rightarrow x^*$ as $k \rightarrow \infty$. \square

Remark 2. An alternative proof of Theorem 1 was suggested by a referee. Proposition 6 guarantees the existence of a fixed real $\delta > 0$, which might depend on x^0, u^0 , such that

$$(67) \quad \inf_{k \geq 0} \min_{1 \leq j \leq n} x_j^k \geq \delta,$$

where $\{x^k\}$ is generated by the algorithm. Define the function $h_\delta: \mathbb{R} \rightarrow \mathbb{R}$ which quadratically extends $\log x$, by

$$(68) \quad h_\delta(x) := \begin{cases} \log x, & \delta/2 \leq x, \\ \log(\delta/2) + \frac{1}{4}(\log(\delta/2))^2 - [x - (\delta/2) - \frac{1}{2}(\log(\delta/2))]^2, & -\infty < x < \delta/2, \end{cases}$$

and form $h^\delta: \mathbb{R}^n \rightarrow \mathbb{R}$ by

$$(69) \quad h^\delta(x) := \sum_{j=1}^n h_\delta(x_j).$$

The function $-h^\delta(x)$ is a strongly zone consistent Bregman function with zone $S = \mathbb{R}^n$, as can be verified according to [10, Defs. 2.1 and 3.1]. By using the auxiliary function $h^\delta(x)$ and by applying Bregman's general method [10, Algorithm 4.1] to the problem

$$(70) \quad \begin{aligned} &\text{Min } [-h^\delta(x)] \\ &\text{subject to } Ax = b. \end{aligned}$$

Theorem 1 can be proved along the following lines. By Proposition 6, the sequence $\{x^k\}$, produced by the algorithm, is bounded. As such, it may be viewed as being generated by Bregman's method [10, Algorithm 4.1] applied to problem (70). Theorem 4.1 of [10] then guarantees that $\lim_{k \rightarrow \infty} x^k = x^*$ where x^* solves (70). The rest follows

as in the proof of Theorem 1. This proof eliminates the need for Propositions 7 and 8 by resorting to Bregman's theory as presented in [10]. Our proof, however, is self-contained.

5. Concluding remarks. We have proposed here a special-purpose algorithm for solving the "log x" entropy optimization problem over linear equality constraints. Although it is a primal-dual algorithm, there is no need in practice to construct and update a dual sequence $\{u^k\}$. All references made here to such a sequence were for the purpose of our theoretical study of this algorithm. As seen from (30)–(35), the new algorithm is of the *row-action* type as defined in [4]. This means that in each iterative step only the immediately previous iterate is needed, and access is required to *only one row of the system* of equations of the feasible set. As discussed at some length in [4] such properties usually make an algorithm potentially advantageous for handling large and sparse systems which arise in various fields of applications.

In image reconstruction from projections, for example, one might encounter such huge and sparse systems (see, e.g., [6]) that would make attempts to apply any general-purpose algorithm, which is not of the row-action type, practically infeasible.

These remarks are based on our familiarity with the results obtained by applying other row-action methods to problems of image reconstruction from projections. We do not have, so far, any computational experience with our new algorithm except for the results of Jain and Ranganath [27], who used it for a spectral estimation problem. Computational experience with this particular algorithm, as well as a study of its efficacy in practical situations, such as in image reconstruction from projections, are open and await investigation.

The significance of the study, presented here, of the convergence of the algorithm, is twofold. From the practical point of view it legitimizes the use of the algorithm as a tool in "log x" entropy optimization problems in fields of applications. On the theoretical side, it demonstrates that the general algorithm of Bregman [10, Algorithm 4.1] is applicable to functions outside the class \mathcal{B} of Bregman functions as described there.

Another recent study of Bregman's method is [13], where relaxation parameters are introduced into the method. In the present paper we do not discuss the possibility of incorporating such parameters. We also leave out some practical considerations such as the construction of x^0 and the calculation of B_k in practice.

Acknowledgments. We are grateful to Ms. Anna Cogan for preparing the manuscript. The constructive remarks of three anonymous referees are greatly appreciated.

A SUPERLINEARLY CONVERGENT FEASIBLE METHOD FOR THE SOLUTION OF INEQUALITY CONSTRAINED OPTIMIZATION PROBLEMS*

ELIANE R. PANIER† AND ANDRÉ L. TITS†

Abstract. When iteratively solving optimization problems arising from engineering design applications, it is sometimes crucial that all iterates satisfy a given set of “hard” inequality constraints, and generally desirable that the objective function value improve at each iteration. In this paper, we propose an algorithm of the successive quadratic programming (SQP) type which, unlike other algorithms of this type, does enjoy such properties. Under mild assumptions, the new algorithm is shown to converge from any initial point, locally superlinearly. Numerically tested, it has proven to be competitive with the most successful currently available nonlinear programming algorithms, while the latter do not exhibit the desired properties.

Key words. constrained optimization, successive quadratic programming, superlinear convergence, engineering design

AMS(MOS) subject classifications. 90C30, 65K10

1. Introduction. While some of the specifications associated with engineering design problems can often be relaxed, others, such as stability or physical realizability, have to be met imperatively (see [13] for a discussion of optimization problems arising from design problems). The former type of specification calls for tradeoff exploration through close interaction between designer and design process. However, this tradeoff exploration can meaningfully take place only once the latter specifications are satisfied. Since each iteration of an optimization algorithm involves one or more function evaluations and since typically, in a design environment, function evaluations call for computationally expensive system simulations, it is essentially required that hard constraints be satisfied *at each iteration*.¹ It is also desirable that the design obtained after each iteration improve on the previous one.

In the simplest case, a design problem can be formulated as

$$(P) \begin{cases} \min f(x) \\ \text{s.t. } x \in X \end{cases}$$

where $X = \{x \text{ s.t. } g_j(x) \leq 0, j = 1, \dots, m\}$ and $f: \mathbb{R}^n \rightarrow \mathbb{R}$ and $g_j: \mathbb{R}^n \rightarrow \mathbb{R}, j = 1, \dots, m$, are smooth functions. For this optimization problem, the stipulations outlined above amount to the requirement that, given $x_0 \in X$, the optimization algorithm construct a sequence $\{x_k\}_{k=0}^\infty$ such that, for all k ,

$$(1.1) \quad x_k \in X$$

and

$$(1.2) \quad f(x_{k+1}) \leq f(x_k).$$

¹ In fact some simulation programs (such as SPICE2 [10]) will refuse parameter values which violate some physical realizability constraints.

Methods of feasible directions [23], [14] satisfy these two requirements. They have been extended to handle problems with functional constraints [3], [15] and multiple objectives [13] and enhanced to efficiently handle design problems [21]. They have been used very successfully in solving engineering design problems arising in diverse application areas [12], [1], [11]. However, they suffer from an important shortcoming in that they are generally *slow*, as their rate of convergence is at best linear.

This paper presents an algorithm which enjoys properties (1.1) and (1.2) as well as a superlinear rate of convergence. This algorithm is of the successive quadratic programming (SQP) type. Successive quadratic programming algorithms were first introduced by Wilson [22]. Subsequently, Robinson [20] showed that Wilson's method is locally quadratically convergent and that it can be viewed as a form of Newton's method for solving the first order necessary conditions of optimality for constrained nonlinear programming problems. The question of global convergence and Hessian approximation were then considered by a number of authors (see e.g. [4], [2]). Numerical experiments have shown that these methods (in particular a version due to Powell [17]) often dramatically outperform algorithms of other classes [6]. However, existing SQP type algorithms do not enjoy properties (1.1) and (1.2).

Given an estimate $x \in X$ of the solution x^* to problem (P) and an estimate H of the Hessian of the Lagrangian at x^* , the SQP iteration yields a search direction d^0 given by the solution of the quadratic program

$$(1.3) \quad \begin{aligned} \min \quad & \frac{1}{2} d^T H d + \langle \nabla f(x), d \rangle \\ \text{s.t.} \quad & g_j(x) + \langle \nabla g_j(x), d \rangle \leq 0, \quad j = 1, \dots, m. \end{aligned}$$

Let us assume for the time being that H is positive definite. Then clearly d^0 is a descent direction for f at x , since, using the first order condition of optimality for (1.3), we get

$$(1.4) \quad \begin{aligned} \langle \nabla f(x), d^0 \rangle &= -\langle H d^0, d^0 \rangle - \sum_j \mu_j \langle \nabla g_j(x), d^0 \rangle \\ &= -\langle H d^0, d^0 \rangle + \sum_j \mu_j g_j(x) \\ &\leq -\rho |d^0|^2 \end{aligned}$$

for some positive ρ and some nonnegative multipliers μ_j . However d^0 may not be a feasible direction at x , since the constraints in (1.3) merely imply, for the constraints active at x ,

$$\langle \nabla g_j(x), d^0 \rangle \leq 0$$

and thus property (1.1) may not be satisfied. Feasibility is recovered if one substitutes in the right-hand side of the constraints of (1.3) a negative number $-\varepsilon$. However the new solution d^1 may not be any more a descent direction for f , thus jeopardizing property (1.2). Indeed, (1.4) now becomes

$$\langle \nabla f(x), d^1 \rangle \leq -\rho |d^1|^2 + \varepsilon \sum_j \mu_j.$$

Choosing $\varepsilon = |d^1|^\nu$, with $\nu > 2$, would resolve this difficulty, at least for d^1 small, which is the case if x is close to the solution of (P). Unfortunately the transformed problem would not be a quadratic program any more. Following an idea used by Herskovits in a different context [5], we propose to solve successively two quadratic programs: first (1.3), giving d^0 , then

$$\begin{aligned} \min \quad & \frac{1}{2} d^T H d + \langle \nabla f(x), d \rangle \\ \text{s.t.} \quad & g_j(x) + \langle \nabla g_j(x), d \rangle \leq -|d^0|^\nu, \quad j = 1, \dots, m \end{aligned}$$

yielding a search direction d^1 . The hope is that d^1 will be small enough, and close enough to d^0 , near the solution to (P), for property (1.2) as well as the basic convergence properties of the SQP type algorithms to be preserved. As shown in a later section, such will indeed be the case, even without assuming positive definiteness of H over the entire space (the milder assumption (4.1) will be used instead).

Once a feasible descent direction is obtained, an Armijo type rule may be suitable as a line search procedure. However, in order to preserve a superlinear rate of convergence, it is necessary to avoid any Maratos-like effect [7], by which the step length is truncated even close to the solution. Mayne and Polak [9] solve this problem in a different context—SQP methods using a penalty function for the stepsize calculation—by replacing the line search by a search along a suitably defined arc, tangent to d^1 at x . In our context, a further “bending” towards the feasible region is necessary to avoid truncation of the step due to infeasibility. It turns out that the amount of bending must be closely monitored. Indeed, the bent unit step, say, $d^1 + \tilde{d}$, must be very close to d^1 when d^1 is small (in the neighborhood of a solution of (P)). Otherwise, $d^1 + \tilde{d}$ may not inherit enough descent properties from d^1 , resulting again in a truncated step. Also, if \tilde{d} is too large, even the unit step iteration may not yield superlinear convergence. A suitable correction \tilde{d} will be obtained as the solution of a linear least squares problem.

The last problem to be addressed is that of global convergence. As suggested above, d^1 is guaranteed to be a descent direction for f only in the neighborhood of a solution to (P). Away from a solution, a first order search direction will be used. A suitable mechanism will ensure that our algorithm selects the SQP direction when a solution is approached, so that superlinear convergence can occur.

The resulting algorithm is relatively complex, as it involves the solution of two quadratic programs and of one linear least squares problem at most iterations. Clearly however, the close relationship between these three problems should result, in a clever implementation, in little more computational effort than that required for the solution of a single quadratic program.

The remainder of this paper is organized as follows. The proposed algorithm is stated in § 2. In § 3, it is shown that, under mild assumptions, this algorithm is convergent irrespective of the initial guess. Rate of convergence analysis is the object of § 4, where conditions for superlinear convergence are put forth. Finally, § 5 is devoted to implementation aspects and to numerical experiments.

2. The algorithm. Throughout the paper, the following two hypotheses will be assumed to hold.

H1. The set X is not empty;

H2. The functions $f, g_j, j = 1, \dots, m$ are continuously differentiable.

The algorithm we propose for solving (P) is as follows.

ALGORITHM A.

Parameters.

$$M > 0, \quad \alpha \in (0, \tfrac{1}{2}), \quad \beta \in (0, 1), \quad \nu > 2, \quad \kappa > 2, \quad \tau \in (2, 3).$$

Data.

$$x_0 \in X, \quad H_0 \in \mathbb{R}^{n \times n}.$$

Step 0. Initialization.

Set $k = 0$.

Step. 1. Computation of a search direction.

(i) Solve

$$(QP_0) \begin{cases} \min \frac{1}{2} d^T H_k d + \langle \nabla f(x_k), d \rangle \\ \text{s.t. } g_j(x_k) + \langle \nabla g_j(x_k), d \rangle \leq 0, \quad j = 1, \dots, m \end{cases}$$

to the extent of obtaining a Kuhn-Tucker point d_k^0 of least norm.

If (QP_0) has no Kuhn-Tucker point or if $|d_k^0| > M$ or if $|H_k d_k^0| > |d_k^0|^{1/2}$, go to (iv).

If $|d_k^0| = 0$ stop.

(ii) Solve

$$(QP) \begin{cases} \min \frac{1}{2} d^T H_k d + \langle \nabla f(x_k), d \rangle \\ \text{s.t. } g_j(x_k) + \langle \nabla g_j(x_k), d \rangle \leq -|d_k^0|^\nu, \quad j = 1, \dots, m \end{cases}$$

to the extent of obtaining a Kuhn-Tucker point d_k of least norm.

If d_k exists, set $\theta_k = \langle \nabla f(x_k), d_k \rangle$.

If (QP) has no Kuhn-Tucker point or if $|d_k| > M$ or if $\theta_k > \min(-|d_k^0|^\kappa, -|d_k|^\kappa)$, go to (iv).

(iii) Compute a correction \tilde{d}_k , solution of the linear least squares problem

$$(LS) \begin{cases} \min \frac{1}{2} |d|^2 \\ \text{s.t. } g_j(x_k + d_k) + \langle \nabla g_j(x_k), d \rangle = -|d_k^0|^\tau \quad \forall j \in I_k \end{cases}$$

where $I_k = \{j \text{ s.t. } g_j(x_k) + \langle \nabla g_j(x_k), d_k \rangle = -|d_k^0|^\nu\}$.

If (LS) has no solution or if $|\tilde{d}_k| > |d_k|$, set $\tilde{d}_k = 0$.

Proceed to Step 2.

(iv) Compute a first order feasible descent direction d_k (see remark below).

Set $\theta_k = \langle \nabla f(x_k), d_k \rangle$.

Set $\tilde{d}_k = 0$.

Step 2. Line search.

Compute t_k , the first number t of the sequence $\{1, \beta, \beta^2, \dots\}$ satisfying

$$(2.1) \quad f(x_k + t d_k + t^2 \tilde{d}_k) \leq f(x_k) + \alpha t \theta_k,$$

$$(2.2) \quad g_j(x_k + t d_k + t^2 \tilde{d}_k) \leq 0, \quad j = 1, \dots, m.$$

Step 3. Updates.

Compute a new approximation H_{k+1} of the Hessian matrix.

Set $x_{k+1} = x_k + t_k d_k + t_k^2 \tilde{d}_k$.

Set $k = k + 1$.

Go back to Step 1. □

Remark. The “first order” direction of Step 1(iv) is any direction satisfying a set of conditions that will be stated later, as the need arises. At this time, let us just point out that algorithms do exist that construct directions satisfying these conditions (e.g. the algorithm in [16] using optimality function θ_ε^2 defined by equation (36) in that paper).

3. Global convergence. In this section we prove that, under mild conditions, the algorithm described in § 1 is convergent.

In addition to H1 and H2, we will assume that the following hypothesis holds.

H3. For any $x \in X$, the vectors $\{\nabla g_j(x), j \in I(x)\}$ are linearly independent, where

$$I(x) \triangleq \{j \text{ s.t. } g_j(x) = 0\}.$$

Before analyzing the convergence properties of Algorithm A, we need to verify that the line search of Step 2 is well defined. A first requirement on the first order direction is needed here.

R1. The direction computed at Step 1(iv) of the algorithm is a strict descent direction for f and for the active constraints associated with the current iterate (i.e., $\langle \nabla f(x_k), d_k \rangle < 0$ and $\langle \nabla g_j(x_k), d_k \rangle < 0$ for all $j \in I(x_k)$).

PROPOSITION 3.1. *The line search yields a step $t_k = \beta^j$ for some finite $j = j(k)$.*

Proof. This is a well-known result in the case when the direction is computed at Step 1(iv) and R1 is satisfied. Thus suppose that the direction is computed through Step 1(i)–(iii). We have

$$f(x_k + td_k + t^2 \tilde{d}_k) = f(x_k) + t \langle \nabla f(x_k + \xi d_k + \xi^2 \tilde{d}_k), d_k + 2\xi \tilde{d}_k \rangle$$

for some $\xi \in [0, t]$. Since f is continuously differentiable, $\theta_k = \langle \nabla f(x_k), d_k \rangle < 0$ (from Step 1(ii)), and $\alpha \in (0, \frac{1}{2})$, there exists $\underline{t} > 0$ such that

$$f(x_k + td_k + t^2 \tilde{d}_k) \leq f(x_k) + t\alpha\theta_k \quad \forall t \in [0, \underline{t}].$$

We also have

$$g_j(x_k + td_k + t^2 \tilde{d}_k) = g_j(x_k) + t \langle \nabla g_j(x_k + \xi d_k + \xi^2 \tilde{d}_k), d_k + 2\xi \tilde{d}_k \rangle$$

for some $\xi \in [0, t]$. Moreover, from the inequalities

$$g_j(x_k) + \langle \nabla g_j(x_k), d_k \rangle \leq -|d_k^0|^\nu < 0, \quad j = 1, \dots, m$$

and

$$g_j(x_k) \leq 0, \quad j = 1, \dots, m,$$

we conclude that either $g_j(x_k) < 0$ or $g_j(x_k) = 0$ and $\langle \nabla g_j(x_k), d_k \rangle < 0$. Therefore, for $j = 1, \dots, m$, there exists some \underline{t}_j such that

$$g_j(x_k + td_k + t^2 \tilde{d}_k) \leq 0 \quad \forall t \in [0, \underline{t}_j]. \quad \square$$

It is of interest to note that this result was obtained without making use of any property of \tilde{d}_k .

Our first convergence result has to do with the sequence of intermediate directions $\{d_k^0\}$.

PROPOSITION 3.2. *Suppose that Algorithm A generates an infinite sequence. Let x^* be a cluster point of this sequence, and $\{x_k\}_{k \in K}$ a subsequence converging to x^* . Suppose moreover that the directions at points x_k , for $k \in K$, are computed through Step 1(i)–(iii). Then, the sequence $\{d_k^0\}_{k \in K}$ tends to zero.*

Proof. We assume by contradiction that there exists a cluster point x^* , a number $\underline{d} > 0$ and subsequences $\{x_k\}_{k \in K}$ and $\{d_k^0\}_{k \in K}$ such that

$$x_k \rightarrow x^*, \quad k \in K, \quad k \rightarrow \infty$$

and

$$|d_k^0| \geq \underline{d} \quad \forall k \in K.$$

We first show that, in that case, the step t_k obtained by the line search is bounded away from zero on K , i.e.,

$$(3.1) \quad \exists \underline{t} > 0 \text{ s.t. } t_k \geq \underline{t} \quad \forall k \in K.$$

From Step 1(ii) we have, for $k \in K$,

$$\theta_k = \langle \nabla f(x_k), d_k \rangle \leq -(\underline{d})^\kappa$$

and

$$g_j(x_k) + \langle \nabla g_j(x_k), d_k \rangle \leq -(\underline{d})^\nu.$$

Then, for $k \in K$, k large enough, we obtain,

$$\langle \nabla f(x_k), d_k \rangle \leq -\delta$$

and

$$\begin{aligned} \langle \nabla g_j(x_k), d_k \rangle &\leq -\delta \quad \forall j \in I(x^*), \\ g_j(x_k) &\leq -\delta \quad \forall j \notin I(x^*) \end{aligned}$$

for some $\delta > 0$. From the identity

$$f(x_k + td_k + t^2 \tilde{d}_k) = f(x_k) + \int_0^1 \langle \nabla f(x_k + t\xi d_k + t^2 \xi^2 \tilde{d}_k), td_k + 2t^2 \xi \tilde{d}_k \rangle d\xi,$$

it then follows that, for $k \in K$, k large enough,

$$\begin{aligned} f(x_k + td_k + t^2 \tilde{d}_k) - f(x_k) - \alpha t \theta_k \\ \leq t \left\{ \int_0^1 [\langle \nabla f(x_k + t\xi d_k + t^2 \xi^2 \tilde{d}_k), d_k + 2t\xi \tilde{d}_k \rangle - \langle \nabla f(x_k), d_k \rangle] d\xi \right. \\ \left. + (1 - \alpha) \langle \nabla f(x_k), d_k \rangle \right\} \\ \leq t \left\{ \sup_{\xi \in [0,1]} |\nabla f(x_k + t\xi d_k + t^2 \xi^2 \tilde{d}_k) - \nabla f(x_k)| |d_k| \right. \\ \left. + 2t \sup_{\xi \in [0,1]} |\nabla f(x_k + t\xi d_k + t^2 \xi^2 \tilde{d}_k)| |\tilde{d}_k| - (1 - \alpha) \delta \right\}. \end{aligned}$$

Since d_k and \tilde{d}_k are bounded and $f \in C^1$, this ensures that there exists $t_f > 0$, independent of k , such that for $t \in [0, t_f]$, $k \in K$, k large enough,

$$f(x_k + td_k + t^2 \tilde{d}_k) - f(x_k) - \alpha t \theta_k \leq 0.$$

Similarly, for $k \in K$, k large enough, $t > 0$ and $j \in I(x^*)$, it holds

$$\begin{aligned} g_j(x_k + td_k + t^2 \tilde{d}_k) - g_j(x_k) &\leq t \left\{ \sup_{\xi \in [0,1]} |\nabla g_j(x_k + t\xi d_k + t^2 \xi^2 \tilde{d}_k) - \nabla g_j(x_k)| |d_k| \right. \\ &\quad \left. + 2t \sup_{\xi \in [0,1]} |\nabla g_j(x_k + t\xi d_k + t^2 \xi^2 \tilde{d}_k)| |\tilde{d}_k| - \delta \right\} \end{aligned}$$

so that there exists some $t_j > 0$ independent of k such that, for $t \in [0, t_j]$, $k \in K$, k large enough,

$$g_j(x_k + td_k + t^2 \tilde{d}_k) \leq 0.$$

Also, there exists $t_j > 0$ independent of k such that, for $t \in [0, t_j]$, $k \in K$, k large enough, and $j \notin I(x^*)$,

$$g_j(x_k + td_k + t^2 \tilde{d}_k) \leq g_j(x_k) + \frac{\delta}{2} \leq -\delta + \frac{\delta}{2} \leq 0 \quad \forall t \in [0, t_j].$$

Our claim (3.1) is thus proven, with $\underline{t} = \min \{t_f, t_j, j = 1, \dots, m\}$.

Now, for $k \in K$, k large enough, we have,

$$\begin{aligned} (3.2) \quad f(x_{k+1}) &\leq f(x_k) + \alpha t_k \theta_k \\ &\leq f(x_k) - \alpha \underline{t} \delta. \end{aligned}$$

On the other hand, from (2.1), the sequence $\{f(x_k)\}$ is monotonically decreasing and hence, since f is continuous, $f(x_k) \rightarrow f(x^*)$ as $k \rightarrow \infty$. This contradicts (3.2). \square

In order to prove global convergence of Algorithm A, we need to strengthen the first requirement on the first order direction, replacing it with R1'.

R1'. If a subsequence $\{x_k\}_{k \in K}$ converges to a point x^* which is not a Kuhn-Tucker point for problem (P), then the corresponding first order directions are bounded and satisfy the inequalities

$$\langle \nabla f(x_k), d_k \rangle \leq -\delta,$$

$$\langle \nabla g_j(x_k), d_k \rangle \leq -\delta \quad \forall i \in I(x^*)$$

for all $k \in K$, for some $\delta > 0$.

THEOREM 3.3. *Algorithm A described in § 2 either stops at a Kuhn-Tucker point or generates a sequence $\{x_k\}$ for which each accumulation point is a Kuhn-Tucker point for (P).*

Proof. The first statement is obvious, the only stopping point being in Step 1(i). Thus, suppose that $\{x_k\}_{k \in K} \rightarrow x^*$. If the first order direction is selected infinitely many times, the result follows from an argument identical to that used in the proof of Proposition 3.2, using requirement R1' and the fact that the function f is monotonically decreasing. We then suppose, without loss of generality, that the direction is always computed through Step 1(i)-(iii) on K and that the active set associated with (QP_0) keeps a constant value

$$I = I_k = \{j \text{ s.t. } g_j(x_k) + \langle \nabla g_j(x_k), d_k^0 \rangle = 0\} \quad \forall k \in K.$$

From Proposition 3.2, we have

$$d_k^0 \rightarrow 0, \quad k \in K, \quad k \rightarrow \infty.$$

Therefore, $I \subset I(x^*)$. Also, the vector d_k^0 satisfies the optimality conditions

$$(3.3a) \quad H_k d_k^0 + \nabla f(x_k) + \sum_{j \in I} (\mu_k)_j \nabla g_j(x_k) = 0,$$

$$(3.3b) \quad (\mu_k)_j \geq 0,$$

for some multiplier vector μ_k . Because $I \subset I(x^*)$, for $k \in K$, k large enough, the vectors $\nabla g_j(x_k)$, $j \in I$ are linearly independent. If we denote by $R_I(x_k)$ the $n \times |I|$ matrix

$$R_I(x_k) = (\nabla g_j(x_k) \text{ s.t. } j \in I)$$

we obtain the expression of the unique multiplier vector μ_k as

$$\mu_k = -(R_I^T(x_k) R_I(x_k))^{-1} R_I(x_k)^T (H_k d_k^0 + \nabla f(x_k)).$$

Due to the condition $|H_k d_k^0| \leq |d_k^0|^{1/2}$ we obtain

$$\mu_k \rightarrow \mu^*, \quad k \in K, \quad k \rightarrow \infty$$

with

$$\mu^* = -(R_I^T(x^*) R_I(x^*))^{-1} R_I(x^*)^T \nabla f(x^*).$$

Taking the limit in (3.3) yields

$$\nabla f(x^*) + \sum_{j \in I} \mu_j^* \nabla g_j(x^*) = 0, \quad \mu_j^* \geq 0. \quad \square$$

We conclude this section by showing that the existence of an accumulation point in the sequence generated by Algorithm A induces some regularity properties on this

sequence. This result will be used in § 4. We first need to introduce a second and last requirement on the first order direction.²

R2. The first order direction satisfies the relation $\langle \nabla f(x_k), d_k \rangle \leq -c|d_k|^\alpha$ for some $\alpha \geq 1$ and $c > 0$.³

PROPOSITION 3.4. *Suppose that the sequence $\{x_k\}$ generated by Algorithm A has some accumulation point. Then*

$$\{|x_{k+1} - x_k|\} \rightarrow 0, \quad k \rightarrow \infty.$$

Proof. Since $f(x_k)$ is monotonically decreasing, existence of an accumulation point of $\{x_k\}$ and continuity of f imply that the sequence $\{f(x_k)\}$ is bounded. Also, the line search in Algorithm A yields

$$f(x_{k+1}) \leq f(x_k) + \alpha t_k \theta_k.$$

It follows that

$$(3.4) \quad t_k \theta_k \rightarrow 0, \quad k \rightarrow \infty.$$

Now $t_k \theta_k$ is bounded from above by $-t_k |d_k|^\kappa$ if the direction is computed through Step 1(i)–(iii) and by $-ct_k |d_k|^\alpha$ if the direction is computed through Step 1(iv). Thus, in both cases, (3.4) and the fact that the step t_k is bounded by 1 imply

$$|t_k d_k| \rightarrow 0, \quad k \rightarrow \infty.$$

Since

$$\begin{aligned} |x_{k+1} - x_k| &\leq t_k |d_k| + t_k^2 |\tilde{d}_k| \\ &\leq 2t_k |d_k| \end{aligned}$$

the claim holds. \square

4. Rate of convergence. In order to study the rate of convergence of the algorithm, we need some stronger regularity assumptions on the functions involved in problem (P). We replace H2 by the following hypothesis.

H2'. The functions $f, g_j, j = 1, \dots, m$ are three times continuously differentiable. Hypotheses H1 and H3 are still assumed to hold.

Let x^* be a Kuhn–Tucker point for (P). Denote by μ^* the unique multiplier vector computed at x^* and, for any $x \in \mathbb{R}^n$ and $\mu \in \mathbb{R}^m$, denote by $L(x, \mu)$ the Lagrangian function

$$L(x, \mu) = f(x) + \sum_j (\mu)_j g_j(x).$$

The optimality conditions associated with x^* can then be written

$$\begin{aligned} \nabla_x L(x^*, \mu^*) &= 0, \\ \mu^* &\geq 0, \quad g_j(x^*) \leq 0, \quad j = 1, \dots, m, \\ (\mu^*)_j g_j(x^*) &= 0, \quad j = 1, \dots, m. \end{aligned}$$

The point x^* is said to satisfy *second order sufficiency conditions with strict complementary slackness* if the multipliers satisfy $\mu_j^* > 0$ for all $j \in I(x^*)$ and if the Hessian of the Lagrangian function $\nabla_{xx} L(x^*, \mu^*)$ is positive definite on the subspace $\{p \text{ s.t. } \langle \nabla g_j(x^*), p \rangle = 0 \text{ for all } j \in I(x^*)\}$.

² We could replace R2 by any condition sufficient for Proposition 3.4 to hold.

³ The direction computed by the method described in [16, eq. (36)] satisfies R2 with $\alpha = 2$ and $c = 1$.

PROPOSITION 4.1. *If some accumulation point x^* of the sequence generated by the algorithm satisfies the second order sufficiency conditions with strict complementary slackness, then the entire sequence converges to x^* .*

Proof. Under the stated assumptions, the Kuhn–Tucker point x^* is isolated (see, e.g., [19]), i.e., for some $\varepsilon > 0$, the ball $B(x^*, \varepsilon)$ does not contain any Kuhn–Tucker point other than x^* . From Proposition 3.4, we have

$$|x_{k+1} - x_k| \rightarrow 0, \quad k \rightarrow \infty.$$

Therefore, for k large enough, $|x_{k+1} - x_k| < \varepsilon/4$ and there exists a subsequence $\{x_k\}_{k \in K}$ such that $|x_k - x^*| < \varepsilon/4$ on K . It is then impossible to leave $B(x^*, \varepsilon)$ without creating another cluster point and hence a Kuhn–Tucker point in that ball. \square

In the sequel, we will assume that the sequence generated by the algorithm converges to such a point x^* . We will denote by R^* and P^* the $n \times |I(x^*)|$ and $n \times n$ matrices, respectively, defined by

$$\begin{aligned} R^* &= \{\nabla g_j(x^*), j \in I(x^*)\}, \\ P^* &= I - R^*(R^{*T}R^*)^{-1}R^{*T}. \end{aligned}$$

Given some iterate x_k close enough to x^* , we will similarly define matrices R_k and P_k by

$$\begin{aligned} R_k &= \{\nabla g_j(x_k), j \in I(x^*)\}, \\ P_k &= I - R_k(R_k^T R_k)^{-1}R_k^T. \end{aligned}$$

Without loss of generality, we will suppose that the matrices H_k are symmetric. We will assume moreover that the sequence $\{H_k\}$ converges to a matrix H^* satisfying

$$(4.1) \quad P^*H^*P^* = P^*\nabla_{xx}^2 L(x^*, \mu^*)P^*.$$

This holds, for example, when one uses secant approximations as in [9] or, under suitable conditions, when one uses the BFGS update formula (see [18]). Hypothesis (4.1) and the second order sufficiency condition guarantee the existence of a positive number ρ satisfying⁴

$$(4.2) \quad d^T P_k H_k P_k d \geq \rho |P_k d|^2 \quad \forall d \in \mathbb{R}^n$$

for k large enough.

Propositions 4.2 and 4.3 give important asymptotic properties.

PROPOSITION 4.2. *For k large enough,*

- (i) (QP₀) has a unique Kuhn–Tucker point of least norm,
(QP) has a unique Kuhn–Tucker point of least norm,
 $\{d_k^0\} \rightarrow 0, \quad \{d_k\} \rightarrow 0,$
where d_k^0 and d_k are computed through Step 1(i) and (ii).
- (ii) $\{\mu_k^0\} \rightarrow \mu^*, \quad \{\mu_k\} \rightarrow \mu^*$
where μ_k^0 and μ_k are the multipliers associated with the quadratic problems (QP₀) and (QP).
- (iii) $I_k^0 \triangleq \{j \text{ s.t. } (\mu_k^0)_j > 0\} = \{j \text{ s.t. } g_j(x_k) + \langle \nabla g_j(x_k), d_k^0 \rangle = 0\} = I(x^*),$
 $I_k \triangleq \{j \text{ s.t. } (\mu_k)_j > 0\} = \{j \text{ s.t. } g_j(x_k) + \langle \nabla g_j(x_k), d_k \rangle = -|d_k^0|^\nu\} = I(x^*).$

⁴ In fact if (4.2) holds, a positive matrix H_k^+ can easily be constructed such that $P_k H_k^+ P_k = P_k H_k P_k$ (see [18]).

Proof. x^* is a Kuhn-Tucker point for the problem

$$\begin{aligned} & \min \frac{1}{2}(x - x^*)^T H^*(x - x^*) + \langle \nabla f(x^*), x - x^* \rangle \\ & \text{s.t. } g_j(x^*) + \langle \nabla g_j(x^*), x - x^* \rangle \leq 0 \end{aligned}$$

at which the second order sufficiency conditions are satisfied with strict complementary slackness and linear independence of the gradients of the active constraints.

We can write $d_k^0 = x - x_k$ where x is solution of the problem

$$\begin{aligned} & \min \frac{1}{2}(x - x_k)^T H_k(x - x_k) + \langle \nabla f(x_k), x - x_k \rangle \\ & \text{s.t. } g_j(x_k) + \langle \nabla g_j(x_k), x - x_k \rangle \leq 0. \end{aligned}$$

Since $x_k \rightarrow x^*$ and $H_k \rightarrow H^*$, parts (i) and (ii) for d_k^0 follow from Theorem 2.1 of [20]. We can also write $d_k = x - x_k$ where x is solution of the problem

$$\begin{aligned} & \min \frac{1}{2}(x - x_k)^T H_k(x - x_k) + \langle \nabla f(x_k), x - x_k \rangle \\ & \text{s.t. } g_j(x_k) + \langle \nabla g_j(x_k), x - x_k \rangle \leq -|d_k^0|^\nu \end{aligned}$$

and, as $d_k^0 \rightarrow 0$, parts (i) and (ii) for d_k also follow from Theorem 2.1 of [20]. That (iii) is true follows from the fact that $\mu_k^0 \rightarrow \mu^*$, $\mu_k \rightarrow \mu^*$, and that, from strict complementarity, $I(x^*) = \{j \text{ s.t. } \mu_j^* > 0\}$. \square

PROPOSITION 4.3. *The solutions of (QP₀) and (QP) satisfy*

$$(4.3) \quad \{d_k^0\} \sim \{d_k\},$$

i.e., there exist some constants $C_1 > 0$, $C_2 > 0$ and an integer \hat{k} such that

$$C_1 |d_k^0| \leq |d_k| \leq C_2 |d_k^0| \quad \forall k \geq \hat{k}.$$

Proof. For k large enough, $I_k^0 = I_k = I(x^*)$ and d_k satisfies

$$(4.4) \quad H_k d_k + \nabla f(x_k) + R_k \mu_k = 0.$$

Let us define Δd_k and $\Delta \mu_k$ by

$$d_k = d_k^0 + \Delta d_k, \quad \mu_k = \mu_k^0 + \Delta \mu_k.$$

We have from (4.4)

$$H_k d_k^0 + \nabla f(x_k) + R_k \mu_k^0 + H_k \Delta d_k + R_k \Delta \mu_k = 0$$

which gives

$$(4.5) \quad H_k \Delta d_k + R_k \Delta \mu_k = 0.$$

Now, Δd_k solves

$$R_k^T \Delta d_k = \begin{pmatrix} -|d_k^0|^\nu \\ \vdots \\ -|d_k^0|^\nu \end{pmatrix}$$

and can be decomposed into

$$\Delta d_k = \Delta d_k^1 + \Delta d_k^2$$

with

$$\Delta d_k^1 = P_k \Delta d_k$$

and

$$(4.6) \quad \Delta d_k^2 = -R_k (R_k^T R_k)^{-1} \begin{pmatrix} |d_k^0|^\nu \\ \vdots \\ |d_k^0|^\nu \end{pmatrix}.$$

Thus, since H_k is bounded, it follows from (4.5) that

$$H_k \Delta d_k^1 + R_k \Delta \mu_k = O(|d_k^0|^\nu).$$

This gives

$$\Delta d_k^{1^T} H_k \Delta d_k^1 + \Delta d_k^T P_k^T R_k \Delta \mu_k = O(|d_k^0|^\nu)$$

and, since $P_k^T R_k = 0$, using (4.2), we get

$$(4.7) \quad |\Delta d_k^1|^2 = O(|d_k^0|^\nu).$$

From (4.6) and (4.7) we thus obtain

$$\Delta d_k = o(|d_k^0|).$$

□

In order to establish the main results, we now need three lemmas.

LEMMA 4.4. *There exists some constant $\gamma > 0$ such that, for k large enough,*

$$\sum_{j \in I(x^*)} (\mu_k)_j g_j(x_k) \leq -\gamma \left(\sum_{j \in I(x^*)} g_j(x_k)^2 \right)^{1/2}.$$

Proof. For k large enough we have, from the convergence of the multipliers,

$$\begin{aligned} \sum_{j \in I(x^*)} (\mu_k)_j g_j(x_k) &\leq \frac{1}{2} \min \{ \mu_j^* \text{ s.t. } j \in I(x^*) \} \sum_{j \in I(x^*)} g_j(x_k) \\ &\leq -\frac{1}{2} \min \{ \mu_j^* \text{ s.t. } j \in I(x^*) \} \left(\sum_{j \in I(x^*)} g_j(x_k)^2 \right)^{1/2}. \end{aligned}$$

We set $\gamma = \frac{1}{2} \min \{ \mu_j^* \text{ s.t. } j \in I(x^*) \}$, which is positive due to strict complementarity. □

LEMMA 4.5. *Direction d_k computed through Step 1(i) and (ii) can be decomposed into $d_k = P_k d_k + d_k^1$ with*

$$|d_k^1| \leq C \left(\sum_{j \in I(x^*)} g_j(x_k)^2 \right)^{1/2} + O(|d_k^0|^\nu)$$

for k large enough, for some $C > 0$.

Proof. The direction d_k satisfies

$$R_k^T d_k = -h_k - \begin{pmatrix} |d_k^0|^\nu \\ \vdots \\ |d_k^0|^\nu \end{pmatrix}$$

where h_k is an $|I(x^*)|$ -vector whose components are the values $g_j(x_k)$ for $j \in I(x^*)$. It is thus possible to rewrite d_k as

$$d_k = P_k d_k + d_k^1$$

with

$$d_k^1 = -R_k (R_k^T R_k)^{-1} \left(h_k + \begin{pmatrix} |d_k^0|^\nu \\ \vdots \\ |d_k^0|^\nu \end{pmatrix} \right).$$

This implies that, for k large enough,

$$|d_k^1| \leq C \left(\sum_{j \in I(x^*)} g_j(x_k)^2 \right)^{1/2} + O(|d_k^0|^\nu)$$

for some C . □

LEMMA 4.6. *There exists a positive constant $\bar{\gamma}$ such that, for k large enough, the solution d_k of (QP) satisfies the inequality*

$$\theta_k = \langle \nabla f(x_k), d_k \rangle \leq -\bar{\gamma} |d_k|^2.$$

Proof. Direction d_k computed through Step 1(ii) satisfies the Kuhn–Tucker conditions

$$\nabla f(x_k) + \sum_{j \in I(x^*)} (\mu_k)_j \nabla g_j(x_k) + H_k d_k = 0$$

and, multiplying by d_k ,

$$\theta_k = - \sum_{j \in I(x^*)} (\mu_k)_j \langle \nabla g_j(x_k), d_k \rangle - d_k^T H_k d_k$$

which yields, using the complementarity conditions,

$$\theta_k = \sum_{j \in I(x^*)} (\mu_k)_j g_j(x_k) + \sum_j (\mu_k)_j |d_k^0|^v - d_k^T H_k d_k.$$

Replacing d_k by its decomposition, we obtain

$$\begin{aligned} \theta_k &= \sum_{j \in I(x^*)} (\mu_k)_j g_j(x_k) + \sum_j (\mu_k)_j |d_k^0|^v - d_k^T P_k H_k P_k d_k \\ &\quad - 2d_k^T P_k H_k d_k^1 - d_k^{1^T} H_k d_k^1. \end{aligned}$$

Using (4.2), Lemmas 4.4 and 4.5, and the fact that the matrices H_k and the multipliers μ_k are bounded, we obtain

$$\theta_k \leq -\rho |d_k|^2 + O(|d_k^0|^v).$$

Since $\{d_k\} \sim \{d_k^0\}$, the claim holds. \square

The next proposition shows that, for k large enough, the algorithm never needs to compute a first order direction.

PROPOSITION 4.7. *For k large enough, the solutions of (QP₀) and (QP) satisfy the following inequalities*

- (i) $|d_k^0| \leq M,$
- (ii) $|H_k d_k^0| \leq |d_k^0|^{1/2},$
- (iii) $|d_k| \leq M,$
- (iv) $\theta_k = \langle \nabla f(x_k), d_k \rangle \leq \min \{-|d_k^0|^\kappa, -|d_k|^\kappa\}.$

Proof. Relations (i)–(iii) obviously hold since the sequences $\{d_k^0\}$ and $\{d_k\}$ converge to zero and the matrices H_k are bounded. Inequality (iv) follows from Lemma 4.6. \square

A crucial requirement for achieving superlinear convergence is that a unit stepsize be used in a neighborhood of the solution. The next proposition shows that Algorithm A does achieve this goal.

PROPOSITION 4.8. *For k large enough, the direction is always computed through Step 1(i)–(iii) and the stepsize t_k is one.*

Proof. (The proof is analogous to that of Proposition 15 in [8]; see also [9].)

In all the relations given in this proof, the phrase “for k large enough” is implicit.

The first part of the theorem is obvious in view of Proposition 4.7. In order to prove the second part, we first show that the property

$$\tilde{d}_k = O(|d_k|^2)$$

holds (close to the solution, \tilde{d}_k is always well defined). By definition, \tilde{d}_k is the minimal norm solution of

$$g_j(x_k + d_k) + \langle \nabla g_j(x_k), \tilde{d}_k \rangle = -|d_k^0|^\tau, \quad j \in I_k.$$

Expanding, we obtain

$$\begin{aligned} g_j(x_k) + \langle \nabla g_j(x_k), d_k \rangle + \langle \nabla g_j(x_k), \tilde{d}_k \rangle \\ + \frac{1}{2} \langle d_k, \nabla_{xx} g_j(x_k + \xi d_k) d_k \rangle = -|d_k^0|^\tau, \quad j \in I_k \end{aligned}$$

for some $0 \leq \xi \leq 1$. Hence, using the definition of I_k

$$R_k^T \tilde{d}_k = O(|d_k|^2).$$

Thus, \tilde{d}_k solves the problem

$$\begin{aligned} \min \frac{1}{2} |\tilde{d}_k|^2 \\ \text{s.t. } R_k^T \tilde{d}_k = O(|d_k|^2) \end{aligned}$$

and, since R_k is full column rank, is given by

$$\tilde{d}_k = R_k (R_k^T R_k)^{-1} O(|d_k|^2),$$

which proves our first claim. Now, according to Step 2 in Algorithm A, two conditions are needed for the line search to yield a unit stepsize, namely feasibility of the resulting point (2.2) and sufficient decrease (2.1). Expanding g_j around $x_k + d_k$ we obtain, for $j \in I(x^*)$,

$$\begin{aligned} (4.8) \quad g_j(x_k + d_k + \tilde{d}_k) &= g_j(x_k + d_k) + \langle \nabla g_j(x_k + d_k), \tilde{d}_k \rangle + O(|d_k|^4) \\ &= g_j(x_k + d_k) + \langle \nabla g_j(x_k), \tilde{d}_k \rangle + O(|d_k|^3) \\ &= -|d_k^0|^\tau + O(|d_k^0|^3). \end{aligned}$$

The last term is negative since the sequence $\{d_k^0\}$ converges to zero. Thus the feasibility condition is satisfied.

We also have, since f is three times continuously differentiable,

$$f(x_k + d_k + \tilde{d}_k) = f(x_k) + \langle \nabla f(x_k), d_k \rangle + \langle \nabla f(x_k), \tilde{d}_k \rangle + \frac{1}{2} d_k^T \nabla_{xx} f(x_k) d_k + O(|d_k|^3).$$

The Kuhn-Tucker conditions

$$\nabla f(x_k) + H_k d_k + \sum_j (\mu_k)_j \nabla g_j(x_k) = 0$$

and the complementarity relations imply

$$\frac{1}{2} \langle \nabla f(x_k), d_k \rangle = -\frac{1}{2} d_k^T H_k d_k - \sum_j (\mu_k)_j \langle \nabla g_j(x_k), d_k \rangle - \frac{1}{2} \sum_j (\mu_k)_j g_j(x_k) + O(|d_k^0|^\nu)$$

and

$$\langle \nabla f(x_k), \tilde{d}_k \rangle = O(|d_k|^3) - \sum_j (\mu_k)_j \langle \nabla g_j(x_k), \tilde{d}_k \rangle.$$

We obtain therefore,

$$\begin{aligned} (4.9) \quad f(x_k + d_k + \tilde{d}_k) - f(x_k) &= \frac{1}{2} \theta_k - \sum_j (\mu_k)_j \langle \nabla g_j(x_k), d_k \rangle \\ &\quad - \sum_j (\mu_k)_j \langle \nabla g_j(x_k), \tilde{d}_k \rangle - \frac{1}{2} d_k^T H_k d_k + \frac{1}{2} d_k^T \nabla_{xx} f(x_k) d_k \\ &\quad + O(|d_k|^\nu) + O(|d_k|^3) - \frac{1}{2} \sum_j (\mu_k)_j g_j(x_k). \end{aligned}$$

Now, since the g_j 's are three times continuously differentiable, the relation

$$g_j(x_k + d_k + \tilde{d}_k) = O(|d_k|^\tau), \quad j \in I(x^*)$$

obtained in (4.8) yields, for $j \in I(x^*)$,

$$g_j(x_k) + \langle \nabla g_j(x_k), d_k \rangle + \langle \nabla g_j(x_k), \tilde{d}_k \rangle + \frac{1}{2} d_k^T \nabla_{xx} g_j(x_k) d_k = O(|d_k|^\tau).$$

Hence,

$$\begin{aligned} & -\sum_j (\mu_k)_j \langle \nabla g_j(x_k), d_k \rangle - \sum_j (\mu_k)_j \langle \nabla g_j(x_k), \tilde{d}_k \rangle \\ & = \sum_j (\mu_k)_j g_j(x_k) + \frac{1}{2} \sum_j (\mu_k)_j d_k^T \nabla_{xx} g_j(x_k) d_k + O(|d_k|^\tau). \end{aligned}$$

Substituting those values into (4.9), we obtain

$$\begin{aligned} f(x_k + d_k + \tilde{d}_k) - f(x_k) &= \frac{1}{2} \theta_k + \frac{1}{2} \sum_j (\mu_k)_j g_j(x_k) \\ & \quad + \frac{1}{2} d_k^T \left(\nabla_{xx} f(x_k) + \sum_j (\mu_k)_j \nabla_{xx} g_j(x_k) - H_k \right) d_k \\ & \quad + O(|d_k|^\tau) + O(|d_k|^\nu). \end{aligned}$$

This, together with Lemmas 4.4 and 4.5, gives

$$\begin{aligned} & f(x_k + d_k + \tilde{d}_k) - f(x_k) - \alpha \theta_k \\ & \leq \left(\frac{1}{2} - \alpha \right) \theta_k + \frac{1}{2} d_k^T P_k \left(\nabla_{xx} f(x_k) + \sum_j (\mu_k)_j \nabla_{xx} g_j(x_k) - H_k \right) P_k d_k \\ & \quad + O(|d_k|^\tau) + O(|d_k|^\nu). \end{aligned}$$

Due to the convergence of the projections of the approximate Hessian matrices, we obtain

$$f(x_k + d_k + \tilde{d}_k) - f(x_k) - \alpha \theta_k \leq \left(\frac{1}{2} - \alpha \right) \theta_k + o(|d_k|^2).$$

In view of Lemma 4.6, the right-hand side of the last inequality is nonpositive. Thus the “sufficient decrease” condition is satisfied. \square

THEOREM 4.9. *Under the stated assumptions, the convergence is two-step superlinear, i.e., the following relation holds*

$$\lim_{k \rightarrow \infty} \frac{|x_{k+2} - x^*|}{|x_k - x^*|} = 0.$$

Proof. The proof is similar to the one of [18, Thm. 1]. \square

5. Implementation and computational results. Several implementation issues have to be addressed. First, the sequence $\{H_k\}$ of $n \times n$ matrices is thus far unspecified, subject only to requirement (4.1). While a secant approximation to the Hessian $\nabla_{xx}^2 L(x_k, \mu_k)$ would be suitable, use of an update formula avoids many function evaluations. Under some assumptions, matrices H_k generated by the BFGS formula [18] are shown to satisfy (4.1). The latter option, with $H_0 = I$, was selected for our experiments. Second, the order in which the tests (2.1) and (2.2) are performed needs to be specified. In our implementation, in line with the premise that the objective function may not be defined outside the feasible set, (2.2) was tested first and (2.1) was tested only when (2.2) was satisfied. Third, Algorithm A as stated does not efficiently handle affine constraints. In our experiments, the correction corresponding to such constraints was set to zero in the right-hand sides of the constraints in (QP) and (LS).

No: number of the test problem in [6].

Code: name of the program.

NF: number of objective function evaluations.

NDF: number of gradient evaluations of the objective function.

FV: objective function value at the final point.

VC: sum of constraint violation, given by $\sum_{j=1}^m \max(0, g_j(x))$, at the final point.

KT: norm of Kuhn-Tucker vector (i.e. norm of the gradient of the Lagrangian function at the final point).

However, in order to avoid potential zigzagging, the right-hand side in the condition defining I_k in (LS) was not set to zero for the affine constraints, but rather the corresponding “=” sign was changed to a “ \geq ”. Finally, *scaling* can be introduced at various places in the algorithm, and values have to be selected for the various parameters. If the right-hand side in the constraints in (QP) is too big, d_k may not be a descent direction for f in the early iterations, while if it is too small, the stepsize may be truncated, due to infeasibility, until a very small neighborhood of the solution is reached. In our experiments, the right-hand side of the constraints in (QP) and of the condition defining I_k in (LS) was replaced by $\max(-|d_k^0|^3, -10^{-2}|d_k^0|)$, which seems to often result in a satisfactory behavior on reasonably well scaled problems. For a similar reason, we replaced the right-hand side of the constraints in (LS) by $\max(-|d_k^0|^{5/2}, -10^{-2}|d_k^0|)$. The right-hand side of the test on θ_k in Step 1(ii) was scaled by a small number. This test was always satisfied throughout our experiments. Finally, we used $\alpha = .3$, $\beta = .8$ and $M = \infty$.

Algorithm A was tested on fourteen of the seventeen problems in [6] which do not involve equality constraints but do include *nonlinear* inequality constraints, and for which a feasible initial point is provided. Problems numbered 67, 70 and 85 were discarded due to some disparity between function values we computed and those given in [6]. When tested on Problem 93, with the chosen values of the algorithm parameters, Algorithm A had to resort to the first order direction (Step 1(ii)) for the initial iterations due to infeasibility of (QP), thus making the performance of Algorithm A dependent on the choice of the first order method. Table 1 shows the results obtained on the thirteen remaining problems. The results obtained with Algorithm A are compared to the best results among those given in [6], i.e., those obtained with algorithms VF02AD and OPRQP. The format of this table is as in [6].

In most cases, Algorithm A is competitive with VF02AD. It always performs better than OPRQP. This is remarkable since neither VF02AD nor OPRQP enjoys properties (1.1) and (1.2). It could be argued that a comparison based only on the number of function evaluations unduly favors Algorithm A, which calls for the solution of up to two quadratic programs and one linear least squares problem at each iteration. However, as pointed out in the introduction, clever implementation should reduce the computational effort needed to solve these three problems to little more than that required for the solution of a single quadratic program. Also, in the context of engineering design problems, function evaluations typically require such extensive computation that time spent in solving quadratic programs can generally be regarded as negligible. Finally, the number of constraint function evaluations is not indicated in Table 1. Typically, the number of such evaluations will be somewhat larger for Algorithm A than for its contenders due to the Maratos effect avoidance scheme.

STRUCTURE OF EXTREMALS IN OPTIMAL CONTROL PROBLEMS*

JACOB KOGAN†

Abstract. In this paper we study the structure of intersections of neighboring extremals in optimal control. The obtained results extend a known criterion for existence of a field of extremals from the calculus of variations to the optimal control theory.

Key words. calculus of variation, conjugate points, field of extremals, optimal control problem

AMS(MOS) subject classification. 49C05

1. Introduction. The classical theory of the calculus of variations presents necessary conditions for absence of conjugate points, namely the points of intersection of neighboring extremals initiating at the same point. The absence of conjugate points in the calculus of variations enables one to construct a field of extremals and to derive sufficient conditions for a strong extremum (see for example [1], [3], [5]–[9], [13]).

In this paper we accept the necessary conditions from the calculus of variations and investigate the structure of intersections of neighboring extremals in optimal control. It is shown in this work that, in contrast with the classical calculus of variations, neighboring extremals in an optimal control problem can intersect each other. On the other hand we demonstrate in this study that the set of intersections of extremals in optimal control possesses a simple elegant structure. The main result of the paper is the following: *Let $x(t)$ be an extremal trajectory defined on a time interval $[t_1, t_2]$. There exists a finite partition $t_1 = r_1 < r_2 < \dots < r_k = t_2$ of the time interval $[t_1, t_2]$ such that for each neighboring extremal $y(t)$ with $y(t_1) = x(t_1)$ and $y(s) = x(s)$ there exists an element r of the partition and the following condition holds:*

$$x(t) = y(t) \text{ on } [t_1, r] \quad \text{and} \quad x(t) \neq y(t) \quad \text{for each } t \in (r, t_2].$$

We show also that the partition is determined by the attainable set of the control system under consideration. We call the point r a branching point of the extremal $x(t)$ and say that $y(t)$ branches out of $x(t)$ at r .

The paper is organized as follows: In the second section we state the problem and introduce the main assumptions. The third section is devoted to study of extremals in a linear control system with a quadratic cost. The fourth section is the main part of the study. We consider there a nonlinear control problem and derive necessary and sufficient conditions for branching.

2. The problem. We introduce first, for the sake of convenience, the following convention: In order to distinguish between functions of a real variable and elements of the real Euclidean space R^n , we shall denote (for example) a function of a real variable by $x(\cdot)$, in contrast with a point x in R^n . The norm of $x \in R^n$ is denoted by $|x|$, $\langle x, y \rangle$ denotes the scalar product in R^n and $\dot{x}(t)$ denotes differentiation with respect to time, i.e. $\dot{x}(t) = dx(t)/dt$. The norm of an $n \times n$ matrix M is denoted by $|M|$, namely $|M| = \max \{|Mx| : |x| = 1\}$.

Consider an optimal control system

$$(2.1) \quad \dot{x}(t) = F(t, x(t), u(t))$$

* Received by the editors January 27, 1986; accepted for publication (in revised form) May 15, 1986.

where $u(\cdot) : [t_1, t_2] \mapsto R^m$ is measurable and $x(\cdot) : [t_1, t_2] \mapsto R^n$ is absolutely continuous, where measurability is understood to be in the Lebesgue sense, and equalities are always "almost everywhere." Following Berkovitz (see [2, p. 22]) we define an admissible pair as follows.

DEFINITION 2.1. Let $x(t)$ be an absolutely continuous function from $[t_1, t_2]$ to R^n and $u(t)$ be a measurable function from $[t_1, t_2]$ to R^m . The pair $(x(t), u(t))$ is admissible if it satisfies (2.1).

Consider a cost functional defined on the set of admissible pairs $(x(t), u(t))$ as follows:

$$(2.2) \quad c(x(\cdot), u(\cdot)) = \int_{t_1}^{t_2} f(t, x(t), u(t)) dt.$$

In order to describe the structure of extremals we need to recall some auxiliary notions.

DEFINITION 2.2. A trajectory $x(t)$ is an extremal trajectory of the optimal control problem (2.1), (2.2) if $(x(t), u(t))$ is an admissible pair and there exists a scalar $\eta_0 \leq 0$ and an absolutely continuous vector valued function $\eta(t)$ which is defined on $[t_1, t_2]$ and is a solution of the following ordinary differential equation:

$$(2.3) \quad \frac{d}{dt} \eta(t) = -\eta_0 \frac{\partial f}{\partial x}(t, x(t), u(t)) - \eta(t) \frac{\partial F}{\partial x}(t, x(t), u(t)),$$

and such that the triple $(x(t), u(t), \eta(t))$ satisfies the Pontryagin Maximum Principle, i.e., the following additional condition holds on $[t_1, t_2]$:

$$(2.4) \quad \begin{aligned} &\eta_0 f(t, x(t), u(t)) + \eta(t) F(t, x(t), u(t)) \\ &= \max_u \{ \eta_0 f(t, x(t), u) + \eta(t) F(t, x(t), u) \} \end{aligned}$$

(see [2, p. 186]). The last definitions show that an extremal trajectory, which is the main object of the study, usually appears together with an admissible control and a corresponding solution of the adjoint equation (2.3). For the sake of the technical convenience we introduce now the notion of an extremal triple.

DEFINITION 2.3. A triple $(x(t), u(t), \eta(t))$ is an extremal triple if $(x(t), u(t))$ is an admissible pair, $\eta(t)$ is a solution of (2.3) and the triple $(x(t), u(t), \eta(t))$ satisfies condition (2.4).

DEFINITION 2.4. The Hamiltonian H of the optimal control problem (2.1), (2.2) is defined as follows:

$$H(t, x, u, \eta) = \eta_0 f(t, x, u) + \eta F(t, x, u).$$

In this paper we consider the structure of regular extremals only. Namely, we suppose throughout that $\eta_0 = -1$.

We present now the definition of a branching point of the extremal trajectory $x(t)$. Suppose that there exists a neighboring extremal $y(t)$ such that $x(t)$ and $y(t)$ coincide over an initial subinterval $[t_1, r]$ of the time interval $[t_1, t_2]$ and differ on the rest of it. Namely, $x(t) = y(t)$ for each $t \in [t_1, r]$ and $x(t) \neq y(t)$ for each $t \in (r, t_2]$. In this case we say that r is a branching point of the extremal trajectory $x(t)$, and $y(t)$ branches out of $x(t)$ at r .

We wish to emphasize that our interest concentrates on the branching points of the extremal trajectory $x(t)$ formed by neighboring extremals initiating at the same point $x(t_1)$, where by a neighboring extremal we mean an extremal $y(t)$ such that the norm $\|x(\cdot), \eta(\cdot) - (y(\cdot), \mu(\cdot))\|_{C[t_1, t_2]}$ is small (how small will be specified later).

Here $\eta(t)$, $\mu(t)$ are the corresponding solutions of the adjoint equation (2.3) and $\sup \{|x(t) - y(t)| + |\eta(t) - \mu(t)| : t \in [t_1, t_2]\}$ is denoted by $\|(x(\cdot), \eta(\cdot)) - (y(\cdot), \mu(\cdot))\|_{C[t_1, t_2]}$.

Let $y(t)$ be an extremal trajectory of the control problem (2.1), (2.2) with $y(t_1) = x(t_1)$. It is shown in the last section (see Theorem 4.2) that there exists a positive ε such that, if $\|(x(\cdot), \eta(\cdot)) - (y(\cdot), \mu(\cdot))\|_{C[t_1, t_2]} < \varepsilon$ and $x(r) \neq y(r)$ for some $r \in [t_1, t_2]$, then $x(t) \neq y(t)$ for each $t \in [r, t_2]$. On the other hand we show by an example (see Example 4.1) that, if the condition $\|(x(\cdot), \eta(\cdot)) - (y(\cdot), \mu(\cdot))\|_{C[t_1, t_2]} < \varepsilon$ is not satisfied, the extremal $y(t)$ can be different from $x(t)$ on a subinterval $[r, r + \delta)$ and intersect $x(t)$ once again on $[r + \delta, t_2]$.

In order to present the formal definition of a branching point we need to define rigorously what is meant by a neighboring extremal in this study. We say, first, that an extremal $y(t)$ is an ε -neighboring extremal if $\|(x(\cdot), \eta(\cdot)) - (y(\cdot), \mu(\cdot))\|_{C[t_1, t_2]} < \varepsilon$. A point r is an ε -branching point of the extremal trajectory $x(t)$ if there exists an ε -neighboring extremal $y(t)$ such that

$$x(t) = y(t) \quad \text{on } [t_1, r], \quad x(t) \neq y(t) \quad \text{on } (r, t_2].$$

It is clear, that if $\varepsilon_1 < \varepsilon_2$, then the set of ε_1 -branching points is a subset of that of ε_2 -branching points. It is shown in the last section (see Definition 4.1) that there exists an $\varepsilon^* > 0$ such that, for each positive ε less than ε^* , the set of ε^* -branching points coincides with that of ε points. From here on this ε^* will define the set of neighboring extremal trajectories as follows.

DEFINITION 2.5. An extremal trajectory $y(t)$ is a neighboring extremal if the inequality $\|(x(\cdot), \eta(\cdot)) - (y(\cdot), \mu(\cdot))\|_{C[t_1, t_2]} < \varepsilon^*$ holds.

This definition enables us to define a branching point as follows.

DEFINITION 2.6. A point r is a branching point of the extremal trajectory $x(t)$ if there exists a neighboring extremal trajectory $y(t)$ such that

$$x(t) = y(t) \quad \text{on } [t_1, r], \quad x(t) \neq y(t) \quad \text{on } (r, t_2].$$

Our main purpose in this work is to determine the conditions under which the branching points of an extremal $x(t)$ exist or do not exist and to characterize the set of branching points of $x(t)$.

Relationship with the calculus of variations. The classical theory of the calculus of variations deals with the linear control system

$$\dot{x}(t) = u(t)$$

with a cost functional

$$\int_{t_1}^{t_2} f(t, x(t), u(t)) dt.$$

Sufficient conditions for **nonexistence** of conjugate points on the interval $[t_1, t_2]$ are the following:

(1) $f_{uu}(t, x(t), u(t))$ is positive definite along the chosen extremal $x(t)$ (the strengthened Legendre condition),

$$(2) \quad \int_{t_1}^{t_2} \begin{pmatrix} h(t) \\ \dot{h}(t) \end{pmatrix}^* \begin{pmatrix} f_{xx}(t, x(t), u(t)) & f_{ux}(t, x(t), u(t)) \\ f_{xu}(t, x(t), u(t)) & f_{uu}(t, x(t), u(t)) \end{pmatrix} \begin{pmatrix} h(t) \\ \dot{h}(t) \end{pmatrix} dt$$

is positive definite for each $h(t)$ such that $h(t_1) = h(t_2) = 0$, where $*$ indicates the transpose, i.e., the second variation of the cost functional along $x(t)$ is positive definite. Namely, if conditions 1 and 2 hold for the extremal $x(t)$, then the interval $[t_1, t_2]$ contains no point conjugate to t_1 (see [8, Thm. 4, p. 123]).

In order to describe the branching points of $x(t)$ we adopt a natural generalization of the sufficient conditions of the calculus of variations namely we assume that the following holds for the extremal triple $(x(t), u(t), \eta(t))$.

Hypothesis 2.1. (1) There exists a positive scalar m such that for each vector $v \in R^m$

$$v^* H_{uu}(t, x(t), u(t), \eta(t)) v \leq -m|v|^2 \quad \text{along } x(t),$$

and for each positive ρ there exists a positive δ such that

$$|H_{uu}(t, x(t), u(t), \eta(t)) - H_{uu}(t, y, w, \xi)| < \rho$$

provided

$$|(t, x(t), u(t), \eta(t)) - (t, y, w, \xi)| < \delta.$$

$$(2) \quad \int_{t_1}^{t_2} \begin{pmatrix} z(t) \\ v(t) \end{pmatrix}^* \begin{pmatrix} H_{xx}(t, x(t), u(t), \eta(t)) & H_{ux}(t, x(t), u(t), \eta(t)) \\ H_{xu}(t, x(t), u(t), \eta(t)) & H_{uu}(t, x(t), u(t), \eta(t)) \end{pmatrix} \begin{pmatrix} z(t) \\ v(t) \end{pmatrix} dt$$

is negative definite for each $v(t)$, $z(t)$ such that

$$z(t) = \int_{t_1}^t \Phi(t, \sigma) B(\sigma) v(\sigma) d\sigma, \quad z(t_2) = 0,$$

where $A(t)$, $B(t)$ are Lebesgue integrable matrices on $[t_1, t_2]$ given by $A(t) = \partial F / \partial x(t, x(t), u(t))$, $B(t) = \partial F / \partial u(t, x(t), u(t))$ and $\Phi(t, t_1)$ is the transition matrix of $d/dt \phi = A(t)\phi$, i.e., $\phi(t) = \Phi(t, t_1)x_1$ is the solution of the equation $d/dt \phi = A(t)\phi$ with $\phi(t_1) = x_1$. In other words: $z(t)$ is a solution of the linear equation

$$\dot{z}(t) = A(t)z(t) + B(t)v(t)$$

with boundary conditions $z(t_1) = z(t_2) = 0$.

We wish to clarify now the connection between Hypothesis 2.1 and the sufficient conditions of the calculus of variations. Note, that in the calculus of variations the cost function $f(t, x, u)$ has continuous first and second partial derivatives with respect to all its arguments. In this case the first condition of Hypothesis 2.1 is just the strengthened Legendre condition. The second condition is well known in the calculus of variations property of the second variation of the cost functional to be positive definite.

We wish to be able to present extremals as solutions of the Hamiltonian system (2.5), (2.6) displayed below. To this end we assume the existence of an optimal feedback as follows.

Hypothesis 2.2. There exists a positive scalar ε_1 such that for each triple (t, x, η) with $|(x, \eta) - (x(t), \eta(t))| < \varepsilon_1$ there exists a unique control function $\bar{u}(t, x, \eta)$ continuously differentiable with respect to (x, η) and measurable in t such that

$$-f(t, x, \bar{u}(t, x, \eta)) + \eta F(t, x, \bar{u}(t, x, \eta)) = \max_u \{-f(t, x, u) + \eta F(t, x, u)\} \quad \text{on } [t_1, t_2].$$

Without any loss of generality (due to Hypothesis 2.1) we shall assume throughout that this ε_1 is sufficiently small in order to guarantee that for each quadruple $(t, y, w, \eta) \in R \times R^n \times R^m \times R^n$ such that $|(y, w, \mu) - (x(t), u(t), \eta(t))| < \varepsilon_1$ the following condition holds:

$$v^* H_{uu}(t, y, w, \mu) v \leq -\frac{m}{2}|v|^2 \quad \text{for each } v \in R^m$$

This assumption enables one to reduce the study of extremals to the study of solutions $(x(t), \eta(t))$ of the following system of ordinary differential equations:

$$(2.5) \quad \dot{x}(t) = H_{\eta}(t, x(t), \bar{u}(t, x(t), \eta(t)), \eta(t)),$$

$$(2.6) \quad \dot{\eta}(t) = -H_x(t, x(t), \bar{u}(t, x(t), \eta(t)), \eta(t)).$$

The presentation of extremals as solutions of the Hamiltonian system (2.5), (2.6) will be extremely useful in this study.

Our first result deals with a linear control system with a quadratic cost functional. We will show in the last section of the paper that, in the case of a nonlinear control system, the branching points of the extremal trajectory $x(t)$ are determined by the linearized system about the extremal $x(t)$. Hence, characterization of the branching points in this simplest case is a significant step forward.

3. Linear control problem. We consider in this section a linear control system

$$(3.1) \quad \dot{x}(t) = A(t)x(t) + B(t)u(t)$$

with a quadratic cost

$$(3.2) \quad c(x(\cdot), u(\cdot)) = \int_{t_1}^{t_2} \begin{pmatrix} x(t) \\ u(t) \end{pmatrix}^* \begin{pmatrix} R_{11}(t) & R_{12}(t) \\ R_{21}(t) & R_{22}(t) \end{pmatrix} \begin{pmatrix} x(t) \\ u(t) \end{pmatrix} dt,$$

where $x \in R^n$, $u \in R^m$ and $A(t)$, $B(t)$, $R_{11}(t)$, $R_{12}(t)$, $R_{21}(t)$, $R_{22}(t)$ are matrices with appropriate dimensionalities whose elements are Lebesgue integrable functions on $[t_1, t_2]$ and $*$ indicates the transpose. For convenience we assume throughout that $R_{12}(t) = R_{21}^*(t)$.

Note that in this case Hypothesis 2.1 turns into the following.

Hypothesis 3.1. (1) $R_{22}(t)$ is uniformly positive definite on $[t_1, t_2]$. Namely, there exists a positive scalar δ such that $u^* R_{22}(t) u \geq \delta |u|^2$ on $[t_1, t_2]$ for each $u \in R^m$.

(2) For each admissible pair $(z(t), v(t))$ with $z(t_1) = z(t_2) = 0$ the cost $c(z(\cdot), v(\cdot)) \geq 0$ and $c(z(\cdot), v(\cdot)) = 0$ if and only if $(z(t), v(t)) = (0, 0)$.

In the case of the linear control problem (3.1), (3.2), Hypothesis 2.2 is fulfilled and one can derive an explicit formula for extremal control as follows:

$$(3.3) \quad \bar{u}(t, x, \eta) = \frac{1}{2} R_{22}^{-1}(t) \{ B^*(t) \eta^* - 2 R_{12}(t) x \}.$$

The adjoint equation is

$$(3.4) \quad \dot{\eta}(t) = 2x^*(t) R_{11}(t) + 2u^*(t) R_{12}(t) - \eta(t) A(t)$$

and the Pontryagin Maximum Principle is

$$(3.5) \quad -2u^*(t) R_{22}(t) - 2x^*(t) R_{12}(t) + \eta(t) B(t) = 0.$$

We wish to show now that branching is a unique possible form of intersection of extremals initiating at the same point. First we mention the following important property of extremals of the linear control problem (3.1), (3.2).

THEOREM 3.1. Let $(x(t), u(t))$ be an extremal pair. Then for each admissible pair $(y(t), w(t))$ with $x(t_1) = y(t_1)$ and $x(t_2) = y(t_2)$

$$c(x(\cdot), u(\cdot)) \leq c(y(\cdot), w(\cdot)) \quad \text{and} \quad c(x(\cdot), u(\cdot)) = c(y(\cdot), w(\cdot))$$

$$\text{if and only if } (x(t), u(t)) = (y(t), w(t)).$$

Proof. We wish to show that $c(y(\cdot), w(\cdot)) - c(x(\cdot), u(\cdot)) \geq 0$. The pair $(x(t), u(t))$ is an extremal pair, hence the first element of the Taylor expansion of the difference vanishes (see e.g. [11, p. 357]). The second (and the last term) of the expansion is $c(y(\cdot) - x(\cdot), w(\cdot) - u(\cdot))$. Due to Hypothesis 3.1, $c(y(\cdot) - x(\cdot), w(\cdot) - u(\cdot)) \geq 0$ and $c(y(\cdot) - x(\cdot), w(\cdot) - u(\cdot)) = 0$ if and only if $x(t) = y(t)$ and $u(t) = w(t)$. This finishes the proof.

Let $(x(t), u(t))$ and $(y(t), w(t))$ be extremal pairs with $x(t_1) = y(t_1)$ and $x(s) = y(s)$ for some $s \in [t_1, t_2]$. Denote

$$\int_{t_1}^s \begin{pmatrix} x(t) \\ u(t) \end{pmatrix}^* \begin{pmatrix} R_{11}(t) & R_{12}(t) \\ R_{21}(t) & R_{22}(t) \end{pmatrix} \begin{pmatrix} x(t) \\ u(t) \end{pmatrix} dt \quad \text{by } c_s(x(\cdot), u(\cdot)).$$

Due to Theorem 3.1, $c_s(x(\cdot), u(\cdot)) \leq c_s(y(\cdot), w(\cdot))$ and $c_s(y(\cdot), w(\cdot)) \leq c_s(x(\cdot), u(\cdot))$, namely $c_s(y(\cdot) - x(\cdot), w(\cdot) - u(\cdot)) = 0$ and $y(t) = x(t)$, $w(t) = u(t)$ on $[t_1, s]$. This remark justifies introduction of the notion of a branching point.

In order to illustrate the phenomenon of branching we wish to consider a simple example. In spite of its simplicity, this example, as will be shown in this section, presents a typical case of branching.

Example 3.1. A linear control system with a nonempty set of branching points. Consider a linear control system

$$\frac{d}{dt}x(t) = B(t)u(t)$$

with a cost functional

$$c(x(\cdot), u(\cdot)) = \int_0^1 u^2(t) dt$$

with $x \in \mathbb{R}^2$, where u is a scalar and $B(t)$ is given by

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \text{for } 0 \leq t < \frac{1}{3}, \quad \begin{pmatrix} 0 \\ 0 \end{pmatrix} \quad \text{for } \frac{1}{3} \leq t < \frac{2}{3}, \quad \begin{pmatrix} 0 \\ 1 \end{pmatrix} \quad \text{for } \frac{2}{3} \leq t \leq 1.$$

An extremal control in this case has the following form

$$u(t) = B^*(t)\eta^*(t),$$

where $\eta(t)$ is a solution of the adjoint ordinary differential equation $\dot{\eta}(t) = 0$ (see [11, p. 180]) and $*$ indicates the transpose. Note, that $\eta(t) = \eta(0)$ and we shall denote it simply as η . It then follows that $u(t) = B(t)^*\eta^*$ for each $t \in [0, 1]$. An extremal trajectory $x(t)$ is, therefore, given by

$$x(t) = x(0) + \int_0^t B(s)B^*(s)\eta^* ds.$$

The product $B(t)B^*(t)$ can easily be computed and the derived extremal trajectory $x(t)$ has the following form:

$$x(t) = x(0) + \gamma(t)$$

where the vector $\gamma(t)$ is given by

$$\begin{pmatrix} t\eta_1 \\ 0 \end{pmatrix} \quad \text{for } 0 \leq t < \frac{1}{3}, \quad \begin{pmatrix} \frac{1}{3}\eta_1 \\ 0 \end{pmatrix} \quad \text{for } \frac{1}{3} \leq t < \frac{2}{3}, \quad \begin{pmatrix} \frac{1}{3}\eta_1 \\ (t - \frac{2}{3})\eta_2 \end{pmatrix} \quad \text{for } \frac{2}{3} \leq t \leq 1.$$

Here η_1, η_2 are the components of the vector η .

We would like to study the extremal trajectories initiating at the same initial point $x(0)$.

The definition of $\gamma(t)$ implies that for each pair of different vectors η, μ such that $\eta_1 = \mu_1$ and $\eta_2 \neq \mu_2$, the corresponding extremal trajectories $x(t)$ and $y(t)$ coincide on the time interval $[0, \frac{2}{3}]$ and are different on $(\frac{2}{3}, 1]$. Namely, if, for instance, $x(0) = 0$, $\eta = (1, 0)$, and $\mu = (1, 1)$ then $x(t)$ is given by

$$\begin{pmatrix} t \\ 0 \end{pmatrix} \text{ for } 0 \leq t < \frac{1}{3}, \quad \begin{pmatrix} \frac{1}{3} \\ 0 \end{pmatrix} \text{ for } \frac{1}{3} \leq t < \frac{2}{3}, \quad \begin{pmatrix} \frac{1}{3} \\ 0 \end{pmatrix} \text{ for } \frac{2}{3} \leq t \leq 1,$$

and $y(t)$ is given by

$$\begin{pmatrix} t \\ 0 \end{pmatrix} \text{ for } 0 \leq t < \frac{1}{3}, \quad \begin{pmatrix} \frac{1}{3} \\ 0 \end{pmatrix} \text{ for } \frac{1}{3} \leq t < \frac{2}{3}, \quad \begin{pmatrix} \frac{1}{3} \\ t - \frac{2}{3} \end{pmatrix} \text{ for } \frac{2}{3} \leq t \leq 1,$$

i.e., $x(t) = y(t)$ on $[0, \frac{2}{3}]$, and $x(t) \neq y(t)$ on $(\frac{2}{3}, 1]$.

Suppose that different extremal trajectories $x(t), y(t)$ coincide on a certain subinterval $[0, \tau]$ of $[0, 1]$. We denote by $\eta(t), \mu(t)$ the corresponding solutions of the adjoint differential equation. In this case $\eta_1 = \mu_1$. On the other hand, inasmuch as $x(t)$ and $y(t)$ are different, $\eta_2 \neq \mu_2$. This means that $\tau = \frac{2}{3}$.

The above considerations prove that $\frac{2}{3}$ is the unique branching point of the considered optimal control problem. Hence, the set of the branching points of this control problem is a finite set. As it will be shown in the end of the section, this result is not incidental, but rather holds for a general linear control system with a convex cost. Namely, the set of branching points is a finite set which does not depend on a chosen extremal.

In order to investigate branching points of extremals, introduction of some additional auxiliary definitions is needed. We present now the formal definition of the space of admissible controls of the linear control system (3.1) defined on a subinterval $[t_1, s]$ of the time interval $[t_1, t_2]$.

DEFINITION 3.1. A measurable function $v(t)$ defined on a subinterval $[t_1, s]$ of the time interval $[t_1, t_2]$ with range in R^m is an admissible control if there exists an absolutely continuous function $\phi(t)$ defined on $[t_1, s]$ with range in R^n which is a solution of the differential equation (3.1), i.e.,

$$\dot{\phi}(t) = A(t)\phi(t) + B(t)v(t) \quad \text{a.e. on } [t_1, s].$$

The space of all admissible controls $v(t)$ defined on the interval $[t_1, s]$ is denoted by $U[t_1, s]$.

For each subspace V of R^n we denote by V^\perp its orthogonal complement in R^n . We introduce now a family of vector spaces which determines branching points of extremal trajectories.

DEFINITION 3.2. For each real number s we define two vector spaces $V(t_1, s)$ and $V(t_1, s^+)$ by the following formulas:

$$V(t_1, s) = \left\{ \int_{t_1}^s \Phi(t_1, t)B(t)v(t) dt \mid v(\cdot) \in U[t_1, s] \right\},$$

$$V(t_1, s^+) = \bigcap_{h>0} V(t_1, s+h),$$

where $\Phi(t, \tau)$ is the transition matrix of $d/dt \phi = A(t)\phi$, i.e., $\phi(t) = \Phi(t, \tau)x_\tau$ is the solution of the equation $d/dt \phi(t) = A(t)\phi(t)$ with $\phi(\tau) = x_\tau$.

Denote the dimension of $V(t_1, s)$ by $\dim V(t_1, s)$. Consider $\dim V(t_1, s)$ as a function of s . Choose s_1, s_2 such that $t_1 \leq s_1 \leq s_2$. Definition 3.2 implies that $V(t_1, s_1)$ is a subspace of $V(t_1, s_2)$. On the other hand for each s the space $V(t_1, s)$ is a subspace

of R^n and, therefore, $\dim V(t_1, s) \leq n$. The above consideration shows that $\dim V(t_1, s)$ is a monotone nondecreasing step function with respect to s . This implies that the number of its discontinuity points is finite. Note, that $V(t_1, s) \subset V(t_1, s^+)$; but $V(t_1, s) \neq V(t_1, s^+)$ if and only if s is a point of discontinuity of $\dim V(t_1, s)$. In the remainder of the section we will show that the points of discontinuity of $\dim V(t_1, s)$ are the branching points of the linear control problem (3.1), (3.2).

At this point we wish to mention a relationship between the vector space $V(t_1, s)$ and the attainable set of the control system (3.1). The attainable set at time s for the control system with initial time t_1 and initial state x_1 is the set of all points $x \in R^n$ such that, for some trajectory $\varphi(t)$ satisfying the condition $\varphi(t_1) = x_1$, the relation $\varphi(s) = x$ holds. In the case when the initial state x_1 is chosen to be 0 the attainable set at time s is a linear subspace of R^n which is denoted by $AT(s; t_1, 0)$.

The set $AT(s; t_1, 0)$ is given by the following formula:

$$AT(s; t_1, 0) = \left\{ \int_{t_1}^s \Phi(s, t) B(t) v(t) dt, v(\cdot) \in U[t_1, s] \right\}.$$

Hence, there is an evident relation between the sets $V(t_1, s)$ and $AT(s; t_1, 0)$, namely

$$V(t_1, s) = \Phi(t_1, s) AT(s; t_1, 0).$$

Since $\Phi(t_1, s)$ is nonsingular, it follows that $\dim V(t_1, s) = \dim AT(s; t_1, 0)$. This implies that the points of discontinuity of $\dim V(t_1, s)$ are exactly the points where the dimension of the attainable set changes. The next statements clarify the importance of this set.

Necessary and sufficient conditions for branching.

LEMMA 3.1. *Let $(x(t), u(t), \eta(t))$ be an extremal triple such that $x(t_1) = 0$ and $\eta(t_1) \in V(t_1, r)^\perp$. Then $(x(t), u(t), \eta(t)) = (0, 0, \eta(t_1)\Phi(t_1, t))$ on $[t_1, r]$.*

Proof. Straightforward verification shows that the triple $(0, 0, \eta(t_1)\Phi(t_1, t))$ is an extremal triple of the optimal control problem (3.1), (3.2) on the initial time interval $[t_1, r]$. Namely, $(0, \eta(t_1)\Phi(t_1, t))$ is a solution of the Hamiltonian system (3.7), (3.8) on the time interval $[t_1, r]$. Note that $(x(t), \eta(t))$ is also a solution of the same Hamiltonian system. Moreover, these two solutions have the same initial conditions, hence $(x(t), \eta(t)) = (0, \eta(t_1)\Phi(t_1, t))$ on $[t_1, r]$. In accordance with (3.3) and the condition $\eta(t_1) \in V(t_1, r)^\perp$ the control $u(t)$ is 0 on $[t_1, r]$.

LEMMA 3.2. *Let $(x(t), u(t), \eta(t))$ be an extremal triple such that $x(t) = 0$ on $[t_1, r]$. Then $\eta(t_1) \in V(t_1, r)^\perp$.*

Proof. Note, that if $x(t) = 0$ on $[t_1, r]$ then

$$0 = \dot{x}(t) = \frac{1}{2} B(t) R_{22}^{-1}(t) B^*(t) \eta^*(t) \quad \text{on } [t_1, r],$$

so that

$$0 = \eta(t) B(t) R_{22}^{-1}(t) B^*(t) \eta^*(t) \quad \text{on } [t_1, r].$$

The matrix $R_{22}^{-1}(t)$ is positive definite, hence $\eta(t) B(t) = 0$ on $[t_1, r]$. This implies, due to formula (3.3), that $u(t) = 0$ on $[t_1, r]$. Then, due to (3.4)

$$\eta(t) = \eta(t_1) \Phi(t_1, t) \quad \text{on } [t_1, r],$$

and finally (3.5) yields

$$\eta(t_1) \Phi(t_1, t) B(t) = 0 \quad \text{on } [t_1, r].$$

In other words $\eta(t_1) \in V(t_1, r)^\perp$.

We present now the main result of the section.

THEOREM 3.2. *Let $(x(t), u(t), \eta(t))$ and $(y(t), w(t), \mu(t))$ be two extremal triples with $x(t_1) = y(t_1)$. Then $x(t) = y(t)$ on $[t_1, r]$ if and only if $\eta(t_1) - \mu(t_1) \in V(t_1, r)^\perp$. If $x(r) = y(r)$, then $(x(t), u(t)) = (y(t), w(t))$ on $[t_1, r]$ and $\eta(t) - \mu(t) = (\eta(t_1) - \mu(t_1))\Phi(t_1, t)$ on $[t_1, r]$.*

Proof. Invoke Lemmas 3.1 and 3.2.

Thus it turns out that the set of branching points does not depend on the chosen extremal trajectory and the cost functional. It makes sense, therefore, to speak about the set of branching points of the linear system (3.1) on the time interval $[t_1, t_2]$. This set is exactly the set of discontinuity points of the function $\dim V(t_1, s)$. In particular, in the case where the coefficients of the system are constants, i.e., $A(t) = A$ and $B(t) = B$, there are no branching points at all.

Remark 3.1. Note that in the case of the linear control system (3.1) with the quadratic cost (3.2) the Hamiltonian system (2.5), (2.6) is a system of linear differential equations with respect to (x, η) . Let $(x(t; \xi), \eta(t; \xi))$ be a solution of this system with $x(t_1; \xi) = 0$ and $\eta(t_1, \xi) = \xi$. For each time $t \in [t_1, t_2]$ consider a linear mapping $\phi_t: R^n \rightarrow R^n$ defined as follows:

$$\phi_t(\xi) = x(t; \xi).$$

In accordance with Theorem 3.2 the rank of the matrix $\partial\phi_t(\cdot)/\partial\xi$ is $\dim V(t_1, t)$. Namely

$$(3.6) \quad \text{rank} \frac{\partial\phi_t(\cdot)}{\partial\xi} = \dim V(t_1, t).$$

On the other hand $\dim V(t_1, t) = \dim AT(t; t_1, 0)$. Hence for each $x \in AT(t; t_1, 0)$ there exists an extremal $x(s)$ with $x(t_1) = 0$ and $x(t) = x$. This remark and the relation (3.6) will be extremely useful for future investigation of the branching points in nonlinear control problems.

4. Nonlinear control problem. In this section we shall be concerned with the nonlinear control problem (2.1), (2.2). The main result of the section is the following: *Let $(x(t), u(t), \eta(t))$ be an extremal triple such that Hypothesis 2.1 and Hypothesis 2.2 are satisfied. The set of branching points of $x(t)$ coincides with that of the linear control system*

$$(4.1) \quad \dot{z}(t) = A(t)z(t) + B(t)v(t),$$

where $A(t) = \partial F / \partial x(t, x(t), u(t))$ and $B(t) = \partial F / \partial u(t, x(t), u(t))$.

However, in order to obtain the result we need to impose an additional restriction. Consider a solution $(y(t), \mu(t))$ of the Hamiltonian system (2.5), (2.6) with $y(t_1) = x_1$, $\mu(t_1) = \xi$. Denote this solution by $(x(t; x_1, \xi), \eta(t; x_1, \xi))$. Once selected, $x(t_1)$ will not be changed throughout this section. Hence, this solution can be unambiguously denoted by $(x(t; \xi), \eta(t; \xi))$.

We wish to ensure the smooth (C^1) dependence of solutions $\{x(t; \xi)\}$ on initial conditions $\{\xi\}$. To this end an additional assumption is introduced.

Assumption 4.1. There exists a Lebesgue integrable function $m(t)$ such that for each extremal triple $(y(t), w(t), \mu(t))$ generated by $\mu(t_1)$ close to $\eta(t_1)$, the following condition holds:

$$\begin{aligned} & \left| \begin{pmatrix} H_\eta(t, y(t), w(t), \mu(t)) \\ -H_x(t, y(t), w(t), \mu(t)) \end{pmatrix} \right| \\ & + \left| \begin{pmatrix} H_{\eta x}(t, y(t), w(t), \mu(t)), & H_{\eta\eta}(t, y(t), w(t), \mu(t)) \\ -H_{xx}(t, y(t), w(t), \mu(t)), & -H_{x\eta}(t, y(t), w(t), \mu(t)) \end{pmatrix} \right| \leq m(t). \end{aligned}$$

The mapping $(x(t; \cdot), \eta(t; \cdot)): R^n \mapsto R^n \times R^n (\xi \mapsto (x(t; \xi), \eta(t; \xi)))$ is, therefore, continuously differentiable with respect to ξ . (A proof can be easily constructed with minor changes from that of [4, Thm. 7.2, p. 25].) Our first goal is to derive sufficient conditions for matching of extremals.

Sufficient conditions for matching of extremals. Consider a solution $(y(t), \mu(t))$ of the Hamiltonian system (2.5), (2.6) with $y(t_1) = x(t_1)$. The matrices $A(t)$, $B(t)$ will henceforth be as defined at the beginning of the section and $V(t_1, r)$ and $\Phi(t_1, t)$ be correspondingly defined. Let ε_2 be a positive constant such that the condition $|\eta(t_1) - \mu(t_1)| < \varepsilon_2$ implies that for each $t \in [t_1, t_2]$

1. $|(x(t), \eta(t)) - (y(t), \mu(t))| < \varepsilon_1$,
2. $|\mu(t_1) - \eta(t_1)| |\Phi(t_1, t)| < \varepsilon_1$.

(We remind the reader, that the constant ε_1 was introduced in Hypothesis 2.2.)

LEMMA 4.1. *Let $(y(t), w(t), \mu(t))$ be an extremal triple such that $y(t_1) = x(t_1)$ and $|\mu(t_1) - \eta(t_1)| < \varepsilon_2$. If $\mu(t_1) - \eta(t_1) \in V(t_1, r)^\perp$, then $(y(t), w(t)) = (x(t), u(t))$ on $[t_1, r]$.*

Denote $(\mu(t_1) - \eta(t_1))\Phi(t_1, t)$ by $\Delta(t)$. The proof consists of the following three steps. First we show that the triple $(x(t), u(t), \eta(t) + \Delta(t))$ is an extremal triple of the control problem (2.1), (2.2) on $[t_1, r]$. Second, note that $(x(t), \eta(t) + \Delta(t))$ and $(y(t), \mu(t))$ are the solutions of the Hamiltonian system (2.5), (2.6) over an initial subinterval $[t_1, r]$ with the same initial conditions $(y(t_1), \mu(t_1))$. This yields

$$x(t) = y(t), \quad \eta(t) + \Delta(t) = \mu(t) \quad \text{on } [t_1, r].$$

Third, using the results of the first and second steps we point out the following relation:

$$u(t) = \bar{u}(t, x(t), \eta(t)) = \bar{u}(t, x(t), \eta(t) + \Delta(t)) = \bar{u}(t, y(t), \mu(t)) = w(t) \quad \text{on } [t_1, r].$$

This will finish the proof.

Proof. We wish to show that the triple $(x(t), u(t), \eta(t) + \Delta(t))$ is an extremal triple of the control problem (2.1), (2.2) over $[t_1, r]$. Note that the relation

$$H(t, x(t), u(t), \eta(t) + \Delta(t)) = \max_u H(t, x(t), u, \eta(t) + \Delta(t)) \quad \text{holds on } [t_1, r].$$

Indeed, due to the definition of $\bar{u}(t, x, \eta)$ (see Hypothesis 2.2)

$$H_u(t, x(t), u(t), \eta(t)) = 0 \quad \text{on } [t_1, t_2],$$

and $H_u(t, x(t), u(t), \eta(t) + \Delta(t)) = H_u(t, x(t), u(t), \eta(t)) + \Delta(t)B(t)$ on $[t_1, r]$.

Since $\mu(t_1) - \eta(t_1) \in V(t_1, r)^\perp$ and all bounded measurable $v(\cdot): [t_1, r] \rightarrow R^m$ belong to $U[t_1, r]$, we have

$$\Delta(t)B(t) = 0 \quad \text{on } [t_1, r].$$

It then follows that

$$H_u(t, x(t), u(t), \eta(t) + \Delta(t)) = 0 \quad \text{on } [t_1, r].$$

Suppose that

$$\max_u H(t, x(t), u, \eta(t) + \Delta(t)) = H(t, x(t), v(t), \eta(t) + \Delta(t)) \quad \text{on } [t_1, r].$$

The last relation yields

$$H_u(t, x(t), v(t), \eta(t) + \Delta(t)) = 0 \quad \text{on } [t_1, r].$$

This implies (in light of a lemma that we shall provide later) that $u(t) = v(t)$ on $[t_1, r]$, namely $u(t) = \bar{u}(t, x(t), \eta(t) + \Delta(t))$ and, therefore, $(x(t), u(t), \eta(t) + \Delta(t))$ is indeed an extremal triple. This completes the proof.

Here is the missing link we promised.

LEMMA 4.2. Let $\Delta(t) = \Delta(t_1)\Phi(t_1, t)$. If $|\Delta(t)| < \varepsilon_1$ for each $t \in [t_1, t_2]$, then the condition

$$H_u(t, x(t), u(t), \eta(t) + \Delta(t)) = 0 \quad \text{on } [t_1, r]$$

implies that $\bar{u}(t, x(t), \eta(t) + \Delta(t)) = u(t)$ on $[t_1, r]$.

Proof. Let $t \in [t_1, r]$. Our main goal is to show that $\bar{u}(t, x(t), \eta(t) + \Delta(t)) = u(t)$. Let λ be a scalar between 0 and 1; then

$$H_u(t, x(t), u(t), \eta(t) + \lambda \Delta(t)) = 0$$

and

$$v H_{uu}(t, x(t), u(t), \eta(t) + \lambda \Delta(t)) v \leq -\frac{m}{2} |v|^2 \quad \text{for each } v \in R^m.$$

Hence (due to the Implicit Function Theorem) for each $\lambda \in [0, 1]$ there exist positive scalars ε_λ and δ_λ , and a unique differentiable with respect to (y, μ) function $v_\lambda(t, y, \mu)$ defined on triples (t, y, μ) in an ε_λ neighborhood of $(t, x(t), \eta(t) + \lambda \Delta(t))$ (i.e. $|(y, \mu) - (x(t), \eta(t) + \lambda \Delta(t))| < \varepsilon_\lambda$) such that

$$H_u(t, y, v_\lambda(t, y, \mu), \mu) = 0 \quad \text{and} \quad v_\lambda(t, x(t), \eta(t) + \theta \Delta(t)) = u(t) \\ \text{for } \theta \in [\lambda - \delta_\lambda, \lambda + \delta_\lambda].$$

Consider a vector valued function $\phi(\theta)$ defined by the relation

$$\phi(\theta) = \bar{u}(t, x(t), \eta(t) + \theta \Delta(t)).$$

Note, that $\phi(\theta)$ is a continuous function (due to Hypothesis 2.2) and $\phi(0) = u(t)$. We intend to show that $\phi(\theta) = \phi(0)$ for each $\theta \in [0, 1]$.

Define a scalar $\lambda \in [0, 1]$ by the relation

$$\lambda = \inf_{\theta} \{ \phi(\theta) \neq \phi(0) \mid \theta \in [0, 1] \}.$$

It is clear that $\lambda \geq 0$, $\phi(\lambda) = \phi(0) = u(t)$, and we will show that $\lambda = 1$. Suppose the opposite, namely $\lambda < 1$. In this case

$$H_u(t, x(t), v_\lambda(t, x(t), \eta(t) + \theta \Delta(t)), \eta(t) + \theta \Delta(t)) = 0 \quad \text{for } \theta \in [\lambda - \delta_\lambda, \lambda + \delta_\lambda],$$

and

$$v_\lambda(t, x(t), \eta(t) + \theta \Delta(t)) = u(t) = \phi(\lambda) = \phi(0) \quad \text{for } \theta \in [\lambda - \delta_\lambda, \lambda + \delta_\lambda].$$

On the other hand

$$H_u(t, x(t), \phi(\theta), \eta(t) + \theta \Delta(t)) = 0 \quad \text{for } \theta \in [0, 1].$$

This implies (due to the Implicit Function Theorem) that

$$\phi(\theta) = u(t) = \phi(\lambda) = \phi(0) \quad \text{for } \theta \in [0, \lambda + \delta_\lambda].$$

This contradiction completes the proof.

The next step is a derivation of necessary conditions for matching of extremals.

Necessary conditions for matching of extremals. Our main goal in the remainder of the section is to show that the condition $x(t) = y(t)$ on $[t_1, r]$ implies that $\eta(t_1) - \mu(t_1) \in V(t_1, r)^\perp$. Consider a solution $(y(t), \mu(t))$ of the Hamiltonian system (2.5), (2.6) with $y(t_1) = x_1$, $\mu(t_1) = \xi$. Denote this solution by $(x(t; \xi), \eta(t; \xi))$. The questions of considerable interest are “how many different ξ steer x_1 to the same terminal point $x(t; \eta(t_1))$?” or, to put it another way, “how many solutions does an equation $x(t; \xi) = x(t; \eta(t_1))$ have?” In other words “how many neighboring extremals intersect $x(s; \eta(t_1))$ at time t ?” The answers to these questions are closely related to knowledge of rank $\partial x / \partial \xi(t; \eta(t_1))$.

In order to determine the rank $\partial x/\partial \xi(t; \eta(t_1))$ we consider the auxiliary linear control system

$$(4.2) \quad \dot{z}(t) = A(t)z(t) + B(t)v(t), \quad z(t_1) = 0$$

with a cost functional

$$(4.3) \quad \int_{t_1}^{t_2} h(t, z(t), v(t)) dt,$$

where $h(t, z, v)$ is a quadratic function with respect to (z, v) , namely

$$h(t, z, v) = \begin{pmatrix} z \\ v \end{pmatrix}^* \begin{pmatrix} R_{11}(t) & R_{12}(t) \\ R_{21}(t) & R_{22}(t) \end{pmatrix} \begin{pmatrix} z \\ v \end{pmatrix},$$

such that Hypothesis 3.1 is satisfied. In this case the adjoint equation has the following form:

$$\dot{\theta} = \frac{\partial h}{\partial z}(t, z(t), v(t)) - \theta A(t).$$

Let $(z(t), \theta(t))$ be an extremal trajectory of the control problem (4.2), (4.3), and a corresponding solution of the adjoint equation with $z(t_1) = 0$ and $\theta(t_1) = \xi$. We denote this pair by $(z(t; \xi), \theta(t; \xi))$. Note that $\text{rank } \partial z/\partial \xi(t; 0)$ is the dimension of the attainable set at time t . Specifically,

$$(4.4) \quad \text{rank } \frac{\partial z}{\partial \xi}(t; 0) = \dim V(t_1, t)$$

(see (3.6) and Remark 3.1).

We intend to construct the linear control problem (4.2), (4.3) in such a way that

$$\text{rank } \frac{\partial x}{\partial \xi}(t; \eta(t_1)) = \text{rank } \frac{\partial z}{\partial \xi}(t; 0) \quad \text{for each } t \in [t_1, t_2],$$

where $x(t; \eta(t_1))$ is the extremal trajectory of the control problem (2.1), (2.2), and $z(t; 0)$ is the extremal trajectory of the linear control problem (4.2), (4.3). The matrices $A(t)$ and $B(t)$ have been already defined and all that we have left to construct is a cost functional $h(t, z, v)$. Define $h(t, z, v)$ as follows:

$$h(t, z, v) = -\frac{1}{2} \begin{pmatrix} z \\ v \end{pmatrix}^* \begin{pmatrix} H_{xx}(t, x(t), u(t), \eta(t)) & H_{ux}(t, x(t), u(t), \eta(t)) \\ H_{xu}(t, x(t), u(t), \eta(t)) & H_{uu}(t, x(t), u(t), \eta(t)) \end{pmatrix} \begin{pmatrix} z \\ v \end{pmatrix}.$$

Here by $*$ we indicate the transpose. Note that Hypothesis 2.1 implies the fulfillment of Hypothesis 3.1 for the linear-quadratic control problem (4.2), (4.3).

Denote by the $(n+n) \times (n+n)$ matrix

$$\Psi(t, t_1) = \begin{pmatrix} \Psi_{11}(t, t_1) & \Psi_{12}(t, t_1) \\ \Psi_{21}(t, t_1) & \Psi_{22}(t, t_1) \end{pmatrix} \quad \text{with } \Psi(t_1, t_1) = I,$$

a fundamental solution of the following linear differential equation:

$$\dot{X} = \begin{pmatrix} H_{xx}(t, x(t), u(t), \eta(t)) & H_{\eta\eta}(t, x(t), u(t), \eta(t)) \\ -H_{x\eta}(t, x(t), u(t), \eta(t)) & -H_{\eta\eta}(t, x(t), u(t), \eta(t)) \end{pmatrix} X,$$

where $X \in R^{n+n}$. In this case

$$(4.5) \quad \frac{\partial x}{\partial \xi}(t; \eta(t_1)) = \Psi_{12}(t, t_1)$$

(see Coddington and Levinson [4, p. 25]). On the other hand a direct computation shows that

$$\frac{\partial z}{\partial \xi}(t; 0) = \Psi_{12}(t, t_1) \text{ and, therefore, } \frac{\partial z}{\partial \xi}(t; 0) = \frac{\partial x}{\partial \xi}(t; \eta(t_1)).$$

This implies that $\text{rank } \partial x / \partial \xi(t; \eta(t_1)) = \dim V(t_1, t)$ (see 4.4). Hence, due to the Implicit Function Theorem, for each $t \in [t_1, t_2]$ there exists a constant $\varepsilon(t) > 0$, such that the set

$$\Xi(t) = \{\xi \mid \xi \in R^n, |\xi - \eta(t_1)| < \varepsilon(t), x(t; \xi) = x(t; \eta(t_1))\}$$

is a subset of an n -dim $V(t_1, t)$ -dimensional manifold.

In what follows we describe the family of the sets $\Xi(t)$; in particular we shall show, that $\Xi(t)$ is an n -dim $V(t_1, t)$ -dimensional manifold for each $t \in [t_1, t_2]$. First, choose a positive ε_3 such that the condition $|\Delta \Phi(t_1, s)| < \varepsilon(s)$ holds for each $|\Delta| < \varepsilon_3$, $t_1 \leq s \leq t_2$. Next, choose a vector Δ in such a way that

$$(1) \quad |\Delta| < \varepsilon_3,$$

$$(2) \quad \Delta \in V(t_1, t)^\perp.$$

(The continuity of $\partial x / \partial \xi(t; \eta(t_1))$ in t (see (4.5)) implies existence of such positive ε_3 .) For each vector Δ satisfying conditions 1 and 2 consider an extremal triple

$$(y(s), w(s), \eta(s) + \Delta \Phi(t_1, s)).$$

Due to Lemma 4.1 the corresponding extremal pair $(y(s), w(s))$ coincides with $(x(s), u(s))$ on $[t_1, t]$, in particular $y(t) = x(t)$. The collection of vectors Δ which satisfy the conditions 1 and 2 above is a linear manifold. The dimension of this linear manifold is

$$\dim V(t_1, t)^\perp = n - \dim V(t_1, t).$$

This implies that

$$\Xi(t) = \{\eta(t_1) + \Delta \mid \Delta \text{ satisfies conditions 1 and 2}\}.$$

Hence $\Xi(t)$ itself is an n -dim $V(t_1, t)$ -dimensional linear manifold.

We obtain, therefore, the following.

LEMMA 4.3.

$$\Xi(t) = \{\xi \mid |\xi - \eta(t_1)| < \varepsilon_3, \xi - \eta(t_1) \in V(t_1, t)^\perp\}.$$

COROLLARY 4.1.

$$\Xi(s) \subset \Xi(\sigma) \quad \text{provided } s \geq \sigma.$$

Proof. If $s \geq \sigma$ then

$$V(t_1, \sigma) \subset V(t_1, s);$$

this implies

$$V(t_1, s)^\perp \subset V(t_1, \sigma)^\perp.$$

The result now follows from Lemma 4.3.

At this point we are able to present the definition of the positive scalar ε^* , which defines the family of the neighboring extremals, as follows.

DEFINITION 4.1. Denote $\min(\varepsilon_2, \varepsilon_3)$ by ε^* . (We wish to remind the reader that ε_2 was introduced in Lemma 4.1.) An extremal trajectory $y(t)$ is a neighboring extremal trajectory if

$$\max_{t_1 \leq t \leq t_2} |x(t) - y(t)| + \max_{t_1 \leq t \leq t_2} |\eta(t) - \mu(t)| < \varepsilon^*.$$

In the case of a linear control system with a quadratic cost functional there exists a unique extremal trajectory which steers an initial point x_1 to a terminal point x_2 over the time interval $[t_1, t_2]$. The next theorem shows that the selected trajectory $x(t)$ has this property "in the small."

THEOREM 4.1. Consider an extremal triple $(y(t), w(t), \mu(t))$. If

- (1) $y(t)$ is a neighboring extremal,
- (2) $y(t_1) = x(t_1)$, $y(r) = x(r)$ for some $r \in [t_1, t_2]$, then $y(t) = x(t)$ on $[t_1, r]$.

Proof. The conditions imply that $\mu(t_1) \in \Xi(r)$. On the other hand, due to Corollary 4.1, the relation $\Xi(r) \subset \Xi(t)$ holds for each t such that $t_1 \leq t < r$. Hence, $\mu(t_1) \in \Xi(t)$ for each $t \in [t_1, r]$. This completes the proof.

We show by the following example that the condition $|(x(\cdot), \eta(\cdot)) - (y(\cdot), \mu(\cdot))|_{C[t_1, t_2]} < \varepsilon^*$ cannot be removed. Hence, Theorem 4.1 has a local nature.

Example 4.1. The notion of neighboring extremal plays an important role in the investigation of branching points. In this example we present a bilinear control problem with extremals $x(t)$ and $y(t)$ satisfying the relations

$$x(0) = y(0), \quad x(\pi) = y(\pi), \quad x(t) \neq y(t) \quad \text{for } t \in (0, \pi).$$

Consider the following bilinear control system:

$$(4.6) \quad \dot{x}_1(t) = u(t)x_2(t),$$

$$(4.7) \quad \dot{x}_2(t) = -u(t)x_1(t),$$

where $u(t)$ is a scalar function.

Consider the cost functional

$$(4.8) \quad c(x(\cdot), u(\cdot)) = \frac{1}{2} \int_0^{2\pi} u^2(t) dt.$$

The adjoint equation has the following form:

$$\dot{\eta}_1(t) = u(t)\eta_2(t), \quad \dot{\eta}_2(t) = -u(t)\eta_1(t).$$

The Hamiltonian H of this problem is given as follows:

$$H(t, x, u, \eta) = -\frac{1}{2}u^2 + (\eta_1x_2 - \eta_2x_1)u.$$

Note that $\eta_1(t)x_2(t) - \eta_2(t)x_1(t)$ is a constant and, therefore, $u(t) = u(0)$ for $t \in [0, 2\pi]$.

The extremal trajectories $x_\omega(t)$ of the above optimal control problem are rotations around the origin with constant angular velocities ω . For each real number ω , the extremals $x_\omega(t)$ and $x_{-\omega}(t)$ initiating at the same point $x(0)$ intersect each other at $t = \pi/\omega$. Hypothesis 2.2 is evidently fulfilled and we will choose ω in such a way that the extremal trajectory $x_\omega(t)$ will satisfy Hypothesis 2.1 on $[0, 2\pi]$.

In order to find the suitable ω , choose the following set of initial conditions:

$$x_1(0) = 1, \quad x_2(0) = 0, \quad \eta_1(0) = 0, \quad \eta_2(0) = -1.$$

Straightforward verification would show that in this case $u(t) = 1$ and

$$x_1(t) = \cos t, \quad x_2(t) = -\sin t, \quad \eta_1(t) = -\sin t, \quad \eta_2(t) = -\cos t.$$

The linearized system about this solution is the following:

$$\dot{z}_1(t) = z_2(t) - v(t) \sin t, \quad \dot{z}_2(t) = -z_1(t) - v(t) \cos t.$$

Those solutions $z(t) = (z_1(t), z_2(t))$ of this linear equation that also satisfy the boundary conditions

$$z_1(0) = z_1(2\pi) = z_2(0) = z_2(2\pi) = 0$$

have the form

$$(4.9) \quad z_1(t) = -\sin t \int_0^t v(s) ds, \quad z_2(t) = -\cos t \int_0^t v(s) ds.$$

We now wish to show that the extremal triple $(x(t), u(t), \eta(t))$ satisfies Hypothesis 2.1. A straightforward computation shows that

(1) $H_{uu}(t, x, u, \eta)$ is identically equal to -1 ,

$$(2) \quad \int_0^{2\pi} \begin{pmatrix} z(t) \\ v(t) \end{pmatrix}^* \begin{pmatrix} H_{xx}(t, x(t), u(t), \eta(t)) & H_{ux}(t, x(t), u(t), \eta(t)) \\ H_{xu}(t, x(t), u(t), \eta(t)) & H_{uu}(t, x(t), u(t), \eta(t)) \end{pmatrix} \begin{pmatrix} z(t) \\ v(t) \end{pmatrix} dt \\ = - \int_0^{2\pi} v^2(t) dt$$

is negative definite for each $z(t)$ satisfying condition (4.9).

On the other hand, the trajectory $y(t) = (\cos t, \sin t)$ is an extremal trajectory of the optimal control problem (4.6)–(4.8) and

$$y(\pi) = x(\pi), \quad y(0) = x(0) \quad \text{but} \quad y(t) \neq x(t) \quad \text{for} \quad 0 < t < \pi.$$

Note that $\mu_1(0) = 0$, $\mu_2(0) = 1$ and $\eta_1(0) = 0$, $\eta_2(0) = -1$; hence $|(x(\cdot), \eta(\cdot)) - (y(\cdot), \mu(\cdot))|_{C[t_1, t_2]} \geq 2$. On the other hand, one can show that in this case ε^* , which defines the extremal trajectories, must be less than 1.

We present now the last necessary definition and state the main result of the section.

DEFINITION 4.2. We denote the set of discontinuity points of the function $\dim V(t_1, s)$ on the interval $[t_1, t_2]$ by $\{r_i\}$.

THEOREM 4.2. Each $r \in \{r_i\}$ is a branching point of the extremal trajectory $x(t)$. Let $y(t)$ be a neighboring extremal trajectory. If $y(t_1) = x(t_1)$ and $y(s) \neq x(s)$ for some $s \in [t_1, t_2]$, then there exists $r \in [t_1, s]$ such that the following conditions hold:

- (1) $r \in \{r_i\}$,
- (2) $y(t) = x(t)$ on $[t_1, r]$,
- (3) $y(t) \neq x(t)$ on $(r, t_2]$.

COROLLARY 4.2. The set of branching points of the extremal trajectory $x(t)$ is a finite set. The number of its elements is no more than the dimension of the state space R^n .

Acknowledgment. The author would like to thank the referee whose valuable remarks and corrections much improved the exposition of the results.

REFINED STUDY ON STRUCTURAL CONTROLLABILITY OF DESCRIPTOR SYSTEMS BY MEANS OF MATROIDS*

KAZUO MUROTA†

Abstract. For a dynamical system described in the descriptor form $F dx/dt = Ax + Bu$, where the coefficients are classified into generic parameters and fixed constants, the structural controllability is investigated under a physically reasonable assumption that can be justified by the dimensional analysis. A necessary and sufficient condition for the structural controllability is given in matroid-theoretic terms; the condition can be tested by efficient algorithms for the matroid union/intersection problem.

Key words. structural controllability; descriptor form; matroid; algebraic independence; polynomial algorithm

AMS(MOS) subject classifications. 93, 93B05, 93B25, 15, 05C50

1. Introduction. Since the notion of structural controllability was introduced in [21], many papers have appeared for its extensions and refinements [2], [3], [10], [11], [24]–[30], [35], [39]. A dynamical system described in the state-space standard form

$$(1.1) \quad dx/dt = Ax + Bu$$

is called structurally controllable if it is controllable in the ordinary sense [18] when the nonvanishing entries of A and B are replaced by independent free parameters. The structural controllability of (1.1) is known to be expressed by graph-theoretic conditions [10], [21], [24], [35].

Though the notion of structural controllability is quite appealing, it is often unjustifiable to assume that the nonvanishing entries of A and B of (1.1) are independent. In this respect, it is more appropriate to work with the descriptor form [22], [23]

$$(1.2) \quad F dx/dt = Ax + Bu$$

($x \in \mathbb{R}^n$ and $u \in \mathbb{R}^m$), which is more elementary and hence more suitable for the representation of a physical structure. The generic controllability of the descriptor system (1.2) is discussed in graph-theoretic terms in [3], [26], [30], [39] under the assumption that the nonvanishing entries of F , A and B of (1.2) are independent parameters.

As will readily be imagined, however, not all the nonvanishing entries of the matrices in (1.2) can be modeled as independent parameters, but some must be fixed constants, usually simple integers such as ± 1 . With this problem of fixed constants taken into account, the generic controllability condition is derived in [2] for the standard form (1.1) when the coefficients can be expressed in “matrix nets” as

$$A = A_0 + \sum_{i=1}^k \mu_i A_i, \quad B = B_0 + \sum_{i=1}^k \mu_i B_i,$$

where A_i and B_i are fixed matrices and μ_i independent free parameters. The condition given in [2] is, however, purely algebraic and cannot readily be tested by efficient algorithms.

In investigating structural aspects of large-scale systems in general, it would be of fundamental importance to set up a mathematical model which accounts for relevant aspects of a real system with sufficient faith and which admits rigorous mathematical

analysis. No less important are algorithmic considerations, especially when combinatorial methods are involved in the analysis of the model. A combinatorial method for systems analysis would not be very powerful for large systems unless it is accompanied by efficient algorithms.

In this respect, the matroid-theoretic point of view can be quite useful both in establishing adequate mathematical models and in constructing efficient algorithms (see, e.g., [14], [15]). In the field of electrical network theory, for example, a number of fundamental problems, such as the problem of the topological degrees of freedom and that of the order of complexity for networks with mutual couplings, have been solved with the aid of matroid-theoretic concepts and algorithms (see, e.g., [14]–[16]). Once results are obtained by means of matroids, it is possible, as a matter of course, to restate all the arguments without reference to matroids. It would, however, make things less clear, hiding the essential simplicity and insight.

In this paper, we will formulate the problem of structural controllability so as to reflect the real situations fairly well and give a solution to it by means of matroids. To be more specific, the generic controllability is considered for a descriptor system (1.2) in which the nonvanishing entries of F , A and B are classified into two groups, i.e., independent free parameters and fixed constants. Following the arguments in [31] on the algebraic implications of the consistency in the system of equations (1.2) with respect to physical dimensions, a physically reasonable assumption is made on the matrix representing the fixed constants. A necessary and sufficient condition for the structural controllability in this refined sense is derived with the aid of the combinatorial canonical form of a layered mixed matrix, the mathematical tool introduced in [32]. The condition can be checked by the efficient combinatorial algorithms for the matroid union/intersection problem or for the independent-flow problem.

The proposed method for testing the structural controllability has several practical advantages. The algorithm is guaranteed to run in $O(n^2(n+m) \log n)$ time in the worst case and runs much faster in many cases. It is free from the numerical difficulty of rounding errors as compared to the technique of parameter variation, which computes the rank of the controllability matrix by substituting several different numerical values to the parameters. The algorithm can be implemented easily as it is composed of the Gaussian elimination on simple rational numbers, the construction of matchings, and the search for paths in graphs. In the special case where no fixed constants are involved, the result of the present paper naturally reduces to the previously known results mentioned above.

2. Preliminaries. This section presents the minimum set of matroid-theoretic concepts to be required in later arguments and gives a brief summary of the combinatorial canonical form of a layered mixed matrix introduced in [32]. See, e.g., [38] for the complete account of matroids.

A matroid is a pair $\mathcal{M} = (S, \mathcal{I})$ of a finite set S and a collection \mathcal{I} of subsets of S such that

- (I1) $\emptyset \in \mathcal{I}$;
- (I2) If $X \in \mathcal{I}$ and $Y \subset X$, then $Y \in \mathcal{I}$;
- (I3) If $X, Y \in \mathcal{I}$ and $|X| = |Y| + 1$, then $Y \cup x \in \mathcal{I}$ for some $x \in X \setminus Y$.

A member of \mathcal{I} is called an *independent set*, and a maximal subset in \mathcal{I} (maximal with respect to set inclusion) a *base*. An element of S is a *coloop* if it is contained in every base. A matroid is called a *free matroid* if every subset is independent in it.

For a matroid \mathcal{M} defined on S and a subset X of S , the *restriction* of \mathcal{M} to X , denoted as $\mathcal{M}|X$, is a matroid on X in which $Y (\subset X)$ is independent iff Y is independent

in \mathcal{M} , and the *contraction* of \mathcal{M} to X , denoted as $\mathcal{M}.X$, is a matroid on X in which $Y (\subset X)$ is independent iff $Y \cup B$ is independent in \mathcal{M} where B is a base of $\mathcal{M}|(S \setminus X)$. A subset X of S consists of coloops of \mathcal{M} iff $\mathcal{M}.X$ is a free matroid.

All bases of a matroid have the same cardinality, which is called the *rank* of the matroid \mathcal{M} and is denoted as $\text{rank}[\mathcal{M}]$. The function $\rho: 2^S \rightarrow \mathbb{Z}$ which assigns the rank of $\mathcal{M}|X$ to $X (\subset S)$ is called the *rank function* of \mathcal{M} ; $\rho(X)$ is the maximum size of an independent set included in X . The rank function ρ^X of $\mathcal{M}.X$ is given by

$$(2.1) \quad \rho^X(Y) = \rho(Y \cup (S \setminus X)) - \rho(S \setminus X) \quad \text{for } Y \subset X.$$

A matroid is also determined by the collection of bases. For a matroid \mathcal{M} on S , its dual, denoted as \mathcal{M}^* , is the matroid on S in which a subset of S is a base iff it is the complement of a base of \mathcal{M} .

Given a matrix A over a field \mathbf{K} , we will denote by $\mathcal{M}(A)$ the matroid defined on the column-set C of A with respect to the ordinary linear dependence among column-vectors of A . A matroid thus obtained is called a linear matroid represented over \mathbf{K} . Let $\mathcal{N}(A)$ designate the (multi)set of nonvanishing entries of a matrix A . In the particular case where $\mathcal{N}(A)$ is algebraically independent [37], the matroid $\mathcal{M}(A)$ is a transversal matroid expressed by the bipartite graph G associated with A ; the vertex-set of G is the union of the row-set R and the column-set C of A , the edge-set of G has the natural one-to-one correspondence with $\mathcal{N}(A)$, and a set $X (\subset C)$ is independent iff X can be matched into R in G .

The relation of algebraic independence over a field also enjoys the matroidal properties. Let \mathbf{K} and $\mathbf{F} (\mathbf{K} \subset \mathbf{F})$ be fields and $S (\subset \mathbf{F})$ a finite set. Then a matroid is defined on S with respect to the algebraic independence over \mathbf{K} . Such a matroid is called an algebraic matroid. The following will be used later as a key property of algebraic independence.

LEMMA 2.1. *Let X and $\{z\}$ be independent in a matroid. If $X \cup z$ is not independent, then $(X \setminus x) \cup z$ is independent for some $x \in X$. \square*

For k matroids $\mathcal{M}_i (i = 1, \dots, k)$ defined on S , their union $\mathcal{M}_1 \vee \dots \vee \mathcal{M}_k$ is a matroid on S in which $X (\subset S)$ is independent iff X can be expressed as $X = X_1 \cup \dots \cup X_k$ with X_i being independent in $\mathcal{M}_i (i = 1, \dots, k)$. The rank function ρ of the union matroid is expressed in terms of the rank functions ρ_i of \mathcal{M}_i as

$$(2.2) \quad \rho(X) = \min \left\{ \sum_{i=1}^k \rho_i(Y) + |X \setminus Y| \mid Y \subset X \right\}, \quad X \subset S.$$

In general, the union of contractions $\mathcal{M}_i.X (X \subset S)$ does not agree with the contraction of the union of \mathcal{M}_i , i.e., $\bigvee_{i=1}^k (\mathcal{M}_i.X) \neq (\bigvee_{i=1}^k \mathcal{M}_i).X$. Still the following holds true.

LEMMA 2.2. *Let $\hat{S} (\subset S)$ be the set of all coloops of $\bigvee_{i=1}^k \mathcal{M}_i$.*

(i) *$\hat{S} = S \setminus X_0$, where X_0 is the (uniquely determined) smallest subset of S that gives the minimum value of*

$$\tilde{\rho}(X) = \sum_{i=1}^k \rho_i(X) - |X|, \quad X \subset S.$$

(ii) *$\bigvee_{i=1}^k (\mathcal{M}_i.\hat{S})$ is the free matroid.*

Proof. (i) Since $\tilde{\rho}$ is submodular, its minimizers constitute a sublattice of 2^S . In particular, there exists the smallest minimizer X_0 of $\tilde{\rho}$. For $x \in S$, $x \in \hat{S}$ iff $\rho(S \setminus x) = \rho(S) - 1$, which is equivalent, by (2.2), to $\min \{\tilde{\rho}(Y) \mid x \notin Y\} = \min \{\tilde{\rho}(Y) \mid Y \subset S\}$, namely to $x \notin X_0$.

$$\text{rank } \bar{A}[R_\infty, C_\infty] = |C_\infty| \quad (< |R_\infty| \text{ if } C_\infty \neq \emptyset).$$

Note that the column-set of \bar{A} has a natural correspondence with that of A .

LEMMA 2.4. $C \setminus C_0$ is the set of all coloops of the matroid $\mathcal{M}(A) = \mathcal{M}(Q) \vee \mathcal{M}(T_1) \vee \mathcal{M}(T_2)$.

Proof. This follows from Lemma 2.2(i), since, by the definition of the combinatorial canonical form and [34, Lemma 5.1(5)], C_0 is the smallest subset of C that gives the minimum of $\tilde{\rho}$ in Lemma 2.2(i), where $k=3$, and ρ_1, ρ_2 and ρ_3 are the rank functions of $\mathcal{M}(Q)$, $\mathcal{M}(T_1)$ and $\mathcal{M}(T_2)$, respectively. \square

When a matrix A over \mathbf{F} is expressed as

$$(2.7) \quad A = Q_A + T_A,$$

where Q_A is a matrix over the subfield \mathbf{K} of \mathbf{F} and $\mathcal{N}(T_A)$ is algebraically independent over \mathbf{K} , it is called a *mixed matrix* with respect to \mathbf{K} . The following is an immediate consequence of Lemma 2.3.

LEMMA 2.5 [33]. Let $A = Q_A + T_A$ be an $m \times n$ mixed matrix. Then we have

$$\text{rank } A = \text{rank } [\mathcal{M}([I|Q_A]) \vee \mathcal{M}([I|T_A])] - m. \quad \square$$

3. Formulation of the structural controllability.

3.1. Controllability of a descriptor system. We consider a linear dynamical system represented by the descriptor form [22], [23]

$$(3.1) \quad F \frac{d\mathbf{x}}{dt} = A\mathbf{x} + B\mathbf{u},$$

where $\mathbf{x} (\in \mathbf{R}^n)$ and $\mathbf{u} (\in \mathbf{R}^m)$ are the descriptor-vector (standing for the internal variables) and the input-vector, respectively, and F , A and B are constant real matrices of sizes $n \times n$, $n \times n$ and $n \times m$, respectively. If we express system (3.1) (with the zero initial state) in terms of the Laplace transform, we have

$$(3.2) \quad [A - sF|B] \begin{pmatrix} \mathbf{x} \\ \mathbf{u} \end{pmatrix} = \mathbf{0},$$

where s is a symbol standing for the differentiation with respect to time. (Throughout this paper, s is treated as an indeterminate.) The coefficient matrix of (3.2) is sometimes called the modal controllability matrix. It should be emphasized that F is not assumed to be nonsingular.

Dynamical behaviors of such a singular differential system have been investigated by many authors [4], [12], [36], [40] and several different definitions for the controllability of the descriptor system have been proposed. In order for system (3.1) to be uniquely solvable for consistent initial conditions, it must satisfy

$$(3.3) \quad \det(A - sF) \neq 0.$$

Following [3], [12], [26], we will adopt the controllability of the exponential modes (or R -controllability of [40]) as the controllability of (3.1). Namely, we will say that (3.1) is controllable if

$$(3.4) \quad \text{rank } [A - zF|B] = n \quad \text{for any complex number } z.$$

This condition is known to be equivalent to the controllability of the state-space system that is derived from (3.1) by the strict equivalence in the sense of [9] for matrix pencils. See [4] for detailed discussions on other possible definitions of the controllability of (3.1).

3.2. Physical observations. When a dynamical system is described in the descriptor form (3.1) in terms of elementary physical variables, it is often justified to assume that the nonvanishing entries of the coefficient matrices F , A and B are classified into two groups, one of generic parameters and the other of fixed constants. In other words, as advocated in [33], we can distinguish two kinds of numbers that characterize physical systems as follows: (i) those numbers representing independent physical parameters such as resistances in electrical networks which, being contaminated by various noises and errors, take inaccurate values independent of one another, so that they can be modeled as algebraically independent generic numbers, and (ii) those numbers accounting for various sorts of conservation laws such as Kirchhoff's, which, stemming from topological incidence relations, are accurate (often ± 1) in value so that no serious numerical difficulty arises in arithmetic operations on them. See [33] for further discussions.

In accordance with this physical consideration, we will assume that the matrices F , A and B in (3.1) are real matrices expressed as

$$(3.5) \quad F = Q_F + T_F, \quad A = Q_A + T_A, \quad B = Q_B + T_B,$$

where Q_F , Q_A and Q_B are matrices with rational entries and $\mathcal{N}(T_F) \cup \mathcal{N}(T_A) \cup \mathcal{N}(T_B)$ (the set of nonvanishing entries of T_F , T_A and T_B) is algebraically independent over the rational number field \mathbf{Q} . This implies that F , A and B are mixed matrices with respect to \mathbf{Q} , of the form (2.7) explained in § 2. According to (3.5), we have

$$(3.6) \quad A - sF = (Q_A - sQ_F) + (T_A - sT_F),$$

which is again a mixed matrix, but with respect to $\mathbf{Q}(s)$, since $\mathcal{N}(T_A - sT_F)$ is algebraically independent over $\mathbf{Q}(s)$. Likewise, the modal controllability matrix $[A - sF|B]$ is a mixed matrix with respect to $\mathbf{Q}(s)$ with the additive decomposition of the form (2.7) given by

$$(3.7) \quad [A - sF|B] = [Q_A - sQ_F|Q_B] + [T_A - sT_F|T_B].$$

It should be clear that from the algebraic point of view, the assumption of the algebraic independence of $\mathcal{N}(T_F) \cup \mathcal{N}(T_A) \cup \mathcal{N}(T_B)$ is tantamount to regarding their members as independent free parameters. As for the fixed constants, the assumption that the entries of Q_F , Q_A and Q_B are rationals is not essential to the subsequent

FIG. 3.1. A simple mechanical system of Example 3.1.

algebraic arguments. In the case where nonrational fixed constants are to be taken into account, we may choose any appropriate extension field of \mathbf{Q} as the subfield. The rationality of fixed constants is needed only to reduce the computational complexity for testing the controllability condition by matroid-theoretic algorithms, as will be discussed in § 4.

Example 3.1. Consider the mechanical system in Fig. 3.1 consisting of two masses m_1 and m_2 , two springs k_1 and k_2 , and a damper f ; u is the force exerted from outside. We may choose $\mathbf{x} = (x_1, x_2, x_3, x_4, x_5, x_6)$ as the descriptor-vector, where x_1 (resp. x_2) is the displacement of mass m_1 (resp. m_2) and x_3 (resp. x_4) is its velocity, x_5 is the force by the damper f , and x_6 is the relative velocity of the two masses. Then the system can be expressed in the descriptor form (3.1) with

$$(3.8) \quad F = \begin{pmatrix} 1 & & & & & \\ & 1 & & & & \\ & & m_1 & & & \\ & & & m_2 & & \\ & & & & 0 & \\ 1 & -1 & & & & 0 \end{pmatrix}, \quad A = \begin{pmatrix} 0 & 1 & & & & \\ & 0 & 1 & & & \\ -k_1 & 0 & -1 & & & \\ & -k_2 & 0 & 1 & & \\ & & -1 & f & & \\ & & & & 1 & \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}.$$

If we regard $\{m_1, m_2, k_1, k_2, f\}$ as independent free parameters, i.e., as being algebraically independent, (3.7) is given by

$$(3.9) \quad [Q_A - sQ_F | Q_B] = \left(\begin{array}{ccccc|c} -s & 1 & & & & 0 \\ & -s & 1 & & & 0 \\ & & 0 & -1 & & 1 \\ & & & 0 & 1 & 0 \\ & & & & -1 & 0 \\ -s & s & & & & 1 & 0 \end{array} \right),$$

$$[T_A - sT_F | T_B] = \left(\begin{array}{ccccc|c} 0 & & & & & 0 \\ & 0 & & & & 0 \\ -k_1 & -sm_1 & & & & 0 \\ & -k_2 & -sm_2 & & & 0 \\ & & & 0 & f & 0 \\ & & & & 0 & 0 \end{array} \right).$$

In actual situations, a small damper might exist in parallel with the spring k_1 . How to deal with such a quantity depends on how we recognize the problem; it may be ignored as above or included as a transcendental element.

The crucial physical observation made in [31] is now introduced. As mentioned above, the fixed constants usually stand for topological/geometrical incidence coefficients, which have no physical dimensions. Thus, it would be natural to expect

that the entries of Q_F , Q_A and Q_B of (3.5) are dimensionless constants. On the other hand, the indeterminate s in (3.2) should have the physical dimension of the inverse of time, since it represents the differentiation with respect to time.

Since the system of equations (3.2) is to represent a physical system, relevant physical dimensions are associated with both the variables (\mathbf{x}, \mathbf{u}) and the equations, or alternatively, with the columns and the rows of the matrix $[A - sF|B]$. Paying particular attention to the dimension of time associated with the matrix $[A - sF|B]$, we denote by c_j and r_i the exponent to the dimension of the inverse of time associated with the j th column and the i th row, respectively. Then, by the principle of dimensional homogeneity [13], [19], the (i, j) entry of $[A - sF|B]$ should have the dimension of the inverse of time with the exponent $r_i - c_j$.

Combining this fact with the nondimensionality of Q_F , Q_A and Q_B , as well as the consideration on the physical dimension of the symbol s , we obtain

$$(3.10) \quad \begin{aligned} r_i - c_j &= 1 && \text{if } (Q_F)_{ij} \neq 0, \\ r_i - c_j &= 0 && \text{if } (Q_A)_{ij} \neq 0, \\ r_i - c_{n+j} &= 0 && \text{if } (Q_B)_{ij} \neq 0. \end{aligned}$$

In the matrix form, this is written as

$$(3.11) \quad [Q_A - sQ_F|Q_B] = \text{diag}(s^{r_1}, \dots, s^{r_n})[Q_A - Q_F|Q_B] \text{diag}(s^{-c_1}, \dots, s^{-c_{n+m}}).$$

This implies that every nonvanishing subdeterminant of $[Q_A - sQ_F|Q_B]$ is a monomial in s with a rational coefficient. Thus, the matrix $[Q_A - sQ_F|Q_B]$ representing the fixed constants enjoys a very simple property.

Based on the above physical observations, we will investigate the controllability of (3.1) in the situation where the coefficient matrices are expressed as (3.5) with the following properties:

- (A1): $\mathcal{N}(T_F) \cup \mathcal{N}(T_A) \cup \mathcal{N}(T_B)$ is algebraically independent over \mathbf{Q} , and
- (A2): Every nonvanishing subdeterminant of $[Q_A - sQ_F|Q_B]$ is of the form αs^p with a rational number α and an integer p .

Whereas a matrix of the form (3.11) obviously satisfies (A2), the converse is also true [31], as stated in Lemma 3.1 below. This characterization of (A2) enables us to check it by an efficient graph-theoretic algorithm. See [31] for the detail.

LEMMA 3.1. $[Q_A - sQ_F|Q_B]$ satisfies (A2) iff it can be expressed as (3.11) for some integers r_i and c_j . \square

It should be noted that in the mechanical system of Example 3.1, the nonvanishing entries of Q_F , Q_A and Q_B are dimensionless and that the assumption (A2) is satisfied indeed.

4. Main results.

4.1. Controllability conditions in terms of matroids. In the first place, the following remarkable consequences of (A1) and (A2) are noted.

LEMMA 4.1.

$$\begin{aligned} \mathcal{M}([I|Q_A - sQ_F|Q_B]) &= \mathcal{M}([I|Q_A - Q_F|Q_B]), \\ \mathcal{M}([I|T_A - sT_F|T_B]) &= \mathcal{M}([I|T_A - T_F|T_B]). \end{aligned}$$

Proof. The former is due to Lemma 3.1, while the latter is immediate from (A1). \square

This lemma asserts that those matroids admit simple representations; the former, defined as a linear matroid over $\mathbf{Q}(s)$, is in reality representable over the subfield \mathbf{Q} ,

and the latter, being a transversal matroid, can be expressed by a bipartite graph. This fact is of practical significance in that it reduces the computational complexity in handling those matroids to a great extent.

We are concerned with combinatorial characterizations of the following conditions:

- (C1): $\det(A - sF) \neq 0$,
- (C2): $\text{rank}[A|B] = n$,
- (C3): $\text{rank}[A - zF|B] = n$ for $z \neq 0$, $z \in \mathbb{C}$.

The first is for the unique solvability given in (3.3). The set of conditions (C2) and (C3) is equivalent to the controllability given in (3.4); (C2) is for the controllability of the zero modes, while (C3) is for the nonzero modes.

The conditions (C1) and (C2) are rephrased as follows.

LEMMA 4.2. $\text{rank}(A - sF) = \text{rank}[\mathcal{M}([I|Q_A - Q_F]) \vee \mathcal{M}([I|T_A - T_F])] - n$. Hence

(C1) is equivalent to

$$(M1): \text{rank}[\mathcal{M}([I|Q_A - Q_F]) \vee \mathcal{M}([I|T_A - T_F])] = 2n.$$

Proof. From (3.6) and Lemma 2.5, we have

$$\text{rank}(A - sF) = \text{rank}[\mathcal{M}([I|Q_A - sQ_F]) \vee \mathcal{M}([I|T_A - sT_F])] - n.$$

Lemma 4.1 then simplifies the right-hand side. \square

LEMMA 4.3.

$$\text{rank}[A|B] = \text{rank}[\mathcal{M}([I|Q_A|Q_B]) \vee \mathcal{M}([I|T_A|T_B])] - n.$$

Hence (C2) is equivalent to

$$(M2): \text{rank}[\mathcal{M}([I|Q_A|Q_B]) \vee \mathcal{M}([I|T_A|T_B])] = 2n.$$

Proof. By the direct application of Lemma 2.5 to (3.7) with $s = 0$. \square

To deal with (C3), we consider three $n \times (3n + m)$ matrices

$$\begin{aligned} Q_D(s) &= [O_n|I_n|Q_A - sQ_F|Q_B], \\ (4.1) \quad T_{D1}(s) &= [I_n|O_n|-sT_F|O_{n,m}], \\ T_{D0} &= [-I_n|-I_n|T_A|T_B] \end{aligned}$$

and a composite $(3n) \times (3n + m)$ matrix

$$(4.2) \quad D(s) = \begin{pmatrix} Q_D(s) \\ T_{D1}(s) \\ T_{D0} \end{pmatrix}.$$

The last $n + m$ columns of $D(s)$ correspond to the variables \mathbf{x} and \mathbf{u} in the natural manner, whereas the first $2n$ columns may be viewed as disjoint copies of the rows of $[A - sF|B]$. Let $\{v_1, \dots, v_n\}$ denote the first n columns and $\{w_1, \dots, w_n\}$ the next n columns of $D(s)$. Then the column-set of $D(s)$, as well as of the three matrices of (4.1), is designated by

$$(4.3) \quad S = \{v_1, \dots, v_n\} \cup \{w_1, \dots, w_n\} \cup \{x_1, \dots, x_n\} \cup \{u_1, \dots, u_m\}.$$

As will be explained in § 5, $\mathcal{N}(T_{D1}(s)) \cup \mathcal{N}(T_{D0})$ may effectively be regarded as being algebraically independent over the subfield $\mathbf{K} = \mathbf{Q}(s)$ by virtually scaling the rows of T_{D1} and T_{D0} as well as the columns of $\{v_1, \dots, v_n\}$ with algebraically independent transcendentals. Hence, by Lemma 2.3, the matroid $\mathcal{M}(D(s))$ is equal to the union $\mathcal{M}(Q_D(s)) \vee \mathcal{M}(T_{D1}(s)) \vee \mathcal{M}(T_{D0})$ of three matroids, each of which is representable without involving symbol s by Lemma 4.1 as follows.

LEMMA 4.4.

$$\mathcal{M}(D(s)) = \mathcal{M}([O|I|Q_A - Q_F|Q_B]) \vee \mathcal{M}([I|O|T_F|O]) \vee \mathcal{M}([I|I|T_A|T_B]).$$

Associated with the matrix $Q_D(s)$ of (4.1) we introduce a weight function ζ_1 on S as follows. By (A2) and Lemma 3.1, there exists a set of integers r_i ($i=1, \dots, n$) and c_j ($j=1, \dots, n+m$) attached to the i th row and the j th column of $[Q_A - sQ_F|Q_B]$ such that (3.11) holds. (Such numbers are not unique from the mathematical point of view.) In case the physical dimensions associated with (3.1) are given, these numbers are readily obtained from the exponents to the inverse time dimension, as discussed in § 3. Even when the dimensions are not known, it is easy to find the numbers r_i and c_j by $O(n(n+m))$ graph operations [31]. The weight function ζ_1 is then defined by

$$(4.4) \quad \zeta_1(v_i) = 0, \quad \zeta_1(w_i) = -r_i, \quad \zeta_1(x_j) = -c_j, \quad \zeta_1(u_j) = -c_{n+j}.$$

For a subset X of S , $\zeta_1(X)$ designates the sum of the weights of the elements of X . Suppose X is independent in $\mathcal{M}([O|I|Q_A - Q_F|Q_B])$ and put $R_X = \{w_1, \dots, w_n\} \setminus X$ and $C_X = (\{x_1, \dots, x_n\} \cup \{u_1, \dots, u_m\}) \cap X$. Then the submatrix of $[Q_A - sQ_F|Q_B]$ corresponding to row-set R_X and column-set C_X is nonsingular and has the determinant of the form αs^p ($\alpha \in \mathbb{Q}$, $\alpha \neq 0$) by Lemma 3.1. The weight $\zeta_1(X)$ represents the exponent p , i.e.,

$$(4.5) \quad p = \zeta_1(X) + r_0, \quad r_0 = \sum_{i=1}^n r_i.$$

Another weight function ζ_2 on S is defined with reference to $\mathcal{M}([I|O|T_F|O])$ by

$$(4.6) \quad \zeta_2(v_i) = 0, \quad \zeta_2(w_i) = 0, \quad \zeta_2(x_j) = 1, \quad \zeta_2(u_j) = 0.$$

Since

$$(4.7) \quad \text{rank } D(z) = \text{rank } [A - zF|B] + 2n \quad \text{for any } z \in \mathbb{C},$$

condition (C3) is equivalent to

$$(4.8) \quad \text{rank } D(z) = 3n \quad \text{for } z \neq 0, \quad z \in \mathbb{C}.$$

Let $\hat{S} (\subset S)$ be the set of coloops of the matroid $\mathcal{M}(D(s))$ that is represented as in Lemma 4.4. Then the following lemma holds true, which will be established later in § 5 by a succession of algebraic arguments by means of the combinatorial canonical form of $D(s)$. Remember that $\mathcal{M}.\hat{S}$ denotes the contraction of a matroid \mathcal{M} to \hat{S} .

LEMMA 4.5. (C3) is equivalent to (M0) and (M3), where

(M0): $\text{rank } [\mathcal{M}([O|I|Q_A - Q_F|Q_B]) \vee \mathcal{M}([I|O|T_F|O]) \vee \mathcal{M}([I|I|T_A|T_B])] = 3n$,
and

(M3): $\zeta_1(X) + \zeta_2(Y)$ is constant for all $X, Y (\subset \hat{S})$ such that $X \cap Y = \emptyset$, X is independent in $\mathcal{M}([O|I|Q_A - Q_F|Q_B]).\hat{S}$, Y is independent in $\mathcal{M}([I|O|T_F|O]).\hat{S}$ and $\hat{S} \setminus (X \cup Y)$ is independent in $\mathcal{M}([I|I|T_A|T_B]).\hat{S}$. \square

Note that (4.5) shows (M3) is unaffected by the choice of ζ_1 and that such subsets X and Y as described in (M3) do exist by Lemma 2.2.

As explained in the proof of Theorem 4.6 below, (M0) is implied by (C1), and therefore (M3) constitutes the essential part. The problem of checking (M3) can be categorized as a version of weighted matroid-partition problem [7]. A special emphasis should be laid on the fact that there exists a well-established efficient combinatorial algorithm for this problem so that (M1), (M2) and (M3) can be checked efficiently by graph manipulations and arithmetic operations on rational numbers without serious numerical difficulty due to rounding errors. The algorithm, adapted to our purpose, will be described in some detail in the latter half of this section.

The main result of the present paper is stated below.

THEOREM 4.6. *Assume (A1) and (A2). The descriptor system (3.1) satisfies (C1), (C2) and (C3) iff*

$$(M1): \text{rank} [\mathcal{M}([I_n|Q_A - Q_F]) \vee \mathcal{M}([I_n|T_A - T_F])] = 2n,$$

$$(M2): \text{rank} [\mathcal{M}([I_n|Q_A|Q_B]) \vee \mathcal{M}([I_n|T_A|T_B])] = 2n,$$

and

$$(M3): \zeta_1(X) + \zeta_2(Y) \text{ is constant for all } X, Y (\subset \hat{S}) \text{ such that } X \cap Y = \emptyset, X \text{ is independent in } \mathcal{M}([O_n|I_n|Q_A - Q_F|Q_B]).\hat{S}, Y \text{ is independent in } \mathcal{M}([I_n|O_n|T_F|O_{n,m}]).\hat{S} \text{ and } \hat{S} \setminus (X \cup Y) \text{ is independent in } \mathcal{M}([I_n|I_n|T_A|T_B]).\hat{S}, \text{ where } \hat{S} \text{ is the set consisting of all coloops of } \mathcal{M}([O|I|Q_A - Q_F|Q_B]) \vee \mathcal{M}([I|O|T_F|O]) \vee \mathcal{M}([I|I|T_A|T_B]).$$

Proof. The theorem follows from Lemmas 4.2, 4.3, and 4.5 if we show that (M0) in Lemma 4.5 is implied by (M1). In fact, by Lemma 4.4, (M0) is equivalent to $\text{rank } D(s) = 3n$, and hence to $\text{rank } [A - sF|B] = n$ by (4.7). This follows obviously from (C1), i.e., from (M1). \square

4.2. Algorithm for testing the controllability condition. The conditions (M1) and (M2) of Theorem 4.6 can be checked efficiently by the matroid union/partition algorithm [7], since the matroids involved are linear matroids represented over the rational numbers and transversal matroids. See [33] for the description of the algorithm for this particular case.

Before presenting a concrete procedure for (M3), we will outline the key idea to cope with the seemingly complicated condition that $\zeta_1(X) + \zeta_2(Y)$ remains constant for all possible choices of (X, Y) with the specified properties. As described in [15], the matroid union/partition problem can be formulated in a natural manner as an independent-flow problem [8]. Then the set of coloops \hat{S} of the union matroid can be identified easily by path-searching on the auxiliary graph associated with a maximum independent flow.

Moreover, by associating an appropriate cost with each arc in the independent-flow problem, the quantity $\zeta_1(X) + \zeta_2(Y)$ can be expressed as the cost of a maximum independent flow. Each arc of the auxiliary graph is then given the “length” that represents the imputed cost. Then (M3) can be shown to be equivalent to the graph-theoretic condition that there exists no directed cycle of nonzero “length” in a certain subgraph, representing \hat{S} , of the auxiliary graph. This condition is known to be further equivalent to the existence of potentials associated with vertices of the subgraph such that the imputed cost, i.e., the “length,” of an arc in a strongly connected component is expressed as the difference of the potentials associated with its two end-vertices.

The concrete procedure for (M3) is as follows. In accordance with [31], [33] we consider the matroid intersection, rather than the union, formulated in the independent-flow problem.

The dual matroid \mathcal{M}_Q^* of $\mathcal{M}_Q = \mathcal{M}([I_n|Q_A - Q_F|Q_B])$ defined on

$$(4.9) \quad \bar{S} = \{w_1, \dots, w_n\} \cup \{x_1, \dots, x_n\} \cup \{u_1, \dots, u_m\}$$

is again a linear matroid over \mathbf{Q} which is expressed by the linear dependence among the row vectors of the matrix

$$(4.10) \quad \begin{array}{l} \mathbf{w}: \\ \mathbf{x}: \\ \mathbf{u}: \end{array} \begin{pmatrix} Q_A - Q_F & Q_B \\ I_n & 0 \\ 0 & I_m \end{pmatrix},$$

the row-set of which is indexed by \bar{S} of (4.9) as indicated.

The underlying graph $G = (V, A^*)$ of the independent-flow problem is defined as follows. It has the union of two disjoint copies of \bar{S} as the vertex-set V :

$$V = V_T \cup V_Q,$$

where

$$V_T = \{w_i^T | i = 1, \dots, n\} \cup \{x_j^T | j = 1, \dots, n\} \cup \{u_j^T | j = 1, \dots, m\},$$

$$V_Q = \{w_i^Q | i = 1, \dots, n\} \cup \{x_j^Q | j = 1, \dots, n\} \cup \{u_j^Q | j = 1, \dots, m\}.$$

In general the copies of $v \in \bar{S}$ in V_T and V_Q are denoted by v^T and v^Q , respectively. The arc-set A^* is given by

$$A^* = A_w \cup A_x \cup A_u \cup A_T,$$

where

$$A_w = \{(w_i^T, w_i^Q) | i = 1, \dots, n\},$$

$$A_x = \{(x_j^T, x_j^Q) | j = 1, \dots, n\},$$

$$A_u = \{(u_j^T, u_j^Q) | j = 1, \dots, m\}$$

and

$$A_T = \mathcal{N}(T_F) \cup \mathcal{N}(T_A) \cup \mathcal{N}(T_B).$$

The arc corresponding to $(T_F)_{ij} (\neq 0)$ (or $(T_A)_{ij} \neq 0$) connects from w_i^T to x_j^T , and the arc $(T_B)_{ij} (\neq 0)$ from w_i^T to u_j^T . Note that G has parallel arcs from w_i^T to x_j^T if $(T_F)_{ij}(T_A)_{ij} \neq 0$.

Each arc is given the unit capacity. The cost function $\gamma: A^* \rightarrow \mathbf{R}$ is defined with reference to (4.4) by

$$(4.11) \quad \gamma(a) = \begin{cases} r_i, & a = (w_i^T, w_i^Q) \in A_w, \\ c_j, & a = (x_j^T, x_j^Q) \in A_x, \\ c_{n+j}, & a = (u_j^T, u_j^Q) \in A_u, \\ 1, & a \in \mathcal{N}(T_F), \\ 0, & a \in \mathcal{N}(T_A) \cup \mathcal{N}(T_B). \end{cases}$$

The entrance-set V^+ of the independent-flow problem is $V^+ = \{w_i^T | i = 1, \dots, n\}$, on which we understand the free matroid is defined, whereas the exit-set V^- is V_Q , to which the matroid \mathcal{M}_Q^* represented by (4.10) is attached (with the obvious correspondence between $V^- = V_Q$ and \bar{S} of (4.9)).

By the integrality, we may assume that an independent flow f from V^+ to V^- in this network is chosen to be integer-valued, i.e.,

$$(4.12) \quad f(a) \in \{0, 1\} \quad \text{for } a \in A^*.$$

By the definition of an independent flow, $f(\delta^+ v) \in \{0, 1\}$ for $v \in V^+$, where $\delta^+ v$ denotes the set of arcs going out of v , and the vector $(f(a) | a \in A_w \cup A_x \cup A_u)$, when identified with a subset of \bar{S} by (4.12), determines a subset, say $J (\subset \bar{S})$, which is independent in the matroid \mathcal{M}_Q^* attached to V^- . By the construction of G , J is independent also in the transversal matroid $\mathcal{M}([I | T_A - T_F | T_B])$.

To define the auxiliary network associated with f , we need to transform the matrix of (4.10), which we denote by P . Since J is independent in \mathcal{M}_Q^* , it can be augmented to a base, say $J \cup J_1$, where $|J \cup J_1| = n + m$. The square submatrix of P with row-set $J \cup J_1$ is then nonsingular, and we define \tilde{P} to be the $(2n + m) \times (n + m)$ matrix obtained from P by post-multiplying the inverse of that submatrix. The row-set of \tilde{P} is still

indexed by \bar{S} and the linear dependence among the row vectors of \tilde{P} represents \mathcal{M}_Q^* . Note that the column-set of \tilde{P} has the natural correspondence with $J \cup J_1$.

The auxiliary network $\bar{N} = (\bar{V}, \bar{A})$ associated with an independent flow f in the present network is defined as follows. (See [8], [15] for the general definition of the auxiliary network for the independent-flow problem.) The vertex-set \bar{V} is identical with V , where the entrance S^+ and the exit S^- is defined as

$$\begin{aligned} S^+ &= \{v \in V^+ | f(\delta^+ v) = 0\}, \\ S^- &= \{v^Q \in V^- | \tilde{P}_{vj} \neq 0 \text{ for some } j \in J_1\}. \end{aligned}$$

The arc-set \bar{A} is given by

$$\bar{A} = B_* \cup B^* \cup A^-,$$

where

$$\begin{aligned} B_* &= \{a | a \in A^*, f(a) = 0\}, \\ B^* &= \{\bar{a} | \bar{a} \text{ is the reorientation of } a \in A^* \text{ such that } f(a) = 1\}, \\ A^- &= \{(u^Q, v^Q) | u \in \bar{S} \setminus J, v \in J, \tilde{P}_{uv} \neq 0, \tilde{P}_{uj} = 0 \text{ for } j \in J_1\}. \end{aligned}$$

The length function $\bar{\gamma}: \bar{A} \rightarrow \mathbf{R}$ is defined by

$$(4.13) \quad \bar{\gamma}(\bar{a}) = \begin{cases} \gamma(\bar{a}) & \text{if } \bar{a} \in B_*, \\ -\gamma(a) & \text{if the reorientation of } \bar{a} \in B^* \text{ is } a \in A^*, \\ 0 & \text{if } \bar{a} \in A^-. \end{cases}$$

Consider the auxiliary network $\bar{N} = (\bar{V}, \bar{A})$ associated with a maximum independent flow, and let $\hat{V} (\subset \bar{V})$ be the set of vertices of \bar{N} which are not reachable to S^- by directed paths in it. The subgraph induced by \hat{V} is denoted as $\hat{G} = (\hat{V}, \hat{A})$ and the subnetwork of \bar{N} , restricted to \hat{G} , as $\hat{N} = (\hat{V}, \hat{A})$. It may be remarked that if (M1) is satisfied, the value of the maximum independent flow is equal to n and therefore S^+ is empty.

The algorithmic characterization of (M3) of Theorem 4.6 is now stated.

THEOREM 4.7. *Suppose (M1) is satisfied. The following three conditions are equivalent.*

- (i) (M3) holds true.
- (ii) The sum of the lengths $\bar{\gamma}(a)$ along any directed cycle in \hat{G} is equal to zero.
- (iii) There exists a "potential" function $\pi: \hat{V} \rightarrow \mathbf{R}$ satisfying

$$\bar{\gamma}(a) = \pi(\partial^- a) - \pi(\partial^+ a)$$

for all $a = (\partial^+ a, \partial^- a) \in \hat{A}$ such that $\partial^+ a$ and $\partial^- a$ belong to the same strongly connected component of \hat{G} .

Proof. The equivalence of (i) and (ii) follows from the well-known facts about the independent-flow problem, while that of (ii) and (iii) is obvious. \square

This theorem provides an efficient way to test (M3). As is well known, a maximum independent flow can be obtained by repeatedly finding a path in auxiliary networks (cf. [15], [33] for the detail of this procedure). The result of [5] implies that the amount of computation needed for finding a maximum independent flow is bounded by $O(n^2(n+m) \log n)$ in the worst case. Then the network $\hat{N} = (\hat{V}, \hat{A})$ can be constructed from the corresponding auxiliary network $\bar{N} = (\bar{V}, \bar{A})$ in $O(|\bar{V}| + |\bar{A}|)$ time in a straightforward manner. Once \hat{N} is constructed, the third condition (iii) above can be checked in $O(|\hat{V}| + |\hat{A}|)$ time with arithmetic operations (subtractions) on rational numbers by finding a spanning forest as well as the decomposition into strongly connected components [1]. Noting that $|\hat{V}| = O(n+m)$ and $|\hat{A}| = O(n(n+m))$, we see that the total amount of computation for testing (M3) is bounded by $O(n^2(n+m) \log n)$ in the worst case.

The other two conditions (M1) and (M2) of Theorem 4.6 can also be checked in $O(n^2(n+m)\log n)$ time in the worst case [5] by the established algorithm for the matroid union/intersection problem. Therefore the proposed algorithm for testing the structural controllability based on Theorem 4.6 is guaranteed to run in $O(n^2(n+m)\log n)$ time even in the worst case, and the actual running time is much less than the bound in many cases, depending on how many fixed constants are involved.

It should also be emphasized that the proposed method is practicable and stable from the numerical point of view; it requires arithmetic operations only on simple rational numbers, typically simple integers such as those representing the underlying topological relations, so that it is free from serious numerical difficulty of rounding errors.

Example 4.1. Recall the mechanical system of Example 3.1. If we choose time $[T]$, length $[L]$ and mass $[M]$ as the fundamental physical dimensions, the dimensions associated with x_j ($j = 1, \cdots, 6$) and u are given by

$$L, L, T^{-1}L, T^{-1}L, T^{-2}LM, T^{-1}L, \text{ and } T^{-2}LM,$$

and those with w_i ($i = 1, \cdots, 6$) by

$$T^{-1}L, T^{-1}L, T^{-2}LM, T^{-2}LM, T^{-2}LM, T^{-1}L.$$

Therefore, $[Q_A - sQ_F|Q_B]$ of (3.9) admits the expression of the form (3.11) with

(4.14)
$$\begin{aligned} c_1 = c_2 = 0, \quad c_3 = c_4 = 1, \quad c_5 = 2, \quad c_6 = 1, \quad c_7 = 2, \\ r_1 = r_2 = 1, \quad r_3 = r_4 = r_5 = 2, \quad r_6 = 1. \end{aligned}$$

The conditions (M1) and (M2) are found to be satisfied, as will be partly mentioned below. The independent-flow problem for (M3) is depicted in Fig. 4.1, in which $V^+ = \{w_1^T, \cdots, w_6^T\}$, $V^- = \{x_1^Q, \cdots, x_6^Q, u^Q, w_1^Q, \cdots, w_6^Q\}$, and the cost $\gamma(a)$ of each arc a is given in parentheses.

As indicated by bold lines, there exists a maximum independent flow f of value 6; it corresponds to $J = \{x_1, x_2, w_1, w_2, w_5, w_6\}$, which is independent both in $\mathcal{M}_Q^* = \mathcal{M}([I|Q_A - Q_F|Q_B])^*$ and in $\mathcal{M}([I|T_A - T_F|T_B])$. This shows that

$$\text{rank} [\mathcal{M}([I|Q_A - Q_F|Q_B]) \vee \mathcal{M}([I|T_A - T_F|T_B])] = 12,$$

or $\text{rank} [A - sF|B] = 6$. Moreover, the flow f of Fig. 4.1 reveals, at the same time, that (M1) is satisfied, since $f((u^T, u^Q)) = 0$.

If J is augmented by $J_1 = \{u\}$ to a base of \mathcal{M}_Q^* , the matrix \tilde{P} is given by

(4.15)
$$\tilde{P} = \begin{array}{c} \begin{array}{cccccc} x_1 & x_2 & w_1 & w_2 & w_5 & w_6 & u \end{array} \\ \begin{array}{l} w_1: \\ w_2: \\ w_3: \\ w_4: \\ w_5: \\ w_6: \\ \hline x_1: \\ x_2: \\ x_3: \\ x_4: \\ x_5: \\ x_6: \\ \hline u: \end{array} \end{array} \begin{array}{cccccc} & & 1 & & & & \\ & & & 1 & & & \\ & & & & 1 & & 1 \\ & & & & -1 & & \\ & & & & 1 & & \\ & & & & & 1 & \\ \hline 1 & & & & & & \\ & 1 & & & & & \\ 1 & & 1 & & & & \\ & 1 & & 1 & & & \\ & & & & -1 & & \\ 1 & -1 & & & & 1 & \\ \hline & & & & & & 1 \end{array}$$

FIG 4.1. Independent-flow problem for Example 4.1. (A maximum independent-flow is drawn in bold lines.)

The associated auxiliary network $\bar{N} = (\bar{V}, \bar{A})$ is drawn in Fig. 4.2, where the “length” $\bar{\gamma}(a)$ is attached in parentheses to each arc a of $B_* \cup B^*$. The entrance S^+ is empty, while the exit $S^- = \{u^Q, w_3^Q\}$. All the vertices except those in $\hat{V} = \{w_1^T, w_1^Q, w_2^T, w_2^Q, w_6^T, w_6^Q\}$ are reachable to S^- , and the subnetwork $\hat{N} = (\hat{V}, \hat{A})$ consists of three disconnected arcs $\hat{A} = \{(w_1^Q, w_1^T), (w_2^Q, w_2^T), (w_6^Q, w_6^T)\}$. Then condition (ii) of Theorem 4.7 is trivially met, and this mechanical system is found to be generically controllable.

Example 4.2. Consider a hypothetical descriptor system (3.1) with $\mathbf{x} = (x_1, x_2, x_3)$, $\mathbf{u} = (u)$, and

$$(4.16) \quad F = \begin{pmatrix} 0 & 0 & p_1 \\ 1 & 1 & p_2 \\ 0 & 0 & 0 \end{pmatrix}, \quad A = \begin{pmatrix} 1 & p_3 & 0 \\ 0 & 0 & 1 \\ -1 & -1 & p_4 \end{pmatrix}, \quad B = \begin{pmatrix} p_5 \\ 0 \\ 0 \end{pmatrix},$$

where $\{p_i | i = 1, \dots, 5\}$ is to be understood as independent parameters. The matrix $[A - sF | B]$ is then a mixed matrix of (3.7) with

$$(4.17) \quad [Q_A - sQ_F | Q_B] = \left(\begin{array}{ccc|c} 1 & 0 & 0 & 0 \\ -s & -s & 1 & 0 \\ -1 & -1 & 0 & 0 \end{array} \right),$$

$$[T_A - sT_F | T_B] = \left(\begin{array}{ccc|c} 0 & p_3 & -sp_1 & p_5 \\ 0 & 0 & -sp_2 & 0 \\ 0 & 0 & p_4 & 0 \end{array} \right).$$

FIG. 4.2. Auxiliary network for Example 4.1. ($S^+ = \emptyset$, $S^- = \{u^Q, w_3^Q\}$.)

Note that the matrix $[Q_A - sQ_F | Q_B]$ above enjoys the property (A2) and it has the expression (3.11) with, e.g.,

$$r_1 = 0, \quad r_2 = 1, \quad r_3 = 0, \quad c_1 = c_2 = 0, \quad c_3 = 1, \quad c_4 = 0.$$

It is easy to see by inspection that (C1) and (C2), or equivalently (M1) and (M2), are satisfied. In Fig. 4.3, the independent-flow problem for (M3) is illustrated, where $V^+ = \{w_1^T, w_2^T, w_3^T\}$, $V^- = \{x_1^Q, x_2^Q, x_3^Q, u^Q, w_1^Q, w_2^Q, w_3^Q\}$, and the cost γ is given in parentheses as before.

The auxiliary network associated with a maximum independent flow f is given in Fig. 4.4 with $\tilde{\gamma}$ in parentheses. The flow f corresponds to the common independent set $J = \{w_3, x_2, x_3\}$. The entrance S^+ is empty and the exit $S^- = \{u^Q\}$, to which the vertices in $\hat{V} = \{x_3^T, x_3^Q, w_2^T, w_2^Q, w_3^T, w_3^Q\}$ are not reachable.

The subnetwork $\hat{N} = (\hat{V}, \hat{A})$, given in Fig. 4.5 with $\tilde{\gamma}$ in parentheses contains two simple directed cycles; the length, relative to $\tilde{\gamma}$, of the cycle consisting of $\{w_2^T, w_2^Q, w_3^Q, w_3^T, x_3^T\}$ vanishes, whereas that of $\{w_2^T, w_2^Q, x_3^Q, x_3^T\}$ does not. Theorem 4.7 reveals that this system does not satisfy (M3), i.e., there exists a nonzero mode that is not controllable. The graph-theoretic arguments of [3], [26], [30], which treat the nonvanishing entries of F , A and B of (4.16) as if they were independent, would fail to detect this fact.

5. Deriving the controllability condition of nonzero modes. This section is devoted to the proof of Lemma 4.5. Recall the matrix $D(s)$ of (4.2) consisting of three matrices

FIG. 4.3. Independent-flow problem for Example 4.2. (A maximum independent-flow is drawn in bold lines.)

FIG. 4.4. Auxiliary network for Example 4.2.

FIG. 4.5. Subnetwork \hat{N} for Example 4.2.

$Q_D(s)$, $T_{D1}(s)$ and T_{D0} of (4.1). By replacing the $3n$ occurrences of unity in $T_{D1}(s)$ and T_{D0} with algebraically independent real numbers, say, t_1, \dots, t_{3n} , we consider another composite $(3n) \times (3n + m)$ matrix $\tilde{D}(s)$, i.e.,

(5.1)
$$\tilde{D}(s) = \begin{pmatrix} Q_D(s) \\ \tilde{T}_{D1}(s) \\ \tilde{T}_{D0} \end{pmatrix},$$

where

(5.2)
$$\begin{aligned} \tilde{T}_{D1}(s) &= [\text{diag}(t_1, \dots, t_n) | O_n | -sT_F | O_{n,m}], \\ \tilde{T}_{D0} &= [-\text{diag}(t_{n+1}, \dots, t_{2n}) | -\text{diag}(t_{2n+1}, \dots, t_{3n}) | T_A | T_B] \end{aligned}$$

and

$$\mathcal{N}(\tilde{T}_{D1}(s)) \cup \mathcal{N}(\tilde{T}_{D0}) \text{ is algebraically independent over } \mathbf{Q}(s).$$

Then $\tilde{D}(s)$ is a matrix of the form (2.3), to which Lemma 2.3 applies with $\mathbf{K} = \mathbf{Q}(s)$.

It has been shown in § 4 that (C3) is equivalent to (4.8). Since the transformation from $D(s)$ to $\tilde{D}(s)$ can be interpreted as scaling of the rows of T_{D1} and T_{D0} as well as the columns of $\{v_1, \dots, v_n\}$ with algebraically independent transcendentals, we see that (4.8) is further equivalent to

(5.3)
$$\text{rank } \tilde{D}(z) = 3n \quad \text{for } z \neq 0, \quad z \in \mathbf{C}.$$

Let $\bar{D}(s)$ be the combinatorial canonical form of $\tilde{D}(s)$, which is obtained by (2.4) with a nonsingular matrix U over $\mathbf{Q}(s)$ (see § 2). It is a block-triangular matrix of the form (2.5) with the column-set C and the row-set R partitioned as

$$\begin{aligned} C &= C_0 \cup C_1 \cup \dots \cup C_r \cup C_\infty, \\ R &= R_0 \cup R_1 \cup \dots \cup R_r \cup R_\infty. \end{aligned}$$

An important consequence of (A2) is that, in the transformation of the form (2.4) connecting $\tilde{D}(s)$ to $\bar{D}(s)$, the matrix $U = U(s)$, which is nonsingular in $\mathbf{Q}(s)$, can be chosen so that each entry is of the form αs^p ($\alpha \in \mathbf{Q}, p \in \mathbf{Z}$) and that

(5.4)
$$\det U(s) = \alpha s^p, \quad \alpha \in \mathbf{Q} \setminus \{0\}, \quad p \in \mathbf{Z}.$$

For instance, $\tilde{D}(s)$ for the system of Example 4.2 is given by

$$(5.5) \quad \tilde{D}(s) = \begin{array}{c|cccccccc|c} v_1 & v_2 & v_3 & w_1 & w_2 & w_3 & x_1 & x_2 & x_3 & u \\ \hline 0 & & & 1 & & & 1 & 0 & 0 & 0 \\ & 0 & & & 1 & & -s & -s & 1 & 0 \\ & & 0 & & & 1 & -1 & -1 & 0 & 0 \\ \hline t_1 & & & 0 & & & 0 & 0 & -sp_1 & 0 \\ & t_2 & & & 0 & & 0 & 0 & -sp_2 & 0 \\ & & t_3 & & & 0 & 0 & 0 & 0 & 0 \\ \hline -t_4 & & & -t_7 & & & 0 & p_3 & 0 & p_5 \\ & -t_5 & & & -t_8 & & 0 & 0 & 0 & 0 \\ & & -t_6 & & & -t_9 & 0 & 0 & p_4 & 0 \end{array}$$

The transformation (2.4) with

$$(5.6) \quad U = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 0 & -1 \\ 0 & 1 & -s \end{pmatrix}$$

makes it into the combinatorial canonical form

$$(5.7) \quad \bar{D}(s) = \begin{array}{c|cccc|ccccc|c} u & w_1 & x_1 & x_2 & v_1 & v_2 & w_2 & w_3 & x_3 & v_3 \\ \hline 0 & 1 & 0 & -1 & & & & 1 & & \\ 0 & 0 & 1 & 1 & & & & -1 & & \\ p_5 & -t_7 & 0 & p_3 & -t_4 & & & & & \\ \hline & & & & t_1 & & & & -sp_1 & \\ & & & & & 0 & 1 & -s & 1 & \\ & & & & & t_2 & 0 & 0 & -sp_2 & \\ & & & & & -t_5 & -t_8 & 0 & 0 & \\ & & & & & 0 & 0 & -t_9 & p_4 & -t_6 \\ \hline & & & & & & & & & t_3 \end{array}$$

with $C_0 = \{u, w_1, x_1, x_2\} (|R_0| = 3)$, $C_1 = \{v_1\}$, $C_2 = \{v_2, w_2, w_3, x_3\}$, $C_3 = \{v_3\}$, and $C_\infty = \emptyset (|R_\infty| = 0)$.

By (5.4), $U(z)$ is nonsingular for any particular complex number $z \neq 0$. Therefore $\tilde{D}(z)$ and $\bar{D}(z)$, as matrices over \mathbb{C} , have a common rank, and (5.3) is expressed with reference to the rank of the diagonal blocks of $\bar{D}(z)$, as follows.

LEMMA 5.1. (C3) is equivalent to the following:

- (i) $R_\infty = \emptyset$,
- (ii) $\text{rank } \bar{D}(z)[R_0, C_0] = |R_0|$ for any $z \neq 0$, $z \in \mathbb{C}$, and
- (iii) $\text{rank } \bar{D}(z)[R_i, C_i] = |R_i|$ for any $z \neq 0$, $z \in \mathbb{C}$; $i = 1, \dots, r$.

Proof. This is immediate from (2.6) and the facts that (C3) is equivalent to (5.3) and that $\tilde{D}(z)$ and $\bar{D}(z)$ have the same rank for each value of $z (\neq 0)$. \square

The following is obvious.

LEMMA 5.2. $R_\infty = \emptyset$ iff (M0) holds true.

The third lemma asserts that condition (ii) of Lemma 5.1 above is always satisfied.

LEMMA 5.3. $\text{rank } \bar{D}(z)[R_0, C_0] = |R_0|$ for any $z \neq 0$, $z \in \mathbb{C}$.

Proof. Let $\bar{D}(s)[R_0, C_0] = \bar{D}_0(s)$ be expressed as

$$(5.8) \quad \bar{D}_0(s) = \begin{pmatrix} Q_0(s) \\ T_1(s) \\ T_0 \end{pmatrix},$$

where $Q_0(s)$ is the matrix over $\mathbf{Q}(s)$ obtained from $Q_D(s)$, and $T_1(s)$ and T_0 are the submatrices, respectively, of $\tilde{T}_{D1}(s)$ and \tilde{T}_{D0} of (5.2). We have

$$(5.9) \quad \text{rank} [\mathcal{M}(Q_0(s)) \vee \mathcal{M}(T_1(s)) \vee \mathcal{M}(T_0)] = |R_0|.$$

Firstly suppose that $z (\neq 0)$ is an algebraic number (over \mathbf{Q}). Then $\mathcal{N}(T_1(z)) \cup \mathcal{N}(T_0)$ is algebraically independent over $\mathbf{Q}(z)$, and therefore Lemma 2.3 yields

$$(5.10) \quad \text{rank } \bar{D}_0(z) = \text{rank} [\mathcal{M}(Q_0(z)) \vee \mathcal{M}(T_1(z)) \vee \mathcal{M}(T_0)].$$

As a consequence of (A2), we have $\mathcal{M}(Q_0(s)) = \mathcal{M}(Q_0(1)) = \mathcal{M}(Q_0(z))$ if $z \neq 0$, whereas $\mathcal{M}(T_1(s)) = \mathcal{M}(T_1(z))$ is obvious. This fact combines (5.9) with (5.10), establishing

$$\text{rank } \bar{D}_0(z) = |R_0| \quad \text{for } z (\neq 0) \text{ algebraic.}$$

Next, consider the case where z is transcendental over \mathbf{Q} . Since $\text{rank } \bar{D}_0(s) = |R_0|$, there exists a nonvanishing minor (subdeterminant) $g(s; \mathcal{N}_T)$ of order $|R_0|$, which may be regarded as a polynomial over \mathbf{Q} in $\{s\} \cup \mathcal{N}_T$, where $\mathcal{N}_T = \mathcal{N}(T_1(1)) \cup \mathcal{N}(T_0)$. It suffices to consider such a $z (\in \mathbf{C} \setminus \{0\})$ that is a root of g , i.e., $g(z; \mathcal{N}_T) = 0$.

This means that $\{z\} \cup \mathcal{N}_T$ is algebraically dependent over \mathbf{Q} , whereas \mathcal{N}_T , as well as $\{z\}$, is algebraically independent over \mathbf{Q} . By Lemma 2.1, there exists $t \in \mathcal{N}_T$ such that $\mathcal{N}'_T = (\mathcal{N}_T \setminus \{t\}) \cup \{z\}$ is algebraically independent.

Since none of the columns of $\bar{D}_0(s)$ is a coloop of $\mathcal{M}(\bar{D}_0(s))$ (see Lemma 2.4), the matrix $\bar{D}_0(s)$ with one column deleted remains of rank $|R_0|$. In particular, there exists a square nonsingular submatrix of $\bar{D}_0(s)$ of order $|R_0|$ that does not contain the entry t . Let $h(s) = h(s; \mathcal{N}_T \setminus \{t\})$ denote its determinant, which is a nontrivial polynomial over \mathbf{Q} in $\{s\} \cup (\mathcal{N}_T \setminus \{t\})$. By the algebraic independence of \mathcal{N}'_T , $h(z)$ does not vanish. This implies that $\bar{D}_0(z)$ is of rank $|R_0|$. \square

Now we turn to condition (iii) of Lemma 5.1. Put $R^* = R \setminus R_0$ and $C^* = C \setminus C_0$.

LEMMA 5.4. Assume (M0) (or equivalently $R_\infty = \emptyset$). Then condition (iii) of Lemma 5.1 is satisfied iff $\det \bar{D}(s)[R^*, C^*]$ can be written as

$$(5.11) \quad \det \bar{D}(s)[R^*, C^*] = \beta s^p,$$

where β is a nonvanishing polynomial in $\mathcal{N}(T_F) \cup \mathcal{N}(T_A) \cup \mathcal{N}(T_B)$ over \mathbf{Q} , and p an integer.

Proof. First note that (M0) implies $|R^*| = |C^*|$. Condition (iii) of Lemma 5.1 is obviously equivalent to

$$\det \bar{D}(z)[R^*, C^*] \neq 0 \quad \text{for any } z \neq 0, \quad z \in \mathbf{C}.$$

Then the assertion above follows immediately. \square

Put

$$(5.12) \quad \bar{D}(s)[R^*, C^*] = \begin{pmatrix} Q^*(s) \\ T_1^*(s) \\ T_0^* \end{pmatrix},$$

where $Q^*(s)$ is the matrix over $\mathbf{Q}(s)$ obtained from $Q_D(s)$, and $T_1^*(s)$ and T_0^* are the submatrices, respectively, of $\tilde{T}_{D1}(s)$ and \tilde{T}_{D0} of (5.2). In the following, $Q^*(s)[X]$ ($X \subset C^*$) means the submatrix of $Q^*(s)$ consisting of the columns of X and all the rows,

and similarly for $T_1^*(s)$ and T_0^* . Recall that $Q^*(s)$, $T_1^*(s)$ and T_0^* all have the full row rank. By the generalized Laplace expansion, we obtain the following.

LEMMA 5.5. *Suppose (M0) holds. Then*

$$(5.13) \quad \det \bar{D}(s)[R^*, C^*] = \sum_{X, Y} \det Q^*(s)[X] \cdot \det T_1^*(s)[Y] \cdot \det T_0^*[C^* \setminus (X \cup Y)],$$

where the summation is taken over all $X, Y (\subset C^*)$ such that X is a base of $\mathcal{M}(Q^*(s))$, Y is a base of $\mathcal{M}(T_1^*(s))$, and $C^* \setminus (X \cup Y)$ is a base of $\mathcal{M}(T_0^*)$.

The matrix $Q^*(s)$ inherits the property that every subdeterminant is of the form αs^p ($\alpha \in \mathbb{Q}, p \in \mathbb{Z}$). For a base $X (\subset C^*)$ of $\mathcal{M}(Q^*(s))$, we have

$$(5.14) \quad \begin{aligned} \det Q^*(s)[X] &= \alpha s^p, \\ \alpha &\in \mathbb{Q} \setminus \{0\}, \quad p = \zeta_1(X) + p_0, \end{aligned}$$

where ζ_1 is defined in (4.4) associated with $Q_D(s)$ and p_0 is an integer independent of X .

For a base $Y (\subset C^*)$ of $\mathcal{M}(T_1^*(s))$, we have similarly

$$(5.15) \quad \begin{aligned} \det T_1^*(s)[Y] &= \beta s^p, \\ \beta &\in \mathbb{Q}[\mathcal{N}(T_F)] \setminus \{0\}, \quad p = \zeta_2(Y). \end{aligned}$$

LEMMA 5.6. *Suppose (M0) holds. Then condition (iii) of Lemma 5.1 is equivalent to (M3) of Lemma 4.5.*

Proof. First notice the relations $\mathcal{M}(Q^*(s)) = \mathcal{M}([O|I|Q_A - Q_F|Q_B]).\hat{S}$, $\mathcal{M}(T_1^*(s)) = \mathcal{M}([I|O|T_F|O]).\hat{S}$, and $\mathcal{M}(T_0^*) = \mathcal{M}([I|I|T_A|T_B]).\hat{S}$, where it should be noted that \hat{S} , the set of coloops of $\mathcal{M}(D(s))$, is identical with C^* if (M0) holds.

Then from Lemma 5.5, (5.14) and (5.15), as well as from the fact that the nonvanishing terms in the right-hand side of (5.13) do not cancel one another (by virtue of the algebraic independence of $\mathcal{N}(T_F) \cup \mathcal{N}(T_A) \cup \mathcal{N}(T_B)$), it follows that $\det \bar{D}(s)[R^*, C^*]$ takes the form of (5.11) iff (M3) holds true. The proof is completed by Lemma 5.4. \square

Finally, Lemma 4.5 follows from Lemmas 5.1, 5.2, 5.3 and 5.6.

6. Conclusion. The result of the present paper includes many previously known results on the structural controllability as special cases. In particular, it is a direct generalization of [30] and [31]; in [30] the structural controllability condition for a descriptor system (without fixed constants) has been expressed in terms of graph-theoretic conditions using the Dulmage–Mendelsohn decomposition [6] of bipartite graphs, and in [29], [31] the structural controllability of a descriptor system is investigated under the same setting as in this paper with an additional assumption of the nonsingularity of F .

There seems to be several different definitions of the controllability of a descriptor system, to which the present approach can readily be adapted.

As has been partly demonstrated in this paper, some of the matroid-theoretic concepts should be useful for the analysis of dynamical systems, just as for electrical networks [14], [16]. See [15], [31] for matroid-theoretic approaches to other dynamical systems problems; the former describes the result of [17] on the controllability condition under some combinatorial constraints, and the latter deals with the problem of determining the dynamical degree [12] of a dynamical system.

Acknowledgments. The author expresses his hearty thanks to Professor Masao Iri of the University of Tokyo for constant discussions and encouragements. Professor

Satoru Fujishige of the University of Tsukuba kindly read the manuscript and suggested improvements. Some comments by the anonymous referees were helpful in revision.

ABSTRACT DYNAMIC PROGRAMMING MODELS UNDER COMMUTATIVITY CONDITIONS*

SERGIO VERDU[†] AND H. VINCENT POOR[‡]

Abstract. The unifying purpose of the abstract dynamic programming models is to find sufficient conditions on the recursive definition of the objective function that guarantee the validity of the dynamic programming iteration. This paper presents backward, forward, and backward-forward models that weaken previous sufficient conditions and that include, but are not restricted to, optimization problems. The backward-forward model is devoted to the simultaneous solution of a collection of interrelated sequential problems based on the independent computation of a cost-to-arrive function and a cost-to-go function. Several extremization and nonextremization problems illustrate the applicability of the proposed models.

Key words. backward and forward dynamic programming operator models, finite and infinite horizon sequential optimization, discrete-time Markov processes, fixed-interval detection and smoothing

AMS(MOS) subject classifications. 90C39, 90C48, 93E20

1. Introduction. The fact that dynamic programming has found application in a wide variety of sequential optimization problems has led several researchers to investigate what class of objective functions can be optimized by dynamic programming. The unifying purpose of the abstract dynamic programming models is not to facilitate the solution of specific problems, but to extract the essential features that guarantee the solvability of a sequential problem by dynamic programming. In the models proposed by Mitten [1], Denardo [2], Nemhauser [3], Karp and Held [4] and Bertsekas [5] it is assumed that the real-valued objective function can be defined recursively by a generating operator or local income function [6] which maps a set of functions of states into itself. If this operator is monotone, then further restrictions such as the contraction-mapping assumption of [2], the continuity conditions of [5] or the finiteness of the state-space [4] suffice to validate the dynamic programming solution in various finite and infinite horizon settings. Also, Brown and Strauch [7] have proposed a related abstract model where the return space is not necessarily the extended real line but a multiplicative lattice.

In this paper we propose an abstract discrete-time dynamic programming model that includes, but is not restricted to, optimization problems. Any functional satisfying a certain commutativity condition with the generating operator (which, unlike previous models, is not restricted to be monotone) of the objective function results in a sequential problem solvable by a dynamic programming iteration. Examples of sequential nonextremization problems fitting this framework are the derivation of marginal probability distributions from decomposable joint distributions, iterative computation of stage-separated functions taking values on additive commutative semigroups with distributive products, generation of symbolic transfer functions, and the computation of unconditional transition probabilities of a Markov process.

Another feature of the framework of this paper is the ability to formulate forward models completely symmetric to backward ones. This enables the analysis of open-loop problems by either approach under the same kind of restrictions (§ 3) and, more significantly, it allows for the formulation of the backward-forward dynamic programming operator model.

The backward-forward model presented in this paper is devoted to the simultaneous solution of a collection of interrelated sequential problems based on the independent computation of a cost-to-arrive function and a cost-to-go function. To fix ideas, consider the following simple example of this method. In a layered network, the shortest path containing a particular arc can obviously be obtained by deleting all other arcs in the same layer and solving for the shortest route by either forward or backward dynamic programming; however, if the problem must be solved for each arc in the network, then rather than repeating the above process, it is more efficient to simply compute the distances of each node from the source and to the destination. Other problems such as fixed-interval minimum error probability detection in data communications and fixed-interval smoothing are shown to fit into this framework.

In § 2, we present an operator model for discrete-time finite-horizon backward and forward problems, and a pair of sufficient conditions, viz., the decomposability of the objective function and the commutativity of operators, are shown to ensure the validity of the dynamic programming iteration. When applied to infimization problems, the commutativity condition is weaker and not more difficult to check in specific problems than the sufficient conditions imposed by previous models. The use of the proposed model is briefly illustrated in § 2 for optimum stochastic control problems, and in § 3 for a variety of deterministic problems with extremization and nonextremization operators. Familiarity with previous abstract dynamic programming models, in particular with the model due to Bertsekas [5] which encompasses most other previous settings, may be advantageous in reading §§ 2 and 3. The formulation and some applications of the backward-forward model are presented in § 4. Finally, § 5 briefly discusses the issues arising in the infinite-horizon problem and sufficient conditions on the commutativity of operators and interchangeability of limits are shown to ensure the validity of the dynamic programming iteration and the fixed-point property of the sought-after function of states.

2. Abstract finite-horizon dynamic programming operator model.

Glossary of notation. The following notation is used throughout the paper.¹

S :	state space.
A :	action space.
μ :	function mapping S to A ; $\mu: S \rightarrow A$.
M :	set of admissible policies from S to A ; $\mu \in M$.
Q :	return space.
L :	Q -valued function of states; $L: S \rightarrow Q$.
H :	operator mapping Q -valued functions of states to Q -valued functions of actions; $H: Q^S \rightarrow Q^A$.
$HL(a)$:	the function of actions $HL: A \rightarrow Q$ evaluated at the point $a \in A$.
V :	operator (functional) mapping Q -valued functions of M to Q ; $V: Q^M \rightarrow Q$.
$V\{q(\mu)\}$:	image in Q of a function $q: M \rightarrow Q$; note that μ is a dummy argument: $V\{q(\mu)\}$ depends on the values of $q(\mu)$ for all $\mu \in M$.
$V\{L_\mu\}$:	Q -valued function of states whose value at $x \in S$ is $V\{L_\mu(x)\}$, where L_μ is a Q -valued function of states parametrized by $\mu \in M$. Analogous notation is used for functions of actions $V\{HL_\mu\}$.
$M_{i,j} = M_i \times \cdots \times M_j$,	
$\mu_{i,j} = (\mu_i, \cdots, \mu_j) \in M_{i,j}$.	

¹ Stage indices are omitted here.

$$\begin{aligned} \mathbf{V}_{i,j}\{q(\mu_{i,j})\} &= \mathbf{V}_i\{\cdots \mathbf{V}_j\{q(\mu_{i,j})\}\cdots\}. \\ p_k: \text{projection of a Cartesian product: } p_k(x_1, \cdots, x_n) &= x_k; \\ p_k: X_1 \times \cdots \times X_n &\rightarrow X_k. \end{aligned}$$

The foregoing return, state and action spaces and operators H and \mathbf{V} take on various meanings depending on the specific problem to which the model is applied. In optimization problems Q is identified with the extended real line and \mathbf{V} is the infimization functional; i.e., for any function $q: M \rightarrow Q$

$$\mathbf{V}\{q(\mu)\} = \inf_{\mu \in M} q(\mu).$$

To fix ideas in a first reading of the sequel, it may be helpful to identify Q and \mathbf{V} with these particular cases.

For $i = 0, \cdots, N$, let M_i be the set of admissible policies mapping S_i to A_i (the state and action spaces at stage i , respectively). Suppose that for each stage $n \in \{0, \cdots, N\}$ we are given a function of states $L_{\mu_n, N}^n: S_n \rightarrow Q$ which is parametrized by the string of policies $\mu_n, N \in M_{n, N}$. ($L_{\mu_n, N}^n(x)$ is the cost incurred by using the policies μ_n, \cdots, μ_N if x is the state at the n th stage.) Then the objective of this section is to investigate under what conditions dynamic programming can be used to find the function of initial states:

$$(1) \quad \mathbf{V}_{0, N}\{L_{\mu_{0, N}}^0\}$$

where $\mathbf{V}_i: Q^{M_i} \rightarrow Q$, $i = 0, \cdots, N$.

The first requisite in order to solve (1) by dynamic programming is the recursive formulation of the sequential dependence of the function of states $L_{\mu_{0, N}}^0$ on the policies $\mu_{0, N}$:

B1. Backward decomposability of the objective function. There exists a collection of operators

$$(2) \quad \begin{aligned} H^i: Q^{S_i} &\rightarrow Q^{A_{i-1}}, \quad i = 1, \cdots, N, \quad \text{such that for all } \mu_{0, N} \in M_{0, N}, \\ L_{\mu_{i-1, N}}^{i-1}(x) &= H^i L_{\mu_{i, N}}^i(\mu_{i-1}(x)), \quad x \in S_{i-1}, \quad i = 1, \cdots, N. \end{aligned}$$

Example. Suppose the objective is to control a deterministic system $x_{k+1} = f(x_k, u_k) \in S$, $u_k \in U$, so as to minimize the cost $\sum_{k=0}^N g(x_k, u_k)$ as a function of $x_0 \in S$. This objective function satisfies property B1. To see this, define

$$(3) \quad A = S \times U, \quad HL(a) = g(a) + L(f(a))$$

and restrict the admissible policies to satisfy $p_1(\mu(x)) = x$. If \mathbf{V} is the infimization operator, then (1) coincides with the sought-after minimum cost. Note that the only difference between the operator H (local income function in optimization problems) and the one used in previous abstract dynamic programming models (e.g., [2] and [5]) is that in those works, the mapping is defined on cartesian products of state and control spaces in lieu of action spaces. While both coincide in this example, the action spaces take on different roles in other problems in the sequel. As we know, we can indeed solve the problem in the present example using dynamic programming; however this is because it satisfies other properties in addition to B1, which are characterized next.

DEFINITION. A Q -valued function of states $R^i: S_i \rightarrow Q$ is a *cost-to-go* function² if

$$R^i(x) = \mathbf{V}_{i, N}\{L_{\mu_{i, N}}^i(x)\} \quad \text{for all } x \in S_i.$$

² This terminology is maintained for nonextremization problems.

THEOREM 2.1. Suppose that property B1 holds and define the following sequence of functions of states $B^i: S_i \rightarrow Q$, $i = 0, \dots, N$:

$$(4a) \quad B^N(x) = V_N\{L_{\mu_N}^N(x)\},$$

and

$$(4b) \quad B^{i-1}(x) = V_{i-1}\{H^i B^i(\mu_{i-1}(x))\}.$$

Then B^i , $i = 0, \dots, N$ are cost-to-go functions if and only if

$$(5) \quad V_{i-1,N}\{H^i L_{\mu_{i,N}}^i(\mu_{i-1}(x))\} = V_{i-1}\{H^i V_{i,N}\{L_{\mu_{i,N}}^i(\mu_{i-1}(x))\}\}$$

for all $x \in S_{i-1}$, $i = 1, \dots, N$.

Proof. Because of (4a) it suffices to show that, for each $i = 1, \dots, N$, if $B^i = V_{i,N}\{L_{\mu_{i,N}}^i\}$, then $B^{i-1} = V_{i-1,N}\{L_{\mu_{i-1,N}}^{i-1}\}$ is equivalent to (5); but this follows immediately from (2) and (4b). \square

COROLLARY. Suppose that B1 and the following condition are satisfied:

B2. Backward commutativity of operators.

$$(6) \quad V_{i,N}\{H^i L_{\mu_{i,N}}^i\} = H^i V_{i,N}\{L_{\mu_{i,N}}^i\}, \quad i = 1, \dots, N.$$

Then, B^i , $i = 0, \dots, N$ are cost-to-go functions and in particular $V_{0,N}\{L_{\mu_{0,N}}^0\} = B^0$.

Property B2 can be represented in the following commutativity diagram:

$$\begin{array}{ccc} Q^{S_i \times M_{i,N}} & \xrightarrow{H^i} & Q^{A_{i-1} \times M_{i,N}} \\ V_{i,N} \downarrow & & \downarrow V_{i,N} \\ Q^{S_i} & \xrightarrow{H^i} & Q^{A_{i-1}} \end{array}$$

where the set of functions of states (resp. actions) parametrized by the elements of $M_{i,N}$ is denoted by $Q^{S_i \times M_{i,N}}$ (resp. $Q^{A_{i-1} \times M_{i,N}}$). The mappings $Q^{S_i \times M_{i,N}} \rightarrow Q^{S_i}$, $Q^{A_{i-1} \times M_{i,N}} \rightarrow Q^{A_{i-1}}$ and $Q^{S_i \times M_{i,N}} \rightarrow Q^{A_{i-1} \times M_{i,N}}$ induced by the pointwise application of the operators $V_{i,N}$ and H^i are denoted with the same symbol. In the special case of optimization problems, property B2 can be viewed as a formalization of a general optimality principle: in order to find the optimal partial return for each action a , it suffices to compute the cost-to-go function at the next stage and evaluate the local income function at a .

The fact that the recursions (2) and (4) are defined backwards is only due to the ordering of the operators V in (1). Mere reversal of the stage indices results in a forward solution of $V_{N,0}\{L_{\mu_{0,N}}^N(x)\}$, $x \in S_N$. The corresponding decomposability and commutativity assumptions are, in this case,

F1. Forward decomposability of the objective function.

$$(2') \quad L_{\mu_{0,i+1}}^{i+1}(x) = H^i L_{\mu_{0,i}}^i(\mu_{i+1}(x)), \quad x \in S_{i+1}, \quad i = 0, \dots, N-1,$$

where

$$L_{\mu_{0,i}}^i: S_i \rightarrow Q; \quad i = 0, \dots, N, \quad H^i: Q^{S_i} \rightarrow Q^{A_{i+1}}, \quad i = 0, \dots, N-1.$$

F2. Forward commutativity of operators.

$$(6') \quad V_{i,0}\{H^i L_{\mu_{0,i}}^i\} = H^i V_{i,0}\{L_{\mu_{0,i}}^i\}, \quad i = 0, \dots, N-1.$$

We then have

THEOREM 2.2. Define the functions $F^i: S_i \rightarrow Q$, $i = 0, \dots, N$ through the recursion:

$$(4a') \quad F^0(x) = V_0\{L_{\mu_0}^0(x)\}$$

and

$$(4b') \quad F^{i+1}(x) = \mathbf{V}_{i+1}\{H^i F^i(\mu_{i+1}(x))\}.$$

Then, under assumptions F1 and F2, F^i are cost-to-arrive functions, i.e., $F^i(x) = \mathbf{V}_{i,0}\{L_{\mu_{0,i}}^i(x)\}$.

If either pair of assumptions is satisfied for a particular problem, then the other one is trivially satisfied for the time-reversed problem. Hence, it is only meaningful to distinguish between the forward and backward versions with respect to the state evolution of the original problem. Rather than presenting only one of the versions and fitting every particular example by possibly reversing the stage indices, we choose to maintain always the original indices and present both the forward and the backward formulations. This is due both to the fact that some problems are solved by forward and backward recursions concurrently (§ 4), and because recursions which evolve in the direction of the system are of interest in some applications (e.g., Viterbi's forward dynamic programming algorithm for real-time decision problems [8]).

When this general framework is applied to specific operators H and \mathbf{V} , the verification of the commutativity property (5), or the stronger version (6), often requires an inductive proof which is common to most problems. Based on such an induction, the next result provides a sufficient condition for B2 (analogously for F2) that entails the verification of the commutativity of H with a single operator \mathbf{V} .

THEOREM 2.3. *Suppose that condition B1 is satisfied, and define the functions $L_{\mu_{i,j}}^{i,j}: S_i \rightarrow Q$, $\mu_{i,j} \in M_{i,j}$, $1 \leq i \leq j \leq N$ through the recursions:*

$$(7a) \quad L_{\mu_j}^{j,j}(x) = \mathbf{V}_{j+1,N}\{L_{\mu_{j,N}}^j(x)\}$$

and

$$(7b) \quad L_{\mu_{i-1,j}}^{i-1,j}(x) = H^i L_{\mu_{i,j}}^{i,j}(\mu_{i-1}(x)).$$

Suppose that, for $1 \leq i \leq j \leq N$, we have

$$(8) \quad \mathbf{V}_j\{H^i L_{\mu_{i,j}}^{i,j}\} = H^i \mathbf{V}_j\{L_{\mu_{i,j}}^{i,j}\}, \quad \text{for all } \mu_{i,j-1} \in M_{i,j-1}.$$

Then condition B2 is satisfied.

Proof. Since $L_{\mu_N}^{N,N} = L_{\mu_N}^N$, particularizing (8) for $i = j = N$ results in $\mathbf{V}_N\{H^N L_{\mu_N}^N\} = H^N \mathbf{V}_N\{L_{\mu_N}^N\}$ (condition B2 for $i = N$). Now fix k and suppose that (4) is satisfied for $k+1, \dots, N$. We will show that under condition (8), we have $\mathbf{V}_{k,N}\{H^k L_{\mu_{k,N}}^k\} = H^k \mathbf{V}_{k,N}\{L_{\mu_{k,N}}^k\}$. The proof will be divided in two stages:

(a) If $\mathbf{V}_{j,N}\{H^j L_{\mu_{j,N}}^j\} = H^j \mathbf{V}_{j,N}\{L_{\mu_{j,N}}^j\}$ and condition (8) holds, then $\mathbf{V}_j\{L_{\mu_{i,j}}^{i,j}\} = L_{\mu_{i,j-1}}^{i,j-1}$ for $1 \leq i < j$ and for all $\mu_{i,j-1} \in M_{i,j-1}$.

(b) If (8) holds and $\mathbf{V}_j\{L_{\mu_{k,j}}^{k,j}\} = L_{\mu_{k,j-1}}^{k,j-1}$ for $k < j \leq N$ and for all $\mu_{k,j-1} \in M_{k,j-1}$, then $\mathbf{V}_{k,N}\{H^k L_{\mu_{k,N}}^k\} = H^k \mathbf{V}_{k,N}\{L_{\mu_{k,N}}^k\}$.

Relationship (a) can be proved by induction: Let $i = j - 1$, then for all $x \in S_i$ and $\mu_i \in M_i$ we have

$$\begin{aligned} L_{\mu_i}^{i,i}(x) &= \mathbf{V}_{j,N}\{L_{\mu_{i,N}}^i(x)\} = \mathbf{V}_{j,N}\{H^j L_{\mu_{j,N}}^j(\mu_i(x))\} \\ &= H^j \mathbf{V}_{j,N}\{L_{\mu_{j,N}}^j\}(\mu_i(x)) = H^j \mathbf{V}_j\{L_{\mu_j}^{j,j}\}(\mu_i(x)) = \mathbf{V}_j\{H^j L_{\mu_j}^{j,j}(\mu_i(x))\} \\ &= \mathbf{V}_j\{L_{\mu_{i,j}}^{i,j}(x)\}, \end{aligned}$$

where the second through sixth equalities follow from (2), (4), (7a), (8), and (7b), respectively. Now suppose that $\mathbf{V}_j\{L_{\mu_{i+1,j}}^{i+1,j}\} = L_{\mu_{i+1,j-1}}^{i+1,j-1}$ for all $\mu_{i+1,j-1} \in M_{i+1,j-1}$ and $i < j - 1$, then, for all $x \in S_i$ and $\mu_i \in M_i$,

$$\begin{aligned} \mathbf{V}_j\{L_{\mu_i}^{i,j}(x)\} &= \mathbf{V}_j\{H^{i+1} L_{\mu_{i+1,j}}^{i+1,j}(\mu_i(x))\} \\ &= H^{i+1} \mathbf{V}_j\{L_{\mu_{i+1,j}}^{i+1,j}\}(\mu_i(x)) \\ &= H^{i+1} L_{\mu_{i+1,j-1}}^{i+1,j-1}(\mu_i(x)) = L_{\mu_{i,j-1}}^{i,j-1}(x), \end{aligned}$$

where the second equation follows from (8). In order to prove (b) it is enough to show that

$$(9) \quad \mathbf{V}_N\{H^k L_{\mu_{k,N}}^k\} = H^k \mathbf{V}_N\{L_{\mu_{k,N}}^k\} \quad \text{for all } \mu_{k,N-1} \in M_{k,N-1},$$

and

$$(10) \quad \mathbf{V}_j\{H^k \mathbf{V}_{j+1,N}\{L_{\mu_{k,N}}^k\}\} = H^k \mathbf{V}_{j,N}\{L_{\mu_{k,N}}^k\} \quad \text{for all } \mu_{k,j-1} \in M_{k,j-1} \text{ and } j = k, \dots, N.$$

Equation (9) follows directly from condition (8). To show (10), note that the assumption in (b) implies that

$$\mathbf{V}_{j+1,N}\{L_{\mu_{k,N}}^k\} = L_{\mu_{k,j}}^{k,j} \quad \text{for all } \mu_{k,j} \in M_{k,j}.$$

So, it suffices to show that

$$\mathbf{V}_j\{H^k L_{\mu_{k,j}}^{k,j}\} = H^k \mathbf{V}_{j,N}\{L_{\mu_{k,N}}^k\},$$

but this readily follows from (7) and (8). \square

Three main differences between the above framework and previous abstract dynamic programming models can be underlined, namely,

(i) Attention is not restricted to extremization operators: $\mathbf{V}_i\{q(\mu)\} = \inf_{\mu \in M} q(\mu)$ or $\sup_{\mu \in M} q(\mu)$. Although, of course, this is the most important case, it is both useful (as illustrated below by several applications) and interesting from a conceptual viewpoint to consider nonextremization operators. Note also that since we do not require the operators \mathbf{V}_i to coincide at each stage we can deal, for example, with extremization problems where inf and sup operators occur successively (e.g., dynamic two-person zero-sum games, where computational schemes based on dynamic programming principles are ubiquitous (cf. [9], [10])).

(ii) In the present model the generating operator of the objective recursive function maps functions of states into functions of actions (as in Dynkin and Yushkevich [11]), rather than into functions of states. In contrast to [11] the duality between states and actions is carried one step further by defining the admissible policies as mappings from the state space to the action space rather than to the underlying control space. The stochastic control formulation of [5], [12, Part I] is equivalent to the special case in which the action space is $A_i \subset S_i \times U_i$, where U_i is a control space and the admissible policies $\mu \in M_i$ are such that the image of each state belongs to its fiber, i.e.,

$$p_1(\mu(x)) = x \quad \text{for all } x \in S_i.$$

Besides its notational convenience, the versatility of the use of general action spaces and action-valued policy functions affords a nice parallelism (§ 3) between forward and backward problems.

(iii) In optimization problems, the commutativity conditions of the present model are weaker than the sufficient conditions imposed on the generating operator by previous models (typically, monotonicity and continuity). In addition, it appears that the strong commutativity condition of Theorem 2.3 (between \mathbf{V}_j and H^i , $i \leq j$) is not more difficult to check directly than previous conditions. Although it is natural to impose the monotonicity condition in order to satisfy commutativity with extremization operators, it is not necessary to do so. For example, consider the problem

$$(11) \quad \min_{x_{0,N} \in S_{0,N}} g_0(x_0, x_1) + [g_1(x_1, x_2) + [\dots + g_{N-1}^2(x_{N-1}, x_N)]^2 \dots]^2; \quad g_i(x_i, x_{i+1}) \in \mathbb{R}.$$

The generating operator $H^i L(x_{i-1}, x_i) = g_{i-1}(x_{i-1}, x_i) + L^2(x_i)$ is not monotone in the function of states, yet it satisfies the above commutativity conditions and, therefore, (11) admits a dynamic programming solution. In order to illustrate how previous conditions imply commutativity, consider the setting due to Bertsekas [5], [12, Part I], which encompasses previous abstract dynamic programming models with real-valued return functions. The finite-horizon assumptions in [12, Prop. 6.1] imply the following conditions:

C1. H^i is monotone and for every $\varepsilon > 0$, there exists $\mu^\varepsilon \in M_j$ such that

$$H^i L_{\mu_{i,j-1}\mu^\varepsilon}^{i,j} - H^i V_j \{L_{\mu_{i,j}}^{i,j}\} \leq \varepsilon.$$

C2. There exists a sequence of policies $\mu_j^k \in M_j$, $k = 0, 1, \dots$, such that

$$L_{\mu_{i,j-1}\mu_j^k}^{i,j} \downarrow \inf_{\mu_j \in M_j} L_{\mu_{i,j}}^{i,j} \quad \text{and} \quad H^i L_{\mu_{i,j-1}\mu_j^k}^{i,j} \downarrow H^i \inf_{\mu_j \in M_j} L_{\mu_{i,j}}^{i,j}.$$

Then, it is straightforward to show that (8) follows from either condition.

In stochastic control problems the key to the existence of μ^ε and $\{\mu_j^k\}$ with the above properties is the fact that the dependence of $L_{\mu_{i,j}}^{i,j}(x)$ on $\mu_{i,j}$ is only through $\mu_{i,j}(x)$. Therefore, for every $\delta > 0$ there exists a uniformly δ -optimum policy $\mu^\delta \in A_j^{S_j}$ (not necessarily in M_j) such that for all $x \in S_j$

$$(12) \quad L_{\mu^\delta}^{i,j}(x) \leq \begin{cases} V_j \{L_{\mu_j}^{i,j}(x)\} + \delta & \text{if } V_j \{L_{\mu_j}^{i,j}(x)\} > -\infty, \\ -1/\delta & \text{if } V_j \{L_{\mu_j}^{i,j}(x)\} = -\infty. \end{cases}$$

In particular cases such μ^δ can be shown to belong to M_j and mild restrictions on the cost-per-stages guarantee that C1 and C2 are satisfied. For example, consider a controlled Markov process problem with additive cost-per-stages:

$$H^i L(a) = g_{i-1}(a) + \int_{S_i} L(\omega) P_{i-1}(d\omega|a), \quad a \in A_{i-1},$$

$$L^{N+1}(x) = r(x), \quad x \in S_{N+1}.$$

If $A_i \subset S_i \times U_i$ and all admissible policies $\mu_i \in M_i$ satisfy $p_1(\mu_i(x)) = x$, for all $x \in S_i$, then it is easy to see that $L_{\mu_{0,N}}^0(x)$ is the expected value of the cost of using $\mu_{0,N} \in M_{0,N}$ when the initial state is $x \in S_0$. To show the existence of $\mu^\delta \in M_j$ satisfying (12), it is enough to assume that the state and control spaces are Borel; A_k , $k = 0, \dots, N$ are analytic sets; the costs-per-stage $g_k: A_k \rightarrow \mathbb{R}$, $k = 0, \dots, N$ and the terminal cost $r: S_{N+1} \rightarrow \mathbb{R}$ are lower semi-analytic; the transition functions are Borel measurable and $M_j = \{\mu \in A_j^{S_j} \text{ such that } p_1(\mu(x)) = x, x \in S_j \text{ and } \mu \text{ is universally measurable}\}$ (see [13], [12, Prop. 7.50]). Now, if $V_{j,N} \{L_{\mu_{j,N}}^j(x)\} > -\infty$ for all $x \in S_j$, then for every $\varepsilon > 0$ we can choose $\mu^\varepsilon \in M_j$ such that C1 is satisfied. On the other hand, if there exists $\mu_j \in M_j$ such that $H^i L_{\mu_{i,j}}^{i,j}(a) < +\infty$ for all $a \in A_{i-1}$, then using (12) we can select $\{\mu_j^k\}$ such that C2 is satisfied. Other stochastic control problems such as those with worst-case, rather than average, objective function and multiplicative nonnegative, rather than additive, costs-per-stage can be shown to satisfy commutativity via conditions C1-C2.

3. Application to classes of backward and forward problems. Once we have illustrated briefly the application of the backward dynamic programming framework and associated commutativity conditions to a class of stochastic control problems, in this section we show the application of the framework of § 2 to classes of backward and forward problems. Because of the causality relation among the state spaces, the utility of the forward formulation is restricted to open-loop problems. The main purpose of the first specific model to be presented (a deterministic optimum control problem) is

to illustrate the symmetry achievable between the backward and forward formulations thanks to the versatility of the action space and action-valued policies. In § 3.2 we present applications of nonextremization operators in a general algebraic setting which includes the conventional finite state-space dynamic programming models.

3.1. Additive-cost deterministic optimum control. It is easy to fit the problem of additive-cost optimum control of a deterministic system $x_{k+1} = f_k(x_k, u_k) \in S_{k+1}$, $u_k \in U_k$, $k = 0, \dots, N$ into the framework of § 2. It is noteworthy that the dynamic programming formulation presented here allows a duality between the forward and backward formulations that unlike previous works, [14], [15] which require the system to be codeterministic, does not impose any restrictions to define the forward dynamic programming recursion. For the backward formulation we make the following identifications:

$$A_i = S_i \times U_i,$$

$$H^i L(a) = g_{i-1}(a) + L(f_{i-1}(a))$$

and

$$M_i = \{\mu \in A_i^{S_i} \text{ such that } p_i(\mu(x)) = x \text{ for all } x \in S_i\}.$$

Note that there is a bijection between the set of admissible policies and the set of admissible controls. On defining L^i through the recursion (2)—with $L^{N+1} = 0$ —it is clear that

$$\inf_{\mu_{0,N} \in M_{0,N}} L_{\mu_{0,N}}^0(x) = \inf_{\substack{u_{0,N} \in U_{0,N} \\ \text{s.t.} \\ x_{k+1} = f_k(x_k, u_k); x_0 = x}} \sum_{k=0}^N g_k(x_k, u_k).$$

In the forward case we define

$$A_i = S_{i-1} \times U_{i-1},$$

$$H^i L(a) = g_i(a) + L(p_i(a))$$

and

$$M_i = \{\mu \in A_i^{S_i} \text{ such that } f_{i-1}(\mu(x)) = x \text{ for all } x \in S_i\}.$$

In this case, there is no one-to-one mapping between the set of admissible policies and the set of admissible controls (had we defined policies as mappings from states to controls, then here we would be able to define the forward recursion only for codeterministic systems); however, there is indeed a bijection between $M_{1,N+1} \times S_{N+1}$ and the subset of $S_0 \times U_{0,N} \times S_{N+1}$ that represents the trajectories of the system. Hence, if L^i is defined through (3')—with $L^0 = 0$ —then it can be checked that

$$\inf_{\mu_{1,N+1} \in M_{1,N+1}} L_{\mu_{1,N+1}}^{N+1}(x) = \inf_{\substack{x_0 \in S_0, u_{0,N} \in U_{0,N} \\ \text{s.t.} \\ x_{k+1} = f_k(x_k, u_k); x_{N+1} = x}} \sum_{k=0}^N g_k(x_k, u_k),$$

and in both cases the strong commutativity property of Theorem 2.3 is obviously satisfied.

3.2. Recursive computation of stage-separated functions. Consider an algebraic system $(Q, +, \cdot)$, where $(Q, +)$ is a commutative semigroup and the internal binary

operation \cdot is left-distributive with respect to additions. Suppose that $S_i, i = 0, \dots, N+1$ are finite sets, $g_i: S_i \times S_{i+1} \rightarrow Q$, and the goal is to compute

$$(13) \quad L_0(x) = \sum_{x_1 \in S_1} \cdots \sum_{x_{N+1} \in S_{N+1}} g_0(x, x_1) \cdot [g_1(x_1, x_2) \cdots [g_N(x_N, x_{N+1})] \cdots]$$

for every $x \in S_0$. Some examples of problems of this type are:

- (i) Shortest path in a layered network with $(\mathbb{R}, \min, +)$.
- (ii) Satisfiability of Boolean clauses with $(\{0, 1\}, \text{OR}, \text{AND})$.
- (iii) Computation of marginal probability distributions, with $(R^+, +, \cdot)$ (§ 4).
- (iv) Symbolic transfer function problems, with $(S, \cup, *)$, where S is the family of sets of finite-length strings of symbols drawn from a finite alphabet, and $*$ denotes string concatenation (see [16] for a generalization of the McNaughton–Yamada algorithm [17] for the computation of regular expressions given arbitrary state graphs).
- (v) Dynamic programming for optimization problems where the return space is only partially ordered. If (G, \geq, \circ) is a conditionally complete associative lattice [7], then the algebraic system $(2^A, \max, \circ)$ satisfies the above properties, where $\max(A, B)$ is the set of maximal elements of $A \cup B$ and \circ is only defined $(a \circ B = \{a \circ b, b \in B\})$ when the left operand is a singleton. Interestingly, the generalized version of the optimality principle given by Brown and Strauch [7] (see also [18]) is a special case of the commutativity condition B2.

The function in (13) can be computed by a backward dynamic programming recursion. Define

$$A_i = S_i \times S_{i+1},$$

$$\mathbf{V}_i\{q(\mu)\} = \sum_{\mu \in M} q(\mu),$$

$$H^i L(a) = g_{i-1}(a) \cdot L(p_2(a)),$$

$$M_i = \{\mu \in A_i^{S_i}, \text{ there exists } x^* \in S_{i+1} \text{ such that } \mu(x) = (x, x^*) \text{ for all } x \in S_i\}.$$

If the recursion (2) is used to define $L_{\mu_i, N}^i$, with $L_{\mu}^N(x) = g_N(\mu(x))$ then it is easy to see that $L_0(x) = \mathbf{V}_{0, N} L_{\mu_{0, N}}^0(x)$. The commutativity condition of Theorem 2.3 follows from the left-distributivity of \cdot with respect to $+$. Analogously, if we identify $A_i = S_{i-1} \times S_i$, $M_i = \{\mu \in A_i^{S_i}; \text{ there exists } x^* \in S_{i-1} \text{ such that } \mu(x) = (x^*, x) \text{ for all } x \in S_i\}$ and $H^i L(a) = L(p_1(a)) \cdot g_i(a)$, then recursion (3') can be used to define $L_{\mu_1, i}^i$, with $L_{\mu}^1(x) = g_0(\mu(x))$, and right-distributivity of \cdot with respect to $+$ implies that forward dynamic programming can be used to recursively compute

$$\sum_{x_0 \in S_0} \cdots \sum_{x_N \in S_N} [\cdots [g_0(x_0, x_1)] \cdot g_1(x_1, x_2)] \cdots] \cdot g_N(x_N, x)$$

for all $x \in S_{N+1}$.

Note that if $(Q, +)$ has an identity element 0 which is also an annihilator of \cdot , i.e., $q + 0 = q$, $q \cdot 0 = 0 \cdot q = 0$ for all $q \in Q$, then a special case of the above formulation is

$$\sum_{u_0 \in U_0} \cdots \sum_{u_N \in U_N} \lambda_0(x, u_0) \cdot [\lambda_1(x_1, u_1) \cdots [\lambda_N(x_N, u_N)] \cdots]$$

subject to $x_{k+1} = f_k(x_k, u_k)$, $x_0 = x$. To see this, let

$$T_i(x_i, x_{i+1}) = \{u_i \in U_i \text{ such that } f_i(x_i, u_i) = x_{i+1}\}$$

and

$$g_i(x_i, x_{i+1}) = \begin{cases} \sum_{u_i \in T_i(x_i, x_{i+1})} \lambda_i(x_i, u_i) & \text{if } T_i(x_i, x_{i+1}) \neq \phi, \\ 0 & \text{if } T_i(x_i, x_{i+1}) = \phi, \end{cases}$$

and use the associative and distributive properties of the algebraic system.

4. Backward-forward finite-horizon dynamic programming.

4.1. General setting and sufficient conditions. Given a collection of sets D_i , operators $V_i: Q^{d_i} \rightarrow Q$, $i = 1, \dots, N$ and a function $J: D_{1,N} \rightarrow Q$, suppose that the goal is to find $V_{1,i-1}\{V_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\}$ for all $d_i \in D_i$ and $i = 1, \dots, N$. Assume that these sets, operators and function J satisfy the following conditions:

BF1. There exists backward and forward decomposable functions (i.e., satisfying properties B1 and F1, respectively) $\{\tilde{L}_{\tilde{\mu}_0, N-1}^0: \tilde{S}_0 \rightarrow Q, \tilde{\mu}_0, N-1 \in \tilde{M}_{0, N-1}\}$, $\{\tilde{L}_{\tilde{\mu}_2, N+1}^{N+1}: \tilde{S}_{N+1} \rightarrow Q, \tilde{\mu}_2, N+1 \in \tilde{M}_{2, N+1}\}$, and mappings $\tilde{\psi}_i: D_i \rightarrow \tilde{M}_{i-1}$, $\tilde{\psi}_i: D_i \rightarrow \tilde{M}_{i+1}$, $i = 1, \dots, N$, such that

$$(14) \quad J(d_1, \dots, d_i, \dots, d_N) = \tilde{L}_{\tilde{\psi}_1, N(d_{1,N})}^0(x_0) = \tilde{L}_{\tilde{\psi}_1, N}^{N+1}(d_{1,N})(x_{N+1})$$

for all $x_0 \in \tilde{S}_0$ and $x_{N+1} \in \tilde{S}_{N+1}$.

BF2. Denote by $\tilde{\Psi}_i: Q^{\tilde{M}_{i-1}} \rightarrow Q^{D_i}$ the mapping induced by $\tilde{\psi}_i$, i.e., $\tilde{\Psi}_i(f) = f \circ \tilde{\psi}_i$ (e.g., [19]). The operators $V_i \circ \tilde{\Psi}_i = \tilde{V}_{i-1}: Q^{\tilde{M}_{i-1}} \rightarrow Q$, $i = 1, \dots, N$, and \tilde{H} , the generating operator of the backward function in BF1 satisfy the strong commutativity condition (8). (Analogously, with $\tilde{V}_{i+1} = V_i \circ \tilde{\Psi}_i$, $\tilde{\Psi}_i: Q^{\tilde{M}_{i+1}} \rightarrow Q^{D_i}$ induced by $\tilde{\psi}_i$.)

Fix an index $1 \leq i \leq N$ and an element $d_i \in D_i$. Because of assumptions BF1 and BF2 we can solve $V_{1,i-1}\{V_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\}$ by either a backward or a forward dynamic programming iteration. However, a separate iteration has to be carried for each index and each element of D_i . If the operators V_i commute, then a backward-forward solution where $V_{1,i-1}\{V_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\}$ is solved simultaneously for all elements and stages is given by the following result.

THEOREM 4.1. *Suppose that conditions BF1 and BF2 are satisfied and that $V_i V_j = V_j V_i$, $1 \leq i < j \leq N$. Define the functions:*

$$B^{i-1}(x) = \tilde{V}_{i-1}\{\tilde{H}^i B^i(\tilde{\mu}_{i-1}(x))\}, \quad B^N(x) = \text{constant},$$

$$F^{i+1}(x) = \tilde{V}_{i+1}\{\tilde{H}^i F^i(\tilde{\mu}_{i+1}(x))\}, \quad F^1(x) = \text{constant}.$$

Then there exist functions $W_i: Q^{\tilde{S}_i} \times D_i \times Q^{\tilde{S}_i}$, $i = 1, \dots, N$ such that

$$(15) \quad V_{1,i-1}\{V_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\} = W_i(F^i, d_i, B^i), \quad d_i \in D_i, i = 1, \dots, N.$$

Proof. The quantity $V_{1,i-1}\{V_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\}$ is a function of $D_{1,i-1}$, d_i , and $D_{i+1,N}$. Theorem 4.1 will follow by showing that the dependence of $V_{1,i-1}\{V_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\}$ on $D_{1,i-1}$ is only through F^i , ($i = 2, \dots, N$), and the dependence on $D_{i+1,N}$ is only through B^i , ($i = 1, \dots, N-1$).

Fix a stage $1 \leq i \leq N$ and an element $d_i \in D_i$. Property BF1 states that for all $x_0 \in \tilde{S}_0$ we have

$$(16) \quad \begin{aligned} & V_{1,i-1}\{V_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\} \\ &= V_{1,i-1}\{\tilde{V}_{i,N-1}\{\tilde{L}_{\tilde{\psi}_1, i-1(d_{1,i-1})\tilde{\psi}_i(d_i)\tilde{\mu}_{i,N-1}}^0(x_0)\}\}. \end{aligned}$$

Now, it will be shown that for any $\tilde{\mu}_{0,i-1} \in \tilde{M}_{0,i-1}$, $\tilde{V}_{i,N-1}\{\tilde{L}_{\tilde{\mu}_{0,N-1}}^0(x_0)\}$ depends on $\tilde{M}_{i,N-1}$ only through B^i , and hence the same is true for the right-hand side of (16). Using the

notation introduced in Theorem 2.3, we have (note that here the horizon for the backward problem is $N-1$)

$$\tilde{L}_{\mu_{0,N-1}}^0(x_0) = \tilde{L}_{\mu_{0,N-1}}^{0,N-1}(x_0).$$

Furthermore, the result in part (a) of the proof of Theorem 2.3 (the conditions for its validity are guaranteed by properties BF1 and BF2) implies that

$$(17) \quad \tilde{\mathbf{V}}_{i,N-1}\{\tilde{L}_{\mu_{0,N-1}}^{0,N-1}\} = \tilde{\mathbf{V}}_{i,N-2}\{\tilde{L}_{\mu_{0,N-2}}^{0,N-2}\} = \cdots = \tilde{L}_{\mu_{0,i-1}}^{0,i-1}.$$

But according to (7b), the right-hand side of (17) depends on $\tilde{M}_{i,N-1}$ only through the function $\tilde{L}_{\mu_{i-1}}^{i-1,i-1}$ which because of (7a) can be written as

$$\begin{aligned} \tilde{L}_{\mu_{i-1}}^{i-1,i-1}(x) &= \tilde{\mathbf{V}}_{i,N-1}\{\tilde{L}_{\mu_{i-1,N-1}}^{i-1}(x)\} \\ &= \tilde{\mathbf{V}}_{i,N-1}\{\tilde{H}^i \tilde{L}_{\mu_{i,N-1}}^i(\tilde{\mu}_{i-1}(x))\} \\ &= \tilde{H}^i \tilde{\mathbf{V}}_{i,N-1}\{\tilde{L}_{\mu_{i,N-1}}^i\}(\tilde{\mu}_{i-1}(x)) \\ &= \tilde{H}^i B^i(\tilde{\mu}_{i-1}(x)) \end{aligned}$$

where the second equation follows from (2), and the third and fourth equations follow from property B2 (which is satisfied because of the strong commutativity condition (8)) and the corollary to Theorem 2.1, respectively.

Using the fact that $\mathbf{V}_i \mathbf{V}_j = \mathbf{V}_j \mathbf{V}_i$, we can write

$$\mathbf{V}_{1,i-1}\{\mathbf{V}_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\} = \mathbf{V}_{i+1,N}\{\mathbf{V}_{1,i-1}\{J(d_1, \dots, d_i, \dots, d_N)\}\}$$

and an entirely analogous reasoning shows that the dependence of $\mathbf{V}_{1,i-1}\{\mathbf{V}_{i+1,N}\{J(d_1, \dots, d_i, \dots, d_N)\}\}$ on $D_{1,i-1}$ is through the cost-to-arrive function F^i . \square

From the above proof it is easy to check that the conditions of Theorem 4.1 guarantee the validity of a backward-forward recursion for problems where several consecutive intermediate elements are fixed, i.e., (15) can be generalized to

$$(18) \quad \mathbf{V}_{1,i-1}\{\mathbf{V}_{j+1,N}\{J(d_1, \dots, d_i, \dots, d_j, \dots, d_N)\}\} = W_{i,j}(F^i, d_{i,j}, B^j), \quad d_{i,j} \in D_{i,j}.$$

Perhaps the simplest example of the backward-forward model is the problem mentioned in the introduction: given a layered network, find for each arc in the network the shortest path from source to destination that contains that arc. The straightforward approach is to run a forward or backward iteration for each arc (deleting all other arcs in the same layer); however, even if we take advantage of the obvious commonality of some of the computations, the number of steps required by this approach is quadratic in the number of layers. In contrast, if the result of Theorem 4.1 is employed (note that the minimization operators commute), then the solution to the shortest path problem requires only two independent (one forward and one backward) dynamic programming recursions, which simply compute the distance of each node from the source and to the destination. Once the cost-to-arrive and cost-to-go are computed for all nodes in the network, the solution is given by $W_{i,i+1}(F^i, d_{i,i+1}, B^{i+1})$ which is simply the sum of the length of each arc and the distances of its head and tail to the destination and from the source, respectively. The next subsection illustrates the application of the backward-forward dynamic programming setting to the problem of finding the sequence of joint distributions of consecutive states of a discrete-time Markov process, and to the problems of fixed-interval detection and smoothing.

4.2. Applications. Consider a Markov process $\{\mathbf{X}_t: (\Omega, \mathcal{F}) \rightarrow (\Omega_t, \mathcal{F}_t), t = 0, \dots, N\}$ whose finite-dimensional distributions are determined by P_0 , an arbitrary

initial probability measure on (Ω_0, F_0) , and by the transition functions P_i , $i = 1, \dots, N$ such that $P_i(x, \cdot)$ is a probability measure on (Ω_i, F_i) , for each $x \in \Omega_{i-1}$ and $P_i(\cdot, B)$ is measurable for each $B \in F_i$. Suppose that the objective is to obtain the sequence of joint distributions of consecutive states, namely,

$$(19) \quad P[X_k \in B_k, X_{k+1} \in B_{k+1}] = \int_{\Omega_{0,k-1} \times B_{k,k+1} \times \Omega_{k+2,N}} \cdots \int P_0(d\omega_0) \prod_{i=1}^N P_i(\omega_{i-1}, d\omega_i).$$

In order to put this problem in the backward-forward framework, let $D_i = \Omega_i \times F_i$, $\mathbf{V}_i\{q(d_i)\} = \int_{\Omega_i} f(\omega) \nu(d\omega)$ for $q(\omega, B) = f(\omega) \nu(B)$, and select $d_k = (x_k, C_k) \in D_k$ and $d_{k+1} = (x_{k+1}, C_{k+1}) \in D_{k+1}$. We make the following identifications for the state, action, policies and generating operators of the backward and forward formulations:

$$\begin{aligned} \tilde{S}_i &= \Omega_i, & \tilde{A}_i &= \Omega_i \times D_{i+1}, \\ \tilde{S}_i &= F_i, & \tilde{A}_i &= D_{i-1} \times \Omega_i, \end{aligned}$$

$$\tilde{H}^j L(a) = P_j(p_1(a), p_3(a)) L(p_2(a)), \quad \tilde{H}^j L(a) = P_{j+1}(p_1(a), p_3(a)) L(p_2(a)).$$

$$\begin{aligned} \tilde{M}_i &= \{\mu \in \tilde{A}_i^{\tilde{S}_i}, \text{ there exists } (\omega, B) \in \Omega_{i+1} \times F_{i+1} \\ &\quad \text{such that } \mu(x) = (x, \omega, B) \text{ for all } x \in \tilde{S}_i\}, \end{aligned}$$

$$\begin{aligned} \tilde{M}_i &= \{\mu \in \tilde{A}_i^{\tilde{S}_i}, \text{ there exists } (\omega, B) \in \Omega_{i-1} \times F_{i-1} \\ &\quad \text{such that } \mu(E) = (\omega, B, E), \text{ for all } E \in \tilde{S}_i\}. \end{aligned}$$

Note that the cost-to-arrive function is now a probability measure and that there is a one-to-one correspondence between D_i and \tilde{M}_{i-1} and between D_i and \tilde{M}_{i+1} . The commutativity conditions follow in this case from the linearity of the integral, and the problem can be solved by either a forward or a backward recursion with respective value functions:

$$F^{i+1}(E) = \int_{\Omega_i} P_{i+1}^G(\omega, E) F^i(d\omega), \quad F^0(E) = P_0^G(E)$$

and

$$B^{i-1}(x) = \int_{\Omega_i} P_i^G(x, d\omega) B^i(\omega), \quad B^{N+1} = 1.$$

Moreover, because of Fubini's theorem, a backward-forward solution given by (18) with $j = i + 1$ is also possible:

$$\mathbf{V}_{0,k-1}\{\mathbf{V}_{k+2,N}\{J(d_0, \dots, d_k, d_{k+1}, \dots, d_N)\}\} = F^k(C_k) P_{k+1}(x_k, C_{k+1}) B^{k+1}(x_{k+1}),$$

so the sought-after relationship is

$$(20) \quad P[X_k \in B_k, X_{k+1} \in B_{k+1}] = \int_{B_k} F^k(dx_k) \int_{B_{k+1}} P_{k+1}(x_k, dx_{k+1}) B^{k+1}(x_{k+1}).$$

Next we examine another application of the backward-forward finite horizon model with nonextremization operators, namely, the problem of fixed-interval minimum probability-of-error detection. Let (Ω, F, P) be a probability space and let $G \subset F$ be the sub- σ -algebra generated by the observation of an F -measurable transformation of a sequence of transmitted symbols $\{u_t \in U_t, t = 0, \dots, N\}$ where U_t , $t = 0, \dots, N$ are finite sets. Optimum decisions based on the a posteriori distribution $P^G[u_0, \dots, u_N]$

can be made according to various optimality criteria; for example, the receiver may select the sequence in $U_{0,N}$ that maximizes $P^G[u_0, \dots, u_N]$ (maximum likelihood sequence detection), or the sequence of arguments that maximizes the marginals $P^G[u_i]$, $i = 0, \dots, N$ (minimum error probability detection). In data-transmission problems such as asynchronous multiuser problems, transmission of convolutionally encoded data and intersymbol interference problems, the a posteriori distribution can be decomposed in product form:

$$P^G[u_0, \dots, u_N] = \prod_{k=0}^N \lambda_k(x_k, u_k) \quad \text{where } x_{k+1} = f_k(x_k, u_k) \text{ and } x_0 \text{ is } G\text{-measurable.}$$

The maximization of the joint distribution (maximum likelihood sequence detection) is a deterministic optimum control problem which fits into the framework presented in § 3.2, and hence can be solved by either a backward or a forward recursion (in real-time applications, the latter is employed in a near-optimum version where decisions are made after a fixed lag—the Viterbi algorithm [8]). If, instead, the optimality criterion is minimum probability-of-error, then the central task of the detector is to compute the marginal a posteriori distribution of each transmitted symbol, i.e.,

$$(21) \quad P^G[u_i] = \sum_{u_{0,i-1} \in U_{0,i-1}} \sum_{u_{i+1,N} \in U_{i+1,N}} \prod_{k=0}^N \lambda_k(x_k, u_k), \quad i = 0, \dots, N.$$

This problem fits also in the framework of § 3.3 and can be solved also by backward or forward dynamic programming. The forward recursion is simplified by noting that in the foregoing data-transmission problems the following condition holds:

S1. For $k = 0, \dots, N$, if there exists $x \in \Omega_k$, $u \in U_k$ and $u' \in U_k$ such that $f_k(x, u) = f_k(x, u')$ then $u = u'$.

Then the corresponding value functions are as follows:

$$(22) \quad F^{k+1}(x) = \sum_{\substack{x_k \in \Omega_k \\ \text{s.t. there exists} \\ u \in U_k, f_k(x_k, u) = x}} F^k(x_k) \lambda_k(x_k, u),$$

and

$$(23) \quad B^k(x) = \sum_{u_k \in U_k} B^{k+1}(f_k(x, u_k)) \lambda_k(x, u_k).$$

In the problem of intersymbol interference a forward dynamic programming solution to the problem of computing the marginal distributions has been reported by Hayes, Cover and Riera [20]. The main shortcoming of this algorithm is that it requires a separate recursion for each value of each transmitted symbol. A more efficient solution is possible by realizing that (21) fits the backward-forward framework of this section, because it can be solved by either backward or forward recursions and its operators (summations) commute. It is easy to check that in this case (15) takes the form

$$(24) \quad \begin{aligned} P^G[u_i] &= \sum_{u_{0,i-1} \in U_{0,i-1}} \sum_{u_{i+1,N} \in U_{i+1,N}} \prod_{k=0}^N \lambda_k(x_k, u_k) \\ &= \sum_{\substack{(x_i, x_{i+1}) \in \Omega_i \times \Omega_{i+1} \\ \text{s.t.} \\ x_{i+1} = f_i(x_i, u_i)}} F^i(x_i) \lambda_i(x_i, u_i) B^{i+1}(x_{i+1}) \end{aligned}$$

which further reduces to

$$(25) \quad P^G[u_i] = \sum_{\substack{x_{i+1} \in \Omega_{i+1} \\ \text{s.t. there exists} \\ x \in \Omega_i, x_{i+1} = f_i(x, u_i)}} F^{i+1}(x_{i+1}) B^{i+1}(x_{i+1})$$

if the following condition is satisfied (e.g., frequently $f_k(\cdot, \cdot)$, $k=0, \dots, N$ is a shift register system).

S2. For $k=0, \dots, N$, if there exists $x \in \Omega_k$, $x' \in \Omega_k$, $u \in U_k$ and $u' \in U_k$ such that $f_k(x, u) = f_k(x', u')$ then $u = u'$.

Thus, as in the problem of finding the shortest path through every arc, the backward-forward solution of the fixed-interval minimum probability-of-error detection problem exhibits linear complexity in the number of transmitted symbols in contrast to the quadratic complexity of the Hayer-Cover-Riera algorithm [20].

Another illustration of the applicability of the backward-forward framework is the problem of fixed-interval maximum a posteriori sequence smoothing of a discrete-time Markov process, i.e., find

$$\arg \max_{x_0 \in \Omega_0} \cdots \max_{x_N \in \Omega_N} p(x_0, \dots, x_N | y_0, \dots, y_N)$$

assuming that conditional probability density functions exist and that $p[y_0, \dots, y_N | x_0, \dots, x_N] = \prod_{k=0}^N p_k(y_k | x_k)$. If $p_k(x_k)$ and $q_k(x_k | x_{k-1})$ denote the unconditional density and the transition density of the Markov process respectively, then we have

$$\begin{aligned} & \arg \max_{x_0 \in \Omega_0} \cdots \max_{x_N \in \Omega_N} p(x_0, \dots, x_N | y_0, \dots, y_N) \\ (26) \quad & = \arg \max_{x_0 \in \Omega_0} \cdots \max_{x_N \in \Omega_N} p_0(x_0) \prod_{k=1}^N q_k(x_k | x_{k-1}) \prod_{k=0}^N p_k(y_k | x_k). \end{aligned}$$

Identifying $\vec{S}_k = \Omega_k = \vec{S}_k$, $\vec{A}_k = \Omega_{k-1} \times \Omega_k = \vec{A}_{k-1}$ and $\vec{M}_k = \{\mu: \text{there exists } x^* \in \vec{S}_{k-1}, \mu(x) = (x^*, x)\}$ and $\vec{M}_k = \{\mu: \text{there exists } x^* \in \vec{S}_{k+1}, \mu(x) = (x, x^*)\}$, we define the recursions:

$$\begin{aligned} & F_0(x_0) = p_0(x_0)p_0(y_0 | x_0), \\ (27) \quad & F_{i+1}(x_{i+1}) = p_{i+1}(y_{i+1} | x_{i+1}) \max_{x_i \in \Omega_i} q_{i+1}(x_{i+1} | x_i) F_i(x_i), \quad i=0, \dots, N-1 \end{aligned}$$

and

$$\begin{aligned} & B_N = 1, \\ (28) \quad & B_{i-1}(x_{i-1}) = \max_{x_i \in \Omega_i} q_i(x_i | x_{i-1}) p_i(y_i | x_i) B_i(x_i), \quad i=1, \dots, N. \end{aligned}$$

Then, the optimization in (26) can be carried out by either a backward or a forward recursion because

$$\begin{aligned} & \max_{x_0 \in \Omega_0} \cdots \max_{x_N \in \Omega_N} p_0(x_0) \prod_{k=1}^N q_k(x_k | x_{k-1}) \prod_{k=0}^N p_k(y_k | x_k) \\ (29) \quad & = \max_{x_N \in \Omega_N} F_N(x_N) = \max_{x_0 \in \Omega_0} p_0(x_0) p_0(y_0 | x_0) B_0(x_0). \end{aligned}$$

Once the optimum terminal state is obtained through (29), the maximizing arguments in (26) can be recovered by backtracking the optimum transitions resulting from the forward or backward recursion. The alternative to this method is the backward-forward recursion, in which one computes both the cost-to-arrive and the cost-to-go through (27) and (28), respectively, and then solves for (cf. Theorem 4.1)

$$\begin{aligned} & \arg \max_{x_i \in S_i} [\max_{x_0 \in S_0} \cdots \max_{x_{i-1} \in S_{i-1}} \max_{x_{i+1} \in S_{i+1}} \cdots \max_{x_N \in S_N} p(x_0, \dots, x_N | y_0, \dots, y_N)] \\ (30) \quad & = \arg \max_{x_i \in S_i} F_i(x_i) B_i(x_i), \quad i=0, \dots, N. \end{aligned}$$

Notice that³

$$(31) \quad F_i(x_i) = K \max_{x_0 \in S_0} \cdots \max_{x_{i-1} \in S_{i-1}} p[x_0, \cdots, x_i | y_0, \cdots, y_i]$$

and

$$(32) \quad B_i(x_i)p_i(x_i) = K \max_{x_{i+1} \in S_{i+1}} \cdots \max_{x_N \in S_N} p[x_i, \cdots, x_N | y_{i+1}, \cdots, y_N],$$

so in some cases the maximizations in the recursions (27) and (28) admit closed-form solutions. For example, in the case of a finite-dimensional linear Gaussian system (where a fixed-interval smoother in terms of the estimates produced by two filters running backwards and forwards, respectively, is well known [21], [22]), the states are (conditionally) jointly Gaussian and unnormalized marginal distributions can be obtained by maximizing with respect to the unwanted variables; hence

$$(33) \quad \begin{aligned} F_i(x_i) &= Kp(x_i | y_0, \cdots, y_i) \\ &= K \exp(-\tfrac{1}{2}\|x_i - \tilde{x}_{i/i}\|_{\tilde{\Sigma}_{i/i}}^2), \end{aligned}$$

$$(34) \quad \begin{aligned} B_i(x_i)p_i(x_i) &= Kp(x_i | y_{i+1}, \cdots, y_N) \\ &= K \exp(-\tfrac{1}{2}\|x_i - \tilde{x}_{i/i+1}\|_{\tilde{\Sigma}_{i/i+1}}^2) \end{aligned}$$

and

$$(35) \quad p_i(x_i) = K \exp(-\tfrac{1}{2}\|x_i - \bar{x}_i\|_{\Sigma_i}^2),$$

where $\tilde{x}_{i/i}$ and $\tilde{\Sigma}_{i/i}$ are the estimate and covariance of a (forward) Kalman filter, $\tilde{x}_{i/i+1}$ and $\tilde{\Sigma}_{i/i+1}$ coincide with the estimate and covariance of a Kalman filter for a derived linear-Gaussian system running backwards, [22], and \bar{x}_i and Σ_i are the unconditional mean and covariance of x_i . Substituting equations (33)–(35) in (30), the sequence of smoothed estimates is given by (cf. [21], [22])

$$(36) \quad \arg \max_{x_i \in R^i} F_i(x_i)B_i(x_i) = [\tilde{\Sigma}_{i/i}^{-1} + \tilde{\Sigma}_{i/i+1}^{-1} - \Sigma_i^{-1}]^{-1}[\tilde{\Sigma}_{i/i}^{-1} \tilde{x}_{i/i} + \tilde{\Sigma}_{i/i+1}^{-1} \tilde{x}_{i/i+1} - \Sigma_i^{-1} \bar{x}_i],$$

$i = 0, \cdots, N.$

5. A glimpse at infinite-horizon models. The finite-horizon commutativity conditions of § 2 are not sufficient to ensure the validity of the dynamic programming recursion in infinite-horizon operator models. In this section we address this problem in the general nonstationary case for backward models. Forward counterparts of all results can be obtained following the approach of § 2. Furthermore, the fixed-point property of the sought-after function of states is studied in the stationary case.

Suppose that sequences of operators $\{V_i: Q^{M_i} \rightarrow Q, i = 0, 1, \cdots\}$, $\{H^i: Q^{S_i} \rightarrow Q^{A_{i-1}}, i = 1, 2, \cdots\}$ and a sequence of functions of states $\{J^i: S_i \rightarrow Q, i = 1, 2, \cdots\}$ are given. Define $L_{\mu_{i,k}}^{i,k}$ $0 \leq i \leq k$ via (7b) and $L_{\mu_k}^{k,k}(x) = H^{k+1}J^{k+1}(\mu_k(x))$. The first goal is to impose conditions to guarantee that the function $V_{0,\infty}\{\lim_{N \rightarrow \infty} L_{\mu_{0,N}}^{0,N}\}: S_0 \rightarrow Q$ can be obtained via a (backward) infinite-horizon dynamic programming recursion, or more generally that $\lim_{N \rightarrow \infty} T_{i,N}J^{N+1}$ is a cost-to-go function, i.e.,

$$(37) \quad V_{i,\infty}\{\lim_{N \rightarrow \infty} L_{\mu_{i,N}}^{i,N}\} = \lim_{N \rightarrow \infty} T_{i,N}J^{N+1}, \quad i = 0, 1, \cdots$$

where the operator $T_i: Q^{S_{i+1}} \rightarrow Q^{S_i}$ is defined by

$$(38) \quad T_i L(x) = V_i\{H^{i+1}L(\mu_i(x))\}.$$

³ K denotes a generic state-independent term which need not coincide in different equations.

It can be shown that (37) holds if the commutativity condition B2 is fulfilled for $L^{i,N}$, $i \leq N = 1, 2, \dots$ (i.e. commutativity holds for finite-horizons) and the following condition is satisfied.

B3. $\lim_{N \rightarrow \infty} V_{i,N}\{L_{\mu_{i,N}}^{i,N}(x)\}$ and $V_{i,\infty}\{\lim_{N \rightarrow \infty} L_{\mu_{i,N}}^{i,N}(x)\}$ exist and are equal for all $x \in S_i$ and $i = 0, 1, \dots$.

As illustrated by the following example, the equality of the functions in B3 is nontrivial. Consider the algebraic system (see § 3.2) $(Q, +, \cdot) = (\{0, 1\}, \text{OR}, \text{AND})$, let $S_i = \{0, 1, \dots\}$ and

$$g_i(j, k) = \begin{cases} 1 & \text{if } k \neq 0 \text{ and } j = 0 \text{ or } k + 1, \\ 0 & \text{otherwise.} \end{cases}$$

In this case any infinite sequence of states $\{\bar{x}_i\}$ results in $\prod_{i=0}^{\infty} g_i(\bar{x}_i, \bar{x}_{i+1}) = 0$; however if $k > N$ then $g_0(0, k) \cdot g_1(k, k-1) \cdot \dots \cdot g_N(k-N+1, k-N) = 1$. Therefore we have that $V_{i,\infty}\{\lim_N L_{\mu_{i,N}}^{i,N}(j)\} = 0$ for $j = 0, 1, \dots$, while $\lim_N V_{i,N}\{L_{\mu_{i,N}}^{i,N}(0)\} = 1$.

The second question of interest in connection with infinite-horizon models is whether the sought-after function $V_{i,\infty}\{\lim_{N \rightarrow \infty} L_{\mu_{i,N}}^{i,N}\}$ is a fixed point of T in stationary problems (i.e., S_i, A_i, H^i, V_i, J^i do not depend on the stage-index). If (18) holds this is obviously the case, because in the stationary case if $V_{i,\infty}\{\lim_{N \rightarrow \infty} L_{\mu_{i,N}}^{i,N}\}$ exists then it does not depend on the stage-index. Nevertheless, even if B2 or B3 fail to be true for a particular problem the following condition is sufficient for $V_{i,\infty}\{\lim_{N \rightarrow \infty} L_{\mu_{i,N}}^{i,N}\}$ to be a fixed point of T in the stationary case.

B4. $HV_{i,\infty}\{\lim_{N \rightarrow \infty} L_{\mu_{i,N}}^{i,N}\}(a)$ and $V_{i,\infty}\{\lim_{N \rightarrow \infty} HL_{M_{i,N}}^{i,N}(a)\}$ exist and coincide for all $a \in A$.

(Note that the above counterexample to B3 satisfies B4.) It can be checked that the contraction assumptions of Denardo [2] and the continuity, uniform growth and linearity conditions of Bertsekas [5] along with the monotonicity of H imply that B3 and B4 are satisfied in stationary infimization problems. In connection with these problems, another question of interest is the existence of (ε) optimal stationary policies; obviously this problem has no counterpart in our formulation with more general operators V .

OPTIMAL CONTROL OF LINEAR SYSTEMS WITH ALMOST PERIODIC INPUTS*

G. DA PRATO† AND A. ICHIKAWA‡

Abstract. In this paper we consider linear time-invariant and periodic systems with periodic forcing terms. We propose new quadratic control problems, both deterministic and stochastic. We also consider stochastic control with partial observation and show that the separation principle holds. Our mathematical models cover both finite and infinite dimensional systems.

Key words. optimal control, filtering, linear periodic systems

1. Introduction. Recently much effort has been devoted to the study of periodic systems and periodic optimization problems [6], [10], [11], [16], [22], [25], [27]. An obvious reason for this is that there are many periodic systems in nature [16], [25], [27]. But another important aspect is that periodic controls are easy to implement compared with general time-varying controls and that they sometimes even produce better performances. In [10] one of the authors has considered the quadratic control problem for a periodic system in infinite dimension and shows that under some stabilizability condition the optimal control is given by a feedback control which involves the periodic solution of a Riccati equation. We have then considered similar problems for stochastic differential equations [12]. We have shown that under partial observation the separation principle holds.

Periodic functions are easy to handle, but they lack some important properties. As we can see from simple examples [15], [16], sums of periodic functions are not periodic in general but almost periodic. Almost periodic functions are generalizations of periodic functions in some sense and were introduced by H. Bohr in 1920s. Since then almost periodic functions and differential equations related to them have been extensively studied [1], [15], [16]. It is known that almost periodic functions naturally appear in many physical systems for example in celestial mechanics or in stable electronic circuits [15], [16], [27]. So it is important to study systems with almost periodic functions.

In this paper we consider linear infinite dimensional time-invariant and periodic systems with almost periodic forcing terms. We consider both deterministic and stochastic cases and propose new quadratic control problems which are natural for almost periodic functions. With slightly different formulation, we also consider stochastic control with partial observation. We shall show that the separation principle holds.

2. The semigroup model. In this section we consider linear systems described by a strongly continuous semigroup and solve quadratic control problems.

2.1. Almost periodic solutions of a differential equation. Let Y be a real separable Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and norm $|\cdot|$. Let $f(t)$, $t \in \mathbb{R}$ be a continuous function in Y . It is said to be almost periodic if from every sequence a_n we can extract a subsequence a'_n such that $\lim_{n \rightarrow \infty} f(t + a'_n)$ exists uniformly on the real line \mathbb{R} . We

denote by $AP(Y)$ the Banach space of all continuous almost periodic functions in Y with sup norm. Periodic functions are almost periodic but the converse is not true; see for example $\cos t + \cos \sqrt{2}t$. Note that almost periodic functions are bounded. It is also easy to see that $AP(\mathbb{R})$ (scalar functions) forms an algebra. Let $f, g \in AP(Y)$. Then the mean value $\lim_{T \rightarrow \infty} 1/T \int_0^T |f(t)|^2 dt$ exists. Thus $\lim_{T \rightarrow \infty} 1/T \int_0^T \langle f(t), g(t) \rangle dt$ defines an inner product on $AP(Y)$ which we denote by $\langle f, g \rangle_{ap}$. The corresponding norm is denoted by $\|\cdot\|_{ap}$. Let $L_{ap}^2(Y)$ be the completion of $AP(Y)$ with respect to this inner product. See for details of almost periodic functions [1], [15], [16].

Now we consider the differential equation

$$(2.1) \quad y' = Ay + f,$$

where A is the infinitesimal generator of a strongly continuous semigroup e^{tA} on Y [8], [23], [26] and $f \in AP(Y)$. If $Y = \mathbb{R}^n$ and $A \in \mathbb{R}^{n \times n}$, then e^{tA} is the usual matrix exponential function. If A is stable i.e., e^{tA} is exponentially stable, then

$$(2.2) \quad y(t) = \int_{-\infty}^t e^{(t-s)A} f(s) ds$$

is well defined and is almost periodic. In fact, let a_n be an arbitrary sequence. Then

$$\begin{aligned} y(t + a_n) &= \int_{-\infty}^{t+a_n} e^{(t+a_n-s)A} f(s) ds \\ &= \int_{-\infty}^t e^{(t-\tau)A} f(\tau + a_n) d\tau. \end{aligned}$$

Now we can easily obtain the uniform convergence of a subsequence of $y(t + a_n)$ since f is almost periodic. In general it does not satisfy (2.1) but we can find a sequence $f_n \in AP(Y)$ such that $f_n \rightarrow f$ in $AP(Y)$ and

$$y_n(t) = \int_{-\infty}^t e^{(t-s)A} f_n(s) ds$$

is the solution of (3.1) with $f = f_n$ converging to y in $AP(Y)$.

A continuous function y on \mathbb{R} is called a mild solution of (2.1) if

$$y(t) = e^{(t-s)A} y(s) + \int_s^t e^{(t-r)A} f(r) dr$$

for any $t \geq s$. Then $y(t)$ given by (2.2) is a unique mild solution of (2.1) in $AP(Y)$. In fact if z is another solution, then $z(t) - y(t) = e^{(t-s)A} [z(s) - y(s)]$. Letting $s \rightarrow -\infty$ and noting that z, y are bounded, we obtain $z(t) - y(t) = 0$ for any t . A more general condition for the existence of an almost periodic mild solution to (2.1) is that e^{tA} satisfies an exponential dichotomy [15], [16] i.e., there exists a projection operator Π such that

(i) $Y_1 \triangleq \Pi Y \subset D(A)$ and $A_1 \triangleq A\Pi$ is a bounded operator on Y_1 with

$$\|e^{-tA_1}\| \leq M_1 e^{-a_1 t}, \quad t \geq 0 \quad \text{for some } M_1 > 0, \quad a_1 > 0.$$

(ii) $A: D(A) \cap Y_2 \rightarrow Y_2$, where $Y_2 = (I - \Pi)Y$ and $A_2 \triangleq A(I - \Pi)$ generates an exponentially stable semigroup on Y_2 . Then

$$y(t) = \int_{-\infty}^t e^{(t-s)A_2} (I - \Pi) f(s) ds - \int_t^\infty e^{(t-s)A_1} \Pi f(s) ds$$

is a unique mild solution of (2.1) in $AP(Y)$.

The conditions (i), (ii) are fulfilled if A satisfies (a), (b) below.

(a) The spectrum decomposition assumption of Kato [8] of the following type: the spectrum $\sigma(A)$ of A has a decomposition

$$\sigma(A) = \sigma_1(A) \cup \sigma_2(A)$$

such that $\sigma_1(A) \subset \{\lambda \in \mathbb{C} : \operatorname{Re} \lambda \geq \delta\}$, $\sigma_2(A) \subset \{\lambda \in \mathbb{C} : \operatorname{Re} \lambda < -\delta\}$ for some $\delta > 0$ and there is a rectifiable simple closed curve Γ that encloses an open set containing $\sigma_1(A)$ in its interior and $\sigma_2(A)$ in its exterior.

Now define

$$\Pi = \frac{1}{2\pi i} \int_{\Gamma} R(\lambda, A) d\lambda,$$

where $R(\lambda, A)$ is the resolvent of A . Then A satisfies the properties (i), (ii) except the exponential stability of e^{tA} . To assure this, it is sufficient to assume;

(b) e^{tA_2} satisfies the spectrum determined growth assumption [8] i.e.,

$$\sup \operatorname{Re} \sigma(A_2) = \lim_{t \rightarrow \infty} \frac{\log |e^{tA_2}|}{t}.$$

Then we have

$$|e^{tA_2}| \leq M_2 e^{-\delta t}, \quad t \geq 0 \quad \text{for some } M_2 > 0.$$

Note that (b) is satisfied for analytic semigroups or compact semigroups. Note also that if $Y = \mathbb{R}^n$, then (i), (ii) holds if A has no pure imaginary eigenvalue.

2.2. Quadratic control: the deterministic case. Now we consider the system

$$(2.3) \quad y' = Ay + Bu + f,$$

where $u \in L_{\text{ap}}^2(U)$, U is a real separable Hilbert space, $B \in L(U, Y)$ and $f \in L_{\text{ap}}^2(Y)$. Let U_{ad} be the class of all controls $u \in L_{\text{ap}}^2(U)$ such that (2.3) has an almost periodic mild solution. We wish to minimize over U_{ad} the cost functional

$$(2.4) \quad J(u) = \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T [|My|^2 + \langle Nu, u \rangle] dt,$$

where $M \in L(Y)$ and $0 < N \in L(U)$ has bounded inverse N^{-1} . We may write (2.4) as

$$(2.5) \quad J(u) = |My|_{\text{ap}}^2 + |N^{1/2}u|_{\text{ap}}^2.$$

This setup guarantees that admissible controls and their responses are necessarily bounded, which is often a requirement in practice. We may relax this as in Remark 2.1 but then we need a formulation as in § 2.6.

It is not clear if there exist any admissible controls. However, if $A - BF$ is stable for some $F \in L(Y, U)$, then the feedback law

$$u = -Fy + v, \quad v \in L_{\text{ap}}^2(U)$$

is admissible and in fact

$$y(t) = \int_{-\infty}^t e^{(t-s)(A-BF)} [Bv(s) + f(s)] ds$$

is the unique mild solution of (2.3) in $AP(Y)$. Because of the presence of f it is reasonable to assume the existence of such F . Here we shall assume slightly more:

$$(2.6) \quad \begin{array}{ll} \text{(i)} & (A, B) \text{ is stabilizable,} \\ \text{(ii)} & (M, A) \text{ is detectable.} \end{array}$$

See [21], [30], for these definitions in finite dimension and [24], [31], for the infinite dimensional case.

PROPOSITION 2.1 ([31], [24]). *Suppose (2.6) holds. Then there exists a unique $0 \leq Q \in L(Y)$ satisfying the algebraic Riccati equation*

$$(2.7) \quad QA + A^*Q + M^*M - QBN^{-1}B^*Q = 0$$

*in the inner product sense [24]. Moreover, $A - BN^{-1}B^*Q$ is stable.*

The immediate consequence of this proposition is that $r(t)$ given by

$$(2.8) \quad r(t) = \int_t^\infty e^{(s-t)(A^* - QBN^{-1}B^*)} Qf(s) ds$$

is in $AP(Y)$ and is the unique mild solution of

$$(2.9) \quad r' + (A^* - QBN^{-1}B^*)r + Qf = 0.$$

The solution to our control problem is given by the following theorem.

THEOREM 2.1. *Assume (2.6). Then there is a unique optimal control for (2.3), (2.4), and it is given by the feedback law*

$$(2.10) \quad \bar{u} = -N^{-1}B^*(Qy + r)$$

and

$$(2.11) \quad J(\bar{u}) = 2\langle r, f \rangle_{\text{ap}} - |N^{-(1/2)}B^*r|_{\text{ap}}^2,$$

where $0 \leq Q$ and r are the unique solutions of (2.7) and (2.8) respectively.

Proof. Note that \bar{u} is admissible since $A - BN^{-1}B^*Q$ is stable. Let u be an arbitrary admissible control and y its response. We differentiate $\langle Qy(t), y(t) \rangle + 2\langle r(t), y(t) \rangle$ formally and remove the terms involving A using (2.7). Then, integrating from 0 to T , we obtain

$$\begin{aligned} & \langle Qy(T), y(T) \rangle + 2\langle r(T), y(T) \rangle - \langle Qy(0), y(0) \rangle - 2\langle r(0), y(0) \rangle \\ &= - \int_0^T [|My|^2 + \langle Nu, u \rangle] dt + \int_0^T |N^{1/2}[u + N^{-1}B^*(Qy + r)]|^2 dt \\ & \quad + \int_0^T [2\langle r, f \rangle - \langle N^{-1}B^*r, B^*r \rangle] dt. \end{aligned}$$

Dividing by T and letting $T \rightarrow \infty$, we obtain

$$(2.12) \quad J(u) = |N^{1/2}[u + N^{-1}B^*(Qy + r)]|_{\text{ap}}^2 + 2\langle r, f \rangle_{\text{ap}} - |N^{-1/2}B^*r|_{\text{ap}}^2$$

where we have used the boundedness of $y(T)$ and $r(T)$. As is well known, this formal procedure can be justified by introducing approximating systems of (2.1), (2.9) with strict solutions [3] and then by passing to the limit. See [3], [9] for arguments based on Yosida approximations of A and [18], [19] for arguments using resolvent operator of A . Now the optimality of \bar{u} and (2.11) follows easily from (2.12). Since $A - BN^{-1}B^*Q$ is stable, the uniqueness of \bar{u} also follows.

2.3. Almost periodic processes. Let (Ω, F, P) be a probability space. Let $y(t)$, $t \in \mathbb{R}$ be a measurable stochastic process in Y . We say that $y(t)$ is weakly almost periodic if $y(t) \in L^2(\Omega, F, P; Y)$ (square integrable) and $Ey(t)$ and $\text{cov}[y(t)]h$, for any $h \in Y$ (mean and covariance) are almost periodic.

Now we consider

$$(2.13) \quad dy = (Ay + f) dt + G dw,$$

where A and f are taken as in § 2.1, H is a real separable Hilbert space, $w(t)$, $t \geq 0$ is an H -valued Wiener process with $\text{cov}[w(t)] = tW$, $W \geq 0$, a nuclear operator on H , and $G \in L(H, Y)$ is strongly continuous and $G(t)h$ for any $h \in H$ is almost periodic. We extend $w(t)$ on \mathbb{R} by setting

$$w(t) = w_1(-t), \quad t < 0$$

where $w_1(t)$, $t \geq 0$ is a Wiener process in H with $\text{cov}[w_1(t)] = tW$ but is independent of $w(t)$, $t \geq 0$. With this convention we are able to consider almost periodic solutions of (2.13). Let $F_t = \sigma\{w(s), s \leq t\}$, $t \in \mathbb{R}$. If A is stable then

$$(2.14) \quad y(t) = \int_{-\infty}^t e^{(t-s)A} f(s) ds + \int_{-\infty}^t e^{(t-s)A} G(s) dw(s)$$

is quadratic mean continuous, F_t -adapted and almost periodic. We define a mild solution of (2.13) as in (2.1). Then (2.14) is the unique mild solution of (2.13). It has a property similar to that of (2.7). We denote by $M_{\text{ap}}^2(Y)$ the space of F_t -adapted almost periodic processes in Y . We define $M_{\text{ap}}^2(U)$ in a similar manner.

2.4. Quadratic control under complete observation. We consider a stochastic version of the control system (2.3):

$$(2.15) \quad dy = (Ay + Bu + f) dt + G(t) dw.$$

Let U_{ad} be the set of all controls $u \in M_{\text{ap}}^2(U)$ for which (2.15) has mild solutions in $M_{\text{ap}}^2(Y)$. We wish to minimize over U_{ad} the cost functional

$$(2.16) \quad J(u) = \lim_{T \rightarrow \infty} \frac{1}{T} E \int_0^T [|My|^2 + \langle Nu, u \rangle] dt.$$

If $A - BK$ is stable for some $K \in L(Y, U)$, then the feedback law

$$u = -Ky + v, \quad v \in M_{\text{ap}}^2(U)$$

is admissible and in fact

$$y(t) = \int_{-\infty}^t e^{(t-s)(A-BK)} [Bv(s) + f(s)] ds + \int_{-\infty}^t e^{(t-s)(A-BK)} G(s) dw(s)$$

is the unique mild solution in $M_{\text{ap}}^2(Y)$. We have a result analogous to Theorem 2.1.

THEOREM 2.2. Assume (2.6). Then there is a unique optimal control for (2.15), (2.16), and it is given by the feedback law

$$(2.17) \quad \bar{u} = -N^{-1}B^*(Qy + r)$$

and

$$(2.18) \quad J(\bar{u}) = 2\langle r, f \rangle_{\text{ap}} - |N^{-(1/2)}B^*r|_{\text{ap}}^2 + \langle \text{tr } GWG^*Q, 1 \rangle_{\text{ap}}$$

where $0 \leq Q$ and r are unique solutions of (2.7), (2.8) respectively, tr denotes the trace of nuclear operators and the last term in (2.18) is the scalar product of real valued almost periodic functions.

Proof. Let y be the mild solution corresponding to an admissible control u . As in the proof of Theorem 2.1 it is possible to justify the formal application of Ito's formula to $\langle Qy(t), y(t) \rangle + 2\langle r(t), y(t) \rangle$ [3], [18], [19]. Then we obtain

$$\begin{aligned} & \langle Qy(T), y(T) \rangle + 2\langle r(T), y(T) \rangle - \langle Qy(0), y(0) \rangle - 2\langle r(0), y(0) \rangle \\ &= \int_0^T \{ |N^{1/2}[u + N^{-1}B^*(Qy + r)]|^2 - |My|^2 - \langle Nu, u \rangle \\ & \quad + 2\langle r, f \rangle - \langle N^{-1}B^*r, r \rangle + \text{tr } GWG^*Q \} dt + 2 \int_0^T \langle Qy + r, Gdw \rangle. \end{aligned}$$

Now, taking expectations, dividing by T and letting $T \rightarrow \infty$, we obtain

$$J(u) = \|N^{1/2}[u + N^{-1}B^*(Qy + r)]\|_{\text{ap}}^2 + 2\langle r, f \rangle_{\text{ap}} - |N^{-(1/2)}B^*r|_{\text{ap}}^2 + \langle \text{tr } GWG^*Q, 1 \rangle_{\text{ap}},$$

where $\|\cdot\|_{\text{ap}}$ denotes the norm in $M_{\text{ap}}^2(U)$. The optimality of \bar{u} and (2.18) follow immediately.

2.5. Quadratic control under partial observation. This subsection is devoted to a more general situation where the system is nondirectly observable and hence feedback controls are not feasible. We first recall usual quadratic problems under partial observations. Given signal and observation processes

$$(2.19) \quad dy = (Ay + Bu + f) dt + G(t) dw, \quad y(0) = y_0,$$

$$(2.20) \quad dz = Cy dt + V dv, \quad z(0) = 0,$$

one wishes to minimize

$$(2.21) \quad J_0(u) = E \int_0^T [|My|^2 + \langle Nu, u \rangle] dt$$

over all controls $u \in L^2((0, T) \times \Omega; U)$ such that $u(t)$ is adapted to $\sigma\{z(s), 0 \leq s \leq t\}$ and (2.19), (2.20) have solutions where $C \in L(Y, R^m)$, $V \in \mathbb{R}^{m \times m}$ nonsingular, v is an m -dimensional Wiener process, $y_0 \in L^2(\Omega, F, P; Y)$ is Gaussian with mean \bar{y}_s and covariance P_0 and $y_0, w(t), v(t)$ are independent. To solve this problem, one needs to consider the filtering problem

$$(2.22) \quad dy = Ay dt + G(t) dw, \quad y(0) = y_0,$$

$$(2.23) \quad dz = Cy dt + V dv, \quad z(0) = 0.$$

The optimal filter $\hat{y}(t)$ of $y(t)$ given $\{z(s), 0 \leq s \leq t\}$ is defined in terms of projections [11], [20] and is given by [4], [8], [11], [20]

$$(2.24) \quad d\hat{y} = A\hat{y} dt + P(t)C^*(VV^*)^{-1}d\eta, \quad \hat{y}(0) = \bar{y}_0,$$

where η is the innovation process [11] given by

$$(2.25) \quad d\eta = dz - C\hat{y} dt$$

and P is the solution of the Riccati equation

$$(2.26) \quad P' - AP - PA^* - GWG^* + PC^*(VV^*)^{-1}CP = 0, \quad P(0) = P_0.$$

Admissible controls for (2.19)–(2.21) are all controls $u \in L^2((0, T) \times \Omega; U)$ such that $u(t) \in L^2(\Omega, H_t, P; U) \cap L^2(\Omega, Z_t, P; U)$ a.e. t , where $H_t = \sigma\{\eta(s), 0 \leq s \leq t\}$ and $Z_t = \sigma\{z(s), 0 \leq s \leq t\}$ see [5], [7], [20]. Define \hat{y} by

$$(2.27) \quad d\hat{y} = (A\hat{y} + Bu + f) dt + P(t)C^*(VV^*)^{-1}d\eta, \quad \hat{y}(0) = \bar{y}_0;$$

then for each admissible control u we have

$$(2.28) \quad J_0(u) = \int_0^T \text{tr } MP(t)M^* dt + E \int_0^T [|M\hat{y}|^2 + \langle Nu, u \rangle] dt.$$

If we denote by $\hat{J}_0(u)$ the second term on the right-hand side of (2.28), then the original problem (2.19)–(2.21) is essentially reduced to the problem of complete observation, (2.27) and $\hat{J}(u)$.

Unfortunately following these steps it is not clear how we can formulate a quadratic control problem for (2.19) and (2.20) in terms of almost periodic functions. So we shall consider a quadratic problem which is slightly different from the previous ones but is nevertheless a natural modification of them.

We take the set of admissible controls

$$(2.29) \quad U_{ad} = \{u \in L^\infty(0, T; L^2(\Omega, F, P; U)) : u(t) \in L^2(\Omega, H_t, P; U) \cap L^2(\Omega, Z_t, P; U) \text{ a.e. } t \text{ such that its response } y \in C_B(0, \infty; L^2(\Omega, F, P; Y))\},$$

where C_B denotes the space of bounded continuous functions. We then wish to minimize

$$(2.30) \quad J(u) = \overline{\lim}_{T \rightarrow \infty} \frac{1}{T} E \int_0^T [|My|^2 + \langle Nu, u \rangle] dt.$$

The requirement in (2.29) is in the spirit of almost periodic functions. In (2.30) we take $\overline{\lim}$ since the limit no longer exists in general.

Remark 2.1. We may replace quadratic problems in §§ 2.2 and 2.4 by problems of the type above. We may also drop boundedness conditions for u and y . Such a problem was considered in [17] for the complete observation case (see also Wonham [28]).

In the sequel we take C , V and G constant and assume the following:

$$(2.31) \quad \begin{aligned} (i) & \quad (A^*, C) \text{ is stabilizable;} \\ (ii) & \quad (W^{1/2}G^*, A^*) \text{ is detectable.} \end{aligned}$$

Then by [8], [21] the solution of the Riccati equation (2.26) converges strongly to $0 \leq P_\infty \in L(Y)$ (see Corollary 3.1). Thus, in this case we have

$$J(u) = \text{tr } MP_\infty M^* + \overline{\lim}_{T \rightarrow \infty} \frac{1}{T} \hat{J}_0(u).$$

We denote by $\hat{J}(u)$ the second term above. Now consider an auxiliary control problem of minimizing $\hat{J}(u)$ over all \hat{U}_{ad} subject to (2.27), where

$$(2.32) \quad \hat{U}_{ad} = \{u \in L^\infty(0, T; L^2(\Omega, F, P; U)) : u(t) \in L^2(\Omega, H_t, P; U) \text{ a.e. } t \text{ such that } \hat{y} \in C_B(0, \infty; L^2(\Omega, F, P; Y))\}.$$

If (2.6) is satisfied, then as Theorem 2.2 holds we can show that the optimal control is given by

$$(2.33) \quad \bar{u} = -N^{-1}B^*(Q\hat{y} + r)$$

and

$$(2.34) \quad \hat{J}(\bar{u}) = 2\langle r, f \rangle_{ap} - |N^{-1/2}B^*r|_{ap}^2 + \text{tr } P_\infty C^*(VV^*)^{-1}CP_\infty Q^*,$$

where Q and r are given as in Theorem 2.1. It is well known [2], [5], [7], [14] that the control \bar{u} is also in U_{ad} i.e., admissible for the control problem defined by (2.19), (2.20) and (2.30). Summing up, we have the separation principles as follows.

THEOREM 2.3. Assume (2.6) and (2.31). Then there is a unique optimal control for the problem defined by (2.19), (2.20), (2.29) and (2.30) and it is given by (2.33). Moreover

$$(2.35) \quad J(\bar{u}) = 2\langle r, f \rangle_{ap} - |N^{-1/2}B^*r|_{ap}^2 + \text{tr } MP_\infty M^* + \text{tr } P_\infty C^*(VV^*)^{-1}CP_\infty Q^*.$$

If we set $f = 0$, then the control problem (2.19), (2.20), (2.30) is the infinite horizon problem with average cost. In this case we have the following corollary.

COROLLARY 2.1. The unique optimal control is given by the feedback law on the filter

$$\bar{u} = -N^{-1}B^*Q\hat{y}$$

and

$$J(\bar{u}) = \text{tr } MP_{\infty}M^* + \text{tr } PC^*(VV^*)^{-1}CPQ.$$

This is the separation principle on infinite horizon. See [2], [5], [7], [14], [20], [30] for the usual separation principle.

2.6. Examples. We give two simple examples.

Example 2.1. A deterministic problem. In § 2.2 we take $Y = U = \mathbb{R}$ and set $A = 3$, $B = 4$, $M = N = 1$ and $f(t) = \sin t$. Then (2.3) is

$$y' = 3y + 4u + \sin t.$$

Then the solution of (2.7) which is nonnegative is $Q = \frac{1}{2}$. Then

$$r(t) = \frac{1}{52}[\cos t + 5 \sin t].$$

It is easy to obtain

$$2\langle r, f \rangle_{\text{ap}} = \frac{5}{52}, \quad |B^*r|_{\text{ap}}^2 = \frac{4}{52}.$$

Thus the optimal control is given by

$$\bar{u} = -2y - \frac{1}{13}(\cos t + 5 \sin t)$$

and

$$J(\bar{u}) = \frac{1}{52}.$$

Here f is periodic, but we may add, for example, $\sin \sqrt{2}t$. Then it becomes almost periodic and we can compute \bar{u} and $J(\bar{u})$ in a similar manner.

Example 2.2. Consider the stochastic parabolic equation

$$dy = \left(\frac{\partial^2}{\partial x^2} y + u \right) dt + \sin x \sin at dw, \quad a \in \mathbb{R}, \quad \text{constant},$$

$$y(t, 0) = y(t, \pi) = 0.$$

In (2.15) we take

$$Y = U = L^2(0, \pi), \quad Ay = \frac{d^2}{dx^2} y, \quad D(A) = H^2(0, \pi) \cap H_0^1(0, \pi), \quad H = \mathbb{R}$$

and $W(t)$ a real standard Wiener process. We take

$$J(u) = \lim_{T \rightarrow \infty} \frac{1}{T} E \int_0^T [|y|^2 + |u|^2] dt.$$

Then the algebraic Riccati equation (2.7) becomes

$$QA + AQ - Q^2 + I = 0,$$

whose solution is $Q = \sqrt{A^2 + I} + A$ i.e.,

$$Qy = \sum_{n=1}^{\infty} (\sqrt{n^4 + 1} - n^2) \langle y, e_n \rangle e_n, \quad e_n = \sqrt{\frac{2}{\pi}} \sin nx.$$

The optimal control is

$$\bar{u} = -(\sqrt{A^2 + I} + A)y$$

and its response \bar{y} is given by

$$\begin{aligned}\bar{y}(t) &= \int_{-\infty}^t e^{-\sqrt{A^2 + I}(t-s)} \sin x \sin as \, dw(s) \\ &= \int_{-\infty}^t e^{-\sqrt{2}(t-s)} \sin as \, dw(s) \sin x.\end{aligned}$$

Thus

$$\bar{u}(t) = -(\sqrt{2} - 1) \int_{-\infty}^t e^{-\sqrt{2}(t-s)} \sin as \, dw(s) \sin x$$

and

$$J(\bar{u}) = \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T \sin^2 at \langle Q \sin x, \sin x \rangle \, dt = \frac{\pi}{2}(\sqrt{2} - 1).$$

3. The evolution operator model. In § 2 we have taken A time-invariant, but here we replace it by $A(t)$, $t \in \mathbb{R}$ with the following properties:

- (i) $A(t) = A(t + \theta)$, $t \in \mathbb{R}$ for some $\theta > 0$.
- (ii) There exists an evolution operator $U(t, s)$, $t \geq s \geq 0$ such that for the initial value problem

$$y' = A(t)y + g(t), \quad y(0) = y_0, \quad g \in L^2(0, \theta; Y)$$

has a unique mild solution

$$(3.1) \quad y(t) = U(t, s)y_0 + \int_0^t Y(t, s)g(s) \, ds.$$

(iii) If n is large, then $n \in \rho(A(t))$ and $A_n(t) = n^2[n - A(t)]^{-1} - nI$ is well defined. Moreover, $y_n(t) \rightarrow y(t)$ in $C([0, \theta], Y)$ where y_n is the strict solution of the approximating systems

$$y'_n = A_n(t)y_n + g, \quad y_n(0) = y_0.$$

(iv) $A^*(t)$ has properties similar to (i)-(iii).

The conditions (3.1) (i)-(iii) are fulfilled if the usual hypotheses of Tanabe and Kato-Tanabe [23], [26] are satisfied. Note that

$$(3.2) \quad U(t + \theta, s + \theta) = U(t, s) \quad \text{for any } t > s.$$

We replace (2.1) by

$$(3.3) \quad y' = A(t)y + f.$$

If $U(t, s)$ is exponentially stable i.e., $|U(t, s)| \leq C_1 e^{-a(t-s)}$, $t \geq s$ for some $C_1 > 0$, $a > 0$, then using (3.2) we can show that

$$y(t) = \int_{-\infty}^t U(t, s)f(s) \, ds$$

is almost periodic and it is the unique mild solution of (3.3). We can construct strict solutions of approximating systems of (3.3) which converge to $y(t)$.

Below we shall consider quadratic problems as in § 2. Since most of the arguments are similar, we omit details of proofs.

3.1. Quadratic control: the deterministic case. We follow § 2.2 and consider

$$(3.4) \quad y' = A(t)y + B(t)u + f(t),$$

$$(3.5) \quad J(u) = \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T [|My|^2 + \langle Nu, u \rangle] dt,$$

where B , M and N are strongly continuous θ -periodic operators and we assume that $0 < N$ has bounded inverse N^{-1} . We take admissible controls as in § 2.2. If $A(t) - B(t)K(t)$, with $K \in L(Y, U)$ θ -periodic strongly continuous, generates an exponentially stable evolution operator (we shall write this as $U_{A-BK}(t-s)$), then the feedback law

$$u = -K(t)y + v(t), \quad v \in L_{ap}^2(U)$$

is admissible. As with (2.6) we assume

- (3.6) (i) (A, B) is stabilizable, i.e., there exists a θ -periodic strongly continuous operator $K \in L(Y, U)$ such that $U_{A-BK}(t, s)$ is exponentially stable;
 (ii) (M, A) is detectable, i.e., there exists a θ -periodic strongly continuous operator $L \in L(Y)$ such that $U_{A^*-M^*L^*}(t, s)$ is exponentially stable.

PROPOSITION 3.1 [10]. *Assume (3.6). Then there exists a unique θ -periodic solution to the Riccati equation*

$$(3.7) \quad Q' + QA + A^*Q + M^*M - QBN^{-1}B^*Q = 0.$$

Moreover, $A - BN^{-1}B^*Q$ generates an exponentially stable evolution operator $U_{A^*-BN^{-1}B^*Q}(t, s)$.

If, further, $U_{A^*-QBN^{-1}B^*}(t, s)$ is exponentially stable, then

$$(3.8) \quad r(t) = \int_t^\infty U_{A^*-QBN^{-1}B^*}(s, t)Q(s)f(s) ds$$

is a unique almost periodic solution of

$$(3.9) \quad r' + [A^*(t) - Q(t)B(t)N^{-1}(t)B^*(t)]r + Q(t)f(t) = 0.$$

THEOREM 3.1. *Assume (3.6) and that $U_{A^*-QBN^{-1}B^*}(t-s)$ is exponentially stable. Then the unique optimal control for (3.4), (3.5) is given by the feedback law*

$$(3.10) \quad \bar{u} = N^{-1}B^*(Qy + r)$$

and

$$(3.11) \quad J(\bar{u}) = 2\langle r, f \rangle_{ap} - |N^{-1/2}B^*r|_{ap}^2$$

where Q and r are given in Proposition 3.1 and in (3.8) respectively.

Proof. Similar to the proof of Theorem 2.1. But we approximate (3.4), (3.9) by systems involving $A_n(t)$ and then employ limit arguments [3], [10].

3.2. Quadratic control with complete observation. We replace (2.15), (2.16) by the following:

$$(3.12) \quad dy = [A(t)y + B(t)u + f(t)] dt + G(t) dw,$$

$$(3.13) \quad J(u) = \lim_{T \rightarrow \infty} \frac{1}{T} E \int_0^T [|My|^2 + \langle Nu, u \rangle] dt,$$

where A , B , M and N are given as in § 3.1 and G as in § 2.4. We define admissible controls as in § 2.4.

THEOREM 3.2. *Assume (3.6) and that $U_{A^*-QBN^{-1}B^*}(t, s)$ is exponentially stable. Then the feedback control*

$$(3.14) \quad \bar{u} = -N^{-1}B^*(Qy + r)$$

is the unique optimal control and

$$(3.15) \quad J(\bar{u}) = 2\langle r, f \rangle_{\text{ap}} - |N^{-1/2}B^*r|_{\text{ap}}^2 + \langle \text{tr } GWG^*Q, 1 \rangle_{\text{ap}},$$

where Q and r are unique solutions of (3.7) and (3.8).

Proof. Similar to the proof of Theorem 2.2.

3.3. Quadratic control with partial observation. The signal and observation processes are respectively

$$(3.16) \quad dy = [A(t)y + B(t)u + f(t)] dt + G(t) dw, \quad y(0) = y_0,$$

$$(3.17) \quad dz = C(t)y dt + V(t) dv, \quad z(0) = 0,$$

and the cost functional is

$$(3.18) \quad J(u) = \overline{\lim}_{T \rightarrow \infty} \frac{1}{T} E \int_0^T [|My|^2 + \langle Nu, u \rangle] dt,$$

where A , B , M and N are given as in § 3.1 and G , C and V are θ -periodic strongly continuous operators.

We consider the filtering problem as in § 2.5 and define the innovations process similarly. Then, taking admissible controls as in (2.29), we parallel the developments to 2.5. We assume (2.31) in the periodic sense, i.e., in the sense of (3.6). Then from [10] there exists a unique θ -periodic solution to the Riccati equation

$$(3.19) \quad P' - AP - PA^* - GWG^* + PC^*(VV^*)^{-1}CP = 0.$$

Moreover, by Lemma 3.1 below the solution of (3.19) with $P(0) = P_0$ converges orbitally to the periodic solution as $t \rightarrow \infty$. Thus we have

$$J(u) = \frac{1}{\theta} \int_0^\theta \text{tr } M(t)\bar{P}(t)M^*(t) dt + \overline{\lim}_{T \rightarrow \infty} \frac{1}{T} \hat{J}_0(u),$$

where $\hat{J}_0(u)$ is defined as (2.28) and \hat{y} is now given by

$$d\hat{y} = [A(t)\hat{y} + B(t)u + f(t)] dt + P(t)C^*(VV^*)^{-1}d\eta, \quad \hat{y}(0) = \bar{y}_0.$$

Thus we have the following.

THEOREM 3.3. *Assume (3.6) and that $U_{A^*-QBN^{-1}B^*}(t, s)$ is exponentially stable. Assume further that (2.31), in the periodic sense, holds. Then*

$$\bar{u} = -N^{-1}B^*(Q\hat{y} + r)$$

is the unique optimal control for (3.16)–(3.18) and

$$J(\bar{u}) = 2\langle r, f \rangle_{\text{ap}} - |N^{-1/2}B^*r|_{\text{ap}}^2 + \frac{1}{\theta} \int_0^\theta \text{tr } [M(t)\bar{P}(t)M^*(t) + \bar{P}(t)C^*(t)(V(t)V^*(t))^{-1}C(t)\bar{P}(t)Q(t)] dt,$$

where \bar{P} , Q are the unique θ -periodic solutions of (3.7) and (3.19) respectively and r is given by (3.8).

Now we shall prove the following lemma.

LEMMA 3.1. Let P be the solution of (3.19) with $P(0) = P_0$ and let \bar{P} be the unique θ -periodic solution of (3.19) with $\bar{P}(0) = \bar{P}_0$. Then

$$(3.20) \quad P(t + n\theta) \rightarrow \bar{P}(t) \text{ strongly for any } t \geq 0 \text{ as } n \rightarrow \infty.$$

Proof. We shall show this in three steps. We denote by $\tilde{P}(t)$ the solution of (3.19) with $\tilde{P}(0) = 0$.

(i) $P_0 \leq \bar{P}_0$. By a comparison theorem, see for instance [10], we know that

$$\tilde{P}(t) \leq P(t) \leq \bar{P}(t).$$

By [10] $\tilde{P}(t + n\theta) \rightarrow \bar{P}(t)$ for any $t \geq 0$ as $n \rightarrow \infty$. Thus $P(t + n\theta) \rightarrow \bar{P}(t)$ as $n \rightarrow \infty$.

(ii) $P_0 \geq \bar{P}_0$. Note that $P(t) \geq \bar{P}(t)$ for any $t \geq 0$. Set $Q(t) = P(t) - \bar{P}(t)$, then

$$Q' - (A - BN^{-1}B^*\bar{P})^*Q - Q(A - BN^{-1}B^*\bar{P}) + QBN^{-1}B^*Q = 0.$$

Let $\bar{U}(t, s)$ be the evolution operator generated by $A - BN^{-1}B^*\bar{P}$. By differentiating we obtain

$$\begin{aligned} \frac{d}{ds} \langle Q(t-s)\bar{U}(s, 0)y, \bar{U}(s, 0)y \rangle &= \langle Q(t-s)BN^{-1}B^*Q(t-s)\bar{U}(s, 0)y, \bar{U}(s, 0)y \rangle \\ &= |N^{-1/2}B^*Q(t-s)\bar{U}(s, 0)y|^2, \quad y \in Y. \end{aligned}$$

Integrating this from 0 to t , we obtain

$$\langle Q(0)\bar{U}(t, 0), \bar{U}(t, 0)y \rangle - \langle Q(t)y, y \rangle = \int_0^t |N^{-1/2}BQ(t-s)\bar{U}(s, 0)y|^2 ds,$$

which implies

$$0 \leq \langle Q(t)y, y \rangle \leq \langle Q(0)\bar{U}(t, 0)y, \bar{U}(t, 0)y \rangle \rightarrow 0 \quad \text{as } t \rightarrow \infty \text{ [10].}$$

Hence $P(t) - \bar{P}(t) \rightarrow 0$ strongly as $t \rightarrow \infty$.

(iii) General case. Choose n large enough so that $P_0 \leq nI$ and $\bar{P}_0 \leq nI$.

Let $R(t)$ be the solution of (3.19) with $R(0) = nI$. Then by (ii) $R(t) - \bar{P}(t) \rightarrow 0$ as $t \rightarrow \infty$. By the comparison theorem we have

$$\tilde{P}(t) \leq P(t) \leq R(t).$$

Now

$$\tilde{P}(t) - \bar{P}(t) \leq P(t) - \bar{P}(t) \leq R(t) - \bar{P}(t).$$

Hence

$$P(t + n\theta) - \bar{P}(t + n\theta) \rightarrow 0 \quad \text{strongly as } n \rightarrow \infty.$$

Remark 3.1. Note that (3.20) is the global asymptotic orbital stability of $\bar{P}(t)$, i.e., the trajectory of $P(t)$ approaches to that of $\bar{P}(t)$ asymptotically.

COROLLARY 3.1. Let A , G , C and V be constant in (2.26). Then under condition (2.31), $P(t) \rightarrow P_\infty$, where $0 \leq P_\infty$ is the unique solution of

$$AP + PA^* + GWG^* - PC^*(VV^*)^{-1}CP = 0$$

and $A^* - P_\infty C^*(VV^*)^{-1}C$ is stable.

FINE MODULI SPACES OF INFINITE DIMENSIONAL LINEAR SYSTEMS*

SHIN KAWASE† AND NIRO YANAGIHARA‡

Abstract. This paper describes the classification problem of continuous families of infinite dimensional linear systems. We are concerned with a family of controllable and observable linear systems $(F(s), G(s), H(s))$ in Banach spaces, which depend continuously on a parameter s in a Hausdorff topological space S . Our problem is to classify such families of systems by isomorphism relation and parametrize them by "moduli." It is known that there exist "moduli" for finite dimensional controllable and observable systems. We show the result fails in the infinite dimensional case, and derive some conditions under which there exist "moduli," i.e., a fine moduli theorem for infinite dimensional systems. The theory of Banach bundles plays an important role in our study.

Key words. moduli space, infinite dimensional system, Banach bundle

AMS(MOS) subject classifications. Primary 93B99; secondary 14D20, 93C25, 93C45, 93C60

1. Introduction. In this paper we consider the problem of classification of continuous families of infinite dimensional linear systems.

Let S be a Hausdorff topological space. We deal with families of systems parametrized by $s \in S$:

$$\frac{dx(t)}{dt} = F(s)x(t) + G(s)u(t),$$

$$y(t) = H(s)x(t),$$

where $x(t) \in X_s$, X_s being a Banach space depending on s , $u(t) \in \mathbb{C}^n$, $y(t) \in \mathbb{C}^m$. $F(s)$ is the infinitesimal generator of a contraction semigroup of class (C_0) on X_s for each $s \in S$, $G(s): \mathbb{C}^n \rightarrow X_s$ and $H(s): X_s \rightarrow \mathbb{C}^m$ are bounded linear operators for each $s \in S$. If $F(s)$, $G(s)$ and $H(s)$ depend continuously on s , then we have a continuous family of systems $\{(F(s), G(s), H(s)); s \in S\}$ (for the precise definition, see Definition 2). Such a family of systems appears, e.g., when dealing with perturbations in distributed systems.

The problem we will consider here is to classify continuous families of systems under the equivalence relation of *isomorphism* (for isomorphism, see Definition 3). For general motivation and background as well as difficulty for the classification problem we refer to [3].

Our problem consists of two parts: (a) find the equivalence classes of *similar* systems (for similarity, see § 2), and (b) parametrize the equivalence classes by the topological space S . The problem is formulated in terms of representability of the functor as follows [6, p. 54].

Let $\text{Top}_H :=$ category of Hausdorff spaces, and $\text{Sets} :=$ category of sets. To each $S \in \text{Top}_H$, there corresponds $\mathcal{F}(S) := \{\text{isomorphism classes of continuous families of systems parametrized by } s \in S\}$. Then the correspondence $\mathcal{F}: S \mapsto \mathcal{F}(S)$ is considered as a contravariant functor from Top_H to Sets . Suppose $\mathcal{M} \in \text{Top}_H$. Let $h_{\mathcal{M}}: \text{Top}_H \rightarrow \text{Sets}$ be the contravariant functor defined by $h_{\mathcal{M}}(S) = \text{Hom}(S, \mathcal{M})$, $S \in \text{Top}_H$, (where $\text{Hom}(S, \mathcal{M}) :=$ the set of all continuous maps from S to \mathcal{M}). If \mathcal{M} represents \mathcal{F} , i.e., there is a functorial isomorphism between \mathcal{F} and $h_{\mathcal{M}}$, then \mathcal{M} is called a *fine moduli space* for \mathcal{F} . (For moduli spaces, see also [3].)

‡ Department of Mathematics, Faculty of Science, Chiba University, Chiba City, 260, Japan.

Unfortunately, fine moduli spaces need not exist for \mathcal{F} in general [6]. So, an important subject in this direction is to find subfunctors which can be represented. Hazewinkel showed that the subfunctor $\mathcal{F}_{c,o}(S) := \{\text{isomorphism classes of continuous families of controllable and observable systems of finite dimension } k \text{ parametrized by } s \in S\}$ is representable, i.e., there exists a fine moduli space [3, p. 151]. The theorem is called the *fine moduli theorem* for $\mathcal{F}_{c,o}$. In the infinite dimensional case, however, the conditions of controllability and observability do not guarantee the existence of a fine moduli space, as shown by a counter example in § 3.

Our aim is to show fine moduli theorems for the infinite dimensional case. Our motivation for this paper is as follows: As shown by Hazewinkel and others, the fine moduli theorem is very powerful in studying finite dimensional systems parametrized by topological spaces. Hence, it would be natural to seek the infinite dimensional version of it. However, to get an infinite dimensional version is not a straightforward generalization of the finite dimensional case. Since, as we have described above, the result of Hazewinkel fails in the infinite dimensional case, we need further considerations on subfunctors and another approach. This leads us to the present paper.

For example, take Theorem 1 in § 3, which says that two continuous families of controllable and observable systems are isomorphic if they are pointwise isomorphic. This theorem plays an important role in deriving the fine moduli theorem, and is apparently the same as Hazewinkel's result for the finite dimensional case [3, p. 152]. However, his method is not applicable to the proof for the infinite dimensional case and some other techniques are required to get the proof.

Section 2 contains some necessary mathematical and system theoretical background. In § 3, we state definitions and results, Theorems 1 and 2. Theorem 1 is the main tool of this paper. Theorem 2 is the fine moduli theorem for infinite dimensional systems, which is our main result. Section 4 contains some lemmas. Sections 5–6 are devoted to the proofs of our theorems.

2. Mathematical and system theoretical preliminaries. In this section, we sketch some results of Banach bundle and system theory which are essential to this paper. For details of Banach bundles we refer to [1] and [2].

Let S be a Hausdorff topological space. By a *fiber set* we mean a triple (π, E, S) in which E is a set and $\pi: E \rightarrow S$ is a map. E is termed the *total set*, π the *projection* of E , S the *base space*, and for $s \in S$, $\pi^{-1}(s)$ is termed the *fiber* over s .

By a *bundle* we mean a fiber set (π, E, S) in which E is a topological space and $\pi: E \rightarrow S$ is a continuous map. By a *Banach family* we mean a fiber set with surjective projection in which each fiber has a given Banach space structure.

DEFINITION 1. A *Banach bundle* over S is a bundle (π, E, S) such that:

- (a) π is open and surjective.
- (b) For each $s \in S$, $\pi^{-1}(s)$ has a Banach space structure.
- (c) $x \mapsto \|x\|$ is continuous on E to \mathbb{R} .
- (d) The operation $+$ is continuous on $\{(x, y) \in E \times E; \pi(x) = \pi(y)\}$.
- (e) For each $\lambda \in \mathbb{C}$, the map $x \mapsto \lambda x$ is continuous on E to E .
- (f) If $s \in S$ and $\{x_i\}$ is any net of elements of E such that $\|x_i\| \rightarrow 0$ and $\pi(x_i) \rightarrow s$, then $x_i \rightarrow 0_s$, where 0_s stands for the zero element of the Banach space $\pi^{-1}(s)$.

We shall often write merely E instead of (π, E, S) .

If E is a fiber set over S , then $\prod E$ denotes the product of all the fibers of E . The members of $\prod E$ are called *selections* of E . If E is a Banach family, then $\prod E$ is a topological vector space. If E is a bundle over S , then the space of selections $\prod E$ contains the set $\Gamma(E)$ of continuous selections as a subspace. We refer to continuous

selections as *sections* of E . If $\gamma \in \Gamma(E)$ and $\phi(s)$, $s \in S$, is a continuous complex function on S , then $\phi\gamma \in \Gamma(E)$ (where $\phi\gamma$ is defined by $(\phi\gamma)(s) = \phi(s)\gamma(s)$). Suppose E is a Banach bundle. Then we denote by $\Gamma_b(E)$ the Banach space of bounded sections γ with the norm given by

$$(2.1) \quad \|\gamma\| = \sup \{\|\gamma(s)\|; s \in S\} < \infty.$$

Let E be a Banach family over S and $\Gamma \subset \prod E$; then we set $\Gamma_s = \{\gamma(s); \gamma \in \Gamma\}$ for $s \in S$. We say $\Gamma \subset \prod E$ is *total* for E if Γ_s spans a dense linear subspace of $\pi^{-1}(s)$ for each $s \in S$.

Let $s_0 \in S$ and U be an open set of S such that $s_0 \in U$. A *halo function* for pair $(U, \{s_0\})$ is a continuous function $\phi: S \rightarrow [0, 1]$ with $\phi(s_0) = 1$ and $\text{supp } \phi \subset U$. Let $s \in U$ and H_s denote the set of all halo functions for $(U, \{s\})$. Then for $\gamma \in \Gamma(E)$

$$\|\gamma(s)\| = \inf \{\|\phi\gamma\|; \phi \in H_s\} \quad [1, \text{p. 14}].$$

Let (π, E, S) and (π_1, E_1, S) be Banach families. If $\Phi: E \rightarrow E_1$ is a map which carries fibers into fibers such that $\Phi(s) := \Phi|_{\pi^{-1}(s)}: \pi^{-1}(s) \rightarrow \pi_1^{-1}(s)$ is a bounded linear map for each $s \in S$, then Φ is called a *Banach family map*. If E and E_1 are Banach bundles and $\Phi: E \rightarrow E_1$ is a continuous map which carries fibers into fibers such that $\Phi(s)$ is linear on each fiber of E , then Φ is called a *Banach bundle map*. Obviously a Banach bundle map is a Banach family map. Let E and E_1 be Banach bundles over S . If $\Phi: E \rightarrow E_1$ is a Banach bundle map, then we define a linear map $\Phi_*: \Gamma(E) \rightarrow \Gamma(E_1)$ by

$$(\Phi_*\gamma)(s) = \Phi(s)\gamma(s) \quad \text{for each } s \in S, \gamma \in \Gamma(E).$$

If $\Phi: E \rightarrow E_1$ is a bounded Banach bundle map (i.e., $\|\Phi(s)\|$ is bounded on S), then $\Phi_*: \Gamma_b(E) \rightarrow \Gamma_b(E_1)$ is a bounded linear operator and

$$(2.2) \quad \|\Phi_*\| \leq \sup \{\|\Phi(s)\|; s \in S\} \quad [1, \text{p. 18}].$$

Let (π, E, S) be a Banach bundle. Let U be a subspace of S , $E_U := \pi^{-1}(U)$ and $\pi_U := \pi|_{\pi^{-1}(U)}$. Then (π_U, E_U, U) is a Banach bundle, called the *reduction* of E to U and denoted by E_U . If E and E_1 are Banach bundles over S and if $\Phi: E \rightarrow E_1$ is a Banach bundle map, then so is $\Phi_U := \Phi|_{E_U}: E_U \rightarrow E_{1U}$.

Here are a few elementary properties of Banach bundles.

PROPOSITION 1 [2, p. 12]. *Let $x \in E$. Suppose that $\{x_i\} (i \in I)$ is a net of elements of E and $\pi(x_i) \rightarrow \pi(x)$ in S . Suppose further that for each $\varepsilon > 0$ we can find a net $\{y_i\}$ of elements of E and an element y of E such that:*

- (a) $y_i \rightarrow y$ in E ,
- (b) $\pi(x_i) = \pi(y_i)$ for each i and $\pi(x) = \pi(y)$,
- (c) $\|x - y\| < \varepsilon$,
- (d) $\|x_i - y_i\| < \varepsilon$ for all large i .

Then $x_i \rightarrow x$ in E .

PROPOSITION 2 [1, p. 20]. *Let E and E_1 be Banach bundles over S , and let $\Phi: E \rightarrow E_1$ be a Banach bundle map. Then Φ is locally bounded, i.e., Φ_U is bounded for each member U of an open covering of S .*

PROPOSITION 3 [2, p. 14]. *Let (π, E, S) be a Banach family and let Γ be a vector subspace of $\prod E$ such that:*

- (a) Γ is total for E ,
- (b) for any $\gamma \in \Gamma$, $s \mapsto \|\gamma(s)\|$ is continuous on S to \mathbb{R} .

Then E has a unique topology so that E is a Banach bundle with $\Gamma \subset \Gamma(E)$.

Let X be a Banach space. An *infinite dimensional linear system* (with n inputs and m outputs) with the *state space* X is a triple of operators (F, G, H) , where F is

the infinitesimal generator of a contraction semigroup $\{e^{Ft}; t \geq 0\}$ of class (C_0) on X , and $G: \mathbb{C}^n \rightarrow X$ and $H: X \rightarrow \mathbb{C}^m$ are bounded linear operators.

$L^1([0, \infty); \mathbb{C}^n)$ is the Banach space of all \mathbb{C}^n -valued summable functions on $[0, \infty)$. $C_B([0, \infty); \mathbb{C}^m)$ is the Banach space of all \mathbb{C}^m -valued continuous bounded functions on $[0, \infty)$ with the sup-norm. $C_B([0, \infty); M(m, n))$ is the Banach space of all $m \times n$ matrix-valued functions f on $[0, \infty)$ such that all column vectors belong to $C_B([0, \infty); \mathbb{C}^m)$, with the norm $\|f\| = \sup \{|f(t)|; t \in [0, \infty)\}$, where $|\cdot|$ denotes the matrix norm.

By the *controllability operator* of a system (F, G, H) , we mean the bounded linear operator $\mathcal{C}: L^1([0, \infty); \mathbb{C}^n) \rightarrow X$ defined by

$$\mathcal{C}u = \int_0^\infty e^{tF} G u(t) dt, \quad u \in L^1([0, \infty); \mathbb{C}^n).$$

By the *observability operator*, we mean the bounded linear operator $\mathcal{O}: X \rightarrow C_B([0, \infty); \mathbb{C}^m)$ defined by

$$(\mathcal{O}x)(t) = H e^{tF} x, \quad x \in X, \quad t \in [0, \infty).$$

If $X =$ the closure of $\text{Range } \mathcal{C}$, the system is *controllable*. If \mathcal{O} is injective, the system is *observable*. We say the system is *exactly controllable* if $\text{Range } \mathcal{C} = X$, and *exactly observable* if $\text{Range } \mathcal{O}$ is closed in $C_B([0, \infty); \mathbb{C}^m)$ [4].

We say two systems (F, G, H) and (F_1, G_1, H_1) with the respective state spaces X and X_1 are *similar* if there exists a bounded and boundedly invertible operator $P: X \rightarrow X_1$ which intertwines the two systems, that is, there hold

$$(2.3) \quad P e^{tF} = e^{tF_1} P, \quad PG = G_1 \quad \text{and} \quad H = H_1 P.$$

In this case, we write $(F, G, H) \sim (F_1, G_1, H_1)$. Let \mathcal{C} and \mathcal{C}_1 be the respective controllability operators, and \mathcal{O} and \mathcal{O}_1 be the respective observability operators. Then we have [4]

$$(2.4) \quad P\mathcal{C} = \mathcal{C}_1 \quad \text{and} \quad \mathcal{O}_1 P = \mathcal{O}.$$

The *weighting pattern* W of a system (F, G, H) is an $m \times n$ matrix-valued function $W(t) = H e^{tF} G$ on $[0, \infty)$. Then $W \in C_B([0, \infty), M(m, n))$. Conversely, if $W \in C_B([0, \infty); M(m, n))$, then W is the weighting pattern of a system, which is called a *realization* of W . If $(F, G, H) \sim (F_1, G_1, H_1)$, then they have the same weighting pattern. The converse is not generally true. However we have the following:

PROPOSITION 4 [4]. *Let (F, G, H) and (F_1, G_1, H_1) be two exactly controllable (resp. exactly observable) systems in Banach spaces with the same weighting pattern. In addition, let both systems be observable (resp. controllable). Then the two systems are similar.*

The *Hankel operator* $H_W: L^1([0, \infty); \mathbb{C}^n) \rightarrow C_B([0, \infty); \mathbb{C}^m)$ associated with a weighting pattern W is a bounded operator defined by

$$(H_W u)(t) = \int_0^\infty W(t+\tau) u(\tau) d\tau, \quad u \in L^1([0, \infty); \mathbb{C}^n).$$

Let \mathcal{C} and \mathcal{O} be the controllability and observability operators of (F, G, H) , respectively. Suppose (F, G, H) is controllable and observable. Then it is exactly observable if and only if

$$(2.5) \quad \text{Range } \mathcal{O} = \text{the closure of Range } H_W,$$

and exactly controllable if and only if

$$(2.6) \quad \text{Range } \mathcal{O} = \text{Range } H_W \quad (\text{see [4]}).$$

PROPOSITION 5 [4]. (a) Let $\mathcal{M}_{c,eo}$ be the set of all weighting patterns of controllable and exactly observable systems. Then,

$$\mathcal{M}_{c,eo} = C_B([0, \infty); M(m, n)).$$

(b) Let $\mathcal{M}_{ec,eo}$ be the set of all weighting patterns of exactly controllable and exactly observable systems. Then,

$$\mathcal{M}_{ec,eo} = \{W \in C_B([0, \infty); M(m, n)) \text{ such that Range } H_W \text{ is closed}\}.$$

3. Definitions and statements of our results.

DEFINITION 2. Let S be a Hausdorff space. A continuous family of linear systems (with n inputs and m outputs) over S (or parametrized by $s \in S$) is a quadruple $(E; \bar{F}, \bar{G}, \bar{H})$ of a bundle and maps defined as follows;

- (a) $E = (\pi, E, S)$ is a Banach bundle.
- (b) \bar{F} is a map from E into E such that:
 - (i) For each $s \in S$, $F(s) (= \bar{F}|_{\pi^{-1}(s)})$ is a linear map from $\pi^{-1}(s)$ to $\pi^{-1}(s)$ and generates a contraction semigroup $\{e^{tF(s)}; t \geq 0\}$ of class (C_0) on $\pi^{-1}(s)$.
 - (ii) Let $(\lambda - F(s))^{-1}$, $\lambda \in \mathbb{C}$, be the resolvent of $F(s)$. Then the map:

$$x \mapsto (\lambda - F(s))^{-1}x, \quad x \in E, \quad s = \pi(x),$$

is a Banach bundle map on E into E .

- (c) \bar{G} is a Banach bundle map from the trivial Banach bundle $S \times \mathbb{C}^n$ to E .
- (d) \bar{H} is a Banach bundle map from E to the trivial Banach bundle $S \times \mathbb{C}^m$.

Remark. Given a continuous family of systems $(E; \bar{F}, \bar{G}, \bar{H})$, for each $s \in S$ we have a system $(F(s), G(s), H(s))$ with the state space $\pi^{-1}(s)$, where $F(s) = \bar{F}|_{\pi^{-1}(s)}$, $G(s) = \bar{G}|(\{s\} \times \mathbb{C}^n)$ and $H(s) = \bar{H}|_{\pi^{-1}(s)}$.

DEFINITION 3. Let $(E; \bar{F}, \bar{G}, \bar{H})$ and $(E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1)$ be continuous families of controllable and observable systems over S . If there exists a bijective Banach bundle map $\bar{P}: E \rightarrow E_1$ such that

- (a) \bar{P}^{-1} is a Banach bundle map,
- (b) there hold $\bar{P}\bar{G} = \bar{G}_1$, $\bar{H} = \bar{H}_1\bar{P}$ and $P(s)e^{tF(s)} = e^{tF_1(s)}P(s)$ for each $s \in S$, where $P(s) = \bar{P}|_{\pi^{-1}(s)}$, then the two systems are said to be *isomorphic*, denoted by $(E; \bar{F}, \bar{G}, \bar{H}) \cong (E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1)$.

If $(E; \bar{F}, \bar{G}, \bar{H}) \cong (E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1)$, then clearly $(F(s), G(s), H(s)) \sim (F_1(s), G_1(s), H_1(s))$ for each $s \in S$. The converse is not generally true. For a counterexample, see [3, p. 136]. However we have the following:

THEOREM 1. Let S be a Hausdorff space. Let $(E; \bar{F}, \bar{G}, \bar{H})$ and $(E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1)$ be continuous families of controllable and observable systems over S . If for each $s \in S$, we have $(F(s), G(s), H(s)) \sim (F_1(s), G_1(s), H_1(s))$, then

$$(E; \bar{F}, \bar{G}, \bar{H}) \cong (E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1).$$

Now, we will show a fine moduli space does not exist for $\mathcal{F}_{c,o}(S) := \{\text{isomorphism classes of continuous families of controllable and observable systems over } S\}$. We consider the case $n = m = 1$. Let $(E; \bar{F}, \bar{G}, \bar{H})$ be the continuous family of systems over $[0, 1]$ defined by:

$$E = [0, 1] \times L^2(-\infty, \infty),$$

$$\pi: E \rightarrow [0, 1]; \text{ the projection of } E,$$

$$e^{tF(s)}: L^2(-\infty, \infty) \rightarrow L^2(-\infty, \infty) \quad \text{for } s \in [0, 1] \text{ and } x \in L^2(-\infty, \infty)$$

$$(e^{tF(s)}x)(\omega) = e^{i\omega t}x(\omega),$$

$$G(s): \mathbb{C} \rightarrow L^2(-\infty, \infty) \quad \text{for } s \in [0, 1] \text{ and } c \in \mathbb{C}$$

$$G(s)c = ((1 + \omega^2)/(1 + s\omega^2))g(\omega)c,$$

$$H(s): L^2(-\infty, \infty) \rightarrow \mathbb{C} \quad \text{for } s \in [0, 1] \text{ and } x \in L^2(-\infty, \infty)$$

$$H(s)x = (\pi/2) \int_{-\infty}^{\infty} ((1 + s\omega^2)/(1 + \omega^2)) \overline{h(\omega)} x(\omega) d\omega,$$

where $(1 + \omega^2)g(\omega)$ and $h(\omega)$ are functions in $L^2(-\infty, \infty)$. If $g(\omega) \neq 0$ and $h(\omega) \neq 0$ for all $\omega \in (-\infty, \infty)$, then clearly $(E; \bar{F}, \bar{G}, \bar{H})$ is a continuous family of controllable and observable systems.

Suppose \mathcal{M} is a fine moduli space for $\mathcal{F}_{c,o}$. Then we have a one-to-one map

$$\Psi([0, 1]): \mathcal{F}_{c,o}([0, 1]) \rightarrow \text{Hom}([0, 1], \mathcal{M}).$$

Let $f \in \text{Hom}([0, 1], \mathcal{M})$ be a morphism corresponding to $\{(E; \bar{F}, \bar{G}, \bar{H})\}$. We note that for $s \neq 0$, each system $(F(s), G(s), H(s))$ is similar to $(F(1), G(1), H(1))$. In fact, the bounded and boundedly invertible operator:

$$P(s): \pi^{-1}(s) \rightarrow \pi^{-1}(1), \quad (P(s)x_s)(\omega) = ((1 + s\omega^2)/(1 + \omega^2))x_s(\omega),$$

where $x_s \in \pi^{-1}(s)$, intertwines $(F(s), G(s), H(s))$ and $(F(1), G(1), H(1))$. This means that f is constant on $(0, 1]$. (Here we note that for each $s \in S$, $\Psi(\{s\})\{(F(s), G(s), H(s))\} = f(s)$.) Since f is continuous, f must be constant on $[0, 1]$. But $(F(0), G(0), H(0))$ is not similar to $(F(1), G(1), H(1))$, because $P(0): \pi^{-1}(0) \rightarrow \pi^{-1}(1)$,

$$(P(0)x_0)(\omega) = x_0(\omega)/(1 + \omega^2), \quad x_0 \in \pi^{-1}(0),$$

does not have any bounded inverse.

From the above example we see that in order to guarantee the existence of fine moduli spaces, we must impose some additional conditions on systems. The following fine moduli theorem shows such conditions.

THEOREM 2 (Fine moduli theorem). *Let S be a Hausdorff space.*

(a) *Let $\mathcal{F}_{c,eo}(S) := \{\text{isomorphism classes of continuous families of controllable and exactly observable systems over } S\}$. Then, there exists a fine moduli space for the contravariant functor $\mathcal{F}_{c,eo}: S \mapsto \mathcal{F}_{c,eo}(S)$.*

(b) *Let $\mathcal{F}_{ec,eo}(S) := \{\text{isomorphism classes of continuous families of exactly controllable and exactly observable systems over } S\}$. Then, there exists a fine moduli space for the contravariant functor $\mathcal{F}_{ec,eo}: S \mapsto \mathcal{F}_{ec,eo}(S)$.*

Remark. From the proof of the theorem in § 6, we get fine moduli space for $\mathcal{F}_{c,eo}$ and $\mathcal{F}_{ec,eo}$, explicitly.

4. Lemmas for the proofs of theorems.

LEMMA 1. *Let $(E; \bar{F}, \bar{G}, \bar{H})$ be a continuous family of systems. Let $\{x_i\} (i \in I)$ be a net in E such that $x_i \rightarrow x$ in E . For each $\varepsilon > 0$ there are $y_i \in D(F(\pi(y_i)))$ and $y \in D(F(\pi(y)))$ (D stands for the domain) in E such that:*

- (a) $y_i \rightarrow y$ in E ,
- (b) $\pi(x_i) = \pi(y_i)$ and $\pi(x) = \pi(y)$,
- (c) $\|x - y\| < \varepsilon$,
- (d) $\|x_i - y_i\| < \varepsilon$ for all large i ,
- (e) $\{\|F(\pi(y_i))y_i\|\}_{i \geq i_0}$ is bounded for sufficiently large i_0 .

Proof. First, we note for any $x \in \pi^{-1}(s)$ and any $\lambda > 0$, $(I - \lambda^{-1}F(s))^{-1}x \in D(F(s))$ and $(I - \lambda^{-1}F(s))^{-1}x \rightarrow x$ as $\lambda \rightarrow \infty$ [5, p. 58].

Now, put $s_i = \pi(x_i)$ and $s = \pi(x)$. Given $\varepsilon > 0$, choose $\lambda > 0$ so that $\|(I - \lambda^{-1}F(s))^{-1}x - x\| < \varepsilon$, and put $y = (I - \lambda^{-1}F(s))^{-1}x$ and $y_i = (I - \lambda^{-1}F(s_i))^{-1}x_i$. Then $y \in D(F(s))$ and $y_i \in D(F(s_i))$. We will show y_i and y satisfy (a)–(e).

By the assumption, $\|x - y\| < \varepsilon$. Since the map $x \mapsto (I - \lambda^{-1}F(s))^{-1}x$, $s = \pi(x)$, is a Banach bundle map on E to E (see Definition 2), it follows that $y_i \rightarrow y$ and hence $x_i - y_i \rightarrow x - y$. Thus $\|x_i - y_i\| \rightarrow \|x - y\| < \varepsilon$. So,

$$\|x_i - y_i\| < \varepsilon \quad \text{for all large } i.$$

Since $\|(I - \lambda^{-1}F(s_i))^{-1}\| \leq 1$ (recall $F(s_i)$ is the infinitesimal generator of a contraction semigroup), we have

$$\|F(s_i)y_i\| = \|\lambda((I - \lambda^{-1}F(s_i))^{-1} - I)x_i\| \leq 2\lambda \cdot \|x_i\|.$$

So, we know $\{\|F(\pi(y_i))y_i\|\}_{i \geq i_0}$ is bounded sufficiently large i_0 . Q.E.D.

COROLLARY. In Lemma 1 we can choose y and y_i as follows:

(a) $y \in D(F(\pi(x))^2)$ and $y_i \in D(F(\pi(x_i))^2)$.

(b) $\{\|F(\pi(x_i))^2y_i\|\}_{i \geq i_0}$ is bounded for sufficiently large i_0 .

Proof. Put $s_i = \pi(x_i)$ and $s = \pi(x)$. Given $\varepsilon > 0$, choose $\lambda > 0$ so that

$$\|(I - \lambda^{-1}F(s))^{-2}x - x\| < \varepsilon,$$

and put $y = (I - \lambda^{-1}F(s))^{-2}x$ and $y_i = (I - \lambda^{-1}F(s_i))^{-2}x_i$. Then $y \in D(F(s)^2)$ and $y_i \in D(F(s_i)^2)$, and in a similar way to the proof of Lemma 1, we can show y_i and y satisfy (a)–(d) in Lemma 1. Further,

$$\|F(s_i)^2y_i\| = \|\lambda^2((I - \lambda^{-1}F(s_i))^{-1} - I)^2x_i\| \leq 4\lambda^2\|x_i\|.$$

Thus, $\{\|F(\pi(x_i))^2y_i\|\}_{i \geq i_0}$ is bounded for sufficiently large i_0 . Q.E.D.

LEMMA 2. Let $(E; \bar{F}, \bar{G}, \bar{H})$ be a continuous family of systems. The Banach family map from E to E defined by

$$x \mapsto e^{tF(s)}x, \quad x \in \pi^{-1}(s),$$

is a Banach bundle map for each $t \geq 0$.

Proof. Suppose that $\{x_i\}$ is a net of elements of E and $x_i \rightarrow x$ in E . Put $s_i = \pi(x_i)$ and $s = \pi(x)$. Given $\varepsilon > 0$, take y_i and $y \in E$ as in the above corollary.

Here, we note for $y \in D(F(s)^2)$ and $n \in \mathbb{N}$ there holds

$$\|e^{tF(s)}y - (I - tn^{-1}F(s))^{-n}y\| \leq t^2(2n)^{-1}\|F(s)^2y\|$$

(see [5, p. 58]). Hence, for given $\varepsilon > 0$, we have for large n ,

$$\begin{aligned} & \|e^{tF(s)}x - (I - tn^{-1}F(s))^{-n}y\| \\ (4.1) \quad & \leq \|e^{tF(s)}x - e^{tF(s)}y\| + \|e^{tF(s)}y - (I - tn^{-1}F(s))^{-n}y\| \\ & \leq \|x - y\| + t^2(2n)^{-1}\|F(s)^2y\| < \varepsilon, \end{aligned}$$

and similarly for sufficiently large i and large n

$$(4.2) \quad \|e^{tF(s_i)}x_i - (I - tn^{-1}F(s_i))^{-n}y_i\| \leq \|x_i - y_i\| + t^2(2n)^{-1}\|F(s_i)^2y_i\| < \varepsilon,$$

since, by the corollary, $\{\|F(\pi(x_i))^2y_i\|\}_{i \geq i_0}$ is bounded for sufficiently large i_0 .

By Definition 2, the map $x \mapsto (\lambda - F(s))^{-1}x$, $s = \pi(x)$, is a Banach bundle map, so for any $n \in \mathbb{N}$ the map $x \mapsto (I - tn^{-1}F(s))^{-n}x$ is a Banach bundle map on E . Hence

$$(4.3) \quad (I - tn^{-1}F(s_i))^{-n}y_i \rightarrow (I - tn^{-1}F(s))^{-n}y.$$

From (4.1), (4.2) and (4.3) it follows, applying Proposition 1,

$$e^{tF(s_i)}x_i \rightarrow e^{tF(s)}x.$$

This means the Banach family map $x \mapsto e^{tF(s)}x$, $x \in \pi^{-1}(s)$, is continuous, and hence it is a Banach bundle map. Q.E.D.

LEMMA 3. Let S be a Hausdorff space and $(E; \bar{F}, \bar{G}, \bar{H})$ be a continuous family of systems over S . Let $\mathcal{C}(s)$ and $\mathcal{O}(s)$ be the controllability and observability operators of $(F(s), G(s), H(s))$, respectively. Then:

(a) The Banach family map $\bar{\mathcal{C}}: S \times L^1([0, \infty); \mathbb{C}^n) \rightarrow E$ (associated with $\mathcal{C}(s)$) defined by

$$\bar{\mathcal{C}}(s, u) = \mathcal{C}(s)u, \quad (s, u) \in S \times L^1([0, \infty); \mathbb{C}^n),$$

is a Banach bundle map.

(b) The Banach family map $\bar{\mathcal{O}}: E \rightarrow S \times C_B([0, \infty); \mathbb{C}^m)$ (associated with $\mathcal{O}(s)$) defined by

$$\bar{\mathcal{O}}x = (s, \mathcal{O}(s)x), \quad x \in \pi^{-1}(s),$$

is a Banach bundle map.

Proof. (a) Let $\{(s_i, u_i)\}$ be a net of elements of $S \times L^1([0, \infty); \mathbb{C}^n)$ such that $(s_i, u_i) \rightarrow (s, 0)$ in $S \times L^1([0, \infty); \mathbb{C}^n)$. Then

$$\|\bar{\mathcal{C}}(s_i, u_i)\| = \|\mathcal{C}(s_i)u_i\| = \left\| \int_0^\infty e^{tF(s_i)} G(s_i) u_i(t) dt \right\| \leq \|G(s_i)\| \cdot \|u_i\|.$$

By Proposition 2, $\bar{\mathcal{C}}$ is locally bounded. Hence $\bar{\mathcal{C}}(s_i, u_i) \rightarrow 0$. This means $\bar{\mathcal{C}}$ is continuous, and hence $\bar{\mathcal{C}}$ is a Banach bundle map.

(b) Suppose that $\{x_i\} (i \in I)$ is a net of elements of E and $x_i \rightarrow x$ in E . We put $\pi(x_i) = s_i$ and $\pi(x) = s$. We will prove $\mathcal{O}(s_i)x_i \rightarrow \mathcal{O}(s)x$.

Given $\varepsilon > 0$, choose y_i and $y \in E$ as in Lemma 1. Then since by Proposition 2, \bar{H} is locally bounded, we have

$$(4.4) \quad \begin{aligned} \|\mathcal{O}(s_i)y_i\| &= \|H(s_i)e^{tF(s_i)}y_i\| \\ &\leq \|H(s_i)\| \cdot \|y_i\| < K, \end{aligned}$$

for all large i , where $K > 0$ is a constant. Next, for $h > 0$, as $\{\|F(\pi(x_i))^2 y_i\|\}_{i \geq i_0}$ is bounded for sufficiently large i_0 , we have

$$(4.5) \quad \begin{aligned} \|(\mathcal{O}(s_i)y_i)(t+h) - (\mathcal{O}(s_i)y_i)(t)\| &= \|H(s_i)e^{(t+h)F(s_i)}y_i - H(s_i)e^{tF(s_i)}y_i\| \\ &\leq \|H(s_i)\| \cdot \|(e^{hF(s_i)} - I)y_i\| \\ &\leq \|H(s_i)\| \cdot h \cdot \|F(s_i)y_i\| < K_1, \end{aligned}$$

for sufficiently large i , where $K_1 > 0$ is a constant. Hence, put $M := \{\mathcal{O}(s_i)y_i \text{ for sufficiently large } i \in I \text{ such that (4.4) and (4.5) hold}\}$. Then M is a subset of $C_B([0, \infty); \mathbb{C}^m)$ consisting of uniformly bounded and equi-continuous functions on $[0, \infty)$. By the Ascoli-Arzelà theorem, we see M is relatively compact. On the other hand, since by Lemma 2 the map: $x \mapsto e^{tF(s)}x$ is a Banach bundle map, we have

$$(\mathcal{O}(s_i)y_i)(t) = H(s_i)e^{tF(s_i)}y_i \rightarrow (\mathcal{O}(s)y)(t) = H(s)e^{tF(s)}y$$

for each $t \geq 0$. From this, it follows that

$$(4.6) \quad \mathcal{O}(s_i)y_i \rightarrow \mathcal{O}(s)y \text{ in } C_B([0, \infty); \mathbb{C}^m).$$

Next,

$$(4.7) \quad \begin{aligned} \|\mathcal{O}(s_i)y_i - \mathcal{O}(s_i)x_i\| &= \|H(s_i)e^{tF(s_i)}y_i - H(s_i)e^{tF(s_i)}x_i\| \\ &\leq \|H(s_i)\| \cdot \|y_i - x_i\| < \varepsilon \|H(s_i)\|, \end{aligned}$$

and similarly

$$(4.8) \quad \|\mathcal{O}(s)y - \mathcal{O}(s)x\| < \varepsilon \|H(s)\|.$$

From (4.6), (4.7) and (4.8), it follows, by applying Proposition 1,

$$\mathcal{O}(s_i)x_i \rightarrow \mathcal{O}(s)x \quad \text{in } C_B([0, \infty); \mathbb{C}^m).$$

Thus $\bar{\mathcal{O}}$ is continuous, and hence $\bar{\mathcal{O}}$ is a Banach bundle map. Q.E.D.

5. Proof of Theorem 1.

First step. Let $P(s)$ be the bounded and boundedly invertible operator intertwining the systems $(F(s), G(s), H(s))$ and $(F_1(s), G_1(s), H_1(s))$. We define a Banach family map $\bar{P}: E \rightarrow E_1$ by

$$\bar{P}x = P(s)x, \quad x \in \pi^{-1}(s).$$

Since for each $s \in S$, $P(s)$ is invertible, so is \bar{P} , and by (2.3) there hold $\bar{P}\bar{G} = \bar{G}_1$, $\bar{H} = \bar{H}_1\bar{P}$ and $P(s)e^{tF(s)} = e^{tF_1(s)}P(s)$ for each $s \in S$. Thus it suffices to prove \bar{P} is a Banach bundle map, that is, \bar{P} is continuous.

Second step. We will show \bar{P} is locally bounded. Let $\mathcal{O}(s)$ and $\mathcal{O}_1(s)$ be the observability operators of $(F(s), G(s), H(s))$ and $(F_1(s), G_1(s), H_1(s))$, respectively. Then, by Lemma 3, the operators $\bar{\mathcal{O}}: E \rightarrow S \times C_B([0, \infty); \mathbb{C}^m)$ and $\bar{\mathcal{O}}_1: E_1 \rightarrow S \times C_B([0, \infty); \mathbb{C}^m)$ associated with $\mathcal{O}(s)$ and $\mathcal{O}_1(s)$, respectively, are Banach bundle maps. Hence, by Proposition 2, for each member U of an open covering of S , $\bar{\mathcal{O}}_U: E_U \rightarrow U \times C_B([0, \infty); \mathbb{C}^m)$ and $\bar{\mathcal{O}}_{1U}: E_{1U} \rightarrow U \times C_B([0, \infty); \mathbb{C}^m)$ are bounded Banach bundle maps on E_U and E_{1U} , the reductions of E and E_1 to U , respectively. Thus

$$\bar{\mathcal{O}}_{U*}: \Gamma_b(E_U) \rightarrow \Gamma_b(U \times C_B([0, \infty); \mathbb{C}^m))$$

and

$$\bar{\mathcal{O}}_{1U*}: \Gamma_b(E_{1U}) \rightarrow \Gamma_b(U \times C_B([0, \infty); \mathbb{C}^m))$$

are bounded operators (see § 2). Further, as both of the systems are observable, $\mathcal{O}(s)$ and $\mathcal{O}_1(s)$ are injective, so are $\bar{\mathcal{O}}_U$ and $\bar{\mathcal{O}}_{1U}$. Hence $\bar{\mathcal{O}}_{U*}$ and $\bar{\mathcal{O}}_{1U*}$ are also injective.

Now, by (2.4) there holds $\mathcal{O}_1(s)P(x) = \mathcal{O}(s)$. Hence $\bar{\mathcal{O}}_{1U}\bar{P}_U = \bar{\mathcal{O}}_U$, and thus $\bar{\mathcal{O}}_{1U*}\bar{P}_{U*} = \bar{\mathcal{O}}_{U*}$. So we have

$$\bar{P}_{U*} = (\bar{\mathcal{O}}_{1U*})^{-1}\bar{\mathcal{O}}_{U*}.$$

This means that \bar{P}_{U*} is a closed operator on a Banach space $\Gamma_b(E_U)$ to $\Gamma_b(E_{1U})$. Applying the closed graph theorem, we see \bar{P}_{U*} is a bounded operator.

Let $\mathcal{C}(s)$ and $\mathcal{C}_1(s)$ be the controllability operators of $(F(s), G(s), H(s))$ and $(F_1(s), G_1(s), H_1(s))$, respectively. Let

$$\Gamma := \{\gamma; \gamma(s) = \mathcal{C}(s)u, u \in L^1([0, \infty); \mathbb{C}^n)\}$$

and

$$\Gamma_1 := \{\gamma_1; \gamma_1(s) = \mathcal{C}_1(s)u, u \in L^1([0, \infty); \mathbb{C}^n)\}.$$

Then by Lemma 3, $\Gamma \subset \Gamma(E)$ and $\Gamma_1 \subset \Gamma(E_1)$. Since $(F(s), G(s), H(s))$ and $(F_1(s), G_1(s), H_1(s))$ are controllable, Γ and Γ_1 are total for E and E_1 , respectively (see § 2). Further, by (2.4) $P(s)\mathcal{C}(s) = \mathcal{C}_1(s)$. Hence

$$(5.1) \quad \bar{P}_*\Gamma = \Gamma_1.$$

Take an $s \in S$. Let U be a member of an open covering of S such that $s \in U$. Let H_s be the set of all halo functions for $(U, \{s\})$. Then we have for all $\gamma \in \Gamma(E)$

$$\begin{aligned} \|P(s)\gamma(s)\| &= \|(\bar{P}_* \gamma)(s)\| \\ &= \inf \{\|\phi \bar{P}_* \gamma\|; \phi \in H_s\} \\ &= \inf \{\|\bar{P}_* \phi \gamma\|; \phi \in H_s\} \\ &= \inf \{\|\bar{P}_{U*} \phi \gamma\|; \phi \in H_s\} \\ &\leq \|\bar{P}_{U*}\| \cdot \inf \{\|\phi \gamma\|; \phi \in H_s\} \\ &= \|\bar{P}_{U*}\| \cdot \|\gamma(s)\|. \end{aligned}$$

Here, we note that (see § 2)

$$(\phi \bar{P}_* \gamma)(s) = \phi(s) P(s) \gamma(s) = P(s) \phi(s) \gamma(s) = (\bar{P}_* \phi \gamma)(s).$$

Since $\Gamma(E)$ is total, $\|P(s)\| \leq \|\bar{P}_{U*}\|$ for $s \in U$, and thus \bar{P} is locally bounded.

Third step. We will show $\bar{P}: E \rightarrow E_1$ is continuous. Let $x_i \rightarrow x$ in E and let U be a member of an open covering of S such that $\pi(x) \in U$. As Γ is total, for $\varepsilon > 0$ we can choose $\gamma \in \Gamma$ such that

$$\|x - \gamma(\pi(x))\| < \varepsilon.$$

Since $\gamma \in \Gamma(E)$ and $\pi(x_i) \rightarrow \pi(x)$, there holds $x_i - \gamma(\pi(x_i)) \rightarrow x - \gamma(\pi(x))$. Hence $\|x_i - \gamma(\pi(x_i))\| \rightarrow \|x - \gamma(\pi(x))\|$. Thus

$$\|x_i - \gamma(\pi(x_i))\| < \varepsilon \quad \text{for all large } i.$$

So, we have

$$\begin{aligned} (5.2) \quad \|\bar{P}x - (\bar{P}_* \gamma)(\pi(x))\| &= \|P(\pi(x))x - P(\pi(x))\gamma(\pi(x))\| \\ &\leq \|P(\pi(x))\| \cdot \|x - \gamma(\pi(x))\| < \varepsilon \cdot \|\bar{P}_{U*}\|, \end{aligned}$$

and similarly for all large i ,

$$(5.3) \quad \|\bar{P}x_i - (\bar{P}_* \gamma)(\pi(x_i))\| < \varepsilon \cdot \|\bar{P}_{U*}\|.$$

Next, by (5.1), $\bar{P}_* \gamma \in \Gamma(E_1)$. So

$$(5.4) \quad (\bar{P}_* \gamma)(\pi(x_i)) \rightarrow (\bar{P}_* \gamma)(\pi(x)).$$

Hence, applying Proposition 1, it follows from (5.2), (5.3) and (5.4) that $\bar{P}x_i \rightarrow \bar{P}x$. Thus \bar{P} is continuous. Q.E.D.

6. Proof of Theorem 2.

Proof of (a). First step. We use the notations of Proposition 5. We prove $\mathcal{M}_{c, eo}$ is a fine moduli space for $\mathcal{F}_{c, eo}$.

Define a map $\Psi(S): \mathcal{F}_{c, eo}(S) \rightarrow \text{Hom}(S, \mathcal{M}_{c, eo})$ by

$$(6.1) \quad \{(E; \bar{F}, \bar{G}, \bar{H})\} \mapsto \bar{\mathcal{O}}\bar{G}$$

for $\{(E; \bar{F}, \bar{G}, \bar{H})\} \in \mathcal{F}_{c, eo}(S)$, where $\bar{\mathcal{O}}$ is the Banach bundle map associated with the observability operator $\mathcal{O}(s)$ of $(F(s), G(s), H(s))$. We note that the Banach bundle map $\bar{\mathcal{O}}G: S \times \mathbb{C}^n \rightarrow S \times C_B([0, \infty); \mathbb{C}^m)$ is identified with an element in $\text{Hom}(S, C_B([0, \infty); M(m, n)))$ ($:=$ the set of all continuous maps from S to $C_B([0, \infty); M(m, n))$), and hence in $\text{Hom}(S, \mathcal{M}_{c, eo})$ (see Proposition 5). So, for each $s \in S$, $(\bar{\mathcal{O}}\bar{G})(s)$ is the weighting pattern of $(F(s), G(s), H(s))$.

Further, from this we see $\bar{\mathcal{O}}\bar{G}$ does not depend on the choice of representatives. Indeed, suppose $(E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1) \in \{(E; \bar{F}, \bar{G}, \bar{H})\}$. Then $(E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1) \cong (E; \bar{F}, \bar{G}, \bar{H})$. Hence for each $s \in S$, $(F_1(s), G_1(s), H_1(s))$ and $(F(s), G(s), H(s))$ have the same weighting pattern (see § 3). So for each $s \in S$, $(\bar{\mathcal{O}}\bar{G})(s) = (\bar{\mathcal{O}}_1\bar{G}_1)(s)$, where $\bar{\mathcal{O}}_1$ is the Banach bundle map associated with the observability operator $\mathcal{O}_1(s)$ of $(F_1(s), G_1(s), H_1(s))$.

Second step. We will show that $\Psi(S)$ is a surjection. To see this, given $\bar{W} \in \text{Hom}(S, \mathcal{M}_{c,eo})$ we will show that there exists a continuous family $(E_0; \bar{F}_0, \bar{G}_0, \bar{H}_0)$ of controllable and exactly observable systems such that

$$(6.2) \quad \Psi(S)\{(E_0; \bar{F}_0, \bar{G}_0, \bar{H}_0)\} = \bar{W}.$$

For each $s \in S$ we have a realization $(F_0(s), G_0(s), H_0(s))$ of $\bar{W}(s)$ as follows [4]:

$$(6.3) \quad \begin{aligned} &\text{State space } X_{0s} = \text{the closure of Range } H_{\bar{W}(s)}, \\ &\{e^{tF_0(s)}\} = \text{the restriction on } X_{0s} \text{ of the left translation} \\ &\text{semigroup on } C_B([0, \infty); \mathbb{C}^m), \\ &G_0(s): \mathbb{C}^n \rightarrow X_{0s}, \quad G_0(s)c = \bar{W}(s)c \quad \text{for } c \in \mathbb{C}^n, \\ &H_0(s): X_{0s} \rightarrow \mathbb{C}^m, \quad H_0(s)x = x(0) \quad \text{for } x \in X_{0s}, \end{aligned}$$

where $H_{\bar{W}(s)}$ is the Hankel operator of $\bar{W}(s)$. Let $\mathcal{C}_0(s)$ and $\mathcal{O}_0(s)$ be the controllability and observability operators of $(F_0(s), G_0(s), H_0(s))$, respectively. Since there hold [4]:

$$(6.4) \quad \begin{aligned} &\mathcal{C}_0(s) = H_{\bar{W}(s)} \text{ and} \\ &\mathcal{O}_0(s) = \text{embedding of the closure of Range } H_{\bar{W}(s)} \text{ into } C_B([0, \infty); \mathbb{C}^m), \end{aligned}$$

$(F_0(s), G_0(s), H_0(s))$ is controllable and exactly observable (see § 2).

Let (π, E_0, S) be the Banach family defined by

$$\pi^{-1}(s) := X_{0s},$$

and let \bar{F}_0, \bar{G}_0 and \bar{H}_0 be the Banach family maps defined by

$$\begin{aligned} \bar{F}_0: E_0 &\rightarrow E_0; & \bar{F}_0|_{\pi^{-1}(s)} &:= F_0(s), \\ \bar{G}_0: S \times \mathbb{C}^n &\rightarrow E_0; & \bar{G}_0|_{(\{s\} \times \mathbb{C}^n)} &:= G_0(s), \\ \bar{H}_0: E_0 &\rightarrow S \times \mathbb{C}^m; & \bar{H}_0|_{\pi^{-1}(s)} &:= H_0(s), \end{aligned}$$

respectively. Thus we have obtained a family of controllable and exactly observable systems $(E_0; \bar{F}_0, \bar{G}_0, \bar{H}_0)$ such that (6.2) holds.

Now, it remains to prove it is a continuous family. Put

$$\Gamma_0 := \{\gamma; \gamma(s) = \mathcal{C}_0(s)u, u \in L^1([0, \infty); \mathbb{C}^n)\}.$$

Then, as $(F_0(s), G_0(s), H_0(s))$ is controllable, Γ_0 is total for E_0 . Moreover, as $\bar{W} \in \text{Hom}(S, \mathcal{M}_{c,eo})$, $H_{\bar{W}(s)}: L^1([0, \infty); \mathbb{C}^n) \rightarrow C_B([0, \infty); \mathbb{C}^m)$ is strongly continuous in $s \in S$. Hence by (6.4)

$$\|\gamma(s)\| = \|\mathcal{C}_0(s)u\| = \|H_{\bar{W}(s)}u\| \quad (\gamma \in \Gamma_0)$$

is a continuous function on S to \mathbb{R} . From Proposition 3, it follows there is a unique topology so that E_0 is a Banach bundle over S . Then, since clearly \bar{F}_0, \bar{G}_0 and \bar{H}_0 are maps which satisfy the conditions of Definition 2, we see $\Psi(S)$ is a map of $\mathcal{F}_{c,eo}(S)$ onto $\text{Hom}(S, \mathcal{M}_{c,eo})$.

Third step. We will show that $\Psi(S)$ is an injection. Suppose for $\{(E; \bar{F}, \bar{G}, \bar{H})\}$ and $\{(E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1)\} \in \mathcal{F}_{c, eo}(S)$,

$$\Psi(S)\{(E; \bar{F}, \bar{G}, \bar{H})\} = \Psi(S)\{(E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1)\}.$$

Then for each $s \in S$, $(F(s), G(s), H(s))$ and $(F_1(s), G_1(s), H_1(s))$ are controllable and exactly observable systems with the same weighting pattern. Hence by Proposition 4, for each $s \in S$ $(F(s), G(s), H(s)) \sim (F_1(s), G_1(s), H_1(s))$, and from Theorem 1, it follows that

$$(E; \bar{F}, \bar{G}, \bar{H}) \cong (E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1).$$

So $\{(E; \bar{F}, \bar{G}, \bar{H})\} = \{(E_1; \bar{F}_1, \bar{G}_1, \bar{H}_1)\}$. This means $\Psi(S)$ is an injection. Thus, we see $\text{Hom}(S, \mathcal{M}_{c, eo})$ is homomorphic to $\mathcal{F}_{c, eo}(S)$.

Proof of (b). We prove $\mathcal{M}_{ec, eo}$ is a fine moduli space for $\mathcal{F}_{ec, eo}$.

Define a map $\Psi(S): \mathcal{F}_{ec, eo}(S) \rightarrow \text{Hom}(S, \mathcal{M}_{ec, eo})$ by

$$(6.1') \quad \{(E; \bar{F}, \bar{G}, \bar{H})\} \mapsto \bar{O}G \quad \text{for } \{(E; \bar{F}, \bar{G}, \bar{H})\} \in \mathcal{F}_{ec, eo}(S).$$

Then, in a similar way to the third step of the above proof, we can show $\Psi(S)$ is an injection. Hence it remains to prove $\Psi(S)$ is a surjection.

Given $\bar{W} \in \text{Hom}(S, \mathcal{M}_{ec, eo})$, let $(E_0; \bar{F}_0, \bar{G}_0, \bar{H}_0)$ be the family of controllable and exactly observable systems defined by (6.3) (note $\mathcal{M}_{ec, eo} \subset \mathcal{M}_{c, eo}$). Since for each $s \in S$ the range of the Hankel operator $H_{\bar{W}(s)}$ associated with $\bar{W}(s)$ is closed (see Proposition 5), it follows from (6.4) that

$$\text{Range } \mathcal{O}_0(s) = \text{the closure of Range } H_{\bar{W}(s)} = \text{Range } H_{\bar{W}(s)}.$$

Hence by (2.6), $(F_0(s), G_0(s), H_0(s))$ is exactly controllable. So we have a continuous family $(E_0; \bar{F}_0, \bar{G}_0, \bar{H}_0)$ of exactly controllable and exactly observable systems such that (6.2) holds. Thus we see $\Psi(S)$ is a surjection. Q.E.D.

A CLASS OF OPTIMIZATION PROBLEMS WITH NONCOMPACT CONSTRAINTS: GENERAL RESULTS AND APPLICATIONS*

KJELL HOLMÅKER†‡ AND DAVID STEWART†

Abstract. Optimization problems recently studied in liver kinetics feature noncompact constraints and highly nonunique solutions. Here a wider class of problems with these properties is considered. It is shown that it is sufficient to solve the problem with an additional, compact constraint. From the solutions of this restricted problem all solutions of the original problem can be obtained. By means of this result and Pontryagin's maximum principle, solutions are found for some problems of liver-kinetic interest.

Key words. existence of optimal controls, noncompact constraints, Pontryagin's maximum principle, liver enzyme kinetics

AMS(MOS) subject classifications. 49A10, 49B10, 92A09, 80A32

1. Introduction. In some recent papers ([1], [3] and [4]) the following optimization (optimal control) problem from liver kinetics has been studied: Let P and M satisfy the system of differential equations

$$(1.1) \quad \begin{aligned} \frac{dP}{dx} &= -\alpha(P)f(x) \\ \frac{dM}{dx} &= \alpha(P)f(x) - \beta(M)g(x) \end{aligned} \quad (0 \leq x \leq L),$$

with nonnegative α and β and with boundary conditions

$$(1.2) \quad P(0) = P_0 > 0, \quad M(0) = 0.$$

Find the minimum of $M(L)$ with respect to all control functions f and g satisfying

$$(1.3) \quad f(x) \geq 0, \quad g(x) \geq 0 \quad \text{for } 0 \leq x \leq L,$$

$$(1.4) \quad \int_0^L f(x) dx = \int_0^L g(x) dx = 1.$$

Here P and M represent the concentrations of two substances in the blood (precursor and metabolite), and the system (1.1) describes a two-stage enzymatic process in the liver. The quantities α and β are proportional to the rates of conversion in the two stages, and f and g describe the distributions of two corresponding kinds of enzymes along a liver capillary of length L . A detailed presentation of the problem can be found in [1].

Because of the noncompactness of the constraints (1.3) and (1.4) it is not clear that the problem has a solution. In [1], [3] and [4] existence was established by various methods under various assumptions on β ([3] is most general in this respect), but these methods are of an ad hoc nature and seem difficult to generalize. In this paper we shall prove an existence theorem for a much more general problem, where (1.1) may be replaced by an arbitrary system which is linear in the control variables and where the constraints on the controls are of the same type as in (1.3) and (1.4). This

is done in § 2, where we show that it is sufficient to look only for solutions where the control vector is constrained to belong to a certain fixed compact set. The problem with this additional constraint has an optimal solution, which is also a solution of the original problem. Furthermore, from the solutions of the restricted problem we can construct all of the infinitely many solutions of the original problem.

In §§ 3–5 we shall apply the results from § 2 to a problem of liver-kinetic interest, but we believe that they have wider applicability. The problem we consider in §§ 3–5 is an extension of problem (1.1)–(1.4), where there is a third kind of enzyme transforming the precursor directly to the end product, thereby by-passing the metabolite. Instead of (1.1) we then have the system

$$\begin{aligned}\frac{dP}{dx} &= -\alpha(P)f(x) - \gamma(P)k(x), \\ \frac{dM}{dx} &= \alpha(P)f(x) - \beta(M)g(x)\end{aligned}$$

where γ is of the same type as α , and k is of the same type as f and g . The addition of the term $-\gamma(P)k(x)$ in the first equation makes the problem considerably more difficult to handle, especially by previously published methods ([1], [3] and [4]). However, we shall show how the results from § 2 enable us to find the solutions. In §§ 3 and 4 we work with the restricted version of the problem, where there is an additional compact constraint, and we apply Pontryagin's maximum principle to obtain (or at least characterize) the solutions. In § 3 we assume that α and γ are strictly monotonic and that β is unimodal (i.e. has a single maximum point), and we find that the problem (in the restricted version) has a unique solution, which can be explicitly calculated.

In § 4 we treat the case where β is strictly monotonic, but α and γ general. A characterization of the optimal controls is given.

In § 5 we treat the case where α , β and γ are general, and we show that certain optimal solutions can be obtained by means of a simpler problem not involving M , β and g . The results of § 4 characterize the solutions of this simpler problem.

2. An existence theorem. We shall consider a class of control systems containing the systems mentioned in § 1 as special cases. Using the standard notation in control theory with t as independent variable, $x = (x_1, \dots, x_n)^T \in \mathbb{R}^n$ as state vector, and $u = (u_1, \dots, u_m)^T \in \mathbb{R}^m$ as control vector, we consider the system

$$\begin{aligned}(2.1) \quad \dot{x} &= \frac{dx}{dt} = A(x)u, \quad 0 \leq t \leq T, \\ x(0) &\in K, \\ u_i(t) &\geq 0, \quad 0 \leq t \leq T, \quad 1 \leq i \leq m, \\ \int_0^T u(t) dt &= a,\end{aligned}$$

and the problem (\mathcal{P}) of minimizing the cost

$$C(u, x) = g(x(T)) + \int_0^T b(x(t))u(t) dt.$$

Here $T > 0$ is fixed, K is a compact set in \mathbb{R}^n , $a = (a_1, \dots, a_m)^T \in \mathbb{R}^m$, $a_i \geq 0$, $a \neq 0$, $A(x)$ is an $n \times m$ matrix and $b(x)$ is an m -row-vector, both continuous as functions of $x \in \mathbb{R}^n$, and g is a real-valued continuous function. The controls u are (Lebesgue)

measurable functions, and the differential equations are understood in the Carathéodory sense.

DEFINITION 2.1. Let v be measurable and nonnegative (i.e., have nonnegative components) and let y be continuous on $[0, T]$. We say that (v, y) is transformed into (u, x) by a rescaling of time, or briefly that (u, x) is a *time transform* of (v, y) , if u is nonnegative, and there exists a $\theta \in L_1(0, T)$ such that $\theta(t) \geq 0$ for $t \in [0, T]$, the function

$$(2.2) \quad \phi(t) = \int_0^t \theta(\tau) d\tau$$

satisfies $\phi(T) = T$, and

$$(2.3) \quad u(t) = v(\phi(t))\theta(t) \quad \text{for almost all } t \in [0, T],$$

$$(2.4) \quad x(t) = y(\phi(t)) \quad \text{for all } t \in [0, T].$$

LEMMA 2.1. If (v, y) is a solution of (2.1), then any (u, x) which is a time-transform of (v, y) is a solution of (2.1) with the same cost, that is

$$C(u, x) = C(v, y).$$

Proof. Let θ and ϕ be as in Definition 2.1 and let u and x be given by (2.3) and (2.4). Note that $\phi: [0, T] \rightarrow [0, T]$ is absolutely continuous with $\phi' = \theta \geq 0$ a.e. We shall make use of the formula

$$(2.5) \quad \int_0^{\phi(t)} F(\sigma) d\sigma = \int_0^t F(\phi(\tau))\theta(\tau) d\tau, \quad t \in [0, T],$$

which holds for any $F \in L_1(0, T)$. A proof of (2.5) can be found, e.g., in [7, p. 377]. From (2.3) and (2.5) it follows that $u_i \in L_1(0, T)$, and we also see that $u_i(t) \geq 0$ on $[0, T]$.

Since (v, y) satisfies (2.1) we have

$$y(s) = y(0) + \int_0^s A(y(\sigma))v(\sigma) d\sigma, \quad 0 \leq s \leq T.$$

Using (2.3)–(2.5), we then get

$$\begin{aligned} x(t) &= y(\phi(t)) = y(0) + \int_0^{\phi(t)} A(y(\sigma))v(\sigma) d\sigma \\ (2.6) \quad &= x(0) + \int_0^t A(y(\phi(\tau)))v(\phi(\tau))\theta(\tau) d\tau \\ &= x(0) + \int_0^t A(x(\tau))u(\tau) d\tau. \end{aligned}$$

Thus x satisfies $dx/dt = A(x)u(t)$ and $x(0) = y(0) \in K$. In the same way we get

$$(2.7) \quad a = \int_0^T v(s) ds = \int_0^T v(\phi(t))\theta(t) dt = \int_0^T u(t) dt,$$

and

$$\begin{aligned} (2.8) \quad \int_0^T b(y(s))v(s) ds &= \int_0^T b(y(\phi(t)))v(\phi(t))\theta(t) dt \\ &= \int_0^T b(x(t))u(t) dt. \end{aligned}$$

Also $x(T) = y(\phi(T)) = y(T)$.

It follows that (u, x) satisfies (2.1) and that

$$C(u, x) = C(v, y). \quad \square$$

LEMMA 2.2. *Let (u, x) be a solution of (2.1). Then there exists a solution (v, y) of (2.1) such that (u, x) is a time-transform of (v, y) , and*

$$\sum_{i=1}^m v_i(s) = T^{-1} \sum_{i=1}^m a_i \quad \text{for all } s \in [0, T].$$

The costs of (u, x) and (v, y) are the same.

Proof. Let

$$\theta(t) = T \left(\sum_{i=1}^m a_i \right)^{-1} \sum_{i=1}^m u_i(t), \quad 0 \leq t \leq T.$$

We define ϕ by (2.2) and ψ by

$$\psi(s) = \min \{t: 0 \leq t \leq T, \phi(t) = s\}, \quad 0 \leq s \leq T.$$

There may be countably many intervals $[\alpha_j, \beta_j]$ where ϕ is constant. We may assume that $\theta(t) = 0$ everywhere in these intervals (if necessary, redefine $u(t)$ on a set of measure zero). Define

$$(2.9) \quad \begin{aligned} y(s) &= x(\psi(s)), \\ v_i(s) &= \begin{cases} \frac{u_i(\psi(s))}{\theta(\psi(s))} & \text{if } \theta(\psi(s)) > 0, \\ \frac{1}{mT} \sum_{i=1}^m a_i & \text{if } \theta(\psi(s)) = 0, \end{cases} \end{aligned}$$

for $s \in [0, T]$ and $1 \leq i \leq m$. Let us show that v_i is measurable. Let f be a measurable real-valued function on $[0, T]$, and let α be any real number. Then

$$E = \{t \in [0, T]: f(t) < \alpha\}$$

is measurable, and

$$\begin{aligned} \{s \in [0, T]: f(\psi(s)) < \alpha\} &= \{s: \psi(s) \in E\} \\ &= \phi \left(E \setminus \bigcup_j (\alpha_j, \beta_j] \right). \end{aligned}$$

But $E \setminus \bigcup_j (\alpha_j, \beta_j]$ is measurable, and ϕ , being absolutely continuous, maps measurable sets onto measurable sets (see, e.g., [6, pp. 248–250]). Thus $s \mapsto f(\psi(s))$ is measurable, and it follows that v_i is measurable. We see that $v_i(s) \geq 0$ and $\sum_{i=1}^m v_i(s) = T^{-1} \sum_{i=1}^m a_i$ for all $s \in [0, T]$. It follows from (2.9) that

$$u(\psi(s)) = v(s)\theta(\psi(s)) \quad \text{for all } s \in [0, T],$$

because $\theta(\psi(s)) = 0$ implies $u(\psi(s)) = 0$. In particular, we have

$$u(\psi(\phi(t))) = v(\phi(t))\theta(\psi(\phi(t))) \quad \text{for all } t \in [0, T].$$

Now $\psi(\phi(t)) \leq t$ for all t , and if $\psi(\phi(t)) < t$, then ϕ is constant on the interval $[\psi(\phi(t)), t]$, so that $\theta = 0$ there; hence $u = 0$ on $[\psi(\phi(t)), t]$, and $u(\psi(\phi(t))) = u(t) = 0$, $\theta(\psi(\phi(t))) = \theta(t) = 0$. Thus

$$(2.10) \quad u(t) = v(\phi(t))\theta(t) \quad \text{for all } t \in [0, T].$$

We also have

$$(2.11) \quad x(t) = y(\phi(t)) \quad \text{for all } t \in [0, T],$$

because $y(\phi(t)) = x(\psi(\phi(t)))$, and if $\psi(\phi(t)) < t$, then again ϕ is constant on $[\psi(\phi(t)), t]$ and $u = 0$ there; thus x is constant on $[\psi(\phi(t)), t]$, so that $x(\psi(\phi(t))) = x(t)$.

Since (u, x) satisfies (2.1), we have

$$x(t) = x(0) + \int_0^t A(x(\tau))u(\tau) d\tau, \quad 0 \leq t \leq T.$$

Using (2.10) and (2.11) and reading (2.6) backwards, we get

$$x(t) = y(0) + \int_0^{\phi(t)} A(y(\sigma))v(\sigma) d\sigma,$$

so that

$$y(s) = x(\psi(s)) = y(0) + \int_0^s A(y(\sigma))v(\sigma) d\sigma.$$

Thus y satisfies the equation $dy/ds = A(y)v(s)$. In the same way we get from (2.7) and (2.8) that $\int_0^T v(s) ds = a$, so that (v, y) satisfies (2.1), and that $C(v, y) = C(u, x)$. \square

LEMMA 2.3. *Let (u, x) be a time-transform of (v, y) and let $\tilde{v} = v$ a.e., $\tilde{v} \geq 0$. Then (u, x) is a time-transform of (\tilde{v}, y) .*

Proof. There is a θ such that (2.3) and (2.4) hold. We want to show that $\tilde{v}(\phi(t))\theta(t) = v(\phi(t))\theta(t)$ a.e. Assume that this is not true. Then there is a set E of positive measure such that $\theta(t) \neq 0$ and $\tilde{v}(\phi(t)) \neq v(\phi(t))$ for $t \in E$. Since $\tilde{v} = v$ a.e., this implies that $m(\phi(E)) = 0$, where m denotes the Lebesgue measure. From (2.5) we get

$$\begin{aligned} 0 = m(\phi(E)) &= \int_0^T \chi_{\phi(E)}(s) ds = \int_0^T \chi_{\phi(E)}(\phi(t))\theta(t) dt \\ &\geq \int_0^T \chi_E(t)\theta(t) dt \geq 0. \end{aligned}$$

Thus $\int_0^T \chi_E(t)\theta(t) dt = 0$, which implies that $\theta(t) = 0$ a.e. on E . This contradiction proves the lemma. \square

Let $(\hat{\mathcal{P}})$ be the problem of minimizing $C(u, x)$ over all (u, x) satisfying (2.1) and the additional constraint

$$(2.12) \quad \sum_{i=1}^m u_i(t) = T^{-1} \sum_{i=1}^m a_i, \quad 0 \leq t \leq T.$$

THEOREM 2.1. *If problem $(\hat{\mathcal{P}})$ has a solution, then it is also a solution of problem (\mathcal{P}) . In this case (u, x) is a solution of (\mathcal{P}) if and only if (u, x) is a time-transform of (v, y) , where (v, y) is a solution of $(\hat{\mathcal{P}})$. If the solution (v_0, y_0) of $(\hat{\mathcal{P}})$ is essentially unique, i.e., every other solution is of the form (v, y_0) , where $v = v_0$ a.e., then (u, x) is a solution of (\mathcal{P}) if and only if (u, x) is a time-transform of (v_0, y_0) .*

Proof. The first statement follows from Lemma 2.2, and the second follows from Lemma 2.1 and 2.2. The last statement follows from Lemma 2.3. \square

THEOREM 2.2. *Assume that (2.1) with (2.12) has solutions and that all solutions x are uniformly bounded, i.e., that there exists a constant c such that $\max_{0 \leq t \leq T} |x(t)| \leq c$ for all x such that (u, x) satisfies (2.1) and (2.12) for some u . (This is the case, for instance, if $|x^T A(x)| \leq c_1(1 + |x|^2)$.) Then problem (\mathcal{P}) has solutions.*

Proof. It follows from general existence theorems in optimal control theory that problem $(\hat{\mathcal{P}})$ has a solution, see e.g. [2, pp. 61–62], [5, pp. 259–262]. It is also easy to give a direct proof in this case: If $\{(u^k, x^k)\}_1^\infty$ is a minimizing sequence, some subsequence of $\{u^k\}$ converges weakly in L_2 ; $\{x^k\}$ is uniformly bounded and equicontinuous, so some subsequence converges uniformly. It follows from Theorem 2.1 that (\mathcal{P}) has solutions. \square

Remark 2.1. There is some redundancy in (2.1) and (2.12), because if

$$\sum_{i=1}^m u_i(t) = T^{-1} \sum_{i=1}^m a_i = \sigma \quad \text{and} \quad \int_0^T u_i(t) dt = a_i$$

for $1 \leq i \leq m-1$, then automatically

$$\int_0^T u_m(t) dt = \int_0^T \left[\sigma - \sum_{i=1}^{m-1} u_i(t) \right] dt = \sigma T - \sum_{i=1}^{m-1} a_i = a_m.$$

Therefore, when dealing with problem $(\hat{\mathcal{P}})$, we can eliminate one of the control variables, say $u_m = \sigma - \sum_{i=1}^{m-1} u_i$, and work with u_1, \dots, u_{m-1} and the constraints $u_i(t) \geq 0$, $\int_0^T u_i(t) dt = a_i$ for $1 \leq i \leq m-1$, and $\sum_{i=1}^{m-1} u_i(t) \leq \sigma$.

In the case $m = 1$, problem $(\hat{\mathcal{P}})$ is trivial, because then $u_1(t) = T^{-1}a_1$ for all t .

3. Solution of the by-pass problem when α and γ are strictly monotonic and β unimodal. Let us now consider the by-pass problem mentioned in § 1. It is described by the following equations:

$$\begin{aligned} \frac{dP}{dx} &= -\alpha(P)f(x) - \gamma(P)k(x), \\ (3.1) \quad \frac{dM}{dx} &= \alpha(P)f(x) - \beta(M)g(x) \quad (0 \leq x \leq L), \\ P(0) &= P_0 > 0, \quad M(0) = 0. \end{aligned}$$

Here α, γ and β are defined and continuously differentiable for $P \geq 0$ and $M \geq 0$, respectively, and they also satisfy

$$\begin{aligned} \alpha(P) &> 0, \quad \gamma(P) > 0 \quad \text{for } P > 0, \quad \beta(M) > 0 \quad \text{for } M > 0, \\ \alpha(0) &= \gamma(0) = \beta(0) = 0. \end{aligned}$$

The control functions f, k and g are measurable and satisfy

$$\begin{aligned} (3.2) \quad f(x) &\geq 0, \quad k(x) \geq 0, \quad g(x) \geq 0 \quad \text{for } 0 \leq x \leq L, \\ \int_0^L f(x) dx &= \int_0^L k(x) dx = \int_0^L g(x) dx = 1. \end{aligned}$$

Let f, k and g satisfy (3.2) and consider system (3.1). To be able to apply the usual existence theorem from the theory of ordinary differential equations, we would like to have β defined in a neighbourhood of 0. We therefore define $\beta(M) = -\beta(-M)$ for $M < 0$, so that $\beta \in C^1(\mathbb{R})$. Then we know that (3.1) has a unique solution in some interval $[0, \varepsilon]$ with $\varepsilon > 0$. As long as the solution exists, we find easily from (3.1) that

$$(3.3) \quad 0 < P(x) \leq P_0, \quad 0 \leq M(x) \leq \max_{0 \leq P \leq P_0} \alpha(P).$$

Therefore the solution can be continued to all of $[0, L]$, and (3.3) holds for all $x \in [0, L]$. The solution is in Carathéodory's sense, i.e., P and M are absolutely continuous and satisfy (3.1) almost everywhere. It follows from (3.3) that the solutions for various admissible f, k and g are uniformly bounded.

The optimization problem is, as in [1], [3] and [4], to minimize $M(L)$. We can now apply Theorem 2.2 and draw the conclusion that there exist optimal solutions.

As Theorem 2.1 shows, it is sufficient to solve the problem under the additional constraint

$$(3.4) \quad f(x) + g(x) + k(x) = 3/L = \sigma, \quad 0 \leq x \leq L.$$

By Remark 2.1 we shall eliminate g and work with f and k as control variables, though we will continue to write g instead of $\sigma - f - k$.

We shall apply Pontryagin's maximum principle to obtain necessary conditions for the restricted problem (that is, including (3.4)). The Hamiltonian for this problem is

$$H(P, M, \eta_P, \eta_M, f, k, \mu_1, \mu_2) \\ = \eta_P(-\alpha(P)f - \gamma(P)k) + \eta_M(\alpha(P)f - \beta(M)g) + \mu_1 f + \mu_2 k.$$

Let (f, k) denote an optimal control vector and (P, M) the corresponding solution of (3.1). From optimal control theory (see, for example, [2, pp. 185–191]) we know that there are absolutely continuous functions η_P and η_M , and constants η_0 , μ_1 and μ_2 such that $(\eta_P(x), \eta_M(x), \mu_1, \mu_2) \neq (0, 0, 0, 0)$ for all x , and

$$\eta'_P = -\frac{\partial H}{\partial P}, \quad \eta'_M = -\frac{\partial H}{\partial M},$$

$$\eta_P(L) = 0, \quad \eta_M(L) = \eta_0, \quad \eta_0 \leq 0$$

where the derivatives of H are to be taken at the point

$$(P(x), M(x), \eta_P(x), \eta_M(x), f(x), k(x), \mu_1, \mu_2),$$

and

$$(3.5) \quad H(P(x), M(x), \eta_P(x), \eta_M(x), f(x), k(x), \mu_1, \mu_2) \\ = \max_{\substack{f, k \geq 0 \\ f+k \leq \sigma}} H(P(x), M(x), \eta_P(x), \eta_M(x), f, k, \mu_1, \mu_2)$$

a.e. on $[0, L]$.

Thus

$$(3.6) \quad \eta'_P = (\eta_P - \eta_M)f\alpha'(P) + \eta_P k\gamma'(P), \quad \eta'_M = \eta_M g\beta'(M).$$

Write H as

$$(3.7) \quad H = s_1 f + s_2 k - \sigma \eta_M \beta(M)$$

where

$$(3.8) \quad s_1 = (\eta_M - \eta_P)\alpha(P) + \eta_M \beta(M) + \mu_1, \\ s_2 = \eta_M \beta(M) - \eta_P \gamma(P) + \mu_2.$$

In evaluating (3.5), it is convenient to introduce the following regions in the s -plane $[s = (s_1, s_2)]$:

$$R_1 = \{s: s_1 > 0, s_1 > s_2\}, \\ R_2 = \{s: s_2 > 0, s_2 > s_1\}, \\ R_3 = \{s: s_1 < 0, s_2 < 0\}, \\ L_1 = \{s: s_2 = 0, s_1 < 0\}, \\ L_2 = \{s: s_1 = 0, s_2 < 0\}, \\ L_3 = \{s: s_1 = s_2 > 0\}, \\ 0 = \{0 = (0, 0)\}.$$

It then follows from (3.5) and (3.7) that

$$(3.9) \quad \begin{aligned} f &= \sigma & \text{if } s \in R_1, & & f &= 0 & \text{if } s \in L_1, \\ k &= \sigma & \text{if } s \in R_2, & & k &= 0 & \text{if } s \in L_2, \\ g &= \sigma & \text{if } s \in R_3, & & g &= 0 & \text{if } s \in L_3, \end{aligned}$$

possibly after a redefinition of f , g and k on a null set (see Fig. 1).

First of all, let us show that $\eta_0 \neq 0$. Assume that $\eta_0 = 0$. Then $\eta_M(L) = 0$, and (3.6) implies first that $\eta_M(x) \equiv 0$ and then (because $\eta_P(L) = 0$) that $\eta_P(x) \equiv 0$. Then (3.8) shows that s_1 and s_2 are constants, and unless $\mu_1 = \mu_2 = 0$, (3.9) shows that one of f , g and k is identically σ or identically 0, in contradiction of (3.2). Thus $\mu_1 = \mu_2 = 0$, so that $(\eta_P(x), \eta_M(x), \mu_1, \mu_2) = (0, 0, 0, 0)$ for all x , which is impossible. Thus $\eta_M(L) = \eta_0 < 0$, and we see from (3.6) that

$$(3.10) \quad \eta_M(x) < 0 \quad \text{for all } x.$$

Of particular importance for the analysis are the derivatives of the switching functions s_1 and s_2 . From (3.8), (3.1) and (3.6) we obtain

$$\begin{aligned} s'_1 &= (\eta_M - \eta_P)\alpha'(P)P' + (\eta'_M - \eta'_P)\alpha(P) + \eta_M\beta'(M)M' + \eta'_M\beta(M) \\ &= (\eta_M - \eta_P)\alpha'(P)[- \alpha(P)f - \gamma(P)k] \\ &\quad + [\eta_M g\beta'(M) - (\eta_P - \eta_M)f\alpha'(P) - \eta_P k\gamma'(P)]\alpha(P) \\ &\quad + \eta_M\beta'(M)[\alpha(P)f - \beta(M)g] + \eta_M g\beta'(M)\beta(M), \\ s'_2 &= \eta_M\beta'(M)M' + \eta'_M\beta(M) - \eta_P\gamma'(P)P' - \eta'_P\gamma(P) \\ &= \eta_M\beta'(M)[\alpha(P)f - \beta(M)g] + \eta_M g\beta'(M)\beta(M) \\ &\quad - \eta_P\gamma'(P)[- \alpha(P)f - \gamma(P)k] - [(\eta_P - \eta_M)f\alpha'(P) + \eta_P k\gamma'(P)]\gamma(P). \end{aligned}$$

That is,

$$(3.11) \quad s'_1 = (f + g)\eta_M\alpha(P)\beta'(M) - kS, \quad s'_2 = f[\eta_M\alpha(P)\beta'(M) + S]$$

where

$$S = (\eta_M - \eta_P)\alpha'(P)\gamma(P) + \eta_P\alpha(P)\gamma'(P).$$

FIG. 1. Decomposition of the switching plane.

So far α, β and γ have been arbitrary (subject to our general conditions), but for the rest of this section we now assume that

$$\alpha'(P) > 0 \quad \text{and} \quad \gamma'(P) > 0 \quad \text{for all } P \geq 0,$$

and that

$$(3.12) \qquad \begin{aligned} \beta'(M) &> 0 \quad \text{for } 0 \leq M < M_0, \\ \beta'(M) &< 0 \quad \text{for } M > M_0. \end{aligned}$$

It is helpful to draw figures showing how the point $s(x)$ can move in the s -plane in different cases. If $S < 0$ and $M < M_0$ it follows from (3.9) and (3.11) that the following movements are possible (see Fig. 2. The arrows denote increasing x): In the region R_1 we have $f = \sigma$, $g = k = 0$, so that $M' > 0$, and we see from (3.11) that $s'_2 < s'_1 < 0$.

If $S < 0$ and $M > M_0$ the following movements are possible (see Fig. 3):

Note that we cannot move along L_3 in any case, because if $s_1 = s_2$ on a set E of positive measure, then $s'_1 = s'_2$ a.e. on E , but $g = 0$ implies $s'_1 - s'_2 = -\sigma S > 0$.

FIG. 2. Paths of (s_1, s_2) for $M < M_0$.

FIG. 3. Paths of (s_1, s_2) for $M > M_0$.

In what follows we will prove that $S(x) < 0$ for all x . We shall distinguish different cases depending on where $s(L)$ lies.

Case 1. $s(L) \in T = R_2 \cup R_3 \cup L_1 \cup 0$.

(i) Define $\xi_1 = \inf \{x \in [0, L]: s(t) \in T \text{ for } x \leq t \leq L\}$. Let us show that $S < 0$ on $[\xi_1, L]$. If this is not true, then, since $S(L) < 0$, there exists a $\xi'_1 \in [\xi_1, L]$ such that $S < 0$ on $(\xi'_1, L]$ and $S(\xi'_1) = 0$. In $R_2 \cup R_3 \cup L_1$ we have $f = 0$. If $s(x) \in 0$ and $f(x) \neq 0$ on a set $E_1 \subseteq (\xi'_1, L]$ of positive measure, then $s'_1 = s'_2 = 0$ a.e. on E_1 . It follows that $S = -\eta_M \alpha(P) \beta'(M)$ and $s'_1 = -(f + g + k)S = -\sigma S > 0$ a.e. on E_1 , which is a contradiction. Thus $f = 0$ a.e. on $[\xi'_1, L]$, and since $\eta_P(L) = 0$, it follows from (3.6) that $\eta_P = 0$ on $[\xi'_1, L]$; hence $S < 0$ there, which contradicts the definition of ξ'_1 . Thus $S < 0$ on $[\xi_1, L]$, and the arguments above show that $f = 0$ and $\eta_P = 0$ on $[\xi_1, L]$. From this it follows that $\xi_1 > 0$. We infer from Figs. 2 and 3 that $s(\xi_1)$ cannot belong to L_3 , because $s(x)$ cannot enter R_2 from there. It cannot belong to 0 either, because $S < 0$ in some neighbourhood to the left of ξ_1 , and, as the figures show, there is no curve leading to 0 that does not lie entirely in T (note that $s'_2 < s'_1 < 0$ in R_1 , if $M < M_0$). Thus $s(\xi_1) \in L_2$, and $s(x) \in R_3$; hence $g(x) = \sigma$, for $x \in (\xi_1, L]$. It also follows that $M(x) < M_0$ for $x \in (\xi_1, L]$, because if $M(\xi'') \geq M_0$ for some $\xi'' \in (\xi_1, L]$, then, since $M' \leq 0$, we get $M \geq M_0$ and $s'_1 \geq 0$ on (ξ_1, ξ'') which is impossible.

(ii) There is a maximal interval $[\xi_2, \xi_1]$ (ξ_2 may be equal to ξ_1) where $s_1 = 0$, $s_2 \leq 0$. If $\xi_2 < \xi_1$, then $k = 0$ and $s'_1 = \sigma \eta_M \alpha(P) \beta'(M) = 0$ on (ξ_2, ξ_1) , so that $\beta'(M) = 0$ and $M = M_0$ there. On (ξ_2, ξ_1) we have from (3.6)

$$\eta'_P = (\eta_P - \eta_M) f \alpha'(P), \quad \eta'_M = 0.$$

As $\eta_P(\xi_1) = 0$ and $\eta_M(\xi_1) < 0$, we see that $\eta_M < \eta_P < 0$ on $[\xi_2, \xi_1)$, so that $S < 0$ and $s'_2 = fS < 0$ there. Assume that $s_2(\xi_2) = 0$, and let

$$\xi'_2 = \inf \{x \geq 0: S < 0 \text{ on } [x, \xi_2]\}.$$

Figures 2 and 3 show that $s_1 \leq 0$, $s_2 = 0$ on $[\xi'_2, \xi_2]$, and, as is shown above, we must have $f = 0$ a.e. there. Then $M' \leq 0$, so that $M \geq M_0$ on $[\xi'_2, \xi_2]$. From (3.6) we obtain

$$\eta'_P = \eta_P k \gamma'(P), \quad \eta'_M = \eta_M g \beta'(M),$$

and since $\eta_P(\xi_2) < 0$, we get $\eta_P < 0$. Moreover, $\eta'_M - \eta'_P \geq 0$, and since $\eta_M(\xi_2) - \eta_P(\xi_2) < 0$, we get $\eta_M - \eta_P < 0$ on $[\xi'_2, \xi_2]$. Thus $S < 0$ on $[\xi'_2, \xi_2]$, which implies that $\xi'_2 = 0$. But it is impossible to have $M \geq M_0$ on all of $[0, \xi_2]$. Therefore $s_2(\xi_2) < 0$.

(iii) The point $s(x)$ might approach $s(\xi_2) \in L_2$ from R_3 , but with ξ'_2 defined as above, we again find that $\xi'_2 = 0$, which leads to $M \geq M_0$ on $[0, \xi_2]$. Thus $s(x)$ approaches $s(\xi_2)$ from R_1 . Let

$$\xi_3 = \inf \{x \geq 0: s(t) \in R_1 \text{ for } x < t < \xi_2\}.$$

Then $\xi_3 > 0$, since otherwise $\int_0^L k(x) dx = 0$. On $[\xi_3, \xi_2]$ we have

$$\eta'_P = \sigma(\eta_P - \eta_M) \alpha'(P), \quad \eta_P(\xi_2) \leq 0,$$

$$\eta'_M = 0, \quad \eta_M(\xi_2) < \eta_P(\xi_2).$$

Therefore $\eta_M < \eta_P < 0$ on $[\xi_3, \xi_2)$, and $S < 0$ there. Furthermore, $M < M_0$ on $[\xi_3, \xi_2)$, because $M' > 0$ there, and $M(\xi_2) \leq M_0$. By Fig. 2 $s(\xi_3) \in L_3$. Since $s(x)$ cannot move along L_3 , it must approach $s(\xi_3)$ from R_2 . Let

$$\xi'_3 = \inf \{x \geq 0: S < 0 \text{ on } [x, \xi_3]\}.$$

On $[\xi'_3, \xi_3]$ we see from Fig. 2 that $s(x) \in R_2$, and we have

$$\begin{aligned}\eta'_P &= \sigma \eta_P \gamma'(P), & \eta_P(\xi_3) &< 0, \\ \eta'_M &= 0, & \eta_M(\xi_3) &< \eta_P(\xi_3),\end{aligned}$$

so that $\eta_M < \eta_P < 0$ on $[\xi'_3, \xi_3]$. Thus $S < 0$ there, which means that $\xi'_3 = 0$. Hence $k = \sigma$ on $[0, \xi_3]$.

The whole curve in Case 1 is shown in Fig. 4.

Case 2. $s(L) \in L_3$.

The situation is the same as in step (iii) of Case 1 (except that we have $\eta_P = 0$ instead of $\eta_P < 0$, but that does not affect the argument), and we can draw the conclusion that $s(x) \in R_2$ for $x \in [0, L]$, that is $k = \sigma$ there, which is impossible.

Case 3. $s(L) \in L_2$.

If $M(L) > M_0$, $s(x)$ must approach $s(L)$ from R_3 , but as in Case 1, step (ii), this implies that $M(x) > M_0$ for all $x \in [0, L]$, which is impossible. If $M(L) \leq M_0$, the analysis is the same as in Case 1, steps (ii) and (iii). But if $M(L) < M_0$, then $g = 0$ on $[0, L]$. Thus $M(L) = M_0$.

Case 4. $s(L) \in R_1$.

Define this time

$$\xi_1 = \inf \{x \in [0, L]: s(t) \in R_1 \text{ for } x \leq t \leq L\}.$$

On $(\xi_1, L]$ we have $f = \sigma$, $g = k = 0$, so that $\xi_1 > 0$. From (3.6) we obtain on $[\xi_1, L]$

$$\eta'_P = \sigma(\eta_P - \eta_M)\alpha'(P), \quad \eta'_M = 0,$$

and since $\eta_P(L) = 0$, we get $\eta_M - \eta_P < 0$, $\eta_P < 0$; hence $S < 0$ on $[\xi_1, L]$. If $s(\xi_1) \in L_3$, we have the same situation as in step (iii) of Case 1, and we can conclude that $k = \sigma$ on $[0, \xi_1]$. But then $g = 0$ on $[0, L]$, which is impossible. Furthermore $M > M_0$ on $(\xi_1, L]$, because if $M(\xi') \leq M_0$ for some $\xi' \in (\xi_1, L]$, then, since $M' > 0$ on (ξ_1, ξ') , $M < M_0$ on $[\xi_1, \xi')$. But then $s'_1 < 0$ there, which is impossible, because $s_1(\xi_1) = 0 < s_1(\xi')$. (This is also clear from Figs. 2 and 3.) The possibility $s(\xi_1) = (0, 0)$ is ruled out by the same arguments as in Case 1, step (ii), when we showed that $s_2(\xi_2) < 0$. Thus $s(\xi_1) \in L_2$. If $M(\xi_1) > M_0$, then as in Case 1, step (ii), we find that $M(x) > M_0$ for all $x \in [0, \xi_1]$. Thus $M(\xi_1) = M_0$. From this point on the analysis is the same as in Case 1; this time $\xi_2 < \xi_1$, because it is only on $[\xi_2, \xi_1]$ that $g \neq 0$.

FIG. 4. Portrait of behaviour of (s_1, s_2) for $M(L) < M_0$.

The whole curve in Case 4 is shown in Fig. 5.

Now we know what possible forms the optimal solution can take. The results can be summarized as in Fig. 6.

Next we want to investigate what is the particular form of the optimal solution for different values of the parameters M_0 , $\beta_0 = \beta(M_0)$, P_0 , P_1 and P_2 , where P_1 and P_2 are defined by

$$\int_{P_1}^{P_0} \frac{ds}{\gamma(s)} = 1, \quad \int_{P_2}^{P_1} \frac{ds}{\alpha(s)} = 1.$$

In all cases $k(x) = \sigma$ for $0 \leq x < \xi_3$ and $k(x) = 0$ for $\xi_3 < x \leq L$. From (3.2) and (3.4) we obtain $\xi_3 = 1/\sigma = L/3$. On the interval $[0, L/3)$ we have $P' = -\sigma\gamma(P)$, $M' = 0$, so that

$$\int_{P(L/3)}^{P_0} \frac{ds}{\gamma(s)} = 1, \quad P\left(\frac{L}{3}\right) = P_1, \quad M\left(\frac{L}{3}\right) = 0.$$

FIG. 5. Portrait of behaviour of (s_1, s_2) for $M(L) > M_0$.

I.	$k = \sigma$	$f = \sigma$	$g = \sigma$
	0	ξ_3	$\xi_2 = \xi_1$ L
II.	$k = \sigma$	$f = \sigma$	$k=0, M=M_0$ $g = \sigma$
	0	ξ_3 ξ_2	ξ_1 L
IIa.	$k = \sigma$	$f = \sigma$	$k=0, M=M_0$
	0	ξ_3 ξ_2	L
III.	$k = \sigma$	$f = \sigma$	$k=0, M=M_0$ $f = \sigma$
	0	ξ_3 ξ_2	ξ_1 L

FIG. 6. The optimal control functions.

Case I. Consider Case I in Fig. 6. From (3.2) and (3.4) we obtain $\xi_2 = \xi_1 = 2L/3$. On the interval $(L/3, 2L/3)$ we have $P' = -\sigma\alpha(P)$, $M' = \sigma\alpha(P)$, so that

$$\int_{P(2L/3)}^{P_1} \frac{ds}{\alpha(s)} = 1, \quad P\left(\frac{2L}{3}\right) = P_2, \quad M\left(\frac{2L}{3}\right) = P_1 - P_2.$$

On the interval $(2L/3, L]$ we have $P' = 0$, $M' = -\sigma\beta(M)$, so that

$$\int_{M(L)}^{P_1 - P_2} \frac{ds}{\beta(s)} = 1.$$

This can occur only if $P_1 - P_2 \leq M_0$ (since $M \leq M_0$ in Fig. 4).

Case II. Consider Case II in Fig. 6. On the interval $(L/3, \xi_2)$ we have $P' = -\sigma\alpha(P)$, $M' = \sigma\alpha(P)$, so that

$$(3.13) \quad \frac{L}{3} \int_{P(\xi_2)}^{P_1} \frac{ds}{\alpha(s)} = \xi_2 - L/3, \quad M(\xi_2) = M_0 = P_1 - P(\xi_2).$$

From this we get

$$(3.14) \quad \xi_2 = \frac{L}{3} \left(1 + \int_{P_1 - M_0}^{P_1} \frac{ds}{\alpha(s)} \right).$$

On the interval (ξ_2, ξ_1) we have $P' = -f(x)\alpha(P)$, and $0 = f(x)\alpha(P) - \beta_0 g(x)$. We obtain

$$(3.15) \quad \begin{aligned} 1 &= \int_{L/3}^{\xi_1} f(x) dx = \int_{P(\xi_1)}^{P_1} \frac{ds}{\alpha(s)}, \quad P(\xi_1) = P_2, \\ \beta_0 \int_{\xi_2}^{\xi_1} g(x) dx &= P(\xi_2) - P(\xi_1) = P_1 - P_2 - M_0. \end{aligned}$$

On the interval $(\xi_1, L]$ we have $P' = 0$, $M' = -\sigma\beta(M)$, so that

$$\begin{aligned} \frac{L}{3} \int_{M(L)}^{M_0} \frac{ds}{\beta(s)} &= L - \xi_1, \\ 1 &= \int_{\xi_2}^L g(x) dx = 3 - \sigma\xi_1 + (P_1 - P_2 - M_0)/\beta_0. \end{aligned}$$

From this we get

$$\begin{aligned} \xi_1 &= \frac{L}{3} [2 + (P_1 - P_2 - M_0)/\beta_0], \\ \int_{M(L)}^{M_0} \frac{ds}{\beta(s)} &= 1 - (P_1 - P_2 - M_0)/\beta_0. \end{aligned}$$

This case can occur only if $0 < P_1 - P_2 - M_0 < \beta_0$.

Case IIa. The limiting case where $\xi_1 = L$ can occur only if $P_1 - P_2 - M_0 = \beta_0$.

Case III. Finally, consider Case III in Fig. 6. As in Case II we obtain (3.13) and (3.14), and instead of (3.15) we get

$$\beta_0 = \beta_0 \int_{\xi_2}^{\xi_1} g(x) dx = P(\xi_2) - P(\xi_1) = P_1 - M_0 - P(\xi_1).$$

On the interval $(\xi_1, L]$ we have $P' = -\sigma\alpha(P)$, $M' = \sigma\alpha(P)$, so that

$$\begin{aligned} \int_{P(L)}^{P_1} \frac{ds}{\alpha(s)} &= 1, \quad P(L) = P_2, \\ \int_{P_2}^{P_1-M_0-\beta_0} \frac{ds}{\alpha(s)} &= 3 - \sigma\xi_1, \quad \xi_1 = L - \frac{L}{3} \int_{P_2}^{P_1-M_0-\beta_0} \frac{ds}{\alpha(s)} = \frac{L}{3} \left[2 + \int_{P_1-M_0-\beta_0}^{P_1} \frac{ds}{\alpha(s)} \right], \\ M(L) &= M_0 + P(\xi_1) - P(L) = P_1 - P_2 - \beta_0. \end{aligned}$$

This case can occur only if $P_1 - P_2 - M_0 > \beta_0$.

For any values of M_0 , β_0 , P_0 , P_1 and P_2 there is an optimal solution of (3.1.2) and (3.4), and it must be included in one of the cases above. The necessary conditions also determine (f, g, k, P, M) uniquely. This is obvious except on the interval (ξ_2, ξ_1) . But there $f + g = \sigma$, and we find that P and f are uniquely determined, P as the solution of

$$P' = -\frac{\sigma\beta_0\alpha(P)}{\beta_0 + \alpha(P)}, \quad P(\xi_2) = P_1 - M_0,$$

and $f(x)$ as

$$f(x) = \frac{\sigma\beta_0}{\beta_0 + \alpha(P(x))}.$$

When the optimal solution of (3.1.2) and (3.4) has been found, it can generate all the optimal solutions of (3.1)–(3.2) as described in Theorem 2.1.

We can summarize our results in the following theorem.

THEOREM 3.1. *Consider the problem of minimizing $M(L)$ subject to (3.1.2) and (3.4). The problem has a unique solution $(\hat{f}, \hat{g}, \hat{k}, \hat{P}, \hat{M})$. If we define P_1 and P_2 by*

$$\int_{P_1}^{P_0} \frac{ds}{\gamma(s)} = 1, \quad \int_{P_2}^{P_1} \frac{ds}{\alpha(s)} = 1,$$

the solution can be described as follows:

(I) *If $P_1 - P_2 \leq M_0$, then the optimal solution is given by Case I in Fig. 6 with $\xi_3 = L/3$, $\xi_2 = \xi_1 = 2L/3$. The optimal value $\hat{M}(L)$ is given by*

$$\int_{\hat{M}(L)}^{P_1-P_2} \frac{ds}{\beta(s)} = 1.$$

(II) *If $0 < P_1 - P_2 - M_0 < \beta_0$, then the optimal solution is given by Case II in Fig. 6 with $\xi_3 = L/3$ and*

$$\xi_2 = \frac{L}{3} \left[1 + \int_{P_1-M_0}^{P_1} \frac{ds}{\alpha(s)} \right], \quad \xi_1 = \frac{L}{3} [2 + (P_1 - P_2 - M_0)/\beta_0].$$

The optimal value $\hat{M}(L)$ is given by

$$\int_{\hat{M}(L)}^{M_0} \frac{ds}{\beta(s)} = 1 - (P_1 - P_2 - M_0)/\beta_0.$$

(IIa) *If $P_1 - P_2 - M_0 = \beta_0$, then the optimal solution is given by Case IIa in Fig. 6 with $\xi_3 = L/3$, ξ_2 as in Case II, and $\xi_1 = L$; furthermore $\hat{M}(L) = M_0$.*

(III) If $P_1 - P_2 - M_0 > \beta_0$, then the optimal solution is given by Case III in Fig. 6 with $\xi_3 = L/3$, ξ_2 as in Case II, and

$$\xi_1 = \frac{L}{3} \left[2 + \int_{P_1 - M_0 - \beta_0}^{P_1} \frac{ds}{\alpha(s)} \right].$$

The optimal value is $\hat{M}(L) = P_1 - P_2 - \beta_0$.

The optimal solutions of (3.1)–(3.2) are

$$\begin{aligned} f(x) &= \theta(x) \hat{f}(\phi(x)), & P(x) &= \hat{P}(\phi(x)), \\ g(x) &= \theta(x) \hat{g}(\phi(x)), & M(x) &= \hat{M}(\phi(x)), \\ k(x) &= \theta(x) \hat{k}(\phi(x)), \end{aligned}$$

where θ is any function in $L_1(0, L)$ such that $\theta \geq 0$,

$$\int_0^L \theta(x) dx = L \quad \text{and} \quad \phi(x) = \int_0^x \theta(t) dt.$$

The optimal value of $M(L)$ is the same as $\hat{M}(L)$.

4. General α , γ , monotonic β . We consider again the by-pass problem but this time with α and γ general and β strictly monotonic (that is, $\beta'(M) > 0$ for all $M \geq 0$). We can still use equations (3.1)–(3.11).

Outside \bar{R}_3 (the closure of R_3) $g = 0$, so there exists a smallest $\xi_1 < L$ such that $s(\xi_1)$ belongs to \bar{R}_3 . Within $R_2 \cup R_3 \cup L_1$ we have $f = 0$, so that $s'_2 = 0$, and within $R_1 \cup R_3 \cup L_2$ we have $k = 0$, so that $s'_1 = \sigma \eta_M \alpha(P) \beta'(M) < 0$. Therefore the point $s(x)$ might leave \bar{R}_3 only at 0 along L_3 . But if $s_1(x) = s_2(x) > 0$ on a set E of positive measure, then $s'_1 = s'_2$ a.e. on E , hence $S = 0$ (since $g = 0$; see (3.11)), and $s'_1 \leq 0$ there. Therefore $s(x)$ cannot leave \bar{R}_3 . When s belongs to \bar{R}_3 , we have $f = 0$ a.e., because if $s_1(x) = s_2(x) = 0$ and $f(x) \neq 0$ on a set of positive measure, then $s'_1(x) = s'_2(x) = 0$ a.e. on that set, and (3.11) gives the contradiction $\eta_M \alpha(P) \beta'(M) = 0$. This means that $\xi_1 > 0$, and that $f = 0$ on $(\xi_1, L]$.

Now, either $s(\xi_1) \in L_2$ or $s(\xi_1) \in 0$. In the first case it follows from what was said above that $s(x)$ will move into R_3 , so that $g = \sigma$ on $(\xi_1, L]$. In the second case $s(x)$ belongs to $L_1 \cup 0$ for all $x \in [\xi_1, L]$. On $(\xi_1, L]$ we have $g + k = \sigma$ a.e. and $\int_{\xi_1}^L g(x) dx = 1$, and since

$$\int_{M(L)}^{M(\xi_1)} \frac{ds}{\beta(s)} = \int_{\xi_1}^L g(x) dx,$$

any g and k satisfying these conditions on $(\xi_1, L]$ are optimal. In particular there is an optimal solution with $g = 0$ on $[\xi_1, \xi']$ and $g = \sigma$ on $(\xi', L]$ for some ξ' , and we consider that solution for the rest of this section. Thus in any case there is a ξ such that $g = 0$ on $[0, \xi]$ and $g = \sigma$ on $(\xi, L]$. It follows that $\xi = 2L/3$ and that $P = P(L)$ and $\eta_P = 0$ on $[\xi, L]$, and $\eta_M = \eta_M(\xi) < 0$ on $[0, \xi]$.

Let us return to the necessary conditions derived in § 3. Since our system is autonomous, the Hamiltonian (3.7) is equal to a constant σc on $[0, L]$. On $[0, \xi]$ we get

$$\max(\sigma s_1 - \sigma \eta_M \beta(M), \sigma s_2 - \sigma \eta_M \beta(M)) = \sigma c,$$

that is,

$$(4.1) \quad \max((\eta_M - \eta_P)\alpha(P) + \mu_1, -\eta_P\gamma(P) + \mu_2) = c,$$

and at $x = \xi = 2L/3$ in particular:

$$\max(\eta_M(\xi)\alpha(P(\xi)) + \mu_1, \mu_2) = c.$$

Case I. In the first case described (see Fig. 7) $s_2(\xi) < s_1(\xi) = 0$, and therefore

$$\mu_2 < \eta_M(\xi)\alpha(P(\xi)) + \mu_1 = c,$$

so that

$$\eta_M(\xi) = \frac{c - \mu_1}{\alpha(P(\xi))} < 0.$$

In R_1 , $s_1 > s_2$, so that

$$-\eta_P\gamma(P) + \mu_2 < \frac{c - \mu_1}{\alpha(P(\xi))}\alpha(P) - \eta_P\alpha(P) + \mu_1 = c.$$

Then

$$\eta_P = (c - \mu_1) \left[\frac{1}{\alpha(P(\xi))} - \frac{1}{\alpha(P)} \right],$$

$$\gamma(P) \left[1 - \frac{\alpha(P(\xi))}{\alpha(P)} \right] < \frac{c - \mu_2}{\mu_1 - c} \alpha(P(\xi)) = \nu,$$

and $f = \sigma$, $k = 0$.

In R_2 , $s_2 > s_1$, and

$$\frac{c - \mu_1}{\alpha(P(\xi))} \alpha(P) - \eta_P\alpha(P) + \mu_1 < -\eta_P\gamma(P) + \mu_2 = c.$$

Then

$$\eta_P = \frac{\mu_2 - c}{\gamma(P)}, \quad \gamma(P) \left[1 - \frac{\alpha(P(\xi))}{\alpha(P)} \right] > \nu,$$

and $f = 0$, $k = \sigma$.

On the line $s_1 = s_2$ we have $\gamma(P)[1 - \alpha(P(\xi))/\alpha(P)] = \nu$.

Thus we see that the function $\psi(P) = \gamma(P)[1 - \alpha(P(\xi))/\alpha(P)]$ is such that

$$(4.2) \quad \begin{aligned} \psi(P) < \nu &\Rightarrow f = \sigma, & k = 0, \\ \psi(P) > \nu &\Rightarrow f = 0, & k = \sigma. \end{aligned}$$

FIG. 7. Possible paths of (s_1, s_2) .

Case II. In the second case $s_1(\xi) \leq 0$, $s_2(\xi) = 0$, and

$$\eta_M(\xi)\alpha(P(\xi)) + \mu_1 \leq \mu_2 = c,$$

so that

$$\alpha(P(\xi)) \geq \frac{c - \mu_1}{\eta_M(\xi)} = \kappa.$$

In R_1 ,

$$-\eta_P\gamma(P) + c < \eta_M(\xi)\alpha(P) - \eta_P\alpha(P) + \mu_1 = c.$$

Then

$$\eta_P = \eta_M(\xi) - \frac{c - \mu_1}{\alpha(P)}, \quad \alpha(P) < \kappa,$$

and $f = \sigma$, $k = 0$.

In R_2 ,

$$\eta_M(\xi)\alpha(P) - \eta_P\alpha(P) + \mu_1 < -\eta_P\gamma(P) + c = c.$$

Then

$$\eta_P = 0, \quad \alpha(P) > \kappa,$$

and $f = 0$, $k = \sigma$.

On the line $s_1 = s_2$, $\alpha(P) = \kappa$. Consequently in this case

$$(4.3) \quad \begin{aligned} \alpha(P) < \kappa &\Rightarrow f = \sigma, & k &= 0, \\ \alpha(P) > \kappa &\Rightarrow f = 0, & k &= \sigma. \end{aligned}$$

Remark 4.1. For certain functions α and γ the condition (4.2) or (4.3) gives information on f and k almost everywhere on $[0, \xi]$, $\xi = 2L/3$. For example, if α and γ are strictly increasing in P , then so is ψ , and since $P' < 0$, (4.2) or (4.3) gives a solution of the form I in Fig. 6. Another example is the case where α and γ are (real) analytic in a neighbourhood of $[P_{\min}, P_0]$, where $P_{\min} > 0$ is the minimum of $P(L)$ over all admissible f and k . In that case there are only finitely many x in $[0, \xi]$ such that $\psi(P(x)) = \nu$ or $\alpha(P(x)) = \kappa$, unless $\alpha(P)$ is constant on $[P_{\min}, P_0]$. If this is so, then any distribution of f and k is optimal.

Remark 4.2. From the equation

$$\int_{M(L)}^{M(\xi)} \frac{ds}{\beta(s)} = 1 \quad \left(\xi = \frac{2L}{3} \right)$$

it follows that $M(\xi)$ is the minimum of

$$\int_0^\xi f(x)\alpha(P(x)) \, dx$$

subject to

$$\begin{aligned} \frac{dP}{dx} &= -\alpha(P)f(x) - \gamma(P)k(x), \\ f(x) &\geq 0, \quad k(x) \geq 0, \quad f(x) + k(x) = \sigma, \quad x \in [0, \xi], \\ \int_0^\xi f(x) \, dx &= \int_0^\xi k(x) \, dx = 1. \end{aligned}$$

5. General α , β and γ . Consider again the by-pass problem from § 3, this time in its original formulation (3.1)–(3.2). Let α , β and γ be arbitrary.

Choose an $L' > 0$ and consider the problem of minimizing

$$\int_0^{L'} f(x) \alpha(P(x)) dx,$$

when

$$P' = -\alpha(P)f(x) - \gamma(P)k(x), \quad 0 \leq x \leq L',$$

$$P(0) = P_0,$$

$$\int_0^{L'} f(x) dx = \int_0^{L'} k(x) dx = 1, \quad f(x), k(x) \geq 0.$$

According to Theorem 2.2 this problem has a solution. Let $(\bar{f}, \bar{k}, \bar{P})$ be any solution, and let λ be the minimum value, so that

$$\lambda = \int_0^{L'} \bar{f}(x) \alpha(\bar{P}(x)) dx.$$

Note that λ actually is independent of L' . If we pose the same problem with L instead of L' , then

$$\left(\frac{L'}{L} \bar{f}\left(\frac{L'x}{L}\right), \frac{L'}{L} \bar{k}\left(\frac{L'x}{L}\right), \bar{P}\left(\frac{L'x}{L}\right) \right)$$

is a solution as is easily verified.

If the restriction $f(x) + k(x) = \sigma$ is applied, Remark 4.2 shows that the solution can be characterized by (4.2) or (4.3).

Now let $L' \in (0, L)$ and extend the definition of \bar{f} , \bar{k} , and \bar{P} to all of $[0, L]$ by setting $\bar{f}(x) = \bar{k}(x) = 0$ and $\bar{P}(x) = \bar{P}(L')$ on $(L', L]$. Then \bar{P} satisfies $\bar{P}' = -\alpha(\bar{P})\bar{f}(x) - \gamma(\bar{P})\bar{k}(x)$ on $[0, L]$. Let $\mu > 0$ be given. We shall construct a particular solution $(\bar{f}, g_\mu, \bar{k}, \bar{P}, M_\mu)$ of (3.1)–(3.2) with g_μ defined as follows:

Case I. If $\lambda \leq \mu$, define $g_\mu(x) = 0$ for $0 \leq x \leq L'$, and $g_\mu(x) \geq 0$ for $L' < x \leq L$ in such a way that $\int_{L'}^L g_\mu(x) dx = 1$. Then $M_\mu(L') = \lambda$, and $M_\mu(L)$ is given by $\int_{M_\mu(L)}^\lambda ds / \beta(s) = 1$.

Case II. Assume that $\mu < \lambda < \mu + \beta(\mu)$. Consider

$$\phi(x) = \int_0^x \bar{f}(t) \alpha(\bar{P}(t)) dt, \quad 0 \leq x \leq L'.$$

Since $\phi(L') = \lambda > \mu$, there is a $y \in (0, L')$ such that $\phi(y) = \mu$. Define $g_\mu(x) = 0$ for $0 \leq x \leq y$, and

$$(5.1) \quad g_\mu(x) = \frac{1}{\beta(\mu)} \bar{f}(x) \alpha(\bar{P}(x))$$

for $y < x \leq L'$. This is permissible, because

$$\int_y^{L'} g_\mu(x) dx = [\phi(L') - \phi(y)] / \beta(\mu) = (\lambda - \mu) / \beta(\mu) < 1.$$

On $(L', L]$ we define $g_\mu(x)$ in such a way that $\int_{L'}^L g_\mu(x) dx = 1 - (\lambda - \mu)/\beta(\mu)$. By the uniqueness of the solution of the differential equation, we have $M_\mu(x) = \mu$ on $[y, L']$, and $M_\mu(L)$ is given by

$$\int_{M_\mu(L)}^\mu \frac{ds}{\beta(s)} = 1 - \frac{\lambda - \mu}{\beta(\mu)}.$$

Case III. Assume that $\lambda \geq \mu + \beta(\mu)$. Again $\phi(y) = \mu$ for some $y \in (0, L')$, and since $\phi(L') = \lambda \geq \mu + \beta(\mu)$, there is a $z \in (y, L']$ such that $\phi(z) = \mu + \beta(\mu)$. We now define $g_\mu(x)$ by expression (5.1) on (y, z) , and $g_\mu(x) = 0$ on $[0, y] \cup [z, L]$. We note that

$$\int_0^L g_\mu(x) dx = \int_y^z g_\mu(x) dx = [\phi(z) - \phi(y)]/\beta(\mu) = 1.$$

We have $M_\mu(x) = \mu$ on $[y, z]$, and

$$\begin{aligned} M_\mu(L) &= \mu + \int_z^{L'} \tilde{f}(x) \alpha(\bar{P}(x)) dx \\ &= \lambda - \int_y^z \tilde{f}(x) \alpha(\bar{P}(x)) dx \\ &= \lambda - \beta(\mu) \int_y^z g_\mu(x) dx = \lambda - \beta(\mu). \end{aligned}$$

Consider the function $F(\mu)$ defined by

$$\begin{aligned} F(\mu) &= \lambda - \beta(\mu) && \text{if } 0 \leq \mu + \beta(\mu) \leq \lambda, \\ \int_{F(\mu)}^\mu \frac{ds}{\beta(s)} &= 1 - \frac{\lambda - \mu}{\beta(\mu)} && \text{if } \mu + \beta(\mu) > \lambda \text{ and } \mu < \lambda, \\ \int_{F(\mu)}^\lambda \frac{ds}{\beta(s)} &= 1 && \text{if } \mu \geq \lambda. \end{aligned}$$

Obviously, $F(\mu) = M_\mu(L)$ for $\mu > 0$. This function is continuous and attains its minimum value for some $\mu^* > 0$. (There may be several such μ^* ; choose one of them.) Put $g^* = g_{\mu^*}$ and $M^* = M_{\mu^*}$.

THEOREM 5.1. *The solution $(\tilde{f}, g^*, \tilde{k}, \bar{P}, M^*)$ of (3.1)–(3.2) constructed above is an optimal solution.*

Proof. Let (f, g, k, P, M) be an arbitrary solution of (3.1)–(3.2). Define

$$\beta_1 = \max \{\beta(M(x)) : x \in [0, L]\},$$

and choose μ_1 and x_1 such that

$$\beta(\mu_1) = \beta_1, \quad M(x_1) = \mu_1.$$

If x_1 cannot be chosen less than L , define

$$\tilde{f}(x) = \begin{cases} 2f(2x) & \text{for } 0 \leq x \leq L/2, \\ 0 & \text{for } L/2 < x \leq L, \end{cases}$$

and $\tilde{g}(x), \tilde{k}(x)$ similarly, and

$$\begin{aligned} \tilde{P}(x) &= \begin{cases} P(2x) & \text{for } 0 \leq x \leq L/2, \\ P(L) & \text{for } L/2 < x \leq L, \end{cases} \\ \tilde{M}(x) &= \begin{cases} M(2x) & \text{for } 0 \leq x \leq L/2, \\ M(L) & \text{for } L/2 < x \leq L. \end{cases} \end{aligned}$$

Then $(\tilde{f}, \tilde{g}, \tilde{\kappa}, \tilde{P}, \tilde{M})$ is a solution of (3.1)–(3.2), and $\tilde{M}(L) = M(L)$. Therefore we may without loss of generality assume that $x_1 < L$. We then choose $L' = x_1$ and $\mu = \mu_1$ and construct $(\tilde{f}, g_{\mu_1}, \tilde{\kappa}, \tilde{P}, M_{\mu_1})$.

Case I. Assume that $\lambda \leq \mu_1$. Then

$$\int_{M_{\mu_1}(L)}^{\mu_1} \frac{ds}{\beta(s)} \geq \int_{M_{\mu_1}(L)}^{\lambda} \frac{ds}{\beta(s)} = 1 \geq \int_{L'}^L g(x) dx \geq \int_{M(L)}^{\mu_1} \frac{ds}{\beta(s)},$$

since $M' \geq -g\beta(M)$, $M(L') = M(x_1) = \mu_1$. Thus $M_{\mu_1}(L) \leq M(L)$.

Case II. Assume that $\mu_1 < \lambda < \mu_1 + \beta(\mu_1)$. By integrating $M'/\beta(M)$ over $[L', L]$ we get

$$\begin{aligned} \int_{M(L)}^{\mu_1} \frac{ds}{\beta(s)} &= \int_{M(L)}^{M(L')} \frac{ds}{\beta(s)} \\ &= \int_{L'}^L g(x) dx - \int_{L'}^L \frac{f(x)\alpha(P(x))}{\beta(M(x))} dx \\ &\leq \int_{L'}^L g(x) dx - \frac{1}{\beta_1} \int_{L'}^L f(x)\alpha(P(x)) dx \\ &= \int_{L'}^L g(x) dx - \frac{1}{\beta_1} \left[\int_0^L f(x)\alpha(P(x)) dx - \int_0^{L'} f(x)\alpha(P(x)) dx \right]. \end{aligned}$$

But $\int_0^L f(x)\alpha(P(x)) dx \geq \lambda$ according to the remark above (λ independent of L'), and

$$\int_0^{L'} f(x)\alpha(P(x)) dx = M(L') + \int_0^{L'} g(x)\beta(M(x)) dx \leq \mu_1 + \beta_1 \int_0^{L'} g(x) dx.$$

Thus

$$\begin{aligned} \int_{M(L)}^{\mu_1} \frac{ds}{\beta(s)} &\leq \int_{L'}^L g(x) dx - \frac{1}{\beta_1} \left[\lambda - \mu_1 - \beta_1 \int_0^{L'} g(x) dx \right] \\ &= 1 - \frac{\lambda - \mu_1}{\beta_1} = \int_{M_{\mu_1}(L)}^{\mu_1} \frac{ds}{\beta(s)}. \end{aligned}$$

Hence $M_{\mu_1}(L) \leq M(L)$.

Case III. Assume that $\lambda \geq \mu_1 + \beta(\mu_1)$. Then

$$\begin{aligned} M(L) &= \int_0^L f(x)\alpha(P(x)) dx - \int_0^L g(x)\beta(M(x)) dx \geq \lambda - \int_0^L g(x)\beta_1 dx \\ &= \lambda - \beta_1 = M_{\mu_1}(L). \end{aligned}$$

We have then proved that $M(L) \geq M_{\mu_1}(L) = F(\mu_1)$, and since by definition $F(\mu_1) \geq F(\mu^*) = M_{\mu^*}(L) = M^*(L)$, we see that $M^*(L)$ is the optimal value. \square

Remark 5.1. This gives a simpler proof of the result in [3].

Remark 5.2. It is easy to see that the function $F(\mu)$ defined above is continuously differentiable; indeed

$$F'(\mu) = \begin{cases} -\beta'(\mu) & \text{if } 0 \leq \mu + \beta(\mu) \leq \lambda, \\ -\frac{(\lambda - \mu)\beta'(\mu)\beta(F(\mu))}{[\beta(\mu)]^2} & \text{if } \mu + \beta(\mu) > \lambda \text{ and } \mu < \lambda, \\ 0 & \text{if } \mu \geq \lambda. \end{cases}$$

In particular $\beta'(\mu)F'(\mu) \leq 0$ for all μ , and we see that μ^* (where minimum is attained) is either λ or a point where $\beta' = 0$. In the latter case, if $\mu^* < \lambda$ and if $\{\mu: \beta'(\mu) = 0\}$ is a finite union of closed intervals (which may be single points), μ^* must be a local maximum point of β . We can also show (without any extra assumptions on β) that if $\mu^* \leq \lambda$, then

$$(5.2) \quad \beta(\mu^*) = \max \{\beta(\mu): 0 \leq \mu \leq \mu^*\}.$$

Proof of (5.2). Let $\mu_0 \in (0, \mu^*]$ be such that $\beta(\mu_0) = \max \{\beta(\mu): 0 \leq \mu \leq \mu^*\}$. Suppose that $\beta(\mu^*) < \beta(\mu_0)$, so that $\mu_0 < \mu^*$.

Case I. If $\mu^* + \beta(\mu^*) \leq \lambda$, then $F(\mu) = \lambda - \beta(\mu)$ for all $\mu \leq \mu^*$, because if $\mu' + \beta(\mu') > \lambda$ for some $\mu' < \mu^*$, then there is a $\mu'' < \mu'$ such that $\mu'' + \beta(\mu'') = \lambda$, and $F(\mu'') = \mu'' < \mu^* \leq \lambda - \beta(\mu^*) = F(\mu^*)$, which is impossible. Thus $\beta(\mu^*) < \beta(\mu_0)$ leads to the contradiction $F(\mu_0) < F(\mu^*)$.

Case II. If $\mu^* \leq \lambda < \mu^* + \beta(\mu^*)$, then

$$\int_{F(\mu^*)}^{\mu^*} \frac{ds}{\beta(s)} = 1 - \frac{\lambda - \mu^*}{\beta(\mu^*)}.$$

If $\mu_0 + \beta(\mu_0) \leq \lambda$, then $F(\mu_0) = \lambda - \beta(\mu_0)$, and

$$\frac{\mu^* - F(\mu^*)}{\beta(\mu_0)} < \int_{F(\mu^*)}^{\mu^*} \frac{ds}{\beta(s)} \leq 1 - \frac{\lambda - \mu^*}{\beta(\mu_0)};$$

hence $F(\mu_0) < F(\mu^*)$. If $\mu_0 + \beta(\mu_0) > \lambda$, then

$$\begin{aligned} \int_{F(\mu_0)}^{\mu_0} \frac{ds}{\beta(s)} &= 1 - \frac{\lambda - \mu_0}{\beta(\mu_0)} = 1 - \frac{\lambda - \mu^*}{\beta(\mu_0)} - \frac{\mu^* - \mu_0}{\beta(\mu_0)} \\ &\geq 1 - \frac{\lambda - \mu^*}{\beta(\mu^*)} - \frac{\mu^* - \mu_0}{\beta(\mu_0)} > \int_{F(\mu^*)}^{\mu^*} \frac{ds}{\beta(s)} - \int_{\mu_0}^{\mu^*} \frac{ds}{\beta(s)} \\ &= \int_{F(\mu^*)}^{\mu_0} \frac{ds}{\beta(s)}, \end{aligned}$$

hence again the contradiction $F(\mu_0) < F(\mu^*)$.

Thus we must have $\beta(\mu^*) = \beta(\mu_0)$. \square

SELF-TUNING TRACKERS*

P. R. KUMAR† AND L. PRALY‡

Abstract. We examine the problem of obtaining adaptive control laws which tune themselves to control laws minimizing the variance of the tracking error between the output of the linear ARMAX system and a specified reference trajectory. If the reference trajectory is sufficiently rich of order greater than or equal to the sum of the degrees of the control and noise polynomials in the ARMAX system, then an adaptive controller is exhibited for which the parameter estimates are strongly consistent. For the linear model following problem where the trajectory to be tracked is generated as the output of a linear system, it is enough for the order of sufficient richness to be greater than the degree of the noise polynomial alone. Further, if the order of sufficient richness is even smaller, as is often the case, then a lower dimensional adaptive controller which does not attempt to estimate all the coefficients of the noise polynomial is self-tuning.

Key words. adaptive control, self-tuning tracker

1. Introduction. The problem of stochastic adaptive control of linear ARMAX systems has received considerable attention over the past decade. The notable pioneering contributions are due to Åström and Wittenmark [1] and Ljung [2], [3]. Subsequently, Goodwin, Ramadge and Caines [4] and Goodwin and Sin [5] have proved the *self-optimality* of some adaptive control algorithms for minimum variance regulation and tracking. By *self-optimality* it is meant that the cost, the time average of the square of the tracking error, is minimal.

Recently a stochastic gradient algorithm has been proved to be *self-tuning* for the *regulation* problem (see [6]). (Recall that in the regulation problem one wants the output of the system to stay as close as possible to zero, whereas in the tracking problem one wants to track a given arbitrary trajectory.) By “self-tuning” it is meant that the adaptive control *law* converges to the optimal control law. This is clearly a property of fundamental interest since it implies that the adaptive controller can be used as a mechanism for tuning to the parameters of an optimal control law.

In this paper we examine the problem of minimum variance *tracking* where the goal is to ensure that the output of the system tracks a specified reference trajectory with minimal average squared tracking error.

From a purely technical viewpoint the analysis of the tracking problem along the lines of [6] has until now been stymied by the fact that a key geometric property of the adaptive control algorithm, which renders the regression and parameter estimate vectors orthogonal, holds only in the regulation problem and not in the case of tracking. Our first contribution here is to show how to overcome this difficulty by enlarging the dimension of the regression vector.

Another well-known difficulty with the tracking problem is that when the reference trajectory to be tracked is a general nonzero trajectory (we call this the *general tracking problem*), then the control law which allows the trajectory to be tracked with minimum variance does require explicit knowledge of the coefficients of the colored noise polynomial, see [4], [6], [12]. This is another feature distinguishing the tracking problem from the regulation problem. Consequently, it is necessary to identify some additional parameters pertaining to the colored noise polynomial in order to obtain self-tuning. Such identification is established in this paper under the natural assumption that the reference trajectory is sufficiently rich of appropriate order.

The second essential contribution of this paper is the examination of how one may obtain self-tuning when the reference trajectory is not so rich as to allow one to identify all the coefficients of the colored noise polynomial. For example, in an important class of practical problems, called *set-point problems*, the output of the system is required to stay as close as possible to a certain specified level. Thus the reference trajectory is a nonzero constant, which is sufficiently rich of order one only. We examine such problems, which violate the richness assumptions of the general tracking problem, by examining the problem of following trajectories which are generated by linear models. We call these the *linear model following problems*. (The set-point problem is a special case of the linear model following problem.) Our second class of main results is to show how one may adjust the *dimension* of the regression vector to the degree of excitation present in the reference trajectory. We then provide a proof of self-tuning of the resulting reduced dimension adaptive controllers.

Our main results are therefore the following:

(i) The adaptive control laws in both the general tracking problem as well as the linear model following problem are self-optimal, i.e., the average squared tracking error is minimal (Theorem 3).

(ii) In the general tracking problem, if the reference trajectory is sufficiently rich of order at least equal to the sum of the degrees of the control and noise polynomials in the ARMAX representation of the system, then the parameter estimates are strongly consistent, i.e., they converge to the true values almost surely (Theorems 6 and 7). This result also implies that the adaptive controller is self-tuning, i.e., the adaptive control law converges to the optimal control almost surely (Theorem 7).

(iii) For the parameter estimates to be strongly consistent in the linear model following problem it is enough for the order of sufficient richness of the reference trajectory to be equal to the degree of the noise polynomial alone (Theorems 6 and 7). This again implies self-tuning (Theorem 7).

(iv) Often, the degree of sufficient richness is even smaller than the degree of the noise polynomial (e.g. the set-point problem). In such linear model following problems, a lower dimensional adaptive controller can be used. This lower dimensional adaptive controller is self-tuning (Theorem 7). The parameter estimates also converge (Theorem 6). However, since no attempt is made at estimating all the coefficients of the noise polynomial, the parameter estimates do not converge to the true values (i.e. we are using a *direct* adaptive control law).

Some comments on the nature of these results in comparison with the results in *deterministic* adaptive control are useful. In deterministic adaptive control, where there is no noise in the system, one can asymptotically obtain zero tracking error. However in stochastic adaptive control there is noise and one wants to reject as much of the noise as possible. Clearly *optimal* noise rejection will depend critically on the knowledge of the correlations inherent in the possibly colored noise. This is where the central problem of estimating the colored noise coefficients enters into the stochastic adaptive

control problem. Indeed, in the present paper, the need for richness in the reference trajectory is intimately related precisely to the need for estimating the model of the colored noise.

2. The adaptive control laws. We consider the ARMAX system

$$(1) \quad y(t) = \sum_{i=1}^p a_i y(t-i) + \sum_{i=1}^q b_i u(t-i) + \sum_{i=1}^s c_i w(t-i) + w(t)$$

where y , u and w are, respectively, the output, input and white noise. The parameters $(a_1, \dots, a_p, b_1, \dots, b_q, c_1, \dots, c_s)$ are unknown. The goal is to design an adaptive control law which ensures that the output follows a given bounded reference trajectory $\{y^*(t)\}$ with minimal average squared tracking error, and such that the adaptive control law asymptotically self-tunes to the optimal control law. It is an added bonus if the true parameters $(a_1, \dots, a_p, b_1, \dots, b_q, c_1, \dots, c_s)$ can also be asymptotically identified.

If the reference trajectory is arbitrary, we shall refer to this problem as the *general tracking problem*. In many problems however the reference trajectory is generated as the output of a *linear model*. We shall refer to such a special case as the *linear model following problem*. The special properties of a reference trajectory generated as the output of a linear model can be usefully exploited, as we will see in the sequel. We now discuss separately the general tracking problem and the linear model following problem.

2.1. The general tracking problem. In this case $\{y^*(t)\}$ is just a reference trajectory to be tracked with no special properties. We will use the following adaptive controller (with the notation $p \vee s := \max(p, s)$).

$$(2) \quad \theta(t+1) = \theta(t) + \frac{\mu \phi(t)}{r(t)} [y(t+1) - y^*(t+1)]$$

where, for the time being, $0 < \mu < 2$ is an arbitrary constant (but see the remark at the end of § 4).

$$(3) \quad r(t+1) := 1 + \sum_{k=0}^{t+1} \phi^T(k) \phi(k),$$

$$(4) \quad \phi(t) := (y(t), \dots, y(t-p \vee s+1), u(t), \dots, u(t-q+1), \\ -y^*(t+1), \dots, -y^*(t-s+1)),$$

$$(5) \quad u(t) := \frac{-1}{\beta_1(t)} \left[\sum_{i=1}^{p \vee s} \alpha_i(t) y(t-i+1) + \sum_{i=2}^q \beta_i(t) u(t-i+1) - \sum_{i=0}^s \gamma_i(t) y^*(t-i+1) \right]$$

where

$$(6) \quad (\alpha_1(t), \dots, \alpha_{p \vee s}(t), \beta_1(t), \dots, \beta_q(t), \gamma_0(t), \dots, \gamma_s(t))^T := \theta(t).$$

Note that (5) can equivalently be written as

$$(7) \quad \phi^T(t) \theta(t) = 0.$$

The motivation behind this adaptive controller is the following. Rewrite the system (1) as,

$$y(t+1) - y^*(t+1) = \left[\sum_{i=1}^p a_i y(t+1-i) + \sum_{i=1}^q b_i u(t+1-i) + \sum_{i=1}^s c_i w(t+1-i) - y^*(t+1) \right] \\ + w(t+1).$$

If one could observe the past of $w(\cdot)$ at each time t , then an optimal controller would

choose $u(t)$ so that the term in $[\cdot \cdot \cdot]$ on the right-hand side above is zero, i.e.

$$u(t) = \frac{-1}{b_1} \left[\sum_{i=1}^p a_i y(t+1-i) + \sum_{i=2}^q b_i u(t+1-i) + \sum_{i=1}^s c_i w(t+1-i) - y^*(t+1) \right],$$

for this would result in $y(t+1) = y^*(t+1) + w(t+1)$, clearly yielding the best possible tracking error. However, the sequence $w(\cdot)$ is *not* observed, and so let us replace it by $y(\cdot) - y^*(\cdot)$, which is what we hope it would be, at least asymptotically. This gives the implementable control law,

$$u(t) = \frac{-1}{b_1} \left[\sum_{i=1}^{p \vee s} (a_i + c_i) y(t+1-i) + \sum_{i=2}^q b_i u(t+1-i) - \sum_{i=1}^s c_i y^*(t+1-i) - y^*(t+1) \right].$$

It can be shown that this control law is actually optimal with respect to the long run average of the square of the tracking error; for more details, see [12]. Let us define,

$$(8) \quad \theta^o := (a_1 + c_1, \dots, a_{p \vee s} + c_{p \vee s}, b_1, \dots, b_q, 1, c_1, \dots, c_s)^T$$

(where, for convenience, we define $c_i := 0$ for $i > s$ and $a_i := 0$ for $i > p$ in (8)), and, under optimal control, the system (1) can be represented as

$$y(t+1) - y^*(t+1) = \phi^T(t) \theta^o + w(t+1),$$

while the optimal control law can be written as one which chooses $u(t)$ to satisfy,

$$\phi^T(t) \theta^o = 0.$$

Our adaptive control scheme (2)–(6) can be interpreted as trying to estimate θ^o when the system is being optimally controlled.

Remark. Note that the $(p \vee s + q + 1)$ th component of θ^o is 1, and hence is a *known* quantity. However, the estimator ignores this knowledge and estimates it anyway by $\gamma_0(t)$. We can therefore regard (2, 3) as an *unnormalized* parameter estimator. It follows that this parameter estimator is one dimension larger than that considered in Goodwin, Ramadge and Caines [4]. In this connection, it is also of interest to note that recently Wei [7] has proposed an estimator for the regulation problem which is one dimension less than [4], [6].

2.2. The linear model following problem. In many situations of interest the reference trajectory is generated, at least asymptotically, as the output of a linear model. We shall suppose that there is a sequence $\{y_m(t)\}$ such that

$$(9) \quad y_m(t) = \sum_{i=1}^l h_i y_m(t-i)$$

and the trajectory to be tracked $y^*(t)$ is asymptotically close to $y_m(t)$ in that

$$(10) \quad \sum_{t=1}^{\infty} (y^*(t) - y_m(t))^2 < +\infty.$$

Without loss of generality we can make the following two assumptions:

- (11)(i) There is no lower order difference equation satisfied by $\{y_m(t)\}$, i.e., there is *no* nontrivial polynomial $\bar{H}(z)$ of degree strictly less than l such that $\bar{H}(z)y_m(t) = 0$ for all t . (z is the *backward* shift operator.)
- (11)(ii) The roots of $H(z) := 1 - \sum_{i=1}^l h_i z^i$ are exactly on the unit circle and there are no repeated roots.

Assumption (11)(i) is without loss of generality since otherwise we could simply replace $H(z)$ in (9) by $\bar{H}(z)$. Note that this also means that the initial conditions on (9) are sufficient to excite *all* the modes of $H(z)$. Assumption (11)(ii) is also without loss of generality due to the following reasons. First, since we intend to work only with *bounded* $\{y^*(t)\}$, and since all the modes of $H(z)$ are excited, we have to assume that $H(z)$ has roots on or outside the unit circle, and also that the roots on the unit circle are not repeated. However, since we are only interested in the *asymptotic* behavior of $\{y^*(t)\}$, we can eliminate all the modes corresponding to roots of $H(z)$ which are strictly outside the unit circle, since they decay geometrically to 0. This leaves us with (11)(ii).

It is worth noting that (11)(i) and (11)(ii) together imply that

$$y_m(t) = d_0 + d_1(-1)^t + \sum d_i \sin(\omega_i t + \delta_i).$$

Depending on how large l is, we will use adaptive controllers with parameter estimators of different dimensions.

Case 1. $l \leq s$. Recall that s is the degree of the noise polynomial in (1). When $l \leq s$, we will reduce the dimension of the parameter estimator by $(s+1-l)$ components by replacing (4)–(6) by the following:

$$(12) \quad \phi(t) := (y(t), \dots, y(t-p \vee s+1), u(t), \dots, u(t-q+1), \\ -y^*(t+1), \dots, -y^*(t+2-l))^T,$$

$$(13) \quad \theta(t) := (\alpha_1(t), \dots, \alpha_{p \vee s}(t), \beta_1(t), \dots, \beta_q(t), \gamma_0(t), \dots, \gamma_{l-1}(t))^T,$$

and

$$(14) \quad u(t) = \frac{-1}{\beta_1(t)} \left[\sum_{i=1}^{p \vee s} \alpha_i(t) y(t-i+1) + \sum_{i=2}^q \beta_i(t) u(t-i+1) - \sum_{i=0}^{l-1} \gamma_i(t) y^*(t-i+1) \right],$$

or equivalently by (7).

The idea underlying the above adaptive control law is the following. If the parameters were known, the minimum variance adaptive control law would be,

$$u(t) = \frac{-1}{b_1} \left[\sum_{i=1}^{p \vee s} (a_i + c_i) y(t-i+1) + \sum_{i=2}^q b_i u(t-i+1) - y^*(t+1) - \sum_{i=1}^s c_i y^*(t-i+1) \right],$$

see [12] for details. In this control law the only terms featuring y^* are $y^*(t+1) + \sum_{i=1}^s y^*(t-i+1) = C(z)y^*(t+1)$. Thus the control law really only requires knowledge of $C(z)y^*(t)$. Let

$$(15) \quad G(z) := \sum_{i=0}^{l-1} g_i z^i$$

be a polynomial satisfying,

$$(16) \quad C(z) = F(z)H(z) + G(z)$$

for some

$$(17) \quad F(z) := \sum_{i=0}^{s-l} f_i z^i.$$

Such polynomials $G(z)$ and $F(z)$ are the remainder and quotient, respectively, when the polynomial $C(z)$ is divided by the polynomial $H(z)$. Then, asymptotically at least,

$$C(z)y^*(t) = [F(z)H(z) + G(z)]y^*(t) = F(z)H(z)y^*(t) + G(z)y^*(t) = G(z)y^*(t),$$

since by (9.10), $H(z)y^*(t) = 0$ holds asymptotically. Thus we only need knowledge of $G(z)y^*(t)$ in order to implement the true minimum variance control law. We can therefore interpret the parameter estimate (13) as trying to estimate

$$(18) \quad \theta^0 := (a_1 + c_1, \dots, a_{pvs} + c_{pvs}, b_1, \dots, b_q, g_0, g_1, \dots, g_{l-1})^T.$$

Remarks. (i) The adaptive controller need not be provided with the precise information about what the polynomial $H(z)$ is. It only needs knowledge of the *degree* of $H(z)$.

(ii) It should be noted that the parameter estimator is no more “unnormalized,” since the coefficients g_0, \dots, g_{l-1} are all unknown.

Case 2: $l \geq s + 1$. Since $(s + 1 - l) \leq 0$ when $l \geq s + 1$, no savings in dimensionality can be achieved. Hence we will use the same adaptive control law as (2)–(7). For this case also we define θ^o as in (8).

3. Sufficient richness. In the sequel we will prove that all the coefficients $(a_1, \dots, a_p, b_1, \dots, b_q, c_1, \dots, c_s)$ can be asymptotically identified when the reference trajectory $\{y^*(t)\}$ is “sufficiently rich” in an appropriate sense. We have the following definition.

DEFINITION. We shall say that a scalar sequence $\{y^*(t)\}$ is *strongly sufficiently rich of order l* if l is the largest nonnegative integer for which there exists an n and an $\varepsilon > 0$ such that

$$\sum_{k=t+1}^{t+n} (y^*(k-1), \dots, y^*(k-l))^T (y^*(k-1), \dots, y^*(k-l)) \geq \varepsilon I_l \quad \text{for all } t \text{ large enough.}$$

I_l here is the $l \times l$ identity matrix.

The following property of $\{y_m(t)\}$, and also $\{y^*(t)\}$, generated by the linear model (9), (10), (11)(i), (ii) should be noted.

LEMMA 1. Suppose $\{y^*(t)\}$ and $\{y_m(t)\}$ satisfy (9)–(11). Then both $\{y^*(t)\}$ and $\{y_m(t)\}$ are strongly sufficiently rich of order l .

Proof. We will show that there exists $\varepsilon > 0$ such that

$$\sum_{k=t+1}^{t+l} Y_l(k-1) \geq \varepsilon I_l \quad \text{for all } t \text{ large enough}$$

where

$$Y_l(k-1) := (y_m(k-1), \dots, y_m(k-l))^T (y_m(k-1), \dots, y_m(k-l)).$$

Suppose this is not true. Then there exists a sequence of vectors $\{x(t_n)\}$, with each $\|x(t_n)\| = 1$ and $x(t_n) := (x_1(t_n), \dots, x_l(t_n))^T$ such that

$$x^T(t_n) \sum_{k=t_n+1}^{t_n+l} Y_l(k-1) x(t_n) \leq \frac{1}{n}.$$

We can also assume without loss of generality that $\lim_n x(t_n) =: x$ exists with $\|x\| = 1$, $x := (x_1, \dots, x_l)^T$. Moreover, since $\{y_m(t)\}$ is bounded, $\{Y_l(k-1)\}$ is also bounded and so

$$\lim_n x^T \sum_{k=t_n+1}^{t_n+l} Y_l(k-1) x = 0.$$

Let $X(z) := \sum_{i=1}^l x_i z^i$. Interpreting z as the *backward* shift operator, we have

$$\lim_n \sum_{k=t_n+1}^{t_n+l} [X(z)y_m(k)]^2 = 0.$$

This implies that

$$\lim_n X(z)y_m(t_n + i) = 0 \quad \text{for } i = 1, 2, \dots, l.$$

Now note that $H(z)X(z)y_m(t) = X(z)H(z)y_m(t) = 0$ and so

$$X(z)y_m(t) = \sum_{k=1}^l \delta_k \lambda_k^t$$

where $\{\lambda_k\}$ is the set of roots of $H(z)$. Hence we have

$$\lim_n \sum_{k=1}^l \delta_k \lambda_k^{t_n+i} = 0 \quad \text{for } i = 1, \dots, l.$$

This can also be written as

$$\lim_n \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 \\ \lambda_1 & \lambda_2 & & & & \lambda_l \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \lambda_1^{l-1} & \lambda_2^{l-1} & & & & \lambda_l^{l-1} \end{bmatrix} \begin{bmatrix} \lambda_1^{t_n+1} & 0 & 0 & 0 & 0 & 0 \\ 0 & \lambda_2^{t_n+1} & & & & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & & & & \lambda_l^{t_n+1} \end{bmatrix} \begin{bmatrix} \delta_1 \\ \delta_2 \\ \vdots \\ \delta_l \end{bmatrix} = 0.$$

The first matrix on the left-hand side above is the Vandermonde matrix which is nonsingular since all the λ_k 's are distinct. Moreover $|\lambda_k| = 1$ for all k , and so it follows that $\delta_k = 0$ for $k = 1, \dots, l$. This however implies that $X(z)y_m(t) = 0$ for all t . However $X(z)$ is a polynomial of degree $l-1$ or less, and by (11)(i), it follows that $X(z) = 0$, i.e., $\|x\| = 0$. This is a contradiction to $\|x\| = 1$, proving that $\{y_m(t)\}$ is indeed strongly sufficiently rich of order l . By (10) it follows trivially that $\{y^*(t)\}$ is also strongly sufficiently rich of order l . (Actually it is enough that $\lim_t (y_m(t) - y^*(t)) = 0$). \square

For future reference, we also have the following result.

LEMMA 2. Let $S(t, z) := \sum_{i=0}^j s_i(t)z^i$. Suppose $\{s_i(t)\}$ is bounded for $i = 0, \dots, j$ and $\lim_t |s_i(t) - s_i(t-1)| = 0$ for $i = 0, \dots, j$. Suppose also that for some sequence $\{x(t)\}$,

$$\lim_N \frac{1}{N} \sum_{t=1}^N [S(t, z)y_m(t)]^2 = 0 \quad \text{and} \quad \lim_N \frac{1}{N} \sum_{t=1}^N x^2(t) = 0.$$

Then there exists a common subsequence $\{t_k\}$ with $\lim_k x(t_k) = 0$ and $\lim_k S(t_k, z) = K(z)H(z)$ for some polynomial $K(z)$. (By $S(t, z)y_m(t)$ we mean $\sum_{i=0}^j s_i(t)y_m(t-i)$.)

Proof. Since $\lim_t |s_i(t) - s_i(t+n)| = 0$ for every n and $\{y_m(t)\}$ is bounded, it is also true that $\lim_N \frac{1}{N} \sum_{t=1}^N [S(t+n, z)y_m(t)]^2 = 0$ for every n . Hence we can sum over n and also add $x^2(t)$ to get

$$\lim_N \frac{1}{N} \sum_{t=1}^N \left\{ x^2(t) + \sum_{n=1}^l [S(t, z)y_m(t-n)]^2 \right\} = 0.$$

Hence there is a subsequence $\{t_k\}$ such that

$$\lim_k S(t_k, z)y_m(t_k - n) = 0 \quad \text{for } n = 1, \dots, l, \quad \lim_k x(t_k) = 0.$$

Further we can also assume without loss of generality that

$$\lim_k S(t_k, z) =: S(z)$$

exists, by which we mean that $\lim_k s_i(t_k) =: s_i$ exists for $i = 0, \dots, j$ and $S(z) := \sum_{i=0}^j s_i z^i$. Further, since $\{y_m(t)\}$ is bounded, it follows that

$$\lim_k S(z)y_m(t_k - n) = 0 \quad \text{for } n = 1, \dots, l.$$

Note that $H(z)S(z)y_m(t) = 0$ for all t , and so

$$S(z)y_m(t) = \sum_{n=1}^l \delta_n \lambda_n^t$$

where $\{\lambda_n\}$ is the set of roots of $H(z)$. Proceeding just as in the proof of Lemma 1, it follows that

$$S(z)y_m(t) = 0 \quad \text{for all } t.$$

Now let $U(z)$ be the greatest common divisor of $S(z)$ and $H(z)$. Then there exist polynomials $R(z)$ and $T(z)$ such that $R(z)S(z) + T(z)H(z) = U(z)$. Hence $U(z)y_m(t) = 0$ for all t . However, since the degree of $U(z)$ is less than or equal to l , it follows from (11)(i) that $U(z) = \xi H(z)$ for some scalar ξ , and so the lemma is proved. \square

4. Assumptions. Define the polynomials

$$A(z) := 1 - \sum_{i=1}^p a_i z^i,$$

$$B(z) := \sum_{i=1}^q b_i z^{i-1},$$

$$C(z) := 1 + \sum_{i=1}^s c_i z^i.$$

Throughout this paper we employ the following assumptions only.

- (19)(i) All the roots of $B(z)$ and $C(z)$ are strictly outside the unit circle.
- (19)(ii) $\operatorname{Re} \left[C(e^{i\omega}) - \frac{\mu}{2} \right] > 0$ for $0 \leq \omega < 2\pi$.
- (19)(iii) $b_1 \neq 0$.
- (19)(iv) $z^{-1}[C(z) - A(z)]$ and $B(z)$ are polynomials of degrees respectively equal to $(p \vee s - 1)$ and $(q - 1)$, which have no common factors.
- (19)(v) $\{w(t)\}$ is a sequence of scalar random variables on a probability space $\{\Omega, F, P\}$, whose distributions are all mutually absolutely continuous with respect to Lebesgue measure.
- (19)(vi) Let $F_t := \sigma\{w(1), \dots, w(t)\}$ be the sub- σ -algebra of F generated by $\{w(1), \dots, w(t)\}$. We assume that there are $\sigma^2 > 0$ and $\delta > 0$ such that

$$E[w(t) | F_{t-1}] = 0 \quad \text{a.s.},$$

$$E[w^2(t) | F_{t-1}] = \sigma^2 \quad \text{a.s.},$$

$$\sup_t E[|w(t)|^{2+\delta} | F_{t-1}] < +\infty \quad \text{a.s.}$$

$$(19)(vii) \quad \|\theta(0)\| > 0.$$

$$(19)(viii) \quad \{y^*(t)\} \text{ is bounded.}$$

It should be noted that the condition (19)(v) guarantees that the controls are well defined a.s. through (5.14) since the event $\{\beta_1(t) = 0\}$ is a null event, see Caines and Meyn [9].

Remark. Let us consider a different constant μ_1 in place of μ in (2). It is easy to verify, see [12], that the resulting adaptive control algorithm produces parameter estimates $\theta_1(t) = (\mu_1/\mu)\theta(t)$ and *identical* inputs and outputs as the original algorithm using μ , provided $\theta_1(0)$ is chosen as $\theta_1(0) := (\mu_1/\mu)\theta(0)$. This property relies on the fact that the control input $u(t)$ is invariant with respect to scaling of $\theta(t)$ in (7). Making use of this observation, it follows that one need not restrict μ to lie in $(0, 2)$; it is enough to have $\mu \neq 0$. Further, one only needs the assumption

$$(19)(ii) \quad \operatorname{Re} C(e^{i\omega}) > 0 \quad \text{for } 0 \leq \omega < 2\pi$$

in place of (19)(ii).

5. Self-optimality. In this section we will prove the following theorem which asserts, among other things, that in all cases the adaptive controller minimizes the average squared tracking error.

THEOREM 3.

$$(20)(i) \quad \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{t=1}^N [y(t) - y^*(t)]^2 = \sigma^2 \quad \text{a.s.,}$$

$$(20)(ii) \quad \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{t=1}^N (E[y(t+1) - y^*(t+1) | F_t])^2 = 0 \quad \text{a.s.,}$$

$$(20)(iii) \quad \limsup_N \frac{1}{N} \sum_{t=1}^N u^2(t) < +\infty \quad \text{a.s.,}$$

$$(20)(iv) \quad \lim_t \|\theta(t) - \theta^o\|^2 \text{ exists and is finite a.s.}$$

Proof. We will abbreviate those details of the proof which are similar to those of Goodwin, Ramadge and Caines [4] or [6]. Let $\tilde{\theta}(t) := \theta(t) - \theta^o$ and define $V(t) := \|\tilde{\theta}(t)\|^2$. Using $r(t) \equiv \phi^T(t)\phi(t)$ and $\phi^T(t)\tilde{\theta}(t) = -\phi^T(t)\theta^o$, we can get

$$\begin{aligned} E[V(t+1) | F_t] &\leq V(t) - \frac{2\mu}{r(t)} \left\{ \phi^T(t)\theta^o - \frac{\mu + \delta}{2} E[y(t+1) - y^*(t+1) | F_t] \right\} \\ &\quad \cdot E[y(t+1) - y^*(t+1) | F_t] - \frac{\mu\delta}{r(t)} (E[y(t+1) - y^*(t+1) | F_t])^2 \\ &\quad + \mu^2 \frac{\phi^T(t)\phi(t)}{r^2(t)} \sigma^2 \end{aligned}$$

for all δ . Choose $\delta > 0$ so small that $[C(z) - (\mu + \delta)/2]$ is strictly positive real. Let us first consider the following case.

Case 1. *General tracking problem or the linear model following problem with $l \geq s + 1$.*

$$\begin{aligned}
 C(z)E[y(t+1) - y^*(t+1)|F_t] &= C(z)[y(t+1) - y^*(t+1) - w(t+1)] \\
 &= [y(t+1) - y^*(t+1) - w(t+1)] \\
 &\quad + [C(z) - 1][y(t+1) - y^*(t+1) - w(t+1)] \\
 &= [y(t+1) - y^*(t+1) - w(t+1)] \\
 &\quad + \sum_{i=1}^s c_i[y(t-i+1) - y^*(t-i+1) - w(t-i+1)] \\
 (21) \quad &= \left[y(t+1) - w(t+1) - \sum_{i=1}^s c_i w(t-i+1) \right] - y^*(t+1) \\
 &\quad + \sum_{i=1}^s c_i[y(t-i+1) - y^*(t-i+1)] \\
 &= \sum_{i=1}^{p \vee s} (a_i + c_i)y(t-i+1) + \sum_{i=1}^q b_i u(t-i+1) \\
 &\quad - y^*(t+1) - \sum_{i=1}^s c_i y^*(t-i+1) \\
 &= \phi^T(t)\theta^o.
 \end{aligned}$$

By the strict positive realness of $[C(z) - (\mu + \delta)/2]$ it therefore follows that

$$\begin{aligned}
 S(n) &:= 2\mu \sum_{t=1}^n \left\{ \phi^T(t)\theta^o - \frac{\mu + \delta}{2} E[y(t+1) - y^*(t+1)|F_t] \right\} E[y(t+1) - y^*(t+1)|F_t] \\
 &\geq K \quad \text{a.s. for all } n, \text{ for some } K.
 \end{aligned}$$

Defining $M(t) := V(t) + S(t-1)/r(t-1)$, and using $r(t) \geq r(t-1) > 0$, it follows that

$$E[M(t+1)|F_t] \leq M(t) - \frac{\mu\delta}{r(t)} (E[y(t+1) - y^*(t+1)|F_t])^2 + \frac{\mu^2 \phi^T(t)\phi(t)}{r^2(t)} \sigma^2.$$

The last term above is summable a.s., and so using the Positive Near Supermartingale Convergence Theorem we can get:

- (i) $\{M(t)\}$ converges a.s.,
- (ii) $\sum_{t=1}^{\infty} \frac{(E[y(t+1) - y^*(t+1)|F_t])^2}{r(t)} < +\infty$ a.s.

Now we claim that $\lim_t r(t) = +\infty$ a.s. Otherwise $r_t = 1 + \sum_{i=1}^t \phi^T(k)\phi(k)$ would lead to $\lim_t \phi(t) = 0$ on a set of positive probability. This in turn would imply $\lim_t y_t = 0$ and $\lim_t u_t = 0$, and from the system equation (1) it would then have to follow that $\lim_t C(z)w(t) = 0$ on a set of positive probability, which we will now contradict as follows. First note that $(C(z)w(t))^2$ is a linear combination of terms of the form $w^2(t-i)$ and $w(t-i)w(t-j)$. Let us first examine the first set of square terms. As a consequence of (19)(vi) and Jensen's and Minkowski's inequalities, it follows that $\sup_t E[|w^2(t) - E(w^2(t)|F_{t-1})|^{1+\delta/2}|F_{t-1}] < \infty$ a.s. Chow's Theorem [10, Thm. 3.3.1] is therefore applicable, and shows that $\lim_N 1/N \sum_{t=1}^N w^2(t) = \sigma^2$ a.s. Now we turn to the cross terms. Since $\sum_{t=1}^{\infty} w^2(t-i) = \infty$ a.s., an appeal to the Local Convergence Theorem for Martingales [11, Lemma 2.3] shows that $\sum_{t=1}^N 2w(t-i)w(t) = o(\sum_{t=1}^N w^2(t-i))$ a.s. Hence

$\lim_N 1/N \sum_{t=1}^N w(t-i)w(t) = 0$ a.s. Adding up the contributions, we get $\lim_N 1/N \sum_{t=1}^N (C(z)w(t))^2 = 1 + \sum_{i=1}^s c_i^2 > 0$ a.s. This provides the required contradiction.

Since $\lim_t r(t) = +\infty$ a.s., Kronecker's Lemma is applicable and gives

$$\lim_N \frac{1}{r(N)} \sum_{t=1}^N (E[y(t+1) - y^*(t+1) | F_t])^2 = 0 \quad \text{a.s.}$$

Utilizing the strictly minimum phase property of $B(z)$ it follows that $\{r(N)/N\}$ is bounded a.s., which proves (20)(iii) and (20)(ii). The same arguments as in Lemma 7 and Lemma 9 of [6] yield (20)(i) and (20)(iv).

Case 2. Linear model following problem with $l \leq s$. Just as in (21) we still get

$$\begin{aligned} C(z)E[y(t+1) - y^*(t+1) | F_t] &= \sum_{i=1}^{p \vee s} (a_i + c_i)y(t-i+1) + \sum_{i=1}^q b_i u(t-i+1) \\ &\quad - C(z)y^*(t+1). \end{aligned}$$

Let $\tilde{y}(t) := y_m(t) - y^*(t)$. Then from (9) and (16) we get

$$\begin{aligned} C(z)y^*(t+1) &= C(z)y_m(t+1) - C(z)\tilde{y}(t+1) \\ &= G(z)y_m(t+1) - C(z)\tilde{y}(t+1) \\ &= G(z)y^*(t+1) + [G(z) - C(z)]\tilde{y}(t+1). \end{aligned}$$

Hence

$$\begin{aligned} C(z)E[y(t+1) - y^*(t+1) | F_t] &= \sum_{i=1}^{p \vee s} (a_i + c_i)y(t-i+1) + \sum_{i=1}^q b_i u(t-i+1) \\ &\quad - G(z)y^*(t+1) + [C(z) - G(z)]\tilde{y}(t+1) \\ &= \phi^T(t)\theta^o + [C(z) - G(z)]\tilde{y}(t+1). \end{aligned}$$

By the strict positive realness property of $[C(z) - (\mu + \delta)/2]$, it follows that

$$\begin{aligned} S(n) &:= 2\mu \sum_{t=1}^n \left\{ \phi^T(t)\theta^o + [C(z) - G(z)]\tilde{y}(t+1) \right. \\ &\quad \left. - \frac{\mu + \delta}{2} E[y(t+1) - y^*(t+1) | F_t] \right\} \\ &\quad \cdot E[y(t+1) - y^*(t+1) | F_t] \\ &\geq K \quad \text{a.s. for all } n, \text{ for some } K. \end{aligned}$$

Defining $M(t) := V(t) + S(t-1)/r(t-1)$, we get

$$\begin{aligned} E[M(t+1) | F_t] &\leq M(t) - \frac{\mu\delta}{r(t)} (E[y(t+1) - y^*(t+1) | F_t])^2 + \mu^2 \frac{\phi^T(t)\phi(t)}{r^2(t)} \sigma^2 \\ &\quad + \frac{2\mu}{r(t)} E[y(t+1) - y^*(t+1) | F_t][C(z) - G(z)]\tilde{y}(t+1). \end{aligned}$$

Define $\bar{y}(t) := [C(z) - G(z)]\tilde{y}(t+1)$, and note that by (10), $\sum_{t=1}^{\infty} \bar{y}^2(t) < +\infty$. For any $\rho > 0$, we have

$$2E[y(t+1) - y^*(t+1) | F_t]\bar{y}(t) \leq \rho^2 (E[y(t+1) - y^*(t+1) | F_t])^2 + \left(\frac{\bar{y}(t)}{\rho} \right)^2.$$

Hence, choose ρ so small that $(\mu\delta - 2\mu\rho^2) > 0$, and note that

$$\begin{aligned} E[M(t+1)|F_t] \leq M(t) - \frac{(\mu\delta - 2\mu\rho^2)}{r(t)} (E[y(t+1) - y^*(t+1)|F_t])^2 \\ + \frac{\mu^2 \phi^T(t)\phi(t)}{r^2(t)} \sigma^2 + \frac{2\mu\bar{y}^2(t)}{\rho^2 r(t)}. \end{aligned}$$

Now both of the last two terms are summable, and so we can again use the Positive Near Supermartingale Convergence Theorem. The rest of the proof is similar to the previous case. \square

By (20)(i) of the above theorem, we see that usage of the adaptive controller leads to a value of σ^2 for the average of the square of the tracking error. In order to justify our claim at the beginning of this section that the adaptive controller *minimizes* the average of the square of the tracking error, we need to show that no other nonanticipative controller, including possibly controllers which utilize knowledge of the parameters (a_i, b_i, c_i) , can realize a smaller value than σ^2 for the average squared tracking error on any set of sample paths of positive measure. This is provided in the following lemma.

LEMMA 4. Consider the ARMAX system (1). Let $F_t := \sigma(w_s \text{ for } s \leq t \text{ and } y_i, u_i \text{ for } i \leq 0)$ be the σ -algebra generated by the past, and let $\{u_t\}$ be any control sequence chosen so that $u_t \in F_t$, i.e. u_t is F_t -measurable for each $t \geq 0$. Then,

$$\liminf_N \frac{1}{N} \sum_{t=1}^N (y(t) - y^*(t))^2 \geq \sigma^2 \quad \text{a.s.}$$

Proof. Define

$$g(t-1) := \left[\sum_{i=1}^p a_i y(t-i) + \sum_{i=1}^a b_i u(t-i) + \sum_{i=1}^s c_i w(t-i) \right],$$

and note that $g(t-1) \in F_{t-1}$. Rewrite the system equation (1) as $y(t) = g(t-1) + w(t)$ and get

$$y^2(t) = \frac{1}{N} \sum_{t=1}^N g^2(t-1) \left[1 + \frac{\sum_{t=1}^N 2g(t-1)w(t)}{\sum_{t=1}^N g^2(t-1)} \right] + \frac{1}{N} \sum_{t=1}^N w^2(t).$$

Appealing to the Local Convergence Theorem for Martingales [12, Lemma 2.3], we know that except on a null set,

$$\begin{aligned} \sum_{t=1}^N 2g(t-1)w(t) &= o\left(\sum_{t=1}^N g^2(t-1)\right) \quad \text{if } \sum_{t=1}^N g^2(t) = \infty, \\ &< \infty \quad \text{if } \sum_{t=1}^N g^2(t) < \infty. \end{aligned}$$

In either case, therefore, it follows that

$$\liminf_N \frac{1}{N} \sum_{t=1}^N g^2(t-1) \left[1 + \frac{\sum_{t=1}^N 2g(t-1)w(t)}{\sum_{t=1}^N g^2(t-1)} \right] \geq 0 \quad \text{a.s.}$$

Hence,

$$\begin{aligned} \liminf_N \frac{1}{N} \sum_{t=1}^N y^2(t) &\geq \lim_N \frac{1}{N} \sum_{t=1}^N w^2(t) \\ &= \sigma^2 \quad \text{a.s.} \end{aligned}$$

The last equality has been proved in the course of the proof of Theorem 3. \square

6. Self-tuning and convergence. In this section we address the self-tuning and convergence properties of the adaptive controllers.

First due to (2.7) we have the same geometrical properties as in [6]. This gives us the following lemma, see [6].

LEMMA 5.

- (22)(i) $\lim_t \|\theta(t)\|$ exists and is finite a.s.
 (22)(ii) For every n , $\lim_t \|\theta(t) - \theta(t-n)\| = 0$ a.s.
 (22)(iii) $\|\theta(t+1)\| \geq \|\theta(t)\|$.
 (22)(iv) If there is a random scalar ξ and a random subsequence $\{t_k\}$ such that
- $$\lim_k \theta(t_k) = \xi \theta^o \quad \text{a.s.}$$

then

$$\lim_t \theta(t) = \xi \theta^o \quad \text{a.s.}$$

So in order to prove that $\lim_t \theta(t) = \xi \theta^o$ it is sufficient to show that there is just one subsequence for almost every sample path along which such a limit exists.

THEOREM 6. (i) Suppose that $\{y^*(t)\}$ in the general tracking problem is strongly sufficiently rich of order $(s+q)$. Then

$$(23) \quad \lim_t \theta(t) = \xi \theta^o \quad \text{a.s.}$$

for some a.s. finite nonzero scalar random variable ξ .

(ii) The result (23) holds in the linear model following problem irrespective of the order of strong sufficient richness of $\{y^*(t)\}$ (using the appropriate definition of θ^o as in (8) or (17)).

Proof. We start with (20)(ii) which can be written as

$$(24) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{[1-A(z)]y(t+1) + zB(z)u(t+1) + [C(z)-1]w(t+1) - y^*(t+1)\}^2 = 0.$$

Define the time varying polynomials

$$P(t, z) := \sum_{i=1}^{p \vee s} \alpha_i(t) z^{i-1},$$

$$Q(t, z) := \sum_{i=1}^q \beta_i(t) z^{i-1},$$

$$R(t, z) := \begin{cases} \sum_{i=0}^{t-1} \gamma_i(t) z^i & \text{in the linear model following problem with } l \leq s, \\ \sum_{i=0}^s \gamma_i(t) z^i & \text{otherwise.} \end{cases}$$

We shall interpret z as the backward shift operator. Thus, to illustrate the notation,

$$Q(t, z)x(t) := \sum_{i=1}^q \beta_i(t)x(t-i+1); \quad Q(t, z)B(z)x(t) := \sum_{i=1}^q \beta_i(t) \sum_{j=1}^q b_j x(t-i-j+2),$$

$$B(z)Q(t, z)x(t) := \sum_{j=1}^q b_j \sum_{i=1}^q \beta_i(t-j+1)x(t-i-j+2).$$

Though $Q(t, z)B(z)x(t) \neq B(z)Q(t, z)x(t)$, it should be noted that if $\{1/N \sum_{t=1}^N x^2(t)\}$ is bounded, then it is true that

$$\lim_N \frac{1}{N} \sum_{t=1}^N [Q(t, z)B(z)x(t) - B(z)Q(t, z)x(t)]^2 = 0.$$

To verify this, one needs to use the facts that $\lim_t \|\theta(t) - \theta(t-n)\| = 0$ a.s. and $\{\theta(t)\}$ is bounded a.s.

Multiplying inside the summation in (24) by $Q(t, z)$, we have

$$\begin{aligned} \lim_N \frac{1}{N} \sum_{t=1}^N \{Q(t, z)[1 - A(z)]y(t+1) + Q(t, z)zB(z)u(t+1) \\ + Q(t, z)[C(z) - 1]w(t+1) - Q(t, z)y^*(t+1)\}^2 = 0 \quad \text{a.s.} \end{aligned}$$

Since

$$\left\{ \frac{1}{N} \sum_{t=1}^N y^2(t) \right\}, \left\{ \frac{1}{N} \sum_{t=1}^N u^2(t) \right\}, \left\{ \frac{1}{N} \sum_{t=1}^N w^2(t) \right\}, \left\{ \frac{1}{N} \sum_{t=1}^N y^{*2}(t) \right\}$$

are all bounded, we can interchange the polynomials above to get

$$\begin{aligned} (25) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{z^{-1}[1 - A(z)]Q(t, z)y(t) + B(z)Q(t, z)u(t) \\ + z^{-1}[C(z) - 1]Q(t, z)w(t) - Q(t, z)y^*(t+1)\}^2 = 0 \quad \text{a.s.} \end{aligned}$$

Now note that the control laws (5) and (14) can be written as

$$(26) \quad Q(t, z)u(t) = -P(t, z)y(t) + R(t, z)y^*(t+1).$$

Substituting (26) in (25) gives

$$\begin{aligned} \lim_N \frac{1}{N} \sum_{t=1}^N \{z^{-1}[1 - A(z)]Q(t, z) - B(z)P(t, z)\}y(t) \\ + z^{-1}[C(z) - 1]Q(t, z)w(t) \\ + \{B(z)R(t, z) - Q(t, z)\}y^*(t+1)\}^2 = 0 \quad \text{a.s.} \end{aligned}$$

Now $y(t) = w(t) + y^*(t) + E[y(t) - y^*(t) | F_{t-1}]$, and so substituting for $y(t)$ gives

$$\begin{aligned} \lim_N \frac{1}{N} \sum_{t=1}^N \{z^{-1}[C(z) - A(z)]Q(t, z) - B(z)P(t, z)\}w(t) \\ + \{B(z)R(t, z) - zB(z)P(t, z) - A(z)Q(t, z)\}y^*(t+1) \\ + \{z^{-1}[1 - A(z)]Q(t, z) - B(z)P(t, z)\}E[y(t) - y^*(t) | F_t]\}^2 = 0 \quad \text{a.s.} \end{aligned}$$

Due to (20)(ii) and the fact that $\{\theta(t)\}$ is bounded, we can drop the last term above and write

$$\begin{aligned} \lim_N \frac{1}{N} \sum_{t=1}^N \{z^{-1}[C(z) - A(z)]Q(t, z) - B(z)P(t, z)\}w(t) \\ + \{B(z)R(t, z) - zB(z)P(t, z) - A(z)Q(t, z)\}y^*(t+1)\}^2 = 0 \quad \text{a.s.} \end{aligned}$$

Since $\lim_t \|\theta(t) - \theta(t-1)\| = 0$ a.s., and since $\{y^*(t+1)\}$ is bounded, we can replace $R(t, z)$, $P(t, z)$ and $Q(t, z)$ above by $R(t-n, z)$, $P(t-n, z)$ and $Q(t-n, z)$, respectively, for any n . Thus

$$\lim_N \frac{1}{N} \sum_{t=1}^N \{ \{z^{-1}[C(z) - A(z)]Q(t-n, z) - B(z)P(t-n, z)\}w(t) + \{B(z)R(t-n, z) - zB(z)P(t-n, z) - A(z)Q(t-n, z)\}y^*(t+1) \}^2 = 0 \quad \text{a.s.}$$

Choose n larger than $(p+q+s)$, and then we can apply Lemma 11 of [6] to deduce that

$$(27) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{z^{-1}[C(z) - A(z)]Q(t-n, z) - B(z)P(t-n, z)\}^2 = 0 \quad \text{a.s.}$$

by which we mean that the average of the square of each coefficient of the polynomial in z is 0; and also

$$(28) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{ \{B(z)R(t-n, z) - zB(z)P(t-n, z) - A(z)Q(t-n, z)\}y^*(t+1) \}^2 = 0 \quad \text{a.s.}$$

Furthermore since $\{y^*(t)\}$ is bounded, (27) also implies that

$$(29) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{ \{ [C(z) - A(z)]Q(t-n, z) - zB(z)P(t-n, z) \} y^*(t+1) \}^2 = 0 \quad \text{a.s.}$$

Subtracting (28) appropriately from (29), we get

$$(30) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{ [C(z)Q(t-n, z) - B(z)R(t-n, z)] y^*(t+1) \}^2 = 0 \quad \text{a.s.}$$

Changing $t-n$ back to t in (27) and (30), we arrive at

$$(31) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{ z^{-1}[C(z) - A(z)]Q(t, z) - B(z)P(t, z) \}^2 = 0 \quad \text{a.s.,}$$

$$(32) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{ [C(z)Q(t, z) - B(z)R(t, z)] y^*(t+1) \}^2 = 0 \quad \text{a.s.}$$

Now let us treat the cases separately.

Case 1. Strong sufficient richness of order greater than or equal to $(q+s)$. This case includes the general tracking problem as well as the linear model following problem with the order of sufficient richness as shown. Since $\{y^*(t)\}$ is strongly sufficiently rich of order greater than or equal to $(q+s)$, there exist n and $\varepsilon > 0$ such that for all large t ,

$$(33) \quad \frac{1}{n} \sum_{k=t+1}^{t+n} (y^*(k+1), \dots, y^*(k-q-s+2))(y^*(k+1), \dots, y^*(k-q-s+2))^T \geq \varepsilon I_{s+q}.$$

Define

$$s_0(t) + s_1(t)z + \dots + s_{q+s-1}(t)z^{q+s-1} := S(t, z) := C(z)Q(t, z) - B(z)R(t, z).$$

Then (32) can also be written as

$$\lim_m \frac{1}{m} \sum_{j=1}^m \left\{ \frac{1}{n} \sum_{k=jn+1}^{jn+n} [S(k, z) y^*(k+1)]^2 \right\} = 0 \quad \text{a.s.}$$

Since $\lim_t \|\theta(t) - \theta(t-1)\| = 0$, we can replace $S(k, z)$ by $S(jn, z)$ to get

$$(34) \quad \lim_m \frac{1}{m} \sum_{j=1}^m \left\{ \frac{1}{n} \sum_{k=jn+1}^{jn+n} [S(jn, z) y^*(k+1)]^2 \right\} = 0 \quad \text{a.s.}$$

Define $\|S(t, z)\|^2 := \sum_{i=0}^{q+s-1} s_i^2(t)$ and (33) implies that

$$\frac{1}{n} \sum_{k=jn+1}^{jn+n} [S(jn, z) y^*(k+1)]^2 \geq \varepsilon \|S(jn, z)\|^2 \quad \text{for all large } j.$$

From (34) it follows that

$$(35) \quad \lim_m \frac{1}{m} \sum_{j=1}^m \|S(jn, z)\|^2 = 0 \quad \text{a.s.}$$

Again, since $\lim_t \|\theta(t) - \theta(t-1)\| = 0$ a.s., (35) implies that

$$(36) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \|S(t, z)\|^2 = 0 \quad \text{a.s.}$$

Adding (31) and (36) gives

$$\begin{aligned} \lim_N \frac{1}{N} \sum_{t=1}^N \{z^{-1}[C(z) - A(z)]Q(t, z) - B(z)P(t, z)\}^2 \\ + \{C(z)Q(t, z) - B(z)R(t, z)\}^2 = 0 \quad \text{a.s.} \end{aligned}$$

Hence there is a common subsequence $\{t_k\}$ such that

$$(37) \quad \lim_k \{z^{-1}[C(z) - A(z)]Q(t_k, z) - B(z)P(t_k, z)\} = 0 \quad \text{a.s.}$$

and

$$(38) \quad \lim_k \{C(z)Q(t_k, z) - B(z)R(t_k, z)\} = 0 \quad \text{a.s.}$$

Since $\{\theta(t)\}$ is bounded, we can also assume without loss of generality that

$$(39) \quad \lim_k Q(t_k, z) =: Q(z); \quad \lim_k P(t_k, z) =: P(z); \quad \lim_k R(t_k, z) =: R(z) \quad \text{a.s.}$$

exist. Hence (37) and (38) imply

$$(40) \quad z^{-1}[C(z) - A(z)]Q(z) - B(z)P(z) = 0 \quad \text{a.s.,}$$

$$(41) \quad C(z)Q(z) - B(z)R(z) = 0 \quad \text{a.s.}$$

However, $Q(z)$ and $P(z)$ are polynomials of degrees less than or equal to $(q-1)$ and $(p \vee s-1)$, respectively. Hence (40) and our assumption (19)(iv) imply that

$$(42) \quad Q(z) = \xi B(z) \quad \text{and} \quad P(z) = \xi z^{-1}[C(z) - A(z)]$$

for some random scalar ξ . Then (41) also shows that $R(z) = \xi C(z)$. Moreover ξ cannot be 0, since otherwise $\lim_k \theta(t_k) = 0$, which is ruled out by (22)(iii) and (19)(vii). From (22)(iv) we obtain the desired result.

Case 2. Linear model following problem with $l < (q + s)$. Since $\lim_t (y_m(t) - y^*(t)) = 0$, we can replace $y^*(t+1)$ by $y_m(t+1)$ in (32). If $s+1 \leq l < q+s$, we shall henceforth define $G(z) := C(z)$, while if $l \leq s$, $G(z)$ is defined as previously by (15), (16). In the latter case also, from (9) and (16) we have $C(z)y_m(t+1) = G(z)y_m(t+1)$. Hence in any case,

$$(43) \quad \lim_N \frac{1}{N} \sum_{t=1}^N \{[G(z)Q(t, z) - B(z)R(t, z)]y_m(t+1)\}^2 = 0 \quad \text{a.s.}$$

Applying Lemma 2 to (43) and (31), we obtain that there is a subsequence $\{t_k\}$ such that (37) holds and also

$$\lim_k [G(z)Q(t_k, z) - B(z)R(t_k, z)] = K(z)H(z) \quad \text{a.s.}$$

Without loss of generality we can also suppose that the limits in (39) exist. Hence

$$(44) \quad G(z)Q(z) - B(z)R(z) = K(z)H(z) \quad \text{a.s.}$$

Also through (31), (40) gives (42). Substituting (42) in (44) yields

$$B(z)[\xi G(z) - R(z)] = K(z)H(z) \quad \text{a.s.}$$

Now note that by (11)(ii) all the roots of $H(z)$ are exactly on the unit circle, while all the roots of $B(z)$ are strictly outside the unit circle by (19)(i). Hence

$$\xi G(z) - R(z) = J(z)H(z) \quad \text{a.s.}$$

for some polynomial $J(z)$. However $[\xi G(z) - R(z)]$ is a polynomial of degree less than or equal to $l-1$, while $H(z)$ is a polynomial of degree exactly l . Hence

$$(45) \quad \xi G(z) - R(z) = 0 \quad \text{a.s.}$$

(42) and (45) now yield the theorem. \square

It is of interest to note that Caines and Lafortune [8] have suggested an adaptive controller which tracks $y^*(t)$ perturbed by white noise. Such a perturbed reference trajectory is strongly sufficiently rich of arbitrary large order (effectively ∞).

Having proved convergence of the parameters to $\xi\theta^0$ under the conditions of Theorem 6, we now have the following results.

THEOREM 7. (i) *In the general tracking problem suppose $\{y^*(t)\}$ is strongly sufficiently rich of order greater than or equal to $(q + s)$. Then*

$$(46) \quad \lim_t \frac{1}{\gamma_0(t)} (\alpha_1(t) - \gamma_1(t), \dots, \alpha_p(t) - \gamma_p(t), \beta_1(t), \dots, \beta_q(t), \gamma_1(t), \dots, \gamma_s(t)) \\ = (a_1, \dots, a_p, b_1, \dots, b_q, c_1, \dots, c_s) \quad \text{a.s.} \quad (\text{with } \gamma_i(t) := 0 \text{ for } i > s).$$

Thus the parameter estimates are strongly consistent. Also

$$(47) \quad \lim_t \frac{1}{\beta_1(t)} (\alpha_1(t), \dots, \alpha_{p \vee s}(t), \beta_2(t), \dots, \beta_q(t), \gamma_0(t), \dots, \gamma_s(t)) \\ = \frac{1}{b_1} (a_1 + c_1, \dots, a_{p \vee s} + c_{p \vee s}, b_2, \dots, b_q, 1, c_1, \dots, c_s) \quad \text{a.s.}$$

setting $a_i := 0$ for $i > p$ and $c_i := 0$ for $i > s$. Hence the adaptive control law (5) self-tunes to the optimal control law a.s.

(ii) In the linear model following problem with $l > s$ the results (46) and (47) continue to hold.

(iii) In the linear model following problem with $l \leq s$ we have,

$$\lim_t \frac{1}{\beta_1(t)} (\alpha_1(t), \dots, \alpha_{pvs}(t), \beta_2(t), \dots, \beta_q(t), \gamma_0(t), \dots, \gamma_{l-1}(t)) \\ = \frac{1}{b_1} (a_1 + c_1, \dots, a_{pvs} + c_{pvs}, b_2, \dots, b_q, g_0, \dots, g_{l-1})$$

setting $a_i := 0$ for $i > p$ and $c_i := 0$ for $i > s$. Here $\{g_0, \dots, g_{l-1}\}$ are defined by (15), (16). Hence the adaptive control law self-tunes to the optimal control law a.s.

7. Concluding remarks. We have proved the convergence of the parameter estimates and the self-tuning property for the *adaptive tracking* problem, justifying the name of *self-tuning trackers*.

For the *general tracking problem*, the convergence depends on whether the reference trajectory is sufficiently rich of appropriate order, as shown in Theorem 7. In the important case of reference trajectories which are not so rich, we have examined the *linear modeling problem*, and shown how one can adjust the *dimension* of the parameter estimator to the order of sufficient richness so as to obtain a self-tuning tracker. It is worth noting that the adaptive controller need not be provided with precise information such as amplitude, frequency or phases of the sinusoids in the reference trajectory. It is enough to know only the number of such components.

An important application, which is a special case of these results, is the problem of maintaining the output at a constant level, i.e., the *set-point problem*. The constant trajectory is sufficiently rich of only order 1, and only one parameter need be estimated to compensate for the colored noise and reject it optimally.

Among the outstanding problems still left unresolved are the following:

(i) Does the least squares based parameter estimation algorithm also possess the above properties? This is of vital interest because the rate of convergence of least squares based algorithms has been observed to be superior to the type of parameter estimation algorithm considered here.

(ii) What robustness properties do these types of self-tuning adaptive control laws possess?

Acknowledgment. The authors would like to thank P. Kokotovic for several stimulating discussions.

SECOND-ORDER NECESSARY CONDITIONS IN CONSTRAINED SEMISMOOTH OPTIMIZATION*

ROBIN W. CHANEY†

Abstract. First- and second-order conditions are given which must necessarily be satisfied by local minimizers for certain finite-dimensional nonsmooth nonlinear programming problems. The problems considered are of standard form, having a finite number of equality and inequality constraints. The principal result does not require a constraint qualification, but does require that the functions be semismooth at the minimizer. The necessary conditions are stated in terms of the generalized gradients of nonsmooth analysis and certain second-order directional derivatives.

Key words. nonsmooth analysis, second-order necessary conditions

1. Introduction. Let $f, g_1, g_2, \dots, g_m, \dots, g_{m+p}$ be real-valued locally Lipschitzian functions on an open set W in n -dimensional real Euclidean space R^n . We consider the problem

P : Minimize $f(x)$, over all x in W such that

$$g_i(x) \leq 0 \quad \text{for } i = 1, \dots, m, \quad \text{and}$$

$$g_i(x) = 0 \quad \text{for } i = m+1, \dots, m+p.$$

Let S be the set of all points in W which are feasible for problem P . Suppose that x^* belongs to S and that the functions f, g_1, \dots, g_{m+p} are all semismooth at x^* [12, p. 961]. We present here a theorem which gives first- and second-order conditions which must necessarily be satisfied if x^* is a local solution to problem P . The theorem is stated in terms of certain Lagrangian functions; it requires no constraint qualification, because it employs a John-type Lagrangian rather than one of the Karush-Kuhn-Tucker type. It generalizes to "semismooth optimization" a theorem due to Ben-Tal [1, Thm. 3.2]; see also Ioffe [10, Thm. 6]. The proof uses a necessity theorem for unconstrained semismooth minimization derived in [5] and a strong version of the Lagrange multiplier rule (see [9, Thm. 6.1.1] and [13, Thm. 1]). In this paper, we shall also discuss a constraint qualification which involves the assumption that there is a unique "normalized" Lagrange multiplier at x^* . Finally, we give an example which illustrates an interesting distinction between the necessary conditions for unconstrained problems and those for constrained problems.

The results presented here are expressed in terms of the generalized gradients of nonsmooth analysis and certain second-order directional derivatives. For a detailed, systematic exposition of nonsmooth analysis, the reader should consult Clarke [9], to which we often refer. An interesting account of the subject (with few proofs) is given by Rockafellar [14]. Information about the second-order directional derivatives used here can be found in [4]; here, we merely give the definitions of these concepts.

We develop elsewhere two second-order sufficiency theorems for problem P which serve as companions to the results of this paper. One of these sufficiency theorems [7, Thm. 3] is a close complement to our necessity theorem, although it is more limited in scope because certain Lagrangian functions are required to be regular at x^* . The sufficiency theorems for problem P given in [7] differ substantially from those proved earlier by the author in [6] and [3].

Ben-Tal and Zowe [2] have developed a general theory of necessary conditions. It is difficult to compare the work in [2] with the present work. Ben-Tal and Zowe do not use nonsmooth analysis (as set forth in [9]) and their point of view is very different from ours.

We turn now to some basic definitions drawn from earlier work. We continue to suppose that $W, f, g_1, \dots, g_{m+p}, x^*$, and S are specified as above.

DEFINITION 1. Let u be a vector in R^n . Suppose that the sequence $\{x_k\}$ in W converges to x^* , with $x_k \neq x^*$ for each k . Then we say that $\{x_k\}$ converges to x^* in direction u in case it is true that the sequence $\{|u|(x_k - x^*)/|x_k - x^*|\}$ converges to u .

DEFINITION 2. Let u be a vector in R^n . The set $\partial_u f(x^*)$ is defined to be the set of all v in R^n for each of which there exist sequences $\{x_k\}$ and $\{v_k\}$ such that $\{x_k\}$ converges to x^* in direction u , $\{v_k\}$ converges to v , and v_k belongs to $\partial f(x_k)$ for each k .

(Here, $\partial f(x)$ stands for the Clarke subdifferential [9, p. 27] of f at x . Note that $\partial_u f(x^*) \subseteq \partial f(x^*)$. The set $\partial_u f(x^*)$ can be said to consist of those generalized gradients of f at x^* which "come to x^* from" direction u .)

DEFINITION 3. The function f is semismooth at x^* if it is true that the sequence $\{v_k \cdot u\}$ converges whenever $\{x_k\}$ and $\{v_k\}$ are sequences such that $\{x_k\}$ converges to x^* in direction u and v_k belongs to $\partial f(x_k)$ for every k .

Remarks. The concept of "semismoothness" is due to Mifflin [12]. Mifflin has shown [12] that if f is semismooth at x^* , then, for each direction u , the classical directional derivative $f'(x^*; u)$ exists and is equal to the limit of every sequence $\{v_k \cdot u\}$ formed as in Definition 3 above. Mifflin has also proved [12] that convex functions, C^1 functions, and certain pointwise maxima of C^1 functions are semismooth. Furthermore, the set of semismooth functions is closed under addition, scalar multiplication, maximization over finite sets, and (in most cases) composition [12, p. 967].

Theorems 1 and 2 below are given in terms of certain second-order directional derivatives, as defined and discussed in [4]. We repeat the basic definitions here.

DEFINITION 4. Let u be a vector in R^n and suppose that v belongs to $\partial_u f(x^*)$. Then $f''_-(x^*, v, u)$ is defined to be the infimum of all numbers

$$\liminf [f(x_k) - f(x^*) - v \cdot (x_k - x^*)]/t_k^2,$$

taken over all triples of sequences $\{x_k\}$, $\{v_k\}$, and $\{t_k\}$ for which

- (a) $t_k > 0$ for each k and $\{x_k\}$ converges to x^* ,
- (b) $\{t_k\}$ converges to 0 and $\{(x_k - x^*)/t_k\}$ converges to u ,
- (c) $\{v_k\}$ converges to v with v_k in $\partial f(x_k)$ for each k .

Similarly, we define $f''_+(x^*, v, u)$ to be the supremum of all numbers

$$\limsup [f(x_k) - f(x^*) - v \cdot (x_k - x^*)]/t_k^2,$$

taken over all triples of sequences $\{x_k\}$, $\{v_k\}$, and $\{t_k\}$ for which (a), (b), and (c) all hold.

Remarks. Note that f''_- and f''_+ depend not only on x^* and u but also on the vector v in $\partial_u f(x^*)$. We term $f''_-(x^*, v, u)$ and $f''_+(x^*, v, u)$ the lower and upper (respectively) second-order directional derivatives of f at x^* and v in the direction u . More information about these concepts is found in [4].

2. The main theorem. In this section, we derive necessary conditions for optimality for problem P . We let W, f, g_i, x^* , and S be as stated in the Introduction.

We state a necessity theorem for unconstrained minimization, which is proved in [5].

Let D^* be the set of all unit vectors u^* in R^n for each of which there exists $\delta' > 0$ such that $v \cdot u^* \leq 0$ if u is a unit vector with $|u - u^*| \leq \delta'$ and if v is in $\partial_u f(x^*)$.

Let f^0 denote (as usual) the Clarke directional derivative. Given a unit vector u^* in R^n , we find that if $f^0(x^*; u^*) \leq 0$ then u^* belongs to D^* ; this is true because $f^0(x^*; \cdot)$ is the support function of $\partial f(x^*)$. Moreover, if f is semismooth at x^* and if u^* belongs to D^* , then we have $f'(x^*; u^*) \leq 0$.

THEOREM 1. *Suppose that f is semismooth at x^* in W and that x^* is an unconstrained local minimizer for $f(x)$, over x in W . If u belongs to D^* , then 0 belongs to $\partial_u f(x^*)$ and $f''_-(x^*, 0, u) \geq 0$.*

Remarks. There will be an application of Theorem 1 in the proof of Theorem 2 below. In order to apply Theorem 1 to a solution x^* to problem P , we must devise a related unconstrained problem to which x^* provides a local solution. This can be done in many ways; but the appropriate method here is to follow an approach used by Clarke [9, p. 229]. We must first make a number of definitions.

We let T be the set of all $w = (w_0, \dots, w_m, \dots, w_{m+p})$ in R^{1+m+p} such that $w_i \geq 0$ for $i = 0, \dots, m$ and $\sum_{i=0}^{m+p} w_i^2 = 1$. We let x^* belong to W (as always) and we put $g_0(x) = f(x) - f(x^*)$. Given x in W and w in T , we let

$$L(x, w) = w_0 f(x) + \sum_{i=1}^{m+p} w_i g_i(x)$$

and

$$L^*(x, w) = \sum_{i=0}^{m+p} w_i g_i(x) = L(x, w) - w_0 f(x^*).$$

For each x in W , we put

$$(1) \quad G(x) = \max \{L^*(x, w) : w \in T\}$$

and

$$T(x) = \{w \in T : G(x) = L^*(x, w)\}.$$

We denote by $\partial L(x, w)$ and $\nabla L(x, w)$, respectively, the subdifferential and gradient of the function $L(\cdot, w)$ at x ; we attach the analogous meaning to $\partial L^*(x, w)$ and $\nabla L^*(x, w)$. We also denote by $L''_+(x^*, w, v, u)$ the upper second-order directional derivative of the function $L(\cdot, w)$ at x^* and v in the direction u .

Next, let us denote by $M(x^*)$ the set of all Lagrange multipliers in T for problem P at x^* ; i.e., $M(x^*)$ is the set of all w in T such that 0 belongs to $\partial L(x^*, w)$ and $w_i g_i(x^*) = 0$ for all $i = 1, \dots, m$.

Finally, let $D^*(G)$ be the set of all unit vectors u^* in R^n for each of which there exists $\delta' > 0$ such that $v \cdot u^* \leq 0$ if u is a unit vector with $|u - u^*| \leq \delta'$ and if v belongs to $\partial_u G(x^*)$.

Thus, again, we note that if u is a unit vector for which $G^0(x^*; u) \leq 0$ then u belongs to $D^*(G)$. And, if u belongs to $D^*(G)$ and if G is semismooth at x^* then $G'(x^*; u) \leq 0$.

THEOREM 2. *Suppose that x^* provides a local solution to problem P and suppose that all the functions f and g_i are semismooth at x^* . Let u belong to $D^*(G)$. Then there exists a Lagrange multiplier w^* in $M(x^*)$ such that 0 belongs to $\partial_u L(x^*, w^*)$, $w_i^* g_i'(x^*; u) = 0$ for all $i = 1, \dots, m$, and $L''_+(x^*, w^*, 0, u) \geq 0$.*

Remarks. We shall discuss the set $D^*(G)$ later. We shall also give an example which will show that, although we can infer $f'' \geq 0$ in Theorem 1, we must settle for $L''_+ \geq 0$ in Theorem 2.

LEMMA 1. (i) If $G(x) > 0$ for x in W then the set $T(x)$ has a single element $w_x = (w_{x0}, \dots, w_{xm}, \dots, w_{x,m+p})$ given by

$$w_{xi} = [\max(0, g_i(x))]/G(x) \quad \text{for } i = 0, \dots, m$$

and

$$w_{xi} = g_i(x)/G(x) \quad \text{for } i = m+1, \dots, m+p.$$

If $G(x) \geq 0$, we have

$$(2) \quad G(x)^2 = \sum_{i=0}^m [\max(0, g_i(x))]^2 + \sum_{i=m+1}^{m+p} g_i(x)^2.$$

(ii) If x^* is a local solution to problem P , then $G(x^*) = 0$ and $G(x) \geq 0$ for all x near x^* .

(iii) x^* is a strict local solution to problem P (i.e., $f(x) > f(x^*)$ for all feasible x near x^* for which $x \neq x^*$) if and only if we have $G(x) > 0 = G(x^*)$ for all x near x^* with $x \neq x^*$.

(iv) If $G(x) > 0$ then $\partial G(x) \subseteq \partial L(x, w_x)$, with w_x as in (i).

Proof. Assertions (ii) and (iii) are easy to verify. We observe also that (iv) is an immediate consequence of (i) and [9, Thm. 2.8.2]. It remains therefore to prove (i). Fix x in W such that $G(x) > 0$ and let w belong to $T(x)$. By the standard Kuhn-Tucker theorem, we infer that multipliers t, s_0, \dots, s_m exist so that $s_i \geq 0$ and $s_i w_i = 0$ for each $i = 0, 1, \dots, m$ and so that

$$(3) \quad -g_i(x) + 2tw_i - s_i = 0 \quad \text{for } i = 0, \dots, m$$

and

$$(4) \quad -g_i(x) + 2tw_i = 0 \quad \text{for } i = m+1, \dots, m+p.$$

Since $\sum_{i=0}^{m+p} w_i^2 = 1$, we infer from (3) and (4) that

$$2t = L^*(x, w) = G(x)$$

and hence that t is positive. Therefore, $w_i = g_i(x)/G(x)$ for $i = m+1, \dots, m+p$. It follows readily that, for $i = 0, \dots, m$, we have $w_i = 0$ if $g_i(x) < 0$ and $w_i = g_i(x)/G(x)$ if $g_i(x) \geq 0$. Thus, $w = w_x$, where w_x is as defined above. Equation (2) follows at once from the formulas for w_x and the equation $G(x) = L^*(x, w_x)$.

Equation (2) also follows readily if $G(x) = 0$.

LEMMA 2. Suppose that x^* provides a local solution to problem P and that the functions f and g_i are all semismooth at x^* . Then the function G is semismooth at x^* .

Proof. Suppose that the sequence $\{x_k\}$ converges to x^* in direction u , with $|u| = 1$. Suppose also that V_k belongs to $\partial G(x_k)$ for each k . We must show that the sequence $\{V_k \cdot u\}$ converges. We know here that $x_k \neq x^*$ for all k . We let $I(x^*)$ denote the set of all $i = 0, \dots, m$ for which $g_i(x^*) = 0$. By Lemma 1, we can assume that $G(x_k) \geq 0$.

We must consider two cases. In the first case, we suppose that $g'_i(x^*; u) \leq 0$ for all i in $I(x^*)$ and $g'_i(x^*; u) = 0$ for all $i = m+1, \dots, m+p$. We proceed with the first case.

We "partition" the sequence $\{V_k \cdot u\}$ into two subsequences, one in which $G(x_k) > 0$ for all k and the other in which $G(x_k) = 0$ for all k ; we shall prove that both sequences (if they are infinite) converge to 0 and so it will follow that $\{V_k \cdot u\}$ converges to 0 in this first case.

So, we treat first the "subcase" in which we assume $G(x_k) > 0$ for all k . According to Lemma 1(i), there exists a unique $w_k = (w_{k0}, \dots, w_{km}, \dots, w_{k,m+p})$ in $T(x_k)$, with

w_{ki} satisfying the formulas given in Lemma 1(i). Furthermore, it follows from Lemma 1(iv) and [9, Prop. 2.3.3] that there exist v_{ki} in $\partial g_i(x_k)$ such that

$$(5) \quad V_k = \sum_{i=0}^{m+p} w_{ki} v_{ki}.$$

Notice that if $g_i(x^*) < 0$ then $w_{ki} = 0$ for all large k . Since each g_i is semismooth at x^* , we infer that the sequence $\{v_{ki} \cdot u\}_k$ converges to $g'_i(x^*; u)$ for each i . If $g'_i(x^*; u) = 0$, then surely $\{w_{ki}(v_{ki} \cdot u)\}_k$ converges to 0. But, if $g'_i(x^*; u) < 0$ for some i then $g_i(x_k) < 0$ for all large k and so (by Lemma 1) $w_{ki} = 0$ for all large k ; hence $\{w_{ki}(v_{ki} \cdot u)\}_k$ converges to 0. We infer from (5) that $\{V_k \cdot u\}$ must converge to 0, in this first subcase.

Next, we treat the subcase in which $G(x_k) = 0$ for all k . Again, we must show that $\{V_k \cdot u\}$ converges to 0. Let E be the set of those points in W at which at least one of f and g_i is not differentiable. Then E has measure 0. By [9, Thm. 2.8.6] and Caratheodory's theorem, we can write

$$V_k = \sum_{j=1}^{n+1} a_{kj} z_{kj}$$

where $a_{kj} \geq 0$, $\sum_{j=1}^{n+1} a_{kj} = 1$, and where, for each k and j , there are sequences $\{x_{kjq}\}_q$ in $W - E$ and $\{w_{kjq}\}_q$ in T such that $\{x_{kjq}\}_q$ converges to x_k , $\{L^*(x_k, w_{kjq})\}_q$ converges to $G(x_k) = 0$, and $\{\nabla L^*(x_{kjq}, w_{kjq})\}_q$ converges to z_{kj} . Notice that if $g_I(x_k) < 0$ for some I and k then $L^*(x_k, w_{kjq}) \leq w_{kjq, I} g_I(x_k) \leq 0$ and so the sequence $\{w_{kjq, I}\}_q$ must converge to 0. For each k and j , we can therefore select x_{kj} in $W - E$ and w_{kj} in T so that

$$|x_{kj} - x_k| \leq \frac{|x_k - x^*|^2}{k}, \quad 0 \leq G(x_k) - L^*(x_k, w_{kj}) \leq \frac{1}{k},$$

$$0 \leq w_{kj, i} < \frac{1}{k} \quad \text{if } g_i(x_k) < 0,$$

and

$$\left| V_k - \sum_{j=1}^{n+1} a_{kj} \nabla L(x_{kj}, w_{kj}) \right| < \frac{1}{k}.$$

It follows that, for each j , $\{x_{kj}\}_k$ converges to x^* in the direction u . Hence, the sequence $\{\nabla g_i(x_{kj}) \cdot u\}_k$ must converge to $g'_i(x^*; u)$, since g_i is semismooth at x^* . Now, if $g'_i(x^*; u) = 0$, it follows then that the sequence $\{a_{kj} w_{kj, i} \nabla g_i(x_{kj}) \cdot u\}_k$ converges to 0. If $g'_i(x^*; u) < 0$ or if $g_i(x^*) < 0$ then $g_i(x_k) < 0$ for all large k and for all j and so $\{w_{kj, i}\}_k$ converges to 0; therefore the sequence $\{a_{kj} w_{kj, i} \nabla g_i(x_{kj}) \cdot u\}_k$ converges to 0. It follows from all of these computations that $\{V_k \cdot u\}$ converges to 0. We have at last completed the proof for the first case.

We must now show that $\{V_k \cdot u\}$ converges if $g'_i(x^*; u) > 0$ for some i in $I(x^*)$ or if $g'_i(x^*; u) \neq 0$ for some $i > m$. It follows that $G(x_k) > 0$ for large k and so we assume $G(x_k) > 0$ for all k . Hence we again have w_k and v_{ki} so that (5) holds. From (2) and Lemma 1(ii), we infer

$$(6) \quad [G'(x^*; u)]^2 = [\max(0, f'(x^*; u))]^2 \\ + \sum_{i \in I(x^*)} [\max(0, g'_i(x^*; u))]^2 + \sum_{i=m+1}^{m+p} [g'_i(x^*; u)]^2.$$

So, we have $G'(x^*; u) > 0$; hence, Lemma 1(i) implies that $\{w_{ki}\}_k$ converges to $[\max(0, g'_i(x^*; u))]/G'(x^*; u)$ for i in $I(x^*)$, that $\{w_{ki}\}_k$ converges to

$g'_i(x^*; u)/G'(x^*; u)$ for $i > m$, and that $\{w_{ki}\}_k$ converges to 0 if $g_i(x^*) < 0$. Thus, in this second case, we find that $\{V_k \cdot u\}$ converges to $Q/G'(x^*; u)$, where

$$Q = \sum_{i \in I(x^*)} [g'_i(x^*; u) \max(0, g'_i(x^*; u))] + \sum_{i=m+1}^{m+p} [g'_i(x^*; u)]^2.$$

LEMMA 3. Suppose that x^* is a local solution to problem P. Suppose that x belongs to W , w^* belongs to T , $G(x) > 0$, and that $w_i^* = 0$ for all $i = 0, \dots, m$ for which $g_i(x) < 0$. Then, with w_x as in Lemma 1, we have

$$\frac{1}{2}|w_x - w^*|^2 = 1 - L^*(x, w^*)/L^*(x, w_x).$$

Proof. Suppose x and w are as above. We have

$$|w_x - w^*|^2 = |w_x|^2 - 2(w_x \cdot w^*) + |w^*|^2 = 2 - 2(w_x \cdot w^*).$$

Because of our assumptions about x and w^* and because of Lemma 1(i), this last equation simplifies to

$$|w_x - w^*|^2 = 2 - 2L^*(x, w^*)/L^*(x, w_x).$$

With these lemmas established, we can now turn to the proof of the theorem.

Proof of Theorem 2. It follows from Lemma 1 that x^* is a local minimizer for $G(x)$. Let u be a unit vector which belongs to the set $D^*(G)$. Because of Lemma 2, we can apply Theorem 1. We infer that 0 belongs to $\partial_u G(x^*)$ and so there exist sequences $\{x_k\}$ and $\{v_k\}$ such that $\{x_k\}$ converges to x^* in direction u , v_k belongs to $\partial G(x_k)$ for each k , and $\{v_k\}$ converges to 0. By passing to subsequences, we can assume $G(x_k) > 0$ for all k or $G(x_k) = 0$ for all k .

Case 1. Assume $G(x_k) > 0$ for all k .

In this case, it follows from Lemma 1 that v_k belongs to $\partial L^*(x_k, w_k) = \partial L(x_k, w_k)$, where w_k is the unique member of $T(x_k)$. We may assume that $\{w_k\}$ converges to w^* in T . There is a positive number M so that, given k , there exists v_k^* in $\partial L(x_k, w^*)$ so that $|v_k - v_k^*| \leq M|w_k - w^*|$. Hence $\{v_k^*\}$ converges to 0 and so 0 belongs to $\partial_u L(x^*, w^*)$. It follows from Lemma 1(i) that $w_i^* g_i(x^*) = 0$ for $i = 1, \dots, m$ and so w^* belongs to $M(x^*)$. From (6), we find that

$$|g'_i(x^*; u)| \leq G'(x^*; u) = 0 \quad \text{for } i > m$$

and

$$g'_i(x^*; u) \leq G'(x^*; u) = 0 \quad \text{for } i \text{ in } I(x^*).$$

Given $i = 1, \dots, m$ with $w_i^* > 0$, we have $w_{ki} > 0$ for large k and so $g_i(x_k) > 0$ for all large k ; therefore, $g'_i(x^*; u) = 0$. And, if $g_i(x^*) < 0$, then Lemma 1 shows that $w_{ki} = 0$ for all large k . We now infer from Lemma 3 that

$$(7) \quad \frac{1}{2}|w_k - w^*|^2 = 1 - \frac{L(x_k, w^*) - L(x^*, w^*)}{L(x_k, w_k) - L(x^*, w_k)} \quad \text{for large } k.$$

Of course, because of Lemma 1, we have

$$(8) \quad L(x_k, w_k) - L(x^*, w_k) = G(x_k) > 0.$$

Since $\{w_k\}$ converges to w^* , it follows from (7) and (8) that

$$(9) \quad L(x_k, w^*) - L(x^*, w^*) > 0 \quad \text{for all large } k.$$

Since $\{v_k^*\}$ converges to 0 and v_k^* belongs to $\partial L(x_k, w^*)$ for each k , we infer from (9) and Definition 4 that $L_+''(x^*, w^*, 0, u) \geq 0$.

Case 2. Assume $G(x_k) = 0$ for all k .

In this case, we abandon the v_k mentioned above. Instead, we observe that we may assume that each x_k is a local solution to problem P . According to the Lagrange multiplier rule (see [9, Thm. 6.1.1] or [13, Thm. 1]), there exists w_k in T so that 0 belongs to $\partial L(x_k, w_k)$ and so that $w_{ki}g_i(x_k) = 0$ for all $i = 1, \dots, m$. We may assume that $\{w_k\}$ converges to w^* in T . As in Case 1, we obtain v_k^* in $\partial L(x_k, w^*)$ such that $|v_k^*| \leq M|w_k - w^*|$. We infer that $\{v_k^*\}$ converges to 0, that 0 belongs to $\partial_u L(x^*, w^*)$, and that w^* belongs to $M(x^*)$. Moreover, since each x_k is feasible for problem P and $w_{ki}g_i(x_k) = 0$ for $i = 1, \dots, m$, it follows that $w_i^*g_i'(x^*; u) = 0$. Finally, we observe that

$$L(x_k, w^*) - L(x^*, w^*) = w_0^*(f(x_k) - f(x^*)) = 0$$

for all large k and so $L_+''(x^*, w^*, 0, u) \geq 0$ in this case also.

PROPOSITION 1. *Suppose that x^* is a local solution to problem P and that the functions f and g_i are all semismooth at x^* . Let $D(x^*)$ be the set of all unit vectors u in R^n for which $f'(x^*; u) \leq 0$, $g_i'(x^*; u) \leq 0$ for all positive i in $I(x^*)$, and $g_i'(x^*; u) = 0$ for all $i = m+1, \dots, m+p$. Then $D^*(G) \subseteq D(x^*)$. If the functions f, g_1, \dots, g_m are also regular [9, p. 39] at x^* and if the functions g_{m+1}, \dots, g_{m+p} are strictly differentiable [9, p. 30] at x^* , then $D^*(G) = D(x^*)$.*

Proof. In view of Lemma 1(ii), we know that $G'(x^*; u)$ is nonnegative for all u . Hence the relation $D^*(G) \subseteq D(x^*)$ follows from (6).

Suppose now that f, g_1, \dots, g_m are also regular at x^* and that g_{m+1}, \dots, g_{m+p} are strictly differentiable at x^* . It follows from (2), [8, Thm. 2.1], and [9, Prop. 2.3.6] that G is regular at x^* . Therefore, if u belongs to $D(x^*)$ then $G^0(x^*; u) = G'(x^*; u) = 0$ and so u belongs to $D^*(G)$.

Remarks. Proposition 1 gives a precise description of the set $D^*(G)$ provided the functions f and g_i satisfy the additional hypotheses concerning regularity and strict differentiability.

If the functions f and g_i are of class C^2 on W , then in Theorem 2 we have

$$L_+''(x^*, w^*, 0, u) = L_-''(x^*, w^*, 0, u) = \frac{1}{2}u \cdot \nabla_{xx}^2 L(x^*, w^*)u.$$

Hence, Proposition 1 shows that Theorem 2 reduces to the theorem of Ben-Tal [1, Thm. 3.2] in this case; see also Ioffe [10, Thm. 6].

COROLLARY 1. *Suppose that x^* provides a local solution to problem P and suppose that the functions f and g_i are all semismooth at x^* . Suppose also that $M(x^*)$ consists of a single vector w^* .*

If u belongs to $D^(G)$, then 0 belongs to $\partial_u L(x^*, w^*)$, $w_i^*g_i'(x^*; u) = 0$ for $i = 1, \dots, m$ and $L_+''(x^*, w^*, 0, u) \geq 0$.*

Remarks. The uniqueness of a "normalized" Lagrange multiplier w^* thus serves as a constraint qualification. To assure that the "0th component" w_0^* is positive, it appears that we need an additional assumption such as calmness [9, p. 240].

The observation just made provides an extension to semismooth optimization of a situation well understood in the case in which f and g_i are of class C^2 on W . So, let f and g_i be of class C^2 on W and suppose x^* is a local solution to P . Kyparisis has shown [11] that the set $\{w \in M(x^*): w_0 > 0\}$ consists of a single element if and only if the problem P and x^* satisfy what Kyparisis terms the *strict* Mangasarian-Fromovitz constraint qualification. Now the strict Mangasarian-Fromovitz constraint qualification implies the usual Mangasarian-Fromovitz constraint qualification [11], which in turn implies that problem P is calm at x^* [9, Cor. 5, p. 244].

To sum up, we find in the C^2 case that the combined requirement of calmness at x^* and uniqueness of the normalized Lagrange multiplier is equivalent to the requirement that the strict Mangasarian-Fromovitz constraint qualification hold for problem P at x^* .

3. An example. We conclude with a specific example which shows that in Theorem 2 we cannot replace L'_+ by L'_- ; this contrasts, of course, with the situation for unconstrained minimization described in Theorem 1. The same example illustrates an interesting point about uniqueness of the Lagrange multiplier.

Example 1. We define seven sets, whose union is R^2 . These sets do not "overlap" in the sense that their interiors are pairwise disjoint. We put

$$\begin{aligned} A_1 &= \{(x, y): x > 0 \text{ and } y \geq x^2\}, \\ A_2 &= \{(x, y): x > 0 \text{ and } 0 \leq y \leq x^2\}, \\ A_3 &= \{(x, y): x > 0 \text{ and } 0 \geq y \geq -x^2\}, \\ A_4 &= \{(x, y): x > 0 \text{ and } y \leq -x^2\}, \\ A_5 &= \{(x, y): x \leq 0 \text{ and } y > 0\}, \\ A_6 &= \{(x, y): x \leq 0 \text{ and } y < 0\}, \\ A_7 &= \{(x, y): x \leq 0 \text{ and } y = 0\}. \end{aligned}$$

The reader may find it helpful to sketch a graph of these seven sets. We define functions g_1 and f on R^2 by setting

$$g_1(x, y) = -y \quad \text{for all } (x, y) \text{ in } R^2$$

and

$$\begin{aligned} f(x, y) &= y - x^2 && \text{if } (x, y) \text{ belongs to } A_1, \\ f(x, y) &= 0 && \text{if } (x, y) \text{ belongs to } A_2 \cup A_6 \cup A_7, \\ f(x, y) &= y && \text{if } (x, y) \text{ belongs to } A_3 \cup A_5, \\ f(x, y) &= -x^2 && \text{if } (x, y) \text{ belongs to } A_4. \end{aligned}$$

It is clear that f is locally Lipschitzian on R^2 ; moreover, f is "piecewise C^2 " [5] near all points of R^2 . Use of [9, Prop. 2.2.4] and [9, Thm. 2.5.1] shows that

$$\begin{aligned} \partial f(x, y) &= \{(-2x, 1)\} && \text{if } (x, y) \text{ belongs to int } A_1, \\ \partial f(x, y) &= \{(0, 0)\} && \text{if } (x, y) \text{ belongs to } A_6 \cup \text{int } A_2, \\ \partial f(x, y) &= \{(0, 1)\} && \text{if } (x, y) \text{ belongs to } A_5 \cup \text{int } A_3, \\ \partial f(x, y) &= \{(-2x, 0)\} && \text{if } (x, y) \text{ belongs to int } A_4, \\ \partial f(x, y) &= \{(0, t): 0 \leq t \leq 1\} && \text{if } (x, y) \in A_7 \cup (A_2 \cap A_3), \\ \partial f(x, y) &= \{(-2tx, t): 0 \leq t \leq 1\} && \text{if } (x, y) \in A_1 \cap A_2, \\ \partial f(x, y) &= \{(-2tx, 1-t): 0 \leq t \leq 1\} && \text{if } (x, y) \in A_3 \cap A_4. \end{aligned}$$

From this complete information about the subdifferential of f , it follows that f is regular and semismooth at the origin.

We now form the problem P of minimizing $f(x, y)$ over all (x, y) in R^2 such that $-y = g_1(x, y) \leq 0$. It is clear that the origin $x^* = (0, 0)$ provides a local solution to problem P and so Theorem 2 is applicable here. Let $u = (1, 0)$. In view of Proposition 1, we know that u belongs to $D^*(G)$.

We now wish to identify those $w = (w_0, w_1)$ in $M(x^*)$ for which $(0, 0)$ belongs to $\partial_u L(x^*, w)$. We shall show also that for all such w we have $L''(x^*, w, 0, u) < 0$.

Thus, we suppose now that w is such that $(0, 0)$ belongs to $\partial_u L(x^*, w)$. Then there exists a sequence $\{(x_k, y_k)\}$ converging to $x^* = (0, 0)$ in direction $u = (1, 0)$ and a sequence $\{v_k\}$ converging to $(0, 0)$ such that v_k belongs to $\partial L(x_k, y_k, w)$ for each k . We may assume that $x_k > 0$ for every k . By passing to subsequences, we find that we may restrict our attention to the following *seven* cases:

Case 1. (x_k, y_k) belongs to $\text{int } A_1$ for all k .

Case 2. (x_k, y_k) belongs to $\text{int } A_2$ for all k .

Case 3. (x_k, y_k) belongs to $\text{int } A_3$ for all k .

Case 4. (x_k, y_k) belongs to $\text{int } A_4$ for all k .

Case 5. (x_k, y_k) belongs to $A_1 \cap A_2$ for all k .

Case 6. (x_k, y_k) belongs to $A_2 \cap A_3$ for all k .

Case 7. (x_k, y_k) belongs to $A_3 \cap A_4$ for all k .

We shall discuss here only the analyses of Cases 5 and 7. The interested reader can verify that no new information (in the sense to be explained below) is obtained in the other five cases.

Case 5. Here we have for each k ,

$$v_k = w_0(-2t_k x_k, t_k) + w_1(0, -1) \quad \text{with } 0 \leq t_k \leq 1.$$

Hence, the fact that $\{v_k\}$ converges to $(0, 0)$ implies $\{t_k\}$ must converge to some s in the closed interval $[0, 1]$; and, we have $w_1 = s w_0$. Since $w_0^2 + w_1^2 = 1$, we infer $w_0 \neq 0$. And, since $y_k = x_k^2$ for all k , we have

$$L(x_k, y_k, w) = w_0(y_k - x_k^2) + s w_0(-y_k) = -s w_0 x_k^2.$$

Hence, $L''(x^*, w, 0, u) = -s w_0 < 0$ if $0 < s \leq 1$.

Case 7. Here we have, for each k ,

$$v_k = w_0(-2t_k x_k, 1 - t_k) + w_1(0, -1) \quad \text{with } 0 \leq t_k \leq 1.$$

The fact that $\{v_k\}$ converges to $(0, 0)$ implies that $\{t_k\}$ converges to some c in $[0, 1]$ and $w_1 = (1 - c)w_0$. (Thus, we have obtained the *same* multipliers w as in Case 5.) Again, we have $w_0 \neq 0$, and, since $y_k = -x_k^2$ for all k , we have

$$L(x_k, y_k, w) = w_0(-x_k^2) + (1 - c)w_0(-y_k) = -c w_0 x_k^2.$$

Hence, if $c > 0$, we have $L''(x^*, w, 0, u) < 0$.

Thus far, we have found that the multipliers w in $M(x^*)$ for which 0 belongs to $\partial_u L(x^*, w)$ are of the form $(w_0, s w_0)$, with $0 \leq s \leq 1$ and $w_0^2 + (s w_0)^2 = 1$. Furthermore, for all such multipliers w , we have $L''(x^*, w, 0, u) < 0$. The interested reader will find that the analyses of the other five cases produce *no* new multipliers w for which $(0, 0)$ belongs to $\partial_u L(x^*, w)$. We can therefore conclude that in Theorem 2 we cannot, in general, replace L'_+ by L''_- .

Remarks. One other conclusion can be drawn from this example. This second conclusion is somewhat disquieting, but not surprising. Notice that the constraints here could hardly be simpler: We have a single (active) constraint given by a linear function having a nonzero gradient. If the function f were of class C^1 on R^2 , we would know that the set $M(x^*)$ is a singleton. But, in Example 1, we have seen that $M(x^*)$ contains all vectors of the form $(w_0, s w_0)$ with $0 \leq s \leq 1$ and $w_0^2 + (s w_0)^2 = 1$. So, $M(x^*)$ can be a "large" set even with the simplest of constraints. Therefore, this example suggests the possibility that the constraint qualification mentioned following Corollary 1 may be much more restrictive in the semismooth case than it is in the smooth case.

We can also examine the question of the restrictive character of our constraint qualification from another point of view. Note that if x^* is an isolated local solution to problem P and if $M(x^*)$ consists of one vector w^* , with $w_0^* > 0$, then we infer from [9, Cor. 2, p. 242] that the "value" function V is strictly differentiable (at the relevant point). Of course, it is well known that, even in the smooth case, the function V can be nondifferentiable.

SPLINE APPROXIMATION FOR RETARDED SYSTEMS AND THE RICCATI EQUATION*

F. KAPPEL† AND D. SALAMON‡

Abstract. The purpose of this paper is to introduce a new spline approximation scheme for retarded functional differential equations. The special feature of this approximation scheme is that it preserves the product space structure of retarded systems and approximates the adjoint semigroup in a strong sense. These facts guarantee the convergence of the solution operators for the differential Riccati equation in a strong sense. Numerical findings indicate a significant improvement in the convergence behaviour over both the averaging and the previous spline approximation scheme.

Key words. retarded functional differential equations, approximation, splines, Riccati equation

1. Introduction. In this paper we introduce a new spline approximation scheme for linear time invariant retarded functional differential equations (RFDEs) and establish a number of convergence results. In particular we show that the approximate feedback law and the solution of the operator Riccati equation, associated with the linear quadratic control problem for this class of systems, converge in the uniform operator topology.

The first step of the general approach is to transform the RFDE

$$(1.1) \quad \dot{x}(t) = Lx_t + B_0u(t), \quad y(t) = C_0x(t)$$

into an abstract Cauchy problem of the form

$$(1.2) \quad \frac{d}{dt}x(t) = \mathcal{A}x(t) + \mathcal{B}u(t), \quad y(t) = \mathcal{C}x(t)$$

in the Hilbert space $\mathcal{X} = \mathbb{R}^n \times L^2[-h, 0; \mathbb{R}^n]$, $h > 0$, where \mathcal{A} is the infinitesimal generator of the strongly continuous semigroup $\mathcal{S}(t)$ which is associated with the uncontrolled delay equation. For systems of the form (1.2) there exists a general theory of the linear quadratic control problem of minimizing the cost functional

$$(1.3) \quad J(u) = \langle x(T), \mathcal{G}x(T) \rangle + \int_0^T [|y(t)|^2 + |u(t)|^2] dt$$

(see e.g. [9], [14], [19]). The optimal control can be characterized as a feedback law which is determined by an operator satisfying the differential Riccati equation (in the case $T < \infty$), respectively, the algebraic Riccati equation (in the case $T = \infty$). These operator Riccati equations involve both the original generator \mathcal{A} and its adjoint operator \mathcal{A}^* . Therefore, in order to approximate the feedback law and the Riccati operator in the strong operator topology, we have to approximate both semigroups $\mathcal{S}(t)$ and $\mathcal{S}^*(t)$ in the strong operator topology (see [20]).

For the approximation of the semigroups we use a Galerkin type scheme, i.e., we define finite dimensional subspaces \mathcal{X}^N of \mathcal{X} and operators \mathcal{A}^N on \mathcal{X}^N which generate semigroups $\mathcal{S}^N(t)$ on \mathcal{X}^N . The classical idea is to choose $\mathcal{X}^N \subset \text{dom } \mathcal{A}$ and define $\mathcal{A}^N = p^N \mathcal{A} p^N$, where p^N is the orthogonal projection of \mathcal{X} onto \mathcal{X}^N . Under appropriate consistency and stability hypotheses the convergence of $\mathcal{S}^N(t)$ to $\mathcal{S}(t)$ in the strong operator topology follows.

These ideas have been used by Banks and Kappel [7] for the development of a spline approximation scheme for RFDEs and have then been applied to problems of optimal control and parameter identification e.g. in [3], [6], [8], [27]. In particular, Kunisch [27] has established weak convergence results for the solution operators of the differential Riccati equations. Numerical findings in [8] indicate that these operators indeed do not converge strongly for the spline scheme developed in [7]. The main reason for this seems to be that the subspace \mathcal{X}^N in [7] has been chosen to be contained in the domain of \mathcal{A} which is different from the domain of \mathcal{A}^* .

In order to overcome this unequal treatment of $\mathcal{S}(t)$ and $\mathcal{S}^*(t)$, our idea was to enlarge the subspace \mathcal{X}^N such that it is neither contained in $\text{dom } \mathcal{A}$ nor in $\text{dom } \mathcal{A}^*$, but contains sufficiently many elements of both domains. Of course, in this situation the approximating operators can no longer be defined by $\mathcal{A}^N = p^N \mathcal{A} p^N$ but have to be defined directly instead (for details see § 5.1). As a result we are able to establish the desired convergence of the solution operators of the Riccati equation in the uniform operator topology for the finite time horizon problem. Despite the fact that in the case of the infinite time horizon problem our scheme always did converge numerically, we were not able to prove this convergence following the approach presented in [20]. The reason is that we do not have the uniform (with respect to N) exponential stability of the approximating semigroups for our scheme (compare the remarks at the end of § 5.3). In this respect the spline approximation scheme differs from the averaging approximation scheme in [4] for which the uniform exponential stability property has been established in [38].

In two preliminary sections we collect some basic facts from the state space and control theory for retarded systems (§ 2) and give a short survey on the theory of the linear quadratic optimal control problem for abstract systems in Hilbert space and for RFDEs (§ 3). In § 4.1 we present a general approximation scheme for abstract Cauchy problems in Banach space. In § 4.2 we consider the problem of approximating the feedback law for the finite time horizon problem following the approach given by Gibson in [20].

The main part of this paper is § 5, where we develop a special spline scheme and prove convergence results along the general ideas given in §§ 4.1 and 4.2. We also give the explicit formulae for the matrices which are necessary for the implementation of our scheme. This scheme has remarkable qualitative properties which will be published elsewhere.

Finally, in § 6 we present some of the many numerical calculations in order to demonstrate the good behaviour of our scheme and the advantage it offers over both the averaging approximation scheme [4], [20] and the spline scheme in [7], [8].

2. State space theory for linear hereditary control systems.

2.1. Linear hereditary control systems. We consider the linear hereditary control system

$$(2.1a) \quad \dot{x}(t) = Lx_t + B_0 u(t), \quad t \geq 0,$$

$$(2.1b) \quad y(t) = C_0 x(t),$$

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^l$, $y(t) \in \mathbb{R}^m$ and x_t is defined by $x_t(s) = x(t+s)$ for $-h \leq s \leq 0$, $h > 0$. Correspondingly B_0 and C_0 are real matrices of appropriate dimensions and L is a bounded linear functional $C(-h, 0; \mathbb{R}^n) \rightarrow \mathbb{R}^n$ given by

$$L\phi = \sum_{j=0}^p A_j \phi(-h_j) + \int_{-h}^0 A_{01}(\tau) \phi(\tau) d\tau, \quad \phi \in C(-h, 0; \mathbb{R}^n),$$

where $0 = h_0 < \dots < h_p = h$ and $A_j \in \mathbb{R}^{n \times n}$, $j = 0, \dots, p$, as well as $A_{01}(\cdot) \in L^2(-h, 0; \mathbb{R}^{n \times n})$. A solution of (2.1a) is a function $x(\cdot) \in L^2_{\text{loc}}(-h, \infty; \mathbb{R}^n)$ which is absolutely continuous with L^2 -derivative on every compact interval $[0, T]$, $T > 0$, and satisfies (2.1a) for almost all $t \geq 0$. It is well known that (2.1a) admits a unique solution $x(t) = x(t; \phi, u)$ for every input $u(\cdot) \in L^2_{\text{loc}}(0, \infty; \mathbb{R}^l)$ and every initial condition

$$(2.2) \quad x(0) = \phi^0, \quad x(\tau) = \phi^1(\tau), \quad -h \leq \tau < 0,$$

where $\phi = (\phi^0, \phi^1) \in M^2 = \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n)$. Moreover, $x(\cdot; \phi, u)$ depends continuously on ϕ and u on compact intervals, i.e., for any $T > 0$ there exists a $K > 0$ such that

$$\sup_{0 \leq t \leq T} |x(t; \phi, u)| \leq K(\|\phi\| + \|u\|_{L^2(0, T; \mathbb{R}^l)}),$$

where $\|\phi\| = (|\phi^0|^2 + |\phi^1|_{L^2}^2)^{1/2}$ for $\phi \in M^2$ (see e.g. [12], [18]). The fundamental solution of (2.1a) will be denoted by $X(t)$ and is the $n \times n$ matrix valued solution of (2.1a) which corresponds to $u \equiv 0$ and $X(0) = I$, $X(\tau) = 0$ for $-h \leq \tau < 0$. The Laplace transform of $X(\cdot)$ is given by $\Delta^{-1}(\lambda)$, where

$$\begin{aligned} \Delta(\lambda) &= \lambda I - L(e^{\lambda \cdot} I) \\ &= \lambda I - \sum_{j=0}^p A_j e^{-\lambda h_j} - \int_{-h}^0 A_{01}(\tau) e^{\lambda \tau} d\tau, \quad \lambda \in \mathbb{C} \end{aligned}$$

is the characteristic matrix of (2.1a). Again it is well known that the forced motion of (2.1a) (in case $\phi = 0$) can be written as

$$(2.3) \quad x(t; 0, u) = \int_0^t X(t-\tau) B_0 u(\tau) d\tau, \quad t \geq 0.$$

2.2. Semigroups and state space description. Existence, uniqueness and continuous dependence results for solutions of RFDEs motivate the definition of the state of system (2.1) to be the pair

$$(2.4) \quad w(t) = (x(t), x_t) \in M^2,$$

which completely describes the past history of the solution at time $t \geq 0$. The evolution of this state is governed by the variation-of-constants formula

$$(2.5) \quad w(t) = S(t)\phi + \int_0^t S(t-s)Bu(s) ds, \quad t \geq 0,$$

which is the infinite dimensional version of (2.3). The input operator $B: \mathbb{R}^l \rightarrow M^2$ is given by

$$Bu = (B_0 u, 0) \in M^2, \quad u \in \mathbb{R}^l,$$

and the semigroup $S(\cdot)$ corresponds to the free motion of the system, i.e., $S(t): M^2 \rightarrow M^2$, $t \geq 0$ is defined by

$$S(t)\phi = (x(t; \phi, 0), x_t(\phi, 0)), \quad t \geq 0, \quad \phi \in M^2.$$

The infinitesimal generator of $S(\cdot)$ is given by

$$(2.6) \quad \begin{aligned} \text{dom } A &= \{\phi \in M^2 \mid \phi^1 \in W^{1,2}, \phi^0 = \phi^1(0)\}, \\ A\phi &:= (L\phi^1, \dot{\phi}^1), \end{aligned}$$

where $W^{1,2}$ denotes the Sobolev space $W^{1,2}(-h, 0; \mathbb{R}^n)$. The function $w(t)$ as defined in (2.5) is a mild solution of the abstract system

$$(2.7) \quad \begin{aligned} \dot{w}(t) &= Aw(t) + Bu(t), \\ y(t) &= Cw(t), \quad w(0) = \phi. \end{aligned}$$

The output operator $C: M^2 \rightarrow \mathbb{R}^m$ is defined by $C\phi = C_0\phi^0$, $\phi \in M^2$.

The operator A^* dual to A is explicitly given by (see e.g. [17]):

$$(2.7) \quad \begin{aligned} \text{dom } A^* &= \left\{ f \in M^2 \mid f^1 + \sum_{j=1}^{p-1} A_j^T f^0 \chi_{[-h, -h_j]} \in W^{1,2}, f^1(-h) = A_p^T f^0 \right\}, \\ [A^*f]^0 &= f^1(0) + A_0^T f^0, \\ [A^*f]^1(\tau) &= A_{01}^T(\tau) f^0 - \frac{d}{d\tau} \left[f^1(\tau) + \sum_{j=1}^{p-1} A_j^T f^0 \chi_{[-h, -h_j]}(\tau) \right]. \end{aligned}$$

The characteristic function of an interval I is denoted by χ_I .

2.3. Stability, stabilizability and controllability. System (2.1) is said to be *stable* if every solution $x(t)$ of the free system (i.e. $u(t) \equiv 0$) tends to zero as t goes to infinity. Equivalently, the semigroup $S(\cdot)$ is exponentially stable, i.e.,

$$\omega_0 = \lim_{t \rightarrow \infty} \frac{1}{t} \ln \|S(t)\| = \sup \{ \text{Re } \lambda \mid \lambda \in \sigma(A) \} < 0$$

(see for instance [22]). The spectrum of A is given by $\sigma(A) = \{\lambda \in \mathbb{C} \mid \det \Delta(\lambda) = 0\}$. Note that $\sigma(A^*) = \sigma(A)$.

The control system (2.1) is said to be *stabilizable* if there exists a control law

$$(2.8) \quad \begin{aligned} u(t) &= K(x(t), x_t) \\ &= K_0 x(t) + \int_{-h}^0 K_1(\tau) x(t+\tau) d\tau, \end{aligned}$$

where $K_0 \in \mathbb{R}^{l \times n}$, $K_1(\cdot) \in L^2(-h, 0; \mathbb{R}^{l \times n})$, such that the closed loop system (2.1), (2.8) is stable. We have the following important characterization (see [33], [36]).

THEOREM 2.1. *The following statements are equivalent:*

- (i) System (2.1) is stabilizable.
- (ii) There exists a $K \in \mathcal{L}(M^2, \mathbb{R}^l)$ such that the operator $A + BK$ generates an exponentially stable C_0 -semigroup.

- (iii) $\text{rank} [\Delta(\lambda), B_0] = n$ for all $\lambda \in \mathbb{C}$ with $\text{Re } \lambda \geq 0$.

The dual result is the following (see e.g. [10] or [36], [37]):

THEOREM 2.2. *The following statements are equivalent:*

- (i) There exists a $H \in \mathcal{L}(\mathbb{R}^m, M^2)$ such that the operator $A + HC$ generates an exponentially stable semigroup.

- (ii) $\text{rank} \begin{pmatrix} \Delta(\lambda) \\ C_0 \end{pmatrix} = n$ for all $\lambda \in \mathbb{C}$ with $\text{Re } \lambda \geq 0$.

System (2.1) is called *detectable* if the statements of the previous theorem are satisfied. A detailed discussion of the duality relations between feedback stabilization and dynamic observation in the product space framework can be found in [36].

3. The linear quadratic control problem.

3.1. Control systems in Hilbert spaces. Let us first deal with general linear control systems in Hilbert spaces \mathcal{X} , \mathcal{U} and \mathcal{Y} described by

$$(3.1) \quad \begin{aligned} \dot{x}(t) &= \mathcal{A}x(t) + \mathcal{B}u(t), & x(0) &= x_0, \\ y(t) &= \mathcal{C}x(t). \end{aligned}$$

We assume that $\mathcal{B} \in \mathcal{L}(\mathcal{U}, \mathcal{X})$, $\mathcal{C} \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$ and that \mathcal{A} is the infinitesimal generator of a C_0 -semigroup $\mathcal{S}(t)$ on \mathcal{X} . System (3.1) will be understood in the sense of mild solutions, i.e., the trajectories of the system are given by

$$(3.2) \quad x(t) = \mathcal{S}(t)x_0 + \int_0^t \mathcal{S}(t-s)\mathcal{B}u(s) ds, \quad t \geq 0$$

for any $x_0 \in \mathcal{X}$ and any input $u(\cdot) \in L^2_{\text{loc}}(0, \infty; \mathcal{U})$.

Let $\mathcal{R} : \mathcal{U} \rightarrow \mathcal{U}$ and $\mathcal{G} : \mathcal{X} \rightarrow \mathcal{X}$ be selfadjoint linear operators satisfying

$$\langle x, \mathcal{G}x \rangle \geq 0 \quad \text{for all } x \in \mathcal{X}$$

and

$$\langle u, \mathcal{R}u \rangle \geq \varepsilon \|u\|^2 \quad \text{for all } u \in \mathcal{U}$$

with some $\varepsilon > 0$. In this section we look at the control problem of minimizing the cost functional

$$(3.3) \quad J(u) = \langle x(T), \mathcal{G}x(T) \rangle + \int_0^T [\|\mathcal{C}x(t)\|^2 + \langle u(t), \mathcal{R}u(t) \rangle] dt,$$

where $x(t)$ is given by (3.2) and $T > 0$ is a fixed final time. For the proof of the following result see [14] and [19].

THEOREM 3.1. *For any $x_0 \in \mathcal{X}$ there exists a unique control function $\bar{u}(\cdot) \in L^2(0, T; \mathcal{U})$ which minimizes the cost functional (3.3) under the constraint (3.2). The optimal control is of feedback form and is given by*

$$(3.4) \quad \bar{u}(t) = -\mathcal{R}^{-1}\mathcal{B}^*\mathcal{P}(t)\bar{x}(t), \quad t \geq 0,$$

where $\bar{x}(t)$ is the mild solution of the Cauchy problem $\dot{x} = (\mathcal{A} - \mathcal{B}\mathcal{R}^{-1}\mathcal{B}^*\mathcal{P}(t))x$, $x(0) = x_0$, and $t \rightarrow \mathcal{P}(t) \in \mathcal{L}(\mathcal{X})$ is the unique operator valued function on $[0, T]$ with the following properties:

- (i) $\mathcal{P}(t)$ is positive semidefinite for every $t \in [0, T]$.
- (ii) The function $t \rightarrow \mathcal{P}(t)x$ is continuous on $[0, T]$ for every $x \in \mathcal{X}$, and satisfies the Riccati integral equation

$$(3.5) \quad \begin{aligned} \mathcal{P}(t)x &= \mathcal{S}^*(T-t)\mathcal{G}\mathcal{S}(T-t)x \\ &+ \int_t^T \mathcal{S}^*(\tau-t)[\mathcal{C}^*\mathcal{C} - \mathcal{P}(\tau)\mathcal{B}\mathcal{R}^{-1}\mathcal{B}^*\mathcal{P}(\tau)]\mathcal{S}(\tau-t)x d\tau, \\ &0 \leq t \leq T, \quad x \in \mathcal{X}. \end{aligned}$$

Moreover, the optimal cost is given by

$$J(\bar{u}) = \langle x_0, \mathcal{P}(0)x_0 \rangle.$$

In [19] it is also shown that $\mathcal{P}(t)$ satisfies

$$(3.6) \quad \mathcal{P}(t)x = \mathcal{S}^*(T-t)\mathcal{G}\Phi(T, t)x + \int_t^T \mathcal{S}^*(\tau-t)\mathcal{C}^*\mathcal{C}\Phi(\tau, t)x d\tau, \quad 0 \leq t \leq T, \quad x \in \mathcal{X}$$

where $\Phi(\tau, t)$ is the evolution operator given by

$$(3.7) \quad \Phi(\tau, t)x = \mathcal{S}(\tau - t)x - \int_t^\tau \mathcal{S}(\tau - \sigma)\mathcal{B}\mathcal{R}^{-1}\mathcal{B}^*\mathcal{P}(\sigma)\Phi(\sigma, t)x \, d\sigma, \\ 0 \leq t \leq \tau \leq T, \quad x \in \mathcal{X}.$$

Let us now consider the problem of minimizing the cost functional

$$(3.8) \quad J(u) = \int_0^\infty [\|\mathcal{C}x(t)\|^2 + \langle u(t), \mathcal{R}u(t) \rangle] \, dt,$$

where again $x(t)$ is given by (3.2). For this situation the following result has been proved (see [14], [15], [41]; further references can be found in the survey paper [9]):

THEOREM 3.2. (a) *The following statements are equivalent:*

(i) *For any $x_0 \in \mathcal{X}$ there exists an input $u(\cdot) \in L^2(0, \infty; \mathcal{U})$ such that the corresponding cost $J(u)$ given by (3.8) and (3.2) is finite.*

(ii) *There exists a positive semidefinite operator $\mathcal{P} \in \mathcal{L}(\mathcal{X})$ satisfying the algebraic Riccati operator equation*

$$(3.9) \quad \langle \mathcal{A}y, \mathcal{P}x \rangle + \langle \mathcal{P}y, \mathcal{A}x \rangle + \langle \mathcal{C}y, \mathcal{C}x \rangle - \langle \mathcal{P}y, \mathcal{B}\mathcal{R}^{-1}\mathcal{B}^*\mathcal{P}x \rangle = 0$$

for all $x, y \in \text{dom } \mathcal{A}$.

(b) *If the statements under (a) are valid, then there exists a unique optimal control $\bar{u}(t)$ which is given by the feedback law*

$$(3.10) \quad \bar{u}(t) = -\mathcal{R}^{-1}\mathcal{B}^*\mathcal{P}\bar{x}(t), \quad t \geq 0,$$

where $\bar{x}(t)$ is the mild solution of the Cauchy problem $\dot{x} = (\mathcal{A} - \mathcal{B}\mathcal{R}^{-1}\mathcal{B}^*\mathcal{P})x$, $x(0) = x_0$, and \mathcal{P} is the minimal solution of (3.9). Moreover, the optimal cost is given by

$$J(\bar{u}) = \langle x_0, \mathcal{P}x_0 \rangle.$$

(c) *Suppose that the statements under (a) are satisfied and let \mathcal{P} be the minimal positive semidefinite solution of (3.9). Moreover, let $\mathcal{P}_T(t)$, $0 \leq t \leq T$, be the unique positive semidefinite solution of (3.5) with $\mathcal{G} = 0$. Then \mathcal{P} is the strong limit of $\mathcal{P}_T(0)$ as T goes to infinity.*

(d) *Suppose that there exists some $\mathcal{K} \in L(\mathcal{Y}, \mathcal{X})$ such that the operator $\mathcal{A} + \mathcal{K}\mathcal{C}$ generates an exponentially stable semigroup. Then there exists at most one positive semidefinite solution of (3.9). Moreover, if such a solution exists, then the closed loop semigroup generated by $\mathcal{A} - \mathcal{B}\mathcal{R}^{-1}\mathcal{B}^*\mathcal{P}$ is exponentially stable.*

3.2. Applications to hereditary systems. Let us first apply Theorem 3.1 to system (Σ) which is associated to system (2.1) in terms of the state concept introduced in § 2. The cost functional for system (2.1) is assumed to be

$$(3.11) \quad J(u) = x(T; \phi, u)^T G_0 x(T; \phi, u) \\ + \int_0^T [\|C_0 x(t; \phi, u)\|^2 + u(t)^T R u(t)] \, dt,$$

where $R \in \mathbb{R}^{l \times l}$ is positive definite and $G_0 \in \mathbb{R}^{n \times n}$ is positive semidefinite. If the operator $G: M^2 \rightarrow M^2$ is defined by $G\phi = (G_0\phi^0, 0)$, $\phi \in M^2$, then the cost functional for system (Σ) is given by (3.3) (with $\mathcal{G} = G$, $\mathcal{C} = C$ and $\mathcal{R} = R$, of course). According

to Theorem 3.1 there exists a unique, positive semidefinite, strongly continuous family $\Pi(\cdot)$ of operators in $\mathcal{L}(M^2)$ which satisfies the Riccati integral equation

$$(3.12) \quad \begin{aligned} \Pi(t)\phi &= S^*(T-t)GS(T-t)\phi \\ &+ \int_t^T S^*(\tau-t)[C^*C - \Pi(\tau)BR^{-1}B^*\Pi(\tau)]S(\tau-t)\phi \, d\tau, \\ \phi &\in M^2, \quad 0 \leq t \leq T. \end{aligned}$$

Let us now look at the structure of the operator $\Pi(t)$. Due to the product space structure of the state space M^2 we can write

$$\Pi(t) = \begin{pmatrix} \Pi_{00}(t) & \Pi_{01}(t) \\ \Pi_{10}(t) & \Pi_{11}(t) \end{pmatrix},$$

where $\Pi_{00}(t)$ is a selfadjoint operator $\mathbb{R}^n \rightarrow \mathbb{R}^n$ which can be represented by a symmetric matrix and $\Pi_{11}(t)$ is a selfadjoint operator $L^2 \rightarrow L^2$. The operator $\Pi_{10}(t)$ can be represented by a matrix-valued function $\Pi_{10}(t, \cdot) \in L^2(-h, 0; \mathbb{R}^{n \times n})$. The adjoint operator $\Pi_{01}(t) = \Pi_{10}^*(t)$ from $L^2 \rightarrow \mathbb{R}^n$ is given by

$$\Pi_{01}(t)\phi = \int_{-h}^0 \Pi_{10}^T(t, \tau)\phi(\tau) \, d\tau, \quad \phi \in L^2.$$

We are mainly interested in the matrices $\Pi_{00}(t)$ and $\Pi_{10}(t, \tau)$, which determine the optimal feedback law

$$(3.13) \quad \bar{u}(t) = -R^{-1}B_0^T \left[\Pi_{00}(t)x(t) + \int_{-h}^0 \Pi_{10}^T(t, \tau)x(t+\tau) \, d\tau \right]$$

for system (2.1). Recall that B^* maps $\phi \in M^2$ to $B_0^T \phi^0 \in \mathbb{R}^l$.

For the rest of this section we assume that system (2.1) is stabilizable and detectable, so that system (Σ) satisfies the assumptions of Theorem 3.2. Hence there exists a positive semi-definite operator $\Pi \in \mathcal{L}(M^2)$ satisfying the algebraic Riccati equation

$$(3.14) \quad A^*\Pi\phi + \Pi A\phi - \Pi BR^{-1}B^*\Pi\phi + C^*C\phi = 0,$$

$\phi \in \text{dom } A$. The equation can be written in this form since every solution \mathcal{P} of (3.9) maps $\text{dom } \mathcal{A}$ into $\text{dom } \mathcal{A}^*$, i.e.,

$$(3.15) \quad \text{range } \Pi \subset \text{dom } A^*.$$

Again the operator Π can be written in block form

$$\Pi = \begin{pmatrix} \Pi_{00} & \Pi_{01} \\ \Pi_{10} & \Pi_{11} \end{pmatrix},$$

where $\Pi_{01} = \Pi_{10}^*$ maps L^2 into \mathbb{R}^n . Hence the optimal feedback law is of the form

$$(3.16) \quad \begin{aligned} u(t) &= -R^{-1}B^*\Pi(x(t), x_t) \\ &= -R^{-1}B_0^T \left[\Pi_{00}x(t) + \int_{-h}^0 \Pi_{10}^T(\tau)x(t+\tau) \, d\tau \right]. \end{aligned}$$

Finally note that the closed loop system (2.1), (3.16) is stable (Theorem 3.2).

4. A general approximation scheme.

4.1. Approximation of the state. In this section we present a general approximation scheme for linear abstract Cauchy problems restricting ourselves to a situation which is of sufficient generality for our purposes.

Let \mathcal{X} be a real Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and corresponding norm $\|\cdot\|$. Furthermore let \mathcal{A} be the infinitesimal generator of the C_0 -semigroup $\mathcal{S}(t)$, $t \geq 0$, on \mathcal{X} . It is a fundamental result that there exists constants $M \geq 1$ and $\omega \in \mathbb{R}$ such that

$$\|\mathcal{S}(t)\| \leq Me^{\omega t}, \quad t \geq 0.$$

In order to approximate the trajectories $\mathcal{S}(t)x_0$, $x_0 \in \mathcal{X}$, it is a standard idea to choose a sequence $\{\mathcal{X}^N\}$ of finite dimensional subspaces of \mathcal{X} with corresponding orthogonal projections

$$p^N: \mathcal{X} \rightarrow \mathcal{X}^N, \quad N = 1, 2, \dots,$$

and to define (in an appropriate way) a sequence $\{\mathcal{A}^N\}$ of linear operators

$$\mathcal{A}^N: \mathcal{X}^N \rightarrow \mathcal{X}^N, \quad N = 1, 2, \dots.$$

With \mathcal{A}^N and $x_0 \in \mathcal{X}$ we associate the Cauchy problem

$$(4.1) \quad \begin{aligned} \dot{x}^N(t) &= \mathcal{A}^N x^N(t), & t \geq 0, \\ x^N(0) &= p^N x_0 \end{aligned}$$

on \mathcal{X}^N . We extend the definition of \mathcal{A}^N to all of \mathcal{X} by $\mathcal{A}^N x = \mathcal{A}^N p^N x$ and define the C_0 -semigroup $\mathcal{S}^N(t)$, $t \geq 0$, on \mathcal{X} by

$$\mathcal{S}^N(t)x_0 = e^{\mathcal{A}^N t} p^N x_0 = e^{\mathcal{A}^N t} p^N x_0 + x_0 - p^N x_0, \quad t \geq 0, \quad x_0 \in \mathcal{X}.$$

The following hypotheses will be used in order to guarantee the desired convergence $\mathcal{S}^N(t)p^N x_0 \rightarrow \mathcal{S}(t)x_0$:

(H1) $\lim_{N \rightarrow \infty} p^N x = x$ for all $x \in \mathcal{X}$.

(H2) There exists constants $\tilde{M} \geq 1$ and $\tilde{\omega} \in \mathbb{R}$ such that

$$\|\mathcal{S}^N(t)x\| \leq \tilde{M}e^{\tilde{\omega}t}\|x\|$$

for all $t \geq 0$, $x \in \mathcal{X}^N$ and $N = 1, 2, \dots$.

(H3) There exists a dense subset $D \subset \text{dom } \mathcal{A}$ which is invariant with respect to $\mathcal{S}(t)$, $t \geq 0$, such that

(i) $\lim_{N \rightarrow \infty} \mathcal{A}^N p^N x = \mathcal{A}x$ for all $x \in D$, and

(ii) for any $x \in D$ there exists a function $m(\cdot, x) \in L^1_{\text{loc}}(0, \infty; \mathbb{R})$ such that

$$\|\mathcal{A}^N p^N \mathcal{S}(t)x\| \leq m(t; x) \quad \text{a.e. on } [0, \infty)$$

for all N .

Hypothesis (H2) is equivalent to

(H2*) For any N there exists a norm $\|\cdot\|_N$ on \mathcal{X}^N such that

(i) For some constant $\tilde{M} \geq 1$

$$\|x\| \leq \|x\|_N \leq \tilde{M}\|x\|, \quad x \in \mathcal{X}^N, \quad N = 1, 2, \dots, \quad \text{and}$$

(ii) for some constant $\tilde{\omega} \in \mathbb{R}$ all operators $\mathcal{A}^N - \tilde{\omega}I$ are dissipative on $(\mathcal{X}^N, \|\cdot\|_N)$ (i.e. $\|(\mathcal{A}^N - \mu I)x\|_N \geq (\mu - \tilde{\omega})\|x\|_N$ for $x \in \mathcal{X}^N$, $\mu > \tilde{\omega}$ or, in case $(\mathcal{X}^N, \|\cdot\|_N)$ is a Hilbert space with inner product $\langle \cdot, \cdot \rangle_N$, $\langle \mathcal{A}^N x, x \rangle_N \leq \tilde{\omega}\|x\|_N^2$ for $x \in \mathcal{X}^N$; cf. [32, Thm. 4.2], [30, p. 244]).

The equivalence of (H2) and (H2*) follows from the well-known relation between exponential estimates for a semigroup and dissipativity properties of its generator (cf., for instance, [32, Thm. 4.3]).

THEOREM 4.1. *Let (H1)–(H3) be satisfied for the sequences \mathcal{X}^N , p^N , \mathcal{A}^N , $N = 1, 2, \dots$. Then for all $x_0 \in \mathcal{X}$*

$$(4.2) \quad \lim_{N \rightarrow \infty} e^{\mathcal{A}^N t} p^N x_0 = \mathcal{S}(t)x_0$$

uniformly for t in bounded intervals.

Proof. If $x_0 \in \text{dom } \mathcal{A}$ then $d/dt \mathcal{S}(t)x_0 = \mathcal{A}\mathcal{S}(t)x_0$. This together with (4.1) implies

$$\mathcal{S}(t)x_0 - \mathcal{S}^N(t)p^N x_0 = \mathcal{S}^N(t)[x_0 - p^N x_0] + \int_0^t \mathcal{S}^N(t-\tau)(\mathcal{A} - \mathcal{A}^N)\mathcal{S}(\tau)x_0 d\tau,$$

$x_0 \in \text{dom } \mathcal{A}$, $0 \leq t \leq T$. Let $x_0 \in D$. Using (H2), we immediately get

$$\|\mathcal{S}(t)x_0 - \mathcal{S}^N(t)p^N x_0\| \leq \tilde{M} e^{\tilde{\omega}T} \left\{ \|x_0 - p^N x_0\| + \int_0^T \|(\mathcal{A} - \mathcal{A}^N)\mathcal{S}(\tau)x_0\| d\tau \right\}$$

for $0 \leq t \leq T$. Then (4.2) follows from (H1), (H3) and Lebesgue's dominated convergence theorem. Note that $\mathcal{S}(\tau)x_0 \in D$ for $\tau \in [0, T]$. A density argument using (H2) completes the proof. \square

The methods in the proof of the previous theorem are well known in connection with numerical approximation of partial differential equations (see for instance the proof of the Lax-Richtmyer equivalence theorem in [21]). For delay equations this approach appears for the first time in [3], [6] and has later on been used in [24]. We equally well could have used the Trotter-Kato theorem [32].

Next we consider the nonhomogeneous problem

$$(4.3a) \quad \dot{x}(t) = \mathcal{A}x(t) + \mathcal{B}u(t), \quad t \geq s,$$

$$(4.3b) \quad x(s) = x_0 \in \mathcal{X},$$

where $u \in L^2_{\text{loc}}(s, \infty; \mathbb{R}^l)$ and \mathcal{B} is a linear operator $\mathbb{R}^l \rightarrow \mathcal{X}$. The unique mild solution $x(t) = x(t; s, x_0, u)$ of (4.3) is given by

$$(4.4) \quad x(t) = \mathcal{S}(t-s)x_0 + \int_s^t \mathcal{S}(t-\tau)\mathcal{B}u(\tau) d\tau, \quad t \geq s.$$

In addition to the approximating sequence \mathcal{X}^N , p^N , \mathcal{A}^N , $N = 1, 2, \dots$, introduced above let us assume that \mathcal{B}^N , $N = 1, 2, \dots$, is a sequence of corresponding input operators $\mathbb{R}^l \rightarrow \mathcal{X}^N$. Then we consider the approximating systems

$$(4.5a) \quad \dot{x}^N(t) = \mathcal{A}^N x^N(t) + \mathcal{B}^N u(t), \quad t \geq s,$$

$$(4.5b) \quad x^N(s) = p^N x_0, \quad x_0 \in \mathcal{X},$$

on \mathcal{X}^N with the unique solution $x^N(t) = x^N(t; s, p^N x_0, u)$ given by

$$(4.6) \quad x^N(t) = \mathcal{S}^N(t-s)p^N x_0 + \int_s^t \mathcal{S}^N(t-\tau)\mathcal{B}^N u(\tau) d\tau, \quad t \geq s,$$

where $\mathcal{S}^N(t): \mathcal{X} \rightarrow \mathcal{X}$ is defined as above.

THEOREM 4.2. *Assume that $\mathcal{S}^N(\cdot)$, $N = 1, 2, \dots$, and $\mathcal{S}(\cdot)$ are C_0 -semigroups on \mathcal{X} such that for constants $M \geq 1$, $\omega \in \mathbb{R}$*

$$\|\mathcal{S}^N(t)\| \leq M e^{\omega t}, \quad t \geq 0, \quad N = 1, 2, \dots,$$

and for all $x_0 \in \mathcal{X}$

$$\lim_{N \rightarrow \infty} \mathcal{S}^N(t)p^N x_0 = \mathcal{S}(t)x_0$$

uniformly on bounded t -intervals. Furthermore assume that

$$\lim_{N \rightarrow \infty} \mathcal{B}^N \xi = \mathcal{B} \xi \quad \text{for all } \xi \in \mathbb{R}^l.$$

Then for all $x_0 \in \mathcal{X}$, $T > 0$ and $\gamma > 0$

$$\lim_{N \rightarrow \infty} x^N(t; s, p^N x_0, u) = x(t; s, x_0, u)$$

uniformly for $0 \leq s \leq t \leq T$ and for $u \in L^2(s, T; \mathbb{R}^l)$ with $\|u\|_{L^2(s, T; \mathbb{R}^l)} \leq \gamma$.

We omit the proof of this result since it is only a slight modification of that given in [4] for a very similar result.

It is clear that in this section without any changes \mathcal{X} could have been a real Banach space.

4.2. Approximation of the feedback law in the optimal problem. We restrict ourselves to the finite time control problem of minimizing the cost functional

$$(4.7) \quad J_s(u) = \langle x(T), \mathcal{G}x(T) \rangle + \int_s^T [\|\mathcal{C}x(t)\|^2 + u(t)^T \mathcal{R}u(t)] dt$$

associated with the Cauchy problem (4.3). We assume that the operators $\mathcal{G}: \mathcal{X} \rightarrow \mathcal{X}$, $\mathcal{R}: \mathbb{R}^l \rightarrow \mathbb{R}^l$, $\mathcal{C}: \mathcal{X} \rightarrow \mathbb{R}^m$ are defined as in § 3.1. As we have seen in that section (with obvious modifications for the case when the initial time s is not necessarily zero), the unique solution of this problem is given by the feedback law

$$(4.8) \quad \bar{u}_s(t) = -\mathcal{R}^{-1} \mathcal{B}^* \mathcal{P}(t) \Phi(t, s) x_0, \quad s \leq t \leq T,$$

where $\mathcal{P}(t): \mathcal{X} \rightarrow \mathcal{X}$ is the unique positive semidefinite solution of the Riccati differential equation (3.5) and $\Phi(t, s)$ is given by (3.7).

Correspondingly, we consider the sequence of control problems of minimizing

$$(4.9) \quad J_s^N(u) = \langle x^N(T), \mathcal{G}x^N(T) \rangle + \int_s^T [\|\mathcal{C}x^N(t)\|^2 + u(t)^T \mathcal{R}u(t)] dt,$$

where $x^N(t) = x^N(t; s, p^N x_0, u)$ is the unique solution of (4.5). The optimal control is given by the feedback law

$$(4.10) \quad \begin{aligned} \bar{u}_s^N(t) &= -\mathcal{R}^{-1} (\mathcal{B}^N)^* \mathcal{P}^N(t) \Phi^N(t, s) p^N x_0 \\ &= -\mathcal{R}^{-1} (\mathcal{B}^N)^* \mathcal{P}^N(t) \Phi^N(t, s) x_0, \quad s \leq t \leq T, \end{aligned}$$

where the strongly continuous, positive semidefinite operator $\mathcal{P}^N(t): \mathcal{X} \rightarrow \mathcal{X}$ and the strongly continuous evolution operator $\Phi^N(t, s): \mathcal{X} \rightarrow \mathcal{X}$ are defined by the equations

$$(4.11) \quad \begin{aligned} \mathcal{P}^N(t)x &= \mathcal{P}^N(T-t)^* p^N \mathcal{G} p^N \Phi^N(T, t)x \\ &\quad + \int_t^T \mathcal{P}^N(\tau-t)^* p^N \mathcal{C}^* \mathcal{C} p^N \Phi^N(\tau, t)x d\tau, \quad t \leq T, \end{aligned}$$

and

$$(4.12) \quad \Phi^N(t, s)x = \mathcal{P}^N(t-s)x - \int_s^t \mathcal{P}^N(t-\tau) \mathcal{B}^N \mathcal{R}^{-1} (\mathcal{B}^N)^* \mathcal{P}^N(\tau) \Phi^N(\tau, s)x d\tau, \quad t \geq s$$

for $x \in \mathcal{X}$. It follows immediately from (4.11) and the fact that $\mathcal{P}^N(t)$ is selfadjoint that

$$(4.13) \quad \mathcal{P}^N(t) = p^N \mathcal{P}^N(t) p^N, \quad t \leq T.$$

This in turn implies, by (4.12), that

$$(4.14) \quad p^N \Phi^N(t, s) = \Phi^N(t, s) p^N, \quad s \leq t \leq T.$$

Note that these two facts justify the second equation in (4.12). Moreover, the optimal cost of (4.9), (4.5) is given by

$$(4.15) \quad J_s^N(\bar{u}_s^N) = \langle x_0, \mathcal{P}^N(s) x_0 \rangle.$$

We remark that $\mathcal{P}^N(t)$, regarded as an operator on \mathcal{X}^N , satisfies the following finite dimensional Riccati differential equation

$$(4.16) \quad \begin{aligned} & \frac{d}{dt} \mathcal{P}^N(t) + (\mathcal{A}^N)^* \mathcal{P}^N(t) + \mathcal{P}^N(t) \mathcal{A}^N \\ & - \mathcal{P}^N(t) \mathcal{B}^N \mathcal{R}^{-1}(\mathcal{B}^N)^* \mathcal{P}^N(t) + p^N \mathcal{C}^* \mathcal{C} p^N = 0, \quad t \leq T, \\ & \mathcal{P}^N(t) = p^N \mathcal{G} p^N. \end{aligned}$$

Obviously, the most interesting question is how the original system (4.3) behaves when the optimal feedback control (4.8) is replaced by the approximate control law

$$(4.17) \quad \hat{u}_s^N(t) = -\mathcal{R}^{-1}(\mathcal{B}^N)^* \mathcal{P}^N(t) \hat{\Phi}^N(t, s) x_0,$$

where $\hat{\Phi}^N(t, s)$ denotes the corresponding closed loop evolution operator on \mathcal{X} which is defined by

$$(4.18) \quad \hat{\Phi}^N(t, s) x = \mathcal{S}(t-s) x - \int_s^t \mathcal{S}(t-\tau) \mathcal{B} \mathcal{R}^{-1}(\mathcal{B}^N)^* \mathcal{P}^N(\tau) \hat{\Phi}^N(\tau, s) x \, d\tau$$

for $x \in \mathcal{X}$ and $s \leq t \leq T$.

All the desired convergence results are contained in the next theorem which is a straight forward consequence of Theorems 6.1–6.3 in [20]. For the convenience of the reader we present the main ideas of the proof.

THEOREM 4.3. *Let us assume that*

- (i) *There exist constants $M \geq 1$, $\omega \in \mathbb{R}$ such that*

$$\|\mathcal{S}^N(t)\| \leq M e^{\omega t}, \quad t \geq 0, \quad N = 1, 2, \dots;$$

- (ii) *For every $x \in \mathcal{X}$*

$$\lim_{N \rightarrow \infty} \mathcal{S}^N(t) p^N x = \mathcal{S}(t) x, \quad \lim_{N \rightarrow \infty} \mathcal{S}^N(t)^* p^N x = \mathcal{S}(t)^* x$$

uniformly on $[0, T]$;

- (iii) *$\lim_{N \rightarrow \infty} \mathcal{B}^N \xi = \mathcal{B} \xi$ for every $\xi \in \mathbb{R}^l$.*

Then, for every $x_0 \in \mathcal{X}$,

- (a) $\lim_{N \rightarrow \infty} J_s^N(\bar{u}_s^N) = \lim_{N \rightarrow \infty} J_s(\hat{u}_s^N) = J_s(\bar{u}_s),$
 (b) $\lim_{N \rightarrow \infty} \bar{u}_s^N(t) = \lim_{N \rightarrow \infty} \hat{u}_s^N(t) = \bar{u}_s(t),$
 (c) $\lim_{N \rightarrow \infty} \Phi^N(t, s) x_0 = \lim_{N \rightarrow \infty} \hat{\Phi}^N(t, s) x_0 = \Phi(t, s) x_0,$
 (d) $\lim_{N \rightarrow \infty} \mathcal{P}^N(s) x_0 = \mathcal{P}(s) x_0$

and the limits are uniform on the domain $0 \leq s \leq t \leq T$. If range \mathcal{G} is finite dimensional, then $\mathcal{P}^N(s)$ converges to $\mathcal{P}(s)$ in the uniform operator topology, uniformly on the interval $[0, T]$.

Proof. Let us introduce the operators $\mathcal{F}_s(t): L^2(s, T; \mathbb{R}^l) \rightarrow \mathcal{X}$, $\mathcal{G}_s: \mathcal{X} \rightarrow L^2(s, T; \mathbb{R}^l)$, $\mathcal{R}_s: L^2(s, T; \mathbb{R}^l) \rightarrow L^2(s, T; \mathbb{R}^l)$ by defining

$$\begin{aligned} \mathcal{F}_s(t)u &= \int_s^t \mathcal{P}(t-\tau)\mathcal{B}u(\tau) d\tau, \\ (4.19) \quad \mathcal{G}_s x &= \mathcal{F}_s(T)^* \mathcal{G}\mathcal{P}(T-s)x + \int_s^T \mathcal{F}_s(\tau)^* \mathcal{C}^* \mathcal{C}\mathcal{P}(\tau-s)x d\tau, \\ \mathcal{R}_s u &= \mathcal{F}_s(T)^* \mathcal{G}\mathcal{F}_s(T)u + \int_s^T \mathcal{F}_s(\tau)^* \mathcal{C}^* \mathcal{C}\mathcal{F}_s(\tau)u d\tau + \mathcal{R}u \end{aligned}$$

for $u \in L^2(s, T; \mathbb{R}^l)$ and $x \in \mathcal{X}$. Of course, $\mathcal{R}u$ is defined by $(\mathcal{R}u)(t) = \mathcal{R}u(t)$, $s \leq t \leq T$. Then it is easy to see that the Fréchet derivative of J_s with respect to u is given by $J'_s(u) = 2\mathcal{R}_s u + 2\mathcal{G}_s x_0$. Since the optimal control \bar{u}_s satisfies $J'_s(\bar{u}_s) = 0$, this implies

$$(4.20) \quad \bar{u}_s = -\mathcal{R}_s^{-1} \mathcal{G}_s x_0.$$

Analogously, we get

$$(4.21) \quad \bar{u}_s^N = -(\mathcal{R}_s^N)^{-1} \mathcal{G}_s^N p^N x_0 = -(\mathcal{R}_s^N)^{-1} \mathcal{G}_s^N x_0$$

where \mathcal{R}_s^N , \mathcal{G}_s^N , \mathcal{F}_s^N are defined as above with $\mathcal{P}(t)$, \mathcal{B} , \mathcal{C} , \mathcal{G} replaced by $\mathcal{P}^N(t)$, \mathcal{B}^N , \mathcal{C}^N , \mathcal{G}^N , respectively. Combining these formulae with (3.7), (4.8) and (4.12), (4.10), we get

$$(4.22) \quad \Phi(t, s)x_0 = \mathcal{P}(t-s)x_0 - \mathcal{F}_s(t)\mathcal{R}_s^{-1}\mathcal{G}_s x_0,$$

$$(4.23) \quad \Phi^N(t, s)x_0 = \mathcal{P}^N(t-s)x_0 - \mathcal{F}_s^N(t)(\mathcal{R}_s^N)^{-1}\mathcal{G}_s^N x_0$$

for every $s \in [0, T]$ and every $t \in [s, T]$.

We have shown in Theorem 4.2 that $\mathcal{F}_s^N(t)$ converges to $\mathcal{F}_s(t)$ in the uniform operator topology, uniformly for $0 \leq s \leq t \leq T$. This implies that for every $x \in \mathcal{X}$

$$(4.24) \quad \lim_{N \rightarrow \infty} \mathcal{G}_s^N x = \mathcal{G}_s x$$

uniformly on $[0, T]$ and moreover $\|\mathcal{R}_s^N - \mathcal{R}_s\| \rightarrow 0$, also uniformly on $[0, T]$. Choosing $\varepsilon > 0$ such that $\xi^T \mathcal{R} \xi \geq \varepsilon \|\xi\|^2$ for $\xi \in \mathbb{R}^l$, we obtain

$$\|\mathcal{R}_s^N u\| \geq \varepsilon \|u\|, \quad u \in L^2(s, T; \mathbb{R}^l), \quad N = 1, 2, \dots$$

and hence

$$(4.25) \quad \lim_{N \rightarrow \infty} \|(\mathcal{R}_s^N)^{-1} - \mathcal{R}_s^{-1}\| = 0$$

uniformly on $[0, T]$.

It follows immediately from (4.22)–(4.25) that $\Phi^N(t, s)$ converges strongly to $\Phi(t, s)$. By (4.11) and (3.6), this implies the strong convergence of the Riccati operators $\mathcal{P}^N(s)$ to $\mathcal{P}(s)$. Now the convergence result on $\hat{\Phi}^N(t, s)$ follows from the inequality

$$\begin{aligned} &\|\Phi(t, s)x - \hat{\Phi}^N(t, s)x\| \\ &\leq \int_s^t \|\mathcal{P}(t-\tau)\mathcal{B}\mathcal{R}^{-1}\| \|[(\mathcal{B}^N)^* \mathcal{P}^N(\tau) - \mathcal{B}^* \mathcal{P}(\tau)]\Phi(\tau, s)x\| d\tau \\ &\quad + \int_s^t \|\mathcal{P}(t-\tau)\mathcal{B}\mathcal{R}^{-1}(\mathcal{B}^N)^* \mathcal{P}^N(\tau)\| \|\hat{\Phi}^N(\tau, s)x - \Phi(\tau, s)x\| d\tau \end{aligned}$$

and Gronwall's lemma. Thus we have established the statements (c) and (d). Statement (b) follows from (c) and (d), since the control functions \bar{u}_s , \bar{u}_s^N , \hat{u}_s^N are given by (4.10), (4.12), (4.19) respectively. Statement (a) is an immediate consequence of (b) and (d), since $J_s^N(\bar{u}_s^N) = \langle x_0, \mathcal{P}^N(s)x_0 \rangle$ and $J_s(\bar{u}_s) = \langle x_0, \mathcal{P}(s)x_0 \rangle$. If range \mathcal{G} is finite dimensional, then the convergence of $\mathcal{P}^N(s)$ in the uniform operator topology can be established by analogous considerations as those in the proof of Theorem 4.2 (see [4]), again by the use of (4.13) and (3.6). \square

5. A special approximation scheme.

5.1. General ideas. In this section we present a general idea how to construct special approximation schemes satisfying the assumptions of § 4.

Let the sequence X^N , $N = 1, 2, \dots$, of subspaces of M^2 be defined by

$$X^N = \left\{ \phi \in M^2 \left| \phi = \hat{e}_0^N \alpha_0 + \sum_{i=1}^p \sum_{j=1}^{k_N} \hat{e}_{ij}^N \alpha_{ij}, \alpha_0, \alpha_{ij} \in \mathbb{R}^n \right. \right\},$$

where the "basis elements" \hat{e}_0^N , \hat{e}_{ij}^N are given by

$$\hat{e}_0^N = (I, 0), \quad \hat{e}_{ij}^N = (0, e_{ij}^N I),$$

i.e., $X^N = \mathbb{R}^n \times Y^N$ with $Y^N = \text{span}(e_{11}^N I, \dots, e_{pk_N}^N I) \subset L^2(-h, 0; \mathbb{R}^n)$. It is clear that $\dim X^N = (pk_N + 1)n$. We assume that

$$(5.1) \quad \begin{aligned} e_{ij}^N | [-h_i, -h_{i-1}] &\in W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}), \\ e_{ij}^N(\tau) &= 0 \quad \text{for } \tau \notin [-h_i, -h_{i-1}]. \end{aligned}$$

Without restriction we may further assume that e_{ij}^N is right-hand continuous on $[-h, 0)$.

Because of the product space structure of the subspaces X^N the orthogonal projections $p^N: M^2 \rightarrow X^N$ are given by

$$p^N \phi = (\phi^0, \pi^N \phi^1) \quad \text{for } \phi = (\phi^0, \phi^1) \in M^2,$$

where π^N is the orthogonal projection $L^2(-h, 0; \mathbb{R}^n) \rightarrow Y^N$. We introduce

$$\hat{E}^N = (\hat{e}_0^N, \hat{e}_{11}^N, \dots, \hat{e}_{pk_N}^N)$$

and denote by $\alpha^N(\phi) = \text{col}(\alpha_0^N, \alpha_{11}^N, \dots, \alpha_{pk_N}^N) \in \mathbb{R}^{n(pk_N+1)}$ the coordinate vector of an element $\phi \in X^N$, i.e.,

$$\phi = \hat{E}^N \alpha^N(\phi), \quad \phi \in X^N.$$

An easy calculation shows

$$(5.2) \quad \alpha^N(p^N \phi) = (Q^N)^{-1} d^N(\phi), \quad \phi \in M^2,$$

where

$$\begin{aligned} d^N(\phi) &= \langle \hat{E}^N, \phi \rangle_{M^2} = \text{col}(\phi^0, \langle e_{11}^N, \phi^1 \rangle_{L^2}, \dots, \langle e_{pk_N}^N, \phi^1 \rangle_{L^2}), \\ Q^N &= \langle \hat{E}^N, \hat{E}^N \rangle_{M^2} = \text{diag}(I, q_1^N \otimes I, \dots, q_p^N \otimes I), \end{aligned}$$

where $q_i^N = (\langle e_{ij}^N, e_{ik}^N \rangle_{L^2})_{j,k=1, \dots, k_N}$ and I is the $n \times n$ identity matrix. For elements in X^N the inner product has the representation

$$(5.3) \quad \langle \phi, \psi \rangle_{M^2} = \alpha^N(\phi)^T Q^N \alpha^N(\psi), \quad \phi, \psi \in X^N.$$

Since for elements $\phi = (\phi^0, \phi^1) \in X^N$ in general $\phi^0 \neq \lim_{\tau \uparrow 0} \phi^1(\tau)$ and ϕ^1 may have jumps of arbitrary size at the delay points $-h_i$, it is clear that X^N is not contained in $\text{dom } A$ nor in $\text{dom } A^*$. However, the operators A and A^* can formally be extended to all of X^N in the following way:

$$(5.4) \quad [A\phi]^0 = A_0\phi^0 + \sum_{i=1}^p A_i\phi^1(-h_i) + \int_{-h}^0 A_{01}(\tau)\phi^1(\tau) d\tau,$$

$$(5.5) \quad [A\phi]^1(\tau) = \frac{d^+}{d\theta} \phi^1(\tau) + \delta_0(\tau)(\phi^0 - \lim_{\tau \uparrow 0} \phi^1(\tau)) \\ + \sum_{i=1}^{p-1} \delta_i(\tau)(\phi^1(-h_i) - \lim_{\tau \uparrow -h_i} \phi^1(\tau)),$$

$$(5.6) \quad [A^*\psi]^0 = \lim_{\tau \uparrow 0} \psi^1(\tau) + A_0^T\psi^0,$$

$$(5.7) \quad [A^*\psi]^1(\tau) = A_{01}^T(\tau)\psi^0 - \frac{d^+}{d\theta} \psi^1(\tau) \\ + \sum_{i=1}^{p-1} \delta_i(\tau)(A_i^T\psi^0 - \psi^1(-h_i) + \lim_{\tau \uparrow -h_i} \psi^1(\tau)) \\ + \delta_p(\tau)(A_p^T\psi^0 - \psi^1(-h))$$

for $\phi, \psi \in X^N$, where δ_i denotes the Dirac delta impulse at $-h_i$, $i = 0, \dots, p$. Below we shall introduce the operators A^N and $(A^N)^*$ by projecting these formal extensions formally back into the subspace X^N . Since jumps of the function components of elements in X^N may occur at $\tau = -h_1$, we have two possible interpretations of δ_i as a functional on X^N , namely the evaluation of either the right-hand or the left-hand limit at $-h_i$. Correspondingly we introduce the following two types of approximate delta impulses which can be obtained. We define

$$\delta_{i,+}^N = \hat{E}^N \gamma_{i,+}^N, \quad i = 1, \dots, p, \\ \delta_{i,-}^N = \hat{E}^N \gamma_{i,-}^N, \quad i = 0, \dots, p-1,$$

where

$$Q^N \gamma_{i,+}^N = \text{col}(0, e_{11}^N(-h_i), \dots, e_{pk_N}^N(-h_i)), \\ Q^N \gamma_{i,-}^N = \text{col}(0, \lim_{\tau \uparrow -h_i} e_{11}^N(\tau), \dots, \lim_{\tau \uparrow -h_i} e_{pk_N}^N(\tau)).$$

The following lemma describes the action of the approximating delta-impulses.

LEMMA 5.1. For any $x \in \mathbb{R}^n$ and $\phi \in M^2$

$$\langle \delta_{i,+}^N x, \phi \rangle_{M^2} = x^T (\pi^N \phi^1)(-h_i), \quad i = 1, \dots, p, \\ \langle \delta_{i,-}^N x, \phi \rangle_{M^2} = x^T \lim_{\tau \uparrow -h_i} (\pi^N \phi^1)(\tau), \quad i = 0, \dots, p-1.$$

Proof. Using (5.2), (5.3) and the definition of $\delta_{i,+}^N$, we get

$$\langle \delta_{i,+}^N x, \phi \rangle_{M^2} = \langle \hat{E}^N \gamma_{i,+}^N x, p^N \phi \rangle_{M^2} = (\gamma_{i,+}^N x)^T Q^N \alpha(p^N \phi) \\ = x^T (0, e_{11}^N(-h_i), \dots, e_{pk_N}^N(-h_i)) \alpha^N(p^N \phi) \\ = x^T (\pi^N \phi^1)(-h_i).$$

The proof for $\delta_{i,-}^N$ is analogous. \square

The following definition of the operators A^N is obtained by formally projecting $A\phi$ as given by (5.4), (5.5) into X^N and putting $p^N\delta_i = \delta_{i,-}^N$, $i = 0, \dots, p-1$.

DEFINITION 5.2. For any $\phi = (\phi^0, \phi^1) \in X^N$ we define

$$\begin{aligned} A^N\phi = & \left(A_0\phi^0 + \sum_{i=1}^p A_i\phi^1(-h_i) + \int_{-h}^0 A_{01}(\tau)\phi^1(\tau) d\tau, \pi^N\left(\frac{d^+}{d\theta}\phi^1\right) \right) \\ & + \delta_{0,-}^N(\phi^0 - \lim_{\tau \uparrow 0} \phi^1(\tau)) + \sum_{i=1}^{p-1} \delta_{i,-}^N(\phi^1(-h_i) - \lim_{\tau \uparrow -h_i} \phi^1(\tau)). \end{aligned}$$

The adjoint operators $(A^N)^*$ are given in

LEMMA 5.3. For any $\psi = (\psi^0, \psi^1) \in X^N$ the operator $(A^N)^*$ is given by

$$\begin{aligned} (A^N)^*\psi = & \left(\lim_{\tau \uparrow 0} \psi^1(\tau) + A_0^T\psi^0, \pi^N\left(A_{01}^T\psi^0 - \frac{d^+}{d\theta}\psi^1\right) \right) \\ & + \sum_{i=1}^{p-1} \delta_{i,+}^N(A_i^T\psi^0 + \lim_{\tau \uparrow -h_i} \psi^1(\tau) - \psi^1(-h_i)) \\ & + \delta_{p,+}^N(A_p^T\psi^0 - \psi^1(-h)). \end{aligned}$$

Proof. By definition of the adjoint operator we get

$$\begin{aligned} \langle (A^N)^*\psi, \phi \rangle_{M^2} &= \langle \psi, A^N\phi \rangle_{M^2} \\ &= (\psi^0)^T \left[A_0\phi^0 + \sum_{i=1}^p A_i\phi^1(-h_i) + \int_{-h}^0 A_{01}(\tau)\phi^1(\tau) d\tau \right] \\ &\quad + \left\langle \psi^1, \pi^N\left(\frac{d^+}{d\theta}\phi^1\right) \right\rangle_{L^2} + \langle \psi, \delta_{0,-}^N(\phi^0 - \lim_{\tau \uparrow 0} \phi^1(\tau)) \rangle_{M^2} \\ &\quad + \sum_{i=1}^{p-1} \langle \psi, \delta_{i,-}^N(\phi^1(-h_i) - \lim_{\tau \uparrow -h_i} \phi^1(\tau)) \rangle_{M^2} \end{aligned}$$

for any $\phi = (\phi^0, \phi^1)$, $\psi = (\psi^0, \psi^1)$ in X^N . By Lemma 5.1 we see

$$\begin{aligned} \langle \psi, \delta_{0,-}^N(\phi^0 - \lim_{\tau \uparrow 0} \phi^1(\tau)) \rangle_{M^2} &= \lim_{\tau \uparrow 0} \psi^1(\tau)^T (\phi^0 - \lim_{\tau \uparrow 0} \phi^1(\tau)), \\ \langle \psi, \delta_{i,-}^N(\phi^1(-h_i) - \lim_{\tau \uparrow -h_i} \phi^1(\tau)) \rangle_{M^2} \\ &= \lim_{\tau \uparrow -h_i} \psi^1(\tau)^T (\phi^1(-h_i) - \lim_{\tau \uparrow -h_i} \phi^1(\tau)), \quad i = 1, \dots, p-1. \end{aligned}$$

Furthermore,

$$\begin{aligned} \left\langle \psi^1, \pi^N\left(\frac{d^+}{d\theta}\phi^1\right) \right\rangle_{L^2} &= \left\langle \psi^1, \frac{d^+}{d\theta}\phi^1 \right\rangle_{L^2} = \sum_{i=1}^p \int_{-h_i}^{-h_{i-1}} \psi^1(\tau)^T \left(\frac{d^+}{d\theta}\phi^1\right)(\tau) d\tau \\ &= \sum_{i=1}^p \left[\lim_{\tau \uparrow -h_{i-1}} \psi^1(\tau)^T \phi^1(\tau) - \psi^1(-h_i)^T \phi^1(-h_i) \right] \\ &\quad - \left\langle \pi^N\left(\frac{d^+}{d\theta}\psi^1\right), \phi^1 \right\rangle_{L^2} \end{aligned}$$

and

$$(\psi^0)^T \int_{-h}^0 A_{01}(\tau)\phi^1(\tau) d\tau = \langle A_{01}^T\psi^0, \phi^1 \rangle_{L^2} = \langle \pi^N(A_{01}^T\psi^0), \phi^1 \rangle_{L^2}.$$

Altogether we have

$$\begin{aligned} \langle (A^N)^* \psi, \phi \rangle_{M^2} = & [\lim_{\tau \uparrow 0} \psi^1(\tau) + A_0^T \psi^0]^T \phi^0 \\ & + \sum_{i=1}^{p-1} [A_i^T \psi^0 + \lim_{\tau \uparrow -h_i} \psi^1(\tau) - \psi^1(-h_i)]^T \phi^1(-h_i) \\ & + [A_p^T \psi^0 - \psi^1(-h)]^T \phi^1(-h) + \left\langle \pi^N \left(A_{01}^T \psi^0 - \frac{d^+}{d\theta} \psi^1 \right), \phi^1 \right\rangle_{L^2}. \end{aligned}$$

The result now follows using Lemma 5.1. \square

Note, that $(A^N)^* \psi$ can formally be obtained by projecting $A^* \psi$ as given by (5.6), (5.7) into X^N but now putting $p^N \delta_i = \delta_{i+}^N$, $i = 1, \dots, p$. Without any additional assumption we have the following.

LEMMA 5.4. *Hypothesis (H2) is valid for the sequence A^N , $N = 1, 2, \dots$ and therefore also for the sequence $(A^N)^*$, $N = 1, 2, \dots$.*

Proof. We introduce an equivalent inner product on M^2 by

$$\langle \phi, \psi \rangle_g = (\phi^0)^T \psi^0 + \int_{-h}^0 \phi^1(\tau)^T \psi^1(\tau) g(\tau) d\tau, \quad \phi, \psi \in M^2,$$

where the weighting function g is right-hand continuous on $[-h, 0)$ and

$$g(\tau) = p - i + 1 \quad \text{for } \tau \in [-h_i, -h_{i-1}), \quad i = 1, \dots, p.$$

It is clear that the corresponding norm $\|\cdot\|_g$ on M^2 is equivalent to the original norm,

$$\|\phi\| \leq \|\phi\|_g \leq \sqrt{p} \|\phi\|, \quad \phi \in M^2.$$

Since $(\phi^0, \phi^1 g) \in X^N$ for any $\phi \in X^N$, we obtain from Lemma 5.1

$$\langle \delta_{i-}^N x, \phi \rangle_g = (p - i) x^T \lim_{\tau \uparrow -h_i} \phi^1(\tau), \quad i = 0, \dots, p - 1,$$

for $x \in \mathbb{R}^n$ and $\phi \in X^N$. Using this equation and Definition 5.2, we get for $\phi \in X^N$

$$\begin{aligned} \langle A^N \phi, \phi \rangle_g = & \left[A_0 \phi^0 + \sum_{i=1}^p A_i \phi^i(-h_i) + \int_{-h}^0 A_{01}(\tau) \phi^1(\tau) d\tau \right]^T \phi^0 \\ & + \left\langle \pi^N \left(\frac{d^+}{d\theta} \phi^1 \right), \phi^1 g \right\rangle_{L^2} + p [\phi^0 - \lim_{\tau \uparrow 0} \phi^1(\tau)]^T \lim_{\tau \uparrow 0} \phi^1(\tau) \\ & + \sum_{i=1}^{p-1} (p - i) [\phi^1(-h_i) - \lim_{\tau \uparrow -h_i} \phi^1(\tau)]^T \lim_{\tau \uparrow -h_i} \phi^1(\tau). \end{aligned}$$

Obviously $\pi^N(\phi^1 g) = \phi^1 g$ and hence

$$\begin{aligned} \left\langle \pi^N \left(\frac{d^+}{d\theta} \phi^1 \right), \phi^1 g \right\rangle_{L^2} &= \left\langle \frac{d^+}{d\theta} \phi^1, \phi^1 g \right\rangle_{L^2} \\ &= \sum_{i=1}^p (p - i + 1) \int_{-h_i}^{-h_{i-1}} \phi^1(\tau)^T \phi^1(\tau) d\tau \\ &= \frac{1}{2} \sum_{i=1}^p (p - i + 1) \left[\lim_{\tau \uparrow -h_{i-1}} |\phi^1(\tau)|^2 - |\phi^1(-h_i)|^2 \right]. \end{aligned}$$

Using this and several times the inequality $\alpha\beta \leq \frac{1}{2}\alpha^2 + \frac{1}{2}\beta^2$, we get for $\phi \in X^N$

$$\begin{aligned} \langle A^N \phi, \phi \rangle_g &\leq \left(|A_0| + \frac{1}{2} \sum_{i=1}^p |A_i|^2 + \|A_{01}\|_{L^2} \right) \|\phi\|_g^2 \\ &\quad + \frac{1}{2} \sum_{i=1}^p |\phi^1(-h_i)|^2 + \frac{p}{2} |\phi^0|^2 - \frac{p}{2} \lim_{\tau \uparrow 0} |\phi^1(\tau)|^2 \\ &\quad + \frac{1}{2} \sum_{i=1}^p (p-i+1) \lim_{\tau \uparrow -h_{i-1}} |\phi^1(\tau)|^2 - |\phi^1(-h_i)|^2 \\ &\quad + \frac{1}{2} \sum_{i=2}^p (p-i+1) [|\phi^1(-h_{i-1})|^2 - \lim_{\tau \uparrow -h_{i-1}} |\phi^1(\tau)|^2] \\ &\leq \omega \|\phi\|_g^2 \end{aligned}$$

with $\omega = p/2 + |A_0| + \frac{1}{2} \sum_{i=1}^p |A_i|^2 + \|A_{01}\|_{L^2}$. This proves (H2*) with $\|\cdot\|_N = \|\cdot\|_g$ for all N . Since $\|S^N(t)\| = \|S^N(t)^*\|$ the proof is finished. \square

In order to verify hypothesis (H3), we need additional assumptions concerning the convergence properties of $\pi^N \phi^1$, $N = 1, 2, \dots$, for ϕ in a suitably restricted subset of M^2 . Observe, that we get from (5.1)

$$\pi^N \phi^1 = \sum_{j=1}^p \pi_j^N(\phi^1 | [-h_j, -h_{j-1})),$$

where π_j^N is the orthogonal projection $L^2(-h_j, -h_{j-1}; \mathbb{R}^n) \rightarrow \text{span}(e_{j1}^N I, \dots, e_{jk_N}^N I)$. We define the sets \tilde{D} and \tilde{D}^* by

$$\begin{aligned} \tilde{D} &= \{\phi \in M^2 \mid \phi^0 = \phi^1(0), \phi^1 \in W^{2,2}(-h, 0; \mathbb{R}^n)\}, \\ \tilde{D}^* &= \left\{ \psi \in M^2 \mid \psi^1(-h) = A_p^T \psi^0, \psi^1 + \sum_{j=1}^{p-1} A_i^T \psi^0 \chi_{[-h_i, -h_{i-1})} \in W^{1,2}(-h, 0; \mathbb{R}^n), \right. \\ &\quad \left. \text{and } A_{01}^T \psi^0 - \frac{d^+}{d\theta} \psi^1 \in W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^n), i = 1, \dots, p \right\}. \end{aligned}$$

Obviously, $\text{dom } A^2 \subset \tilde{D} \subset \text{dom } A$ and $\text{dom } (A^*)^2 \subset \tilde{D}^* \subset \text{dom } A^*$. Furthermore we put

$$\kappa(N) = \max(\|\delta_{0,-}^N\|, \dots, \|\delta_{p-1,-}^N\|, \|\delta_{1,+}^N\|, \dots, \|\delta_{p,+}^N\|),$$

where $\|\delta_{i,\pm}^N\|$ is the norm of $\delta_{i,\pm}^N$ considered as an operator $\mathbb{R}^n \rightarrow M^2$. We impose the following hypothesis:

(A) There exists a sequence $\rho(N)$ with $\lim_{N \rightarrow \infty} \rho(N) = 0$ such that for $i = 1, \dots, p$

$$\begin{aligned} \text{(i)} \quad (1 + \kappa(N)) \|f - \pi_i^N f\|_{L^\infty} + \|f - \pi_i^N f\|_{L^2} \\ + \left\| \frac{d}{d\theta} (f - \pi_i^N f) \right\|_{L^2} \leq \rho(N) \|f\|_{W^{2,2}} \end{aligned}$$

for all $f \in W^{2,2}(-h_i, -h_{i-1}; \mathbb{R}^n)$, and

$$\text{(ii)} \quad \|f - \pi_i^N f\|_{L^2} \leq \rho(N) \|f\|_{W^{1,2}}$$

for all $f \in W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^n)$.

LEMMA 5.5. Assume that (A) is satisfied. Then the following is true:

(a) Assumption (H1) is satisfied.

(b) For any $\phi \in \tilde{D}$

$$\|A^N p^N \phi - A\phi\|_{M^2} \leq \gamma_0 \rho(N) \|\phi^1\|_{W^{2,2}}, \quad N = 1, 2, \dots,$$

where γ_0 is a constant independent of ϕ and N .

(c) If in addition $A_{01} \in W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^{n \times n})$, $i = 1, \dots, p$, then for any $\psi \in \tilde{D}^*$

$$\begin{aligned} & \| (A^N)^* p^N \psi - A^* \psi \|_{M^2} \\ & \leq \gamma_0 \rho(N) \sum_{i=1}^p (\| \psi^1 \|_{W^{2,2}(-h_i, -h_{i-1}; \mathbb{R}^n)} + \| A_{01}^T \psi^0 \|_{W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^n)}), \end{aligned}$$

$N = 1, 2, \dots$, where again γ_0 is a constant independent of ϕ and N .

Proof. (a) is obvious from (A). In order to prove (b), we put $\phi^N = \pi^N \phi^1$ and get, using (2.6) and Definition 5.2, for $\phi \in \tilde{D}$

$$\begin{aligned} & \| A^N p^N \phi - A \phi \|_{M^2} \\ & \leq \sum_{i=1}^p |A_i| \| \phi^N - \phi^1 \|_{L^\infty} + \| A_{01} \|_{L^2} \| \phi^N - \phi^1 \|_{L^2} \\ & \quad + \left\| \pi^N \left(\frac{d^+}{d\theta} \phi^N - \dot{\phi}^1 \right) \right\|_{L^2} + \| \pi^N(\dot{\phi}^1) - \dot{\phi}^1 \|_{L^2} \\ & \quad + \| \delta_{0,-}^N \| | \phi^0 - \lim_{\tau \uparrow 0} \phi^N(\tau) | + \sum_{i=1}^{p-1} \| \delta_{i,+}^N \| | \phi^N(-h_i) - \lim_{\tau \uparrow -h_i} \phi^N(\tau) | \\ & \leq \sum_{i=1}^p |A_i| \| \phi^N - \phi^1 \|_{L^\infty} + \| A_{01} \|_{L^2} \| \phi^N - \phi^1 \|_{L^2} \\ & \quad + \left\| \frac{d^+}{d\theta} (\phi^N - \phi^1) \right\|_{L^2} + \| \pi^N(\dot{\phi}^1) - \dot{\phi}^1 \|_{L^2} \\ & \quad + \kappa(N) \left\{ | \phi^1(0) - \lim_{\tau \uparrow 0} \phi^N(\tau) | + \sum_{i=1}^{p-1} | \phi^N(-h_i) - \phi^1(-h_i) | + \sum_{i=1}^{p-1} | \phi^1(-h_i) - \lim_{\tau \uparrow -h_i} \phi^N(\tau) | \right\} \\ & \leq \left[\sum_{i=1}^p |A_i| + (2p-1)\kappa(N) \right] \| \phi^N - \phi^1 \|_{L^\infty} \\ & \quad + \| A_{01} \|_{L^2} \| \phi^N - \phi^1 \|_{L^2} + \left\| \frac{d^+}{d\theta} (\phi^N - \phi^1) \right\|_{L^2} + \| \pi^N(\dot{\phi}^1) - \dot{\phi}^1 \|_{L^2} \\ & \leq \gamma_0 \rho(N) \| \phi^1 \|_{W^{2,2}}, \end{aligned}$$

where in the last step we have used assumption (A). γ_0 is an appropriately chosen constant.

(c) Using (2.7), Lemma 5.3 and $\psi \in D(A^*)$, we get

$$\begin{aligned} & \| (A^N)^* p^N \psi - A^* \psi \|_{M^2} \leq | \lim_{\tau \uparrow 0} \psi^N(\tau) - \psi^1(0) | \\ & \quad + \left\| \pi^N \left(A_{01}^T \psi^0 - \frac{d^+}{d\theta} \psi^N \right) - A_{01}^T \psi^0 + \frac{d^+}{d\theta} \psi^1 \right\|_{L^2} \\ & \quad + \sum_{i=1}^{p-1} \| \delta_{i,+}^N \| | A_i^T \psi^0 + \lim_{\tau \uparrow -h_i} \psi^N(\tau) - \psi^N(-h_i) | \\ & \quad + \| \delta_{p,+}^N \| | A_p^T \psi^0 - \psi^N(-h) | \\ & \leq (1 + (2p-1)\kappa(N)) \| \psi^1 - \psi^N \|_{L^\infty} \\ & \quad + \left\| \pi^N \left(A_{01}^T \psi^0 - \frac{d^+}{d\theta} \psi^1 \right) - \left(A_{01}^T \psi^0 - \frac{d^+}{d\theta} \psi^1 \right) \right\|_{L^2} \\ & \quad + \left\| \frac{d^+}{d\theta} (\psi^1 - \psi^N) \right\|_{L^2}. \end{aligned}$$

Under the given assumptions we have $\psi^1 \in W^{2,2}(-h_i, -h_{i-1}; \mathbb{R}^n)$, $i = 1, \dots, p$. Therefore we get from (A), (ii)

$$\begin{aligned} & \left\| \pi^N \left(A_{01}^T \psi^0 - \frac{d^+}{d\theta} \psi^1 \right) - \left(A_{01}^T \psi^0 - \frac{d^+}{d\theta} \psi^1 \right) \right\|_{L^2} \\ & \leq \rho(N) \sum_{i=1}^p \left\| A_{01}^T \psi^0 - \frac{d^+}{d\theta} \psi^1 \right\|_{W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^n)} \\ & \leq \rho(N) \sum_{i=1}^p (\|A_{01}^T \psi^0\|_{W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^n)} + \|\psi^1\|_{W^{2,2}(-h_i, -h_{i-1}; \mathbb{R}^n)}) \end{aligned}$$

and

$$\begin{aligned} \|(A^N)^* p^N \psi - A^* \psi\|_{M^2} & \leq \gamma_0 \rho(N) \sum_{i=1}^p (\|A_{01}^T \psi^0\|_{W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^n)} \\ & \quad + \|\psi^1\|_{W^{2,2}(-h_i, -h_{i-1}; \mathbb{R}^n)}). \quad \square \end{aligned}$$

It is clear that under the conditions of Lemma 5.5, hypothesis (H3), (i) is satisfied for X^N , p^N , A^N , $N = 1, 2, \dots$, if we take $D = \text{dom } A^2$, and for X^N , p^N , $(A^N)^*$, $N = 1, 2, \dots$, if we take $D = \text{dom } (A^*)^2$. The next lemma establishes (H3), (ii).

LEMMA 5.6. Assume that (A) is satisfied.

(a) There exist constants $\tilde{M} \geq 1$ and $\omega \in \mathbb{R}$ such that for all $\phi \in \text{dom } A^2$

$$\|A^N p^N S(t) \phi\|_{M^2} \leq \tilde{M} e^{\omega t} |\phi|_2, \quad t \geq 0, \quad N = 1, 2, \dots,$$

where $|\phi|_2 = \|\phi\| + \|A\phi\| + \|A^2\phi\|$.

(b) If in addition $A_{01} \in W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^{n \times n})$, $i = 1, \dots, p$, then there exist constants $M^* \geq 1$ and $\omega \in \mathbb{R}$ such that for all $\psi \in \text{dom } (A^*)^2$

$$\|(A^N)^* p^N S^*(t) \psi\|_{M^2} \leq M^* e^{\omega t} |\psi|_2^*, \quad t \geq 0, \quad N = 1, 2, \dots,$$

where $|\psi|_2^* = \|\psi\| + \|A^* \psi\| + \|(A^*)^2 \psi\|$.

Proof. (a) Since $S(\cdot)$ restricted to $\text{dom } A^2$ is a C_0 -semigroup on $\text{dom } A^2$ equipped with the graph norm $|\cdot|_2$, we have

$$|S(t) \phi|_2 \leq M e^{\omega t} |\phi|_2, \quad t \geq 0, \quad \phi \in \text{dom } A^2,$$

with some constants $M \geq 1$, $\omega \in \mathbb{R}$. From

$$A^k \phi = \left(L \left(\frac{d^{k-1}}{d\theta^{k-1}} \phi^1 \right), \frac{d^k}{d\theta^k} \phi^1 \right),$$

$k = 1, 2, \dots$, $\phi \in \text{dom } A^k$, we see that

$$\|\phi^1\|_{W^{2,2}} \leq |\phi|_2, \quad \phi \in \text{dom } A^2.$$

Therefore, for $\phi \in \text{dom } A^2$

$$\|(S(t) \phi)^1\|_{W^{2,2}} \leq M e^{\omega t} |\phi|_2, \quad t \geq 0$$

and by Lemma 5.5, (b)

$$\begin{aligned} \|A^N p^N S(\phi)\| & \leq \|AS(t) \phi\| + \|A^N p^N S(t) \phi - AS(t) \phi\| \\ & \leq M e^{\omega t} \|A\phi\| + \gamma_0 \rho(N) M e^{\omega t} |\phi|_2 \\ & \leq M(1 + \gamma_0 \rho(N)) e^{\omega t} |\phi|_2, \quad t \geq 0, \quad N = 1, 2, \dots \end{aligned}$$

(b) As in part (a) we have

$$|S^*(t)\psi|_2^* \leq M e^{\omega t} |\psi|_2^*, \quad t \geq 0, \quad \psi \in \text{dom}(A^*)^2.$$

Using (2.7), $(A^*)^2\psi = (\dots, A_{01}^T(\psi^1(0) + A_0^T\psi^0) - d^+/d\theta(A_{01}^T\psi^0 - d^+/d\theta\psi^1))$ and $d^+/d\theta(A_{01}^T\psi^0 - d^+/d\theta\psi^1) = A_{01}^T\psi^0 - \dot{\psi}^1$ on the intervals $[-h_i, -h_{i-1}]$, $i = 1, \dots, p$, it is not difficult to see that for a constant $\kappa = \kappa(\|A_{01}\|_{L^2}, \|d^+/d\theta A_{01}\|_{L^2})$ the following estimate is valid:

$$\sum_{i=1}^p \|\psi^1\|_{W^{2,2}(-h_i, -h_{i-1}; \mathbb{R}^n)} \leq \kappa |\psi|_2^*, \quad \psi \in \text{dom}(A^*)^2.$$

The rest of the proof is analogous to that for part (a) but now using Lemma 5.5, (c). \square

From Lemmas 5.4–5.6 it immediately follows that under the assumption specified in these lemmas Theorem 4.1 applies to the sequences $X^N, p^N, A^N, (A^N)^*$, $N = 1, 2, 3, \dots$, defined in this section. The approximating control systems on X^N are given by (compare (4.5) and (4.9))

$$\begin{aligned} \dot{w}^N(t) &= A^N w^N(t) + B^N u(t), \\ (\Sigma^N) \quad y^N(t) &= C^N w^N(t), \quad t \geq 0, \\ w^N(0) &= p^N \phi, \quad \phi \in M^2, \end{aligned}$$

with the cost functional

$$(5.8) \quad J^N(u) = \langle w^N(T), G w^N(T) \rangle + \int_0^T [|y^N(t)|^2 + u(t)^T R u(t)] dt,$$

where the input and output operators are given by

$$\begin{aligned} B^N u &= p^N B u = B u, \quad u \in \mathbb{R}^l, \\ C^N \phi &= C p^N \phi = C \phi, \quad \phi \in X^N. \end{aligned}$$

As in § 3.2 we assume that $R \in \mathbb{R}^{l \times l}$ is positive definite, $G_0 \in \mathbb{R}^{n \times n}$ is positive semidefinite and $G: M^2 \rightarrow M^2$ is defined by $G\phi = (G_0\phi^0, 0)$. The Riccati operators corresponding to (Σ^N) and (5.8) satisfy

$$\Pi^N(t) = p^N \Pi(t) p^N, \quad 0 \leq t \leq T,$$

and (restricted to X^N)

$$\begin{aligned} &\frac{d}{dt} \Pi^N(t) + (A^N)^* \Pi^N(t) + \Pi^N(t) A^N \\ (5.9) \quad &- \Pi^N(t) B^N R^{-1} (B^N)^* \Pi^N(t) + (C^N)^* C^N = 0, \quad 0 \leq t \leq T, \\ &\Pi^N(T) = G^N. \end{aligned}$$

Here G^N is the restriction of G to X^N .

It follows from the results of this section that Theorem 4.3 applies to system (Σ^N) with (5.8). More precisely, we have the following theorem which may be considered as the main result of this paper.

THEOREM 5.7. *Let hypothesis (A) be satisfied and assume that $A_{01} \in W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^{n \times n})$ for $i = 1, \dots, p$. Then*

$$\lim_{N \rightarrow \infty} \|\Pi(t) - \Pi^N(t)\| = 0$$

uniformly for $0 \leq t \leq T$.

Of course, also assertions (a)–(c) of Theorem 4.3 are true for system (Σ^N) , (5.8) and (Σ) , (3.1) (or equivalently (2.1), (3.1)).

5.2. Matrix representations. For implementation of a scheme obtained along the lines described in the previous section we have to compute matrix representations $[A^N]$, $[(A^N)^*]$, $[B^N]$, $[C^N]$ and $[G^N]$ of the operators A^N , $(A^N)^*$, B^N , C^N and G^N , respectively, with respect to the basis \hat{E}^N . How to compute the coordinate vector of $p^N \phi$ for $\phi \in M^2$ has already been shown (see (5.2)).

Define the $k_N \times k_N$ -matrices h_i^N , $i = 1, \dots, p$, and g_i^N , $i = 1, \dots, p-1$, by

$$h_i^N = \left(\left\langle e_{il}^N, \frac{d^+}{d\theta} e_{im}^N \right\rangle_{L^2} - \lim_{\tau \uparrow -h_{i-1}} e_{il}^N(\tau) e_{im}^N(\tau) \right)_{l,m=1, \dots, k_N},$$

$$g_i^N = (\lim_{\tau \uparrow -h_i} e_{i+1,l}^N(\tau) e_{i,m}^N(-h_i))_{l,m=1, \dots, k_N}$$

and put

$$A_{ij}^N = \langle A_{01}, e_{ij}^N I \rangle_{L^2}, \quad i = 1, \dots, p, \quad j = 1, \dots, k_N,$$

$$\alpha_i^N = (A_i e_{i1}^N(-h_i) + A_{i1}^N, \dots, A_i e_{ik_N}^N(-h_i) + A_{ik_N}^N) \in \mathbb{R}^{n \times nk_N},$$

$i = 1, \dots, p$, and

$$\beta^N = \text{col} \left(\lim_{\tau \uparrow 0} e_{11}^N(\tau) I, \dots, \lim_{\tau \uparrow 0} e_{1k_N}^N(\tau) I \right) \in \mathbb{R}^{nk_N \times n}.$$

Furthermore, define the $(pk_N + 1)n \times (pk_N + 1)n$ -matrix H^N by

$$H^N = \begin{pmatrix} A_0 & \alpha_1^N & \cdots & \alpha_p^N \\ \beta^N & h_1^N \otimes I & \begin{array}{c} 0 \text{---} 0 \\ \diagdown \quad \diagup \\ 0 \end{array} & 0 \\ 0 & g_1^N \otimes I & \begin{array}{c} \diagdown \quad \diagup \\ 0 \end{array} & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \begin{array}{c} 0 \text{---} 0 \\ \diagdown \quad \diagup \\ 0 \end{array} & 0 \end{pmatrix}.$$

PROPOSITION 5.8. (a) $[A^N] = (Q^N)^{-1} H^N$.

(b) $[(A^N)^*] = (Q^N)^{-1} (H^N)^T$.

(c) $[B^N] = \text{col} (B_0, 0, \dots, 0) \in \mathbb{R}^{n(pk_N+1) \times l}$.

(d) $[C^N] = (C_0, 0, \dots, 0) \in \mathbb{R}^{m \times n(pk_N+1)}$.

(e) $[G^N] = \begin{pmatrix} G_0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix} \in \mathbb{R}^{n(pk_N+1) \times n(pk_N+1)}$.

Proof. $[A^N]$ is characterized by

$$\alpha^N(A^N \phi) = [A^N] \alpha^N(\phi), \quad \phi \in X^N.$$

On the other hand we get from (5.2) and $\phi = \hat{E}^N \alpha^N(\phi)$

$$\alpha^N(A^N \phi) = (Q^N)^{-1} d^N(A^N \phi) = (Q^N)^{-1} \langle \hat{E}^N, A^N \hat{E}^N \rangle \alpha^N(\phi),$$

i.e.,

$$[A^N] = (Q^N)^{-1} \langle \hat{E}^N, A^N \hat{E}^N \rangle.$$

From Definition 5.2 we get

$$\begin{aligned} A^N \hat{e}_0^N &= (A_0, 0) + \delta_{0,-}^N, \\ A^N \hat{e}_{ij}^N &= \left(A_i e_{ij}^N(-h_i) + A_{ij}^N, \pi^N \left(\frac{d^+}{d\theta} e_{ij}^N \right) \right) \\ &\quad - \delta_{i-1,-}^N \lim_{\tau \uparrow -h_{i-1}} e_{ij}^N(\tau) + \delta_{i,-}^N e_{ij}^N(-h_i), \end{aligned}$$

$i = 1, \dots, p-1, j = 1, \dots, k_N$, and

$$\begin{aligned} A^N \hat{e}_{pj}^N &= \left(A_p e_{pj}^N(-h) + A_{pj}^N, \pi^N \left(\frac{d^+}{d\theta} e_{pj}^N \right) \right) \\ &\quad - \delta_{p-1,-}^N \lim_{\tau \uparrow -h_{p-1}} e_{pj}^N(\tau), \quad j = 1, \dots, k_N. \end{aligned}$$

Observing

$$\left\langle e_{il}^N, \pi^N \left(\frac{d^+}{d\theta} e_{km}^N \right) \right\rangle_{L^2} = \left\langle e_{il}^N, \frac{d^+}{d\theta} e_{km}^N \right\rangle_{L^2},$$

Lemma 5.1 and (5.2) we obtain by straightforward calculation

$$\langle \hat{E}^N, A^N \hat{E}^N \rangle = H^N.$$

In order to prove the representation for $[(A^N)^*]$, we use (5.3) and get

$$\begin{aligned} \alpha^N(\phi)^T Q^N [(A^N)^*] \alpha^N(\psi) &= \alpha^N(\phi)^T Q^N \alpha^N((A^N)^* \psi) \\ &= \langle \phi, (A^N)^* \psi \rangle = \langle A^N \phi, \psi \rangle = \alpha^N(A^N \phi)^T Q^N \alpha^N(\psi) \\ &= \alpha^N(\phi)^T [A^N]^T Q^N \alpha^N(\psi) = \alpha^N(\phi)^T (H^N)^T \alpha^N(\psi) \end{aligned}$$

for all $\phi, \psi \in X^N$, i.e.,

$$[(A^N)^*] = (Q^N)^{-1} (H^N)^T.$$

For $u \in \mathbb{R}^l$ we have

$$\begin{aligned} \alpha^N(B^N u) &= \alpha^N((B_0 u, 0)) = (Q^N)^{-1} d^N((B_0 u, 0)) \\ &= (Q^N)^{-1} \text{col}(B_0 u, 0, \dots, 0) = \text{col}(B_0, 0, \dots, 0) u, \end{aligned}$$

which proves the given form of $[B^N]$. The proofs for $[C^N]$ and $[G^N]$ are analogous. \square

It is obvious from Proposition 5.8 that $[(A^N)^*] = (Q^N)^{-1} [A^N] Q^N$. Therefore we do not get the standard Riccati matrix differential equation if we take everywhere in (5.9) the matrix representations of the operators involved. In order to overcome this difficulty we define

$$(5.10) \quad \Gamma^N(t) = Q^N [\Pi^N(T-t)], \quad 0 \leq t \leq T,$$

and get from (5.9) the standard Riccati equation for $\Gamma^N(t)$

$$\begin{aligned} (5.11) \quad \frac{d}{dt} \Gamma^N &= [A^N]^T \Gamma^N + \Gamma^N [A^N] \\ &\quad - \Gamma^N [B^N] R^{-1} [B^N]^T \Gamma^N + [C^N]^T [C^N], \quad 0 \leq t \leq T, \\ \Gamma^N(0) &= [G^N]. \end{aligned}$$

Note, that $[(B^N)^*] = [B^N]^T$, $[(C^N)^*] = [C^N]^T$ and that $\Pi^N(t)^* = \Pi^N(t)$ implies $\Gamma^N(t)^T = \Gamma^N(t)$.

Equation (5.11) can advantageously be solved using a method due to Casti and Kailath (see for instance [35, pp. 304 ff.]) which we indicate here for $p = 1$ and $A_{01} \equiv 0$. We define

$$W_0 = A_0^T G_0 + G_0 A - G_0 B_0 R^{-1} B_0^T G_0 + C_0^T C_0$$

and the $2n \times (k_N + 1)n$ -matrices

$$F_1^N = \begin{pmatrix} W_0 & 0 & \cdots & 0 & G_0 A_1 \\ A_1^T G_0 & 0 & \cdots & 0 & 0 \end{pmatrix}, \quad F_2^N = \begin{pmatrix} I & 0 & \cdots & 0 \\ 0 & \cdots & 0 & I \end{pmatrix}.$$

Then

$$\Gamma^N(t) = [G^N] + \int_0^t L_1^N(\tau)^T L_2^N(\tau) d\tau,$$

where

$$\begin{aligned} \frac{d}{dt} L_i^N(t) &= L_i^N(t) ([A^N] - [B^N] R^{-1} [B^N]^T \Gamma^N(t)), \\ L_i^N(0) &= F_i^N, \quad i = 1, 2. \end{aligned}$$

Note that this is a system of $4n^2(k_N + 1)$ differential equations compared to the $n^2(k_N + 1)^2$ differential equations of system (5.11) (in case $p = 1$, $A_{01} \equiv 0$).

If in the optimal feedback law (3.13) for the delay system (2.1) we use $\Pi^N(t)$ instead of $\Pi(t)$ we get the suboptimal controls (compare (4.17))

$$(5.12) \quad \hat{u}^N(t) = -R^{-1} B^* \Pi^N(t) p^N(\hat{x}^N(t), \hat{x}_t^N), \quad 0 \leq t \leq T,$$

where $\hat{x}^N(t)$ is the solution of (2.1) with $u(t) = \hat{u}^N(t)$. We introduce the $n \times n$ -matrices $\Pi_0^N(t)$, $\Pi_{11}^N(t)$, \dots , $\Pi_{pk_N}^N(t)$ by

$$(5.13) \quad \Pi^N(t) = \begin{pmatrix} \Pi_0^N(t) & * & \cdots & * \\ \Pi_{11}^N(t) & & & \\ \vdots & & & \\ \Pi_{pk_N}^N(t) & * & \cdots & * \end{pmatrix}$$

and define

$$(5.14) \quad \Pi_1^N(t, \tau) = \sum_{i=1}^p \sum_{j=1}^{k_N} \Pi_{ij}^N(t)^T e_{ij}^N(\tau)$$

for $-h \leq \tau \leq 0$ and $0 \leq t \leq T$. Then the control law (5.12) takes the following form:

$$\begin{aligned} \hat{u}^N(t) &= -R^{-1} [B^N]^T [\Pi^N(t)] (Q^N)^{-1} d^N((\hat{x}^N(t), \hat{x}_t^N)) \\ &= -R^{-1} (B_0^T, 0, \dots, 0) [\Pi^N(t)]^T d^N((\hat{x}^N(t), \hat{x}_t^N)) \\ (5.15) \quad &= -R^{-1} B_0^T \left\{ \Pi_0^N(t)^T \hat{x}^N(t) \right. \\ &\quad \left. + \sum_{i=1}^p \sum_{j=1}^{k_N} \Pi_{ij}^N(t)^T \int_{-h}^0 e_{ij}^N(\tau) \hat{x}^N(t+\tau) d\tau \right\} \\ &= -R^{-1} B_0^T \left\{ \Pi_0^N(t) \hat{x}^N(t) + \int_{-h}^0 \Pi_1^N(t, \tau) \hat{x}^N(t+\tau) d\tau \right\}. \end{aligned}$$

The additional condition used in [20] in order to prove convergence results analogous to those contained in Theorem 4.3 for the infinite time horizon problem in general cannot be satisfied for concrete realizations of the approximation scheme presented in this section. Especially this condition is not satisfied for the concrete realization of the scheme using spline functions as described in the next section. Despite this fact we did also numerical computations using the spline scheme for the infinite time horizon problem (see § 6.2). Therefore we conclude this section with a short description of the equations governing the approximation of this problem. Consider system (Σ^N) with the cost functional

$$(5.16) \quad J^N(u) = \int_0^\infty [|y^N(t)|^2 + u(t)^T R u(t)] dt.$$

The feedback law which minimizes $J^N(u)$ subject to (Σ^N) is governed by the Riccati operator Π^N which satisfies $\Pi^N = p^N \Pi^N p^N$ and (restricted to X^N) the algebraic Riccati equation

$$(5.17) \quad (A^N)^* \Pi^N + \Pi^N A^N - \Pi^N B R^{-1} B^* \Pi^N + C^* C = 0.$$

Analogously to (5.10) we define $\Gamma^N = Q^N [\Pi^N]$ and obtain the standard algebraic Riccati matrix equation

$$(5.18) \quad [A^N]^T \Gamma^N + \Gamma^N [A^N] - \Gamma^N [B^N] R^{-1} [B^N]^T \Gamma^N + [C^N]^T [C^N] = 0.$$

Note, that as for the finite time horizon problem, $\Gamma^N = (\Gamma^N)^T$ follows from $\Pi^N = (\Pi^N)^*$. Using Π^N instead of Π in the feedback law (3.16) we get by analogous computations as in (5.15) the suboptimal control law

$$(5.19) \quad \hat{u}^N = -R^{-1} B_0^T \left\{ \Pi_0^N \hat{x}^N(t) + \int_{-h}^0 \Pi_1^N(\tau) \hat{x}^N(t+\tau) d\tau \right\}, \quad t \geq 0,$$

where $\Pi_1^N(\tau) = \sum_{i=1}^p \sum_{j=1}^{k_N} (\Pi_{ij}^N)^T e_{ij}(\tau)$ and the $n \times n$ -matrices Π_0^N , Π_{ij}^N , $i=1, \dots, p$, $j=1, \dots, k_N$, are defined by

$$[\Pi^N] = \begin{pmatrix} \Pi_0^N & * & \cdots & * \\ \Pi_{11}^N & \vdots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ \Pi_{pk_N}^N & * & \cdots & * \end{pmatrix}$$

(compare (5.13) and (5.14)).

5.3. The spline scheme. In this section we give a realization of the scheme developed in § 5.1 by using first order spline functions.

For $N=1, 2, \dots$ we choose the meshpoints

$$t_{ij}^N = -h_{i-1} - j \frac{r_i}{N}, \quad i=1, \dots, p, \quad j=0, \dots, N,$$

where $r_i = h_i - h_{i-1}$ and define the basis splines

$$e_{i0}^N(\tau) = \begin{cases} \frac{N}{r_i}(\tau - t_{i1}^N) & \text{for } t_{i1}^N \leq \tau < t_{i0}^N, \\ 0 & \text{elsewhere,} \end{cases}$$

$$e_{ij}^N(\tau) = \begin{cases} -\frac{N}{r_i}(\tau - t_{i,j-1}^N) & \text{for } t_{ij}^N \leq \tau < t_{i,j-1}^N, \\ \frac{N}{r_i}(\tau - t_{i,j+1}^N) & \text{for } t_{i,j+1}^N \leq \tau < t_{i,j}^N, \\ 0 & \text{elsewhere,} \end{cases}$$

$j = 1, \dots, N-1$, and

$$e_{iN}^N(\tau) = \begin{cases} -\frac{N}{r_i}(\tau - t_{i,N-1}^N) & \text{for } t_{iN}^N \leq \tau < t_{i,N-1}^N, \\ 0 & \text{elsewhere,} \end{cases}$$

$i = 1, \dots, p$. Note, that compared to § 5.1 we slightly have changed the enumeration of the e_{ij}^N (j running from 0 to N now). We have $k_N = N+1$ and therefore $\dim X^N = (p(N+1)+1)n$.

An easy computation shows that the matrices q_i^N which determine Q^N (recall $Q^N = \text{diag}(I, q_1^N \otimes I, \dots, q_p^N \otimes I)$) are given by $q_i^N = (r_i/N)q^N$, where

$$q^N = \begin{pmatrix} \frac{1}{3} & \frac{1}{6} & 0 & 0 \\ \frac{1}{6} & \frac{2}{3} & 0 & 0 \\ 0 & 0 & \frac{2}{3} & \frac{1}{6} \\ 0 & 0 & \frac{1}{6} & \frac{1}{3} \end{pmatrix} \in \mathbb{R}^{(N+1) \times (N+1)}.$$

For the approximating delta impulses we have

LEMMA 5.9. For all $N = 1, 2, \dots$,

$$\begin{aligned} \|\delta_{i+}^N\| &\leq \left(\frac{6N}{r_i}\right)^{1/2}, & i = 1, \dots, p, \\ \|\delta_{i-}^N\| &\leq \left(\frac{6N}{r_{i+1}}\right)^{1/2}, & i = 0, \dots, p-1. \end{aligned}$$

Proof. Using (5.3) and the definition of δ_{i+}^N and Q^N we get for any $x \in \mathbb{R}^n$

$$\begin{aligned} \|\delta_{i+}^N x\|^2 &= (\gamma_{i+}^N x)^T Q^N (Q^N)^{-1} Q^N \gamma_{i+}^N x \\ &= \frac{N}{r_i} x^T (0, \dots, 0, I) (q^N \otimes I)^{-1} \text{col}(0, \dots, 0, I) x \\ &\leq \frac{6N}{r_i} |x|^2, \end{aligned}$$

where we have used $\lambda_{\min}(q^N) \geq 1/6$. The estimate for δ_{i-}^N is analogous. \square

As a consequence of Lemma 5.9 we have

$$\kappa(N) \leq \left(\frac{6N}{\rho}\right)^{1/2} \quad \text{with } \rho = \min_{i=1, \dots, p} r_i.$$

PROPOSITION 5.10. Hypothesis (A) is satisfied for the spline scheme with $\rho(N) = \text{const}/N$. As a consequence Theorem 5.7 is valid for the spline scheme.

Proof. The following estimates are standard estimates for spline functions:

$$\|f - \pi_i^N f\|_{L^2} \leq \frac{\text{const}}{N^2} \|\ddot{f}\|_{L^2},$$

$$\left\| \frac{d}{d\theta} (f - \pi_i^N f) \right\|_{L^2} \leq \frac{\text{const}}{N} \|\dot{f}\|_{L^2}$$

for $f \in W^{2,2}(-h_i, -h_{i-1}; \mathbb{R}^n)$ (see [39, Thm. 6.5]) and

$$\|f - \pi_i^N f\|_{L^2} \leq \frac{\text{const}}{N} \|\dot{f}\|_{L^2}$$

for $f \in W^{1,2}(-h_i, -h_{i-1}; \mathbb{R}^n)$ (see [39, Exercise 6.1]). In order to get the estimate for the L^∞ -norm, we observe that $\pi_i^N f = \chi^N$, where χ^N is the cubic type *I* interpolating spline for $\Phi(\tau) = \int_{-h_i}^\tau \int_{-h_i}^\theta f(\sigma) d\sigma d\theta$, $\tau \in [-h_i, -h_{i-1}]$ (see, for instance, [39, Proof of Thm. 6.6]). Note, that interpolating cubic splines in [39] are always type *I* interpolating splines in the terminology of [1]. Then we get from [23, Thm. 5.7.1] (with $L = d^2/d\theta^2$ and $m = 2$) or [11, p. 235] (with $m = r = 2$, $q = \infty$)

$$\|f - \pi_i^N f\|_{L^\infty} \leq \text{const} \left(\frac{1}{N} \right)^{3/2} \|f\|_{W^{2,2}}$$

for $f \in W^{2,2}(-h_i, -h_{i-1}; \mathbb{R}^n)$. These estimates together with Lemma 5.9 imply (A). \square

Using $e_{i,j}^N(-h_i) = 1$ for $j = N$ and $= 0$ for $j = 0, \dots, N-1$, $\lim_{\tau \uparrow -h_i} e_{i+1,j}^N(\tau) = 1$ for $j = 0$ and $= 0$ for $j = 1, \dots, N$, we immediately get

$$\alpha_i^N = (A_{i0}^N, \dots, A_{i,N-1}^N, A_{iN}^N + A_i), \quad i = 1, \dots, p,$$

$$\beta^N = \text{col}(I, 0, \dots, 0),$$

$$h_i^N = \begin{pmatrix} -\frac{1}{2} & -\frac{1}{2} & 0 & 0 \\ & \frac{1}{2} & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{2} \\ 0 & 0 & \frac{1}{2} & -\frac{1}{2} \end{pmatrix} \in \mathbb{R}^{(N+1) \times (N+1)}, \quad i = 1, \dots, p,$$

and

$$g_i^N = \begin{pmatrix} 0 & 0 & 1 \\ & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \in \mathbb{R}^{(N+1) \times (N+1)}, \quad i = 1, \dots, p-1.$$

Recall Proposition 5.8 for the matrix representations of A^N and $(A^N)^*$.

We conclude this section with some remarks:

(1) As we already mentioned in the Introduction, the spline scheme developed in this paper has interesting qualitative properties. For instance the relations between the state concept as defined in (2.4) and the dual state concept which are governed by the so called structural operator F are preserved under approximation (see [10], [13], [16], [17], [28], [31]). These results will be published elsewhere (see also [26]).

(2) Another very important property of the spline scheme is that the approximating systems (Σ^N) are stable, stabilizable or detectable for all N sufficiently large whenever the delay system has the property (see [26]).

(3) In order to use the results of [20] for the infinite time horizon problem, the approximation scheme should have the following property: If the delay system (2.1) is stable, i.e. $\|S(t)\| \leq M e^{-\varepsilon t}$, $t \geq 0$, with $M \geq 1$, $\varepsilon > 0$, then there exist constants $\tilde{M} \geq 1$ and $\tilde{\varepsilon} > 0$ such that for all N sufficiently large

$$\|S^N(t)\| \leq \tilde{M} e^{-\tilde{\varepsilon} t}, \quad t \geq 0.$$

It can be shown that this property is not satisfied for our spline scheme (see [26] for details).

(4) The assumption $e_{ij}^N |[-h_i, -h_{i-1}] \in W^{1,2}(-h_i, -h_{i-1}; \mathbb{R})$ can easily be weakened. One can allow jumps of e_{ij}^N in the interval $[-h_i, -h_{i-1}]$. Then the definition of A^N has to be modified by adding additional terms containing the approximating delta impulses corresponding to these additional jumps. This idea has been used in [34], where a realization of the scheme using piecewise linear functions is investigated. If one uses stepfunctions then one obtains the well-known averaging scheme.

(5) An important feature of the scheme developed in § 5.1 is that due to the product space structure of X^N orthogonality of the functions e_{ij}^N , $i = 1, \dots, p$, $j = 1, \dots, k_N$, implies orthogonality of the "basis elements"

$$\hat{e}_0^N, \hat{e}_{ij}^N, \quad i = 1, \dots, p, \quad j = 1, \dots, k_N.$$

This property has been exploited in [25] where a very efficient realization of the scheme by using Legendre polynomials is discussed.

6. Numerical results for the optimal control problem. The spline algorithm presented in § 5.3 was applied to a large number of examples. In this section we present the numerical findings for some of those examples. The numerical results confirm the theoretical results in case of the finite time horizon problem. The scheme performs also very well in case of the infinite time horizon problem. This is shown by two examples which already have been considered in the literature [8].

6.1. An example with finite final time. This is the problem of minimizing

$$J(u) = \frac{3}{2}x(3)^2 + \frac{1}{2} \int_0^3 u(t)^2 dt$$

subject to

$$(6.1) \quad \begin{aligned} \dot{x}(t) &= x(t-1) + u(t), & 0 \leq t \leq T=3, \\ \phi^0 &= \phi^1(0), & \phi^1(t) \equiv 1. \end{aligned}$$

For this example we have $n=1$, $p=1$, $A_{01} \equiv 0$, $A_0 = C_0 = 0$, $A_1 = B_0 = 1$, $G_0 = \frac{3}{2}$ and $R = \frac{1}{2}$. The optimal controls, trajectories and costs were calculated in [5] using the maximum principle and are given by

$$\bar{u}(t) = \begin{cases} -\frac{\delta}{2}[(t-2)^2 + 3], & 0 \leq t \leq 1, \\ \delta(t-3), & 1 \leq t \leq 2, \\ -\delta, & 2 \leq t \leq 3, \end{cases}$$

$$\bar{x}(t) = \begin{cases} 1+t-\delta\left[\frac{3t}{2}+\frac{1}{6}(t-2)^3+\frac{4}{3}\right], & 0 \leq t \leq 1, \\ \frac{3}{2}+\frac{t^2}{2}-\delta\left[4+\frac{3}{4}(t-1)^2+\frac{1}{24}(t-3)^4+\frac{4}{3}(t-1)-\frac{1}{2}(t-3)^2\right], & 1 \leq t \leq 2, \\ -\delta\left[\frac{547}{120}+5(t-2)+\frac{3}{2}(t-2)^2+\frac{1}{4}(t-2)^3-\frac{1}{6}(t-4)^3+\frac{1}{120}(t-4)^5\right], & 2 \leq t \leq 3, \end{cases}$$

$$J(\bar{u}) = \frac{329}{60} \delta^2 \quad \text{where } \delta = \frac{185}{329}.$$

The matrix valued function $[\Pi^N(t)]$, $0 \leq t \leq 3$, was computed as indicated in § 5.2. The suboptimal trajectories $\hat{x}^N(t)$ were obtained solving (6.1) with $u(t) = \hat{u}^N(t)$, $\hat{u}^N(t)$ given by (5.15), by a modified Runge-Kutta procedure. Then $\hat{u}^N(t)$ was computed from (5.15).

The numerical results we obtained are presented in Tables 6.1 and 6.2. We observe that the error $|\hat{u}^N(t) - \bar{u}(t)|$ is larger around $t = 1$ and $t = 2$ compared to other points in $[0, 3]$ because there $\bar{u}(t)$ has jumps in the derivative whereas $\hat{u}^N(t)$ is continuously differentiable on $[0, 3]$. In Table 6.2 we didn't include the values for $t = 0$ because always $\hat{x}^N(0) = \bar{x}(0)$ for our algorithm.

6.2. Two examples for the infinite time horizon problem. For the examples equation (5.18) was solved using the Newton-Kleinman algorithm as presented in [35], for instance. The Lyapunov matrix equation which has to be solved in each step of this algorithm was solved using the quadratically convergent procedure given by R. A. Smith [40] (see also [35, p. 297]). The suboptimal trajectories $\hat{x}^N(t)$ and controls $\hat{u}^N(t)$ were calculated as for the example in § 6.1 using (5.19). The two examples were already considered in [8] where the approximation was done based on the spline algorithm developed in [7].

The first example is Example 4.1 in [8] and considers the minimization of

$$J(u) = \int_0^\infty [x(t)^2 + u(t)^2] dt$$

subject to

$$\begin{aligned} \dot{x}(t) &= x(t) + x(t-1) + u(t), \quad t \geq 0, \\ \phi^0 &= 0, \quad \phi^1(t) = \sin \pi t, \quad -1 \leq t \leq 0. \end{aligned}$$

In this case we have $n = p = 1$, $A_0 = A_1 = B_0 = C_0 = R = 1$. In Table 6.3 we give the values for $J(\hat{u}^N)$ and the optimal costs $J^N = \langle \Pi^N p^N(\phi^0, \phi^1), p^N(\phi^0, \phi^1) \rangle$ for the approximating systems (Σ^N) with cost functional (5.16) and the corresponding values obtained in [8].

In Table 6.4 we show the values of Π_0^N , Π_{1N}^N and for Π_0^N as obtained in [8]. Since $\text{range } \Pi \subset \text{dom } A^*$ (cf. (3.15)), we have $A_1^T \Pi_{00} \phi^0 = (\Pi_{10} \phi^0)(-1)$ for all $\phi^0 \in \mathbb{R}^n$. Therefore in case of this example we should have

$$\Pi_0^N - \Pi_{1N}^N \rightarrow 0 \quad \text{as } N \rightarrow \infty.$$

In Table 6.5 we give the values for $\Pi_1^N(\tau)$, which governs the distributed feedback in

(6.3), at the knots $-j/N$, $j=0, \dots, N$, for $N=4, 8, 16$ and 32 . We clearly see that $\Pi_1^N(\tau)$ converges uniformly on $-1 \leq \tau \leq 0$ as $N \rightarrow \infty$. Note, that $\Pi_1^N(\tau)$ is a continuous piecewise linear function on $[-1, 0]$ with knots at $-j/N$, $j=0, \dots, N$.

In Tables 6.6 and 6.7 we present the values for $\hat{u}^N(t)$ on $0 \leq t \leq 4$ and for $\hat{x}^N(t)$ on $0 \leq t \leq 3$, respectively.

The results of this example show a significant improvement in the qualitative behavior of our spline scheme compared to the scheme presented in [8]. In both schemes $\Pi_1^N(\tau)$ is a continuous piecewise linear function on $[-1, 0]$. But in [8] this function is increasingly oscillatory with increasing N (compare Figs. 4.1–4.4 in [8]), whereas in our scheme $\Pi_1^N(\tau)$ is strictly monotone and obviously converging in the supremum norm. This property of our scheme becomes very important if one wants to implement the approximating feedback law in a real system. Our scheme seems also to be more accurate as far as approximation of Π_{00} by Π_0^N and of $J(\bar{u})$ by $J^N(\hat{u}^N)$ or J^N is concerned.

The next example is Example 4.2 in [8] and considers a simplified model for the Mach number control loop for the National Transonic Facility at NASA Langley

Research Center. For details see [2] or [8]. The problem is to

minimize

$$J(u) = \int_0^\infty [x^T(t) C_0^T C_0 x(t) + u^2(t)] dt$$

subject to

$$(6.2) \quad \dot{x}(t) = \begin{pmatrix} -a & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -\omega^2 & -2\xi\omega \end{pmatrix} x(t) + \begin{pmatrix} 0 & ka & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} x(t-0.33) + \begin{pmatrix} 0 \\ 0 \\ \omega^2 \end{pmatrix} u(t), \quad t \geq 0,$$

$$\phi^0 = \text{col}(-0.1, 8.547, 0) = \phi^1(t), \quad -0.33 \leq t \leq 0.$$

We have $C_0 = (100, 0, 0)$, $n = 3$, $p = 1$, $k = -0.0117$, $\xi = 0.8$, $\omega = 0.6$ and $1/a = 1.964$. Because of the simple structure of this problem it is possible to calculate the true solution following an idea contained in [29]. If we put for $t \geq 0$, $h = 0.33$

$$y_1(t) = x_1(t+h), \quad y_2(t) = x_2(t), \quad y_3(t) = x_3(t),$$

we obtain by a simple calculation

$$(6.3) \quad \frac{d}{dt} \begin{pmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{pmatrix} = \begin{pmatrix} -a & ka & 0 \\ 0 & 0 & 1 \\ 0 & -\omega^2 & -2\xi\omega \end{pmatrix} \begin{pmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ \omega^2 \end{pmatrix} u(t).$$

The cost functional takes the form

$$(6.4) \quad J(u) = 10^4 \int_0^h x_1(t)^2 dt + \int_0^\infty [10^4 y_1(t)^2 + u(t)^2] dt,$$

where

$$(6.5) \quad x_1(t) = e^{-at} \phi_1^0 + ak \int_0^t e^{-a(t-\tau)} \phi_2^1(\tau-h) d\tau, \quad 0 \leq t \leq h$$

is not dependent on $u(t)$ on the interval $[0, h]$. Therefore minimizing $J(u)$ subject to (6.2) is equivalent to minimizing

$$\tilde{J}(u) = \int_0^\infty [10^4 y_1(t)^2 + u(t)^2] dt$$

subject to (6.3) with initial data

$$(6.6) \quad y_1(0) = x_1(h), \quad y_2(0) = x_2(0), \quad y_3(0) = x_3(0).$$

The solution of the latter problem is given by the feedback law

$$\bar{u}(t) = -(0, 0, \omega^2) \tilde{\Pi}_0 \bar{y}(t),$$

where $\bar{y}(t)$ is the solution of (6.3) with $u(t) = \bar{u}(t)$ and initial data (6.6). $\tilde{\Pi}_0$ is the solution of the algebraic Riccati equation

$$(6.7) \quad \tilde{A}^T \tilde{\Pi}_0 + \tilde{\Pi}_0 \tilde{A} - \tilde{\Pi}_0 B_0 B_0^T \tilde{\Pi}_0 + C_0^T C_0 = 0,$$

where \tilde{A} is the system matrix in (6.5) and B_0 , C_0 are the same as for (6.2).

Equation (6.7) was solved numerically to give

$$\tilde{\Pi}_0 = \begin{pmatrix} 8220.51099 & -11.61086 & -1.12107 \\ -11.61086 & 0.01851 & 0.00186 \\ -1.12107 & 0.00186 & 0.00019 \end{pmatrix}.$$

The optimal costs for the original problem are given by (see (6.4))

$$(6.8) \quad \begin{aligned} J(\bar{u}) &= \tilde{J}(\bar{u}) + 10^4 \int_0^h \bar{x}_1(t)^2 dt \\ &= \bar{y}^T(0) \tilde{\Pi}_0 \bar{y}(0) + 10^4 \int_0^h \bar{x}_1(t)^2 dt. \end{aligned}$$

Using (6.5) it is easy to calculate $J(\bar{u})$. In Table 6.8 we give the values for $J(\bar{u})$, $J(\hat{u}^N)$ and $J^N = \langle \Pi^N p^N(\phi^0, \phi^1), p^N(\phi^0, \phi^1) \rangle$ and the values available in [8].

TABLE 6.8

N	$J(\hat{u}^N)$	J^N	$J(\hat{u}^N), [8]$	$J^N, [8]$
4	136.39587	136.40499	136.7354	138.7345

16	136.40250	136.40521	—	—
$J(\bar{u})$		136.40490		

Computing $J(\bar{u})$ for general initial data (ϕ^0, ϕ^1) by using (6.8), (6.6) and (6.5) and comparing the result with

$$J(\bar{u}) = (\phi^0)^T \Pi_{00} \phi^0 + 2(\phi^0)^T \Pi_{01} \phi^1 + \langle \phi^1, \Pi_{11} \phi^1 \rangle_{L^2},$$

we immediately obtain an explicit representation of Π :

$$\begin{aligned} \Pi_{00} &= \begin{pmatrix} e^{-ah} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \tilde{\Pi}_0 \begin{pmatrix} e^{-ah} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} + 10^4 \frac{1 - e^{-2ah}}{2a} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \\ \Pi_{01} \phi^1 &= ak \begin{pmatrix} e^{-ah} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \tilde{\Pi}_0 \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \int_{-h}^0 e^{a\tau} \phi^1(\tau) d\tau \\ &\quad + 10^4 k e^{-ah} \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \int_{-h}^0 \frac{e^{-a\tau} - e^{a\tau}}{2} \phi^1(\tau) d\tau \end{aligned}$$

or, equivalently, $(\Pi_{01}^* \phi^0)(\theta) = \Pi_1(\theta) \phi^0$ with

$$\Pi_1(\theta) = ak \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \tilde{\Pi}_0 \begin{pmatrix} e^{-ah} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} e^{a\theta} + 10^4 k e^{-ah} \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \frac{e^{-a\theta} - e^{a\theta}}{2},$$

$-h \leq \theta \leq 0$, and

$$\begin{aligned} (\Pi_{11} \phi^1)(\theta) &= a^2 k^2 e^{a\theta} \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \tilde{\Pi}_0 \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \int_{-h}^0 e^{a\tau} \phi^1(\tau) d\tau \\ &\quad + ak^2 \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \int_{-h}^0 \frac{e^{-a|\tau-\theta|} - e^{a(\tau+\theta)}}{2} \phi^1(\tau) d\tau, \quad -h \leq \theta \leq 0. \end{aligned}$$

In Table 6.9 we present the values for Π_0^N , Π_0^N as computed in [8] and Π_{00} , whereas in Table 6.10 we give the values for the second row of $\Pi_1^N(-jh/4)$ and $\Pi_1(-jh/4)$ for $j=0, \dots, 4$. The other rows of these matrices are always zero. Again, our scheme is more accurate compared to the scheme in [8] and $\Pi_1^N(\theta)$ converges uniformly on $[-h, 0]$ to $\Pi_1(\theta)^T$.

STATE CONSTRAINED CONTROL PROBLEMS GOVERNED BY VARIATIONAL INEQUALITIES*

ZHENG-XU HE†

Abstract. We will consider various types of problems of minimizing some given cost functional over all pairs of states and controls subject to some parabolic or elliptic variational inequality and some state constraints. Our aim is to derive the first order optimality conditions for optimal pairs of these problems.

Key words. optimal control, state constraints, parabolic variational inequality, elliptic variational inequality, optimal pair, optimality conditions

AMS(MOS) subject classifications. Primary 49B22; secondary 49A29

1. Introduction. We will study some classes of control problems governed by the nonlinear parabolic system

$$y'(t) + Ay(t) + Fy(t) \ni Bu(t), \quad t \in (0, 1)$$

with the state constraints

$$y(t) \in K, \quad t \in [0, 1], \quad y(1) \in K_1,$$

or governed by the elliptic system

$$Ay + Fy \ni Bu$$

with

$$y \in K,$$

where A is a linear self-adjoint positive definite operator in the state space H , F is the subdifferential of some lower-semicontinuous (l.s.c.) convex function on H , B is a linear continuous operator from the space of controls to H , and both K and K_1 are closed subsets of H . In the absence of the state constraints, these problems have been treated by V. Barbu [1], [2] and [3], where first order necessary conditions were derived under suitable conditions. For those results, we refer to [4] where a unified approach to the theory of optimality conditions was presented. Using somewhat different methods, the above problems were also studied in [6], [7], [8], [14] and [15].

In this paper, we will extend the results of V. Barbu to the above problems with state constraints. For this purpose, we will employ the notion of "normal cone" defined in [9] and [10]. Our results may also be compared with those of [5, Chap. 4] (and of [12] in the finite dimensional case), but there are important differences between them due to the nonconvexity of the data and the nonlinearity of state equation in the present problems.

To avoid a lengthy exposition, we will consider mainly the following problem:

(P) Minimize

$$(1.1) \quad G_0(y, u) = \int_0^1 (g(t, y(t)) + h(u(t))) dt + \phi_0(y(1))$$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U)$ subject to the equation

* Received by the editors July 24, 1985; accepted for publication November 26, 1985.

$$(1.2) \quad \begin{aligned} y'(t) + Ay(t) + \beta(y(t) - \Psi) &\ni Bu(t) + f(t) \quad \text{a.e. } t \in (0, 1), \\ y(0) &= y_0, \end{aligned}$$

and the state constraints

$$(1.3) \quad y(t) \in K \quad \forall t \in [0, 1],$$

$$(1.4) \quad y(1) \in K_1.$$

Here $H = L^2(\Omega)$, Ω denotes a fixed bounded domain in R^N with smooth boundary Γ ; U is another Hilbert space; $g: [0, 1] \times H \rightarrow R$, $h: U \rightarrow R$ and $\phi_0: H \rightarrow R$ are given functions; K and K_1 are closed subsets of H ; $A: D(A_H) \subseteq H \rightarrow H$ is a symmetric linear elliptic operator; β is a maximal monotone graph in $R \times R$; B is a linear continuous operator from U to H ; $f \in L^2(0, 1; H)$, $\Psi \in W^{1,2}([0, 1]; H)$ and $y_0 \in H$.

Some other types of state constrained control problems will be briefly discussed. Since the proofs in these cases are very similar to that for (P), they will be omitted. Practically, all control problems in [4] may be generalized by adding the state constraints, and the optimality conditions could be derived by our method.

The content of the paper is the following. In § 2, we will discuss problem (P) and give the main results. Sections 3 and 4 will be devoted to the proof of these results. In § 5, we will give some results for the state constrained boundary control problems of parabolic type, while in § 6 we will discuss the state constrained control problems governed by elliptic variational inequalities. Finally, some examples will be given in § 7, the emphasis will be placed in verifying hypothesis (H6) given in § 2.

We will keep the notation of [4, Chaps. 5, 6 and 3]. So, the norms of H , V and U will be denoted by $\|\cdot\|_2$, $\|\cdot\|$ and $\|\cdot\|_U$, respectively (V will be described in § 2); (\cdot, \cdot) will denote the pairing between V and V^* as well as the scalar product in $H \times H$; $\langle \cdot, \cdot \rangle$ will denote the scalar product in $U \times U$.

We conclude this section by recalling some facts concerning the normal cones and the subgradients defined in [9] and [10]. Let E be a Banach space with the norm $\|\cdot\|$, and let $\varphi: E \rightarrow [-\infty, +\infty]$ be any function. If φ is finite at a point $z \in E$, then the *upper subderivative* of φ at z with respect to $y \in E$ is defined to be

$$(1.5) \quad \varphi^\uparrow(z; y) = \sup_{\rho > 0} \inf_{\delta > 0} \sup \left\{ \inf_{\|y - y'\| \leq \rho} \frac{\varphi(z' + ty') - \alpha'}{t}; \alpha' \geq \varphi(z'), \right. \\ \left. t > 0, \|z' - z\| + |\alpha' - \varphi(z)| + t < \delta \right\}.$$

The function $y \mapsto \varphi^\uparrow(z; y)$ is sublinear and l.s.c. [9, Thm. 2], and the *subdifferential* (or the set of *subgradients*) of φ at z is

$$(1.6) \quad \partial\varphi(z) = \{z^* \in E^*; z^*(y) \leq \varphi^\uparrow(z; y) \quad \forall y \in E\}.$$

The set $\partial\varphi(z)$ is weak-star closed and convex in E^* , $\partial\varphi(z)$ is not empty if and only if $\varphi^\uparrow(z; 0)$ is not $-\infty$ (see [9, Thm. 4]).

Let C be any subset of E , and denote by ψ_C the indicator function of C , i.e.,

$$\psi_C(y) = \begin{cases} 0 & \text{if } y \in C, \\ +\infty & \text{if } y \notin C. \end{cases}$$

Then by [9, Eq. (7.9)], for any $z \in C$, the *normal cone* $N_C(z)$ to C at z is characterized by

$$(1.7) \quad N_C(z) = \partial\psi_C(z).$$

But, if we let $d_C: E \rightarrow R$ be the function

$$(1.8) \quad d_C(z) = \inf \{ \|y' - y\|; y' \in C \},$$

then it is not difficult to verify that for any $y \in E$ and $z \in C$,

$$d_C^\uparrow(z; y) > 0 \text{ implies } \psi_C^\uparrow(z; y) = +\infty,$$

and so

$$d_C^\uparrow(z; y) \leq \psi_C^\uparrow(z; y) \quad \forall y \in E.$$

It follows that

$$(1.9) \quad \partial d_C(z) \subseteq \partial \psi_C(z) = N_C(z) \quad \forall z \in C.$$

Since $N_C(z)$ is a cone with vertex in the origin, by (1.9) we see that the cone spanned by $\partial d_C(z)$ is included in $N_C(z)$.

2. Hypotheses and the main results. As in [4, § 5.1], we assume that there is a Hilbert space V , which is dense in H , such that

$$V \subseteq H = H^* \subseteq V^*$$

algebraically and topologically, and the following conditions hold:

(H1) The injection of V in H is compact.

(H2) A is a linear and symmetric operator from V to V^* satisfying $(Ay, y) \geq \omega \|y\|^2 - \alpha |y|_2^2$ for all $y \in V$, for some $\omega > 0$ and $\alpha \in R$.

(H3) β is a maximal monotone graph in $R \times R$ such that $0 \in \beta(0)$, and there exists $C \geq 0$ such that

$$(Ay, \xi(y - \Psi(\cdot, t))) \geq -C(1 + |\xi(y - \Psi(\cdot, t))|_2)(1 + |y - \Psi(\cdot, t)|_2) \quad \forall t \in [0, 1],$$

for any $y \in D(A_H) = \{z \in V; Az \in H\}$ and every increasing function $\xi \in C^1(R)$ with $\xi(0) = 0$, $\dot{\xi} \leq 1$.

(H4) $h: U \rightarrow (-\infty, +\infty]$ is l.s.c. and convex.

(H5) $g: [0, 1] \times H \rightarrow R$ is measurable in t , $g(\cdot, 0) \in L^\infty(0, 1)$, and for every $r > 0$, there exists $L_r > 0$ independent of t , such that

$$|g(t, y) - g(t, z)| + |\phi_0(y) - \phi_0(z)| \leq L_r |y - z|_2 \quad \forall t \in [0, 1], |y|_2 + |z|_2 \leq r.$$

We will assume throughout that $y_0 \in V$ and

$$\int_\Omega j(y_0(x) - \Psi(x, 0)) \, dx < +\infty,$$

where $j: R \rightarrow R$ is the convex function such that $\partial j = \beta$. The equation (1.2) has for every $u \in L^2(0, 1; U)$ a unique solution $y = y(u)$ belonging to $W^{1,2}([0, 1]; H) \cap L^2(0, 1; D(A_H)) \cap C([0, 1]; V)$.

If there exists an admissible pair (y, u) , i.e. a pair satisfying (1.2), (1.3) and (1.4), such that

$$(2.1) \quad H_0(u) = \int_0^1 h(u(t)) \, dt < +\infty,$$

and if $G_0(y, u) \rightarrow +\infty$ for (y, u) admissible and $\|u\|_{L^2(0,1;U)} \rightarrow +\infty$, then the control problem (P) admits at least one optimal pair. The proof is the same with that of [4, Prop. 5.1]. However, in order to derive the optimality conditions, we need an additional hypothesis.

Let (y^*, u^*) be a fixed optimal pair for (P). Let $\varepsilon \in (0, +\infty]$. We define $\phi^\varepsilon: L^\infty(0, 1; H) \times H \rightarrow [-\infty, +\infty]$ by

$$(2.2) \quad \phi^\varepsilon(z, z_1) = \inf \{ G_0(y, u); y(t) \in z(t) + K \text{ a.e. } t \in (0, 1), y(1) \in z_1 + K_1, (y, u) \text{ satisfies (1.2), } \|y - y^*\|_\infty \leq \varepsilon, \|u - u^*\|_2 \leq \varepsilon \},$$

where $\|\cdot\|_\infty$ and $\|\cdot\|_2$ denote the norms of $L^\infty(0, 1; H)$ and $L^2(0, 1; U)$, respectively, and the infimum of the empty set is $+\infty$. Note that $\phi^\varepsilon(0, 0) = G_0(y^*, u^*)$ is finite and independent of ε , and $\phi^\varepsilon \leq \phi^{\varepsilon'}$ if $\varepsilon' \leq \varepsilon$.

The last hypothesis is:

(H6) There exists $\varepsilon \in (0, +\infty]$ such that

$$\liminf_{\substack{\|z\|_\infty \rightarrow 0 \\ |z_1|_2 \rightarrow 0}} (\phi^\varepsilon(z, z_1) - \phi^\varepsilon(0, 0)) / (\|z\|_\infty + |z_1|_2) > -\infty.$$

Let $s > N/2$ and let $Y = H^s(\Omega) \cap V$. Denote $Q = \Omega \times (0, 1)$, and

$$(2.3) \quad \mathcal{K} = \{y \in L^\infty(0, 1; H); y(t) \in K \text{ a.e. } t \in (0, 1)\}.$$

\mathcal{K} is evidently a closed subset of $L^\infty(0, 1; H)$. We have (compare with [4, Thms. 5.1 and 5.2]):

THEOREM 2.1. *Let (y^*, u^*) be any optimal pair of the control problem (P) where β is locally Lipschitz. Suppose that (H1)–(H6) are satisfied. Then there exist $p \in BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$, $\mu \in (L^\infty(Q))^*$, $\lambda \in (L^\infty(0, 1; H))^*$ and $q_1 \in H$ such that*

$$(2.4) \quad p' - Ap - \mu - \lambda \in \partial g(t, y^*) \quad \text{a.e. in } Q,$$

$$(2.5) \quad \mu_a(x, t) \in p(x, t) \partial \beta(y^*(x, t) - \Psi) \quad \text{a.e. in } Q,$$

$$(2.6) \quad p(1) + q_1 + \partial \phi_0(y^*(1)) \ni 0,$$

$$(2.7) \quad \lambda \in N_{\mathcal{K}}(y^*), \quad q_1 \in N_{K_1}(y^*(1)),$$

$$(2.8) \quad B^*p(t) \in \partial h(u^*(t)) \quad \text{a.e. } t \in (0, 1),$$

where by μ_a we denote the absolutely continuous part of μ .

Furthermore, if in addition β satisfies

$$(2.9) \quad \dot{\beta}(r) \leq C(|\beta(r)| + |r| + 1) \quad \text{a.e. } r \in \mathbb{R},$$

for some $C \geq 0$, then $\mu = \mu_a \in L^1(Q)$.

THEOREM 2.2. *Let (y^*, u^*) be any optimal pair for the control problem (P) with*

$$(2.10) \quad \beta(r) = \begin{cases} 0 & \text{if } r > 0, \\ (-\infty, 0] & \text{if } r = 0, \\ \phi & \text{if } r < 0. \end{cases}$$

Suppose (H1)–(H6) hold. Then there exist $p \in BV([0, 1]; Y^) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$, $\lambda \in (L^\infty(0, 1; H))^*$ and $q_1 \in H$ such that*

$$(2.11) \quad (p' - Ap - \lambda)_a \in \partial g(t, y^*) \quad \text{a.e. in } \{y^* > \Psi\},$$

$$(2.12) \quad p(f + Bu^* - Ay^* - y^{*'}) = 0 \quad \text{a.e. in } Q,$$

$$(2.13) \quad p(1) + q_1 + \partial \phi_0(y^*(1)) \ni 0,$$

$$(2.14) \quad \lambda \in N_{\mathcal{K}}(y^*), \quad q_1 \in N_{K_1}(y^*(1)),$$

$$(2.15) \quad B^*p(t) \in \partial h(u^*(t)) \quad \text{a.e. } t \in (0, 1).$$

Remark 2.1. It may be seen from the proofs given in §§ 3 and 4 that Theorems 2.1 and 2.2 also hold for local solutions (y^*, u^*) for the problem (P), i.e. for the pair (y^*, u^*) which minimizes $G_0(y, u)$ over all (y, u) satisfying (1.2), (1.3), (1.4) and $\|y - y^*\|_\infty < \varepsilon_0$, $\|u - u^*\|_2 \leq \varepsilon_0$, for some prescribed $\varepsilon_0 > 0$.

Remark 2.2. Our results also apply (with some minor modifications) to the problem (P) where G_0 has the following form

$$(2.16) \quad G_0(y, u) = \int_0^1 (g(t, y(t)) + h(u(t))) dt + \psi_0(y, y(1)) + H'_0(u),$$

where $H'_0: L^2(0, 1; U) \rightarrow (-\infty, +\infty]$ is convex and l.s.c., and $\psi_0: L^\infty(0, 1; H) \times H \rightarrow R$ is locally Lipschitz. We may also replace the state constraint (1.3) by the following more general one:

$$(2.17) \quad y \in \mathcal{K},$$

where \mathcal{K} is an arbitrary closed subset of $L^2(0, 1; H)$.

Remark 2.3. Hypothesis (H6) is essential to deduce the optimality conditions in our problem where state constraints are present. As a matter of fact, if $\beta = 0$ and if $g(t, \cdot)$, ϕ_0 , K and K_1 are convex, then (H6) is implied by the optimality conditions (of Theorem 2.1).

Here is the argument: Suppose that (2.4)–(2.8) hold. Let $(z, z_1) \in L^\infty(0, 1; H) \times H$, and let (y, u) be a pair satisfying (1.2) and

$$y(t) \in z(t) + K, \quad y(1) \in z_1 + K_1.$$

Multiplying (2.4) by $y - y^*$, and then integrating by parts over $[0, 1]$, we get by (1.2) that

$$(2.18) \quad \begin{aligned} (p(1), y(1) - y^*(1)) - \int_0^1 (p, B(u - u^*)) dt - \lambda(y - y^*) \\ \leq \int_0^1 g(t, y) dt - \int_0^1 g(t, y^*) dt. \end{aligned}$$

As $y - z \in \mathcal{K}$ and $y(1) - z_1 \in K_1$, we have by (2.7) that

$$\lambda(y^* - y) = \lambda(y^* - (y - z)) - \lambda(z) \geq -\lambda(z),$$

and

$$(q_1, y^*(1) - y(1)) = (q_1, y^*(1) - (y(1) - z_1)) - (q, z_1) \geq -(q_1, z_1).$$

It follows by (2.18), (2.6) and (2.8) (note that $\mu = \mu_a = 0$) that

$$\phi^\infty(z, z_1) - \phi^\infty(0, 0) \geq -\lambda(z) - (q_1, z),$$

which implies (H6) with $\varepsilon = \infty$.

3. Some lemmas. For the proof of Theorems 2.1 and 2.2, we will use a similar argument as that in [4, §§ 5.1, 5.2, 5.3 and 5.4]. But before that, some lemmas will be necessary.

LEMMA 3.1. Let $\gamma \in L^\infty(Q)$ be any positive function, let $\zeta \in (L^\infty(0, 1; H))^*$ and $p_1 \in H$. Then there exists a unique solution $p \in BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$ to the following equation:

$$(3.1) \quad \begin{aligned} p'(t) - Ap(t) - \gamma p(t) &= \zeta \quad \text{in } (0, 1), \\ p(1) &= p_1. \end{aligned}$$

Furthermore, there exists a constant $C \geq 0$ independent of γ such that

$$(3.2) \quad \|p\|_{L^\infty(0,1;H)} + \|p\|_{L^2(0,1;V)} + \|\gamma p\|_{L^1(Q)} \leq C(\|\zeta\|_{(L^\infty(0,1;H))^*} + |p_1|_2).$$

Remark 3.1. Equation (3.1) should be interpreted as follows: for any $z \in W^{1,2}([0, 1]; Y)$ (or equivalently, for any $z \in W^{1,2}([0, 1]; H) \cap L^2(0, 1; D(A_H))$) with $z(0) = 0$,

$$(3.3) \quad (p_1, z(1)) - \int_0^1 (p, z' + Az + \gamma z) dt = \zeta(z).$$

Proof of Lemma 3.1. The uniqueness follows by the fact that for any $y \in L^2(0, 1; H)$ there exists some $z \in W^{1,2}([0, 1]; H) \cap L^2(0, 1; D(A_H))$ such that $z(0) = 0$ and

$$z' + Az + \gamma z = y.$$

To establish the existence and relation (3.2), we first assume that

$$\zeta \in L^2(0, 1; H) \quad \text{and} \quad p_1 \in V.$$

In this case, the solution p to (3.1) exists and belongs to $W^{1,2}([0, 1]; H) \cap L^2(0, 1; D(A_H))$. Multiplying (3.1) by p , and then integrating over $[t, 1]$, we obtain

$$|p(t)|_2^2 + \int_t^1 (Ap(\tau), p(\tau)) d\tau + \int_t^1 \int_\Omega \gamma p(\tau)^2 dx d\tau = |p(1)|_2^2 + \int_t^1 (\zeta(\tau), p(\tau)) d\tau.$$

Using (H2) and $\gamma \geq 0$, we get

$$|p(t)|_2^2 + \omega \int_t^1 \|p(\tau)\|^2 d\tau \leq |p_1|_2^2 + \alpha \int_t^1 |p(\tau)|_2^2 d\tau + \int_t^1 (\zeta(\tau), p(\tau)) d\tau,$$

by which we deduce

$$\|p\|_{L^\infty(0,1;H)} + \|p\|_{L^2(0,1;V)} \leq C_1(\|\zeta\|_{L^1(0,1;H)} + |p_1|_2)$$

for some $C_1 \geq 0$ depending on ω and α . An argument similar to that of [4, Lemma 5.3] also shows

$$\int_Q |\gamma p| dx dt \leq C_2(\|\zeta\|_{L^1(0,1;H)} + |p_1|_2),$$

with $C_2 \geq 0$ independent of γ . Combining the last two relations, we conclude (3.2) with $C = C_1 + C_2$.

Now let $\zeta \in (L^\infty(0, 1; H))^*$ and $p_1 \in H$. Then there exist some sequences $\zeta^n \in L^2(0, 1; H)$ and $p_1^n \in V$ such that

$$(3.4) \quad \begin{aligned} \zeta^n &\rightarrow \zeta \quad \text{weak star in } (L^\infty(0, 1; H))^*, \\ p_1^n &\rightarrow p_1 \quad \text{weakly in } H. \end{aligned}$$

Let p^n be the solution of:

$$(3.5) \quad \begin{aligned} (p^n)' - Ap^n - \gamma p^n &= \zeta^n \quad \text{in } (0, 1), \\ p^n(1) &= p_1^n. \end{aligned}$$

Then as we have shown

$$(3.6) \quad \|p^n\|_{L^\infty(0,1;H)} + \|p^n\|_{L^2(0,1;V)} + \|\gamma p^n\|_{L^1(Q)} \leq C(\|\zeta^n\|_{(L^\infty(0,1;H))^*} + |p_1^n|_2).$$

So there is a subsequence of p^n (still denoted by p^n) such that

$$(3.7) \quad \begin{aligned} p^n &\rightarrow p \quad \text{weak star in } L^\infty(0, 1; H), \\ &\quad \text{weakly in } L^2(0, 1; V), \quad \text{strongly in } L^2(0, 1; H), \end{aligned}$$

$$(3.8) \quad (p^n)' = Ap^n - \gamma p^n + \zeta^n \rightarrow p' \quad \text{weak star in } (L^\infty(0, 1; Y))^*,$$

for some $p \in L^\infty(0, 1; H) \cap L^2(0, 1; V)$. Since $p^n(t)$ is bounded in H for each t , and the inclusion of $H = H^*$ in Y^* is compact, we may apply the theorem of Helly to conclude that

$$(3.9) \quad p^n(t) \rightarrow p(t) \quad \text{in } Y^* \text{ for any } t \in [0, 1],$$

and $p \in BV([0, 1]; Y^*)$. Tending to the limit in (3.5) and (3.6), and using (3.4), (3.7) and (3.8), we may deduce (3.1) and (3.2). Q.E.D.

Remark 3.2. From the proof of Lemma 3.1, we see that if $\zeta^n \in (L^\infty(0, 1; H))^*$ and $p_1^n \in H$ satisfy (3.4), then we have (3.7), (3.8) and (3.9), where p^n and p are solutions to (3.5) and (3.1) respectively.

LEMMA 3.2. Let $g(t, \cdot)$, ϕ_0 and β be Fréchet differentiable with $\dot{\beta} \in L^\infty(R) \cap C(R)$ and let $h = h(t, u): [0, 1] \times U \rightarrow R$ be a function which is measurable in t , Fréchet differentiable and convex in u and satisfies

$$(3.10) \quad \nabla h(\cdot, u(\cdot)) \in L^2(0, 1; U) \quad \text{whenever } u \in L^2(0, 1; U).$$

Assume that (\bar{y}, \bar{u}) is a local solution (in the sense of Remark 2.1) for the problem:

Minimize

$$\int_0^1 (g(t, y(t)) + h(t, u(t))) dt + \phi_0(y(1)) + \psi_0(y, y(1))$$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U)$ subject to (1.2),

where $\psi_0: L^\infty(0, 1; H) \times H \rightarrow R$ is Lipschitz in some neighborhood of $(\bar{y}, \bar{y}(1))$. Then there exist $p \in BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$, $\lambda \in (L^\infty(0, 1; H))^*$ and $q_1 \in H$ such that

$$(3.11) \quad p' - Ap - \dot{\beta}(\bar{y} - \Psi)p - \lambda = \nabla g(t, \bar{y}(t)) \quad \text{in } (0, 1),$$

$$(3.12) \quad p(1) + q_1 + \nabla \phi_0(\bar{y}(1)) = 0,$$

$$(3.13) \quad (\lambda, q_1) \in \partial \psi_0(\bar{y}, \bar{y}(1)),$$

$$(3.14) \quad B^*p(t) = \nabla h(t, \bar{u}(t)) \quad \text{a.e. } t \in (0, 1).$$

Proof. For any $v \in L^2(0, 1; U)$ and $\rho > 0$, we let y_ρ be the solution to equation (1.2) with $u = u_\rho = \bar{u} + \rho v$. For ρ small enough, we have:

$$(3.15) \quad \begin{aligned} &\int_0^1 (g(t, y_\rho(t)) + h(t, \bar{u}(t) + \rho v(t))) dt + \phi_0(y_\rho(1)) + \psi_0(y_\rho, y_\rho(1)) \\ &\quad \geq \int_0^1 (g(t, \bar{y}(t)) + h(t, \bar{u}(t))) dt + \phi_0(\bar{y}, \bar{y}(1)) + \psi_0(\bar{y}(1)). \end{aligned}$$

It is not difficult to see that

$$(3.16) \quad \lim_{\rho \searrow 0} \frac{1}{\rho} (y_\rho - \bar{y}) = z(v) \quad \text{in } C([0, 1]; H)$$

where $z(v) \in W^{1,2}([0, 1]; H) \cap L^2(0, 1; D(A_H))$ denotes the solution to

$$(3.17) \quad \begin{aligned} z(v)' + Az(v) + \beta(\bar{y} - \Psi)z(v) &= Bv, \\ z(v)(0) &= 0. \end{aligned}$$

So

$$(3.18) \quad \begin{aligned} \lim_{\rho \searrow 0} \frac{1}{\rho} \int_0^1 (g(t, y_\rho(t)) - g(t, \bar{y}(t))) dt &= \int_0^1 (\nabla g(t, \bar{y}(t)), z(v)) dt, \\ \lim_{\rho \searrow 0} \frac{1}{\rho} (\phi_0(y_\rho(1)) - \phi_0(\bar{y}(1))) &= (\nabla \phi_0(\bar{y}(1)), z(v)(1)), \end{aligned}$$

and since ψ_0 is Lipschitz near $(y, y(1))$,

$$(3.19) \quad \limsup_{\rho \searrow 0} \frac{1}{\rho} (\psi_0(y_\rho, y_\rho(1)) - \psi_0(\bar{y}, \bar{y}(1))) \leq \psi_0^\dagger(\bar{y}, \bar{y}(1); z(v), z(v)(1)).$$

On the other hand, we have for $\rho \in (0, 1]$,

$$\begin{aligned} \int_0^1 \langle \nabla h(t, \bar{u}(t)), v(t) \rangle dt &\leq \int_0^1 \frac{1}{\rho} (h(t, \bar{u}(t) + \rho v(t)) - h(t, \bar{u}(t))) dt \\ &\leq - \int_0^1 \langle \nabla h(t, \bar{u}(t) + v(t)), v(t) \rangle dt, \end{aligned}$$

and

$$\lim_{\rho \searrow 0} \frac{1}{\rho} (h(t, \bar{u}(t) + \rho v(t)) - h(t, \bar{u}(t))) = \langle \nabla h(t, \bar{u}(t)), v(t) \rangle \quad \text{a.e. } t \in (0, 1).$$

Then it follows by (3.10) that

$$(3.20) \quad \lim_{\rho \searrow 0} \frac{1}{\rho} \int_0^1 (h(t, \bar{u}(t) + \rho v(t)) - h(t, \bar{u}(t))) dt = \int_0^1 \langle \nabla h(t, \bar{u}(t)), v(t) \rangle dt.$$

Now let Z be the following linear space:

$$Z = \{z \in W^{1,2}([0, 1]; H); z = z(v) \text{ for some } v \in L^2(0, 1; U)\},$$

and define $T: Z \rightarrow \mathbb{R}$ by

$$(3.21) \quad \begin{aligned} T(z(v)) &= - \int_0^1 ((\nabla g(t, \bar{y}(t)), z(v)) + \langle \nabla h(t, \bar{u}(t)), v \rangle) dt \\ &\quad - (\nabla \phi_0(\bar{y}(1)), z(v)(1)). \end{aligned}$$

Then we obtain by (3.15), (3.18), (3.19), (3.20) and the Lipschitz continuity of ψ_0 near $(\bar{y}, \bar{y}(1))$ that

$$(3.22) \quad T(z) \leq \psi_0^\dagger(\bar{y}, \bar{y}(1); z, z(1)) \leq C(\|z\|_\infty + |z(1)|_2),$$

for any $z \in Z$, where C is the Lipschitz constant of ψ_0 in a small neighborhood of $(\bar{y}, \bar{y}(1))$. The last inequality also shows that T is well defined, i.e., for any $v, w \in L^2(0, 1; U)$ we have

$$T(z(v)) = T(z(w)) \quad \text{whenever } z(v) = z(w).$$

T is obviously linear, then by the Hahn-Banach theorem, there exists some $(\lambda, q_1) \in (L^\infty(0, 1; H))^* \times H$ such that

$$(3.23) \quad \lambda(z) + (q_1, z(1)) = T(z) \quad \forall z \in Z,$$

and

$$\lambda(y) + (q_1, y_1) \leq \psi_0^*(\bar{y}, \bar{y}(1); y, y_1) \quad \forall (y, y_1) \in L^\infty(0, 1; H) \times H.$$

The last inequality shows (3.13). By Lemma 3.1, there exists a unique solution p to (3.11) and (3.12). From (3.21), (3.23) and (3.17), we may deduce

$$\int_0^1 \langle \nabla h(t, u(t)) - B^*p(t), v(t) \rangle dt = 0 \quad \forall v \in L^2(0, 1; U),$$

which yields (3.14). Q.E.D.

LEMMA 3.3. Let $g(t, \cdot)$, ϕ_0 and β be Fréchet differentiable with $\dot{\beta} \in L^\infty(R) \cap C(R)$. Let (\bar{y}, \bar{u}) be a local solution for the problem:

Minimize

$$(3.24) \quad G(y, u) = G_0(y, u) + \psi_0(y, y(1)) + \frac{1}{2} \int_0^1 |u - u^*|_U^2 dt$$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U)$ subject to (1.2),

where G_0 is defined by (1.1) and $\psi_0: L^\infty(0, 1; H) \times H \rightarrow R$ is Lipschitz in some neighborhood of $(\bar{y}, \bar{y}(1))$. Then there exist $p \in BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$, $\lambda \in (L^\infty(0, 1; H))^*$ and $q_1 \in H$ such that

$$(3.25) \quad p' - Ap - \dot{\beta}(\bar{y} - \Psi)p - \lambda = \nabla g(t, \bar{y}(t)) \quad \text{in } (0, 1),$$

$$(3.26) \quad p(1) + q_1 + \nabla \phi_0(\bar{y}(1)) = 0,$$

$$(3.27) \quad (\lambda, q_1) \in \partial \psi_0(\bar{y}, \bar{y}(1)),$$

$$(3.28) \quad B^*p(t) \in \partial h(\bar{u}(t)) + \bar{u} - u^* \quad \text{a.e. } t \in (0, 1).$$

Proof. Let $h_\rho: U \rightarrow R$ be the function

$$h_\rho(u) = \inf \left\{ \frac{1}{2\rho} |u - v|_U^2 + h(v); v \in U \right\},$$

where $\rho > 0$. Consider the approximating problem:

Minimize

$$\int_0^1 (g(t, y(t)) + h_\rho(u(t)) + \frac{1}{2} |u(t) - u^*(t)|_U^2 + \frac{1}{2} |u(t) - \bar{u}(t)|_U^2) dt \\ + \phi_0(y(1)) + \psi_0(y, y(1))$$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U)$ subject to (1, 2) and

$$\|y - \bar{y}\|_\infty \leq \varepsilon_0, \quad \|u - \bar{u}\|_2 \leq \varepsilon_0,$$

with $\varepsilon_0 > 0$ small enough. Let $(\bar{y}_\rho, \bar{u}_\rho)$ be an optional pair to the above problem which obviously exists. Then we may show that

$$(3.29) \quad \begin{aligned} \bar{u}_\rho &\rightarrow \bar{u} \quad \text{in } L^2(0, 1; U) \text{ for } \rho \searrow 0, \\ \bar{y}_\rho &\rightarrow \bar{y} \quad \text{in } W^{1,2}([0, 1]; H) \cap L^2(0, 1; D(A_H)) \text{ for } \rho \searrow 0. \end{aligned}$$

Applying Lemma 3.2, we deduce that there exist for any ρ small enough some p_ρ , λ_ρ and $q_{1\rho}$ such that

$$\begin{aligned}
 (3.30) \quad & p'_\rho - Ap_\rho - \dot{\beta}(\bar{y}_\rho - \Psi)p_\rho - \lambda_\rho = \nabla g(t, \bar{y}_\rho) \quad \text{in } (0, 1), \\
 & p_\rho(1) + q_{1\rho} + \nabla \phi_0(\bar{y}_\rho(1)) = 0, \\
 & (\lambda_\rho, q_{1\rho}) \in \partial \psi_0(\bar{y}_\rho, \bar{y}_\rho(1)), \\
 & B^*p_\rho(t) = \nabla h_\rho(\bar{u}_\rho(t)) + \bar{u}_\rho - u^* + \bar{u}_\rho - \bar{u} \quad \text{a.e. } t \in (0, 1).
 \end{aligned}$$

In virtue of (3.29) and the Lipschitz continuity of ψ_0 near $(\bar{y}, \bar{y}(1))$, we have

$$(3.31) \quad \|\lambda_\rho\|_{(L^\infty(0,1;H))^*} + |q_{1\rho}|_2 \leq C_1,$$

here and in the following C_i , $i = 1, 2, \dots$, are some positive constants independent of $\rho > 0$ (ρ small enough). By (H5), we also get

$$(3.32) \quad \|\nabla g(t, \bar{y}_\rho)\|_\infty + |\nabla \phi_0(\bar{y}_\rho(1))|_2 \leq C_2.$$

Since $\dot{\beta} \geq 0$, we deduce from (3.30), (3.31), (3.32) and Lemma 3.1 that p_ρ is bounded in $BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$ for $\rho \searrow 0$. An argument similar to the last part of the proof of Lemma 3.1 shows for some sequence $\rho_m \rightarrow 0$, and some $p \in BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$,

$$\begin{aligned}
 (3.33) \quad & p_{\rho_m} \rightarrow p \quad \text{weak star in } L^\infty(0, 1; H), \\
 & \text{weakly in } L^2(0, 1; V), \quad \text{strongly in } L^2(0, 1; H),
 \end{aligned}$$

$$(3.34) \quad (p_{\rho_m})' \rightarrow p' \quad \text{weak star in } (L^\infty(0, 1; Y))^*,$$

$$(3.35) \quad p_{\rho_m}(t) \rightarrow p(t) \quad \text{in } Y^* \quad \forall t \in [0, 1].$$

Since $\dot{\beta}$ is continuous and bounded, we may get by (3.29) that

$$\dot{\beta}(\bar{y}_{\rho_m} - \Psi) \rightarrow \dot{\beta}(\bar{y} - \Psi) \quad \text{weak star in } L^\infty(Q).$$

Combining this with (3.33), we get

$$(3.36) \quad \dot{\beta}(\bar{y}_{\rho_m} - \Psi)p_{\rho_m} \rightarrow \dot{\beta}(\bar{y} - \Psi)p \quad \text{weakly in } L^2(0, 1; H).$$

By (3.31), (3.32) and (3.29), we may assume that

$$\begin{aligned}
 (3.37) \quad & \lambda_{\rho_m} \rightarrow \lambda \quad \text{weak star in } (L^\infty(0, 1; H))^*, \\
 & q_{1\rho_m} \rightarrow q_1 \quad \text{weakly in } H. \\
 (3.38) \quad & \nabla g(t, \bar{y}_{\rho_m}) \rightarrow \nabla g(t, \bar{y}) \quad \text{weak star in } L^\infty(0, 1; H), \\
 & \nabla \phi_0(\bar{y}_{\rho_m}(1)) \rightarrow \nabla \phi_0(\bar{y}(1)) \quad \text{weakly in } H.
 \end{aligned}$$

Now tending to the limit in (3.30) for $\rho = \rho_m \searrow 0$, using (3.29), (3.33), (3.34), (3.35), (3.36), (3.37) and (3.38), we may conclude that p , λ and q_1 satisfy (3.25)–(3.28) (for the proof of (3.27), see also [4, Prop. 1.11(ii)]). Q.E.D.

4. Proof of Theorems 2.1 and 2.2. By (H6), there exist $\varepsilon > 0$ and $r_0 > 0$ such that

$$(4.1) \quad M = - \inf_{\|z\|_\infty + |z|_2 \leq r_0} (\phi^\varepsilon(z, z_1) - \phi^\varepsilon(0, 0)) / (\|z\|_\infty + |z|_2)$$

is not $+\infty$. Define the functions $d: L^\infty(0, 1; H) \rightarrow [0, +\infty)$ and $d_1: H \rightarrow [0, \infty)$ by

$$(4.2) \quad d(y) = \inf \{\|y - z\|_\infty, z \in \mathcal{K}\},$$

where \mathcal{K} is the set (2.3), and

$$(4.3) \quad d_1(y_1) = \inf \{|y_1 - z_1|_2; a_1 \in K_1\},$$

respectively. Let $\tilde{\phi}: [0, +\infty) \rightarrow [0, +\infty]$ be the function:

$$(4.4) \quad \tilde{\phi}(r) = -\inf \{\phi^\varepsilon(z, z_1) - \phi^\varepsilon(0, 0); \|z\|_\infty + |z_1|_2 \leq r\}.$$

Then $\tilde{\phi}$ is nonnegative and increasing in r . By (4.1), we have

$$\tilde{\phi}(r) \leq Mr \quad \text{if } 0 \leq r \leq r_0.$$

Then we may construct a continuous function $\tilde{\psi}: [0, +\infty) \rightarrow [0, +\infty]$ satisfying the properties:

$$(4.5) \quad \tilde{\psi}(r) = Mr \quad \forall r \in [0, r_0/2],$$

$$(4.6) \quad \tilde{\psi}(r) \geq \tilde{\phi}(r) \quad \forall r \in [0, +\infty).$$

Let $\psi_0: L^\infty(0, 1; H) \times H \rightarrow [0, +\infty]$ be the function defined by:

$$(4.7) \quad \psi_0(y, y_1) = \tilde{\psi}(d(y) + d_1(y_1)).$$

We have:

LEMMA 4.1. *Let (y^*, u^*) be an arbitrary optimal pair for the control problem (P) and suppose (H6) holds. Then (y^*, u^*) solves locally the following problem:*

Minimize

$$(4.8) \quad G(y, u) = G_0(y, u) + \psi_0(y, y(1))$$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U)$ subject to (1.2).

Proof. Assume contrarily that there exists a pair (y, u) satisfying (1.2) such that

$$G(y, u) < G(y^*, u^*),$$

and

$$(4.9) \quad \|y - y^*\|_\infty \leq \varepsilon_0 = \varepsilon, \quad \|u - u^*\|_2 \leq \varepsilon_0 = \varepsilon.$$

Then by (4.7) and (4.8),

$$G_0(y, u) + \tilde{\psi}(d(y) + d_1(y(1))) < G_0(y^*, u^*).$$

As $\tilde{\psi}$ is continuous, there exists some $\delta > 0$ such that

$$G_0(y, u) + \tilde{\psi}(d(y) + d_1(y(1)) + \delta) < G_0(y^*, u^*).$$

By (4.6), we get

$$\tilde{\phi}(d(y) + d_1(y(1)) + \delta) < -(G_0(y, u) - G_0(y^*, u^*)),$$

which in virtue of (2.2), (4.9), (4.2) and (4.3) contradicts (4.4). Lemma 4.1 is proved.

It is easy to see from (4.5), (4.7) and (1.9) that

$$\partial\psi_0(y^*, y^*(1)) = M(\partial d(y^*) \times \partial d_1(y^*(1))) \subseteq N_{\mathcal{K}}(y^*) \times N_{K_1}(y^*(1)).$$

So in virtue of Lemma 4.1, Theorems 2.1 and 2.2 follow from Propositions 4.1 and 4.2 below.

PROPOSITION 4.1. *Let (y^*, u^*) be any local optimal pair for the following problem:*

(P') *Minimize*

$$G(y, u) = G_0(y, u) + \psi_0(y, y(1))$$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U)$ subject to (1.2).

Suppose that (H1)–(H5) hold and $\psi_0: L^\infty(0, 1; H) \times H \rightarrow (-\infty, +\infty]$ is Lipschitz in some neighborhood of $(y^*, y^*(1))$. If β is locally Lipschitz, then there exist $p \in BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$, $\mu \in (L^\infty(Q))^*$, $\lambda \in (L^\infty(0, 1; H))^*$ and $q_1 \in H$ such that

$$(4.10) \quad p' - Ap - \mu - \lambda \in \partial g(t, y^*) \quad \text{a.e. in } Q,$$

$$(4.11) \quad \mu_a(x, t) \in p(y, t) \partial \beta(y^*(x, t) - \Psi) \quad \text{a.e. in } Q,$$

$$(4.12) \quad p(1) + q_1 + \partial \phi_0(y^*(1)) \ni 0,$$

$$(4.13) \quad (\lambda, q_1) \in \partial \psi_0(y^*, y^*(1)),$$

$$(4.14) \quad B^*p(t) \in \partial h(u^*(t)) \quad \text{a.e. } t \in (0, 1).$$

Furthermore, if in addition β satisfies (2.9), then $\mu = \mu_a \in L^q(Q)$.

PROPOSITION 4.2. Let β be defined by (2.10). Under the assumptions of Proposition 4.1, there exist $p \in BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$, $\lambda \in (L^\infty(0, 1; H))^*$ and $q_1 \in H$ such that

$$(4.15) \quad (p' - Ap - \lambda)_a \in \partial g(t, y^*) \quad \text{a.e. in } \{y^* > \Psi\},$$

$$(4.16) \quad p(f + Bu^* - Ay^* - y^{*'}) = 0 \quad \text{a.e. in } Q,$$

$$(4.17) \quad p(1) + q_1 + \partial \phi_0(y^*(1)) \ni 0,$$

$$(4.18) \quad (\lambda, q_1) \in \partial \psi_0(y^*, y^*(1)),$$

$$(4.19) \quad B^*p(t) \in \partial h(u^*(t)) \quad \text{a.e. } t \in (0, 1).$$

Proof of Propositions 4.1 and 4.2. We will proceed as in the proof of [4, Thms. 5.1 and 5.2]. The notations of [4, § 5.2] will be implicitly used.

Let $\rho > 0$. Then there exists at least one solution (y_ρ, u_ρ) to the following approximating problem:

$$(P'_\rho) \quad \begin{aligned} &\text{Minimize} \\ &G^\rho(y, u) = \int_0^1 (g^\rho(t, y(t)) + h(t, u(t)) + \tfrac{1}{2}\|u(t) - u^*(t)\|_U^2) dt \\ &\quad + \phi_0^\rho(y(1)) + \psi_0(y, y(1)) \\ &\text{over all } (y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U) \text{ subject to} \\ &y' + Ay + \beta^\rho(y - \Psi) = Bu + f \quad \text{a.e. } t \in (0, 1), \\ &y(0) = y_0, \\ &\text{and } \|y - y^*\|_\infty \leq \varepsilon_0, \|u - u^*\|_2 \leq \varepsilon_0. \end{aligned}$$

As in the proof of [4, Lemma 5.2], we may show that for $\rho \searrow 0$,

$$(4.21) \quad u_\rho \rightarrow u^* \quad \text{in } L^2(0, 1; U),$$

$$(4.22) \quad y_\rho \rightarrow y^* \quad \text{in } L^2(0, 1; V) \cap C([0, 1]; H),$$

$$\text{weakly in } W^{1,2}([0, 1]; H) \cap L^2(0, 1; D(A_H)),$$

$$(4.23) \quad \beta^\rho(y_\rho - \Psi) \rightarrow \eta \quad \text{weakly in } L^2(0, 1; H)$$

where $\eta = f + Bu^* - Ay^* - y^{*'} \in \beta(y^* - \Psi)$.

By Lemma 3.3, there exist for any $\rho > 0$ small enough, some $p_\rho \in BV([0, 1]; Y^*) \cap L^\infty(0, 1; H) \cap L^2(0, 1; V)$, $\lambda_\rho \in (L^\infty(0, 1; H))^*$ and $q_{1\rho} \in H$ such that

$$(4.24) \quad p'_\rho - Ap_\rho - \dot{\beta}^\rho(y_\rho - \Psi)p_\rho - \lambda_\rho = \nabla g^\rho(t, y_\rho(t)) \quad \text{in } (0, 1),$$

$$(4.25) \quad p_\rho(1) + q_{1\rho} + \nabla \phi_0^\rho(y_\rho(1)) = 0,$$

$$(4.26) \quad (\lambda_\rho, q_{1\rho}) \in \partial \psi_0(y_\rho, y_\rho(1)),$$

$$(4.27) \quad B^*p_\rho(t) \in \partial h(u_\rho(t)) + u_\rho - u^*(t) \quad \text{a.e. in } (0, 1).$$

In virtue of the Lipschitz continuity of ψ_0 near $(y^*, y^*(1))$ and (4.22), we have for ρ small,

$$(4.28) \quad \|\lambda_\rho\|_{(L^\infty(0,1;H))^*} + |q_{1\rho}|_2 \leq C_1.$$

(As before, C_i , $i = 1, 2, \dots$, denote constants independent of ρ .) By hypothesis (H5),

$$(4.29) \quad \|\nabla g^\rho(\cdot, y_\rho(\cdot))\|_\infty + |\nabla \phi_0^\rho(y_\rho(1))|_2 \leq C_2.$$

Using Lemma 3.1, we deduce from (4.24), (4.25), (4.28) and (4.29) that

$$(4.30) \quad \|p_\rho\|_{L^\infty(0,1;H)} + \|p_\rho\|_{L^2(0,1;V)} + \int_Q |\dot{\beta}^\rho(y_\rho - \Psi)p_\rho| \, dx \, dt \leq C_3.$$

By (4.22), (4.28), (4.29) and (4.30), we may select a sequence $\rho_m \searrow 0$ such that

$$(4.31) \quad \lambda_{\rho_m} \rightarrow \lambda \quad \text{weak star in } (L^\infty(0, 1; H))^*,$$

$$(4.32) \quad q_{1\rho_m} \rightarrow q_1 \quad \text{weakly in } H,$$

$$(4.33) \quad \nabla g^{\rho_m}(t, y_{\rho_m}(t)) \rightarrow \zeta \quad \text{weak star in } L^\infty(0, 1; H),$$

$$(4.34) \quad \nabla \phi_0^{\rho_m}(y_{\rho_m}(1)) \rightarrow q_2 \quad \text{weakly in } H,$$

$$(4.35) \quad p_{\rho_m} \rightarrow p \quad \text{weak star in } L^\infty(0, 1; H),$$

$$\text{weakly in } L^2(0, 1; V),$$

$$(4.36) \quad \dot{\beta}^{\rho_m}(y_{\rho_m} - \Psi)p_{\rho_m} \rightarrow \mu \quad \text{weak star in } (L^\infty(Q))^*,$$

for some $\lambda \in (L^\infty(0, 1; H))^*$, $q_1 \in H$, $\zeta \in L^\infty(0, 1; H)$, $q_2 \in H$, $p \in L^\infty(0, 1; H) \cap L^2(0, 1; V)$ and $\mu \in (L^\infty(Q))^*$. As in the last part of the proof of Lemma 3.1, we may infer that $p \in BV([0, 1]; Y^*)$ and

$$p_{\rho_m}(t) \rightarrow p(t) \quad \text{in } Y^* \quad \forall t \in [0, 1].$$

As in [5, Lemma 5.4], we get

$$(4.37) \quad \zeta(t) \in \partial g(t, y^*(t)) \quad \text{a.e. } t \in (0, 1),$$

and

$$(4.38) \quad q_2 \in \partial \phi_0(y^*(1)).$$

Tending to the limit in (4.24)–(4.27), it follows that p , λ and q_1 satisfy the following equations

$$(4.39) \quad p' - Ap - \mu - \lambda \in \partial g(t, y^*),$$

$$(4.40) \quad p(1) + q_1 + \partial \phi_0(y^*(1)) \ni 0,$$

$$(4.41) \quad (\lambda, q_1) \in \partial \psi_0(y^*, y^*(1)),$$

$$(4.42) \quad B^*p(t) \in \partial h(u^*(t)) \quad \text{a.e. } t \in (0, 1),$$

where μ is the limit in (4.36).

Now the argument of [4, § 5.3] and [4, § 5.4] may be repeated here word for word, and it completes the proof of Propositions 4.1 and 4.2. Q.E.D.

5. State constrained boundary control problems. We will consider here the state constrained control systems with nonlinear boundary value conditions. The other types of state constrained boundary control problems may be studied in the same way. Since the proof of the results is similar to that in the previous case (using [4, § 6.1]), it will be omitted. Our results constitute extensions of [4, Thms. 6.1 and 6.2].

Let Ω be a bounded domain of R^N with smooth boundary $\Gamma = \partial\Omega$. Assume Γ_1 and Γ_2 are two disjoint and smooth parts of Γ such that $\Gamma = \Gamma_1 \cup \Gamma_2$. Let $a_{jk} \in C^1(\bar{\Omega})$, $a_0 \in L^\infty(\Omega)$, with $a_{jk} = a_{kj}$ for $j, k = 1, 2, \dots, N$. Assume that for some $\omega > 0$, we have

$$(5.1) \quad \sum_{j,k=1}^N a_{jk}(x) \xi_j \xi_k \geq \omega \|\xi\|^2 \quad \forall x \in \Omega, \quad \xi \in R^N.$$

Define A_0 to be the following second order differential operator

$$(5.2) \quad A_0 y = - \sum_{j,k=1}^N (a_{jk}(x) y_{x_j})_{x_k} + a_0(x) y(x).$$

We will consider the problem:

(P_b) Minimize

$$(5.3) \quad G_1(y, u_1, u_2) = \int_0^1 (g(t, y(t)) + h_1(u_1(t)) + h_2(u_2(t))) dt + \phi_0(y(1))$$

over all $y \in W([0, 1]; H^1(\Omega)) = L^2(0, 1; H^1(\Omega)) \cap W^{1,2}([0, 1]; H^1(\Omega)^*)$
and $(u_1, u_2) \in L^2(0, 1; U_1) \times L^2(0, 1; U_2)$ subject to

$$(5.4) \quad \begin{cases} y_t + A_0 y = f_0 & \text{in } Q = \Omega \times (0, 1), \\ y(x, 0) = y_0(x), & x \in \Omega, \\ \frac{\partial y}{\partial \nu} + \beta_i(y) \ni B_i u_i + f_i & \text{in } \Sigma_i = \Gamma_i \times (0, 1), \quad i = 1, 2, \dots, \end{cases}$$

and

$$(5.5) \quad y(t) \in K, \quad t \in [0, 1],$$

$$(5.6) \quad y(1) \in K_1.$$

Here $f_0 \in L^2(Q)$, $f_i \in L^2(\Gamma_i)$, $i = 1, 2$; U_i are Hilbert spaces with the scalar products $\langle \cdot, \cdot \rangle_i$; B_i are linear continuous operators from U_i to $L^2(\Gamma_i)$; $\partial y / \partial \nu$ denotes the conormal derivative on Γ ; y_t is the derivative of y with respect to t ; β_i are maximal graphs in $R \times R$ such that $0 \in \beta_i(0)$; $g: [0, 1] \times H \rightarrow R$ and $\phi_0: H \rightarrow R$ satisfy (H5) of § 2; $h_i: U_i \rightarrow (-\infty, +\infty]$ satisfy (H4) of § 2; and $y_0 \in H^1(\Omega)$ is such that

$$j_i(y_0) \in L^1(\Gamma_i),$$

where

$$\partial j_i = \beta_i, \quad i = 1, 2.$$

Let (y^*, u^*) be any optimal pair to the control problem (P_b). We define for each $\varepsilon \in (0, +\infty]$ the function $\phi_b^\varepsilon: L^\infty(0, 1; H) \times H \rightarrow [-\infty, +\infty]$ by

$$(5.7) \quad \phi_b^\varepsilon(z, z_1) = \inf \{ G_1(y, u); y(t) \in z(t) + K, y(1) \in z_1 + K_1, \\ (y, u) \text{ satisfies (5.4), } \|y - y^*\|_\infty \leq \varepsilon, \|u - u^*\|_2 \leq \varepsilon \}.$$

Then we have:

THEOREM 5.1. *Let (y^*, u_1^*, u_2^*) be any optimal solution for the control problem (P_b) where β_i are locally Lipschitz functions satisfying (2.9). Assume that for some $\varepsilon > 0$,*

$$(5.8) \quad \liminf_{\|z\|_\infty + |z_1|_2 \rightarrow 0} (\phi_b^\varepsilon(z, z_1) - \phi_b^\varepsilon(0, 0)) / (\|z\|_\infty + |z_1|_2) \neq -\infty.$$

Then there exist $p \in BV([0, 1]; (H^1(\Omega))^) \cap L^2(0, 1; L^2(\Omega)) \cap L^2(0, 1; H^1(\Omega))$, $\lambda \in (L^\infty(0, 1; H))^*$ and $q_1 \in L^2(\Omega)$ such that $\partial p / \partial \nu \in L^1(\Sigma)$ and*

$$(5.9) \quad p_t - A_0 p - \lambda \in \partial g(t, y^*) \quad \text{in } Q,$$

$$(5.10) \quad \partial p / \partial \nu + p \partial \beta_i(y^*) \ni 0 \quad \text{on } \Gamma_i, \quad i = 1, 2,$$

$$(5.11) \quad p(1) + q_1 + \partial \phi_0(y^*(1)) \ni 0,$$

$$(5.12) \quad \lambda \in N_{\mathcal{H}}(y^*), \quad q_1 \in N_{K_1}(y^*(1)),$$

$$(5.13) \quad B_i^* p(t) \in \partial h_i(u_i^*(t)) \quad \text{a.e. } t \in (0, 1), \quad i = 1, 2,$$

where \mathcal{H} is the set (2.3).

THEOREM 5.2. *Suppose that $\Gamma_1 = \Gamma$, $\Gamma_2 = \phi$, $h_1 = h$ and $\beta_1 = \beta$ is given by (2.10). Let (y^*, u^*) be an optimal pair for the control problem (P_b) and assume that (5.8) is satisfied for some $\varepsilon > 0$. Then there exist $p \in BV([0, 1]; (H^1(\Omega))^*) \cap L^\infty(0, 1; L^2(\Omega)) \cap L^2(0, 1; H^1(\Omega))$, $\lambda \in (L^\infty(0, 1; H))^*$ and $q_1 \in L^2(\Omega)$ such that $\partial p / \partial \nu \in (L^\infty(\Sigma))^*$ and*

$$(5.14) \quad p_t - A_0 p - \lambda \in \partial g(t, y^*) \quad \text{in } Q,$$

$$(5.15) \quad \left(\frac{\partial p}{\partial \nu} \right)_a = 0 \quad \text{in } \{(\sigma, t) \in \Sigma; y^*(\sigma, t) > 0\},$$

$$(5.16) \quad p = 0 \quad \text{a.e. in } \left\{ (\sigma, t) \in \Sigma; y^*(\sigma, t) = 0, Bu^* - \frac{\partial y^*}{\partial \nu} - f_1 > 0 \right\},$$

$$(5.17) \quad p(1) + q_1 + \partial \phi_0(y^*(1)) \ni 0,$$

$$(5.18) \quad \lambda \in N_{\mathcal{H}}(y^*), \quad q_1 \in N_{K_1}(y^*(1)),$$

$$(5.19) \quad B^* p(t) \in \partial h(u^*(t)) \quad \text{a.e. } t \in (0, 1).$$

Remark 5.1. A function $p \in BV([0, 1]; (H^1(\Omega))^*) \cap L^2(0, 1; H^1(\Omega))$ is said to be the solution of the equation

$$(5.20) \quad \begin{aligned} p_t - A_0 p &= \zeta \quad \text{in } Q, \\ \frac{\partial p}{\partial \nu} &= \eta \quad \text{on } \Sigma, \\ p(1) &= p_1, \end{aligned}$$

with $\zeta \in (L^\infty(0, 1; H))^*$, $\eta \in (L^\infty(\Sigma))^*$ and $p_1 \in L^2(\Omega)$, if for any $y \in W^{1,2}([0, 1]; H^1(\Omega))$ with $y / \Sigma \in L^\infty(\Sigma)$ and $y(0) = 0$,

$$(5.21) \quad \sum_{j,k=1}^N \int_0^1 \int_\Omega a_{jk} \frac{\partial y}{\partial x_j} \frac{\partial y}{\partial x_k} dx dt + \int_0^1 (p, y_t) dt + (p_1, y(1)) = \zeta(y) + \eta(y / \Sigma).$$

6. State constrained control of elliptic variational inequalities. The state constrained control problems governed by elliptic variational inequalities are in parallel with those governed by parabolic variational inequalities. Here we will consider as a model the

distributed control problem. The proof for the results (i.e. for Theorems 6.1 and 6.2 below) may be simply a combination of a lemma like Lemma 4.1 and [4, Thms. 3.2 and 3.3].

The state constrained distributed control problem is of the following type.

(P_e) Minimize

$$(6.1) \quad g(y) + h(u)$$

over all $y \in H_0^1(\Omega) \cap H^2(\Omega)$, $u \in U$ subject to

$$(6.2) \quad A_0 y + \beta(y - \Psi) \ni f + Bu \quad \text{a.e. in } \Omega,$$

and

$$(6.3) \quad y \in K,$$

where $g: L^2(\Omega) \rightarrow \mathbb{R}$ is a locally Lipschitz function; U is a Hilbert space; $h: U \rightarrow (-\infty, +\infty]$ is convex and l.s.c.; A_0 has the same meaning as in § 5; β is a maximal graph in $\mathbb{R} \times \mathbb{R}$ with $0 \in \beta(0)$; $\Psi \in H^2(\Omega)$, $\Psi \leq 0$ on Γ ; $f \in L^2(\Omega)$; $B: U \rightarrow L^2(\Omega)$ is linear and continuous; K is a closed subset of $H = L^2(\Omega)$.

Let (y^*, u^*) be any optimal pair for the control problem (P_e). Define for any $\varepsilon \in (0, +\infty]$ the function $\phi_\varepsilon^*: H \rightarrow [-\infty, +\infty]$ by

$$(6.4) \quad \phi_\varepsilon^*(z) = \inf \{g(y) + h(u); y \in z + K, (y, u) \text{ satisfies (6.2)}, \\ |y - y^*|_2 \leq \varepsilon, |u - u^*|_U \leq \varepsilon\}.$$

We have (compare with [4, Thms. 3.2 and 3.3]):

THEOREM 6.1. *Let $(y^*, u^*) \in H_0^1(\Omega) \times U$ be any optimal pair for the control problem (P_e) where $\beta: \mathbb{R} \rightarrow \mathbb{R}$ is locally Lipschitz and monotonically increasing function. Assume that for some $\varepsilon \in (0, +\infty]$,*

$$(6.5) \quad \liminf_{|z|_2 \rightarrow 0} (\phi_\varepsilon^*(z) - \phi_\varepsilon^*(0)) / |z|_2 \neq -\infty.$$

Then there exist $p \in H_0^1(\Omega)$, $\lambda, \xi \in L^2(\Omega)$ such that $A_0 p \in (L^\infty(\Omega))^$ and*

$$(6.6) \quad -(A_0 p)_a - p \partial \beta(y^* - \Psi) \ni \lambda + \xi, \quad \xi \in \partial g(y^*) \quad \text{in } \Omega,$$

$$(6.7) \quad \lambda \in N_K(y^*),$$

$$(6.8) \quad B^* p \in \partial h(u^*).$$

Moreover, if either $1 \leq N \leq 3$ or β satisfies (2.9), then $A_0 p \in L^1(\Omega)$ and (6.6) becomes

$$(6.9) \quad -A_0 p - p \partial \beta(y^* - \Psi) \ni \lambda + \xi, \quad \xi \in \partial g(y^*) \quad \text{in } \Omega.$$

THEOREM 6.2. *Let (y^*, u^*) be any optimal pair for the control problem (P_e) where β is defined by (2.10). Assume that (6.5) holds for some $\varepsilon \in (0, +\infty]$. Then there exist $p \in H_0^1(\Omega)$, $\lambda, \xi \in L^2(\Omega)$ with $A_0 p \in (L^\infty(\Omega))^*$, $\xi \in \partial g(y^*)$ and*

$$(6.10) \quad (A_0 p)_a + \xi + \lambda = 0 \quad \text{a.e. in } \{y^* > \Psi\},$$

$$(6.11) \quad p(A_0 y^* - f - Bu^*) = 0 \quad \text{a.e. in } \Omega,$$

$$(6.12) \quad (A_0 p + \xi + \lambda, \chi(y^* - \Psi)) = 0 \quad \forall \chi \in C^1(\bar{\Omega}),$$

$$(6.13) \quad \lambda \in N_K(y^*),$$

$$(6.14) \quad B^* p \in \partial h(u^*),$$

$$(6.15) \quad (A_0 p + \xi + \lambda, p) \leq 0.$$

If $1 \leq N \leq 3$, then (6.10) reduces to

$$(6.16) \quad (y^* - \Psi)(A_0 p + \xi + \lambda) = 0.$$

7. Examples. We will discuss some specific cases of the control problems studied in the previous sections.

Example 1. (The state constrained convex control problem.) Consider the following problem

(Q₁) Minimize

$$(7.1) \quad G_0(y, u) = \int_0^1 (g(t, y) + h(u)) dt + \phi_0(y(1))$$

over $(y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U)$ subject to

$$(7.2) \quad y' + Ay = Bu(t) + f(t),$$

and

$$(7.3) \quad y(t) \in K, \quad \forall t \in [0, 1],$$

$$(7.4) \quad y(1) \in K_1.$$

Here $H, U, g, h, \phi_0, A, B, f, y_0, K$ and K_1 have the same meaning as in § 2. In addition, we assume that

$g(t, \cdot)$ and ϕ_0 are convex functions,

K and K_1 are convex sets.

Problem (Q₁) is referred to as state constrained convex control problem.

We note that in this case ϕ^ε defined by (2.2) is l.s.c. (if $\varepsilon \in (0, +\infty)$), proper and convex. So we have

PROPOSITION 7.1. *Hypothesis (H6) is satisfied for $\varepsilon \in (0, +\infty)$ if and only if*

$$(7.5) \quad \partial\phi^\varepsilon(0) \text{ is not empty.}$$

In particular, if $0 \in \text{int } D(\phi^\varepsilon)$, then (H6) holds.

Proof. The “if” part is obvious. Let us prove the “only if” part. Since ϕ^ε is convex, it is subdifferentially regular at $(0, 0)$ (see [9, Prop. 3]), i.e.

$$(\phi^\varepsilon)^\dagger(0, 0; z, z_1) = \liminf_{\substack{(z', z'_1) \rightarrow (z, z_1) \\ \rho \searrow 0}} \frac{\phi^\varepsilon(\rho z', \rho z'_1) - \phi^\varepsilon(0, 0)}{\rho}.$$

So hypothesis (H6) says that

$$(\phi^\varepsilon)^\dagger(0, 0; 0, 0) \neq -\infty,$$

which implies (7.5) by [9, Thm. 4]. Q.E.D.

Let K_h be the subset

$$(7.6) \quad K_h = \{y(1) \in H; (y, u) \text{ satisfies (7.2), (7.3) and } H_0(u) < +\infty\},$$

where $H_0: L^2(0, 1; U) \rightarrow (-\infty, +\infty]$ is defined by

$$(7.7) \quad H_0(u) = \int_0^1 h(u(t)) dt.$$

PROPOSITION 7.2. *Suppose that there exists a pair (\bar{z}, \bar{v}) satisfying (7.2), (7.4) and $H_0(\bar{v}) < +\infty$, such that*

$$(7.8) \quad \bar{z}(t) \in \text{int } K \quad \forall t \in [0, 1].$$

If either $\text{int } K_1 \cap K_h$ or $K_1 \cap \text{int } K_h$ is not empty, and if

$$(7.9) \quad \lim_{\substack{\|u\|_2 \rightarrow +\infty \\ y(u) \in \mathcal{H}}} \int_0^1 (g(t, y(u)) + h(u)) dt = +\infty,$$

where $y(u)$ denotes the solution of (7.2) and \mathcal{H} is the set (2.3), then (H6) is satisfied.

Proof. Since z is continuous from $[0, 1]$ to H , it follows by (7.8) that there is some $\rho > 0$ such that

$$(7.10) \quad z \in K \quad \text{whenever } |z - \bar{z}(t)|_2 \leq \rho \quad \text{for some } t.$$

Define $\Lambda: H \rightarrow [-\infty, +\infty]$ by

$$(7.11) \quad \Lambda(z_1) = \inf \{G_0(y, u); (y, u) \text{ satisfies (7.2), (7.3) and } y(1) = z_1\}.$$

Obviously, Λ is convex; by (7.9), Λ is also l.s.c. and proper. It is easy to see that

$$(7.12) \quad D(\Lambda) = K_h$$

and

$$(7.13) \quad \min \{\Lambda(z_1); z_1 \in K\} = \phi^\varepsilon(0, 0) = \Lambda(y^*(1)).$$

Fix $\varepsilon \in (0, 1]$. Let $(z, z_1) \in L^\infty(0, 1; H) \times H$, and let (y, u) be any solution of (7.2) such that

$$(7.14) \quad y(t) \in z(t) + K \quad \text{a.e. } t \in (0, 1),$$

$$(7.15) \quad y(1) \in z_1 + K_1,$$

$$(7.16) \quad \|y - y^*\|_\infty \leq \varepsilon, \quad \|u - u^*\|_2 \leq \varepsilon.$$

Set

$$(7.17) \quad \bar{y} = \frac{\rho}{\rho + \|z\|_\infty} y + \frac{\|z\|_\infty}{\rho + \|z\|_\infty} \bar{z}.$$

Then

$$\bar{y} = \frac{\rho}{\rho + \|z\|_\infty} (y - \bar{z}) + \frac{\|z\|_\infty}{\rho + \|z\|_\infty} \left(\frac{\rho z}{\|z\|_\infty} + \bar{z} \right).$$

This together with (7.14) and (7.10) implies that

$$\bar{y}(t) \in K \quad \forall t \in [0, 1].$$

Let

$$(7.18) \quad \bar{u} = \frac{\rho}{\rho + \|z\|_\infty} u + \frac{\|z\|_\infty}{\rho + \|z\|_\infty} \bar{v},$$

then (y, u) satisfies (7.2) and (7.3). Therefore (see (7.11)):

$$(7.19) \quad G_0(\bar{y}, \bar{u}) \geq \Lambda(\bar{y}(1)).$$

Since $g(t, \cdot)$, ϕ_0 and h are convex, we get by (7.17) and (7.18) that

$$\begin{aligned} G_0(\bar{y}, \bar{u}) &= \int_0^1 (g(t, \bar{y}) + h(\bar{u})) dt + \phi_0(\bar{y}(1)) \\ &\leq \frac{\rho}{\rho + \|z\|_\infty} \left(\int_0^1 (g(t, y) + h(u)) dt + \phi_0(y(1)) \right) \\ &\quad + \frac{\|z\|_\infty}{\rho + \|z\|_\infty} \left(\int_0^1 (g(t, \bar{z}) + h(\bar{v})) dt + \phi_0(\bar{z}(1)) \right) \\ &= \frac{\rho}{\rho + \|z\|_\infty} G_0(y, u) + \frac{\|z\|_\infty}{\rho + \|z\|_\infty} G_0(\bar{z}, \bar{v}). \end{aligned}$$

From (7.16), we see that $G_0(y, u)$ is bounded from below. So by the last inequality and (7.19), we obtain

$$G_0(y, u) \geq G_0(\bar{y}, \bar{u}) - C_1 \|z\|_\infty \geq \Lambda(\bar{y}(1)) - C_1 \|z\|_\infty, \quad C_1 > 0.$$

Then, it is easy to see that (H6) holds if we show

$$(7.20) \quad \Lambda(\bar{y}(1)) \geq \phi^\varepsilon(0, 0) - C_2(\|z\|_\infty + |z_1|_2), \quad C_2 > 0,$$

where (by (7.17))

$$(7.21) \quad \bar{y}(1) = \frac{\rho}{\rho + \|z\|_\infty} y(1) + \frac{\|z\|_\infty}{\rho + \|z\|_\infty} \bar{z}(1)$$

and $y(1)$ satisfies (7.15). By (7.21), (7.15) and (7.16), we have

$$(7.22) \quad \bar{y}(1) \in z_2 + K_1, \quad |z_2|_2 \leq C_3(\|z\|_\infty + |z_1|_2), \quad C_3 > 0.$$

Let $\psi_1: H \rightarrow [0, +\infty]$ be the indicator function of K_1 . By relation (7.13),

$$(7.23) \quad \min \{ \Lambda(z_1) + \psi_1(z_1); z_1 \in H \} = \Lambda(y^*(1)) + \psi_1(y^*(1)) = \phi^\varepsilon(0, 0).$$

Using (7.12), (7.23), (7.22) and the hypotheses of the proposition, we see easily that relation (7.20) (and hence Hypothesis (H6)) follows by the following lemma.

LEMMA 7.1. *Let Λ and $\psi_1: H \rightarrow (-\infty, +\infty]$ be two l.s.c. proper convex functions. Assume that either $\text{int } D(\Lambda) \cap D(\psi_1)$ or $D(\Lambda) \cap \text{int } D(\psi_1)$ is not empty. If $\Lambda + \psi_1$ attains its minimum at some point $y_1^* \in H$, then there exists some constant $C \geq 0$ such that*

$$(7.24) \quad \Lambda(y_1) + \psi_1(y_1 - z_2) \geq \Lambda(y_1^*) + \psi_1(y_1^*) - C|z_2|_2$$

for all $y_1 \in H$ and $z_2 \in H$.

Proof. Since $(\text{int } D(\Lambda) \cap D(\psi_1)) \cup (D(\Lambda) \cap \text{int } D(\psi_1))$ is not empty, it follows by a well-known theorem of Rockafellar that

$$\partial(\Lambda + \psi_1) = \partial\Lambda + \partial\psi_1.$$

In particular

$$0 \in \partial(\Lambda + \psi_1)(y_1^*) = \partial\Lambda(y_1^*) + \partial\psi_1(y_1^*).$$

Let $q_1 \in \partial\psi_1(y_1^*)$ with $-q_1 \in \partial\Lambda(y_1^*)$, then

$$\begin{aligned} \Lambda(y_1) + \psi_1(y_1 - z_2) &\geq \Lambda(y_1^*) + (-q_1, y_1 - y_1^*) + \psi_1(y_1^*) + (q_1, y_1 - z_2 - y_1^*) \\ &= \Lambda(y_1^*) + \psi_1(y_1^*) - (q_1, z_2). \end{aligned}$$

This yields (7.24) with $C = |q_1|_2$. Q.E.D.

Remark 7.1. Problem (Q_1) is also referred to as convex control problem of Bolza. It was studied in [5, Chap. 4] under somewhat different assumptions. When the control space U and the state space H are finite dimensional, this problem was thoroughly studied in [11] and [12] (see also the survey [13]). The hypotheses of Proposition 7.2 can be compared with those in [4, Chap. 4] and [12]. The function ϕ^ε has a similar form as “ φ ” defined in [13, § 12]. Using the argument of Remark 2.3, we may show that hypothesis (H6) is also necessary for the optimality conditions in the context of [5, Chap. 4] and [12].

In the special case of distributed control systems, a problem of this type has been studied by Mackenroth [6].

Example 2. Consider the following nonlinear control problem:

(Q_2) Minimize

$$G_0(y, u) = \int_0^1 (g(t, y(t)) + h(u(t))) dt + \phi_0(y(1))$$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times L^2(0, 1; U)$ subject to

$$y \geq \Psi, \quad y_t - \Delta y - Bu \geq 0 \quad \text{in } Q = \Omega \times (0, 1),$$

$$(7.25) \quad (y - \Psi)(y_t - \Delta y - Bu) = 0 \quad \text{in } Q,$$

$$\alpha_2 \frac{\partial y}{\partial \nu} + \alpha_1 y = 0 \quad \text{on } \partial\Omega \times (0, 1),$$

$$y(x, 0) = 0 \quad \text{in } \Omega,$$

and

$$(7.26) \quad \int_{\Omega} j_0(x, y(x, t)) dx \leq b_0 \quad \forall t \in [0, 1],$$

$$(7.27) \quad \int_{\Omega} j_1(x, y(x, 1)) dx \leq b_1,$$

where Δ is the Laplace operator: $\alpha_1 \geq 0$, $\alpha_2 \geq 0$, $\alpha_1 + \alpha_2 > 0$; $B: U \rightarrow H$ is linear and continuous; g, h and ϕ_0 satisfy hypotheses (H4) and (H5), and

$$(7.28) \quad h(0) \neq +\infty,$$

$j_0, j_1: \Omega \times \mathbb{R} \rightarrow \mathbb{R}$ are measurable in $x \in \Omega$, continuous, nondecreasing and convex in $y \in \mathbb{R}$,

$$(7.29) \quad j_0(x, 0) = j_1(x, 0) = 0 \quad \text{a.e. } x \in \Omega,$$

and there exists a positive constant M such that

$$(7.30) \quad j_i(x, y) \leq M(y^2 + 1) \quad \text{a.e. } x \in \Omega \quad \forall y \in \mathbb{R}, \quad i = 0, 1;$$

b_0 and b_1 are positive constants; $\Psi \in L^\infty(0, 1; H^2(\Omega)) \cap W^{1,2}([0, 1]; H)$,

$$(7.31) \quad \Psi \leq 0 \quad \text{a.e. in } Q.$$

The system (7.25) describes the obstacle problem (see [4, pp. 138–142]). The control problem (Q_2) is a particular case of problem (P) with

$$(7.32) \quad V = \begin{cases} H_0^1(\Omega) & \text{for } \alpha_2 = 0, \\ H^1(\Omega) & \text{for } \alpha_2 > 0, \end{cases}$$

$$(7.33) \quad (Au, v) = \begin{cases} \int_{\Omega} \nabla u \nabla v \, dx & \text{for } \alpha_2 = 0, \\ \int_{\Omega} \nabla u \nabla v \, dx + \frac{\alpha_1}{\alpha_2} \int_{\Gamma} u \cdot v \, d\sigma & \text{for } \alpha_2 > 0, \end{cases}$$

for any $u, v \in V$,

$$(7.34) \quad K = \left\{ y \in L^2(\Omega) : \int_{\Omega} j_0(x, y(x)) \, dx \leq b_0 \right\},$$

$$(7.35) \quad K_1 = \left\{ y_1 \in L^2(\Omega) : \int_{\Omega} j_1(x, y_1(x)) \, dx \leq b_1 \right\},$$

and β defined by (2.10).

The verification of (H1)–(H3) is standard (for (H3), see e.g. [4, p. 137]). Let (y^*, u^*) be any optimal pair. Let us show that (H6) is also satisfied. By (7.29) and (7.30), we may find some $\rho > 0$ such that

$$(7.36) \quad \int_{\Omega} j_0(x, z(x)) \leq b_0, \quad \int_{\Omega} j_1(x, z(x)) \leq b_1 \quad \text{whenever } |z|_2 \leq \rho.$$

Let $(z, z_1) \in L^\infty(0, 1; H) \times H$ with

$$(7.37) \quad \|z\|_\infty + |z_1|_2 \leq 1,$$

and let (y, u) be any solution of (7.25) satisfying

$$(7.38) \quad y(t) \in z(t) + K, \quad y(1) \in z_1 + K_1$$

and

$$(7.39) \quad \|y - y^*\|_\infty \leq 1, \quad \|u - u^*\|_2 \leq 1.$$

Denote $d = \|z\|_\infty + |z_1|_2$ and set

$$(7.40) \quad \bar{y} = \frac{\rho}{\rho + d} y, \quad \bar{u} = \frac{\rho}{\rho + d} u.$$

Then by (7.25) and (7.31) we have

$$\bar{y} \geq \Psi, \quad \bar{y}_t - \Delta \bar{y} - B\bar{u} \geq 0 \quad \text{in } Q,$$

$$\alpha_2 \frac{\partial \bar{y}}{\partial \nu} + \alpha_1 \bar{y} = 0 \quad \text{on } \partial\Omega \times (0, 1),$$

$$y(x, 0) = 0 \quad \text{in } \Omega.$$

Let \tilde{y} be the solution to (7.25) where u is replaced by \bar{u} , then we may show that

$$(7.41) \quad \bar{y} \geq \tilde{y} \quad \text{in } Q,$$

and

$$(7.42) \quad \|\tilde{y} - y\|_{L^\infty(0,1;H)} \leq C_1 \|\bar{u} - u\|_{L^2(0,1;U)} \leq C_2 d,$$

where C_1 and C_2 are some positive constants independent of d . In fact, relation (7.41) follows by an argument similar to that of [16, Thm. 6.4, Chap. 2], and relation (7.42) is trivial. Since j_0 is nondecreasing in its second variable, it follows by (7.41) that

$$\int_{\Omega} j_0(x, \tilde{y}(x, t)) \, dx \leq \int_{\Omega} j_0(x, \bar{y}(x, t)) \, dx = \int_{\Omega} j_0\left(x, \frac{\rho}{\rho + d} y(x, t)\right) \, dx.$$

Since j_0 is convex, we may deduce from the last inequality and (7.38), (7.29), (7.36) that

$$\begin{aligned} \int_{\Omega} j_0(x, \tilde{y}(x, t)) \, dx &\leq \int_{\Omega} j_0\left(x, \frac{\rho}{\rho+d}(y(x, t) - z(x, t)) + \frac{d}{\rho+d}\left(\frac{\rho z(x, t)}{d}\right)\right) \, dx \\ &\leq \frac{\rho}{\rho+d} \int_{\Omega} j_0(x, y(x, t) - z(x, t)) \, dx \\ &\quad + \frac{d}{\rho+d} \int_{\Omega} j_0\left(x, \frac{\rho z(x, t)}{d}\right) \, dx \\ &\leq \frac{\rho}{\rho+d} b_0 + \frac{d}{\rho+d} b_0 = b_0. \end{aligned}$$

Similarly,

$$\int_{\Omega} j_1(x, y(x, 1)) \, dx \leq b_1.$$

Therefore $y(t) \in K$ and $y(1) \in K_1$, and so

$$(7.43) \quad \phi^1(0, 0) = G_0(y^*, u^*) \leq G_0(\tilde{y}, \bar{u}).$$

On the other hand, since $g(t, \cdot)$ and ϕ_0 are locally Lipschitz and h is convex, we may deduce from (7.39), (7.40), (7.37), (7.28) and (7.42) that

$$G_0(\tilde{y}, \bar{u}) \leq G_0(y, u) - C_3 d = G_0(y, u) - C_3(\|z\|_{\infty} + |z_1|_2),$$

where C_3 is some positive constant. It follows then (see (7.43))

$$\phi^1(0, 0) \leq G_0(y, u) - C_3(\|z\|_{\infty} + |z_1|_2).$$

This implies (see (2.2)):

$$\phi^1(0, 0) \leq \phi^1(z, z_1) + C(\|z\|_{\infty} + |z_1|_2)$$

for any (z, z_1) satisfying (7.37). Hence (H6) holds for $\varepsilon = 1$.

Now all assumptions of Theorem 2.2 are verified. So, if (y^*, u^*) is an optimal pair for the control problem (Q_2) , then there exist $p \in BV([0, 1]; Y^*) \cap L^{\infty}(0, 1; H) \cap L^2(0, 1; V)$, $\lambda \in (L^{\infty}(0, 1; H))^*$ and $q_1 \in H$ such that

$$(7.44) \quad (p_t + \Delta p - \lambda)_a \in \partial g(t, y^*) \quad \text{a.e. in } \{y^* > \Psi\},$$

$$(7.45) \quad p(BU^* + \Delta y^* - y_t^*) = 0 \quad \text{a.e. in } \Omega \times (0, 1),$$

$$(7.46) \quad \alpha_1 p + \alpha_2 \frac{\partial p}{\partial \nu} = 0 \quad \text{on } \partial\Omega \times (0, 1),$$

$$(7.47) \quad -p(1) \in q_1 + \partial\phi_0(y^*(1)),$$

$$(7.48) \quad \lambda \in N_{\mathcal{H}}(y^*),$$

$$(7.49) \quad q_1 \in N_{K_1}(y^*(1)),$$

$$(7.50) \quad B^*p(t) \in \partial h(u^*(t)) \quad \text{a.e. } t \in (0, 1).$$

For the convex sets K and K_1 defined by (7.34) and (7.35) we have

$$N_K(y) = \begin{cases} \{0\} & \text{if } \int_{\Omega} h_0(x, y(x)) \, dx < b_0, \\ \text{Cone}(\partial h_0(x, y)) & \text{otherwise,} \end{cases}$$

$$N_{K_1}(y_1) = \begin{cases} \{0\} & \text{if } \int_{\Omega} h_1(x, y_1(x)) dx < b_1, \\ \text{Cone}(\partial h_1(x, y_1)) & \text{otherwise,} \end{cases}$$

where $\text{Cone}(\partial h_i(x, y))$ is the closed cone in $L^2(\Omega)$ spanned by the set

$$\partial h_i(x, y) = \{z \in L^2(\Omega); z(x) \in \partial_y h_i(x, y(x)) \text{ a.e. } x \in \Omega\}.$$

So (7.49) means that

$$(7.51) \quad q_1 = \begin{cases} 0 & \text{if } \int_{\Omega} h_1(x, y^*(1)) dx < b, \\ \text{Cone}(\partial h_1(x, y^*(1))) & \text{otherwise.} \end{cases}$$

Since $\lambda \in (L^\infty(0, 1; H))^*$, we have $\lambda = \lambda_a + \lambda_s$, where λ_s is the singular part of λ . Then we may infer from (7.48) that

$$(7.52) \quad \lambda_a(t) \in N_K(y^*(t)) = \begin{cases} \{0\} & \text{if } \int_{\Omega} h_0(x, y^*(t)) dx < b_0, \\ \text{Cone}(\partial h_0(x, y^*(t))) & \text{otherwise,} \end{cases}$$

for a.e. $t \in (0, 1)$ and

$$(7.53) \quad \lambda_s \in N_{\mathcal{K}}(y^*).$$

Note that

$$(p_t - \Delta p - \lambda)_a = \dot{p} - \Delta p - \lambda_a,$$

so by (7.40) we get

$$(7.54) \quad \dot{p} - \Delta p - \lambda_a \in \partial g(t, y^*) \text{ a.e. in } \{y^* > \Psi\},$$

and if $p_t = \dot{p} + (p_s)_t$, then

$$(7.55) \quad (p_s)_t = \lambda_s \text{ in } \{y^* > \Psi\}.$$

Since $y^*, \Psi \in W^{1,2}([0, 1]; L^2(\Omega)) \cap L^2(0, 1; H^2(\Omega))$, $\Delta y^* - y_t^* = \Delta \Psi - \Psi_t$ a.e. in $\{y^* = \Psi\}$. So (7.45) implies that

$$p = 0 \text{ a.e. in } \{y^* = \Psi\} \cap \{Bu^* + \Delta \Psi - \Psi_t \neq 0\}.$$

If we have in addition

$$Bu^* + \Delta \Psi - \Psi_t \neq 0 \text{ a.e. in } Q,$$

then

$$(7.56) \quad p = 0 \text{ a.e. in } \{y^* = \Psi\}.$$

Example 3. (Optimal control of the melting and solidification process.) Let Ω be a bounded domain in R^N with the boundary $\Gamma = \partial\Omega = \Gamma_1 \cup \Gamma_2$, where Γ_1 and Γ_2 are two disjoint smooth surfaces in R^N . Let F_d be a closed subset of $\bar{Q} = \bar{\Omega} \times [0, 1]$, and let \mathcal{U}_{ad} be a bounded, closed and convex subset of the space $H^{3/2, 3/4}(\Gamma_1 \times (0, 1))$, where

$H^{3/2,3/4}(\Gamma_1 \times (0, 1))$ denotes the Hilbert space of traces on $\Gamma_1 \times (0, 1)$ of functions from $W^{1,2}([0, 1]; L^2(\Omega)) \cap L^2(0, 1; H^2(\Omega))$. We will impose that

$$(7.57) \quad u(x, 0) = 0, u(x, t) \geq 0 \quad \text{a.e. } x \in \Gamma_1, \quad t \in (0, 1) \quad \forall u \in \mathcal{U}_{\text{ad}}.$$

Let $H_1: \mathcal{U} = H^{3/2,3/4}(\Gamma_1 \times (0, 1)) \rightarrow \mathbb{R}$ be any l.s.c. and convex function, and let $g: [0, 1] \times L^2(\Omega) \rightarrow \mathbb{R}$ and $\phi_0: L^2(\Omega) \rightarrow \mathbb{R}$ be two functions satisfying (H5). We will consider the following control problem:

(Q₃) Minimize

$$G_1(y, u) = \int_0^1 g(t, y(t)) dt + \phi_0(y(1)) + H_1(u)$$

over all $(y, u) \in W^{1,2}([0, 1]; L^2(\Omega)) \times \mathcal{U}_{\text{ad}}$ subject to

$$y \geq 0, y_t - \Delta y - f \geq 0 \quad \text{a.e. in } Q = \Omega \times (0, 1),$$

$$y(y_t - \Delta y - f) = 0 \quad \text{a.e. in } Q,$$

$$(7.58) \quad y = u \quad \text{on } \Gamma_1 \times (0, 1),$$

$$y = 0 \quad \text{on } \Gamma_2 \times (0, 1),$$

$$y(x, 0) = 0 \quad \text{a.e. } x \in \Omega,$$

and

$$(7.59) \quad y(x, t) = 0 \quad \text{a.e. } (x, t) \in F_d.$$

The system (7.58) arises from the melting and solidification process (see [14, pp. 16–17]). The state constraint (7.59) means that the portion $\{x \in \bar{\Omega}; (x, t) \in F_d\}$ is required to be solid at time t . When $\phi_0 = 0$, $H_1 = 0$, and g is the following function:

$$g(t, y) = \int_{\Omega} |y(x) - z_d(x, t)|^2 dx \quad \forall y \in L^2(\Omega),$$

with $z_d \in L^2(Q) = L^2(0, 1; L^2(\Omega))$, the above problem reduces to the problem studied in [14, § 5.2, Chap. 2].

Let $H_0: \mathcal{U} \rightarrow [0, +\infty]$ be the indicator function of \mathcal{U}_{ad} , i.e.

$$H_0(u) = \begin{cases} 0 & \text{if } u \in \mathcal{U}_{\text{ad}}, \\ +\infty & \text{if } u \in \mathcal{U} \setminus \mathcal{U}_{\text{ad}}. \end{cases}$$

Define $G_0: W^{1,2}([0, 1]; H) \times \mathcal{U} \rightarrow \mathbb{R}$ by

$$(7.60) \quad G_0(y, u) = G_1(y, u) + H_0(u).$$

Set

$$\mathcal{K} = \left\{ y \in L^\infty(0, 1; L^2(\Omega)), \int_{F_d} (y(x, t))^2 dx dt \leq 0 \right\}.$$

Then problem (Q₃) is equivalent to the following one:

(Q_{3'}) Minimize $G_0(y, u)$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times \mathcal{U}$ subject to (7.58) and

$$(7.61) \quad \int_{F_d} (y(x, t))^2 dx dt \leq 0.$$

Let $\delta > 0$ be small. Consider the following approximating problem:

$$(Q_3^\delta) \quad \text{Minimize } G_0(y, u)$$

over all $(y, u) \in W^{1,2}([0, 1]; H) \times \mathcal{U}$ subject to (7.58) and

$$(7.62) \quad \int_{F_d} (y(x, t))^2 dx dt \leq \delta^2.$$

If there exists a pair (y_0, u_0) satisfying (7.58) and (7.62) such that $u_0 \in \mathcal{U}_{ad}$, then the problem (Q_3^δ) admits at least one optimal pair, say (y_δ, u_δ) . The set $\{(y_\delta, u_\delta), \delta > 0\}$ is bounded in $W^{1,2}([0, 1]; H) \times \mathcal{U}_{ad}$, and any limit point (in the weak sense) of $\{(y_\delta, u_\delta), \delta \searrow 0\}$ is an optimal pair for the problem (Q_3') .

Problem (Q_3^δ) is different from problem (P) given in § 1, but it may be treated in the same way. We can show as in Example 2 that Hypothesis (H6) (more precisely, a similar hypothesis as (H6)) is satisfied provided that there exists some solution $(y_0, u_0) \in W^{1,2}([0, 1]; H) \times \mathcal{U}_{ad}$ to (7.58) such that

$$(7.63) \quad \int_{F_d} (y_0(x, t))^2 dx dt < \delta^2 \quad (\text{Slater's Condition}).$$

In this case, for any optimal pair (y_δ, u_δ) of (Q_3^δ) , there exist $p_\delta \in BV([0, 1]; (H^s(\Omega))^*) \cap L^\infty(0, 1; L^2(\Omega)) \cap L^2(0, 1; H^1(\Omega))$ and some constant $\tilde{\lambda}_\delta \geq 0$ such that

$$(7.64) \quad ((p_\delta)_t + \Delta p_\delta)_a \in \tilde{\lambda}_\delta y_\delta \chi_{F_d} + \partial g(t, y_\delta) \quad \text{a.e. in } \{y_\delta > 0\},$$

$$(7.65) \quad \tilde{\lambda}_\delta \left(\delta^2 - \int_{F_d} (y_\delta(x, t))^2 dx dt \right) = 0,$$

$$(7.66) \quad p_\delta f = 0 \quad \text{a.e. in } \{y_\delta = 0\},$$

$$(7.67) \quad p_\delta = 0 \quad \text{on } (\Gamma_1 \cup \Gamma_2) \times (0, T),$$

$$(7.68) \quad p_\delta(1) + \partial \phi_0(y_\delta(1)) \ni 0,$$

$$(7.69) \quad -\frac{\partial p_\delta / \partial \nu}{\Gamma_1 \times (0, 1)} \in \partial H_0(u_\delta) + \partial H_1(u_\delta) = N_{\mathcal{U}_{ad}}(u_\delta) + \partial H_1(u_\delta), \quad \text{in } \mathcal{U}^*,$$

where χ_{F_d} is the characteristic function of F_d :

$$\chi_{F_d}(x) = \begin{cases} 0 & \text{if } x \in Q \setminus F_d, \\ 1 & \text{if } x \in F_d. \end{cases}$$

When $\delta \searrow 0$, we do not know whether $(p_\delta, \tilde{\lambda}_\delta)$ converges or not.

Acknowledgment. The author is greatly indebted to Professor V. Barbu for suggesting the problem and giving very helpful advice.

REGULAR SYNTHESIS FOR TIME-OPTIMAL CONTROL OF SINGLE-INPUT REAL ANALYTIC SYSTEMS IN THE PLANE*

H. J. SUSSMANN†

Abstract. For arbitrary single-input real analytic systems in the plane, in which the control enters linearly, we prove the existence of a regular synthesis for the optimal control problem in which it is desired to minimize the integral of a strictly positive real analytic Lagrangian that does not depend on the control variable. The analysis proceeds by applying our previous results on nondegenerate \mathcal{C}^∞ systems, as well as those on arbitrary real analytic ones, to study the local structure of the time-optimal trajectories. The structure of the optimal trajectories for our problem is derived by reparametrization of time. The existence of a synthesis is then proved by using subanalytic set theory.

Key words. time optimal control, two-dimensional systems, regular synthesis

AMS(MOS) classification numbers. 93C10, 93B15, 93B20

1. Introduction. This is the third of a series of papers devoted to the analysis of real-analytic time-optimal control problems with a single input in a two-dimensional state space. The previous papers ([A], [B]) established piecewise regularity properties for the optimal trajectories. Here we will use these results to prove the existence of a regular synthesis. As a preliminary, we prove in § 2 that the flow that corresponds to the singular control is subanalytic. We then state and prove the main result in § 3.

We use all the notation and definitions of [A] and [B].

2. Subanalyticity of the Z -flow. Let Σ be a C.A.S. which has the DSAP. We defined in § 6 of [A] what is meant by a Z -trajectory. Let \mathcal{F}^Z denote the set of all triples (q_0, q_1, t) such that there exists a Z -trajectory γ for which $\gamma(0) = q_0$, $\gamma(t) = q_1$, $t \geq 0$. The set \mathcal{F}^Z is the *graph of the Z -flow*. Our goal here is to prove that \mathcal{F}^Z is a subanalytic subset of $M \times M \times \mathbb{R}$, if Σ actually has the SAP.

Let us define a *maximal turnpike* to be a turnpike S such that there is no turnpike S' with the property that $S \subseteq S'$, $S \neq S'$.

LEMMA 2.1. *Let Σ be a C.A.S. which has the DSAP. Then:*

- (a) *Every turnpike is contained in a maximal turnpike;*
- (b) *The maximal turnpikes are pairwise disjoint analytic arcs that are semianalytic sets;*
- (c) *The set of maximal turnpikes is locally finite.*

Proof. Let \mathcal{S} be a CASA stratification of M , which is compatible with the set $\text{NO}(\Sigma)$ of ordinary points of Σ , with the sets $\{q: \Delta_A(q) = 0\}$, $\{q: \Delta_B(q) = 0\}$, and with the vector fields X and Y . Form a new partition \mathcal{S}' of M , whose elements are the strata of \mathcal{S} which are subsets of $\text{NO}(\Sigma)$, and the connected components of $M - \text{NO}(\Sigma)$. It is easy to see that \mathcal{S}' is also a CASA stratification of M , which is compatible with X , Y , $\text{NO}(\Sigma)$, and the zero sets of Δ_A and Δ_B . Now call a zero-dimensional stratum $\{p\}$ *nice* if p has a neighborhood U such that $U \cap \text{NO}(\Sigma)$ is a connected analytic arc S in U , such that each of the vector fields X , Y is either everywhere tangent to S or nowhere tangent to S , and that Δ_A either vanishes identically on S , or never vanishes on S .

Let E be the union of all the one-dimensional strata of \mathcal{S}' , and of all the nice zero-dimensional strata. Then E is a semianalytic subset of M (because it is a union of strata of \mathcal{S}'), and it is an embedded analytic one-dimensional submanifold of M . The connected components of E are therefore semianalytic subsets of M , and they clearly form a locally finite family. So all our conclusions will follow if we prove that

(2.I) Every turnpike is contained in a component of E that is a maximal turnpike.

To prove (2.I), let S be a turnpike. Then $S \subseteq \text{NO}(\Sigma)$, and so $S \subseteq E$, unless there is a zero-dimensional stratum $\{p\} \in \mathcal{S}'$ which is not nice, but is such that $p \in S$. But this latter possibility is easily excluded: if $p \in S$ and $\{p\} \in \mathcal{S}'$, then it follows from the definition of a turnpike that p is nice. So S is a subset of E . Since S is connected, S is a subset of some connected component S' of E . We now show that S' is a maximal turnpike. The definition of E clearly implies that S' has a neighborhood U such that S' is relatively closed in U , that $U - S' \subseteq \Omega(A) \cap \Omega(B)$, and that U is open and connected. Moreover, $S' \subseteq \text{NO}(\Sigma)$. So S' is an INOA. Clearly, S' is a union of one-dimensional strata S_i of \mathcal{S}' , and of nice zero-dimensional strata $\{p_j\}$. Since $S \subseteq S'$, there is at least one point $q \in S'$ such that the following holds:

(2.II) The vectors $X(q)$ and $Y(q)$ are linearly independent, and they point to opposite sides of S' .

It is clear that the set of $q \in S'$ for which (2.II) holds is relatively open in S' . On the other hand, if (2.II) fails at one $q \in S'$, then it also fails for \tilde{q} near q . (Reason: if $q \in S_i$ for some i , then S_i is compatible with Δ_A , X and Y ; if $\{q\} \in \mathcal{S}'$, and $\{q\}$ is nice, then $q \in S^* \subseteq S'$, and S^* is relatively open in S' , and compatible with Δ_A , X , and Y .) So the set of $q \in S'$ for which (2.II) holds is relatively closed in S' . Therefore (2.II) holds throughout S' .

Let U be a neighborhood of S' which is open, connected, satisfies $U - S' \subseteq \Omega(A) \cap \Omega(B)$, and is such that $U - S'$ has exactly two connected components. Let U_X , U_Y be the connected components of $U - S'$ towards which X , Y point. So $U_X \neq U_Y$, $U_X \cup U_Y = U - S'$ and $U_X \cap U_Y = \emptyset$. The function f is well defined and nonzero on $U_X \cup U_Y$. So f has constant sign on U_X and on U_Y . Since S is a turnpike, $f(q) < 0$ for $q \in U_X$, q near S . So $f < 0$ on U_X . Similarly, $f > 0$ on U_Y . Therefore S' is a turnpike. We now show that S' is a maximal turnpike. Suppose that $S' \subseteq S''$, $S' \neq S''$, and that S'' is a turnpike. By what has already been shown, S'' is contained in some connected component S''' of E . Since $S' \subseteq S''$, it follows that $S' = S'''$, which is a contradiction. So S' is maximal. \square

From now on we always assume that Σ has the strong accessibility property.

For each maximal turnpike S , define \mathcal{F}^S to be the set of all triples (q_0, q_1, t) such that $\gamma(0) = q_0$, $\gamma(t) = q_1$, $t \geq 0$, for some trajectory $\gamma \in \text{Traj}(\Sigma)$ which is entirely contained in $\text{Clos } S$. In view of Lemma 2.1 it is clear that, if $\mathcal{MT}(\Sigma)$ denotes the set of maximal turnpikes of Σ , then

$$(2.1) \quad \mathcal{F}^Z = \bigcup \{ \mathcal{F}^S : S \in \mathcal{MT}(\Sigma) \}.$$

Since $\mathcal{F}^S \subseteq S \times S \times \mathbb{R}$, it is clear that the \mathcal{F}^S form a locally finite family of subsets of $M \times M \times \mathbb{R}$. To prove that \mathcal{F}^Z is subanalytic, it suffices therefore to show that each \mathcal{F}^S is subanalytic in $M \times M \times \mathbb{R}$.

Let $S \in \mathcal{MT}(\Sigma)$. For each point $p \in S$, there exists a unique convex combination $Z_S(p)$ of the vectors $X(p)$, $Y(p)$, which is tangent to S at p . It is clear that Z_S is an analytic vector field on S . The Σ -trajectories which are contained in S are exactly the integral curves of Z_S .

We are now ready to dispose of the easiest case, namely, when S is compact (i.e., diffeomorphic to a circle). In this case, it is clear that $(q_0, q_1, t) \in \mathcal{F}^S$ if and only if $q_0 \in S$, $q_1 \in S$, $t \geq 0$, and $q_1 = \Phi_t^{Z_S}(q_0)$. The map

$$(2.2) \quad (q_0, q_1, t) \rightarrow q_1 - \Phi_t^{Z_S}(q_0),$$

from $S \times S \times \mathbb{R}$ to \mathbb{R}^2 , is analytic. Therefore \mathcal{F}^S is the intersection of $\{(q_0, q_1, t): t \geq 0\}$ with an analytic subset of $S \times S \times \mathbb{R}$, and so \mathcal{F}^S is semianalytic in $S \times S \times \mathbb{R}$. Since $S \times S \times \mathbb{R}$ is a closed analytic submanifold of $M \times M \times \mathbb{R}$, it follows that \mathcal{F}^S is semianalytic in $M \times M \times \mathbb{R}$.

Now consider the case when S is not compact, i.e., when S is diffeomorphic to \mathbb{R} . Fix a point $\bar{q} \in S$, and let S_+^* , S_-^* be the connected components of $S - \{\bar{q}\}$, labelled so that the vector $Z_S(\bar{q})$ points into S_+^* . Let

$$(2.3a) \quad S_+ = S_+^* \cup \{\bar{q}\},$$

$$(2.3b) \quad S_- = S_-^* \cup \{\bar{q}\}.$$

Define \mathcal{F}_+^S to be the set of those (q_0, q_1, t) such that $t \geq 0$ and that, for some trajectory γ of Σ which is entirely contained in $\text{Clos } S_+$, we have $q_0 = \gamma(0)$, $q_1 = \gamma(t)$. Define \mathcal{F}_-^S similarly, using S_- instead of S_+ . We will prove that \mathcal{F}_+^S and \mathcal{F}_-^S are subanalytic in $M \times M \times \mathbb{R}$. Since both proofs are similar, we will only consider the case of \mathcal{F}_+^S .

The arc S_+ is diffeomorphic to the half-line $[0, \infty[$ by means of a map $\psi: [0, \infty[\rightarrow S_+$, which is the restriction to $[0, \infty[$ of a C^ω diffeomorphism $\tilde{\psi}: \mathbb{R} \rightarrow S$.

We now prove the following.

LEMMA 2.2. *One and only one of the following cases occurs:*

$$(2.IIIa) \quad \lim_{t \rightarrow +\infty} \psi(t) = \infty;$$

$$(2.IIIb) \quad \text{There exists a } p \in M \text{ such that } p \notin S \text{ and } \lim_{t \rightarrow +\infty} \psi(t) = p.$$

(The meaning of (2.IIIa) is: "for every compact $K \subseteq M$ there is a $t_K \in [0, \infty[$ such that $\psi(t) \notin K$ for $t_K < t < \infty$ ".)

Proof. Assume (2.IIIa) does not hold. Then there is a compact $K \subseteq M$ such that there is an increasing sequence $\{t_n\}$ with $t_n \rightarrow +\infty$ as $n \rightarrow \infty$, and $\psi(t_n) \in K$ for all n . Clearly, we may assume that K is semianalytic. Let

$$(2.4) \quad I = \psi^{-1}(S_+ \cap (M - K)).$$

Then I is relatively open in $[0, \infty[$, and so I is a union of a finite or countably infinite family \mathcal{A} of relatively open subintervals of $[0, \infty[$. No $J \in \mathcal{A}$ can be unbounded (because $t_n \notin I$ for all n , and $t_n \rightarrow +\infty$). Suppose that \mathcal{A} were infinite. Let $K' \subseteq M$ be compact, semianalytic and such that $K \subseteq \text{Int } K'$. Then the set $S_+ \cap (K' - K)$ is semianalytic and relatively compact. Therefore $S_+ \cap (K' - K)$ has finitely many arcwise components. On the other hand, $S_+ \cap (K' - K)$ is the union of the $\psi(J) \cap K'$, $J \in \mathcal{A}$, and it is clear that each $\psi(J) \cap K'$ is nonempty (because, if a is an endpoint of J , $a \neq 0$, then $\psi(a) \in K$, and so $\psi(t) \in K'$ for $t \in J$, t near (a)). Moreover, if P_1, P_2 belong to $\psi(J_1) \cap K'$, $\psi(J_2) \cap K'$, for $J_1 \in \mathcal{A}$, $J_2 \in \mathcal{A}$, $J_1 \neq J_2$, it is clear that P_1 and P_2 cannot be connected by an arc in $S_+ \cap K'$, and so they belong to different components of $S_+ \cap K'$. So $S_+ \cap K'$ has infinitely many arcwise components, and we have reached a contradiction. Therefore \mathcal{A} is finite. Since each member of \mathcal{A} is bounded, we see that $\psi(t) \in K$ for t large enough. From this it follows in particular that $\psi(S_+)$ is relatively compact. Therefore, there is a sequence $\{t_n^0\}$ such that $0 \leq t_n^0$, that $t_n^0 \rightarrow +\infty$, and that $\lim_{n \rightarrow \infty} \psi(t_n^0) = p$ exists. If K is a compact ball centered at p and contained in M , then there is a sequence $\{t_n\}$ such that $t_n \rightarrow +\infty$ and that $\psi(t_n) \in K$ for all n . Therefore the preceding reasoning

applies to this K , and we may conclude that $\psi(t) \in K$ for large enough t . Since this is true for every ball centered at p , we conclude that $p = \lim_{t \rightarrow \infty} \psi(t)$. We now show that $p \notin S$. This follows, simply, from the fact that $\tilde{\psi}$ is a homeomorphism from \mathbb{R} onto S , and that the topology of S is induced by the topology of M (i.e. S is embedded). If $p \in S$, let $q_n = \psi(n)$, $p = \tilde{\psi}(\bar{t})$ ($\bar{t} \in \mathbb{R}$). Since $q_n \rightarrow p$ in M , we have $q_n \rightarrow p$ in S , and so $n \rightarrow \bar{t}$ as $n \rightarrow \infty$, which is a contradiction. \square

If (2.IIIa) holds, then the subanalyticity of \mathcal{F}_+^S is easy to prove. Let $\bar{\gamma}$ be the maximal integral curve of Z_S such that $\bar{\gamma}(0) = \bar{q}$. Then $\bar{\gamma}(t) \in S_+$ for $t \geq 0$, $t \in \text{Dom}(\gamma)$. The domain of $\bar{\gamma}$ is an interval $]a, b[$, with $-\infty \leq a < 0 < b \leq +\infty$. Clearly, $\bar{\gamma}(]a, b[) = S$, $\bar{\gamma}(]a, 0]) = S_-$, and $\bar{\gamma}([0, b[) = S_+$ (because Z_S never vanishes on S and so, via $\tilde{\psi}$, Z_S corresponds to a vector field $\phi(t)\partial_t$ on \mathbb{R} , where ϕ is a strictly positive analytic function on \mathbb{R}). Therefore there exists an analytic function $\rho: S \rightarrow \mathbb{R}$ such that, if $q \in S$, it follows that $q = \bar{\gamma}(\rho(q))$. In particular, if q_0, q_1 are in S , and $t \in \mathbb{R}$, then $(q_0, q_1, t) \in \mathcal{F}_+^S$ if and only if $t \geq 0$, $q_0 \in S_+$, $q_1 \in S_+$, and $t = \rho(q_1) - \rho(q_0)$. Moreover, (q_0, q_1, t) cannot be in \mathcal{F}_+^S unless both q_0 and q_1 are in S_+ (since (2.IIIa) implies that S_+ is closed in M). So \mathcal{F}_+^S is precisely the set of those $(q_0, q_1, t) \in S \times S \times \mathbb{R}$ characterized by $q_0 \in S_+$, $q_1 \in S_+$, $t \geq 0$, $t = \rho(q_1) - \rho(q_0)$. Since S_+ is semianalytic in S , it is clear that \mathcal{F}_+^S is semianalytic in $S \times S \times \mathbb{R}$. On the other hand, the set $S_+ \times S_+ \times \mathbb{R}$ is actually closed in $M \times M \times \mathbb{R}$ (because S_+ is closed in M), and so the inclusion map $\mu: S \times S \times \mathbb{R} \rightarrow M \times M \times \mathbb{R}$ is proper on $S_+ \times S_+ \times \mathbb{R}$. Therefore \mathcal{F}_+^S is subanalytic as a subset of $M \times M \times \mathbb{R}$.

The case when (2.IIIb) holds requires more work. The function $\rho: S \rightarrow \mathbb{R}$ is defined exactly as before. Also, we let p denote the limit of $\psi(t)$ as $t \rightarrow +\infty$. The main step in our proof that \mathcal{F}_+^S is subanalytic in $M \times M \times \mathbb{R}$ is to make a more detailed study of what happens near p .

Since $p \in M$, and Σ is supposed to have the strong accessibility property everywhere on M , it follows in particular that $X(p)$ and $Y(p)$ cannot both vanish. Assume, without loss of generality, that $X(p) \neq 0$. Then we can define a square coordinate chart, centered at p , and of radius $\varepsilon > 0$, whose domain is an open set U , and which is such that $X \upharpoonright U = \partial_x$. The set $S_+ \cap U$ is a one-dimensional semianalytic submanifold of U , and p belongs to its closure. Therefore, by making U smaller, we may assume that $S_+ \cap U$ is either a horizontal segment, or a set of the form $\{(x, y): x = \lambda(y), y \in I\}$, where I is some interval of the form $]a, 0[$ or $]0, b[$, $\lambda: I \rightarrow]-\varepsilon, \varepsilon[$ is analytic, and $\lim_{s \rightarrow 0, s \in I} \lambda(s) = 0$. The possibility that $S_+ \cap U$ is a horizontal segment is excluded, because then X would be everywhere tangent to S_+ , contradicting the fact that S is a turnpike. So $S_+ \cap U$ is the graph of a function λ as above. Let us assume that I is of the form $]0, b[$ (the other case is similar).

Since $S_+ \cap U$ is semianalytic, the function λ is given by a Puiseux series

$$(2.5) \quad \lambda(y) = \sum_{j=1}^{\infty} a_j y^{j/N},$$

which converges for $0 < y < \delta$, if δ is sufficiently small. The vector field $Y \upharpoonright U$ has components α, β , which are analytic functions of (x, y) on U .

A tangent vector $V(y)$ to S_+ at $(\lambda(y), y)$ is given by

$$(2.6) \quad V(y) = (\nu(y), 1),$$

where

$$(2.7) \quad \nu(y) = \frac{d\lambda}{dy}(y) = \sum_{j=1}^{\infty} \frac{j}{N} a_j y^{j/N-1}.$$

So, in order to compute $Z_S(\lambda(y), y)$, we must determine the coefficient $\sigma(y)$ such that $\sigma(y)\partial_x + (1 - \sigma(y))Y(\lambda(y), y)$ is a multiple of $V(y)$, and then let

$$(2.8) \quad Z_S(\lambda(y), y) = \sigma(y)\partial_x + (1 - \sigma(y))Y(\lambda(y), y).$$

A simple computation shows that

$$(2.9) \quad \sigma(y) = \frac{\beta(\lambda(y), y)\nu(y) - \alpha(\lambda(y), y)}{1 + \beta(\lambda(y), y)\nu(y) - \alpha(\lambda(y), y)}.$$

The components of $Z_S(\lambda(y), y)$ are, therefore, $\sigma(y) + (1 - \sigma(y))\alpha(\lambda(y), y)$ and $(1 - \sigma(y))\beta(\lambda(y), y)$, respectively, where σ is given by (2.9). In particular, if $t \rightarrow (x(t), y(t))$ is an integral curve of Z_S , the function $y(\cdot)$ satisfies

$$(2.10) \quad \frac{dy}{dt} = [1 - \sigma(y)]\beta(\lambda(y), y).$$

Therefore

$$(2.11) \quad \frac{dt}{dy} = \theta(y),$$

where

$$(2.12) \quad \theta(y) = \{[1 - \sigma(y)]\beta(\lambda(y), y)\}^{-1}.$$

It is clear that λ is an analytic function of $y^{1/N}$, and so $y \rightarrow \alpha(\lambda(y), y)$ and $y \rightarrow \beta(\lambda(y), y)$ are analytic functions of $y^{1/N}$. On the other hand, ν is a meromorphic function of $y^{1/N}$, and so σ is meromorphic in $y^{1/N}$ as well. So θ is a meromorphic function of $y^{1/N}$. That is, θ satisfies

$$(2.13) \quad \theta(y) = \sum_{j=j_0}^{\infty} \theta_j y^{j/N},$$

where the series in (2.13) converges for $0 < y < \delta_0$, if δ_0 is small enough, and where j_0 is an integer, and $\theta_{j_0} \neq 0$.

If we let

$$(2.14) \quad \tau^*(y) = \sum_{\substack{j_0 \leq j < \infty \\ j \neq -N}} \left(\frac{j}{N} + 1\right)^{-1} \theta_j y^{j/N+1} + \bar{\theta}$$

(where $\bar{\theta}$ is an arbitrary constant) and

$$(2.15) \quad \tau(y) = \tau^*(y) + \theta_{-N} \log y$$

(where “log” denotes natural logarithm), then $\tau:]0, \delta_0[\rightarrow \mathbb{R}$ is analytic, and its y -derivative is θ , so that τ is, up to a constant, the time along the Z_S -trajectory, which is obtained by suitably reparametrizing the set $\{(\lambda(y), y): 0 < y < \delta_0\}$ (that is: $\tau(y) = \rho(\lambda(y), y) + \text{constant}$).

Now fix a \hat{y} such that $0 < \hat{y} < \delta_0$, and let \hat{S}_+ denote the compact set

$$(2.16) \quad \{p\} \cup \{(\lambda(y), y): 0 < y \leq \hat{y}\}.$$

Let $\hat{\mathcal{F}}_+^S$ denote the set of those (q_0, q_1, t) such that $q_0 \in \hat{S}_+$, $q_1 \in \hat{S}_+$, $t \geq 0$, and $q_0 = \gamma(0)$, $q_1 = \gamma(t)$ for some $\gamma \in \text{Traj}(\Sigma)$ which is contained in \hat{S} . We will prove that $\hat{\mathcal{F}}_+^S$ is subanalytic in $U \times U \times \mathbb{R}$. It is clear that the function τ is strictly decreasing on $]0, \delta_0[$ (because, as y decreases, the point $(\lambda(y), y)$ moves towards p , i.e., in the direction of the Z_S -trajectory). So the limit $\tau(0+)$ exists, and is either finite or equal to $+\infty$. If

$\tau(0+) = +\infty$, then no trajectory of Σ which is contained in \hat{S}_+ can contain both p and a point in $\hat{S}_+ - \{p\}$. So, in this case, if $q_i = (x_i, y_i)$, $i = 0, 1$, we have that $(q_0, q_1, t) \in \hat{\mathcal{F}}_+^S$ if and only if either

$$(2.IV_i) \quad q_0 \in \hat{S}_+, q_1 \in \hat{S}_+, q_0 \neq p \neq q_1, t \geq 0, \text{ and } t = \tau(y_1) - \tau(y_0), \text{ or}$$

$$(2.IV_{ii}) \quad q_0 = q_1 = p \text{ and } t = 0 \text{ or}$$

$$(2.IV_{iii}) \quad q_0 = q_1 = p, t \geq 0, \text{ and } 0 \text{ is a convex combination of } X(p) \text{ and } Y(p).$$

Let us define P to be the set $\{p\} \times \{p\} \times [0, \infty)$ if 0 is a convex combination of $X(p)$ and $Y(p)$, and let P be the empty set otherwise. Then we have shown that, if $\tau(0+) = +\infty$, the set $\hat{\mathcal{F}}_+^S$ is the union of P and of the set $^*\hat{\mathcal{F}}_+^S$ of those (q_0, q_1, t) for which (2.IV_i) holds.

If $\tau(0+) < +\infty$, then conditions (2.IV_i), (2.IV_{ii}) or (2.IV_{iii}) imply that $(q_0, q_1, t) \in \hat{\mathcal{F}}_+^S$, but there are other possibilities as well, namely

$$(2.IV_{iv}) \quad q_0 \in \hat{S}_+, q_0 \neq p, q_1 = p, t \geq 0, \text{ and } t = \tau(0+) - \tau(y_0), \text{ and}$$

$$(2.IV_v) \quad q_0 \in \hat{S}_+, q_0 \neq p, q_1 = p, t \geq 0, t \geq \tau(0+) - \tau(y_0) \text{ and } 0 \text{ is a convex combination of } X(p) \text{ and } Y(p).$$

Precisely, if $\tau(0+) < +\infty$, the point (q_0, q_1, t) is in $\hat{\mathcal{F}}_+^S$ if and only if (2.IV_i), (2.IV_{ii}), (2.IV_{iii}), (2.IV_{iv}) or (2.IV_v) holds. The set of points where (2.IV_{ii}) or (2.IV_{iii}) holds is P . The set Q of points where (2.IV_{iv}) holds is the intersection of $\text{Clos } ^*\hat{\mathcal{F}}_+^S$ and of $(\hat{S}_+ - \{p\}) \times \{p\} \times \mathbb{R}$, so Q is subanalytic in $U \times U \times \mathbb{R}$ if $^*\hat{\mathcal{F}}_+^S$ is. Finally, the set Q' of points where (2.IV_v) holds is empty if 0 is not a convex combination of $X(p)$ and $Y(p)$, and is equal to

$$(2.17) \quad \{(q_0, q_1, t): (\exists t')(0 \leq t' \leq t \wedge (q_0, q_1, t') \in Q)\}$$

if 0 is a combination of $X(p)$ and $Y(p)$. In either case, Q' is subanalytic in $U \times U \times \mathbb{R}$ if Q is.

Summarizing the preceding observations, we have shown that, whether $\tau(0+)$ is finite or infinite, the set $\hat{\mathcal{F}}_+^S$ is the union of $^*\hat{\mathcal{F}}_+^S$ and of finitely many sets that are subanalytic in $U \times U \times \mathbb{R}$ if $^*\hat{\mathcal{F}}_+^S$ is. So the subanalyticity of $\hat{\mathcal{F}}_+^S$ in $U \times U \times \mathbb{R}$ will follow if we prove that $^*\hat{\mathcal{F}}_+^S$ is subanalytic in $U \times U \times \mathbb{R}$.

To prove that $^*\hat{\mathcal{F}}_+^S$ is subanalytic in $U \times U \times \mathbb{R}$, we first write

$$(2.18) \quad \tau^*(y) = y^{-k/N} \tau^{**}(y),$$

where $\tau^{**}(y)$ is given by a power series in $y^{1/N}$ which converges for $0 < y < \delta_0$, and k is a nonnegative integer. The equation

$$(2.19) \quad t = \tau(y_1) - \tau(y_0)$$

is therefore equivalent to

$$(2.20) \quad \zeta_0^k \zeta_1^k t = \zeta_0^k \tau^{**}(\zeta_1^N) - \zeta_1^k \tau^{**}(\zeta_0^N) + N \theta_{-N} \zeta_0^k \zeta_1^k (\log \zeta_1 - \log \zeta_0)$$

if $t \neq 0$, $0 < y_0 < \delta_0$, $0 < y_1 < \delta_0$, $\zeta_0 = y_0^{1/N}$ and $\zeta_1 = y_1^{1/N}$.

If $\theta_{-N} = 0$, the subanalyticity of $^*\hat{\mathcal{F}}_+^S$ in $U \times U \times \mathbb{R}$ follows easily. Indeed, if $t \neq 0$, $0 < y_0 < \delta_0$, $0 < y_1 < \delta_0$, then the point $(q_0, q_1, t) \in U \times U \times \mathbb{R}$ is in $^*\hat{\mathcal{F}}_+^S$ if and only if the following hold:

$$(2.V_i) \quad q_0 \in \hat{S}_+, q_1 \in \hat{S}_+, q_0 \neq p \neq q_1 \text{ and } t > 0;$$

$$(2.V_{ii}) \quad \text{There exist } \zeta_0, \zeta_1 \text{ such that } 0 \leq \zeta_0 \leq \hat{y}^{1/N}, 0 \leq \zeta_1 \leq \hat{y}^{1/N}, \zeta_0^N = y_0, \zeta_1^N = y_1, \text{ and}$$

$$(2.21) \quad \zeta_0^k \zeta_1^k t = \zeta_0^k \tau^{**}(\zeta_1^N) - \zeta_1^k \tau^{**}(\zeta_0^N).$$

Equation (2.21) is of the form $\eta(\zeta_0, \zeta_1, t) = 0$, where η is an analytic function on W , where

$$(2.22) \quad W =]-\delta_0^{1/N}, \delta_0^{1/N}[\times]-\delta_0^{1/N}, \delta_0^{1/N}[\times \mathbb{R}.$$

So, if we let D denote the set of all $(\zeta_0, \zeta_1, t, y_0, y_1)$ in $W \times]-\delta_0, \delta_0[\times]-\delta_0, \delta_0[$ that satisfy (2.21) and $0 < y_0 \leq \hat{y}$, $0 < y_1 \leq \hat{y}$, $\zeta_0^N = y_0$, $\zeta_1^N = y_1$, then the projection $\pi: (\zeta_0, \zeta_1, t, y_0, y_1) \rightarrow (t, y_0, y_1)$, from $W \times]-\delta_0, \delta_0[\times]-\delta_0, \delta_0[$ to $\mathbb{R} \times]-\delta_0, \delta_0[\times]-\delta_0, \delta_0[$, is proper on $\text{Clos } D$, and therefore maps D to a subanalytic subset of $\mathbb{R} \times]-\delta_0, \delta_0[\times]-\delta_0, \delta_0[$. This clearly implies that ${}^*\hat{\mathcal{F}}_+^S$ is subanalytic in $U \times U \times \mathbb{R}$ (since ${}^*\mathcal{F}_+^S$ is the set of those $(q_0, q_1, t) = (x_0, y_0, x_1, y_1, t)$ such that either $q_0 \in \hat{S}_+$, $q_1 \in \hat{S}_+$, $(y_0, y_1, t) \in \pi(D)$, and $t > 0$, or $q_0 \in \hat{S}$, $q_0 = q_1$, $t = 0$).

If $\theta_{-N} \neq 0$, then a slightly more complicated reasoning is needed. Clearly, a point $(q_0, q_1, t) \in U \times U \times \mathbb{R}$ for which $t > 0$ is in ${}^*\hat{\mathcal{F}}_+^S$ if and only if (2.Vi) holds and, in addition:

$$(2.Viii) \quad \begin{aligned} &\text{There exist } \zeta_0, \zeta_1, \omega \text{ such that } 0 \leq \zeta_0 \leq \hat{y}^{1/N}, 0 \leq \zeta_1 \leq \hat{y}^{1/N}, \zeta_0^N = y_0, \\ &\zeta_1^N = y_1, \zeta_0 e^\omega = \zeta_1, \text{ and} \\ &\zeta_0^k \zeta_1^k t = \zeta_0^k \tau^{**}(\zeta_1^N) - \zeta_1^k \tau^{**}(\zeta_0^N) + N\theta_{-N} \zeta_0^k \zeta_1^k \omega. \end{aligned}$$

(Naturally, the equation $\zeta_0 e^\omega = \zeta_1$ is included to make sure that ω is equal to $\log \zeta_1 - \log \zeta_0$.)

The proof that ${}^*\hat{\mathcal{F}}_+^S$ is subanalytic in $U \times U \times \mathbb{R}$ proceeds as before, except that W is replaced by $\mathbb{R} \times W$, because of the new coordinate ω . We now let D denote the set of all $(\omega, \zeta_0, \zeta_1, t, y_0, y_1)$ that satisfy $t > 0$ and all the equalities and inequalities of (2.Viii). The subanalyticity of ${}^*\hat{\mathcal{F}}_+^S$ then follows if we prove that the projection π onto the last three coordinates, regarded as a map from $\mathbb{R} \times W \times]-\delta_0, \delta_0[\times]-\delta_0, \delta_0[$ to $\mathbb{R} \times]-\delta_0, \delta_0[\times]-\delta_0, \delta_0[$, is proper on $\text{Clos } D$. This requires that we prove that, as long as $(\omega, \zeta_0, \zeta_1, t, y_0, y_1) \in D$, and t remains bounded, it follows that ω is bounded, and that $|\zeta_0|, |\zeta_1|$ are bounded by a constant c which is less than $\delta_0^{1/N}$. The bound for $|\zeta_0|, |\zeta_1|$ is trivial (just let $c = \hat{y}^{1/N}$). Therefore the only problem is to prove that, as long as $(\omega, \zeta_0, \zeta_1, t, y_0, y_1) \in D$, and t is bounded, it follows that ω is bounded. Equivalently (since $\omega = \log \zeta_1 - \log \zeta_0 = 1/N \log(y_1/y_0)$) we need an a priori bound of the form

$$(2.23) \quad \left| \log \left(\frac{y_1}{y_0} \right) \right| \leq C(T)$$

for $(q_0, q_1, t) \in {}^*\hat{\mathcal{F}}_+^S$, $0 < t \leq T$, where the constant $C(T)$ is only allowed to depend on T .

To get the bound (2.23), consider first the case when $j_0 = -N$. Then $\tau^*(y)$ is bounded for $y \in [0, \hat{y}]$ and so, if $(q_0, q_1, t) \in {}^*\hat{\mathcal{F}}_+^S$, we have

$$(2.24) \quad t = \tau^*(y_1) - \tau^*(y_0) + \theta_{-N} \left(\log \frac{y_1}{y_0} \right),$$

so that

$$\left| \log \left(\frac{y_1}{y_0} \right) \right| \leq \frac{T + 2C}{|\theta_{-N}|}$$

as long as $0 < t \leq T$, if C is an upper bound for $|\tau^*|$ on $[0, \hat{y}]$. So the desired bound holds.

Next consider the case when $j_0 \neq -N$. Since we are assuming that $\theta_{-N} \neq 0$, it necessarily follows that $j_0 < -N$. Therefore $\tau^*(y)$ is asymptotic to y^{-r} as $y \rightarrow 0$, for some $r > 0$. Choose the constant $\bar{\theta}$ (which so far was arbitrary) so that $\tau(\hat{y}) = 1$. Then

$\tau(y) \geq 1$ for $0 < y \leq \hat{y}$, and $\tau(y)$ is asymptotic to y^{-r} as $y \rightarrow 0+$. So there are constants C_0, C_1 such that $0 < C_0 < C_1$, and that

$$(2.25) \quad C_0 y^{-r} \leq \tau(y) \leq C_1 y^{-r}$$

for $0 < y \leq \hat{y}$. So, if $0 < y_1 \leq y_0 \leq \hat{y}$, and $t = \tau(y_1) - \tau(y_0)$, we have

$$t \geq C_0 y_1^{-r} - C_1 y_0^{-r},$$

so that

$$(2.26) \quad C_0 \left(\frac{y_0}{y_1} \right)^r \leq C_1 + t y_0^r.$$

If $0 < t \leq T$, (2.26) gives

$$(2.27) \quad \log \left(\frac{y_0}{y_1} \right) \leq \frac{1}{r} \log \left(\frac{C_1 + T \hat{y}^r}{C_0} \right).$$

Since $y_1 \leq y_0$, we also have $\log(y_0/y_1) \geq 0$, and so the bound (2.23) follows. As explained before, this completes the proof that ${}^*\hat{\mathcal{F}}_+^S$ is subanalytic in $U \times U \times \mathbb{R}$. Therefore, we have proved that $\hat{\mathcal{F}}_+^S$ is subanalytic in $U \times U \times \mathbb{R}$. Since $U \times U \times \mathbb{R}$ is open in $M \times M \times \mathbb{R}$, and $\hat{\mathcal{F}}_+^S$ is a subset of $\hat{S}_+ \times \hat{S}_+ \times \mathbb{R}$, which is contained in $U \times U \times \mathbb{R}$ and is closed in $M \times M \times \mathbb{R}$, it follows that $\hat{\mathcal{F}}_+^S$ is subanalytic in $M \times M \times \mathbb{R}$.

Now we are ready to complete the proof that \mathcal{F}_+^S is subanalytic in $M \times M \times \mathbb{R}$. Let S^* be the closed subarc of S which goes from \bar{q} to \hat{q} . Let \mathcal{B} be the set of those (q_0, q_1, t) such that $q_0 \in S^*$, $q_1 \in S^*$ and $(q_0, q_1, t) \in \mathcal{F}_+^S$. Let S^{**} be a slightly larger open arc, containing S^* . Then the function ρ is analytic on S^{**} , and \mathcal{B} is the subset of $S^{**} \times S^{**} \times \mathbb{R}$ characterized by the conditions $q_0 \in S^*$, $q_1 \in S^*$, $t \geq 0$ and $t = \rho(q_1) - \rho(q_0)$. So \mathcal{B} is subanalytic in $S^{**} \times S^{**} \times \mathbb{R}$. On the other hand, the inclusion from $S^{**} \times S^{**} \times \mathbb{R}$ to $M \times M \times \mathbb{R}$ is proper on $S^* \times S^* \times \mathbb{R}$, and $\mathcal{B} \subseteq S^* \times S^* \times \mathbb{R}$. So \mathcal{B} is subanalytic in $M \times M \times \mathbb{R}$.

Now, if $(q_0, q_1, t) \in M \times M \times \mathbb{R}$, then it is clear that (q_0, q_1, t) is in \mathcal{F}_+^S if and only if one of the following three conditions holds:

- (2.VIi) $(q_0, q_1, t) \in \mathcal{B}$;
- (2.VIii) $(q_0, q_1, t) \in \hat{\mathcal{F}}_+^S$;
- (2.VIiii) There exist t', t'' such that $0 \leq t' \leq t$, $0 \leq t'' \leq t$, $t' + t'' = t$ and that $(q_0, \hat{q}, t') \in \mathcal{B}$, $(\hat{q}, q_1, t'') \in \hat{\mathcal{F}}_+^S$.

So \mathcal{F}_+^S is the union of three subanalytic subsets of $M \times M \times \mathbb{R}$, and is therefore subanalytic in $M \times M \times \mathbb{R}$.

We have now proved that, if S is a noncompact maximal turnpike, and if \bar{q} , S_+ , S_- , \mathcal{F}_+^S , \mathcal{F}_-^S are defined as above, then \mathcal{F}_+^S is subanalytic in $M \times M \times \mathbb{R}$. A similar proof shows that \mathcal{F}_-^S is subanalytic in $M \times M \times \mathbb{R}$ as well. (Or, equivalently, the proof for \mathcal{F}_-^S can be reduced to that for \mathcal{F}_+^S by changing the signs of X and Y .) We are now ready to prove that \mathcal{F}^S is subanalytic. With the diffeomorphism $\tilde{\psi}: \mathbb{R} \rightarrow S$ defined as before, let $p_+ = \lim_{t \rightarrow +\infty} \tilde{\psi}(t)$, $p_- = \lim_{t \rightarrow -\infty} \tilde{\psi}(t)$, so that each of p_+ , p_- exists, and is either infinite or a point of M . (Recall that the meaning of " $p_+ = \infty$ " was explained earlier. A similar interpretation is understood for " $p_- = \infty$ ".) If both p_- , p_+ are infinite, or if exactly one of them is finite, or if both are finite but $p_- \neq p_+$, then it is easy to see that, if ξ is any trajectory of Σ which is contained in $\text{Clos } S$, then either ξ is contained in $\text{Clos } S_-$, or it is contained in $\text{Clos } S_+$, or is a concatenation of two

trajectories ξ_- , ξ_+ , contained in $\text{Clos } S_-$, $\text{Clos } S_+$, respectively. So, if $(q_0, q_1, t) \in M \times M \times \mathbb{R}$, the point (q_0, q_1, t) belongs to \mathcal{F}^S if and only if one of the following three conditions holds:

- (2.VIIi) $(q_0, q_1, t) \in \mathcal{F}_-^S$;
- (2.VIIii) $(q_0, q_1, t) \in \mathcal{F}_+^S$;
- (2.VIIiii) There exist t' , t'' such that $0 \leq t' \leq t$, $0 \leq t'' \leq t$, $t' + t'' = t$ and that $(q_0, \bar{q}, t') \in \mathcal{F}_-^S$ and $(\bar{q}, q_1, t'') \in \mathcal{F}_+^S$.

This clearly shows that \mathcal{F}^S is subanalytic in $M \times M \times \mathbb{R}$.

There remains the exceptional case when p_- , p_+ are both finite and equal (e.g., if S is a circle minus one point). In this case, if the time parameter along the integral curve of Z_S approaches infinity as one approaches p_+ via either S_+ or S_- , then it is still true that $(q_0, q_1, t) \in \mathcal{F}^S$ if and only if one of (2.VIIi, ii, iii) holds, and this implies, exactly as before, that \mathcal{F}^S is subanalytic in $M \times M \times \mathbb{R}$. However, if the time parameter remains finite as we approach p_+ via S_- and via S_+ , then $\text{Clos } S$ carries a periodic singular trajectory. If we let $T > 0$ denote the period, then, if $(q_0, q_1, t) \in M \times M \times \mathbb{R}$, and if $0 \leq t \leq T$, we have that $(q_0, q_1, t) \in \mathcal{F}^S$ if and only if (2.VIIi), (2.VIIii) or (2.VIIiii) holds, or

- (2.VIIiv) $(q_1, q_0, T - t)$ satisfies one of (2.VIIi, ii, iii).

This shows that $\mathcal{F}^S \cap (M \times M \times [0, T])$ is subanalytic in $M \times M \times \mathbb{R}$. Since $\mathcal{F}^S \cap (M \times M \times [nT, (n+1)T])$ is obtained from $\mathcal{F}^S \cap (M \times M \times [0, T])$ by the translation $(q_0, q_1, t) \rightarrow (q_0, q_1, t + nT)$, this set is subanalytic as well. So \mathcal{F}^S is subanalytic in $M \times M \times \mathbb{R}$.

We have proved the following.

THEOREM 2.3. *Let Σ be a C.A.S. that has the SAP. If S is a maximal turnpike of Σ , then \mathcal{F}^S is a subanalytic subset of $M \times M \times \mathbb{R}$. \square*

From this we also get the following.

COROLLARY 2.4. *Let Σ be a C.A.S. that has the SAP. Then \mathcal{F}^Z is a subanalytic subset of $M \times M \times \mathbb{R}$.*

3. Existence of regular synthesis. We are now ready to piece together all our preceding results and prove the existence of a regular synthesis. We will rely heavily on the general abstract theorems of [Su 6] (cf. also [Su 3] for an outline, without proof, of some of these results). Here we will limit ourselves to a precise statement of all the definitions involved, so as to show that the general theorems of [Su 6] apply.

First, consider a control system

$$(3.1) \quad \dot{x} = F(x, u), \quad x \in M, \quad u \in U,$$

where M is a manifold of class C^k ($k = \infty$ or $k = \omega$), U is a compact subset of \mathbb{R}^m for some m , and F is of class C^k jointly in x, u . A *feedback control flow* for (3.1) on a subset S of M is a choice $\Gamma = \{\Gamma_x : x \in S\}$ of a family of admissible pairs $\Gamma_x = (u_x(\cdot), \gamma_x)$, such that each γ_x is a trajectory of (3.1) starting at x and entirely contained in S , and the following *compatibility condition* holds:

$$(3.I) \quad \text{If } t \in \text{Dom}(\gamma_x) \text{ and } \gamma_x(t) = y, \text{ then } u_y(\cdot) = u_x(\cdot) \upharpoonright (\text{Dom}(\gamma_x) \cap [t, \infty[) \\ \text{and } \gamma_y = \gamma_x \upharpoonright (\text{Dom}(\gamma_x) \cap [t, \infty[).$$

(Clearly, Condition (3.I) says that Γ is “memoryless.”)

A feedback control flow Γ on S is said to *steer* S to a point $p \in S$ if, for every $x \in S$, the trajectory γ_x ends at p (i.e., $\gamma_x(\max \text{Dom}(\gamma_x)) = p$). Clearly, if Γ steers S to

p , then it is always possible to make a time translation, so as to assume that, for every x , the domain $\text{Dom}(\gamma_x)$ is an interval of the form $[-\tau_x, 0]$, with $\tau_x \geq 0$. Whenever we talk about a Γ steering S to p , we will always assume that this modification has been carried out.

If $p \in M$, let $\text{Contr}(p)$ denote the set of all points in M that can be steered to p , in finite time, by a trajectory of (3.1). A *feedback control flow with target p* is a feedback control flow on $\text{Contr}(p)$, which steers $\text{Contr}(p)$ to p .

Now suppose that a Lagrangian function $L: M \times U \rightarrow \mathbb{R}$ is given, and that L is of class C^k and nonnegative. For each x, y , we may consider the optimal control problem $P_L(x, y)$ of minimizing the integral

$$\int_{t \in \text{Dom}(\gamma)} L(\gamma(t), u(t)) dt$$

among all admissible pairs $(u(\cdot), \gamma)$ such that γ starts at x and ends at y . An *L -optimal feedback control flow with target p* is a feedback control flow Γ with target p , which has the property that, for each $x \in \text{Contr}(p)$, the admissible pair Γ_x is a solution of $P_L(x, p)$. An *L -extremal feedback control flow with target p* is a feedback control flow Γ with target p such that, for each $x \in \text{Contr}(p)$, the pair Γ_x satisfies the Maximum Principle for the problem $P_L(x, p)$.

It is clear that if Γ is L -optimal then Γ is L -extremal. For individual trajectories, it is well known that extremality does not imply optimality. The main point of the theory of the *regular synthesis* is that, for *feedback control flows* Γ with target p , L -optimality is actually equivalent to L -extremality, provided that Γ satisfies some extra regularity conditions. A *regular synthesis* is, roughly, an L -extremal feedback control flow Γ with target p , which satisfies the regularity conditions (so that, in particular, it follows that Γ is optimal). In order to give a precise definition of regular synthesis we will first define what it means for a Γ (L -extremal or not) to be “regular,” and we will then define a *regular synthesis* to be a Γ which is both regular and L -extremal. Our definition of regularity will be such that, when Γ is regular, L -extremality implies L -optimality. Therefore, the class of regular feedback control flows has the nice property that, for Γ in this class, the Maximum Principle is both a necessary and a sufficient condition for optimality. If, in addition, one can prove general existence theorems within this class, then it will be clear that regular feedback control flows are a natural class of objects at which to look.

Our definition of regularity is taken from [Su 6], and is a modification of definitions given by other authors (e.g., Boltyanskii [Bo], Baytman [Ba], Brunovsky [Br1]). First define a *piecewise C^k vector field* on a set S to be a 6-tuple $(\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \mathbf{X}, \mathbf{E}, \epsilon)$ where:

- (3.IIi) \mathcal{P} is a finite or countably infinite partition of S into connected, embedded submanifolds of class C^k ;
- (3.IIii) $\mathcal{P}_1, \mathcal{P}_2$ are subsets of \mathcal{P} such that $\mathcal{P}_1 \cup \mathcal{P}_2 = \mathcal{P}$, $\mathcal{P}_1 \cap \mathcal{P}_2 = \emptyset$;
- (3.IIiii) \mathbf{X} is a family $\{X_P: P \in \mathcal{P}_1\}$ such that, for each $P \in \mathcal{P}_1$, X_P is a vector field of class C^k on P ;
- (3.IIiv) ϵ is a family $\{\epsilon_P: P \in \mathcal{P}_2\}$ of continuous functions $\epsilon_P: P \rightarrow]0, \infty[$ and \mathbf{E} is a family $\{E_P: P \in \mathcal{P}_2\}$, such that each E_P is a continuous map $E_P: \{(q, t): q \in P, 0 \leq t < \epsilon_P(q)\} \rightarrow S$, with the property that there exists a $P' \in \mathcal{P}_1$ such that E_P maps $\{(q, t): q \in P, 0 < t < \epsilon_P(q)\}$ into P' in a C^k fashion, and that each curve $t \rightarrow E_P(q, t)$, $0 < t < \epsilon_P(q)$ is an integral curve of $X_{P'}$;

- (3.IIv) If $P \in \mathcal{P}_1$, and if, for some $q \in P$, there is a positive time $T(q)$ such that $\Phi_t^{X_P}(q)$ is defined for $0 \leq t < T(q)$ but not for $t = T(q)$, but $\Phi_t^{X_P}(q)$ has a limit $\xi(q)$ as $t \rightarrow T(q)-$, and $\xi(q) \in S - P$, then the same is true for every $q \in P$ and, moreover, there is a $P' \in \mathcal{P}$ such that $\xi(q) \in P'$ for all $q \in P$, and the maps $T(\cdot): P \rightarrow \mathbb{R}$, $\xi(\cdot): P \rightarrow P'$ are of class C^k ;
- (3.IIvi) If $P \in \mathcal{P}_2$, then either $X_P \equiv 0$ or X_P never vanishes on P .

If $\mathcal{V} = (\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \mathbf{X}, \mathbf{E}, \epsilon)$ is a piecewise C^k vector field on S , then those points $p \in S$ which belong to a $P \in \mathcal{P}_1$ such that $X_P \equiv 0$ are called *terminal points* of \mathcal{V} . The set of all such points is the *terminal set* of \mathcal{V} (notation: $\text{Term}(\mathcal{V})$). A *trajectory* of \mathcal{V} is a continuous curve $\gamma: I \rightarrow S$, where I is some interval, such that

- (3.IIIi) If $t \in I$, $t \neq \sup I$, and $\gamma(t) \in P \in \mathcal{P}_1$, then $\gamma(t) \notin \text{Term}(\mathcal{V})$, and there exists a $\delta > 0$ such that $\gamma \upharpoonright [t, t + \delta]$ is an integral curve of X_P ;
- (3.IIIii) If $t \in I$, $t \neq \sup I$, and $\gamma(t) \in P \in \mathcal{P}_2$, then there exists a $\delta > 0$ such that $\gamma(t + \tau) = E_P(\gamma(t), \tau)$ for $0 < \tau < \delta$.

It is clear from the definition of trajectories that there is local existence and global uniqueness of trajectories in the forward direction; i.e. (a) given $t_0 \in \mathbb{R}$, $q_0 \in S$, $q_0 \notin \text{Term}(\mathcal{V})$, there is a $\delta > 0$ and a \mathcal{V} -trajectory γ defined on $[t_0, t_0 + \delta[$, such that $\gamma(t_0) = q_0$ and (b) if γ_1, γ_2 are \mathcal{V} -trajectories such that $\gamma_1(t_0) = \gamma_2(t_0)$ for some t_0 , then $\gamma_1 \equiv \gamma_2$ on $\text{Dom}(\gamma_1) \cap \text{Dom}(\gamma_2) \cap [t_0, \infty[$. So, for any $q \in S - \text{Term}(\mathcal{V})$, there is a unique *maximal* forward trajectory from q , i.e., a trajectory $\gamma_q^{\mathcal{V}}$ of \mathcal{V} , such that $0 \in \text{Dom}(\gamma_q^{\mathcal{V}})$, that $\text{Dom}(\gamma_q^{\mathcal{V}}) \subseteq [0, \infty[$, that $\gamma_q^{\mathcal{V}}(0) = q$, and that $\gamma_q^{\mathcal{V}}$ cannot be extended to a \mathcal{V} -trajectory on an interval I such that

$$\text{Dom}(\gamma_q) \not\subseteq I \subseteq [0, \infty[.$$

A *piecewise C^k feedback control law* for the system (3.1) on a set S is a pair $\mathcal{V}' = (\mathcal{V}, \mathbf{u})$, where:

- (3.IV i) $\mathcal{V} = (\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \mathbf{X}, \mathbf{E}, \epsilon)$ is a piecewise C^k vector field on S ;
- (3.IV ii) \mathbf{u} is a family $\{u_P: P \in \mathcal{P}_1\}$, such that each u_P is a map $u_P: P \rightarrow U$, of class C^k , such that

$$(3.2) \quad X_P(q) = F(q, u_P(q))$$

for all $q \in P$.

If $\mathcal{V}' = (\mathcal{V}, \mathbf{u})$ is a piecewise C^k feedback control law on S , then we can define an *admissible control*

$$u_q^{\mathcal{V}'}: \text{Dom}(\gamma_q^{\mathcal{V}}) \rightarrow U$$

by letting

$$(3.3) \quad u_q^{\mathcal{V}'}(t) = u_P(\gamma_q^{\mathcal{V}}(t))$$

if $\gamma_q^{\mathcal{V}}(t) \in P \in \mathcal{P}_1$, and by defining $u_q^{\mathcal{V}'}(t)$ in an arbitrary fashion if $\gamma_q^{\mathcal{V}}(t) \in P \in \mathcal{P}_2$. (It follows from the definition of a trajectory that the set of those $t \in \text{Dom}(\gamma_q^{\mathcal{V}})$ for which $\gamma_q^{\mathcal{V}}(t)$ is in some $P \in \mathcal{P}_2$ is finite or countable.) The pair $(u_q^{\mathcal{V}'}, \gamma_q^{\mathcal{V}}) = \Gamma_q^{\mathcal{V}'}$ is clearly admissible.

If \mathcal{V} is a piecewise C^k vector field on S (or if \mathcal{V}' is a piecewise C^k feedback control law on S), we say that \mathcal{V} (or \mathcal{V}') is *completely terminating* if $\text{Dom}(\gamma_q^{\mathcal{V}})$ is a compact interval for each $q \in S$. It is then clear that, if $q \in S$, the point $\gamma_q^{\mathcal{V}}(\max \text{Dom}(\gamma_q^{\mathcal{V}}))$ is in $\text{Term}(\mathcal{V})$. When \mathcal{V} is completely terminating, it is more convenient to define a new trajectory $\hat{\gamma}_q^{\mathcal{V}}$ by letting $\hat{\gamma}_q^{\mathcal{V}}(t) = \gamma_q^{\mathcal{V}}(t + \max \text{Dom}(\gamma_q^{\mathcal{V}}))$ for

$-\max \text{Dom}(\gamma_q^\mathcal{V}) \leq t \leq 0$. Then $\hat{\gamma}_q^\mathcal{V}$ terminates exactly at time 0. If $\mathcal{V}' = (\mathcal{V}, u)$ is a piecewise C^k completely terminating feedback control law, then we can also define $\hat{u}_q^{\mathcal{V}'}$ in a similar fashion. Now the pair

$$\hat{\Gamma}_q^{\mathcal{V}'} = (\hat{u}_q^{\mathcal{V}'}, \hat{\gamma}_q^{\mathcal{V}'})$$

is admissible for each $q \in S$ and, moreover, it is easy to see that the family $\hat{\Gamma}^{\mathcal{V}'} = \{\hat{\Gamma}_q^{\mathcal{V}'} : q \in S\}$ satisfies the compatibility property. Therefore $\hat{\Gamma}^{\mathcal{V}'}$ is a feedback control flow. We call $\hat{\Gamma}^{\mathcal{V}'}$ the *feedback control flow generated by \mathcal{V}'* .

If \mathcal{V} (or \mathcal{V}') is completely terminating, we say that \mathcal{V} (or \mathcal{V}') *terminates in a finite number of steps* if, for each $q \in S$, there exists a finite partition π of $\text{Dom}(\hat{\gamma}_q^\mathcal{V})$ into intervals such that, for each $I \in \pi$, $\hat{\gamma}_q^\mathcal{V}(I)$ is entirely contained in one member of \mathcal{P} .

Now, let $\mathcal{V}' = (\mathcal{V}, u)$ be completely terminating in a finite number of steps. For each $q \in S$, let $\tau^\mathcal{V}(q)$ denote the *termination time* of $\gamma_q^\mathcal{V}$, i.e., the length of $\text{Dom}(\gamma_q^\mathcal{V})$. It follows easily from our definitions that $\tau^\mathcal{V}$ is of class C^k on each $P \in \mathcal{P}_1$, and $P \not\subseteq \text{Term}(\mathcal{V})$, then X_P never vanishes on P , and

$$X_P(\tau^\mathcal{V} \upharpoonright P) \equiv -1.$$

Therefore, if $P \in \mathcal{P}_1$, $P \not\subseteq \text{Term}(\mathcal{V})$, the C^k function $\tau^\mathcal{V} \upharpoonright P$ has a nowhere vanishing gradient. So, if $q \in P$, the set $N(q)$ of those $q' \in P$ such that $\tau^\mathcal{V}(q') = \tau^\mathcal{V}(q)$ is a C^k submanifold of P , of codimension one. We say that $q \in P$ is a *Lipschitz point* if there is a neighborhood W of q in P and a constant $C > 0$, such that

$$(3.4) \quad \text{dist}(\hat{\gamma}_{q'}^\mathcal{V}(t), \hat{\gamma}_q^\mathcal{V}(t)) \leq C \text{dist}(q', q')$$

for all $q' \in W \cap N(q)$, and all $t \in [-\tau^\mathcal{V}(q), 0]$. (Here “dist” is the distance relative to some Riemannian metric on M .) We say that \mathcal{V}' has the *Lipschitz regularity property* if, for every $P \in \mathcal{P}_1$, the set of Lipschitz points of P is dense in P .

Now suppose that $\mathcal{V}' = (\mathcal{V}, u)$ is a piecewise C^k feedback control flow on S which completely terminates, and suppose that $\text{Term}(\mathcal{V}')$ consists of a single point p . Let L be a Lagrangian function as above. We define the *cost function* V , corresponding to \mathcal{V}' and L , by letting

$$(3.5) \quad V(q) = \int_{-\tau^{\mathcal{V}'}(q)}^0 L(\hat{\gamma}_q^{\mathcal{V}'}(t), \hat{u}_q^{\mathcal{V}'}(t)) dt.$$

We shall say that \mathcal{V}' satisfies the *near continuity property* if the following three conditions hold:

- (3.Vi) V is lower semicontinuous on S ;
- (3.Vii) For every $\delta > 0$ and every neighborhood W of p in M , there exists a submanifold W' of M such that $W' \subseteq W \cap S$, that all the vector fields $F(\cdot, u)$ are tangent to W' , and that $V(q) < \delta$ for all $q \in W'$ (it is not required that $p \in W'$);
- (3.Viii) Whenever $\gamma : I \rightarrow S$ is an integral trajectory of some vector field $F(\cdot, u)$, $u \in U$, then $t \rightarrow V(\gamma(t))$ is left continuous on I .

Notice that, if the feedback control flow $\hat{\Gamma}'$ actually were an L -optimal feedback control flow with target $p \in M$, then condition (3.Viii) would follow from (3.Vi). (Indeed, let γ be an integral curve of $F(\cdot, u)$ in $\text{Contr}(p)$, and let $t_n \rightarrow t$, $t_n \in \text{Dom}(\gamma)$, $t \in \text{Dom}(\gamma)$. Then $\liminf V(\gamma(t_n)) \geq V(\gamma(t))$ by the lower semicontinuity of V . On the other hand:

$$(3.6) \quad V(\gamma(t_n)) \leq \int_{t_n}^t L(\gamma(s), u) ds + V(\gamma(t)),$$

and so $\limsup V(\gamma(t_n)) \leq V(\gamma(t))$. Also, condition (3.Vii) follows automatically if, for instance, the system (3.1) is analytic. (This is quite easy to prove; see [Su 6].)

We are now ready to define regular synthesis. A C^k *regular synthesis* for the system (3.1), with Lagrangian L and target p , is an L -extremal feedback control flow Γ with target p , which is the flow $\hat{\Gamma}^{\mathcal{V}'}$ generated by a piecewise C^k feedback control law $\mathcal{V}' = (\mathcal{V}, u)$ which is completely terminating in finitely many steps, and satisfies the Lipschitz regularity and near continuity properties.

One of the main theorems of [Su 6] is that, if Γ is a C^k regular synthesis in the sense of the preceding definition, then Γ is optimal, if the control system satisfies a mild regularity condition. (Precisely the condition that the rank of the Lie algebra generated by the vector fields $F(\cdot, u)$ be constant along the integral curves of these vector fields. The condition is always satisfied when the $F(\cdot, u)$ are analytic.)

We are now ready to state the main theorem of this paper.

THEOREM 3.1. *Consider a control system Σ given by:*

$$\dot{x} = F(x) + uG(x), \quad |u| \leq 1, \quad x \in M,$$

where M is a two-dimensional analytic manifold, and F, G are analytic vector fields on M . Let $p \in M$ be such that the following "nonexplosion condition" holds:

(NE) For every $T > 0$ there exists a compact subset $K(T)$ of M such that, if $\gamma: [a, b] \rightarrow M$ is a trajectory of Σ , such that $\gamma(b) = p$ and $b - a \leq T$, then γ is entirely contained in $K(T)$.

Then the problem of reaching p in minimum time admits a C^ω regular synthesis Γ . Moreover, Γ can be chosen to be the feedback control flow generated by a $\mathcal{V}' = (\mathcal{V}, u)$ such that, if \mathcal{P} is the partition corresponding to \mathcal{V} , and if, for $T > 0$, K_T is the set of points that can be steered to p in time $\leq p$, then each K_T only meets finitely many members of \mathcal{P} .

Proof. We let M_0 denote the integral manifold through p of the Lie algebra L of vector fields generated by F and G . Clearly, the set $\text{Contr}(p)$ is contained in M_0 and so, in order to construct the synthesis, it suffices to work with the restriction of our system to M_0 . If $\dim M_0 < 2$ then the existence of the regular synthesis is a completely trivial matter. So we shall assume that $\dim M_0 = 2$, i.e. that Σ has the accessibility property at p . We now replace M by M_0 , i.e. we assume that M is itself the integral manifold of L through p . If L_0 is the ideal of L generated by G , then it follows from [Su J] that the dimension of $L_0(q)$ is the same for all $q \in M$. Obviously, the common value of this dimension is either two or one. In the former case, Σ has the SAP everywhere, and in the latter case Σ has the SAP nowhere.

The strategy of our proof will be to construct an *optimal* feedback control flow Γ with target p . Then we will invoke the results of [Su 6] to conclude that Γ is generated by a \mathcal{V}' that has all the desired properties. Before we construct Γ , let us observe that condition (NE) implies, in particular, that for every $q \in \text{Contr}(p)$ there exists a time-optimal trajectory γ going from q to p . So, if we define $V(q)$ to be the infimum of the times along all the trajectories γ from q to p , then $V(q)$ is actually attained by some γ . Moreover, it is easy to see (using (NE) again) that V is lower semicontinuous on $\text{Contr}(p)$. As explained earlier, the near-continuity property will then follow automatically.

So, what we really need is to construct an optimal Γ that is generated by a \mathcal{V}' which is a piecewise C^ω feedback control law which completely terminates in finitely many steps and satisfies the Lipschitz regularity condition. According to the main

theorem of [Su 6], such a generator \mathcal{V}' will exist if Γ is a *subanalytic feedback*. So all we need is to construct an optimal feedback Γ with target p , which is subanalytic.

First recall that a *subanalytic feedback* is a feedback control law $\Gamma = \{\Gamma_x\}$ with the property that each of the maps

$$(x, t) \rightarrow u_x(t)$$

and

$$(x, t) \rightarrow \gamma_x(t)$$

is subanalytic. (That is, the sets $\{(x, t, y): y = u_x(t)\}$ and $G_\Gamma = \{(x, t, z): z = \gamma_x(t)\}$ are subanalytic in $M \times \mathbb{R} \times \mathbb{R}$, $M \times \mathbb{R} \times M$, respectively.) Next observe that, if Γ is a feedback control flow with target p , and if $(x, t) \rightarrow \gamma_x(t)$ is subanalytic, then it automatically follows that, after a suitable modification, one can assume that $(x, t) \rightarrow u_x(t)$ is subanalytic. (Proof: let A be the set of those (x, t) such that $x \in \text{Contr}(p)$, $t \in \text{Dom}(\gamma_x)$. Recall that we are assuming that $\text{Dom}(\gamma_x)$ is of the form $[a, 0]$. Then A is the projection of G_Γ under the map $\pi: (x, t, y) \rightarrow (x, t)$, from $M \times \mathbb{R} \times M$ to $M \times \mathbb{R}$. Since π is proper on $\text{Clos } G_\Gamma$, because of (NE), it follows that A is subanalytic in $M \times \mathbb{R}$. Let A' be the set of those $(x, t) \in A$ for which $\lim_{h \rightarrow 0+} (\gamma_x(t+h) - \gamma_x(t))/h$ exists. Then it is easy to see that A' is subanalytic in $M \times \mathbb{R}$. Let A'' be the set of those $(x, t) \in A'$ such that $G(\gamma_x(t)) \neq 0$. Define $u_x(t) = 0$ if $(x, t) \in A - A''$. If $(x, t) \in A''$, let $u_x(t)$ be the unique u such that

$$\lim_{h \rightarrow 0+} \frac{\gamma_x(t+h) - \gamma_x(t)}{h} = F(\gamma_x(t)) + uG(\gamma_x(t)).$$

Then the map $(x, t) \rightarrow u_x(t)$ is subanalytic.)

So all we have to do is to find a way to select, for each $x \in \text{Contr}(p)$, a time-optimal trajectory $\gamma_x: [-V(x), 0] \rightarrow M$, so that the γ_x are compatible (i.e., whenever $\gamma_x(t) = \gamma_y(t)$ for some $t \leq 0$, then $\gamma_x(\tau) = \gamma_y(\tau)$ for $t \leq \tau \leq 0$) and that $(x, t) \rightarrow \gamma_x(t)$ is subanalytic.

If Σ has the SAP, let \mathcal{A} be the set whose elements are the symbols X , Y , and one symbol S for each maximal turnpike $S \in \mathcal{MT}(\Sigma)$. If Σ does not have the SAP, let \mathcal{A} consist of X and Y alone.

For each integer $n \geq 0$, let K_n be the subset of $\text{Contr}(p)$ which consists of those points $x \in \text{Contr}(p)$ which can be steered to p in time $\leq n$, i.e.,

$$(3.7) \quad K_n = \{x: x \in \text{Contr}(p) \wedge V(x) \leq n\}.$$

Then K_n is compact. Let \mathcal{A}_n be the subset of \mathcal{A} whose elements are X , Y , and—if Σ has the SAP—all the maximal turnpikes S of Σ such that $\text{Clos } S$ meets K_n . Since $\mathcal{MT}(\Sigma)$ is locally finite, it is clear that \mathcal{A}_n is a finite set. We claim that:

- (3.VI) For each n , there exists an integer $N(n) \geq 0$ such that, if $x \in K_n$, then x can be time-optimally steered to p by means of a trajectory γ which is a concatenation of at most $N(n)$ pieces, each of which is a ξ -trajectory for some $\xi \in \mathcal{A}_n$.

To prove this, we use our theorems on the structure of trajectories. If Δ has the SAP, then it follows from Theorem 3.18 of [B] that every $q \in K_n$ has a neighborhood $U(q)$ such that there is a $\nu(q)$ with the property that, if γ is a time-optimal trajectory in $U(q)$, then γ is a concatenation of at most $\nu(q)$ pieces, each of which is either an X -trajectory, or a Y -trajectory, or an S -trajectory for some $S \in \mathcal{MT}(\Sigma)$. (By definition, if $S \in \mathcal{MT}(\Sigma)$ an S -trajectory is a trajectory of Σ which is contained in $\text{Clos } S$.) Clearly,

we can choose $U(q)$ so that $U(q) \cap \text{Clos } S = \emptyset$ for all $S \in \mathcal{MT}(\Sigma)$ such that $(\text{Clos } S) \cap K_n = \emptyset$. Then, if γ is time-optimal in $U(q)$, γ is a concatenation of at most $\nu(q)$ pieces, each of which is a ξ -trajectory for a $\xi \in \mathcal{A}_n$. Next choose a finite covering of K_n , of the form $\mathcal{U} = \{U(q_1), \dots, U(q_m)\}$, and let $\bar{\nu} = \max(\nu(q_1), \dots, \nu(q_m))$. Let $\alpha > 0$ be a Lebesgue number for \mathcal{U} (i.e., an $\alpha > 0$ such that, whenever a set $J \subseteq K_n$ has diameter $\leq \alpha$, with respect to some fixed metric, then J is contained in one of the $U(q_i)$). Let $C > 0$ be such that $\|F(x)\| + \|G(x)\| \leq C$ for $x \in K_n$, and let $\beta > 0$ be such that $\beta C < \alpha$. Let μ be an integer such that $\mu\beta > n$. If $x \in K_n$, let $\gamma: [-V(x), C] \rightarrow M$ be a time-optimal trajectory from x to p . Then γ is a concatenation of at most μ pieces γ_j , such that $\text{Dom}(\gamma_j) = I_j$ is an interval of length $< \beta$. Therefore $\gamma_j(I_j)$ has diameter $< \alpha$. So each $\gamma_j(I_j)$ is contained in one of the $U(q_i)$. Therefore each γ_j is a concatenation of at most $\bar{\nu}$ pieces, each of which is a ξ -trajectory for some $\xi \in \mathcal{A}_n$. So γ is a concatenation of at most $N(n)$ pieces, each of which is a ξ -trajectory for some $\xi \in \mathcal{A}_n$, if we take $N(n) = \mu\bar{\nu}$. This completes the proof of (3.VI) when Σ has the SAP. If Σ does not have the SAP, i.e., if $\Delta_B \equiv 0$ on M , then the proof of (3.VI) is almost identical, except that we use Theorem 4.2 of [B] instead of Theorem 3.18 of [B]. For each $q \in K_n$ we choose $\nu(q)$, $U(q)$ such that, whenever it is possible to go time-optimally from an $r_1 \in U(q)$ to an $r_2 \in U(q)$ by means of a trajectory in $U(q)$, then one can go time-optimally from r_1 to r_2 by means of a trajectory which is bang-bang with at most $\nu(q) - 1$ switchings. The finite cover \mathcal{U} , and the numbers $\alpha, C, \beta, \bar{\nu}, \mu, N(n)$ are defined as before. If $x \in K_n$, one can find a time-optimal $\gamma: [-V(x), 0]$ from x to p , and then express γ as before as a concatenation of at most μ γ_j 's, each of which is contained in one $U(q_i)$. Therefore there is a γ_j^* that has the same endpoints as γ_j , is defined on the same domain as γ_j , and is bang-bang with at most $\bar{\nu} - 1$ switchings. If γ^* denotes the concatenation of the γ_j^* , then γ^* goes from x to p in the same time as γ , and γ^* is a concatenation of no more than $N(n)$ pieces, each of which is in $\text{Traj}(X \vee Y)$. So (3.VI) holds in this case as well.

If $\xi = (\xi_1, \dots, \xi_m)$ is a finite sequence of elements of \mathcal{A} , define a set

$$D(\xi) \subseteq M \times \mathbb{R}$$

to be the set of all pairs (x, t) such that x can be steered to p in time t by means of a trajectory γ which is a concatenation $\gamma_m * \dots * \gamma_1$, where each γ_i is a ξ_i trajectory. Then we have, if η denotes the sequence (ξ_2, \dots, ξ_m) :

$$(3.8) \quad (x, t) \in D(\xi) \Leftrightarrow (\exists s)(0 \leq t \leq s \wedge (\exists y)((x, y, s) \in \mathcal{F}^{\xi_1} \wedge (y, t-s) \in D(\eta))).$$

If (x, t) remains in a compact subset of $M \times \mathbb{R}$, then t is bounded by an n , and therefore the y which appears in the formula, if it exists at all, must actually be in K_n . So all the quantifiers in (3.8) are bounded. Therefore it follows, by induction, that all the $D(\xi)$ are subanalytic in $M \times \mathbb{R}$. Moreover, it is clear that they are closed.

We now define, by induction on n , a family Γ^n of subanalytic feedback flows on K_n , such that Γ^n steers all of K_n to p , and that each trajectory of Γ^n is time-optimal. Moreover, the Γ^n will be so constructed that Γ^n agrees with Γ^{n-1} on K_{n-1} .

The definition of Γ^0 is obvious. Suppose that $\Gamma^0, \dots, \Gamma^n$ have been constructed. Let $\Gamma_x^n = (u_x^n, \gamma_x^n)$, for $x \in K_n$. The set

$$G_n = \{(x, t, y): y = \gamma_x^n(t)\}$$

is subanalytic in $M \times M \times \mathbb{R}$, and is relatively compact (because it is contained in $K_n \times [-n, 0] \times K_n$). So its projection via $(x, t, y) \rightarrow x$ is subanalytic. Therefore K_n is subanalytic in M .

Let ξ_1, \dots, ξ_r be the elements of \mathcal{A}_{n+1} . For $\rho = 1, \dots, N(n+1)$, let E'_ρ denote the set of all elements $x \in K_{n+1} - K_n$ such that there is a time-optimal trajectory γ

which steers x to some element y of K_n in time $V(x) - V(y)$, and which is a concatenation of at most ρ pieces, each of which is a ξ -trajectory for some $\xi \in \mathcal{A}_{n+1}$. It is clear that the sets E'_ρ increase with ρ , and that $E'_{N(n+1)} = K_{n+1} - K_n$. Let $E_\rho = E'_\rho \cup K_n$.

We will construct Γ^{n+1} by constructing, for each $\rho \in \{0, \dots, N(n+1)\}$, a subanalytic feedback $\Gamma^{n+1, \rho}$ on E_ρ , which steers all of E_ρ to p , and which is such that each trajectory of $\Gamma^{n+1, \rho}$ is time-optimal. Moreover, the $\Gamma^{n+1, \rho}$ will be so constructed that $\Gamma^{n+1, 0} = \Gamma^n$, and that each $\Gamma^{n+1, \rho}$, $\rho > 0$, agrees with $\Gamma^{n+1, \rho-1}$ on $E_{\rho-1}$. Once this construction is carried out, then we can take Γ^{n+1} to be $\Gamma^{n+1, N(n+1)}$.

It is clear that $\Gamma^{n+1, 0}$ must be taken to be Γ^n . Assume that $0 \leq \rho < N(n+1)$, and that $\Gamma^{n+1, 0}, \dots, \Gamma^{n+1, \rho}$ have been constructed. We must construct $\Gamma^{n+1, \rho+1}$. First observe that, if $\Gamma^{n+1, \rho} = (u_x^{n+1, \rho}, \gamma_x^{n+1, \rho})$ for $x \in E_\rho$, then E_ρ is the projection via $(x, t, y) \rightarrow x$ of the relatively compact subanalytic subset

$$G_{n, \rho} = \{(x, t, y) : y = \gamma_x^{n+1, \rho}(t)\}$$

of $M \times M \times \mathbb{R}$. So E_ρ is subanalytic in M . Moreover, we have $t = -V(x)$, $x \in E_\rho$, if and only if $(x, t, p) \in G_{n, \rho}$. So the graph of $V|_{E_\rho}$ is subanalytic in $M \times \mathbb{R}$.

Now let

$$H_\rho = E_{\rho+1} - E_\rho.$$

A point x belongs to H_ρ iff it belongs to K_{n+1} and it can be steered in time $V(x) - V(y)$ to some $y \in K_n$ by a trajectory γ which is a concatenation of $\rho + 1$ pieces, each of which is a ξ -trajectory for some $\xi \in \mathcal{A}_{n+1}$, but it cannot be steered in time $V(x) - V(y)$ to any $y \in K_n$ by a γ which only involves ρ pieces. If γ is a trajectory with $\rho + 1$ pieces which steers x to $y \in K_n$ in time $V(x) - V(y)$, let \tilde{x} be the point where the first piece of γ ends. If δ steers y to p time-optimally (i.e., in time $V(y)$), then the concatenation $\delta * \gamma$ steers x to p in time $V(x)$; i.e., time-optimally. If $\tilde{\gamma}$ is the result of eliminating from γ its first piece, then $\delta * \tilde{\gamma}$ is time-optimal. Therefore $\tilde{\gamma}$ steers \tilde{x} to y in time $V(\tilde{x}) - V(y)$.

Since $\tilde{\gamma}$ is a concatenation of ρ pieces, each of which is a ξ -trajectory for a $\xi \in \mathcal{A}_{n+1}$, we conclude that $\tilde{x} \in E_\rho$. Therefore, if $x \in H_\rho$, then:

(3.VII) x can be steered to a $y \in E_\rho$ in time $V(x) - V(y)$ by means of a trajectory γ which is a ξ -trajectory for some $\xi \in \mathcal{A}_{n+1}$.

Conversely, it is easy to see that, if $x \in K_{n+1}$, $x \notin E_\rho$, then (3.VII) implies that $x \in H_\rho$.

For each $\sigma = 0, \dots, r$, let H_ρ^σ denote the set of those $x \in K_{n+1}$ that can be steered to some $y \in E_\rho$ in time $V(x) - V(y)$ by means of a γ which is a ξ_i -trajectory for some $i \in \{1, \dots, \sigma\}$. Then

$$\emptyset = H_\rho^0 \subseteq H_\rho^1 \subseteq \dots \subseteq H_\rho^r = H_\rho.$$

If we let $L_\rho^\sigma = H_\rho^\sigma \cup E_\rho$, then $E_\rho = L_\rho^0 \subseteq L_\rho^1 \subseteq \dots \subseteq L_\rho^r = E_{\rho+1}$.

We will construct $\Gamma^{n+1, \rho+1}$ by constructing, by induction on σ , subanalytic feedbacks $\Gamma^{n+1, \rho+1, \sigma}$ that steer all of L_ρ^σ to p and are time-optimal. Moreover, we will construct them in such a way that $\Gamma^{n+1, \rho+1, \sigma}$ agrees with $\Gamma^{n+1, \rho+1, \sigma-1}$ on $L_\rho^{\sigma-1}$, and that $\Gamma^{n+1, \rho+1, 0} = \Gamma^{n+1, \rho}$.

Assuming that $\sigma < r$, and that $\Gamma^{n+1, \rho+1, 0}, \dots, \Gamma^{n+1, \rho+1, \sigma}$ have been defined, let us define $\Gamma^{n+1, \rho+1, \sigma+1}$. If $x \in L_\rho^\sigma$, then we choose $\Gamma_x^{n+1, \rho+1, \sigma+1}$ to be $\Gamma_x^{n+1, \rho+1, \sigma}$. If $x \in L_\rho^{\sigma+1}$ but $x \notin L_\rho^\sigma$, then x can be steered to some $y \in E_\rho$ in time $V(x) - V(y)$ by means of a $\xi_{\sigma+1}$ -trajectory. Let δ be the maximal $\xi_{\sigma+1}$ -trajectory through x , parametrized in such a way that $\delta(-V(x)) = x$. Then there is a $\bar{t} > -V(x)$ such that $\delta(\bar{t}) = y \in E_\rho$, and that $\bar{t} = -V(y)$. Let $\bar{\delta} = \delta|_{[-V(x), \bar{t}]}$. If $\eta : [-V(y), 0] \rightarrow M$ steers y time-optimally to p , then $\eta * \bar{\delta}$ is time-optimal. Therefore $V(\delta(t)) = -t$ for $-V(x) \leq t \leq \bar{t}$.

It is clear that $\delta(\bar{t}) \in L_\rho^\sigma$. Let J be the set of those $t \in [-V(x), \bar{t}]$ such that $\delta(t) \in L_\rho^\sigma$. Let $t^* = \inf J$. We prove that $t^* \in J$. Let $t_m \searrow t^*$ be such that $t_m \in J$. Then $\delta(t_m) \in L_\rho^\sigma$, so that $\delta(t_m)$ can be steered to some $y_m \in E_\rho$ in time $\tau_m = V(\delta(t_m)) - V(y_m)$ by means of a trajectory γ_m that is a $\xi_{i(m)}$ -trajectory for some $i(m) \in \{1, \dots, \sigma\}$. By replacing $\{t_m\}$ by a subsequence, if necessary, we may assume that all the $i(m)$ are equal to a fixed $\bar{i} \in \{1, \dots, \sigma\}$.

Since $y_m \in E_\rho$, it is possible to steer y_m to a $z_m \in K_n$ in time $V(y_m) - V(z_m)$ by means of a trajectory γ'_m which is a concatenation of ρ pieces $\gamma'_{m,1}, \dots, \gamma'_{m,\rho}$, such that each $\gamma'_{m,j}$ is a $\xi_{i(m,j)}$ -trajectory for some $\xi_{i(m,j)} \in \mathcal{A}_{n+1}$. Since there is only a finite number of sequences $(i(1), \dots, i(\rho))$ of elements of $\{1, \dots, r\}$, we may assume (after passing to a subsequence, if necessary) that there is a fixed sequence $i^*(1), \dots, i^*(\rho)$, such that all the $\gamma'_{m,j}$ are $\xi_{i^*(j)}$ -trajectories for all m , and all j . Finally select, for each m , a time-optimal trajectory γ''_m that goes from z_m to p .

By passing to a subsequence, we may assume that the z_m, y_m, τ_m converge, as well as the times along all the $\gamma'_{m,j}$, and all the endpoints of $\gamma'_{m,j}$. Moreover, we can assume that the trajectories $\gamma''_m * \gamma'_m * \gamma_m$ converge uniformly. The limiting trajectory η is a concatenation $\gamma'' * \gamma' * \gamma$, where: (a) γ is a $\xi_{\bar{i}}$ -trajectory that steers $\delta(t^*)$ to $y = \lim y_m$, (b) γ' is a concatenation $\gamma'_1 * \dots * \gamma'_\rho$, where each γ'_j is a $\xi_{i^*(j)}$ -trajectory, and, moreover, γ' steers y to $z = \lim z_m$, (c) γ'' steers z to p .

Since $\gamma''_m * \gamma'_m * \gamma_m$ steers $\delta(t_m)$ to p in time $V(\delta(t_m))$ (i.e., $-t_m$), it follows that $\gamma'' * \gamma' * \gamma$ steers $\delta(t^*)$ to p in time $-t^*$, i.e., in time $V(\delta(t^*))$. So $\gamma'' * \gamma' * \gamma$ is time-optimal. Therefore γ' steers y to z in time $V(y) - V(z)$. Since $z_m \in K_n$, we conclude that $z \in K_n$, and so $y \in E_\rho$. Moreover, γ steers $\delta(t^*)$ to y in time $V(\delta(t^*)) - V(y)$. Since $\delta(t^*) \in K_{n+1}$, it follows that $\delta(t^*) \in L_\rho^\sigma$. Therefore $t^* \in J$, as asserted.

So, if $x \in L_\rho^{\sigma+1}$ but $x \notin L_\rho^\sigma$, the trajectory δ defined above is entirely contained in $L_\rho^{\sigma+1} - L_\rho^\sigma$, until a first time t^* is reached when $\delta(t^*) \in L_\rho^\sigma$. We define, for such an x , the trajectory $\gamma_x^{n+1, \rho+1, \sigma+1}$ as follows: we follow δ up to the time t^* , and then we follow $\gamma_{\delta(t^*)}^{n+1, \rho+1, \sigma}$. This defines a family of trajectories, one for each $x \in L_\rho^{\sigma+1}$, and it is clear that the trajectories obtained in this way constitute a compatible family and that the feedback control law so defined agrees with $\Gamma^{n+1, \rho+1, \sigma}$ on L_ρ^σ . This completes the definition of $\Gamma^{n+1, \rho+1, \sigma+1}$. The only remaining point is to show that $\Gamma^{n+1, \rho+1, \sigma+1}$ is subanalytic. Naturally, it is a part of our inductive hypothesis that $\Gamma^{n+1, \rho+1, \sigma}$ is subanalytic.

A triple (x, t, y) satisfies $y = \gamma_x^{n+1, \rho+1, \sigma+1}(t)$ if and only if one of the following conditions holds:

- (3.VIIIi) $y = \gamma_x^{n+1, \rho+1, \sigma}(t)$;
- (3.VIIIii) There exist τ, z, s such that:
 - (a) $z \in L_\rho^\sigma$ and $\tau > 0, \tau \leq n+1$,
 - (b) $(x, z, \tau) \in \mathcal{F}^{\xi_{\sigma+1}}$,
 - (c) there is no pair (z', τ') such that $0 < \tau' < \tau, z' \in L_\rho^\sigma$, and $(x, z, \tau') \in \mathcal{F}^{\xi_{\sigma+1}}$,
 - (d) $z = \gamma_x^{n+1, \rho+1, \sigma}(s)$ and $-n-1 \leq s \leq 0$,
 - (e) there exists no sequence ξ of elements of \mathcal{A}_{n+1} , of length $\leq N(n+1)$ such that there is an s' for which $0 \leq s' < \tau - s$ and $(x, s') \in D(\xi)$,
 - (f) either $t \geq s$ and $y = \gamma_z^{n+1, \rho+1, \sigma}(t)$, or $t < s$ and $(x, y, \tau - s + t) \in \mathcal{F}^{\xi_{\sigma+1}}$.

From this restatement of the definition of $\Gamma^{n+1, \rho+1, \sigma+1}$, together with the subanalyticity of all the sets \mathcal{F}^ξ , it follows that $\Gamma^{n+1, \rho+1, \sigma+1}$ is indeed a subanalytic feedback.

As explained above, this completes the inductive construction of the $\Gamma^{n+1,\rho+1,\sigma}$ for a given n, ρ . Then the inductive construction of the $\Gamma^{n+1,\rho}$ for a given n is also complete, and so the construction of the Γ^n is complete. We now define Γ by letting $\Gamma_x = \Gamma_x^n$ if $x \in K_n$. Then Γ is an optimal feedback control law on $\text{Contr}(p)$, with target p , and is subanalytic. As explained above, the theorem of [Su 6] then implies the existence of a regular synthesis.

As for the last assertion of our statement, it follows from the results of [Su 6]. Indeed, the partition \mathcal{P} constructed in the proof of the main theorem of [Su 6] is finite on each compact set K such that the time $\tau(x)$ along γ_x is bounded for $x \in K$, and that all the $\gamma_x, x \in K$, are Lipschitzian in t with a fixed constant. Clearly, the sets K_T satisfy this condition.

We conclude this section with a brief outline of an obvious extension of Theorem 3.1. If we have an analytic system Σ as has been considered here, and if we want to minimize an integral $\int L(x(t)) dt$, where L is analytic and $L(x) > 0$ for all x , then we can form the system Σ' given by

$$\dot{x} = \frac{F(x)}{L(x)} + u \frac{G(x)}{L(x)}.$$

The trajectories of Σ' are exactly the Σ -trajectories, reparametrized by cost. So, if the time-optimal problem for Σ' has a regular synthesis, we get a regular synthesis for the problem of minimizing $\int L$ for Σ . The precise hypotheses required are: (a) analyticity of F, G, L , (b) strict positivity of L and (c) a "nonexplosion" condition. The non-explosion condition is exactly that of Theorem 3.1, except that "time" has to be replaced by "cost" throughout. (That is, we must assume that, for each $T > 0$, there is a compact $K(T)$ such that, whenever γ steers an $x \in \text{Contr}(p)$ to p with cost less than T , then γ is entirely contained in $K(T)$.)

The conclusion then is the same as that of Theorem 3.1, except that the definition of regular synthesis has to be modified, so as to substitute "cost" for "time."

OPTIMAL CONTROL FOR A BACKWARD PARABOLIC SYSTEM*

P. H. RIVERA†‡ AND C. F. VASCONCELLOS†

Abstract. In this paper the authors study two problems of optimal control for systems governed by a backward parabolic equation, when the \mathcal{U}_{ad} has nonempty interior.

Key words. optimal control, backward equation, nonwell-posed problem

AMS(MOS) subject classifications. 49A22, 35K99

1. Introduction. The objective of this paper is to present certain results on two problems of optimal control related to the partial differential operator $\partial z / \partial t + m(t) \Delta z$, in which $m: [0, T] \rightarrow \mathbb{R}$ is a smooth function changing the sign in $]0, T[$.

In J. L. Lions [4] we find the origin of the above problems, where he solved the control problem, that is, existence of optimal couple and optimality system for the backward parabolic problem:

$$\begin{aligned} (1.1) \quad & \frac{\partial z}{\partial t} + \Delta z = v \quad \text{in } Q, \\ & z = 0 \quad \text{on } \Sigma, \\ & z(0) = z_0 \quad \text{in } \Omega \end{aligned}$$

where Ω is a bounded open subset of \mathbb{R}^n with smooth boundary Γ and Q is the cylinder $\Omega \times]0, T[$, with lateral boundary $\Sigma = \Gamma \times]0, T[$. Lions considered $L^2(Q)$ as the admissible convex set for his problem.

In [4], Lions also proposed studying the same type of problem, where instead of constant coefficient $m = 1$, as in the case (1.1), we have the following state equation:

$$\begin{aligned} (1.2) \quad & \frac{\partial z}{\partial t} + m(t) \Delta z = v \quad \text{in } Q, \\ & z = 0 \quad \text{on } \Sigma, \\ & z(0) = z_0 \quad \text{in } \Omega \end{aligned}$$

where m is defined as above.

In Rivera [8] it is shown that the problem (1.1) is well posed when we consider some special functional space.

The functional space introduced by Rivera is defined as follows:

$$\text{Let } A = -\Delta \text{ with domain } D(A) = H_0^1(\Omega) \cap H^2(\Omega).$$

Let

$$W = \left\{ u \in \bigcap_{\nu=0}^{\infty} D(A^\nu) : \sum_{\nu=0}^{+\infty} \frac{1}{\nu!} |A^\nu u|_\Omega^2 < +\infty \right\}.$$

‡ Deceased.

This is a Hilbert space with the norm

$$\|u\|_1^2 = \sum_{\nu=0}^{+\infty} \frac{1}{\nu!} |A^\nu u|_\Omega^2, \quad u \in W$$

where we represent by $|\cdot|_\Omega$ the norm of $L^2(\Omega)$.

Since A has a discrete spectrum, then W contains all the eigenfunctions of A ; hence W is dense in $L^2(\Omega)$. For related subjects see also Medeiros [7].

In this paper we prove, in § 2, the existence and uniqueness of a solution of the backward parabolic problem (1.2) when we consider the special space W which was defined above.

In § 3 we study the optimal control problems. First of all we consider a closed convex subset K of $H^{-1}(\Omega)$ and the following state equation:

$$\begin{aligned} \frac{\partial z}{\partial t} + m(t) \Delta z &= v \quad \text{in } Q, \\ z &= 0 \quad \text{on } \Sigma, \\ z(0) &\in K. \end{aligned} \tag{1.3}$$

The cost functional is defined by:

$$J(v, z) = |z - z_d|_Q^2 + N|v|_Q^2, \quad (v, z) \in L^2(Q) \times L^2(Q) \tag{1.4}$$

with $z_d \in L^2(Q)$ and $N > 0$.

To complete this paper, we study the final state optimal control which the state equation is given by:

$$\begin{aligned} \frac{\partial z}{\partial t} + m(t) \Delta z &= f \quad \text{in } Q, \\ z &= 0 \quad \text{on } \Sigma, \\ z(0) &= v \quad \text{in } \Omega. \end{aligned} \tag{1.5}$$

The cost functional is defined by:

$$J(v, z) = |z - z_d|_Q^2 + N\|v\|_{H^{-1}}^2, \quad (v, z) \in H^{-1}(\Omega) \times L^2(Q) \tag{1.6}$$

where z_d belongs to $L^2(Q)$ and $N > 0$.

In both problems we show the existence of a couple (u, y) such that $J(u, y) = \inf J(v, z)$, where $\{v, z\}$ are in suitable function spaces.

Moreover, we give necessary conditions for a couple $\{u, y\}$ to be an optimal couple; that is, we show that if a couple $\{u, y\}$ is an optimal couple, there exists an adjoint state p satisfying a system which will be defined in § 3 and is known by the optimality system.

We must note that the optimality system is crucial for the numerical approach to the optimal problem.

In this paper we denote $L^2(\Omega)$ by H and its scalar product by $(\cdot | \cdot)_\Omega$.

We denote by $H^1(\Omega)$ the Sobolev space of order one on Ω and by $H_0^1(\Omega)$ the closure in $H^1(\Omega)$ of the infinitely differentiable functions on Ω with compact support.

We represent $H_0^1(\Omega)$ by V and the norm in V shall be denoted by $\|\cdot\|$.

2. Existence of solution for the backward parabolic problem. We shall prove in this section that the system (1.2) is well posed when we pick up z_0 in W and v in $L^2(0, T; W)$.

For this we assume the following:

(2.1) Let $m(t)$ be a real function defined on $[0, T]$, $T > 0$, satisfying the following conditions:

- (i) m is continuously differentiable on $[0, T]$;
- (ii) m is monotonic decreasing in this interval;
- (iii) There exists $0 < T_0 < T$ such that $m(T_0) = 0$.

THEOREM 2.1. Suppose given $z_0 \in W$ and $v \in L^2(0, T; W)$. Then there exists a unique vector function $z: [0, T] \rightarrow H$ satisfying the following conditions:

$$(2.2) \quad z \in L^\infty(0, T; D(A)) \cap C([0, T]; V), \quad z' \in L^2(Q);$$

(2.3) There exists $c_0 > 0$ such that

$$\int_0^T |m(s)| \|z(s)\|^2 ds < c_0;$$

$$(2.4) \quad z' - m(t)Az = v \quad \text{in } L^2(Q);$$

$$(2.5) \quad z(0) = z_0.$$

Moreover the linear mapping $(z_0, v) \rightarrow (z, z')$ is continuous from $W \times L^2(0, T; W)$ into $L^\infty(0, T; D(A)) \times L^2(Q)$.

Before proving Theorem 2.1 we shall prove the following two propositions.

Let us represent by m_0, v_0 the restrictions, respectively, of m, v to the interval $[0, T_0]$.

PROPOSITION 2.1. There exists a unique vector function $x: [0, T_0] \rightarrow H$ such that

$$(2.6) \quad x \in C([0, T_0]; D(A)), \quad x' \in L^2(0, T_0; H).$$

(2.7) There exists $c_1 > 0$ such that

$$\int_0^{T_0} |m_0(s)| \|x(s)\|^2 ds \leq c_1,$$

$$(2.8) \quad x' - m_0(t)Ax = v_0 \quad \text{in } L^2(0, T_0; H),$$

$$x(0) = z_0.$$

Moreover, the linear mapping $(z_0, v_0) \rightarrow (x, x')$ is continuous from $W \times L^2(0, T; W)$ into $C([0, T_0]; D(A)) \times L^2(0, T_0; H)$.

Proof. Let w_1, \dots, w_ν, \dots be the eigenvectors of the operator A .

For each $j = 1, 2, \dots$, let f_j and g_j be the functions defined by:

$$(2.9) \quad (i) \quad f_j(t) = (z_0 | w_j)_\Omega \exp \left(\lambda_j \int_0^t m_0(s) ds \right), \quad j = 1, \dots, \nu,$$

$$(ii) \quad g_j(t) = \int_0^t (v_0(s) | w_j)_\Omega \exp \left(\lambda_j \int_s^t m_0(\sigma) d\sigma \right) ds, \quad j = 1, \dots, \nu.$$

Then, the function $h_j(t) = f_j(t) + g_j(t)$ is absolutely continuous on $[0, T_0]$ and satisfies, almost everywhere, the following system:

$$(2.10) \quad (i) \quad h_j'(t) - \lambda_j m_0(t) h_j(t) = (v_0(t) | w_j)_\Omega \quad \text{on }]0, T_0[,$$

$$(ii) \quad h_j(0) = (z_0 | w_j)_\Omega, \quad j = 1, \dots, \nu$$

where $\lambda_j, j = 1, 2, \dots, \nu$ are eigenvalues of A .

Hence, we deduce that $x_\nu(t) = \sum_{j=1}^\nu h_j(t)w_j$ is a solution of the following system:

$$(2.11) \quad (i) \quad (x'_\nu(t)|w_j)_\Omega - m_0(t)(Ax_\nu(t)|w_j)_\Omega = (v_0(t)|w_j)_\Omega,$$

$$(ii) \quad x_\nu(0) = \sum_{j=1}^\nu (z_0|w_j)_\Omega w_j.$$

We note that

$$(2.12) \quad (i) \quad |f_j(t)|^2 \leq \alpha_1 \sum_{k=0}^\infty (k!)^{-1} |(A^k z_0|w_j)_\Omega|^2 = S_j,$$

$$(ii) \quad |g_j(t)|^2 \leq \alpha_1 T_0 \sum_{k=0}^\infty (k!)^{-1} \int_0^{T_0} |(A^k v_0(s)|w_j)_\Omega|^2 ds = D_j,$$

$$j = 1, \dots, \nu \quad \text{and} \quad 0 \leq t \leq T_0$$

where $c = T_0 m_0(0)$ and $\alpha_1 = \exp(c^2)$.

Hence, we conclude that

$$(2.13) \quad |x_\nu(t)|_\Omega^2 \leq K_1 K_0, \quad \nu = 1, 2, \dots, \quad 0 \leq t \leq T_0 \quad \text{where} \quad K_0 = \|z_0\|_1^2 + \int_0^{T_0} \|v_0(s)\|_1^2 ds \\ \text{and} \quad K_1 = 2\alpha_1(1 + T_0).$$

Therefore by (2.13) we obtain:

$$(2.14) \quad \int_0^t m_0(s) \|x_\nu(s)\|^2 ds \leq K_2 K_0, \quad \nu = 1, 2, \dots, \quad 0 \leq t \leq T_0$$

where $K_2 = \frac{1}{2}(K_1 + 1 + K_1 T_0)$.

On the other hand, using (2.9), we have

$$(2.15) \quad (i) \quad |f'_j(t)| \leq m_0(0) \sum_{k=0}^\infty c^k (k!)^{-1} |(A^{k+1} z_0|w_j)_\Omega|,$$

$$(ii) \quad |g'_j(t)| \leq |(v_0(t)|w_j)_\Omega| \\ + m_0(0) \sum_{k=0}^\infty c^k (k!)^{-1} \int_0^{T_0} |(A^{k+1} v_0(s)|w_j)_\Omega| ds.$$

If we choose $\varepsilon > 0$ such that $0 < s = 1 + \varepsilon < 2$, there is $\alpha_0(\varepsilon) = \alpha_0 > 0$ which satisfies, for $u \in W$:

$$(2.16) \quad \sum_{k=0}^\infty (k!)^{-s} |A^{k+1} u|_\Omega^2 \leq \alpha_0 \|u\|_1^2.$$

Thus by (2.15) it follows that x'_ν belongs to $L^2(0, T_0; H)$ and

$$(2.17) \quad \|x'_\nu\|_{L^2(0, T_0; H)}^2 \leq K_3 K_0, \quad \nu = 1, 2, \dots$$

where $K_3 = 2T_0 \alpha_2 \alpha_0(1 + 2T_0) + 4$ and $\alpha_2 = m_0^2(0) \sum_{k=0}^\infty c^{2k} / (k!)^{s-2}$.

Now, since the series $\sum_{j=1}^\infty S_j$ and $\sum_{j=1}^\infty D_j$ converge, we obtain by (2.12) that

$$(2.18) \quad \lim_{\nu \rightarrow +\infty} x_\nu(t) = x(t) = \sum_{j=1}^\infty h_j(t)w_j \quad \text{in } H \text{ and uniformly in } t \in [0, T_0].$$

By the same argument we obtain:

$$(2.19) \quad \lim_{\nu \rightarrow +\infty} Ax_\nu(t) = Ax(t) \quad \text{in } H, \text{ uniformly in } t \in [0, T_0].$$

Now, existence of the solution of (2.8) follows using standard methods.

To prove the uniqueness we use the theorem of Lions and Malgrange [6].

PROPOSITION 2.2. *Let y_0 be in $D(A)$, v_1 in $L^2(0, T_1; D(A))$ and $m_1: [0, T_1] \rightarrow \mathbb{R}$, be a continuous monotonic increasing function such that $m_1(0) = 0 < m_1(T_1)$, where $T_1 > 0$.*

Then, there exists a unique vector function $y: [0, T_1] \rightarrow H$ such that

$$(2.20) \quad \begin{aligned} y &\in C([0, T_1]; V) \cap L^\infty(0, T_1; D(A)), \\ y' &\in L^2(0, T_1; V). \end{aligned}$$

$$(2.21) \quad \text{There exists } c_2 > 0 \text{ such that}$$

$$(2.22) \quad \begin{aligned} \int_0^{T_1} m_1(t) |Ay(t)|_\Omega^2 dt &\leq c_2, \\ y' + m_1(t)Ay &= v_1 \quad \text{in } L^2(0, T_1; H), \\ y(0) &= y_0. \end{aligned}$$

Moreover the linear mapping $(y_0, v_1) \rightarrow (y, y')$ is continuous from $D(A) \times L^2(0, T_1; D(A))$ into $L^\infty(0, T_1; D(A)) \times L^2(0, T_1; V)$.

Proof. We prove this proposition using the usual methods.

Proof of Theorem 2.1. Let $T_1 = T - T_0$ and let y_0 be $x(T_0)$, where $x: [0, T_0] \rightarrow H$ satisfies Proposition 2.1. We also consider $v_1(t) = v(t + T_0)$, $t \in]0, T_1[$ and $m_1(t) = -m(t + T_0)$, $t \in [0, T_1]$.

Under the above assumptions there is $y: [0, T_1] \rightarrow H$ which satisfies Proposition 2.2.

Then, if we define $z: [0, T] \rightarrow H$ by:

$$z(t) = \begin{cases} x(t) & \text{if } t \in [0, T_0], \\ y(t - T_0) & \text{if } t \in [T_0, T], \end{cases}$$

we can prove that z is the unique function which satisfies Theorem 2.1.

Remark 2.1. In Proposition 2.1, if we consider in $W \times L^2(0, T_0; W)$ the norm of $H \times L^2(0, T_0; H)$, the linear mapping $(z_0, v_0) \mapsto (x, x')$ is not continuous.

In fact let $x_\nu(t)$ be defined by:

$$x_\nu(t) = \frac{1}{\lambda_\nu} \left\{ \exp \left(\lambda_\nu \int_0^t m_0(s) ds \right) - 1 \right\} w_\nu, \quad t \in [0, T_0].$$

Then, for each $\nu = 1, 2, \dots$, x_ν satisfies

$$\begin{aligned} x'_\nu(t) - m_0(t)Ax_\nu &= m_0(t)w_\nu \\ x_\nu(0) &= 0 \end{aligned}$$

and

$$\int_0^{T_0} |m_0(t)w_\nu|_\Omega^2 dt \leq T_0 |m_0(0)|^2.$$

But $\lim_{\nu \rightarrow +\infty} \|Ax_\nu\|_\infty = +\infty$.

3. Optimal control problems. In this section the function $m(t)$ is that defined by the conditions (2.1) and we suppose that it is $C^\infty(0, T)$ instead of (i).

Optimal control for system (1.3). Let \mathcal{U}_{ad} be a closed convex subset of $L^2(Q)$ with nonempty interior. We also assume that the convex subset K has nonempty interior.

Then by Theorem 2.1, it follows that $X_{\text{ad}} = \{(v, z) \in \mathcal{U}_{\text{ad}} \times L^2(Q) : (v, z) \text{ satisfies (1.3)}\}$ is a nonempty closed convex subset of $L^2(Q) \times L^2(Q)$. Therefore it follows by [1] that the problem

$$(3.1) \quad \inf \{J(v, z) : (v, z) \in X_{\text{ad}}\}$$

has a unique solution $(u, y) \in X_{\text{ad}}$, where $J(v, z)$ is defined by (1.4).

THEOREM 3.1. *If \mathcal{U}_{ad} and K have nonempty interiors, then the optimal couple $(u, y) \in X_{\text{ad}}$ is characterized by the set (u, y, p) , the solution of the following system:*

$$(3.2) \quad \begin{aligned} \frac{\partial y}{\partial t} + m(t) \Delta y &= u \quad \text{in } Q, \\ -\frac{\partial p}{\partial t} + m(t) \Delta p &= y - z_d \quad \text{in } Q; \end{aligned}$$

$$(3.3) \quad \begin{aligned} y &= 0, \quad p = 0 \quad \text{on } \Sigma, \\ p(x, T) &= 0 \quad \text{in } \Omega, \\ y(0) &\in K, \quad p(0) \in H_0^1(\Omega); \end{aligned}$$

$$(3.4) \quad \begin{aligned} \langle k - y(0), p(0) \rangle_{H^{-1}H_0^1} &\geq 0 \quad \forall k \in K, \\ (p + Nu|v - u)_Q &\geq 0 \quad \forall v \in \mathcal{U}_{\text{ad}}. \end{aligned}$$

Remark 3.1. We consider the inner product in $H^{-1}(\Omega)$ defined by $(q|k)_{H^{-1}} = (\Lambda^{-1}q|\Lambda^{-1}k)_{H_0^1}$, where $\Lambda: H_0^1(\Omega) \rightarrow H^{-1}(\Omega)$ is the canonical isomorphism.

Moreover we observe that if p and q belong to $H^{-1}(\Omega)$ and $\langle p, \psi \rangle_{H^{-1}H_0^1} = (q|\psi)_{H^{-1}}$, $\forall \psi \in \mathcal{D}(\Omega)$, then $p \in H_0^1(\Omega)$ and $p = \Lambda^{-1}q$.

Remark 3.2. If $\mathcal{U}_{\text{ad}} = L^2(Q)$ and $K = H^{-1}(\Omega)$, then $(3.4)_1$ and $(3.4)_2$ are similar to

$$(3.5) \quad p(0) = 0, \quad p + Nu = 0.$$

Remark 3.3. If $\mathcal{U}_{\text{ad}} = \{v \in L^2(Q) : \|v - v_0\| \leq r\}$ then (cf. Lions [3]) $(3.4)_2$ is similar to

$$u = v_0 - \frac{p + Nv_0}{\|p + Nv_0\|_Q} r.$$

Proof of Theorem 3.1. Let Z be the set defined by:

$$(3.6) \quad Z = \left\{ z \in L^2(Q) : \frac{\partial z}{\partial t} + m(t) \Delta z \in L^2(Q), z = 0 \text{ on } \Sigma \right\}$$

and for each $\varepsilon > 0$ we define

$$J_\varepsilon(v, z, k) = J(v, z) + \frac{1}{\varepsilon} \left\| \frac{\partial z}{\partial t} + m(t) \Delta z - v \right\|_Q^2 + \frac{1}{\varepsilon} \|z(0) - k\|_{H^{-1}}^2$$

where $(v, z, k) \in \mathcal{U}_{\text{ad}} \times Z \times K$.

We can prove that there exists $(u_\varepsilon, y_\varepsilon, k_\varepsilon)$ belonging to $\mathcal{U}_{\text{ad}} \times Z \times K$, which is a unique solution of the penalized problem:

$$J_\varepsilon(u_\varepsilon, y_\varepsilon, k_\varepsilon) = \inf \{J_\varepsilon(v, z, k) : (v, z, k) \in \mathcal{U}_{\text{ad}} \times Z \times K\}.$$

Moreover, $J_\varepsilon(u_\varepsilon, y_\varepsilon, k_\varepsilon) \leq J_\varepsilon(u, y, y(0)) = J(u, y)$ for all $\varepsilon > 0$; hence there is $c_0 > 0$ such that

$$(3.7) \quad |y_\varepsilon|_Q \leq c_0, \quad |u_\varepsilon|_Q \leq c_0 \quad \forall \varepsilon > 0,$$

$$(3.8) \quad \left\| \frac{\partial y_\varepsilon}{\partial t} + m(t) \Delta y_\varepsilon - u_\varepsilon \right\|_Q \leq \sqrt{\varepsilon} c_0, \quad \|k_\varepsilon - y_\varepsilon(0)\|_{H^{-1}} \leq \sqrt{\varepsilon} c_0 \quad \forall \varepsilon > 0.$$

Therefore, we can prove that

$$\begin{aligned}(u_\varepsilon, y_\varepsilon) &\rightarrow (u, y) \quad \text{strong in } L^2(Q) \times L^2(Q), \\ \lim_{\varepsilon \rightarrow 0^+} k_\varepsilon &= y(0) \quad \text{strong in } H^{-1}(\Omega), \\ \lim_{\varepsilon \rightarrow 0^+} J_\varepsilon(u_\varepsilon, y_\varepsilon, k_\varepsilon) &= J(u, y).\end{aligned}$$

On the other hand, since

$$J'_\varepsilon(u_\varepsilon, y_\varepsilon, k_\varepsilon) \cdot (v - u_\varepsilon, z - y_\varepsilon, k - k_\varepsilon) \geq 0, \quad (v, z, k) \in \mathcal{U}_{\text{ad}} \times Z \times K,$$

we obtain:

$$(3.9) \quad (y_\varepsilon - z_d | z)_Q = \left(p_\varepsilon \left| \frac{\partial z}{\partial t} + m(t) \Delta z \right|_Q + (q_\varepsilon | z(0))_{H^{-1}}, \quad z \in Z,$$

$$(3.10) \quad (p_\varepsilon + Nu_\varepsilon | v - u_\varepsilon)_Q \geq 0 \quad \forall v \in \mathcal{U}_{\text{ad}},$$

$$(3.11) \quad (q_\varepsilon | k - k_\varepsilon)_{H^{-1}} \geq 0 \quad \forall k \in K$$

where $p_\varepsilon = -1/\varepsilon \{ \partial y_\varepsilon / \partial t + m(t) \Delta y_\varepsilon - u_\varepsilon \}$ and $q_\varepsilon = -1/\varepsilon \{ y_\varepsilon(0) - k_\varepsilon \}$.

Now, since \mathcal{U}_{ad} and K have nonempty interiors there are $r > 0, v_0 \in \mathcal{U}_{\text{ad}} \cap L^2(0, T; W)$ and $k_0 \in K \cap W$ such that

$$S_r(v_0) = \{v \in L^2(Q) : |v - v_0|_Q \leq r\} \subset \mathcal{U}_{\text{ad}},$$

$$S_r(k_0) = \{k \in H^{-1}(\Omega) : \|k - k_0\|_{H^{-1}} \leq r\} \subset K.$$

Moreover, there is $z_0 \in L^2(Q)$ such that $(v_0, z_0) \in X_{\text{ad}}$ (cf. Theorem 2.1).

Using (3.9), we obtain:

$$(y_\varepsilon - z_d | y_\varepsilon - z_0)_Q + \varepsilon |p_\varepsilon|_Q^2 + \varepsilon \|q_\varepsilon\|_{H^{-1}}^2 = (p_\varepsilon | u_\varepsilon - v_0)_Q + (q_\varepsilon | k_\varepsilon - k_0)_{H^{-1}}.$$

Now, adding $(Nu_\varepsilon | u_\varepsilon - v_0)_Q$ to both sides of the above expression, we have by (3.7) and (3.8)

$$|(Nu_\varepsilon + p_\varepsilon | u_\varepsilon - v_0)_Q + (q_\varepsilon | k_\varepsilon - k_0)_{H^{-1}}| \leq C_1 \quad \forall \varepsilon > 0;$$

hence, by (3.10) and (3.11) we obtain:

$$(3.12) \quad (p_\varepsilon + Nu_\varepsilon | v - v_0)_Q + (q_\varepsilon | k - k_0)_{H^{-1}} \geq -C_1 \quad \forall (v, k) \in \mathcal{U}_{\text{ad}} \times K.$$

On the other hand, if $w_\varepsilon = p_\varepsilon + Nu_\varepsilon$ and $w_\varepsilon \neq 0$ (if $w_\varepsilon = 0$ then p_ε is a bounded family) then $v = v_0 - rw_\varepsilon / |w_\varepsilon|_Q \in \mathcal{U}_{\text{ad}}$ and $k = k_0 - rq_\varepsilon / |q_\varepsilon|_{H^{-1}} \in K$.

Hence, replacing in (3.12) we have $C > 0$ such that:

$$|p_\varepsilon|_Q \leq C, \quad \|q_\varepsilon\|_{H^{-1}(\Omega)} \leq C \quad \forall \varepsilon > 0.$$

Therefore, there are p in $L^2(Q)$, q in $H^{-1}(\Omega)$ and subsequences also denoted by $\{p_\varepsilon\}$ and $\{q_\varepsilon\}$ such that

$$p_\varepsilon \rightarrow p \quad \text{weak in } L^2(Q),$$

$$q_\varepsilon \rightarrow q \quad \text{weak in } H^{-1}(\Omega).$$

Passing to the limit in (3.9) and (3.11), we obtain:

$$(3.13) \quad (y - z_d | z)_Q = \left(p \left| \frac{\partial z}{\partial t} + m(t) \Delta z \right|_Q + (q | z(0))_{H^{-1}} \quad \forall z \in Z,$$

$$(3.14) \quad (k - y(0) | q)_{H^{-1}} \geq 0 \quad \forall k \in K.$$

From (3.13) we have (3.2)₂, (3.3)₁ and (3.3)₂; moreover we also have that $\langle p(0), \psi \rangle_{H^{-1}H_0^1} = (q|\psi)_{H^{-1}}$, $\psi \in \mathcal{D}(\Omega)$. Hence by Remark 3.1 and by (3.14) we obtain (3.3)₃ and (3.4)₁.

Finally passing to the limit in (3.10), we obtain (3.4)₂.

Remark 3.4. If $K = \{0\}$, Theorem 3.1 is the same, except for (3.3)₃ and (3.4)₁ which are replaced by $y(0) = 0$.

Optimal control for system (1.5). Let \mathcal{U}_{ad} be a closed convex subset of $H^{-1}(\Omega)$ with nonempty interior; we also consider $f \in L^2(0, T; W) \subset L^2(Q)$ fixed.

Then, by Theorem 2.1 it follows that $X_{\text{ad}} = \{(v, z) \in \mathcal{U}_{\text{ad}} \times L^2(Q) : (v, z) \text{ satisfies (1.5)}\}$ is a nonempty closed convex subset of $H^{-1}(\Omega) \times L^2(Q)$. Therefore, it follows by Lions [1] that the problem

$$(3.15) \quad \inf \{J(v, z) : (v, z) \in X_{\text{ad}}\}$$

has a unique solution $(u, y) \in X_{\text{ad}}$ where $J(v, z)$ is defined by (1.6).

THEOREM 3.2. *If \mathcal{U}_{ad} has a nonempty interior, then the optimal couple (u, y) is characterized by the solution (u, y, p) of the following system:*

$$(3.16) \quad \begin{aligned} \frac{\partial y}{\partial t} + m(t) \Delta y &= f \quad \text{in } Q, \\ -\frac{\partial p}{\partial t} + m(t) \Delta p &= y - z_d \quad \text{in } Q, \end{aligned}$$

$$(3.17) \quad \begin{aligned} y &= p = 0 \quad \text{on } \Sigma, \\ p(x, T) &= 0 \quad \text{in } \Omega, \\ y(0) &= u, \quad p(0) \in H_0^1(\Omega), \end{aligned}$$

$$(3.18) \quad (\Lambda p(0) + Nu | v - u)_{H^{-1}} \geq 0 \quad \forall v \in \mathcal{U}_{\text{ad}}.$$

Remark 3.5. (i) If $\mathcal{U}_{\text{ad}} = H^{-1}(\Omega)$ then (3.18) is similar to

$$Nu + \Lambda p(0) = 0.$$

(ii) If $\mathcal{U}_{\text{ad}} = \{v \in H^{-1}(\Omega) : \|v - v_0\|_{H^{-1}} \leq r\}$ then

$$u = v_0 - \frac{\Lambda p(0) + Nv_0}{\|\Lambda p(0) + Nv_0\|_{H^{-1}}} r \quad (\text{cf. Lions [3]}).$$

Proof of Theorem 3.2. Let Z be the set defined by (3.6) and for each $\varepsilon > 0$ we define

$$J_\varepsilon(v, z) = J(v, z) + \frac{1}{\varepsilon} \left| \frac{\partial z}{\partial t} + m(t) \Delta z - f \right|_Q^2 + \frac{1}{\varepsilon} \|z(0) - v\|_{H^{-1}}^2$$

where $(v, z) \in \mathcal{U}_{\text{ad}} \times Z$.

We can prove that there exists $(u_\varepsilon, y_\varepsilon)$ in $\mathcal{U}_{\text{ad}} \times Z$ which is the unique solution of the penalized problem:

$$J_\varepsilon(u_\varepsilon, y_\varepsilon) = \inf \{J_\varepsilon(v, z) : (v, z) \in \mathcal{U}_{\text{ad}} \times Z\}.$$

Moreover, $J_\varepsilon(u_\varepsilon, y_\varepsilon) \leq J_\varepsilon(u, y) = J(u, y)$, for all $\varepsilon > 0$; hence there is $c_0 > 0$ such that

$$(3.19) \quad |y_\varepsilon|_Q \leq c_0, \quad \|u_\varepsilon\|_{H^{-1}} \leq c_0 \quad \forall \varepsilon > 0$$

$$(3.20) \quad \left| \frac{\partial y_\varepsilon}{\partial t} + m(t) \Delta y_\varepsilon - f \right|_Q \leq \sqrt{\varepsilon} c_0, \quad \|y_\varepsilon(0) - u_\varepsilon\|_{H^{-1}} \leq \sqrt{\varepsilon} c_0.$$

Therefore, we can prove that

$$(u_\varepsilon, y_\varepsilon) \rightarrow (u, y) \text{ strong in } H^{-1}(\Omega) \times L^2(Q),$$

$$\lim_{\varepsilon \rightarrow 0^+} J_\varepsilon(u_\varepsilon, y_\varepsilon) = J(u, y).$$

On the other hand, since

$$J'_\varepsilon(u_\varepsilon, y_\varepsilon) \cdot (v - u_\varepsilon, z - y_\varepsilon) \geq 0 \quad \forall (v, z) \in \mathcal{U}_{\text{ad}} \times Z,$$

we obtain:

$$(3.21) \quad (y_\varepsilon - z_d | z)_Q = \left(p_\varepsilon \left| \frac{\partial z}{\partial t} + m(t) \Delta z \right|_Q + (q_\varepsilon | z(0))_{H^{-1}} \right) \quad \forall z \in Z,$$

$$(3.22) \quad (q_\varepsilon + Nu_\varepsilon | v - u_\varepsilon)_{H^{-1}} \geq 0 \quad \forall v \in \mathcal{U}_{\text{ad}}$$

where

$$p_\varepsilon = -\frac{1}{\varepsilon} \left\{ \frac{\partial y_\varepsilon}{\partial t} + m(t) \Delta y_\varepsilon - f \right\} \quad \text{and} \quad q_\varepsilon = -\frac{1}{\varepsilon} \{ y_\varepsilon(0) - u_\varepsilon \}.$$

Now, since \mathcal{U}_{ad} has a nonempty interior, then there are $r > 0$, and $v_0 \in \mathcal{U}_{\text{ad}} \cap W$ such that

$$S_r(v_0) = \{v \in H^{-1}(\Omega) : \|v - v_0\|_{H^{-1}} \leq 0\} \subset \mathcal{U}_{\text{ad}}.$$

Moreover there is $z_0 \in L^2(Q)$ such that $(v_0, z_0) \in X_{\text{ad}}$ (cf. Theorem 2.1).

Using (3.21), we obtain:

$$(y_\varepsilon - z_d | y_\varepsilon - z_0)_Q + \varepsilon \|p_\varepsilon\|_Q^2 + \varepsilon \|q_\varepsilon\|_{H^{-1}}^2 = (q_\varepsilon | u_\varepsilon - v_0)_{H^{-1}}.$$

Adding $(Nu_\varepsilon | u_\varepsilon - v_0)_{H^{-1}}$ to both sides of the above expression, we have by (3.19) and (3.20):

$$|(q_\varepsilon + Nu_\varepsilon | u_\varepsilon - v_0)_{H^{-1}}| \leq C_1 \quad \forall \varepsilon > 0;$$

hence, by (3.22), we obtain

$$(3.23) \quad (q_\varepsilon + Nu_\varepsilon | v - v_0)_{H^{-1}} \geq -C_1 \quad \forall v \in \mathcal{U}_{\text{ad}}.$$

Since

$$v = v_0 - r \frac{Nu_\varepsilon + q_\varepsilon}{\|Nu_\varepsilon + q_\varepsilon\|_{H^{-1}}} \in \mathcal{U}_{\text{ad}}$$

we obtain by (3.23) $C > 0$ such that

$$(3.24) \quad \|q_\varepsilon\|_{H^{-1}} \leq C \quad \forall \varepsilon > 0.$$

Estimates for $\{p_\varepsilon\}$. By (3.21) and Remark 3.1 we obtain:

$$-\frac{\partial p_\varepsilon}{\partial t} + m(t) \Delta p_\varepsilon = y_\varepsilon - z_d \quad \text{in } \mathcal{D}'(Q),$$

$$p_\varepsilon = 0 \quad \text{on } \Sigma,$$

$$p_\varepsilon(T) = 0 \quad \text{in } \Omega,$$

$$p_\varepsilon(0) = \Lambda^{-1} q_\varepsilon \quad (\text{hence } p_\varepsilon(0) \in H_0^1(\Omega)).$$

We consider the interval $[0, T_0 - \delta]$ in which $m(t) > 0$; then (cf. Lions and Magenes [5]) p_ε belongs to $L^2(0, T_0 - \delta; H_0^1(\Omega))$, p'_ε belongs to $L^2(0, T_0 - \delta; L^2(\Omega))$. Moreover,

$$\frac{1}{2} \frac{d}{dt} \|p_\varepsilon(t)\|_\Omega^2 + m(t) \|p_\varepsilon(t)\|_{H_0^1} = (z_d - y_\varepsilon | p_\varepsilon)_Q, \quad 0 < t < T_0 - \delta;$$

hence by (3.19) and (3.24) there is $C > 0$ such that

$$(3.25) \quad \|p_\varepsilon\|_{L^2(0, T_0; L^2(\Omega))} \leq C \quad \forall \varepsilon > 0.$$

In the same way, if we consider the interval $[T_0 + \delta, T]$, since $m(t) < 0$, $T_0 + \delta \leq t \leq T$, and $p_\varepsilon(T) = 0$, then there exists $C > 0$ such that

$$(3.26) \quad \|p_\varepsilon\|_{L^2(T_0, T; L^2(\Omega))} \leq C \quad \forall \varepsilon > 0.$$

Therefore, by (3.24), (3.25) and (3.26), there are p in $L^2(Q)$, q in $H^{-1}(\Omega)$ and subsequences also denoted by $\{p_\varepsilon\}$ and $\{q_\varepsilon\}$ such that

$$\begin{aligned} p_\varepsilon &\rightarrow p \quad \text{weak in } L^2(Q), \\ q_\varepsilon &\rightarrow q \quad \text{weak in } H^{-1}(\Omega). \end{aligned}$$

Passing to the limit in (3.21) and (3.22), we have

$$(3.27) \quad (y - z_d | z)_Q = \left(p \left| \frac{\partial z}{\partial t} + m(t) \Delta z \right|_Q + (q | z(0))_{H^{-1}} \right) \quad \forall z \in Z,$$

$$(3.28) \quad (q + Nu | v - u)_{H^{-1}} \geq 0 \quad \forall v \in \mathcal{U}_{ad}.$$

By (3.27) we have (3.16)₂, (3.17)₁ and (3.17)₂; by Remark 3.1 and (3.28) we have (3.17)₃ and (3.18).

Acknowledgment. We wish to thank Professor L. A. Medeiros for his comments and suggestions.

INVARIANCE OF THE REACHABLE SET UNDER NONLINEAR PERTURBATIONS*

THOMAS I. SEIDMAN†

Abstract. For the abstract controlled Volterra equation

$$(*) \quad x(t) = \bar{x}(t) + \int_0^t \Psi(t, s) [\phi(s, x(s)) + \mathbf{B}(s)v(s)] ds$$

on $[0, T]$, we consider the reachable set $\mathcal{K}_\phi := \{x(T): (*) \text{ for some } v \in \mathcal{V}\}$. Viewing $\phi(\cdot, \cdot)$ as a nonlinear perturbation of an otherwise linear control problem, conditions are obtained under which $\mathcal{K}_\phi = \mathcal{K}_0$ for a suitable class \mathcal{F} of such nonlinear perturbations ϕ whenever the linear problem is known to have a reachable set invariant under affine perturbations: $\phi(\cdot, \cdot) = g \in \mathcal{G}$. The results generalize those obtained by Naito [7] for control of the heat equation.

Key words. reachable, nonlinear, perturbation, control system, semigroup, fixed point

AMS(MOS) subject classifications. 93B05, 93C10, 93C25

1. Introduction. We consider a linear control system governed by an equation of the form

$$(1.1) \quad \dot{x} + \mathbf{A}x = \bar{f} + \mathbf{B}v, \quad x(0) = 0.$$

Here $x(\cdot)$ is to take values in a Banach space \mathcal{X} and v is \mathcal{V} -valued with, say, $\mathbf{B}: \mathcal{V} \rightarrow \mathcal{X}$. It is now standard that such abstract ODEs can be used to model distributed parameter systems corresponding to partial differential equations (e.g. wave and diffusion equations) and to equations with delay, etc. We do not require that \mathbf{A}, \mathbf{B} be independent of t so the “variation of parameters” formulation leads to an integral equation of the form

$$(1.2) \quad x(t) = \int_0^t \Psi(t, s) [\bar{f}(s) + \mathbf{B}(s)v(s)] ds + \Psi(t, 0)x_0,$$

involving the *transition operators* (impulse response function)

$$(1.3) \quad \Psi(t, s): \mathcal{X} \rightarrow \mathcal{X} \quad \text{for } 0 \leq s \leq t \leq T.$$

(Here we have arbitrarily fixed the *terminal time* T . Note that in certain circumstances one knows [10] that the reachable set is independent of T .) Without further reference (for awhile) to the abstract ODE (1.1) except for motivation, we take (1.2)—with suitable hypotheses regarding the family of operators in (1.3)—as defining the system. In this context $x(\cdot)$ is referred to as a *mild solution* of (1.1). The theory, especially for the autonomous case $\{\Psi(t, s) = \Psi_0(t - s)\} = C_0$ semigroup on \mathcal{X} , has been extensively treated; cf., e.g., [5] and references there.

As v ranges over a space \mathcal{V} of *admissible control functions*, we denote the corresponding solutions of (1.2) by $x_0(\cdot; v)$. The *reachable set* is then

$$(1.4) \quad \mathcal{K}_0 := \{x_0(T; v): v \in \mathcal{V}\}.$$

In writing (1.4) we have suppressed explicit indication of the dependence of \mathcal{K}_0 on the terminal time T and on the operators Ψ, \mathbf{B} . More to the point is that (1.4) does

* Received by the editors January 13, 1985; accepted for publication (in revised form) May 27, 1986. This work was supported in part by Air Force Office of Scientific Research grant AFOSR-82-0271.

† Department of Mathematics, University of Maryland Baltimore County, Catonsville, Maryland 21228.

not indicate any dependence of \mathcal{H}_0 on the (fixed) function \bar{f} appearing in (1.1), (1.2) since our present concern is with the effect of perturbing (1.1), (1.2) by replacing \bar{f} with $f = \bar{f} + g$. This will be an affine perturbation of the problem if g is a fixed function—say, drawn from a function space \mathfrak{Z} —but becomes more interesting if we consider nonlinear perturbations of the form

$$(1.5) \quad \begin{aligned} g(t) &:= \phi(t, x(t)), \\ f &= \bar{f} + g = \bar{f} + \phi(\cdot, x) \end{aligned}$$

so that (1.2) is now an integral equation of second kind:

$$(1.6) \quad x(t) = \bar{x}(t) + \int_0^t \Psi(t, s) [\phi(s, x(s)) + \mathbf{B}(s)v(s)] ds$$

where $\bar{x}(\cdot)$ is the (fixed) solution of (1.2) with $v = 0$.

We now take (1.6) as defining the dynamics under suitable conditions to ensure the existence of solutions $x = x_\phi(\cdot; v)$ of (1.6) for $v \in \mathfrak{V}$. The principal result of this paper is that the reachable set

$$(1.7) \quad \mathcal{H}_\phi := \{x_\phi(T; v) : v \in \mathfrak{V}\}$$

is invariant: $\mathcal{H}_\phi = \mathcal{H}_0$ for ϕ in a suitable class \mathfrak{F} of nonlinear perturbations, provided $\Psi, \mathbf{B}, \mathfrak{V}$ are such that the reachable set is known a priori to be invariant under affine perturbations $\phi = g \in \mathfrak{Z}$, already a fairly strong controllability hypothesis.

It is convenient at this point to introduce two relevant mappings, one linear and one nonlinear. We first define the linear mapping

$$(1.8) \quad \mathbf{T} : g \mapsto \int_0^T \Psi(T, s)g(s) ds$$

so that for the affine case one has

$$(1.9) \quad x_g(T; v) := \bar{x}(T) + \mathbf{T}(g + \mathbf{B}v).$$

(Note that, hopefully without introducing confusion, we have continued to use the letter \mathbf{B} also to denote the multiplication operator: $v(\cdot) \mapsto \mathbf{B}(\cdot)v(\cdot)$ acting on $v \in \mathfrak{V}$.) Next, supposing we have a unique solution $x_\phi(\cdot; v)$ of (1.6) for (every) $v \in \mathfrak{V}$, we define the *nonlinear* mappings Φ, \mathbf{G} by

$$(1.10) \quad \begin{aligned} \Phi : x &\mapsto \phi(\cdot, x(\cdot)), \\ \mathbf{G} = \mathbf{G}_\phi : v &\mapsto G_\phi(\cdot; v) := \phi(\cdot, x_\phi(\cdot; v)) = \Phi x_\phi. \end{aligned}$$

Inserting this in (1.6) gives

$$x_\phi(t; v) = \bar{x}(t) + \int_0^t \Psi(t, s) [G_\phi(s; v) + \mathbf{B}(s)v(s)] ds$$

so

$$(1.11) \quad x_\phi(T; v) = \bar{x}(T) + \mathbf{T}[\mathbf{G}_\phi v + \mathbf{B}v].$$

Let us consider now the controllability hypothesis that the reachable set is invariant under affine perturbations by $g \in \mathfrak{Z}$ —i.e., that $\mathcal{H}_g = \mathcal{H}_0$ for $g \in \mathfrak{Z}$. To have $\xi \in \mathcal{H}_0$ means that $\xi = \bar{x}(T) + \mathbf{T}\mathbf{B}v_0$ for some $v_0 \in \mathfrak{V}$. Comparing this with (1.9), we see that to have $\xi \in \mathcal{H}_g$ we must find $v \in \mathfrak{V}$ such that $\xi = \bar{x}(T) + \mathbf{T}g + \mathbf{T}\mathbf{B}v$ so, taking the difference and using the linearity of \mathbf{T}, \mathbf{B} , one must have

$$(1.12) \quad \mathbf{T}(g + \mathbf{B}w) = 0$$

for some $w = (v - v_0) \in \mathfrak{B}$. We impose the hypothesis

(H₀). (i) $\mathbf{T}: \mathfrak{B} \rightarrow \mathcal{X}$ and $\mathbf{TB}: \mathfrak{B} \rightarrow \mathcal{X}$ are continuous,

(ii) For each $g \in \mathfrak{B}$ there exists $w \in \mathfrak{B}$ such that $\mathbf{TB}w = -\mathbf{T}g$, i.e., (1.12).

Clearly this implies that $\mathcal{K}_g \supset \mathcal{K}_0$ for each $g \in \mathfrak{B}$ —and also conversely, since $\xi \in \mathcal{K}_g$ leads to the same condition (1.12) to have $\xi \in \mathcal{K}_0$. Hence (H₀)(ii) is equivalent to invariance of the reachable set under affine perturbations from \mathfrak{B} :

(H'₀). \mathcal{K}_g is independent of g for $g \in \mathfrak{B}$.

This condition (H₀) does not involve any nonlinearity but only the relation between \mathfrak{B} and $\mathbf{B}\mathfrak{B}$, given Ψ which defined \mathbf{T} . Indeed, in view of the linearity of \mathbf{T} we may equivalently write (H₀)(ii) in the form

(H''₀). $\mathbf{T}(\mathfrak{B}) \subset \mathbf{T}(\mathbf{B}\mathfrak{B}) = \mathcal{K}_0$.

Suppose now, that $\mathfrak{B}, \mathfrak{B}$ are given such that (H₀) holds. We wish to obtain a class \mathfrak{F} of nonlinearities such that

(H₁). $\mathbf{G} = \mathbf{G}_\phi: \mathfrak{B} \rightarrow \mathfrak{B}$ for each $\phi \in \mathfrak{F}$,

i.e., for each $\phi \in \mathfrak{F}$ we wish to know that the integral equation (1.6) has a solution $x_\phi(\cdot; v)$ for each $v \in \mathfrak{B}$ and that the substitution (1.10) then gives a function $g := \mathbf{G}_\phi(v)$ which is in \mathfrak{B} . Our object is an invariance result generalizing (H'₀): that

(*) \mathcal{K}_ϕ is independent of ϕ for $\phi \in \mathfrak{F}$

or, equivalently since we assume $0 \in \mathfrak{F}$, that $\mathcal{K}_\phi = \mathcal{K}_0$ for $\phi \in \mathfrak{F}$. Note that if we fix $\phi \in \mathfrak{F}$ and $\xi \in \mathcal{K}_0$ as earlier, then (H₁), (H₀) give a composed map¹

$$(1.13) \quad \tilde{w} \in \mathfrak{B} \mapsto g := \mathbf{G}_\phi(v_0 + \tilde{w}) \in \mathfrak{B} \mapsto w \in \mathfrak{B} \quad \text{giving (1.12).}$$

Existence of a fixpoint for the map (1.13) would show $\xi \in \mathcal{K}_\phi$. This, for each $\xi \in \mathcal{K}_0$, would show $\mathcal{K}_\phi \supset \mathcal{K}_0$; the converse, that $\mathcal{K}_\phi \subset \mathcal{K}_0$, follows easily from (H₀), (H₁). Our strategy, then, is to impose suitable hypotheses under which (1.13) can be shown to admit applicability of the Schauder Fixpoint theorem.

This paper is very much in the line of the “fixpoint theory approach to nonlinear controllability” for which see, e.g., [3] and the references therein. While most work along these lines has been intended to show (approximate) controllability to the entire state space, the considerations here have been stimulated by the original results [7] of Naito, introducing the problem of invariance of the exactly reachable set \mathcal{K}_0 under various perturbations. In [7], Naito introduced the hypothesis (H₀) in the context of a parabolic equation such as

$$(1.14) \quad \begin{aligned} \dot{x} &= \Delta x + \phi + \mathbf{B}v \quad \text{on } \mathcal{Q} := (0, T) \times \Omega, \Omega \subset \mathbb{R}^m, \\ x &= 0 \quad \text{on } \Sigma := (0, T) \times \partial\Omega, \end{aligned}$$

showing invariance of the reachable set for $\phi: \mathbb{R} \rightarrow \mathbb{R}$ uniformly bounded and uniformly Lipschitzian in (the pointwise values of) x on \mathcal{Q} . His argument immediately applies to (1.1) with $-\mathbf{A}$ generating a C_0 semigroup $\Psi(t-s)$ of compact operators on \mathcal{X} and autonomous bounded $\mathbf{B}: \mathcal{V} \rightarrow \mathcal{X}$ so also $\mathbf{B}: \mathfrak{B} := L^2([0, T] \rightarrow \mathcal{V}) \rightarrow L^2([0, T] \rightarrow \mathcal{X}) =: \mathfrak{B}$. The hypothesis (H₀) is then taken as a condition on \mathbf{B} .

Our objective here, accepting the formulation in terms of the controllability hypothesis (H₀), is to generalize the abstract setting and to weaken the hypotheses of [7]. In particular, we seek results such that

¹ At this point, of course, (1.13) is not a well-determined map—even accepting (H₀), (H₁)—since (1.12) does not, in general, uniquely determine w . However Lemma 2 will resolve this by asserting the existence of a continuous operator $\mathbf{C}: g \mapsto w: \mathfrak{B} \rightarrow \mathfrak{B}$.

A, B need not be autonomous (so the transition operator $\Psi(t, s)$ need not be a semigroup);

$\Psi(t, s)$ need not be compact: some compactness is needed for the general approach but we explore alternate ways of obtaining this which may, e.g., permit applications to hyperbolic equations;

B need not be bounded (so we may consider, e.g., boundary control);

The nonlinearity ϕ need not be bounded in range and may not be Lipschitzian (or may involve a Lipschitz condition with respect to a different norm so, e.g., in (1.14) one might take $\phi = \phi(t, x, \nabla x)$). One might also consider ϕ spatially nonlocal so one could treat

$$(1.15) \quad \phi : [0, T] \times \mathcal{X} \rightarrow \mathcal{Z},$$

with, for example, \mathcal{X}, \mathcal{Z} spaces of functions on Ω and $[\Phi x](t, w) := \phi(t, x(t, \cdot))(\omega)$; see § 5, Remark 3.

A summary of the set of (abstract) results obtained is given by Theorem 3. Some remarks as to possible contexts (in which various hypotheses might be verified) are presented in § 5 although, so far, little can be said about verifiability of (H_0) in the most interesting case: $\mathcal{H}_0 \neq \mathcal{X}$. For the moment, the hope for positive results (of some substantial generality) along these lines is a proposal for continued investigation. Another proposal would be for a comparable investigation of possible invariance of the approximately reachable set \mathcal{H}_0 (closure in \mathcal{X}) with (H_0'') replaced by $T(\mathfrak{J}) \subset \mathcal{H}_0$ and with suitable conditions imposed on the nonlinearity ϕ .

2. Continuity and the control map. Since we are defining a reachable set by evaluating the solution $x(\cdot)$ of (1.2) or (1.6) at $t = T$, we wish to consider as part of the definition of a solution that

$$(2.1) \quad x(\cdot) \in \mathfrak{X} := C([0, T] \rightarrow \mathcal{X})$$

so point evaluation makes sense. We assume directly that $\bar{x} \in \mathfrak{X}$, but must impose conditions on Ψ , **B** and \mathfrak{J} , \mathfrak{V} which ensure \mathcal{X} -continuity in t for the integral. For simplicity we will only consider \mathfrak{J} , \mathfrak{V} of the form:

$$(2.2) \quad \mathfrak{J} := L^p([0, T] \rightarrow \mathcal{Z}), \quad \mathfrak{V} := L^{p'}([0, T] \rightarrow \mathcal{V})$$

for suitable p, p' ($1 < p, p' < \infty$) and separable Banach spaces \mathcal{Z}, \mathcal{V} . (Obviously, for consistency one must take \mathcal{Z} and \mathcal{X} to be spaces of the same kind of objects. For example, one might have $\mathcal{Z} \subset \mathcal{X}$ or, perhaps, have $\mathcal{X} := L^2(\Omega)$ and $\mathcal{Z} = \text{span}\{z_1, \dots, z_n\}$ with each $z_k \in L^1(\Omega)$ for some $\Omega \subset \mathbb{R}^m$; see Remark 3.) We will assume

$$(2.3) \quad \begin{aligned} & \text{(i)} \quad \bar{x} \in \mathfrak{X}, \Psi(\cdot, \cdot), \mathbf{B}(\cdot) \text{ are suitably measurable,} \\ & \text{(ii)} \quad |\Psi(t, s)|_{\mathcal{X} \rightarrow \mathcal{X}} \leq \rho_1(t-s) \quad \text{with } \rho_1 \in L_+^q(0, T) (1/p + 1/q = 1), \\ & \text{(iii)} \quad |\Psi(t, s)\mathbf{B}(s)|_{\mathcal{V} \rightarrow \mathcal{X}} \leq \rho_2(t-s) \quad \text{with } \rho_2 \in L_+^{q'}(0, T) (1/p' + 1/q' = 1), \\ & \text{(iv)} \quad |\Psi(t, s) - \Psi(r, s)|_{\mathcal{X} \rightarrow \mathcal{X}} \leq \varepsilon, \quad |[\Psi(t, s) - \Psi(r, s)]\mathbf{B}(s)|_{\mathcal{V} \rightarrow \mathcal{X}} \leq \varepsilon \end{aligned}$$

for $0 \leq s \leq r - \varepsilon, r < t = r + h \leq T$ with $\varepsilon = \varepsilon(h) \rightarrow 0+$ as $h \rightarrow 0+$.

Under these assumptions we will have the desired continuity.

LEMMA 1. Assume (2.3) and the form (2.2) for $\mathfrak{J}, \mathfrak{V}$. Then the linear operator **S** given by

$$(2.4) \quad [\mathbf{S}g](t) := \int_0^t \Psi(t, s)g(s) ds$$

is well defined and continuous from \mathfrak{J} to \mathfrak{X} . Further, for g in a bounded subset of \mathfrak{J} one has a uniform modulus of continuity (depending only on (2.3) and the bound on $\|g\|_{\mathfrak{J}}$)

for **Sg**. Similarly, **SB** is continuous from \mathfrak{V} to \mathfrak{X} , again with a uniform modulus of continuity (depending only on (2.3) and a bound on $\|v\|_{\mathfrak{V}}$) for **SBv**.

Proof. Setting $y := \mathbf{S}g$ for $g \in \mathfrak{V}$, we have

$$\begin{aligned} |y(t) - y(r)|_{\mathfrak{X}} &\leq \int_{r-\varepsilon}^{r+h} |\Psi(t, s)|_{\mathfrak{X} \rightarrow \mathfrak{X}} |g(s)|_{\mathfrak{X}} ds \\ &\quad + \int_{r-\varepsilon}^r |\Psi(r, s)|_{\mathfrak{X} \rightarrow \mathfrak{X}} |g(s)|_{\mathfrak{X}} ds \\ &\quad + \int_0^{r-\varepsilon} |\Psi(t, s) - \Psi(r, s)|_{\mathfrak{X} \rightarrow \mathfrak{X}} |g(s)|_{\mathfrak{X}} ds \\ &\leq \left[\left(\int_{r-\varepsilon}^{r+h} \rho_1^q \right)^{1/q} + \left(\int_{r-\varepsilon}^r \rho_1^q \right)^{1/q} + \varepsilon(r-\varepsilon)^{1/q} \right] \|g\|_{\mathfrak{V}} \end{aligned}$$

with $\varepsilon = \varepsilon(h)$, ρ_1 as in (2.3). (Note: for $t < \varepsilon(h)$ one replaces $(r-\varepsilon)$ by 0.) Taking $r=0$ and $0 < t = h \leq T$, one obtains

$$\|\mathbf{S}\|_{\mathfrak{V} \rightarrow \mathfrak{X}} \leq \|\rho_1\|_{L^q}.$$

Since $\varepsilon \rightarrow 0$ as $h \rightarrow 0$, one has an estimate for the modulus of continuity as desired. The estimates for **SB**: $\mathfrak{V} \rightarrow \mathfrak{X}$ are essentially the same. \square

Note that **T**, as given by (1.8), is just **S** followed by evaluation at $t = T$ so continuity of **S**: $\mathfrak{V} \rightarrow \mathfrak{X}$ and of **SB**: $\mathfrak{V} \rightarrow \mathfrak{X}$ immediately give continuity of **T**: $\mathfrak{V} \rightarrow \mathfrak{X}$ and of **TB**: $\mathfrak{V} \rightarrow \mathfrak{X}$, i.e., $(H_0)(i)$. With this in hand, we make the following observation.

LEMMA 2. Assume (H_0) . Then there exists a continuous control map **C**: $\mathfrak{V} \rightarrow \mathfrak{V}$ of linear growth

$$(2.5) \quad \mathbf{TBC}g + \mathbf{T}g = 0, \quad \|Cg\|_{\mathfrak{V}} \leq \alpha \|g\|_{\mathfrak{V}} \quad \text{for } g \in \mathfrak{V}$$

for some fixed $\alpha > 0$. (If $\mathcal{N} := \mathcal{N}(\mathbf{TB})$ admits a closed complement in \mathfrak{V} , e.g., if \mathfrak{V} is a Hilbert space, then one may take **C** to be linear.)

Proof. As **TB** is continuous by $(H_0)(i)$, its nullspace \mathcal{N} is closed so we may consider the quotient space $\mathfrak{V}_0 := \mathfrak{V}/\mathcal{N}$. It is standard that **TB** factors through the canonical projection **P**: $\mathfrak{V} \rightarrow \mathfrak{V}_0$ so one has a continuous linear injection **T**₀: $\mathfrak{V}_0 \rightarrow \mathfrak{X}$ with **TB** = **T**₀**P**. In this context $(H_0)(ii)$ gives existence, for each $g \in \mathfrak{V}$, of $\tilde{w} := \mathbf{P}w \in \mathfrak{V}_0$ such that **Tg** = $-\mathbf{TB}w = -\mathbf{T}_0\tilde{w}$ and this \tilde{w} is unique by the injectivity of **T**₀. Thus, there is a well-defined map **C**₀: $\mathfrak{V} \rightarrow \mathfrak{V}_0$: $g \mapsto \tilde{w}$ such that **Tg** + **T**₀**C**₀ $g = 0$; clearly **C**₀ is linear. Introducing the continuous linear operator

$$\mathbf{L}: \mathfrak{V} \times \mathfrak{V}_0 \rightarrow \mathfrak{X}: [g, \tilde{w}] \mapsto (\mathbf{T}g + \mathbf{T}_0\tilde{w}),$$

we see that the closed subspace $\mathcal{N}(\mathbf{L}) \subset \mathfrak{V} \times \mathfrak{V}_0$ is just the graph of **C**₀. The Closed Graph theorem thus gives continuity of **C**₀: $\mathfrak{V} \rightarrow \mathfrak{V}_0$. (If \mathcal{N} admits a complement in \mathfrak{V} , we can identify \mathfrak{V}/\mathcal{N} with this complement—call it $\mathfrak{V}_0 \subset \mathfrak{V}$ —and so take **C** = **C**₀ linear.) At this point, the Michael Selection theorem (cf. [6, Thm. 7.2]) gives a continuous $\Gamma: \mathfrak{V}_0 \rightarrow \mathfrak{V}$ (a right inverse of the open surjection **P**) with $\|\Gamma(w)\|_{\mathfrak{V}} \leq \lambda \|w\|_{\mathfrak{V}_0}$, where $\lambda > 1$ was arbitrary. We take **C**: $\mathfrak{V} \rightarrow \mathfrak{V}$ to be the composition $\Gamma \circ \mathbf{C}_0$: $\mathfrak{V} \rightarrow \mathfrak{V}_0 \rightarrow \mathfrak{V}$ and have (2.5) with $\alpha = \lambda \|\mathbf{C}_0\|$. (Remark: When **C** is permitted to be nonlinear we note that uniform continuity is not asserted and, in particular, (2.5) gives linear growth but not a Lipschitz condition.) \square

3. Nonlinear perturbation. Our next goal is the introduction of a class \mathfrak{F} of nonlinearities for which (H_1) can be verified. Indeed, we will want to impose conditions on $\phi \in \mathfrak{G}$ enabling us also to verify the hypothesis

(H_2) . For each $v \in \mathfrak{V}$ consider the map **W**₀: $w \mapsto \mathbf{G}_\phi(v_0 + w)$; then there is a ball \mathfrak{B} (depending on $v_0 \in \mathfrak{V}$, $\phi \in \mathfrak{F}$, etc.) in \mathfrak{V} which is invariant under **W** := **CW**₀.

Note that we have separated out (H_2) for convenience of exposition but it is only meaningful in the context of (H_0) , (H_1) which, e.g., ensure the continuity of $\mathbf{W}_0: \mathfrak{B} \rightarrow \mathfrak{Z}$ and that \mathbf{C} is defined as in (2.5). The map \mathbf{W} is, of course, as in (1.13); compare footnote 1. We also state one final hypothesis:

(H_3) . The map $\mathbf{W}_0: w \mapsto \mathbf{G}_\phi(v_0 + w)$ is compact from \mathfrak{B} to \mathfrak{Z} for each $v_0 \in \mathfrak{B}$. The hypotheses (H_0) – (H_3) are, of course, to be used for application of the Schauder Fixpoint theorem in proving Theorem 1 below. Following that proof, we consider specific assumptions leading to verification of (H_1) – (H_2) ; discussion of alternative approaches to the compactness in (H_3) is the content of the next section.

THEOREM 1. *Let $\Psi(\cdot, \cdot)$, $\mathbf{B}(\cdot)$, \mathfrak{Z} , \mathfrak{B} , \mathfrak{F} be such that (H_0) – (H_3) hold for each $\phi \in \mathfrak{F}$. Then the reachable set $\mathcal{K}_\phi := \{x_\phi(T; v) : v \in \mathfrak{B}\}$, defined by (1.6), is independent of $\phi \in \mathfrak{F}$, i.e., $\mathcal{K}_\phi = \mathcal{K}_0$.*

Proof. The argument is as indicated in § 1. Given $\phi \in \mathfrak{F}$, for any $\xi \in \mathcal{K}_0$ we have $v_0 \in \mathfrak{B}$ such that $\xi = x_0(T; v_0) = \bar{x}(T) + \mathbf{TB}v_0$. With this ϕ , v_0 we have \mathbf{W}_0 , \mathbf{W} defined and continuous by Lemmas 1 and 2, using (H_0) , (H_1) . By (H_2) , (H_3) , then, the set

$$\mathfrak{B}_* := [\text{closed convex hull of } \mathbf{W}\mathfrak{B}; \mathfrak{B} \text{ as in } (H_2)]$$

is compact, convex, and invariant under \mathbf{W} ; we now redefine \mathbf{W} to be its restriction to \mathfrak{B}_* . The Schauder Fixpoint theorem then applies to give a fixpoint \hat{w} ; set $\hat{v} := v_0 + \hat{w}$, $\hat{x} := x_\phi(\cdot; \hat{v})$, and $\hat{g} := \phi\hat{x} = \mathbf{G}_\phi\hat{v}$. The definition gives

$$\begin{aligned}\hat{x}(T) &= \bar{x}(T) + \mathbf{T}\hat{g} + \mathbf{TB}(v_0 + \hat{w}) \\ &= (\bar{x}(T) + \mathbf{TB}v_0) + (\mathbf{T}\hat{g} + \mathbf{TB}\hat{w}).\end{aligned}$$

Since $\hat{w} = \mathbf{W}\hat{w} = \mathbf{C}\mathbf{G}_\phi(v_0 + \hat{w}) = \mathbf{C}\hat{g}$, the definition of \mathbf{C} gives $\mathbf{T}\hat{g} + \mathbf{TB}\hat{w} = 0$ so $x_\phi(T; \hat{v}) = \hat{x}(T) = \bar{x}(T) + \mathbf{TB}v_0 = \xi$. Thus, $\xi \in \mathcal{K}_0$ implies $\xi \in \mathcal{K}_\phi$ so $\mathcal{K}_0 \subset \mathcal{K}_\phi$. Conversely, for any $\xi \in \mathcal{K}_\phi$ we have $v \in \mathfrak{B}$ for which

$$\xi = x_\phi(T; v) = \bar{x}(T) + \mathbf{T}g + \mathbf{TB}v \quad \text{with } g := \mathbf{G}_\phi v.$$

Now let w_0 correspond to g as in (H_0) , e.g., $w_0 := \mathbf{C}g$. Then $\mathbf{T}g + \mathbf{TB}w_0 = 0$ so, setting $v_0 := v - w_0$, we have

$$\begin{aligned}x_0(T; v_0) &= \bar{x}(T) + \mathbf{TB}v_0 \\ &= (\bar{x}(T) + \mathbf{T}g + \mathbf{TB}v) - (\mathbf{T}g + \mathbf{TB}w_0) \\ &= \xi - 0 = \xi.\end{aligned}$$

Thus, $\xi \in \mathcal{K}_\phi$ implies $\xi \in \mathcal{K}_0$ so $\mathcal{K}_\phi = \mathcal{K}_0$. This, for each $\phi \in \mathfrak{F}$, shows the desired invariance of the reachable set under these quasilinear perturbations. \square

We will devote the remainder of this section to providing a set of conditions on ϕ (i.e. part of the specification of \mathfrak{F}) under which (H_1) , (H_2) can be verified. The next section will then consider possible approaches leading to verification of the compactness assumption of the theorem.

To obtain somewhat greater generality than otherwise, introduce yet another Banach space \mathcal{Y} and consider (1.6) as an integral equation for \mathcal{Y} -valued functions. (Obviously, for consistency \mathcal{X} and \mathcal{Y} must be spaces of the same kind of objects but, perhaps, with different norms. For example, one might consider $\mathcal{X} := L^2(\Omega)$ and $\mathcal{Y} := H^1(\Omega)$ for some region $\Omega \subset \mathbb{R}^m$.)

For each $\phi \in \mathfrak{F}$ we will assume

$$(3.1) \quad \begin{aligned} \phi: [0, T] \times \mathcal{Y} &\rightarrow \mathcal{X} \text{ satisfies Carathéodory conditions and a growth} \\ &\text{condition} \quad |\phi(s, \eta)|_{\mathcal{X}} \leq \alpha(s) + \beta|\eta|_{\mathcal{Y}} \quad (\eta \in \mathcal{Y}) \end{aligned}$$

where \mathcal{X} is as in (2.2) and $\alpha \in L^p_+(0, T)$, $0 \leq r < 1$. With this r we set

$$(3.2) \quad \mathcal{Y} := L^p([0, T] \rightarrow \mathcal{Y})$$

with $\bar{p} := rp$; with no loss of generality we may assume r in (3.1) gives $1 < \bar{p} < p < \infty$. We will use an exponentially weighted norm

$$(3.3) \quad \|y(\cdot)\|_{\mathcal{Y}} := \left[\int_0^T |e^{-\mu t} y(t)|_{\mathcal{Y}}^{\bar{p}} dt \right]^{1/\bar{p}}$$

with the value of the parameter $\mu \geq 0$ to be specified later. By Krasnoselski's theorem (cf., e.g., [2]) one then has

(3.4) $\phi: y \mapsto \phi(\cdot, y(\cdot))$ is continuous from \mathcal{Y} into \mathcal{Z} , taking bounded sets to bounded sets with

$$\|\phi(\cdot, y)\|_{\mathcal{Z}} \leq \|\alpha\|_{L^p} + \beta e^{\mu T} \|y\|_{\mathcal{Y}}^r.$$

We next consider conditions along the lines of (2.3):

- (3.5) (i) $\bar{x} \in \mathcal{X} \cap \mathcal{Y}$,
 (ii) $|\psi(t, s)|_{\mathcal{X} \rightarrow \mathcal{Y}} \leq \bar{\rho}_1(t-s)$ for some $\bar{\rho}_1 \in L_+^{\bar{q}}(0, T)$, where $1/\bar{q} + 1/p \leq 1 + 1/\bar{p}$ (e.g. $\bar{q} = 1$ since $\bar{p} < p$),
 (iii) $|\psi(t, s)\mathbf{B}(s)|_{\mathcal{V} \rightarrow \mathcal{Y}} \leq \rho_2(t-s)$ for some $\rho_2 \in L_+(0, T)$, where $1/\bar{q}' + 1/p' \leq 1 + 1/\bar{p}$

with a Lipschitz condition of the form

$$(3.6) \quad |\psi(t, s)[\phi(s, \eta) - \phi(s, \eta')]|_{\mathcal{Y}} \leq \bar{\rho}_3(t-s)|\eta - \eta'|_{\mathcal{W}} \quad \text{for some } \bar{\rho}_3 \in L_+^1(0, T).$$

THEOREM 2. Assume (H_0) , suppose ϕ satisfies (3.1) giving (3.4), and assume (3.5), (3.6). Then (1.6) has a (unique) solution $x_\phi(\cdot, v) \in \mathcal{X} \cap \mathcal{Y}$ for each $v \in \mathcal{Z}$ and (H_1) , (H_2) hold.

Proof. We choose $\mu \geq 0$ large enough so that

$$(3.7) \quad \|e^{-\mu \tau} \bar{\rho}_3\|_{L^1} =: \theta < 1$$

and use this to define the norm in (3.3). Define a map $F = F_v: y \mapsto F(y, v)$ by the right-hand side of (1.6):

$$(3.8) \quad \begin{aligned} Fy &:= \bar{x} + S\phi y + SBv =: F(y, v), \quad \text{i.e.,} \\ [F_v y](t) &:= \bar{x}(t) + \int_0^t \psi(t, s)[\phi(s, y(s)) + \mathbf{B}(s)v(s)] ds. \end{aligned}$$

Clearly a fixpoint of F_v is a solution of the integral equation (1.6). The form of the hypotheses permits us to use convolution estimates and we recall (cf., e.g., [8, p. 106]) that convolutions $f * g$ satisfy

$$(3.9) \quad \|f * g\|_{L^\pi} \leq C \|f\|_{L^{\pi'}} \|g\|_{L^{\pi''}} \quad (\text{note the fixed support } [0, T])$$

for $1 \leq \pi, \pi', \pi'' < \infty$ and $1/\pi \geq 1/\pi' + 1/\pi'' - 1$.

The estimates which show contractivity of F_v with respect to (3.3) and then estimate the fixpoint $x_\phi(\cdot; v)$ are fairly standard consequences of the hypotheses. We have

$$e^{-\mu t} |[Fy](t)|_{\mathcal{Y}} \leq |e^{-\mu t} \bar{x}(t)|_{\mathcal{Y}} + [\hat{\rho}_1 * \hat{\alpha} + \beta \hat{\rho}_1 * \hat{\eta}' + \hat{\rho}_2 * |v(\cdot)|_{\mathcal{V}}](t)$$

where

$$\begin{aligned} \hat{\rho}_1(\tau) &:= e^{-\mu \tau} \bar{\rho}_1(\tau), & \hat{\rho}_2(\tau) &:= e^{-\mu \tau} \bar{\rho}_2(\tau), \\ \hat{\alpha}(\tau) &:= e^{-\mu \tau} \alpha(\tau), & \hat{\eta}(\tau) &:= |e^{-\mu \tau} y(\tau)|_{\mathcal{Y}}. \end{aligned}$$

Hence

$$\|\mathbf{F}y\|_{\mathcal{Y}} \leq \|\bar{x}\|_{\mathcal{W}} + C\|\rho_1\|_{L^q}(\|\hat{\alpha}\|_{L^p} + \beta\|y\|_{\mathcal{Y}}^r + C\|\hat{\rho}_2\|_{L^q}\|v\|_{\mathcal{X}})$$

so $\mathbf{F}_v: \mathcal{Y} \rightarrow \mathcal{Y}$ and any fixpoint $y = x_\phi(\cdot; v)$ must satisfy

$$(3.10) \quad \|x_\phi(\cdot; v)\|_{\mathcal{Y}} = \mathcal{O}(\|v\|_{\mathcal{X}})$$

since $r < 1$. Using (3.6), (3.7), (3.9) gives

$$(3.11) \quad \|\mathbf{F}(y, v) - \mathbf{F}(y', v')\|_{\mathcal{Y}} \leq \theta\|y - y'\|_{\mathcal{Y}} + c\|v - v'\|_{\mathcal{X}}$$

where c is the L^q -norm of $\hat{\rho}_2$. With $v = v'$ this gives contractivity so $x_\phi(\cdot; v)$ is well-defined in \mathcal{Y} for each $v \in \mathcal{X}$. From (3.4) with $y := x_\phi(\cdot; v)$ we have $\mathbf{G}_\phi v := \phi(\cdot, y) \in \mathcal{Z}$ with

$$(3.12) \quad \|\mathbf{G}_\phi v\|_{\mathcal{Z}} = \mathcal{O}(\|v\|_{\mathcal{X}}^r) \text{ uniformly in } \phi \text{ satisfying (3.4)–(3.6) and, noting } (H_0)(i), \text{ we have } x_\phi(r, v) \in \mathcal{X} \text{ as well. Now } \mathcal{W}_0 \text{ factors as}$$

$$\mathcal{W}_0: w \mapsto x_\phi(\cdot; v_0 + w) =: y \mapsto \phi(\cdot; y): \mathcal{X} \rightarrow \mathcal{Y} \rightarrow \mathcal{Z},$$

with the first map (Lipschitz) continuous by (3.11) and the second map continuous by (3.4). This gives (H_1) . Using Lemma 2 and combining (3.12) with (2.7), we have

$$(3.13) \quad \|\mathbf{W}v\|_{\mathcal{X}} \leq \alpha\|\mathbf{G}_\phi v\|_{\mathcal{Z}} = \mathcal{O}(\|v\|_{\mathcal{X}}^r).$$

Since $r < 1$, this clearly gives (H_2) . \square

Remark 1. We note from Theorems 1 and 2 that the original space \mathcal{X} plays little role except, in terms of \mathcal{X} -continuity just at the terminal time T , to justify the consideration (and boundedness) of the maps \mathbf{T} , \mathbf{TB} in $(H_0)(i)$ so as to permit applicability of Lemma 2.

Let us now write $\hat{\mathbf{S}} = \hat{\mathbf{S}}_\phi$ for the solution map of (1.6) so

$$(3.14) \quad \hat{\mathbf{S}}: v \mapsto x_\phi(\cdot; v): \mathcal{X} \rightarrow \mathcal{Y}.$$

The principal concern of the proof of Theorem 2 was to show that $\hat{\mathbf{S}}_\phi$ is well defined and uniformly Lipschitz continuous for ϕ satisfying (3.4)–(3.6). As noted, \mathbf{W} factors as

$$(3.15) \quad \begin{array}{ccccccc} \mathcal{X} & \longrightarrow & \mathcal{X} & \xrightarrow{\hat{\mathbf{S}}_\phi} & \mathcal{Y} & \xrightarrow{\phi} & \mathcal{Z} \xrightarrow{c} \mathcal{X} \\ & & \downarrow \mathbf{SB} & & & & \downarrow \mathbf{s} \\ & & & & & & \mathcal{X}. \end{array}$$

Other than to validate our original notion of solution for (1.6), one could omit direct reference to $(H_0)(i)$ in the hypotheses for Theorem 2. \square

4. Compactness. Our object, in this section, is to indicate some approaches—i.e., alternative conditions supplementary to those considered in proving Theorems 2 and 3—leading to verification of the compactness hypothesis (H_3) . We will provide three such approaches: the first, using the Arzela–Ascoli theorem, imposes the strongest conditions on ϕ and returns to the interpretation of solutions of (1.6) as continuous \mathcal{X} -valued functions, while the second and third, using the Aubin Compactness theorem [1], return to the differential equation (1.1) with $f = g = \mathbf{G}_\phi(v)$. Each approach, then, limits the generality of the setting of the last section for existence/continuity.

We recall, before proceeding directly with the approaches to showing compactness of the map \mathbf{W}_0 , a compactness argument from [10].

LEMMA 3. *Let $F: \mathcal{Y} \times \mathcal{X} \rightarrow \mathcal{Y}$ (with \mathcal{Y} complete metric) and suppose*

$$(4.1) \quad (i) \quad F \text{ is uniformly contractive on } \mathcal{Y}, \text{ i.e., for some } \theta < 1 \\ d_{\mathcal{Y}}(F(y, w), F(y', w)) \leq \theta d_{\mathcal{Y}}(y, y') \quad (y, y' \in \mathcal{Y}, w \in \mathcal{X});$$

- (ii) For every compact set \mathfrak{A} in \mathfrak{Y} the set $F(\mathfrak{A}, \mathfrak{B}) := \{F(y, w) : y \in \mathfrak{A}, w \in \mathfrak{B}\}$ is precompact in \mathfrak{Y} .

Then the set $\mathcal{F}_{\mathfrak{B}}$ of fixpoints ($\mathcal{F}_{\mathfrak{B}} := \{y \in \mathfrak{Y} : y = F(y, w) \text{ for some } w \in \mathfrak{B}\}$) is precompact in \mathfrak{Y} .

Proof. See [10] for details, but we sketch the argument here. For any choice of $y_0 \in \mathfrak{Y}$, set $\mathfrak{A}_0 := \{y_0\}$ and, recursively, let \mathfrak{A}_{k+1} be the closure of the set $F(\mathfrak{A}_k, \mathfrak{B})$ so, by (ii), each \mathfrak{A}_k is compact. Using (i) to obtain the standard estimate of the Contractive Mapping Principle, one sees that $\mathcal{F}_{\mathfrak{B}}$ is uniformly approximable within $\varepsilon/2$ by some \mathfrak{A}_k and, by compactness, this \mathfrak{A}_k has a finite cover by $(\varepsilon/2)$ -balls. Hence $\mathcal{F}_{\mathfrak{B}}$ has a finite cover by ε -balls for each $\varepsilon > 0$ so $\mathcal{F}_{\mathfrak{B}}$ is precompact. \square

We now proceed to discuss approaches to the verification of the compactness hypothesis (H_3) used in Theorem 1.

Approach 1. In contrast to Remark 1, concerning existence, the space \mathfrak{X} plays a key role in this approach. We assume the continuity of \mathbf{S} , \mathbf{SB} as in Lemma 1 and that (1.6) has a unique solution $x_\phi(\cdot; v) \in \mathfrak{X}$ for each v in \mathfrak{B} with $\{x_\phi(\cdot; v)\}$ bounded in \mathfrak{X} for v bounded in \mathfrak{B} ; for this approach we may well be using the argument of Theorem 2 with, say, $\mathfrak{Y} = \mathfrak{X}$. Now impose an additional condition comparable to (3.1) but with a hypothesis of compact embedding:

- (4.2) For some space $\hat{\mathfrak{X}}$ such that $\mathfrak{X} \hookrightarrow \hat{\mathfrak{X}}$ is a compact embedding, assume $\phi : [0, T] \times \hat{\mathfrak{X}} \rightarrow \mathfrak{Z}$ satisfies Carathéodory conditions and a condition:

$$|\phi(s, \xi)|_{\mathfrak{Z}} \leq \alpha_M(s) \quad \text{for } \xi \in \hat{\mathfrak{X}} \quad \text{with } |\xi|_{\hat{\mathfrak{X}}} \leq M$$

where, for each $M \in \mathbb{R}^+$, one has $\alpha_M \in L^p_+(0, T)$.

This suffices to ensure compactness of \mathbf{W}_0 —we argue as follows: For v in a bounded subset of \mathfrak{B} we have $\{x_\phi(\cdot; v)\}$ in a bounded subset of $\mathfrak{X} = C([0, T] \rightarrow \mathfrak{X})$ by assumption and, from Lemma 1, equicontinuous from $[0, T]$ to \mathfrak{X} . By the Arzela–Ascoli theorem this gives $\{y = \{x_\phi(\cdot; v)\}\}$ in a compact subset of $\hat{\mathfrak{X}} := C([0, T] \rightarrow \hat{\mathfrak{X}})$ whence in a compact subset of, e.g., $\hat{\mathfrak{X}} := L^p([0, T] \rightarrow \hat{\mathfrak{X}})$. Boundedness in $\hat{\mathfrak{X}}$ gives some bound M on $|\eta|_{\hat{\mathfrak{X}}}$ for the relevant application of the inequality in (4.2) so Krasnoselski's theorem gives continuity of the map

$$y \mapsto \phi(\cdot, y) : \{y \in \hat{\mathfrak{X}}_p : |y(t)| \leq M \text{ on } [0, T]\} \rightarrow \mathfrak{Z}.$$

Thus, for v in a bounded subset of \mathfrak{B} one has $\{\phi(\cdot, x_\phi(\cdot; v)) = \mathbf{G}_\phi v\}$ in a compact subset of \mathfrak{Z} , i.e., \mathbf{W}_0 is compact. We note that this approach imposes no compactness condition involving the transition operators $\Psi(\cdot, \cdot)$. \square

Approach 2. For this approach we return to the differential equation so

$$(4.3) \quad \dot{x} = \mathbf{B}v + \phi(\cdot, x) - \mathbf{A}x, \quad x(0) = x_0.$$

While our earlier interpretation treated \mathbf{A} , \mathbf{B} as (possibly) unbounded operators, we now impose the extremely weak assumption that there is some space $\tilde{\mathfrak{Y}}$ such that (with $1 < \tilde{p}, \tilde{q} < \infty$; $1/\tilde{p} + 1/\tilde{q} = 1$)

$$(4.4) \quad \begin{aligned} \text{(i)} \quad & \mathfrak{Y} \hookrightarrow \tilde{\mathfrak{Y}}, \quad \mathfrak{X} \hookrightarrow \tilde{\mathfrak{Y}}, \\ \text{(ii)} \quad & |\mathbf{A}(t)|_{\mathfrak{Y} \rightarrow \tilde{\mathfrak{Y}}} \leq \alpha(t), \quad \alpha \in L^{\tilde{q}}(0, T) (1/\tilde{q} + 1/p < 1), \\ \text{(iii)} \quad & |\mathbf{B}(t)|_{\mathfrak{V} \rightarrow \tilde{\mathfrak{Y}}} \leq \beta(t), \quad \beta \in L^{\tilde{q}'}_+(0, T) (1/\tilde{q}' + 1/p' < 1). \end{aligned}$$

Then (4.3), (4.4) give

$$(4.5) \quad \text{Bounds on } x \text{ in } \mathfrak{Y} := L^{\tilde{p}}([0, T] \rightarrow \mathfrak{Y}), \text{ on } v \text{ in } \mathfrak{B}, \text{ and on } g := \phi(\cdot, x) \text{ in } \mathfrak{Z} \text{ give a bound on } \dot{x} \text{ in } L^{\tilde{p}}([0, T] \rightarrow \tilde{\mathfrak{Y}}).$$

Suppose, then, we were to assume, as for Theorem 2, that ϕ satisfies (3.1), (3.5), (3.6). The proof of Theorem 2 then gives, for v in any bounded subset of \mathfrak{B} ,

- (i) the existence of a solution $x = x_\phi(\cdot; v) \in \mathfrak{Y}$ for each v ,
- (ii) bounds, as for (4.5) on $x \in \mathfrak{Y}$, $g := \phi(\cdot, x) \in \mathfrak{Z}$; hence also on \dot{x} .

Now impose an additional condition supplementing (3.1) but with a hypothesis of compact embedding:

- (4.6) For some space $\hat{\mathfrak{Y}}$ such that $\mathfrak{Y} \hookrightarrow \hat{\mathfrak{Y}}$ is a compact embedding, assume $\phi: [0, T] \times \hat{\mathfrak{Y}} \rightarrow \mathfrak{Z}$ satisfies Carathéodory conditions and a growth condition

$$|\phi(s, \eta)|_{\mathfrak{Z}} \leq \alpha(s) + \beta |\eta|_{\hat{\mathfrak{Y}}}^r \quad (\eta \in \hat{\mathfrak{Y}})$$

with r as in (3.1) and $\alpha \in L^r_+(0, T)$.

By the Aubin Compactness theorem [1] we have, using (4.5) and the bound on $\{x = x_\phi(\cdot; v)\}$ in \mathfrak{Y} for v in a bounded subset $\mathfrak{B} \subset \mathfrak{B}$, that $\{x_\phi(\cdot; v)\}$ is in a compact subset of $\hat{\mathfrak{Y}} := L^p([0, T] \rightarrow \hat{\mathfrak{Y}})$. Using (4.6), Krasnoselski's theorem (compare (3.4)) gives continuity of $\phi: \hat{\mathfrak{Y}} \rightarrow \mathfrak{Z}$. Thus, combining these, we have $\{\phi(\cdot; x_\phi(\cdot, v)) = \mathbf{G}_\phi v\}$ in a compact subset of \mathfrak{Z} . Under these hypotheses also, then, we have shown that the map \mathbf{W}_0 is compact. \square

For this approach also, note that the supplementary hypotheses (4.4), (4.6) did not impose any compactness condition involving $\psi(\cdot, \cdot)$.

Approach 3. This really will split into two related approaches, using Lemma 3. For the first of these, as for the previous approach, we will assume (4.3), (4.4) to obtain (4.5) so that the Aubin theorem will be applicable. The supplementary hypothesis to be imposed will no longer involve ϕ but, rather, will be a strengthening of (3.5)(iii). Thus, we assume that (3.1), (3.5), (3.6) hold, with (3.5)(iii) replaced by

- (4.7) $|\psi(t, s)\mathbf{B}(s)|_{\mathfrak{Y} \rightarrow \hat{\mathfrak{Y}}} \leq \bar{\rho}_2(t-s)$ for some $\bar{\rho}_2 \in L^q_+(0, T)$ with $1/\bar{q}' + 1/p' \leq 1 + 1/\bar{p}$ and some $\hat{\mathfrak{Y}}$ such that $\hat{\mathfrak{Y}} \hookrightarrow \mathfrak{Y}$ is a compact embedding.

We wish to employ Lemma 3 to show that, for $v \in \mathfrak{B} = (\text{bounded in } \mathfrak{B})$, one has $\{x = x_\phi(\cdot; v)\} =: \mathcal{F}_{\mathfrak{B}}$ precompact in \mathfrak{Y} . The map \mathbf{F} under consideration here is, of course, that defined by (3.8), for which (4.1)(i) is already known from the proof of Theorem 2; we need only use (4.7) and the Aubin theorem to demonstrate (4.1)(ii).

Suppose, then, we were to have $v \in \mathfrak{B}$ and $y \in \mathfrak{A} = (\text{compact in } \mathfrak{Y})$. By (3.4) we would have $\phi \mathfrak{A}$ compact in \mathfrak{Z} so $\mathbf{S}\phi \mathfrak{A}$ compact in \mathfrak{Y} . Hence, it will suffice to show that (4.7) ensures compactness for the linear map $\mathbf{SB}: \mathfrak{B} \rightarrow \mathfrak{Y}$, whence we have precompactness of the set $\mathbf{SB}\mathfrak{B}$ and so also of $F(\mathfrak{A}, \mathfrak{B}) = \mathbf{S}\phi \mathfrak{A} + \mathbf{SB}\mathfrak{B} + \bar{x}$. We note that \mathbf{SB} is just the solution operator for the differential equation

$$(4.8) \quad \dot{y} = -\mathbf{A}y + \mathbf{B}v, \quad y(0) = 0,$$

i.e., (4.3) without ϕ and with $x_0 = 0$. We next show that (4.7) makes $\mathbf{SB}: \mathfrak{B} \rightarrow \mathfrak{Y}$ continuous. The estimate is like the one we used in the proof of Theorem 2 to obtain (3.10), although we do need to consider the exponential weight factor here:

$$y(t) := [\mathbf{SB}v](t) := \int_0^t \psi(t, s)\mathbf{B}(s)v(s) ds,$$

$$|y(t)|_{\hat{\mathfrak{Y}}} \leq \int_0^t \bar{\rho}_2(t-s)|v(s)|_{\mathfrak{Y}} ds = [\bar{\rho}_2 * |v|_{\mathfrak{Y}}](t),$$

$$\|y\|_{\hat{\mathfrak{Y}}} \leq C \|\bar{\rho}_2\|_{L^q(0, T)} \|v\|_{\mathfrak{B}}.$$

For $v \in \mathfrak{V}$ we have thus bounded $\{y \in \mathbf{SB}v\}$ in $\hat{\mathfrak{Y}}$ and, using (4.8), (4.4) as in (4.5), have a bound on $\{y: y \in \mathbf{SB}\mathfrak{V}\} =: \mathfrak{S}'$ in $\hat{\mathfrak{Y}}$. Thus, applying the Aubin theorem [1] gives precompactness of $\mathbf{SB}\mathfrak{V}$ in \mathfrak{Y} and so applicability of Lemma 3 to give precompactness in \mathfrak{Y} of $\mathcal{F}_{\mathfrak{V}} = \mathbf{S}_{\phi}\mathfrak{V}$. This shows the map \mathbf{S}_{ϕ} is compact and so $\mathbf{W}_0: w \mapsto \phi \mathbf{S}_{\phi}(w + v_0)$ is compact as desired.

Within the same context we also note the sufficiency of a somewhat different supplementary hypothesis: instead of replacing (3.5)(iii) by the stronger version (4.7), we now retain (3.5) unchanged and supplement it by a compactness condition on the transition operator $\Psi(\cdot, \cdot)$:

(4.9) For some $\hat{\mathcal{U}}$ such that $\mathcal{U} \hookrightarrow \hat{\mathcal{U}}$ is a compact embedding, assume that for $\delta > 0$ one has

$$|\psi(t, t - \delta)|_{\hat{\mathcal{U}} \rightarrow \mathcal{U}} \leq M_{\delta} (\delta \leq t \leq T).$$

We show that this too gives compactness of the operator $\mathbf{SB}: \mathfrak{V} \rightarrow \mathfrak{Y}$ and so gives applicability of Lemma 3 as above. Now, given (3.5)(iii) we have a bound on $\mathbf{SB}: \mathfrak{V} \rightarrow \mathfrak{Y}$. Thus, for v bounded in \mathfrak{V} , we have a bound on $\mathfrak{S} := \{y := \mathbf{SB}v\}$ in \mathfrak{Y} and, as in (4.5), a bound on $\mathfrak{S}' = \{y\}$ in $\hat{\mathfrak{Y}}$. Using the Aubin theorem again, this gives compactness in $\hat{\mathfrak{Y}} := L^p([0, T] \rightarrow \hat{\mathcal{U}})$ for \mathfrak{S} . Note that in the context of (4.3), (4.8) we expect the transition operator to satisfy the "causality condition"

$$(4.10) \quad \psi(t, r)\psi(r, s) = \psi(t, s) \quad (0 \leq s \leq r \leq t \leq T).$$

If we define $\mathbf{D}_{\delta}: y \mapsto y_{\delta}$ for $\delta > 0$ by setting

$$(4.11) \quad y_{\delta}(t) := \begin{cases} 0, & t \leq \delta, \\ \psi(t, t - \delta)y(t - \delta), & \delta \leq t \leq T, \end{cases}$$

then $|y_{\delta}(t)|_{\mathcal{U}} \leq M_{\delta}|y(t - \delta)|_{\hat{\mathcal{U}}}$ and $\mathbf{D}_{\delta}: \hat{\mathfrak{Y}} \rightarrow \mathfrak{Y}$ is continuous whence $\mathbf{D}_{\delta}\mathfrak{S}$ is compact in \mathfrak{Y} for each $\delta > 0$. Note that (4.10) gives, for $\delta \leq t \leq T$,

$$\begin{aligned} y_{\delta}(t) &= \psi(t, t - \delta) \int_0^{t - \delta} \psi(t - \delta, s) \mathbf{B}(s)v(s) ds \\ &= \int_0^{t - \delta} \psi(t, s) \mathbf{B}(s)v(s) ds, \quad \delta \leq t \leq T \end{aligned}$$

so using (3.5)(iii) gives

$$\begin{aligned} |y(t) - y_{\delta}(t)| &= \left| \int_{t - \delta}^t \psi(t, s) \mathbf{B}(s)v(s) ds \right|_{\mathcal{U}} \\ &\leq \int_{t - \delta}^t \bar{\rho}_2(t - s)|v(s)|_{\mathcal{V}} ds \\ &= [\bar{\rho}_{2,\delta} * |v|_{\mathcal{V}}](t) \end{aligned}$$

where $\bar{\rho}_{2,\delta}$ is the restriction of $\bar{\rho}_2$ to $[0, \delta]$. Thus, using (3.9),

$$(4.12) \quad \|y - y_{\delta}\|_{\mathfrak{Y}} \leq C \|\bar{\rho}_{2,\delta}\|_{L^{q'}(0,\delta)} \|v\|_{\mathfrak{V}}.$$

As in the argument for Lemma 3, this permits us to show precompactness of \mathfrak{S} in \mathfrak{Y} by finding a finite covering by ε -balls: choosing δ small enough, one can make $\|\bar{\rho}_{2,\delta}\|$

as small as desired so each $y \in \mathfrak{S}$ is within $\varepsilon/2$ of $y_\delta \in \mathbf{D}_\delta \tilde{\mathfrak{S}}$ for $0 < \delta \leq \delta(\varepsilon)$ while the compactness of $\mathbf{D}_\delta \tilde{\mathfrak{S}}$ permits finding a finite covering of $\mathbf{D}_\delta \tilde{\mathfrak{S}}$ by $(\varepsilon/2)$ -balls. Thus $\mathfrak{S} := \mathbf{S}\mathbf{B}\mathfrak{B}$ is precompact in \mathfrak{Y} for \mathfrak{B} bounded in \mathfrak{B} and, as above, this implies (4.1)(ii) for such \mathfrak{B} and applicability of Lemma 3, etc. Once again we have demonstrated the compactness of \mathbf{W}_0 . \square

Remark 2. In Approach 3 the Lipschitz condition (3.6) was used to obtain the contractivity condition (4.1)(i), which, in turn, was needed both to show existence in \mathfrak{Y} of solutions of (4.3) and also for application of Lemma 3 to obtain compactness. In the first two approaches the compactness was obtained without appeal to (4.1)(i) and, indeed, it is possible there to omit (3.6) as a hypothesis while still retaining the final conclusion: invariance of the reachable set ($\mathcal{H}_\phi = \mathcal{H}_0$).

Note that showing $\mathcal{H}_\phi \subset \mathcal{H}_0$ used no property of ϕ except that $\phi: \mathfrak{Y} \rightarrow \mathfrak{Z}$ but to prove $\mathcal{H}_0 \subset \mathcal{H}_\phi$ required an analysis of properties of \mathbf{W}_0 . Note that all the estimates used to show (3.13)—hence, to determine an invariant ball $\mathfrak{B} = \mathfrak{B}_{\mathfrak{B}}$ for \mathbf{W} —depend² on v_0 , on \bar{x} , on the α, β and r of (3.1) or (4.6), and on $\bar{\rho}_1, \bar{\rho}_2$ in (3.5). The choice of $\bar{\rho}_3$ in (3.6) did not enter into (3.13). Indeed, for Approaches 1 and 2 the Lipschitz condition (3.6) plays a role only in ensuring that (1.6) does have a solution in \mathfrak{Y} for each $v \in \mathfrak{B}$ (so \mathbf{S}_ϕ is well defined) and in showing that \mathbf{S}_ϕ is continuous. We now intend to dispense with a direct analysis of \mathbf{S}_ϕ .

Suppose, then, we were to be given (H_0) , (2.3) and (3.5) with $\mathfrak{Y} = \mathcal{X}$ together with a function ϕ satisfying (3.1) and (4.2) but not (3.6). Now let \mathcal{F}_* be the set of all $\tilde{\phi}$ satisfying (3.1), (4.2) (with the same data: $\alpha, \beta, r, \alpha_M$) and also satisfying (3.6) with some fixed choice of $\bar{\rho}_3$. Fixing v_0 , we can find fixed sets (i.e., independent of $\phi \in \mathcal{F}_*$) $\mathfrak{B}_{\mathfrak{B}}, \mathfrak{B}_{\mathfrak{Y}}, \mathfrak{B}_{\mathfrak{Z}}$ with $\mathfrak{B}_{\mathfrak{B}}$ bounded in \mathfrak{B} , $\mathfrak{B}_{\mathfrak{Y}}$ compact in $\mathcal{X} := C([0, T] \rightarrow \mathcal{X})$, and such that

$$(4.13) \quad \mathbf{S}_\phi(v_0 + \mathfrak{B}_{\mathfrak{B}}) \subset \mathfrak{B}_{\mathfrak{Y}}, \quad \tilde{\phi}\mathfrak{B}_{\mathfrak{Y}} \subset \mathfrak{B}_{\mathfrak{Z}}, \quad \mathbf{C}\mathfrak{B}_{\mathfrak{Z}} \subset \mathfrak{B}_{\mathfrak{B}}$$

for each $\tilde{\phi} \in \mathcal{F}_*$. Since we will only be interested in $\phi(\cdot, x)$ for x in the compact set $\mathfrak{B}_{\mathfrak{Y}}$, we can³ approximate ϕ by $\tilde{\phi}_k \in \mathcal{F}_*$ for which, say,

$$(4.14) \quad \|\tilde{\phi}_k(\cdot, x) - \phi(\cdot, x)\|_{\mathfrak{Z}} \leq \frac{1}{k} \quad (x \in \mathfrak{B}_{\mathfrak{Y}}).$$

Since each $\tilde{\phi}_k$ is in \mathcal{F}_* (so Theorem 2 applies and Approach 1 to compactness is available) we may apply Theorem 1 and have a fixpoint $w_k \in \mathfrak{B}_{\mathfrak{B}}$ of $\mathbf{W} = \mathbf{W}_k$ (i.e., defined as above using $\tilde{\phi}_k$ for ϕ); let x_k be the corresponding solution of (1.6) and let $g_k := \phi_k(\cdot, x_k)$. We have x_k in the compact set $\mathfrak{B}_{\mathfrak{Y}}$ so, extracting a subsequence if necessary, we have convergence: $x_k \rightarrow x_*$ in the sense of \mathcal{X} for some $x_* \in \mathfrak{B}_{\mathfrak{Y}}$. Now, setting $g_* := \phi(\cdot, x_*)$, we have

$$\begin{aligned} \|g_k - g_*\|_{\mathfrak{Z}} &= \|\phi_k(\cdot, x_k) - \phi(\cdot, x_*)\|_{\mathfrak{Z}} \\ &\leq \|\phi_k(\cdot, x_k) - \phi(\cdot, x_k)\|_{\mathfrak{Z}} + \|\phi(\cdot, x_k) - \phi(\cdot, x_*)\|_{\mathfrak{Z}}. \end{aligned}$$

The first term goes to 0 by (4.14) while $x_k \rightarrow x_*$ in \mathcal{X} clearly gives $x_k \rightarrow x_*$ in $\mathfrak{Y} := \bar{L}^p([0, T] \rightarrow \mathcal{X})$ and so, using (4.2) and Krasnoselski's theorem to obtain continuity of $\phi: \mathfrak{Y} \rightarrow \mathfrak{Z}$, the second term also goes to 0. Thus, $g_k \rightarrow g_*$ in \mathfrak{Z} so $w_k := \mathbf{C}g_k \rightarrow \mathbf{C}g_* =: w_*$

² Note that in using (4.2) in Approach 1 we did *not* suggest that it replace (3.1) which, as observed here, plays a key role in determining \mathfrak{B} .

³ In view of the assumption (2.3)(ii), the approximation can be accomplished relatively straightforwardly. The construction is rather cumbersome and we relegate it to the Appendix.

by the continuity of \mathbf{C} . But now we have

$$\begin{aligned} x_k &\rightarrow x_* \quad \text{in } \mathfrak{X}, \\ \bar{x}_k &= x + \mathbf{S}g_k + \mathbf{SB}(v_0 + w_k) \\ &\rightarrow \bar{x} + \mathbf{S}g_* + \mathbf{SB}(v_0 + w_*) \quad \text{in } \mathfrak{X} \quad (\text{by Lemma 1}) \\ &= \bar{x} + \mathbf{S}\phi(\cdot, x_*) + \mathbf{SB}(v_0 + w_*). \end{aligned}$$

Hence x_* does indeed satisfy⁴ the limit equation: (1.6) using ϕ itself. Finally, since $w_* = \mathbf{C}g_*$ it follows that $x_*(T) = \bar{x}(T) + [\mathbf{SB}v_0](T)$. As in the proof of Theorem 1, this suffices to show $\mathcal{H}_0 \subset \mathcal{H}_\phi$ and so the invariance.

The argument is almost the same for situations in which one might apply Approach 2. Suppose, then, we are given the conclusions of Lemma 2, (3.5), (4.4) in the context of a differential equation (4.3) with a function $\tilde{\phi}$ satisfying (4.6) but not (3.6). Now let $\tilde{\mathfrak{F}}_*$ be the set of all $\tilde{\phi}$ satisfying (4.6) with the same α, β, r and also satisfying (3.6) with some choice of \tilde{p}_3 . As above, we find $\mathfrak{B}_{\mathfrak{Z}}$ (bounded in \mathfrak{B}), $\mathfrak{B}_{\mathfrak{Y}}$, $\mathfrak{B}_{\mathfrak{Z}}$ such that (4.13) holds for each $\tilde{\phi}$ in $\tilde{\mathfrak{F}}_*$. Since the set $\mathfrak{B}_{\mathfrak{Y}}$ can be defined solely by the bounds obtained from (4.6), (4.4), its compactness in \mathfrak{Y} follows from Aubin's theorem without reference to the Lipschitz condition (3.6). Again, noting the compactness of $\mathfrak{B}_{\mathfrak{Y}}$ —hence the uniform continuity of $\tilde{\phi}$ on $\mathfrak{B}_{\mathfrak{Y}}$ —we expect to approximate ϕ on $\mathfrak{B}_{\mathfrak{Y}}$ as in (4.14) by a sequence $\{\tilde{\phi}_k\}$ in $\tilde{\mathfrak{F}}_*$. The remainder of the argument continues as earlier: Taking the fixpoints $w_k \in \mathfrak{B}_{\mathfrak{W}}$ of $\mathbf{W} = \mathbf{W}_k$ given by using Approach 2 with Theorem 2 and the proof of Theorem 1, let $y_k \in \mathfrak{B}_{\mathfrak{Y}}$ be the corresponding solutions and, noting compactness of $\mathfrak{B}_{\mathfrak{Y}}$ in \mathfrak{Y} , assume $y_k \rightarrow y_*$. Now $g_k := \tilde{\phi}_k(\cdot, y_k) \rightarrow g_* := \phi(\cdot, y_*)$ in \mathfrak{Z} and $w_k := \mathbf{C}g_k \rightarrow w_* := \mathbf{C}g_*$ as earlier. It is now the continuity of $\mathbf{S}: \mathfrak{Z} \rightarrow \mathfrak{Y}$ and $\mathbf{SB}: \mathfrak{B} \rightarrow \mathfrak{Y}$ given by (3.5) which gives

$$x_* \leftarrow x_k \rightarrow \bar{x} + \mathbf{S}\phi(\cdot, x_*) + \mathbf{SB}(v_0 + w_*)$$

and so the limit equation. Again this suffices to show $\mathcal{H}_0 \subset \mathcal{H}_\phi$ and so the desired invariance. \square

At this point it seems useful to gather together the results we have obtained. Recall that the basic setting is the abstract integral equation

$$(4.15) \quad x(t) = \bar{x}(t) + \int_0^t \Psi(t, s)[\phi(s, x(s)) + \mathbf{B}(s)v(s)] ds$$

or essentially equivalently, the differential equation

$$(4.16) \quad \dot{x}(t) = \phi(t, x(t)) + \mathbf{B}(t)v(t) + \mathbf{A}(t)x(t), \quad x(0) = x_0$$

for $0 \leq t \leq T$. Without seeking the most general possible version of what has been demonstrated in the previous sections, we consider:

- (4.17) (i) Banach spaces $\mathfrak{X}, \mathfrak{Y}, \mathfrak{Z}$ (of comparable elements) and \mathcal{V} ;
 (ii) Exponents $1 < p, p', \bar{p} < \infty$ with $\bar{p} = rp, r < 1$;
 (iii) $\mathfrak{X} := C([0, T] \rightarrow \mathfrak{X})$, $\mathfrak{Y} := L^{\bar{p}}([0, T] \rightarrow \mathfrak{Y})$,
 $\mathfrak{Z} := L^p([0, T] \rightarrow \mathfrak{Z})$, $\mathfrak{B} := L^{p'}([0, T] \rightarrow \mathcal{V})$;
 (iv) Operators $\Psi(t, s), \mathbf{B}(s)$, measurable for $0 \leq s \leq t \leq T$ and with
 $\Psi(t, \tau)\Psi(\tau, s) = \Psi(t, s)$;

⁴ Note that without the Lipschitz condition (3.6) we do not necessarily know the uniqueness of this solution.

- (v) A function $\phi: [0, T] \times \mathcal{Y} \rightarrow \mathcal{X}$ satisfying Carathéodory conditions and a function $\bar{x} \in \mathcal{X} \cap \mathcal{Y}$

and impose the conditions (2.3), (3.5), i.e.,

- (4.18) (i) $|\psi(t, s)|_{\mathcal{X} \rightarrow \mathcal{X}} \leq \rho_1(t-s)$ with $\rho_1 \in L_+^q(0, T)(1/q + 1/p = 1)$,
 (ii) $|\psi(t, s)|_{\mathcal{X} \rightarrow \mathcal{Y}} \leq \bar{\rho}_1(t-s)$ with $\bar{\rho}_1 \in L_+^{\bar{q}}(0, T)(1/\bar{q} + 1/p \leq 1 + 1/\bar{p})$,
 (iii) $|\psi(t, s)\mathbf{B}(s)|_{\mathcal{Y} \rightarrow \mathcal{X}} \leq \rho_2(t-s)$ with $\rho_2 \in L_+^q(0, T)(1/q' + 1/p' = 1)$,
 (iv) $|\psi(t, s)\mathbf{B}(s)|_{\mathcal{Y} \rightarrow \mathcal{Y}} \leq \bar{\rho}_2(t-s)$ with $\bar{\rho}_2 \in L_+^{\bar{q}}(0, T)$
 $(1/\bar{q}' + 1/p' \leq 1 + 1/\bar{p})$,
 (v) $|\psi(t, s) - \psi(t', s)|_{\mathcal{X} \rightarrow \mathcal{X}} \leq \varepsilon$, $|\psi(t, s) - \psi(t', s)]\mathbf{B}(s)|_{\mathcal{Y} \rightarrow \mathcal{X}} \leq \varepsilon$
 for $0 \leq s \leq t' - \varepsilon$, $t' < t = t' + h \leq T$ with $\varepsilon = \varepsilon(h) \rightarrow 0+$ as $h \rightarrow 0+$.

Under the conditions (4.18)(i), (4.18)(iii), (4.18)(v) we showed (Lemma 2) existence of continuous operators $\mathbf{S}: \mathcal{Y} \rightarrow \mathcal{X}$, $\mathbf{SB}: \mathcal{Y} \rightarrow \mathcal{X}$ such that the solution of $[\dot{x} + \mathbf{A}x = g + \mathbf{B}v$, $x(0) = 0]$ is given by $x = \mathbf{S}g + \mathbf{SB}v$, and of continuous operators $\mathbf{T}: \mathcal{Y} \rightarrow \mathcal{X}$, $\mathbf{TB}: \mathcal{Y} \rightarrow \mathcal{X}$ such that $\mathbf{T}g := [\mathbf{S}g](T)$, $\mathbf{TB}v := [\mathbf{SB}v](T)$. In terms of these we make the underlying assumption that

(H₀) $\mathcal{R}(T) \subset \mathcal{R}(\mathbf{TB})$, i.e., for each $f \in \mathcal{Y}$ there exists $v \in \mathcal{Y}$ such that $\mathbf{T}(g + \mathbf{B}v) = 0$. This is, of course, quite a strong controllability assumption, corresponding to the invariance of the reachable set

$$\mathcal{K}_g := \{x(T): x \text{ satisfies (4.15) for some } v \in \mathcal{Y}\}$$

as g ranges over \mathcal{Y} , i.e., taking

$$\phi(t, \xi) := g(t) \quad \text{for some } g \in \mathcal{Y}.$$

We have treated (H₀) here as given a priori and did not attempt to investigate specific situations for which it might be verifiable; see, however, Remark 3 in the next section.

THEOREM 3. Assume (4.17), (4.18) and assume that ϕ satisfies a growth condition:

$$(4.19) \quad |\phi(s, \eta)|_{\mathcal{X}} \leq \alpha(s) + \beta|\eta|_{\hat{\mathcal{Y}}}^r \quad \text{with } \alpha \in L_+^p(0, T), \quad r < 1,$$

and a Lipschitz condition:

$$(4.20) \quad |\psi(t, s)[\phi(s, \eta) - \phi(s, \eta')]|_{\mathcal{Y}} \leq \bar{\rho}_3(t-s)|\eta - \eta'|_{\mathcal{Y}} \quad \text{with } \bar{\rho}_3 \in L_+^1(0, T)$$

or, for Cases 1 and 2 below, can be approximated as in Remark 2, (4.14) by $\{\tilde{\phi}_k\}$ satisfying this condition. We consider four cases in the assumption regarding ϕ :

Case 1. $\hat{\mathcal{Y}} = \mathcal{Y} = \mathcal{X} \hookrightarrow \hat{\mathcal{X}}$ (compact embedding) and (4.19) is supplemented by

$$(4.21) \quad |\phi(s, \eta)|_{\mathcal{X}} \leq \alpha_M(s) \quad \text{for } |\eta|_{\hat{\mathcal{X}}} \leq M$$

with $\alpha_M \in L_+^p(0, T)$ for each $M > 0$.

Case 2. Consider (4.15) as equivalent to (4.16) with \mathbf{A} , \mathbf{B} as in (4.4) for some $\tilde{\mathcal{Y}}$ ($\mathcal{Y}, \mathcal{X} \hookrightarrow \tilde{\mathcal{Y}}$); for (4.20) assume $\mathcal{Y} \hookrightarrow \hat{\mathcal{Y}}$ is a compact embedding.

Case 3. Consider (4.15) equivalent to (4.16) with \mathbf{A} , \mathbf{B} as in (4.4); require (4.20) directly for ϕ ; taking $\hat{\mathcal{Y}} \hookrightarrow \mathcal{Y}$ (compact embedding) replace (4.18)(iv) by

$$(4.22) \quad |\psi(t, s)\mathbf{B}(s)|_{\mathcal{Y} \rightarrow \hat{\mathcal{Y}}} \leq \bar{\rho}_2(t-s) \quad \text{with } \bar{\rho}_2 \in L_+^{\bar{q}}(0, T) \quad (1/\bar{q}' + 1/p' \leq 1 + 1/\bar{p}).$$

Case 4. Consider (4.15) equivalent to (4.16) with \mathbf{A} , \mathbf{B} as in (4.4); require (4.20) directly for ϕ_k taking $\mathcal{V} \hookrightarrow \mathcal{Q}$ (compact embedding) and assume

$$(4.23) \quad |\psi(t, t - \varepsilon)|_{\mathcal{Q} \rightarrow \mathcal{Q}} \leq M_\varepsilon \quad (\pi \leq t \leq T)$$

for each $\varepsilon > 0$ and some M_ε .

Then if one has invariance of the reachable set under affine perturbations in \mathfrak{J} , i.e., if

(4.24) For each $g \in \mathfrak{J}$ there is some control $v \in \mathfrak{V}$ such that

$$\int_0^T \psi(T, s) \mathbf{B}(s) v(s) ds = \int_0^T \psi(T, s) g(s) ds;$$

then one also has invariance of the reachable set ($\mathcal{K}_\phi = \mathcal{K}_0$) for the nonlinear perturbation (4.15).

Proof. This merely summarizes the preceding discussions. \square

5. Further remarks. In this section we supplement the rather abstract discussion above by some remarks on possible settings in which various of the hypotheses can be verified.

Remark 3. The most difficult of the hypotheses made is (H_0) . Clearly, for any case in which \mathcal{K}_0 is the entire state space \mathcal{X} this is immediate. The results obtained are then very much along the main line of development of this fixed point approach to nonlinear control.

An equally immediate verification is available if $\mathfrak{J} \subset \mathbf{B}\mathfrak{V}$, say, if $p' \leq p$ in (2.2) and $\mathcal{X} \subset \mathbf{B}\mathcal{V}$. In this case, however, the final conclusion is equally immediate without the machinery of this paper: given $\xi \in \mathcal{K}_0$ with $x' + \mathbf{A}x = \mathbf{B}v_0$ giving $x(\tau) = \xi$, we need only take $g := \phi x \in \mathfrak{J}$ for this x and take w such that $\mathbf{B}w = -g$. Then $v := v_0 + w$ gives $x' + \mathbf{A}x = \phi(\cdot, x) + \mathbf{B}v$ with, of course, the same terminal value ξ since one has the same solution x .

The only other situation for which, *as of now*, we can show how to verify (H_0) involves ϕ of the form

$$(5.1) \quad \phi(t, \eta) := \sum_i^n \phi_k(t, \eta) z_k$$

where each $\phi_k(t, \cdot)$ is a scalar-valued functional, i.e., $\mathcal{X} = \text{span}\{z_1, \dots, z_n\}$ is finite-dimensional. If one were to have, e.g., an autonomous equation, so $\psi(\cdot, \cdot)$ is the semigroup generated by $-\mathbf{A}$, then requiring invariance of \mathcal{X} under \mathbf{A} (hence under ψ) and that $\mathcal{X} \subset \mathcal{K}_0$ would be sufficient to ensure (H_0) ; note that exact nullcontrollability for the linear problem would ensure $\mathcal{X} \subset \mathcal{K}_0$. In particular, this method of verification for (H_0) would apply for boundary control of the heat equation (see Remark 4 below) if each z_k were an eigenfunction of $[-\Delta; BC]$. Somewhat more generally, we may consider any closed (e.g. finite-dimensional) subspace $\mathcal{X}_* \subset \mathcal{K}_0$ and assume that \mathcal{X} is such that

$$(5.2) \quad \psi(T, s)z \in \mathcal{X}_* \quad \text{for } z \in \mathcal{X}, \quad s \in (0, T).$$

The point is that (1.8) shows that (5.2) gives $\mathbf{T}g \in \mathcal{X}_* \subset \mathcal{K}_0$ for each $g \in \mathfrak{J}$, assuming the integral converges (for which we need our other hypotheses), which gives (H_0'') . \square

Remark 4. We next consider settings for which the hypotheses for Lemma 1 can be verified.

The simplest case (compare [7]) would be to have $\mathcal{X} = \mathcal{X}$ and ψ continuous on the triangle $\{0 \leq s \leq t \leq T\}$ to be bounded operators on \mathcal{X} with $\mathbf{B}(\cdot)$ continuous on $[0, T]$ to bounded operators: $\mathcal{V} \rightarrow \mathcal{X}$.

The conditions (2.3) were designed to consider, e.g., such possibilities as the heat equation with \mathcal{L} "nastier" than $L^2(\Omega)$. Slightly more generally, take $\mathcal{X} := L^2(\Omega)$ and $-\mathbf{A}$ the generator of an analytic semigroup. If \mathbf{A} is second order, then $\mathcal{D}(\mathbf{A}^\sigma) = H^{2\sigma}(\Omega)$ to within consideration of boundary conditions. A standard estimation (cf., e.g., [5]) gives

$$(5.3) \quad |\psi(\tau)z|_{\mathcal{X}} \leq |\mathbf{A}^\sigma \psi(\tau)| |\mathbf{A}^{-\sigma} z|_{\mathcal{X}} \leq M\tau^{-\sigma} |z|_{\mathcal{X}}$$

for $\mathcal{X} := H^{-2\sigma}(\Omega)$. If we take $\sigma < 1/q := 1 - 1/p$, then setting $\rho_1(\tau) := M\tau^{-\sigma}$ in (2.3)(ii) gives $\rho_1 \in L^q$. Again, a standard semigroup estimation gives, with this choice of \mathcal{X} ,

$$(5.4) \quad \begin{aligned} |\psi(t+h-s) - \psi(t-s)|_{\mathcal{X} \rightarrow \mathcal{X}} &\approx \left| \mathbf{A} \int_{t-s}^{t-s+h} \psi(\tau) d\tau \right|_{\mathcal{X}} \\ &\leq M \int_{t-s}^{t-s+h} \tau^{-(1+\sigma)} d\tau \leq Mh\delta^{-(1+\sigma)} \end{aligned}$$

got $h > 0$, $t-s \geq \delta > p$. Thus, since $\sigma < 1$, we may take

$$\delta = \delta(h) := h^{1/2}, \quad \varepsilon := \max \{ \delta, Mh\delta^{-(1+\sigma)} \}$$

to have $\varepsilon = \varepsilon(h) \rightarrow 0$ as $h \rightarrow 0$, giving the first part of (2.3)(iv). Similar considerations apply to $\psi\mathbf{B}$.

Of particular interest, also, is the possibility of treating boundary control in this framework. While some more general situations could be treated, we take \mathbf{A} as above, so the equation is an autonomous parabolic equation of the form

$$(5.5) \quad \dot{x} + \mathbf{A}_0 x = \phi(\cdot, x), \quad \beta x = v.$$

Here β is a boundary operator and what corresponds to \mathbf{B} is the effect of the control v appearing in the boundary conditions on the evolution of x . We have written \mathbf{A}_0 in (5.5) to indicate that specification of the domain $\mathcal{D}(\mathbf{A})$ includes homogeneous boundary conditions [$\beta y = 0$]; \mathbf{A}_0 is the same (elliptic) differential operator "pointwise". We take $\mathcal{X} \subset \mathcal{X} = \mathcal{Y} := L^2(\Omega)$; \mathcal{V} will be a space of functions on $\partial\Omega$ —say, $L^2(\Gamma) = \{\text{functions in } L^2(\partial\Omega) \text{ with support in } \Gamma\}$ for some choice of $\Gamma \subset \partial\Omega$. Assuming 0 is not an eigenvalue of \mathbf{A} , we define a Green's operator \mathbf{D} by

$$(5.6) \quad \mathbf{D}: \zeta \rightarrow z: \mathcal{V} \rightarrow \mathcal{X} \quad \text{with } \mathbf{A}_0 z = 0, \quad \beta z = \zeta.$$

The important point now is that standard trace and regularity theory for these elliptic operators tells us (assuming $\partial\Omega$ is smooth enough) that

$$(5.7) \quad \mathbf{A}^\sigma \mathbf{D}: \mathcal{V} \rightarrow \mathcal{X} \quad \text{is bounded for } \sigma < \bar{\sigma}$$

where $\bar{\sigma} := \frac{3}{4}$ if β is the Dirichlet trace and $\bar{\sigma} = \frac{3}{4}$ if β is (uniformly) of first order, e.g., the Neumann conditions.

We now use the fact that there is a variation of parameters formula corresponding to (1.2), for this situation⁵:

$$(5.8) \quad x(t) = \psi(t, 0)x(0) + \int_0^t [\psi(t-s)\phi(s, x(s)) + \mathbf{A}^{1-\sigma}\psi(t-s)\mathbf{A}^\sigma \mathbf{D}v(s)] ds.$$

⁵ See, e.g., [2] for this, but we sketch an argument: In (5.5) write $x = y + z$ with $z := \mathbf{D}v$ so $\dot{y} + \mathbf{A}y = \phi - \dot{z}$. An integration by parts of the variation of parameters formula for y leads to (5.8) since $d\psi/dt = \mathbf{A}\psi = \mathbf{A}^{1-\sigma}\psi\mathbf{A}^\sigma$.

This essentially replaces the previous use of $[\Psi(t, s)\mathbf{B}(s)]$ by use of $[\mathbf{A}^{1-\sigma}\Psi(t-s)] \times [\mathbf{A}^\sigma \mathbf{D}]$. Noting (5.7), we can use the same kind of estimate $|\mathbf{A}^\lambda \Psi(\tau)| = \mathcal{O}(\tau^{-\lambda})$ as for (5.3) above to verify the hypotheses. We will take $\hat{\mathcal{Y}} := \mathcal{D}(\mathbf{A}^\varepsilon)$ in (4.7) = (4.22) for our “compactness hypothesis,” noting that $\mathcal{D}(\mathbf{A}^\varepsilon) = H^{2\varepsilon}(\Omega) \hookrightarrow L^2(\Omega) = \mathcal{Y}$ is a compact embedding for $\varepsilon > 0$.

Suppose we let β be the Dirichlet trace. If Γ is a large enough part of $\partial\Omega$, it is known that we have exact nullcontrollability whence, as in Remark 3, (H_0) is verifiable for ϕ as in (5.1) with z_k eigenfunctions of \mathbf{A} ; in any case, assume that (H_0) holds. Since $\mathcal{X} \subset \mathcal{X} = \mathcal{Y}$, we may take $\rho_1, \bar{\rho}_1$ to be constant in (4.18). We may take $\rho_2(\tau) := M\tau^{-(1-\sigma)}$ in $L^{q'}$ with $q' < \frac{4}{3}$ (as $\sigma < \bar{\sigma} = \frac{1}{4}$ here so $1 - \sigma > \frac{3}{4}$) corresponding to taking $p' > 4$ for (2.2). For (4.22) with $\hat{\mathcal{Y}} = H^{2\varepsilon}(\Omega)$, we may take $\bar{\rho}_2(\tau) := M\tau^{-(1-\sigma+\varepsilon)}$ and want this to be in $L^{\bar{q}'}$. Since we may choose any $\sigma < \frac{1}{4}$, $\varepsilon > 0$, this only requires $q' > \frac{4}{3}$ also which means that there are essentially no new restrictions on \bar{p} or p . While we cannot simply apply Theorem 3 directly to this boundary control setting, it is clear that the discussion here can be viewed either as an interpretation of the theorem in that setting or as indicating the requisite (minor) modifications of the arguments: either way we now may take the theorem as applicable. We conclude that if we can verify the Carathéodory and growth conditions on ϕ and (H_0) for

$$(5.9) \quad \begin{aligned} \mathcal{X} &:= L^2(\Omega) \supset \mathcal{X}, \\ \mathfrak{J} &:= L^p([0, T] \rightarrow \mathcal{X}), \quad 1 < p < \infty, \\ \mathfrak{B} &:= L^{p'}([0, T] \rightarrow L^2(\Gamma)), \quad 4 < p' < \infty, \end{aligned}$$

then the perturbation by ϕ appearing in (5.5) does not alter the exactly reachable set $\mathcal{H}_0 \subset \mathcal{X}$ associated with the linear boundary control problem.

The case for first order boundary control is similar. Now we have $\bar{\sigma} = \frac{3}{4}$ so we can have any $q' < 4$ (corresponding to $p' > \frac{4}{3}$) by again taking p_2 of the form $M\tau^{-(1-\sigma)}$, since now $1 - \sigma$ can be arbitrarily close to $\frac{1}{4}$. Similarly, we have $q' < 4$ and again there is no new restriction on p, \bar{p} . The situation is just as for (5.9) except that now we have $\frac{4}{3} < p' < \infty$ for \mathfrak{B} . \square

Remark 5. We turn finally to consideration of settings for which the hypotheses of Theorem 2 can be verified.

The conditions (3.1)–(3.6), specifically the introduction of the space \mathcal{Y} as distinguished from \mathcal{X} , were formulated so as to permit consideration of such problems as, e.g.,

$$(5.10) \quad \dot{x} - \Delta x = \phi(\cdot, x, \nabla x) + \mathbf{B}v, \quad x|_{\partial\Omega} = 0$$

on a suitable bounded region Ω in \mathbb{R}^m . Here, we might have $\mathcal{X} \subset \mathcal{X} := L^2(\Omega)$ but wish to take $\mathcal{Y} := H_0^1(\Omega) = \mathcal{D}(\mathbf{A}^{1/2})$ to have some suitable kind of (Lipschitz) continuity for the dependence of ϕ on the state x . The point is that if we think of $\phi = \phi(\cdot, x, \xi)$ with Lipschitz continuity and sublinear (power r) growth in the pair $[x, \xi]$, then this choice of \mathcal{Y} gives

$$(5.11) \quad \begin{aligned} |\phi(\cdot, x, \nabla x)|_{\mathcal{X}} &\leq \alpha + \beta(|x|_{\mathcal{X}} + |\nabla x|_{\mathcal{X}}^r) \\ &\leq \alpha + \beta'|x|_{\mathcal{Y}}^r \end{aligned}$$

and, as in Remark 4, we use the standard semigroup estimate (for such analytic semigroups)

$$(5.12) \quad |\Psi(\tau)|_{\mathcal{X} \rightarrow \mathcal{Y}} \leq M|\mathbf{A}^{1/2}\Psi(\tau)|_{\mathcal{X} \rightarrow \mathcal{X}} \leq M\tau^{-1/2}.$$

That is (5.12) corresponds to taking $\bar{\rho}_1(\tau) = M\tau^{-1/2}$ in (4.18)(ii) which is admissible since, as we noted at (3.5)(ii), we can always take $\bar{q} = 1$. Note that if, e.g., we were to take $p = p' = 2$ then we would expect, according to Theorem 2, a solution in

$$\mathfrak{X} \cap \mathfrak{Y} = C([0, T] \rightarrow L^2(\Omega)) \cap L^2([0, T] \rightarrow H_0^1(\Omega)),$$

which is exactly the standard estimate obtainable by energy methods.⁶

Note that in writing (5.10) we do *not* necessarily assume that $\phi(\cdot, \cdot)$ is defined as a Nemytsky operator *pointwise spatially* but admit possibilities along the lines of (5.1) with the functionals $\phi_k(t, \cdot)$ uniformly continuous from \mathfrak{Y} , e.g., integral functionals over Ω involving $x, \nabla x$ suitably. Thus, the discussion of Remark 3 can contribute to the verification of (H_0) for a problem of this sort. Alternatively, if one were to take $\mathfrak{X} = \mathcal{X}$ then one would require a very strong controllability assumption to have (H_0) . \square

Appendix. As promised in footnote 4, we wish to verify the possibility of approximating ϕ as in (4.14). In view of the assumption (2.3)(ii) and the setting $\mathfrak{Y} = \mathcal{X} \rightarrow \mathcal{X}$, our task is to approximate ϕ satisfying (3.1), (4.2) by $\tilde{\phi}$ such that

$$\begin{aligned} \text{(A.1)} \quad & \text{(i)} \quad \|\phi(\cdot, x) - \tilde{\phi}(\cdot, x)\|_3 \leq \bar{\varepsilon} \quad \text{for all } x \in \mathfrak{B}_\mathfrak{Y}, \\ & \text{(ii)} \quad |\tilde{\phi}(x, \eta) - \tilde{\phi}(s, \eta')|_{\mathcal{X}} \leq C|\eta - \eta'|_{\mathcal{X}} \quad \text{for all } \eta, \eta' \in \mathcal{R}. \end{aligned}$$

Here it is given that $\mathfrak{B}_\mathfrak{Y}$ is compact in $C([0, T] \rightarrow \mathcal{X})$ so we have $x(s) \in \mathcal{R}$ for $s \in [0, T]$, $x \in \mathfrak{B}_\mathfrak{Y}$ for some compact set $\mathcal{R} \subset \mathcal{X}$; with no loss of generality, take \mathcal{R} convex. The approximation is to be possible with $\bar{\varepsilon} > 0$ in (A.1)(i) arbitrarily small; the Lipschitz constant C in (A.1)(ii) will in general depend on $\tilde{\phi}$ (i.e., on $\bar{\varepsilon}, \dots$). Note that $\phi: [0, T] \times \mathcal{X} \rightarrow \mathcal{X}$ satisfies Carathéodory conditions by (4.2) so, in particular, $\phi(s, \cdot)$ is uniformly continuous on \mathcal{R} for a.e. s —there exists $\delta(\varepsilon, s) \geq 0$ with

$$\begin{aligned} \text{(A.2)} \quad & \text{(i)} \quad |\phi(s, \eta) - \phi(s, \eta')|_{\mathcal{X}} \leq \varepsilon \quad \text{for } \eta, \eta' \in \mathcal{R}, \quad |\eta - \eta'|_{\mathcal{X}} \leq \delta(\varepsilon, s), \\ & \text{(ii)} \quad \text{meas } \mathcal{S}(\bar{\delta}) \rightarrow 0 \quad \text{as } \bar{\delta} \rightarrow 0, \quad \text{where } \mathcal{S}(\bar{\delta}) = \mathcal{S}(\bar{\delta}, \varepsilon) := \{s: \delta(\varepsilon, s) < \bar{\delta}\}. \end{aligned}$$

Since $\mathcal{S}(\bar{\delta})$ decreases with $\bar{\delta}$, (4.2) permits us to choose $\bar{\delta} = \bar{\delta}(\varepsilon)$ such that the restriction of $\phi(\cdot, x)$ to $\mathcal{S}(\bar{\delta})$ has \mathfrak{B} -norm less than ε for all (measurable) $x: [0, T] \rightarrow \mathcal{R}$; set $\mathcal{S}^c(\bar{\delta}) = [0, T] \setminus \mathcal{S}(\bar{\delta})$. Now take a finite covering of \mathcal{R} by $\delta/4$ -balls with centers $\{\eta_1, \dots, \eta_N\}$ in \mathcal{R} and set $\mathcal{R}' := \text{hull}(\eta_1, \dots, \eta_N)$. Let \mathbf{P} be a Lipschitzian retraction of \mathcal{R} to \mathcal{R}' such that $|\eta - \mathbf{P}(\eta)| \leq \bar{\delta}/2$, possible as each point of \mathcal{R} is within $\bar{\delta}/4$ of \mathcal{R}' . We may assume \mathcal{R}' can be triangulated: partitioned into simplices $\{S_j\}$ with vertices which may be taken from among $\{\eta_1, \dots, \eta_N\}$, introducing more vertices from \mathcal{R}' if necessary, such that $\text{diam } \bar{S}_j \leq \delta/2$. Now set

$$\text{(A.3)} \quad \tilde{\phi}_0(s, \eta_n) := \phi(s, \eta_n) \quad (n = 1, \dots, N') \quad \text{and } \tilde{\phi}_0(s, \cdot) \text{ piecewise linear (the "pieces" being the simplices } S_j)$$

and then define

$$\text{(A.4)} \quad \tilde{\phi}(s, \eta) := \begin{cases} \phi(x, \bar{\eta}) & \text{for } s \in \mathcal{S}(\bar{\delta}, \varepsilon) \quad (\text{using any } \bar{\eta} \text{ fixed in } \mathcal{R}'), \\ \tilde{\phi}_0(s, \mathbf{P}(\eta)) & \text{for } s \notin \mathcal{S}(\bar{\delta}, \varepsilon), \quad \eta \in \mathcal{R}. \end{cases}$$

⁶ That is, multiply by x , use the Divergence Theorem, integrate over $[0, t]$ and then apply the Gronwall Inequality. (It would also be possible to take $\mathfrak{Y} := H^1(\Omega) \cap H^{2\sigma}(\Omega)$ for any $r < 1$ since this would give $\bar{\rho}(\tau) = M\tau^{-\sigma}$ in $L^1(0, T)$ but these methods do not give the result: $x \in L^2([0, T] \rightarrow H^2(\Omega))$ which is obtainable for (5.10) by a slightly different energy method, multiplying by \dot{x} , etc.)

One can uniformly bound the Lipschitz constants for $\tilde{\phi}_0(s, \cdot)$ on each simplex S_j in view of the bound $1/\bar{\delta}$ for $\{\phi(s, \eta_n)|_x\}$ and the minimum separation of the (finitely many) points $\{\eta_n\}$. Hence this $\tilde{\phi}$ is uniformly Lipschitzian in the sense of (A.1)(ii). To see (A.1)(i), suppose $\eta \in \mathcal{R}$ and $P(\eta) \in S_j (j = j(\eta))$ where S_j has vertices $\{\eta_k\}_{j(\eta)}$. As $|\eta - P(\eta)|_x \leq \bar{\delta}/2$ and $\text{diam } S_j \leq \bar{\delta}/2$ we have $|\eta - \eta_k|_x \leq \bar{\delta}$ so (A.2)(i) gives $|\phi(s, \eta) - \tilde{\phi}_0(s, \eta_k)|_x \leq \varepsilon$ for $s \in \mathcal{S}(\bar{\delta}, \varepsilon)$ and so $|\phi(s, \eta) - \tilde{\phi}(s, \eta)|_x \leq \varepsilon$ since $\tilde{\phi}(s, \eta) \in \text{hull } \{\phi_0(s, \eta_k)\}_{j(\eta)}$ by the piecewise linearity. Thus, by the choice of $\bar{\delta}$,

$$\begin{aligned} \|\phi(\cdot, x) - \tilde{\phi}(\cdot, x)\|_3 &\leq 2\varepsilon + \left[\int_{[0, T] \setminus \mathcal{S}(\bar{\delta}, \varepsilon)} |\phi(\cdot, x) - \tilde{\phi}(\cdot, x)|^r \right]^{1/p} \\ &\leq 2\varepsilon + T^{1/p} \varepsilon \end{aligned}$$

which gives (A.1)(i) as $\varepsilon > 0$ is arbitrary. \square

DUALITY THEOREMS FOR AN OPTIMAL CONTROL PROBLEM WITH A LINEAR UNBOUNDED OPERATOR*

H. DIETRICH†

Abstract. The present paper applies the duality theory of Fenchel and Rockafellar to problems of optimal control with a linear operator-type equation and with a linear unbounded operator. If the linear operator is everywhere densely defined and closed, we can prove duality theorems and conditions for optimality. The results are applied to optimal control problems for systems with concentrated and distributed parameters.

Key words. duality theory, optimal control theory

AMOS(MOS) subject classification. 49A55, 49B27

1. Introduction and statement of the problem. Throughout this paper B_i , $i = 1, 2, 3$, will denote real reflexive Banach spaces with the dual spaces B_i^* . As usual, $\langle \cdot, \cdot \rangle_i$ will denote the canonical pairing between B_i and B_i^* , $i = 1, 2, 3$.

For the product space $B_1 \times B_2 \times B_3$ with the dual $B_1^* \times B_2^* \times B_3^*$ we define the canonical pairing by

$$\langle \cdot, \cdot \rangle_{1 \times 2 \times 3} = \langle \cdot, \cdot \rangle_1 + \langle \cdot, \cdot \rangle_2 + \langle \cdot, \cdot \rangle_3.$$

Furthermore let $\bar{R} := R \cup \{-\infty\} \cup \{+\infty\}$.

Many papers use the duality theory of Fenchel and Rockafellar for investigation of optimal control problems for distributed parameter systems (Lions [10], Ekeland and Temam [5], Barbu and Precupanu [2], Heins and Mitter [7], Mackenroth [11], [12], Mossino [13], Outrata [14]).

In the functional analytical description of such problems it is usual to choose the corresponding spaces of functions, for example as Sobolev spaces, so that the differential operators are continuous on the whole space. It is known that various differential operators can be unbounded. Under suitable assumptions on the unbounded operator we can use the duality theory of Fenchel and Rockafellar for investigation of such optimal control problems with an unbounded linear operator in the equation of state. We consider the following primal problem (P) of optimal control with a linear operator-type equation of state

$$(1.1) \quad \inf(P) := \inf \left\{ G(y, u) \left| \begin{array}{l} Ay + Bu + f = 0 \\ y \in D(A) \cap X, u \in U \end{array} \right. \right\}$$

where we let the cost function $G \in (B_1 \times B_2 \rightarrow \bar{R})$ be a real proper convex and lower semicontinuous function; let X or U , respectively, be a nonempty closed and convex set in B_1 or B_2 ; let $f \in B_3$ be a given element; let $B \in L(B_2, B_3)$ be a linear and continuous operator on B_2 and let the linear unbounded operator $A \in (B_1 \rightarrow B_3)$ in B_1 have an everywhere dense domain $D(A) \subset B_1$.

*Received by the editors February 2, 1984; accepted for publication (in revised form) June 25, 1986.

We assume that there exists an element $(y, u) \in (X \cap D(A)) \times U$ with $(y, u) \in \text{dom } G$ (the effective domain on the function G) and $Ay + Bu + f = 0$. Therefore for problem (1.1) $\inf(P) < +\infty$ is valid.

We interpret the variable y as variable of state, the variable u as variable of control.

The main objectives of this paper are the following:

- (i) To present a dual problem by duality theory according to Fenchel and Rockafellar's formalism;
- (ii) To show the duality relations and the necessary and sufficient conditions of optimality if certain conditions are given for G, A, B, X and U ;
- (iii) To show a lower bound for $\inf(P)$ by means of the dual problem;
- (iv) To show how the duality theory may be applied to certain control processes described by linear ordinary and partial differential equations and to quadratic and norm-minimal problems of optimal control.

This paper presents a new form of the dual problem different from works of Lions [10], Mossino [13], Mackenroth [11], [12] and Outrata [14] and is a generalization of known results on linear unbounded and closed operators A . This generalization is founded on the paper by Rockafellar [15].

2. The dual problem (D) and the relations between (P) and (D). If the primal minimization problem (1.1) is given, we consider a family of perturbed minimization problems

$$(2.1) \quad \varphi(x, v, w) = \inf_{y, u} F(y, u, x, v, w)$$

with

$$(2.2) \quad F(y, u, x, v, w) = G(y + x, u + v) + \delta((y, u, w) | K), \quad x \in B_1, v \in B_2, w \in B_3$$

and

$$K = \left\{ (y, u, w) \in B_1 \times B_2 \times B_3 \left| \begin{array}{l} Ay + Bu + f + w = 0 \\ y \in D(A) \cap X, u \in U \end{array} \right. \right\}$$

where $\delta(\cdot | K)$ is the indicator function of K .

The initial problem (P) corresponds to the value $(x, v, w) = (0, 0, 0)$. By means of the theory of Rockafellar in [15] (see also Ekeland and Temam [5]) we can derive the following dual problem (D) by introducing appropriate perturbations of (P) in (2.1) and (2.2). In the sense of convex analysis we introduce the support function of the sets $X \subset B_1$ and $U \subset B_2$ and we denote them by σ_X and σ_U , where for example

$$\sigma_X(y^*) = \sup_{y \in X} \langle y^*, y \rangle_1$$

holds.

THEOREM 1. *If A is a linear, everywhere densely defined and closed operator, the dual problem (D) of (P) is*

$$(2.3) \quad \sup(D) := \sup \left\{ \langle f, w^* \rangle_3 - G^*(x^*, v^*) - \sigma_X(-x^* - A^* w^*) - \sigma_U(-v^* - B^* w^*) \left| \begin{array}{l} x^* \in B_1^*, v^* \in B_2^* \\ w^* \in D(A^*) \end{array} \right. \right\}$$

and $\sup(D) \leq \inf(P)$ is valid.

In formula (2.3) G^* means the conjugate function of G , and A^* , or B^* , respectively, means the adjoint operator of A , or B .

Proof. A simple calculation shows that the conjugate function F^* of F from (2.2) is of the form

$$F^*(y^*, u^*, x^*, v^*, w^*) = -\langle f, w^* \rangle_3 + G^*(x^*, v^*) - \inf_{u \in U} \langle u, v^* - u^* + B^* w^* \rangle_2 \\ - \inf_{y \in D(A) \cap X} [\langle y, x^* - y^* \rangle_1 + \langle Ay, w^* \rangle_3].$$

Since the linear unbounded operator A is an everywhere densely defined and closed operator, it follows that

$$(2.4) \quad F^* = \begin{cases} -\langle f, w^* \rangle_3 + G^*(x^*, v^*) + \sigma_X(-x^* + y^* - A^* w^*) \\ + \sigma_U(-v^* + u^* - B^* w^*) & \text{if } w^* \in D(A^*), \\ +\infty & \text{otherwise,} \end{cases} \quad y^*, x^* \in B_1^*, \quad u^*, v^* \in B_2^*$$

and therefore we obtain (2.3) with $\sup(D) \leq \inf(P)$.

Remark 1. The case $A \in L(B_1, B_3)$ is contained in Theorem 1.

Remark 2. If the operator A is not closed, duality gaps can occur, independent of the properties of G, B, X and U . The following theorems show that for a closed operator A and certain conditions on G, B, X and U duality relations are valid.

The dual problem (2.3) is a problem of optimization without restrictions if the sets X and U are bounded. In contrast to recent papers, (2.3) does not contain the adjoint equation to $Ay + Bu + f = 0$ explicitly.

THEOREM 2. Let $G(y, u)$ be bounded below and continuous at (\bar{y}, \bar{u}) . If one of the following conditions (i) or (ii) is valid:

(i) There exists the inverse operator A^{-1} of A which is continuous on $R(A)$ (the range of A), for every $u \in U$ we have $Bu + f \in R(A)$; furthermore, there exist elements $\bar{y} \in D(A) \cap \text{int } X$ and $\bar{u} \in U$ such that $A\bar{y} + B\bar{u} + f = 0$ is valid.

(ii) The inverse operator B^{-1} of B is continuous on $R(B)$, for every $y \in D(A) \cap X$ we have $Ay + f \in R(B)$, and there exist elements $\bar{y} \in D(A) \cap X$ and $\bar{u} \in \text{int } U$ such that $A\bar{y} + B\bar{u} + f = 0$ is valid. Then the duality relation

$$\inf(P) = \max(D)$$

is true.

Proof. We prove (i); then the proof of (ii) is analogous. We show the subdifferentiability of $\varphi(x, v, w)$ at $(0, 0, 0)$ (see [15, Thms. 16, 17]). $\varphi(x, v, w)$ defined by (2.1) is proper convex. We have $\varphi(x, v, w) \leq G(A^{-1}w + A^{-1}(-B\bar{u} - f) + x, \bar{u} + v) =: g(x, v, w)$ for every $(x, v, w) \in V$ where V is a neighborhood of zero in $B_1 \times B_2 \times R(A)$. A is closed and A^{-1} is continuous, and this implies $R(A) \subset B_3$ is a closed subspace of B_3 .

Since $g(x, v, w)$ under the given assumptions is bounded above on a neighborhood of $(0, 0, 0)$ we have the subdifferentiability of $\varphi(x, v, w)$ at $(0, 0, 0)$.

LEMMA 1. If one of the following conditions (i)-(iv) is valid, the primal problem (P) possesses an optimal solution:

(i) X and U are bounded.

(ii) $G(y, u)$ is coercive on the set K_0 , where

$$K_0 = \left\{ (y, u) \in B_1 \times B_2 \left| \begin{array}{l} Ay + Bu + f = 0 \\ y \in D(A) \cap X, u \in U \end{array} \right. \right\}.$$

(iii) U is a bounded set and for every $u \in U$ we have $Bu + f \in R(A)$. The operator A^{-1} is continuous on $R(A)$.

(iv) X is a bounded set and for every $y \in D(A) \cap X$ we have $Ay + f \in R(B)$. The operator B^{-1} is continuous on $R(B)$.

The proof of this lemma follows from [5, Chap. II, Prop. 1.2]. In the following we show the duality relation:

$$(2.5) \quad \min (P) = \sup (D).$$

THEOREM 3. *If one of the following conditions is valid, the duality relation (2.5) holds:*

- (i) X and U are bounded sets.
- (ii) There exists an element $w^* \in D(A^*)$ with $(-A^*w^*, -B^*w^*) \in \text{int}(\text{dom } G^*)$.
- (iii) The set U is bounded and there exists an element $w^* \in D(A^*)$ such that $G^*(y^*, u^*)$ is continuous relative to the variable y^* in a neighborhood $V(-A^*w^*)$ of the element $-A^*w^*$ and for any fixed element $u^* = v^* \in B_2^*$, where $(y^*, v^*) \in \text{dom } G^*$ with $y^* \in V(-A^*w^*)$ holds.
- (iv) The set X is bounded and there exists an element $w^* \in D(A^*)$ such that $G^*(y^*, u^*)$ is continuous relative to the variable u^* in a neighborhood $V(-B^*w^*)$ of the element $-B^*w^*$ and for any fixed element $y^* = x^* \in B_1^*$, where $(x^*, u^*) \in \text{dom } G^*$ with $u^* \in V(-B^*w^*)$ holds.

To prove this theorem we apply [15, Thms. 16', 17']. A is a closed operator and this implies that the set K (2.2) is a closed set in $B_1 \times B_2 \times B_3$, and therefore the function F (2.2) is proper convex and lower semicontinuous. Analogous to the proof of Theorem 2, we can show the subdifferentiability of the perturbed function $\psi(y^*, u^*)$ of the dual problem

$$(2.6) \quad \Psi(y^*, u^*) = \sup \left\{ -F^*(y^*, u^*, x^*, v^*, w^*) \mid \begin{array}{l} x^* \in B_1^*, v^* \in B_2^* \\ w^* \in D(A^*) \end{array} \right\}$$

at $(y^*, u^*) = (0, 0)$ for the conditions (i)-(iv).

3. Conditions for optimality and the lower bound for $\inf (P)$. The duality relations $\inf (P) = \max (D)$, or $\min (P) = \sup (D)$, respectively, imply necessary and sufficient conditions for optimal solutions of primal or dual problems. An element (y, u) is called admissible for the primal problem if $(y, u) \in (D(A) \cap X) \times U$, $(y, u) \in \text{dom } G$ and $Ay + Bu + f = 0$ hold. An element $(x^*, v^*, w^*) \in \text{dom } F^*(0, 0, x^*, v^*, w^*)$ is called admissible for the dual problem.

With this notation we can show the following theorems.

THEOREM 4. *Let $\inf (P) = \max (D)$, and let (y_0, u_0) be admissible for the primal problem. Then (y_0, u_0) is an optimal solution of (P) if and only if there exists an element (x_0^*, v_0^*, w_0^*) admissible for (D) such that*

$$(3.1) \quad \begin{aligned} (x_0^*, v_0^*) &\in \partial G(y_0, u_0), \\ \langle y - y_0, x_0^* + A^*w_0^* \rangle_1 &\geq 0 \quad \forall y \in X, \\ \langle u - u_0, v_0^* + B^*w_0^* \rangle_2 &\geq 0 \quad \forall u \in U \end{aligned}$$

is valid.

THEOREM 5. *Let $\min (P) = \sup (D)$ and let (x_0^*, v_0^*, w_0^*) be admissible for the dual problem. Then (x_0^*, v_0^*, w_0^*) is an optimal solution of (D) if and only if there exists an admissible element (y_0, u_0) for (P) such that (3.1) is valid.*

The proofs of Theorem 4, or Theorem 5, respectively, follow from [15, Thm. 16 or Thm. 16']. For $X = B_1$ and $U = B_2$ the dual problem (2.3) is of the form

$$(3.2) \quad \sup (D) = \sup \{ \langle f, w^* \rangle_3 - G^*(-A^*w^*, -B^*w^*) \mid w^* \in D(A^*) \}.$$

Since the operator A is closed, it follows that the domain $D(A^*)$ of the adjoint operator A^* to A is everywhere densely defined in B_3^* . By

$$(3.3) \quad L(y, u) = -Ay - Bu$$

we define an everywhere densely defined linear and closed operator $L \in (B_1 \times B_2 \rightarrow B_3)$ with the domain $D(L) = D(A) \times B_2$. The adjoint operator $L^* \in (B_3^* \rightarrow B_1^* \times B_2^*)$ is

$$(3.4) \quad L^*w^* = (-A^*w^*, -B^*w^*), \quad w^* \in D(A^*) = D(L^*)$$

and we can write the dual problem (3.2) in the form

$$(3.5) \quad \sup (D) = \sup \{ \langle f, w^* \rangle_3 - G^*(L^*w^*) \mid w^* \in D(A^*) \}.$$

Let the function G^* be continuous in a point of image of the operator L^* . By [15, Thm. 19(i)] and Theorems 3 and 5 above, it follows that an element $w_0^* \in D(A^*)$ is an optimal solution of (D) if and only if

$$(3.6) \quad f \in L\partial G^*(L^*w_0^*)$$

is valid.

If we denote by $G^{*'}(y^*, u^*)$ the Gâteaux-derivative of the function $G^*(y^*, u^*)$, the following formula for a lower bound of $\inf (P)$ holds.

LEMMA 2. *Let G^* be continuous in a point of $R(L^*)$, and let $G^{*'}(y^*, u^*)$ be strongly monotone and Lipschitz continuous on $R(L^*)$. Let the dual problem (3.5) have an optimal solution. Then the formula*

$$(3.7) \quad \min (P) \geq \langle f, w^* \rangle_3 - G^*(L^*w^*) + \frac{m}{2M^2} \frac{\langle LG^{*'}(L^*w^*) - f, w^* \rangle_3^2}{\|L^*w^*\|_{1^* \times 2^*}^2}$$

holds for every $w^* \in D(A^*)$ with $L^*w^* \neq 0$ and $G^{*'}(L^*w^*) \in D(L)$, where $M > 0$ is the Lipschitz constant and $m > 0$ is the constant of the strong monotonicity of $G^{*'}$.

Proof. Analogous to [6] we can show that the following inequality holds

$$G^*(x^*) - G^*(y^*) \geq \langle G^{*'}(y^*), x^* - y^* \rangle_{1 \times 2} + \frac{m}{2} \|x^* - y^*\|_{1^* \times 2^*}^2.$$

For $x^* = L^*w^*$ and $y^* = L^*w_0^*$, where w_0^* is an optimal solution of (D), the lower bound (3.7) follows from this inequality and the Lipschitz continuity of $G^{*'}$.

In most cases lower bounds for optimal control problems are constructed for quadratic and norm-minimal problems of optimal control (Yavin [17], Benker [3], Chan and Ho [4]). The lower bound (3.7) complements the known results.

4. Application to quadratic and norm-minimal optimal control problems. We consider the following optimal control problem

$$(4.1) \quad \inf (P) = \inf \left\{ \frac{1}{2} \|y - R\|_1^2 + \frac{k}{2} \|u\|_2^2 \mid \begin{array}{l} Ay + Bu + f = 0 \\ y \in D(A) \cap X, u \in U \end{array} \right\}$$

with $k > 0$. Let $B_i = B_i^* = H_i$, $i = 1, 2, 3$, be Hilbert spaces. Let $R \in H_1$ be a given element and let the assumptions of § 1 be valid. Following § 2, we can immediately write a dual problem to (4.1). The form of the dual problem is, to a certain degree, dependent on the kind of perturbation in the primal problem. Through a suitable perturbation of the primal problem (4.1), which considers the specific structure of (4.1), in the following we obtain a convenient dual problem different from the dual problem of

(4.1) based on (2.3). We define the following perturbed function of the primal problem (4.1):

$$(4.2) \quad \varphi(w) = \inf_{y,u} \left[\frac{1}{2} \|y - R\|_1^2 + \frac{k}{2} \|u\|_2^2 + \delta((y, u, w) | K) \right]$$

with K as in (2.2).

If A is a linear everywhere densely defined and closed operator, the dual problem related to (4.1) is

$$(4.3) \quad \sup(D) = \sup_{w^* \in D(A^*)} g(w^*)$$

with

$$g(w^*) = \langle f, w^* \rangle_3 + \frac{1}{2} \|(I - P_X)(R - A^*w^*)\|_1^2 - \frac{1}{2} \|R - A^*w^*\|_1^2 + \frac{1}{2} \|R\|_1^2 \\ + \frac{k}{2} \left\| (I - P_U) \left(\frac{-1}{k} B^*w^* \right) \right\|_2^2 - \frac{1}{2k} \|B^*w^*\|_2^2$$

(I is the identic operator; P_X , or P_U , respectively, is the operator of the projection in the Hilbert space H_1 or H_2 on the set X or U). We can show the following duality theorem analogous to Theorem 3 using [15, Thm. 19(i)].

THEOREM 6. *It is always true that $\min(P) = \sup(D)$. The dual cost function $g(w^*)$ is subdifferentiable for every $w^* \in D(A^*)$ with $P_X(R - A^*w^*) \in D(A)$, with*

$$(4.4) \quad \partial g(w^*) = \left\{ AP_X(R - A^*w^*) + BP_U \left(\frac{-1}{k} B^*w^* \right) + f \right\}.$$

If for a $w^* \in D(A^*)$ we have $P_X(R - A^*w^*) \notin D(A)$, then we have $\partial g(w^*) = \emptyset$.

An element $w_0^* \in D(A^*)$ is an optimal solution of (D) if and only if

$$(4.5) \quad AP_X(R - A^*w_0^*) + BP_U \left(\frac{-1}{k} B^*w_0^* \right) + f = 0$$

holds. The element (y_0, u_0) with $y_0 = P_X(R - A^*w_0^*)$ and $u_0 = P_U(-1/k B^*w_0^*)$ is the optimal solution of (4.1).

Remark 3. If the operator $A \in L(H_1, H_3)$ is a linear and continuous operator on H_1 the cost function $g(w^*)$ of the dual problem (4.3) is Fréchet-differentiable for every $w^* \in D(A^*) = H_3$, since by Holmes [8] the function

$$f(\cdot) = \frac{1}{2} \|(I - P)(\cdot)\|^2,$$

possesses the Fréchet-derivative

$$f'(\cdot) = (I - P)(\cdot)$$

where P is the operator of projection on a convex and closed set in a Hilbert space.

The remaining results of §§ 2 and 3 are transferable to problem (4.1).

Next we consider the following problem of optimal control, which is equivalent to a norm-minimal control problem

$$(4.6) \quad \inf(P) = \inf \left\{ \frac{1}{2} \|Cy - R\|_4^2 \mid \begin{array}{l} Ay + Bu + f = 0 \\ y \in D(A) \cap X, u \in U \end{array} \right\}$$

where the assumptions of § 1 are valid and A is a linear everywhere densely defined and closed operator. Let B_4 be a real reflexive Banach space (a space of observation)

with the dual B_4^* , let $R \in B_4$ be a given element and let $C \in L(B_1, B_4)$. As a perturbed function of the problem (4.6), we define

$$(4.7) \quad \varphi(x, w) = \inf_{y, u} \left[\frac{1}{2} \|Cy + x - R\|_4^2 + \delta((y, u, w)|K) \right]$$

with K as in (2.2). Then we obtain for the dual problem to (4.6)

$$(4.8) \quad \sup(D) = \sup \left\{ \langle f, w^* \rangle_3 - \frac{1}{2} \|x^*\|_{4^*}^2 - \langle R, x^* \rangle_4 - \sigma_U(-B^*w^*) - \sigma_X(-C^*x^* - A^*w^*) \mid \begin{array}{l} x^* \in B_4^* \\ w^* \in D(A^*) \end{array} \right\}.$$

The results of §§ 2 and 3 are transferable to problem (4.6). For example, if $\inf(P) = \max(D)$ holds, we obtain the following as necessary and sufficient conditions for the optimality of an admissible element (y_0, u_0) for (P): (y_0, u_0) is the optimal solution of (P) if and only if there exists an element (x_0^*, w_0^*) admissible for (D) such that

$$(4.9) \quad \begin{aligned} -x_0^* &\in J(Cy_0 - R), \\ \langle y - y_0, C^*x_0^* + A^*w_0^* \rangle_1 &\geq 0 \quad \forall y \in X, \\ \langle u - u_0, B^*w_0^* \rangle_2 &\geq 0 \quad \forall u \in U \end{aligned}$$

is valid, where $J \in (B_4 \rightarrow 2^{B_4^*})$ is the duality mapping of B_4 .

5. Application to control processes described by linear ordinary and partial differential equations. First we consider an optimal control problem for a Cauchy problem with an ordinary differential operator of the second order: the operator $A \in L_2(0, 1) \rightarrow L_2(0, 1)$ given by

$$Ay(x) = p_0(x) \cdot y''(x) + p_1(x) \cdot y'(x) + p_2(x) \cdot y(x)$$

with the domain

$$(5.1) \quad D(A) = \left\{ y(x) \in L_2(0, 1) \mid \begin{array}{l} y' \text{ is absolutely continuous on } (0, 1) \\ y'' \in L_2(0, 1), y(0) = y'(0) = 0 \end{array} \right\}$$

where $p_i(x)$; $i = 0, 1, 2$ are real functions on $[0, 1]$ such that $p_0''(x)$, $p_1'(x)$ and $p_2(x)$ are continuous on $[0, 1]$ and $p_0(x) < 0$ for every $x \in [0, 1]$. A is a linear unbounded everywhere densely defined and closed operator in $L_2(0, 1)$ (see [9, Chap. III, §2.3]). The inverse operator A^{-1} exists on $R(A) = L_2(0, 1)$ and is continuous. Now we can apply the above results. In particular, we choose in (4.1): $H_1 = H_2 = H_3 = L_2(0, 1)$, $B = -I$, $f(x) = 0$, $R(x) = 1$, $k = 1$, $Ay(x) = -y''(x) + y'(x) + y(x)$ with $D(A)$ by (5.1). Then the dual problem related to this problem is of the form

$$(5.2) \quad \sup_{w^* \in D(A^*)} \left[\frac{1}{2} \int_0^1 [(I - P_X)(1 + w^{*''} + w^{*'} - w^*)]^2 dx + \frac{1}{2} \int_0^1 [(I - P_U)w^*]^2 dx + \frac{1}{2} \int_0^1 (1 - (1 + w^{*''} + w^{*'} - w^*)^2 - w^{*2}) dx \right]$$

where $A^*w^* = -w^{*''} - w^{*'} + w^*$, $A^* \in (L_2(0, 1) \rightarrow L_2(0, 1))$ with

$$D(A^*) = \left\{ w^* \in L_2(0, 1) \mid \begin{array}{l} w^{*'} \text{ is absolutely continuous on } (0, 1) \\ w^{*''} \in L_2(0, 1), w^*(1) = w^{*'}(1) = 0 \end{array} \right\}$$

for any convex and closed set X and U in $L_2(0, 1)$. Always

$$\min (P) = \sup (D).$$

For $X = U = L_2(0, 1)$ it follows from (4.5) for the optimal solution $w_0^*(x)$ of (D) that

$$w_0^{*(4)}(x) - 3 \cdot w_0^{*(2)}(x) + 2 \cdot w_0^*(x) = 1$$

with the conditions

$$\begin{aligned} w_0^*(1) = w_0^{*'}(1) = 0, \quad 1 + w_0^{*(2)}(0) + w_0^{*'}(0) - w_0^*(0) &= 0, \\ w_0^{*(3)}(0) + w_0^{*(2)}(0) - w_0^{*'}(0) &= 0. \end{aligned}$$

The system has a unique solution $w_0^*(x)$.

Next we consider an optimal control problem for a class of homogeneous boundary value problems of Dirichlet.

Let $G \subset R^n$ be a bounded open domain with boundary Γ . We consider the differential operator $E \in (L_2(G) \rightarrow L_2(G))$ given by

$$Ey(x) = - \sum_{i,j=1}^n \frac{\partial}{\partial x_i} \left[a_{ij}(x) \frac{\partial y(x)}{\partial x_j} \right] + c(x) \cdot y(x)$$

with $D(E) = C_0^\infty(G)$. Let $a_{ij}(x) = a_{ji}(x)$, $i, j = 1, 2, \dots, n$, and let $c(x) \geq 0$ be real functions from $\bar{C}^\infty(G)$ with

$$(5.3) \quad \sum_{i,j=1}^n a_{ij}(x) \cdot d_i \cdot d_j \geq \beta \sum_{i=1}^n d_i^2 \quad \forall x \in G,$$

$$\forall d = (d_1, d_2, \dots, d_n) \in R^n \quad \text{and} \quad \beta > 0.$$

The operator $A \in (L_2(G) \rightarrow L_2(G))$ with

$$(5.4) \quad D(A) = \left\{ y(x) \in \dot{W}_2^1(G) \left| - \sum_{i,j=1}^n \frac{\partial}{\partial x_i} \left[a_{ij}(x) \frac{\partial y(x)}{\partial x_j} \right] + c(x)y(x) \in L_2(G) \right. \right\}$$

is the extension by Friedrichs of the operator E (see [16, Satz 17.11, Satz 29.1]). A is a linear unbounded everywhere densely defined and closed operator, which is self adjoint, and because of (5.3) is strongly monotone. The operator A^{-1} is continuous on $R(A) = L_2(G)$. Therefore the above results are applicable.

To illustrate the application of the results, we consider a special example. We choose the following Dirichlet problem:

$$\begin{aligned} -\Delta y + y + u + f &= 0 \quad \text{in } G, \\ y &= 0 \quad \text{on } \Gamma \end{aligned}$$

with the operator $A = I - \Delta$, and $D(A)$ according to (5.4). Let $f \in L_2(G)$ be a given element, and, for example, consider the quadratic control problem (4.1).

Then we have $B = I$, $H_i = L_2(G)$, $i = 1, 2, 3$, $X \subset L_2(G)$ and $U \subset L_2(G)$. The dual problem (4.3) is of the form

$$\begin{aligned} \sup_{w^* \in D(A)} & \left[\int_G \left[f \cdot w^* + R(I - \Delta)w^* - \frac{1}{2}((I - \Delta)w^*)^2 - \frac{1}{2k} w^{*2} \right] dx \right. \\ & \left. + \frac{1}{2} \int_G \left(\left[(I - P_X)(R + \Delta w^* - w^*) \right]^2 + k \left[(I - P_U) \left(-\frac{w^*}{k} \right) \right]^2 \right) dx \right]. \end{aligned}$$

Finally we will apply the formula for the lower bound to this problem. In formula (3.7) we choose

$$G(y, u) = \frac{1}{2} \|y - R\|_1^2 + \frac{k}{2} \|u\|_2^2,$$

$k = 1$, $f = 0$, $R = 4$, the domain $G \subset \mathbb{R}^2$ as a circle of unit radius with the center at the origin and

$$w^*(x) = 1 - x_1^2 - x_2^2 \in D(I - \Delta).$$

Then we have $m = M = 1$, the condition

$$G^{*'}(L^* w^*) = \begin{pmatrix} -A^* w^* + R \\ -\frac{1}{k} B^* w^* \end{pmatrix} \in D(L)$$

is valid, and we obtain

$$25.133 > 8\pi = G(0, 0) \geq \min(P) \geq \frac{243\pi}{31} > 24.626.$$

Analogously we can solve other problems of optimal control, in particular for homogeneous and inhomogeneous problems of Dirichlet and Neumann or problems with parabolic equations.

The advantage of using a linear unbounded operator consists of the possibility that for a boundary value problem we can choose a suitable simple space, because the differential operator A is only defined on an everywhere dense subspace. On the other hand, the dual problem acquires a complicated form because of the unboundedness of the operator. This we can see in the dual of the quadratic control problem (4.3), where the Fréchet-differentiability of the cost function $g(w^*)$ for the dual problem disappears.

MODULAR FEEDBACK LOGIC FOR DISCRETE EVENT SYSTEMS*

P. J. RAMADGE† AND W. M. WONHAM‡

Abstract. We examine a modular approach to the synthesis of state feedback controls for the problem of maintaining a predicate on the state set of a discrete dynamic system invariant. Dynamical systems are modeled by automata together with a mechanism for enabling and disabling a subset of state transitions. The basic problem of interest is to ensure by appropriate control action that a given predicate on the state set of the process remains invariantly true whenever it is initially satisfied. Assuming the predicate can be decomposed into the conjunction or disjunction of component predicates, we determine conditions under which it is possible to synthesize the appropriate control in a modular fashion.

Key words. discrete event systems, modular control, supervisory control

AMS(MOS) subject classification. 93

1. Introduction. We examine a modular approach to the synthesis of state feedback controls for the problem of maintaining a predicate on the state set of a discrete dynamic system invariant. Our setting is the supervisory control framework developed in [6], [9].

The concept of modular control synthesis for discrete-event processes was first suggested and partially investigated in [5]. Some early work on this topic has also been reported in [10]. This paper is intended to be the first part of a comprehensive study of modular control synthesis in the supervisory control framework. Here we concentrate on nondynamic controls, i.e., state feedback. The basic control problem of interest is to ensure by appropriate control action that a given predicate P on the state set of the process remains invariantly true whenever it is initially satisfied. Assuming the predicate P can be decomposed into the conjunction or disjunction of component predicates, we determine conditions under which it is possible to synthesize the appropriate control in a modular fashion. Our investigation of modular synthesis is continued in a companion paper [5] where we examine the modular synthesis of supervisors, i.e., dynamic controllers, to achieve specified closed loop output behaviors.

The paper is organized as follows. In §§ 2–6 we review the basic supervisory control framework as well as introduce the concepts and definitions needed later in the paper. Section 7 contains the main results on the modular synthesis of feedback controls while § 8 deals with the modular determination of extremal control-invariant predicates. In § 9 we present two simple examples.

2. Controlled discrete event processes. We recall the basic definition of a controlled discrete-event process. For a more detailed discussion of this model the reader is referred to [7]. Descriptions of similar models for discrete-event systems can also be found in [3] and [1].

Let

$$G = (\Sigma, Q, \delta, q_0)$$

be an automaton. Here Q is the set of states, q_0 is the initial state, Σ is a finite set of output symbols, and $\delta: \Sigma \times Q \rightarrow Q$ (in general a partial function) is the state transition function.¹

We interpret G as a device that starts in the state q_0 and generates a sequence of events, i.e. state transitions, subject to the range of transitions permitted by the function δ . Each event is assumed to occur spontaneously, asynchronously and instantaneously, and to result in an output from the set Σ . Note that this is a nonstandard interpretation of the automaton structure.

To adjoin a control mechanism to G , we designate a subset $\Sigma_c \subseteq \Sigma$ of controllable events and set $\Sigma_u = \Sigma - \Sigma_c$. Control consists of specifying for each controllable event whether it is *enabled* (permitted to occur) or *disabled* (prevented from occurring). The set of *control patterns* for G is defined to be

$$\Gamma = \{\gamma: \gamma: \Sigma \rightarrow \{0, 1\} \text{ and } \gamma(\sigma) = 1 \text{ for each } \sigma \in \Sigma_u\}.$$

Events labeled by $\sigma \in \Sigma$ are enabled by γ if $\gamma(\sigma) = 1$, and disabled by γ if $\gamma(\sigma) = 0$.

The extended process

$$G_c = (\Gamma \times \Sigma, Q, \delta_c, q_0)$$

with

$$\delta_c(\gamma, \sigma, q) = \begin{cases} \delta(\sigma, q) & \text{if } \gamma(\sigma) = 1, \\ \text{undefined} & \text{otherwise} \end{cases}$$

is called a *Controlled Discrete-Event Process* (CDEP). It is identical to the original process, and hence carries the same information, except that the control mechanism is now explicitly displayed.

In this paper we make extensive use of the algebraic structure of the set Γ . For each $\gamma_1, \gamma_2 \in \Gamma$ and each $\sigma \in \Sigma$ define

$$\begin{aligned} (\sim \gamma)(\sigma) &= \begin{cases} \sim \gamma(\sigma) & \text{if } \sigma \in \Sigma_c, \\ 1 & \text{otherwise,} \end{cases} \\ (\gamma_1 \wedge \gamma_2)(\sigma) &= \begin{cases} \gamma_1(\sigma) \wedge \gamma_2(\sigma) & \text{if } \sigma \in \Sigma_c, \\ 1 & \text{otherwise,} \end{cases} \\ \gamma_1 \vee \gamma_2 &= \sim((\sim \gamma_1) \wedge (\sim \gamma_2)). \end{aligned}$$

It is then readily shown that $(\Gamma; \sim, \wedge, \vee)$ is a Boolean algebra. Indeed it is clear that Γ is isomorphic to the family of subsets of Σ_c .

3. Example. A simple workstation in a manufacturing system is modeled by the following CDEP:

¹ In some situations it is convenient to add to the definition of G a subset $Q_m \subseteq Q$ of marker states, see e.g. [7]. However, this is not needed here.

In this diagram each state represents an activity, while transitions between states, i.e., events, represent the completion of one activity and the start of another. In the initial state I the machine is idle, in state F it is fetching a part from its input buffer, in state W it is working, and in state D it is depositing a part in its output buffer. These constitute the normal modes of machine operation. In state X the machine is broken down and awaits repair. Each state transition is labeled by its corresponding output.

In the notation of § 2 we have

$$Q = \{I, F, W, D, X\}, \quad \Sigma = \{a, b, c, d, f, r\}, \quad q_0 = I,$$

and the state transition function δ is displayed in the above graph.

Certain events are deemed controllable. Usually these are selected, subject to cost and feasibility constraints,² by the machine designer. If

$$\Sigma_c = \{a, c, r\}$$

then the machine's access to its input and output buffers and its repair can all be controlled. A control pattern simply consists of a specification of which events in Σ_c are enabled (i.e., permitted to occur), e.g., a and c but not r .

4. Predicates. Define a (unary) *predicate* on the nonempty set Q to be a function $P: Q \rightarrow \{0, 1\}$, i.e., a characteristic function on Q . Let \mathcal{P} denote the family of all predicates on Q , and define the operators \sim (*negation*), \wedge (*conjunction*), and \vee (*disjunction*) on \mathcal{P} by

$$\begin{aligned} (\sim P)(q) &= 1 \text{ iff } P(q) = 0, \\ (P_1 \wedge P_2)(q) &= 1 \text{ iff } P_1(q) = 1 \text{ and } P_2(q) = 1, \\ P_1 \vee P_2 &= \sim((\sim P_1) \wedge (\sim P_2)). \end{aligned}$$

\mathcal{P} together with the above operators forms a Boolean algebra. Indeed under the correspondence

$$P \leftrightarrow Q_P = \{q: q \in Q \text{ and } P(q) = 1\}$$

\mathcal{P} is isomorphic to the Boolean algebra of all subsets of Q . Thus in what follows the terms "predicate" and "subset" can be interchanged without essential loss.

Other operators on \mathcal{P} can be defined in terms of \wedge , \vee , and \sim . For example, *implication* is defined for each P_1 and $P_2 \in \mathcal{P}$ by

$$P_1 \Rightarrow P_2 = \sim P_1 \vee P_2.$$

We say that P is *true* at q if $P(q) = 1$, and *false* at q if $P(q) = 0$. Let 1 denote the predicate on Q which is true at all $q \in Q$, i.e., $1(q) = 1$, for each $q \in Q$, and 0 denote the predicate which is false at all $q \in Q$ (corresponding to the subsets Q and \emptyset , respectively).

Let P_1 , P_2 and P be predicates on Q . We say that P_1 and P_2 are equivalent *relative to* P , written $P_1 = P_2(\text{rel } P)$, if $P_1 \wedge P = P_2 \wedge P$. It is a straightforward matter to show that equivalence *rel* P is a congruence on the Boolean algebra \mathcal{P} .

The standard partial order on \mathcal{P} is defined by

$$P_1 \leq P_2 \quad \text{iff } P_1 \wedge P_2 = P_1.$$

Equivalently,

$$P_1 \leq P_2 \quad \text{iff } P_2 = 1(\text{rel } P_1) \quad \text{iff } (P_1 \Rightarrow P_2) = 1.$$

² For example, machine breakdown is always uncontrollable.

With respect to this partial order $P_1 \wedge P_2$ is the greatest lower bound and $P_1 \vee P_2$ the least upper bound of P_1 and P_2 . Each nonempty subset $U \subseteq \mathcal{P}$ has a unique greatest lower bound and a unique least upper bound in \mathcal{P} . These predicates are denoted $\inf U$ (or $\wedge U$) and $\sup U$ (or $\vee U$), respectively. Similarly each monotone sequence $\{P_j\}$ of predicates on Q has a limit in \mathcal{P} . For example, if $P_j \leq P_{j+1}$, for each index j , then we have

$$\lim_{j \rightarrow \infty} P_j = \inf \{P_j\} = \bigwedge_{j=0}^{\infty} P_j.$$

5. Predicate transforms. The transition function δ of the automaton G induces two useful transformations on the family of predicates $\mathcal{P} = \{0, 1\}^Q$.

First, for each $\sigma \in \Sigma$ we introduce a partial function

$$\delta_\sigma = \delta(\sigma, q)$$

and a predicate

$$D_\sigma(q) = \begin{cases} 1 & \text{if } \delta_\sigma(q) \text{ is defined,} \\ 0 & \text{otherwise.} \end{cases}$$

Then for each $\sigma \in \Sigma$ define the transformation $\text{wp}_\sigma: \mathcal{P} \rightarrow \mathcal{P}$ by

$$\text{wp}_\sigma(P)(q) = \begin{cases} 1 & \text{if } \delta_\sigma(q) \text{ is defined and } P(\delta_\sigma(q)) = 1, \\ 0 & \text{otherwise.} \end{cases}$$

When δ_σ is a total function on Q , $\text{wp}_\sigma(P)$ is simply the composition of the functions δ_σ and P . More generally $\text{wp}_\sigma(P)$ equals $P \cdot \delta_\sigma$ at those states q where $D_\sigma(q) = 1$ (i.e. $\delta_\sigma(q)$ is defined) and is zero elsewhere. From this it is evident that $\text{wp}_\sigma(P)(q) = 1$ is the weakest condition that guarantees that $\delta_\sigma(q)$ satisfies P . Hence, following Dijkstra [2], we call $\text{wp}_\sigma(P)$ the *weakest precondition* of P under σ .

As pointed out in [2] a variation of the above transform is useful when it is enough to guarantee that $\delta_\sigma(q)$ does not satisfy $\sim P$. For this define the *weakest liberal precondition* of P :

$$\text{wlp}_\sigma(P) = \text{wp}_\sigma(P) \vee \sim D_\sigma.$$

Note that if $\text{wlp}_\sigma(P)(q) = 1$, then either $\delta_\sigma(q)$ is undefined or $\delta_\sigma(q)$ satisfies P . In either case $\delta_\sigma(q)$ does not satisfy $\sim P$.

To illustrate these concepts, consider again the CDEP of § 3. If

$$P = (q = X)$$

then we have

$$\text{wp}_f(P) = (q \neq I)$$

and

$$\text{wlp}_f(P) = 1.$$

Notice that the weakest precondition specifies the set of all states from which an event with output f takes the process to the state X . On the other hand, the weakest liberal precondition appends to this set all states from which an event with output f is impossible (as defined by the process dynamics).

The second transformation induced on \mathcal{P} by δ is defined by

$$\text{sp}_\sigma(P)(q) = \begin{cases} 1 & \text{if } q = \delta_\sigma(q') \text{ for some } q' \in Q_P, \\ 0 & \text{otherwise.} \end{cases}$$

Clearly given that P is initially satisfied, $\text{sp}_\sigma(P)$ is the strongest condition whose truth can be inferred after a state transition under the map δ_σ . Hence we call $\text{sp}_\sigma(P)$ the *strongest postcondition* of P under σ .

The transforms wp_σ and sp_σ specify the action of G on predicates on the state set of G . As such they provide an alternative higher level description of the system dynamics which is particularly well suited, as we shall see, to the study of certain invariance problems.

It is readily shown that each of the above predicate transforms distributes over both a conjunction and a disjunction of predicates, see for example, Dijkstra [2, pp. 18–19]. We frequently use this fact in the following form. If $\{P_j, j \in J\} \subseteq \mathcal{P}$ is a set of predicates on Q , then

$$(5.1) \quad \text{wlp}_\sigma \left(\bigwedge_j P_j \right) = \bigwedge_j \text{wlp}_\sigma(P_j)$$

and

$$(5.2) \quad \text{wlp}_\sigma \left(\bigvee_j P_j \right) = \bigvee_j \text{wlp}_\sigma(P_j).$$

The proof of these equalities is straightforward.

6. State feedback. A *state feedback* for the CDEP G_c is a total function $f: Q \rightarrow \Gamma$. The application of f to G_c yields the closed loop process G_c^f defined by

$$G_c^f = (\Sigma, Q, \delta_c^f, q_0)$$

with

$$\delta_c^f(\sigma, q) = \delta_c(f(q), \sigma, q).$$

Note that G_c^f is again a process with output set Σ . Informally we regard G_c^f as a subsystem of G which has been constructed by the removal of certain state transitions.

For each $\sigma \in \Sigma$, the σ -component of the feedback $f \in \Gamma^Q$ is the map $f_\sigma: Q \rightarrow \{0, 1\}$ with

$$f_\sigma(q) = f(q)(\sigma).$$

The map f_σ gives precisely the conditions under which events associated with output σ are enabled under the control f . Clearly f is completely characterized by the set $\{f_\sigma: \sigma \in \Sigma\}$. This suggests that to synthesize a feedback map it is sufficient to synthesize each of its components individually. Of course for each $\sigma \in \Sigma_u$ we must have $f_\sigma = 1$. Hence it is only necessary to specify the components of f for $\sigma \in \Sigma_c$.

In addition to decomposing a feedback synthesis the component maps have the advantage of being predicates on the state set Q of G_c . This permits feedback to be analyzed within the algebra $\mathcal{P} = \{0, 1\}^Q$. For example, if wlp_σ is the predicate transform introduced in § 4 for G_c , and wlp_σ^f is the corresponding predicate transform for G_c^f , then it is readily verified that for each $\sigma \in \Sigma$, and $P \in \mathcal{P}$

$$(6.1) \quad \text{wlp}_\sigma^f(P) = \text{wlp}_\sigma(P) \vee \sim f_\sigma.$$

This relation will find frequent application in following sections.

Since Γ is a Boolean algebra, we can define a Boolean algebra on Γ^Q by point-wise definition of the algebraic operations. For example, if $f, g \in \Gamma^Q$, then $(f \wedge g)(q) = f(q) \wedge g(q)$.

This algebraic structure permits feedback controls to be constructed in a modular fashion, e.g., $h = f \wedge g$. It is precisely this aspect of control synthesis that we wish to investigate in the current paper.³

7. Control invariance. We consider the simple but fundamental problem of ensuring by control action that a given predicate on the state set of G_c remains invariantly true whenever it is initially satisfied.

This is equivalent to ensuring that a certain subset of states is invariant in the closed loop process, a problem that has been extensively studied in other contexts, see e.g. [4], [8]. Our primary purpose here, however, is to exploit the algebraic structure inherent in the supervisory control framework to synthesize modular solutions to the problem.

Throughout this section we let $G_c = (\Gamma \times \Sigma, Q, \delta_c, q_0)$ be a fixed CDEP and $\mathcal{P} = \{0, 1\}^Q$.

A predicate $P \in \mathcal{P}$ is said to be *control-invariant* (with respect to G_c) if for some feedback $f \in \Gamma^Q$ we have

$$(7.1) \quad P \leq \text{wlp}_\sigma^f(P) \quad \text{for each } \sigma \in \Sigma.$$

This ordering implies that if P is true at a state $q \in Q$, then P is true at all states reachable from q in the closed loop process G_c^f . Hence P will be invariantly true whenever it is initially satisfied.

It is a simple matter to characterize the control-invariant predicates in a “feedback independent” fashion. Say that the predicate $P \in \mathcal{P}$ is Σ_u -invariant (with respect to G_c) if

$$P \leq \text{wlp}_\sigma(P) \quad \text{for each } \sigma \in \Sigma_u.$$

We then have the following proposition:

PROPOSITION 7.1. *A predicate P is control-invariant iff P is Σ_u -invariant.*

Proof.

IF. Define the feedback f component-wise by

$$f_\sigma(q) = \begin{cases} 1 & \text{if } \sigma \in \Sigma_u, \\ 0 & \text{if } \sigma \in \Sigma_c. \end{cases}$$

Then for $\sigma \in \Sigma_u$

$$\text{wlp}_\sigma^f(P) = \text{wlp}_\sigma(P) \vee (\sim f_\sigma) = \text{wlp}_\sigma(P).$$

Thus $P \leq \text{wlp}_\sigma(P) = \text{wlp}_\sigma^f(P)$.

Alternatively, for $\sigma \in \Sigma_c$

$$\text{wlp}_\sigma^f(P) = \text{wlp}_\sigma(P) \vee \sim f_\sigma = \text{wlp}_\sigma(P) \vee 1 = 1.$$

Thus $P \leq 1 = \text{wlp}_\sigma^f(P)$.

ONLY IF. For $\sigma \in \Sigma_u$ we have $\text{wlp}_\sigma^f = \text{wlp}_\sigma(P)$. Hence if $P \leq \text{wlp}_\sigma^f(P)$, then $P \leq \text{wlp}_\sigma(P)$. \square

³ It is readily verified that modular constructions carry over to each component of the maps f and g , e.g., $(f \wedge g)_\sigma = f_\sigma \wedge g_\sigma$.

A predicate P' on Q satisfying the relation

$$P \leq (P' \Rightarrow \text{wlp}_\sigma(P))$$

is said to be a σ -friend of P .

By applying relation (6.1) to (7.1) we see that a predicate P is control-invariant in G_c iff for some $f \in \Gamma^Q$

$$P \leq \text{wlp}_\sigma(P) \vee \sim f_\sigma \quad \text{for each } \sigma \in \Sigma$$

or equivalently iff for some $f \in \Gamma^Q$

$$P \leq (f_\sigma \Rightarrow \text{wlp}_\sigma(P)) \quad \text{for each } \sigma \in \Sigma.$$

Thus f ensures that P is invariant in G_c^f iff for each $\sigma \in \Sigma_c$ the σ -component of f is a σ -friend of P . It follows that if P is control-invariant, then we can synthesize a feedback to ensure the invariance of P by selecting for the σ -component of f any σ -friend of P .

Let

$$F_\sigma(P) = \{P' : P' \text{ is a } \sigma\text{-friend of } P\}.$$

This set has the following properties:

PROPOSITION 7.2. *Let P be a control-invariant predicate and $\sigma \in \Sigma$. Then $F_\sigma(P)$ is nonempty and is closed under arbitrary conjunctions and disjunctions. In particular, $F_\sigma(P)$ has a unique maximal and a unique minimal element.*

Proof. It follows from the definition of control-invariance that $F_\sigma(P)$ is nonempty. Let $\{P_j, j \in J\} \subseteq F_\sigma(P)$. Now for each $j \in J$ we have

$$P \leq \text{wlp}_\sigma(P) \vee \sim P_j.$$

Hence

$$P \leq \bigwedge_j (\text{wlp}_\sigma(P) \vee \sim P_j) = \text{wlp}_\sigma(P) \vee \sim \left(\bigvee_j P_j \right).$$

The proof for conjunction is similar. \square

We can think of $\sup F_\sigma(P)$ as the least restrictive, or alternatively the most permissive control among the σ -friends of P . The dual predicate $\inf F_\sigma(P)$ is somewhat less interesting; although it ensures that P is invariant under the event σ it generally does so in an unnecessarily restrictive fashion.

It is clear that whether or not P_1 is a σ -friend of P depends only on the structure of P_1 on the set of states where P is true. Thus for the purposes of control-invariance we may regard potential feedback components P_1 and P_2 as equivalent, with respect to the predicate P , if $P_1 \wedge P = P_2 \wedge P$, i.e., if $P_1 = P_2(\text{rel } P)$.

We end our preliminary results with the following characterization of the class of predicates $F_\sigma(P)$.

PROPOSITION 7.3. *Let P be a control-invariant predicate and $\sigma \in \Sigma_c$. Then*

$$P' \in F_\sigma(P) \quad \text{iff } P' \leq \text{wlp}_\sigma(P)(\text{rel } P)$$

i.e., $P' \leq \text{wlp}_\sigma(P)$ at those q where $P(q) = 1$.

COROLLARY 7.1. *Let $P \in \mathcal{P}$ be control-invariant and $\sigma \in \Sigma_c$. Then*

$$\sup F_\sigma(P) = \text{wlp}_\sigma(P)(\text{rel } P).$$

Proof. We have

$$P \leq (P' \Rightarrow \text{wlp}_\sigma(P)) \quad \text{iff } (P' \Rightarrow \text{wlp}_\sigma(P)) = 1(\text{rel } P),$$

$$\text{iff } P' \leq \text{wlp}_\sigma(P)(\text{rel } P). \quad \square$$

Armed with Propositions 7.1 and 7.3, we are now ready to determine whether or not control-invariance problems admit modular solutions.

Let P_1, \dots, P_k be predicates on the state set Q and

$$(7.2) \quad P = g(P_1, \dots, P_k)$$

be constructed from the P_i by a finite number of conjunctions and disjunctions. We think of (7.2) as a modular specification of P . Our aim is to exploit this structure to analyze the control-invariance of P in terms of the component predicates P_1, \dots, P_k . It will be sufficient to consider the case $k = 2$.

It is a simple matter to show that the control-invariance of P is implied by the control-invariance of the predicates P_i . For this we use the fact that conjunction and disjunction are monotone operators, i.e., $P_1 \leq P_2$ and $T_1 \leq T_2$ together imply that $P_1 \wedge T_1 \leq P_2 \wedge T_2$.

PROPOSITION 7.4. $P_1 \wedge P_2$ and $P_1 \vee P_2$ are control-invariant whenever P_1 and P_2 are control-invariant.

Proof. For each $\sigma \in \Sigma_u$ we have $P_1 \leq \text{wlp}_\sigma(P_1)$ and $P_2 \leq \text{wlp}_\sigma(P_2)$. Hence

$$P_1 \wedge P_2 \leq \text{wlp}_\sigma(P_1) \wedge \text{wlp}_\sigma(P_2) = \text{wlp}_\sigma(P_1 \wedge P_2) \quad \text{by (5.1).}$$

The proof for disjunction is similar. \square

The more interesting question concerns modular feedback synthesis. The problem is to determine when we can synthesize a σ -friend of P from the σ -friends of the P_i . Our first result deals with conjunction.

PROPOSITION 7.5. Let $P_1, P_2 \in \mathcal{P}$ and $\sigma \in \Sigma_c$. Then $f_\sigma \in F_\sigma(P_1)$ and $g_\sigma \in F_\sigma(P_2)$ together imply that

$$f_\sigma \wedge g_\sigma \in F_\sigma(P_1 \wedge P_2).$$

Proof. Let $f_\sigma \in F_\sigma(P_2)$ and $g_\sigma \in F_\sigma(P_2)$. Then

$$\begin{aligned} (f_\sigma \wedge g_\sigma) \wedge (P_1 \wedge P_2) &= (f_\sigma \wedge P_1) \wedge (g_\sigma \wedge P_2) \\ &\leq (\text{wlp}_\sigma(P_1) \wedge P_1) \wedge (\text{wlp}_\sigma(P_2) \wedge P_2) \quad \text{by Proposition 7.3} \\ &= (P_1 \wedge P_2) \wedge (\text{wlp}_\sigma(P_1) \wedge \text{wlp}_\sigma(P_2)) \\ &= (P_1 \wedge P_2) \wedge \text{wlp}_\sigma(P_1 \wedge P_2) \quad \text{by (5.1).} \end{aligned}$$

Thus by Proposition 7.3 $f_\sigma \wedge g_\sigma \in F_\sigma(P_1 \wedge P_2)$. \square

Proposition 7.5 shows that the conjunction of any pair of σ -friends of P_1 and P_2 yields a σ -friend of P . Thus it is always possible to synthesize a σ -friend of $P = P_1 \wedge P_2$ in a modular fashion.

For a similar construction to be viable in the case of the disjunction operator it is necessary to place additional restrictions on the choice of f_σ and g_σ .

PROPOSITION 7.6. Let $P_1, P_2 \in \mathcal{P}$ and $\sigma \in \Sigma_c$. Then $f_\sigma \in F_\sigma(P_1)$, $g_\sigma \in F_\sigma(P_2)$, $f_\sigma \leq (\text{wlp}_\sigma(P_1) \vee \text{wlp}_\sigma(P_2))(\text{rel } P_2)$, and $g_\sigma \leq (\text{wlp}_\sigma(P_1) \vee \text{wlp}_\sigma(P_2))(\text{rel } P_1)$ together imply that

$$f_\sigma \vee g_\sigma \in F_\sigma(P_1 \vee P_2).$$

Proof. We have

$$\begin{aligned}
 (f_\sigma \vee g_\sigma) \wedge (P_1 \vee P_2) &= (f_\sigma \wedge P_1) \vee (f_\sigma \wedge P_2) \vee (g_\sigma \wedge P_1) \vee (g_\sigma \wedge P_2) \\
 &\leq (\text{wlp}_\sigma(P_1) \wedge P_1) \vee (\text{wlp}_\sigma(P_1) \wedge P_2) \\
 &\quad \vee (\text{wlp}_\sigma(P_2) \wedge P_1) \vee (\text{wlp}_\sigma(P_2) \wedge P_2) \\
 &= (P_1 \vee P_2) \wedge (\text{wlp}_\sigma(P_1) \vee \text{wlp}_\sigma(P_2)) \\
 &= (P_1 \vee P_2) \wedge \text{wlp}_\sigma(P_1 \vee P_2) \quad \text{by (5.2).}
 \end{aligned}$$

Hence $f_\sigma \vee g_\sigma \in F_\sigma(P_1 \vee P_2)$. \square

The additional assumptions in Proposition 7.6 are easily interpreted. The standard assumption $f_\sigma \in F_\sigma(P_1)$ requires that on the set Q_1 where P_1 is true σ is enabled only if the corresponding state transition maps into Q_1 . The additional assumption $f_\sigma \leq (\text{wlp}_\sigma(P_1) \vee \text{wlp}_\sigma(P_2))(\text{rel } P_2)$ requires that on the set Q_2 where P_2 is true σ is enabled only if the corresponding state transition maps into Q_1 or Q_2 . Thus the second condition restricts f_σ on the set $Q_2 - Q_1$ with the purpose of ensuring compatibility with the predicate P_2 .⁴

We end this section by determining conditions under which a modular control synthesis using the conjunction and disjunction operators preserves the maximality of the control.

PROPOSITION 7.7. *Let $P_1, P_2 \in \mathcal{P}$ be control-invariant, $\sigma \in \Sigma_c, f_\sigma = \sup F_\sigma(P_1)(\text{rel } P_1)$ and $g_\sigma = \sup F_\sigma(P_2)(\text{rel } P_2)$. Then*

$$f_\sigma \wedge g_\sigma = \sup F_\sigma(P_1 \wedge P_2)(\text{rel } P_1 \wedge P_2).$$

Proof. Let $h_\sigma = \sup F_\sigma(P_1 \wedge P_2)$. Then

$$\begin{aligned}
 (P_1 \wedge P_2) \wedge h_\sigma &= (P_1 \wedge P_2) \wedge \text{wlp}_\sigma(P_1 \wedge P_2) \\
 &= (P_1 \wedge \text{wlp}_\sigma(P_1)) \wedge (P_2 \wedge \text{wlp}_\sigma(P_2)) \\
 &= (P_1 \wedge f_\sigma) \wedge (P_2 \wedge g_\sigma) \\
 &= (P_1 \wedge P_2) \wedge (f_\sigma \wedge g_\sigma). \quad \square
 \end{aligned}$$

Proposition 7.7 shows that the least restrictive σ -friend of the modular predicate $P_1 \wedge P_2$ can be synthesized by forming the conjunction of the least restrictive controls for the component predicates P_1 and P_2 . Thus no loss of maximality need result from a modular synthesis over the conjunction operator.

To prove an analogous result to Proposition 7.7 for the disjunction operator, it is necessary to place further assumptions on the maps f_σ and g_σ .

PROPOSITION 7.8. *Let $P_1, P_2 \in \mathcal{P}$ be control-invariant, $\sigma \in \Sigma_c, f_\sigma = \text{wlp}_\sigma(P_1)(\text{rel } P_1 \vee P_2)$ and $g_\sigma = \text{wlp}_\sigma(P_2)(\text{rel } P_1 \vee P_2)$. Then*

$$f_\sigma \vee g_\sigma = \sup F_\sigma(P_1 \vee P_2)(\text{rel } P_1 \vee P_2).$$

Proof. Similar to the proof of Proposition 7.7. \square

8. Extremal control invariant predicates. We continue with the notation and setting of § 7. Since in general not every predicate $P \in \mathcal{P}$ will be control-invariant, it is of interest to exploit the order structure of \mathcal{P} to find good control-invariant approximations to P .

⁴ A simple condition which ensures that $f_\sigma \leq (\text{wlp}_\sigma(P_1) \vee \text{wlp}_\sigma(P_2))(\text{rel } P_2)$ for all predicates P_2 is $f_\sigma \leq \text{wlp}_\sigma(P_1)$. However, this may be restrictive in problems involving more than just invariance.

We begin with a quick review of two (essentially) standard results. First, there are two optimal control-invariant approximations to $P \in \mathcal{P}$: the weakest control-invariant predicate stronger than P (denoted P^\uparrow) and the strongest control-invariant predicate weaker than P (denoted P^\downarrow). Second, each of these predicates can be characterized as an extremal fixpoint of an appropriate monotone lattice map. We then turn our attention to the modular computation of P^\uparrow and P^\downarrow . Our main result is that the transform \uparrow is an automorphism of the algebra (\mathcal{P}, \wedge) while the transform \downarrow is an automorphism of the algebra (\mathcal{P}, \vee) .

For $P \in \mathcal{P}$ define

$$CI_{<}(P) = \{P' : P' \in \mathcal{P}, P' \leq P \text{ and } P' \text{ is control-invariant}\}.$$

$CI_{<}(P)$ is simply the set of control-invariant predicates on Q that are stronger than P .

Since 0 is control-invariant, $CI_{<}(P)$ is nonempty. By a straightforward extension of Proposition 7.4 it can be shown that $CI_{<}(P)$ is closed under arbitrary disjunctions. Then since $CI_{<}(P)$ is bounded above by P , it must have a unique maximal element. Denote this predicate by P^\uparrow . We can think of P^\uparrow as the best control-invariant approximation to P among the predicates which logically imply P . Of course we may have $P^\uparrow = 0$.

Similarly we define

$$CI_{>}(P) = \{P' : P' \in \mathcal{P}, P \leq P' \text{ and } P' \text{ is control-invariant}\}.$$

$CI_{>}(P)$ is the set of all control-invariant predicates on Q that are weaker than P .

Since 1 is control-invariant, $CI_{>}(P)$ is nonempty. Again by a straightforward extension of Proposition 7.4 it can be shown that $CI_{>}(P)$ is closed under arbitrary conjunctions. Hence since $CI_{>}(P)$ is bounded below by P , it has a unique minimal element. Denote this predicate by P^\downarrow . We can think of P^\downarrow as the tightest boundary we can place around P by control action. Of course, it is possible that $P^\downarrow = 1$.

To develop the fixpoint characterization of the predicate P^\uparrow we bring in the map $H : \mathcal{P} \rightarrow \mathcal{P}$ with

$$H(P') = P \wedge \left(\bigwedge_{\Sigma_u} \text{wlp}_\sigma(P') \right).$$

A predicate P' such that $H(P') = P'$ is said to be a *fixpoint* of the map H . It is not difficult to show that P^\uparrow is the unique maximal fixpoint of the map H . However, for our current purposes it will be sufficient to show that P^\uparrow is simply a fixpoint of H . This follows by noting that $P^\uparrow \leq \text{wlp}_\sigma(P^\uparrow)$ for each $\sigma \in \Sigma_u$, and hence

$$P^\uparrow = P \wedge P^\uparrow \leq P \wedge \left(\bigwedge_{\Sigma_u} \text{wlp}_\sigma(P^\uparrow) \right) = H(P^\uparrow).$$

But $P \wedge \left(\bigwedge_{\Sigma_u} \text{wlp}_\sigma(P^\uparrow) \right)$ is clearly Σ_u -invariant and less than P . Hence by the maximality of P^\uparrow we must have $H(P^\uparrow) \leq P^\uparrow$. To complete our characterization of P^\uparrow we introduce the sequence of predicates:

$$(8.1) \quad P_0 = P, \quad P_{j+1} = H(P_j).$$

This leads to our desired result:

PROPOSITION 8.1. *The sequence defined by (8.1) is monotone decreasing and $P^\uparrow = \bigwedge_{j=0}^{\infty} P_j$.*

Proof. We use the fact that H is monotone, i.e., $P_1 \leq P_2$ implies that $H(P_1) \leq H(P_2)$, and the fact that P^\uparrow is a fixpoint of H .

To begin

$$P_1 = H(P_0) \leq P = P_0$$

and if $P_j \leq P_{j-1}$, then

$$P_{j+1} = H(P_j) \leq H(P_{j-1}) = P_j.$$

Hence $P_0 \geq P_1 \geq P_2 \geq \dots$.

Now $P^\uparrow \leq P = P_0$ and if $P^\uparrow \leq P_j$, then

$$P^\uparrow = H(P^\uparrow) \leq H(P_j) = P_{j+1}.$$

Thus $P^\uparrow \leq \bigwedge_{j=0}^{\infty} P_j$.

For the reverse ordering it will be sufficient to show that $\bigwedge_{j=0}^{\infty} P_j$ is control-invariant. Fix $\sigma \in \Sigma_u$. Then by Proposition 7.1 we must show that

$$\bigwedge_{j=0}^{\infty} P_j \leq \text{wlp}_\sigma \left(\bigwedge_{j=0}^{\infty} P_j \right).$$

Now for each j

$$P_{j+1} = P \wedge \left(\bigwedge_{\omega \in \Sigma_u} \text{wlp}_\omega (P_j) \right) \leq \text{wlp}_\sigma (P_j).$$

Hence

$$\bigwedge_{j=0}^{\infty} P_j \leq \bigwedge_{j=0}^{\infty} \text{wlp}_\sigma (P_j) = \text{wlp}_\sigma \left(\bigwedge_{j=0}^{\infty} P_j \right). \quad \square$$

It is possible to provide an analogous fixpoint characterization of the predicate P^\downarrow . For this we introduce the map $G: \mathcal{P} \rightarrow \mathcal{P}$ with

$$G(P') = P \vee \left(\bigvee_{\Sigma_u} \text{sp}_\sigma (P') \right).$$

It can then be shown that P^\downarrow is the unique minimal fixpoint of G . Proceeding as before we define

$$(8.2) \quad R_0 = P, \quad R_{j+1} = G(R_j), \quad j \geq 0.$$

This leads to the following proposition:

PROPOSITION 8.2. *The sequence defined by (8.2) is monotone increasing and $P^\downarrow = \bigvee_{j=0}^{\infty} R_j$. \square*

We are now ready for the main results of this section. Our objective is to determine the relationship between the transforms \uparrow and \downarrow and the algebraic operations of conjunction and disjunction on \mathcal{P} . We first consider the transform \uparrow .

THEOREM 8.1. *For each $P_1, P_2 \in \mathcal{P}$*

$$P_1^\uparrow \wedge P_2^\uparrow = (P_1 \wedge P_2)^\uparrow$$

and

$$P_1^\uparrow \vee P_2^\uparrow \leq (P_1 \vee P_2)^\uparrow.$$

Proof.

(a) It is clear from the definition of \uparrow that if $P_1 \leq P_2$, then $P_1^\uparrow \leq P_2^\uparrow$, i.e., \uparrow is a monotone operator.

Set $P = P_1 \wedge P_2$. Since $P \leq P_1$ and $P \leq P_2$ it follows that $P^\uparrow \leq P_1^\uparrow$ and $P^\uparrow \leq P_2^\uparrow$. Thus $P^\uparrow \leq P_1^\uparrow \wedge P_2^\uparrow$. For the reverse ordering we note that $P_1^\uparrow \wedge P_2^\uparrow \leq P$ and hence that $P_1^\uparrow \wedge P_2^\uparrow \leq P^\uparrow$.

(b) The assertion follows immediately from Proposition 5.4 and the definition of $(P_1 \wedge P_2)^\uparrow$. \square

Not surprisingly a dual result holds for the \downarrow transform.

THEOREM 8.2. *For each $P_1, P_2 \in \mathcal{P}$*

$$P_1^\downarrow \wedge P_2^\downarrow \cong (P_1 \wedge P_2)^\downarrow$$

and

$$P_1^\downarrow \vee P_2^\downarrow = (P_1 \vee P_2)^\downarrow.$$

Proof. Similar to the proof of Theorem 8.1. \square

Theorem 8.1 indicates that the operation of forming the supremal control-invariant predicate (\uparrow) is an automorphism of the algebra (\mathcal{P}, \wedge) . This is a pleasing result from the point of view of modular synthesis since it implies that no loss of optimality is incurred in computing \uparrow by modularizing over a conjunction of predicates, i.e., to compute $(P_1 \wedge P_2)^\uparrow$ we can first compute P_1^\uparrow and P_2^\uparrow , then form their conjunction.

The same is not true of disjunction. In computing \uparrow , a modularization over a disjunction of predicates need not yield the maximal solution.

The corresponding results for the operation of forming the infimal control-invariant predicate (\downarrow) are dual to the above. Namely, the \downarrow transform is an automorphism of the algebra (\mathcal{P}, \vee) but not in general of the algebra (\mathcal{P}, \wedge) .

9. Examples.

Example 9.1. In a simple manufacturing system we consider two machines and two buffers connected in the configuration shown below.

The M_i are CDEPs with the following state diagrams:

As in the previous example each state represents an activity, while transitions between states, i.e. events, mark the completion of one activity and the start of another. In detail: in state I_i , M_i is “idle”; in state F_i , M_i is “fetching” a part from its input buffer (B_2 in the case of M_1 , and B_1 in the case of M_2); in state W_i , M_i is “working”; in state D_i , M_i is “depositing” a part in its output buffer (B_1 in the case of M_1 and B_2 in the case of M_2). (There may also be states and events associated with breakdown

and repair, and with the addition or removal of parts, but we assume that these are not relevant to the task at hand.)

Each buffer is modeled as an event driven automaton that records the number of workpieces in the buffer, i.e., each buffer is an automaton with state set \mathbf{N} (the natural numbers) and with the state transitions

$$B_1: \quad c_1: n \rightarrow n + 1,$$

$$a_2: n \rightarrow n - 1,$$

$$B_2: \quad c_2: n \rightarrow n + 1,$$

$$a_1: n \rightarrow n - 1.$$

Let

$$\Sigma = \{a_i, b_i, c_i, d_i; i = 1, 2\}, \quad Q_i = \{I_i, F_i, W_i, D_i\}, \quad i = 1, 2$$

and for the state space of the machine/buffer system we take $Q = Q_1 \times Q_2 \times \mathbf{N} \times \mathbf{N}$. For $(q_1, q_2, i, j) \in Q$: q_1 is the state of M_1 , q_2 is the state of M_2 , i is the state of B_1 , and j is the state of B_2 . Let

$$\Sigma_c = \{a_i, c_i; i = 1, 2\}$$

be the set of controllable events and assume that we can model the concurrent operation of M_1 and M_2 by "shuffling" their state transitions (see e.g. [6]).

Our aim is to ensure that the conjunction P of the following predicates is invariant:

- (1) Mutually exclusive use of B_1 : $P_1 = [q \neq (D_1, F_2)]$,
- (2) Mutually exclusive use of B_2 : $P_2 = [q \neq (F_1, D_2)]$,
- (3) Capacity of B_1 : $P_3 = (0 \leq i) \wedge (i \leq N)$,
- (4) Capacity of B_2 : $P_4 = (0 \leq j) \wedge (j \leq N)$.

It is readily shown that each of these predicates is control-invariant. Hence by Proposition 7.4 $P = \bigwedge_{i=1}^4 P_i$ is control-invariant.

Some elementary computation yields

$$\begin{aligned} \text{wlp}_\sigma(P_1) &= \begin{cases} (q_1, q_2) \neq (D_1, I_2) & \text{if } \sigma = a_2, \\ (q_1, q_2) \neq (W_1, F_2) & \text{if } \sigma = c_1, \\ 1 & \text{otherwise.} \end{cases} \\ \text{wlp}_\sigma(P_2) &= \begin{cases} (q_1, q_2) \neq (F_1, W_2) & \text{if } \sigma = c_2, \\ (q_1, q_2) \neq (I_1, D_2) & \text{if } \sigma = a_1, \\ 1 & \text{otherwise.} \end{cases} \\ \text{wlp}_\sigma(P_3) &= \begin{cases} i \neq N & \text{if } \sigma = c_1, \\ i \neq 0 & \text{if } \sigma = a_2, \\ 1 & \text{otherwise.} \end{cases} \\ \text{wlp}_\sigma(P_4) &= \begin{cases} j \neq N & \text{if } \sigma = c_2, \\ j \neq 0 & \text{if } \sigma = a_1, \\ 1 & \text{otherwise.} \end{cases} \end{aligned}$$

Now by Corollary 7.1 we know that $f_{i\sigma} = \text{wlp}_\sigma(P_i)$ is a σ -friend of P_i , $i = 1, \dots, 4$ (in fact it is equivalent $\text{rel}(P_i)$ to the supremal σ -friend of P_i). These component maps can be combined in a variety of ways to yield valid solutions to our problem. For

example, to obtain a feedback that ensures P_1 and P_3 are invariant (i.e., a controller for the buffer B_1) we form $g_\sigma = f_{1\sigma} \wedge f_{3\sigma}$, viz:

$$\begin{aligned} g_{a_1} &= g_{c_2} = 1, \\ g_{a_2} &= [(q_1, q_2) \neq (D_1, I_2) \wedge (i \neq 0)], \\ g_{c_1} &= [(q_1, q_2) \neq (W_1, F_2) \wedge (i \neq N)]. \end{aligned}$$

By Proposition 7.5 we know that g_σ is a σ -friend of $P_1 \wedge P_3$ (in fact by Proposition 7.7 it is equivalent $\text{rel}(P_1 \wedge P_3)$ to the supremal σ -friend of $P_1 \wedge P_3$). A similar procedure can be used to form a control for the buffer B_2 . Alternatively we can specify a single global control for each controlled event by forming $f_\sigma = \bigwedge_{i=1}^4 f_{i\sigma}$. This yields a single (centralized if you like) feedback that ensures P is invariant.

Example 9.2. Consider a simplified version of the example of ([9, § 7]) to which the reader is referred for any explained terminology below. A cat and a mouse are placed in the maze shown in Fig. 9.1. Each doorway in the maze must be traversed in the direction indicated and is either for the exclusive use of the cat (displayed as $-|\uparrow|$) or for the exclusive use of the mouse (displayed as $-|\downarrow|$). In addition each door, with the exception of c_7 , can be opened or closed as required in order to control the movement of the cat and the mouse. Our objective is to ensure that the cat and the mouse never occupy the same room simultaneously.

As our model of the system we adopt the CDEP $G_c = (Q, \Gamma \times \Sigma, \delta, q_0)$ shown in Fig. 9.2 (see [9, § 7] for further details). Here

$$\begin{aligned} \Sigma &= \{c_i, m_j : 1 \leq i \leq 7, 1 \leq j \leq 6\}, \\ Q &= \{(i, j) : 0 \leq i \leq 4, 0 \leq j \leq 4\}, \\ q_0 &= (2, 4), \\ \Sigma_u &= \{c_7\}. \end{aligned}$$

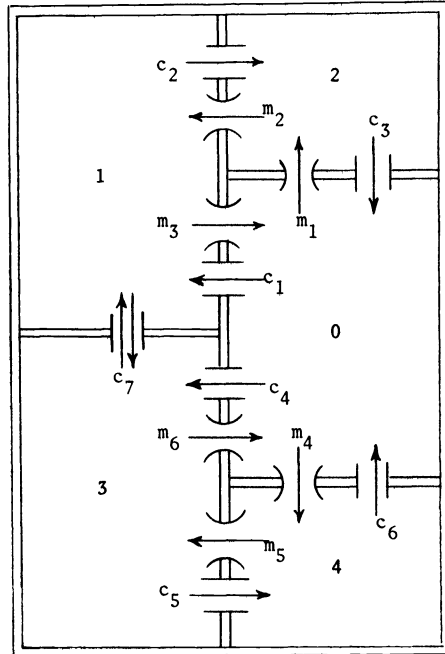

FIG. 9.1. Example 9.2: Maze for cat and mouse.

FIG. 9.2. Example 9.2: Model for cat and mouse.

We want to find a feedback $f \in \Gamma^Q$ such that $P = (i \neq j)$ is an invariant of the closed loop process.

We begin by computing P^\dagger :

$$P_0 = (i \neq j),$$

$$P_1 = H(P_0)$$

$$= P_0 \wedge \text{wlp}_{c_7}(P_0)$$

$$= (i \neq j) \wedge [(i, j) \neq (1, 3)] \wedge [(i, j) \neq (3, 1)],$$

$$P_2 = H(P_1)$$

$$= (i \neq j) \wedge [(i, j) \neq (1, 3)] \wedge [(i, j) \neq (3, 1)]$$

$$= P_1.$$

Hence

$$P^\dagger = (i \neq j) \wedge [(i, j) \neq (1, 3)] \wedge [(i, j) \neq (3, 1)].$$

To find an appropriate feedback solution, we use Corollary 7.1 and set $f_\sigma = \text{wlp}_\sigma(P^\dagger)$. This yields

$$\begin{aligned} f_{c_1} &= [q \neq (0, 1) \wedge q \neq (0, 3)], & f_{m_1} &= [q \neq (2, 0)], \\ f_{c_2} &= [q \neq (1, 2)], & f_{m_2} &= [q \neq (1, 2) \wedge q \neq (3, 2)], \\ f_{c_3} &= [q \neq (2, 0)], & f_{m_3} &= [q \neq (0, 1)], \\ f_{c_4} &= [q \neq (1, 2) \wedge q \neq (0, 1)], & f_{m_4} &= [q \neq (4, 0)], \\ f_{c_5} &= [q \neq (3, 4)], & f_{m_5} &= [q \neq (3, 4) \wedge q \neq (1, 4)], \\ f_{c_6} &= [q \neq (4, 0)], & f_{m_6} &= [q \neq (0, 3)]. \end{aligned}$$

This control implements the following policy. A door that does not access rooms 1 or 3 is closed iff the cat and the mouse are occupying the rooms connected by that door. However, the doors m_2 , m_5 , c_1 , and c_4 (i.e. the doors accessing rooms 1 or 3) require special attention. For example, door c_1 is closed iff the cat is in room 0 and the mouse is in either of rooms 1 or 3. The condition for closing each of the remaining doors follows a similar pattern.

10. Conclusion. We have shown that for the invariant predicate problem it is possible to construct a feedback solution in a modular fashion. Specifically, if the predicate of interest is specified by a conjunction of predicates, e.g., $P = P_1 \wedge P_2$, then it is possible to construct a state feedback to ensure the invariance of the supremal control-invariant predicate stronger than P (i.e. P^\dagger) by first solving the equivalent problem for P_1 and P_2 and forming the conjunction of the solutions. Further, this procedure does not result in any loss of optimality in either the achievable invariant or the maximality of the control.

Although we have restricted attention to state feedback control, all is not lost if the state of the process cannot be measured. Provided the initial state of the process is known it is possible to track the process state by recording the sequence of generated outputs. In practice this is achieved by driving an automaton model G of the process by the output sequence. The pair $S = (G, f)$, where f is the desired feedback map, yields a valid supervisor for the process which can be further simplified if desired using the results of [6].

RELAXATION METHODS FOR NETWORK FLOW PROBLEMS WITH CONVEX ARC COSTS*

DIMITRI P. BERTSEKAS[†], PATRICK A. HOSEIN[†] AND PAUL TSENG[†]

Abstract. We consider the standard single commodity network flow problem with both linear and strictly convex possibly nondifferentiable arc costs. For the case where all arc costs are strictly convex we study the convergence of a dual Gauss-Seidel type relaxation method that is well suited for parallel computation. We then extend this method to the case where some of the arc costs are linear. As a special case we recover a relaxation method for the linear minimum cost network flow problem proposed in Bertsekas [1] and Bertsekas and Tseng [2].

Key words. network flow, relaxation methods, parallel computation

1. Introduction. Consider a directed graph with set of nodes N and set of arcs A . We will write $j \sim (i, k)$ to denote that the start and end nodes of arc j are i and k , respectively. The network incidence matrix is denoted by E and has elements e_{ij} given by

$$(1) \quad e_{ij} = \begin{cases} 1 & \text{if } i \text{ is the start node of arc } j, \\ -1 & \text{if } i \text{ is the end node of arc } j, \\ 0 & \text{otherwise.} \end{cases}$$

We denote by x_j the *flow* of arc j , and by d_i the *deficit* of node i which is defined by

$$(2) \quad d_i = \sum_{j \in A} e_{ij} x_j \quad \forall i \in N.$$

In words d_i is the balance of flow outgoing from i and flow coming into i . The vectors with coordinates x_j and d_i are denoted x and d respectively. Thus (2) is written as

$$(3) \quad d = Ex.$$

In what follows the association of particular deficit vectors and flow vectors via (3) should be clear from the context.

Each arc j has associated with it a cost function $f_j: R \rightarrow (-\infty, +\infty]$. We consider the problem of minimizing total cost subject to a conservation of flow constraint at each node:

$$(4) \quad \begin{aligned} &\text{minimize} \quad f(x) = \sum_{j \in A} f_j(x_j) \\ &\text{subject to} \quad x \in C \end{aligned}$$

where C is the *circulation subspace*:

$$(5) \quad C = \{x | d_i = 0, i \in N\} = \{x | Ex = 0\}.$$

We make the following assumptions on f_j .

Assumption A. Each function f_j is convex, lower semicontinuous, and there exists at least one feasible solution for problem (4), i.e., the effective domain of f

$$\text{dom}(f) = \{x | f(x) < +\infty\}$$

and the circulation subspace C have a nonempty intersection.

Assumption B. The conjugate convex function of each f_j defined by

$$(6) \quad g_j(t_j) = \sup_{x_j} \{t_j x_j - f_j(x_j)\}$$

is real valued, i.e., $-\infty < g_j(t_j) < +\infty$ for all $t_j \in \mathbb{R}$.

Assumption B implies that $f_j(x_j) > -\infty$ for all x_j and j . It follows that the set of points where f_j is real valued, denoted $\text{dom}(f_j)$, is a nonempty interval the right and left endpoints of which (possibly $+\infty$ or $-\infty$) we denote by c_j and l_j , respectively, i.e.,

$$c_j = \sup \{x_j | f_j(x_j) < +\infty\}, \quad l_j = \inf \{x_j | f_j(x_j) < +\infty\}.$$

We call c_j and l_j the *upper and lower capacity bounds* of f_j respectively. It is easily seen that Assumptions A and B imply that for every t_j there is some $x_j \in \text{dom}(f_j)$ attaining the supremum in (6), and furthermore

$$\lim_{|x_j| \rightarrow +\infty} f_j(x_j) = +\infty.$$

It follows that the cost function of (4) has bounded level sets, and therefore (using also the lower semicontinuity of f) *there exists at least one optimal flow vector*.

Assumptions A and B are satisfied, if, for example, f_j is of the form

$$(7) \quad f_j(x_j) = \begin{cases} \hat{f}_j(x_j) & \text{if } x_j \in [l_j, c_j], \\ \infty & \text{otherwise} \end{cases}$$

where l_j , c_j are given upper and lower bounds on the flow of arc j , and \hat{f}_j is a real valued convex function on the real line \mathbb{R} . In this case $g_j(t_j)$ is linear for $|t_j|$ large enough with slopes l_j and c_j as t_j approaches $-\infty$ and $+\infty$, respectively (see Fig. 1.1).

Problem (4) is called the *optimal distribution problem* in Rockafellar [3]. The same reference develops in detail a duality theory (a refinement of what can be obtained from Fenchel's duality theorem) involving the dual problem

$$(8) \quad \begin{aligned} &\text{minimize} && g(t) \triangleq \sum_{j \in A} g_j(t_j) \\ &\text{subject to} && t \in C^\perp \end{aligned}$$

where t is the vector with coordinates t_j , $j \in A$, and C^\perp is the orthogonal complement of C . We call t_j the *tension* of the arc j and C^\perp the *tension subspace*. From (1)–(3) and

FIG. 1.1. Primal cost function of the form (7) and its dual.

(5) we have that $t \in C^\perp$ if and only if there exist scalars p_i , $i \in N$, called *prices*, such that

$$(9) \quad t_j = p_i - p_k \quad \forall j \in A \text{ with } j \sim (i, k),$$

or equivalently

$$(10) \quad t = E^T p$$

where E^T is the transpose of the network incidence matrix E and p is the vector with coordinates p_i , $i \in N$. Therefore the dual problem (8) can also be written as

$$(11) \quad \begin{array}{ll} \text{minimize} & q(p) \\ \text{subject to} & \text{no constraints on } p \end{array}$$

where q is the *dual functional*

$$(12) \quad q(p) = \sum_{\substack{j \in A \\ j \sim (i, k)}} g_j(p_i - p_k).$$

As shown in [3, p. 349], Assumption A guarantees that there is no duality gap in the sense that the primal and dual optimal costs are opposites of each other.

An important fact for the purposes of the present paper is that (in view of Assumption B above) *the dual problem (11) is an unconstrained optimization problem*. If each function f_j is strictly convex, the dual functional is also differentiable ([4, p. 253]) and as a result unconstrained smooth optimization methods can be applied for solution. This is particularly so since the gradient of the dual cost can be easily calculated. Indeed, when f_j is strictly convex, for every tension vector t there exists a unique flow vector x such that

$$(13) \quad x_j = \arg \max_{z_j} \{t_j z_j - f_j(z_j)\} \quad \forall j \in A$$

and it can be shown [4, p. 218] that x_j is the gradient of g_j at t_j

$$(14) \quad x_j = \nabla g_j(t_j) \quad \forall j \in A.$$

From (1) and (12) we see that for a given price vector p the partial derivatives of the dual functional q are given by

$$(15) \quad \frac{\partial q(p)}{\partial p_i} = \sum_{j \in A} e_{ij} \nabla g_j(t_j) \quad \forall i \in N.$$

Equivalently (cf. (2)), *the partial derivative $\partial q(p)/\partial p_i$ equals the deficit of node i when the arc flows x_j are the unique scalars defined by (13)*.

The differentiability of the dual cost when the primal cost is strictly convex motivates a Gauss-Seidel type of algorithm whereby, given a price vector p , one calculates the corresponding flows $x_j = \nabla g_j(t_j)$, $j \in A$, chooses a node i with positive (negative) deficit and decreases (increases) p_i up to the point where the corresponding partial derivative $\partial q/\partial p_i$ becomes zero. (This amounts to minimizing the dual functional q along the coordinate p_i .) One then repeats the procedure iteratively. The algorithm above is attractive not only because of its simplicity but also because *it lends itself naturally to distributed computation*, whereby minimization along different price coordinates is carried out simultaneously by several processors. Indeed, this can be done

in an asynchronous format as described and analyzed in Bertsekas and El Baz [5]. Simulations of a synchronous parallel method of this type [19] have shown remarkable speedup in computation time.

Gauss-Seidel relaxation methods for unconstrained optimization have been studied extensively [6]–[10]. However they typically require for convergence something like a strict convexity assumption on the cost minimized as well as boundedness of its level sets (see [10] for a counterexample). Unfortunately the dual cost (12) always has unbounded level sets since adding the same constant to all node prices leaves the cost unchanged. Even if we remove this degree of freedom by restricting the price of some special node to be zero (i.e. passing to a quotient space), the dual cost may still have unbounded levels sets and is not strictly convex when the functions f_j are nondifferentiable as in the important special case (7) where they imply capacity constraints. One contribution of the present paper (§ 2) is to show convergence of a flow sequence generated by the Gauss-Seidel method to the unique optimal solution of the primal problem (4). Convergence of the corresponding price vector sequence to some optimal solution of the dual problem (11) is also shown assuming the dual has an optimal solution. For this we actually require that the minimization along coordinates be done only approximately. Furthermore nodes can be relaxed in arbitrary order. The only requirement is that each node is relaxed infinitely often. This result is new and is remarkable in that it requires a rather unconventional method of proof. It improves on a result by Pang [11] (see also an earlier paper by Cottle and Pang [12]) which asserts convergence of the flow vector sequence under the assumption that g_j is of the form (7) with \hat{f}_j differentiable, and strongly convex (rather than just strictly convex as we assume). Pang's result requires exact minimization along each coordinate and contains no assertion on convergence of the price vector sequence; however it applies to a more general problem where the primal cost function need not be separable and the linear constraints need not have a network structure. The paper by Cottle and Pang [12] asserts subsequence convergence to a dual optimal solution for a transportation problem with quadratic arc costs but also uses a nondegeneracy assumption and places a restriction in the way relaxation is carried out. This result is strengthened in our analysis as described above.

When some of the arc cost functions f_j are not strictly convex, the dual cost is not differentiable, and the Gauss-Seidel method breaks down. However Bertsekas [1] and Bertsekas and Tseng [2] have proposed methods that are conceptually related to Gauss-Seidel and work with linear arc costs. They allow line minimization along directions involving several coordinates to cope with situations where minimizing along a single coordinate is not possible. Computational experimentation with standard benchmark problems and a code named RELAX [1], [2] shows that these methods are very promising and outperform, in terms of computation time, some of the best primal simplex and primal dual codes currently available. The second objective of this paper is to propose in § 3 a new relaxation method that in some sense bridges the gap between the strictly convex arc cost Gauss-Seidel method described earlier and the Bertsekas-Tseng linear arc cost version. We show that this method works with both linear and nonlinear (convex) arc costs and contains as special cases both relaxation methods described above. To our knowledge the only other known algorithm for network problems with both linear and nonlinear, possibly nondifferentiable, arc costs is Rockafellar's fortified descent method [3, Chap. 9]. Our algorithm relates in roughly the same way to the Bertsekas-Tseng relaxation method, as Rockafellar's relates to the classical primal-dual method. We note that the methods considered here for linear costs and, more generally, not strictly convex costs are not easily parallelizable. Related

synchronous and asynchronous relaxation methods that admit massive parallelization have been proposed recently in [20], [21].

The last section of the paper provides results of computational experimentation with codes implementing both of the relaxation algorithms proposed.

2. The relaxation method for strictly convex arc costs. In this section in addition to Assumptions A and B, there will be a standing assumption that each f_j is *strictly convex*. Two important consequences of this assumption are that *the optimal flow vector is unique* and *the conjugate functions g_j are differentiable* (in addition to being real valued by Assumption B). Indeed it is easily verified (see also [3] and [4, p. 218]) that we have for all t_j

$$(16) \quad \nabla g_j(t_j) = \arg \max_{x_j} \{t_j x_j - f_j(x_j)\}.$$

Furthermore $\nabla g_j(t_j)$ is the unique scalar x_j satisfying together with t_j the *Complementary Slackness (CS) condition*

$$(17) \quad f_j^-(x_j) \leq t_j \leq f_j^+(x_j)$$

where $f_j^-(x_j)$ and $f_j^+(x_j)$ denote the left and right derivatives of f_j at x_j (see Fig. 2.1). These derivatives are defined in the usual way for x_j in the interior of $\text{dom}(f_j)$. When $-\infty < l_j < c_j$ we define

$$f_j^+(l_j) = \lim_{\xi \downarrow l_j} f_j^+(\xi), \quad f_j^-(l_j) = -\infty.$$

When $l_j < c_j < +\infty$ we define

$$f_j^-(c_j) = \lim_{\xi \uparrow c_j} f_j^-(\xi), \quad f_j^+(c_j) = +\infty.$$

Finally when $l_j = c_j$ we define $f_j^-(l_j) = -\infty$, $f_j^+(c_j) = +\infty$. Note that $\nabla g_j(t_j)$ is continuous and monotonically nondecreasing. We define the *deficit functions* d_i by

$$d_i(p) = \sum_{j \in A} e_{ij} \nabla g_j(t_j) \quad \forall i \in N$$

where $t = E^T p$, and denote by $d(p)$ the vector with coordinates $d_i(p)$. Note that the definition of d is identical to that given in (2), except that here we have used the strict convexity of f_j to express flow and deficit as functions of the dual price vector. In view of the form of the dual functional, the relation above yields

$$d_i(p) = \frac{\partial q(p)}{\partial p_i} \quad \forall i \in N.$$

Since $d_i(p)$ is a partial derivative of a differentiable convex function, we have that $d_i(p)$ is *continuous and monotonically nondecreasing in the coordinate p_i* .

FIG. 2.1. The left and right derivatives of f_j .

We now define a Gauss-Seidel type of algorithm similar to the one sketched in § 1 whereby at each iteration a node s with positive (negative) deficit $d_s(p)$ is chosen and p_s is decreased (increased) with the aim of decreasing the dual cost $q(p)$. More formally, we initially choose a price vector p and a fixed scalar δ in the interval $(0, 1)$. Then we execute repeatedly the relaxation iteration described below.

Relaxation iteration for strictly convex arc costs.

If $d_i(p) = 0 \forall i \in N$ then STOP.

Else

Choose any node s . Set $\beta = d_s(p)$.

If $\beta = 0$, do nothing.

If $\beta > 0$, then decrease p_s so that $0 \leq d_s(p) \leq \delta\beta$.

If $\beta < 0$, then increase p_s so that $0 \geq d_s(p) \geq \delta\beta$.

The only assumption we make regarding the order in which nodes are chosen for relaxation is the following.

Assumption C. Every node in N is chosen as the node s in the relaxation iteration an infinite number of times.

The relaxation iteration is well defined, in the sense that every step in the iteration is executable. To see this suppose that $\beta > 0$ and there does not exist a $\Delta < 0$ such that $d_s(p + \Delta e_s) \leq \delta\beta$, where e_s denotes the s th coordinate vector. Then using the definition of d , l_j , and c_j , it is easily seen that

$$\lim_{\Delta \rightarrow -\infty} d_s(p + \Delta e_s) = \sum_{e_{sj} > 0} e_{sj} l_j + \sum_{e_{sj} < 0} e_{sj} c_j \geq \delta\beta > 0,$$

which implies that the flow deficit of node s is positive for any flow x within the upper and lower arc capacity bounds and contradicts the existence of a feasible flow (Assumption A). An analogous argument can be made for the case where $\beta < 0$.

In order to obtain our convergence result we must show that the sequence of flow vectors generated by the relaxation algorithm approaches the circulation subspace C (given by (5)). The line of argument that we will use is as follows: We will lower bound the amount of improvement in the dual functional q per iteration by a positive quantity. We will then show that if the sequence of flow vectors do not approach the circulation subspace, the quantity itself can be lower bounded by a positive constant which implies that the optimal dual functional has a value of $-\infty$. This will contradict the finiteness of the optimal primal cost.

We will denote the price vector generated at the r th iteration by p^r , $r = 0, 1, 2, \dots$ and the node operated on at the r th iteration by s^r , $r = 0, 1, 2, \dots$. To simplify notation we will denote

$$t^r = E^T p^r, \quad x_j^r = \nabla g_j(t_j^r).$$

We denote by x^r the vector with coordinates x_j^r , $j \in A$. Note the symmetry following from the CS condition (16) or (17): x_j^r is the gradient of the dual cost g_j at t_j^r , while t_j^r is a subgradient of the primal cost f_j at x_j^r . For any directed cycle Y of the network we will use Y^+ to denote the set of arcs $\{j \in A \mid j \text{ is positively oriented in } Y\}$, and Y^- to denote $Y \setminus Y^+$. We first show three preliminary results.

PROPOSITION 2.1. *We have for all r such that $p^{r+1} \neq p^r$ [i.e. $d_{s^r}(p^r) \neq 0$]*

$$(18) \quad q(p^r) - q(p^{r+1}) \geq \sum_{j \in A} [f_j(x_j^{r+1}) - f_j(x_j^r) - (x_j^{r+1} - x_j^r) t_j^r] > 0,$$

with equality holding if line minimization is used [$d_{s^r}(p^{r+1}) = 0$].

Proof. Fix an index $r \geq 0$. Denote $s = s^r$ and $\Delta = p_s^{r+1} - p_s^r$. From (6), (12) and (16) we have

$$q(p^r) = \sum_{j \in A} [t_j^r x_j^r - f_j(x_j^r)] \quad \forall r \geq 0.$$

Therefore

$$\begin{aligned} q(p^r) - q(p^{r+1}) &= \sum_{j \in A} [t_j^r x_j^r - f_j(x_j^r)] - \sum_{j \in A} [t_j^{r+1} x_j^{r+1} - f_j(x_j^{r+1})] \\ &= \sum_{j \in A} [t_j^r x_j^r - f_j(x_j^r)] - \sum_{j \in A} [(t_j^r + e_{sj} \Delta) x_j^{r+1} - f_j(x_j^{r+1})] \\ &= \sum_{j \in A} [f_j(x_j^{r+1}) - f_j(x_j^r) - (x_j^{r+1} - x_j^r) t_j^r - e_{sj} \Delta x_j^{r+1}] \\ &= \sum_{j \in A} [f_j(x_j^{r+1}) - f_j(x_j^r) - (x_j^{r+1} - x_j^r) t_j^r] - \Delta \sum_{j \in A} e_{sj} x_j^{r+1} \\ &= \sum_{j \in A} [f_j(x_j^{r+1}) - f_j(x_j^r) - (x_j^{r+1} - x_j^r) t_j^r] - \Delta d_s(p^{r+1}). \end{aligned}$$

Since $\Delta d_s(p^{r+1}) \leq 0$ (and $d_s(p^{r+1}) = 0$ if we use line minimization) the left side of (18) follows. The right side of (18) follows from the strict convexity of f_j and the fact $x_j^{r+1} \neq x_j^r$. QED

PROPOSITION 2.2. *The sequence $\{x^r\}$ is bounded.*

Proof. We first note that at every iteration the total deficit does not increase, i.e.,

$$\sum_{i \in N} |d_i(p^{r+1})| \leq \sum_{i \in N} |d_i(p^r)|.$$

(This follows from the fact that a flow change on an arc reflects itself in a change of the deficit of its start node and an opposite change in the deficit of its end node. Furthermore the deficit of node s^r chosen for relaxation at the r th iteration cannot increase in absolute value or change sign during that iteration.) It follows that $\{d(p^r)\}$ is bounded. We now argue by contradiction. Suppose $\{x^r\}$ is unbounded. Then there must exist an arc j and a subsequence R such that $|x_j^r| \rightarrow +\infty$ as $r \rightarrow \infty$, $r \in R$. Since $\{d(p^r)\}$ is bounded it follows (passing into another subsequence if necessary) that there exists a directed cycle Y such that $x_j^r \rightarrow +\infty$ for all $j \in Y^+$, and $x_j^r \rightarrow -\infty$ for all $j \in Y^-$ as $r \rightarrow \infty$, $r \in R$. Since by the CS condition (17)

$$f_j^-(x_j^r) \leq t_j^r \leq f_j^+(x_j^r),$$

and also

$$\sum_{j \in Y^+} t_j^r - \sum_{j \in Y^-} t_j^r = 0,$$

we have for all r

$$\sum_{j \in Y^+} f_j^-(x_j^r) - \sum_{j \in Y^-} f_j^+(x_j^r) \leq 0.$$

This is a contradiction since $x_j^r \rightarrow +\infty$ implies $f_j^-(x_j^r) \rightarrow +\infty$ while $x_j^r \rightarrow -\infty$ implies $f_j^+(x_j^r) \rightarrow -\infty$. QED

The next result is remarkable in that it shows that under a mild restriction on the way the relaxation iteration is carried out (which is typically very easy to satisfy in practice), the sequence of price vectors approaches the dual optimal set in an unusual manner. The result depends on the monotonicity of the functions ∇g_j .

PROPOSITION 2.3. *Given $p \in R^{|N|}$, let s be a node and let \bar{p} denote a dual price vector obtained by applying the relaxation iteration to p using node s . Assume in addition that \bar{p} is chosen so that*

$$(19a) \quad \text{if } d_s(p) > 0 \text{ then } d_s[\bar{p} + \alpha(p - \bar{p})] > 0 \quad \forall \alpha > 0,$$

$$(19b) \quad \text{if } d_s(p) < 0 \text{ then } d_s[\bar{p} + \alpha(p - \bar{p})] < 0 \quad \forall \alpha > 0.$$

Then for all $k \in N$, and all optimal dual price vectors p^ we have*

$$(20) \quad \min \{p_i - p_i^* | i \in N\} \leq \bar{p}_k - p_k^* \leq \max \{p_i - p_i^* | i \in N\}.$$

Note. Assumption (19) when $d_s(p) > 0$ [$d_s(p) < 0$] is equivalent to assuming that \bar{p}_s is chosen greater (less) or equal to the largest (smallest) minimizing point of the dual cost along the s th coordinate starting from p . It is automatically satisfied if the dual cost has a unique minimizing point along the line $\{p + \alpha e_s | \alpha \in R\}$.

Proof. Fix an optimal dual price vector p^* and consider an arbitrary price vector \tilde{p} . Let k be such that $\tilde{p}_k - p_k^* = \max \{\tilde{p}_i - p_i^* | i \in N\}$. We have

$$\tilde{p}_k - p_k^* \geq \tilde{p}_i - p_i^* \quad \forall i \neq k$$

so that

$$\tilde{p}_k - \tilde{p}_i \geq p_k^* - p_i^* \quad \forall j \sim (k, i), \quad \tilde{p}_i - \tilde{p}_k \leq p_i^* - p_k^* \quad \forall j \sim (i, k).$$

Since ∇g_j is a nondecreasing function, we have that

$$\nabla g_j(\tilde{p}_k - \tilde{p}_i) \geq \nabla g_j(p_k^* - p_i^*) \quad \forall j \sim (k, i), \quad \nabla g_j(\tilde{p}_i - \tilde{p}_k) \leq \nabla g_j(p_i^* - p_k^*) \quad \forall j \sim (i, k).$$

Thus $d_k(\tilde{p}) \geq d_k(p^*) = 0$.

The desired assertion (20) holds if $d_s(p) = 0$ since then we have $\bar{p} = p$. Assume that $d_s(p) < 0$. Consider the vector \tilde{p} defined by

$$\tilde{p}_i = \begin{cases} p_i & \text{if } i \neq s, \\ p_s^* + \max \{p_j - p_j^* | j \in N\} & \text{if } i = s. \end{cases}$$

Then we have $\tilde{p}_s - p_s^* = \max \{\tilde{p}_i - p_i^* | i \in N\} = \max \{p_i - p_i^* | i \in N\}$ and by the preceding argument we have $d_s(\tilde{p}) \geq 0$. Therefore, using assumption (19), we have $\bar{p}_s \leq \tilde{p}_s$ while at the same time $p_s < \bar{p}_s$, and $p_i = \bar{p}_i$ for all $i \neq s$. The assertion (20) follows. The proof is similar when $d_s(p) > 0$. Q.E.D.

Note that Proposition 2.3 implies among other things that, if (19) is satisfied at all iterations, the sequence $\{p^r\}$ generated by the relaxation method is bounded. Furthermore if we can show that $\{p^r\}$ accumulates at an optimal price vector, the proposition implies that $\{p^r\}$ must converge to that vector. We are now ready to show our main result.

PROPOSITION 2.4. *Let $\{p^r, x^r\}$ be a sequence generated by the relaxation method for strictly convex arc costs. Then*

$$(21) \quad (a) \quad \lim_{r \rightarrow \infty} d(p^r) = 0.$$

$$(22) \quad (b) \quad \lim_{r \rightarrow \infty} x^r = x^*$$

where x^* is the unique optimal flow vector.

$$(c) \quad \lim_{r \rightarrow \infty} q(p^r) = -f(x^*) = \inf_p q(p).$$

(d) If condition (19) is satisfied at each iteration, and the dual problem has an optimal solution, then

$$(23) \quad \lim_{r \rightarrow \infty} p^r \rightarrow p^*$$

where p^* is some optimal price vector.

Proof. (a) We first show that

$$(24) \quad \lim_{r \rightarrow \infty} d_{s^r}(p^r) = 0.$$

Indeed, if this is not so there must exist an $\varepsilon > 0$ and a subsequence R such that $|d_{s^r}(p^r)| \geq \varepsilon$ for all $r \in R$. Without loss of generality we assume that $d_{s^r}(p^r) \geq \varepsilon$ for all $r \in R$. Since $\delta |d_{s^r}(p^r)| \geq |d_{s^r}(p^{r+1})|$ we have that at the r th iteration some arc incident to node s^r must change its flow by at least Δ where $\Delta = (1 - \delta)\varepsilon/|A|$. By passing to a subsequence if necessary we assume that this happens for the same arc j^* for all $r \in R$, and that $x_{j^*}^{r+1} - x_{j^*}^r \geq \Delta$, for all $r \in R$. Using the boundedness of $\{x^r\}$ (Proposition 2.2) we may also assume that the subsequence $\{x_{j^*}^r\}_{r \in R}$ converges to some x_{j^*} . Using the convexity of f_j and Proposition 2.1 we have

$$\begin{aligned} q(p^r) - q(p^{r+1}) &\geq f_{j^*}(x_{j^*}^{r+1}) - f_{j^*}(x_{j^*}^r) - (x_{j^*}^{r+1} - x_{j^*}^r) t_{j^*}^r \\ &\geq f_{j^*}(x_{j^*}^r + \Delta) - f_{j^*}(x_{j^*}^r) - \Delta t_{j^*}^r \\ &\geq f_{j^*}(x_{j^*}^r + \Delta) - f_{j^*}(x_{j^*}^r) - \Delta f_{j^*}^+(x_{j^*}^r). \end{aligned}$$

Taking the limit as $r \rightarrow \infty$, $r \in R$ and using the facts $x_{j^*}^r \rightarrow x_{j^*}$ and $\lim_{r \rightarrow \infty} f_{j^*}^+(x_{j^*}^r) \leq f_{j^*}^+(x_{j^*})$ (in view of the upper semicontinuity of $f_{j^*}^+$) we obtain

$$\liminf_{\substack{r \rightarrow \infty \\ r \in R}} [q(p^r) - q(p^{r+1})] \geq f_{j^*}(x_{j^*} + \Delta) - f_{j^*}(x_{j^*}) - \Delta f_{j^*}^+(x_{j^*}) > 0.$$

This implies that $\lim_{r \rightarrow \infty} q(p^r) = -\infty$. But this is not possible because from (6) and (12) we have $q(p) \geq -\sum_{j \in A} f_j(x_j)$ for all p and $x \in C$. Therefore (24) is proved by contradiction.

We now show (21). Choose any $i \in N$. Take any $\varepsilon > 0$ and let R be the set of indices r such that $d_i(p^r) > 2\varepsilon$. Assume without loss of generality that $d_i(p^r) < \varepsilon$ for all r with $i = s^r$ (cf. (24)). For every $r \in R$ let r' be the first index with $r' > r$ such that $i = s^{r'}$. Then during iterations $r, r+1, \dots, r'-1$ node i is not chosen for relaxation while its deficit decreases from greater than 2ε to lower than ε . We claim that during these iterations the total deficit $\sum_{k \in N} |d_k(p)|$ is decreased by an amount of more than 2ε . To see this, note that the total absolute deficit cannot increase at any iteration as noted earlier in the proof of Proposition 2.2. Next observe that for any of the iterations $r, r+1, \dots, r'-1$, say \bar{r} , for which the deficit of i is decreased by an amount $\xi > 0$ from a positive value $d_i(p^{\bar{r}}) > 0$, it must be that the node s chosen for relaxation is a neighbor of i and has a negative deficit $d_s(p^{\bar{r}}) < 0$. Since all increase in $d_s(p^r)$ during the iteration must be matched by decreases of the deficits of the neighbor nodes of s , and the deficit of s will remain nonpositive after the iteration, it follows that the total absolute deficit will be decreased by at least $2 \min \{\xi, d_i(p^{\bar{r}})\}$ during the iteration. This shows that during iterations $r, r+1, \dots, r'-1$ the total absolute deficit must decrease by more than 2ε . It follows that the set R of indices r for which $d_i(p^r) > 2\varepsilon$ cannot be infinite. Since $\varepsilon > 0$ is arbitrary we obtain $\limsup_{r \rightarrow \infty} d_i(p^r) \leq 0$. Similarly we can show that $\liminf_{r \rightarrow \infty} d_i(p^r) \geq 0$ and therefore $d_i(p^r) \rightarrow 0$.

(b) For all r and arcs j we have the CS condition

$$(25) \quad f_j^-(x_j^r) \leq t_j^r \leq f_j^+(x_j^r).$$

If Y is any cycle we have

$$\sum_{j \in Y^+} t_j^r - \sum_{j \in Y^-} t_j^r = 0,$$

so from (25) we obtain

$$(26) \quad \sum_{j \in Y^+} f_j^-(x_j^r) - \sum_{j \in Y^-} f_j^+(x_j^r) \leq 0 \leq \sum_{j \in Y^+} f_j^+(x_j^r) - \sum_{j \in Y^-} f_j^-(x_j^r).$$

Let $\{x^r\}_{r \in R}$ be a subsequence converging to some \bar{x} (cf. Proposition 2.2). Then from (26) and the lower (upper) semicontinuity of $f_j^-(f_j^+)$, we have for all cycles Y

$$\sum_{j \in Y^+} f_j^-(\bar{x}_j) - \sum_{j \in Y^-} f_j^+(\bar{x}_j) \leq 0 \leq \sum_{j \in Y^+} f_j^+(\bar{x}_j) - \sum_{j \in Y^-} f_j^-(\bar{x}_j),$$

while from part (a) we have $\bar{x} \in C$. This implies that \bar{x} is an optimal flow ([3, Chap. 8]) and therefore must be equal to the unique optimal flow x^* . Since, by Proposition 2.2, $\{x^r\}$ is bounded we obtain $x^r \rightarrow x^*$.

(c) For every arc j for which $l_j < c_j$ there are three possibilities:

- (1) $\{t_j^r\}$ is bounded.
- (2) $x_j^* = c_j < +\infty$, $x_j^r \leq x_j^*$ and $-\infty < \liminf_{r \rightarrow \infty} t_j^r \leq \limsup_{r \rightarrow \infty} t_j^r = +\infty$.
- (3) $x_j^* = l_j > -\infty$, $x_j^r \geq x_j^*$ and $-\infty = \liminf_{r \rightarrow \infty} t_j^r \leq \limsup_{r \rightarrow \infty} t_j^r < +\infty$,

while for an arc j with $l_j = c_j$ we must have $x_j^* = x_j^r$ for all r . Using this fact we can easily see that we can construct a subsequence R such that

$$\sum_{j \in A} t_j^r(x_j^r - x_j^*) \leq \sum_{j \in B} t_j^r(x_j^r - x_j^*) \quad \forall r \in R$$

where B is a set of arcs j such that $\{t_j^r\}_R$ is bounded. We have (since $t^r \in C^\perp$, $x^* \in C$, and therefore $\sum_{j \in A} t_j^r x_j^* = 0$)

$$f(x^r) + q(p^r) = \sum_{j \in A} t_j^r x_j^r = \sum_{j \in A} t_j^r(x_j^r - x_j^*) \leq \sum_{j \in B} t_j^r(x_j^r - x_j^*).$$

Since $x_j^r \rightarrow x_j^*$ and $\{t_j^r\}_R$ is bounded for $j \in B$ we obtain by taking the limit above $f(x^*) + \lim_{r \rightarrow \infty} q(p^r) \leq 0$. On the other hand we have for all p using (6) and (12) $f(x^*) + q(p) \geq 0$. This together with the preceding relation show the desired result.

(d) By Proposition 2.3, $\{p^r\}$ is bounded. Let $\{p^r\}_{r \in R}$ be a subsequence converging to a vector p^* and let $t^* = E^T p^*$. We have for all $j \in A$

$$f_j^-(x_j^r) \leq t_j^r \leq f_j^+(x_j^r) \quad \forall r \in R.$$

It follows using part (b) and the lower (upper) semicontinuity of $f_j^-(f_j^+)$ that for all $j \in A$, $f_j^-(x_j^*) \leq t_j^* \leq f_j^+(x_j^*)$ where x^* is the optimal flow vector. Therefore t^* satisfies together with x^* the complementary slackness conditions and must be dual optimal. Proposition 2.3 shows that $\{p^r\}$ cannot have two different dual optimal price vectors as limit points and the conclusion follows. QED

3. The relaxation method for mixed linear and strictly convex arc costs. We first introduce some terminology. We will say that a point $b \in \text{dom}(f_j)$ is a *breakpoint* of f_j if $f_j^-(b) < f_j^+(b)$. Note that the dual functional q , as given by (12), is separable and is piecewise either linear or strictly convex. Roughly speaking each linear piece (breakpoint) of the primal cost function f_j corresponds to a breakpoint (linear piece) of the dual cost function g_j (see Fig. 3.1).

FIG. 3.1. Correspondence between the breakpoints of f_j and the linear pieces of g_j (and vice versa).

Assumption D. $f_j^+(x_j) > -\infty$ and $f_j^-(x_j) < +\infty$ for all $x_j \in \text{dom}(f_j)$.

In the terminology of ([3, Chap. 8]), Assumption D implies that every feasible primal solution is regularly feasible and guarantees, together with Assumptions A and B, that the dual problem has an optimal solution ([3, p. 360]). For a given $\varepsilon > 0$, we say that $x \in R^{|A|}$ and $p \in R^{|N|}$ satisfy ε -Complementary Slackness (ε -CS for short) if

$$(27) \quad f_j^-(x_j) - \varepsilon \leq t_j \leq f_j^+(x_j) + \varepsilon \quad \forall j \in A$$

where $t = E^T p$. For a given p , (27) defines upper and lower bounds, called ε -bounds, on the flow vector:

$$(28) \quad l_j^\varepsilon = \min \{ \xi | f_j^+(\xi) \geq t_j - \varepsilon \}, \quad c_j^\varepsilon = \max \{ \xi | f_j^-(\xi) \leq t_j + \varepsilon \} \quad \forall j \in A.$$

Then x and p satisfying ε -CS is equivalent to

$$(29) \quad x_j \in [l_j^\varepsilon, c_j^\varepsilon] \quad \forall j \in A$$

where $t = E^T p$. For a given t_j , we can obtain l_j^ε and c_j^ε from the graph of the subdifferential mapping of f_j as shown in Figs. 3.2-3.3. Intuition suggests that if x is in the

FIG. 3.2. Graph of f_j .

FIG. 3.3. Graph of ∂f_j and ε -bounds corresponding to t_j .

circulation subspace C , x and p satisfy ε -CS and ε is small, then both x and p should be near optimal. This idea will be made precise later when we explore the near optimality properties of the solution generated by a relaxation algorithm that uses the notion of ε -CS. The definition of ε -CS is related to the ε -subgradient idea introduced in nondifferentiable optimization in [13] as well as to the fortified descent method of Rockafellar [3]. The latter method, however, for a given p and $t = E^T p$, uses different lower and upper bounds on x_j given by

$$\inf_{\Delta > 0} \frac{g_j(t_j + \Delta) - g_j(t_j) + \varepsilon}{\Delta} \quad \text{and} \quad \sup_{\Delta > 0} \frac{g_j(t_j) - g_j(t_j - \Delta) - \varepsilon}{\Delta}.$$

Our bounds of (28) seem simpler for implementation purposes particularly when some of the cost functions f_j are linear within their effective domain.

For a given x within the ε -bounds, we define the *deficit* of node i as in (2) and say that a sequence of nodes $\{n_1 \cdots n_k\}$ forms a *flow augmenting path* if

$$d_{n_1} < 0, d_{n_k} > 0 \quad \text{and} \quad \begin{cases} x_j < c_j^\varepsilon & \text{if } j \sim (n_m, n_{m+1}), \\ x_j > l_j^\varepsilon & \text{if } j \sim (n_{m+1}, n_m), \end{cases} \quad m \in \{1, \dots, k-1\}.$$

Let

$$\mu_m = \begin{cases} c_j^\varepsilon - x_j & \text{if } j \sim (n_m, n_{m+1}), \\ x_j - l_j^\varepsilon & \text{if } j \sim (n_{m+1}, n_m), \end{cases} \quad m \in \{1, \dots, k-1\}.$$

We will call

$$\mu = \min \{-d_{n_1}, d_{n_k}, \mu_1, \dots, \mu_{k-1}\}$$

the *capacity* of the path. The relaxation algorithm of this section uses the labeling method of Ford and Fulkerson [14] for finding flow augmenting paths and for augmenting flow along them.

For a given tension vector $t \in C$ and any subset of nodes S , we define $C_\varepsilon(S, t)$ by

$$(30) \quad C_\varepsilon(S, t) = \sum_{j \in [S, N \setminus S]} l_j^\varepsilon - \sum_{j \in [N \setminus S, S]} c_j^\varepsilon$$

where we use the notation

$$[S, N \setminus S] = \{j | j \sim (i, k), i \in S, k \notin S\}, \quad [N \setminus S, S] = \{j | j \sim (i, k), i \notin S, k \in S\}.$$

We also define the $|N|$ -vector $u(S)$ by

$$u_i(S) = \begin{cases} -1 & \text{if } i \in S, \\ 0 & \text{if } i \notin S. \end{cases}$$

The importance of these notions is due to the fact that for any $\varepsilon \geq 0$, $C_\varepsilon(S, t) > 0$ implies that $u(S)$ is a dual descent direction at p , where p is any price vector satisfying $E^T p = t$. This follows from the fact that the directional derivative of q at p in the direction $u(S)$ defined by

$$q'(p; u(S)) = \lim_{\Delta \downarrow 0} \frac{q(p + \Delta u(S)) - q(p)}{\Delta}$$

is easily verified to be

$$q'(p; u(S)) = \sum_{j \in [N \setminus S, S]} c_j^0 - \sum_{j \in [S, N \setminus S]} l_j^0 \leq -C_\varepsilon(S, t)$$

where c_j^0, l_j^0 are the ε -bounds corresponding to $\varepsilon = 0$, and we are making use of the fact $c_j^0 \leq c_j^\varepsilon, l_j^0 \geq l_j^\varepsilon$, for all $\varepsilon \geq 0$.

We now describe the relaxation algorithm. The algorithm is iterative and uses the ε -CS idea. The scalar ε is kept fixed throughout the algorithm. At the beginning of

each iteration we have a dual price vector p and a flow vector x satisfying $l_j^\varepsilon \leq x_j \leq c_j^\varepsilon$ for all $j \in A$. If $x \in C$ then we terminate. Otherwise we use labeling to either find a flow augmenting path, in which case a flow augmentation is performed to bring x "closer" to C ; or to find a dual descent direction, in which case a dual descent along this direction is performed. When each f_j is linear within its effective domain, $\varepsilon = 0$, and all problem data is integer, the algorithm coincides with the relaxation method of [1], [2]. When each f_j is strictly convex and $\varepsilon = 0$ the algorithm coincides with the exact line minimization version of the algorithm of the previous section ($\delta = 0$).

Relaxation iteration.

Step 0. Given p and x satisfying $l_j^\varepsilon \leq x_j \leq c_j^\varepsilon$ for all j , let t and d be the corresponding tension and deficit vectors.

Step 1. Pick a node s such that $d_s > 0$. If no such node exists terminate. Else set all nodes to be unlabeled and unscanned. Give the label 0 to node s . Set $S = \emptyset$ and go to Step 2.

Step 2. Choose a labeled but unscanned node k . Set $S \leftarrow S \cup \{k\}$ and go to Step 3.

Step 3. Scan the label of the node k as follows: Give the label k to all unlabeled nodes m such that $x_j < c_j^\varepsilon$ for $j \sim (m, k)$ and to all unlabeled nodes m such that $x_j > l_j^\varepsilon$ for $j \sim (k, m)$. If $C_\varepsilon(S, t) > 0$ then go to Step 5. Else if for any of the nodes m labeled from k we have $d_m < 0$ then go to Step 4. Else go to Step 2.

Step 4. (Flow Augmentation Step). A flow augmenting path has been found which starts at the node m (with $d_m < 0$) identified in Step 3 and ends at the node s . The path can be constructed by tracing labels starting from m . Let μ be the capacity of the path. Increase by μ the flow of all arcs on the path oriented in the direction from m to s , decrease by μ the flow of all other arcs on the path. Update the deficit vector d and return.

Step 5. (Dual Descent Step). Determine λ^* such that

$$q(p + \lambda^* u(S)) = \min_{\lambda > 0} \{q(p + \lambda u(S))\}.$$

Set $p \leftarrow p + \lambda^* u(S)$ and update the bounds l_j^ε and c_j^ε . Update x to maintain the ε -CS condition $l_j^\varepsilon \leq x_j \leq c_j^\varepsilon$ and return.

Validity and finite termination of the relaxation iteration. We will show that, under Assumption D, all steps in the Relaxation Iteration are executable and that the iteration terminates in a finite number of operations.

Steps 0, 1, and 3 are trivially executable. Step 2 is certainly executable on its first pass since the node s is labeled but unscanned. To show that it remains executable on subsequent passes we only need to verify that each time we go to Step 2 from Step 3 there always exists a labeled but unscanned node. In Step 2, if all labeled nodes are also scanned we have

$$\begin{aligned} \sum_{i \in S} d_i &= \sum_{j \in [S, N \setminus S]} x_j - \sum_{j \in [N \setminus S, S]} x_j \\ &= \sum_{j \in [S, N \setminus S]} l_j^\varepsilon - \sum_{j \in [N \setminus S, S]} c_j^\varepsilon = C_\varepsilon(S, t). \end{aligned}$$

Since node s has positive deficit and all other labeled nodes have nonnegative deficits we obtain that $C_\varepsilon(S, t) > 0$ and therefore in the previous pass through Step 3 we would have branched to Step 5 rather than to Step 2. Step 4 is executable since the rule for

labeling ensures that a flow augmenting path exists from node m to node s , so a flow augmentation is possible. Step 5 is executable since $C_\varepsilon(S, t) > 0$ implies that $u(S)$ is a dual descent direction at p , and we can show that there exists a minimizing stepsize λ^* . To see this assume the contrary, i.e., that there does not exist a stepsize λ^* achieving the minimum along the direction $u(S)$. In that case the convexity of q implies that

$$q'(p + \lambda u(S); u(S)) < 0 \quad \forall \lambda > 0,$$

$$\lim_{\lambda \rightarrow +\infty} q'(p + \lambda u(S); u(S)) \leq 0.$$

Then it can be easily seen that either

$$\sum_{j \in [S, N \setminus S]} l_j - \sum_{j \in [N \setminus S, S]} c_j > 0,$$

in which case Assumption A is violated [$\text{dom}(f) \cap C$ is empty], or

$$\sum_{j \in [S, N \setminus S]} l_j - \sum_{j \in [N \setminus S, S]} c_j = 0$$

and either $f_j^+(l_j) = -\infty$ for some $j \in [S, N \setminus S]$ or $f_j^-(c_j) = +\infty$ for some $j \in [N \setminus S, S]$, in which case Assumption D is violated. To complete the proof that the relaxation iteration terminates in a finite number of operations we note that we cannot loop between Step 2 and Step 3 infinitely often since the number of scanned nodes is increased by one each time we visit Step 3.

We next show that the relaxation algorithm, when applied in conjunction with an easily implementable labeling rule, terminates in a finite number of iterations. The proof may be divided into two separate parts. The first part involves showing that the number of dual descent steps is not infinite. This is done by arguing that the optimal dual cost is necessarily $-\infty$ if the number of dual descent steps is infinite. The second part involves showing that the number of flow augmentations between successive dual descent steps is finite. This is done by choosing an appropriate labeling scheme for the relaxation algorithm and showing that the number of flow augmentations is finite under the chosen scheme. For this purpose we will propose two schemes: *breadth-first search* and *arc discrimination*.

We first show that the stepsize in each dual descent step is bounded from below by ε . Indeed our definition of ε -CS was motivated primarily by this fact.

PROPOSITION 3.1. *The stepsize in each dual descent step is greater than ε .*

Proof. Under Assumption B, $q(p)$ is subdifferentiable everywhere. Let S denote the subset of nodes corresponding to the dual descent direction generated by the relaxation iteration. In other words, the dual descent direction u is given by

$$(31) \quad u_i = \begin{cases} -1 & \text{if } i \in S, \\ 0 & \text{if } i \notin S, \end{cases}$$

and S satisfies $C_\varepsilon(S, t) > 0$. Now consider p' given by $p' = p + \varepsilon u$ and $t' = E^T p'$. Then

$$t'_j = t_j - \varepsilon \quad \text{if } j \in [S, N \setminus S],$$

$$t'_j = t_j + \varepsilon \quad \text{if } j \in [N \setminus S, S],$$

$$t'_j = t_j \quad \text{otherwise,}$$

so that

$$l_j^\varepsilon = \min \{ \xi | f_j^+(\xi) \geq t_j - \varepsilon \} = \min \{ \xi | f_j^+(\xi) \geq t_j' \} \quad \text{for all } j \in [S, N \setminus S],$$

$$c_j^\varepsilon = \max \{ \xi | f_j^-(\xi) \leq t_j + \varepsilon \} = \max \{ \xi | f_j^-(\xi) \leq t_j' \} \quad \text{for all } j \in [N \setminus S, S].$$

Therefore

$$q'(p'; u) = - \sum_{j \in [S, N \setminus S]} l_j^\varepsilon + \sum_{j \in [N \setminus S, S]} c_j^\varepsilon = -C_\varepsilon(S, t) < 0.$$

Since q is convex, $q'(p; u) < 0$ and $q'(p + \varepsilon u; u) < 0$ imply that $q'(p + \alpha u; u) < 0$ for all $\alpha \in [0, \varepsilon]$. Therefore the stepsize in a dual descent step is greater than ε . QED

We will now use Proposition 3.1 to prove that the number of dual descent steps is necessarily finite. The following result is a first step in this direction.

PROPOSITION 3.2. *Let p^r denote the price vector generated by the relaxation algorithm just before the r th dual descent step. Then for each $r \in \{0, 1, 2, \dots\}$*

$$(32) \quad q(p^r) - q(p^{r+1}) > \sum_{\substack{j \in [S', N \setminus S'] \text{ or} \\ j \in [N \setminus S', S']}} [f_j(\Psi_j^r) - f_j(X_j^r) - (\Psi_j^r - X_j^r)t_j'] \geq 0$$

where we define

$$\Psi_j^r = \begin{cases} g_j^+(t_j' - \varepsilon) & \text{if } j \in [S', N \setminus S'], \\ g_j^-(t_j' + \varepsilon) & \text{if } j \in [N \setminus S', S'], \end{cases} \quad X_j^r = \begin{cases} g_j^-(t_j') & \text{if } j \in [S', N \setminus S'], \\ g_j^+(t_j') & \text{if } j \in [N \setminus S', S'], \end{cases}$$

and S^r denotes the node subset corresponding to the descent direction at the r th dual descent step.

Proof. From the definition of Ψ_j^r and X_j^r we have that

$$g_j(t_j') = X_j^r t_j' - f_j(X_j^r), \quad g_j(t_j' - \varepsilon) = \Psi_j^r(t_j' - \varepsilon) - f_j(\Psi_j^r) \quad \forall j \in [S', N \setminus S'],$$

$$g_j(t_j') = X_j^r t_j' - f_j(X_j^r), \quad g_j(t_j' + \varepsilon) = \Psi_j^r(t_j' + \varepsilon) - f_j(\Psi_j^r) \quad \forall j \in [N \setminus S', S'].$$

From the definition of q , S^r and $u(S^r)$ we have that

$$q(p^r + \varepsilon u(S^r)) = q(p^r) + \sum_{j \in [S', N \setminus S']} [g_j(t_j' - \varepsilon) - g_j(t_j')] \\ + \sum_{j \in [N \setminus S', S']} [g_j(t_j' + \varepsilon) - g_j(t_j')]$$

and from Proposition 3.1 we have that

$$q(p^r) - q(p^{r+1}) \geq q(p^r) - q(p^r + \varepsilon u(S^r)).$$

Combining the above three sets of equalities and inequalities we obtain that

$$q(p^r) - q(p^{r+1}) \geq \sum_{j \in [S', N \setminus S']} [[X_j^r t_j' - f_j(X_j^r)] - [(t_j' - \varepsilon)\Psi_j^r - f_j(\Psi_j^r)]] \\ + \sum_{j \in [N \setminus S', S']} [[X_j^r t_j' - f_j(X_j^r)] - [(t_j' + \varepsilon)\Psi_j^r - f_j(\Psi_j^r)]] \\ = \sum_{\substack{j \in [S', N \setminus S'] \text{ or} \\ j \in [N \setminus S', S']}} [f_j(\Psi_j^r) - f_j(X_j^r) - (\Psi_j^r - X_j^r)t_j'] \\ + \varepsilon \left[\sum_{j \in [S', N \setminus S']} \Psi_j^r - \sum_{j \in [N \setminus S', S']} \Psi_j^r \right].$$

Since

$$\begin{aligned} \sum_{j \in [S^r, N \setminus S^r]} \Psi_j^r - \sum_{j \in [N \setminus S^r, S^r]} \Psi_j^r &= \sum_{j \in [S^r, N \setminus S^r]} g_j^+(t_j^r - \varepsilon) - \sum_{j \in [N \setminus S^r, S^r]} g_j^-(t_j^r + \varepsilon) \\ &\geq \sum_{j \in [S^r, N \setminus S^r]} g_j^-(t_j^r - \varepsilon) - \sum_{j \in [N \setminus S^r, S^r]} g_j^+(t_j^r + \varepsilon) \\ &= -q'(p^r + \varepsilon u(S^r); u(S^r)) > 0 \end{aligned}$$

(where the last strict inequality is obtained from Proposition 3.1) the left side of (32) follows. The right side of (32) follows from the convexity of f_j . QED

PROPOSITION 3.3. *Under Assumption D the number of dual descent steps is finite.*

Proof. We will argue by contradiction. Suppose that the number of dual descent steps is infinite. We denote the price vector, the tension vector and the flow vector generated by the relaxation algorithm at the r th dual descent step by p^r , t^r , and x^r , respectively. First we show the following property of the sequence $\{t^r\}$:

For each j

$$(33) \quad \{t_j^r\}_R \rightarrow +\infty \text{ for some subsequence } R \Rightarrow c_j < +\infty, \quad f_j(c_j) < \infty,$$

$$(34) \quad \{t_j^r\}_R \rightarrow -\infty \text{ for some subsequence } R \Rightarrow l_j > -\infty, \quad f_j(l_j) > -\infty.$$

If $\{t^r\}$ is bounded then (33), (34) trivially hold. Consider a subsequence R such that $\{t^r\}_R$ is unbounded. Without loss of generality suppose that, for each arc $j \in A$, $\{t_j^r\}$ is either bounded, or tends to ∞ , or tends to $-\infty$. We now partition N into a collection of nonempty subsets N_0, N_1, \dots, N_L ($L \geq 1$) such that

$$\{(p_i^r - p_k^r)\} \rightarrow \infty \quad \text{if } \alpha > \beta \text{ and } i \in N_\alpha, k \in N_\beta.$$

(One way to construct such a collection is to consider a graph identical to the original except that all arcs j such that $\{t_j^r\}_R$ is bounded are discarded, and all arcs j such that $\{t_j^r\}_R \rightarrow -\infty$ are reversed in their orientation. Since the sum of tensions along a directed cycle is zero we see that this graph is acyclic. The set N_0 is the set of nodes of this acyclic graph having no outgoing arcs. The set N_1 is obtained similarly after all arcs incident to N_0 in the acyclic graph have been discarded, etc.)

For $a = 1, 2, \dots, L$, we define the following arc sets:

$$\begin{aligned} A_a^+ &= \left\{ j \sim (i, k) \mid i \in \bigcup_{\tau \geq a} N_\tau, k \in \bigcup_{\tau < a} N_\tau \right\}, \\ A_a^- &= \left\{ j \sim (i, k) \mid i \in \bigcup_{\tau < a} N_\tau, k \in \bigcup_{\tau \geq a} N_\tau \right\}. \end{aligned}$$

Then each set $A_a^+ \cup A_a^-$ is a cut in the network and

$$(35) \quad \begin{aligned} t_j^r &\rightarrow +\infty, r \in R \quad \text{if and only if } j \text{ belongs to some } A_a^+, \\ t_j^r &\rightarrow -\infty, r \in R \quad \text{if and only if } j \text{ belongs to some } A_a^-. \end{aligned}$$

Consider any fixed positive scalar Δ . Equation (35) implies that for all a

$$(36) \quad \lim_{r \rightarrow \infty, r \in R} g_j^-(t_j^r - \Delta) = c_j \quad \forall j \in A_a^+, \quad \lim_{r \rightarrow \infty, r \in R} g_j^+(t_j^r + \Delta) = l_j \quad \forall j \in A_a^-.$$

Since

$$q'(p^r + \Delta u; u) = - \sum_{j \in A_a^+} g_j^-(t_j^r - \Delta) + \sum_{j \in A_a^-} g_j^+(t_j^r + \Delta)$$

where u is given by

$$u_i = \begin{cases} -1 & \text{if } i \in \bigcup_{\tau \cong a} N_\tau, \\ 0 & \text{otherwise,} \end{cases}$$

it follows from (36) that

$$(37) \quad \lim_{r \rightarrow \infty, r \in R} q'(p^r + \Delta u; u) = - \sum_{j \in A_a^+} c_j + \sum_{j \in A_a^-} l_j.$$

Let Θ denote the right-hand side quantity in (37). We will argue that $\Theta = 0$. Clearly we cannot have $\Theta > 0$ since this would imply that there does not exist a primal feasible solution. We also cannot have $\Theta < 0$ since then (37) implies that for r sufficiently large

$$q(p^r + \Delta u) \leq q(p^r) + \Delta \Theta.$$

This is not possible since Δ can be chosen arbitrarily large while $q(p^r)$ is nonincreasing with r . This leaves the only possibility that $\Theta = 0$ or that

$$\sum_{j \in A_a^+} c_j = \sum_{j \in A_a^-} l_j, \quad a = 1, \dots, L.$$

It follows that for every feasible flow vector we have

$$x_j = c_j \quad \forall j \in A_a^+, \quad x_j = l_j \quad \forall j \in A_a^-, \quad a = 1, \dots, L.$$

This implies (33) and (34).

Now we will bound from below the amount of improvement in the dual cost per dual descent step by a positive constant. Proposition 3.1 assures us that at each dual descent step the step length is more than ε . Consider the interval $[\frac{1}{4}\varepsilon, \frac{3}{4}\varepsilon]$, which we denote by I . Also let u^r denote the dual descent direction at the r th dual descent step. We have that the dual cost is decreasing on the line segment connecting t^r and t^{r+1} . It follows from (33), (34) and Assumption D that there exists a subsequence R such that for r sufficiently large, $r \in R$, we have for all $\Delta \in I$

$$\begin{aligned} q'(p^r + \Delta u^r; u^r) &= \sum_{j \in J^+} c_j v_j^r + \sum_{j \in J^-} l_j v_j^r + \sum_{\substack{j \in J^0 \\ v_j^r > 0}} g_j^+(t_j^r + \Delta v_j^r) v_j^r \\ &\quad + \sum_{\substack{j \in J^0 \\ v_j^r < 0}} g_j^-(t_j^r + \Delta v_j^r) v_j^r < 0 \end{aligned}$$

where we define

$$\begin{aligned} J^+ &= \{j | \{t_j^r\}_{r \in R} \rightarrow \infty\}, & J^- &= \{j | \{t_j^r\}_{r \in R} \rightarrow -\infty\}, \\ J^0 &= \{j | \{t_j^r\}_{r \in R} \text{ is bounded} \} \end{aligned}$$

and $v^r = E^T u^r$. Consider a fixed $r \in R$. Define $\Theta: R \rightarrow R$ by

$$\Theta(\Delta) = q(p^r + \Delta u^r).$$

We consider two cases. In case (i) the right derivative of $\Theta(\Delta)$ assumes at most $2|A|$ distinct values in the interval I . In case (ii) the right derivative of $\Theta(\Delta)$ assumes more than $2|A|$ distinct values in the interval I . In case (i) $q(p^r + \Delta u^r)$ is linear for Δ in some subinterval I' of I of length at least $\varepsilon/4|A|$ and it follows that $q'(p^r + \Delta u^r; u^r)$ over I' is linear of the form

$$(38) \quad q'(p^r + \Delta u^r; u^r) = \sum_{j \in J^+} c_j v_j^r + \sum_{j \in J^-} l_j v_j^r + \sum_{j \in J^0} b_j v_j^r$$

where $v^r = E^T u^r$ and b_j denotes some breakpoint of f_j . This implies that, for each $j \in J^0$ such that $v_j^r \neq 0$, the dual functional $g_j(t_j^r + \Delta v_j^r)$ is linear with slope b_j for Δ in I^r . For each $j \in J^0$, $\{t_j^r\}_{r \in R}$ is bounded, and therefore the number of distinct linear pieces of g_j of length $\geq \varepsilon/4|A|$ encountered during the course of the algorithm is finite. This together with the fact that v^r is chosen from a finite set imply that $q'(p^r + \Delta u^r; u^r)$ (cf. (38)) can only assume one of a finite set of values over the subinterval I^r . It follows that in case (i) we can bound the amount of dual cost improvement from below by $\delta\varepsilon/4|A|$ where δ is some positive scalar. This implies that case (i) can occur for only a finite set of indexes r (for otherwise the dual cost tends to $-\infty$) and we need only to consider case (ii). In case (ii) for each $r \in R$ there must exist a $j \in J^0$ such that $v_j^r \neq 0$ and the right derivative of the function $h(\Delta)$ defined by $h(\Delta) = g_j(t_j^r + \Delta v_j^r)$ assumes at least three distinct values in the interval I . Since v_j^r equals either 1 or -1 it follows that either $t_j^{r+1} \geq t_j^r + \varepsilon$ and $g_j^+(t_j^r + \Delta_1) < g_j^-(t_j^r + \Delta_2)$ for at least two points $\Delta_1 < \Delta_2$ in I or $t_j^{r+1} \leq t_j^r - \varepsilon$ and $g_j^+(t_j^r - \Delta_2) < g_j^-(t_j^r - \Delta_1)$ for at least two points $\Delta_1 < \Delta_2$ in I . Passing to a subsequence if necessary, we can assume that it is the same j and either $t_j^{r+1} \geq t_j^r + \varepsilon$ or $t_j^{r+1} \leq t_j^r - \varepsilon$ for all $r \in R$ that are sufficiently large. Without loss of generality we will assume that $t_j^{r+1} \geq t_j^r + \varepsilon$ for all $r \in R$ that are sufficiently large. Since $j \in J^0$ the subsequence $\{t_j^r\}_{r \in R}$ is bounded and therefore has a limit point t_j^* . Passing to a subsequence if necessary, we assume that $\{t_j^r\}$ converges to t_j^* . Then it follows that there exists a fixed interval L such that

$$(39) \quad L \subset [t_j^r, t_j^r + \varepsilon] \quad \forall r \in R, r \text{ sufficiently large}$$

and

$$\eta_1 < \eta_2 \quad \text{and} \quad g_j^+(\eta_1) < g_j^-(\eta_2)$$

for at least two distinct points η_1 and η_2 in L . We then define

$$\xi_1 = g_j^-(\eta_1), \quad \xi_2 = g_j^+(\eta_2).$$

Then ξ_1 and ξ_2 belong to the interval

$$[g_j^-(a), g_j^+(b)]$$

where a, b are the left and the right endpoints of L , respectively, and they satisfy

$$(40) \quad \xi_1 < \xi_2 \quad \text{and} \quad f_j^+(\xi_1) < f_j^-(\xi_2).$$

Then for r sufficiently large, $r \in R$, we obtain (cf. (39)) that

$$(41) \quad g_j^+(t_j^r) \leq \xi_1 < \xi_2 \leq g_j^-(t_j^r + \varepsilon).$$

It follows from Proposition 3.2 that for all sufficiently large $r \in R$

$$(42) \quad \begin{aligned} q(p^r) - q(p^{r+1}) &\geq f_j(g_j^-(t_j^r + \varepsilon)) - f_j(g_j^+(t_j^r)) - f_j^+(g_j^+(t_j^r))(g_j^-(t_j^r + \varepsilon) - g_j^+(t_j^r)) \\ &\geq f_j(\xi_2) - f_j(\xi_1) - f_j^+(\xi_1)(\xi_2 - \xi_1) \end{aligned}$$

where the second inequality follows from (41) and the convexity of f_j . From (40) and the convexity of f_j we obtain that the right-hand side of (42) is positive. Therefore the dual cost improvement per dual descent is bounded from below by a positive constant, and the dual cost tends to $-\infty$, contradicting Assumption A. QED

The second part of our finite termination proof involves showing that the number of flow augmentations between successive dual descent steps is finite. Since the ε -bounds remain unchanged between successive dual descent steps, the issue in effect is whether the labeling algorithm used will solve finitely the max flow problem with the given ε -bounds taken as capacity constraints. It was shown by Ford and Fulkerson

([14, p. 126]) that, when the data is irrational, an arbitrary choice of labeled nodes may result in an infinite number of flow augmentations, so a more specific scheme for labeling is necessary to deal with irrational data. Here we propose two such schemes: breadth-first search and arc discrimination. In practice, the data is always rational, being stored on a finite precision machine, and therefore finite convergence is assured even if labeling is done arbitrarily.

Breadth-first search is a well-known scheme used in labeling. It can be easily implemented using a FIFO queue. In [15, Chap. 9.3, 16] it was shown that, under breadth-first search, the number of flow augmentations is finite if *all* nodes with positive deficit are labeled initially. We now show that the same conclusion holds if a *single* node with positive deficit is labeled initially, as is the case for the relaxation iteration. This fact requires a nontrivial proof and, to our knowledge, is not reported in the literature.

PROPOSITION 3.4. *When labeling is done by breadth-first search, the number of flow augmentations between successive dual descent steps is finite.*

Proof. We will assume that the number of flow augmentations is infinite and obtain a contradiction. For simplicity, we call a node with negative deficit a *source* and a node with positive deficit a *sink*. Since the number of flow augmentations is infinite, after a while the set of sources and sinks must become fixed (since a source cannot become a sink or vice versa) and the set of flow augmenting paths must repeat (since all flow augmenting paths are simple and therefore there are only a finite number of them). Let P be the set of flow augmenting paths that repeat infinitely often. We say that an arc belonging to a path $p \in P$ is *saturated in the direction of p* if the flow of the arc is at the upper (lower) bound and the arc is oriented from the source (sink) of p to the sink (source) of p .

Consider a path $p \in P$. After a flow augmentation using p as the path, some arc of p will become saturated in the direction of p . Let A_p denote the set of arcs on p that become saturated in the direction of p infinitely often. A_p is clearly nonempty. We will show, by induction, that A_p is empty when breadth-first search is done and thus obtain a contradiction.

Initialization. For all $p \in P$, every $a \in A_p$ is at least one arc away from the sink t of p .

Proof. This is true since if the arc on p incident to t is saturated, it must remain saturated from then on.

kth inductive step. Suppose that, for all $p \in P$, every $a \in A_p$ is at least k arcs away from the sink of p . We will show that, for all $p \in P$, every $a \in A_p$ is $k+1$ arcs away from the sink of p . Suppose the contrary. Then there exists a $p \in P$, whose source and sink we denote by s and t respectively, and an arc a in A_p such that a is k arcs away from t . After a becomes saturated, there must be a flow augmenting path p' to unsaturate it (see Fig. 3.4). From the inductive hypothesis, the arcs on p between a and t are unsaturated in the direction of p . Since the labeling is done by breadth-first search,

FIG. 3.4. p' unsaturating the arc a .

this implies that the number of arcs on the subpath p'_1 (see Fig. 3.4) must be *strictly* less than that of the subpath p_1 (otherwise during the iteration that generated p' as the flow augmenting path node t would have been labeled before node t'). It follows that, just before the iteration that generated path p , some arc of the subpath p'_1 must be saturated in the direction of p' (otherwise during the iteration that generated p node t' would be labeled before node t). This arc must then belong to $A_{p'}$. Since the number of arcs on p'_1 is strictly less than k , the inductive hypothesis is contradicted.

Since the inductive hypothesis holds for all k and the number of arcs on each flow augmenting path is at most $|N| - 1$, it follows that A_p is empty for all p and the desired contradiction is obtained. QED

In the arc discrimination scheme, the order in which nodes are labeled and scanned is given by the following simple rule:

Each labeled but unscanned node records whether it is connected to an unlabeled neighbor by an arc whose flow is strictly between the lower and upper bounds. A node with such a neighbor is scanned first.

The proof of finite convergence under this scheme is given in [17]. The implementation of the arc discrimination scheme requires more global information than breadth-first search. However, when the relaxation algorithm is extended to operate on both positive and negative deficit nodes between successive dual descent steps, which had been shown to be computationally beneficial in the case of linear cost problems, arc discrimination can still be shown to yield finite convergence. It is not known if this is also true of breadth-first search.

Propositions 3.3 and 3.4 show that the relaxation algorithm of this section terminates after a finite number of iterations. Since the algorithm only terminates when all the node deficits have zero value, the final flow vector x must belong to C . Since ε -CS is maintained at all iterations of the algorithm, it follows that x and the final dual price vector must satisfy ε -CS also.

We next show that we can bring the cost of the solution generated by the relaxation algorithm arbitrarily close to the optimal cost by taking ε sufficiently small. The main part of the argument is embodied in the next proposition.

PROPOSITION 3.5. *Let x and p satisfy ε -CS, and let ξ and p satisfy CS. If $x \in C$ then*

$$0 \leq f(x) + q(p) \leq \varepsilon \sum_{j \in A} |x_j - \xi_j|.$$

Proof. Let $t = E^T p$. Since ξ and p satisfy CS we have

$$f_j(\xi_j) = \xi_j t_j - g_j(t_j) \quad \forall j \in A.$$

Take an arc j such that $x_j \geq \xi_j$. Then by convexity of f_j

$$f_j(x_j) + (\xi_j - x_j)f_j^-(x_j) \leq f_j(\xi_j) = \xi_j t_j - g_j(t_j).$$

Hence

$$\begin{aligned} f_j(x_j) + g_j(t_j) &\leq (x_j - \xi_j)(f_j^-(x_j) - t_j) + x_j t_j \\ &\leq |x_j - \xi_j| \varepsilon + x_j t_j \end{aligned}$$

where the second inequality follows from ε -CS. This inequality is similarly obtained when $x_j \leq \xi_j$, so we have

$$f_j(x_j) + g_j(t_j) \leq |x_j - \xi_j| \varepsilon + x_j t_j \quad \forall j \in A.$$

From the definition of g_j we also have

$$x_j t_j \leq f_j(x_j) + g_j(t_j) \quad \forall j \in A.$$

By combining these two inequalities and adding over all $j \in A$, we obtain

$$\sum_{j \in A} x_j t_j \leq \sum_{j \in A} [f_j(x_j) + g_j(t_j)] \leq \varepsilon \sum_{j \in A} |x_j - \xi_j| + \sum_{j \in A} x_j t_j.$$

Since $x \in C$ we have $\sum_{j \in A} x_j t_j = 0$ and the result follows. QED

From Proposition 3.5 we can obtain a simple bound on the suboptimality of the solution in the special case where $l_j > -\infty$ and $c_j < +\infty$ for all $j \in A$.

COROLLARY 3.1. *Let x and p satisfy ε -CS. If $x \in C$, and $-\infty < l_j \leq c_j < +\infty$ for all $j \in A$, then*

$$0 \leq f(x) + q(p) \leq \varepsilon \sum_{j \in A} (c_j - l_j).$$

For the general case we have the following.

PROPOSITION 3.6. *Let $x(\varepsilon)$ and $p(\varepsilon)$ denote any flow and price vector pair such that $x(\varepsilon)$ and $p(\varepsilon)$ satisfy ε -CS and $x(\varepsilon) \in C$. Then $f(x(\varepsilon)) + q(p(\varepsilon)) \rightarrow 0$ as $\varepsilon \rightarrow 0$.*

Proof. First we show that $x(\varepsilon)$ remains bounded as $\varepsilon \rightarrow 0$. If $x(\varepsilon)$ is not bounded as $\varepsilon \rightarrow 0$, then since $x(\varepsilon) \in C$ for all $\varepsilon > 0$ there exists a directed cycle Y and a sequence $\{\varepsilon_n\} \rightarrow 0$ such that $c_j = +\infty$, $x_j(\varepsilon_n) \rightarrow +\infty$ for all $j \in Y^+$ and $l_j = -\infty$, $x_j(\varepsilon_n) \rightarrow -\infty$ for all $j \in Y^-$. By Assumption B

$$\lim_{\xi \rightarrow +\infty} f_j^-(\xi) = +\infty \quad \text{for all } j \in Y^+, \quad \lim_{\xi \rightarrow -\infty} f_j^+(\xi) = -\infty \quad \text{for all } j \in Y^-.$$

This implies that for n sufficiently large,

$$(43) \quad t_j(\varepsilon_n) > t_j(\varepsilon_0) \quad \text{for all } j \in Y^+ \quad \text{and} \quad t_j(\varepsilon_n) < t_j(\varepsilon_0) \quad \text{for all } j \in Y^-$$

where $t(\varepsilon_n) = E^T p(\varepsilon_n)$. Since $t(\varepsilon_n) = E^T p(\varepsilon_n)$ we have

$$\sum_{j \in Y^+} t_j(\varepsilon_n) - \sum_{j \in Y^-} t_j(\varepsilon_n) = 0 \quad \text{for all } n,$$

which contradicts (43). Therefore $x(\varepsilon)$ is bounded as $\varepsilon \rightarrow 0$.

Now we will show that $\xi_j(\varepsilon) - x_j(\varepsilon)$ is bounded for all $j \in A$ as $\varepsilon \rightarrow 0$, where $\xi(\varepsilon)$ is some vector satisfying $f_j^-(\xi_j(\varepsilon)) \leq t_j(\varepsilon) \leq f_j^+(\xi_j(\varepsilon))$, for all $j \in A$. If $c_j < \infty$ then $\xi_j(\varepsilon)$ is trivially bounded from above. If $c_j = +\infty$ then by Assumption B we have $f_j^-(\xi) \rightarrow +\infty$ as $\xi \rightarrow +\infty$. Since $x_j(\varepsilon)$ is bounded we have that $t_j(\varepsilon)$ is bounded from above which in turn implies that $\xi_j(\varepsilon)$ is bounded from above. Similarly, we can argue that $\xi_j(\varepsilon)$ is bounded from below. Therefore $|\xi_j(\varepsilon) - x_j(\varepsilon)|$ is bounded for all $j \in A$ as $\varepsilon \rightarrow 0$. This then completes our proof in view of Proposition 3.5. QED

Unfortunately Proposition 3.6 does not tell us how small ε must be to achieve a certain degree of near optimality. We need to solve the problem first for some guess ε to obtain $x(\varepsilon)$ and $\xi(\varepsilon)$, evaluate the quality of the solution on the basis of the gap $f(x(\varepsilon)) + q(p(\varepsilon))$ between primal and dual solution, and then decide whether ε needs to be decreased. If however the bounds l_j and c_j are finite, we can, by Corollary 3.1, obtain an a priori estimate on ε .

4. Computational experimentation. Two experimental codes implementing the methods of the paper were developed and tested on linear benchmark problems and nonlinear variations.

The first code, named NRELAX, implements the relaxation method for strictly convex problems of § 2. The second code, named MNRELAX, implements the method for mixed linear and strictly convex problems of § 3. Both codes were written in Fortran on a VAX 11-750 and were compiled and run under the VMS version 3.7 operating system.

TABLE 1

Times for NETGEN benchmark problems. MNRELAX uses $\varepsilon = 0$. Times in this and subsequent tables are in secs on a VAX 11-750. All codes are written in Fortran and compiled under VMS version 3.7.

The test problems were generated using the public domain code NETGEN [18]. There are 40 "standard" benchmark linear cost problems that can be obtained using this code. We tested our codes with some of these problems either in their standard (linear cost) form or in a modified form whereby a quadratic cost was added to the linear cost of some or all of the arcs as discussed below. In order to test coding efficiency we tested MNRELAX with $\varepsilon = 0$ against the very efficient linear cost code RELAX-II (see [1], [2]) under identical conditions on the first 30 NETGEN benchmark problems. The two codes are close to being mathematically equivalent on linear cost problems but MNRELAX uses floating point arithmetic. The results shown in Table 1 appear to indicate that MNRELAX is coded fairly efficiently.

There were two issues that we wanted to clarify through the experimentation:

- (a) The effect of the parameter ε on the performance of MNRELAX;
- (b) The relative efficiency of NRELAX versus MNRELAX with optimal choice of the parameter ε on strictly convex problems.

A large number of experiments some of which are presented in Tables 2 and 3 showed that for all except some very "difficult" problems it is best to operate

TABLE 2

Times for NETGEN benchmark problems modified so that 50% of the arcs have an additional quadratic cost with coefficient from the range [5, 10]. Numbers in parentheses where present indicate significant digits of accuracy of the answer. In MNRELAX ε is kept constant during the solution of each problem.

MNRELAX with $\varepsilon = 0$ and terminate the iterations when the deficit of all nodes becomes sufficiently close to zero. Indeed it appears that for such problems the time required for MNRELAX to terminate increases with ε . The reason is probably that with large ε the intervals defined by the ε -bounds become larger and, as a result, a large number of flow augmentations are needed before a descent direction can be found. Given that a large value of ε leads also to inaccurate solutions (see Proposition 3.5), it appears that for most problems the best way to operate MNRELAX is with $\varepsilon = 0$ or with ε very small.

When $\varepsilon = 0$ and all arc costs are strictly convex, MNRELAX and NRELAX are mathematically equivalent. However NRELAX is somewhat faster because of more efficient coding as shown in Table 3.

Finally in Table 4 we show results obtained on some "difficult" problems with strictly convex arc costs. These problems were constructed by choosing the quadratic cost coefficients of some arcs to be very small relative to others as described in Table 4. This is similar to a situation in nonlinear unconstrained minimization where the Hessian matrix of the cost function has some eigenvalues that are very small relative to other eigenvalues. For this class of problems MNRELAX with nonzero ε can outperform both NRELAX and MNRELAX with $\varepsilon = 0$. This is not surprising in view of the coordinate descent interpretation of NRELAX. The version of MNRELAX that we found most efficient for these problems is one whereby we start with a moderate value

TABLE 3

Times for NETGEN benchmark problems modified so that all arcs have an additional quadratic cost with coefficient from the range [5, 10]. Numbers in parentheses where present indicate significant digits of accuracy of the answer. In MNRELAX ϵ is kept constant during solution of each problem.

of ϵ , operate MNRELAX to termination, then reduce ϵ by a factor of 10 and repeat the process up to the point where primal and dual values differ by a specified accuracy. Still, the proper starting value for ϵ was not easy to determine and it was necessary to do some initial experimentation with several of these difficult problems. The conclusion is that the methods of this paper may not be successful for such problems. We do not know, however, of a better alternative.

TABLE 4

Times for NETGEN benchmark problems modified so that all arcs have an additional quadratic term. In 50% of the arcs the quadratic cost coefficient was small as indicated. In the other 50% of the arcs the quadratic cost coefficient was from the range [5, 10]. Numbers in parentheses where present indicate significant digits of accuracy of the answer. In MNRELAX ϵ is progressively decreased during solution of each problem.

SOME PROPERTIES OF CONSTRAINED VISCOSITY SOLUTIONS OF HAMILTON-JACOBI-BELLMAN EQUATIONS*

PAOLA LORETI†

Abstract. We consider an optimal control problem with space constraints and we show some properties of the optimal cost function. Our main result is the equality between the value functions of four optimal control problems and the constrained viscosity solution of the Hamilton-Jacobi-Bellman equation.

Key words. optimal control, Hamilton-Jacobi equation, relaxed control, viscosity solution, space constraints

AMS(MOS) subject classification. 49C20

1. Introduction. In this paper we deal with an optimal control problem with state constraints: our goal is to show how to use the existing knowledge on solution of Hamilton-Jacobi-Bellman equations in order to prove various properties of the optimal cost function.

We want to explain briefly what we mean by optimal control problems with state constraints. Let Ω be a smooth open set of \mathbb{R}^n . We consider the optimal control of the solution of an ordinary differential equation (the state process) where the control acts on the coefficients of the equation. The problem is to minimize a certain cost function over all controls such that the state process remains in $\bar{\Omega}$ (the closure of Ω) for all $t \geq 0$.

To explain our results, let us first recall a few facts. As is well known, a certain nonlinear partial equation called the Hamilton-Jacobi-Bellman equation is associated with general optimal control problems via the dynamic programming principle. This equation is of the form

$$(H-J) \quad u(x) + H(x, Du(x)) = 0 \quad \text{in } \Omega$$

where u is a scalar function on $\bar{\Omega}$; where Du is the gradient of u ; and H , called the Hamiltonian, is a continuous function on $\bar{\Omega} \times \mathbb{R}^n$. Our results will use the notion of the viscosity solution of (H-J) equations introduced in [3], [4]. In [6] it is proved that the usual dynamic programming argument shows that the optimal cost function (the value function) is a viscosity solution for the associated Hamilton-Jacobi-Bellman equation. On the other hand, the knowledge that there exists a unique viscosity solution of the Hamilton-Jacobi-Bellman equation, without knowing a priori whether the value function is continuous, implies that this solution is the value function [7], [8].

The optimal control problems we consider are different from those treated in [7], [8] by the state constraints we are imposing which should yield a particular boundary condition on $\partial\Omega$ for the value function. M. H. Soner [9] introduced a notion of constrained viscosity solution which combines the usual viscosity formulation in Ω and a related formulation on $\partial\Omega$.

We recall the definition in § 2. It is easy (see [9], [2]) to check that the value function is such a constrained viscosity solution if we know it is continuous on $\bar{\Omega}$. In addition uniqueness of constrained viscosity solutions was proved by Soner [9] and general existence results are obtain in [2] by PDE techniques.

Therefore, to characterize the value function as the unique constrained viscosity solution two strategies are possible. The first consists in proving that the value function

* Received by the editors May 19, 1986; accepted for publication (in revised form) September 3, 1986. This work was done while the author was visiting C  remade-Universit   Paris IX and was sponsored by Consiglio Nazionale Delle Ricerche under grant 203.01.36.

† Dipartimento di Matematica, Universit   di Rome, P. le Aldo Moro 5, 00100 Rome, Italy.

of an optimal control problem with state constraints is a continuous function. Then one concludes using the above results. This is what was proven by M. H. Soner [9]. In [9] it is proven that an appropriate geometric assumption implies that the value function is continuous on $\bar{\Omega}$. The second strategy uses the existence of a unique constrained viscosity solution of the Hamilton–Jacobi–Bellman associated with our control problem which is

$$(H-J-B) \quad u(x) + \max_{a \in A} \{-b(x, a) \cdot Du(x) - f(x, a)\} = 0.$$

Our goal is to show that this existence result (with some additional information on the approximation of the solution) enables us to check directly that the unique constrained viscosity solution is the value function. Even if one of the main results we show is contained in [9] our proof is entirely different and is probably more flexible, allowing us to solve similar problems like optimal control problems with space constraints and different boundary assumptions, and an optimal control problem with a final target. We will come back to these questions in future publications.

In addition, in the course of checking that the constrained viscosity solution is the value function we will show some other results of independent interest. More precisely, we show the equivalence of the value functions obtained by considering three other problems. Two of these, say (\hat{P}) , (\hat{P}_0) , are relaxed optimal control problems with state constraints, respectively, in $\bar{\Omega}$ or Ω . The third one is an optimal control problem with state constraints in Ω , say (P_0) , and we will denote by (P) our original problem. We call \hat{u} , \hat{u}_0 , u_0 , u the value functions of (\hat{P}) , (\hat{P}_0) , (P_0) , (P) , respectively, and \bar{u} the unique constrained viscosity solution of the (H–J–B) equation under the same geometric assumption as in Soner [9] on the controls at the boundary. Then, our main result is

$$(1.1) \quad \bar{u}(x) = \hat{u}(x) = \hat{u}_0(x) = u_0(x) = u(x) \quad \forall x \in \bar{\Omega}.$$

Let us briefly sketch the proof of this result. Our method will rely on [2] where the theory of existence, uniqueness and approximation of constrained viscosity solutions of the (H–J) equation is developed. Our result is achieved in two steps. First, we consider a method to approximate the constrained viscosity solution, introduced in [2]. This method of penalty type consists in extending the problem in \mathbb{R}^n and in introducing a function that penalizes the distance to the set $\bar{\Omega}$. In [2] it is proved that the sequence obtained by this method, which is a sequence of viscosity solutions for an appropriate (H–J) equation in \mathbb{R}^n , converges to the constrained viscosity solution of the (H–J–B) equation. For this approximated problem, the relation between viscosity solutions and both standard and relaxed value functions are well known and we check that passing to the limit they converge to the relaxed value functions \hat{u} .

The second step consists in showing just that

$$(1.2) \quad \hat{u} = \hat{u}_0 \quad \forall x \in \Omega.$$

This is achieved by the use of another approximation method which consists in restricting the (H–J–B) equation in certain appropriate subset Ω , say Ω_δ . We show that the sequence of constrained viscosity solution of the (H–J–B) on $\bar{\Omega}_\delta$ converges to $\hat{u}_0 \in C(\bar{\Omega})$, a viscosity solution of the (H–J–B) equation. Using the first step, we show (1.2). Then we show

$$(1.3) \quad \begin{aligned} \hat{u}_0(x) &= u_0(x) = u(x) & \forall x \in \Omega, \\ u_0(x) &= \bar{u}(x) & \forall x \in \partial\Omega \end{aligned}$$

by a very simple argument and it is easy to check (1.1).

We conclude this introduction with a summary of the paper: in § 2 we recall some basic definitions and notation, and we describe the optimal control problem with state constraints we are considering. In § 3, we present the main result of the paper, which is proved in §§ 4 and 5.

2. Statement of the problem and some known properties.

2.1. Statement of the problem. Let Ω be a smooth open set of \mathbb{R}^n , that we assume to be bounded, for simplicity. We denote by $\bar{\Omega}$, $\partial\Omega$, respectively, the closure and the boundary of Ω . Let A be a compact metric space. We consider functions $b \in C(\mathbb{R}^n \times A; \mathbb{R}^n)$, $f \in C(\mathbb{R}^n \times A; \mathbb{R})$ satisfying

$$(2.1) \quad |b(x, a) - b(x', a)| \leq C|x - x'|, \quad |b(x, a)| \leq C,$$

$$(2.2) \quad |f(x, a) - f(x', a)| \leq w(|x - x'|), \quad |f(x, a)| \leq C,$$

for all $(x, x', a) \in \mathbb{R}^n \times \mathbb{R}^n \times A$ for some constant $C > 0$ and where $w(t) \rightarrow 0$, $t \rightarrow 0^+$.

We introduce the controlled process

$$(2.3) \quad \dot{x}_t = b(x_t, a_t), \quad x_0 = x \in \bar{\Omega}$$

where the function a_t is the control (process) that we choose as follows:

$$(2.4) \quad \mathcal{A}_x = \{a \in L^\infty(\mathbb{R}^+; A) / \forall t \in \mathbb{R}^+, x_t \in \bar{\Omega}\}.$$

In other words we consider controls $a \in L^\infty(\mathbb{R}^+; A)$ such that the corresponding state of the system (state process) remains in $\bar{\Omega}$ for all $t \geq 0$.

Finally, we introduce the cost function

$$(2.5) \quad J(x, a) = \int_0^{+\infty} f(x_t, a_t) e^{-t} dt.$$

We want to minimize the cost function over all controls $a \in \mathcal{A}_x$, i.e., we want to determine the value function

$$(2.6) \quad u(x) = \inf_{a \in \mathcal{A}_x} J(x, a).$$

Here, in order to have a meaningful infimum, we assume that $\mathcal{A}_x \neq \emptyset \forall x \in \bar{\Omega}$ and this is the case in particular if we assume (see [9] where such an assumption was introduced):

$$(2.7) \quad \exists \nu > 0 / \forall x \in \partial\Omega, \quad \exists a \in A / b(x, a) \cdot n(x) \leq -\nu < 0.$$

We assume throughout the paper (2.1), (2.2) and we will not recall these assumptions.

2.2. Viscosity solutions. Let $u: \bar{\Omega} \rightarrow \mathbb{R}$ and $H: \bar{\Omega} \times \mathbb{R}^n \rightarrow \mathbb{R}$ be continuous functions.

DEFINITION 2.1. u is a viscosity subsolution (resp. supersolution) on Ω (or $\bar{\Omega}$) of the Hamilton–Jacobi equation

$$(2.8) \quad u(x) + H(x, Du(x)) = 0 \quad \text{in } \Omega$$

if, for all $\varphi \in C^1(\bar{\Omega})$ such that $u - \varphi$ has a local maximum (resp. minimum) in $x \in \Omega$ (or $\bar{\Omega}$) we have

$$u(x) + H(x, D\varphi(x)) \leq 0 \quad (\text{resp. } \geq 0).$$

Finally, u is a constrained viscosity solution of the equation (2.8) if it is a viscosity subsolution on Ω and a viscosity supersolution on $\bar{\Omega}$ of (2.8).

(See [3], [4] and [9] for the definition of viscosity solution and constrained viscosity solution, respectively.)

2.3. Known results. We consider the equation (H-J-B)

$$(2.9) \quad u(x) + \max_{a \in A} \{-b(x, a) \cdot Du(x) - f(x, a)\} = 0 \quad \text{in } \Omega.$$

By [2] it is known that under the assumptions (2.1), (2.2) and (2.7) that (2.9) admits a unique constrained viscosity solution \bar{u} in $C(\bar{\Omega})$. The uniqueness part is due to Soner and it is slightly improved in [2].

Furthermore, such a solution can be obtained as the limit of viscosity solutions of various approximated problems (see § 4). In [2] it is proved that $u \in C^{0,a}(\bar{\Omega})$ for some $a > 0$ but we will not use this result here.

3. The main result.

3.1. Relaxed controls. Let $M(A)$ be the dual space of $C(A)$ endowed with the weak-star topology of $C(A)^*$, i.e., the space of bounded measures on A .

We want to define the class of admissible relaxed controls for our problem. To this end we introduce the class

$$\hat{\mathcal{A}} = \{\hat{a} \in L^\infty(\mathbb{R}^+, M(A)) / \hat{a}_s \text{ is a probability measure for almost every } s \in \mathbb{R}^+\}.$$

We consider the state of the system corresponding to the control $\hat{a}_t \in \hat{\mathcal{A}}$

$$(3.1) \quad x(t) = x + \int_0^t \int_A b(x_s, a) d\hat{a}_s(a) ds \quad \forall t \in \mathbb{R}^+, \quad \forall x \in \mathbb{R}^n.$$

We say that \hat{a} is admissible for the point $x \in \bar{\Omega}$ if $\hat{a} \in \hat{\mathcal{A}}$ and \hat{a} constrains the relaxed state to lie in $\bar{\Omega}$ and we write $\hat{a} \in \hat{\mathcal{A}}_x$. In other words, we have for all $t \geq 0$

$$(3.2) \quad \hat{\mathcal{A}}_x = \{\hat{a}_t \in \hat{\mathcal{A}} / x_t \in \bar{\Omega}, \forall t \in \mathbb{R}^+\}.$$

3.2. Four different problems.

3.2.1. We begin with relaxed problems. We introduce the relaxation of the problem (2.6), i.e., we consider

$$(3.3) \quad \hat{u}(x) = \inf_{\hat{a} \in \hat{\mathcal{A}}_x} J(x, \hat{a})$$

where $x \in \bar{\Omega}$, $\hat{\mathcal{A}}_x$ is given by (4.2) and $J(x, \hat{a})$ is given by

$$(3.4) \quad J(x, \hat{a}) = \int_0^{+\infty} \int_A f(x_t, a) e^{-t} d\hat{a}_t(a) dt.$$

3.2.2. We also introduce the class of controls

$$(3.5) \quad \hat{\mathcal{A}}_x^0 = \{\hat{a} \in \hat{\mathcal{A}} / x_t \in \Omega, \forall t > 0\},$$

and we consider the associated value function

$$(3.6) \quad \hat{u}_0(x) = \inf_{\hat{a} \in \hat{\mathcal{A}}_x^0} J(x, \hat{a})$$

where $x \in \bar{\Omega}$ and $\hat{\mathcal{A}}_x^0$ is given by (3.5).

3.2.3. We finally consider the class of controls given by

$$(3.7) \quad \mathcal{A}_x^0 = \{a \in A / x_t \in \Omega, \forall t > 0\}.$$

We want to determine

$$(3.8) \quad u_0(x) = \inf_{a \in \mathcal{A}_x^0} J(x, a)$$

where $x \in \bar{\Omega}$, \mathcal{A}_x^0 , $J(x, a)$ are given, respectively, by (3.7) and (2.5).

3.2.4. Finally, let us recall that our original corresponds to the following class of problems:

$$\mathcal{A}_x = \{a \in \mathcal{A} / x_t \in \bar{\Omega}, \forall t > 0\}$$

and the value function is given by

$$u(x) = \inf_{a \in \mathcal{A}_x} J(x, a).$$

3.3. The main result.

THEOREM 3.1. *We assume (2.7). Then all the preceding value functions coincide with the unique constrained viscosity solution \bar{u} of (2.9), i.e., we have*

$$\hat{u} = \hat{u}_0 = u_0 = u = \bar{u} \quad \text{on } \bar{\Omega}.$$

The proof is given in §§ 4 and 5. In § 4 we prove that $\bar{u} = \hat{u}$ for all $x \in \bar{\Omega}$ and in § 5 we show the other equalities.

Remark. For our problem, by the definition of constrained viscosity solution, the result above implies the continuity of the value function.

4. Constrained viscosity solutions and the representation of the solution.

4.1. Representation of the solution.

PROPOSITION 4.1. *The unique constrained solution of the equation (2.8) is the relaxed value function, i.e.,*

$$\bar{u}(x) = \hat{u}(x) \quad \forall x \in \bar{\Omega}$$

where \hat{u} is given by (3.3).

Proof. Following [2], we consider the approximated problem

$$(4.1) \quad u_\varepsilon(x) + \max_{a \in A} \{-b(x, a) \cdot Du_\varepsilon - f(x, a)\} = \frac{p(x)}{\varepsilon} \quad \text{in } \mathbb{R}^n.$$

In (4.1) p is a function in $BUC(\mathbb{R}^n)$ such that

$$(4.2) \quad \forall \varepsilon > 0, \delta > 0, p(x) \geq \delta \text{ if } d(x, \bar{\Omega}) \geq \varepsilon, p(x) = 0 \text{ in } \bar{\Omega}.$$

By [6] there exists, for every $\varepsilon > 0$, a unique viscosity solution u_ε in $BUC(\mathbb{R}^n)$ of (4.1). By [2] the sequence u_ε , which is nondecreasing with respect to $\varepsilon > 0$, converges uniformly on $\bar{\Omega}$ to the constrained viscosity solution of (2.8).

On the other hand (see [6]) u^ε is the following value function:

$$(4.3) \quad u_\varepsilon(x) = \inf_{a \in \mathcal{A}} \int_0^{+\infty} \left[f(x_t, a_t) + \frac{p(x_t)}{\varepsilon} \right] e^{-t} dt.$$

We write

$$(4.4) \quad J^\varepsilon(x, a) = \int_0^{+\infty} \left[f(x_t, a_t) + \frac{p(x_t)}{\varepsilon} \right] e^{-t} dt.$$

But, in this case, from [1] and [10] we deduce

$$(4.5) \quad u_\varepsilon(x) = \inf_{\hat{a} \in \hat{\mathcal{A}}} \int_0^{+\infty} \int_A \left[f(x_t, a) + \frac{p(x_t)}{\varepsilon} \right] e^{-t} d\hat{a}_t dt$$

denoting by

$$(4.6) \quad J^\varepsilon(x, \hat{a}) = \int_0^{+\infty} \int_A \left[f(x_t, a) + \frac{p(x_t)}{\varepsilon} \right] e^{-t} d\hat{a}_t(a) dt.$$

Indeed, we observe that $\hat{\mathcal{A}}_x \subseteq \hat{A}$ and thus

$$(4.7) \quad u_\varepsilon(x) \leq \inf_{\hat{a} \in \hat{\mathcal{A}}_x} J(x, \hat{a}).$$

Passing to the limit, we find

$$\bar{u}(x) \leq \hat{u}(x) \quad \forall x \in \bar{\Omega}.$$

We want to show the converse. We consider an optimal relaxed control \hat{a}_t^ε ; without loss of generality we may assume that \hat{a}_t^ε (considering a subsequence if necessary) converges weakly star in $L^\infty([0, T]; M(A))$ to $\hat{a}_t \in \hat{A}$ as ε goes to 0. This is a consequence of the fact that the convex set

$$\hat{\mathcal{A}}_T = \{\hat{a}|_{[0, T]} / \hat{a} \in \hat{\mathcal{A}}\}$$

is sequentially compact in $L^\infty([0, T], M(A))$ endowed with the weak-star topology [1].

Next, we observe that $\{x_t^\varepsilon\}$ is a uniform and equicontinuous class of functions on $[0, T]$ for each $T > 0$. By the Ascoli-Arzelà Theorem, choosing a subsequence if necessary, we have

$$(4.8) \quad x_t^\varepsilon \xrightarrow{\varepsilon \rightarrow 0} x_t \quad \text{uniformly on } [0, T] \quad \forall T < +\infty.$$

Thus, the weak-star convergence of the sequence \hat{a}_t^ε implies

$$(4.9) \quad \int_0^{+\infty} \int_A (f(x_t^\varepsilon, a) d\hat{a}_t^\varepsilon(a)) e^{-t} dt \xrightarrow{\varepsilon \rightarrow 0} J(x, \hat{a}).$$

If $\hat{a}_t \in \hat{\mathcal{A}}_x$ then

$$(4.10) \quad u_\varepsilon(x) = J^\varepsilon(x, \hat{a}_t^\varepsilon) \geq J(x, \hat{a}) - \varepsilon \geq \inf_{\hat{a} \in \hat{\mathcal{A}}_x} J(x, \hat{a}) - \varepsilon$$

and we conclude the proof letting ε go to 0.

To conclude, we just have to show that $\hat{a}_t \in \hat{\mathcal{A}}_x$. Now, since $u^\varepsilon(x) \leq c$ for all $x \in \mathbb{R}^n$, by the definition (3.3),

$$\int_0^{+\infty} \int_A f(x_t^\varepsilon, a) d\hat{a}_t^\varepsilon(a) e^{-t} dt + \frac{1}{\varepsilon} \int_0^{+\infty} p(x_t^\varepsilon) e^{-t} dt \leq C.$$

By (1.2),

$$\int_0^{+\infty} \int_A f(x_t^\varepsilon, a) d\hat{a}_t^\varepsilon(a) e^{-t} dt \geq -C.$$

Thus

$$\int_0^{+\infty} \frac{p(x_t^\varepsilon)}{\varepsilon} e^{-t} dt \leq 2C$$

and passing to the limit for all $T < +\infty$

$$\int_0^T p(x_t) dt = 0.$$

Therefore $x(t) \in \bar{\Omega}$, for all $t \leq T$, for all $T < +\infty$ and we conclude the proof since $\hat{a}_t \in \hat{A}_x$. \square

5. Properties of the value functions.

5.1. Internal approximation.

LEMMA 5.1. For all $x \in \Omega$, $\hat{u}(x) = \hat{u}_0(x)$.

Proof. Let $\Omega_\delta = \{x \in \Omega / d(x, \bar{\Omega}) \leq \delta\}$ be with $\delta > 0$. We notice that, for δ small enough, the following assumption holds:

$$(5.1) \quad \exists \nu < 0, \quad \forall x \in \partial\Omega_\delta, \quad \exists a \in A \quad b(x, a) \cdot n(x) \leq -\nu < 0$$

where ν does not depend on δ . In fact if (2.7) holds we may consider $y \in \partial\Omega_\delta$ with $y = x - \delta n(x)$; then

$$b(y, a) \cdot n(y) \leq -\frac{\nu}{2} < 0$$

for δ small enough.

By (5.1) and [2] there exists a unique constrained viscosity solution $u_\delta \in C(\bar{\Omega}_\delta)$ of the equation

$$(5.2) \quad u_\delta(x) + \max_{a \in A} \{-b(x, a) \cdot Du_\delta(x) - f(x, a)\} = 0 \quad \text{in } \Omega_\delta.$$

By Proposition 4.1

$$(5.3) \quad u_\delta(x) = \inf_{\hat{a}_t \in \hat{\mathcal{A}}_x^\delta} J(x, \hat{a}) \quad \forall x \in \Omega_\delta$$

where

$$(5.4) \quad \hat{\mathcal{A}}_x^\delta = \{\hat{a} \in \hat{\mathcal{A}} / x_t \in \bar{\Omega}_\delta, \forall t \in \mathbb{R}^+\}.$$

Obviously, (5.3) yields

$$(5.5) \quad |u_\delta(x)| \leq C$$

and by [2] we know that the following a priori estimate holds:

$$(5.6) \quad |u_\delta(x) - u_\delta(y)| \leq \mu(d_\delta(x, y)) \quad \forall \delta > 0$$

where

$$d_\delta(x, y) = |x - y| + k|d_\delta(x) - d_\delta(y)|, \quad x, y \in \bar{\Omega}_\delta$$

and

$$d_\delta(x) = \text{dist}(x, \partial\Omega_\delta)$$

where μ is uniformly continuous modulus independent by δ . In fact we observe, using (5.1) and the proofs on [2], that k does not depend on δ . Therefore

$$(5.7) \quad |u_\delta(x) - u_\delta(y)| \leq \mu(|x - y|).$$

Thus, by the Ascoli-Arzelà Theorem, there exists $\underline{u} \in C(\bar{\Omega})$ and

$$(5.8) \quad \sup_{\bar{\Omega}_\delta} |u_\delta - \underline{u}| \xrightarrow{\delta \rightarrow 0} 0.$$

And, by standard stability results on viscosity solutions [6], $\underline{u} \in C(\bar{\Omega})$ is the viscosity solution of the problem (2.8).

By their definitions we observe that the following relations between the various classes of controls we consider hold:

$$(5.9) \quad \hat{\mathcal{A}}_x \supseteq \hat{\mathcal{A}}_x^0 \supseteq \mathcal{A}_x^\delta.$$

Hence, by (2.2), (3.3) and (3.6) we obtain

$$(5.10) \quad \hat{u} \leq \hat{u}_0 \leq u_\delta \quad \forall x \in \bar{\Omega}_\delta$$

and letting δ go to 0, we find

$$(5.11) \quad \hat{u} \leq \hat{u}_0 \leq \underline{u}.$$

On the other hand, $\hat{u}(x)$ is the maximal viscosity subsolution of (2.8) (see [1], [2]) and thus

$$(5.12) \quad \underline{u} \leq \hat{u} \quad \forall x \in \bar{\Omega}$$

and because of (5.10) and (5.12), the lemma is proved.

5.2. Relations with the function u_0 .

LEMMA 5.2. For all $x \in \Omega$, $\hat{u}_0(x) = u_0(x)$.

Proof. Let \hat{a}_t be such that $x_t \in \Omega$ and

$$(5.13) \quad \hat{u}_0(x) \geq J(x, \hat{a}_t) - \varepsilon.$$

By the Lyapunov Theorem [10] there exists $a_t^n \in \mathcal{A}$

$$(5.14) \quad a_t^n \xrightarrow{n \rightarrow +\infty} \hat{a}_t \quad \text{weak star in } L^\infty([0, T], M(A)).$$

Therefore, for all $T < +\infty$ and for all $t \in [0, T]$

$$(5.15) \quad x_t^n \rightarrow x_t \quad \text{uniformly on compact subsets of } \Omega.$$

Hence, for all $T < +\infty$, $x_t^n \in \Omega$, for all $t \in [0, T]$, for n large enough. Then, we consider the sequence

$$(5.16) \quad \bar{a}_t^n = a_t^n 1_{[0, T]} + \tilde{a}_t^n 1_{[T, +\infty]}$$

where \tilde{a}_{t-T}^n is any admissible control for the point x_T^n . ($\tilde{a}_{t-T}^n \in \mathcal{A}_{x_T^n}$) where x_T^n is the solution at time T of (2.3) corresponding to a_t^n .

We observe that \bar{a}_t^n is any admissible sequence for $x \in \Omega$. Hence, we have

$$(5.17) \quad J(x, \bar{a}_t^n) \geq \inf_{a_t \in \mathcal{A}_x^0} J(x, a_t)$$

and we pass to the limit as n, T go to ∞

$$(5.18) \quad \hat{u}_0(x) + \varepsilon \geq J(x, \hat{a}_t) \geq \inf_{a_t \in \mathcal{A}_x^0} J(x, a_t).$$

Letting ε go to 0, we deduce

$$(5.19) \quad \hat{u}_0 \geq u_0 \quad \forall x \in \Omega.$$

We just have to prove the converse. This is an easy consequence of the classical fact that every classical control can be written as a relaxed control with Dirac measure. Hence

$$(5.20) \quad u_0 \leq \hat{u}_0 \quad \forall x \in \bar{\Omega}$$

and we conclude.

5.3. Conclusion.

LEMMA 5.3. For all $x \in \bar{\Omega}$, $u_0(x) = \bar{u}(x)$.

Proof. We just have to prove the lemma for $x \in \partial\Omega$. By standard dynamic programming

$$u_0(x) = \inf_{a_t \in \mathcal{A}_x^0} \int_0^h f(x_s, a_s) e^{-s} ds + u_0(x_h) e^{-h}$$

and since $x_h \in \Omega$, $u_0 = \bar{u}$ on Ω , we deduce that

$$u_0(x) = \inf_{a_t \in \mathcal{A}_x^0} \int_0^h f(x_s, a_s) e^{-s} ds + \bar{u}(x_h) e^{-h}.$$

Next, we pass to limit to the limit as h goes to 0 and we obtain

$$(5.21) \quad u_0(x) = \bar{u}(x) \quad \forall x \in \bar{\Omega}.$$

We conclude the proof of Theorem 3.1. Indeed we observe that

$$(5.22) \quad \mathcal{A}_x^0 \subseteq \mathcal{A}_x \subseteq \hat{\mathcal{A}}_x,$$

$$(5.23) \quad \mathcal{A}_x^0 \subseteq \hat{\mathcal{A}}_x^0 \subseteq \hat{\mathcal{A}}_x.$$

Hence we have

$$(5.24) \quad u_0 \geq u \geq \hat{u} \quad \text{in } \bar{\Omega},$$

$$(5.25) \quad u_0 \geq \hat{u}_0 \geq \hat{u} \quad \text{in } \bar{\Omega}.$$

By Lemma 5.3 we have

$$(5.26) \quad u_0 = \bar{u} \quad \text{in } \bar{\Omega}.$$

By Proposition 4.1 we have

$$(5.27) \quad \bar{u} = \hat{u} \quad \text{in } \bar{\Omega}.$$

Then, by (5.24), (5.25), we obtain

$$u = u_0 = \hat{u} \quad \text{in } \bar{\Omega}, \quad u_0 = \hat{u}_0 = \hat{u} \quad \text{in } \bar{\Omega}.$$

Hence, we have

$$\bar{u} = \hat{u} = \hat{u}_0 = u_0 = u \quad \text{in } \bar{\Omega}$$

and we conclude. \square

Remark. The results utilized here can be generalized to a set Ω not bounded (see [2], [9]), so our results, which do not utilize the boundedness of Ω , hold also if Ω is not bounded.

Acknowledgment. The author wishes to thank Professor Pierre-Louis Lions for useful discussions and suggestions.

REACHING ZERO RAPIDLY*

STEVEN OREY[†], VICTOR PESTIEN[‡] AND WILLIAM SUDDERTHS

Abstract. The controlled process $X(t)$ with values in $(-\infty, 0]$ is given by a stochastic differential equation:

$$dX(t) = \mu(t) dt + \sigma(t) dW_t, \quad X(0) = x$$

where the nonanticipative controls μ and σ are to be chosen so that $(\mu(t), \sigma(t))$ remains in a given set \mathcal{S} . The object is to maximize (minimize) the expectation of β^T where $0 < \beta < 1$ ($\beta > 1$) and T is the hitting time of zero. A complete solution is given for any \mathcal{S} , and an application is made to continuous-time red-and-black.

Key words. stochastic control, gambling theory

AMS(MOS) subject classifications. 60G40, 60J60, 93E20

Introduction. Consider a process $\{X_1(t)\}$ on $(-\infty, 0]$ given by a stochastic differential equation:

$$dX_1(t) = \mu(t) dt + \sigma(t) dW_t, \quad X_1(0) = x_1$$

where $\{W_t\}$ is standard Brownian motion and $\{\mu(t)\}$ and $\{\sigma(t)\}$ are nonanticipative controls to be chosen so that $(\mu(t), \sigma(t))$ remains in a specified set \mathcal{S} . Let T be the first time X_1 reaches the origin. In [2] the problems of minimizing or maximizing the expected value of T were solved for any \mathcal{S} ; the value function and optimal strategies were given explicitly in terms of \mathcal{S} . Minimizing the expected value of T is a natural criterion for getting to the origin rapidly. However, there are other criteria, two of which are considered here.

Our first problem is to maximize the expected value of β^T , where β is a positive constant less than one. The second problem is to minimize the expected value of β^T where now the constant β is chosen greater than one. In both cases we obtain a complete solution, for arbitrary \mathcal{S} .

The problems are of unequal difficulty. The first problem is actually quite easy. The reason the second problem is harder is that in the solution one must distinguish between the two cases $I < \infty$ and $I = \infty$, where the quantity I is defined by

$$I = \inf_{\varepsilon > 0} \sup \{ \mu + \varepsilon \sigma^2 : (\mu, \sigma) \in \mathcal{S} \}.$$

As is common in control theory problems, we obtain a natural candidate $Q(x_1)$ for a value function and try to prove it correct by applying an appropriate verification theorem. As it turns out, Q is indeed the correct value function if and only if $I < \infty$. Hence there must be something in the application of the verification theorem distinguishing between $I < \infty$ and $I = \infty$, and this indicates we should expect technical difficulties. The $I < \infty$, $I = \infty$ dichotomy also appeared in [2], but in the present work more delicate constructions for overcoming the obstacles are required.

The solutions of the two general problems make it possible for us to solve the particular problems of discounted ($0 < \beta < 1$) and inflated ($\beta > 1$) red-and-black. It is shown here for the continuous-time problem, as it was by Klugman [3] in discrete time, that bold play is optimal for subfair, discounted red-and-black. The superfair case is also explicitly solved here for the continuous-time problem although it remains open in discrete time.

1. Preliminaries. We begin by explaining the continuous time gambling set-up of [4] and [2].

A *continuous-time gambling problem* is a triple (F, Σ, u) where

- (1.1) the *state space* F is a Borel subset of the Euclidean space \mathbb{R}^d having nonempty interior,
- (1.2) the *gambling house* Σ is a mapping which assigns to each $x \in F$ a nonempty collection $\Sigma(x)$ of processes $X = \{X_t, t \geq 0\}$ with state space F such that $X_0 = x$ and X has right-continuous paths with left-limits,
- (1.3) the *utility function* u is a Borel function from F to the real line.

A process $X \in \Sigma(x)$ is said to be *available* at x . Each available X is defined on some probability space (Ω, \mathcal{F}, P) and is adapted to an increasing filtration $(\mathcal{F}_t, t \geq 0)$ of complete subsigma fields of \mathcal{F} . The probability space and filtration may depend on X .

A player, starting at position $x \in F$, selects a process $X \in \Sigma(x)$ and receives payoff $u(X)$ defined by

$$(1.4) \quad u(X) = E[\limsup_{t \rightarrow \infty} u(X_t)].$$

The expectation occurring on the right is assumed to be well defined for every available process X .

The *value function* V is defined by

$$V(x) = \sup \{u(X) : X \in \Sigma(x)\}$$

for every $x \in F$. A process $X \in \Sigma(x)$ is *optimal* at x if

$$u(X) = V(x).$$

From now on, each process $X = \{X_t\}$ under consideration will be an *Ito process* of the form

$$(1.5) \quad X_t = x + \int_0^t \alpha(s) ds + \int_0^t \beta(s) dW_s,$$

where $W = \{W_t\}$ is a standard m -dimensional Brownian motion process on (Ω, \mathcal{F}, P) adapted to increasing, right-continuous σ -fields $\{\mathcal{F}_t\}$ and \mathcal{F}_t is independent of $\{W_{t+s} - W_t, s \geq 0\}$. The function $\alpha = \alpha(t, \omega)$ is to be \mathbb{R}^d -valued, progressively measurable, and such that

$$(1.6) \quad \int_0^t |\alpha(s)| ds < \infty \quad \text{a.s. for all } t.$$

The function $\beta = \beta(t, \omega)$ has as values real $d \times m$ matrices, is progressively measurable, and satisfies

$$(1.7) \quad \int_0^t |\beta(s)|^2 ds < \infty \quad \text{a.s. for all } t.$$

For each pair (a, b) , where $a \in \mathbb{R}^d$ is a $d \times 1$ vector and b is a $d \times m$ real-valued matrix, define the differential operator $D(a, b)$ for sufficiently smooth functions $Q: \mathbb{R}^d \rightarrow \mathbb{R}$ by the following:

$$D(a, b)Q(y) = Q_x(y)a + \frac{1}{2} \sum_{i=1}^d \sum_{j=1}^d Q_{x_i x_j}(y)(bb')_{ij}$$

where

$$Q_x(y) = \left(\frac{\partial Q}{\partial x_1}, \dots, \frac{\partial Q}{\partial x_d} \right), \quad Q_{x_i x_j} = \frac{\partial^2 Q}{\partial x_i \partial x_j},$$

and b' is the transpose of b .

We now specify $\Sigma(x)$ by specifying the possible values of α and β . To this end, let $C(x)$ be, for each $x \in F$, a nonempty set of pairs (a, b) , where $a \in \mathbb{R}^d$ and b is a real $d \times m$ matrix. (The idea is that $C(x)$ is the set from which a player at state x may choose the value of (α, β) .) Assume also that every available process X is absorbed at the time T_X of its first exit from F^0 , the interior of F . These conditions define a function Σ_C on F where $\Sigma_C(x)$ is the collection of all processes X having paths in F and satisfying (1.5), (1.6), and (1.7) together with

$$(1.8) \quad (\alpha(t, \omega), \beta(t, \omega)) \in C(X_t(\omega)) \quad \text{for all } (t, \omega),$$

$$(1.9) \quad (\alpha(t, \omega), \beta(t, \omega)) = (0, 0) \quad \text{for all } t \geq T_X(\omega),$$

$$(1.10) \quad C(x) = \{(0, 0)\} \quad \text{for } x \in F - F^0.$$

Let Σ be a gambling house such that $\Sigma(x) \subset \Sigma_C(x)$ for every $x \in F$. The following proposition is related to other verification lemmas in [2] and [4]. Since the hypotheses here differ slightly from those in [2] and [4], we provide a proof.

PROPOSITION 1.1. *Let G be an open subset of \mathbb{R}^d which contains F . Suppose $Q: G \rightarrow \mathbb{R}$ has continuous second order derivatives on G and that for every $x \in F^0$ and every $X \in \Sigma(x)$,*

- (i) $E[\limsup_{t \rightarrow \infty} Q(X_t)] \geq E[\limsup_{t \rightarrow \infty} u(X_t)],$
- (ii) $P[D(\alpha(t), \beta(t))Q(x_t) \leq 0 \text{ for all } t \geq 0] = 1, \text{ where } \alpha \text{ and } \beta \text{ are related to } X \text{ as in (1.5),}$
- (iii) *there exists an integrable random variable Y such that for all $t \geq 0$, $Q(X_t) \geq Y$.*

Then $Q \geq V$.

Proof. Let $x_0 \in F$ and $X \in \Sigma(x_0)$. For each $t \geq 0$, Ito's Lemma gives

$$(1.11) \quad Q(X_t) = Q(x_0) - A_t + M_t$$

where

$$A_t = - \int_0^t D(\alpha(s), \beta(s))Q(X_s) ds$$

and

$$M_t = \int_0^t Q_x(X_s)\beta(s) dW_s.$$

Notice that by conditions (ii) and (iii),

$$M_t = Q(X_t) - Q(x_0) + A_t \geq Y - Q(x_0)$$

holds for all $t \geq 0$ with probability one. Therefore the local martingale M_t is a supermartingale (see [1, VI.29]), and if τ is any almost-surely finite stopping time,

$$(1.12) \quad EM_\tau \leq EM_0 = 0.$$

From (1.11), (1.12) and condition (ii),

$$EQ(X_\tau) \leq Q(x_0).$$

By condition (i) and by Lemma 1 of [4], it follows that $Q \geq V$. \square

2. Maximizing $E[\beta^T]$, $0 < \beta < 1$. We formalize the first problem from the introduction as a continuous-time gambling problem in \mathbb{R}^2 . The first coordinate x_1 will be constrained to $(-\infty, 0]$ and indicates the player's position, while the second coordinate x_2 in $(-\infty, \infty)$ increases at a constant rate one and merely keeps track of the time. Define $F = \{x \in \mathbb{R}^2: x = (x_1, x_2), -\infty < x_1 \leq 0\}$. By our conventions each process X available at x will be absorbed at $T = T_X = \inf\{t: X_1(t) = 0\}$.

Let $\mathcal{S} \subseteq \mathbb{R} \times [0, \infty)$ and

$$(2.1) \quad C_0 = \left\{ \begin{pmatrix} \mu \\ 1 \end{pmatrix}, \begin{pmatrix} \sigma \\ 0 \end{pmatrix} : (\mu, 0) \in \mathcal{S} \right\}$$

and for every x in the interior of F , $C(x) = C_0$. Every $X \in \Sigma_C(x)$ can be specified by stochastic differential equations

$$(2.2) \quad \begin{aligned} dX_1(t) &= \mu(t) dt + \sigma(t) dW_t, \\ dX_2(t) &= dt, \\ X_1(0) &= x_1, \quad X_2(0) = x_2, \end{aligned}$$

where μ and σ are progressively measurable and $(\mu(t), \sigma(t)) \in \mathcal{S}$, $t < T$, $X(t) = X(T)$ for $t \geq T$.

Our utility function will be

$$(2.3) \quad u(x) = \beta^{x_2}.$$

Note that for $T < \infty$,

$$X_1(T) = 0, \quad X_2(T) = T + X_2(0)$$

and so

$$(2.4) \quad u(X) = E(\beta^{T+x_2}).$$

Here we interpret β^{T+x_2} as 0 if $T = \infty$. Now let $\Sigma(x) = \Sigma_C(x)$. The value function $V(x_1, x_2)$ must clearly have the form

$$(2.5) \quad V(x_1, x_2) = \beta^{x_2} V(x_1).$$

The form of $V(x_1)$ is also easily obtained. Given $X \in \Sigma(x)$ and $y \in [x, 0]$, let T_{xy} be the first time X attains y . Consider the problem of maximizing $E[\beta^{T_{xy}}]$ and denote the corresponding value function by V_{xy} . One easily sees $V_{xy} = V(x-y)$. It now appears that $T_{x0} = T_{xy} + T_{y0}$ and hence a stopping time argument gives $V(x) = V(x-y) \cdot V(y)$, leading to

$$(2.6) \quad V(x_1) = e^{\lambda x_1}, \quad \lambda \geq 0.$$

Also, since the problem of minimizing $E[\beta^{T_{xy}}]$ looks the same as that of minimizing $E[\beta^{T_{x-y}}]$, one expects to obtain optimal strategies of the form $\mu(x) \equiv \mu$ and $a(x) \equiv a$,

where we write $a(x) = \sigma^2(x)$ and μ and a will be constants depending on \mathcal{S} . If $a = 0$ and $\mu \leq 0$, then the process reaches zero with probability zero. So assume the maximum of a and μ is positive. For such a constant strategy the expected payoff is $W(x_1, x_2) = \beta^{x_2} W(x_1)$, with $W(x_1)$ satisfying

$$\frac{1}{2}aW'' + \mu W' + (\log \beta) W = 0, \quad W(0) = 1.$$

But again W should be an exponential $e^{\lambda x_1}$ with $\lambda \geq 0$, and this implies

$$(2.7) \quad W(x_1) = e^{\lambda x_1},$$

where

$$(2.8) \quad \lambda = \lambda(\mu, a) = \begin{cases} \frac{-\mu + \sqrt{\mu^2 - 2a \log \beta}}{a}, & a > 0, \\ \frac{-(\log \beta)}{\mu}, & a = 0, \quad \mu > 0. \end{cases}$$

Notice that in the case $a > 0$, λ is the positive root of

$$(2.9) \quad \frac{1}{2}a\lambda^2 + \mu\lambda + \log \beta = 0.$$

For fixed λ , the relation between λ , μ , and a in (2.8) defines a line in the (μ, a) -plane, namely

$$(2.10) \quad l_\lambda: a = \frac{-2}{\lambda}\mu - \frac{2 \log \beta}{\lambda^2}.$$

For our purposes, only

$$(2.11) \quad \bar{l}_\lambda = l_\lambda \cap \{(\mu, a): a \geq 0\}$$

is relevant. It now appears that to optimize the expected payoff in (2.7) we want to use strategies whose (μ, a) -pairs lie on \bar{l}_{λ^*} , where

$$(2.12) \quad \lambda^* = \inf \{\lambda(\mu, \sigma^2): (\mu, \sigma) \in \mathcal{S}, \max(\sigma, \mu) > 0\}.$$

THEOREM 2.1. *If $\mathcal{S} \subseteq (-\infty, 0] \times \{0\}$, then $V(x_1, x_2) = 0$. Otherwise,*

$$(2.13) \quad V(x_1, x_2) = \beta^{x_2} e^{\lambda^* x_1}$$

with λ^* as defined in (2.12).

Proof. The first assertion of the theorem is obvious. Assume then that \mathcal{S} contains a point (μ, σ) with $\max(\mu, \sigma^2) > 0$. Let $Q(x_1, x_2) = \beta^{x_2} e^{\lambda^* x_1}$. By (2.5) and (2.7) one can realize expected payoffs arbitrarily close to $Q(x_1, x_2)$, so that $Q(x_1, x_2) \leq V(x_1, x_2)$. For the opposite inequality use Proposition 1.1. It must be checked that Q satisfies conditions (i)–(iii). Condition (iii) is immediate. Condition (i) follows from the fact that for every available process $X = \{X_t\}$,

$$\limsup_{t \rightarrow \infty} Q(X_t) = \limsup_{t \rightarrow \infty} u(X_t) = \begin{cases} \beta^{T+x_2} & \text{if } T < \infty, \\ 0 & \text{if } T = \infty. \end{cases}$$

Condition (ii) follows once we have checked

$$(2.14) \quad \frac{1}{2}\sigma^2(\lambda^*)^2 + \mu\lambda^* + \log \beta \leq 0, \quad (\mu, \sigma) \in \mathcal{S}.$$

In the case $\sigma^2 = 0$, $\mu = 0$, this is immediate from the definitions of $\lambda(\mu, \sigma^2)$ and λ^* . In the case $\sigma^2 > 0$, (2.14) follows again from these definitions together with the fact that λ^* lies between 0 and $\lambda = \lambda(\mu, \sigma^2)$, which is the positive root of the equation (2.9). \square

Example. Discounted, continuous-time red-and-black. Suppose an investor has initial fortune y , $0 < y < 1$, and seeks to attain a fortune of 1. If $Y(t)$ is the player's fortune at time $t \geq 0$, he can invest $s(t)Y(t)$, $0 \leq s(t) \leq 1$, in a venture with rate of return μ_0 and standard deviation $\sigma_0 > 0$. More formally, the process $y(t)$ is given by a stochastic differential equation:

$$dY(t) = s(t)Y(t)[\mu_0 dt + \sigma_0 dW_t], \quad Y(0) = y$$

where $s(t)$ is a nonanticipative function such that $0 \leq s(t) \leq 1$. If the object is to maximize the probability of reaching 1, then (cf. [4], [5]) *bold play*, for which $s(t) \equiv 1$, is optimal in the *subfair case* ($\mu_0 \leq 0$), and *proportional play*, for which $s(t) \equiv c$ ($0 < c < 2\mu_0\sigma_0^{-2}$), is optimal in the *superfair case* ($\mu_0 > 0$). Here the value of the goal is discounted at rate β and the object is to maximize $E\beta^T$, where $T = \inf\{t \geq 0: Y(t) = 1\}$. The problem can be reduced to a special case of the problem of this section by the change of coordinates

$$(2.15) \quad X_1(t) = \log Y(t).$$

By Ito's formula,

$$dX_1(t) = (s(t)\mu_0 - \frac{1}{2}s(t)^2\sigma_0^2) dt + s(t)\sigma_0 dW_t.$$

The control set \mathcal{S} is now a one-parameter family

$$(2.16) \quad \mathcal{S} = \{(s\mu_0 - \frac{1}{2}s^2\sigma_0^2, s\sigma_0): 0 \leq s \leq 1\},$$

and formula (2.8) can be written in the form

$$(2.17) \quad \begin{aligned} \lambda(\mu, \sigma^2) &= \lambda(s) \\ &= \frac{-(\mu_0 - \frac{1}{2}s\sigma_0^2) + \sqrt{q(s)}}{s\sigma_0^2} \quad \text{if } s > 0 \end{aligned}$$

where $q(s) = (\mu_0 - \frac{1}{2}s\sigma_0^2)^2 - 2\sigma_0^2 \log \beta$. After some algebra it follows from (2.17) that, for $\mu_0 \leq 0$, $\lambda'(s) \leq 0$ on $(0, 1]$ and, hence, the infimum $\lambda^* = \lambda(1)$. So bold play is again optimal in the subfair case. Consider next the superfair case $\mu_0 > 0$.

Define the number

$$c = c(\mu_0, \sigma_0, \beta) = \frac{\mu_0}{\sigma_0^2} - \frac{2(\log \beta)}{\mu_0}.$$

More algebra shows that $\lambda'(s) > 0$ if and only if $s > \text{maximum}(c, 0)$. Thus if $c \geq 1$, λ is decreasing on $(0, 1]$ and bold play is optimal yet again. If $0 < c < 1$, an optimal strategy is given by $s(t) \equiv c$. If $c \leq 0$, there is no optimal strategy, but $s(t) \equiv \varepsilon$ for small positive ε will be almost optimal. An analogous problem in discrete time was solved by Klugman [3] in the subfair case, but the discrete-time superfair problem remains open.

3. Minimizing $E[\beta^T]$, $1 < \beta$. Again we fit the problem into the set-up of § 1. Since we discussed maximization problems there, we will seek to maximize $-\beta^T$. That is, we proceed exactly as in § 2, assuming (2.1), (2.2) but now defining

$$(3.1) \quad u(x) = -\beta^{x_2},$$

so that $u(X) = -E(\beta^{T+x_2})$. Let

$$\Sigma(x) = \{X \in \Sigma_C(x): u(X) > -\infty\} = \{X \in \Sigma_C(x): E\beta^T < \infty\},$$

and we have

$$(3.2) \quad V(x_1, x_2) = \beta^{x_2} V(x_1).$$

The arguments that lead to (2.6) now give

$$(3.3) \quad V(x_1) = -e^{\lambda x_1}, \quad \lambda \leq 0.$$

Again let us consider the expected payoff $W(x_1, x_2)$ for a constant strategy $\mu(t) \equiv \mu$ and $\sigma(t) \equiv \sigma$, $\sigma^2 = a$. If $a = 0$ and $\mu > 0$, obviously

$$(3.4) \quad W(x_1, x_2) = -\beta^{x_2} e^{\lambda x_1}$$

where $\lambda = -\log \beta / \mu$. If $a > 0$, $\mu > 0$, the expected payoff is of the form $W(x_1, x_2) = -\beta^{x_2} W(x_1)$, where $W(x_1)$ satisfies

$$(3.5) \quad \frac{1}{2}a W'' + \mu W' + (\log \beta) W = 0$$

and $W(0) = -1$. To see what condition to impose at $-\infty$ consider the problem as a limit of problems on the interval $[-M, 0]$, $M \rightarrow \infty$. So we consider (3.5) with $W(0) = -1$ and $W(-M) = -k_M$, with k_M chosen appropriately. Since in the limiting problem the process will hit zero with probability one and receive no help from the boundary on the left, it is appropriate to choose $k_M = 0$ (actually all choices of $k_M \geq 0$ which do not grow too rapidly with M will lead to the same limiting result). This limiting procedure gives us

$$(3.6) \quad W(x_1) = -e^{\lambda x_1},$$

for $\mu \geq \sqrt{2a \log \beta}$, where $\lambda = (-\mu + \sqrt{\mu^2 - 2a \log \beta})/a$ is the maximal root of the equation

$$(3.7) \quad f(\nu) = \frac{1}{2}a\nu^2 + \mu\nu + \log \beta = 0.$$

If

$$(3.8) \quad \mu < \sqrt{2a \log \beta},$$

the roots of (3.7) are not real and the expected payoff from the constant strategy $\mu(t) \equiv \mu$ and $\sigma(t) \equiv \sigma$ is $-\infty$. In every case, the expected payoff $W(x_1, x_2)$ is given by (3.4), where

$$(3.9) \quad \lambda = \lambda(\mu, a, \beta) = \begin{cases} \frac{-\mu + \sqrt{\mu^2 - 2a \log \beta}}{a}, & \mu \geq \sqrt{2a \log \beta}, \\ \frac{-\log \beta}{\mu}, & a = 0, \quad \mu > 0, \\ -\infty & \text{otherwise.} \end{cases}$$

Condition (3.8) holds if and only if (μ, a) lies on the left of the semi-parabola

$$(3.10) \quad p: \mu^2 = 2a \log \beta, \quad \mu > 0$$

in the (μ, a) -plane. Furthermore all points on the same line segment

$$l_\lambda: a = \frac{-2}{\lambda} \mu - \frac{2 \log \beta}{\lambda^2}, \quad 0 \leq a \leq \frac{\mu^2}{2 \log \beta}$$

give rise to constant strategies with the same expected payoff $-\beta^{x_2} e^{-\lambda x_1}$, $-\infty < \lambda < 0$. Observe that l_λ is the line segment connecting the point $(-\log \beta / \lambda, 0)$ on the μ -axis to the point $(-2 \log \beta / \lambda, 2 \log \beta / \lambda^2)$ on p ; at the latter point p and l_λ are tangential. Now set

$$(3.11) \quad \lambda^* = \lambda^*(\beta) = \sup \{ \lambda(\mu, \sigma^2, \beta) : (\mu, \sigma) \in \mathcal{S} \}.$$

Notice that, for $\lambda = \lambda(\mu, a, \beta) > -\infty$, the function $f(\nu)$ given in (3.7) is increasing to the right of $\nu = \lambda$. Also, $f(\lambda) = 0$ and $\lambda^* \geq \lambda$. Hence

$$(3.12) \quad \frac{1}{2}\sigma^2\nu^2 + \mu\nu + \log \beta \geq 0, \quad (\mu, \sigma) \in \mathcal{S}, \quad \lambda^* \leq \nu.$$

We define

$$(3.13) \quad I = \inf_{\varepsilon > 0} \sup \{ \mu + \varepsilon\sigma^2 : (\mu, \sigma) \in \mathcal{S} \}$$

and observe that the condition

$$(3.14) \quad I < \infty$$

holds if and only if \mathcal{S} is contained below some line with negative slope.

LEMMA 3.1. Assume $I = \infty$. Then $V(x_1, x_2) = -\beta^{x_2}$.

Proof. The assumption allows one to specify, for any $x_1 < 0$ and $\varepsilon > 0$ an $X \in \Sigma(x_1)$ with $ET < \varepsilon$. This was shown in [2]. This means that for $x_1 < 0$ and $\varepsilon > 0$ it is possible to find $X^{(1)} \in \Sigma(x_1)$ with $P[T > \varepsilon] < \frac{1}{2}$. Next, we find $X^{(2)} \in \Sigma(X^{(1)}(\varepsilon))$ such that $P[T > \varepsilon/2] < 2^{-2}$. Then $X \in \Sigma(x_1)$ is constructed as follows: X agrees with $X^{(1)}$ up to time ε ; if $X^{(1)} \neq 0$, then $X_{\varepsilon+t} = X_t^{(2)}$ for $0 \leq t \leq \varepsilon/2$; etc. Then for the process X , $E\beta^T \leq \beta^{2\varepsilon}$. Since ε is arbitrary the lemma follows by (3.2). \square

In view of Lemma 3.1 and the considerations preceding it, one might hope that if $I < \infty$,

$$V(x_1, x_2) = -\beta^{x_2} e^{\lambda^* x_1}.$$

We will now prove that this is indeed the case.

Some difficulties occur where points on the semi-parabola p introduced in (3.10) lie on the boundary of \mathcal{S} without belonging to \mathcal{S} . To deal with these we choose a sequence (β_n) of positive reals increasing up to β . Use (3.9) to define

$$(3.15) \quad \lambda_n(\mu, \sigma^2) = \lambda(\mu, \sigma^2, \beta_n)$$

and set

$$(3.16) \quad \lambda_n^* = \lambda^*(\beta_n) = \sup \{ \lambda_n(\mu, \sigma^2) : (\mu, \sigma) \in \mathcal{S} \}.$$

Note $\lambda_n^* \leq 0$ and λ_n^* decreases as a function of n . Finally let

$$(3.17) \quad \lambda^* = \inf_n \lambda_n^*$$

which is consistent with (3.11).

THEOREM 3.2(a). If $I < \infty$ and $\lambda^* > -\infty$ then

$$V(x_1, x_2) = -\beta^{x_2} e^{\lambda^* x_1}.$$

(b) If $I < \infty$ and $\lambda^* = -\infty$ then

$$V(x_1, x_2) = -\infty.$$

(c) If $I = \infty$ then

$$V(x_1, x_2) = -\beta^{x_2}$$

(that is, $E[\beta^T]$ can be made arbitrarily close to 1).

The proof of the theorem will involve the use of Proposition 1.1. We will construct a sequence of functions $Q_n(x_1, x_2) = \beta^{x_2} Q_n(x_1)$. Let us concentrate on the second factor and write simply x for x_1 . Consider the inequality

$$(3.18) \quad \frac{1}{2}\sigma^2 Q_n''(x) + \mu Q_n'(x) + (\log \beta) Q_n(x) \leq 0.$$

Let

$$(3.19) \quad U_n(x) = \frac{Q'_n(x)}{\lambda_n^* Q_n(x)}.$$

Then

$$U'_n(x) = \frac{1}{\lambda_n^*} \left[\frac{Q''_n(x)}{Q_n(x)} - \left[\frac{Q'_n(x)}{Q_n(x)} \right]^2 \right]$$

and so

$$U'_n(x) + \lambda_n^* (U_n(x))^2 = \frac{1}{\lambda_n^*} \frac{Q''_n(x)}{Q_n(x)}.$$

If Q_n is negative, the inequality (3.18) holds if and only if

$$(3.20) \quad \frac{1}{2} \sigma^2 \lambda_n^{*2} (U_n(x))^2 + \mu \lambda_n^* U_n(x) + \log \beta + \frac{1}{2} \sigma^2 \lambda_n^* U'_n(x) \geq 0.$$

Our plan is to define an appropriate sequence of functions U_n so that (3.20) holds for all (μ, σ) in \mathcal{S} . Then, using the relation (3.19), we transform U_n into Q_n and obtain inequality (3.18) for all $(\mu, \sigma) \in \mathcal{S}$.

The next lemma involves a construction of the functions U_n .

LEMMA 3.3. *Let $\{k_n : n \geq 1\}$ be positive constants. There exists a sequence $\{U_n : n \geq 1\}$ of real functions with domain $(-\infty, 1)$ such that*

- (i) U_n is continuously differentiable, $n \geq 1$;
- (ii) $0 < U_n(x) \leq 1$, $x < 1$, $n \geq 1$;
- (iii) $\lim_{n \rightarrow \infty} U_n(x) = 1$, $x \leq 0$;
- (iv) $\int_{-\infty}^0 U_n(x) dx < \infty$;
- (v) $0 < U'_n(x) \leq k_n U_n(x)$, $n \geq 1$, $x \leq 0$.

Proof. For each n define

$$U_n(x) = \begin{cases} 1, & -n < x < 1, \\ c_n \int_{-\infty}^{x+n} y e^{k_n y} dy, & x < -n \end{cases}$$

where $c_n = [\int_{-\infty}^0 y e^{k_n y} dy]^{-1}$. Then (i)–(iii) are easily checked. Integration by parts gives

$$U_n(x) = \frac{c_n}{k_n} e^{k_n(x+n)} \left(x+n - \frac{1}{k_n} \right), \quad x < -n.$$

The last identity implies (iv) and also

$$U_n(x) \geq \frac{c_n}{k_n} e^{k_n(x+n)} (x+n), \quad x < -n.$$

That is,

$$U_n(x) \geq \frac{1}{k_n} U'_n(x),$$

establishing property (v). \square

Assume now that $I < \infty$ (see (3.13)), and $\lambda^* > -\infty$. Then there exist positive constants ρ and M such that

$$(3.21) \quad \text{for all } (\mu, \sigma) \text{ in } \mathcal{S}, \quad \mu + \rho \sigma^2 \leq M.$$

For each positive integer n let

$$(3.22) \quad k_n = \begin{cases} \min \left\{ 2\rho, \frac{-2\rho \log(\beta/\beta_n)}{M\lambda_n^*} \right\}, & \lambda_n^* < 0, \\ 2\rho, & \lambda_n^* = 0. \end{cases}$$

With these constants k_n , let U_n be functions satisfying the conditions of Lemma 3.3.

LEMMA 3.4. Assume $\lambda^* > -\infty$, (3.21), and let $\{U_n: n \geq 1\}$ be the sequence of functions specified above. Then for $n \geq 1$, $x < 0$ and $(\mu, \sigma) \in \mathcal{S}$, inequality (3.20) holds.

Proof. The assertion is clear for $\lambda^* = 0$. So we suppose $\lambda^* < 0$. By properties (ii) and (v) of Lemma 3.3 and the definition of k_n in (3.22) we have

$$(3.23) \quad U'_n(x) \leq \frac{-2\rho \log(\beta/\beta_n)}{M\lambda_n^*}.$$

Let $g_n(x)$ denote the expression on the left of (3.20).

Case 1: $\mu \geq 0$, $\lambda_n^* < 0$. Use (3.21) to obtain

$$(3.24) \quad \rho\sigma^2 \leq \mu + \rho\sigma^2 \leq M.$$

Now write

$$(3.25) \quad g_n(x) = \left[\frac{1}{2} \sigma^2 \lambda_n^{*2} (U_n(x))^2 + \mu \lambda_n^* U_n(x) + \log \beta_n \right] + \log \frac{\beta}{\beta_n} + \frac{1}{2} \sigma^2 \lambda_n^* U'_n(x).$$

Since $\lambda_n^* \leq \lambda_n^* U_n(x) \leq 0$, the expression in brackets is greater than or equal to zero by (3.12). Then (3.24) and (3.23) show that the sum of the last two terms in (3.25) is nonnegative. Hence $g_n(x) \geq 0$, as desired.

Case 2: $\mu < 0$, $\lambda_n^* < 0$. Use (3.21) to obtain

$$(3.26) \quad \begin{aligned} g_n(x) &\geq \frac{1}{2} \sigma^2 (\lambda_n^* U_n(x))^2 + \mu \lambda_n^* U_n(x) + \log \beta + \frac{\lambda_n^* (M - \mu)}{2\rho} U'_n(x) \\ &\geq \mu \lambda_n^* \left[U_n(x) - \frac{1}{2\rho} U'_n(x) \right] + \frac{M\lambda_n^*}{2\rho} U'_n(x) + \log \beta. \end{aligned}$$

By properties (ii) and (v) of Lemma 3.3 and the definition of k_n in (3.22),

$$U_n(x) - \frac{1}{2\rho} U'_n(x) \geq 0 \quad \text{and} \quad U'_n(x) \leq \frac{-2\rho \log \beta}{M\lambda_n^*}.$$

Using these inequalities in (3.26) and recalling $\mu < 0$, $\lambda_n^* < 0$ one concludes $g_n(x) \geq 0$. \square

The next lemma will be used to create processes whose payoffs approach $-\beta^{x_2} e^{\lambda x_1}$.

LEMMA 3.5. If $I < \infty$, $\lambda^* > -\infty$, then there exists a sequence $\{(\mu_k, \sigma_k): k \geq 1\}$ of elements of \mathcal{S} such that the sequence converges in \mathbb{R}^2 to a limit $(\bar{\mu}, \bar{\sigma})$ and

$$(3.27) \quad \frac{1}{2} (\lambda^* \bar{\sigma})^2 + \lambda^* \bar{\mu} + \log \beta = 0.$$

(Note $(\bar{\mu}, \bar{\sigma})$ might not lie in \mathcal{S} .)

Proof. Using the definition of λ^* , there is a strictly increasing sequence $\{n_k; k \geq 1\}$ of positive integers and a sequence $\{(\mu_k, \sigma_k): k \geq 1\}$ of elements of \mathcal{S} such that

$$\lim_{k \rightarrow \infty} \lambda_{n_k}(\mu_k, \sigma_k^2) = \lambda^*.$$

By passing to a subsequence if necessary, we can assume that either (Case 1) $\sigma_k > 0$ and $\mu_k \geq \sigma_k \sqrt{2 \log \beta_{n_k}}$ for each k or (Case 2) $\sigma_k = 0$ and $\mu_k > 0$ for each k . Since $I < \infty$,

the set $\{(\mu, \sigma): (\mu, \sigma) \in \mathcal{S}, \mu \geq 0\}$ is a bounded subset of \mathbb{R}^2 . Thus by passing to a further subsequence, we can assume the sequence converges in \mathbb{R}^2 .

Case 1. $\sigma_k > 0$ and $\mu_k \geq \sigma_k \sqrt{2 \log \beta_{n_k}}$ for each k . By definition,

$$\lambda_{n_k}(\mu_k, \sigma_k) = \frac{-\mu_k + \sqrt{\mu_k^2 - 2\sigma_k^2 \log \beta_{n_k}}}{\sigma_k^2},$$

and so for each k ,

$$\frac{1}{2}[\lambda_{n_k}(\mu_k, \sigma_k^2)]^2 \sigma_k^2 + [\lambda_{n_k}(\mu_k, \sigma_k^2)]\mu_k + \log \beta_{n_k} = 0.$$

Taking the limit as $k \rightarrow \infty$, we get (3.27).

Case 2. $\sigma_k = 0$ and $\mu_k > 0$ for each k . By definition,

$$\lambda_{n_k}(\mu_k, \sigma_k^2) = \frac{-\log \beta_{n_k}}{\mu_k}.$$

Take limits to get $\lambda^* \bar{\mu} = -\log \beta$ and $\bar{\sigma} = 0$, and (3.27) follows. \square

Proof of the theorem. (a) Define $Q: (-\infty, 0] \times \mathbb{R} \rightarrow \mathbb{R}$ by

$$Q(x_1, x_2) = -\beta^{x_2} e^{\lambda^* x_1}.$$

To show $Q \leq V$, begin by fixing $x_1 \leq 0$ and $x_2 \in \mathbb{R}$. By Lemma 3.5, there is a sequence $\{(\mu_k, \sigma_k): k \geq 1\}$ in \mathcal{S} satisfying relation (3.27). Let $\varepsilon > 0$ and use (3.27) to create two functions $\hat{\mu}: [0, \infty) \rightarrow \mathbb{R}$ and $\hat{\sigma}: [0, \infty) \rightarrow \mathbb{R}$ such that

$$(\hat{\mu}(s), \hat{\sigma}(s)) \in \{(\mu_k, \sigma_k): k \geq 1\}$$

for each $s \geq 0$,

$$(3.28) \quad \int_0^\infty \left| \frac{1}{2} \lambda^{*2} [\hat{\sigma}(s)]^2 + \lambda^* \hat{\mu}(s) + \log \beta \right| ds < \log(1 + \varepsilon),$$

and

$$(3.29) \quad \inf \{\hat{\mu}(s): s \geq 0\} > 0.$$

Let X be the process given by

$$X_1(t) = x_1 + \int_0^t \hat{\mu}(s) ds + \int_0^t \hat{\sigma}(s) dW_s, \quad X_2(t) = x_2 + t$$

for $t \leq T$, where $T = \inf \{t: X_1(t) = 0\}$, and $X(t) = X(T)$ for $t \geq T$. Notice that (3.29) guarantees that the stopping time T is finite almost surely.

The aim is to show that X has payoff near $-\beta^{x_2} e^{\lambda^* x_1}$. Define the process Y by

$$Y_t = \exp \left[\lambda^* \left[X_1(t) - \int_0^t \hat{\mu}(s) ds \right] - \frac{\lambda^{*2}}{2} \int_0^t \hat{\sigma}^2(s) ds \right].$$

That is,

$$Y_t = \exp \left[\lambda^* x_1 + \lambda^* \int_0^t \hat{\sigma}(s) dW_s - \frac{\lambda^{*2}}{2} \int_0^t \hat{\sigma}^2(s) ds \right].$$

By Ito's formula,

$$Y_t = \exp [\lambda^* x_1] + \lambda^* \int_0^t Y_s \hat{\sigma}(s) dW_s,$$

and so $\{Y_t\}$ is a local martingale. Further, since $\{Y_t\}$ is nonnegative, it follows (see Dellacherie and Meyer [1, VI.29]) that $EY_T \leq EY_0$. That is,

$$(3.30) \quad E \left\{ \exp \left[- \int_0^T \left\{ \lambda^* \hat{\mu}(s) + \frac{1}{2} \lambda^{*2} \hat{\sigma}^2(s) \right\} ds \right] \right\} \leq \exp [\lambda^* x_1].$$

Using (3.28), (3.30), and the fact that $X_1(T) = 0$ a.s.,

$$E\beta^T = E[\exp[(\log \beta)T]] \leq (1 + \varepsilon) \exp[\lambda^* x_1].$$

Thus X is available at (x_1, x_2) because $E\beta^T < \infty$, and X has payoff at least $-\beta^{x_2}(1 + \varepsilon) \exp[\lambda^* x_1] = (1 + \varepsilon)Q(x_1, x_2)$. We conclude $Q \leq V$.

To show $Q \geq V$ we would like to apply Proposition 1.1. However, Q does not satisfy (iii) of that proposition. So we construct a sequence $\{Q_n\}$ converging pointwise to Q such that Proposition 1.1 applies to each Q_n .

For each $n \geq 1$, define $Q_n: (-\infty, 1) \times \mathbb{R} \rightarrow \mathbb{R}$ by

$$(3.31) \quad Q_n(x_1, x_2) = -\beta^{x_2} \exp \left[- \int_{x_1}^0 \lambda_n^* U_n(y) dy \right].$$

Notice that $\lim_{n \rightarrow \infty} Q_n(x) = Q(x)$ for each x in $F = (-\infty, 0] \times \mathbb{R}$ because of properties (ii) and (iii) of Lemma 3.3 and the dominated convergence theorem. Also, each Q_n is twice continuously differentiable because of property (i) of Lemma 3.3.

Now verify the conditions of Proposition 1.1 with Q_n ($n \geq 1$) in place of Q . Condition (i) is immediate. For condition (ii), let $x = (x_1, x_2) \in F^0$ and check that for each (μ, σ) in \mathcal{S} ,

$$(3.32) \quad \left[\frac{\partial}{\partial x_2} + \frac{1}{2} \sigma^2 \frac{\partial^2}{\partial x_1^2} \right] Q_n(x_1, x_2) \\ = Q_n(x_1, x_2) \left(\frac{1}{2} \sigma^2 \lambda_n^{*2} [U_n(x_1)]^2 + \frac{1}{2} \sigma^2 \lambda_n^* U_n'(x_1) + \mu \lambda_n^* U(x_1) + \log \beta \right).$$

Use Lemma 3.4 and the fact that $Q_n(x_1, x_2) \leq 0$ to show that the expression (3.32) is nonpositive. For condition (iii), let $x \in \Sigma_C(x)$ and use (3.31) and (ii) and (iv) of Lemma 3.3 to see that

$$(3.33) \quad Q_n(X_1(t), X_2(t)) \geq -C\beta^{X_2(t)} \geq -C\beta^{x_2+T}$$

where C is a constant satisfying $0 < C < \infty$. Now $E(\beta^T) < \infty$ for each $X \in \Sigma_C(x)$, and hence condition (iii) follows from (3.33). Thus Proposition 1.1 shows that $Q_n \geq V$ for each n and hence that $Q \geq V$. This completes the proof of (a) of the theorem.

(b) We reduce the result to (a). The hypothesis for (b) is that $I < \infty$ and $\lambda^* = -\infty$. Let $\varepsilon > 0$ and consider a new problem based on the set

$$\mathcal{S}_\varepsilon = \mathcal{S} \cup \{(\varepsilon, 0)\}.$$

The quantity corresponding to λ^* for the new problem is

$$\lambda_\varepsilon^* = \frac{-\log \beta}{\varepsilon}.$$

Thus part (a) can be applied to obtain the value function

$$V_\varepsilon(x_1, x_2) = -\beta^{x_2 - x_1/\varepsilon} \quad \text{for } x_1 \leq 0, \quad x_2 \in \mathbb{R}.$$

Clearly $V(x_1, x_2) \geq V_\varepsilon(x_1, x_2) \rightarrow -\infty$ as $\varepsilon \rightarrow 0$, and so the proof of (b) is finished.

(c) This was proved in Lemma 3.1. \square

Example. Inflated, continuous-time red-and-black. The problem considered here is the same as that in the example of § 2 except that $\beta > 1$ and the player seeks to minimize $E\beta^T$. (Imagine a borrower of \$1.00 who must pay back β^T if the loan is repaid at time T .) After the change of coordinates (2.15), the control set \mathcal{S} is given by (2.16) and is obviously bounded so that $I < \infty$. The quantity $\lambda(\mu, \sigma^2) = \lambda(s)$ is given by (2.17) if $s > 0$ and $\mu > \sqrt{2\sigma^2 \log \beta}$. Substitute $\mu = s\mu_0 - \frac{1}{2}s^2\sigma_0^2$, $\sigma = s\sigma_0$ and the latter condition reduces to $s \leq M$, $M = 2\mu_0/\sigma_0^2 - 2\sqrt{2(\log \beta)}/\sigma_0$. To reiterate, $\lambda(s)$ is given by (2.17) if $0 < s \leq M$ and $\lambda(s) = -\infty$ if not. Notice that, in the subfair case ($\mu_0 \leq 0$), $M < 0$, and consequently $\lambda^* = -\infty$ and, by Theorem 3.2, $V = -\infty$. In the superfair case ($\mu_0 > 0$), one shows that $\lambda'(s) > 0$ if and only if $0 < s < M \wedge c$ where $c = \mu_0/\sigma_0^2 - 2(\log \beta)/\mu_0$. Thus $\lambda^* = \lambda(s^*)$ where $s^* = (M \wedge c \wedge 1) \vee 0$, and V is given by Theorem 3.2.

ASYMPTOTIC PROPERTIES OF DISTRIBUTED AND COMMUNICATING STOCHASTIC APPROXIMATION ALGORITHMS*

HAROLD J. KUSHNER† AND G. YIN‡

Abstract. The asymptotic properties of extensions of the type of distributed or decentralized stochastic approximation proposed in [1] are developed. Such algorithms have numerous potential applications in decentralized estimation, detection and adaptive control, or in decentralized Monte Carlo simulation for system optimization (where they can exploit the possibilities of parallel processing). The structure involves several isolated processors (recursive algorithms) that communicate to each other asynchronously and at random intervals. The asymptotic (small gain) properties are derived. The communication intervals need not be strictly bounded, and they and the system noise can depend on the (communicating) system state. State space constraints are also handled. In many applications, the dynamical terms are merely indicator functions, or have other types of discontinuities. The “typical” such case is also treated, as is the case where there is noise in the communication. The linear stochastic differential equation satisfied by the (interpolated) asymptotic normalized error sequence is derived, and issued to compare alternative algorithms and communication strategies. Weak convergence methods provide the basic tools.

1. Introduction. Tsitsiklis [1] and Tsitsiklis, Bertsekas and Athens [2] proposed a very interesting model for a decentralized (distributed) recursive algorithm of the stochastic approximation (SA) type, with only asynchronous communications between the separate processors, and developed a scheme for proving w.p.1 (with probability 1) convergence. That work appears to be the first of its type for the decentralized SA problem. Such distributed algorithms are of rapidly growing interest. Various potential applications in adaptive control, estimation and in communication networks were proposed; e.g., several processors might do an identification of the parameters of an identical linear system (but with different inputs) and occasionally (asynchronously) share their latest estimates, or several processors might do Monte Carlo simulations of the SA type to locate the minimum of a regression function, and occasionally share their estimates. There are two main purposes for algorithms of the type discussed here and in [1]: exploiting the opportunities provided by parallel processing for Monte Carlo methods of system optimization or evaluation, situations in which there are physically separate systems (estimators, trackers, controllers) acting on or following essentially the same physical system; and occasionally communicating to take advantage of the “others” information.

The assumptions in [1] were fairly strong with respect to the great variety of potential applications, and the method of analysis required numerous detailed estimates. We analyze essentially the same algorithm here. In addition to getting the basic convergence results, our methods can handle the constrained (projected) algorithm, the case where the noise and the communication intervals depend on the state, the

general rate of convergence problem, and the case where there is communication noise. Instead of letting the “gain” parameter go to zero as $n \rightarrow \infty$ (as frequently done in classical SA) we keep it a constant, and work with convergence in the sense of weak convergence. There are several reasons for this. First, when we work with practical systems the chosen gains almost never go to zero, since one usually wants an algorithm that can track slow changes and is robust with respect to large bursts of noise. Our method can be adapted to get weak and even w.p.1 convergence when the gains do go to zero, and we comment on this in § 8. Even if the gains do go to zero, w.p.1 convergence is not much more useful or interesting than weak convergence. Weak convergence methods locate the points where the process spends most time (asymptotically), and as time goes to ∞ , an increasing (to one) proportion of time is spent arbitrarily close to such points. Then, one can often use the powerful “large deviations” methods to show, under very broad conditions, that ultimate escape from a small neighborhood of such points is impossible (when the gains go to zero) [3], [4]. Alternatively, once the weak convergence methods have located the “stable points” perturbed Lyapunov methods such as that in [10] can often be used to get w.p.1 convergence. One of the key questions in the analysis of any algorithm is the rate of convergence (the asymptotic normalized variance), and the analysis of the “rate” is almost always done via weak convergence methods. General background and applications in many areas are in [6]–[8]. Weak convergence methods are also *much easier* to use than the standard w.p.1 oriented methods; in many cases, a valid result can be obtained almost by inspection. This and the wide variety of problems which can be handled make it a more widely useful tool than “w.p.1” methods. The symbol \Rightarrow is used to denote weak convergence, and some definitions and properties of this convergence are stated in Appendix A.

The methods used here are quite efficient. Problems with potentially unbounded intercommunication intervals (e.g., where the interval is geometrically distributed) can be handled. We can also treat important cases where the dynamics are discontinuous or where the communication intervals and system noise depend on the system state, or where there are state space constraints. The case of discontinuous dynamics is of considerable importance in applications: often an estimate increases or decreases by a fixed amount ε —depending simply on whether a certain event occurred or not. Similarly, for state dependent communication times, a processor might want to communicate either if a given amount of time has passed since the last communication or if the state of the processor has changed by more than a given amount. In many applications (e.g., the decentralized form of the automata routing problem in [5]) the noise is naturally state dependent.

A theory of “rate of convergence” is also developed, which allows an objective comparison among alternative algorithms. Using this, in §§ 6 and 7, we comment on and compare the behavior of the algorithm with the centralized and various “deterministically” decentralized forms, in order to get a better understanding of its behavior and to see what the preferable communication strategies are. We can also allow “noise” in the communication, such as might be the case if the processors were physically separated and communicated via a noisy radio link (see § 7).

The basic algorithm will be described next. Section 2 contains a “technical” estimate which will be useful in the sequel. Section 3 deals with the basic weak convergence result in the function spaces $D[0, \infty)$ or $C[0, \infty)$ (see the Appendix for the definitions) and shows that a suitable continuous time interpolation $X^\varepsilon(\cdot)$ of the iterates $\{X_n\}$ converges weakly to the solution of a certain ODE as the gain parameter $\varepsilon \rightarrow 0$. The state dependent noise/intercommunication time case and the discontinuous

dynamics case are also treated here. Section 4 concerns a “projection” algorithm to handle state space constraints. Here, the limit satisfies a “projected” ODE. The asymptotics of $X^\varepsilon(t_\varepsilon + \cdot)$ are dealt with in § 5, where $t_\varepsilon \rightarrow \infty$ as $\varepsilon \rightarrow 0$. This yields the ultimately desired result concerning the location of the iterates for large n and small ε . Finally, the rate of convergence and comparison with a centralized processor is developed in §§ 6 and 7. A discussion of some of the probable advantages and uses of the algorithm appears in § 7. Section 8 contains a comment on the case where ε is replaced by $\varepsilon_n \rightarrow 0$.

The basic algorithm. We assume that there are q parallel processors, each with a state variable of dimension r . Let X_n^i denote the state of processor i at time n and define $X_n = (X_n^1, \dots, X_n^q)$. The symbol X generally denotes a qr -vector (not a random variable), which we partition as $X = (X^1, \dots, X^q)$, where each X^i is an r -vector. The “observation” of processor i at time n is $b^i(X_n^i, \xi_n^i)$, where ξ_n^i is the “noise”. Define the random variable $\xi_n = (\xi_n^1, \dots, \xi_n^q)$, and the generic dummy variable $\xi = (\xi^1, \dots, \xi^q)$, and write $B(X, \xi) = (b^1(X^1, \xi^1), \dots, b^q(X^q, \xi^q))$. Write $b^i(X^i, \xi^i) = (b_1^i(X^i, \xi^i), \dots, b_r^i(X^i, \xi^i))$, the $b_k^i(\cdot)$ being scalar valued. (All the above vectors are column vectors.) For vectors X^i in E^r , we often write simply x . The use of the “super vectors” X and X_n and their specializations below seems unavoidable, since all of the q processors are interconnected.

Let $\{A_n\}$ be a sequence of (possibly random) $qr \times qr$ matrices, where A_n can be written in the form

$$A_n = \begin{pmatrix} a_{11}(n) & \cdots & a_{q1}(n) \\ a_{1q}(n) & \cdots & a_{qq}(n) \end{pmatrix},$$

where each $a_{ij}(n)$ is a *diagonal* $r \times r$ matrix with nonnegative entries and $\sum_i a_{ij}(n) = I_r$, the identity matrix in E^r , Euclidean r -space (i.e. the “matrix valued” rows of A_n are “convexifying”). Note that the matrix indexing is not standard. The subscripts are of the form (source, destination) = (column, row). Suppose that there is a scalar $\alpha_0 > 0$ such that $a_{ii} \geq \alpha_0 I_r$ and, for $i \neq j$, either $a_{ij}(n) = 0$ or else $a_{ij}(n) \geq \alpha_0 I_r$.

The algorithm to be studied is

$$(1.1) \quad X_{n+1}^i = \sum_j a_{ji}(n) X_n^j + \varepsilon b^i(X_n^i, \xi_n^i), \quad X_{n+1} = A_n X_n + \varepsilon B(X_n, \xi_n).$$

At time n , processor i ($i = 1, \dots, q$) decides whether or not to communicate the current value of its state to any other processor and takes an observation $b^i(X_n^i, \xi_n^i)$. If there is no communication to processor i , then we set $a_{ii}(n) = I_r$ and $a_{ji}(n) = 0$ for $j \neq i$, and the iteration (for processor i at time n) is of the standard SA type: $X_{n+1}^i = X_n^i + \varepsilon b^i(X_n^i, \xi_n^i)$. If there are any communications to processor i from some processors $j \neq i$ at time n , then for such communicating processors j , $a_{ji}(n) \geq \alpha_0 I_r$, and the updated state X_{n+1}^i for processor i is a convex combination of X_n^i and of the states X_n^j communicated to it, added to its own SA increment $\varepsilon b^i(X_n^i, \xi_n^i)$. The requirement that either (for $j \neq i$) $a_{ji}(n) \geq \alpha_0 I_r$ or $a_{ji}(n) = 0$ simply means that if processor j communicates to processor i at time n , processor i can choose to ignore the communication, but if it incorporates the received X_n^j into its own state, it must do so in a “nontrivial” way. For notational simplicity, we omit the symbol for the ε dependence of X_n . The results (and methods) would not change if bounded communication delays were included in the model.

In [1], the algorithm was slightly more complex, since the dimensions of the X^i were not necessarily the same and a somewhat more complicated block structure of A_n was used. But, with no additional mathematical work (although with a more complex

notation), such extensions can readily be incorporated into our framework. It should be clear from the development that many related algorithms and conditions can be treated by essentially identical methods. Reference [14] discusses the asymptotic behavior of interacting stochastic approximations, in terms of the actual elapsed (random) computation (not iterate) times.

2. Some preparatory estimates. This section is devoted to obtaining the rate of convergence of the product $A_n \cdots A_k$ as $n \rightarrow \infty$. We use the following assumption.

(C2.1) Let F_n be an increasing sequence of σ -algebras such that F_n measures $\{X_i, i \leq n, \xi_i, A_i, i < n\}$. There are a scalar $p_0 > 0$ and integer m_0 such that

(2.1) P_{F_n} {processor i communicates to processor j on $[n, n + m_0) \cong p_0$ and j does not ignore the received message}

for all n and i, j , and $i \neq j$.

Remark. In [1], it was assumed that there is an m_0 such that $p_0 = 1$. Assumption (C2.1) covers the case where at each instant each processor flips a coin to decide whether to communicate or not. More generally, there often is a process $\{\tilde{A}_n\}$ such that $\{\tilde{A}_i, \xi_i, i < n, X_i, i \leq n\}$ is Markov, and A_n is a component of \tilde{A}_n . With this model, if F_n denotes the minimal σ -algebra that measures $\{\tilde{A}_i, \xi_i, i < n, X_i, i \leq n\}$, then (C2.1) covers many interesting cases where the intercommunication intervals are not bounded a priori, and might be "state" dependent. The condition seems to be unrestrictive.

For $n \geq k$, define $\Phi(n|k) = A_n \cdots A_k$ and set $\Phi(n|n+1) = I_{qr}$, the identity matrix in E^{qr} .

LEMMA 2.1. Assume (C2.1) and the conditions on $\{A_n\}$ in § 1. Then $\Phi_k \equiv \lim_n \Phi(n|k)$ exists w.p.1 and for each $i \leq r$, all the rows $i, i+r, \dots, i+qr-r$ of Φ_k are equal. Also

(2.1a) $E|\Phi(n|k) - \Phi_k| \rightarrow 0$ geometrically as $n - k \rightarrow \infty$,

(2.1b) $E_{F_k}|\Phi(n|k) - \Phi_k| \rightarrow 0$ geometrically as $n - k \rightarrow \infty$

uniformly in k and ω (w.p.1). Also $E_{F_n}\Phi(n|k)$ converges to Φ_k geometrically, uniformly in ω, k , as $n \rightarrow \infty$.

Remark. The fact that the limit Φ_k exists is almost obvious if we look at the $\{A_n\}$ as transition matrices for a Markov chain. The proof is in Appendix B.

Remark on other cases. One can readily work with the case where all of the processors do not necessarily communicate with each other. We comment on only one special case. Let processors $1, \dots, q_1$ communicate to each other but not to the other processors, and let processors $q_1 + 1, \dots, q$, communicate only to processors $1, \dots, q_1$ but not to each other. Then $\Phi(n|k)$ converges geometrically to a matrix Φ_k , which takes the form

$$\Phi_k = \begin{bmatrix} M_{q_1+1,1}^k & \cdots & M_{q_1}^k \\ \vdots & & \\ 0 & M_{q_1+1,q_1}^k & \cdots & M_{qq_1}^k \\ I_r & & & 0 \\ 0 & \ddots & & I_r \end{bmatrix}.$$

The $i, i+r, \dots$ rows of the upper right-hand block are not necessarily equal.

3. Convergence: The limit ODE. *Nonstate-dependent* $\{A_n, \xi_n\}$. We will work with several sets of assumptions. First, the basic convergence theorem will be proved when

the sequences $\{A_n\}$ and $\{\xi_n\}$ are nonstate-dependent and independent of each other, and then the restrictions will be weakened. Theorem 3.1 is the basic weak convergence theorem, from which most other results will follow. Let E_n denote expectation, conditioned on $\{X_i, i \leq n, A_i, \xi_i, i < n\}$. We will use subsets of the following assumptions. Recall that the $X = (X^1, \dots, X^q)$ and x are dummy variables.

(C3.1) $\{A_k\}$ and $\{\xi_n\}$ are independent of each other.

(C3.2) Let $\{\hat{\xi}_k\}$ be a sequence of bounded random variables and $\{\tilde{\xi}_k\}$ a sequence of random variables with zero mean and bounded 4th moment. Write $\xi = (\hat{\xi}, \tilde{\xi})$, $\xi_n = (\hat{\xi}_n, \tilde{\xi}_n)$, and let $B(X, \xi) = B_0(X, \hat{\xi}) + B_1(X) \tilde{\xi}$, where the $B_i(\cdot)$ are continuous ($B_0(\cdot, \hat{\xi})$ uniformly in $\hat{\xi}$).

(C3.3) There is a continuous function $\bar{B}(X) \equiv (\bar{b}^1(X^1), \dots, \bar{b}^q(X^q))$ such that

$$E_k B_0(X, \hat{\xi}_n) - \bar{B}(X) \rightarrow 0, \quad E_k \tilde{\xi}_n \rightarrow 0$$

in probability for each vector X , as $n - k \rightarrow \infty$.

(C3.4) There are a matrix $\bar{\Phi}$ and a sequence $m_\varepsilon \rightarrow \infty$ such that $\varepsilon m_\varepsilon \equiv \delta_\varepsilon \rightarrow 0$ and

$$E \left| \frac{1}{m_\varepsilon} \sum_{k=n}^{n+m_\varepsilon-1} E_n \Phi_k - \bar{\Phi} \right| \xrightarrow{\varepsilon} 0 \quad \text{uniformly in } n.$$

Remark and Definition. (C3) can be extended in various ways to time varying limits: e.g., let continuous $\Phi(t)$ replace Φ , when $n\varepsilon \rightarrow t$; we can even replace (C3.4) by a condition guaranteeing the ratios in (C3.4) are in some set of matrices M with a probability tending to unity as $\varepsilon \rightarrow 0$. But the statement of the limit result then becomes much more complicated.

Under the conditions of Lemma 2.1, $\bar{\Phi}$ must have the form

$$\bar{\Phi} = \begin{bmatrix} \bar{\phi}_1, \dots, \bar{\phi}_q \\ \bar{\phi}_1, \dots, \bar{\phi}_q \end{bmatrix} \equiv \begin{bmatrix} \hat{\Phi} \\ \hat{\Phi} \end{bmatrix}$$

where the $\bar{\phi}_i$ are diagonal $r \times r$ matrices with diagonal denoted by $(\bar{\phi}_{i1}, \dots, \bar{\phi}_{ir})$ and $\sum_j \bar{\phi}_{ji} = 1$. For any vector X we have the form $\bar{\Phi}X = (y, \dots, y)$ (column vector) and $\Phi_k X = (y_k, \dots, y_k)$ for some y and y_k in E^r . Let $\hat{\Phi}$ denote the row of $r \times r$ matrices $[\bar{\phi}_1, \dots, \bar{\phi}_q]$. Let $\bar{B}(x)$ denote $\bar{B}(x, x, \dots, x)$, and $B(x, \xi)$ denote $B(x, x, \dots, \xi)$.

(C3.5) The ODE (3.1) has a unique solution for each initial condition

$$\begin{aligned} \dot{x}_1 &= \bar{\phi}_{11} \bar{b}_1^1(x) + \dots + \bar{\phi}_{q1} \bar{b}_1^q(x) \\ &\vdots \\ \dot{x}_r &= \bar{\phi}_{1r} \bar{b}_r^1(x) + \dots + \bar{\phi}_{qr} \bar{b}_r^q(x) \end{aligned} = \hat{\Phi} \bar{B}(x). \quad (3.1)$$

(C3.3') There are a continuous $\bar{B}(\cdot)$ and $m_\varepsilon \rightarrow \infty$ such that $\varepsilon m_\varepsilon \equiv \delta_\varepsilon \rightarrow 0$ and

$$\frac{1}{m_\varepsilon} \sum_n^{n+m_\varepsilon-1} E_n B(X, \xi_k) \xrightarrow{\varepsilon} \bar{B}(X)$$

in probability for each vector X , uniformly in n .

(C3.4') There is a matrix $\bar{\Phi}$ such that, as $n - k \rightarrow \infty$,

$$E|E_k \Phi_n - \bar{\Phi}| \rightarrow 0.$$

Let n_ε be a sequence tending to ∞ and such that $\sqrt{\varepsilon} n_\varepsilon \rightarrow 0$, and, for $n \geq n_\varepsilon$,

$$\sup_k P\{|\Phi(k + n_\varepsilon | k) - \Phi_k| \geq \varepsilon^2\} \leq \varepsilon^2.$$

There is such a sequence, by Lemma 2.1. In fact, we can use $n_\varepsilon = O(\log 1/\varepsilon)$. Define

$$X_0^\varepsilon = \Phi(n_\varepsilon | 0) X_0 + \varepsilon \sum_{p=0}^{n_\varepsilon-1} \Phi_{k+1} B(X_k, \xi_k)$$

and for $t \geq 0$ define $X^\varepsilon(\cdot)$ by $X^\varepsilon(t) = X_n$ for $t \in [(n - n_\varepsilon)\varepsilon, (n - n_\varepsilon + 1)\varepsilon)$. Write $X^\varepsilon(\cdot) = (X^{\varepsilon,1}(\cdot), \dots, X^{\varepsilon,q}(\cdot))$. It will turn out that, for any initial conditions X_0^i , the vectors X_n^i , $i \leq q$, rapidly come close together (due to the communication and convexification). This leads to an (asymptotic in ε) jump in the process $X_{[t/\varepsilon]}$ at $t = 0$. For this reason, we start $X^\varepsilon(\cdot)$ slightly away (n_ε steps) from the origin of the $\{X_n\}$ process.

THEOREM 3.1. *Assume (C2.1), the conditions on $\{A_n\}$ in § 1, and (C3.1), (C3.2), (C3.5) and either (C3.3), (C3.4) or (C3.3'), (C3.4'). Define $X(0)$ and x_0 by $X(0) = \lim_\varepsilon X_0^\varepsilon \equiv (x_0, \dots, x_0)$. Then $X^\varepsilon(\cdot)$ is tight in $D[0, \infty)$ and converges weakly to a process $X(\cdot) = (x(\cdot), \dots, x(\cdot))$, where $x(\cdot)$ satisfies (3.1) with initial condition x_0 .*

Proof. Part 1. The proofs are essentially the same for the pairs (C3.3), (C3.4) and (C3.3'), (C3.4'), and we work only with the first pair. We often use Schwarz' inequality and the inequality (for $a \geq 0$), $E|\Phi(n|k) - \Phi_k|^{1+a} \leq \text{constant} \cdot E|\Phi(n|k) - \Phi_k|$, without specific mention. Iterating (1.1) and letting $n \geq n_\varepsilon$ yields

$$\begin{aligned} X_{n+1} &= \Phi(n|0)X_0 + \varepsilon \sum_0^{n_\varepsilon-1} \Phi(n|k+1)B(X_k, \xi_k) + \varepsilon \sum_{n_\varepsilon}^n \Phi(n|k+1)B(X_k, \xi_k) \\ (3.2) \quad &= X_0^\varepsilon + \varepsilon \sum_{n_\varepsilon}^n \Phi_{k+1} B(X_k, \xi_k) + \varepsilon \psi_n^\varepsilon + [\Phi(n|0) - \Phi(n_\varepsilon|0)]X_0 \end{aligned}$$

where

$$\psi_n^\varepsilon = \sum_0^n [\Phi(n|k+1) - \Phi_{k+1}]B(X_k, \xi_k).$$

For the purposes of the weak convergence proof, we can assume (w.l.o.g.) that $\{X_k\}$ is bounded by simply truncating the dynamical terms, i.e., changing $B(\cdot, \xi)$ so that it is zero for large $|X|$. If the theorem is true for *each such truncation*, then by the uniqueness assumption (C3.5), it is true as stated. Henceforth we assume this boundedness.

Part 2. Next, we show that $\sup_{\varepsilon, n} E|\psi_n^\varepsilon|^3 < \infty$. All norms are in the l_∞ sense. We have

$$\begin{aligned} E|\psi_n^\varepsilon|^3 &\leq \text{constant} \cdot \sum_{i,j,k} E|\Phi(n|i+1) - \Phi_{i+1}| |\Phi(n|j+1) - \Phi_{j+1}| |\Phi(n|k+1) - \Phi_{k+1}| \\ &\quad \cdot [1 + |\tilde{\xi}_i| |\tilde{\xi}_j| |\tilde{\xi}_k|]. \end{aligned}$$

By Holder's inequality, the summand is bounded above by

$$\begin{aligned} E^{1/12} [|\Phi(n|i+1) - \Phi_{i+1}|^{12} \cdot E^{1/12} |\Phi(n|j+1) - \Phi_{j+1}|^{12} \cdot E^{1/12} |\Phi(n|k+1) - \Phi_{k+1}|^{12} \\ \cdot [1 + E^{3/4} |\tilde{\xi}_i|^4 \cdot E^{3/4} |\tilde{\xi}_j|^4 E^{3/4} |\tilde{\xi}_k|^4]. \end{aligned}$$

By (C3.2) and the geometric convergence in Lemma 2.1 and the boundedness of $\Phi(n|i)$ and Φ_i , there is a $d \in [0, 1)$ such that this term is bounded above by (constant) $d^{n-i} d^{n-j} d^{n-k}$. Thus $\sup_{\varepsilon, n} E|\psi_n^\varepsilon|^3 < \infty$. From this and (3.2) (and the truncation of $B(\cdot, \cdot)$)

$$\sup_{\varepsilon, n \geq n_\varepsilon} E|X_{n+1} - X_n|^2 / \varepsilon^2 < \infty,$$

and $\{|X_{n+1} - X_n|/\varepsilon, n \geq n_\varepsilon, \varepsilon\}$ is uniformly integrable. Thus, $\{X^\varepsilon(\cdot)\}$ is tight in $D[0, \infty)$ and all limit paths are Lipschitz continuous (in t).

Part 3. We fix and work with a weakly convergent subsequence of $\{X^\varepsilon(\cdot)\}$, also indexed by ε , and with the limit denoted by $X(\cdot)$. Skorokhod imbedding (see the Appendix) will be used where useful, without specific mention. Thus, we can assume, where needed, that $X^\varepsilon(\cdot) \rightarrow X(\cdot)$ uniformly on bounded time intervals, w.p.1.

We will show, for each real valued function $f(\cdot)$ with compact support and continuous second derivatives, that the $M_f(\cdot)$ defined by

$$(3.3) \quad M_f(t) = f(X(t)) - f(X(0)) - \int_0^t f'_X(X(s)) \bar{\Phi} \bar{B}(X(s)) ds$$

is a (continuous) martingale. Since $M_f(\cdot)$ is a Lipschitz-continuous martingale (since $X(\cdot)$ is Lipschitz continuous), it is a constant. Thus, since $M_f(0) = 0$, we have $M_f(t) = 0$ or, equivalently, $\dot{X} = \bar{\Phi} \bar{B}(X)$. By the properties of Φ_k for each $i \leq r$, the $i, i+r, \dots, i+qr-r$ rows of $\bar{\Phi}$ are equal. Thus all r -vector components of the limit $X(\cdot)$ must be equal, i.e., $X(\cdot)$ is of the form $(x(\cdot), \dots, x(\cdot))$, for $x(t) \in E^r$. This and $\dot{X} = \bar{\Phi} \bar{B}(X)$ implies that $x(\cdot)$ satisfies (3.1).

We need only show the martingale property. To do this, we need only show that for any integer p and continuous bounded $h(\cdot)$ and $t_i \leq t, i \leq p, s > 0$,

$$(3.4) \quad Eh(X(t_i), i \leq p) \left[f(X(t+s)) - f(X(t)) - \int_t^{t+s} f'_X(X(u)) \bar{\Phi} \bar{B}(X(u)) du \right] = 0.$$

To simplify the notation (and w.l.o.g.), let t and s be integral multiples of $\varepsilon m_\varepsilon \equiv \delta_\varepsilon$ (see (C3.4) for the definition of m_ε) and define the index set $I_l^\varepsilon = \{n: lm_\varepsilon + n_\varepsilon \leq n < lm_\varepsilon + m_\varepsilon + n_\varepsilon\}$. By Taylor's Theorem and (3.2),

$$(3.5) \quad \begin{aligned} f(X^\varepsilon(t+s)) - f(X^\varepsilon(t)) &= \sum_{l \leq l\delta_\varepsilon < t+s} [f(X_{lm_\varepsilon+m_\varepsilon+n_\varepsilon}^\varepsilon) - f(X_{lm_\varepsilon+n_\varepsilon}^\varepsilon)] \\ &= \varepsilon \sum_{l \leq l\delta_\varepsilon < t+s} f'_X(X_{lm_\varepsilon+n_\varepsilon}^\varepsilon) \sum_{k \in I_l^\varepsilon} \Phi_{k+1} B(X_k, \xi_k) \\ &\quad + \text{error terms,} \end{aligned}$$

where the error term is of the order of the sum of (all norms are in the l_∞ sense)

$$\begin{aligned} &\varepsilon \sum_l |\psi_{lm_\varepsilon+n_\varepsilon}^\varepsilon|, \varepsilon^2 \sum_l |\psi_{lm_\varepsilon+n_\varepsilon}^\varepsilon|^2, \varepsilon, \\ &\sum_l |\Phi(lm_\varepsilon + m_\varepsilon + n_\varepsilon|0) - \Phi(n_\varepsilon|0)| \cdot |X_0|, \\ &\sum_k \varepsilon^2 (1 + |\tilde{\xi}_k|^2) \end{aligned}$$

where the sums are over all l such that $t \leq l\delta_\varepsilon < t+s$ and k is summed over $t \leq \varepsilon k - \varepsilon n_\varepsilon < t+s$. The mean values of the error terms go to zero as $\varepsilon \rightarrow 0$.

By (3.5),

$$(3.6) \quad \begin{aligned} &\lim_\varepsilon Eh(X^\varepsilon(t_i), i \leq p) [f(X^\varepsilon(t+s)) - f(X^\varepsilon(t))] \\ &= \lim_\varepsilon Eh(X^\varepsilon(t_i), i \leq p) \left[\varepsilon \sum_{l \leq l\delta_\varepsilon < t+s} f'_X(X_{lm_\varepsilon+n_\varepsilon}^\varepsilon) \sum_{k \in I_l^\varepsilon} \Phi_{k+1} B(X_k, \xi_k) \right]. \end{aligned}$$

We now rearrange the terms in a more convenient way. Define

$$\hat{B}_l^\varepsilon = \frac{1}{m_\varepsilon} \sum_{k \in I_l^\varepsilon} \Phi_{k+1} B(X_k, \xi_k)$$

and define the function $B^\varepsilon(\cdot)$ by

$$B^\varepsilon(t) = f'_X(X_{lm_\varepsilon+n_\varepsilon}^\varepsilon) E_{lm_\varepsilon+n_\varepsilon} \hat{B}_l^\varepsilon \quad \text{for } l\delta_\varepsilon \leq t < l\delta_\varepsilon + \delta_\varepsilon.$$

Since $X^\varepsilon(t_i)$, $i \leq p$, is measurable on the σ -algebra $F_{l_{m_\varepsilon+n_\varepsilon}}$, for $l\delta_\varepsilon \geq t$ (3.6) can be rewritten as

$$(3.7) \quad \begin{aligned} & \lim_{\varepsilon} Eh(X^\varepsilon(t_i), i \leq p) \left[\delta_\varepsilon \sum_{t \leq l\delta_\varepsilon < t+s} f'_X(X^\varepsilon_{l_{m_\varepsilon+n_\varepsilon}}) \hat{B}_l^\varepsilon \right] \\ &= \lim_{\varepsilon} Eh(X^\varepsilon(t_i), i \leq p) \int_t^{t+s} B^\varepsilon(u) du. \end{aligned}$$

If

$$(3.8) \quad B^\varepsilon(u) \xrightarrow{\varepsilon} f'_X(X(u)) \bar{\Phi} \bar{B}(X(u))$$

in probability for almost all u , then the second limit in (3.7) would be

$$Eh(X(t_i), i \leq p) \int_t^{t+s} f'_X(X(u)) \bar{\Phi} \bar{B}(X(u)) du.$$

Using this and taking limits in (3.6) yields the desired result (3.4), and we will be done. Thus, we need only show (3.8).

Fix u and for $\varepsilon > 0$, define l_ε by $u \in [l_\varepsilon \delta_\varepsilon, l_\varepsilon \delta_\varepsilon + \delta_\varepsilon)$. Then we need to show that

$$(3.9) \quad \frac{1}{m_\varepsilon} \sum_{k \in I_{l_\varepsilon}^\varepsilon} E_{l_\varepsilon m_\varepsilon + n_\varepsilon} f'_X(X_k) \Phi_{k+1} B(X_k, \xi_k) \xrightarrow{P} f'_X(X(u)) \bar{\Phi} \bar{B}(X(u)).$$

By (C3.2) (and the truncation), we can replace the X_k in (3.9) by $X_{l_\varepsilon m_\varepsilon + n_\varepsilon}$ without changing the limit. Using this and the independence assumption (C3.1), we can rewrite (3.9) as

$$(3.10) \quad \frac{1}{m_\varepsilon} \sum_{k \in I_{l_\varepsilon}^\varepsilon} f'_X(X_{l_\varepsilon m_\varepsilon + n_\varepsilon}) E_{l_\varepsilon m_\varepsilon + n_\varepsilon} \Phi_{k+1} E_{l_\varepsilon m_\varepsilon + n_\varepsilon} B(X_{l_\varepsilon m_\varepsilon + m_\varepsilon}, \xi_k) + \text{error term},$$

where the error term goes to zero in the mean. By the convergence of $X^\varepsilon(\cdot)$ to $X(\cdot)$ and using $l_\varepsilon \delta_\varepsilon \rightarrow u$, and (C3.3), (C3.4), we get that (3.10) converges in the mean to the right side of (3.9) as $\varepsilon \rightarrow 0$ and the proof is concluded. (The “intermediate” details in the last part of the proof are very similar to those in the “centralized” case. See [8, Chap. 5.2] or [9].) Q.E.D.

State dependent $\{A_n\}$ and $\{\xi_n\}$ and/or discontinuous dynamics. The state dependent “communication” and noise are most conveniently modeled by a “Markov” dependence. This will allow $\{A_n\}$ and $\{\xi_n\}$ to depend on the state in a variety of ways: A_n can depend (statistically) on recent events or changes in the X_n -sequence greater than a given magnitude over some time interval, or time elapsed since recent communications or on the “levels” of recent communications (i.e., the degree of “convexification” or incorporation of received data into one’s own estimate can depend on the nature or timing of recent receptions, transmissions, etc.). To be precise, we suppose that there is a bounded sequence of random variables $\{\tilde{A}_n\}$ such that A_n is a component of \tilde{A}_n and, for each $\varepsilon > 0$, $(X_n, \tilde{A}_{n-1}, \xi_{n-1})$ is a Markov process with a homogeneous transition function. The \tilde{A}_n can incorporate other data, e.g., time elapsed since last reception, transmission, etc. The case where some components of $B(\cdot, \cdot)$ are merely indicator functions (hence, not continuous functions) is of particular importance in applications. Such “Markovianizations” seem to be quite natural for many problems. It might be hard to explicitly evaluate the ODE’s here, but the character of the results is clear and precisely what is wanted.

Example. For one example of the appearance of state dependent noise, see the “routing” problem in [5]. In that example, inputs to a service or communication system occur at random, and the service times are random (correlated or not). The parameter

x (the state) determines the probability that incoming events are routed along particular channels. The effective noise is a consequence of the queue length or occupancy level of each channel; its statistics are dependent on the routing parameter. A Markov dependence model was appropriate there. The routing parameter at time n increased or decreased by ε , depending on whether or not certain events occurred at time n ; hence the dynamics were discontinuous. The model used in this section includes “decentralized” generalizations of such problems.

Assume that the marginal one-step transition function is of the product (conditionally independent) form. For some P_C and P_N

$$(3.11) \quad P\{\tilde{A}_1 \in B_1, \xi_1 \in B_2 | X_1, \tilde{A}_0, \xi_0\} = P_C\{\tilde{A}_1 \in B_1 | X_1, \tilde{A}_0\} P_N\{\xi_1 \in B_2 | X_1, \xi_0\}$$

(C denotes “communication”; N denotes “noise”). The P_C and P_N will not depend on ε . (We could allow some ε -dependence, but, in many applications, ε is merely a step size parameter and does not affect the distribution of the A_n , \tilde{A}_n or ξ_n other than via the values of the X_n (e.g., as in the above example).) The product from (3.11) is a natural generalization of (C3.1). Here the noise and intercommunication intervals are independent, conditional on the state. For each fixed X , the P_C and P_N in (3.11) can be considered to be one-step transition functions for “fixed X ” Markov chains which we denote by $\{\tilde{A}_n(X)\}$, $\{\xi_n(X)\}$. Let $P_C\{\tilde{A}_n, n, \cdot | X\}$ and $P_N\{\xi, n, \cdot | X\}$ denote the associated n -step transition functions. Then $P_C\{\tilde{A}, 1, \cdot | X\} = P_C\{\tilde{A}_1 \in \cdot | \tilde{A}_0 = A, X\}$, etc. The fixed- X processes are, of course, homogeneous. Let E_C^X and E_N^X denote the associated expectations.

Several assumptions will now be given, followed by some remarks concerning extensions. The assumptions are phrased so as to cover many potential applications. Again, recall that the X and x are vectors not random variables.

$$(C3.6) \quad E^X[A_n \cdots A_1 | \tilde{A}_0 = \tilde{A}] \equiv F_n(\tilde{A}, X) \text{ is continuous in } (\tilde{A}, X).$$

$$(C3.7) \quad \text{For each bounded and continuous functions } f_i(\cdot), \quad i=1,2, \int f_1(\xi_1) P_N(\xi, 1, d\xi_1 | X) \text{ and } \int f_2(\tilde{A}_1) P_C(\tilde{A}, 1, d\tilde{A}_1 | X) \text{ are continuous in } (\xi, X) \text{ and } (\tilde{A}, X) \text{ respectively.}$$

$$(C3.8) \quad \{\xi_n\} \text{ is bounded.}$$

$$(C3.9) \quad \text{For each vector } X \text{ of the form } X = (x, x, \cdots, x), \text{ let the pair of processes } \{\tilde{A}_n(X), \xi_n(X)\} \text{ associated with the } n\text{-step transition function } P_C\{\tilde{A}, n, \cdot | X\} P_N\{\xi, n, \cdot | X\} \text{ have a unique invariant measure and which is of the product form } P_C^x\{\cdot\} P_N^x\{\cdot\}.$$

$$(C3.10) \quad \int B(X, \xi_1) P(\xi, 1, d\xi_1 | X) \text{ is continuous in } (X, \xi).$$

Remark. Since the two fixed X -processes are independent, the product form in (C3.9) will hold if the processes are aperiodic. Under the conditions of Lemma 2.1, the $F_n(\tilde{A}, X)$ in (C3.6) converge geometrically (uniformly in \tilde{A}, X) to a function $\Phi(\tilde{A}, X)$, which must be continuous under (C3.6). By the discussion associated with Theorem 3.1, we see that $\Phi(\tilde{A}, X)$ has the form

$$\Phi(\tilde{A}, X) = \begin{bmatrix} \bar{\phi}_1(\tilde{A}, X) & \cdots & \bar{\phi}_q(\tilde{A}, X) \\ \vdots & & \vdots \\ \bar{\phi}_1(\tilde{A}, X) & \cdots & \bar{\phi}_q(\tilde{A}, X) \end{bmatrix} \equiv \begin{bmatrix} \hat{\Phi}(\tilde{A}, X) \\ \vdots \\ \hat{\Phi}(\tilde{A}, X) \end{bmatrix}$$

where $\phi_i(\tilde{A}, X)$ is a diagonal $(r \times r)$ matrix. Write $\phi_i(\tilde{A}, X) = \text{diag}[\phi_{i1}(\tilde{A}, X), \cdots, \phi_{ir}(\tilde{A}, X)]$.

If X takes the form $X = (x, x, \cdots, x)$ for $x \in E'$, we might simply write x for X .

$$(C3.11) \quad \text{The ODE (3.12) has a unique solution for each initial condition (analogous to (3.1)—the } \tilde{A} \text{ and } \tilde{\xi} \text{ are simply averaged out with respect to the invariant measure)}$$

$$(3.12) \quad \begin{aligned} \dot{x}_1 &= \sum_j \int \bar{\phi}_{j1}(\tilde{A}, x) P_C^x \{d\tilde{A}\} \int b_1^j(x, \xi^j) P_N^x(d\xi^j) \\ &\quad \vdots \\ \dot{x}_r &= \sum_j \int \bar{\phi}_{jr}(\tilde{A}, x) P_C^x \{d\tilde{A}\} \int b_r^j(x, \xi^j) P_N^x(d\xi^j) \end{aligned} = \hat{\Phi}(x) \bar{B}(x)$$

where

$$\hat{\Phi}(x) = \int \hat{\Phi}(\tilde{A}, x) P_C^x(d\tilde{A}), \quad \bar{B}(x) = \int B(x, \xi) P_N^x(d\xi).$$

Write

$$\bar{\Phi}(x) = \begin{bmatrix} \hat{\Phi}(X) \\ \vdots \\ \hat{\Phi}(x) \end{bmatrix}.$$

Under (C3.7), (C3.9) and (C3.10), the right side of (3.12) is continuous.

Remarks on the assumptions. In many applications, \tilde{A} takes only a finite number of values. Then the appropriate topology is the discrete topology and the \tilde{A} -continuity required in (C3.6) and (C3.7) always holds, since then all functions of \tilde{A} are continuous. The one-step smoothing assumption in (C3.10) can be replaced by a k -step smoothing assumption, and Theorem 3.2 will still hold. Since $\Phi(\tilde{A}, X)$ is continuous (see above remark), a Φ_k -analogue of (C3.10) is not needed. In (3.12) we are simply averaging the dynamics with respect to the invariant measures. If the invariant measure is not unique, then the right side of (3.12) is set valued and P_N^x and P_C^x range over all the invariant measures. We use (C3.8) here to avoid some details. Extensions to cover typical unbounded $\{\xi_n\}$ cases are possible via essentially the same method. To see how this can be done, see the proof for the “centralized” case in [8, Chap. 5.3] or in [9].

THEOREM 3.2. Assume (C2.1), the conditions on $\{A_n\}$ in § 1, (C3.2) (without the $\tilde{\xi}$ component) and (C3.6) to (C3.10). Then $\{X^\varepsilon(\cdot)\}$ is tight in $D[0, \infty)$ and converges weakly to $X(\cdot) = (x(\cdot), \dots, x(\cdot))$, where $x(\cdot)$ satisfies (3.12) and $X(0) = (x(0), \dots, x(0)) = \Phi_0 X_0$.

Proof. $\{X^\varepsilon(\cdot)\}$ is tight and all limits are Lipschitz continuous for the same reasons as in Theorem 3.1. Let ε index a weakly convergent subsequence with limit denoted by $X(\cdot)$. As in Theorem 3.1, $X(\cdot)$ has the form $X(\cdot) = (x(\cdot), \dots, x(\cdot))$. Owing to the Markov assumption, E_k denotes conditioning on $(X_k, \xi_{k-1}, \tilde{A}_{k-1})$. By the method of proof of Theorem 3.1, we need only show that the left side of (3.9) converges in probability to $f'_X(X(u))\bar{\Phi}(X(u))\bar{B}(X(u))$ for $X(u)$ of the form $X(u) = (x(u), \dots, x(u))$. The f_X term does not play an important role and we discard it henceforth.

We use the “truncation” method and notation discussed in Theorem 3.1. Thus, we can suppose that $B(\cdot, \cdot)$ and $\{X_n\}$ are bounded. For each ν , rewrite (3.9) as (using the conditional independence implied by (3.11))

$$(3.13) \quad \begin{aligned} H^\varepsilon &\equiv \frac{1}{m_\varepsilon} \sum_{k \in I_{I_\varepsilon}^\varepsilon} E_{m_\varepsilon I_\varepsilon + n_\varepsilon} E_k \Phi_{k+1} E_k B(X_k, \xi_k) \\ &= \frac{1}{m_\varepsilon} \sum_{k \in I_{I_\varepsilon}^\varepsilon} E_{m_\varepsilon I_\varepsilon + n_\varepsilon} E_k (A_{k+\nu} \cdots A_{k+1}) E_k B(X_k, \xi_k) + Q^\varepsilon, \end{aligned}$$

where $E|Q^\varepsilon| \rightarrow 0$ uniformly in ε , as $\nu \rightarrow \infty$, by Lemma 2.1.

We next estimate $E_{k+1} A_{k+\nu} \cdots A_{k+1}$. All norms are in the l_∞ sense. Since the $\{X_n\}$ and $\{\tilde{A}_n\}$ lie in a compact set, the function of δX defined by

$$\delta_i(|\delta X|) = \sup_{\tilde{A}, X} |F_i(\tilde{A}, X) - F_i(\tilde{A}, X + \delta X)|$$

can be supposed to go to zero as $|\delta X| \rightarrow 0$. We have $E_n A_n = F_1(\tilde{A}_{n-1}, X_n) = F_1(\tilde{A}_{n-1}, X_{n-1}) + \Delta_1(\tilde{A}_{n-1}, X_{n-1}, X_n)$, where $|\Delta_1(\tilde{A}_{n-1}, X_{n-1}, X_n)| \leq \delta_1(|X_n - X_{n-1}|)$. Next we can write $E_{n-1} A_n A_{n-1} = E_{n-1}(E_n A_n) A_{n-1} = E_{n-1} F_1(\tilde{A}_{n-1}, X_{n-1}) A_{n-1} + \Delta_1(\tilde{A}_{n-1}, X_{n-1}, X_n) A_{n-1}$. Note that

$$(3.14) \quad E_{n-1} F_1(\tilde{A}_{n-1}, X_{n-1}) A_{n-1} = F_2(\tilde{A}_{n-2}, X_{n-1}) = E_{C^{n-1}} A_n A_{n-1},$$

which is just the expectation for the two-step fixed X -process with X fixed at X_{n-1} . Using this and $|A_n| = 1$, we have

$$(3.15) \quad E_{n-1} A_n A_{n-1} = F_2(\tilde{A}_{n-2}, X_{n-2}) + \text{error terms},$$

where

$$\begin{aligned} |\text{error terms}| &= |(F_2(\tilde{A}_{n-2}, X_{n-1}) - F_2(\tilde{A}_{n-2}, X_{n-2})) + \Delta_1(\tilde{A}_{n-1}, X_{n-1}, X_n) A_{n-1}| \\ &\leq \delta_2(|X_{n-1} - X_{n-2}|) + \delta_1(|X_n - X_{n-1}|). \end{aligned}$$

Continuing in this way, we get

$$(3.16) \quad E_{k+1} A_{k+\nu} \cdots A_{k+1} = F_\nu(\tilde{A}_k, X_k) + T_k^{\varepsilon, \nu},$$

where

$$|T_k^{\varepsilon, \nu}| \leq \sum_{i=1}^{\nu} \delta_i(|X_{\nu+k-i+1} - X_{\nu+k-i}|)$$

and $E|T_k^{\varepsilon, \nu}| \xrightarrow{\varepsilon} 0$ for each ν , uniformly in k , owing to the convergence of the $X^\varepsilon(\cdot)$.

Putting the estimate (3.16) into (3.13) yields that

$$\begin{aligned} (3.17) \quad H^\varepsilon &= \frac{1}{m_\varepsilon} \sum_{k \in I_{I_\varepsilon}^\varepsilon} E_{m_\varepsilon l_\varepsilon + n_\varepsilon} F_\nu(\tilde{A}_k, X_k) B(X_k, \xi_k) + Q_\nu^\varepsilon \\ &\quad + \frac{1}{m_\varepsilon} \sum_{k \in I_{I_\varepsilon}^\varepsilon} E_{m_\varepsilon l_\varepsilon + n_\varepsilon} T_k^{\varepsilon, \nu} B(X_k, \xi_k). \end{aligned}$$

The last two right-hand terms in (3.17) go to zero in mean as $\varepsilon \rightarrow 0$ and then $\nu \rightarrow \infty$, and can be neglected. The sequence $F_\nu(\tilde{A}, X)$ converges uniformly to the continuous function $\Phi(\tilde{A}, X)$ as $\nu \rightarrow \infty$. Thus, the limit (as $\varepsilon \rightarrow 0$, $\nu \rightarrow \infty$) of the first term on the right side of (3.16) is the same if $\Phi(\tilde{A}, X)$ replaces $F_\nu(\tilde{A}, X)$.

Now we are in a position to use the result of [8, Chap. 5.3] or [9]. By the arguments (for the Markov model) in either of these references (which, when adapted to our current situation, require the continuity of $\Phi(\cdot, \cdot)$, and (C3.7), (C3.8) and (C3.10)) and the fact that $X^\varepsilon(\cdot) \rightarrow X(\cdot)$, we have

$$(3.18) \quad \frac{1}{m_\varepsilon} \sum_{k \in I_{I_\varepsilon}^\varepsilon} E_{m_\varepsilon l_\varepsilon + n_\varepsilon} \Phi(\tilde{A}_k, X_k) B(X_k, \xi_k) \rightarrow \int \Phi(\tilde{A}, X(u)) B(X(u), \xi) m^{x(u)}(d\tilde{A} d\xi),$$

where $m^X(\cdot)$ is an invariant measure for the process $\{\tilde{A}_n(X), \xi_n(X)\}$. Since $X(u) = (x(u), \cdots, x(u))$, the uniqueness and product form of the invariant measure in (C3.9) yields that $m^x(d\tilde{A} d\xi) = P_C^x(d\tilde{A}) \cdot P_N^x(d\xi)$. Thus the right side of (3.18) equals

$$\bar{\Phi}(x(u)) \bar{B}(x(u)) = \int \Phi(\tilde{A}, x(u)) P_C^{x(u)}(d\tilde{A}) \cdot \int B(x(u), \xi) P_N^{x(u)}(d\xi),$$

and the proof is concluded. Q.E.D.

4. State space constraints: a projection algorithm. In many applications, it is desirable to confine the iterates to a compact set L , and if they ever leave L , the algorithm will project them back onto L . Such algorithms are ubiquitous in applications, even if not explicitly defined or assumed; e.g., the ambiguous notion of “monitoring” in adaptive control which implicitly assumes some sort of projection. We treat two special, but useful, cases.

4.1. Assumptions and problem formulation.

(C4.1) Let $g_i(x)$, $i \leq \alpha$, be real valued continuously differentiable functions on E' and define $L = \{x: g_i(x) \leq 0, i \leq \alpha\}$. Let L be bounded, convex and the closure of its interior. Also (w.l.o.g.) assume that the gradient $g_{ix}(x)$ is not zero if $g_i(x) = 0$.

Let $\pi_L(y)$ denote the (unique) closest point on L to $y \in E'$. We use the projected form of algorithm (1.1):

$$(4.1) \quad \tilde{X}_{n+1} = A_n X_n + \varepsilon b(X_n, \xi_n), \quad X_{n+1}^i = \pi_L(\tilde{X}_{n+1}^i), \quad i \leq q.$$

Thus, each processor projects independently and the constraint set is the same for each. We now set the problem up so that previous results can be used.

Define $\rho_n = (\rho_n^1, \dots, \rho_n^q)$, where $\rho_n^i = [X_{n+1}^i - \tilde{X}_{n+1}^i]/\varepsilon$ and define $\tilde{\psi}_n^\varepsilon = \psi_n^\varepsilon + \sum_0^n [\Phi(n|k+1) - \Phi_{k+1}] \rho_k$. Then for $n \geq n_\varepsilon$ (n_ε was defined below (C3.4'))

$$(4.2) \quad \begin{aligned} X_{n+1} = X_0^\varepsilon + \varepsilon \sum_{n_\varepsilon}^n \Phi_{k+1} B(X_k, \xi_k) + \varepsilon \sum_{n_\varepsilon}^n \Phi_{k+1} \rho_k + \varepsilon \tilde{\psi}_n^\varepsilon \\ + [\Phi(n|0) - \Phi(n_\varepsilon|0)] X_0, \end{aligned}$$

where

$$X_0^\varepsilon = \Phi(n_\varepsilon|0) X_0 + \varepsilon \sum_0^{n_\varepsilon-1} \Phi_{k+1} [B(X_k, \xi_k) + \rho_k].$$

The two cases which we treat are covered by ((C4.1), (C4.2)) and (C4.3), respectively.

(C4.2) The matrices $a_{ij}(n)$ in A_n take the form $a_{ij}(n) = \alpha_{ij}(n) I_r$ where $\alpha_{ij}(n)$ is a scalar valued random variable and $\sum_i \alpha_{ij}(n) = 1$.

Under (C4.2) each of the scalar components “communicated” from a processor j to processor i are incorporated the same way into the updated estimates of processor i . In (C4.3), L takes the form of a hyper-rectangle.

(C4.3) There are bounded g_{1i} and g_{2i} such that $L = \{x: g_{1i} \leq x_i \leq g_{2i}, i \leq r\}$.

DEFINITIONS. For a vector field $h(\cdot)$ in E' , define the projection onto L by (for $x \in L$) $\pi(x, h(x)) = \lim_{\Delta \rightarrow 0} [\pi_L(x + \Delta h(x)) - x]/\Delta$. By the convexity of L , the limit is unique. Define the convex cone

$$C(x) = \left\{ y: y = \sum_{i \in A(x)} \lambda_i g_{ix}(x), \lambda_i \geq 0 \right\}$$

where $A(x)$ is the set of constraints $\{i: g_i(x) = 0\}$ (the active constraints at x). Note that $\rho_n^i \in -C(X_{n+1}^i)$. Write $A_n \rho_n = (Z_n^1, \dots, Z_n^q)$, where $Z_n^i \in E'$. Under (C4.2), each Z_n^i is a convex combination of vectors in the $-C(X_{n+1}^j)$, $j \leq q$. We will see below that the same property holds under (C4.2'). The same conditions apply when A_k or Φ_k replaces A_n .

The theorem is stated under the conditions of Theorem 3.1, but there is an analogous result under the conditions of Theorem 3.2.

THEOREM 4.1. Assume the conditions of Theorem 3.1, and either (C4.1), (C4.2) or

(C4.3). Let the solution to (4.3) (the projected form of (3.1)) be unique. Then $\{X^\varepsilon(\cdot)\}$ converges weakly to $X(\cdot)$, where $X(\cdot) = (x(\cdot), \dots, x(\cdot))$ and

$$(4.3) \quad \dot{x} = \pi(x, \hat{\Phi} \bar{B}(x)).$$

Equivalently,

$$(4.4) \quad \dot{x} = \hat{\Phi} \bar{B}(x) + \nu(x), \quad x(t) \in L$$

where $\nu(x(t)) \in -C(x(t))$. Also $X(0)$ takes the form $X(0) = \Phi_0 X_0 = (x(0), \dots, x(0))$, if $X_0^i \in L$.

Proof. Only (4.4) will be proved, since (4.4) implies (4.3). No truncation (see Theorem 3.1) is needed here since $X_n^i \in L$, a compact set. Define the process $\bar{R}^\varepsilon(\cdot)$ by

$$\bar{R}^\varepsilon(t) = \varepsilon \sum_{n_\varepsilon}^n \Phi_{k+1} \rho_k \quad \text{for } t \in [(n - n_\varepsilon)\varepsilon, (n - n_\varepsilon + 1)\varepsilon]$$

(analogous to the definition of $X^\varepsilon(\cdot)$ above Theorem 3.1). All norms below are in the l_∞ sense. For $X_n^i \in L$, the qr -vector components of $A_n X_n$ are all in L under either (C4.2) or (C4.3). Thus $|\rho_n^\varepsilon| \leq |B(X_n, \xi_n)|$. Hence, the proof of uniform integrability of $\{\psi_n^\varepsilon\}$ and $\{\rho_n^\varepsilon\}$ is the same as that for $\{\psi_n^\varepsilon\}$ given in Theorem 3.1. Thus $\{X^\varepsilon(\cdot), \bar{R}^\varepsilon(\cdot)\}$ is tight and all weak limits are Lipschitz continuous. Henceforth, we fix and work with a weakly convergent subsequence, also indexed by ε , and with a limit denoted by $(X(\cdot), \bar{R}(\cdot))$.

As in Theorem 3.1, for $i \leq q$, the $i, i+r, \dots, i+rq-r$ th rows of Φ_k are equal. Then so are the same components of $\Phi_{k+1} B(X_k, \xi_k)$ and of $\Phi_{k+1} \rho_k$. Thus (as in Theorem 3.1) $X(\cdot) = (x(\cdot), \dots, x(\cdot))$ and $\bar{R}(\cdot) = (R(\cdot), \dots, R(\cdot))$, where $x(t)$ and $R(t)$ are in E' , and

$$(4.5) \quad \dot{x} = \hat{\Phi} \bar{B}(x) + \dot{R}(t).$$

Obviously $x(t) \in L$. Thus, we need only show that $\dot{R}(t) \in -C(x(t))$ for almost all t .

Write $X^\varepsilon(\cdot) = (X^{\varepsilon,1}(\cdot), \dots, X^{\varepsilon,q}(\cdot))$. Let $x(t)$ be in the interior of L for $t \in [t_1, t_2]$ with $t_1 < t_2$. Then, by the weak convergence (i.e. convergence of all $X^{\varepsilon,i}(\cdot)$ to $x(\cdot)$) the $X^{\varepsilon,i}(t)$, $i \leq q$, are the strictly interior to L on $[t_1, t_2]$ with a probability which tends to unity as $\varepsilon \rightarrow 0$. Thus, for small ε , the cones $C(X^{\varepsilon,i}(t))$, $i \leq q$, $t_1 \leq t \leq t_2$, will be empty with a probability which tends to unity as $\varepsilon \rightarrow 0$. Thus $R(t) = 0$ for $t_1 \leq t \leq t_2$.

We will now consider the case where $x(t)$ is on the boundary of L for $t \in [t_1, t_2]$, $t_1 < t_2$. The general case follows by the same argument. Skorokhod imbedding will be used (see the Appendix), so that we can assume that the convergence is w.p.1 on each bounded time interval. Note that $C(x)$ is an upper semicontinuous function of x in the sense that if $x_n \rightarrow x$, then

$$(4.6) \quad C(x) \supset \bigcap_{n=k=n}^{\infty} C(x_k).$$

Let $(g_{i_1 x}(x(t)), \dots, g_{i_a x}(x(t))) \equiv (\nu_1, \dots, \nu_a)$ be the gradient vectors of the active constraints at $x = x(t)$, and let C_β denote the convex cone formed by the vectors in a β -neighborhood of (ν_1, \dots, ν_a) .

By the weak convergence (i.e., the convergence of all $X^{\varepsilon,i}(\cdot)$ to $x(\cdot)$) and (4.6), for each $\beta > 0$ and $\gamma > 0$, there are $\beta_1 > 0$ and $\varepsilon_1 > 0$ such that for $\varepsilon \leq \varepsilon_1$,

$$(4.7) \quad P\{\rho_k^i \in -C_\beta, i \leq q, \text{ all } k \text{ such that } |\varepsilon(k - n_\varepsilon) - t| \leq \beta_1\} \geq 1 - \gamma,$$

i.e., for $\varepsilon(k - n_\varepsilon)$ close enough to t , the ρ_k^i are in a "small neighborhood" of $-C(x(t))$ with probability close to unity.

Now, assume (C4.1), (C4.2). Then, each of the q r -vector components of $\Phi_{k+1} \rho_k$ is also in such a "small neighborhood" with a probability close to unity, for $\varepsilon(k - n_\varepsilon)$ close to t . This implies that $R(t) \in -C(x(t))$, for almost all t .

Write $x(t) = (x_1(t), \dots, x_r(t))$. Assume (C4.3), and let $\varepsilon(k - n_\varepsilon)$ be close to t . Then $C(x(t))$ is particularly simple. Write $\rho_k^j = (\rho_k^{j1}, \dots, \rho_k^{jr})$ where the ρ_k^{ji} are scalar valued. If $x_i(t) = g_{1i}$ (the lower limit) then (using the weak convergence) $X^\varepsilon(\cdot) \Rightarrow (x(\cdot), \dots, x(\cdot))$, the ρ_k^{ji} must be (asymptotically in ε) ≥ 0 for all j , with a probability arbitrarily close to unity. Similarly, if $x_i(t) = g_{2i}$ (the upper limit), then (asymptotically in ε) the ρ_k^{ji} must be ≤ 0 for all j . By the properties of Φ_{k+1} , the same property must hold for the respective components $(i, i+r, i+2r, \dots)$ of $\Phi_{k+1}\rho_k$.

The conclusion follows from this last remark, since if $x = (x_1, \dots, x_r)$, where $x_i = g_{1i}$, $i \leq r_1$, $x_i = g_{2i}$, $r_1 < i \leq r_2$ and $g_{1i} < x_i < g_{2i}$, $r_2 < i \leq r$, then we have that $-C(x)$ is the collection of vectors whose first r_1 components are nonnegative, the next $r_2 - r_1$ are nonpositive and the last $r - r_2$ are zero. Q.E.D.

5. The asymptotics of $X^\varepsilon(\cdot)$ for large t and small ε . Weak convergence in $D[0, \infty)$ or in $C[0, \infty)$ basically gives information on the locations and/or distribution of $X^\varepsilon(\cdot)$ for small ε , and for t confined to some large, but still bounded, interval. See, e.g., the discussion of the topology of these spaces in the Appendix. It is important to have a convergence result which is valid uniformly in (large) t for small ε , and such a result is readily available by appropriate modifications of the previous results. One usually requires that the ODE satisfied by the limit processes is stable; hence we assume the following:

(C5.1) Let (3.1) (or (3.12) for the state dependent $\{A_n, \xi_n\}$ case) have a unique stable (in the sense of Lyapunov) point θ which is globally attracting.

Let $t_\varepsilon \rightarrow \infty$ as $\varepsilon \rightarrow 0$. Frequently, if (C5.1) (and the conditions of Theorem 3.1 or 3.2) holds, then $X^\varepsilon(t_\varepsilon + \cdot)$ converges weakly to a constant process $\bar{X}(\cdot)$, where $\bar{X}(t) = (\theta, \dots, \theta)$. This is precisely the desired asymptotic result, since it says (roughly) that if the algorithm is "stable" then, after a fixed "transient period" (independent of ε), the $X^{t_\varepsilon}(\cdot)$ are arbitrarily close to θ in the sense of weak convergence. Condition (5.1) below will be dealt with later in this section.

We suppose now that the set

$$(5.1) \quad M = \{X^\varepsilon(t), t \geq 0, \varepsilon > 0\}$$

is bounded in probability (tight), i.e., for each $\eta > 0$ there is a $k_\eta < \infty$ such that $P\{|X^\varepsilon(t)| \geq k_\eta\} \leq \eta$ for all $\varepsilon > 0$, $t \geq 0$.

THEOREM 5.1. Assume tightness of (5.1), and the conditions of Theorem 3.1 or 3.2. Then $X^\varepsilon(t_\varepsilon + \cdot)$ converges weakly to the constant process (θ, \dots, θ) .

Discussion of the main idea of the development. Choose $T > 0$ and consider a convergent subsequence of the pair of processes $\{X^\varepsilon(t_\varepsilon + \cdot), X^\varepsilon(t_\varepsilon - T + \cdot)\}$, with limit denoted by $(X(\cdot), X_T(\cdot)) = (x(\cdot), \dots, x(\cdot); x_T(\cdot), \dots, x_T(\cdot))$ (recall that all the r -vector components of the limits are equal). We have $X(0) = X_T(T)$. The value of $X_T(0)$ is unknown, but all the possible such $X_T(0)$, over all T and convergent subsequences, belong to a tight set, with the same η and k_η as above. By this and the stability condition (A5.1) and Theorem 3.1 (or Theorem 3.2), for any $\delta > 0$ there is a $T_\delta < \infty$ such that for $T \geq T_\delta$, $X_T(T) = (x_T(T), \dots, x_T(T))$ will be in a δ -neighborhood of (θ, \dots, θ) with probability $\geq 1 - \delta$. This yields the desired conclusion, since it implies that $X(0) = (\theta, \dots, \theta)$ w.p.1. Thus, to get the asymptotic (in t and ε) result, only (5.1) must be shown.

Next, consider the projection algorithm of § 4 and assume (C5.1').

(C5.1') Let (4.4) have a unique stable (in the sense of Lyapunov) point θ which is attracting in L .

Under (C5.1'), (5.1) is automatically bounded, and if $t_\varepsilon \rightarrow \infty$ as $\varepsilon \rightarrow 0$ then under the additional conditions of § 4, $X^\varepsilon(t_\varepsilon + \cdot) \Rightarrow \bar{X}(\cdot)$, where $\bar{X}(t) = (\theta, \dots, \theta)$. Some

form of projection algorithm is usually used in practical algorithms, and so the tightness condition on (5.1) is not burdensome.

5.1. Sharper bounds on the asymptotic errors $(X_n^i - \theta)$, for large εn and small ε . Under additional "stability" conditions, one can get order of magnitude estimates for $(X^{i,\varepsilon}(t) - \theta)$ for large t and small ε . We do one case here in preparation for the rate of convergence work in § 6. We will need the following assumption.

(C5.2) There is a twice continuously differentiable Lyapunov function $0 \leq \bar{V}(x) \rightarrow \infty$ and $\bar{V}(x) > 0$ for $x \neq \theta$ such that for some $\lambda > 0$ and $K < \infty$, $\bar{V}'_x(x) \hat{\Phi} \bar{B}(x) \leq -\lambda \bar{V}(x)$, $|\bar{V}_x(x)|^2 \leq K(\bar{V}(x) + 1)$ and $\bar{V}_{xx}(\cdot)$ is bounded.

Define

$$(5.2) \quad V(X) = \sum_1^q \bar{V}(X^i) \quad \text{for } X = (X^1, \dots, X^q).$$

(C5.3) Case (C3.2), but where $B_0(X, \hat{\xi})$ and $B_1(X)$ are bounded and have bounded and continuous X -derivatives (uniformly in $\hat{\xi}$, for B_0).

(C5.4) There is a constant K such that

$$E \left| \sum_{\nu}^{\nu+m} E_{\nu}(\Phi_{k+1} B(X, \xi_k) - \bar{\Phi} \bar{B}(X)) \right|^2 \leq K[V(X) + 1],$$

for all positive m and ν . Similarly for the derivatives B_X and \bar{B}_X replacing B and \bar{B} , respectively.

Remark. Case (C5.4) essentially implies a "low" correlation between data in the remote past and in the distant future. There is an analogous result to Theorem 5.1 for the state dependent $\{A_n, \xi\}$ case, and for the constrained case.

THEOREM 5.2. Assume (C5.1) to (C5.4). There is an $N_{\varepsilon} < \infty$ for each small ε such that

$$(5.3) \quad EV(X_n) = O(\varepsilon), \quad n \geq N_{\varepsilon}.$$

Proof. We always assume $n \geq n_{\varepsilon}$, so that $E|\Phi(n|0) - \Phi_0|^a = O(\varepsilon^2)$ for any $a > 0$. Write

$$(5.4) \quad \begin{aligned} X_{n+1} - X_n &= [\Phi(n|0) - \Phi(n-1|0)]X_0 + \varepsilon(\psi_n^{\varepsilon} - \psi_{n-1}^{\varepsilon}) \\ &\quad + \varepsilon \bar{\Phi} \bar{B}(X_n) + \varepsilon[\Phi_{n+1} B(X_n, \xi_n) - \bar{\Phi} \bar{B}(X_n)] \end{aligned}$$

and

$$(5.5) \quad \begin{aligned} E_n V(X_{n+1}) - V(X_n) &= \varepsilon V'_X(X_n) E_n [\Phi(n|0) - \Phi(n-1|0)] X_0 \\ &\quad + \varepsilon V'_X(X_n) E_n (\psi_n^{\varepsilon} - \psi_{n-1}^{\varepsilon}) + \varepsilon V'_X(X_n) \bar{\Phi} \bar{B}(X_n) \\ &\quad + \varepsilon V'_X(X_n) E_n [\Phi_{n+1} B(X_n, \xi_n) - \bar{\Phi} \bar{B}(X_n)] + \text{error term}, \end{aligned}$$

where $E|\text{error term}| = O(\varepsilon^2)$. By (C5.2) and $n \geq n_{\varepsilon}$, the expectation of the first term on the right-hand side of (5.5) is $O(\varepsilon^2)(1 + EV(X_n))$. Write Φ_n in the form

$$\Phi_n = \begin{bmatrix} \hat{\Phi}_n \\ \vdots \\ \hat{\Phi}_n \end{bmatrix},$$

where $\hat{\Phi}_n$ is an $r \times qr$ matrix. For $n \geq n_{\varepsilon}$,

$$(5.6) \quad |X_n^i - X_n^j| = O_n(\varepsilon^2) + O(\varepsilon)|\psi_n^{\varepsilon}|,$$

where $E|O_n(\varepsilon^2)|^2 = O(\varepsilon^4)$, uniformly in $n \geq n_{\varepsilon}$.

Using (5.6), rewrite the last two terms on the right side of (5.5) as, respectively,

$$(5.7) \quad \begin{aligned} & \varepsilon \sum_i \bar{V}'_x(X_n^i) \hat{\Phi} \bar{B}(X_n^i) + \text{error term}, \\ & \varepsilon \sum_i \bar{V}'_x(X_n^i) E_n [\hat{\Phi}_{n+1} B(X_n^i, \xi_n) - \hat{\Phi} \bar{B}(X_n^i)] + \text{error term}, \end{aligned}$$

where by (C5.2), $E|\text{error term}| = O(\varepsilon^2)(1 + EV(X_n))$.

We now define the perturbations to the Lyapunov function.

Define

$$V_1^\varepsilon(n) \text{ by } V_1^\varepsilon(n) = -\varepsilon V'_x(X_n) \psi_{n-1}^\varepsilon.$$

We have

$$(5.8) \quad E|V_1^\varepsilon(n)| = O(\varepsilon)(1 + EV(X_n)),$$

$$(5.9) \quad EV_1^\varepsilon(n+1) - EV_1^\varepsilon(n) \leq -\varepsilon EV'_x(X_n)(\psi_n^\varepsilon - \psi_{n-1}^\varepsilon) + O(\varepsilon^2)E(1 + V(X_n)).$$

Define $V_2^{i\varepsilon}(n)$:

$$(5.10) \quad V_2^{i\varepsilon}(n) = \varepsilon \sum_{j=n}^{\infty} \bar{V}'_x(X_n^i) E_n [\hat{\Phi}_{j+1} B(X_n^i, \xi_j) - \hat{\Phi} \bar{B}(X_n^i)].$$

By (C5.2) and (C5.4),

$$(5.11) \quad E|V_2^{i\varepsilon}(n)| = O(\varepsilon)(1 + EV(X_n)).$$

Also,

$$(5.12) \quad E_n V_2^{i\varepsilon}(n+1) - V_2^{i\varepsilon}(n) = -\varepsilon \bar{V}'_x(X_n^i) E_n [\hat{\Phi}_{n+1} B(X_n^i, \xi_n) - \hat{\Phi} \bar{B}(X_n^i)] + \text{error term},$$

where by (C5.4), $E|\text{error term}| = O(\varepsilon^2)(1 + EV(X_n))$.

Now, define the perturbed Lyapunov function $V^\varepsilon(n) = V(X_n) + V_1^\varepsilon(n) + \sum_1^q V_2^{i\varepsilon}(n)$, and evaluate $E_n V^\varepsilon(n+1) - V^\varepsilon(n)$ and cancel the terms $\pm \varepsilon V'_x(X_n)(\psi_n^\varepsilon - \psi_{n-1}^\varepsilon)$ and $\pm \varepsilon \sum_j \bar{V}'_x(X_n^i) E_n [\hat{\Phi}_{n+1} B(X_n^i, \xi_j) - \hat{\Phi} \bar{B}(X_n^i)]$ to get

$$(5.13) \quad \begin{aligned} E_n V^\varepsilon(n+1) - V^\varepsilon(n) &= \varepsilon \sum_i \bar{V}'_x(X_n^i) \hat{\Phi} \bar{B}(X_n^i) + \text{error terms}, \\ E|\text{error term}| &= O(\varepsilon^2)(1 + EV(X_n)). \end{aligned}$$

Using (C5.2) and the bounds on $E|V_1^\varepsilon(n)|$ and on $E|V_2^{i\varepsilon}(n)|$, we get

$$(5.14) \quad \begin{aligned} EV^\varepsilon(n+1) - EV^\varepsilon(n) &\leq -\lambda \varepsilon \sum_i E \bar{V}(X_n^i) + O(\varepsilon^2)(1 + EV(X_n)) \\ &\leq -\lambda \varepsilon EV^\varepsilon(n) + O(\varepsilon^2)(1 + EV^\varepsilon(n)). \end{aligned}$$

Hence, for small $\varepsilon > 0$,

$$(5.15) \quad EV^\varepsilon(n) \leq \left(1 - \frac{\lambda \varepsilon}{2}\right)^{n-n_e} V^\varepsilon(n_e) + O(\varepsilon).$$

This, together with the bounds on $E|V_1^\varepsilon(n)|$ and on $E|V_2^{i\varepsilon}(n)|$, yields the theorem. Q.E.D.

6. Rate of convergence: qualitative asymptotic properties. The Lyapunov function in (C5.2) is often locally quadratic about θ in the sense that $\bar{V}(x) = (x - \theta)'Q(x - \theta) + O(|x - \theta|^3)$ for $Q > 0$. If this is true, then Theorem 5.1 implies that

$\{(X_n^i - \theta)/\varepsilon^{1/2}, i \leq q, n \geq N_\varepsilon, \varepsilon > 0\}$ is tight. In this section, we are interested in the asymptotic normalized errors, and we assume this tightness, whether or not the Lyapunov function is of the above form and the conditions of Theorem 5.1 hold. In particular, we will suppose that there are numbers $\tilde{N}_\varepsilon < \infty$ for each small $\varepsilon > 0$ so that

$$(6.1) \quad \left\{ \frac{X_n^i - \theta}{\sqrt{\varepsilon}}, i \leq q, n \geq \tilde{N}_\varepsilon, \varepsilon > 0 \right\} \text{ is tight, } \quad Eb^i(\theta, \xi_k^i) = 0.$$

Under (6.1), one can apply the methods of the “centralized” case to get a classical rate of convergence result.

Much information concerning the asymptotic behavior and comparison with other algorithms can be obtained from such a result. The method and results will be discussed in an informal way so that the main ideas are clear. Despite the informality, the conditions needed for the proof will generally be stated. The proofs follow standard lines in weak convergence theory and are not hard. Our aim is to exhibit the asymptotic behavior of the suitably normalized errors, then specialize them to simple cases where a comparison can be made with “centralized” forms of the algorithm, so that one can see the effects and value of the decentralization, and evaluate alternative forms of the communication and algorithms. The discussion is continued in § 7. Such insights are needed at this stage of development of the “decentralized” algorithms as a guide to future developments, and are perhaps more important than a rigorous development along the standard lines. We will use (6.1), the boundedness of $B(\cdot, \cdot)$ in each bounded X -set and that $B(\cdot, \xi)$ has a continuous (uniformly in ξ) derivative, and $EB(X, \xi) = 0$.

For any R^s valued function $p(\cdot) = (p^1(\cdot), \dots)$ of x (or X), let $(p(\theta))_x$ denote the (Jacobian) matrix whose i th row is the x (respectively, X) gradient of $p^i(\cdot)$. Recall the definitions of $\bar{\phi}_i$ and $\hat{\Phi}$ (above (C3.5)), and of $\hat{\Phi}_n$ (in Theorem 5.1). Define the matrix $M = (\hat{\Phi} \bar{B}(\theta))_x$ and suppose that it is stable. Let

$$\frac{1}{n} \sum_m^{n+m} (\hat{\Phi}_{k+1} B(\theta, \xi_k))_x \rightarrow (\hat{\Phi} \bar{B}(\theta))_x = M$$

in probability as $n \rightarrow \infty$ and $m \rightarrow \infty$.

Define $U_n^\varepsilon = (X_n - \bar{\theta})/\sqrt{\varepsilon}$, where $\bar{\theta} = (\theta, \theta, \dots, \theta)$. Recall the definition of n_ε given below (C3.4') and that n_ε can be chosen such that $\sqrt{\varepsilon} n_\varepsilon \rightarrow 0$. Given $N > 0$, we have, for $n \geq n_\varepsilon + N$,

$$(6.2) \quad \begin{aligned} U_{n+1}^\varepsilon &= \Phi(n|N) U_N^\varepsilon + \sqrt{\varepsilon} \sum_N^{N+n_\varepsilon} \Phi(n|k+1) B(X_k, \xi_k) \\ &\quad + \sqrt{\varepsilon} \sum_{N+n_\varepsilon+1}^n \Phi_{k+1} B(X_k, \xi_k) + \sqrt{\varepsilon} \hat{\psi}_n^\varepsilon, \end{aligned}$$

$$\hat{\psi}_n^\varepsilon = \sum_{N+n_\varepsilon}^n [\Phi(n|k+1) - \Phi_{k+1}] B(X_k, \xi_k).$$

Define (for $n \geq N + n_\varepsilon$)

$$W_n^\varepsilon = \sqrt{\varepsilon} \sum_{N+n_\varepsilon+1}^n \Phi_{k+1} B(\bar{\theta}, \xi_k).$$

Let $N \geq \tilde{N}_\varepsilon$. For $t \geq 0$, define the process $U^\varepsilon(\cdot)$ by $U^\varepsilon(t) = U_n^\varepsilon$ for $t \in [\varepsilon(n - N - n_\varepsilon), \varepsilon(n - N - n_\varepsilon + 1))$ and define $W^\varepsilon(\cdot)$ similarly from $\{W_n^\varepsilon\}$. By Taylor's Theorem and

the definition of n_ε ,

$$(6.3) \quad \begin{aligned} U_{n+1}^\varepsilon = & \Phi_N U_N^\varepsilon + O_n(\varepsilon^2) U_N^\varepsilon + \tilde{O}_n(n_\varepsilon \sqrt{\varepsilon}) + O(\sqrt{\varepsilon}) \hat{\psi}_n^\varepsilon \\ & + \varepsilon \sum_{N+n_\varepsilon+1}^n (\Phi_{k+1} B(\bar{\theta}, \xi_k))_X U_k^\varepsilon + W_n^\varepsilon + o(\varepsilon) \sum_{N+n_\varepsilon+1}^n O(|U_k^\varepsilon|), \end{aligned}$$

where $E|O_n(\varepsilon^2)|^2 = O(\varepsilon^4)$ since $n \geq n_\varepsilon$, and $E|\tilde{O}_n(n_\varepsilon \sqrt{\varepsilon})| = O(n_\varepsilon \sqrt{\varepsilon})$. Also $(\Phi_{k+1} B(\bar{\theta}, \xi_k))_X$ denotes the matrix whose rows are the X -gradients of the components of $\Phi_{k+1} B(X, \xi_k)$ evaluated at $X = (\theta, \theta, \dots) = \bar{\theta}$.

In order to study the weak convergence of $U^\varepsilon(\cdot)$, we can truncate the dynamics (as in Theorem 3.1) if $\{U_k^\varepsilon\}$ is not bounded: wherever U_k^ε appears in (6.3), we simply replace it by $U_k^\varepsilon q_m(U_k^\varepsilon)$, where $q_m(u) = 1$ for $|u| \leq m$, and is a smooth function with compact support. We get the weak convergence with use of q_m , and then let $m \rightarrow \infty$. The uniqueness of the solution to the limit (6.9) below guarantees that the procedure works. For notational simplicity we simply suppose that $\{U_k^\varepsilon\}$ is bounded. Suppose that $\{W^\varepsilon(\cdot)\}$ is tight and has continuous limits. Then this also holds for $\{U^\varepsilon(\cdot)\}$. Also, the second, third, fourth and last terms on the right side of (6.3) disappear in the limit. The limit of any convergent subsequence satisfies

$$(6.4) \quad U(t) = U(0) + \int_0^t (\bar{\Phi} \bar{B}(\bar{\theta}))_X U(s) ds + W(t)$$

where $W(\cdot)$ is the limit of $\{W^\varepsilon(\cdot)\}$.

6.1. The limits of $\{W^\varepsilon(\cdot)\}$. Under broad conditions $W(\cdot)$ is a Wiener process. The most convenient expression for the covariance matrix depends on the statistical properties of the $\{\Phi_{n+1}, \xi_n\}$. Under the appropriate mixing and stationarity (including the special case in § 7 below), we have

$$(6.5) \quad EW(t)W'(t) = t \sum_{-\infty}^{\infty} E\Phi_{k+1}B(\bar{\theta}, \xi_k)B'(\bar{\theta}, \xi_0)\Phi_1'.$$

We now give some conditions under which $W(\cdot)$ is the asserted Wiener process. Let

$$(6.6) \quad E \left| \sum_n^{n+m-1} \Phi_{k+1} B(\bar{\theta}, \xi_k) \right|^4 \leq \text{Constant} \cdot m^2,$$

then $\{W^\varepsilon(\cdot)\}$ is tight and all limits are continuous [6]. If

$$(6.7) \quad \sum_n^{m+n-1} \Phi_{k+1} B(\bar{\theta}, \xi_k) / \sqrt{m}$$

converges in distribution to a normal random variable (with mean zero) as $n \rightarrow \infty$ and $m \rightarrow \infty$, then $W(\cdot)$ is a Gaussian process. If, for $t_1 \leq t_2 \leq t_3 \leq t_4$,

$$(6.8) \quad E[W^\varepsilon(t_4) - W^\varepsilon(t_3)][W^\varepsilon(t_2) - W^\varepsilon(t_1)]' \xrightarrow{\varepsilon} 0,$$

then the increments of the limit $W(\cdot)$ are orthogonal and the limit is a (nonstandard) Wiener process. The proofs follow standard lines in weak convergence theory [6]. Properties (6.6) and (6.8) hold if the $\{A_k\}$ is independent of the $\{\xi_k\}$ and the dependence among the ξ_k decreases fast enough as the time difference increases. Henceforth we assume that $W(\cdot)$ is the zero mean Wiener process with covariance (6.5).

For the same reasons that the $X(\cdot)$ of § 3 took the form $X(\cdot) = (x(\cdot), \dots, x(\cdot))$ for $x(t) \in E^r$, we have $U(\cdot) = (u(\cdot), \dots, u(\cdot))$ and $W(\cdot) = (w(\cdot), \dots, w(\cdot))$. Then (6.4) reduces to

$$(6.9) \quad du = Mu \, dt + dw.$$

The $w(\cdot)$ is an r -dimensional Wiener process. In fact that $W(\cdot)$ reduces to $(w(\cdot), \dots, w(\cdot))$ is obvious via an examination of the form of W_n^ε , since all the q (r -vector) components of each component of the sum in W_n^ε must be equal. The covariance of $w(1)$ can be obtained from (6.5): if we write

$$\Phi_k = \begin{bmatrix} \phi_1(k), & \dots, & \phi_q(k) \\ \vdots & & \vdots \\ \phi_1(k), & \dots, & \phi_q(k) \end{bmatrix}$$

where the $\phi_i(k)$ are diagonal, (6.5) reduces to

$$(6.10) \quad \text{cov } w(1) = \bar{R} = \sum_{-\infty}^{\infty} E \left[\sum_1^q \phi_i(k+1) b^i(\theta, \xi_k^i) \right] \left[\sum_1^q \phi_i(k+1) b^i(\theta, \xi_k^i) \right]'$$

If $N \rightarrow \infty$ fast enough as $\varepsilon \rightarrow 0$, then the limit $u(\cdot)$ is the stationary solution to (6.9).

The stationary covariance

$$(6.11) \quad \int_0^\infty e^{M't} \bar{R} e^{M't'} dt$$

of (6.9) is a standard measure of the "rate of convergence" or asymptotic quality of the algorithm, and can be used as a basis of comparison among alternative algorithms.

6.2. A special case. We specialize to a simple case in order to get some insight into the asymptotic behavior. Let $\{\xi_k\}$ be independent of $\{A_k\}$ with $\{\xi_k^i, i \leq q, k = 1, 2, \dots\}$ mutually independent with $\text{cov } b^i(\theta, \xi_k^i) \equiv R_i$. Then

$$(6.12) \quad \text{cov } w(1) = \sum_1^q \lim_m \frac{1}{m} \sum_n^{n+m} \phi_i(k) R_i \phi_i(k).$$

6.3. A scalar system. Let $r = 1$. Then $\phi_i(k)$ and $\bar{\phi}_i$ are scalars and

$$\sum_1^q \bar{\phi}_i = 1 = \sum_1^q \phi_i(k).$$

Let $b^i(\cdot, \cdot) = b(\cdot, \cdot)$ and $R_i = R$ not depend on i . Then (6.9) becomes ($\bar{b}_x(\theta) < 0$),

$$(6.13) \quad du = \bar{b}_x(\theta) u \, dt + \sigma_D d\tilde{w}$$

where $\tilde{w}(\cdot)$ is a *standard* Wiener process and (where by the expectation E we mean the ergodic mean in (6.12))

$$\sigma_D^2 = R \sum_1^q E \phi_i^2(n).$$

The stationary variance of $u(\cdot)$ is $\sigma_D^2/2|\bar{b}_x(\theta)| \equiv \text{var}_D$.

6.4. Comparison with a "centralized" algorithm. Define the following centralized algorithm, under the scalar system assumptions of the above paragraph:

$$(6.14) \quad Z_{n+1} = Z_n + \varepsilon b(Z_n, \xi_n^1), \quad \{\xi_n^1, n = 1, 2, \dots\} \text{ i.i.d.}$$

Define $V_n = (Z_n - \theta)/\sqrt{\varepsilon}$ and define $v^\varepsilon(\cdot)$ by $v^\varepsilon(t) = V_n$ on $[n\varepsilon, n\varepsilon + \varepsilon)$. If $t_\varepsilon \rightarrow \infty$ fast enough as $\varepsilon \rightarrow 0$, then under appropriate conditions [8] $v^\varepsilon(t_\varepsilon + \cdot) \Rightarrow v(\cdot)$, where

$$(6.15) \quad dv = \bar{b}_x(\theta)v dt + \sqrt{\bar{R}} d\tilde{w}.$$

The stationary variance of (6.15) is $R/2|\bar{b}_x(\theta)| = \text{var}_C$. Since

$$\frac{\text{var}_D}{\text{var}_C} = E \sum_1^q \phi_i^2(n) < 1,$$

the decentralized algorithm yields an improvement. The infimum of the ratio occurs when the $E\phi_i^2(n)$, $i \leq q$, are all equal, an *unattainable* case (to which we can come close, see § 7). In this limit, $1/q = \text{var}_D/\text{var}_C$. This limit can be obtained if the communications are simultaneous, and the A_i are appropriately symmetric.

A fairer comparison accounts for the fact that the decentralized algorithm uses a total of q observations per iterate. Using the same number in the centralized algorithm (6.14), we rewrite it as

$$(6.16) \quad \bar{Z}_{n+1} = \bar{Z}_n + \frac{\varepsilon}{q} \sum_1^q b(\bar{Z}_n, \xi_n^i), \quad \{\xi_n^i, i \leq q, n = 1, 2, \dots\} \text{ i.i.d.}$$

Define \bar{V}_n^ε and $\bar{v}^\varepsilon(\cdot)$ as the V_n^ε and $v^\varepsilon(\cdot)$ were defined, but based on $\{\bar{Z}_n\}$. Under appropriate conditions $\bar{v}^\varepsilon(t_\varepsilon + \cdot) \Rightarrow \bar{v}(\cdot)$, where

$$(6.17) \quad d\bar{v} = \bar{b}_x(\theta)\bar{v} dt + \sqrt{R/q} d\tilde{w},$$

with stationary covariance $R/2q|b_x(\theta)| = \text{var}_{qC}$ and

$$(6.18) \quad \text{var}_D/\text{var}_{qC} = q \sum_1^q E\Phi_i^2(n) \geq 1.$$

The ratio (6.18) can be used to decide on the proper tradeoff between the asymptotic error and the communication policy. Reasons why the decentralized algorithm might be preferable are discussed in § 7. Analogous results are, of course, obtainable for the general vector case.

7. Asymptotic properties: discussion and comparison.

7.1. Independent $\{A_n\}$. We evaluate $\text{var}_D/\text{var}_C$ under the conditions of the last § 6.4 where $q = 2$ and the $\{A_n\}$ are i.i.d. In particular, let $c \in [0, 1)$, and let the processors act independently, with p = probability that i communicates to $j \neq i$ at time n . With no communication (probability $(1-p)^2$), $A_n = I$; if 2 communicates to 1, but not conversely (probability $p(1-p)$), then

$$A_n = \begin{bmatrix} 1-c & c \\ 0 & 1 \end{bmatrix} = A^{21}.$$

If 1 communicates to 2 (but not conversely), then

$$A_n = \begin{bmatrix} 1 & 0 \\ c & 1-c \end{bmatrix} = A^{12}.$$

If both communicate to each other, then

$$A_n = \begin{bmatrix} 1-c & c \\ c & 1-c \end{bmatrix} = A^0.$$

(See Table 1.) The *optimum* value of the ratio of the variances is unity, a value closely approximated by small c . Clearly a larger p is desirable. As $c \rightarrow 0$, the ratio improves,

TABLE 1
Values for $2 \text{ var}_D / \text{var}_C = \text{var}_D \text{ var}_{2C}$.

$p \backslash c$	0.05	0.25	0.5
0.1	1.036	1.13	1.312
0.3	1.016	1.104	1.26
0.7	1.008	1.048	1.13

but the size of the ψ_n^e would increase. This implies that one must wait longer for the stationary variance to be a good indicator of the actual performance (the effects of the communication are realized more slowly). Similarly, this is the case for small p . But, in all cases, the average performance is much better than that for the centralized algorithm (6.14). To compute (6.18) (and, hence, Table 1) one need only calculate $E\Phi\Phi'$, where $\Phi = \lim_n A_n \cdots A_1$ and the A_i are i.i.d. and distributed as above.

7.2. A deterministic communication scheme. We retain the assumptions of § 7.1, except for those on the communications. Let m and m_1 be integers with $m_1 \leq m/2$. Processor 2 communicates to 1 each m units of time, and 1 communicates to 2 m_1 units of time later. We use A^{12} , A^{21} (when $m_1 \neq 0$) and A^0 (when $m_1 = 0$). For $m_1 = 0$, $(2 \text{ var}_D / \text{var}_C) = 1$, for all $0 < 1 < c$. For $m_1 \neq 0$, we have Table 2. The values of m and m_1 appear only in the values of ψ_n^e , which increases as m and m_1 increase. The values of $\text{var}_D / \text{var}_{2C}$ are substantially worse when processor 1 communicates to processor 2 more often than the reverse communication rate, for deterministic communication times. This suggests that a relatively balanced communication strategy is better and that a processor should “respond” as soon as possible after it receives a “message” from another processor.

7.3. Discussion. It is clear that the decentralized algorithm takes advantage of the possibilities of parallel processing, since its variance is better than that of the classical algorithm (6.14), and can be nearly as good as that of the fully centralized algorithm (6.16). But there is another advantage, which can be considerable. Simulations with recursive algorithms such as (6.14) indicate that a key problem concerns the frequently slow recovery from the effects of large “bursts” of noise, i.e., from a large “random” jump in the state value. This effect would not show up in the asymptotic variance estimates, but is of considerable importance in practice, particularly when the algorithm is not in operation for a very long time. The nature of the “convexification” should often reduce the magnitude of this problem and “robustify” the process. In a sense, the decentralized algorithm would perform much better than the worst of q -identical (but not communicating) processors, and (in a tracking system, for example) would reduce the chances of any one processor losing track. In applications to optimization or systems evaluation by Monte Carlo simulation one can use “variance reduction”

TABLE 2
 $2 \text{ var}_D / \text{var}_C = \text{var}_D / \text{var}_{2C}$.

c	$2 \text{ var}_D / \text{var}_C$
0.1	1.0028
0.3	1.03
0.5	1.11

ideas in choosing appropriate correlations among the sets $\{\xi_n^i, n = 1, 2, \dots\}$, $i \leq q$. We hope that this, together with the above “robustifying” property, would yield good behavior.

7.4. An example. The following is an example which opens up many new possibilities. Consider two receivers—say, digital phase locked loops—each receiving a signal from the same source, but the two being physically separated. Each must estimate the phase or epoch of the signal pulse (and perhaps the phase of the carrier). Suppose that the source is much farther from the receivers than they are from each other, so that more reliable communication between the receivers is possible. It might be possible to improve each other’s estimates by occasional communications. This communication would transfer the estimates—as well as allow the receivers to improve the mutual synchronization of their clocks or oscillators—so that the transferred estimates could be meaningfully used.

7.5. Communication noise. In examples such as the preceding, one would normally have communication noise. This is readily incorporated into the analysis. Write (1.1) as

$$(7.1) \quad X_{n+1} = A_n(X_n + \tilde{\delta}_n) + \varepsilon B(X_n, \xi_n),$$

where $\tilde{\delta}_n$ represents the communication noise. For the algorithm to be useful at all, this noise should be of an order no larger than ε . Then write $\tilde{\delta}_n = \varepsilon \delta_n$, and proceed as before.

Even if $\tilde{\delta}_n = O(\sqrt{\varepsilon})$ and $E\tilde{\delta}_n = 0$, useful results can be obtained. If the interpolation of

$$\left\{ \sum_{k=0}^n \Phi(n|k) \tilde{\delta}_k \right\}$$

converges weakly to a Wiener process $\tilde{W}(\cdot)$, then we might have $X^\varepsilon(\cdot) \Rightarrow X(\cdot)$:

$$dX = \bar{\Phi} \bar{B}(X) dt + d\tilde{W}.$$

Again $X(\cdot)$ takes the form $(x(\cdot), \dots, x(\cdot))$, under appropriate conditions on $\{\tilde{\delta}_n\}$.

7.6. An alternative algorithm. To get additional insight into the behavior of decentralized algorithms, we formally compare (1.1) with a reasonable alternative. Suppose that the processors communicate and “convexify” only the changes in the states since the last communication. In particular, let $q = 2$ and let $\{\tau_n^i\}$, $i = 1, 2$, denote the communication times of the two processors, with $|\tau_{n+1}^i - \tau_n^i|$ bounded. Here processor 2 communicates to processor 1 at $\{\tau_n^1\}$, and similarly for the reverse communication. We proceed purely formally, and suppose that the dynamics are smooth and bounded. Define $\{\tilde{X}_n^i\}$ by $\tilde{X}_{\tau_k^i}^i = X_{\tau_k^i}^i$ and

$$(7.2) \quad \tilde{X}_{n+1}^i = \tilde{X}_n^i + \varepsilon b^i(\tilde{X}_n^i, \xi_n^i), \quad \tau_k^i \leq n < \tau_{k+1}^i - 1.$$

For $\alpha \varepsilon(0, 1/2]$, set

$$(7.3) \quad \begin{aligned} X_{\tau_{k+1}^1}^1 &= X_{\tau_k^1}^1 + (1 - \alpha) \varepsilon \sum_{\tau_k^1}^{\tau_{k+1}^1 - 1} b^1(\tilde{X}_n^1, \xi_n^1) + \alpha \varepsilon \sum_{\tau_k^1}^{\tau_{k+1}^1 - 1} b^2(\tilde{X}_n^2, \xi_n^2), \\ X_{\tau_{k+1}^2}^2 &= X_{\tau_k^2}^2 + \alpha \varepsilon \sum_{\tau_k^2}^{\tau_{k+1}^2 - 1} b^1(\tilde{X}_n^1, \xi_n^1) + (1 - \alpha) \varepsilon \sum_{\tau_k^2}^{\tau_{k+1}^2 - 1} b^2(\tilde{X}_n^2, \xi_n^2). \end{aligned}$$

Owing to the smoothness and boundedness assumptions, there are $O_n^i(\varepsilon^2) = O(\varepsilon^2)$ and a process $\hat{X}_n = (\hat{X}_n^1, \hat{X}_n^2)$ satisfying (7.4) and which equals (modulo $O(\varepsilon^2)$) $(\hat{X}_n^1, \hat{X}_n^2)$ and $(X_{\tau_k}^1, X_{\tau_k}^2)$ (at the communication times)

$$(7.4) \quad \begin{aligned} \hat{X}_{n+1}^1 &= \hat{X}_n^1 + (1-\alpha)\varepsilon b^1(\hat{X}_n^1, \xi_n^1) + \alpha\varepsilon b^2(\hat{X}_n^2, \xi_n^2) + O_n^1(\varepsilon^2), \\ \hat{X}_{n+1}^2 &= \hat{X}_n^2 + \alpha\varepsilon b^1(\hat{X}_n^1, \xi_n^1) + (1-\alpha)\varepsilon b^2(\hat{X}_n^2, \xi_n^2) + O_n^2(\varepsilon^2). \end{aligned}$$

The “size” of the O_n^i depend on the bound on $|\tau_{k+1}^i - \tau_k^i|$. From this point on, one can use standard theory for the centralized case to get both the ODE and the asymptotic normalized variance. Define $\hat{X}^\varepsilon(\cdot)$ as $X^\varepsilon(\cdot)$ was defined, and similarly for $\hat{U}^\varepsilon(\cdot)$. The limit ODE is

$$(7.5) \quad \dot{\hat{X}} = \frac{(1-\alpha)\bar{b}^1(\hat{X}^1) + \alpha\bar{b}^2(\hat{X}^2)}{\alpha\bar{b}^1(\hat{X}^1) + (1-\alpha)\bar{b}^2(\hat{X}^2)} = \hat{B}(\hat{X}^1, \hat{X}^2).$$

The limit $\hat{U}(\cdot)$ of $\{\hat{U}^\varepsilon(\cdot)\}$ satisfies

$$(7.6) \quad d\hat{U} = \dot{M}\hat{U}dt + d\hat{W},$$

where

$$\begin{aligned} \text{cov } \hat{W}(1) &= \sum_{-\infty}^{\infty} E\bar{\xi}_n\bar{\xi}_0', \\ \bar{\xi}_n &= \begin{bmatrix} (1-\alpha)b^1(\theta, \xi_n^1) + \alpha b^2(\theta, \xi_n^2) \\ \alpha b^1(\theta, \xi_n^1) + (1-\alpha)b^2(\theta, \xi_n^2) \end{bmatrix}, \\ \dot{M} &= (\hat{B}(\theta, \theta))_X, \end{aligned}$$

and we suppose that \dot{M} is a stable matrix.

7.7. Comparison of the alternative (7.2), (7.3) with (1.1). We use the special scalar case of § 7.1, where $\{\xi_n^i\}$ are i.i.d. and $b^1(\cdot, \cdot) = b^2(\cdot, \cdot) = b(\cdot, \cdot)$. Then (again $\bar{b}_x(\theta) < 0$)

$$\begin{aligned} \dot{\hat{X}} &= \begin{bmatrix} (1-\alpha)\bar{b}(\hat{X}^1) + \alpha\bar{b}(\hat{X}^2) \\ \alpha\bar{b}(\hat{X}^1) + (1-\alpha)\bar{b}(\hat{X}^2) \end{bmatrix}, \\ d\hat{U} &= \bar{b}_x(\theta) \begin{bmatrix} (1-\alpha) & \alpha \\ \alpha & (1-\alpha) \end{bmatrix} \hat{U}dt + d\hat{W} = M\hat{U}dt + d\hat{W}, \\ \text{cov } \hat{W}(1) &= E b^2(\theta, \xi_n^i) \begin{bmatrix} (1-\alpha)^2 + \alpha^2 & 2\alpha(1-\alpha) \\ 2\alpha(1-\alpha) & (1-\alpha)^2 + \alpha^2 \end{bmatrix}. \end{aligned}$$

Let var_{D2} denote the stationary variance of $\hat{U}(\cdot)$. As $\alpha \uparrow \frac{1}{2}$, this converges to the infimal value, equal to var_{2C} . But at $\alpha = \frac{1}{2}$, the matrix M is singular. Thus, again, there seems to be a trade-off between the “minimal asymptotic variance” and the length of time one must wait for the asymptotic estimates to be valid or, similarly, for the communication to be effective. At this point, the alternative algorithm does not seem to offer any clear advantages. It was investigated simply because of the idea that there might be an advantage in communicating only recent data.

8. Stochastic approximation with $\varepsilon_n \rightarrow 0$. The entire development can be repeated if ε is replaced by $0 < \varepsilon_n \rightarrow 0$, $\sum \varepsilon_n = \infty$. One then gets results of classical stochastic approximation type, and we only make a few formal comments. We use $X_{n+1} = A_n X_n + \varepsilon_n b(X_n, \xi_n)$. Define $t_n = \sum_{i=0}^{n-1} \varepsilon_i$ and (for $t \geq 0$) define $X^n(\cdot)$ by $X^n(t) = X_{n+i}$ for $t \in [t_{n+i} - t_n, t_{n+i+1} - t_n)$. Under the conditions of Theorem 5.1, $\overline{\lim}_n EV(X_n) < \infty$.

Given either this or the use of the projection algorithm of § 4, one can get the appropriate ODE which characterizes the limit paths. If this has the appropriate stability properties (as in § 5), we can show that $X^{\varepsilon,i}(\cdot) \Rightarrow x(\cdot) \equiv \theta$. The ODE is the same as that in the previous sections, for all the same cases.

If $\sum \varepsilon_n^2 < \infty$, then the idea in [10] can be adapted to get w.p.1 convergence results.

Appendix A. Some results in weak convergence. For some integer s , let $D[0, \infty)$ denote the space of E^s -valued functions on $[0, \infty)$ which are right continuous and have left-hand limits, with the Skorokhod topology [7, Chap. 2]. This topology is defined as follows. Let A be the set of strictly increasing Lipschitz continuous functions from $[0, \infty)$ onto $[0, \infty)$. Define the metric

$$d(x(\cdot), y(\cdot)) = \inf_{\lambda \in A} \max \left\{ \sup_{s > t \geq 0} \left| \log \left(\frac{\lambda(s) - \lambda(t)}{s - t} \right) \right|, \int_0^\infty e^{-\tau} d_\tau(x(\cdot), y(\cdot), \lambda) d\tau \right\}$$

where $d_\tau(x(\cdot), y(\cdot), \lambda) = \min(1, \sup_t |x(\lambda(t) \cap \tau) - y(t \cap \tau)|)$.

Define $\{Z_n^\varepsilon\}$ and $\{Z^\varepsilon(\cdot)\}$ by $Z_{n+1}^\varepsilon = Z_n^\varepsilon + \varepsilon F_n^\varepsilon$, $Z^\varepsilon(t) = Z_n^\varepsilon$ for $t \in [n\varepsilon, (n+1)\varepsilon)$. If $\{Z_0^\varepsilon\}$ is tight and the $\{F_n^\varepsilon\}$ are uniformly integrable, then $\{Z^\varepsilon(\cdot)\}$ is tight in $D[0, \infty)$ and all weak limits are absolutely continuous.

Let $Z^\varepsilon(\cdot) \Rightarrow Z(\cdot)$ in $D[0, \infty)$. By a suitable choice of the probability space, the weak convergence becomes convergence w.p.1 in the metric of $D[0, \infty)$ [13, Thm. 3.1.1]. That is, there is a probability space $(\tilde{\Omega}, \tilde{B}, \tilde{P})$ with processes $\{\tilde{Z}^\varepsilon(\cdot)\}$, $\tilde{Z}(\cdot)$ defined on it so that for each Borel set B in $D[0, \infty)$, $\tilde{P}\{\tilde{Z}^\varepsilon(\cdot) \in B\} = P\{Z^\varepsilon(\cdot) \in B\}$, $\tilde{P}\{\tilde{Z}(\cdot) \in B\} = P\{Z(\cdot) \in B\}$ and $\tilde{Z}^\varepsilon(\cdot) \rightarrow \tilde{Z}(\cdot)$ w.p.1 in the topology of $D[0, \infty)$. The use of this representation often facilitates the analysis and characterization of the limits.

Appendix B. Proof of Lemma 2.1. The proofs of (2.1a) and (2.1b) are essentially the same and only (2.1a) will be proved. We will evaluate $E|\Phi(n|k) - \Phi_k|$ by a slight variation of the proof of [1, Lemma 5.2.1]. Owing to the block diagonal structure of the A_n , when we calculate the product $\Phi(n|k)$, the r sets of rows $(i, i+r, \dots, i+qr-r)$, $i \leq r$, do not interact and we can (and will) let $r=1$ without loss of generality.

The geometric convergence of $\Phi(n|k)$ to Φ_k was proved in [1, Lemma 5.2.1] when $p_0=1$ (see (A2.4) below). By (C2.1), there are $\alpha_1 > 0$ and an increasing sequence of (finite w.p.1) random times $\{N_i\}$ such that the components of $\Phi(N_{2i+1}|N_{2i})$ are all $\geq \alpha_1$ w.p.1. This and the convergence result for $p_0=1$ imply that $\Phi(n|k)$ converges w.p.1 to some matrix Φ_k as $n \rightarrow \infty$. All the rows of such a limit must be equal, and the entries of each row must sum to unity. Let $\phi_1(k), \dots, \phi_q(k)$ denote the scalar elements of any row of Φ_k , and let the vectors v_1, \dots, v_q span E^q , and define $e = (1, 1, \dots, 1)$. Define $c(x) = \sum \phi_i(k)x_i$ where $x = (x_1, \dots, x_q)$. Both e and x are column vectors. Then $\Phi_k x = c(x)e$. All norms here and elsewhere are in the l_∞ sense.

For a matrix M ,

$$(A2.1) \quad |M| = \sup_{|x|=1} |Mx| \leq \sum |Mv_i|.$$

Thus, we need only show, for any vector x , that $E|\Phi(n|k)x - c(x)e| \xrightarrow{n} 0$ geometrically. Define $x(n|k) = \Phi(n|k)x$. Let $c(n|k)$ denote the minimum value of the components of $x(n|k)$. We can write $x(n|k) = y(n|k) + c(n|k)e$, where all the components of $y(n|k)$ are nonnegative and

$$(A2.2) \quad E|\Phi(n|k)x - c(x)e| \leq E|y(n|k)| + E|c(x) - c(n|k)|.$$

By the "convexification" properties of the A_n ,

$$(A2.3a) \quad |y(n+1|k)| \leq |y(n|k)|,$$

$$(A2.3b) \quad c(n|k) \leq c(n+1|k) \leq c(n|k) + |y(n|k)|.$$

By (C2.1), there is an $\alpha_0 > 0$ such that w.p. p_0 (conditioned on F_n) all the elements of $\Phi(n + m_0|n)$ are $\geq \alpha_0$. This, together with the "convexification" property of the A_n implies that

$$(A2.4) \quad E|y(n + m_0|k)| \leq (1 - \alpha_0 p_0) E|y(n|k)|.$$

(If $p_0 = 1$, then drop the E in (A2.4), and (A2.3), (A2.4) yield w.p.1 convergence.) The asserted geometric convergence is a consequence of (A2.3), (A2.4) and the w.p.1 convergence of $\Phi(n|k)$ (hence of $c(n|k)$ to $c(x)$). The last sentence of the lemma follows by a similar argument. Q.E.D.

THE RELATIONSHIP BETWEEN THE MAXIMUM PRINCIPLE AND DYNAMIC PROGRAMMING*

FRANK H. CLARKE† AND RICHARD B. VINTER‡

Abstract. Let $V(t, x)$ be the infimum cost of an optimal control problem, viewed as a function of the initial time and state (t, x) . Dynamic Programming is concerned with the properties of $V(\cdot, \cdot)$ and in particular with its characterization as a solution to the Hamilton–Jacobi–Bellman equation. Heuristic arguments have long been advanced relating the Maximum Principle to Dynamic Programming according to

$$p(t) = -V_x(t, x_0(t)).$$

Here $x_0(\cdot)$ is the minimizing state function under consideration and $p(\cdot)$ is the costate function of the Maximum Principle. In this paper we examine the validity of such claims and find that this relationship, interpreted as a differential inclusion involving the generalized gradient, is indeed true, almost everywhere and at the endpoints, for a very large class of nonsmooth optimal control problems.

Key words. optimal control, Maximum Principle, Dynamic Programming

AMS(MOS) subject classifications. 49B10, 49C05

1. Introduction. Our purpose in this paper is to relate the costate function which appears in the Maximum Principle and the value function associated with perturbations in the initial time and state, and thereby to clarify the relationship between the Maximum Principle and Dynamic Programming. For the most part our framework is that of the following free final state optimal control problem:

$$\begin{aligned} & \text{Minimize} && \int_0^1 L(t, x(t), u(t)) dt + h(x(1)) \\ (1.1) \quad & \text{subject to} && \dot{x}(t) = f(t, x(t), u(t)) \quad \text{a.e. } t \in [0, 1], \\ & && x(0) = x_0, \\ (1.2) \quad & && u(t) \in U_t \quad \text{a.e. } t \in [0, 1], \\ (1.3) \quad & && x(t) \in \Omega_t \quad \text{all } t \in [0, 1]. \end{aligned}$$

The data for the problem are the following: functions $f: [0, 1] \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$, $L: [0, 1] \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$, $h: \mathbb{R}^n \rightarrow \mathbb{R}$, a vector $x_0 \in \mathbb{R}^n$, and sets

$$U \in [0, 1] \times \mathbb{R}^m, \quad \Omega \in [0, 1] \times \mathbb{R}^n.$$

(For any set $A \subset [0, 1] \times \mathbb{R}^m$ and point $t \in [0, 1]$ we denote by A_t the set $\{x: (t, x) \in A\}$.)

Given a subinterval $I \subset [0, 1]$, a *control function* (on I) is a (Lebesgue) measurable function $u(\cdot): I \rightarrow \mathbb{R}^m$ which satisfies (1.2) (when I replaces $[0, 1]$).

A *process* (on I) is a pair of functions $(x(\cdot), u(\cdot))$ on I of which $u(\cdot)$ is a control function and $x(\cdot): I \rightarrow \mathbb{R}^n$ is an absolutely continuous function which satisfies the differential equation (1.1) and the constraint (1.3) (when I replaces the interval $[0, 1]$), and for which $s \mapsto L(s, x(s), u(s))$ is integrable. If $x(\cdot)$ is the first component of some process, $x(\cdot)$ is called a *state function*. A process $(x(\cdot), u(\cdot))$ on $[0, 1]$ is *admissible* if $x(0) = x_0$. The process is *minimizing* if it minimizes the value of the cost function $\int L dt + h$ over all admissible processes.

A tube T is a subset of Ω of the form

$$\{(t, x): \|x - z(t)\| < \delta\}$$

for some $\delta > 0$ and some continuous function $z(\cdot)$. We also refer to this set as the δ -tube about $z(\cdot)$. We loosely refer to "state functions in a tube T about $z(\cdot)$ " when we have in mind state functions having graphs in a tube about $z(\cdot)$.

Let $(x_0(\cdot), u_0(\cdot))$ be a minimizing process contained in some tube.

Under certain conditions (the precise nature of which is unimportant at this juncture) the Maximum Principle asserts: there exists a costate function $p(\cdot): [0, 1] \rightarrow \mathbb{R}^n$ such that

$$(1.4) \quad -\dot{p}(t) = p(t) \cdot f_x(t, x_0(t), u_0(t)) - L_x(t, x_0(t), u_0(t)) \quad \text{a.e. } t \in [0, 1],$$

$$(1.5) \quad -p(1) = h_x(x_0(1))$$

and, a.e. $t \in [0, 1]$,

$$(1.6) \quad p(t) \cdot f(t, x_0(t), u_0(t)) - L(t, x_0(t), u_0(t)) = \max_{u \in U_t} \{p(t) \cdot f(t, x(t), u) - L(t, x_0(t), u)\}.$$

Now define the value function $V(\cdot, \cdot): [0, 1] \times \mathbb{R}^n \rightarrow \bar{\mathbb{R}}$ to be

$$(1.7) \quad V(t, x) = \inf \left\{ \int_t^1 L(s, x(s), u(s)) ds + h(x(1)) \right\}.$$

Here the infimum is taken over processes $(x(\cdot), u(\cdot))$ on $[t, 1]$ for which $x(t) = x$. When no such processes exist the value is $+\infty$.

If $V(\cdot, \cdot)$ happens to be continuously differentiable on the interior of some tube T about $x_0(\cdot)$ we find under mild assumptions that $V(\cdot, \cdot)$ satisfies the Hamilton-Jacobi-Bellman equation there:

$$(1.8) \quad V_t(t, x) + \min_{u \in U_t} \{V_x(t, x) \cdot f(t, x, u) + L(t, x, u)\} = 0, \quad (t, x) \in T.$$

Also

$$(1.9) \quad V(1, x) = h(x), \quad x \in \Omega_1,$$

and

$$(1.10) \quad (V_t + V_x \cdot f + L)(t, x_0(t), u_0(t)) = 0 \quad \text{a.e. } t \in [0, 1].$$

Solving (1.8) and (1.9) for $V(\cdot, \cdot)$ is the basis of the Dynamic Programming approach in Optimal Control Theory. In introductory treatments of optimal control theory the connection between the Maximum Principle and Dynamic Programming is usually described in the following terms (here we quote from [4, pp. 297ff.]): "the adjoint (i.e., costate) variables \cdots equal the negative of the rate of change of the performance index with respect to the corresponding state variables." This simply means

$$(1.11) \quad -\dot{p}(t) = V_x(t, x_0(t)).$$

See also [3] and [10].

The grounds for this assertion are as follows: (1.8) and (1.10) imply the following for each $t \in [0, 1]$ and x in a neighborhood of $x_0(t)$:

$$(1.12) \quad (V_t + V_x f + L)(t, x_0(t), u_0(t)) \leq (V_t + V_x f + L)(t, x, u_0(t)),$$

and for each $t \in [0, 1]$ and $u \in U_t$

$$(1.13) \quad (V_x f + L)(t, x_0(t), u_0(t)) \leq (V_x f + L)(t, x_0(t), u).$$

Now write

$$-q(t) = V_x(t, x_0(t)).$$

Then (1.13) amounts to the "maximization of the Hamiltonian condition" (1.6) (when $p(\cdot)$ replaces $q(\cdot)$). If for each t the right-hand side of (1.12) is a continuously differentiable function of x , we deduce from this inequality that

$$\frac{\partial}{\partial x} [V_t(t, x) + V_x(t, x)f(t, u_0(t), x) + L(t, x, u_0(t))] \Big|_{x=x_0(t)} = 0.$$

If we also assume $V(\cdot, \cdot)$ is twice continuously differentiable, and $f(\cdot, \cdot, \cdot)$ and $L(\cdot, \cdot, \cdot)$ are continuously differentiable in x , then we obtain

$$(V_{tx} + V_{xx}f + V_x f_x + L_x)(t, x_0(t), u_0(t)) = 0.$$

But

$$\frac{d}{dt} V_x(t, x_0(t)) = (V_{tx} + V_{xx}f)(t, x_0(t), u_0(t))$$

whence $q(t)$ ($= -V_x(t, x_0(t))$) satisfies the costate differential equation (1.4) for $p(\cdot)$. Finally (1.9) implies

$$-q(1) = V_x(1, x(1)) = h_x(x_0(1)),$$

which is the transversality condition (1.5).

The relationship between the Maximum Principle and Dynamic Programming would appear then to have been explained. But such impressions are illusory. Indeed it is difficult to justify our heuristic arguments in a setting of any generality. They are based on (among other things) the assumption that $V(\cdot, \cdot)$ is smooth and, to quote Pontryagin et al. [12, p. 7], "It must be noted that the assumption on the continuous differentiability of the functional does not hold in the simplest cases." The point is also emphasized by Berkovitz [2] and Fleming and Rischel [9].

This leads to our central preoccupation in this paper: the extent to which the relationship (1.11) bridging the Maximum Principle and the Dynamic Programming technique is valid, under more or less the weakest hypotheses evoked in proof of the Maximum Principle.

While it is not reasonable to assume continuous differentiability of $V(\cdot, \cdot)$, we can expect $V(t, \cdot)$ to be Lipschitz continuous for each $t \in [0, 1]$. In the circumstances it is natural to replace (1.11) by the inclusion

$$(1.14) \quad -p(t) \in \partial_x V(t, x_0(t))$$

where $\partial_x V$ denotes the partial generalized gradient.

Our main result is that, for a very large class of nonsmooth free endpoint problems, we can choose a costate function $p(\cdot)$ which satisfies the inclusion (1.14) for $t = 0$ and 1, and on a subset of $(0, 1)$ of full measure. We are able to show also that the inclusion (1.14) is still valid for some costate function when a terminal constraint of the form " $x(1) \in C_1$ " is present, provided some verification function is substituted for $V(\cdot, \cdot)$. Here we take advantage of recent advances in our understanding of verification functions [6] that permit us to replace the terminally constrained problem by an equivalent free endpoint problem involving a nonsmooth penalty term and thereby to reduce the problem to one we already know how to deal with.

We conclude this introduction by describing the basic idea behind our methods. For any measurable function $\alpha(\cdot): [0, 1] \rightarrow \{\xi: \|\xi\| < 1\}$ and control function $u(\cdot)$ on $[0, 1]$, let $x(\cdot)$ be a solution to

$$(1.15) \quad \dot{x}(t) = f(t, x(t), u(t)) + \alpha(t) \quad \text{a.e. } t \in [0, 1].$$

If (1.8) were valid we could write

$$(V_t + V_x \cdot (f + \alpha) - V_x \alpha)|_{(t, x(t), \alpha = \alpha(t))} + L(t, x(t), u(t)) \geq 0$$

for all $t \in [0, 1]$. Integrating over $[0, 1]$ we obtain

$$\int_0^1 \frac{d}{dt} V(t, x(t)) dt - \int_0^1 V_x(t, x(t)) \alpha(t) dt + \int_0^1 L(t, x(t), u(t)) dt \geq 0,$$

i.e.,

$$(1.16) \quad \int_0^1 L(t, x(t), u(t)) dt + h(x(1)) - V(0, x(0)) - \int_0^1 V_x(t, x(t)) \alpha(t) dt \geq 0.$$

We now treat the left-hand side of (1.16) as a cost function for an auxiliary optimal control problem with dynamics (1.15), where $\alpha(\cdot)$ is treated as an additional control variable and where the initial and terminal values of the state function are unconstrained. Since

$$\int_0^1 L(t, x_0(t), u_0(t)) dt + h(x_0(1)) - V(0, x_0(0)) = 0$$

by definition of the value function, it follows from (1.16) that $(x_0(\cdot), (u_0(\cdot), \alpha(\cdot) \equiv 0))$ is a solution to the auxiliary optimal control problem. Now apply the Maximum Principle to the auxiliary problem at $(x_0(\cdot), (u_0(\cdot), \alpha(\cdot) \equiv 0))$. This leads to the conclusion that there is an absolutely continuous function $p(\cdot): [0, 1] \rightarrow \mathbb{R}^n$ satisfying the usual conditions in the Maximum Principle for the original problem (i.e., $p(\cdot)$ is a costate function). But the presence of the terms involving $V(\cdot, \cdot)$ in the cost and the $\alpha(\cdot)$ control in the dynamics implies in addition

$$-p(t) = V_x(t, x_0(t)) \quad \text{a.e. } t \in [0, 1]$$

(we get this from the maximization of the Hamiltonian condition), and

$$-p(0) = V_x(0, x_0)$$

(from the transversality condition). These are the desired relations.

Of course we are not, in general, justified in using (1.8) because we cannot expect $V(\cdot, \cdot)$ to be continuously differentiable. However, a kind of nonsmooth version of the inequality (1.16) can be proved. This provides an auxiliary problem. Applying the Maximum Principle to that problem gives a costate function with the hoped-for properties. Derivation of the nonsmooth inequality involves consideration of state functions, in some extended sense, which are discontinuous, and some rather delicate approximations.

Earlier work is available on the connection between Dynamic Programming and the Maximum Principle, in the absence of restrictive hypotheses. This takes the form of necessary conditions expressed in terms of generalized gradients of the value function. It is established in [14] that the pseudo-Hamiltonian function evaluated along

some selector of $t \rightarrow \partial_x V(t, x_0(t))$ is maximized at the optimal control. See also [11] for a result of this nature. Showing that we can also arrange for the selector to satisfy the costate differential inclusion in a general nonsmooth setting, and thereby express the full Maximum Principle in terms of the value function, is a more formidable task. This is accomplished for the first time in the present paper. Expanded versions of some of the proofs involved are available in [7].

2. Hypotheses. Throughout the paper $(x_0(\cdot), u_0(\cdot))$ is taken to be a fixed minimizing process for the optimal control problem. Define \tilde{f} :

$$\tilde{f} = \begin{bmatrix} L \\ f \end{bmatrix}.$$

The following hypotheses remain always in force:

- (H1) $(t, u) \rightarrow \tilde{f}(t, x, u)$ is $\mathcal{L} \times \mathcal{B}^m$ measurable for each fixed $x \in \mathbb{R}^n$, where $\mathcal{L} \times \mathcal{B}^m$ denotes the σ -algebra, generated by product sets whose first element is a Lebesgue subset of $[0, 1]$ and whose second is a Borel set in \mathbb{R}^m .
- (H2) U is a Borel measurable set.
- (H3) For each $t \in [0, 1]$ and $u \in U_t$, $\tilde{f}(t, \cdot, u)$ is Lipschitz continuous on Ω_t , with rank at most $k(t)$ ($k(t)$ does not depend on u), and $k(\cdot) \in L^1(0, 1)$.
- (H4) There exists a function $c(\cdot) \in L^1(0, 1)$ such that

$$\|\tilde{f}(t, x_0(t), u)\| \leq c(t) \quad \text{for all } u \in U_t, t \in [0, 1].$$

- (H5) $h(\cdot)$ is a locally Lipschitz continuous function.

As before (see (1.7)), we take the value function $V(\cdot, \cdot): \Omega \rightarrow \bar{\mathbb{R}}$ to be

$$V(t, x) = \inf \left\{ \int_t^1 L(s, x(s), u(s)) ds + h(x(1)) \right\}$$

where the infimum is taken over processes on $[t, 1]$ which satisfy $x(t) = x$, and once again we set the value to $+\infty$ when no such processes exist.

Concerning $V(\cdot, \cdot)$ we impose the following.

- (H6) There exists a tube Ω' about $x_0(\cdot)$, $\Omega' \subset \Omega$, and a constant r such that for each $t \in [0, 1]$, $V(\cdot, t)$ is Lipschitz continuous on Ω_t with rank at most r .

Hypothesis (H6) on the value function is very mild. In fact it is almost superfluous, since one is most often interested in examples of the optimal control problem in which $\Omega = [0, 1] \times \mathbb{R}^n$; for such examples (H6) is implied by the other hypotheses. See [7], where this and some other properties of the value function are proved.

3. The main result. Define the pseudo-Hamiltonian function $H(\cdot, \cdot, \cdot, \cdot)$:

$$H(t, x, p, u) = p \cdot f(t, x, u) - L(t, x, u).$$

THEOREM 3.1. *There exists an absolutely continuous function $p(\cdot): [0, 1] \rightarrow \mathbb{R}^n$ and a subset $\Sigma \subset [0, 1]$ of full Lebesgue measure such that*

$$(3.1) \quad -\dot{p}(t) \in \partial_x H(t, x_0(t), p(t), u_0(t)) \quad \text{a.e. } t \in [0, 1],$$

$$(3.2) \quad H(t, x_0(t), p(t), u_0(t)) = \max_{u \in U_t} H(t, x_0(t), p(t), u) \quad \text{a.e. } t \in [0, 1]$$

and

$$(3.3) \quad -p(t) \in \partial_x V(t, x_0(t)) \quad \text{for all } t \in \{0\} \cup \{1\} \cup \Sigma.$$

Here $\partial_x(\cdot)$ denotes the partial generalized gradient in the x -variable [5, p. 63], i.e.,

$$\partial_x V(t, x) = \text{co} \{ \lim V_x(t, x_i) : x_i \rightarrow x, V(t, \cdot) \text{ is differentiable at } x_i, i = 1, 2, \dots \}.$$

Notice that the theorem incorporates the Maximum Principle since the new condition on the costate function (3.3) implies the transversality condition

$$-p(1) \in \partial_x h(x_0(1)),$$

the only component of the Maximum Principle not explicitly present. This follows from the fact that $V(1, \cdot) = h(\cdot)$.

4. An example. For nonsmooth problems it is possible that, associated with the minimizing process $(x_0(\cdot), u_0(\cdot))$, there are many possible costate functions. (The set of costate functions comprises all absolutely continuous functions $p(\cdot)$ which satisfy the costate equation (3.1), have the "maximization of the Hamiltonian" property, and for which $-p(1) \in \partial_x h(x_0(1))$.)

One might speculate that any costate function $p(\cdot)$ satisfies the inclusion

$$-p(t) \in \partial_x V(t, x_0(t))$$

(almost everywhere and at the endpoints). The purpose of the following example is to illustrate that this is not the case.

$$\begin{aligned} &\text{Minimize} && g(x(1)) \\ &\text{subject to} && \dot{x}(t) = x(t)u(t) \quad \text{a.e. } t \in [0, 1], \\ &&& x(0) = 0, \\ &&& u(t) \in [0, 1] \quad \text{a.e. } t \in [0, 1], \\ &&& x(t) \in \mathbb{R}, \quad \text{all } t \in [0, 1]. \end{aligned}$$

Here

$$g(x) = \begin{cases} -x & \text{if } x > 0, \\ -e^{1/2}x & \text{if } x \leq 0. \end{cases}$$

A minimizing process is $\{x_0(\cdot) \equiv 0, u_0(\cdot) \equiv 0\}$. Indeed $x(\cdot) \equiv 0$ is the only possible state function. In order to evaluate $V(t, x)$, $(t, x) \in [0, 1] \times \mathbb{R}^n$, we must look at the associated control problem with initial time t and initial state x . The terminal cost function is monotonic decreasing, so it is minimized by making $x(1)$ as large as possible. We achieve this by selecting $u(\cdot) \equiv 1$ if $x > 0$ and $u(\cdot) \equiv 0$ if $x \leq 0$. We can now calculate $V(t, x)$:

$$V(t, x) = \begin{cases} -e^{(1-t)}x & \text{if } x > 0, \\ -e^{1/2}x & \text{if } x \leq 0. \end{cases}$$

The information supplied by the Maximum Principle concerning the minimizing process $(x_0(\cdot), u_0(\cdot))$ is: there exists $p(\cdot) : [0, 1] \rightarrow \mathbb{R}$ satisfying

$$-\dot{p}(t) = u_0(t) \quad \text{a.e. } t \in [0, 1]$$

such that

$$p(t)x_0(t)u_0(t) = \max_{u \in [0, 1]} p(t)x_0(t)u \quad \text{a.e. } t \in [0, 1],$$

and because the generalized gradient of $g(\cdot)$ at $x_0(1)$ is

$$\partial_x g(x_0(1)) = [-e^{1/2}, -1],$$

it follows that

$$-p(1) \in [-e^{1/2}, -1].$$

But $x_0(\cdot) \equiv 0$, $u_0(\cdot) \equiv 0$. A costate function then is a function $p(\cdot)$ satisfying

$$p(\cdot) \equiv \lambda, \quad \lambda \in [-e^{1/2}, -1].$$

Notice that we can arrange that

$$-p(t) \in \partial_x V(t, x_0(t)), \quad \text{all } t \in [0, 1]$$

by choosing $\lambda = -e^{1/2}$. But this inclusion fails (on a set of positive measure) if any other value of λ is adopted.

In this example then there are uncountably many costate functions, but only one of them satisfies the inclusion.

5. Some special cases. The assertions of Theorem 3.1 do not exclude the possibility that $-p(t) \notin \partial_x V(t, x_0(t))$ for all t 's in some null set in $(0, 1)$. This is probably unavoidable under the hypotheses considered. However, the question arises whether this null set can be eliminated in special circumstances. We seek then additional hypotheses under which (3.3) can be strengthened to

$$(5.1) \quad -p(t) \in \partial_x V(t, x_0(t)) \quad \text{for all } t \in [0, 1].$$

One direction in which we can proceed is to introduce regularity hypotheses on the multifunction $t \rightarrow \partial_x V(t, x_0(t))$.

PROPOSITION 5.1. *Suppose that the multifunction $t \rightarrow \partial_x V(t, x_0(t))$ is upper semicontinuous on $[0, 1]$. Then condition (3.3) can be strengthened to (5.1).*

Proof. Take any $t \in [0, 1]$. Let $\{t_i\}$ be a sequence such that $t_i \rightarrow t$ as $i \rightarrow \infty$ and $p(t_i) \in \partial_x V(t_i, x_0(t_i))$ for $i = 1, 2, \dots$. Since $p(t_i) \rightarrow p(t)$ and $t_i \rightarrow t$, as $i \rightarrow \infty$, it follows from upper semicontinuity that $p(t) \in \partial_x V(t, x_0(t))$. \square

COROLLARY 5.2. *Suppose that for every $t \in [0, 1]$ $V(t, \cdot)$ is convex, condition (3.3) can be strengthened to (5.1).*

In the proof of this corollary, and subsequently in this paper, we adopt the notation: B^k is the open unit ball, centre the origin, in \mathbb{R}^k . When there is no need to emphasize the dimension of the vector space concerned, we write B^k briefly as B .

Proof. Under the hypotheses $V(\cdot, \cdot)$ is continuous on some tube T about $x_0(\cdot)$ (see [7]). Take any $t \in (0, 1)$, $p \in \mathbb{R}^n$ and sequences $\{t_i\}$, $\{p_i\}$ such that $t_i \rightarrow t$ and $p_i \rightarrow p$, and suppose that $p_i \in \partial_x V(t_i, x_0(t_i))$. In view of Proposition 5.1 it suffices to show that

$$(5.2) \quad p \in \partial_x V(t, x_0(t)).$$

Let $\delta > 0$ be such that $(t, x_0(t)) + \delta B^{n+1} \subset T$. Choose any $\xi \in \frac{1}{2} \delta B^n$. Since $V(t_i, \cdot)$ is convex,

$$V(t_i, \xi + x_0(t_i)) - V(t_i, x_0(t_i)) \geq p_i \cdot \xi.$$

For i sufficiently large, $(t_i, \xi + x_0(t_i))$ and $(t_i, x_0(t_i))$ both lie in T . By continuity we can pass to the limit:

$$V(t, \xi + x_0(t)) - V(t, x_0(t)) \geq p \cdot \xi.$$

This inequality holds for all $\xi \in \frac{1}{2} \delta B^n$. Since $V(t, \cdot)$ is convex the inequality extends however to all of \mathbb{R}^n . We have shown (5.2). \square

There is at least one important case when the hypotheses of Corollary 5.2 are satisfied, as we shall see later in the section.

Our next special case concerns control problems with smooth data. Our results here involve the concept of strict differentiability: a function $\psi(\cdot): \mathbb{R}^k \rightarrow \mathbb{R}^l$ admits a strict derivative at $x \in \mathbb{R}^k$, an $l \times k$ matrix denoted by $D_s\psi(x)$, if, for all $v \in \mathbb{R}^k$,

$$\lim_{\substack{x' \rightarrow x \\ \lambda \downarrow 0}} \frac{F(x' + \lambda v) - F(x')}{\lambda} = D_s\psi(x) \cdot v.$$

An important property of a function $\psi(\cdot)$ which is strictly differentiable at a point x is that the function is Lipschitz continuous in a neighborhood of x , and

$$\partial\psi(x) = \{D_s\psi(x)\}$$

where $\partial\psi(x)$ refers to the generalized Jacobian

$$\partial\psi(x) = \text{co} \{ \lim \psi_x(x_i): x_i \rightarrow x, \psi(\cdot) \text{ is differentiable at } x_i, i = 1, 2, \dots \}.$$

This follows from [5, Props. 2.2.1, 2.6.2(e)].

PROPOSITION 5.3. *Suppose that for almost every $t \in [0, 1]$ the functions*

$$x \rightarrow f(t, x, u_0(t)) \quad \text{and} \quad x \rightarrow L(t, x, u_0(t))$$

are strictly differentiable at $x_0(t)$. Suppose

$$(5.3) \quad x \rightarrow h(x) \text{ is strictly differentiable at } x_0(1).$$

Then condition (3.3) can be strengthened to (5.1).

Proof. Let $\delta > 0$ be such that $V(t, \cdot)$ is Lipschitz continuous on $x(t) + \delta B$ for all $t \in [0, 1]$. For any $t \in [0, 1]$ consider the auxiliary control problem (P_t) :

$$\text{Minimize } \int_t^1 L(t, x(t), u(t)) dt + h(x(1)) - V(t, x(t)) \text{ over processes}$$

$$(x(\cdot), u(\cdot)) \text{ on } [t, 1].$$

By definition of $V(\cdot, \cdot)$ and the principle of optimality, a minimizing process for (P_t) is $(x_0(\cdot), u_0(\cdot))$ restricted to $[t, 1]$. The maximum principle [5, Thm. 5.2.1] tells us: there exists $p'(\cdot): [t, 1] \rightarrow \mathbb{R}^n$ such that

$$-p'(s) = D_s H(t, x_0(s), p'(s), u_0(s)) \quad \text{a.e. } s \in [t, 1],$$

$$H(t, x_0(s), p'(s), u_0(s)) = \max_{u \in U_s} H(t, x_0(s), p'(s), u) \quad \text{a.e. } s \in [t, 1],$$

$$-p'(1) = D_s h(x(1)),$$

$$(5.4) \quad -p'(t) \in \partial_x V(t, x_0(t)).$$

($D_s(\cdot)$ denotes the strict derivative in the x -variable. Note that H is strictly differentiable in x since f and L are.) Now define $p(\cdot) := p^0(\cdot)$. Choose any $t \in [0, 1]$; then $p'(\cdot)$ and $p(\cdot)$ must coincide on $[t, 1]$ (and in particular at t) since they are both solutions there to the differential equation in $q(\cdot)$

$$-\dot{q}(s) = q(s) \cdot D_s f(s, x_0(s), u_0(s)) - D_s L(s, x_0(s), u_0(s))$$

with initial condition

$$-q(1) = D_s h(x(1))$$

and this differential equation has a unique solution. But now (5.1) follows from (5.4). \square

This covers the smooth case, since continuous differentiability implies strict differentiability. The proof of Proposition 5.3 is very much more straightforward than

that available for Theorem 3.1, and readers with interests only in smooth problems might be tempted to think that Proposition 5.3 and its proof were adequate for their purposes, although of course the nonsmoothness of V persists. This however, is not necessarily the case since, when we try to prove analogous results to (5.1) in the presence of a terminal constraint

$$(5.5) \quad x(1) \in C_1$$

(see § 6), we need to apply Theorem 3.1 to an auxiliary problem with a penalty term to accommodate the constraint (5.5). This penalty term must, in general, be non-differentiable and so, even if the data are smooth, the uniqueness argument above does not automatically provide an easy way to obtain the desired inclusions. We mention that the uniqueness argument in the proof of Proposition 5.3 has previously been used by Barbu [1, p. 209] to relate the costate function and the value function for certain optimal control problems involving distributed parameter systems.

We can slightly weaken hypothesis (5.3) in Proposition 5.3 to admit some degree of nonsmoothness.

PROPOSITION 5.4. *The conclusions of Proposition 5.3 remain valid if hypothesis (5.3) is replaced by either*

(a) *$h(\cdot)$ is expressible as a sum of functions*

$$h(\cdot) = h_1(\cdot) + h_2(\cdot),$$

in which $h_1(\cdot)$ is strictly differentiable at $x_0(1)$ and $h_2(\cdot)$ is concave at $x_0(1)$, or

(b) *$V(0, \cdot)$ is expressible as a sum of functions*

$$V(0, \cdot) = v_1(\cdot) + v_2(\cdot),$$

in which $v_1(\cdot)$ is strictly differentiable at x_0 and $v_2(\cdot)$ is convex at x_0 .

Proof. We prove just (b); (a) is proved in a similar way. Let $(x(\cdot), u(\cdot))$ be any admissible process on $[0, t]$. By Lemma 8.3 below

$$\int_0^t L(s, x(s), u(s)) ds + V(t, x(t)) - V(0, x(0)) \geq 0.$$

By assumption $V(0, \cdot) = v_1(\cdot) + v_2(\cdot)$, in which $v_1(\cdot)$ is strictly differentiable at x_0 and $v_2(\cdot)$ is convex. Select any $g \in \partial v_2(x_0)$. Then

$$\int_0^t L(s, x(s), u(s)) ds + V(t, x(t)) - v_1(x_0) - g \cdot (x(0) - x_0) - v_2(x_0) \geq 0.$$

However, by the principle of optimality,

$$\int_0^t L(s, x_0(s), u_0(s)) ds + V(t, x_0(t)) - v_1(x_0) - v_2(x_0) = 0.$$

It follows that, for any $t \in [0, 1]$, $(x_0(\cdot), u_0(\cdot))$ restricted to $[0, t]$ is minimizing for the control problem

$$\begin{aligned} &\text{Minimize } \int_0^t L ds + V(t, x(t)) - v_1(x(0)) - g \cdot (x(0) - x_0) \text{ over control processes} \\ &(x(\cdot), u(\cdot)) \text{ on } [0, t]. \end{aligned}$$

We now invoke the Maximum Principle for each $t \in [0, 1]$. There results a costate $p'(\cdot)$ with the usual properties, notably

$$(5.6) \quad -p'(t) \in \partial_x V(t, x_0(t)),$$

and

$$-p'(0)(= -D_s v_1(x_0) + g) \in \partial_x V(0, x_0).$$

Let $p(\cdot) := p^1(\cdot)$. Then since for each $t \in [0, 1]$, $p'(\cdot)$ and $p^1(\cdot)$ are both solutions to

$$-\dot{q}(s) = q(s) \cdot D_s f(s, x_0(s), u_0(s)) - D_s L(s, x_0(s), u_0(s)),$$

$$q(0) = -D_s v_1(x_0) - g,$$

and this equation has only one solution, (5.6) implies (5.1). \square

There is one case, of some importance, when additional hypothesis (b) of Proposition 5.4 is directly verifiable. This is the case of optimal control problems involving linear dynamics and a convex terminal cost function.

PROPOSITION 5.5. *Assume that $\Omega = [0, 1] \times \mathbb{R}^n$, $h(\cdot)$ is convex and that*

$$\begin{bmatrix} L \\ f \end{bmatrix}(t, x, u) = \begin{bmatrix} a(t)x + b(t)u \\ A(t)x + B(t)u \end{bmatrix}$$

for integrable vector and matrix valued functions $a(\cdot)$, $b(\cdot)$, $A(\cdot)$ and $B(\cdot)$. Suppose also that

$$U_t \text{ is compact a.e. } t \in [0, 1],$$

and

$$\operatorname{ess\,sup}_{t \in [0, 1]} \|U_t\| < \infty.$$

Then condition (3.3) can be strengthened to (5.1).

Proof. In view of Proposition 5.4 it suffices to show that $V(0, \cdot)$ is convex. In fact $V(t, \cdot)$ is convex for all $t \in [0, 1]$ as we shall see.

Define the $(n+1) \times (n+1)$ block matrix $\tilde{A}(t)$ and the $(n+1) \times m$ block matrix $\tilde{B}(t)$ by

$$\tilde{A}(t) = \begin{bmatrix} 0 & -a(t) \\ 0 & A(t) \end{bmatrix}, \quad \tilde{B}(t) = \begin{bmatrix} -b(t) \\ B \end{bmatrix}$$

and let $\Phi(\cdot, \cdot)$ be the transition matrix associated with the time-varying differential equation

$$\dot{y} = \tilde{A}(t)y.$$

Now for each $t \in [0, 1]$ define the mapping M_t from control functions into \mathbb{R}^{n+1} according to

$$M_t(u(\cdot)) = \int_t^1 \Phi(1, s) \tilde{B}(s) u(s) ds$$

and the linear mapping $\Lambda_t: \mathbb{R}^{n+1} \rightarrow \mathbb{R}^n$ by

$$\Lambda_t x = \Phi(1, t) \begin{bmatrix} 0 \\ x \end{bmatrix}.$$

Write

$$R_t = \operatorname{range} \{M_t\}.$$

By Aumann's Theorem (see, e.g., [5, p. 256]), R_t is a compact convex set.

Finally define $\tilde{h}: \mathbb{R}^{n+1} \rightarrow \mathbb{R}$ to be

$$\tilde{h}((y^0, y)) = y^0 + h(y).$$

Using the standard representation of the solution to inhomogeneous linear differential equations in terms of the transition matrix, we easily confirm that

$$(5.7) \quad V(t, x) = \min_{\xi \in R_t} \tilde{h}(\Lambda_t x + \xi).$$

Take arbitrary $x_1, x_2 \in \mathbb{R}^n$ and $\varepsilon \in [0, 1]$. Let ξ_1 (ξ_2) be a minimizing element in the expression on the right-hand side of (5.7) when x takes value x_1 (x_2). We now deduce from the convexity of the function \tilde{h} and the convexity of the set R_t that

$$\begin{aligned} \varepsilon V(t, x_1) + (1 - \varepsilon) V(t, x_2) &= \varepsilon \tilde{h}(\Lambda_t x_1 + \xi_1) + (1 - \varepsilon) \tilde{h}(\Lambda_t x_2 + \xi_2) \\ &\geq \tilde{h}(\Lambda_t(\varepsilon x_1 + (1 - \varepsilon)x_2) + \bar{\xi}) \end{aligned}$$

where $\bar{\xi} = \varepsilon \xi_1 + (1 - \varepsilon) \xi_2$

$$\geq V(t, \varepsilon x_1 + (1 - \varepsilon)x_2).$$

The convexity of $V(t, \cdot)$ is proved. \square

We note, incidentally, that the problem that Proposition 5.5 addresses is an instance for which the hypotheses of Corollary 5.2 are verifiable. Indeed, as we point out in the proof of Proposition 5.5, for the "linear-convex" problem $V(t, \cdot)$ is convex for all $t \in [0, 1]$. Thus Corollary 5.2 affords an independent proof of Proposition 5.5.

6. Problems with terminal constraints. In this section we aim to give new information about the costate function $p(\cdot)$, in situations where the state function $x(\cdot)$ is constrained to satisfy $x(1) \in C_1$. The properties to be described undoubtedly remain true within a broader framework than that which we adopt; we limit attention to a pure terminal cost problem and impose extra hypotheses though, in order to avail ourselves directly of results from [6] and thereby greatly to simplify our proofs. The problem considered is

$$\begin{aligned} &\text{Minimize} && h(x(1)) \\ &\text{subject to} && \dot{x}(t) = f(t, x(t), u(t)) \quad \text{a.e. } t \in [0, 1], \\ &&& x(0) = x_0, \\ &&& x(1) \in C_1, \\ &&& u(t) \in U_t \quad \text{a.e. } t \in [0, 1], \\ &&& x(t) \in \Omega_t, \quad \text{all } t \in [0, 1]. \end{aligned}$$

A process (on $[0, 1]$) will be called minimizing if it minimizes $h(x(1))$ over processes $(x(\cdot), u(\cdot))$ satisfying the problem's constraints (which now include " $x(1) \in C_1$ ").

Let $(x_0(\cdot), u_0(\cdot))$ be a minimizing process such that some tube about $x_0(\cdot)$ is contained in Ω .

Define the multifunction $F(\cdot, \cdot)$:

$$F(t, x) = f(t, x, U_t), \quad \text{all } (t, x) \in [0, 1] \times \mathbb{R}^n.$$

In addition to the hypotheses of § 2, we impose the following throughout this section:

(H7). $F(\cdot, \cdot)$ takes values compact, convex sets in \mathbb{R}^n and is continuous in the sense that

$$\text{dist}(F(t', x'), F(t, x)) \rightarrow 0 \quad \text{if } (t', x') \rightarrow (t, x) \quad \text{in } \Omega$$

($\text{dist}(\cdot, \cdot)$ is the Hausdorff distance function).

(H8) There is a constant \bar{k} such that

$$\text{dist}(F(t, x'), F(t, x)) \leq \bar{k}|x' - x| \quad \text{for all } t \in [0, 1], \quad x, x' \in \Omega_t.$$

(H9) $F(\cdot, \cdot)$ is uniformly bounded on Ω .

(H10) C_1 is closed.

The usual Maximum Principle now asserts existence of a real number λ ($\lambda = 0$ or 1) and an absolutely continuous function $p(\cdot): [0, 1] \rightarrow \mathbb{R}^n$ ($\lambda, p(\cdot)$ not both zero) such that

$$\begin{aligned} -\dot{p}(t) &\in \partial_x H(t, x_0(t), p(t), u_0(t)) \quad \text{a.e. } t \in [0, 1], \\ -p(1) &\in N_{C_1}(x_0(1)) + \lambda \partial_x g(x_0(1)), \end{aligned}$$

and

$$H(t, x_0(t), p(t), u_0(t)) = \max_{u \in U_t} H(t, x_0(t), p(t), u) \quad \text{a.e. } t \in [0, 1].$$

Here

$$H(t, x, p, u) = p \cdot f(t, x, u).$$

Let us recall in passing that a minimizing process is customarily called “normal” if the number λ in such conditions as above cannot be taken zero, i.e., if the conditions are nondegenerate in the sense that they make some reference to the cost function. The precise notion of normality required for later purposes is the following.

DEFINITION 6.1. The minimizing process $(x_0(\cdot), u_0(\cdot))$ will be said to be *normal* if the only absolutely continuous function $\tilde{p}(\cdot): [0, 1] \rightarrow \mathbb{R}^n$ which satisfies

$$(-\dot{\tilde{p}}(t), \dot{x}_0(t)) \in \partial \tilde{H}(t, x_0(t), \tilde{p}(t)) \quad \text{a.e. } t \in [0, 1]$$

and

$$-\tilde{p}(1) \in N_{C_1}(x_0(1))$$

is

$$\tilde{p}(\cdot) \equiv 0.$$

Here $\tilde{H}(t, x, p)$, the “true Hamiltonian,” is

$$\tilde{H}(t, x, p) = \sup_{u \in U_t} p \cdot f(t, x, u)$$

and $\partial \tilde{H}$ denotes the generalized gradient of $(x, p) \rightarrow \tilde{H}(t, x, p)$. Normality as defined here relates to nondegeneracy of first order optimality conditions expressed in terms of generalized gradients of the true Hamiltonian (see [5, p. 147]).

Even in the presence of a terminal constraint we may define the value function $V(\cdot, \cdot): [0, 1] \times \mathbb{R}^n \rightarrow \bar{\mathbb{R}}$:

$$V(t, x) = \inf \{h(x(1))\}$$

where the infimum is over the processes $\{x(\cdot), u(\cdot)\}$ on $[t, 1]$ which satisfy the constraints of the problem, modified to involve the time-interval $[t, 1]$ and the initial condition $x(t) = x$ ($V(\cdot, \cdot)$ takes values $+\infty$ if no such processes exist), and we might hope to show in certain circumstances that $p(\cdot)$ can be chosen to satisfy the inclusion

$$-p(t) \in \partial_x V(t, x_0(t)),$$

appropriately interpreted.

When we add the terminal constraint $x(1) \in C_1$ there is however the very real possibility that, for all $t \in [0, 1]$, $V(t, \cdot)$ will not be Lipschitz continuous on a neighborhood of $\{x_0(t)\}$ and, worse, might take finite values only on a set having empty interior. It is not clear how our methods could be modified to overcome these difficulties; establishing such a relationship between some costate function and $V(\cdot, \cdot)$ remains a challenging open problem. (Note that the inclusion, if it applies in situations having any degree of generality, must involve generalized gradients of possibly non-Lipschitz continuous, extended valued functions.)

However, the approach of earlier sections does provide an answer to a related question. To pose this we need to bring verification functions into the discussion.

DEFINITION 6.2. Let $(x(\cdot), u(\cdot))$ be some process on $[0, 1]$ which satisfies the constraints. Then a Lipschitz continuous function $W(\cdot, \cdot)$ defined on some δ -tube T^δ about $x(\cdot)$ is said to be a *verification function* (for $(x(\cdot), u(\cdot))$) if

$$(6.1) \quad \min_{(\alpha, \beta) \in \partial W(t, x)} \{\alpha - H(t, x, -\beta)\} = 0, \quad \text{for all } (t, x) \in \text{int } \{T^\delta\},$$

$$(6.2) \quad W(1, x) = h(x) \quad \text{for all } x \in \{\xi: \|\xi - z(1)\| < \delta\} \cap C_1,$$

and

$$(6.3) \quad W(0, x_0) = h(x(1)).$$

The significance of there being a verification function $W(\cdot, \cdot)$ on some tube $T \subset \Omega$ for an admissible process $(x(\cdot), u(\cdot))$ is that $(x(\cdot), u(\cdot))$ is a minimizing process among admissible processes whose state functions lie in some (possibly narrower) tube about $x(\cdot)$, i.e., $W(\cdot, \cdot)$ *verifies* the (local) optimality of $(x(\cdot), u(\cdot))$. This is shown in [6]. Of course there is an intimate relationship between verification functions for $(x_0(\cdot), u_0(\cdot))$ and the value function $V(\cdot, \cdot)$: $V(\cdot, \cdot)$ satisfies conditions (6.2) and (6.3) in the definition of a verification function $W(\cdot, \cdot)$ and we can expect $V(\cdot, \cdot)$ to satisfy (6.1), which will be recognized as a version of the Hamilton-Jacobi-Bellman equation, at least on neighborhoods where $V(\cdot, \cdot)$ is Lipschitz continuous. The difference is that there can exist a (Lipschitz continuous) verification function for $(x_0(\cdot), u_0(\cdot))$ even when $V(\cdot, \cdot)$ is very ill behaved (has effective domain with empty interior, say). Existence of verification functions has been established under quite mild conditions, as is illustrated by the following result, proved in [5] and [6].

PROPOSITION 6.3. Suppose the minimizing process $(x_0(\cdot), u(\cdot))$ is normal. Then there is a verification function for $(x_0(\cdot), u_0(\cdot))$.

After this detour we are ready to return to our modified question: when can we choose some costate function $p(\cdot)$ and some verification function $W(\cdot, \cdot)$ for $(x_0(\cdot), u_0(\cdot))$ such that

$$-p(t) \in \partial_x W(t, x_0(t))?$$

An answer is provided by the following theorem.

THEOREM 6.4. Suppose that the minimizing process $(x_0(\cdot), u_0(\cdot))$ is normal. Then there exists an absolutely continuous function $p(\cdot): [0, 1] \rightarrow \mathbb{R}^n$, a verification function $W(\cdot, \cdot)$ for $(x_0(\cdot), u_0(\cdot))$ and a subset $\Sigma \subset [0, 1]$ of full measure such that

$$-\dot{p}(t) \in \partial_x H(t, x_0(t), p(t), u_0(t)) \quad \text{a.e. } t \in [0, 1],$$

$$H(t, x_0(t), p(t), u_0(t)) = \max_{u \in U_t} H(t, x_0(t), p(t), u) \quad \text{a.e. } t \in [0, 1],$$

$$-p(1) \in N_{C_1}(x_0(1)) + \partial h(x_0(1)),$$

$$-p(t) \in \partial_x W(t, x_0(t)) \quad \text{for all } t \in \{0\} \cup \{1\} \cup \Sigma.$$

Proof. By Theorem 4.1 and Lemmas 6.3–6.6 of [6] there exist $K, \varepsilon > 0$ such that $(x_0(\cdot), u_0(\cdot))$ is a minimizing process for the *free* endpoint problem

$$\begin{aligned} \text{Minimize} \quad & K \int_0^1 \max \{ \|x(t) - z(t)\| - \varepsilon, 0 \} dt + K d_{C_1}(x(1)) + h(x(1)) \\ \text{subject to} \quad & \dot{x} = f(t, x, u), \quad x(0) = x_0, \\ & u(t) \in U_t \quad \text{a.e. } t \in [0, 1], \\ & x(t) \in X_t \quad \text{for all } t \in [0, 1]. \end{aligned}$$

Here X is the 2ε -tube about $x_0(\cdot)$. $d_{C_1}(\cdot)$ denotes the Euclidean distance function. It is shown further in [6] that the value function for this problem is Lipschitz continuous on some tube about $x_0(\cdot)$ and is a verification function (relative to the original terminally constrained problem) for $(x_0(\cdot), u_0(\cdot))$. Now apply Theorem 3.1 to this free endpoint problem. This is permissible since, as we easily check, the free endpoint problem satisfies the necessary hypotheses. The assertions of Theorem 6.4 follow. \square

7. Discrete approximation of integrals. An important step in the proof of Theorem 3.1 will be the construction of sequences of discrete approximations to certain integrals with desirable convergence properties. The necessary machinery is provided in this section.

Define the functions $\psi_N(\cdot): \mathbb{R} \rightarrow \mathbb{R}$, $N = 1, 2, \dots$:

$$\psi_N(s) = \sum_{j=-\infty}^{+\infty} \frac{j}{N} \chi_{[j/N, (j+1)/N)}(s)$$

in which $\chi_A(\cdot)$ denotes the function taking value 1 on A and zero elsewhere. We see that $\psi_N(\cdot)$ is a piecewise constant approximation to the straight line through the origin of unit slope.

Let $g(\cdot): [0, 1] \rightarrow \mathbb{R}^n$ be a function. In order to simplify certain formulae to follow we consider $g(\cdot)$ extended to the whole real line: off $[0, 1]$ we define its value to be zero.

Now for any $\tau \in [0, 1]$ and positive integer N , the function $\tilde{g}_{N,\tau}(\cdot)$:

$$(7.1) \quad \tilde{g}_{N,\tau}(s) = g(\tau + \psi_N(s - \tau)),$$

which can alternatively be written

$$\tilde{g}_{N,\tau}(s) = \sum_{j=-\infty}^{+\infty} g\left(\tau + \frac{j}{N}\right) \chi_{[j/N + \tau, (j+1)/N + \tau)}(s),$$

is a piecewise constant approximation to $g(\cdot)$.

The following proposition, drawn to our attention by P. Loewen, concerns the relationship between the indefinite integrals of $g(\cdot)$ and $\tilde{g}_{N,\tau}(\cdot)$. It is a special case of a result due to Doob [8, p. 440ff.], implicit in his construction of the stochastic integral.

PROPOSITION 7.1. *Let $g(\cdot)$ be an $\mathcal{L}^\infty(0, 1; \mathbb{R}^n)$ function, and let $\tilde{g}_{N,\tau}(\cdot)$ be the function defined by (7.1). Then there exists a subset $S \subset [0, 1]$, of full measure, and a subsequence $\{N_j\}$ (of the positive real numbers) such that*

$$\sup_{t \in [0, 1]} \left\| \int_0^t (\tilde{g}_{N_j,\tau}(s) - g(s)) ds \right\| \rightarrow 0$$

as $j \rightarrow \infty$ for all $\tau \in S$.

Proof. Extend $g(\cdot)$ to all of \mathbb{R} , as in the preceding discussion. We show first that

$$(7.2) \quad \lim_{h \rightarrow 0} \int_0^1 \|g(s+h) - g(s)\| ds = 0.$$

Let K be a uniform bound on the values of $g(\cdot)$. Take $\varepsilon > 0$. By Lusin's theorem (see [13, p. 53]), extended to the vector case, there exist a function \tilde{g} , continuous on $[0, 1]$, taking value 0 off $[0, 1]$ and having values bounded by K , and a measurable set Ω_ε , with $|\Omega_\varepsilon| \leq \varepsilon$, such that

$$\tilde{g}(s) = g(s) \quad \text{for all } s \in [0, 1] \setminus \Omega_\varepsilon.$$

For any h

$$\begin{aligned} \int_0^1 \|g(s+h) - g(s)\| \, ds &\leq \int_0^1 \|\tilde{g}(s+h) - \tilde{g}(s)\| \, ds \\ &\quad + \int_0^1 [\|\tilde{g}(s+h) - g(s+h)\| + \|\tilde{g}(s) - g(s)\|] \, ds \\ &\leq \int_0^1 \|\tilde{g}(s+h) - \tilde{g}(s)\| \, ds + 4K\varepsilon. \end{aligned}$$

But the integrals on the right-hand side have limit 0 as $h \rightarrow 0$, by the Dominated Convergence Theorem, since the integrals are majorized by the constant function $2K$ and since they converge pointwise to zero (except possibly at 0 or 1). It follows that

$$\limsup_{h \rightarrow 0} \int_0^1 \|g(s+h) - g(s)\| \, ds \leq 4K\varepsilon.$$

Since $\varepsilon > 0$ was arbitrary, (7.2) follows.

Now define $d_N(\tau)$:

$$d_N(\tau) = \int_0^1 \|g(\tau + \psi_N(s - \tau)) - g(s)\| \, ds.$$

Then

$$\begin{aligned} \int_0^1 d_N(\tau) \, d\tau &= \int_0^1 \int_0^1 \|g(\tau + \psi_N(s - \tau)) - g(s)\| \, ds \, d\tau \\ (7.3) \quad &= \int_{-1}^{+1} \left\{ \int_{0 \vee \sigma}^{1 \wedge (1+\sigma)} \|g(s - \sigma + \psi_N(\sigma)) - g(s)\| \, ds \right\} d\sigma. \end{aligned}$$

To obtain the last expression we have changed variables $\sigma = s - \tau$ ($a \wedge b, a \vee b$ denote $\min\{a, b\}, \max\{a, b\}$, respectively).

But for fixed σ ,

$$\int_{0 \vee \sigma}^{1 \wedge (1+\sigma)} \|\cdot \cdot \cdot\| \, ds \leq \int_0^1 \|g(s - \sigma + \psi_N(\sigma)) - g(s)\| \, ds \rightarrow 0$$

as $N \rightarrow \infty$, by (7.2). Another application of the Dominated Convergence Theorem yields

$$\int_0^1 d_N(\tau) \, d\tau \rightarrow 0$$

as $N \rightarrow \infty$, i.e., $d_N(\cdot) \rightarrow 0$ strongly in L^1 . But then, for a suitable subsequence $\{N_j\}$, $d_{N_j}(\cdot) \rightarrow 0$ almost everywhere. Since

$$\sup_{t \in [0, 1]} \left\| \int_0^t (g(\tau + \psi_{N_j}(s - \tau)) - g(s)) \, ds \right\| \leq d_{N_j}(\tau)$$

for all $\tau \in [0, 1]$, the proposition is proved. \square

Now we introduce an approximation $g_{N,\tau}$ to the measure associated with $g(\cdot)$, namely $A \rightarrow \int_A g(s) ds$:

$$g_{N,\tau} = \frac{1}{N} \sum_{j=-\infty}^{+\infty} g\left(\tau + \frac{j}{N}\right) \delta_{\{j/N + \tau\}}.$$

Here δ_t denotes the unit measure concentrated at t .

COROLLARY 7.2. *Let $g(\cdot)$ be an $\mathcal{L}^\infty(0, 1; \mathbb{R}^n)$ function. Then there exists a subsequence $\{N_j\}$ and a subset $S \subset [0, 1]$ of full measure, such that, for $\tau \in S$,*

$$\sup_{t \in [0, 1]} \left\| \int_0^t dg_{N_j,\tau}(s) - \int_0^t g(s) ds \right\| \rightarrow 0 \quad \text{as } j \rightarrow \infty.$$

Proof. Scrutiny of the formulae for $g_{N,\tau}(\cdot)$ and $\tilde{g}_{N,\tau}(\cdot)$ reveals that, for any t , $\tau \in [0, 1]$ and integer N ,

$$\left\| \int_0^t \tilde{g}_{N,\tau}(s) ds - \int_0^t dg_{N,\tau}(s) \right\| \leq \sup_{s \in [0, 1]} g(s) \cdot \frac{1}{N}.$$

The assertions of the corollary now follow from Proposition 7.1, since the values of $g(\cdot)$ are uniformly bounded. \square

8. Proof of Theorem 3.1. Fix $\delta > 0$ such that the δ -tube about $x_0(\cdot)$ is contained in the set Ω' of hypothesis (H6).

We shall say a triple $(x(\cdot), u(\cdot), \alpha(\cdot))$ is a *perturbed process* (on $[0, 1]$) if $\mu(\cdot)$ is a measurable \mathbb{R}^m -valued function such that $u(t) \in \Omega_t$, a.e., $\alpha(\cdot)$ is a measurable \mathbb{R}^n -valued function such that

$$\|\alpha(t)\| < 1 \quad \text{a.e. } t \in [0, 1],$$

and $x(\cdot)$ is an absolutely continuous \mathbb{R}^n -valued function such that

$$x(t) = f(t, x(t), u(t)) + \alpha(t) \quad \text{a.e. } t \in [0, 1].$$

Let $(x(\cdot), u(\cdot), \alpha(\cdot))$ be any perturbed process such that $x(\cdot)$ is contained in the δ -tube about $x_0(\cdot)$. Define

$$(8.1) \quad \sigma_\delta(t, \alpha) := \max \{p \cdot \alpha : p \in \partial_x V(t, x) : \|x - x_0(t)\| \leq \delta\}.$$

The following lemma is proved in [7].

LEMMA 8.1. *The function $t \rightarrow \sigma_\delta(t, \alpha(t))$ is measurable and essentially bounded.*

According to Corollary 7.2, we can choose an irrational number $\tau \in [0, 1]$ and a subsequence $\{N_i\}$ of the positive integers such that

$$(8.2) \quad \sup_{t \in [0, 1]} \left\| \int_{[0, t]} d\alpha_i(s) - \int_0^t \alpha(s) ds \right\| \rightarrow 0$$

and

$$(8.3) \quad \int_{[0, 1]} d\sigma_i(s) \rightarrow \int_0^1 \sigma_\delta(s, \alpha(s)) ds$$

as $i \rightarrow \infty$. Here the measures α_i and σ_i are defined by

$$\alpha_i = \frac{1}{N_i} \sum_{j=m_i}^{n_i} \alpha\left(\tau + \frac{j}{N_i}\right) \delta_{\{j/N_i + \tau\}}$$

and

$$\sigma_i = \frac{1}{N_i} \sum_{j=m_i}^{n_i} \sigma_\delta \left(\tau + \frac{j}{N_i}, \alpha \left(\tau + \frac{j}{N_i} \right) \right) \delta_{\{j/N_i + \tau\}}$$

where

$$(8.4) \quad m_i = \min \left\{ j: \tau + \frac{j}{N_i} > 0 \right\} \quad \text{and} \quad n_i = \max \left\{ j: \tau + \frac{j}{N_i} < 1 \right\}.$$

(τ is chosen irrational to ensure that neither 0 nor 1 can be a mesh point, and thereby to simplify certain formulae that follow.)

Consider now the integral equation

$$(8.5) \quad y(t) = x(0) + \int_0^t f(s, y(s), u(s)) ds + \int_{[0,t]} d\alpha_i(s) \quad \text{all } t \in [0, 1].$$

A fairly routine application of [5, Thm. 3.1.6] in which we use (8.2) (see [7] for details) yields the following lemma.

LEMMA 8.2. *There exists a positive integer i_0 such that for all $i > i_0$ the integral equation (8.5) has a solution, $x_i(\cdot)$, in the δ -tube about $x_0(\cdot)$, and*

$$\sup_{t \in [0,1]} \|x_i(t) - x(t)\| \rightarrow 0 \quad \text{as } i \rightarrow \infty.$$

We shall require also the following version of the principle of optimality.

LEMMA 8.3. *Let $A \subset \Omega$ be a tube about $x_0(\cdot)$ on which $V(\cdot, \cdot)$ is finite. Suppose that $(x(\cdot), u(\cdot))$ is a process on $[a, b]$ with graph in A . Then*

$$\int_a^b L(s, x(s), u(s)) ds + V(b, x(b)) - V(a, x(a)) \geq 0.$$

Proof. We readily deduce from hypotheses (H3) and (H4) that $s \rightarrow L(s, x(s), u(s))$ is an integrable function. Since $V(\cdot, \cdot)$ is finite at $(b, x(b))$ there exists a sequence of processes $(x_i(\cdot), u_i(\cdot))$ on $[b, 1]$ such that $x_i(b) = x(b)$ for each i and

$$(8.6) \quad V(b, x(b)) = \lim_i \int_b^1 L(s, x_i(s), u_i(s)) ds + h(x_i(1)).$$

We concatenate the processes $(x(\cdot), u(\cdot))$ on $[a, b]$ and $(x_i(\cdot), u_i(\cdot))$ on $[b, 1]$ to obtain the process $(\tilde{x}_i(\cdot), \tilde{u}_i(\cdot))$ on $[a, 1]$, for each i . Since $V(\cdot, \cdot)$ is the infimum cost

$$\int_a^1 L(s, \tilde{x}_i(s), \tilde{u}_i(s)) ds + h(\tilde{x}_i(1)) - V(a, x(a)) \geq 0$$

whence

$$\int_a^b L(s, x(s), u(s)) ds + \int_b^1 L(s, x_i(s), u_i(s)) ds + h(x_i(1)) - V(a, x(a)) \geq 0.$$

We now prove the lemma by noting (8.6) and passing to the limit. \square

LEMMA 8.4. *The generalized process satisfies the inequality*

$$(8.7) \quad \int_0^1 L(t, x(t), u(t)) dt + h(x(1)) + \int_0^1 \sigma_\delta(t, -\alpha(t)) dt - V(0, x(0)) \geq 0.$$

Proof. Take $i > i_0$. The proof hinges on the observation that the solution $x_i(\cdot)$ to the integral equation (8.5) evolves according to an ordinary differential equation

$$\dot{z}(t) = f(t, x(t), u(t))$$

on the subintervals $[j/N_i + \tau, (j+1)/N_i + \tau]$, $j = m_i, \dots, n_i - 1$, $[0, a_i]$ and $[b_i, 1]$. (Here $a_i = \tau + m_i/N_i$, $b_i = \tau + m_i/N_i$); the integers m_i, n_i were defined in (8.4).) The observation, coupled with Lemma 8.3, leads to the following conclusions:

$$\int_0^{a_i} L(t, x_i(t), u(t)) dt + V(a_i, x_i(a_i^-)) - V(0, x(0)) \geq 0,$$

$$\int_{j/N_i + \tau}^{(j+1)/N_i + \tau} L(t, x_i(t), u(t)) dt + V(t, x_i(t^-))|_{t=(j+1)/N_i + \tau} - V(t, x_i(t^+))|_{t=j/N_i + \tau} \geq 0$$

for $j = m_i, m_i + 1, \dots, n_i - 1$, and

$$\int_{b_i}^1 L(t, x_i(t), u(t)) dt + V(1, x_i(1)) - V(b_i, x(b_i^+)) \geq 0.$$

Adding these inequalities we have

$$(8.8) \quad \int_0^1 L(t, x_i(t), u(t)) dt + V(1, x_i(1)) - V(0, x(0)) + q_i \geq 0$$

where

$$q_i = \sum_{j=m_i}^{n_i} V(t, x_i(t^-)) - V(t, x_i(t^+))|_{t=(j/N_i + \tau)}.$$

Note that since $x_i(\cdot)$ satisfies the integral equation (8.5)

$$x_i(t^+) = x_i(t^-) + N_i^{-1} \alpha(t)$$

for $t = j/N_i + \tau$, $j = m_i, \dots, n_i$, and so q_i can alternatively be expressed as

$$(8.9) \quad q_i = \sum_{j=m_i}^{n_i} [V(t, x_i(t^-)) - V(t, x_i(t^-) + N_i^{-1} \alpha(t))]|_{t=(j/N_i + \tau)}.$$

Recall that, by assumption, $V(t, \cdot)$ is Lipschitz continuous on $\{x_0(t)\} + \delta B$, for each $t \in [0, 1]$. Since $x_i(\cdot)$ is in the δ -tube about $x_0(\cdot)$,

$$x_i(t^-), x_i(t^-) + \frac{1}{N_i} \alpha(t) \in \{x_0(t)\} + \delta B$$

for $t = j/N_i + \tau$, $j = m_i, \dots, n_i$. By the Mean Value Theorem for generalized gradients (see [5, Thm. 2.3.7])

$$V(t, x_i(t^-)) - V\left(t, x_i(t^-) + \frac{1}{N_i} \alpha(t)\right) \in \frac{1}{N_i} \partial_x V(t, \xi_i(t)) \cdot (-\alpha(t))$$

for some $\xi_i(t) \in \{x_0(t)\} + \delta B$, when t assumes values $j/N_i + \tau$, $j = m_i, \dots, n_i$. It follows from (8.9) that

$$q_i \leq \frac{1}{N_i} \sum_{j=m_i}^{n_i} \sigma_\delta(t, -\alpha(t))|_{t=(j/N_i + \tau)}.$$

(The function $\sigma_\delta(\cdot, \cdot)$ was defined by (8.1).) By (8.8)

$$\int_0^1 L(t, x_i(t), u(t)) dt + V(1, x_i(1)) - V(0, x(0)) + \frac{1}{N_i} \sum_{j=m_i}^{n_i} \sigma_\delta(t, -\alpha(t))|_{t=(j/N_i + \tau)} \geq 0.$$

We now pass to the limit $i \rightarrow \infty$. Since $x_i(\cdot)$ converges uniformly to $x(t)$, and in view of property (8.3), the result is (8.7). \square

We denote by P_δ the following optimal control problem:

$$\begin{aligned} \text{Minimize } & \int_0^1 L(t, x(t), u(t)) dt + \int_0^1 \sigma_\delta(t, -\alpha(t)) dt + h(x(1)) - V(0, x(0)) \\ \text{subject to } & \dot{x}(t) = f(t, x(t), u(t)) + \alpha(t) \quad \text{a.e. } t \in [0, 1], \\ & u(\cdot) \in U_t \quad \text{a.e. } t \in [0, 1], \\ & \alpha(t) \in B \quad \text{a.e. } t \in [0, 1], \\ & x(t) \in X_t^\delta \quad \text{all } t \in [0, 1]. \end{aligned}$$

Here X^δ is the δ -tube about $x_0(\cdot)$. As usual, B is the open unit ball (in \mathbb{R}^n). In P_δ , the control variable is the pair of vectors $(u(t), \alpha(t))$. Lemma 8.4 can now be re-expressed in the following terms.

LEMMA 8.5. *The extended process $(x_0(\cdot), u_0(\cdot), \alpha(\cdot) \equiv 0)$ solves P_δ .*

It is a straightforward task to check that the hypotheses are satisfied under which the Maximum Principle [5, Thm. 5.2.1] applies, at the minimizing process $(x_0(\cdot), u_0(\cdot), \alpha(\cdot) \equiv 0)$. We use in particular Lemma 8.1. Bearing in mind that P_δ is a free left and right endpoint problem, we conclude the following: let

$$H(t, x, p, u) = p \cdot f(t, x, u) - L(t, x, u)$$

as before. Then there exists an absolutely continuous function $p(\cdot): [0, 1] \rightarrow \mathbb{R}^n$ such that

$$(8.10) \quad \begin{cases} -\dot{p}(t) \in \partial_x H(t, x_0(t), p(t), u_0(t)) & \text{a.e. } t \in [0, 1], \\ -p(1) \in \partial h(x_0(1)), \quad -p(0) \in \partial_x V(0, x_0(0)), \\ H(t, x_0(t), p(t), u_0(t)) = \max_{u \in U_t} H(t, x_0(t), p(t), u) & \text{a.e. } t \in [0, 1], \end{cases}$$

and

$$(8.11) \quad \max_{\alpha \in B} \{p(t) \cdot \alpha - \sigma_\delta(t, -\alpha)\} = 0 \quad \text{a.e. } t \in [0, 1].$$

Take a point $t \in [0, 1]$ at which (8.11) is true. Then

$$(8.12) \quad -p(t) \in S_\delta(t)$$

where

$$S_\delta(t) = \overline{\text{co}} \cup \{\partial_x V(t, \xi): \|\xi - x_0(t)\| \leq \delta\},$$

for otherwise $-p(t)$ and the closed convex set $S_\delta(t)$ can be strictly separated, i.e., there exists an n -vector $\bar{\alpha} \in B$ such that

$$\begin{aligned} p(t) \cdot \bar{\alpha} &> \max \{-r \cdot \bar{\alpha}: r \in S_\delta(t)\} \\ &= \sigma_\delta(t, -\bar{\alpha}) \end{aligned}$$

in contradiction of (8.11).

Up to this point $\delta > 0$ has been fixed. Now let $\{\delta_i\}$, $\delta_i \downarrow 0$, be a sequence of numbers such that the δ_i -tube about $x_0(\cdot)$ is contained in Ω' for all i . Replace δ by δ_i , and write $p_i(\cdot)$ in place of the costate $p(\cdot)$ satisfying (8.10) et seq.

We deduce from the costate differential inclusion and the transversality conditions that

$$\frac{d}{dt} \|p_i(t)\| \leq k(t)[1 + \|p_i(t)\|]$$

where $k(\cdot)$ is the function of hypothesis (H3), and

$$p_i(1) \leq K$$

for all i , where K is the rank of $h(\cdot)$ on some suitable neighborhood of $x_0(1)$. Application of Gronwall's inequality tells us that the $p_i(\cdot)$'s are uniformly bounded and the $\dot{p}_i(\cdot)$'s are dominated by a common integrable function. The hypotheses are met then under which [5, Thm. 3.1.7] applies to the inclusions

$$\dot{p}_i(t) \in G(t, p_i(t)) \quad \text{a.e. } t \in [0, 1]$$

where $G(t, z) := \partial_x H(t, x_0(t), z, u_0(t))$. We conclude that, following extraction of a suitable subsequence,

$$\sup_{t \in [0, 1]} \|p_i(t) - p(t)\| \rightarrow 0$$

for some absolutely continuous function $p(\cdot): [0, 1] \rightarrow \mathbb{R}^n$ satisfying

$$-\dot{p}(t) \in \partial_x H(t, x_0(t), p(t), u_0(t)) \quad \text{a.e.}$$

We deduce

$$-p(1) \in \partial_x h(x_0(1)) \quad \text{and} \quad -p(0) \in \partial_x V(0, x_0(0))$$

from the transversality conditions and the upper semicontinuity of the generalized gradient of a locally Lipschitz function. A simple contradiction argument, in which we employ hypotheses (H3) and (H4), leads to the following conclusion:

$$(8.13) \quad H(t, x_0(t), p(t), u_0(t)) = \max_{u \in U_t} H(t, x_0(t), p(t), u)$$

for all $t \in \cap_i M_i$, where M_i is the set on which the Hamiltonian is maximized for problem P_{δ_i} . So (8.13) is true almost everywhere.

Finally we examine the implications of " $-p_i(t) \in S_{\delta_i}(t)$ a.e." (see (8.12)).

Evidently,

$$(8.14) \quad -p(t) \in \bigcap_{\varepsilon > 0} \overline{\text{co}} \{ \partial_x V(t, \xi) : \|\xi - x_0(t)\| \leq \varepsilon \}$$

for all t belonging to some subset $S \subset [0, 1]$ of full measure. We claim that, for any $t \in S$,

$$(8.15) \quad -p(t) \in \partial_x V(t, x_0(t)).$$

Otherwise we can strictly separate the point $-p(t)$ and the closed convex set $\partial_x V(t, x_0(t))$, i.e., there exists $q \in \mathbb{R}^n$ and $\gamma > 0$ such that

$$-p(t) \cdot q - \gamma > \max_{s \in \partial_x V(t, x_0(t))} s \cdot q = D_x^0 V(t, x_0(t); q).$$

Here D_x^0 denotes the generalized directional derivative with respect to the x variable. (We have used the fact that $D_x^0 V$ is the polar function of the set $\partial_x V$.) Since the generalized directional derivative is upper semicontinuous in its arguments [5, Prop. 2.1.1]

$$-p(t) \cdot q - \frac{\gamma}{2} > D_x^0 V(t, \xi; q)$$

whenever $\xi \in \{x_0(t)\} + \varepsilon_1 B$, for some $\varepsilon_1 > 0$. Then

$$\begin{aligned} -p(t) \cdot q - \frac{\gamma}{2} &> \sup \{ s \cdot q : s \in \bigcup \{ \partial_x V(t, \xi) : \|\xi - x_0(t)\| \leq \varepsilon_1 \} \} \\ &= \max \{ s \cdot q : s \in \overline{\text{co}} \bigcup \{ \partial_x V(t, \xi) : \|\xi - x_0(t)\| \leq \varepsilon_1 \} \}. \end{aligned}$$

But this means that

$$-p(t) \notin \overline{\text{co}} \{ \partial_x V(t, \xi) : \|\xi - x_0(t)\| \leq \varepsilon_1 \}$$

in contradiction of (8.14). (8.15) is then true on a subset of full measure.

This completes the proof of Theorem 3.1. \square

NONSMOOTH CALCULUS IN FINITE DIMENSIONS*

D. E. WARD† AND J. M. BORWEIN‡

Abstract. The notion of subgradient, originally defined for convex functions, has in recent years been extended, via the “upper subderivative,” to cover functions that are not necessarily convex or even continuous. A number of calculus rules have been proven for these generalized subgradients. This paper develops the finite-dimensional generalized subdifferential calculus for (strictly) lower semicontinuous functions under considerably weaker hypotheses than those previously used. The most general finite-dimensional convex subdifferential calculus results are recovered as corollaries. Other corollaries given include new necessary conditions for optimality in a nonsmooth mathematical program. Various chain rule formulations are considered. Equality in the subdifferential calculus formulae is proven under hypotheses weaker than the usual “subdifferential regularity” assumptions.

Key words. Clarke tangent cone, upper subderivative, subgradient, contingent cone, subdifferential regularity

AMS(MOS) subject classifications. Primary 46G05; secondary 58C20, 90C30.

1. Introduction. Let E be a real locally convex Hausdorff topological vector space (l.c.t.v.s.) with dual space E^* . For $x \in E$, denote by $\mathcal{N}(x)$ the set of all neighborhoods of x .

DEFINITION 1.1. Let $C \subset E$ and $x_0 \in \text{cl } C$. The *Clarke tangent cone* to C at x_0 is the set

$$(1.1) \quad T_C(x_0) := \{y \in E \mid \forall Y \in \mathcal{N}(y), \exists X \in \mathcal{N}(x_0), \text{ and } \exists \lambda > 0 \text{ such that } \forall x' \in X \cap C \text{ and } \forall t \in (0, \lambda), \exists y' \in Y \text{ with } x' + ty' \in C\}.$$

The *normal cone* to C at x_0 is the set

$$(1.2) \quad N_C(x_0) := T_C(x_0)^0 := \{z \in E^* \mid \langle y, z \rangle \leq 0 \ \forall y \in T_C(x_0)\}.$$

$T_C(x_0)$ is always closed and contains the origin. More important, it is always a convex set. (See [17], [20, Chap. 1].)

DEFINITION 1.2. Let $f: E \rightarrow \bar{\mathbf{R}}$ be an extended-real-valued function on E . The *domain* of f is the set

$$(1.3) \quad \text{dom } f := \{x \in E \mid f(x) < +\infty\}.$$

The *epigraph* of f is the set

$$(1.4) \quad \text{epi } f := \{(x, r) \in E \times \mathbf{R} \mid f(x) \leq r\}.$$

Let $x_0 \in E$ be a point at which f is finite, and let $y \in E$. The upper subderivative of f at x_0 in the direction y is defined by

$$(1.5) \quad f^\uparrow(x_0; y) := \inf \{r \mid (y, r) \in T_{\text{epi } f}(x_0, f(x_0))\}.$$

Notice that $f^\uparrow(x_0; y)$ is defined precisely so that

$$(1.6) \quad \text{epi } f^\uparrow(x_0; y) = T_{\text{epi } f}(x_0, f(x_0)).$$

By (1.6), $f^\uparrow(x_0; \cdot)$ has several important properties. Since $T_{\text{epi } f}(x_0, f(x_0))$ is closed, $f^\uparrow(x_0; \cdot)$ is lower semicontinuous (l.s.c.), and since $T_{\text{epi } f}(x_0, f(x_0))$ is a convex cone, $f^\uparrow(x_0; \cdot)$ is convex and positively homogeneous. As a result, either

(a) $f^\uparrow(x_0; 0) = 0$, in which case $f^\uparrow(x_0; \cdot)$ is *proper*, i.e., is somewhere finite and never $= -\infty$, or

(b) $f^\uparrow(x_0; 0) = -\infty$, in which case $f^\uparrow(x_0; \cdot)$ is equal to $-\infty$ throughout its domain. For further discussion of the idea of associating directional derivatives with approximating cones to epigraphs of functions, in particular the Clarke tangent cone, see [12], [7] and [20, Chap. 3].

DEFINITION 1.3. Let $f: E \rightarrow \bar{\mathbf{R}}$ and $x_0 \in E$ be such that $f(x_0)$ is finite. The *subgradient* of f at x_0 is the set

$$(1.7) \quad \partial f(x_0) := \{x^* \in E^* \mid \langle y, x^* \rangle \leq f^\uparrow(x_0; y) \forall y \in E\}.$$

The notation $\partial f(x_0)$ is the same as that for the subgradient of a convex function or the Clarke subgradient of a locally Lipschitzian function, and justifiably so. If f is locally Lipschitzian, $\partial f(x_0)$ coincides with the Clarke subgradient, which in turn coincides with the ordinary subgradient for convex functions if f is convex. (See [18], [19], [20].)

In [19], Rockafellar introduced the following direct characterization of $f^\uparrow(x_0; \cdot)$:

$$(1.8) \quad f^\uparrow(x_0; y) = \sup_{Y \in \mathcal{N}(y)} \inf_{\substack{N \in \mathcal{N}(x_0, f(x_0)) \\ \lambda > 0}} \sup_{\substack{(x, \alpha) \in \text{epi } f \cap N \\ t \in (0, \lambda)}} \inf_{y' \in Y} \frac{f(x + ty) - \alpha}{t}.$$

If f is l.s.c., this definition reduces to

$$(1.9) \quad \begin{aligned} f^\uparrow(x_0; y) &= \limsup_{\substack{x \rightarrow x_0 \\ f \\ t \downarrow 0}} \inf_{y' \rightarrow y} \frac{f(x + ty') - f(x)}{t} \\ &:= \sup_{\substack{y \in \mathcal{N}(y) \\ \lambda > 0}} \inf_{\substack{X \in \mathcal{N}(x_0) \\ \lambda > 0}} \sup_{\substack{x \in X \\ t \in (0, \lambda) \\ f(x) \equiv f(x_0) + \lambda}} \inf_{y' \in Y} \frac{f(x + ty') - f(x)}{t}. \end{aligned}$$

If f is continuous, $f^\uparrow(x_0; y)$ may be written more simply as

$$(1.10) \quad \begin{aligned} f^\uparrow(x_0; y) &= \limsup_{\substack{x \rightarrow x_0 \\ t \downarrow 0}} \inf_{y' \rightarrow y} \frac{f(x + ty') - f(x)}{t} \\ &:= \sup_{Y \in \mathcal{N}(y)} \inf_{\substack{x \in \mathcal{N}(x_0) \\ \lambda > 0}} \sup_{\substack{x \in X \\ t \in (0, \lambda)}} \inf_{y' \in Y} \frac{f(x + ty') - f(x)}{t}. \end{aligned}$$

Rockafellar used characterization (1.8) in [18] to extend the subdifferential calculus to the subgradient of (1.7). (See also [6, § 2.9].)

In this paper, we show that if E is finite-dimensional and $f: E \rightarrow \bar{\mathbf{R}}$ is strictly l.s.c., the hypotheses in the subdifferential calculus theorems of [18] can be considerably weakened, and the hypotheses required in proving multiplier rules for nonsmooth mathematical programs can be correspondingly weakened. This is in analogy with the convex case, where in finite dimensions, interiority assumptions are replaced by assumptions about relative interiors. In fact, the convex subgradient calculus of § 23 of [16] can be entirely recaptured as a special case of the results presented here.

Our method of proof differs from that of [18] in that instead of working directly with $f^\uparrow(x_0; \cdot)$ as defined in (1.8), we use an “inversion theorem” (see [4]), the relationship in (1.6), and underlying properties of the Clarke tangent cone.

Here is an outline of the remainder of the paper. In § 2, we list the definitions and collect the preliminary results that we will use in proving subdifferential calculus

formulae. In § 3, we prove our two main subdifferential calculus formulae and give a number of corollaries. In § 4, we apply the results of § 3 to the study of necessary optimality conditions in nonsmooth mathematical programming. In particular, we prove a finite-dimensional version of Theorem 6 of [18] under weaker hypotheses and apply a “Dubovitskii–Milyutin” approach to prove a “Fritz John type” result as in [26]. We investigate in § 5 the possibility of extending a chain rule of Hiriart-Urruty [11, Chap. 8] to functions which are not necessarily locally Lipschitzian. In § 6 we prove inequalities involving the contingent [1] and Ursescu [9] directional derivatives. We then combine these results with those of § 3 to give conditions for equality in the subdifferential calculus theorems of § 3 that somewhat relax the usual “subdifferential regularity” conditions. We also give a generalization of one of our results of § 4 through the use of “upper convex approximates” to these directional derivatives.

An excellent background reference for this paper is Chapter 7 of Aubin and Ekeland’s recent book [3]. In particular, Corollary 3.4 and Propositions 3.10 and 3.14 are derived in [3] by an approach in many ways similar to that employed here.

Two entirely different approaches to this subject can be found in the significant papers [13] and [22]. In [13], Ioffe essentially proves Theorem 3.2 and its corollaries as special cases of corresponding formulae in the calculus of “approximate subdifferentials.” Rockafellar in [22] derives subgradient inclusions (3.3), (3.6), (3.30) and (4.2) by an approach that is “dual” to that taken here and in [18]. The methods used in [22] center around the concepts of the normal cone and proximal normals. Both [13] and [22] go further than this present work in some directions. On the other hand, the chain rule formulation in Theorem 3.17 and the material in § 6 are not discussed in either [13] or [22]. In fact, it is not clear how one might derive Theorem 3.17 by the methods of [13], and the methods of [22] do not readily yield conditions for equality in subdifferential calculus formulae. References [3], [6], [11], [13], [18], [22] and this work combine to form quite an extensive body of information about the generalized subdifferential calculus.

2. Preliminaries.

DEFINITION 2.1. Let E, E_1 be l.c.t.v.s. A function $G: E \rightarrow E_1$ is said to be *strictly differentiable* at $x_0 \in E$ if there exists a linear mapping $\nabla G(x_0): E \rightarrow E_1$ such that

$$(2.1) \quad \lim_{\substack{x \rightarrow x_0 \\ y' \rightarrow y \\ t \downarrow 0}} \frac{G(x + ty') - G(x)}{t} = \nabla G(x_0)y$$

for all $y \in E$.

DEFINITION 2.2. Let E be an l.c.t.v.s.

(a) The set $C \subset E$ is said to be closed near $x_0 \in C$ if there exists $X \in \mathcal{N}(x_0)$ such that $X \cap C$ is closed.

(b) The function $f: E \rightarrow \bar{\mathbf{R}}$ is *strictly l.s.c.* at $x_0 \in E$ if for some $\alpha > f(x_0)$, the function $\min\{f, \alpha\}$ is l.s.c.

It is observed in [21] that if f is strictly l.s.c. at x_0 , then the set $\text{epi } f$ is closed near $(x_0, f(x_0))$.

DEFINITION 2.3. $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ is *isotone* on $D \subset \mathbf{R}^n$ if $F(x) \leq F(y)$ whenever $x, y \in D$ and $x \leq y$ (with respect to the coordinate ordering). F is *strictly isotone* in the i th coordinate at $x := (x_1, \dots, x_n) \in \mathbf{R}^n$ if $F(x) < F(y)$ whenever $x \leq y$ and $x_i < y_i$.

The result that allows us to weaken the “constraint qualifications” of [18] is the following special case of Theorem 4.1 of [4], which itself follows from Ekeland’s variational principle [8] (see also [3, § 7.6]).

THEOREM 2.4. *Let $G: \mathbf{R}^p \rightarrow \mathbf{R}^q$ be strictly differentiable at $x_0 \in D \cap G^{-1}(0)$, where $D \subset \mathbf{R}^p$ is closed near x_0 . Assume that*

$$(2.2) \quad \nabla G(x_0) T_D(x_0) = \mathbf{R}^q.$$

Then

$$(2.3) \quad T_D(x_0) \cap \nabla G(x_0)^{-1}(0) \subset T_{D \cap G^{-1}(0)}(x_0).$$

We will use the following two properties of the Clarke tangent cone in our proofs in § 3. The first follows easily from (1.1).

PROPOSITION 2.5. *Let E, E_1 be l.c.t.v.s., and let $x_0 \in C \subset E$ and $y_0 \in D \subset E_1$. Then*

$$(2.4) \quad T_{C \times D}(x_0, y_0) = T_C(x_0) \times T_D(y_0).$$

PROPOSITION 2.6. *Let E, E_1 be l.c.t.v.s. and $A: E \rightarrow E_1$ be linear and continuous. Let $z_0 \in C \subset E$. Suppose that A is relatively open on C at z_0 ; i.e.,*

$$(2.5) \quad \text{For each } X \in \mathcal{N}(z_0), \text{ there exists } Z \in \mathcal{N}(Az_0) \text{ such that } Z \cap A(C) \subset A(X \cap C).$$

Then

$$(2.6) \quad A(T_C(z_0)) \subset T_{A(C)}(Az_0).$$

Proof. Let $y \in T_C(z_0)$ and $Y \in \mathcal{N}(A(y))$. Then $Y' := A^{-1}(Y)$ is in $\mathcal{N}(y)$. There exists $\lambda > 0$, $X \in \mathcal{N}(z_0)$ such that for all $t \in (0, \lambda)$ and for all $x' \in X \cap C$,

$$(x' + tY') \cap C \neq \emptyset.$$

By (2.5), there exists $Z \in \mathcal{N}(Az_0)$ such that

$$Z \cap A(C) \subset A(X \cap C).$$

Then for each $z \in Z \cap A(C)$, there exists $x' \in X \cap C$ such that $A(x') = z$. For such an x' , $(x' + tY') \cap C \neq \emptyset$ for all $t \in (0, \lambda)$. Hence $Ax' + tY \cap A(C) \neq \emptyset$ for all $t \in (0, \lambda)$, and so $A(y) \in T_{A(C)}(Az_0)$. Thus $A(T_C(z_0)) \subset T_{A(C)}(Az_0)$. \square

Remark 2.7. (a) Condition (2.5) holds in particular whenever A is open and one-to-one on C .

(b) Proposition 2.6 is a special case of Corollary 4.2 of [4] (see also [14]).

In § 3, we will establish calculus rules involving functions of two forms:

(a) $h := f_1 + f_2 \circ F$, where $f_1: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ is strictly l.s.c. at x_0 , $f_2: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ is strictly l.s.c. at $F(x_0)$, and $F: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is strictly differentiable at $x_0 \in \text{dom } f_1 \cap F^{-1}(\text{dom } f_2)$.

(b) $h := F \circ f$, where $f = (f_1, \dots, f_n)$, each $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ is strictly l.s.c. at x_0 , and $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ is isotone.

In (b), we define $F(f(x))$ to be $+\infty$ whenever $f_i(x) = +\infty$ for some i . We also adopt the convention that if $f_i(x) = -\infty$ for some i ,

$$h(x) = \inf \{F(y) \mid f_i(x) < y_i, i = 1, \dots, n, y = (y_1, \dots, y_n)\}.$$

Under this convention, we have

$$(2.7) \quad \text{epi } h = \{(x, z) \mid \exists y_i \in \mathbf{R} \text{ with } f_i(x) \leq y_i, i = 1, \dots, n, F(y_1, \dots, y_n) \leq z\}$$

because F is isotone. We will use this fact in § 3.

The proofs of our calculus rules will consist of two stages:

Stage 1: Establish an inequality involving upper subderivatives with the help of (1.6), Proposition 2.6, Theorem 2.4 and Proposition 2.5.

Stage 2: Use that inequality and a convex subdifferential calculus formula to establish a corresponding inclusion for the subgradients of (1.7).

As part of stage 1, we will make use of the following lemma, which shows that upper subderivatives preserve isotonicity.

LEMMA 2.8. *Let $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be finite at $x_0 \in \mathbf{R}^n$ and isotone on a neighborhood of x_0 . Then $F^\dagger(x_0; \cdot)$ is isotone on \mathbf{R}^n .*

Proof. Let $y_1, y_2 \in \mathbf{R}^n$ with $y_1 \leq y_2$ and $F^\dagger(x_0; y_2) \leq d$. It suffices to show that $F^\dagger(x_0; y_1) \leq d$. To this end, let $\varepsilon > 0$ and $U \in \mathcal{N}(0)$ be given. Suppose F is isotone on $X_1 \in \mathcal{N}(x_0)$. There exists $X_2 \in \mathcal{N}(x_0)$ and $\lambda_0 > 0$ such that

$$X_2 + (0, \lambda_0)(y_i + U) \subset X_1 \quad \text{for } i = 1, 2.$$

Since $(y_2, d) \in T_{\text{epi } F}(x_0, F(x_0))$, there exist $X \subset X_2$, $X \in \mathcal{N}(x_0)$, $\delta > 0$, and $\lambda \in (0, \lambda_0)$ such that for all $x \in X$, $r \in (F(x_0) - \delta, F(x_0) + \delta)$ with $F(x) \leq r$, and for all $t \in (0, \lambda)$, there exists $h \in U$ such that

$$\frac{F(x + t(y_2 + h)) - r}{t} \leq d + \varepsilon.$$

Now $x + t(y_1 + h) \leq x + t(y_2 + h)$ and both $x + t(y_1 + h)$ and $x + t(y_2 + h)$ are in X_1 . By isotonicity of F on X_1 ,

$$\frac{F(x + t(y_1 + h)) - r}{t} \leq \frac{F(x + t(y_2 + h)) - r}{t},$$

and hence $(y_1, d) \in T_{\text{epi } F}(x_0, F(x_0))$, as required. \square

In order to carry out Stage 2, we will require two convex subdifferential calculus formulae. The first is simply a combination of Theorems 23.8 and 23.9 of [16]. We provide a proof of the second result.

THEOREM 2.9 (cf. [16, Thms. 23.8, 23.9]). *Let $f_1: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$, $f_2: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be proper convex functions, and let $A: \mathbf{R}^m \rightarrow \mathbf{R}^n$ be linear. Let $x_0 \in \text{dom } f_1 \cap A^{-1}(\text{dom } f_2)$. Assume that*

$$(2.8) \quad A(\text{ri dom } f_1) \cap \text{ri dom } f_2 \neq \emptyset.$$

Then

$$(2.9) \quad \partial(f_1 + f_2 \circ A)(x_0) = \partial f_1(x_0) + A^T \partial f_2(Ax_0).$$

THEOREM 2.10. *Let $f_i: \mathbf{R}^{m_i} \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots, n$, be proper convex functions and let $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be convex, proper and isotone. Call $f := (f_1, \dots, f_n)$. Assume $x_0 \in \bigcap_{i=1}^n \text{dom } f_i$ and $f(x_0) \in \text{dom } F$. Suppose that*

$$(2.10) \quad \text{int}(\text{dom } F) \cap \text{range } f \neq \emptyset.$$

Then

$$(2.11) \quad \partial(F \circ f)(x_0) = \{\partial(\lambda \cdot f)(x_0) \mid \lambda \in \partial F(f(x_0))\}.$$

If, in addition,

$$(2.12) \quad \bigcap_{i=1}^n \text{ri dom } f_i \neq \emptyset,$$

then

$$(2.13) \quad \partial(F \circ f)(x_0) = \{\lambda \cdot (\partial f_1(x_0), \dots, \partial f_n(x_0)) \mid \lambda \in \partial F(f(x_0))\}.$$

Proof. Let $\lambda \in \partial F(f(x_0))$ and $x^* \in \partial(\lambda \cdot f)(x_0)$. Then $\lambda \geq 0$ and

$$\begin{aligned} x^*(x - x_0) &\leq (\lambda \cdot f)(x) - (\lambda \cdot f)(x_0) \\ &= \lambda \cdot (f(x) - f(x_0)) \\ &\leq F(f(x)) - F(f(x_0)) \\ &= (F \circ f)(x) - (F \circ f)(x_0). \end{aligned}$$

Thus $x^* \in \partial(F \circ f)(x_0)$, so

$$\{\lambda \cdot (\partial f_1(x_0), \dots, \partial f_n(x_0)) \mid \lambda \in \partial F(f(x_0))\} \subset \{\partial(\lambda \cdot f)(x_0) \mid \lambda \in \partial F(f(x_0))\} \subset \partial(F \circ f)(x_0).$$

Conversely, suppose $x_0^* \in \partial(F \circ f)(x_0)$.

Call $h := F \circ f$. Since F is isotone, $h(x) = \min \{F(y) \mid f(x) \leq y\}$ for all $x \in \bigcap_{i=1}^n \text{dom } f_i$. Then $h^*(x_0) := \sup_x x_0^* \cdot x - h(x) = \sup_{x,y} \{x_0^* \cdot x - F(y) \mid y - f(x) \geq 0\}$. Assumption (2.10) guarantees the existence of a Slater point for the above concave program, so we may apply the Lagrange multiplier theorem of [16, § 28]: There exists $\lambda \geq 0$ such that

$$\begin{aligned} h^*(x_0^*) &= \sup_{x,y} x_0^* \cdot x - F(y) + \lambda \cdot (y - f(x)) \\ &= F^*(\lambda) + (\lambda \cdot f)^*(x_0^*). \end{aligned}$$

Then

$$\begin{aligned} x_0^* \cdot x &= h(x_0) + h^*(x_0^*) \\ &= F(f(x_0)) + (\lambda \cdot f)^*(x_0^*) + F^*(\lambda), \end{aligned}$$

and so

$$x_0^* \cdot x_0 + \lambda \cdot f(x_0) = \lambda \cdot f(x_0) + (\lambda \cdot f)^*(x_0^*) + F(f(x_0)) + F^*(\lambda).$$

We now have

$$x_0^* \cdot x_0 = \lambda \cdot f(x_0) + (\lambda \cdot f)^*(x_0^*) \quad \text{and} \quad \lambda \cdot f(x_0) = F(f(x_0)) + F^*(\lambda),$$

implying that

$$\lambda \in \partial F(f(x_0)) \quad \text{and} \quad x_0^* \in \partial(\lambda \cdot f)(x_0).$$

Thus $\partial(F \circ f)(x_0) \subset \{\partial(\lambda \cdot f)(x_0) \mid \lambda \in \partial F(f(x_0))\}$. If in addition (2.12) holds, Theorem 23.8 of [16] gives $x_0^* \in \partial(\lambda \cdot f)(x_0) = \lambda \cdot (\partial f_1(x_0), \dots, \partial f_n(x_0))$, so that (2.13) holds. \square

Remark 2.11. Since $\text{int}(\text{dom } F) \neq \emptyset$ (because F is proper and isotone), (2.10) is equivalent to the seemingly weaker condition

$$\text{ri}(\text{dom } F) \cap \text{ri}(\text{range } f) \neq \emptyset.$$

Remark 2.12. If $\lambda = 0$ in Theorem 2.10, λf_i should be interpreted as the indicator function of $\text{dom } f_i$ (Definition 3.3). This is in keeping with the convention that $(F \circ f)(x) = +\infty$ whenever some $f_i(x) = +\infty$. As a result, $\partial f_i(x_0)$ should be interpreted as $\partial^\infty f_i(x_0)$ in (2.13) and (3.27) (see Definition 3.13).

3. The main theorems and their corollaries. In Stage 1 of the proof of our first calculus formula, we will need a technical lemma verifying that condition (2.5) is satisfied for the appropriate A , C , and z_0 . In the proof of this lemma, for $x = (x_1, \dots, x_p) \in \mathbb{R}^p$ and $\varepsilon > 0$, we use the notation

$$B_\varepsilon(x) := \{y = (y_1, \dots, y_p) \in \mathbb{R}^p : |y_i - x_i| \leq \varepsilon, i = 1, \dots, p\}.$$

LEMMA 3.1. *Let $f_1: \mathbb{R}^n \rightarrow \bar{\mathbb{R}}$, $f_2: \mathbb{R}^m \rightarrow \bar{\mathbb{R}}$ be l.s.c., and let $F: \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^m$ be continuous at $x_0 \in \mathbb{R}^n$. Assume $f_1(x_0)$ and $f_2(F(x_0))$ are finite. Define $A: \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^m \times \mathbb{R} \rightarrow \mathbb{R}^n \times \mathbb{R}$ by $A(x, y, z, r) := (x, y + r)$ and $G: \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^m \times \mathbb{R} \rightarrow \mathbb{R}^m$ by $G(x, y, z, r) := F(x) - z$.*

Then (2.5) is satisfied with A as above, $C := (\text{epi } f_1 \times \text{epi } f_2) \cap G^{-1}(0)$, and $z_0 := (x_0, f_1(x_0), F(x_0), f_2(F(x_0)))$.

Proof. Let $\varepsilon > 0$ be given, and let $X := B_\varepsilon(z_0)$. Since f_1, f_2 are l.s.c. and F is continuous, there exists $\delta \in (0, \varepsilon/3)$ such that for all $x \in B_\delta(x_0)$, we have

$$\begin{aligned} f_1(x) &\geq f_1(x_0) - \varepsilon/3, \\ F(x) &\in B_{\varepsilon/3}(F(x_0)), \\ (f_2 \circ F)(x) &\geq (f_2 \circ F)(x_0) - \varepsilon/3. \end{aligned}$$

Define $N := B_\delta(z_0)$. Since A is surjective, $Z := A(N) \in \mathcal{N}(A z_0)$. We will now verify that $Z \cap A(C) \subset A(X \cap C)$. To do so, let $(\bar{x}, \bar{r}) \in Z \cap A(C)$. Since $(\bar{x}, \bar{r}) \in Z$, there exists $(x, y, z, r) \in N$ with $x = \bar{x}$, $y + r = \bar{r}$. Since $(\bar{x}, \bar{r}) \in A(C)$, there exists $(x', y', z', r') \in C$ with $x' = \bar{x}$, $y' + r' = \bar{r}$, and $f_1(x') \leq y'$, $z' = F(x')$, $f_2(z') \leq r'$. Now $x' \in B_\delta(x_0)$, so $z' \in B_{\varepsilon/3}(F(x_0))$. Also $\bar{r} \in B_{\varepsilon/3}(f_1(x_0)) + B_{\varepsilon/3}(f_2(F(x_0)))$, so $\bar{r} \in B_{2\varepsilon/3}(f_1(x_0) + f_2(F(x_0)))$. Finally, since $y' + r' = \bar{r}$ and $y' \geq f_1(x_0) - \varepsilon/3$, we conclude that $y' \in B_\varepsilon(f_1(x_0))$ and $r' \in B_\varepsilon(f_2(F(x_0)))$. Thus $(x', y', z', r') \in X$, and so $(\bar{x}, \bar{r}) \in A(X \cap C)$. We conclude that $Z \cap A(C) \subset A(X \cap C)$. \square

We now proceed to the first of our two main theorems.

THEOREM 3.2. *Let $F: \mathbf{R}^n \rightarrow \mathbf{R}^m$ be strictly differentiable at x_0 , $f_1: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ finite and strictly l.s.c. at x_0 , and $f_2: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ finite and strictly l.s.c. at $F(x_0)$. Assume that*

$$(3.1) \quad \nabla F(x_0) \text{ dom } f_1^\dagger(x_0; \cdot) - \text{dom } f_2^\dagger(x_0; \cdot) = \mathbf{R}^m.$$

Then for all $y \in \mathbf{R}^n$,

$$(3.2) \quad (f_1 + f_2 \circ F)^\dagger(x_0; y) \leq f_1^\dagger(x_0; y) + f_2^\dagger(F(x_0); \nabla F(x_0)y).$$

Moreover,

$$(3.3) \quad \partial(f_1 + f_2 \circ F)(x_0) \subset \partial f_1(x_0) + (\nabla F(x_0))^T \partial f_2(F(x_0)).$$

Proof. Call $f := f_1 + f_2 \circ F$. Then

$$\begin{aligned} \text{epi } f &= \{(x_1, r) \in \mathbf{R}^n \times \mathbf{R} \mid f_1(x_1) \leq r_1, f_2(x_2) \leq r_2, r = r_1 + r_2, \\ &\quad F(x_1) - x_2 = 0, \text{ for some } x_2 \in \mathbf{R}^m, r_1, r_2 \in \mathbf{R}\}. \end{aligned}$$

Define A , G , and C , and z_0 as in Lemma 3.1, and define $D := \text{epi } f_1 \times \text{epi } f_2$. Then $A(D \cap G^{-1}(0)) = \text{epi } f$.

Now

$$\begin{aligned} \text{epi } f^\dagger(x_0; \cdot) &= T_{A(D \cap G^{-1}(0))}(x_0, f(x_0)) \quad \text{by (1.6)} \\ &\supset A(T_{D \cap G^{-1}(0)}(z_0)) \end{aligned}$$

by Lemma 3.1 and Proposition 2.6. Next observe that (3.1) and Proposition 2.5 ensure that $\nabla G(z_0) T_D(z_0) = \mathbf{R}^m$. We can therefore apply Theorem 2.4 to obtain

$$T_{D \cap G^{-1}(0)}(z_0) \supset T_D(z_0) \cap \nabla G(z_0)^{-1}(0).$$

Thus

$$\begin{aligned} A(T_{D \cap G^{-1}(0)}(z_0)) &\supset A(T_D(z_0) \cap \nabla G(z_0)^{-1}(0)) \\ &= A((\text{epi } f_1^\dagger(x_0; \cdot) \times \text{epi } f_2^\dagger(F(x_0); \cdot)) \\ &\quad \cap \nabla G(z_0)^{-1}(0)) \quad (\text{by Proposition 2.5}) \\ &= A(\{(h_1, r_1, h_2, r_2) \in \mathbf{R}^n \times \mathbf{R} \times \mathbf{R}^m \times \mathbf{R} \mid f_1^\dagger(x_0; h_1) \\ &\quad \leq r_1, f_2^\dagger(F(x_0); h_2) \leq r_2, \nabla F(x_0)h_1 = h_2\}) \\ &= \{(h, r_1 + r_2) \in \mathbf{R}^n \times \mathbf{R} \mid f_1^\dagger(x_0; h) \leq r_1, f_2^\dagger(F(x_0); \nabla F(x_0)h) \leq r_2\} \\ &= \text{epi } [f_1^\dagger(x_0; \cdot) + f_2^\dagger(F(x_0); \nabla F(x_0)(\cdot))]. \end{aligned}$$

Therefore $\text{epi } f^\uparrow(x_0; \cdot) \supset \text{epi } [f_1^\uparrow(x_0; \cdot) + f_2^\uparrow(F(x_0)(\cdot))]$, and so (3.2) holds. The rest of the proof is much as in [18]. Set $p_1 := f_1^\uparrow(x_0; \cdot)$ and $p_2 := f_2^\uparrow(F(x_0); \cdot)$. If either $p_1(0)$ or $p_2(0)$ is $-\infty$, equality holds in (3.3), since (3.2) shows that both sides of the inclusion are then empty. Assume, then, that $p_1(0) = p_2(0) = 0$.

Then

$$\begin{aligned} \partial f(x_0) &= \{z \in \mathbf{R}^n \mid (f_1 + f_2 \circ F)^\uparrow(x_0; y) \geq \langle y, z \rangle \forall y \in \mathbf{R}^n\} \\ &\subset \{z \mid p_1(y) + p_2(\nabla F(x_0)y) \geq \langle y, z \rangle \forall y \in \mathbf{R}^n\} \\ &= \partial(p_1 + p_2 \circ \nabla F(x_0))(0). \end{aligned}$$

Since p_1 and p_2 are convex and proper, and since (3.1) holds, we may apply Theorem 2.9 to obtain

$$\begin{aligned} \partial(p_1 + p_2 \circ \nabla F(x_0))(0) &= \partial p_1(0) + \nabla F(x_0)^T \partial p_2(0) \\ &= \partial f_1(x_0) + \nabla F(x_0)^T \partial f_2(F(x_0)) \end{aligned}$$

by definition, and so (3.3) holds. \square

We can now obtain improved versions, in the finite-dimensional case, of results in [17] and [18].

DEFINITION 3.3. Let $C \subset E$. The *indicator function* of C , denoted i_C , is defined by

$$i_C(x) = \begin{cases} 0 & \text{if } x \in C, \\ +\infty & \text{otherwise.} \end{cases}$$

Observe that for $x_0 \in C$, $i_C^\uparrow(x_0; \cdot) = i_{T_C(x_0)}(\cdot)$ and $\partial i_C(x_0) = N_C(x_0)$. The following is a strengthening of Theorem 5 of [17], which has also been proved by Aubin [2], [3].

COROLLARY 3.4. Let $F_2: \mathbf{R}^m \rightarrow \mathbf{R}^m$ be strictly differentiable at x_0 , and let $C_1 \subset \mathbf{R}^n$ be closed near x_0 and $C_2 \subset \mathbf{R}^m$ closed near $F(x_0)$. Suppose that

$$(3.4) \quad \nabla F(x_0) T_{C_1}(x_0) - T_{C_2}(F(x_0)) = \mathbf{R}^m.$$

Then

$$(3.5) \quad T_{C_1 \cap F^{-1}(C_2)}(x_0) \supset T_{C_1}(x_0) \cap \nabla F(x_0)^{-1} T_{C_2}(F(x_0))$$

and

$$(3.6) \quad N_{C_1 \cap F^{-1}(C_2)}(x_0) \subset N_{C_1}(x_0) + \nabla F(x_0)^T N_{C_2}(F(x_0)).$$

Proof. Let $f_1 := i_{C_1}$, $f_2 := i_{C_2}$ in Theorem 3.2. Then (3.1) becomes (3.4), and (3.5) and (3.6) follow from (3.2) and (3.3), respectively. \square

It is interesting to note that Theorem 2.4, which is used in proving Corollary 3.4, is itself a special case of Corollary 3.4.

Remark 3.5. If $F = A$ is linear, (3.4) can be weakened to

$$(3.7) \quad A(T_{C_1}(x_0)) - T_{C_2}(Ax_0) = \text{span}(AC_1 - C_2).$$

To see this, suppose $C \subset \mathbf{R}^p$, $x_0 \in C$. For a given affine set S with $\text{aff } C \subset S \subset \mathbf{R}^p$, denote by $T_C^S(x_0)$ the Clarke tangent cone of C at x_0 where C is considered as a subset of S rather than as a subset of \mathbf{R}^p . It is easy to see that $T_C^S(x_0) = T_C(x_0)$. Without loss of generality, we may assume $x_0 = 0$, since $T_{C-x_0}(0) = T_C(x_0)$ and $x_0 \in C_1 \cap A^{-1}(C_2)$ if and only if $0 \in (C_1 - x_0) \cap A^{-1}(C_2 - Ax_0)$. Call $V := \text{span } C_1$ and $W := \text{span}(AC_1 - C_2)$. If (3.7) holds, then $A(T_{C_1}(x_0)) - T_{C_2}^W(Ax_0) = W$ and A may be considered as $A: V \rightarrow W$. By Corollary 3.4, $T_{C_1 \cap A^{-1}(C_2)}^V(x_0) \supset T_{C_1}^V(x_0) \cap A^{-1} T_{C_2}^W(Ax_0)$, which is the same as (3.5).

COROLLARY 3.6. Let $f_1: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}, f_2: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be finite and strictly l.s.c. at x_0 . Assume that

$$(3.8) \quad \text{dom } f_1^\dagger(x_0; \cdot) - \text{dom } f_2^\dagger(x_0; \cdot) = \mathbf{R}^n.$$

Then for all $y \in \mathbf{R}^n$,

$$(3.9) \quad (f_1 + f_2)^\dagger(x_0; y) \leq f_1^\dagger(x_0; y) + f_2^\dagger(x_0; y).$$

In addition,

$$(3.10) \quad \partial(f_1 + f_2)(x_0) \subset \partial f_1(x_0) + \partial f_2(x_0).$$

Proof. Set $m = n$ and $F := I$ in Theorem 3.2. \square

Remark 3.7. (a) Corollary 3.6 is more general than the specialization of Theorem 2 of [18] to strictly l.s.c. functions with finite-dimensional domains, since Rockafellar's assumption

$$(3.11) \quad \text{dom } f_1^\dagger(x_0; \cdot) \cap \text{int dom } f_2^\dagger(x_0; \cdot) \neq \emptyset$$

implies, but is not implied by (3.8). Here is an example which satisfies (3.8) but not (3.11): Define $f_1: \mathbf{R}^2 \rightarrow \mathbf{R}, f_2: \mathbf{R}^2 \rightarrow \mathbf{R}$ by $f_1(x, y) := |x|^{1/2}, f_2(x, y) := |y|^{1/2}$. Then $\text{dom } f_1^\dagger(0; \cdot) = 0 \times \mathbf{R}$ and $\text{dom } f_2^\dagger(0; \cdot) = \mathbf{R} \times 0$, both of which have empty interior.

(b) Condition (3.8) can actually be weakened to

$$(3.12) \quad \text{dom } f_1^\dagger(x_0; \cdot) - \text{dom } f_2^\dagger(x_0; \cdot) = \text{span}(\text{dom } f_1 - \text{dom } f_2).$$

To see this, simply observe that we can again assume that $x_0 = 0$, and we can then replace \mathbf{R}^n by $S := \text{span}(\text{dom } f_1 - \text{dom } f_2)$, considering f_1 and f_2 as $f_1: S \rightarrow \bar{\mathbf{R}}$ and $f_2: S \rightarrow \bar{\mathbf{R}}$.

It is not possible, however, to weaken the hypothesis still further to

$$(3.13) \quad \text{ri dom } f_1^\dagger(x_0; \cdot) \cap \text{ri dom } f_2^\dagger(x_0; \cdot) \neq \emptyset.$$

For example, let $C_1 := \{(x, y) \mid y = x^2\}, C_2 := \{(x, y) \mid y = -x^2\}$, and $f_1 := i_{C_1}, f_2 := i_{C_2}$. Let $x_0 = (0, 0)$. Then $f_1^\dagger(x_0; \cdot) = f_2^\dagger(x_0; \cdot) = i_{\mathbf{R} \times 0}(\cdot)$, while

$$(f_1 + f_2)^\dagger(x_0; \cdot) = i_{T_{C_1 \cap C_2}(x_0)}(\cdot) = i_{\{(0,0)\}}(\cdot).$$

Hence (3.9) does not hold for $y = (x, 0)$ with $x \neq 0$, although (3.13) is satisfied.

(c) If f_1 and f_2 are not strictly l.s.c., then (3.8) may hold without either (3.9) or (3.10) being satisfied. For example, let $C_1 := \mathbf{Q}$, the set of rational numbers, and let $C_2 = (\mathbf{R}/\mathbf{Q}) \cup \{0\}$. Define $f_1 := i_{C_1}, f_2 := i_{C_2}$, and let $x_0 = 0$. Then $T_{C_1}(0) = T_{C_2}(0) = \mathbf{R}$, so (3.8) holds, and $f_1^\dagger(x_0; \cdot) = f_2^\dagger(x_0; \cdot) = i_{\mathbf{R}}(\cdot)$. However, $C_1 \cap C_2 = \{0\}$, so we have $(f_1 + f_2)^\dagger(x_0; \cdot) = i_{\{0\}}(\cdot)$, and (3.9) does not hold for $y \neq 0$.

DEFINITION 3.8. Let $C \subset \mathbf{R}^p$. Define

$$\Delta^n C := \{(x_1, \dots, x_n) \mid x_i \in C, x_1 = x_2 = \dots = x_n\}.$$

DEFINITION 3.9. Let $C_i \subset \mathbf{R}^m, i = 1, \dots, n$ be convex sets. The sets $C_i, i = 1, \dots, n$, are said to be in *strong general position* [27] if

$$(3.14) \quad 0 \in \text{int} \left[\Delta^{n-1} C_1 - \prod_{j=2}^n C_j \right].$$

If the sets are cones, (3.14) is equivalent to

$$(3.15) \quad \Delta^{n-1} C_1 - \prod_{j=2}^n C_j = \mathbf{R}^{(n-1)m}.$$

Another equivalent way to write (3.14) is

$$(3.16) \quad 0 \in \text{int} \left[\Delta^n \mathbf{R}^m - \prod_{j=1}^n C_j \right].$$

(see [27] for a thorough discussion of this concept.) By (3.16), the order in which the sets in (3.14) are listed does not matter.

The following is an important special case of Corollary 3.4:

PROPOSITION 3.10 ([26], [3]). *Let $D_i \subset \mathbf{R}^m$, $i = 1, \dots, n$ be closed near $y_0 \in \bigcap_{i=1}^n D_i$. Assume $T_{D_i}(y_0)$, $i = 1, \dots, n$ are in strong general position. Then*

$$(3.17) \quad T_{D_1 \cap \dots \cap D_n}(y_0) \supset \bigcap_{i=1}^n T_{D_i}(y_0)$$

and

$$(3.18) \quad N_{D_1 \cap \dots \cap D_n}(y_0) \subset \sum_{i=1}^n N_{D_i}(y_0).$$

Proof. Call $C_1 := D_1 \times \dots \times D_n$, and let C_2 be the origin in $\mathbf{R}^{(n-1)m}$. Define $F: \mathbf{R}^{nm} \rightarrow \mathbf{R}^{(n-1)m}$ by $F(x_1, \dots, x_n) := (x_1 - x_2, \dots, x_1 - x_n)$. Apply Corollary 3.4 with $x_0 := (y_0, \dots, y_0)$. By Proposition 2.5, (3.4) reduces to $T_{D_i}(y_0)$, $i = 1, \dots, n$, being in strong general position. By (3.5),

$$T_{\Delta^n(D_1 \cap \dots \cap D_n)}(y_0, \dots, y_0) \supset (T_{D_1}(y_0) \times \dots \times T_{D_n}(y_0)) \cap \Delta^n \mathbf{R}^m, \quad \text{or}$$

$$\Delta^n T_{D_1 \cap \dots \cap D_n}(y_0) \supset \Delta^n \bigcap_{i=1}^n T_{D_i}(y_0).$$

Thus (3.17) holds. Finally, (3.18) follows from (3.6). \square

Remark 3.11. By (3.7), the strong general position assumption can be weakened to

$$(3.19) \quad \Delta^{n-1} T_{D_1}(y_0) - \prod_{i=2}^n T_{D_i}(y_0) = \prod_{j=2}^n \text{span}(D_1 - D_j).$$

We can derive from Proposition 3.10 a formula for the subgradient of $f(x) := \max_{1 \leq i \leq n} f_i(x)$, where $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ are strictly l.s.c. We start with a lemma which we will use to show that the condition “ $\text{dom } f_i^\uparrow(x_0; \cdot)$, $i = 1, \dots, n$, are in strong general position” is sufficient to guarantee this subgradient formula.

LEMMA 3.12. *Suppose $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots, n$ are such that*

$$\Delta^{n-1} \text{dom } f_1 - \prod_{i=2}^n \text{dom } f_i = \mathbf{R}^{m(n-1)}.$$

Then

$$\Delta^{n-1} \text{epi } f_1 - \prod_{i=2}^n \text{epi } f_i = (\mathbf{R}^m \times \mathbf{R})^{n-1}.$$

Proof. We must show $(\mathbf{R}^m \times \mathbf{R})^{n-1} \subset \Delta^{n-1} \text{epi } f_1 - \prod_{i=2}^n \text{epi } f_i$. Let $(y_1, s_1, \dots, y_{n-1}, s_{n-1}) \in (\mathbf{R}^m \times \mathbf{R})^{n-1}$. Then there exist $x_i \in \text{dom } f_i$, $i = 1, \dots, n$ such that $x_1 - x_i = y_{i-1}$, $i = 2, \dots, n$. Choose r_i , $i = 1, \dots, n$, such that $r_i \geq f_i(x_i)$. If $r_1 - r_2 < s_1$, replace r_1 by $s_1 + r_2$. If $r_1 - r_2 > s_1$, replace r_2 by $r_1 - s_1$. Now if $r_1 - r_3 > s_2$, replace r_3 by $r_1 - s_2$. If $r_1 - r_3 < s_2$, replace r_1 by $s_2 + r_3$ and r_2 by $s_2 + r_3 - s_1$. Proceed in this manner. After $k-1$ steps, we have $r_1 - r_i = s_{i-1}$, $i = 2, \dots, k$. If $r_1 - r_{k+1} > s_k$, replace r_{k+1} by $r_1 - s_k$. If $r_1 - r_{k+1} < s_k$, replace r_1 by $s_k + r_{k+1}$ and replace r_j , $j = 2, \dots, k$ by $s_k + r_{k+1} - s_{j-1}$.

After $n-1$ steps, we obtain $r_1 - r_i = s_{i-1}$, $i = 2, \dots, n$, and $(x_i, r_i) \in \text{epi } f_1$. Thus $(y_i, s_j) \in \Delta^{n-1} \text{epi } f_1 - \prod_{i=2}^n \text{epi } f_i$ and so $(\mathbf{R}^m \times \mathbf{R})^{n-1} \subset \Delta^{n-1} \text{epi } f_1 - \prod_{i=2}^n \text{epi } f_i$. \square

DEFINITION 3.13. Let $f: E \rightarrow \bar{\mathbf{R}}$ be finite at $x \in E$. The *asymptotic generalized gradient* of f at x is the set

$$\partial^\infty f(x) = \{z \in E^* \mid (z, 0) \in N_{\text{epi } f}(x, f(x))\}.$$

In our next result, we will use the fact that if $\partial f(x) \neq \emptyset$, then

$$(3.20) \quad N_{\text{epi } f}(x, f(x)) = \bigcup_{\lambda > 0} \lambda(\partial f(x), -1) \cup (\partial^\infty f(x), 0)$$

([18], [6]).

PROPOSITION 3.14. Let $f_i: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots, n$ be strictly l.s.c. and finite at x_0 . Define $f(x) := \max_{1 \leq i \leq n} f_i(x)$ and $I(x) := \{i \in \{1, \dots, n\} \mid f_i(x) = f(x)\}$. Suppose that f_i is continuous at x_0 for each $i \notin I(x_0)$, and suppose that $\text{dom } f_i^\uparrow(x_0; \cdot)$, $i = 1, \dots, n$, are in strong general position. Then for all $y \in \mathbf{R}^n$,

$$(3.21) \quad f^\uparrow(x_0; y) \leq \max_{I(x_0)} f_i^\uparrow(x_0; y).$$

If also $\partial f_i(x_0)$, $i \in I(x_0)$, are nonempty, then

$$(3.22) \quad \partial f(x_0) \subset \sum_{I(x_0)} (\lambda_i \partial f_i(x_0) \cup \partial^\infty f_i(x_0))$$

for some $\lambda_i \geq 0$ with $\sum_{I(x_0)} \lambda_i = 1$.

Proof. Call $D_i := \text{epi } f_i$, $i = 1, \dots, n$. Since f_j , $j \in I(x_0)$, are strictly l.s.c. and f_j , $j \notin I(x_0)$, are continuous at x_0 , $T_{D_j}(x_0, f(x_0)) = \mathbf{R}^{m+1}$ for all $j \notin I(x_0)$. Thus we only need to consider D_j with $j \in I(x_0)$. By Lemma 3.12, our assumption that $\text{dom } f_i^\uparrow(x_0; \cdot)$, $i = 1, \dots, n$, are in strong general position implies that $T_{D_i}(x_0, f(x_0))$, $i \in I(x_0)$, are also in strong general position. We may then apply Proposition 3.10. By (3.17),

$$\text{epi } f^\uparrow(x_0; \cdot) \supset \text{epi } \max_{i \in I(x_0)} f_i^\uparrow(x_0; \cdot),$$

which gives (3.21). If also $\partial f_i(x_0)$, $i \in I(x_0)$, are nonempty, we have by (3.18) and (3.20) that

$$\bigcup_{\lambda > 0} \lambda(\partial f(x_0), -1) \subset \sum_{i \in I(x_0)} \left(\bigcup_{\lambda_i > 0} \lambda_i(\partial f_i(x_0), -1) \cup (\partial^\infty f_i(x_0), 0) \right).$$

To obtain (3.22), set $\lambda = 1$ on the left-hand side of the above inclusion. \square

In the proof of our second main result, we will use another technical lemma to ensure that we may apply Proposition 2.6.

LEMMA 3.15. Let $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots, n$ be finite and strictly l.s.c. at x_0 , and let $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be l.s.c. Call $f := (f_1, \dots, f_n)$. Assume $F(f(x_0))$ is finite and F is isotone on $B_{t_0}(f(x_0)) + \mathbf{R}_+^n$ for some $t_0 > 0$. Define

$$A: \mathbf{R}^{nm+2n+1} \rightarrow \mathbf{R}^{m+1} \quad \text{by}$$

$$A(x_1, y_1, \dots, x_n, y_n, z_1, \dots, z_n, r) := (x_1, r).$$

(Here $x_i \in \mathbf{R}^m$, $y_i, z_i \in \mathbf{R}$.) Define

$$G: \mathbf{R}^{nm+2n+1} \rightarrow \mathbf{R}^{m(n-1)+n} \quad \text{by}$$

$$G(x_1, y_1, \dots, x_n, y_n, z_1, \dots, z_n, r) = (x_1 - x_2, \dots, x_1 - x_n, y_1 - z_1, \dots, y_n - z_n).$$

Assume for each $j \in \{1, \dots, n\}$ that either

- (1) f_j is continuous at x_0 , or
- (2) F is strictly isotone in the j th coordinate at $f(x_0)$.

Then (2.5) is satisfied with A as above,

$$C := (\text{epi } f_1 \times \dots \times \text{epi } f_n \times \text{epi } F) \cap G^{-1}(0), \text{ and}$$

$$z_0 := (x_0, f_1(x_0), \dots, x_0, f_n(x_0), f_1(x_0), \dots, f_n(x_0), F(f(x_0))).$$

Proof. For a given $\varepsilon > 0$, let $X := B_\varepsilon(z_0)$. Let $I \subset \{1, \dots, n\}$ be the set of coordinates in which F is strictly isotone at $f(x_0)$. For $t > 0$, define $U_t := \{(y_1, \dots, y_n) \in \mathbb{R}^n \mid y_i \geq f_i(x_0) - t, i = 1, \dots, n\}$. Suppose $i \in I$. We claim that there exists $\mu_i \in (0, t_0)$ such that

$$F(f_1(x_0) - \mu_i, \dots, f_i(x_0) + \varepsilon, \dots, f_n(x_0) - \mu_i) > F(f(x_0)).$$

If not, then for all $t \in (0, t_0)$,

$$F(f_1(x_0) - t, \dots, f_i(x_0) + \varepsilon, \dots, f_n(x_0) - t) \leq F(f(x_0)).$$

But since F is l.s.c., it follows that

$$F(f_1(x_0), \dots, f_i(x_0) + \varepsilon, \dots, f_n(x_0)) \leq F(f(x_0)).$$

This contradicts our assumption that $i \in I$. So for each $i \in I$, we can choose $\mu_i \in (0, t_0)$ with

$$\delta_i := F(f_1(x_0) - \mu_i, \dots, f_i(x_0) + \varepsilon, \dots, f_n(x_0) - \mu_i) - F(f(x_0)) > 0.$$

Let $\mu = \min_I \mu_i$, and let $\delta = \frac{1}{2} \min_I \delta_i$. Then if $r \in B_\delta(F(f(x_0))) \cap F(U_\mu)$, it follows from the isotonicity of F that $r = F(y)$ for some $y = (y_1, \dots, y_n)$ with $y_i \leq f_i(x_0) + \varepsilon$ for all $i \in I$.

Now by assumptions (1) and (2), there exists $\delta_0 \in (0, \min(\mu, \delta))$ such that $f_j(x) \in B_\mu(f_j(x_0))$ whenever $x \in B_{\delta_0}(x_0)$, $j \notin I$ and $f_j(x) \geq f_j(x_0) - \mu$ whenever $x \in B_{\delta_0}(x_0)$, $j \in I$. Let $N = B_{\delta_0}(z_0)$. Again $Z := A(N) \in \mathcal{N}(Az_0)$. We will now show that $Z \cap A(C) \subset A(X \cap C)$. Suppose $(\bar{x}, \bar{r}) \in Z \cap A(C)$. Since $(\bar{x}, \bar{r}) \in A(N)$, \bar{x} must be in $B_{\delta_0}(x_0)$, and \bar{r} in $B_{\delta_0}(F(f(x_0)))$. Since $(\bar{x}, \bar{r}) \in A(C)$, there exists $y \in \mathbb{R}^n$ with $f(\bar{x}) \leq y$ and $F(y) \leq \bar{r}$. Thus $\bar{y} = f(\bar{x})$ satisfies $F(\bar{y}) \leq \bar{r}$, $\bar{y}_i \in B_\mu(f_j(x_0))$ for all $j \notin I$, and $f_j(x_0) - \mu \leq \bar{y}_j \leq f_j(x_0) + \varepsilon$ for all $j \in I$. We conclude that $(\bar{x}, \bar{y}_1, \dots, \bar{x}, \bar{y}_n, \bar{y}_1, \dots, \bar{y}_n, \bar{r}) \in X \cap C$, and so $(\bar{x}, \bar{r}) \in A(X \cap C)$. \square

Remark 3.16. The hypotheses of Lemma 3.15 hold in the following important cases:

- (a) $F(y_1, \dots, y_n) := \sum_{i=1}^n y_i$ and each f_n strictly l.s.c. at x_0 .
- (b) $F(y_1, \dots, y_n) := \prod_{i=1}^n y_i$ and each f_j positive and strictly l.s.c. at x_0 .
- (c) $F(y_1, \dots, y_n) := \max_{1 \leq j \leq n} y_j$ and each f_j strictly l.s.c. at x_0 , with f_j continuous at x_0 for all $j \notin I(x_0)$, where $I(x_0) := \{i \in \{1, \dots, n\} \mid f_i(x_0) = \max_{1 \leq j \leq n} f_j(x_0)\}$.

THEOREM 3.17. Let $f_i: \mathbb{R}^m \rightarrow \bar{\mathbb{R}}$, $i = 1, \dots, n$ be finite and strictly l.s.c. at x_0 , and define $f := (f_1, \dots, f_n)$. Let $F: \mathbb{R}^n \rightarrow \bar{\mathbb{R}}$ be finite at $f(x_0)$, isotone on the union of some neighborhood of $f(x_0)$ and $\text{Range } f + \mathbb{R}_+^n$, and l.s.c. Assume that for each $j \in \{1, \dots, n\}$, either

$$(3.23) \quad f_j \text{ is continuous at } x_0, \text{ or}$$

$$(3.24) \quad F \text{ is strictly isotone in the } j\text{th coordinate at } f(x_0).$$

Assume also that

$$(3.25) \quad (\Delta^n \mathbb{R}^n \times \text{dom } F^\uparrow(f(x_0); \cdot)) - S = \mathbb{R}^{nm+n}$$

where

$$S := \{(y_1, \dots, y_n, r_1, \dots, r_n) \mid (y_i, r_i) \in \text{epi } f_i^\uparrow(x_0; \cdot), i = 1, \dots, n\}.$$

Then for all $y \in \mathbf{R}^m$,

$$(3.26) \quad (F \circ f)^\uparrow(x_0; y) \leq F^\uparrow(f(x_0); f_1^\uparrow(x_0; y), \dots, f_n^\uparrow(x_0; y)).$$

If in addition each $f_i^\uparrow(x_0; \cdot)$ is proper, then

$$(3.27) \quad \partial(F \circ f)(x_0) \subset \{\lambda \cdot (\partial f_1(x_0), \dots, \partial f_n(x_0)) \mid \lambda \in \partial F(f(x_0))\}.$$

Proof. Call $h := F \circ f$. Since F is isotone on $\text{Range } f + \mathbf{R}_+^n$,

$$\text{epi } h = \{(x, r) \in \mathbf{R}^m \times \mathbf{R}, \exists (y_1, \dots, y_n) \in \mathbf{R}^n \text{ with } F(y_1, \dots, y_n) \leq r, f_i(x) \leq y_i, 1 \leq i \leq n\}.$$

Define the functions G and A as in Lemma 3.15, and define

$$D := \text{epi } f_1 \times \dots \times \text{epi } f_n \times \text{epi } F,$$

$$C := D \cap G^{-1}(0).$$

Then $\text{epi } h = A(C)$. Assumptions (3.23) and (3.24) allow us to apply Lemma 3.15 and Proposition 2.6. Thus

$$\begin{aligned} \text{epi } h^\uparrow(x_0; \cdot) &= T_{A(C)}(x_0, h(x_0)) \quad (\text{by (1.6)}) \\ &\supset A(T_C(z_0)) \quad \text{where } z_0 \\ &:= (x_0, f_1(x_0), \dots, x_0, f_n(x_0), f_1(x_0), \dots, f_n(x_0), h(x_0)) \\ &\quad (\text{by Lemma 3.15 and Proposition 2.6}) \\ &\supset A(T_D(z_0) \cap \nabla G(z_0)^{-1}(0)) \end{aligned}$$

by Theorem 2.4, since (3.25) says exactly that

$$\begin{aligned} \nabla G(z_0) T_D(z_0) &= \mathbf{R}^{(n-1)m+n}, \\ &= \{(x, r) \in \mathbf{R}^m \times \mathbf{R} \mid \exists y \in \mathbf{R}^n \text{ with } f_i^\uparrow(x_0; x) \leq y_i, F^\uparrow(f(x_0); y) \leq r\} \\ &= \{(x, r) \mid F^\uparrow(f(x_0); f_1^\uparrow(x_0; x), \dots, f_n^\uparrow(x_0; x)) \leq r\} \end{aligned}$$

since $F^\uparrow(f(x_0); \cdot)$ is itself isotone (Lemma 2.8). Thus $\text{epi } h^\uparrow(x_0; \cdot) \supset \text{epi } F^\uparrow(f(x_0); f_1^\uparrow(x_0; \cdot), \dots, f_n^\uparrow(x_0; \cdot))$, and so (3.26) holds.

Now if $F^\uparrow(f(x_0); 0) = -\infty$, (3.26) shows that both sides of (3.27) are empty. Assume, then, that $F^\uparrow(f(x_0); \cdot)$ is proper. Since each $f_i^\uparrow(x_0; \cdot)$ is convex and proper and (3.25) implies that (2.10) and (2.12) hold for $F^\uparrow(f(x_0); \cdot)$ and $(f_1^\uparrow(x_0; \cdot), \dots, f_n^\uparrow(x_0; \cdot))$, we may apply Theorem 2.10. We have

$$\begin{aligned} \partial(F \circ f)(x_0) &= \{z \in \mathbf{R}^m \mid (F \circ f)^\uparrow(x_0; y) \geq \langle y, z \rangle \forall y \in \mathbf{R}^m\} \\ &\subset \{z \in \mathbf{R}^m \mid F^\uparrow(f(x_0); f_1^\uparrow(x_0; y), \dots, f_n^\uparrow(x_0; y)) \geq \langle y, z \rangle \forall y \in \mathbf{R}^m\} \\ &= \partial((F^\uparrow(f(x_0); \cdot)) \circ (f_1^\uparrow(x_0; \cdot), \dots, f_n^\uparrow(x_0; \cdot)))(0) \\ &= \{\lambda \cdot (\partial f_1^\uparrow(x_0; \cdot)(0), \dots, \partial f_n^\uparrow(x_0; \cdot)(0)) \mid \lambda \in \partial F^\uparrow(f(x_0); \cdot)(0)\} \\ &= \{\lambda \cdot (\partial f_1(x_0), \dots, \partial f_n(x_0)) \mid \lambda \in \partial F(f(x_0))\}. \quad \square \end{aligned}$$

Remark 3.18. (a) Assumption (3.25) reduces to a simple, familiar-looking form in important special cases. For example, if $n = 1$, (3.25) becomes

$$(3.28) \quad \text{Range } f_1^\uparrow(x_0; \cdot) - \text{dom } F^\uparrow(f_1(x_0); \cdot) = \mathbf{R}.$$

If F is as in Remark 3.16(a) or (b), (3.25) reduces to the assumption that $\text{dom } f_i^\uparrow(x_0; \cdot)$, $i = 1, \dots, n$ are in strong general position.

(b) The assumption that $f_i^\uparrow(x_0; 0) = 0$, $i = 1, \dots, n$ is not needed in important special cases. For example, if F is as in Remark 3.16(a) or (b) and $f_i^\uparrow(x_0; 0) = -\infty$ for some i , then both sides of (3.27) will equal \emptyset .

(c) Corollaries of Theorem 3.17 include Corollary 3.6, Proposition 3.10, and Proposition 3.14 (without our having to use Lemma 3.12).

(d) Any isotone function $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ is directionally Lipschitzian for all $y \leq 0$; i.e.,

$$\inf_{\substack{Y \in \mathcal{N}(y) \\ N \in \mathcal{N}(x_0, F(x_0)) \\ \lambda > 0}} \sup_{\substack{y' \in Y \\ (x, \alpha) \in N \cap \text{epi } F \\ t \in (0, \lambda)}} \frac{F(x + ty') - \alpha}{t} < +\infty$$

for all $y \leq 0$ (see [19, Prop. 4]). This property plays a crucial role in the subdifferential calculus results of [18]. However, there is no analogue of Theorem 3.17 for F merely directionally Lipschitzian, as we will see in § 5.

From Theorem 3.17 we can derive an extension of Corollary 3.6 to n functions, and a product rule for (locally) nonnegative functions.

COROLLARY 3.19. *Let $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots, n$ be strictly l.s.c. and finite at x_0 , and suppose that $\text{dom } f_i^\uparrow(x_0; \cdot)$, $i = 1, \dots, n$ are in strong general position. Then for all $y \in \mathbf{R}^m$,*

$$(3.29) \quad (f_1 + \dots + f_n)^\uparrow(x_0; y) \leq \sum_{i=1}^n f_i^\uparrow(x_0; y).$$

Moreover,

$$(3.30) \quad \partial(f_1 + \dots + f_n)(x_0) \subset \sum_{i=1}^n \partial f_i(x_0).$$

Proof. Let $F(x_1, \dots, x_n) = \sum_{i=1}^n x_i$ in Theorem 3.17. F is continuous and strictly isotone in each coordinate. Assumption (3.25) in this case reduces to $\text{dom } f_i^\uparrow(x_0; \cdot)$, $i = 1, \dots, n$ being in strong general position. As explained in Remark 3.18(b), the assumption that each $f_i^\uparrow(x_0; 0) = 0$ is not needed. Then (3.29) follows from (3.26) and (3.30) from (3.27). \square

COROLLARY 3.20. *Let $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots, n$ be nonnegative on \mathbf{R}^m and strictly l.s.c. and positive at $x_0 \in \bigcap_{i=1}^n \text{dom } f_i$. Suppose that $\text{dom } f_i^\uparrow(x_0; \cdot)$, $i = 1, \dots, n$, are in strong general position. Then for all $y \in \mathbf{R}^m$,*

$$(3.31) \quad \left(\prod_{i=1}^n f_i \right)^\uparrow(x_0; y) \leq \sum_{i=1}^n \left(\prod_{j \neq i} f_j(x_0) \right) f_i^\uparrow(x_0; y).$$

Moreover,

$$(3.32) \quad \partial \left(\prod_{i=1}^n f_i \right)(x_0) \subset \sum_{i=1}^n \left(\prod_{j \neq i} f_j(x_0) \right) \partial f_i(x_0).$$

Proof. Let $F(x_1, \dots, x_n) = \prod_{i=1}^n x_i$ in Theorem 3.17. F is continuous and strictly isotone in each coordinate since f_i is nonnegative. Condition (3.25) again reduces to $\text{dom } f_i^\uparrow(x_0; \cdot)$, $i = 1, \dots, n$, being in strong general position. As explained in Remark 3.18(b), the assumption that each $f_i^\uparrow(x_0; \cdot) = 0$ is not needed. Then (3.31) follows from (3.26) and (3.32) from (3.27). \square

One special case of Corollary 3.20 is a quotient rule where the denominator is continuous and positive.

LEMMA 3.21. Suppose $g : E \rightarrow \bar{\mathbf{R}}$ is continuous and positive at $x_0 \in \text{dom } g$. Then

$$(3.33) \quad \left(\frac{1}{g}\right)^\uparrow(x_0; y) = \frac{(-g)^\uparrow(x_0; y)}{(g(x_0))^2} \quad \text{for all } y \in E,$$

and

$$(3.34) \quad \partial\left(\frac{1}{g}\right)(x_0) = \frac{1}{(g(x_0))^2} \partial(-g)(x_0).$$

Proof. First observe that (3.34) follows immediately from (3.33) because $1/(g(x_0))^2 > 0$. To prove (3.33), use (1.10) to write

$$\begin{aligned} \left(\frac{1}{g}\right)^\uparrow(x_0; y) &= \limsup_{\substack{x \rightarrow x_0 \\ t \downarrow 0}} \inf_{y' \rightarrow y} \frac{(1/g(x + ty')) - (1/g(x))}{t} \\ &= \limsup_{\substack{x \rightarrow x_0 \\ t \downarrow 0}} \inf_{y' \rightarrow y} \frac{(-g)(x + ty') - (-g)(x)}{t} \cdot \frac{1}{g(x + ty')(g(x))} \\ &= \limsup_{\substack{x \rightarrow x_0 \\ t \downarrow 0}} \inf_{y' \rightarrow y} \frac{(-g)(x + ty') - (-g)(x)}{t} \lim_{\substack{x \rightarrow x_0 \\ t \downarrow 0 \\ y' \rightarrow y}} \frac{1}{g(x + ty')g(x)} \end{aligned}$$

(by Lemma 5.2, which we prove in § 5).

$$= \frac{1}{(g(x_0))^2} (-g)^\uparrow(x_0; y). \quad \square$$

PROPOSITION 3.22. Let $f : \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ be nonnegative on $\text{dom } f$ and strictly l.s.c. and positive at x_0 , and let $g : \mathbf{R}^m \rightarrow \mathbf{R}$ be positive and continuous at $x_0 \in \text{dom } g \cap \text{dom } f$. Assume that

$$(3.35) \quad \text{dom } f^\uparrow(x_0; \cdot) - \text{dom } (-g)^\uparrow(x_0; \cdot) = \mathbf{R}^m.$$

Then

$$(3.36) \quad \left(\frac{f}{g}\right)^\uparrow(x_0; y) \leq \frac{f(x_0)(-g)^\uparrow(x_0; y) + g(x_0)f^\uparrow(x_0; y)}{(g(x_0))^2} \quad \text{for all } y \in \mathbf{R}^m$$

and

$$(3.37) \quad \partial\left(\frac{f}{g}\right)(x_0) \subset \frac{f(x_0)\partial(-g)(x_0) + g(x_0)\partial f(x_0)}{(g(x_0))^2}.$$

Proof. By Lemma 3.21, $\text{dom } (1/g)^\uparrow(x_0; \cdot) = \text{dom } (-g)^\uparrow(x_0; \cdot)$, so (3.35) ensures that we can apply Corollary 3.20 with $n = 2$, $f_1 := f$, and $f_2 := 1/g$. By (3.31) and (3.33),

$$\begin{aligned} \left(\frac{f}{g}\right)^\uparrow(x_0) &\leq f(x_0)\left(\frac{1}{g}\right)^\uparrow(x_0; y) + \frac{1}{g(x_0)}f^\uparrow(x_0; y) \\ &= \frac{f(x_0)}{(g(x_0))^2}(-g)^\uparrow(x_0; y) + \frac{1}{g(x_0)}f^\uparrow(x_0; y) \\ &= \frac{f(x_0)(-g)^\uparrow(x_0; y) + g(x_0)f^\uparrow(x_0; y)}{(g(x_0))^2}. \end{aligned}$$

Similarly, by (3.32) and (3.34),

$$\begin{aligned} \partial\left(\frac{f}{g}\right)(x_0) &\subset f(x_0)\partial\left(\frac{1}{g}\right)(x_0) + \frac{1}{g(x_0)}\partial f(x_0) \\ &= \frac{f(x_0)}{(g(x_0))^2}\partial(-g)(x_0) + \frac{1}{g(x_0)}\partial f(x_0) \\ &= \frac{f(x_0)\partial(-g)(x_0) + g(x_0)\partial f(x_0)}{(g(x_0))^2}. \end{aligned} \quad \square$$

Remark 3.23. If g is locally Lipschitzian near x_0 , then $(-g)^\uparrow(x_0; y) = -g^\uparrow(x_0; y)$, $\partial(-g)(x_0) = -\partial g(x_0)$, and (3.35) is automatically satisfied. If in addition f is locally Lipschitzian near x_0 , Proposition 3.22 almost reduces to the quotient rule of [11, Chap. 8] and [6, Chap. 2]. (The hypotheses of Proposition 3.22 include the assumption that $f(x_0) \neq 0$, which is not needed in [6] or [11].)

4. Application to constrained optimization problems.

PROPOSITION 4.1 ([18], [20]). *Suppose $f: E \rightarrow \bar{\mathbf{R}}$ has a local minimum at $x_0 \in E$. Then $0 \in \partial f(x_0)$.*

Combining Proposition 4.1 with subdifferential calculus results of the preceding section, we can give a strengthened version, in finite dimensions, of [18, Thm. 6].

PROPOSITION 4.2. *Suppose the problem*

$$\min \{f(x) \mid x \in C\}$$

has a local minimum at $x_0 \in C$, where $f: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ is strictly l.s.c. at x_0 and $C \subset \mathbf{R}^n$ is closed near x_0 . Assume

$$(4.1) \quad \text{dom } f^\uparrow(x_0; \cdot) - T_C(x_0) = \mathbf{R}^n.$$

Then

$$(4.2) \quad 0 \in \partial f(x_0) + N_C(x_0).$$

Proof. Let $f_1 := f$, $f_2 := i_C$ in Corollary 3.6. The function $f + i_C$ is minimized at x_0 , so by Proposition 4.1, $0 \in \partial(f + i_C)(x_0)$. Assumption (4.1) is (3.8) in this case, so $\partial(f + i_C)(x_0) \subset \partial f(x_0) + \partial i_C(x_0) = \partial f(x_0) + N_C(x_0)$, and $0 \in \partial f(x_0) + N_C(x_0)$. \square

We will next consider a particular constraint set, the set $C := \{x \mid g(x) \leq 0\}$ for a strictly l.s.c. function $g: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$.

PROPOSITION 4.3 (cf. [18, Thm. 5]). *Suppose $g: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ is strictly l.s.c. at $x_0 \in g^{-1}(0)$, and let $C := \{x \mid g(x) \leq 0\}$. Assume $0 \notin \partial g(x_0)$. Then*

$$(4.3) \quad T_C(x_0) \subset \{y \mid g^\uparrow(x_0; y) \leq 0\}.$$

If in addition $\partial g(x_0)$ is nonempty, then

$$(4.4) \quad N_C(x_0) \subset \left(\bigcup_{\lambda > 0} \lambda \partial g(x_0) \right) \cup \partial^\infty g(x_0).$$

Proof. In Proposition 3.10, let $n = 2$, $D_1 := \{(z, u) \in \mathbf{R}^m \times \mathbf{R} \mid u = 0\}$, and $D_2 := \text{epi } g$. To apply Proposition 3.10, we must verify that $T_{D_1}(x_0, 0) - T_{D_2}(x_0, 0) = \mathbf{R}^{m+1}$; i.e., that $\{(z, u) \mid u = 0\} - \text{epi } g^\uparrow(x_0; \cdot) = \mathbf{R}^{m+1}$. To do so, suppose that $(x', r') \in \mathbf{R}^m \times \mathbf{R}$. Since $0 \notin \partial g(x_0)$, there exists $y \in \mathbf{R}^m$ with $g^\uparrow(x_0; y) < 0$. Now $g^\uparrow(x_0; \cdot)$ is positively homogeneous, so for any $\bar{r} \in \mathbf{R}$, there exists $\bar{y} \in \mathbf{R}^m$ with $(\bar{y}, \bar{r}) \in \text{epi } g^\uparrow(x_0; \cdot)$. Let y' be such that $g^\uparrow(x_0; y') \leq -r'$. Then $(x', r') = (x' + y', 0) - (y', -r')$. Thus $\{(z, u) \mid u = 0\} - \text{epi } g^\uparrow(x_0; \cdot) = \mathbf{R}^{m+1}$. Now by (3.17), $T_{D_1 \cap D_2}(x_0, 0) \supset T_{D_1}(x_0, 0) \cap T_{D_2}(x_0, 0)$; i.e.,

$T_{C \times 0}(x_0, 0) \supset (\mathbf{R}^m \times 0) \cap \text{epi } g^\uparrow(x_0; \cdot)$. Hence $T_C(x_0) \supset \{y \mid g^\uparrow(x_0; y) \leq 0\}$. By (3.18), $N_{D_1 \cap D_2}(x_0, 0) \subset N_{D_1}(x_0, 0) + N_{D_2}(x_0, 0)$; i.e., $N_{C \times 0}(x_0, 0) \subset 0 \times \mathbf{R} + N_{D_2}(x_0, 0)$. If $\partial g(x_0) \neq \emptyset$, we have by (3.20) that

$$N_{D_2}(x_0) = \bigcup_{\lambda > 0} \lambda(\partial g(x_0), -1) \cup (\partial^\infty g(x_0), 0).$$

Hence

$$N_{C \times 0}(x_0, 0) \subset (0 \times \mathbf{R}) + \left(\bigcup_{\lambda > 0} \lambda(\partial g(x_0), -1) \cup (\partial^\infty g(x_0), 0) \right)$$

and (4.4) holds.

By combining Propositions 4.2 and 4.3 and applying Proposition 3.10, we can obtain the following Kuhn–Tucker Theorem:

THEOREM 4.4. *Let $f: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ and $g_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots, n$, be strictly l.s.c. at x_0 , $D \subset \mathbf{R}^m$ closed near x_0 , and $G: \mathbf{R}^m \rightarrow \mathbf{R}^p$ strictly differentiable at x_0 , a local minimizer of*

$$(P) \quad \min \{f(x) \mid g_i(x) \leq 0, i = 1, \dots, n, G(x) = 0, x \in D\}.$$

Call $I(x) := \{i \in \{1, \dots, n\} \mid g_i(x) = 0\}$. Assume that $0 \notin \partial g_i(x_0)$ and $\partial g_i(x_0) \neq \emptyset$ for each $i \in I(x_0)$, that g_i is continuous at x_0 for each $i \notin I(x_0)$, and that $\nabla G(x_0)\mathbf{R}^m = \mathbf{R}^p$. In addition, assume that $\text{dom } f^\uparrow(x_0; \cdot)$, $\nabla G(x_0)^{-1}(0)$, $T_D(x_0)$, and $\{y \mid g^\uparrow(x_0; y) \leq 0\}$, $i \in I(x_0)$, are in strong general position. Then

$$(4.5) \quad 0 \in \partial f(x_0) + \sum_{i \in I(x_0)} (\lambda_i \partial g_i(x_0) \cup \partial g_i^\infty(x_0)) + \lambda \nabla G(x_0) + N_D(x_0)$$

for some $\lambda_i \geq 0$ and $\lambda \in \mathbf{R}$.

Proof. Denote by C the constraint set in Program (P). Since $\nabla G(x_0)\mathbf{R}^m = \mathbf{R}^p$, $\nabla G(x_0)^{-1}(0) \subset T_{G^{-1}(0)}(x_0)$ by Theorem 2.4. (In fact, these two sets are equal). By our strong general position assumption, we have

$$\{y \mid g^\uparrow(x_0; y) \leq 0, i \in I(x_0), y \in T_D(x_0), \nabla G(x_0)y = 0\} \subset T_C(x_0)$$

by Propositions 4.3 and 3.10. Thus the strong general position assumption guarantees that (4.1) holds. By Proposition 4.2,

$$0 \in \partial f(x_0) + N_C(x_0),$$

and (4.5) then follows immediately from (3.18) of Proposition 3.10 and Proposition 4.3. \square

Remark 4.5. In the case in which f and g_i , $i \in I(x_0)$ are strictly differentiable, our general position assumption and $\nabla G(x_0)\mathbf{R}^m = \mathbf{R}^p$ comprise the familiar Mangasarian–Fromovitz constraint qualification.

It is also possible to derive necessary optimality conditions for (P) via the following “Dubovitskii–Milyutin” result, due to Watkins [26]:

THEOREM 4.6. *Let $C_i \subset \mathbf{R}^m$, $i = 1, \dots, p$ be closed near x_0 with $\bigcap_{i=1}^p C_i = \{x_0\}$, and suppose that at least one of the sets $T_{C_i}(x_0)$, $i = 1, \dots, p$ is not a subspace. Then there exist $a_i \in N_{C_i}(x_0)$, $i = 1, \dots, p$, not all equal to zero, such that $\sum_{i=1}^p a_i = 0$.*

In [26], a “Fritz John type” theorem is derived from Theorem 4.6 for a constrained optimization problem involving locally Lipschitzian functions. Using Proposition 4.3, we can generalize this result beyond the locally Lipschitzian case.

THEOREM 4.7. *Posit the assumptions of Theorem 4.4, with the exception of the strong general position hypothesis. Assume, in addition, that f is directionally Lipschitzian at x_0 , that $\partial f(x_0)$ is nonempty, and that $0 \notin \partial f(x_0)$. Then*

$$(4.6) \quad 0 \in (\lambda_0 \partial f(x_0) \cup \partial^\infty f(x_0)) + \sum_{i \in I(x_0)} (\lambda_i \partial g_i(x_0) \cup \partial^\infty g_i(x_0)) + \lambda \nabla G(x_0) + N_D(x_0)$$

for some $\lambda_0 \geq 0$, $\lambda_i \geq 0$, and $\lambda \in \mathbf{R}$. Moreover, λ_0 , λ_i , $i \in I(x_0)$, λ , and the elements of $\partial^\infty f(x_0)$, $\partial^\infty g_i(x_0)$, and $N_D(x_0)$ in (4.6) are not all equal to zero.

Proof. Again call C the feasible set in (P). There exists $\varepsilon > 0$ such that $f(x) \geq f(x_0)$ for all $x \in B_\varepsilon(x_0)$. Let

$$C_0 = \{x \in B_\varepsilon(x_0) \mid f(x) \leq f(x_0) - \|x - x_0\|^2\},$$

$$C_i := \{x \in \mathbf{R}^n \mid g_i(x) \leq 0\}, i = 1, \dots, n,$$

$$C_{n+1} := \{x \in \mathbf{R}^n \mid G(x) = 0\} \quad \text{and} \quad C_{n+2} = D.$$

Since x_0 is a local minimizer for (P), $\bigcap_{i=0}^{n+2} C_i = \{x_0\}$. Consider first the case in which $T_{C_0}(x_0)$ is not a subspace. Then by Theorem 4.6, $0 \in \sum_{i=0}^{n+2} N_{C_i}(x_0)$. Call $\tilde{f}(x) := f(x) - f(x_0) + \|x - x_0\|^2$. By Corollary 3.6, $\partial \tilde{f}(x_0) \subset \partial f(x_0)$ and $\partial^\infty \tilde{f}(x_0) = \partial^\infty f(x_0)$ (see [22, Prop. 2.4]). Thus

$$\begin{aligned} N_{C_0}(x_0) &\subset \bigcup_{\lambda > 0} \lambda \partial \tilde{f}(x_0) \cup \partial^\infty \tilde{f}(x_0) \\ &\subset \bigcup_{\lambda > 0} \lambda \partial f(x_0) \cup \partial^\infty f(x_0). \end{aligned}$$

Again $\nabla G(x_0)^{-1}(0) = T_{C_{n+1}}(x_0)$. For $i \in \{1, \dots, n\} \setminus I(x_0)$, $N_{C_i}(x_0) = \{0\}$. Combining these facts and (4.4), we obtain (4.6).

Now suppose $T_{C_0}(x_0)$ is a subspace. Since f is directionally Lipschitzian at x_0 and $0 \notin \partial f(x_0)$, $T_{C_0}(x_0)$ has nonempty interior [18], which means that $T_{C_0}(x_0) = \mathbf{R}^n$. Hence $x_0 \in \text{int } C_0$ [17], contradicting the fact that x_0 is a local minimizer for (P). \square

The additional assumption that $\nabla G(x_0)^{-1}(0)$, $T_D(x_0)$, and $\{y \mid g_i^+(x_0; y) \leq 0\}$, $i \in I(x_0)$ are in strong general position is enough to guarantee that the element of $\lambda_0 \partial f(x_0) \cup \partial^\infty f(x_0)$ in (4.6) is nonzero (see [26, Remarks 1, 2]). This produces another Kuhn-Tucker type result.

5. Limitations of the generalized subdifferential calculus. In § 3, we obtain “chain rules” for $(F \circ f)^\dagger(x_0; \cdot)$ and $\partial(F \circ f)(x_0)$ with F and f of these types:

(a) $F: \mathbf{R}^m \rightarrow \mathbf{R}$ l.s.c., $f: \mathbf{R}^m \rightarrow \mathbf{R}^n$ strictly differentiable at x_0 .

(b) $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ l.s.c. and isotone, $f = (f_1, \dots, f_n)$ with each $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ l.s.c., and (3.23) or (3.24) satisfied.

(In fact, (a) can be encompassed by (b)—e.g. [18, Thm. 3]).

Are other general chain rules possible? In particular, is there a chain rule for $F: \mathbf{R}^n \rightarrow \mathbf{R}$ directionally Lipschitzian (or strictly differentiable) and $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ l.s.c.? We answer this question by considering possible extensions of the following chain rule for Clarke subgradients. (See [5, Prop. 10] and [11, Chap. 8].)

THEOREM 5.1. *Let E be a normed space and $f: E \rightarrow \bar{\mathbf{R}}$ be locally Lipschitzian near x_0 , and let $F: \mathbf{R} \rightarrow \mathbf{R}$ be continuously differentiable near x_0 . Then*

$$(5.1) \quad (F \circ f)^0(x_0; y) = F'(f(x_0))f^0(x_0; y) \quad \text{for all } y \in E,$$

and

$$(5.2) \quad \partial(F \circ f)(x_0) = F'(f(x_0))\partial f(x_0).$$

In attempting to extend Theorem 5.1, it does not seem possible to apply the techniques used in the proofs of Theorems 3.2 and 3.17. We will proceed instead by examining limits of the form (1.10). We start by deriving a technical lemma involving these limits which we have already applied in the proof of Lemma 3.21.

LEMMA 5.2. Let E, E_1 be l.c.t.v.s., and let $g: E \times E_1 \rightarrow \bar{\mathbf{R}}$ and $h: E \times E_1 \rightarrow \bar{\mathbf{R}}$ be extended-real-valued functions. Suppose

$$\lim_{\substack{x \rightarrow x_0 \\ y \rightarrow y_0}} h(x, y) = A \quad \text{and} \quad \limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} g(x, y) = B.$$

Then

- (i) $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} h(x, y)g(x, y) = AB$ if $0 < A < +\infty$.
(ii) The same equation holds for $-\infty < A \leq 0$ if g is bounded in a neighborhood of (x_0, y_0) .

Proof of (i). For any given $\lambda \in (0, A)$, there exist $X_1 \in \mathcal{N}(x_0)$, $Y_1 \in \mathcal{N}(y_0)$ such that $A - \lambda \leq h(x, y) \leq A + \lambda$ for all $x \in X_1$, $y \in Y_1$. We first establish $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} h(x, y)g(x, y) \leq AB$.

Case 1. $0 \leq B < +\infty$. Let $Y \in \mathcal{N}(y)$ and $\varepsilon > 0$ be given. Choose $\lambda \in (0, A)$ small enough so that $(A + B)\lambda + \lambda^2 < \varepsilon$ and X_1, Y_1 as above. Then there exists $X_2 \in \mathcal{N}(x_0)$ such that for all $x \in X_2$, there exists $y \in Y \cap Y_1$ with $g(x, y) \leq B + \lambda$. Thus for all $x \in X_1 \cap X_2$, there exists $y \in Y \cap Y_1$ with $h(x, y)g(x, y) \leq (A + \lambda)(B + \lambda) = AB + (A + B)\lambda + \lambda^2 \leq AB + \varepsilon$. Since ε was arbitrary, $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} h(x, y)g(x, y) \leq AB$.

Case 2. $-\infty < B < 0$. Let $Y \in \mathcal{N}(y)$ and $\varepsilon > 0$ be given. Let $\lambda \in (0, \min(A, -B))$ be such that $(A - B)\lambda \leq \varepsilon$, and choose X_1, Y_1 as above. There exists $X_2 \in \mathcal{N}(x_0)$ such that for each $x \in X_2$, there exists $y \in Y \cap Y_1$ with $g(x, y) \leq B + \lambda$. So for each $x \in X_1 \cap X_2$, there exists $y \in Y \cap Y_1$ with $h(x, y)g(x, y) \leq (A - \lambda)(B + \lambda) = AB + (A - B)\lambda - \lambda^2 \leq AB + \varepsilon$. Since ε was arbitrary, $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} h(x, y)g(x, y) \leq AB$.

Case 3. $B = -\infty$. Let $m < 0$ and $Y \in \mathcal{N}(y)$ be given, and choose $\lambda \in (0, A)$ and X_1, Y_1 as above. There exists $X_2 \in \mathcal{N}(x_0)$ such that for all $x \in X_2$, there exists $y \in Y \cap Y_1$ with $g(x, y) \leq m/(A - \lambda)$. Then for all $x \in X_1 \cap X_2$, there exists $y \in Y \cap Y_1$ such that $h(x, y)g(x, y) \leq (A - \lambda)(m/(A - \lambda)) = m$. Since m was arbitrary, $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} h(x, y)g(x, y) = -\infty = AB$.

Case 4. $B = +\infty$. Choose $\lambda \in (0, A)$, and let $X \in \mathcal{N}(x_0)$ and $M > 0$ be given. Choose X_1, Y_1 as above. There exists $Y \in \mathcal{N}(y_0)$ such that for some $x \in X \cap X_1$, $g(x, y) \geq M$ for all $y \in Y$. So there exists $x \in X \cap X_1$ such that for all $y \in Y \cap Y_1$, $h(x, y)g(x, y) \geq M(A - \lambda)$. Since M and X were arbitrary, $\lim_{x \rightarrow x_0} \sup \inf_{y \rightarrow y_0} g(x, y)h(x, y) = +\infty = AB$. We have now established that $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} g(x, y)h(x, y) \leq AB$. It then follows that

$$\begin{aligned} B &= \limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} g(x, y) \\ &\leq \lim_{\substack{x \rightarrow x_0 \\ y \rightarrow y_0}} \frac{1}{h(x, y)} \limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} g(x, y)h(x, y) \\ &= \frac{1}{A} \limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} g(x, y)h(x, y). \end{aligned}$$

Hence $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} g(x, y)h(x, y) \geq AB$, and (i) holds.

We leave the proof of (ii), which is similar, to the reader. We make the important observation that if $A \leq 0$, local boundedness of g is required in both the proof of $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} h(x, y)g(x, y) \leq AB$ and that of $\limsup_{x \rightarrow x_0} \inf_{y \rightarrow y_0} h(x, y)g(x, y) \geq AB$. \square

We can now prove what seems to be the best possible extension of Theorem 5.1.

THEOREM 5.3. *Let E be an l.c.t.v.s. and $f: E \rightarrow \bar{\mathbf{R}}$ continuous at $x_0 \in E$, and let $F: \mathbf{R} \rightarrow \mathbf{R}$ be continuously differentiable near $f(x_0)$. Assume $F'(f(x_0)) > 0$. Then for all $y \in E$,*

$$(5.3) \quad (F \circ f)^\uparrow(x_0; y) = F'(f(x_0))f^\uparrow(x_0; y).$$

Moreover,

$$(5.4) \quad \partial(F \circ f)(x_0) = F'(f(x_0))\partial f(x_0).$$

Proof.

$$\begin{aligned} (F \circ f)^\uparrow(x_0; y) &= \limsup_{\substack{x \rightarrow x_0 \\ t \downarrow 0}} \inf_{y' \rightarrow y} \frac{(F \circ f)(x + ty') - (F \circ f)(x)}{t} \\ &= \limsup_{\substack{x \rightarrow x_0 \\ t \downarrow 0}} \inf_{y' \rightarrow y} F'(z(t, x, y)) \frac{f(x + ty') - f(x)}{t} \end{aligned}$$

(for some $z(t, x, y)$ between $f(x)$ and $f(x + ty')$ by the classical mean value theorem)

$$= \lim_{\substack{x \rightarrow x_0 \\ t \downarrow 0 \\ y' \rightarrow y}} F'(z(t, x, y)) \limsup_{\substack{x \rightarrow x_0 \\ t \downarrow 0}} \inf_{y' \rightarrow y} \frac{f(x + ty') - f(x)}{t}$$

(by Lemma 5.2(i))

$$= F'(f(x_0))f^\uparrow(x_0; y)$$

since f is continuous at x_0 and F is continuously differentiable near $f(x_0)$.

Now if $f^\uparrow(x_0; 0) = -\infty$, $(F \circ f)^\uparrow(x_0; 0)$ will by (5.3) also equal $-\infty$, and both sides of (5.4) will be empty. Otherwise,

$$\begin{aligned} \partial(F \circ f)(x_0) &= \partial(F \circ f)^\uparrow(x_0; \cdot)(0) \\ &= \partial(F'(f(x_0))f^\uparrow(x_0; \cdot))(0) \\ &= F'(f(x_0))\partial f^\uparrow(x_0; \cdot)(0) \end{aligned}$$

since $\partial f^\uparrow(x_0; \cdot)(0)$ is nonempty

$$= F'(f(x_0))\partial f(x_0). \quad \square$$

Remark 5.4. (a) If $F'(f(x_0)) < 0$, neither inclusion of (5.4) will hold in general. For example, define $F: \mathbf{R} \rightarrow \mathbf{R}$ by $F(x) := -x$ and $f: \mathbf{R} \rightarrow \mathbf{R}$ by $f(x) := -|x|^{1/2}$. Then $\partial(F \circ f)(0) = \mathbf{R}$, but $\partial f(0) = \emptyset$. On the other hand, if $F(x) := -x$ but $f(x) := |x|^{1/2}$, $\partial(F \circ f)(x_0) = \emptyset$ while $F'(f(x_0))\partial f(x_0) = \mathbf{R}$.

(b) There are also counterexamples for $F'(f(x_0)) = 0$. Define $F: \mathbf{R} \rightarrow \mathbf{R}$ by $F(x) := x^2$ and $f: \mathbf{R} \rightarrow \mathbf{R}$ as in (a). Then $\partial(F \circ f)(0) = [-1, 1]$, but $F'(f(x_0)) = 0$ and $\partial f(0) = \emptyset$. On the other hand, if $F(x) := -x^{4/3}$ and $f(x) := |x|^{1/2}$, then $\partial(F \circ f)(0) = \emptyset$ while $F'(f(0)) = 0$ and $\partial f(0) = \mathbf{R}$.

We now have at least a partial answer to our original questions. Even if F is continuously differentiable and f is continuous, the requirement that F be locally isotone seems to be needed in order to prove a chain rule for upper subderivatives.

The difficulty seems to lie in the “nonradial” nature of ∂f for general f . If f is locally Lipschitzian, $f^0(x_0; -y) = (-f)^0(x_0; y)$ and $\partial(-f)(x_0) = -\partial f(x_0)$. These relationships would allow us to extend Theorem 5.3 to $F'(f(x_0)) < 0$ if they held in general, but they do not—e.g. consider $f: \mathbf{R} \rightarrow \mathbf{R}$ defined by $f(x) := |x|^{1/2}$ and $x_0 = 0$.

A more thorough discussion of the subject of this section is given in [24, § 3.5].

6. Contingent derivatives, Ursescu derivatives and subdifferential regularity. In this section, we consider the tangent cones

$$(6.1) \quad K_C(x_0) := \{y \in E \mid \forall Y \in \mathcal{N}(y), \forall \lambda > 0, \exists t \in (0, \lambda), \\ \exists y' \in Y \text{ such that } x_0 + ty' \in C\}$$

and

$$(6.2) \quad k_C(x_0) := \{y \in E \mid \forall Y \in \mathcal{N}(y), \exists \lambda > 0 \text{ such that } \forall t \in (0, \lambda), \exists y' \in Y \text{ with } x_0 + ty' \in C\}.$$

$K_C(x_0)$ is the well-known *contingent cone*. For more information on these cones, see [23], [7], [25], [24].

From (6.1) and (6.2), we see that

$$T_C(x_0) \subset k_C(x_0) \subset K_C(x_0)$$

for any $C \subset E$ and $x_0 \in \text{cl } C$. If C is a convex set or a differentiable manifold, all three cones coincide ([20, Chap. 2] and Theorem 2.4).

Let $f: E \rightarrow \bar{\mathbf{R}}$ be an extended real-valued function. Paralleling the development in § 1, define

$$(6.3) \quad f_+(x_0; y) := \inf \{r \mid (y, r) \in K_{\text{epi } f}(x_0, f(x_0))\}$$

and

$$(6.4) \quad f_{\square}(x_0; y) := \inf \{r \mid (y, r) \in k_{\text{epi } f}(x_0, f(x_0))\}.$$

The directional derivative $f_+(x_0; y)$ (respectively, $f_{\square}(x_0; y)$) has been called the *contingent derivative* (*Ursescu derivative*) of f at x_0 in the direction y [1], [9]. Since $T_{\text{epi } f}(x_0, f(x_0)) \subset k_{\text{epi } f}(x_0, f(x_0)) \subset K_{\text{epi } f}(x_0, f(x_0))$, $f_+(x_0; \cdot) \leq f_{\square}(x_0; \cdot) \leq f^{\uparrow}(x_0; \cdot)$. Definitions (6.3) and (6.4) are made exactly so that

$$(6.5) \quad \text{epi } f_+(x_0; \cdot) := K_{\text{epi } f}(x_0, f(x_0))$$

and

$$(6.6) \quad \text{epi } f_{\square}(x_0; \cdot) := k_{\text{epi } f}(x_0, f(x_0)).$$

There are also direct characterizations of $f_+(x_0; y)$ and $f_{\square}(x_0; y)$. It is well known that

$$(6.7) \quad f_+(x_0; y) = \liminf_{\substack{t \downarrow 0 \\ y' \rightarrow y}} \frac{f(x_0 + ty') - f(x_0)}{2}$$

(e.g., [20, Chap. 3]), and it is not difficult to show [7], [25], [9] that

$$(6.8) \quad f_{\square}(x_0; y) = \limsup_{t \downarrow 0} \inf_{y' \rightarrow y} \frac{f(x_0 + ty') - f(x_0)}{t}.$$

$K_C(x_0)$ and $k_C(x_0)$ are closed cones, so $f_+(x_0; \cdot)$ and $f_{\square}(x_0; \cdot)$ are l.s.c. and positively homogeneous. $K_C(x_0)$ and $k_C(x_0)$ are not in general convex, so it is not possible to directly associate convex subgradient sets with $f_+(x_0; \cdot)$ and $f_{\square}(x_0; \cdot)$ as we did with $f^{\uparrow}(x_0; \cdot)$ in Definition 1.3. It is possible, however, to prove calculus formulas for $f_+(x_0; \cdot)$ and $f_{\square}(x_0; \cdot)$, and in particular to derive the subdifferential calculus for convex functions by combining these formulae with those in § 3. We now proceed to do so, beginning with a counterpart to Theorem 3.17. Notice that it holds quite generally, with no need for the assumption of finite dimensionality or conditions (3.23), (3.24) and (3.25).

PROPOSITION 6.1. Let E be an l.c.t.v.s., let $f_i: E \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots, n$ be finite at x_0 , and call $f := (f_1, \dots, f_n)$. Let $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be finite at $f(x_0)$ and isotone on the union of $\text{Range } f + \mathbf{R}_+^n$ and $B_\varepsilon(f(x_0))$ for some $\varepsilon > 0$. Then if $y \in E$ is such that $(f_i)_+(x_0; y)$, $i = 1, \dots, n$ are finite,

$$(6.9) \quad (F \circ f)_+(x_0; y) \geq F_+(f(x_0); (f_1)_+(x_0; y), \dots, (f_n)_+(x_0; y)).$$

Alternatively, if $(f_1)_\square(x_0; y)$, $(f_i)_+(x_0; y)$, $i = 2, \dots, n$ are finite, then

$$(6.10) \quad (F \circ f)_\square(x_0; y) \geq F_+(f(x_0); (f_1)_\square(x_0; y), (f_2)_+(x_0; y), \dots, (f_n)_+(x_0; y)).$$

Proof. Let $(y, r) \in K_{\text{epi}(F \circ f)}(x_0, (F \circ f)(x_0))$. To prove (6.9), it suffices to show that

$$((f_1)_+(x_0; y), \dots, (f_n)_+(x_0; y), r) \in K_{\text{epi } F}(f(x_0), F(f(x_0))).$$

To this end, let $\lambda > 0$ and $\delta > 0$ be given. Call $z_i = (f_i)_+(x_0; y) - \delta$, and choose $\lambda_0 \in (0, \lambda)$ such that for all i , $f_i(x_0) + [0, \lambda_0]z_i \geq f_i(x_0) - \varepsilon$. Then there exist $Y_i \in \mathcal{N}(y)$, $\lambda_i \in (0, \lambda_0)$ such that for all $t \in (0, \lambda_i)$ and all $y' \in Y_i$,

$$\frac{f_i(x_0 + ty') - f_i(x_0)}{t} \geq z_i, \quad i = 1, \dots, n.$$

In addition, there exist $\bar{y} \in \bigcap_{i=1}^n Y_i$, $\bar{t} \in (0, \min_i \lambda_i)$ such that

$$\frac{(F \circ f)(x_0 + \bar{t}\bar{y}) - (F \circ f)(x_0)}{\bar{t}} \leq r + \delta.$$

Now since $f_i(x_0) + \bar{t}z_i \leq f_i(x_0 + \bar{t}\bar{y})$ and F is isotone,

$$\frac{F(f(x_0) + \bar{t}(z_1, \dots, z_n)) - F(f(x_0))}{\bar{t}} \leq r + \delta.$$

Thus $((f_1)_+(x_0; y), \dots, (f_n)_+(x_0; y), r) \in K_{\text{epi } F}(f(x_0), F(f(x_0)))$, and so (6.9) holds.

Now let $(y, r) \in k_{\text{epi}(F \circ f)}(x_0, (F \circ f)(x_0))$. To prove (6.10), it suffices to show that $((f_1)_\square(x_0; y), (f_2)_+(x_0; y), \dots, (f_n)_+(x_0; y), r) \in K_{\text{epi } F}(f(x_0), F(f(x_0)))$. To this end, let $\delta > 0$ and $\lambda > 0$ be given. Call $z_1 = (f_1)_\square(x_0; y) - \delta$, $z_i = (f_i)_+(x_0; y) - \delta$, $i = 2, \dots, n$. Again choose $\lambda_0 \in (0, \lambda)$ such that $f_i(x_0) + [0, \lambda_0]z_i \geq f_i(x_0) - \varepsilon$. There exist $Y_i \in \mathcal{N}(y)$, $\lambda_i \in (0, \lambda_0)$ such that for all $t \in (0, \lambda_i)$ and all $y' \in Y_i$, $((f_i(x_0 + ty') - f_i(x_0))/t) \geq z_i$, $i = 2, \dots, n$, and there exists $Y_1 \in \mathcal{N}(y)$ such that for all $t > 0$, there exists $t' \in (0, t)$ with $((f_1(x_0 + t'y) - f_1(x_0))/t') \geq z_1$ for all $y' \in Y_1$. In addition, there exists $\bar{y} \in \bigcap_{i=1}^n Y_i$ and $\lambda_1 \in (0, \lambda_0)$ such that for all $t \in (0, \lambda_1)$, $((F \circ f)(x_0 + t\bar{y}) - (F \circ f)(x_0))/t \leq r + \delta$. Thus for some $\bar{t} \in (0, \min_i \lambda_i)$, $f_i(x_0) + \bar{t}z_i \leq f_i(x_0 + \bar{t}\bar{y})$. By the isotonicity of F , $((F(f(x_0) + \bar{t}(z_1, \dots, z_n)) - F(f(x_0)))/\bar{t}) \leq r + \delta$. Hence $((f_1)_\square(x_0; y), (f_2)_+(x_0; y), \dots, (f_n)_+(x_0; y), r) \in K_{\text{epi } F}(f(x_0), F(f(x_0)))$, and so (6.10) holds. \square

Inequality (6.9) does not hold with “+” replaced by “ \square ”. For example, let $n = 2$ and $F(x_1, x_2) := x_1 + x_2$; and consider $f_1: \mathbf{R} \rightarrow \mathbf{R}$ and $f_2: \mathbf{R} \rightarrow \mathbf{R}$ defined by

$$f_1(x) := \begin{cases} 0 & \text{if } x \leq 0, \\ x & \text{if } \frac{1}{2^{n+1}} < x \leq \frac{1}{2^n} \text{ and } n \text{ is odd,} \\ 2x & \text{if } \frac{1}{2^{n+1}} < x \leq \frac{1}{2^n} \text{ and } n \text{ is even,} \end{cases}$$

$$f_2(x) := \begin{cases} 0 & \text{if } x \leq 0, \\ x & \text{if } \frac{1}{2^{n+1}} < x \leq \frac{1}{2^n} \text{ and } n \text{ is even,} \\ 2x & \text{if } \frac{1}{2^{n+1}} < x \leq \frac{1}{2^n} \text{ and } n \text{ is odd.} \end{cases}$$

Then if $y \geq 0$,

$$(f_1)_{\square}(0; y) = (f_2)_{\square}(0; y) = 2y$$

while

$$(f_1 + f_2)(x) = \begin{cases} 0 & \text{if } x \leq 0, \\ 3x & \text{if } x > 0, \end{cases}$$

so that $(f_1 + f_2)_{\square}(0; y) = 3y$. Thus for $y > 0$,

$$(f_1 + f_2)_{\square}(0; y) = 3y < 4y = (f_1)_{\square}(0; y) + (f_2)_{\square}(0; y).$$

PROPOSITION 6.2. *Let E, E^1 be l.c.t.v.s., let $F: E \rightarrow E^1$ be strictly differentiable at $x_0 \in E$, and let $f: E^1 \rightarrow \bar{\mathbf{R}}$ be finite at $F(x_0)$. Then for all $y \in E^1$,*

$$(6.11) \quad (f \circ F)_+(x_0; y) \geq f_+(F(x_0); \nabla F(x_0)y)$$

and

$$(6.12) \quad (f \circ F)_{\square}(x_0; y) \geq f_{\square}(F(x_0); \nabla F(x_0)y).$$

Proof. Let $(y, r) \in K_{\text{epi}(f \circ F)}(x_0, (f \circ F)(x_0))$. To prove (6.11), it suffices to show that $(\nabla F(x_0)y, r) \in K_{\text{epi } f}(F(x_0), f(F(x_0)))$. Let $Z \in \mathcal{N}(\nabla F(x_0)y)$, $\lambda > 0$, and $\delta > 0$ be given. There exist $Y \in \mathcal{N}(y)$ and $\lambda_1 \in (0, \lambda)$ such that $((F(x_0 + ty') - F(x_0))/t) \in Z$ for all $y' \in Y$ and $t \in (0, \lambda_1)$. In addition, there exist $\bar{y} \in Y$ and $\bar{t} \in (0, \lambda_1)$ such that $((f \circ F)(x_0 + \bar{t}\bar{y}) - (f \circ F)(x_0))/\bar{t} \leq r + \delta$. Call $\bar{z} := ((F(x_0 + \bar{t}\bar{y}) - F(x_0))/\bar{t})$. Then $\bar{z} \in Z$ and $((f(F(x_0) + \bar{t}\bar{z}) - f(F(x_0)))/\bar{t}) \leq r + \delta$. Hence $(\nabla F(x_0)y, r) \in K_{\text{epi } f}(F(x_0), f(F(x_0)))$, and (6.11) holds. The proof of (6.12) is very similar to the proof of (6.11), and we leave it to the reader. \square

We can now give conditions under which equality holds in Theorems 3.2 and 3.17.

DEFINITION 6.3. The function $f: E \rightarrow \bar{\mathbf{R}}$ is said to be *subdifferentially regular* at $x_0 \in \text{dom } f$ if $f_+(x_0; y) = f^{\dagger}(x_0; y)$ for all $y \in E$. It is said to be *subdifferentially weakly regular* at x_0 if $f_{\square}(x_0; y) = f^{\dagger}(x_0; y)$ for all $y \in E$.

PROPOSITION 6.4. *Suppose the hypotheses of Theorem 3.17 are satisfied, including the assumption that each $f_i^{\dagger}(x_0; \cdot)$ is proper. Assume in addition that F is subdifferentially regular at $f(x_0)$, f_2, \dots, f_n are subdifferentially regular at x_0 , and f_1 is subdifferentially weakly regular at x_0 . Then equality holds in (3.26) and (3.27).*

Proof. By (6.10) and our regularity hypothesis, for all $y \in \mathbf{R}^n$,

$$\begin{aligned} (F \circ f)^{\dagger}(x_0; y) &\geq (F \circ f)_{\square}(x_0; y) \\ &\geq F_+(f(x_0); (f_1)_{\square}(x_0; y), (f_2)_+(x_0; y), \dots, (f_n)_+(x_0; y)) \\ &= F^{\dagger}(f(x_0); f_1^{\dagger}(x_0; y), \dots, f_n^{\dagger}(x_0; y)), \end{aligned}$$

so equality holds in (3.26). Equality in (3.27) follows from equality in (3.26). \square

PROPOSITION 6.5. *Suppose the hypotheses of Theorem 3.2 are satisfied, and that either*

$$(6.13) \quad f_1 \text{ is subdifferentially regular at } x_0 \text{ and } f_2 \text{ is subdifferentially weakly regular at } F(x_0), \text{ or}$$

$$(6.14) \quad f_1 \text{ is subdifferentially weakly regular at } x_0, \text{ and } f_2 \text{ is subdifferentially regular at } F(x_0).$$

Then equality holds in (3.3). If in addition $f_1^\uparrow(x_0; 0) = f_2^\uparrow(F(x_0); 0) = 0$, equality holds in (3.2) also.

Proof. If either $f_1^\uparrow(x_0; 0)$ or $f_2^\uparrow(F(x_0); 0)$ is $-\infty$, (3.2) implies that $(f_1 + f_2 \circ F)^\uparrow(x_0; 0) = -\infty$, and both sides of (3.3) are empty. Otherwise apply Proposition 6.1 with $n = 2$ and $F: \mathbf{R}^2 \rightarrow \mathbf{R}$ defined by $F(x_1, x_2) = x_1 + x_2$. If (6.13) holds, then for all $y \in \mathbf{R}^n$,

$$\begin{aligned} (f_1 + f_2 \circ F)^\uparrow(x_0; y) &\geq (f_1 + f_2 \circ F)_\square(x_0; y) \\ &\geq (f_1)_+(x_0; y) + (f_2 \circ F)_\square(x_0; y) \quad (\text{by (6.10)}) \\ &\geq (f_1)_+(x_0; y) + (f_2)_\square(F(x_0); \nabla F(x_0)y) \quad (\text{by (6.12)}) \\ &= (f_1)^\uparrow(x_0; y) + f_2^\uparrow(F(x_0); \nabla F(x_0)y). \end{aligned}$$

If (6.14) holds, then similarly, for all $y \in \mathbf{R}^n$,

$$\begin{aligned} (f_1 + f_1 \circ F)^\uparrow(x_0; y) &\geq (f_1 + f_2 \circ F)_\square(x_0; y) \\ &\geq (f_1)_\square(x_0; y) + (f_2 \circ F)_+(x_0; y) \quad (\text{by (6.10)}) \\ &\geq (f_1)_\square(x_0; y) + (f_2)_+(F(x_0); \nabla F(x_0)y) \quad (\text{by (6.11)}) \\ &= (f_1)^\uparrow(x_0; y) + f_2^\uparrow(F(x_0); \nabla F(x_0)y). \end{aligned}$$

In either case, equality holds in (3.2), and equality in (3.3) follows. \square

Remark 6.6. The conditions in Propositions 6.4 and 6.5 guaranteeing equality in the subdifferential calculus formulae of § 3 are less stringent than those given in [18]. For example, let $C_1 := \bigcup_{n=0}^\infty [2^{2n}, 2^{2n+1}]$ and $C := C_1 \cup (-C_1) \cup \{0\}$. Then $T_C(0) = k_C(0) = \{0\}$, but $K_C(0) = \mathbf{R}$. In Proposition 6.5, let $F := I$ and $x_0 := 0$. Define $f_1: \mathbf{R} \rightarrow \mathbf{R}$ by $f_1(x) := 0$, and let $f_2: \mathbf{R} \rightarrow \bar{\mathbf{R}}$ be i_C . Since (3.8) and (6.13) are satisfied, equality holds in (3.9) and (3.10), even though the condition for equality given in Theorem 2 of [18]—that both f_1 and f_2 be subdifferentially regular at x_0 —is not satisfied. Observe also that the regularity conditions in Propositions 6.4 and 6.5 are still valid in the infinite-dimensional setting of [18].

Since convex functions are subdifferentially regular, Propositions 6.4 and 6.5 enable us to rederive convex subdifferential calculus results, in particular Theorems 2.9 and 2.10. Thus Theorems 3.2 and 3.17, which are proved by means of Theorems 2.9 and 2.10, combine with Propositions 6.4 and 6.5 to yield Theorems 2.9 and 2.10 as special cases. We list below one further convex subdifferential calculus result.

PROPOSITION 6.7. *Let $F: \mathbf{R}^n \rightarrow \mathbf{R}^m$ be strictly differentiable at x_0 , let $f_1: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be convex, proper, and strictly l.s.c. at x_0 , and let $f_2: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ be convex, proper, and strictly l.s.c. at $F(x_0)$, where $x_0 \in \text{dom } f_1 \cap F^{-1}(\text{dom } f_2)$. Assume that*

$$(6.15) \quad \nabla F(x_0)x_0 - F(x_0) \in \text{int}(\nabla F(x_0) \text{dom } f_1 - \text{dom } f_2).$$

Then

$$(6.16) \quad \partial(f_1 + f_2 \circ F)(x_0) = \partial f_1(x_0) + \nabla F(x_0)^T \partial f_2(x_0).$$

Proof. By Theorem 3.2 and Proposition 6.5, equality will hold in (6.16) as long as $\nabla F(x_0) \text{dom } f_1^\uparrow(x_0; \cdot) - \text{dom } f_2^\uparrow(F(x_0); \cdot) = \mathbf{R}^m$, which in this case is equivalent to

$$\nabla F(x_0) \text{cone}(\text{dom } f_1 - x_0) - \text{cone}(\text{dom } f_2 - F(x_0)) = \mathbf{R}^m$$

(see [16], § 23). This reduces to

$$\text{cone}(\nabla F(x_0) \text{dom } f_1 - \text{dom } f_2 - \nabla F(x_0)x_0 + F(x_0)) = \mathbf{R}^m,$$

which is equivalent to (6.15). \square

COROLLARY 6.8 (cf. [17], Thm. 23.8). *Let $f_1: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ and $f_2: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ be convex, proper and l.s.c., and let $x_0 \in \text{dom } f_1 \cap \text{dom } f_2$. Assume that*

$$(6.17) \quad \text{ri dom } f_1 \cap \text{ri dom } f_2 \neq \emptyset.$$

Then

$$(6.18) \quad \partial(f_1 + f_2)(x_0) = \partial f_1(x_0) + \partial f_2(x_0).$$

Proof. By Proposition 6.7 with $m = n$ and $F := I$, (6.18) will hold if $\text{cone}(\text{dom } f_1 - \text{dom } f_2) = \mathbf{R}^m$. By (3.12) of Remark 3.7 (b), this assumption can be weakened to $\text{cone}(\text{dom } f_1 - \text{dom } f_2) = \text{span}(\text{dom } f_1 - \text{dom } f_2)$, which is equivalent to (6.17). \square

REMARK 6.9. We saw in Remark 3.7 (b) that hypothesis (3.8) of Corollary 3.6 cannot be weakened to (3.13). The reason is that $\text{aff dom } f^\uparrow(x_0; \cdot)$ can be of smaller dimension than $\text{aff dom } f$, as in the example given there. If f is convex and proper, however, $\text{aff dom } f^\uparrow(x_0; \cdot) = \text{aff dom } f$, and assumption (6.17) is sufficient to give (6.18).

It is possible by the techniques of § 3 to prove analogues of (3.2) and (3.26) involving contingent and Ursescu directional derivatives. To do so, we need counterparts of Theorem 2.4 and Propositions 2.5 and 2.6.

THEOREM 6.10. *Let $G: \mathbf{R}^p \rightarrow \mathbf{R}^q$ be strictly differentiable at $x_0 \in G^{-1}(0)$, and let $D \subset \mathbf{R}^p$ be closed near x_0 . Assume (2.2) holds. Then*

$$(6.19) \quad K_D(x_0) \cap \nabla G(x_0)^{-1}(0) \subset K_{D \cap G^{-1}(0)}(x_0)$$

and

$$(6.20) \quad k_D(x_0) \cap \nabla G(x_0)^{-1}(0) \subset k_{D \cap G^{-1}(0)}(x_0).$$

Proof. The inclusion (6.19) is a special case of [4, Thm. 4.1(a)]. The proof of (6.20) is entirely analogous to that of [4, Thm. 4.1]. \square

PROPOSITION 6.11. *Let E, E_1 be l.c.t.v.s., and let $x_0 \in C \subset E$ and $y_0 \in D \in E_1$. Then*

$$(6.21) \quad k_{C \times D}(x_0, y_0) = k_C(x_0) \times k_D(y_0),$$

$$(6.22) \quad K_{C \times D}(x_0, y_0) \subset K_C(x_0) \times K_D(y_0),$$

$$(6.23) \quad K_{C \times D}(x_0, y_0) \supset K_C(x_0) \times k_D(y_0).$$

The proof of Proposition 6.11 is a straightforward consequence of (6.1) and (6.2). That equality does not in general hold in (6.22) is demonstrated by an example in § 2 of [4].

PROPOSITION 6.12. *Let E, E_1 be l.c.t.v.s. and $A: E \rightarrow E_1$ be linear and continuous. Let $z_0 \in C \subset E$. Then*

$$(6.24) \quad A(K_C(z_0)) \subset K_{A(C)}(Az_0)$$

and

$$(6.25) \quad A(k_C(z_0)) \subset k_{A(C)}(Az_0).$$

Inclusion (6.24) is well known (see, for example, [1], [3]). The proof of (6.25) parallels that of (6.24).

THEOREM 6.13. *Let $f_i: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$, $i = 1, \dots$, be finite and strictly l.s.c. at x_0 , and call $f := (f_1, \dots, f_n)$. Let $F: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be finite and strictly l.s.c. at $f(x_0)$ and isotone on the union of $\text{Range } f + \mathbf{R}_+^n$ and $B_\varepsilon(f(x_0))$ for some $\varepsilon > 0$. Suppose (3.25) holds. Then for all $y \in \mathbf{R}^n$,*

$$(6.26) \quad (F \circ f)_\square(x_0; y) \leq F_\square(f(x_0); (f_1)_\square(x_0; y), \dots, (f_n)_\square(x_0; y))$$

and

$$(6.27) \quad (F \circ f)_+(x_0; y) \leq F_{\square}(f(x_0); (f_1)_+(x_0; y), (f_2)_{\square}(x_0; y), \dots, (f_n)_{\square}(x_0; y)).$$

Equality holds in (6.26) if $(f_i)_{\square}(x_0; y) = (f_i)_+(x_0; y)$, $i = 2, \dots, n$ for all $y \in \mathbf{R}^m$, $F_{\square}(f(x_0); z) = F_+(f(x_0); z)$ for all $z \in \mathbf{R}^n$, and $(f_i)_+(x_0; y)$, $i = 1, \dots, n$ are never $-\infty$.

Proof of (6.26). Let $h := F \circ f$, and define A and G as in Lemma 3.15 and Theorem 3.17. Define

$$D := \text{epi } f_1 \times \dots \times \text{epi } f_n \times \text{epi } F \text{ and } C := D \cap G^{-1}(0).$$

As in Theorem 3.17, $\text{epi } h = A(C)$. Then

$$\begin{aligned} \text{epi } h_{\square}(x_0; \cdot) &= k_{A(C)}(x_0, h(x_0)) \\ &\supset A(k_C(z_0)) \end{aligned}$$

where $z_0 := (x_0, f_1(x_0), \dots, x_0, f_n(x_0), f_1(x_0), \dots, f_n(x_0), h(x_0))$, by (6.25). Now assumption (3.25) guarantees that $\nabla G(x_0)T_D(z_0) = \mathbf{R}^{(n-1)m+n}$, so we may apply Theorem 6.10. By (6.20) and (6.21),

$$\begin{aligned} A(k_C(z_0)) &\supset A(k_D(z_0) \cap \nabla G(z_0)^{-1}(0)) \\ &= \{(x, r) \in \mathbf{R}^m \times \mathbf{R} \mid \exists y \in \mathbf{R}^n \text{ with} \\ &\quad (f_i)_{\square}(x_0; x) \leq y_i, F_{\square}(f(x_0); y) \leq r\} \\ &= \text{epi } F_{\square}(f(x_0); (f_1)_{\square}(x_0; \cdot), \dots, (f_n)_{\square}(x_0; \cdot)) \end{aligned}$$

since $F_{\square}(f(x_0); \cdot)$ is itself isotone (as in Lemma 2.8). Hence $\text{epi } h_{\square}(x_0; \cdot) \supset \text{epi } F_{\square}(f(x_0); (f_1)_{\square}(x_0; \cdot), \dots, (f_n)_{\square}(x_0; \cdot))$, and (6.26) holds. The proof of (6.27) is similar and uses (6.24), (6.19), and (6.23). That equality holds in (6.26) and (6.27) under the given assumptions is a consequence of Proposition 6.1. \square

THEOREM 6.14. Let $F: \mathbf{R}^n \rightarrow \mathbf{R}^m$ be strictly differentiable at x_0 , let $f_1: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ be finite and strictly l.s.c. at x_0 , and let $f_2: \mathbf{R}^m \rightarrow \bar{\mathbf{R}}$ be finite and strictly l.s.c. at $F(x_0)$. Assume (3.1) holds. Then for all $y \in \mathbf{R}^n$,

$$(6.28) \quad (f_1 + f_2 \circ F)_{\square}(x_0; y) \leq (f_1)_{\square}(x_0; y) + (f_2)_{\square}(F(x_0); \nabla F(x_0)y)$$

and

$$(6.29) \quad (f_1 + f_2 \circ F)_+(x_0; y) \leq (f_1)_{\square}(x_0; y) + (f_2)_+(F(x_0); \nabla F(x_0)y),$$

$$(6.30) \quad (f_1 + f_2 \circ F)_+(x_0; y) \leq (f_1)_+(x_0; y) + (f_2)_{\square}(F(x_0); \nabla F(x_0)y).$$

If $(f_1)_+(x_0; \cdot)$ and $(f_2)_+(F(x_0); \nabla F(x_0)(\cdot))$ are never $-\infty$, equality holds in (6.28) and (6.29) if $(f_1)_{\square}(x_0; \cdot) = (f_1)_+(x_0; \cdot)$ and in (6.30) if $(f_2)_{\square}(F(x_0); \nabla F(x_0)(\cdot)) = (f_2)_+(F(x_0); \nabla F(x_0)(\cdot))$.

Proof. The proofs of (6.28), (6.29) and (6.30) are analogous to that of Theorem 3.2, using Theorem 6.10 and Propositions 6.11 and 6.12. That equality holds under the given assumptions is a consequence of Propositions 6.1 and 6.2. \square

We give here two consequences of Theorem 6.14.

COROLLARY 6.15. Let $C_1 \subset \mathbf{R}^n$ be closed near x_0 , let $F: \mathbf{R}^n \rightarrow \mathbf{R}^m$ be strictly differentiable at x_0 , and let $C_2 \subset \mathbf{R}^m$ be closed near $F(x_0)$. Assume that (3.4) holds. Then

$$(6.31) \quad k_{C_1 \cap F^{-1}(C_2)}(x_0) = k_{C_1}(x_0) \cap \nabla F(x_0)^{-1}k_{C_2}(F(x_0)),$$

$$\begin{aligned} (6.32) \quad K_{C_1}(x_0) \cap \nabla F(x_0)^{-1}K_{C_2}(F(x_0)) &\supset K_{C_1 \cap F^{-1}(C_2)}(x_0) \\ &\supset k_{C_1}(x_0) \cap \nabla F(x_0)^{-1}K_{C_2}(F(x_0)), \end{aligned}$$

and

$$(6.33) \quad K_{C_1 \cap F^{-1}(C_2)}(x_0) \supset K_{C_1}(x_0) \cap \nabla F(x_0)^{-1} k_{C_2}(F(x_0)).$$

Proof. In (6.31), $k_{C_1 \cap F^{-1}(C_2)}(x_0) \subset k_{C_1}(x_0) \cap \nabla F(x_0)^{-1} k_{C_2}(F(x_0))$ always holds. The opposite inclusion follows from (6.28) with $f_1 := i_{C_1}$ and $f_2 := i_{C_2}$. The first inclusion in (6.32) always holds, while the second is (6.29) with $f_1 := i_{C_1}$ and $f_2 := i_{C_2}$. Similarly, (6.33) follows from (6.30). \square

COROLLARY 6.16. *Let $f_1: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$, $f_2: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be finite and strictly l.s.c. at $x_0 \in \mathbf{R}^n$. Assume (3.8) holds. Then for all $y \in \mathbf{R}^n$,*

$$(6.34) \quad (f_1 + f_2)_{\square}(x_0; y) \leq (f_1)_{\square}(x_0; y) + (f_2)_{\square}(x_0; y)$$

and

$$(6.35) \quad (f_1 + f_2)_{+}(x_0; y) \leq (f_1)_{+}(x_0; y) + (f_2)_{\square}(x_0; y).$$

Equality holds in (6.34) and (6.35) if $(f_2)_{\square}(x_0; \cdot) = (f_2)_{+}(x_0; y)$ and if $(f_1)_{+}(x_0; \cdot)$ and $(f_2)_{+}(x_0; \cdot)$ are never equal to $-\infty$.

Proof. Take $m = n$ and $F := I$ in Theorem 6.14. \square

In the special case in which $f_{\square}(x_0; \cdot)$ is convex, we can define $\partial^k f(x_0) := \partial(f_{\square}(x_0; \cdot))(0)$ and can obtain results like the following:

PROPOSITION 6.17. *Let $f_1: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ and $f_2: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be finite and strictly l.s.c. at x_0 . Assume that $(f_1)_{\square}(x_0; \cdot)$ and $(f_2)_{\square}(x_0; \cdot)$ are convex, and that (3.8) holds. Then*

$$(6.36) \quad \partial^k(f_1 + f_2)(x_0) \subset \partial^k f_1(x_0) + \partial^k f_2(x_0).$$

Equality holds in (6.36) if $(f_1)_{\square}(x_0; \cdot) = (f_1)_{+}(x_0; \cdot)$ or $(f_2)_{\square}(x_0; \cdot) = (f_2)_{+}(x_0; \cdot)$ —in particular, if f_1 or f_2 is convex.

Proof. Since (3.8) holds, so does (6.34), and (6.36) follows from (6.34). Equality under the given assumptions follows from Corollary 6.16 and the fact that if either $(f_1)_{\square}(x_0; \cdot)$ or $(f_2)_{\square}(x_0; \cdot)$ is not proper, both sides of (6.36) are empty. \square

It is interesting to note that assumptions involving $f^{\uparrow}(x_0; \cdot)$ are required in these results on $f_{+}(x_0; \cdot)$ and $f_{\square}(x_0; \cdot)$. The same is true of Ioffe's results on approximate subdifferentials [13].

We now present an example which satisfies the hypothesis of Proposition 6.17 even though f_1 and f_2 are not convex.

Example 6.18. Define $f_1: \mathbf{R} \rightarrow \mathbf{R}$ by

$$f_1(x) := \begin{cases} 0 & \text{if } x \leq 0, \\ \frac{1}{2^{n+1}} & \text{if } \frac{1}{2^{n+1}} < x \leq \frac{1}{2^n}, \quad n = 0, \pm 1, \pm 2, \dots, \end{cases}$$

and define $f_2: \mathbf{R} \rightarrow \mathbf{R}$ by

$$f_2(x) := \begin{cases} 0 & \text{if } x \leq 0, \\ \frac{1}{4^{(n+1)}} & \text{if } \frac{1}{4^{(n+1)}} < x \leq \frac{1}{4^n}, \quad n = 0, \pm 1, \pm 2, \dots \end{cases}$$

It is not hard to see that

$$f_1^{\uparrow}(0; y) = f_2^{\uparrow}(0; y) = \begin{cases} 0 & \text{if } y \leq 0, \\ +\infty & \text{if } y > 0, \end{cases}$$

$$(f_1)_\square(0; y) = (f_2)_\square(0; y) = \begin{cases} 0 & \text{if } y \leq 0, \\ y & \text{if } y > 0, \end{cases}$$

$$(f_1 + f_2)_\square(0; y) = \begin{cases} 0 & \text{if } y \leq 0, \\ 2y & \text{if } y > 0, \end{cases}$$

$$(f_1)_+(0; y) = \begin{cases} 0 & \text{if } y \leq 0, \\ y/2 & \text{if } y > 0, \end{cases}$$

$$(f_2)_+(0; y) = \begin{cases} 0 & \text{if } y \leq 0, \\ y/4 & \text{if } y > 0, \end{cases}$$

$$(f_1 + f_2)_+(0; y) = \begin{cases} 0 & \text{if } y \leq 0, \\ 3y/4 & \text{if } y > 0. \end{cases}$$

Then $\text{dom } f_1^\uparrow(0; \cdot) = \text{dom } f_2^\uparrow(0; \cdot) = \{y \mid y \leq 0\}$, so (3.8) is satisfied and (6.36) holds. In fact $\partial_\square(f_1 + f_2)(0) = [0, 2]$ while $\partial_\square f_1(0) = \partial_\square f_2(0) = [0, 1]$, so equality holds in (6.36) even though $(f_i)_+(x_0; \cdot) \neq (f_i)_\square(x_0; \cdot)$, $i = 1, 2$.

If $f_\square(x_0; \cdot)$ is not convex, it is still possible to define a notion of subgradient for f by means of upper convex approximates.

DEFINITION 6.19 (cf. [15]). The function $h: E \rightarrow \bar{\mathbf{R}}$ is an *upper convex approximate* for $f: E \rightarrow \bar{\mathbf{R}}$ at $x_0 \in \text{dom } f$ if

(a) $h(y) \leq f_\square(x_0; y)$ for all $y \in E$, and

(b) $h(\cdot)$ is convex and positively homogeneous. The set $\partial_h^k(x_0) := \{x' \in E^* \mid h(y) \leq \langle y, x' \rangle \forall y \in E\}$ is called an *h -subgradient* of f at x_0 .

Specific examples of upper convex approximates include $f^\uparrow(x_0; \cdot)$, $f^0(x_0; \cdot)$, the asymptotic epiderivatives of [9], [10], and the upper convex approximations of [15]. As one might expect, not as much can be said about general upper convex approximates as can be determined about specific ones like $f^0(x_0; \cdot)$ or $f^\uparrow(x_0; \cdot)$; however, necessary conditions for minimality can be expressed in terms of upper convex approximates [24], [25]. We will not develop this concept in detail here, except to mention the following generalizations of Propositions 4.1 and 4.2:

PROPOSITION 6.20. Suppose $f: E \rightarrow \bar{\mathbf{R}}$ has a local minimum at $x_0 \in E$ and $h(x_0; \cdot): E \rightarrow \bar{\mathbf{R}}$ is an upper convex approximate for f at x_0 . Then

$$0 \leq f_\square(x_0; y) \leq h(x_0; y) \quad \text{for all } y \in E$$

and

$$0 \in \partial_h^k f(x_0).$$

PROPOSITION 6.21. Let $f: \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be strictly l.s.c. at x_0 , and let $C \subset \mathbf{R}^n$ be closed near x_0 . Suppose $x_0 \in X$ is a local minimizer of the problem $\min \{f(x) \mid x \in C\}$. Assume (4.1) holds. Let $h(x_0; \cdot): \mathbf{R}^n \rightarrow \bar{\mathbf{R}}$ be an upper convex approximate for f at x_0 such that $h(x_0; y) \leq f^\uparrow(x_0; y)$ for all $y \in \mathbf{R}^n$, and let D be a convex subcone of $k_C(x_0)$ satisfying $T_C(x_0) \subset D \subset k_C(x_0)$. Then

$$(6.37) \quad 0 \in \partial_h^k f(x_0) + D^0.$$

Proof. $f + i_C$ is locally minimized at x_0 , so for all $y \in \mathbf{R}^n$,

$$\begin{aligned} 0 &\leq (f + i_C)_\square(x_0; y) \\ &\leq f_\square(x_0; y) + (i_C)_\square(x_0; y) \end{aligned}$$

(by Corollary 6.16, since (4.1) holds)

$$\begin{aligned} &= f_\square(x_0; y) + i_{k_C}(x_0)^{(y)} \\ &\leq h(x_0; y) + i_D(y). \end{aligned}$$

Now $\text{dom } h(x_0; \cdot) \supset \text{dom } f^\dagger(x_0; \cdot)$ and $D \subset T_C(x_0)$ by hypothesis, so (4.1) implies that $\text{dom } h(x_0; \cdot) - D = \mathbf{R}^n$. Hence

$$0 \in \partial(h(x_0; \cdot) + i_D(\cdot))(0) = \partial_h f(x_0) + D^0$$

by Theorem 23.8 of [16] and so (6.37) holds. \square

Acknowledgments. We are grateful to G. G. Watkins for his help with the proof of Theorem 4.7, and to the referee for suggestions which improved the presentation of this work.

FEEDBACK CONTROL OF ANALYTIC NONLINEAR SYSTEMS BY EXTENDED LINEARIZATION*

WILLIAM T. BAUMANN† AND WILSON J. RUGH‡

Abstract. For multi-input, multi-output, analytic, nonlinear systems, a design method based on the family of linearizations of the system, parameterized by the family of constant operating points, is considered. Using the Cauchy-Kowalewski Theorem it is shown that nonlinear state feedback control laws and output/observer feedback control laws exist such that the eigenvalues of the family of closed-loop linearizations have specified, analytically-scheduled values with respect to the family of closed-loop operating points.

Key words. nonlinear control, feedback control, eigenvalue placement, nonlinear observers

AMS(MOS) subject classification. 93C10

1. Introduction. In many practical situations, control of a nonlinear system is approached by linearizing the system about a nominal constant operating point, and then applying linear feedback control methods. When control over a wider range of operation is required, the process is repeated at distinct constant operating points, and an overall controller is pieced together from the resulting linear control designs. This approach is often referred to as gain scheduling. Recently the authors have been working on a systematic reformulation and extension of this practical approach, called design by extended linearization.

The goal of the extended-linearization method is to design a nonlinear feedback controller for the nonlinear system such that each member of the family of linearizations of the closed-loop system achieves some specified (linear) control objective. In this paper, which is an extension of [1] to the multi-input case, we show that a nonlinear state feedback control law can be constructed so as to place the eigenvalues of the family of closed-loop linearizations at specified locations, which may be a function of the closed-loop operating point. A similar approach is used to design a nonlinear observer such that the eigenvalues of the family of linearized error equations have specified locations. Feedback of the observed state yields a closed-loop system whose family of linearizations exhibits the eigenvalue separation property, and has the specified eigenvalue locations. Although this approach typically is local in nature, it applies to a broad class of systems, and yields output feedback control laws.

The initial step in the design approach involves determining parameterized families of linearized feedback gains for the family of system linearizations. Although this is related to work on parameterized linear systems, the local nature of our problem makes this first step essentially trivial. The second, and major, step is to synthesize a nonlinear feedback gain that does not explicitly depend on the parameters in the linearized feedback gains. In the multi-input case, this requires the solution of total differential equations that involve nontrivial integrability conditions (the classical Frobenius theorem).

Recent work on so-called pseudo-linearization, by variable change and state feedback, is related to our approach in that the closed-loop linearization family is required to be constant with respect to the closed-loop family of operating points, though the issues of state observation and output feedback were not addressed [3], [4]. For single-input systems with state feedback, comparison of [1] and [3] shows that similar hypotheses are required for the somewhat different objectives. However, for multi-input systems with state feedback, comparison of the results here with those in [4] shows that the objective of eigenvalue placement requires weaker hypotheses.

The mathematical developments in the sequel involve real-analytic functions. Results typically apply in a sufficiently small neighborhood of an appropriate point, although this local restriction often will be left understood. The following notation for differentiation will be used. If $f(x): \mathbf{R} \rightarrow \mathbf{R}^p$, then Df is a column vector $[df_1/dx \cdots df_p/dx]^T$, and if $f(x): \mathbf{R}^n \rightarrow \mathbf{R}^p$, then Df denotes the $p \times n$ Jacobian matrix of partial derivatives. If $f(x, y): \mathbf{R}^m \times \mathbf{R}^n \rightarrow \mathbf{R}^p$, then D_1f represents the partial derivative with respect to x , and D_2f the partial derivative with respect to y . Evaluation of a derivative is indicated in the customary fashion, e.g., $D_1f(x_0, y_0)$.

2. State feedback control. We assume that the nonlinear system to be controlled can be described by a constant-parameter, analytic differential equation, and that the nominal constant operating (equilibrium) point corresponds to zero input and zero state. That is, the system can be described by (suppressing t -arguments)

$$(2.1) \quad \dot{x} = f(x, w)$$

where $f(\cdot, \cdot): \mathbf{R}^n \times \mathbf{R}^m \rightarrow \mathbf{R}^n$ is analytic in a neighborhood of the origin, with $f(0, 0) = 0$. The family of constant operating points corresponding to nonzero constant inputs, $w(t) = \varepsilon$, also will be of interest. We will assume throughout that the linearization of (2.1) about zero satisfies the following hypotheses:

- (H1) (1) $[D_1f(0, 0), D_2f(0, 0)]$ is a controllable pair,
 (2) $D_1f(0, 0)$ is invertible,
 (3) $D_2f(0, 0)$ is full rank.

Then, by the implicit function theorem,

$$(2.2) \quad f(x, \varepsilon) = 0$$

has a unique analytic solution $x(\varepsilon)$ in an open neighborhood of $\varepsilon = 0$. Typically the argument of x will be suppressed.

The state feedback control laws to be considered have the form

$$(2.3) \quad w = u - k(x)$$

where $k(\cdot): \mathbf{R}^n \rightarrow \mathbf{R}^m$ is analytic, $k(0) = 0$, and $u \in \mathbf{R}^m$ is an external input. This control law yields a closed-loop system described by the analytic state equation

$$(2.4) \quad \dot{x} = f(x, u - k(x))$$

that retains a constant operating point at $u = 0$, $x = 0$. Again, the family of constant operating points corresponding to nonzero constant inputs, $u(t) = \beta$, will be of interest, so it will be assumed that the specified eigenvalues of the linearized closed-loop system are nonzero (in addition to self-conjugate). Then $D_1f(0, 0) - D_2f(0, 0)Dk(0)$ is invertible, and, as a consequence,

$$(2.5) \quad f(x_c, \beta - k(x_c)) = 0$$

has a unique analytic solution $\mathbf{x}_c(\beta)$ in an open neighborhood of $\beta = 0$. Let

$$(2.6) \quad \varepsilon(\beta) = \beta - k(\mathbf{x}_c(\beta));$$

then $\varepsilon(\beta)$ is analytic, with $\varepsilon(0) = 0$, and from (2.2),

$$(2.7) \quad \mathbf{x}(\varepsilon(\beta)) = \mathbf{x}_c(\beta).$$

In the remainder of the paper, the families of constant operating points for both the open- and closed-loop systems will be parameterized by ε , and $\mathbf{x}(\varepsilon)$ (or simply \mathbf{x}) will represent the equilibrium state. For the closed-loop system, the parameter ε is related to the constant input $u(t) = \beta$ via (2.6), and it is easy to show that this relation is invertible.

Linearization of the closed-loop system about a closed-loop operating point yields the linear state equation

$$(2.8) \quad \dot{x} = [D_1 f(\mathbf{x}, \varepsilon) - D_2 f(\mathbf{x}, \varepsilon) Dk(\mathbf{x})]x + D_2 f(\mathbf{x}, \varepsilon)u$$

where x and u now indicate deviations from \mathbf{x} and β , respectively. The goal of this section is to prove the following theorem:

THEOREM 2.1. *Suppose the analytic system (2.1) satisfies (H1). Then there exists an analytic feedback gain $k(\cdot): \mathbf{R}^n \rightarrow \mathbf{R}^m$ with $k(0) = 0$ such that the eigenvalues of the closed-loop linearization (2.8) are specified, analytic functions of ε in an open neighborhood of $\varepsilon = 0$.*

Since the linearization of (2.1) about the nominal operating point at zero is assumed to be controllable, it is not difficult to find an analytic $Q(\cdot): \mathbf{R}^m \rightarrow \mathbf{R}^{m \times n}$ such that the matrix $D_1 f(\mathbf{x}, \varepsilon) - D_2 f(\mathbf{x}, \varepsilon)Q(\varepsilon)$ has the specified eigenvalues. The problem lies in synthesizing a state feedback gain $k(\cdot)$ that does not depend explicitly on ε , and that satisfies

$$(2.9) \quad Dk(\mathbf{x}(\varepsilon)) = Q(\varepsilon).$$

However, unless $Q(\varepsilon)$ satisfies certain integrability conditions there can be no solution to (2.9). Thus our approach to the problem consists of several steps. After determining the integrability conditions, a general form for $Q(\cdot)$ that gives the specified eigenvalue locations and contains $(n-1)m$ undetermined functions is given in Lemma 2.2. It is then shown in Lemma 2.4 that these undetermined functions can be chosen so that $Q(\cdot)$ satisfies the integrability conditions. Finally, the proof of Theorem 2.1 is completed by showing how to construct a function $k(\cdot)$ satisfying (2.9).

To address the integrability conditions, consider the function $\hat{k}(\varepsilon) = k(\mathbf{x}(\varepsilon))$. If $k(\cdot): \mathbf{R}^n \rightarrow \mathbf{R}^m$ is an analytic solution of (2.9) then $\hat{k}(\cdot): \mathbf{R}^m \rightarrow \mathbf{R}^m$ is an analytic solution of

$$(2.10) \quad D\hat{k}(\varepsilon) = Q(\varepsilon)D\mathbf{x}(\varepsilon).$$

Thus existence of a solution to (2.10) is necessary for existence of a solution to (2.9). Let $\hat{k}_i(\varepsilon)$ denote the i th entry of $\hat{k}(\varepsilon)$ and $q_i(\varepsilon)$ the i th row of $Q(\varepsilon)$, then (2.10) can be written row-wise as

$$(2.11) \quad D\hat{k}_i = q_i D\mathbf{x}.$$

By the Frobenius theorem, a necessary and sufficient condition that (2.11) have a solution is that mixed second partial derivatives on the right side commute [6]. That is,

$$\frac{\partial}{\partial \varepsilon_j} [q_i D_k \mathbf{x}] = \frac{\partial}{\partial \varepsilon_k} [q_i D_j \mathbf{x}], \quad j, k = 1, \dots, m, \quad k > j.$$

Expanding this, and using the fact that mixed second partial derivatives of \mathbf{x} commute, we get

$$D_j q_i D_k \mathbf{x} = D_k q_i D_j \mathbf{x}, \quad j, k = 1, \dots, m, \quad k > j.$$

Therefore, transposing the left side of this expression and considering each value of j separately, the integrability conditions for (2.11) can be written in matrix form as the set of conditions

$$(2.12) \quad H_j D_j q_i^T = \begin{bmatrix} D_{j+1} q_i \\ \vdots \\ D_m q_i \end{bmatrix} D_j \mathbf{x}, \quad i = 1, \dots, m, \quad j = 1, \dots, m-1$$

where

$$(2.13) \quad H_j = [D_{j+1} \mathbf{x} | \dots | D_m \mathbf{x}]^T.$$

To show that an appropriate $Q(\varepsilon)$ exists, two technical lemmas will be given, the proofs of which are simplified if a convenient transformation is made at the outset. From the hypotheses on (2.1), it can be assumed without loss of generality that a linear coordinate change has been applied to (2.1) so that the pair $[D_1 f(0, 0), D_2 f(0, 0)]$ is in Brunovsky canonical form (without feedback) [5, p. 501]. It is also assumed that an input transformation has been performed so that $D_2 f(0, 0)$ has zero entries, except for ones in positions $(1, 1), (k_1 + 1, 2), \dots, (k_1 + \dots + k_{m-1} + 1, m)$, where the Kronecker indices k_i are ordered as $k_1 \leq k_2 \leq \dots \leq k_m$. Once the closed-loop eigenvalues are specified, this form allows the straightforward choice of a matrix $Q^0 \in \mathbb{R}^{m \times n}$ such that $D_1 f(0, 0) - D_2 f(0, 0) Q^0$ is in top companion form, has the eigenvalues specified at $\beta = 0$, and is controllable from the first component of the input. We let $q_{i+} = [q_{i1}, \dots, q_{i, n-k_i}]^T$ and $q_{i-} = [q_{i, n-k_i+1}, \dots, q_{in}]^T$ and define q_{i+}^0 and q_{i-}^0 in the obvious, consistent manner.

LEMMA 2.2. *Suppose the analytic system (2.1) satisfies (H1). Then given m analytic functions $q_{i+}(\varepsilon): \mathbb{R}^m \rightarrow \mathbb{R}^{n-k_i}$ with $q_{i+}(0) = q_{i+}^0$, there exist analytic functions $q_{i-}(\varepsilon, q_{1+}, \dots, q_{m+})$ with $q_{i-}(0, q_{1+}^0, \dots, q_{m+}^0) = q_{i-}^0$ such that the linearized closed-loop system (2.8), (2.9) has the specified eigenvalues that are analytic functions of ε in an open neighborhood of $\varepsilon = 0$.*

Proof. For convenience, let

$$\begin{aligned} P &= sI - D_1 f(\mathbf{x}, \varepsilon) + D_2 f(\mathbf{x}, \varepsilon) Q, \\ \det P &= s^n + p_1(\varepsilon, Q) s^{n-1} + \dots + p_n(\varepsilon, Q), \\ p(\varepsilon, Q) &= [p_1(\varepsilon, Q) \dots p_n(\varepsilon, Q)]^T, \\ d &= [q_{m-}^T | \dots | q_{1-}^T]^T. \end{aligned}$$

Then, for the given analytic $q_{i+}(\varepsilon)$, we want to choose analytic $q_{i-}(\varepsilon, q_{1+}, \dots, q_{m+})$ such that for all ε in an open neighborhood of $\varepsilon = 0$, $p(\varepsilon, Q)$ equals the specified vector of characteristic polynomial coefficients (which are functions of ε). This will be accomplished by showing that $\partial p(\varepsilon, Q) / \partial d|_{\varepsilon=0, Q=Q^0}$ is invertible, so that the implicit function theorem can be applied to complete the proof. The analyticity of the q_{i-} follows from the fact that p is analytic [6, p. 272].

We first find an expression for $\partial p(\varepsilon, Q) / \partial q_i|_{\varepsilon=0, Q=Q^0}$. Using Laplace's expansion about the j th column of P gives

$$\det P = \sum_{k=1}^n [P]_{kj} [P]^{kj}$$

where $[M]_{ij}$ is the (i, j) element of M and $[M]^{ij}$ is the cofactor of $[M]_{ij}$. Since q_{ij} , the j th entry of q_i , appears only in the j th column of P ,

$$\begin{aligned} \frac{\partial}{\partial q_{ij}} \det P|_{\varepsilon=0, Q=Q^0} &= \sum_{k=1}^n [P]^{kj}|_{\varepsilon=0, Q=Q^0} \frac{\partial}{\partial q_{ij}} [P]_{kj}|_{\varepsilon=0, Q=Q^0} \\ &= \sum_{k=1}^n [\text{Adj}(sI - D_1 f(0, 0) + D_2 f(0, 0) Q^0)]_{jk} [D_2 f(0, 0)]_{ki} \end{aligned}$$

where $\text{Adj}(M)$ is the adjugate matrix of M . Letting $A = D_1 f(0, 0)$, $B = D_2 f(0, 0)$, and b_i be the i th column of B , we can write

$$\frac{\partial}{\partial q_i} \det P|_{\varepsilon=0, Q=Q^0} = b_i^T \text{Adj}(sI - A + BQ^0)^T.$$

Using a standard resolvent identity we obtain

$$\begin{aligned} \frac{\partial}{\partial q_i} \det P|_{\varepsilon=0, Q=Q^0} &= \{b_i s^{n-1} + [(A - BQ^0)b_i + p_1(0, Q^0)b_i]s^{n-2} + \cdots \\ &\quad + [(A - BQ^0)^{n-1}b_i + \cdots + p_{n-1}(0, Q^0)b_i]\}^T. \end{aligned}$$

Finally,

$$(2.14) \quad \frac{\partial}{\partial q_i} p(\varepsilon, Q)|_{\varepsilon=0, Q=Q^0} = R^T [b_i | (A - BQ^0)b_i | \cdots | (A - BQ^0)^{n-1}b_i]^T$$

where R is an upper triangular Toeplitz matrix with first row $[1 \ p_1(0, Q^0) \cdots p_{n-1}(0, Q^0)]$. Now we can write

$$(2.15) \quad \frac{\partial}{\partial d} p(\varepsilon, Q)|_{\varepsilon=0, Q=Q^0} = R^T C^T$$

where C consists of particular rows chosen from $[b_i | (A - BQ^0)b_i | \cdots | (A - BQ^0)^{n-1}b_i]$. Because of the special forms chosen for A , B and Q^0 , it is not hard to verify that C is an upper triangular matrix with ones on the main diagonal. Thus, (2.15) is invertible. \square

The following corollary, obtained by considering (2.14) for $i = 1$, will be needed in § 3.

COROLLARY 2.3. *Suppose the analytic system (2.1) satisfies (H1). Then given $m - 1$ analytic functions $q_2(\varepsilon), \cdots, q_m(\varepsilon): \mathbf{R}^m \rightarrow \mathbf{R}^n$, with $q_2(0) = q_2^0, \cdots, q_m(0) = q_m^0$, there exists an analytic function $q_1(\varepsilon, q_2, \cdots, q_m)$ with $q_1(0, q_2^0, \cdots, q_m^0) = q_1^0$ such that the linearized closed-loop system (2.8), (2.9) has the specified eigenvalues for all ε in an open neighborhood of $\varepsilon = 0$.*

Now it must be shown that a matrix $Q(\varepsilon)$ of the form in Lemma 2.2 can be chosen to satisfy the integrability conditions (2.12), in order to establish the existence of a solution $\hat{k}(\varepsilon)$ to (2.10).

LEMMA 2.4. *Suppose the analytic system (2.1) satisfies (H1). Then there exists an analytic $Q(\varepsilon)$ such that, in an open neighborhood of $\varepsilon = 0$, (2.8), (2.9) has eigenvalues that are specified, analytic functions of ε , and (2.12) is satisfied.*

Proof. The notation

$$(2.16) \quad q_{i-} = q_{i-}(\varepsilon_1, \cdots, \varepsilon_m, q_{1+}, \cdots, q_{m+}), \quad q_{i+} = q_{i+}(\varepsilon_1, \cdots, \varepsilon_m)$$

$i = 1, \cdots, m$, will be used, where the q_{i+} are as yet unspecified, and the q_{i-} are as in Lemma 2.2 for the specified eigenvalues. Using the chain rule, with careful attention to the differentiation notation, the derivative of q_{i-} with respect to ε_j can be written as

$$(2.17) \quad D_{m+1}q_{i-} - D_j q_{1+} + \cdots + D_{2m}q_{i-} - D_j q_{m+} + D_j q_{i-}.$$

Then the set of conditions (2.12) can be expressed solely in terms of the q_{i+} as

$$(2.18) \quad G_j \begin{bmatrix} D_j q_{1+} \\ \vdots \\ D_j q_{m+} \end{bmatrix} = F_j(\varepsilon, q_{1+}, \dots, q_{m+}, D_{j+1} q_{1+}, \dots, D_m q_{m+}), \quad j = 1, \dots, m-1$$

where each F_j is a known, analytic function,

$$(2.19) \quad G_j = \begin{bmatrix} H_j^{1+} & & 0 \\ & \ddots & \\ 0 & & H_j^{m+} \end{bmatrix} + \begin{bmatrix} H_j^{1-} D_{m+1} q_{1-} & \cdots & H_j^{1-} D_{2m} q_{1-} \\ \vdots & & \vdots \\ H_j^{m-} D_{m+1} q_{m-} & \cdots & H_j^{m-} D_{2m} q_{m-} \end{bmatrix},$$

$j = 1, \dots, m-1$

is an $m(m-j) \times n(m-1)$ matrix partitioned so that the diagonal blocks are of dimension $(m-j) \times (n-k_i)$, $i = 1, \dots, m$, and where

$$[H_j^{i+} \quad H_j^{i-}] = H_j$$

is a partitioning of H_j into $(m-j) \times (n-k_i)$ and $(m-j) \times k_i$ blocks.

Using the fact that $D\mathbf{x}(0) = -[D_1 f(0, 0)]^{-1} D_2 f(0, 0)$, and the special forms of $D_1 f(0, 0)$ and $D_2 f(0, 0)$, we can see that $H_1|_{\varepsilon=0}$ has zero entries, except in columns $k_1, k_1 + k_2, \dots, n$. By using a preliminary constant state feedback the elements in these columns can be specified arbitrarily within the constraint that $H_1|_{\varepsilon=0}$ be full rank. Thus, we will assume that a preliminary state feedback has been performed (prior to choosing Q^0), such that $H_1|_{\varepsilon=0}$ is full rank and its n th column is zero. Keeping in mind the ordering of the Kronecker indices, this implies that $H_j^{i-}|_{\varepsilon=0} = 0$ and $H_j^{i+}|_{\varepsilon=0}$ is full rank for $i = 1, \dots, m$; $j = 1, \dots, m-1$. Hence $G_j|_{\varepsilon=0}$ is full rank for $j = 1, \dots, m-1$.

Now, independent equations can be appended to each equation in (2.18) in such a way that each augmented G_j, \tilde{G}_j , is invertible in an open neighborhood of $\varepsilon = 0$. Multiplying the augmented equations by \tilde{G}_j^{-1} yields the set of equations

$$(2.20) \quad \begin{bmatrix} D_j q_{1+} \\ \vdots \\ D_j q_{m+} \end{bmatrix} = \tilde{F}_j(\varepsilon, q_{1+}, \dots, q_{m+}, D_{j+1} q_{1+}, \dots, D_m q_{m+}), \quad j = 1, \dots, m-1.$$

For a given j and appropriate initial conditions, there exists a solution to (2.20), and hence a solution to (2.12) for that value of j , by the Cauchy-Kowalewski Theorem. What must be shown, however, is that there is a solution satisfying (2.12) for $j = 1, \dots, m-1$ simultaneously. To this end, we will use (2.20) to construct a trial solution, \hat{q}_i , to (2.12), and then verify that this is indeed a solution to (2.12). For $j = m-1$, set $\varepsilon_1 = \dots = \varepsilon_{m-2} = 0$ in (2.20) and consider the resulting equation in the independent variables $\varepsilon_{m-1}, \varepsilon_m$. Using the initial conditions $q_{i+}(0, \dots, 0, \varepsilon_m) = q_{i+}^0$, $i = 1, \dots, m$, an analytic solution exists in an open neighborhood of $\varepsilon_{m-1} = \varepsilon_m = 0$ by the Cauchy-Kowalewski Theorem. Addressing (2.20) for $j = m-2$ in the same fashion, with $\varepsilon_1 = \dots = \varepsilon_{m-3} = 0$, there exists an analytic solution using as the initial condition the previously determined solution of the $j = m-1$ case. Continuing in this manner, there exist analytic solutions $\hat{q}_{i+}(\varepsilon_1, \dots, \varepsilon_m)$, $i = 1, \dots, m$, for (2.20) with $j = 1$ in an open neighborhood of $\varepsilon = 0$.

Finally, it will be shown that

$$\hat{q}_i(\varepsilon_1, \dots, \varepsilon_m) = [\hat{q}_{i+}^T q_{i-}^T(\varepsilon_1, \dots, \varepsilon_m, \hat{q}_{1+}, \dots, \hat{q}_{m+})], \quad i = 1, \dots, m$$

satisfy the conditions (2.12). Since the following argument is independent of i , the index i will be dropped and \hat{q}_k will be written for \hat{q}_{ik} . Assuming that (2.12) is satisfied for $j = 1, \dots, J-1$, it will be shown that \hat{q} satisfies (2.12) for $j = J$. In scalar terms, (2.12) with $j = J$ is

$$(2.21) \quad \sum_{k=1}^n D_J q_k D_l \mathbf{x}_k = \sum_{k=1}^n D_l q_k D_J \mathbf{x}_k, \quad l = J+1, \dots, m.$$

Now, \hat{q} satisfies (2.21) if and only if

$$(2.22) \quad D_m^{d_m} \dots D_1^{d_1} \left[\sum_{k=1}^n D_J \hat{q}_k D_l \mathbf{x}_k \right] \Big|_0 = D_m^{d_m} \dots D_1^{d_1} \left[\sum_{k=1}^n D_l \hat{q}_k D_J \mathbf{x}_k \right] \Big|_0$$

for $l = J+1, \dots, m$ and $d_1, \dots, d_m = 0, 1, \dots$. By the inductive hypothesis

$$(2.23) \quad \sum_{k=1}^n D_j \hat{q}_k D_l \mathbf{x}_k = \sum_{k=1}^n D_l \hat{q}_k D_j \mathbf{x}_k, \quad j = 1, \dots, J-1, \quad l = j+1, \dots, m.$$

Applying D_J to (2.23) we get

$$(2.24) \quad \sum_{k=1}^n D_J D_j \hat{q}_k D_l \mathbf{x}_k + \sum_{k=1}^n D_j \hat{q}_k D_J D_l \mathbf{x}_k = \sum_{k=1}^n D_J D_l \hat{q}_k D_j \mathbf{x}_k + \sum_{k=1}^n D_l \hat{q}_k D_J D_j \mathbf{x}_k, \\ j = 1, \dots, J-1, \quad l = j+1, \dots, m.$$

Specializing (2.23) to $l = J$ and then applying D_l we obtain

$$(2.25) \quad \sum_{k=1}^n D_l D_j \hat{q}_k D_J \mathbf{x}_k + \sum_{k=1}^n D_j \hat{q}_k D_l D_J \mathbf{x}_k = \sum_{k=1}^n D_l D_J \hat{q}_k D_j \mathbf{x}_k + \sum_{k=1}^n D_J \hat{q}_k D_l D_j \mathbf{x}_k \\ j = 1, \dots, J-1, \quad l = 1, \dots, m.$$

Subtraction of (2.25) from (2.24) results in

$$\sum_{k=1}^n D_J D_j \hat{q}_k D_l \mathbf{x}_k + \sum_{k=1}^n D_j \hat{q}_k D_l D_J \mathbf{x}_k = \sum_{k=1}^n D_l D_j \hat{q}_k D_J \mathbf{x}_k + \sum_{k=1}^n D_l \hat{q}_k D_J D_j \mathbf{x}_k.$$

That is,

$$(2.26) \quad D_j \left[\sum_{k=1}^n D_J \hat{q}_k D_l \mathbf{x}_k \right] = D_j \left[\sum_{k=1}^n D_l \hat{q}_k D_J \mathbf{x}_k \right], \quad j = 1, \dots, J-1, \quad l = j+1, \dots, m,$$

is satisfied in an open neighborhood of $\varepsilon = 0$, since (2.23) is satisfied in an open neighborhood of $\varepsilon = 0$. Therefore, (2.22) is satisfied for all values of d_1, \dots, d_m , with the possible exception of $d_1 = \dots = d_{J-1} = 0$. But this case follows from the fact that $\hat{q}(0, \dots, 0, \varepsilon_J, \dots, \varepsilon_m)$ satisfies (2.21) with $\varepsilon_1 = \dots = \varepsilon_{J-1} = 0$ due to the iterative construction.

Since $Q(\varepsilon)$ can be chosen to satisfy the integrability conditions (2.12), there exists a solution $\hat{k}(\varepsilon)$ to (2.10). To complete the proof of Theorem 2.1, we need only show that existence of $\hat{k}(\varepsilon)$ implies existence of a solution $k(\cdot)$ to (2.9).

Proof of Theorem 2.1. Since (H1) is satisfied, $D\mathbf{x}(0) = -[D_1 f(0, 0)]^{-1} D_2 f(0, 0)$ is full rank and there are m components, say $\mathbf{x}_1, \dots, \mathbf{x}_m$ for convenience, such that the

function $\mathbf{g}(\varepsilon) = [\mathbf{x}_1, \dots, \mathbf{x}_m]^T$ has a local inverse by the inverse function theorem. Using $k_i(\varepsilon)$ and $Q(\varepsilon)$ from Lemma 2.4, we complete the proof by verifying that

$$(2.27) \quad k_i(x) = \hat{k}_i(\mathbf{g}^{-1}(x_1, \dots, x_m)) + \sum_{j=m+1}^n q_{ij}(\mathbf{g}^{-1}(x_1, \dots, x_m)) \\ \times [x_j - \mathbf{x}_j(\mathbf{g}^{-1}(x_1, \dots, x_m))]$$

satisfies (2.9). Differentiating (2.27) with respect to x_j , $j = m+1, \dots, n$, and evaluating at \mathbf{x} we obtain

$$\frac{\partial k_i}{\partial x_j}(\mathbf{x}) = q_{ij}(\mathbf{g}^{-1}(\mathbf{x}_1, \dots, \mathbf{x}_m)) = q_{ij}(\varepsilon), \quad i = 1, \dots, n, \quad j = m+1, \dots, n.$$

Proceeding similarly for x_j , $j = 1, \dots, m$ we get

$$\begin{aligned} \frac{\partial k_i}{\partial x_j}(\mathbf{x}) &= \sum_{k=1}^n \sum_{l=1}^m q_{ik}(\varepsilon) D_l \mathbf{x}_k D_j \mathbf{g}_l^{-1}(\mathbf{x}_1, \dots, \mathbf{x}_m) \\ &\quad - \sum_{k=m+1}^n \sum_{l=1}^m q_{ik}(\varepsilon) D_l \mathbf{x}_k D_j \mathbf{g}_l^{-1}(\mathbf{x}_1, \dots, \mathbf{x}_m) \\ &= \sum_{k=1}^m \sum_{l=1}^m q_{ik}(\varepsilon) D_l \mathbf{x}_k D_j \mathbf{g}_l^{-1}(\mathbf{x}_1, \dots, \mathbf{x}_m) \\ &= q_{ij}(\varepsilon), \quad i = 1, \dots, n, \quad j = 1, \dots, m. \end{aligned}$$

Remark 2.5. It is tempting to attack the proof of Theorem 2.1 by first reducing the controllable multi-input nonlinear system to a controllable single-input nonlinear system, and then applying the single-input results. However, the single-input system has a one-dimensional operating point manifold, and hence the result would hold only on a one-dimensional subset of the m -dimensional operating point manifold.

3. State observation. The approach in § 2 also can be used to address the problem of observing the state of (2.1) given an output signal

$$(3.1) \quad y = h(x)$$

where $h(\cdot): \mathbf{R}^n \rightarrow \mathbf{R}^p$, $m \leq p < n$, is analytic with $h(0) = 0$. Corresponding to the constant operating points for (2.1), the constant-operating-point output is defined by

$$(3.2) \quad \mathbf{y}(\varepsilon) = h(\mathbf{x}(\varepsilon)).$$

Also, it will be assumed that (2.1), (3.1) satisfy the following hypotheses:

- (H2) (1) $[D_1 f(0, 0), Dh(0)]$ is an observable pair,
 (2) $D_1 f(0, 0)$ is invertible,
 (3) $D\mathbf{y}(0), Dh(0)$ are full rank.

The proposed observer for (2.1), (3.1) is described by

$$(3.3) \quad \dot{\hat{\mathbf{x}}} = f(\hat{\mathbf{x}}, w) + g(y) - g(\hat{y}), \quad \hat{y} = h(\hat{\mathbf{x}})$$

where $g(\cdot): \mathbf{R}^p \rightarrow \mathbf{R}^n$ is analytic with $g(0) = 0$. Denoting the difference (error) between the actual and observed state by $\tilde{\mathbf{x}} = \mathbf{x} - \hat{\mathbf{x}}$, $\tilde{\mathbf{x}}$ satisfies

$$(3.4) \quad \dot{\tilde{\mathbf{x}}} = f(\mathbf{x}, w) - f(\hat{\mathbf{x}}, w) - g(y) + g(\hat{y}).$$

This error equation has constant operating points for $w = \varepsilon$, $x = \hat{x} = \mathbf{x}$, and $y = \hat{y} = \mathbf{y}$. Linearizing (3.4) about such an operating point yields the linearized error equation,

$$(3.5) \quad \dot{\tilde{x}} = [D_1 f(\mathbf{x}, \varepsilon) - Dg(\mathbf{y}) Dh(\mathbf{x})] \tilde{x}.$$

The main result is as follows.

THEOREM 3.1. *Suppose the analytic system (2.1), (3.1) satisfies (H2). Then there exists an analytic observer gain $g(\cdot): \mathbf{R}^p \rightarrow \mathbf{R}^n$ with $g(0) = 0$ such that the eigenvalues of the linearized error equation (3.5) are specified, analytic functions of ε in an open neighborhood of $\varepsilon = 0$.*

Remark 3.2. With the choice of $g(\cdot)$ described above, (3.3) is an observer for the original system in the following sense. When the system state, x , is close to the constant operating point \mathbf{x} , and the estimate of x , \hat{x} , is close to \mathbf{x} , then \hat{x} will approach x and the error will be described approximately by (3.5).

Proof. It will be convenient to perform a linear change of output coordinates, and write (3.1), (3.2) as

$$(3.6) \quad y = Gh(x), \quad \mathbf{y}(\varepsilon) = Gh(\mathbf{x}(\varepsilon))$$

where G is a real, invertible, $p \times p$ matrix that is chosen as follows. Differentiating (3.6), we obtain

$$D\mathbf{y}(0) = -G \quad Dh(0)[D_1 f(0, 0)]^{-1} D_2 f(0, 0).$$

Deletion of the first column from both sides yields a $p \times (m-1)$ matrix equation, and since $\text{rank } D\mathbf{y}(0) = m$, with $m \leq p$, it follows that an invertible G can be chosen such that the first row is $[D_2 \mathbf{y}_1(0) \cdots D_m \mathbf{y}_1(0)] = 0$, and the $m-1$ columns are linearly independent.

From (H2) it follows that $[D_1 f(0, 0), GDh(0)]$ is an observable pair, and it can be assumed, as in the proof of Theorem 2.1, that the pair $[D_1 f(0, 0)^T, Dh(0)^T G^T]$ is in Brunovsky canonical form (without feedback) [5, p. 501]. Then by Corollary 2.3 there exists an $n \times p$ matrix $Q(\varepsilon)$ such that the eigenvalues of

$$(3.7) \quad D_1 f(\mathbf{x}, \varepsilon)^T - Dh^T(\mathbf{x}) G^T Q^T(\varepsilon)$$

have specified values with respect to ε . Furthermore, all columns of Q except the first can be left unspecified. The proof will be completed by showing that these unspecified columns can be chosen so that there exists an analytic $g(\cdot)$ with $g(0) = 0$ and

$$(3.8) \quad Dg(\mathbf{y}(\varepsilon)) = Q(\varepsilon).$$

When $\hat{g}(\varepsilon) = g(\mathbf{y}(\varepsilon))$, (3.8) implies

$$(3.9) \quad D\hat{g}(\varepsilon) = Q(\varepsilon) D\mathbf{y}(\varepsilon)$$

and existence of an analytic solution to (3.9) is necessary for existence of an analytic solution to (3.8). Following the development leading to (2.12), the integrability conditions for (3.9) can be written in the form

$$(3.10) \quad H_j D_j q_i^T = \begin{bmatrix} D_{j+1} q_i \\ \vdots \\ D_m q_i \end{bmatrix} D_j \mathbf{y}, \quad i = 1, \dots, n, \quad j = 1, \dots, m-1$$

where

$$(3.11) \quad H_j = [D_{j+1} \mathbf{y} | \cdots | D_m \mathbf{y}]^T.$$

The i th entry of the first column of Q will be written as $q_{i1} = q_{i1}(\varepsilon_1, \dots, \varepsilon_m, q_{1*}, \dots, q_{n*})$, where $q_{k*} = [q_{k2} \dots q_{kp}]$, and then the derivative of q_{i1} with respect to ε_j is given by

$$D_j q_{1*} D_{m+1} q_{i1}^T + \dots + D_j q_{n*} D_{m+n} q_{i1}^T + D_j q_{i1}.$$

Using this expression we can write the set of conditions in (3.10) in the form

$$(3.12) \quad W_j \begin{bmatrix} D_j q_{1*}^T \\ \vdots \\ D_j q_{n*}^T \end{bmatrix} = F_j(\varepsilon, q_{1*}, \dots, q_{n*}, D_{j+1} q_{1*}, \dots, D_m q_{n*}), \quad j = 1, \dots, m-1$$

where W_j is the $n(m-j) \times n(p-1)$ matrix partitioned into $(m-j) \times (p-1)$ blocks given by

$$(3.13) \quad W_j = \begin{bmatrix} V_j & & 0 \\ & \ddots & \\ 0 & & V_j \end{bmatrix} + \begin{bmatrix} z_j D_{m+1} q_{11} & \dots & z_j D_{m+n} q_{11} \\ & \ddots & \\ z_j D_{m+1} q_{n1} & \dots & z_j D_{m+n} q_{n1} \end{bmatrix},$$

$$V_j = \begin{bmatrix} D_{j+1} y_2 & \dots & D_{j+1} y_p \\ \vdots & & \vdots \\ D_m y_2 & \dots & D_m y_p \end{bmatrix}, \quad z_j = \begin{bmatrix} D_{j+1} y_1 \\ \vdots \\ D_m y_1 \end{bmatrix}.$$

Now, by virtue of the choice of G , $z_1(0), \dots, z_{m-1}(0)$ are zero and $V_1(0), \dots, V_{m-1}(0)$ have full rank. Thus the coefficient matrices W_1, \dots, W_{m-1} have full rank in an open neighborhood of $\varepsilon = 0$. The remainder of the proof follows from the proofs of Lemma 2.4 and Theorem 2.1, with $g(\cdot)$ replacing $k(\cdot)$, and y replacing x .

Remark 3.3. An observer of dimension $n-p$ can be constructed as shown in [1] and a result similar to Theorem 3.1 can be proved. Also it should be noted that the observer and state feedback results can be combined to give an output feedback control law in the usual way [1].

4. Example. In the preceding sections, special forms for linear systems and particular matrix partitionings were used to prove the invertibility of certain matrices. However, for specific examples, there are easier ways to proceed. The following simple example is meant to clarify the basic steps of the design methodology. Only the state feedback computations will be illustrated. Less simple examples probably would not yield closed-form solutions and would have to be approached via (truncated) series expansion methods.

Consider the bilinear system

$$\dot{x} = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix} x + \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix} x u_1 + \begin{bmatrix} -1 \\ -1 \end{bmatrix} u_1 + \begin{bmatrix} 0 \\ -1 \end{bmatrix} u_2.$$

An easy calculation gives

$$x = \frac{1}{2(\varepsilon_1 + 1)} \begin{bmatrix} 2\varepsilon_1 \\ \varepsilon_1 + \varepsilon_2 + \varepsilon_1 \varepsilon_2 \end{bmatrix}, \quad D_x = \begin{bmatrix} \frac{1}{(1+\varepsilon_1)^2} & 0 \\ \frac{1}{2(1+\varepsilon_1)^2} & \frac{1}{2} \end{bmatrix},$$

$$D_1 f(x, \varepsilon) = \begin{bmatrix} 1 + \varepsilon_1 & 0 \\ \varepsilon_1 & 2 \end{bmatrix}, \quad D_2 f(x, \varepsilon) = \frac{1}{\varepsilon_1 + 1} \begin{bmatrix} -1 & 0 \\ -1 & -1 - \varepsilon_1 \end{bmatrix}.$$

From (2.10), dropping the arguments of each $q_{ij}(\varepsilon_1, \varepsilon_2)$,

$$D\hat{k}(\varepsilon) = \begin{bmatrix} \frac{2q_{11} + q_{12}}{2(1 + \varepsilon_1)^2} & \frac{q_{12}}{2} \\ \frac{2q_{21} + q_{22}}{2(1 + \varepsilon_1)^2} & \frac{q_{22}}{2} \end{bmatrix}$$

and the integrability conditions in (2.12) are

$$(4.1) \quad D_1 q_{12} = \frac{2D_2 q_{11} + D_2 q_{12}}{(1 + \varepsilon_1)^2}, \quad D_1 q_{22} = \frac{2D_2 q_{21} + D_2 q_{22}}{(1 + \varepsilon_1)^2}.$$

If the closed-loop poles are to be placed at -2 , independent of the operating point, $Q(\varepsilon)$ must satisfy

$$\det[sI - D_1 f(\mathbf{x}, \varepsilon) + D_2 f(\mathbf{x}, \varepsilon)Q(\varepsilon)] = s^2 + 4s + 4.$$

Ignoring the q_{i+} , q_{i-} partitioning as unnecessary in this case, and solving this equation for q_{11} and q_{12} in terms of q_{21} and q_{22} yields

$$q_{11} = -\frac{q_{22}(q_{21}(\varepsilon_1 + 1) + \varepsilon_1 + \varepsilon_1^2) + q_{21}(7 + 8\varepsilon_1 + \varepsilon_1^2) - 9 - 8\varepsilon_1 + \varepsilon_1^2}{q_{22} + q_{21} + 1},$$

$$q_{12} = -\frac{(\varepsilon_1 + 1)q_{22}^2 + (8\varepsilon_1 + 8)q_{22} + 16\varepsilon_1 + 16}{q_{22} + q_{21} + 1}.$$

Substituting $q_{11}(\varepsilon_1, \varepsilon_2, q_{21}, q_{22})$ and $q_{12}(\varepsilon_1, \varepsilon_2, q_{21}, q_{22})$ for $q_{11}(\varepsilon_1, \varepsilon_2)$ and $q_{12}(\varepsilon_1, \varepsilon_2)$, respectively, in (4.1), we obtain (2.18) for this case as

$$(4.2) \quad \begin{bmatrix} D_3 q_{12} & D_4 q_{12} \\ 0 & 1 \end{bmatrix} \begin{bmatrix} D_1 q_{21} \\ D_1 q_{22} \end{bmatrix} = \begin{bmatrix} -D_1 q_{12} \\ 0 \end{bmatrix}.$$

Note that since ε_2 does not appear explicitly, the solution will not depend upon ε_2 if the initial condition does not, and therefore all terms involving derivatives with respect to ε_2 have been set to zero. Choosing the initial conditions

$$q_{21}(0, \varepsilon_2) = 0, \quad q_{22}(0, \varepsilon_2) = 0,$$

we can solve (4.2) to yield

$$q_{21}(\varepsilon_1, \varepsilon_2) = \varepsilon_1, \quad q_{22}(\varepsilon_1, \varepsilon_2) = 0.$$

Thus (2.10) has the form

$$D\hat{k}(\varepsilon) = \begin{bmatrix} \frac{-\varepsilon_1^2 - 8\varepsilon_1 + 1}{(1 + \varepsilon_1)^2} & -8 \\ \frac{\varepsilon_1}{(1 + \varepsilon_1)^2} & 0 \end{bmatrix}$$

which can be integrated to yield

$$\hat{k}(\varepsilon) = \begin{bmatrix} -\varepsilon_1 - \frac{8}{1 + \varepsilon_1} - 6 \ln |1 + \varepsilon_1| - 8\varepsilon_2 + 8 \\ \frac{1}{1 + \varepsilon_1} + \ln |1 + \varepsilon_1| - 1 \end{bmatrix}.$$

Since $\varepsilon_1 = \mathbf{x}_1/(1 - \mathbf{x}_1)$ and $\varepsilon_2 = 2\mathbf{x}_2 - \mathbf{x}_1$, (2.27) gives

$$k(\mathbf{x}) = \begin{bmatrix} \frac{-x_1}{1 - x_1} + 6 \ln |1 - x_1| + 16x_1 - 16x_2 \\ -x_1 - \ln |1 - x_1| \end{bmatrix}.$$

NECESSARY OPTIMALITY CONDITIONS FOR THE CONTROL OF SEMILINEAR HYPERBOLIC BOUNDARY VALUE PROBLEMS*

MARTIN BROKATE†

Abstract. This paper develops the differential version of Pontryagin's principle for optimal (interior and boundary) control of a first-order semilinear hyperbolic system in one space dimension with nonlinear boundary conditions. The proof uses first order necessary conditions for constrained optimization in Banach space as well as the method of characteristics.

Key words. hyperbolic system, optimal control, necessary conditions, characteristics

AMS(MOS) subject classifications. 49B22, 35L50

1. Introduction. We consider optimal control of semilinear hyperbolic systems in one space dimension of type

$$z_t + A(t, x)z_x = f(t, x, u, z)$$

in a domain Ω whose boundary consists of spacelike, timelike and characteristic portions. We prove necessary optimality conditions along the following line of reasoning: In one space dimension, the method of characteristics enables one to rewrite the IBVP as a Volterra system of integral equations with regular kernel. This provides sup-norm estimates for the state z . On the other hand, a differentiable source f and differentiable (nonlinear) boundary conditions lead to substitution (Nemytskii) operators which are differentiable in sup-norm function spaces. It is the strength of the method of characteristics that this interplay works for quite a general form of the domain Ω , of the boundary conditions and without additional assumptions on the source f . On the other hand, these arguments usually cannot be extended to hyperbolic systems in more than one space dimension, which is a severe limitation.

Anyway, if one proceeds in the manner described above, one obtains a constrained optimization problem of differentiable type in Banach spaces. We show that the "abstract" maximum principle from [30] can be applied and derive the first order conditions.

In the context of optimal control, the constraint qualification (which guarantees nondegenerate first-order necessary conditions) usually is equivalent to well-posedness of the IVP, respectively, IBVP plus some controllability property. Since we do not want to study the latter, we restrict ourselves to a control problem consisting of a well-posed IBVP and pure control constraints only.

Pontryagin-type and variational maximum principles for control of hyperbolic systems have been developed at least since the early 1960's (see Cesari [1], Butkovsky et al. [2], [3]). Many results for linear-quadratic problems in n space are presented in Lions [4]. Recently, convex problems in one space dimension have been treated in [5]–[7]. If more general nonlinearities enter the picture, the simplest situation is the control problem consisting of the characteristic IVP with nonlinear source f ,

$$(1.1) \quad \begin{aligned} z_{xt} &= f(t, x, u, z, z_x, z_t) \quad \text{in } (0, T) \times (0, 1), \\ z(0, x) &= f_0(x), \quad z(t, 0) = f_1(t), \end{aligned}$$

with distributed control $u = u(t, x)$, plus some cost functional and control restriction. Consequently, this problem (or slight generalizations) has been tackled by various authors with various techniques (see [8]–[12] and [13, pp. 233 ff.]), and a Pontryagin-type maximum principle (adjoint BVP, Hamiltonian is maximized by optimal control) has been established. Also, optimal singular controls have been investigated [14]–[16].

Nonlinear control of second-order IBVP has been treated with controls in the coefficients [17] and with piecewise continuous interior and boundary controls [18]–[20], even in n space [21], [22], and necessary conditions are given there.

The method adopted in this paper is a standard one for control of ODE's [23]–[25] and also has been applied to control of FDE's [26], but it has not been used for hyperbolic equations except in the linear-quadratic case [27]. Because it leads directly only to the differential version of the maximum condition, the results presented here are slightly weaker if applied to the problems in the paper cited above. On the other hand, this method permits a unified treatment of various IBVP's and is quite easily adapted if one modifies the way the control variable enters the problem (e.g. for the situation in [28]).

It would be interesting to know whether the techniques of [23]–[25] can be generalized in order to yield the assertion that the Hamiltonian is maximized along the optimal trajectory.

In this paper, we do not want to discuss the question of existence of optimal controls seriously. Due to the general geometry and boundary conditions there is no existence result, which could be cited, for the control problem considered here. However, if the controls are constrained pointwise by a priori bounds, then from Lions [4] and Ahmed and Teo [13] and the references cited there, one gets the impression that the overall picture is similar to the situation in optimal control of ODE's: a bounded measurable optimal control exists, if the control problem has convex structure with respect to the control (e.g., if the set of admissible velocities at a given point is convex, or if some Cesari property holds). Otherwise, convexity must be obtained by admitting generalized controls (see e.g. [37], [38]).

The paper is organized as follows: in § 2, notation and formulas needed later are developed to transform the hyperbolic control problem (consisting of (2.2)–(2.4), (2.12), (2.13)) into the Banach space setting of § 2.6. The main theorem is stated in § 3 and proved in § 4. It is illustrated with a control problem for the semilinear wave equation in § 5.

2. The control problem.

2.1. The domain Ω and its boundary. Let Ω be an open bounded set in \mathbb{R}^2 . We assume $\partial\Omega$ to be of the form

$$\begin{aligned} \partial\Omega &= \Gamma_0 \cup \Gamma_1 \cup \Gamma_2 \cup \Gamma_T, \\ (2.1) \quad \Gamma_i &= \{(t, b_i(t)) \mid 0 \leq t \leq T\}, \quad i = 1, 2, \\ \Gamma_0 &= \{0\} \times [b_1(0), b_2(0)], \quad \Gamma_T = \{T\} \times [b_1(T), b_2(T)] \end{aligned}$$

where $b_1, b_2: [0, T] \rightarrow \mathbb{R}$ are piecewise C^1 and $b_1(t) < b_2(t)$ for $t \in (0, T)$. We allow $b_1(0) = b_2(0)$ and $b_1(T) = b_2(T)$. (See Fig. 1.)

2.2. Cost functional and control restrictions. We consider a state $z: \bar{\Omega} \rightarrow \mathbb{R}^n$, an interior control $u: \Omega \rightarrow \mathbb{R}^m$ and a boundary control $u^B: [0, T] \rightarrow \mathbb{R}^p$. We want to minimize

FIG. 1

the functional

$$(2.2) \quad \begin{aligned} \tilde{J}(z, u, u^B) = & \int \int_{\Omega} L(t, x, u, z) \, dx \, dt + \int_{b_1(T)}^{b_2(T)} L^T(x, z(T, x)) \, dx \\ & + \int_0^T L^B(t, u^B(t), z(t, b_1(t)), z(t, b_2(t))) \, dt \end{aligned}$$

subject to the pointwise control restrictions

$$(2.3) \quad u(t, x) \in U, \quad u^B(t) \in U^B \quad \text{a.e.}$$

where U and U^B are closed convex sets in \mathbb{R}^m , respectively \mathbb{R}^p .

2.3. The differential equation in Ω . We consider the semilinear first order system

$$(2.4) \quad z_t + A(t, x)z_x = f(t, x, u, z) \quad \text{for } (t, x) \in \Omega$$

where $A(t, x)$ is a diagonal $n \times n$ -matrix. If A is not diagonal, but diagonalizable, a transformation of z yields a system of form (2.4) with A diagonal [29, p. 44 ff.]. The classical method of characteristics consists of that transformation and the observation that one obtains a solution of (2.4) if one integrates f along the characteristics $(t, x_i(t))$ given by $x'_2 = a_i(t, x_i)$. Or, equivalently, if the coordinate transformation $\varphi_i = \varphi_i(t, s)$ satisfies $D_s \varphi_i(t, s) = (1, a_i(\varphi_i(t, s)))$, and if we set

$$y_i(t, s) = z_i(\varphi_i(t, s)),$$

then (2.4) becomes

$$y_i(t, s) = y_i(t, s_0) + \int_{s_0}^s f(\varphi_i(t, \tau), u, y) \, d\tau.$$

2.4. The characteristic transformation φ_i . We need a formal description of φ_i corresponding to a diagonal entry a_i of A . For momentary convenience, we drop

subscripts i, j and write $a(P), b'(P)$ instead of $a_i(t, b_j(t)), b'_j(t)$, if $P = (t, b_j(t)) \in \Gamma_1 \cup \Gamma_2$. We need characteristics which reach the boundary to do so transversally.

DEFINITION 2.1. We say that $a = a(t, x)$ is a regular left characteristic for Ω , if

- (i) a is C^1 on an open set containing $\bar{\Omega}$;
- (ii) There exists an $\varepsilon > 0$ such that for all $P \in \Gamma_1 \cup \Gamma_2$ either $a(P) = b'(P)$ or $a(P) - b'(P) \geq \varepsilon$;
- (iii) The initial and terminal portions $\Gamma_{\text{in}}, \Gamma_{\text{ter}}$ of $\partial\Omega$ are connected, where we define

$$\Gamma_{\text{char}} := \{P \mid P \in \Gamma_1 \cup \Gamma_2 \text{ and } a(P) = b'(P)\},$$

$$\Gamma_{\text{in}} := \text{cl}(\Gamma_0 \cup (\Gamma_1 \setminus \Gamma_{\text{char}})),$$

$$\Gamma_{\text{ter}} := \text{cl}(\Gamma_T \cup (\Gamma_2 \setminus \Gamma_{\text{char}})).$$

A regular right characteristic is defined by (i)–(iii) with the roles of Γ_1 and Γ_2 interchanged and the inequality sign in (ii) reversed. The matrix A is a regular characteristic matrix for Ω if each entry is a regular left or right characteristic.

As an example, two standard situations for the 1D wave equation written as system $z_{1t} + z_{1x} = f_1, z_{2t} - z_{2x} = f_2$ are depicted in Fig. 2. The second corresponds to (1.1) rotated by $\pi/4$. If $a(t, x)$ is a regular left characteristic, we define the corresponding φ by

$$(2.5) \quad \varphi(t, s) = (t + s, x(t, s))$$

where $x(t, s)$ is the solution of the parametrized IVP

$$(2.6) \quad \begin{aligned} \frac{\partial}{\partial s} x(t, s) &= a(t + s, x(t, s)), \\ x(t, -t) &= b_1(0) - t, \quad t \leq 0, \\ x(0, t) &= b_1(t), \quad t \geq 0. \end{aligned}$$

For right characteristics, take $x(t, -t) = b_2(0) + t$, respectively, $x(t, 0) = b_2(t)$, as initial conditions. Standard theory of ODE's implies that $\varphi(t, s)$ is well defined, continuous

FIG. 2

in t , C^1 in s , and that the same holds for $D\varphi(t, s)$ for $t < 0$, and $t > 0$ if b_1 is C^1 around t . For such t we have

$$(2.7) \quad D\varphi(t, s) = \begin{pmatrix} 1 & 1 \\ \frac{\partial}{\partial t}x(t, s) & a(\varphi(t, s)) \end{pmatrix}$$

and if we define

$$(2.8) \quad \Psi(t, s) = \det D\varphi(t, s),$$

the chain rule and (2.6) imply

$$(2.9) \quad \begin{aligned} \frac{\partial}{\partial s}\Psi(t, s) &= \frac{\partial a}{\partial x}(\varphi(t, s)) \cdot \Psi(t, s), \\ \Psi(t, 0) &= a(P) - b'(P), \quad P = \varphi(t, 0), \quad t > 0, \\ \Psi(t, -t) &= 1 \quad (-1 \text{ for right characteristic}), \quad t < 0. \end{aligned}$$

To define the transformed region $G (= \varphi^{-1}(\Omega))$ we set

$$(2.10) \quad \begin{aligned} \gamma^0(t) &= \begin{cases} 0, & t \geq 0, \\ -t, & t \leq 0, \end{cases} \\ \gamma^s(t) &= \sup \{s \mid \varphi(t, s) \in \bar{\Omega}\}, \\ T^- &= b_1(0) - b_2(0), \\ G &= \{(t, s) \mid T^- \leq t \leq T, \gamma^0(t) \leq s \leq \gamma^s(t)\}. \end{aligned}$$

Hence γ^0 , γ^s correspond to Γ_{in} , Γ_{ter} . Γ_{char} corresponds to boundary portions of G with constant t value. It helps to visualize (2.10) for the examples in Fig. 2. Because of Definition 2.1, (2.8), (2.9) we know that

$$(2.11) \quad \Psi(t, s) \text{ is bounded away from zero in } G.$$

Now we have the following.

LEMMA 2.2. *Let φ_i denote the transformation corresponding to a regular characteristic $a_i = a_i(t, x)$. Then:*

- (i) $\varphi_i: G_i \rightarrow \Omega$ is well defined by (2.5), (2.6), (2.10);
- (ii) φ_i is continuous and bijective;
- (iii) *There are finitely many intervals I_k covering \mathbb{R} such that $\varphi_i|_{G_i \cap (I_k \times \mathbb{R})}$ can be extended to a C^1 -diffeomorphism defined on an open subset of \mathbb{R}^2 .*

Furthermore let $\varphi_{ij}: G_i \rightarrow G_j$ be defined by $\varphi_{ij} = \varphi_j^{-1} \circ \varphi_i$ and denote

$$\varphi_{ij}(t, s) = (t_{ij}(t, s), s_{ij}(t, s)).$$

Then

$$(iv) \quad t_{ij}(t, s) + s_{ij}(t, s) = t + s.$$

Proof. Equation (2.11) and the inverse function theorem yield (i)–(iii). Equation (2.5) implies (iv).

2.5. The boundary conditions on $\partial\Omega$. According to standard theory, we expect the IBVP for (2.4) with fixed control u to be well posed if, along each portion of $\partial\Omega$, we prescribe the values of the z_i 's whose characteristics originate at that portion as a function of the z_j 's whose characteristics end there. Thus, if Γ_0 does not degenerate to a point, we have the initial conditions for $P = (0, x) \in \Gamma_0$:

$$(2.12) \quad z_i(P) = z_{i0}(x), \quad 1 \leq i \leq n.$$

FIG. 3

For $P = (t, x) \in \Gamma_{\text{in}}(i)$, $t > 0$, we take, slightly generalizing,

$$(2.13) \quad z_i(P) = g_i(t, u^B(t), z^P(P), z^Q(Q))$$

where z^P is the subvector of z consisting of components z_j with $P \in \Gamma_{\text{ter}}(j)$, and $Q = (t, \bar{x})$ lies on the opposite boundary.

In order to write (2.13) for the transformed domains G_i , we introduce auxiliary functions r_j, \bar{r}_j . If $P = (t, x) \in \Gamma_{\text{ter}}(j) \setminus \Gamma_T$, we define $r_j(t)$ by

$$(2.14) \quad \varphi_j(r_j(t), t - r_j(t)) = (t, x)$$

(this is possible because of 2.1(iii) and (2.5)). The implicit function theorem and (2.7), (2.8), (2.11) imply that r_j is piecewise C^1 and

$$(2.15) \quad r'_j(t) \Psi_j(r_j(t), t - r_j(t)) = a_j(P) - b'(P).$$

If $P = (T, x) \in \Gamma_T$, we define $\bar{r}_j(x)$ by

$$(2.16) \quad \varphi_j(\bar{r}_j(x), T - \bar{r}_j(x)) = (T, x).$$

Analogous considerations yield a well-defined \bar{r}_j which is piecewise C^1 and satisfies

$$(2.17) \quad \bar{r}'_j(x) \Psi_j(\bar{r}_j(x), T - \bar{r}_j(x)) = -1.$$

These considerations prove the following.

LEMMA 2.3. *If $a_j = a_j(t, x)$ is a regular characteristic for Ω , then r_j, \bar{r}_j are well defined on intervals determined by $\Gamma_{\text{ter}}(j)$ and piecewise C^1 . Furthermore, $r'_j, \bar{r}'_j, (\bar{r}_j^{-1})'$ are bounded.*

If Γ_T or Γ_0 degenerates to a single point, we have to exclude the infinite zigzagging of Fig. 3. This is done formally by the following.

Assumption 2.4. We say that (j, i) is a degenerate pair at T if Γ_T consists of a single point and g_i depends explicitly on z_j .

Consider the directed graph Z_T with integers i as nodes and all degenerate pairs (j, i) as vertices. Then Z_T must not contain a cycle.

The same is assumed at 0.

2.6. The hyperbolic control problem (C) in characteristic form. We state the control problem (C) in a compact notation. See § 2.7. Assume that A is a regular characteristic matrix. With T^- from (2.10), set $S = T - T^-$. For

$$(2.18) \quad \begin{aligned} u &\in L_\infty(\Omega; \mathbb{R}^m), & u^B &\in L_\infty(0, T; \mathbb{R}^P), \\ y &\in C(0, S; L_\infty(T^-, T))^n \\ &(\text{i.e. } y_i(\cdot, s) \in L_\infty(T^-, T) \text{ for } s \in [0, S]) \end{aligned}$$

minimize

$$\begin{aligned}
 J(y, u, u^B) = & \int \int_{\Omega} L(t, x, u(t, x), y(\varphi^{-1}(t, x))) \, dx \, dt \\
 (2.19) \quad & + \int_0^T L^B(t, u^B(t), y(r(t), S)) \, dt \\
 & + \int_{b_1(T)}^{b_2(T)} L^T(x, y(\bar{r}(x), S)) \, dx
 \end{aligned}$$

subject to the state equations

$$(2.20) \quad y(t, s) = y(t, 0) + \int_0^s (F(u, y))(t, \tau) \, d\tau,$$

$$(2.21) \quad y(t, 0) = g(t, u^B(t), y(r(t), S))$$

and the control restrictions

$$(2.22) \quad u(t, x) \in U \quad \text{a.e.}, \quad u^B(t) \in U^B \quad \text{a.e.}$$

where U, U^B are closed convex sets and $F = (F_1, \dots, F_n)$ is defined by

$$(2.23) \quad (F_i(u, y))(t, \tau) = f_i(\varphi_i(t, \tau), u(\varphi_i(t, \tau)), y(\varphi^{-1}(\varphi_i(t, \tau))))$$

if $(t, \tau) \in G_i$ and $(F_i(u, y))(t, \tau) = 0$ otherwise.

2.7. Comments and explanations concerning problem (C).

(1) We have used the abbreviation

$$y(r(t), S) \equiv (y_1(r_1(t), S), \dots, y_n(r_n(t), S))$$

and likewise $y(\bar{r}(x), S), y(\varphi^{-1}(t, x))$.

(2) The convention $F_i(u, y) = 0$ outside $G_i = \varphi_i^{-1}(\Omega)$ enables one to pick up the initial values at $y(t, 0)$ and the terminal values at $y(t, S)$.

(3) The initial conditions (2.12) are included in (2.21) by a suitable definition $g = g(t)$ for $t < 0$.

(4) In accordance with § 2.5, for $t > 0$, the function $g_i(t, \cdot)$ depends on y_j only if the corresponding $P = (t, x) \in \Gamma_{\text{ter}}(j)$. Therefore, $y_j(r_j(t), S)$ is well defined.

(5) The foregoing remarks show that problem (C) is indeed a weak formulation of (2.2)–(2.4), (2.12), (2.13).

(6) Concerning the states y_i , the space $C([T^-, T] \times [0, S])$ is too small if we include discontinuous controls, and the space $L_\infty([T^-, T] \times [0, S])$ only causes additional complications concerning the trace $y(\cdot, S)$.

3. The maximum principle. We consider problem (C) as a special case of

$$\begin{aligned}
 (P) \quad & \text{Minimize} \quad J(y, v) \\
 & \text{subject to} \quad K(y, v) = 0, \quad v \in C
 \end{aligned}$$

where $J: Y \times V \rightarrow \mathbb{R}$, $K: Y \times V \rightarrow Y$ are continuously Fréchet-differentiable mappings defined on Banach spaces Y and V (whose duals are denoted by Y^*, V^*) and C is a closed convex subset of V .

THEOREM 3.1 (Lagrange Multiplier Theorem). *Let (y_*, v_*) be a solution of problem (P) with assumptions as stated, and let $D_y K(y_*, v_*): Y \rightarrow Y$ be surjective. Then there is a unique $q^* \in Y^*$ which solves the adjoint equation*

$$(3.1) \quad D_y J(y_*, v_*) - q^* \circ D_y K(y_*, v_*) = 0.$$

Furthermore, the maximum condition

$$(3.2) \quad \langle D_v J(y_*, v_*) - q^* \circ D_v K(y_*, v_*), v - v_* \rangle \geq 0 \quad \forall v \in C$$

holds.

Proof. This is a special case of Theorem 4.1(a) in [30]. Uniqueness trivially follows from (3.1) since $D_y K$ is surjective. \square

If $\text{int}(C) \neq \emptyset$, Theorem 3.1 is already part of the theory in [23] (see [24]). The work by Zowe and Kurcyusz [30] relies mainly on the stability theory of Robinson (see e.g. [31], [32]). A systematic exposition of the latter with emphasis on necessary optimality conditions may be found in [33].

As can be seen from [30]–[33], the existence part of Theorem 3.1 still holds if the assumption of surjectivity of $D_y K(y_*, v_*)$ is relaxed to the condition of Slater type

$$0 \in \text{int}(D_y K(y_*, v_*)Y + D_v K(y_*, v_*)(C - v_*)).$$

However, having also guaranteed uniqueness of q^* by (3.1) will be very convenient later on, since a general element of Y^* will be quite irregular, but we will be able to show that there exists a solution to (3.1) which has more regularity.

The differentiability needed in Theorem 3.1 will be guaranteed by the following.

Assumption 3.2. The functions L, L^B, L^T, g, f in problem (C) are measurable in (t, x) , differentiable in (y, u, u^B) . They are, together with their first derivatives, bounded on bounded sets in (t, x, y, u, u^B) -space and continuous in (y, u, u^B) uniformly with respect to (t, x) . For the derivatives at the optimal point we use an abbreviated notation; for example, $D_{yi} F(t, \tau)^T$ denotes the transpose of the vector $D_{yi} F(y_*, u_*)(t, \tau)$, the j th component therefore being

$$D_{yi} f(\varphi_j(t, \tau), u_*(\varphi_j(t, \tau)), y_{*1}(\varphi_1^{-1} \varphi_i(t, \tau)), \dots, y_{*n}(\varphi_n^{-1} \varphi_j(t, \tau))).$$

We apply Theorem 3.1 to problem (C) and get the following.

THEOREM 3.3. *Let Assumptions 2.4 and 3.2 hold. Let (y_*, u_*, u_*^B) be a solution of problem (C). Then there exists a unique $q \in C(0, S; L_\infty(T^-, T))^n$ which solves the adjoint equation*

$$(3.3) \quad \begin{aligned} q_i(t, s) = & q_i(t, S) + \int_s^S D_{yi} L(t, \tau) + \frac{\partial a_i}{\partial x}(\varphi_i(t, \tau)) q_i(t, \tau) \\ & + D_{yi} F(t, \tau)^T q(\varphi^{-1} \varphi_i(t, \tau)) d\tau \end{aligned}$$

with the boundary conditions

$$(3.4) \quad \begin{aligned} q_i(\bar{r}_i(x), S) &= D_{yi} L^T(x) \quad \text{if } x \in \text{dom } \bar{r}_i, \\ q_i(r_i(t), S) &= \alpha_i(t)^{-1} \left[D_{yi} L^B(t) + \sum_{j=1}^n D_{yi} g_j(t) |\Psi_j(t, 0)| q_j(t, 0) \right] \quad \text{if } t \in \text{dom } r_i, \\ q_i(t, S) &= 0 \quad \text{otherwise} \end{aligned}$$

where

$$\begin{aligned} \alpha_i(t) &= |a_i(P) - b'(P)| \quad \text{if } P = (t, x) \in \Gamma_{\text{ter}}(i), \\ \Psi_j(t, 0) &= a_j(P) - b'(P) \quad \text{if } P = (t, x) \in \Gamma_{\text{in}}(j). \end{aligned}$$

Moreover, the following maximum conditions hold

$$(3.5) \quad \langle D_u f(t, x)^T q(\varphi^{-1}(t, x)) + D_u L(t, x), u - u_*(t, x) \rangle \geq 0 \quad \text{a.e. in } \Omega,$$

$$(3.6) \quad \left\langle \sum_{j=1}^n D_u g_j(t) |\Psi_j(t, 0)| q_j(t, 0) + D_u L^B(t), u - u_*^B(t) \right\rangle \geq 0 \quad \text{a.e. in } t$$

for all $u \in U$, respectively, $u \in U^B$.

Proof. The proof is given in § 4. \square

Despite the somewhat technical character of this theorem we can observe that the adjoint q has the same regularity as the state y (namely, absolutely continuous along characteristics, L_∞ across them). Furthermore, portions of $\partial\Omega$ which are terminal for y are initial for q and vice versa. Characteristic portions of $\partial\Omega$ are identical for y and q .

For a rectangular domain Ω we write down the maximum principle in original (t, x) -coordinates. In this case, regularity of $A(t, x)$ in Definition 2.1 means that A is nonsingular along the vertical boundaries.

THEOREM 3.4. *Let $\Omega = (0, T) \times (0, 1)$, let Assumption 3.2 hold and let (y_*, u_*, u_*^B) be a solution of problem (C). Then there exists a unique $p \in L_\infty(\Omega)^n$ whose components p_i are absolutely continuous along the i th characteristic family and are L_∞ along the boundaries, which solves the adjoint IBVP in reverse time:*

$$(3.7) \quad \frac{\partial p}{\partial t} + A(t, x) \frac{\partial p}{\partial x} = -D_y L(t, x) - \left(D_y f(t, x)^T + \frac{\partial A}{\partial x}(t, x) \right) p,$$

$$(3.8) \quad p(T, x) = D_y L^T(x), \quad x \in (0, 1),$$

$$(3.9) \quad |a_i(t, X)| p_i(t, X) = D_{y_i} g(t)^T |A(t, X)| p(t, X) + D_{y_i} L^B(t).$$

Moreover, the maximum conditions

$$(3.10) \quad \langle D_u f(t, x)^T p(t, x) + D_u L(t, x), u - u_*(t, x) \rangle \geq 0 \quad \text{a.e. in } \Omega,$$

$$(3.11) \quad \langle D_u g(t)^T |A(t, X)| p(t, X) + D_u L^B(t), u - u_*^B(t) \rangle \geq 0 \quad \text{a.e. in } t$$

hold for all $u \in U$, respectively, $u \in U^B$. In (3.9), the left side is evaluated at the boundary $X = 0$ or $X = 1$, which is terminal for the i th characteristic family, whereas the j th component of the vector $|A(t, X)| p(t, x)$ in (3.9), (3.11) is evaluated at the boundary which is initial for the j th characteristic family ($|A|$ denotes $(|a_{ij}|)_{i,j}$).

Proof. Take q from Theorem 3.3, set

$$p_i(t, x) = q_i(\varphi_i^{-1}(t, x)).$$

With (2.5), (2.6), (3.3) evaluate the identity

$$\frac{\partial}{\partial s} p_i(\varphi_i(t, s)) = \frac{\partial}{\partial s} q_i(t, s)$$

to obtain (3.7). The boundary conditions are a direct transcription from (3.4). \square

For the linear-quadratic problem with interior control and space-dependent coefficients, Theorem 3.4 is given in [13, p. 211].

From (2.4) and (3.7) one sees that singularities in u_* , u_*^B spread forward respectively backwards in time along the characteristics. Jump conditions may be developed to describe that situation (compare [18], [20], [21]).

4. Proof of Theorem 3.3. We denote

$$(4.1) \quad D := (T^-, T) \times (0, S).$$

4.1. The operators J and K . Following § 2.6, we set

$$Y = C(0, S; L_\infty(T^-, T))^n, \quad V = L_\infty(\Omega; \mathbb{R}^m) \times L_\infty(0, T; \mathbb{R}^p),$$

equipped with the sup-norm. The closed convex set $C \subset V$ is defined by

$$C = \{(u, u^B) \mid u(t, x) \in U \text{ a.e. and } u^B(t) \in U^B \text{ a.e.}\}.$$

We want to define $J: Y \times V \rightarrow \mathbb{R}$ by (2.19) and $K: Y \times V \rightarrow Y$ by

$$(Ky)(t, s) = y(t, s) - g(t, u^B(t), y(r(t), S)) - \int_0^s (F(y, u))(t, \tau) d\tau$$

with F from (2.23). We have the canonical embedding $Y \rightarrow L_\infty(D)$ (it is easily seen to be well defined on the set of continuous, piecewise linear maps $[0, S] \rightarrow L_\infty(T^-, T)$ which is dense in Y) and Assumption 3.2 implies that

$$F: L_\infty(D; \mathbb{R}^n) \times L_\infty(\Omega; \mathbb{R}^m) \rightarrow L_\infty(D; \mathbb{R}^n)$$

is well defined and continuously Fréchet-differentiable.

Fubini's theorem then implies that

$$y \rightarrow \int_0^s y(t, \tau) d\tau$$

defines a linear continuous map from $L_\infty(D)$ to Y .

The boundary term is composed of an evaluation at $s = S$, a continuous Fréchet-differentiable operator from $L_\infty(0, T; \mathbb{R}^p) \times L_\infty(T^-, T; \mathbb{R}^n)$ to $L_\infty(T^-, T; \mathbb{R}^n)$ and the canonical map $L_\infty(T^-, T; \mathbb{R}^n) \rightarrow Y$. Therefore, K (and similarly J) is well defined and continuously Fréchet-differentiable. The derivatives of J and K are given by

$$(4.2) \quad \begin{aligned} DJ(y_*, u_*, u_*^B)(y, u, u^B) &= \iint_\Omega D_y L(t, x) y(\varphi^{-1}(t, x)) + D_u L(t, x) u(t, x) dx dt \\ &+ \int_0^T D_y L^B(t) y(r(t), S) + D_u L^B(t) u^B(t) dt \\ &+ \int_{b_1(T)}^{b_2(T)} D_y L^T(x) y(\bar{r}(x), S) dx, \end{aligned}$$

$$(4.3) \quad \begin{aligned} (DK(y_*, u_*, u_*^B)(y, u, u^B))_i(t, s) &= y_i(t, s) - D_y g_i(t) y(r(t), S) \\ &- D_u g_i(t) u^B(t) - \int_0^s D_y F_i(t, \tau) y(\varphi^{-1} \varphi_i(t, \tau)) + D_u F_i(t, \tau) u(\varphi_i(t, \tau)) d\tau. \end{aligned}$$

4.2. The linearized integral equation. Theorem 3.1 requires $D_y K: Y \rightarrow Y$ to be surjective. From (4.3) we see that this is a direct consequence of the following lemma.

LEMMA 4.1. Consider the integral equation for y_i , $1 \leq i \leq n$,

$$(4.4) \quad y_i(t, s) = h_i(t, s) + \sum_{j=1}^n g_{ij}(t) y_j(r_j(t), S) + \int_0^s \sum_{j=1}^n f_{ij}(t, \tau) y_j(\varphi_{ij}(t, \tau)) d\tau$$

with given functions $h_i \in C(0, S; L_\infty(T^-, T))$, $g_{ij} \in L_\infty(T^-, T)$, $f_{ij} \in L_\infty(D)$.

Assume $f_{ij}(t, \tau) = 0$ outside G_i and if Γ_T consists of a single point, then for each (i, j) either $g_{ij}(t) = 0$ in a neighbourhood of T or (i, j) is a degenerate pair at T (and the same for 0).

Then (4.4) has a unique solution $y \in Y$.

Proof. It is well known that unique solvability of hyperbolic problems in dimension 1 can be proved by successive approximation (see [34] for IVP's and [35, pp. 471 ff.] for IBVP's). To account for the present situation, we define an equivalent norm on Y such that the linear part of the right-hand side of (4.4) has operator norm less than 1. For $y = (y_1, \dots, y_n) \in Y$ we define

$$\begin{aligned} \|y\| &= \max \{\|y_i\|_i : 1 \leq i \leq n\}, \\ (4.5) \quad \|y_i\|_i &= \sup \{n_i(t, s) | y_i(t, s) | : (t, s) \in D\}, \\ n_i(t, s) &= c_i(t) \exp [-M(t + \gamma_i^0(t)) - L(\min \{s, \gamma_i^s(t)\} - \gamma_i^0(t))]. \end{aligned}$$

We set $c_i \equiv 1$ if no degeneracy in the sense of Assumption 2.4 occurs; otherwise, if e.g. Γ_0 is degenerate, we change c_i on some small interval $[0, \varepsilon_0]$ to

$$(4.6) \quad c_i(t) = \min \{1, c_j(t) [4n \|g_{ij}\|_\infty]^{-1} : (j, i) \in Z_0\}.$$

Because of Assumption 2.4 this procedure is well defined, and there exists a global bound

$$c_i(t)^{-1} \leq C_0, \quad 1 \leq i \leq n, \quad T^- \leq t \leq T.$$

Since Y can be identified with a subspace of $L_\infty(D)$, (4.5) defines an equivalent norm on Y . We set

$$\delta_i(t) = \gamma_i^s(t) - \gamma_i^0(t)$$

and choose $C_1 > 0$ such that

$$(4.7) \quad \frac{c_i(t)}{c_j(t)} |g_{ij}(t)| \exp (-C_1 \delta_j(t)) \leq \frac{1}{2n}$$

for all $1 \leq i, j \leq n$, $T^- \leq t \leq T$. This is possible because of (4.6) and the hypothesis of the lemma. In (4.5) we now choose

$$M = L + C_1$$

and with the notation

$$\sigma = \min \{s, \gamma_i^s(t)\},$$

we estimate the integral term in (4.4) for fixed (t, s) :

$$\begin{aligned} n_i(t, s) \left| \int_0^s \sum_{j=1}^n f_{ij}(t, \tau) y_j(\varphi_{ij}(t, \tau)) d\tau \right| \\ \leq n_i(t, s) \int_0^\sigma \|f\|_\infty \sum_{j=1}^n n_j(\varphi_{ij}(t, \tau))^{-1} \|y_j\|_j d\tau \\ \leq n_i(t, s) C_0 \|f\|_\infty \int_0^\sigma \sum_{j=1}^n \|y_j\|_j \exp [(M - L)(t_{ij}(t, \tau) + \gamma_j^0(t_{ij}(t, \tau)))] \\ \cdot \exp [L(t + \tau)] d\tau \quad \text{from Lemma 2.2 (iv)} \\ \leq c_i(t) C_0 \|f\|_\infty \cdot \frac{1}{L} \sum_{j=1}^n \|y_j\|_j \cdot \exp [C_1(T + S)]. \end{aligned}$$

We therefore get the norm of the integral term as small as we want if we choose L large enough. The boundary term is estimated as follows:

$$\begin{aligned}
 n_i(t, s) \left| \sum_{j=1}^n g_{ij}(t) y_j(r_j(t), S) \right| &\leq n_i(t, s) \sum_{j=1}^n |g_{ij}(t)| n_j(r_j(t), \gamma_j^s(r_j(t)))^{-1} \|y_j\|_j \\
 &= \sum_{j=1}^n \frac{c_i(t)}{c_j(t)} |g_{ij}(t)| \|y_j\|_j \exp[(L-M)(\gamma_j^s(r_j(t)) - \gamma_j^0(r_j(t)))] \\
 &\quad \cdot \exp[(L-M)\gamma_j^0(t)] \cdot \exp[-L \min\{s, \gamma_i^s(t)\}] \\
 &\quad \text{(where we have used } r_j(t) + \gamma_j^s(r_j(t)) = t) \\
 &\leq \sum_{j=1}^n \frac{c_i(t)}{c_j(t)} |g_{ij}(t)| \exp(-C_1 \delta_j(t)) \leq \frac{1}{2} \quad \text{by (4.7).}
 \end{aligned}$$

The lemma is proved. \square

4.3. The adjoint equation. From Theorem 3.1, we obtain a unique $q^* \in Y^*$ which satisfies (3.1), (3.2). Now, Y^* is a subspace of $L_\infty(D)^*$ which is the space of all finitely additive measures on D [36]. We show that actually (3.1) has a solution q^* of the form

$$(4.8) \quad q_i^*(y_i) = \int_D \rho_i(t, s) y_i(t, s) ds dt + \int_{T^-}^T \rho_i^B(t) y_i(t, S) dt$$

where $\rho_i \in L_\infty(D)$, $\rho_i^B \in L_\infty(T^-, T)$. To prove this, we apply the left side of (3.1) to an arbitrary $y_i \in C(0, S; L_\infty(T^-, T))$, using (4.2), (4.3) and assuming (4.8):

$$\begin{aligned}
 B_i(y_i) &:= \left[D_{yi} J - \sum_{j=1}^n (q_j^* \circ D_{yi} K_j) \right] (y_i) \\
 &= \iint_{\Omega} D_{yi} L(t, x) y_i(\varphi_i^{-1}(t, x)) dx dt + \int_0^T D_{yi} L^B(t) y_i(r_i(t), S) dt \\
 &\quad + \int_{b_1(T)}^{b_2(T)} D_{yi} L^T(x) y_i(\bar{r}_i(x), S) dx - \iint_D \rho_i(t, s) y_i(t, s) ds dt \\
 &\quad - \int_{T^-}^T \rho_i^B(t) y_i(t, S) dt + \sum_{j=1}^n \int_{T^-}^T D_{yi} g_j(t) y_i(r_i(t), S) \\
 &\quad \cdot \left[\rho_j^B(t) + \int_0^S \rho_j(t, s) ds \right] dt \\
 &\quad + \sum_{j=1}^n \int_{T^-}^T \int_0^S \rho_j(t, s) \int_0^S D_{yi} f_i(\varphi_j(t, \tau)) y_i(\varphi_{ji}(t, \tau)) d\tau ds dt \\
 &\quad + \sum_{j=1}^n \int_{T^-}^T \rho_j^B(t) \int_0^S D_{yi} f_j(\varphi_j(t, \tau)) y_i(\varphi_{ji}(t, \tau)) d\tau dt.
 \end{aligned}$$

We define

$$(4.9) \quad \tilde{\rho}_i(t, s) = \rho_i^B(t) + \int_s^S \rho_i(t, \tau) d\tau$$

and obtain by partial integration and substitution (which is valid because of Lemmas 2.2, 2.3 and Fubini's theorem)

$$\begin{aligned}
 B_i(y_i) = & \int \int_D y_i(t, s) \left[D_{yi} L(\varphi_i(t, s)) |\Psi_i(t, s)| - \rho_i(t, s) \right. \\
 & \left. + \sum_j D_{yi} f_j(\varphi_i(t, s)) \tilde{\rho}_j(\varphi_{ij}(t, s)) |\Psi_i(t, s)| |\Psi_j(t, s)|^{-1} \right] ds dt \\
 & + \int_{T^-}^T y_i(t, S) \left[-\tilde{\rho}_i(t, S) + D_{yi} L^T(\bar{r}_i(t)) |D\bar{r}_i^{-1}(t)| + D_{yi} L^B(r_i^{-1}(t)) |Dr_i^{-1}(t)| \right. \\
 & \left. + \sum_j D_{yi} g_j(r_j^{-1}(t)) \tilde{\rho}_j(r_j^{-1}(t), 0) |Dr_j^{-1}(t)| \right] dt.
 \end{aligned}$$

Therefore, a q^* of form (4.8) satisfies (3.1) if and only if the bracketed terms vanish identically. The first term vanishes if and only if

$$\begin{aligned}
 (4.10) \quad \tilde{\rho}_i(t, s) = & \tilde{\rho}_i(t, S) + \int_s^S |\Psi_i(t, s)| \\
 & \cdot \left[D_{yi} L(\varphi_i(t, s)) + \sum_j D_{yi} f_j(\varphi_i(t, s)) \tilde{\rho}_j(\varphi_{ij}(t, s)) \cdot |\Psi_j(t, s)|^{-1} \right] ds.
 \end{aligned}$$

But (4.10) with the boundary condition inserted from the second bracket constitutes a system of integral equations for $\tilde{\rho}_i$ of form (4.4) in reverse coordinates $(T-t, S-s)$. For this reverse problem, the considerations of §§ 2.4, 2.5 as well as the hypotheses of Lemma 4.1 also hold. Therefore, a unique solution $\tilde{\rho} \in Y$ exists and ρ, ρ^B can be obtained via (4.9). We now set

$$q_i(t, s) = \tilde{\rho}_i(t, s) |\Psi_i(t, s)|^{-1}$$

and since we have from (2.9) that

$$\frac{\partial}{\partial s} q_i = |\Psi_i|^{-1} \frac{\partial}{\partial s} \tilde{\rho}_i - \tilde{\rho}_i |\Psi_i|^{-2} \frac{\partial}{\partial s} a_i,$$

we see that (4.10) implies the adjoint equation (3.3) and the boundary conditions for $\tilde{\rho}_i(t, S)$ yield (3.4) with the aid of (2.15), (2.17). Since $\tilde{\rho}$ is unique, q is unique.

4.4. The maximum condition. Since q^* is unique, the adjoint computed in § 4.3 also satisfies the maximum condition (3.2). From (4.2), (4.3) and (4.8), we evaluate (3.2) for arbitrary $u \in L_\infty(\Omega; \mathbb{R}^n)$:

$$\begin{aligned}
 (D_u J - q^* \circ D_u K)(u) &= \int \int_D D_u L(t, x) u(t, x) dx dt \\
 &+ \sum_{i=1}^n \int \int_D \rho_i(t, s) \int_0^s D_u f_i(\varphi_i(t, \tau)) u(\varphi_i(t, \tau)) d\tau ds dt \\
 &+ \sum_{i=1}^n \int_{T^-}^T \rho_i^B(t) \int_0^S D_u f_i(\varphi_i(t, s)) u(\varphi_i(t, s)) ds dt \\
 &= \int \int_\Omega u(t, x) \left[D_u L(t, x) + \sum_{i=1}^n \tilde{\rho}_i(\varphi_i^{-1}(t, x)) D_u f_i(t, x) |\Psi_i^{-1}(t, x)| \right] dx dt
 \end{aligned}$$

where again we use partial integration and substitution. Therefore, (3.2) implies

$$\iint_{\Omega} \langle D_u L(t, x) + D_u f(t, x)^T q(\varphi^{-1}(t, x)), u(t, x) - u_*(t, x) \rangle dx dt \geq 0$$

for all admissible u , and a standard argument using Lusin's theorem yields (3.5). In the same way, (3.6) is obtained. This completes the proof of Theorem 3.3. \square

5. The semilinear wave equation. The theorems of § 3 can be applied to control problems for a hyperbolic system of order n if the system can be reduced to a first-order system with regular characteristic matrix and if the boundary conditions are such that admissible controls produce a state which is L_∞ up to derivatives of order $n-1$. We illustrate this with the following control problem for the semilinear wave equation in $\Omega = (0, T) \times (0, 1)$:

Minimize

$$(5.1) \quad J(w) = \int_0^1 \tilde{L}^T(x, w(T, x), w_t(T, x)) dx$$

subject to

$$(5.2) \quad \begin{aligned} w_{tt} - w_{xx} &= \tilde{f}(t, x, u, w, w_t, w_x) \quad \text{in } \Omega, \\ w(0, x) &= w_0(x), \quad w_t(0, x) = w_1(x), \end{aligned}$$

$$(5.3) \quad \begin{aligned} \frac{\partial w}{\partial n}(t, X) &= \tilde{g}_X(t, u_X^B, w(t, X)), \quad X = 0, 1, \\ u(t, x) &\in U, \quad u_0^B(t) \in U_0^B, \quad u_1^B(t) \in U_1^B \quad \text{a.e.} \end{aligned}$$

where n is the exterior normal. We write (5.2) as a first-order system

$$z_t + Az_x = f(t, x, u, z)$$

with the four variables

$$z_1 \equiv w_t - w_x, \quad z_2 \equiv w_t + w_x, \quad z_3 \equiv w, \quad z_4 \equiv w$$

and $A = \text{diag}(1, -1, 1, -1)$,

$$f = \begin{pmatrix} \tilde{f}(t, x, u, z_3, \frac{1}{2}(z_2 + z_1), \frac{1}{2}(z_2 - z_1)) \\ \tilde{f}(t, s, u, z_4, \frac{1}{2}(z_2 + z_1), \frac{1}{2}(z_2 - z_1)) \\ z_2 \\ z_1 \end{pmatrix}.$$

The boundary conditions (5.3) become

$$(5.4) \quad \begin{aligned} &\left. \begin{aligned} z_1 &= z_2 + 2\tilde{g}_0(t, u_0^B, z_4) \\ z_3 &= z_4 \end{aligned} \right\} \text{at } X = 0, \\ &\left. \begin{aligned} z_2 &= z_1 + 2\tilde{g}_1(t, u_1^B, z_3) \\ z_4 &= z_3 \end{aligned} \right\} \text{at } X = 1. \end{aligned}$$

The cost functional can be written as

$$(5.5) \quad J(z) = \int_0^1 \tilde{L}^T\left(x, \frac{z_3 + z_4}{2}(T, x), \frac{z_1 + z_4}{2}(T, x)\right) dx.$$

From Theorem 3.4 we obtain the adjoint system

$$(5.6) \quad \begin{aligned} p_{1t} + p_{1x} &= -\frac{1}{2}(C_1 - C_2)(p_1 + p_2) - p_4, & p_{2t} - p_{2x} &= -\frac{1}{2}(C_1 + C_2)(p_1 + p_2) - p_3, \\ p_{3t} + p_{3x} &= -Bp_1, & p_{4t} - p_{4x} &= -Bp_2 \end{aligned}$$

where we abbreviate $B = D_w \tilde{f}$, $C_1 = D_{wt} \tilde{f}$, $C_2 = D_{wx} \tilde{f}$. One verifies directly that $\tilde{p} = p_1 + p_2$ is a weak solution of

$$(5.7) \quad \tilde{p}_{tt} - \tilde{p}_{xx} = B\tilde{p} - (C_1 \tilde{p})_t - (C_2 \tilde{p})_x,$$

which is the adjoint equation one obtains formally from the linearization of (5.2). The end conditions are

$$p_1(T, x) = p_2(T, x) = \frac{1}{2} D_w \tilde{L}, \quad p_3(T, x) = p_4(T, x) = \frac{1}{2} D_w \tilde{L},$$

which can be written in terms of \tilde{p} as

$$(5.8) \quad \tilde{p}(T, x) = D_w \tilde{L}, \quad \tilde{p}_t(T, x) = -C_1 \tilde{p}(T, x) - D_w \tilde{L}.$$

The adjoint boundary conditions are (note $|a_i| = 1$, $b'_j = 0$)

$$\left. \begin{aligned} p_2 &= p_1 \\ p_4 &= p_3 + 2D_w \tilde{g}_0 \cdot p_1 \end{aligned} \right\} \text{at } X = 0,$$

$$\left. \begin{aligned} p_1 &= p_2 \\ p_3 &= p_4 + 2D_w \tilde{g}_1 \cdot p_2 \end{aligned} \right\} \text{at } X = 1,$$

which are expressed by \tilde{p} as

$$(5.9) \quad \frac{\partial \tilde{p}}{\partial n}(t, X) = D_w \tilde{g}_X \cdot \tilde{p}(t, X) \pm C_2 \cdot \tilde{p}(t, X)$$

with the plus sign at $X = 1$ and the minus sign at $X = 0$. The maximum conditions (3.10), (3.11) become

$$(5.10) \quad \begin{aligned} \langle \tilde{p}(t, x) D_u \tilde{f}(t, x), u - u_*(t, x) \rangle &\geq 0 && \text{a.e. in } \Omega, \\ \langle \tilde{p}(t, 0) D_u \tilde{g}_0(t), u - u_0^B(t) \rangle &\geq 0 && \text{a.e. in } (0, T), \\ \langle \tilde{p}(t, 1) D_u \tilde{g}_1(t), u - u_1^B(t) \rangle &\geq 0 && \text{a.e. in } (0, T) \end{aligned}$$

for all u in U , U_0^B , U_1^B , respectively. The system (5.7)–(5.10) constitutes the differential version of the maximum principle.

We might also consider boundary conditions of the form

$$\tilde{g}(t, w) = 0.$$

These are treated by taking the time derivative and writing down conditions analogous to (5.4). However, boundary conditions of form

$$w = \tilde{g}(t, u^B)$$

fall outside the scope of Theorem 3.4. Here, for nondifferentiable boundary controls the first-order system does not have L_∞ solutions.

SUFFICIENT CONDITIONS FOR LOCAL CONTROLLABILITY WITH UNBOUNDED CONTROLS*

J. BASTO GONÇALVES†

Abstract. Local controllability of analytic affine control systems Σ with an arbitrary number of controls is studied, without any restriction on the dimension of the Lie algebra T' generated by the input vector fields.

A sufficient condition for local controllability at a point is obtained, first for scalar input systems and then generalized in two different ways to the multi-input case. In all versions, this involves the computation of Lie brackets at the point under consideration and the verification of a criterion of the type considered by Sussmann (this Journal, 16 (1978), pp. 790–802).

As an application, controllability of systems defined on \mathbb{R}^n and with constant input vector fields is studied.

Key words. nonlinear analytic systems, affine systems, local controllability, Lie brackets

AMS(MOS) subject classifications. 93B05, 93C10, 93C15, 49E15, 34H05

Introduction. This article studies the local controllability of affine control systems Σ with dynamics $\dot{x} = f(x, u) = X(x) + \sum_{i=1}^s u_i X^i(x)$ on the n -dimensional analytic manifold M . The codimension of Σ is the codimension of the Lie algebra T' generated by the input vector fields at every point in M .

Local controllability of nonlinear systems is one of the basic problems of the geometric theory of control systems, but besides the importance it has on its own, in [3], [8], [13]–[15] global controllability has been shown to depend on the existence of points where the system is locally controllable in some sense,

There are not many easy methods of verifying local controllability, besides the linear test, and all sources with the exception of [19] assume Σ to be a scalar input or a codimension one system; the conditions presented in this paper attempt to provide criteria as simple to use as that test and valid for any codimension.

It would be nicer to be able to use bounded controls, but the lack of criteria for local controllability and specially for global controllability in that situation fully justifies the approach followed here.

The methods now presented are a development of the ideas introduced by Hermes [9]–[12], Sussmann [19], [20] and Hunt [13]–[15] and already studied by Bacciotti and Stefani [3] and the author [5], [6]; in particular, the sufficient conditions for local controllability proved here are natural generalizations to arbitrary codimension of the computational sufficient condition presented in [5]. For recent and related work see [17] and [21].

Basically the method works like this: around p we can choose coordinates on a neighbourhood U so that U looks like a product of open sets $S_1 \times S_2$ in $\mathbb{R}^{n-k} \times \mathbb{R}^k$ with S_1 the integral submanifold of T' through p .

As controls appear linearly and are unbounded, the trajectories of the input vector fields X^i will be assumed to be admissible trajectories of Σ [13]–[15]. We can move in S_1 as we please, and therefore if local controllability at p along directions tangent to S_2 is proved, we have local controllability of Σ at p .

In the above coordinates and if $X(x_1, x_2) = (X_1(x_1, x_2), X_2(x_1, x_2))$, we can consider in S_2 a family of vector fields with parameter x_1 given by $X_2(x_1, x_2)$; considering the movement in S_2 , we have to prove that family to be locally controllable (to be rigorous the correct family is not that one, but it takes the same values at p , and the criterion we are going to use involves just that.)

It is well known that given a family of vector fields a sufficient condition for local controllability at a point p is that 0 belongs to the interior of the convex hull of the values of the vector fields at that point.

If $k = 1$ this last condition applied to the family above is fulfilled if arbitrarily near p we have X pointing to opposite sides of S_1 ; this condition already appears in one form or another in [3], [5], [6], [10].

To obtain a sufficient condition when $k > 1$ we consider the trajectory of X through p and project it in S_1 parallel to S_2 ; Let X' be a vector field in M belonging to T' such that its trajectory through p is that projection. X' is not uniquely defined, but that does not alter the situation.

Let us consider the vectors in $T_p M$ defined by $v_i = (\text{ad}^i X', X)(p)$ and let W_i be the projection onto $T_p S_2$ parallel to $T_p S_1$ of the subspace generated by v_j with $j = 1, \dots, i$.

Assume that $X(p) = X'(p) \neq 0$ and (i) $W = \bigcup W_i = T_p S_2$; (ii) if i is even $W_i = W_{i-1}$; then the system Σ is locally controllable at p .

In fact, if β is the trajectory of X' through p , the components of $X(\beta(t))$ along S_2 can be written in a suitable basis as $a(t) = a_1(t)e_{n-k+1} + \dots + a_n(t)e_n$, where the least order term in t of each $a_i(t)$ is odd, using the Campbell-Baker-Hausdorff formula [9]; it is quite easy to verify that 0 belongs to the interior of the convex hull of the set $\{a(t), |t| \text{ small and nonzero}\}$.

For scalar input systems ($k = n - 1$) we obtain a better condition, with the input vector field substituted for X' , generalizing a condition already obtained for systems defined on a plane ($n = 2$) in [16].

For general systems we also obtain a sufficient condition involving only the input vector fields, an extension to $n > 2$ of the previous one.

Applying those sufficient conditions to systems defined on \mathbb{R}^n with constant input vector fields, we obtain sufficient conditions for their local controllability at a point; if the codimension of the systems is one, we have then a sufficient condition for global controllability which reduces to Theorem 2 in [2] for systems in the plane.

1. Basic results and definitions. We shall study the local controllability of affine control systems Σ with dynamics $\dot{x} = f(x, u) = X(x) + \sum_{i=1}^s u_i X^i(x)$, defined on an n -dimensional connected analytic manifold M . The system Σ is said to have codimension k if the Lie algebra T' generated by the input vector fields X^1, \dots, X^s has codimension k at every point in M .

Denote by T the Lie algebra generated by X, X^1, \dots, X^s and let T_0 be the Lie algebra containing $(\text{ad}^k X, X^i)$ with $k \geq 0, i = 1, \dots, s$ and $(\text{ad}^j X, Y)$ defined by Y if $j = 0$ and inductively by $(\text{ad}^j X, Y) = [X, (\text{ad}^{j-1} X, Y)]$ if $j > 0$.

The definition of local controllability adopted here will be the following: Σ is said to be locally controllable at $p \in M$ if for every neighbourhood U of p the set $A(p, U)$ of the points attainable from p in positive time without leaving U contains p in its interior.

$A(p, U)$ is defined as the set of points p such that there exists a piecewise C^1 continuous map $c: [0, T] \rightarrow U$ verifying

- (i) $c(0) = p, c(T) = p'$ with $T \in \mathbb{R}^+$,

(ii) There exists t_0, t_1, \dots, t_m such that $0 = t_0 < t_1 < \dots < t_m = T$ and c in $]t_{i-1}, t_i[$ is an integral curve γ_i of $f(\cdot, u_i)$ for some $u_i \in \mathbb{R}^s$.

If the map $(\tau_1, \dots, \tau_m) \rightarrow x = \gamma_m(\tau_m) \circ \dots \circ \gamma_1(\tau_1)p$ has rank n at the point (t_1, \dots, t_m) , the corresponding point p' is said to be normally reachable from p [18].

The set of attainability from p , denoted by $A(p)$, is defined by $A(p) = A(p, M)$, and the set $A(p, T, U)$ of attainability from p in positive time T without leaving U is defined as $A(p, U)$, but with fixed T .

Σ is locally accessible at p if $A(p, U)$ has a nonempty interior for any neighbourhood U of p ; it is obviously a necessary condition for local controllability at p . A necessary and sufficient condition for local accessibility in the analytic case is that the Lie algebra \mathbf{T} has dimension n at p [22].

Σ is strongly accessible at p if $A(p, T) = A(p, T, M)$ with positive T has a nonempty interior; in the analytic case a necessary and sufficient condition is that the Lie algebra \mathbf{T}_0 has dimension n at p [22].

Denote by L_p the leaf of \mathbf{T}' containing p , and by $X_t(p)$ the trajectory of X through p at $t = 0$; strong accessibility at p is a necessary condition for local controllability of Σ at p , as well as $X(p) \in \mathbf{T}'(p)$ [5].

The constant codimension assumption is important in the last statement, as the following example shows.

Example (Bacciotti [4]). $M = \mathbb{R}^2$, $s = 1$, $p = 0$; $X = e_1$, $X^1 = x_2 e_1 + x_1 e_2$, $X^2 = x_1 e_1 + x_2 e_2$. It is easy to see that \mathbf{T}' is two-dimensional everywhere except at p , where the dimension is zero, and that we have local controllability at all points of M including $p = 0$.

On the other hand, $X(0) \neq 0$ and therefore the conclusions of Theorem 1 and Proposition 2 of [5] are not verified.

In the proof of Theorem 1 in [5] and when $X(p)$ is not tangent to L_p we need to construct an $(n-1)$ -dimensional submanifold N , containing $L_p \cap V$ and such that $X(p) \notin T_p N$. The important point missed there is that N has to be foliated by the leaves of \mathbf{T}' ; we describe briefly the alterations needed to correct the situation.

If \mathbf{T}' has constant dimension, we can use the Frobenius theorem to construct N and then $\dim \mathbf{T}' = n$ on U ; otherwise we can still use that theorem around points of maximal local dimension.

THEOREM 1.1. *If Σ is locally controllable at every point of an open set $U \subset M$, then $\dim \mathbf{T}' = n$ on an open dense set U' in U .*

Proof. In view of the above remarks it is enough to show that the set U' of the points in U where \mathbf{T}' has maximal dimension is open and dense in U . That U' is open is obvious.

Assume $U - U'$ has a nonempty interior A and choose a point p' in it where \mathbf{T}' has maximal dimension when restricted to A . We can now apply the Frobenius theorem in a neighbourhood of p' inside A to construct the submanifold N already mentioned; therefore Σ cannot be locally controllable at p' . \square

Now we have, as in [5], the following proposition.

PROPOSITION 1.2. *If Σ is locally controllable at p and \mathbf{T}' has constant dimension or has maximal local dimension at p , then $X(p)$ belongs to $\mathbf{T}'(p)$.*

The other results in [5] are not affected by these changes; note that if the system is not analytic we have to consider the smallest integrable distribution containing the associated vector fields, instead of \mathbf{T}' .

The definitions above can also be made for families D of vector fields, instead of control systems; we just require that c is an integral curve of some vector field belonging to D in (ii) when defining the set $A(p, U)$.

Of particular interest are the families $D_{\Sigma} = \{X, X^1, \dots, X^s, -X^1, \dots, -X^s\}$ and $D_{\Sigma^-} = \{-X, X^1, \dots, X^s, -X^1, \dots, -X^s\}$ as the next lemma shows.

LEMMA 1.3. *If D_{Σ} and D_{Σ^-} are locally controllable, so is Σ .*

Proof. Local controllability of Σ follows from the local controllability of the family of vector fields $D' = \{X, X + uX^1, \dots, X + uX^s, X - uX^1, \dots, X - uX^s, u \in \mathbb{R}^+\}$ or equivalently of the family $D'' = \{X, \varepsilon X + X^1, \dots, \varepsilon X + X^s, \varepsilon X - X^1, \dots, \varepsilon X - X^s, \varepsilon \in \mathbb{R}^+\}$.

From the local controllability of D_{Σ^-} it follows that there exists a neighbourhood V of p such that $V \subset A(p, U; D_{\Sigma^-})$, therefore $p \in A(p', U; D_{\Sigma})$ for every $p' \in V$.

As D_{Σ} has to be locally accessible, its restriction to V has the normal reachability property from p [18], i.e., some y in $A(p, V; D_{\Sigma})$ is normally reachable from p . Since p is attainable from y , it follows that p (and every point in $A(p, U; D_{\Sigma})$) is normally reachable from p for the family D_{Σ} .

From the stability of normal reachability for small perturbations [7, Prop. 4.2] we can say that there exists a neighbourhood W of p attainable from p without leaving U using vector fields in D'' corresponding to small values of ε ; this means the use of large values for the control, but as there are no a priori bounds, we can say that Σ is locally controllable. \square

The criteria of local controllability presented in this paper are independent of the sign of X ; if they are verified for a system Σ with dynamics $\dot{x} = f(x, u) = X(x) + \sum_{i=1}^s u_i X^i(x)$ they are also verified for the system Σ^- with dynamics $\dot{x} = -f(x, u) = -X(x) - \sum_{i=1}^s u_i X^i(x)$. Thus if they are proved for the D_{Σ} they are automatically true for Σ , in view of the previous lemma; this justifies that the trajectories of the input vector fields X^i will be assumed to be admissible trajectories of Σ .

2. Scalar input systems. Let Σ be a scalar input analytic affine system, of the form $\dot{x} = X(x) + uX^1(x)$; we are going to study the local controllability of Σ around a point p , where the following conditions are verified: Σ is strongly accessible at p , $X(p) \in T'(p)$ and moreover $X^1(p) \neq 0$. With these assumptions S_1 is a one-dimensional submanifold of M .

We denote by $W_i(x)$ the subspace of $T_x M$ generated by the vectors $(\text{ad}^j X^1, X(x))$ with $j = 1, \dots, i$, and by W_{∞} the union of the W_i for all i .

THEOREM 2.1. *If $W_i(p) = W_{i-1}(p)$ for i even and $T_p M = W_{\infty}(p) + T_p S_1$ then the system Σ is locally controllable at p .*

Proof. First note that we can assume $X(p) \neq 0$ without any loss of generality, since otherwise we can substitute any other associated vector field for X without changing the hypothesis; also, in convenient local coordinates we can have $p = 0$ and $X^1 = e_1$.

The system being analytic and strongly accessible, X and X^1 are linearly independent at every point $x(t) = te_1$ with $0 < |t| < \varepsilon$ if $\varepsilon \in \mathbb{R}^+$ is sufficiently small, and by continuity we have $T_{x(t)} M = W_{\infty}(x(t)) + T_{x(t)} S_1$ for small $|t|$.

We can then apply Proposition 4.2 in [9] to obtain the following lemma.

LEMMA 2.2. *For each $|t| \neq 0$ sufficiently small, there exist $n - 2$ analytic vector fields $Y^i (i = 1, 2, \dots, n - 2)$, commuting between themselves and with X , and such that $X(x(t)), X^1(x(t)), Y^1(x(t)), \dots, Y^{n-2}(x(t))$ are linearly independent.*

Therefore there exists an integral submanifold N_t of the distribution generated by the vector fields Y^i and X containing $x(t)$; moreover $X^1(x(t))$ is not tangent to it.

Around $x(t)$ the projection $\pi: (x_1, x_2, \dots, x_n) \rightarrow (0, x_2, \dots, x_n)$ is a diffeomorphism when restricted to N_t ; that projection takes the restriction of X to N_t into a vector field Z' defined on a neighbourhood of the origin in $\{x_1 = 0\}$, and $Z'(0) = \underline{X}(x(t))$, where \underline{X} is obtained from X by substituting 0 for the first component.

We have thus defined on a neighbourhood of the origin in $\{x_1 = 0\}$ a family Ψ of vector fields Z^t , with $|t| \neq 0$ small. We claim that if that family is locally controllable at the origin, so is Σ .

As previously noted, we can assume the trajectories of X^1 and also of $-X^1$ to be admissible trajectories of Σ , therefore if (x_1, x_2, \dots, x_n) is reachable from the origin so is the set $(]x_1 - \delta, x_1 + \delta[, x_2, \dots, x_n)$ for $|\delta|$ small.

Thus, proving that if a point in $\{x_1 = 0\}$ is attainable from the origin for the family Ψ , it is also attainable for Σ , is equivalent to proving the above claim.

Suppose $y = (0, x_2, \dots, x_n)$ is attainable for Ψ using only one vector field Z^t ; to reach that point following trajectories of Σ we just have to go from the origin to $x(t)$ along X^1 , follow X from there until the point in N_t which projects on y , and then follow $-X^1$ until y .

It is easy to see that the situation is not altered if there are several vector fields in Ψ involved, and we can be careful and not leave any fixed neighbourhood of the origin in M , therefore our claim is proved.

It remains to be shown that Ψ is locally controllable; using the criterion in [19] concerning the values of the vector fields at the point under consideration, it is enough to show that 0 belongs to the interior in $\{x_1 = 0\}$ of the convex hull of the values of $Z_t(0) = \underline{X}(x(t))$ for $|t| \neq 0$ and small.

The assumption $W_i(p) = W_{i-1}(p)$ for i even means that $v_i = (\text{ad}^i X^1, X)(p)$ can be written as a linear combination of v_j with j odd and smaller than i ; this is also true for the corresponding projections \underline{v}_i and \underline{v}_j .

Using the Campbell-Baker-Hausdorff formula [9] we can write $X(x(t)) = X(0) - tv_1 + t^2/2!v_2 - \dots$, for small $|t|$; projecting on $\{0\} \times \mathbb{R}^{n-1}$ and bearing in mind the remark above, we obtain $Z^t = \underline{X}(x(t)) = a_1(t)\underline{v}_1 + \dots + a_j(t)\underline{v}_j + \dots + a_m(t)\underline{v}_m$, where j is odd, m is the lowest j for which $W_j(p) = W_\infty(p)$.

In the power series $a_j(t)$ the lowest degree in t is of course odd, and we have either $a_j(t) = -t^j/j! + o(t^j)$ or $a_j(t) = o(t^j)$; define $b_j(t)$ as $-t^j/j!$ or 0 so that $a_j(t) = b_j(t) + o(t^j)$, and let $z(t) = b_1(t)\underline{v}_1 + \dots + b_j(t)\underline{v}_j + \dots + b_m(t)\underline{v}_m$.

It is now trivial to verify that if we take enough values of t in the interval $]0, \varepsilon[$ with ε positive and as small as we want, we obtain $n-1$ linearly independent vectors z_1, \dots, z_{n-1} among the corresponding $z(t)$, and we can get their symmetric vectors by taking the symmetric times; it follows that 0 belongs to the interior in $\{0\} \times \mathbb{R}^{n-1}$ of the convex hull of

$$\{z_1, \dots, z_{n-1}, z_n = -z_1, \dots, z_{2n-2} = -z_{n-1}\}.$$

There exists then a positive δ such that if $|y_i - z_i| < \delta$ the origin belongs to the interior in $\{0\} \times \mathbb{R}^{n-1}$ of the convex hull of $\{y_1, \dots, y_{2n-2}\}$; if we take ε small enough, we have $|Z^t - z(t)| < \delta$ if $|t| < \varepsilon$, and thus the interior of the convex hull of $\{Z^t, |t| \neq 0 \text{ and small}\}$ contains the origin.

Therefore the family Ψ is locally controllable at the origin and so is Σ . \square

The following example is due to Jakubczyk and was presented by Sussmann in [20].

Example. Let $M = \mathbb{R}^3$, and $X(x, y, z) = (0, x, x^3 + y^2)$, $X^1(x, y, z) = e_1$; the local controllability of this system, proved in [20], cannot be established with the linear test nor using the sufficient condition presented there; the condition of Theorem 2.1 is very easy to apply and gives a positive answer:

$$v_1 = (\text{ad}^1 X^1, X)(x) = (0, 1, 3x^2),$$

$$v_2 = (\text{ad}^2 X^1, X)(x) = (0, 0, 6x),$$

$$v_3 = (\text{ad}^3 X^1, X)(x) = (0, 0, 6).$$

At $(x, y, z) = 0, v_1 = e_2, v_2 = 0, v_3 = 6e_3$, and therefore $W_2 = W_1 = \{0\} \times \mathbb{R} \times \{0\}$, $W_\infty = W_3 = \{0\} \times \mathbb{R} \times \mathbb{R}$, and $T_0 S_1 = \mathbb{R} \times \{0\} \times \{0\}$; we have $\mathbb{R}^3 = T_0 S_1 + W_\infty$, and the system is locally controllable at the origin.

3. Multi-input systems. The system Σ will now be supposed to have codimension k and $s > 1$, and we assume the necessary conditions $\dim T_0(p) = n$ and $X(p) \in T'(p)$ to be verified.

For multi-input systems the first version of the sufficient condition involves a vector field Y that will play the role X^1 has played for scalar input systems. The construction of Y has already been explained in [5], and goes as follows: locally, around p , M looks like $\mathbb{R}^{n-k} \times \mathbb{R}^k$, where we can take p as the origin and $X(0) = e_1$, with the leaves of T' defined by $(x_{n-k+1}, \dots, x_n) = a \in \mathbb{R}^k$; let $\alpha(t)$ be the trajectory of X through p , and $\beta(t)$ its projection on the leaf S_1 of T' containing the origin, $\beta(t) = (\alpha_1(t), \dots, \alpha_{n-k}(t), 0, \dots, 0)$.

Now we can define a vector field Y belonging to T' such that its trajectory through $p = 0$ is β : $Y(x_1, \dots, x_n) = \underline{X}(\alpha(t))$, where \underline{X} is the projection of X on the first $n-k$ coordinates, and $x_1 = \alpha_1(t)$; note that t can be defined from $x_1 = \alpha_1(t)$ near the origin because $X(0) = e_1$.

We denote by $W'_i(x)$ the subspace of $T_x M$ generated by the vectors $(\text{ad}^j Y, X)(x)$ with $j = 1, \dots, i$, and by W'_∞ the union of the W'_i for all i .

We can now state a sufficient condition for local controllability at p , similar to Theorem 2.1.

THEOREM 3.1. *If $W'_i(p) = W'_{i-1}(p)$ for i even and $T_p M = W'_\infty(p) + T_p S_1$ then the system Σ is locally controllable at p .*

Proof. The proof is the repetition, with obvious adaptations, of the proof of Theorem 2.1; we just have to substitute Y for X^1 , except that the rank condition that allows the use of Proposition 4.2 in [9] to obtain Lemma 2.2 is not valid in this case.

We have to construct N_t , a k -dimensional submanifold transverse to $\mathbb{R}^{n-k} \times \{0\}$ and passing through $\beta(t)$, such that X is tangent to it at every point. If the last component of $X(\beta(t))$ is nonzero, for instance, let H be the plane defined by the $k-1$ vectors $e_{n-k+1}, \dots, e_{n-1}$ containing $\beta(t)$; near this point, let us say on a neighbourhood H' of $\beta(t)$ in H , X is transverse to H , and therefore $N_t = \{X_t(H'), |t| \text{ small}\}$ is the required submanifold. \square

For $k = 1$ this theorem reduces to the computational sufficient condition proved in [5] for codimension one control systems.

The construction of the vector field Y can be quite difficult in particular examples, and it would be much nicer to have a condition just in terms of the associated vector fields of the system Σ , as in Theorem 2.1.

We denote by ${}_r W_i(x)$ the subspace of $T_x M$ generated by the vectors $(\text{ad}^j X^r, X)(x)$ with $j = 1, \dots, i$, and $r = 1, \dots, s$, by ${}_r W_\infty$ the union of the ${}_r W_i$ for all i and by W_∞ the subspace spanned by the union of the ${}_r W_\infty$ for all r .

We can state a new sufficient condition for local controllability at p .

THEOREM 3.2. *If ${}_r W_i(p) = {}_r W_{i-1}(p)$ for i even and any r , and $T_p M = W_\infty(p) + T_p S_1$, then the system Σ is locally controllable at p .*

Proof. Reasoning according to the proof of Theorem 2.1, we can construct families Ψ_r , symmetric at p and spanning ${}_r W_\infty(p)$; if we define Ψ as the family of all vector fields belonging to some Ψ_r , we see that 0 belongs to the interior (in the complement of S_1) of the convex hull of the values of Ψ at p ; as in the proof of Theorem 2.1, the local controllability of Ψ implies that of Σ , and we can then conclude that Σ is locally controllable at p . \square

Remarks. (i) It is clear from the proof that we do not need ${}_rW_i(p) = {}_rW_{i-1}(p)$ for i even to be true for every r , if the subspace W spanned by the union of the ${}_rW_\infty$ for those r for which that property is verified is such that $T_pM = W + T_pS_1$.

(ii) It is not necessary to have ${}_rW_i(p) = {}_rW_{i-1}(p)$ if this is true for their projections on a complement of T_pS_1 .

As an example of the usefulness of this condition, we are going to consider systems with $M = \mathbb{R}^n$, $X^i = e_i$ ($i = 1, 2, \dots, s = n - k$); their local and global controllability has already been studied in [2].

A very easy computation shows that

$$(\text{ad}^j X^r, X)(x) = (\partial^j / \partial x_r^j \varphi_1, \dots, \partial^j / \partial x_r^j \varphi_n)$$

where φ_i is the i th component of X .

Therefore Σ verifies ${}_rW_i(p) = {}_rW_{i-1}(p)$ for i even and any r , if all functions φ_j have an odd (or infinite) order zero with respect to x_r at p (i.e. $\varphi_j(p) = 0$ and the first nonzero derivative at p with respect to x_r is odd) for every $r = 1, \dots, s = n - k$. In fact we have only to consider $j \geq n - k + 1$ as noted in Remark (ii).

Let $d(i, r)$ be the order of the zero p of φ_i with respect to x_r , the smallest $j \geq 0$ for which $\partial^j / \partial x_r^j \varphi_i$ is nonzero at p , with $r = 1, \dots, s = n - k$ and $i = n - k + 1, \dots, n$; the dimension of the projection of ${}_rW_\infty$ is at least the number of functions φ_i , $i \geq n - k + 1$, having different order at p with respect to x_r , the number of different $d(i, r)$.

Denote by ${}^{\#}d$ the maximum number of different $d(i, r)$ corresponding to different values of i (i.e. ${}^{\#}d$ is the maximum of the cardinals of all possible sets A such that the elements of A are numbers $d(i, r)$, all different and corresponding to the different i). It is clear that if ${}^{\#}d \geq k$ then $T_pM = W_\infty(p) + T_pS_1$ is verified.

This completes the proof of Proposition 3.3 below.

PROPOSITION 3.3. Σ is locally controllable at p if every $d(i, r)$ is odd and ${}^{\#}d \geq k$.

A slightly more general statement can be obtained if in the definition of ${}^{\#}d$ we only consider those r for which $d(i, r)$ is odd irrespective of i , taking in account the remark following Theorem 3.2; ${}^{\#}d \geq k$ is then a sufficient condition for local controllability.

Theorem 2 in [2] is a consequence of this proposition for $k = 1$ and $n = 2$, noting that if the hypothesis above is verified at one point (at least) of every leaf of T' , then global controllability follows from Theorem 4.2 in [3].

With $k = 1$ and for any dimension n , if $d(n, r)$ is odd for some r on at least a point in every leaf of T' (in this case $\{x_n = \text{const.}\}$), one has global controllability, noting that in this case ${}^{\#}d \geq 1$.

PROPOSITION 3.4. Let Σ be a codimension one system; if for any x_n the function φ_n has an odd order zero with respect to some x_i ($i = 1, \dots, s = n - 1$) then Σ is globally controllable.

Proof. It follows from Theorem 3.2 that Σ is locally controllable at the zero where the hypothesis is verified; since to each x_n corresponds a leaf of T' , to prove global controllability is enough to invoke Theorem 4.2 of [3]. \square

For a more general treatment of local and global controllability of codimension one systems, see [6].

Acknowledgments. Andrea Bacciotti pointed out the mistake in [5] and gave me the example used in this paper; he looked through the correction as well, and I am very thankful for his interest and cooperation.

Thanks are also due to an anonymous referee for many suggestions to improve the rigour of the presentation, especially the treatment of the trajectories of the input vector fields as admissible trajectories.

LEGENDRE-TAU APPROXIMATION FOR FUNCTIONAL DIFFERENTIAL EQUATIONS PART II: THE LINEAR QUADRATIC OPTIMAL CONTROL PROBLEM*

KAZUFUMI ITO[†] AND RUSSELL TEGLAS[‡]

Abstract. A numerical scheme based on the Legendre-tau approximation is proposed to approximate the feedback solution to the linear quadratic optimal control problem for hereditary differential systems. The convergence property is established using the Trotter-Kato theorem. The method yields very good approximations at low orders and provides an approximation technique for computing closed-loop eigenvalues of the feedback system. A comparison with existing methods (based on "averaging" and "spline" approximations) is made.

Key words. Legendre-tau approximations, hereditary differential equations, linear quadratic regulator problem

AMS(MOS) subject classifications. 34K35, 65N35, 93C20

1. Introduction. This paper is the continuation of the study [9] on the use of Legendre-tau approximation for functional differential equations (FDE) and concerns the problem of constructing feedback solutions to linear quadratic regulator problems for hereditary systems. This problem has received a rather extensive study and we refer to [15], [2] and [4] for the summary of the earlier contributions. Our approach is based upon the pioneering work of Banks and Burns [2] who clarified the idea of approximating FDE by systems of finite-dimensional ordinary differential equations and applied it to optimal control problems, i.e., the convergence of a particular numerical scheme (so called "averaging" approximation) is established, using the Trotter-Kato Theorem of linear semigroups. Recently, Gibson [8] has developed the approximation theory for the Riccati equations associated with a hereditary system and applied it to the averaging approximation scheme.

The purposes of this paper are (i) to apply the basic idea developed in [9] to the linear quadratic regulator problem, (ii) to prove convergence of numerical approximations of the feedback control laws, and (iii) to demonstrate the feasibility of our numerical schemes.

For the multiple point delay case, the solution to the algebraic Riccati equation (ARE) has jump discontinuities as shown in [8]. With this consideration, an extended version of the scheme described in [9] is developed for such a case in § 3.

It has been shown in [8] that if a sequence $S^N(t)$ of approximating semigroups converges to the solution semigroup $S(t)$, the solution Π^N to the algebraic Riccati equation corresponding to the N th approximation is uniformly bounded, and the solution Π to ARE is unique, then Π^N converges weakly to Π . This implies the strong

convergence of approximating optimal feedback gains. In § 3, we show the strong convergence of $S^N(t)$ to $S(t)$ using Trotter–Kato theorem. In Lemma 5.2 we show the uniform boundedness of $\|\Pi^N\|$ for certain special cases.

Moreover, Gibson has shown that if (i) the exponential stability is preserved under approximation, and (ii) the adjoint of approximate semigroups converges strongly to the adjoint semigroup, then Π^N converges strongly to Π . For the single point delay case, (i) and (ii) hold for the Legendre-tau approximation (see our paper [10, Part III]), and the numerical computations for several examples indicate the strong convergence of Π^N . Moreover, we show a rather interesting result in Theorem 5.1. It says that if a sequence of approximate solutions to ARE converges weakly to the solution to ARE, then the closed loop system which results from the approximate feedback control law is exponentially stable for sufficiently large orders of approximation.

As will be discussed in § 6, the tau method may offer considerable improvements over other methods (e.g. those discussed in [4], [8]) and it gives a good approximation to the closed loop eigenvalue.

The following is a brief summary of the contents of this paper. In § 2 we review the equivalence results between FDE and abstract Cauchy problems on the product space $\mathbb{R}^n \times L_2$ and results on the regulator problem for hereditary differential systems. In § 3 we introduce the numerical scheme based on the Legendre-tau approximation for the multiple point delay case and discuss the basic convergence of approximate semigroups using the Trotter–Kato theorem. In § 4 we show how one can use the numerical scheme described in § 3 to obtain the feedback solutions. In § 5 we state the basic convergence property of approximate solutions to ARE. Finally, in § 6 we present numerical results and compare these results with those obtained by other methods [4], [8].

Throughout this paper the following notation will be used. $r > 0$ stands for the largest delay time appearing in the FDE. The Hilbert space of \mathbb{R}^n -valued square integrable functions on the interval $[a, b]$ is denoted by $L_2([a, b]; \mathbb{R}^n)$. When the underlying space and interval can be understood from the context, we will abbreviate the notation and simply write L_2 , $L_2^{\text{loc}}([0, \infty); \mathbb{R}^n)$, or L_2^{loc} , is the space of \mathbb{R}^n -valued locally square integrable functions on the semi-infinite interval $[0, \infty)$. H^k is the Sobolev space of \mathbb{R}^n -valued functions f on a compact interval with $f^{(k-1)}$ absolutely continuous and $f^{(k)} \in L_2$. We denote by Z the product space $\mathbb{R}^n \times L_2([-r, 0]; \mathbb{R}^n)$. Given an element $z \in Z$, $\eta \in \mathbb{R}^n$ and $\phi \in L_2$ denote the two coordinates of z : $z = (\eta, \phi)$. The bracket $\langle \cdot, \cdot \rangle_H$ stands for the inner product in the Hilbert space H and the subscript for the underlying Hilbert space will be omitted when understood from the context. $\|\cdot\|$ denotes the norm for elements of a Banach space and for operators between Banach spaces, while $|\cdot|$ denotes the Euclidean norm in \mathbb{R}^n .

If X and Y are Banach spaces, then the space of bounded operators from X to Y is denoted by $\mathcal{L}(X, Y)$. $\mathcal{D}(\mathcal{A})$ denotes the domain of a linear operator \mathcal{A} . χ_I denotes the characteristic function of the interval I . Finally, for any function ϕ of independent variable θ , we shall use ϕ or $(\partial/\partial\theta)\phi$ to denote the derivative of ϕ with respect to θ .

2. Riccati equations. In this section, we state the type of problems to be considered and recall some results on the linear quadratic regulator problem for hereditary differential systems.

Given $(\eta, \phi) \in Z$ and $u \in L_2^{\text{loc}}([0, \infty), \mathbb{R}^n)$, we consider the initial value problem

$$(2.1) \quad \frac{d}{dt}x(t) = \int_{-r}^0 d\mu(\theta)x(t+\theta) + Bu(t), \quad x(0) = \eta, \quad x(\theta) = \phi(\theta), \quad \theta \in [-r, 0)$$

where μ is a matrix-valued function of bounded variation on $[-r, 0]$ with the form

$$(2.2) \quad \mu(\theta) = \sum_{i=0}^l A_i \chi_{(-\theta_i, 0]}(\theta) + \int_{-r}^{\theta} A(s) ds$$

with $0 = \theta_0 < \theta_1 < \dots < \theta_l = r$. A_i and $A(\cdot)$ are $n \times n$ matrices, the elements of the latter being square integrable on $[-r, 0]$. Alternatively, for $t \geq 0$

$$\int_{-r}^0 d\mu(\theta)x(t+\theta) = \sum_{i=0}^l A_i x(t-\theta_i) + \int_{-r}^0 A(\theta)x(t+\theta) d\theta.$$

It is well known [2], [5], [6] that for $(\eta, \phi) \in Z$ and $u \in L_2^{\text{loc}}$, (2.1) admits a unique solution $x \in L_2([-r, T]; \mathbb{R}^n) \cap H^1([0, T]; \mathbb{R}^n)$ for any $T \geq 0$, and that (2.1) can be formulated as an evolution equation on Z

$$(2.3) \quad \frac{d}{dt}z(t) = \mathcal{A}z(t) + \mathcal{B}u(t), \quad t \geq 0$$

where $z(t) = (x(t), x(t+\cdot)) \in Z$, $t \geq 0$ and $\mathcal{B}u = (Bu, 0) \in Z$ for $u \in \mathbb{R}^m$. The infinitesimal generator \mathcal{A} is defined by

$$(2.4) \quad \mathcal{D}(\mathcal{A}) = \{(\eta, \phi) \in Z \mid \eta = \phi(0) \text{ and } \dot{\phi} \in L_2\}$$

and for $(\phi(0), \phi) \in \mathcal{D}(\mathcal{A})$

$$(2.5) \quad \mathcal{A}(\phi(0), \phi) = \left(\int_{-r}^0 d\mu(\theta)\phi(\theta), \dot{\phi} \right).$$

The C_0 -semigroup generated by \mathcal{A} on Z will be denoted by $\{S(t) \mid t \geq 0\}$.

Consider the optimal control problem on a finite interval $[0, T]$: for given initial $(\eta, \phi) \in Z$,

$$(2.6) \quad \text{minimize } J(u; [0, T]) = \int_0^T (|Cx(t)|^2 + |u(t)|^2) dt + |Rx(T)|^2,$$

over $u \in L_2([0, T]; \mathbb{R}^m)$ subject to (2.1). Here C and R are $p \times n$ matrices. Within the framework of (2.3), (2.6) can be written as

$$\mathcal{J}(u) = \int_0^T (|\mathcal{C}z(t)|^2 + |u(t)|^2) dt + |\mathcal{R}z(T)|^2$$

where $\mathcal{C}(\eta, \phi) = C\eta$ and $\mathcal{R}(\eta, \phi) = R\eta$ for $(\eta, \phi) \in Z$. It then follows from [1], [7] that the optimal solution u^0 to (2.6) is given by

$$(2.7) \quad u^0(t) = -\mathcal{B}^*\Pi(t)z^0(t), \quad t \geq 0$$

where $\Pi(\cdot)$ is the unique solution, within a class of nonnegative (definite) selfadjoint operators for which $\langle \Pi(t)z, z \rangle$ is absolutely continuous on $[0, T]$, of the Riccati equation

$$(2.8) \quad \frac{d}{dt}\langle \Pi(t)z, z \rangle = -2\langle \mathcal{A}z, \Pi(t)z \rangle + \langle \mathcal{B}^*\Pi(t)z, \mathcal{B}^*\Pi(t)z \rangle - \langle \mathcal{C}z, \mathcal{C}z \rangle$$

for all $z \in \mathcal{D}(\mathcal{A})$,

$$\Pi(T) = \mathcal{R}^*\mathcal{R},$$

and $z^0(t)$ satisfies the evolution equation

$$(2.9) \quad \frac{d}{dt}z^0(t) = (\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi(t))z^0(t), \quad t \geq 0,$$

$$z^0(0) = (\eta, \phi).$$

Now we consider the optimal control problem on the infinite interval. For given initial data $z = (\eta, \phi)$, minimize the cost functional

$$(2.10) \quad J(u, z) = \int_0^\infty (|\mathcal{C}z(t)|^2 + |u(t)|^2) dt,$$

subject to (2.3).

DEFINITION 2.1. (i) $(\mathcal{A}, \mathcal{B})$ is stabilizable if there exists a bounded operator \mathcal{K} such that $\mathcal{A} - \mathcal{B}\mathcal{K}$ generates a uniformly exponentially stable semigroup.

(ii) $(\mathcal{C}, \mathcal{A})$ is detectable if $(\mathcal{A}^*, \mathcal{C}^*)$ is stabilizable.

Remark 2.2 (e.g. [16]). For hereditary differential systems, condition (ii) is equivalent to

$$z \in \mathcal{D}(\mathcal{A}), \quad \mathcal{A}z = \lambda z, \quad \mathcal{C}z = 0$$

for $\lambda \in \mathbb{C}^+$ imply that $z \equiv 0$. Moreover, (ii) holds if and only if

$$\text{rank} [\Delta(\lambda)^T, C^T] = n \quad \text{for all } \lambda \in \mathbb{C}^+$$

where $\Delta(\lambda) = \lambda I - \int_{-r}^0 d\mu(\theta) e^{\lambda\theta}$.

An operator $\Pi \in \mathcal{L}(Z)$ is a solution of the algebraic Riccati equation (ARE) if

$$(ARE) \quad 2\langle \mathcal{A}z, \Pi z \rangle - \langle \mathcal{B}^* \Pi z, \mathcal{B}^* \Pi z \rangle + \langle \mathcal{C}z, \mathcal{C}z \rangle = 0 \quad \text{for all } z \in \mathcal{D}(\mathcal{A}).$$

The next theorem follows from [7], [19].

THEOREM 2.3. (i) If $(\mathcal{A}, \mathcal{B})$ is stabilizable, then (ARE) has a self-adjoint, nonnegative solution.

(ii) If $(\mathcal{C}, \mathcal{A})$ is detectable, then (ARE) has at most, one selfadjoint, nonnegative solution. Moreover, if Π denotes the said solution, then $\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi$ generates a uniformly exponentially stable semigroup.

(iii) If $(\mathcal{A}, \mathcal{B})$ is stabilizable and $(\mathcal{C}, \mathcal{A})$ is detectable, then (ARE) has a unique selfadjoint, nonnegative solution and the optimal control to (2.10) is given

$$(2.11) \quad u^0(t) = -\mathcal{B}^* \Pi z^0(t),$$

where $z^0(t)$ is the mild solution to

$$\frac{d}{dt} z^0(t) = (\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi) z^0(t), \quad z^0(0) = z.$$

In what follows, we assume that condition (iii) in Theorem 2.3 holds and recall some of the important results due to Gibson [8].

THEOREM 2.4. If Π is the selfadjoint, nonnegative solution to (ARE), then

$$\Pi Z \subset \mathcal{D}(\mathcal{A}^*).$$

Note that $\mathcal{D}(\mathcal{A}^*)$ consists of elements $(y, \psi) \in Z$ for which $z(\theta) = \psi(\theta) - \sum_{i=1}^l A_i^T \chi_{(-\theta_i, 0]} y$ is absolutely continuous on $[-r, 0]$ with $z(-r) = 0$, [18]. If we write Π as a matrix of operators on $Z = \mathbb{R}^n \times L_2$,

$$(2.12) \quad \Pi = \begin{bmatrix} \Pi^{00} & \Pi^{01} \\ \Pi^{10} & \Pi^{11} \end{bmatrix}$$

where Π^{00} is a nonnegative, symmetric $n \times n$ matrix, $\Pi^{10}(\cdot)$ is a square integrable matrix function on $[-r, 0]$, $\Pi^{01} = \Pi^{10*}$ and

$$\Pi^{01} \phi = \int_{-r}^0 \Pi^{10}(\theta)^T \phi(\theta) d\theta, \quad \phi \in L_2,$$

and Π^{11} is a nonnegative, selfadjoint operator on L_2 , then from (2.11) the optimal control u^0 may be written as follows:

$$u^0(t) = -B^T \left(\Pi^{00}x(t) + \int_{-r}^0 \Pi^{10}(\theta)^T x(t+\theta) d\theta \right).$$

From Theorem 2.4 we have the following.

THEOREM 2.5. $\Pi^{10}(\cdot)$ is piecewise absolutely continuous on $[-r, 0]$ with the jump conditions at $-\theta_i$, $1 \leq i \leq l-1$

$$(2.13) \quad \Pi^{10}((-\theta_i)^+) - \Pi^{10}((-\theta_i)^-) = A_i^T \Pi^{00}.$$

Also,

$$(2.14) \quad \Pi^{10}(-r) = A_l^T \Pi^{00}.$$

Let us define an operator on $Z \times Z$

$$\mathcal{H} = \begin{bmatrix} \mathcal{A} & -\mathcal{B}\mathcal{B}^* \\ -\mathcal{C}^*\mathcal{C} & -\mathcal{A}^* \end{bmatrix}$$

with $\mathcal{D}(\mathcal{H}) = \mathcal{D}(\mathcal{A}) \times \mathcal{D}(\mathcal{A}^*)$. Then we have the following.

THEOREM 2.6. \mathcal{H} is closed and densely defined and has compact resolvent. For a complex number λ with $\text{Re } \lambda < 0$,

$$\lambda \in \sigma(\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi) \quad \text{if } \lambda \in \sigma(\mathcal{H}).$$

The algebraic and geometric multiplicities of λ as an eigenvalue of $\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi$ are finite and are identical to the respective multiplicities of λ as an eigenvalue of \mathcal{H} . Moreover, λ is an eigenvalue of \mathcal{H} if $\det \hat{\Delta}(\lambda) = 0$ where

$$(2.15) \quad \hat{\Delta}(\lambda) = \lambda I - \begin{bmatrix} \int_{-r}^0 d\mu(\theta) e^{\lambda\theta} & -BB^T \\ -C^TC & -\int_{-r}^0 d\mu(\theta)^T e^{-\lambda\theta} \end{bmatrix}.$$

3. Legendre-tau approximations. As pointed out in § 2, for the multiple point delay case, $\Pi^{10}(\cdot)$ has jump discontinuities. If we were to try to approximate the solution to $\Pi^{10}(\cdot)$ using a series of polynomials on $[-r, 0]$, we would observe the so-called Gibbs phenomenon. To avoid this difficulty, we proceed as follows. For simplicity of exposition we deal with the system of the form

$$(3.1) \quad \begin{aligned} \frac{d}{dt}x(t) &= A_0x(t) + A_1x(t + (-\theta_1)^+) + A_2x(t - \theta_2) \\ &\quad + \int_{-r}^0 A(\theta)x(t+\theta) d\theta + Bu(t), \end{aligned}$$

with $-r = -\theta_2 < -\theta_1 < 0$.

Alternatively, if $z(t, \theta) = x(t + \theta)$, then

$$(3.1a) \quad \frac{\partial}{\partial t}z(t, \theta) = \frac{\partial}{\partial \theta}z(t, \theta), \quad -r \leq \theta \leq 0,$$

$$(3.1b) \quad \frac{d}{dt}z(t, 0) = A_0z(t, 0) + A_1z(t, -\theta_1) + A_2z(t, -r) + \int_{-r}^0 A(\theta)z(t, \theta) d\theta + Bu(t).$$

The approximate solution $z^N(t, \theta)$ is assumed to be represented as

$$(3.2) \quad z^N(t, \theta) = \sum_{k=0}^N a_k^N(t) p_k^{(1)}(\theta) \chi_{(-\theta_1, 0]}(\theta) + \sum_{k=0}^N b_k^N(t) p_k^{(2)}(\theta) \chi_{[-r, -\theta_1]}(\theta)$$

where

$$p_k^{(1)}(\theta) = P_k((2\theta + \theta_1)/\theta_1), \quad p_k^{(2)}(\theta) = P_k((2(\theta + \theta_1) + \theta_2 - \theta_1)/(\theta_2 - \theta_1)),$$

for $0 \leq k \leq N$ and $\{P_k\}_{k \geq 0}$ are the Legendre polynomials on $[-1, 1]$. Note that $(\partial/\partial\theta)z^N$ is given by the following as an element in H^{-1} .

$$\begin{aligned} \frac{\partial}{\partial\theta} z^N(t, \theta) &= \sum_{k=0}^N (2/\Delta_1) a_k^N(t) \dot{p}_k^{(1)}(\theta) \chi_{(-\theta_1, 0]}(\theta) \\ &\quad + \sum_{k=0}^N (2/\Delta_2) b_k^N(t) \dot{p}_k^{(2)}(\theta) \chi_{[-r, -\theta_1]}(\theta) \\ &\quad + \left(\sum_{k=0}^N a_k^N(t) p_k^{(1)}(\theta) - \sum_{k=0}^N b_k^N(t) p_k^{(2)}(\theta) \right) \delta(\theta - \theta_1) \end{aligned}$$

where $\Delta_1 = \theta_1$, $\Delta_2 = \theta_2 - \theta_1$ and $\delta(\cdot)$ is the delta function. The underlying ideas of the tau method for approximating (3.1) are: (i) equating (3.1a) in the sense that

$$(3.3) \quad \left\langle \frac{\partial}{\partial t} z^N(t, \theta) - \frac{\partial}{\partial\theta} z^N(t, \theta), f \right\rangle_{L_2} = 0$$

for all

$$f \in \left\{ f \in L_2 \left| f = \sum_{k=0}^{N-1} \alpha_k p_k^{(1)} \chi_{(-\theta_1, 0]} + \sum_{k=0}^N \beta_k p_k^{(2)} \chi_{[-r, -\theta_1]}, \alpha_k, \beta_k \in \mathbb{R}^n \right. \right\},$$

and (ii) imposing (3.1b) on the approximate solution $z^N(t, \theta)$. From (i) we obtain $(2N+1)$ equations:

$$(3.4) \quad \begin{aligned} \frac{d}{dt} a_k^N(t) &= (2/\Delta_1) (S^N a^N)_k, \quad 0 \leq k \leq N-1, \\ \frac{d}{dt} b_k^N(t) &= (2/\Delta_2) (S^N b^N)_k + \sum_{i=0}^N ((-1)^i a_i^N - b_i^N) (2k+1)/\Delta_2, \quad 0 \leq k \leq N \end{aligned}$$

where S^N is the matrix representation of the derivative $\partial/\partial\theta$ (i.e. if the vector a is associated with a series of Legendre polynomials whose coefficients are the components of a , then the components of $S^N a$ give the Legendre coefficients of the derived series), and is given by

$$(3.5) \quad S^N = \begin{bmatrix} 0 & 1 & 0 & 1 & 0 & \cdots & 1 & 0 \\ 0 & 0 & 3 & 0 & 3 & \cdots & 0 & 3 \\ 0 & 0 & 0 & 5 & 0 & \cdots & 5 & 0 \\ \vdots & & & & & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & \cdots & 2N-3 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 2N-1 \end{bmatrix} \otimes I$$

for N even. Here I is the $n \times n$ identity matrix and \otimes denotes Kronecker product. From (ii) we obtain an equation for a_N^N , i.e.,

$$\frac{d}{dt} \left(\sum_{k=0}^N a_k^N(t) \right) = \int_{-r}^0 d\mu(\theta) z^N(t, \theta) + Bu(t)$$

or

$$(3.6) \quad \frac{d}{dt} a_N^N(t) = - \sum_{k=0}^{N-1} \frac{d}{dt} a_k^N(t) + \int_{-r}^0 d\mu(\theta) z^N(t, \theta) + Bu(t).$$

Here one needs the following modification in order to ensure the numerical stability of our scheme (see the proof of Lemma 3.3 for detailed discussions). Equation (3.6) is replaced by

$$(3.6)' \quad \frac{d}{dt} a_N^N(t) = - \sum_{k=0}^{N-1} \frac{d}{dt} a_k^N + \int_{-r}^0 d\mu^N(\theta) z^N(t, \theta) + Bu(t)$$

where

$$\int_{-r}^0 d\mu^N(\theta) \phi(\theta) = A_0 \phi(0) + A_1 \phi((- \theta_1)^+) + A_2 \phi(-r) + \int_{-r}^0 A^N(\theta) \phi(\theta) d\theta$$

with

$$A^N(\theta) = \sum_{k=0}^{N-1} \left[\frac{2k+1}{\theta_1} \int_{-\theta_1}^0 A(\xi) p_k^{(1)}(\xi) d\xi \right] p_k^{(1)}(\theta) \quad \text{on } [-\theta_1, 0]$$

and

$$A^N(\theta) = A(\theta) \quad \text{on } [-r, -\theta_1].$$

Hence, from (3.4) and (3.6)' we obtain a system of ordinary differential equations for $\text{col}(b_0^N, \dots, b_N^N, a_0^N, \dots, a_N^N)$:

$$(3.7) \quad \begin{aligned} \frac{d}{dt} \begin{bmatrix} \beta^N \\ \alpha^N \end{bmatrix} &= A^N \begin{bmatrix} \beta^N \\ \alpha^N \end{bmatrix} + B^N u(t), \\ B^N &= (e_{2N+2} \otimes I) B \end{aligned}$$

where $\alpha^N = \text{col}(a_0^N, a_1^N, \dots, a_N^N)$, $\beta^N = \text{col}(b_0^N, b_1^N, \dots, b_N^N)$ and $e_{2N+2} = \text{col}(0, 0, \dots, 1) \in \mathbb{R}^{2N+2}$. If we define the matrices $J^{(1)}$, $J^{(2)}$ and \tilde{S} by

$$\begin{aligned} J^{(1)} &= \overbrace{[u, u, \dots, u]}^{N+1} \otimes I, \\ J^{(2)} &= \overbrace{[u, -u, \dots, u, (-1)^N u]}^{N+1} \otimes I, \end{aligned}$$

with $u = \text{col}(1, 3, \dots, 2N+1)$, and

$$\tilde{S}^N = \left[\begin{array}{c} S^N \\ \left(0, -1, -3, \dots, -\frac{N(N+1)}{2} \right) \otimes I \end{array} \right],$$

then A^N is given by $A^N = A_0^N + A_\mu^N$, where

$$A_0^N = \begin{bmatrix} \frac{1}{\Delta_2} (2S^N - J^{(1)}) & \frac{1}{\Delta_2} J^{(2)} \\ 0 & \frac{2}{\Delta_1} \tilde{S}^N \end{bmatrix}$$

and

$$A_{\mu}^N = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ F_0 \cdots F_N & D_0^N \cdots D_N^N \end{bmatrix}$$

with

$$D_k^N = (A_0 + (-1)^k A_1) + (1 - \delta_{k,N}) \int_{-\theta_1}^0 A(\theta) p_k^{(1)}(\theta) d\theta$$

and

$$F_k = (-1)^k A_2 + \int_{-r}^{-\theta_1} A(\theta) p_k^{(2)}(\theta) d\theta \quad \text{for } 0 \leq k \leq N$$

where $\delta_{k,N}$ is the Kronecker delta.

Note that in the case when $\theta_1 = r$, the approximation scheme described above for (3.1) is exactly the same as that given in [9]. Let us introduce the orthogonal projection Q^N on Z . For any $z = (\eta, \phi)$, Q^N is defined by

$$Q^N z = \left(\eta, \sum_{k=0}^{N-1} \alpha_k p_k^{(1)}(\theta) \chi_{(-\theta_1, 0]} + \sum_{k=0}^N \beta_k p_k^{(2)}(\theta) \chi_{[-r, -\theta_1]} \right),$$

where

$$(3.8) \quad \alpha_k = \frac{2k+1}{\Delta_2} \int_{-r}^{-\theta_1} \phi(\theta) p_k^{(2)}(\theta) d\theta, \quad 0 \leq k \leq N-1,$$

$$(3.9) \quad \beta_k = \frac{2k+1}{\Delta_1} \int_{-\theta_1}^0 \phi(\theta) p_k^{(1)}(\theta) d\theta, \quad 0 \leq k \leq N,$$

and we define the projection operator L^N on Z by

$$(3.10) \quad \begin{aligned} L^N z &= Q^N z + a_N(0, p_N^{(1)} \chi_{[-\theta_1, 0]}), \\ a_N &= \eta - \sum_{k=0}^{N-1} \alpha_k p_k^{(1)}(0) = \eta - \sum_{k=0}^{N-1} \alpha_k. \end{aligned}$$

Immediately, we can obtain the following lemma.

LEMMA 3.1. *If $(\eta^N, \phi^N) = L^N(\eta, \phi)$, then $\phi^N(0) = \eta^N = \eta$. For $N \geq 1$,*

$$(3.11) \quad L^N Q^N = L^N \quad \text{and} \quad Q^N L^N = Q^N.$$

Moreover, if

$$L^N z = \sum_{k=0}^N a_k(p_k^{(1)}(0), p_k^{(1)} \chi_{(-\theta_1, 0]}) + \sum_{k=0}^N b_k(0, p_k^{(2)} \chi_{[-r, -\theta_1]})$$

and

$$Q^N z = \sum_{k=0}^{N-1} \alpha_k(0, p_k^{(1)} \chi_{(-\theta_1, 0]}) + \eta(1, 0) + \sum_{k=0}^N \beta_k(0, p_k^{(2)} \chi_{[-r, -\theta_1]}),$$

then we have

$$a_k = \alpha_k, \quad 0 \leq k \leq N-1, \quad b_k = \beta_k, \quad 0 \leq k \leq N,$$

and $a_N = \eta - \sum_{k=0}^{N-1} \alpha_k$; i.e.,

$$\Omega^N(b_0, \dots, b_N, a_0, \dots, a_{N-1}, a_N)^T = (\beta_0, \dots, \beta_N, \alpha_0, \dots, \alpha_{N-1}, \eta)^T$$

where

$$\Omega^N = \left[\begin{array}{c|cccc} I & & & & 0 \\ \hline & & & & 0 \\ & & I & & \vdots \\ 0 & & & & 0 \\ \hline & 1 & 1 & \cdots & 1 \end{array} \right].$$

As shown in [9], the tau method without the modification of (3.6) can be interpreted as follows. Let

$$(3.12) \quad z^N(t) = (z^N(t, 0), z^N(t, \cdot)) \in Z$$

where $z^N(t, \cdot)$ is given by (3.2). Then $z^N(t)$, $t \geq 0$ satisfies

$$(3.13) \quad \frac{d}{dt} z^N(t) = L^N \mathcal{A} z^N - L^N \mathcal{B} u(t), \quad z^N(0) = L^N z.$$

From (3.11), the function

$$(3.14) \quad \tilde{z}^N(t) = Q^N z^N(t), \quad z \geq 0$$

satisfies

$$\frac{d}{dt} \tilde{z}^N(t) = Q^N \mathcal{A} L^N \tilde{z}^N(t) + \mathcal{B} u(t), \quad \tilde{z}^N(0) = Q^N z.$$

Similarly, for the modified scheme with (3.6)' the function defined by (3.14) satisfies

$$\frac{d}{dt} \tilde{z}^N(t) = \mathcal{A}^N \tilde{z}^N(t) + \mathcal{B} u(t)$$

where

$$(3.15) \quad \mathcal{A}^N(\eta, \phi) = Q^N \left(\int_{-r}^0 d\mu^N(\theta) \phi^N(\theta), \dot{\phi}^N \right)$$

with

$$(\eta, \phi^N) = L^N(\eta, \phi) \quad \text{for } (\eta, \phi) \in Z.$$

To establish convergence for the tau approximation, we will use the Trotter-Kato theorem (see [13, Chap. III, Thm. 4.6]).

THEOREM 3.2. *Let $S(t)$ and $S^N(t)$, $N \geq 1$ be C_0 -semigroups acting on a Banach space X with infinitesimal generators \mathcal{A} and \mathcal{A}^N respectively. Assume that the following conditions are satisfied:*

(i) (stability). *There exists a constant ω such that*

$$\|S(t)\|_X \leq e^{\omega t} \quad \text{and} \quad \|S^N(t)\|_X \leq e^{\omega t}, \quad t \geq 0.$$

(ii) (consistency). *There exists a subset \mathcal{D} contained in $\mathcal{D}(\mathcal{A}) \cap \bigcap_{N=1}^{\infty} \mathcal{D}(\mathcal{A}^N)$ which together with $\text{Range}(\lambda I - \mathcal{A})$ for some $\lambda > 0$ is dense in X and such that $\mathcal{A}^N \phi \rightarrow \mathcal{A} \phi$ for all $\phi \in \mathcal{D}$ as $N \rightarrow \infty$. Then for all $\phi \in X$,*

$$\|S^N(t)\phi - S(t)\phi\| \rightarrow 0$$

uniformly on bounded t -intervals.

The following lemma concerns the question of stability of the tau approximation for (3.1). Following an idea in [2], we define the norm $\|\cdot\|_g$ on Z by

$$\|z\|_g = |\eta|^2 + \int_{-r}^0 |\phi(\theta)|^2 g(\theta) d\theta \quad \text{for } z = (\eta, \phi) \in Z,$$

where g is the piecewise constant function on $[-r, 0]$ defined by

$$(3.16) \quad g(\theta) = \begin{cases} 1, & \theta \in [-r, -\theta_1], \\ 2, & \theta \in (-\theta_1, 0]. \end{cases}$$

LEMMA 3.3. *Let $\{S^N(t), t \geq 0\}$ be the semigroup on Z generated by \mathcal{A}^N defined by (3.15). Then there exists a positive constant ω such that*

$$\|S^N(t)\|_g \leq e^{\omega t}, \quad t \geq 0,$$

i.e., for all $z \in Z$, $\langle A^N z, z \rangle_g \leq \omega \|Q^N z\|_g^2 \leq \omega \|z\|_g^2$, where $\langle \cdot, \cdot \rangle_g$ denotes the inner product on Z :

$$(3.17) \quad \langle (\eta^1, \phi^1), (\eta^2, \phi^2) \rangle_g = \langle \eta^1, \eta^2 \rangle_{\mathbb{R}^n} + \int_{-r}^0 \langle \phi^1, \phi^2 \rangle_{\mathbb{R}^n} g(\theta) d\theta.$$

Proof. Let

$$(\eta, \phi) = L^N z = \left(\eta, \sum_{k=0}^N a_k p_k^{(1)} \chi_{(-\theta_1, 0]} + \sum_{k=0}^N b_k p_k^{(2)} \chi_{[-r, -\theta_1]} \right)$$

where a_k, b_k are given in Lemma 3.1 and let $(\eta, \tilde{\phi}) = Q^N z$. Since p_N is orthogonal to all polynomials of degree at most $N-1$, it follows from (3.4), (3.6)', and (3.7) that

$$(3.18) \quad \begin{aligned} \langle \mathcal{A}^N z, z \rangle_g &= \left\langle \int_{-r}^0 d\mu^N(\theta) \phi(\theta), \eta \right\rangle + \int_{-r}^{-\theta_1} \langle \dot{\phi}(\theta), \phi(\theta) \rangle d\theta \\ &\quad + 2 \int_{-\theta_1}^0 \langle \dot{\phi}(\theta), \phi(\theta) \rangle d\theta + \left\langle \sum_{i=0}^N ((-1)^i a_i - b_i), \sum_{k=0}^N b_k \right\rangle. \end{aligned}$$

Note that

$$\phi(0) = \eta, \quad \phi((-\theta_1)^-) = \sum_{k=0}^N b_k, \quad \phi((-\theta_1)^+) = \sum_{k=0}^N (-1)^k a_k.$$

Then the right-hand side of (3.18) becomes

$$\begin{aligned} &= \left\langle \int_{-r}^0 d\mu^N(\theta) \phi(\theta), \phi(0) \right\rangle + \frac{1}{2} |\phi((-\theta_1)^-)|^2 - |\phi(-r)|^2 + |\phi(0)|^2 - |\phi((-\theta_1)^+)|^2 \\ &\quad + \langle \phi((-\theta_1)^+), \phi((-\theta_1)^-) \rangle - |\phi((-\theta_1)^-)|^2 \\ &= \left\langle A_0 \phi(0) + A_1 \phi((-\theta_1)^+) + A_2 \phi(-r) + \int_{-r}^0 A(\theta) \tilde{\phi}(\theta) d\theta, \phi(0) \right\rangle \\ &\quad - \frac{1}{2} |\phi(-r)|^2 - \frac{1}{2} |\phi((-\theta_1)^+) - \phi((-\theta_1)^-)|^2 - \frac{1}{2} |\phi((-\theta_1)^+)|^2 + |\phi(0)|^2, \end{aligned}$$

where the term $\int_{-r}^0 A(\theta) \tilde{\phi}(\theta) d\theta$ is a result of the modification (3.6)'. Without the modification, instead, we have $\int_{-r}^0 A(\theta) \phi(\theta) d\theta$. But in general, the absolute value of

this cannot be bounded by $(\text{constant}) \times \|Q^N z\|$ since $\|Q^N z\|^2 = |\eta|^2 + \|\tilde{\phi}\|_{L_2}^2$. Now, the right-hand side of (3.18) is bounded by

$$\begin{aligned} & \leq \left(1 + |A_0| + \frac{1}{2}|A_1^T A_1| + \frac{1}{2}|A_2^T A_2|\right) |\phi(0)|^2 \\ & \quad + \left(\int_{-r}^0 |A(\theta)|^2 d\theta\right)^{1/2} \left(\int_{-r}^0 |\tilde{\phi}(\theta)|^2 d\theta\right)^{1/2} |\phi(0)| \\ & \leq \omega \|Q^N z\|_g^2 \leq \omega \|z\|_g^2, \end{aligned}$$

where

$$\omega = 1 + |A_0| + \frac{1}{2}|A_1^T A_1| + \frac{1}{2}|A_2^T A_2| + \frac{1}{2}\|A(\cdot)\|_{L_2},$$

and we used the relation $2\langle x, y \rangle \leq |x|^2 + |y|^2$ for $x, y \in \mathbb{R}^n$, and the fact that Q^N is symmetric w.r.t. $\langle \cdot, \cdot \rangle_g$ —inner product. Q.E.D.

Next we will prove the consistency of the tau approximation. Let us denote by \mathcal{D}^k , $k \geq 1$, the domain of the k th power of \mathcal{A} . Then \mathcal{D}^k is dense in Z . Let us introduce the graph norm on \mathcal{D}^k :

$$\|z\|_{\mathcal{D}^k} = \left(\sum_{i=0}^k \|\mathcal{A}^i z\|_Z^2 \right)^{1/2} \quad \text{for } z \in \mathcal{D}^k.$$

Note that $\|\phi\|_{H^k} \leq \|z\|_{\mathcal{D}^k}$ for all $z = (\phi(0), \phi) \in \mathcal{D}^k$.

LEMMA 3.4. $\|(\mathcal{A}^N - \mathcal{A})z\| \rightarrow 0$ as $N \rightarrow \infty$ for all $z \in \mathcal{D}^k$, $k \geq 2$.

To prove this lemma, we need the following technical lemma.

LEMMA 3.5. Let us define the projection operator P^N of $L_2[-1, 1]$ by

$$P^N f = \sum_{k=0}^N f_k P_k, \quad f_k = \frac{2k+1}{2} \int_{-1}^1 f(x) P_k(x) dx.$$

Then for any positive integer m , there exists a constant K such that

$$|P^N f(\pm 1) - f(\pm 1)| \leq KN^{-m+1/2} \|f\|_{H^m}$$

and

$$\left| \frac{d}{dx} (P^N f)(\pm 1) - \frac{d}{dx} f(\pm 1) \right| \leq KN^{-m+5/2} \|f\|_{H^m}.$$

Proof. Note that for $k \geq 1$, P_k satisfies

$$\mathcal{L}P_k + k(k+1)P_k = 0$$

where \mathcal{L} is the differential operator:

$$(\mathcal{L}f)(x) = \frac{d}{dx} \left((1-x^2) \frac{d}{dx} f \right).$$

Thus for $k \geq 1$ and $f \in H^1$,

$$f_k = -\frac{2k+1}{2k(k+1)} \int_{-1}^1 f(x) \mathcal{L}P_k dx = \frac{2k+1}{2k(k+1)} \int_{-1}^1 (1-x^2) \frac{d}{dx} P_k \frac{d}{dx} f dx.$$

Using the relation

$$(3.19) \quad (1-x^2) \frac{d}{dx} P_k = \frac{k(k+1)}{2k+1} (P_{k+1} - P_{k-1}),$$

we obtain

$$f_k = \frac{1}{2} \int_{-1}^1 (P_{k+1} - P_{k-1}) \frac{d}{dx} f dx.$$

It then follows that

$$(P^N f)(\pm 1) = \sum_{k=0}^N (\pm 1)^k a^k = a_0 + \left(\frac{1}{2} \sum_{k:\text{even}} \pm \frac{1}{2} \sum_{k:\text{odd}} \right) \int_{-1}^1 (P_{k+1} - P_{k-1}) \dot{f} dx.$$

If N is even, then

$$\begin{aligned} (P^N f)(\pm 1) &= a_0 - \frac{1}{2} \int_{-1}^1 (P_1 \pm P_0) \dot{f} dx + \frac{1}{2} \int_{-1}^1 (P_{N+1} \pm P_N) \dot{f} dx \\ (3.20) \quad &= \frac{1}{2} \int_{-1}^1 f dx - \frac{1}{2} \int_{-1}^1 (x \pm 1) \dot{f} dx + \frac{1}{2} \int_{-1}^1 (P_{N+1} \pm P_N) \dot{f} dx \\ &= f(\pm 1) + \frac{1}{2} \int_{-1}^1 (P_{N+1} \pm P_N) \dot{f} dx. \end{aligned}$$

Similarly, for N odd,

$$(3.21) \quad (P^N f)(\pm 1) = f(\pm 1) + \frac{1}{2} \int_{-1}^1 (P_N \pm P_{N+1}) \dot{f} dx.$$

If $m = 2k + 1$, $k \geq 0$, then

$$\int_{-1}^1 P_N \dot{f} dx = \left(-\frac{1}{N(N+1)} \right)^k \int_{-1}^1 (\mathcal{L}^k P_N) \dot{f} dx = \left(-\frac{1}{N(N+1)} \right)^k \int_{-1}^1 P_N (\mathcal{L}^k \dot{f}) dx.$$

And, if $m = 2k + 2$, $k \geq 0$, then

$$\int_{-1}^1 P_N \dot{f} dx = \left(-\frac{1}{N(N+1)} \right)^{k+1} \int_{-1}^1 (1-x^2) \frac{d}{dx} P_N \frac{d}{dx} (\mathcal{L}^k \dot{f}) dx$$

and from (3.19)

$$= \left(-\frac{1}{N(N+1)} \right)^k \frac{1}{2N+1} \int_{-1}^1 (P_{N+1} - P_{N-1}) \frac{d}{dx} (\mathcal{L}^k \dot{f}) dx.$$

Since \mathcal{L}^k is a differentiable operator of order $2k$ with polynomial coefficients on $[-1, 1]$, there exists a constant c_k for $k \geq 0$ such that

$$\|\mathcal{L}^k \dot{f}\| \leq c_k \|f\|_{H^{2k+1}} \quad \text{and} \quad \left\| \frac{d}{dx} (\mathcal{L}^k \dot{f}) \right\| \leq c_k \|f\|_{H^{2k+2}}.$$

Now, the first inequality of the lemma follows from (3.20) and (3.21).

To prove the second inequality, we note that

$$\frac{d}{dx} (P^N f)(\pm 1) = \sum_{k=0}^N (\mp 1)^k \frac{k(k+1)}{2} f_k = \frac{1}{2} \sum_{k=0}^N (\mp 1)^k \left(\frac{2k+1}{2} \right) \int_{-1}^1 (\mathcal{L} f) P_k dx.$$

Then the same arguments as above enable us to obtain the second inequality. Q.E.D.

Proof of Lemma 3.4. From the definition (3.10) of L^N

$$z^N = L^N z = (\phi^N(0), \phi^N), \quad \phi^N = \phi^{(1)} \chi_{(-\theta_1, 0]} + \phi^{(2)} \chi_{[-r, -\theta_1]}$$

where

$$\phi^{(1)} = \sum_{k=0}^N a_k p_k^{(1)} \quad \text{on } (-\theta_1, 0], \quad \phi^{(2)} = \sum_{k=0}^N b_k p_k^{(2)} \quad \text{on } [-r, -\theta_1]$$

and $\{a_k\}$ and $\{b_k\}$ are as given in Lemma 3.1. It then follows from (3.4) and (3.6)' that

$$\mathcal{A}^N z = (\eta^N, \psi^N)$$

with

$$\begin{aligned} \eta^N &= \int_{-r}^0 d\mu^N(\theta) \phi^N, \\ \psi^N &= \dot{\phi}^{(1)} \chi_{(-\theta_1, 0]} + \dot{\phi}^{(2)} \chi_{[-r, -\theta_1]} \\ &\quad + (\phi^{(1)}(-\theta_1) - \phi^{(2)}(-\theta_1)) \sum_{k=0}^N \frac{2k+1}{\Delta_2} p_k^{(2)} \chi_{[-r, -\theta_1]}. \end{aligned}$$

Thus, for $z \in \mathcal{D}(\mathcal{A})$,

$$\begin{aligned} \delta &= \|(\mathcal{A}^N - \mathcal{A})z\| \leq \|\dot{\phi}^{(1)} - \dot{\phi}\|_{L_2[-\theta_1, 0]} + \|\dot{\phi}^{(2)} - \dot{\phi}\|_{L_2[-r, -\theta_1]} \\ &\quad + |\phi^{(1)}(-\theta_1) - \phi^{(2)}(-\theta_1)| \left(\sum_{k=0}^N \frac{2k+1}{\Delta_2} \right)^{1/2} \\ &\quad + \left| \int_{-r}^0 d\mu^N(\theta) \phi^N(\theta) - \int_{-r}^0 d\mu(\theta) \phi(\theta) \right| \\ &= \delta_1 + \delta_2 + \delta_3 + \delta_4. \end{aligned} \tag{3.22}$$

Here, we note that

$$\phi^{(1)} = \tilde{\phi}^{(1)} + (\phi(0) - \tilde{\phi}^{(1)}(0)) p_N^{(1)} \quad \text{on } [-\theta_1, 0], \tag{3.23}$$

where

$$\tilde{\phi}^{(1)} = \sum_{k=0}^{N-1} a_k p_k^{(1)} \quad \text{on } [-\theta_1, 0].$$

From (3.6)', for $z = (\phi(0), \phi) \in \mathcal{D}(\mathcal{A})$,

$$\begin{aligned} &\int_{-r}^0 d\mu^N(\theta) \phi^N(\theta) - \int_{-r}^0 d\mu(\theta) \phi(\theta) \\ &= A_1(\phi^{(1)}(-\theta_1) - \phi(-\theta_1)) + A_2(\phi^{(2)}(-r) - \phi(-r)) \\ &\quad + \int_{-\theta_1}^0 A(\theta)(\tilde{\phi}^{(1)} - \phi) d\theta + \int_{-r}^{-\theta_1} A(\theta)(\phi^{(2)} - \phi) d\theta \end{aligned}$$

where from (3.23)

$$\phi^{(1)}(-\theta_1) = \tilde{\phi}^{(1)}(-\theta_1) + (-1)^N (\phi(0) - \tilde{\phi}^{(1)}(0)).$$

It then follows that

$$\begin{aligned} \delta_4 &\leq |A_1| (|\tilde{\phi}^{(1)}(-\theta_1) - \phi(-\theta_1)| + |\tilde{\phi}^{(1)}(0) - \phi(0)|) + |A_2| |\phi^{(2)}(-r) - \phi(-r)| \\ &\quad + \|A(\cdot)\|_{L_2} (\|\tilde{\phi}^{(1)} - \phi\|_{L_2[-\theta_1, 0]} + \|\phi^{(2)} - \phi\|_{L_2[-r, -\theta_1]}). \end{aligned}$$

It now follows from Lemma 3.5 and Lemmas 3.1 and 3.2 in [9] that

$$\begin{aligned} |\delta_4| &\leq K((2|A_1| + |A_2|) N^{-k+1/2} + 2\|A(\cdot)\|_{L_2} N^{-k}) \|z\|_{\mathcal{D}^k} \\ &\leq K_4 N^{-k+1/2} \|z\|_{\mathcal{D}^k}. \end{aligned}$$

From Lemma 3.2 in [9]

$$\delta_2 \leq K_2 N^{-k+3/2} \|z\|_{\mathcal{D}^k}.$$

From (3.23)

$$\delta_1 \leq \|\dot{\tilde{\phi}}^{(1)} - \dot{\phi}\|_{L_2[-\theta_1, 0]} + \sqrt{N(N+1)} |\tilde{\phi}^{(1)}(0) - \phi(0)|$$

where we used the fact that

$$\int_{-1}^1 |\dot{P}_N(\theta)|^2 d\theta = N(N+1).$$

It then follows from Lemma 3.5 and Lemma 3.2 in [9] that

$$\delta_1 \leq K_1 N^{-k+3/2} \|z\|_{\mathcal{D}^k}.$$

Since

$$\begin{aligned} |\phi^{(1)}(-\theta_1) - \phi^{(2)}(-\theta_1)| &\leq |\phi^{(1)}(-\theta_1) - \phi(-\theta_1)| + |\phi^{(2)}(-\theta_1) - \phi(-\theta_1)| \\ &\leq |\tilde{\phi}^{(1)}(-\theta_1) - \phi(-\theta_1)| + |\tilde{\phi}^{(1)}(0) - \phi(0)| + |\phi^{(2)}(-\theta_1) - \phi(-\theta_1)|, \end{aligned}$$

it follows from Lemma 3.5 that

$$\delta_3 \leq K_3 N^{-k+3/2} \|z\|_{\mathcal{D}^k}.$$

Hence from (3.22)

$$\|(\mathcal{A}^N - \mathcal{A})z\|_Z \leq \tilde{K} N^{-k+3/2} \|z\|_{\mathcal{D}^k}, \quad k \geq 2$$

where \tilde{K} is independent of N . Q.E.D.

Now we state the convergence result for the tau approximation.

THEOREM 3.6. *Let $S^N(t)$, $t \geq 0$ be the semigroup on Z generated by \mathcal{A}^N defined by (3.15). Then for all $z \in Z$*

$$\|S^N(t)z - S(t)z\| \rightarrow 0$$

uniformly on bounded t -intervals.

Proof. The theorem follows from Theorem 3.2. X is the Hilbert space Z equipped with the inner product (3.17). The stability (i) follows from Lemma 3.3. Note that the weighted norm $\|\cdot\|_g$ and $\|\cdot\|_Z$ norm are equivalent, i.e.,

$$|z|_Z^2 \leq \|z\|_g^2 \leq 2\|z\|_Z^2 \quad \text{for } z = (\eta, \phi) \in Z.$$

Thus, from Lemma 3.4

$$\|\mathcal{A}^N z - \mathcal{A}z\|_g \rightarrow 0 \quad \text{for } z \in \mathcal{D}^2.$$

Since \mathcal{D}^2 and $(\lambda I - \mathcal{A})\mathcal{D}^2$ for λ sufficiently large are dense in Z , the statement (ii) in Theorem 3.2 holds if we choose $\mathcal{D} = \mathcal{D}^2$. Q.E.D.

Remark. Although we will not pursue the details here, one can prove that the adjoint semigroups $S^N(t)^*$ also converge strongly to $S^*(t)$ uniformly on bounded t -intervals.

4. An approximation scheme for the Riccati equation. In this section, we discuss an approximation scheme for the regulator problem (2.10) based upon the Legendre-tau approximation.

Let us consider the N th approximate problem to (2.10)

$$(4.1) \quad \text{Minimize } J^N(u, \tilde{z}) = \int_0^\infty (|\tilde{z}^N(t)|^2 + |u(t)|^2) dt,$$

subject to (3.15):

$$\frac{d}{dt}\tilde{z}^N(t) = \mathcal{A}^N\tilde{z}^N(t) + \mathcal{B}u(t), \quad z^N(0) = \tilde{z} = Q^N z.$$

It follows from Theorem 2.3 that if $(\mathcal{A}^N, \mathcal{B})$ is stabilizable and $(\mathcal{C}, \mathcal{A}^N)$ is detectable, then there exists a unique solution Π^N to $(\text{ARE})^N$:

$$(\text{ARE})^N \quad (\mathcal{A}^N)^* \Pi^N + \Pi^N \mathcal{A}^N - \Pi^N \mathcal{B} \mathcal{B}^* \Pi^N + \mathcal{C}^* \mathcal{C} = 0,$$

and the optimal solution to (4.1) is given by

$$(4.2) \quad u^N(t) = -\mathcal{B}^* \Pi^N \tilde{z}^N(t)$$

where $\tilde{z}^N(t)$, $t \geq 0$ satisfies

$$\frac{d}{dt}\tilde{z}^N(t) = (\mathcal{A}^N - \mathcal{B} \mathcal{B}^* \Pi^N) \tilde{z}^N(t), \quad z^N(0) = \tilde{z}.$$

Remark. For the single point delay case, we are able to prove that if $(\mathcal{A}, \mathcal{B})$ is stabilizable (respectively, $(\mathcal{C}, \mathcal{A})$ is detectable), then for N sufficiently large $(\mathcal{A}^N, \mathcal{B})$ is stabilizable (respectively, $(\mathcal{C}, \mathcal{A}^N)$ is detectable) [10]. The proof is based upon the characterization of detectability in Remark 2.2.

In terms of the Legendre coordinate system,

$$\begin{aligned} \tilde{z}^N(t) = & \sum_{k=0}^{N-1} a_k^N(t)(0, p_k^{(1)} \chi_{(-\theta_1, 0]}) \\ & + \eta^N(t)(1, 0) + \sum_{k=0}^N b_k^N(t)(0, p_k^{(2)} \chi_{[-r, -\theta_1]}). \end{aligned}$$

It then follows from Lemma 3.1 and (3.7) that

$$\tilde{\xi}^N(t) = (b_0^N, \dots, b_N^N, a_0^N, \dots, a_{N-1}^N, \eta^N)^T, \quad t \geq 0$$

satisfies

$$(4.3) \quad \frac{d}{dt}\tilde{\xi}^N(t) = \tilde{A}^N \tilde{\xi}^N(t) + B^N u(t), \quad \tilde{\xi}^N(0) = \tilde{\xi}$$

where $\tilde{A}^N = \Omega^N A^N (\Omega^N)^{-1}$ and $\tilde{\xi}$ is the vector representation of $Q^N z$ in terms of Legendre coordinates. A^N , B^N and Ω^N are given in § 3. Thus we can write (4.1) as

$$(4.4) \quad \text{Minimize } J^N(u, \tilde{\xi}) = \int_0^\infty (|\tilde{C}^N \tilde{\xi}^N(t)|^2 + |u(t)|^2) dt$$

subject to (4.3), where $\tilde{C}^N = C^N (\Omega^N)^{-1}$ with

$$C^N = \begin{pmatrix} 0 & |C|C| \cdots |C \end{pmatrix} \in \mathbb{R}^{p \times 2n(N+1)}$$

Hence the optimal solution u^N to (4.1) can be also given by

$$u^N(t) = -(B^N)^T \Sigma^N \tilde{\xi}^N(t),$$

where Σ^N satisfies the matrix Riccati equation

$$(4.5) \quad (\tilde{A}^N)^T \Sigma^N + \Sigma^N \tilde{A}^N - \Sigma^N B^N (B^N)^T \Sigma^N + (\tilde{C}^N)^T \tilde{C}^N = 0.$$

If $(\mathcal{A}^N, \mathcal{B})$ is stabilizable and $(\mathcal{C}, \mathcal{A}^N)$ is detectable, then (4.5) has a unique, symmetric, nonnegative definite solution. Σ^N can be computed effectively by Potter's method (e.g. [14], [11]), which involves the eigenvalue-eigenvector decomposition of the matrix

$$(4.6) \quad H^N = \begin{bmatrix} \tilde{A}^N & -B^N(B^N)^T \\ -(\tilde{C}^N)^T \tilde{C}^N & -(\tilde{A}^N)^T \end{bmatrix}.$$

Let us define the matrix $\hat{\Sigma}^N$ by

$$\hat{\Sigma}^N = \Lambda^N \Sigma^N \Lambda^N$$

where Λ^N is a diagonal matrix:

$$\Lambda^N = \text{diag} \left(\frac{\Delta_2}{1}, \dots, \frac{\Delta_2}{2k+1}, \dots, \frac{\Delta_2}{2N+1}, \frac{\Delta_1}{1}, \dots, \frac{\Delta_1}{2k+1}, \dots, \frac{\Delta_1}{2N-1}, 1 \right) \otimes I,$$

and define the $n \times n$ matrices σ_{ij} , $0 \leq i, j \leq 2N+1$ by

$$(4.7) \quad \sigma_{ij} = (e_{i+1} \otimes I)^T \hat{\Sigma}^N (e_{j+1} \otimes I)$$

where e_i is the i th unit vector in \mathbb{R}^{2N+2} , i.e.,

$$e_i = (\underbrace{0, \dots, 0}_{i-1}, 1, 0 \dots 0)^T.$$

LEMMA 4.1. Suppose $(\mathcal{A}^N, \mathcal{B})$ is stabilizable and $(\mathcal{C}, \mathcal{A}^N)$ is detectable. Then for $z = (\eta, \phi) \in Z$, $\Pi^N z = (y, \psi)$ with

$$\begin{aligned} y &= \sigma \eta + \int_{-\theta_1}^0 \sum_{k=0}^{N-1} (\sigma_{\cdot, k+N+1}) p_k^{(1)}(\theta) \phi(\theta) d\theta \\ &\quad + \int_{-r}^{-\theta_1} \sum_{k=0}^M (\sigma_{\cdot, k}) p_k^{(2)}(\theta) \phi(\theta) d\theta, \end{aligned}$$

and

$$\begin{aligned} \psi(\theta) &= \sum_{i=0}^{N-1} \left[(\sigma_{i+N+1, \cdot}) \eta + \int_{-\theta_1}^0 \sum_{k=0}^{N-1} (\sigma_{i+N+1, k+N+1}) p_k^{(1)}(\theta) \phi(\theta) d\theta \right. \\ &\quad \left. + \int_{-r}^{-\theta_1} \sum_{k=0}^N (\sigma_{i+N+1, k}) p_k^{(2)}(\theta) \phi(\theta) d\theta \right] p_i^{(1)}(\theta) \chi_{(-\theta_1, 0]} \\ &\quad + \sum_{i=0}^N \left[(\sigma_{i, \cdot}) \eta + \int_{-\theta_1}^0 \sum_{k=0}^{N-1} (\sigma_{i, k+N+1}) p_k^{(1)}(\theta) \phi(\theta) d\theta \right. \\ &\quad \left. + \int_{-r}^{-\theta_1} \sum_{k=0}^N (\sigma_{i, k}) p_k^{(2)}(\theta) \phi(\theta) d\theta \right] p_i^{(2)}(\theta) \chi_{[-r, -\theta_1]} \end{aligned}$$

where the symbol (\cdot) stands for $2N+1$, $\sigma = \sigma_{2N+1, 2N+1}$.

Proof. It is known [19] that

$$\langle \Pi^N z, z \rangle_Z = \langle \Sigma^N \tilde{\xi}, \tilde{\xi} \rangle_{\mathbb{R}^{2n(N+1)}} = \min J^N(u)$$

for all $z \in Z$, where $\tilde{\xi}$ is the vector representation of $Q^N z$. Since Σ^N and Π^N are symmetric,

$$(4.8) \quad \langle \Pi^N z^1, z^2 \rangle_Z = \langle \Sigma^N \tilde{\xi}^1, \tilde{\xi}^2 \rangle_{\mathbb{R}^{2n(N+1)}}$$

for all $z^i = (\eta^i, \phi^i) \in Z$, $i = 1, 2$, where $\tilde{\xi}^i$ is the vector representation of $Q^N z^i$ for $i = 1, 2$. Note that

$$\Lambda^N \tilde{\xi}^i = (\underline{\beta}^i, \underline{\alpha}^i, \gamma^i)^T, \quad i = 1, 2$$

where for $i = 1, 2$

$$(4.9) \quad \beta_k^i = \int_{-r}^{-\theta_1} \phi^i(\theta) p_k^{(2)}(\theta) d\theta, \quad \alpha_k^i = \int_{-\theta_1}^0 \phi^i(\theta) p_k^{(1)}(\theta) d\theta, \quad \gamma^i = \eta^i.$$

Then

$$\langle \Sigma^N \tilde{\xi}^1, \tilde{\xi}^2 \rangle = (\underline{\beta}^1, \underline{\alpha}^1, \gamma^1)^T \hat{\Sigma}^N (\underline{\beta}^2, \underline{\alpha}^2, \gamma^2).$$

Now, if $\Pi^N(\eta^1, \phi^1) = (y, \psi)$, then

$$\langle \Pi^N(\eta^1, \phi^1), (\eta^2, \phi^2) \rangle_2 = \langle \eta^2, y \rangle + \int_{-\theta_1}^0 \langle \phi^2(\theta), \psi(\theta) \rangle d\theta + \int_{-r}^{-\theta_1} \langle \phi^2(\theta), \psi(\theta) \rangle d\theta.$$

Equating (4.8), we obtain

$$y = \sigma \eta^1 + \sum_{k=0}^{N-1} (\sigma_{\cdot, k+N+1}) \alpha_k^1 + \sum_{k=0}^N (\sigma_{\cdot, k}) \beta_k^1$$

and

$$\begin{aligned} \psi(\theta) = & \sum_{i=0}^{N-1} \left[(\sigma_{i+N+1, \cdot}) \eta^1 + \sum_{i=0}^{N-1} (\sigma_{i+N+1, k+N+1}) \alpha_k^1 + \sum_{k=0}^N (\sigma_{i+N+1, k}) \beta_k^1 \right] p_i^{(1)} \chi_{(-\theta_1, 0]} \\ & + \sum_{i=0}^N \left[(\sigma_{i, \cdot}) \eta^1 + \sum_{k=0}^{N-1} (\sigma_{i, k+N+1}) \alpha_k^1 + \sum_{k=0}^N (\sigma_{i, k}) \beta_k^1 \right] p_i^{(2)} \chi_{[-r, -\theta_1]}, \end{aligned}$$

which completes the proof along with (4.9). Q.E.D.

COROLLARY 4.2. *The optimal solution u^N to (4.1) can be written in the operator form:*

$$u^N(t) = -\mathcal{K}^N z^N(t).$$

$\mathcal{K}^N \in \mathcal{L}(Z, \mathbb{R}^m)$ is given by

$$\mathcal{K}^N z = B^T \left(\Pi_N^{00} \eta + \int_{-r}^0 \Pi_N^{10}(\theta)^T \phi(\theta) d\theta \right) \quad \text{for } z = (\eta, \phi) \in Z$$

where

$$\Pi_N^{00} = \sigma,$$

and

$$\begin{aligned} \Pi_N^{10}(\theta) = & \sum_{i=0}^{N-1} (\sigma_{i+N+1, \cdot}) p_i^{(1)}(\theta) \chi_{(-\theta_1, 0]} \\ & + \sum_{i=0}^N (\sigma_{i, \cdot}) p_i^{(2)}(\theta) \chi_{[-r, -\theta_1]}, \quad -r \leq \theta \leq 0. \end{aligned}$$

Proof. Since $\mathcal{B}^*(\eta, \phi) = B^T \eta$, the corollary follows from Lemma 4.1 and (4.2). Q.E.D.

5. Convergence proof. In this section we discuss the convergence property of Π^N .

THEOREM 5.1. Suppose Π^N satisfies the N th algebraic Riccati equation $(\text{ARE})^N$. If $\{\Pi^N\}$ is uniformly bounded on Z and $(\mathcal{C}, \mathcal{A})$ is detectable, then

- (i) Π^N converges weakly to Π which is the unique solution to ARE;
- (ii) there exists an integer N_0 such that if $N \geq N_0$, then

$$(5.1) \quad \|S^N(t)\| \leq M e^{-\omega t}$$

for some positive constants M and ω , where $\{S^N(t), t \geq 0\}$ is the semigroup on Z generated by $\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi^N$.

Proof of (i). Although (i) follows from Theorems 3.6 and 6.7 in [8], we will give an alternative proof here. Since $\{\Pi^N\}$ is uniformly bounded on Z , by Theorem 6.5 in [8], there exists a subsequence $\{\Pi^{N_j}\}$ which converges weakly to some nonnegative, selfadjoint operator Π . If $(\mathcal{C}, \mathcal{A})$ is detectable, then from Theorem 2.3, ARE has at most one nonnegative, selfadjoint solution. Hence, we only need to show Π satisfies ARE. Without loss of generality we can assume that Π^N converges weakly to Π . Note that for $N \geq 1$, Π^N satisfies $(\text{ARE})^N$. Since $\dim(R^m) < \infty$, $\mathcal{B}^*\Pi^N$ converges strongly to $\mathcal{B}^*\Pi$. It now follows from Lemma 3.4

$$(5.2) \quad 2\langle \mathcal{A}z, \Pi z \rangle - \langle \mathcal{B}^*\Pi z, \mathcal{B}^*\Pi z \rangle + \langle \mathcal{C}z, \mathcal{C}z \rangle = 0 \quad \text{for all } z \in \mathcal{D}^2.$$

Since $\mathcal{D}^2 = \mathcal{D}(\mathcal{A}^2)$ is dense in $\mathcal{D}(\mathcal{A})$, a simple limit argument shows that (5.2) holds for all $z \in \mathcal{D}(\mathcal{A})$, i.e., Π is a solution to ARE.

Proof of (ii). First of all, we note that $\tilde{\mathcal{A}} = \mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi$ generates a uniformly exponentially stable semigroup $\{\tilde{S}(t), t \geq 0\}$ on Z , i.e., there exist positive constants \tilde{M} and $\tilde{\omega}$ such that

$$(5.3) \quad \|\tilde{S}(t)\| \leq \tilde{M} e^{-\tilde{\omega}t}, \quad t \geq 0.$$

For $z \in \mathcal{D}(\mathcal{A})$

$$(\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi^N)z = \tilde{\mathcal{A}}z - \mathcal{B}(\mathcal{B}^*\Pi - \mathcal{B}^*\Pi^N)z.$$

Thus,

$$(5.4) \quad S^N(t)z = \tilde{S}(t)z + \int_0^t \tilde{S}(t-s)\mathcal{B}(\mathcal{B}^*\Pi - \mathcal{B}^*\Pi^N)S^N(s)z \, ds \quad \text{for all } z \in Z.$$

For $t \geq r$, we may write (5.4) as

$$(5.5) \quad S^N(t)z = \tilde{S}(t-r)\tilde{z} + \int_r^t \tilde{S}(t-s)\mathcal{B}(\mathcal{B}^*\Pi - \mathcal{B}^*\Pi^N)S^N(s)z \, ds,$$

with

$$(5.6) \quad \tilde{z} = \tilde{S}(r)z + \int_0^r \tilde{S}(r-s)\mathcal{B}(\mathcal{B}^*\Pi - \mathcal{B}^*\Pi^N)S^N(s)z \, ds.$$

From [5] we have that $\tilde{S}(r)z \in \mathcal{D}(\tilde{\mathcal{A}})$ for all z and $\|\tilde{S}(r)z\|_{\mathcal{D}(\tilde{\mathcal{A}})} \leq \gamma_1 \|z\|_Z$ for some positive constant γ_1 . If

$$z(t) = (x(t), x(t+\cdot)) = \int_0^t \tilde{S}(t-s)\mathcal{B}u(s) \, ds, \quad t \geq 0,$$

then $x(t) \in H^1([-r, T]; \mathbb{R}^n)$ for any $T \geq 0$ and satisfies

$$\begin{aligned} \frac{d}{dt}x(t) &= \int_{-r}^0 d\mu(\theta)x(t+\theta) - BB^T \Pi^{00}x(t) - BB^T \int_{-r}^0 \Pi^{10}(\theta)^T x(t+\theta) d\theta + Bu(t) \\ &\equiv \int_{-r}^0 d\tilde{\mu}(\theta)x(t+\theta) + Bu(t). \end{aligned}$$

Hence for $u \in L_2^{\text{loc}}([0, \infty); \mathbb{R}^n)$, $z(t) \in \mathcal{D}(\tilde{\mathcal{A}})$ and

$$(5.7) \quad \tilde{\mathcal{A}} \int_0^t \tilde{S}(t-s) \mathcal{B}u(s) ds = \left(\int_{-r}^0 d\tilde{\mu}(\theta)x(t+\theta), \psi(t+\cdot) \right)$$

where

$$\psi(t) = \int_{-r}^0 d\tilde{\mu}(\theta)x(t+\theta) + Bu(t), \quad t \geq 0,$$

and

$$\psi(t) = 0 \quad \text{for } t < 0.$$

Here we note that

$$(5.8) \quad \left\| \int_{-r}^0 d\tilde{\mu}(\theta)x(\cdot + \theta) \right\|_{L_2([a, b], \mathbb{R}^n)} \leq \gamma_2 \|x\|_{L_2([a-r, b], \mathbb{R}^n)}$$

for $b \geq a \geq 0$, where $\gamma_2 = \int_{-r}^0 |d\tilde{\mu}|$. Since $\{\Pi^N\}$ is uniformly bounded, it now follows from (5.6) and (5.7) that $\tilde{z} \in \mathcal{D}(\tilde{\mathcal{A}})$ for all $z \in Z$ and

$$(5.9) \quad \|\tilde{z}\|_{\mathcal{D}(\tilde{\mathcal{A}})} \leq \gamma_3 \|z\|_Z,$$

for some positive constant γ_3 . From (5.5) and (5.7), $S^N(t)z \in \mathcal{D}(\tilde{\mathcal{A}})$, $t \geq r$ for $z \in Z$ and

$$(5.10) \quad \tilde{\mathcal{A}}S^N(t)z = \tilde{S}(t-r)\tilde{\mathcal{A}}\tilde{z} + \tilde{\mathcal{A}} \int_r^t \tilde{S}(t-s) \mathcal{B}F^N(\tilde{\mathcal{A}}S^N(s)z) ds$$

where $F^N : Z \rightarrow \mathbb{R}^m$ is given by

$$F^N = (\mathcal{B}^*\Pi - \mathcal{B}^*\Pi^N)\tilde{\mathcal{A}}^{-1}.$$

Since $0 \notin P\sigma(\tilde{\mathcal{A}})$, $(\tilde{\mathcal{A}})^{-1}$ exists and moreover, it is compact [18]. Note that

$$(F^N)^* = (\tilde{\mathcal{A}}^*)^{-1}(\Pi\mathcal{B} - \Pi^N\mathcal{B}) \in \mathcal{L}(\mathbb{R}^m, Z).$$

Since $\Pi^N\mathcal{B}$ converges weakly to $\Pi(\mathcal{B})$ as $N \rightarrow \infty$ and $(\tilde{\mathcal{A}})^{-1}$ is compact, $(F^N)^*$ converges strongly to zero. Hence, the finite dimensionality of \mathbb{R}^m implies

$$\|(F^N)^*\| = \|F^N\| \rightarrow 0 \quad \text{as } N \rightarrow \infty,$$

i.e., for any $\varepsilon > 0$ there exists an integer $N_0(\varepsilon)$ such that $\|F^N\| \leq \varepsilon$ for $N \geq N_0$.

For $z \in Z$, let us define the Z -valued function $\beta^N(t)$, $t \geq r$ by

$$\beta^N(t) = \tilde{\mathcal{A}}S^N(t)z.$$

Then from (5.7) and (5.10)

$$\beta^N(t) = \tilde{S}(t-r)\tilde{\mathcal{A}}\tilde{z} + \left(\int_{-r}^0 d\tilde{\mu}(\theta)x(t+\theta), \psi(t+\cdot) \right)$$

where for $t \geq 0$

$$\psi(t) = \int_{-r}^0 d\tilde{\mu}(\theta)x(t+\theta) + BF^N\beta^N(t)$$

and

$$(5.11) \quad (x(t), x(t+\cdot)) = \int_r^t \tilde{S}(t-s)\mathcal{B}F^N\beta^N(s) ds, \quad t \geq r$$

with $x(t) = 0$, $t \leq r$. Now from (5.8), for $T > r$

$$\begin{aligned} \left(\int_r^T \|\beta^N(t)\|^2 dt \right)^{1/2} &\leq \|\tilde{\mathcal{A}}\tilde{z}\| \left(\int_r^T \|\tilde{S}(t-r)\|^2 dt \right)^{1/2} + \gamma_2 \left(\int_0^T |x(t)|^2 dt \right)^{1/2} \\ &\quad + \gamma_2 \left(\int_r^T \int_{t-2r}^t |x(s)|^2 ds dt \right)^{1/2} \\ &\quad + |B| \|F^N\| \left(\int_r^T \int_{t-r}^t \|\beta^N(s)\|^2 ds dt \right)^{1/2}, \end{aligned}$$

and from (5.3) and (5.11),

$$\begin{aligned} &\leq (\tilde{M}/(2\tilde{\omega})^{1/2}) \|\tilde{\mathcal{A}}\tilde{z}\| \\ &\quad + |B| \|F^N\| \left(\frac{\tilde{M}}{\tilde{\omega}} \gamma_2(1+(2r)^{1/2}) + (r)^{1/2} \right) \left(\int_r^T \|\beta^N(s)\|^2 ds \right)^{1/2} \end{aligned}$$

where we used Fubini's theorem and Young's inequality. Thus, from (5.9)

$$\int_r^T \|\beta^N(t)\|_N^2 dt \leq \left(\frac{\tilde{M}^2}{\tilde{\omega}} \right) \gamma_3^2 \|z\|_Z^2 + 2 \|F^N\|^2 \gamma^2 \int_r^T \|\beta^N(s)\|^2 ds,$$

where

$$\gamma = |B| \left(\frac{\tilde{M}}{\tilde{\omega}} \gamma_2(1+(2r)^{1/2}) + (r)^{1/2} \right).$$

If we choose ε such that $2\varepsilon^2\gamma^2 \leq \frac{1}{2}$, then it follows that for $T \geq r$

$$\int_r^T \|\beta^N(t)\|_N^2 dt \leq 2 \left(\frac{\tilde{M}^2}{\tilde{\omega}} \right) \gamma_3^2 \|z\|_Z^2.$$

Note that $S^N(t)z = \tilde{\mathcal{A}}^{-1}\beta^N(t)$, $t \geq r$ and $\tilde{\mathcal{A}}^{-1} \in \mathcal{L}(Z)$. Hence, for $T \geq r$

$$\int_r^T \|S^N(t)z\|^2 dt \leq 2 \left(\frac{\tilde{M}^2}{\tilde{\omega}} \right) \gamma_3^2 \|\tilde{\mathcal{A}}^{-1}\|^2 \|z\|_Z^2.$$

It now follows from Lemma 7.4 in [8] that there exist positive constants M and ω such that

$$\|S^N(t)\| \leq M e^{-\omega t}, \quad t \geq 0 \quad \text{for } N \geq N_0(\varepsilon). \quad \text{Q.E.D.}$$

The next lemma concerns the uniform boundedness of $\{\Pi^N\}$ in Theorem 5.1(i).

LEMMA 5.2. *Consider the system with the form*

$$(5.12) \quad \frac{d}{dt}x(t) = \sum_{i=0}^l A_i x(t-\theta_i) + Bu(t).$$

If the pair (A_0, B) is controllable and the range of B contains the range of A_i , $1 \leq i \leq l$, then $\{\Pi^N\}$ is a uniformly bounded sequence on Z .

Proof. For simplicity of exposition we consider the case, $l = 2$. The approximate solution $z^N(t) = (z^N(t, 0), z^N(t, \cdot)) \in Z$ of initial value problem (5.17) satisfies

$$(5.13) \quad \begin{aligned} \frac{d}{dt} z^N(t, 0) &= A_0 z^N(t, 0) + A_1 z^N(t, (-\theta_1)^+) + A_2 z^N(t, -r) + Bu(t), \\ \frac{\partial}{\partial t} z^N(t, \theta) &= \frac{\partial}{\partial \theta} z^N(t, \theta), \quad -r \leq \theta \leq 0 \end{aligned}$$

where the second equation holds in the sense of (3.3). Since (A_0, B) is controllable, then there exists an $m \times n$ matrix K such that the matrix $(A_0 - BK)$ has distinct negative real eigenvalues λ_i , $1 \leq i \leq n$ with $\max_{1 \leq i \leq n} \lambda_i \leq -3/2$. Since the eigenvalues of $(A_0 - BK)$ are distinct, there exists a nonsingular matrix P such that

$$P^{-1}(A_0 - BK)P = \Lambda = \text{diag}(\lambda_1, \dots, \lambda_n).$$

Let us consider the feedback control law to (4.1):

$$(5.14) \quad \tilde{u}(t) = -Kz^N(t, 0) - (B^T B)^{-1} B^T (A_1 z^N(t, (-\theta_1)^+) + A_2 z^N(t, -r)).$$

Then (5.13) has the closed loop equation

$$(5.15) \quad \begin{aligned} \frac{d}{dt} z^N(t, 0) &= (A_0 - BK)z^N(t, 0), \quad \frac{\partial}{\partial t} z^N(t, \theta) = \frac{\partial}{\partial \theta} z^N(t, \theta). \end{aligned}$$

If $\hat{z}^N(t) = (P^{-1}z^N(t, 0), P^{-1}z^N(t, \cdot))$, $t \geq 0$, then $\hat{z}^N(\cdot)$ satisfies

$$\frac{d}{dt} \hat{z}^N(t, 0) = \Lambda \hat{z}^N(t, 0), \quad \frac{\partial}{\partial t} \hat{z}^N = \frac{\partial}{\partial \theta} \hat{z}^N.$$

By using the same arguments given in the proof of Lemma 3.3, we obtain

$$\begin{aligned} \frac{1}{2} \frac{d}{dt} \|Q^N \hat{z}^N(t)\|_g^2 &\leq \langle \Lambda \hat{z}^N(t, 0), \hat{z}^N(t, 0) \rangle + |\hat{z}^N(t, 0)|^2 \\ &\quad - \frac{1}{2} |\hat{z}^N(t, (-\theta_1)^+)|^2 - \frac{1}{2} |\hat{z}^N(t, -r)|^2 \\ &\leq -\frac{1}{2} (|\hat{z}^N(t, 0)|^2 + |\hat{z}^N(t, (-\theta_1)^+)|^2 + |\hat{z}^N(t, -r)|^2) \end{aligned}$$

where we used the fact that $\Lambda \leq -3I/2$. Integration of this with respect to t yields

$$\|Q^N \hat{z}^N(t)\|_g^2 - \|Q^N \hat{z}^N(0)\|_g^2 \leq - \int_0^t (|\hat{z}^N(s, 0)|^2 + |\hat{z}^N(s, (-\theta_1)^+)|^2 + |\hat{z}^N(s, -r)|^2) ds$$

for all $t \geq 0$. Thus, for all $t \geq 0$,

$$\int_0^t |\hat{z}^N(s, 0)|^2 ds, \quad \int_0^t |\hat{z}^N(s, (-\theta_1)^+)|^2 ds,$$

and

$$\int_0^t |\hat{z}^N(s, -r)|^2 ds \leq \|Q^N \hat{z}^N(0)\|_g^2 \leq \|\hat{z}\|_g^2 \leq \sigma_{\max}(P^{-T}P^{-1}) \|z\|_g^2.$$

Since $\|z\|_g^2 \leq 2\|z\|_2^2$, it now follows from (5.14) and (5.15) that

$$\langle \Pi^N z, z \rangle \leq J^N(\tilde{u}, z) = \int_0^\infty (|Cz^N(t, 0)|^2 + |\tilde{u}(t)|^2) dt \leq \beta \|z\|_2^2$$

for some positive constant β . Since Π^N is nonnegative and selfadjoint, for $N \geq 1$, $\Pi^N \leq \beta I$. Q.E.D.

6. Numerical examples and conclusions. In this section, we discuss some numerical examples which demonstrates the feasibility of the Legendre-tau method for approximating the optimal feedback solution. We only consider examples of optimal control on the infinite interval. We solved the Riccati equation (4.5) for the matrix Σ^N using Potter's method. All computations were performed using MATLAB developed by Cleve Moler [12] which provides easy access to matrix software developed by LINPACK and EISPACK projects.

The N th feedback control is given by

$$(6.1) \quad u^N(t) = -B^T \left(\Pi_N^{00} x(t) + \int_{-r}^0 \Pi_N^{10}(\theta)^T x(t+\theta) d\theta \right)$$

where Π_N^{00} and Π_N^{10} are given in terms of the coefficients of Σ^N in Corollary 4.2. The strong convergence of Π^N to Π implies $\Pi_N^{00} \rightarrow \Pi^{00}$ and $\Pi_N^{10} \rightarrow \Pi^{10}$ in $L_2([-r, 0]; \mathbb{R}^{n \times n})$. We also discuss below how closely Π_N^{00} and Π_N^{10} approximate the conditions described in Theorem 2.5 and how closely the eigenvalues of the N th Hamiltonian matrix H^N in (4.6) approximate the closed-loop eigenvalues of $\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi$.

Example 6.1 (Gibson [8, Example 8.1]). Consider the scalar differential equation

$$(6.2) \quad \frac{d}{dt} x(t) = x(t) + x(t-1) + u(t);$$

the performance index of (2.6) is

$$(6.3) \quad J(u, (\eta, \phi)) = \int_0^\infty (x^2(t) + u^2(t)) dt.$$

For each N , Π_N^{00} is a scalar and $\Pi_N^{10}(\cdot)^T \in L_2([-1, 0]; \mathbb{R})$ and $B \equiv 1$ in (6.1). Table 1 shows the numerical results for Π_N^{00} and the expansion coefficients of Π_N^{10} , i.e.,

$$\Pi_N^{10}(\theta) = \sum_{k=0}^{N-1} a_k^N P_k(2\theta+1), \quad -1 \leq \theta \leq 0,$$

and how closely we have approximated the boundary condition (2.14).

TABLE 1

N	2	4	6	8
Π_N^{00}	2.8139	2.8094	2.8094	2.8094
$k=0$	1.44222	1.4267	1.4267	1.4267
1	-1.0844	-1.0438	-1.0438	-1.0438
2		0.2919	0.2919	0.2919
3		-0.0424	-0.0420	-0.0420
$\{a_k^N\}$ 4			0.0046	0.0046
5			-0.0004	-0.0004
6				2.3×10^{-5}
7				1.2×10^{-6}
$ \Pi_N^{00} - \Pi_N^{10}(-1) $	0.3074	0.0046	2.3×10^{-5}	5.3×10^{-8}

For comparison, the following are obtained using the average (AVE) scheme [8] and the linear spline (SPL) scheme [4].

$$\Pi_{74}^{00}(\text{AVE}) = 2.8130, \quad \Pi_{32}^{00}(\text{SPL}) = 2.8091.$$

Note that both schemes have not fully converged yet. However, for the Legendre-tau method, the result for $N = 4$ appears to give a fairly good approximation of the optimal feedback, e.g.,

$$|\Pi_4^{00} - \Pi_8^{00}| = 4.4 \times 10^{-7}, \quad \|\Pi_4^{10} - \Pi_8^{10}\|_{L_2[-1,0]} = 1.5 \times 10^{-3}.$$

Table 2 compares $\Pi_{74}^{10}(\theta)(\text{AVE})$ and $\Pi_4^{10}(\theta)(\text{L-T})$, where L-T denotes the Legendre-tau approximation.

TABLE 2

$\ \Pi_{74}^{10}(\theta)(\text{AVE}) - \Pi_4^{10}(\theta)(\text{L-T})\ _{L_2} = 1.9 \times 10^{-2}$		
θ	$\Pi_{74}^{10}(\theta)(\text{AVE})$	$\Pi_4^{10}(\theta)(\text{L-T})$
0.0	0.6435	0.6323
-0.1	0.7273	0.7225
-0.2	0.8258	0.8273
-0.3	0.9607	0.9519
-0.4	1.1023	1.1013
-0.5	1.2694	1.2807
-0.6	1.4965	1.4951
-0.7	1.7315	1.7497
-0.8	2.0480	2.0494
-0.9	2.3748	2.3994
-1.0	2.7541	2.8048

The oscillatory behavior exhibited by the spline approximation to Π^{10} [4] has not been observed for the Legendre-tau approximation.

Table 3 shows the eigenvalues λ_i^N of H^N which give the relatively small equation error $|\det \hat{\Delta}(\lambda_i^N)|$ where $\hat{\Delta}(\lambda)$ is given by (2.15), i.e., in this example

$$\hat{\Delta}(\lambda) = (\lambda - 1 - e^{-\lambda})(\lambda + 1 + e^{\lambda}) - 1.$$

In Table 3, the numbers inside () stand for the corresponding equation errors $|\det \hat{\Delta}(\lambda)|$ to the eigenvalues λ_i^N .

Example 6.2 (Gibson [8, Example 8.3]). We consider the problem of minimizing

$$(6.4) \quad J(u) = \int_0^\infty (y^2(t) + \dot{y}^2(t) + u^2(t)) dt,$$

subject to the harmonic oscillator with delayed restoring force and delayed damping given by

$$(6.5) \quad \frac{d^2}{dt^2} y(t) + \frac{d}{dt} y(t-1) + y(t-1) = u(t).$$

If we define $x(t) \in \mathbb{R}^2$ by

$$x(t) = \left(y(t), \frac{d}{dt} y(t) \right)^T,$$

	<i>i</i> = 1	−1.4011 (1.2 × 10 ^{−14})	
	<i>i</i> = 2	−1.6344 ± 4.1827 <i>i</i> (6.7 × 10 ^{−14})	
	<i>i</i> = 3	−2.4256 ± 10.6890 <i>i</i> (2.1 × 10 ^{−10})	
	<i>i</i> = 4	−3.1695 ± 23.3811 <i>i</i> (4.5 × 10 ^{−4})	

then (6.4) and (6.5) are equivalent to

$$J(u; (\eta, \phi)) = \int_0^\infty (|x(t)|^2 + u^2(t)) \, dt$$

and

$$\frac{d}{dt}x(t) = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 0 & 0 \\ -1 & -1 \end{bmatrix} x(t-1) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t),$$

respectively.

The optimal control in feedback form is

(6.6)

$$u(t) = -\Pi_{,21}^{00}x_1(t) - \Pi_{,22}^{00}x_2(t) - \int_{-1}^0 (\Pi_{,12}^{10}(\theta)x_1(t+\theta) + \Pi_{,22}^{10}(\theta)x_2(t+\theta)) \, d\theta$$

where $\Pi_{,i,j}^{00}$ and $\Pi_{,i,j}^{10}(\theta)$ are the (i, j) -elements of the matrix Π^{00} and $\Pi^{10}(\theta)$, respectively. The N th feedback control law is

(6.7)

$$u^N(t) = -\Pi_{N,21}^{00}x_1(t) - \Pi_{N,22}^{00}x_2(t) - \int_{-1}^0 (\Pi_{N,12}^{10}(\theta)x_1(t+\theta) + \Pi_{N,22}^{10}(\theta)x_2(t+\theta)) \, d\theta.$$

Note that if we define $\xi(t) \in \mathbb{R}^2$ by

$$\xi(t) = \left(y(t), \frac{d}{dt}y(t) + y(t) \right)^T,$$

then (6.4) and (6.5) are equivalent to

$$(6.8) \quad J(u; (\tilde{\eta}, \tilde{\phi})) = \int_0^\infty (\xi(t)^T Q \xi(t) + u^2(t)) dt,$$

with

$$Q = \begin{bmatrix} 2 & -1 \\ -1 & 1 \end{bmatrix},$$

and

$$(6.9) \quad \frac{d}{dt}\xi(t) = \begin{bmatrix} -1 & 1 \\ -1 & 1 \end{bmatrix} \xi(t) + \begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix} \xi(t-1) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t),$$

respectively. Here, the initial conditions

$$(6.10) \quad \tilde{\eta} = (0, 0)^T \quad \text{and} \quad \xi_2(\theta) = 0, \quad -1 \leq \theta \leq 0$$

yield $\xi(t) \equiv 0$, $t \geq 0$, regardless of the initial functions $\xi_1(\theta)$, $-1 \leq \theta \leq 0$. Hence, for the initial conditions in (6.10) and any initial history $\xi_1(\cdot)$, the optimal control is $u(t) = 0$, $t \geq 0$. Therefore, the optimal control $u(t)$ must have the form

$$(6.11) \quad u(t) = -\tilde{\Pi}_{,21}^{00}\xi_1(t) - \tilde{\Pi}_{,22}^{00}\xi_2(t) - \int_{-1}^0 \tilde{\Pi}_{,22}^{10}(\theta)\xi_1(t+\theta) d\theta$$

where $\tilde{\Pi}$ corresponds to the minimization problem to (6.8) and (6.9).

Note that $\xi_2(t) = x_1(t) + x_2(t)$, $t \geq 1$. Hence, it follows from (6.6) and (6.11) that

$$\Pi_{,12}^{10} = \Pi_{,22}^{10}.$$

Similarly,

$$\Pi_{N,12}^{10} = \Pi_{N,22}^{10}, \quad N \geq 1.$$

Numerically, we have the results in Table 4.

TABLE 4

	$\Pi_2^{00} = \begin{bmatrix} 2.1407 & 1.2988 \\ 1.2988 & 1.8611 \end{bmatrix}$	$\Pi_4^{00} = \begin{bmatrix} 2.1387 & 1.2963 \\ 1.2963 & 1.8579 \end{bmatrix}$		
	$\Pi_6^{00} = \begin{bmatrix} 2.1387 & 1.2963 \\ 1.2963 & 1.8579 \end{bmatrix}$	$\Pi_8^{00} = \begin{bmatrix} 2.1387 & 1.2963 \\ 1.2963 & 1.8579 \end{bmatrix}$		
N	2	4	6	8
$k=0$	-0.8846	-0.8821	-0.8821	-0.8821
1	0.8971	0.8969	0.8969	0.8969
2	-0.0835	-0.0835	-0.0835	-0.0835
3	-0.0031	-0.0030	-0.0030	-0.0030
$\{a_k^N\}$	4	0.0014	0.0014	0.0014
5		-0.0001	-0.0001	-0.0001
6				2.4×10^{-6}
7				2.4×10^{-7}
$ \Pi_N^{10}(-1) - A_1^T \Pi_N^{00} $	0.2182	0.0024	1.3×10^{-5}	3.5×10^{-8}

In Table 4, $\{a_k^N\}_{k=0}^{N-1}$ are the expansion coefficients of $\Pi_{N,12}^{10}(\theta)$, i.e.,

$$\Pi_{N,12}^{10}(\theta) = \sum_{k=0}^{N-1} a_k^N P_k(2\theta + 1), \quad -1 \leq \theta \leq 0.$$

Moreover, we have

$$|\Pi_4^{00} - \Pi_8^{00}| = 6.3 \times 10^{-7}, \quad \|\Pi_{4,12}^{10} - \Pi_{8,12}^{10}\|_{L_2} = 4.8 \times 10^{-4}.$$

Again, one can see that the result for $N = 4$ gives a fairly good approximation. For comparison, the following are obtained by AVE and SPLINE schemes:

(AVE)
$$\Pi_{22}^{00}(\text{AVE}) = \begin{bmatrix} 2.1034 & 1.2574 \\ 1.2574 & 1.8123 \end{bmatrix},$$

(SPL)
$$\Pi_{16}^{00}(\text{SPL}) = \begin{bmatrix} 2.1389 & 1.2963 \\ 1.2963 & 1.8576 \end{bmatrix}.$$

Table 5 compares $\Pi_{22,1,2}^{10}(\theta)(\text{AVE})$ [8, p. 137] and $\Pi_{4,1,2}^{10}(\theta)(\text{L-T})$.

In this example, the closed-loop eigenvalues of $\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi$ are roots of the characteristic equation $\det \hat{\Delta}(\lambda) = 0$, where

$$\begin{aligned} \hat{\Delta}(\lambda) &= \begin{bmatrix} \lambda I - A_0 - e^{-\lambda} A_1 & -B B^T \\ -I & \lambda I + A_0 + e^{\lambda} A_1 \end{bmatrix}, \\ A_0 &= \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad A_1 = \begin{bmatrix} 0 & 0 \\ -1 & -1 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}. \end{aligned}$$

Table 6 lists the eigenvalues λ_i^N of H^N which lies in the left half plane of C and give the relatively small equation error $|\det \hat{\Delta}(\lambda_i^N)|$.

Example 6.3. Here we deal with the equation which has multiple point delays

(6.12)
$$\frac{d}{dt} x(t) = x(t) + 2x(t-1) + x(t-2) + u(t),$$

with the cost functional

$$J(u, (\eta, \phi)) = \int_0^\infty (x^2(t) + u^2(t)) \, dt.$$

Table 7 shows the numerical results for Π_N^{00} and $\Pi_N^{10}(\theta)$ and how closely we have approximated the jump condition (2.13) and the boundary condition (2.14).

We have the function values of $\Pi_N^{10}(\theta)$ in Table 8. In this example, the closed loop characteristic equation is given by

$$\hat{\Delta}(\lambda) = (\lambda - 1 - 2e^{-\lambda} - e^{-2\lambda})(\lambda + 1 + 2e^{\lambda} + e^{2\lambda}) - 1 = 0.$$

Table 9 shows the eigenvalues of H^N in the same manner as before.

The numerical results presented here reveal that numerically one has strong convergence of Π^N for the Legendre-tau approximation. We have not proved the strong convergence of Π^N in the general case (except for single point delay case [10]). It requires a careful study of the asymptotic behavior of the spectra of \mathcal{A}^N . However, the efficiency of the numerical schemes is most important from the practical point of view. We observe, from the numerical results of this section, that the Legendre-tau method provides faster convergence and better approximation at low orders (i.e. small N) than the AVE and SPLINE schemes. In the above examples, the results corresponding to $N = 4$ give a fairly good approximation of the optimal feedback gain.

As further evidence of the usefulness of the Legendre-tau approximation, one can use it as an approximation technique for computing closed-loop eigenvalues of the feedback system. Note that eigenvalues close to the origin are approximated quite well at low orders on the above examples.

From these observations, we believe the Legendre-tau approximation scheme offers one of the favorable methods for construction of feedback gains. In future investigations, our efforts for constructing feedback gains for delay systems will be combined with the approach to finite-order compensator design for distributed parameter systems [17], developed by J. M. Schumacher to develop a design procedure for the construction of compensators for delay systems.

STABILITY IN TWO-STAGE STOCHASTIC PROGRAMMING*

STEPHEN M. ROBINSON† AND ROGER J.-B. WETS‡

Abstract. We analyze the effect of changes in problem functions and/or distributions in certain two-stage stochastic programming problems with recourse. Under reasonable assumptions the locally optimal value of the perturbed problem will be continuous and the corresponding set of local optimizers will be upper semicontinuous with respect to the parameters (including the probability distribution in the second stage).

Key words. stochastic programming, recourse, stability, sensitivity analysis, weak convergence

AMS(MOS) subject classifications. 90C42, 90C31

1. Introduction. This paper analyzes the effect of perturbations in problem data on the optimal value and optimal policy set of certain two-stage stochastic programming problems. We show that under reasonable assumptions, such as are likely to be satisfied in practice, the optimal value will be continuous in the perturbations and the optimal policy set will be an upper semicontinuous multifunction. The problem data being perturbed may include the probability distribution of the right-hand side in the second-stage problem, and therefore a particular contribution of this paper is the identification of appropriate classes of probability distributions for which such stability results can be proved, as well as a suitable topology for those distributions.

Several previous works, including [3]–[5] and [12], have dealt with various aspects of stability in stochastic optimization, often by applying general theorems about stability in nonlinear optimization involving, e.g., differentiability conditions. We do not require any differentiability for the results of this paper, but rather employ the continuity results of [10]. Those results are also the basis for the recent work of Kall [8] of which the authors became aware after having completed the research for this paper. Although the approach of [8] differs somewhat in emphasis from that adopted here, the results for two-stage stochastic programming are closely related to ours.

In the remainder of this section we state precisely the problem that we shall consider, and the ways in which it can be perturbed. Then, in § 2, we identify an appropriate combination of topologies for a space of functions and a space of probability measures, so that the expectation operator will be a continuous function on the product of the two spaces. We then show how to apply this knowledge, together with results from [10], to analyze the stability of the stochastic programming problem under consideration. In § 3 we show how to apply these results to the commonly-used model of two-stage stochastic linear programming with complete fixed recourse, and we present two examples to show how the continuity results we obtain can yield information important in practical applications.

We shall be concerned here with minimizing (in x) the function defined by

$$(1.1) \quad c(p, x) + \int Q(p, x, \xi) P(d\xi),$$

where p is a perturbation parameter, c is an extended real valued function, Q is a function of p, x and a random variable ξ , and P is a probability measure. Detailed technical assumptions about these objects will be stated in § 2.

Problem (1.1) is called a *two-stage* problem because the function Q is generally not explicitly prescribed, but instead is defined by means of an “inner” optimization problem. Often this is a linear programming problem of the form

$$(1.2) \quad Q(p, x, \xi) := \inf \{ \langle h^*, y \rangle \mid Wy = t(p, x, \xi), y \geq 0 \}.$$

This class of problems has a long history; see e.g. [2], [7], [13] and further references therein.

It is clear from the form of (1.1) that in order to deal with our problem we have to gain information about how an expectation behaves when both the function involved, and the probability measure with respect to which the expectation is taken, can vary. We then have to apply this information to analyze continuity of the optimal value and optimal solutions of (1.1) as functions of the pair (p, P) . This analysis is done in the next section.

2. Continuity analysis. Let \mathcal{P} be a family of probability measures on $(\mathbb{R}^m, \mathcal{B})$, where \mathcal{B} is the σ -algebra of Borel sets, and let \mathcal{F} be a family of continuous real-valued functions on \mathbb{R}^m . In this section we first exhibit appropriate conditions on, and topologies for, \mathcal{F} and \mathcal{P} so that the quantity

$$\langle f, P \rangle := \int f(\xi) P(d\xi)$$

will be a well-defined, continuous function on $\mathcal{F} \times \mathcal{P}$. We then use these conditions to analyze the stability of the optimization problem (1.1).

For our purposes convenient topologies will be those of uniform convergence on compact sets for \mathcal{F} and weak convergence for \mathcal{P} . The latter is defined as follows: if $Z(\mathbb{R}^m)$ represents the class of all probability measures on $(\mathbb{R}^m, \mathcal{B})$, if $\{P_n\} \subset Z(\mathbb{R}^m)$ and $P \in Z(\mathbb{R}^m)$, then we say P_n *converges weakly to* P (written $P_n \Rightarrow P$) if $\langle f, P_n \rangle$ converges to $\langle f, P \rangle$ for every f belonging to the class $C(\mathbb{R}^m)$ of bounded, continuous real-valued functions on \mathbb{R}^m . This notion of weak convergence amounts to convergence in the topological space $(Z(\mathbb{R}^m), \tau)$, where the topology τ has for its base at an element $P \in Z(\mathbb{R}^m)$ the sets of the form

$$\{s \in Z(\mathbb{R}^m) \mid |\langle f_i, s \rangle - \langle f_i, P \rangle| < \varepsilon, i = 1, \dots, k\},$$

where $\varepsilon > 0$, k is a positive integer, and the f_i all belong to $C(\mathbb{R}^m)$. For more information about weak convergence, see [1].

To see why we need some restrictions on \mathcal{F} and \mathcal{P} to make $\langle \cdot, \cdot \rangle$ continuous, consider the example in which P_0 is the probability measure on \mathbb{R} having mass 1 at $x = 0$, and P is that having mass $6/(\pi k)^2$ at $x = k$ for $k = 1, 2, \dots$, (P is a probability measure because $\sum_{k=1}^{\infty} k^{-2} = \pi^2/6$). For $n = 1, 2, \dots$, let $P_n := (1 - n^{-1})P_0 + n^{-1}P$. Now for any bounded function f on \mathbb{R} , one has

$$|\langle f, P_n \rangle - \langle f, P_0 \rangle| \leq 2\beta n^{-1}$$

where β is the bound on f . Therefore $P_n \Rightarrow P_0$. However, with $g(x) := x$ we have $\langle g, P_n \rangle = +\infty$ for each n , but $\langle g, P_0 \rangle = 0$. Thus even $\langle g, \cdot \rangle$ for a fixed g is not continuous.

The difficulty in this example arose from the fact that, intuitively speaking, P_n had too much mass in regions where g was large. To avoid this problem we shall use a slight extension of the idea of uniform integrability [1]. If \mathcal{P} is a family of probability measures on $(\mathbb{R}^m, \mathcal{B})$ we shall say that the family \mathcal{F} is *uniformly integrable* with respect

to the family \mathcal{P} if for each $\varepsilon > 0$ there is a compact set K in \mathbb{R}^m such that for each $f \in \mathcal{F}$ and each $P \in \mathcal{P}$,

$$\int_{cK} |f(\xi)| P(d\xi) < \varepsilon$$

where cK denotes the complement of K . With this definition we can then prove the following theorem.

THEOREM 2.1. *Let \mathcal{F} and \mathcal{P} be endowed with the topologies of uniform convergence on compact sets and weak convergence, respectively. If \mathcal{F} is uniformly integrable with respect to \mathcal{P} , then $\langle \cdot, \cdot \rangle$ is continuous on $\mathcal{F} \times \mathcal{P}$.*

Proof. Let $f_0 \in \mathcal{F}$ and $P_0 \in \mathcal{P}$, and choose $\varepsilon > 0$. We shall exhibit neighborhoods U of f_0 in \mathcal{F} and V of P_0 in \mathcal{P} , such that if $(f, P) \in U \times V$ then $|\langle f, P \rangle - \langle f_0, P_0 \rangle| < 4\varepsilon$.

First, use the hypothesis to find a compact set K such that for each $f \in \mathcal{F}$ and each $P \in \mathcal{P}$, $\int_{cK} |f(\xi)| P(d\xi) < \varepsilon$. Let $d(\xi, K) := \inf \{\|\xi - k\| \mid k \in K\}$, the point-to-set distance function, and let $K_1 := \{\xi \in \mathbb{R}^m \mid d(\xi, K) \leq 1\}$. Define $\theta(\xi) := \max \{0, 1 - d(\xi, K)\}$; note that θ is a continuous function taking the values 1 on K and 0 on cK_1 . Now define

$$U := \{f \in \mathcal{F} \mid \sup \{|\langle f(\xi) - f_0(\xi) | \xi \in K_1 \rangle| \} < \varepsilon\};$$

this is a neighborhood of f_0 in the topology of \mathcal{F} . Let

$$V := \{P \in \mathcal{Z}(\mathbb{R}^m) \mid |\langle f_0 \theta, P \rangle - \langle f_0 \theta, P_0 \rangle| < \varepsilon\};$$

note that this is a neighborhood of P_0 since $(f_0 \theta)(\xi) := f_0(\xi) \theta(\xi)$ is a continuous bounded function. Choose $(f, P) \in U \times V$ and write

$$(2.1) \quad \begin{aligned} |\langle f, P \rangle - \langle f_0, P_0 \rangle| &\leq |\langle f \theta - f_0 \theta, P \rangle| + |\langle f_0 \theta, P \rangle - \langle f_0 \theta, P_0 \rangle| \\ &\quad + |\langle f(1 - \theta), P \rangle| + |\langle f_0(1 - \theta), P_0 \rangle|. \end{aligned}$$

The first term on the right in (2.1) is less than ε since $|f(\xi) \theta(\xi) - f_0(\xi) \theta(\xi)| \leq |f(\xi) - f_0(\xi)|$ and since $f \in U$; recall that θ is zero off K_1 , and P is a probability measure. The second term is less than ε by definition of V , and the last two terms are each less than ε because $(1 - \theta)$ is zero on K so that those terms represent integrals over cK . This completes the proof.

With the continuity result of Theorem 2.1, we are able to analyze the stability properties of the optimization problem (1.1). For a family \mathcal{P} of probability measures on $(\mathbb{R}^m, \mathcal{B})$ and a topological space Π , let Q be a real-valued function on $\Pi \times \mathbb{R}^n \times \mathbb{R}^m$. For $p \in \Pi$, $x \in \mathbb{R}^n$ and $P \in \mathcal{P}$, let

$$(2.2) \quad I(p, P, x) := \int Q(p, x, \xi) P(d\xi),$$

provided that the integral exists and is not $-\infty$. Then the optimization problem described in § 1 can be expressed as

$$(2.3) \quad \inf_x h(p, P, x)$$

where

$$(2.4) \quad h(p, P, x) := c(p, x) + I(p, P, x)$$

and where c is a given extended-real-valued function from $\Pi \times \mathbb{R}^n$ to $(-\infty, +\infty]$.

We shall establish continuity properties of (2.3) by using results from [10]. Since in general the function $h(p, P, \cdot)$ may not be convex, we deal with local minimizers; in the convex case there will of course also be global minimizers. To specify precisely the objects we shall study, we recall from [10] the concept of *complete local minimizing set* (CLM set): for given values $p_0 \in \Pi$ and $P_0 \in \mathcal{P}$, a set $M \subset \mathbb{R}^n$ is called a CLM set for $h(p_0, P_0, \cdot)$ with respect to an open set $G \subset \mathbb{R}^n$, if (i) $M \subset G$, and (ii) the set of

minimizers of $h(p, P_0, \cdot)$ on $\text{cl } G$ is M . Roughly speaking, to say M is a CLM set is to say that it contains all of the nearby minimizers of the function being studied.

We shall suppose that an open bounded set G has been found such that if for $(p, P) \in \Pi \times \mathcal{P}$ we define

$$(2.5) \quad \theta(p, P) := \inf \{h(p, P, x) \mid x \in \text{cl } G\}$$

and

$$(2.6) \quad \Theta(p, P) := \{x \in \text{cl } G \mid h(p, P, x) = \theta(p, P)\},$$

then $\Theta(p_0, P_0)$ is a CLM set for $h(p_0, P_0, \cdot)$ with respect to G . We shall then study the behavior of θ and Θ as the pair (p, P) varies near (p_0, P_0) .

To use the results of [10] we need to introduce the additional idea of epi-upper semicontinuity (epi-usc) at a point. We say that the function c appearing in (2.4) is epi-usc at $x_0 \in \mathbb{R}^n$ (as $p \rightarrow p_0$) if

$$c(p_0, x_0) \geq \sup_{V \in \mathcal{N}(x_0)} \limsup_{p \rightarrow p_0} \inf_{x \in V} c(p, x),$$

where $\mathcal{N}(x_0)$ denotes the neighborhood system of x_0 . The property of epi-usc at x_0 holds in particular if $c(\cdot, x_0)$ is usc at p_0 . However, it can hold in many other situations too, including some in which $c(p, x_0) = +\infty$ for $p \neq p_0$ but $c(p_0, x_0)$ is finite, so that $c(\cdot, x_0)$ is obviously not usc at p_0 . For more details see [10].

The next theorem employs some terms that we now define. An extended-real-valued function f is *proper* if it never takes $-\infty$ and it is not identically $+\infty$. The *effective domain* of f is the set of arguments for which f is not $+\infty$. Finally, the multivalued function Θ is *Berge-usc* at (p_0, P_0) if for each open set W in \mathbb{R}^n with $W \supset \Theta(p_0, P_0)$, there is a neighborhood U of (p_0, P_0) in $\Pi \times \mathcal{P}$ such that for each $(p, P) \in U$, $\Theta(p, P) \subset W$.

THEOREM 2.2. *Let Q and P be as previously defined, let I be defined by (2.2) and h by (2.4), and let G be an open bounded set in \mathbb{R}^n . Assume the following hypotheses:*

- (i) Q is continuous on $\Pi \times (\text{cl } G) \times \mathbb{R}^m$.
- (ii) The collection $\mathcal{F} := \{Q(p, x, \cdot) \mid p \in \Pi, x \in \text{cl } G\}$ is uniformly integrable with respect to the family \mathcal{P} .
- (iii) The function c is lsc on $\Pi \times \text{cl } G$, and is epi-usc at some point $x_0 \in \Theta(p_0, P_0)$, with $c(p_0, x_0)$ finite.
- (iv) $\Theta(p_0, P_0)$ is a CLM set for $h(p_0, P_0, \cdot)$ with respect to G .

Then we have

- (a) $\theta(p_0, P_0)$ is finite and θ is continuous at (p_0, P_0) .
- (b) Θ is Berge-usc at (p_0, P_0) .
- (c) There is a neighborhood U of (p_0, P_0) such that for each $(p, P) \in U$, the function $h(p, P, \cdot)$ restricted to $\text{cl } G$ is proper and $\Theta(p, P)$ is a nonempty, compact CLM set for $h(p, P, \cdot)$ with respect to G .

Proof. We apply Theorem 4.3 of [10] to problem (2.3) to obtain conclusions (a)–(c). Thus the only proof required is verification that the hypotheses needed in [10] hold for (2.3). We list these hypotheses below, indicating for each why it holds here.

- (1) $G \cap \text{dom } h(p_0, P_0, \cdot) \neq \emptyset$: finiteness of $c(p_0, x_0)$ (Hypothesis (iii)) and the fact that I is continuous on $\mathcal{F} \times \mathcal{P}$ (Theorem 2.1 with Hypotheses (i) and (ii)).
- (2) $\Theta(p_0, P_0)$ is a CLM set with respect to G : Hypothesis (iv).
- (3) h is epi-usc at $x_0 \in \Theta(p_0, P_0)$ as $(p, P) \rightarrow (p_0, P_0)$: Proposition 2.8 of [10] together with epi-usc of c at x_0 (Hypothesis (iii)), continuity of I on $\mathcal{F} \times \mathcal{P}$ (see (1) above), and continuity of Q (Hypothesis (i)).

(4) h is lsc on $\Pi \times \mathcal{P} \times \text{cl } G$: lsc of c on $\Pi \times \text{cl } G$ (Hypothesis (iii)) with continuity of I on $\mathcal{F} \times \mathcal{P}$ and continuity of Q .

This completes the proof of Theorem 2.2.

Theorem 2.2 gives a general continuity result for (1.1) under Hypotheses (i)–(iv). In the next section we specialize this result to two-stage stochastic linear programming with complete fixed recourse, showing how to verify the hypotheses in that case.

3. Application to stochastic linear programming. We are concerned in this section with the particular case of (1.1) for which

$$(3.1) \quad Q(p, x, \xi) = \inf_y \{ \langle h^*, y \rangle \mid Wy = t(p, x, \xi), y \geq 0 \},$$

where W is a linear transformation from \mathbb{R}^k to \mathbb{R}^l , $h^* \in \mathbb{R}^k$, and t is a function from $\Pi \times \text{cl } G \times \mathbb{R}^m$ to \mathbb{R}^l , with G an open set in \mathbb{R}^n (the same G as in Theorem 2.2). The special form of Q in (3.1) reflects a situation in which realizations of the random variable ξ lead to adjustment processes whose costs can be modeled by linear programming. The sum of the expected adjustment (or recourse) cost and the cost $c(p, x)$ of adopting the policy x then comprises the total cost $h(p, P, x)$ to be minimized. We shall first show how to apply Theorem 2.2 to (3.1), and then discuss two practical examples in which the conclusions of that theorem yield important information.

Recall that in order to apply Theorem 2.2 to (3.1) we need to know that Q is continuous on $\Pi \times (\text{cl } G) \times \mathbb{R}^m$, that the collection

$$\mathcal{F} := \{ Q(p, x, \cdot) \mid p \in \Pi, x \in \text{cl } G \}$$

is uniformly integrable with respect to a given family \mathcal{P} of probability measures, and that for some fixed elements $p_0 \in \Pi$ and $P_0 \in \mathcal{P}$, the set $\Theta(p_0, P_0)$ defined by (2.5) is a CLM set for $h(p_0, P_0, \cdot)$ with respect to G . There is also a continuity condition on c , detailed in Hypothesis (iii) of Theorem 2.2. Here we concentrate on the first two requirements with the form of Q given by (3.1).

In all of our analysis of (3.1) we shall assume the *complete recourse condition*

$$(3.2) \quad \{ Wy \mid y \geq 0 \} = \mathbb{R}^l.$$

This condition says that no matter what value t assumes in (3.1), the programming problem has a feasible point. We shall also assume that the dual of that problem is feasible:

$$(3.3) \quad \{ u^* \mid W^* u^* \leq h^* \} \neq \emptyset.$$

If we define a function v on \mathbb{R}^l by

$$(3.4) \quad v(z) := \inf_y \{ \langle h^*, y \rangle \mid Wy = z, y \geq 0 \},$$

then v has the following (well-known) properties.

LEMMA 3.1. *Under Hypotheses (3.2) and (3.3), the function v defined by (3.4) is a finite, Lipschitzian, positively homogeneous convex function on \mathbb{R}^l , and for each z there is a $y(z)$ attaining the infimum in (3.4).*

Proof. The existence of $y(z)$ follows from the elementary duality theory of linear programming. This shows that v is finite everywhere. It is clearly convex and positively homogeneous, so we need only prove Lipschitz continuity. Since the cone on the left side of (3.2) is assumed to be \mathbb{R}^l , its polar $\{ u^* \mid W^* u^* \leq 0 \}$ must be the origin. But this polar is the recession cone of the dual feasible set on the left side of (3.3), so that set (for any fixed h^*) is bounded [11, Thm. 8.4]. However, the conjugate function v^* is just the indicator of that set: thus v^* has a bounded effective domain, so v is Lipschitzian [11, Cor. 13.3.3]. This proves Lemma 3.1.

We can now state conditions for the properties of Q in which we are interested.

THEOREM 3.2. Assume that (3.2) and (3.3) hold, and that in addition

(a) t is continuous on $\Pi \times (\text{cl } G) \times \mathbb{R}^m$, and

(b) The collection $\{\|t(p, x, \cdot)\| \mid p \in \Pi, x \in \text{cl } G\}$ is uniformly integrable with respect to \mathcal{P} .

Then the function Q given by (3.1) satisfies Hypotheses (i) and (ii) of Theorem 2.2.

Proof. Continuity of Q is obvious from assumption (a) and Lemma 3.1. For uniform integrability we note that since $v(0) = 0$, we have for any z

$$(3.5) \quad |v(z)| = |v(z) - v(0)| \leq \lambda \|z\|$$

where λ is the Lipschitz constant given by Lemma 3.1. As Q is the composition of v with t , its uniform integrability follows from assumption (b) and (3.5). This completes the proof.

In practice one often finds t given by an expression of the form

$$(3.6) \quad t(p, x, \xi) = a(p, x) + S(p)\xi + T(p, \xi)x$$

where $a: \Pi \times \text{cl } G \rightarrow \mathbb{R}^l$, $S: \Pi \rightarrow \mathcal{L}(m, l)$ (the space of linear transformations from \mathbb{R}^m to \mathbb{R}^l) and $T: \Pi \times \mathbb{R}^m \rightarrow \mathcal{L}(n, l)$. If all of these functions are continuous then assumption (a) of Theorem 3.2 is satisfied. Further, if Π and $\text{cl } G$ are compact, if T satisfies a growth condition of the form

$$\|T(p, \xi)\| \leq \alpha \|\xi\|^\gamma$$

where $\gamma \geq 1$, and if the members of \mathcal{P} happens to come from a family of density functions dominated for $\|\xi\| \geq \delta$ by some function of the form $\beta \|\xi\|^{-\eta}$, where β and δ are any positive numbers and $\eta > \gamma + m$, then assumption (b) will also hold. Many common probability density functions fall into this category.

We conclude by considering two examples. Although these are mostly for illustrative purposes, the first of them is of great importance in the everyday use of mathematical programming techniques to analyze decision making in an uncertain environment.

Example 3.3. Scenario analysis. When mathematical programming models are used as a tool to help in decision making at the policy level (see for example [6], [9]) the “practitioner” approach to handling uncertainty is through reliance on a technique known as *scenario analysis*. Typically, the situation is as follows: a policy must be laid out for the next T years. It corresponds to a sequence of decisions x^1, \dots, x^T , with x^t the decision in period t . In the PILOT model [9], these decisions are related to energy planning and involve such questions as the number and the type of generating plants to support or to start in order to supply the energy needed for industrial and individual consumption. The model is usually of the type

$$(3.7) \quad \begin{aligned} & \text{minimize} && \sum_{t=1}^T f_t(x^t) \\ & \text{subject to} && \sum_{j=1}^l A_{tj} x^j = b_t, \quad t = 1, \dots, T, \\ & && x^t \in C_t \subset \mathbb{R}^n, \quad t = 1, \dots, T, \end{aligned}$$

assuming that the dynamics are linear (the A_{tj} are m by n matrices, $b_t \in \mathbb{R}^m$). The constraints $x^t \in C_t$ represent the limitations imposed on the possible alternatives available in period t . The vectors b_t include the projections for supply and demand in period t . The associated costs (not necessarily purely monetary) are modeled by introducing the objective function

$$f(x) := \sum_{t=1}^T f_t(x^t)$$

that may, as is the case here, or may not be time-separable. Of course, the only decision that is crucial is x^1 . The subsequent decisions x^2, \dots, x^T are only included in the model to measure the implications that a poor or good choice of x^1 may have on the remainder of the planning period. In some sense it would be more appropriate to formulate the problem as

$$(3.8) \quad \begin{aligned} & \underset{x^1 \in C_1}{\text{minimize}} && f_1(x^1) + R(x^1) \\ & \text{subject to} && A_{11}x^1 = b_1 \end{aligned}$$

where

$$(3.9) \quad R(x^1) = \inf_{\substack{x^2, \dots, x^T \\ x^t \in C_t}} \left\{ \sum_{t=2}^T f_t(x^t) \mid \sum_{j=2}^t A_{tj}x^j = b_t - A_{t1}x^1, t=2, \dots, T \right\}.$$

If demands and supplies may be sufficiently well known for period (or stage) 1, so that we may consider b^1 to be given, there is usually much uncertainty as to the values to assign to b_2, \dots, b_T ; obviously we are painfully hampered by lack of data to make reliable predictions for the faraway future. To overcome this obstacle, one technique is to rely on scenario analysis. Instead of solving the optimization problem (3.8) for one choice of

$$\xi := (b_2, \dots, b_T),$$

the problem is solved for a number of possible scenarios

$$\xi^l := (b_2^l, \dots, b_T^l) \quad \text{for } l = 1, \dots, L,$$

generating a collection of solutions $\{x^{1l}, l = 1, \dots, L\}$. These solutions are then analyzed: how does solution x^{1l} “hold up” if instead of scenario ξ^l , the actual outcome turns out to be ξ^k , with $k \neq l$; what is the “best”/“worst” solution; how should one combine the “optimal” solutions to reach a desirable mix; and so on. This involves solving problem (3.8) a very large number of times and nonetheless being left with no more than an educated guess about a potentially good choice of x^1 .

A second approach is to rely on the model of stochastic programming with recourse to analyze such a situation. As before, we accept the future as describable by a range of scenarios, that we again denote by ξ^1, \dots, ξ^L . But this time we attach probabilities p_1, \dots, p_L to these scenarios and instead of solving (3.8) for each possible scenario ξ^1, \dots, ξ^L , we solve the following stochastic optimization problem:

$$(3.10) \quad \begin{aligned} & \underset{x^1 \in C_1}{\text{minimize}} && f_1(x^1) + Q(x^1) \\ & \text{subject to} && A_{11}x^1 = b_1, \end{aligned}$$

with

$$(3.11) \quad \begin{aligned} Q(x_1) &= E \left\{ \inf_{\substack{x^2, \dots, x^T \\ x^t \in C_t}} \sum_{t=2}^T f_t(x^t) \mid \sum_{j=2}^t A_{tj}x^j = \mathbf{b}_t - A_{t1}x^1, t=2, \dots, T \right\} \\ &= \inf_{x^1 \in C_1} \left\{ \sum_{l=1}^L p_l \sum_{t=2}^T f_t(x^{1l}) \mid \sum_{j=2}^t A_{tj}x^{1l} = b_t^l - A_{t1}x^1, t=2, \dots, T; l=1, \dots, L \right\}; \end{aligned}$$

we write \mathbf{b}_t in boldface to suggest that we now view it as a random vector whose possible realizations are b_t^1, \dots, b_t^L . The solution generated by (3.10) takes into account not just one scenario, but *all* of them and if one can argue that the (somewhat arbitrarily) assigned probabilities p_1, \dots, p_L do correspond to the best available information, then the optimal solution x^1 would provide a reliable basis for arriving at a decision in period 1.

The advantage of relying on a stochastic programming model, instead of on scenario analysis, does not stop at the observation that a solution of (3.10) will take into account all eventualities, whereas each individual solution of (3.8) only takes into account one scenario. In fact Theorem 2.2 provides the convincing argument. It informs us that, under perturbations of the probability measure that we have assigned somewhat arbitrarily to the scenarios, the set of solutions to (3.10) as it depends on these "probabilities" is "continuous" (in the sense of upper semicontinuity). Hence a parametric analysis of the behavior of x^1 , with respect to p_1, \dots, p_L , will reveal a "continuous" behavior that allows us to zero in on the stable characteristics of the optimal solutions. Scenario analysis only considers as possible values for the vector (p_1, \dots, p_L) the extreme points of the simplex of probabilities, and thus it is very difficult, if not impossible, to recognize the built-in stabilities.

Example 3.4. Approximation schemes. To solve stochastic programming problems one must usually rely on a discretization of the probability measure, in order to be able to calculate the integral that appears in the objective function (for a general discussion cf. [14]). The discretization is refined, in the appropriate fashion, to guarantee the convergence of the solutions of the approximating problems to the solution of the given problem. Theorem 2.2 allows us to work out the conditions that would guarantee local convergence. Earlier results [13, Thm. 3.9] required global convergence and were, for all practical purposes, only useful in the convex setting. Similarly, Theorem 2.2 allows us to deal with a situation when we have only partial information about the probability measure associated with the random elements of the problem. We can think of this last case as a refined version of "scenario analysis."

BOUNDARY CONTROL OF THE TIMOSHENKO BEAM*

JONG UHN KIM† AND YURIKO RENARDY‡

Abstract. It is shown that the Timoshenko beam can be uniformly stabilized by means of a boundary control. A numerical study on the spectrum is also presented.

Key words. Timoshenko beam, uniform stabilization, exponential decay, boundary control, energy method, C_0 -semigroup, linear stability, eigenvalues, spectral method

0. Introduction. The purpose of this paper is to investigate uniform stabilization of the Timoshenko beam with boundary control. The motion of a beam can be described by the Euler beam equation when the cross-sectional dimensions are small in comparison with the length of the beam. If the cross-sectional dimensions are not negligible, the effect of the rotatory inertia should be considered and the motion is better described by the Rayleigh beam equation. If the deflection due to shear is also taken into account in addition to the rotatory inertia, we arrive at a still more accurate model, which is called the Timoshenko beam. Its motion is described by the following system of equations:

$$(0.1) \quad \rho \frac{\partial^2 w}{\partial t^2} - K \frac{\partial^2 w}{\partial x^2} + K \frac{\partial \phi}{\partial x} = 0,$$

$$(0.2) \quad I_p \frac{\partial^2 \phi}{\partial t^2} - EI \frac{\partial^2 \phi}{\partial x^2} + K \left(\phi - \frac{\partial w}{\partial x} \right) = 0.$$

Here, t is the time variable and x is the space coordinate along the beam in its equilibrium position. We denote by $w(x, t)$ the deflection of the beam from the equilibrium line, which is described by $w = 0$, and by $\phi(x, t)$ the slope of the deflection curve when the shearing force is neglected; for the precise meaning of ϕ , see Timoshenko [11] or Traill-Nash and Collar [12]. We assume that the motion occurs in the w - x -plane and that $0 \leq x \leq L$. The coefficients ρ , I_p , E and I are the mass per unit length, the mass moment of inertia of the cross section, Young's modulus and the moment of inertia of the cross section, respectively. The coefficient K is equal to kGA , where G is the modulus of elasticity in shear, A is the cross sectional area and k is a numerical factor depending on the shape of the cross section. The boundary condition we employ at $x = 0$ is

$$(0.3) \quad w(0, t) = 0, \quad \phi(0, t) = 0,$$

which is for the clamped end at $x = 0$, and the boundary control at $x = L$ is of the form

$$(0.4) \quad K\phi(L, t) - K \frac{\partial w}{\partial x}(L, t) = \alpha \frac{\partial w}{\partial t}(L, t),$$

$$(0.5) \quad EI \frac{\partial \phi}{\partial x}(L, t) = -\beta \frac{\partial \phi}{\partial t}(L, t)$$

where α and β are positive constants depending on the control device. This boundary control corresponds to a control mechanism which monitors $\partial w/\partial t$ and $\partial \phi/\partial t$ at $x = L$ and transforms them into the lateral force and moment applied at $x = L$, respectively. Russell [10] and Washizu [13] derived (0.1) and (0.2) through the energy principle by using the natural energy of the beam given by

$$(0.6) \quad \varepsilon(t) = \frac{1}{2} \int_0^L \left\{ \rho \left[\frac{\partial w}{\partial t} \right]^2 + I_\rho \left[\frac{\partial \phi}{\partial t} \right]^2 + K \left(\phi - \frac{\partial w}{\partial x} \right)^2 + EI \left[\frac{\partial \phi}{\partial x} \right]^2 \right\} dx.$$

One can also derive an equivalent fourth-order equation in terms of w ; see Timoshenko [11] and Traill-Nash and Collar [12]. In particular, [12] discusses various boundary conditions.

This paper consists of two main parts. In the first part, we show that the energy $\varepsilon(t)$ decays exponentially fast under (0.3), (0.4) and (0.5). For the one-dimensional wave equation with boundary control, Quinn and Russell [9] established the exponential decay of solutions. Later, Chen [1], [2] obtained the same result for a wave equation in any space dimension under some geometrical conditions on the domain. A very restrictive part of these conditions was eliminated by Lagnese [5] with the aid of a new energy estimate. Lagnese [6] also extended the result to linear elastodynamic systems. In contrast to the above works, Lasiecka and Triggiani [7] employed boundary feedback acting in the Dirichlet boundary condition to achieve exponential decay of solutions to the wave equation. More recently, Chen et al. [3] discussed the case of a chain of Euler beams and obtained a similar result. Our result for the Timoshenko beam is most closely related to [3]. We use the energy method combined with C_0 -semigroup theory as in [1]–[3], [5] and [6]. The essence of the method is to construct a suitable energy functional associated with $\varepsilon(t)$. Details are given in § 2.

The second part of this paper is concerned with a numerical study. Since the nature of the spectrum is an important question in the investigation of the stability of a linear system, we carried out numerical experiments on the spectrum of (0.1) and (0.2) under (0.3)–(0.5). We express the temporal variation of the eigenfunction in normal modes of the form $e^{\lambda t}$, transforming (0.1)–(0.5) to ordinary differential equations with boundary conditions. The Chebyshev-tau method [4], [8] is used to discretize the spatial variation of the eigenfunctions, thus yielding a matrix eigenvalue problem with discrete complex-valued eigenvalues λ . These are computed using a NAG routine in quadruple precision on a VAX 11/785. Results of numerical experiments are presented in § 3.

1. Notation and preliminaries. We shall use the notation

$$f_t = \partial_t f = \frac{\partial f}{\partial t}, \quad f_x = \partial_x f = \frac{\partial f}{\partial x}, \quad f_{xx} = \partial_{xx} f = \frac{\partial^2 f}{\partial x^2}, \quad \text{etc.}$$

L^2 always denotes $L^2(0, 1)$ and we write

$$H^m = \left\{ f: f, \left[\frac{d}{dx} \right]^k f \in L^2, k = 1, \dots, m \right\}.$$

Our basic function space \mathcal{G} is the set of all quadruplets

$$z = \begin{bmatrix} w_1 \\ w_2 \\ \phi_1 \\ \phi_2 \end{bmatrix}$$

satisfying

$$\begin{aligned} w_1 &\in H^1, \quad w_1(0) = 0, \quad w_2 \in L^2, \\ \phi_1 &\in H^1, \quad \phi_1(0) = 0, \quad \phi_2 \in L^2, \end{aligned}$$

equipped with the inner product

$$(1.1) \quad \langle z, \tilde{z} \rangle_{\mathcal{G}} = \int_0^1 \left\{ \frac{K}{\rho} (\partial_x w_1)(\partial_x \tilde{w}_1) + w_2 \tilde{w}_2 + \frac{EI}{I_\rho} (\partial_x \phi_1)(\partial_x \tilde{\phi}_1) + \phi_2 \tilde{\phi}_2 \right\} dx.$$

We shall also use the function space \mathcal{S} which is the set of all quadruplets

$$z = \begin{bmatrix} w_1 \\ w_2 \\ \phi_1 \\ \phi_2 \end{bmatrix}$$

satisfying

$$\begin{aligned} w_1 &\in H^2, \quad w_1(0) = 0, \quad w_2 \in H^1, \quad w_2(0) = 0, \\ \phi_1 &\in H^2, \quad \phi_1(0) = 0, \quad \phi_2 \in H^1, \quad \phi_2(0) = 0, \\ K\phi_1(1) - K\partial_x w_1(1) &= \alpha w_2(1), \quad EI\partial_x \phi_1(1) = -\beta \phi_2(1), \end{aligned}$$

equipped with the inner product induced by $H^2 \times H^1 \times H^2 \times H^1$. Here, K , α , E , I and β are the same as in the previous section. It is easy to show that \mathcal{S} is dense in \mathcal{G} .

We define the operator Λ in \mathcal{G} :

$$(1.2) \quad \Lambda = \begin{bmatrix} 0 & \text{id} & 0 & 0 \\ (K/\rho)\partial_{xx} & 0 & -(K/\rho)\partial_x & 0 \\ 0 & 0 & 0 & \text{id} \\ (K/I_\rho)\partial_x & 0 & (EI/I_\rho)\partial_{xx} - (K/I_\rho)\text{id} & 0 \end{bmatrix}$$

where id is the identity mapping and the domain of Λ is taken to be \mathcal{S} . It is then easy to see that (0.1), (0.2) with (0.3), (0.4) and (0.5) can be put in the abstract form:

$$(1.3) \quad \frac{dz}{dt} = \Lambda z \quad \text{where } z = \begin{bmatrix} w \\ w_t \\ \phi \\ \phi_t \end{bmatrix} \text{ and } L \text{ is taken to be } 1.$$

We also observe the following.

LEMMA 1.1. Λ is an infinitesimal generator of a C_0 -semigroup in \mathcal{G} .

Proof. Let us write $\Lambda = \Lambda_0 + \Lambda_1$, where

$$(1.4) \quad \Lambda_0 = \begin{bmatrix} 0 & \text{id} & 0 & 0 \\ (K/\rho)\partial_{xx} & 0 & 0 & 0 \\ 0 & 0 & 0 & \text{id} \\ 0 & 0 & (EI/I_\rho)\partial_{xx} & 0 \end{bmatrix}$$

with $\mathcal{D}(\Lambda_0) = \mathcal{S}$ and

$$(1.5) \quad \Lambda_1 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & -(K/\rho)\partial_x & 0 \\ 0 & 0 & 0 & 0 \\ (K/I_\rho)\partial_x & 0 & -(K/I_\rho)\text{id} & 0 \end{bmatrix}.$$

It is apparent that Λ_1 is a bounded linear operator on \mathcal{G} . Thus, it is enough to show that Λ_0 is an infinitesimal generator of a C_0 -semigroup. By virtue of the Lumer-Phillips theorem, it is enough to show that

$$(1.6) \quad \langle \Lambda_0 z, z \rangle_{\mathcal{G}} \leq c \|z\|_{\mathcal{G}}^2 \quad \text{for all } z \in \mathcal{S},$$

where c is a positive constant, and that

$$(1.7) \quad \text{Range of } (\lambda \text{ id} - \Lambda_0) = \mathcal{G} \quad \text{for some } \lambda > c.$$

By integration by parts using the boundary condition of $z \in \mathcal{S}$, we find that

$$\begin{aligned} \langle \Lambda_0 z, z \rangle_{\mathcal{G}} &= \frac{K}{\rho} w_2(1) \partial_x w_1(1) + \frac{EI}{I_\rho} \phi_2(1) \partial_x \phi_1(1) \\ &= \frac{1}{\rho} (K \phi_1(1) - \alpha w_2(1)) w_2(1) - \frac{\beta}{I_\rho} \phi_2(1)^2 \\ (1.8) \quad &\leq \frac{1}{4\rho\alpha} K^2 \phi_1(1)^2 \\ &\leq \frac{1}{4\rho\alpha} K^2 \int_0^1 (\partial_x \phi_1)^2 dx \\ &\leq \frac{K^2}{4\rho\alpha EI} I_\rho \|z\|_{\mathcal{G}}^2, \end{aligned}$$

from which (1.6) follows. We next prove (1.7) for any $\lambda > 0$. Let $\lambda > 0$ and

$$\begin{bmatrix} f_1 \\ f_2 \\ g_1 \\ g_2 \end{bmatrix} \in \mathcal{G}.$$

Then, we have to find

$$\begin{bmatrix} w_1 \\ w_2 \\ \phi_1 \\ \phi_2 \end{bmatrix} \in \mathcal{S}$$

such that

$$(1.9) \quad \lambda w_1 - w_2 = f_1,$$

$$(1.10) \quad \lambda w_2 - \frac{K}{\rho} \partial_{xx} w_1 = f_2,$$

$$(1.11) \quad \lambda \phi_1 - \phi_2 = g_1,$$

$$(1.12) \quad \lambda \phi_2 - \frac{EI}{I_\rho} \partial_{xx} \phi_1 = g_2.$$

We can find $\phi_1 \in H^2$ such that

$$(1.13) \quad \left(\lambda^2 - \frac{EI}{I_\rho} \partial_{xx} \right) \phi_1 = g_2 + \lambda g_1,$$

$$(1.14) \quad \phi_1(0) = 0, \quad \beta \lambda \phi_1(1) + EI \partial_x \phi_1(1) = \beta g_1(1).$$

In fact, ϕ_1 is given by

$$(1.15) \quad \phi_1(x) = c \sinh \mu x - \frac{I_p}{\mu EI} \int_0^x (g_2(s) + \lambda g_1(s)) \sinh \mu(x-s) ds$$

where $\mu = \lambda(I_p/EI)^{1/2}$ and c is uniquely determined from $\beta\lambda\phi_1(1) + EI \partial_x \phi_1(1) = \beta g_1(1)$.

Then, ϕ_2 is determined by (1.13). It is obvious that $\phi_2 \in H^1$, $\phi_2(0) = 0$ and $EI \partial_x \phi_1(1) = -\beta\phi_2(1)$. Similarly, we can find $w_1 \in H^2$ such that

$$(1.16) \quad \left(\lambda^2 - \frac{K}{\rho} \partial_{xx} \right) w_1 = f_2 + \lambda f_1,$$

$$(1.17) \quad w_1(0) = 0, \quad \alpha\lambda w_1(1) + K \partial_x w_1(1) = K\phi_1(1) + \alpha f_1(1).$$

Then, w_2 is determined from (1.19). It is easy to see that

$$\begin{bmatrix} w_1 \\ w_2 \\ \phi_1 \\ \phi_2 \end{bmatrix} \in \mathcal{S}$$

and (1.9)–(1.12) hold.

We shall use the following elementary inequality later on:

$$(1.18) \quad \int_0^1 w_x^2 dx \leq 2 \int_0^1 (\phi - w_x)^2 dx + 2 \int_0^1 \phi_x^2 dx$$

for all $\phi \in H^1$, $w \in H^1$ satisfying $\phi(0) = 0$.

2. Statement and proof of the main result. In this section, we take $L = 1$ without loss of generality. Let $S(t)$ be the C_0 -semigroup in \mathcal{G} generated by Λ in the previous section. We assert the following.

THEOREM 2.1. *The operator norm of $S(t)$ satisfies*

$$(2.1) \quad \|S(t)\| \leq M e^{-rt} \quad \text{for all } t \geq 0$$

where M and r are positive constants.

Before giving details of the proof, we shall outline our arguments. Let us fix any $z_0 \in \mathcal{S}$. Using $\varepsilon(t)$ associated with $S(t)z_0$, we define

$$(2.2) \quad F(t) = \mu t \varepsilon(t) + G(S(t)z_0)$$

where μ is a positive constant depending only on the coefficients of (0.1), (0.2), and $G(\cdot)$ is a suitable functional on \mathcal{G} such that

$$(2.3) \quad |G(z)| \leq C \|z\|_{\mathcal{G}}^2 \quad \text{for all } z \in \mathcal{G}.$$

With the aid of (1.18), we can derive that

$$(2.4) \quad d_1 \|S(t)z_0\|_{\mathcal{G}}^2 \leq \varepsilon(t) \leq d_2 \|S(t)z_0\|_{\mathcal{G}}^2$$

holds for all $t \geq 0$, where d_1 and d_2 are positive constants depending only on the coefficients of (0.1) and (0.2). We then show that

$$(2.5) \quad F(t) \leq M_1 \|z_0\|_{\mathcal{G}}^2$$

holds for all $t \geq 0$, where M_1 is a positive constant depending only on α , β and the coefficients of (0.1) and (0.2). Formulae (2.3) and (2.4) imply

$$(2.6) \quad \|S(t)z_0\|_{\mathcal{G}}^2 \leq \frac{1}{t} M_2 \|z_0\|_{\mathcal{G}}^2 \quad \text{for all } t > 0$$

where M_2 is a positive constant depending only on α , β and the coefficients of (0.1) and (0.2). Since \mathcal{S} is dense in \mathcal{G} , (2.6) implies

$$(2.7) \quad \|S(t)z\|_{\mathcal{G}} \leq \left[\frac{M_2}{t} \right]^{1/2} \|z_0\|_{\mathcal{G}} \quad \text{for all } z \in \mathcal{G}.$$

Finally, we use the semigroup property of $S(t)$ to arrive at (2.1).

Proof of Theorem 2.1. Fix any $z_0 \in \mathcal{S}$. Then,

$$(2.8) \quad S(t)z_0 \in C([0, \infty); \mathcal{S}) \cap C^1([0, \infty); \mathcal{G})$$

and

$$(2.9) \quad \frac{d}{dt} S(t)z_0 = \Lambda S(t)z_0 \quad \text{for every } t \geq 0.$$

Hence, we can write

$$(2.10) \quad S(t)z_0 = \begin{bmatrix} w(x, t) \\ \partial_t w(x, t) \\ \phi(x, t) \\ \partial_t \phi(x, t) \end{bmatrix}$$

where $w(x, t)$ and $\phi(x, t)$ satisfy (0.1)–(0.5).

We now construct $F(t)$:

$$(2.11) \quad \begin{aligned} F(t) = & \frac{\mu t}{2} \int_0^1 \{ \rho w_t^2 + I_\rho \phi_t^2 + K(\phi - w_x)^2 + EI\phi_x^2 \} dx \\ & + \rho \int_0^1 x w_t w_x dx + I_\rho \int_0^1 x \phi_t \phi_x dx + \frac{1}{2+\eta} I_\rho \int_0^1 \phi \phi_t dx \\ & - \frac{1}{2+\eta} \rho \int_0^1 w w_t dx \end{aligned}$$

where μ and η are positive constants which will be determined later on. By virtue of (2.8) and (2.10), we can differentiate (2.11) to obtain

$$(2.12) \quad \frac{dF}{dt} = \mu J_1 + \mu t J_2 + \sum_{n=3}^9 J_n$$

where

$$\begin{aligned} J_1 = \varepsilon(t) &= \frac{1}{2} \int_0^1 \{ \rho w_t^2 + I_\rho \phi_t^2 + K(\phi - w_x)^2 + EI\phi_x^2 \} dx, \\ J_2 &= \int_0^1 \{ \rho w_t w_{tt} + I_\rho \phi_t \phi_{tt} + K(\phi - w_x)(\phi_t - w_{xt}) + EI\phi_x \phi_{xt} \} dx, \end{aligned}$$

$$\begin{aligned}
J_3 &= \rho \int_0^1 x w_t w_{xt} dx, & J_6 &= I_\rho \int_0^1 x \phi_{tt} \phi_x dx, \\
J_4 &= \rho \int_0^1 x w_{tt} w_x dx, & J_7 &= \frac{1}{2+\eta} I_\rho \int_0^1 \phi \phi_{tt} dx, \\
J_5 &= I_\rho \int_0^1 x \phi_t \phi_{xt} dx, & J_8 &= \frac{1}{2+\eta} I_\rho \int_0^1 \phi_t^2 dx, \\
J_9 &= -\frac{\rho}{2+\eta} \int_0^1 w_t^2 dx - \frac{\rho}{2+\eta} \int_0^1 w w_{tt} dx.
\end{aligned}$$

Using (0.1)–(0.5), we can integrate by parts to arrive at

$$(2.13) \quad J_2 = -\alpha w_t(1, t)^2 - \beta \phi_t(1, t)^2,$$

$$(2.14) \quad J_3 = \frac{1}{2} \rho w_t(1, t)^2 - \frac{1}{2} \rho \int_0^1 w_t^2 dx,$$

$$\begin{aligned}
(2.15) \quad J_4 &= \int_0^1 x w_x (K w_{xx} - K \phi_x) dx \\
&= \frac{1}{2} K w_x(1, t)^2 - \frac{1}{2} K \int_0^1 w_x^2 dx - K \int_0^1 x w_x \phi_x dx,
\end{aligned}$$

$$(2.16) \quad J_5 = \frac{1}{2} I_\rho \phi_t(1, t)^2 - \frac{1}{2} I_\rho \int_0^1 \phi_t^2 dx,$$

$$\begin{aligned}
(2.17) \quad J_6 &= \int_0^1 x \phi_x (EI \phi_{xx} - K \phi + K w_x) dx \\
&= \frac{1}{2} EI \phi_x(1, t)^2 - \frac{1}{2} EI \int_0^1 \phi_x^2 dx - \frac{1}{2} K \phi(1, t)^2 \\
&\quad + \frac{1}{2} K \int_0^1 \phi^2 dx + K \int_0^1 x \phi_x w_x dx,
\end{aligned}$$

$$\begin{aligned}
(2.18) \quad J_7 &= \frac{1}{2+\eta} \int_0^1 \phi (EI \phi_{xx} - K \phi + K w_x) dx \\
&= \frac{1}{2+\eta} EI \phi(1, t) \phi_x(1, t) - \frac{1}{2+\eta} EI \int_0^1 \phi_x^2 dx \\
&\quad - \frac{1}{2+\eta} K \int_0^1 \phi^2 dx + \frac{1}{2+\eta} K \phi(1, t) w(1, t) \\
&\quad + \frac{1}{2+\eta} \rho \int_0^1 w_{tt} w dx - \frac{1}{2+\eta} K w_x(1, t) w(1, t) \\
&\quad + \frac{1}{2+\eta} K \int_0^1 w_x^2 dx.
\end{aligned}$$

Let us choose $\eta > 0$ such that

$$(2.19) \quad K \left(\frac{1}{2} - \frac{1}{2+\eta} \right) \leq \frac{1}{4} EI,$$

and then, choose $\mu > 0$ such that

$$(2.20) \quad \mu(2K + EI) \leq \left(\frac{1}{4} + \frac{1}{2+\eta}\right) EI,$$

$$(2.21) \quad 2\mu \leq \frac{1}{2} - \frac{1}{2+\eta}.$$

Then, we find that

$$(2.22) \quad \begin{aligned} \frac{dF}{dt} \leq & -\frac{1}{2} \left(\frac{1}{4} + \frac{1}{2+\eta}\right) EI \int_0^1 \phi_x^2 dx - \frac{K}{2} \left(\frac{1}{2} - \frac{1}{2+\eta}\right) \int_0^1 w_x^2 dx \\ & - \alpha \mu t w_t(1, t)^2 - \beta \mu t \phi_t(1, t)^2 + \frac{1}{2} \rho w_t(1, t)^2 \\ & + \frac{1}{2} K w_x(1, t)^2 + \frac{1}{2} I_\rho \phi_t(1, t)^2 + \frac{1}{2} EI \phi_x(1, t)^2 \\ & - \frac{1}{2} K \phi(1, t)^2 + \frac{1}{2+\eta} EI \phi(1, t) \phi_x(1, t) \\ & + \frac{1}{2+\eta} K \phi(1, t) w(1, t) - \frac{1}{2+\eta} K w_x(1, t) w(1, t). \end{aligned}$$

By means of (0.4) and (0.5) and the inequalities

$$(2.23) \quad \phi(1, t)^2 \leq \int_0^1 \phi_x(x, t)^2 dx,$$

$$(2.24) \quad w(1, t)^2 \leq \int_0^1 w_x(x, t)^2 dx$$

we deduce from (2.22) that for all $t \geq T$,

$$(2.25) \quad \frac{dF}{dt} \leq 0$$

where T is a positive constant depending only on α, β and the coefficients of (0.1) and (0.2). Consequently, we arrive at (2.5). The argument following (2.5) completes the proof.

Remark 2.2. Finally, we remark that our arguments with the same energy functional also yield exponential stabilization for a hinged boundary condition at $x = 0$:

$$(2.26) \quad w(0, t) = 0, \quad \frac{\partial \phi}{\partial x}(0, t) = 0.$$

However, in this case it seems necessary to impose the zero mean condition $\int_0^1 \phi dx = 0$ in order to avoid some technical difficulties (see [1]).

3. Numerical study of the spectrum. We present numerical results on the linear stability of our system. We use normal mode analysis and set

$$(3.1) \quad w(x, t) = e^{\lambda t} P(x),$$

$$(3.2) \quad \phi(x, t) = e^{\lambda t} Q(x).$$

Thus, (0.1)–(0.5) become the following system of ordinary differential equations with boundary conditions:

$$(3.3) \quad -KP_{xx} + KQ_x + \lambda^2 \rho P = 0,$$

$$(3.4) \quad -EIQ_{xx} + K(Q - P_x) + \lambda^2 I_\rho Q = 0,$$

$$(3.5) \quad P = Q = 0 \quad \text{at } x = 0,$$

$$(3.6) \quad EIQ_x + \lambda \beta Q = 0 \quad \text{at } x = L,$$

$$(3.7) \quad K(Q - P_x) - \lambda \alpha P = 0 \quad \text{at } x = L.$$

This system is of the form $A_0 + A_1 \lambda + A_2 \lambda^2 = 0$, where

$$(3.8) \quad A_0 = \begin{bmatrix} -KP_{xx} + KQ_x \\ -EIQ_{xx} + K(Q - P_x) \\ P(0) \\ Q(0) \\ EIQ_x(L) \\ KQ(L) - KP_x(L) \end{bmatrix},$$

$$(3.9) \quad A_1 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ \beta Q(L) \\ -\alpha P(L) \end{bmatrix},$$

$$(3.10) \quad A_2 = \begin{bmatrix} \rho P \\ I_\rho Q \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}.$$

We rewrite this in the form

$$(3.11) \quad \det \begin{bmatrix} \lambda & -A_0 \\ 1 & A_1 + \lambda A_2 \end{bmatrix} = 0$$

so that our system takes on the customary form $A = \lambda B$, where

$$(3.12) \quad A = \begin{bmatrix} 0 & -A_0 \\ 1 & A_1 \end{bmatrix},$$

$$(3.13) \quad B = \begin{bmatrix} -1 & 0 \\ 0 & -A_2 \end{bmatrix}.$$

We discretize $P(x)$ and $Q(x)$ by the Chebyshev-tau method [4], [8]. This is a spectral method where the expansion functions are the Chebyshev polynomials $T_n(z)$ defined by $T_n(\cos \theta) = \cos n\theta$ when $z = \cos \theta$. This method approximates discrete eigenvalues belonging to C^∞ eigenfunctions with infinite-order accuracy.

We rescale the spatial variable to $z = (2x)/L - 1$, so that $-1 \leq z \leq 1$. We set

$$(3.14) \quad P(z) = \sum_{n=0}^N p_n T_n(z),$$

$$(3.15) \quad Q(z) = \sum_{n=0}^N q_n T_n(z)$$

and substitute into (3.3)–(3.7). Thus, there are $2N+2$ unknowns. In the differential equations, we equate coefficients of like powers of the Chebyshev polynomials. Since the first equation (3.3) contains P_{xx} , it yields equations for the coefficients up to degree $N-2$ in the polynomials, thus giving $N-1$ equations. Similarly, (3.4) yields $N-1$ equations. In the tau approximation, the expansion functions $T_n(z)$ are not required to satisfy the boundary conditions individually. The four boundary conditions are imposed as part of the conditions determining the coefficients p_n and q_n . The total number of equations is $2N+2$. The size of the final matrix equation $A = \lambda B$ is $4N+4$ square. Our computer program uses the NAG routine F02GJF to compute the eigenvalues in complex quadruple precision on a VAX 11/785.

The accuracy of our numerical results was established in the following way. The eigenvalues must satisfy the characteristic equation:

$$(3.16) \quad \det \begin{bmatrix} m_{11}(\lambda) & m_{12}(\lambda) & m_{13}(\lambda) & m_{14}(\lambda) \\ m_{21}(\lambda) & m_{22}(\lambda) & m_{23}(\lambda) & m_{24}(\lambda) \\ m_{31}(\lambda) & m_{32}(\lambda) & m_{33}(\lambda) & m_{34}(\lambda) \\ m_{41}(\lambda) & m_{42}(\lambda) & m_{43}(\lambda) & m_{44}(\lambda) \end{bmatrix} = 0$$

where, for $j = 1, 2, 3, 4$

$$(3.17) \quad \begin{aligned} m_{1j} &= 1, \quad m_{2j} = I_p \lambda^2 \eta_j - EI \eta_j^3, & m_{3j} &= (EI \eta_j + \beta \lambda) e^{\eta_j L}, \\ m_{4j} &= \left(EI \lambda \eta_j^2 - I_p \lambda^3 - \frac{\alpha}{\rho} I_p \lambda^2 \eta_j + \frac{\alpha}{\rho} EI \eta_j^3 \right) e^{\eta_j L}, \end{aligned}$$

and η_j are the roots of

$$(3.18) \quad \eta^2 = \frac{1}{2EI} \left[\lambda^2 \left(I_p + \frac{\rho EI}{K} \right) \pm \left(\lambda^4 \left(I_p - \frac{\rho EI}{K} \right)^2 - 4\rho EI \lambda^2 \right)^{1/2} \right].$$

In order to check that our computed eigenvalues satisfy the determinant equation (3.16), we have chosen moderate-sized parameters so that the evaluation of the determinant avoids cancellation between large numbers. We choose $\rho = 1$, $K = 1.5$, $I_p = 2$, $E = 2.5$, $I = 3$, $L = 0.1$, $\alpha = 3.5$ and $\beta = 4.1$. Computations at $N = 15, 20, 25$ and 30 showed that a few eigenvalues are already converged to about 15 digits at $N = 15$. About 12 eigenvalues at $N = 15$ are converged to at least 5 digits, and satisfy (3.16) to that accuracy. All converged eigenvalues have negative real parts and are either real or complex conjugates. The number of digits to which each pair is a complex conjugate is an indication of the amount of roundoff error present. The eigenvalues consist of two groups. One group is lined up approximately along the line -4.47 and the imaginary parts are almost multiples, starting with $\lambda = -4.4709$ and then $\lambda = -4.4769 \pm 38.475i$, $-4.4770 \pm 76.951i$ and so on. The other group is lined up approximately along -34.45 , and the imaginary parts are almost multiples, starting with $\lambda = -34.505$ and then $\lambda = -34.446 \pm 60.829i$, $-34.452 \pm 121.68i$ and so on.

Computations were done at the following set of parameters to model a solid aluminum bar: $\rho = 400 \text{ g/cm}$, $K = 2.8 \times 10^{13} \text{ g} \cdot \text{cm/sec}^2$, $I_p = 3,332 \text{ g} \cdot \text{cm}$, $E = 7.6 \times 10^{11} \text{ g/cm/sec}^2$, $I = 833 \text{ cm}^4$ and $L = 200 \text{ cm}$. We allow α and β to be

- (i) $\alpha = 10^3 \text{ g/sec}$, $\beta = 10^7 \text{ g} \cdot \text{cm}^2/\text{sec}$;
- (ii) $\alpha = 2 \times 10^3 \text{ g/sec}$, $\beta = 2 \times 10^7 \text{ g} \cdot \text{cm}^2/\text{sec}$;
- (iii) $\alpha = 5 \times 10^3 \text{ g/sec}$, $\beta = 5 \times 10^7 \text{ g} \cdot \text{cm}^2/\text{sec}$.

By comparing the results of $N = 40$ and $N = 45$, we conclude that about 20 complex conjugate pairs have converged to 5 digits at $N = 40$, and there are no real-valued eigenvalues. The results for case (i) are plotted in Figs. 1 and 2. Figure 2 is a magnification of Fig. 1 close to the origin. All eigenvalues have negative real parts. Figure 1 does not indicate that the ratio $\text{Im}(\lambda)/\text{Re}(\lambda)$ approaches a constant for large $|\lambda|$. Results of cases (i)–(iii) are displayed in Table 1. Essentially, the real parts of λ are approximately proportional to α or β and the imaginary parts of the three cases

FIG. 1. The graph displays the upper half quadrant of the first 23 complex conjugate pairs of case (i).

FIG. 2. The graph is a magnification of Fig. 1 close to the origin to clarify the location of the eigenvalues there.

TABLE 1

This table displays to 5 digits the first 22 to 23 complex conjugate pairs for cases (i)–(iii) described in § 3.

−0.90827E+01	±0.67186E+05	−0.18165E+02	±0.67186E+05	−0.45405E+02	±0.67187E+05
−0.99853E+01	±0.71509E+05	−0.19970E+02	±0.71509E+05	−0.49919E+02	±0.71510E+05
−0.11047E+02	±0.75828E+05	−0.22093E+02	±0.75828E+05		

are approximately equal. This indicates that when α and β are zero, the real parts are zero and the eigenvalues are purely imaginary. The relative importance of the damping terms in our computations is seen from the dimensionless equations. There are 6 dimensionless parameters: $C_1 = L\bar{Q}/\bar{P}$, where \bar{Q} is the scale of Q and \bar{P} is the scale of P , $C_2 = \lambda^2 \rho L^2 / K$, $C_3 = KL^2 / EI$, $C_4 = \lambda^2 I_p L^2 / EI$, $C_5 = \lambda \beta L / EI$ and $C_6 = \lambda \alpha L / K$. Our values for case (i) are: $C_2 = \lambda^2 \times 6 \times 10^{-7}$, $C_3 = 1.8 \times 10^3$, $C_4 = \lambda^2 \times 2 \times 10^{-7}$, $C_5 = \lambda \times 3 \times 10^{-6}$ and $C_6 = \lambda \times 7 \times 10^{-9}$. The dimensionless equations are

$$(3.19) \quad -P_{xx} + C_1 Q_x + C_2 P = 0,$$

$$(3.20) \quad -Q_{xx} + C_3 Q - \frac{C_3}{C_1} P + C_4 Q = 0,$$

$$(3.21) \quad P = Q = 0 \quad \text{at } x = 0,$$

$$(3.22) \quad Q_x + C_5 Q = 0 \quad \text{at } x = 1,$$

$$(3.23) \quad C_1 Q - P_x - C_6 P = 0 \quad \text{at } x = 1$$

where P , Q and x have been made dimensionless. The largest eigenvalues in Fig. 1 are $O(10^5)$ so that C_5 is $O(10^{-1})$ and C_6 is $O(10^{-3})$, indicating that the damping terms are not large. For the smallest eigenvalues, the damping terms are small so that the property of proportionality of $\text{Re}(\lambda)$ to α or β may be an asymptotic behavior for small damping.

We note that the qualitative features obtained for the computation with moderate data are very different from those of the model of an aluminium bar. This is reminiscent of the qualitative differences in Figs. 5 and 7 of Chen et al. [3].

Acknowledgments. We are very grateful to Professors K. Hannsgen and R. Wheeler for suggesting this problem and for useful discussions. We are also much indebted to Professor J. Burns whose help was indispensable in revising the previous manuscript.

FINITE DIMENSIONAL FILTERS FOR A CLASS OF NONLINEAR SYSTEMS AND IMMERSION IN A LINEAR SYSTEM*

J. LEVINE†

Abstract. We study the finite dimensionality of the filter associated with the following system:

$$(\Sigma) \begin{cases} dx_t = f(x_t) dt, & x_0: \text{random with probability measure } \mu_0, \\ dy_t = h(x_t) dt + J dv_t, & y_0 = 0. \end{cases}$$

Σ is distinguished by the absence of noise in the dynamics.

A necessary and sufficient condition for the existence of a finite dimensional filter is obtained, providing an explicit formula for the minimal filter. Furthermore, this condition is proved to be equivalent to each of the following properties:

- The finite dimensionality of the estimation algebra (the Lie algebra associated to the D-M-Z equation);
- The immersibility of Σ in a linear system (input-output equivalence with a linear system of larger dimension).

Key words. finite dimensional filtering, realization of nonlinear systems, immersion into linear systems, estimation algebra

AMS(MOS) subject classification. 93E11

1. Introduction. After R. Brockett [5], V. Benes [3], Mitter [19], Ocone [20], and others (see also the beautiful survey paper by Marcus [18]), most of the works on finite dimensional filters (FDF) make explicit use of the finite dimensionality of the estimation algebra (the formal Lie algebra generated by the drift and diffusion operators of the Duncan-Mortensen-Zakai (D-M-Z) equation, considered as an infinite dimensional bilinear system).

A general method, outlined by Brockett [5], consists of finding sufficient conditions for finite dimensionality of the estimation algebra and of obtaining a filter by the Wei-Norman integration technique. Nevertheless, its complexity is such that finding new classes of systems admitting FDF constitutes a challenge to virtuosity (see for example [22]).

General necessity results can also be found in [7], and seem to be as difficult to exploit as Brockett's method.

Another stream [2], [6], [18], [19], consists in classifying the transformations that leave the estimation algebra unchanged. Diffeomorphic changes of coordinates in the state-space and gauge transformations are among those invariant transformations.

A natural question then arises as to whether one can characterize the existence of FDF directly from the system's input-output mapping rather than from the estimation algebra. Note that for discrete-time systems the input-output approach is useful (see [15]), whereas Lie algebraic ideas actually do not have a discrete-time counterpart.

The purpose of this paper is precisely to give a complete answer to this question for the particular class of systems without dynamical noise.

* Received by the editors September 11, 1985; accepted for publication (in revised form) November 18, 1986. This work has been partly supported by the French Army.

More precisely, we consider a system of the following form:

$$(\Sigma) \begin{cases} dx_t = f(x_t) dt, & x_0: \text{random with probability measure } \mu_0, \\ dy_t = h(x_t) dt + J dv_t, & y_0 = 0. \end{cases}$$

In applications, it may be interesting to modelize systems without dynamical noises in at least two situations:

—Processes with short life duration, or short observation histories.

—Processes with fast-slow time scales, without noise in the fast components and small noises in the slow ones.

By FDF, we mean a *universal finite dimensional filter* (see [7], [18]), or, roughly speaking, a finite dimensional diffusion ξ_t driven by the observation process of Σ such that the unnormalized conditional measure of x_t knowing the observations history up to time t is obtained as a function of ξ_t only.

Our main result is that Σ admits FDF if and only if there exists an immersion from Σ into a linear system.

This result turns out to be quite negative since, on the one hand, the systems that are immersible into one that is linear are rare and on the other hand since, at least for our restricted class of systems without dynamical noise, finite dimensionality of the filter reduces in some sense to linearity.

The same result was obtained by Hijab [12] for a slightly different problem: Hijab considered systems Σ with scalar observations, and addressed the existence problem of finite dimensional realizations of the scalar input-output map $Y_t \rightarrow E(h(x_t)|Y_t)$, where Y_t denotes any continuous path of observations between 0 and t . Using formal arguments, he showed that the immersion property of Σ into a linear system is necessary and sufficient for the existence of a finite dimensional realization. We use here similar input-output realization ideas.

Coming back to the FDF problem, our results generalize those of Roth and Loparo [21] who proved that a sufficient condition for Σ to admit FDF is that the estimation algebra is nilpotent.

The paper is organized as follows. In § 2, we give an explicit formula for the unnormalized conditional measure. The necessary and sufficient condition for the existence of FDF is proved in § 3 and the minimal filter is explicitly obtained. Finally, § 4 is devoted to the study of the equivalence between existence of FDF and immersibility into a linear system.

2. The unnormalized conditional measure. Let us assume that $x_t \in \mathbf{R}^n$, $y_t \in \mathbf{R}^p$, x_0 : random with probability measure μ_0 on \mathbf{R}^n , and v_t is a standard Brownian motion of \mathbf{R}^p , dv_t being its Stratonovitch differential. J is an invertible $p \times p$ matrix.

We denote x' for x transpose, $Y_t = \{y_s | 0 \leq s \leq t\}$, and we also assume that

$$(2.1) \quad \begin{aligned} f &\in C^\infty(\mathbf{R}^n; \mathbf{R}^n), & h &\in C^\infty(\mathbf{R}^n; \mathbf{R}^p), \\ \exists c_1 > 0 \text{ s.t. } |x'f(x)| &\leq c_1(1 + \|x\|^2) & \forall x \in \mathbf{R}^n, \\ \exists c_2 > 0 \text{ s.t. } |\operatorname{div} f(x)| &\leq c_2 & \forall x \in \mathbf{R}^n, \end{aligned}$$

with $\operatorname{div} f(x) = \sum_{i=1}^n (\partial f_i / \partial x_i)(x)$.

Formulae (2.1) ensure that the flow $(x, t) \rightarrow X_t(x)$ of the differential equation $\dot{x} = f(x)$, with $X_0(x) = x$, is such that X_t is a C^∞ diffeomorphism of \mathbf{R}^n , for all $t \geq 0$. We also denote $(X_t)_* \mu_0$ the image of μ_0 by X_t .

THEOREM 1. Suppose that (2.1) holds. Then the unnormalized conditional measure of x_t knowing Y_t , noted π_t^Y , exists and is given by:

(2.2)

$$\pi_t^Y(x) = \exp \left[\sum_{i,j=1}^p \int_0^t h_i(X_{s-t}(x))(JJ')_{i,j}^{-1} dy_s^j - \frac{1}{2} \int_0^t \|J^{-1}h(X_{s-t}(x))\|^2 ds \right] \cdot (X_t)_* \mu_0(x) \\ \forall t \geq 0 \quad \text{a.e. } x \in \mathbf{R}^n, \quad Y \text{ a.s.}$$

Furthermore, π_t^Y solves the D-M-Z equation (in Stratonovitch form and in the sense of distributions):

$$(2.3) \quad d\pi_t^Y = \left[-\operatorname{div}(f\pi_t^Y) - \frac{1}{2} \|J^{-1}h\|^2 \pi_t^Y \right] dt + \sum_{i,j=1}^p h_i(JJ')_{i,j}^{-1} \pi_t^Y dy_t^j, \\ \pi_0^Y = \mu_0.$$

Proof. Let Q_t be the law of (x_t, Y_t) , and let us define Q_0^t by:

$$\frac{dQ_t}{dQ_0^t} = Z_t$$

with

$$Z_t = \exp \left[\int_0^t h'(X_{s-t}(x))(JJ')^{-1} dy_s - \frac{1}{2} \int_0^t \|J^{-1}h(X_{s-t}(x))\|^2 ds \right].$$

By Girsanov's Theorem, y_t is a Wiener process independent of x_t for Q_0^t .

On the other hand, the probability measure of x_t is the image by the flow X_t of μ_0 , denoted by:

$$\mu_t(x) = (X_t)_* \mu_0(x) \quad \text{a.e. } x \in \mathbf{R}^n.$$

Thus $Q_0^t = \mu_t \otimes P_{F_t}$, with P the Wiener measure on $(C^0(\mathbf{R}_+; \mathbf{R}^p), F_t)$. Hence, $Q_t = Z_t \cdot \mu_t \otimes P_{F_t}$ and $\pi_t^Y = Z_t \cdot \mu_t$, which proves the result.

Equations (2.3) are trivially obtained by the Itô–Stratonovitch formula for $\langle \phi, \pi_t^Y \rangle$ for every $\phi \in C^\infty$ with compact support in \mathbf{R}^n .

3. Existence of finite dimensional filters and their minimal realization.

DEFINITION 1. An FDF for Σ is a stochastic system on \mathbf{R}^r :

$$(3.1) \quad d\xi_t = a(\xi_t) dt + \sum_{i=1}^p b_i(\xi_t) dy_t^i, \\ \pi_t^Y = \sigma(\xi_t, \cdot) \cdot \nu_t \quad \text{in the sense of measures on } \mathbf{R}^n, \quad Y \text{ a.s.,}$$

with $a, b_1, \dots, b_p \in C^\infty(\mathbf{R}^r; \mathbf{R}^r)$, a having linear growth, b_i bounded for all i , ν_t bounded positive measure on \mathbf{R}^n , for all $t \geq 0$, $\sigma \in C^\infty(\mathbf{R}^r \times \mathbf{R}^n; \mathbf{R}_+)$, and ξ_0 s.t. $\mu_0 = \sigma(\xi_0, \cdot) \cdot \nu_0$.

Our FDF's definition is, apart from integrability details, equivalent to the definition of universal filters of [7] (see also [18]), but appears more naturally with (2.2).

The FDF problem can be seen as a special case of realization theory for nonlinear systems in the following sense: one can see the mapping $dY \rightarrow \pi^Y$ as an input-output mapping where the Stratonovitch differentials of the observations play the role of the inputs and where the unnormalized conditional measure plays the role of the output. A filter is thus a realization of this input-output mapping, and it is finite dimensional if the dimension of its state-space is finite.

Of course, by construction, this mapping is causal. Nevertheless, the input set which is considered in realization theory, namely the set of piecewise constant controls,

has P -measure 0. Furthermore, the output is infinite dimensional (for each t and Y , π_t^Y is a bounded positive measure on \mathbf{R}^n). Consequently, the standard theory does not apply.

Let us introduce the following notation. If h_i denotes the i th component of the function h in Σ , let us denote $L_f h_i(x)$ the Lie derivative of h_i along f :

$$(3.2) \quad L_f h_i(x) = \sum_{j=1}^n f_j(x) \frac{\partial h_i}{\partial x_j}(x), \quad L_f^k h_i = L_f(L_f^{k-1} h_i) \quad \forall k \geq 1, \quad L_f^0 h_i = h_i.$$

We also need the following space:

$$(3.3) \quad \mathbf{H} = \mathbf{R}\text{-Span} \{L_f^k h_i | 1 \leq i \leq p, \forall k \geq 0\}.$$

In terms of system theory, \mathbf{H} is the observations space of Σ [10].

THEOREM 2. *The three following assertions are equivalent:*

- (i) Σ has an FDF.
- (ii) $\dim \mathbf{H} < \infty$.
- (iii) $\exists r \in \mathbf{N}, \exists \theta_1, \dots, \theta_r \in \mathbf{H}, \exists A \in \mathbf{R}^{r \times r}, \exists B_1, \dots, B_p \in \mathbf{R}^{1 \times r}$ such that

$$(3.4) \quad \begin{aligned} L_f \theta &= A\theta, \\ h_i &= B_i \theta \quad \forall i = 1, \dots, p, \end{aligned}$$

with $\theta(x) = (\theta_1(x), \dots, \theta_r(x))'$.

Proof. Assertion (i) implies (ii): Suppose that an r -dimensional filter exists, given by (3.1). Comparing (2.2) and (3.1), we obtain:

$$\left(\exp \int_0^t h'(X_{s-t}(\cdot))(JJ')^{-1} dy_s \right) \eta_t = \sigma(\xi_t, \cdot) \cdot \nu_t$$

with

$$(3.5) \quad \eta_t = \left(\exp -\frac{1}{2} \int_0^t \|J^{-1} h(X_{s-t}(\cdot))\|^2 ds \right) (X_t)_* \mu_0.$$

Thus, η_t is absolutely continuous with respect to ν_t , and if we denote $d\eta_t/d\nu_t$ its Radon-Nikodým derivative (which is necessarily a nonnegative C^∞ function), we have:

$$(3.6) \quad \sum_{i,j=1}^p \int_0^t h_i(X_{s-t}(x))(JJ')_{ij}^{-1} dy_s^j = \log \sigma(\xi_t, x) - \log \frac{d\eta_t}{d\nu_t}(x).$$

On the other hand, since $Y \rightarrow \pi_t^Y$ and $Y \rightarrow \sigma(\xi_t)$ are two descriptions of the same input-output map, they must coincide for P -almost every input in $C^0(\mathbf{R}_+; \mathbf{R}^p)$.

But, in virtue of the following integration by parts formula:

$$\int_0^t h'(X_s(x))(JJ')^{-1} dy_s = h'(X_t(x))(JJ')^{-1} y_t - \int_0^t L_f h'(X_s(x))(JJ')^{-1} y_s ds$$

it is immediately seen from (2.2) that π_t^Y is continuous from $C^0(\mathbf{R}_+; \mathbf{R}^p)$ (endowed with the uniform topology) to $M_+(\mathbf{R}^n)$ (endowed with the strong topology). Thus, the equality of the two aforementioned input-output maps, and therefore (3.6), must hold for every observation path in $C^0(\mathbf{R}_+; \mathbf{R}^p)$. In particular, (3.6) holds for every observation path of the form: $y_t + \varepsilon \int_0^t u_s ds$, with $\varepsilon \geq 0$, $u \in L^2(\mathbf{R}_+; \mathbf{R}^p)$, and $Y \in C^0(\mathbf{R}_+; \mathbf{R}^p)$.

Now, with $u \in L^2(\mathbf{R}_+; \mathbf{R}^p)$, let us compute the directional derivative of both sides of (3.6) with respect to y in the direction $\int_0^t u_s ds$, in the quadratic mean sense. Precisely,

changing y_t into $y_t + \varepsilon \int_0^t u_s ds$ in (3.6), we get:

$$(3.7) \quad \int_0^t h'(X_{s-t}(x))(JJ')^{-1}(dy_s + \varepsilon u_s ds) = \log \sigma(\xi_t^\varepsilon, x) - \log \frac{d\eta_t}{d\nu_t}(x)$$

where ξ_t^ε is the solution of

$$(3.8) \quad d\xi_t^\varepsilon = a(\xi_t^\varepsilon) dt + \sum_{i=1}^p b_i(\xi_t^\varepsilon)(dy_t^i + \varepsilon u_t^i dt)$$

with $\xi_0^\varepsilon = \xi_0$.

Denoting "l.i.m." the limit in the mean-square sense, we obviously have:

$$(3.9) \quad \begin{aligned} \text{l.i.m.}_{\varepsilon \rightarrow 0} \frac{1}{\varepsilon} & \left(\int_0^t h'(X_{s-t}(x))(JJ')^{-1}(dy_s + \varepsilon u_s ds) - \int_0^t h'(X_{s-t}(x))(JJ')^{-1} dy_s \right) \\ &= \int_0^t h'(X_{s-t}(x))(JJ')^{-1} u_s ds. \end{aligned}$$

On the other hand, it is well known (see for example [1]) that the mapping $\varepsilon \rightarrow \xi_t^\varepsilon$ is mean-square differentiable around $\varepsilon = 0$ and, denoting $\zeta_t = \text{l.i.m.}_{\varepsilon \rightarrow 0} (1/\varepsilon)(\xi_t^\varepsilon - \xi_t)$, it is straightforward to check that ζ satisfies:

$$d\zeta_t = \frac{\partial a}{\partial \xi}(\xi_t) \zeta_t dt + \sum_{i=1}^p \frac{\partial b_i}{\partial \xi}(\xi_t) \zeta_t dy_t^i + \sum_{i=1}^p b_i(\xi_t) u_t^i dt$$

with $\zeta_0 = 0$. Thus, introducing $T(t, s)$ the fundamental matrix solution of

$$dT(t, s) = \frac{\partial a}{\partial \xi}(\xi_t) T(t, s) dt + \sum_{i=1}^p \frac{\partial b_i}{\partial \xi}(\xi_t) T(t, s) dy_t^i,$$

$$T(s, s) = I,$$

we easily get

$$\zeta_t = \sum_{i=1}^p \int_0^t T(t, s) b_i(\xi_s) u_s^i ds.$$

Hence

$$\text{l.i.m.}_{\varepsilon \rightarrow 0} \frac{1}{\varepsilon} (\log \sigma(\xi_t^\varepsilon, x) - \log \sigma(\xi_t, x)) = \left\langle \frac{\partial \log \sigma}{\partial \xi}(\xi_t, x), \sum_{i=1}^p \int_0^t T(t, s) b_i(\xi_s) u_s^i ds \right\rangle$$

for every t, x , and every u in $L^2(\mathbf{R}_+; \mathbf{R}^p)$, where $\langle \cdot, \cdot \rangle$ denotes the scalar product of \mathbf{R}^r . Thus, grouping (3.6), (3.7) and (3.9), we have proved that

$$(3.10) \quad \int_0^t h'(X_s(x))(JJ')^{-1} u_s ds = \left\langle \frac{\partial \log \sigma}{\partial \xi}(\xi_t, X_t(x)), \sum_{i=1}^p \int_0^t T(t, s) b_i(\xi_s) u_s^i ds \right\rangle$$

$$\forall u \in L^2(\mathbf{R}_+; \mathbf{R}^p), \quad \forall t \geq 0, \quad \forall x \in \mathbf{R}^n, \quad \text{and with probability 1.}$$

Now, i being fixed, let us denote 1_i the p -dimensional vector whose i th component is 1, all the others being 0.

Let us choose $\tau \in [0, t]$, and

$$u_s = 1_{[0, \tau]}(s)(JJ')1_i \quad \forall s \in \mathbf{R}_+.$$

Equation (3.10) becomes

$$\int_0^\tau h_i(X_s(x)) ds = \left\langle \rho(\xi_t, X_t(x)), \sum_{j=1}^p \int_0^\tau T(t, s) b_j(\xi_s) (JJ')_{j,i} ds \right\rangle$$

$$\forall \tau \in [0, t], \quad \forall i = 1, \dots, p,$$

with

$$\rho(\xi_t, X_t(x)) = \frac{\partial \log \sigma}{\partial \xi}(\xi_t, X_t(x)).$$

Differentiating with respect to τ , we obtain:

$$(3.11) \quad h_i(X_\tau(x)) = \left\langle \rho(\xi_t, X_t(x)), \sum_{j=1}^p T(t, \tau) b_j(\xi_\tau) (JJ')_{j,i} \right\rangle$$

$$\forall \tau \in [0, t] \text{ and } \forall i = 1, \dots, p.$$

Let us denote

$$[a, b] = \frac{\partial b}{\partial \xi} a - \frac{\partial a}{\partial \xi} b$$

the Lie bracket of the vector fields a and b , and

$$ad_a^k b = [a, ad_a^{k-1} b] \quad \forall k \geq 1 \quad \text{with } ad_a^0 b = b.$$

Applying the Itô-Stratonovitch formula to (3.11) (see [4]), we obtain:

$$L_f h_i(X_\tau(x)) d\tau = \sum_{j=1}^p \left\langle \rho(\xi_t, X_t(x)), T(t, \tau) \left([a, b_j](\xi_\tau) d\tau + \sum_{k=1}^p [b_k, b_j](\xi_\tau) dy_\tau^k \right) (JJ')_{j,i} \right\rangle.$$

Thus

$$(3.12) \quad L_f h_i(X_\tau(x)) = \sum_{j=1}^p \langle \rho(\xi_t, X_t(x)), T(t, \tau) ad_a b_j(\xi_\tau) (JJ')_{j,i} \rangle,$$

$$\sum_{j=1}^p \langle \rho(\xi_t, X_t(x)), T(t, \tau) [b_k, b_j](\xi_\tau) (JJ')_{j,i} \rangle = 0 \quad \forall k = 1, \dots, p \quad \forall \tau.$$

From (3.12) it is not difficult to prove by induction that for every $\alpha = 0, 1, \dots$

$$(3.13) \quad L_f^\alpha h_i(X_\tau(x)) = \sum_{j=1}^p \langle \rho(\xi_t, X_t(x)), T(t, \tau) ad_a^\alpha b_j(\xi_\tau) (JJ')_{j,i} \rangle,$$

$$\sum_{j=1}^p \langle \rho(\xi_t, X_t(x)), T(t, \tau) [b_k, ad_a^{\alpha-1} b_j](\xi_\tau) (JJ')_{j,i} \rangle = 0 \quad \forall k = 1, \dots, p.$$

Therefore, at $\tau = t$, and using the fact that X_t is a diffeomorphism

$$(3.14) \quad L_f^k h_i(x) = \sum_{j=1}^p \langle \rho(\xi_t, x), ad_a^k b_j(\xi_t) (JJ')_{j,i} \rangle \quad \forall k \geq 0 \quad \forall i = 1, \dots, p \quad \forall x$$

and, since $ad_a^k b_j(\xi_t)$ for every j, k , is independent of x ,

$$\mathbf{H} = \mathbf{R}\text{-Span} \{L_f^k h_i | 1 \leq i \leq p, k \geq 0\} \subset \mathbf{R}\text{-Span} \{\rho_1(\xi_t, \cdot), \dots, \rho_r(\xi_t, \cdot)\}$$

which proves that $\dim \mathbf{H} \leq r$.

Assertion (ii) implies (iii): Let $\theta_1, \dots, \theta_r$ be a basis of \mathbf{H} . Since $h_i \in \mathbf{H}$ and $L_f \mathbf{H} \subset \mathbf{H}$, the assertion is proved.

Assertion (iii) implies (i): Let us consider the r -dimensional diffusion (3.1) with

$$a(\xi) = -A'\xi, \quad b_i(\xi) = (B'(JJ')^{-1})_i \quad \forall i = 1, \dots, p$$

where $(B'(JJ')^{-1})_i$ denotes the i th column of $B'(JJ')^{-1}$, and the output functions

$$\nu_t = \eta_t \quad (\text{given by (3.5)}), \quad \sigma(\xi, x) = \exp \sum_{i=1}^r \xi^i \theta_i(x).$$

We have the following:

$$\begin{aligned} \xi'_t \theta(X_t(x)) &= \int_0^t \theta(X_s(x)) d\xi'_s + \int_0^t \xi'_s L_f \theta(X_s(x)) ds \\ &= \sum_{i,j=1}^p \int_0^t B_i \theta(X_s(x)) (JJ')_{i,j}^{-1} dy_s^j \\ &= \int_0^t h'(X_s(x)) (JJ')^{-1} dy_s. \end{aligned}$$

Thus

$$\sigma(\xi_t, x) \nu_t = \left(\exp \int_0^t h'(X_{s-t}(x)) (JJ')^{-1} dy_s \right) \nu_t = \pi_t^Y(x)$$

which proves that (a, b, ν, σ) is an r -dimensional filter for Σ . \square

In fact, we have almost proved the following minimal realization result.

THEOREM 3. *If $\dim \mathbf{H} = r < \infty$, the minimal realization of Σ 's filter is linear of dimension r , and explicitly given by:*

$$(3.15) \quad d\xi_t = -A'\xi_t dt + \sum_{i=1}^p (B'(JJ')^{-1})_i dy_t^i, \quad \xi_0 = 0,$$

$$\pi_t^Y = \exp \left(\sum_{i=1}^r \xi_t^i \theta_i \right) \cdot \nu_t,$$

with $A, B_1, \dots, B_p, \theta_1, \dots, \theta_r$ given in (iii) of Theorem 2, $\nu = \eta$ (given in (3.5)), and $(B'(JJ')^{-1})_i$ being the i th column of $B'(JJ')^{-1}$.

Proof. In (i) implies (ii), we have proved that $\dim \mathbf{H}$ is less than or equal to the dimension of any realization. On the other hand, in (iii) implies (i), the system (3.15) is proved to be a realization; and since it has the same dimension as \mathbf{H} , the result is proved. \square

Remark 1. If the unnormalized conditional measure has a density still denoted π_t^Y , the relation (3.10) can be interpreted as the gradient in the sense of Malliavin (see for example [14]) of the logarithm of π_t^Y and, by (3.13), the differentiability of this gradient with respect to τ can be seen as a robustness result in the spirit of [8].

Remark 2. In the finite dimensional deterministic nonlinear realization theory, the dimension of the minimal realization is determined by the rank of Jakubczyk (see [13]) of the input-output map. This result still holds in our infinite dimensional framework since it can be checked that this rank is precisely equal to $\dim \mathbf{H}$ and, by Theorem 3, to the dimension of the minimal filter.

Remark 3. In [21], Roth and Loparo propose to exploit the fact that the D-M-Z equation (2.3) is an ordinary first order partial differential equation after transformation into robust form, and to compute a filter via the method of characteristics. Our method has the advantages of being simpler and of providing explicitly the minimal filter.

Notice also that this filter is obtained without using Wei-Norman equations. The reader can check with the results of the next section that this method applies and produces a nonminimal and not completely explicit filter.

On the other hand, the filter (3.15) is linear and this fact is made clear in the next section, where we identify the class of systems for which (ii) of Theorem 2 holds as the class of systems that are immersible into a linear one.

4. FDF, immersion in a linear system and estimation algebra. Let us first recall what is meant by immersion in a linear system [9], [12], and by estimation algebra [5]:

DEFINITION 2. Σ is said to be immersible in the linear system Λ :

$$(\Lambda) \begin{cases} dz_t = Az_t dt, & z_0 \in \mathbf{R}^m \\ dy_t = Bz_t dt + J dv_t, & y_0 = 0 \end{cases}$$

if there exists a C^∞ mapping θ from \mathbf{R}^n to \mathbf{R}^m (m arbitrary) satisfying:

$$(4.1) \quad h(X_t(x)) = B e^{At} \theta(x) \quad \forall x \in \mathbf{R}^n \quad \forall t \geq 0.$$

The mapping θ is called the immersion from Σ to Λ .

Thus, the concept of immersion simply means that a nonlinear system has the same input-output behavior as a linear system, which has possibly a larger dimension.

DEFINITION 3. Let us denote by L_0, \dots, L_p the following operators:

$$(4.2) \quad L_0 \phi = L_f \phi - \frac{1}{2} \|J^{-1} h\|^2 \phi, \quad L_i \phi = \left(\sum_{j=1}^p (JJ')^{-1}_{i,j} h_j \right) \phi$$

$$\forall i = 1, \dots, p, \quad \forall \phi \in C^\infty(\mathbf{R}^n; \mathbf{R}).$$

The estimation algebra of Σ , denoted $E(\Sigma)$ is the Lie algebra generated by L_0, \dots, L_p .

THEOREM 4. *The following conditions are equivalent:*

- (i) Σ has an FDF.
- (ii) Σ is immersible in a linear system.
- (iii) $E(\Sigma)$ is finite dimensional.

Furthermore, if there is an immersion from Σ to the linear system Λ , then one can find an isomorphism of Lie algebras from $E(\Sigma)$ to $E(\Lambda)$.

Proof. Condition (i) equivalent to (ii): Assume first that $\dim \mathbf{H} = r < \infty$. By (iii) of Theorem 2, there exist r functions $\theta_1, \dots, \theta_r$, satisfying:

$$L_f \theta = A \theta, \quad h_i = B_i \theta, \quad i = 1, \dots, p$$

and $\mathbf{H} = \mathbf{R}\text{-Span} \{ \theta_1, \dots, \theta_r \}$.

Thus, denoting $z_t = \theta(x_t)$, we have:

$$\begin{aligned} dz_t &= L_f \theta(x_t) dt = Az_t dt, \\ dy_t &= h(x_t) dt + J dv_t = Bz_t dt + J dv_t, \end{aligned}$$

with B the matrix whose lines are B_1, \dots, B_p , and this proves that θ is the desired immersion. Conversely, if θ is an immersion from Σ to Λ , using (4.1), we have for every t, x and $i = 1, \dots, p$:

$$h_i(X_t(x)) = B_i e^{At} \theta(x)$$

and, differentiating with respect to t , it is easy to obtain for every t, x, i and every $k \geq 0$:

$$L_f^k h_i(X_t(x)) = B_i A^k e^{At} \theta(x).$$

Thus, at $t = 0$, we have:

$$\mathbf{H} = \mathbf{R}\text{-Span} \{L_f^k h_i | i = 1, \dots, p, k \geq 0\} \subset \mathbf{R}\text{-Span} \{\theta_1, \dots, \theta_r\}$$

and thus $\dim \mathbf{H} \leq r$. The conclusion follows from Theorem 2.

Condition (i) equivalent to (iii): It is not difficult to check that for every $k \geq 0$, $i, j = 1, \dots, p$, and every $\phi \in C^\infty(\mathbf{R}^n; \mathbf{R})$:

$$ad_{L_0}^k L_i(\phi) = \left(\sum_{j=1}^p (JJ')_{ij}^{-1} L_f^k h_j \right) \phi, \quad [L_j, ad_{L_0}^k L_i](\phi) = 0$$

which proves that the estimation algebra of Σ is:

$$E(\Sigma) = \mathbf{R} \cdot L_0 \oplus \mathbf{R}\text{-Span} \{(L_f^k h_i) \cdot | k \geq 0, i = 1, \dots, p\}$$

where \cdot denotes the multiplication operator. Thus, clearly, we have $\dim \mathbf{H} \leq \dim E(\Sigma) \leq \dim \mathbf{H} + 1$, which proves the equivalence.

Isomorphism of estimation algebras. Let $E(\Sigma)$ be defined as in the preceding paragraph. By the same arguments, we can easily check that the estimation algebra $E(\Lambda)$ of the corresponding linear system Λ in which Σ is immersed is:

$$E(\Lambda) = \mathbf{R} \cdot M_0 \oplus \mathbf{R}\text{-Span} \{(B_i A^k z) \cdot | k \geq 0, i = 1, \dots, p\}$$

with M_0 defined by:

$$M_0(\psi) = L_{Az} \psi - \frac{1}{2} \|J^{-1} Bz\|^2 \psi \quad \forall \psi \in C^\infty(\mathbf{R}^m; \mathbf{R}).$$

Let Θ be the linear mapping from $E(\Sigma)$ to $E(\Lambda)$ defined as follows:

$$\Theta(L_0) = M_0, \quad \Theta((L_f^k h_i) \cdot) = (B_i A^k z) \cdot, \quad \forall i = 1, \dots, p, \quad \forall k \geq 0.$$

It is a consequence of the immersion that $E(\Sigma)$ and $E(\Lambda)$ have the same dimension and thus Θ is one to one. Also it is straightforward to check that

$$\Theta([L, M]) = [\Theta(L), \Theta(M)] \quad \forall L, M \in E(\Sigma)$$

which achieves the proof. \square

Remark 4. In [12], the equivalence between (ii) and (iii) is proved for one-dimensional outputs ($p = 1$), and in [21] a special case of Theorem 4 is obtained: If $E(\Sigma)$ is nilpotent, then Σ has an FDF.

Remark 5. As a consequence of Theorems 3 and 4, it appears that there is a duality, in the classical meaning of the theory of linear systems, between the minimal filter (3.15) and the linear system Λ in which Σ is immersed.

Remark 6. One might try to take profit of the linearity of Λ by remarking that a filter can be obtained via Makowski's method [17] for linear systems with non-Gaussian initial measure. Unfortunately, this filter has twice the minimal dimension and is not completely explicit since it involves an inverse Fourier transform.

Remark 7. In the language of statistics, the state ξ of the minimal filter is a finite dimensional vector of sufficient statistics, and it must be noted that, similarly to the static parameter estimation problem, the conditional measure belongs to an exponential family.

Remark 8. The results of this section prove that the existence of FDF is basically a property of linear systems when expressed in suitable (nonminimal) coordinates, and thus is quite restrictive. Real applications exist however (see [16] where the problem is solved in discrete time).

Acknowledgments. The author is indebted to Professors E. Pardoux, M. Fliess and R. Marino for very helpful suggestions.

STATE CONSTRAINTS IN OPTIMAL CONTROL: A CASE STUDY IN PROXIMAL NORMAL ANALYSIS*

FRANK H. CLARKE[†] AND PHILIP D. LOEWEN[‡]

Abstract. We consider an optimal control problem on a given interval $[0, T]$ whose trajectories must satisfy the state constraint $g(t, x(t)) \leq 0$ a.e. Infinite-dimensional perturbations of this constraint give rise to a value function V , whose epigraph is a closed set containing sensitivity information, controllability and penalization results and even necessary conditions for optimality. Studying $\text{epi } V$ when the domain of V is $L^2[0, T]$ and $AC^2[0, T]$ allows the derivation of a variety of necessary conditions, each with its own merits, and provides a concrete illustration of the intricacies of infinite-dimensional proximal normal analysis.

Key words. optimal control, state constraints, necessary conditions, value function, proximal analysis, proximal normal analysis

AMS(MOS) subject classification. 49B10

Foreword. Value functions have a long and distinguished history in the study of dynamic optimization. For instance, they provide the cornerstone of the Hamilton–Jacobi sufficiency theory. Until recently, however, the role of such functions in the study of necessary conditions has been limited to their appearance in rather informal attempts to motivate and interpret multiplier rules like the maximum principle. The passage from informal arguments to the rigorous and systematic use of value functions in the study of necessary conditions is not an easy one, the main obstacle being lack of smoothness. Value functions are defined by minimization, an operation which may produce corners, discontinuities, and even infinite values. Functions with such bad behaviour, although beyond the capacity of classical analysis, can be successfully studied using generalized gradients. The modern theory of nonsmooth analysis is now capable of giving value functions a rigorous treatment which does justice to their intuitive significance.

The present article is designed to substantiate the assertions above in the case of a well-known problem: the derivation of necessary conditions for optimal control problems with state constraints. We consider a differential inclusion formulation:

$$P(0) \quad \min \{f(x(0), x(T)) : x'(t) \in F(t, x(t)) \text{ a.e., } x(0) \in C, g(t, x(t)) \leq 0\}.$$

Additive perturbations of the state constraint $g(t, x) \leq 0$ lead to a value function V which dominates the discussion. Besides its obvious sensitivity implications, a first-order analysis of the behaviour of V near 0 permits the simultaneous derivation and interpretation of necessary conditions and controllability results. This completely new approach leads to necessary conditions comparable to those in the literature [11], [14], [16]–[18], with the considerable advantage of an interpretation which is both intuitive and rigorous.

1. Introduction. Let H be a Hilbert space on which a lower semicontinuous function $V: H \rightarrow \mathbf{R} \cup \{+\infty\}$ is given; assume $V(0) < +\infty$. The *generalized gradient* of V at 0, denoted $\partial V(0)$, is a closed convex set of points in $H^* = H$ which describes the local behaviour of V near 0. Although this set can be defined in terms of limits of

difference quotients, a geometrical definition based on the closed set $\text{epi } V = \{(\alpha, r): r \geq V(\alpha)\}$ has recently proven extremely useful. We define

$$(1.1) \quad \begin{aligned} \partial V(0) &= \{\zeta: (\zeta, -1) \in N_{\text{epi } V}(0, V(0))\}, \\ \partial^\infty V(0) &= \{\zeta: (\zeta, 0) \in N_{\text{epi } V}(0, V(0))\}, \end{aligned}$$

where $N_{\text{epi } V}(0, V(0))$ denotes the normal cone to the set $\text{epi } V$ at $(0, V(0))$, a set for which the next paragraph provides a formula.

Let C be a closed subset of H containing a point c . The set of *proximal normals* to C at c , denoted $PN_C(c)$, consists of all $v \in H$ with the following property:

$$(1.2) \quad \exists M > 0 \text{ s.t. } \langle v, c' - c \rangle \leq M \|c' - c\|^2 \quad \forall c' \in C.$$

The set $PN_C(c)$ is a convex cone containing 0. The normal cone to C at c can be recovered from the proximal normal cones nearby:

$$(1.3) \quad N_C(c) = \text{cl co} \{w - \lim_{i \rightarrow \infty} v_i: v_i \in PN_C(c_i), c_i \rightarrow c \text{ in } C\}.$$

This is the "proximal normal formula" due to Clarke [6], whose validity in infinite-dimensional Banach spaces has recently been established by Borwein and Strojwas [3] (see also [13]). Its relevance to us is that it essentially reduces the study of N_C to the study of vectors v obeying (1.2). And (1.2) can be viewed as an optimization problem in its own right, since it says that c minimizes the functional $\langle -v, c' \rangle + M \|c' - c\|^2$ over C . When C is the epigraph of a suitably chosen value function V , we find that $\partial V(0)$ can thus be studied in terms of a sequence of auxiliary minimization problems of a particularly simple form. This approach has been used in a broad range of finite-dimensional applications (see [6], [9], [5], [8], [15] for example); and infinite-dimensional applications are multiplying quickly ([7], [12]).

In our application, the proximal normal inequality (1.2) leads to an auxiliary optimization problem of the same form as $P(0)$, but without state constraints:

$$(Q) \quad \min \{f(x(0), x(T)): x'(t) \in F(t, x(t)) \text{ a.e., } x(0) \in C\}.$$

Necessary conditions for optimality in (Q) are well known, and involve the *distance function* $d_C(x) = \inf \{ \|x - c\|: c \in C \}$ and the *Hamiltonian* $H(t, x, p) = \sup \{ p \cdot v: v \in F(t, x) \}$.

PROPOSITION 1.1 [5]. *Let the data in problem (Q) obey (H1)–(H4) listed in §2. If x solves (Q), and $\rho > (2K_f + 2)(1 + K \ln K)$, then there exists an arc $p \in AC([0, T]; \mathbf{R}^n)$ such that*

- (a) $(-p'(t), x'(t)) \in \partial H(t, x(t), p(t))$ a.e.;
- (b) $(p(0), -p(T)) \in (\delta_0, \delta_T) + \rho |(1, E)| \partial d_C(x(0)) \times \{0\}$ for some $(\delta_0, \delta_T) \in \partial f(x(0), x(T))$.

Here ∂H signifies the generalized gradient of H in the (x, p) variables only, and $E = \delta_0 - p(0)$.

We conclude this introduction by noting that when the domain H of a lower semicontinuous (l.s.c.) function $V: H \rightarrow \mathbf{R} \cup \{+\infty\}$ is infinite dimensional, complications unknown when $H = \mathbf{R}^n$ may arise. For example, we may have $\partial V(0) = \emptyset$ and $\partial^\infty V(0) = \{0\}$ even for a lower semicontinuous convex function V . J. M. Borwein gives an example of such a situation in [2], where he also identifies a class of comparatively well-behaved functions. He calls a lower semicontinuous map $V: H \rightarrow \mathbf{R} \cup \{+\infty\}$ *Lipschitz-like at 0* if $V(0) < +\infty$ and if there exist an open set Ω containing $(0, V(0))$, a closed convex set C with locally weakly compact polar, and a constant $\varepsilon > 0$ such that

$$(1.4) \quad \Omega \cap \text{epi } V + \lambda C \subseteq \text{epi } V \quad \forall \lambda \in (0, \varepsilon).$$

This condition is easy to verify whenever V is directionally Lipschitzian at 0. Moreover, it holds for any lower semicontinuous function V when $H = \mathbf{R}^n$, since one may then choose $\Omega = \mathbf{R}^n \times \mathbf{R}$ and $C = \{(0, 0)\}$. (In particular, many Lipschitz-like functions on \mathbf{R}^n fail to be directionally Lipschitzian.)

PROPOSITION 1.2 [2]. *If a lower semicontinuous map $V: H \rightarrow \mathbf{R} \cup \{+\infty\}$ is Lipschitz-like at 0, then the following are equivalent:*

- (a) V is Lipschitz near 0;
- (b) $\partial^\infty V(0) = \{0\}$;
- (c) $\partial V(0)$ is bounded and nonempty.

Consequently, any such V obeys either $\partial V(0) \neq \emptyset$ or $\partial^\infty V(0) \neq \{0\}$.

PROPOSITION 1.3. *Let $P \subseteq H$ be a closed convex cone with vertex at 0 and nonempty interior. If an l.s.c. map $V: H \rightarrow \mathbf{R} \cup \{+\infty\}$ is finite at 0 and obeys*

$$(1.5) \quad \beta - \alpha \in P \Rightarrow V(\alpha) \leq V(\beta),$$

then V is Lipschitz-like at 0.

Proof. To verify (1.4), take $\varepsilon = 1$, $\Omega = H \times \mathbf{R}$, and $C = -P \times \{0\}$. Any point in the left side of (1.4) has the form $(\alpha, v) + (-\beta, 0)$ for $v \geq V(\alpha)$ and $\beta \in P$. Then (1.5) implies $V(\alpha - \beta) \leq V(\alpha) \leq v$, so $(\alpha - \beta, v) \in \text{epi } V$ as required. The local weak compactness of C^0 follows because $\text{int } P \neq \emptyset$. \square

2. The value function. Let B denote the closed unit ball in \mathbf{R}^n . The following hypotheses concerning the data of problem $P(0)$ are assumed throughout this paper:

- (H1) The multifunction $F: [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}^n$ has nonempty compact convex values. For each $x \in \mathbf{R}^n$, $F(\cdot, x)$ is measurable.
- (H2) There are nonnegative functions $\varphi(t), k(t) \in L^2[0, T]$ such that
 - (a) $F(t, x) \subseteq \varphi(t)B \quad \forall t \in [0, T], \quad \forall x \in \mathbf{R}^n$;
 - (b) $F(t, y) \subseteq F(t, x) + k(t)|y - x|B \quad \forall t \in [0, T], \quad \forall x, y \in \mathbf{R}^n$.
 We define $K_F = \exp(\int_0^T k(t) dt)$.

(H3) The set C is compact.

(H4) The function $f: \mathbf{R}^n \times \mathbf{R}^n \rightarrow \mathbf{R}$ is globally Lipschitz of rank K_F .

These are standard assumptions for problem $P(0)$, identical to those in [5] except for the assumption $k \in L^2$ in (H2) instead of $k \in L^1$ in [5]. This condition assures that any F -trajectory (i.e. any absolutely continuous function x obeying $x'(t) \in F(t, x(t))$ a.e.) lies in the Hilbert space

$$(2.1) \quad AC^2([0, T], \mathbf{R}^n) = \{x = AC([0, T]; \mathbf{R}^n): x' \in L^2([0, T]; \mathbf{R}^n)\}.$$

This space, also known as $H^1(0, T)$ or $W^{1,2}(0, T)$, comes with inner product

$$(2.2) \quad \langle x, y \rangle = x(0) \cdot y(0) + \int_0^T x'(t) \cdot y'(t) dt;$$

evidently AC^2 is isometric to $\mathbf{R}^n \times L^2$, with $x(t)$ and $(x_0, v(t))$ being identified iff $x(t) = x_0 + \int_0^t v(s) ds$. In particular, $x_i(t)$ converges weakly in AC^2 to $x(t)$ iff $x_i(0) \rightarrow x(0)$ and $x'_i \rightarrow x'$ weakly in L^2 . When this is the case, one has $\sup_i \|x'_i\|_2 < +\infty$, and the Arzela-Ascoli Theorem implies that $x_i \rightarrow x$ uniformly on $[0, T]$.

The conditions governing the state constraint function $g: [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}$ depend on our choice of the perturbation scheme and the interpretation of the state constraint. In general terms, let H be a Hilbert space of functions $\alpha: [0, T] \rightarrow \mathbf{R}$, and let $P \subseteq H$ be a closed convex cone with vertex at 0 defining the "positive" elements of H : write

$\alpha \leq_P 0$ iff $-\alpha \in P$. Then additive perturbations of the state constraint by elements $\alpha \in H$ give rise to a value function $V: H \rightarrow \mathbf{R} \cup \{+\infty\}$ as follows:

$$P(\alpha) \quad V(\alpha) := \min \{f(x(0), x(T)): x'(t) \in F(t, x(t)) \text{ a.e., } x(0) \in C, \\ g(t, x(t)) + \alpha(t) \leq_P 0\}.$$

One possible choice of H is $L^2[0, T]$, with P consisting of all functions which are nonnegative almost everywhere; another possibility is $H = AC^2[0, T]$ with P consisting of functions which are nonnegative everywhere. In any case, $\alpha(\cdot)$ and $g(\cdot, x(\cdot))$ must be comparable, so we cannot hope to get far without the following assumption.

- (h5) For all F -trajectories x , the map $t \rightarrow g(t, x(t))$ lies in H ; also, if a sequence of F -trajectories $\{x_i\}$ converges to x weakly in AC^2 , then $g(t, x_i(t)) \rightarrow g(t, x(t))$ weakly in H .

The hypothesis will be strengthened considerably when we come to consider specific choices for H and P . For our present purposes, however, it is enough to establish a satisfactory existence property and prove the lower semicontinuity of V .

PROPOSITION 2.1. (a) *Let $\{x_i\}$ be a sequence of F -trajectories with $x_i(0) \in C$. Then $\{x_i\}$ has a subsequence converging weakly in AC^2 to an F -trajectory x such that $x(0) \in C$.*

(b) *Suppose that, along with the sequence $\{x_i\}$ in part (a), there is a sequence $\{\alpha_i\} \subseteq H$ such that $g(t, x_i(t)) + \alpha_i(t) \in -P$ for all i , and such that $\alpha_i \rightarrow \alpha$ weakly in H . Then the subsequence in (a) can be chosen so that one obtains the limiting relationship $g(t, x(t)) + \alpha(t) \in -P$.*

(c) *If $V(\alpha) < +\infty$ for some α , then $P(\alpha)$ has a solution.*

(d) *The function V is weakly sequentially lower semicontinuous. (In particular, V is norm lower semicontinuous.)*

Proof. Proposition 2.1(a) is a minor revision of [5, Thm. 3.1.7, p. 118]; in view of (h5), (b) follows immediately from (a).

To prove (c), let $\{x_i\}$ be a minimizing sequence for $P(\alpha)$. Taking $\alpha_i = \alpha$ in (b), we find that there is a subsequence along which x_i tends weakly in AC^2 (hence uniformly) to an F -trajectory x obeying both $x(0) \in C$ and $g(t, x(t)) + \alpha(t) \in -P$. By (H4), $f(x(0), x(T)) = \lim f(x_i(0), x_i(T)) = V(\alpha)$.

As for (d), let $\alpha_i \rightarrow \alpha$ weakly in H and $V(\alpha_i) \rightarrow v$. We must show $v \geq V(\alpha)$. If $v = +\infty$ this is trivial, so assume $v < +\infty$. Then (c) gives a solution x_i for each $P(\alpha_i)$: in particular,

$$V(\alpha_i) = f(x_i(0), x_i(T)) \quad \text{and} \quad g(t, x_i(t)) + \alpha_i(t) \in -P.$$

Mimicking the arguments of (c) leads to the conclusion that $v = f(x(0), x(T))$ for some limiting F -trajectory x admissible for $P(\alpha)$. Hence $V(\alpha) \leq v$ as required. \square

Without specifying the space H further, we can state the basic features of a proximal normal to the closed set $\text{epi } V$ in $H \times \mathbf{R}$.

THEOREM 2.2. *Let $(\zeta, -\varepsilon) \in PN_{\text{epi } V}(\alpha^*, v^*)$. Then there is a constant $M > 0$ and a solution x^* for $P(\alpha^*)$ such that*

- (a) $\varepsilon \geq 0$ and $\varepsilon[v^* - f(x^*(0), x^*(T))] = 0$;
 (b) $-\zeta \in N_P(r^*)$, where $r^*(t) = -g(t, x^*(t)) - \alpha^*(t)$;
 (c) among all F -trajectories x starting in C , x^* minimizes

$$\varepsilon f(x(0), x(T)) + \langle \zeta(t), g(t, x(t)) \rangle + M \|g(t, x(t)) - g(t, x^*(t))\|^2 \\ + M |f(x(0), x(T)) - f(x^*(0), x^*(T))|^2.$$

Proof. For any F -trajectory x starting in C , we have

$$V(-g(t, x(t))) \leq f(x(0), x(T)).$$

Moreover, this inequality is preserved if a scalar $s \geq 0$ is added to the right side and a function $r \in P$ is subtracted from the argument of V . Thus

$$(-g(t, x(t)) - r(t), f(x(0), x(T)) + s) \in \text{epi } V.$$

From the definition of a proximal normal (1.2), there exists $M > 0$ such that (suppressing the t -dependence of x for simplicity)

$$(2.3) \quad \begin{aligned} &\langle (\zeta, -\varepsilon), (-g(t, x) - r, f(x) + s) - (\alpha^*, v^*) \rangle \\ &\leq M \|(-g(t, x) - r, f(x) + s) - (\alpha^*, v^*)\|^2. \end{aligned}$$

Now since $V(\alpha^*) \leq v^* < +\infty$, Proposition 2.1(c) implies that $P(\alpha^*)$ has a solution x^* . Taking $x = x^*$ and $r = r^* = -\alpha^* - g(t, x^*)$ in (2.3) gives

$$0 \leq \varepsilon(s - v^* + f(x^*(0), x^*(T))) + M|s - v^* + f(x^*(0), x^*(T))|^2 \quad \forall s \geq 0.$$

This implies that $s^* = v^* - f(x^*(0), x^*(T))$ gives a minimum to the right-hand side over the set $[0, +\infty)$. Hence the right derivative of this expression must vanish if $s^* > 0$, or at least be nonnegative if $s^* = 0$. This is conclusion (a).

If we now take $x = x^*$ and $s = s^*$ in (2.3), we get

$$\langle -\zeta, r - r^* \rangle \leq M \|r - r^*\|^2 \quad \forall r \in P.$$

This says $-\zeta \in PN_P(r^*)$, which implies $-\zeta \in N_P(r^*)$ by the proximal normal formula. This is conclusion (b).

Finally, taking $r = r^*$ and $s = s^*$ in (2.3) gives conclusion (c). \square

The conclusions of Theorem 2.2 illustrate the general claims made in § 1: the proximal normals which will ultimately characterize $\partial V(0)$ can be understood in terms of the differential inclusion problem (c) *without state constraints*. Conclusion (a) simply captures the geometrically obvious fact that a proximal normal to an epigraph must point downward. Since P is a closed convex cone, conclusion (b) may be decomposed as follows:

$$(2.4) \quad -\zeta \in N_P(r^*) \Leftrightarrow \langle \zeta, r^* \rangle = 0 \quad \text{and} \quad -\zeta \in N_P(0).$$

Note that none of our calculations so far have precluded the study of equality state constraints of the form $g(t, x(t)) = 0$. The choice $P = \{0\}$ allows Proposition 2.1 and Theorem 2.2 to be used in this case also.

3. The choice $H = L^2[0, T]$. A Hilbert space of functions very common in analysis is $L^2[0, T]$, with the inner product

$$\langle \alpha, \beta \rangle = \int_0^T \alpha(t) \beta(t) dt.$$

Given a closed subset J of $[0, T]$, a natural choice for the positive cone is

$$P = \{\alpha \in L^2[0, T]: \alpha(t) \geq 0 \text{ a.e. } t \in J\}.$$

In this case the state constraint $g(t, x(t)) \leq_P 0$ must be interpreted as

$$g(t, x(t)) \leq 0 \quad \text{a.e. } t \in J.$$

With these specifications, the value function $V: L^2[0, T] \rightarrow \mathbf{R} \cup \{+\infty\}$ of § 2 is well defined and permits a straightforward application of proximal normal analysis. Loewen has given a detailed account of this procedure in [12]. We sketch his main results in this section, paying particular attention to the subtleties of the infinite-dimensional context.

We proceed under the following hypothesis.

- (H5) The state constraint function $g: [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}$ is Lebesgue measurable in t and Lipschitz in x , with $|g(t, y) - g(t, x)| \leq K_g |y - x|$ for all $t \in [0, T]$, $x, y \in \mathbf{R}^n$. Also $\int_0^T |g(t, 0)|^2 < +\infty$.

(Note that (H5) \Rightarrow (h5), and that any function g defined only on $J \times \mathbf{R}^n$ but satisfying (H5) on J is easily extended to $[0, T] \times \mathbf{R}^n$ in a way which preserves (H5).)

LEMMA 3.1. Let $r^* \in P$ and $\zeta \in L^2[0, T]$ be given. The following are equivalent:

- (a) $-\zeta \in N_P(r^*)$;
- (b) $\zeta(t) \geq 0$ a.e., $\zeta(t)r^*(t) = 0$ a.e., $\zeta(t) = 0$ a.e. $t \notin J$.

Proof. Clearly (b) \Rightarrow (a). Conversely, $-\zeta \in N_P(r^*)$ implies both $\langle \zeta, r^* \rangle = 0$ and $\langle \zeta, r \rangle \geq 0$ for all $r \in P$ by (2.4). The second of these statements implies $\zeta(t) \geq 0$ a.e., with $\zeta(t) = 0$ a.e. $t \notin J$. The first then forces $\zeta(t)r^*(t) = 0$ a.e. \square

PROPOSITION 3.2. Let $(\zeta, -\varepsilon) \in PN_{\text{epi } V}(\alpha^*, v^*)$. Then $P(\alpha^*)$ has a solution x^* to which there corresponds an arc $p \in AC^2([0, T]; \mathbf{R}^n)$ and a measurable selection $\gamma(t) \in \partial_x g(t, x^*(t))$ a.e. such that

- (a) $\varepsilon \geq 0$, $-\zeta \in N_P(-g(t, x^*(t)) - \alpha^*(t))$;
- (b) $(-p'(t) + \zeta(t)\gamma(t), x^{*'}(t)) \in \partial H(t, x^*(t), p(t))$ a.e.;
- (c) $(p(0), -p(T)) \in \varepsilon \partial f(x^*(0), x^*(T)) + N_C(x^*(0)) \times \{0\}$.

Proof. Conclusion (a) follows from Theorem 2.2(a). Items (b) and (c) arise when Proposition 1.1 is applied to the minimization problem described in Theorem 2.2(c). Details are given in [12]. \square

PROPOSITION 3.3. Assume $V(0) < +\infty$. Suppose $(\zeta, -\varepsilon) = w\text{-}\lim (\zeta_i, -\varepsilon_i)$ for a weakly convergent sequence $(\zeta_i, -\varepsilon_i)$ of vectors proximal normal to $\text{epi } V$ at base points $(\alpha_i, v_i) \rightarrow (0, V(0))$. Then $P(0)$ has a solution x to which there corresponds an arc p and a measurable selection $\gamma(t) \in \partial_x g(t, x(t))$ a.e. on $\{t \in [0, T]: \zeta(t) \neq 0\}$ such that

- (a) $\varepsilon \geq 0$, $-\zeta \in N_P(-g(t, x(t)))$;
- (b) $(-p'(t) + \zeta(t)\gamma(t), x'(t)) \in \partial H(t, x(t), p(t))$ a.e.;
- (c) $(p(0), -p(T)) \in \varepsilon \partial f(x(0), x(T)) + N_C(x(0)) \times \{0\}$.

Proof. Proposition 3.2 asserts that to each α_i there corresponds a solution x_i to $P(\alpha_i)$ together with corresponding quantities p_i and γ_i such that conclusions (a)–(c) hold for each i . We are now concerned with their validity in the limit.

The arguments of Proposition 2.1 show that $\{x_i\}$ has a subsequence converging uniformly to a limiting arc x which actually solves $P(0)$. Hence conclusions (c) _{i} show that $\{p_i(T)\}$ is a bounded sequence, while $\{p'_i\}$ is a sequence of functions bounded in $L^2([0, T]; \mathbf{R}^n)$ by (b) _{i} . So along a further subsequence, p_i converges uniformly to some arc p , and $p'_i \rightarrow p'$ weakly in L^2 . Taking limits in (c) _{i} with the aid of [5, Prop. 2.1.5(b)] and [5, Prop. 2.4.2] yields conclusion (c). (To be completely precise, we recover (c) from the slightly stronger versions of (c) _{i} in which $N_C(x_i(0))$ is replaced by $R\partial d_C(x_i(0))$ for a large constant R independent of i , as in Proposition 1.1(b).)

As for (a), it is clear that the weak limit of points $\varepsilon_i \geq 0$ and $\zeta_i \in P$ obeys $\varepsilon \geq 0$ and $\zeta \in P$. Also, the uniform convergence of x_i to x implies that $g(t, x_i(t)) \rightarrow g(t, x(t))$ strongly in $L^2[0, T]$. Consequently the relationship $\zeta_i(t)[g(t, x_i(t)) + \alpha_i(t)] = 0$ a.e. $t \in J$ implies $\zeta(t)g(t, x(t)) = 0$ a.e. $t \in J$. Finally, $\zeta(t) = 0$ a.e. $t \notin J$ is obvious, so we have $-\zeta \in N_P(-g(t, x(t)))$ as (a) asserts.

Finally, it remains to verify (b). By a modification of [17, Lemma 4.5], we are assured that the bounded sequence $\gamma_i(t)\zeta_i(t)$ in $L^2([0, T]; \mathbf{R}^n)$ has a subsequence converging weakly to $\gamma(t)\zeta(t)$, where ζ is the given weak limit of $\{\zeta_i\}$ and where $\gamma(t) \in \partial_x g(t, x(t))$ a.e. on $\{t: \zeta(t) \neq 0\}$. Therefore the left-hand sides $(-p'_i + \gamma_i\zeta_i, x'_i)$ converge weakly to $(-p' + \gamma\zeta, x')$. At the same time, the Hamiltonian arguments

(x_i, p_i) converge uniformly to (x, p) . By [5, Prop. 3.1.7], the limiting relationship (b) follows. \square

Proposition 3.3 enables us to give a succinct characterization of $N_{\text{epi } V}(0, V(0))$. Let us write Σ for the set of solutions to $P(0)$; for every $x \in \Sigma$ and $\varepsilon > 0$, we write $M^\varepsilon(x)$ for the collection of all vectors ζ satisfying Proposition 3.3(a)–(c). We then have

$$(3.1) \quad N_{\text{epi } V}(0, V(0)) = \text{cl co } [N \cup N^\infty],$$

where

$$(3.2) \quad \begin{aligned} N &= \{\lambda(\zeta, -1) : \lambda \geq 0, \zeta \in M^1(\Sigma) \cap \partial V(0)\}, \\ N^\infty &= \{(\zeta, 0) : \zeta \in M^0(\Sigma) \cap \partial^\infty V(0)\}. \end{aligned}$$

Lines (3.1) and (3.2) carry information about the sensitivity of problem $P(\alpha)$, and about its relation to multiplier rules. For example, if $N_{\text{epi } V}(0, V(0)) \neq \{0\}$ then (3.1) implies that $N \cup N^\infty$ contains a nonzero point. Definitions (3.2) then imply that either $M^1(\Sigma)$ or $M^0(\Sigma) \setminus \{0\}$ is nonempty. This fact, which we may write as

$$(3.3) \quad M^1(\Sigma) \cup [M^0(\Sigma) \setminus \{0\}] \neq \emptyset,$$

affirms that some solution x to $P(0)$ has either a nontrivial multiplier with $\varepsilon = 0$ or else a multiplier with $\varepsilon = 1$.

We emphasize that the multiplier rule (3.3) is valid only under the assumption that $N_{\text{epi } V}(0, V(0)) \neq \{0\}$. If the domain of V were finite-dimensional, this assumption would hold automatically. But with $H = L^2[0, T]$ the situation is considerably more delicate, and it is possible for every weakly convergent sequence appearing in the proximal normal formula (1.3) to converge to zero. J. M. Borwein [2] presents a comparatively simple instance of $P(\alpha)$, meeting all our hypotheses, for which this pathology occurs. In the remainder of this report we will discuss three ways to avoid this problem. The first is to introduce a certain constraint qualification (“calmness”) to guarantee the nontriviality of $N_{\text{epi } V}(0, V(0))$. Alternatively, one can use different limiting techniques along a sequence of proximal normals to derive a nontrivial multiplier rule without regard for monitoring the sensitivity of $P(\alpha)$. Finally, one can start over at the beginning with a different choice of H , in the hopes that a “smaller” infinite-dimensional space might give better results. Each of these alternatives has a lesson to teach: the dense validity of the calmness condition shows that the analysis above is not trivial; taking weak limits of measures leads to the most widely applicable necessary conditions given in this paper; and the analysis when $H = AC^2[0, T]$ shows how strongly the outcome of the proximal normal approach depends upon the choice of V ’s domain, while giving sensitivity information unknown until now.

Calmness. Problem $P(\alpha)$ is *calm* at α_0 if $V(\alpha_0) < +\infty$ and

$$\liminf_{\alpha \rightarrow \alpha_0} \frac{V(\alpha) - V(\alpha_0)}{\|\alpha - \alpha_0\|} > -\infty.$$

Since $V : L^2[0, T] \rightarrow \mathbf{R} \cup \{+\infty\}$ is lower semicontinuous, [1, Thm. VI.65, p. 281] implies that the points at which $P(\alpha)$ is calm are dense in $\text{Dom } V = \{\alpha \in L^2[0, T] : V(\alpha) < +\infty\}$.

Calmness is a well-respected constraint qualification in other settings—the calculus of variations and mathematical programming, for example [5]. Here, too, it guarantees the nontriviality and normality of the necessary conditions proposed in (3.3).

THEOREM 3.4. *Suppose $P(\alpha)$ is calm at 0. Then for any $x \in \Sigma$ there is a vector $\zeta \in L^2[0, T]$, an arc p , and a measurable selection $\gamma(t) \in \partial_x g(t, x(t))$ a.e. on $\{t: \zeta(t) \neq 0\}$ such that*

$$(a) \quad \zeta(t) \geq 0 \text{ a.e., } \zeta(t)g(t, x(t)) = 0 \text{ a.e., } \zeta(t) = 0 \text{ a.e. } t \notin J;$$

$$(b) \quad (-p'(t) + \zeta(t)\gamma(t), x'(t)) \in \partial H(t, x(t), p(t)) \text{ a.e.};$$

$$(c) \quad (p(0), -p(T)) \in \partial f(x(0), x(T)) + N_C(x(0)) \times \{0\}.$$

If x is the only element of Σ , then ζ may be chosen to lie in $\partial V(0)$; in any case, we have

$$(3.4) \quad \partial V(0) = \text{cl co } [M^1(\Sigma) \cap \partial V(0) + M^0(\Sigma) \cap \partial^\infty V(0)].$$

Proof. Formula (3.4) is valid even without the assumption of calmness, being a direct consequence of (3.1)–(3.2) ([13, Prop. 4.2]). But when $P(\alpha)$ is calm at 0, [12, Prop. III.4.2] implies $\partial V(0) \neq \emptyset$, so (3.4) has nontrivial content. Indeed, one of its consequences is that $M^1(\Sigma) \cap \partial V(0) \neq \emptyset$. Consequently there exists $x \in \Sigma$ and $\zeta \in \partial V(0)$ such that (a)–(c) hold. If Σ is a singleton then the proof is complete. If Σ contains several points, then we may fix our attention on any $x^* \in \Sigma$ and consider the modified problem $P^*(\alpha)$, which is identical to $P(\alpha)$ in every way except that the cost functional $f(x(0), x(T))$ is replaced by $f(x(0), x(T)) + (\int_0^T |x(t) - x^*(t)|^2 dt)^2$. Now $\Sigma^* = \{x^*\}$ and

$$V^*(\alpha) \geq V(\alpha) \quad \forall \alpha, \quad V^*(0) = V(0).$$

Consequently $P^*(\alpha)$ is calm at 0, and the conclusions derived above allow one to choose $\zeta^* \in \partial V^*(0)$ such that (a*)–(c*) hold. These conclusions reduce immediately to the desired results (a)–(c). \square

In order to compare the conclusions of Theorem 3.4 with the known necessary conditions of Vinter and Pappas [17], let us define an arc

$$q(t) = p(t) - \int_0^t \gamma(s)\zeta(s) ds.$$

Then conditions (a)–(c) become

$$(a) \quad \zeta(t) \geq 0 \text{ a.e., } \zeta(t)g(t, x(t)) = 0 \text{ a.e., } \zeta(t) = 0 \text{ a.e. } t \notin J;$$

$$(b) \quad (-q'(t), x'(t)) \in \partial H\left(t, x(t), q(t) + \int_0^t \gamma(s)\zeta(s) ds\right);$$

$$(c) \quad (q(0), -q(T) - \int_0^T \gamma(s)\zeta(s) ds) \in \partial f(x(0), x(T)) + N_C(x(0)) \times \{0\}.$$

To recover the measure conditions of [17], it suffices to introduce the nonnegative measure μ via $d\mu = \zeta(t) dt$. Conclusion (a) then states that μ is supported on $J \cap \text{cl } \{t: g(t, x(t)) = 0\}$, while conclusions (b) and (c) assume the forms given in [17]. Thus Theorem 3.4 is very close in spirit to the necessary conditions proposed in the literature, with one very significant advantage: it shows that the measure μ may be taken to be absolutely continuous with respect to Lebesgue measure, with a square-integrable density ζ . This advantage is due both to the method of proof via proximal normals, and to the assumption of calmness—a condition known to hold arbitrarily near to any problem of interest.

Remark. The proximal normal approach used here adapts very easily to the treatment of *equality state constraints*, which have the form $g(t, x(t)) = 0$ a.e. Indeed, it suffices to take the positive cone $P = \{0\}$ to find that Theorem 3.4 remains valid in this case, except that conclusion (a), which states that $-\zeta \in N_P(-g(t, x(t)))$, becomes trivial. In the remainder of this paper, however, we make much more use of the detailed properties of N_P . To go beyond Theorem 3.4 in the case of equality state constraints would therefore require separate study.

Weak* convergence of measures. The scope of proximal normal analysis goes considerably beyond the simple application of (1.3). For example, the theory guarantees that for any closed subset C of a Hilbert space, the boundary of C contains a dense subset of points c where $PN_C(c) \neq \{0\}$. So even in the case where $N_C(c) = \{0\}$, there is no shortage of nontrivial proximal normal cones based near c . In terms of our problem, we can certainly find a weakly convergent sequence of unit vectors $(\zeta_i, -\varepsilon_i) \in PN_{\text{epi } v}(\alpha_i, v_i)$ at points $(\alpha_i, v_i) \rightarrow (0, V(0))$. Despite the possibility that every such sequence might tend weakly to zero in $L^2 \times \mathbf{R}$, nontrivial results are still available if we take limits in a different topology. The cost of doing so is the loss of sensitivity information about $P(\alpha)$; the benefit is a proof of known necessary conditions which is closely related to the proximal approach, but which requires no constraint qualification.

Given a weakly convergent sequence of unit vectors $(\zeta_i, -\varepsilon_i)$ as described above, Proposition 3.2 asserts that there is a sequence x_i of solutions to $P(\alpha_i)$ such that certain conclusions hold for some p_i and γ_i . Let us define constants m_i , arcs q_i , and measures μ_i via

$$(3.5) \quad m_i = \varepsilon_i + \|\zeta_i\|_1,$$

$$(3.6) \quad q_i(t) = \left(p_i(t) - \int_0^t \gamma_i(s) \zeta_i(s) ds \right) / m_i,$$

$$(3.7) \quad d\mu_i = (\zeta_i(t)/m_i) dt.$$

We then have

$$-m_i q_i'(t) = -p_i'(t) + \gamma_i(t) \zeta_i(t) \quad \text{a.e.},$$

and the conclusions of Proposition 3.2 imply

$$(3.8) \quad \varepsilon_i \geq 0, \quad \zeta_i(t) \geq 0 \quad \text{a.e.}, \quad \zeta_i(t) = 0 \quad \text{a.e. } t \notin J,$$

$$(3.9) \quad (-q_i'(t), x_i'(t)) \in \partial H\left(t, x_i(t), q_i(t) + \int_0^t \gamma_i(s) d\mu_i(s)\right),$$

$$(3.10) \quad \left(q_i(0), -q_i(T) - \int_0^T \gamma_i(s) d\mu_i(s) \right) \in \left(\frac{\varepsilon_i}{m_i} \right) \partial f(x_i(0), x_i(T)) + N_C(x_i(0)) \times \{0\}.$$

Definitions (3.5) and (3.7), together with condition (3.8), imply that each μ_i is a nonnegative measure supported on $J \subseteq [0, T]$ with $\mu_i(J) \leq 1$. Hence some subsequence of $\{\mu_i\}$ converges weakly* to a nonnegative measure μ supported on J with

$$\mu(J) = \lim_{i \rightarrow \infty} \mu_i(J).$$

Defining $\lambda_i = \varepsilon_i/m_i \in [0, 1]$ implies that (perhaps along a further subsequence) $\lambda_i \rightarrow \lambda$ for some $\lambda \in [0, 1]$, and that $\lambda + \mu(J) = 1$. Now exactly the same limiting argument used in [5, p. 129] establishes the following result, in which we use the notation

$$\overline{N_C}(c) = \{\lim n_i : n_i \in N_C(c_i), c_i \rightarrow c \text{ in } C\},$$

$$\overline{\partial_x g}(t, x) = \{\lim z_i : z_i \in \partial_x g(t_i, x_i), (t_i, x_i) \rightarrow (t, x)\}.$$

PROPOSITION 3.5. *Assume (H1)–(H5). If $V(0) < +\infty$ then $P(0)$ has a solution x to which there correspond an arc q , a measurable function γ , a constant λ and a nonnegative measure μ such that*

(a) $\lambda \in [0, 1]$, μ is supported on J , and $\lambda + \mu(J) = 1$;

(b) $\gamma(t) \in \overline{\partial_x g}(t, x(t)) \mu$ -a.e.;

- (c) $(-q'(t), x'(t)) \in \partial H(t, x(t), q(t) + \int_0^t \gamma(s) d\mu(s));$
 (d) $(q(0), -q(T) - \int_0^T \gamma(s) d\mu(s)) \in \lambda \partial f(x(0), x(T)) + \overline{N_C}(x(0)) \times \{0\}.$

The only substantial difference between Proposition 3.5 and [17, Thm. 3.1] concerns the support of the measure μ . In [17], Vinter and Pappas assume that g is upper semicontinuous in t and deduce that μ is supported on the set of "active" constraint times

$$J \cap \{t: g(t, x(t)) = 0\}.$$

Taking $J = [0, T]$ for simplicity, we now derive their result from Proposition 3.5.

THEOREM 3.6 [17]. *In addition to (H1)–(H5), assume that $J = [0, T]$ and that $g(\cdot, x)$ is upper semicontinuous (u.s.c.) for each fixed x . Then for every solution x to $P(0)$, there correspond an arc q , a measurable function γ , a constant λ , and a nonnegative measure μ such that*

- (a) $\lambda \in [0, 1]$, μ is supported on $\{t: g(t, x(t)) = 0\}$, and $\lambda + \mu[0, T] = 1;$
 (b) $\gamma(t) \in \overline{\partial_x g}(t, x(t))$ μ -a.e.;
 (c) $(-q'(t), x'(t)) \in \partial H(t, x(t), q(t) + \int_0^t \gamma(s) d\mu(s));$
 (d) $(q(0), -q(T) - \int_0^T \gamma(s) d\mu(s)) \in \lambda \partial f(x(0), x(T)) + \overline{N_C}(x(0)) \times \{0\}.$

Proof. Let us assume for the moment that x is the unique solution to $P(0)$. This temporary hypothesis will be dispensed with later. For any positive integer i , consider the problem $P_i(0)$ which is identical to $P(0)$ in every way except that the closed set J is replaced by

$$J_i = \{t: g(t, x(t)) \geq -1/i\}.$$

(J_i is closed because g is u.s.c. in t .) Now x remains the unique local solution for $P_i(0)$, since any arc y which is admissible for $P_i(0)$ and obeys $\|y - x\|_\infty \leq (iK_g)^{-1}$ has

$$g(t, y(t)) \leq 0 \quad \text{for } t \in J_i,$$

$$g(t, y(t)) \leq g(t, x(t)) + K_g \|y - x\|_\infty < (-1/i) + i^{-1} = 0 \quad \text{for } t \notin J_i.$$

Thus y is admissible for $P(0)$ and hence performs strictly worse than x . We may apply Proposition 3.5 to $P_i(0)$ to find q_i , γ_i , λ_i , and μ_i , such that

- (a)_i $\lambda_i \in [0, 1]$, μ_i is supported on J_i , and $\lambda_i + \mu_i[0, T] = 1;$
 (b)_i $\gamma_i(t) \in \overline{\partial_x g}(t, x(t))$ μ_i -a.e.;

(c)_i $(-q'_i(t), x'(t)) \in \partial H\left(t, x(t), q_i(t) + \int_0^t \gamma_i(s) d\mu_i(s)\right);$

(d)_i $\left(q_i(0), -q_i(T) - \int_0^T \gamma_i(s) d\mu_i(s)\right) \in \lambda_i \partial f(x(0), x(T)) + \overline{N_C}(x(0)) \times \{0\}.$

Once again, there is a subsequence along which $\mu_i \rightarrow \mu$ weak*, $\lambda_i \rightarrow \lambda$, $q_i \rightarrow q$ uniformly, $\gamma_i d\mu_i \rightarrow \gamma d\mu$ weak* for some $\gamma(t) \in \overline{\partial_x g}(t, x(t))$ μ -a.e., and so on. Taking limits in (b)_i–(d)_i yields (b)–(d) of the theorem. As for conclusion (a), the support of μ_i is the closed set J_i . Since $J_1 \supseteq J_2 \supseteq \dots$, it follows that the support of the limiting measure μ lies in

$$\bigcap_{i=1}^{\infty} J_i = \{t: g(t, x(t)) = 0\},$$

as required.

Now if x is one of several solutions to $P(0)$, then it is easy to define a modified problem $P^*(0)$ for which x is the unique solution and the conclusions derived above imply that x obeys (a)–(d). The idea here is to modify the objective function $f(y(0), y(T))$ by adding a term of the form $\int_0^T |y(t) - x(t)|^2 dt$. Details are given in the proof of [5, Thm. 3.5.2]. \square

4. The choice $H = AC^2[0, T]$. In the special case when the state constraint function $g(t, x)$ is smooth, the mapping $t \rightarrow g(t, x(t))$ actually lies in $AC^2[0, T]$ for any F -trajectory x . The space AC^2 , defined in (2.1), (2.2), has certain advantages over L^2 as the domain of V . The most striking of these is that the natural positive cone

$$P = \{\alpha \in AC^2[0, T]: \alpha(t) \geq 0 \forall t \in [0, T]\}$$

actually has interior. Hence Propositions 1.2 and 1.3 imply that either $\partial V(0) \neq \emptyset$ or $\partial^\infty V(0) \neq \{0\}$, and consequently that weak limits of proximal normals will yield both nontrivial necessary conditions and meaningful sensitivity results without any constraint qualifications at all. These facts make it worthwhile to pursue the analysis when $H = AC^2[0, T]$ even though this space is more difficult to work with than $L^2[0, T]$ and despite the extra regularity assumptions which must be imposed on F and g to complete the analysis.

Throughout this section, (H1)–(H4) of § 2 are augmented by

(H5) The function $g: \mathbf{R}^n \rightarrow \mathbf{R}$ is autonomous and of class C^2 on \mathbf{R}^n .

(H6) The nonnegative function φ appearing in (H2)(a) is actually constant.

The smoothness of g required by (H5) will appear as a necessary evil in the proof of Proposition 4.4. Explicit time dependence of g can be allowed, provided that $\partial g / \partial t$ is smooth in x , but we have chosen to simplify the presentation by taking $\partial g / \partial t \equiv 0$.

Let us now interpret the conclusions of Theorem 2.2 in the space $H = AC^2[0, T]$. The first step is to consider the normal cone $N_P(r^*)$.

PROPOSITION 4.1. *Let $r^* \in P$ and $\zeta \in AC^2[0, T]$ be given. The following are equivalent:*

(a) $-\zeta \in N_P(r^*)$;

(b) *there is a finite nonnegative measure μ with support in $Z[r^*] = \{t \in [0, T]: r^*(t) = 0\}$ such that*

$$\zeta(t) = \mu[0, T] + t\mu(0, T) - \int_0^t \mu(0, s) ds.$$

Proof. The arguments of Hestenes [10, p. 50] show that $-\zeta \in N_P(0)$ if and only if $\zeta'(t)$ is a nonincreasing function which obeys

$$(4.1) \quad \zeta(0) \geq \zeta'(0+), \quad \zeta'(T-) \geq 0.$$

Recalling (2.4), one may verify that a function of this sort obeys $\langle \zeta, r^* \rangle = 0$ iff ζ is constant on all relatively open subintervals of $\Omega[r^*] = \{t \in [0, T]: r^*(t) > 0\}$ and equality holds in (4.1) iff $r^*(0) > 0$, respectively, $r^*(T) > 0$. Certainly the ζ defined in (b) meets these criteria; conversely, any ζ in $-N_P(r^*)$ gives rise to a measure as in (b) when we set

$$\mu\{0\} = \zeta(0) - \zeta'(0+), \quad \mu\{T\} = \zeta'(T-), \quad \mu(s, t) = \zeta'(s) - \zeta'(t). \quad \square$$

The conclusions of Proposition 4.1 support the following remarkable fact.

PROPOSITION 4.2. *Let $\{\zeta_i\}$ be a sequence in $-N_P(0)$ converging weakly to ζ . Then $\{\zeta_i\}$ actually converges strongly to ζ ; in fact, $\{\zeta'_i\}$ converges to ζ' in every $L^p[0, T]$ for $p \in [1, \infty)$.*

Proof. Since $\{\zeta_i\}$ is weakly convergent, it is norm bounded. In particular, there exists $M > 0$ such that $\zeta_i(0) \in [0, M]$ for all i . From (4.1) it follows that $\zeta'_i(t) \in [0, M]$ for all i a.e. Moreover, each ζ'_i is nonincreasing (see the proof of Proposition 4.1). Thus Helly's selection theorem implies that any subsequence of ζ'_i has a further subsequence converging pointwise to a nonincreasing limit function, which must be

ζ' . This shows that $\zeta'_i \rightarrow \zeta'$ a.e., so the bounded convergence theorem implies that $\zeta'_i \rightarrow \zeta'$ in any $L^p[0, T]$, $p \in [1, \infty)$. In particular $\zeta'_i \rightarrow \zeta'$ in L^2 and it follows that $\zeta_i \rightarrow \zeta$ strongly in $AC^2[0, T]$. \square

COROLLARY 4.3. *Let $\{r_i\} \subseteq P$ be a sequence converging weakly to r , and let $\{\zeta_i\}$ be a sequence converging weakly to ζ while obeying $-\zeta_i \in N_P(r_i)$ for all i . Then one has $-\zeta \in N_P(r)$.*

Proof. We have $\zeta_i \in -N_P(r_i) \subseteq -N_P(0)$ for all i by (2.4). Since $-N_P(0)$ is convex and strongly closed, it is also weakly closed and $\zeta \in -N_P(0)$. Also by (2.4), we have $\langle \zeta_i, r_i \rangle = 0$ for all i . Now $r_i \rightarrow r$ weakly by assumption and $\zeta_i \rightarrow \zeta$ strongly by Proposition 4.2, so we obtain $\langle \zeta, r \rangle = 0$ in the limit. From (2.4) it now follows that $-\zeta \in N_P(r)$. \square

Now we turn to the remaining conclusions of Theorem 2.2.

PROPOSITION 4.4. *Let $(\zeta, -\varepsilon) \in PN_{\text{epi } v}(\alpha^*, v^*)$. Then $P(\alpha^*)$ has a solution x^* to which there corresponds an arc $p \in AC^2([0, T]; \mathbf{R}^n)$ such that*

- (a) $\varepsilon \geq 0$ and $-\zeta \in N_P(-g(x^*(t)) - \alpha^*(t))$;
- (b) $(-p'(t) + \zeta'(t)g_{xx}(x^*(t))x^{*'}(t), x^{*'}(t)) \in \partial H(t, x^*(t), p(t) - \zeta'(t)g_x(x^*(t)))$ a.e.;
- (c) $(p(0) - \zeta(0)g_x(x^*(0)), -p(T)) \in \varepsilon \partial f(x^*(0), x^*(T)) + N_C(x^*(0)) \times \{0\}$.

Proof. Conclusion (a) follows from Theorem 2.2(a, b); we will deduce conclusions (b) and (c) from Theorem 2.2(c). We know that among all F -trajectories x starting in C , x^* gives the lowest value to the functional

$$\begin{aligned} \varepsilon f(x(0), x(T)) + \zeta(0)g(x(0)) + \int_0^T \zeta'(t)g(x(t))' dt \\ + M|g(x(0)) - g(x^*(0))|^2 + M|f(x(0), x(T)) - f(x^*(0), x^*(T))|^2 \\ + M \int_0^T |g(x(t))' - g(x^*(t))'|^2 dt. \end{aligned}$$

Now a careful review of Clarke's proof of [5, Thm. 3.2.6] (the result we have quoted as Proposition 1.1) shows that the necessary conditions for this minimization problem are the same as those when $M = 0$. The intuitive reason for this is that the conclusions of Proposition 1.1 are first-order conditions, and the terms multiplied by M here are all of second order. The technical justification of this fact relies on (H6).

To write the first-order conditions when $M = 0$ we introduce the auxiliary state $y \in AC[0, T]$, governed by

$$y'(t) = \zeta'(t)g_x(x(t))x'(t), \quad y(0) = 0.$$

Then the arc (x^*, y^*) , where $y^*(t) = \int_0^t \zeta'(s)g_x(x^*(s))x^{*'}(s) ds$, satisfies the conclusions of Proposition 1.1 for the problem of minimizing

$$\varepsilon f(x(0), x(T)) + \zeta(0)g(x(0)) + y(T)$$

over all trajectories $(x(t), y(t))$ for the multifunction

$$G(t, x, y) = \{(v, \zeta'(t)g_x(x)v) : v \in F(t, x)\}.$$

The Hamiltonian for this problem, evaluated at (x, y, p, q) , equals

$$\sup \{pv + q\zeta'(t)g_x(x)v : v \in F(t, x)\} = H(t, x, p + q\zeta'(t)g_x(x)).$$

We deduce the existence of arcs $p(t)$ and $q(t) \equiv -1$ such that

$$\begin{aligned} (-p'(t), x^{*'}(t)) \in \{(d - \zeta'(t)g_{xx}(x^*(t))e, e) : (d, e) \in \partial H(t, x^*(t), p(t) - \zeta'(t)g_x(x^*(t)))\}, \\ (p(0), -p(T)) \in \varepsilon \partial f(x^*(0), x^*(T)) + (\zeta(0)g_x(x^*(0)), 0) + N_C(x^*(0)) \times \{0\}. \end{aligned}$$

These reduce easily to the desired conclusions (b) and (c). \square

Remark 4.5. The crux of the preceding proof is our ability to take $M = 0$ when writing down necessary conditions for the auxiliary problem solved by x^* . This is the only place in the development where (H6) is required. For smooth relaxed problems where $F(t, x) = \psi(t, x, U)$, even (H6) can be removed. Indeed, let $\psi: [0, T] \times \mathbf{R}^n \times \mathbf{R}^n \rightarrow \mathbf{R}^n$ be measurable in t , differentiable in x , with $\psi_x(t, \cdot, \cdot)$ jointly continuous, and suppose U is compact. We also require $F(t, x) = \psi(t, x, U)$ to obey (H1), (H2). In this situation the analysis of the auxiliary problem solved by x^* involves the additional arc y given by

$$\begin{aligned} y'(t) &= \zeta'(t)g_x(x(t))x'(t) + M|g_x(x(t))x'(t) - g_x(x^*(t))x^{*'}(t)|^2, \\ y(0) &= 0, \end{aligned}$$

and the arc (x^*, y^*) really minimizes

$$\begin{aligned} \varepsilon f(x(0), x(T)) + \zeta(0)g(x(0)) + y(T) + M|g(x(0)) - g(x^*(0))|^2 \\ + M|f(x(0), x(T)) - f(x^*(0), x^*(T))|^2 \end{aligned}$$

over all trajectories $(x(t), y(t))$ for the multifunction

$$G(t, x, y) = \{(v, \zeta'(t) \cdot g_x(x)v + M|g_x(x)v - g_x(x^*(t))x^{*'}(t)|^2): v \in \psi(t, x, U)\}.$$

This multifunction is not convex, but it does satisfy all other hypotheses of Proposition 1.1. And since we are dealing with a free-endpoint problem, it follows [5, p. 117] that (x^*, y^*) continues to solve the problem above when $\text{co } G$ is used instead of G . The latter problem satisfies the hypotheses of Proposition 1.1, in whose conclusions the Hamiltonian is now effectively

$$\mathcal{H}_M(t, x, p) = \sup \{(p - \zeta'(t)g_x(x)) \cdot v - M|g_x(x)v - g_x(x^*(t))x^{*'}(t)|^2: v \in \psi(t, x, U)\}.$$

Under the above conditions on ψ , $\mathcal{H}_M(t, \cdot, \cdot)$ can be viewed as the maximum over the fixed compact set U of a family of functions whose (x, p) -gradients are continuous in x, p , and u . Consequently this function is regular [5, Thm. 2.8.2]. Since $\mathcal{H}_M(t, x, p) \leq \mathcal{H}_0(t, x, p)$ with equality when $x = x^*(t)$, it follows that

$$\partial \mathcal{H}_M(t, x^*(t), p) \subseteq \partial \mathcal{H}_0(t, x^*(t), p) \quad \forall p \in \mathbf{R}^n.$$

Thus the Hamiltonian inclusion for the auxiliary problem, when $M > 0$, implies the Hamiltonian inclusion we would obtain for the problem when $M = 0$, and the proof of Proposition 4.4 proceeds as above. Clearly, any hypotheses ensuring that $\mathcal{H}_M(t, \cdot, \cdot)$ is regular may be used in place of $F(t, x) = \psi(t, x, U)$ in this argument. \square

To simplify our study of the limiting stability of Proposition 4.4(a)–(c), we introduce some notation. The set $\Sigma(\alpha)$ will consist of all solutions $x(\cdot)$ of problem $P(\alpha)$: by Proposition 2.1(c), $V(\alpha) < +\infty \Rightarrow \Sigma(\alpha) \neq \emptyset$. If $x \in \Sigma(\alpha)$ and $\varepsilon \geq 0$, the *index ε multiplier set for x* , denoted $M^\varepsilon(x)$, consists of all $\zeta \in AC^2[0, T]$ for which there is an arc $p(\cdot)$ such that

- (a) $\varepsilon \geq 0$ and $-\zeta \in N_P(-g(x(\cdot)) - \alpha(\cdot))$;
- (b) $(-p'(t) + \zeta'(t)g_{xx}(x(t))x'(t), x'(t)) \in \partial H(t, x(t), p(t) - \zeta'(t)g_x(x(t)))$ a.e.;
- (c) $(p(0) - \zeta(0)g_x(x(0)), -p(T)) \in \varepsilon \partial f(x(0), x(T)) + \overline{N_C}(x(0)) \times \{0\}$.

(Recall the definition of $\overline{N_C}$ given just before Proposition 3.5.)

The multiplier sets have a useful scaling property:

$$(4.2) \quad \zeta \in M^\varepsilon(x) \Leftrightarrow \forall \lambda > 0, \quad \lambda \zeta \in M^{\lambda \varepsilon}(x).$$

In case $\Sigma(\alpha)$ contains several points, we define $M^\varepsilon(\Sigma(\alpha))$ to be the union of $M^\varepsilon(x)$ over x in $\Sigma(\alpha)$. This definition allows Proposition 4.4 to be restated as follows:

$$(4.3) \quad (\zeta, -\varepsilon) \in PN_{\text{epi } V}(\alpha^*, v^*) \Rightarrow \zeta \in M^\varepsilon(\Sigma(\alpha^*)).$$

To emphasize the relationship between the multiplier sets defined here and those current in the literature ([17], [5]), we introduce the arc q and the measure μ via

$$(4.4) \quad q(t) = p(t) - \zeta(0)g_x(x(0)) - \int_0^t \zeta'(s)g_{xx}(x(s))x'(s) ds,$$

$$(4.5) \quad \zeta(t) = \mu[0, T] + t\mu(0, T) - \int_0^t \mu(0, s) ds.$$

(Compare Proposition 4.1.)

We may then reduce $p(t) - \zeta'(t)g_x(x(t))$ to

$$\begin{aligned} q(t) + \mu[0, T]g_x(x(0)) + \int_0^t \mu[s, T]g_x(x(s))' ds - \mu[t, T]g_x(x(t)) \\ = q(t) + \int_0^t g_x(x(s)) d\mu(s). \end{aligned}$$

It follows that $M^\varepsilon(x)$ can also be written as the set of all ζ of the form (4.5) arising from a nonnegative measure μ on $[0, T]$ and an arc q such that

- (a') $\varepsilon \geq 0$ and $\text{supp } (\mu) \subseteq \{t \in [0, T]: g(x(t)) + \alpha(t) = 0\}$;
- (b') $(-q'(t), x'(t)) \in \partial H(t, x(t), q(t) + \int_0^t g_x(x(s)) d\mu(s))$;
- (c') $(q(0), -q(T) - \int_0^T g_x(x(s)) d\mu(s)) \in \varepsilon \partial f(x(0), x(T)) + \overline{N_C}(x(0)) \times \{0\}$.

In view of (4.3), the following result makes a statement about weak limits of proximal normals.

PROPOSITION 4.6. *Let $\{\alpha_i\} \subseteq AC^2[0, T]$ be a sequence converging strongly to α , along which $V(\alpha_i) \rightarrow V(\alpha)$. If a sequence $\{(\zeta_i, -\varepsilon_i)\} \subseteq AC^2[0, T] \times \mathbf{R}$ converges weakly to $(\zeta, -\varepsilon)$ and obeys $\zeta_i \in M^{\varepsilon_i}(\Sigma(\alpha_i))$ for all i , then we have the limiting relationship $\zeta \in M^\varepsilon(\Sigma(\alpha))$. Moreover, $\zeta_i \rightarrow \zeta$ in norm.*

Proof. Since $\zeta_i \in M^{\varepsilon_i}(\Sigma(\alpha_i))$ for all i , it follows that ζ_i is a weakly convergent sequence of elements in $-N_P(0)$. Proposition 4.2 implies that $\zeta_i \rightarrow \zeta$ strongly in $AC^2[0, T]$.

Implicit in the hypotheses of this result is the existence of a solution x_i to each $P(\alpha_i)$, with a corresponding arc p_i , for which the conditions (a)–(c) defining $\zeta_i \in M^{\varepsilon_i}(x_i)$ hold. Now the growth and Lipschitz conditions (H2) on the multifunction F imply similar restrictions on ∂H (see [5, Prop. 3.2.4, p. 121]), so some subsequence of (x_i, p_i) converges weakly in AC^2 to a limiting arc (x, p) . This follows from Proposition 2.1(a); the proof of Proposition 2.1 also shows that one has $g(x(t)) + \alpha(t) \in -P$ and $f(x(0), x(T)) \leq \limsup f(x_i(0), x_i(T)) \leq V(\alpha)$. Hence $x \in \Sigma(\alpha)$.

Now since $\zeta_i'(t)g_{xx}(x_i(t))$ is bounded and converges pointwise to $\zeta'(t)g_{xx}(x(t))$ by Proposition 4.2 and (H5), we infer that

$$(-p_i'(t) + \zeta_i'(t)g_{xx}(x_i(t))x_i'(t), x_i'(t)) \rightarrow (-p'(t) + \zeta'(t)g_{xx}(x(t))x'(t), x'(t))$$

weakly in $L^2([0, T], \mathbf{R}^n \times \mathbf{R}^n)$. Also

$$(x_i(t), p_i(t) - \zeta_i'(t)g_x(x_i(t))) \rightarrow (x(t), p(t) - \zeta'(t)g_x(x(t))) \quad \text{a.e.}$$

The proof of [5, Thm. 3.1.7] shows that this allows us to pass to the limit in Proposition 4.4(b) to obtain

$$(-p'(t) + \zeta'(t)g_{xx}(x(t))x'(t), x'(t)) \in \partial H(t, x(t), p(t) - \zeta'(t)g_x(x(t))) \quad \text{a.e.}$$

Finally, Proposition 4.4(c) states that for some $\delta_i \in \partial f(x_i(0), x_i(T))$ one has

$$(p_i(0) - \zeta_i(0)g_x(x_i(0)), -p_i(T)) - \varepsilon_i \delta_i \in N_C(x_i(0)) \times \{0\}.$$

By passing to a further subsequence if necessary, we may assume that $\delta_i \rightarrow \delta \in \partial f(x(0), x(T))$; it follows that

$$(p(0) - \zeta(0)g_x(x(0)), p(T)) - \varepsilon\delta \in \overline{N_C}(x(0)) \times \{0\}.$$

This completes the proof. \square

COROLLARY 4.7. *If $V(\alpha) < +\infty$ and $M^0(\Sigma(\alpha)) = \{0\}$, then $M^1(\Sigma(\alpha))$ is bounded.*

Proof. If the conclusion were false, then $M^1(\Sigma(\alpha))$ would contain a sequence ζ_i with $\|\zeta_i\| \rightarrow +\infty$. Consider the vectors $z_i = \zeta_i / \|\zeta_i\|$. They form a bounded sequence, so we can extract a subsequence converging weakly to some z . By (4.2), we have

$$z_i \in M^{\varepsilon_i}(\Sigma(\alpha)), \quad \varepsilon_i = \|\zeta_i\|^{-1} \rightarrow 0.$$

It follows from Proposition 4.6 that $z_i \rightarrow z$ strongly, so $\|z\| = 1$, and that $z \in M^0(\Sigma(\alpha))$. This is a contradiction. \square

The following result, using the notation $\Sigma = \Sigma(0)$, establishes the relationship between the multiplier sets $M^e(\Sigma)$ and $N_{\text{epi } V}(0, V(0))$.

PROPOSITION 4.8. *Assume $V(0) < +\infty$, and define N, N^∞ as in (3.2). Then*

$$(4.6) \quad N_{\text{epi } V}(0, V(0)) = \text{cl co } [N \cup N^\infty].$$

In particular, $N \cup N^\infty$ contains nonzero points and therefore

$$(4.7) \quad M^1(\Sigma) \cup [M^0(\Sigma) \setminus \{0\}] \neq \emptyset.$$

Proof. Propositions 1.2 and 1.3 imply that $N_{\text{epi } V}(0, V(0))$ contains nonzero points, so (4.7) will follow immediately once we prove (4.6). Now the definitions given in (1.1) show that the inclusion \supseteq holds in (4.6). To prove the reverse inclusion, it suffices to show that any weak limit of proximal normals $(\zeta, -\varepsilon)$ as described in Proposition 4.6 lies in $N \cup N^\infty$. This is clear if $\varepsilon = 0$, for then $\zeta \in \partial^\infty V(0)$ by construction, while $\zeta \in M^0(\Sigma)$ by Proposition 4.6. So $(\zeta, 0) \in N^\infty$. Likewise, if $\varepsilon > 0$ then the vector $(\zeta, -\varepsilon)/\varepsilon = (\zeta/\varepsilon, -1)$ lies in $N_{\text{epi } V}(0, V(0))$ by construction, so $\zeta/\varepsilon \in \partial V(0)$. But we also have $\zeta/\varepsilon \in M^1(\Sigma)$ by Proposition 4.6 and the scaling property (4.2). Hence $(\zeta, -\varepsilon) \in N$. \square

Conclusion (4.7) is a succinct statement of the necessary conditions for optimality in $P(0)$. It says that some $x \in \Sigma$ either gives rise to a multiplier $\zeta \in M^1(x)$, or else yields a nontrivial multiplier $\zeta \in M^0(x)$. This is easily extended to treat each x in Σ separately: indeed, the same proof as in [5, Thm. 3.5.2] establishes the following.

THEOREM 4.9 (Necessary Conditions). *Let $V(0) < +\infty$. Then $\Sigma \neq \emptyset$, and*

$$(4.8) \quad M^1(x) \cup [M^0(x) \setminus \{0\}] \neq \emptyset \quad \forall x \in \Sigma.$$

As advertised, however, proximal normal analysis does more than offer a new approach to necessary conditions for optimality. It also enables us to write down a formula for $\partial V(0)$.

THEOREM 4.10 (Sensitivity). *Let $V(0) < +\infty$ and assume (H1)–(H6). Then*

$$(4.9) \quad \partial V(0) = \text{cl co } [\partial V(0) \cap M^1(\Sigma) + \partial^\infty V(0) \cap M^0(\Sigma)].$$

If $M^0(\Sigma) = \{0\}$ then $\partial^\infty V(0) = \{0\}$. In this case $\partial V(0)$ is a nonempty norm-compact convex subset of $AC^2[0, T]$ obeying

$$\text{ext } \partial V(0) \subseteq M^1(\Sigma).$$

Proof. Conclusion (4.9) follows straight from Propositions 4.8 and [13, Prop. 4.2]. To deduce the additional conclusions, note first that $M^0(\Sigma) = \{0\}$ implies $N^\infty = \{0\}$, so

N contains nonzero points by Proposition 4.8. In particular, $\partial V(0)$ is a nonempty set which, by (4.9), obeys

$$(4.10) \quad \partial V(0) = \text{cl co } [\partial V(0) \cap M^1(\Sigma)] \subseteq \text{cl co } M^1(\Sigma).$$

Now $M^1(\Sigma)$ is a bounded set by Corollary 4.7, so the set $\partial V(0)$ is a nonempty, closed, convex, and bounded subset of $-N_P(0)$. It follows that every sequence ζ_i chosen from $\partial V(0)$ has a weakly convergent subsequence, and that this subsequence actually converges strongly by Proposition 4.2. So $\partial V(0)$ is compact, as claimed. The conclusion that $\text{ext } \partial V(0) \subseteq M^1(\Sigma)$ follows from (4.10) and the fact that $M^1(\Sigma)$ is closed is proven in Proposition 4.6. \square

Controllability and penalization. Problem $P(0)$ is called *normal* if $M^0(\Sigma) = \{0\}$. From Theorem 4.10 we deduce that the value function for a normal problem is Lipschitz near 0, a fact which has attractive consequences both for controllability and for exact penalization. For instance, a value function which is Lipschitz near 0 must certainly be finite near 0, from which it follows that a feasible trajectory for the system

$$x'(t) \in F(t, x(t)) \quad \text{a.e.,} \quad x(0) \in C, \quad g(x(t)) \leq -\alpha(t) \quad \forall t$$

exists whenever α is chosen sufficiently near to 0 in AC^2 . Of course, a Lipschitz condition on V implies more than the local finiteness of V , so stronger controllability conclusions than this are readily available. We will not present these in detail: the reader may consult [5, Thm. 3.5.3] to discover the spirit of such results.

A related issue, with applications in numerical analysis, is exact penalization. If the original problem is normal, then all of its solutions will be found among the solutions to a modified problem in which there are no state constraints. The AC^2 -norm is used in the following result.

COROLLARY 4.11. *Suppose $P(0)$ is normal, and $x^* \in \Sigma$. Then there is a constant $M > 0$ so large that x^* provides a local solution for the problem*

$$\min \{f(x(0), x(T)) + M \|g(x(t))^+\| : x'(t) \in F(t, x(t)) \text{ a.e., } x(0) \in C\}.$$

Here $g^+ = \max\{0, g\}$, and “local solution” refers to a neighbourhood of x^* in the norm topology of AC^2 .

Proof. Since $P(0)$ is normal, $V(\cdot)$ is Lipschitz near 0 by Theorem 4.10. In particular, there exist positive constants ε and M such that

$$\|\alpha\| < \varepsilon \Rightarrow V(0) \leq V(\alpha) + M \|\alpha\|.$$

Now (H5) ensures that the mapping $x \rightarrow g(x)^+$ from AC^2 into AC^2 is continuous near x^* , so there exists $\delta > 0$ such that $\|x - x^*\| < \delta$ implies $\|g(x(\cdot))^+\| < \varepsilon$. But for any F -trajectory x with $x(0) \in C$, one has $V(-g(x(\cdot))^+) \leq f(x(0), x(T))$. So if x also obeys $\|x - x^*\| < \delta$, we obtain

$$\begin{aligned} f(x^*(0), x^*(T)) &= V(0) \\ &\leq V(-g(x)^+) + M \|g(x)^+\| \\ &\leq f(x(0), x(T)) + M \|g(x)^+\|. \end{aligned} \quad \square$$

AN ANALYSIS OF THE POLE-ZERO CANCELLATIONS IN H^∞ -OPTIMAL CONTROL PROBLEMS OF THE FIRST KIND*

D. J. N. LIMEBEER† AND Y. S. HUNG‡

Abstract. The aim of this paper is to study the pole-zero cancellations which occur in a class of H^∞ -optimal control problems which may be embedded in the configuration of Fig. 1. H^∞ control problems are said to be of the first kind if both $P_{12}(s)$ and $P_{21}(s)$ are square but not necessarily of the same size. It is primarily this class of problems which will concern us here. A general bound on the McMillan degree of all controllers which are stabilizing and lead to a closed loop which satisfies $\|\mathcal{R}(s)\|_\infty \leq \rho$ (ρ need not be optimal in the L^∞ -norm sense) is derived. As illustrated in Fig. 1, $\mathcal{R}(s)$ is the transfer function relating $y_1(s)$ to $u_1(s)$. If the McMillan degree of $P(s)$ in Fig. 1 is n , we show that in the single-loop (SISO) case the corresponding (unique) H^∞ -optimal controller never requires more than $n-1$ states. In the multivariable case, there is a continuum of optimal controllers whose McMillan degree satisfies this same bound, although other controllers with higher McMillan degree also exist. The derivation of these bounds require several steps, each of which is of independent system theoretic interest.

Key words. pole-zero cancellations, H^∞ -optimal control, approximation theory, Nehari's Theorem, degree bounds

AMS(MOS) subject classification. 93C35

1. Introduction. Figure 1 represents a generalized, or abstract, regulator configuration in which a large class of H^∞ -optimal control problems may be embedded. If $P_{12}(s)$ and $P_{21}(s)$ are square, we call the associated problem a problem of the first kind. (Problems of the second kind are characterized by having either $P_{12}(s)$ or $P_{21}(s)$ nonsquare. If both off-diagonal blocks are nonsquare, the problem is said to be of the third kind.) Depending on the specific design situation, the inputs $u_1(s)$ could be references, external disturbances, sensor noise signals or the outputs of models representing unknown plant dynamics. The outputs $y_1(s)$, on the other hand, may be plant outputs, plant inputs or the signals driving plant perturbation models. The H^∞ control problem for Fig. 1 is to minimize the L^∞ -norm of $\mathcal{R}(s)$ as $K(s)$ is allowed to range over the set of all stabilizing controllers. The general theory of these problems is now well developed and we refer the reader to the expository articles of Francis and Doyle [10], Doyle et al. [6], Safonov et al. [22] and the numerous references therein for details.

FIG. 1. Generalized regulator configuration.

‡ Electronic and Electrical Engineering Department, University of Surrey, Guildford, Surrey, England.

The purpose of this paper is to carry out a detailed analysis of the cancellation phenomena which occur as a result of H^∞ -optimality in the standard regulator configuration mentioned above. Although algorithms for computing these controllers already exist [6], [22], the procedure is so involved that issues such as McMillan degree propagation and the final controller order are obscure. A naive inspection of the procedure may lead one to suspect that the controller degree is several times higher than that of $P(s)$. Since high order controllers are inevitably preceded by computations in high dimensional state-space, expensive and unreliable computations are likely to cause difficulty in complicated design situations. For these reasons, it is our opinion that the complete structural analysis of the computational framework which is presented here will lead to improved computational methods and will also shed light on several aspects of the theory. Our approach is to analyse the entire calculation process in the state-space. This has the advantage of establishing clear links between the theoretical development and existing computer algorithms [6], [22] and also allows one to use Glover's explicit parametrization of all solutions to the Nehari extension problem [12]. This methodology has also been successfully employed in the analysis of cancellation phenomena in H^∞ problems of the second kind. This will be reported on elsewhere [16].

The paper is organized as follows: In § 2 we define notation, describe the problem in specific terms and briefly review the relevant parametrization and optimization theory. Theorem 2.1 is a reformulation of an existing result and it gives an explicit state-space characterization of all the solutions of the L^∞ -norm optimization problem in terms of bounded real type equations. In § 3, we establish by way of balancing two Riccati equations associated with the parametrization, the role of the right and left half plane zeros of $P_{12}(s)$ and $P_{21}(s)$. In the case of some problems of the first kind, the lowest achievable infinity norm of the closed loop can be expressed in terms of the solutions to these Riccati equations. Lemma 3.1 and Theorem 3.2 are new results. In § 4, we study the pole-zero cancellations which occur in the closed loop of Fig. 1 when $K(s)$ is chosen to be H^∞ -optimal (or suboptimal in a sense to be defined later). This will lead to a general McMillan degree bound for all these controllers. An illustrative example is presented which shows that midcalculation model reduction can produce undesirable effects if done in an ill-advised way. An extension of the McMillan degree bound to the case of minimum entropy controllers is also given in this section. The five results given in § 4 are all believed to be new. Section 5 contains the conclusions. All the proofs have been placed in a series of Appendices.

Some of the proofs involve long calculations. For the reader's convenience, we have written the paper so that no loss of continuity is experienced if these proofs are not studied in the first instance.

2. Notation and background theory.

2.1. Notation.

\mathbb{R}, \mathbb{C}	fields of real and complex numbers,
$\mathbb{R}(s)$	field of rational functions in s with real coefficients,
$\mathbb{F}^{m \times l}$	set of $m \times l$ matrices with elements in \mathbb{F} ($=\mathbb{R}, \mathbb{C}, \mathbb{R}(s)$ etc.),
$\mathbb{C}_+, \bar{\mathbb{C}}_+$	open (resp. closed) right half plane,
$\mathbb{C}_-, \bar{\mathbb{C}}_-$	open (resp. closed) left half plane,
$\lambda(A), \lambda_{\max}(A)$	eigenvalues of a square matrix A , largest eigenvalue of A ,
A^*	complex conjugate transpose of $A \in \mathbb{C}^{m \times l}$ (transpose if $A \in \mathbb{R}^{m \times l}$),
$\text{In}(A)$	$=(\pi, \nu, \delta)$, the inertia of A , where π, ν and δ are the number of eigenvalues of A in $\mathbb{C}_+, \mathbb{C}_-$ and the $j\omega$ (imaginary) axis,
$A \geq 0, A > 0$	A is positive semidefinite (resp. positive definite),
$A \leq 0, A < 0$	A is negative semidefinite (resp. negative definite),

RL^∞	space of matrices in $\mathbb{R}(s)^{m \times l}$ which have no poles on the $j\omega$ axis (including the point at ∞),
$\ \cdot\ _\infty$	L^∞ -norm of matrices in RL^∞ ,
RH_+^∞, RH_-^∞	subspaces of RL^∞ of matrices which have no poles in \mathbb{C}_+ (resp. \mathbb{C}_-),
Γ_G	Hankel operator associated with $G(s) \in RH_+^\infty$,
$\sigma_i(G(s))$	i th Hankel singular value of $G(s)$ (i.e. of Γ_G) in decreasing order of magnitude,
$\ G(s)\ _H$	$=\sigma_1(G(s))$, the Hankel norm of $G(s)$,
$\operatorname{Re}(s), \bar{s}, s $	the real part, complex conjugate and modulus of $s \in \mathbb{C}$,
$G^*(s)$	$=G(-\bar{s})^*$, the parahermitian conjugate of $G(s)$,
$\Rightarrow, \Leftarrow, \Leftrightarrow$	implies, is implied by, if and only if.

Associated with a transfer function matrix $G(s) \in \mathbb{R}(s)^{m \times l}$ of McMillan degree n is a state-space realization

$$(2.1a) \quad G(s) = D + C(sI - A)^{-1}B$$

where $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times l}$, $C \in \mathbb{R}^{m \times n}$, and $D \in \mathbb{R}^{m \times l}$. We will use the alternative notation $G(s) = (A, B, C, D)$ or

$$(2.1b) \quad G(s) = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array} \right].$$

In the above notation, we have $G^*(s) = (-A^*, C^*, -B^*, D^*)$ and in the case that D is nonsingular, we also have $G^{-1}(s) = (A - BD^{-1}C, BD^{-1}, -D^{-1}C, D^{-1})$. If $G^{-1}(s) = G^*(s)$, then $G(s)$ is all-pass. $G(s)$ is called stable (asymptotically stable) if it has no poles in \mathbb{C}_+ (resp. $\bar{\mathbb{C}}_+$).

If $G(s) = (A, B, C, D)$ the system matrix corresponding to the given realization is defined as [19]

$$\left[\begin{array}{c|c} sI - A & -B \\ \hline C & D \end{array} \right]$$

and the system zeros are defined to be the points at which the system matrix loses normal rank. In the case when D is nonsingular, the system zeros are also given by $\lambda(A - BD^{-1}C)$. The input decoupling zeros (uncontrollable modes) are points at which $[sI - A \ B]$ loses rank. The output decoupling zeros (unobservable modes) are the points at which $[sI - A^* \ C^*]$ loses rank. In the sequel, the term “zero” refers to “system zero” unless stated otherwise. Obviously, {input decoupling zeros} \cup {output decoupling zeros} is a subset of both $\lambda(A)$ and the set of system zeros. The realization (A, B, C, D) is minimal if it has no input/output decoupling zeros. A sufficient condition for this is that all system zeros are distinct from $\lambda(A)$.

If $G_1(s) = (A_1, B_1, C_1, D_1)$ and $G_2(s) = (A_2, B_2, C_2, D_2)$ then the cascade system $G_1G_2(s)$ has a realization given by

$$(2.2) \quad \left[\begin{array}{c|c} A_1 & B_1 \\ \hline C_2 & D_2 \end{array} \right] \left[\begin{array}{c|c} A_2 & B_2 \\ \hline C_1 & D_1 \end{array} \right] = \left[\begin{array}{cc|c} A_1 & B_1C_2 & B_1D_2 \\ 0 & A_2 & B_2 \\ \hline C_1 & D_1C_2 & D_1D_2 \end{array} \right],$$

where we have taken the “multiplication” of two realizations to mean cascading the two systems. This is not to be confused with ordinary matrix multiplication. The context will always make the distinction between these two possible interpretations clear.

If a basis change T is introduced into the state-space of $G(s)$, we will take this to mean $G(s) = (TAT^{-1}, TB, CT^{-1}, D)$. The McMillan degree of $G(s)$ will be written as $\deg(G)$ and the set of poles of $G(s)$ will be denoted {poles of G }.

Let $P(s)$ be a partitioned matrix with a state-space realization given by

$$(2.3) \quad P(s) = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} (s) = \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{22} \end{array} \right],$$

then

$$(2.4) \quad P_{ij}(s) = C_i(sI - A)^{-1}B_j + D_{ij}$$

is a state-space realization of $P_{ij}(s)$. A linear fractional transformation of the partitioned matrix P and a matrix K is defined as

$$F_l(P, K) = P_{11} + P_{12}K(I - P_{22}K)^{-1}P_{21}$$

where K is of dimension $l \times m$ if P_{22} has dimension $m \times l$.

2.2. Problem description. Consider the generalized regulator configuration illustrated in Fig. 1. From the equations governing this diagram we see that the transfer function relating y_1 to u_1 is given by

$$\begin{aligned} \mathcal{R}(s) &= F_l(P, -K) \\ &= P_{11} - P_{12}K(I + P_{22}K)^{-1}P_{21}. \end{aligned}$$

We seek to bound the McMillan degrees of all the compensators $K(s)$ which simultaneously achieve an internally stable closed loop and minimize $\|\mathcal{R}(s)\|_\infty$. Throughout this paper we will assume that $P_{12}(s)$ and $P_{21}(s)$ are square (although not necessarily of the same size). We also assume that both D_{12} and D_{21} are nonsingular and that $P_{12}(s)$ and $P_{21}(s)$ have no zeros on the imaginary axis.

It is worth noting that two particular H^∞ -optimal control problems which have already received particular attention can be posed in the above setting. The first is the optimal sensitivity problem which has been analysed by Zames and others [3], [7], [8], [21], [27], [28]. In this case we wish to minimize the L^∞ -norm of a weighted sensitivity operator given by

$$(2.5) \quad \mathcal{R}_s(s) = [W_2(I + GK)^{-1}W_1](s)$$

where $G(s)$ is the transfer function of a square plant, and $W_1(s)$ and $W_2(s)$ are weighting matrices. If we put

$$(2.6) \quad P_s(s) = \left[\begin{array}{c|c} W_2W_1 & W_2G \\ \hline W_1 & G \end{array} \right] (s),$$

then direct calculation shows that

$$\mathcal{R}_s(s) = F_l(P_s(s), -K(s)).$$

The second problem is the optimal robustness problem which has been studied by Glover [13] and Kimura [15]. In the case of optimal robustness with respect to additive perturbations to the plant transfer function, we wish to minimize the L^∞ -norm of

$$(2.7) \quad \mathcal{R}_a(s) = [W_2K(I + GK)^{-1}W_1](s).$$

It can be readily shown that if we set

$$(2.8) \quad P_a(s) = \left[\begin{array}{c|c} 0 & W_2 \\ \hline -W_1 & G \end{array} \right] (s)$$

then

$$\mathcal{R}_a(s) = F_l(P_a(s), -K(s)).$$

In the sequel, we will study the general class of problems of the first kind and establish common pole-zero cancellation properties which are shared by the specific problems just mentioned.

2.3. Review of H^∞ -optimization theory. The solution of H^∞ -optimal control problems may be subdivided into two distinct steps. In the first, all the compensators which lead to an internally stable closed loop in Fig. 1 are parametrized. The second step then identifies a subclass of stabilizing compensators which minimize $\|\mathcal{R}(s)\|_\infty$ or else satisfy $\|\mathcal{R}(s)\|_\infty \leq \rho \in \mathbb{R}$. In the following sections, we will briefly describe the calculations involved in these two steps.

2.3.1. Parametrization of all stabilizing controllers. Let $P(s)$ in Fig. 1 be given by (2.3) and suppose that (A, B_2, C_2) is stabilizable and detectable. Under these conditions $K(s)$ stabilizes the feedback system in Fig. 1 if and only if it stabilizes $P_{22}(s)$. Further, such stabilizing compensators always exist [6], [22]. Let

$$(2.9) \quad P_{22}(s) = N_r(s)D_r^{-1}(s) = D_l^{-1}(s)N_l(s)$$

be right and left rational coprime fractional factorizations of $P_{22}(s)$ and

$$(2.10) \quad \begin{bmatrix} V_r & U_r \\ -N_l & D_l \end{bmatrix}(s) \begin{bmatrix} D_r & -U_l \\ N_r & V_l \end{bmatrix}(s) = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}$$

the corresponding Bezout identities. All the matrices in (2.10) belong to RH_+^∞ and the set of all compensators which stabilize $P_{22}(s)$, and thus also $P(s)$, are given by [4], [26]

$$(2.11) \quad K(s) = (U_l + D_r Q)(V_l - N_r Q)^{-1}(s)$$

$$(2.12) \quad = (V_r - Q N_l)^{-1}(U_r + Q D_l)(s)$$

in which the indicated inverses are assumed to exist and $Q(s) \in RH_+^\infty$. It is easy to verify that

$$(2.13) \quad K(I + P_{22}K)^{-1}(s) = (U_l + D_r Q)D_l(s).$$

Hence

$$(2.14) \quad \begin{aligned} \mathcal{R}(s) &= [P_{11} - P_{12}K(I + P_{22}K)^{-1}P_{21}](s) \\ &= [(P_{11} - P_{12}U_l D_l P_{21}) - (P_{12}D_r)Q(D_l P_{21})](s) \\ &= [T_{11} - T_{12}QT_{21}](s) \end{aligned}$$

where the $T_{ij}(s)$ are defined in an obvious way. Equation (2.14) shows that $\mathcal{R}(s)$ is parametrized linearly in $Q(s)$. Since $\mathcal{R}(s) \in RH_+^\infty$ if and only if $Q(s) \in RH_+^\infty$, we would expect that T_{11} , T_{12} and T_{21} all belong to RH_+^∞ .

Since (A, B_2) is stabilizable, there exists a state feedback matrix F such that $A - B_2 F$ is stable. Similarly, since (A, C_2) is detectable there exists an output injection matrix H such that $A - H C_2$ is stable. Given any such pair of stabilizing matrices F and H , the right and left coprime factorizations of P_{22} together with the solutions of the Bezout identities are given by [6], [18]

$$(2.15) \quad \begin{bmatrix} D_r & -U_l \\ N_r & V_l \end{bmatrix}(s) = \left[\begin{array}{c|cc} A - B_2 F & B_2 & H \\ -F & I & 0 \\ \hline C_2 - D_{22} F & D_{22} & I \end{array} \right]$$

and

$$(2.16) \quad \begin{bmatrix} V_r & U_r \\ -N_l & D_l \end{bmatrix} (s) = \left[\begin{array}{c|cc} A - HC_2 & B_2 - HD_{22} & H \\ \hline F & I & 0 \\ -C_2 & -D_{22} & I \end{array} \right].$$

Using (2.11) and (2.12), it can be verified by direct calculation that the family of all stabilizing compensators can be parametrized in terms of the linear fractional transformation [6]

$$(2.17) \quad K(s) = F_l(K_0(s), Q(s))$$

where

$$(2.18) \quad \begin{aligned} K_0(s) &= \begin{bmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{bmatrix} (s) = \begin{bmatrix} V_r^{-1} U_r & V_r^{-1} \\ V_l^{-1} & V_l^{-1} N_r \end{bmatrix} (s) \\ &= \left[\begin{array}{c|cc} A - B_2 F - HC_2 + HD_{22} F & -H & B_2 - HD_{22} \\ \hline -F & 0 & I \\ C_2 - D_{22} F & I & D_{22} \end{array} \right]. \end{aligned}$$

A routine computation will show that the realization of $K_0(s)$ in (2.18) is minimal if (A, B_2, C_2) is minimal.

In order to simplify later calculations, it is helpful at this point to scale (2.3) by replacing it with

$$(2.19) \quad P(s) = \left[\begin{array}{c|cc} A & B_1 & B_2 S_1 \\ \hline C_1 & D_{11} & D_{12} S_1 \\ S_2 C_2 & S_2 D_{21} & S_2 D_{22} S_1 \end{array} \right],$$

in which $S_1 = D_{12}^{-1}$ and $S_2 = D_{21}^{-1}$. From now on we will assume that $P(s)$ has been scaled so that both the (1, 2) and (2, 1) blocks of the D -matrix are identities; we therefore assume that the S_i 's have already been absorbed into B_2 , C_2 and D_{22} . Such an assumption does not incur any loss of generality in our development because the effect of any prescaling on the compensator to bring $P(s)$ into the form of (2.19) may be reversed by replacing $K(s)$ with $S_1 K(s) S_2$ at the end of the design process [22]. We now make the following specific choices of the pair of stabilizing matrices F and H , as was suggested by Doyle et al. [6]:

$$(2.20) \quad F = C_1 + B_2^* X$$

where X is the unique positive semidefinite stabilizing solution to the algebraic Riccati equation

$$(2.21) \quad X(A - B_2 C_1) + (A - B_2 C_1)^* X - X B_2 B_2^* X = 0$$

and

$$(2.22) \quad H = B_1 + Y C_2^*$$

where Y is the unique positive semidefinite stabilizing solution to the algebraic Riccati equation

$$(2.23) \quad Y(A - B_1 C_2)^* + (A - B_1 C_2) Y - Y C_2^* C_2 Y = 0.$$

It can be shown that the $T_{ij}(s)$ of (2.14) are then given by

$$(2.24) \quad T(s) = \begin{bmatrix} T_{11} & T_{12} \\ T_{21} & 0 \end{bmatrix} (s) = \left[\begin{array}{cc|cc} A - B_2 F & B_2 F & B_1 & B_2 \\ 0 & A - H C_2 & -Y C_2^* & 0 \\ \hline -B_2^* X & F & D_{11} & I \\ 0 & C_2 & I & 0 \end{array} \right].$$

Note that $T_{12}(s)$, $T_{21}(s)$ and $T_{11}(s)$ belong to RH_+^∞ as expected. Further, F and H have been chosen to make $T_{12}(s)$ and $T_{21}(s)$ inner [6].

2.3.2. Parametrization of all H^∞ -optimal controllers. In this section we briefly review the parametrization of all optimal $Q(s) \in RH_+^\infty$ which solve the minimization problem

$$(2.25) \quad \min \| (T_{11} - T_{12} Q T_{21})(s) \|_\infty = \| T_{12}^* T_{11} T_{21}^*(-s) \|_H, \quad Q \in RH_+^\infty$$

or suboptimal $Q(s) \in RH_+^\infty$ which satisfy

$$(2.26) \quad \| (T_{11} - T_{12} Q T_{21})(s) \|_\infty \leq \rho \in \mathbb{R}$$

for some given $\rho > \| T_{12}^* T_{11} T_{21}^*(s) \|_H$.

Due to the norm-preserving properties of the inner matrices $T_{12}(s)$ and $T_{21}(s)$, we may write [21]

$$(2.27) \quad \| (T_{11} - T_{12} Q T_{21})(s) \|_\infty = \| (T_{12}^* T_{11} T_{21}^* - Q)(s) \|_\infty.$$

From (2.24), we obtain

$$(2.28) \quad T_{12}^* T_{11} T_{21}^*(s) = \left[\begin{array}{cc|c} -(A - B_2 F)^* & X(B_2 D_{11} - B_1) C_2 Y & X(B_1 - B_2 D_{11}) \\ 0 & -(A - H C_2)^* & -C_2^* \\ \hline -B_2^* & (F - D_{11} C_2) Y & D_{11} \end{array} \right]$$

which shows that $T_{12}^* T_{11} T_{21}^*(s) \in RH_-^\infty$. Setting $T_{12}^* T_{11} T_{21}^*(s) = X^*(s)$ we get

$$(2.29) \quad \| (T_{11} - T_{12} Q T_{21})(s) \|_\infty = \| X(s) - Q^*(s) \|_\infty$$

which turns (2.25) into a multivariable version of the Nehari extension problem [17]. We will call any $Q(s) \in RH_+^\infty$ which satisfies (2.26) a ρ -suboptimal extension. Glover has shown that all $Q^*(s)$ which satisfy (2.25) or (2.26) may be generated by means of a balanced realization of $X(s)$. In [12], the characterization of all $Q^*(s)$ in the general nonsquare case is given in terms of a linear fractional transformation of transfer function matrices (see [12, Thm. 8.7]). We will however need a state-space version of this characterization in order to derive the main results in § 4. This is stated in the next theorem and a proof which makes use of [12, Thm. 8.7] is given in Appendix A.

THEOREM 2.1. *Let $X(s) = (A, B, C, D)$ be a stable, minimal and balanced realization with Hankel singular values*

$$\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_k > \sigma_{k+1} = \sigma_{k+2} = \dots = \sigma_{k+r} > \sigma_{k+r+1} \geq \dots \geq \sigma_n > 0.$$

Assume that the Hankel singular values have been arranged so that the gramians are given by

$$(2.30) \quad \text{diag}(\Sigma, \sigma_{k+1} I_r)$$

where

$$\Sigma = \text{diag}(\sigma_1, \dots, \sigma_k, \sigma_{k+r+1}, \sigma_n)$$

and let (A, B, C) be partitioned conformally with (2.30)

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \quad B = \begin{bmatrix} B_1 \\ B_2 \end{bmatrix}, \quad C = [C_1 \quad C_2].$$

Also let

$$(2.31) \quad \Gamma = \Sigma^2 - \sigma_{k+1}^2 I.$$

Then for any error system $E(s) = X(s) - \hat{X}(s) - Q^*(s)$ with

(a) $\|E(j\omega)\|_\infty \leq \sigma_{k+1}$;

(b) $\hat{X}(s)$ is stable of McMillan degree k and $Q^*(s)$ is totally unstable there exists $\hat{A}, \hat{B}, \hat{C}$ and \hat{D} such that $E(s)$ has a realization

$$(2.32) \quad E(s) = \left[\begin{array}{cc|cc|c} A_{11} & A_{12} & 0 & 0 & B_1 \\ A_{21} & A_{22} & 0 & 0 & B_2 \\ 0 & 0 & \Gamma^{-1}(\sigma_{k+1}^2 A_{11}^* + \Sigma A_{11} \Sigma & \Gamma^{-1} C_1^* \hat{C} & \Gamma^{-1}(\Sigma B_1 + \sigma_{k+1} C_1^* \hat{D}) \\ & & -\sigma_{k+1} C_1^* \hat{D} B_1^* & & \\ 0 & 0 & -\sigma_{k+1} \hat{B} B_1^* & \hat{A} & \sigma_{k+1} \hat{B} \\ \hline C_1 & C_2 & -(C_1 \Sigma + \sigma_{k+1} \hat{D} B_1^*) & \hat{C} & \sigma_{k+1} \hat{D} \end{array} \right] = \begin{bmatrix} A_e & B_e \\ C_e & D_e \end{bmatrix}$$

which satisfies both

$$(2.33) \quad \begin{bmatrix} -(A_e P_e + P_e A_e^* + B_e B_e^*) & -(B_e D_e^* + P_e C_e^*) \\ -(D_e B_e^* + C_e P_e) & \sigma_{k+1}^2 I - D_e D_e^* \end{bmatrix} = \begin{bmatrix} L_e \\ W_e \end{bmatrix} [L_e^* | W_e^*],$$

and

$$(2.34) \quad \begin{bmatrix} -(A_e^* Q_e + Q_e A_e + C_e^* C_e) & -(C_e^* D_e + Q_e B_e) \\ -(D_e^* C_e + B_e^* Q_e) & \sigma_{k+1}^2 I - D_e^* D_e \end{bmatrix} = \begin{bmatrix} L_{ed}^* \\ W_{ed}^* \end{bmatrix} [L_{ed} | W_{ed}]$$

where in the above equations

$$P_e = \begin{bmatrix} \Sigma & 0 & I & 0 \\ 0 & \sigma_{k+1} I_r & 0 & 0 \\ I & 0 & \Sigma \Gamma^{-1} & 0 \\ 0 & 0 & 0 & \sigma_{k+1}^2 \hat{P} \end{bmatrix}, \quad Q_e = \begin{bmatrix} \Sigma & 0 & -\Gamma & 0 \\ 0 & \sigma_{k+1} I_r & 0 & 0 \\ -\Gamma & 0 & \Sigma \Gamma & 0 \\ 0 & 0 & 0 & \hat{Q} \end{bmatrix}$$

and

$$(2.35a) \quad L_e^* = [0 \ 0 \ \sigma_{k+1} \hat{W}^* C_1 \Gamma^{-1} \ \sigma_{k+1} \hat{L}^*], \quad L_{ed} = [0 \ 0 \ -\sigma_{k+1} \hat{W}_d B_e^* \ \hat{L}_d]$$

for some $\hat{L}, \hat{L}_d, \hat{W}, \hat{W}_d, \hat{P} = \hat{P}^* < 0, \hat{Q} = \hat{Q}^* < 0$ and further

$$(2.35b) \quad W_e = \sigma_{k+1} \hat{W}, \quad W_{ed} = \sigma_{k+1} \hat{W}_d \quad \text{and} \quad P_e Q_e = \sigma_{k+1}^2 I. \quad \square$$

Remark 2.1. Note that (2.33) and (2.34) are reminiscent of the state-space characterization of bounded real matrices [1], as one would expect because of the condition (a) on $E(s)$. We note however that $E(s)$ is in general not bounded real in the strict sense since it may contain unstable poles.

Remark 2.2. When giving a bounded real type state-space characterization of ρ -suboptimal extensions we make use of the idea given in [12, Remark 8.4]. In this case (2.33) and (2.34) remain in force, $\Gamma = \Sigma^2 - \rho^2 I$ replaces (2.31) (with $\sigma_k > \rho > \sigma_{k+1}$),

$$(2.36) \quad E(s) = \left[\begin{array}{cc|cc|c} A & 0 & 0 & 0 & B \\ 0 & \Gamma^{-1}(\rho^2 A^* + \Sigma A \Sigma - \rho C^* \hat{D} B^*) & \Gamma^{-1} C^* \hat{C} & \Gamma^{-1}(\Sigma B + \rho C^* \hat{D}) & \\ 0 & -\rho \hat{B} B^* & \hat{A} & \rho \hat{B} & \\ \hline C & -(C \Sigma + \rho \hat{D} B^*) & \hat{C} & \rho \hat{D} & \end{array} \right]$$

replaces (2.32),

$$(2.37) \quad P_e = \begin{bmatrix} \Sigma & I & 0 \\ I & \Sigma\Gamma^{-1} & 0 \\ 0 & 0 & \rho^2\hat{P} \end{bmatrix}, \quad Q_e = \begin{bmatrix} \Sigma & -\Gamma & 0 \\ -\Gamma & \Sigma\Gamma & 0 \\ 0 & 0 & \hat{Q} \end{bmatrix}$$

and

$$L_e^* = [0 \quad \rho\hat{W}^*C\Gamma^{-1} \quad \rho\hat{L}^*], \quad L_{ed} = [0 \quad -\rho\hat{W}_dB^* \quad \hat{L}_d],$$

replace (2.35a) and $W_e = \rho\hat{W}$, $W_{ed} = \rho\hat{W}_d$ and $P_eQ_e = \rho^2I$ replace (2.35b).

For readers who are interested in following through the proof for the ρ -suboptimal case, (A.4) in Appendix A should be replaced by

$$(2.38) \quad \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}(s) = \left[\begin{array}{c|cc} \Gamma^{-1}(\rho^2A^* + \Sigma A \Sigma) & \Gamma^{-1}\Sigma B & -\Gamma^{-1}C^* \\ \hline C\Sigma & D & I \\ -\rho B^* & \rho I & 0 \end{array} \right].$$

Conditions (A.5) and (A.6) remain valid but (A.7) no longer applies.

Remark 2.3. Theorem 2.1 and Remark 2.2 are more general than we need in H^∞ -optimal control problems since they give a state-space characterization of all error systems associated with Hankel norm approximation problems whereas we are only interested in optimal anticausal (or Nehari) type approximations. Specifically, we will make use of Theorem 2.1 (or Remark 2.2) with $k=0$ (zeroth order Hankel approximation) so that $\hat{X}(s)=0$ and $Q(s)$ becomes a Nehari extension (or ρ -suboptimal extension) of $X(s)$. Also $\|E(s)\|_\infty = \sigma_1$ or $\|E(s)\|_\infty \leq \rho$ (where $\rho > \sigma_1$) for the optimal or ρ -suboptimal case respectively. \square

COROLLARY 2.2. In the notation of Theorem 2.1 and Remark 2.2 let $k=0$ and $U(s)=[\hat{A}, \hat{B}, \hat{C}, \hat{D}]$ (see (2.32) and the proof of Theorem 2.1). Then

(i) If $Q(s)$ is a Nehari extension of $X(s)$,

$$(2.39) \quad \deg(Q) \leq \deg(X) - r + \deg(U)$$

where r is the multiplicity of the largest Hankel singular value of X ;

(ii) If $Q(s)$ is a ρ -suboptimal extension of $X(s)$,

$$(2.40) \quad \deg(Q) \leq \deg(X) + \deg(U). \quad \square$$

This corollary follows immediately from an inspection of (2.32) and (2.36).

Remark 2.4. For $k=0$, Theorem 2.1 characterizes all

$$(2.41) \quad E(s) = X(s) - Q^*(s)$$

satisfying conditions (a) and (b). At certain points in the sequel, it is more convenient to work with a realization for $E^*(s) = X^*(s) - Q(s)$ instead of (2.41). For this purpose, we remark here that the form of the bounded real type equations (2.33) and (2.34) is invariant under parahermitian conjugation. It is easy to see that if $E(s) \rightarrow E^*(s)$, then we only need to perform the following substitutions in (2.33) and (2.34)

$$\begin{aligned} A_e &\rightarrow -A_e^*, & B_e &\rightarrow C_e^*, & C_e &\rightarrow -B_e^*, \\ D_e &\rightarrow D_e^*, & P_e &\rightarrow -Q_e, & Q_e &\rightarrow -P_e. \end{aligned}$$

3. Balancing Riccati equations. In this section we will establish some preliminary results which will be needed in the later analysis.

It is well known that the H^∞ -optimization problem given by (2.25), or equivalently (2.29), is equivalent to a matrix version of the classical Nevanlinna–Pick interpolation problem, the set of interpolation points being the right half plane zeros of $T_{12}(s)$ and $T_{21}(s)$. Since $T_{12}(s)$ and $P_{12}(s)$, and $T_{21}(s)$ and $P_{21}(s)$ have the same zeros, it is clear that the set of interpolation points is

$$\{\text{zeros of } P_{12}(s) \text{ in } \mathbb{C}_+\} \cup \{\text{zeros of } P_{21}(s) \text{ in } \mathbb{C}_+\}.$$

In this section we will bring this issue into sharp focus by balancing the two Riccati equations (2.21) and (2.23). Furthermore, we will show that the number of right half plane zeros of $P_{12}(s)$ and $P_{21}(s)$ are given, respectively, by the ranks of the solutions X and Y to these two equations.

Consider a change of basis T in the state-space of $P(s)$ in (2.19). In this new basis, $P(s)$ becomes

$$P(s) = \left[\begin{array}{c|cc} TAT^{-1} & TB_1 & TB_2 \\ \hline C_1 T^{-1} & D_{11} & I \\ C_2 T^{-1} & I & D_{22} \end{array} \right]$$

and the algebraic Riccati equation (2.21) becomes

$$(3.1) \quad X(TAT^{-1} - TB_2 C_1 T^{-1}) + (TAT^{-1} - TB_2 C_1 T^{-1})^* X - XTB_2 B_2^* T^* X = 0$$

or equivalently

$$(3.2) \quad T^* XT(A - B_2 C_1) + (A - B_2 C_1)^* T^* XT - T^* XTB_2 B_2^* T^* XT = 0.$$

This shows that the effect of the basis change on X is the congruence transformation

$$(3.3) \quad X \rightarrow T^{-*} XT^{-1}$$

where T^{-*} denotes $(T^*)^{-1}$. Similarly, in the new basis, equation (2.23) becomes

$$(3.4) \quad T^{-1} YT^{-*}(A - B_1 C_2)^* + (A - B_1 C_2)T^{-1} YT^{-*} - T^{-1} YT^{-*} C_2^* C_2 T^{-1} YT^{-*} = 0$$

and hence the effect of the basis change is

$$(3.5) \quad Y \rightarrow TYT^*.$$

(Incidentally, in problems of the second and third kind, (3.1) and/or (3.4) have an additional constant term. This term makes no difference to the balancing arguments.)

Combining (3.3) and (3.5) we obtain

$$(3.6) \quad YX \rightarrow TYXT^{-1}$$

and it is immediate from (2.20) and (2.22) that

$$(3.7) \quad F \rightarrow FT^{-1},$$

$$(3.8) \quad H \rightarrow TH.$$

Condition (3.6) shows that $\lambda(YX)$ are invariant under basis changes in the state-space of $P(s)$. Conditions (3.3) and (3.5), together with $X = X^* \geq 0$ and $Y = Y^* \geq 0$, suggest that we may use the construction in [12, Appendix B] to find a basis change T so that in the new basis

$$(3.9) \quad Y = \begin{bmatrix} \tilde{\Sigma}_1 & & & \\ & \tilde{\Sigma}_2 & & \\ & & 0 & \\ & & & 0 \end{bmatrix} = \begin{bmatrix} \Sigma_1 & 0 \\ 0 & 0 \end{bmatrix}$$

and

$$(3.10) \quad X = \begin{bmatrix} \tilde{\Sigma}_1 & & & \\ & 0 & & \\ & & \tilde{\Sigma}_3 & \\ & & & 0 \end{bmatrix}$$

are balanced diagonal matrices. The balancing of the positive definite solutions of standard LQG type Riccati equations has been studied by Joncheere and Silverman [14]. For convenience of analysis we introduce a permutation matrix J such that

$$(3.11) \quad JXJ^* = \begin{bmatrix} \tilde{\Sigma}_1 & & & \\ & \tilde{\Sigma}_3 & & \\ & & 0 & \\ & & & 0 \end{bmatrix} = \begin{bmatrix} \Sigma_2 & 0 \\ 0 & 0 \end{bmatrix}.$$

Clearly $\Sigma_1 > 0$ and $\Sigma_2 > 0$.

For notational simplicity, we will absorb the coordinate transformation matrix T into the state-space matrices and rewrite TAT^{-1} , TB_2, \dots of (3.1) and (3.4) as A, B_2, \dots . If we set $M = A - B_1 C_2$ and $C_2 = (C_{21} | C_{22})$, where the partitioning is consistent with that in (3.9), we obtain from (2.23)

$$(3.12) \quad \begin{bmatrix} \Sigma_1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} M_{11}^* & M_{21}^* \\ M_{12}^* & M_{22}^* \end{bmatrix} + \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix} \begin{bmatrix} \Sigma_1 & 0 \\ 0 & 0 \end{bmatrix} - \begin{bmatrix} \Sigma_1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} C_{21}^* \\ C_{22}^* \end{bmatrix} [C_{21} \ C_{22}] \begin{bmatrix} \Sigma_1 & 0 \\ 0 & 0 \end{bmatrix} = 0.$$

The (1, 1) block of (3.12) yields

$$(3.13) \quad \Sigma_1 M_{11}^* + M_{11} \Sigma_1 - \Sigma_1 C_{21}^* C_{21} \Sigma_1 = 0,$$

that is,

$$(3.14) \quad M_{11} - \Sigma_1 C_{21}^* C_{21} = -\Sigma_1 M_{11}^* \Sigma_1^{-1}.$$

From the (1, 2) block of (3.12) one obtains

$$(3.15) \quad \Sigma_1 M_{21}^* = 0 \Rightarrow M_{21} = 0.$$

Making use of (2.22) and what has been deduced above,

$$(3.16) \quad \begin{aligned} A - HC_2 &= M - YC_2^* C_2 \\ &= \begin{bmatrix} M_{11} - \Sigma_1 C_{21}^* C_{21} & M_{12} - \Sigma_1 C_{21}^* C_{22} \\ 0 & M_{22} \end{bmatrix} \\ &= \begin{bmatrix} -\Sigma_1 M_{11}^* \Sigma_1^{-1} & M_{12} - \Sigma_1 C_{21}^* C_{22} \\ 0 & M_{22} \end{bmatrix}. \end{aligned}$$

Applying [12, Thm. 3.3(2)] to (3.13) establishes the implication

$$(3.17) \quad \delta(\Sigma_1^{-1}) = 0 \Rightarrow 0 = \pi(-\Sigma_1^{-1}) \geq \nu(M_{11}).$$

Since we have assumed that $P_{21}(s)$ has no zeros on the imaginary axis, $\delta(M_{11}) = 0$ and therefore

$$(3.18) \quad \text{In}(M_{11}) = (\text{rank}(Y), 0, 0).$$

Note that $\{\lambda(M_{11})\} \equiv \{\text{right half plane zeros of } P_{21}(s)\}$. Since $A - HC_2$ is asymptotically stable so too is M_{22} .

Defining $Z = J(A - B_2C_1)J^*$ and $(JB_2)^* = \hat{B}_2^* = [\hat{B}_{12}^* | \hat{B}_{22}^*]$ we obtain from (2.21)

$$(3.19) \quad \begin{bmatrix} \Sigma_2 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} Z_{11} & Z_{12} \\ Z_{21} & Z_{22} \end{bmatrix} + \begin{bmatrix} Z_{11}^* & Z_{21}^* \\ Z_{12}^* & Z_{22}^* \end{bmatrix} \begin{bmatrix} \Sigma_2 & 0 \\ 0 & 0 \end{bmatrix} - \begin{bmatrix} \Sigma_2 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \hat{B}_{12}^* \\ \hat{B}_{22}^* \end{bmatrix} [\hat{B}_{12}^* | \hat{B}_{22}^*] \begin{bmatrix} \Sigma_2 & 0 \\ 0 & 0 \end{bmatrix} = 0.$$

By an argument similar to the one given for (3.12), we have that

$$(3.20) \quad Z_{11} - \hat{B}_{12} \hat{B}_{12}^* \Sigma_2 = -\Sigma_2^{-1} Z_{11}^* \Sigma_2,$$

$$(3.21) \quad Z_{12} = 0,$$

$$(3.22) \quad \text{In}(Z_{11}) = (\text{rank}(X), 0, 0),$$

$$(3.23) \quad J(A - B_2F)J^* = \begin{bmatrix} -\Sigma_2^{-1} Z_{11}^* \Sigma_2 & 0 \\ Z_{21} - \hat{B}_{22} \hat{B}_{12}^* \Sigma_2 & Z_{22} \end{bmatrix},$$

and that Z_{22} is asymptotically stable. The eigenvalues of Z_{11} are the right half plane zeros of $P_{12}(s)$. Next, we partition the matrices

$$(3.24) \quad J[B_1 | B_2] = [\hat{B}_1 | \hat{B}_2] = \begin{bmatrix} \hat{B}_{11} & \hat{B}_{12} \\ \hat{B}_{21} & \hat{B}_{22} \end{bmatrix},$$

$$(3.25) \quad F = [F_1 | F_2]$$

where \hat{B}_1 and \hat{B}_2 are partitioned conformally with (3.11) and F is partitioned conformally with (3.9). Making use of (3.16), (3.23), (3.24) and (3.25), we can rewrite (2.24) as

$$(3.26) \quad \begin{bmatrix} T_{11} & T_{12} \\ T_{21} & 0 \end{bmatrix} (s) = \left[\begin{array}{cc|cc} J(A - B_2F)J^* & JB_2F & JB_1 & JB_2 \\ 0 & A - HC_2 & -YC_2^* & 0 \\ \hline -B_2^* J^* X J^* & F & D_{11} & I \\ 0 & C_2 & I & 0 \end{array} \right] \\ = \left[\begin{array}{cc|cc|cc} -\Sigma_2^{-1} Z_{11}^* \Sigma_2 & 0 & \hat{B}_{12} F_1 & \hat{B}_{12} F_2 & \hat{B}_{11} & \hat{B}_{12} \\ Z_{21} - \hat{B}_{22} \hat{B}_{12}^* \Sigma_2 & Z_{22} & \hat{B}_{22} F_1 & \hat{B}_{22} F_2 & \hat{B}_{21} & \hat{B}_{22} \\ \hline 0 & 0 & -\Sigma_1 M_{11}^* \Sigma_1^{-1} & M_{12} - \Sigma_1 C_{21}^* C_{22} & -\Sigma_1 C_{21}^* & 0 \\ 0 & 0 & 0 & M_{22} & 0 & 0 \\ \hline -\hat{B}_{12}^* \Sigma_2 & 0 & F_1 & F_2 & D_{11} & I \\ 0 & 0 & C_{21} & C_{22} & I & 0 \end{array} \right] \\ = \left[\begin{array}{cc|cc} -Z_{11}^* & \Sigma_2 \hat{B}_{12} F_1 \Sigma_1 & \Sigma_2 \hat{B}_{11} & \Sigma_2 \hat{B}_{12} \\ 0 & -M_{11}^* & -C_{21}^* & 0 \\ \hline -\hat{B}_{12}^* & F_1 \Sigma_1 & D_{11} & I \\ 0 & C_{21} \Sigma_1 & I & 0 \end{array} \right].$$

Thus

$$(3.27) \quad T_{12} = \left[\begin{array}{c|c} -Z_{11}^* & \Sigma_2 \hat{B}_{12} \\ \hline -\hat{B}_{12}^* & I \end{array} \right]; \quad T_{21} = \left[\begin{array}{c|c} -M_{11}^* & -C_{21}^* \\ \hline C_{21} \Sigma_1 & I \end{array} \right].$$

It follows from (3.13) that $T_{21}(s)$ has observability gramian Σ_1 and controllability gramian Σ_1^{-1} . Similarly, $T_{12}(s)$ has observability gramian Σ_2^{-1} and controllability gramian Σ_2 . Equations (3.18) and (3.22), $\Sigma_1 > 0$ and $\Sigma_2 > 0$ together with [12, Thm. 3.3(5)] establishes the minimality of the realizations in (3.27). To deduce that the realization (3.26) is also minimal, we note that the A -matrix of the inverse system of (3.26) is similar to

$$(3.28) \quad \begin{bmatrix} Z_{11} & (\hat{B}_{12}D_{11} - \hat{B}_{11})C_{21} \\ 0 & M_{11} \end{bmatrix}.$$

It follows from this that the realization (3.26) has no left half plane zeros and since this realization is asymptotically stable, it must be minimal as well because no pole-zero cancellations can occur. We remark however that the realization for $T_{11}(s)$ need not be minimal. Replacing the realization (2.24) by (3.26) allows the realization (2.28) for $T_{12}^* T_{11} T_{21}^*(s)$ to be replaced by

$$(3.29) \quad T_{12}^* T_{11} T_{21}^*(s) = \left[\begin{array}{cc|c} Z_{11} & (\hat{B}_{12}D_{11} - \hat{B}_{11})C_{21} & \hat{B}_{11} - \hat{B}_{12}D_{11} \\ 0 & M_{11} & -\Sigma_1 C_{21}^* \\ \hline -\hat{B}_{12}^* \Sigma_2 & F_1 - D_{11}C_{21} & D_{11} \end{array} \right]$$

which need not be minimal. The results of our analysis up to this point are now summarized in the next lemma for easy reference.

LEMMA 3.1.

- (i) The number of zeros of $P_{12}(s)$ in $\mathbb{C}_+ = \text{rank}(X)$.
- (ii) The number of zeros of $P_{21}(s)$ in $\mathbb{C}_+ = \text{rank}(Y)$.
- (iii) The realization in (3.26) is minimal with $\text{degree} = (\text{rank}(X) + \text{rank}(Y))$.
- (iv) The realizations for $T_{12}(s)$ and $T_{21}(s)$ in (3.27) are minimal with $\text{deg}(T_{12}) = \text{rank}(X)$ and $\text{deg}(T_{21}) = \text{rank}(Y)$.
- (v) $\text{deg}(T_{12}^* T_{11} T_{21}^*) \leq \text{rank}(X) + \text{rank}(Y)$.

Early in this section we showed that $\lambda(YX)$ are invariant with respect to an arbitrary similarity transformation in the state-space of $P(s)$. It is natural to ask whether or not these invariants contain any fundamental information pertaining to the optimal solutions of H^∞ control problems. We conclude this section with a result which shows that the lowest achievable L^∞ -norm for the closed loop may be expressed in terms of $\lambda_{\max}(YX)$ in the case of certain specific problems of the first kind. These problems are: (i) The unweighted optimal sensitivity problem; (ii) the unweighted optimal complementary sensitivity problem; (iii) the unweighted problem associated with optimal robustness towards multiplicative perturbations at the plant input, and (iv) the weighted optimal robustness problem.

THEOREM 3.2. If Ξ is the set of all stabilizing compensators, then

$$(3.30) \quad (i) \quad \inf_{K \in \Xi} \|(I + GK)^{-1}(s)\|_\infty = (1 + \lambda_{\max}(YX))^{1/2};$$

$$(3.31) \quad (ii) \quad \inf_{K \in \Xi} \|GK(I + GK)^{-1}(s)\|_\infty = (1 + \lambda_{\max}(YX))^{1/2};$$

$$(3.32) \quad (iii) \quad \inf_{K \in \Xi} \|KG(I + KG)^{-1}(s)\|_\infty = (1 + \lambda_{\max}(YX))^{1/2};$$

- (iv) If $W_1(s)$ and $W_2(s)$ are stable and minimum phase frequency dependent weights with proper inverses, then

$$(3.33) \quad \inf_{K \in \Xi} \|W_1 K (I + GK)^{-1} W_2(s)\|_\infty = \lambda_{\max}(YX)^{1/2}. \quad \square$$

Remark 3.1. A detailed analysis will reveal that the Riccati equations defining X and Y in the case of problems (i) and (ii) are the same and therefore that

$$(3.34) \quad \inf_{K \in \Xi} \|(I + GK)^{-1}\|_{\infty} = \inf_{K \in \Xi} \|GK(I + GK)^{-1}\|_{\infty}.$$

This result was originally proved by Kwakernaak in the SISO case and Glover in the MIMO case (private communication). In general, the (X, Y) pairs associated with the other problems given in Theorem 3.2 are different leading to different achievable L^{∞} -norm infima. It may be shown by counterexample that the results for problems (i), (ii) and (iii) do not carry over to the weighted case. \square

4. Main results. In this section we consider the pole-zero cancellation properties of the H^{∞} -optimal (or suboptimal) system of Fig. 1 and we will derive general McMillan degree bounds for all H^{∞} -optimal controllers (denoted K_{opt}) or suboptimal controllers (denoted K_{sopt}) for problems of the first kind. An outline of our development is as follows.

Let $n = \deg(P)$, $t = \deg(\mathcal{R})$ and let $m =$ (number of cancellations which occur between $P(s)$ and $K(s)$ as a result of closing the feedback loop in Fig. 1). Then

$$t = n + \deg(K) - m,$$

that is

$$\deg(K) = t + m - n.$$

To obtain an upper bound for $\deg(K)$, we proceed in two steps:

(1) Theorems 4.1, 4.2 and 2.1 establish an upper bound t_b for the McMillan degree t of all optimal closed-loop transfer functions $\mathcal{R}(s)$, and

(2) Theorem 4.3 establishes an upper bound m_b for the number of pole-zero cancellations between $P(s)$ and $K(s)$. Given such bounds, we then have

$$(4.1) \quad \deg(K) \leq t_b + m_b - n.$$

In the case of single-input-single-output (SISO) problems we will show that

$$(4.2) \quad \deg(K_{\text{opt}}) \leq n - 1,$$

$$(4.3) \quad \deg(K_{\text{sopt}}) \leq n.$$

In the case of multivariable (MIMO) problems, we will show that there is a continuum of controllers which satisfy the bounds given in (4.2) and (4.3). These results are stated in Theorem 4.4. We remark that a bound of this type has already been discovered by Glover in the special case of the optimal robustness problem [13].

In an earlier paper, Zames and Francis [28] established that there are interpolation constraints associated with both the right half plane poles and zeros of the plant in the single loop optimal sensitivity problem. If the weighted sensitivity is given by

$$(4.4) \quad s(s) = w(s)/(1 + g(s)k(s)),$$

then they have shown that

$$(4.5) \quad s(z_i) = w(z_i)$$

at each right half plane zero z_i of $g(s)$, and that

$$(4.6) \quad s(p_i) = 0$$

at each right half plane pole. These observations lead us to an interesting factorization phenomenon which may occur in H^{∞} control problems of the first kind. We will

motivate the main idea by way of the unweighted sensitivity minimization problem (weights are neglected for ease of exposition).

From (2.6), we have after prescaling that

$$(4.7) \quad P(s) = \begin{bmatrix} I & G(s)D^{-1} \\ I & G(s)D^{-1} \end{bmatrix} = \left[\begin{array}{c|cc} A & 0 & BD^{-1} \\ C & I & I \\ C & I & I \end{array} \right].$$

Substituting into (2.20) to (2.24) we get

$$(4.8) \quad \begin{bmatrix} T_{11}(s) & T_{12}(s) \\ T_{21}(s) & 0 \end{bmatrix} = \left[\begin{array}{cc|cc} A - BD^{-1}F & YC^*C & YC^* & BD^{-1} \\ 0 & A - HC & -YC^* & 0 \\ -D^{-*}B^*X & C & I & I \\ 0 & C & I & 0 \end{array} \right]$$

after the change of basis

$$(4.9) \quad T = \begin{bmatrix} I & -I \\ 0 & I \end{bmatrix}.$$

An inspection of (4.8) shows that it can be factorized as

$$(4.10) \quad \begin{bmatrix} T_{11}(s) & T_{12}(s) \\ T_{21}(s) & 0 \end{bmatrix} = \begin{bmatrix} \tilde{T}_{11}(s) & T_{12}(s) \\ I & 0 \end{bmatrix} \begin{bmatrix} T_{21}(s) & 0 \\ 0 & I \end{bmatrix}$$

where

$$(4.11) \quad \tilde{T}_{11}(s) = \left[\begin{array}{c|c} A - BD^{-1}F & YC^* \\ -D^{-*}B^*X & I \end{array} \right].$$

Consequently, $\mathcal{R}(s)$ can be written as

$$(4.12) \quad \mathcal{R}(s) = (\tilde{T}_{11}(s) - T_{12}Q(s))T_{21}(s)$$

in which we note also that $\{\text{zeros of } T_{21}\} \equiv \{\text{poles of } G\}$ and $\{\text{zeros of } T_{12}\} \equiv \{\text{zeros of } G\}$. At each pole of $G(s)$ there exists a vector x_i such that

$$(4.13) \quad T_{21}(p_i)x_i = 0 \quad \text{for all } Q(s) \text{ in } RH_+^\infty$$

which implies

$$(4.14) \quad \mathcal{R}(p_i)x_i = 0.$$

This is a generalization of (4.6) to the MIMO case. The point we want to emphasize, however, is that in certain H^∞ control problems, T_{11} may have natural all-pass common factors with T_{12} and/or T_{21} , as illustrated in (4.12). Theorem 4.1 gives a general treatment of the properties of this type of all-pass common factor.

THEOREM 4.1. *Let*

$$(4.15) \quad \begin{bmatrix} G & A_1 \\ A_2 & 0 \end{bmatrix}(s) = \left[\begin{array}{cc|cc} A_{11} & A_{12} & B_{11} & B_{12} \\ 0 & A_{22} & B_{21} & 0 \\ C_{11} & C_{12} & D & I \\ 0 & C_{22} & I & 0 \end{array} \right]$$

in which $A_1(s)$ and $A_2(s)$ are assumed inner. Suppose also that the realizations for $A_1(s)$ and $A_2(s)$ given in (4.15) are minimal. Then there exists a change of basis such that

(4.15) can be put into the form

$$(4.16) \quad \begin{bmatrix} G & A_1 \\ A_2 & 0 \end{bmatrix} (s) = \left[\begin{array}{cccc|cc} \tilde{A}_{00} & \tilde{A}_{01} & \tilde{A}_{02} & \tilde{A}_{03} & \tilde{B}_{01} & \tilde{B}_{02} \\ 0 & \tilde{A}_{11} & \tilde{A}_{12} & \tilde{A}_{13} & \tilde{B}_{11} & \tilde{B}_{12} \\ 0 & 0 & \tilde{A}_{22} & \tilde{A}_{23} & \tilde{B}_{21} & 0 \\ 0 & 0 & 0 & \tilde{A}_{33} & \tilde{B}_{31} & 0 \\ \hline \tilde{C}_{10} & \tilde{C}_{11} & \tilde{C}_{12} & \tilde{C}_{13} & D & I \\ 0 & 0 & \tilde{C}_{22} & \tilde{C}_{23} & I & 0 \end{array} \right],$$

which admits the following factorizations

$$(4.17) \quad A_1(s) = A_l(s) \tilde{A}_1(s) = \left[\begin{array}{c|c} \tilde{A}_{00} & \tilde{B}_{02} \\ \hline \tilde{C}_{10} & I \end{array} \right] \left[\begin{array}{c|c} \tilde{A}_{11} & \tilde{B}_{12} \\ \hline \tilde{C}_{11} & I \end{array} \right],$$

$$(4.18) \quad A_2(s) = \tilde{A}_2(s) A_r(s) = \left[\begin{array}{c|c} \tilde{A}_{22} & \tilde{B}_{21} \\ \hline \tilde{C}_{22} & I \end{array} \right] \left[\begin{array}{c|c} \tilde{A}_{33} & \tilde{B}_{31} \\ \hline \tilde{C}_{23} & I \end{array} \right],$$

$$(4.19) \quad G(s) = A_l(s) \tilde{G}(s) A_r(s) = \left[\begin{array}{c|c} \tilde{A}_{00} & \tilde{B}_{02} \\ \hline \tilde{C}_{10} & I \end{array} \right] \left[\begin{array}{ccc|c} \tilde{A}_{11} & \tilde{A}_{12} & \tilde{B}_{11} & \\ 0 & \tilde{A}_{22} & \tilde{B}_{21} & \\ \hline \tilde{C}_{11} & \tilde{C}_{12} & D & \end{array} \right] \left[\begin{array}{c|c} \tilde{A}_{33} & \tilde{B}_{31} \\ \hline \tilde{C}_{23} & I \end{array} \right].$$

Further

(a) $\tilde{A}_1(s)$, $\tilde{A}_2(s)$, $A_l(s)$, $A_r(s)$, are inner.

(b) The factorizations in (4.17), (4.18), and (4.19) are minimal in the sense that

$$(4.20) \quad \deg(A_1) = \deg(A_l) + \deg(\tilde{A}_1),$$

$$(4.21) \quad \deg(A_2) = \deg(A_r) + \deg(\tilde{A}_2),$$

$$(4.22) \quad \deg(G) = \deg(A_l) + \deg(\tilde{G}) + \deg(A_r).$$

(c) $A_1^* G A_2^*(s) = \tilde{A}_1^* \tilde{G} \tilde{A}_2^*(s)$ has a minimal realization given by

$$(4.23) \quad \left[\begin{array}{ccc|c} -\tilde{A}_{11}^* & \tilde{A}_{12} + \tilde{B}_{11} \tilde{B}_{21}^* + \tilde{C}_{11}^* (\tilde{C}_{12} + D \tilde{B}_{21}^*) & \tilde{C}_{11}^* D + \tilde{B}_{11} & \\ 0 & -\tilde{A}_{22}^* & -\tilde{C}_{22}^* & \\ \hline -\tilde{B}_{12}^* & \tilde{C}_{12} + D \tilde{B}_{21} & D & \end{array} \right]. \quad \square$$

The proof of this result, which is inspired by the work of Van Dooren and DeWilde [23], is given in Appendix C.

Theorem 2.1 shows that the realization (3.29) for $T_{12}^* T_{11} T_{21}^*(s)$ is controllable if and only if $T_{11}(s)$ and $T_{12}(s)$ have no common inner left divisors and that it is observable if and only if $T_{11}(s)$ and $T_{21}(s)$ have no common inner right divisors. The realization is thus minimal if and only if neither type of factor exists. However, if such inner common factors do exist, they may be extracted to form the cascade factorization

$$(4.24) \quad \begin{bmatrix} T_{11} & T_{12} \\ T_{21} & 0 \end{bmatrix} (s) = \begin{bmatrix} A_l(s) & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} \tilde{T}_{11} & \tilde{T}_{12} \\ \tilde{T}_{21} & 0 \end{bmatrix} (s) \begin{bmatrix} A_r(s) & 0 \\ 0 & I \end{bmatrix}$$

in which $A_l(s)$ and $A_r(s)$ are inner. Consequently, we have

$$(4.25) \quad \mathcal{R}(s) = A_l(s) [\tilde{T}_{11} - \tilde{T}_{12} Q \tilde{T}_{21}] (s) A_r(s).$$

Furthermore, a minimal realization for

$$(4.26) \quad \begin{bmatrix} \tilde{T}_{11} & \tilde{T}_{12} \\ \tilde{T}_{21} & 0 \end{bmatrix} (s)$$

will lead directly to a minimal realization for $\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*(s)$. Hence the function to be minimized in (2.25) or (2.26) can be written

$$(4.27) \quad \|(T_{11} - T_{12} Q T_{21})(s)\|_\infty = \|(\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^* - Q)(s)\|_\infty.$$

Using Theorem 2.1 or Remark 2.2, $Q(s)$ can therefore be obtained as a Nehari extension or ρ -suboptimal extension of $\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*(s)$. It then follows from Theorem 2.1 and Remarks 2.2 and 2.4 that the corresponding "error system"

$$(4.28) \quad E(s) = (\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^* - Q)(s)$$

satisfies the bounded real type equations given in (2.33) and (2.34). These equations form the basis of the hypothesis of the next theorem which enables us to deduce that the set of poles of $(\tilde{T}_{11} - \tilde{T}_{12} Q \tilde{T}_{21})(s)$ reduce to a subset of the poles of Q .

THEOREM 4.2. *Let*

$$(4.29) \quad \begin{bmatrix} G & A_1 \\ A_2 & 0 \end{bmatrix} (s) = \left[\begin{array}{cc|cc} A_{11} & A_{12} & B_{11} & B_{12} \\ 0 & A_{22} & B_{21} & 0 \\ \hline C_{11} & C_{12} & D & I \\ 0 & C_{22} & I & 0 \end{array} \right]$$

in which $A_1(s)$ and $A_2(s)$ are inner and their realizations

$$(4.30) \quad A_1(s) = \left[\begin{array}{c|c} A_{11} & B_{12} \\ \hline C_{11} & I \end{array} \right] \quad \text{and} \quad A_2(s) = \left[\begin{array}{c|c} A_{22} & B_{21} \\ \hline C_{22} & I \end{array} \right]$$

are also minimal and balanced. Then

(a)

$$(4.31) \quad \begin{aligned} A_1^* G A_2^* (s) &= \left[\begin{array}{cc|c} -A_{11}^* & -C_{11}^*(C_{12} + DB_{21}^*) - A_{12} - B_{11}B_{21}^* & C_{11}^*D + B_{11} \\ 0 & -A_{22}^* & C_{22}^* \\ \hline -B_{12}^* & -(C_{12} + DB_{21}^*) & D \end{array} \right] \\ &= \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array} \right]; \end{aligned}$$

(b) for any

$$Q(s) = \left[\begin{array}{c|c} \hat{A} & \hat{B} \\ \hline \hat{C} & \hat{D} \end{array} \right]$$

such that

$$(4.32) \quad (A_1^* G A_2^* - Q)(s) = \left[\begin{array}{cc|c} A & 0 & B \\ 0 & \hat{A} & \hat{B} \\ \hline \underline{C} & -\hat{C} & \underline{D} - \hat{D} \end{array} \right] := \left[\begin{array}{c|c} \tilde{A} & \tilde{B} \\ \hline \tilde{C} & \tilde{D} \end{array} \right]$$

satisfies the bounded real type equations

$$(4.33) \quad \begin{bmatrix} -(\tilde{A}\tilde{P} + \tilde{P}\tilde{A}^* + \tilde{B}\tilde{B}^*) & -(\tilde{B}\tilde{D}^* + \tilde{P}\tilde{C}^*) \\ -(\tilde{D}\tilde{B}^* + \tilde{C}\tilde{P}) & \sigma^2 I - \tilde{D}\tilde{D}^* \end{bmatrix} = \begin{bmatrix} L \\ W \end{bmatrix} [L^* | W^*]$$

and

$$(4.34) \quad \begin{bmatrix} -(\tilde{A}^*\tilde{Q} + \tilde{Q}\tilde{A} + \tilde{C}^*\tilde{C}) & -(\tilde{C}^*\tilde{D} + \tilde{Q}\tilde{B}) \\ -(\tilde{D}^*\tilde{C} + \tilde{B}^*\tilde{Q}) & \sigma^2 I - \tilde{D}^*\tilde{D} \end{bmatrix} = \begin{bmatrix} L_d^* \\ W_d^* \end{bmatrix} [L_d | W_d]$$

in which

$$(4.35) \quad (i) \quad \tilde{P}\tilde{Q} = \sigma^2 I \text{ for some } \sigma \in \mathbb{R}, \text{ and}$$

$$(4.36) \quad (ii) \quad L^* = [0 | L_{21}^*], \quad L_d = [0 | L_{d21}]$$

where the partitioning of L and L_d is conformable with that of \tilde{B} and \tilde{C} in (4.32), we have

$$(4.37) \quad (i) \quad (G - A_1 Q A_2)(s) = \left[\frac{\hat{A}}{C_{11} Q_{13} - \hat{C}} \middle| \frac{\hat{B} - P_{23}^* B_{21}}{\hat{D}} \right]$$

where P_{23} and Q_{13} are the $(2, 3)$ and $(1, 3)$ partitions of \tilde{P} and \tilde{Q} (see (D.1) in Appendix D).

$$(4.38) \quad (ii) \quad \{\text{poles of } Q\} \supseteq \{\text{poles of } (G - A_1 Q A_2)\}.$$

Proof. See Appendix D.

Clearly, if we substitute $\tilde{T}_{11}(s)$, $\tilde{T}_{12}(s)$ and $\tilde{T}_{21}(s)$ into $G(s)$, $A_1(s)$, $A_2(s)$ of the last theorem, it follows immediately from part (b)(ii) that

$$(4.39) \quad \{\text{poles of } Q\} \supseteq \{\text{poles of } (\tilde{T}_{11} - \tilde{T}_{12} Q \tilde{T}_{21})\}$$

and this together with Theorem 4.1 and (4.25) yields

$$(4.40) \quad \{\text{poles of } Q\} \cup \{\text{poles of } A_r\} \cup \{\text{poles of } A_l\} \supseteq \{\text{poles of } \mathcal{R}\}.$$

Given (4.40), it follows that an upper bound for the McMillan degree of $\mathcal{R}(s)$ is

$$(4.41) \quad t \leq \deg(A_r) + \deg(A_l) + \deg(Q) = t_b.$$

Further, we have by Corollary 2.2 that

$$(4.42) \quad \deg(Q_{\text{opt}}) \leq \deg(\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*) + \deg(U) - r$$

in the case of optimal extensions (r is the multiplicity of the largest Hankel singular value of $\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*(s)$); and

$$(4.43) \quad \deg(Q_{\text{sopt}}) \leq \deg(\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*) + \deg(U)$$

in the case of ρ -suboptimal extensions. Now (3.26) and Lemma 3.1 in combination with (4.24) and Theorem 4.1 imply that

$$(4.44) \quad \deg(\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*) = \text{rank}(X) + \text{rank}(Y) - \deg(A_r) - \deg(A_l).$$

Direct substitution of this into the previous two inequalities and then into (4.41) yields

$$(4.45a) \quad t_{\text{opt}} \leq t_b = \text{rank}(X) + \text{rank}(Y) + \deg(U) - r$$

and

$$(4.45b) \quad t_{\text{sopt}} \leq t_b = \text{rank}(X) + \text{rank}(Y) + \deg(U)$$

which provides a McMillan degree bound for the closed-loop system and completes step 1 of our analysis.

We will now begin the second step. In order to establish a McMillan degree bound on all $K_{\text{opt}}(s)$ and $K_{\text{sopt}}(s)$ controllers, we need to bound the number of cancellations between $P(s)$ and $K(s)$ in Fig. 1; we call this bound m_b as was given in (4.1). In Theorem 4.3, we will show that every unobservable mode of the system in Fig. 1 is due to a cancellation with a zero of $P_{12}(s)$ and every uncontrollable mode is due to a cancellation with a zero of $P_{21}(s)$. (After this paper had been submitted for publication,

it came to our attention that a result similar to Theorem 4.3 had been discovered independently by Anderson and Linnemann [29].)

THEOREM 4.3. *Let*

$$(4.46) \quad \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} (s) = \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{22} \end{array} \right]$$

in which $P_{12}(s) \in \mathbb{R}^{p_1 \times m_2}(s)$ with $m_2 \leq p_1$ and $P_{21}(s) \in \mathbb{R}^{p_2 \times m_1}(s)$ with $p_2 \leq m_1$. Suppose also that

$$(4.47) \quad K(s) = \left[\begin{array}{c|c} \hat{A} & \hat{B} \\ \hline \hat{C} & \hat{D} \end{array} \right]$$

is a minimal realization and that the well posedness condition $\det(I + D_{22}\hat{D}) \neq 0$ is satisfied. Then in the closed loop of Fig. 1

- (a) every unobservable mode is a zero of $P_{12}(s)$ and
- (b) every uncontrollable mode is a zero of $P_{21}(s)$.

Proof. See Appendix E.

Using this theorem, we see that the number of cancellations m between $P(s)$ and $K(s)$ is bounded above by

$$(4.48) \quad \begin{aligned} m \leq & \{\text{number of zeros of } P_{12}(s) \text{ in } \mathbb{C}_-\} \\ & + \{\text{number of zeros of } P_{21}(s) \text{ in } \mathbb{C}_-\} = m_b. \end{aligned}$$

This follows from the fact that any other cancellation (i.e. one corresponding to a right half plane zero of $P_{12}(s)$ or $P_{21}(s)$) violates the proven internal stability of the closed loop.

From (4.48) and Lemma 3.1, we have

$$(4.49) \quad \begin{aligned} m_b = & \{\text{number of zeros of } P_{12}(s) \text{ in } \mathbb{C}_-\} \\ & + \{\text{number of zeros of } P_{21}(s) \text{ in } \mathbb{C}_-\} \\ = & \{n - \text{rank}(X)\} + \{n - \text{rank}(Y)\} \\ = & 2n - \text{rank}(X) - \text{rank}(Y). \end{aligned}$$

We are now ready to prove the main theorem by combining together the results which have been established. Substitution of (4.45) and (4.49) into (4.1) proves the following.

THEOREM 4.4. *For any H^∞ -optimal control problem of the first kind, every H^∞ -optimal controller satisfies*

$$(i) \quad \deg(K_{\text{opt}}) \leq n - r + \deg(U)$$

where r is the multiplicity of the largest Hankel singular value of $\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*(s)$, and every ρ -suboptimal controller satisfies

$$(ii) \quad \deg(K_{\text{sopt}}) \leq n + \deg(U). \quad \square$$

Furthermore, (4.2) and (4.3) follow from the fact that $\deg(U) = 0$ if $U(s)$ is chosen constant. In the SISO case only $U = 1$ is allowed.

4.1. Computations. In this section we assemble together the ideas presented so far into an algorithm style procedure for solving H^∞ control problems of the first kind.

ALGORITHM.

- (1) Given $P(s)$ as in (2.3), do a prescaling to get $P(s)$ into the form (2.19).
- (2) Solve the Riccati equations (2.21) and (2.23) and evaluate the stabilizing matrices F and H using (2.20) and (2.22).
- (3) Assemble $T_{12}^* T_{11} T_{21}^*(s)$ as in (2.28).
- (4) Remove the hidden modes of $T_{12}^* T_{11} T_{21}^*(s)$. This can be done in a numerically reliable way by balanced truncation methods. The result is a minimal realization for $\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*(s)$. Note the balancing process for model reduction at this step forms the bulk of the computation required at the next step.
- (5) Determine a Nehari or ρ -suboptimal extension $Q(s)$ of $\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*(s)$ using Theorem 2.1 or Remark 2.2.
- (6) Back substitute $Q(s)$ into (2.17).
- (7) The previous step will typically produce a nonminimal realization for the (sub-)optimal controller $K(s)$. Again, a minimal realization may be obtained by balanced truncation methods; the bounds given in Theorem 4.4 must apply.

It should be noted that the model reduction performed in step 4 will simultaneously remove all the nonminimal states in (2.28) introduced by the left half plane zeros of $P_{12}(s)$ and $P_{21}(s)$, and the all-pass common factors shared by $T_{11}(s)$ and $T_{12}(s)$, and $T_{11}(s)$ and $T_{21}(s)$. Although Theorem 4.1 is an essential component of the theory, it does not need to be implemented in software. The second model reduction (step 7) is used to remove any nonminimal states introduced by cancellations predicted by Theorem 4.3.

4.2. Model reduction considerations. It is natural to consider reducing the number of controller states by model reduction methods such as those discussed in [12]. If we suppose that $\Delta\mathcal{R}(s)$ is the change in $\mathcal{R}(s)$ produced by the model reduction error $\Delta K(s)$, then the difficulty with this approach is that any general bound on $\|\Delta\mathcal{R}(s)\|_\infty$ in terms of a bound on $\|\Delta K(s)\|_\infty$ tends to be weak. An alternative and less direct approach is to consider the possibility of model reducing $Q(s)$ before obtaining $K(s)$ by back substitution. An argument might be that if $\Delta Q(s)$ is the perturbation produced by the model reduction of $Q(s)$, then by (2.14)

$$(4.50) \quad \mathcal{R}(s) + \Delta\mathcal{R}(s) = [T_{11} - T_{12}(Q + \Delta Q)T_{21}](s)$$

leads to

$$(4.51) \quad \|\Delta\mathcal{R}(s)\|_\infty = \|\Delta Q(s)\|_\infty,$$

since $T_{12}(s)$ and $T_{21}(s)$ are inner. Further, if the reduced order model of $Q(s)$ is obtained by retaining the first k states of a truncated balanced realization, then

$$(4.52) \quad \|\Delta\mathcal{R}(s)\|_\infty \leq 2 \sum_{i=k+1}^n \sigma_i(Q).$$

This inequality follows from [12, Thm. 9.6] and shows that it is possible to reduce the number of states of $Q(s)$ while simultaneously keeping track of the resulting maximum possible increase in $\|\mathcal{R}(s)\|_\infty$. However, contrary to the objective, this approach will tend to increase the number of controller states rather than decrease it. This is because replacing $Q(s)$ with a lower order approximation will destroy the ‘‘built in’’ cancellations predicted by our previous results. Since $K(s) = F_r(K_0(s), Q(s))$ and $\deg(K_0) = n$

we see that

$$(4.53) \quad \begin{aligned} \deg(K_{\text{opt}}) &= \deg(K_0) + \deg(Q) \\ &\quad - (\text{no. of cancellations between } K_0 \text{ and } Q_{\text{opt}}) \\ &\leq n-1 \text{ (in the case } \deg(U) = 0 \text{ in Theorem 4.4).} \end{aligned}$$

If Q_{opt} is replaced by an approximation $Q_a(s)$, then in general the cancellations no longer occur and the corresponding controller $K_a(s)$ has higher degree than that of $K_{\text{opt}}(s)$, specifically

$$\deg(K_a) = \deg(K_0) + \deg(Q_a) \geq n.$$

This point is now illustrated with an example.

Example 4.1. Consider the unweighted robust stabilization problem in which we seek

$$\inf_{K \in \Xi} \|K(I + GK)^{-1}\|_\infty \quad (\Xi \text{ is the set of stabilizing compensators}).$$

Referring back to (2.8) we recall that the corresponding $P(s)$ matrix is

$$P(s) = \begin{bmatrix} 0 & I \\ -I & G(s) \end{bmatrix}$$

and after scaling ($S_2 = -I$ and $S_1 = I$) we get

$$P(s) = \left[\begin{array}{c|cc} A & 0 & B \\ \hline 0 & 0 & I \\ -C & I & -D \end{array} \right].$$

If

$$G(s) = \{(s+3)\}/\{(s-1)(s-2)(s-3)\},$$

we get (by computer) a calculation which is based on § 4.1 that

$$Q_{\text{opt}} = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array} \right] = \left[\begin{array}{cc|c} -1.54049 & 0.89744 & 307.989 \\ -0.912165 & -0.17001 & 60.1637 \\ -0.083009 & 0.0159534 & 61.4750 \end{array} \right]$$

which has Hankel singular values 8.2979 and 2.8229. The corresponding optimal controller $K_{\text{opt}}(s)$ has McMillan degree two and has Hankel singular values 38.084 and 8.3797.

In a second calculation, we replaced $Q_{\text{opt}}(s)$ with a 1-state truncated balanced realization. In this case $K(s)$ had McMillan degree four with Hankel singular values: 38.065, 8.3596, 0.0016269 and 0.00010428. In this example therefore, removing a state from $Q_{\text{opt}}(s)$ leads to an increase of two in the McMillan degree of the controller. \square

4.3. Minimum entropy controllers. In a private communication N. J. Young pointed out to us that Arov and Krein [2] had studied a class of ρ -suboptimal extensions, which they called minimum entropy extensions. Assuming that $\|\mathcal{R}(s)\|_\infty \leq \rho = 1$ (a convenient normalization), we define the entropy of the closed loop system at some point $s_0 \in \mathbb{C}_-$ by

$$(4.54) \quad I(\mathcal{R}; s_0) = -\frac{1}{2\pi} \int_{-\infty}^{\infty} \ln |\det(I - \mathcal{R}^*(j\omega)\mathcal{R}(j\omega))| \frac{\text{Re}(s_0)}{|j\omega - s_0|^2} d\omega.$$

Using the fact that $\det(I + AB) = \det(I + BA)$, it is easy to see that inner matrices are entropy preserving. Since $\mathcal{R}(s) = T_{12}ET_{21}(s)$, where $E(s)$ is given by (4.28), it is clear that $I(\mathcal{R}; s_0) = I(E; s_0)$. From now on we will work with $E(s)$ knowing that it has the same entropy as the closed loop transfer function matrix $\mathcal{R}(s)$.

After some introductory comments we will state the result of Arov and Krein and thus show that (4.54) may be minimized while ensuring $\|\mathcal{R}(s)\|_\infty \leq 1$ with the aid of an n -state controller. It will be shown that the controller which minimizes the closed loop entropy is generated by setting $U = -H_{22}^*(s_0)$ in the general parametrization of all Nehari extensions.

From [12] we recall that

$$(4.55) \quad \begin{aligned} E^*(s) &= (\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*)^*(s) - H_{11}(s) \\ &\quad + H_{12}(s)U(s)(I + H_{22}(s)U(s))^{-1}H_{21}(s), \end{aligned}$$

or alternatively,

$$(4.56) \quad E^*(s) = \{A(s)U(s) + B(s)\}\{C(s)U(s) + D(s)\}^{-1}$$

in which

$$(4.57) \quad A(s) := \{(\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*)^*(s) - H_{11}\}H_{21}^{-1}(s)H_{22}(s) + H_{12}(s),$$

$$(4.58) \quad B(s) := \{(\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*)^*(s) - H_{11}\}H_{21}^{-1}(s),$$

$$(4.59) \quad C(s) := H_{21}^{-1}(s)H_{22}(s),$$

$$(4.60) \quad D(s) := H_{21}^{-1}(s).$$

Substituting from (2.38), using $\rho = 1$, we get

$$(4.61) \quad \begin{bmatrix} A(s) & B(s) \\ C(s) & D(s) \end{bmatrix} = \left[\begin{array}{cc|cc} A & 0 & -\Sigma\Gamma^{-1}C^* & -\Gamma^{-1}B \\ 0 & -A^* & \Gamma^{-1}C^* & \Gamma^{-1}\Sigma B \\ \hline C & 0 & I & 0 \\ 0 & B^* & 0 & I \end{array} \right]$$

in which we have denoted

$$(\tilde{T}_{12}^* \tilde{T}_{11} \tilde{T}_{21}^*)^*(s) = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array} \right].$$

Also, (4.61) is easily shown to be J -unitary, that is

$$(4.62) \quad \begin{bmatrix} A(s) & B(s) \\ C(s) & D(s) \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix} \begin{bmatrix} A^*(s) & C^*(s) \\ B^*(s) & D^*(s) \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix}.$$

From the J -unitary equations we get

$$(4.63) \quad A(s)A^*(s) - B(s)B^*(s) = I,$$

$$(4.64) \quad C(s)C^*(s) - D(s)D^*(s) = -I,$$

$$(4.65) \quad A(s)C^*(s) - B(s)D^*(s) = 0.$$

Also

$$(4.66) \quad (4.64) \Rightarrow D^{-1}(s)D^{-*}(s) = I - H_{22}(s)H_{22}^*(s)$$

$$(4.67) \quad \Rightarrow \|H_{22}(s)\|_\infty \leq 1.$$

Glover [12] has shown that $H_{22}(s) \in RH_-^\infty$; a fact which is required in the proof of Theorem 4.5.

THEOREM 4.5 (Arov and Krein [2]). *If $I(H_{22}; s_0) < \infty$, $s_0 \in \mathbb{C}_-$ and $\|U(s)\|_\infty \leq 1$, then*

$$I(\mathcal{R}; s_0) = I(H_{22}; s_0) + I(U; s_0) + \ln |\det (I + H_{22}(s_0)U(s_0))|.$$

Also, there exists a unique U_0 such that $I(\mathcal{R}; s_0)$ attains a minimum value of

$$I(\mathcal{R}; s_0) = I(H_{22}; s_0) + \ln |\det (I - H_{22}(s_0)H_{22}^*(s_0))|/2.$$

The optimizing U_0 is given by

$$U_0 = -H_{22}^*(s_0).$$

A proof which mimics the discrete time proof in [2] is given in Appendix F.

5. Conclusions. Our purpose was to carry out a detailed analysis of the pole-zero cancellations which occur in the class of H^∞ -optimal control problems described in § 2.2. If $\deg(P) = n$, we have shown that SISO H^∞ controllers never require more than $n-1$ states and that MIMO problems have a continuum of controllers whose McMillan degree satisfy this same bound. A general bound on $\deg(K)$ has been derived for all Nehari and ρ -suboptimal extensions and is given in Theorem 4.4. The bounds in Theorem 4.4 are tight in the sense that there exist problems for which they are met with equality. We have found in numerous examples that these bounds typically give the actual McMillan degree of the controller.

It is our belief that state-space dimension inflation is an important consideration in practical H^∞ design problems. Apart from being interesting in its own right, a complete cancellation theory is a prerequisite for the development of reliable computational software. Example 4.1 is an illustration of how a seemingly sensible, but ill-advised intermediate model reduction step may aggravate the problem of degree inflation rather than alleviate it.

H^∞ design problems which may be embedded in Fig. 1 but with either $P_{12}(s)$ or $P_{21}(s)$, or both, nonsquare have been studied by several researchers [6], [9], [10], [11], [22], [25]. In this class of problems cancellation phenomena are more difficult to analyse [16]. However, the added complexity and iterative nature of their solution makes a cancellation theory even more essential. An additional layer of difficulty is introduced by the various scaling strategies which are introduced in the μ -synthesis work of Doyle [5], Doyle et al. [6], Safonov [20] and others.

Appendix A.

Proof of Theorem 2.1. By assumption, the Hankel singular values have been ordered so that

$$(A.1) \quad \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} \Sigma & 0 \\ 0 & \sigma_{k+1}I \end{bmatrix} + \begin{bmatrix} \Sigma & 0 \\ 0 & \sigma_{k+1}I \end{bmatrix} \begin{bmatrix} A_{11}^* & A_{21}^* \\ A_{12}^* & A_{22}^* \end{bmatrix} + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} [B_1^* | B_2^*] = 0$$

and

$$(A.2) \quad \begin{bmatrix} A_{11}^* & A_{21}^* \\ A_{12}^* & A_{22}^* \end{bmatrix} \begin{bmatrix} \Sigma & 0 \\ 0 & \sigma_{k+1}I \end{bmatrix} + \begin{bmatrix} \Sigma & 0 \\ 0 & \sigma_{k+1}I \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} + \begin{bmatrix} C_1^* \\ C_2^* \end{bmatrix} [C_1 | C_2] = 0$$

are satisfied.

Next, we invoke [12, Thm. 8.7] which states that all error systems with the desired properties may be generated by

$$(A.3) \quad \hat{X}(s) + Q^*(s) = H_{11}(s) - H_{12}(s)U(s)(I + H_{22}(s)U(s))^{-1}H_{21}(s)$$

in which

$$(A.4) \quad H(s) = \begin{bmatrix} H_{11}(s) & H_{12}(s) \\ H_{21}(s) & H_{22}(s) \end{bmatrix} = \left[\begin{array}{c|cc} \Gamma^{-1}(\sigma_{k+1}^2 A_{11}^* + \Sigma A_{11} \Sigma) & \Gamma^{-1} \Sigma B_1 & -\Gamma^{-1} C_1^* \\ \hline C_1 \Sigma & D & I \\ -\sigma_{k+1} B_1^* & \sigma_{k+1} I & 0 \end{array} \right]$$

and

$$(A.5) \quad U(s) \in RH_-^\infty$$

satisfies

$$(A.6) \quad \|U(j\omega)\|_\infty \leq 1$$

and

$$(A.7) \quad C_2 + U(s)B_2^* = 0.$$

In order that we may obtain the required state-space characterization of all error systems we assume that an arbitrary $U(s)$ with the desired properties has a minimal state-space realization $U(s) = (\hat{A}, \hat{B}, \hat{C}, \hat{D})$. Since $\|U(j\omega)\|_\infty \leq 1 \Leftrightarrow I - U(j\omega)U^*(j\omega) \geq 0$, the bounded real lemma [1, p. 308] ensures the existence of $\hat{P} = \hat{P}^* < 0$, $\hat{Q} = \hat{Q}^* < 0$, \hat{L} , \hat{W} , \hat{L}_d and \hat{W}_d such that

$$(A.8) \quad \begin{bmatrix} -(\hat{A}\hat{P} + \hat{P}\hat{A}^* + \hat{B}\hat{B}^*) & -(\hat{B}\hat{D}^* + \hat{P}\hat{C}^*) \\ -(\hat{D}\hat{B}^* + \hat{C}\hat{P}) & I - \hat{D}\hat{D}^* \end{bmatrix} = \begin{bmatrix} \hat{L} \\ \hat{W} \end{bmatrix} [\hat{L}^* | \hat{W}^*]$$

and

$$(A.9) \quad \begin{bmatrix} -(\hat{A}^*\hat{Q} + \hat{Q}\hat{A} + \hat{C}^*\hat{C}) & -(\hat{C}^*\hat{D} + \hat{Q}\hat{B}) \\ -(\hat{D}^*\hat{C} + \hat{B}^*\hat{Q}) & I - \hat{D}^*\hat{D} \end{bmatrix} = \begin{bmatrix} \hat{L}_d^* \\ \hat{W}_d^* \end{bmatrix} [\hat{L}_d | \hat{W}_d]$$

are satisfied.

$$(A.10) \quad (A.7) \Rightarrow C_2 + U(\infty)B_2^* = 0 \Rightarrow C_2 + \hat{D}B_2^* = 0,$$

$$(A.11) \quad \begin{aligned} (A.7) \text{ and } (A.10) &\Rightarrow \hat{C}(sI - \hat{A})^{-1}\hat{B}B_2^* = 0 \\ &\Rightarrow \hat{B}B_2^* = 0 \quad (\text{since } [\hat{A}, \hat{C}] \text{ is observable}). \end{aligned}$$

The condition $\|U(j\omega)\|_\infty \leq 1$ implies that there exists a spectral factor $\Delta(s)$ such that

$$(A.12) \quad I - U^*(s)U(s) = \Delta^*(s)\Delta(s),$$

$$(A.7) \Rightarrow B_2 U^*(s)U(s)B_2^* = C_2^* C_2,$$

$$(A.13) \quad (A.12) \Rightarrow B_2 B_2^* - B_2 \Delta^*(s)\Delta(s)B_2^* = C_2^* C_2.$$

The (2, 2) blocks of (A.1) and (A.2) $\Rightarrow B_2 B_2^* = C_2^* C_2$ and this together with (A.13) means

$$(A.14) \quad \Delta(s)B_2^* = 0.$$

Multiplying (A.7) on the left by $U^*(s)$ we get

$$U^*(s)C_2 + U^*(s)U(s)B_2^* = 0$$

$$\Leftrightarrow U^*(s)C_2 + B_2^* - \Delta^*(s)\Delta(s)B_2^* = 0 \quad (\text{by (A.12)})$$

$$(A.15) \quad \Rightarrow U^*(s)C_2 + B_2^* = 0 \quad (\text{by (A.14)}).$$

Hence

$$(A.16) \quad (A.15) \Rightarrow U^*(\infty)C_2 + B_2^* = \hat{D}^*C_2 + B_2^* = 0,$$

$$(A.17) \quad (A.15) \text{ and } (A.16) \Rightarrow \hat{B}^*(sI + \hat{A}^*)^{-1}\hat{C}^*C_2 = 0$$

$$(A.18) \quad \Rightarrow \hat{C}^*C_2 = 0 \quad (\text{by the controllability of } [\hat{A}, \hat{B}]).$$

The state-space model (2.32) for $E(s)$ can be obtained by deriving a state-space realization for the linear fractional transformation (A.3) from the realizations of $H(s)$ and $U(s)$.

Equations (2.33) and (2.34) are proved by simple calculations which are reminiscent of those in [12]. We will begin with the (1, 1) block of (2.33). The validity of partitions (1, 1), (1, 2), (2, 1) and (2, 2) follows directly from (A.1).

$$\begin{aligned} \text{partition (1, 3)} &= A_{11} + (\sigma_{k+1}^2 A_{11} + \Sigma A_{11}^* \Sigma - \sigma_{k+1} B_1 \hat{D}^* C_1) \Gamma^{-1} \\ &\quad + B_1 (B_1^* \Sigma + \sigma_{k+1} \hat{D}^* C_1) \Gamma^{-1} \\ &= (A_{11} \Sigma^2 - \sigma_{k+1}^2 A_{11} + \sigma_{k+1}^2 A_{11} + \Sigma A_{11}^* \Sigma \\ &\quad - (A_{11} \Sigma + \Sigma A_{11}^*) \Sigma) \Gamma^{-1} \quad (\text{by (A.1)}) \\ &= 0. \end{aligned}$$

$$\text{partition (1, 4)} = -\sigma_{k+1} B_1 \hat{B}^* + \sigma_{k+1} B_1 \hat{B}^* = 0.$$

$$\begin{aligned} \text{partition (2, 3)} &= A_{21} + B_2 (B_1^* \Sigma + \sigma_{k+1} \hat{D}^* C_1) \Gamma^{-1} \\ &= (A_{21} \Sigma^2 - \sigma_{k+1}^2 A_{21} - (\sigma_{k+1} A_{12}^* + A_{21} \Sigma) \Sigma \\ &\quad + (A_{12}^* \Sigma + \sigma_{k+1} A_{21}) \sigma_{k+1}) \Gamma^{-1} \quad (\text{by (A.1, A.2, A.10)}) \\ &= 0. \end{aligned}$$

$$\text{partition (2, 4)} = \sigma_{k+1} B_2 \hat{B}^* = 0 \quad (\text{by (A.11)}).$$

$$\begin{aligned} \text{partition (3, 1)} &= \Gamma^{-1} \{ \sigma_{k+1}^2 A_{11}^* + \Sigma A_{11} \Sigma - \sigma_{k+1} C_1^* \hat{D} B_1^* + \Sigma^2 A_{11}^* - \sigma_{k+1}^2 A_{11}^* \\ &\quad + (\Sigma B_1 + \sigma_{k+1} C_1^* \hat{D}) B_1^* \} \\ &= \Gamma^{-1} \{ \Sigma A_{11} \Sigma + \Sigma^2 A_{11}^* - \Sigma (A_{11} \Sigma + \Sigma A_{11}^*) \} \quad (\text{by (A.1)}) \\ &= 0. \end{aligned}$$

$$\begin{aligned} \text{partition (3, 2)} &= \Gamma^{-1} \{ \Sigma^2 A_{21}^* - \sigma_{k+1}^2 A_{21}^* + (\Sigma B_1 + \sigma_{k+1} C_1^* \hat{D}) B_2^* \} \\ &= \Gamma^{-1} \{ \Sigma^2 A_{21}^* - \sigma_{k+1}^2 A_{21}^* - \Sigma (\sigma_{k+1} A_{12} + \Sigma A_{21}^*) \\ &\quad + \sigma_{k+1} (\sigma_{k+1} A_{12}^* + \Sigma A_{12}) \} \\ &= 0 \quad (\text{by (A.1), (A.2), (A.10)}). \end{aligned}$$

$$\begin{aligned} \text{partition (3, 3)} &= \Gamma^{-1} \{ (\sigma_{k+1}^2 A_{11}^* + \Sigma A_{11} \Sigma - \sigma_{k+1} C_1^* \hat{D} B_1^*) \Sigma \\ &\quad + \Sigma (\sigma_{k+1}^2 A_{11} + \Sigma A_{11}^* \Sigma - \sigma_{k+1} B_1 \hat{D}^* C_1) \\ &\quad + (\Sigma B_1 + \sigma_{k+1} C_1^* \hat{D}) (B_1^* \Sigma + \sigma_{k+1} \hat{D}^* C_1) \\ &\quad + \sigma_{k+1}^2 C_1^* \hat{W} \hat{W}^* C_1 \} \Gamma^{-1} \\ &= \Gamma^{-1} \{ \sigma_{k+1}^2 A_{11}^* \Sigma + \Sigma A_{11} \Sigma^2 + \sigma_{k+1}^2 \Sigma A_{11}^* + \Sigma^2 A_{11} \Sigma \\ &\quad - \Sigma (A_{11} \Sigma + \Sigma A_{11}^*) \Sigma \\ &\quad - \sigma_{k+1}^2 (A_{11}^* \Sigma + \Sigma A_{11}) \} \Gamma^{-1} \\ &= 0 \quad (\text{by (A.1), (A.2), (A.8)}). \end{aligned}$$

$$\begin{aligned}
\text{partition (3, 4)} &= \Gamma^{-1} \{ \sigma_{k+1}^2 C_1^* \hat{C} \hat{P} - \sigma_{k+1} \Sigma B_1 \hat{B}^* \\
&\quad + (\Sigma B_1 + \sigma_{k+1} C_1^* \hat{D}) \sigma_{k+1} \hat{B}^* + \sigma_{k+1}^2 C_1^* \hat{W} \hat{L}^* \} \\
&= \sigma_{k+1}^2 \Gamma^{-1} C_1^* \{ \hat{C} \hat{P} + \hat{D} \hat{B}^* + \hat{W} \hat{L}^* \} \\
&= 0 \quad (\text{by (A.8)}). \\
\text{partition (4, 1)} &= -\sigma_{k+1} \hat{B} \hat{B}_1^* + \sigma_{k+1} \hat{B} \hat{B}_1^* = 0. \\
\text{partition (4, 2)} &= \sigma_{k+1} \hat{B} \hat{B}_2^* = 0 \quad (\text{by (A.11)}). \\
\text{partition (4, 3)} &= \{ -\sigma_{k+1} \hat{B} \hat{B}_1^* \Sigma + \sigma_{k+1}^2 \hat{P} \hat{C}^* C_1 + \sigma_{k+1} \hat{B} (B_1^* \Sigma + \sigma_{k+1} \hat{D}^* C_1) \\
&\quad + \sigma_{k+1}^2 \hat{L} \hat{W}^* C_1 \} \Gamma^{-1} \\
&= \sigma_{k+1}^2 \{ \hat{P} \hat{C}^* + \hat{B} \hat{D}^* + \hat{L} \hat{W}^* \} C_1 \Gamma^{-1} \\
&= 0 \quad (\text{by (A.8)}). \\
\text{partition (4, 4)} &= \sigma_{k+1}^2 (\hat{A} \hat{P} + \hat{P} \hat{A}^* + \hat{B} \hat{B}^* + \hat{L} \hat{L}^*) \\
&= 0 \quad (\text{by (A.8)}).
\end{aligned}$$

The (2, 1) and therefore also the (1, 2) blocks of (2.33) are verified next.

$$\begin{aligned}
\text{partition (1, 1)} &= \sigma_{k+1} \hat{D} \hat{B}_1^* + C_1 \Sigma - C_1 \Sigma - \sigma_{k+1} \hat{D} \hat{B}_1^* = 0. \\
\text{partition (1, 2)} &= \sigma_{k+1} (\hat{D} \hat{B}_2^* + C_2) = 0 \quad (\text{by (A.10)}). \\
\text{partition (1, 3)} &= \{ \sigma_{k+1} \hat{D} (B_1^* \Sigma + \sigma_{k+1} \hat{D}^* C_1) + C_1 \Sigma^2 - \sigma_{k+1}^2 C_1 \\
&\quad - (C_1 \Sigma + \sigma_{k+1} \hat{D} \hat{B}_1^*) \Sigma + \sigma_{k+1}^2 \hat{W} \hat{W}^* C_1 \} \Gamma^{-1} \\
&= \sigma_{k+1}^2 \{ \hat{D} \hat{D}^* - I + \hat{W} \hat{W}^* \} C_1 \\
&= 0 \quad (\text{by (A.8)}).
\end{aligned}$$

$$\text{partition (1, 4)} = \sigma_{k+1}^2 \{ \hat{D} \hat{B}^* + \hat{C} \hat{P} + \hat{W} \hat{L}^* \} = 0 \quad (\text{by (A.8)}).$$

The (2, 2) block of (2.33) follows immediately from (A.8); (2.33) is thus proven. The validity of (2.34) is established in the same way—in this case use is made of equations (A.1), (A.2), (A.9), (A.16) and (A.18). Since the calculations are very similar to those used to establish (2.33), these details are omitted. \square

Appendix B.

Proof of Theorem 3.2. As one would expect, the proofs associated with problems (i) to (iii) are similar. We will therefore only prove the result in the case of (i); the sensitivity proof being marginally more intricate than the others.

Equation (2.6) shows that the $P(s)$ matrix associated with the unweighted sensitivity problem is

$$(B.1) \quad P(s) = \begin{bmatrix} I & G \\ I & G \end{bmatrix} (s)$$

which has a state-space realization

$$(B.2) \quad P(s) = \left[\begin{array}{c|cc} A & 0 & B \\ \hline C & I & D \\ C & I & D \end{array} \right] (s).$$

After scaling as in (2.19), we get

$$(B.3) \quad P(s) = \left[\begin{array}{c|cc} A & 0 & BD^{-1} \\ \hline C & I & I \\ C & I & I \end{array} \right] (s).$$

We have already established that the interpolation points are the right half plane zeros of $G(s)$ and that the left half plane zeros play no part. For simplicity, we will assume that $G(s)$ has all its zeros in \mathbb{C}_+ . If this is not the case, the Riccati equation balancing theory of this section may be used to reduce the general problem to one in which $\operatorname{Re}[\lambda(A - BD^{-1}C)] > 0$. We leave the details to the reader.

If we now substitute the various partitions of (B.3) into (2.20) to (2.23) we obtain

$$(B.4) \quad X(A - BD^{-1}C) + (A - BD^{-1}C)^*X - XBD^{-1}D^{-*}B^*X = 0,$$

$$(B.5) \quad YA^* + AY - YC^*CY = 0,$$

$$(B.6) \quad F = C + D^{-*}B^*X,$$

$$(B.7) \quad H = YC^*.$$

Since $\operatorname{Re}[\lambda(A - BD^{-1}C)] > 0$ by assumption, the stabilizing solution X to (B.4) is nonsingular.

Next, we use (B.3) and (B.4) to (B.7) in (2.28) to obtain

$$(B.8) \quad T_{12}^* T_{11} T_{21}^* = \left[\begin{array}{cc|c} -\{A - BD^{-1}(C + D^{-*}B^*X)\}^* & XBD^{-1}CY & XBD^{-1} \\ 0 & -\{A - YC^*C\}^* & C^* \\ \hline D^{-*}B^* & -D^{-*}B^*XY & I \end{array} \right].$$

Introducing the basis change

$$(B.9) \quad T = \begin{bmatrix} I & -XY \\ 0 & I \end{bmatrix}$$

gives

$$(B.10) \quad T_{12}^* T_{11} T_{21}^* = \left[\begin{array}{cc|c} -\{A - BD^{-1}(C + D^{-*}B^*X)\}^* & 0 & X(BD^{-1} - YC^*) \\ 0 & -\{A - YC^*C\}^* & C^* \\ \hline D^{-*}B^* & 0 & I \end{array} \right] \\ = \left[\begin{array}{c|c} -\{A - BD^{-1}(C + D^{-*}B^*X)\}^* & X(BD^{-1} - YC^*) \\ \hline D^{-*}B^* & I \end{array} \right].$$

The fact that the (1, 2) block of the A -matrix in (B.10) is zero may be proved using (B.4) Y and X (B.5).

The equation defining the observability gramian of $T_{12}^* T_{11} T_{21}^*(s)$ is

$$(B.11) \quad -\{A - BD^{-1}(C + D^{-*}B^*X)\}Q - Q\{A - BD^{-1}(C + D^{-*}B^*X)\}^* \\ + BD^{-1}D^{-*}B = 0.$$

Comparison of (B.11) with $X^{-1}(B.4)X^{-1} = 0$ reveals that

$$(B.12) \quad Q = -X^{-1} < 0.$$

The equation defining the controllability gramian of $T_{12}^* T_{11} T_{21}^*(s)$ is

$$(B.13) \quad \{A - BD^{-1}(C + D^{-*}B^*X)\}^*P + P\{A - BD^{-1}(C + D^{-*}B^*X)\} \\ - X(BD^{-1} - YC^*)(D^{-*}B^* - CY)X = 0.$$

Substituting $PX^{-1}(B.4)$ and $(B.4)X^{-1}P$ into (B.13) we get

$$(B.14) \quad X(A - BD^{-1}C)X^{-1}P + PX^{-1}(A - BD^{-1}C)^*X \\ + X(BD^{-1} - YC^*)(D^{-*}B^* - CY)X = 0.$$

Substitution of (B.4) and (B.5) into (B.14) now shows that (B.13) is satisfied by

$$(B.15) \quad P = -X(I + YX) < 0,$$

whence

$$PQ = I + XY$$

and

$$\|(T_{12}^* T_{11} T_{21}^*(s))\|_H = \lambda_{\max}(PQ)^{1/2} = [1 + \lambda_{\max}(YX)]^{1/2}.$$

Finally, we know (from the discussion of § 2) that

$$\inf_{K \in \Xi} \|(I + GK)^{-1}(s)\|_{\infty} = \|(T_{12}^* T_{11} T_{21}^*)^*(s)\|_H,$$

and this concludes the proof of (i). Parts (ii) and (iii) and the unweighted version of (iv) can be proved using similar calculations. To prove the weighted version of (iv), one may invoke the ideas in [13] whereby a weighted optimal robustness problem can be transformed into an equivalent unweighted problem. These details are left to the interested reader. \square

Appendix C.

Proof of Theorem 4.1. We may assume without loss of generality that the realizations for $A_1(s)$ and $A_2(s)$ are balanced. Since they are minimal also, the following six all-pass equations [12] are satisfied.

$$(C.1) \quad A_{11} + A_{11}^* + B_{12} B_{12}^* = 0,$$

$$(C.2) \quad A_{11} + A_{11}^* + C_{11}^* C_{11} = 0,$$

$$(C.3) \quad C_{11} + B_{12}^* = 0,$$

$$(C.4) \quad A_{22} + A_{22}^* + B_{21} B_{21}^* = 0,$$

$$(C.5) \quad A_{22} + A_{22}^* + C_{22}^* C_{22} = 0,$$

$$(C.6) \quad C_{22} + B_{21}^* = 0.$$

The first part of the proof will be concerned with the extraction of a maximal degree all-pass left factor $A_1(s)$ from $A_1(s)$ and $G(s)$. Let us consider

$$(C.7) \quad A_1^* G(s) = \left[\begin{array}{c|c} \frac{-A_{11}^*}{-B_{12}^*} & \frac{C_{11}^*}{I} \end{array} \right] \left[\begin{array}{cc|c} A_{11} & A_{12} & B_{11} \\ 0 & A_{22} & B_{21} \\ \hline C_{11} & C_{12} & D \end{array} \right]$$

$$= \left[\begin{array}{ccc|c} -A_{11}^* & C_{11}^* C_{11} & C_{11}^* C_{12} & C_{11}^* D \\ 0 & A_{11} & A_{12} & B_{11} \\ 0 & 0 & A_{22} & B_{21} \\ \hline -B_{12}^* & C_{11} & C_{12} & D \end{array} \right].$$

Introducing the change of basis

$$T = \left[\begin{array}{ccc} I & I & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{array} \right]$$

and then making use of (C.2) and (C.3) we obtain

$$(C.8) \quad A_1^* G(s) = \left[\begin{array}{cc|c} -A_{11}^* & A_{12} + C_{11}^* C_{12} & C_{11}^* D + B_{11} \\ 0 & A_{22} & B_{21} \\ \hline -B_{12}^* & C_{12} & D \end{array} \right].$$

Our purpose now is to show that all the uncontrollable modes in $A_1^*G(s)$ are the poles of $A_1^*(s)$. Since (A_{22}, B_{21}) is controllable by assumption, every uncontrollable mode in (C.8) is an eigenvalue of $-A_{11}^*$. First, we observe that without loss of generality, we may assume that the state-space basis of the realization in (4.15) has been chosen so that in addition to (C.1)–(C.6), we have

$$(C.9) \quad A_{12} + C_{11}^* C_{12} = 0.$$

To show that this is so, consider the following change of basis in (4.15)

$$(C.10) \quad \begin{bmatrix} \bar{A}_{11} & \bar{A}_{12} \\ 0 & \bar{A}_{22} \end{bmatrix} = \begin{bmatrix} I & T \\ 0 & I \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} I & -T \\ 0 & I \end{bmatrix},$$

$$(C.11) \quad [\bar{C}_{11} \quad \bar{C}_{12}] = [C_{11} \quad C_{12}] \begin{bmatrix} I & -T \\ 0 & I \end{bmatrix}.$$

We now demonstrate that T may be chosen to make

$$(C.12) \quad \bar{A}_{12} + \bar{C}_{11}^* \bar{C}_{12} = 0.$$

From (C.10) and (C.11), (C.12) is equivalent to

$$(C.13) \quad (A_{12} + TA_{22} - A_{11}T) + C_{11}^*(C_{12} - C_{11}T) = 0.$$

Using (C.2), (C.13) becomes

$$(C.14) \quad A_{11}^*T + TA_{22} + (A_{12} + C_{11}^*C_{12}) = 0.$$

Since A_{11} and A_{22} are stable, (C.14) always admits a unique solution in T . Such a T ensures that the transformed state-space matrices satisfy (C.12). For notational simplicity, we assume that this basis change has been carried out initially and we revert to the original notation. In view of (C.9), (C.8) becomes

$$(C.15) \quad A_1^*G(s) = \left[\begin{array}{cc|c} -A_{11}^* & 0 & C_{11}^*D + B_{11} \\ 0 & A_{22} & B_{21} \\ \hline -B_{12}^* & C_{12} & D \end{array} \right].$$

If the realization (C.15) has any uncontrollable modes (which must be eigenvalues of $-A_{11}^*$) we may introduce a basis change

$$(C.16) \quad T = \begin{bmatrix} U_1 & 0 \\ 0 & I \end{bmatrix}$$

in which U_1 is orthogonal, to transform (C.15) to [24]

$$A_1^*G(s) = \left[\begin{array}{ccc|c} -\tilde{A}_{00}^* & 0 & 0 & \tilde{C}_{10}^*D + \tilde{B}_{01} \\ -\tilde{A}_{01}^* & -\tilde{A}_{11}^* & 0 & \tilde{C}_{11}^*D + \tilde{B}_{11} \\ 0 & 0 & A_{22} & B_{21} \\ \hline -\tilde{B}_{02}^* & -\tilde{B}_{12}^* & C_{12} & D \end{array} \right],$$

in which all the uncontrollable modes are eigenvalues of $-\tilde{A}_{00}^*$. That is

$$(C.17) \quad \tilde{C}_{10}^*D + \tilde{B}_{01} = 0$$

and thus

$$(C.18) \quad A_1^*G(s) = \left[\begin{array}{cc|c} -\tilde{A}_{11}^* & 0 & \tilde{C}_{11}^*D + \tilde{B}_{11} \\ 0 & A_{22} & B_{21} \\ \hline -\tilde{B}_{12}^* & C_{12} & D \end{array} \right]$$

is a controllable realization.

Introducing the basis of (C.18) into (4.15) allows us to write

$$(C.19) \quad [G \ A_1](s) = \left[\begin{array}{ccc|cc} \tilde{A}_{00} & \tilde{A}_{01} & \tilde{A}_{02} & \tilde{B}_{01} & \tilde{B}_{02} \\ 0 & \tilde{A}_{11} & \tilde{A}_{12} & \tilde{B}_{11} & \tilde{B}_{12} \\ 0 & 0 & A_{22} & B_{21} & 0 \\ \hline \tilde{C}_{10} & \tilde{C}_{11} & C_{12} & D & I \end{array} \right]$$

in which we have by (C.9)

$$(C.20) \quad \begin{bmatrix} \tilde{A}_{02} \\ \tilde{A}_{12} \end{bmatrix} + \begin{bmatrix} \tilde{C}_{10}^* \\ \tilde{C}_{11}^* \end{bmatrix} C_{12} = 0.$$

Noting that orthogonal transformations map balanced realizations into balanced realizations in the case of minimal realizations of inner matrices gives

$$(C.21) \quad \begin{bmatrix} \tilde{A}_{00} & \tilde{A}_{01} \\ 0 & \tilde{A}_{11} \end{bmatrix} + \begin{bmatrix} \tilde{A}_{00}^* & 0 \\ \tilde{A}_{01}^* & \tilde{A}_{11}^* \end{bmatrix} + \begin{bmatrix} \tilde{C}_{10}^* \\ \tilde{C}_{11}^* \end{bmatrix} [\tilde{C}_{10} | \tilde{C}_{11}] = 0,$$

$$(C.22) \quad [\tilde{C}_{10} | \tilde{C}_{11}] + [\tilde{B}_{02}^* | \tilde{B}_{12}^*] = 0.$$

Substituting for \tilde{A}_{01} from (C.21), \tilde{A}_{02} from (C.20), \tilde{B}_{01} from (C.17) and \tilde{B}_{02}^* from (C.22) into (C.19) we get

$$(C.23) \quad [G \ A_1](s) = \left[\begin{array}{ccc|cc} \tilde{A}_{00} & -\tilde{C}_{10}^* \tilde{C}_{11} & -\tilde{C}_{10}^* C_{12} & -\tilde{C}_{10}^* D & -\tilde{C}_{10}^* \\ 0 & \tilde{A}_{11} & \tilde{A}_{12} & \tilde{B}_{11} & \tilde{B}_{12} \\ 0 & 0 & A_{22} & B_{21} & 0 \\ \hline \tilde{C}_{10} & \tilde{C}_{11} & C_{12} & D & I \end{array} \right]$$

$$(C.24) \quad = \left[\begin{array}{c|c} \tilde{A}_{00} & -\tilde{C}_{10}^* \\ \hline \tilde{C}_{10} & I \end{array} \right] \left[\begin{array}{cc|cc} \tilde{A}_{11} & \tilde{A}_{12} & \tilde{B}_{11} & \tilde{B}_{12} \\ 0 & A_{22} & B_{21} & 0 \\ \hline \tilde{C}_{11} & C_{12} & D & I \end{array} \right]$$

$$(C.25) \quad = A_l(s) [\bar{G} \ \tilde{A}_1](s)$$

where $A_l(s)$ and $\tilde{A}_1(s)$ are as given in (4.17) (note that $\tilde{B}_{02}^* = -\tilde{C}_{10}^*$). It follows immediately from (C.21) and (C.22) that $A_l(s)$ and hence also $\tilde{A}_1(s)$ are inner.

By using dual arguments, we can extract a maximal degree all-pass right factor $A_r(s)$ from $\bar{G}(s)$ and $A_2(s)$. We begin this calculation with the change of basis

$$(C.26) \quad T = \begin{bmatrix} I & S \\ 0 & I \end{bmatrix}$$

in the state-space of

$$(C.27) \quad \begin{bmatrix} \bar{G} \\ A_2 \end{bmatrix}(s) = \left[\begin{array}{cc|c} \tilde{A}_{11} & \tilde{A}_{12} & \tilde{B}_{11} \\ 0 & A_{22} & B_{21} \\ \hline \tilde{C}_{11} & C_{12} & D \\ 0 & C_{22} & I \end{array} \right]$$

where S is the unique solution of

$$(C.28) \quad \tilde{A}_{11} S + S A_{22}^* - \tilde{A}_{12} - \tilde{B}_{11} B_{21}^* = 0.$$

The purpose of this basis change is to transform the realization (C.27) to

$$(C.29) \quad \begin{bmatrix} \bar{G} \\ A_2 \end{bmatrix}(s) = \left[\begin{array}{cc|c} \tilde{A}_{11} & \hat{A}_{12} & \tilde{B}_{11} \\ 0 & A_{22} & B_{21} \\ \hline \tilde{C}_{11} & \hat{C}_{12} & D \\ 0 & C_{22} & I \end{array} \right]$$

in which

$$(C.30) \quad \hat{A}_{12} + \tilde{B}_{11} B_{21}^* = 0.$$

Next, a second orthogonal transformation

$$T = \begin{bmatrix} I & 0 \\ 0 & U_2 \end{bmatrix}$$

together with arguments which are duals of those invoked previously (see equations (C.15) to (C.25)) allow us to write

$$(C.31) \quad \begin{bmatrix} \bar{G} \\ A_2 \end{bmatrix} (s) = \left[\begin{array}{cc|c} \tilde{A}_{11} & \tilde{A}_{12} & \tilde{B}_{11} \\ 0 & \tilde{A}_{22} & \tilde{B}_{21} \\ \hline \tilde{C}_{11} & \tilde{C}_{12} & D \\ 0 & \tilde{C}_{22} & I \end{array} \right] \left[\begin{array}{c|c} \tilde{A}_{33} & \tilde{B}_{31} \\ \hline -\tilde{B}_{31}^* & I \end{array} \right]$$

$$(C.32) \quad = \begin{bmatrix} \tilde{G} \\ \tilde{A}_2 \end{bmatrix} (s) A_r(s)$$

in which both $\tilde{A}_2(s)$ and $A_r(s)$ are inner. Further,

$$(C.33) \quad \begin{aligned} \bar{G} A_2^*(s) &= \tilde{G} \tilde{A}_2^*(s) \\ &= \left[\begin{array}{cc|c} \tilde{A}_{11} & \tilde{A}_{12} + \tilde{B}_{11} \tilde{B}_{21}^* & \tilde{B}_{11} \\ 0 & -\tilde{A}_{22}^* & -\tilde{C}_{22}^* \\ \hline \tilde{C}_{11} & \tilde{C}_{12} + D \tilde{B}_{21}^* & D \end{array} \right] \end{aligned}$$

is an observable realization.

Equations (4.17), (4.18), (4.19) and parts (a) and (b) of the theorem have now been established and it remains for us to prove (c). Multiplying (C.33) on the left by $\tilde{A}_1^*(s)$ and using (C.21) and (C.22) we get

$$(C.34) \quad \tilde{A}_1^* \tilde{G} \tilde{A}_2^*(s) = \left[\begin{array}{cc|c} -\tilde{A}_{11}^* & \tilde{A}_{12} + \tilde{B}_{11} \tilde{B}_{21}^* + \tilde{C}_{11}^* (\tilde{C}_{12} + D \tilde{B}_{21}^*) & \tilde{C}_{11}^* D + \tilde{B}_{11} \\ 0 & -\tilde{A}_{22}^* & -\tilde{C}_{22}^* \\ \hline -\tilde{B}_{12}^* & \tilde{C}_{12} + D \tilde{B}_{21}^* & D \end{array} \right].$$

The minimality of the realization in (C.34) is established by first showing that it is observable. Using (C.21) and (C.22) we have that

$$(C.35) \quad \begin{aligned} &\left[\begin{array}{cc|c} sI + \tilde{A}_{11}^* & -\tilde{A}_{12} - \tilde{B}_{11} \tilde{B}_{21}^* - \tilde{C}_{11}^* (\tilde{C}_{12} + D \tilde{B}_{21}^*) & \\ 0 & sI + \tilde{A}_{22}^* & \\ \hline -\tilde{B}_{12}^* & \tilde{C}_{12} + D \tilde{B}_{21}^* & \end{array} \right] \\ &= \begin{bmatrix} I & 0 & -\tilde{C}_{11}^* \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix} \left[\begin{array}{cc|c} sI - \tilde{A}_{11} & -\tilde{A}_{12} - \tilde{B}_{11} \tilde{B}_{21}^* & \\ 0 & sI + \tilde{A}_{22}^* & \\ \hline \tilde{C}_{11} & \tilde{C}_{12} + D \tilde{B}_{21}^* & \end{array} \right]. \end{aligned}$$

Since the $[A, C]$ pair in (C.33) is observable, and because the polynomial matrices on both sides of (C.35) have the same Smith form, the realization in (C.34) is also observable [19].

The minimality of the realization in (C.34) can now be established by showing that it is controllable. We note that

$$(C.36) \quad \left[\begin{array}{cc|c} sI + \tilde{A}_{11}^* & -\tilde{A}_{12} - \tilde{B}_{11}\tilde{B}_{21}^* - \tilde{C}_{11}^*(\tilde{C}_{12} + D\tilde{B}_{21}^*) & \tilde{C}_{11}^*D + \tilde{B}_{11} \\ 0 & sI + \tilde{A}_{22}^* & -\tilde{C}_{22}^* \end{array} \right] \\ = \left[\begin{array}{cc|c} sI + \tilde{A}_{11}^* & -\tilde{A}_{12} - \tilde{C}_{11}^*\tilde{C}_{12} & \tilde{C}_{11}^*D + \tilde{B}_{11} \\ 0 & sI - \tilde{A}_{22} & \tilde{B}_{21} \end{array} \right] \left[\begin{array}{ccc} I & 0 & 0 \\ 0 & I & 0 \\ 0 & -\tilde{B}_{21}^* & I \end{array} \right].$$

The first matrix on the right of (C.36) is the $[sI - A, B]$ pair of a controllable realization of $\tilde{A}_1^* \tilde{G}(s)$. To show this we assemble from (C.34), (C.31) and (C.32)

$$(C.37) \quad [\tilde{G} \quad \tilde{A}_1(s)] = \left[\begin{array}{cc|cc} \tilde{A}_{11} & \tilde{A}_{12} & \tilde{B}_{11} & \tilde{B}_{12} \\ 0 & \tilde{A}_{22} & \tilde{B}_{21} & 0 \\ \hline \tilde{C}_{11} & \tilde{C}_{12} & D & I \end{array} \right]$$

and thus

$$(C.38) \quad \tilde{A}_1^* \tilde{G}(s) = \left[\begin{array}{cc|c} -\tilde{A}_{11}^* & \tilde{A}_{12} + \tilde{C}_{11}^*\tilde{C}_{12} & \tilde{C}_{11}^*D + \tilde{B}_{11} \\ 0 & \tilde{A}_{22} & \tilde{B}_{21} \\ \hline -\tilde{B}_{12}^* & \tilde{C}_{12} & D \end{array} \right].$$

Hence

$$(C.39) \quad \tilde{A}_1^* \tilde{G} A_r(s) = \tilde{A}_1^*(s) \tilde{G}(s) \\ = \left[\begin{array}{cc|c} -\tilde{A}_{11}^* & \tilde{A}_{12} + \tilde{C}_{11}^*\tilde{C}_{12} & \tilde{C}_{11}^*D + \tilde{B}_{11} \\ 0 & \tilde{A}_{22} & \tilde{B}_{21} \\ \hline -\tilde{B}_{12}^* & \tilde{C}_{12} & D \end{array} \right] \left[\begin{array}{cc} \tilde{A}_{33} & \tilde{B}_{31} \\ -\tilde{B}_{31}^* & I \end{array} \right].$$

This cascade realization is system similar (in the sense defined in [19]) to the controllable realization in (C.18) and thus both realizations in (C.39) are controllable. This shows that the realization of (C.38) is controllable as required. The controllability and thus minimality of (C.34) now follows. This completes the proof of the minimality of (4.23). \square

Appendix D.

Proof of Theorem 4.2. Since the realizations for $A_1(s)$ and $A_2(s)$ in (4.30) are assumed to be minimal and balanced, equations (C.1) to (C.6) are again satisfied. The proof of part (a) follows by a direct calculation which is similar to the analysis contained in the proof of Theorem 4.1 and is consequently omitted.

To prove part (b), we will need a number of equations which can be deduced from various partitions of (4.33) to (4.36). Since \tilde{P} and \tilde{Q} in (4.33) and (4.34) are symmetric, we may introduce the notation

$$(D.1) \quad \tilde{P} = \begin{bmatrix} P_{11} & P_{12} & P_{13} \\ P_{12}^* & P_{22} & P_{23} \\ P_{13}^* & P_{23}^* & P_{33} \end{bmatrix}, \quad \tilde{Q} = \begin{bmatrix} Q_{11} & Q_{12} & Q_{13} \\ Q_{12}^* & Q_{22} & Q_{23} \\ Q_{13}^* & Q_{23}^* & Q_{33} \end{bmatrix}$$

where the partitioning is conformable with \tilde{A} of (4.32) in which \underline{A} is partitioned as in (4.31). The (2, 2) partition of the (1, 1) block of (4.33) gives

$$(D.2) \quad -A_{22}^* P_{22} - P_{22} A_{22} + C_{22}^* C_{22} = 0$$

and this together with (C.5) $\Rightarrow P_{22} = -I$. The (3, 2) partition of the (1, 1) block of (4.33) gives

$$(D.3) \quad \hat{A} P_{23}^* - P_{23}^* A_{22} + \hat{B} C_{22} = 0.$$

The (1, 1) partition of the (1, 1) block of (4.34) gives

$$(D.4) \quad -A_{11}Q_{11} - Q_{11}A_{11}^* + B_{12}B_{12}^* = 0$$

and this together with (C.1) $\Rightarrow Q_{11} = -I$. The (1, 3) partition of the (1, 1) block of (4.34) gives

$$(D.5) \quad -A_{11}Q_{13} + Q_{13}\hat{A} + B_{12}\hat{C} = 0.$$

Making use of (C.3), the (1, 1) partition of the (1, 2) block of (4.34) gives

$$(D.6) \quad B_{12}\hat{D} - B_{11} + Q_{12}C_{22}^* + Q_{13}\hat{B} = 0.$$

The (2, 1) partition of (4.35) gives

$$(D.7) \quad Q_{13}P_{23}^* = P_{12} + Q_{12}.$$

If we make use of (C.6), the (1, 2) partition of the (2, 1) block of (4.33) yields

$$(D.8) \quad -\hat{D}C_{22} - B_{12}^*P_{12} + C_{12} - \hat{C}P_{23}^* = 0.$$

Finally, the (1, 2) partition of the (1, 1) block of (4.34) together with (C.3) gives

$$(D.9) \quad -A_{11}Q_{12} + A_{12} + B_{11}B_{21}^* - Q_{12}A_{22}^* = 0.$$

By direct calculation we obtain

$$(D.10) \quad (G - A_1QA_2)(s) = \left[\begin{array}{cc|c} A_{11} & A_{12} & B_{11} \\ 0 & A_{22} & B_{21} \\ \hline C_{11} & C_{12} & D \end{array} \right] - \left[\begin{array}{ccc|c} A_{11} & B_{12}\hat{D}C_{22} & B_{12}\hat{C} & B_{12}\hat{D} \\ 0 & A_{22} & 0 & B_{21} \\ 0 & \hat{B}C_{22} & \hat{A} & \hat{B} \\ \hline C_{11} & \hat{D}C_{22} & \hat{C} & \hat{D} \end{array} \right].$$

The rest of the proof is based on detailed manipulations of the state-space realizations of $A_1QA_2(s)$ in (D.10). First, we introduce the change of basis

$$(D.11) \quad T = \left[\begin{array}{ccc} I & 0 & Q_{13} \\ 0 & I & 0 \\ 0 & 0 & I \end{array} \right]$$

and this together with (D.5) yields

$$(D.12) \quad A_1QA_2(s) = \left[\begin{array}{ccc|c} A_{11} & (B_{12}\hat{D} + Q_{13}\hat{B})C_{22} & 0 & B_{12}\hat{D} + Q_{13}\hat{B} \\ 0 & A_{22} & 0 & B_{21} \\ 0 & \hat{B}C_{22} & \hat{A} & \hat{B} \\ \hline C_{11} & \hat{D}C_{22} & \hat{C} - C_{11}Q_{13} & \hat{D} \end{array} \right].$$

Next, the coordinate transformation

$$(D.13) \quad T = \left[\begin{array}{ccc} I & 0 & 0 \\ 0 & I & 0 \\ 0 & -P_{23}^* & I \end{array} \right]$$

together with (D.3) gives

$$(D.14) \quad A_1QA_2(s) = \left[\begin{array}{ccc|c} A_{11} & (B_{12}\hat{D} + Q_{13}\hat{B})C_{22} & 0 & B_{12}\hat{D} + Q_{13}\hat{B} \\ 0 & A_{22} & 0 & B_{21} \\ 0 & 0 & \hat{A} & \hat{B} - P_{23}^*B_{21} \\ \hline C_{11} & \hat{D}C_{22} + \hat{C}P_{23}^* - C_{11}Q_{13}P_{23}^* & \hat{C} - C_{11}Q_{13} & \hat{D} \end{array} \right].$$

A third change of basis

$$(D.15) \quad T = \begin{bmatrix} I & -Q_{12} & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix}$$

leads to

(D.16)

$$A_1 Q A_2(s)$$

$$= \left[\begin{array}{ccc|c} A_{11} & (B_{12}\hat{D} + Q_{13}\hat{B})C_{22} - Q_{12}A_{22} + A_{11}Q_{12} & 0 & B_{12}\hat{D} + Q_{13}\hat{B} - Q_{12}B_{21} \\ 0 & A_{22} & 0 & B_{21} \\ 0 & 0 & \hat{A} & \hat{B} - P_{23}^*B_{21} \\ \hline C_{11} & \hat{D}C_{22} + \hat{C}P_{23}^* - C_{11}Q_{13}P_{23}^* + C_{11}Q_{12} & \hat{C} - C_{11}Q_{13} & \hat{D} \end{array} \right].$$

Substituting (D.6) C_{22} and (D.9) into the (1, 2) block of the A -matrix in the above realization together with (C.5) and (C.6) gives

$$(D.17) \quad (B_{12}\hat{D} + Q_{13}\hat{B})C_{22} - Q_{12}A_{22} + A_{11}Q_{12} = A_{12}.$$

Substituting (D.6) and (C.6) into the (1, 1) block of the B -matrix in (D.16), we obtain

$$(D.18) \quad B_{12}\hat{D} + Q_{13}\hat{B} - Q_{12}B_{21} = B_{11}.$$

Finally, (D.7), (D.8) and (C.3) will verify that

$$(D.19) \quad \hat{D}C_{22} + \hat{C}P_{23}^* - C_{11}Q_{13}P_{23}^* + C_{11}Q_{12} = C_{12}.$$

Thus

$$(D.20) \quad A_1 Q A_2(s) = \left[\begin{array}{ccc|c} A_{11} & A_{12} & 0 & B_{11} \\ 0 & A_{22} & 0 & B_{21} \\ 0 & 0 & \hat{A} & \hat{B} - P_{23}^*B_{21} \\ \hline C_{11} & C_{12} & \hat{C} - C_{11}Q_{13} & \hat{D} \end{array} \right].$$

Consequently

$$(D.21) \quad (G - A_1 Q A_2)(s) = \left[\begin{array}{c|c} \hat{A} & \hat{B} - P_{23}^*B_{21} \\ \hline -\hat{C} - C_{11}Q_{13} & \hat{D} - \hat{D} \end{array} \right]$$

and this proves (b)(i). Part (b)(ii) is obvious. \square

Appendix E.

Proof of Theorem 4.3. The equations describing the closed loop of Fig. 1 are

$$\dot{x} = Ax + B_1u_1 + B_2u_2,$$

$$y_1 = C_1x + D_{11}u_1 + D_{12}u_2,$$

$$y_2 = C_2x + D_{21}u_1 + D_{22}u_2,$$

$$\dot{\hat{x}} = \hat{A}\hat{x} + \hat{B}y_2,$$

$$u_2 = -(\hat{C}\hat{x} + \hat{D}y_2).$$

Eliminating the variables u_2 and y_2 leads to the following state-space model for the closed loop

$$(E.1) \quad \begin{bmatrix} \dot{x} \\ \dot{\hat{x}} \end{bmatrix} = \begin{bmatrix} A - B_2 \hat{D} M C_2 & -B_2 [I - \hat{D} M D_{22}] \hat{C} \\ \hat{B} M C_2 & \hat{A} - \hat{B} M D_{22} \hat{C} \end{bmatrix} \begin{bmatrix} x \\ \hat{x} \end{bmatrix} + \begin{bmatrix} B_1 - B_2 \hat{D} M D_{21} \\ \hat{B} M D_{22} \end{bmatrix} [u_1],$$

$$(E.2) \quad [y_1] = [C_1 - D_{12} \hat{D} M C_2 \quad -D_{12} [I - \hat{D} M D_{22}] \hat{C}] \begin{bmatrix} x \\ \hat{x} \end{bmatrix} + [D_{11} - D_{12} \hat{D} M D_{21}] [u_1]$$

in which

$$(E.3) \quad M := (I + D_{22} \hat{D})^{-1}.$$

If s_0 is an unobservable mode of the closed loop state-space model (E.1)–(E.3), then there exists a vector $[w_1^* w_2^*]^* \neq 0$ such that

$$(E.4) \quad \begin{bmatrix} s_0 I - A + B_2 \hat{D} M C_2 & B_2 [I - \hat{D} M D_{22}] \hat{C} \\ -\hat{B} M C_2 & s_0 I - \hat{A} + \hat{B} M D_{22} \hat{C} \\ C_1 - D_{12} \hat{D} M C_2 & -D_{12} [I - \hat{D} M D_{22}] \hat{C} \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = 0.$$

Defining

$$z_2 := -\hat{D} M C_2 w_1 - [I - \hat{D} M D_{22}] \hat{C} w_2$$

we have from (E.4) that

$$(E.5) \quad \left[\begin{array}{c|c} s_0 I - A & -B_2 \\ \hline C_1 & D_{12} \end{array} \right] \begin{bmatrix} w_1 \\ z_2 \end{bmatrix} = 0.$$

The proof of the (a) part is concluded by establishing that $[w_1^* w_2^*]^* \neq 0 \Rightarrow [w_1^* z_2^*]^* \neq 0$. Suppose for contradiction that $[w_1^* z_2^*]^* = 0$. This implies that

$$(E.6) \quad \begin{aligned} [I - \hat{D} M D_{22}] \hat{C} w_2 &= 0 \\ \Leftrightarrow (I + \hat{D} D_{12})^{-1} \hat{C} w_2 &= 0 \\ \Leftrightarrow \hat{C} w_2 &= 0. \end{aligned}$$

We also have from (E.4) that

$$(E.7) \quad (s_0 I - \hat{A}) w_2 = 0.$$

Equations (E.6) and (E.7) taken together contradict the assumed minimality of the realization in (4.47) which proves the (a) condition. The (b) part may be established by a parallel sequence of arguments. \square

Appendix F.

Proof of Theorem 4.5. We begin by pointing out that

$$(F.1) \quad (4.66) \Rightarrow I(H_{22}; s_0) = -\frac{1}{\pi} \int_{-\infty}^{\infty} [\ln |\det D(j\omega)| \operatorname{Re}(s_0) / \{|j\omega - s_0|^2\}] d\omega.$$

Next, by invoking the system of J -unitary equations (4.63) to (4.65), one may verify that (note that if $G(s)$ is J -unitary, so also is $G^*(s)$)

$$(F.2) \quad I - E(s)E^*(s) = (D + CU)^{-*} \{I - U^* U\} (D + CU)^{-1}(s)$$

so that

$$(F.3) \quad \begin{aligned} \det(I - E^* E)(s) &= \{\det(D + CU)\}^{-2} \det(I - U^* U) \\ &= \{\det(D(I + D^{-1}CU))\}^{-2} \det(I - U^* U) \\ &= \{\det(D)\}^{-2} \{\det(I + H_{22}U)\}^{-2} \det(I - U^* U). \end{aligned}$$

Therefore

$$(F.4) \quad \begin{aligned} I(E; s_0) &= -\frac{1}{2\pi} \int_{-\infty}^{\infty} \{-2 \ln |\det(D)| - 2 \ln |\det(I + H_{22}U)| \\ &\quad + \ln |\det(I + U^*U)|\} \operatorname{Re}(s_0)/\{|j\omega - s_0|^2\} d\omega \\ &= I(H_{22}; s_0) + I(U; s_0) \end{aligned}$$

$$(F.5) \quad + \frac{1}{\pi} \int_{-\infty}^{\infty} [\ln |\det(I + H_{22}U)| \operatorname{Re}(s_0)/\{|j\omega - s_0|^2\}] d\omega.$$

Since $s_0 \in \mathbb{C}_-$, $H_{22}(s) \in RH_-^\infty$ and $U(s) \in RH_-^\infty$ we have by Poisson's integral formula

$$(F.6) \quad \frac{1}{\pi} \int_{-\infty}^{\infty} [\ln |\det(I + H_{22}U)| \operatorname{Re}(s_0)/\{|j\omega - s_0|^2\}] d\omega = \ln |\det[I + H_{22}(s_0)U(s_0)]|.$$

Hence

$$(F.7) \quad I(E; s_0) = I(H_{22}; s_0) + I(U; s_0) + \ln |\det[I + H_{22}(s_0)U(s_0)]|$$

which proves the first part.

We now need to prove that

$$(F.8) \quad I(U; s_0) + \ln |\det(I + H_{22}(s_0)U(s_0))|$$

attains a minimum at $U_0 = -H_{22}^*(s_0)$. This is obvious when $H_{22}(s_0) = 0$ since $I(U; s_0) \geq 0$ and $I(0; s_0) = 0$. Let us now suppose that $H_{22}(s_0) \neq 0$ and consider the *constant* linear fractional map:

$$(F.9) \quad \Theta_0(U(s)) = (\Theta_{11}U(s) + \Theta_{12})(\Theta_{21}U(s) + \Theta_{22})^{-1}$$

where the Θ_{ij} are sub-blocks of the J -unitary matrix Θ given by

$$(F.10) \quad \Theta = \begin{bmatrix} \Theta_{11} & \Theta_{12} \\ \Theta_{21} & \Theta_{22} \end{bmatrix} = \begin{bmatrix} (I_m - X_0^* X_0)^{-1/2} & -(I_m - X_0^* X_0)^{-1/2} X_0^* \\ -(I_n - X_0 X_0^*)^{1/2} X_0 & (I_n - X_0 X_0^*)^{1/2} \end{bmatrix}$$

where

$$X_0 := -H_{22}(s_0) \in \mathbb{C}^{n \times m}.$$

By applying (F.7) to (F.9) we get

$$(F.11) \quad I(\Theta_0; s_0) = I(X_0; s_0) + I(U; s_0) + \ln |\det(I + H_{22}(s_0)U(s_0))|$$

and substituting (F.11) into (F.7) we get

$$(F.12) \quad I(E; s_0) = I(H_{22}; s_0) + I(\Theta_0; s_0) - I(X_0; s_0).$$

Since $I(\Theta_0(U(s)); s_0) \geq 0$ and $I(\Theta_0(X_0^*); s_0) = 0$ we have that the minimum value of $I(E; s_0)$ is given by

$$\begin{aligned} I(E; s_0) &= I(H_{22}; s_0) - I(X_0; s_0) \\ &= I(H_{22}; s_0) + \frac{1}{2} \ln |\det(I - H_{22}(s_0)H_{22}^*(s_0))| \quad (\text{by (F.1)}) \end{aligned}$$

which completes the proof. \square

AN OPTIMAL STOCHASTIC PRODUCTION PLANNING PROBLEM WITH RANDOMLY FLUCTUATING DEMAND*

W. H. FLEMING†, S. P. SETHI‡ AND H. M. SONER§

Abstract. This paper considers an infinite horizon stochastic production planning problem with demand assumed to be a continuous-time Markov chain. The problems with control (production) and state (inventory) constraints are treated. It is shown that a unique optimal feedback solution exists, after first showing that convex viscosity solutions to the associated dynamic programming equation are continuously differentiable.

Key words. production planning, stochastic optimal control, viscosity solutions

Introduction. Thompson and Sethi [13] consider a production-inventory model which determines production rates over time to minimize an integral representing a discounted quadratic loss function. The model is solved both with and without nonnegative production constraints. It is shown that there exists a turnpike level of inventory, to which the optimal inventory levels approach monotonically over time. The model was generalized by Sethi and Thompson [11] and Bensoussan et al. [1] by incorporating an additive white noise term in the dynamics of the inventory process.

In this paper we consider an analogue of the Thompson-Sethi model, in which the demand rate $z(t)$ is a finite state Markov chain. A similar, but technically more complicated, analysis applies if $z(t)$ is a jump Markov process or a reflected diffusion subject to bounds $0 < z_0 \leq z(t) \leq z_1 < \infty$ (see [7]). We denote by $y(t)$, $p(t)$ the inventory level and the production rate. Production is the control variable, subject to the constraint $p(t) \geq 0$. In § 5 we impose the state constraint $y(t) \geq y_{\min}$ on the inventory level.

The control objective is to minimize an expected discounted cost of the form (4.1), which involves convex holding or shortage costs $h(y)$ and productions costs $c(p)$. The value (or minimum cost) $v(y, z)$ defined in (1.4) for initial data $y(0) = y$, $z(0) = z$ obeys the dynamic programming equation (1.6). Special features of the model allow us to show that $v(\cdot, z)$ is convex and that the quantity $\partial v / \partial y$ which appears in the dynamic programming equation exists and is continuous. The optimal feedback production law $p^*(y, z)$ is expressed as a function of $\partial v / \partial y$ by formula (4.3). We do not know that $p^*(\cdot, z)$ is Lipschitz continuous. However, since $p^*(\cdot, z)$ is a nonincreasing function of y , the differential equation

$$\frac{dy^*}{dt} = p^*(y^*(t), z(t)) - z(t), \quad y^*(0) = y,$$

has a unique solution for the optimal inventory level $y^*(t)$.

We begin in § 1 by formulating a more general class of discounted optimal control problems with Markov chain parameter $z(t)$. It is elementary that the value function is convex in the state y , provided the state dynamics are linear in state y and control p and the cost criterion is convex jointly in (y, p) ; see Lemma 1.1. In § 2 we find that the value $v(y, z)$ is the unique solution to the dynamic programming equation, and that the gradient $\nabla_y v$ is continuous. For the continuity of $\nabla_y v$, an additional assumption (2.2) on the Hamiltonian appearing in the dynamic programming equation is needed.

In § 3 we discuss optimal controls, both from the viewpoint of dynamic programming and the theory of controlled piecewise deterministic processes. Under a strict convexity condition (3.1) on the cost criterion, there is a continuous optimal control policy $p^*(y, z)$ and the corresponding optimal control process $p^*(t)$ is unique.

These results are applied to the production planning model in § 4. Finally, in § 5 the analysis is modified to deal with a state-space constraint $y(t) \geq y_{\min}$. Such a constraint imposes an inequality (5.2) on $\partial v / \partial y$ at y_{\min} .

The production planning model considered here does not impose any upper bound on the production rate. A more interesting extension of the problem involves production processes, which are bounded from above by a stochastic process representing the capacity of the production system. The capacity process over time may be modelled as a jump process or a piecewise deterministic process [5], [14]. Moreover, there may be several different products competing for a variety of scarce capacities. This is a problem faced by flexible manufacturing systems [10], upon which the methods developed in this paper have some bearing.

1. Discounted optimal control problems with Markov chain parameters. Let us begin with a model of the following rather general form, and then specialize. Let $y(t), p(t), z(t)$ denote, respectively, state, control and parameter processes for $t \geq 0$. We assume that $y(t) \in R^n, p(t) \in K, z(t) \in Z$ for each $t \geq 0$, where R^n is n -dimensional Euclidean space, K is a closed convex subset of some Euclidean space, $0 \in K$ and Z is a finite set. The parameter process $z(t)$ is a finite state continuous time Markov chain, defined on some underlying probability space (Ω, \mathcal{F}, P) with jumping rate $q_{zz'}$ from state z to state z' . The associated generator L of the Markov chain $z(t)$ has the form

$$(1.1) \quad Lg(z) = \sum_{z' \neq z} q_{zz'} [g(z') - g(z)].$$

In the general formulation, the state dynamics are $dy(t) = f(y(t), p(t), z(t))dt, t \geq 0$. Actually we shall consider only f of the special form (1.5) below. A control process $P = \{p(t, \omega), t \geq 0, \omega \in \Omega\}$ will be called *admissible* if: (i) P is adapted to $\mathcal{F}_t = \sigma(z(s): 0 \leq s \leq t)$; (ii) $\sup \{|p(t, \omega)|: t \geq 0, \omega \in \Omega\} < \infty$; (iii) $p(t, \omega) \in K$ for all $t \geq 0$ and $\omega \in \Omega$ (in whatever follows the ω -dependence will be suppressed). Let \mathcal{A} denote the set of admissible control processes.

We consider a cost criterion $I(y, p)$ about which the following assumptions are made:

- $$(1.2) \quad \begin{aligned} & \text{(a) } I(\cdot, \cdot) \text{ is convex on } R^n \times K, \\ & \text{(b) } -C \leq I(y, p) \leq C_N(1 + |y|^m) \text{ whenever } |p| \leq N, \\ & \text{(c) } \lim_{|p| \rightarrow \infty} I(y, p)|p|^{-1} = +\infty \text{ if } K \text{ is unbounded} \end{aligned}$$

where m, C are fixed constants and C_N may depend on N . Let $\alpha > 0$ denote the

discount rate. For every $P \in \mathcal{A}$ and $y = y(0)$, $z = z(0)$, let

$$(1.3) \quad J(y, z, P) = E \int_0^\infty e^{-\alpha t} l(y(t), p(t)) dt.$$

The value function is

$$(1.4) \quad v(y, z) = \inf \{J(y, z, P) : P \in \mathcal{A}\}.$$

From now on, let us assume that the dynamics have the following special form:

$$(1.5) \quad dy(t) = [B(z(t))p(t) + C(z(t))]dt, \quad t > 0.$$

(In the simple production planning model to be considered in § 4, both $y(t)$ and $p(t)$ are scalar valued and $B(z) = 1$, $c(z) = -z$.) Instead of (1.5) we could take equally well $dy(t) = [A(z(t))y(t) + B(z(t))p(t) + C(z(t))]dt$ provided that the eigenvalues of $A(z)$ have strictly negative real parts.

LEMMA 1.1. *For each $z \in Z$, $v(\cdot, z)$ is convex on R^n and $-C \leq v(y, z) \leq C(1 + |y|^m)$ for some $C > 0$.*

This lemma is easily proved, after observing that $J(\cdot, z, \cdot)$ is convex jointly in (y, P) for each $z \in Z$ and $p(t) \equiv 0$ is an admissible control process.

The dynamic programming equation associated with this optimal stochastic control problem is as follows:

$$(1.6) \quad \alpha v(y, z) = H(y, z, \nabla v(y, z)) + Lv(y, z), \quad y \in R^n, \quad z \in Z$$

where ∇v is the gradient in y

$$Lv(y, z) = [Lv(y, \cdot)](z) = \sum_{z' \neq z} q_{zz'} [v(y, z') - v(y, z)]$$

and for $y, z, r \in R^n \times Z \times R^n$

$$(1.7) \quad H(y, z, r) = \inf_{P \in K} [l(y, p) + (B(z)p + C(z)) \cdot r].$$

Since Z is a finite set, (1.6) is a system of nonlinear first order PDE's in y , coupled through the zeroth order term Lv .

We are concerned with solutions to (1.6) belonging to the following space D_0 .

DEFINITION 1.2. We say that a real-valued function v with domain $R^n \times Z$ is in D_0 if

- (i) $v(\cdot, z)$ is convex on R^n for each $z \in Z$,
- (ii) $-C \leq v(y, z) \leq C(1 + |y|^\beta)$, for suitable C and β (depending on v),
- (iii) The gradient $\nabla v(y, z)$ is continuous.

The following "verification theorem" is standard, but for completeness we indicate the proof.

THEOREM 1.3. *Let $v \in D_0$ satisfy the dynamic programming equation (1.6). Then*

- (a) $v(y, z) \leq J(y, z, P)$ for all $P \in \mathcal{A}$,
- (b) Suppose that there are $P^* \in \mathcal{A}$, $y^*(t)$ that satisfies (1.5) with $y^*(0) = y$, $r^*(t) = \nabla v(y^*(t), z(t))$, and

$$H(y^*(t), z(t), r^*(t)) = l(y^*(t), p^*(t)) + (B(z(t))p^*(t) + C(z(t)) \cdot r^*(t))$$

a.e. in t with probability 1. Then

$$v(y, z) = J(y, z, P^*).$$

Proof. For $T < \infty$, we have the usual dynamic programming relation

$$(1.8) \quad v(y, z) \leq E \int_0^T e^{-\alpha t} l(y(t), p(t)) dt + e^{-\alpha T} v(y(T), z(T)).$$

Since any admissible P is bounded, $|y(t)| \leq c_1 t + c_2$ for suitable constants c_1, c_2 . We obtain (a) as $T \uparrow \infty$, using the polynomial growth condition (ii) in Definition 1.2. In part (b), inequality (1.8) becomes an equality. \square

In the next section we shall show that, under an additional condition (2.2) on H , the value function in fact belongs to D_0 .

2. Viscosity solutions to the dynamic programming equation. The definition of viscosity solution used here is a straightforward generalization of the original definition given by M. G. Crandall and P.-L. Lions [4]. See also [3], [9] for more information.

Let v be a continuous function on $R^n \times Z$. For each (y, z) we define convex subsets $D_y^\pm v(y, z)$ of R^n , as follows:

$$D_y^+ v(y, z) = \{r \in R^n : \limsup_{h \rightarrow 0} (v(y+h, z) - v(y, z) - r \cdot h) |h|^{-1} \leq 0\},$$

$$D_y^- v(y, z) = \{r \in R^n : \liminf_{h \rightarrow 0} (v(y+h, z) - v(y, z) - r \cdot h) |h|^{-1} \geq 0\}.$$

We say that any continuous function v is a *viscosity solution* of (1.6), if for each y, z : (i) $\alpha v(y, z) \leq H(y, z, r) + Lv(y, z)$ for all $r \in D_y^+ v(y, z)$, and (ii) $\alpha v(y, z) \geq H(y, z, r) + Lv(y, z)$ for all $r \in D_y^- v(y, z)$.

Remark 2.1. v is differentiable in the y -direction at (y, z) if and only if $D_y^+ v(y, z)$ and $D_y^- v(y, z)$ are both singletons. In this case, the singleton is the gradient $\nabla v(y, z)$. Moreover, if v is convex in y , then $D_y^+ v(y, z)$ is empty unless v is differentiable there and $D_y^- v(y, z)$ coincides with the set of subdifferentials in the sense of convex analysis,

$$(2.1) \quad D_y^- v(y, z) = \overline{\text{co}} \Gamma(y, z)$$

where

$$\Gamma(y, z) = \{r = \lim_{n \rightarrow \infty} \nabla v(y_n, z) : y_n \rightarrow y \text{ as } n \rightarrow \infty \text{ and } v(\cdot, z) \text{ is differentiable at } y_n\}$$

and where $\overline{\text{co}} \Gamma$ denotes the convex closure of Γ . (See [2, Thm. 251, pp. 63].)

We now make the additional assumption that the Hamiltonian $H(y, z, \cdot)$ is constant on no nontrivial convex set:

$$(2.2) \quad \text{If } H(y, z, \lambda r_1 + (1-\lambda)r_2) = \text{constant in } \lambda \text{ for } 0 \leq \lambda \leq 1, \text{ then } r_1 = r_2.$$

THEOREM 2.2. *Let (2.2) hold and let v be a viscosity solution to the dynamic programming equation (1.6). If, in addition $v(\cdot, z)$ is convex for each z , then $\nabla v(y, z)$ exists for all (y, z) and $\nabla v(\cdot, z)$ is continuous on R^n .*

Proof. By Remark 2.1 and formula (2.1) it suffices to show that $D_y^- v(y, z)$ is a singleton. If $v(\cdot, z)$ is differentiable at y_n , then (1.7) holds at (y_n, z) :

$$\alpha v(y_n, z) - H(y_n, z, \nabla v(y_n, z)) - Lv(y_n, z) = 0.$$

We then obtain, taking $y_n \rightarrow y$ as $n \rightarrow \infty$,

$$\alpha v(y, z) - H(y, z, r) - Lv(y, z) = 0 \quad \text{for } r \in \Gamma(y, z).$$

Moreover, $H(y, z, \cdot)$ is concave, and hence by (2.1)

$$\alpha v(y, z) - H(y, z, r) - Lv(y, z) \leq 0 \quad \text{for } r \in D_y^- v(y, z).$$

However, the viscosity property implies the opposite inequality, and hence

$$\alpha v(y, z) - H(y, z, r) - Lv(y, z) = 0 \quad \text{for } r \in D_y^- v(y, z).$$

Thus, for fixed (y, z) , $H(y, z, \cdot)$ is constant on the convex set $D_y^- v(y, z)$. By (2.2), $D_y^- v(y, z)$ is a singleton, which proves Theorem 2.2. \square

The remainder of this section consists of a proof that the value function $v(y, z)$ defined by (1.4) is a viscosity solution to (1.6): the argument is rather standard.

LEMMA 2.3. *Suppose K is bounded. Then v is a viscosity solution to (1.6).*

Proof. It is a direct modification of Theorem 1.1 of [12]. \square

THEOREM 2.4. *v is a viscosity solution to (1.6).*

Proof. Let $K_m = \{p \in K : |p| \leq m\}$ and v_m be the optimal value function of the corresponding control problem. Then, v_m is a viscosity solution to (1.7) with $H(y, z, r)$ replaced with $H_m(y, z, r) = \min_{p \in K_m} \{r \cdot [B(z)p + c(z)] + l(y, p)\}$. Also, v_m converges to v uniformly on bounded subsets of R^n as m tends to infinity.

Take $r \in D_y^- v(y_0, z_0)$. For each $\varepsilon > 0$, let $\varphi^\varepsilon(y, z) = \varphi(y, z) - \varepsilon(y - y_0)^2$ where $\varphi(y, z_0) = v(y_0, z_0) + r(y - z_0)$, and $\varphi(y, z) = v(y, z)$ if $z \neq z_0$. Since v is convex, the map $y \mapsto v(y, z_0) - \varphi^\varepsilon(y, z)$ has a strict maximum at y_0 . Therefore, $y \mapsto v_m(y, z_0) - \varphi^\varepsilon(y, z_0)$ has a maximum at y_m , and y_m converges to y_0 as m tends to infinity. But this implies that $\nabla \varphi^\varepsilon(y_m, z_0) \in D_y^- v_m(y_m, z_0)$ and the viscosity property of v_m implies that

$$\alpha v_m(y_m, z_0) \geq H_m(y_m, z_0, r - 2\varepsilon(y_m - y_0)) + Lv_m(y_m, z_0).$$

Now send m to infinity, and then ε to zero in the above inequality, to obtain

$$\alpha v(y_0, z_0) \geq H(y_0, z_0, r) + Lv(y_0, z_0) \quad \text{for all } r \in D_y^- v(y_0, z_0).$$

The reversed inequality for $r \in D_y^+ v(y, z)$ is proved by a similar argument. \square

3. Optimal controls. Let us now assume the following stricter form of convexity for the cost criterion l than what was assumed in (1.2)(a)

$$(3.1) \quad l(\lambda y_1 + (1 - \lambda)y_2, \lambda p_1 + (1 - \lambda)p_2) \\ = \lambda l(y_1, p_1) + (1 - \lambda)l(y_2, p_2) \quad \text{for some } 0 < \lambda < 1 \text{ implies } p_1 = p_2.$$

For example, for the production planning problem that will be considered in § 4, $l(y, p) = c(p) + h(y)$ and (3.1) holds if h is convex on R^n and l is strictly convex on K . Assumption (3.1) also holds, if $l(\cdot, \cdot)$ is convex and the second derivative of l in p exists and is positive at each (y, p) .

Condition (3.1) implies, in particular, strict convexity of $l(y, \cdot)$, by taking $y = y_1 = y_2$. This fact together with the superlinear growth condition (1.2)(c) imply that the minimum in (1.7) is attained at a unique $P = \Phi(y, z, r)$. Moreover, Φ is continuous on $R^n \times Z \times R^n$. Consider the control policy

$$(3.2) \quad p^*(y, z) = \Phi(y, z, \nabla v(y, z)),$$

where v is the value function. By Theorems 2.2 and 2.4, p^* is continuous. The differential equation,

$$(3.3) \quad dy(t) = [B(z(t))p^*(y(t), z(t)) + C(z(t))] dt,$$

has locally a solution $y^*(t)$. Let us assume the following:

$$(3.4) \quad \text{There exists a bounded solution } y^*(t) \text{ to (3.3) for } t \geq 0.$$

In § 4 we shall verify (3.4) in the production planning example. The control process $P^* = \{p^*(t); t \geq 0\}$, where

$$(3.5) \quad p^*(t) = p^*(y^*(t), z(t))$$

is admissible, by the superlinear growth condition (1.2)(c) and is optimal, by the verification Theorem 1.3(b). Also, a straightforward application of (3.1) yields that P^* is unique. This implies, in particular, uniqueness of $y^*(t)$. We sum these results into the following proposition.

PROPOSITION 3.1. *Let (3.1) and (3.4) hold. Suppose $P \in \mathcal{A}$ and $J(y, z, P) = v(y, z)$. Then with probability 1, $P(t) = P^*(t)$ for almost all $t > 0$. In particular, there is a unique solution to (3.3).*

Proof. For $0 < \lambda \leq 1$, let $P^\lambda = \lambda P + (1 - \lambda)P^*$, $y^\lambda = \lambda y + (1 - \lambda)y^*$, where $y(t)$ is a solution to (1.5) corresponding to P , with $y(0) = y$. By convexity of l and J , $J(y, z, P^\lambda) = v(y, z)$ which implies with probability one

$$l(y^\lambda(t), p^\lambda(t)) = \lambda l(y(t), p(t)) + (1 - \lambda)l(y^*(t), p^*(t))$$

for almost all $t \geq 0$. Assumption (3.1) then implies, with probability one, $p(t) = p^*(t)$ for almost all $t \geq 0$. \square

Remark 3.2. The optimal policy P^* was obtained by the method of dynamic programming. The theory of piecewise deterministic processes [5], [14] provides an alternate approach. In the present context, the piecewise deterministic theory considers bounded, Borel measurable functions $\pi = [0, \infty) \times R^n \times Z \rightarrow K$. Given initial data $y(0) = y$, $z(0) = z$, each such π determines an admissible control process P as follows. Let $\tau_0 = 0$ and $\tau_1 < \tau_2 < \dots$ denote the successive jump times of the Markov chain $z(t)$ and let

$$p(t) = \pi(t - \tau_i, y(\tau_i), z(\tau_i^+)), \quad \tau_i < t \leq \tau_{i+1}$$

where $y(t)$ is determined by solving (1.5) successively on each interval $[\tau_i, \tau_{i+1}]$. An optimal π^* is found as follows. For fixed z , as in (3.4), assume that there is a solution to

$$(3.6) \quad d\tilde{y}(t) = [B(z)p^*(\tilde{y}(t), z) + C(z)] dt,$$

with $\tilde{y}(0) = y$. Let

$$(3.7) \quad \pi^*(t, y, z) = p^*(\tilde{y}(t), z).$$

We claim that $\pi^*(\cdot, y, z)$ is unique, almost everywhere on $[0, \infty)$, for each y, z . This can be seen by slightly modifying the uniqueness proof above. We write the dynamic programming equation (1.6) as follows. Let

$$q_z = \sum_{z' \neq z} q_{zz'}, \quad v_1(y, z) = \sum_{z' \neq z} q_{zz'} v(y, z').$$

Then (1.6) becomes

$$(3.8) \quad (\alpha + q_z)v(y, z) = H(y, z, \nabla v) + v_1(y, z).$$

For fixed z , (3.8) is the dynamic programming equation for a discounted deterministic control problem, with dynamics (3.6), discount factor $\alpha + q_z$ and cost criterion $l(y, p) + v_1(y, z)$. As before, $p^*(\cdot, z)$ is an optimal feedback control and $\pi^*(\cdot, y, z)$ determined by (3.7) is the unique optimal (open loop) control.

4. Production planning problem. Let us return to the model mentioned in the Introduction. We now have the following:

$$y(t) = \text{inventory level at time } t \quad (y(t) \in R),$$

$$p(t) = \text{production rate at time } t \quad (p(t) \geq 0),$$

$$z(t) = \text{demand rate at time } t \quad (z(t) \in Z).$$

In the notation of § 1, we now have $n = 1$, $K = [0, \infty)$. The demand process is a finite state Markov chain, with state space $Z = \{z_1, \dots, z_M\}$. The dynamics are as follows:

$$dy(t) = [p(t) - z(t)] dt.$$

Thus, in (1.5), $B(z) = 1$ and $C(z) = -z$. It is assumed that $z_i > 0$ for all $i = 1, \dots, M$. We assume that the cost criterion has the form

$$l(y, p) = h(y) + c(p)$$

and we seek to minimize

$$(4.1) \quad J(y, z, P) = E \int_0^\infty e^{-\alpha t} [h(y(t)) + c(p(t))] dt.$$

The following assumptions are made about the holding cost h and production cost c :

(A1) h is convex, nonnegative on $(-\infty, \infty)$ with $h(0) = 0$.

(A2) c is twice continuously differentiable, nonnegative on

$$[0, \infty) \text{ with } c'(0) = c(0) = 0 \text{ and } c''(p) > 0 \text{ for } p > 0.$$

(A3) $C(|y|^\beta - 1) \leq h(y) \leq C(|y|^\gamma + 1)$ for all $y \in R$.

(A4) $C(|p|^\nu - 1) \leq c(p)$ for all $p \geq 0$,

where $C > 0$ and $\gamma, \beta, \nu > 1$ are fixed constants.

The Hamiltonian H in (1.7) now takes the form $H(y, z, r) = F(r) - zr + h(y)$ where

$$(4.2) \quad F(r) = \min_{p \geq 0} [pr + c(p)].$$

The assumption (2.2) is satisfied since $z > 0$ for all $z \in Z$, $F(r)$ is strictly concave for $r < 0$ and $F(r) = 0$ for $r \geq 0$. Theorems 2.2 and 2.4 imply that the value function $v(y, z)$ belongs to the class D_0 and is the unique viscosity solution to the dynamic programming equation.

The optimal feedback production policy is now given by

$$(4.3) \quad p^*(y, z) = \begin{cases} (c')^{-1} \left(-\frac{\partial}{\partial y} v(y, z) \right) & \text{if } \frac{\partial}{\partial y} v(y, z) > 0, \\ 0 & \text{if } \frac{\partial}{\partial y} v(y, z) \leq 0. \end{cases}$$

Since v is convex in y , and $(c')^{-1}$ is an increasing function, p^* is nonincreasing in y . Therefore, the differential equation

$$(4.4) \quad dy(t) = [p^*(y(t), z(t)) - z(t)] dt$$

has a unique solution $y^*(t)$ (see [8, Thm. 6.2].)

In the rest of the section, we shall show that y^* satisfies (3.4).

LEMMA 4.1. *There is a constant C , depending only on the initial condition $y^*(0) = y$, such that $|y^*(t)| \leq C$ for all $t \geq 0$.*

Proof. Let $\bar{y} = \sup \{y \in (-\infty, \infty) : p^*(y, z) \geq z \text{ for some } z \in Z\}$. Since v is convex in y and is nonnegative, (4.3) implies that \bar{y} is finite. Similarly, let $\tilde{y} = \inf \{y \in (-\infty, \infty) : p^*(y, z) \leq z \text{ for some } z \in Z\}$. Suppose that \tilde{y} is not finite. Then, there is $z \in Z$ such that $(\partial/\partial y)v(y, z) \geq -c'(z)$ for all $y \in R$. But this contradicts with Lemma 4.2, which follows. Now one completes the proof of the lemma, by observing that $[\tilde{y}, \bar{y}]$ is an attracting set for the differential equation (4.4). We refer to this set as the *turnpike set* in [7]. \square

Let $\bar{z} = \max \{z \in Z\}$.

LEMMA 4.2. *For each y, z , $v(y, z) \geq C(|y| - 1)$ for a suitable constant $C > c'(\bar{z})$.*

Proof. Let $\bar{v}(y)$ be the value function of the following variational problem:

$$\bar{v}(y) = \inf \left\{ \int_0^\infty e^{-\alpha t} \left[h(y(t)) + C \left| \frac{d}{dt} y(t) \right|^\nu \right] dt; y(0) = y \text{ and } y(\cdot) \in W^{1,\infty} \right\}$$

with $\nu > 1$. In view of (A4), $\bar{v}(y) \leq v(y, z)$ for a suitable $C > 0$. It suffices to show that $\bar{v}(y)|y|^{-1}$ converges to $M > \sup \{c'(z): z \in Z\}$ as y tends to $-\infty$. Since $\bar{v}(\cdot)$ is convex, $M = -\lim_n (d/dy)\bar{v}(y_n)$ where $\{y_n\}$ is any sequence which converges to $-\infty$ and $\bar{v}(\cdot)$ is differentiable at y_n , invoke Theorem 2.4 to conclude

$$(4.5) \quad \alpha \bar{v}(y_n) = \bar{F}\left(\frac{d}{dy} \bar{v}(y_n)\right) + h(y_n)$$

where $\bar{F}(r) = \sup \{rp + c|p|^\nu: -\infty < p < \infty\} = -\bar{c}|r|^{\nu/(\nu-1)}$. The positivity of \bar{v} yields $M \in [0, \infty]$. Suppose that $M < \infty$. Then divide (4.5) by $|y_n|$ and pass to the limit to obtain

$$\alpha M = \alpha \lim_n \bar{v}(y_n)|y_n|^{-1} = \lim_n h(y_n)|y_n|^{-1} = \infty.$$

Hence $M = \infty$ and the proof of the lemma is complete. \square

5. Inventory constraints. In this section, in addition to the nonnegative production constraint earlier, we impose the constraint that the inventory level cannot fall below a certain prescribed level y_{\min} . For each $y, z \in [y_{\min}, \infty) \times Z$, the set of admissible production processes $\mathcal{A}(y, z)$ is given by

$$\mathcal{A}(y, z) = \left\{ P \in \mathcal{A}: y + \int_0^t [p(s) - z(s)] ds \geq y_{\min} \text{ for all } t \geq 0 \right\}.$$

Then the corresponding value function is

$$v(y, z) = \inf \{J(y, z, P): P \in \mathcal{A}(y, z)\}.$$

The following characterization of v is a straightforward analogue of Theorem 1.1 of [12].

THEOREM 5.1. *The value function v for the constrained problem is in D_0 and is the only solution to the following equation:*

$$(5.1) \quad \alpha v(y, z) = H\left(y, z, \frac{\partial}{\partial y} v(y, z)\right) + Lv(y, z), \quad y, z \in [y_{\min}, \infty) \times Z,$$

$$(5.2) \quad \frac{\partial}{\partial y} v(y_{\min}, z) \leq -c'(z), \quad z \in Z.$$

Proof. The first two conditions in the definition of D_0 are easily verified after observing that if $P \in \mathcal{A}(y, z)$ and $\hat{P} \in \mathcal{A}(\hat{y}, z)$, then $\frac{1}{2}P + \frac{1}{2}\hat{P} \in \mathcal{A}(\frac{1}{2}y + \frac{1}{2}\hat{y}, z)$ and $J(\cdot, z, \cdot)$ is convex for each $z \in Z$.

Repeating the proofs of Theorems 2.2 and 2.4 we show that v is continuously differentiable in the y -variable on (y_{\min}, ∞) and satisfies (5.1). Define $(\partial/\partial y)v(y_{\min}, z)$ as the limit of $(\partial/\partial y)v(y, z)$ as y approaches y_{\min} from above (this limit exists due to the convexity of v in y). Now proceed as in Lemma 2.3 and use the fact that for any $P \in \mathcal{A}(y, z)$ the corresponding inventory level $y(t)$ is no less than y_{\min} , to obtain:

$$(5.3) \quad \alpha v(y_{\min}, z) \geq H(y_{\min}, z, r) + Lv(y_{\min}, z) \quad \text{for } r \leq \frac{\partial}{\partial y} v(y_{\min}, z)$$

(also, see Theorem 1.1 of [12]). Equations (5.1) and (5.3) yield

$$(5.4) \quad H(y_{\min}, z, \frac{\partial}{\partial y} v(y_{\min}, z)) \geq H(y_{\min}, z, r) \quad \text{for } r \leq \frac{\partial}{\partial y} v(y_{\min}, z).$$

The inequality (5.2) follows from (5.4), after observing that the map $r \rightarrow H(y_{\min}, z, r)$ achieves its maximum only at $r = -c'(z)$.

Uniqueness follows from the verification theorem, by observing that the optimal feedback policy P^* constructed in (3.5) is admissible on account of (5.2). \square

Remark 5.2. For each $\varepsilon > 0$, define $h^\varepsilon(y) = h(y) + [(1/\varepsilon) - 1] \max\{y_{\min} - y, 0\}$. Let v^ε be the value function of the unconstrained problem with inventory cost h^ε . Then, the following estimate is proved in [7]:

$$0 \leq v(y, z) - v^\varepsilon(y, z) \leq \sqrt{\varepsilon} K_R \quad \text{for } y, z \in [y_{\min}, R] \times Z$$

where K_R is a suitable constant.

QUASI-NEWTON METHODS AND UNCONSTRAINED OPTIMAL CONTROL PROBLEMS*

C. T. KELLEY[†] AND E. W. SACHS[‡]

Abstract. We prove a mesh-independence result for the BFGS method in Hilbert space and apply it to a class of unconstrained optimal control problems. A new fourth order discretization scheme is used in the implementation. Observations from numerical experiments are presented.

Key words. optimal control, BFGS method

AMS(MOS) subject classifications. 65H10, 49D15

1. Introduction. Quasi-Newton methods play an important role in the numerical solution of problems in unconstrained optimization. Optimal control problems in their discretized form can be viewed as optimization problems and therefore be solved by quasi-Newton methods. Since the discretized problems do not solve the original infinite-dimensional control problem but rather approximate it up to a certain accuracy, various approximations of the control problem need to be considered. It is known that an increase in the dimension of optimization problems can have a negative effect on the convergence rate of the quasi-Newton method which is used to solve the problem. The purpose of this paper is to investigate this behavior and to explain how this drawback can be avoided for a class of optimal control problems. We show how to use the infinite-dimensional original problem to predict the speed of convergence of the BFGS-method [1], [8], [11], [23] for the finite-dimensional approximations.

In several papers [7], [15], [25], [28] the DFP-method [4], [9] and its application to optimal control problems were considered but rates of convergence were given at best for quadratic problems. In [26], [27] a linear rate of convergence was proved in Hilbert spaces and applied to optimal control. All the applications to optimal control problems were carried out for finite-dimensional approximations. This fact is important, because in [24] it was shown, that contrary to the finite-dimensional case [2], the BFGS-method can converge very slowly when applied to an infinite-dimensional problem. Hence it is desirable to know whether this convergence behavior can occur also for fine discretizations of control problems.

Sufficient [18] and characteristic [13] conditions for the superlinear rate were given in other analyses. As in the linear case for Broyden's method [29] and the conjugate gradient method [3], [10], an additional assumption on the initial approximation of the Hessian, i.e., one that approximates the true Hessian up to a compact operator, is needed to guarantee superlinear convergence (see [12]). In [10] a connection to quadratic control problems is shown. Here we want to consider nonlinear control problems and their discretization.

Let $L: \mathbb{R}^{n+m+1} \rightarrow \mathbb{R}$, $f: \mathbb{R}^{n+m+1} \rightarrow \mathbb{R}^n$ for some $n, m \in \mathbb{N}$ and consider the following optimal control problem:

$$(1.1) \quad \begin{aligned} &\text{Minimize} \quad \int_0^T L(x(t), u(t), t) dt \\ &\text{subject to} \quad \dot{x}(t) = f(x(t), u(t), t), x(0) = x_0. \end{aligned}$$

If we think of $x(t) = x(u, t)$ being dependent on u , then the cost function can be written in terms of u only:

$$F(u) = \int_0^T L(x(u, t), u(t), t) dt.$$

The gradient of F is given by

$$\nabla F(u) = p(\cdot)^T f_u(x(\cdot), u(\cdot), \cdot) + L_u(x(\cdot), u(\cdot), \cdot),$$

where p solves the adjoint equation

$$(1.2) \quad -\dot{p}(t) = p(t)^T f_x(x(t), u(t), t) + L_x(x(t), u(t), t)$$

with $p(T) = 0$ (see e.g. [19]). Hence each gradient evaluation involves the solution of an additional system of differential equations. If one wants to apply Newton's method to the numerical solution of the control problems in order to use a higher order method, it becomes necessary to compute the second derivative of $F(\cdot)$. Even in the one-dimensional case, $m = n = 1$, this calculation is quite tedious. $\nabla^2 F(u)$ is given as follows.

Define $H: \mathbb{R}^3 \rightarrow \mathbb{R}$ by $H(x, u, t) = p(t)f(x, u, t) + L(x, u, t)$ for fixed $p(t)$, then with $\langle u, v \rangle = \int_0^T u(t)v(t) dt$

$$\begin{aligned} \langle w, \nabla^2 F(u)v \rangle &= \langle \xi(w), H_{xx}(x, u, \cdot) \xi(v) \rangle + \langle w, H_{uu}(x, u, \cdot) v \rangle \\ &\quad + \langle w, H_{ux}(x, u, \cdot) \xi(v) \rangle + \langle \xi(w), H_{xu}(x, u, \cdot) v \rangle \end{aligned}$$

where x solves (1.1), p solves (1.2) and $\xi(w)$ is the solution of

$$\dot{\xi}(t) = \xi(t)^T f_x(x(u, t), u(t), t) + f_u(x(u, t), u(t), t)w(t), \quad \xi(0) = 0.$$

Also for the finite-dimensional approximations, the computation of the Hessian is not a simple task. Therefore, the quasi-Newton methods where the Hessian is approximated by an updating procedure provide a useful alternative because of their superlinear rate of convergence under certain assumptions.

In order to minimize a twice Fréchet-differentiable function F over a Hilbert space H one chooses in the BFGS-method an operator $B_0 \in \mathcal{L}(H)$, the space of linear continuous invertible operators on H , and some $u_0 \in H$ and defines the following sequence: Given $u_i \in H$, $B_i \in \mathcal{L}(H)$.

(i) Solve $B_i s_i = -\nabla F(u_i)$;

(ii) Let $u_{i+1} = u_i + s_i$

$$(1.3) \quad y_i = \nabla F(u_{i+1}) - \nabla F(u_i);$$

(iii) Let

$$B_{i+1} = B_i + \frac{\langle y_i, \cdot \rangle}{\langle s_i, y_i \rangle} y_i - \frac{\langle B_i s_i, \cdot \rangle}{\langle s_i, B_i s_i \rangle} B_i s_i.$$

In this paper we will investigate finite-dimensional approximations of this algorithm.

In the second section we will show how the convergence behavior of the BFGS-method for finite-dimensional approximations is influenced by the convergence

behavior of the BFGS-method applied to the infinite-dimensional problem. The statements will be phrased in terms of the number of iterates which are required to achieve a certain termination criterion. This approach, which we also used for the solution of nonlinear integral equations [16] will be taken because no uniform convergence rate estimates are available for the family of approximating problems. This is in contrast to the analyses of discretized control problems solved by the gradient projection method or conditional gradient method [6] and Newton's method [21]. The results in § 2 can be applied to any sequence of approximating problems. In the third section we show how to utilize these techniques for finite difference approximations of the optimal control problem. We point out that our goal is not to estimate the error between the solutions of the discretized and the original problem which can be found in the existing literature [14]. Since the discretized problems also need to be solved by some algorithm we deduce statements on the convergence of this algorithm, in our case the BFGS-method, for the whole family of discretized problems. The nature of the discretized problem, i.e., the fourth order Runge-Kutta scheme with Hermite interpolation at intermediate points, does not assure the symmetry of the Hessian of the approximating problem. Since these problems, however, are still close to the original one with a self-adjoint Hessian, we used an approximate version of the BFGS-method on these problems and the numerical results are quite successful. A numerical example demonstrates that the proper choice of the initial approximation B_0 with regard to the compactness requirement leads to qualitatively different convergence behavior for the finite-dimensional problems. These results for optimal control problems underscore the observation made by the authors in [16] for integral equations and in [17] for elliptic differential equations that quasi-Newton methods can be successful, also for infinite-dimensional problems when the special structure of the problem is taken into account.

2. An approximation of the infinite-dimensional BFGS-method. The BFGS-method was introduced by Broyden [1], Fletcher [8], Goldfarb [11] and Shanno [23] as a version of quasi-Newton methods which takes into account the symmetry and positive definiteness of the Hessian of the function to be minimized. In this paper, we first consider the infinite-dimensional analysis.

Let H be a Hilbert space and

$$F: H \rightarrow R$$

a nonlinear twice continuously Fréchet-differentiable functional on H . We consider the following minimization problem.

Find $u_* \in H$ with

$$(P) \quad F(u_*) \leq F(u) \quad \text{for all } u \in H.$$

Any solution u_* of (P) is also a solution of the nonlinear equation

$$(E) \quad G(u_*) = 0$$

where $G(u) = \nabla F(u)$. The BFGS-method, outlined in § 1, finds solutions of (E) iteratively by updating linear operators B_i which approximate $G'(u_i)$ and by solving a linear equation for each step. Daniel [3] pointed out in 1965 that for conjugate gradient methods a superlinear rate of convergence can be attained in Hilbert spaces if, for example, the initial approximation B_0 of the Jacobian of G is close and differs only by a compact operator. Recently, Griewank [12] showed that a similar result holds for the BFGS-method.

We will show in § 3 that for a large class of optimal control problems the compactness condition can be satisfied in a natural way. However, the numerical solution of (E) and (P) requires some sort of discretization. If we approximate the space H by finite-dimensional spaces H^N and replace F by F^N defined on H^N , then we obtain problems of the type

$$(P^N) \quad \text{Minimize } F^N(u^N), \quad u^N \in H^N.$$

With this approach we are automatically assured that the Hessian of F^N is symmetric. The positive definiteness of the Hessian $\nabla^2 F^N$ at the solution u_*^N is an additional requirement of convergence theorems for finite-dimensional quasi-Newton methods. For control problems, however, we take the different point of view in this paper that we want to solve the Pontryagin maximum principle which is a classical approach for solving control problems by gradient or Newton's method, see e.g., the review article by Polak [20]. We approximate the necessary optimality conditions $G(u^*)=0$ and solve these approximate problems by a finite-dimensional analogue of a quasi-Newton method for the infinite-dimensional problem. The approximate functions G^N need not be gradients of scalar valued functions and, in general, they are not if defined by finite difference schemes. A choice of G^N as the gradient of some F^N would result in the loss of the simple structure of the discrete version of (1.2). Instead of (E) we solve:

$$(E^N) \quad \text{Find } u_*^N \in H^N \text{ with } G^N(u_*^N) = 0.$$

Except for simple discretization schemes such as Euler's method, however, it is not reasonable to assume that G^N has a Jacobian which is symmetric. Computational results indicate that it is still possible to treat these problems successfully with an approximate version of the infinite-dimensional BFGS-method.

Let $\langle \cdot, \cdot \rangle_N$ denote the inner product on H^N and let $G^N: H^N \rightarrow H^N$ be Fréchet-differentiable. Let some initial approximations $u_0^N \in H^N$ and $B_0^N \in \mathcal{L}(H^N)$ for the solution u_*^N and the Jacobian of G^N at u_*^N be given such that B_0^N is symmetric with regard to the inner product $\langle \cdot, \cdot \rangle_N$.

Then with $i=0$,

$$(2.1a) \quad \text{solve } B_i^N s_i^N = -G^N(u_i^N), \quad s_i^N \in H^N,$$

$$(2.1b) \quad \text{set } u_{i+1}^N = u_i^N + s_i^N, \\ y_i^N = G^N(u_{i+1}^N) - G^N(u_i^N),$$

and

$$(2.1c) \quad B_{i+1}^N = B_i^N + \frac{\langle y_i^N, \cdot \rangle_N}{\langle s_i^N, y_i^N \rangle_N} y_i^N - \frac{\langle B_i^N s_i^N, \cdot \rangle_N}{\langle s_i^N, B_i^N s_i^N \rangle_N} B_i^N s_i^N.$$

The inner product $\langle \cdot, \cdot \rangle_N$ on the N -dimensional space H^N is not the Euclidean inner product on \mathbb{R}^N and therefore, algorithm (2.1), in general, is not identical with the BFGS-method on \mathbb{R}^N . In order to ensure that the convergence behavior of $\{u_i^N\}$ is similar to that of $\{u_i\}$ for large N , we impose the following conditions on H^N .

Let $\{P^N\}$ denote a sequence of linear prolongation operators

$$P^N: H^N \rightarrow Z$$

where Z is a normed subspace of H with $\|\cdot\|_Z \cong \|\cdot\|_H$. For the application to control problems, where H^N is a space of N -dimensional vectors, P^N may be interpreted as a piecewise polynomial interpolation operator.

We introduce a notion of Z -convergence as follows: A sequence $u^N \in H^N$ is Z -convergent to $u \in Z$, i.e., $u^N \rightarrow_Z u$, if

$$(2.2) \quad \lim_{N \rightarrow \infty} \|P^N u^N - u\|_Z = 0.$$

We also have to assume that the discrete inner products approximate the original one in the following sense:

(A1) If $u_j^N \rightarrow_Z u_j \in Z$ for $j = 1, 2$, then

$$\lim_{N \rightarrow \infty} \langle u_1^N, u_2^N \rangle_N = \langle u_1, u_2 \rangle.$$

Since for control problems the evaluation of G^N includes the numerical solution of differential equations, the Z -convergence of $G^N(u^N)$ to $G(u)$ may require more smoothness of u than $u \in Z$. Hence we introduce a subspace W of smooth functions in Z and because the iterates should remain in W we assume the following:

(A2) There is $u_* \in W$ with $G(u_*) = 0$ such that G is defined for all $u \in W$ sufficiently near u_* in the Z -norm, and if for a sequence $u^N \in H^N$, $u^N \rightarrow_Z u \in W$, then

$$G^N(u^N) \xrightarrow{Z} G(u) \in W.$$

These assumptions enable us to show the following theorem.

THEOREM 2.1. Assume that (A1) and (A2) hold. Let $u_0^N \in H^N$, $u_0 \in W$, $(B_0^N)^{-1} \in \mathcal{L}(H^N)$, $B_0^{-1} \in \mathcal{L}(Z)$ such that for $i = 0$

$$(2.3) \quad B_i^{-1}(W) \subset W,$$

$$(2.4) \quad u_i^N \xrightarrow{Z} u_i$$

and

$$(2.5) \quad (B_i^N)^{-1} v^N \xrightarrow{Z} B_i^{-1} v$$

for all sequences $v^N \in H^N$ which are Z -convergent to $v \in W$. If for u_1 and B_1 as given by (1.3) we have $B_1^{-1} \in \mathcal{L}(Z)$ and $G(u_1)$ well defined, then for N large enough we have

$$(2.6) \quad (B_1^N)^{-1} \in \mathcal{L}(H^N)$$

and (2.3)–(2.5) hold for $i = 1$.

Proof. Note, that in the case

$$(2.7) \quad \langle s_0^N, y_0^N \rangle_N \neq 0 \quad \text{and} \quad \langle s_0^N, B_0^N s_0^N \rangle_N \neq 0,$$

$(B_0^N)^{-1}$ can be updated directly by

$$(2.8) \quad (B_1^N)^{-1} = (B_0^N)^{-1} + \frac{\langle s_0^N, \cdot \rangle_N}{\langle s_0^N, y_0^N \rangle_N} w_0^N + \frac{\langle w_0^N, \cdot \rangle_N}{\langle s_0^N, y_0^N \rangle_N} s_0^N - \frac{\langle w_0^N, y_0^N \rangle_N}{\langle s_0^N, y_0^N \rangle_N^2} \langle s_0^N, \cdot \rangle_N s_0^N,$$

$$w_0^N = s_0^N - (B_0^N)^{-1} y_0^N.$$

In the infinite-dimensional case a similar formula holds for B_1^{-1} . By (A2) we know that $G(u_0) \in W$ and with (2.3) we obtain $s_0 = -B_0^{-1} G(u_0) \in W$. Hence

$$u_1 \in W \quad \text{and} \quad y_0 = G(u_1) - G(u_0) \in W.$$

From this and the formula for B_1^{-1} it is easy to see that B_1^{-1} leaves W invariant. Condition (2.4) and (A2) imply that

$$G^N(u_0^N) \xrightarrow{Z} G(u_0).$$

By (2.5)

$$s_0^N \xrightarrow{Z} s_0$$

and (2.4) holds as for $i = 1$. In addition,

$$y_0^N \xrightarrow{Z} y_0$$

holds. Together with (A1) this yields

$$(2.9a) \quad \lim_{N \rightarrow \infty} \langle s_0^N, y_0^N \rangle_N = \langle s_0, y_0 \rangle,$$

$$(2.9b) \quad \lim_{N \rightarrow \infty} \langle s_0^N, B_0^N s_0^N \rangle_N = \langle s_0, B_0 s_0 \rangle.$$

Since by assumption B_1^{-1} is well defined, we know that $\langle s_0, y_0 \rangle$ and $\langle s_0, B_0 s_0 \rangle$ are both nonzero. Hence (2.9) ensures that (2.7) holds for N sufficiently large. If we update $(B_1^N)^{-1}$ and B_1^{-1} according to (2.8), then (2.4), (A1) and (2.9) together yield (2.6). Then for any sequence $v^N \in H^N$, which is Z -convergent to $v \in W$, (A1) implies (2.5) for $i = 1$. This completes the proof.

If $B_i^{-1} \in \mathcal{L}(Z)$ for $1 \leq i \leq i^*$, then we can show with an induction argument based on Theorem 2.1 that

$$(2.10) \quad \lim_{N \rightarrow \infty} \max_{1 \leq i \leq i^*} \|P^N u_i^N - u_i\|_Z = 0$$

holds for any integer $i^* \geq 1$.

A reasonable choice of a termination criterion for (E^N) is $\|G^N(u^N)\|_N$ being sufficiently small. Let $i(\varepsilon)$ denote the smallest iteration index for which the norm of the gradient is less than ε :

$$i(\varepsilon) = \min \{i \in \mathbb{N}: \|G(u_i)\| < \varepsilon\},$$

$$i_N(\varepsilon) = \min \{i \in \mathbb{N}: \|G^N(u_i^N)\|_N < \varepsilon\}.$$

The following relation holds between i and i_N .

THEOREM 2.2. *Let all the assumptions in Theorem 2.1 hold, $G(u_i)$ be defined and $B_i^{-1} \in \mathcal{L}(Z)$ for all $i \geq 1$. Then for each $\varepsilon > 0$ there exists $N_\varepsilon \in \mathbb{N}$ with*

$$(2.11) \quad i(\varepsilon + \delta) \leq i_N(\varepsilon) \leq i(\varepsilon)$$

for all $N > N_\varepsilon$ and $\delta > 0$.

Proof. Equation (2.10) and (A2) imply that for each i

$$G^N(u_i^N) \xrightarrow{Z} G(u_i)$$

and by (A1)

$$(2.12) \quad \lim_{N \rightarrow \infty} \|G^N(u_i^N)\|_N = \|G(u_i)\|.$$

Clearly, if $\|G(u_i)\| < \varepsilon$ then $\|G^N(u_i^N)\|_N < \varepsilon$ for N sufficiently large, and therefore

$$i_N(\varepsilon) \leq i(\varepsilon).$$

Hence

$$(2.13) \quad \lim_{N \rightarrow \infty} \max_{1 \leq i \leq i(\varepsilon)} \|\|G^N(u_i^N)\|_N - \|G(u_i)\|\| = 0.$$

If, now, for a given $\delta > 0$, $i_N(\varepsilon) < i(\varepsilon + \delta)$ for infinitely many N then there is $j < i(\varepsilon)$ and a sequence $N_k \rightarrow \infty$ such that

$$\|G^{N_k}(u_j^{N_k})\|_{N_k} \geq \varepsilon + \delta.$$

Letting $N_k \rightarrow \infty$ we have $\|G(u_j)\| \geq \varepsilon + \delta$ which contradicts (2.13).

Theorem 2.2 is independent of any rate of convergence for the infinite-dimensional problem and would therefore also be useful to explain slow convergence behavior for the finite-dimensional approximations. For the superlinear rate we state the following theorem.

THEOREM 2.3. *Let $G: H \rightarrow H$, $G^N: H^N \rightarrow H^N$ be continuously Fréchet-differentiable and $u_* \in H$ such that*

$$G(u_*) = 0, \quad G'(u_*) \text{ is self-adjoint, positive definite.}$$

Choose $B_0 \in \mathcal{L}(H)$, $B_0^{-1} \in \mathcal{L}(Z)$, $u_0 \in Z$ such that

$$B_0 - G'(u_*) \text{ is compact}$$

and $\|B_0 - G'(u_)\|$ and $\|u_0 - u_*\|$ are sufficiently small to yield the superlinear convergence of the BFGS-iterates for (E). Select H^N , G^N , $u_0^N \in H^N$, $B_0^N \in \mathcal{L}(H^N)$ such that (A1), (A2), (2.3)–(2.5) hold. Then for the BFGS-iterates u_i^N for (E^N) the following is true:*

For each $\varepsilon > 0$ there exists N_ε with

$$(2.14) \quad i(\varepsilon) - 1 \leq i_N(\varepsilon) \leq i(\varepsilon) \quad \text{for } N \geq N_\varepsilon.$$

Proof. The superlinear rate for (E) follows from [12]. The updates B_i^N are well defined by using an induction argument identical to the proof of Theorem 2.1.

Note now that $\|G(u_i)\|$ is a strictly decreasing sequence. To see this note that boundedness and invertibility of $G'(u_*)$ imply that there are c_1 and c_2 so that for all u sufficiently near u_*

$$c_1 \|u - u_*\| \leq \|G(u)\| \leq c_2 \|u - u_*\|.$$

We let $\lambda_n = \|u_{n+1} - u_*\| / \|u_n - u_*\|$. For n sufficiently large, $\lambda_n < c_2 / c_1$ by the superlinear convergence and hence, for n large

$$\begin{aligned} \|G(u_{n+1})\| &\leq c_2 \|u_{n+1} - u_*\| \leq c_2 \lambda_n \|u_n - u_*\| \\ &\leq \frac{c_2}{c_1} \lambda_n \|G(u_n)\| < \|G(u_n)\|. \end{aligned}$$

Hence, for δ sufficiently small

$$i(\varepsilon + \delta) \geq i(\varepsilon) - 1,$$

which implies (2.14) instead of (2.11).

Let us point out that (2.14) gives an estimate for the number of iterates necessary to achieve a certain stopping criterion for the finite-dimensional problem that is independent on the dimension N and is only determined by the iterate number of the infinite-dimensional analogue. For this problem, however, the superlinear rate can be proved directly. Theorem 2.3 also does not require that B_0^N is self-adjoint or even positive definite as long as (2.4) holds. This facilitates the application to control problems in the next section.

3. Optimal control problem. We want to apply the BFGS-method to optimal control problems which are formulated in infinite-dimensional spaces. Let

$$f: \mathbb{R}^{n+m+1} \rightarrow \mathbb{R}^n, \quad L: \mathbb{R}^{n+m+1} \rightarrow \mathbb{R}$$

be given functions. Then the optimal control problem is given by:

$$(OCa) \quad \text{Minimize} \quad \int_0^T L(x(t), u(t), t) dt$$

$$(OCb) \quad \text{subject to} \quad \dot{x}(t) = f(x(t), u(t), t), \quad x(0) = x_0.$$

Suppose that for a given control u the differential equation (OCb) is uniquely solvable with solution x denoted by

$$x = Su.$$

Then we can define an objective on $L_m^2[0, T] = H$

$$(3.1) \quad F(u) = \int_0^T L(Su(t), u(t), t) dt.$$

For the convergence analysis we assume that F is twice continuously Fréchet-differentiable on an open convex set containing u_* and all iterates. Then we can express the gradient $\nabla F(u)$ of F at u through a system of adjoint equations (see e.g. [19]):

$$(3.2) \quad \nabla F(u) = p(\cdot)^T f_u(x(\cdot), u(\cdot), \cdot) + L_u(x(\cdot), u(\cdot), \cdot)$$

where x satisfies (OCb) and p solves

$$(3.3) \quad -\dot{p}(t) = p(t)^T f_x(x(t), u(t), t) + L_x(x(t), u(t), t) \quad \text{with } p(T) = 0.$$

As we have seen in the previous section, the important condition for superlinear convergence is imposed on the Hessian of F , which is of a rather complicated form for control problems. We observe in (3.2) that x and p as solutions of differential equations depend on u through a compact operator and hence the second derivative does too. This leads to the following theorem.

THEOREM 3.1. *Suppose that F is twice Fréchet-differentiable in a neighborhood of $u \in L_2^m[0, T]$. Then with p defined in (3.3) and*

$$(3.4) \quad H(x, u) = p^T f(x, u) + L(x, u),$$

the operator $R: L_2^m[0, T] \rightarrow L_2^m[0, T]$ defined by

$$(Rv)(t) = (\nabla^2 F(u)(v))(t) - H_{uu}(x(t), u(t))v(t)$$

is compact.

The proof follows from the fact that the Hessian of F is given by

$$\nabla^2 F(u) = M^* H_{xx}(x, u) M + M^* H_x(x, u) + H_{ux}(x, u) M + H_{uu}$$

where $Mv = \xi$ denotes the solution of

$$\dot{\xi}(t) = \xi(t)^T f_x(x(t), u(t)) + v(t)^T f_u(x(t), u(t)), \quad \xi(0) = 0.$$

Obviously, M and its adjoint operator M^* are compact operators, so that the multiplication operator H_{uu} is the only noncompact part in $\nabla^2 F(u)$, which must be known exactly. Since

$$H_{uu}(x, u) = p^T f_{uu}(x, u) + L_{uu}(x, u),$$

all control problems with $f_{uu} = 0$ and L_{uu} known are examples where this demand is reasonable. This includes problems where the control u enters the differential equation linearly, i.e.,

$$\dot{x}(t) = q(t, x(t))u(t) + r(t, x(t)), \quad x(0) = x_0,$$

and the objective function L depends on u , for example, in the following form:

$$(3.5) \quad \int_0^T (N(t, x(t)) + \alpha(t)u^2(t)) dt, \quad \alpha \text{ given.}$$

In order to satisfy the compactness condition on $B_0 - \nabla^2 F(u_*)$, we would have to choose in the case of (3.5) for B_0

$$(3.6) \quad (B_0 v)(t) = \alpha(t)v(t), \quad t \in [0, T].$$

Then we might expect a superlinear rate of convergence. If $\alpha(t) \neq 1$ and we choose $B_0 = I$, we do not necessarily obtain a superlinear rate. The numerical examples illustrate this point.

As an application of the results in the second section we consider a finite difference discretization of a control problem. Various authors have studied these problems in connection with the convergence of solutions or optimal values of discretized problems to the solution or optimal value of the original problem (see e.g. [14]). In this section we investigate the performance of quasi-Newton methods when applied to the finite-dimensional approximations of optimal control problems.

In the sequel we solve $G(u) = \nabla f(u) = 0$, where for given control u the state x is computed by (OCb) and the adjoint p by (3.3). Therefore, instead of discretizing (OC) and having to compute the gradient of the finite difference scheme for (OCb), we discretize the differential equations (OCb) and (3.3) and set $\nabla F(u) = 0$ in (3.2) at the grid points. Although it is known (see e.g. [19, p. 68]) that the gradient for a discretization of the optimal control problem (OC) can be expressed through a finite difference adjoint equation, we found similar to the results in [14] that this gradient differs from a discretization of the equation $\nabla F(u) = 0$. One exception to this observation is Euler's method which, however, is inadequate for our purposes because it is a low order discretization scheme. If a Runge-Kutta scheme is applied to the state equation (OCb) or the adjoint equation (3.3) this requires the evaluation of u and x at intermediate points. We introduce these points as additional variables for the controls u only and interpolate to obtain values for x at these intermediate points.

Let $N \in \mathbb{N}$ be the discretization parameter and let us restrict for our examples to the one-dimensional case: The time interval $[0, T]$ is divided into $2N$ subinterval of equal length $h/2$, where

$$(3.7) \quad h = \frac{T}{N}.$$

Let $u \in \mathbb{R}^{2N+1}$ be given. For given x_0, \dots, x_{sj-2} compute x_{2j}, x_{2j-1} by

$$(3.8a) \quad k_1 = hf(u_{2j-2}, x_{2j-2}),$$

$$(3.8b) \quad k_2 = hf(u_{2j-1}, x_{2j-2} + \frac{1}{2}k_1),$$

$$(3.8c) \quad k_3 = hf(u_{2j-1}, x_{2j-2} + \frac{1}{2}k_2),$$

$$(3.8d) \quad k_4 = hf(u_{2j}, x_{2j-2} + k_3),$$

$$(3.8e) \quad x_{2j} = \frac{1}{6}(k_1 + 2k_2 + 2k_3 + k_4),$$

$$(3.8f) \quad k_1^+ = hf(u_{2j}, x_{2j}),$$

$$(3.8g) \quad x_{2j-1} = \frac{1}{2}(x_{2j} + x_{2j-2}) + \frac{1}{8}(k_1 + k_1^+).$$

The formulas (3.8) represent a Runge-Kutta scheme of fourth order, i.e., the global truncation error for the values $\{x_{2j}\}_{j=1}^N$ is of order $O(h^4)$. For the odd indices we use (3.8g), i.e., a Hermite interpolation based on x_{2j-2} and x_{2j} , which has a local truncation error of $O(h^4)$. Hence the error for all points $x_i, i = 0, \dots, 2N$ is of order $O(h^4)$. The

equations for the adjoint equation which is backward in time are: Given $p_{2N}, p_{2N-1}, \dots, p_{2j}$, compute p_{2j-1}, p_{2j-2} as follows. Let $\varphi(x, u, p) = pf_x(x, u) + L_x(x, u)$

$$(3.9a) \quad k_1 = h\varphi(x_{2j}, u_{2j}, p_{2j}),$$

$$(3.9b) \quad k_2 = h\varphi(x_{2j-1}, x_{2j-1}, p_{2j} + \frac{1}{2}k_1),$$

$$(3.9c) \quad k_3 = h\varphi(x_{2j-1}, x_{2j-1}, p_{2j} + \frac{1}{2}k_2),$$

$$(3.9d) \quad k_4 = h\varphi(x_{2j-2}, x_{2j-2}, p_{2j} + k_3),$$

$$(3.9e) \quad p_{2j-2} = \frac{1}{6}(k_1 + 2k_2 + 2k_3 + k_4),$$

$$(3.9f) \quad k_1^+ = h\varphi(x_{2j-2}, u_{2j-2}, p_{2j-2}),$$

$$(3.9g) \quad p_{2j-1} = \frac{1}{2}(p_{2j} + p_{2j-2}) + \frac{1}{8}(k_1 + k_1^+).$$

The endpoint condition for $p \in \mathbb{R}^{2N+1}$ is $p_{2N} = 0$. In order to apply the approximate BFGS-method in § 2 we need to satisfy assumptions (A1) and (A2). Let us choose

$$(3.10) \quad H = L_2[0, T], \quad Z = C[0, T]$$

with the usual norms. The subspace W and the finite-dimensional spaces are

$$(3.11) \quad W = C^5[0, T], \quad H^N = \mathbb{R}^{2N+1}$$

with inner products which stem from the composite Simpson's rule

$$(3.12) \quad \langle u^N, v^N \rangle_N = \frac{T}{6N} \left(u_0^N v_0^N + 2 \sum_{j=1}^{N-1} u_{2j}^N v_{2j}^N + 4 \sum_{j=1}^N u_{2j-1}^N v_{2j-1}^N + u_{2N}^N v_{2N}^N \right).$$

The prolongations $P^N: H^N \rightarrow Z$ are defined as follows:

$$(3.13) \quad \text{For } u \in \mathbb{R}^{2N+1} \text{ let } P^N u \in C[0, T] \text{ be the piecewise parabolic interpolant with } (P^N u)(t_j) = u_j, t_j = jT/2N, j = 0, \dots, 2N.$$

The nonlinear mapping $G^N: \mathbb{R}^{2N+1} \rightarrow \mathbb{R}^{2N+1}$ is defined as follows:

For $u^N \in \mathbb{R}^{2N+1}$ let $x^N \in \mathbb{R}^{2N+1}$ be the solution of (3.8) and let $p^N \in \mathbb{R}^{2N+1}$ be the solution of (3.9). Then

$$(3.14) \quad (G^N u^N)_i = p_i^N f_u(x_i^N, u_i^N) + L_u(x_i^N, u_i^N).$$

LEMMA 3.1. Assume there exists an optimal control $u_* \in C^5[0, T]$ and (OCb) is uniquely solvable for all u sufficiently close to u_* in the $C[0, T]$ -norm. If $f_x, L_x, f_u, L_u \in C^5[0, T]$, then (A1) and (A2) are satisfied with the definitions (3.10)–(3.14).

Proof. If (2.2) is satisfied, then for $u_1, u_2 \in Z$

$$(3.15) \quad \lim_{N \rightarrow \infty} \max_{0 \leq j \leq 2N} |u_{i,j}^N - u_i(t_j)| = 0, \quad i = 1, 2.$$

Since u_1 and u_2 are continuous on $[0, T]$, the quadrature rule (3.12) implies that

$$\lim_{N \rightarrow \infty} \langle u_1^N, u_2^N \rangle_N = \int_0^T u_1(t) u_2(t) dt,$$

which proves (A1).

If $u \in W = C^5[0, T]$ is chosen, then, by the smoothness assumptions on f and L , any solutions x and p of differential equations (OCb) and (3.3) lie in W and Gu is an element of W . If

$$u^N \xrightarrow{Z} u \in W,$$

then for the corresponding trajectories and solutions of the adjoint equations

$$x^N \xrightarrow{Z} x, \quad p^N \xrightarrow{Z} p.$$

By (3.14) this implies

$$G^N u^N \xrightarrow{Z} Gu.$$

Obviously (3.8)–(3.14) are not the only choices which are feasible. An Euler scheme with a simple quadrature rule would yield the same results theoretically, but the numerical observations are easier to obtain for a higher order scheme. The Runge–Kutta scheme with Hermite interpolation for intermediate points approximates the true solution up to order 4, which under appropriate smoothness on f and L , means that the gradient is approximated up to that order. The same order of accuracy holds for the second approximation, the inner product, which is done by composite Simpson's rule. In fact, one can see from the formula for the updated iterate u_1 , with the inverse of B_0 , that u_1^N differs from u_1 , by an order of four; this is why set $W = C^5[0, T]$.

The numerical example represents a simple production inventory model (see [22, p. 145]) which is described as follows:

$$\text{Min} \int_0^T e^{-\rho t} \left(\frac{d}{2} (x(t) - a(t))^2 + \frac{c}{2} (u(t) - b(t))^2 \right) dt$$

such that

$$\dot{x}(t) = u(t) - s(t), \quad x(0) = x_0.$$

The parameters were chosen as follows:

$$\rho = 1, \quad d = c = 1, \quad a = 15, \quad b = 30, \quad s(t) = t^2, \quad x_0 = 10.$$

Using Pontryagin's maximum principle, it is possible to compute the optimal control u_* for the infinite-dimensional problem. It is of the form

$$u_*(t) = \alpha_1 \lambda_1 e^{\lambda_1 t} + \alpha_2 \lambda_2 e^{\lambda_2 t} + t^2 - 2t + 4$$

where $\lambda_{1/2} = (1 \pm \sqrt{5})/2$ and α_i are other constants (see [22, p. 145f] for details). The Hessian of F for this problem is given by

$$\nabla^2 F(u)(v) = d \int_t^T e^{-\rho s} \int_0^s v(\sigma) d\sigma + c e^{-\rho t} v(t).$$

The first summand of the Hessian is a compact operator from $L_2[0, T]$ into itself and the second is not. By the theory from the previous sections it is important for the superlinear convergence of the iterates that the noncompact part is approximated correctly in the initial approximation of the Hessian. We consider two choices for B_0 :

$$(3.16) \quad B_0 = \alpha I \quad \text{and} \quad B_0 = H_{uu}$$

where $(H_{uu}v)(t) = c e^{-\rho t} v(t)$. For given T we choose α in (3.16) such that $\|\alpha I - H_{uu}\|$ is small. A simple estimate yields

$$\frac{\|G'(u_*) - H_{uu}\| - \|G'(u_*) - \alpha I\|}{\|G'(u_*)\|} \leq \frac{\|\alpha I - H_{uu}\|}{\|G'(u_*)\|} \leq 0.041 [0.19]$$

for $\alpha = 0.86$ and $T = 0.3$ [$\alpha = 0.63$ and $T = 1.0$]. For each case of α and T , this indicates that aside from the compactness the two choices for B_0 , αI and H_{uu} have roughly the same relative distance from the Jacobian at the root.

Analogous to (3.16) we choose B_0^N as diagonal matrices,

$$B_0^N = \text{diag } \alpha \quad \text{and} \quad B_0^N = \text{diag } d,$$

where

$$\alpha_j = \alpha \quad \text{and} \quad d_j = c e^{-\rho t_j}$$

for $j = 0, \dots, 2N$ with t_j as in (3.13). Furthermore, we let

$$u_0 = u_* + 1 \quad \text{and} \quad (u_0^N)_j = u_*(t_j) + 1$$

for $j = 0, \dots, 2N$.

Condition (2.3) follows from the choices of B_0^{-1} , whereas (2.4) and (2.5) are a consequence of the choice P^N .

In Tables 1 and 2 we list the number of iterates $i_N(\varepsilon)$ necessary to achieve the tolerance in the norm of the gradient.

Tables 3 and 4 show that not only is $i_N(\varepsilon)$ quite different for αI and H_{uu} but also that the convergence behavior is qualitatively different. The numbers tabulated are as follows:

$$\sigma_i = \|s_i^N\|_N, \quad \gamma_i = \|G^N(u_i^N)\|_N,$$

$$\eta_i = \|u_i^N - \bar{u}_*^N\|_N, \quad \bar{v}^N = \{v(t_i)\}_{i=0}^{2N}.$$

The sequence σ_i/σ_{i-1} illustrates the difference between linear and superlinear convergence behavior in Tables 3 and 4. The linear rate of convergence which is observed in Tables 3 and 4 even for the case where B_0 is not H_{uu} , is to be expected from known theory (see e.g. Dennis [5]). Since the optimal control u_* for the infinite-dimensional problem is known, we also list the distance between u_i^N and u_* . The numbers for η_i indicate that for $B_0 = \alpha I$ the last three iterations are redundant because the predicted and also the actual magnitude of the discretization error exceeds the distance between u_i^N and \bar{u}_*^N . This effect is delayed when the accuracy is increased. In Table 4 also observe that an error bound of 10^{-9} which is reasonable from the discretization results in a large difference in the iteration count:

$$i_{200}(10^{-9}) = 6 \quad \text{for } B_0 = H_{uu},$$

$$i_{200}(10^{-9}) = 15 \quad \text{for } B_0 = 0.63I.$$

The computations were done on the Cyber 205 at Purdue University in single precision. Single precision on the 205 is roughly 14 place decimal accuracy.

EXISTENCE OF OVERTAKING SOLUTIONS TO INFINITE DIMENSIONAL CONTROL PROBLEMS ON UNBOUNDED TIME INTERVALS*

D. A. CARLSON[†], A. HAURIE[‡] AND A. JABRANE[‡]

Abstract. The optimal control of an infinite-dimensional linear control system with unbounded time interval is considered. The results obtained are an extension to a Hilbert space setting of the results reported in Brock and Haurie [Math. Oper. Res., 1 (1976), pp. 337-346]. In particular, it is shown that (under appropriate conditions) overtaking optimal trajectories asymptotically approach a unique optimal steady state. This is the so-called *turnpike* property found in the economics literature. When this condition is combined with an associated optimal control problem, results concerning the existence of overtaking optimal solutions are obtained. Both distributed and boundary controls are considered. Finally we demonstrate the applicability of our results by considering several examples arising in the context of economics and resources management.

Key words. overtaking solutions, optimal control, distributed parameter and boundary control

AMS(MOS) subject classifications. Primary 49A10; secondary 90A

Introduction and motivation. The theory of optimal control of lumped parameter systems defined on an infinite time horizon stemmed from two main fields of applications:

- (i) the regulator problem where a stabilizing feedback with constant gain is to be designed for a given linear system, and
- (ii) the optimal economic growth model where a path of optimal capital accumulation is searched for, which permits an optimal asymptotic sustainable consumption in the economy.

A classical reference for the first problem is [23] and for the second class of problems is [1].

The extension of the regulator problem to a class of systems having infinite-dimensional state and controls (e.g. distributed parameter systems) has retained considerable attention in the systems theory literature. As examples of such generalizations we cite [25] and [12].

In the present paper we are interested in obtaining an extension to a Hilbert space setting of the existence results obtained in [3], [4], [8] and [24] for overtaking solutions of infinite horizon control problems. This previous work is clearly related to the second field of application, as it is based on an intensive use of convex analysis and it implies, as a by-product, the fundamental elements of the *turnpike* property of optimal economic growth models. This property states that, under sufficient regularity and convexity conditions, a unique optimal steady state is an asymptotic attractor of all optimal trajectories. Another distinctive feature in [8] is that it establishes a link between the optimal control problem considered and an associated convex problem of Lagrange, as introduced in [30], the solution of the second problem being also the desired solution of the first problem.

Some generalizations to a Hilbert space setting, of the work of Rockafellar, have already been made by Viorel Barbu [3]. However, to our knowledge, the concept of overtaking optimality, the existence of such optimal trajectories and the relationship to the turnpike property has not yet been the object of a complete study for infinite-dimensional systems.

There is a need for such a generalization, as more economic models deal with distributed parameter systems where the *space* variable is either associated with a regional distribution of the economic variables (e.g. investment and capital as in [22], advertisement and goodwill as in [13]) or associated with the age distribution of a population as in [21] and [20]). Indeed the extension of the *turnpike* property to such models, so intimately linked to dynamic economic models since the work of Dorfman, Samuelson and Solow [14], Gale [18], McKenzie [28], as well as the proof that there exists an optimal solution to the problem posed, should be an important step toward the diffusion of these models as valid economic paradigms.

The paper is organized as follows: in § 1 the optimal control problem is formulated for the case of distributed control. In § 2 the *turnpike* property is established. In § 3 the associated problem of Lagrange is defined, its solution is proved to exist, a fundamental inequality is established, and these properties are used for proving that the solution of the associated problem of Lagrange is also overtaking optimal solution for the original problem. In § 4 these results are extended to the case of mixed (boundary and distributed) control. Finally, § 5 presents two examples dealing with typical economic and resources management models.

1. The optimal control problem. We consider a system described by the following input-output relationship:

$$(1.1) \quad x(t) = S(t)x^0 + \int_0^t S(t-s)Bu(s) ds, \quad t \geq 0$$

where E and F are separable Hilbert spaces, $x^0 \in E$, $\{S(t); t \geq 0\}$ is a strongly continuous semigroup on E with generator A , $u(\cdot) \in L^2_{loc}(R^+, F)$, the space of all strongly measurable functions $u(\cdot): R^+ \rightarrow F$, which are square-integrable on every finite interval $[0, T]$, and $B: F \rightarrow E$ a bounded linear operator.

Thus $x(\cdot)$ is the *mild solution* of the state equation

$$(1.2a) \quad \dot{x}(t) = Ax(t) + Bu(t), \quad t \geq 0,$$

$$(1.2b) \quad x(0) = x^0$$

where A is a possibly unbounded, closed and densely defined operator in E .

In addition we know (see [2], [7]) that although a mild solution need not be absolutely continuous it does satisfy the following *mild* differential equation:

$$(1.3a) \quad \forall y \in \mathcal{D}(A^*), \quad \frac{d}{dt} \langle x(t), y \rangle = \langle x(t), A^*y \rangle + \langle Bu(t), y \rangle \quad \text{a.e. } t \geq 0,$$

$$(1.3b) \quad \lim_{t \rightarrow 0^+} \langle x(t), y \rangle = \langle x^0, y \rangle$$

where A^* is the adjoint operator associated with A , with domain $\mathcal{D}(A^*)$. We impose the following additional constraints on state and control:

$$(1.4) \quad \forall t \geq 0 \quad x(t) \in X, \quad \text{a convex and closed subset of } E$$

and

$$u(t) \in U(x(t)) \subset F \quad \forall t \geq 0 \quad \text{where } U(\cdot): X \rightarrow 2^F$$

is a point to set mapping which is convex valued and satisfies

$$(1.5) \quad \alpha U(x) + (1 - \alpha)U(x') \subset U(\alpha x + (1 - \alpha)x') \quad \forall x, x' \in X, \quad \forall \alpha \in [0, 1],$$

$$(1.6) \quad \{u_n \xrightarrow{w} u, x_n \xrightarrow{w} x, u_n \in U(x_n) \forall n\} \Rightarrow u \in U(x)$$

where \xrightarrow{w} stands for the weak convergence in E . Notice that (1.6) implies that $U(x)$ is weakly closed, for each x in X .

The performance of the system on any interval $[0, t]$, $t \geq 0$ is evaluated by the cost functional

$$(1.7) \quad x_0(t; u(\cdot), x(\cdot)) \triangleq \int_0^t f_0(x(s), u(s)) ds$$

where $f_0: E \times F \rightarrow R$ is a convex functional which is lower semicontinuous on $E \times F$ and satisfies the following growth condition: there exists $K_1 > 0$ and $K > 0$ such that

$$(1.8) \quad \|x\|^2 + \|u\|^2 > K_1 \Rightarrow f_0(x, u) \geq K(\|x\|^2 + \|u\|^2).$$

We call $\mathcal{S}(x^0)$ the set of pairs $(u(\cdot), x(\cdot))$ where

- (i) $u(\cdot) \in L_{loc}^2(R^+, F)$,
- (ii) $x(\cdot)$ is given by (1.1),
- (iii) $x(t) \in X$ and $u(t) \in U(x(t))$ for all $t \geq 0$.

Then $u(\cdot)$ is called an *admissible control* at x^0 , and $x(\cdot)$ is the *associated trajectory*.

Since we consider our model on an infinite horizon, we do not a priori assume the convergence of (1.7) as $t \rightarrow \infty$. Hence we need to consider the following weaker notions of optimality.

DEFINITION 1. $(\hat{u}(\cdot), \hat{x}(\cdot)) \in \mathcal{S}(x^0)$ is *overtaking* (resp. *weakly overtaking*) *optimal* at x^0 if for any other pair $(u(\cdot), x(\cdot)) \in \mathcal{S}(x^0)$

$$(1.9) \quad \liminf_{t \rightarrow \infty} \{x_0(t; u(\cdot), x(\cdot)) - x_0(t; \hat{u}(\cdot), \hat{x}(\cdot))\} \geq 0, \\ \text{(resp. } \limsup_{t \rightarrow \infty} \{x_0(t; u(\cdot), x(\cdot)) - x_0(t; \hat{u}(\cdot), \hat{x}(\cdot))\} \geq 0. \quad \square$$

These are the optimality concepts used in [8]. The weak overtaking optimality concept was also studied in [19] from the point of view of necessary conditions for optimality in lumped parameter systems. For other recent contributions to the theory of optimal control on infinite time horizon making use of these solution concepts see [9], [10], [11], [17] and [24].

2. The turnpike property. In this section we investigate the asymptotic convergence properties of optimal trajectories in the sense of Definition 1 in § 1. In the economics literature these are the so-called *turnpike* properties first introduced by Samuelson [32] in the context of economic growth theory.

Assume the following.

Assumption 1. The optimal steady state problem (OSSP) consisting of

$$\begin{aligned} & \text{Min } f_0(x, u) \\ & \text{s.t. } 0 = \langle x, A^*y \rangle + \langle Bu, y \rangle \quad \forall y \in \mathcal{D}(A^*), \\ & \quad x \in X, \\ & \quad u \in U(x) \end{aligned}$$

has a solution denoted (\bar{x}, \bar{u}) , with \bar{x} uniquely defined.

By the convexity assumptions already made on $f_0(\cdot, \cdot)$, X , and $U(\cdot)$, the OSSP is a convex programming problem in a Hilbert space. Thus there exists $\bar{p} \in \mathcal{D}(A^*)$ such that (see [31], [15])

$$(2.1) \quad f_0(\bar{x}, \bar{u}) \leq f_0(x, u) - (\langle x, A^* \bar{p} \rangle + \langle Bu, \bar{p} \rangle)$$

for every x in X and u in $U(x)$. Let $L_0: E \times F \rightarrow [0, +\infty]$ be defined by

$$(2.2) \quad L_0(x, u) = \begin{cases} f_0(x, u) - f_0(\bar{x}, \bar{u}) - \langle x, A^* \bar{p} \rangle - \langle Bu, \bar{p} \rangle & \text{if } x \in X \text{ and } u \in U(x), \\ +\infty & \text{otherwise.} \end{cases}$$

Then we have $L_0(\bar{x}, \bar{u}) = 0$. Furthermore, since L_0 differs from f_0 through an affine function of x and u , it still satisfies the growth property (1.8), with f_0 replaced by L_0 .

As a consequence of this property we have the following technical lemma, whose proof is relegated to § 7.

LEMMA 1. *If an admissible pair $(\tilde{x}(\cdot), \tilde{u}(\cdot)) \in \mathcal{S}(x_0)$ is such that*

$$(2.3) \quad \int_0^\infty L_0(\tilde{x}(t), \tilde{u}(t)) dt < \infty;$$

then necessarily $\tilde{x}(\cdot)$ is bounded and for every fixed $T > 0$ there exists a constant $C(T)$ s.t.

$$(2.4) \quad \forall t \geq 0 \quad \int_t^{t+T} \|\tilde{u}(s)\|^2 ds \leq C(T).$$

Proof. The proof is given in § 7.

We can now establish the *Weak Turnpike Theorem*.

THEOREM 1. *Under Assumption 1 if $(\tilde{u}(\cdot), \tilde{x}(\cdot)) \in \mathcal{S}(x^0)$ is such that*

$$(2.5) \quad \limsup_{T \rightarrow \infty} \left[\int_0^T (f_0(\tilde{x}(t), \tilde{u}(t)) - f_0(\bar{x}, \bar{u})) dt \right] = \alpha < \infty,$$

then necessarily

$$(2.6) \quad \frac{1}{T} \int_0^T \tilde{x}(t) dt \xrightarrow{w} \bar{x} \text{ as } t \rightarrow \infty.$$

Proof. First we show that (2.3) is satisfied. As a result of the nonnegativity of L_0 it suffices to exhibit a sequence $\{T_k\}$, $T_k \rightarrow \infty$ as $k \rightarrow \infty$, such that, for a given constant C

$$(2.7) \quad \forall k = 1, 2, \dots \quad \int_0^{T_k} L_0(\tilde{x}(t), \tilde{u}(t)) dt < C.$$

According to (2.5), (2.7) will be satisfied if for a given sequence $\{T_k\}$ the set

$$\{\langle \tilde{x}(T_k), \bar{p} \rangle : k = 1, 2, \dots\}$$

is bounded. We show now that one can obtain such a sequence.

We claim, first, that under Assumption 1 there exists a constant $\bar{C} > 0$ such that

$$(2.8) \quad \left\| \frac{1}{T} \int_0^T \tilde{x}(t) dt \right\| \leq \bar{C} \quad \forall T > 0.$$

Suppose the contrary, then there exists a sequence $\{T_k\}$ $T_k \rightarrow \infty$ as $k \rightarrow \infty$ such that

$$\left\| \frac{1}{T_k} \int_0^{T_k} \tilde{x}(t) dt \right\| \rightarrow +\infty \quad \text{as } k \rightarrow \infty.$$

Using Jensen's inequality on f_0 and relation (1.8) we obtain the following from (2.5)

$$(2.9) \quad K \left\| \frac{1}{T_k} \int_0^{T_k} \tilde{x}(t) dt \right\|^2 - f_0(\bar{x}, \bar{u}) \leq \frac{1}{T_k} \int_0^{T_k} \{f_0(\tilde{x}(t), \tilde{u}(t)) - f_0(\bar{x}, \bar{u})\} dt \leq \frac{\alpha}{T_k}.$$

As k tends to infinity the right-hand side in (2.9) goes to zero whereas the left-hand side goes to infinity. This is a contradiction, and so (2.8) holds.

Notice that a similar argument would show that there exists a positive constant \bar{C}' such that

$$(2.10) \quad \left\| \frac{1}{T} \int_0^T \tilde{u}(t) dt \right\| \leq \bar{C}' \quad \forall T > 0.$$

Suppose, now, that for every sequence $\{T_k\}$, the set $\{\langle x(T_k), \bar{p} \rangle : k = 1, \dots\}$ is unbounded or, equivalently, that

$$(2.11) \quad \forall C > 0, \exists \bar{T} > 0 \quad \text{s.t. } \forall t > \bar{T} \\ |\langle \tilde{x}(t), \bar{p} \rangle| > C.$$

Since $\tilde{x}(\cdot)$ is continuous, by (2.11), $\langle \tilde{x}(t), \bar{p} \rangle$ keeps a constant sign in $[\bar{T}, \infty)$ and therefore, for any $T > \bar{T}$

$$(2.12) \quad \left| \frac{1}{T} \int_{\bar{T}}^T \langle x(t), \bar{p} \rangle dt \right| = \frac{1}{T} \int_{\bar{T}}^T |\langle x(t), \bar{p} \rangle| dt.$$

Take C such that

$$(2.13) \quad C > \bar{C} \|\bar{p}\|.$$

Then, using (2.8) and (2.12), we obtain

$$(2.14) \quad \left| \frac{1}{T} \int_{\bar{T}}^T \langle \tilde{x}(t), \bar{p} \rangle dt \right| \leq \bar{C} \|\bar{p}\| + \frac{1}{T} \left\| \int_0^{\bar{T}} \tilde{x}(t) dt \right\| \cdot \|\bar{p}\|.$$

When T goes to infinity in (2.14) the R.H.S. tends to $\bar{C} \|\bar{p}\|$ whereas the L.H.S. remains greater than C , and this contradicts (2.13). This establishes (2.7).

Integrating the state equation in the mild form (2.3), we have

$$(2.15) \quad \frac{1}{T} \langle \tilde{x}(T) - x^0, z \rangle = \left\langle \frac{1}{T} \int_0^T \tilde{x}(t) dt, A^* z \right\rangle + \left\langle B \frac{1}{T} \int_0^T \tilde{u}(t) dt, z \right\rangle.$$

By Lemma 1, $\tilde{x}(\cdot)$ is bounded, and since X and $U(\cdot)$ are convex, any weak cluster point (x^*, u^*) of the set

$$\left\{ \left(\frac{1}{T} \int_0^T \tilde{x}(t) dt, \frac{1}{T} \int_0^T \tilde{u}(t) dt \right), T > 0 \right\}$$

is an admissible pair for the OSSP. By Jensen's inequality and the lower semicontinuity of f_0 , the inequality (2.5) yields

$$(2.16) \quad f_0(x^*, u^*) \leq f_0(\bar{x}, \bar{u}).$$

Therefore, by the uniqueness of \bar{x} (Assumption 1), we have from (2.16) that

$$x^* = \bar{x}$$

and this completes the proof. \square

Remark 1. The *weak turnpike property* relates to the weak convergence of the average state $(1/T) \int_0^T \tilde{x}(t) dt$ toward \bar{x} as soon as the inequality (2.5) is satisfied.

Remark 2. As a consequence of (2.16) the average control $(1/T) \int_0^T \tilde{u}(t) dt$ has to converge weakly toward an optimal control \bar{u} for the OSSP.

In order to obtain a stronger turnpike property we introduce the set

$$(2.17) \quad G = \{x \in E : \exists u \in F \text{ s.t. } L_0(x, u) = 0\}$$

and the following definition.

DEFINITION 2. Let \mathcal{F} be the family of all trajectories $x(\cdot) \in \mathcal{S}(X)$ such that

$$(2.18) \quad x(t) \in G \quad \text{a.e. on } [0, \infty).$$

We say that G has Property \mathcal{C} (for *Convergence*) if $x(t) \xrightarrow{w} \bar{x}$ as $t \rightarrow \infty$, uniformly in \mathcal{F} .

The following theorem is an adaptation of results obtained in [24] for lumped parameter systems.

THEOREM 2. Under Assumption 1, if G has the property \mathcal{C} and if a feasible pair $(\tilde{x}(\cdot), \tilde{u}(\cdot))$ is such that

$$(2.19) \quad \int_0^\infty L_0(\tilde{x}(t), \tilde{u}(t)) dt < \infty;$$

then, necessarily, $\tilde{x}(t)$ converges weakly to \bar{x} as $t \rightarrow \infty$.

Proof. Assume the contrary. Then, there exist $\bar{y} \in E$, $\bar{y} \neq 0$, times $t_k \rightarrow \infty$ and an $\varepsilon > 0$ such that

$$(2.20) \quad |\langle \tilde{x}(t_k) - \bar{x}, \bar{y} \rangle| \geq \varepsilon \quad \text{for all } k \geq 1.$$

Let t_0 be such that, for any $x(\cdot) \in \mathcal{F}$,

$$(2.21) \quad |\langle x(t) - \bar{x}, \bar{y} \rangle| < \frac{\varepsilon}{2} \quad \text{a.e. on } (t_0, \infty).$$

Define $u_k(t) = \tilde{u}(t_k - t_0 + t)$ and $x_k(t) = \tilde{x}(t_k - t_0 + t)$, $t \geq 0$. A simple calculation involving (1.1) shows that $(x_k(\cdot), u_k(\cdot))$ is a feasible pair such that $x_k(0) = \tilde{x}(t_k - t_0)$. Further, Lemma 1 implies that $\{u_k(\cdot)\}$ is bounded in $L^2(0, T, F)$ for any fixed $T > 0$, and $\{x(t_k - t_0)\}$ is bounded in E . Thus, extracting a subsequence if necessary, we may suppose that for each $T > 0$

$$(2.22) \quad \begin{aligned} u_k &\rightarrow u^* \quad \text{weakly in } L^2(0, T, F), \\ x_k(0) &\rightarrow x_0^* \quad \text{weakly in } E. \end{aligned}$$

Furthermore, it is easy to see that

$$(2.23) \quad x_k \rightarrow x^* \quad \text{weakly in } L^2(0, T; E)$$

and $(x^*(\cdot), u^*(\cdot))$ is a feasible pair such that

$$(2.24) \quad \lim_{t \rightarrow 0^+} \langle x^*(t), y \rangle = \langle x_0^*, y \rangle \quad \forall y \in \mathcal{D}(A^*).$$

Since $L_0 \geq 0$, then, using (2.19) we obtain

$$(2.25) \quad \int_0^T L_0(x_k(t), u_k(t)) dt = \int_{t_k - t_0}^{T + t_k - t_0} L_0(x(t), u(t)) dt \rightarrow 0 \quad \text{as } k \rightarrow \infty.$$

On the other hand the lower semicontinuity of f_0 implies that, for every $T > 0$, the convex function $\varphi: (x(\cdot), u(\cdot)) \rightarrow \int_0^T L_0(x(t), u(t)) dt$ is lower semicontinuous (l.s.c.) on $L^2(0, T, E) \times L^2(0, T, F)$. Since L_0 is convex and l.s.c., then for every $k \in \mathbb{R}$, the set

$$\phi = \left\{ (x, u) \in L^2(0, T, E) \times L^2(0, T, F): \int_0^T L_0(x(t), u(t)) dt \leq k \right\}$$

is convex and closed. It is well known that a convex set is closed iff it is weakly closed. Hence ϕ is weakly closed and convex and then the function φ is weakly l.s.c. Hence (2.25), (2.22) and (2.23) imply that

$$\int_0^T L_0(x^*(t), u^*(t)) dt = 0 \quad \forall T > 0.$$

Since $L_0 \geq 0$, this implies that $L_0(x^*(t), u^*(t)) = 0$ a.e. on $[0, +\infty)$. Hence $x^*(\cdot)$ is in \mathcal{F} , and, according to Property \mathcal{C} , $x^*(t)$ converges weakly to \bar{x} as $t \rightarrow \infty$. For k sufficiently large we have

$$\begin{aligned} |\langle \tilde{x}(t_k) - \bar{x}, \bar{y} \rangle| &= |\langle x_k(t_0) - \bar{x}, \bar{y} \rangle| \\ &\leq |\langle x_k(t_0) - x^*(t_0), \bar{y} \rangle| + |\langle x^*(t_0) - \bar{x}, \bar{y} \rangle| \\ &\leq \varepsilon, \end{aligned}$$

which contradicts (2.20). \square

Remark 3. The turnpike property relates to the weak convergence of $\tilde{x}(t)$ toward \bar{x} as $t \rightarrow \infty$, when the inequality (2.19) holds.

Remark 4. If, instead of weak convergence, strong convergence (in the norm of E) is assumed in Property \mathcal{C} , then a strong turnpike property holds where $\|\tilde{x}(t) - \bar{x}\| \rightarrow 0$ as $t \rightarrow \infty$, when (2.19) holds.

The usefulness of Theorem 2 for infinite horizon optimal control problems is illustrated by the following corollary.

COROLLARY 1. In addition to the hypotheses given in Theorem 2, let us suppose that there exists a pair $(\tilde{u}(\cdot), \tilde{x}(\cdot))$ in $\mathcal{P}(x^0)$ such that

$$(2.26) \quad \int_0^\infty L_0(\tilde{x}(t), \tilde{u}(t)) dt < \infty.$$

Then if in the class of all bounded trajectories, there exists an overtaking optimal solution, say $(\hat{u}(\cdot), \hat{x}(\cdot))$, it happens that

$$\lim_{t \rightarrow +\infty} \hat{x}(t) = \bar{x} \quad \text{in the weak sense.}$$

Proof. Since $(\hat{u}(\cdot), \hat{x}(\cdot))$ is overtaking optimal we have

$$\liminf_{T \rightarrow \infty} \left\{ \int_0^T f_0(\tilde{x}(t), \tilde{u}(t)) - f_0(\hat{x}(t), \hat{u}(t)) dt \right\} \geq 0.$$

Thus we may write,

$$\begin{aligned} 0 \leq \liminf_{T \rightarrow \infty} \left[\int_0^T L_0(\tilde{x}(t), \tilde{u}(t)) - L_0(\hat{x}(t), \hat{u}(t)) \right. \\ \left. + \int_0^T \left\{ \frac{d}{dt} \langle \tilde{x}(t) - \hat{x}(t), \bar{p} \rangle \right\} dt \right]. \end{aligned}$$

Therefore, for any $\varepsilon > 0$ there exists $T(\varepsilon) > 0$ such that for all $T \geq T(\varepsilon)$,

$$-\varepsilon \leq \int_0^T L_0(\tilde{x}(t), \tilde{u}(t)) - L_0(\hat{x}(t), \hat{u}(t)) dt + \langle \tilde{x}(T) - \hat{x}(T), \bar{p} \rangle,$$

or equivalently,

$$0 \leq \int_0^T L_0(\hat{x}(t), \hat{u}(t)) dt < \varepsilon + \int_0^T L_0(\tilde{x}(t), \tilde{u}(t)) dt + \langle \tilde{x}(T) - \hat{x}(T), \bar{p} \rangle.$$

The boundedness of \hat{x} along with the assumption made on $(\tilde{u}(\cdot), \tilde{x}(\cdot))$ ensures that the right-hand side of the above inequality is bounded as $T \rightarrow +\infty$. Thus,

$$\int_0^{+\infty} L_0(\hat{x}(t), \hat{u}(t)) dt < \infty,$$

so that by Theorem 2 we must have

$$\lim_{t \rightarrow \infty} \hat{x}(t) = \bar{x} \quad \text{in the weak sense.} \quad \square$$

The assumption made on the pair $(\tilde{u}(\cdot), \tilde{x}(\cdot))$ given by (2.26) above is guaranteed for example if there exists a pair $(u(\cdot), x(\cdot)) \in \mathcal{S}(x^0)$ defined only on $[0, T]$ for some finite $T > 0$ satisfying the terminal condition $x(T) = \bar{x}$. Having such a control allows us to define $(\tilde{u}(\cdot), \tilde{x}(\cdot))$ in $\mathcal{S}(x^0)$ by the following:

$$(\tilde{u}(t), \tilde{x}(t)) = \begin{cases} (u(t), x(t)) & \text{if } 0 \leq t < T, \\ (\bar{u}, \bar{x}) & \text{if } T \leq t. \end{cases}$$

Conditions for such a controllability property are well known; see for example [2, § 4.9].

3. Sufficient conditions for existence of overtaking optimal solutions. In this section we associate with the originally defined control problem a so-called *Associated Problem of Lagrange* (APL). For this problem we are able to adapt an approach due to V. Barbu [3], [4], which shows the existence of a solution which is optimal in the usual sense. Under Assumption 1 (resp. Property \mathcal{C}) we will show that a solution to the APL leads to a weakly overtaking (resp. overtaking) optimal solution for the original problem.

We begin by defining the APL as consisting of minimizing the functional

$$(3.1) \quad \int_0^\infty L_0(x(t), u(t)) dt$$

over all pairs $(u(\cdot), x(\cdot)) \in \mathcal{S}(x^0)$.

Assumption 2. There exists $(\tilde{u}(\cdot), \tilde{x}(\cdot)) \in \mathcal{S}(x^0)$ such that

$$(3.2) \quad \int_0^\infty L_0(\tilde{x}(t), \tilde{u}(t)) dt < \infty.$$

LEMMA 2. Under Assumptions 1 and 2 there exists $(\hat{u}(\cdot), \hat{x}(\cdot)) \in \mathcal{S}(x^0)$ such that for all $(u(\cdot), x(\cdot)) \in \mathcal{S}(x^0)$

$$(3.3) \quad \int_0^\infty L_0(\hat{x}(t), \hat{u}(t)) dt \leq \lim_{T \rightarrow \infty} \int_0^T L_0(x(t), u(t)) dt.$$

Proof. Let

$$\varphi = \inf \left\{ \int_0^\infty L_0(x(t), u(t)) dt, (x, u) \in \mathcal{S}(x^0) \right\}.$$

By Assumption 2 φ is finite. Let $(x_n(\cdot), u_n(\cdot)) \in \mathcal{S}(x^0)$ be a minimizing sequence. For any fixed $T > 0$ we claim that the sequence $\{(x_n(\cdot), u_n(\cdot))\}$ is bounded in $L^2(0, T, E) \times L^2(0, T, F)$.

Suppose the contrary, i.e., there exists a divergent subsequence $\{(x_{n_k}(\cdot), u_{n_k}(\cdot))\}$. Consider the family of sets Ω_k defined by

$$\Omega_k = \{t \in [0, T]: \|x_{n_k}(t)\|^2 + \|u_{n_k}(t)\|^2 > K_1\}.$$

Obviously we have

$$(3.4) \quad \int_{\Omega_k} \{\|x_{n_k}(t)\|^2 + \|u_{n_k}(t)\|^2\} dt \rightarrow \infty \quad \text{as } k \rightarrow \infty.$$

On the other hand, the coercivity assumption (1.8) made on f_0 shows that, since L_0 is nonnegative,

$$(3.5) \quad \begin{aligned} K \int_{\Omega_k} \{\|x_{n_k}(t)\|^2 + \|u_{n_k}(t)\|^2\} dt &\leq \int_{\Omega_k} L_0(x_{n_k}(t), u_{n_k}(t)) dt \\ &\leq \int_0^\infty L_0(x_{n_k}(t), u_{n_k}(t)) dt. \end{aligned}$$

The right-hand side is finite, and thus contradicts (3.4). Therefore, for any fixed $T > 0$, the sequence $\{u_n\}$, respectively $\{x_n\}$, is bounded in $L^2(0, T, F)$, respectively $L^2(0, T, E)$.

By extracting a subsequence if necessary, we may find $(\hat{x}(\cdot), \hat{u}(\cdot))$ such that for each $T > 0$

$$(3.6) \quad u_n \rightarrow \hat{u} \quad \text{weakly in } L^2(0, T, F),$$

$$(3.7) \quad x_n \rightarrow \hat{x} \quad \text{weakly in } L^2(0, T, E),$$

and moreover, where $\hat{u} \in L_{\text{loc}}^2(\mathbb{R}^+, F)$ and $\hat{x}(t) = S(t)x^0 + \int_0^t S(t-s)B\hat{u}(s) ds$, for $t \geq 0$. The hypotheses made on $U(\cdot)$ and X show that $(\hat{x}(\cdot), \hat{u}(\cdot)) \in \mathcal{S}(x^0)$. Relations (3.6), (3.7) combined with the weak l.s.c. of the functions $\delta_T: L^2(0, T, E) \times L^2(0, T, F) \rightarrow [0, +\infty]$ defined by

$$\delta_T(x, u) = \int_0^T L_0(x(t), u(t)) dt,$$

shows that $\int_0^\infty L_0(\hat{x}(t), \hat{u}(t)) dt \leq \varphi$. Hence the result follows. \square

The next lemma establishes a comparison property between the performance criteria associated with two admissible pairs for the original control problem.

LEMMA 3. Let $(\hat{x}(\cdot), \hat{u}(\cdot))$ and $(x(\cdot), u(\cdot))$ be in $\mathcal{S}(x^0)$ and assume that $(\hat{x}(\cdot), \hat{u}(\cdot))$ is a solution to the APL. Then the following holds:

$$(3.8) \quad \begin{aligned} &\forall \varepsilon > 0, \exists T(\varepsilon) > 0 \quad \text{s.t. } \forall T \geq T(\varepsilon) \\ &\int_0^T \{f_0(\hat{x}(t), \hat{u}(t)) - f_0(x(t), u(t))\} dt < \varepsilon + \langle x(T) - \hat{x}(T), \bar{p} \rangle. \end{aligned}$$

Proof. The proof is similar to the one of Lemma 3.3 in [8], except for the fact that a calculus of variations formalism was used in [8]. \square

The next two theorems are then direct extensions of similar results obtained in [8] for lumped parameter systems.

THEOREM 3. *Under Assumptions 1 and 2 there exists a weakly overtaking optimal pair.*

Proof. By Lemma 2 there exists a solution x^* for the APL. Assume that x^* is not weakly overtaking optimal. Then there is a pair $(x(\cdot), u(\cdot)) \in \mathcal{S}(x^0)$ such that

$$(3.9) \quad \forall \varepsilon > 0, \quad \exists T_1 > 0: \quad \forall t > T_1 \\ \int_0^t f_0(x^*(s), u^*(s)) ds > \int_0^t f_0(x(s), u(s)) ds + \varepsilon.$$

By Lemma 3 we have

$$(3.10) \quad \forall \varepsilon' > 0, \quad \exists T_2 > 0 \quad \text{s.t.} \quad \forall t > T_2 \\ \int_0^t \{f_0(x^*(s), u^*(s)) - f_0(x(s), u(s))\} ds < \varepsilon' + \langle x(t) - x^*(t), \bar{p} \rangle;$$

taking $\varepsilon' = \varepsilon/2$ and $T \geq \max(T_1, T_2)$ we have

$$(3.11) \quad \frac{\varepsilon}{2} < \langle x(T) - x^*(T), \bar{p} \rangle.$$

Remembering that $\lim_{T \rightarrow \infty} (1/T) \int_0^T x^*(t) dt = \bar{x}$ in the weak sense, then, if the same property holds for $x(\cdot)$, we have

$$\frac{\varepsilon}{2} \leq \lim_{t \rightarrow \infty} \frac{1}{T} \int_0^T \langle x(t) - x^*(t), \bar{p} \rangle dt = 0,$$

which is a contradiction.

Suppose now that $\lim_{T \rightarrow \infty} (1/T) \int_0^T x(t) dt \neq \bar{x}$ in the weak sense. The contrapositive of Theorem 1 shows that

$$(3.12) \quad \int_0^\infty \{f_0(x(t), u(t)) - f_0(\bar{x}, \bar{u})\} dt = \infty.$$

A simple calculation, using (3.7), shows that for every $\varepsilon > 0$, there exists $T' > 0$ s.t. for every $T > T'$

$$(3.13) \quad \int_0^T L_0(x^*(t), u^*(t)) dt + \langle x^*(T) - x_0, \bar{p} \rangle - \varepsilon \\ > \int_0^T \{f_0(x(t), u(t)) - f_0(\bar{x}, \bar{u})\} dt.$$

Since $x^*(\cdot)$ is bounded and is a solution of the APL, (3.13) contradicts (3.10). \square

THEOREM 4. *If, in addition to the assumptions of the previous theorem, one assumes that the set G satisfies Property \mathcal{C} , then there exists an overtaking trajectory in the subclass $\mathcal{S}_B(x_0)$ consisting of bounded trajectories emanating from x_0 .*

Proof. By Lemma 2, there exists a solution x^* for the APL and by Lemma 1 $(x^*(\cdot), u^*(\cdot)) \in \mathcal{S}_B(x_0)$. Consider any other pair $(x(\cdot), u(\cdot)) \in \mathcal{S}_B(x^0)$ and define

$$(3.14) \quad e(T) = \int_0^T \{f(x^*(t), u^*(t)) - f(x(t), u(t))\} dt.$$

Using Lemma 3 and (3.14), we obtain

$$(3.15) \quad \forall \varepsilon > 0, \quad \exists T > 0: \quad \forall t \geq T \quad e(t) < \varepsilon + \langle x(t) - x^*(t), \bar{p} \rangle;$$

by Theorem 2, $x^*(t)$ converges weakly to \bar{x} as $t \rightarrow +\infty$. Assume that the same holds for $x(\cdot)$. Then taking t sufficiently large in (3.15), we have

$$\forall \varepsilon > 0, \quad \exists T > 0 \quad \text{s.t.} \quad \forall t \geq T$$

$$\int_0^t f_0(x^*(t), u^*(t)) dt < \int_0^t f_0(x(t), u(t)) dt + \varepsilon.$$

Thus x^* is overtaking optimal.

Now if $\lim_{t \rightarrow \infty} x(t) \neq \bar{x}$ in the weak sense then, by Theorem 2,

$$(3.16) \quad \int_0^\infty L_0(x(t), u(t)) dt = +\infty.$$

A simple calculation using (3.14) shows that

$$(3.17) \quad e(T) = \int_0^T \{L_0(x^*(t), u^*(t)) - L_0(x(t), u(t))\} dt + \langle x^*(T) - x(T), \bar{p} \rangle.$$

Since $x(\cdot)$ and $x^*(\cdot)$ are bounded and x^* is a solution for the APL, then, taking the limit in (3.17) and using (3.16) we have

$$\lim_{T \rightarrow \infty} e(T) = -\infty,$$

and therefore, x^* is overtaking optimal in $\mathcal{S}_B(x_0)$. \square

4. Extension to the case of systems with distributed and boundary controls. We now extend the existence results obtained in § 3 to the case of infinite-dimensional control problems with distributed and boundary control. By appealing to the boundary control theory of Fattorini [16] and Barbu [5] we transform the boundary control system to a linear evolution equation on a Hilbert space. This allows us to exploit the results of previous sections and give sufficient conditions for the “turnpike” property to hold as well as conditions for the existence of overtaking solutions.

We consider the following control system:

$$(4.1) \quad \dot{x}(t) = \sigma x(t) + B_1 u_1(t),$$

$$(4.2) \quad \gamma x(t) = B_2 u_2(t),$$

with initial condition

$$(4.3) \quad x(0) = x^0,$$

and the following additional constraints

$$(4.4) \quad x(t) \in X \subset E_1, \quad u_i(t) \in U_i(x(t)) \subset F_i, \quad i = 1, 2, t \in [0, \infty)$$

where E_1 , E_2 , F_1 and F_2 are separable Hilbert spaces, $x^0 \in E_1$, σ is a closed, linear and densely defined operator on E_1 , γ is a linear operator (the boundary operator) with domain in E_1 and range in E_2 , and $B_i: F_i \rightarrow E_i$, $i = 1, 2$, are linear continuous operators.

The sets X and $U_i(x)$, $i = 1, 2$, $x \in X$, satisfy the assumptions (1.4)–(1.6).

A solution to the system (4.1)–(4.3) satisfies the following input–output relation

$$(4.5) \quad x(t) = S(t)x^0 + \int_0^t S(t-s)(B_1 u_1(s) + \sigma B u_2(s)) ds - A \int_0^t S(t-s) B u_2(s) ds$$

where the operators A , B and $S(\cdot)$ are defined in the assumptions below.

(A1) We assume that $\mathcal{D}(\sigma) \subset \mathcal{D}(\gamma)$ (here $\mathcal{D}(\cdot)$ denotes the domain), and that the restriction of γ to $\mathcal{D}(\sigma)$ is continuous w.r.t. the graph norm of $\mathcal{D}(\sigma)$.

(A2) The operator $A: \mathcal{D}(A) \subset E_1 \rightarrow E_1$, defined by

$$(4.6) \quad Ay = \sigma y,$$

$$(4.7) \quad y \in \mathcal{D}(A) \triangleq \{y \in \mathcal{D}(\sigma): \gamma y = 0\}$$

is the infinitesimal generator of a strongly continuous semigroup $\{S(t): t \geq 0\}$ on E_1 .

(A3) There exists a linear continuous operator $B: F_2 \rightarrow E_1$, such that

$$(4.8) \quad \sigma B \in \mathcal{L}(F_2, E_1),$$

$$(4.9) \quad \gamma(Bv) = B_2 v \quad \forall v \in F_2,$$

$$(4.10) \quad \|Bv\|_{E_1} \leq c \|B_2 v\|_{E_2} \quad \forall v \in F_2.$$

(A4) For each $t \geq 0$ and $v \in L^2_{\text{loc}}([0, \infty), F_2)$

$$(4.11) \quad \int_0^t S(t-s) B v(s) ds \in \mathcal{D}(A)$$

and there exists $\delta \in L^2_{\text{loc}}(0, \infty)$ such that

$$(4.12) \quad \|AS(t)B\| \leq \delta(t) \quad \text{a.e.},$$

$$(4.13) \quad \forall t \geq 0, \quad \forall h \in [0, 1] \quad \int_t^{t+h} \delta(s) ds \leq \mathcal{K}.$$

Under the above hypotheses, the expression (4.5) is well defined for $u_i(\cdot) \in L^2_{\text{loc}}([0, \infty), F_i)$, $i = 1, 2$, and agrees with the formulation presented in [5] by Barbu.

The performance of the system on any interval $[0, t]$, $t \geq 0$, is evaluated by the cost functional

$$(4.14) \quad x_0(t; u(\cdot), x(\cdot)) = \int_0^t f_0(x(s), u_1(s), u_2(s)) ds$$

where $f_0: E_1 \times F_1 \times F_2 \rightarrow \mathbb{R}$ is a convex lower semicontinuous functional, which satisfies the following coercivity assumption: there exist positive constants K_1 and K such that the following hold:

$$(4.15) \quad \|x\|^2 + \|u_1\|^2 + \|u_2\|^2 \geq K_1 \quad \text{implies} \quad \frac{f_0(x, u_1, u_2)}{\|x\|^2 + \|u_1\|^2 + \|u_2\|^2} \geq K.$$

The steady-state system corresponding to (4.1), (4.2) is defined by

$$(4.16) \quad 0 = \sigma x + B_1 u_1,$$

$$(4.17) \quad \gamma x = B_2 u_2.$$

Under (A2), (A3), this system can be rewritten as follows:

$$(4.18) \quad 0 = A(x - Bu_2) + B_1u_1 + \sigma Bu_2.$$

Assume the following.

Assumption 3. The optimal steady-state problem (OSSP) consisting of

$$\text{Min } f_0(x, u_1, u_2)$$

$$(4.19) \quad \text{s.t. } 0 = \langle x - Bu_2, A^*z \rangle + \langle B_1u_1 + \sigma Bu_2, z \rangle \quad \forall z \in \mathcal{D}(A^*),$$

$$(4.20) \quad x \in X, \quad u_2 \in U_1(x), \quad u_2 \in U_2(x)$$

has a unique solution $(\bar{x}, \bar{u}_1, \bar{u}_2)$.

THEOREM 5. Under Assumption 3 if $((u_1(\cdot), u_2(\cdot)), x(\cdot)) \in \mathcal{S}(x^0)$ is such that

$$(4.21) \quad \limsup_{T \rightarrow \infty} \int_0^T (f_0(x(t), u_1(t), u_2(t)) - f_0(\bar{x}, \bar{u}_1, \bar{u}_2)) dt < \infty,$$

then

$$(4.22) \quad \frac{1}{T} \int_0^T x(t) dt \xrightarrow{w} \bar{x} \quad \text{as } T \rightarrow \infty,$$

and

$$(4.23) \quad \frac{1}{T} \int_0^T u_i(t) dt \xrightarrow{w} \bar{u}_i, \quad i = 1, 2 \quad \text{as } T \rightarrow \infty.$$

Proof. Proceeding exactly as in Theorem 1, it is easy to show that any weak cluster point $(\tilde{x}, \tilde{u}_1, \tilde{u}_2)$ of the set

$$\left\{ \left(\frac{1}{T} \int_0^T x(t) dt, \frac{1}{T} \int_0^T u_1(t) dt, \frac{1}{T} \int_0^T u_2(t) dt \right) : T > 0 \right\}$$

satisfies

$$(4.24) \quad f_0(\tilde{x}, \tilde{u}_1, \tilde{u}_2) \leq f_0(\bar{x}, \bar{u}_1, \bar{u}_2).$$

It remains to show that $(\tilde{x}, \tilde{u}_1, \tilde{u}_2)$ satisfies (4.19). From (4.5) we may rewrite $x(t)$ as

$$(4.25) \quad x(t) = \alpha(t) + \beta(t) - A\eta(t)$$

where

$$(4.26) \quad \alpha(t) = S(t)x^0 + \int_0^t S(t-s)B_1u_1(s) ds,$$

$$(4.27) \quad \beta(t) = \int_0^t S(t-s)\sigma Bu_2(s) ds,$$

$$(4.28) \quad \eta(t) = \int_0^t S(t-s)Bu_2(s) ds.$$

The functions, $\alpha(\cdot)$, $\beta(\cdot)$, and $\eta(\cdot)$ are the mild solutions to the systems $\dot{\alpha}(t) = A\alpha(t) + B_1u_1(t)$, $\alpha(0) = x^0$; $\dot{\beta}(t) = A\beta(t) + \sigma Bu_2(t)$, $\beta(0) = 0$; $\dot{\eta}(t) = A\eta(t) + Bu_2(t)$, $\eta(0) = 0$, respectively. Hence for all $z \in \mathcal{D}(A^*)$

$$(4.29) \quad \langle \alpha(t), A^*z \rangle = \frac{d}{dt} \langle \alpha(t), z \rangle - \langle B_1u_1(t), z \rangle,$$

$$(4.30) \quad \langle\langle \beta(t), A^*z \rangle\rangle = \frac{d}{dt} \langle\langle \beta(t), z \rangle\rangle - \langle\langle \sigma B u_2(t), z \rangle\rangle.$$

Moreover, since $\eta(t) \in \mathcal{D}(A)$ by (A6), $\eta(\cdot)$ is a weak solution and so it satisfies

$$(4.31) \quad \langle\langle A\eta(t), y \rangle\rangle = \frac{d}{dt} \langle\langle \eta(t), y \rangle\rangle - \langle\langle B u_2(t), y \rangle\rangle \quad \forall y \in E.$$

Combining (2.14), (2.15), (2.16) gives, for all $z \in \mathcal{D}(A^*)$

$$(4.32) \quad \begin{aligned} \langle\langle x(t), A^*z \rangle\rangle &= \frac{d}{dt} \langle\langle \alpha(t) + \beta(t) - A\eta(t), z \rangle\rangle \\ &\quad - \langle\langle B_1 u_1(t), z \rangle\rangle - \langle\langle \sigma B u_2(t), z \rangle\rangle + \langle\langle B u_2(t), A^*z \rangle\rangle. \end{aligned}$$

Notice that we apply (4.31) with $y = A^*z$. Integrating (4.32) and using (4.25), we obtain

$$(4.33) \quad \begin{aligned} \frac{1}{T} \int_0^T \langle\langle x(t), A^*z \rangle\rangle dt &= \frac{1}{T} \langle\langle x(T) - x^0, z \rangle\rangle \\ &\quad - \frac{1}{T} \int_0^T \langle\langle B_1 u_1(t) + \sigma B u_2(t), z \rangle\rangle dt \\ &\quad + \frac{1}{T} \int_0^T \langle\langle B u_2(t), A^*z \rangle\rangle dt. \end{aligned}$$

Letting $T \rightarrow \infty$, we obtain (4.19) for any weak cluster point $(\tilde{x}, \tilde{u}_1, \tilde{u}_2)$, if $x(\cdot)$ is bounded. By taking account of (4.12) and (4.13) the proof of the boundedness of $x(\cdot)$ is a direct adaptation of the proof of Lemma 1. \square

Once again the convexity assumptions we have imposed allow us to define the nonnegative convex lower semicontinuous functional $L_0: E_1 \times F_1 \times F_2 \rightarrow \mathbb{R}$ by

$$(4.34) \quad L_0(x, u_1, u_2) = \begin{cases} f_0(x, u_1, u_2) - f_0(\bar{x}, \bar{u}_1, \bar{u}_2) - \langle\langle x - B u_2, A^* \bar{p} \rangle\rangle - \langle\langle B_1 u_1 + \sigma B u_2, \bar{p} \rangle\rangle \\ \quad \forall x \in X, \quad u_i \in U_i(x), \quad i = 1, 2, \\ +\infty \quad \text{otherwise} \end{cases}$$

where \bar{p} is a fixed element in $\mathcal{D}(A^*)$.

THEOREM 6. *Under Assumption 3, if G satisfies property \mathcal{C} then every pair $(u(\cdot), x(\cdot)) \in \mathcal{S}(x^0)$ which satisfies*

$$(4.35) \quad \int_0^\infty L_0(x(t), u_1(t), u_2(t)) dt < \infty$$

has the property that

$$(4.36) \quad x(t) \xrightarrow{w} \bar{x} \quad \text{as } t \rightarrow \infty.$$

Proof. The proof is identical to the proof of Theorem 2 in [2], with obvious modifications to account for the boundary control u_2 . \square

With these results it is now a routine task to obtain the desired existence results. The statements and the proofs of the existence theorems remain exactly the same as in § 3.

THEOREM 7. *If there exists $(\tilde{u}(\cdot), \tilde{x}(\cdot)) \in \mathcal{S}(x^0)$ such that (4.35) holds and if Assumption 3 holds then there exists a weakly overtaking optimal pair $((u_1^*(\cdot), u_2^*(\cdot)), x^*(\cdot))$.*

THEOREM 8. *If in addition to hypotheses of Theorem 7, the set G satisfies property \mathcal{C} , then there exists an overtaking optimal pair.*

5. Examples.

5.1. A regional economic growth model. The following model is a slight modification to a model proposed in [20, § 6.3].

$$(5.1) \quad \text{Min} \int_0^\infty \int_0^h f_0(C(t, y), K(t, y)) dy dt$$

$$(5.2) \quad \text{s.t.} \quad \frac{\partial}{\partial t} K(t, y) = I(t, y) + \alpha \frac{\partial^2}{\partial y^2} K(t, y) - \mu(y) K(t, y),$$

$$I(t, y) + C(t, y) \leq F(K(t, y)),$$

$$(5.3) \quad I(t, y) \geq 0, \quad C(t, y) \geq 0, \quad K(t, y) \geq 0,$$

$$\forall t \geq 0, \quad \forall y \in [0, h],$$

$$K(0, y) = K^0(y) \quad \text{given for } y \in [0, h],$$

$$(5.4) \quad \frac{\partial K}{\partial y}(t, 0) = \frac{\partial K}{\partial y}(t, h) = 0.$$

Here $K(t, y)$ represents the stock of capital in the economy at time t which is available at location y . The control variables $I(t, y)$ and $C(t, y)$ represent respectively the investment rate and consumption rate at time t , location y . $F(\cdot)$ is the production function, assumed to be concave and Lipschitz continuous, and $\mu(y)$ is the depreciation rate of capital at location y , assumed to be a continuous function of y . The boundary conditions represent the fact that all capital remains in the region $[0, h]$. The cost functional $f_0(C(t, y), K(t, y))$ is the negative of the utility derived from consumption and capitalization at (t, y) . We assume that f_0 is strictly convex, in C , decreasing and convex in K . The meaning of having K in the performance criterion could be related to, e.g., environmental costs associated with the presence of production equipments.

For a justification of the diffusion term in (4.14) we refer the reader to [20].

We now formulate this system in the framework considered here by introducing

$$E \triangleq L^2[0, h],$$

$$X \triangleq \{x \in E: x(y) \geq 0, x(y) \leq \tilde{K}\},$$

$$(5.5) \quad U(x) \triangleq \{u \in E \times E: u(y) = (I(y), C(y)) \geq 0, I(y) + C(y) \leq F(x(y))\},$$

$$A \triangleq \alpha \frac{\partial^2}{\partial y^2} - \mu(y) \quad \text{with} \quad \mathcal{D}(A) = \left\{ x \in E: \frac{\partial x}{\partial y}, \frac{\partial^2 x}{\partial y^2} \in E \text{ and } \frac{\partial x}{\partial y}(0) = \frac{\partial x}{\partial y}(h) = 0 \right\}.$$

The upper bound \tilde{K} for the state variable x which corresponds to the capital stock K is ensured by the classical Inada economic growth conditions (see [1]). This boundedness property is stronger than the coercivity condition (1.8). We intend to show that there exists an overtaking (or weakly overtaking) solution at any initial state $x_0 = K_0$

which is *strictly sustainable*, i.e., such that there exists a consumption function C_0 and an investment function I_0 such that, a.e. on $[0, h]$

$$\begin{aligned}
 (5.6) \quad & \frac{\partial^2 K_0(y)}{\partial y^2} - \mu K_0(y) + I_0(y) = 0, \\
 & I_0(y) + C_0(y) < F(K_0(y)), \\
 & I_0(y) > 0, \quad C_0(y) > 0, \\
 & \frac{\partial K}{\partial y}(0) = \frac{\partial K}{\partial y}(h) = 0.
 \end{aligned}$$

We shall establish the following properties: (i) the OSSP has a unique solution $(\bar{K}, \bar{C}, \bar{I})$, (ii) the steady state \bar{K} is asymptotically reachable from K_0 , and (iii) the set G has the Property \mathcal{C} if f_0 is also strictly convex in K . Properties (i) and (ii) imply the existence of a weakly overtaking solution at K_0 . Properties (i)–(iii) imply the existence of an overtaking solution of K_0 . (Theorems 3 and 4, respectively.)

(i) The OSSP is formulated as follows:

$$\begin{aligned}
 (5.7) \quad & \text{Min } \int_0^h f_0(K(y), C(y)) dy \\
 & \text{s.t. } \frac{\partial^2 K(y)}{\partial y^2} - \mu K(y) + I(y) = 0, \\
 & I(y) + C(y) \leq F(K(y)), \\
 & K(y) \geq 0, \quad I(y) \geq 0, \quad C(y) \geq 0, \\
 & \frac{\partial K}{\partial y}(0) = 0 = \frac{\partial K}{\partial y}(h).
 \end{aligned}$$

This is a standard optimal control problem for which there exists a solution (e.g. see Lee and Markus [27]). The strict convexity of f_0 w.r.t. C ensures the uniqueness of the optimal steady state consumption \bar{C} . Since f_0 is strictly decreasing in C , the output constraint is active at the optimum, and the optimal steady state solution satisfies

$$\begin{aligned}
 (5.8) \quad & \frac{\partial^2 \bar{K}(y)}{\partial y^2} - \mu \bar{K}(y) + F(\bar{K}(y)) - \bar{C}(y) = 0, \\
 & \bar{K}(y) \geq 0, \quad \bar{C}(y) \geq 0, \\
 & \frac{\partial \bar{K}}{\partial y}(0) = 0, \quad \frac{\partial \bar{K}}{\partial y}(h) = 0.
 \end{aligned}$$

Since F is Lipschitz, the uniqueness of \bar{C} implies the uniqueness of \bar{K} . This establishes that this system satisfies Assumption 1. The multiplier \bar{p} will be defined as the adjoint variable in the Pontryagin maximum principle for the control problem (5.7).

(ii) To establish the asymptotic reachability of \bar{K} from K_0 , let us consider, for a given $\alpha > 0$ the following function

$$(5.8) \quad \tilde{K}(t, y) = e^{-\alpha t} K_0(y) + (1 - e^{-\alpha t}) \bar{K}(y).$$

Let us also define the functions

$$(5.9) \quad \tilde{I}(t, y) = e^{-\alpha t} [I_0(y) - \alpha(K_0(y) - \bar{K}(y))] + (1 - e^{-\alpha t}) \bar{I}(y),$$

$$(5.10) \quad \tilde{C}(y, t) = e^{-\alpha t} [C_0(y) + \alpha(K_0(y) - \bar{K}(y))] + (1 - e^{-\alpha t}) \bar{C}(y).$$

If α is taken small enough, since K_0 is strictly sustainable (5.6), \tilde{I} and \tilde{C} remain nonnegative for all $t \geq 0$. Furthermore

$$(5.11) \quad \tilde{I}(t, y) + \tilde{C}(t, y) = e^{-\alpha t}(I_0(y) + C_0(y)) + (1 - e^{-\alpha t})(\bar{I}(y) + \bar{C}(y))$$

and, by the concavity of F ,

$$(5.12) \quad \tilde{I} + \tilde{C} \leq F(\tilde{K}).$$

It is straightforward to check that $(\tilde{K}, \tilde{I}, \tilde{C})$ constitute an admissible pair $(x, u) \in \mathcal{S}(x_0)$, which converges asymptotically toward \bar{K} .

Now let us consider the integral

$$(5.13) \quad J(T) = \int_0^T \int_0^h \{f_0(\tilde{C}(t, y), \tilde{K}(t, y)) - f_0(\bar{C}(y), \bar{K}(y))\} dy dt.$$

By the convexity of f_0 , we have

$$(5.14) \quad J(T) \leq \int_0^T \int_0^h e^{-\alpha t} [f_0(C_0(y) + \alpha(K_0(y) - \bar{K}(y)), K_0(y)) - f_0(\bar{C}(y), \bar{K}(y))] dy dt.$$

Clearly $J(T)$ remains bounded above when $T \rightarrow \infty$. This establishes Assumption 2.

Therefore Theorem 3 applies, and there exists a weakly overtaking optimal trajectory at K_0 .

(iii) Assume now that f_0 is also strictly convex in K . Then the set G reduces to the singleton $\{\bar{K}\}$ and, therefore, the Property \mathcal{C} is trivially verified. In that case, Theorem 4 guarantees the existence of an overtaking solution at K_0 .

5.2. The cattle ranching problem. This problem has been formulated in [13]. It concerns a cattle rancher who must decide the number of cattle in different age groups to be bought and sold at each instant in order to maximize his profit.

To conform to our notation we reformulate the problem as follows.

Let $x(t, y)$ denote the density of cattle of age y at time t , $y \in [0, h] \subset \mathbb{R}$. The cattle are slaughtered at age h . The control variable $u(t, y)$ is the number of y -aged cattle bought at time t ; when $u(t, y)$ is negative, that means a sale. The process is governed by the system:

$$(5.15) \quad \frac{\partial x}{\partial t} = -\frac{\partial x}{\partial y} + u,$$

$$(5.16) \quad x(0, y) = x^0(y)$$

where $x^0(\cdot): [0, h] \rightarrow \mathbb{R}$ is the given initial state which is assumed to satisfy

$$(5.17) \quad x^0(0) = 0.$$

The birth rate of the cattle at any time t is assumed to be 0, which means that the following boundary condition holds:

$$(5.18) \quad x(t, 0) = 0, \quad t \geq 0.$$

In addition, we assume the state constraints

$$(5.19) \quad 0 \leq x(t, y) \leq \alpha \quad \text{a.e. } t \geq 0 \quad \forall y \in [0, h]$$

for a given $\alpha > 0$ which represents the ranch capacity constraint. The control $u(t, y)$ is supposed to be nonnegative which means that no cattle is sold below the age of maturity.

$$(5.20) \quad 0 \leq u(t, y) \quad \text{a.e. } t \geq 0 \quad \forall y \in [0, h].$$

The objective function for the cattle rancher is given by

$$(5.21)$$

$$x_0(T; u(\cdot), x(\cdot)) = \int_0^T \left[\int_0^h \{P(y)u(t, y) + C(y)x(t, y) + D[u(t, y) - d(y)]^2\} dy - Qx(t, h) \right] dt$$

where $P(y)$ is the unit price of cattle of age y , $C(y)$ is the unit feeding cost of cattle of age y , Q is the selling price of mature cattle (of age h), and D is a positive constant associated with a quadratic cost for deviation of the control from a desired level $d(y)$.

To formulate (5.18)–(5.22) as a problem of type (1.1) we set

$$E = L^2(0, h) \quad \text{with usual norm,}$$

$$A = -\frac{\partial}{\partial y} \quad \text{with domain } \mathcal{D}(A) = H_0^1(0, h),$$

the Sobolev space of functions which are $L^2(0, h)$ with derivatives, in the sense of distributions, in $L^2(0, h)$, and vanish at $y = 0$ ([25]). The solution of (5.15) with (5.16) is given by

$$(5.22) \quad x(t, \tau) = \begin{cases} x_0(\tau - t) + \int_0^t u(s, \tau - t + s) ds & \text{if } 0 \leq t \leq \tau, \\ \int_0^\tau u(t - \tau + s, s) ds & \text{if } t \geq \tau. \end{cases}$$

Introduce

$$(5.23) \quad X \triangleq \{x: x \in L^2(0, h), x(0) = 0, 0 \leq x \leq \alpha\},$$

$$(5.24) \quad U(x) \triangleq U = \{u: u \in L^2(0, h), 0 \leq u(y)\},$$

$$(5.25) \quad g(x, u) = \int_0^h \{P(y)u(y) + C(y)x(y) + D(u(y) - d(y))^2\} dy,$$

$$(5.26) \quad f_0(x, u) = -Qx(h) + g_0(x, u).$$

It can be readily checked that X is closed and convex in E , $U(\cdot) \equiv U$ satisfies (1.4)–(1.7), and g_0 is convex and continuous if $P(\cdot)$, $C(\cdot)$ and $d(\cdot)$ are continuous. However, f_0 is not well defined over $L^2(0, h) \times L^2(0, h)$ because of the boundary term $Qx(h)$. Nevertheless, the theory still holds with minor modifications. We shall show that (i) the OSSP is well defined and admits a unique solution, (ii) there exists a functional L'_0 , slightly different from L_0 introduced in § 2, (iii) the reachability of the optimal steady state and the Property \mathcal{C} are guaranteed.

(i) The OSSP can be formulated as follows:

$$(5.27) \quad \text{Min} \left[-Qx(h) + \int_0^h \{C(\tau)x(\tau) + P(\tau)u(\tau) + D(u(\tau) - d(\tau))^2\} d\tau \right]$$

$$(5.28) \quad \text{s.t.} \quad \frac{dx(\tau)}{d\tau} = u(\tau),$$

$$(5.29) \quad x(0) = 0,$$

$$(5.30) \quad 0 \leq x(\tau) \leq \alpha,$$

$$(5.31) \quad 0 \leq u(\tau).$$

This problem is well defined since (5.28), (5.29) admits a continuous solution yielding

$$(5.32) \quad x(h) = x(0) + \int_0^h u(\tau) d\tau.$$

The convex optimal control problem (5.27)–(5.31) admits a unique solution which satisfies the maximum principle. Thus there exists an adjoint function

$$\bar{p}(\cdot) : [0, h] \rightarrow \mathbb{R}$$

such that

$$(5.33) \quad \frac{d\bar{p}(y)}{dy} = -C(y) \quad \text{a.e. on } [0, h],$$

$$(5.34) \quad \bar{p}(h) = -Q$$

and such $\bar{u}(y)$ maximizes the concave function

$$(5.35) \quad -u(\tau)[\bar{p}(\tau) + P(\tau) - 2Dd(\tau) + Du(\tau)]$$

s.t. $u(\tau) \geq 0$. Therefore the OSSP has a unique solution given by

$$\begin{aligned} \bar{p}(\tau) &= -Q + \int_{\tau}^h C(s) ds, \\ \bar{u}(\tau) &= \begin{cases} 0 & \text{if } \bar{p}(\tau) + P(\tau) - 2Dd(\tau) > 0, \\ \frac{1}{2D}(2Dd(\tau) - \bar{p}(\tau) - P(\tau)) & \text{otherwise,} \end{cases} \\ \bar{x}(\tau) &= \int_0^{\tau} \bar{u}(s) ds, \quad \tau \in [0, h]. \end{aligned}$$

(ii) Let us consider the functional

$$(5.36) \quad L'_0(x, u) = g_0(x, u) - f_0(\bar{x}, \bar{u}) + \langle \bar{p}', x \rangle + \langle \bar{p}, u \rangle$$

where $\bar{p}'(\tau)$ stands for $d\bar{p}(\tau)/d\tau$. If we assume that x is a $\mathcal{D}(A)$ then $L'_0(x, u)$ must be nonnegative, since $x(h)$ is well defined, and (5.33) reduces to the separation property for the OSSP. Since $\mathcal{D}(A)$ is dense in E , $L'_0(x, u)$ is nonnegative in $E \times F$. The existence theory of § 3 can then be developed with L'_0 replacing L_0 .

(iii) Let $\tilde{u}(t, y)$ be defined by

$$\tilde{u}(t, y) = \begin{cases} 0 & \text{if } t < h, \\ \bar{u}(y) & \text{if } t \geq h. \end{cases}$$

Then it is easy to check that the associated state trajectory satisfies $\tilde{x}(t, y) = \bar{x}(y)$ for $t > 2h$. We thus have reachability of the steady state in a finite time. Property \mathcal{C} is trivially verified for L'_0 . Therefore there exists an overtaking solution for any initial condition x_0 .

5.3. Example with boundary control. To illustrate the application of the above results concerning the boundary control problems we present the following simple example. This example is the infinite horizon analogue of the "Mixed Dirichlet Problem" considered in Barbu [5]. Specifically, we let $\Omega \subset \mathbb{R}^n$ be a bounded open set with smooth boundary Γ and we let X and U_2 denote fixed, closed bounded intervals of \mathbb{R} . The boundary-control system we consider is as follows:

$$\begin{aligned}
 (5.37) \quad & \frac{\partial x}{\partial t}(t, \tau) - \Delta_\tau x(t, \tau) = 0 \quad \text{for } (t, \tau) \in [0, \infty) \times \Omega, \\
 & x|_\Gamma = u_2 \quad \text{for } t \in [0, \infty), \\
 & x(0, \tau) = x^0(\tau) \quad \text{for } \tau \in \Omega, \\
 & x(t, \tau) \in X \quad \text{for } (t, \tau) \in [0, \infty) \times \Omega, \\
 & u_2(t, \tau) \in U_2 \quad \text{for } (t, \tau) \in [0, \infty) \times \Gamma.
 \end{aligned}$$

Following Barbu [5] we let $E_1 = F_1 = L^2(\Omega)$, $E_2 = H^{-1/2}(\Gamma)$ and $F_2 = L^2(\Gamma)$. Further, we define the operators $B_i: E_i \rightarrow F_i$, $i = 1, 2$, by $B_1 \triangleq 0$, $B_2 \triangleq I$ and we define $\sigma: \mathcal{D}(\sigma) \rightarrow E_1$ as $\sigma = \Delta_\tau$, $\mathcal{D}(\sigma) = \{x \in L^2(\Omega): \Delta x \in L^2(\Omega)\}$. We define the operator $\gamma: E_1 \rightarrow E_2$ as the "trace" operator $\gamma_0 y$ which is well defined and belongs to $H^{-1/2}(\Gamma)$ for each $y \in \mathcal{D}(\sigma)$. Finally, we take $A: \mathcal{D}(A) \rightarrow E_1$ to be $A = \Delta$, $\mathcal{D}(A) = H_0^1(\Omega) \cap H^2(\Omega)$, and we define the linear operator $B: F_2 \rightarrow F_1$ by $Bu = w_u$, where $w_u \in L^2(\Omega)$ is the unique solution (generalized) to the Dirichlet boundary-value problem

$$\Delta w_u = 0 \quad \text{in } \Omega, \quad w_u|_\Gamma = u.$$

With this notation it follows, exactly as in [5], that the hypotheses (A1)–(A4) are satisfied. Further, since X and U_2 are compact intervals the Assumptions 1 and 2 are trivially met.

To describe the performance of the system on any interval $[0, t]$ we let $g: \Omega \times \mathbb{R} \rightarrow \mathbb{R}$ and $h_0: U_2 \rightarrow \mathbb{R}$ be two given functions satisfying the following conditions:

(i) g is continuous and convex in x , measurable in τ , and satisfies the growth condition

$$|g(\tau, x)| \leq c|x|^2 + \zeta(\tau) \quad \text{a.e. in } \Omega \times \mathbb{R}$$

where $c > 0$ is constant and $\zeta \in L^2(\Omega)$.

(ii) h_0 is convex and lower semicontinuous.

With these functions we define $f_0: E_1 \times F_2 \rightarrow \mathbb{R}$ by

$$f_0(x, u_2) = \int_\Omega g(\tau, x(\tau)) \, d\tau + \int_\Gamma h(u_2(\sigma)) \, d\sigma.$$

This function is seen to be lower semicontinuous (see [5]). To summarize, the optimal control problem we consider consists of "minimizing" the integral

$$\int_0^{+\infty} f_0(x(t), u_2(t)) \, dt$$

over all pairs of functions $(u_2(\cdot), x(\cdot))$ in $L^2_{\text{loc}}([0, \infty); L_2(\Gamma)) \times C([0, \infty); L_2(\Omega))$ satisfying the relations (1.5) and (1.4) (with the obvious modifications to account for the absence of the distributed control u_1).

The optimal steady-state problem consists of minimizing

$$f_0(x, u_2)$$

over all $(u_2, x) \in L_2(\Gamma) \times L_2(\Omega)$ satisfying the Dirichlet boundary-value problem

$$\begin{aligned}\Delta_\tau x(\tau) &= 0 \quad \text{in } \Omega, \\ x|_\Gamma &= u_2\end{aligned}$$

as well as the constraints

$$x(\tau) \in X \quad \text{and} \quad u_2(\tau) \in U_2.$$

For $u_2 \in L^2(\Omega)$, the Dirichlet boundary-value problem above has a unique generalized solution $\bar{x} \in L^2(\Omega)$. Therefore, if the interval X is taken sufficiently large there exists feasible pairs (\bar{u}_2, \bar{x}) and so the optimal steady-state problem will have solutions. To assert uniqueness we need only require strict convexity of f_0 .

Consequently, the existence results of § 4 are applicable if one can show there exists a feasible pair (\tilde{u}_2, \tilde{x}) satisfying

$$\int_0^{+\infty} L_0(x(t), u_2(t)) dt < \infty$$

where L_0 is given as in (2.19). To this end, take $\tilde{u}_2(t) = \tilde{u}$ a.e. and $\tilde{x}(\cdot)$ the corresponding trajectory emanating from x_0 . Since (\bar{u}_2, \bar{x}) is a steady state pair, it satisfies (5.3) with $x^0(\tau) = \bar{x}(\tau)$ and $u_2(t, \tau) = \bar{u}_2(\tau)$. Hence the difference $(\tilde{x}(t) - \bar{x})$ satisfies (5.3) with $u_2 \equiv 0$ and x_0 replaced by $x_0 - \bar{x}$ and then

$$\tilde{x}(t) - \bar{x} = S(t)(x_0 - \bar{x}).$$

Since the semigroup generated by Δ_τ is exponentially stable we have

$$\|\tilde{x}(t) - \bar{x}\| \leq M e^{-\mu t}$$

where M at μ are positive constants.

If the cost function g is quadratic, i.e.,

$$g(\tau, x(\tau)) = c(\tau)\|x(\tau)\|^2 + g(\tau),$$

then the exponential stability implies Assumption 2, therefore there exists an overtaking solution at any x_0 .

For more formulations of the function g , checking Assumption 2 would require more specific computations.

6. Conclusions. The results presented here extend the existence theory for overtaking optimal solutions of infinite horizon optimal control problems given in Brock and Haurie [8] to the case where the state dynamics are described by a mild solution of a linear control system on a Hilbert space. These results permit us to consider both distributed and boundary control problems, and their applicability is demonstrated by the examples given in § 5. In addition our work incorporates the recent advances to the theory given in Leizarowitz [24] which eliminate the compactness of the state constraint set, X , as well as the uniqueness of the optimal steady state. The compactness of X is removed by assuming that the cost integrand satisfies the coercivity relation (1.8) and the uniqueness of the optimal steady state is removed by assuming that the

set G (given in (2.7)) enjoys the convergence property \mathcal{C} . The set G utilized in [24] differs from ours. In our notation, the set G of [24] is a subset of $\mathcal{D}(A) \times E$ and is defined by

$$G = \{(x, z): \exists u \in U(x) \text{ such that } L_0(x, u) = 0 \text{ and } z = Ax + Bu\}.$$

In our setting $G \subset E$. Further, in [24] the convergence property \mathcal{C} is shown to hold if the differential inclusion

$$\dot{x}(t) \in \{z \in E: (x(t), z) \in G\}$$

has no “elliptic solutions” (see [24, Thm. 5.2]). Moreover the nonexistence of elliptic solutions is a generic property (see [24, Thm. 7.1]). At present it is not known if a similar result holds in the setting considered here. Further, as we consider only mild solutions of the control system, the arguments given in [24] clearly cannot be extended directly. Hence the question requires further investigation.

In closing, we mention that another direction for research would be the introduction of nonlinearities into the control system. From our remarks in the Introduction it is evident that as the development of distributed parameter economic models progresses, there will be a need to consider such problems.

7. Proof of Lemma 1. Let $(\tilde{u}, \tilde{x}) \in \mathcal{S}(x_0)$ be as indicated in Lemma 1. We first show that for each $T > 0$, there exists a constant $C(T) > 0$ such that

$$(2.4) \quad \int_t^{T+t} \|\tilde{u}(s)\|^2 ds < C(T).$$

To do this we proceed by contradiction and suppose there exists $T > 0$ and a sequence $\{t_k\}_{k=1}^\infty$ with $t_k \rightarrow \infty$ as $k \rightarrow \infty$ such that

$$\lim_{k \rightarrow \infty} \int_{t_k}^{t_k+T} \|\tilde{u}(s)\|^2 ds = +\infty.$$

For each index, k , we let $\Omega_k = \{t \in [t_k, t_k + T]: \|\tilde{u}(t)\|^2 \geq K_2\}$, where K_2 is as given in the growth condition (1.8) (with f_0 replaced by L_0) and let $\Omega'_k = [t_k, t_k + T] \setminus \Omega_k$. With this notation we observe that for each $k = 1, 2, \dots$,

$$\int_{\Omega_k} \|\tilde{u}(t)\|^2 dt \leq K_2 \text{ measure } (\Omega'_k) \leq K_2 T.$$

This implies that

$$\lim_{k \rightarrow \infty} \int_{\Omega_k} \|\tilde{u}(t)\|^2 dt = +\infty,$$

and so from the growth condition (1.8) and the nonnegativeness of L_0 , we arrive at

$$\begin{aligned} +\infty &= \lim_{k \rightarrow \infty} \int_{\Omega_k} \|\tilde{u}(t)\|^2 dt \\ &\leq \lim_{k \rightarrow \infty} \int_{\Omega_k} L_0(\tilde{x}(s), \tilde{u}(s)) ds \\ &\leq \int_0^{+\infty} L_0(\tilde{x}(s), \tilde{u}(s)) ds \\ &< +\infty, \end{aligned}$$

an obvious contradiction of (2.3). Hence the conclusion (2.4) holds.

We now show that $\|\tilde{x}(t)\|$ is bounded for all $t \geq 0$. To this end, we define for each $T > 0$, the set

$$\Omega_T = \{t \geq T: \|\tilde{x}(t)\|^2 > K_2\}$$

where K_2 is as indicated above. As a result of the growth condition (1.8), the nonnegativeness of L_0 , and the integrability condition (2.3) we have

$$\begin{aligned} 0 \leq \text{measure}(\Omega_T) &\leq \frac{1}{K_2} \int_{\Omega_T} \|\tilde{x}(t)\|^2 dt \\ &\leq \frac{1}{K_2} \int_{\Omega_T} L_0(\tilde{x}(t), \tilde{u}(t)) dt \\ &\leq \frac{1}{K_2} \int_T^\infty L_0(\tilde{x}(t), \tilde{u}(t)) dt, \end{aligned}$$

which implies

$$\lim_{T \rightarrow \infty} [\text{measure}(\Omega_T)] = 0.$$

Therefore, we can choose $T > 1$ sufficiently large so that

$$\text{measure}(\Omega_T) < \frac{1}{2}.$$

We now observe that since the map $t \rightarrow \|\tilde{x}(t)\|$ is continuous on $[0, T]$, there exists a constant $A_1 > 0$ so that

$$\|\tilde{x}(t)\| \leq A_1 \quad \text{on } [0, T].$$

Further, for $t \in [T, \infty) \setminus \Omega_T$ we have

$$\|\tilde{x}(t)\| \leq \sqrt{K_2}.$$

Hence the desired result follows if we can show $\|\tilde{x}(t)\|$ is bounded on Ω_T . To see this we observe that, since $\text{measure}(\Omega_T) < \frac{1}{2}$, for each $t \in \Omega_T$, there exists $h \in [0, 1]$ so that $t+h \notin \Omega_T$. Indeed if no such h exists, the interval $[t-h, t] \subset \Omega_T$ implying $\text{measure}(\Omega_T) > 1$. By appealing to the variation of constants formula (1.1) with $\sigma = t-h$ we obtain

$$\begin{aligned} \|\tilde{x}(t)\| &= \|\tilde{x}(\sigma+h)\| \\ &= \left\| S(\sigma+h)x_0 + \int_0^{\sigma+h} S(\sigma+h-s)B\tilde{u}(s) ds \right\| \\ &= \left\| S(h) \left[S(\sigma)x_0 + \int_0^\sigma S(\sigma-s)B\tilde{u}(s) ds \right] + \int_\sigma^{\sigma+h} S(\sigma+h-s)B\tilde{u}(s) ds \right\| \\ &= \left\| S(h)\tilde{x}(\sigma) + \int_\sigma^{\sigma+h} S(\sigma+h-s)B\tilde{u}(s) ds \right\|. \end{aligned}$$

Since $\{S(t): t \geq 0\}$ is a strongly continuous semigroup, there exists $C_1 > 0$ such that $\|S(t)\| \leq C_1$ for all $t \geq 0$. Hence, by the triangle inequality,

$$\begin{aligned} \|\tilde{x}(t)\| &\leq C_1 \|\tilde{x}(\sigma)\| + C_1 \|B\| \int_\sigma^{\sigma+h} \|\tilde{u}(s)\| ds \\ &\leq C_1 \|\tilde{x}(\sigma)\| + C_1 \|B\| \int_\sigma^{\sigma+1} \|\tilde{u}(s)\| ds \\ &\leq C_1 \|\tilde{x}(\sigma)\| + C_1 \|B\| \left(\int_\sigma^{\sigma+1} \|\tilde{u}(s)\|^2 ds \right)^{1/2} \end{aligned}$$

where the last inequality follows from the Hölder Inequality.

From the first part of our proof (with $T = 1$) there exists a constant $C = C(1) > 0$ such that for all $\sigma > 0$

$$\int_{\sigma}^{\sigma+1} \|\tilde{u}(s)\|^2 ds \leq C(1).$$

Therefore we obtain, with $C_2 = C_1 \|B\| \sqrt{C(1)}$,

$$\begin{aligned} \|\tilde{x}(t)\| &\leq C_1 \|\tilde{x}(\sigma)\| + C_2 \\ &= C_1 \|\tilde{x}(t-h)\| + C_2 \\ &\leq C_1 \max \{A_1, \sqrt{K_2}\} + C_2 \end{aligned}$$

for all $t \in \Omega_T$, and so the desired result follows.

SENSITIVITY ANALYSIS OF CONTROL CONSTRAINED OPTIMAL CONTROL PROBLEMS FOR DISTRIBUTED PARAMETER SYSTEMS*

JAN SOKOŁOWSKI†

Abstract. The differential stability of solutions to control constrained quadratic optimal control problems for distributed parameter systems is investigated in this paper. The form of the right-derivatives of optimal controls for such problems with respect to the real parameter is derived. The differential sensitivity of optimal controls with respect to the perturbations of the coefficients of the state equation as well as to the deformations of the domain of integration is considered. The right-derivative of an optimal control with respect to the parameter is obtained in the form of an optimal control to the auxiliary control constrained optimal control problem.

Key words. distributed parameter system, sensitivity analysis, right-derivative of optimal control, Euler derivative, Lagrange derivative, shape sensitivity analysis

AMS(MOS) subject classification. 49B22

1. Introduction. This paper is devoted to the sensitivity analysis of a class of optimal control problems for distributed parameter systems. Sufficient conditions for the directional differentiability of an optimal control with respect to the parameter for an abstract quadratic control constrained optimal control problem are presented. The conditions are verified for a class of optimal control problems provided the related metric projection onto the set of admissible controls is directionally differentiable. The differentiable stability of solutions to convex, constrained optimal control problems is investigated by Malanowski [5] for a system of ordinary differential equations. The same method of the proof is used by Malanowski and Sokołowski [6] for the sensitivity analysis of a control problem for a system of elliptic equations.

Our approach is based on results of the sensitivity analysis of solutions to abstract variational inequalities and on differential stability of the metric projection onto the set of admissible controls. We refer the reader to Sokołowski [10], for related results on the sensitivity analysis of the convex, constrained optimization problems.

Since in many applications the functional parameters of a model for a distributed parameter system are not known exactly, the presented results on the sensitivity analysis can be used to compute increments of the optimal control corresponding to increments of the functional parameters of the model. Some related numerical results for an optimal control problem arising from air quality control are presented in [15]. On the other hand the results on the shape sensitivity analysis of an optimal control problem can be used for the optimal design of the distributed parameter systems. We refer the reader to [16] for related results on the shape sensitivity analysis of boundary optimal control problems for parabolic systems.

In this article we investigate the local sensitivity of optimal controls for two different examples. In § 3, a boundary optimal control problem for a system described by a parabolic equation is considered. The local sensitivity of an optimal control with respect to the perturbations of the boundary conditions is examined.

In § 4, a distributed control problem for the Laplace equation is taken under consideration. The local sensitivity of an optimal control with respect to the deformations of the domain of integration is investigated. The existence of the so-called Euler (material) derivative of an optimal control in the direction of a vector field is shown. Furthermore, the form of the so-called Lagrange derivative of an optimal control is derived.

We refer the reader to Haraux [2] and Mignot [7] for abstract results on differential stability of solutions to variational inequalities. Applications of some abstract results of this type to the shape sensitivity analysis of elliptic free boundary problems are given by Sokołowski and Zolesio [11]–[13]. A compilation of results on sensitivity analysis in nonlinear programming is presented in Fiacco [1].

The outline of this paper is as follows. Section 2 describes the results obtained for an abstract optimal control problem. In § 3 the sensitivity analysis of a boundary optimal control problem of a parabolic initial-boundary problem is presented. Section 4 describes the results obtained for the shape sensitivity of a distributed optimal control problem for the Laplace equation. Standard notation [4] is used throughout this paper.

2. Sensitivity analysis of an optimal control problem. Our object is to determine the form of right derivative of an optimal control problem to the abstract optimal control problem (P^ε) defined in § 2.1 with respect to the parameter ε at $\varepsilon = 0$. Let u^ε denote a unique optimal solution to problem (P^ε) , $\varepsilon \in [0, \delta)$, $\delta > 0$. We prove the existence and uniqueness of an element q , the so-called sensitivity coefficient for the problem (P^0) , such that for $\varepsilon > 0$, ε small enough

$$(2.1) \quad u^\varepsilon = u^0 + \varepsilon q + o(\varepsilon).$$

2.1. Optimal control problem. We shall use the following notation. Let U, Y, W, H be Hilbert spaces. We identify U with its dual U' and we denote by $\Lambda \in \mathcal{L}(H, H')$ the canonical isomorphism. Let there be given linear, continuous mappings $L^\varepsilon \in \mathcal{L}(Y, W)$, $B^\varepsilon \in \mathcal{L}(U, W)$, $C^\varepsilon \in \mathcal{L}(Y, H)$, $N^\varepsilon \in \mathcal{L}(U, U)$, $\varepsilon \in [0, \delta)$ and elements $z^\varepsilon \in H$, $v^\varepsilon \in U$, $\varepsilon \in [0, \delta)$. We assume that there exists the inverse mapping

$$(2.2) \quad (L^\varepsilon)^{-1} \in \mathcal{L}(W, Y) \quad \forall \varepsilon \in [0, \delta)$$

and denote

$$(2.3) \quad S^\varepsilon = C^\varepsilon (L^\varepsilon)^{-1} B^\varepsilon \in \mathcal{L}(U, H),$$

$$(2.4) \quad A^\varepsilon = (S^\varepsilon)^* \Lambda S^\varepsilon + N^\varepsilon \in \mathcal{L}(U, U)$$

where $(S^\varepsilon)^* \in \mathcal{L}(H', U)$ denotes the adjoint mapping.

Let $N^\varepsilon \in \mathcal{L}(U, U)$ be a selfadjoint mapping for all $\varepsilon \in [0, \delta)$ such that $N^0 = NI$. I denotes identity mapping in U . We assume that there exists a constant $\varepsilon > 0$ such that

$$(2.5) \quad (N^\varepsilon v, v)_U \geq \alpha \|v\|_U^2 \quad \forall v \in U, \quad \forall \varepsilon \in [0, \delta).$$

Let us denote by U_{ad} the set of admissible controls. We assume that $U_{\text{ad}} \subset U$ is a closed and convex subset.

We shall consider an optimal control problem for the system described by the state equation of the form

$$(2.6) \quad L^\varepsilon y^\varepsilon(v) = B^\varepsilon v + \eta^\varepsilon, \quad \forall v \in U, \quad \forall \varepsilon \in [0, \delta)$$

where $\eta^\varepsilon \in W$, $\varepsilon \in [0, \delta]$ are given elements. We assume in the sequel that $\eta^\varepsilon = 0$, for all $\varepsilon \in [0, \delta)$.

Let us consider the following optimal control problem.

Problem (P^ε). Find an element $u^\varepsilon \in U_{\text{ad}}$ which minimizes the cost functional

$$(2.7) \quad J^\varepsilon(v) = \frac{1}{2} \|C^\varepsilon y^\varepsilon(v) - z^\varepsilon\|_H^2 + \frac{1}{2} (N^\varepsilon(v - v^\varepsilon), v - v^\varepsilon)_U$$

over the set U_{ad} .

It can be verified [3] that under our assumptions for a fixed parameter $\varepsilon \in [0, \delta)$, there exists a unique element $u^\varepsilon \in U_{\text{ad}}$ such that

$$(2.8) \quad J^\varepsilon(u^\varepsilon) \leq J^\varepsilon(v) \quad \forall v \in U_{\text{ad}}, \quad \forall \varepsilon \in [0, \delta).$$

It can be shown that the element u^ε is given by a unique solution of the following variational inequality:

$$(2.9) \quad \begin{aligned} u^\varepsilon &\in U_{\text{ad}}, \\ a^\varepsilon(u^\varepsilon, v - u^\varepsilon) &\geq (f^\varepsilon, v - u^\varepsilon)_U \quad \forall v \in U_{\text{ad}} \end{aligned}$$

where the bilinear form $a^\varepsilon(\cdot, \cdot): U \times U \rightarrow \mathbb{R}$ and the element $f^\varepsilon \in U$ are defined as given below:

$$(2.10) \quad a^\varepsilon(u, v) = (A^\varepsilon u, v)_U \quad \forall u, v \in U,$$

$$(2.11) \quad f^\varepsilon = (S^\varepsilon)^* \Lambda z^\varepsilon + N^\varepsilon v^\varepsilon.$$

Let us consider the variational inequality (2.9) for $\varepsilon = 0$. We denote by $\Pi: U \rightarrow U$ the mapping defined as follows:

For any $f \in U$ the element Πf is given by a unique solution of the variational inequality

$$(2.12) \quad \begin{aligned} \Pi f &\in U_{\text{ad}}, \\ a^0(\Pi f, v - \Pi f) &\geq (f, v - \Pi f)_U \quad \forall v \in U_{\text{ad}}. \end{aligned}$$

It can be proved that the element $\Pi f \in U$ minimizes the cost functional

$$(2.13) \quad I(v) = \frac{1}{2} \|S^0 v\|_H^2 + N \|v - f\|_U^2$$

over the set U_{ad} . Furthermore, $u^0 = \Pi f^0$. In order to derive the form of the sensitivity coefficient q in (2.1) we assume that there exists a continuous and positively homogeneous mapping

$$(2.14) \quad \Pi': U \rightarrow U$$

such that for $\tau > 0$, τ small enough

$$(2.15) \quad \forall v \in U: \Pi(f^0 + \tau v) = \Pi(f^0) + \tau \Pi'(v) + o(\tau) \quad \text{in } U$$

where $\|o(\tau)\|_U / \tau \rightarrow 0$ with $\tau \downarrow 0$.

Remark 1. In some cases the assumption (2.15) can be verified [10] using the related results [2], [7], [9] on the differential stability of the metric projection in space U onto the convex set U_{ad} . The explicit form of the mapping Π' is derived in Sokołowski [10] for the particular case of the so-called polyhedral set U_{ad} . We present an example of the polyhedral set U_{ad} in § 3.

THEOREM 1. Assume that condition (2.15) is verified; furthermore assume that for $\varepsilon > 0$, ε small enough,

$$(2.16) \quad A^\varepsilon = A^0 + \varepsilon A_1 + R_\varepsilon \quad \text{in } \mathcal{L}(U, U),$$

$$(2.17) \quad f^\varepsilon = f^0 + \varepsilon f_1 + r_\varepsilon \quad \text{in } U$$

where $A_1, R_\varepsilon \in \mathcal{L}(U, U)$, $f_1, r_\varepsilon \in U$ are given elements for $\varepsilon \in [0, \delta)$ such that $\|R_\varepsilon\|_{\mathcal{L}(U, U)}/\varepsilon \rightarrow 0$, $\|r_\varepsilon\|_U/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$. Then for $\varepsilon > 0$, ε small enough

$$(2.18) \quad u^\varepsilon = u^0 + \varepsilon \Pi'(f_1 - A_1 u^0) + o(\varepsilon) \quad \text{in } U$$

where $\|o(\varepsilon)\|_U/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$.

Proof. It can be proved that by (2.9), (2.16), (2.17) there exists a constant $C < +\infty$ such that

$$(2.19) \quad \|u^\varepsilon - u^0\|_U \leq C\varepsilon \quad \forall \varepsilon \in [0, \delta).$$

From (2.9), (2.16), (2.17), taking into account (2.19) we obtain

$$(2.20) \quad u^\varepsilon = \Pi(f^0 + \varepsilon(f_1 - A_1 u^0) + r(\varepsilon))$$

where $\|r(\varepsilon)\|_U/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$.

On the other hand, there exists a constant C_1 such that

$$(2.21) \quad \|\Pi(f_1) - \Pi(f_2)\|_U \leq C_1 \|f_1 - f_2\|_U \quad \forall f_1, f_2 \in U.$$

Hence

$$(2.22) \quad \Pi(f^0 + \varepsilon(f_1 - A_1 u^0) + r(\varepsilon)) = \Pi(f^0 + \varepsilon(f_1 - A_1 u^0)) + o(\varepsilon)$$

where $\|o(\varepsilon)\|_U/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$. We can conclude from (2.15), (2.20), (2.22) that

$$(2.23) \quad \begin{aligned} u^\varepsilon &= \Pi(f^0 + \varepsilon(f_1 - A_1 u^0)) + o(\varepsilon) \\ &= \Pi(f^0) + \varepsilon \Pi(f_1 - A_1 u^0) + o(\varepsilon) \\ &= u^0 + \varepsilon \Pi'(f_1 - A_1 u^0) + o(\varepsilon) \end{aligned}$$

which completes the proof.

Remark 2. Let us assume that for $\varepsilon \in [0, \delta)$:

$$(2.24) \quad N^\varepsilon = NI + \varepsilon N_1 + r_1(\varepsilon), \quad N_1, r_1(\varepsilon) \in \mathcal{L}(U, U),$$

$$(2.25) \quad S^\varepsilon = S^0 + \varepsilon S_1 + r_2(\varepsilon), \quad S_1, r_2(s) \in \mathcal{L}(U, H),$$

$$(2.26) \quad z^\varepsilon = z^0 + \varepsilon z_1 + r_3(\varepsilon), \quad z_1, r_3(\varepsilon) \in H,$$

$$(2.27) \quad v^\varepsilon = v^0 + \varepsilon v_1 + r_4(\varepsilon), \quad v_1, r_4(\varepsilon) \in U$$

where $r_i(\varepsilon)/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$ for $i = 1, \dots, 4$ in norms of spaces $\mathcal{L}(U, U)$, $\mathcal{L}(U, H)$, H , U , respectively.

It can be shown that (2.24)–(2.27) imply (2.16), (2.17). In this case the element $f_1 \in U$ and the mapping $A_1 \in \mathcal{L}(U, U)$ are defined as follows:

$$(2.28) \quad f_1 = (S^0)^* \Lambda z_1 + S_1^* \Lambda z_0 + N v_1 + N_1 v^0,$$

$$(2.29) \quad A_1 = S_1^* \Lambda S^0 + (S^0)^* \Lambda S_1 + N_1.$$

Remark 3. Theorem 1 is presented in a different setting in [9], [11], [12].

3. Sensitivity analysis of boundary optimal control problems. This section is devoted to the sensitivity analysis of a boundary optimal control problem (P^ε) for a parabolic equation. The functional coefficient $c_\varepsilon(\cdot, \cdot)$ in the mixed boundary conditions depends on the parameter $\varepsilon \in [0, \delta)$. We prove that the optimal control u^ε is right differentiable with respect to the parameter ε . Furthermore, the sensitivity coefficient q for the problem (P^0) is given by a unique solution of an auxiliary optimal control problem (Q) .

3.1. Parabolic equation. Let $\Omega \subset R^n$ be a given bounded domain with smooth boundary $\Gamma = \partial\Omega$. We denote $Q = \Omega \times (0, t_1)$, $\Sigma = \Gamma \times (0, t_1)$ where $t_1 > 0$ is a given constant. We shall use the following notation [7] for functional spaces:

$$(3.1) \quad U = H = L^2(\Sigma),$$

$$(3.2) \quad W = L^2(0, t_1; (H^1(\Omega))'),$$

$$(3.3) \quad Y = W(0, t_1) = \left\{ \phi \in L^2(0, t_1; H^1(\Omega)) \left| \frac{\partial \phi}{\partial t} \in L^2(0, t_1; (H^1(\Omega))') \right. \right\}.$$

We assume that there are given elements $c_0(\cdot, \cdot)$, $c_1(\cdot, \cdot)$, $r_\varepsilon(\cdot, \cdot) \in L^\infty(\Sigma)$, $\varepsilon \in [0, \delta)$ such that $c_0(x, t) \geq c > 0$ for a.e. $(x, t) \in \Sigma$, $\|r_\varepsilon\|_{L^\infty(\Sigma)}/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$.

We denote

$$(3.4) \quad c_\varepsilon(x, t) = c_0(x, t) + \varepsilon c_1(x, t) + r_\varepsilon(x, t), \quad (x, t) \in \Sigma.$$

Let $v \in L^2(\Sigma)$ be a given control. The state $y^\varepsilon(v) \in W(0, t_1)$ is given by a unique weak solution of the following parabolic equation:

$$(3.5) \quad \frac{\partial y}{\partial t}(v; x, t) - \Delta y^\varepsilon(v; x, t) = 0 \quad \text{in } Q,$$

$$(3.6) \quad \frac{\partial y}{\partial n}(v; x, t) + c_\varepsilon(x, t)y^\varepsilon(v; x, t) = v(x, t) \quad \text{on } \Sigma,$$

$$(3.7) \quad y^\varepsilon(v; x, 0) = 0 \quad \text{on } \Omega.$$

It can be shown [4] that $y^\varepsilon(v; \cdot, \cdot) \in H^{3/2, 3/4}(Q)$ therefore the trace $y^\varepsilon(v)|_\Sigma \in L^2(\Sigma)$ is well defined, hence a bounded linear mapping

$$(3.8) \quad S_\varepsilon : L^2(\Sigma) \ni v \rightarrow y^\varepsilon(v)|_\Sigma \in L^2(\Sigma)$$

is defined for all $\varepsilon \in [0, \delta)$. It can be verified [4] that the mapping (3.8) is compact and selfadjoint for every $\varepsilon \in [0, \delta)$. Furthermore, for $\varepsilon > 0$, ε small enough

$$(3.9) \quad S_\varepsilon = S_0 + \varepsilon S_1 + R_\varepsilon \quad \text{in } \mathcal{L}(L^2(\Sigma), L^2(\Sigma))$$

where $\|R_\varepsilon\|_{\mathcal{L}(L^2(\Sigma), L^2(\Sigma))}/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$. The linear, compact, selfadjoint mapping S_1 is defined as follows:

$$(3.10) \quad S_1 v = \overset{\text{def}}{z(v)}|_\Sigma \quad \forall v \in L^2(\Sigma)$$

where the element $z(v) \in W(0, t_1)$ is given by a unique weak solution of the parabolic equation

$$(3.11) \quad \frac{\partial z}{\partial t}(v; x, t) - \Delta z(v; x, t) = 0 \quad \text{in } Q,$$

$$(3.12) \quad \frac{\partial z}{\partial n}(v; x, t) + c_0(x, t)z(v; x, t) = -c_1(x, t)y^0(v; x, t) \quad \text{on } \Sigma,$$

$$(3.13) \quad z(v; x, 0) = 0 \quad \text{on } \Omega.$$

In this example the mapping (2.4) is defined by

$$(3.14) \quad A^\varepsilon = S_\varepsilon S_\varepsilon + NI \in \mathcal{L}(L^2(\Sigma), L^2(\Sigma))$$

where $N > 0$ is a given constant.

3.2. Boundary optimal control problem. Let us consider the following optimal control problem.

Problem (P^ε). Find an element $u^\varepsilon \in L^2(\Sigma)$ which minimizes the cost functional

$$(3.15) \quad I_\varepsilon(v) = \frac{1}{2} \|S_\varepsilon v - z_d\|_{L^2(\Sigma)}^2 + \frac{N}{2} \|v\|_{L^2(\Sigma)}^2$$

over the set of admissible controls of the form

$$(3.16) \quad U_{\text{ad}} = \{v \in L^2(\Sigma) | 0 \leq v(x, t) \leq M \text{ for a.e. } (x, t) \in \Sigma\}$$

where $M > 0$ is a given constant and $z_d \in L^2(\Sigma)$ is a given element.

A unique optimal control u^ε is given [8] by a unique solution of the following optimality system.

Find elements $(u^\varepsilon, y^\varepsilon, p^\varepsilon) \in U_{\text{ad}} \times W(0, t_1) \times W(0, t_1)$ which satisfy the following system:

State equation.

$$(3.17) \quad \begin{aligned} \frac{\partial y^\varepsilon}{\partial t}(u^\varepsilon; x, t) - \Delta y^\varepsilon(u^\varepsilon; x, t) &= 0 \quad \text{in } Q, \\ \frac{\partial y^\varepsilon}{\partial n}(u^\varepsilon; x, t) + c_\varepsilon(x, t)y^\varepsilon(u^\varepsilon; x, t) &= u^\varepsilon(x, t) \quad \text{on } \Sigma, \\ y^\varepsilon(u^\varepsilon; x, 0) &= 0 \quad \text{on } \Omega. \end{aligned}$$

Adjoint-state equation.

$$(3.18) \quad \begin{aligned} -\frac{\partial p^\varepsilon}{\partial t}(x, t) - \Delta p^\varepsilon(x, t) &= 0 \quad \text{in } Q, \\ \frac{\partial p^\varepsilon}{\partial n}(x, t) + c_\varepsilon(x, t)p^\varepsilon(x, t) &= y^\varepsilon(u^\varepsilon; x, t) - z_d(x, t) \quad \text{on } \Sigma, \\ p^\varepsilon(x, t_1) &= 0 \quad \text{on } \Omega. \end{aligned}$$

Optimality condition.

$$(3.19) \quad \int_{\Sigma} (Nu^\varepsilon(x, t) + p^\varepsilon(x, t))(v(x, t) - u^\varepsilon(x, t)) \, d\Sigma \geq 0 \quad \forall v \in U_{\text{ad}}.$$

The optimality condition (3.19) can be represented in the equivalent form

$$(3.20) \quad u^\varepsilon = P_{U_{\text{ad}}} \left(-\frac{1}{N} p^\varepsilon \right)$$

where for any element $f \in L^2(\Sigma)$ its metric projection $P_{U_{\text{ad}}}f$ in space $L^2(\Sigma)$ onto the set U_{ad} is given by a unique solution of the following variational inequality:

$$P_{U_{\text{ad}}}f \in U_{\text{ad}},$$

$$(3.21) \quad \int_{\Sigma} \{((P_{U_{\text{ad}}}f)(x, t) - f(x, t))(v(x, t) - (P_{U_{\text{ad}}}f)(x, t))\} \, d\Sigma \geq 0 \quad \forall v \in U_{\text{ad}}.$$

3.3. Sensitivity analysis. We derive the form of the sensitivity coefficient $q \in L^2(\Sigma)$ for the problem (P^0).

We will use the following notation:

$$(3.22) \quad \eta = S_1 z_1 - (S_0 S_1 + S_1 S_0) u^0, \quad \eta \in L^2(\Sigma),$$

$$(3.23) \quad \chi = \frac{1}{N} S_0 (z_d - S_0 u^0), \quad \chi \in L^2(\Sigma).$$

Furthermore, by $K(\Sigma) \subset L^2(\Sigma)$ we denote the closed, convex cone of the following form:

$$(3.24) \quad K(\Sigma) = \left\{ v \in L^2(\Sigma) \mid v(x, t) \geq 0 \text{ a.e. on } \Xi_0, v(x, t) \leq 0 \text{ a.e. on } \Xi_M, \right. \\ \left. \int_{\Xi_0 \cup \Xi_M} \chi(x, t) v(x, t) d\Sigma = 0 \right\}$$

where

$$(3.25) \quad \Xi_0 = \{(x, t) \in \Sigma \mid u^0(x, t) = 0\},$$

$$(3.26) \quad \Xi_M = \{(x, t) \in \Sigma \mid u^0(x, t) = M\}.$$

THEOREM 2. *There exists a unique sensitivity coefficient $q \in L^2(\Sigma)$ for the problem (P^0) , i.e., for $\varepsilon > 0$, ε small enough*

$$(3.27) \quad u^\varepsilon = u^0 + \varepsilon q + o(\varepsilon) \quad \text{in } L^2(\Sigma)$$

where $\|o(\varepsilon)\|_{L^2(\Sigma)}/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$.

The element q is given by a unique solution of the following optimal control problem.

Problem (Q). Find an element $q \in L^2(\Sigma)$ which minimizes the cost functional

$$(3.28) \quad I(v) = \frac{1}{2} \|S_0 v\|_{L^2(\Sigma)}^2 + \frac{N}{2} \left\| v - \frac{1}{N} \eta \right\|_{L^2(\Sigma)}^2$$

over the cone $K(\Sigma) \subset L^2(\Sigma)$.

Proof. We shall apply Theorem 1. To do this we must verify all assumptions of this theorem.

Since in our case $A^\varepsilon = S_\varepsilon S_\varepsilon + NI$ it follows from (3.9) that (2.16) holds with $A_1 = S_0 S_1 + S_1 S_0$. Since $f^\varepsilon = S_\varepsilon z_d$, it follows that (2.17) holds with $f_1 = S_1 z_d$.

Let us verify condition (2.15). For a given function $f \in L^2(\Sigma)$, the corresponding element $\Pi f \in L^2(\Sigma)$ minimizes the cost functional

$$(3.29) \quad I(v) = \frac{1}{2} \|S_0 v\|_{L^2(\Sigma)}^2 + \frac{N}{2} \left\| v - \frac{1}{N} f \right\|_{L^2(\Sigma)}^2$$

over the set (3.16).

It can be shown that there exists a constant $C < +\infty$ such that

$$(3.30) \quad \|\Pi(f^0 + \tau h) - \Pi f^0\|_{L^2(\Sigma)} \leq C\tau \|h\|_{L^2(\Sigma)}.$$

From (3.30) it follows that there exists an element $\Pi' \in L^2(\Sigma)$ such that for a subsequence still denoted $\tau \downarrow 0$

$$(3.31) \quad \Pi(f^0 + \tau h) = \Pi f^0 + \tau \Pi' + r(\tau) \quad \text{in } L^2(\Sigma)$$

where $r(\tau)/\tau \rightarrow 0$ weakly in $L^2(\Sigma)$ with $\tau \downarrow 0$. It can be shown [3] that for $\tau > 0$, τ small enough

$$(3.32) \quad P_{U_{ad}}(\chi + \tau v) = P_{U_{ad}}(\chi) + \tau P_{K(\Sigma)}(v) + o(\tau) \quad \text{in } L^2(\Sigma) \quad \forall v \in L^2(\Sigma)$$

where $\|o(\tau)\|_{L^2(\Sigma)}/\tau \rightarrow 0$ with $\tau \downarrow 0$.

Let us denote $r_1(\tau) = S_0 S_0 r(\tau)$, then we have $\|r_1(\tau)\|_{L^2(\Sigma)}/\tau \rightarrow 0$ with $\tau \downarrow 0$ since $S_0 \in \mathcal{L}(L^2(\Sigma), L^2(\Sigma))$ is compact.

Observe that

$$\begin{aligned} \Pi(f^0 + \tau h) &= P_{U_{ad}}\left(\frac{1}{N}(f^0 + \tau h - S_0 S_0 \Pi(f^0 + \tau h))\right) \\ (3.33) \quad &= P_{U_{ad}}\left(\frac{1}{N}(f^0 - S_0 S_0 u^0) + \frac{\tau}{N}(h - S_0 S_0 \Pi') + r_1(\tau)\right) \\ &= P_{U_{ad}}(\chi) + \tau P_{K(\Sigma)}\left(\frac{1}{N}(h - S_0 S_0 \Pi')\right) + o(\tau). \end{aligned}$$

From (3.31), (3.33) it follows that

$$(3.34) \quad \Pi' = P_{K(\Sigma)}\left(\frac{1}{N}(h - S_0 S_0 \Pi')\right),$$

i.e., $\Pi' = \Pi'(h)$ minimizes the cost functional

$$(3.35) \quad I(v) = \frac{1}{2} \|S_0 v\|_{L^2(\Sigma)}^2 + \frac{N}{2} \left\| v - \frac{1}{N} h \right\|_{L^2(\Sigma)}^2$$

over the set $K(\Sigma)$.

Denote $\eta = f_1 - A_1 u^0$ then by Theorem 1 we obtain $q = \Pi'(\eta)$.

4. Shape sensitivity analysis. This section is devoted to the sensitivity analysis of an optimal control problem (P_ε) for the Laplace equation defined in a domain $\Omega_\varepsilon \subset \mathbb{R}^n$. In this case the domain of integration depends on the parameter $\varepsilon \in [0, \delta)$.

We recall briefly [14] how to construct a family of domains $\{\Omega_\varepsilon\} \subset \mathbb{R}^n$, $\varepsilon \in [0, \delta)$, depending on a given vector field $V(\cdot, \cdot)$. We prove that an optimal control u_ε to problem (P_ε) is right differentiable with respect to the parameter ε .

The sensitivity coefficient for problem (P^0) is obtained in the form of an optimal control for the auxiliary optimal control problem.

4.1. Family of domains $\{\Omega_\varepsilon\}$. We define a family of domains $\{\Omega_\varepsilon\} \subset \mathbb{R}^n$ depending on the parameter $\varepsilon \in [0, \delta)$. Let $\Omega \subset \mathbb{R}^n$ be a given domain with a smooth boundary $\Gamma = \partial\Omega$. Let us assume that there is given a vector field $V(\cdot, \cdot) \in C^1([0, \delta_0]; C^2(\mathbb{R}^n, \mathbb{R}^n))$. We denote by $T_\varepsilon = T_\varepsilon(V)$ the mapping

$$(4.1) \quad T_\varepsilon(V): \mathbb{R}^n \ni X \rightarrow x(\varepsilon, X) \in \mathbb{R}^n$$

where the vector function $x(t) = x(t, X)$, $t \in [0, \delta)$, $X \in \mathbb{R}^n$, is given by the solution of the ordinary differential equation:

$$\begin{aligned} (4.2) \quad &\frac{d}{dt} x(t) = V(t, x(t)), \quad t \in (0, \delta), \\ &x(0) = X. \end{aligned}$$

The mapping (4.1) is defined for $\varepsilon \in [0, \delta)$, $\delta < \delta_0$. We denote by $DT_\varepsilon(X)$, $DT_\varepsilon^{-1}(X)$, ${}^*DT_\varepsilon^{-1}(X)$ the Jacobian matrix of the mapping (4.1) evaluated at point $X \in \Omega$, inverse

of matrix $DT_\varepsilon(X)$ and transposed matrix $DT_\varepsilon^{-1}(X)$, respectively. We denote by Ω_ε the domain of the form

$$(4.3) \quad \Omega_\varepsilon = \{x \in R^n \mid \exists X \in \Omega \text{ such that } x = x(\varepsilon, X)\}, \text{ i.e., } \Omega_\varepsilon = T_\varepsilon(V)(\Omega).$$

We will consider the Laplace equation defined in the domain Ω_ε

$$(4.4) \quad \begin{aligned} -\Delta y_\varepsilon(v_\varepsilon; x) &= v_\varepsilon(x) \quad \text{in } \Omega_\varepsilon, \\ y_\varepsilon(x) &= 0 \quad \text{on } \partial\Omega_\varepsilon \end{aligned}$$

where $v_\varepsilon \in L^2(\Omega_\varepsilon)$ is a given element. The solution to (4.4) is uniquely determined and belongs to $H_0^1(\Omega_\varepsilon) \cap H^2(\Omega_\varepsilon)$. Hence a bounded, selfadjoint, compact linear mapping

$$(4.5) \quad F_\varepsilon : L^2(\Omega_\varepsilon) \ni v_\varepsilon \rightarrow y_\varepsilon(v_\varepsilon) \in L^2(\Omega_\varepsilon)$$

is defined for any $\varepsilon \in [0, \delta)$.

4.2. Optimal control problem. Let $z_d \in H^1(R^n)$ be a given element. We denote $z_\varepsilon = z_d|_{\Omega_\varepsilon} \in H^1(\Omega_\varepsilon)$.

Let us consider the following optimal control problem.

Problem (P_ε) . Find an element $u_\varepsilon \in L^2(\Omega_\varepsilon)$ which minimizes the cost functional

$$(4.6) \quad J_\varepsilon(v_\varepsilon) = \frac{1}{2} \|F_\varepsilon v_\varepsilon - z_\varepsilon\|_{L^2(\Omega_\varepsilon)}^2 + \frac{N}{2} \|v_\varepsilon\|_{L^2(\Omega_\varepsilon)}^2$$

over the set of admissible controls

$$(4.7) \quad U_{\text{ad}}^\varepsilon = \{v_\varepsilon \in L^2(\Omega_\varepsilon) \mid 0 \leq v_\varepsilon(x) \leq M \text{ a.e. on } \Omega_\varepsilon\}$$

where $M > 0$ is a given constant.

It can be shown that an optimal control u_ε for the problem (P_ε) is given by a unique solution of the following optimality system:

$$(4.8) \quad \begin{aligned} -\Delta y_\varepsilon &= u_\varepsilon \quad \text{in } \Omega_\varepsilon, & y_\varepsilon &= 0 \quad \text{on } \partial\Omega_\varepsilon, \\ -\Delta p_\varepsilon &= y_\varepsilon - z_\varepsilon \quad \text{in } \Omega_\varepsilon, & p_\varepsilon &= 0 \quad \text{on } \partial\Omega_\varepsilon, \\ u_\varepsilon &\in U_{\text{ad}}^\varepsilon: \int_{\Omega_\varepsilon} (Nu_\varepsilon + p_\varepsilon)(v_\varepsilon - u_\varepsilon) dx \geq 0 \quad \forall v_\varepsilon \in U_{\text{ad}}^\varepsilon, \end{aligned}$$

hence the optimal control takes the following form:

$$(4.9) \quad u_\varepsilon(x) = \max \left\{ 0, \min \left\{ -\frac{1}{N} p_\varepsilon(x), M \right\} \right\}, \quad x \in \Omega_\varepsilon$$

since $p_\varepsilon \in H_0^1(\Omega_\varepsilon)$ from (4.9), it follows that

$$(4.10) \quad u_\varepsilon \in H_0^1(\Omega_\varepsilon) \quad \forall \varepsilon \in [0, \delta).$$

We denote by $\tilde{u}_\varepsilon \in H_0^1(R^n)$ an extension of the function $u_\varepsilon \in H_0^1(\Omega_\varepsilon)$:

$$(4.11) \quad \tilde{u}_\varepsilon(x) = \begin{cases} u_\varepsilon(x), & x \in \Omega_\varepsilon, \\ 0, & x \in R^n \setminus \Omega_\varepsilon, \end{cases} \quad \begin{matrix} \varepsilon \in [0, \delta), \\ \varepsilon \in [0, \delta). \end{matrix}$$

4.3. Sensitivity analysis. We will prove that the function $\tilde{u}_\varepsilon|_\Omega \in L^2(\Omega)$ is right differentiable with respect to the parameter ε at $\varepsilon = 0$. This means that there exists the so-called Lagrange derivative $u'(\Omega)$ of the optimal control u_ε in the direction of a vector field $V(\cdot, \cdot)$.

We will use the following notation. Let us consider the system of two coupled Laplace equations:

$$(4.12) \quad \begin{aligned} -\Delta y &= 0 \quad \text{in } \Omega, & y &= v_n \frac{\partial z}{\partial n} \quad \text{on } \partial\Omega, \\ -\Delta z &= \phi \quad \text{in } \Omega, & z &= 0 \quad \text{on } \partial\Omega \end{aligned}$$

where $\phi \in L^2(\Omega)$ is a given function, $n(x)$, $x \in \partial\Omega$ denotes the unit outward normal vector on $\partial\Omega$ and $v_n(x) = \langle V(0, x), n(x) \rangle_{R^n}$, $x \in \partial\Omega$ is the normal component of the vector field on $\partial\Omega$. The solution (y, z) to (4.12) is uniquely determined and belongs to $H^1(\Omega) \times (H_0^1(\Omega) \cap H^2(\Omega))$ hence a linear, selfadjoint, compact mapping

$$(4.13) \quad F_1 : L^2(\Omega) \ni \phi \rightarrow y(\phi) \in L^2(\Omega)$$

is defined.

We denote by $\eta, \chi \in L^2(\Omega)$ the elements:

$$(4.14) \quad \chi = \frac{1}{N} F_0(z_d - F_0 u_0),$$

$$(4.15) \quad \eta = F_1 z_d - (F_1 F_0 + F_0 F_1) u_0.$$

Furthermore we denote by $K(\Omega)$ the cone

$$(4.16) \quad K(\Omega) = \left\{ \phi \in L^2(\Omega) \left| \begin{aligned} &\phi(x) \geq 0 \text{ a.e. on } \Xi_0, \phi(x) \leq 0 \text{ a.e. on } \Xi_M, \\ &\int_{\Xi_0 \cup \Xi_M} \chi(x) \phi(x) dx = 0 \end{aligned} \right. \right\}.$$

THEOREM 3. *There exists a unique element $u'(\Omega) \in L^2(\Omega)$ such that for $\varepsilon > 0$, ε small enough:*

$$(4.17) \quad \tilde{u}_\varepsilon|_\Omega = u_0 + \varepsilon u'(\Omega) + o(\varepsilon) \quad \text{in } L^2(\Omega)$$

where $\|o(\varepsilon)\|_{L^2(\Omega)}/\varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$.

The Lagrange derivative $u'(\Omega)$ is given by a unique solution of the following optimal control problem.

Problem (P'). Find an element $u'(\Omega) \in L^2(\Omega)$ which minimizes the cost functional

$$(4.18) \quad I(v) = \frac{1}{2} \|F_0 v\|_{L^2(\Omega)}^2 + \frac{N}{2} \left\| v - \frac{1}{N} \eta \right\|_{L^2(\Omega)}^2$$

over the cone $K(\Omega) \subset L^2(\Omega)$.

Proof. The proof is divided into three parts.

Step 1. We apply Theorem 1 in order to prove that there exists a unique element $\dot{u}(\Omega) \in L^2(\Omega)$ such that

$$(4.19) \quad \lim_{\varepsilon \downarrow 0} \|(u_\varepsilon \circ T_\varepsilon - u_0)/\varepsilon - \dot{u}(\Omega)\|_{L^2(\Omega)} = 0.$$

The element $\dot{u}(\Omega)$ denotes the Euler (material) derivative of an optimal control u_ε in the direction of a vector field $V(\cdot, \cdot)$.

Step 2. Taking into account the relationship between the Lagrange derivative and the Euler derivative [14]:

$$(4.20) \quad u'(\Omega) = \dot{u}(\Omega) - \langle \text{grad } u_0, V(0) \rangle_{R^n}$$

we derive the form of the Lagrange derivative $u'(\Omega)$.

Step 3. We prove that the domain derivative $u'(\Omega)$ minimizes the cost functional (4.18) over the cone $K(\Omega)$.

Step 1. Euler Derivative $\dot{u}(\Omega)$. We define an optimal control problem (P^ε) such that a unique optimal control u^ε for this problem takes the form

$$(4.21) \quad u^\varepsilon = u_\varepsilon \circ T_\varepsilon \quad \forall \varepsilon \in [0, \delta).$$

To this end we transport the state equation (4.4), the cost functional (4.6) and the set of admissible controls (4.7) from the domain Ω_ε to the fixed domain Ω using the mapping (4.1). We obtain the state equation in the form of the following elliptic boundary-value problem

$$(4.22) \quad \begin{aligned} -\text{div}(B^\varepsilon(x) \cdot \text{grad } y^\varepsilon(v; x)) &= b^\varepsilon(x)v(x) \quad \text{in } \Omega, \\ y^\varepsilon(v; x) &= 0 \quad \text{on } \partial\Omega \end{aligned}$$

where $v \in L^2(\Omega)$ is a given element, $B^\varepsilon = \det(DT_\varepsilon)^* DT_\varepsilon^{-1}$. DT_ε^{-1} is a matrix function and $b^\varepsilon = \det(DT_\varepsilon)$, $\varepsilon \in [0, \delta)$.

The solution $y^\varepsilon(v)$ of the problem (4.21) is uniquely determined and belongs to $H_0^1(\Omega) \cap H^2(\Omega)$. Hence a compact, selfadjoint linear mapping

$$(4.23) \quad F^\varepsilon : L^2(\Omega) \ni v \rightarrow y^\varepsilon(v) \in L^2(\Omega)$$

is defined.

It can be shown that [14]

$$(4.24) \quad F^\varepsilon = F_0 + \varepsilon F' + R_\varepsilon \quad \text{in } \mathcal{L}(L^2(\Omega), L^2(\Omega))$$

where the mapping F_0 is defined by (4.5) for $\varepsilon = 0$, the mapping F' is defined below and $\|R_\varepsilon\|_{\mathcal{L}(L^2(\Omega), L^2(\Omega))} / \varepsilon \rightarrow 0$ with $\varepsilon \downarrow 0$. The mapping $F' \in \mathcal{L}(L^2(\Omega), L^2(\Omega))$ is defined in the following way:

For any element $\phi \in L^2(\Omega)$, the element $w = F'\phi$ is given by a unique solution of the following boundary value problem:

$$-\Delta w(x) = \text{div } V(0, x)\phi(x) + \text{div}(B'(x) \cdot \text{grad } z(x)) \quad \text{in } \Omega, \quad w(x) = 0 \quad \text{on } \partial\Omega.$$

Here $z = F_0\phi \in H_0^1(\Omega) \cap H^2(\Omega)$, and

$$B'(x) = \lim_{\varepsilon \downarrow 0} (B^\varepsilon(x) - B^0(x)) / \varepsilon = \text{div } V(0, x)I - *DV(0, x) - DV(0, x), \quad x \in \Omega.$$

$DV(0, x)$ is the Jacobian matrix of $V(0, x)$, $x \in \Omega$.

We define the cost functional $J^\varepsilon(v)$, $v \in L^2(\Omega)$ of the form

$$(4.25) \quad J^\varepsilon(v) = \frac{1}{2}(b^\varepsilon(F^\varepsilon v - z^\varepsilon), F^\varepsilon v - z^\varepsilon)_{L^2(\Omega)} + \frac{N}{2}(b^\varepsilon v, v)_{L^2(\Omega)}.$$

Here $z^\varepsilon = z_d \circ T_\varepsilon \in H^1(\Omega)$, and the set of admissible controls

$$(4.26) \quad U_{\text{ad}} = \{v \in L^2(\Omega) \mid 0 \leq v(x) \leq M \text{ a.e. on } \Omega\}.$$

Let us consider the optimal control problem.

Problem (P^ε) . Find an element $u^\varepsilon \in L^2(\Omega)$ which minimizes the cost functional (4.25) over the set (4.26).

It can be verified that a unique optimal control u^ε for the problem (P^ε) takes the form (4.21). Let us verify the assumptions of Theorem 1 in the case of problem (P^ε) . In this case $U = H = W = L^2(\Omega)$, $Y = H_0^1(\Omega) \cap H^2(\Omega)$, the mapping $A^\varepsilon \in \mathcal{L}(L^2(\Omega), L^2(\Omega))$ and the element $f^\varepsilon \in L^2(\Omega)$ are given by

$$(4.27) \quad A^\varepsilon = F^\varepsilon b^\varepsilon F^\varepsilon + N b^\varepsilon,$$

$$(4.28) \quad f^\varepsilon = F^\varepsilon b^\varepsilon z^\varepsilon.$$

It can be shown [14] that

$$(4.29) \quad b^\varepsilon = 1 + \varepsilon \operatorname{div} (V(0)) + o(\varepsilon) \quad \text{in } L^\infty(\Omega),$$

$$(4.30) \quad z^\varepsilon = z_d + \varepsilon \langle \operatorname{grad} z_d, V(0) \rangle_{R^n} + o(\varepsilon) \quad \text{in } L^2(\Omega),$$

therefore, by (4.24) and (4.27)–(4.30) it follows that the assumptions (2.16), (2.17) are satisfied, and we have

$$(4.31) \quad A_1 = F'F_0 + F_0F' + F_0\beta F_0 + N\beta,$$

$$(4.32) \quad f_1 = F'z_d + F_0\beta z_d + F_0 \langle \operatorname{grad} z_d, V(0) \rangle_{R^n}.$$

Here $\beta = \operatorname{div} (V(0))$, $V(0) = V(0, \cdot)$.

Finally, assumption (2.15) can be verified using exactly the same argument as in the proof of Theorem 2. The element $\Pi'(h)$ is a unique minimizer of the cost functional

$$(4.33) \quad I(v) = \frac{1}{2} \|F_0 v\|_{L^2(\Omega)}^2 + \frac{N}{2} \left\| v - \frac{1}{N} h \right\|_{L^2(\Omega)}^2$$

over the cone $K(\Omega)$ defined by (4.16), for any $h \in L^2(\Omega)$. Since all assumptions of Theorem 1 are verified, from (2.18) it follows that

$$(4.34) \quad \begin{aligned} \dot{u}(\Omega) = \Pi'(f_1 - A_1 u_0) = \Pi'(F'z_d + F_0\beta z_d + F_0 \langle \operatorname{grad} z_d, V(0) \rangle_{R^n} \\ + (F'F_0 + F_0F' + F_0\beta F_0 + N\beta)u_0). \end{aligned}$$

Step 2. Lagrange Derivative $u'(\Omega)$. From (4.20), (4.34) we obtain

$$(4.35) \quad \begin{aligned} u'(\Omega) = \Pi'(F'z_d + F_0\beta z_d + F_0 \langle \operatorname{grad} z_d, V(0) \rangle_{R^n} \\ + (F'F_0 + F_0F' + F_0\beta F_0 + N\beta)u_0) - \langle \operatorname{grad} u_0, V(0) \rangle_{R^n} \end{aligned}$$

and

$$(4.36) \quad u'(\Omega) \in K_v(\Omega) = \{\phi \in L^2(\Omega) \mid \exists \psi \in K(\Omega) \text{ such that } \phi = \psi - \langle \operatorname{grad} u_0, V(0) \rangle_{R^n}\}.$$

Observe that $\operatorname{grad} u_0(x) = 0$ a.e. $\Xi_0 \cup \Xi_M$ hence $K_v(\Omega) = K(\Omega)$ for any vector field V whence

$$(4.37) \quad u'(\Omega) \in K(\Omega).$$

From (4.35), (4.37) it follows that the Lagrange derivative $u'(\Omega) \in L^2(\Omega)$ is a unique minimizer of the cost functional

$$(4.38) \quad \begin{aligned} I_1(v) = \frac{1}{2} \|F_0 v + F_0 \langle \operatorname{grad} u_0, V(0) \rangle_{R^n}\|_{L^2(\Omega)}^2 \\ + \frac{N}{2} \left\| v + \langle \operatorname{grad} u_0, V(0) \rangle_{R^n} \right. \\ \left. - \frac{1}{N} ((F'F_0 + F_0F' + F_0\beta F_0 + N\beta)u_0 \right. \\ \left. + F'z_d + F_0\beta z_d + F_0 \langle \operatorname{grad} z_d, V(0) \rangle_{R^n}) \right\|_{L^2(\Omega)} \end{aligned}$$

over the cone $K(\Omega)$.

Therefore the Lagrange derivative is given by a unique solution of the following variational inequality:

$$(4.39) \quad \begin{aligned} u'(\Omega) &\in K(\Omega), \\ a_0(u'(\Omega), \phi - u'(\Omega)) &\geq G(u_0, V(0), \phi - u'(\Omega)) \quad \forall \phi \in K(\Omega) \end{aligned}$$

where

$$(4.40) \quad a_0(u, \phi) = (F_0 u, F_0 \phi)_{L^2(\Omega)} + N(u, \phi)_{L^2(\Omega)} \quad \forall u, \phi \in L^2(\Omega),$$

$$(4.41) \quad \begin{aligned} G(u_0, V(0), \phi) &= (f_1, \phi)_{L^2(\Omega)} - a_0(\langle \text{grad } u_0, V(0) \rangle_{R^n}, \phi) \\ &\quad - (A_1 u_0, \phi)_{L^2(\Omega)} \quad \forall \phi \in \{K(\Omega) - K(\Omega)\}. \end{aligned}$$

Step 3. We must prove that

$$(4.42) \quad G(u_0, V(0), \phi) = (\eta, \phi)_{L^2(\Omega)} \quad \forall \phi \in \{K(\Omega) - K(\Omega)\}.$$

We will use the same argument as in [13]. It can be shown [14] that for any vector field $V(\cdot, \cdot) \in C^1([0, \delta]; C^2(R^n, R^n))$ such that

$$(4.43) \quad v_n \stackrel{\text{def}}{=} \langle V(0), n \rangle_{R^n} = 0 \quad \text{on } \partial\Omega$$

we have $u'(\Omega) = 0$. Since the mapping

$$C^2(R^n, R^n) \ni V(0) \rightarrow G(u_0, V(0), \phi) \in R$$

is linear for all $\phi \in \{K(\Omega) - K(\Omega)\}$ it implies that $G(u_0, V(0), \phi) = 0$ for every $\phi \in \{K(\Omega) - K(\Omega)\}$ for any vector field $V(0)$ which satisfies (4.42). Hence there exists the distribution $g_n(\phi) \in \mathcal{D}'_1(\partial\Omega)$ such that

$$(4.44) \quad G(u_0, V(0), \phi) = \langle g_n(\phi), v_n \rangle_{\mathcal{D}'_1(\partial\Omega) \times \mathcal{D}_1(\partial\Omega)} \quad \forall \phi \in \{K(\Omega) - K(\Omega)\}.$$

From (4.41) by integration by parts, taking into account (4.43) we obtain (4.42) in the following way.

In what follows in view of (4.44), we neglect terms of the form

$$\int_{\Omega} \langle V(0, x), R(x) \rangle_{R^n} dx$$

where $R(\cdot) \in L^2(\Omega; R^n)$ is a given element. For example, we write

$$\begin{aligned} \int_{\Omega} \xi(x) \operatorname{div} V(0, x) dx &= - \int_{\Omega} \langle V(0, x), \operatorname{grad} \xi(x) \rangle_{R^n} dx + \int_{\partial\Omega} v_n(x) \xi(x) dx \\ &= \int_{\partial\Omega} v_n(x) \xi(x) dx + \dots \quad \text{for any } \xi \in H^1(\Omega) \\ &= 0 + \dots \quad \text{for any } \xi \in H^1_0(\Omega). \end{aligned}$$

Let us consider subsequently all terms in (4.41).

(i) For the first term

$$(f_1, \phi)_{L^2(\Omega)} = (F' z_d, \phi)_{L^2(\Omega)} + (F_0 \beta z_d, \phi)_{L^2(\Omega)} + (F_0 \langle \operatorname{grad} z_d, V(0) \rangle_{R^n}, \phi)_{L^2(\Omega)}$$

we have

$$\begin{aligned} (F' z_d, \phi)_{L^2(\Omega)} &= (F_1 z_d, \phi)_{L^2(\Omega)} + \dots, \\ (F_0 \beta z_d, \phi)_{L^2(\Omega)} &= 0 + \dots, \\ (F_0 \langle \operatorname{grad} z_d, V(0) \rangle_{R^n}, \phi)_{L^2(\Omega)} &= 0 + \dots, \end{aligned}$$

therefore,

$$(f_1, \phi) = (F_1 z_d, \phi)_{L^2(\Omega)} + \dots$$

(ii) For the second term

$$\begin{aligned} -a_0(\langle \text{grad } u_0, V(0) \rangle_{R^n}, \phi) &= -(F_0(\langle \text{grad } u_0, V(0) \rangle_{R^n}), F_0 \phi)_{L^2(\Omega)} \\ &\quad - (\langle \text{grad } u_0, V(0) \rangle_{R^n}, \phi)_{L^2(\Omega)} \\ &= -(\langle \text{grad } u_0, V(0) \rangle_{R^n}, (F_0 F_0 + N) \phi)_{L^2(\Omega)} \\ &= 0 + \dots \end{aligned}$$

(iii) For the third term

$$-(A_1 u_0, \phi)_{L^2(\Omega)} = ((F' F_0 + F_0 F' + F_0 \beta F_0 + N \beta) u_0, \phi)_{L^2(\Omega)}$$

we have

$$\begin{aligned} (F' F_0 u_0, \phi)_{L^2(\Omega)} &= (F_1 F_0, \phi)_{L^2(\Omega)} + \dots, \\ (F_0 F' u_0, \phi)_{L^2(\Omega)} &= (F_0 F_1 u_0, \phi)_{L^2(\Omega)} + \dots, \\ (F_0 \beta F_0 u_0, \phi)_{L^2(\Omega)} &= (\beta F_0 y_0, F_0 \phi)_{L^2(\Omega)} \\ &= \int_{\Omega} \text{div } V(0, x) (F_0 u_0)(x) (F_0 \phi)(x) \, dx = 0 + \dots \end{aligned}$$

since $F_0 u_0, F_0 \phi \in H_0^1(\Omega)$.

Let us recall that by (4.10) it follows that $u_0 \in H_0^1(\Omega)$. Hence

$$\begin{aligned} (N \beta u_0, \phi)_{L^2(\Omega)} &= N \int_{\Omega} \text{div } V(0, x) u_0(x) \phi(x) \, dx \\ &= -N \int_{\Omega} \langle V(0, x), \text{grad } (u_0(x) \phi(x)) \rangle_{R^n} \, dx \\ &= 0 + \dots \quad \forall \phi \in H_0^1(\Omega); \end{aligned}$$

therefore,

$$-(A_1 u_0, \phi)_{L^2(\Omega)} = ((F_1 F_0 + F_0 F_1) u_0, \phi)_{L^2(\Omega)} + \dots$$

and in view of (4.15), we obtain the representation (4.42) of the distribution (4.44), provided the set $\{K(\Omega) - K(\Omega)\} \cap H_0^1(\Omega)$ is dense in the set $\{K(\Omega) - K(\Omega)\} \subset L^2(\Omega)$.

Remark 4. Let us present an equivalent form of the problem (P').

Problem (P'). Find an element $u'(\Omega) \in L^2(\Omega)$ which minimizes the cost functional

$$(4.45) \quad I(u) = \frac{1}{2} \int_{\Omega} (z(u; x))^2 \, dx + \int_{\partial \Omega} v_n(x) \frac{\partial z}{\partial n}(u; x) \frac{\partial p_0}{\partial n}(x) \, d + \frac{N}{2} \int_{\Omega} (u(x))^2 \, dx$$

over the cone $K(\Omega)$.

The element $z(u; \cdot) \in H^1(\Omega)$ is given by a unique weak solution of the following elliptic boundary value problem:

$$(4.46) \quad \begin{aligned} -\Delta z(u; x) &= u(x) \quad \text{in } \Omega, \\ z(u; x) &= v_n(x) \frac{\partial y_0}{\partial n}(u_0; x) \quad \text{on } \partial \Omega. \end{aligned}$$

The element $p_0 \in H_0^1(\Omega) \cap H^2(\Omega)$ is given by the solution of the adjoint-state equation in the system (4.8) for $\varepsilon = 0$.

Acknowledgment. The author is very indebted to Professor Kazimierz Malanowski for stimulating discussions concerning the sensitivity analysis of optimal control problems.

OPTIMAL PORTFOLIO AND CONSUMPTION DECISIONS FOR A "SMALL INVESTOR" ON A FINITE HORIZON*

IOANNIS KARATZAS†, JOHN P. LEHOCZKY‡ AND STEVEN E. SHREVE§

Abstract. A general consumption/investment problem is considered for an agent whose actions cannot affect the market prices, and who strives to maximize total expected discounted utility of both consumption and terminal wealth. Under very general conditions on the nature of the market model and on the utility functions of the agent, it is shown how to approach the above problem by considering separately the two more elementary ones of maximizing utility of consumption only and of maximizing utility of terminal wealth only, and then appropriately composing them. The optimal consumption and wealth processes are obtained quite explicitly. In the case of a market model with constant coefficients, the optimal portfolio and consumption rules are derived very explicitly in feedback form (on the current level of wealth).

Key words. portfolio and consumption processes, utility functions, stochastic control, martingale representation theorems, change of probability measure, Feynman-Kac Theorem

1. Introduction. This paper treats a very general consumption/investment decision problem for a single agent, endowed with some initial wealth, who can consume the wealth at some rate C_t and invest it in any of $d+1$ available assets. The agent is attempting to maximize a linear combination of two quantities, namely:

- (i) $E \int_0^T \exp(-\int_0^t \beta(s) ds) U_1(C_t) dt$, the total expected discounted *utility from consumption* over the time-interval $[0, T]$, and
- (ii) $E[\exp(-\int_0^T \beta(s) ds) U_2(X_T)]$, the expected *utility from terminal wealth*.

The $d+1$ *assets* or *securities* available to the agent in this paper are very general. One of them is a *bond*, a security whose instantaneous rate of return may fluctuate (possibly randomly), but which is otherwise riskless. The other assets are *stocks*, risky securities whose prices have randomly fluctuating mean rates of return $b_i(t)$ and dispersion coefficients $\sigma_{ij}(t)$. Section 2 provides a careful exposition of these matters. The stock prices are driven by d independent Wiener processes; these represent the sources of uncertainty in the market model, which we assume to be *complete* in the sense of Harrison and Pliska (1981) and Bensoussan (1984). In our context, completeness amounts to nondegeneracy of the "diffusion" matrix $a(t) = \sigma(t)\sigma^T(t)$, as imposed by condition (2.3).

This condition guarantees, roughly speaking, that "there are exactly as many stocks as there are sources of uncertainty in the market model." It also enables us to construct a new probability measure under which the stock prices, discounted at the rate $r(\cdot)$ of the bond, become local martingales; this fact is of great importance in the modern theory of financial economics, and we refer the reader to Harrison and Pliska (1981), (1983) for a fuller account of its ramifications.

* Received by the editors September 8, 1986; accepted for publication January 27, 1987. Part of this research was carried out while I. Karatzas was visiting the Center for Stochastic Processes, University of North Carolina in Chapel Hill during April-May of 1986, and also during a brief sojourn by I. Karatzas and S. Shreve at the Institute of Mathematics and its Applications, University of Minnesota in Minneapolis in June of 1986.

The processes $r(t)$, $b_i(t)$, $\sigma_{ij}(t)$; $1 \leq i, j \leq d$ and $\beta(t)$, the instantaneous discount rate in the economy, will be collectively referred to as the *coefficients of the market model*. We assume that our agent is a "small investor," in that his decisions do not influence the asset prices which are treated as exogenous.

Single-agent consumption/investment problems have been investigated by a number of authors. A significant plateau was reached by Merton (1969), (1971). In the special case of a market model with constant coefficients, he found closed-form solutions for the associated Bellman equations in the infinite-horizon and the zero-bequest, finite-horizon cases, when the utility of consumption belongs to the HARA class, i.e., $U_1(c) = ac^p$, $-1 < p < 1$, $p \neq 0$ or $U_1(c) = a \log c$. The infinite-horizon model was generalized by Karatzas, Lehoczky, Sethi and Shreve (1986) (abbreviated hereafter as KLSS (1986)) who presented closed-form expressions for the value function and the optimal consumption and investment policies, corresponding to general utility functions and general assumptions concerning the effect of *bankruptcy*, a possibility altogether ignored by previous authors. The work cited thus far allows short-selling of both the bond and stocks; indeed, such short-selling is mandated by the optimal investment process. A model in which such short-selling is prohibited, but in which the interest rate on the bond and the mean rate of return on the only stock are constant and equal, was studied by Lehoczky, Sethi and Shreve (1983).

The present paper generalizes previous work in two major ways. First, the time-horizon is finite and general utility functions for consumption and terminal wealth are allowed. Second, the coefficients of the market model are required only to be adapted and bounded processes. This means that stock prices can fluctuate in an almost arbitrary, not necessarily Markovian fashion. Such generality notwithstanding, explicit results for the solution of the problem are provided, and it is shown how to use the resulting formulas in order to derive more simply the results of Merton (1969) and KLSS (1986). The methodology that accounts for both the simplicity and generality is the *Girsanov change of probability measure*, which removes the differences in mean rates of return among the investments and thus endows certain processes with the martingale property. Such an idea appeared in the context of option pricing in Harrison and Kreps (1979) and was more fully developed by Harrison and Pliska (1981). To our knowledge, this is its first application to optimal consumption and investment.

In this paper, an eminent role is played by the process ζ of (4.6), which is closely related to the Radon-Nikodým derivative of the measure transformation mentioned earlier. This process starts at $\zeta_0 = 1$ and satisfies a *linear* stochastic differential equation (cf. (4.7)) with random coefficients, determined by the market model only and not by the utility functions of the investor. These functions determine in turn, in a surprisingly simple way, the number $y > 0$ that serves as the initial value of the process

$$Y_t = y\zeta_t,$$

in terms of which the optimal consumption and wealth processes C^* , X^* are constructed in (6.7) and (6.8). Thus, in a sense, the only real decision on the part of the investor takes place at $t = 0$ with the determination of the constant $y > 0$; cf. (1.3) below. Once this decision has been taken, the further evolution of the processes Y , C^* and X^* depends only on the market, and not on the investor's preferences (utility functions).

The article is organized as follows: § 2 contains a detailed discussion on consumption/portfolio process pairs which are *admissible* from the point of view of the investor, i.e., do not get him into debt (negative wealth) when his initial endowment is $x \geq 0$. Section 3 lists our assumptions on the utility functions. Section 4 discusses the optimization problem when *utility comes only from consumption*; we exhibit two strictly

decreasing functions G_1 and \mathcal{X}_1 on $(0, \infty)$, the latter with inverse \mathcal{Y}_1 , such that the optimal consumption and wealth processes are given by (4.9), (4.10) with $y = \mathcal{Y}_1(x)$ and the value function for this problem is given by the composition $V_1(x) = G_1(\mathcal{Y}_1(x))$.

Section 5 solves the “complementary” optimization problem, in which *utility is derived only from terminal wealth*; a version of this problem was discussed by Pliska (1986). Again, we produce two strictly decreasing functions G_2 , \mathcal{X}_2 and set $\mathcal{Y}_2 = \mathcal{X}_2^{-1}$; the optimal consumption process is then identically equal to zero, the optimal wealth is given by (5.8) with $y = \mathcal{Y}_2(x)$, and the value function for this problem is $V_2(x) = G_2(\mathcal{Y}_2(x))$.

In § 6 we take up the original problem, in which *utility comes from both consumption and terminal wealth*. Here the situation is most interesting: it is shown that the investor has to divide at time $t = 0$ his endowment $x \geq 0$ into two parts:

$$(1.1) \quad x_1 \geq 0, \quad x_2 \geq 0, \quad x_1 + x_2 = x.$$

From then on, he faces two separate problems: one with initial wealth x_1 and utility coming *only* from consumption, the other with initial wealth x_2 and utility coming *only* from terminal wealth. The “superposition” of his actions for these individual problems yields an optimal procedure for the original one, provided that the splitting (1.1) is done in such a way as to produce “equipartition in the y -scale”:

$$(1.2) \quad x_1 = \mathcal{X}_1(y), \quad x_2 = \mathcal{X}_2(y)$$

where y is now determined uniquely via

$$(1.3) \quad \mathcal{X}(y) \triangleq \mathcal{X}_1(y) + \mathcal{X}_2(y) = x;$$

the value function for this problem is then given as

$$(1.4) \quad V(x) = V_1(x_1) + V_2(x_2) = G(\mathcal{X}^{-1}(x))$$

where $G \triangleq G_1 + G_2$.

In § 7 we specialize this problem to the case of *constant coefficients*. We employ results from KLSS (1986) and ideas from the theory of option pricing in order to characterize the functions \mathcal{X} , G above in terms of suitable Cauchy problems for a degenerate parabolic equation, and we then obtain the solutions of these Cauchy problems in closed form (Proposition 7.3 and Remark 7.4). We also provide the optimal consumption and portfolio strategies in explicit “feedback” form (Theorem 7.7).

2. Portfolio and consumption processes. Let us consider a market in which $d + 1$ assets (or “securities”) are traded continuously on the fixed time-horizon $[0, T]$, $0 < T < \infty$. One of these assets, called the *bond*, has a price which evolves according to the differential equation

$$(2.1) \quad dP_0(t) = r(t)P_0(t)dt, \quad P_0(0) = p_0, \quad 0 \leq t \leq T.$$

The remaining d assets, called *stocks*, are risky; their prices are modelled by the linear stochastic differential equations:

$$(2.2) \quad dP_i(t) = P_i(t) \left[b_i(t) dt + \sum_{j=1}^d \sigma_{ij}(t) dW_t^{(j)} \right], \quad P_i(0) = p_i, \quad 0 \leq t \leq T$$

for $i = 1, 2, \dots, d$. Here $W = \{W_t = (W_t^{(1)}, \dots, W_t^{(d)})^T, \mathcal{F}_t; 0 \leq t \leq T\}$ is a d -dimensional Brownian motion on (Ω, \mathcal{F}, P) and the filtration $\{\mathcal{F}_t\}$ is the augmentation under P of $\mathcal{F}_t^W = \sigma(W_s; 0 \leq s \leq t)$, $0 \leq t \leq T$. The *interest rate* process $\{r(t), \mathcal{F}_t; 0 \leq t \leq T\}$, as well as the vector of *mean rates of return* $\{b(t) = (b_1(t), \dots, b_d(t))^T, \mathcal{F}_t; 0 \leq t \leq T\}$

and the *dispersion matrix* $\{\sigma(t) = (\sigma_{ij}(t))_{1 \leq i, j \leq d}, \mathcal{F}_t; 0 \leq t \leq T\}$ are assumed to be measurable, adapted and bounded, uniformly in $(t, \omega) \in [0, T] \times \Omega$. We introduce the *covariance matrix* $a(t) \triangleq \sigma(t)\sigma^T(t)$ and assume that for some $\varepsilon > 0$,

$$(2.3) \quad \xi^T a(t, \omega) \xi \geq \varepsilon \|\xi\|^2 \quad \forall \xi \in \mathbb{R}^d, \quad (t, \omega) \in [0, T] \times \Omega.$$

LEMMA 2.1. *Under the assumption (2.3), the matrices $\sigma^T(t, \omega)$ and $\sigma(t, \omega)$ are invertible and we have*

$$(2.4) \quad \|(\sigma^T(t, \omega))^{-1} \xi\| \leq \frac{1}{\sqrt{\varepsilon}} \|\xi\| \quad \forall \xi \in \mathbb{R}^d,$$

$$(2.5) \quad \|(\sigma(t, \omega))^{-1} \xi\| \leq \frac{1}{\sqrt{\varepsilon}} \|\xi\| \quad \forall \xi \in \mathbb{R}^d$$

for every $(t, \omega) \in [0, T] \times \Omega$.

Proof. For a $(d \times d)$ matrix Γ we recall the operator norm

$$\|\Gamma\| \triangleq \sup_{\xi \neq 0} \frac{\|\Gamma \xi\|}{\|\xi\|}$$

and can show easily that $\|\Gamma^T\| = \|\Gamma\|$. Now (2.3) implies that $\sigma^T(t, \omega)$ is nonsingular, for otherwise we could find a vector $\xi \in \mathbb{R}^d \setminus \{0\}$ which would make $\|\xi^T a(t, \omega) \xi\| = \|\sigma^T(t, \omega) \xi\|^2 = 0$. Letting $\xi = (\sigma^T(t, \omega))^{-1} \eta$, we may then rewrite (2.3) as

$$\|(\sigma^T(t, \omega))^{-1} \eta\| \leq \frac{1}{\sqrt{\varepsilon}} \|\eta\| \quad \forall \eta \in \mathbb{R}^d$$

for every $(t, \omega) \in [0, T] \times \Omega$, which is equivalent to $\|(\sigma^T(t, \omega))^{-1}\| \leq 1/\sqrt{\varepsilon}$. Because $\|(\sigma(t, \omega))^{-1}\| = \|(\sigma^T(t, \omega))^{-1}\|$, the condition (2.3) is equivalent to

$$\xi^T \sigma^T(t, \omega) \sigma(t, \omega) \xi \geq \varepsilon \|\xi\|^2 \quad \forall \xi \in \mathbb{R}^d$$

for every $(t, \omega) \in [0, T] \times \Omega$. From this relation we derive (2.5), in the same way that we established (2.4) from (2.3). \square

We envision now an investor who starts with some initial endowment $x \geq 0$ and invests it in the $d + 1$ assets described above. Let $N_i(t)$ denote the number of shares of asset i owned by the investor at time t . Then $X_0 = x = \sum_{i=0}^d N_i(0) p_i$, and the investor's *wealth* at time t is

$$(2.6) \quad X_t = \sum_{i=0}^d N_i(t) P_i(t).$$

If the trading of shares (and hence the adjustment of the portfolio) is allowed to take place only at discrete time points, say at $\dots t - h, t, t + h, \dots$ and there is no infusion or withdrawal of funds, then

$$(2.7) \quad X_{t+h} - X_t = \sum_{i=0}^d N_i(t) [P_i(t+h) - P_i(t)].$$

On the other hand, if the investor chooses at time $t + h$ to consume an amount hC_{t+h} and reduce the wealth accordingly, then (2.7) should be replaced by

$$(2.8) \quad X_{t+h} - X_t = \sum_{i=0}^d N_i(t) [P_i(t+h) - P_i(t)] - hC_{t+h}.$$

The continuous-time analogue of (2.8) is

$$dX_t = \sum_{i=0}^d N_i(t) dP_i(t) - C_t dt,$$

which becomes

$$(2.9) \quad dX_t = (r(t)X_t - C_t) dt + \sum_{i=1}^d (b_i(t) - r(t))\pi_i(t) dt + \sum_{i=1}^d \sum_{j=1}^d \pi_i(t)\sigma_{ij}(t) dW_t^{(j)}$$

if we take (2.1), (2.2), (2.6) into account and denote by $\pi_i(t) \triangleq N_i(t)P_i(t)$ the amount invested in the stock i , $1 \leq i \leq d$.

DEFINITION 2.2. A *portfolio process* $\pi = \{\pi(t) = (\pi_1(t), \dots, \pi_d(t))^T, \mathcal{F}_t; 0 \leq t \leq T\}$ is a measurable, adapted, \mathcal{R}^d -valued process for which

$$(2.10) \quad \sum_{i=1}^d \int_0^T \pi_i^2(t) dt < \infty \quad \text{a.s.}$$

A *consumption process* $C = \{C_t, \mathcal{F}_t; 0 \leq t < \infty\}$ is a measurable, adapted process with values in $[0, \infty)$ and

$$(2.11) \quad \int_0^T C_t dt < \infty \quad \text{a.s.}$$

Remark 2.3. Any component of the vector $\pi(t)$ may become negative, which is to be interpreted as short-selling that particular stock. The amount

$$\pi_0(t) \triangleq X_t - \sum_{i=1}^d \pi_i(t)$$

invested in the bond may also become negative, and this corresponds to borrowing at the interest rate $r(t)$.

The conditions (2.10), (2.11) guarantee that the stochastic differential equation (2.9) has the unique, strong solution

$$(2.12) \quad \begin{aligned} X_t = \exp \left(\int_0^t r(s) ds \right) & \left\{ x + \int_0^t \exp \left(- \int_0^s r(u) du \right) [\pi^T(s)(b(s) - r(s)\mathbf{1}) - C_s] ds \right. \\ & \left. + \int_0^t \exp \left(- \int_0^s r(u) du \right) \pi^T(s)\sigma(s) dW_s \right\}, \end{aligned}$$

$0 \leq t \leq T$

where $\mathbf{1}$ is the d -dimensional vector with every component equal to 1. All vectors are column vectors, and transposition is denoted by the superscript T .

DEFINITION 2.4. A pair (π, C) of portfolio and consumption processes is said to be *admissible for the initial endowment* $x \geq 0$ if the wealth process X of (2.12) satisfies

$$(2.13) \quad X_t \geq 0, \quad 0 \leq t \leq T \quad \text{a.s.}$$

We denote by $\mathcal{A}(x)$ the class of all such pairs. \square

If $b(t) = r(t)\mathbf{1}$; $0 \leq t \leq T$, then the discount factor $\exp \{-\int_0^t r(u) du\}$ exactly offsets the rate of growth of all assets, and (2.12) shows that

$$(2.14) \quad M_t \triangleq X_t \exp \left(- \int_0^t r(u) du \right) - x + \int_0^t C_s \exp \left(- \int_0^s r(u) du \right) ds$$

is a stochastic integral. In other words, the process consisting of current wealth plus cumulative consumption, both properly discounted, is a local martingale. When $b(t) \neq r(t)\mathbf{1}$, M of (2.14) is no longer a local martingale under P , but becomes one under a

new probability measure \tilde{P} that removes the drift term $\pi^T(t)(b(t) - r(t)\mathbf{1})$ from (2.9). More specifically, recall from Lemma 2.1 that the process

$$(2.15) \quad \theta(t) \triangleq (\sigma(t))^{-1}(b(t) - r(t)\mathbf{1}), \quad 0 \leq t \leq T$$

is bounded, and let

$$(2.16) \quad Z_t \triangleq \exp \left\{ - \sum_{i=1}^d \int_0^t \theta_i(s) dW_s^{(i)} - \frac{1}{2} \int_0^t \|\theta(s)\|^2 ds \right\}.$$

Then $\{Z_t, \mathcal{F}_t; 0 \leq t \leq T\}$ is a martingale; the new probability measure

$$(2.17) \quad \tilde{P}(A) \triangleq E[Z_T 1_A], \quad A \in \mathcal{F}_T$$

is such that P and \tilde{P} are mutually absolutely continuous on \mathcal{F}_T , and

$$(2.18) \quad \tilde{W}_t \triangleq W_t + \int_0^t \theta(s) ds, \quad 0 \leq t \leq T$$

is a standard, d -dimensional Brownian motion under \tilde{P} (Girsanov (1960) or Karatzas and Shreve (1987, § 3.5)). In terms of \tilde{W} , we may rewrite (2.12) as

$$(2.19) \quad \begin{aligned} X_t \exp \left(- \int_0^t r(u) du \right) + \int_0^t C_s \exp \left(- \int_0^s r(u) du \right) ds \\ = x + \int_0^t \exp \left(- \int_0^s r(u) du \right) \pi^T(s) \sigma(s) d\tilde{W}_s. \end{aligned}$$

For any $(\pi, C) \in \mathcal{A}(x)$, the left-hand side of (2.19) is nonnegative and the right-hand side is a local martingale under \tilde{P} . It follows that the left-hand side, and hence also $X_t \exp(-\int_0^t r(u) du)$, is a nonnegative supermartingale under \tilde{P} . Now with

$$(2.20) \quad \tau_0 = T \wedge \inf \{0 \leq t \leq T; X_t = 0\},$$

we have from Chung (1982, Thm. 1.4) or Karatzas and Shreve (1987, Problem 1.3.29) that

$$(2.21) \quad X_t = 0, \quad \tau_0 \leq t \leq T \quad \text{holds a.s. on } \{\tau_0 < T\}.$$

We say that *bankruptcy occurs at time* τ_0 on the event $\{\tau_0 < T\}$.

The supermartingale property yields in (2.19):

$$(2.22) \quad \tilde{E} \left[X_T \exp \left(- \int_0^T r(u) du \right) + \int_0^T C_t \exp \left(- \int_0^t r(u) du \right) dt \right] \leq x,$$

whence the following *necessary conditions for admissibility*:

$$(2.23) \quad \tilde{E} \int_0^T C_t \exp \left(- \int_0^t r(u) du \right) dt \leq x,$$

$$(2.24) \quad \tilde{E} \left[X_T \exp \left(- \int_0^T r(u) du \right) \right] \leq x.$$

These conditions will also turn out to be “sufficient” for admissibility, in the sense of Propositions 2.6 and 2.8.

DEFINITION 2.5. For a given $x \geq 0$, let

(i) $\mathcal{C}(x)$ (respectively, $\mathcal{D}(x)$) denote the class of consumption processes which satisfy (2.23) (resp., (2.23) as an equality),

(ii) $\mathcal{L}(x)$ (respectively, $\mathcal{M}(x)$) denote the class of nonnegative random variables B on $(\Omega, \mathcal{F}_T, \tilde{P})$ which satisfy

$$(2.25) \quad \tilde{E} \left[B \exp \left(- \int_0^T r(u) du \right) \right] \leq x$$

(resp., (2.25) as an equality),

(iii) $\mathcal{P}(x)$ denote the class of portfolio processes, such that $(\pi, 0) \in \mathcal{A}(x)$ and the corresponding terminal wealth X_T belongs to $\mathcal{M}(x)$. \square

We shall show that $\mathcal{C}(x)$ consists of exactly those “reasonable” consumption processes, for which an investor, starting out with wealth x at time $t=0$, is able to construct a portfolio that will avoid debt (i.e., negative wealth) on $[0, T]$, almost surely.

PROPOSITION 2.6. *For every given $C \in \mathcal{C}(x)$, there exists a portfolio process π such that $(\pi, C) \in \mathcal{A}(x)$.*

Proof. Let $D \triangleq \int_0^T C_t \exp \left(- \int_0^t r(u) du \right) dt$, and define the nonnegative process

$$(2.26) \quad \begin{aligned} \xi_t &\triangleq \tilde{E} \left[\int_t^T C_s \exp \left(- \int_t^s r(u) du \right) ds \middle| \mathcal{F}_t \right] + (x - \tilde{E}D) \cdot \exp \left(\int_0^t r(u) du \right) \\ &= \left\{ x + m_t - \int_0^t C_s \exp \left(- \int_0^s r(u) du \right) ds \right\} \exp \left(\int_0^t r(u) du \right), \end{aligned}$$

where

$$m_t \triangleq \tilde{E}(D | \mathcal{F}_t) - \tilde{E}D = \frac{E[DZ_T | \mathcal{F}_t]}{Z_t} - E(DZ_T),$$

thanks to the so-called “Bayes rule” (Karatzas and Shreve (1987, Lemma 3.5.3)). By choosing a proper modification, we may assume that the paths of the martingale

$$N_t \triangleq E[DZ_T | \mathcal{F}_t], \quad 0 \leq t \leq T$$

are P -a.s. right-continuous and admit finite left-hand limits (Karatzas and Shreve (1987, Thms. 1.3.8, 1.3.13)). Now the fundamental representation result for Brownian martingales (Karatzas and Shreve (1987, Problem 3.4.16)) guarantees the existence of a measurable, $\{\mathcal{F}_t\}$ -adapted and \mathcal{R}^d -valued process Y with

$$(2.27) \quad \sum_{j=1}^d \int_0^T Y_j^2(t) dt < \infty$$

and

$$(2.28) \quad N_t = E(DZ_T) + \sum_{j=1}^d \int_0^t Y_j(s) dW_s^{(j)}, \quad 0 \leq t \leq T$$

valid a.s. P . We conclude that $m_t = u(N_t, Z_t) - E(DZ_T)$, where $u(x, y) = x/y$, and from Itô’s rule we obtain with $\varphi(t) \triangleq (1/Z_t)(Y(t) + N_t \theta(t))$:

$$(2.29) \quad m_t = \sum_{j=1}^d \int_0^t \varphi_j(s) d\tilde{W}_s^{(j)}, \quad 0 \leq t \leq T.$$

We have used the relations

$$(2.30) \quad dZ_t = -Z_t \theta^T(t) dW_t$$

and (2.18). Now define

$$(2.31) \quad \pi(t) \triangleq \exp \left(\int_0^t r(u) du \right) (\sigma^T(t))^{-1} \varphi(t)$$

so that (2.26) becomes (2.19) when we make the identifications $\xi = X$, $m = M$. Condition (2.10) follows from (2.4), (2.27), the boundedness of $\|\theta\|$, and the path continuity of Z and N ; the latter is a consequence of (2.28). \square

Remark 2.7. The wealth process $X \equiv \xi$ in (2.26), corresponding to any $C \in \mathcal{D}(x)$, is given by

$$(2.32) \quad X_t = \tilde{E} \left[\int_t^T C_s \exp \left(- \int_t^s r(u) du \right) ds \middle| \mathcal{F}_t \right], \quad 0 \leq t \leq T.$$

In particular then, $X_T = 0$ almost surely.

PROPOSITION 2.8. *For every given $B \in \mathcal{L}(x)$, there exists a pair $(\pi, C) \in \mathcal{A}(x)$ with corresponding wealth process X , such that*

$$X_T = B \quad \text{a.s. } \tilde{P}.$$

Proof. Let $Q \triangleq B \exp \left(- \int_0^T r(u) du \right)$, and define the nonnegative process η by

$$(2.33) \quad \begin{aligned} \eta_t \exp \left(- \int_0^t r(u) du \right) &\triangleq \tilde{E}(Q | \mathcal{F}_t) + (x - \tilde{E}Q) \cdot \left(1 - \frac{t}{T} \right) \\ &= x + m_t - \rho t, \quad 0 \leq t \leq T \end{aligned}$$

where $m_t = \tilde{E}(Q | \mathcal{F}_t) - \tilde{E}Q$, $\rho = (\tilde{x} - EQ)/T$. Obviously, $\eta_0 = x$ and $\eta_T = B$ hold almost surely. We obtain a stochastic integral representation of the form (2.29) for the \tilde{P} -martingale m ; then (2.33) is cast in the form (2.19) once we take π as in (2.31),

$$C_t = \rho \cdot \exp \left(\int_0^t r(u) du \right), \quad 0 \leq t \leq T$$

and $X = \xi$.

COROLLARY 2.9. *For any given $B \in \mathcal{M}(x)$, there exists a portfolio process $\pi \in \mathcal{P}(x)$ with corresponding wealth process*

$$(2.34) \quad X_t = \tilde{E} \left[B \exp \left(- \int_t^T r(u) du \right) \middle| \mathcal{F}_t \right], \quad 0 \leq t \leq T. \quad \square$$

Proposition 2.8 and the relation (2.24) show that $\mathcal{L}(x)$ consists of precisely those “levels of terminal wealth” which are *attainable* from the initial endowment $x \geq 0$, via the usage of some portfolio/consumption pair that avoids debt. The terminology here is due to Pliska (1986). Corollary 2.9 shows that the “extreme” elements of $\mathcal{L}(x)$ are attainable by strategies that mandate zero consumption.

3. Utility functions. Consider a strictly increasing, strictly concave and C^1 function $U: (0, \infty) \rightarrow \mathcal{R}$ with $U(0) \triangleq \lim_{c \downarrow 0} U(c) \geq -\infty$, $U'(\infty) \triangleq \lim_{c \rightarrow \infty} U'(c) = 0$. We allow the possibility that $U'(0) \triangleq \lim_{c \downarrow 0} U'(c) = \infty$. A function with these properties will be called a *utility function* in the sequel.

Because $U': [0, \infty] \rightarrow_{\text{onto}} [0, U'(0)]$ is strictly decreasing, it has a strictly decreasing inverse $I: [0, U'(0)] \rightarrow_{\text{onto}} [0, \infty]$. We extend I to be a continuous function on the entirety of $[0, \infty]$ by setting $I(y) \equiv 0$ for $U'(0) \leq y \leq \infty$, and note that

$$(3.1) \quad U(I(y)) \geq U(c) + yI(y) - yc, \quad 0 \leq c < \infty, \quad 0 < y < \infty.$$

For part of our development in §§ 4–6, we shall need to impose the assumption

$$(3.2) \quad U \in C^2 \quad \text{and} \quad U'' \text{ is nondecreasing on } (0, \infty).$$

Under this condition, I is convex on $(0, \infty)$ and continuously differentiable on $(0, \infty) \setminus \{U'(0)\}$. If we define $I'(U'(0)) = 0$ in the case $U'(0) < \infty$, then because $I'(y) = 0$ for every $y > U'(0)$, the identity

$$(3.3) \quad (U(I(y)))' = yI'(y)$$

becomes valid on the entirety of $(0, \infty)$. This identity is also valid on $(0, \infty)$ if $U'(0) = \infty$.

4. Maximization of utility from consumption. In this section we formulate and study a particular stochastic control problem for the “small investor” model of § 2. Suppose that, in addition to the data given there, we have a measurable, $\{\mathcal{F}_t\}$ -adapted and uniformly bounded discount process $\{\beta(t), \mathcal{F}_t; 0 \leq t \leq T\}$, as well as a utility function U_1 . The objective will be to maximize the expected discounted utility from consumption

$$(4.1) \quad J_1(x; \pi, C) = E \int_0^T \exp\left(-\int_0^t \beta(s) ds\right) U_1(C_t) dt$$

with an initial endowment $x \geq 0$, over the class $\mathcal{A}_1(x)$ of portfolio/consumption pairs $(\pi, C) \in \mathcal{A}(x)$ for which

$$(4.2) \quad E \int_0^T \exp\left(-\int_0^t \beta(s) ds\right) U_1^-(C_t) dt < \infty.$$

The expectation in (4.1) is well defined for every pair $(\pi, C) \in \mathcal{A}_1(x)$; of course, $\mathcal{A}_1(x) \equiv \mathcal{A}(x)$ if $U_1(0) > -\infty$.

We denote by

$$(4.3) \quad V_1(x) \triangleq \sup_{(\pi, C) \in \mathcal{A}_1(x)} J_1(x; \pi, C)$$

the value function for this problem, which is trivial if $x = 0$. Indeed, the admissibility condition (2.23) implies then $V_1(0) = U_1(0) \cdot E \int_0^T \exp(-\int_0^t \beta(s) ds) dt$, and this obviously can be achieved by $\pi \equiv 0$, $C \equiv 0$. We concentrate, therefore, on $x > 0$.

Because utility comes only from consumption, it is plausible that one should strive to increase the net effect of the latter, up to the permissible limit dictated by (2.23), by considering only consumption processes C in $\mathcal{D}(x)$.

PROPOSITION 4.1. *For every $x > 0$ we have*

$$V_1(x) = \sup_{\substack{(\pi, C) \in \mathcal{A}_1(x) \\ C \in \mathcal{D}(x)}} J(x; \pi, C).$$

Proof. Take $(\pi, C) \in \mathcal{A}_1(x)$ and observe that the number $z \triangleq \tilde{E} \int_0^T \exp(-\int_0^t r(u) du) C_t dt$ lies in $[0, x]$. If $z > 0$, we may define $\hat{C}_t \triangleq (x/z) C_t$ so that $\hat{C} \in \mathcal{D}(x)$, and construct a portfolio process $\hat{\pi}$ such that $(\hat{\pi}, \hat{C}) \in \mathcal{A}(x)$; cf. Proposition 2.6 and Remark 2.7. Because $U_1(C_t) \leq U_1(\hat{C}_t)$; $0 \leq t \leq T$ and C satisfies (4.2), so does \hat{C} , i.e., $(\hat{\pi}, \hat{C}) \in \mathcal{A}_1(x)$ and we have

$$(4.4) \quad J_1(x; \pi, C) \leq J_1(x; \hat{\pi}, \hat{C}).$$

If $z = 0$ then $C_t = 0$, a.e. $t \in [0, T]$, almost surely, and the consumption process \hat{C} given by

$$(4.5) \quad \hat{C}_t \equiv \hat{c} \triangleq \frac{x}{\tilde{E} \int_0^T \exp(-\int_0^t r(u) du) dt}, \quad 0 \leq t \leq T$$

belongs to $\mathcal{D}(x)$. Again, (4.4) holds for some $\hat{\pi}$ chosen so that $(\hat{\pi}, \hat{C}) \in \mathcal{A}_1(x)$. \square

Recall the Radon–Nikodým derivative martingale Z of (2.16). The related process

$$(4.6) \quad \zeta_t \triangleq Z_t \exp \left(\int_0^t (\beta(u) - r(u)) du \right), \quad 0 \leq t \leq T$$

will be of fundamental significance in what follows. It determines the optimal consumption process, $C^{(1)}$ of (4.9) below, in a very direct and explicit manner. It is easily seen from (2.30) to satisfy the linear stochastic differential equation

$$(4.7) \quad d\zeta_t = (\beta(t) - r(t))\zeta_t dt - \zeta_t \theta^T(t) dW_t,$$

whose importance we already documented in KLSS (1986) in the context of constant coefficients and infinite-horizon.

We recall now from § 3 the notation I_1 for the inverse of the function U'_1 , and assume

$$(4.8) \quad \mathcal{X}_1(y) \triangleq \tilde{E} \int_0^T \exp \left(- \int_0^t r(u) du \right) I_1(y\zeta_t) dt < \infty, \quad \forall 0 < y < \infty.$$

LEMMA 4.2. *Under the condition (4.8), the function \mathcal{X}_1 defined there is continuous and strictly decreasing on $(0, \infty)$ with $\mathcal{X}_1(0) \triangleq \lim_{y \downarrow 0} \mathcal{X}_1(y) = \infty$, $\mathcal{X}_1(\infty) \triangleq \lim_{y \rightarrow \infty} \mathcal{X}_1(y) = 0$.*

Proof. Because I_1 is nonincreasing, and strictly decreasing on $(0, U'_1(0))$, we need only show that

$$P \left[Z_t \exp \left\{ \int_0^t (\beta(s) - r(s)) ds \right\} < \frac{U'_1(0)}{y}; \text{ some } 0 \leq t \leq T \right] > 0$$

holds for every fixed $y \in (0, \infty)$. But

$$\begin{aligned} & \log \left[Z_t \exp \left\{ \int_0^t (\beta(s) - r(s)) ds \right\} \right] \\ &= - \sum_{j=1}^d \int_0^t \theta_j(s) dW_s^{(j)} - \frac{1}{2} \int_0^t \|\theta(s)\|^2 ds + \int_0^t (\beta(s) - r(s)) ds \\ &= B_{A(t)} + \int_0^t \left\{ \beta(s) - r(s) - \frac{1}{2} \|\theta(s)\|^2 \right\} ds \end{aligned}$$

where B is a standard, one-dimensional Brownian motion and $A(t) = \int_0^t \|\theta(s)\|^2 ds$. The strict monotonicity of \mathcal{X} now follows easily from the properties of Brownian motion and the boundedness of the processes $\|\theta\|$, $\beta - r$. The other properties claimed for \mathcal{X} are also inherited from I_1 . \square

Let us denote by $\mathcal{Y}_1: [0, \infty] \xrightarrow{\text{onto}} [0, \infty]$ the inverse of the function \mathcal{X}_1 . For a fixed number $x_1 \in (0, \infty)$ we introduce the consumption process

$$(4.9) \quad C_t^{(1)} \triangleq I_1(\mathcal{Y}_1(x_1)\zeta_t), \quad 0 \leq t \leq T,$$

which belongs to $\mathcal{D}(x_1)$. Thanks to Proposition 2.6 and (2.32), (2.19), there exists a portfolio $\pi^{(1)}$ such that $(\pi^{(1)}, C^{(1)}) \in \mathcal{A}(x_1)$, and the corresponding wealth process $X^{(1)}$ is given by

$$\begin{aligned} (4.10) \quad X_t^{(1)} \exp \left(- \int_0^t r(u) du \right) &= \tilde{E} \left[\int_t^T C_s^{(1)} \exp \left(- \int_0^s r(u) du \right) ds \middle| \mathcal{F}_t \right] \\ &= x_1 - \int_0^t C_s^{(1)} \exp \left(- \int_0^s r(u) du \right) ds \\ &\quad + \int_0^t \exp \left(- \int_0^s r(u) du \right) (\pi^{(1)}(s))^T \sigma(s) d\tilde{W}_s. \end{aligned}$$

In particular, $X^{(1)}$ is nonnegative on $[0, T)$ and vanishes at $t = T$. If $U_1'(0) = \infty$, then $X^{(1)}$ is positive on $[0, T)$.

THEOREM 4.3. *Let us assume that (4.8) holds. Then for any $x_1 > 0$ and with $C^{(1)} \in \mathcal{D}(x_1)$ given by (4.9), the pair $(\pi^{(1)}, C^{(1)})$ constructed above belongs to $\mathcal{A}_1(x_1)$ and is optimal for the problem of (4.3):*

$$(4.11) \quad V_1(x_1) = E \int_0^T \exp\left(-\int_0^t \beta(s) ds\right) U_1(C_t^{(1)}) dt.$$

Proof. It suffices to show that $C^{(1)}$ satisfies (4.2) and to establish the comparison

$$(4.12) \quad E \int_0^T \exp\left(-\int_0^t \beta(s) ds\right) U_1(C_t) dt \leq E \int_0^T \exp\left(-\int_0^t \beta(s) ds\right) U_1(C_t^{(1)}) dt$$

for any other $C \in \mathcal{C}(x_1)$ with the property (4.2).

Recall now the process ζ of (4.6) and observe that, for any $C \in \mathcal{C}(x_1)$, the integral of ζC with respect to the measure

$$(4.13) \quad \nu(dt, d\omega) \triangleq \exp\left(-\int_0^t \beta(s, \omega) ds\right) dt P(d\omega)$$

on $\Theta = [0, T] \times \Omega$ is given by

$$(4.14) \quad \int_{\Theta} \zeta C d\nu = \tilde{E} \int_0^T \exp\left(-\int_0^t r(u) du\right) C_t dt \triangleq x_1,$$

with equality if $C \in \mathcal{D}(x_1)$. For any $C \in \mathcal{C}(x_1)$, the comparison (3.1) yields

$$(4.15) \quad U_1(C_t^{(1)}) \geq U_1(C_t) + \mathcal{Y}_1(x_1) \zeta_t C_t^{(1)} - \mathcal{Y}_1(x_1) \zeta_t C_t, \quad 0 \leq t \leq T$$

almost surely. Corresponding to the special choice $C = \hat{C} \in \mathcal{D}(x_1)$ of (4.5) with x replaced by x_1 , the right-hand side of (4.15) is integrable with respect to the measure ν of (4.13); recalling (4.14), we see that the value of this integral is actually $U_1(\hat{C}) \cdot E \int_0^T \exp\left(-\int_0^t \beta(s) ds\right) dt$. It follows then that $C^{(1)}$ satisfies (4.2).

Let us now take an arbitrary $C \in \mathcal{C}(x_1)$ with the property (4.2), integrate both sides of (4.15) against the measure ν of (4.13), and recall (4.14); we obtain the comparison (4.12). \square

In order to guarantee the finiteness of the value function V_1 in (4.3) and to obtain a useful representation for it, let us impose the condition

$$(4.16) \quad E \int_0^T \exp\left(-\int_0^t \beta(u) du\right) |U_1(I_1(y\zeta_t))| dt < \infty \quad \forall 0 < y < \infty.$$

We shall have more to say about the conditions (4.8), (4.16) in Lemma 4.6 below, as well as in § 7, where we specialize the model to the case of constant coefficients.

PROPOSITION 4.4. *Suppose that the utility function U_1 obeys the conditions (3.2), (4.8) and (4.16). Then the function $G_1: (0, \infty) \rightarrow \mathcal{R}$ given by*

$$(4.17) \quad G_1(y) \triangleq E \int_0^T \exp\left(-\int_0^t \beta(u) du\right) U_1(I_1(y\zeta_t)) dt, \quad 0 < y < \infty$$

is strictly decreasing, continuously differentiable, and satisfies

$$(4.18) \quad G_1'(y) = y\mathcal{X}'_1(y), \quad 0 < y < \infty$$

as well as

$$(4.19) \quad V_1(x) = G_1(\mathcal{Y}_1(x)), \quad 0 < x < \infty.$$

Proof. Under condition (3.2), the function \mathcal{X}_1 of (4.8) inherits the convexity on $(0, \infty)$ from I_1 . Fix $y > 0$ and observe that

$$\begin{aligned}\mathcal{X}_1(y) - \mathcal{X}_1(y - \delta) &= \tilde{E} \int_0^T \exp\left(-\int_0^t r(u) du\right) \{I_1(y\xi_t) - I_1((y - \delta)\xi_t)\} dt \\ &\leq \delta \cdot \tilde{E} \int_0^T \exp\left(-\int_0^t r(u) du\right) \xi_t I'_1(y\xi_t) dt\end{aligned}$$

holds for $0 < \delta < y$. It follows that the left-hand derivative $D^-\mathcal{X}_1(y)$ satisfies

$$-\infty < D^-\mathcal{X}_1(y) \leq \varphi(y) \triangleq E \int_0^T \exp\left(-\int_0^t \beta(u) du\right) \xi_t I'_1(y\xi_t) dt$$

where this last function $\varphi(\cdot)$ is easily seen to be nondecreasing and continuous. In a similar manner, one shows

$$\varphi(y) \leq D^+\mathcal{X}_1(y) < \infty.$$

A convex function of a real variable, whose left- and right-hand derivatives bound a continuous function $\varphi(\cdot)$ in such a way, must be continuously differentiable (Karatzas and Shreve (1987, Problem 3.6.20(iv))) with $\varphi(\cdot)$ as its derivative:

$$(4.20) \quad \mathcal{X}'_1(y) = E \int_0^T \exp\left(-\int_0^t \beta(u) du\right) \xi_t^2 I'_1(y\xi_t) dt.$$

On the other hand, the double inequality

$$\delta(y + \delta)\xi_t^2 I'_1(y\xi_t) \leq U_1(I_1((y + \delta)\xi_t)) - U_1(I_1(y\xi_t)) \leq \delta y \xi_t^2 I'_1((y + \delta)\xi_t)$$

follows easily from (3.3) and the convexity of I_1 , and yields, in conjunction with (4.16), (4.20):

$$\delta(y + \delta)\mathcal{X}'_1(y) \leq G_1(y + \delta) - G_1(y) \leq \delta y \mathcal{X}'_1(y + \delta).$$

The conclusion (4.18) now follows easily; (4.19) is a consequence of Theorem 4.3.

Remark 4.5. Differentiation in (4.19) shows that

$$V'_1(x) = \mathcal{Y}_1(x), \quad V''_1(x) = \mathcal{Y}'_1(x), \quad 0 \leq x < \infty.$$

Because \mathcal{X}_1 is strictly decreasing, \mathcal{Y}'_1 is negative and V_1 is strictly concave. Because $\mathcal{X}_1(\infty) = 0$, we also have $V'_1(0) = \infty$.

LEMMA 4.6. *If $U_1(0) > -\infty$, then (4.16) implies (4.8).*

Proof. From the concavity of U_1 we have in this case

$$(4.21) \quad 0 \leq cU'_1(c) \leq U_1(c) - U_1(0) \leq |U_1(c)| + |U_1(0)|$$

for every $0 \leq c < \infty$, whence

$$y\xi_t I_1(y\xi_t) \leq |U_1(I_1(y\xi_t))| + |U_1(0)|.$$

From this inequality it follows that

$$\begin{aligned}y\mathcal{X}_1(y) &= y \cdot E \int_0^T \exp\left(-\int_0^t \beta(u) du\right) \xi_t I_1(y\xi_t) dt \\ &\leq |U_1(0)| \cdot E \int_0^T \exp\left(-\int_0^t \beta(u) du\right) dt \\ &\quad + E \int_0^T \exp\left(-\int_0^t \beta(u) du\right) |U_1(I_1(y\xi_t))| dt < \infty\end{aligned}$$

holds for every $0 < y < \infty$. \square

Remark 4.7. In the important special case $U(c) = \log c$, the functions of (4.8), (4.17) are given by

$$\mathcal{X}_1(y) = \frac{\alpha_1}{y} \quad \text{and} \quad G_1(y) = -\alpha_1 \cdot \log y + \delta_1,$$

respectively, where

$$\alpha_1 \triangleq E \int_0^T \exp \left(- \int_0^t \beta(u) du \right) dt$$

and

$$\delta_1 \triangleq E \int_0^T \exp \left(- \int_0^t \beta(u) du \right) \cdot \left\{ \sum_{i=1}^d \int_0^t \theta_i(u) dW_u^{(i)} - \int_0^t \left(\beta(u) - r(u) - \frac{1}{2} \|\theta(u)\|^2 \right) du \right\} dt.$$

In particular, the conditions (4.8) and (4.16) are satisfied rather trivially, and the value function is given by (4.19) as

$$V_1(x) = \alpha_1 \cdot \log \left(\frac{x}{\alpha_1} \right) + \delta_1, \quad 0 < x < \infty.$$

5. Maximization of utility from terminal wealth. With a utility function U_2 as in § 3, the problem now is to maximize the expected discounted utility from terminal wealth

$$(5.1) \quad J_2(x; \pi, C) \triangleq E \left[\exp \left(- \int_0^T \beta(s) ds \right) U_2(X_T) \right]$$

over the class $\mathcal{A}_2(x)$ of pairs $(\pi, C) \in \mathcal{A}(x)$ for which

$$(5.2) \quad E \left[\exp \left(- \int_0^T \beta(s) ds \right) U_2^-(X_T) \right] < \infty.$$

Obviously $\mathcal{A}_2(x) \equiv \mathcal{A}(x)$ if $U_2(0) > -\infty$. We denote the value function of this problem by

$$(5.3) \quad V_2(x) \triangleq \sup_{(\pi, C) \in \mathcal{A}_2(x)} J_2(x; \pi, C).$$

Again, the case $x = 0$ is uninteresting: for every $(\pi, C) \in \mathcal{A}(x)$ we have $X_T = 0$ a.s. from (2.24), and thus $V_2(0) = U_2(0) \cdot E \exp \left(- \int_0^T \beta(u) du \right)$; this is achieved by $\pi \equiv 0, C \equiv 0$. We shall take $x > 0$ from now on.

This problem is analogous, and in a certain sense complementary, to that of the preceding section, with the same process ζ of (4.6) playing again a distinguished role.

Because utility comes now only from terminal wealth, it is quite reasonable that the latter should be increased, within the constraints mandated by the level of the initial endowment as quantified by (2.24), by considering portfolio processes π in the class $\mathcal{P}(x)$ of Definition 2.5.

The following is, then, an analogue of Proposition 4.1.

PROPOSITION 5.1. *For every $x > 0$ we have*

$$V_2(x) = \sup_{\substack{(\pi, 0) \in \mathcal{A}_2(x) \\ \pi \in \mathcal{P}(x)}} J_2(x; \pi, 0).$$

Proof. For any $(\pi, C) \in \mathcal{A}(x)$, the number $\lambda \triangleq \tilde{E}(X_T \exp(-\int_0^T r(u) du))$ is in $[0, x]$ by virtue of (2.24). If $\lambda > 0$, then $B \triangleq (x/\lambda)X_T$ belongs to $\mathcal{M}(x)$. From Proposition 2.8 and Corollary 2.9, there exists a portfolio $\hat{\pi} \in \mathcal{P}(x)$ with corresponding terminal wealth $\hat{X}_T = B \geq X_T$, a.s. Obviously then $(\hat{\pi}, 0) \in \mathcal{A}_2(x)$ and

$$(5.4) \quad J_2(x; \pi, C) \leq J_2(x; \hat{\pi}, 0).$$

On the other hand, if $\lambda = 0$, the role of the random variable B above can be played by the number

$$(5.5) \quad b \triangleq \frac{x}{\tilde{E}[\exp(-\int_0^T r(u) du)]} > 0,$$

and we also have $X_T = 0$, a.s. The same reasoning as before leads to (5.4) for some $\hat{\pi} \in \mathcal{P}(x)$. \square

Recalling from § 3 the notation I_2 for the inverse of U'_2 , we introduce now the condition

$$(5.6) \quad \mathcal{X}_2(y) \triangleq \tilde{E} \left[\exp \left(- \int_0^T r(s) ds \right) I_2(y \zeta_T) \right] < \infty \quad \forall 0 < y < \infty$$

and notice, just as in Lemma 4.2, that the function \mathcal{X}_2 is continuous and strictly decreasing on $(0, \infty)$, with $\mathcal{X}_2(0) \triangleq \lim_{y \downarrow 0} \mathcal{X}_2(y) = \infty$ and $\mathcal{X}_2(\infty) \triangleq \lim_{y \rightarrow \infty} \mathcal{X}_2(y) = 0$. Let us denote by $\mathcal{Y}_2: [0, \infty] \rightarrow_{\text{onto}} [0, \infty]$ the inverse of this function.

For a fixed number $x_2 \in (0, \infty)$, we introduce the random variable

$$(5.7) \quad X_T^{(2)} \triangleq I_2(\mathcal{Y}_2(x_2) \zeta_T).$$

Obviously $X_T^{(2)} \in \mathcal{M}(x_2)$, and from Corollary 2.9 we can find $\pi^{(2)} \in \mathcal{P}(x_2)$ with corresponding wealth process $X^{(2)}$ given, as in (2.34), by

$$(5.8) \quad \begin{aligned} X_t^{(2)} \exp \left(- \int_0^t r(u) du \right) &\triangleq \tilde{E} \left[X_T^{(2)} \exp \left(- \int_0^T r(u) du \right) \middle| \mathcal{F}_t \right] \\ &= x_2 + \int_0^t \exp \left(- \int_0^s r(u) du \right) (\pi^{(2)}(s))^T \sigma(s) d\tilde{W}_s. \end{aligned}$$

THEOREM 5.2. *Let us assume that (5.6) holds. Then for any $x_2 > 0$ the above pair $(\pi^{(2)}, 0)$ belongs to $\mathcal{A}_2(x_2)$ and is optimal for the problem (5.3):*

$$(5.9) \quad V_2(x_2) = E \left[\exp \left(- \int_0^T \beta(s) ds \right) U_2(X_T^{(2)}) \right].$$

Proof. It suffices to show that the random variable $X_T^{(2)} \in \mathcal{M}(x_2)$ of (5.7) satisfies (5.2), and that for any other random variable $X_T \in \mathcal{L}(x_2)$ satisfying this condition we have

$$(5.10) \quad E \left[\exp \left(- \int_0^T \beta(s) ds \right) U_2(X_T) \right] \leq E \left[\exp \left(- \int_0^T \beta(s) ds \right) U_2(X_T^{(2)}) \right].$$

The argument imitates the proof of Theorem 4.3; it hinges on the consequence of (3.1):

$$U_2(X_T^{(2)}) \geq U_2(X_T) + y \zeta_T X_T^{(2)} - y \zeta_T X_T \quad \text{a.s.}$$

which is valid for every $X_T \in \mathcal{L}(x_2)$ and is applied, first to the constant $b \in \mathcal{M}(x_2)$ of (5.5) with $x = x_2$, and then to an arbitrary $X_T \in \mathcal{L}(x_2)$ which satisfies (5.2). The details are omitted. \square

The condition

$$(5.11) \quad E \left[\exp \left(- \int_0^T \beta(u) du \right) |U_2(I_2(y\xi_T))| \right] < \infty \quad \forall y \in (0, \infty)$$

guarantees the finiteness of the value function V_2 .

PROPOSITION 5.3. *Let the utility function U_2 satisfy (3.2), (5.6) and (5.11). Then the function $G_2: (0, \infty) \rightarrow \mathcal{R}$ given by*

$$(5.12) \quad G_2(y) \triangleq E \left[\exp \left(- \int_0^T \beta(s) ds \right) U_2(I_2(y\xi_T)) \right], \quad 0 < y < \infty$$

is strictly decreasing, continuously differentiable, and satisfies

$$(5.13) \quad G_2'(y) = y\mathcal{X}_2'(y), \quad 0 < y < \infty,$$

$$(5.14) \quad V_2(x) = G_2(\mathcal{Y}_2(x)), \quad 0 < x < \infty.$$

The proof follows that of Proposition 4.4. Finally, just as in Lemma 4.6, if $U_2(0) > -\infty$ then (5.11) implies (5.6).

Remark 5.4. Just as in Remark 4.5, under the conditions of Proposition 5.3 the function V_2 is strictly concave with $V_2'(0) = \infty$. This follows from the formulas

$$V_2'(x) = \mathcal{Y}_2(x), \quad V_2''(x) = \mathcal{Y}_2'(x), \quad 0 \leq x < \infty.$$

Remark 5.5. In the special case $U_2(c) = \log c$, we have

$$\mathcal{X}_2(y) = \frac{\alpha_2}{y}, \quad G_2(y) = -\alpha_2 \cdot \log y + \delta_2,$$

$$V_2(x) = \alpha_2 \cdot \log \left(\frac{x}{\alpha_2} \right) + \delta_2$$

where

$$\alpha_2 \triangleq E \exp \left(- \int_0^T \beta(u) du \right),$$

$$\delta_2 \triangleq E \left[\exp \left(- \int_0^T \beta(u) du \right) \left\{ \sum_{i=1}^d \int_0^T \theta_i(u) dW_u^{(i)} - \int_0^T \left(\beta(u) - r(u) - \frac{\|\theta(u)\|^2}{2} \right) du \right\} \right].$$

6. Maximization of utility from both consumption and terminal wealth. A stochastic control problem, which is arguably more interesting than those studied in §§ 4 and 5, concerns the maximization of the total expected discounted utility

$$(6.1) \quad \begin{aligned} J(x; \pi, C) &\triangleq J_1(x; \pi, C) + J_2(x; \pi, C) \\ &= E \left[\int_0^T \exp \left(- \int_0^t \beta(s) ds \right) U_1(C_t) dt \right] \\ &\quad + E \left[\exp \left(- \int_0^T \beta(s) ds \right) U_2(X_T) \right] \end{aligned}$$

from both consumption and terminal wealth, over the class $\mathcal{A}_{1,2}(x) \triangleq \mathcal{A}_1(x) \cap \mathcal{A}_2(x)$:

$$(6.2) \quad V(x) \triangleq \sup_{(\pi, C) \in \mathcal{A}_{1,2}(x)} J(x; \pi, C).$$

Unlike the two problems studied already, this one calls for balancing *competing objectives*. Single-minded determination to “become rich” (i.e., to maximize $J_2(x; \pi, C)$)

mandates no consumption whatsoever—recall Theorem 5.2. On the other hand, single-minded “consumerism” (i.e., maximization of $J_1(x; \pi, C)$) will leave the investor broke at the end; cf. Remark 2.7 and Theorem 4.3. Both these alternatives are suboptimal in the present context.

We shall demonstrate that the proper compromise between these two competing objectives can be drawn in a very simple way. At time $t = 0$ the investor simply divides the endowment x into two parts $x_1 \geq 0$, $x_2 \geq 0$ with $x_1 + x_2 = x$; for the amount x_1 (respectively, x_2) the investor will face, from then on, an optimization problem with utility coming *only* from consumption (respectively, *only* from terminal wealth). It will be shown just how x_1 , x_2 should be determined, in order for the resulting procedure to be optimal.

Throughout this section it will be assumed that U_1 , U_2 are utility functions (§ 3) for which (3.2), (4.8), (4.16) and (5.6), (5.11) hold.

PROPOSITION 6.1. *For $x \geq 0$ and an arbitrary portfolio/consumption pair $(\pi, C) \in \mathcal{A}_{1,2}(x)$, let*

$$x_1 \triangleq \tilde{E} \int_0^T \exp \left(- \int_0^t \beta(u) du \right) C_t dt.$$

Then there exists a pair $(\tilde{\pi}, \tilde{C}) \in \mathcal{A}_{1,2}(x)$ such that

$$(6.3) \quad J(x; \pi, C) \leq J(x; \tilde{\pi}, \tilde{C}) = V_1(x_1) + V_2(x - x_1).$$

In particular,

$$(6.4) \quad V(x) \leq V_*(x) \triangleq \max_{\substack{x_1, x_2 \in [0, \infty) \\ x_1 + x_2 = x}} [V_1(x_1) + V_2(x_2)] = \max_{\substack{y_1, y_2 \in [0, \infty] \\ \mathcal{G}_1(y_1) + \mathcal{G}_2(y_2) = x}} [G_1(y_1) + G_2(y_2)].$$

Proof. From (2.22) we have that $x_1 \in [0, x]$ and

$$\tilde{E} \left[\exp \left(- \int_0^T r(u) du \right) X_T \right] \leq x_2 \triangleq x - x_1.$$

If $x_i = 0$, take $\pi^{(i)} \equiv 0$, $C^{(i)} \equiv 0$. If $x_1 > 0$, then the pair $(\pi^{(1)}, C^{(1)})$ of Theorem 4.3, with corresponding wealth process $X^{(1)}$ as in (4.10), is optimal for $V_1(x_1)$. Similarly, if $x_2 > 0$, the pair $(\pi^{(2)}, 0)$ of Theorem 5.2, with $y = \mathcal{Q}_2(x_2)$ and corresponding wealth process $X^{(2)}$ as in (5.8), is optimal for $V_2(x_2)$. Now let $\tilde{C} \triangleq C^{(1)}$, $\tilde{\pi} \triangleq \pi^{(1)} + \pi^{(2)}$ and observe from (4.10), (5.8) that $\tilde{X} \triangleq X^{(1)} + X^{(2)}$ can be written in the form (2.19):

$$\begin{aligned} \tilde{X}_t \exp \left(- \int_0^t r(u) du \right) &= x - \int_0^t \tilde{C}_s \exp \left(- \int_0^s r(u) du \right) ds \\ &\quad + \int_0^t \exp \left(- \int_0^s r(u) du \right) \tilde{\pi}^T(s) \sigma(s) d\tilde{W}_s \\ (6.5) \quad &= \tilde{E} \left[\int_t^T \tilde{C}_s \exp \left(- \int_0^s r(u) du \right) ds \right. \\ &\quad \left. + \tilde{X}_T \exp \left(- \int_0^T r(u) du \right) \middle| \mathcal{F}_t \right] \end{aligned}$$

because $X_T^{(1)} = 0$, a.s. The process \tilde{X} is nonnegative, and thus $(\tilde{\pi}, \tilde{C}) \in \mathcal{A}_{1,2}(x)$. Now C belongs to $\mathcal{D}(x_1)$ and satisfies (4.2), whereas X_T belongs to $\mathcal{L}(x_2)$ and satisfies (5.2);

from (4.11), (4.12) and (5.9), (5.10) we obtain the following comparisons:

$$E \int_0^T \exp \left(- \int_0^t \beta(u) du \right) U_1(C_t) dt \leq E \int_0^T \exp \left(- \int_0^t \beta(u) du \right) U_1(C_t^{(1)}) dt = V_1(x_1),$$

$$E \left[\exp \left(- \int_0^T \beta(u) du \right) U_2(X_T) \right] \leq E \left[\exp \left(- \int_0^T \beta(u) du \right) U_2(X_T^{(2)}) \right] = V_2(x_2).$$

Memberwise addition leads to (6.3). The identity in (6.4) is a consequence of Propositions 4.4 and 5.3. \square

Remarks 4.5 and 5.4 show that for any initial endowment $x > 0$, the maximum over $x_1, x_2 \in [0, \infty)$, $x_1 + x_2 = x$ indicated in (6.4) is obtained by $x_1 > 0$, $x_2 > 0$ which satisfy $V_1'(x_1) = V_2'(x_2)$. Recalling from these remarks that $\mathcal{V}_i(x_i) = V_i'(x_i)$; $i = 1, 2$, we conclude that the constrained maximization in the last expression of (6.4) is achieved by

$$y_1 = y_2 \equiv y$$

where this common value is determined uniquely by

$$(6.6) \quad \mathcal{X}_1(y) + \mathcal{X}_2(y) = x.$$

With y specified by (6.6), we recall the process ζ of (4.4) and set:

$$(6.7) \quad C_t^* \triangleq I_1(y\zeta_t), \quad X_T^* \triangleq I_2(y\zeta_T),$$

$$(6.8) \quad X_t^* \triangleq \tilde{E} \left[\int_t^T C_s^* \exp \left(- \int_t^s r(u) du \right) ds + X_T^* \exp \left(- \int_t^T r(u) du \right) \middle| \mathcal{F}_t \right]$$

for $0 \leq t \leq T$. The process X^* is nonnegative with

$$X_0^* = \tilde{E} \int_0^T I_1(y\zeta_s) \exp \left(- \int_0^s r(u) du \right) ds + \tilde{E} \left[\exp \left(- \int_0^T r(u) du \right) I_2(y\zeta_T) \right]$$

$$= \mathcal{X}_1(y) + \mathcal{X}_2(y) = x.$$

Remark 2.7, Corollary 2.9 and the idea of superposition of portfolio, consumption and wealth processes as in the proof of Proposition 6.1 can be employed to show that X^* is the wealth process corresponding to the pair $(\pi^*, C^*) \in \mathcal{A}_{1,2}(x)$, for a suitable portfolio π^* .

THEOREM 6.2. *The above pair $(\pi^*, C^*) \in \mathcal{A}_{1,2}(x)$ is optimal for the problem (6.2).*

Proof. From (4.17), (5.12) and (6.4) we have

$$(6.9) \quad V(x) \geq E \left[\int_0^T \exp \left(- \int_0^t \beta(u) du \right) U_1(C_t^*) dt \right. \\ \left. + \exp \left(- \int_0^T \beta(u) du \right) U_2(X_T^*) \right]$$

$$= E \left[\int_0^T \exp \left(- \int_0^t \beta(u) du \right) U_1(I_1(y\zeta_t)) dt \right]$$

$$+ E \left[\exp \left(- \int_0^T \beta(u) du \right) U_2(I_2(y\zeta_T)) \right]$$

$$= G_1(y) + G_2(y) = V_*(x) \geq V(x),$$

because the value of $y > 0$ determined by (6.6) achieves the maximum in (6.4). \square

Remark 6.3. The functions

$$(6.10) \quad \begin{aligned} \mathcal{X}(y) &\triangleq \mathcal{X}_1(y) + \mathcal{X}_2(y) \\ &= \tilde{E} \left[\int_0^T \exp \left(- \int_0^t r(u) du \right) I_1(y \zeta_t) dt + \exp \left(- \int_0^T r(u) du \right) I_2(y \zeta_T) \right], \end{aligned}$$

$$(6.11) \quad \begin{aligned} G(y) &\triangleq G_1(y) + G_2(y) \\ &= E \left[\int_0^T \exp \left(- \int_0^t \beta(u) du \right) U_1(I_1(y \zeta_t)) dt \right. \\ &\quad \left. + \exp \left(- \int_0^T \beta(u) du \right) U_2(I_2(y \zeta_T)) \right], \end{aligned}$$

are C^1 and strictly decreasing on $(0, \infty)$, and satisfy

$$(6.12) \quad G'(y) = y \mathcal{X}'(y)$$

there (cf. (4.18), (5.13)). The former actually maps $[0, \infty]$ onto itself, with $\mathcal{X}(0) = \infty$, $\mathcal{X}(\infty) = 0$; if we denote its inverse by $\mathcal{Y}: [0, \infty] \rightarrow^{\text{onto}} [0, \infty]$, then (6.9) and (6.6) show that the value function V of (6.2) is representable as

$$(6.13) \quad V(x) = G(\mathcal{Y}(x)), \quad 0 < x < \infty.$$

As in Remarks 4.5 and 5.4, V is strictly concave with $V'(0) = \infty$ and $V'(x) = \mathcal{Y}(x)$; $0 \leq x < \infty$. It is shown in the next section that the functions \mathcal{X} , G (and thus also V) above can be computed *in closed form* in the case of constant coefficients β , r , b and σ , for fairly general utility functions U_1 , U_2 .

Example 6.4. In the case $U_1(c) = U_2(c) = \log c$, the functions of (6.10), (6.11) and (6.13) are given by

$$\mathcal{X}(y) = \frac{\alpha}{y}, \quad G(y) = -\alpha \cdot \log y + \delta, \quad 0 < y < \infty$$

and

$$V(x) = \alpha \cdot \log \left(\frac{x}{\alpha} \right) + \delta, \quad 0 < x < \infty$$

where $\alpha \triangleq \alpha_1 + \alpha_2$, $\delta \triangleq \delta_1 + \delta_2$ in the notation of Remarks 4.7 and 5.5.

7. Model with constant coefficients. The developments in §§ 4–6 were based on martingale methods and provided useful and very explicit information about the optimal consumption and wealth processes, in the respective problems treated there. Concerning the optimal portfolio process, however, these methods were able to ascertain only its existence, without shedding much light on its properties or providing any useful characterizations. In order to amend this drawback, we shall specialize in this section the model to the case of *constant coefficients*

$$(7.1) \quad \beta(t) \equiv \beta, \quad r(t) \equiv r, \quad b(t) \equiv b, \quad \sigma(t) \equiv \sigma, \quad 0 \leq t \leq T$$

where β , r are given real number, b is a fixed vector in \mathcal{R}^d and σ is a constant, nonsingular $(d \times d)$ -matrix. The section culminates with Theorem 7.7, which provides the optimal portfolio/consumption pair in a closed and “feedback” form.

It will be assumed throughout that the utility functions U_j ; $j=1, 2$ satisfy the conditions of § 3, including (3.2); in addition, it will be supposed that they are of class C^3 and

$$(7.2) \quad \lim_{c \downarrow 0} \frac{(U'_j(c))^2}{U''_j(c)} \text{ exists,}$$

$$(7.3) \quad \lim_{c \rightarrow \infty} \frac{(U'_j(c))^\alpha}{U''_j(c)} = 0 \quad \text{for some } \alpha > 2,$$

$$(7.4) \quad U_j(0) > -\infty$$

hold for $j=1, 2$. These are certainly not the weakest conditions which permit the ensuing analysis, but they are convenient for our purposes. Furthermore, they include all of the so-called HARA functions (see KLSS (1986) for a definition) except for $U_j(c) = \log c$. We have dealt with this case separately, however, in Remarks 4.7 and 5.5.

The assumption of constant coefficients will permit us to employ "Markovian" methods, such as the Hamilton-Jacobi-Bellman (HJB) equation of Dynamic Programming (Proposition 7.6), in contrast to the "martingale" techniques of the previous sections. In this regard, it will be helpful to consider the problem of § 6 with initial times other than zero. Thus, for fixed $(t, x) \in [0, T] \times (0, \infty)$, we define the value function

$$(7.5) \quad V(t, x) = \sup_{(\pi, C) \in \mathcal{A}(t, x)} E \left[\int_t^T e^{-\beta s} U_1(C_s) ds + e^{-\beta T} U_2(X_T) \right]$$

where the class $\mathcal{A}(t, x)$ consists of those portfolio/consumption process pairs for which the corresponding wealth process

$$(7.6) \quad \begin{aligned} X_s = x + \int_t^s (rX_u - C_u) du + \sum_{i=1}^d \int_t^s (b_i - r) \pi_i(u) du \\ + \sum_{i=1}^d \sum_{j=1}^d \int_t^s \pi_i(u) \sigma_{ij} dW_u^{(j)}, \quad t \leq s \leq T \end{aligned}$$

remains nonnegative, almost surely. Corresponding to a given consumption process C , there exists a portfolio π with $(\pi, C) \in \mathcal{A}(t, x)$ if and only if

$$E \int_t^T Z_t^s e^{-r(s-t)} C_s ds \leq x$$

(Proposition 2.6), where we employ the notation

$$(7.7) \quad Z_s^t \triangleq \exp \{ -\theta^T (W_s - W_t) - \frac{1}{2} \|\theta\|^2 (s-t) \}, \quad \zeta_s^t \triangleq e^{(\beta-r)(s-t)} Z_s^t, \quad t \leq s \leq T.$$

Now for $(t, y) \in [0, T] \times (0, \infty)$ we consider the process

$$(7.8) \quad Y_s^{(t, y)} \triangleq y \zeta_s^t, \quad t \leq s \leq T$$

and the functions

$$(7.9) \quad G(t, y) \triangleq E \left[\int_t^T e^{-\beta(s-t)} U_1(I_1(Y_s^{(t, y)})) ds + e^{-\beta(T-t)} U_2(I_2(Y_T^{(t, y)})) \right],$$

$$(7.10) \quad S(t, y) \triangleq E \left[\int_t^T e^{-\beta(s-t)} Y_s^{(t, y)} I_1(Y_s^{(t, y)}) ds + e^{-\beta(T-t)} Y_T^{(t, y)} I_2(Y_T^{(t, y)}) \right],$$

$$(7.11) \quad \mathcal{X}(t, y) \triangleq \frac{S(t, y)}{y}.$$

We shall show (Lemmas 7.1, 7.2) that G and S are well defined and finite, and then just as in Lemma 4.2, we have that for every $0 \leq t < T$ the function $\mathcal{X}(t, \cdot)$ is continuous and strictly decreasing on $(0, \infty)$, with $\mathcal{X}(t, 0) \triangleq \lim_{y \downarrow 0} \mathcal{X}(t, y) = \infty$ and $\mathcal{X}(t, \infty) \triangleq \lim_{y \rightarrow \infty} \mathcal{X}(t, y) = 0$. We denote by $\mathcal{Y}(t, \cdot): [0, \infty] \rightarrow_{\text{onto}} [0, \infty]$ the inverse of $\mathcal{X}(t, \cdot)$, namely

$$(7.12) \quad \mathcal{Y}(t, \mathcal{X}(t, y)) = y, \quad 0 \leq t < T, \quad 0 \leq y \leq \infty.$$

If we define, for any given $x > 0$, the processes

$$(7.13) \quad \eta_s^{(t,x)} \triangleq \mathcal{Y}(t, x) \cdot \xi_s^t,$$

$$(7.14) \quad C_s^{(t,x)} \triangleq I_1(\eta_s^{(t,x)}), \quad t \leq s \leq T$$

and the random variable

$$(7.15) \quad X_T^{(t,x)} \triangleq I_2(\eta_T^{(t,x)}),$$

then we can show, as in Theorem 6.2, that

$$(7.16) \quad V(t, x) = E \left[\int_t^T e^{-\beta s} U_1(C_s^{(t,x)}) ds + e^{-\beta T} U_2(X_T^{(t,x)}) \right].$$

The new feature here is that, for $y = \mathcal{Y}(t, x)$, one has $\eta^{(t,x)} = Y^{(t,y)}$ from (7.8), (7.13), and consequently

$$(7.17) \quad V(t, x) = e^{-\beta t} G(t, \mathcal{Y}(t, x)), \quad 0 \leq t \leq T, \quad 0 < x < \infty.$$

On the other hand, by analogy with (6.8), the optimal wealth process is seen to be as follows:

$$(7.18) \quad \begin{aligned} X_s^{(t,x)} &\triangleq E \left[\int_s^T e^{-r(\theta-s)} Z_\theta^s I_1(\eta_\theta^{(t,x)}) d\theta + e^{-r(T-s)} Z_T^s I_2(\eta_T^{(t,x)}) \middle| \mathcal{F}_s \right] \\ &= \frac{1}{Y_s^{(t,y)}} E \left[\int_s^T e^{-\beta(\theta-s)} Y_\theta^{(t,y)} I_1(Y_\theta^{(t,y)}) d\theta + e^{-\beta(T-t)} Y_T^{(t,y)} I_2(Y_T^{(t,y)}) \middle| \mathcal{F}_s \right] \\ &\equiv \frac{S(s, Y_s^{(t,y)})}{Y_s^{(t,y)}} = \mathcal{X}(s, \eta_s^{(t,x)}), \quad t \leq s \leq T, \end{aligned}$$

almost surely. In (7.18) we used the “Bayes rule” for conditional expectations under the measure $Z_\theta^t dP$ (cf. proof of Proposition 2.6) and the Markov property for $\{Y_s^{(t,y)}, \mathcal{F}_s; t \leq s \leq T\}$.

Our program now is to characterize G, S of (7.9), (7.10) in terms of two Cauchy problems involving the *linear* differential operator

$$L\varphi(t, y) \triangleq \gamma y^2 \frac{\partial^2 \varphi(t, y)}{\partial y^2} + (\beta - r)y \frac{\partial \varphi(t, y)}{\partial y} - \beta \varphi(t, y),$$

where

$$\gamma \triangleq \frac{1}{2} \|\theta\|^2, \quad \theta \triangleq \sigma^{-1}(b - r\mathbf{1})$$

in accordance with (2.15). We shall produce *closed-form* solutions for these Cauchy problems (7.23), (7.24) and (7.25), (7.26), and thus also for the function $\mathcal{X}(t, y)$ of (7.11). In this manner, an expression for the value function $V(t, x)$ will be made available via (7.17).

We shall need the following Feynman–Kac result, whose proof is deferred to the Appendix.

LEMMA 7.1. Let the real-valued function $q(t, y)$ be defined and continuous on $[0, T] \times (0, \infty)$, as well as Hölder continuous in y uniformly with respect to (t, y) on compact subsets of the domain. Also, let $f: (0, \infty) \rightarrow \mathbb{R}$ be continuous, and assume that both q, f satisfy a growth condition of the form

$$(7.19) \quad \max_{0 \leq t \leq T} |u(t, y)| \leq K(1 + y^\alpha + y^{-\alpha}), \quad 0 < y < \infty$$

for some $K > 0$, $\alpha > 0$. Then the function

$$(7.20) \quad H(t, y) = E \left[\int_t^T e^{-\beta(s-t)} q(s, Y_s^{(t,y)}) ds + e^{-\beta(T-t)} f(Y_T^{(t,y)}) \right]$$

solves the Cauchy problem

$$(7.21) \quad \left(\frac{\partial}{\partial t} + L \right) H(t, y) + q(t, y) = 0, \quad 0 \leq t < T, \quad 0 < y < \infty$$

$$(7.22) \quad H(T, y) = f(y), \quad 0 < y < \infty,$$

and is actually the unique solution of (7.21), (7.22) in the class of $C([0, T] \times (0, \infty)) \cap C^{1,2}([0, T) \times (0, \infty))$ functions which satisfy a growth condition of the type (7.19). \square

We shall use Lemma 7.1 to characterize G and S as the unique solutions to the Cauchy problems

$$(7.23) \quad \left(\frac{\partial}{\partial t} + L \right) G(t, y) + U_1(I_1(y)) = 0, \quad 0 \leq t < T, \quad 0 < y < \infty,$$

$$(7.24) \quad G(T, y) = U_2(I_2(y)), \quad 0 < y < \infty,$$

and

$$(7.25) \quad \left(\frac{\partial}{\partial t} + L \right) S(t, y) + yI_1(y) = 0, \quad 0 \leq t < T, \quad 0 < y < \infty,$$

$$(7.26) \quad S(T, y) = yI_2(y), \quad 0 < y < \infty,$$

respectively. We will then solve these Cauchy problems explicitly. For this second task, we introduce the function

$$(7.27) \quad v(t, y, \xi) \triangleq \begin{cases} \xi e^{-\beta(T-t)} \Phi(-\mu_-(T-t, y, \xi)) - y e^{-r(T-t)} \Phi(-\mu_+(T-t, y, \xi)), & 0 \leq t < T, \\ (\xi - y)^+, & t = T, \end{cases}$$

for $0 < y, \xi < \infty$, where

$$\Phi(z) \triangleq \frac{1}{\sqrt{2\pi}} \int_{-\infty}^z e^{-x^2/2} dx, \quad \mu_{\pm}(t, y, \xi) = \frac{1}{\sqrt{2\gamma t}} \left[\log \left(\frac{y}{\xi} \right) + (\beta - r \pm \gamma)t \right].$$

Straightforward computation shows that, for fixed ξ , v is of class $C([0, T] \times (0, \infty)) \cap C^{1,2}([0, T) \times (0, \infty))$ and solves the Cauchy problem

$$(7.28) \quad \left(\frac{\partial}{\partial t} + L \right) v(t, y, \xi) = 0, \quad 0 \leq t < T, \quad 0 < y < \infty,$$

$$(7.29) \quad v(T, y, \xi) = (\xi - y)^+, \quad 0 < y < \infty.$$

It is apparent that for $0 \leq t \leq T$,

$$(7.30) \quad \overline{\lim}_{y \rightarrow \infty} \frac{|v(t, y, \xi)|}{y} < \infty, \quad \overline{\lim}_{\xi \rightarrow \infty} \frac{|v(t, y, \xi)|}{\xi} < \infty,$$

and from the Mills' ratio (e.g. McKean (1969, p. 4))

$$\sqrt{2\pi}\Phi(-z) \leq \frac{1}{z} e^{-z^2/2}$$

one can also establish that for every $\alpha > 0$,

$$(7.31) \quad \overline{\lim}_{y \downarrow 0} y^{-\alpha} |v(t, y, \xi)| < \infty, \quad \overline{\lim}_{\xi \downarrow 0} \xi^{-\alpha} |v(t, y, \xi)| < \infty.$$

In particular, for each fixed $0 < \xi < \infty$, Lemma 7.1 can be invoked to provide the stochastic representation

$$(7.32) \quad v(t, y, \xi) = E[e^{-\beta(T-t)}(\xi - Y_T^{(t,y)})^+].$$

We also introduce the functions

$$(7.33) \quad g(y) \triangleq \frac{U_1(I_1(y))}{\beta} - \frac{1}{\gamma(\lambda_+ - \lambda_-)} \left\{ \frac{y^{1+\lambda_+}}{1+\lambda_+} J_+(y) - \frac{y^{1+\lambda_-}}{1+\lambda_-} J_-(y) \right\},$$

$$(7.34) \quad s(y) \triangleq \frac{yI_1(y)}{r} - \frac{1}{\gamma(\lambda_+ - \lambda_-)} \left\{ \frac{y^{1+\lambda_+}}{\lambda_+} J_+(y) - \frac{y^{1+\lambda_-}}{\lambda_-} J_-(y) \right\},$$

where

$$(7.35) \quad J_+(y) = \int_0^{I_1(y)} \frac{d\eta}{(U'_1(\eta))^{\lambda_+}}, \quad J_-(y) = \int_1^{I_1(y)} \frac{d\eta}{(U'_1(\eta))^{\lambda_-}},$$

and λ_+ , λ_- are the positive and negative roots, respectively, of the quadratic equation

$$(7.36) \quad \gamma\lambda^2 - (r - \beta - \gamma)\lambda - r = 0.$$

Note that $\lambda_+\lambda_- = -r/\gamma$, $(1+\lambda_+)(1+\lambda_-) = -\beta/\gamma$, and $\lambda_- < -1$. Direct computation shows that

$$(7.37) \quad g'(y) = -\frac{1}{\gamma(\lambda_+ - \lambda_-)} \{y^{\lambda_+} J_+(y) - y^{\lambda_-} J_-(y)\},$$

$$(7.38) \quad g''(y) = -\frac{1}{\gamma(\lambda_+ - \lambda_-)} \{\lambda_+ y^{\lambda_+-1} J_+(y) - \lambda_- y^{\lambda_--1} J_-(y)\},$$

$$(7.39) \quad s'(y) = \frac{I_1(y)}{r} - \frac{1}{\gamma(\lambda_+ - \lambda_-)} \left\{ \frac{1+\lambda_+}{\lambda_+} y^{\lambda_+} J_+(y) - \frac{1+\lambda_-}{\lambda_-} y^{\lambda_-} J_-(y) \right\},$$

$$(7.40) \quad s''(y) = -\frac{1}{\gamma(\lambda_+ - \lambda_-)} \{(1+\lambda_+)y^{\lambda_+-1} J_+(y) - (1+\lambda_-)y^{\lambda_--1} J_-(y)\},$$

and

$$(7.41) \quad Lg(y) + U_1(I_1(y)) = 0,$$

$$(7.42) \quad Ls(y) + yI_1(y) = 0.$$

Our arguments will utilize the following growth, integrability, and limit properties, whose proofs are deferred to the Appendix.

LEMMA 7.2. *Each of the functions $g(y)$, $s(y)$, $U_j(I_j(y))$, $yI_j(y)$; $j = 1, 2$, satisfies the growth condition (7.19) for some $K > 0$, $\alpha > 0$. Furthermore, each of these functions is of class $C^2(0, \infty)$ and satisfies the integrability conditions*

$$(7.43) \quad \int_1^\infty \xi |f''(\xi)| d\xi < \infty, \quad \int_0^1 \xi^\alpha |f''(\xi)| d\xi < \infty$$

for some $\alpha > 0$. Finally, the limit property

$$(7.44) \quad \lim_{\xi \rightarrow \infty} \xi f'(\xi) = 0$$

holds for each of the above-named functions. For $s(y)$, $yI_j(y)$; $j = 1, 2$ we have

$$(7.45) \quad \lim_{\xi \rightarrow \infty} f(\xi) = 0,$$

whereas

$$(7.46) \quad \lim_{\xi \rightarrow \infty} g(\xi) = \frac{U_1(0)}{\beta}, \quad \lim_{\xi \rightarrow \infty} U_j(I_j(\xi)) = U_j(0), \quad j = 1, 2. \quad \square$$

Lemmas 7.1 and 7.2 imply that G and S , defined by (7.9) and (7.10), are indeed characterized by the Cauchy problems (7.23), (7.24) and (7.25), (7.26).

PROPOSITION 7.3. *The functions G , S of (7.9), (7.10) admit the following stochastic representations:*

$$(7.47) \quad G(t, y) = g(y) + E[e^{-\beta(T-t)}\{U_2(I_2(Y_T^{(t,y)})) - g(Y_T^{(t,y)})\}],$$

$$(7.48) \quad S(t, y) = s(y) + E[e^{-\beta(T-t)}\{Y_T^{(t,y)}I_2(Y_T^{(t,y)}) - s(Y_T^{(t,y)})\}],$$

and are expressible in closed form as

$$(7.49) \quad G(t, y) = g(y) + \left(U_2(0) - \frac{U_1(0)}{\beta} \right) e^{-\beta(T-t)} + \int_0^\infty (U_2(I_2(\xi)) - g(\xi))'' v(t, y, \xi) d\xi,$$

$$(7.50) \quad S(t, y) = s(y) + \int_0^\infty (\xi I_2(\xi) - s(\xi))'' v(t, y, \xi) d\xi.$$

Proof. We deal with the function G only; the treatment for S is similar. Because of the growth assertions in Lemma 7.2 and the special form (7.7), (7.8) of $Y^{(t,y)}$, the functions $G_1(t, y) \triangleq g(y)$, $G_2(t, y) \triangleq E[e^{-\beta(T-t)}U_2(I_2(Y_T^{(t,y)}))]$ and $G_3(t, y) \triangleq E[-e^{-\beta(T-t)}g(Y_T^{(t,y)})]$, as well as their sum $\hat{G} \triangleq G_1 + G_2 + G_3$, satisfy growth conditions of the type (7.19). By virtue of (7.41) and Lemma 7.1, these functions satisfy in $[0, T) \times (0, \infty)$ the equations

$$\left(\frac{\partial}{\partial t} + L \right) G_1(t, y) + U_1(I_1(y)) = 0, \quad \left(\frac{\partial}{\partial t} + L \right) G_j(t, y) = 0, \quad j = 2, 3,$$

and the terminal conditions

$$G_2(T, y) = U_2(I_2(y)), \quad G_1(T, y) = -G_3(T, y) = g(y).$$

Thus \hat{G} solves the Cauchy problem (7.23), (7.24) which characterizes G ; (7.47) follows.

Turning to (7.49), we note first that the integral on the right-hand side is defined because of (7.30), (7.31), (7.43). In conjunction with Fubini's Theorem, (7.32) yields

$$(7.51) \quad \begin{aligned} & \int_0^\infty (U_2(I_2(\xi)) - g(\xi))'' v(t, y, \xi) d\xi \\ &= E \int_0^\infty e^{-\beta(T-t)} (U_2(I_2(\xi)) - g(\xi))'' (\xi - Y_T^{(t,y)})^+ d\xi. \end{aligned}$$

Integration by parts shows that

$$\int_0^\infty f''(\xi)(\xi - y)^+ d\xi = f(y) + \lim_{\xi \rightarrow \infty} \xi f'(\xi) - \lim_{\xi \rightarrow \infty} f(\xi)$$

for any function f for which the limits are defined. Relations (7.44)–(7.46) thus allow us to evaluate (7.51) and discover that (7.49) is equivalent to (7.47). \square

Remark 7.4. The nonnegative function $\mathcal{X}(t, y)$ of (7.11) satisfies the Cauchy problem

$$(7.52) \quad \mathcal{X}_t(t, y) + \gamma y^2 \mathcal{X}_{yy}(t, y) + (\beta - r + 2\gamma)y \mathcal{X}_y - r \mathcal{X}(t, y) + I_1(y) = 0, \\ 0 \leq t < T, \quad 0 < y < \infty,$$

$$(7.53) \quad \mathcal{X}(T, y) = I_2(y), \quad 0 < y < \infty.$$

For its inverse $\mathcal{Y}(t, x)$, as in (7.21), we have

$$(7.54) \quad \mathcal{Y}_x(t, \mathcal{X}(t, y)) = \frac{1}{\mathcal{X}_y(t, y)} < 0, \quad \mathcal{Y}_t(t, \mathcal{X}(t, y)) = -\frac{\mathcal{X}_t(t, y)}{\mathcal{X}_y(t, y)}.$$

Furthermore, it can be shown by analogy with (6.12) that

$$(7.55) \quad G_y(t, y) = y \cdot \mathcal{X}_y(t, y), \quad 0 \leq t < T, \quad 0 < y < \infty.$$

Example 7.5. In the special case $U_1(c) = U_2(c) = c^\delta$ for some $\delta \in (0, 1)$, we set

$$k = \frac{1}{1-\delta} \left(\beta - r\delta - \frac{\gamma\delta}{1-\delta} \right)$$

and

$$p(t) = \begin{cases} \frac{1 - e^{-k(T-t)}}{k} + e^{-k(T-t)}, & k \neq 0, \\ 1 + T - t, & k = 0. \end{cases}$$

Then

$$G(t, y) = p(t) \left(\frac{y}{\delta} \right)^{\delta/(\delta-1)}, \quad S(t, y) = \delta G(t, y), \quad \mathcal{X}(t, y) = p(t) \left(\frac{y}{\delta} \right)^{1/(\delta-1)},$$

and

$$V(t, x) = e^{-\beta t} (p(t))^{1-\delta} x^\delta.$$

PROPOSITION 7.6. *The function $V(t, x) : [0, T] \times \mathcal{R} \rightarrow \mathcal{R}$ of (7.16) satisfies the following initial-boundary value problem for the Hamilton–Jacobi–Bellman (HJB) equation of dynamic programming, associated with the stochastic control problem (7.5) and the dynamics (7.6):*

(7.56)

$$V_t(t, x) + \max_{\substack{c \geq 0 \\ \pi \in \mathcal{R}^d}} \left[\frac{1}{2} \|\sigma^T \pi\|^2 \cdot V_{xx}(t, x) + \{(rx - c) + \pi^T(b - r\mathbf{1})\} \cdot V_x(t, x) + e^{-\beta t} U_1(c) \right] = 0 \\ \text{in } [0, T) \times (0, \infty),$$

(7.57)

$$V(T, x) = e^{-\beta T} U_2(x), \quad 0 \leq x < \infty,$$

(7.58)

$$V(t, 0) = \left(U_2(0) - \frac{U_1(0)}{\beta} \right) e^{-\beta T} + \frac{U_1(0)}{\beta} e^{-\beta t}, \quad 0 \leq t \leq T.$$

Proof. The last two conditions are quite obvious; on the other hand, if we recall the expression (7.17) for V , we can cast the HJB equation (7.56), with the help of (7.54), (7.55), in the form

$$(7.59) \quad G_t(t, \mathcal{Y}(t, x)) - \beta G(t, \mathcal{Y}(t, x)) + G_y(t, \mathcal{Y}(t, x)) \mathcal{Y}_t(t, x) + rx \mathcal{Y}(t, x) \\ + \max_{c \geq 0} [U_1(c) - c \mathcal{Y}(t, x)] + \max_{\pi \in \mathcal{R}^d} \left[\frac{1}{2} \|\sigma^T \pi\|^2 \mathcal{Y}_x(t, x) + \pi^T(b - r\mathbf{1}) \mathcal{Y}(t, x) \right] = 0.$$

The maximizations over $c \geq 0$, $\pi \in \mathcal{R}^d$ are achieved by

$$(7.60) \quad \hat{c} = I_1(\mathcal{Y}(t, x)),$$

and

$$(7.61) \quad \hat{\pi} = -(\sigma\sigma^T)^{-1}(b - r\mathbf{1}) \frac{\mathcal{Y}(t, x)}{\mathcal{Y}_x(t, x)},$$

respectively. Substitution of these values into the right-hand side of (7.59) makes the latter read as follows:

$$\begin{aligned} G_t(t, \mathcal{Y}(t, x)) - \beta G(t, \mathcal{Y}(t, x)) + G_y(t, \mathcal{Y}(t, x)) \cdot \mathcal{Y}_t(t, x) + \{rx - I_1(\mathcal{Y}(t, x))\} \mathcal{Y}(t, x) \\ - \gamma \frac{\mathcal{Y}^2(t, x)}{\mathcal{Y}_x(t, x)} + U_1(I_1(\mathcal{Y}(t, x))), \end{aligned}$$

or equivalently, with the change of variable $y = \mathcal{Y}(t, x)$ and the help of (7.23):

$$\begin{aligned} G_t(t, y) - \beta G(t, y) - y\mathcal{X}_t(t, y) + ry\mathcal{X}(t, y) - yI_1(y) - \gamma y^2\mathcal{X}_y(t, y) + U_1(I_1(y)) \\ = y[-\mathcal{X}_t(t, y) + r\mathcal{X}(t, y) - (\beta - r + 2\gamma)y\mathcal{X}_y(t, y) - \gamma y^2\mathcal{X}_{yy}(t, y) - I_1(y)]. \end{aligned}$$

But this last expression vanishes, thanks to (7.52). \square

Notice that we have achieved a closed-form solution of the *strongly nonlinear* HJB equation (7.56), by solving instead the two *linear* equations (7.23), (7.25) subject to the appropriate initial and growth conditions, and then performing the composition (7.17).

The functional form of the maximizers in (7.60), (7.61) now suggests very strongly the nature of an optimal portfolio/consumption process pair in *feedback form*, i.e., in terms of the current level of wealth. Let us recall from (7.18) the optimal wealth process $X^{(t,x)}$ for the problem (7.5).

THEOREM 7.7. *The pair $(\pi^{(t,x)}, C^{(t,x)})$ given by*

$$(7.62) \quad C_s^{(t,x)} = I_1(\mathcal{Y}(s, X_s^{(t,x)})),$$

$$(7.63) \quad \pi_s^{(t,x)} \triangleq -(\sigma\sigma^T)^{-1}(b - r\mathbf{1}) \frac{\mathcal{Y}(s, X_s^{(t,x)})}{\mathcal{Y}_x(s, X_s^{(t,x)})}$$

for $t \leq s \leq T$, belongs to $\mathcal{A}(t, x)$ and is optimal for the stochastic control problem of (7.5).

Proof. It suffices to show that $X^{(t,x)}$ is the wealth process corresponding to the pair $(\pi^{(t,x)}, C^{(t,x)})$ above. Now (7.62) is just a restatement of (7.14), because of (7.18); applying Itô's rule to the latter, in conjunction with

$$d\eta_s^{(t,x)} = (\beta - r)\eta_s^{(t,x)} ds - \eta_s^{(t,x)} \theta^T dW_s, \quad t \leq s \leq T, \quad \eta_t^{(t,x)} = x$$

and (7.52), we obtain:

$$\begin{aligned} dX_s^{(t,x)} &= \mathcal{X}_t(s, \eta_s^{(t,x)}) ds + \mathcal{X}_y(s, \eta_s^{(t,x)}) d\eta_s^{(t,x)} + \gamma(\eta_s^{(t,x)})^2 \mathcal{X}_{yy}(s, \eta_s^{(t,x)}) ds \\ &= (rX_s^{(t,x)} - C_s^{(t,x)}) ds + (b - r\mathbf{1})^T \pi_s^{(t,x)} ds + (\pi_s^{(t,x)})^T \sigma dW_s. \end{aligned}$$

But this is equation (7.6) in differential form. \square

Example 7.5 (continued). In this case (7.62), (7.63) read as follows:

$$C_s^{(t,x)} = \frac{X_s^{(t,x)}}{p(s)}, \quad \pi_s^{(t,x)} = (\sigma\sigma^T)^{-1}(b - r\mathbf{1}) \frac{X_s^{(t,x)}}{1 - \delta}, \quad t \leq s \leq T.$$

8. Appendix.

Proof of Lemma 7.1. For any solution $H(t, y)$ of (7.21), (7.22) in the indicated class, the function $\mathcal{H}(t, z) \triangleq H(t, e^z)$:

- (i) belongs to $C([0, T] \times \mathcal{R}) \cap C^{1,2}([0, T] \times \mathcal{R})$,
- (ii) satisfies a growth condition of the type

$$(8.1) \quad \max_{0 \leq t \leq T} |\mathcal{H}(t, z)| \leq M e^{\alpha|z|}, \quad z \in \mathcal{R}$$

for some $M > 0$, $\alpha > 0$, and

(iii) solves the Cauchy problem with constant coefficients

$$(8.2) \quad \mathcal{H}_t + \gamma \mathcal{H}_{zz} + (\beta - r - \gamma) \mathcal{H}_z - \beta \mathcal{H} + q(t, e^z) = 0, \quad [0, T] \times \mathcal{R},$$

$$(8.3) \quad \mathcal{H}(T, z) = f(e^z), \quad z \in \mathcal{R}.$$

Conversely, if $\mathcal{H}(t, z)$ is a function which satisfies (i)–(iii) above, then $H(t, y) \triangleq \mathcal{H}(t, \log y)$ belongs to $C([0, T] \times (0, \infty)) \cap C^{1,2}([0, T] \times (0, \infty))$, satisfies the Cauchy problem (7.21)–(7.22), as well as a growth condition of the type (7.19).

For every given $(t, z) \in [0, T] \times \mathcal{R}$, let us now consider the process

$$L_s^{(t,z)} \triangleq z + (\beta - r - \gamma)(s - t) - \theta^T(W_s - W_t), \quad t \leq s \leq T.$$

Friedman (1975, Thm. 6.4.6, p. 142) proves the existence of a function $\mathcal{H}(t, z)$ with properties (i) and (iii) and satisfying the growth condition

$$\max_{0 \leq t \leq T} |\mathcal{H}(t, z)| \leq M e^{\varepsilon z^2}, \quad z \in \mathcal{R}$$

for every $\varepsilon > 0$ and some $M = M(\varepsilon)$. According to Karatzas and Shreve (1987, Problem 5.7.7), this function is unique and has the stochastic representation

$$\mathcal{H}(t, z) = E \left[\int_t^T e^{-\beta(s-t)} q(s, \exp(L_s^{(t,z)})) ds + e^{-\beta(T-t)} f(\exp(L_T^{(t,z)})) \right],$$

from which one can obtain the growth condition (8.1). If we take $\log y = z$, then $\log Y_s^{(t,y)} = L_s^{(t,z)}$, and $H(t, y) \triangleq \mathcal{H}(t, \log y)$ is given by the right-hand side of (7.20) and satisfies the assertions of the lemma. \square

Proof of Lemma 7.2. We simplify the notation by writing $U = U_1$, $I = I_1$. We assume that

$$(8.4) \quad U'(0) = \infty,$$

for when $U'(0) < \infty$ we have $I(y) = 0$ for y sufficiently large, and then the assertions of the lemma are more easily proved. We observe from concavity that $cU'(c) \leq U(c) - U(0)$, so according to (7.4),

$$(8.5) \quad \lim_{c \downarrow 0} cU'(c) = 0.$$

From (8.4), (8.5) and the Fundamental Theorem of Calculus,

$$\lim_{c \downarrow 0} \frac{U''(c)}{(U'(c))^2} = \lim_{c \downarrow 0} \frac{1}{c} \int_0^c \frac{U''(\eta)}{(U'(\eta))^2} d\eta = -\lim_{c \downarrow 0} \frac{1}{cU'(c)} = \infty,$$

so in the presence of (8.4), (8.5) the existence of the limit in (7.2) implies the stronger statement:

$$(8.6) \quad \lim_{c \downarrow 0} \frac{(U'(c))^2}{U''(c)} = 0.$$

Finally, from L'Hôpital's rule and (7.3) we obtain

$$(8.7) \quad \lim_{c \rightarrow \infty} (U'(c))^\alpha U(c) = 0 \quad \text{for some } \alpha > 0.$$

To study the properties of $U(I(y))$, $yI(y)$, $g(y)$ and $s(y)$, we make the change of variable $y = U'(c)$. In particular,

$$\lim_{y \downarrow 0} y^\alpha U(I(y)) = \lim_{c \rightarrow \infty} (U'(c))^\alpha U(c) = 0$$

for some $\alpha > 0$, by (8.7). This establishes (7.19) for $U(I(y))$. Similarly,

$$\begin{aligned} \lim_{y \downarrow 0} y^{\alpha+1} I(y) &= \lim_{c \rightarrow \infty} c (U'(c))^{\alpha+1} \leq \lim_{c \rightarrow \infty} (U(c) - U(0)) (U'(c))^\alpha \\ &= 0, \end{aligned}$$

so $yI(y)$ also satisfies (7.19). L'Hôpital's rule yields

$$\begin{aligned} \lim_{y \downarrow 0} y^{\alpha-1+\lambda_+} J_+(y) &= \lim_{c \rightarrow \infty} (U'(c))^{\alpha-1+\lambda_+} \int_0^c \frac{d\eta}{(U'(\eta))^{\lambda_+}} \\ &= \frac{1}{1-\lambda_+-\alpha} \lim_{c \rightarrow \infty} \frac{(U'(c))^\alpha}{U''(c)} = 0 \quad \text{for some } \alpha > 2. \end{aligned}$$

Likewise,

$$(8.8) \quad \lim_{y \downarrow 0} y^{\alpha-1+\lambda_+} J_-(y) = 0 \quad \text{for some } \alpha > 2.$$

Finally,

$$\begin{aligned} (8.9) \quad \lim_{y \rightarrow \infty} y^{1+\lambda_-} J_-(y) &= \lim_{c \downarrow 0} (U'(c))^{1+\lambda_-} \int_1^c \frac{d\eta}{(U'(\eta))^{\lambda_-}} \\ &= -\frac{1}{1+\lambda_-} \lim_{c \downarrow 0} \frac{(U'(c))^2}{U''(c)} = 0 \end{aligned}$$

by (8.6). This concludes the proof that (7.19) is satisfied by all the functions under consideration. On the other hand, just as in (8.9) we have

$$(8.10) \quad \lim_{y \rightarrow \infty} y^{1+\lambda_+} J_+(y) = 0,$$

and taken together, these relations give us (7.44) when $f = g$ or $f = s$. The proof of (7.45) hinges on the observation from (8.5) that

$$(8.11) \quad \lim_{\xi \rightarrow \infty} \xi I(\xi) = \lim_{c \downarrow 0} c U'(c) = 0.$$

For the function $U(I(\xi))$, (7.44) becomes

$$(8.12) \quad \lim_{\xi \rightarrow \infty} \xi \frac{d}{d\xi} U(I(\xi)) = \lim_{\xi \rightarrow \infty} \xi^2 I'(\xi) = \lim_{c \downarrow 0} \frac{(U'(c))^2}{U''(c)} = 0.$$

For the function $\xi I(\xi)$, we have

$$\xi \frac{d}{d\xi} (\xi I(\xi)) = \xi I(\xi) + \xi^2 I'(\xi),$$

and (7.44) follows from (8.11), (8.12). It is now easy to verify (7.46).

It remains only to establish (7.43) for the functions under consideration, and for this it suffices to prove that

$$(8.13) \quad \int_1^\infty \xi |I'(\xi)| d\xi < \infty,$$

$$(8.14) \quad \int_1^\infty \xi^2 |I''(\xi)| d\xi < \infty,$$

$$(8.15) \quad \int_1^\infty \xi^{\lambda_+} |J_+(\xi)| d\xi < \infty,$$

$$(8.16) \quad \int_1^\infty \xi^{\lambda_-} |J_-(\xi)| d\xi < \infty,$$

and for some $\alpha > 0$:

$$(8.17) \quad \int_0^1 \xi^\alpha |I'(\xi)| d\xi < \infty,$$

$$(8.18) \quad \int_0^1 \xi^{\alpha+1} |I''(\xi)| d\xi < \infty,$$

$$(8.19) \quad \int_0^1 \xi^{\alpha-1+\lambda_+} |J_+(\xi)| d\xi < \infty,$$

and

$$(8.20) \quad \int_0^1 \xi^{\alpha-1+\lambda_-} |J_-(\xi)| d\xi < \infty.$$

In each of these integrals, we will make the change of variables $c = I(\xi)$, so $d\xi = U''(c) dc$, $I'(\xi) = 1/U''(c) \leq 0$, and $I''(\xi) = -U'''(c)/(U''(c))^3 \geq 0$. Beginning with (8.13), we write

$$\int_1^\infty \xi |I'(\xi)| d\xi = \int_0^{I(1)} U'(c) dc = U(I(1)) - U(0) < \infty.$$

Because of (8.13), finiteness of the integral in (8.14) is equivalent to finiteness of

$$\begin{aligned} \int_1^\infty [\xi^2 I''(\xi) + 2\xi I'(\xi)] d\xi &= \int_0^{I(1)} \frac{d}{dc} \left[\frac{(U'(c))^2}{U''(c)} \right] dc \\ &= \frac{1}{U''(I(1))} - \lim_{c \downarrow 0} \frac{(U'(c))^2}{U''(c)} = \frac{1}{U''(I(1))}, \end{aligned}$$

thanks to (8.6). Because U' is decreasing, we may bound (8.15) by

$$\begin{aligned} \int_1^\infty \xi^{\lambda_+} |J_+(\xi)| d\xi &= \int_0^{I(1)} (U'(c))^{\lambda_+} |U''(c)| \int_0^c \frac{d\eta}{(U'(\eta))^{\lambda_+}} dc \\ &\leq - \int_0^{I(1)} c U''(c) dc \\ &= -c U'(c) \Big|_{c=0}^{c=I(1)} + \int_0^{I(1)} U'(c) dc. \end{aligned}$$

These last expressions are finite because of (8.5) and (7.4). In (8.16) we integrate by parts to obtain

$$\begin{aligned} \int_{U'(1)}^\infty \xi^{\lambda_-} |J_-(\xi)| d\xi &= - \int_0^1 (U'(c))^{\lambda_-} U''(c) \int_c^1 \frac{d\eta}{(U'(\eta))^{\lambda_-}} dc \\ &= - \frac{1}{1+\lambda_-} (U'(c))^{1+\lambda_-} \int_c^1 \frac{d\eta}{(U'(\eta))^{\lambda_-}} \Big|_{c=0}^{c=1} - \frac{1}{1+\lambda_-} \int_0^1 U'(c) dc. \end{aligned}$$

We conclude from (8.9) that the resulting expression is finite.

Now let us take up (8.17)–(8.20). For (8.17) we write

$$(8.21) \quad \int_0^1 \xi^\alpha |I'(\xi)| d\xi = \int_{I(1)}^\infty (U'(c))^\alpha dc \leq \text{const.} \int_{I(1)}^\infty U''(c) dc < \infty$$

where we have used (7.3). Because of (8.17), finiteness of the integral in (8.18) is equivalent to finiteness of

$$\begin{aligned} \int_0^1 [\xi^{\alpha+1} I''(\xi) + (\alpha+1) \xi^\alpha I'(\xi)] d\xi &= \int_{I(1)}^\infty \frac{d}{dc} \left[\frac{(U'(c))^{\alpha+1}}{U''(c)} \right] dc \\ &= \frac{1}{U''(c)} - \lim_{c \rightarrow \infty} \frac{(U'(c))^{\alpha+1}}{U''(c)}, \end{aligned}$$

and again we use (7.3). From the monotonicity of U' , we may bound the integral in (8.19) by

$$\begin{aligned} \int_0^1 \xi^{\alpha-1+\lambda_+} |J_+(\xi)| d\xi &= \int_{I(1)}^\infty (U'(c))^{\alpha-1+\lambda_+} |U''(c)| \int_0^c \frac{d\eta}{(U'(\eta))^{\lambda_+}} dc \\ &\leq - \int_{I(1)}^\infty c (U'(c))^{\alpha-1} U''(c) dc \\ &= -\frac{c}{\alpha} (U'(c))^\alpha \Big|_{c=I(1)}^{c=\infty} + \frac{1}{\alpha} \int_{I(1)}^\infty (U'(c))^\alpha dc \\ &\leq \frac{I(1)}{\alpha} + \frac{1}{\alpha} \int_{I(1)}^\infty (U'(c))^\alpha dc; \end{aligned}$$

we conclude as in (8.21). For (8.20) we write

$$\int_0^{U(1)} \xi^{\alpha-1+\lambda_-} |J_-(\xi)| d\xi = \int_1^\infty (U'(c))^{\alpha-1+\lambda_-} |U''(c)| \int_1^c \frac{d\eta}{(U'(\eta))^{\lambda_-}} dc.$$

According to (8.8), $(U'(c))^{\alpha-1+\lambda_-} \int_1^c (d\eta/(U'(\eta))^{\lambda_-})$ is bounded for $c \geq 1$, and (8.20) follows from the integrability on $[1, \infty)$ of U'' . \square

Acknowledgments. We wish to thank the Center for Stochastic Processes, University of North Carolina in Chapel Hill and the Institute of Mathematics and its Applications, University of Minnesota for their hospitality.

Note added in proof. Lemma 4.2 notwithstanding, the function \mathcal{X}_1 defined by (4.8) might not be strictly decreasing on $(0, \infty)$, because we may have $A_\infty \triangleq \int_0^\infty \|\theta(s)\|^2 ds < \infty$, a.s. However, \mathcal{X}_1 is strictly decreasing on $(0, \bar{y}_1)$, as is G_1 defined by (4.17), where

$$\bar{y}_1 \triangleq \sup \{ y > 0 : \mathcal{X}_1(y) > 0 \}$$

is in $(0, \infty]$. Consequently, we must restrict \mathcal{X}_1 to $(0, \bar{y}_1]$ in order to obtain an “inverse” $\mathcal{Y}_1 : [0, \infty] \rightarrow_{\text{onto}} [0, \bar{y}_1]$. The same comments apply to \mathcal{X}_2 defined by (5.6), to its “inverse” $\mathcal{Y}_2 : [0, \infty] \rightarrow_{\text{onto}} [0, \bar{y}_2]$, where

$$\bar{y}_2 \triangleq \sup \{ y > 0 : \mathcal{X}_2(y) > 0 \}$$

and to G_2 defined by (5.12).

The functions \mathcal{X} of (6.10) and G of (6.11) are strictly decreasing on $(0, \bar{y}_1 \vee \bar{y}_2)$. We should define $\mathcal{Y} : [0, \infty] \rightarrow_{\text{onto}} [0, \bar{y}_1 \vee \bar{y}_2]$ to be the inverse of \mathcal{X} restricted to

$[0, \bar{y}_1 \vee \bar{y}_2]$.

In § 7, the assumption should be made that there is at least one stock whose mean rate of return is different from the interest rate, i.e., $\theta \triangleq \sigma^{-1}(b - r\mathbf{1})$ is nonzero. Under this assumption Lemma 4.2 and its proof are correct, as are the conclusions drawn from it in §§ 5–7.

OPTIMAL STABILIZATION OF FAMILIES OF LINEAR STOCHASTIC DIFFERENTIAL EQUATIONS WITH JUMP COEFFICIENTS AND MULTIPLICATIVE NOISE*

WILLIAM E. HOPKINS, JR.†

Abstract. Stabilization of families of finite-dimensional linear systems by constant linear feedback is studied by introducing a sequence of finite horizon parameter optimization problems. If the set of stabilizing constant linear feedback controllers is not empty and a regularity condition holds, a subsequence of solutions to the optimization problems converges to a constant stabilizing controller.

Key words. robust stabilization, stochastic stabilization, stochastic control, parameter optimization

AMS(MOS) subject classifications. 49B60, 93E15, 93E20

1. Introduction. The design of controllers for deterministic linear systems with parameter uncertainties has been studied using guaranteed cost control [4], zero sensitivity [17], geometric [20] and minimax [9], [16] methods, bounding methods for Lyapunov equations [14], [19], nonlinear controllers [11], and dynamic compensators [5], [6]. Quadratic mean stabilizability for families of stochastic systems with multiplicative noise has also been studied [7], [20], [21]. For families of deterministic linear systems, a parameter optimization problem was formulated in [8] that has a solution if and only if there exists a stabilizing state feedback controller, which may be computed as a solution of the first order necessary conditions. The contributions of this paper are: (i) the generalization of that result to output feedback control of systems with jump Markov coefficients and additive and multiplicative white Gaussian noise, and (ii) the definition of a sequence of finite time horizon optimization problems whose solutions converge to solutions of the infinite horizon problem whenever the latter exists and a regularity condition holds. If the set of stabilizing controllers is not empty, the latter result permits the computation of stabilizing controllers without any prior knowledge of that set.

To illustrate these results, consider the problem of stabilizing the family of linear systems $(d/dt)\xi = A_i\xi + Bu$, where i runs over a finite index set, by finding a constant control $u = -K\xi$ that minimizes the functional $\sum_i \int_0^T (\xi^T \xi + u^T u) dt$. If the initial condition is a zero-mean Gaussian random variable with unit covariance, the expected value of this functional is

$$(1) \quad \begin{aligned} & \sum_i \text{trace}(P_i(T)) \quad \text{if } T < \infty, \\ & \sum_i \text{trace}(Y_i) \quad \text{if } T = \infty, \end{aligned}$$

subject to the constraint that $P_i(t)$ be the solution of the matrix differential equation

$$\frac{d}{dt} P_i = (A_i - BK)^T P_i + P_i (A_i - BK) + I + K^T K, \quad P_i(0) = 0$$

* Received by the editors February 18, 1986; accepted for publication (in revised form) January 27, 1987. This work was supported by the National Science Foundation under grant ECS-8351621.

† Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544.

and Y_i be the solution of the corresponding Lyapunov equation. This problem may be solved by introducing multiplier matrices $W_i(t)$, Z_i , adjoining the constraint to the cost functional with the inner product

$$\sum_i \int_0^T \text{trace} (P_i(t) W_i(t)) dt \quad \text{if } T < \infty,$$

$$\sum_i \text{trace} (Y_i Z_i) \quad \text{if } T = \infty,$$

and computing Fréchet derivatives. The resulting necessary condition for a minimum is that K be a solution of the nonlinear equation

$$(2) \quad K = \begin{cases} \left(\sum_i \int_0^T B^T P_i(t) W_i(t) dt \right) \left(\sum_i \int_0^T W_i(t) dt \right)^{-1} & \text{if } T < \infty, \\ \left(\sum_i B^T Y_i Z_i \right) \left(\sum_i Z_i \right)^{-1} & \text{if } T = \infty \end{cases}$$

where the multiplier matrices are defined by

$$-\frac{d}{dt} W_i = (A_i - BK) W_i + W_i (A_i - BK)^T, \quad W_i(T) = I,$$

$$(A_i - BK) Z_i + Z_i (A_i - BK)^T + I = 0.$$

For this example, the results of this paper are as follows:

- (i) For each $T < \infty$, (1) is minimized by a solution K_T^* of (2).
- (ii) If the pairs (A_i, B) can be simultaneously stabilized by constant state feedback and $T = \infty$, then (1) is minimized by a (stabilizing) solution of (2) which may be computed from K_T^* in the limit $T \rightarrow \infty$.

The proofs involve constrained optimization and rely on the divergence of (1) as the norm of K becomes large. The novel idea here is that restricting the optimization to *constant* controls for $T < \infty$ allows convergence to be proven by showing that

$$\lim_{T \rightarrow \infty} \int_0^T W_i(t) dt = Z_i, \quad \lim_{T \rightarrow \infty} \int_0^T P_i(t) W_i(t) dt = Y_i Z_i.$$

These limits may be computed by interpreting the integrals as responses of a stable linear system having the impulse response $W_i(T-t)$ and driven by convergent forcing functions.

An interesting feature of this example is that it provides an algorithm for solving matrix Riccati equations. If there is only one system and it is controllable, then (2) may be rewritten as follows:

$$(3a) \quad K = B^T \int_0^T P(t) W(t) dt \left(\int_0^T W(t) dt \right)^{-1} \quad \text{if } T < \infty,$$

$$(3b) \quad A^T Y + Y A + I - Y B B^T Y = 0 \quad \text{if } T = \infty.$$

Therefore, the unique, positive definite solution of the Riccati equation (3b) may be computed as the limit of solutions of (3a) as $T \rightarrow \infty$.

2. A parameter optimization problem. The model of parameter uncertainty used in this paper is parametric dependence on a random variable a taking values in a closed and bounded subset S of a Euclidean space according to a known probability distribution $\mu(da)$. The linear system consists of an autonomous, finite-state jump Markov process $\beta(t) \in \{1, 2, \dots, N\}$ with prior distribution $\nu \in R^N$, $\nu_i > 0$, and generator $\pi \in R^{N \times N}$ which depends continuously on the random variable, and a controlled, stochastic differential equation with additive and multiplicative white Gaussian noise whose coefficients and prior distribution depend on both the jump process and the random variable:

$$(4) \quad \begin{aligned} d\xi &= [A_\beta \xi + B_\beta u] dt + \sum_{j=1}^q D_\beta^j \xi dv_j + \delta F_\beta dv_0, \quad t > 0, \\ \xi(0) &= x \in R^n. \end{aligned}$$

Here $\delta \in \{0, 1\}$, $v_0 \in R^n$, $v_i \in R^1$, $1 \leq i \leq q$ are independent standard Wiener processes, and the coefficient matrices A_i , D_i^j , $F_i \in R^{n \times n}$, $B_i \in R^{n \times m}$ are continuous functions on S . It is assumed that $F_i F_i^T > 0$, the zero eigenvalue of π has multiplicity one, and the random variable x has a positive-definite second moment σ .

An optimization problem is defined by considering the expected value of the finite-horizon, quadratic cost functional

$$V_T(a, i, x) = \frac{1}{1 + \delta T} E \left\{ \int_0^T e^{(1-\delta)\lambda_\beta t} (\xi^T Q_\beta \xi + u^T u) dt \mid \xi(0) = x, \beta(0) = i \right\}$$

and seeking constant output feedback controls to minimize the averages

$$J_T(K) = E\{V_T(a, i, x)\} \quad \text{for } T < \infty, \quad J_\infty(K) = \lim_{T \rightarrow \infty} J_T(K).$$

Here $Q_i \in R^{n \times n}$, $Q_i = Q_i^T \geq 0$, and $\lambda_i \in R$ are continuous functions on S . The parameter δ allows the simultaneous study of both infinite horizon ($\delta = 0$) and average cost ($\delta = 1$) criteria for the limit problem.

The admissible controls are restricted to the gain schedule $u = -K_\gamma \eta$, where γ , η are noiseless observations of β , ξ . Here $\eta(t) = C\xi(t)$ where $C \in R^{r \times n}$ is of full rank, and $\gamma(t) = j$ whenever $\beta(t) \in I_j$ where $\bigcup_{j=1}^M I_j$ is a disjoint partition of $\{1, 2, \dots, N\}$. (For example, β , γ might correspond to a multi-dimensional jump process, only some of whose components are measured.)

Computation of the optimal feedback gains involves solving systems of transcendental equations. For $T < \infty$, the minimization of J_T is carried out by transforming the problem into a parameter optimization problem with terminal cost. For notational convenience, denote $K = (K_1, \dots, K_M)$, $U = \prod_{i=1}^M R^{m \times r}$, define an indicator function by $\theta_i = j$ whenever $i \in I_j$, and introduce $G_i = A_i - B_i K_{\theta_i} C$. For $P \in R^{n \times n}$, define

$$(5) \quad L_i(P) = G_i^T P + P G_i + \sum_{j=1}^q (D_i^j)^T P D_i^j, \quad L_i^*(P) = P G_i^T + G_i P + \sum_{j=1}^q D_i^j P (D_i^j)^T.$$

PROPOSITION 1.

$$J_T(K) = \frac{1}{1 + \delta T} \sum_{i=1}^N \int_S \nu_i (\text{trace}(P_i(T, T)\sigma) + p_i(T, T)) \mu(da)$$

where $P_i(t, T)$, $p_i(t, T)$, $1 \leq i \leq N$, are defined for $K \in U$ by

$$\begin{aligned} \frac{d}{dt} P_i &= L_i(P_i) + \sum_{j=1}^N \pi_{ij} P_j + (Q_i + C^T K_{\theta_i}^T K_{\theta_i} C) e^{(1-\delta)\lambda_i(T-t)}, \quad 0 < t \leq T, \\ P_i(0, T) &= 0, \\ \frac{d}{dt} p_i &= \sum_{j=1}^N \pi_{ij} p_j + \delta \operatorname{trace}(F_i^T P_i F_i), \quad 0 < t \leq T, \\ p_i(0, T) &= 0. \end{aligned} \quad (6)$$

To state the first order necessary conditions for a minimum, define adjoint variables $W_i(t, T)$, $w_i(t, T)$, $1 \leq i \leq N$, by

$$\begin{aligned} -\frac{d}{dt} W_i &= L_i^*(W_i) + \sum_{k=1}^N \pi_{ki} W_k + \delta w_i F_i F_i^T, \quad 0 \leq t < T, \\ W_i(T, T) &= \nu_i \sigma, \\ -\frac{d}{dt} w_i &= \sum_{k=1}^N \pi_{ki} w_k, \quad 0 \leq t < T, \\ w_i(T, T) &= \nu_i \end{aligned} \quad (7)$$

and set $f^T = (f_1^T, \dots, f_M^T)$ where

$$\begin{aligned} f_i^T(K) &= \left(\sum_{i \in I_i} \int_0^T \int_S B_i^T P_i W_i C^T \mu(da) dt \right) \\ &\cdot \left(\sum_{i \in I_i} \int_0^T \int_S e^{(1-\delta)\lambda_i(T-t)} C W_i C^T \mu(da) dt \right)^{-1}. \end{aligned} \quad (8)$$

THEOREM 1. *The equation $K = f^T(K)$ has a solution K_T^* that minimizes J_T over U .*

The limit problem of minimizing J_∞ requires further assumptions and a more complicated notation. Define $\Gamma_1 \in R^{n^2 N \times n^2 N}$ by

$$\Gamma_1 = \pi \otimes I_{n^2} + \operatorname{diag} \left[I_n \otimes (G_i)^T + (G_i)^T \otimes I_n + \sum_{j=1}^q (D_i^j)^T \otimes (D_i^j)^T \right]$$

and define the open sets

$$U_0 = \bigcap_{a \in S} U_0(a), \quad U_0(a) = \{K \in U: \max \{\operatorname{real}(\sigma(\Gamma_1))\} + (1-\delta) \max_i \{\lambda_i\} < 0\}.$$

PROPOSITION 2. *If $K \in U_0$ then*

$$J_\infty(K) = (1-\delta) \sum_{i,j=1}^N \int_S \nu_i \operatorname{trace}(Y_{ij} \sigma) \mu(da) + \delta N \sum_{i,j=1}^N \int_S \alpha_i \operatorname{trace}(F_i^T Y_{ij} F_i) \mu(da)$$

where α is the normalized left zero eigenvector of π and Y_{ij} , $1 \leq i, j \leq N$, are defined for $K \in U_0$ by

$$L_i(Y_{ij}) + \sum_{k=1}^N \pi_{ik} Y_{kj} + (1-\delta)\lambda_j Y_{ij} + \chi_{\{i=j\}}(Q_i + C^T K_{\theta_i}^T K_{\theta_i} C) = 0.^1 \quad (9)$$

(As will be seen in Lemma 1, § 4, $U_0(a)$ is a set of feedback gains for which (9) uniquely defines Y_{ij} as a positive-semidefinite, symmetric matrix.)

¹ $\chi_{\{i=j\}} = \begin{cases} 0 & \text{if } i \neq j, \\ 1 & \text{if } i = j. \end{cases}$

To state the first order necessary conditions for a minimum, define adjoint matrices Z_{ij} , $1 \leq i, j \leq N$, for the limit problem by

$$(10) \quad L_i^*(Z_{ij}) + \sum_{k=1}^N \pi_{ki} Z_{kj} + (1-\delta) \lambda_j Z_{ij} + (1-\delta) \nu_i \sigma + \delta N \alpha_i F_i F_i^T = 0$$

and for $K \in U_0$ set $f^\infty = (f_1^\infty, \dots, f_M^\infty)$ where

$$(11) \quad f_i^\infty(K) = \left(\sum_{i \in I_i} \int_S \sum_{j=1}^N B_i^T Y_{ij} Z_{ij} C^T \mu(da) \right) \left(\sum_{i \in I_i} \int_S C Z_{ii} C^T \mu(da) \right)^{-1}.$$

Finally, the following regularity hypothesis implies J_∞ is differentiable at its minimum: There exists a symmetric matrix $\bar{Q} \in R^{n \times n}$ satisfying $0 \leq \bar{Q} \leq Q_i$ such that $X_{ij} \in R^{n \times n}$, $1 \leq i, j \leq N$, defined for $a \in S$, $K \in U_0$ by

$$(12) \quad L_i(X_{ij}) + \sum_{k=1}^N \pi_{ik} X_{kj} + (1-\delta) \lambda_j X_{ij} + \chi_{\{i=j\}} \bar{Q} = 0$$

satisfies

$$(13) \quad \lim_{K \rightarrow K_0} \sum_{i,j=1}^N \int_S \text{trace}(X_{ij}) \mu(da) = +\infty \quad \text{for all } K_0 \in \partial U_0.$$

THEOREM 2. *If U_0 is not empty and (13) holds then the equation $K = f^\infty(K)$ has a solution K_∞^* that minimizes J_∞ over U_0 . Conversely, if $K = f^\infty(K)$ has a solution then U_0 is not empty.*

THEOREM 3. *Suppose U_0 is not empty and (13) holds. Let T_i be an unbounded sequence of positive numbers, and let $K_{T_i}^*$ be a solution of $K = f^{T_i}(K)$ that minimizes J_{T_i} . Then $K_{T_i}^*$ has a subsequence which converges to a solution of $K = f^\infty(K)$ that minimizes J_∞ over U_0 .*

The proofs of Theorems 1–3 will be given in § 4. Using integral representations of $P_i(T, T)$, $p_i(T, T)$, and Y_{ij} , the optimization problems will be recast as ordinary minimization problems for scalar functions of several variables. The equations $K = f^T(K)$, $K = f^\infty(K)$, correspond to the requirement that the first derivatives of J_T , J_∞ be equal to zero. The convergence properties will follow from limits to be proven in Proposition 5. (An equivalent derivation of equations (7), (8) (respectively (10), (11)) consists of using $\sum_i \int_0^T \int_S \text{trace}(M_i N_i) \mu(da) dt$ (respectively, $\sum_i \int_S \text{trace}(M_i N_i) \mu(da)$) to adjoin equations (6) (respectively, (9)) to the cost J_T (respectively, J_∞) and computing Fréchet derivatives.)

3. Discussion of results. Theorem 2 is important because of the following connection between stability and the set U_0 . (The proof is given in Appendix A.)

PROPOSITION 3. *Assume $K \in U_0$. If $\delta = 0$ and $\max \{\lambda_i\} \geq 0$ then ξ is stable in quadratic mean. If $\delta = 1$ then ξ has an invariant probability distribution.*

Calling the system (4) stable if either of the conclusions of the proposition holds, we find that Theorems 2 and 3 characterize stabilizing controls when $(1-\delta) \max \{\lambda_i\} \geq 0$. If the model is deterministic apart from the initial data and the parameter a , then quadratic mean stability is the same as Lyapunov stability for every $a \in S$. Therefore, the theorems apply to problems of simultaneous stabilization of families of linear, deterministic systems. If the model includes Gaussian noise but no jump process, the theorems apply to problems of quadratic mean stabilization in the case of multiplicative noise, and to weak stochastic stabilization in the case of additive noise.

Theorem 2 may also be interpreted as a generalization of the result that stabilizability and detectability imply the existence of a unique, positive semi-definite solution of the matrix, algebraic Riccati equation [24]: The equation $K = f^\infty(K)$ generalizes the

Riccati equation, the hypothesis $U_0 \neq \emptyset$ plays the role of stabilizability, and the regularity hypothesis plays the role of detectability. Subject to the regularity hypothesis, f^∞ has a fixed point if and only if U_0 is not empty. There is no claim of uniqueness. The novelty of Theorem 1 is the restriction of admissible controls to *constant* rather than time-varying feedback gains. Although J_T can be redefined for, and minimized with respect to, time-varying controls, study of the passage to the limit appears to be technically intractable unless S is a singleton set. In that case, results are known for some nonlinear systems [18]. Theorem 3 is important for computing stabilizing controllers. Since gradient methods for computing fixed points of f^∞ require an initial guess $K_0 \in U_0$, they are not practical if the set U_0 is unknown. Theorem 3 ensures that at least one sequence of fixed points of f^T converges to U_0 as $T \rightarrow \infty$, and since $\lim_{T \downarrow 0} K_T^* = 0$, that sequence may be computed without any "initial guess." However, rates of convergence are not known. Numerical algorithms could be based on solving $K = f^T(K)$ for $T \rightarrow \infty$, or Theorem 3 could be used to compute starting points for gradient search algorithms.

When S is a singleton set, some special cases of Theorem 2 are known. The case when (4) is deterministic and $\delta = 0$ recovers the output feedback regulator problem studied by Levine and Athans [12]. State feedback regulation ($\delta = 0$) of a linear differential equation modulated by a jump process, and some state feedback, long run average cost problems ($\delta = 1$) with no jump process were studied by Wonham [23], [22]. Recently, Mariton and Bertrand have studied the former problem when the control is independent of the jump process [13], and Hyland and Bernstein [10] have studied extensions of the latter problem with dynamic output feedback control. In [2], the state feedback problem with no jump process and only multiplicative noise was studied as an approximation for a control problem with wide bandwidth disturbances.

Whereas most previous work on stabilization of uncertain systems has focused on developing verifiable sufficient conditions, Theorem 2 gives an analytical characterization as solvability of a set of transcendental equations. The difficult issue of verifiable criteria is hidden in the regularity hypothesis and the assumption that U_0 is nonempty. Many sufficient conditions for U_0 to be nonempty are given in the references cited in the Introduction. The regularity hypothesis (13) is the weaker assumption that the solution of (12) has singularities which are not integrable.

PROPOSITION 4. *Suppose $Q_i > 0$ and either $N = 1$ or $\pi_{ij} > 0$, $i \neq j$. The regularity hypothesis (13) holds if either (i) S is a finite set and μ is positive on S , or (ii) S is a finite interval, $\mu(da) \geq \phi(a) da$ where $\phi > 0$, and L_i, λ_i, π are polynomial functions of a .*

The proof of Proposition 4 is given in Appendix A. It is not known if (13) holds for polynomial parametrizations when S is a hypercube. Also, the regularity hypothesis may fail when some discount rates are negative and the jump process is not irreducible.

Example 1. For the scalar problem $(d/dt)\xi = A_\beta \xi + u$, $u = -K\xi$, consider choosing K independent of the jump process β to minimize $E \int_0^\infty (\xi^2 + u^2) dt$. (Here $\delta = 0$ and $\theta_i = 1$.) Then $U_0 = (K_0, \infty)$ where K_0 is the maximum real part of any eigenvalue of $\frac{1}{2}\pi + \text{diag}[A_i]$, and the regularity hypothesis holds if

$$(14) \quad \lim_{K \downarrow K_0} \int_S \text{trace} \left(KI_N - \frac{1}{2} \pi - \text{diag}[A_i] \right)^{-1} \mu(da) = +\infty.$$

The equation $K = f^\infty(K)$ may be rewritten as follows:

$$(15) \quad \frac{2K}{1 + K^2} = \frac{\int_S \nu^T(KI_N - \frac{1}{2}\pi - \text{diag}(A_i))^{-2} J\mu(da)}{\int_S \nu^T(KI_N - \frac{1}{2}\pi - \text{diag}(A_i))^{-1} J\mu(da)}$$

where $J = (1, \dots, 1)^T$. By calculus, (14) implies (15) has a solution in U_0 . Depending on the data, (15) may also have solutions in $(-\infty, K_0)$. (This example was studied in [8] in the case $N = 1$.)

Example 2. Suppressing subscripts and superscripts let $d\xi = (A\xi + Bu) dt + D\xi dv$, where $u = -KC\xi$,

$$A = \begin{pmatrix} 0 & 1 \\ 0 & -1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad D = \sqrt{a} \begin{pmatrix} 2 \\ -1 \end{pmatrix} (\varepsilon 2).$$

For the case $C = I_2$ it was shown in [20] that (i) for any $\varepsilon \geq 0$, $a_0 > 0$, there exists a feedback K which stabilizes the system for all $a \in [0, a_0)$, and (ii) if $\varepsilon = 1$, then one may take $a_0 = \infty$. For the case $C = (1, 0)$, let $\varepsilon \in R$, $S = [0, a_2]$, $a_2 > 0$, $\mu(da) = da/a_2$, $\delta = \lambda = 0$, $Q = \bar{Q} = \sigma = I_2$. Then $\det(\Gamma_1) = b_2 K^2 + b_1 K + b_0$, where $b_2 = -32a$, $b_1 = 4 - 8a(\varepsilon^2 - 4\varepsilon + 1)$, $b_0 = -2a\varepsilon^2$. Let $\bar{a}(1) = +\infty$ and for $\varepsilon \neq 1$ let $\bar{a}(\varepsilon)$ denote the unique positive solution of $(b_1)^2 - 4b_2b_0 = 0$. Applying the Routh-Hurwitz stability criterion to the characteristic polynomial of Γ_1 , it may be shown that U_0 is nonempty if and only if $a_2 < \bar{a}(\varepsilon)$. If $a_2 < \bar{a}(\varepsilon)$ then $U_0 = (K_-, K_+) \subseteq (0, \infty)$ where K_{\pm} are the ordered roots of $\det(\Gamma_1)|_{a=a_2} = 0$, $U_0 \rightarrow (0, \infty)$ as $a_2 \downarrow 0$, and $U_0 \rightarrow \emptyset$ as $a_2 \uparrow \bar{a}(\varepsilon)$. Equation (11) has the form

$$K = \int_0^{a_2} \frac{\sum_{i=0}^4 c_i K^i}{(b_2 K^2 + b_1 K + b_0)^2} da \bigg/ \int_0^{a_2} \frac{d_1 K + d_0}{b_2 K^2 + b_1 K + b_0} da$$

where c_i, d_i are quadratic polynomials in a for every ε . By Proposition 4 the regularity hypothesis holds and by Theorem 2 equation (11) has a stabilizing solution $K_{\infty}^* \in U_0$ if $a_2 < \bar{a}(\varepsilon)$.

4. Proofs. The compactness of S and the continuity of $P_i, W_i, Y_{ij}, Z_{ij}, X_{ij}$ with respect to a justify the frequent use of Fubini's theorem and the dominated convergence theorem. Several of the proofs use the fact that $\int_0^{\infty} e^{At} C e^{Bt} dt$ is the unique solution of $AX + XB + C = 0$ if A, B are square matrices and the sum of the maximum real parts of their eigenvalues is negative. Also, since the zero eigenvalue of π has multiplicity one, there exist $\alpha \in R^N$, $\alpha_i > 0$, $\Lambda(t) \in R^{N \times N}$, continuous on S , such that $e^{\pi t} = J\alpha^T + \Lambda$, where $J = (1, \dots, 1)^T$ and $\|\Lambda\| \leq \kappa e^{-t/\kappa}$, $\kappa > 0$. The proofs of Propositions 2 and 5 use the fact that if A is a stable matrix and $g(t)$ is continuously differentiable, then by a version of l'Hospital's rule [15, p. 375]

$$\lim_{T \rightarrow \infty} \frac{1}{1 + \delta T} \int_0^T e^{A(T-t)} g(t) dt = -A^{-1} \lim_{t \rightarrow \infty} \left((1 - \delta)g(t) + \delta \frac{d}{dt} g(t) \right)$$

whenever the limit on the right-hand side exists.

LEMMA 1. (i) If $K \in U$ then $P_i(t, T)$ are symmetric, positive-semidefinite matrices and $W_i(t, T)$ are symmetric positive-definite matrices. (ii) If $K \in U_0$, then Y_{ij}, X_{ij} are symmetric, positive-semidefinite matrices uniquely defined by (9), (12) respectively, and Z_{ij} are symmetric, positive-definite matrices uniquely defined by (10).

Proof of part (ii). (The proof of part (i) is similar.) Define $\bar{X}, \bar{Y}, \bar{Z} \in R^{n^2 N \times N}$ by $\bar{X} = (\text{vec}(X_{ij}))_{i,j=1}^N$, $\bar{Y} = (\text{vec}(Y_{ij}))_{i,j=1}^N$, $\bar{Z} = (\text{vec}(Z_{ij}))_{i,j=1}^N$, and define $\Gamma_2 \in R^{N \times N}$, $\Gamma_4 \in R^{n^2 N \times N}$, $\Gamma_5, \Gamma_6 \in R^{n^2 N}$ for $a \in S$, $K \in U_0$, by²

$$\begin{aligned} \Gamma_2 &= \text{diag}[\lambda_i], & \Gamma_4 &= \text{diag}[\text{vec}(Q_i + C^T K_{\theta_i}^T K_{\theta_i} C)], \\ \Gamma_5 &= (\alpha_i \text{vec}(F_i F_i^T))_{i=1}^N, & \Gamma_6 &= (\nu_i \text{vec}(\sigma))_{i=1}^N. \end{aligned}$$

² For any matrix E , $\text{vec}(E)$ denotes the vector of stacked columns of E [3].

By properties of Kronecker products [3], (9), (10), (12) are equivalent to

$$(9') \quad \Gamma_1 \bar{Y} + (1 - \delta) \bar{Y} \Gamma_2 + \Gamma_4 = 0,$$

$$(10') \quad \Gamma_1^T \bar{Z} + (1 - \delta) \bar{Z} \Gamma_2 + \delta N \Gamma_5 J^T + (1 - \delta) \Gamma_6 J^T = 0,$$

$$(12') \quad \Gamma_1 \bar{X} + (1 - \delta) \bar{X} \Gamma_2 + \text{diag} [\text{vec} (\bar{Q})] = 0.$$

Therefore, the existence of unique, symmetric solutions follows from the definition of U_0 and the symmetry of (5).

To prove $Z_{ij} > 0$, define $E_{ij} = (1 - \delta) \nu_i \sigma + \delta N \alpha_i F_i F_i^T > 0$,

$$\bar{\pi} = \pi^T - \text{diag} \left[\sum_{j=i}^N \pi_{ji} \right], \quad \bar{\lambda}_{ij} = \lambda_j + \sum_{j=i}^N \pi_{ji},$$

let $\bar{\beta}$ be a Markov jump process on $\{1, 2, \dots, N\}$ with generator $\bar{\pi}$, and let ξ^j be the solution starting at x of

$$d\xi^j = \left(G_{\bar{\beta}} + \frac{1}{2} (1 - \delta) \bar{\lambda}_{\bar{\beta}} I_n \right)^T \xi^j dt + \sum_{k=1}^q (D_{\bar{\beta}}^k)^T \xi^j dv_k.$$

Then $Z_{ij} > 0$ since for fixed j the solution of (10) has the representation

$$E \left\{ \int_0^\infty (\xi^j)^T E_{\bar{\beta}j} \xi^j dt \mid \xi^j(0) = x, \bar{\beta}(0) = i \right\} = x^T Z_{ij} x.$$

The semi-definiteness of Y_{ij} , X_{ij} is proved similarly.

Proof of Proposition 1. V_T is a quadratic function of x and $V_T = v(0, x)/(1 + \delta T)$, where v satisfies the backward system of linear, partial differential equations ($x \in R^n$)

$$\frac{\partial}{\partial t} v(t, x) + Lv(t, x) + \text{diag} [x^T (Q_i + C_i^T K_{\theta_i}^T K_{\theta_i} C_i) x] e^{(1-\delta)\lambda_i t} = 0, \quad 0 \leq t < T,$$

$$v(T, x) = 0.$$

Here L is the generator of the joint process β, ξ :

$$L = \pi + \text{diag} \left[x^T G_i^T \frac{\partial}{\partial x} + \frac{1}{2} \text{trace} \left(\left(\delta F_i F_i^T + \sum_{j=1}^q D_i^j x x^T (D_i^j)^T \right) \frac{\partial^2}{\partial x^2} \right) \right].$$

Therefore, by a standard calculation $v_i(0, x) = x^T P_i(T, T)x + p_i(T, T)$ and the result follows.

Proof of Theorem 1. Since $P_i \geq 0$, Proposition 1 and a comparison theorem imply there exists a constant κ , independent of T , such that

$$(16) \quad J_T(K) \geq \frac{\kappa}{1 + \delta T} \sum_{i=1}^N \int_S \left(\text{trace} (\hat{P}_i(T)) + \delta \int_0^T \text{trace} (\hat{P}_i(t)) \right) \mu(da)$$

where $\hat{P}_i(t)$ are defined by

$$\frac{d}{dt} \hat{P}_i = \left(G_i + \frac{1}{2} \pi_{ii} \right)^T \hat{P}_i + \hat{P}_i \left(G_i + \frac{1}{2} \pi_{ii} \right) + C^T K_{\theta_i}^T K_{\theta_i} C e^{(1-\delta)\lambda_i(T-t)}, \quad 0 < t \leq T,$$

$$\hat{P}_i(0) = 0.$$

Therefore, $\lim_{\|K\| \rightarrow \infty} J_T = \infty$, implying J_T is minimized by some $K_T^* \in U$. The fact that K_T^* is a fixed point of f^T follows from Proposition B1, Appendix B, by a long calculation using Kronecker products to express (6) and (7) in vector form. The details are omitted.

Proof of Proposition 2. Define $P_{ij}(t, T)$, $p_{ij}(t, T)$, by

$$(17) \quad \begin{aligned} \frac{d}{dt} P_{ij} &= L_i(P_{ij}) + \sum_{k=1}^N \pi_{ik} P_{kj} + \chi_{\{i=j\}} (Q_i + C^T K_{\theta_i}^T K_{\theta_i} C) e^{(1-\delta)\lambda_i(T-t)}, \quad 0 < t \leq T, \\ P_{ij}(0, T) &= 0, \\ \frac{d}{dt} p_{ij} &= \sum_{k=1}^N \pi_{ik} p_{kj} + \delta \operatorname{trace}(F_i^T P_{ij} F_i), \\ p_{ij}(0, T) &= 0. \end{aligned}$$

Then $P_i = \sum_{j=1}^N P_{ij}$, $p_i = \sum_{j=1}^N p_{ij}$, and

$$J_T(K) = \frac{1}{1+\delta T} \sum_{i,j=1}^N \int_S \nu_i(\operatorname{trace}(P_{ij}(T, T)\sigma) + p_{ij}(T, T)) \mu(da).$$

The formula then holds by the following calculations. Let $\bar{P}(t, T) = (\operatorname{vec}(P_{ij}))_{i,j=1}^N$, $\bar{p}(t, T) = (p_{ij})_{i,j=1}^N$, and define $\Gamma_3, \bar{\Gamma}_3(t) \in \mathbb{R}^{N \times N}$ by

$$(\Gamma_3)_{ij} = \operatorname{trace}(F_i^T Y_{ij} F_i), \quad (\bar{\Gamma}_3)_{ij} = \operatorname{trace}(F_i P_{ij}(t, T) F_i).$$

By properties of Kronecker products [3], (17) is equivalent to

$$(18) \quad \begin{aligned} \frac{d}{dt} \bar{P} &= \Gamma_1 \bar{P} + \Gamma_4 e^{(1-\delta)\Gamma_2(T-t)}, \quad 0 < t \leq T, \\ \bar{P}(0, T) &= 0. \end{aligned}$$

Therefore,

$$\bar{P}(t, T) = \bar{P}(t, t) e^{(1-\delta)\Gamma_2(T-t)}, \quad \bar{P}(T, T) = \int_0^T e^{\Gamma_1 t} \Gamma_4 e^{(1-\delta)\Gamma_2 t} dt,$$

$$\bar{p}(T, T) = \delta \int_0^T e^{\pi(T-t)} \bar{\Gamma}_3(t) dt$$

and $\bar{p}(t, t)$ satisfies $(d/dt)\bar{p} = \pi\bar{p} + (1-\delta)\bar{p}\Gamma_2 + \delta\bar{\Gamma}_3$. If $K \in U_0$, then

$$\lim_{T \rightarrow \infty} \frac{1}{1+\delta T} \bar{P}(T, T) = (1-\delta) \int_0^\infty e^{\Gamma_1 t} \Gamma_4 e^{(1-\delta)\Gamma_2 t} dt = (1-\delta) \bar{Y}.$$

If $\delta = 0$, then $\bar{p}(T, T) = 0$ and if $\delta = 1$, then

$$\lim_{T \rightarrow \infty} \frac{1}{T} \bar{p}(T, T) = \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T (J\alpha^T + \Lambda(T-t)) \bar{\Gamma}_3(t) dt = J\alpha^T \Gamma_3.$$

Proof of Theorem 2. $\bar{G}_i = G_i + \frac{1}{2}(\pi_{ii} + (1-\delta)\lambda_i)$ is stable if $K \in U_0$. Therefore, by Lemma 1, Proposition 2, and a comparison theorem,

$$J_\infty(K) \geq \kappa_1 \sum_{i=1}^N \int_S \operatorname{trace}(\hat{X}_i) \mu(da), \quad \kappa_1 > 0$$

where \hat{X}_i are the unique solutions of $\bar{G}_i^T \hat{X}_i + \hat{X}_i \bar{G}_i + C^T K_{\theta_i}^T K_{\theta_i} C = 0$. Therefore, $\lim_{\|K\| \rightarrow \infty} J_\infty = \infty$, implying J_∞ is minimized by some $K_\infty^* \in \text{closure}(U_0)$. Also,

$$J_\infty(K) \geq \kappa_2 \sum_{i,j=1}^N \int_S \operatorname{trace}(X_{ij}) \mu(da), \quad \kappa_2 > 0.$$

Therefore, the regularity hypothesis (13) implies $K_\infty^* \notin \partial U_0$. The fact that K_∞^* is a fixed point of f^∞ follows from Proposition B1, Appendix B, by a long calculation using Kronecker products to express (9), (10) in vector form. The details are omitted.

PROPOSITION 5. Let $E \in R^{n \times n}$ and $K_T \in U$ for $T > 0$. If $\lim_{T \rightarrow \infty} K_T = K_\infty \in U_0$, then

$$(i) \quad \lim_{T \rightarrow \infty} \frac{1}{1 + \delta T} \int_0^T e^{(1-\delta)\lambda_i(T-t)} W_i(t, T) dt|_{K=K_T} = \left(1 - \delta + \frac{\delta}{N}\right) Z_{ii}|_{K=K_\infty};$$

$$(ii) \quad \lim_{T \rightarrow \infty} \frac{1}{1 + \delta T} \int_0^T P_{ij}(t, T) E W_i(t, T) dt|_{K=K_T} = \left(1 - \delta + \frac{\delta}{N}\right) Y_{ij} E Z_{ij}|_{K=K_\infty}.$$

Proof. By the continuity of W_i , Z_{ij} , P_{ij} , Y_{ij} with respect to t , a , K , there is no loss of generality in assuming $K_T = K_\infty$. Define $\bar{\Gamma}_5(t) \in R^{n^2 N}$ by $\bar{\Gamma}_5 = ((e^{\pi^T t} \nu)_i \text{vec}(F_i F_i^T))_{i=1}^N$ and note $\lim_{t \rightarrow \infty} \bar{\Gamma}_5(t) = \bar{\Gamma}_5$. Define $\bar{W}_i = W_i$ and let $\bar{W}(t, T) = (\text{vec}(W_{ij}))_{i,j=1}^N$. Then (7) is equivalent to

$$-\frac{d}{dt} \bar{W} = \Gamma_1^T \bar{W} + \delta \bar{\Gamma}_5(T-t) J^T, \quad 0 \leq t < T,$$

$$\bar{W}(T, T) = \Gamma_6 J^T$$

and (10) is equivalent to

$$(19) \quad \bar{Z} = \int_0^\infty e^{\Gamma_1^T t} ((1-\delta)\Gamma_6 J^T + \delta N \Gamma_5 J^T) e^{(1-\delta)\Gamma_2 t} dt.$$

Therefore

$$\frac{1}{1 + \delta T} \int_0^T \bar{W}(t, T) e^{(1-\delta)\Gamma_2(T-t)} dt = I_1 + \delta I_2,$$

$$I_1 = \frac{1}{1 + \delta T} \int_0^T e^{\Gamma_1^T t} \Gamma_6 J^T e^{(1-\delta)\Gamma_2 t} dt,$$

$$I_2 = \frac{1}{1 + T} \int_0^T \int_0^t e^{\Gamma_1^T(t-s)} \bar{\Gamma}_5(s) J^T ds dt.$$

To prove part (i) it suffices to show that $I_1 + \delta I_2$ converges to (19). If $\delta = 0$, then I_1 converges to (19), and if $\delta = 1$, then I_1 converges to zero and I_2 converges to the solution of $\Gamma_1^T z + \Gamma_5 J^T = 0$.

The proof of part (ii) depends on the equations for Y_{ij} , Z_{ij} decoupling with respect to j . Define $\bar{P}_i = \bar{P} e_i$, $\bar{W}_i = \bar{W} e_i$, $\bar{Y}_i = \bar{Y} e_i$, $\bar{Z}_i = \bar{Z} e_i$.³ Then by (18) and (19)

$$\bar{P}_i(t, T) = \bar{P}_i(t, t) e^{(1-\delta)\lambda_i(T-t)}, \quad \bar{P}_i(t, t) = \int_0^t e^{\Gamma_1^s \Gamma_4} e_i e^{(1-\delta)\lambda_i s} ds,$$

$$\bar{Y}_i = \int_0^\infty e^{\Gamma_1^s \Gamma_4} e_i e^{(1-\delta)\lambda_i s} ds,$$

$$\bar{W}_i(t, T) = e^{\Gamma_1^T(T-t)} \Gamma_6 + \delta \int_t^T e^{\Gamma_1^T(s-t)} \bar{\Gamma}_5(T-s) ds,$$

$$\bar{Z}_i = \int_0^\infty e^{\Gamma_1^T t} ((1-\delta)\Gamma_6 + \delta N \Gamma_5) e^{(1-\delta)\lambda_i t} dt.$$

³ e_i denotes the vector consisting of zeros except for a one in the i th position.

By a change of coordinates and order of integration,

$$\begin{aligned} \frac{1}{1+\delta T} \int_0^T \bar{W}_i(t, T) \bar{P}_i^T(t, T) dt &= I_3 + \delta I_4, \\ I_3 &= \frac{1}{1+\delta T} \int_0^T e^{\Gamma_1^T(T-t)} \Gamma_6 e^{(1-\delta)\lambda_i(T-t)} \bar{P}_i^T(t, t) dt, \\ I_4 &= \frac{1}{1+T} \int_0^T e^{\Gamma_1^T(T-t)} \left(\int_0^t \bar{\Gamma}_5(t-s) \bar{P}_i^T(s, s) ds \right) dt. \end{aligned}$$

To prove part (ii) it suffices to show that $I_3 + \delta I_4$ converges to $\bar{Z}_i \bar{Y}_i^T$. If $\delta = 0$, then I_3 converges to the solution of $\Gamma_1^T x + \lambda_i x + \Gamma_6 \bar{Y}_i^T = 0$. If $\delta = 1$, then I_3 converges to zero and, by repeated application of l'Hospital's rule, I_4 converges to the solution of $\Gamma_1^T x + \Gamma_5 \bar{Y}_i^T = 0$.

LEMMA 2. Let $K_T \in U$ for $T > 0$. If U_0 is not empty, the regularity hypothesis (13) holds, and $\lim_{T \rightarrow \infty} K_T = K_\infty \notin U_0$, then

$$\lim_{T \rightarrow \infty} \sum_{i,j=1}^N \int_S \text{trace}(P_{ij}(T, T)) \mu(da)|_{K=K_T} = +\infty.$$

Proof. Let $U_0^1 \subseteq U_0$, $U_0^2 \subseteq U - U_0$ be bounded. Since S is compact and Γ_1 is a continuous function of a, K , by (18) there exist positive constants κ, τ such that for any $T \geq \tau$, $K^1 \in U_0^1$, $K_2 \in U_0^2$,

$$\text{trace}(P_{ij}(T, T))|_{K=K^1} \leq \kappa \text{trace}(P_{ij}(T, T))|_{K=K^2}.$$

The result follows by (13) since $\lim_{T \rightarrow \infty} \text{trace}(P_{ij}(T, T))|_{K=K^1} \geq \text{trace}(X_{ij})|_{K=K^1}$.

Proof of Theorem 3. Let $\varepsilon > 0$. By Propositions 1 and 2 and (17) there are constants κ, τ_0 such that for $T \geq \tau_0$,

$$\begin{aligned} J_\infty(K_\infty^*) + \varepsilon &\geq J_T(K_\infty^*) \geq J_T(K_T^*) \\ (20) \quad &\geq \frac{\kappa}{(1+\delta T)} \sum_{i,j=1}^N \int_S \left(\text{trace}(P_{ij}(T, T)) \right. \\ &\quad \left. + \delta \int_0^T \text{trace}(P_{ij}(t, t)) dt \right) \mu(da)|_{K=K_T^*}. \end{aligned}$$

Therefore, there exist constants ρ, τ_1 such that $K_{T_i}^* \in U_0$ and $\|K_{T_i}^*\| < \rho$ for $T_i \geq \tau_1$, since otherwise equation (16) or Lemma 2 would contradict (20). Hence (20) and Proposition 5 imply the limit of each convergent subsequence minimizes J_∞ and is a fixed point of f^∞ .

5. Conclusion. For a large class of families of linear systems with uncertainty, this paper has shown that, subject to a mild regularity hypothesis, stabilizability is equivalent to solvability of a system of transcendental equations. These are the stationary equations for a related parameter optimization problem. A procedure for their solution has been given.

Several minor extensions of Theorems 1-3 are possible. For instance, if (4) is generalized to include control dependent noise in the form

$$d\xi = [A_\beta \xi + B_\beta u] dt + \sum_{j=1}^q [D_\beta^j \xi + E_\beta^j u] dv_j + \delta F_\beta dv_0,$$

then Theorems 1-3 hold with D_i^j replaced by $D_i^j - E_i^j K_\theta C$ in (5) and the right-hand sides of (8), (11) replaced by the unique solutions X of the linear equations

$$(8') \quad \sum_{i \in I_1} \int_0^T \int_S \left(I_m e^{(1-\delta)\lambda_i(T-t)} + \sum_{k=1}^q (E_i^k)^T P_i E_i^k \right) X C W_i C^T \mu(da) dt$$

$$= \sum_{i \in I_1} \int_0^T \int_S \left(B_i^T P_i + \sum_{k=1}^q (E_i^k)^T P_i D_i^k \right) W_i C^T \mu(da) dt,$$

$$(11') \quad \sum_{i \in I_1} \int_S \left(X C Z_{ii} C^T + \sum_{j=1}^N \sum_{k=1}^q (E_i^k)^T Y_{ij} E_i^k X C Z_{ij} C^T \right) \mu(da)$$

$$= \sum_{i \in I_1} \int_S \sum_{j=1}^N \left(B_i^T Y_{ij} + \sum_{k=1}^q (E_i^k)^T Y_{ij} D_i^k \right) Z_{ij} C^T \mu(da).$$

The results may also be extended to certain cases when $F_i F_i^T$ is not positive definite, the observation structures C, I_j depend on a , and the control is affine in the null space of B_i . Open problems include study of the solution space of (11), study of numerical methods for solving (8), (11), including determination of rates of convergence of K_T^* , and extensions to jump processes with continuous state space.

Appendix A.

Proof of Proposition 3. Since $(1-\delta) \max \{\lambda_i\} \geq 0$ implies Γ_1 is stable, let \tilde{X}_i , $1 \leq i \leq N$, denote the unique solution of $L_i(\tilde{X}_i) + \sum_{j=1}^N \pi_{ij} \tilde{X}_j + I_n = 0$. If $a \in S$ and $\delta = 0$, then as in the proof of Proposition 2

$$E \left\{ \int_0^\infty \xi^T \xi dt \mid \xi(0) = x, \beta(0) = i \right\} = x^T \tilde{X}_i x,$$

implying $E\{\|\xi(t)\|^2 \mid \xi(0) = x, \beta(0) = i\} \rightarrow 0$ as $t \rightarrow \infty$. If $\delta = 1$, then

$$\lim_{T \rightarrow \infty} E \left\{ \frac{1}{T} \int_0^T \xi^T \xi dt \right\} = N \sum_{i=1}^N \int_S \alpha_i \text{trace}(F_i^T \tilde{X}_i F_i) \mu(da).$$

Therefore, $\xi(t)$ has bounded second moments, implying the existence of an invariant probability distribution [1].

Proof of Proposition 4. Choose $\bar{Q} = \varepsilon I_n$, $\varepsilon > 0$ and let $K_0 \in U_0$. Since S is closed and bounded, $K_0 \in \partial U_0(a_0)$ for some $a_0 \in S$. Furthermore, it may be shown that $\partial U_0(a_0)$ is a subset of the curve $\{K \in U: \det(\Gamma_1) + (1-\delta) \max_i \{\lambda_i\} \mid_{a=a_0} = 0\}$ and $\lim_{\kappa \rightarrow \kappa_0} \sum_{i,j=1}^N \text{trace}(X_{ij}) = +\infty$ for $a = a_0$. The result follows trivially in (i) while in (ii) it follows from the inequality:

$$\sum_{i,j=1}^N \int_S \text{trace}(X_{ij}) \mu(da) \geq \kappa \int_S (1+g)/h da$$

where $\kappa > 0$ and g, h are polynomials in (a, K) vanishing at (a_0, K_0) .

Appendix B. The notation does not correspond to that used in the body of the paper. Let S be a closed and bounded subset of a Euclidean space. Let $A \in R^{n \times n}$, $b(t)$, \bar{b} , $c \in R^n$ be continuous functions of $t \in [0, T]$, $a \in S$, $k \in R^m$, which are continuously differentiable in k . Let $\Omega = \{k: \text{real}(\sigma(A)) < 0 \text{ for all } a \in S\}$. Define

$$J_T(k) = \int_S c^T g(T) \mu(da), \quad g(t) = \int_0^t e^{A(t-s)} b(s) ds, \quad h(t) = e^{A^T(T-t)} c$$

and for $k \in \Omega$ define

$$J_{\infty}(k) = \int_S c^T \bar{g} \mu(da), \quad \bar{g} = -A^{-1} \bar{b}, \quad \bar{h} = -(A^T)^{-1} c.$$

PROPOSITION B1.

(i) If J_T has a local minimum at $k^* \in R^m$ then

$$\int_0^T \int_S h^T(t) \left(\frac{\partial A}{\partial k_i} g(t) + \frac{\partial b}{\partial k_i}(t) \right) \mu(da) dt \Big|_{k=k^*} = 0, \quad 1 \leq i \leq m.$$

(ii) If J_{∞} has a local minimum at $k^* \in \Omega$ then

$$\int_S \bar{h}^T \left(\frac{\partial A}{\partial k_i} \bar{g} + \frac{\partial \bar{b}}{\partial k_i} \right) \mu(da) \Big|_{k=k^*} = 0, \quad 1 \leq i \leq m.$$

Proof. Because Ω is open, the formulas follow from a computation of the gradient of $J(k)$, utilizing the formulas $(\partial/\partial k_i)A^{-1} = -A^{-1}(\partial A/\partial k_i)A^{-1}$ and (27) of [3],

$$\frac{\partial}{\partial k_i} e^{At} = \int_0^t e^{A(t-s)} \frac{\partial A}{\partial k_i} e^{As} ds.$$

INFINITE HORIZON OPTIMIZATION FOR FINITE STATE MARKOV CHAIN*

ARIE LEIZAROWITZ†

Abstract. We consider the infinite horizon optimal control of a finite state Markov chain from the point of view of overtaking optimality and the long-run average cost. The stochastic model is cast into a deterministic framework by considering the distribution of the original state as a new state. Using known results about deterministic control systems we obtain short proofs of existence and characterization of stationary overtaking optimal strategies for the stochastic problem.

We characterize and prove existence of stationary strategies which have a minimal cost growth rate in the class of all nonanticipative strategies. Restricting our attention only to stationary strategies we show that for every given initial state there exists an overtaking optimal strategy. Finally, under more restrictive conditions, we establish the existence of a stationary overtaking optimal strategy for all the initial values.

Key words. infinite horizon control problem, long-run minimal cost, overtaking optimal, finite state Markov chain

1. Introduction. This paper studies infinite horizon control of a finite state Markov chain from the point of view of the overtaking optimality criterion and the long-run average cost. The stochastic model is cast into a deterministic framework by considering the distribution of the original states as the new state. Using known results about deterministic control systems will enable us to give short proofs of existence and characterization of stationary overtaking optimal strategies for the stochastic problem.

We shall consider *nonanticipative strategies*, namely strategies for which the value of the control applied at time k depend on the values of the controlled process up to time k . Here $k = 0, 1, 2, \dots$ is the discrete time variable. A subclass of this set is composed of the *Markov strategies* for which the value of the control at the time k is a function of k and the current state of the controlled process at this time. Of special interest are the Markov strategies which are *stationary strategies*, namely, the value of the control u which is applied at time k depends only on the current state of the controlled process, and not on the time variable k .

There are two main results in this paper. One is concerned with the existence and characterization of stationary strategies which have a minimal cost growth rate in the class of all nonanticipative strategies, while the second is about overtaking optimal strategies in the class of all stationary strategies. In the first main result we prove the existence of a stationary strategy with a minimal long-run average cost and we show how it can be computed. Existence results about strategies with a minimal long-run average cost have been displayed in the literature under various assumptions. In Whittle's book [10] it is assumed that the set of action controls is finite. In Kushner's study [6] it is assumed that the controls take values in a countable set. In our framework the set of admissible controls is considerably larger, and the result about strategies with a minimal long-run average cost will be established while assuming that the set of admissible control values is convex and compact. Moreover, any two states communicate after a finite number of steps under the action of a stationary admissible strategy. These assumptions are denoted in the sequel as Assumption B. The convexity assumption is natural since we allow *mixing of controls*. Namely, we assume that if v_1, \dots, v_k

† Department of Mathematics, Carnegie-Mellon University, Pittsburgh, Pennsylvania 15213.

are some possible action controls and if $\lambda_i > 0$ are such that $\sum_{i=1}^k \lambda_i = 1$, then the action of choosing v_i with probability λ_i is a possible control also.

In [1] Borkar proved the existence of stationary strategies with a minimal cost growth rate for Markov chains. The framework of his treatment is different from ours. The state space in [1] is denumerable rather than finite, and the optimization is a.s. rather than of the expected average cost. However, the cost expression considered in [1] is a function of the current state only, while we consider a cost expression which depends on both the current state and the applied control.

The other main result is concerned with overtaking optimality of stationary strategies. We will establish the existence of a stationary overtaking optimal strategy for every initial state. Moreover, the existence of a stationary overtaking optimal strategy for all the initial states will be established under the following assumption. Let $\{1, 2, \dots, n\}$ be the state space. Then for every initial state i at time $k=0$ and a distribution $p = (p_1, \dots, p_n)$ with $p_i > 0$, $1 \leq i \leq n$ there is a control u for which the distribution of the process at time $k=1$ is p . We will demonstrate in an example that this assumption, which looks quite restrictive, holds naturally in certain systems. We want to emphasize that this assumption, which is denoted in the sequel as Assumption A, is needed only in the part of the paper which deals with overtaking optimality in § 6. The existence of optimal strategies with a minimal long-run average cost is proved, in § 5, under the relaxed Assumption B described above. The Assumption A is employed merely as an auxiliary tool in § 4.

We will show that, under Assumption A, the stationary strategy with a minimal cost growth rate possesses an additional optimality property. Denote this strategy by σ_0 and let σ be any nonanticipative strategy. Then there is a constant K such that the cost of σ_0 on the time interval $[0, k]$ is not larger than that of σ on this interval by more than K , and this for every $k \geq 1$. This property clearly implies that σ_0 has a minimal cost growth rate. One can, however, construct two nonanticipative strategies, both having a minimal long-run average cost. Nevertheless, the difference between their respective costs on the time intervals $[0, k]$ diverge to infinity as k grows to infinity.

The fact that the minimal cost growth is attained by a stationary strategy gives some justification to restricting the discussion to the class of stationary strategies. Moreover, we assume that the cost incurred when applying a certain control while the system occupies a given state does not depend on the time when this control is employed. Therefore one expects that strategies which are optimal in a reasonable sense would be stationary. Indeed, we will prove that under Assumption B there exists an overtaking optimal stationary strategy, for every given initial state. However, under Assumption A, we will establish the following much stronger property: Every stationary strategy with a minimal long-run average cost is in fact overtaking optimal, for all the initial states, in the class of stationary strategies. This main result will also provide us with a computational tool for overtaking optimal stationary strategies. In the course of proving our main result we will show that the deterministic problem associated with our stochastic problem has the remarkable property of having overtaking optimal solutions with respect to a *vector cost criterion*.

We will consider now some possible extensions and discuss some inherent limitations of our approach. Concerning overtaking optimal strategies, there are several possible extensions. One is to establish the existence of overtaking stationary strategies in the class of all the *Markov strategies*, rather than in the smaller class of stationary strategies. Another possible extension is to relax the controllability assumption that every distribution can be obtained in a unit time from any initial state. Our approach has the inherent limitation of requiring this in order to exploit results about the

deterministic control systems. It would be desirable to prove existence and characterize overtaking optimal strategies under the natural assumption that the constraint set for admissible controls is convex and compact. Such a result is motivated by the two main results of this paper. Another possible extension is to consider controlled Markov chains with infinite denumerable state space.

Our approach is to consider the distribution of the states as a new state, and accordingly we study the expected cost values. Thus there is no hope to get a.s. optimality results. This, however, is not much of a limitation as far as overtaking optimality is concerned, since, in general, one can hardly expect a.s. optimization in this context.

The paper is organized as follows. In § 2 we describe the stochastic control problem and display examples which satisfy the assumptions of our model. In § 3 we associate a deterministic control problem with the original stochastic one. The existence and computation of a stationary optimal strategy with a minimal long run average cost is proved in § 4 under Assumption A and in § 5 under the relaxed Assumption B.

In § 6 we restrict our attention to stationary strategies and show that, under Assumption B, there exists an overtaking optimal stationary strategy for every initial state. Furthermore, assuming Assumption A, we will show that every stationary strategy with a minimal long-run average cost is in fact overtaking optimal for every initial state.

2. The stochastic control problem. We consider the controlling of a discrete time stochastic process which is defined on a probability space (Ω, F, P) . The state space of the controlled process is the finite set $\{1, 2, \dots, n\}$. We denote the discrete time variable by $k = 0, 1, 2, \dots$. If we apply a control u at time k while the system occupies the state i , $1 \leq i \leq n$, then as a result the system will occupy the state j at time $k+1$ with probability $p_{ij}(u)$, which does not depend on time k . We assume that the class of controls is *closed under mixing*, namely: If u_1, \dots, u_k are admissible controls, and $\lambda_i \geq 0$, $\sum_{i=1}^k \lambda_i = 1$, then the control u which is obtained by choosing u_i with probability λ_i is an admissible control also.

We denote by S the following subset of R^n :

$$S = \left\{ q \in R^n : q_i > 0, \sum_{i=1}^n q_i = 1 \right\}$$

where q_i denotes the i th component of q . S is a convex subset of R^n , and let \tilde{S} be the smallest affine subset of R^n which contains S . Then we denote by $\text{rel int } S$ and by ∂S , respectively, the interior and boundary of S as a subset of \tilde{S} (see Rockafellar [8]).

Suppose that when the system occupies the state i then a cost $\phi(i, u)$ incurred if the control u is applied. If the control u is obtained by mixing the controls u_1, \dots, u_k with the respective probabilities $\lambda_1, \dots, \lambda_k$, then the cost of using it when the system occupies the state i is $\sum_{j=1}^k \lambda_j \phi(i, u_j)$. For a given state i and $q \in S$, let $U_i(q)$ be the set of all the controls u such that $p_{ij}(u) = q_j$ for all $1 \leq j \leq n$ (q_j is the j th component of q). Then we define

$$\phi_i(q) = \inf \{ \phi(i, u) : u \in U_i(q) \}$$

agreeing that the infimum over the empty set is $+\infty$. $\phi_i(q)$ is the infimal cost for obtaining the distribution q at the next sampling time if the present state is i . We thus consider the set of all stochastic matrices $M = (M_{ij})$, $1 \leq i, j \leq n$, as the set of our admissible controls. The controller chooses at every instant of time such a matrix M , and if the system occupies the state i at that time then the incurred cost is $\phi_i(M_i)$, where M_i is the i th row of M .

Remark. Because we allow mixing of controls in the original framework of the model, the set of admissible stochastic matrices is convex.

We say that $q \in R^n$ is positive and denote $q > 0$ if $q_j > 0$ for every $1 \leq j \leq n$. We shall assume the following.

ASSUMPTION A.

- (i) Let $q \in S$ be positive. Then for every i there is a control u such that $p_{ij}(u) = q_j$ for all $1 \leq j \leq n$.
 - (ii) The cost expression $q \rightarrow \phi_i(q)$ satisfies
- $$(2.1) \quad \lim \phi_i(q) = \infty \quad \text{as } q \rightarrow \partial S$$
- for every $1 \leq i \leq n$.

Remark. The meaning of (i) is that every distribution $q > 0$ can be achieved in a unit time from every initial state by a choice of a suitable control. Example 2.2 will display systems for which this holds under natural assumptions.

To explain the meaning of (ii) we observe that if q belongs to ∂S then at least one state is a.s. unoccupied. Thus assuming (ii) means that all the states communicate in the unit time interval, under the action of every admissible control. Moreover, an action which guarantees a high probability for the nonoccupancy of a certain state would also be very expensive and the relation between these two quantities is expressed in (2.1). These remarks are further demonstrated in the following example.

Example 2.1. We consider a continuous time Markov chain with the state space $\{1, \dots, n\}$. If $t \rightarrow A(t)$ is its generator and $t \rightarrow q(t)$ is its distribution at time t , then

$$(2.2) \quad \frac{dq}{dt} = A^T(t)q(t), \quad q(0) = q_0$$

where q_0 is the initial distribution at time $t = 0$, and A^T is the transpose of A (see e.g. Elliott [4]). The entries $A_{ij}(t)$ of the matrix $A(t)$ determine the rates of transition from i to j at the time t . In the case of a controlled Markov chain the controller can influence these values. The function $A(\cdot)$ is thus the control function and we assume in this example that the class of admissible controls is composed of all the continuous functions $t \rightarrow A(t)$ such that $A_{ij}(t) \geq 0$ for $i \neq j$ and $A_{ii}(t) = -\sum_{j \neq i} A_{ij}(t)$. This assumption will be much relaxed in Example 2.2. Let \mathcal{A} denote the set of $n \times n$ matrices A such that $A_{ij} \geq 0$ whenever $i \neq j$ and $A_{ii} = -\sum_{j \neq i} A_{ij}$. Let $X \subset R^n$ be the subspace $\{x \in R^n: \sum_{i=1}^n x_i = 0\}$ where x_i is the i th component of x . Then for every $q \in \text{rel int } S$ we have

$$\{A^T q: A \in \mathcal{A}\} = X,$$

as can easily be seen from the definition of \mathcal{A} and the fact that $A^T q$ is a convex combination of the columns of A^T with the weights $\{q_1, \dots, q_n\}$. From this it follows that for every $q \in \text{rel int } S$ and every initial distribution q_0 there is an admissible control $A(\cdot)$ such that the solution $q(\cdot)$ of (2.2) satisfies $q(1) = q$. Thus Assumption A(i) holds.

The following discussion serves as motivation and explanation of A(ii). If for two different states i and j the value of $A_{ij}(t)$ is very small then this means that transitions from i to j in a short time interval after t are very unlikely to occur. On the other hand very large values of $A_{ij}(t)$ mean that there is a high probability that the state will change from i to j during such a time interval. Thus we see that extreme values of A_{ij} correspond to a more predictable behavior of the system. It is, however, reasonable to expect that controls which achieve a less random behavior of the system will also be the more expensive ones. Thus a reasonable cost expression in the present model is

$$(2.3) \quad \sum_{i \neq j} \phi(A_{ij}(t)) dt$$

where $\phi: R^+ \rightarrow R^+$ is a convex function satisfying $\lim \phi(\xi) = \infty$ as $\xi \rightarrow \infty$ or $\varepsilon \rightarrow 0+$. (The convexity is natural in light of the possibility of mixing controls.)

For a given i let $C_i(\alpha, \beta)$ be the set of all values $q(1)$, where $q(\cdot)$ is a solution of (2.2) and where $A(\cdot)$ runs over all the possible measurable functions $t \rightarrow A(t)$ such that $0 < \alpha \leq A_{ij} \leq \beta$ for all $0 \leq t \leq 1$ and all $i \neq j$, $1 \leq i, j \leq n$. It is not hard to see that $C_i(\alpha, \beta)$ is a closed set and $C_i(\alpha, \beta) \subset \text{rel int } S$, namely $C_i(\alpha, \beta)$ is bounded away from ∂S . (Consider $t \rightarrow A(t)$ as matrices whose entries are bounded elements of $L^2[0, 1]$. Then the solutions of (2.2) are uniformly continuous. For a sequence $\{A_k(\cdot)\}_{k=0}^\infty$ of controls with a corresponding solution $\{q_k(\cdot)\}_{k=0}^\infty$ we can assume that $A_k(\cdot) \rightarrow A_0(\cdot)$ weakly and $q_k(\cdot) \rightarrow q_0(\cdot)$ strongly, both in $L_2[0, 1]$. Therefore $q_0(\cdot)$ is the solution corresponding to $A_0(\cdot)$.) This means that if q is sufficiently close to ∂S , then there must be values of $A_{ij}(t)$ which are either very small or very large, thus causing the cost expression in (2.3) to become large.

The following example relaxes the assumption on \mathcal{A} in Example 2.1.

Example 2.2. The controlled process is as described in Example 2.1. Let $X \subset R^n$ be the subspace $\{x \in R^n: \sum_{i=1}^n x_i = 0\}$ and let a_1, \dots, a_n be in X such that $(a_i)_j > 0$ whenever $j \neq i$. Denote by K the convex hull of a_1, \dots, a_n (namely the smallest convex set in X which contains $\{a_1, \dots, a_n\}$). We assume that K has a nonempty interior as a subset of X , and moreover, zero belongs to this interior. Then every $x \in X$ can be written as

$$(2.4) \quad x = \sum_{i=1}^n \alpha_i a_i$$

for some $\alpha_i \geq 0$, $1 \leq i \leq n$. Let the set of all admissible values for the controls \mathcal{A}_0 be defined by

$$\mathcal{A}_0 = \left\{ A: A = \begin{pmatrix} - & u_1 a_1^T & - \\ & \vdots & \\ - & u_n a_n^T & - \end{pmatrix} u_i > 0, 1 \leq i \leq n \right\}$$

where the n vectors a_i , $1 \leq i \leq n$, are as above. An admissible control is thus a continuous function $t \rightarrow A(t)$ such that $A(t) \in \mathcal{A}_0$ for every $0 \leq t \leq 1$.

Thus the situation is that, for every given state, the rates of transition to the other states during short time intervals have fixed ratios on which the controller does not have any influence at all. The controller can choose the "intensities" of the transitions from each state and at all the times, and thus can either increase or decrease all the transition rates from a certain state by the same factor. In this framework a control function can be identified with a continuous function $u: [0, 1] \rightarrow R^n$ such that each component $u_i(t)$ is nonnegative for all $0 \leq t \leq 1$.

Let $q \in \text{rel int } S$ and consider the set

$$C_q = \{A^T q: A \in \mathcal{A}_0\}.$$

Then we claim that $C_q = X$. Let $x \in X$; then it can be written as in (2.4) for some nonnegative α_i , $1 \leq i \leq n$, and then

$$x = \begin{pmatrix} | & & | \\ u_1 a_1 & \cdots & u_n a_n \\ | & & | \end{pmatrix} q$$

where $u_i = \alpha_i/q_i$, which proves that $x \in C_q$. Therefore for every initial distribution q_0 and every $q \in \text{rel int } S$ there is an admissible control $t \rightarrow A(t)$ such that the solution $q(1)$ of (2.2) satisfies $q(1) = q$, namely Assumption A(i) holds.

PROPOSITION 2.3. *Let Assumption A hold. Then $q \rightarrow \phi_i(q)$ is a convex function on $\text{rel int } S$ for every $1 \leq i \leq n$. For every $q \in \text{rel int } S$ and $1 \leq i \leq n$, we have $\phi_i(q) > -\infty$.*

Proof. It follows from the possibility of mixing controls that whenever q_1 and q_2 are in $\text{rel int } S$ and $q = \frac{1}{2}(q_1 + q_2)$, then $\phi_i(q) \leq \frac{1}{2}[\phi_i(q_1) + \phi_i(q_2)]$, which proves the convexity of $\phi_i(\cdot)$. If a convex function is larger than $-\infty$ somewhere in the relative interior of its effective domain then it is greater than $-\infty$ everywhere (see Rockafellar [8]). Thus the second assertion of the proposition follows from (2.1). \square

We consider the control problem on an infinite time interval. The controller chooses a strategy σ in order to control the system's dynamics. In our framework a strategy is a sequence $\{M^{(k)}\}_{k=1}^{\infty}$ of stochastic matrices. Thus if

$$M^{(k)} = \begin{pmatrix} - & M_1^{(k)} & - \\ & \vdots & \\ - & M_n^{(k)} & - \end{pmatrix}$$

where $M_j^{(k)}$ is the j th row of $M^{(k)}$, then $M_i^{(k)}$ is the distribution of the states of the system at time $k+1$ if it occupies the state i at time k .

DEFINITION 2.4. Let the random variable $\zeta^{(k)}$ be the state of the system at time k . A strategy $\sigma = \{M^{(k)}\}_{k=0}^{\infty}$ is nonanticipative if $M^{(k)}$ is a function of $\zeta^{(0)}, \dots, \zeta^{(k)}$ only. A Markov strategy is a sequence $\{M^{(k)}\}_{k=0}^{\infty}$ of stochastic matrices (with no functional dependence of $M^{(k)}$ on $\zeta^{(0)}, \dots, \zeta^{(k-1)}$). A Markov strategy σ is a stationary strategy if $\sigma = \{M\}_{k=0}^{\infty}$ for some fixed stochastic matrix M .

With every initial state i and every Markov strategy $\sigma = \{M^{(k)}\}_{k=0}^{\infty}$ there is associated a Markov chain $\{\zeta^{(k)}\}_{k=0}^{\infty}$ where

$$P(\zeta^{(0)} = i) = 1 \quad \text{and} \quad \zeta^{(k)} \in \{1, 2, \dots, n\}.$$

The conditional distribution of $\zeta^{(k+1)}$ given that $\zeta^{(k)} = j$ is given by $M_j^{(k)}$, the j th row of $M^{(k)}$

$$P(\zeta^{(k+1)} = l | \zeta^{(k)} = j) = M_{jl}^{(k)}.$$

We denote by $x^{(k)}$ the distribution of $\zeta^{(k)}$ and thus have the relation

$$(2.5) \quad x^{(k+1)} = (M^{(k)})^T x^{(k)}$$

(where M^T is the transpose of M).

If the system occupies the state i then the cost $\phi_i(M_i)$ is incurred if the control M is applied. Thus the expected cost on the $[0, N]$ time interval which corresponds to the strategy σ is

$$(2.6) \quad C_N(i, \sigma) = E_i \sum_{k=0}^{N-1} \phi_{\zeta^{(k)}}(M_{\zeta^{(k)}}^{(k)}).$$

We call the sequence $\{C_N(i, \sigma)\}_{N=1}^{\infty}$ the cost flow which corresponds to σ , and are interested in the behavior of this sequence as N tends to infinity. We will be interested in finding a sequence which is minimal according to one of the following criterions: The minimal long-run average cost, or the overtaking optimality criterion. A cost flow $\{C_N\}$ has a minimal long-run average if $\lim_{N \rightarrow \infty} (1/N)C_N$ exists and is not larger than $\lim_{N \rightarrow \infty} \inf (1/N)C'_N$ for every other cost flow $\{C'_N\}_{N=1}^{\infty}$. (The overtaking optimality criterion will be defined in the next section.) We write (2.6) as

$$(2.7) \quad C_N(i, \sigma) = \sum_{k=0}^{N-1} \left[\sum_{j=1}^n x_j^{(k)} \phi_j(M_j^{(k)}) \right]$$

where

$$x_j^{(k)} = P(\zeta^{(k)} = j | \zeta^{(0)} = i, \sigma),$$

namely $x^{(k)}$, is the distribution of $\zeta^{(k)}$ given the initial state i and the strategy σ . Motivated by (2.5) and (2.7) we define the following function: Let x and y be in $\text{rel int } S$, then

$$(2.8) \quad u(x, y) = \inf \left\{ \sum_{j=1}^n x_j \phi_j(M_j) : M^T x = y \right\}$$

where the infimum is carried over all the stochastic matrices M which satisfy the equation $M^T x = y$. It is easy to see that $u(x, y)$ is finite whenever y is in $\text{rel int } S$.

3. The associated deterministic problem. We now relate a deterministic control problem to the stochastic control problem described in the previous section. To every sequence $\bar{x} = \{x_k\}_{k=0}^\infty$, where $x_k \in S$, there corresponds the cost flow

$$(3.1) \quad C_N(\bar{x}) = \sum_{k=0}^{N-1} u(x_k, x_{k+1})$$

where u is the function defined in (2.8). Let the initial value x_0 be fixed. We want to find a sequence \bar{x} for which the cost flow $\{C_N(\bar{x})\}$ is minimal, either according to the long-run average cost criterion, or according to the overtaking optimality criterion. More precisely, if \bar{x} is such that

$$\lim_{N \rightarrow \infty} \frac{1}{N} C_N(\bar{x}) \leq \liminf_{N \rightarrow \infty} \frac{1}{N} C_N(\bar{y})$$

for every other \bar{y} with $y_0 = x_0$, then we say that \bar{x} has a *minimal cost growth rate*. As mentioned, it can also be minimal in a more refined sense, namely in the *overtaking optimality sense*. This notion was introduced in the economic literature by Gale [5], von Weizsacker [9] and used in the control literature by, e.g., Brock and Haurie [2] and Carlson [3]. A version of this notion is given by the following.

DEFINITION 3.1. Let the initial value x_0 be fixed. We say that \bar{x} is an overtaking optimal sequence if for every \bar{y} with $y_0 = x_0$ and every $\varepsilon > 0$ there exists an N_0 such that

$$C_N(\bar{x}) < C_N(\bar{y}) + \varepsilon$$

for all $N \geq N_0$.

Namely, up to an arbitrarily small $\varepsilon > 0$ the sequence \bar{x} is better than any other sequence from a certain time on. In particular, it follows that \bar{x} has a minimal cost growth rate.

PROPOSITION 3.2. For every $x, y \in \text{rel int } S$ the infimum in (2.8) is attained for some stochastic matrix with positive rows. The function $(x, y) \rightarrow u(x, y)$ is continuous on $(\text{rel int } S) \times (\text{rel int } S)$.

Proof. For given $x, y \in \text{rel int } S$, it follows from (2.1) and (2.8) that there is a minimizing sequence of stochastic matrices $\{M_j\}_{j=1}^\infty$ such that $(M_j)_l \in K \subset \text{rel int } S$ for every $j \geq 1$ and $1 \leq l \leq n$, where K is a compact set, and

$$u(x, y) = \lim_{j \rightarrow \infty} \sum_{i=1}^n x_i \phi_i((M_j)_i).$$

(Here $(M_j)_l$ is the l th row of M_j .) We can assume that $M_j \rightarrow M_0$ as $j \rightarrow \infty$ and then $u(x, y) = \sum_{i=1}^n x_i \phi_i((M_0)_i)$, proving the first assertion. A similar argument proves that $(x, y) \rightarrow u(x, y)$ is a lower semicontinuous function in $(\text{rel int } S) \times (\text{rel int } S)$.

Let $(x, y) \in (\text{rel int } S) \times (\text{rel int } S)$ and let $u(x, y) = \sum_{i=1}^n x_i \phi_i(M_i)$ where M is a stochastic matrix with positive rows M_i , $i \leq i \leq n$. Given an $\varepsilon > 0$ we can find a $\delta > 0$ such that whenever $x', y' \in \text{rel int } S$ satisfy $|x - x'| + |y - y'| < \delta$ then there is a stochastic matrix M' with $\|M' - M\| < \varepsilon$ satisfying $y' = (M')^T x'$ (here $\|\cdot\|$ is a norm on the space of $n \times n$ matrices). This follows from the observation that $y = M^T x$ is equivalent to saying that y is a convex combination of the rows of M with the weights x_1, \dots, x_n . Therefore the function $(x, y) \rightarrow u(x, y)$ is also upper semicontinuous in $(\text{rel int } S) \times (\text{rel int } S)$. This concludes the proof of the proposition. \square

Thus there is a correspondence between the original stochastic control problem with state space consisting of n points and the deterministic control problem of minimizing the cost flow $C_N(\bar{x})$ in (3.1), for sequences $\bar{x} = \{x_k\}_{k=0}^\infty$ in S . As described above every initial state i and a strategy σ induces a sequence \bar{x} in S . On the other hand, for the sequence $\{x_k\}_{k=0}^\infty$ in $\text{rel int } S$ there exist, by Proposition 3.2, matrices $\{M^{(k)}\}_{k=0}^\infty$ such that $x_{k+1} = (M^{(k)})^T x_k$ for $k \geq 0$, and x_k is the distribution of $\zeta^{(k)}$ where $\{\zeta^{(k)}\}_{k=0}^\infty$ is the Markov chain associated with the initial distribution x_0 and the strategy $\sigma = \{M^{(k)}\}_{k=0}^\infty$. The cost flows corresponding to \bar{x} and to σ and x_0 are the same.

4. Strategies with a minimal cost growth rate. The deterministic problem which was described in § 3 was studied by Leizarowitz [7] in light of the overtaking criterion. The framework is to consider sequences $\bar{x} = \{x_k\}_{k=0}^\infty$ in a compact set D in R^n and study the associated cost flows

$$C_N(\bar{x}) = \sum_{k=0}^{N-1} u(x_k, x_{k+1}).$$

The function $u(\cdot, \cdot)$ is assumed to be continuous on $D \times D$. The following result was established there [7, Thm. 3.1].

THEOREM 4.1. *There exist constants $K > 0$ and μ such that:*

(i) *For every \bar{x} in D*

$$(4.1) \quad \sum_{k=0}^{N-1} [u(x_k, x_{k+1}) - \mu] > -K \quad \text{for all } N \geq 1.$$

(ii) *There is a sequence \bar{x}^* in D such that*

$$(4.2) \quad \left| \sum_{k=0}^{N-1} [u(x_k^*, x_{k+1}^*) - \mu] \right| < K \quad \text{for all } N \geq 1.$$

Remark. It is clear that the constant μ is unique, and it describes the minimal cost growth rate possible for sequences in D . The sequence \bar{x}^* which is mentioned in the theorem indeed has a cost flow with this minimal cost growth rate. It is not true, however, that any sequence with a minimal cost growth rate satisfies (4.2). It is true for stationary strategies: If σ is stationary and of a minimal cost growth, then $|C_N(x_0, \sigma) - \mu N| < K$ for some K and all $N \geq 1$. This is easily obtained for $\sigma = \{M\}_{k=0}^\infty$ by considering $C_N(z_0, \sigma)$ where z_0 satisfies $M^T z_0 = z_0$ and $u(z_0, z_0) = \mu$, realizing that $C_n(z_0, \sigma) = \mu N$ for every $N \geq 1$ and $C_n(i, \sigma) - \mu N > -K$ for some K and all $N \geq 1$ and i .

It is also proved in § 8 of [7] that if $u(\cdot, \cdot)$ is continuous on $R^n \times R^n$ and $u(x, y) \rightarrow \infty$ as $|x| + |y| \rightarrow \infty$ the conclusions of Theorem 4.1 remain true for sequences in R^n . In fact, the same proof as that in [7] implies that these conclusions still hold under the assumption that $u(x, y) \rightarrow \infty$ as $|y| \rightarrow \infty$ uniformly for x in R^n . Thus, since $\text{rel int } S$ is homeomorphic to R^{n-1} and $u(\cdot, \cdot)$ in (2.8) is such that

$$\lim u(x, y) = \infty \quad \text{as } y \rightarrow \partial S$$

uniformly for $x \in S$ we conclude that the relations (4.1) and (4.2) hold when we consider sequences in $\text{rel int } S$.

Let σ be a nonanticipative strategy and let, as in (2.6), $C_N(i, \sigma)$ be the expected cost while using σ on the $[0, N]$ time interval beginning at the initial state i . If, however, the initial state is i with probability x_i , $1 \leq i \leq n$, then the expected cost is given by

$$(4.3) \quad \sum_{i=1}^n x_i C_N(i, \sigma) = x^T \cdot C_N(\sigma)$$

where we denote $x = (x_i)_{i=1}^n$ in R^n and $C_N(\sigma)$ is the point in R^n whose i th component is $C_N(i, \sigma)$. We have the following result.

PROPOSITION 4.2. *There is a Markov strategy σ_0 such that the following holds:*

$$(4.4) \quad C_N(i, \sigma_0) < C_N(i, \sigma) + K \quad \text{for all } N \geq 1$$

for some constant K and for every initial state i and a nonanticipative strategy σ . In particular the strategy σ_0 has a minimal cost growth rate

$$\lim_{N \rightarrow \infty} \frac{1}{N} C_N(i, \sigma_0) \leq \liminf_{N \rightarrow \infty} \frac{1}{N} C_N(i, \sigma)$$

for every nonanticipative σ and every $1 \leq i \leq n$.

Proof. Let $u(\cdot, \cdot)$ be the function defined in (2.8). It follows from Theorem 4.1 and the discussion following it that there is a sequence $\bar{x}^* = \{x_k^*\}_{k=0}^\infty$ in $\text{rel int } S$ for which (4.1) and (4.2) hold. It follows from Proposition 3.2 that there is a sequence of matrices $\{M^{(k)}\}_{k=0}^\infty$ such that

$$(4.5) \quad x_{k+1}^* = (M^{(k)})^T x_k^* \quad \text{for all } k \geq 0$$

and

$$(4.6) \quad u(x_k^*, x_{k+1}^*) = \sum_{j=1}^n (x_k^*)_j \phi_j(M_j^{(k)}).$$

Let σ_0 be the Markov strategy $\{M^{(k)}\}_{k=0}^\infty$. Using the notation employed in (4.3), we get from (4.5) and (4.6) that

$$(4.7) \quad -K' \leq (x_0^*)^T \cdot C_N(\sigma_0) - \mu N \leq K'$$

for some constant K' and all $N \geq 1$. Since the following holds for every $1 \leq i \leq n$ and every $N \geq 1$

$$C_N(i, \sigma_0) - \mu N \geq -K',$$

it follows from (4.7) and the fact that $x_0^* \in \text{rel int } S$ that there is a constant K'' such that

$$(4.8) \quad |C_N(i, \sigma_0) - \mu N| \leq K''$$

for all $N \geq 1$ and all $1 \leq i \leq n$.

We now claim that

$$(4.9) \quad C_N(i, \sigma) - \mu N \geq -K'$$

for every nonanticipative strategy σ , all $1 \leq i \leq n$ and all $N \geq 1$. This is true for every Markov strategy, as a consequence of Theorem 4.1. Now let σ be any nonanticipative strategy, say $\sigma = \{N^{(k)}\}_{k=0}^\infty$, where each $N^{(k)}$ is now a random matrix which is measurable with respect to the σ -algebra that is generated by the random variables $\zeta^{(0)}, \dots, \zeta^{(k)}$. Let the distribution $x^{(0)}$ of $\zeta^{(0)}$ be given and let $x^{(k)} \in R^n$ be defined by

$$(x^{(k)})_j = P(\zeta^{(k)} = j).$$

Thus $\{x^{(k)}\}_{k=0}^\infty$ is the sequence of distributions of $\{\zeta^{(k)}\}_{k=0}^\infty$ as determined by the strategy $\sigma = \{N^{(k)}\}_{k=0}^\infty$. Let us define also

$$(4.10) \quad L^{(k)} = EN^{(k)}.$$

Then $\bar{\sigma} = \{L^{(k)}\}_{k=0}^\infty$ is a Markov strategy and we will show that

$$(4.11) \quad C_N(i, \sigma) \geq C_N(i, \bar{\sigma})$$

for every $N \geq 1$ and every $1 \leq i \leq n$, which will imply the validity of (4.9) for σ , since (4.9) holds for Markov strategies.

To prove (4.11) we will show that $\{L^{(k)}\}_{k=1}^\infty$ in (4.10) and $\{x^{(k)}\}_{k=0}^\infty$ are related by

$$(4.12) \quad x^{(k+1)} = (L^{(k)})^T x^{(k)},$$

which means that $\{x^{(k)}\}_{k=0}^\infty$ is the sequence of distributions of the Markov chain $\{\bar{\zeta}^{(k)}\}_{k=0}^\infty$ which corresponds to the Markov strategy $\bar{\sigma}$. We have

$$\begin{aligned} P(\zeta^{(k+1)} = j_{k+1} | \zeta^{(k)} = j_k) \\ &= E[P(\zeta^{(k+1)} = j_{k+1} | \zeta^{(0)}, \zeta^{(1)}, \dots, \zeta^{(k)}) | \zeta^{(k)} = j_k] \\ &= E[N_{\zeta^{(k)}, j_{k+1}}^{(k)}(\zeta^{(0)}, \dots, \zeta^{(k)}) | \zeta^{(k)} = j_k] = L_{j_k, j_{k+1}}^{(k)}. \end{aligned}$$

Therefore

$$\begin{aligned} P(\zeta^{(k+1)} = j_{k+1}) &= \sum_{j_k=1}^n P(\zeta^{(k+1)} = j_{k+1} | \zeta^{(k)} = j_k) \cdot P(\zeta^{(k)} = j_k) \\ &= \sum_{i=1}^n x_i^{(k)} L_{i, j_{k+1}}^{(k)} \end{aligned}$$

which is the equality (4.12). To obtain the estimate (4.11) we examine a typical term in the cost expression (2.6). Thus we have that

$$\begin{aligned} E\phi_{\zeta^{(k)}}(N_{\zeta^{(k)}}^{(k)}) &= E(E(\phi_{\zeta^{(k)}}(N_{\zeta^{(k)}}^{(k)}) | \zeta^{(k)})) \\ &= \sum_{i=1}^n x_i^{(k)} E(\phi_i(N_i^{(k)}) | \zeta^{(k)} = i) \\ &\geq \sum_{i=1}^n x_i^{(k)} \phi_i(E(N_i^{(k)} | \zeta^{(k)} = i)) \end{aligned}$$

where we used Jensen's inequality in the last step. But since $E(N_i^{(k)} | \zeta^{(k)} = i) = (L^{(k)})_i$, we get the estimate

$$(4.13) \quad E\phi_{\zeta^{(k)}}(N_{\zeta^{(k)}}^{(k)}) \geq \sum_{i=1}^n x_i^{(k)} \phi_i((L^{(k)})_i).$$

Summing (4.13) for $k=0, 1, \dots, N-1$ and recalling (4.12), we get (4.11), since the whole discussion holds for every initial state $1 \leq i < n$. As explained above this proves the validity of (4.9) for every nonanticipative strategy σ . Now the inequality (4.4) is a consequence of (4.8) and (4.9). Dividing (4.4) by N and letting $N \rightarrow \infty$ we get that σ_0 has a minimal cost growth rate. By (4.7) $\lim_{N \rightarrow \infty} (1/N)C_N(i, \sigma_0)$ exists and is equal to μ . \square

The Markov strategy σ_0 which has a minimal cost growth rate is not guaranteed to be a stationary strategy, namely such that $M^{(k)} = M$ for some fixed stochastic matrix and all $k \geq 0$. However, since the problem is time homogeneous and defined on an infinite horizon, one expects the existence of a stationary strategy with a minimal long-run average cost. This we will now prove.

To this end we will carefully examine the constant μ which is guaranteed in Theorem 4.1. It is proved in [7] that

$$(4.14) \quad \mu = \inf \left\{ \frac{1}{N} \sum_{k=0}^{N-1} u(x_k, x_{k+1}) \right\}$$

where the infimization is carried over all the integers $N \geq 1$ and all the possible choices of sequences $\{x_k\}_{k=0}^N$ such that $x_0 = x_N$. For a general discrete time deterministic control system, the infimum in (4.14) is not realizable for a finite N and a finite sequence $\{x_k\}_{k=0}^N$. However, we will see that for the function $u(\cdot, \cdot)$ in (2.8) which is associated with our stochastic control problem, the infimum in (4.14) is realized for $N = 1$, namely there is a point $\theta \in \text{rel int } S$ such that

$$(4.15) \quad \mu = u(\theta, \theta).$$

This will be demonstrated while proving Theorem 4.4. Assume now that (4.15) holds and let M be a stochastic matrix with positive rows such that

$$(4.16) \quad \mu = \sum_{j=1}^n \theta_j \phi_j(M_j) \quad \text{and} \quad \theta = M^T \theta.$$

The existence of such an M follows from Proposition 3.2.

PROPOSITION 4.3. *Assume that $\theta \in \text{rel int } S$ satisfies (4.15) and M is a stochastic matrix for which (4.16) holds. Let σ^* be the stationary strategy*

$$\sigma^* = \{M\}_{k=0}^{\infty}.$$

Then σ^ has a minimal cost growth rate for every initial state i and*

$$\lim_{N \rightarrow \infty} \frac{1}{N} C_N(i, \sigma^*) = \mu.$$

Moreover, there is a constant K such that

$$(4.17) \quad C_N(i, \sigma^*) \leq C_N(i, \sigma) + K$$

for all the nonanticipative strategies σ , and all $N \geq 1$, $1 \leq i \leq n$.

Proof. Let θ and M satisfy (4.15) and (4.16). The constant sequence

$$\bar{x}^* = \{\theta\}_{k=0}^{\infty}$$

is such that

$$\sum_{k=0}^N [u(x_k^*, x_{k+1}^*) - \mu] = 0 \quad \text{for all } N \geq 0.$$

Therefore we can choose, in the proof of Proposition 4.2, the strategy σ_0 to be equal to σ^* . Hence σ^* possesses all the properties of σ_0 in Proposition 4.2, which completes the proof of the proposition. \square

THEOREM 4.4. *There is a stationary strategy σ^* with a minimal cost growth and which satisfies relation (4.17). Such is the strategy $\sigma^* = \{M\}_{k=0}^{\infty}$ where M satisfies (4.16).*

Proof. As discussed above the only thing that remains to prove is the existence of a point $\theta \in \text{rel int } S$ satisfying equation (4.15). Let $N \geq 1$ and let $x^{(0)}, \dots, x^{(N)}$ be a sequence in $\text{rel int } S$ such that $x^{(0)} = x^{(N)}$. To prove the existence of a θ as in (4.15) it is enough to show that there is a $z \in \text{rel int } S$ satisfying

$$(4.18) \quad u(z, z) \leq \frac{1}{N} \sum_{k=0}^{N-1} u(x^{(k)}, x^{(k+1)}).$$

This will show that the infimum in (4.14) can be computed using $N = 1$, which is our assertion. The right-hand side of (4.18) is

$$(4.19) \quad \frac{1}{N} \left\{ \sum_{j=1}^n x_j^{(0)} \phi_j(M_j^{(0)}) + \sum_{j=1}^n x_j^{(1)} \phi_j(M_j^{(1)}) + \cdots + \sum_{j=1}^n x_j^{(N-1)} \phi_j(M_j^{(N-1)}) \right\}$$

where the stochastic matrices $\{M^{(k)}\}_{k=0}^{N-1}$ are such that

$$(4.20) \quad x^{(k+1)} = (M^{(k)})^T x^{(k)}, \quad k = 0, 1, \dots, N-1.$$

Changing the order of summation in (4.19) we get

$$(4.21) \quad \frac{1}{N} \left\{ \sum_{j=1}^n \sum_{k=0}^{N-1} (x^{(k)})_j \phi_j(M_j^{(k)}) \right\} = \sum_{j=1}^n z_j \sum_{k=0}^{N-1} \frac{x_j^{(k)}}{N z_j} \phi_j(M_j^{(k)})$$

where we denoted $z_j = (1/N) \sum_{k=0}^{N-1} x_j^{(k)}$. Then $z = \{z_j\}_{j=1}^n$ is in $\text{rel int } S$. For every fixed j the numbers $\{x_j^{(k)} / N z_j\}_{k=0}^{N-1}$ are positive and sum up to 1. Therefore, by the convexity of $\phi_j(\cdot)$, the expression in the right-hand side of (4.21) is not less than

$$(4.22) \quad \sum_{j=1}^n z_j \phi_j \left(\frac{1}{N z_j} \sum_{k=0}^{N-1} x_j^{(k)} M_j^{(k)} \right) = \sum_{j=1}^n z_j \phi_j(q_j)$$

where $q_j = (1/N z_j) \sum_{k=0}^{N-1} x_j^{(k)} M_j^{(k)}$ is a convex combination of points in $\text{rel int } S$ and hence is in $\text{rel int } S$ itself. Let Q be the stochastic matrix whose j th row is q_j . Then we claim that

$$(4.23) \quad Q^T z = z.$$

The last equation is equivalent to saying that z is a convex combination of the rows of Q with the weights $\{z_j\}_{j=1}^\infty$. But

$$\begin{aligned} \sum_{j=1}^n z_j q_j &= \frac{1}{N} \sum_{j=1}^n \sum_{k=0}^{N-1} x_j^{(k)} M_j^{(k)} \\ &= \frac{1}{N} \sum_{k=0}^{N-1} \sum_{j=1}^n x_j^{(k)} M_j^{(k)} = \frac{1}{N} \sum_{k=0}^{N-1} x^{(k+1)} \end{aligned}$$

where the last equality follows from (4.20). However,

$$\frac{1}{N} \sum_{k=0}^{N-1} x^{(k+1)} = \frac{1}{N} \sum_{k=0}^{N-1} x^{(k)} = z$$

since $x^{(0)} = x^{(N)}$. This proves the equality (4.23). It now follows from (4.21), (4.22) and (4.23) that

$$u(z, z) \leq \frac{1}{N} \sum_{k=0}^{N-1} u(x^{(k)}, x^{(k+1)})$$

and, as explained above, this completes the proof of the theorem. \square

5. Stationary strategies with a minimal cost-growth rate—a general constraint set for the controls. In the discussion up to now we assumed Assumption A(i) namely that every distribution can be realized from every initial state in a unit time by some control. This assumption will now be relaxed and we will assume that the controls take values in some convex and compact set. The convexity assumption is natural since we allow, in the original framework, mixing of controls.

Let \mathcal{M} be the set of stochastic matrices which are admissible controls for our system. If the system occupies the state i and the control $M \in \mathcal{M}$ is employed, then the cost $\phi_i(M_i)$ is incurred. We assume the following:

ASSUMPTION B.

- (i) The set \mathcal{M} is convex and compact.
- (ii) The functions $\phi_i: \mathcal{M} \rightarrow R^1 \cup \{\infty\}$ are lower semicontinuous and bounded below for every $1 \leq i \leq n$.
- (iii) If $M \in \mathcal{M}$, then any two states communicate on some time interval $[0, n_0]$ under the action of the stationary strategy $\sigma = \{M\}_{k=0}^\infty$, namely $((M^T)^{n_0})_{ij} > 0$ for some n_0 .

We shall prove in this section that for a constraint set \mathcal{M} as in Assumption B there is a stationary strategy $M \in \mathcal{M}$ which is of a minimal cost growth rate among all the nonanticipative strategies. For every $M \in \mathcal{M}$ let $\psi(M)$ be the point whose i th component is $\phi_i(M_i)$. The functions $\phi_i(\cdot)$ can take the value $+\infty$, and we agree to interpret scalar products $x^T \cdot \psi(M)$ as equal to

$$\sum_{x_i > 0} x_i \phi_i(M_i)$$

and possibly equal to $+\infty$. We define the following:

$$(5.1) \quad u(x, y) = \min \{x^T \cdot \psi(M) : M^T x = y, M \in \mathcal{M}\}.$$

PROPOSITION 5.1. *The function $u(\cdot, \cdot)$ is lower semicontinuous.*

Proof. Let $(x^i, y^i) \rightarrow (x^0, y^0)$ as $i \rightarrow \infty$, and let $M^i \in \mathcal{M}$ be such that

$$u(x^i, y^i) = (x^i)^T \psi(M^i) \quad \text{and} \quad (M^i)^T x^i = y^i.$$

Then there is an $M^0 \in \mathcal{M}$ such that $(M^0)^T x^0 = y^0$. Let j be such that $(x^0)_j > 0$. Then we claim that

$$(5.2) \quad (x^0)_j \phi_j((M^0)_j) \leq \liminf_{i \rightarrow \infty} (x^i)_j \phi_j((M^i)_j).$$

This is clear if $\phi_j((M^i)_j) \rightarrow \infty$ as $i \rightarrow \infty$, and it follows from the lower semicontinuity of $\phi_j(\cdot)$ if $\{\phi_j((M^i)_j)\}_{i=1}^\infty$ is bounded. If $(x^0)_j = 0$, then (5.2) holds again since $\phi_j(\cdot)$ is bounded below. Thus we have

$$u(x^0, y^0) \leq (x^0)^T \psi(M^0) \leq \liminf_{i \rightarrow \infty} u(x^i, y^i)$$

proving the assertion of the proposition. \square

Let σ be any nonanticipative strategy with control values in \mathcal{M} . Then, by the same proof as that of (4.11), there is a Markov strategy $\bar{\sigma}$ such that (4.11) holds for every $N \geq 1$. The proof of (4.11) did not make use of Assumption A, while the convexity assumption on \mathcal{M} guarantees that the expectation of the random controls with values in \mathcal{M} are also in \mathcal{M} . Thus we can consider from now on only Markov strategies and establish the existence of a stationary strategy with a minimal long-run average cost is this smaller class.

The constant μ which is the minimal cost growth rate is given by

$$(5.3) \quad \mu = \inf \left\{ \liminf_{N \rightarrow \infty} \frac{1}{N} \sum_{k=0}^{N-1} u(x_k, x_{k+1}) \right\}$$

where N varies over all the integers and $\{x_k\}_{k=1}^\infty$ varies over all the sequences in S such that $x_{k+1} = M^T x_k$, $M \in \mathcal{M}$ (which depends on x_k, x_{k+1}).

PROPOSITION 5.2. *For every $\varepsilon > 0$ there are points $z_1, z_2 \in S$ such that*

$$|z_1 - z_2| < \varepsilon \quad \text{and} \quad u(z_1, z_2) < \mu + \varepsilon.$$

Proof. Given ε , there is by (5.3) a sequence $\{x_k\}_{k=0}^N \subset S$ such that

$$\frac{1}{N} \sum_{k=0}^{N-1} u(x_k, x_{k+1}) < \mu + \varepsilon$$

where N can be taken arbitrarily large. We define

$$(5.4) \quad z_1 = \frac{1}{N} \sum_{k=0}^{N-1} x_k, \quad z_2 = \frac{1}{N} \sum_{k=1}^N x_k.$$

Repeating the calculation between (4.18) and (4.23) in the proof of Theorem 4.4, while using the fact that \mathcal{M} is convex, we get that there is a matrix $M \in \mathcal{M}$ such that

$$(5.5) \quad z_2 = M^T z_1 \quad \text{and} \quad \sum_{i=1}^n (z_1)_i \phi_i(M_i) \leq \mu + \varepsilon$$

and therefore $u(z_1, z_2) \leq \mu + \varepsilon$. But if N is large enough, then it follows from (5.4) that $|z_1 - z_2| < \varepsilon$, which concludes the proof. \square

THEOREM 5.3. *Let \mathcal{M} satisfy Assumption B. Then there is a stationary strategy $\sigma_0 = \{M_0\}_{k=0}^\infty$ which is of a minimal cost growth rate in the class of all nonanticipative strategies with control values in \mathcal{M} . M_0 is any matrix such that*

$$(5.6) \quad M_0^T z_0 = z_0, \quad z_0^T \cdot \psi(M_0) = u(z_0, z_0), \quad M_0 \in \mathcal{M}$$

and

$$(5.7) \quad u(z_0, z_0) = \min_{z \in S} u(z, z).$$

Proof. As remarked above, it is enough to establish the existence of an optimal stationary strategy as in the theorem in the smaller class of Markov strategies $\{M^{(k)}\}_{k=0}^\infty$, $M^{(k)} \in \mathcal{M}$ for all $k \geq 0$. It follows from Proposition 5.2 that there is a z_0 such that $u(z_0, z_0) = \mu$, thus z_0 also satisfies (5.7).

Let M_0 be such that (5.6) is satisfied and consider the stationary strategy $\sigma_0 = \{M_0\}_{k=0}^\infty$. It follows from Assumption B(iii) that the corresponding Markov chain has a unique equilibrium distribution z_0 . Thus, if $x^{(k)}$ is the distribution of the Markov chain at the time k , then

$$\frac{1}{N} \sum_{k=0}^{N-1} u(x^{(k)}, x^{(k+1)}) \rightarrow u(z_0, z_0) = \mu$$

proving that σ_0 is of a minimal cost growth rate. \square

6. Overtaking optimal strategies. In this section we confine our attention to stationary strategies, i.e., $\sigma = \{M\}_{k=0}^\infty$ for some stochastic matrix M . In this situation it is easy to derive simple expressions for the cost flows. We will prove that under Assumption B for every initial state there exists an overtaking optimal strategy (recall Definition 3.1). The difficulty is to obtain a stationary strategy which is overtaking optimal for all the initial states. We will show that under Assumption A every stationary strategy with a minimal long-run average cost is in fact overtaking optimal for all the initial states.

We assume now that Assumption B holds. Let $M \in \mathcal{M}$, $\sigma = \{M\}_{k=0}^\infty$, $\{\zeta^{(k)}\}_{k=0}^\infty$ be the Markov chain associated with this strategy and the initial distribution $x^{(0)}$, and $\{x^{(k)}\}_{k=0}^\infty$ is the corresponding distributions. Then $x^{(k+1)} = M^T x^{(k)}$ and it is well known that

$$(6.1) \quad x^{(k)} \rightarrow z \quad \text{exponentially fast as } k \rightarrow \infty$$

for some $z \in \text{rel int } S$ which satisfies $z = M^T z$ (see Kushner [6, Lemma 3, p. 54]). Thus we get a mapping

$$(6.2) \quad M \rightarrow \phi(M) = z^M$$

which associates with every $M \in \mathcal{M}$ the equilibrium distribution z^M , and we claim the following.

PROPOSITION 6.1. *The mapping in (6.2) is continuous.*

Proof. Let $\{M_l\}$ and $\{z_l\}$, $l \geq 1$, be related by $z_l = (M_l)^T z_l$, and suppose that $M_l \in \mathcal{M}$ and $M_l \rightarrow M_0$ as $l \rightarrow \infty$. Then the uniqueness of z_0 implies that every convergent subsequence of $\{z_l\}_{l=1}^\infty$ must coverage to z_0 , implying that $z_l \rightarrow z_0$ as $l \rightarrow \infty$ and proving the proposition. \square

For a stationary strategy $\sigma = \{M\}_{k=0}^\infty$ and an initial state i we have

$$(6.3) \quad \frac{1}{N} C_N(i, \sigma) \rightarrow (z^M)^T \cdot \phi(M) \quad \text{as } N \rightarrow \infty$$

where we denote $(\phi(M))^T = (\phi_1(M_1), \dots, \phi_n(M_n))$. By Assumption B every $\phi_j(\cdot)$ is a lower semicontinuous function. Thus it follows that the right-hand side of (6.3) is a lower semicontinuous function of M , and it obtains its minimal value on \mathcal{M} . Let the minimal value be μ and the compact set of matrices where it is obtained be $\mathcal{M}_0 \subset \mathcal{M}$. Thus we have for every $M \in \mathcal{M}_0$

$$\mu = (z^M)^T \cdot M^k \phi(M) \quad \text{for every } k \geq 0.$$

For a stationary $\sigma = \{M\}_{k=0}^\infty$ and an initial state i we consider the *modified cost flow*

$$\tilde{C}_N(i, \sigma) = C_N(i, \sigma) - \mu N$$

which is equal to $\sum_{k=0}^{N-1} (x^{(k)} - z^M)^T \cdot \phi(M)$, namely

$$(6.4) \quad \tilde{C}_N(i, \sigma) = (e_i - z^M)^T \cdot \sum_{k=0}^{N-1} M^k \phi(M)$$

(e_i is the i th vertex of S). By (6.1) the limit in (6.4) exists as $N \rightarrow \infty$ and we denote

$$\psi(i, M) = \lim_{N \rightarrow \infty} \tilde{C}_N(i, \sigma)$$

and

$$(6.5) \quad \psi(i, M) = \lim_{N \rightarrow \infty} (e_i - z^M)^T \cdot \sum_{k=0}^{N-1} M^k \phi(M)$$

and $(\psi(M))^T = (\psi(1, M), \dots, \psi(n, M))$. For an initial distribution $x^{(0)}$ the modified expected cost is then $(x^{(0)})^T \cdot \psi(M)$. In order for a strategy $\sigma = \{M^i\}_{k=0}^\infty$ to be overtaking optimal for the initial state i it must satisfy $\psi(i, M^i) \leq \psi(i, M)$ for every $M \in \mathcal{M}$. If $\sigma = \{M^*\}_{k=0}^\infty$ is to be overtaking optimal for all the initial states, then it must satisfy $\psi(M^*) \leq \psi(M)$ for every $M \in \mathcal{M}$, the inequality being understood componentwise.

The discussion which leads to (6.4) shows that for every $y \in R^n$ the limit

$$(6.6) \quad \lim_{N \rightarrow \infty} (x - z^M)^T \cdot \sum_{k=0}^{N-1} M^k y$$

exists for every $x \in S$. If we denote

$$X = \left\{ w \in R^n : \sum_{i=1}^n w_i = 0 \right\}$$

then the limit in (6.6) defines a linear function on X which can be represented uniquely as

$$w \rightarrow w^T \cdot \eta(y)$$

for some $\eta(y) \in X^n$. Then $\eta(y)$ depends linearly on y , therefore, it depends on it continuously. It follows that we can write (6.5) as

$$\psi(i, M) = (e_i - z^M)^T \cdot \eta(\phi(M)),$$

hence $\psi(i, M)$ depends continuously on M and it attains its minimal value on \mathcal{M}_0 , say at M^i . Then $\sigma = \{M^i\}_{k=0}^\infty$ is an overtaking optimal strategy for the initial state i . We thus have proved the following.

THEOREM 6.2. *Let Assumption B hold and let the initial state be i . Then there is a stationary strategy $\sigma = \{M^i\}_{k=0}^\infty$ which is overtaking optimal in the class of all stationary strategies.*

We will assume now that Assumption A holds and will establish the existence of a stationary strategy which is overtaking optimal for all the initial states. In fact we will prove the stronger result, that is, that every stationary strategy with a minimal cost growth rate is overtaking optimal for all the initial states.

Let $\{M_i\}_{k=0}^\infty$ be the overtaking optimal strategy guaranteed by Theorem 6.2 for the initial state i . We assume that at least one of the matrices M_i , $1 \leq i \leq n$, is not overtaking optimal for all the initial states. We shall now show that this assumption leads into a contradiction. We define the matrix M^* as the stochastic matrix whose i th row is equal to the i th row of M_i . We define the following strategies: $\sigma^* = \{M^*\}_{k=0}^\infty$ is a stationary strategy. Let σ_N , $N \geq 1$, be the nonanticipative strategy which coincides with σ^* as long as there occurred no more than N changes of states. If after N changes of states the state is j , then from that time on σ_N coincides with the stationary strategy $\{M_j\}_{k=0}^\infty$. Note that σ_N is not a Markov strategy. Finally, let σ_0 be a strategy which coincides with the stationary strategy $\{M_i\}_{k=0}^\infty$ if the initial state is i , and where the initial state is a random variable $\zeta^{(0)}$.

We also define the sequence of random times $k_1 < k_2 < \dots < k_l < \dots$ where changes of states occur, namely, $\zeta_r = i$ for $0 \leq r < k_1$, and $\zeta_{k_1} \neq i$, $\zeta_r = \zeta_{k_1}$ for $k_1 \leq r < k_2$ and $\zeta_{k_2} \neq \zeta_{k_1}$, and so on.

The expected modified cost of σ_1 if the initial state is i is given by

$$(6.7) \quad \sum_{j \neq i} \{[\phi_i((M_i)_i) - \mu]E(k_1 | \zeta_{k_1} = j) + \psi(M_j, j)\}P(\zeta_{k_1} = j)$$

(here $(M_i)_i$ is the i th row of M_i). This expression is not greater than

$$(6.8) \quad \sum_{j \neq i} [\phi_i((M_i)_i) - \mu]E(k_1 | \zeta_{k_1} = j) + \psi(M_i, j)P(\zeta_{k_1} = j)$$

for every $1 \leq i \leq n$, since $\psi(M_j, j) \leq \psi(M_i, j)$. However, since at least one of the strategies $\{M_i\}_{k=0}^\infty$ is not overtaking optimal for every initial state, there is some i for which the expression in (6.7) is strictly smaller than that in (6.8). This discussion implies the following.

PROPOSITION 6.3. *Assume that at least one of the strategies $\{M_i\}_{k=0}^\infty$ is not overtaking optimal for every initial state. Let the initial state $\zeta^{(0)}$ have a distribution $\theta \in \text{rel int } S$. Then the cost of applying the strategy σ_1 is strictly smaller than that of applying the strategy σ_0 .*

Proof. The assertion follows from the above discussion and from the fact that with a positive probability the initial state is one for which a strict inequality between the expression (6.7) and (6.8) will occur. \square

We are looking now for a special probability distribution for $\zeta^{(0)}$, say θ^* , which will have the following property: If $\zeta^{(k)}$ is the Markov chain which is obtained while employing the strategy σ^* then the distribution of $\zeta^{(k_l)}$ is θ^* for every $l \geq 1$, where $\{k_l\}_{l=1}^\infty$ are the random times of changes of states.

LEMMA 6.4. *There exists a $\theta^* \in \text{rel int } S$ as asserted above.*

Proof. The probability that $\zeta^{(k_l)} = j$ if the initial state is i and we employ the strategy σ^* is given by

$$N_{ij} = \begin{cases} 0 & \text{if } j = i, \\ \frac{M_{ij}^*}{1 - M_{ii}^*} & \text{if } j \neq i. \end{cases}$$

If $n = 2$ (the number of states) then

$$N = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad \theta^* = \begin{pmatrix} \frac{1}{2} \\ \frac{1}{2} \end{pmatrix}$$

satisfies the assertion of the theorem. If $n > 2$ then N^2 has only positive entries and there is a unique $\theta^* \in \text{rel int } S$ which satisfies $N^T \theta^* = \theta^*$. This θ^* is the one we are looking for. \square

THEOREM 6.5. *If the stationary strategy $\{M_i\}_{k=0}^\infty$ is overtaking optimal for the initial state i then it is overtaking optimal for every initial state. In particular there is an overtaking optimal strategy, for all the initial states, in the class of stationary strategies.*

Proof. Assume that the assertion of the theorem is false. Let θ^* be as in Lemma 6.4 and assume that it is the initial distribution. If we employ the strategy σ_1 then the distribution of $\zeta^{(k_1)}$ will be θ^* also. Therefore the expected modified cost of applying σ_1 , after time k , is equal to the expected modified cost of applying σ_0 from the initial time. It thus follows from Proposition 6.3 that the expected modified cost of applying σ_1 up to time k_1 is negative, say $-\varepsilon$. Then, since the distribution of $\zeta^{(k_1)}$ is given by θ^* , it follows that the expected modified cost of applying σ_2 on the time interval $[k_1, k_2]$ is $-\varepsilon$ also; and, in fact, the expected modified cost of applying σ_2 on $[0, k_2]$ is -2ε . It then follows that the expected modified cost of applying the nonanticipative strategy σ_N on the time interval $[0, k_N]$ is $-N\varepsilon$, which tends to $-\infty$ as N tends to $+\infty$. This, however, is a contradiction to Proposition 4.2 and the inequality (4.9), which implies that there is some lower bound on the modified costs of all the nonanticipative strategies and for all the times. This concludes the proof of the theorem. \square

We shall now establish our main result.

THEOREM 6.6. *Let $\sigma = \{M\}_{k=0}^\infty$ be a stationary strategy which has a minimal cost growth rate. Then σ is overtaking optimal for every initial state, in the class of all stationary strategies.*

Proof. By Theorem 6.5 there exists an overtaking optimal strategy $\sigma^* = \{M^*\}_{k=0}^\infty$ and if σ is not overtaking optimal then

$$(6.9) \quad \psi(M^*, i) < \psi(M, i)$$

for some initial state i .

It follows from (6.9) that there is an integer L such that the following holds:

$$(6.10) \quad C_N(i, \sigma^*) < C_N(i, \sigma) - \varepsilon$$

for some $\varepsilon > 0$, for this i , and for all $N > L$.

Let i be the initial state, and let $\{\zeta^{(k)}\}_{k=0}^\infty$ and $\{\eta^{(k)}\}_{k=0}^\infty$ be the Markov chains corresponding to σ^* and σ , respectively. Let k_1 be the first time k which is greater than L where the equality $\zeta^{(k)} = \eta^{(k)} = i$ occurs. Inductively, let k_{r+1} be the first time

k which is larger than $k_r + L$ where the equality $\zeta^{(k)} = \eta^{(k)} = i$ occurs. Clearly $P(k_r < \infty) = 1$ for every $r \geq 1$. It follows from (6.10) that

$$E_i C_{k_i}(i, \sigma^*) \leq E_i C_{k_i}(i, \sigma) - \varepsilon.$$

It also follows from (6.10) that for every $r \geq 1$

$$(6.11) \quad E_{\zeta^{(k_r)}} C_{k_{r+1}-k_r}(\zeta^{(k_r)}, \sigma^*) < E_{\eta^{(k_r)}} C_{k_{r+1}-k_r}(\eta^{(k_r)}, \sigma) - \varepsilon.$$

Adding the inequalities (6.11) for $1 \leq r \leq l-1$, we get

$$(6.12) \quad E_i C_{k_l}(i, \sigma^*) \leq E_i C_{k_l}(i, \sigma) - l\varepsilon.$$

The strategy σ is such that

$$(6.13) \quad |C_N(i, \sigma) - \mu N| < K$$

for some $K > 0$ and all $N \geq 1$, since it is stationary and of a minimal cost growth rate. Also, for every strategy σ'

$$C_N(i, \sigma') - \mu N \geq -K$$

for all $N \geq 1$. Therefore, also for every random time $k(\omega)$

$$(6.14) \quad E[C_k(i, \sigma') - k\mu] \geq -K, \quad E[C_k(i, \sigma) - k\mu] \leq K.$$

Taking $\sigma' = \sigma^*$ and letting $l \rightarrow \infty$, however, we find that (6.12) contradicts (6.14). This concludes the proof of the theorem. \square

Theorem 6.6 provides us with a tool of computing overtaking optimal strategies. We have to compute the function $(x, y) \rightarrow u(x, y)$ and consider its restriction to the diagonal $z \rightarrow u(z, z)$. Let z_0 be in $\text{rel int } S$ such that

$$u(z_0, z_0) \leq u(z, z)$$

for every $z \in S$. We have then to compute the stochastic matrix M_0 which satisfies the relations

$$M_0^T z_0 = z_0, \quad \sum_{i=1}^n (z_0)_i \phi_i((M_0)_i) = u(z_0, z_0).$$

This matrix M_0 is such that $\sigma_0 = \{M_0\}_{k=0}^\infty$ is overtaking optimal for every initial state.

Acknowledgment. I would like to thank Professor Steven Orey for many fruitful discussions concerning this work.
