

DIRECT MINIMAL BALANCED REALIZATION FROM IMPULSE RESPONSE MATRICES USING I/O MAP DECOMPOSITION*

B. S. LEE† AND F. W. FAIRMAN†

Abstract. Fundamental properties of I/O maps for linear continuous-time systems are used to formulate a method for determining a minimal (balanced) realization directly from a given impulse response matrix.

Key words. finite dimensional systems, minimal realization, balanced realization

1. Introduction. Work on the nature and properties of balanced realizations of finite dimensional linear time-invariant systems has been ongoing since the initial introduction of this class of realizations by Moore [1], [2]. A minimal realization is said to be balanced if its controllability and observability Gramians are equal and diagonal. Recent work has generalized and extended the original concept to *LQG* feedback control systems [3] and to time-varying systems [4], [5].

However, the determination of a balanced realization for a given transfer function has not received much attention in the literature. Except for the method given in [6] for scalar transfer functions having simple poles, to date the general methods for obtaining a balanced realization given by Moore [1], [2] and Laub [7] require the determination of an initial minimal realization. Starting with the system's transfer function matrix, Moore's algorithm involves the minimal realization of the given transfer function matrix, the solution of two Lyapunov equations and the singular value decomposition of two positive definite matrices. A step-by-step description of Moore's algorithm is given as

- (i) Determine a minimal realization.
- (ii) Solve the Lyapunov equation for the controllability Gramian of the realization determined in (i).
- (iii) Singular value decompose the Gramian determined in (ii).
- (iv) Calculate the realization which results from changing the coordinates through the use of a coordinate transformation matrix made up from the matrices determined in (iii).
- (v) Solve the Lyapunov equation for the observability Gramian for the realization determined in (iv).
- (vi) Singular value decompose the Gramian determined in (v).
- (vii) Calculate the balanced realization which results from changing the coordinates through the use of a co-ordinate transformation matrix composed from matrices determined in (vi).

On the other hand, Laub's method [7] requires both the controllability and observability Gramians of the initial realization (i.e., the solution of two Lyapunov equations). Moreover, the requirement for two singular value decompositions in [2] is replaced by a Cholesky decomposition and an eigenvalue-eigenvector problem for a real symmetric matrix in [7].

Starting with the system's transfer function matrix, the algorithm developed here for achieving a minimal (balanced) realization involves the partial fraction expansion of the given transfer function matrix, the Cholesky decomposition of a positive definite

† Department of Electrical Engineering, Queen's University, Kingston, Ontario, Canada K7L 3N6.

real symmetric matrix and the singular value decomposition of a real matrix. The steps involved in the execution of this algorithm are given as

(1) Determine the poles and partial fraction coefficient matrices of the transfer function matrix.

(2) Form three real matrices \bar{K} , \bar{V} and $\bar{\Lambda}$ directly from the poles and partial fraction coefficient matrices.

(3) Perform Cholesky decomposition on the real positive definite matrix \bar{V} , i.e. $\bar{V} = \bar{L}\bar{L}^T$.

(4) Singular value decompose

$$\bar{L}_q^T \bar{K}^T [I_p \otimes \bar{V}] \bar{K} \bar{L}_q = [U_1 \ U_2] \begin{bmatrix} \Sigma^2 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} U_1^T \\ U_2^T \end{bmatrix}$$

where $\bar{L}_q = [I_q \otimes \bar{L}]$.

(5) Calculate the balanced realization (A, B, C^T) as

$$A = T_1^{-1} \bar{A} T_1, \quad B = T_1^{-1} \bar{B}, \quad C^T = \bar{C}^T T_1,$$

where

$$\begin{aligned} \bar{A} &= [I_q \otimes \bar{\Lambda}], & \bar{B} &= [I_q \otimes \gamma(0)], \\ \bar{C}^T &= [I_p \otimes \gamma(0)^T] \bar{K}, & T_1 &= \bar{L}_q U_1 \Sigma^{-1/2} \end{aligned}$$

and $\gamma(t)$ is a vector of time multiplied exponentials which are related to the poles of the transfer function matrix and $[\cdot \otimes \cdot]$ is the Kronecker product.

Notice that an arbitrary minimal realization is not required and that there is no need to solve any Lyapunov equations.

The development of the algorithm is carried out by considering single-input single-output (SISO) systems first. The algorithm developed for this class of systems is then extended to enable the balanced realization of multi-input, multi-output (MIMO) systems.

Notation peculiar to this paper which is employed in the sequel is stated now as follows: I_r is the r by r identity matrix; Γ^i denotes the i th diagonal block of some square block diagonal matrix Γ ; E is a parity matrix, i.e., E is a diagonal matrix with diagonal elements $\{e_i; i = 1, 2, \dots, n\}$ where $e_i \in \{1, -1\}$; j is context dependent being either a positive integer or $(-1)^{1/2}$.

2. General properties of I/O maps. Let the system be specified by its transfer function $h_L(s)$ as

$$(1) \quad h_L(s) = \frac{n(s)}{d(s)}$$

where $n(s)$, $d(s)$ are coprime polynomials with real coefficients and all zeros of $d(s)$ have nonzero negative real part (stability assumption). In the sequel interest will focus on the inverse transform of $h_L(s)$ (impulse response) which is given in the general form (for proper rational $h_L(s)$) as

$$(2) \quad h(t) = \sum_{i=1}^m \sum_{j=1}^{n_i} m_{ij} t^{j-1} e^{\lambda_i t} = \alpha^T \gamma(t)$$

where $\lambda_i, m_{ij} \in C^1$ and $\lambda_i \neq \lambda_j$ when $i \neq j$. Also $n = \sum_{i=1}^m n_i$ and

$$\alpha^T = [\alpha_1^T, \alpha_2^T, \dots, \alpha_m^T], \quad \alpha_i^T = [m_{i1}, m_{i2}, \dots, m_{in_i}],$$

$$\gamma^T(t) = [\gamma_1^T(t), \gamma_2^T(t), \dots, \gamma_m^T(t)], \quad \gamma_i^T(t) = [1, t, \dots, t^{n_i-1}] e^{\lambda_i t}.$$

Next recall that a minimal realization (A, b, c^T) of $h_L(s)$ must satisfy

$$(3) \quad h_L(s) = c^T(sI - A)^{-1}b, \quad h(t) = c^T e^{At}b,$$

where $A \in C^{n \times n}$, $c \in C^n$ and n is minimal.

Then the controllability and observability Gramians W_c, W_o over the infinite interval $[0, \infty)$ as well as the input and output maps $f_c(t), f_o(t)$ are defined as

$$(4) \quad W_c = \int_0^\infty f_c(t) f_c^T(t) dt, \quad f_c(t) = e^{At}b,$$

$$(5) \quad W_o = \int_0^\infty f_o(t) f_o^T(t) dt, \quad f_o(t) = e^{A^T t} c^T,$$

where $W_c, W_o \in R^{n \times n}$ are nonsingular.

The existence of W_c, W_o follows from stability of $h_L(s)$ and the nonsingularity of these matrices is a consequence of the minimality of the realization. When the realization is balanced W_c, W_o are equal and diagonal, i.e., $W_c = W_o = \Sigma$. The I/O maps, $f_c(t)$ and $f_o(t)$ are considered now in some detail.

Properties of a matrix F , relating the I/O maps, are given in the following theorem.

THEOREM 1. *For a minimal realization (A, b, c^T) of a stable SISO system the I/O maps are related by a constant square matrix F as*

$$(6) \quad f_o(t) = F f_c(t)$$

where

$$(7) \quad A^T = F A F^{-1},$$

$$(8) \quad c = F b,$$

$$(9) \quad F \text{ is nonsingular and symmetric.}$$

Proof. Recall that a minimal realization and its dual, (A^T, c, b^T) , are related by a unique symmetric co-ordinate transformation matrix [8, Thm. 2.4.7 and Ex. 2.4.16]. Therefore it follows directly that (6) holds with F satisfying (7)–(9).

It should be pointed out that the foregoing result is closely related to a result obtained in [9]. Notice that the Gramians can now be related by using (6) as

$$(10) \quad W_o = F W_c F.$$

It is interesting to notice from (2), (4) that every entry of e^{At} is a linear combination of exponential functions of the form $t^i \exp[\lambda_p t]$ where λ_p is a pole of the transfer function and t^i is due to the multiplicity of that pole. This observation leads to the conclusion that each entry of the I/O maps must be a linear combination of the above-mentioned exponential functions. Thus the input and output maps can be expressed as

$$(11) \quad f_c(t) = G_c \gamma(t), \quad f_o(t) = G_o \gamma(t),$$

where $G_c, G_0 \in C^{n \times n}$ and $\gamma(t)$ was defined in (2). Moreover, the nature of $\gamma(t)$ implies that there exists a constant matrix Λ such that

$$(12) \quad \frac{d}{dt} \gamma(t) = \Lambda \gamma(t)$$

where

$$\Lambda = \text{Diag} [\Lambda^1, \Lambda^2, \dots, \Lambda^m],$$

$$\Lambda^i = \begin{bmatrix} \lambda_i & 0 & \cdots & 0 & 0 \\ 1 & \lambda_i & \cdots & 0 & 0 \\ 0 & 2 & \cdots & 0 & 0 \\ 0 & 0 & & \vdots & \vdots \\ \vdots & \vdots & & \lambda_i & 0 \\ 0 & 0 & \cdots & n_i - 1 & \lambda_i \end{bmatrix}.$$

Next (11) enables the Gramians, (4), (5), to be rewritten as

$$(13) \quad W_c = G_c V G_c^T, \quad W_0 = G_0 V G_0^T,$$

where $V = \int_0^\infty \gamma(t) \gamma^T(t) dt$ and $\gamma(t)$ is defined in (2). Notice that since W_c, W_0 are nonsingular, therefore, $G_c G_0$ and V must be nonsingular.

Now it is readily shown by using (11), (12) and comparing the expressions obtained for the time derivative of $f_c(t), f_0(t)$ obtained using (4), (5) with those obtained using (11) that

$$(14) \quad \begin{aligned} A &= G_c \Lambda G_c^{-1}, & A^T &= G_0 \Lambda G_0^{-1}, \\ b &= G_c \gamma(0), & c &= G_0 \gamma(0). \end{aligned}$$

An expression for the impulse response involving $\gamma(t)$, F and G_c is developed now. This expression will be of central importance to the realization algorithm to be developed later in the paper. Notice that if A is scaled by a nonzero scalar k and b and c are unchanged then $h(t)$, $\gamma(t)$, and hence both maps have their time variable scaled by k . This observation leads to the following I/O map decomposition of the impulse response

$$(15) \quad h(t) = c^T e^{(1/2)At} e^{(1/2)At} b = f_0^T(t/2) f_c(t/2).$$

Moreover, using (6) and (11) this expression for the impulse response can be rewritten as

$$(16) \quad h(t) = \gamma^T(t/2) K \gamma(t/2)$$

where

$$(17) \quad K = G_c^T F G_c.$$

The basis for the method being developed here can now be indicated. As can be seen from (8), (14) the determination of a balanced realization is essentially complete once *appropriate* values for F and G_c have been determined. In the sequel it is shown that F can always be assumed to be a parity (sign, signature) matrix E . Therefore, the determination of E and G_c so that the realization is balanced requires the simultaneous satisfaction of (13), (17) with F assumed to be an unknown parity matrix and W_c an unknown positive definite diagonal matrix.

Before taking up the problem of determining E , G_c from (13), (17), it is shown that V can be determined directly from the poles, that K can be determined directly from the partial fraction expansion coefficients, and that (13), (17) can be rewritten in terms of real matrices.

Notice that the matrix V which is needed in (13) can readily be computed from a knowledge of the factors of the denominator polynomial as

$$(18) \quad (V_{ij})_{pq} = \frac{(p+q-2)!}{[-(\lambda_i + \lambda_j)]^{p+q-1}}$$

where $V_{ij} \in C^{n_i \times n_j}$ is the ij th block of V and

$$V_{ij} = \int_0^\infty \Gamma_{ij}(t) e^{(\lambda_i + \lambda_j)t} dt,$$

$$(\Gamma_{ij}(t))_{pq} = t^{p+q-2}.$$

Moreover it is shown in the Appendix that the matrix K which is needed in (17) can be evaluated directly from the partial fraction expansion coefficients as

$$(19) \quad K = \text{Diag}[K^1, K^2, \dots, K^m]$$

where

$$(K^i)_{pq} = \begin{cases} \frac{(p+q-2)!}{(p-1)!(q-1)!} m_{i,p+q-1}, & p+q < n_i+1, \\ 0, & \text{otherwise.} \end{cases}$$

Thus the K matrix is block diagonal with diagonal blocks being upper cross-diagonal with coefficients on rays parallel to the cross diagonal being related to the coefficients in the binomial expansion, e.g.,

$$(20) \quad K^i = \begin{bmatrix} m_{i,1} & m_{i,2} & m_{i,3} & m_{i,4} & m_{i,5} & \cdot & \cdot & m_{i,n_i} \\ m_{i,2} & 2m_{i,3} & 3m_{i,4} & 4m_{i,5} & \cdot & \cdot & \cdot & 0 \\ m_{i,3} & 3m_{i,4} & 6m_{i,5} & \cdot & \cdot & \cdot & \cdot & 0 \\ m_{i,4} & 4m_{i,5} & \cdot & \cdot & \cdot & \cdot & \cdot & 0 \\ m_{i,5} & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 \\ m_{i,n_i} & 0 & 0 & \cdot & \cdot & \cdot & \cdot & 0 \end{bmatrix}.$$

Notice from the foregoing that the first row of K^i is α_i^T , (2). Also notice that $\gamma_i^T(0)K^i = \alpha_i^T$ and hence that $\gamma^T(0)K = \alpha^T$. Thus it follows from this observation and from (12) that $h(t) = c^T e^{At} b$ when $A = \Lambda$, $b = \gamma(0)$ and $c^T = \gamma^T(0)K$. This simple fact will play an important role in the development of the realization algorithm.

Thus from the foregoing it is seen that the matrices K and V can be readily determined directly from the partial fraction expansion of the transfer function. However, these matrices are complex in general. Considerable reduction in the computational burden would result if it were possible to modify the foregoing approach so that all matrices involved in (13), (17) were real. It turns out that this is possible due to the fact that the impulse response function is real. For $h(t)$ to be real, any complex λ_i 's must occur in conjugate pairs, i.e., if $\text{Im}[\lambda_i] \neq 0$ then $\text{Im}[\lambda_i] = -\text{Im}[\lambda_j]$ for i, j integers $\in [1, m]$ and $i = j$. Therefore, the λ_i 's (2), can be arranged so that conjugate

pairs are denoted by consecutive indices and the complex λ_i 's are denoted by the lowest indices viz.

$$(21) \quad \begin{aligned} \lambda_{2i-1} &= \lambda_{2i}^*, & i &= 1, 2, \dots, \nu, \\ \lambda_i &= \text{real scalar}, & i &= 2\nu+1, 2\nu+2, \dots, m. \end{aligned}$$

It also follows from the realness of the impulse response that the coefficients in the expansion of the impulse response, (2), must satisfy

$$(22) \quad \begin{aligned} m_{2i-1,j} &= m_{2i,j}^*, & i &= 1, 2, \dots, \nu, \\ & & j &= 1, 2, \dots, n_i, \\ m_{ij} &= \text{real scalar}, & i &= 2\nu+1, 2\nu+2, \dots, m, \\ & & j &= 1, 2, \dots, n_i, \end{aligned}$$

where n_i is the multiplicity of the corresponding pole. Moreover, the block diagonal matrices Λ and K (12), (19) become

$$(23) \quad \begin{aligned} \Lambda &= \text{Diag} [\Lambda^1, \Lambda^{1*}, \Lambda^2, \Lambda^{2*}, \dots, \Lambda^\nu, \Lambda^{2\nu+1}, \Lambda^{2\nu+2}, \dots, \Lambda^m], \\ K &= \text{Diag} [K^1, K^{1*}, K^2, K^{2*}, \dots, K^\nu, K^{2\nu+1}, K^{2\nu+2}, \dots, K^m]. \end{aligned}$$

Consider next the block diagonal complex matrix J where

$$(24) \quad J = \text{Diag} [J^1, J^2, \dots, J^\nu, I_\delta]$$

where

$$\begin{aligned} \delta &= n - 2 \sum_{i=1}^{\nu} n_i, \\ J^i &= \frac{1}{\sqrt{2}} \begin{bmatrix} I_{n_i} & I_{n_i} \\ -jI_{n_i} & jI_{n_i} \end{bmatrix}, \quad \begin{aligned} i &= 1, 2, \dots, \nu, \\ j &= \sqrt{-1}, \end{aligned} \end{aligned}$$

and n_i is the multiplicity of the complex poles of $h_L(s)$ at λ_{2i} or λ_{2i-1} .

Then it can be seen by inspection of the matrices resulting from the indicated matrix multiplications that

$$(25) \quad \begin{aligned} \bar{K} &= J^{-T} K J^{-1} = \text{real, symmetric}, \\ \bar{\Lambda} &= J \Lambda J^{-1} = \text{real}, \\ \bar{V} &= J V J^T = \text{real, symmetric, positive definite.} \end{aligned}$$

The real symmetry of \bar{V} follows from

$$(26) \quad \bar{V} = \int_0^\infty \beta(t) \beta^T(t) dt$$

where

$$\begin{aligned} \beta(t) &= J \gamma(t), \\ \gamma(t) &= [\gamma_1(t), \gamma_1^*(t), \dots, \gamma_\nu^*(t), \gamma_{2\nu+1}(t), \dots, \gamma_m(t)]. \end{aligned}$$

Moreover the block matrices in \bar{K} and $\bar{\Lambda}$ are readily calculated as

$$(27) \quad \begin{aligned} \bar{K} &= \text{Diag} [\bar{K}^1, \bar{K}^2, \dots, \bar{K}^\nu, \bar{K}^{2\nu+1}, \bar{K}^{2\nu+2}, \dots, \bar{K}^m], \\ \bar{\Lambda} &= \text{Diag} [\bar{\Lambda}^1, \bar{\Lambda}^2, \dots, \bar{\Lambda}^\nu, \bar{\Lambda}^{2\nu+1}, \bar{\Lambda}^{2\nu+2}, \dots, \bar{\Lambda}^m] \end{aligned}$$

where

$$\bar{K}^i = \begin{cases} \left[\begin{array}{c|c} R_e[K^i] & -I_m[K^i] \\ \hline -I_m[K^i] & -R_e[K^i] \end{array} \right], & i = 1, 2, \dots, \nu, \\ K^i, & i = 2\nu + 1, \dots, m, \end{cases}$$

$$\bar{\Lambda}^i = \begin{cases} \left[\begin{array}{c|c} R_e[\Lambda^i] & I_m[\Lambda^i] \\ \hline I_m[\Lambda^i] & R_e[\Lambda^i] \end{array} \right], & i = 1, 2, \dots, \nu, \\ \Lambda^i, & i = 2\nu + 1, \dots, m, \end{cases}$$

and K^i, Λ^i are specified in (23).

In the sequel the positive definiteness of \bar{V} will be important. This property is given now in the following theorem.

THEOREM 2. *The \bar{V} matrix is real, symmetric and positive definite.*

Proof. Suppose (A, b, c^T) is a balanced realization. Then the controllability Gramian, (4), is diagonal and satisfies the following Lyapunov equation [10]

$$(28) \quad A\Sigma + \Sigma A^T = -bb^T.$$

Next, pre and post multiplying this equation by G_c^{-1} and G_c^{-T} , respectively, and using (13), (14) yields

$$(29) \quad \Lambda V + V\Lambda^T = -\gamma(0)\gamma^T(0).$$

Again pre- and post-multiplying (29) by J and J^T , respectively, and using (25) yields

$$(30) \quad \bar{\Lambda}\bar{V} + \bar{V}\bar{\Lambda}^T = -\bar{b}\bar{b}^T$$

where $\bar{b} = J\gamma(0)$.

Recall that $\bar{\Lambda}$ is real. It can also be seen from the block structure of J and $\gamma(0)$ that \bar{b} must be real. Moreover, $\bar{\Lambda}, \bar{b}$ are the system "A" and "b" matrices which result from changing the co-ordinates of the balanced realization by the co-ordinate transformation matrix $G_c J^{-1}$. Therefore, it follows that the controllability of (A, b) and stability of A guarantee the controllability of $(\bar{\Lambda}, \bar{b})$ and stability of $\bar{\Lambda}$. Thus it follows from these conditions and a well-known theorem [10, p. 86], that \bar{V} satisfying (30) is unique, real, symmetric and positive definite. This completes the proof of the theorem.

Before taking up the use of (18), (19), (25) in the development of a method for solving (13), (17) as discussed following (17), it needs to be established that for any transfer function there always exist balanced realizations with F being a parity matrix. This task is accomplished in the next section.

3. Symmetry properties of I/O maps for balanced realizations. Recall [2] that a minimal realization is said to be balanced if the controllability and observability Gramians (4), (5) are diagonal and equal, i.e.

$$(31) \quad W_c = W_o = \Sigma$$

where $\Sigma = \text{Diag}[\sigma_1, \sigma_2, \dots, \sigma_n]$ with $\sigma_i > 0$ and real for all integers $i \in [1, n]$. The σ_i 's have been referred to as the second order modes of the system [2].

In order to show the properties of F which result from having the realization balanced, a general result concerning a class of complex symmetric matrices is needed. This result is given now in the following

LEMMA 1. *If $Q \in C^{n \times n}$ is symmetric and $Q^2 = I$ then Q is similar to a parity matrix with the similarity transformation matrix $V \in C^{n \times n}$ satisfying*

$$V^T V = I_n.$$

Proof. The fact that Q is symmetric implies that its singular value decomposition can be written as

$$Q = V\Sigma V^T \quad \text{with } V^T V = I_n.$$

Then squaring both sides and using the fact that Q is self inverse leads to the conclusion that Σ^2 must be the identity matrix. Thus Σ must be a parity matrix and the proof is complete.

The properties of F that result from having the realization balanced are now stated in the following theorem.

THEOREM 3. *If (A, b, c^T) is a minimal balanced realization of a stable scalar transfer function then F in Theorem 1 is*

- 1) *a parity (signature, sign) matrix if all the second-order modes are distinct,*
- 2) *similar to a parity matrix if they are not distinct with the transformation matrix being orthogonal, i.e.*

$$V^T F V = \text{parity matrix with } V^T V = I_n.$$

Proof. Since the realization is assumed to be balanced (31) holds and (10) becomes

$$(32) \quad \Sigma = F\Sigma F.$$

Now since Σ and F are each nonsingular it follows that

$$(33) \quad F^{-1} = \Sigma^{-1} F \Sigma.$$

Now let Σ be arranged so that any repeated second order modes appear in succession along the diagonal, i.e.

$$\Sigma = \text{Diag} [\sigma_1 I_{r_1}, \sigma_2 I_{r_2}, \dots, \sigma_{r_m} I_{r_m}]$$

where there are m distinct second-order modes and σ_i is repeated r_i times. Using this form for Σ in (33) and equating like positioned blocks on either side of (33) yields

$$(34) \quad (F^{-1})_{ij} = \frac{\sigma_j}{\sigma_i} F_{ij}$$

where F is partitioned so as to enable block multiplication in (33) and F_{ij} refers to the r_i by r_j block viz.

$$F = \begin{bmatrix} F_{11} & F_{12} & \cdots & F_{1m} \\ F_{21} & F_{22} & \cdots & F_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ F_{m1} & F_{m2} & \cdots & F_{mm} \end{bmatrix}.$$

Now since F is symmetric so is F^{-1} and (34) implies

$$(35) \quad \frac{\sigma_i}{\sigma_j} F_{ji}^T = \frac{\sigma_j}{\sigma_i} F_{ij}.$$

But $F_{ij} = F_{ji}^T$ (Theorem 1) and $\sigma_i = \sigma_j$, $\sigma_i, \sigma_j > 0$ (assumed). Therefore, the off-diagonal blocks in F must be null, i.e.

$$(36) \quad F_{ij} = 0, \quad i \neq j.$$

Thus F must be a block diagonal matrix. Moreover, it is seen from (32) that the diagonal blocks must satisfy

$$(37) \quad F_{ii}^2 = I_{r_i}.$$

Then it follows from Lemma 1 and the block diagonal nature of F that F must be similar to a parity matrix.

Finally if all the second order modes are distinct, i.e. diagonal elements of Σ all different, then the foregoing shows that F must be a parity matrix. This completes the proof of the theorem.

From the foregoing it is now possible to state the following important theorem.

THEOREM 4. *It is always possible to choose the co-ordinates for a balanced realization such that F is a parity matrix.*

Proof. Recall that if T is a co-ordinate transformation matrix which transforms the realization (A, b, c^T) to $(\tilde{A}, \tilde{b}, \tilde{c}^T)$ then the controllability and observability Gramians in the original co-ordinates, namely W_c and W_o , are related to the controllability and observability Gramians in the new co-ordinates, namely \tilde{W}_c and \tilde{W}_o , as

$$(38) \quad \tilde{W}_c = T^{-1} W_c T^{-T}, \quad \tilde{W}_o = T^T W_o T.$$

Moreover, the relation between W_o , W_c and F , (10) implies that the F -matrix for (A, b, c^T) , namely F , is related to the F -matrix for $(\tilde{A}, \tilde{b}, \tilde{c}^T)$ namely \tilde{F} as

$$(39) \quad \tilde{F} = T^T F T.$$

Next suppose F is not a parity matrix. Then from the proof of Theorem 3, F is a block diagonal matrix having diagonal blocks which are self-inverse, i.e. diagonal blocks satisfying (37). Hence from Lemma 1 it follows that there exists a block diagonal matrix T having diagonal blocks satisfying

$$(40) \quad T_{ii}^{-1} F_{ii} T_{ii} = E_{ii},$$

where

$$E_{ii} = \text{parity matrix} \quad \text{and} \quad T_{ii}^{-1} = T_{ii}^T.$$

It follows that $T^T = T^{-1}$ and the system obtained by transforming the co-ordinates by T has a F -matrix, namely \tilde{F} , (39), which is a parity matrix. This completes the proof of Theorem 4.

The foregoing result is of importance in that it guarantees the existence of balanced realizations having the E -symmetry property corresponding to any stable transfer function. This fact was shown recently in a quite different fashion [11]. It is used in the next section to develop an algorithm for determining a balanced realization for a given transfer function by using the properties of I/O maps where it is assumed that the co-ordinates are such that F is a parity matrix.

4. Balancing algorithm: SISO case. Recall that a balanced realization has Gramians which satisfy (31). Recall also from Theorem 4 that it is always possible for F in Theorem 1 to be a parity matrix E . Therefore, when the realization is balanced with $F = E$, (13), (17) becomes

$$(41) \quad \Sigma = G_c V G_c^T,$$

$$(42) \quad K = G_c^T V G_c.$$

Now the need for complex matrices in these equations can be eliminated by using the results developed in § 3. Solving (25) for K and V and substituting in (41), (42) yields,

$$(43) \quad \Sigma = G \bar{V} G^T,$$

$$(44) \quad \bar{K} = G^T E G,$$

where

$$(45) \quad G = G_c J^{-1}.$$

The foregoing real equations can be combined to enable G , E and Σ to be determined as an eigenvalue-eigenvector problem. This is done by solving (44) for E and using the result to multiply (43). This gives rise to the following equation.

$$(46) \quad E\Sigma = G\bar{V}\bar{K}G^{-1}.$$

Notice that G diagonalizes $\bar{V}\bar{K}$ and that $E\Sigma$ and $\bar{V}\bar{K}$ are real. Therefore, G must be real. Also notice that in order for the G matrix satisfying (46) to yield a balanced realization, G must also satisfy (43) or (44). Since \bar{V} has been shown to be positive definite, real and symmetric, (43) is used with (46) to determine G using the numerically stable approach given in [12, pp. 337-338].

Notice that the product of the symmetric matrices \bar{V} and \bar{K} is symmetric only if \bar{V} and \bar{K} commute. In general these matrices do not commute. Therefore, to simplify the determination of G let the positive definite matrix \bar{V} be decomposed by Cholesky decomposition as

$$(47) \quad \bar{V} = LL^T$$

where L is real, lower triangular and nonsingular since \bar{V} is positive definite (Theorem 2). Therefore, it follows from (46) that if (α_i, u_i) is an eigenvalue-eigenvector pair for $L^T\bar{K}L$ then (α_i, Lu_i) is an eigenvalue-eigenvector pair for $\bar{V}\bar{K}$. However, since $L^T\bar{K}L$ is real and symmetric, its eigenvalues are real and it can be diagonalized by a real orthogonal matrix U .

From the foregoing it is seen that

$$(48) \quad \Sigma = \text{Diag} [|\alpha_1|, |\alpha_2|, \dots, |\alpha_n|],$$

$$(49) \quad E = \text{Diag} [\text{Sgn} [\alpha_1] \text{Sgn} [\alpha_2], \dots, \text{Sgn} [\alpha_n]].$$

Moreover $G^{-1} = LUS$ satisfies (46) with S diagonal. However, (44) must also be satisfied. This requirement is met by setting $S = \Sigma^{-1/2}$. Therefore using (14), (25), (45), it is seen that a balanced realization can be composed as

$$(50) \quad \begin{aligned} A &= \Sigma^{1/2} U^T L^{-1} \bar{A} L U \Sigma^{-1/2}, \\ b &= \Sigma^{1/2} U^T L^{-1} J \gamma(0), \\ c &= E b. \end{aligned}$$

To show that this realization is balanced, notice from (44) that the realization $(\bar{A}, J\gamma(0), \gamma^T(0)J^T\bar{K})$ equivalent to (50) with co-ordinate transformation matrix $T = \Sigma^{1/2} U^T L^{-1}$. Moreover, assuming $W_c = \Sigma$ in (38) gives $\tilde{W}_c = \bar{V}$ which was shown, (30), to be the controllability Gramian for $(\bar{A}, J\gamma(0))$. The fact that $W_0 = \Sigma$ follows from (10) since F is a parity matrix. Thus the realization determined by (50) is indeed balanced.

Finally, the realization (50) has impulse (2). This is seen by using the equivalence just mentioned and (25) to show that

$$c^T e^{At} b = \gamma^T(0) K e^{At} \gamma(0).$$

Then from the structure of $\gamma(0)$ and K , (2), (19), (20) as well as from (12) it follows that

$$\gamma^T(0) K = \alpha^T, \quad e^{At} \gamma(0) = \gamma(t).$$

Thus $c^T e^{At} b$ is seen to have an impulse response given by (2).

5. Balancing algorithm: MIMO case. In this section, Kronecker products [13] are used to extend the algorithm given in the previous section to enable the balancing of MIMO systems. This extension is not straightforward however, since F (Theorem 1) can no longer be assumed in general, to be a parity matrix.

Let the system's transfer function matrix be expanded in partial fractions as

$$(51) \quad H_L(s) = \sum_{i=1}^m \sum_{j=1}^{n_i} (s - \lambda_i)^{-j} H_{ij}, \quad r = \sum_{i=1}^m n_i$$

where $H_{ij} \in C^{p \times q}$ and $H_L(s)$ is assumed rational. Then the impulse response matrix (weighting matrix or pattern) is given as

$$(52) \quad H(t) = \sum_{i=1}^m e^{\lambda_i t} \sum_{j=1}^{n_i} M_{ij} t^{j-1} = \alpha^T [\gamma(t) \otimes I_q]$$

where $M_{ij} = (H_{ij}/(j-1)!)$ and $[\cdot \otimes \cdot]$ indicates Kronecker product.

$$\begin{aligned} \alpha^T &= [\alpha_1^T, \alpha_2^T, \dots, \alpha_m^T], & \alpha_i^T &= [M_{i1}, M_{i2}, \dots, M_{i,n_i}], \\ \gamma^T(t) &= [\gamma_1^T(t), \gamma_2^T(t), \dots, \gamma_m^T(t)], & \gamma_i^T &= [1, t, \dots, t^{n_i-1}] e^{\lambda_i t}. \end{aligned}$$

Notice that r , the sum of the n_i 's, is the degree of the least common denominator of $H_L(s)$ and also that r is the degree of the minimal polynomial of A , where (A, B, C^T) is any minimal realization of $H_L(s)$, [14, p. 108]. Moreover, since the maximal dimension of any of the blocks of the Jordan form for A associated with λ_i is n_i , [15, p. 226], it follows that the largest power of t multiplying $\exp(\lambda_i t)$ in any element of $\exp(At)$ is $n_i - 1$. Therefore, the least common denominator of the transfer function matrix plays the same role as the denominator polynomial of $h_L(s)$ in the SISO case for the determination of the vector of time multiplied exponentials, $\gamma(t)$. However, since the degree of the least common denominator r is in general not the same as the dimension of the minimal realization, it is important to notice that $\gamma(t)$ is defined by (2) with n replaced by r .

Next, let $H(t)$ be written as a matrix of scalar time functions

$$(53) \quad H(t) = [H_{ij}(t)], \quad i = 1, 2, \dots, p, \quad j = 1, 2, \dots, q.$$

Now each $H_{ij}(t)$ can be considered as the impulse response of a SISO system. Therefore, from (16) it is seen that

$$(54) \quad H_{ij}(t) = \gamma^T(t/2) K^{ij} \gamma(t/2)$$

where $\gamma(t)$ is determined from the least common denominator of $H_L(s)$ for reasons given earlier and K^{ij} is determined using (19). This observation enables the impulse response matrix to be written in terms of Kronecker products as

$$(55) \quad H(t) = [I_p \otimes \gamma^T(t/2)] K [I_q \otimes \gamma(t/2)]$$

where

$$K = [K^{ij}], \quad K \in C^{pr \times qr}.$$

In the sequel, the following rules for Kronecker products will be used [13],

$$(56) \quad \begin{aligned} [A \otimes B][C \otimes D] &= [AC \otimes BD], \\ [A \otimes B]^T &= [A^T \otimes B^T]. \end{aligned}$$

Proceeding in a similar fashion, the relations (11) can be generalized so that maps of a minimal realization of $H_L(s)$, (A, B, C^T) , having dimension n can be written as

$$(57) \quad \begin{aligned} e^{At}B &= F_c(t) = G_c[I_q \otimes \gamma(t)], \\ e^{A^T t}C &= F_0(t) = G_0[I_p \otimes \gamma(t)] \end{aligned}$$

where

$$G_c \in C^{n \times qr}, \quad G_0 \in C^{n \times pr}.$$

Now it follows from these expressions that

$$(58) \quad B = G_c[I_q \otimes \gamma(0)], \quad C = G_0[I_p \otimes \gamma(0)].$$

Moreover, proceeding in the same manner as was used to show (14) it follows that

$$(59) \quad A = G_c[I_q \otimes \Lambda]G_c^\#, \quad A^T = G_0[I_p \otimes \Lambda]G_0^\#$$

where $G_c^\#$ and $G_0^\#$ are right inverses of G_c and G_0 respectively. The fact that G_c and G_0 are each full row rank will become evident in what follows.

Notice at this point that once appropriate values for G_c and G_0 are obtained a realization, (A, B, C^T) , can be calculated from (58), (59).

Next, using the factorization, (15), and the expressions, (57), for the I/O maps it is seen from (55) that

$$(60) \quad K = G_0^T G_c.$$

Next, following the same procedure used to obtain (13) enables the Gramians to be expressed as

$$(61) \quad W_c = G_c[I_q \otimes V]G_c^T,$$

$$(62) \quad W_0 = G_0[I_p \otimes V]G_0^T$$

where V is given in (13) with $\gamma \in C^r$.

Note that the nonsingularity of W_c and W_0 due to the fact that (A, B, C^T) is a minimal realization implies that G_0 and G_c are full (row) rank.

The method to be developed for determining $G_c(G_0)$ depends on (60), (61) ((60), (62)). However, the need for working with complex matrices in connection with these equations can be eliminated in a manner similar to that used earlier in the SISO case. Ordering the poles in the manner specified in (21) it follows that

$$(63) \quad \begin{aligned} \bar{K} &= [I_p \otimes J^{-T}]K[I_q \otimes J^{-1}], \\ \bar{\Lambda} &= J\Lambda J^{-1}, \quad \bar{V} = JVJ^T, \end{aligned}$$

where K is defined in (55) and J is defined in (24) with n replaced by r .

A minimal balanced realization can now be determined in the manner specified in the following

THEOREM 5. *A minimal balanced realization can be obtained as*

$$A = T_1^{-1}\bar{A}T_1, \quad B = T_1^{-1}\bar{B}, \quad C^T = \bar{C}^T T_1$$

where

$$\begin{aligned} \bar{A} &= [I_q \otimes \bar{\Lambda}], \quad \bar{B} = [I_q \otimes J\gamma(0)], \quad \bar{C}^T = [I_p \otimes \gamma^T(0)J^T]\bar{K}, \\ T &= [T_1^1 \ T_2], \quad T_1 = \bar{L}_q U_1 \Sigma^{-1/2}, \quad T_2 = \bar{L}_q U_2 \end{aligned}$$

and U_1, U_2, Σ are determined using singular value decomposition on a real symmetric matrix viz.

$$\bar{L}_q^T \bar{K}^T [I_p \otimes \bar{V}] \bar{K} \bar{L}_q = [U_1^T \mid U_2^T] \left[\begin{array}{c|c} \Sigma^2 & 0 \\ \hline 0 & 0 \end{array} \right] \begin{bmatrix} U_1^T \\ U_2^T \end{bmatrix}$$

and \bar{L}_q is determined using Cholesky decomposition as

$$[I_q \otimes \bar{V}] = \bar{L}_q \bar{L}_q^T, \quad \bar{L}_q = [I_q \otimes \bar{L}], \quad \bar{L} \bar{L}^T = \bar{V}.$$

Proof. Proceeding in a manner similar to the end of the previous section, it can be shown that $H(t) = \bar{C}^T e^{\bar{A}t} \bar{B}$. Moreover, using (63), (12) it can be shown that the controllability Gramian, (4), for this realization is $[I_q \otimes \bar{V}]$. Since this Gramian is full rank, the realization $(\bar{A}, \bar{B}, \bar{C}^T)$ must be controllable. Moreover, from (57) it is seen that G_c for this realization is a qr dimension identity matrix and from (60), $\bar{G}_0 = K^T$. Hence, from (62) it is seen that the observability Gramian for this realization is $\bar{K}^T [I_p \otimes \bar{V}] \bar{K}$.

Let T be a co-ordinate transformation matrix which transforms $(\bar{A}, \bar{B}, \bar{C}^T)$ to $(\tilde{A}, \tilde{B}, \tilde{C}^T)$ and \bar{W}_0, \bar{W}_c to \tilde{W}_0, \tilde{W}_c respectively viz.

$$\tilde{A} = T^{-1} \bar{A} T, \quad \tilde{B} = T^{-1} \bar{B}, \quad \tilde{C}^T = \bar{C}^T T,$$

$$\tilde{W}_c = T^{-1} \bar{W}_c T^{-T}, \quad \tilde{W}_0 = T^T \bar{W}_0 T.$$

Let T be chosen so that $\tilde{W}_c \tilde{W}_0$ is diagonal, i.e.,

$$T^T \bar{W}_0 \bar{W}_c T^{-T} = \left[\begin{array}{c|c} \Sigma^2 & 0 \\ \hline 0 & 0 \end{array} \right].$$

Now since \bar{W}_0 and \bar{W}_c are each symmetric and \bar{W}_c is positive definite, T can be determined using the numerically stable approach given in [12, pp. 337-338] by determining U_1, U_2 as indicated in the statement of the theorem. Notice the T matrix which results yield

$$\begin{aligned} \tilde{W}_0 &= \left[\begin{array}{c|c} \Sigma & 0 \\ \hline 0 & 0 \end{array} \right], & \tilde{W}_c &= \left[\begin{array}{c|c} \Sigma & 0 \\ \hline 0 & I \end{array} \right], \\ \tilde{A} &= \left[\begin{array}{c|c} \tilde{A}_{11} & \tilde{A}_{12} \\ \hline \tilde{A}_{21} & \tilde{A}_{22} \end{array} \right]_{n \times (n+r)}, & \tilde{B} &= \left[\begin{array}{c} \tilde{B}_1 \\ \tilde{B}_2 \end{array} \right], \\ \tilde{C} &= [\tilde{C}_1 \mid \tilde{C}_2]_{(n+r) \times n} \text{ with } \tilde{A}_{12} = 0, \tilde{C}_2 = 0. \end{aligned}$$

Thus it follows from \tilde{W}_0 , and \tilde{W}_c and the zero block structure of $(\tilde{A}, \tilde{B}, \tilde{C}^T)$ that $(\tilde{A}_{11}, \tilde{B}_1, \tilde{C}_1^T)$ is a minimal balanced realization of $H(t)$. Moreover, $A = \tilde{A}_{11}$, $B = \tilde{B}_1$, $C^T = \tilde{C}_1$ follows by direct calculation.

The fact that \tilde{A}_{12} and \tilde{C}_2 are each null can be shown as follows. From the singular value decomposition indicated in the theorem it follows that

$$U_2^T \bar{L}_q^T \bar{K}^T [I_p \otimes \bar{V}] \bar{K} \bar{L}_q U_2 = 0$$

and since $[I_p \otimes \bar{V}]$ is nonsingular it follows that

$$\text{Range} [\bar{L}_q U_2] \subset \text{Null} [\bar{K}]$$

which from the dependency of \bar{W}_0 on \bar{K} implies that

$$\text{Range} [\bar{L}_q U_2] \subset \text{Null} [\bar{W}_0].$$

Next it is easily shown directly from the Lyapunov equation governing \bar{W}_0 that

$$\text{Range} [\bar{L}_q U_2] \subset \text{Null} [\bar{C}^T], \quad \text{Range} [\bar{L}_q U_2] \subset \text{Null} [\bar{C}^T \bar{A}].$$

Thus it follows that $\text{Range} [\bar{L}_q U_2] \subset \text{Null} [\bar{\Omega}_0]$ which implies that \tilde{A}_{12} and \tilde{C}_2 must each be null.

An analysis of the foregoing theorem reveals that use of the co-ordinate transformation matrix T simultaneously diagonalizes both Gramians and puts the original controllable realization $(\bar{A}, \bar{B}, \bar{C}^T)$ in a form (observability decomposed form, [8, p. 362]) which enables the immediate extraction of the observable part.

Finally notice that U_2 need not be computed as it is not needed in the formulation of the balanced realization. In addition the singular value decomposition mentioned in Theorem 5 can be replaced by the computationally less demanding task of determining the nonzero eigenvalues and corresponding orthonormal eigenvectors of real symmetrix $\bar{L}_q^T \bar{K}^T [I_p \otimes \bar{V}] \bar{K} \bar{L}_q$.

This completes the proof of the theorem.

6. Conclusion. A method for determining a minimal balanced realization from a given transfer function matrix has been developed. The method requires the Laplace inversion of the transfer function matrix, the Cholesky decomposition of a real, symmetric, positive definite matrix and the determination of the nonzero eigenvalues and corresponding eigenvectors of a real, symmetric matrix. Unlike Moore's method [2], and Laub's modification [7], the determination of a minimal realization is not required at the outset and no Lyapunov equations need to be solved. Moreover, in [2], [7] the extent to which the controllability Gramian of the initial realization is ill conditioned, depends on that realization. Thus there is no guarantee in [2], [7] that a bad choice for the initial realization will not be made causing numerical instability in subsequent calculations. Any ill conditioning that occurs in the proposed method arises directly from the nature of the given transfer function matrix and not from any choice involved in the execution of the algorithm.

Finally, the problem of obtaining an arbitrary minimal realization of a transfer function matrix is often quite difficult and has engaged the attention of many researchers in the past. The apparent numerically beneficial features of the present algorithm for determining balanced realizations would seem to argue well for its use in determining a minimal realization even when balancing is not required.

Appendix. Determination of K from impulse response coefficients. Since F is symmetric and nonsingular (Theorem 1) and G_c is nonsingular, (13), it follows from (17) that K must be symmetric and nonsingular. Moreover, it can be seen from a comparison of the expression (2), (16) for the impulse response that K can always be assumed to be a block diagonal matrix, i.e.

$$(A1) \quad K = \text{Diag} [K^1, K^2, \dots, K^m], \quad K^i \in C^{n_i \times n_i}.$$

Now it turns out that K is related to Λ in the manner specified in the following theorem.

THEOREM A1. $K\Lambda = \Lambda^T K$ where Λ is defined by (12).

Proof. Differentiating the impulse response as given in (16) and using (12) yields

$$(A2) \quad \frac{d}{dt} h(t) = \frac{1}{2} \gamma^T(t/2) [\Lambda^T K + K \Lambda] \gamma(t/2).$$

Alternatively, differentiating the first expression for the impulse response given in (15) and using (6), (11) yields

$$(A3) \quad \frac{d}{dt} h(t) = \gamma^T(t/2) G_c^T F A G_c \gamma(t/2).$$

Then using (14) and the relation for K , F and G_c , (17) enables (A3) to be rewritten as

$$(A4) \quad \frac{d}{dt} h(t) = \gamma^T(t/2) K \Lambda \gamma(t/2).$$

Finally, the desired relation (A1) results from the comparison of the right-hand sides of (A2) and (A4). This completes the proof of the theorem.

The foregoing theorem, together with the structure of Λ , implies that the elements of the diagonal blocks of K must satisfy a number of rather specific properties. These properties are given now in the following corollary.

COROLLARY A1. *Each diagonal block of K , say $K^p \in C^{n_p \times n_p}$ for any integer $p \in [1, m]$ has elements $\{K_{ij}^p: i, j \in [1, n_p]\}$ satisfying*

$$(A5) \quad K_{ij}^p = \frac{j}{i-1} K_{i-1, j+1}^p \quad \begin{array}{l} i = 2, 3, \dots, n_p, \\ j = 1, 2, \dots, n_p - 1, \end{array}$$

$$(A6) \quad = \frac{i}{j-1} K_{i+1, j-1}^p \quad \begin{array}{l} i = 1, 2, \dots, n_p - 1, \\ j = 2, 3, \dots, n_p, \end{array}$$

and

$$(A7) \quad K_{n_p, j}^p = 0 \quad j = 2, 3, \dots, n_p,$$

$$(A8) \quad K_{i, n_p}^p = 0 \quad i = 2, 3, \dots, n_p.$$

Proof. From Theorem 1 it follows that

$$(A9) \quad K^p \Lambda^p = (\Lambda^p)^T K^p \quad p = 1, 2, \dots, m.$$

Then the relations given in the corollary are obtained by equating like positioned entries on either side of (A9).

The foregoing properties of K are now used to show that all entries below (to the right of) the cross diagonal in each diagonal block of K must be zero while the entries on and to the left of the cross diagonal are each a scalar multiple of a coefficient in the expression for the impulse response (2).

COROLLARY A2. *K^p is upper cross triangular. Furthermore, nonzero (ij) th elements of K^p are related to the first row element $K_{1, i+j-1}^p$ as*

$$(A10) \quad K_{ij}^p = \frac{(i+j-2)!}{(i-1)!(j-1)!} K_{1, i+j-1}^p \quad i+j < n_p + 1.$$

In addition, the sums S_r of elements along rays parallel to the cross diagonal are given as

$$(A11) \quad S_r = \sum_{i=1}^r K_{i, r-i+1}^p = 2^{r-1} K_{1r}^p \quad r = 1, 2, \dots, n_p.$$

Proof. From recursion on (A5) and using (A7), it can be seen easily that K^p is upper cross triangular. Furthermore, recursion on (A6) yields (A10). Now, substitution of (A10) with $j = r - i + 1$ into (A11) yields

$$S_r = K_{1r}^p \sum_{i=0}^{r-1} \frac{(r-1)!}{i!(r-i+1)!} = K_{1r}^p (1+1)^{r-1} = 2^{r-1} K_{1r}^p.$$

This completes the proof.

COROLLARY A3. *If $K^p \in C^{n_p \times n_p}$ is a typical diagonal block of K , then its entries K_{ij}^p must satisfy the following property*

$$(A12) \quad \begin{aligned} K_{ij}^p &= \frac{(i+j-2)!}{(i-1)!(j-1)!} m_{p,i+j-1} & i+j < n_p+1, \\ &= 0 & i+j > n_p+1, \end{aligned}$$

where $\{m_{p,j}; j = 1, 2, \dots, n_p-1\}$ are the coefficients in the impulse response $h(t)$, (2).

Proof. Recall that the portion of the impulse response arising from the transfer function pole at λ_p of multiplicity n_p is given as

$$(A13) \quad h_p(t) = e^{\lambda_p t} [m_{p1} + m_{p2}t + m_{p3}t^2 + \dots + m_{p,n_p}t^{n_p-1}].$$

Now from (16) with $\gamma(t)$ and K , partitioned as in (2) and (19) it is seen that

$$(A14) \quad h_p(t) = \gamma_p^T(t/2) K^p \gamma_p(t/2).$$

Then with K_{ij}^p indicating the ij th element of K_p it is seen comparing (A13) and (A14) that

$$(A15) \quad k_{pj} = \sum_{i=1}^j K_{i,j+1-i}^p \left(\frac{1}{2}\right)^{j-1} \quad j = 1, 2, \dots, n_p,$$

$$(A16) \quad 0 = \sum_{j=1}^{n_p-1-l} K_{j+1+l, n_p+1-j}^p \quad l = 0, 1, \dots, n_p-2.$$

Now, referring to Corollary A2 and the expression for S_r , (A11), it is seen that

$$(A17) \quad m_{pj} = K_{1j}^p \quad j = 1, 2, \dots, n_p.$$

This completes the proof of Corollary A3 and the formula, (19), for determining the elements of K directly from the coefficients of the impulse response has been validated.

Acknowledgment. The authors wish to thank the referees for suggesting several improvements for the presentation of this work.

ESTIMATION OF DISCONTINUOUS COEFFICIENTS IN PARABOLIC SYSTEMS: APPLICATIONS TO RESERVOIR SIMULATION*

PATRICIA K. LAMM†

Abstract. We present spline-based techniques for estimating spatially varying parameters that appear in parabolic distributed systems (typical of those found in reservoir simulation problems). In particular, we discuss the problem of determining discontinuous coefficients, estimating both the functional shape and points of discontinuity for such parameters. In addition, our ideas may also be applied to problems with unknown initial conditions and unknown parameters appearing in terms representing external forces. Convergence results and a summary of numerical performance of the resulting algorithms are given.

Key words. parameter estimation, discontinuous coefficients, parabolic distributed systems, spline approximations

AMS(MOS) subject classifications. 65K, 49

1. Introduction. We present here our efforts related to the estimation of discontinuous spatially varying coefficients in parabolic distributed systems. Although our ideas are applicable to a wide class of problems in which the determination of discontinuous coefficients is of importance (e.g., the propagation of waves through layered media; the dynamics of beams with “discontinuous” elastic properties), our work here is motivated by an inverse problem in reservoir simulation commonly referred to as “history matching”. The problem in this case is to determine unknown parameters (such as permeability, porosity) that appear as coefficients in model reservoir equations. “Optimal” choices of these parameters should provide the best match between the observed and simulated production history at one or more wells. Information about these coefficients (functional shape and location of discontinuities) provides insight into physical properties of the reservoir and can indicate the location of abrupt structural changes; in addition, precise determination of these parameters is essential to the process of accurately simulating and predicting reservoir behavior.

The governing reservoir equations describe mathematically the physical and chemical processes occurring during primary hydrocarbon recovery or during enhanced recovery efforts (secondary or tertiary forms of recovery). Mathematical models vary widely depending on the physical process being described (miscible or immiscible fluid flow, thermal or fluid injection, etc.) and the types of observations available. Common to each model however is a system of rate equations (derived from Darcy’s law, which relates flow rate to fluid pressure gradients) as well as appropriate conservation laws and equations of state. The resulting dynamical system is typically distributed in nature and of parabolic type [22], [23]; unknown parameters quite often include the porosity of surrounding rock, or the ratio of pore volume to total volume, and (relative) permeability, which is the ability of the rock to transmit fluid [23]. Due to spatial changes in underground structure, it is highly likely that these parameters will vary spatially and contain numerous discontinuities.

In order to solve the inverse problem, data in the form of fluid pressure (or flow rate) is collected at the wells and used in a numerical parameter estimation process. There have been a large number of substantial contributors to the development of theoretical concepts and numerical algorithms for the history matching problem. An exhaustive list of related references would be too lengthy to include here; instead we refer the reader to [23] for an excellent survey of the outstanding efforts in this area. One numerical approach commonly taken involves subdividing the reservoir into a grid of smaller blocks; constant-valued parameters (which are allowed to vary independently from block to block) are then estimated. Unfortunately, if accurate solutions are desired, the grid size often must be quite small and thus the number of unknown parameters, as well as the dimension of the state space, can be very large—as many as 50,000 parameters or more [22]. (This is an unfortunate consequence of the fact that the parameters of interest—as well as state variables—are infinite-dimensional yet computations must be performed in a finite-dimensional setting.) Our goal here is to avoid some of the difficulties associated with the approach described above. Specifically, our ideas involve separating the order of state approximation from that of parameter estimation, so that the need for an approximate state space of high dimension does not impose the same requirements on the dimension of an approximate parameter space; this is accomplished by searching for parameters in classes of functions with quite general spatially varying representations. In order to focus attention on the problems associated with estimating spatially varying discontinuous coefficients in this context, we consider an archetypical model of (parabolic) distributed type that admittedly is a simplified version of the fluid pressure equations associated with reservoir simulation (see [22], [23], and the references therein); nevertheless the model selected here is a prototype that contains the essential parameter-dependent terms for which we may begin our investigations. In the sections that follow we define the model equations of interest and construct an approximation framework in which we wish to consider the parameter estimation problem. Convergence results are presented for problems associated with either spatially distributed or “discrete” sample data. Finally, we discuss numerical implementation in general, and in the context of particular examples. It is our intent in this report to examine convergence properties and implementation problems associated with these methods; we do not address such important questions as identifiability, observability, or general underlying properties of the governing partial differential equation system.

The notation used throughout is standard: For $I \subseteq \mathbb{R}$ (the real line), we shall denote by $C(I; X)$ the space of continuous functions $f: I \rightarrow X$ with uniform norm $|\cdot|_\infty$; by $L_2(I; X)$ we mean the usual space of square-integrable “functions” $f: I \rightarrow X$ with L_2 norm $|\cdot|_{L_2(I; X)}$ and inner product $\langle \cdot, \cdot \rangle_{L_2(I; X)}$. The Sobolev spaces $H^p(I; X)$ and $H_0^p(I; X)$ are defined as usual (see, for example, [1]). Whenever $X = \mathbb{R}$, we shall simplify notation by writing $C(I)$ and $L_2(I)$, respectively, and, where no confusion results, by writing $|\cdot|$ (and $\langle \cdot, \cdot \rangle$) for the norm (and inner product) on $L_2(0, 1)$. In addition, no notational distinction will be made between a function $f: I \rightarrow \mathbb{R}$ and its restriction to $I_1 \subseteq I$.

2. The parameter estimation problem. As our fundamental state system we consider the scalar parabolic distributed system

$$\begin{aligned}
 (2.1) \quad & \frac{\partial u}{\partial t}(t, x) = \frac{1}{\rho(x)} \frac{\partial}{\partial x} \left(q(x) \frac{\partial u}{\partial x}(t, x) \right) + f(t, x; r(x)), \quad (t, x) \in (0, T) \times (0, 1), \\
 & u(t, 0) = u(t, 1) = 0, \\
 & u(0, x) = u_0(x).
 \end{aligned}$$

Here q and ρ are discontinuous (positive) functions representing the permeability and porosity properties, respectively, of the fluid and surrounding rock; the points of discontinuity in these functions correspond to abrupt spatial changes in the physical flow region (such as might be associated with layered media). Both q and ρ are typically unknown so we shall consider the problem of estimating these parameters, as well as the function r , $r(x) \in R^p$, and the initial condition u_0 , from observations of the state variable u .

To simplify notation, we assume that q is discontinuous at one point only, $x = \xi$, and that q is represented by

$$q = \phi_1 + H_\xi \phi_2$$

where ϕ_1 and ϕ_2 are continuous on $[0, 1]$; here H_ξ is the usual Heaviside function on $[0, 1]$ given by $H_\xi = 1$ on $[\xi, 1]$, $H_\xi = 0$ otherwise. There is a straightforward extension of our ideas to the case where

$$q = \phi_1 + \sum_{i=2}^{\mu} H_{\xi_{i-1}} \phi_i$$

$0 = \xi_0 < \xi_1 < \xi_2 < \dots < \xi_\mu = 1$, except that notational difficulties become excessive. (We later demonstrate our approximation and estimation techniques for multiple discontinuity problems in the section on numerical findings.) In addition, we simplify our presentation by assuming $\rho \equiv 1$ and note that there is no difficulty in extending our ideas to the case $\rho = \kappa_1 + \sum_{i=2}^{\mu} H_{\xi_{i-1}} \kappa_i$, where $\kappa_1, \dots, \kappa_\mu$ are unknown [30]. Given the parameterization chosen for q we define the parameter vector $\gamma = (\xi, \phi_1, \phi_2, r, u_0) = (s, u_0)$ as an element of the parameter set $\Gamma \subseteq \tilde{\Gamma} = \mathcal{S} \times L_2(0, 1)$, where, for m, \bar{m} fixed,

$$\mathcal{S}(m, \bar{m}) = \{s = (\xi, \phi_1, \phi_2, r) \in R \times C[0, 1] \times C[0, 1] \times L_2((0, 1); R^p) \mid \xi \in (0, 1), \\ \phi_i \in C^1[0, 1], \text{ and } 0 < m \leq \phi_i(x) \leq \bar{m} \text{ for } i = 1, 2, \text{ and } x \in [0, 1]\}.$$

Concerning Γ and the applied force f , we make the following (standing) hypotheses:

(H1) The parameter set Γ is compact;

(H2) For every $r \in L_2((0, 1); R^p)$, the map $t \rightarrow f(t, \cdot; r(\cdot)): [0, T] \rightarrow L_2(0, 1)$ is Hölder continuous with exponent α , $0 < \alpha < 1$.

(H3) The map $r \rightarrow f(\cdot, \cdot; r(\cdot))$ is continuous from $L_2((0, 1); R^p)$ to $L_2((0, T) \times (0, 1))$.

The parameter estimation problem associated with (2.1) consists of finding a parameter $\gamma^* \in \Gamma$ that is “optimal” in the sense of providing the best match between observed data and model solutions to (2.1). Although a number of criteria may be used to measure “fit to data,” we consider first a least squares criterion J that is defined in conjunction with distributed data: That is, given distributed observations $\hat{u}_i \in L_2(0, 1)$ at discrete times $t_i \in (0, T)$, $i = 1, \dots, n$, we seek $\gamma^* \in \Gamma$ that minimizes

$$(2.2) \quad J(\gamma) = \sum_{i=1}^n \int_0^1 |\mathcal{C}(t_i, x; \gamma)u(t_i, x; \gamma) - \hat{u}_i(x)|^2 dx$$

over all $\gamma \in \Gamma$. For each (t_i, x) , the output map $\mathcal{C}(t_i, x; \gamma): R \rightarrow R$ is assumed to be continuous in γ and such that the mapping $x \rightarrow \mathcal{C}(t_i, x; \gamma)\psi(x)$ is in $L_2(0, 1)$ whenever $\psi \in L_2(0, 1)$. We note that data generally is not available in the distributed form given here; often this difficulty can be handled by fitting a curve (using linear interpolation, for example) to discrete data.

We also treat the problem of truly discrete data, i.e., $\hat{u}_{ij} \in R$ is observed sample data at (t_i, x_j) , $j = 1, \dots, \tilde{n}$. In this case the parameter estimation problem consists of determining $\tilde{\gamma}^* \in \Gamma$ that minimizes a “pointwise” fit-to-data criterion,

$$(2.3) \quad \tilde{J}(\gamma) = \sum_{i=1}^n \sum_{j=1}^{\tilde{n}} |\mathcal{C}(t_i, x_j; \gamma)u(t_i, x_j; \gamma) - \hat{u}_{ij}|^2$$

over $\gamma \in \Gamma$. The use of discrete sample data leads to increased technical detail and additional smoothness hypotheses on u_0 and f . We consider this particular estimation problem in § 3.1.

The parameter estimation problems described above are examples of a large class of problems (“inverse” problems) that are widely known to be ill-posed (see, for example, [26] and [31]) from both a theoretical and computational standpoint. The difficulties arise from several sources: a lack of continuous dependence of parameter estimates γ on observed data \hat{u}_i , \hat{u}_{ij} ; the fact that one cannot, in general, assume the existence of a unique parameter γ^* that provides a perfect match of model to data (i.e., $J(\gamma^*) = 0$) due to noise typically present in observed data and the inability of the model to exactly describe the physical problem [19], [20]; and the numerical instabilities (for example, the problem of “highly oscillatory” parameter estimates [26]) that often appear in parameter estimation schemes when the infinite-dimensional parameter space is replaced by a space of (fairly large) finite dimension. A number of approaches have been studied in an effort to alleviate some of these difficulties and restore a type of problem stability. Among these are regularization techniques (see, for example, [26], [27]), imbedding techniques (e.g., [2]), and the parameter set compactness criteria taken here and in a number of related papers (e.g., [4]–[18], [21]). Compactness alone however is not sufficient to avoid the before-mentioned highly oscillatory behavior sometimes seen in parameter approximations; we do not observe such behavior in examples presented here (and in related efforts) due to the fact that we use higher order (cubic, quintic) spline approximations for parameters and thus feel justified in practice in keeping the dimension of the parameter approximation space relatively low. Indeed, we have successfully used this approach in a number of applications and in problems using “real” collected data [12], [13], [14]. It is easy to envision a number of applications, in particular the large oil reservoir problems of interest here, where it is possible that one will need to increase the dimension of the approximate parameter space and thus potentially have to confront such numerical instability problems. In this situation it seems appropriate to add a regularization term to the least squares functionals J (or \tilde{J}).

We turn now to consideration of the parameter estimation problem of interest here (where $\gamma \in \Gamma$ is unknown and to be determined) and first consider the existence of solutions u of (2.1) for a given parameter $\gamma = (\xi, \phi_1, \phi_2, r, u_0) \in \Gamma$. Defining $u(t) \equiv u(t, \cdot) \in L_2(0, 1)$, we may rewrite (2.1) as an initial value problem in u ,

$$(2.4) \quad \begin{aligned} u_t &= \mathcal{A}(q)u(t) + F(t; r), & t \in (0, T), \\ u(0) &= u_0. \end{aligned}$$

Here $q = \phi_1 + H_\xi \phi_2$, $F(t; r) = f(t, \cdot; r(\cdot))$ and the operator $\mathcal{A}(q)$ is defined by $\mathcal{A}(q)\psi = \mathcal{D}(q\mathcal{D}\psi)$ for $\psi \in \text{dom } \mathcal{A}(q) = V_q$, where $V_q = \{\psi \in H_0^1(0, 1) | q\mathcal{D}\psi \in H^1(0, 1)\}$ (throughout we shall use \mathcal{D} to denote the spatial differentiation operator $\partial/\partial x$). We note that solutions u satisfy the continuity equation

$$(2.5) \quad (q\mathcal{D}u)(\xi^-) = (q\mathcal{D}u)(\xi^+),$$

which represents continuity of stress across a transition point, ξ , between distinct spatial regions (layers of porous media, for example).

Our first result is a statement of existence, uniqueness, and regularity properties of solutions of (2.1). In [30] we provide details for a proof of this theorem that uses properties of $\mathcal{A}(q)$ (a self-adjoint, densely defined operator with $\sigma(\mathcal{A}(q)) \subseteq (-\infty, 0)$) to argue that $\mathcal{A}(q)$ generates an analytic semigroup [25], [35] on $L_2(0, 1)$.

THEOREM 2.1. *Let $\gamma = (\xi, \phi_1, \phi_2, r, u_0)$ be given in Γ and let $q = \phi_1 + H_\xi \phi_2$. There exists a unique (classical) solution u to (2.1) with the property that $u(t) \in V_q$ for any $t > 0$. In addition, if $u_0 \in V_q$, then the map $t \mapsto \mathcal{A}(q)u(t)$ is in $C([0, T]; L_2(0, 1))$.*

We note that if u is a solution of (2.1) then u also satisfies (2.1) in a weak sense; i.e., u satisfies

$$(2.6) \quad \begin{aligned} \langle u_t(t), v \rangle &= -\langle q \mathcal{D}u(t), \mathcal{D}v \rangle + \langle F(t; r), v \rangle, \quad t \in (0, T), \\ u(0) &= u_0 \end{aligned}$$

for every $v \in H_0^1(0, 1)$. Applying the Gronwall inequality directly to this formulation, we may argue the continuous dependence of solutions on (possibly unknown) initial data (see [31]) to obtain the following.

COROLLARY 2.1. *The mapping $u_0 \mapsto u(t; \xi, \phi_1, \phi_2, r, u_0): L_2(0, 1) \rightarrow L_2(0, 1)$ is continuous, uniform in $(\xi, \phi_1, \phi_2, r) \in \mathcal{S}$ and $t \in (0, T)$.*

3. A spline-based approximation scheme. Standard numerical optimization schemes applied to the problem of minimizing J (or \tilde{J}) over Γ typically generate a minimizing sequence of parameter iterates, starting from an initial guess, γ^0 . However, schemes of this type generally require that $u(\gamma)$ (the solution of (2.1)) be evaluated as the parameter γ is updated; it is therefore desirable to combine estimation of an optimal parameter γ^* with approximation techniques for solving (2.1). With this goal in mind, we describe a spline-based state/parameter approximation scheme in the same spirit of the ideas found in [7], [11]–[15], [17], [29] to name a few of the related references in this area for (continuous coefficient) parabolic problems.

The convergence arguments developed below are similar to standard variational-type estimates often used in association with finite element approximations (see, for example, [35, p. 129]; [3], [24], [36]) although the estimates given here are complicated somewhat by the presence of unknown parameters. This variational approach was taken in [12], [13], [14] for the problem of estimating continuous coefficients in parabolic systems; we require a somewhat different treatment here primarily due to the fact that we allow discontinuous coefficients, where the points of discontinuity are unknown (necessitating parameter-dependent approximation spaces $X^N(q)$). Thus, an interesting aspect of our approach (and often a source of difficulties) involves the fact that our approximation spaces change with every choice of parameter iterate. We note that although the theoretical problems are quite different, our construction of approximating spaces $X^N(q)$ is somewhat similar to the ideas found in [4], [16], [21]; there the problem was to estimate unknown delays appearing in functional differential equations (there is a correspondence between our treatment of an unknown point of discontinuity and the approach taken in those references to handle an unknown delay, at least from the standpoint of numerical approximation schemes). We turn now to a precise statement of the approximation scheme under consideration.

For any $\gamma = (\xi, \phi_1, \phi_2, r, u_0) \in \Gamma$, we construct parameter-dependent spaces and operators as follows: For $q = \phi_1 + H_\xi \phi_2$ and $N = 1, 2, \dots$, we define $X^N(q) = \text{span} \{B_i^N(q), i = 1, \dots, 2N - 1\}$, where $B_i^N(q)$ denotes the i th continuous piecewise-linear B -spline basis element (satisfying homogeneous boundary conditions) with knots

at $\{x_k^N(q), k=0, \dots, 2N\}$. Here $x_k^N(q) = k\xi/N$, $k=0, \dots, N$, and $x_k^N(q) = \xi + (k-N)(1-\xi)/N$, for $k=N+1, \dots, 2N$. The piecewise linear elements are characterized by $B_i^N(q)(x_k^N) = \delta_{ik}$ for $i, k=1, \dots, 2N-1$ ($B_i^N(q)(0) = B_i^N(q)(1) = 0$); see Figs. 1-3. We remark that in general, for $\gamma, \tilde{\gamma} \in \Gamma$ and $q = \phi_1 + H_\xi \phi_2$, $\tilde{q} = \tilde{\phi}_1 + H_{\tilde{\xi}} \tilde{\phi}_2$, we do not have $X^N(q) \subseteq X^N(\tilde{q})$, nor do we have $X^N(q) \subseteq V_q$ (note that although an element $\psi^N \in X^N(q)$ does have a discontinuity in its first derivative at ξ , ψ^N does not satisfy the continuity equation (2.5) associated with q). As will be illustrated in § 4, this particular ξ -dependent structure for $X^N(q)$ has been chosen in order to minimize computational difficulties that arise when ξ is unknown (and ξ is thus changing throughout an iterative estimation scheme). We take a general Galerkin approach to

FIG. 1. B_i^N , $i=1, \dots, N-1$.FIG. 2. B_N^N .

FIG. 3. B_i^N , $i = N+1, \dots, 2N-1$.

define approximating state systems and then obtain convergence findings by working *directly* with the weak form of these equations. As an alternative approach to that taken here one could define approximating operators $\mathcal{A}^N(q)$ for $\mathcal{A}(q)$ and investigate the sense in which $\mathcal{A}^N(q)$ “converges” to $\mathcal{A}(q)$ (see, for example, Example 2.2 of [28], or [29], for approximating operators that might be used in this context).

For $\gamma \in \Gamma$ fixed and $N=1, 2, \dots$, we seek an approximation to $u(t; \gamma)$ of the form $u^N(t; \gamma) = \sum_{i=1}^{2N-1} w_i^N(t; \gamma) B_i^N(q)$, where the coefficients w_i^N are determined by the system of ordinary differential equations (ODE),

$$(3.1) \quad \begin{aligned} \langle u_i^N(t; \gamma), B_i^N(q) \rangle &= -\langle q \mathcal{D} u^N(t; \gamma), \mathcal{D} B_i^N(q) \rangle + \langle F(t; r), B_i^N(q) \rangle, \quad t \in (0, T), \\ \langle u^N(0; \gamma), B_i^N(q) \rangle &= \langle u_0, B_i^N(q) \rangle, \end{aligned}$$

for $i=1, \dots, 2N-1$. Alternatively, u^N satisfies

$$(3.2) \quad \begin{aligned} \langle u_i^N(t; \gamma), v \rangle &= -\langle q \mathcal{D} u^N(t; \gamma), \mathcal{D} v \rangle + \langle F(t; r), v \rangle, \quad t \in (0, T), \\ u^N(0; \gamma) &= P^N(q) u_0 \end{aligned}$$

for all $v \in X^N(q)$; here $P^N(q): L_2(0, 1) \rightarrow X^N(q)$ denotes the orthogonal projection (with respect to the usual L_2 topology) along $X^N(q)^\perp$. Associated with (3.1) is an approximate estimation problem, namely that of finding $\tilde{\gamma}^N \in \gamma$ that minimizes

$$(3.3) \quad J^N(\gamma) = \sum_{i=1}^n \int_0^1 |\mathcal{E}(t_i, x; \gamma) u^N(t_i; \gamma)(x) - \hat{u}_i(x)|^2$$

over Γ , where $u^N(\gamma)$ is the solution of (3.1) corresponding to $\gamma \in \Gamma$.

Our initial findings concerning the N th approximate problem (3.1), (3.3) are immediate consequences of the fact that (3.1) is an ODE on $X^N(q)$ and that the basis elements $B_i^N(q)$ (and their spatial derivatives) are continuous in ξ (see § 4 for a more detailed examination of (3.1)).

THEOREM 3.1. *For each N and any $\gamma \in \Gamma$, there exists a unique solution $u^N(\gamma)$ of (3.1), $u^N(t; \gamma) \in X^N(q)$ with the property that the mapping $\gamma \rightarrow u^N(t; \gamma): \Gamma \rightarrow L_2(0, 1)$ is continuous for each $t \in (0, T)$. In addition, the mapping $u_0 \rightarrow u^N(t; (s, u_0)): L_2(0, 1) \rightarrow L_2(0, 1)$ is continuous, uniform in N , $s = (\xi, \phi_1, \phi_2, r) \in \mathcal{S}$, and $t \in (0, 1)$.*

COROLLARY 3.1. *For each N , there exists a solution $\bar{\gamma}^N \in \Gamma$ for the problem of minimizing J^N over Γ .*

An essential step in the process of correlating state variable approximation with the problem of estimating an optimal parameter $\gamma^* \in \Gamma$ (for the original parameter identification problem) is the establishment of the convergence of $u^N(t; \gamma^N)$ to $u(t; \bar{\gamma})$ for any sequence $\{\gamma^N\}$ in Γ that converges to $\bar{\gamma} \in \Gamma$. In what follows we assume that $\{\gamma^N\}$ is given in Γ , $\gamma^N = (\xi^N, \phi_1^N, \phi_2^N, r^N, u_0^N)$, with $\gamma^N \rightarrow \bar{\gamma} = (\bar{\xi}, \bar{\phi}_1, \bar{\phi}_2, \bar{r}, \bar{u}_0) \in \Gamma$ (in the usual product topology on Γ); in addition, we assume that $0 < \bar{\xi} < 1$ (and, in the case of multiple discontinuities, $|\bar{\xi}_k - \bar{\xi}_{k-1}| > 0$, $k = 1, \dots, \mu$). Given $q^N = \phi_1^N + H_{\bar{\xi}^N} \phi_2^N$, we shall henceforth simplify notation and abbreviate $P^N \equiv P^N(q^N)$, $X^N \equiv X^N(q^N)$, and $x_k^N \equiv x_k^N(q^N)$, $k = 0, \dots, 2N$.

LEMMA 3.1. *Let ψ be given in $V_{\bar{q}}$, where $\bar{q} = \bar{\phi}_1 + H_{\bar{\xi}} \bar{\phi}_2$. There exist constants c_1 and c_2 , independent of N , such that*

$$(3.4) \quad |\psi - P^N \psi| \leq c_1 N^{-2} |\mathcal{A}(\bar{q}) \psi|$$

and, for N sufficiently large,

$$(3.5) \quad |\mathcal{D}(\psi - P^N \psi)| \leq c_2 N^{-1} |\mathcal{A}(\bar{q}) \psi|.$$

The proof of these basic linear spline estimates is detailed in [30, pp. 17, 18] where standard arguments (see, for example, [35, pp. 16, 17, 78]) are modified to take into account that $\mathcal{D}\psi$, $\psi \in V_{\bar{q}}$, is discontinuous at $\bar{\xi}$. We note that since $V_{\bar{q}}$ is dense in both $L_2(0, 1)$ and $H_0^1(0, 1)$ (in the respective topologies), we may actually weaken the assumptions on ψ and obtain

$$(3.6) \quad |\psi - P^N \psi| \rightarrow 0 \quad \text{as } N \rightarrow \infty \quad \text{for } \psi \in L_2(0, 1),$$

$$(3.7) \quad |\mathcal{D}(\psi - P^N \psi)| \rightarrow 0 \quad \text{as } N \rightarrow \infty \quad \text{for } \psi \in H_0^1(0, 1)$$

where the rates of convergence depend on ψ . Spline estimates (3.4)–(3.7) are used to establish the convergence of state variable approximations in the result that follows.

THEOREM 3.2. *Assume $\{\gamma^N\}$ is given in Γ such that $\gamma^N \rightarrow \bar{\gamma}$ in Γ . Then for each $t \in (0, T)$,*

$$u^N(t; \gamma^N) \rightarrow u(t; \bar{\gamma}) \quad \text{in } L_2(0, 1)$$

as $N \rightarrow \infty$, where u^N is the solution of (3.1) associated with γ^N and u is the solution of (2.1) associated with $\bar{\gamma}$.

Proof. Due to the dense inclusions of $V_{\bar{q}}$ in $L_2(0, 1)$, and the continuous dependence of u , u^N on initial data (Corollary 2.1 and Theorem 3.1), it suffices to argue convergence for the case that $\bar{\gamma} = (\bar{\xi}, \bar{\phi}_1, \bar{\phi}_2, \bar{r}, \bar{u}_0)$ satisfies $\bar{u}_0 \in V_{\bar{q}}$ so that $u(t; \bar{\gamma}) \in V_{\bar{q}}$, $t \in (0, 1)$.

Denoting $u(t) \equiv u(t; \bar{\gamma})$, $u^N(t) \equiv u^N(t; \gamma^N)$, we note that

$$|u^N(t) - u(t)| \leq |u^N(t) - P^N u(t)| + |P^N u(t) - u(t)|$$

where the second term is $\mathcal{O}(N^{-2})$ from (3.4). To consider the first term, we observe that solutions u , u^N of (2.1), (3.1), respectively, satisfy (2.6) and (3.2) for $v \in X^N$ so that these latter equations may be used to establish that

$$\begin{aligned} \left\langle \frac{d}{dt}(u^N(t) - P^N u(t)), v \right\rangle &= -\langle q^N \mathcal{D}(u^N(t) - P^N u(t)), \mathcal{D}v \rangle + \left\langle \frac{d}{dt}(u(t) - P^N u(t)), v \right\rangle \\ &\quad + \langle \bar{q} \mathcal{D}u(t) - q^N \mathcal{D}P^N u(t), \mathcal{D}v \rangle + \langle F^N(t) - F(t), v \rangle, \end{aligned}$$

for $v \in X^N$, $F(t) \equiv F(t; \bar{r})$, $F^N(t) \equiv F(t, r^N)$, and $q^N = \phi_1^N + H_{\bar{\xi}}^N \phi_2^N$. Letting $v = u^N(t) - P^N u(t) \in X^N$, we argue that

$$\begin{aligned} \frac{1}{2} \frac{d}{dt} |u^N(t) - P^N u(t)|^2 &\leq \frac{1}{2} \left| \frac{d}{dt} (u(t) - P^N u(t)) \right|^2 \\ &\quad + \frac{1}{4m} |\bar{q} \mathcal{D}u(t) - q^N \mathcal{D}(P^N u(t))|^2 + \frac{1}{2} |F^N(t) - F(t)|^2 \\ &\quad + |u^N(t) - P^N u(t)|^2, \end{aligned}$$

where we have repeatedly used the inequality $ab \leq \frac{1}{2}(a^2 + b^2)$. An application of the Gronwall inequality thus yields

$$|u^N(t) - P^N u(t)|^2 \leq e^{2T} \{\tau_1^N + \tau_2^N + \tau_3^N + \tau_4^N\}$$

where

$$\begin{aligned} \tau_1^N &= |u^N(0, \gamma^N) - P^N u(0; \bar{\gamma})|^2, \\ \tau_2^N &= \int_0^T \left| \frac{d}{dt} (u(s; \bar{\gamma}) - P^N u(s; \bar{\gamma})) \right|^2 ds, \\ \tau_3^N &= \frac{1}{2m} \int_0^T |\bar{q} \mathcal{D}u(s, \bar{\gamma}) - q^N \mathcal{D}(P^N u(s; \bar{\gamma}))|^2 ds, \\ \tau_4^N &= \int_0^T |F(s; r^N) - F(s; \bar{r})|^2 ds. \end{aligned}$$

We obtain $\tau_4^N \rightarrow 0$ as $N \rightarrow \infty$ from hypothesis (H3) and note that $\tau_1^N \rightarrow 0$ since $\tau_1^N = |P^N u_0^N - P^N \bar{u}_0| \leq |u_0^N - \bar{u}_0|$. Further τ_2^N may be rewritten [30]

$$\tau_2^N = \int_0^T |u_t(s) - P^N u_t(s)|^2 ds,$$

so that dominated convergence of the integrand is guaranteed from Theorem 2.1 ($s \rightarrow u_t(s)$ is in $L_2((0, T), L_2(0, 1))$ since $u_0 \in V_{\bar{q}}$).

Finally, for N sufficiently large,

$$\begin{aligned} m\tau_3^N &\leq \int_0^T |(\bar{q} - q^N) \mathcal{D}u(s)|^2 + \int_0^T |q^N \mathcal{D}(u(s) - P^N u(s))|^2 \\ &\leq 2 \int_0^T |(\bar{\phi}_1 - \phi_1^N) \mathcal{D}u(s)|^2 + 4 \int_0^T |H_{\bar{\xi}}(\bar{\phi}_2 - \phi_2^N) \mathcal{D}u(s)|^2 \\ &\quad + 4 \int_0^T |(H_{\bar{\xi}} - H_{\xi^N}) \phi_2^N \mathcal{D}u(s)|^2 + \bar{m}^2 \int_0^T |\mathcal{D}(u(s) - P^N u(s))|^2 \\ &\leq 4(|\bar{\phi}_1 - \phi_1^N|_{\infty}^2 + |\bar{\phi}_2 - \phi_2^N|_{\infty}^2) \int_0^T |\mathcal{D}u(s)|^2 \\ &\quad + 2\bar{m}^2 |\bar{\xi} - \xi^N| \int_0^T |\mathcal{D}u(s)|^2 + (\bar{m}c_2 N^{-1})^2 \int_0^T |\mathcal{A}(\bar{q})u(s)|^2 \end{aligned}$$

where we have used (3.5) in the last inequality. Further,

$$\begin{aligned} \int_0^T |\mathcal{D}u(s)|^2 &= \int_0^T \langle \mathcal{D}u(s), \mathcal{D}u(s) \rangle \leq m^{-1} \int_0^T \langle \bar{q} \mathcal{D}u(s), \mathcal{D}u(s) \rangle \\ &\leq m^{-1} \int_0^T |\mathcal{A}(\bar{q})u(s)| |u(s)| < \infty \end{aligned}$$

so that $\tau_3^N \rightarrow 0$ as $N \rightarrow \infty$.

Finally, we turn to parameter convergence (a compactness result) and the parameter estimation problem.

THEOREM 3.3. *For each N let $\bar{\gamma}^N$ denote a solution for the problem of minimizing J^N over Γ . There exists $\gamma^* \in \Gamma$ and a subsequence $\{\bar{\gamma}^{N_k}\}$ of $\{\bar{\gamma}^N\}$ such that*

- (i) $\bar{\gamma}^{N_k} \rightarrow \gamma^*$ in the product topology on Γ ,
- (ii) $u^{N_k}(t; \bar{\gamma}^{N_k}) \rightarrow u(t; \gamma^*)$ for each $t \in (0, T)$,
- (iii) $J^{N_k}(\bar{\gamma}^{N_k}) \rightarrow J(\gamma^*)$,
- (iv) γ^* is a solution to the original parameter estimation problem, namely that of minimizing $J(\gamma)$ over Γ .

Proof. Parts (i)–(iii) are immediate consequences of hypothesis (H1), and Theorem 3.2. To prove part (iv), it suffices to note that

$$J(\gamma^*) = \lim_{N_k \rightarrow \infty} J^{N_k}(\bar{\gamma}^{N_k}) \leq \lim_{N_k \rightarrow \infty} J^{N_k}(\gamma) = J(\gamma) \quad \text{for any } \gamma \in \Gamma$$

($\bar{\gamma}^{N_k}$ is a minimizer for J^{N_k} over Γ), so that γ^* is a solution for the problem of minimizing J over Γ .

Remark 3.1. Our efforts to this point have been focused on state variable approximation only; we must also consider discretization of the infinite-dimensional parameter space Γ in order to implement numerical optimization algorithms. The problem of further approximating parameter sets has been the subject of recent studies (see [12], [17], and [29]); we shall summarize, in particular, the results of [17] as they pertain to the problem at hand. For ease of presentation we shall assume that r, u_0 , are known (there is an easy extension of these ideas to the case where these functional parameters are unknown) so that $\gamma = (\xi, \phi_1, \phi_2)$ is the vector of parameters to be estimated. Since we use cubic B -spline approximations to approximate the functional parameters in our numerical examples (§ 4), we shall restrict our attention to a theory based on cubic splines only; a more general theory may be found in [17]. To this end, we assume the (more regular) parameter set Γ satisfies the following additional hypothesis:

(H4) $\Gamma \subseteq \tilde{\mathcal{F}}(m, \bar{m})$ is compact in the $R \times C^1[0, 1] \times C^1[0, 1]$ topology,

where $\tilde{\mathcal{F}}(m, \bar{m}) \equiv \{s = (\xi, \phi_1, \phi_2) \in [\delta, 1 - \delta] \times C^1[0, 1] \times C^1[0, 1] \mid 0 < m \leq \phi_i(x) \leq \bar{m} \text{ for } x \in [0, 1], \phi_i \in H^2(0, 1), \text{ and } |\mathcal{D}^2 \phi_i| \leq \bar{m}, i = 1, 2\}$, ($\delta \in (0, 1)$ is fixed).

For each M we define the finite-dimensional (approximate) parameter sets Γ^M by $\Gamma^M \equiv i^M(\Gamma)$; here $i^M: R \times C^1[0, 1] \times C^1[0, 1] \rightarrow R \times C^2[0, 1] \times C^2[0, 1]$ is given by $i^M(\xi, \phi_1, \phi_2) \equiv (\xi, \mathcal{J}^{M, \xi} \phi_1, \mathcal{J}^{M, \xi} \phi_2)$ where $\mathcal{J}^{M, \xi} \phi$ is defined to be the (unique) cubic spline function $\tilde{\phi}(x)$ satisfying $\tilde{\phi}(x_k^M) = \phi(x_k^M)$, $k = 0, 1, \dots, 2M$, and $\mathcal{D}\tilde{\phi}(x_0^M) = \mathcal{D}\phi(x_0^M)$, $\mathcal{D}\tilde{\phi}(x_{2M}^M) = \mathcal{D}\phi(x_{2M}^M)$ (see, for example, [35, Chap. 4]). The knots x_k^M are the ξ -dependent knots described earlier in this section. As is true with the approximation of state variables, the resulting numerical scheme is greatly simplified if the mesh depends on ξ , as well as on M . We shall defer to § 4 a more detailed discussion on computational features of the resulting algorithm.

Numerical implementation of our scheme to estimate functional parameters thus amounts to an optimization problem in the setting of a “double approximation” (approximation of the state variable and parameter spaces) framework, namely the problem of minimizing J^N over Γ^M . Theoretical findings relevant to this task are summarized in the theorem below, the proof of which may be found in [30, pp. 26, 27].

THEOREM 3.4. *Let $\Gamma^M \equiv i^M(\Gamma)$, where Γ satisfies (H4), and let $\bar{\gamma}^{N, M}$ denote a solution to the problem of minimizing J^N over Γ^M . Then there is a subsequence $\{\bar{\gamma}^{N_k, M^j}\}$ of $\{\bar{\gamma}^{N, M}\}$ such that $\bar{\gamma}^{N_k, M^j} \rightarrow \gamma^*$, where γ^* is a solution to the problem of minimizing J over Γ . In fact, any convergent subsequence has as its limit a solution to the original estimation problem.*

3.1. Approximate estimation problems associated with “discrete” data. It is possible, under additional smoothness assumptions on solutions, to use variational-type estimates (similar to those found above or in [12], [37]) to argue H^1 convergence of state variables. Results of this type lead naturally to a statement about the approximation of a solution for the problem of minimizing the “pointwise” fit-to-data criterion \tilde{J} (see (2.3)) over Γ .

For this formulation we follow the ideas of [37] and add an assumption (which in general may impose additional conditions on parameters and the applied force f) to the hypotheses (H1)–(H3) already assumed:

(H5) For any $\gamma \in \Gamma$, the mapping $s \rightarrow u_t(s; \gamma)$ is in $L_2((0, T); H_0^1(0, 1))$.

Although we define approximate state spaces $X^N(q)$ as before, we now seek approximations u^N to u that satisfy

$$(3.8) \quad \begin{aligned} \langle u_t^N(t), v \rangle &= -\langle q \mathcal{D} u^N(t), \mathcal{D} v \rangle + \langle F(t; r), v \rangle, \quad t \in (0, T), \\ u^N(0) &= \mathcal{P}^N(q) u_0 \end{aligned}$$

for all $v \in X^N(q)$; here \mathcal{P}^N differs from P^N defined in (3.2) in that $\mathcal{P}^N: H_0^1(0, 1) \rightarrow X^N(q)$ is the orthogonal projection in the $H_0^1(0, 1)$ (rather than $L_2(0, 1)$) topology. In addition, the parameter set Γ is taken to be a subset of $\hat{\mathcal{S}} \times H_0^1(0, 1)$, where $\hat{\mathcal{S}} \equiv \{(\xi, \phi_1, \phi_2, r) \in \mathcal{S} \mid \|\mathcal{D}\phi_i\|_\infty \leq \bar{m}, i = 1, 2\}$.

It is easily shown that there exists a unique solution $u^N(\gamma)$ to (3.8) that depends continuously on parameters; in addition, we obtain convergence findings that are H^1 analogues of earlier approximation results. We state only these results and refer the reader to [30, pp. 29–35] for proofs. Extensions of these findings are also possible in order to include ρ as a parameter or to prove a “double approximation” theorem similar to Theorem 3.4.

THEOREM 3.5. *Let $\{\gamma^N\}$ be given in Γ with $\gamma^N \rightarrow \bar{\gamma} \in \Gamma$ in the $\mathcal{S} \times H_0^1(0, 1)$ topology. Then, for each $t \in [0, T)$,*

$$u^N(t; \gamma^N) \rightarrow u(t; \bar{\gamma}) \quad \text{in } H_0^1(0, 1) \quad \text{as } N \rightarrow \infty.$$

THEOREM 3.6. *For each N , let $\tilde{\gamma}^N$ denote a solution for the problem of minimizing \tilde{J}^N over Γ , where*

$$\tilde{J}^N(\gamma) = \sum_{i=1}^n \sum_{j=1}^{\tilde{n}} |\mathcal{C}(t_i, x_j; \gamma) u^N(t_i, x_j; \gamma) - \hat{u}_{ij}|^2$$

and u^N is the solution of (3.8) associated with $\gamma \in \Gamma$. Then there exists $\tilde{\gamma}^ \in \Gamma$ and a subsequence $\{\tilde{\gamma}^{N_k}\}$ of $\{\tilde{\gamma}^N\}$ such that $\tilde{\gamma}^{N_k} \rightarrow \tilde{\gamma}^*$, $\tilde{J}^{N_k}(\tilde{\gamma}^{N_k}) \rightarrow \tilde{J}(\tilde{\gamma}^*)$, and $\tilde{\gamma}^*$ is a solution for the problem of minimizing \tilde{J} over Γ .*

4. Implementation and numerical findings. A desirable feature of the spline-based scheme developed in preceding sections is the ease of implementation of the approximation ideas, especially when the points of discontinuity ξ_i , $i = 1, \dots, \mu - 1$, for coefficients are unknown and to be estimated. In what follows we describe how the particular *state* approximation framework chosen here serves to facilitate (from a computational standpoint) the *parameter* estimation/approximation process. We conclude the section by presenting our findings for some representative test examples.

We begin by examining the approximating ordinary differential equation (3.1) rewritten here in terms of $w^N(t; \gamma) \equiv (w_1^N(t; \gamma), w_2^N(t; \gamma), \dots, w_{2N-1}^N(t; \gamma))^T$, where

the w_i^N , defined in § 3, are the coefficients in the expansion $u^N(t; \gamma) = \sum_{i=1}^{2N-1} w_i^N(t; \gamma) B_i^N(q)$. Using this notation, the ODE may be written

$$(4.1) \quad \begin{aligned} Q^N w^N(t) &= -K^N w^N(t) + G^N(t), \quad t \in (0, T), \\ w^N(0) &= w_0^N; \end{aligned}$$

here the $(2N-1)$ -square matrices $Q^N = Q^N(\gamma)$ and $K^N = K^N(\gamma)$ have entries

$$Q_{i,j}^N = \langle B_j^N(q), B_i^N(q) \rangle, \quad K_{i,j}^N = \langle q \mathcal{D} B_j^N(q), \mathcal{D} B_i^N(q) \rangle,$$

while the perturbation term and initial condition satisfy

$$G^N(t) = G^N(t; \gamma) \equiv (\langle F(t; r), B_1^N(q) \rangle, \dots, \langle F(t; r), B_{2N-1}^N(q) \rangle)^T$$

and

$$w_0^N = w_0^N(\gamma) \equiv (Q^N)^{-1} (\langle u_0, B_1^N(q) \rangle, \dots, \langle u_0, B_{2N-1}^N(q) \rangle)^T,$$

respectively.

In order to best indicate some of the advantages of the chosen approximation framework, we first consider the special case where only q is unknown, where $q = \phi_1 + H_\xi \phi_2$, and ϕ_1 and ϕ_2 are constants. First, it is easy to see how our choice of a linear spline approximation scheme yields matrices K^N and Q^N that are quite simple in structure: For a given value of q , the inner products appearing in these matrices may be determined from explicit formulas (depending on N and ξ), a few of which are given here. For example, diagonal entries in the (tridiagonal) matrices Q^N and K^N are given by

$$(4.2) \quad \begin{aligned} Q_{i,i}^N &= 2\xi/3N, \quad i = 1, \dots, N-1, \\ Q_{N,N}^N &= 1/3N, \\ Q_{i,i}^N &= 2(1-\xi)/3N, \quad i = N+1, \dots, 2N-1, \end{aligned}$$

$$(4.3) \quad K_{i,i}^N = 2N\phi_1/\xi, \quad i = 1, \dots, N-1,$$

$$(4.4) \quad K_{N,N}^N = N\phi_1/\xi + N(\phi_1 + \phi_2)/(1-\xi),$$

$$(4.4) \quad K_{i,i}^N = 2N(\phi_1 + \phi_2)/(1-\xi), \quad i = N+1, \dots, 2N-1,$$

with similar representations for off-diagonal elements. We note that we are able to avoid time-consuming and error-producing numerical quadratures; in addition, our approach is more desirable (from a computational point of view) than a method based on a uniform mesh size. For example, if for each N we simply subdivide $[0, 1]$ into units of length $1/N$ (so that position of ξ is not taken into account) the matrix Q^N will be fixed throughout the estimation process; this however is at the expense of considerable added difficulties associated with evaluating entries in K^N . Using a uniform mesh, some of the inner products must be “broken up” at the point ξ , e.g.,

$$\langle q \mathcal{D} B_j^N, \mathcal{D} B_i^N \rangle = \phi_1 \int_0^\xi \mathcal{D} B_j^N \mathcal{D} B_i^N + (\phi_1 + \phi_2) \int_\xi^1 \mathcal{D} B_j^N \mathcal{D} B_i^N,$$

requiring (multiple) numerical quadratures every time that q (and thus ξ) is updated. In contrast, with the ξ -dependent structure chosen here we need only recombine simple algebraic expressions (such as those given in (4.2)–(4.4)) to obtain the elements of K^N .

Many of these computational advantages are still present in the case where the ϕ_i are not assumed to be constant. If, for example, M and N are fixed and Γ^M consists

of cubic spline element approximations for ϕ_1, ϕ_2 (defined on a ξ -dependent mesh of points x_k^M) many of the quadratures may still be performed in advance of the iterative process. In particular, if we let $\phi_n^M(x) = \sum_{m=1}^{k(M)} \gamma_{n,m}^M \mathcal{G}_m^M(x)$, for $n = 1, 2$, where \mathcal{G}_m^M are the usual cubic B -spline basis elements defined using the mesh points $\{x_k^M, k = 0, \dots, 2M\}$, we find that $K_{i,j}^N = \langle q^M \mathcal{D}B_j^N, \mathcal{D}B_i^N \rangle$ may now be written as

$$(4.5) \quad K_{i,j}^N = \sum_{m=1}^{k(M)} \gamma_{1,m}^M \langle \mathcal{G}_m^M \mathcal{D}B_j^N, \mathcal{D}B_i^N \rangle_{L_2(0,\xi)} + \sum_{m=1}^{k(M)} (\gamma_{1,m}^M + \gamma_{2,m}^M) \langle \mathcal{G}_m^M \mathcal{D}B_j^N, \mathcal{D}B_i^N \rangle_{L_2(\xi,1)}.$$

Since simple explicit algebraic expressions (in terms of ξ and M) exist for \mathcal{G}_m^M , the quadrature in (4.5) may also be evaluated analytically (yielding expressions involving ξ, M , and N), avoiding numerical integration.

We consider here numerical examples where γ is known and we have generated synthetic data for use in testing our ideas. In all examples presented here, we assume that r and u_0 are known and fixed at their true values so that only $q = \phi_1 + H_\xi \phi_2$ is unknown (i.e., $\gamma = (\xi, \phi_1, \phi_2)$) and to be determined. The special problems associated with estimating this discontinuous coefficient have been the focus of our efforts throughout; the problem of identifying continuous functional parameters and initial conditions has been considered elsewhere [16], [17], [21]. For each example that follows, both γ^* and $u(\gamma^*)$ are selected in advance while the appropriate forcing function f is artificially determined by substituting $\gamma^*, u(\gamma^*)$ into (2.1). For chosen sample times $t_i, i = 1, \dots, n$, and sampling locations $x_j, j = 1, \dots, \tilde{n}$ (discrete data is used for these examples), data is generated by setting $\hat{u}_{ij} = u(t_i, x_j; \gamma^*)$, with random noise added in some cases. We note that the sample data is *not* generated using our spline-based scheme; rather, the data is constructed from an analytic expression for the solution and thus is independent of the methods we illustrate here.

We begin the parameter estimation process by supplying an initial guess of γ^0 to IMSL's minimization routine ZXSSQ (a Levenberg-Marquardt algorithm) which numerically attempts to determine a minimum, for given N , to \tilde{J}^N (using $\mathcal{C} \equiv 1$ in (2.3)) over a fixed constraint set Γ^M . Here $u^N(\gamma)$ is the solution to (3.1) calculated using IMSL's DGEAR, an ODE solver, where the known values of u_0 and f are used in the equations. We note that although we are actually using the cost functional associated with discrete observations \hat{u}_{ij} , the approximating equations (4.1) differ somewhat from those given in (3.8) (where an H^1 projection \mathcal{P}^N is used instead of the usual L_2 projection P^N). Indeed it is not surprising that, in practice, we obtain pointwise convergence of the approximating states under hypotheses more general than those needed in § 3.1 so that we may, in fact, relax some of the restrictions on the approximating system.

Example 4.1. In our first example we take

$$q^*(x) = \begin{cases} 15, & 0 \leq x < .6, \\ 50, & .6 \leq x \leq 1, \end{cases}$$

and define $u(t, \cdot; \gamma^*) \in \text{dom } \mathcal{A}(q^*)$ by

$$u(t, x; \gamma^*) = \begin{cases} x(70 - 100x)(t^2 + 2), & 0 \leq x < .6, \\ (15 - 15x)(t^2 + 2), & .6 \leq x \leq 1. \end{cases}$$

In Examples 4.1(a)–4.1(c) below we seek to estimate $\gamma = (\xi, \phi_1, \phi_2) \in \Gamma \subseteq \mathbb{R}^3$ (with true value $\gamma^* = (.6, 15, 50)$) using an initial guess of $\gamma^0 = (.8, 30, 30)$. In each case we obtain the converged values $\tilde{\gamma}^N$ for $N = 4, 8, 16$, and 24, using γ^0 to start the iterative scheme

for $N = 4$, and previous converged values as start-up for $N = 8, 16, 24$ (e.g., $\bar{\gamma}^4$ is used as initial guess for the $N = 8$ run). We note that convergence was also obtained (in this and other examples) for other choices of start-up values γ^0 . In the present example we were also able to obtain similar findings using $\gamma^0 = (.99, 30, 30)$ (so that ξ^0 is far from the true value, ξ^*).

Example 4.1(a). Data is generated for this example using $\hat{u}_{ij} = u(t_i, x_j; \gamma^*)$ for $t_i = .5i, i = 1, \dots, 4$, and $x_j = .1j, j = 1, \dots, 9$. Our findings are reported in Table 4.1(a).

Example 4.1(b). We repeat the last example except that spatial sampling locations are now given by $x_j = .1j + .05, j = 0, 1, \dots, 9$ (so that there is no spatial observation point at ξ^* , the point of discontinuity). We summarize our results in Table 4.1(b) and note there is little change between this example and Example 4.1(a).

Example 4.1(c). We repeat Example 4.1(a), but add noise to the data. In this case we define $\hat{u}_{ij} = u(t_i, x_j; \gamma^*) + r_{ij}$ where $\{r_{ij}\}$ are Gaussian random numbers which (with 98% certainty) fall in the range $[-.06\bar{u}, .06\bar{u}]$, $\bar{u} = \sum_{i,j} \hat{u}_{ij} / (n\tilde{n})$. Our findings for this example are summarized in Table 4.1(c).

In the examples that follow we shall shorten our discussion by abbreviating the length (and number) of tables and by displaying some results graphically. The rather detailed presentation given for Example 4.1 was provided simply for the purpose of observing if noise in the data or changes in the placement of data affected the outcome.

In Example 4.2 below, we illustrate the use of our methods in problems with two discontinuities ξ_1, ξ_2 , in q ; the example also serves to illustrate that we are able to accurately estimate ξ_i even when the forcing function f does not contain discontinuities at each of those points.

Example 4.2. We seek here the “true” value of q given by

$$q^* = \begin{cases} 1.0, & 0 \leq x < .2, \\ 6.0, & .2 \leq x < .6, \\ 0.5, & .6 \leq x \leq 1. \end{cases}$$

In this case, $\gamma^* = (\xi_1^*, \xi_2^*, \phi_1^*, \phi_2^*, \phi_3^*) = (.2, .6, 1, 6, .5)$ and the true solution corresponding to γ^* is

$$u(t, x; \gamma^*) = \begin{cases} 30x, & 0 \leq x < .2, \\ 5x + 5, & .2 \leq x < .6, \\ -200x^2 + 300x - 100, & .6 \leq x \leq 1, \end{cases}$$

with data available at $t_i = .5i, i = 1, \dots, 4$, and $x_j = .1j, j = 1, \dots, 9$. For an initial guess of $\gamma^0 = (.3, .7, 5, 5, 5)$ we determined $\bar{\gamma}^8 = (.200, .600, 1.000, 6.000, .5000)$ after 501 CP seconds, with $\bar{J}^8 = 8.3 \times 10^{-6}$.

We consider now two examples where the “true” $q^* = \phi_1^* + H_{\xi^*} \phi_2^*$ involves non-constant values of ϕ_1^* and ϕ_2^* . In each case we search for approximate ϕ_1 and ϕ_2 in the cubic spline space constructed using an $M = 1$ level of approximation (see § 3).

Example 4.3. Here we seek to estimate the “true” parameter

$$q^* = \begin{cases} 2x + 12, & 0 \leq x < .6, \\ 1100x^2/9, & .6 \leq x < 1, \end{cases}$$

starting from the initial guess for q of $q^0 \equiv 3$ on $[0, 1]$ (with start-up value for ξ of $\xi = .5$). The solution

$$u(t, x; \gamma^*) = \begin{cases} (70x - 100x^2)(t^2 + 2), & 0 \leq x < .6, \\ 15(1 - x)(t^2 + 2), & .6 \leq x \leq 1, \end{cases}$$

is used to generate data at $t_i = .5i, i = 1, \dots, 4$, and $x_j = .1j, j = 1, \dots, 9$. In Fig. 4a we compare the estimated $\bar{q}^{N,M} = \bar{\phi}_1^{N,M} + H_{\bar{\xi}^N} \bar{\phi}_2^{N,M}$ ($N = 16, M = 1$) with the “true” coefficient q^* . Figure 4b is the same graph that has been enlarged and restricted to the interval $[.4, .63]$ in order to better distinguish between “true” and approximate curves.

Example 4.4. Again we estimate a functional parameter with true representation given by

$$q^* = \begin{cases} 27.424 - 40x, & 0 \leq x < .3, \\ 90(x - .3)^2 + 18, & .3 \leq x \leq 1. \end{cases}$$

Data is generated as in Example 4.3, using instead the solution

$$u(t, x; \gamma^*) = \begin{cases} 200xt^2(.5 - x), & 0 \leq x < .3, \\ 17.143t^2(1 - x), & .3 \leq x \leq 1. \end{cases}$$

The start-up guess of

$$q^0 = \begin{cases} 18, & 0 \leq x < .2, \\ 48, & .2 \leq x \leq 1, \end{cases}$$

is depicted in Fig. 2, along with the “converged” value of $\bar{q}^{N,M}$ for $N = 24, M = 1$. In this particular example, ϕ_1 and ϕ_2 were estimated easily but we were unable, at the

FIG. 4a. Example 4.3.

FIG. 4b. Example 4.3.

outset, to move ξ from its initial guess of $\xi^0 = .2$. The results displayed in Fig. 5 are actually the outcome of a multistep process whereby the ϕ_i were held fixed while we iterated on ξ and then the process was repeated with ξ fixed and ϕ_i changing (see [30] for a full discussion of this example). This somewhat adaptive algorithm is a common approach taken, often of necessity, when real data is used in connection with model-building applications, e.g. [13], [14]. The difficulties experienced in this particular example may be due to some well-known limitations of the optimization scheme (Levenberg-Marquardt) we chose to use with our approximation ideas. It has been our experience that difficulties sometimes arise when this scheme is used in conjunction

FIG. 5. Example 4.4.

with more than 7 or 8 unknown parameters (there are 9 degrees of freedom in this example). We note that we did *not* experience such difficulties in the last example (also with 9 degrees of freedom) possibly due to the fact that the difference between $q(\xi^+)$ and $q(\xi^-)$ is much greater in that example, making the problem more sensitive to the placement of ξ .

Finally, we remark that a drawback of our approximation framework is that we must specify the *number* of discontinuities in advance of the estimation process. Fortunately, it is possible to overestimate and underestimate this number and still obtain useful information. This will be the focus of our last two examples.

Example 4.5. We repeat Example 4.2 except that we assume throughout that q is discontinuous at only one point (while two discontinuities are actually present in q^*); we also allow spatial variation in ϕ_1 and ϕ_2 and approximate using cubic splines. An initial guess for q and a converged estimate $\bar{q}^{N,M}$ ($N = 24$, $M = 1$) are depicted in Fig. 6 where it is interesting to note that the initial guess of $\xi^0 = .4$ converges to a value close to that of the true (second) discontinuity, $\xi_2^* = .6$. In addition, to the right of this point the estimated shape of q begins to approximate the constant function ϕ_3^* , while to the left of that point the rapidly increasing estimated shape gives an indication that we have underestimated the number of discontinuities present.

Example 4.6. We repeat Example 4.1, except that now we *overestimate* the number of discontinuities in q . We assume throughout that $q = \phi_1 + H_{\xi_1} \phi_2 + H_{\xi_2} \phi_3$ where ϕ_1 , ϕ_2 , and ϕ_3 are constants. For an initial guess of

$$q^0 = \begin{cases} 25, & 0 \leq x < .5, \\ 5, & .5 \leq x < .7, \\ 20, & .7 \leq x \leq 1, \end{cases}$$

we obtained ($N = 8$, 291 CP seconds)

$$\bar{q}^8 = \begin{cases} 14.95, & 0 \leq x \leq .503, \\ 14.99, & .503 \leq x \leq .600, \\ 50.05, & .600 \leq x \leq 1; \end{cases}$$

FIG. 6. Example 4.5.

repeating the same example but with a different initial guess,

$$q^0 = \begin{cases} .001, & 0 \leq x < .333, \\ .001, & .333 \leq x < .667, \\ .001, & .667 \leq x \leq 1, \end{cases}$$

we observed the following converged values ($N = 16$)

$$\bar{q}^{16} = \begin{cases} 2.44, & 0 \leq x < .0001, \\ 15.05, & .0001 \leq x < .6001, \\ 49.88, & .6001 \leq x \leq 1. \end{cases}$$

A close inspection of either result reveals that we were, in fact, able to accurately estimate q^* (as defined in Example 4.1), even though a two-discontinuity approximation structure was incorrectly used throughout.

Remark 4.1. We note that our success in numerical examples given here is not due to the fact that “true” parameters happen to lie in the approximating spaces Γ^M . We have also observed equally good results in examples where the parameters cannot be fit exactly by elements of Γ^M for any M (e.g., see Example 4.2 of [17], or see [6], [9], [32] for a number of examples in the context of several applications).

Remark 4.2. We recognize that some of the success seen in our test examples is due to our choice of approximate parameter spaces Γ^M , where M is small. Indeed, an advantage of our approach from a computational standpoint is that the choice of M need not depend on the size (i.e., N) of the approximate state space. Because M is small (and thus the number of unknowns is kept small) we are able to achieve success with an optimization scheme like the Levenberg–Marquardt algorithm. In applications where one might desire to increase the size of the parameter space, it is likely that a direct gradient algorithm will be required to handle the larger number of parameter degrees of freedom.

5. Concluding remarks. In conclusion, we have developed a spline-based approximation framework for the problem of estimating discontinuous functional coefficients

(including locations of discontinuities) in one-dimensional parabolic equations. We feel that some positive aspects of our approach include the separate treatment of approximations for state variables and for parameters. Computational advantages of this framework are seen in the combination of approximate state spaces of *large* dimension with parameter spaces of *small* dimension; when such an approach is justified, the latter often facilitates the numerical parameter search. In addition, our scheme has been developed specifically to minimize any computational difficulties associated with unknown points of discontinuity that are continually being updated throughout an iterative estimation algorithm.

We are currently working to further develop these ideas and to extend the theory to other applications, e.g., hyperbolic (seismic) equations and higher order (elastic beam) systems. We are also working to develop a related theory for two-dimensional domains, although for obvious reasons this is not simply a trivial extension of the ideas presented thus far.

Acknowledgment. The author would like to express appreciation to Professor H. T. Banks for numerous insightful discussions during the course of this work.

AN APPROACH TO DISCRETE-TIME STOCHASTIC CONTROL PROBLEMS UNDER PARTIAL OBSERVATION*

GIOVANNI B. DI MASI† AND WOLFGANG J. RUNGGLALDIER‡

Abstract. We consider a general class of discrete-time nonlinear stochastic control problems with partial observation, for which in general only ε -optimal controls exist, and provide a method for explicitly computing them. Transforming, as usual, these problems into equivalent ones with complete observation leads to various difficulties, in particular to a nonlinear filtering problem. We first define a subclass of the given problems such that the associated nonlinear filtering problem can be explicitly solved and, for each $\delta > 0$, a δ -optimal control computed. We then show that, under suitable assumptions, for each original problem and each given $\varepsilon > 0$, a problem in the particular class and a $\delta > 0$ can be found, such that a δ -optimal control for the latter is ε -optimal for the former.

Key words. stochastic control, nonlinear filtering, ε -optimal controls, approximate dynamic programming

1. Introduction. Consider the following discrete-time stochastic control problem: a partially observable process $\{x_t, y_t\}$, $x_t, y_t \in \mathbb{R}$, with x_t the unobservable and y_t the observable components, is given for $t = 0, 1, \dots, T$ on some probability space (Ω, \mathcal{F}, P) by

$$(1.1a) \quad x_{t+1} = a(x_t, u_t) + \sigma(x_t)v_{t+1}, \quad x_0 = v_0,$$

$$(1.1b) \quad y_t = c(x_t) + w_t, \quad y_0 = w_0,$$

where $\{v_t\}$ and $\{w_t\}$ are independent standard white Gaussian noises and $\{u_t\}$ is a sequence of admissible controls, namely such that u_t takes values in a given set $U \subset \mathbb{R}$ and depends only on past and present observations $y^t := \{y_0, \dots, y_t\}$ and past controls $u^{t-1} := \{u_0, \dots, u_{t-1}\}$. Defining the value function

$$(1.2) \quad v(u) := E \left\{ \sum_{t=0}^{T-1} r(x_t, u_t) + b(x_T) \right\}$$

where $r(x, u)$ and $b(x)$ are given cost functions, it is desired to find, for any given $\varepsilon > 0$, an ε -optimal control $\{u_t^\varepsilon\}$, i.e. an admissible control such that

$$v(u^\varepsilon) \leq \inf_u v(u) + \varepsilon$$

where the inf is over all admissible controls u .

The usual first step in approaching a stochastic control problem with partial observation as (1.1)–(1.2) is (see e.g. [2], [4]) to transform it into an “equivalent” problem with complete observation by taking as new state at time t the conditional density of x_t given y^t . The equivalence is in the sense that to each optimal (ε -optimal) control in one problem there corresponds an optimal (ε -optimal) control in the other. The major difficulty that arises with this approach is that the new state takes values

in an infinite-dimensional space, namely the Borel space [4, App. 5.2] of all probability densities over the real line.

Our approach here consists of two steps. First, in analogy to an approach used by the authors [3] to obtain approximate solutions to discrete-time nonlinear filtering problems in additive white Gaussian noise, we define a particular class of problems of the type (1.1)–(1.2) such that, given any $\delta > 0$, a δ -optimal control can be explicitly computed. Second, we show under suitable assumptions that for each problem (1.1)–(1.2) and each $\varepsilon > 0$, it is possible to construct a problem in the particular class so that a δ -optimal control for the latter is ε -optimal for the former. This second step is the main subject of § 2, where we also describe the particular class of problems of type (1.1)–(1.2). A method for actually obtaining a δ -optimal control for the problems in the particular class is then presented in § 3.

2. ε -optimal control for the original problem. In this section we shall consider a particular class of problems of the type (1.1)–(1.2) and show that, given $\varepsilon > 0$, it is possible to obtain an ε -optimal control for the original problem (1.1)–(1.2) provided that for a suitable δ , a δ -optimal control for a problem in the particular class has been obtained.

The procedure followed here consists of constructing for each problem (1.1)–(1.2) a corresponding problem in the particular class and in showing that a δ -optimal control for the latter is ε -optimal for the former. The problem in the particular class will be called the approximating problem and a δ -optimal control for it will be called a solution to the approximating problem.

2.1. The particular class. Consider the following particular case of problem (1.1)–(1.2):

$$(2.1a) \quad x_{t+1} = \sum_{i,k=1}^n a_i(k) I_{D_i}(x_t) I_{U_k}(u_t) + \sum_{i=1}^n \sigma_i I_{D_i}(x_t) v_{t+1},$$

$$(2.1b) \quad y_t = \sum_{i=1}^n c_i I_{D_i}(x_t) + w_t,$$

$$(2.2) \quad v(u^{T-1}) = E \left\{ \sum_{t=0}^{T-1} \left[\sum_{i,k=1}^n r_i(k) I_{D_i}(x_t) I_{U_k}(u_t) \right] + \sum_{i=1}^n b_i I_{D_i}(x_T) \right\}$$

where $a_i(k)$, $r_i(k)$, σ_i , b_i , c_i ($i, k = 1, \dots, n$) are given real numbers, $\{D_i\}$ is a finite partition of the real line into intervals, $\{U_k\}$ is a class of disjoint intervals on \mathbb{R} and the admissible control set is given by $U = \bigcup_k U_k$. In other words, this class consists of problems (1.1)–(1.2) with a , r , σ , b , c step functions, and U a finite union of intervals.

It is clear from the particular structure of (2.1)–(2.2) that the conditional probabilities $\pi_t^i := P\{x_t \in D_i | y^t, u^{t-1}\}$, $i = 1, \dots, n$ contain all the information on the past history (y^t, u^{t-1}) which is relevant for control purposes so that the vector $\pi_t = [\pi_t^1, \dots, \pi_t^n]$ can be taken as state variable of the equivalent complete-observation control problem.

It is also clear from (2.1)–(2.2) that the choice of a particular value for the control u_t reduces to the choice of a $k = 1, \dots, n$, so that in this subsection we shall consider $U = \{1, \dots, n\}$.

Furthermore, exploiting the particular structure of (2.1), it is possible to determine the transition law for π_t ; in fact, using the recursive Bayes formula, it is easily seen that

$$(2.3) \quad \pi_{t+1}^j = G^j(\pi_t, y_{t+1}, u_t) := \frac{\sum_{i=1}^n \pi_t^i p_{ij}(u_t) f_j(y_{t+1})}{\sum_{i=1}^n \sum_{h=1}^n \pi_t^i p_{ih}(u_t) f_h(y_{t+1})}$$

where

$$(2.4) \quad p_{ij}(u_i) = \frac{1}{\sqrt{2\pi}\sigma_i} \int_{D_i} \exp \left[-\frac{(x - a_i(u_i))^2}{2\sigma_i^2} \right] dx,$$

$$(2.5) \quad f_j(y_{t+1}) = \frac{1}{\sqrt{2\pi}} \exp \left[-\frac{1}{2}(y_{t+1} - c_j)^2 \right]$$

and the initial condition is given by

$$(2.6) \quad \pi_0^j = P\{x_0 \in D_j\}, \quad j = 1, \dots, n.$$

Notice that the denominator in (2.3) is the conditional density $g(y_{t+1}|y^t, u^t)$.

The equivalent complete-observation problem is characterized by the state space $\Pi = \{\pi | \pi^i \in [0, 1], i = 1, \dots, n; \sum_i \pi^i = 1\}$ by the state-transition law

$$(2.7) \quad \pi_{t+1} = G(\pi_t, y_{t+1}, u_t)$$

as given in (2.3), by admissible control sequences $\{u_t\}$ such that $u_t \in U$ depends only on π_t , and cost functions given, with abuse of notation, by

$$(2.8a) \quad r(\pi_t, u_t) = E\{r(x_t, u_t) | y^t, u^{t-1}\} = \sum_{i=1}^n \pi_t^i r_i(u_t),$$

$$(2.8b) \quad b(\pi_T) = E\{b(x_T) | y^T, u^{T-1}\} = \sum_{i=1}^n \pi_T^i b_i.$$

2.2. Construction of the approximating problem. The main purpose of this subsection is to construct for each problem (1.1)–(1.2) a corresponding problem in the particular class (2.1)–(2.2) such that a δ -optimal control for the latter is ε -optimal for the former. We shall use the following assumptions (where it is implicit that U can be partitioned into intervals):

A.1. There exist sequences of step functions $a^{(n)}(x, u)$, $\sigma^{(n)}(x)$, $c^{(n)}(x)$, $r^{(n)}(x, u)$, $b^{(n)}(x)$ such that $\|a^{(n)}(x, u) - a(x, u)\|$, $\|\sigma^{(n)}(x) - \sigma(x)\|$, $\|c^{(n)}(x) - c(x)\|$, $\|r^{(n)}(x, u) - r(x, u)\|$, $\|b^{(n)}(x) - b(x)\| \rightarrow 0$ as $n \rightarrow \infty$ where $\|\cdot\|$ denotes the sup norm.

A.2. The functions $\sigma(x)$, $c(x)$ and $b(x)$ are Lipschitz continuous with Lipschitz constants L_σ , L_c and L_b respectively. Furthermore, $a(x, u)$ and $r(x, u)$ are Lipschitz continuous in x , uniformly in u , with Lipschitz constants L_a and L_b respectively.

Furthermore, let $B, C, B^{(n)}, C^{(n)}$ denote constants such that $\|b(x)\| \leq B$, $\|b^{(n)}(x)\| \leq B$, $\|r(x, u)\| \leq B$, $\|r^{(n)}(x, u)\| \leq B$, $\|c(x)\| \leq C$, $\|c^{(n)}(x)\| \leq C$, $\|b^{(n)}(x) - b(x)\| \leq B^{(n)}$, $\|r^{(n)}(x, u) - r(x, u)\| \leq B^{(n)}$, $\|c^{(n)}(x) - c(x)\| \leq C^{(n)}$.

The approximating problem is constructed by first approximating the process $\{x_t\}$, defined for a given admissible control u in (1.1a), by a process $\{x_t^{(n)}\}$ satisfying (2.1a) for the same control u . For this purpose, given $n \in \mathbb{N}$, let $a^{(n)}(x, u)$ and $\sigma^{(n)}(x)$ be step functions according to assumption A.1. The approximating process is then defined by

$$(2.9) \quad x_{t+1}^{(n)} = a^{(n)}(x_t^{(n)}, u_t) + \sigma^{(n)}(x_t^{(n)})v_{t+1}, \quad x_0^{(n)} = x_0 = v_0.$$

Furthermore, since the original observation process $\{y_t\}$ defined in (1.1b) provides the only available data, we want the approximating problem to generate this same observation process. To this end we use an absolutely continuous transformation of probability measures. Given $n \in \mathbb{N}$, let $c^{(n)}(x)$ be a step function according to assumption A.1 and consider the processes

$$(2.10) \quad \lambda_t = \prod_{s=1}^t \exp [c(x_s)y_s - \frac{1}{2}c^2(x_s)], \quad \lambda_0 = 1,$$

$$(2.11) \quad \lambda_t^{(n)} = \prod_{s=1}^t \exp [c^{(n)}(x_s^{(n)})y_s - \frac{1}{2}c^{(n)2}(x_s^{(n)})], \quad \lambda_0^{(n)} = 1.$$

Letting $\mathcal{F}_t = \sigma\{w^t, v^t\}$, define the probability measures P_0 and $P^{(n)}$ by

$$(2.12) \quad \left. \frac{dP_0}{dP} \right|_{\mathcal{F}_t} = \lambda_t^{-1}, \quad \left. \frac{dP^{(n)}}{dP_0} \right|_{\mathcal{F}_t} = \lambda_t^{(n)}$$

and denote by E_0 and $E^{(n)}$ the corresponding expectations. We have the following.

PROPOSITION 2.1. *The process y_t defined in (1.1b) is under P_0 standard white Gaussian noise independent of $\{v_t\}$, while under $P^{(n)}$ it satisfies*

$$(2.13) \quad y_t = c^{(n)}(x_t^{(n)}) + w_t^{(n)}$$

where $w_t^{(n)}$ is a $P^{(n)}$ -standard white Gaussian noise independent of $\{v_t\}$. Furthermore the process v_t has the same distribution under P , P_0 and $P^{(n)}$.

Proof. It is easily seen that for an \mathcal{F}_t -adapted process z_t

$$E_0\{z_t | \mathcal{F}_{t-1}\} = E \left\{ \frac{z_t \lambda_t^{-1}}{\lambda_{t-1}^{-1}} \middle| \mathcal{F}_{t-1} \right\}.$$

Then, using (1.1b) and the fact that x_t is \mathcal{F}_{t-1} -measurable, we have for $\alpha \in \mathbb{R}$

$$\begin{aligned} E_0\{\exp[i\alpha y_t] | \mathcal{F}_{t-1}\} &= E\{\exp[i\alpha y_t] \exp[c(x_t)y_t - \frac{1}{2}c^2(x_t)]^{-1} | \mathcal{F}_{t-1}\} \\ &= \exp[i\alpha c(x_t) - \frac{1}{2}c^2(x_t)] E\{\exp[w_t(i\alpha - c(x_t))] | \mathcal{F}_{t-1}\} \\ &= \exp[-\frac{1}{2}\alpha^2], \end{aligned}$$

which shows that y_t is a (P_0, \mathcal{F}_t) -standard white Gaussian noise and is therefore independent of $\{v_t\}$. Furthermore, since $\lambda_0 = 1$, v_t preserves its distribution under P_0 .

In an analogous way it is possible to show that under $P^{(n)}$ (2.13) holds and v_t again preserves its distribution. \square

For each $n \in \mathbb{N}$ we now have an approximating problem defined on $(\Omega, \mathcal{F}, P^{(n)})$ by

$$(2.14a) \quad x_{t+1}^{(n)} = a^{(n)}(x_t^{(n)}, u_t) + \sigma^{(n)}(x_t^{(n)})v_{t+1}, \quad x_0^{(n)} = x_0 = v_0,$$

$$(2.14b) \quad y_t = c^{(n)}(x_t^{(n)}) + w_t^{(n)}, \quad y_0 = w_0^{(n)},$$

$$(2.15) \quad v^{(n)}(u) = E^{(n)} \left\{ \sum_{t=0}^{T-1} r^{(n)}(x_t^{(n)}, u_t) + b^{(n)}(x_T^{(n)}) \right\}$$

where $\{v_t\}$ and $\{w_t^{(n)}\}$ are independent $P^{(n)}$ -standard Gaussian white noises and $r^{(n)}$ and $b^{(n)}$ are step functions according to assumption A.1.

2.3. ε -optimality of the solution of the approximating problem. In this subsection we assume that for every $\delta > 0$ a δ -optimal control for problem (2.14)–(2.15) has already been obtained. Such control, hereafter denoted by $u^{n,\delta}$, can then be applied to the original problem (1.1)–(1.2) and we shall show that for $\varepsilon > 0$ given, an $n \in \mathbb{N}$ and a $\delta > 0$ can be found such that

$$(2.16) \quad v(u^{n,\delta}) \leq \inf_u v(u) + \varepsilon.$$

In Proposition 2.2 below we shall first give a sufficient condition for (2.16) to hold.

PROPOSITION 2.2. *If for all admissible controls u*

$$(2.17) \quad |v^{(n)}(u) - v(u)| \leq \frac{\varepsilon}{2} - \delta \quad \left(0 < \delta < \frac{\varepsilon}{2} \right),$$

then

$$(2.18) \quad v(u^{n,\delta}) \leq \inf_u v(u) + \varepsilon.$$

Proof. Denoting by u^δ a δ -optimal control for the original problem (1.1)–(1.2) and using (2.17) we have

$$(2.19) \quad \begin{aligned} \inf_u v(u) &\geq v(u^\delta) - \delta \geq v^{(n)}(u^\delta) - \frac{\varepsilon}{2} \geq \inf_u v^{(n)}(u) - \frac{\varepsilon}{2} \\ &\geq v^{(n)}(u^{n,\delta}) - \frac{\varepsilon}{2} - \delta \geq v(u^{n,\delta}) - \varepsilon. \end{aligned} \quad \square$$

Using Proposition 2.2, our problem now reduces to that of finding for $\varepsilon > 0$ given, an $n \in \mathbb{N}$ and a δ ($0 < \delta < \varepsilon/2$) such that for any admissible control (2.17) holds. This will follow from Theorem 2.1 below, which shows that for each n we can explicitly construct a bound $K^{(n)}$ such that $|v^{(n)}(u) - v(u)| \leq K^{(n)}$ for all u and $\lim_{n \rightarrow \infty} K^{(n)} = 0$. In what follows we shall assume that an admissible control sequence u has been fixed; the results then hold for any such u . In order to prove the main Theorem 2.1 we need some preliminary results.

LEMMA 2.1. *Under A.1 and A.2 we have for $t \geq 1$*

$$(2.20) \quad E|x_t^{(n)} - x_t| \leq A_t^{(n)}$$

where

$$(2.21) \quad A_t^{(n)} = (\|a^{(n)} - a\| + \sqrt{2/\pi} \|\sigma^{(n)} - \sigma\|) \left[\sum_{s=0}^{t-1} (L_a + \sqrt{2/\pi} L_\sigma)^s \right]$$

is independent of the control u and $\rightarrow 0$ as $n \rightarrow \infty$.

Proof. From (1.1a) and (2.14a)

$$\begin{aligned} |x_{t+1}^{(n)} - x_{t+1}| &\leq |a^{(n)}(x_t^{(n)}, u_t) - a(x_t^{(n)}, u_t)| + |a(x_t^{(n)}, u_t) - a(x_t, u_t)| \\ &\quad + |\sigma^{(n)}(x_t^{(n)}) - \sigma(x_t^{(n)})| |v_{t+1}| + |\sigma(x_t^{(n)}) - \sigma(x_t)| |v_{t+1}| \\ &\leq \|a^{(n)} - a\| + L_a |x_t^{(n)} - x_t| + \|\sigma^{(n)} - \sigma\| |v_{t+1}| + L_\sigma |x_t^{(n)} - x_t| |v_{t+1}| \end{aligned}$$

and, taking into account that $E|v_{t+1}| = \sqrt{2/\pi}$, we have

$$E|x_{t+1}^{(n)} - x_{t+1}| \leq (L_a + \sqrt{2/\pi} L_\sigma) E|x_t^{(n)} - x_t| + \|a^{(n)} - a\| + \sqrt{2/\pi} \|\sigma^{(n)} - \sigma\|$$

from which the result follows. \square

Remark 2.1. From the proof of Lemma 2.1 it follows immediately using Proposition 2.1 that (2.20) holds also when the expectation there is computed with respect to P_0 or $P^{(n)}$.

LEMMA 2.2. *Under A.1 and A.2 we have*

$$(2.22) \quad E_0|\lambda_T - \lambda_T^{(n)}| \leq \Lambda^{(n)}$$

where

$$(2.23) \quad \Lambda^{(n)} = 2T(L_c A_T^{(n)} + C^{(n)})(2C + \sqrt{2/\pi})$$

with $A_T^{(n)}$ given by (2.21), so that $\Lambda^{(n)} \rightarrow 0$ as $n \rightarrow \infty$.

Proof. Using the assumptions and the inequality $|e^x - e^y| \leq (e^x + e^y)|x - y|$ we have

$$\begin{aligned} |\lambda_T - \lambda_T^{(n)}| &\leq (\lambda_T + \lambda_T^{(n)}) \cdot \sum_{s=1}^T \left(|c(x_s) - c^{(n)}(x_s^{(n)})| |y_s| + \frac{1}{2} |c^2(x_s) - c^{(n)2}(x_s^{(n)})| \right) \\ &\leq (\lambda_T + \lambda_T^{(n)}) \sum_{s=1}^T (L_c |x_s - x_s^{(n)}| + C^{(n)}) (|y_s| + C). \end{aligned}$$

Then, using (1.1b), (2.14b), the independence of $(x_s - x_s^{(n)})$ and w_s , Lemma 2.1 and Remark 2.1,

$$\begin{aligned} E_0 |\lambda_T - \lambda_T^{(n)}| &\leq E \left\{ \sum_{s=1}^T (L_c |x_s - x_s^{(n)}| + C^{(n)})(2C + |w_s|) \right\} \\ &\quad + E^{(n)} \left\{ \sum_{s=1}^T (L_c |x_s - x_s^{(n)}| + C^{(n)})(2C + |w_s^{(n)}|) \right\} \\ &\leq 2T(L_c A_t^{(n)} + C^{(n)})(2C + \sqrt{2/\pi}). \end{aligned} \quad \square$$

Finally, the following Theorem 2.1 provides the sufficient condition in Proposition 2.2.

THEOREM 2.1. *Under A.1 and A.2 we have for all admissible controls u*

$$(2.24) \quad |v(u) - v^{(n)}(u)| \leq K^{(n)}$$

where

$$(2.25) \quad K^{(n)} = (T+1)(B\Lambda^{(n)} + L_b A_T^{(n)} + B^{(n)})$$

with $A_T^{(n)}$ and $\Lambda^{(n)}$ given by (2.21) and (2.23), so that $K^{(n)} \rightarrow 0$ as $n \rightarrow \infty$.

Proof. Using Lemmas 2.1 and 2.2 we have

$$\begin{aligned} |v(u) - v^{(n)}(u)| &= \left| E_0 \left\{ \lambda_T \left[\sum_{s=0}^{T-1} r(x_s, u_s) + b(x_T) \right] - \lambda_T^{(n)} \left[\sum_{s=0}^{T-1} r(x_s^{(n)}, u_s) + b(x_T^{(n)}) \right] \right\} \right| \\ &\leq E_0 \left\{ |\lambda_T - \lambda_T^{(n)}| \left[\sum_{s=0}^{T-1} |r(x_s, u_s)| + |b(x_T)| \right] \right\} \\ &\quad + E_0 \left\{ \lambda_T^{(n)} \left[\sum_{s=0}^{T-1} |r(x_s, u_s) - r(x_s^{(n)}, u_s)| + |b(x_T) - b(x_T^{(n)})| \right] \right\} \\ &\quad + E_0 \left\{ \lambda_T^{(n)} \left[\sum_{s=0}^{T-1} |r(x_s^{(n)}, u_s) - r^{(n)}(x_s^{(n)}, u_s)| + |b(x_T^{(n)}) - b^{(n)}(x_T^{(n)})| \right] \right\} \\ &\leq (T+1)(\Lambda^{(n)} B + L_b A_T^{(n)} + B^{(n)}). \end{aligned} \quad \square$$

3. δ -optimal control for the approximating problem. The purpose of this section is to determine a δ -optimal control for the approximating problem (2.14)–(2.15) or, equivalently, for the corresponding complete-observation problem described in 2.1, which in the sequel will be referred to as problem (P) and is given by

$$(3.1) \quad \begin{cases} \pi_{t+1} = G(\pi_t, y_{t+1}, u_t), & \pi_0^j = P\{x_0 \in D_j\}, \quad j = 1, \dots, n, \end{cases}$$

$$(3.2) \quad \begin{cases} v^{(n)}(u) = E^{(n)} \left\{ \sum_{t=0}^{T-1} r(\pi_t, u_t) + b(\pi_T) \right\}. \end{cases}$$

Problem (P) has the states taking values in a finite dimensional space, but its possible values are still infinite. The approach used here to obtain a δ -optimal control for problem (P) consists in approximating it by a problem (\bar{P}) whose state space is finite and for which, as the control set is already finite, an optimal control can be actually computed. This latter control, when suitably extended, will then be shown to be δ -optimal for (P). In this sense the approach to be presented here can be considered an extension of some recent approaches concerning “approximate dynamic programs” which have been proposed for complete-observation problems, in particular Markovian

decision problems (see e.g. [1], [5], [6]). The main idea in [1], [5], [6] is to partition the state space into a finite number of subsets, each characterized by a representative element, and to approximate the original problem by one whose state space is given by the representative elements. A direct application of these methods to our problem (P) leads to various difficulties, in particular that of determining the transition law of the approximating finite state problem. It therefore appears more convenient to exploit the partially observable nature of the original problem (2.14)–(2.15) and to first discretize the observation process y_t .

For $Q, q \in \mathbb{N}$ given, consider the following partition $\{Y_i : i = 1, \dots, \bar{q}; \bar{q} = 2Qq + 2\}$ of \mathbb{R} :

$$(3.3) \quad \begin{cases} Y_1 = (-\infty, -Q), \\ Y_i = [-Q + (i-2)/q, -Q + (i-1)/q), & i = 2, \dots, \bar{q} - 1, \\ Y_{\bar{q}} = [Q, +\infty), \end{cases}$$

and let $\{\eta_i : \eta_i \in Y_i; i = 1, \dots, \bar{q}\}$ be a set of representative elements of the partition. Then, defining the projection

$$(3.4) \quad \bar{y}(y) = \sum_{i=1}^{\bar{q}} \eta_i I_{Y_i}(y),$$

consider the finite valued process $\{\bar{y}_t\}$ (discretized observation process) given by

$$(3.5) \quad \bar{y}_t = \bar{y}(y_t)$$

and set, with abuse of notation,

$$(3.6) \quad \bar{y}(y^t) := \bar{y}^t.$$

Furthermore, let

$$(3.7) \quad \bar{f}_j(\eta_i) := P^{(n)}\{\bar{y}_t = \eta_i \mid x_t \in D_j\} = \frac{1}{\sqrt{2\pi}} \int_{Y_i} \exp\left[-\frac{1}{2}(y - c_j)^2\right] dy.$$

It is clear that the vector $\bar{\pi}_t = [\bar{\pi}_t^1, \dots, \bar{\pi}_t^n]$ of conditional probabilities $\bar{\pi}_t^i = P^{(n)}\{x_t^{(n)} \in D_i \mid \bar{y}^t, u^{t-1}\}$ is a sufficient statistic for the problem with the discretized observation process $\{\bar{y}_t\}$ and it satisfies, analogously to (2.3), the recursive relation

$$(3.8) \quad \bar{\pi}_{t+1}^j = \bar{G}^j(\bar{\pi}_t, \bar{y}_{t+1}, u_t) := \sum_{i=1}^n \bar{\pi}_t^i p_{ij}(u_t) \bar{f}_j(\bar{y}_{t+1}) \Big/ \sum_{i=1}^n \sum_{h=1}^n \bar{\pi}_t^i p_{ih}(u_t) \bar{f}_h(\bar{y}_{t+1})$$

where $p_{ij}(u_t)$ and $\bar{f}_j(\bar{y}_{t+1})$ are given by (2.4) and (3.7), and the initial condition is $\bar{\pi}_0^j = P^{(n)}\{x_0 \in D_j\} = \pi_0^j$.

The finite state problem (\bar{P}) approximating (P) is now given by

$$(3.9) \quad \begin{cases} \bar{\pi}_{t+1} = \bar{G}(\bar{\pi}_t, \bar{y}_{t+1}, u_t), & \bar{\pi}_0 = \pi_0, \\ \bar{v}^{(n)}(u) = E^{(n)}\left\{\sum_{s=0}^{T-1} r(\bar{\pi}_s, u_s) + b(\bar{\pi}_T)\right\}. \end{cases} \quad (\bar{P})$$

Let

$$(3.11) \quad \bar{u}_t(\bar{\pi}_t) = \bar{u}_t(\bar{y}^t, \bar{u}^{t-1})$$

be an optimal control for problem (\bar{P}) and extend it to all the histories of problem (P) by setting

$$(3.12) \quad \bar{u}_t(y^t, \bar{u}^{t-1}) := \bar{u}_t(\bar{y}(y^t), \bar{u}^{t-1}).$$

It remains to show that by choosing Q and q sufficiently large, the control $\{\bar{u}_t\}$ defined in (3.12) is δ -optimal for problem (P), i.e. for the original problem (2.14)–(2.15).

This is the purpose of the rest of this section, where the main result is given in the final Theorem 3.1.

LEMMA 3.1. *Letting*

$$(3.13) \quad p := \min_{i,h,u} p_{ih}(u) > 0, \quad L := n/p^2,$$

we have for all π_1, π_2, y, u

$$(3.14) \quad \max_j |G^j(\pi_1, y, u) - G^j(\pi_2, y, u)| \leq L \max_i |\pi_1^i - \pi_2^i|.$$

Proof. Using the relations $p_{ih}(u) \leq 1$ ($i, h = 1, \dots, n$), $\sum_i \pi_i^l = 1$ ($l = 1, 2$) and $\sum_{i,h} \pi_1^i p_{ih}(u) f_h(y) \geq \sum_i \pi_1^i p_{ij}(u) f_j(y)$, we have

$$\begin{aligned} & |G^j(\pi_1, y, u) - G^j(\pi_2, y, u)| \\ &= \frac{|\sum_{i,h} \pi_1^i p_{ij}(u) f_j(y) \pi_2^i p_{ih}(u) f_h(y) - \sum_{i,h} \pi_2^i p_{ij}(u) f_j(y) \pi_1^i p_{ih}(u) f_h(y)|}{(\sum_{i,h} \pi_1^i p_{ih}(u) f_h(y))(\sum_{i,h} \pi_2^i p_{ih}(u) f_h(y))} \\ &\leq \frac{f_j(y) \sum_{i,h} \pi_1^i f_h(y) |\sum_l (\pi_1^l \pi_2^i - \pi_2^l \pi_1^i)|}{(\sum_i \pi_1^i p_{ij}(u) f_j(y))(\sum_{i,h} \pi_2^i p_{ih}(u) f_h(y))} \\ &\leq \frac{\sum_{i,h} f_h(y) |\pi_1^i - \pi_2^i|}{p^2 \sum_{i,h} \pi_2^i f_h(y)} \end{aligned}$$

from which (3.14) follows. \square

In what follows we shall assume, without loss of generality, $c_1 \leq c_2 \leq \dots \leq c_n$.

LEMMA 3.2. *If $y \notin [-Q, Q]$, we have for every $j = 1, \dots, n$ and all π, u*

$$(3.15) \quad |G^j(\pi, y, u) - \bar{G}^j(\pi, \bar{y}(y), u)| \leq G(Q)$$

where

$$(3.16) \quad G(Q) = \left[1 + p / \max \left\{ \sum_{h \neq n} \exp \left[(c_h - c_n)Q - \frac{1}{2}(c_h^2 - c_n^2) \right], \sum_{h \neq 1} \exp \left[(c_1 - c_h)Q - \frac{1}{2}(c_h^2 - c_1^2) \right] \right\} \right]^{-1}$$

so that $G(Q) \rightarrow 0$ as $Q \rightarrow +\infty$.

Proof. Assuming first $y \geq Q$, we have for $j < n$

$$\begin{aligned} (3.17) \quad 0 &\leq G^j(\pi, y, u) \leq \sum_i \sum_{h \neq n} \pi^i p_{ih}(u) f_h(y) / \sum_i \sum_h \pi^i p_{ih}(u) f_h(y) \\ &= \left[1 + \sum_i \pi^i p_{in} \exp \left[-\frac{1}{2}(y - c_n)^2 \right] / \sum_i \sum_{h \neq n} \pi^i p_{ih} \exp \left[-\frac{1}{2}(y - c_h)^2 \right] \right]^{-1} \\ &\leq \left[1 + p / \sum_{h \neq n} \exp \left[(c_h - c_n)y - \frac{1}{2}(c_h^2 - c_n^2) \right] \right]^{-1} \\ &\leq \left[1 + p / \sum_{h \neq n} \exp \left[(c_h - c_n)Q - \frac{1}{2}(c_h^2 - c_n^2) \right] \right]^{-1} \end{aligned}$$

and for $h = j$

$$\begin{aligned} (3.18) \quad 0 &\leq 1 - G^n(\pi, y, u) = \sum_i \sum_{h \neq n} \pi^i p_{ih}(u) f_h(y) / \sum_i \sum_h \pi^i p_{ih}(u) f_h(y) \\ &\leq \left[1 + p / \sum_{h \neq n} \exp \left[(c_h - c_n)Q - \frac{1}{2}(c_h^2 - c_n^2) \right] \right]^{-1}. \end{aligned}$$

Noticing now that

$$\begin{aligned} & \int_Q^{+\infty} \exp \left[-\frac{1}{2}(y - c_h)^2 \right] dy \Big/ \int_Q^{+\infty} \exp \left[-\frac{1}{2}(y - c_n)^2 \right] dy \\ & \leq \exp \left[-\frac{1}{2}(Q - c_h)^2 \right] \Big/ \exp \left[-\frac{1}{2}(Q - c_n)^2 \right] \end{aligned}$$

we obtain the same bounds (3.17) and (3.18) for $\bar{G}^j(\pi, \bar{y}(y), u)$, so that (3.15) is proved for $y \geq Q$. The case $y < -Q$ can be proved analogously, simply replacing n by 1 and Q by $-Q$. \square

Notice now that with $f_j(y)$ as defined in (2.5) we have that if $|y - \bar{y}| < 1/q$, then for all j

$$(3.19) \quad |f_j(y) - f_j(\bar{y})| < 1/q.$$

Furthermore, notice that if $y \in [-Q, Q]$ and if $Y(y)$ denotes the set of the partition (3.3) containing y , then by the mean value theorem for integrals we have for all π and u

$$\begin{aligned} (3.20) \quad \bar{G}^j(\pi, \bar{y}(y), u) &= \sum_i \pi^i p_{ij}(u) \int_{Y(y)} \exp \left[-\frac{1}{2}(y - c_j)^2 \right] dy \\ &\quad \Big/ \sum_{i,h} \pi^i p_{ih}(u) \int_{Y(y)} \exp \left[-\frac{1}{2}(y - c_h)^2 \right] dy \\ &= \sum_i \pi^i p_{ij}(u) f_j(y_j(y)) \Big/ \sum_{i,h} \pi^i p_{ih}(u) f_h(y_h(y)) \end{aligned}$$

with $y_j(y)$ and $y_h(y)$ suitable elements in $Y(y)$. Letting

$$(3.21) \quad f(Q) := [\min_h \min \{f_h(-Q), f_h(Q)\}]^{-1}$$

so that for all $y \in [-Q, Q]$ and all h

$$(3.22) \quad f_h^{-1}(y) \leq f(Q),$$

we have

LEMMA 3.3. *If $y \in [-Q, Q]$, we have for every $j = 1, \dots, n$ and all π, u*

$$(3.23) \quad |G^j(\pi, y, u) - \bar{G}^j(\pi, \bar{y}(y), u)| \leq 2f(Q)/q$$

where $f(Q)$ is given by (3.21).

Proof. Using (3.19) through (3.22) we have

$$\begin{aligned} & |G^j(\pi, y, u) - \bar{G}^j(\pi, \bar{y}(y), u)| \\ & \leq \sum_{i,i,h} \pi^i \pi^i p_{ij}(u) p_{ih}(u) f_j(y) |f_h(y) - f_h(y_h(y))| \\ & \quad \Big/ \sum_i \pi^i p_{ij}(u) f_j(y) \sum_{i,h} \pi^i p_{ih}(u) f_h(y_h(y)) \\ & \quad + \sum_{i,i,h} \pi^i \pi^i p_{ij}(u) p_{ih}(u) f_h(y) |f_j(y) - f_j(y_j(y))| \\ & \quad \Big/ \sum_{i,h} \pi^i p_{ih}(u) f_h(y) \sum_i \pi^i p_{ij}(u) f_j(y_j(y)) \\ & \leq \sum_{i,h} \pi^i p_{ih}(u) |f_h(y) - f_h(y_h(y))| \Big/ \sum_{i,h} \pi^i p_{ih}(u) f_h(y_h(y)) \\ & \quad + \sum_i \pi^i p_{ij}(u) |f_j(y) - f_j(y_j(y))| \Big/ \sum_i \pi^i p_{ij}(u) f_j(y_j(y)) \\ & \leq 2f(Q)/q. \end{aligned}$$

\square

Now let

$$(3.24) \quad G(Q, q) = \max \{G(Q), 2f(Q)/q\}$$

so that

$$(3.25) \quad \lim_{\substack{Q, q \rightarrow \infty \\ q \geq f(Q)^{1+\gamma}, \gamma > 0}} G(Q, q) = 0$$

and, making explicit the dependence of π_t and $\bar{\pi}_t$ on (y^t, u^{t-1}) and (\bar{y}^t, u^{t-1}) respectively, define

$$(3.26) \quad \Delta_t := \sup_{y^t} \max_{u^{t-1}} \max_j |\pi_t^j(y^t, u^{t-1}) - \bar{\pi}_t^j(\bar{y}(y^t), u^{t-1})|.$$

We then have

PROPOSITION 3.1. *With L as defined in (3.13) we have for all t*

$$\Delta_t \leq G(Q, q)(L^T - 1)/(L - 1).$$

Proof. $\Delta_0 = 0$; furthermore, by definition,

$$\begin{aligned} \pi_t^j(y^t, u^{t-1}) &= G^j(\pi_{t-1}(y^{t-1}, u^{t-2}), y_t, u_{t-1}), \\ \bar{\pi}_t^j(\bar{y}(y^t), u^{t-1}) &= \bar{G}^j(\bar{\pi}_{t-1}(\bar{y}(y^{t-1}), u^{t-2}), \bar{y}_t, u_{t-1}). \end{aligned}$$

Therefore, using Lemmas 3.1, 3.2 and 3.3,

$$\begin{aligned} &|\pi_t^j(y^t, u^{t-1}) - \bar{\pi}_t^j(\bar{y}(y^t), u^{t-1})| \\ &\leq |G^j(\pi_{t-1}, y_t, u_{t-1}) - G^j(\bar{\pi}_{t-1}, y_t, u_{t-1})| \\ &\quad + |G^j(\bar{\pi}_{t-1}, y_t, u_{t-1}) - \bar{G}^j(\bar{\pi}_{t-1}, \bar{y}_t, u_{t-1})| \\ &\leq L \max_i |\pi_{t-1}^i - \bar{\pi}_{t-1}^i| + G(Q, q) \end{aligned}$$

so that $\Delta_{t+1} \leq L\Delta_t + G(Q, q)$, from which the result follows. \square

THEOREM 3.1. *Let $\{\bar{u}_t\}$ be the control sequence given by (3.12). Then*

$$\begin{aligned} &\left| \inf_{\{u_t\}} E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\pi_s, u_s) + b(\pi_T) \right\} - E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\pi_s, \bar{u}_s) + b(\pi_T) \right\} \right| \\ &\leq nBTG(Q, q)(L^T - 1)/(L - 1), \end{aligned}$$

where the inf is over all control sequences $\{u_t\}$ such that u_t depends on π_t or equivalently, on (y^t, u^{t-1}) and where $G(Q, q)$ is defined in (3.24) and goes to zero according to (3.25).

Proof. From (2.8) and the definition of π_t and $\bar{\pi}_t$ we immediately have

$$(3.27) \quad E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\pi_s, \bar{u}_s) + b(\pi_T) \right\} = E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\bar{\pi}_s, \bar{u}_s) + b(\bar{\pi}_T) \right\}.$$

Furthermore

$$\begin{aligned} &\inf_{\{u_t\}} E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\pi_s, u_s) + b(\pi_T) \right\} - E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\bar{\pi}_s, \bar{u}_s) + b(\bar{\pi}_T) \right\} \\ (3.28) \quad &\leq E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\pi_s, \bar{u}_s) + b(\pi_T) \right\} - E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\bar{\pi}_s, \bar{u}_s) + b(\bar{\pi}_T) \right\} = 0. \end{aligned}$$

On the other hand, letting u^γ be a γ -optimal control for problem (P) ($\gamma > 0$), we have by the definition of \bar{u}_t , by (2.8) and by Proposition 3.1

$$\begin{aligned}
 (3.29) \quad & E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\bar{\pi}_s, \bar{u}_s) + b(\bar{\pi}_T) \right\} - \inf_{\{u_t\}} E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\pi_s, u_s) + b(\pi_T) \right\} \\
 & \leq \left| E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\bar{\pi}_s, u_s^\gamma) + b(\bar{\pi}_T) \right\} - E^{(n)} \left\{ \sum_{s=0}^{T-1} r(\pi_s, u_s^\gamma) + b(\pi_T) \right\} \right| + \gamma \\
 & \leq E^{(n)} \left\{ \sum_{s=0}^{T-1} \sum_{i=1}^n |\bar{\pi}_s^i - \pi_s^i| |r_i(u_s^\gamma)| + \sum_{i=1}^n |\bar{\pi}_T^i - \pi_T^i| |b_i| \right\} + \gamma \\
 & \leq nBTG(Q, q)(L^T - 1)/(L - 1) + \gamma.
 \end{aligned}$$

Combining (3.27), (3.28) and (3.29), we have the result.

DISCOUNTED MDP'S: DISTRIBUTION FUNCTIONS AND EXPONENTIAL UTILITY MAXIMIZATION*

KUN-JEN CHUNG†‡ AND MATTHEW J. SOBEL†§

Abstract. The present value of the rewards associated with a discrete-time Markov process has a probability distribution which depends on the initial state. The first part of the paper applies fixed point theory to a system of equations for the distribution functions of the present value. The second part of the paper expands the model to a Markov decision process (MDP) and considers the maximization of the expected utility of the present value when the utility function is exponential.

Key words. Markov decision process, distribution of present value, exponential utility, fixed point

AMS(MOS) subject classifications. 90C39, 90C47, 90A06

1. Introduction. Let X_1, X_2, \dots be the sequence of single period rewards of a Markov decision process (hereafter called MDP). The present value of this sequence is

$$(1) \quad B = \sum_{n=1}^{\infty} \beta^{n-1} X_n$$

where $0 < \beta < 1$ is discount factor. We emphasize that B is a random variable.¹

The criterion *maximize* $E(B)$ is the focus of the literature concerned with discounted MDP's. However practical applications of stochastic models often require more information about a criterion than merely its expected value. This paper elicits other characteristics of B .

Von Neumann and Morgenstern's expected utility theorem concerns a "rational" decision maker who compares alternative random payoffs, i.e. random variables. The theorem states necessary and sufficient conditions for a partial ordering of the random variables to be equivalent to the existence of a "utility" function $u(\cdot)$ such that X is preferred to Y if, and only if, $E[u(X)] > E[u(Y)]$. See Fishburn [6] for details.

If the utility function $u(\cdot)$ is linear then the partial ordering of random variables depends only on their expected values. Hence, most of the MDP literature assumes implicitly that a decision maker has a linear utility function, i.e. is risk-neutral. As in [9] and [15], we use the label *risk-sensitive* for the complement of risk-neutral. Thus, a risk-sensitive model assumes implicitly that a decision maker has a *nonlinear* utility function. Most of the consequent optimization problems are more difficult than in the linear case.

The next section of the paper assumes that a particular stationary policy has already been chosen and proceeds to partially characterize the distribution function of B . Thus, the model can be regarded as a Markov chain in which a random reward

§ Part of this work was performed at the University of Arizona, Tucson, Arizona 85287.

¹ B is a random variable under the usual measurability assumptions.

X_n is associated with occupying a state during period n . The probability distribution of X_n depends on the identity of the state occupied during period n .

The last section of the paper examines the optimization of the expected value of a particular nonlinear utility function, namely

$$(2) \quad \text{maximize } E(-e^{-\lambda B}) \quad (\lambda > 0).$$

Exponential utility functions have attractive properties which are mentioned in § 3 of the paper. There we show that problem (2) satisfies an optimality equation. However, the equation is intrinsically an approximation problem and § 3 discusses some monotone approximations. The discounting of rewards distinguishes § 3 from past work on the optimization of exponential utility functions.

Suppose that S is the set of states and that a stationary policy is used. Let $F_s(\cdot)$ be the distribution function of B when s is the initial state. Section 2 of the paper concerns a system of equations satisfied by $\{F_s(\cdot) : s \in S\}$. The major result is negative. The solution of the equations is a fixed point of a mapping which is nonexpansive but generally not a contraction.

Section 2.1 presents notation which is used throughout the paper. Section 2.2 contains preliminary results and § 2.3 has the fixed-point results. The negative results concerning contraction mappings are presented in § 2.4. For background on MDP's see Bertsekas [1], Denardo [3], or Heyman and Sobel [8].

2. Distribution function of the present value.

2.1. Notation. Consider a Markov decision process with discount factor β ($0 < \beta < 1$). Let S be the state space. Let A_s be the set of actions available in state s , and $C = \{(s, a) : s \in A_s, s \in S\}$. Throughout the paper, we assume that C contains only finitely many elements. Such a model is called a *finite* MDP. Let s_n , a_n and X_n indicate the state, action and reward in the n th period. We assume that s_{n+1} and X_n are random variables which depend only on s_n and a_n . Suppose that there is a countable² sample space K such that $P\{X_n \in K\} = 1$ for all n . Let

$$p_{sjk}^a = P\{s_{n+1} = j, X_n = k | s_n = s, a_n = a\}.$$

We assume that K lies in a compact set; this corresponds to the assumption that there is $b < \infty$ such that

$$P\{0 \leq X_1 \leq b | s_1 = s, a_1 = a\} = 1 \quad \text{for all } (s, a) \in C.$$

For simplicity of exposition, we refrain from adding "with probability one" to statements that depend on the rewards being nonnegative and bounded with probability one rather than everywhere.

The notation p_{sjk}^a permits a nondegenerate conditional distribution of X_n given s_n , a_n and s_{n+1} . The notation p_{sj}^a is common in the MDP literature and corresponds to replacement of X_n by its conditional expected value. The Appendix contains a simple example which illustrates that the notation p_{sjk}^a is essential in the first half of this paper.

The present value of the single period rewards is $B = \sum_{n=1}^{\infty} \beta^{n-1} X_n$ which takes values only in $[0, u]$ where $u = b/(1 - \beta)$. Suppose that the stationary policy δ is used to choose actions, i.e. $a_n = \delta(s_n)$ for all n . Let B_s denote the random variable B if $s_1 = s$ and $a_n = \delta(s_n)$ for all n . Let $F_s(x) = P(B_s \leq x)$ be the distribution function of B_s and let $p_{sjk} = p_{sjk}^{\delta(s)}$.

² We assume that K is countable only for expository convenience.

The main purpose of § 2 of the paper is to use fixed point theory to explore the behavior of the vector of distribution functions $F(\cdot) = (F_s(\cdot), s \in S)$. Therefore, δ is suppressed in the notation for the remainder of § 2.

2.2. Preliminary results. Let $\mathcal{X} = [0, u]$ and let \mathcal{B} be the smallest σ -algebra of subsets of \mathcal{X} which contains all the open subsets of \mathcal{X} . It is well known that there is a one-to-one correspondence between measures on \mathcal{B} and distribution functions supported by $[0, u]$. Therefore, we identify measures on \mathcal{B} with the corresponding distribution functions; let Y denote the latter set. Let V be the space of all real-valued continuous functions on \mathcal{X} . For any $f \in V$ we write $\|f\| = \sup \{|f(x)|: x \in \mathcal{X}\}$. V is a Banach space under the norm $\|\cdot\|$. A linear functional Λ on V is a mapping $f \rightarrow \Lambda(f)$ of V into the real line such that for any two constants α and γ and any two elements f and g of V the equation $\Lambda(\alpha f + \gamma g) = \alpha \Lambda(f) + \gamma \Lambda(g)$ is valid. Let V^* denote the set of all continuous linear functionals on V . Therefore, if $\Lambda \in V^*$, we have $\|\Lambda\| = \sup \{|\Lambda(f)|: f \in V, \|f\| \leq 1\}$.

Let $E = \times_{i \in S} V^*$. Then E is a Banach space if its norm is

$$\|H\| = \max \{\|H_i\|: i \in S\} \quad \text{where } H = [H_i(\cdot); i \in S] \in E.$$

The following result, whose proof is in [2], connects linear functionals on V with measures on \mathcal{B} .

LEMMA 1. *Let $\mathcal{X} = [0, u]$ and Λ be a nonnegative linear functional on V (i.e. $\Lambda(f) \geq 0$ if $f \geq 0$) with $\Lambda(1) = 1$. Then there exists a unique measure w on \mathcal{B} such that $\Lambda(f) = \int_0^u f dw$, $f \in V$.*

This lemma shows that there is a map from a subset of V^* into Y . Trivially, this map is one-to-one, i.e., each measure w in Y corresponds to only one linear functional on V , defined by $\alpha(f) = \int f dw$ for all $f \in V$. Thus, one can identify Y with the corresponding subset of V^* . In particular, we have the following metric on Y . If v and w are probability measures on \mathcal{B} , then

$$(1) \quad \|w - v\| = \sup \left\{ \left| \int f dw - \int f dv \right|; \|f\| \leq 1, f \in V \right\}.$$

Let $\mathcal{X} = \times_{i \in S} Y$. If $H = [H_i(\cdot); i \in S] \in \mathcal{X}$ and $G = [G_i(\cdot); i \in S] \in \mathcal{X}$, we define

$$(2) \quad \begin{aligned} \|H - G\| &= \sup \{\|H_i - G_i\|: i \in S\} \\ &= \sup \left\{ \left| \int_0^u f dH_i - \int_0^u f dG_i \right|; f \in V, \|f\| \leq 1, i \in S \right\}. \end{aligned}$$

It is convenient to define $T = S \times K$ and $F_j^k(x) = F_j[(x - k)/\beta]$. The formula

$$(3) \quad F_s(x) = \sum_{(j,k) \in T} p_{sjk} F_j^k(x) \quad (s \in S)$$

was obtained in [22] (see [8, § 4.5] for this form). Therefore, a mapping $M: \mathcal{X} \rightarrow E$ can be defined via (3), as follows

$$M(G)_s(x) = \sum_{(j,k) \in T} p_{sjk} G_j^k(x)$$

for $s \in S$ if $G = [G_i(\cdot); i \in S] \in \mathcal{X}$ and $G_j^k(x)$ denotes $G_j[(x - k)/\beta]$. It is clear that $M[G]_s$ is a distribution function for $s \in S$. Also, if $x \geq u$, $k \in K$, and $j \in S$, then

$$(4) \quad 1 \geq G_j^k(x) \geq G_j^k[b/(1 - \beta)] \geq G_j^b(u) \geq G_j(u) = 1.$$

If $x < 0$, $k \in K$ and $j \in S$, then

$$(5) \quad G_j\left(\frac{x - k}{\beta}\right) = 0.$$

Therefore, $M(G) \in \mathcal{X}$ so M maps \mathcal{X} into itself. From the definition of M , $G = [G_i(\cdot); i \in S] \in \mathcal{X}$ is a fixed point of M if, and only if, G satisfies (3) for all $s \in S$. The following section establishes several properties of M .

2.3. Fixed-point theorems.

LEMMA 2. *The set Y is a weakly compact convex subset of V^* . Therefore, \mathcal{X} is a weakly compact convex subset of E .*

Proof. It is clear that $\{w_\alpha\} \subset Y$ converges in the weak topology to a distribution $w \in Y$ if, and only if, $\int f dw_\alpha \rightarrow \int f dw$ for every $f \in V$. From [2, Prop. 8.10, 8.15, pp. 162–165], Y is weakly compact. The convexity of Y is trivial so Tyhonov's theorem [23] implies that \mathcal{X} is a weakly compact convex subset of E .

The mapping M has the following properties.

THEOREM 1.

- (a) M is a nonexpansive mapping (i.e. $\|MH - MG\| \leq \|H - G\|$),
- (b) M is weakly continuous,
- (c) M is an affine mapping (i.e. $M[\alpha H + (1 - \alpha)G] = \alpha M(H) + (1 - \alpha)M(G)$ for all $H, G \in \mathcal{X}$; $0 \leq \alpha \leq 1$),
- (d) $M: \mathcal{X} \rightarrow \mathcal{X}$ has a fixed point in \mathcal{X} .

Proof. (a) Let $G = [G_i(\cdot); i \in S] \in \mathcal{X}$ and $H = [H_i(\cdot); i \in S] \in \mathcal{X}$. We employ the notation $H_j^k(x) = H_j[(x - k)/\beta]$ and $G_j^k(x) = G_j[(x - k)/\beta]$.

$$\begin{aligned}
 & \|M[H]_s - M[G]_s\| \\
 &= \left\| \sum_{(j,k) \in T} p_{sjk} H_j^k(x) - \sum_{(j,k) \in T} p_{sjk} G_j^k(x) \right\| \\
 &\leq \sum_{(j,k) \in T} p_{sjk} \|H_j^k(x) - G_j^k(x)\| \\
 &= \sum_{(j,k) \in T} p_{sjk} \sup \left\{ \left| \int_0^u f(x) dH_j^k(x) - \int_0^u f(x) dG_j^k(x) \right| : \|f\| \leq 1, f \in V \right\} \\
 &\leq \sum_{(j,k) \in T} p_{sjk} \|H_j - G_j\| \\
 &\leq \sum_{(j,k) \in T} p_{sjk} \|H - G\| = \|H - G\|.
 \end{aligned}$$

Since $s \in S$ is arbitrary, $\|MH - MG\| \leq \|H - G\|$.

(b) Suppose $G_\alpha = [G_{\alpha i}(\cdot); i \in S]$ converges weakly to $G = [G_i(\cdot); i \in S]$. Then $G_{\alpha i}(x)$ weakly converges to $G_i(x)$ for all $i \in S$, and $\int f(x) dG_{\alpha i}(x) \xrightarrow{\alpha} \int f(x) dG_i(x)$ for all $i \in S$, and $f \in V$. Let $G_{\alpha j}^k(x)$ denote $G_{\alpha j}[(x - k)/\beta]$. Since $M[G_\alpha]_s(x) = \sum_{(j,k) \in T} p_{sjk} G_{\alpha j}^k(x)$,

$$\begin{aligned}
 \int f(x) dM[G_\alpha]_s &= \int f(x) dM[G_\alpha]_s(x) = \sum_{(j,k) \in T} p_{sjk} \int f(x) dG_{\alpha j} \left(\frac{x - k}{\beta} \right) \\
 &= \sum_{(j,k) \in T} p_{sjk} \int f(k + \beta y) dG_{\alpha j}(y) \\
 &\xrightarrow{\alpha} \sum_{(j,k) \in T} p_{sjk} \int f(k + \beta y) dG_j(y) \\
 &= \sum_{(j,k) \in T} p_{sjk} \int f(x) dG_j^k(x).
 \end{aligned}$$

Hence $M[G_\alpha]_s(x) \xrightarrow{\alpha} M[G]_s(x)$ for all $s \in S$ so M is weakly continuous.

(c) Let $H, G \in \mathcal{Z}$ and $0 \leq \alpha \leq 1$.

$$\begin{aligned} M[\alpha H + (1 - \alpha)G]_s(x) &= \sum_{(j,k) \in T} p_{sjk} [\alpha H_j^k(x) + (1 - \alpha)G_j^k(x)] \\ &= \alpha \sum_{(j,k) \in T} p_{sjk} H_j^k(x) + (1 - \alpha) \sum_{(j,k) \in T} p_{sjk} G_j^k(x) \\ &= \alpha M[H]_s(x) + (1 - \alpha)M[G]_s(x). \end{aligned}$$

So M is affine.

(d)³ Now $M: \mathcal{Z} \rightarrow \mathcal{Z}$ is weakly continuous, and \mathcal{Z} is a weakly compact subset of E . Therefore, the Schauder and Tyhonov fixed point theorems [20], [23] imply that M has a fixed point in \mathcal{Z} .

2.4. Contraction mappings. Although M is a nonexpansive mapping, it is not generally a contractive mapping. Moreover, in general it is not true that $\|MH - MG\| < \|H - G\|$. For a simple counterexample, let

$$\begin{aligned} S &= \{1, 2\}, p_{112} = p_{121} = p_{211} = p_{222} = 0.5, \beta = 0.9, b = 2, u = 20, \\ K &= \{1, 2\}, G = [G_1(\cdot), G_2(\cdot)] \quad \text{and} \quad H = [H_1(\cdot), H_2(\cdot)], \\ G_s(x) &= \begin{cases} 0 & \text{if } x < 0, \\ 1 & \text{if } x \geq 0, \end{cases} \quad H_s(x) = \begin{cases} 0 & \text{if } x < 20, \\ 1 & \text{if } x \geq 20, \end{cases} \end{aligned}$$

for $s = 1, 2$. So, $\|MG - MH\| = 2 = \|G - H\|$.

The preceding example is not isolated. We now characterize a family of counterexamples. Suppose $D_i = \{k \in K: \text{there exists some } j \in S \text{ such that } p_{ijk} > 0\}$, $W_i = \{|k_1 - k_2| > 0: k_1, k_2 \in D_i\}$, and $W = \bigcap_{i \in S} W_i$. For the remainder of § 2.4 it is convenient to denote the mapping M as $M(\beta, b)$.

THEOREM 2. *If $\beta u \notin W_s$ for some s , then $M(\beta, b)$ is not a contractive mapping.*

Proof. Since $\sum_{(j,k) \in T} p_{sjk} = 1$, for every $\varepsilon > 0$ there exist finitely many points k_1, k_2, \dots, k_n in D_s such that $\sum_{i=1}^n \sum_{j \in S} p_{sjk_i} \geq 1 - \varepsilon/4$. By assumption $(\beta u + D_s) \cap D_s = \emptyset$. Therefore, if $L_1 = \{k_1, k_2, \dots, k_n\}$ and $L_2 = \{\beta u + k_1, \beta u + k_2, \dots, \beta u + k_n\}$, then $L_1 \cap L_2 = \emptyset$. Define a continuous function g on $L_1 \cup L_2$ as follows:

$$g(x) = \begin{cases} 1 & \text{if } x \in L_1, \\ -1 & \text{if } x \in L_2. \end{cases}$$

A well-known theorem of Tietze [18] implies that g has a continuous extension $\bar{g}: [0, u] \rightarrow [-1, 1]$. Let $G = [G_s(\cdot); s \in S]$ and $H = [H_s(\cdot); s \in S]$ where $G_s(\cdot)$ and $H_s(\cdot)$ are the unit jump functions at 0 and u , respectively, for all $s \in S$. Then

$$\begin{aligned} &\|(MG)s - (MH)s\| \\ &= \sup \left\{ \left| \sum_{(j,k) \in T} p_{sjk} \int f(x) d \left[G_j \left(\frac{x-k}{\beta} \right) - H_j \left(\frac{x-k}{\beta} \right) \right] \right| : \|f\| \leq 1, f \in V \right\} \\ &\geq \left| \sum_{(j,k) \in T} p_{sjk} \int \bar{g}(x) d[G_j^k(x) - H_j^k(x)] \right| \\ &= \left| \sum_{\substack{(j,k) \in T \\ k \in L_1}} p_{sjk} \int \bar{g}(x) d[G_j^k(x) - H_j^k(x)] \right. \\ &\quad \left. + \sum_{\substack{(j,k) \in T \\ k \notin L_1}} p_{sjk} \int \bar{g}(x) d[G_j^k(x) - H_j^k(x)] \right| \end{aligned}$$

³ This proof of (d) depends only on the properties of M and \mathcal{Z} . Alternatively, one could argue from (3) that the vector of distribution functions $F(\cdot) = (F_s(\cdot); s \in S)$ is a fixed point.

$$\begin{aligned}
& \geq \left| \sum_{\substack{(j,k) \in T \\ k \in L_1}} p_{sjk} \int \bar{g}(x) d[G_j^k(x) - H_j^k(x)] \right| - \sum_{\substack{(j,k) \in T \\ k \notin L_1}} p_{sjk} \int \bar{g}(x) d[G_j^k(x) - H_j^k(x)] \\
& = \left| \sum_{\substack{(j,k) \in T \\ k \in L_1}} p_{sjk} [\bar{g}(k) - \bar{g}(\beta u + k)] \right| - \left| \sum_{\substack{(j,k) \in T \\ k \notin L_1}} p_{sjk} [\bar{g}(k) - \bar{g}(\beta u + k)] \right| \\
& = 2 \sum_{\substack{(j,k) \in T \\ k \in L_1}} p_{sjk} - \sum_{\substack{(j,k) \in T \\ k \notin L_1}} p_{sjk} [|\bar{g}(k)| + |\bar{g}(\beta u + k)|] \\
& \geq 2(1 - \varepsilon/4) - 2(\varepsilon/4) = 2 - \varepsilon.
\end{aligned}$$

But ε is an arbitrary positive number; so $\|(MG)_s - (MH)_s\| \geq 2$, i.e., $\|MG - MH\| \geq 2$.

The nonexpansiveness of $M(\beta, b)$ implies $2 \leq \|MG - MH\| \leq \|G - H\| = 2$; so $\|MG - MH\| = \|G - H\| = 2$ and $M(\beta, b)$ is not a contractive mapping. \square

Since K is countable, it follows from Theorem 2 that, except for countably many values of β , $M(\beta, b)$ is not a contractive mapping. Furthermore, if W is a finite set, then, except for finitely many values of β , $M(\beta, b)$ is not a contractive mapping.

COROLLARY 1. *If W is empty, then for all $0 < \beta < 1$, $M(\beta, b)$ is not a contractive mapping.*

COROLLARY 2. *Let $w_0 = \sup W$. If $\beta > w_0/(b + w_0)$, then $M(\beta, b)$ is not a contractive mapping.*

Proof. If $\beta u \in W$, there is a number $w \in W$ such that $\beta u = w$, i.e., $\beta b/(1 - \beta) = w$. So $\beta = w/(b + w) \leq w_0/(b + w_0)$. Hence, if $\beta > w_0/(b + w_0)$, then $\beta u \notin W$. Theorem 2 implies that $M(\beta, b)$ is not a contractive mapping.

The inequality $w_0 \leq b$ implies $w_0/(b + w_0) \leq \frac{1}{2}$. Hence, if $\beta > \frac{1}{2}$, then $M(\beta, b)$ is not a contractive mapping.

COROLLARY 3. *For each β , $0 < \beta < 1$, there exists $c > 0$ such that $P\{0 \leq X_1 \leq c | s_1 = s, a_1 = s\} = 1$ for all $(s, a) \in C$ and $M(\beta, c)$ is not a contractive mapping.*

Proof. For each $0 < \beta < 1$, there is a number $c > 0$ such that $w_0/(c + w_0) < \beta$ and $P\{0 \leq X_1 \leq c | s_1 = s, a_1 = a\} = 1$ for all $(s, a) \in C$ determines when $M(\beta, c)$ is not a contractive mapping. \square

It follows from Corollary 3 that the value of c which satisfies $P\{0 \leq X_1 \leq c | s_1 = s, a_1 = a\} = 1$ for all $(s, a) \in C$ determines when $M(\beta, c)$ is not a contractive mapping. That is, let $J = \{c: P\{0 \leq X_1 \leq c | s_1 = s, a_1 = a\} = 1 \text{ for all } (s, a) \in C\}$, and $J_c = \{\beta \in (0, 1) | M(\beta, c) \text{ is not a contractive mapping and } c \in J\}$; then $J_{c_1} \subseteq J_{c_2}$ if $c_2 \geq c_1$ and $c_1, c_2 \in J$.

For all $1 \leq i, j \in S$, let $H_{ij} = \sup \{k \in K: p_{ijk} > 0\}$ and $h_{ij} = \inf \{k \in K: p_{ijk} > 0\}$, and let $\alpha = \max \{(H_{ij} - h_{ij})/(2H_{ij} - h_{ij}): i \in S, j \in S\} = (H_{s_p} - h_{s_p})/[2(H_{s_p} - h_{s_p}) + h_{s_p}]$ for some $s \in S$ and $p \in S$. Then $0 < \alpha \leq \frac{1}{2}$.

COROLLARY 4. *If $\beta > \alpha$, then $M(\beta, b)$ is not a contractive mapping.*

Proof. If $\beta > \alpha$, then $\min \{\beta u + h_{ij}: i \in S, j \in S\} > \max \{H_{ij}: i, j \in S\}$ which implies $(\beta u + D) \cap D = \emptyset$ where $D = \bigcup_{i \in S} D_i$. Therefore $\beta u \notin W$. Theorem 2 implies that $M(\beta, b)$ is not a contractive mapping.

Comments. 1°. In fact, $0 \leq \alpha \leq \frac{1}{2}$, so, from Corollary 4, $\beta > \frac{1}{2}$ also implies that $M(\beta, b)$ is not a contractive mapping.

2°. Let $0 \leq \varepsilon < \frac{1}{2}$ and $\alpha = \varepsilon$; so $H_{s_p} = (1 - \varepsilon)h_{s_p}/(1 - 2\varepsilon) \geq h_{s_p}$. From the above argument, for any $0 < \beta < 1$, $M(\beta, b)$ may fail to be a contractive mapping.

2.5. Convergence.

DEFINITION. Let $x_1 \in \mathcal{X}$ and let $\{x_n\}_{n=1}^\infty$ be the sequence defined by $x_{n+1} = (1 - t_n)x_n + t_n Mx_n$, where $\{t_n\}_{n=1}^\infty$ is a real sequence. If a sequence $\{t_n\}_{n=1}^\infty$ satisfies the following two conditions, $\{x_n\}_{n=1}^\infty$ will be said to satisfy condition:

$$(a) \quad \sum_{n=1}^{\infty} t_n = \infty,$$

(b) there exists $0 < h < 1$ such that $0 < t_n < h < 1$ for all n .

Note that if $t_n \in [g, h]$ for all n and $0 < g < h < 1$, then it is obvious that the sequence $\{t_n\}_{n=1}^\infty$ satisfies (a) and (b).

Ishikawa [10] and others have investigated iterative methods to compute a fixed point of a nonexpansive mapping. The following result is [10, Lemma 2].

LEMMA 3. *If there exist $x_1 \in \mathcal{X}$ and $\{t_n\}_{n=1}^\infty$ that satisfy Condition A, then $x_n - Mx_n$ converges to zero in norm as $n \rightarrow \infty$.*

THEOREM 3. *Suppose $x_1 \in \mathcal{X}$ and $\{t_n\}_{n=1}^\infty$ satisfy Condition A.*

(a) *Then every subsequence $\{x_{n_i}\}$ of $\{x_n\}$ contains a subsequence that converges weakly to a fixed point of M .*

(b) *If M has a unique fixed point ν in \mathcal{X} , then $\{x_n\}_{n=1}^\infty$ converges weakly to ν .*

(c) *If there are a strongly compact subset of D of \mathcal{X} and a subsequence $\{x_{n_i}\}$ of $\{x_n\}$ such that $x_{n_i} \in D$ for all n_i then $\{x_n\}_{n=1}^\infty$ converges in norm to a fixed point of M .*

Proof. (a) Since \mathcal{X} is a weakly compact convex subset of E , $\{x_{n_i}\}$ contains a subsequence $\{x_{n_i}\}_{i=1}^\infty$ which converges weakly to a point ν . A well-known theorem of Mazur [14] implies that there is a sequence of convex combinations $\{\nu_n\}$ such that $\nu_n = \sum_{i=n}^N \lambda_i x_{n_i}$ where $\sum_{i=n}^N \lambda_i = 1$, and $\lambda_i = \lambda_i(n) \geq 0$, $n \leq i \leq N = N(n)$ which converges to ν in norm. Since M is nonexpansive and affine,

$$\begin{aligned} \|M\nu - \nu\| &= \|M\nu - M\nu_n + M\nu_n - \nu_n + \nu_n - \nu\| \\ &\leq 2\|\nu - \nu_n\| + \|M\nu_n - \nu_n\| \leq 2\|\nu - \nu_n\| + \sum_{i=n}^N \lambda_i \|Mx_{n_i} - x_{n_i}\| \end{aligned}$$

which implies that ν is a fixed point of M since $\lim_{n \rightarrow \infty} \|\nu_n - \nu\| = 0$ and $\lim_{i \rightarrow \infty} \|Mx_{n_i} - x_{n_i}\| = 0$.

(b) If M has a unique fixed point ν_0 in \mathcal{X} , (a) implies that $\{x_n\}$ converges weakly to ν_0 .

(c) Strong convergence of $\{x_n\}$ is a direct consequence of [10, Thm. 1].

3. Exponential utility.

3.1. Background. This section concerns maximization of $E[u_\lambda(B)]$ for the utility function $u_\lambda(x) = -e^{-\lambda x}$. This utility function has several attractions. First, the local risk aversion coefficient, i.e. $-u''(x)/u'(x)$, is constant with respect to x if, and only if, either $u(x) = c + dx$ or $u(x) = c + d e^{-\lambda x}$. If $u(\cdot)$ exhibits risk aversion and is increasing i.e. $u''(\cdot) < 0$ and $u'(\cdot) > 0$, then $u(x) = x + d e^{-\lambda x}$ with $d < 0$ and $\lambda > 0$. Second, $u(x) = c + d e^{-\lambda x}$ with $d < 0$ and $\lambda > 0$ is the only risk-averse increasing utility function whose risk premium is invariant with respect to wealth. That is, let $\alpha_X = E(X)$ and let π_X be the "risk-premium" for X : $u(\alpha_X - \pi_X) = E[u(X)]$. Then $\pi_X = \pi_{X+k}$ for all real numbers k and random variables X such that $|\alpha_X| < \infty$ if, and only if, either $u(\cdot)$ is linear or $u(x) = c + d e^{-\lambda x}$. If $d > 0$ then $\lambda > (<) 0$ implies risk aversion (risk preference).

Several writers have analyzed dynamic models with exponential utility functions. Let $B_n = \sum_{i=1}^n X_i$. Howard and Matheson [9] studied the maximization of $E[u_\lambda(B_n)]$ both for fixed n and as $n \rightarrow \infty$. Let $B_\infty = \lim_{n \rightarrow \infty} B_n$ if the limit exists. Denardo and Rothblum [4] studied the maximization of $E[u_\lambda(B_\infty)]$ in a stopping problem. That is,

the model in [4] is an MDP in which each set A_s includes an action which “stops” the decision process. The models in [9] and [4] exhibit risk-sensitivity but lack time-preference; the absence of discounting is the principal difference between their models and ours.

Jaquette [11], [12] studies the same problem as ours, namely maximization of $E[u_\lambda(B)]$. The analysis in [11] exploits the fact that $E[u_\lambda(B)]$ is the negative of the Laplace transform of B . As a result, there is a $\lambda_0 > 0$ and a stationary policy which is optimal for all $0 < \lambda < \lambda_0$. It is shown in [11] that such a stationary policy is also “moment optimal,” that is, it lexicographically maximizes the sequence of signed moments of B . The sign is positive (negative) if the moment is odd (even). In [12], λ is fixed and, perhaps, $\lambda \geq \lambda_0$. Let an optimal policy consist of a sequence $\delta_1, \delta_2, \dots$ of single-period decision rules. Jaquette shows that there is an optimal policy such that there exists $N < \infty$ with $\delta_n = \delta_N$ for all $n \geq N$. He also presents an example due to J. M. Harrison which implies that generally $N > 1$; that is, it is possible for all stationary policies to be suboptimal.

Porteus [15], [16] and Eagle [5] present dynamic choice theories which are compatible with exponential *intra*-period utility functions. Porteus describes a process in which preferences are based on the evolution of a decision-maker’s wealth. Eagle’s model begins with preferences based on consumption which is constrained by wealth. Thus, he infers a utility function for wealth.

References [15], [16] and [5] assume that in each period the decision-maker would accept a certainty equivalent as a terminal payment in lieu of continuing the dynamic choice process. They observe that their processes can be interpreted as having different intertemporal resolutions of uncertainty than in [11], [12] (hence, different also from ours). The models in [15], [16] and [5] share the property that there is a stationary optimal policy. Following the proof of Theorem 4 (below) we comment on this property of their models.

The models in [4], [5], [9], [11], [12], [15], [16] all have the following property. The conditional distribution of the reward X_n , given s_n , a_n , and s_{n+1} is degenerate. In our notation, the transition probabilities in those papers are written p_{sj}^a rather than p_{sjk}^a as in this paper. A simple example in the Appendix illustrates the manner in which nondegenerate conditional distributions occur in practice. However, the mathematics of exponential utility optimization does not depend on whether or not the conditional distributions (of the X_n ’s) are degenerate. A transformation (below between (7) and (7’)) permits suppression of the triple-subscript notation p_{sjk}^a for the remainder of the paper’s main text. Although the within-period randomness is not relevant to the analysis of MDP’s with risk-neutral criteria, ignoring its presence in risk-sensitive MDP’s would alter numerical results (such as which policy is optimal).

The results in [4], [5], [9], [11], [12], [15], [16] (such as optimality of a stationary policy in [5], [15], [16]) are preserved if the models in those papers are enlarged to nondegenerate conditional distributions of X_n . Thus, we shall ignore this difference between other models and ours when we compare results. Moreover, every MDP can be made to possess degenerate conditional distributions by suitably enlarging the state space.

3.2. Optimality equations. Let $B(n) = \sum_{i=1}^n \beta^{i-1} X_i$ with B continuing to denote $B(\infty)$. For each $s \in S$ and $\lambda \geq 0$ let $f_0(s, \lambda) = -1$,

$$(6) \quad \begin{aligned} f_n(s, \lambda) &= \sup \{E(-e^{-\lambda B(n)} | s_1 = s)\} & (n = 1, 2, \dots), \\ f(s, \lambda) &= \sup \{E(-e^{-\lambda B} | s_1 = s)\} \end{aligned}$$

where the suprema are over all *policies*, i.e. nonanticipative decision rules for choosing the actions a_1, a_2, \dots .

It can be shown that

$$(7) \quad \begin{aligned} f_n(s, \lambda) &= \max \{E[e^{-\lambda X_1} f_{n-1}(s_2, \beta\lambda) | s_1 = s, a_1 = a]; a \in A_s\} \\ &= \max \left\{ \sum_{j \in S} q_{sj}^a(\lambda) f_{n-1}(j, \beta\lambda) : a \in A_s \right\} \end{aligned}$$

where $q_{sj}^a(\lambda) = \sum_{k \in K} p_{sjk}^a e^{-\lambda k}$. Note that (7) can be written

$$(7') \quad f_n^\lambda = \max_{\delta} \{Q_\delta(\lambda) f_{n-1}^\lambda : \delta \in \Delta\}$$

where f_n^λ is the vector with coordinates $f_n(s, \lambda)$, $Q_\delta(\lambda)$ is the matrix whose (s, j) th element is $q_{sj}^{\delta(s)}(\lambda)$, and $\Delta = \times_{s \in S} A_s$. Let π be a policy and

$$v(\pi, s, \lambda) = E_\pi(-e^{-\lambda B} | s_1 = s)$$

where E_π denotes the expectation with respect to the probability distribution of B induced by π . Then π^* is said to be λ -optimal if

$$v(\pi^*, s, \lambda) \geq v(\pi, s, \lambda) \quad \text{for all } s \in S \text{ and } \pi.$$

Let R denote the set of real numbers.

THEOREM 4.⁴ (a) For each $s \in S$ and $\theta > 0$,

$$\lim_{n \rightarrow \infty} f_n(s, \theta) = f(s, \theta)$$

with $f_n(s, \theta) \leq f_{n+1}(s, \theta)$ for all n .

(b) For each $s \in S$ and $\theta > 0$,

$$(8) \quad f(s, \theta) = \max \left\{ \sum_{j \in S} q_{sj}^a f(j, \beta\theta) : a \in A_s \right\}.$$

That is,

$$(8') \quad f^\theta = \max_{\delta} Q_\delta(\theta) f^{\beta\theta}$$

where f^θ is the vector with components $f(s, \theta)$.

(c) Let $a = \delta_{n\lambda}(s) \in A_s$ attain the maximum in (8) when $\theta = \beta^{n-1}\lambda$ and let $\pi(\lambda) = (\delta_{1\lambda}, \delta_{2\lambda}, \dots)$ be the policy which uses the single period rule $\delta_{n\lambda}$ in period n . Then $\pi(\lambda)$ is λ -optimal.

Proof. Fix $\lambda > 0$. Since $B(n) \geq 0$ for all n , $-1 \leq -\exp[-\lambda B(n)] \leq 0$ so $-1 \leq f_n(s, \lambda) \leq 0$ for all n, s , and λ . Therefore, for all $\theta \geq 0$, $-e \leq f_0^\theta \leq f_1^\theta$ where e is the S -vector in which all components are one. Induction leads to $f_n^\theta \leq f_{n+1}^\theta$ for all $\theta \geq 0$. It follows from

$$(9) \quad P\{0 \leq X_i \leq u \text{ for all } i\} = 1$$

that $P\{0 \leq B - B(n) \leq \beta^n u / (1 - \beta)\} = 1$. Therefore, $f_n^\theta \leq f^\theta \leq f_n^\theta \exp[-\theta \beta^n u / (1 - \beta)] \leq f^\theta \exp[-\theta \beta^n u / (1 - \beta)]$; so $f^\theta = \lim_{n \rightarrow \infty} f_n^\theta$.

In order to prove that f satisfies (8), fix s and θ and let

$$J_n(\theta, \delta) = Q_\delta(\theta) f_{n-1}^{\beta\theta}.$$

⁴ We are grateful to a referee for suggesting much shorter proofs of parts (a) and (c) than our original ones.

Pointwise monotone convergence of f_n implies the same property for J_n : $J_n(\theta, \delta) \leq J_{n+1}(\theta, \delta)$ and there exists $J(\theta, \delta) = \lim_{n \rightarrow \infty} J_n(\theta, \delta)$. Let $n \rightarrow \infty$ in (7') to obtain

$$(10) \quad f_n^\theta \leq \max \{Q_\delta(\theta) f^{\beta\theta} : \delta \in \Delta\}$$

so

$$(11) \quad f^\theta \leq \max \{Q_\delta(\theta) f^{\beta\theta} : \delta \in \Delta\}.$$

In order to obtain the reverse inequality let $n \rightarrow \infty$ in (7'):

$$f^\theta \geq \lim_{n \rightarrow \infty} \max \{Q_\delta(\theta) f_{n-1}^{\beta\theta} : \delta \in \Delta\}.$$

For each s , A_s is a finite set; so $J_n(\theta, \cdot)$ is trivially upper semicontinuous and converges pointwise uniformly to $J(\theta, \cdot)$. Therefore

$$\lim_{n \rightarrow \infty} \max \{Q_\delta(\theta) f_{n-1}^{\beta\theta} : \delta \in \Delta\} = \max \{Q_\delta(\theta) f^{\beta\theta} : \delta \in \Delta\}$$

so reversing the inequality in (11) yields a valid statement and (8) is true.

In order to establish (c), define $\pi(\lambda)$ as in the statement of (c). An induction which employs (8) and starts at $n = 1$ establishes

$$f(s, \lambda) = E_{\pi(\lambda)}[-e^{-\lambda B(n)} | f(s_{n+1}, \beta^n \lambda) | | s_1 = s]$$

for all $n = 1, 2, \dots$. However, $|f(s_{n+1}, \beta^n \lambda)| \rightarrow 1$ as $n \rightarrow \infty$ because (9) implies $\exp[-\beta^n \lambda u / (1 - \beta)] \leq f(s_{n+1}, \beta^n \lambda) \leq 1$ for all n (all with probability one). Therefore, $f(s, \lambda) = E_{\pi(\lambda)}(-e^{-\lambda B} | s_1 = s)$.

Comments. 1°. A result analogous to Theorem 4 is valid for minimization problems. That is, if “inf” replaces “sup” in (6), then (7) and (8) are valid with “min” replacing “max” and parts (a) and (c) of Theorem 4 remain true.

2°. Theorem 4 is valid under more general conditions concerning the sets of actions. For each $s \in S$, suppose that A_s is a compact set and $J_n(\theta, \cdot)$ is continuous on Δ . Parts (a) and (b) of the theorem are valid with “sup” instead of “max” in (8) but the supremum is always attained. Part (c) is valid if “supremum” replaces “maximum.” Dini’s theorem [18] is invoked in order to establish (8).

3°. The inductive proof of $f_n^\theta \leq f_{n+1}^\theta$ depends on rewards being nonnegative and salvage values not depending on the terminal state. Nonnegativity entails no loss of generality beyond the compactness assumptions already made. Also, (7) and (7') remain valid if $f_0(s, \theta) = -\exp[-\lambda L(s)]$ replaces $f_0(s, \theta) = -1$ when $L(s)$ is the salvage value of terminal state s .

4°. It is insightful to compare (8) with the functional equations corresponding to the infinite horizon models in Porteus [15] and [16] and Eagle [5]. Our equation is

$$(8) \quad f(s, \theta) = \max \left\{ \sum_{j \in S} q_{sj}^a(\theta) f(j, \beta\theta) : a \in A_s \right\},$$

the equation corresponding to [15] and [16] is

$$(12a) \quad f(s, \theta) = \max \left\{ -\frac{\beta}{\theta} \log \left[\sum_{j \in S} q_{sj}^a(\theta/\beta) e^{-\theta f(j, \theta)} \right] : a \in A_s \right\},$$

and the equation corresponding to [5] is

$$(12b) \quad -e^{-\theta f(s, \theta)} = \max \left\{ -\sum_{j \in S} q_{sj}^a(\theta) e^{-\theta \beta f(j, \theta)} : a \in A_s \right\}.$$

Notice in (12a) and (12b) (which are implicit but do not appear in [5], [15], [16]) that wherever $f(\cdot, \cdot)$ appears on the right side, the second argument (θ) is the same quantity which appears in the second argument of $f(\cdot, \cdot)$ on the left side. With an infinite horizon, in (12a) and (12b) the decision-maker expects to have the same preference ordering next period as this period. In (8), however, the second argument is θ on the left side and $\beta\theta$ on the right side. Since $\theta > \beta\theta$, the decision-maker expects to be less risk-averse next period than at present. It should not be surprising that it may be optimal to use a different decision rule next period than at present, i.e., a nonstationary policy.

5°. The results in [21] can be used to construct proofs of the existence of a stationary optimal policy in the models in [5], [15] and [16]. Our comment in 4° above corresponds to the "stationarity of preference" axiom in [21]. If C is at most denumerable (i.e. if S and A_s for each $s \in S$ are at most denumerable), then a stationary policy is optimal if any policy is optimal. Moreover, if C is finite then policy improvement algorithms for [5], [15], [16] can be inferred from [21]. Such an algorithm is described in [5] but the result for [15] and [16] is new.

6°. Theorem 4 is closely related to results obtained by Furukawa and Iwamoto [7], Kreps [13], and Schäl [19]. First, $u_\lambda(x) \leq 0$ for all x so it follows from [19] that all policies are " u_λ -equalizing" and that a policy is λ -optimal if, and only if, it is " u_λ -thrifty." Second, $u_\lambda(\cdot)$ would be encompassed by the results in [7] (cf. Example 3) if it were replaced by $+e^{-\lambda x}$ (or if one minimized $E[u_\lambda(B)]$ instead of maximizing it.) Third, parts (a) and (b) of Theorem 4 show that part (e) of the corollary and Proposition 1 in [13] are valid for $u_\lambda(\cdot)$ with a restriction to Markov policies. Last, an alternative proof of part (c) of Theorem 4 could be based on part (c) of the corollary in [13].

3.3. Approximations. We continue to assume that the MDP is finite, i.e. $\# C < \infty$ where $C = \{(s, a); a \in A_s, s \in S\}$. Suppose δ attains the maximum on the right side of (8') when $\theta = \lambda$, \mathcal{D} denotes the set of bounded real-valued functions on $S \times (0, \infty)$, and

$$g_\lambda(s) = g(s, \lambda) \quad \text{for } g \in \mathcal{D}, \quad g_\lambda = [g_\lambda(s); s \in S], \quad (g_\lambda)_m = \min \{g_\lambda(s); s \in S\}, \\ (g_\lambda)^M = \max \{g_\lambda(s); s \in S\} \quad \text{and} \quad Lg_\lambda = \max \{Q_\delta(\lambda)g_{\lambda\beta}; \delta \in \Delta\}.$$

The following result is similar to [17, Prop. 1].

LEMMA 4. *For $g \in \mathcal{D}$ and $h \in \mathcal{D}$, suppose α attains Lg_λ , i.e. $Lg_\lambda = Q_\alpha(\lambda)g_{\lambda\beta}$. Then $Lh_\lambda - Lg_\lambda \geq Q_\alpha(h_{\beta\lambda} - g_{\beta\lambda})$.*

Proof.

$$Lh_\lambda - Lg_\lambda = \max \{Q_\delta h_{\beta\lambda}; \delta \in \Delta\} - Q_\alpha g_{\beta\lambda} \geq Q_\alpha h_{\beta\lambda} - Q_\alpha g_{\beta\lambda} = Q_\alpha(h_{\beta\lambda} - g_{\beta\lambda}). \quad \square$$

It is convenient to employ the notation $\xi = Lv_\lambda - v_{\beta\lambda} - f_\lambda + f_{\beta\lambda}$. Let

$$\gamma = \max \{E(e^{-\lambda X_1} | s_1 = s, a_1 = a); (s, a) \in C\}.$$

We assume $\gamma < 1$ which is true if for every $(s, a) \in C$ there is $(j, k) \in T$ such that $k > 0$ and $p_{sjk}^a > 0$. The following bounds are not useful but are the basis (in Corollary 5, below) of practical bounds.

THEOREM 5. *If $\gamma < 1$, then for all $v \in \mathcal{D}$,*

$$(13) \quad Lv_\lambda - \xi + e(\xi)_m / (1 - \gamma) \leq Lv_\lambda + \gamma e(\xi)_m / (1 - \gamma) \leq f_\lambda \\ \leq Lv_\lambda + \gamma e(\xi)^M / (1 - \gamma) \leq Lv_\lambda - \xi + e(\xi)^M / (1 - \gamma).$$

Proof. Let Q be induced by a single stage rule which attains Lf_λ . Then

$$Lv_\lambda - Lf_\lambda \geq Q(v_{\beta\lambda} - f_{\beta\lambda}), \quad \xi \geq (Q - I)(v_{\beta\lambda} - f_{\beta\lambda})$$

because

$$Lf_\lambda = f_\lambda, \quad (I - Q)^{-1}\xi \geq -(v_{\beta\lambda} - f_{\beta\lambda}),$$

$f_{\beta\lambda} \leq v_{\beta\lambda} + (I - Q)^{-1}\xi = v_{\beta\lambda} + (I - Q)^{-1}Q\xi + (I - Q)^{-1}(\xi - Q\xi) \leq \xi + v_{\beta\lambda} + (I - Q)^{-1}Q\xi$,
that is,

$$f_\lambda \leq Lv_\lambda + (I - Q)^{-1}Q\xi \leq Lv_\lambda + \mathbf{e}\gamma(\xi)^M/(1 - \gamma)$$

which is the third inequality in (13). The fourth inequality is implied by $\xi \leq (1 - \gamma)\mathbf{e}(\xi)^M/(1 - \gamma)$.

Suppose Q_α is induced by a single-stage rule which attains Lv_λ . Then

$$\begin{aligned} Lf_\lambda - Lv_\lambda &\geq Q_\alpha(f_{\beta\lambda} - v_{\beta\lambda}), & -\xi &\geq (Q_\alpha - I)(f_{\beta\lambda} - v_{\beta\lambda}), \\ & & -(I - Q_\alpha)^{-1}(-\xi) &\leq f_{\beta\lambda} - v_{\beta\lambda}, \\ & & v_{\beta\lambda} + (I - Q_\alpha)^{-1}\xi &\leq f_{\beta\lambda}. \end{aligned}$$

That is,

$$f_{\beta\lambda} \geq v_{\beta\lambda} + \sum_{l=0}^{\infty} Q_\alpha^l \xi \geq v_{\beta\lambda} + \xi + \mathbf{e}\gamma(\xi)_m/(1 - \gamma) = \xi + v_{\beta\lambda} + \mathbf{e}\gamma(\xi)_m/(1 - \gamma).$$

So $f_\lambda \geq Lv_\lambda + \mathbf{e}\gamma(\xi)_m/(1 - \gamma)$ which is the second inequality in (13). The first inequality is implied by $\xi \geq \mathbf{e}(\xi)_m$. \square

The bounds in Theorem 5 are impractical because they depend on the function whose bounds are sought. Corollary 5 (below) removes this defect. Let

$$c_\theta(s) = -\min \left\{ \sum_{j \in S} q_{sj}^a(\theta): a \in A_s \right\} = \max \{ E(-e^{-\theta X_1} | s_1 = s, a_1 = a): a \in A_s \}$$

and let $c_\theta = [c_\theta(s); s \in S]$. Then $X_1 \leq B \leq X_1 + \beta b + \beta^2 b + \cdots$ implies

$$(14) \quad c_\theta \leq f^\theta \leq c_\theta e^{-\beta\theta u}.$$

COROLLARY 5. *If $\gamma < 1$ and $v \in \mathcal{D}$ then*

$$Lv_\lambda + \gamma \mathbf{e}(Lv_\lambda - v_{\beta\lambda} - e^{-\beta u} c_\lambda + c_{\beta\lambda})_m/(1 - \gamma) \leq f_\lambda \leq Lv_\lambda + \gamma \mathbf{e}(Lv_\lambda - v_{\beta\lambda})^M/(1 - \gamma).$$

Proof. The upper bound follows from the upper bound in Theorem 5 and the fact that each component of f^θ is nondecreasing in θ ; so $f^{\lambda\beta} \leq f^\lambda$. The lower bound follows from the lower bound in Theorem 5 and (14) which implies

$$f^\lambda - f^{\lambda\beta} \leq c_\lambda e^{-\beta u} - c_{\beta\lambda}.$$

3.4. A pointless procedure. Let \mathcal{F} be the set of all bounded real-valued functions on S . Fix $\lambda (\lambda > 0)$. For each $u \in \mathcal{F}$ and $v \in \mathcal{F}$, let $d(u, v) = \sup \{|u(s, \lambda) - v(s, \lambda)|: s \in S\}$. Then $(\mathcal{F}, d(\cdot, \cdot))$ is a complete metric space.

Without loss of generality, we assume that $P\{X_1 > 1 | s_1 = s, s_2 = j, a_1 = a\} = 1$ so $\sum_{j \in S} q_{sj}^a(\theta) < 1$, $(s, a) \in C$, $\theta > 0$. Define a mapping $\Gamma: \mathcal{F} \rightarrow \mathcal{F}$ where $\Gamma u(s) = \max \{\sum_{j \in S} q_{sj}^a(\theta) u(j, \theta): a \in A_s\}$ for $s \in S$. Then $d(\Gamma u, \Gamma v) \leq e^{-\theta} d(u, v)$ for all $u, v \in \mathcal{F}$. Hence, Γ is a contraction mapping, and the fixed-point theorem for contraction mappings guarantees that Γ has a unique fixed point. Since $\Gamma 0 = 0$ it follows that 0 is the fixed point of Γ . Therefore, the equation

$$g(s, \theta) = \max \left\{ \sum_{j \in S} q_{sj}^a(\theta) g(j, \theta): a \in A_s \right\}$$

has the unique solution $g(s, \theta) = 0$ for all $s \in S$ and $\theta > 0$. Therefore, iterating Γ from any initial function does not necessarily yield improving approximations of f in (8).

Appendix. This example illustrates that the notation p_{sjk}^a is essential in some risk-sensitive models. The following MDP models a single product's inventory process in which excess demand is lost, there is storage space for at most two items, demand each period is equally likely to be 0, 1, 2, or 3, and demands in successive periods are independent random variables. We assume that the replenishment decision is made each period before demand is known, but ordered goods are delivered immediately. Suppose that the unit purchase cost is \$1, the unit holding cost for end-of-period inventory is \$1, and there is a \$1 penalty for each unit of demand which exceeds supply.

Let a denote the inventory level after replenishment; nonnegative replenishment quantities are equivalent to $a_n \geq s_n$. Thus, $S = \{0, 1, 2\}$ and $C = \{(0, 0), (0, 1), (0, 2), (1, 1), (1, 2), (2, 2)\}$. Since excess demand is lost, $s_{n+1} = (a_n - D_n)^+$ where D_n denotes the quantity demanded in period n . The net profit in period n is

$$\begin{aligned} X_n &= a_n - s_n + (a_n - D_n)^+ + (D_n - a_n)^+ \\ &= a_n - s_n + s_{n+1} + D_n - a_n + s_{n+1} = -s_n + 2s_{n+1} + D_n \end{aligned}$$

which uses the identity $\min\{x, y\} = x - (x - y)^+$.

Suppose for some n that $s_n = 1$, $a_n = 2$, and $s_{n+1} = 0$. Then $X_n = -1 + D_n$. We know $D_n \geq 2$ because $s_{n+1} = 0 = (a_n - D_n)^+ = (2 - D_n)^+$; so $D_n \in \{2, 3\}$. That is, $X_n = 1$ and $X_n = 2$ are equally likely and $p_{101}^2 = p_{102}^2 = 0.5$. The main point is that there are k and l , $k \neq l$, such that $p_{10k}^2 > 0$ and $p_{10l}^2 > 0$.

In this example, X_n cannot be given as a deterministic function of s_n , a_n , and s_{n+1} .

REALIZATION THEORY FOR HAMILTONIAN SYSTEMS*

J. BASTO GONÇALVES†

Abstract. We prove that control systems of the Hamiltonian type have a quasi-minimal realization on a state space of minimal dimension, of one of two types: a Hamiltonian system or the suspension of a time-dependent Hamiltonian system.

These realizations are unique up to a symplectomorphism, in the first case, or a canonical transformation, in the second one.

When the Lie algebra of the initial system Σ , assumed to be analytic, is finite dimensional, we obtain a characterization of the state space and the dynamics of the quasi-minimal realization in terms of the coadjoint actions of Lie groups associated with Σ ; an example is given applying these results.

Using control theoretic methods, we prove the Kostant-Kirillov-Souriau theorem; the technique used for systems with finite dimensional Lie algebra is closely related to the theory developed by those authors.

Key words. Hamiltonian systems, realization, quasi-minimality, nonlinear systems

AMS(MOS) subject classifications. 93B20, 93C10, 93C15, 3H05, 58F05, 70G99

Introduction. The work on Hamiltonian control systems began with Brockett [5] as an attempt to present a control theoretic point of view of problems in analytical mechanics involving external forces. The precise basic formalism and first results on their realization are due to van der Schaft [13]–[16].

Our definition of Hamiltonian control system corresponds to a special case of [13], and was independently introduced in [3], along with a result about the equivalence of Hamiltonian systems (Theorem 4.1 here). Using this definition we obtain a more complete description of the construction of realizations of minimal dimension (quasi-minimal realizations) containing the results of [13], [14], [15], [16], where strong accessibility is assumed.

We extend the results to the nonstrongly accessible case, where the quasi-minimal realization is a suspension of a time-dependent Hamiltonian system, thereby proving that any complete smooth or analytic Hamiltonian control system has a quasi-minimal realization, either a Hamiltonian system or the suspension of a time dependent Hamiltonian system. The constructions are based on the theory introduced in [11] and developed in [4].

We prove that the symplectic (contact) structures obtained are characteristic of the given system, in the sense that any equivalence between the two quasi-minimal realizations preserves them, being a symplectomorphism (canonical transformation).

If the initial system has a finite dimensional Lie algebra, the constructions use the moment map [1], [2], [9], [17], [22] (general references for symplectic geometry and Hamiltonian vector fields), under quite natural assumptions, and the resulting state spaces are either an orbit of the coadjoint action of G (the associated group of diffeomorphisms) on the dual of its Lie algebra, or $\mathbb{R} \times S$, where S is an orbit of the coadjoint action of G_0 (a subgroup of G) on the dual of its Lie algebra; the dynamics are given by that action, in the first case, or its suspension, in the second case. For related work, developing some of the techniques presented here, see [7]. As an

interesting by-product we give an easy proof of the Kostant–Kirillov–Souriau theorem [17], [9].

1. Basic definitions. Let M be a smooth or analytic connected manifold; a symplectic form w on M is a closed nondegenerate 2-form, and the pair (M, w) is called a symplectic manifold.

Let $s: V(M) \rightarrow \Omega^1(M)$ be defined by $s(X) = w(X, \cdot)$, where $V(M)$ and $\Omega^1(M)$ are the set of smooth (or analytic) vector fields, respectively 1-forms, on M . Then s is a linear isomorphism, and we can define the map $j: C(M) \rightarrow V(M)$ by $j(h) = s^{-1}(dh)$, $C(M)$ being the set of smooth, or analytic, functions on M ; clearly if $X_h = j(h)$ then $w(X_h, \cdot) = dh$.

X_h is said to be a Hamiltonian vector field, and h the corresponding Hamiltonian (function). We denote by $H(M)$ the set of Hamiltonian vector fields, the image of j .

A map $f: M' \rightarrow M''$ between two symplectic manifolds is a symplectomorphism if $f^*w'' = w'$. In particular, this implies f is a local diffeomorphism [1, p. 177].

PROPOSITION 1.1 [1, p. 188]. *If X is a Hamiltonian vector field then:*

(i) $L_X w = 0$.

(ii) *If $\{X_i\}$ is the associated pseudo-group of diffeomorphisms, then $X_i^* w = w$.*

The Poisson bracket of two functions g and h in $C(M)$ is defined by $\{g, h\} = w(X_h, X_g)$.

PROPOSITION 1.2 [1, p. 194]. (i) $C(M)$ with the Poisson bracket $\{\cdot, \cdot\}$ is a Lie algebra.

(ii) $X_{\{g, h\}} = [X_g, X_h]$.

(iii) $H(M)$ is a Lie subalgebra of $V(M)$.

PROPOSITION 1.3. [10, p. 261]. *The sequence $0 \rightarrow \mathbb{R} \xrightarrow{i} C(M) \xrightarrow{j} H(M) \rightarrow 0$, where i is the natural inclusion as a subspace of constants, is an exact sequence of Lie algebras.*

Let $P: M \times \mathbb{R}^m \rightarrow \mathbb{R}$ be a C^2 function such that P_u defined by $P_u(x) = P(x, u)$ is a smooth (analytic) function on the symplectic manifold M . We define $f: M \times \mathbb{R}^m \rightarrow TM$ by $f(\cdot, u)$ being the Hamiltonian vector field corresponding to the function P_u , and take U as the family of piecewise constant maps from $[0, +\infty[$ into \mathbb{R}^m ; then $\Sigma = (M, \Omega = \mathbb{R}^m, f, U)$ is a control system, as considered in [20], the Hamiltonian control system defined by P .

We denote by D the set of associated vector fields $f(\cdot, u)$ with u in Ω —which we assume to be complete—and by $G(S)$ the group (semi-group) of diffeomorphisms generated by finite products of diffeomorphisms associated to vector fields in D (corresponding to nonnegative time).

Σ is said to be reachable or orbit-minimal if the orbit of any point in M under the action of G is M .

Some difficulties arise when we try to define the corresponding system with outputs within the framework of [20], since the output maps should be $y: M \times \Omega \rightarrow \Omega$, with $y(x, u) = \partial/\partial u P(x, u)$. We define the output space to be Ω ; instead of one output map we consider a family of maps $(y_u, u \in \Omega)$, $y_u(x) = y(x, u)$, and the system with outputs will be $\Sigma = (M, \Omega, f, U, \Omega, \{y_u\})$. It has been proved in [3] that the relevant properties concerning observability and quasi-minimal realizations, as stated in [4], are not altered if we define indistinguishability by: x' and x'' are (weakly) indistinguishable if for every $g \in S(G)$ and $u \in \Omega$ we have $y_u(gx') = y_u(gx'')$.

The observability codistribution Q is the smallest G -invariant codistribution containing the differentials of the components of the output maps; if $\dim Q = n$ then Σ is locally weakly observable [4]. The observability distribution Δ is defined by $\Delta = \{X \in V(M), Q \cdot X = 0\}$.

Let $P(D)$ be the smallest G -invariant distribution containing D [19]. A realization is said to be quasi-minimal [4] if $\dim P(D) = n$ (reachable realization) and $\dim Q = n$ (weakly observable realization); its state space has minimal dimension for all possible realizations.

2. Quasi-minimality. Given a system Σ , we denote by P_0 the distribution generated by vector fields of the form $g_*(X - X')$, with $g \in G$ and $X, X' \in D$; P_0 is the smallest G -invariant distribution containing the differences of vector fields in D .

PROPOSITION 2.1. *If Σ is a reachable Hamiltonian system and $\dim P_0 = n$ then Σ is quasi-minimal.*

Proof. If we prove that $Q = w(P_0, \cdot)$ then the condition $\dim P_0 = n$ implies that $\dim Q = n$, and as $\dim P(D) = n$, Σ will be quasi-minimal.

Let g be in G and $X^i \lrcorner w = dP(\cdot, u_i)$, $i = 1, 2$. Then $g_*(X^1 - X^2) \lrcorner w = g^{-1*}(dP(\cdot, u_1) - dP(\cdot, u_2))$ as can be verified by an easy calculation bearing in mind that g is a symplectomorphism, and so $P_0 \lrcorner w$ is generated by these elements.

On the other hand, Q is generated by elements of the form

$$g^* d \frac{\partial}{\partial u_i} P(\cdot, u) = g^* \frac{\partial}{\partial u_i} dP(\cdot, u).$$

Essentially the situation is as follows: given a smooth (or analytic) map $q: \mathbb{R}^m \rightarrow \mathbb{R}^n$ we compare the subspace V generated by the vectors $\partial/\partial u_i q(u)$ with the subspace V' generated by the vectors $q(u) - q(u')$.

From $\partial/\partial u_i q(u) = \lim (q(u+h) - q(u))/h$ as $h \rightarrow 0$, and since V' is closed, we see that V is contained in V' .

Now let u, u' be two distinct points; we can write the difference $q(u') - q(u)$ as the sum over $i = 1, 2, \dots, m$ of $q(u+ih) - q(u+(i-1)h)$, with $h = (u' - u)/m$; also $q(u+ih) - q(u+(i-1)h) = \partial/\partial u q(u+(i-1)h) \cdot h + o(h)$, and the first term in the right-hand side is in V . Therefore $q(u') - q(u)$ is the sum of a term in V plus a term $m \times o(h)$, which tends to zero as m tends to ∞ .

Again closeness of subspaces in finite dimensions allows us to conclude that V contains V' , and thus $V' = V$. \square

Given a Hamiltonian system Σ and x in M , an equivalent reachable realization Σ' can be obtained by restricting Σ to the orbit M' of G through x ; in general Σ' is not Hamiltonian.

We can define a new system Π from Σ by just altering the output maps: instead of $\partial/\partial u P(\cdot, u)$ we consider $P(\cdot, u)$. The two systems have the same dynamics, and the restriction of Π to M' is a reachable realization.

Let Δ^* be the observability distribution of Π' , and TM'^w the w -orthogonal of TM' : $w(x)(T_x M', v) = 0$ if $v \in TM'^w(x)$.

To obtain a quasi-minimal realization from Π' we have to quotient out the observability distribution [4]. Since here Δ^* is shown to be the intersection of TM' and its w -orthogonal, the resulting state space M_1 is a symplectic manifold on which the projection of Π' is quasi-minimal.

In fact, as $P(\cdot, u)$ is constant on the integral submanifolds of Δ^* so is $\partial/\partial u P(\cdot, u)$, and therefore we can also project Σ' on the same state space, obtaining a reachable system Σ_1 .

Σ_1 is not locally weakly observable (and a fortiori is not quasi-minimal) in general, but we shall prove that it is Hamiltonian and give a necessary and sufficient condition for being a quasi-minimal realization.

LEMMA 2.2. $M_1 = M'/\Delta^*$ is a symplectic manifold.

Proof. From [4] we know that M_1 is a smooth or analytic Hausdorff manifold and Δ^* a sub-bundle of TM' . Therefore if Δ^* is the intersection of TM' and its w -orthogonal, M_1 is a symplectic manifold [22].

By definition, Δ^* is contained in TM' ; it is easy to see that for the system Π' the observability codistribution can be obtained as $Q^* = w(P(D), \cdot)$: Q^* is generated by elements of the form $g^* dh$, where g is in G and h is a component of an output map, which can also be written as $w(g_*^{-1}X, \cdot)$. Then $\Delta^* = \{X \in V(M'), Q^* \cdot X = w(P(D), X) = 0\}$, and thus Δ^* is also contained in the w -orthogonal of $P(D)$; but $P(D) = TM'$ because Π' is reachable system, and the result follows from [22]. \square

THEOREM 2.3. *Any initialized Hamiltonian system (Σ, x) has an equivalent reachable Hamiltonian realization (Σ_1, x_1) . Σ_1 is a quasi-minimal realization if the condition of Proposition 2.1 is verified for Σ_1 .*

Proof. We take Σ_1 as defined before, and x_1 as the projection of x on M_1 . Since we have already seen that Σ_1 is reachable we need only to prove it is Hamiltonian and then the last assertion follows from Proposition 2.1.

It is enough to show that X is the Hamiltonian vector field corresponding to h_1 in the diagram below:

$$\begin{array}{ccc} TM & \xleftarrow{X_h} & M \xrightarrow{h} \mathbb{R} \\ \downarrow \pi_* & & \downarrow \pi \nearrow h_1 \\ TM_1 & \xleftarrow{X} & M_1 \end{array}$$

From the definition of w_1 on the quotient manifold M_1 and if $\pi(x) = x_1$, $\pi_*v = v_1$, we have:

$$\pi^*w_1(X(x_1), v_1) = w(X_h(x), v) = dh(x) \cdot v = \pi^*dh_1(x) \cdot v = \pi^*(dh_1(x_1) \cdot v_1).$$

As v_1 is arbitrary, $w_1(X, \cdot) = dh_1$. \square

This is a generalization of a similar result of van der Schaft [15], [16], obtained for affine systems, using essentially the same technique.

A time-dependent Hamiltonian control system on a symplectic manifold M is a system of the form:

$$\dot{x} = X_{P(t, \cdot, u)}(x), \quad y_{u,t}(x) = \frac{\partial}{\partial u} P(t, \cdot, u)$$

where P is a smooth or analytic function defined on $\mathbb{R} \times M \times \mathbb{R}^m$. To study this system as an autonomous system we can construct its suspension to the contact manifold $(\mathbb{R} \times M, p^*w)$ where $p: \mathbb{R} \times M \rightarrow M$ is the canonical projection. We have then

$$(t, x) = \left(\frac{\partial}{\partial t}, X_{P(t, \cdot, u)}(x) \right), \quad y_u(t, x) = \frac{\partial}{\partial u} P(t, x, u).$$

Let us assume now that we have a reachable Hamiltonian system Σ for which $\text{codim } P_0 = 1$; the approach used in [21] for the nonstrongly accessible case allows us to view Σ as the suspension of a time-dependent system defined on a maximal integral submanifold W of P_0 . In fact, there exists a covering projection $\pi: \mathbb{R} \times W \rightarrow M$ such that if we pull-back the function P , the associated vector fields and the symplectic form on M , we get an equivalent reachable Hamiltonian system, defined on $\mathbb{R} \times W$;

for this system the associated vector fields have the form $\partial/\partial t + q((t, x), u)$, with $q((t, x), u') = 0$ if u' in Ω corresponds to the flow used in the definition of π [21].

We can assume then that Σ is defined on a symplectic manifold $M = \mathbb{R} \times W$, and $f((t, x), u) = \partial/\partial t + q((t, x), u)$ with $\partial/\partial t(t, x) \perp w = dP(t, x, 0)$ and

$$q(t, \cdot, u) \perp dP'(t, \cdot, u), \quad P'(\cdot, u) = P(\cdot, u) - P(\cdot, 0);$$

note that $\partial/\partial u P = \partial/\partial u P'$.

The vector fields $q(\cdot, u)$ belong to TW (to be rigorous to $T\{t\} \times W$) and we can identify P_0 with TW by the same abuse of language.

LEMMA 2.4. *If Δ is the observability distribution of Σ , then $M_2 = M/\Delta$ has the form $M_2 = \mathbb{R} \times W_2$ where W_2 is a symplectic manifold.*

Proof. We have $P_0 = TW$, as explained before, and since $\dim \Delta + \dim P_0 = 2n$ [22] as they are w -orthogonal, $\dim \Delta = \text{codim } P_0 = 1$. Also, as $P_0/P_0 \cap \Delta$ has even dimension [22], $\dim P_0 \cap \Delta = 1$ and thus Δ is contained in $P_0 = TW$ and coincides with its intersection with TW^w , i.e. Δ is the intersection of TW with its w -orthogonal.

We can then write $M_2 = M/\Delta = (\mathbb{R} \times W)/\Delta = \mathbb{R} \times (W/TW \cap TW^w) = \mathbb{R} \times W_2$, and W_2 is a symplectic manifold [22]. \square

THEOREM 2.5. *A reachable Hamiltonian system Σ , with $\text{codim } P_0 = 1$, has a quasi-minimal realization Σ_2 which is the suspension of a time-dependent Hamiltonian system.*

Proof. Quasi-minimality results from the construction of Σ_2 as the projection of Σ on M_2 according to the procedure put forward in [11], [4] and used in the construction of Σ_1 . We have only to prove that $w(q_2(t, \cdot, u), \cdot) = dP'_2(t, \cdot, u)$ as in Theorem 3, writing $f_2(\cdot, u) = \partial/\partial t + q_2(\cdot, u)$ in the diagram below:

$$\begin{array}{ccccc} T\mathbb{R} \times TW & \xleftarrow{f(\cdot, u)} & \mathbb{R} \times W & \xrightarrow{P(\cdot, u)} & \mathbb{R} \\ \downarrow \text{id} \times \pi_* & & \downarrow \text{id} \times \pi & \nearrow P_2(\cdot, u) & \\ T\mathbb{R} \times TW_2 & \xleftarrow{f_2(\cdot, u)} & \mathbb{R} \times W_2 & & \end{array}$$

Since $\pi^*(q_2 \perp w_2) = q \perp w = dP'(t, \cdot, u) = \pi^*(dP'_2(t, \cdot, u))$ we can conclude that $q_2(t, \cdot, u) \perp w_2 = dP'_2(t, \cdot, u)$ as needed. \square

3. Hamiltonian systems with finite dimensional Lie algebra. In this section we consider only complete analytic Hamiltonian systems, such that T , the smallest Lie algebra in $V(M)$ containing D , is finite dimensional. G denotes the group of diffeomorphisms generated by the associated vector fields, as before.

THEOREM 3.1 [12]. (i) *G is a Lie transformation group on M , with action $\mu(g, x) = gx$.*

(ii) *The Lie algebra \mathfrak{g} of G is isomorphic to T through the isomorphism $\varphi: \mathfrak{g} \rightarrow T$, $\varphi(v)(x) = \mu_{x*}(v)$ where $\mu_x(g) = \mu(g, x)$.*

(iii) *Given $v \in \mathfrak{g}$ the vector field $\varphi(v)$ in T corresponding to v is complete.*

LEMMA 3.2. *$\text{Im } \varphi$ belongs to $H(M)$.*

Proof. If $\varphi(v)$ is in D it is a Hamiltonian vector field, and since $\text{im } \varphi = T$ every vector field in $\text{im } \varphi$ is a linear combination of Lie brackets of Hamiltonian vector fields, therefore a Hamiltonian vector field. \square

The action of G on M is symplectic, from Proposition 1.1(ii); it is a Poisson action if there exists a Lie algebra homomorphism β making the following diagram

commutative:

$$\begin{array}{ccc}
 & & \mathfrak{g} \\
 & \swarrow b & \downarrow \varphi \\
 0 \rightarrow \mathbb{R} \rightarrow C(M) & \xrightarrow{j} & H(M) \rightarrow 0
 \end{array}$$

From now on, we assume the action of G on M to be Poisson. Then we can define the moment map J of μ by $J: M \rightarrow \mathfrak{g}^*$, $J(x)v = \varphi(v)(x)$.

THEOREM 3.3 [1], [2], [10]. *If Ad_g^* is the coadjoint action of G on \mathfrak{g}^* , the following diagram is commutative:*

$$\begin{array}{ccc}
 M & \xrightarrow{\mu_g} & M \\
 \downarrow J & & \downarrow J \\
 \mathfrak{g}^* & \xrightarrow{\text{Ad}_g^*} & \mathfrak{g}^*
 \end{array}$$

THEOREM 3.4 [1], [2], [10]. *Let W be an orbit of the coadjoint action of G . Then:*

(i) *If $\Phi(v)$ is the vector field in \mathfrak{g}^* corresponding to v we have $J_*\varphi(v) = \Phi(v)$ and $\Phi(v)(a) \cdot v' = a \cdot [v, v']$, with $a \in \mathfrak{g}^*$ and $v, v' \in \mathfrak{g}$.*

(ii) *W has a canonical symplectic form defined by $w'(a)(\Phi(v), \Phi(v')) = a \cdot [v, v']$.*

(iii) *The vector field $\Phi(v)$ in W has Hamiltonian $h_v: W \rightarrow \mathbb{R}$, $h_v(a) = a \cdot v$.*

Example. Let $M = \mathbb{R}^6$, with w the usual symplectic form, and P given by $P(x, u) = g_0(x) + u_1 g_1(x) + u_2 g_2(x)$, where $g_0(x) = x_3 x_5 - x_2 x_6$, $g_1(x) = x_1 x_5 - x_2 x_4$, $g_2(x) = x_1 x_6 - x_3 x_4$.

An easy computation shows that, if X^i is defined by $X^i \lrcorner w = dg_i$, we have $[X^1, X^2] = X^0$, $[X^2, X^0] = X^1$, $[X^0, X^1] = X^2$. Therefore $\mathbf{T} = \mathbf{T}_0$ and is finite dimensional; from the above relations we see that \mathbf{T} is isomorphic to $\mathfrak{so}(3)$ through:

$$X^i \rightarrow A_i = \begin{pmatrix} 0 & e_{1i} & e_{2i} \\ \vdots & \vdots & \vdots \\ -e_{1i} & 0 & -e_{0i} \\ \vdots & \vdots & \vdots \\ -e_{2i} & e_{0i} & 0 \end{pmatrix}$$

with $i = 0, 1, 2$ and $e_{ij} = 0$ if $i \neq j$ and 1 if $i = j$.

Moreover, we can identify $\mathfrak{so}(3)$ with \mathbb{R}^3 by means of the map 1 defined by $1(e_1) = A_1$, $1(e_2) = A_2$, $1(e_3) = A_0$, and then the bracket in $\mathfrak{so}(3)$ corresponds to the usual vector product in \mathbb{R}^3 .

Defining an action of $\text{SO}(3)$ in \mathbb{R}^6 by means of

$$(A, x) \rightarrow \begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix} x = A \cdot x$$

we see that $X^i(x) = d/dt (\exp tA_i \cdot x)|_{t=0}$ for $i = 0, 1, 2$. Thus we can assume we have been given an action $\text{SO}(3) \times \mathbb{R}^6 \rightarrow \mathbb{R}^6$, the maps $x \rightarrow A \cdot x$ being symplectomorphisms for every A in $\text{SO}(3)$.

If we identify \mathbb{R}^6 with $T^*\mathbb{R}^3$ the above action is induced by the usual action of $\text{SO}(3)$ on \mathbb{R}^3 , and thus is a Poisson action [2, p. 377]. Having identified $\mathfrak{so}(3)$ with \mathbb{R}^3 , we can identify $\mathfrak{so}(3)^*$ with \mathbb{R}^3 as well, using the Euclidean structure.

It is easy to see that the adjoint action of $SO(3)$ on \mathbb{R}^3 is equivalent to the usual action (but not the same: for instance the usual action of $\exp tA_0$ is the adjoint action of $\exp tA_1$) and therefore they have the same orbits: the orbit of x is the set $\{y \in \mathbb{R}^3, \|y\| = \|x\|\}$. From the definition of coadjoint action, its orbits are exactly the same.

As we know that the moment map does exist, we can compute it as $J(x)e_1 = g_1(x)$, $J(x)e_2 = g_2(x)$, $J(x)e_3 = -g_0(x)$. Denoting by p_i the projection of \mathbb{R}^3 on the i th factor, we have:

$$\begin{array}{ccc} \mathbb{R}^6 \times \mathbb{R}^2 & \xrightarrow{P} & \mathbb{R} \\ J \times \text{id} \downarrow & \nearrow (-p_3 \pm u_1 p_1 + u_2 p_2) & \\ \mathbb{R}^3 \times \mathbb{R}^2 & & \end{array}$$

Therefore we can project the original system in \mathbb{R}^3 , through J , and clearly the dynamics of the new system will be given by the coadjoint action and the output maps will be p_1 and p_2 . To obtain a reachable system we have to consider its restriction to an orbit of the coadjoint action; this is a symplectic manifold, and later we shall prove that we get a Hamiltonian system Σ by the procedure just outlined.

In this case it will be a quasi-minimal realization since we have already seen that $[X^1, X^2] = X^0$ and we can then apply Proposition 2.1.

In conclusion, the quasi-minimal realization Σ is defined on a sphere in \mathbb{R}^3 with the canonical symplectic form; the associated vector fields corresponding to X^i are rotations around the axis, their Hamiltonians being the restriction to that sphere of the canonical projections of \mathbb{R}^3 . \square

In the remaining part of this section, we shall generalize and justify the above construction, including the nonstrongly accessible case.

From the definition of J and as we have already done in the previous example, we see that, for every v in \mathfrak{g} , $\beta(v)$ factors as follows:

$$\begin{array}{ccc} M & \xrightarrow{\beta(V)} & \mathbb{R} \\ J \downarrow & \nearrow h_v & \\ \mathfrak{g}^* & & \end{array}$$

This means that we can define P' by

$$\begin{array}{ccc} M \times \mathbb{R}^m & \xrightarrow{P} & \mathbb{R} \\ J \times \text{id} \downarrow & \nearrow P' & \\ \mathfrak{g}^* \times \mathbb{R}^m & & \end{array}$$

and let P_1 be the restriction of P' to $M_1 \times \mathbb{R}^m$.

THEOREM 3.5. *Let x in M be such that $J(x)$ belongs to M_1 . The initialized Hamiltonian system (Σ, x) corresponding to the function P projects down on M_1 through J , defining a reachable Hamiltonian system $(\Sigma_1, J(x))$ corresponding to the function P_1 , with dynamics given by the coadjoint action of G . Σ_1 is quasi-minimal if it is strongly accessible.*

Proof. We first remark Σ_1 is well defined: if $P(\cdot, u)$ is constant on the fibres of J so is $\partial/\partial u P(\cdot, u)$. Defining J' as the restriction of J to M' , the orbit of D through x , we have $P = (J', \text{id})^* P_1$ and $X_{P(\cdot, u)} = J'_* X_{P(\cdot, u)}$ in view of Theorem 3.4.

If we define y_1 from $\partial/\partial u P$ as we have defined P_1 from P , it is trivial to verify that $y_1 = \partial/\partial u P_1$, therefore Σ_1 is a Hamiltonian system, the other properties following directly from the construction. Note that for analytic systems $\dim P_0 = n$ is equivalent to strong accessibility [21]. \square

We consider now a reachable but not strongly accessible Hamiltonian system Σ defined on an orbit M of the coadjoint action of G on \mathfrak{g}^* . The action of G on M is symplectic, and has a moment given by the inclusion $i: M \rightarrow \mathfrak{g}^*$; the submanifold W considered in the previous section is the orbit of G_0 , the Lie subgroup of G corresponding to the Lie subalgebra T_0 of T isomorphic to a certain subalgebra \mathfrak{g}_0 of \mathfrak{g} with codimension one.

Considering $\mathfrak{g}^* = \mathbb{R}^* \times \mathfrak{g}_0^*$ and $p_0: \mathfrak{g}^* \rightarrow \mathfrak{g}_0^*$ the canonical projection, let i_0 be the map $i_0: M \rightarrow \mathfrak{g}_0^*$ defined by $i_0 = p_0 \circ i$.

G_0 acts by symplectomorphisms on M , and the action has a moment map given by i_0 ; therefore if $x \in W$, $i_0(W)$ is the orbit W_2 of $i_0(x)$ under the coadjoint action of B_0 on \mathfrak{g}_0^* .

If we consider the map $\pi_2: W \rightarrow W_2$, restriction of i_0 to W , we see π_2 is an analytic submersion, since W_2 can be interpreted as a maximal integral submanifold of an analytic distribution on \mathfrak{g}_0^* [6].

LEMMA 3.6. *The kernel of π_{2*} is the w -orthogonal of TW .*

Proof. Identifying the tangent space at a point of \mathfrak{g}^* with \mathfrak{g}^* , we can represent a vector in $T_x W$ by $\{x, v\}$, with v in \mathfrak{g} , and $\{\cdot, \cdot\}$ defined by the relation $\{x, v\} \cdot v' = x \cdot [v, v']$ for any $v \in \mathfrak{g}$ [2].

Now, if $\{x, v\}$ is in the w -orthogonal of TW at x and $\{x, v'\}$ belongs to TW , we have $w(\{x, v\}, \{x, v'\}) = x \cdot [v, v'] = 0$; as $\{x, v'\}$ belonging to TW is the same as v' belonging to \mathfrak{g}_0^* , that can be written as $\{x, v\} \cdot v' = 0$ for any v' in \mathfrak{g}_0^* and, from the definition of π_2 , $\{x, v\}$ belongs to the kernel of π_{2*} . \square

As in the previous section, we can take the system as being defined on $\mathbb{R} \times W$ and pull-back everything by π .

THEOREM 3.7. *If Σ is reachable but not strongly accessible, it has a quasi-minimal realization which is the suspension of a time-dependent Hamiltonian system on an orbit of the coadjoint action of G_0 on \mathfrak{g}_0^* , with dynamics given by the suspension of that action.*

Proof. Taking into account the previous lemma we obtain a quasi-minimal realization Σ_2 from Σ by projecting on $\mathbb{R} \times W_2$ through $(\text{id}, \pi^* \pi_2)$. The resulting system is the suspension of a time-dependent Hamiltonian system since this was the construction already used in Theorem 2.5.

Now if g is an element of G we can write it as a product $g_1 \circ \dots \circ g_k$ with g_i the flow of an associated vector field X^i during the time t_i ; let $t' = t_1 + \dots + t_k$.

If (t, x) belongs to $\mathbb{R} \times W$ then $g(t, x) = (t + t', g'x)$ where g' is an element of G_0 given by $g' = (\partial/\partial t)_{-t'} \circ g$; in the projection on $\mathbb{R} \times W_2$ the action of g becomes $(t, x_2) \rightarrow (t + t', \text{Ad}_g^* x_2)$ where Ad^* refers to the coadjoint action of G_0 ; but this is exactly what we mean by the suspension of that action. \square

Now we turn to the Kostant-Kirillov-Souriau theorem.

THEOREM 3.8 [17], [9]. *If a Lie group G acts transitively on a symplectic manifold M , and the action is Poisson, then M is a covering space of the corresponding orbit W of the coadjoint action of G .*

Proof. The action induces a Lie algebra T of Hamiltonian vector fields in M isomorphic to \mathfrak{g} , and we consider a complete Hamiltonian control system Σ for which the set D of associated vector fields generates T , with the corresponding Hamiltonians as output maps: if v_1, \dots, v_k is a basis of \mathfrak{g} and X^i their respective Hamiltonian vector fields in M , $X^i \lrcorner w = df_i$, we define Σ from the map $P(x, u) = u_1 f_1(x) + \dots + u_k f_k(x)$.

The system Σ is reachable and strongly accessible, therefore quasi-minimal; if Σ' is the minimal realization of Σ defined on the state space M' , from [20] we know the projection $p: M \rightarrow M'$ is a covering projection, since Σ satisfies the observability rank condition.

If Σ_1 is the realization on W equivalent to Σ , constructed by using the moment map, the projection $p_1: W \rightarrow M'$ is also a covering projection by exactly the same argument as before, and we have the following commutative diagram:

$$\begin{array}{ccc} M & \xrightarrow{\quad} & M' \\ & \searrow J & \nearrow p_1 \\ & W & \end{array}$$

From [18, p. 64] J is a covering projection (being obviously surjective), therefore M is a covering space of W . \square

4. Equivalence of Hamiltonian systems. If Σ and Σ' are minimal (quasi-minimal) realizations and F is a homomorphism between them, F is a diffeomorphism (local diffeomorphism), smooth or analytic according to the class of the given systems [20], [4].

For Hamiltonian systems we can also prove:

THEOREM 4.1. *Let Σ and Σ' be two Hamiltonian systems with outputs, Σ reachable, and $F: M \rightarrow M'$ a homomorphism; then F is a (smooth, analytic) symplectomorphism.*

Proof. We need to prove that $F^*w_2 = w_1$ or equivalently $w' = F^*w_2 - w_1 = 0$; we know [20] that F is smooth or analytic, according to the class we are working in, and it has also been proved in [3] that if X is in D_1 , the family of associated vector fields of Σ_1 , then $w'(X, \cdot) = dS$ for some function S independent of X .

Clearly $L_X S = 0$, since $dS \cdot X = w'(X, X) = 0$, and therefore S is constant along trajectories of vector fields in D_1 ; as Σ_1 is reachable, S is constant on M_1 and $dS = 0$.

Let g_1 belong to G_1 . By Lemma 5(ii) in [15] there exists g_2 in G_2 such that $F \circ g_1 = g_2 \circ F$; then

$$g_1^* F^* w_2 = (F \circ g_1)^* w_2 = (g_2 \circ F)^* w_2 = F^* g_2^* w_2 = F^* w_2,$$

and also

$$g_1^* w' = g_1^* (F^* w_2 - w_1) = F^* w_2 - w_1 = w'.$$

Now if X belongs to D_1 , we have

$$g_1^* X \lrcorner w' = g_1^{-1*} (X \lrcorner g_1^* w') = g_1^{-1*} (X \lrcorner w') = 0$$

and since Σ_1 is reachable the vectors of the form $g_1^* X$ span the tangent space of M_1 at every point, thus $w' = 0$. \square

Now let Σ be the suspension of a time-dependent Hamiltonian system on M ; then $\mathbb{R} \times M$ has a contact structure (a closed two-form of maximal rank) w defined by $w = p^* w$, where w is the symplectic form on M and p is the projection $\mathbb{R} \times M \rightarrow M$. The analogue of a symplectomorphism for contact structures is a canonical transformation [1, p. 384], a map $\mathbb{R} \times M_1 \rightarrow \mathbb{R} \times M_2$ satisfying:

- (i) F is a diffeomorphism.

(ii) The diagram below is commutative:

$$\begin{array}{ccc} \mathbb{R} \times M_1 & \xrightarrow{F} & \mathbb{R} \times M_2 \\ & \searrow \pi_1 & \swarrow \pi_2 \\ & \mathbb{R} & \end{array}$$

(iii) There exists a (smooth, analytic) map $K: \mathbb{R} \times M_1 \rightarrow \mathbb{R}$ such that $F^* \underline{w}_2 = \underline{w}_1 + dK \wedge dt$.

We can now state an analogue of the previous theorem:

THEOREM 4.2. *Let Σ_1, Σ_2 be quasi-minimal realizations as in Theorem 3.8; if the homomorphism F between them is the suspension of a diffeomorphism $\Phi: M_1 \rightarrow M_2$, then F is a canonical transformation and Φ is a symplectomorphism.*

Proof. It is clear that F satisfies (i) and (ii), and we only have to prove (iii).

As in the previous proof we can obtain, for X in D_1 , $\underline{w}' = F^* \underline{w}_2 - \underline{w}_1$ that $X \lrcorner \underline{w}'(t, x) = d_x K(t, x)$ for some function on $\mathbb{R} \times M_1$ independent of X , and thus $L_X K = \partial/\partial t K$ as $X \lrcorner d_x K = \underline{w}'(X, X) = 0$; in particular this means K is independent of x in M_1 , and $X \lrcorner \underline{w}' = 0$.

If g_1 and g_2 are corresponding elements in G_1 and G_2 respectively we have $g_1^* X \lrcorner \underline{w}' = g_1^{-1*} (X \lrcorner g_1^* \underline{w}')$, and from [1] also:

$$\begin{aligned} g_1^* \underline{w}_1 &= g_1^* p_1^* \underline{w}_1 = (p_1 \circ g_1)^* \underline{w}_1 = \underline{w}_1 - dP_1 \wedge dt_1, \\ g_1^* F^* \underline{w}_2 &= F^* g_2^* p_2^* \underline{w}_2 = F^* (\underline{w}_2 - dP_2 \wedge dt_2) \end{aligned}$$

where dP_1 and dP_2 are taken at the value of u , supposed constant, corresponding to g_1 and g_2 .

Then, as $F^* dP_2 = dP_1 + \partial/\partial t K dt_1$ and $F^* dt_2 = dt_1$, we have $g_1^* \underline{w}' = \underline{w}'$ and therefore $g_1^* X \lrcorner \underline{w}' = 0$. It is easy to see, by induction, that this remains true if g_1 corresponds to a piecewise-constant control, because then g_1 is a finite product of elements of G_1 of the type just considered. We can conclude that $\underline{w}' = 0$ as in the previous proof and this means F is a canonical transformation. \square

Acknowledgments. I would like to thank P. Crouch for his many suggestions and the encouragement he gave me, and Professor Krener for his advice; P. Barros contributed also with a very valuable suggestion.

Part of this work was done at the Control Theory Centre of the University of Warwick, and the continued financial support of the Calouste Gulbenkian Foundation has been invaluable.

DISTRIBUTED ASYNCHRONOUS RELAXATION METHODS FOR CONVEX NETWORK FLOW PROBLEMS*

DIMITRI P. BERTSEKAS† AND DIDIER EL BAZ‡

Abstract. We consider the solution of the single commodity strictly convex network flow problem in a distributed asynchronous computation environment. The dual of this problem is unconstrained, differentiable, and well suited for solution via Gauss-Seidel relaxation. We show that the structure of the dual allows the successful application of a distributed asynchronous method whereby relaxation iterations are carried out in parallel by several processors in arbitrary order and with arbitrarily large interprocessor communication delays.

Key words. parallel computation, distributed algorithms, network flows, asynchronous relaxation, coordinate descent

1. Introduction. Consider a directed graph with set of nodes N and set of arcs A . Each arc (i, j) has associated with it a cost function $g_{ij}: R \rightarrow (-\infty, +\infty]$. We denote by f_{ij} the flow of the arc (i, j) and consider the problem of minimizing total cost subject to a conservation of flow constraint at each node

$$(1) \quad \begin{aligned} &\text{minimize} \quad \sum_{(i,j) \in A} g_{ij}(f_{ij}) \\ &\text{subject to} \quad \sum_{(m,i) \in A} f_{mi} - \sum_{(i,j) \in A} f_{ij} = 0 \quad \forall i \in N. \end{aligned}$$

We assume that problem (1) has at least one feasible solution. We also make the following standing assumptions on g_{ij} :

- (a) g_{ij} is strictly convex, and lower semicontinuous;
- (b) the conjugate convex function of g_{ij} , defined by

$$(2) \quad g_{ij}^*(t_{ij}) = \sup_{f_{ij}} \{t_{ij}f_{ij} - g_{ij}(f_{ij})\},$$

is real valued, i.e. $-\infty < g_{ij}^*(t_{ij}) < \infty$ for all real t_{ij} . (Because of the strict convexity assumed in (a) above, g_{ij}^* is also continuously differentiable and its gradient denoted $\nabla g_{ij}^*(t_{ij})$ is the unique f_{ij} attaining the supremum in (2) (see [7, pp. 218, 253]).)

It is easily seen from (2) that assumption (b) implies that $\lim_{|f_{ij}| \rightarrow \infty} g_{ij}(f_{ij}) = \infty$. Therefore the objective function of the primal problem (1) has bounded level sets [7, § 8]. It follows that there exists an optimal solution for problem (1) which must be unique in view of the strict convexity assumed in (a).

The problem above is of great practical interest and has been studied for a long time. Except for strict convexity our assumptions are not overly restrictive. For example they are satisfied in the following two cases:

- 1) The *constrained case* where g_{ij} is of the form

$$(3) \quad g_{ij}(f_{ij}) = \begin{cases} \infty & \text{if } f_{ij} \notin [l_{ij}, c_{ij}], \\ \hat{g}_{ij}(f_{ij}) & \text{otherwise,} \end{cases}$$

where l_{ij} and c_{ij} are given lower and upper bounds on the arc flow, and \hat{g}_{ij} is a strictly convex, real valued function defined on the real line R .

2) The *unconstrained case* where g_{ij} is strictly convex, real valued and its right and left derivatives g_{ij}^+ and g_{ij}^- satisfy

$$(4) \quad \lim_{f_{ij} \rightarrow \infty} g_{ij}^+(f_{ij}) = \infty, \quad \lim_{f_{ij} \rightarrow -\infty} g_{ij}^-(f_{ij}) = -\infty.$$

A dual problem for (1) is given by

$$(5) \quad \begin{aligned} &\text{minimize } q(p) \\ &\text{subject to no constraints on the vector } p = \{p_i | i \in N\}, \end{aligned}$$

where q is the dual functional given by

$$(6) \quad q(p) = \sum_{(i,j) \in A} g_{ij}^*(p_i - p_j).$$

We refer to p as a *price vector* and its components p_i as *prices*. The i th price is really a Lagrange multiplier associated with the i th conservation of flow constraint. The duality between problems (1) and (5) is well known and is explored in great detail in the recent book by Rockafellar [1]. The earlier book by Rockafellar [7] gives the necessary and sufficient condition for optimality of a pair (f, p) . A feasible flow vector $f = \{f_{ij} | (i, j) \in A\}$ is optimal for (1) and a price vector $p = \{p_i | i \in N\}$ is optimal for (5) if and only if for all arcs (i, j) [7, pp. 337-338]

$$p_i - p_j \text{ is a subgradient of } g_{ij} \text{ at } f_{ij}.$$

An equivalent condition is

$$(7) \quad f_{ij} = \nabla g_{ij}^*(p_i - p_j) \quad \forall (i, j) \in A.$$

Any one of these equivalent relations is referred to as the *complementary slackness condition*, and is shown in Fig. 1.

Since the dual problem is unconstrained and differentiable it is natural to consider algorithmic solution by a descent iterative method. The Gauss-Seidel relaxation method is particularly interesting in this respect since it admits a simple implementation. Given a price vector p , a node i is selected and its price p_i is changed (relaxed) to a value \hat{p}_i such that

$$(8) \quad \sum_{(m,i) \in A} \nabla g_{mi}^*(p_m - \hat{p}_i) = \sum_{(i,j) \in A} \nabla g_{ij}^*(\hat{p}_i - p_j).$$

It is easily seen (compare with the definition (6) of the dual cost q) that this equation is equivalent to $\partial q / \partial p_i = 0$, so the dual cost is minimized at \hat{p}_i with respect to the i th price, all other prices being kept constant. The algorithm proceeds by relaxing the prices of all nodes in cyclic order and repeating the process. The convergence of this algorithm does not follow immediately from standard results on relaxation methods [2], [3], [4] since these results require some assumption that is akin to strict convexity of the dual objective function which does not hold here (for a counterexample, see Powell [5]). However Cottle and Pang [6] have shown convergence of a network algorithm based on relaxation. It applies to transportation problems with quadratic cost function, and involves certain restrictions in the way relaxation is carried out. Their result is substantially extended in Bertsekas, Hosein and Tseng [19].

Our main objective in this paper is to explore the convergence properties of distributed versions of the relaxation method just described. Here we assume that each price p_i is under the control of a separate processor who changes p_i to \hat{p}_i on the basis

FIG. 1. Complementary slackness condition diagram for cost function $g_{ij}(f_{ij}) = |f_{ij}| + \frac{1}{2}(f_{ij})^2$.

of (8) and communicates the new value to the other processors. One can consider a parallel computation procedure carried out in an orderly manner whereby all processors exchange their current prices before carrying out their relaxation iteration. Mathematically this would be equivalent to a Jacobi type of relaxation procedure. We would like to consider, however, a much more general procedure whereby the communication between processors is not regular, and the information available at some processors regarding prices of other processors may be arbitrarily out-of-date. In addition we allow some processors to iterate more frequently than others. Models of such asynchronous algorithms have been formulated some time ago and by now there is considerable understanding of their convergence properties (see [8]–[16]; [17] is a survey). It turns out that the dual problem (5) has structure that allows us to show that the asynchronous relaxation method has satisfactory convergence properties. This is particularly true when the dual problem (5) has an essentially unique optimal solution. Otherwise satisfactory convergence depends on the starting point. These results are all

new and are shown in § 3. The next section analyzes the structure of the dual solution set and provides some preliminary analysis.

The results of this paper carry over verbatim to the case where the conservation of flow constraint has the form

$$\sum_{(m,i) \in A} f_{mi} - \sum_{(i,j) \in A} f_{ij} = b_i \quad \forall i \in N$$

where b_i are given scalars with $\sum_{i \in N} b_i = 0$. The dual cost of (6) must then include the term $\sum_{i \in N} b_i p_i$, and the relaxation equation (8) must include an additional term b_i in its right side. This extension is important from the practical point of view, but we have restricted attention to the case where $b_i = 0, \forall i \in N$ in order to simplify notation.

The results of this paper can also be extended in a simple manner to network problems with positive gains and strictly convex arc costs. This extension was mentioned to us by P. Tseng who also showed [20] two additional interesting facts. First that Proposition 2 holds even if the strict convexity assumption of (a) is removed thereby including the important class of linear minimum cost flow problems. Second that, within the class of monotropic programming problems, the largest class for which the monotonicity property of Proposition 1 holds is the class of network flow problems with positive gains.

Our notational conventions are that a subscript denotes a node or processor index, and a superscript denotes a time or iteration index. All vector inequalities should be interpreted in a coordinatewise sense. In order to simplify notation we have implicitly assumed that there is at most one arc associated with any ordered pair of nodes i and j , so that the arc notation (i, j) has a unambiguous meaning. However this assumption is not essential to any of our results.

2. Structure of the optimal dual solution set. Our standing assumptions, (a) and (b), guarantee that the primal problem (1) has a unique optimal solution. Existence of an optimal solution of the dual problem can be guaranteed under an additional (mild) regular feasibility assumption in which case the existence theorem of [1, p. 360] applies. On the other hand the optimal solution of the dual problem is never unique since adding the same constant to all coordinates of a price vector p leaves the dual cost unaffected. We can remove this degree of freedom by constraining the price of one node, say node N , to be zero. (With slight abuse of notation we number nodes as $1, 2, \dots, N$.) Thus we consider the *reduced dual optimal solution set* P^* defined by

$$(9) \quad P^* = \{p^* \mid q(p^*) = \min_p q(p), p_N^* = 0\}$$

where q is the dual objective function

$$(10) \quad q(p) = \sum_{(i,j) \in A} g_{ij}^*(p_i - p_j).$$

For the most part of the paper, we will operate under the following assumption.

Assumption 1. The reduced dual optimal solution set P^* is nonempty and compact.

Assumption 1 is not overly restrictive. For example let $\{f_{ij}^* \mid (i, j) \in A\}$ be the unique primal optimal solution, and consider the set of arcs

$$(11) \quad \hat{A} = \{(i, j) \mid f_{ij}^* \text{ lies in the interior of the set } \{f_{ij} \mid g_{ij}(f_{ij}) < \infty\}\}.$$

Then Assumption 1 is satisfied if the subgraph (N, \hat{A}) is connected. To see this note that for all arcs $(i, j) \in \hat{A}$ we have a bounded set of subgradients of g_{ij} at f_{ij}^* thereby implying a bounded set of price differences $p_i - p_j$ corresponding to dual optimal solutions [cf. (6)]. Note that in the unconstrained case mentioned in the previous

section every arc belongs to \hat{A} ; so, if the original graph is connected, Assumption 1 is satisfied. The constrained case of the previous section can be converted to the unconstrained case by replacing constraints by nondifferentiable penalty functions (see [18, § 5.5]). For example, assuming a dual optimal solution exists, a constraint $f_{ij} \geq 0$ can be eliminated by adding to the cost g_{ij} a penalty $c \max\{0, -f_{ij}\} + [\max\{0, -f_{ij}\}]^2$ with c positive and sufficiently large.

Consider now the set

$$(12) \quad P = \{p \mid p_N = 0\}$$

and for $i = 1, \dots, N-1$, the point-to-set mapping R_i which assigns to a price vector $p \in P$ the set of all prices \hat{p}_i that minimize the dual cost along the i th price starting from p , i.e. (cf. (8))

$$(13) \quad R_i(p) = \left\{ \hat{p}_i \mid \sum_m \nabla g_{mi}^*(p_m - \hat{p}_i) = \sum_j \nabla g_{ij}^*(\hat{p}_i - p_j) \right\}.$$

It is well known that a real valued convex function having one compact level set, has all its level sets compact [7, p. 70]. Therefore under Assumption 1 the sets $R_i(p)$, $p \in P$ are all nonempty, compact intervals. It follows that under Assumption 1 the (point-to-point) mappings

$$(14) \quad \bar{R}_i(p) = \max_{\hat{p}_i \in R_i(p)} \hat{p}_i,$$

$$(15) \quad \underline{R}_i(p) = \min_{\hat{p}_i \in R_i(p)} \hat{p}_i,$$

are well defined on the set P . We call \bar{R}_i (\underline{R}_i) the i th *maximal (minimal) relaxation mapping*. It gives the maximal (minimal) minimizing point of the dual cost along the i th coordinate starting from its argument. The point-to-set mapping R_i is called the *i*th *relaxation mapping*.

Some key facts are given in the following proposition.

PROPOSITION 1. *Let Assumption 1 hold. The mappings \bar{R}_i and \underline{R}_i are continuous on P . They are also monotone on P in the sense that for any $p, p' \in P$, $i = 1, \dots, N-1$ we have*

$$(16) \quad \bar{R}_i(p) \leq \bar{R}_i(p') \quad \text{if } p \leq p',$$

$$(17) \quad \underline{R}_i(p) \leq \underline{R}_i(p') \quad \text{if } p \leq p'.$$

Proof. To show continuity of \bar{R}_i we argue by contradiction. Suppose there exists a convergent price vector sequence $p^k \rightarrow p$ such that the corresponding sequence $\{\bar{R}_i(p^k)\}$ does not converge to $\bar{R}_i(p)$. By passing to a subsequence if necessary suppose that for some $\delta > 0$ we have

$$(18) \quad \bar{R}_i(p) \geq \bar{R}_i(p^k) + \delta \quad \forall k$$

(the proof is very similar if $\delta < 0$ and the inequality is reversed). By the definition of \bar{R}_i we have

$$(19) \quad \sum_m \nabla g_{mi}^*(p_m - \bar{R}_i(p)) = \sum_j \nabla g_{ij}^*(\bar{R}_i(p) - p_j),$$

$$(20) \quad \sum_m \nabla g_{mi}^*(p_m^k - \bar{R}_i(p^k)) = \sum_j \nabla g_{ij}^*(\bar{R}_i(p^k) - p_j^k) \quad \forall k.$$

Since $p^k \rightarrow p$ it follows using (18) that for sufficiently large k we have

$$\begin{aligned} p_m^k - \bar{R}_i(p^k) &> p_m - \bar{R}_i(p) \quad \forall (m, i) \in A, \\ \bar{R}_i(p^k) - p_j^k &< \bar{R}_i(p) - p_j \quad \forall (i, j) \in A. \end{aligned}$$

Therefore for sufficiently large k we have using the convexity of g_{mi}^* , g_{ij}^*

$$\begin{aligned}\nabla g_{mi}^*(p_m^k - \bar{R}_i(p^k)) &\geq \nabla g_{mi}^*(p_m - \bar{R}_i(p)) \quad \forall (m, i) \in A, \\ \nabla g_{ij}^*(\bar{R}_i(p^k) - p_j^k) &\leq \nabla g_{ij}^*(\bar{R}_i(p) - p_j) \quad \forall (i, j) \in A.\end{aligned}$$

Using these relations together with (19), (20) we obtain for all sufficiently large k

$$(21) \quad f_{mi} \triangleq \nabla g_{mi}^*(p_m - \bar{R}_i(p)) = \nabla g_{mi}^*(p_m^k - \bar{R}_i(p^k)) \quad \forall (m, i) \in A,$$

$$(22) \quad f_{ij} \triangleq \nabla g_{ij}^*(\bar{R}_i(p) - p_j) = \nabla g_{ij}^*(\bar{R}_i(p^k) - p_j^k) \quad \forall (i, j) \in A.$$

Consider the intervals I_{mi} and I_{ij} given by

$$\begin{aligned}I_{mi} &= \{t \mid \nabla g_{mi}^*(t) = f_{mi}\} \quad \forall (m, i) \in A, \\ I_{ij} &= \{t \mid \nabla g_{ij}^*(t) = f_{ij}\} \quad \forall (i, j) \in A.\end{aligned}$$

For k sufficiently large so that (21), (22) hold we have

$$\begin{aligned}\bar{R}_i(p) &= \max \{\hat{p}_i \mid \hat{p}_i \in p_m - I_{mi}, (m, i) \in A, \hat{p}_i \in I_{ij} - p_j, (i, j) \in A\}, \\ \bar{R}_i(p^k) &= \max \{\hat{p}_i \mid \hat{p}_i \in p_m^k - I_{mi}, (m, i) \in A, \hat{p}_i \in I_{ij} - p_j^k, (i, j) \in A\}.\end{aligned}$$

Since $p^k \rightarrow p$, it is evident from these relations that $\bar{R}_i(p^k) \rightarrow \bar{R}_i(p)$ thereby contradicting (18).

To show monotonicity of \bar{R}_i we again argue by contradiction. Suppose there exist p and p' such that $p'_j \geq p_j$, $\forall j = 1, \dots, N-1$ but $\bar{R}_i(p) > \bar{R}_i(p')$. It follows then that

$$\begin{aligned}p'_m - \bar{R}_i(p') &> p_m - \bar{R}_i(p) \quad \forall (m, i) \in A, \\ \bar{R}_i(p') - p'_j &< \bar{R}_i(p) - p_j \quad \forall (i, j) \in A.\end{aligned}$$

Therefore

$$(23) \quad \nabla g_{mi}^*(p'_m - \bar{R}_i(p')) \geq \nabla g_{mi}^*(p_m - \bar{R}_i(p)) \quad \forall (m, i) \in A,$$

$$(24) \quad \nabla g_{ij}^*(\bar{R}_i(p') - p'_j) \leq \nabla g_{ij}^*(\bar{R}_i(p) - p_j) \quad \forall (i, j) \in A.$$

Since by definition we have

$$(25) \quad \sum_m \nabla g_{mi}^*(p'_m - \bar{R}_i(p')) = \sum_i \nabla g_{ij}^*(\bar{R}_i(p') - p'_j),$$

$$(26) \quad \sum_m \nabla g_{mi}^*(p_m - \bar{R}_i(p)) = \sum_j \nabla g_{ij}^*(\bar{R}_i(p) - p_j),$$

it follows that equality holds in (23), (24), i.e.

$$\begin{aligned}f_{mi} &\triangleq \nabla g_{mi}^*(p'_m - \bar{R}_i(p')) = \nabla g_{mi}^*(p_m - \bar{R}_i(p)), \\ f_{ij} &\triangleq \nabla g_{ij}^*(\bar{R}_i(p') - p'_j) = \nabla g_{ij}^*(\bar{R}_i(p) - p_j).\end{aligned}$$

Consider the intervals

$$I_{mi} = \{t \mid \nabla g_{mi}^*(t) = f_{mi}\}, \quad I_{ij} = \{t \mid \nabla g_{ij}^*(t) = f_{ij}\},$$

and let

$$\delta = \bar{R}_i(p) - \bar{R}_i(p').$$

We have for all $(m, i) \in A$

$$p'_m - \bar{R}_i(p') \in I_{mi}, \quad p_m - \bar{R}_i(p) \in I_{mi}$$

and since $p_m \leq p'_m$ we obtain

$$p_m - \bar{R}_i(p) \leq p'_m - \bar{R}_i(p') - \delta \leq p'_m - \bar{R}_i(p').$$

Therefore

$$p'_m - \bar{R}_i(p') - \delta \in I_{mi} \quad \forall (m, i) \in A$$

and similarly

$$\bar{R}_i(p') + \delta - p_j \in I_{ij} \quad \forall (i, j) \in A.$$

It follows that

$$\bar{R}_i(p') + \delta \in R_i(p')$$

thereby contradicting the maximal nature of \bar{R}_i [cf. (14)].

The proof of continuity and monotonicity of \bar{R}_i is analogous with the one just given for \bar{R}_i and is omitted. Q.E.D.

The monotonicity and continuity of the mappings \bar{R}_i and \bar{R}_i imply a thus far unreported and somewhat surprising property of the optimal dual solution set.

PROPOSITION 2. *Let Assumption 1 hold. There exist a maximal and a minimal optimal solution of the dual problem, i.e. there exist $\bar{p} \in P^*$ and $\underline{p} \in P^*$ such that*

$$(27) \quad \underline{p} \leq p \leq \bar{p} \quad \forall p \in P^*.$$

Proof. Since P^* is nonempty and compact it contains a noninferior element \bar{p} for which there is no vector $p \in P^*$ such that $p \neq \bar{p}$ and $p_i \geq \bar{p}_i$ for all i . From the definition of \bar{R}_i and the optimality of \bar{p} we have $\bar{p}_i \leq \bar{R}_i(\bar{p})$ for all i . Furthermore for all i the vector $(\bar{p}_1, \dots, \bar{p}_{i-1}, R_i(\bar{p}), \bar{p}_{i+1}, \dots, \bar{p}_N)$ belongs to P^* so from noninferiority of \bar{p} it follows that $\bar{R}_i(\bar{p}) \leq \bar{p}_i$. Therefore we have $\bar{p}_i = \bar{R}_i(\bar{p})$ for all i . Let now \tilde{p} be a price vector obtained from \bar{p} according to

$$\tilde{p}_i = \begin{cases} \bar{p}_i + \delta, & i = 1, \dots, N-1, \\ 0, & i = N, \end{cases}$$

where $\delta > 0$ is sufficiently large so that

$$(28) \quad \tilde{p} \geq p \quad \forall p \in P^*.$$

It is easily seen that we have $\bar{R}_i(\tilde{p}) \leq \tilde{p}_i$, for all i so, using the monotonicity of \bar{R}_i shown in Proposition 1, we obtain

$$(29) \quad \bar{p} \leq \bar{R}^{k+1}(\tilde{p}) \leq \bar{R}^k(\tilde{p}) \quad \forall k$$

where $\bar{R}: R^{N-1} \rightarrow R^{N-1}$ is the mapping

$$(30) \quad \bar{R}(p) = [\bar{R}_1(p), \dots, \bar{R}_{N-1}(p)]$$

and \bar{R}^k is the composition of \bar{R} with itself k times. From (29) we see that the sequence $\bar{R}^k(\tilde{p})$ converges to some \hat{p} and by continuity of \bar{R} we must have $\hat{p} = \bar{R}(\hat{p})$ as well as $\hat{p} \geq \bar{p}$. Since $\hat{p} = \bar{R}(\hat{p})$ implies that $\hat{p} \in P^*$ it follows from the choice of \bar{p} that $\hat{p} = \bar{p}$. Also from (28), (29) and the fact $p \leq \bar{R}(p)$ for all $p \in P^*$ we obtain $\hat{p} = \bar{p} \geq p$ for all $p \in P^*$ which shows that \bar{p} is a maximal element of P^* . The proof for existence of a minimal element \underline{p} is entirely similar. Q.E.D.

3. Convergence analysis of asynchronous relaxation. The model of distributed asynchronous computation we adopt is described in [11], [12]. With each node $i = 1, \dots, N-1$ we associate a processor that computes from time to time some element

of $R_i(p)$ (here p is the latest price vector available to processor i), and sets the price p_i to this element. This price is then communicated at some later time to all other processors. Computation and communication at the various processors need not be synchronized. The precise model is as follows.

At each time instant, node i can be in one of three possible states *compute*, *transmit*, or *idle*. In the compute state node i computes a new price p_i . In the transmit state node i communicates the price p_i obtained from its own latest computation to one or more nodes m ($m \neq i$). In the idle state node i does nothing related to the solution of the problem.

We assume that computation and transmission for each node takes place in time intervals $[t_1, t_2]$ with $t_1 < t_2$, but do not exclude the possibility that a node may be simultaneously transmitting to more than one node nor do we assume that the transmission intervals to these nodes have the same origin and/or termination. We also make no assumptions on the length, timing and sequencing of computation and transmission intervals other than the following.

Assumption 2. For every node i and time $t \geq 0$ there exists a time $t' > t$ such that $[t, t']$ contains at least one computation interval for i and at least one transmission interval from i to each node m such that $(m, i) \in A$ or $(i, m) \in A$.

Assumption 2 is very natural. It states in essence that no node “drops out of the algorithm” permanently—perhaps due to a hardware failure. Without this assumption there is hardly anything we can hope to prove.

Each node i has a buffer B_{im} for each $m \neq i$ where it stores the latest transmission from m , as well as a buffer B_{ii} where it stores its own price estimate p_i . The contents for each buffer B_{im} at time t are denoted $p_m^t(i)$. Thus $p_m^t(i)$ is, for every t, i and m an estimate of the price p_m available at node i at time t . It is important to realize in what follows that *the buffer contents $p_m^t(i)$, and $p_m^t(i')$ at two different nodes i and i' need not coincide at all times. If $i \neq m$ and $i' \neq m$ the buffer contents $p_m^t(i)$, and $p_m^t(i')$ need not coincide at any time t .* The vector of all buffer contents of node i is denoted $p'(i)$, i.e.,

$$p'(i) = \{p_m^t(i) \mid m = 1, \dots, N-1\}.$$

The rules according to which the buffer contents $p_m^t(i)$ are updated are as follows:

(1) If $[t_1, t_2]$ is a transmission interval from node m to node i , the contents of the buffer B_{im} at time t_1 are transmitted and entered in the buffer B_{im} at time t_2 , i.e.

$$(31) \quad p_m^{t_2}(i) = p_m^{t_1}(m).$$

(2) If $[t_1, t_2]$ is a computation interval for node i , the content of the buffer B_{ii} is replaced at time t_2 with an element of $R_i(p^t(i))$, i.e.

$$(32) \quad p_i^{t_2}(i) \in R_i(p^t(i)).$$

(3) The contents of a buffer B_{ii} can change only at the end of a computation interval for node i . The contents of a buffer B_{im} , $i \neq m$ can change only at the end of a transmission interval from m to i .

The algorithm based on (32) will be called *Asynchronous Relaxation Method (ARM)*.

Our objective is to derive conditions under which limit points of the sequences $\{p^t(i)\}$ are optimal solutions of the dual problem (5). The following proposition is our main result. The proof is based on a general convergence theorem given in [12] (see also [17]) and applicable to asynchronous iterative algorithms such as the one just described. The key property that makes asynchronous convergence possible is the monotonicity of the mappings \bar{R}_i and \underline{R}_i shown in Proposition 1. This property is also

present in dynamic programming models and has been similarly exploited to show the validity of asynchronous versions of the successive approximation method [11].

PROPOSITION 3. *Let Assumptions 1 and 2 hold. For any initial buffer contents $p^0(i) \in P$, $i = 1, \dots, N-1$, each limit point of the sequences $\{p'(i)\}$ generated by the ARM belongs to the set*

$$(33) \quad \bar{P} = \{p \mid p \leq p \leq \bar{p}\}$$

where \bar{p} and p are the maximal and minimal dual optimal solutions. In particular, if the reduced dual optimal solution set P^* consists of a unique vector p^* we have

$$(34) \quad \lim_{i \rightarrow \infty} p'(i) = p^*, \quad i = 1, \dots, N-1.$$

Proof. Let $p, \tilde{p} \in P$ be price vectors such that

$$p \leq p^0(i) \leq \tilde{p} \quad \forall i = 1, \dots, N-1$$

and such that

$$\begin{aligned} p &\leq \underline{R}(p) \leq p \leq \bar{p} \leq \bar{R}(\tilde{p}) \leq \tilde{p}, \\ \lim_{k \rightarrow \infty} \underline{R}^k(p) &= \underline{p}, \quad \lim_{k \rightarrow \infty} \bar{R}^k(\tilde{p}) = \bar{p}. \end{aligned}$$

(The existence of such vectors was established in the proof of Proposition 2.) Consider the sets

$$(35) \quad \bar{P}^k = \{p \mid \underline{R}^k(p) \leq p \leq \bar{R}^k(\tilde{p})\}, \quad k = 1, 2, \dots.$$

Note that the sequence $\{\bar{P}^k\}$ is nested and that the common intersection of the sequence is the set \bar{P} of (33).

We will apply now a convergence theorem given in [12, § 3] (or [17, Prop. 3.1]). According to this theorem the desired result will be proved if the following three conditions are satisfied. (Rather than consulting the references just cited, the reader may wish to think through the proof of this since it is rather simple.)

(a) If $p \in \bar{P}^k$ then for every i the vector p' with coordinates

$$p'_j = \begin{cases} p_j & \text{if } j \neq i, \\ R_i(p) & \text{if } j = i \end{cases}$$

(cf. equation (32) associated with computation at node i) also belongs to \bar{P}^k .

(b) If $p \in \bar{P}^k$ and $\hat{p} \in \bar{P}^k$ then, for every i and m , the vector p' with coordinates

$$p'_j = \begin{cases} p_j & \text{if } j \neq m, \\ \hat{p}_m & \text{if } j = m \end{cases}$$

(cf. equation (31) associated with transmission from node m to node i) also belongs to \bar{P}^k .

(c) If $p(1), \dots, p(N-1)$ belong to \bar{P}^k then the vector p' with coordinates

$$\begin{aligned} p'_j &= R_j(p(j)), \quad j = 1, \dots, N-1, \\ p'_N &= 0 \end{aligned}$$

(cf. a computation (32) at each node followed by a transmission to every other node) belongs to \bar{P}^{k+1} .

It is easily seen that all the conditions stated above are satisfied in our case so the desired conclusion follows. Q.E.D.

Proposition 3 shows that the ARM has satisfactory convergence when P^* has a unique element. One way to guarantee this is to consider the optimal solution f^* of the primal problem (1) and the set of arcs

$$\tilde{A} = \{(i, j) \in A \mid g_{ij} \text{ is differentiable at } f_{ij}^*\}.$$

Then, if the graph (N, \tilde{A}) is connected, P^* consists of a unique point in view of the complementary slackness condition (7). In order to improve the convergence properties when P^* has more than one point it is necessary to modify the ARM so that a computation at node i replaces p_i with $\bar{R}_i(p)$ (not just any element of $R_i(p)$). We call this the *maximal* ARM. If in place of $\bar{R}_i(p)$ we use $\underline{R}_i(p)$ the resulting method is called the *minimal* ARM.

PROPOSITION 4. *Let Assumptions 1 and 2 hold. Assume that the starting buffer contents satisfy*

$$(36) \quad p^0(i) \geq \bar{p} \quad \forall i = 1, \dots, N-1.$$

Then if $\{p'(i)\}$ is generated by the maximal ARM we have

$$(37) \quad \lim_{t \rightarrow \infty} p^t(i) = \bar{p}, \quad i = 1, \dots, N-1.$$

Proof. The proof is identical to the one of Proposition 3 except that the set \bar{P}^k of (35) should be replaced by

$$\bar{P}^k = \{p \mid \bar{p} \leq p \leq \bar{R}^k(\bar{p})\}. \quad \text{Q.E.D.}$$

There is a similar result for the minimal ARM whereby \bar{p} is replaced by \underline{p} and condition (36) is replaced by $p^0(i) \leq \underline{p}$ for all i . The following example demonstrates that the results of Proposition 3 and 4 cannot be improved.

Example. Consider the 3-node network shown in Fig. 2. The arc costs are

$$g_{12}(f_{12}) = (f_{12})^2, \quad g_{23}(f_{23}) = |f_{23}| + (f_{23})^2, \quad g_{31}(f_{31}) = |f_{31}| + (f_{31})^2$$

and the optimal primal solution is

$$f_{12}^* = f_{23}^* = f_{31}^* = 0.$$

The reduced dual optimal solution set is derived from condition (7) and is given by

$$P^* = \{p \mid p_3 = 0, p_1 = p_2, -1 \leq p_1 \leq 1, -1 \leq p_2 \leq 1\}.$$

The results of Proposition 3 and 4 are illustrated in Fig. 3. To see that the ARM as well as the maximal and minimal ARM may not converge to a dual optimal solution, let the buffer contents of processors 1 and 2 be both equal to $(-1, 1)$ and let both processors update the respective price coordinates and then exchange the results of the computation. Then the buffer contents will be $(1, -1)$, and by repeating this process one more time the buffer contents will become again $(-1, 1)$ thereby completing a cycle. Therefore in general we cannot expect convergence of the ARM to the optimal solution set if the latter contains more than one element. Similarly the maximal and

FIG. 2

FIG. 3. Structure of the optimal solution set, and convergence regions of the ARM, the maximal ARM, and the minimal ARM.

minimal ARM need not converge to \bar{p} and \tilde{p} respectively if the initial buffer contents do not belong to the appropriate regions [cf. (36)]. Note that this counterexample applies also to a synchronous Jacobi method.

MODULE THEORETIC ZERO STRUCTURES FOR SYSTEM MATRICES*

BOSTWICK F. WYMAN† AND MICHAEL K. SAIN‡

Abstract. The foundation for a coordinate-free theory of the poles of a linear dynamical system was laid in 1965 by the module-theoretic work of Kalman. However, although the theoretical and application importance of transfer function zeros for feedback system design was widely known for single input, single output systems by 1955, it remained for Rosenbrock in 1970 to propose the ideas of transmission zeros, input-decoupling zeros, and output-decoupling zeros for multi-input, multi-output systems, by means of matrix theoretic methods. A coordinate-free, module-theoretic treatment of transmission zeros for a multi-input, multi-output transfer function was given in 1981 by Wyman and Sain. This paper extends these coordinate-free, module-theoretic studies to include systems which need not be controllable or observable. Interpretation of the Rosenbrock system matrix is given on three levels: rational, finitely generated free-modular, and torsion divisible. On the second level, an Ω -Zero Module Z_Ω is defined and imbedded in a short exact sequence showing that the input-decoupling zero module is contained as a factor module in Z_Ω . On the third level, a Γ -Zero Module Z_Γ is defined and imbedded in a short exact sequence showing that the output-decoupling zero module is contained as a submodule in Z_Γ . Both structures are studied further in regard to transmission zero module information with emphasis on lumped zeros, and the cases of right and left invertible transfer functions are given in detail. Not surprisingly, these investigations can support considerable fine detail, which is in accord with the widely held belief that questions on the nature of multivariable zeros must be broadly based.

Key words. zeros, zero modules, system zeros

AMS(MOS) subject classifications. 93B25, 13C10

1. Introduction. This paper is a contribution to the algebraic theory of zeros of a linear multivariable system. The importance of zeros of transfer functions was well understood in classical design, reaching a high level of refinement in the well-known text of Truxal [27]. It can perhaps be said that the “modern era” of the theory of zeros of multivariable systems began with Rosenbrock [23]. In this work Rosenbrock defined the *transmission zeros*, *input-decoupling zeros* and *output-decoupling zeros* of a linear system. The transmission zeros describe properties of the input/output map associated with a system, and the decoupling zeros measure obstructions to the controllability and observability of the system itself.

Since Rosenbrock’s pioneering work, a number of authors have considered multivariable zeros from various points of view. Francis and Wonham [8] contains a summary and comparison of several different approaches, and another survey can be found in MacFarlane and Karcnias [19]. The book edited by Fallside [7] contains several papers dealing with both poles and zeros. An important dynamical interpretation appears in Desoer and Schulman [6]. There is a close connection between multivariable zeros and geometric control theory; see, for example, Wonham [30, Chap. 4]. Numerical computation of multivariable zeros has been treated in Davison and Wang [5], Laub and Moore [18] and Van Dooren [28]. Zeros of square systems are important in the work of Bart, et al. [2].

* Received by the editors July 3, 1984, and in revised form July 2, 1985. A brief preliminary report of some of the ideas, without proof, was presented in the Proceedings of the 20th Allerton Conference on Communication, Control, and Computing, which was supported by the National Aeronautics and Space Administration under grant NAG 2-34/35.

Following Kalman's module-theoretic work on the poles of a linear system, the authors introduced the notion of the multivariable *zero module* to capture the structure of the transmission zeros of a system in an economical, coordinate-free way; see Wyman and Sain [32], [34]. The zero module has also been considered by Fuhrmann and Hautus [11] and Conte and Perdon [4]. All of this work has been restricted to the module-theoretic study of *transmission* zeros. Horan [14] contains module-theoretic studies of certain types of decoupling zeros.

The note by Fuhrmann and Hautus [11] is particularly important as an inspiration for the present paper. Namely these authors establish that if $G(s) = C(sI - A)^{-1}B$, and if (A, B, C) is controllable and observable, then the zero module of the Rosenbrock system matrix is isomorphic to the zero module of $G(s)$ itself. This result, together with the earlier work of Rosenbrock and others, suggests the task of examining the zero module structures associated with the system matrix in general.

The goal of the present paper is to study the overall zeros of a system which need not be controllable or observable. Particular attention needs to be paid to the possible interactions of transmission and decoupling zeros. In order to study the internal structure of a system, it is first necessary to choose a method of describing the system structure. For the purposes of this paper we deal with the classical representation $(A, B, C, D(s))$ leading to the (not necessarily proper) transfer function matrix $G(s) = C(sI - A)^{-1}B + D(s)$. See § 2 for more details.

The *system matrix*

$$\Sigma = \begin{bmatrix} sI - A & B \\ -C & D(s) \end{bmatrix}$$

introduced in Rosenbrock [23] combines the crucial data of a linear multivariable system into an extraordinarily convenient and useful package. The goal of this paper is to study the coordinate-free meaning of the system matrix and, in so doing, to obtain a unified description of the different sorts of zeros a system can have and of how they fit together.

From a commutative algebra point of view, the main idea is that the system matrix really defines three very different abstract functions. First, it defines a linear transformation between two vector spaces over the field of rational functions. In this form it contains zero information of the most coarse kind, namely information about the kernel and cokernel of the transfer function $G(s)$. The second appearance of the system matrix is as a map between two free modules, and in this case the *cokernel* is an appropriate zero module construction. Third, the system matrix defines a module homomorphism between two (infinitely generated) torsion divisible modules. In this case the *kernel* of the mapping contains the appropriate zero information.

Section 2 of this paper contains preliminaries and notation; and it gives a brief review of abstract realization theory. Section 3 contains some required material about modules. Section 4 introduces the system matrix, presents some basic definitions, and discusses the $k(s)$ -vector space theory. Section 5 discusses the divisible module case. Highlights are a discussion of a natural module theory setting for Rosenbrock's output decoupling zeros and a discussion of the Desoer-Schulman blocked transmission philosophy extending Wyman and Sain [34] to nonminimal systems. A general discussion of the zero-module associated to the free-module system matrix interpretation is given in § 6. This section also contains a detailed discussion of Rosenbrock's input decoupling zeros. Section 7 studies right-invertible systems from the free-module point of view, and § 8 discusses left-invertible systems from the torsion-divisible module point of view.

Prerequisites and general references. To understand the technical results of this paper, the reader should be familiar with the theory of principal ideal domains and the general tools of commutative diagrams and exact sequences. Kalman [16], [17] introduced modules into system theory, emphasizing the role of poles and realization theory. More recent expositions can be found in Sain [25, Chap. 7] and Fuhrmann [9], [12]. The study of multivariable zeros by module-theoretic tools was begun by Wyman and Sain [32], [34]. The present work can best be viewed as a continuation of these papers.

A thorough introduction to finitely generated modules (used for states and inputs) appears in Hartley and Hawkes [13], and divisible modules (used for outputs) are discussed in Sharpe and Vamos [26]. More advanced material on modules, with emphasis on diagrams and exact sequences, can be found in Atiyah and MacDonald [1].

The system matrix was introduced in Rosenbrock [23] which contained precise definitions of zeros from a polynomial “invariant-factor” point of view. The system matrix has figured extensively in the subsequent literature, including Morf [22], Molinari [21], Fuhrmann [10], Verghese, et al. [29], Rosenbrock [24], and Kailath [15, Chap. 8].

2. Systems, modules, and the realization diagram. Suppose that k is a field, and that X , U , and Y are finite dimensional vector spaces over k . Let $A: X \rightarrow X$, $B: U \rightarrow X$, $C: X \rightarrow Y$, and $D_i: U \rightarrow Y$, $i = 0, \dots, l$ be k -linear transformations. The algebraic results of this paper are motivated by the study of the continuous-time system

$$\begin{aligned}\dot{x} &= Ax + Bu, \\ y &= Cx + D_0u + D_1\dot{u} + \dots + D_lu^{(l)}\end{aligned}$$

(if k is the real or complex field), and the discrete-time system

$$\begin{aligned}x(t+1) &= Ax(t) + Bu(t), \\ y(t) &= Cx(t) + D_0u(t) + D_1u(t+1) + \dots + D_lu(t+l)\end{aligned}$$

over an arbitrary field k .

Let s be an indeterminate, and denote by $k[s]$ the ring of polynomials and by $k(s)$ the field of rational functions in s over k . We will describe the dynamical behavior of systems in terms of modules over $k[s]$ and vector spaces over $k(s)$. If V is a finite dimensional vector space over k , then $V(s)$ is the $k(s)$ -vector space defined abstractly as a tensor product $V(s) = V \otimes_k k(s)$, or concretely as column vectors $k(s)^n$ if V is k^n .

Each system gives a *transfer function* $G(s): U(s) \rightarrow Y(s)$ which is a $k(s)$ -linear transformation given by

$$G(s) = C(sI - A)^{-1}B + D(s),$$

where $D(s) = D_0 + D_1(s) + \dots + D_ls^l$ considered as a $k(s)$ -linear transformation which can be defined by matrices with polynomial entries.

A detailed algebraic study of systems begins with the introduction of three quite different types of $k[s]$ -modules, which we may call modules of “state-type,” “input-type,” and “output-type.”

State modules are finite-dimensional vector spaces X over k which are equipped with a k -linear map $A: X \rightarrow X$, so that a $k[s]$ -module action can be defined by $p(s)x = p(A)x$ for every polynomial $p(s)$ in $k[s]$ and every x in X . Conversely, if V is a $k[s]$ -module on a finite-dimensional vector space over k , then multiplication by s induces a k -linear transformation A on V . Modules of this kind are *finitely-generated* and *torsion*.

Input modules are finitely-generated free modules. If U is an m -dimensional space over k , we denote by ΩU the free $k[s]$ -module given by $\Omega U = U \otimes_k k[s] \cong k[s]^m$. This module can be used to study inputs, since any k -linear map $B: U \rightarrow X$ extends in a natural way to a $k[s]$ -module map $\tilde{B}: \Omega U \rightarrow X$ defined by

$$\tilde{B}(u_0 + u_1 s + \cdots + u_r s^r) = Bu_0 + ABu_1 + \cdots + A^r Bu_r.$$

The image $\tilde{B}(\Omega U)$ of this map is called the “controllability subspace” of X , and the pair (A, B) is called “controllable” if $\tilde{B}(\Omega U) = X$. In any case, the image is an A -invariant subspace (or a submodule) and the cokernel $X/\tilde{B}(\Omega U)$ is called the “module of input-decoupling zeros” of (A, B) .

Output modules are less familiar. If Y is a p -dimensional space over k , we denote by ΓY the factor module $Y(s)/\Omega Y$, which makes sense since ΩY is a $k[s]$ -submodule of the set $Y(s)$ of rational vectors. An element of ΓY can be thought of as an equivalence class containing a unique strictly proper representative

$$y = y_1 s^{-1} + y_2 s^{-2} + \dots + y_n s^{-n} + \dots, y_i \text{ in } Y.$$

If $[y]$ denotes the equivalence class in ΓY containing y , then the action of s is given by

$$s[\mathbf{v}] = [v_2s^{-1} + v_3s^{-2} + \dots + v_ns^{-n+1} + \dots].$$

To use the module ΓY to study outputs, first define $\pi: \Gamma Y \rightarrow Y$ by $\pi[y] = y_1$ (the coefficient of s^{-1}). Then any k -linear map $C: X \rightarrow Y$ extends naturally to a $k[s]$ -module map $\tilde{C}: X \rightarrow \Gamma Y$ such that $\pi\tilde{C} = C$. Namely, $\tilde{C}x$ is the equivalence class in ΓY of $C(sI - A)^{-1}x = \sum_{i=0}^{\infty} CA^i x s^{-i-1}$. The kernel of \tilde{C} is called the submodule of unobservable states, or the module of "output-decoupling-zeros." Note that ΓY is a torsion divisible module. However, ΓY is not finitely generated, and there is no single polynomial which annihilates every member of ΓY .

All of the modules and spaces discussed so far fit together in the fundamental commutative *realization diagram* (Fig. 1). Here we denote by $i: \Omega U \rightarrow U(s)$ the inclusion map, and by $p: Y(s) \rightarrow \Gamma Y$ the natural projection, and we define $G^*: \Omega U \rightarrow \Gamma Y$ by $G^* = pGi$.

3. Module structure and the snake lemma. The theory of finitely generated (f.g.) modules has been used in algebraic system theory for some time. Here we only recall

FIG. 1

that every f.g. $k[s]$ -module is isomorphic to a direct sum $M \cong F \oplus T$, where F is a free module and T is a finite dimensional torsion module (that is, of state type). A thorough treatment of the corresponding structure theory for output modules (which are not finitely generated) can be found in Sharpe and Vamos [26], but the present discussion together with Conte and Perdon [3] should be adequate for system-theoretic applications. We will be considering modules of the form ΓW (W a finite dimensional space over k) together with their submodules. A module of the form ΓW is torsion and divisible, but not f.g. A submodule M of ΓW is necessarily torsion but not necessarily divisible, and M may be f.g. or not. A single element m of M is called divisible (in M) if for any polynomial $p(s)$ the equation $p(s)m' = m$ can be solved for m' (in M ! We know it can be solved in ΓW). The set of all divisible elements of M form a submodule M_{div} , the maximal divisible submodule of M . A general result assures that M is isomorphic to a direct sum: $M \cong M_{\text{div}} \oplus M/M_{\text{div}}$ (since divisible modules over a polynomial ring are *injective*). The factor module M/M_{div} is not f.g. in general, but it will be in the system-theoretic applications.

We proceed to an abstract discussion of "polynomial matrices." Suppose given two vector spaces V and W and a $k[s]$ -module map $T_\Omega: \Omega V \rightarrow \Omega W$. Then T_Ω induces a $k(s)$ -linear map $T(s): V(s) \rightarrow W(s)$. If bases are chosen, T_Ω can be represented by a polynomial matrix, and the same matrix gives the $k(s)$ -linear map $T(s)$. Finally, the map $T(s)$ maps ΩV to ΩW (by construction), so it gives a map $T_\Gamma: \Gamma V \rightarrow \Gamma W$ on equivalence classes. The moral is that a polynomial matrix defines three mappings with three different pairs of domains and ranges. These three mappings, T_Ω , $T(s)$, and T_Γ have very different algebraic properties. They appear in Fig. 2 whose horizontal rows are exact sequences. The two center columns are short exact sequences.

The kernels and cokernels of these maps are related by the "Snake Lemma" which provides a six term exact sequence:

$$\begin{aligned} 0 \rightarrow \ker T_\Omega &\xrightarrow{\bar{i}_v} \ker T(s) \xrightarrow{\bar{\pi}_v} \ker T_\Gamma \xrightarrow{\Delta} \text{coker } T_\Omega \\ &\xrightarrow{\bar{i}_w} \text{coker } T(s) \xrightarrow{\bar{\pi}_w} \text{coker } T_\Gamma \rightarrow 0. \end{aligned}$$

$$\begin{array}{ccccccc} & & 0 & & 0 & & \\ & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \ker T_\Omega & \longrightarrow & \Omega V & \xrightarrow{T_\Omega} & \Omega W \longrightarrow \text{coker } T_\Omega \longrightarrow 0 \\ & & \downarrow \bar{i}_v & & \downarrow i_v & & \downarrow i_w & & \downarrow \bar{i}_w \\ 0 & \longrightarrow & \ker T(s) & \longrightarrow & V(s) & \xrightarrow{T(s)} & W(s) \longrightarrow \text{coker } T(s) \longrightarrow 0 \\ & & \downarrow \bar{\pi}_v & & \downarrow \pi_v & & \downarrow \pi_w & & \downarrow \bar{\pi}_w \\ 0 & \longrightarrow & \ker T_\Gamma & \longrightarrow & \Gamma V & \xrightarrow{T_\Gamma} & \Gamma W \longrightarrow \text{coker } T_\Gamma \longrightarrow 0 \\ & & & & \downarrow & & \downarrow & & \\ & & & & 0 & & 0 & & \end{array}$$

FIG. 2

The proof, which can be found, for example, in Atiyah and MacDonald [1, p. 23], supplies explicit constructions for all the mappings.

4. The system matrix and the internal zeros of a system. Suppose given, as in § 2, a field k , vector spaces U , X , and Y , k -linear maps $A: X \rightarrow X$, $B: U \rightarrow X$, $C: X \rightarrow Y$, and a $k[s]$ -module map $D_\Omega: \Omega U \rightarrow \Omega Y$. The map D_Ω gives also a $k(s)$ -linear map $D(s): U(s) \rightarrow Y(s)$. We refer to these data as a system $\Sigma = (A, B, C, D(s))$ with transfer function $G(s) = C(sI - A)^{-1}B + D(s)$, $G(s): U(s) \rightarrow Y(s)$.

The (Rosenbrock) *System Matrix* of this system, written symbolically

$$\Sigma = \begin{bmatrix} sI - A & B \\ -C & D(s) \end{bmatrix}$$

is a $k(s)$ -linear map

$$\Sigma: X(s) \oplus U(s) \rightarrow X(s) \oplus Y(s).$$

Recalling that $D(s)$ comes from a polynomial matrix map D_Ω , we see that the system matrix also defines two $k[s]$ -module maps

$$\Sigma_\Omega: \Omega X \oplus \Omega U \rightarrow \Omega X \oplus \Omega Y,$$

$$\Sigma_\Gamma: \Gamma X \oplus \Gamma U \rightarrow \Gamma X \oplus \Gamma Y.$$

These maps are shown together in the exact commutative diagram of Fig. 3. These two mappings can be used to define two kinds of "internal zero module" for the given system.

MAIN DEFINITION. Let $\Sigma = (A, B, C, D(s))$ be a system with System Matrix Σ .

(a) The Ω -Zero Module of Σ is $Z_\Omega = \text{coker } \Sigma_\Omega$.

(b) The Γ -Zero Module of Σ is $Z_\Gamma = \ker \Sigma_\Gamma$.

According to the Snake Lemma, we have a six term exact sequence which relates these two modules:

$$0 \rightarrow \ker \Sigma_\Omega \rightarrow \ker \Sigma \rightarrow \ker \Sigma_\Gamma \xrightarrow{\Delta} \text{coker } \Sigma_\Omega \rightarrow \text{coker } \Sigma \rightarrow \text{coker } \Sigma_\Gamma \rightarrow 0.$$

As a corollary of the Snake Lemma, we can write

$$Z_\Gamma = (\text{torsion divisible module}) \oplus M_1.$$

$$Z_\Omega = (\text{f.g. free module}) \oplus M_2.$$

Here M_1 and M_2 are isomorphic f.g. torsion modules (that is, of state-type) which should be thought of as the "lumped" zeros of the system. The other components

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \ker \Sigma_\Omega & \longrightarrow & \Omega X \oplus \Omega U & \xrightarrow{\Sigma_\Omega} & \Omega X \oplus \Omega Y & \longrightarrow & \text{coker } \Sigma_\Omega \longrightarrow 0 \\ & & & & \downarrow i_{XU} & & \downarrow i_{XY} & & \\ 0 & \longrightarrow & \ker \Sigma & \longrightarrow & X(s) \oplus U(s) & \xrightarrow{\Sigma} & X(s) \oplus Y(s) & \longrightarrow & \text{coker } \Sigma \longrightarrow 0 \\ & & & & \downarrow \pi_{XU} & & \downarrow \pi_{XY} & & \\ 0 & \longrightarrow & \ker \Sigma_\Gamma & \longrightarrow & \Gamma X \oplus \Gamma U & \xrightarrow{\Sigma_\Gamma} & \Gamma X \oplus \Gamma Y & \longrightarrow & \text{coker } \Sigma_\Gamma \longrightarrow 0 \end{array}$$

FIG. 3

represent different sorts of “generic zeros” and deserve a great deal of further study. In this section we characterize the rational vector spaces $\ker \Sigma$ and $\operatorname{coker} \Sigma$ as a first step in our analysis. In later sections we study the zero modules Z_Ω and Z_Γ .

THEOREM 1. *Suppose given a system $\Sigma = (A, B, C, D(s))$ with system matrix Σ and transfer function $G(s)$. Then there are $k(s)$ -vector space isomorphisms*

$$\ker \Sigma \cong \ker G(s),$$

$$\operatorname{coker} \Sigma \cong \operatorname{coker} G(s).$$

In particular, Σ is monic if and only if $G(s)$ is monic, and Σ is epic if and only if $G(s)$ is epic.

Proof. We define a mapping $\alpha: U(s) \rightarrow X(s) \oplus U(s)$ by $\alpha(u(s)) = (-(sI - A)^{-1}Bu(s), u(s))$. Then α is $k(s)$ -linear and monic, and a straightforward calculation shows that α on $\ker G(s)$ is epic on to $\ker \Sigma$.

To establish the isomorphism of cokernels, we first define a map

$$\beta: X(s) \oplus Y(s) \rightarrow Y(s)/G(s)U(s)$$

by $\beta(x(s), y(s)) \equiv y(s) + C(sI - A)^{-1}x(s) \pmod{G(s)U(s)}$. Since β is obviously epic, we must show that $\beta(x(s), y(s)) = 0$ if and only if $(x(s), y(s)) = \Sigma(x_0(s), u(s))$ for some $(x_0(s), u(s))$ in $X(s) \oplus U(s)$. We omit this calculation, which shows that the following sequence is exact:

$$X(s) \oplus U(s) \xrightarrow{\Sigma} X(s) \oplus Y(s) \xrightarrow{\beta} Y(s)/G(s)U(s) \rightarrow 0.$$

In other words, $\operatorname{coker} \Sigma \cong Y(s)/G(s)U(s) = \operatorname{coker} G(s)$.

5. Blocked transmissions and the Γ -zero module. In this section we relate the Γ -Zero Module to a set of strictly proper input signals which can be blocked by the output of a suitably chosen initial state. As a dividend, the output-decoupling zeros of the system are identified as a submodule of the Γ -zeros. In the case of minimal systems, the blocking result follows from Wyman and Sain [34].

The system $\Sigma = (A, B, C, D(s))$ gives rise to a $k(s)$ -linear transfer function $G(s): U(s) \rightarrow Y(s)$, and also (from Fig. 1) a $k[s]$ -module map $G^*: \Omega U \rightarrow \Gamma Y$. In this section we must consider a third version of the transfer function adapted to strictly proper input signals.

Consider the exact $k[s]$ -module sequence

$$0 \rightarrow \Omega U \rightarrow U(s) \xrightarrow{\pi_u} \Gamma U \rightarrow 0.$$

Let γ be an equivalence class in ΓU , with strictly proper representative u_γ . The map $\sigma: \Gamma U \rightarrow U(s)$ defined by $\sigma(\gamma) = u_\gamma$ is a k -linear map satisfying $\pi_u \circ \sigma = \operatorname{id}_{\Gamma U}$, but it is not $k[s]$ or $k(s)$ -linear. Nevertheless, we define the map $G_\# = \pi_y \circ G(s) \circ \sigma$, yielding the commutative diagram (Fig. 4):

$$\begin{array}{ccc} & U(s) & \xrightarrow{G(s)} & Y(s) \\ \sigma \nearrow & & & \searrow \pi_y \\ \Gamma U & \xrightarrow{G_\#} & & \Gamma Y \end{array}$$

FIG. 4

We say that a strictly proper input $[\mathbf{u}]$ can be *blocked* by the output of a state x_0 in X (compare Wyman and Sain [34] and Desoer and Schulman [6]) if $G_*[\mathbf{u}] + \tilde{C}x_0 = 0$, where $\tilde{C}: X \rightarrow \Gamma Y$ is the output map from Fig. 1. We denote the set of all blockable-signal equivalence classes by $Z_{\text{signal}} \subset \Gamma U$. That is,

$$Z_{\text{signal}} = \{\gamma: G_*\gamma + \tilde{C}x_0 = 0 \text{ for some } x_0 \text{ in } X\}.$$

Since G_* is only k -linear, a little work is required to show that Z_{signal} is a module. Calculations very similar to results in [34] establish that Z_{signal} is a $k[s]$ -submodule of ΓU .

Consider the projection map $p_2: \Gamma X \oplus \Gamma U \rightarrow \Gamma U$ defined by $p_2([\mathbf{x}], [\mathbf{u}]) = [\mathbf{u}]$. Recall that $Z_\Gamma = \ker \Sigma_\Gamma$ is a submodule of $\Gamma X \oplus \Gamma U$. We claim that p_2 maps Z_Γ onto $Z_{\text{signal}} \subset \Gamma U$. Suppose that $([\mathbf{x}], [\mathbf{u}])$ lies in $\ker \Sigma_\Gamma$, or that

$$\begin{bmatrix} sI - A & B \\ -C & D(s) \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \mathbf{u} \end{bmatrix} \equiv 0 \pmod{\Omega X \oplus \Omega Y}.$$

In particular there is a polynomial vector x_{poly} in ΩX such that $(sI - A)\mathbf{x} + B\mathbf{u} = x_{\text{poly}}$. In fact, a degree argument shows that $x_{\text{poly}} = x_0$ in X since \mathbf{x} and \mathbf{u} are strictly proper. Then $\mathbf{x} = -(sI - A)^{-1}B\mathbf{u} + (sI - A)^{-1}x_0$. Also,

$$\begin{aligned} -C\mathbf{x} + D(s)\mathbf{u} &= y_{\text{poly}}, \\ G(s)\mathbf{u} - C(sI - A)^{-1}x_0 &= y_{\text{poly}}, \\ G_*[\mathbf{u}] - \tilde{C}x_0 &\equiv 0 \pmod{\Omega Y} \end{aligned}$$

which shows that $[\mathbf{u}]$ lies in Z_{signal} .

Conversely, if γ in ΓU satisfies $G_*\gamma - \tilde{C}x_0 = 0$, write $\mathbf{u} = \sigma(\gamma)$ and let $\mathbf{x} = -(sI - A)^{-1}B\mathbf{u} + (sI - A)^{-1}x_0$. Then it follows that $([\mathbf{x}], \gamma)$ lies in $\ker \Sigma_\Gamma$ and $p_2([\mathbf{x}], \gamma) = \gamma$. That is, $p_2: \ker \Sigma_\Gamma \rightarrow Z_{\text{signal}}$ is a $k[s]$ -module epimorphism.

To identify the kernel of p_2 , suppose $p_2([\mathbf{x}], [\mathbf{u}]) = 0$ in ΓU . Then $[\mathbf{u}] = 0$ in ΓU , and

$$\begin{bmatrix} sI - A & B \\ -C & D(s) \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ 0 \end{bmatrix} \equiv \begin{bmatrix} 0 \\ 0 \end{bmatrix} \pmod{\Omega X \oplus \Omega Y}.$$

From $(sI - A)[\mathbf{x}] = 0$ in ΓX , it follows as above that $(sI - A)\mathbf{x} = x_0$ for some state x_0 in X , or that $\mathbf{x} = (sI - A)^{-1}x_0$. Also $\tilde{C}x_0 = C(sI - A)^{-1}x_0 = 0$ in ΓY , so that x_0 is an *unobservable* state. That is

$$\ker p_2 = \{(\mathbf{x}, 0): \mathbf{x} = (sI - A)^{-1}x_0 \text{ and } \tilde{C}x_0 = 0\}.$$

Following Rosenbrock [23, p. 65] it is reasonable to call the set of unobservable states the *output-decoupling zero module*

$$Z_{\text{o.d.}} = \{x \text{ in } X: \tilde{C}x = 0\}.$$

To establish the connection between this module and Rosenbrock's definition, consider the polynomial matrix

$$\mathbf{C} = \begin{bmatrix} sI - A \\ C \end{bmatrix},$$

which defines two $k[s]$ -module maps $C_\Omega: \Omega X \rightarrow \Omega X \oplus \Omega Y$, and $C_\Gamma: \Gamma X \rightarrow \Gamma X \oplus \Gamma Y$. It is not difficult to prove that $\ker C_\Gamma \cong \ker \tilde{C}$ as $k[s]$ -modules.

Rosenbrock defined output decoupling zeros in terms of the invariant factors of \mathbf{C} . The usual view is that the invariant factors of \mathbf{C} describe the structure of the module $\text{coker } C_\Omega$. However, an application of the Snake Lemma shows immediately that $\ker C_\Gamma$

is isomorphic to the torsion submodule of $\text{coker } C_\Omega$. This justifies the name $Z_{\text{o.d.}}$ for $\ker \tilde{C}$, and allows us to summarize this section with the following theorem.

THEOREM 2. *Suppose given a system $\Sigma = (A, B, C, D(s))$ with transfer function $G(s) = C(sI - A)^{-1}B + D(s)$. Let $\tilde{C}: X \rightarrow \Gamma Y$ be the observability map, let $Z_{\text{o.d.}} = \ker \tilde{C}$ be the output-decoupling zero module. Let $Z_\Gamma = \ker \Sigma_\Gamma$ be the Γ -zero module defined by the system matrix Σ , and let Z_{signal} be the module of strictly proper input signals which can be blocked by states of X . Then there is an exact sequence*

$$0 \rightarrow Z_{\text{o.d.}} \rightarrow Z_\Gamma \rightarrow Z_{\text{signal}} \rightarrow 0.$$

In particular, if Σ is observable, then Z_Γ and Z_{signal} are isomorphic $k[s]$ -modules.

6. The Ω -zero module. We begin with a brief discussion of input-decoupling zeros (Rosenbrock [23, p. 64]). Suppose given $A: X \rightarrow X$ and $B: U \rightarrow X$ as usual. Consider the $k[s]$ -module map $[sI - A \ B]: \Omega X \oplus \Omega U \rightarrow \Omega X$ defined by

$$[sI - A \ B] \begin{bmatrix} x(s) \\ u(s) \end{bmatrix} = (sI - A)x(s) + Bu(s).$$

An exercise in diagram chasing establishes that the cokernel of $[sI - A \ B]$ is isomorphic to the cokernel of the controllability map $\tilde{B}: \Omega U \rightarrow X$, or that

$$\Omega X / [sI - A \ B](\Omega X \oplus \Omega U) \cong X / \tilde{B}(\Omega U).$$

Since Rosenbrock refers to the invariant factors of $[sI - A \ B]$ as “input-decoupling zeros” it is reasonable to call $\text{coker } [sI - A \ B]$ or, equivalently, $X / \tilde{B}(\Omega U)$, the *input-decoupling zero module* $Z_{\text{i.d.}}$ of the system.

The following theorem, whose proof parallels § 5 and is therefore omitted, summarizes the Ω -results.

THEOREM 3. *Suppose given a system $(A, B, C, D(s))$ with transfer function $G(s) = C(sI - A)^{-1}B + D(s)$. Let $\tilde{B}: \Omega U \rightarrow X$ be the reachability map, and consider $\ker \tilde{B} \subset \Omega U$ and $\text{coker } \tilde{B} = Z_{\text{i.d.}}$, the input-decoupling zero module. Let $Z_\Omega = \text{coker } \Sigma_\Omega$ be the Ω -Zero Module, defined using the system matrix Σ . Then there is an exact sequence of $k[s]$ -modules*

$$0 \rightarrow \Omega Y / G(s)(\ker \tilde{B}) \xrightarrow{i} Z_\Omega \xrightarrow{j} Z_{\text{i.d.}} \rightarrow 0$$

where i and j are induced from the maps

$$i(y) = \begin{bmatrix} 0 \\ y \end{bmatrix} \bmod \Sigma_\Omega(\Omega X \oplus \Omega U),$$

$$j \begin{bmatrix} x \\ y \end{bmatrix} = x \bmod \tilde{B}(\Omega U).$$

The first term of the exact sequence can be put in a more familiar form using coprime factorization theory. Suppose $G(s) = P(s)Q^{-1}(s)$ is a coprime factorization with $Q(s): \Omega U \rightarrow \Omega U$ and $P(s): \Omega U \rightarrow \Omega Y$, with $\ker \tilde{B} = Q(s)\Omega U$ and $G(s)(\ker \tilde{B}) = P(s)\Omega U \subset \Omega Y$. Then $\Omega Y / G(s)(\ker \tilde{B}) \cong \Omega Y / P(s)\Omega U$. For minimal systems, this calculation agrees with an earlier description of the (transmission) zero module given in Wyman and Sain [32] for transfer functions (and therefore minimal systems).

7. The Ω -zero module for right-invertible systems. Suppose the system $\Sigma = (A, B, C, D(s))$ has a right-invertible transfer function $G(s) = C(sI - A)^{-1}B + D(s)$. That is, $G(s)$ is epic as a $k(s)$ -linear transformation, so according to Theorem 1, $\text{coker } \Sigma = 0$, where Σ is the $k(s)$ -form of the system matrix, Z_Ω is a torsion module.

According to the exact sequence of Theorem 3, with $Z_1 = \Omega Y / G(s)(\ker \tilde{B})$,

$$0 \rightarrow Z_1 \xrightarrow{i} Z_\Omega \xrightarrow{j} Z_{i.d.} \rightarrow 0.$$

To study Z_1 , consider the transmission zeros of a transfer function $G(s)$ (Wyman and Sain [32])

$$Z(G) = \frac{G^{-1}(\Omega Y) + \Omega U}{\ker G + \Omega U}.$$

If $G(s)$ is right-invertible, an alternative description holds. There is an isomorphism of $k[s]$ -modules

$$Z(G) \cong \Omega Y / G(s)(\ker G^*)$$

where $G^* : \Omega U \rightarrow \Gamma Y$ is the restricted input/output map of realization theory as described in Fig. 1. To verify this isomorphism, consider the basic result

$$Z(G) \cong G^{-1}(\Omega Y) / G^{-1}(\Omega Y) \cap (\ker G + \Omega U).$$

Roughly speaking, the map $G : G^{-1}(\Omega Y) \rightarrow \Omega Y$ induces the required isomorphism: $Z(G) \rightarrow \Omega Y / G(s)(\ker G^*)$. The technical details are omitted.

Since $G^* = \tilde{C} \circ \tilde{B}$, from Fig. 1, it follows that $\ker \tilde{B} \subset \ker G^*$, giving a natural projection

$$\pi : \Omega Y / G(s)(\ker \tilde{B}) \rightarrow \Omega Y / G(s)(\ker G^*),$$

or, using earlier notation:

$$\pi : Z_1 \rightarrow Z(G).$$

If the system is observable, then \tilde{C} is monic and $\ker \tilde{B} = \ker G^*$, showing that π is the identity map in this case. We can summarize the work so far:

THEOREM 4. *Suppose $\Sigma = (A, B, C, D(s))$ is an observable system with right-invertible transfer function $G(s)$. Then there is an exact sequence*

$$0 \rightarrow Z(G) \rightarrow Z_\Omega \rightarrow Z_{i.d.} \rightarrow 0,$$

in which Z_Ω is the (finitely generated torsion) Ω -Zero Module, $Z(G)$ is the transmission zero module, and $Z_{i.d.}$ is the input decoupling zero module.

If the system is not observable, it will be necessary to examine the kernel of $\pi : Z_1 \rightarrow Z(G)$. Call the kernel Z_2 and consider the exact sequence

$$0 \rightarrow Z_2 \rightarrow Z_1 \xrightarrow{\pi} Z(G) \rightarrow 0.$$

It is easy to establish that

$$Z_2 \cong \frac{G(s)(\ker G^*)}{G(s)(\ker \tilde{B})}.$$

The study of Z_2 is technical, but if $\ker \tilde{C} \cap X_{rch}$ is the space of reachable, unobservable states, there is an epimorphism

$$\beta : \ker \tilde{C} \cap X_{rch} \rightarrow Z_2$$

defined by $\beta(x) \equiv G(s)u \pmod{G(s)(\ker \tilde{B})}$, whenever $x = \tilde{B}u$.

We do not proceed to compute $\ker \beta$ in general, although several examples are included at the end of this section to show that β is not necessarily monic. The results can be summarized in the following refinement of Theorem 4.

THEOREM 5. *Suppose a system is given with right invertible transfer function $G(s)$. Then Z_Ω is a torsion module, and there are two exact sequences:*

$$\begin{aligned} 0 \rightarrow Z_1 \rightarrow Z_\Omega \rightarrow Z_{i.d.} \rightarrow 0, \\ 0 \rightarrow Z_2 \rightarrow Z_1 \rightarrow Z(G) \rightarrow 0 \end{aligned}$$

and an epimorphism

$$\beta : Z_{o.d.} \cap X_{rch} \rightarrow Z_2 \rightarrow 0.$$

The map β is an isomorphism if $G(s)$ is a square invertible transfer function, but otherwise it may have a kernel.

Although Theorems 4 and 5 are quite technical, several intuitive conclusions can be drawn. If $G(s)$ is right invertible, then Z_Ω and the modules related to it have no free part, so they are intuitive system-theoretic objects. The module Z_Ω contains the input-decoupling zeros as a factor module, and it also contains the transmission zeros as a subfactor (that is, as a factor module of a submodule). This means in particular that all the numerical input decoupling and transmission zeros really correspond to rank drops of the system matrix. On the other hand, the output decoupling zeros affect Z_Ω in a more complicated way. Modes of the system which are both uncontrollable and unobservable occur in the Ω -Zero Module only once (by virtue of being input zeros). Finally, since the map β discussed above need not be monic, under some conditions output decoupling zeros do not appear as rank drops in the system matrix. This phenomenon is related to the kernel of $G(s)$ as a map of vector spaces.

The rest of this section consists of examples illustrating some of the phenomena.

Example 1. Consider the system (A, b, c^T) with

$$A = \begin{bmatrix} a_1 & 0 \\ 0 & a_2 \end{bmatrix}, \quad b = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad c^T = [0 \quad 1],$$

where $a_1 \neq a_2$. The corresponding transfer function is $g(s) = 1/(s - a_2)$, with transmission zero module $Z(g) = (0)$. Smith-form calculations give (up to isomorphism) $Z_\Omega \cong Z_{i.d.} \cong Z_{o.d.} \cong k[s]/(s - a_1)$. That is, the mode corresponding to a_1 is both unreachable and unobservable, but it is only counted once in Z_Ω .

Since $Z_{o.d.} \cap X_{rch} = (0)$, Theorem 5 implies that $Z_2 = (0)$, so that $Z_1 \cong Z(g) = (0)$, which implies that $j: Z_\Omega \rightarrow Z_{i.d.}$ is an isomorphism. This calculation is an explicit alternative to Smith form calculations.

Example 2. Consider the system (A, b, c^T) given by

$$A = \begin{bmatrix} -1 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -3 \end{bmatrix}, \quad b = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}, \quad c^T = [1 \quad 1 \quad 1].$$

The transfer function is

$$g(s) = \frac{2(s+2)}{(s+1)(s+3)}$$

and the transmission-zero module is

$$Z(g) \cong k[s]/(s+2).$$

The system is observable, but the mode with eigenvalue -2 is unreachable, so:

$$Z_{i.d.} \cong k[s]/(s+2); \quad Z_{o.d.} = (0).$$

Theorem 4 applies, so Z_Ω fits into the exact sequence

$$0 \rightarrow Z(g) \rightarrow Z_\Omega \rightarrow Z_{\text{i.d.}} \rightarrow 0.$$

From this information alone, there are just two possibilities for Z_Ω , namely

$$(a) \quad \text{“split”} \quad Z_\Omega \cong k[s]/(s+2) \oplus k[s]/(s+2),$$

or

$$(b) \quad \text{“not split”} \quad Z_\Omega \cong k[s]/(s+2)^2.$$

In this case, Z_Ω is not split. On the other hand, if the output map is changed to $C^T = (1, 0, 1)$, then the analysis is the same up to the exact sequence, but Z_Ω splits!

Example 3. This example shows that the map β of Theorem 5 is not necessarily monic. Consider (A, B, c^T) ,

$$A = \begin{bmatrix} a_1 & 0 \\ 0 & a_2 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad c^T = [1 \quad 0]$$

with

$$G(s) = \begin{bmatrix} \frac{1}{s-a_1} & 0 \end{bmatrix},$$

$$Z(G) = (0),$$

$$Z_{\text{i.d.}} = (0),$$

$$Z_{\text{o.d.}} = k[s]/(s-a_2).$$

Direct calculation shows that $Z_\Omega = 0$, so (in the notation of Theorem 5) Z_1 and Z_2 are both zero. On the other hand, $X_{\text{rch}} = X$, so $Z_{\text{o.d.}} \cap X_{\text{rch}} = Z_{\text{o.d.}} \neq (0)$, and β is not monic.

8. The Γ -zero module for left-invertible systems. In this section we state results analogous to those in § 7.

Assume given a system $\Sigma = (A, B, C, D(s))$ which has a left-invertible transfer function $G(s)$. That is, $G(s)$ is monic, and according to § 4 so is the $k(s)$ -linear transformation corresponding to the system matrix Σ . It follows that the Γ -Zero Module Z_Γ is finitely generated and isomorphic to the torsion submodule of Z_Ω . From Theorem 2, § 5, we recall the exact sequence

$$0 \rightarrow Z_{\text{o.d.}} \rightarrow Z_\Gamma \rightarrow Z_{\text{signal}} \rightarrow 0.$$

The inclusion $Z_{\text{o.d.}} \rightarrow Z_\Gamma$ shows that Z_Γ contains information about the output-decoupling zeros. Define $\tilde{B}_1 = p \circ \tilde{B}$, for p the natural projection onto $X/\ker \tilde{C}$.

The analogue of Theorem 5 consists of two exact sequences.

THEOREM 6. *Suppose given a system with left-invertible transfer function $G(s)$. Then Z_Γ is a torsion module, and there are two exact sequences:*

$$0 \rightarrow Z_{\text{o.d.}} \rightarrow Z_\Gamma \rightarrow Z_{\text{signal}} \rightarrow 0,$$

$$0 \rightarrow Z(G) \rightarrow Z_{\text{signal}} \xrightarrow{\bar{\alpha}} X_{\text{obs}}/\tilde{B}_1(\Omega U).$$

If $G(s)$ is square and invertible, then $\bar{\alpha}$ is epic, but in general, $\bar{\alpha}$ may not be epic.

Example. Consider the system (A, b, C)

$$A = \begin{bmatrix} a_1 & 0 \\ 0 & a_2 \end{bmatrix}, \quad b = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix},$$

with transfer function

$$G(s) = \begin{bmatrix} 1/(s - a_1) \\ 0 \end{bmatrix}$$

which is monic but not epic. It is easy to see that

$$Z(G) = Z_{o.d.} = (0),$$

$$Z_{i.d.} \cong k[s]/(s - a_2).$$

A Smith-form calculation gives

$$Z_\Omega \cong k[s],$$

a free module of rank 1. Since Z_Γ is isomorphic to the torsion submodule of Z_Ω , we get

$$Z_\Gamma = (0).$$

Also (see Theorem 6 above) $Z_{\text{signal}} = 0$, but $X_{\text{obs}}/\tilde{B}_1(\Omega U) \cong Z_{i.d.} \neq (0)$, so $\bar{\alpha}$ is not epic in this case.

9. Conclusions. The modern, coordinate-free approach to studying poles of linear dynamical systems was set into motion by Kalman [16]. Wyman and Sain [32], [34] proposed a module-theoretic treatment of transmission zeros for transfer functions in an analogous manner.

This paper extends these module theoretic studies to systems which need not be controllable or observable. The Rosenbrock system matrix is studied on three levels: rational, finitely generated free-modular, and torsion divisible. Two zero modules, Z_Ω and Z_Γ , are defined on the system level; and exact sequences are developed to relate them to modules of input-decoupling zeros and output-decoupling zeros. In the cases for which the system transfer function has a right or a left inverse, certain of the fine zero structures have been specially examined.

The modules Z_Ω and Z_Γ may be expected to capture the key concepts which may be advanced in a coordinate-free study of zero module structures for the Rosenbrock system matrix. Not surprisingly, these concepts admit considerable depth of analysis, which indicates that the notion of zero is a rich system theoretic area for research.

Finally, if $G(s) = P(s)D^{-1}(s)Q(s) + R(s)$ is a polynomial matrix description, then the corresponding system matrix is

$$\begin{bmatrix} D(s) & Q(s) \\ -P(s) & R(s) \end{bmatrix}.$$

Most of the present paper can be extended immediately to this case.

PARAMETER ESTIMATION, REGULARITY AND THE PENALTY METHOD FOR A CLASS OF TWO POINT BOUNDARY VALUE PROBLEMS*

K. KUNISCH[†] AND L. W. WHITE[‡]

Abstract. We study a penalization technique for a class of parameter estimation problems associated with elliptic equations. Moreover, a regularization phenomenon of the minimizers is discussed for various parameters in the equation and for different observation operators. Finally it is shown that under weak assumptions the norm constraints are active.

Key words. inverse problems, least squares, regularity of solution

AMS(MOS) subject classifications. 35R25, 35R30

1. Introduction. In this paper we study parameter estimation problems and their approximations for a simple class of two point boundary value problems. We use the output-least-squares approach and formulate the parameter estimation problem as a constrained optimization problem. Two distinct kinds of constraints arise: certain pointwise constraints on the coefficients guarantee well-posedness of the equation, whereas norm bounds are used to argue existence of the solution of the optimization problem. When the original infinite dimensional problem is approximated by finite dimensional problems, then these constraints need to be translated to conditions on the elements in the subspaces that approximate the sets of admissible coefficients. This can lead to quite involved technicalities [8]. When solving the approximate optimization problems with a computer it is natural at first to try to ignore these constraints and to use one of the many available software packages for unconstrained optimization. This approach is successful for some problems ([2], [3] et al.) but can lead to serious difficulties with others. Some examples illustrating this point are given in § 6, where it is shown that the numerical solution or the optimal (i.e. "identified") parameter may exhibit extraneous oscillations or may not converge at all, when only unconstrained optimization is carried out. One of the possibilities to overcome such difficulties is to use a regularization approach, see [4], [7] for example. Other possibilities include the use of constrained optimization routines or a penalty function approach. In this paper we investigate the latter. More specifically, we transform the norm bounds to penalization terms and keep the pointwise bounds (which are more readily implemented on a computer) as explicit constraints. Such a penalty function technique is shown to be effective both theoretically and numerically; we show for our model equation that a satisfactory convergence theory can be obtained and that in problems that did not converge or contained the above mentioned oscillations, the implementation of the norm constraint as a penalty term led to successful numerical results.

The motivation for considering a boundary value problem is that it serves as a technically simple example to demonstrate some of the special behavior that optimization problems arising from parameter estimation problems have, in addition to being of practical relevance, see [2], for instance, for a discussion of the use of elliptic equations in modelling large space antennas. We show that under weak assumptions (guaranteeing the nonvanishing of a Lagrange multiplier), the minimizers of the optimization problems enjoy a certain regularity phenomenon; they are necessarily smoother than the functions in the class over which the minimization is carried out. To our knowledge, this is the first time that a regularization phenomenon is documented for parameter estimation problems. It can be used advantageously in the penalization method. Without regularity, when the coefficients in the equation as well as the state equation are approximated, these two limit processes, together with the limit process appearing due to the penalization term, must go to infinity in a certain order to achieve convergence. In the presence of additional regularity of the solution of the parameter estimation problem, these limits can be taken essentially independently of each other. We expect that regularity results of this kind will also be useful for the study of the rate of convergence in parameter estimation problems; see [5], for instance, where smoothness requirements are made without further discussion.

Finally we obtain the result that under the same conditions that guarantee the regularity effect of the minimizers, the norm constraints must be active. This implies that the solution will change as the norm bounds change and that it will not exist, in general, without these norm bounds. This result is remarkable from the modeling point of view and has stimulated that, in a further investigation on the sensitivity of inverse problem, sensitivity is not only considered with respect to the observations but also with respect to the constraints defining the admissible parameter set [4].

The paper is organized as follows: In § 2 we summarize some results on two point boundary value problems that are needed in the remainder of the paper. A penalization method is discussed in § 3 and in § 4 we establish the above mentioned regularity results and the fact that the norm constraints may be active. Section 5 is devoted to employing these results to improve upon the approximation theorems of § 3. The numerical examples are discussed in § 6.

2. Generalities. Let us consider the equation

$$(2.1) \quad \begin{aligned} & -(a(x)u_x)_x + b(x)u_x + c(x)u = f \quad \text{for } 0 < x < 1, \\ & u(0) = u(1) = 0, \end{aligned}$$

where $f \in L^2(0, 1)$ and

$$q = (a, b, c) \in Q \subset \tilde{Q} = W^{1,2}(0, 1) \times W^{1,2}(0, 1) \times L^2(0, 1),$$

with \tilde{Q} endowed with the Hilbert-space product topology. By employing the mean value theorem for integrals one can show that

$$(2.2) \quad |\varphi|_{L^\infty} \leq d |\varphi|_{W^{1,2}} \quad \text{for } \varphi \in W^{1,2}(0, 1) \quad \text{where } d = \sqrt{2},$$

and $W^{1,2}(0, 1)$ is endowed with the $(\int_0^1 |\varphi(s)|^2 ds + \int_0^1 |\dot{\varphi}(s)|^2 ds)^{1/2}$ -norm. Let $\tilde{\alpha} > 0$ and define

$$Q = \left\{ q \in \tilde{Q}: \tilde{\alpha} \leq a(x), |a|_{W^{1,2}} \leq \mu, |b|_{W^{1,2}} \leq \mu, |c|_{L^2} \leq \mu, c(x) \geq \tilde{c} > \frac{d^2 \mu^2}{4 \tilde{\alpha}} \right\}.$$

In $W_0^{1,2}(0, 1) \times W_0^{1,2}(0, 1)$ we define for each $q \in \tilde{Q}$ the form

$$(2.3) \quad l(u, v; q) = (au_x, v_x) + (bu_x, v) + (cu, v),$$

where (\cdot, \cdot) denotes the inner product in $L^2(0, 1)$. It is simple to verify that

$$(2.4) \quad |l(u, v; q)| \leq C_1 |u|_{W_0^{1,2}} |v|_{W_0^{1,2}},$$

and

$$(2.5) \quad l(u, u; q) \geq C_2 |u|_{W_0^{1,2}}^2,$$

for all $q \in Q$ and $u, v \in W_0^{1,2}$, with $C_1 > 0$ and $C_2 > 0$. Here $W_0^{1,2}(0, 1)$ is endowed with the $(\int_0^1 |\dot{\varphi}(x)|^2 dx)^{1/2}$ -norm. We give the details for (2.5) and take $u \in W_0^{1,2}$. Further τ_1 is chosen so that $\tilde{c} - \tau_1(d^2\mu^2/4\tilde{\alpha}) > 0$. Then

$$\begin{aligned} l(u, u; q) &= (au_x, a_x)_{L^2} + (bu_x, u) + (cu, u) \\ &\geq \tilde{\alpha} |u_x|_{L^2}^2 + \tilde{c} |u|_{L^2}^2 - \sup_x |b(x)| |u_x|_{L^2} |u|_{L^2} \\ &\geq \tilde{\alpha} |u_x|_{L^2}^2 + \tilde{c} |u|_{L^2}^2 - d\mu |u_x|_{L^2} |u|_{L^2} \\ &\geq \tilde{\alpha} \left(1 - \frac{1}{\tau_1}\right) |u_x|_{L^2}^2 + \left(\tilde{c} - \frac{d^2\mu^2\tau_1}{4\tilde{\alpha}}\right) |u|_{L^2}^2 \\ &\geq \tilde{\alpha} \left(1 - \frac{1}{\tau_1}\right) |u_x|_{L^2}^2, \end{aligned}$$

which implies (2.5) with $C_2 = \tilde{\alpha}(1 - 1/\tau_1)$.

We shall frequently use the following

Remark 2.1. There exist positive constants c_1, c_2 and δ such that for $q \in Q_\delta$ with

$$Q_\delta = \left\{ q \in \tilde{Q}: |a|_{W^{1,2}} \leq \mu + \delta, |b|_{W^{1,2}} \leq \mu + \delta, \right. \\ \left. |c|_{L^2} \leq \mu + \delta, a(x) \geq \tilde{\alpha}, c(x) \geq \tilde{c} \geq \frac{d^2\mu^2}{4\alpha} \right\}$$

we have $|l(u, v; q)| \leq c_1 |u|_{W^{1,2}} |v|_{W^{1,2}}$, and $l(u, u; q) \geq c_2 |u|_{W^{1,2}}^2$.

The Lax-Milgram theorem implies for each $q \in Q_\delta$ the existence of a unique solution $u(q) \in W_0^{1,2}(0, 1)$ of (2.1) satisfying

$$(2.6) \quad l(u(q), v; q) = (f, v) \quad \text{for all } v \in W_0^{1,2}(0, 1).$$

By Remark 2.1 we also have

$$|u(q)|_{W^{1,2}}^2 \leq c_2^{-1} |(u(q), f)| \leq c_2^{-1} |u(q)|_{L^2} |f|_{L^2}$$

and therefore

$$(2.7) \quad |u(q)|_{W^{1,2}} \leq c_2^{-1} |f|_{L^2},$$

for every $q \in Q_\delta$ and $f \in L^2(0, 1)$. Since $a \in W^{1,2}(0, 1)$ we further have $au_{xx} = -a_x u_x + bu_x + cu - f$ and consequently $u \in W^{2,2}(0, 1)$. By (2.7) there exists a constant $c_3 = c_3(\tilde{c}, d, \mu, \alpha, \delta)$ such that

$$(2.8) \quad |u(q)|_{W^{2,2}} \leq c_3 |f|_{L^2}.$$

Remark 2.2. Let

$$Q_P = \{q \in \tilde{Q}: \tilde{\alpha} \leq a(x), |b(x)| \leq d\mu, \tilde{c} \leq c(x) \text{ for almost all } x \in [0, 1]\}.$$

The calculation after (2.5) reveals that $l(u, u; q) \geq C_2 |u|_{W_0^{1,2}}^2$ for all $q \in Q_P$ and $u \in W_0^{1,2}(0, 1)$. Moreover, for each $q \in Q_P$ there exists a constant $C_3 = C_3(q)$ such that $|l(u, v; q)| \leq C_3 |u|_{W^{1,2}} |v|_{W^{1,2}}$ for all u and v in $W_0^{1,2}(0, 1)$. Therefore there exists a solution $u(q) \in W^{2,2}(0, 1)$ of (2.1) for every $q \in Q_P$. Note also, that $Q \subset Q_P$, since $|b|_{L^\infty} \leq d|b|_{W^{1,2}} \leq d\mu$. This remark will frequently be used in § 3.

If the dependence of u on q and f is relevant, we denote the solution of (2.1) by $u(q, f)$.

LEMMA 2.1. (a) *The set Q is weakly closed and weakly compact in \tilde{Q} . If Q_{ad} is the intersection of Q with a closed convex set in \tilde{Q} , then Q_{ad} is weakly closed and weakly compact as well.*

(b) *If $f^k \rightharpoonup f$ in $L^2(0, 1)$ and $q^k \rightharpoonup q^0$ in \tilde{Q} with $q^0 \in Q$ and $q^k \in Q_P$, then $u(q^k, f^k) \rightharpoonup u(q^0, f)$ in $W^{2,2}(0, 1)$.*

Remark 2.3. If $Q_{\text{ad}} = Q \cap \{b \in W_0^{1,2}(0, 1)\}$, then $d = \frac{1}{2}$.

Proof of Lemma 2.1. Since (a) is obvious, we immediately turn to (b). Since $q^k \rightharpoonup q^0$ there exists a constant k_0 , such that $q^k \in Q_\delta$ for $k \geq k_0$ and by Remark 2.1 $u(q^k, f^k)$ is uniformly bounded in $W^{2,2}(0, 1)$ for $k \geq k_0$. Consequently there exists a subsequence $\{k_j\}$ and $z \in W^{2,2}(0, 1)$ so that $u(q^{k_j}, f^{k_j}) \rightharpoonup z$ in $W^{2,2}(0, 1)$. We have for every $v \in W_0^{1,2}(0, 1)$

$$(a^{k_j} u_x(q^{k_j}, f^{k_j}), v_x) + (b^{k_j} u_x(q^{k_j}, f^{k_j}), v) + (c^{k_j} u(q^{k_j}, f^{k_j}), v) = (f^{k_j}, v).$$

Taking the limit as $k_j \rightarrow \infty$, we find with $q^0 = (a^0, b^0, c^0)$

$$(a^0 z_x, v_x) + (b^0 z_x, v) + (c^0 z, v) = (f, v),$$

for all $v \in W_0^{1,2}(0, 1)$. This implies $z = u(q^0, f)$. The usual subsequence argument implies $u(q^k, f^k) \rightharpoonup u(q^0, f)$ [11, p. 116].

In the following sections we shall use finite dimensional (Galerkin) approximations of (2.1) that converge uniformly in $q \in Q$. So let $H^N \subset W_0^{1,2}$ be a sequence of finite dimensional linear subspaces and consider

$$(2.9) \quad l(u, v^N; q) = (f, v^N) \quad \text{for all } v^N \in H^N.$$

Again the Lax-Milgram theorem implies the existence of unique solutions $u^N(q)$ of (2.9) for each $q \in Q_\delta$. By (2.6) and (2.9) we have

$$l(u(q) - u^N(q), v^N; q) = 0 \quad \text{for all } v^N \in H^N.$$

Therefore for all $v^N \in H^N$

$$\begin{aligned} c_2 \|u(q) - u^N(q)\|_{W^{1,2}}^2 &\leq l(u(q) - u^N(q), u(q) - v^N; q) \\ &\leq c_1 \|u(q) - u^N(q)\|_{W^{1,2}} \|u(q) - v^N\|_{W^{1,2}}, \end{aligned}$$

so that

$$(2.10) \quad \|u(q) - u^N(q)\|_{W^{1,2}} \leq c_1 c_2^{-1} \inf_{v^N \in H^N} \|u(q) - v^N\|_{W^{1,2}},$$

for all $q \in Q_\delta$.

We make the following standard assumption.

(H1) For each $N = 1, 2, \dots$ the subspaces satisfy $H^N \subset W_0^{1,2}(0, 1)$ and $\|\varphi - P_1^N \varphi\|_{W^{1,2}} \leq \rho(N) \|\varphi\|_{W^{2,2}}$,

where $P_1^N: W^{1,2}(0, 1) \rightarrow H^N$ is the orthogonal projection in the $W^{1,2}(0, 1)$ norm, and $\lim_{N \rightarrow \infty} \rho(N) = 0$.

From (2.8) and (2.10) we derive the following

LEMMA 2.2. *Let (H1) hold and take q in Q_δ . Then*

$$\|u(q) - u^N(q)\|_{W^{1,2}} \leq \tilde{\rho}(N) \|f\|_{L^2},$$

with $\lim_{N \rightarrow \infty} \tilde{\rho}(N) = 0$ independent of $q \in Q_\delta$.

COROLLARY 2.1. *Let (H1) hold and let $q^N \rightharpoonup q^0$, with $q^0 \in Q$ and $q^N \in Q_P$. Then*

$$u^N(q^N) \rightarrow u(q^0) \quad \text{in } W^{1,2}(0, 1).$$

This corollary follows directly from Lemmas 2.1 and 2.2. In the final lemma of this section we discuss the dependence of u^N on q and f .

LEMMA 2.3. *Let $H^N \subset W_0^{1,2}(0, 1)$ for each $N = 1, 2, \dots$. Then*

(a) $|u^N(q)|_{W^{1,2}} \leq c_2^{-1} |f|_{L^2}$ for each $q \in Q_\delta$.

(b) *If moreover $q^k \rightharpoonup q^0$ in \tilde{Q} with $q^0 \in Q_\delta$ and $q^k \in Q_P$, and $f^k \rightharpoonup f$ in $L^2(0, 1)$, then*

$$u^N(q^k, f^k) \rightarrow u^N(q^0, f) \quad \text{in } W^{1,2}(0, 1).$$

The proof of this lemma is simple and will therefore not be included.

3. Penalization. Let $z \in Z$, with Z the observation space which is assumed to be a Banach space, and let $C: W^{1,2}(0, 1) \rightarrow Z$ be the associated observation operator. For $q \in Q_P$ we put

$$J(q) = |Cu(q) - z|_Z^2.$$

Note that $u(q)$ is well defined by Remark 2.2.

We then formulate the parameter estimation problem as the optimization problem:

(P) Minimize $J(q)$ over $q \in Q$ subject to $u(q)$ satisfying (2.6).

Throughout we make the following assumption:

(H2) C is a bounded linear operator from $W^{1,2}(0, 1)$ to Z .

In particular we could take $Z = Z_1 = L^2(0, 1)$ and $C_1\varphi = \varphi$, or $Z = Z_2 = \mathbb{R}$ and $C_2\varphi = \varphi(x_0)$, $x_0 \in [0, 1]$, or $Z = Z_3 = L^2(0, 1)$ and $C_3\varphi = \dot{\varphi}$.

Note that (P) is a restricted optimization problem; the *pointwise constraints* guarantee well-posedness of the equation (2.1) whereas the *norm constraints* in the characterization of Q are essential to establish existence of solutions to (P). Several investigations concerning the approximation of (P) by finite dimensional problems have been carried out, both theoretically and numerically for many classes of partial differential equations [2], [3], [8]. For practical purposes the approximating optimization problems have commonly been implemented by employing unconstrained optimization packages, so that the constraints used in defining Q have essentially been ignored. A penalization technique appears to parallel what is done in practice and we consequently study penalization techniques for the simple model problem (P).

First we define the penalization functionals:

$$\psi_A(a) = \begin{cases} 0 & \text{if } |a|_{W^{1,2}} \leq \mu, \\ (|a|_{W^{1,2}} - \mu)^2 & \text{if } |a|_{W^{1,2}} > \mu; \end{cases}$$

and functionals ψ_B and ψ_C are defined in an analogous manner. We also put

$$\Psi(q) = \psi_A(a) + \psi_B(b) + \psi_C(c),$$

and note that

$$(3.1) \quad |q| \rightarrow \infty \quad \text{implies } \Psi(q) \rightarrow \infty.$$

Remark 3.1. The pointwise bounds appearing in Q_P can be more readily implemented in computer algorithms than the norm constraints that are defining Q .

Associated with Ψ and the approximating state equations we consider

$$(P_M) \quad \min_{q \in Q_P} (J(q) + M\Psi(q)),$$

$$(P^N) \quad \min_{q \in Q} J^N(q) = \min_{q \in Q} |Cu^N(q) - z|^2 \quad \text{where } u^N(q) \text{ satisfies (2.9) and}$$

$$(P_M^N) \quad \min_{q \in Q_P} (J^N(q) + M\Psi(q)).$$

LEMMA 3.1. Assume that $H^N \subset W_0^{1,2}$ and that (H2) holds. Then there exist solutions $\bar{q} \in Q$, $\bar{q}^N \in Q$, $\bar{q}_M \in Q_P$ and $\bar{q}_M^N \in Q_P$ of (P), (P^N) , (P_M) and (P_M^N) respectively.

Proof. Since Ψ is radially unbounded and since $J(q) \geq 0$, $J^N(q) \geq 0$, the existence of minimizers \bar{q}_M and \bar{q}_M^N in Q_P of (P_M) and (P_M^N) easily follows (see [9, p. 8]). Next let $q^k \in Q$ be a minimizing sequence for (P). Then there exists a subsequence $\{q^{k_n}\}$ with $q^{k_n} \rightharpoonup \bar{q}$ in \tilde{Q} with $\bar{q} \in Q$. By Lemma 2.1, $u(q^{k_n}) \rightarrow u(\bar{q})$ in $W^{1,2}(0, 1)$ and further $J(q^{k_n}) \rightarrow J(\bar{q})$. Since $\inf_{q \in Q} J(q) = \lim_{k_n \rightarrow \infty} J(q^{k_n})$, it follows that \bar{q} solves (P). The existence of a minimizer for (P^N) is guaranteed by Lemma 2.3(b).

THEOREM 3.1. Let the approximation assumption (H1) and (H2) hold and let q^* be a weak limit point of $\{\bar{q}_M^N\}$, such that $\bar{q}_M^N \rightharpoonup q^*$ in \tilde{Q} with $N_k \rightarrow \infty$, $M_k \rightarrow \infty$ as $k \rightarrow \infty$. Then $q^* \in Q$, q^* is a solution of (P), $u^{N_k}(\bar{q}_M^N) \rightarrow u(q^*)$ in $W^{1,2}(0, 1)$ and $J^{N_k}(\bar{q}_M^N) + M_k \Psi(\bar{q}_M^N) \rightarrow J(q^*)$ as $k \rightarrow \infty$.

Proof. The verification of this result can be given by well-known arguments. Let $q \in Q$ be arbitrary. Then

$$J^{N_k}(\bar{q}_M^N) + M_k \Psi(\bar{q}_M^N) \leq J^{N_k}(q).$$

But $\{J^{N_k}(q): q \in Q, N = 1, 2, \dots\}$ is bounded as a consequence of (H2) and Lemma 2.3(a). Therefore, there exists a constant K such that

$$(3.2) \quad J^{N_k}(\bar{q}_M^N) + M_k \Psi(\bar{q}_M^N) \leq K.$$

Since $J^N(\bar{q}_M^N) \geq 0$ we have by (3.2) that $\lim_{k \rightarrow \infty} \Psi(\bar{q}_M^N) \rightarrow 0$, which implies that $q^* \in Q$. For each $q \in Q$ the following inequalities hold:

$$(3.3) \quad J^{N_k}(\bar{q}_M^N) \leq J^{N_k}(\bar{q}_M^N) + M_k \Psi(\bar{q}_M^N) \leq J^{N_k}(q) + M_k \Psi(q) = J^{N_k}(q).$$

From Corollary 2.1 we conclude that

$$(3.4) \quad \begin{aligned} \lim_{k \rightarrow \infty} u^{N_k}(\bar{q}_M^N) &= u(q^*) \quad \text{in } W^{1,2}(0, 1) \quad \text{and} \\ \lim_{N \rightarrow \infty} u^N(q) &= u(q) \quad \text{in } W^{1,2}(0, 1). \end{aligned}$$

Taking the limit as $k \rightarrow \infty$ in (3.3) and recalling (H2), we arrive at

$$J(q^*) \leq J(q) \quad \text{for all } q \in Q,$$

so that q^* is in fact a solution of (P). The remaining claims follow from (3.4) and (3.3) with $q = q^*$.

Remark 3.2. The conclusion of Theorem 3.1 is not changed if M in $J(q) + M\Psi(q)$ is replaced by $h(M)$ with $\lim_{M \rightarrow \infty} h(M) = \infty$. The proof of Theorem 3.1 reveals that $\Psi(\bar{q}_M^N) = O(h(M_k)^{-1})$ as $k \rightarrow \infty$.

Remark 3.3. Problems (P^N) and (P_M^N) are not finite dimensional, since Q is an infinite dimensional coefficient space. If \tilde{Q} is replaced by \tilde{Q}_F , where \tilde{Q}_F is a finite dimensional subspace of \tilde{Q} , and Q and Q_P are replaced by $Q \cap \tilde{Q}_F$ and $Q_P \cap \tilde{Q}_F$, then Theorem 3.1 remains correct and (P^N) and (P_M^N) are finite dimensional problems (compare also Lemma 2.1). Otherwise a further approximation of the coefficients is required, which we describe next.

Let $Q^m \subset \tilde{Q}$ be a sequence of finite dimensional subspaces of \tilde{Q} satisfying:

(H3) For each $q \in \tilde{Q} \cap Q_P$ and $m = 1, 2, \dots$ there exists $\tilde{q}^m \in Q^m \cap Q_P$ such that $|q - \tilde{q}^m| = \rho(m)$, and $\lim_{m \rightarrow \infty} \rho(m) = 0$.

Consider the problems:

$$(P_M^{N,m}) \quad \min_{q \in Q^m \cap Q_P} J^N(q) + M\Psi(q).$$

Clearly solutions $\bar{q}_M^{N,m}$ of $(P_M^{N,m})$ exist. In the next theorem the notation $w\text{-lim}$ is used to denote the weak limit.

THEOREM 3.2. *Let (H1)–(H3) hold and let q^* be a weak iterated limit point of $\bar{q}_M^{N,m}$, such that $q^* = w\text{-}\lim_{i \rightarrow \infty} w\text{-}\lim_{k \rightarrow \infty} \bar{q}_{M_i}^{N_i, m_k}$, with $N_i \rightarrow \infty$, $M_i \rightarrow \infty$ as $i \rightarrow \infty$ and $m_k \rightarrow \infty$ as $k \rightarrow \infty$. Then q^* is a solution of (P), $\lim_{i \rightarrow \infty} \lim_{k \rightarrow \infty} u^{N_i}(\bar{q}_{M_i}^{N_i, m_k}) = u(q^*)$ in $W^{1,2}$, and*

$$\lim_{i \rightarrow \infty} \lim_{k \rightarrow \infty} J^{N_i}(\bar{q}_{M_i}^{N_i, m_k}) = J(q^*).$$

Proof. Let $q \in Q$ be arbitrary and choose $\tilde{q}^m \in Q^m \cap Q_P$ according to (H3). Then we have

$$(3.5) \quad J^{N_i}(\bar{q}_{M_i}^{N_i, m_k}) + M_i \Psi(\bar{q}_{M_i}^{N_i, m_k}) \leq J^{N_i}(\tilde{q}^{m_k}) + M_i \Psi(\tilde{q}^{m_k}).$$

For each i we have $\lim_{k \rightarrow \infty} (J^{N_i}(\tilde{q}^{m_k}) + M_i \Psi(\tilde{q}^{m_k})) = J^{N_i}(q)$ and consequently

$$(3.6) \quad \lim_{i \rightarrow \infty} \lim_{k \rightarrow \infty} (J^{N_i}(\tilde{q}^{m_k}) + M_i \Psi(\tilde{q}^{m_k})) = J(q)$$

by Lemma 2.3(b) and Lemma 2.2. In particular, the left-hand side of (3.5) is nonnegative and bounded. This implies that $\lim_{i \rightarrow \infty} \lim_{k \rightarrow \infty} \psi(\bar{q}_{M_i}^{N_i, m_k}) = 0$ from which we conclude that $q^* \in Q$. Next we put $\bar{q}_{M_i}^{N_i, 0} = w\text{-}\lim_{k \rightarrow \infty} \bar{q}_{M_i}^{N_i, m_k}$ and note that $\bar{q}_{M_i}^{N_i, 0} \in Q_P$. Taking the limit with respect to k in

$$J^{N_i}(\bar{q}_{M_i}^{N_i, m_k}) \leq J^{N_i}(\tilde{q}^{m_k}) + M_i \Psi(\tilde{q}^{m_k}),$$

we find for sufficiently large i

$$(3.7) \quad J^{N_i}(\bar{q}_{M_i}^{N_i, 0}) \leq J^{N_i}(q),$$

by Lemma 2.3(b) and since $q^* = w\text{-}\lim_{i \rightarrow \infty} \bar{q}_{M_i}^{N_i, 0} \in Q$. Taking the limit as $i \rightarrow \infty$ in (3.7) leads to

$$(3.8) \quad J(q^*) \leq J(q)$$

by Corollary 2.1. Since q was an arbitrary element of Q , this implies that q^* is a solution of (P). The remaining assertions are easily verified and the proof is complete.

Remark 3.4. The proof of the previous result depends strongly on the fact that the limits are taken iteratively; in general (3.6) and (3.8) will not be true for arbitrary order of the limits. This shortcoming cannot be overcome by replacing M by a function $h(M)$ with $\lim_{M \rightarrow \infty} h(M) = \infty$.

Remark 3.5. We give an example for subspaces Q^m , so that (H3) is satisfied. Let $S_1^m(0, 1) = \{\text{set of piecewise linear spline functions with knots at } i/m, i = 0, \dots, m\}$ and $Q^m = \bigotimes_{i=1}^3 S_1^m(0, 1)$. By $P^m: \tilde{Q} \rightarrow Q^m \cap Q_P$ we denote the projection operator which associates to each element $q \in \tilde{Q}$ the unique element $P^m q \in Q^m \cap Q_P$ with shortest distance to q , [6, p. 249]. To verify (H3) for this case, let $q = (a, b, c) \in (W^{2,2}(0, 1) \times W^{2,2}(0, 1) \times W^{1,2}(0, 1)) \cap Q_P$ and note that

$$(3.9) \quad |q - P^m q|_{\tilde{Q}} \leq K_1 m^{-1} |q|_{W^{2,2} \times W^{2,2} \times W^{1,2}},$$

where K_1 is independent of q and N . This estimate is easily obtained by employing the interpolation operation and well-known spline estimates (see e.g. [12, Chap. 2]). For $q \in \tilde{Q} \cap Q_P$ note that $P^m q$ coincides with the Hilbert space projection of q onto Q^m . Moreover, for every $q \in \tilde{Q} \cap Q_P$ there exists a sequence $q^l \in (W^{2,2}(0, 1) \times W^{2,2}(0, 1) \times W^{1,2}(0, 1)) \cap Q_P$ with $\lim_{l \rightarrow \infty} q^l = q$ in \tilde{Q} . These last two facts, together with (3.9) and the triangle inequality imply that (H3) holds for linear spline approximations of the coefficients.

Remark 3.6. The calculations in the previous example depend strongly on the interpolation properties of linear spline functions; this is reflected, for example, in (3.9) where the interpolation operator also realizes the pointwise constraints associated with Q_P . In general norm or pointwise bounds can only be achieved in the limit (as for example, when cubic splines are used to approximate the coefficients). In this case it may be necessary that an additional index is used allowing that the coefficients of the finite dimensional problem satisfy the constraints characterizing Q only approximately (compare [8, § 4]). We shall not follow up on these ideas here but rather continue to develop a technique that allows one to replace the iterated limit in Theorem 3.2 by a result that guarantees that the various limits may be taken independently.

4. Regularity. In this section we consider again the equation

$$(4.1) \quad \begin{aligned} & -(au_x)_x + bu_x + cu = f \quad \text{on } (0, 1), \\ & u(0) = u(1) = 0. \end{aligned}$$

We first assume that a and c are fixed and that there exists at least one \tilde{b} with $(a, \tilde{b}, c) \in Q$. This leaves b to be estimated and we assume either of the two observations C_i , $i = 1$ or 2 , described at the beginning of § 3 to be available. For $i = 1$ we let $z_1 \in L^2(0, 1)$, whereas $z_2 \in \mathbb{R}$. We further put

$$J_i(b) = |C_i u(b) - z_i|^2,$$

where we now denote the parameter dependence of u by $u(b)$. The parameter estimation problems for $i = 1$ or 2 become:

(P_i) Minimize $J_i(b)$ over B subject to $u(b)$ satisfying (4.1).

Here $B = \{b \in W^{1,2}(0, 1) : |b|_{W^{1,2}} \leq \mu\}$. Analogous to the definition of Q_δ in § 2 we put $B_\delta = \{b \in W^{1,2}(0, 1) : |b|_{W^{1,2}} \leq \mu + \delta\}$. The existence of a solution of (P_i) is guaranteed by Lemma 3.1. We next calculate the Fréchet derivative of the function $b \rightarrow u(b)$.

LEMMA 4.1. *The mapping $b \rightarrow u(b)$ from $B \subset W^{1,2}(0, 1)$ into $W^{2,2}(0, 1)$ is Fréchet differentiable with the Fréchet differential with increment h denoted by $\delta_b u(b)h = \eta(h)$ with $\eta(h)$ the unique solution of*

$$(4.2) \quad \begin{aligned} & -(a\eta(h)_x)_x + b\eta_x(h) + c\eta(h) = -hu_x(b), \quad \text{in } (0, 1), \\ & \eta(h)(0) = \eta(h)(1) = 0. \end{aligned}$$

Proof. The verification is quite standard but we include it for the purpose of completeness. Let $h \in W^{1,2}(0, 1)$ and $b \in B$ and note that there exists $\varepsilon(h) > 0$ such that for any $\varepsilon \in (0, \varepsilon(h))$ the element $b + \varepsilon h \in B_\delta$ and $u(b + \varepsilon h)$ exists. Set $u^\varepsilon = \varepsilon^{-1}(u(b + \varepsilon h) - u(b))$ and observe that u^ε must satisfy

$$(4.3) \quad \begin{aligned} & -(au_x^\varepsilon)_x + bu_x^\varepsilon + cu^\varepsilon = -hu_x(b + \varepsilon h), \\ & u^\varepsilon(0) = u^\varepsilon(1) = 0. \end{aligned}$$

From Lemma 2.1 it follows that $u(b + \varepsilon h) \rightarrow u(b)$ in $W^{1,2}(0, 1)$ as $\varepsilon \rightarrow 0$. Applying Lemma 2.1 once again to (4.3), we find that u^ε converges weakly in $W^{2,2}(0, 1)$ and thus strongly in $W^{1,2}(0, 1)$. We denote this limit by $\eta(h)$. As a consequence of u^ε satisfying (4.3) and the limit behavior of u^ε , we observe that $u^\varepsilon \rightarrow \eta(b)$ as $\varepsilon \rightarrow 0$ strongly in $W^{2,2}(0, 1)$ as well. Thus, the limit $\eta(h)$ is the Gateaux derivative of the mapping $b \rightarrow u(b)$ with increment h , i.e. $\eta(h) = \delta u(b)h$, and it satisfies

$$(4.4) \quad \begin{aligned} & -(a\eta_x(h))_x + b\eta_x(h) + c\eta(h) = -hu_x(b) \quad \text{in } (0, 1), \\ & \eta(h)(0) = \eta(h)(1) = 0. \end{aligned}$$

Note that $h \rightarrow \eta(h)$ is a bounded linear operator from $W^{1,2}(0, 1)$ to $W^{2,2}(0, 1)$. That $h \rightarrow \eta(h)$ is the Fréchet differential of u at b with increment h can be seen as follows: let $h \in W^{1,2}(0, 1)$ with $|h|_{W^{1,2}} \leq \delta$, and set

$$\Delta(h) = |h|_{W^{1,2}}^{-1}(u(b+h) - u(b) - \eta(h)).$$

We note that $\Delta(h)$ satisfies

$$(4.5) \quad \begin{aligned} -(a\Delta_x(h))_x + b\Delta_x(h) + c\Delta(h) &= \frac{h}{|h|_{W^{1,2}}}(u_x(b+h) - u_x(b)), \\ \Delta(h)(0) &= \Delta(h)(1) = 0. \end{aligned}$$

From (2.8) we have

$$|\Delta(h)|_{W^{2,2}} \leq c_3 |u_x(b+h) - u_x(b)|_{L^2}.$$

Lemma 2.1 now implies that $|\Delta(h)|_{W^{2,2}} \rightarrow 0$ whenever $|h|_{W^{1,2}} \rightarrow 0$. Thus, we have established the lemma.

Since the functionals $b \rightarrow J_i(b)$ are the composition of Fréchet differentiable functions, they are themselves Fréchet differentiable; we find

$$(4.6) \quad \delta_b J_1(b)h = 2 \int_0^1 (u(b) - z_1) \eta(h) dx$$

and

$$(4.7) \quad \delta_b J_2(b)h = 2(u(b)(x_0) - z_2) \eta(h)(x_0).$$

To get a different representation of the Fréchet differential of J_i , we introduce the adjoint problems

$$(4.8) \quad \begin{aligned} -(ap_x^1)_x - (bp^1)_x + cp^1 &= u(b) - z_1, \\ p^1(0) &= p^1(1) = 0, \end{aligned}$$

and

$$(4.9) \quad \begin{aligned} -(ap_x^2)_x - (bp^2)_x + cp^2 &= (u(b)(x_0) - z_2) \delta(x_0), \\ p^2(0) &= p^2(1) = 0, \end{aligned}$$

where $\delta(x_0)$ denotes the Dirac delta measure with mass at $x_0 \in (0, 1)$. Existence and regularity of unique solutions to equations (4.8) and (4.9) are shown in an analogous manner as for equation (2.1). We find

LEMMA 4.2. *Let $b \in B$. There exist unique solution p^i of (4.8) and (4.9) with $p^1 \in W^{2,2}(0, 1) \cap W_0^{1,2}(0, 1)$ and $p^2 \in W_0^{1,2}(0, 1)$.*

We now obtain the Fréchet differential of J_i in terms of p_i by multiplying (4.8) and (4.9) by $\eta(h)$ and integrating by parts. Thus, we see that

$$(4.10) \quad \delta_b J_i(b)h = -2 \int_0^1 u_x(b) p^i h dx$$

for $i = 1$ or 2 and $h \in W^{1,2}(0, 1)$.

We next investigate *regularity* of the solutions \bar{b}_i of (P_i) . Our approach is to incorporate the explicit optimization constraints into a Lagrangian functional to be minimized over the larger set B_δ . The set B_δ is unavoidable since it is essential to have $b \rightarrow u(b)$ and its Fréchet derivative defined on B . We are able to obtain an Euler equation since the admissible parameters are contained in the interior of B_δ . Another

point to be remembered is that $b \rightarrow u(b)$ is not linear. Hence, the functionals J_i are not convex. Accordingly we use the generalized Kuhn-Tucker theorem for local optimization theory. We define functionals G on $W^{1,2}(0, 1)$ by

$$G(b) = |b|_{W^{1,2}}^2 - \mu^2$$

and observe that the Fréchet differential of G at b with increment h is given by

$$(4.11) \quad \delta_b G(b)h = 2 \int_0^1 (b_x h_x + bh) dx = 2 \int_0^1 (-b_{xx} + b)h dx + [b_x(1)h(1) - b_x(0)h(0)].$$

The right-hand side of (4.11) defines a continuous linear functional on $W^{1,2}(0, 1)$. In terms of G the estimation problems are given by:

(P_i^{*}) Minimize $J_i(b)$ subject to $G(b) \leq 0$ and (4.1).

The Kuhn-Tucker theorem [10, p. 249] asserts that if \bar{b}_i solves (P_i^{*}) and if \bar{b}_i is a *regular point* of the inequality $G(b) \leq 0$, and there exists $\lambda \geq 0$ such that the Lagrangian

$$\Lambda_i(b) = J_i(b) + \lambda G(b)$$

is stationary at \bar{b}_i . We note that $\Lambda_i(b)$ is defined on B_δ which contains B in its interior. To verify that \bar{b}_i is indeed a regular point of $G(b) \leq 0$, we need to verify that if $G(\bar{b}_i) \leq 0$ then there exists an $\tilde{h} \in W^{1,2}(0, 1)$ with $G(\bar{b}_i) + \delta G(\bar{b}_i)h < 0$. Set $h = -\bar{b}_i$. Then

$$\begin{aligned} G(\bar{b}_i) - \delta_b G(\bar{b}_i)\bar{b}_i &= (|\bar{b}_i|_{W^{1,2}}^2 - \mu^2) - 2|\bar{b}_i|_2 W^{1,2} \\ &= -(|\bar{b}_i|_{W^{1,2}}^2 + \mu^2) < 0. \end{aligned}$$

Thus, if \bar{b}_i is a solution of (P_i^{*}) then

$$\delta_b \Lambda_i(\bar{b}_i)h = 0 \quad \text{and} \quad \lambda G(\bar{b}_i) = 0,$$

since $\bar{b}_i \in B \subset \text{int } B_\delta$. From (4.10) and (4.11) it follows that

$$\int_0^1 [-u_x(\bar{b}_i)p^i + \lambda(\bar{b}_i - (\bar{b}_i)_{xx})]h dx + \lambda[\bar{b}_x(1)h(1) - \bar{b}_x(0)h(0)] = 0,$$

for all $h \in W^{1,2}(0, 1)$. Accordingly we have the Euler equation

$$(4.12) \quad \begin{aligned} \lambda(-(\bar{b}_i)_{xx} + \bar{b}_i) &= u_x(\bar{b}_i)p^i \quad \text{in } (0, 1), \\ \lambda(\bar{b}_i)_x(1) &= \lambda(\bar{b}_i)_x(0) = 0. \end{aligned}$$

We observe that since $u_x(\bar{b}_i)$ and p^i both belong to $W_0^{1,2}(0, 1)$, their product belongs to $W_0^{1,2}(0, 1)$ as well. This follows by the product rule or, more generally, by the Banach algebraic properties of $W^{m,p}(\Omega)$ (see [1, p. 115]).

First we consider the case of distributed observations, $i = 1$. Suppose that $\lambda = 0$. Then (4.12) implies

$$(4.13) \quad u_x(\bar{b}_1)p^1 = 0 \quad \text{on } [0, 1].$$

In this case $[0, 1] = \bigcup_{j=1}^\infty I_j$ with $u_x(\bar{b}_1)$ or p^1 identically zero on I_j . If $u_x(\bar{b}_1) = 0$ on I_j , then $u(\bar{b}_1)(x) = f(x) c^{-1}(x) = \text{constant}$ almost everywhere on I_j by (4.1). On the other hand, if $p = 0$ and I_j then $u(\bar{b}_1) = z_1$ on I_j by (4.8). We thus have:

LEMMA 4.3. *If fc^{-1} is nonconstant (a.e.) on every subinterval of $[0, 1]$, then either $u(\bar{b}_1) = z_1$ on $[0, 1]$ and $u(\bar{b}_1)$ is a solution of (4.1) with $|\bar{b}_1| \leq \mu$ for every solution \bar{b}_1 of (P₁) or every Lagrange multiplier associated with the constraint $|b|_{W^{1,2}} \leq \mu$ is positive.*

A special case arises when z_1 is obtained from piecewise linear interpolation of discrete data. Then z_1 is not sufficiently smooth to be a candidate for a solution of (4.1); if moreover fc^{-1} is nonconstant on every subinterval of $(0, 1)$, then $\lambda > 0$.

If $u(\bar{b}_1) \neq z_1$ almost everywhere on $[0, 1]$, then by the above considerations, $u(\bar{b}_1) = \text{constant}$ on $[0, 1]$ and as a consequence of the Dirichlet boundary conditions we have $u(\bar{b}_1) = 0$ on $[0, 1]$. This leads to

LEMMA 4.4. *Let \bar{b}_1 be a solution of (P_1) with $u(b_1)(x) \neq z_1(x)$ a.e. on $[0, 1]$. Then either $f = 0$ (a.e.) on $[0, 1]$ or every Lagrange multiplier associated with the constraint $|b|_{W^{1,2}} \leq \mu$ is positive.*

In the case $\lambda > 0$, any solution \bar{b}_1 of (P_1) satisfies the Neumann problem

$$(4.14) \quad \begin{aligned} -(\bar{b}_1)_{xx} + \bar{b}_1 &= \frac{1}{\lambda} u_x(\bar{b})p \quad \text{in } (0, 1), \\ (\bar{b}_1)_x(1) &= (\bar{b}_1)_x(0) = 0, \end{aligned}$$

where $u_x(\bar{b})p \in W_0^{1,2}(0, 1)$.

LEMMA 4.5. *If $\lambda > 0$, then the solution \bar{b}_1 of (P_1) belongs to $W^{3,2}(0, 1)$ and $|\bar{b}_1|_{W^{1,2}} = \mu$.*

Lemmas 4.1 and 4.2 can obviously be used to give sufficient conditions for nontriviality of λ . A different condition guaranteeing $\lambda > 0$ is given by:

(Λ) There exists an interval $W \subset [0, 1]$ such that $fc^{-1} \neq \text{constant}$ and $\mu(b_1) \neq z$ a.e. on W .

We will show that (Λ) implies that (4.13) cannot hold and that therefore $\lambda > 0$. In fact, if (4.13) holds, then there exists an interval $V_1 \subset W$ such that $u_x(\bar{b}_1) = 0$ or $p = 0$ on V_1 . Using (4.1) and (4.8) this contradicts (Λ) and $\lambda > 0$.

We summarize some of the results for the case $i = 1$ in a theorem.

THEOREM 4.1. (a) *If fc^{-1} is nonconstant (a.e.) on every subinterval of $[0, 1]$ and z_1 is not a solution of (4.1) for any $b \in B$ then all solutions \bar{b}_1 of (P_1) belong to $W^{3,2}(0, 1)$.*

(b) *If $u(\bar{b}_1)(x) \neq z_1(x)$ a.e. for a solution \bar{b}_1 of (P_1) and $f \neq 0$ in $L^2(0, 1)$, then $\bar{b}_1 \in W^{3,2}(0, 1)$.*

(c) *If (Λ) holds for a solution \bar{b}_1 of (P_1) , then $\bar{b}_1 \in W^{3,2}(0, 1)$. In all these cases $\lambda > 0$, $(\bar{b}_1)_x(0) = (\bar{b}_1)_x(1) = 0$ and $|\bar{b}_1| = \mu$.*

For the case $i = 2$ we easily find an analogous result.

THEOREM 4.2. *Let fc^{-1} be nonconstant (a.e.) on an open interval containing x_0 . Then either $z_2 = u(b)(x_0)$ for some $b \in B$ or every solution \bar{b}_2 of (P_2) belongs to $W^{3,2}(0, 1)$, $(\bar{b}_2)_x(0) = (\bar{b}_2)_x(1) = 0$ and $|\bar{b}_2|_{W^{1,2}} = \mu$.*

Remark 4.1. Quite similar calculations can be used to discuss regularity for the case when the observation operator is given by $C_3\varphi = \dot{\varphi}$. In this case the optimization problem becomes:

$$(P_3) \quad \min_{b \in B} |C_3 u(q) - z_3|^2,$$

for a given $z_3 \in L^2(0, 1)$. One can derive the following result: If fc^{-1} is nonconstant on every subinterval of $[0, 1]$, then $z_3 \in W^{1,2}(0, 1)$ and $u_x(\bar{b}_3) = z_3$ for some (and thus all) solutions \bar{b}_3 of (P_3) or $\bar{b}_3 \in W^{3,2}(0, 1)$, $(\bar{b}_3)_x(0) = (\bar{b}_3)_x(1) = 0$ and $|\bar{b}_3|_{W^{1,2}} = \mu$ for all solutions \bar{b}_3 of (P_3) .

We next turn to discuss a certain regularity property that occurs when c is estimated. The calculations are similar to the case that we just described when estimating b and will therefore be omitted.

Let us assume that a , b and f are known, with $b = 0$ and $f \in L^2(0, 1)$, and that c has to be estimated in

$$(4.15) \quad \begin{aligned} -(au_x)_x + cu &= f \quad \text{in } [0, 1], \\ u(0) &= u(1) = 0, \end{aligned}$$

where $a(x) \geq \alpha > 0$ and $|a|_{W^{1,2}} \leq \mu$. Let $C = \{c \in L^2(0, 1): |c|_{L^2} \leq \tilde{\mu}, \text{ with } \tilde{\mu} \in (0, 2\alpha)\}$ and $C_\delta = \{c \in L^2(0, 1): |c|_{L^2} \leq \alpha + (\tilde{\mu}/2)\}$.

Note that $\tilde{\mu} < \alpha + (\tilde{\mu}/2) < 2\alpha$. Using Remark 2.3, one can easily show that there exist constants c_4 and c_5 such that for all φ and ψ in $W_0^{1,2}(0, 1)$ and $c \in C_\delta$ we have $l(\varphi, \varphi) \geq c_4 |\varphi|_{W_0^{1,2}}$ and $|l(\varphi, \psi)| \leq c_5 |\psi|_{W_0^{1,2}} |\varphi|_{W_0^{1,2}}$. As before we consider the problems:

$$(P_i^c) \quad \min J_i(c) = \min |C_i u(c) - z_i|^2 \text{ over } C \text{ subject to } u(c) \text{ satisfying (4.15)}$$

or equivalently

$$(P_i^c) \quad \min J_i(c) = \min |C_i u(c) - z_i|^2 \text{ such that } G(c) \leq 0 \text{ and } u(c) \text{ satisfies (4.15).}$$

Here $G(c) = |c|_{L^2}^2 - \tilde{\mu}^2$, $i = 1$ or 2 and $u(c)$ denotes the solution of (4.15). Note that $J_i(c)$ is defined on C_δ . Again any solution \bar{c} of (P_i^c) is seen to be a regular point of $G(c) \leq 0$ and there exists a $\lambda \geq 0$ such that \bar{c} is a stationary point of $\Lambda: C_\delta \rightarrow \mathbb{R}$ given by

$$\Lambda(c) = J_i(c) + \lambda G(c).$$

We now restrict ourselves to the case of distributed observations C_1 . For every $h \in L^2(0, 1)$ we have

$$(4.16) \quad \delta_c \Lambda(\bar{c})h = 2 \int_0^1 (u(\bar{c}_1)(x) - z_1(x))(\delta_c u(\bar{c}_1)h)(x) dx + 2\lambda (\bar{c}_1, h)_{L^2} = 0,$$

where for $c \in L^2(0, 1)$, $\delta_c u(c): L^2(0, 1) \rightarrow W^{2,2}(0, 1)$ is given by $\delta_c u(c)h = \eta(h)$, with $\eta(h) \in W^{2,2}(0, 1)$ satisfying

$$(4.17) \quad \begin{aligned} -(a\eta_x(h))_x + c\eta(h) &= -hu(c), \\ \eta(0) &= \eta(1) = 0. \end{aligned}$$

Consider the adjoint equation given by

$$(4.18) \quad \begin{aligned} -(ap_x)_x + cp &= u(c) - z_1 \quad \text{in } (0, 1), \\ p(0) &= p(1) = 0. \end{aligned}$$

From (4.17) and (4.18) we conclude that

$$(4.19) \quad \int_0^1 (u(c) - z_1)\eta(h) dx = - \int_0^1 pu(c)h dx.$$

Using this in (4.16), we obtain

$$(4.20) \quad \int_0^1 (-pu(\bar{c}_1) + \lambda \bar{c}_1)h dx = 0 \quad \text{for all } h \in L^2(0, 1).$$

Therefore we have the relationship

$$(4.21) \quad \lambda \bar{c}_1(x) - p(x)u(\bar{c}_1)(x) = 0 \quad \text{almost everywhere in } [0, 1].$$

If $\lambda = 0$, then $p(x)u(x) = 0$ for all $x \in [0, 1]$, since p and u are continuous. Suppose $p(\xi) \neq 0$ for some $\xi \in [0, 1]$; then $p(x) \neq 0$ for all x in an interval V containing ξ . This implies that $u(\bar{c}_1) = 0$ on V and consequently $f = 0$ a.e. on V . If we assume that f is not a.e. zero on any subinterval of $[0, 1]$, then from this last observation we obtain that $p = 0$ on $[0, 1]$ or $\lambda = 0$. In the case $p = 0$ on $[0, 1]$ we have $u(\bar{c}_1) = z_1$ on $[0, 1]$ by (4.19) and therefore $z_1 \in W^{2,2}(0, 1)$.

THEOREM 4.3. *If f is not almost everywhere zero on any subinterval of $[0, 1]$, then either $z_1 = u(c)$ in $[0, 1]$ for some $c \in C$ or $\lambda > 0$. If $\lambda > 0$, then $\bar{c}_1 = (1/\lambda)pu(\bar{c}_1)$, $\bar{c}_1 \in W^{2,2}(0, 1)$ and $|\bar{c}_1|_{L^2} = \mu$.*

The case of point observation C_2 is treated quite similarly. We only need to replace (4.16), (4.18) and (4.19) by

$$(4.16') \quad \delta_c \Lambda(\bar{c}_2)h = 2(u(\bar{c}_2)(x_0) - z_2)(\delta_c u(\bar{c}_2)h)(x_0) + 2\lambda(\bar{c}_2, h)_{L^2} = 0,$$

$$(4.18') \quad \begin{aligned} -(ap_x)_x + cp &= (u(c)(x_0) - z_2)\delta(x^0), \\ p(0) &= p(1) = 0 \end{aligned}$$

and

$$(4.19') \quad (u(c)(x_0) - z_2)\eta(h)(x_0) = - \int_0^1 pu(c)h \, dx.$$

We therefore obtain $\delta_c \Lambda(\bar{c}_2)h = -2 \int_0^1 pu(\bar{c}_2)h \, dx + 2\lambda(\bar{c}_2, h)_{L^2} = 0$, which is (4.20). Proceeding as in the case of distributed observations, we derive the following result:

THEOREM 4.4. *If f is not almost everywhere zero on any subinterval of $[0, 1]$, then either $z_2 = u(c)(x_0)$ for some $c \in C$ or $\lambda > 0$. If $\lambda > 0$, then $\bar{c}_2 = (1/\lambda)pu(\bar{c}_2)$, $\bar{c}_2 \in W^{1,2}(0, 1)$ and $|\bar{c}_2|_{L^2} = \mu$.*

Remark 4.2. The study of possible regularity of a in (4.1), and more generally, of pointwise and norm bounds simultaneously requires a somewhat different analysis which will be carried out elsewhere.

5. Penalization in the presence of regularity. We return to the case of estimating b that was discussed at the beginning of § 4, and make use of the regularity $\bar{b} \in W^{3,2}(0, 1)$ that was shown to hold for the solutions \bar{b} of (P_i) .

The following condition is assumed to hold for the subspaces of the approximating functions for the coefficient b . Let $B_P = \{b \in W^{1,2}: |b(x)| \leq d\mu \text{ for all } x \in [0, 1]\}$.

(H4) The sequence of finite dimensional linear subspaces $B^m \subset W^{1,2}(0, 1)$ satisfies that for each $b \in W^{3,2}(0, 1)$ with $|b|_{W^{1,2}} \leq \mu$ there exists a sequence $\tilde{b}^m \in B^m \cap B_P$ with $|\tilde{b}^m - b|_{W^{1,2}} \leq \rho_B(m)|b|_{W^{3,2}}$ and $\lim_{m \rightarrow \infty} \rho_B(m) = 0$ independently of b .

If B^m , $m = 1, 2, \dots$, is chosen as the space of linear spline functions with equidistant knots (i/m) , $i = 0, \dots, m$, then $\rho_B(m) = O(1/m^2)$. Since $|b|_\infty \leq d\mu$ for b with $|b|_{W^{1,2}} \leq \mu$, one can take $Q^m b \in B^m \cap B_P$, where Q^m denotes the quasi-interpolation operator (see [13, pp. 299, 230]); compare also Remark 3.5.

For $i = 1$ or 2 we consider the problems

$$(P_{i_h(m)}^{N,m}) \quad \min_{b \in B^m \cap B_P} (J^N(b) + h(m)\psi_B(b)).$$

By Remark 2.2 and Lemma 3.1 there exist solutions $\bar{b}_{h(m)}^{N,m}$ of $(P_{i_h(m)}^{N,m})$, if only (H1) and (H2) hold. Utilizing the regularity results for the convection coefficient given in § 4, we now improve the approximation result of Theorem 3.2.

THEOREM 5.1. *Assume that (H1), (H2) and (H4) hold, and that $\lim_{m \rightarrow \infty} h(m) = \infty$, $\lim_{m \rightarrow \infty} h(m)\rho_B(m)^2 = 0$. If b^* is any weak limit point of $\{\bar{b}_{h(m)}^{N,m}\}$, such that $\bar{b}_{h(m_k)}^{N,m_k} \rightharpoonup b^*$ in $W^{1,2}(0, 1)$ and $N_k \rightarrow \infty$, $m_k \rightarrow \infty$ as $k \rightarrow \infty$, then $b^* \in B$ is a solution of (P_i) , $u(\bar{b}_{h(m_k)}^{N,m_k}) \rightarrow u(b^*)$ in $W^{1,2}(0, 1)$ and $J^{N_k}(\bar{b}_{h(m_k)}^{N,m_k}) + h(m_k)\psi_B(\bar{b}_{h(m_k)}^{N,m_k}) \rightarrow J(b^*)$.*

Proof. Let \bar{b} be any solution of (P_i) , for $i = 1$ or 2 and determine \tilde{b}^{m_k} according to (H4). Then for all k the inequality

$$(5.1) \quad J^{N_k}(\bar{b}_{h(m_k)}^{N,m_k}) + h(m_k)\psi_B(\bar{b}_{h(m_k)}^{N,m_k}) \leq J^{N_k}(\tilde{b}^{m_k}) + h(m_k)\psi_B(\tilde{b}^{m_k})$$

holds. If $|\bar{b}| < \mu$, then $\lim_{k \rightarrow \infty} h(m_k) \psi_B(\tilde{b}^{m_k}) = 0$. Otherwise we have $h(m_k) \psi_B(\tilde{b}^{m_k}) = h(m_k)(|\tilde{b}^{m_k}|_{W^{1,2}} - \mu)^2 \leq h(m_k)|\tilde{b}^{m_k}|_{W^{1,2}} - |\bar{b}|_{W^{1,2}}|^2 \leq h(m_k)(|\tilde{b}^{m_k} - \bar{b}|_{W^{1,2}})^2 = h(m_k) \rho_B(m_k)^2 |\bar{b}|_{W^{2,2}}$, and again $\lim_{k \rightarrow \infty} h(m_k) \psi_B(\tilde{b}^{m_k}) = 0$.

Consequently the right-hand side of (5.1) converges to $J(\bar{b})$ as $k \rightarrow \infty$, and the left-hand side of (5.1) is bounded. This implies that $\lim_{k \rightarrow \infty} \psi_B(\bar{b}_{h(m_k)}^{N_k, m_k}) = 0$ and therefore $b^* \in B$. Since

$$(5.2) \quad J^{N_k}(\bar{b}_{h(m_k)}^{N_k, m_k}) \leq J^{N_k}(\bar{b}_{h(m_k)}^{N_k, m_k}) + h(m_k) \psi_B(\bar{b}_{h(m_k)}^{N_k, m_k}),$$

we have from (5.1)

$$(5.3) \quad J^{N_k}(\bar{b}_{h(m_k)}^{N_k, m_k}) \leq J^{N_k}(\tilde{b}^{m_k}) + h(m_k) \psi_B(\tilde{b}^{m_k}),$$

for all k . Corollary 2.1 implies that $u^{N_k}(\tilde{b}^{m_k}) \rightarrow u(\bar{b})$ and $u^{N_k}(\bar{b}_{h(m_k)}^{N_k, m_k}) \rightarrow u(b^*)$ in $W^{1,2}(0, 2)$ as $k \rightarrow \infty$. Therefore, taking the limit as $k \rightarrow \infty$ in (5.3), we have

$$(5.4) \quad J_i(b^*) \leq J_i(\bar{b}).$$

Since \bar{b} is an arbitrary solution of (P_i) , b^* is a solution as well.

The convergence of the states has already been discussed. The final claim concerning convergence of the penalized fit-to-data criteria follows from (5.2)–(5.4), where we note that (5.4) holds with the inequality replaced by an equality.

6. Numerical examples. In this section we give some numerical data for the identification of the coefficients b and c in (2.1) via the output least squares method; in these examples unconstrained minimization is not successful numerically, whereas realization of the norm constraint by a penalty functional leads to quite satisfactory fits of the “unknown” coefficient \bar{b} or \bar{c} . In all our examples the observation z was taken as the known analytical solution u corresponding to a parameter \bar{b} or \bar{c} as was used in the L^2 -fit-to-data criterion. It is our experience with earlier calculations that adding small amounts of noise to the data does not significantly change the numerical results and we have thus not considered this case here.

To solve the problems $(P_M^{N, m})$, we took as subspaces H^N cubic B -splines with an equidistant grid $\{i/N\}_{i=0}^N$ and modified to satisfy Dirichlet boundary conditions and for Q^m piecewise linear spline functions or again cubic B -splines, with grid $\{i/m\}_{i=0}^m$. Thus $\dim(H^N) = N + 1$ and $\dim(Q^m) = m + 1$ in the case of linear spline functions and $\dim(Q^m) = m + 3$ for cubic B -splines. The minimization was carried out by Newton's method with the derivatives of the discretized systems calculated analytically. The startup value for the unknown coefficient was chosen as the constant function 2 in all cases. In all graphs the *solid lines* represent the true solution, whereas the *dotted lines* represent the numerical approximation.

Example 6.1. Here we search for the coefficient $\bar{c} = \sqrt{2} \cos 2\pi x$ in

$$(6.1) \quad \begin{aligned} -4u_{xx} + \bar{c}u &= f \quad \text{in } (0, 1), \\ u(0) &= u(1) = 0, \end{aligned}$$

where $f(x) = (4\pi^2 + \sqrt{2} \cos 2\pi x) \sin \pi x$. The solution of (6.1) is given by $u(\bar{c}) = \sin \pi x$. The penalty functional, slightly different from the previous section, was taken to be

$$\psi(c) = \begin{cases} (|c|_{L^2}^2 - 1)^2 & \text{if } |c|_{L^2} > 1, \\ 0 & \text{if } |c|_{L^2} \leq 1. \end{cases}$$

Thus the fit-to-data criterion is given by

$$|u^N(c^m) - z|^2 + M\psi(c^m)$$

c ESTIMATE
 $c(x) = \sqrt{2} \cos 2\pi x, N = 20, m = 21, M = 0$

FIG. 4

with $z = u(\bar{c})$. In Figs. 1-6 we give the graphs of the converged values for $\bar{c}_M^{N,m}$ and $u^N(\bar{c}_M^{N,m})$ in the case that $N=20$, $m=21$ and for the values $M=0, .1$, and 10 . The graph for $M=1$ is indistinguishable from that for $M=.1$. The best fits are obtained for $M=.1$ and 1 ; for $M=10$ the result is less accurate, which might be attributed to the well-known numerical ill-conditioning of the penalty method for large values of

FIG. 6

the penalty parameter M . The reader should observe that several different scales are used for the graphs.

Example 6.2. We now identify $\bar{b} = \sqrt{2} \cos \pi x$ in

$$(6.2) \quad \begin{aligned} -4u_{xx} + \bar{b}u_x + 4u &= f \quad \text{in } (0, 1), \\ u(0) &= u(1) = 0, \end{aligned}$$

where $f(x) = (4\pi^2 + 4) \sin \pi x + \sqrt{2}\pi \cos^2 \pi x$. The solution of (6.2) is given by $u(\bar{b}) = \sin \pi x$. As a penalty functional we took

$$(6.3) \quad \psi(b) = \begin{cases} (|b|_{H^1}^2 - (1 + \pi^2))^2 & \text{if } |b|_{H^1} > 1 + \pi^2, \\ 0 & \text{if } |b|_{H^1} \leq 1 + \pi^2, \end{cases}$$

and the fit-to-data criterion is defined accordingly. In Figs. 7-9 we give the graphs of the converged values $\bar{b}_M^{N,m}$ for $N=10$, $M=.01$ and various values of m , when the approximating subspaces Q^m are taken as linear spline functions. We carried out the same calculations with M changed to be .001 and .1 and obtained almost identical results. It is remarkable to observe that a reasonable fit was obtained even when $m > N$. For $M=0$ the optimization algorithm did not converge. In Fig. 10 we show the result when instead of linear splines we take cubic B -splines for the space Q^m and choose $N=10$, $m=7$ and $M=.01$. For $N=10$, $m=4, 6$, or 9 and $M=.001$ or .1 the results we obtained were rather similar. For all the calculations shown in Figs. 7-12 the converged value $\bar{u}^N(b^m)$ gave a very good approximation to $u(\bar{b})$ and we therefore do not show the plots for these cases.

Finally we present the results that we obtained when the penalty functional (6.3) was replaced by

$$(6.4) \quad \psi(b) = \begin{cases} (|b|_{L^2}^2 - 1)^2 & \text{if } |b|_{L^2} > 1, \\ 0 & \text{if } |b|_{L^2} \leq 1. \end{cases}$$

Again Q^m was taken as the space of linear spline functions with knots at $\{i/m\}_{i=0}^m$.

 $b(x) = \sqrt{2} \cos(\pi x)$, $N = 10$, $m = 9$, $M = .01$

FIG. 8

b ESTIMATE
 $b(x) = \sqrt{2} \cos(\pi x)$, $N = 10$, $m = 11$, $M = .01$

FIG. 9

Figures 11 and 12 give the results for the case $N = 10$, $M = 1$ and $m = 6$ and 11. We made several other runs with different values for M and m . Throughout the penalty functional (6.3) employing the H^1 -norm produced better fits than the (6.4) criterion which uses the L^2 -norm.

THE LINEAR QUADRATIC CONTROL PROBLEM FOR INFINITE DIMENSIONAL SYSTEMS WITH UNBOUNDED INPUT AND OUTPUT OPERATORS*

A. J. PRITCHARD† AND D. SALAMON‡

Abstract. This paper establishes a general semigroup framework for solving quadratic control problems with infinite dimensional state space and unbounded input and output operators.

Key words. infinite dimensional systems, linear quadratic control, unbounded inputs and outputs, semigroups

AMS(MOS) subject classification. 93C25

1. Introduction. The object of this paper is to present a general semigroup theoretic framework for solving the linear quadratic control problem (LQCP) for systems with an infinite dimensional state space and unbounded input and output operators.

The LQCP has been one of the central research problems in the area of mathematical systems theory for more than twenty years. This is partly due to its beautiful mathematical structure. Furthermore, the LQCP provides a link between the area of optimal control and structure theory for linear control systems, and last, but not least, the infinite time quadratic cost problem leads to a numerically stable procedure for stabilizing a linear system by feedback.

For finite dimensional systems the LQCP is now well understood (see e.g. Willems [28], Wonham [29]) and a more or less complete generalization of the finite dimensional theory has been developed for infinite dimensional systems with bounded input and output operators (see e.g. Datko [6], Curtain and Pritchard [4], Lions [19], Gibson [10], Bensoussan, Delfour and Mitter [2], Zabczyk [30]).

In many dynamical systems, the control and observation processes are severely limited. For example there may be delays in the control actuators and measurement devices. Also for systems described by partial differential equations (PDE) it may not be possible to influence or sense the state at each point of the spatial domain. Instead controls and sensors are restricted to a few points or parts of the boundary. Modelling such limitations results in unbounded input and output operators. For infinite dimensional systems with unbounded input and output operators the LQCP has recently been studied by various authors. One of the first papers in this direction was by Lukes and Russell [20] and involved spectral operators. The classical reference for parabolic systems is of course the book of Lions [19]. His results have only recently been generalized to parabolic systems with a larger degree of unboundedness in the input and output operators (Pollock and Pritchard [22], Balakrishnan [1], Flandoli [9], Lasiecka and Triggiani [16], Sorine [26], [27]). The LQCP for first order hyperbolic PDE's has been studied by Russell [23]. Lasiecka and Triggiani [18] consider the higher dimensional wave equation with Dirichlet boundary control. In their paper the resulting optimal feedback operator is unbounded. For retarded systems with input delays we refer to Ichikawa [12] and Delfour [8] and for neutral systems with output delays to Datko [7] and Ito and Tarn [14].

‡ Forschungsschwerpunkt Dynamische Systeme, Universität Bremen, West Germany.

All of these papers deal with very specific classes of infinite dimensional systems—so far, no attempt has apparently been made to develop a general semigroup theoretic approach for the infinite dimensional LQCP with unbounded input and output operators which applies both to parabolic and hyperbolic PDE's as well as to retarded and neutral functional differential equations (FDE). In the present paper we fill this gap. An essential feature in our approach is that the semigroup $S(t)$ which describes the dynamics of the homogeneous equation is not assumed to have any smoothing properties. This is possible by means of the theory developed in Salamon [25, Chap. 1.3] and provides the basis for our approach to the LQCP.

In § 2 we solve the finite quadratic control problem in the general semigroup theoretic framework. In particular, we derive the existence of a unique-nonnegative solution $P(t)$ of the operator differential Riccati equation and we show that the unique optimal control is given by a time-varying feedback law involving this operator $P(t)$. We point out that the solution operator $P(t)$ of the Riccati equation has smoothing properties and that the associated feedback operator is bounded.

Section 3 is devoted to the infinite time problem and the solution is described in terms of the operator algebraic Riccati equation. The solution of the algebraic Riccati equation is derived as the limit operator of the solutions of the differential equation on the interval $[0, T]$ as T tends to infinity. Generalizing the results of Zabczyk [30], we establish relationships between the stabilizability and detectability properties of the system and existence and uniqueness results for the algebraic Riccati equation.

In § 4 we show how our general theory applies to parabolic and hyperbolic PDE's with boundary control as well as for neutral FDE's with output delays. For these special classes of infinite dimensional systems we do not derive substantial new results. We do, however, obtain a number of known results, which have not even been published, as simple straightforward consequences of our general theory. Another application of this theory to retarded FDE's with delays in control and observation will be the subject of a follow up paper.

2. Finite time control. In a formal sense our basic model is

$$(2.1) \quad \begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t), & x(t_0) &= x_0, \\ y(t) &= Cx(t), & t_0 &\leq t \leq t_1, \end{aligned}$$

where $u(\cdot) \in L^2[t_0, t_1; U]$, $y(\cdot) \in L^2[t_0, t_1; Y]$, U and Y are Hilbert spaces and A is the infinitesimal generator of a strongly continuous semigroup $S(t)$ on a Hilbert space H . In order to allow for possible unboundedness of the operators B and C , we assume that $B \in \mathcal{L}(U, V)$, and $C \in \mathcal{L}(W, Y)$ where W, V are Hilbert spaces such that

$$(2.2) \quad W \subset H \subset V$$

with continuous dense injections. Of course, we interpret (2.1) in the mild form which means that its solution $x(t)$ is given by the variation-of-constants formula

$$(2.3a) \quad x(t) = S(t - t_0)x_0 + \int_{t_0}^t S(t - \sigma)Bu(\sigma) d\sigma, \quad t_0 \leq t \leq t_1.$$

In order to make this formula precise and to allow for trajectories in all three spaces W, H, V , we have to assume that $S(t)$ is also a strongly continuous semigroup on W and V and that the following hypotheses are satisfied.

(H1) There exists some constant $b > 0$ such that $\int_{t_0}^{t_1} S(t_1 - \sigma)Bu(\sigma) d\sigma \in W$ and $\|\int_{t_0}^{t_1} S(t_1 - \sigma)Bu(\sigma) d\sigma\|_W \leq b\|u(\cdot)\|_{L^2(t_0, t_1; U)}$ for every $u(\cdot) \in L^2(t_0, t_1; U)$.

(H2) There exists some constant $c > 0$ such that $\|CS(\cdot - t_0)x\|_{L^2(t_0, t_1; Y)} \leq c\|x\|_V$ for every $x \in W$.

Remarks 2.1. (i) Hypothesis (H1) implies that for every $x_0 \in W$ and every $u(\cdot) \in L^2(t_0, t_1; U)$ formula (2.3a) defines a continuous function $x(\cdot)$ on the interval $[t_0, t_1]$ with values in W . Hence the output can in this case be defined by

$$(2.3b) \quad y(t) = CS(t - t_0)x_0 + C \int_{t_0}^t S(t - \sigma)Bu(\sigma) d\sigma, \quad t_0 \leq t \leq t_1,$$

and is a continuous function on the interval $[t_0, t_1]$ with values in Y . If $x_0 \in V$, then $x(\cdot)$ is only a continuous function with values in V and (2.3b) does not make sense directly. But if (H2) is satisfied, then for any $x_0 \in V$ we will use the expression $CS(t - t_0)x_0$, $t_0 \leq t \leq t_1$, to denote the function in $L^2(t_0, t_1; Y)$ which is obtained by continuous extension to $x_0 \in V$ of the operator which maps $x_0 \in W$ into $CS(\cdot - t_0)x_0 \in L^2(t_0, t_1; Y)$. In this sense the right-hand side of (2.3b) is a well defined L^2 -function of t with values in Y .

(ii) In the above sense the expression $CS(t)Bu$ has a well defined meaning as a function of t for every $u \in U$. But the expression $CS(t - \sigma)Bu(\sigma)$ will in general not be a well defined function of σ . Therefore the operator C cannot be taken under the integral sign in (2.3b).

(iii) In the following we identify the Hilbert spaces H , U , Y with their duals. Then it follows from (2.2) by duality that

$$V^* \subset H \subset W^*$$

with continuous, dense injections. Furthermore, the adjoint semigroup $S^*(t)$ is a strongly continuous semigroup on all three spaces V^* , H , W^* .

(iv) Hypothesis (H1) is satisfied if and only if the following dual statement holds.

$$(H1^*) \quad \|B^*S^*(t_1 - \cdot)x\|_{L^2(t_0, t_1; U)} \leq b\|x\|_{W^*}, \quad x \in V^*.$$

This is a simple consequence of the identity

$$\left\langle x, \int_{t_0}^{t_1} S(t_1 - \sigma)Bu(\sigma) d\sigma \right\rangle_{V^*, V} = \int_{t_0}^{t_1} \langle B^*S^*(t_1 - \sigma)x, u(\sigma) \rangle_U d\sigma$$

for $x \in V^*$ and $u(\cdot) \in L^2(t_0, t_1; U)$ and the fact that $W^{**} = W$. Similarly, the dual statement of (H2) is the following.

(H2*) For every $y(\cdot) \in L^2(t_0, t_1; Y)$ we have

$$\left\| \int_{t_0}^{t_1} S^*(\tau - t_0)C^*y(\tau) d\tau \right\|_{V^*} \leq c\|y(\cdot)\|_{L^2(t_0, t_1; Y)}.$$

(v) In view of hypothesis (H1*) the expression $B^*S^*(t)x$ has a well defined meaning as an L^2 function of t for every $x \in W^*$, in particular when $x = C^*y$ with $y \in Y$.

Associated with the control system (2.3) is the performance index

$$(2.4) \quad J(u) = \langle x(t_1), Gx(t_1) \rangle_{V, V^*} + \int_{t_0}^{t_1} [\|Cx(t)\|_Y^2 + \langle u(t), Ru(t) \rangle_U] dt,$$

where $G \in \mathcal{L}(V, V^*)$ is a nonnegative definite operator and $R \in \mathcal{L}(U)$ satisfies

$$\langle u, Ru \rangle_U \geq \varepsilon \|u\|_U^2$$

for some $\varepsilon > 0$ and every $u \in U$.

Now let us consider system (2.3) with the feedback control

$$(2.5) \quad u_F(t) = F(t)x(t), \quad t_0 \leq t \leq t_1,$$

where $F(t) \in \mathcal{L}(V, U)$ is strongly continuous on the interval $[t_0, t_1]$. Then we may define a mild evolution operator $\Phi_F(t, s) \in \mathcal{L}(V)$, $t_0 \leq s \leq t \leq t_1$, via

$$(2.6) \quad \Phi_F(t, s)x = S(t-s)x + \int_s^t S(t-\sigma)BF(\sigma)\Phi_F(\sigma, s)x \, d\sigma$$

(see Curtain and Pritchard [4]).

Remarks 2.2. (i) It follows from (2.6) that $\Phi_F(t, s)$ satisfies the equation

$$(2.7) \quad \Phi_F(t, s)x - x = \int_s^t \Phi_F(t, \sigma)[A + BF(\sigma)]x \, d\sigma, \quad t_0 \leq s \leq t \leq t_1$$

for every $x \in \mathcal{D}_V(A)$ (the domain of A regarded as an unbounded, closed operator on V). Equivalently the function $s \rightarrow \Phi_F(t, s)x \in V$ is continuously differentiable on the interval $[t_0, t]$ for every $x \in \mathcal{D}_V(A)$ and satisfies

$$(2.8) \quad \frac{\partial \Phi_F(t, s)x}{\partial s} = -\Phi_F(t, s)[A + BF(s)]x, \quad t_0 \leq s \leq t \leq t_1$$

(see Curtain and Pritchard [4].)

(ii) It is well known that the evolution operator satisfies the equation

$$(2.9) \quad \Phi_F(t, s)x = S(t-s)x + \int_s^t \Phi_F(t, \sigma)BF(\sigma)S(\sigma-s)x \, d\sigma$$

for $t_0 \leq s \leq t \leq t_1$ and $x \in V$. (See Curtain and Pritchard [4].)

(iii) Often we will consider the feedback system with an additional forcing input $v(\cdot)$ so that

$$(2.10) \quad u(t) = F(t)x(t) + v(t)$$

in (2.3). It follows easily from (2.9) that—for this control function—the corresponding solution of (2.3) is given by

$$(2.11) \quad x(t) = \Phi_F(t, t_0)x_0 + \int_{t_0}^t \Phi_F(t, \sigma)Bv(\sigma) \, d\sigma, \quad t_0 \leq t \leq t_1.$$

(iv) Using (2.6), it is easy to see that $\Phi_F(t, s)$ is also a strongly continuous evolution operator on W and V and has the following properties.

(H1') There exists a constant $b' > 0$ such that

$$\left\| \int_{t_0}^t \Phi_F(t, \sigma)Bu(\sigma) \, d\sigma \right\|_W \leq b' \|u(\cdot)\|_{L^2(t_0, t; U)}$$

for every $u(\cdot) \in L^2(t_0, t_1; U)$ and every $t \in [t_0, t_1]$.

(H2') There exists a constant $c' > 0$ such that

$$\|C\Phi_F(\cdot, s)x\|_{L^2(s, t_1; Y)} \leq c' \|x\|_V$$

for every $x \in W$ and every $s \in [t_0, t_1]$

The dual properties are the following:

(H1')* The inequality

$$\|B^*\Phi_F^*(t, \cdot)x\|_{L^2(t_0, t; U)} \leq b' \|x\|_{W^*}$$

holds for every $x \in V^*$ and every $t \in [t_0, t_1]$.

(H2')* The inequality

$$\left\| \int_s^{t_1} \Phi_F^*(\tau, s) C^* y(\tau) d\tau \right\|_{V^*} \leq c' \|y(\cdot)\|_{L^2(s, t_1; Y)}$$

holds for every $y(\cdot) \in L^2(t_0, t_1; Y)$ and every $s \in [t_0, t_1]$.

Using the condition (H2') and its dual, we can define a strongly continuous operator $P_F(t) \in \mathcal{L}(V, V^*)$, by

$$(2.12) \quad \begin{aligned} P_F(t)x = & \Phi_F^*(t_1, t) G \Phi_F(t_1, t)x + \int_t^{t_1} \Phi_F^*(\tau, t) C^* C \Phi_F(\tau, t)x d\tau \\ & + \int_t^{t_1} \Phi_F^*(\tau, t) F^*(\tau) R F(\tau) \Phi_F(\tau, t)x d\tau \end{aligned}$$

for $t_0 \leq t \leq t_1$ and $x \in V$. Then the cost of the feedback control (2.5) corresponding to an initial state $x_0 \in V$ is given by

$$(2.13) \quad J(u_F) = \langle x_0, P_F(t_0)x_0 \rangle_{V, V^*}.$$

If the initial state is in H , then this expression can be interpreted via the inner product in H .

Remark 2.3. The adjoint operator of $P_F(t) \in \mathcal{L}(V, V^*)$ is still an operator from V to V^* and coincides with $P_F(t)$. In this sense one can say that $P_F(t)$ is self adjoint. Equivalently, the operator $i^{-1}P_F(t)$ on the Hilbert space V is self adjoint with respect to the inner product on V where $i: V \rightarrow V^*$ is the canonical isometric isomorphism. Finally, $P_F(t)$ is self adjoint in the above sense if and only if its restriction to H is a self adjoint operator on H .

A formula comparing the cost of an arbitrary control $u(\cdot) \in L^2(t_0, t_1; U)$ with the cost of the feedback control (2.5) will play an important role in our analysis. In the proof of this result we will need to interchange some integrals. At some points this becomes a delicate problem since we will have to operate with terms like $C\Phi_F(t, s)B$. In order to make the results precise, we need a third hypothesis.

(H3) Suppose that

$$Z = \mathcal{D}_V(A) \subset W$$

with a continuous, dense embedding where the Hilbert space Z is endowed with the graph norm of A , regarded as an unbounded, closed operator on V . This assumption is not very restrictive. It is satisfied by all known examples of systems which satisfy (H1) and (H2) if the spaces W and V are chosen appropriately. In the following we summarize some important consequences of (H3).

Remarks 2.4. (i) If (H3) is satisfied, then A can be regarded as a bounded operator from Z into V . Correspondingly A^* becomes a bounded operator from V^* into Z^* . On the other hand A can be restricted to a closed, densely defined operator on Z . Its adjoint in this sense coincides with the above operator $A^*: V^* \rightarrow Z^*$ (Salamon [25, Lemma 1.3.2]) and moreover

$$\mathcal{D}_{W^*}(A^*) \subset \mathcal{D}_{Z^*}(A^*) = V^*.$$

(ii) It is a well-known fact from semigroup theory that

$$T_t x = \int_0^t S(s)x ds \in \mathcal{D}_V(A) = Z$$

for every $x \in V$ and every $t \geq 0$. If (H3) is satisfied, then T_t is a strongly continuous family of bounded, linear operators from V into W . It is easy to see that the adjoint operator $T_t^* \in \mathcal{L}(W^*, V^*)$ is given by

$$T_t^* x = \int_0^t S^*(s)x \, ds \in \mathcal{D}_{W^*}(A^*) \subset V^*$$

for $x \in W^*$ and $t \geq 0$.

(iii) If (H1), (H2) and (H3) are satisfied, then the following equation holds for every $u \in U$ and every $t \geq 0$

$$C \int_0^t S(s)Bu \, ds = CT_t Bu = \int_0^t CS(s)Bu \, ds.$$

This seems like a trivial fact; however, we were not able to establish this identity without assuming (H3). Note that the LHS of the above equation has to be interpreted in terms of (H1) and the RHS in terms of (H2). For establishing the equation one must approximate $Bu \in V$ by a sequence of elements in W . Then the term on the LHS will not converge in general unless range $T_t \subset W$.

LEMMA 2.5. *Suppose that (H1), (H2), (H3) are satisfied; let $F(t) \in \mathcal{L}(V, U)$, $t_0 \leq t \leq t_1$, be strongly continuous and let $\Phi_F(t, s) \in \mathcal{L}(V) \cap \mathcal{L}(W)$ be defined by (2.6). Moreover, let $u(\cdot) \in L^2(t_0, t_1; U)$ and $y(\cdot) \in L^2(t_0, t_1; U)$ be given. Then*

$$(2.14) \quad \int_{t_0}^{t_1} \int_s^{t_1} \langle C\Phi_F(t, s)Bu(s), y(t) \rangle_Y \, dt \, ds = \int_{t_0}^{t_1} \left\langle C \int_{t_0}^t \Phi_F(t, s)Bu(s) \, ds, y(t) \right\rangle_Y \, dt$$

where the first expression must be interpreted in terms of (H2) and the second in terms of (H1).

Proof. First note that, by (2.6) and (H1), $\Phi_F(t, s) - S(t-s) \in \mathcal{L}(V, W)$. Hence it is enough to establish the desired equation with $\Phi_F(t, s)$ replaced by $S(t-s)$. Secondly it is easy to see that with $T_t \in \mathcal{L}(V, W)$ defined as in Remark 2.4(ii) the equations

$$\begin{aligned} x(t) &= \int_{t_0}^t S(t-s)Bu(s) \, ds = \int_{t_0}^t T_{t-s}Bu(s) \, ds \in W, \\ z(s) &= \int_s^{t_1} S^*(t-s)C^*y(t) \, dt = - \int_s^{t_1} T_{t-s}^*C^*y(t) \, dt \in V^* \end{aligned}$$

hold for $u(\cdot) \in \mathcal{C}^1[t_0, t_1; U]$ with $u(t_0) = 0$ and $y(\cdot) \in \mathcal{C}^1[t_0, t_1; Y]$ with $y(t_1) = 0$. Interchanging integrals, we obtain from these identities that

$$\begin{aligned} \int_{t_0}^{t_1} \langle Cx(t), y(t) \rangle_Y \, dt &= \int_{t_0}^t \langle Bu(s), z(s) \rangle_{V, V^*} \, ds \\ &= \int_{t_0}^{t_1} \int_s^{t_1} \langle CS(t-s)Bu(s), y(t) \rangle_Y \, dt \, ds. \end{aligned}$$

Now the statement of the lemma follows from the fact that both sides of this equation depend continuously on $u(\cdot) \in L^2[t_0, t_1; U]$ and $y(\cdot) \in L^2[t_0, t_1; Y]$.

Now we are in the position to prove the desired comparison formula for the feedback control (2.5).

LEMMA 2.6. *Suppose that (H1), (H2), (H3) are satisfied; let $F(t) \in \mathcal{L}(V, U)$ be strongly continuous on the interval $[t_0, t_1]$ and let $P_F(t) \in \mathcal{L}(V, V^*)$ be defined by (2.12)*

and (2.6). Then the following equation holds for every $x_0 \in V$ and every $u(\cdot) \in L^2(t_0, t_1; U)$

$$\begin{aligned}
 J(u) - \langle x_0, P_F(t_0)x_0 \rangle_{V, V^*} &= \int_{t_0}^{t_1} \langle R^{-1}B^*P_F(t)x(t) \\
 &\quad + u(t), R[R^{-1}B^*P_F(t)x(t) + u(t)] \rangle dt \\
 (2.15) \quad &- \int_{t_0}^{t_1} \langle R^{-1}B^*P_F(t)x(t) \\
 &\quad + F(t)x(t), R[R^{-1}B^*P_F(t)x(t) + F(t)x(t)] \rangle dt
 \end{aligned}$$

where $x(t)$, $t_0 \leq t \leq t_1$, is given by (2.3).

Proof. We sketch only the main steps of the proof for the case $x_0 \in W$. Let $x(t)$ be the mild solution of (2.1) given by (2.3) and define

$$\begin{aligned}
 v(t) &= u(t) - F(t)x(t), \\
 z(t) &= \int_{t_0}^t \Phi_F(t, s)Bv(s) ds = x(t) - \Phi_F(t, t_0)x_0
 \end{aligned}$$

for $t_0 \leq t \leq t_1$ (see Remark 2.2(iii)). Then applying Lemma 2.5, we can obtain

$$\begin{aligned}
 2\operatorname{Re} \int_{t_0}^{t_1} \int_s^{t_1} \langle C\Phi_F(t, s)z(s), C\Phi_F(t, s)Bv(s) \rangle dt ds \\
 = \operatorname{Re} \int_{t_0}^{t_1} \int_s^{t_1} \langle Cz(t), C\Phi_F(t, s)Bv(s) \rangle dt ds = \int_{t_0}^{t_1} \|Cz(t)\|_Y^2 dt
 \end{aligned}$$

and therefore, again using Lemma 2.5,

$$\begin{aligned}
 2\operatorname{Re} \int_{t_0}^{t_1} \int_s^{t_1} \langle C\Phi_F(t, s)x(s), C\Phi_F(t, s)Bv(s) \rangle dt ds \\
 = 2\operatorname{Re} \int_{t_0}^{t_1} \langle C\Phi_F(t_1, t_0)x_0, Cz(t) \rangle dt + \int_{t_0}^{t_1} \|Cz(t)\|_Y^2 dt \\
 = \int_{t_0}^{t_1} \|Cx(t)\|_Y^2 dt - \int_{t_0}^{t_1} \|C\Phi_F(t, t_0)x_0\|_Y^2 dt.
 \end{aligned}$$

Analogous identities can be derived in a more straightforward way when C^*C is replaced by $G \in \mathcal{L}(V, V^*)$ or $F^*(t)RF(t) \in \mathcal{L}(V, V^*)$. Using first (2.12) and then these identities, we get

$$\begin{aligned}
 2\operatorname{Re} \int_{t_0}^{t_1} \langle P_F(s)x(s), Bv(s) \rangle ds \\
 = \langle x(t_1), Gx(t_1) \rangle - \langle \Phi_F(t_1, t_0)x_0, G\Phi_F(t_1, t_0)x_0 \rangle \\
 + \int_{t_0}^{t_1} \|Cx(t)\|^2 dt - \int_{t_0}^{t_1} \|C\Phi_F(t, t_0)x_0\|^2 dt \\
 + \int_{t_0}^{t_1} \langle F(t)x(t), RF(t)x(t) \rangle dt \\
 - \int_{t_0}^{t_1} \langle F(t)\Phi_F(t, t_0)x_0, RF(t)\Phi_F(t, t_0)x_0 \rangle dt \\
 = J(u) - \langle x_0, P_F(t_0)x_0 \rangle - \int_{t_0}^{t_1} \langle u(t), Ru(t) \rangle dt
 \end{aligned}$$

$$+ \int_{t_0}^{t_1} \langle F(t)x(t), RF(t)x(t) \rangle dt.$$

It is easy to see that this equation implies (2.15).

We are now able to prove the main result of this section.

THEOREM 2.7. *Let (H1), (H2) and (H3) be satisfied. Then there exists a unique strongly continuous self adjoint, nonnegative operator $P(t) \in \mathcal{L}(V, V^*)$ $t_0 \leq t \leq t_1$, solving the integral Riccati equation.*

$$(2.16) \quad \begin{aligned} P(t)x = & \Phi^*(t_1, t)G\Phi(t_1, t)x \\ & + \int_t^{t_1} \Phi^*(s, t)[C^*C + P(s)BR^{-1}B^*P(s)]\Phi(s, t)x ds \end{aligned}$$

for $x \in W$ and $t_0 \leq t \leq t_1$ where $\Phi(s, t) = \Phi_F(s, t)$ is the evolution operator defined by (2.6) with $F(t) = -R^{-1}B^*P(t) \in \mathcal{L}(V, U)$. Furthermore there is a unique optimal control which minimizes the performance index (2.4) subject to (2.3). This optimal control is given by the feedback control law

$$(2.17) \quad u_F(t) = -R^{-1}B^*P(t)x(t)$$

and the optimal cost is

$$(2.18) \quad J(u_F) = \langle x_0, P(t_0)x_0 \rangle.$$

Proof. We regard (2.16) as a fixed point problem which is to be solved by iteration. Let us define the sequence $P_k(t) \in \mathcal{L}(V, V^*)$ recursively through

$$P_0(t) = 0, \quad P_k(t) = P_F(t), \quad F(t) = -R^{-1}B^*P_{k-1}(t)$$

for $k \in \mathbb{N}$ and $t_0 \leq t \leq t_1$, where $P_F(t)$ is given by (2.12). Let us also define

$$\Phi_k(s, t) = \Phi_F(s, t), \quad F(t) = -R^{-1}B^*P_k(t),$$

so that

$$(2.19) \quad \begin{aligned} \langle z, P_{k+1}(t)x \rangle_{V, V^*} = & \langle \Phi_k(t_1, t)z, G\Phi_k(t_1, t)x \rangle_{V, V^*} \\ & + \int_t^{t_1} \langle C\Phi_k(s, t)z, C\Phi_k(s, t)x \rangle_Y ds \\ & + \int_t^{t_1} \langle B^*P_k(s)\Phi_k(s, t)z, RB^*P_k(s)\Phi_k(s, t)x \rangle_U ds \end{aligned}$$

holds for $t_0 \leq t \leq t_1$ and $x \in W$. Applying Lemma 2.6 to $F(t) = -R^{-1}B^*P_{k-1}(t)$ and $u_k(t) = -R^{-1}B^*P_k(t)x(t)$, we obtain

$$(2.20) \quad \begin{aligned} \langle x_0, P_{k+1}(t_0)x_0 \rangle = & J(u_k) = \langle x_0, P_k(t_0)x_0 \rangle \\ & - \int_{t_0}^{t_1} \langle [P_k(\tau) - P_{k-1}(\tau)]x(\tau), BR^{-1}B^* \\ & \cdot [P_k(\tau) - P_{k-1}(\tau)]x(\tau) \rangle d\tau \\ & \leq \langle x_0, P_k(t_0)x_0 \rangle \end{aligned}$$

for $k \in \mathbb{N}$ and $x_0 \in V$. Thus the sequence $\langle x_0, P_k(t_0)x_0 \rangle_{V, V^*}$, $k \in \mathbb{N}$, is monotonically decreasing and positive. Applying Kato's result [15, p. 454, Thm. 3.3] to the monotonically decreasing sequence of nonnegative operators $i^{-1}P_k(t_0)$ on V where $i: V \rightarrow V^*$ is

the canonical isomorphism (Remark 2.3), we obtain the strong convergence of this sequence to a nonnegative limit operator on V . Hence the operators $P_k(t_0) \in \mathcal{L}(V, V^*)$ converge strongly to a nonnegative self adjoint operator $P(t_0) \in \mathcal{L}(V, V^*)$. The same conclusion is valid for every $t \in [t_0, t_1]$ since $t_0 \leq t_1$ can be chosen arbitrarily.

Moreover, (2.20) shows that the operators $P_k(t) \in \mathcal{L}(V, V^*)$, $t_0 \leq t \leq t_1$, $k \in \mathbb{N}$ are uniformly bounded. Hence the limit operator $P(t) \in \mathcal{L}(V, V^*)$ is strongly measurable and uniformly bounded on the interval $[t_0, t_1]$. Therefore we can introduce a strongly continuous evolution operator $\Phi(s, t) = \Phi_F(s, t) \in \mathcal{L}(V) \cap \mathcal{L}(W)$ which is defined by (2.6) with $F(t) = -R^{-1}B^*P(t)$.

Our next step is to show that the function $\Phi_k(\cdot, t)x - \Phi(\cdot, t)x \in \mathcal{C}[t, t_1; W]$ converges to zero in the sup-norm for every $x \in V$ and every $t \in [t_0, t_1]$. For this purpose let us consider the identity

$$\begin{aligned} \Phi(s, t)x - \Phi_k(s, t)x &= \int_t^s S(s-\tau)BR^{-1}B^*[P_k(\tau) - P(\tau)]\Phi(\tau, t)x d\tau \\ &\quad - \int_t^s S(s-\tau)BR^{-1}B^*P_k(\tau)[\Phi(\tau, t)x - \Phi_k(\tau, t)x] d\tau \end{aligned}$$

and apply Gronwall's lemma. Then the desired convergence of $\Phi_k(s, t)x$ follows from the pointwise strong convergence of $P_k(\tau)$ to $P(\tau)$ together with the dominated convergence theorem.

As a consequence of this convergence result we obtain that $\Phi_k(s, t)$ converges to $\Phi(s, t)$ both in $\mathcal{L}(V)$ and in $\mathcal{L}(W)$ and that this convergence is uniform for $t \leq s \leq t_1$ (t fixed). This allows us to apply the dominated convergence theorem to formula (2.19) and hence $P(t)$ satisfies the integral Riccati equation (2.16). Finally it follows easily from (2.16) together with the strong continuity of $\Phi(s, t)$ and $\Phi^*(s, t)$ in both variables and in both spaces V and W that the operator $P(t) \in \mathcal{L}(V, V^*)$ is strongly continuous on the interval $[t_0, t_1]$. Thus we have proved the existence of a solution to (2.16).

In order to prove the uniqueness for the solution of (2.16) together with the statements on the optimal control, let us assume that $P(t) \in \mathcal{L}(V, V^*)$ is any strongly continuous, nonnegative solution of (2.16). Moreover, let $x_0 \in V$, $u(\cdot) \in L^2(t_0, t_1; U)$ be given, let $x(t) \in V$ be the corresponding solution of (2.1) which is given by (2.3) and define $v(t) = u(t) + R^{-1}B^*P(t)x(t)$ for $t_0 \leq t \leq t_1$. Then it follows from Lemma 2.6 that

$$(2.21) \quad J(u) = \langle x_0, P(t_0)x_0 \rangle + \int_{t_0}^{t_1} \langle v(t), Rv(t) \rangle dt.$$

Hence the optimal control is unique and given by the feedback law (2.17) and the optimal cost is given by (2.18). Moreover, we conclude from (2.21) that $\langle x_0, P(t_0)x_0 \rangle = \langle x_0, \hat{P}(t_0)x_0 \rangle$ for any two nonnegative solutions $P(t)$, $\hat{P}(t) \in \mathcal{L}(V, V^*)$ of (2.16) and any $x_0 \in V$. Since $t_0 \leq t_1$ can be chosen arbitrarily, this proves the uniqueness of the solution to (2.16). \square

The following result shows that the integral Riccati equation (2.16) can be converted into a differential Riccati equation.

PROPOSITION 2.8. *Suppose that (H1), (H2) and (H3) are satisfied and let $P(t) \in \mathcal{L}(V, V^*)$ be a nonnegative, self adjoint, strongly continuous operator on the interval $[t_0, t_1]$. Moreover, let the evolution operator $\Phi(s, t) = \Phi_F(s, t) \in \mathcal{L}(V)$ be defined by (2.6) with $F(t) = -R^{-1}B^*P(t)$. Then the following statements are equivalent.*

- (i) *Equation (2.16) holds for every $x \in W$ and every $t \in [t_0, t_1]$.*

(ii) For every $x \in W$ and every $t \in [t_0, t_1]$ the following equation holds

$$(2.22) \quad P(t)x = \Phi^*(t_1, t)GS(t_1 - t)x + \int_t^{t_1} \Phi^*(s, t)C^*CS(s - t)x \, ds.$$

(iii) For every $x \in W$ and every $t \in [t_0, t_1]$ the following equation holds:

$$(2.23) \quad \begin{aligned} P(t)x &= S^*(t_1 - t)GS(t_1 - t)x \\ &+ \int_t^{t_1} S^*(s - t)[C^*C - P(s)BR^{-1}B^*P(s)]S(s - t)x \, ds. \end{aligned}$$

(iv) For every $x \in Z$ the function $P(t)x$, $t_0 \leq t \leq t_1$ is continuously differentiable with values in Z^* and satisfies the differential Riccati equation

$$(2.24a) \quad \frac{d}{dt}P(t)x + A^*P(t)x + P(t)Ax - P(t)BR^{-1}B^*P(t)x + C^*Cx = 0,$$

$$(2.24b) \quad P(t_1)x = Gx.$$

In this equation A is regarded as a bounded operator from Z into V .

Proof. The equivalence of the statements (i), (ii) and (iii) can be established in a straightforward way using the formulae (2.6) and (2.9) together with Lemma 2.5.

In order to prove that (iii) implies (iv), note that the equation

$$(2.25) \quad \langle CS(t)z, CS(t)x \rangle - \langle Cz, Cx \rangle = \int_0^t [\langle CS(s)Az, CS(s)x \rangle + \langle CS(s)z, CS(s)Ax \rangle] \, ds$$

holds for all $x, z \in \mathcal{D}_W(A)$ and every $t \geq 0$. It follows from (H3) and (H2) that both sides of this equation depend continuously on $x, z \in Z = \mathcal{D}_V(A) \subset W$ and that $\mathcal{D}_Z(A) \subset \mathcal{D}_W(A) \subset Z$. Consequently $\mathcal{D}_W(A)$ is dense in Z and hence (2.25) holds for all $x, z \in Z$.

From (2.25) we see that the function $\langle z, P(t)x \rangle$ —defined by (2.23)—is continuously differentiable on the interval $[t_0, t_1]$ for all $x, z \in Z$ and satisfies the equation

$$\begin{aligned} \frac{d}{dt} \langle z, P(t)x \rangle &= -\langle S(t_1 - t)Az, GS(t_1 - t)x \rangle - \langle S(t_1 - t)z, GS(t_1 - t)Ax \rangle \\ &\quad - \langle Cz, Cx \rangle + \langle z, P(t)BR^{-1}B^*P(t)x \rangle \\ &\quad - \int_t^{t_1} [\langle CS(s - t)Az, CS(s - t)x \rangle \\ &\quad \quad + \langle CS(s - t)z, CS(s - t)Ax \rangle] \, ds \\ &\quad + \int_t^{t_1} \langle S(s - t)Az, P(s)BR^{-1}B^*P(s)S(s - t)x \rangle \, ds \\ &\quad + \int_t^{t_1} \langle S(s - t)z, P(s)BR^{-1}B^*P(s)S(s - t)Ax \rangle \, ds \\ &= -\langle Az, P(t)x \rangle - \langle z, P(t)Ax \rangle \\ &\quad - \langle Cz, Cx \rangle + \langle z, P(t)BR^{-1}B^*P(t)x \rangle. \end{aligned}$$

This implies

$$\langle z, P(t)x \rangle_{Z, Z^*} = \left\langle z, Gx + \int_t^{t_1} [A^*P(s)x + P(s)Ax - P(s)BR^{-1}B^*P(s)x + C^*Cx] ds \right\rangle_{Z, Z^*}$$

and hence (2.24a). Thus we have proved that (iii) implies (iv).

Conversely, let us assume that $P(t)$ satisfies (2.24). Then the following equation holds for every $x \in Z$ and every $t \in [t_0, t_1]$

$$\begin{aligned} S^*(t_1 - t)GS(t_1 - t)x - P(t)x &= \int_t^{t_1} \frac{d}{ds} S^*(s - t)P(s)S(s - t)x ds \\ &= \int_t^{t_1} S^*(s - t)[\dot{P}(s) + A^*P(s) + P(s)A]S(s - t)x ds \\ &= \int_t^{t_1} S^*(s - t)[C^*C - P(s)BR^{-1}B^*P(s)]S(s - t)x ds \end{aligned}$$

where the integral has to be understood in the Hilbert space Z^* and $\dot{P}(t)$ is the strong derivative of $P(t)$, $t_0 \leq t \leq t_1$ regarded as an operator in $\mathcal{L}(Z, Z^*)$. \square

3. Infinite time control. In this section we consider the control problem of minimizing the performance index

$$(3.1) \quad J(u) = \int_0^\infty [\|y(t)\|_Y^2 + \langle u(t), Ru(t) \rangle_U] dt$$

where $y(t)$ is again the output of (2.1) with $t_0 = 0$, i.e.

$$(3.2) \quad y(t) = CS(t)x_0 + C \int_0^t S(t-s)Bu(s) ds, \quad t \geq 0.$$

For this infinite time problem it is not clear that the cost will be finite for any control input $u(\cdot) \in L^2(0, \infty; U)$. So we add this as another hypothesis.

(H4) For every $x_0 \in V$ there exists a $u_{x_0}(\cdot) \in L^2[0, \infty; U]$ such that $J(u_{x_0}) < \infty$.

We will derive the optimal control via the solution of an *algebraic Riccati equation* which is actually the stationary version of (2.24). For this sake we consider the finite time control problems of minimizing the cost functionals.

$$(3.3) \quad J_T(u) = \int_0^T [\|y(t)\|_Y^2 + \langle u(t), Ru(t) \rangle_U] dt$$

subject to the constraint (3.2). The corresponding Riccati operator will be denoted by $P_T(t) \in \mathcal{L}(V, V^*)$ and satisfies the equation

$$(3.4) \quad P_T(t)x = \int_t^T S^*(s - t)[C^*C - P_T(s)BR^{-1}B^*P_T(s)]S(s - t)x ds$$

for every $x \in W$ and every $t \in [0, T]$.

LEMMA 3.1.

$$P_{T-\alpha}(t) = P_T(t + \alpha), \quad 0 \leq t \leq T - \alpha.$$

Proof. The operator $P_T(t + \alpha)$ satisfies the equation

$$\begin{aligned} P_T(t + \alpha)x &= \int_{t+\alpha}^T S^*(s - t - \alpha)[C^*C - P_T(s)BR^{-1}B^*P_T(s)]S(s - t - \alpha)x \, ds \\ &= \int_t^{T-\alpha} S^*(s - t)[C^*C - P_T(s + \alpha)BR^{-1}B^*P_T(s + \alpha)]S(s - t)x \, ds \end{aligned}$$

for $x \in W$ and $0 \leq t \leq T - \alpha$. Thus the statement of the lemma follows from the equivalence of (2.16) and (2.23) (Proposition 2.8) together with the uniqueness result (Theorem 2.7). \square

We will derive the solution of the *algebraic Riccati equation* as the limit of the solutions to *integral Riccati equations* as T goes to infinity. For this we need the following preliminary result which is a special case of Proposition 2.8.

COROLLARY 3.2. *Suppose that the hypotheses (H1), (H2) and (H3) are satisfied and let $P \in \mathcal{L}(V, V^*)$ be a nonnegative, self adjoint operator. Moreover, let $S_p(t) \in \mathcal{L}(V) \cap \mathcal{L}(W)$ be the strongly continuous semigroup which is generated by $A - BR^{-1}B^*P: \mathcal{D}_V(A) \rightarrow V$, i.e. $S_p(t)$ satisfies the equation*

$$(3.5) \quad S_p(t)x = S(t)x - \int_0^t S(t-s)BR^{-1}B^*PS_p(s)x \, ds$$

for $x \in V$ and $t \geq 0$. Then the following statements are equivalent.

(i) For every $x \in W$ and every $t \geq 0$

$$(3.6) \quad Px = S_p^*(t)PS_p(t)x + \int_0^t S_p^*(s)[C^*C + PBR^{-1}B^*P]S_p(s)x \, ds.$$

(ii) For every $x \in W$ and every $t \geq 0$

$$(3.7) \quad Px = S_p^*(t)PS(t)x + \int_0^t S_p^*(s)C^*CS(s)x \, ds.$$

(iii) For every $x \in W$ and every $t \geq 0$

$$(3.8) \quad Px = S^*(t)PS(t)x + \int_0^t S^*(s)[C^*C - PBR^{-1}B^*P]S(s)x \, ds.$$

(iv) For every $x \in Z$ the following equation holds in Z^*

$$(3.9) \quad A^*Px + PAx - PBR^{-1}B^*Px + C^*Cx = 0.$$

Now we are in the position to prove the main result of this section.

THEOREM 3.3. *Let (H1), (H2) and (H3) be satisfied. Then the following statements hold.*

(i) *The hypothesis (H4) is satisfied if and only if there exists a nonnegative self adjoint solution $P \in \mathcal{L}(V, V^*)$ of (3.9).*

(ii) *If (H4) is satisfied, then there exists a unique optimal control $u_p(\cdot) \in L^2(0, \infty; U)$ which is given by the feedback law.*

$$(3.10) \quad u_p(t) = -R^{-1}B^*Px(t), \quad t \geq 0,$$

where $P \in \mathcal{L}(V, V^*)$ is the (unique) minimal solution of (3.9). Moreover, the optimal cost is given by

$$(3.11) \quad J(u_p) = \langle x_0, Px_0 \rangle.$$

(iii) *If (H4) is satisfied, then the minimal solution $P \in \mathcal{L}(V, V^*)$ of (3.9) is strong limit of $P_T(0) \in \mathcal{L}(V, V^*)$ as T goes to infinity where $P_T(t)$ is defined by (3.4).*

Proof. First recall that the optimal control of the finite time problem on the interval $[0, T]$ is given by $u_T(t) = -R^{-1}B^*P_T(t)x(t)$, $0 \leq t \leq T$, and the optimal cost by $J_T(u_T) = \langle x_0, P_T(0)x_0 \rangle$ (Theorem 2.7). So (H4) implies that

$$\langle x_0, P_T(0)x_0 \rangle = J_T(u_T) \leq J_T(u_{x_0}) \leq J(u_{x_0}) < \infty$$

and thus there exists a limit of the increasing function $\langle x_0, P_T(0)x_0 \rangle$, $T \geq 0$, for every $x_0 \in V$. Hence there exists a nonnegative, self adjoint operator $P \in \mathcal{L}(V, V^*)$ which is the strong limit of $P_T(0)$ (Kato [15, p. 454, Thm. 3.3], compare the proof of Theorem 2.7).

By Lemma 3.1,

$$(3.12) \quad Px = s - \lim_{T \rightarrow \infty} P_T(t)x \in V^*$$

exists uniformly in t on every compact time interval. Making use of formula (3.4), we obtain for $x \in W$ and $t \geq 0$

$$\begin{aligned} Px &= \lim_{T \rightarrow \infty} P_T(0)x \\ &= \lim_{T \rightarrow \infty} \int_0^T S^*(s)[C^*C - P_T(s)BR^{-1}B^*P_T(s)]S(s)x \, ds \\ &= \lim_{T \rightarrow \infty} \int_t^T S^*(t)S^*(s-t)[C^*C - P_T(s)BR^{-1}B^*P_T(s)]S(s-t)S(t)x \, ds \\ &\quad + \lim_{T \rightarrow \infty} \int_0^t S^*(s)[C^*C - P_T(s)BR^{-1}B^*P_T(s)]S(s)x \, ds \\ &= \lim_{T \rightarrow \infty} S^*(t)P_T(t)S(t)x + \int_0^t S^*(s)[C^*C - PBR^{-1}B^*P]S(s)x \, ds \\ &= S^*(t)PS(t)x + \int_0^t S^*(s)[C^*C - PBR^{-1}B^*P]S(s)x \, ds \end{aligned}$$

and hence $P \in \mathcal{L}(V, V^*)$ is a solution of (3.6), (3.7), (3.8) and (3.9).

Conversely, let $Q \in \mathcal{L}(V, V^*)$ be any nonnegative solution of (3.9) and let $u_Q(t) = -R^{-1}B^*Qx(t)$ be the corresponding feedback control law with the associated closed loop semigroup $S_Q(t) \in \mathcal{L}(V) \cap \mathcal{L}(W)$. Then the following inequality holds for every $x_0 \in V$

$$\begin{aligned} (3.13) \quad \langle x_0, Qx_0 \rangle &= \lim_{t \rightarrow \infty} \left\{ \langle S_Q(t)x_0, QS_Q(t)x_0 \rangle \right. \\ &\quad \left. + \int_0^t \langle S_Q(s)x_0, [C^*C + QBR^{-1}B^*Q]S_Q(s)x_0 \rangle \, ds \right\} \\ &\geq \int_0^\infty \langle S_Q(t)x_0, [C^*C + QBR^{-1}B^*Q]S_Q(s)x_0 \rangle \, ds \\ &= J(u_Q) \end{aligned}$$

and hence (H4) is satisfied. Moreover, the operator $P \in \mathcal{L}(V, V^*)$ defined by (3.12) satisfies the inequality

$$\langle x_0, Px_0 \rangle = \lim_{T \rightarrow \infty} \langle x_0, P_T(0)x_0 \rangle \leq \lim_{T \rightarrow \infty} J_T(u) = J(u)$$

for every admissible control $u(\cdot) \in L^2(0, \infty; U)$. This shows that P is the minimal positive semidefinite solution of (3.6). Finally, taking $Q = P$, we conclude that the unique optimal control is given by (3.10) with cost (3.11). \square

Although the above theorem yields a solution to the infinite time problem, in a sense it is unsatisfactory. This is because we are not sure of a unique solution to the algebraic Riccati equation and also we cannot be sure that the semigroup $S_p(t)$ is exponentially stable. In order to resolve those difficulties, we need another hypothesis.

(H5) If $x_0 \in V$ and $u(\cdot) \in L^2(0, \infty; U)$ are such that $J(u) < \infty$, then $x(\cdot) \in L^2(0, \infty; V)$ where $x(t)$, $t \geq 0$, is given by (2.3) with $t_0 = 0$.

THEOREM 3.4. *Let (H1), (H2), (H3) and (H5) be satisfied. Then the algebraic Riccati equation (3.9) has at most one nonnegative, self adjoint solution $P \in \mathcal{L}(V, V^*)$. Moreover, if P is such a solution, then the closed loop semigroup $S_p(t) \in \mathcal{L}(V)$ is exponentially stable.*

Proof. If $P \in \mathcal{L}(V, V^*)$ is a positive semidefinite solution of (3.9), then the inequality (3.13) with $Q = P$ shows that the closed loop control $u_p(t) = -R^{-1}B^*Px(t)$ has a finite cost for every initial state $x_0 \in V$. By hypothesis (H5) this means that

$$\int_0^\infty \|S_p(t)x_0\|_V^2 dt < \infty$$

for every $x_0 \in V$. Hence it follows from a result of Datko [5] that the semigroup $S_p(t) \in \mathcal{L}(V)$ is exponentially stable (see Curtain and Pritchard [4]). The stability of $S_p(t)$ shows that we have equality in (3.13) and hence

$$J(u_p) = \langle x_0, Px_0 \rangle.$$

Now let $Q \in \mathcal{L}(V, V^*)$ be another nonnegative solution of (3.9) and let us apply Lemma 2.6 to the performance index

$$J_{T,Q}(u) = \langle x(T), Qx(T) \rangle + \int_0^T [\|y(t)\|_Y^2 + \langle u(t), Ru(t) \rangle] dt$$

as well as the feedback $F(t) = -R^{-1}B^*Q$ and the control input $u_p(t)$. Then $P_F(t) \equiv Q$ and hence the inequality

$$\begin{aligned} \langle x_0, Px_0 \rangle &= J(u_p) = \lim_{T \rightarrow \infty} J_{T,Q}(u_p) \\ &= \lim_{T \rightarrow \infty} \left[\langle x_0, Qx_0 \rangle + \int_0^T \langle R^{-1}B^*Qx(t) + u_p(t), R[R^{-1}B^*Qx(t) + u_p(t)] \rangle dt \right] \\ &\equiv \langle x_0, Qx_0 \rangle \end{aligned}$$

holds for every $x_0 \in V$. Interchanging the roles of P and Q , we conclude that $P = Q$. \square

Finally, let us briefly discuss the hypotheses (H4) and (H5) which are chosen in a general sense but are difficult to check in concrete examples. In most cases it might be desirable to replace them by stronger assumptions which are easier to check.

Remarks 3.5. Let (H1) and (H2) be satisfied.

(i) Suppose that system (2.1) is *stabilizable* in the sense that there exists a feedback operator $F \in \mathcal{L}(V, U)$ such that the closed loop semigroup $S_F(t) \in \mathcal{L}(V)$ defined by

$$S_F(t)x = S(t)x + \int_0^t S(t-s)BFS_F(s)x ds$$

for $t \geq 0$ and $x \in V$ is exponentially stable. Then hypothesis (H4) is satisfied.

In fact, there is an instant $T > 0$ and a constant $c_T > 0$ such that the inequalities

$$\|S_F(T)\|_{\mathcal{L}(V)} < 1, \quad \|CS_F(\cdot)x\|_{L^2(0,T;Y)} \leq c_T \|x\|_V$$

hold for every $x \in W$. This implies that

$$\|CS_F(\cdot)x\|_{L^2(0,\infty;Y)} \leq c_T \sum_{k=0}^{\infty} \|S_F(T)\|_{\mathcal{L}(V)}^k \|x\|_V$$

for $x \in W$ and hence (H4) is satisfied.

(ii) Suppose that system (2.1) is *detectable* in the sense that there exists an operator $K \in \mathcal{L}(Y, V)$ such that the output injection semigroup $S_K(t) \in \mathcal{L}(V)$ defined by

$$S_K(t)x = S(t)x + \int_0^t S_K(t-s)KCS(s)x \, ds$$

for $t \geq 0$ and $x \in W$ (see Salamon [25, Thm. I.3.9]) is exponentially stable. Then hypothesis (H5) is satisfied.

In fact, if $x(t) \in V$ and $y(t) \in Y$ are defined by (2.3) for $x_0 \in V$ and $u(\cdot) \in L^2_{\text{loc}}(0, \infty; U)$, then it is easy to see

$$x(t) = S_K(t)x_0 + \int_0^t S_K(t-s)[Bu(s) - Ky(s)] \, ds, \quad t \geq 0.$$

Hence $J(u) < \infty$ implies that $x(\cdot) \in L^2(0, \infty; V)$.

(iii) If (H4) and (H5) are satisfied, then system (2.1) is stabilizable in the sense of (i). (Theorems 3.3 and 3.4.)

(iv) For finite dimensional systems (H5) is equivalent to detectability in the sense of (ii). It seems to be an open problem whether this equivalence extends to the infinite dimensional situation.

4. Examples.

4.1. Neutral systems with output delays. We consider the linear neutral functional differential equation (NFDE)

$$(4.1) \quad \frac{d}{dt}(x(t) - Mx_t) = Lx_t + B_0u(t), \quad y(t) = Cx_t,$$

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$, $y(t) \in \mathbb{R}^p$ and x_t is defined by $x_t(\tau) = x(t + \tau)$, $-h \leq \tau \leq 0$, $h > 0$. B_0 is an $n \times m$ matrix and L, M, C are bounded linear functionals from $\mathcal{C} = \mathcal{C}[-h, 0; \mathbb{R}^n]$ into \mathbb{R}^n and \mathbb{R}^p respectively. These can be represented by matrix-functions $\eta(\tau)$, $\mu(\tau)$, $\gamma(\tau)$ of bounded variation in the following way

$$\begin{aligned} L\phi &= \int_{-h}^0 d\eta(\tau)\phi(\tau), & M\phi &= \int_{-h}^0 d\mu(\tau)\phi(\tau), \\ C\phi &= \int_{-h}^0 d\gamma(\tau)\phi(\tau), & \phi &\in \mathcal{C}. \end{aligned}$$

In order to guarantee the existence and uniqueness of solutions of (4.1), we will always assume

$$(4.2) \quad \mu(0) = \lim_{\tau \uparrow 0} \mu(\tau).$$

Moreover, we will assume at some places that $M: \mathcal{C} \rightarrow \mathbb{R}^n$ is of the special form

$$(4.3) \quad M\phi = \sum_{j=1}^{\infty} A_{-j}\phi(-h_j) + \int_{-h}^0 A_{-\infty}(\tau)\phi(\tau) \, d\tau, \quad \phi \in \mathcal{C},$$

where $0 < h_j \leq h$, $A_{-j} \in \mathbb{R}^{n \times n}$ for $j \in \mathbb{N}$, $A_{-\infty}(\cdot) \in L^1[-h, 0; \mathbb{R}^{n \times n}]$ and $\sum_{j=1}^{\infty} \|A_{-j}\| < \infty$.

A function $x(\cdot) \in L^2_{\text{loc}}(-h, \infty; \mathbb{R}^n)$ is said to be a solution of (4.1) if the function $w(t) = x(t) - Mx_t$ is absolutely continuous with an L^2 -derivative on every compact interval $[0, T]$, $T > 0$, and if $\dot{w}(t) = Lx_t + B_0u(t)$ for almost every $t \geq 0$. It is well known (Burns, Herdman and Stech [3], Salamon [25]) that (4.1) admits a unique solution $x(t)$, $t \geq -h$, for every input $u(\cdot) \in L^2_{\text{loc}}(0, \infty; \mathbb{R}^m)$ and every initial condition

$$(4.4) \quad \lim_{t \downarrow 0} x(t) - Mx_t = \phi^0, \quad x(\tau) = \phi^1(\tau), \quad -h \leq \tau < 0,$$

where $\phi = (\phi^0, \phi^1) \in M^2 = \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n)$. Moreover it has been shown in [3], [25] that the evolution of the state

$$(4.5) \quad \hat{x}(t) = (x(t) - Mx_t, x_t) \in M^2$$

of system (4.1), (4.4) can be described by the formula

$$(4.6) \quad \hat{x}(t) = S(t)\phi + \int_0^t S(t-s)Bu(s) ds$$

where $B \in \mathcal{L}(\mathbb{R}^m, M^2)$ maps $u \in \mathbb{R}^m$ into the pair $Bu = (B_0u, 0)$ and $S(t) \in \mathcal{L}(M^2)$ is the strongly continuous semigroup generated by A , where

$$D(A) = \{\phi \in M^2: \phi^1 \in W^{1,2}, \phi^0 = \phi^1(0) - M\phi^1\}, \quad A\phi = (L\phi^1, \dot{\phi}^1).$$

Here $W^{1,2}$ denotes the Sobolev space $W^{1,2}(-h, 0; \mathbb{R}^n)$.

Obviously, the dense subspace

$$W = \{(\phi(0) - M\phi, \phi): \phi \in W^{1,2}\} = \mathcal{D}(A)$$

of M^2 —endowed with the $W^{1,2}$ norm—is invariant under $S(t)$ and $S(t)$ can be restricted to a strongly continuous semigroup on W .

The output of the system (4.1) may be described through the operator

$$C: W \rightarrow \mathbb{R}^p, \quad C\phi = \int_{-h}^0 d\gamma(\tau)\phi^1(\tau), \quad \phi \in W.$$

Remarks 4.1. (i) The infinitesimal generator A of $S(t)$ can be interpreted as a bounded operator from W into M^2 . By duality, M^2 can be regarded as a dense subspace of W^* and A^* extends to a bounded operator from M^2 into W^* .

(ii) It has been proved in Burns, Herdman and Stech [3] and Salamon [25] that system (4.1) satisfies the hypotheses (H1) and (H2) with $H = V = M^2$ and the subspace $W \subset M^2$ as defined above. Hypothesis (H1) says that the state $\hat{x}(T) \in M^2$ of (4.1) defined by (4.5) is in W for every input $u(\cdot) \in L^2(0, T; \mathbb{R}^m)$ and zero initial condition and that $\hat{x}(T) \in W$ depends continuously on $u(\cdot) \in L^2[0, T; \mathbb{R}^m]$. Hypothesis (H2) says that the output $y(\cdot)$ of the free system (4.1) (i.e. $u(t) \equiv 0$) is in $L^2(0, T; \mathbb{R}^p)$ and depends in this space continuously on the initial state $\phi \in M^2$.

(iii) If $M: \mathcal{C} \rightarrow \mathbb{R}^n$ is given by (4.3), then it is known that the semigroup $S(t) \in \mathcal{L}(M^2)$ is exponentially stable if and only if

$$\omega_0 = \sup \{\operatorname{Re} \lambda: \det \Delta(\lambda) = 0\} < 0$$

where $\Delta(\lambda) = \lambda[I - M(e^\lambda)] - L(e^\lambda)$, $\lambda \in \mathbb{C}$, is the characteristic matrix of the NFDE (4.1). A necessary condition for the exponential stability of $S(t)$ is the stability of the difference operator which means that

$$(4.7) \quad \sup \left\{ \operatorname{Re} \lambda: \det \left[I - \sum_{j=1}^{\infty} A_{-j} e^{-\lambda h_j} \right] = 0 \right\} < 0.$$

These facts have been established by Henry [11] for $S(t) \in \mathcal{L}(W)$. They extend to $S(t) \in \mathcal{L}(M^2)$ because of the similarity of these two semigroups through the transformation $\mu I - A: W \rightarrow M^2$ with $\mu \notin \sigma(A)$.

(iv) If $M: \mathcal{C} \rightarrow \mathbb{R}^n$ is given by (4.3) and if (4.7) holds, then system (4.1) is *stabilizable* in the sense that there exists a feedback operator $F \in \mathcal{L}(M^2, \mathbb{R}^m)$ such that the closed loop semigroup $S_F(t) \in \mathcal{L}(M^2)$ generated by $A + BF$ is exponentially stable if and only if

$$(4.8) \quad \text{rank} [\Delta(\lambda), B_0] = n \quad \forall \lambda \in \mathbb{C}, \quad \text{Re } \lambda \geq 0$$

(Pandolfi [21], Salamon [25]).

(v) If $M: \mathcal{C} \rightarrow \mathbb{R}^n$ is given by (4.3) and if (4.7) holds, then system (4.1) is *detectable* in the sense that there exists an output injection operator $K \in \mathcal{L}(\mathbb{R}^p, M^2)$ such that the closed loop semigroup $S_K(t) \in \mathcal{L}(M^2)$ generated by $A + KC$ is exponentially stable if and only if

$$(4.9) \quad \text{rank} \begin{bmatrix} \Delta(\lambda) \\ C(e^{\lambda \cdot}) \end{bmatrix} = n \quad \forall \lambda \in \mathbb{C}, \quad \text{Re } \lambda \geq 0$$

(Salamon [25]).

Associated with the system (4.1) we consider the performance index

$$(4.10) \quad J(u) = \int_0^\infty [\|y(t)\|_{\mathbb{R}^p}^2 + \|u(t)\|_{\mathbb{R}^m}^2] dt.$$

Then we have the following theorem (compare Ito and Tarn [14] and Datko [7]).

THEOREM 4.2. *Assume $M: \mathcal{C} \rightarrow \mathbb{R}^n$ is given by (4.3) and (4.7) is satisfied; then the following statements hold.*

(i) *If (4.8) is satisfied, there exists, for every initial state $\phi \in M^2$, a unique optimal control which minimizes the cost functional (4.10). This optimal control is given by the feedback law*

$$(4.11) \quad u_\pi(t) = -B^* \pi \hat{x}(t)$$

where $\pi \in \mathcal{L}(M^2)$ is the minimal selfadjoint, nonnegative operator which satisfies the algebraic Riccati equation

$$(4.12) \quad A^* \pi + \pi A + C^* C - \pi B B^* \pi = 0$$

(this equation must be understood in the space $\mathcal{L}(W, W^*)$). Moreover the optimal cost is given by

$$(4.13) \quad J(u_\pi) = \langle \phi, \pi \phi \rangle_{M^2}.$$

(ii) *If (4.9) is satisfied, then there exists at most one nonnegative self adjoint solution $\pi \in \mathcal{L}(M^2)$ of (4.12). Moreover if π is such a solution, the closed loop semigroup $S_\pi(t) \in \mathcal{L}(M^2)$ generated by $A - B B^* \pi$ is exponentially stable.*

4.2. Parabolic systems. Consider the system

$$(4.14) \quad \dot{x} = Ax + Bu, \quad y = Cx$$

where A is a self adjoint operator on a real Hilbert space H . We assume that A has a compact resolvent operator and that the spectrum of A consists of a strictly decreasing sequence λ_n , $n \in \mathbb{N}$, of real eigenvalues with associated eigenvector $\phi_n \in H$, $\|\phi_n\| = 1$. Then A generates the strongly continuous semigroup $S(t)$ on H given by

$$S(t)x = \sum_{n=1}^{\infty} e^{\lambda_n t} \langle x, \phi_n \rangle \phi_n.$$

We assume that W and V are given by

$$W = \left\{ x \in H \left| \sum_{n=1}^{\infty} \gamma_n \langle x, \phi_n \rangle^2 < \infty \right. \right\},$$

$$V^* = \left\{ x \in H \left| \sum_{n=1}^{\infty} \beta_n^{-1} \langle x, \phi_n \rangle^2 < \infty \right. \right\}$$

with the obvious inner products, where β_n and γ_n are positive sequences satisfying $0 < \beta_n \leq 1 \leq \gamma_n < \infty$ for $n \in \mathbb{N}$. Then the space V can be represented as a space of sequences in the following way

$$V = \left\{ x \in \mathbb{R}^{\mathbb{N}} \left| \sum_{n=1}^{\infty} \beta_n x_n^2 < \infty \right. \right\}$$

and the injection $H \subset V$ is given by identifying $x \in H$ with the sequence $\{\langle x, \phi_n \rangle\}_{n \in \mathbb{N}} \in V$. Finally, we assume that the sequences $b_n \in U$, $c_n \in Y$ satisfy

$$(4.15) \quad \sum_{n=1}^{\infty} \beta_n \|b_n\|_U^2 < \infty, \quad \sum_{n=1}^{\infty} \gamma_n^{-1} \|c_n\|_Y^2 < \infty$$

and that the operators $B \in \mathcal{L}(U, V)$ and $C \in \mathcal{L}(W, Y)$ are given by

$$Cx = \sum_{n=1}^{\infty} c_n \langle x, \phi_n \rangle, \quad Bu = \{\langle b_n, u \rangle\}_{n \in \mathbb{N}}.$$

LEMMA 4.3. (i) Let $n_0 = \max \{n \in \mathbb{N} \mid \lambda_n \geq 0\}$ and suppose that

$$(4.16) \quad \sum_{n=n_0+1}^{\infty} \frac{\gamma_n \|b_n\|^2}{|\lambda_n|} < \infty;$$

then hypothesis (H1) is satisfied.

(ii) If

$$(4.17) \quad \sum_{n=n_0+1}^{\infty} \frac{\|c_n\|^2}{\beta_n |\lambda_n|} < \infty,$$

then hypothesis (H2) is satisfied.

Proof. Statement (ii) is the dual of (i) and statement (i) follows from the inequality

$$\begin{aligned} \left\| \int_0^T S(t-s) Bu(s) ds \right\|_W &= \sum_{n=1}^{\infty} \gamma_n \left(\int_0^T e^{\lambda_n(T-s)} b_n u(s) ds \right)^2 \\ &\leq \sum_{n=1}^{\infty} \gamma_n \int_0^T e^{2\lambda_n s} ds \|b_n\|^2 \|u(\cdot)\|_{L^2[0,T;U]}^2 \\ &\leq \left[\sum_{n=1}^{n_0} \gamma_n \int_0^T e^{2\lambda_n s} ds \|b_n\|^2 + \sum_{n=n_0+1}^{\infty} \frac{\gamma_n \|b_n\|^2}{2|\lambda_n|} \right] \|u(\cdot)\|_{L^2[0,T;U]}^2. \end{aligned}$$

In concrete examples the sequences b_n , c_n are given and the spaces W and V have to be chosen in such a way that (H1), (H2) and (H3) are satisfied. The next lemma shows under which conditions this is possible.

LEMMA 4.4. Let the sequences $b_n \in U$, $c_n \in Y$, $\lambda_n \in \mathbb{R}$ be given such that λ_n is strictly decreasing and tends to $-\infty$. Then there exist positive sequences β_n , γ_n satisfying (4.15)–(4.17) if and only if

$$(4.18) \quad \sum_{n=n_0+1}^{\infty} \frac{\|b_n\| \cdot \|c_n\|}{|\lambda_n|^{1/2}} < \infty.$$

Furthermore, if (4.18) holds, then the sequences β_n, γ_n can be chosen such that $\beta_n \leq \gamma_n \leq \beta_n |\lambda_n|$ for almost every $n \in \mathbb{N}$.

Proof. The necessity of (4.18) is obvious. Conversely if (4.18) holds, then it is easy to see that the sequences

$$\beta_n = \begin{cases} \|c_n\|/\|b_n\| |\lambda_n|^{1/2}, & b_n \neq 0, \quad c_n \neq 0, \quad \lambda_n \neq 0, \\ n^2 \|c_n\|^2 / |\lambda_n|, & b_n = 0, \quad c_n \neq 0, \quad \lambda_n \neq 0, \\ 1/n^2 \|b_n\|^2, & b_n \neq 0, \quad c_n = 0, \quad \lambda_n \neq 0, \\ 1 & \text{otherwise,} \end{cases}$$

$$\gamma_n = \begin{cases} |\lambda_n|^{1/2} \|c_n\|/\|b_n\|, & b_n \neq 0, \quad c_n \neq 0, \quad \lambda_n \neq 0, \\ n^2 \|c_n\|^2, & b_n = 0, \quad c_n \neq 0, \quad \lambda_n \neq 0, \\ |\lambda_n|/n^2 \|b_n\|^2, & b_n \neq 0, \quad c_n = 0, \quad \lambda_n \neq 0, \\ \max\{1, |\lambda_n|\} & \text{otherwise,} \end{cases}$$

satisfy the requirements of the lemma.

Remarks 4.5. (i) The condition $\gamma_n = \beta_n |\lambda_n|$ for almost every $n \in \mathbb{N}$ (with at most a finite number of exceptions) means that

$$\mathcal{D}_V(A) \subset \mathcal{D}_V((-A)^{1/2}) = \left\{ x \in V \mid \sum_{n=1}^{\infty} \beta_n |\lambda_n| x_n^2 < \infty \right\} = W \subset V$$

so that (H3) is satisfied.

(ii) We can assume without loss of generality that $W \subset H \subset V$, i.e. the sequences β_n and γ_n^{-1} are bounded. This can always be achieved by redefining b_n, c_n, β_n and γ_n .

(iii) It is well known that system (4.14) is stabilizable in the space V if and only if $b_n \neq 0$ for $n = 1, \dots, n_0$ (Curtain and Pritchard [4]).

The system is detectable through the unbounded output operator $C: W \rightarrow Y$ if and only if $c_n \neq 0$ for $n = 1, \dots, n_0$. This follows from an obvious generalization of the standard result for bounded output operators using a perturbation result in Salamon [25].

We are now in the position to apply the Theorems 3.3 and 3.4 to the Cauchy problem (4.14) with the performance index (4.10). Hence there exists a unique nonnegative operator $P \in \mathcal{L}(V, V^*)$ satisfying the algebraic Riccati equation.

$$(4.19) \quad AP + PA - PBB^*P + C^*C = 0$$

if $b_n \neq 0$ and $c_n \neq 0$ for $n = 1, \dots, n_0$. Furthermore the optimal control is given by the feedback law

$$(4.20) \quad u(t) = -B^*Px(t).$$

Example 4.6. As a specific example consider

$$(4.21a) \quad z_t = z_{\xi\xi}, \quad 0 < \xi < 1,$$

$$(4.21b) \quad z_{\xi}(t, 0) = u(t), \quad z_{\xi}(t, 1) = 0, \quad t > 0,$$

$$(4.21c) \quad y(t) = \int_0^1 c(\xi) z(t, \xi) d\xi, \quad t > 0.$$

It can be shown (see Curtain and Pritchard [4]) that this system is equivalent to a Cauchy problem of the form (4.14) with $H = L^2[0, 1]$, $\lambda_0 = 0$, $\phi_0(\xi) \equiv 1$, $\lambda_n = -n^2\pi^2$, $\phi_n(\xi) = \sqrt{2} \cos n\pi\xi$, and $Bu = -\delta u$ (δ being the Dirac delta impulse at $\xi = 0$). Hence

we get $b_0 = -1$, $b_n = -\sqrt{2}$ for $n \in \mathbb{N}$ and $c_n = \langle c, \phi_n \rangle$ for $n = 0, 1, 2, \dots$. So condition (4.18) is satisfied if and only if

$$\sum_{n=1}^{\infty} \frac{|c_n|}{n} < \infty.$$

This allows for arbitrary bounded linear output operators $C : L^2[0, 1] \rightarrow \mathbb{R}$ and even for a class of unbounded output operators. If C is bounded, then c_n is square summable and we may choose $\gamma_n = 1$, $\beta_n = n^{-2}$, which means that

$$W = L^2[0, 1], \quad V^* = H^1[0, 1].$$

Remark 4.7. Existence and uniqueness results for the differential Riccati equation associated with parabolic systems have been established by Pritchard and Pollock [22], Flandoli [9] and Sorine [26], [27] under weaker hypothesis. The assumptions in these papers are, roughly speaking, that A is a self adjoint nonpositive operator on H and that

$$W = V^* = \mathcal{D}((-A)^{1/2}).$$

In [9] and [22] it is assumed that the function $\|CS(t)B\|_{\mathcal{L}(U, V)}$ is integrable on $[0, T]$, whereas our results are only applicable if this function is square integrable. However, in [9] and [22] the Riccati operator $P(t)$ will only be in $\mathcal{L}(V, H) \cap \mathcal{L}(H, V^*)$ and correspondingly the optimal feedback operator $F(t) = -B^*P(t)$ will only be in $\mathcal{L}(H, U)$ as opposed to $\mathcal{L}(V, U)$.

4.3. Hyperbolic systems. Consider the system

$$(4.22) \quad \dot{z} = Az + Bu, \quad y = Cz,$$

where A is a self adjoint operator on a real Hilbert space H . We assume that A has a compact resolvent operator and that its (simple) negative eigenvalues $\lambda_n = -\omega_n^2$ satisfy

$$(4.23) \quad \omega_1 \geq \delta, \quad \omega_{n+1} - \omega_n \geq \delta, \quad n \in \mathbb{N},$$

for some $\delta > 0$. The corresponding eigenvectors are denoted by $\phi_n \in H$, $\|\phi_n\| = 1$. Furthermore, we assume that the spaces W_0, V_1 are given by

$$W_0 = \left\{ x \in H \left| \sum_{n=1}^{\infty} \gamma_n |\lambda_n| \langle x, \phi_n \rangle^2 < \infty \right. \right\},$$

$$V_1^* = \left\{ x \in H \left| \sum_{n=1}^{\infty} \beta_n^{-1} \langle x, \phi_n \rangle^2 < \infty \right. \right\},$$

where β_n and γ_n are positive sequences satisfying $0 \leq \beta_n \leq 1 \leq \gamma_n \leq \beta_n |\lambda_n|$ for $n \in \mathbb{N}$. Finally, we assume that the sequences $b_n \in U$, $c_n \in Y$ satisfy

$$(4.24) \quad \sum_{n=1}^{\infty} \beta_n \|b_n\|^2 < \infty, \quad \sum_{n=1}^{\infty} \frac{\|c_n\|^2}{\gamma_n |\lambda_n|} < \infty,$$

and that the operators $B \in \mathcal{L}(U, V_1)$, $C \in \mathcal{L}(W_0, Y)$ are given by

$$B^*x = \sum_{n=1}^{\infty} \langle x, \phi_n \rangle b_n, \quad Cx = \sum_{n=1}^{\infty} \langle x, \phi_n \rangle c_n.$$

Defining $V \subset H$ by

$$V = \mathcal{D}((-A)^{1/2}) = \left\{ x \in H \left| \sum_{n=1}^{\infty} |\lambda_n| \langle x, \phi_n \rangle^2 < \infty \right. \right\}$$

and identifying H with its dual, we obtain that $V \subset H \subset V^*$ and A extends to a bounded operator from V to V^* . In order to transform (2.22) into a first order system, we introduce the product space

$$\mathcal{H} = V \times H$$

with inner product

$$\langle x, \hat{x} \rangle = \sum_{n=1}^{\infty} [|\lambda_n| \langle x_0, \phi_n \rangle \langle \hat{x}, \phi_n \rangle + \langle x_1, \phi_n \rangle \langle \hat{x}_1, \phi_n \rangle].$$

Then the operator $\mathcal{A}: \mathcal{D}(\mathcal{A}) \rightarrow \mathcal{H}$ defined by

$$\mathcal{A} = \begin{bmatrix} 0 & I \\ A & 0 \end{bmatrix}, \quad \mathcal{D}(\mathcal{A}) = \mathcal{D}(A) \times V$$

is the infinitesimal generator of the strongly continuous semigroup $\mathcal{L}(t) \in \mathcal{L}(\mathcal{H})$ which is given by

$$\mathcal{L}(t)x = \begin{bmatrix} \sum_{n=1}^{\infty} [(\cos \omega_n t) \langle x_0, \phi_n \rangle + \omega_n^{-1} (\sin \omega_n t) \langle x_1, \phi_n \rangle] \phi_n \\ \sum_{n=1}^{\infty} [\omega_n (\sin \omega_n t) \langle x_0, \phi_n \rangle + (\cos \omega_n t) \langle x_1, \phi_n \rangle] \phi_n \end{bmatrix}.$$

Finally, we introduce the spaces

$$\mathcal{W} = \left\{ x \in \mathcal{H} \left| \sum_{n=1}^{\infty} \gamma_n [|\lambda_n| \langle x_0, \phi_n \rangle^2 + \langle x_1, \phi_n \rangle^2] < \infty \right. \right\},$$

$$\mathcal{V}^* = \left\{ x \in \mathcal{H} \left| \sum_{n=1}^{\infty} \beta_n^{-1} [|\lambda_n| \langle x_0, \phi_n \rangle^2 + \langle x_1, \phi_n \rangle^2] < \infty \right. \right\}$$

and the operators $\mathcal{B} \in \mathcal{L}(U, \mathcal{V})$, $\mathcal{C} \in \mathcal{L}(\mathcal{W}, Y)$ by

$$\mathcal{B} = \begin{bmatrix} 0 \\ B \end{bmatrix}, \quad \mathcal{C} = [C \quad 0].$$

Then (4.22) is equivalent to the Cauchy problem

$$(4.25) \quad \dot{x} = \mathcal{A}x + \mathcal{B}u, \quad y = \mathcal{C}x,$$

by means of the identification $x = (z, \dot{z})$. Note that we identify $\mathcal{H} = V \times H$ with its dual.

LEMMA 4.8. (i) *If*

$$(4.26) \quad \sup_{n \in \mathbb{N}} \gamma_n \|b_n\|_U^2 < \infty,$$

then the operator \mathcal{B} satisfies (H1).

(ii) *If*

$$(4.27) \quad \sup_{n \in \mathbb{N}} \frac{\|c_n\|_Y^2}{\beta_n |\lambda_n|} < \infty,$$

then the operator \mathcal{C} satisfies (H2).

Proof. Statement (ii) is the dual of (i). In order to prove statement (i), note first that

$$\int_0^T \mathcal{L}(T-s) \mathcal{B}u(s) ds = \begin{bmatrix} \sum_{n=1}^{\infty} \omega_n^{-1} \int_0^T (\sin \omega_n(T-s)) \langle b_n, u(s) \rangle ds \phi_n \\ \sum_{n=1}^{\infty} \int_0^T (\cos \omega_n(T-s)) \langle b_n, u(s) \rangle ds \phi_n \end{bmatrix}$$

for every $u(\cdot) \in L^2[0, T; U]$ and hence

$$\begin{aligned}
 & \left\| \int_0^T \mathcal{L}(T-s) \mathcal{B}u(s) ds \right\| \\
 &= \sum_{n=1}^{\infty} \gamma_n \left\{ \left[\int_0^T (\sin \omega_n(T-s)) \langle b_n, u(s) \rangle ds \right]^2 \right. \\
 &\quad \left. + \left[\int_0^T (\cos \omega_n(T-s)) \langle b_n, u(s) \rangle ds \right]^2 \right\} \\
 &\leq (\sup_{n \in \mathbb{N}} \gamma_n \|b_n\|^2) \sum_{n=1}^{\infty} \left\{ \left\| \int_0^T (\sin \omega_n(T-s)) u(s) ds \right\|^2 \right. \\
 &\quad \left. + \left\| \int_0^T \cos \omega_n(T-s) u(s) ds \right\|^2 \right\} \\
 &\leq \text{const.} (\sup_{n \in \mathbb{N}} \gamma_n \|b_n\|^2) \cdot \|u(\cdot)\|_{L^2[0, T; U]}^2.
 \end{aligned}$$

The final inequality is a consequence of (4.23) together with some properties of Fourier series (see Ingham [13] and Russell [24]).

The next lemma shows under which conditions the spaces \mathcal{W} and \mathcal{V} can be chosen in such a way that (H1), (H2), (H3) are satisfied if the sequences b_n, c_n are given.

LEMMA 4.9. *Let the sequences $b_n \in U$, $c_n \in Y$, $\lambda_n \in \mathbb{R}$ be given such that (4.23) is satisfied. Then there exist positive sequences β_n, γ_n satisfying (4.24), (4.26) and (4.27) if and only if*

$$(4.28) \quad \sum_{n=1}^{\infty} \frac{\|b_n\|^2 \cdot \|c_n\|^2}{|\lambda_n|} < \infty.$$

Furthermore, if (4.28) holds, then the sequences β_n, γ_n can be chosen such that $\mathcal{D}_{\mathcal{V}}(\mathcal{A}) \subset \mathcal{W} \subset \mathcal{V}$.

Proof. The necessity of (4.28) is obvious. Conversely, if (4.28) holds, then it is easy to see that the sequences

$$\begin{aligned}
 \beta_n &= \begin{cases} \|c_n\|^2 / |\lambda_n|, & \|b_n\|_U \|c_n\| \geq 1 \quad \text{or } b_n = 0, \quad c_n \neq 0, \\ 1 / \|b_n\|^2 |\lambda_n|, & \|b_n\| \|c_n\| \leq 1 \quad \text{and } b_n \neq 0, \\ 1 / |\lambda_n|, & b_n = 0, \quad c_n = 0, \end{cases} \\
 \gamma_n &= \begin{cases} 1 / \|b_n\|^2, & b_n \neq 0, \\ \|c_n\|^2, & b_n = 0, \quad c_n \neq 0, \\ 1, & b_n = 0, \quad c_n = 0, \end{cases}
 \end{aligned}$$

satisfy the requirements of the lemma. In particular β_n / γ_n is bounded and $\gamma_n \leq \beta_n |\lambda_n|$ for every $n \in \mathbb{N}$.

We are now in the position to apply Theorem 2.7 to the Cauchy problem (4.25) with the performance index

$$(4.29) \quad J(u) = \int_0^T [\|y(t)\|^2 + \|u(t)\|^2] dt.$$

Hence there exists a unique nonnegative strongly continuous operator $\mathcal{P}(t) \in \mathcal{L}(\mathcal{V}, \mathcal{V}^*)$ satisfying the differential Riccati equation

$$\begin{aligned}
 & \frac{d}{dt} \mathcal{P}(t)x + \mathcal{A}^* \mathcal{P}(t)x + \mathcal{P}(t)\mathcal{A}x - \mathcal{P}(t)\mathcal{R}\mathcal{B}^* \mathcal{P}(t)x + \mathcal{C}^* \mathcal{C}x = 0, \\
 & \mathcal{P}(T)x = 0, \quad x \in \mathcal{D}_{\mathcal{V}}(\mathcal{A}).
 \end{aligned}
 \tag{4.30}$$

Furthermore, the optimal control is given by the feedback law

$$(4.31) \quad u(t) = -\mathcal{B}^* \mathcal{P}(t)x(t).$$

Example 4.10. As a specific example we consider the system

$$(4.32a) \quad z_{tt} = z_{\xi\xi}, \quad 0 < \xi < 1, \quad t > 0,$$

$$(4.32b) \quad z(t, 0) = u(t), \quad z(t, 1) = 0, \quad t > 0,$$

$$(4.32c) \quad y(t) = \int_0^1 c(\xi) z(t, \xi) d\xi, \quad t > 0,$$

in the Hilbert space

$$\mathcal{H} = H_0^1[0, 1] \times L^2[0, 1]$$

which we identify with its dual. Then the operator $A = \Delta : H^2[0, 1] \cap H_0^1[0, 1] \rightarrow L^2[0, 1]$ has the eigenvalues $\lambda_n = n^2 \pi^2$ with corresponding eigenfunctions $\phi_n(\xi) = \sqrt{2} \sin n\pi\xi$. Furthermore, the input operator for (2.32) takes the form $Bu = -\delta' u$, where δ' is the distributional derivative of the Dirac delta impulse at $\xi = 0$ (see Curtain and Pritchard [4]). Hence

$$b_n = \sqrt{2} n\pi, \quad c_n = \sqrt{2} \int_0^1 c(\xi) \sin n\pi\xi d\xi$$

for $n \in \mathbb{N}$. So condition (4.28) is satisfied if c_n is square integrable. The proof of Lemma 4.9 shows that we may choose

$$\beta_n = \max \left\{ \frac{|c_n|^2}{|\lambda_n|}, \frac{1}{|\lambda_n|^2} \right\}, \quad \gamma_n = \frac{1}{|\lambda_n|}, \quad n \in \mathbb{N}.$$

In particular this means that the boundary control system (4.32) has continuous solutions in the space

$$L^2[0, 1] \times H^{-1}[0, 1]$$

for every input $u(\cdot) \in L^2[0, T]$. This result has also been established by Lasiecka and Triggiani [17]. For the output operator we can allow an arbitrary bounded linear map from $L^2[0, 1]$ into \mathbb{R} . The space \mathcal{V} depends on this map. In any case $\mathcal{W} \subset \mathcal{V}$ and hence $\mathcal{P}(t) : \mathcal{V} \rightarrow \mathcal{V}^*$ has a smoothing effect with respect to \mathcal{W} .

Remark 4.11. An analogous result has been developed by Lasiecka and Triggiani [18] for the higher dimensional wave equation. In their paper the output operator is the identity on the displacement component of the state in $\mathcal{W} = L^2 \times H^{-1}$. This case cannot be treated within our framework. However, the results in [18] are weaker than ours. The uniqueness for the solution of the Riccati equation has not been established in [18]. Furthermore, the Riccati operator in [18] is in $\mathcal{L}(\mathcal{W})$ and does not have smoothing properties with respect to \mathcal{W} . Consequently the feedback operator becomes unbounded with respect to this space. It seems that for hyperbolic PDE's our assumptions are close to the weakest possible in order to derive a bounded feedback operator.

THE MAXIMUM PRINCIPLE FOR AN OPTIMAL SOLUTION TO A DIFFERENTIAL INCLUSION WITH END POINTS CONSTRAINTS*

HALINA FRANKOWSKA†

Abstract. We derive Pontryagin's maximum principle for a general optimal control problem using the set-valued version of variational equation. We achieve this aim by exploiting an adequate differential calculus of set-valued maps. Furthermore, the calmness condition is replaced by a surjectivity condition involving reachable sets of the "set-valued linearization" of the initial control problem. Duality then provides both the "adjoint differential inclusion" and the maximum principle.

Key words. differential inclusion, tangent cone, derivative of a set-valued map, convex process, variational inclusion, maximum principle

AMS(MOS) subject classifications. 49B10, 49B34, 49B30, 93C15

1. Introduction. We shall derive the maximum principle for the optimization problem

$$(1) \quad \text{minimize} \left\{ g(x(0), x(1)) + \int_0^1 \phi(x(\tau)) d\tau \right\}$$

over the solutions to a differential inclusion

$$(2) \quad x'(t) \in F(x(t))$$

satisfying end points constraints

$$(3) \quad x(0) \in C_0, \quad x(1) \in C_1.$$

By regarding this problem as an abstract optimization problem

$$(4) \quad \min_{x \in \mathcal{K}} \phi(x)$$

where \mathcal{K} is the set of solutions to (2), (3) in an appropriate functional space, the maximum principle is the three-century-old Fermat rule stating that the gradient of the functional ϕ vanishes at a solution \bar{x} of (4) lying in the interior of \mathcal{K} . Since most often in infinite-dimensional space \mathcal{K} has an empty interior (i.e., \bar{x} lies in the boundary of \mathcal{K}) this Fermat rule becomes

$$(5) \quad \langle \phi'(\bar{x}), w \rangle \geq 0$$

for all w in $T_{\mathcal{K}}(\bar{x})$, where $T_{\mathcal{K}}(\bar{x})$ is the contingent cone to \mathcal{K} at \bar{x} , introduced by Bouligand in the 1930s (see Aubin-Ekeland [3, Chap. 7]).

When we wish to derive the maximum principle from this inequality, we observe that we cannot "characterize explicitly" all the elements of this cone, but only of a subcone. We already followed this abstract approach in Frankowska [12] by using an appropriate subcone: the intermediate tangent cone $I_{\mathcal{K}}(\bar{x})$, introduced by Ursescu [22]. Hence we shall deduce the maximum principle from inequality (5), when w ranges over a closed convex subcone of the intermediate tangent cone. The convexity allows us to state a dual version of the Fermat rule (5), which is the familiar form in which the maximum principle is stated.

* Received by the editors December 4, 1984, and in revised form August 26, 1985.

† CEREMADE, Université de Paris—Dauphine, 75775 Paris, France.

We may always choose the Clarke tangent cone $C_{\mathcal{K}}(\bar{x})$, introduced by Clarke in [6]. We refer also to Clarke [7], Rockafellar [17] and Aubin-Ekeland [3, Chap. 7], for an exhaustive exposition of the properties of this cone. Let us mention only a result of J. Treiman [20], generalizing to the case of Banach spaces a result of Cornet [8]. It implies in essence that when a subcone of the contingent cone is lower semicontinuous, it is actually a subcone of the Clarke tangent cone. However, the choice of the Clarke tangent cone is not always wise. First, it involves unnecessary regularity assumptions. Second, it happens to be difficult to handle and to characterize explicitly. This is the reason why we state our results for an arbitrary closed convex subcone of the intermediate tangent cone.

In this paper, we replace the “calmness” assumption introduced in Clarke [7] by a surjectivity assumption, which involves naturally the end points constraints.

The outline of the paper is as follows. In § 2 we recall some notions with which we are dealing. Section 3 is devoted to the study of the derivative of the solutions set of the differential inclusion (2). In the fourth section we derive the maximum principle. An example is provided in § 5.

2. Tangent cones. We recall first

DEFINITION 2.1. Let K be a subset of a Banach space E and $x \in \bar{K}$ (closure of K).

(a) Bouligand's contingent cone:

$$T_K(x) := \left\{ w \in E : \liminf_{h \rightarrow 0+} \text{dist} \left(w, \frac{K-x}{h} \right) = 0 \right\},$$

(b) Intermediate tangent cone:

$$I_K(x) := \left\{ w \in E : \lim_{h \rightarrow 0+} \text{dist} \left(w, \frac{K-x}{h} \right) = 0 \right\},$$

(c) Clarke's tangent cone:

$$C_K(x) := \left\{ w \in E : \lim_{\substack{h \rightarrow 0+ \\ y \rightarrow x \\ K}} \text{dist} \left(w, \frac{K-y}{h} \right) = 0 \right\},$$

(d) Dubovickii-Miljutine tangent cone:

$$D_K(x) := \{ w \in E : \exists \varepsilon > 0, x +]0, \varepsilon][w + \varepsilon B) \subset K \},$$

where B denotes the closed unit ball in E .

All the above sets are cones. (a), (b), (c) are closed, (d) is open. Moreover if K is convex then $T_K(x) = C_K(x) = I_K(x)$, $D_K(x) = \text{Int } T_K(x)$.

The cone $C_K(x)$ is always convex and

$$C_K(x) \subset I_K(x) \subset T_K(x), \quad \text{Int } C_K(x) \subset D_K(x) \subset I_K(x).$$

For further properties of $T_K(x)$ see Aubin-Ekeland [3, Chap. 7]. The cone $C_K(x)$ was studied in Clarke [7], Rockafellar [17] and Aubin-Ekeland [3]. For the cone $D_K(x)$ see Dubovickii-Miljutine [9]. Properties of $I_K(x)$ are given in Ursescu [22].

We recall

DEFINITION 2.2. For $Q: \mathbb{R} \times E \rightarrow \mathbb{R} \cup \{+\infty\}$, set

$$\limsup_{h \rightarrow 0+} \inf_{u' \rightarrow u} Q(h, u') := \sup_{\varepsilon > 0} \inf_{\delta > 0} \sup_{h \in]0, \delta[} \inf_{u' \in u + \varepsilon \tilde{B}} Q(h, u')$$

(see Rockafellar [17]).

DEFINITION 2.3. For $f: E \rightarrow \mathbb{R} \cup \{+\infty\}$, $x \in \text{Dom}(f)$, $u \in E$ set

$$i_+f(x)(u) := \limsup_{h \rightarrow 0+} \inf_{u' \rightarrow u} \frac{f(x + hu') - f(x)}{h}.$$

If $\text{Ep} f$ denotes the epigraph of f , we observe that

$$I_{\text{Ep} f}(x, f(x)) = \text{Ep } i_+f(x)$$

(see Frankowska [12]).

Here we shall use the closed convex subcones of the intermediate tangent cone $I_K(x)$. The Clarke tangent cone $C_K(x)$ is the first example of such a subcone. Another example is provided by the *asymptotic tangent cone* given by

$$I_K^a(x) = \{u \in I_K(x) : u + I_K(x) \subset I_K(x)\}.$$

$I_K^a(x)$ is a closed convex cone and $C_K(x) \subset I_K^a(x) \subset I_K(x)$.

In this paper we shall study a “linearization” of a differential inclusion given by a closed (convex) process. We recall

DEFINITION 2.4. Let E, E_1 be Banach spaces and let $A: E \rightrightarrows E_1$ be a set-valued map. A is called a closed (respectively, convex) process if $\text{graph } A$ is a closed (respectively, convex) cone. The transposed process $A^*: E_1^* \rightrightarrows E^*$ of a closed convex process $A: E \rightrightarrows E_1$ is defined by

$$v \in A^*(u) \text{ if and only if for all } (x, y) \in \text{graph } A, \langle v, x \rangle \leq \langle u, y \rangle.$$

DEFINITION 2.5 [13]. Let E, E_1 be given Banach spaces and let $F: E \rightrightarrows E_1$ be a set-valued map, Lipschitzian at x and $y \in F(x)$. The intermediate derivative $dF(x, y)$ of F at (x, y) is a set-valued map from E into E_1 defined by

$$dF(x, y)(u) = \left\{ v \in E_1 : \lim_{h \rightarrow 0+} \text{dist} \left(v, \frac{F(x + hu) - y}{h} \right) = 0 \right\}$$

for all $u \in E$, or equivalently

$$v \in dF(x, y)(u) \text{ if and only if } (u, v) \in I_{\text{graph } F}(x, y).$$

In the case of single-valued maps, this notion generalizes the Fréchet derivative.

EXAMPLE 2.6. Let $F: E \rightrightarrows E_1$ be a set-valued map, Lipschitzian at x , $y \in F(x)$. Then $dF(x, y)$ is a closed process.

The cones $I_{\text{graph } F}^a(x, y)$ and $C_{\text{graph } F}(x, y)$ define closed convex processes $d_aF(x, y)$, $CF(x, y)$, respectively, by

$$v \in d_aF(x, y)(u) \text{ if and only if } (u, v) \in I_{\text{graph } F}^a(x, y),$$

$$v \in CF(x, y)(u) \text{ if and only if } (u, v) \in C_{\text{graph } F}(x, y).$$

In the next two lemmas we study some properties of the intermediate derivative $dF(x, y)$.

LEMMA 2.7. Let $F: E \rightrightarrows \mathbb{R}^n$ be a given set-valued map, Lipschitzian at x with a constant M and $y \in F(x)$. If F is differentiable at (x, y) , in the sense that

$$T_{\text{graph } F}(x, y) = I_{\text{graph } F}(x, y),$$

then the map $dF(x, y)(\cdot)$ is an M -Lipschitzian closed process. If, moreover, it is soft in the sense that

$$T_{\text{graph } F}(x, y) = C_{\text{graph } F}(x, y),$$

then $dF(x, y)$ is a closed convex process.

Proof. The set $dF(x, y)(0) \neq \emptyset$ because it contains zero. Pick any $u \in E$ such that $dF(x, y)(u) \neq \emptyset$ and let $v \in dF(x, y)(u)$, $u_1 \in E$. For all small $h > 0$ let $v_h \in (F(x + hu) - y)/h$ be such that $\lim_{h \rightarrow 0+} v_h = v$. By Lipschitzianity, for all small $h > 0$, there exists $w_h \in (F(x + hu_1) - y)/h$ such that $\|w_h - v_h\| \leq M\|u - u_1\|$. So there exists a subsequence $\{w_{h_i}\}$ converging to some w . Thus

$$(u_1, w) \in T_{\text{graph } F}(x, y), \quad \|v - w\| \leq M\|u - u_1\|.$$

By the assumption of Lemma 2.7,

$$w \in dF(x, y)(u_1).$$

The second statement follows from the convexity of Clarke's tangent cone. \square

LEMMA 2.8. *Let $F: E \rightrightarrows E_1$ be a Lipschitzian at x set-valued map with convex images and $y \in F(x)$. Then for all $u \in \text{Dom } dF(x, y) := \{w: dF(x, y)(w) \neq \emptyset\}$, $dF(x, y)(u)$ is a closed convex set and*

$$\text{cl}(dF(x, y)(u) + T_{F(x)}(y)) \subset dF(x, y)(u).$$

Proof. Fix $u \in \text{Dom } dF(x, y)$. The set $dF(x, y)(u)$ is closed because $\text{graph } dF(x, y)$ is closed. It is convex because F has convex images. To prove the last statement we have to verify that

$$dF(x, y)(u) + \bigcup_{h>0} \frac{1}{h}(F(x) - y) \subset dF(x, y)(u).$$

Pick $h_0 > 0$ and $v \in dF(x, y)(u)$ and let w be so that $y + h_0 w \in F(x)$. For all small $h > 0$ let $v_h \in E_1$ be such that $\lim_{h \rightarrow 0+} v_h = v$ and

$$(2.9) \quad y + hv_h \in F(x + hu).$$

Since F is Lipschitzian at x there exists $M > 0$ such that for all $h > 0$ sufficiently small

$$(2.10) \quad y + h_0 w \in F(x + hu) + h|u|MB.$$

By the convexity of $F(x + hu)$ and (2.9), (2.10) for all small $h > 0$

$$\left(1 - \frac{h}{h_0}\right)(y + hv_h) + \frac{h}{h_0}(y + h_0 w) \in F(x + hu) + \frac{h^2}{h_0}|u|MB.$$

Hence

$$y + h(v_h + w) - \frac{h^2}{h_0}v_h \in F(x + hu) + \frac{h^2}{h_0}|u|MB$$

and by Definition 2.5, $v + w \in dF(x, y)(u)$. \square

In this paper we consider families of uniformly Lipschitzian closed processes. The next lemma provides a sufficient condition for the uniform Lipschitz continuity.

Let $A: E \rightrightarrows E_1$ be a given closed convex process. If $\text{Dom}(A) := \{x \in E: A(x) \neq \emptyset\} = E$ the Robinson-Ursescu theorem (see Robinson [16], Ursescu [21] or Aubin-Ekeland [3, p. 132]) tells us that A is M -Lipschitzian for some $M > 0$ and that for all $q \in \text{Dom}(A^*)$

$$\sup_{p \in A^*(q)} \|p\| \leq M\|q\|.$$

LEMMA 2.11. *Let T be a topological space and let $A_\tau: \mathbb{R}^n \rightrightarrows \mathbb{R}^q$, $\tau \in T$ be a family of closed convex processes. Assume that the map $\tau \rightarrow \text{graph } A_\tau$ is lower semicontinuous at τ_0 . Then the following statements are equivalent.*

- (i) The processes A_τ are uniformly Lipschitzian on a neighborhood V of τ_0 , in the sense that there exists a constant $M > 0$ such that

$$A_\tau \text{ is } M\text{-Lipschitzian for all } \tau \in V,$$

- (ii) $\text{Dom } A_{\tau_0} = \mathbb{R}^n$.

Proof. Clearly (i) implies (ii). Conversely assume that (ii) is verified. By the Robinson–Ursescu theorem, $A_{\tau_0}(\cdot)$ is γ -Lipschitzian for some $\gamma > 0$. Let $u_0, \dots, u_n \in \mathbb{R}^n$ be such that

$$B \subset \text{Int co } \{u_i : i = 0, \dots, n\},$$

$$m = \max_i \|u_i\|.$$

By Lipschitzianity, for all i there exists

$$v_i \in A_{\tau_0}(u_i) \cap \gamma m B.$$

By the lower semicontinuity of graph A_τ there exists a neighborhood V of τ_0 such for all $\tau \in V$ and $i = 0, \dots, n$ we can find

$$(2.12) \quad (u_i(\tau), v_i(\tau)) \in \text{graph } (A_\tau) \cap (mB \times 2\gamma mB)$$

such that

$$B \subset \text{Int co } \{u_i(\tau) : i = 0, \dots, n\}.$$

Since graph A_τ is convex, we deduce from (2.12) that for all $u \in mB$

$$A_\tau(u) \cap 2\gamma mB \neq \emptyset$$

and thus

$$\frac{1}{2\gamma} B \subset A_\tau^{-1}(B).$$

This inclusion implies that $A_\tau(\cdot)$ is Lipschitzian with a constant 2γ . \square

COROLLARY 2.13. Let $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^q$ be a set-valued map. Assume that there exists a family of closed convex processes $P(x, y): \mathbb{R}^n \rightrightarrows \mathbb{R}^q$, $(x, y) \in \text{graph } F$ satisfying

$$\{u \in \mathbb{R}^n : \exists v \in \mathbb{R}^q, (u, v) \in \liminf_{\substack{(x', y') \rightarrow (x, y) \\ (x', y') \in \text{graph } F}} \text{graph } P(x, y)\} = \mathbb{R}^n.$$

Then, for all compact set $G \subset \text{graph } F$, any family of closed convex processes $A(x, y): \mathbb{R}^n \rightrightarrows \mathbb{R}^q$, $(x, y) \in G$ satisfying

$$\text{graph } P(x, y) \subset \text{graph } A(x, y) \text{ for all } (x, y) \in G$$

is uniformly Lipschitzian.

Proof. By the compactness of G it is enough to show that for all $(x, y) \in \text{graph } F$ there exist $\varepsilon > 0$ and $M > 0$ such that for all $(x', y') \in ((x, y) + \varepsilon B) \cap \text{graph } F$ $A(x', y')$ is M -Lipschitzian. Fix $(x, y) \in \text{graph } F$ and set

$$Q = \liminf_{\substack{(x', y') \rightarrow (x, y) \\ (x', y') \in \text{graph } F}} \text{graph } P(x', y').$$

For all $(x', y') \in \text{graph } F$ and $u \in \mathbb{R}^n$ set

$$S(x', y')(u) = \begin{cases} \{v \in \mathbb{R}^q : (u, v) \in Q\} & \text{if } (x', y') = (x, y), \\ P(x', y')(u) & \text{otherwise.} \end{cases}$$

By Lemma 2.11 there exist $\varepsilon > 0$, $M > 0$ such that for all $(x', y') \in ((x, y) + \varepsilon B) \cap \text{graph } F$ $S(x', y')$ is M -Lipschitzian, i.e., $(1/M)B \subset S(x'y')^{-1}(B) \subset P(x'y')^{-1}(B) \subset A(x', y')^{-1}(B)$. This implies the M -Lipschitzianity of $A(x', y')$. \square

We shall need the following

LEMMA 2.14. *Let $\phi: \mathbb{R}^n \rightarrow \mathbb{R}$ be a Lipschitzian function and $f: L^1(0, 1) \rightarrow \mathbb{R}$ be defined by*

$$f(x) = \int_0^1 \phi(x(\tau)) d\tau.$$

Further let $z \in L^1(0, 1)$ and $\psi: [0, 1] \times \mathbb{R}^n \rightarrow \mathbb{R}$ be such a function that

- (i) $\psi(\cdot, u)$ is measurable for all $u \in \mathbb{R}^n$,
- (ii) $\{\psi(\tau, \cdot): \tau \in [0, 1]\}$ is a family of uniformly Lipschitzian convex functions and $\psi(\tau, 0) = 0$ for all $\tau \in [0, 1]$,
- (iii) $\psi(\tau, \cdot) \geq i_+ \phi(z(\tau))(\cdot)$ for almost all $\tau \in [0, 1]$.

Then the function $g: L^1(0, 1) \rightarrow \mathbb{R}$ defined by

$$g(u) = \int_0^1 \psi(\tau, u(\tau)) d\tau$$

is convex, Lipschitzian. Furthermore $g \geq i_+ f(z)$ and if ξ is a subgradient of g at zero, then for almost all $\tau \in [0, 1]$

$$\xi(\tau) \in \partial \psi(\tau, 0).$$

Proof. It is enough to prove the last statement. By Fatou's lemma and Lipschitzianity of ϕ , for all $u \in L^1(0, 1)$

$$\begin{aligned} i_+ f(z)(u) &\leq \int_0^1 \limsup_{h \rightarrow 0+} \frac{\phi(z(\tau) + hu(\tau)) - \phi(z(\tau))}{h} d\tau \\ &= \int_0^1 i_+ \phi(z(\tau))(u(\tau)) d\tau \leq \int_0^1 \psi(\tau, u(\tau)) d\tau = g(u). \end{aligned}$$

If $\xi \in \partial g(0)$, then $\xi \in L^\infty(0, 1)$ and for all $u \in L^1(0, 1)$

$$\int_0^1 \langle \xi(\tau), u(\tau) \rangle d\tau \leq \int_0^1 \psi(\tau, u(\tau)) d\tau.$$

We may assume that ξ is a bounded function. Since $\psi(\tau, \cdot) - \langle \xi(\tau), \cdot \rangle$ are uniformly Lipschitzian functions equal to zero at the point zero and u is an arbitrary function of $L^1(0, 1)$ the last inequality implies that for almost all $\tau \in [0, 1]$ and all $x \in \mathbb{R}^n$, $\psi(\tau, x) - \langle \xi(\tau), x \rangle \geq 0$, equivalently,

$$\psi(\tau, x) - \psi(\tau, 0) \geq \langle \xi(\tau), x \rangle$$

which ends the proof. \square

3. The intermediate derivative of the solution set to the differential inclusion $x' \in F(x)$. Let $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a set-valued map. Recall that a function x of the Sobolev space $W^{1,1}(0, 1)$ is called a solution to the differential inclusion

$$(3.1) \quad x' \in F(x)$$

whenever $x'(t) \in F(x(t))$ almost everywhere in $[0, 1]$. We denote by S_1 the set of all solutions of (3.1) defined on the time interval $[0, 1]$. For all $\eta \in \mathbb{R}^n$ set

$$S(\eta) = \{x \in S_1: x(0) = \eta\}.$$

Let z belong to S_1 . For deriving the maximum principle we need to regard S as a set-valued map from \mathbb{R}^n to the space $C(0, 1)$ of continuous functions on $[0, 1]$ into \mathbb{R}^n and to characterize the derivative $dS(z(0), z)$ (the intermediate derivative of $S: \mathbb{R}^n \rightrightarrows C(0, 1)$).

We denote by $\text{co } F$ the set-valued map whose value at x is equal to the convex hull of $F(x)$.

Consider the convexified inclusion

$$(3.2) \quad x' \in \text{co } F(x)$$

and let S_1^{co} denote the set of solutions of (3.2) defined on the time interval $[0, 1]$. For all $\eta \in \mathbb{R}^n$ set

$$S^{\text{co}}(\eta) = \{x \in S_1^{\text{co}}: x(0) = \eta\}.$$

We wish to compare $dS(z(0), z)$ and $dS^{\text{co}}(z(0), z)$.

THEOREM 3.3. *Assume that F has compact images and is Lipschitzian on a neighborhood of $z([0, 1])$. Then*

$$dS(z(0), z) = dS^{\text{co}}(z(0), z).$$

Proof. Let $\varepsilon > 0$ be so that F is Lipschitzian on $z([0, 1]) + 2\varepsilon B$. By the Filippov-Ważewski relaxation theorem (see Aubin-Cellina [2, p. 128]) for all $x \in S^{\text{co}}(\eta)$ satisfying $x([0, 1]) \subset z([0, 1]) + \varepsilon B$ there exists a sequence $x_i \in S(\eta)$, $i \geq 1$ which converges to x in $C(0, 1)$. Hence the result. \square

In the theorem below we characterize subsets of $dS(z(0), z)$.

THEOREM 3.4. *Assume that F has compact images and is Lipschitzian on a neighborhood of $z([0, 1])$. Then the set of solutions to the differential inclusion*

$$(3.5) \quad \begin{aligned} w'(t) &\in d \text{co } F(z(t), z'(t))(w(t)) \quad \text{a.e. in } [0, 1], \\ w(0) &= \eta, \end{aligned}$$

is contained in $dS(z(0), z)(\eta)$.

Proof. From [13] follows that every solution of the inclusion (3.5) is contained in $dS^{\text{co}}(z(0), z)(\eta)$. Theorem 3.3 ends the proof. \square

4. The maximum principle. Consider the differential inclusion

$$(4.1) \quad x' \in F(x)$$

and let S_1 denote the set of all solutions of (4.1) defined on $[0, 1]$.

Let C_0, C_1 be subsets of \mathbb{R}^n and let

$$\phi: \mathbb{R}^n \rightarrow \mathbb{R}, \quad g: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$$

be given Lipschitzian functions.

Consider the problem

$$(4.2) \quad \text{minimize } \left\{ g(x(0), x(1)) + \int_0^1 \phi(x(t)) dt: x \in S_1, x(0) \in C_0, x(1) \in C_1 \right\}.$$

Let z be a solution of (4.2). We wish to prove the maximum principle by using a “linearization” of differential inclusion (4.1) along z . For this we consider:

I. A family of closed convex processes $A(t): \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ where $t \in [0, 1]$ satisfying

$$(4.3) \quad \begin{aligned} t \rightarrow A(t)(x) &\text{ is a measurable map,} \\ A(t)(x) &\subset d \text{co } F(z(t), z'(t))(x), \end{aligned}$$

for all $x \in \mathbb{R}^n$.

II. A family of convex functions $\psi(t): \mathbb{R}^n \rightarrow \mathbb{R}$, where $t \in [0, 1]$, such that for all $u \in \mathbb{R}^n$

$$(4.4) \quad \begin{aligned} & t \rightarrow \psi(t)(u) \text{ is measurable,} \\ & \psi(t)(u) \geq i_+ \phi(z(t))(u), \quad \psi(t)(0) = 0, \\ & \psi(t)(\cdot) \text{ is positively homogeneous.} \end{aligned}$$

III. A convex function $\psi_1: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ such that

$$(4.5) \quad \begin{aligned} & \psi_1 \geq i_+ g(z(0), z(1)), \quad \psi_1(0) = 0, \\ & \psi_1 \text{ is positively homogeneous.} \end{aligned}$$

IV. Closed convex cones $P, Q \subset \mathbb{R}^n$ satisfying

$$(4.6) \quad P \subset I_{C_0}(z(0)),$$

$$(4.7) \quad \emptyset \neq \text{Int } Q \subset D_{C_1}(z(1))$$

We denote their negative polars by

P^-, Q^- , respectively.

Let us consider the linearization

$$(4.8) \quad \begin{aligned} & w'(t) \in \text{cl}(A(t)w(t) + T_{\text{co } F(z(t))}(z'(t))) \quad \text{a.e. in } [0, 1], \\ & w(0) \in P, \end{aligned}$$

and let $R(1)$ denote the reachable set of (4.8) at time 1, i.e.,

$$R(1) = \{w(1): w \in W^{1,1}(0, 1) \text{ is a solution of (4.8)}\}.$$

Remark. Lemma 2.8 implies that $\text{cl}(A(t)w + T_{\text{co } F(z(t))}(z'(t))) \subset d \text{ co } F(z(t), z'(t))(w)$.

THEOREM 4.9. Assume that $z \in S_1$ solves problem (4.2), F has compact images and is Lipschitzian on a neighborhood of $z([0, 1])$. Let $\{A(t): t \in [0, 1]\}$ be a family of uniformly Lipschitzian closed convex processes, let $\{\psi(t): t \in [0, 1]\}$ be a family of uniformly Lipschitzian convex functions, let ψ_1 be a Lipschitzian convex function, and let P, Q be closed convex cones such that the relations (4.3)–(4.7) are satisfied.

If the following surjectivity assumption holds true

- (i) $R(1) - Q = \mathbb{R}^n$, or equivalently
 - (ii) there exists a solution \bar{w} of (4.8) such that $\bar{w}(1) \in \text{Int } Q$,
- then there exists a $q \in W^{1,\infty}(0, 1)$ satisfying

- (a) the adjoint inclusion:

$$q'(t) \in A^*(t)(-q(t)) + \partial\psi(t)(0),$$

- (b) the maximum principle:

$$\langle q(t), z'(t) \rangle = \max_{e \in F(z(t))} \langle q(t), e \rangle,$$

- (c) the transversality condition:

$$(q(0), -q(1)) \in \partial\psi_1(0) + P^- \times Q^-.$$

Remark. In particular if for a.e. $t \in [0, 1]$ the set-valued map F is soft at $(z(t), z'(t))$, then by Lemma 2.7 the theorem holds with $A(t) = dF(z(t), z'(t))$.

Proof. Fix any number $p > 1$. We introduce the following notation:

$$E = L^p(0, 1), \quad W = W^{1,p}(0, 1), \quad T = \mathbb{R}^n \times \mathbb{R}^n,$$

$$\gamma \in \mathcal{L}(W, T): \gamma(x) = (x(0), x(1)),$$

$$L \in \mathcal{L}(W, E): Lx = \dot{x},$$

$$f: E \rightarrow E: f(x) = \int_0^1 \phi(x(t)) dt,$$

$$\mathcal{F}: E \rightrightarrows E: \mathcal{F}(x) = \{y \in E: y(t) \in F(x(t)) \text{ a.e.}\}.$$

With this new notation, z solves the following problem

$$\text{minimize } \{f(x) + g \circ \gamma(x): Lx \in \mathcal{F}(x); x(0) \in C_0, x(1) \in C_1\}.$$

For all $t \in [0, 1]$, $x \in \mathbb{R}^n$ set

$$G(t, x) := \text{cl} (A(t)x + T_{\infty F(z(t))}(z'(t))).$$

The set-valued map G is measurable in t and Lipschitzian in x . Moreover, for almost all $t \in [0, 1]$ graph $G(t, \cdot)$ is a closed convex cone. Hence by the time-dependent version of the Filippov theorem (see Clarke [7, p. 115]), $W^{1,\infty}(0, 1)$ -solutions of (4.8) are dense in $W^{1,1}(0, 1)$ -solutions of (4.8). Therefore we may assume

(ii)' there exists a solution $\bar{w} \in W^{1,\infty}(0, 1)$ of (4.8) such that $\bar{w}(1) \in \text{Int } Q$.

Moreover the set reachable at time 1 by $W^{1,\infty}(0, 1)$ -solutions of (4.8) is dense in $R(1)$.

We shall proceed in several steps.

Step 1. Denote by SL the set of all solutions of (4.8) belonging to $W^{1,p}(0, 1)$ which satisfy $w(1) \in Q$. We claim that for all $w \in SL$

$$(4.10) \quad \int_0^1 \psi(t)(w(t)) dt + \psi_1(\gamma w) \geq 0.$$

Indeed by the convexity of SL and the remarks preceding Step 1

$$(4.11) \quad \{w(1): w \in SL\} - Q = \mathbb{R}^n.$$

Let $\bar{w} \in W^{1,\infty}(0, 1)$ be as in assumption (ii)'. Then for all $n \geq 1$ and $w \in SL$ the function

$$w_n = \left(1 - \frac{1}{n}\right)w + \frac{1}{n}\bar{w} \in SL.$$

Moreover,

$$(4.12) \quad \begin{aligned} w_n(1) &\subset D_{C_1}(z(1)), \\ w_n &\rightarrow w \quad \text{in } W^{1,p}(0, 1). \end{aligned}$$

Since $\{\psi(t)\}$ are uniformly Lipschitzian and ψ_1 is Lipschitzian it is enough to prove (4.10) for all w_n . So fix n . By Lemma 2.8 and Theorem 3.4 for all $h > 0$ there exist $w_n^h \in W^{1,1}(0, 1)$ satisfying $z + hw_n^h \in S_1$, $w_n^h \rightarrow w_n$ in $C(0, 1)$.

By Lipschitzianity of F and Filippov's theorem (see Aubin-Cellina [2, p. 120]) we may assume that $z(0) + hw_n^h(0) \in C_0$. Moreover by (4.12) for all h sufficiently small $z(1) + hw_n^h(1) \in C_1$. Since z is a solution and f, g are Lipschitzian, we obtain

$$\begin{aligned} 0 &\leq \limsup_{h \rightarrow 0+} \frac{f(z + hw_n^h) - f(z)}{h} + \limsup_{h \rightarrow 0+} \frac{g \circ \gamma(z + hw_n^h) - g \circ \gamma(z)}{h} \\ &= i_+ f(z)(w_n) + i_+ g(\gamma z)(\gamma w_n). \end{aligned}$$

Lemma 2.14 and assumptions (4.4), (4.5) end the proof of Step 1.

Step 2. We claim that for all $u, e \in E$ there exists a solution $w \in W^{1,p}(0, 1)$ of the differential inclusion

$$w'(t) \in G(t, w(t) + u(t)) + e(t),$$

$$w(0) \in P, \quad w(1) \in Q.$$

Indeed since $G(t, \cdot)$ are uniformly Lipschitzian there exist $w_1 \in W^{1,p}(0, 1)$ satisfying

$$w'_1(t) \in G(t, w_1(t) + u(t)) + e(t) \quad \text{a.e.},$$

$$w_1(0) = 0$$

(see [7, p. 115]). On the other hand by (4.11) there exists $w_2 \in W^{1,p}(0, 1)$ satisfying

$$w'_2(t) \in G(t, w_2(t)),$$

$$w_2(0) \in P,$$

$$-w_1(1) \in w_2(1) - Q.$$

Consider then $w = w_1 + w_2$.

By convexity, for almost all t

$$\begin{aligned} w'(t) &= w'_1(t) + w'_2(t) \in G(t, w_1(t) + u(t)) + e(t) + G(t, w_2(t)) \\ &\subset G(t, w(t) + u(t)) + e(t) \end{aligned}$$

and

$$w(0) = w_2(0) \in P,$$

$$w(1) = w_1(1) + w_2(1) \in Q,$$

which ends the proof of Step 2.

Step 3. Consider the closed convex process $Q: E \rightrightarrows E$ given by

$$Q(x) = \{y \in E: y(t) \in G(t, x(t)) \text{ a.e.}\}$$

and let $N_{\text{co } F(z(t))}(z'(t))$ denote the normal cone (of convex analysis) to $\text{co } F(z(t))$ at $z'(t)$.

We claim that the transposed process $Q^*: E^* \rightrightarrows E^*$ is given by $p \in Q^*(q)$ if and only if for almost all $t \in [0, 1]$

$$(4.13) \quad q(t) \in -N_{\text{co } F(z(t))}(z'(t)),$$

$$(4.14) \quad p(t) \in A(t)^*(q(t)).$$

Indeed fix $q \in E^*$ and $p \in Q^*(q)$. Then for all $(x, y) \in \text{graph } Q$ $\langle p, x \rangle \leq \langle q, y \rangle$. Since $0 \in G(t, 0)$ it implies that for all measurable set $A \subset [0, 1]$ and all measurable functions $x, y: A \rightrightarrows B$ satisfying $y(t) \in G(t, x(t))$ a.e. in A

$$(4.15) \quad \int_A \langle (p(t), -q(t)), (x(t), y(t)) \rangle dt \leq 0.$$

Let A' be the set of all $t \in [0, 1]$ such that

$$\sup_{(a,b) \in \text{graph } G(t, \cdot)} \langle (p(t), -q(t)), (a, b) \rangle > 0.$$

It is measurable. We check that its measure $\mu(A')$ is zero. Indeed there exists a measurable set $A \subset A'$ and $\varepsilon > 0$ such that $\mu(A') = 2\mu(A)$ and for all $t \in A$, $\sup \{ \langle (p(t), -q(t)), (a, b) \rangle: (a, b) \in (B \times B) \cap \text{graph } G(t, \cdot) \} \geq \varepsilon$. The set-valued map

$$A \ni t \rightarrow \text{graph } G(t, \cdot) \cap \{(a, b) \in B \times B: \langle (p(t), -q(t)), (a, b) \rangle \geq \varepsilon\}$$

is measurable with closed nonempty images. Thus it has a measurable selection, a function $u(t) \in \text{graph } G(t, \cdot) \cap B \times B$ such that for all $t \in A$ $\langle p(t), -q(t) \rangle, u(t) \rangle \geq \varepsilon$. Inequality (4.15) implies then that $\mu(A) = 0$. Hence for almost all $t \in [0, 1]$ and all $a \in \mathbb{R}^n$, $b \in \text{cl}(A(t)(a) + T_{\text{co}F(z(t))}(z'(t)))$, $\langle p(t), a \rangle \leq \langle q(t), b \rangle$. Setting $a = 0$ we deduce (4.13). Because zero is contained in the tangent cone we also obtain that for almost all t and all $(a, b) \in \text{graph } A(t)$ $\langle p(t), a \rangle \leq \langle q(t), b \rangle$. This implies (4.14). One can easily check that if $p, q \in E^*$ satisfy the inclusions (4.13), (4.14) then $p \in Q^*(q)$.

Step 4. For all $w \in W$ set

$$\begin{aligned}\pi(w) &:= \int_0^1 \psi(\tau)(w(\tau)) \, d\tau, \\ \omega(t) &= \begin{cases} \psi_1(t) & \text{if } t \in P \times Q, \\ +\infty & \text{otherwise,} \end{cases} \\ \Pi &= \partial\pi(0), \quad \Omega = \partial\omega(0)\end{aligned}$$

(the subdifferentials of π and ω at zero in the sense of convex analysis). Steps 1, 2 and Lemma 3.4 [12] imply that there exist $\bar{q} \in W^{1,p^*}(0, 1)$ (where $1/p + 1/p^* = 1$) and $\xi \in \Pi \subset L^\infty(0, 1)$ satisfying

$$-\bar{q}' \in \xi + Q^*(\bar{q}), \quad (-\bar{q}(0), \bar{q}(1)) \in \Omega.$$

By Lemma 2.14, $\xi(t) \in \partial\psi(t)(0)$ a.e. Set $q = -\bar{q}$. Step 3 implies that q satisfies the adjoint inclusion (a) and the maximum principle (b). Because $\{A(t)^*(-q(t)): t \in [0, 1]\}$ is a bounded set and $\xi \in L^\infty(0, 1)$ we also obtain that $q' \in L^\infty(0, 1)$.

Since $\Omega = \partial\psi_1(0) + P^- \times Q^-$ we obtain the transversality condition (c). So the proof is complete. \square

5. An example. Let U be a compact metric space and let a continuous function $f: \mathbb{R}^n \times U \rightarrow \mathbb{R}^n$ be given. Consider the control system

$$(5.1) \quad x' = f(x, u(t)), \quad u(t) \in U.$$

We denote by S_1 the set of solutions of (5.1).

Let two subsets $C_0, C_1 \subset \mathbb{R}^n$ and Lipschitzian functions $\phi: \mathbb{R}^n \rightarrow \mathbb{R}$, $g: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ be given.

We study the problem

$$\text{minimize } \left\{ g(x(0), x(1)) + \int_0^1 \phi(x(t)) \, dt : x \in S_1, x(0) \in C_0, x(1) \in C_1 \right\}.$$

Assume that a trajectory-control pair (z, \bar{u}) solves the above problem and let $N_{C_0}(z(0))$, $N_{C_1}(z(1))$ denote the Clarke normal cone to C_0 at $z(0)$ and to C_1 at $z(1)$, respectively.

Consider the linear inclusion

$$(5.2) \quad \begin{aligned} w' &\in \frac{\partial f}{\partial x}(z(t), \bar{u}(t))w + T_{\text{co}f(z(t), U)}(z'(t)), \\ w(0) &\in C_{C_0}(z(0)). \end{aligned}$$

We denote by

$$R(1) = \{w(1): w \in W^{1,1}(0, 1) \text{ is a solution of (5.2)}\}.$$

THEOREM 5.3. Assume that there exist $L > 0$ and an open neighborhood V of $z([0, 1])$ such that $f(\cdot, u)$ is L -Lipschitzian for all $u \in U$, and for almost all t , the derivatives

$(\partial f/\partial x)(z(t), \bar{u}(t))$, $\phi'(z(t))$ and the derivative $g'(z(0), z(1))$ are well-defined. Assume further that Clarke's tangent cone $C_{C_1}(z(1))$ has a nonempty interior. If the following surjectivity assumption holds true:

- (i) $R(1) - C_{C_1}(z(1)) = \mathbb{R}^n$,
 - (ii) there exists a solution \bar{w} of (5.2) such that $\bar{w}(1) \in \text{Int } C_{C_1}(z(1))$,
- then there exists $q \in W^{1,\infty}(0, 1)$ satisfying

$$q'(t) = \phi'(z(t)) - \frac{\partial f}{\partial x}(z(t), \bar{u}(t))^* q(t),$$

$$\langle q(t), f(z(t), \bar{u}(t)) \rangle = \max_{u \in U} \langle q(t), f(z(t), u) \rangle,$$

$$(q(0), -q(1)) \in g'(z(0), z(1)) + N_{C_0}(z(0)) \times N_{C_1}(z(1)).$$

Proof. One can easily verify that for $F(\cdot) = f(\cdot, U)$

$$\frac{\partial f}{\partial x}(z(t), \bar{u}(t)) \in dF(z(t), z'(t)) \subset d \text{ co } F(z(t), z'(t)).$$

Moreover, for all t the map

$$A(t): w \rightarrow \frac{\partial f}{\partial x}(z(t), \bar{u}(t))w$$

is L -Lipschitzian closed convex process and

$$A(t)^*(w) = \frac{\partial f}{\partial x}(z(t), \bar{u}(t))^* w.$$

Theorem 4.9 ends the proof. \square

A GENERAL THEOREM ON LOCAL CONTROLLABILITY*

H. J. SUSSMANN†

Abstract. We prove a general sufficient condition for local controllability of a nonlinear system at an equilibrium point. Earlier results of Brunovsky, Hermes, Jurdjevic, Crouch and Byrnes, Sussmann and Grossmann, are shown to be particular cases of this result. Also, a number of new sufficient conditions are obtained. All these results follow from one simple general principle, namely, that local controllability follows whenever brackets with certain symmetries can be “neutralized,” in a suitable way, by writing them as linear combinations of brackets of a lower degree. Both the class of symmetries and the definition of “degree” can be chosen to suit the problem.

Key words. nonlinear control, local controllability, nilpotent approximation, symmetries

AMS(MOS) subject classifications. 49B10, 93C10

Introduction. In recent years, several papers have been published giving sufficient conditions for a nonlinear control system to be locally controllable from a point. (Cf. Brunovsky [3], Crouch and Byrnes [5], Grossmann [8], Hermes [10]–[13], Jurdjevic [14], Stefani [21], [22], Sussmann [24], [25].) The purpose of this article is to prove a general theorem which contains all these results as particular cases and, in addition, gives stronger results. Our result (Theorem 2.4) shows that many known sufficient conditions can be derived in a unified way from a single general principle, namely, the combination of a nilpotent approximation with the use of input symmetries. Section 2 is devoted to the statement of the main theorem, preceded by an outline of the basic facts and definitions needed for its formulation. Section 3 reviews the basic formalism needed to set up the nilpotent approximation, and proves a number of technical lemmas needed to turn this approximation into a tool for establishing local controllability results. Sections 4 and 5 introduce the basic ingredients of our main result, namely, dilations and invariant elements. The proof of the main theorem is then given in § 6. In § 7, we review in detail the various controllability results referred to above, and explain how they all follow from our result. We also prove stronger versions of several of those theorems, and some new sufficient conditions. Finally, in § 8 we discuss some of the limitations of our method. In addition to the observations of § 8, we remark that there are recent results by R. M. Bianchini and G. Stefani, as well as work by H. Knobloch and K. Wagner, which provide new sufficient conditions that are not contained in the ones given here.

1. Preliminaries. The local controllability problem has a long history, beginning with the classical controllability theory for linear systems, and the first nonlinear local controllability result, namely, the theorem which states that if the linearization of a system at an equilibrium point p is controllable, then the system itself is locally controllable from p in small time (i.e. for every $T > 0$, the time T reachable set from p contains p in its interior; cf., for example, Lee and Markus [17]). This “small-time local controllability” property, henceforth abbreviated as STLC, is of interest to control theorists for a number of reasons, such as: (a) that a sufficient condition for STLC is obviously equivalent to a necessary condition for the constant trajectory $x(t) \equiv p$ to

* Received by the editors April 3, 1985. This research was partially supported by the National Science Foundation under grant MCS 78-02442.

lie on the boundary of the attainable set from p ; since the simplest form of the Pontryagin Maximum Principle is precisely one such necessary condition, the STLC problem can be viewed as a particular case of the general problem of “high order optimality conditions;” (b) that STLC is equivalent to an important property of the optimal time function V , namely, continuity at p . (Here V is defined by letting $V(q)$ be the infimum of all the times T such that q can be reached from p in time T . If we wish to study the more common V function, defined in terms of the time it takes to steer q to p , then the continuity of V at p is equivalent to the STLC property for the system obtained by running the original system backwards.)

More recently, the problem has attracted the interest of “differential geometric control theorists,” i.e. of those who take the point of view that a control system is primarily a family of vector fields on a manifold, and a lot of the control-theoretically interesting information about the system should be contained in the Lie brackets of these vector fields (cf. [9], [16], [19], [23], [26]). At the early stages of the development of this “Lie theoretic approach,” attention was concentrated on proving those results that followed most naturally from the method. In particular, it was recognized right away that the Lie algebraic method yielded a complete characterization of local controllability for real analytic systems with the somewhat unnatural property of being “symmetric,” i.e. such that every trajectory run backwards is also a trajectory. (Hermann [9], Lobry [19]; the result is known as “Chow’s Theorem.”) On the other hand, for “reasonable” (i.e. not necessarily symmetric, but real-analytic) systems, the method yielded a complete characterization of a property which is related to, but not quite the same as, STLC. D. Elliott introduced the name “accessibility property” to refer to the property that the reachable set from p has an interior point. The so-called “positive form of Chow’s Theorem” (Krener [16]; cf. also [23]) characterizes this property in terms of Lie brackets. In 1974, P. Brunovsky [3] started from the observation that the “Lie theoretic” theorem about symmetric systems does not even give the most classical of all local controllability theorems, namely, the one for linear systems. He then proceeded to single out a class of systems (called “odd systems”) which could be proved to be STLC by Lie theoretic methods, and contained the class of linear systems. Since then, other local controllability results have been proved, as indicated above. The common feature of all these results is the exploitation of certain “structural symmetries” of a problem.

The traditional approach towards proving local controllability theorems has been to construct “control variations.” Heuristically, if one can construct control variations in all possible directions, then the reachable set ought to be a full neighborhood of the starting point. The argument can usually be made rigorous by some topological consideration. Ideally, the construction of variations in various directions should involve Lie bracket calculations. In practice, however, these calculations become rather cumbersome, and a different method is desirable which would construct, once and for all, a large collection of variations. One such method was used by us in [25], to prove a conjecture of H. Hermes. (Our earlier paper [24], which proved a different sufficient condition for STLC, was based on constructing variations, and it has only recently become clear to us that the result of [24] also follows using the method of [25].) The goal of the present paper is to prove the most general result that can be obtained by means of the method of [25].

A brief outline of the approach is as follows. Since a control system is primarily a family $\mathcal{V} = \{V_i: i \in I\}$ of vector fields, one can associate with it the Lie algebra $L(\mathcal{V})$ of vector fields generated by \mathcal{V} . Forgetting about rigor, one can think about “the Lie group” $G(\mathcal{V})$ with Lie algebra $L(\mathcal{V})$, and obtain an “action” of $G(\mathcal{V})$ on the state

space of the system. A $g \in G(\mathcal{V})$ is a product of exponentials $\exp(t_j V_{i_j})$, and therefore the result gp of acting on p by g is a point obtained by starting from p and following integral trajectories of the V_i , with switchings of vector fields allowed, and with motion “backwards in time” permitted as well. Those g ’s for which all the t_j are positive constitute a subsemigroup S of $G(\mathcal{V})$, which gives rise to the true trajectories of the control system. The reachable set from p is $S \cdot p$. For \mathcal{V} to be locally controllable from p , $S \cdot p$ has to have a nonempty interior, and so $G(\mathcal{V})p$ must be open, which means that, at least locally, $G(\mathcal{V})$ has to act transitively. If H is the isotropy group at p of this action, then a sufficient condition for p to be an interior point of $S \cdot p$ is that the interior of S in $G(\mathcal{V})$ should contain an element of H .

To make this rigorous, an algebraic formalism is needed to surmount the obstacles arising from the fact that $L(\mathcal{V})$ is, in general, infinite dimensional, and therefore $G(\mathcal{V})$ is not a well defined “Lie group.” Rather than work with $L(\mathcal{V})$ one works formally, with a free Lie algebra $L(\mathbf{X})$ in indeterminates X_i , and with its completion, the Lie algebra $\hat{L}(\mathbf{X})$ of formal Lie series in the X_i . Then there is a well defined group $\hat{G}(\mathbf{X})$, the group of exponentials of Lie series (cf., for example, Serre [20]). The controls can be embedded in $\hat{G}(\mathbf{X})$ as a subsemigroup S , by means of a map which assigns to each control a noncommutative formal power series, obtained by solving the differential equation of the system formally, using the indeterminates rather than the vector fields. (This map, introduced by Chen in [4], has been extensively used in control theory by M. Fliess, under the name of “Chen series,” cf. [6], [7].) Although obvious convergence and integrability difficulties arise if one tries to make $\hat{G}(\mathbf{X})$ act on the state space, the subsemigroup S does act in an obvious way, since S is identified with the set of admissible controls. And the series of a control $u(\cdot)$ contains a lot of information about the action of $u(\cdot)$. (More precisely, it is an asymptotic series, and it converges in the analytic case if $u(\cdot)$ is sufficiently small, cf. [1], [2], [7], [18], [25].) Since $\hat{G}(\mathbf{X})$ is not yet a true Lie group, one then makes a nilpotent approximation $G^N(\mathbf{X})$ of $\hat{G}(\mathbf{X})$ by killing all brackets of degree $> N$. If I is finite, $G^N(\mathbf{X})$ is now a Lie group in the usual sense. Then there is a corresponding approximating semigroup S^N . Although it is not possible in general to have $G^N(\mathbf{X})$ act on the state space, one can still define an “approximate action” and an “approximate isotropy group.” To get local controllability one must be able to prove (modulo technicalities) that the interior of S^N intersects the isotropy group. This we do by proving a general lemma that says that the interior of S^N always contains an element of a “very special form.” It then follows that, if one hypothesizes that all these “very special” elements are in the isotropy group, one gets controllability. As will be made clear in § 7, all known local controllability theorems amount to various forms of this hypothesis.

The special elements are obtained as the fixed points of the action of a finite group Λ on “input symmetries.” An input symmetry is, roughly, a linear map from $L(\mathbf{X})$ to $L(\mathbf{X})$ whose exponential maps S to S . Examples of such symmetries are: (a) multiplying a control by -1 , if its range of values permits it; (b) interchanging two controls; (c) time reversal. If a system has many symmetries, then there will be few Λ -fixed elements, and the resulting local controllability theorem will be very strong. As an example, we remark that the introduction of time-reversal, which was not used in [25], enables us here to prove a result which is considerably stronger than the Hermes conjecture proved in [25].

It turns out that the condition that certain “special elements” of the semigroups S^N be in the “isotropy group” can be rephrased, by passing to the logarithms, as the requirement that certain Lie brackets should vanish at p . It then becomes apparent that one can do slightly better. The brackets need not vanish. It suffices for them to

be “neutralized,” i.e. expressible as linear combinations of brackets of lower degree. And there is a certain amount of freedom as to the concept of “degree” to be used. One can use any one-parameter group of dilations to define “degree,” provided that certain technical conditions hold.

In order to avoid unnecessary complications, we will only work with systems that can be studied using a free Lie algebra generated by a *finite* set of indeterminates. That is, we will only study systems where the collection \mathcal{V} of associated vector fields is either finite, or a set of linear combinations of a finite set of vector fields. That is, we will only work with systems of the form

$$(1.1) \quad \dot{x} = \sum_{i=1}^k v_i g_i(x)$$

where the control $v = (v_1, \dots, v_k)$ is required to satisfy a constraint $v \in J$, where J is some subset of \mathbb{R}^k . It is then clear that we can assume that J linearly spans \mathbb{R}^k . If J does not affinely span \mathbb{R}^k , let A be the affine hull of J . By making a linear change of coordinates, we may assume that A is the set $\{1\} \times \mathbb{R}^{k-1}$. Then the system (1.1) becomes

$$(1.2) \quad \dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$$

with control constraint $u = (u_1, \dots, u_m) \in K$. (Here K is such that $J = \{1\} \times K$, and $m = k - 1$.)

If J affinely spans \mathbb{R}^k , then we let $f_0 \equiv 0$, $m = k$, $g_i = f_i$ for $i = 1, \dots, m$, $K = J$, $u_i = v_i$ for $i = 1, \dots, m$. Then our system is also of the form (1.2), with a control constraint $u \in K$, where K affinely spans \mathbb{R}^m . It is in this form that, from now on, all our systems will be expressed.

2. Statement of the main theorem. In this section we will state our main local controllability theorem. In order to get to the statement as quickly as possible, we will omit a number of definitions. Detailed definitions of all the concepts occurring in the statement are given in subsequent sections.

We consider control systems of the form

$$(2.1) \quad \dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x), \quad x \in M$$

with a control constraint

$$(2.2) \quad u = (u_1, \dots, u_m) \in K$$

where

(CS1) M is a smooth (i.e. C^∞) manifold,

(CS2) $\mathbf{f} = (f_0, \dots, f_m)$ is an $(m+1)$ -tuple of C^∞ vector fields on M ,

and

(CS3) K is a subset of \mathbb{R}^m such that

$$(2.3) \quad \text{Aff}(K) = \mathbb{R}^m.$$

Here $\text{Aff}(K)$ denotes the affine hull of K , i.e. the set of all finite linear combinations $\sum \alpha_i u^i$ with the $u^i \in K$, $\alpha_i \in \mathbb{R}$, and $\sum_i \alpha_i = 1$.

To specify a system we must give M , f and K . So we will simply refer to the triple $\Sigma = (M, f, K)$ as the control system, it being understood that M , f and K are supposed to satisfy (CS1), (CS2) and (CS3).

An *admissible control* for Σ is a Lebesgue integrable, K -valued function defined on some interval $[0, T]$. If $u(\cdot): [0, T] \rightarrow K$ is an admissible control, a *trajectory* for $u(\cdot)$ is an absolutely continuous curve $x(\cdot): [0, T] \rightarrow M$ such that

$$(2.4) \quad \dot{x}(t) = f_0(x(t)) + \sum_{i=1}^m u_i(t) f_i(x(t))$$

for almost all $t \in [0, T]$.

If $q \in M$ is of the form $x(T)$ for some trajectory such that $x(0) = p$, then q will be said to be *reachable from p in time T* . The set of all q that are reachable from p in time T for the system $\Sigma = (M, f, K)$ is the *time T reachable set from p* , and will be denoted by $\text{Reach}(\Sigma, T, p)$. Also we write

$$(2.5) \quad \text{Reach}(\Sigma, \leq T, p) = \bigcup_{0 \leq t \leq T} \text{Reach}(\Sigma, t, p)$$

for $T \geq 0$.

The system Σ is *small-time locally controllable* (STLC) from p if p is an interior point of $\text{Reach}(\Sigma, \leq T, p)$ for all $T > 0$. An equivalent characterization of this condition involves the optimal time function $V_{\Sigma, p}$. We define $V_{\Sigma, p}(q)$ to be the infimum of those T such that q is reachable from p in time T . (If no such T exists, then $V_{\Sigma, p}(q) = +\infty$.) Then Σ is STLC from p if and only if $V_{\Sigma, p}$ is continuous at p .

One can also consider the reachable sets obtained by restricting the class of admissible controls. For instance, we let $\text{Reach}_{pc}(\Sigma, T, p)$, $\text{Reach}_{pc}(\Sigma, \leq T, p)$ be the reachable sets obtained by using *piecewise constant* controls, and we say that Σ is STLC_{pc} from p if p is an interior point of $\text{Reach}_{pc}(\Sigma, \leq T, p)$ for all $T > 0$. The sufficient condition stated below in our main theorem is for STLC. However, under the hypotheses of the theorem, STLC and STLC_{pc} are equivalent, as will be observed below (cf. Proposition 2.3), so that the distinction between these two types of controllability need not worry us here.

If K is compact and convex, then one can also consider the sets reachable by bang-bang controls. (A bang-bang control is a piecewise constant control with values in the set of extreme points of K .) The corresponding small-time local controllability property is denoted by STLC_{bb} . Again, Proposition 2.3 will show that STLC and STLC_{bb} are equivalent under the hypotheses of our main theorem.

If \mathcal{F} is a family of C^∞ vector fields on a manifold M , then $L(\mathcal{F})$ denotes the Lie algebra of vector fields generated by the elements of \mathcal{F} . If \mathcal{V} is any set of vector fields on M , and $p \in M$, then we write

$$(2.6) \quad \mathcal{V}(p) = \{V(p) : V \in \mathcal{V}\}.$$

The family \mathcal{F} is said to satisfy the *Lie algebra rank condition* (LARC) at p if $L(\mathcal{F})(p)$ is the whole tangent space of M at p . An \mathcal{F} -trajectory is a curve $x(\cdot)$ which is a finite concatenation of integral arcs of members of \mathcal{F} . (Note: if an integral arc γ of a member f of \mathcal{F} is reparametrized by reversing the sense of time, then the resulting curve is an integral arc of $-f$, and need not be an \mathcal{F} -trajectory, since $-f$ need not belong to \mathcal{F} .) The family \mathcal{F} has the *accessibility property* (AP) from p if, for every $T > 0$, the set of points that can be reached from p by \mathcal{F} -trajectories in time $\leq T$ has a nonempty

interior. The following is a standard result from accessibility theory (the “positive form of Chow’s Theorem,” cf. Krener [16], Sussmann and Jurdjevic [23]).

PROPOSITION 2.1. *Let \mathcal{F} be a family of C^∞ vector fields on a C^∞ manifold M . Then the LARC at p implies the AP from p . Conversely, the AP from p implies the LARC at p if M is a real-analytic manifold and the members of \mathcal{F} are real-analytic.*

To a system Σ of the form (2.1), with a control constraint (2.2), we associate the family \mathcal{F}_Σ whose members are all the vector fields $f_0 + \sum_{i=1}^m u_i f_i$, for $(u_1, \dots, u_m) \in K$. The hypothesis that $\text{Aff}(K) = \mathbb{R}^m$ implies that the linear span of the members of \mathcal{F}_Σ is precisely the same as the linear span of f_0, \dots, f_m . Therefore $L(\mathcal{F}_\Sigma) = L(\mathbf{f})$, so that \mathcal{F}_Σ satisfies the LARC at p if and only if \mathbf{f} does. On the other hand, it is easy to see that an \mathcal{F}_Σ trajectory is precisely the same as a trajectory of Σ for a piecewise constant control. Hence Σ cannot be STLC_{pc} from p unless \mathcal{F}_Σ satisfies the AP from p . On the other hand, if f_0, \dots, f_m are real analytic vector fields, \mathcal{F}_Σ satisfies the AP from p if and only if \mathbf{f} satisfies the LARC from p . Therefore, in the analytic case, it is no restriction to assume that \mathbf{f} satisfies the LARC from p , if we seek to characterize the STLC_{pc} property. Actually, it is easy to prove:

PROPOSITION 2.2. *A system Σ of the form (2.1), with a control constraint (2.2), and f_0, \dots, f_m real analytic, cannot be STLC from a point p unless \mathbf{f} satisfies the LARC from p .*

Moreover, when the LARC from p holds, the distinction between STLC , STLC_{pc} and STLC_{bb} disappears, as shown by the following result, whose proof is given in the Appendix.

PROPOSITION 2.3. *Let Σ be a system of the form (2.1), with a control constraint (2.2) that satisfies (2.3). Assume that \mathbf{f} satisfies the LARC at p .*

Let \tilde{K} be the closure of the convex hull of K , and let $\tilde{\Sigma}$ be the system $(M, \mathbf{f}, \tilde{K})$. Then $\tilde{\Sigma}$ is SLTC from p if and only if Σ is SLTC_{pc} from p .

In particular, Proposition 2.3 implies that, for an arbitrary Σ , the STLC and STLC_{pc} properties from p are equivalent, if \mathbf{f} satisfies the LARC at p . Also, if K is compact and convex, STLC and STLC_{bb} are equivalent.

The sufficient condition for STLC to be proved here involves two main ingredients, namely, a finite group of symmetries and a one-parameter group of dilations. The symmetries considered will be mappings of a Lie algebra which is naturally associated to our problem. Precisely, we consider $L(\mathbf{X})$, the free Lie algebra in the indeterminates $\mathbf{X} = (X_0, \dots, X_m)$. We will be interested in linear maps $\lambda : L(\mathbf{X}) \rightarrow L(\mathbf{X})$ which are not necessarily Lie algebra automorphisms, but have a weaker property which we now define.

Let L be a Lie algebra over \mathbb{R} . We define $[L]^k$ for $k = 1, 2, \dots$ by $[L]^1 = L$, $[L]^{k+1} = [L, L^k]$. Clearly, any Lie algebra automorphism of L maps each $[L]^k$ into itself. A linear mapping $\lambda : L \rightarrow L$ which is a linear isomorphism and satisfies $\lambda([L]^k) \subseteq [L]^k$ for each k will be called a *pseudoautomorphism* of L .

In the particular case when L is $L(\mathbf{X})$, the $[L]^k$ are the ideals $L_k(\mathbf{X})$, where $L_k(\mathbf{X})$ is the sum of all the homogeneous components $L^{j, \text{hom}}(\mathbf{X})$ of degree j , for $j \geq k$. If $\lambda : L(\mathbf{X}) \rightarrow L(\mathbf{X})$ is a pseudoautomorphism, then λ gives rise to a linear map $\hat{\lambda}$ from $\hat{L}(\mathbf{X})$ to $\hat{L}(\mathbf{X})$, where $\hat{L}(\mathbf{X})$ is the Lie algebra of formal Lie series in X_0, \dots, X_m . (If $S \in \hat{L}(\mathbf{X})$, and $S = \sum_{j=1}^{\infty} S_j$, where S_j is homogeneous of degree j , then $\hat{\lambda}$ is defined by $\hat{\lambda}(S) = \sum_j \lambda(S_j)$. The sum is well defined because, for each k , the only terms that may contribute to the homogeneous component of degree k are the $\lambda(S_j)$ for $j \leq k$.) It is clear that $\hat{\lambda}\hat{\mu} = \hat{\lambda}\hat{\mu}$ if λ, μ are pseudoautomorphisms.

The class of controls is embedded as a subsemigroup $\hat{S}(\mathbf{X}, K)$ of the group $\hat{G}(\mathbf{X}) = \{\exp(Z) : Z \in \hat{L}(\mathbf{X})\}$. A pseudoautomorphism λ of $L(\mathbf{X})$ gives rise to a mapping

$\lambda^\#$ from $\hat{G}(\mathbf{X})$ to $\hat{G}(\mathbf{X})$ by letting

$$(2.7) \quad \lambda^\#(\exp(Z)) = \exp(\hat{\lambda}(Z)) \quad \text{for } Z \in \hat{L}(\mathbf{X}).$$

An *input symmetry* for Σ is a pseudoautomorphism λ of $L(\mathbf{X})$ such that the corresponding map $\lambda^\#$ maps $\hat{S}(\mathbf{X}, K)$ to $\hat{S}(\mathbf{X}, K)$. (Actually, the definition of input symmetry only depends on m and K , and not on the particular choice of M, f_0, \dots, f_m .)

The second important ingredient is a one parameter group of dilations $\{\Delta(\rho): 0 < \rho < \infty\}$ of the linear space $V = L^{1,\text{hom}}(\mathbf{X})$. Then Δ gives rise to groups of dilations Δ^Λ, Δ^L of the free associative algebra $A(\mathbf{X})$ in the indeterminates X_0, \dots, X_m , and of $L(\mathbf{X})$, respectively. Also, one obtains a one-parameter group $\hat{\Delta}^\Lambda$ of automorphisms of the algebra $\hat{A}(\mathbf{X})$ of formal power series in X_0, \dots, X_m . We call Δ *compatible* with $\hat{S}(\mathbf{X}, K)$ if the $\hat{\Delta}^\Lambda(\rho)$ map $\hat{S}(\mathbf{X}, K)$ into itself for $0 < \rho \leq 1$. (Equivalently, Δ is compatible with $\hat{S}(\mathbf{X}, K)$ if and only if, for every $u = (u_1, \dots, u_m) \in K$ and every ρ such that $0 < \rho \leq 1$, $\Delta(\rho)(X_0 + \sum_{i=1}^m u_i X_i)$ is of the form $T(X_0 + \sum_{i=1}^m v_i X_i)$ for some $T > 0$, $v = (v_1, \dots, v_m) \in K$.)

A group of dilations Δ as above can be used to define the Δ -degree of an element Z of $A(\mathbf{X})$. We call Z Δ -homogeneous of degree r if $\Delta^\Lambda(\rho)(Z) = \rho^r Z$ for every ρ . If Z is arbitrary, then Z is a finite sum of homogeneous elements, and the Δ -degree of Z (denoted by $\deg_\Delta(Z)$) is the largest of the degrees of the homogeneous components of Z .

If $\mathbf{f} = (f_0, \dots, f_m)$ is an $(m+1)$ -tuple of C^∞ vector fields on a C^∞ manifold M , then we can consider the map $\text{Ev}(\mathbf{f})$ which assigns to every element P of $L(\mathbf{X})$ the vector field obtained by plugging in each f_i for the corresponding indeterminate X_i . If $p \in M$, then we also define the map $\text{Ev}_p(\mathbf{f})$, from $L(\mathbf{X})$ to the tangent space $T_p M$, given by $\text{Ev}_p(\mathbf{f})(P) = \text{Ev}(\mathbf{f})(P)(p)$.

We now define what it means for a $Z \in L(\mathbf{X})$ to be Δ -neutralized for \mathbf{f} at p . If Z is Δ -homogeneous, we say that Z is Δ -neutralized for \mathbf{f} at p if $\text{Ev}_p(\mathbf{f})(Z)$ can be expressed as a sum of vectors $\text{Ev}_p(\mathbf{f})(Q_j)$, where the Q_j are elements of $L(\mathbf{X})$ such that $\deg_\Delta(Q_j) < \deg_\Delta(Z)$. (Clearly, the Q_j can always be chosen to be Δ -homogeneous.) If Z is not necessarily homogeneous, then we write Z as a sum of homogeneous components, and we say that Z is Δ -neutralized for \mathbf{f} at p if each homogeneous component is.

With these definitions, our main result is the following.

THEOREM 2.4. *Let $\Sigma = (M, \mathbf{f}, K)$ be a control system, and let $p \in M$. Assume that:*

- (i) Σ satisfies the Lie algebra rank condition at p ,
- (ii) there exist (a) a finite group Λ of input symmetries and (b) a one-parameter group of dilations $\Delta = \{\Delta(\rho): \rho > 0\}$ of $L^{1,\text{hom}}(\mathbf{X})$ which is compatible with $\hat{S}(\mathbf{X}, K)$, such that every Λ -fixed element of $L(\mathbf{X})$ is Δ -neutralized for \mathbf{f} at p .

Then Σ is small-time locally controllable at p .

3. Exponential Lie series and the nilpotent approximation. We review the basic facts about the formalism of noncommutative power series and nilpotent approximation (cf. [4], [6], [25]). The idea is to solve (2.1) formally, by using indeterminates X_0, \dots, X_m rather than the vector fields f_0, \dots, f_m , and then regard a given control system as an action of a "Lie group" $\hat{G}(\mathbf{X})$ of exponential Lie series, together with the specification of a subsemigroup $\hat{S}(\mathbf{X}, K)$ which is identified with the class of controls. We now make this precise.

Let $\mathbf{X} = (X_0, \dots, X_m)$ be a finite sequence of indeterminates. We let $A(\mathbf{X})$ denote the free associative algebra over \mathbb{R} generated by the X_j . For any multiindex $I = (i_1, \dots, i_k)$, with $i_j \in \{0, \dots, m\}$ for $j = 1, \dots, k$, we let $X_I = X_{i_1} \cdots X_{i_k}$. Then $A(\mathbf{X})$ is the set of all sums $\sum_I a_I X_I$, where the coefficients a_I are real numbers, the summation

runs over all possible multiindices I , and all but finitely many a_I vanish. (It is understood that $X_\phi = 1$.)

We also let $\hat{A}(\mathbf{X})$ denote the set of all *formal power series* in the noncommuting indeterminates X_j , i.e. the set of all sums $\sum_I a_I X_I$ as above, except that the a_I are no longer required to vanish for all but finitely many I . In both $A(\mathbf{X})$ and $\hat{A}(\mathbf{X})$, addition is done componentwise, and multiplication is carried out using the formula $X_I X_J = X_{I*J}$, where $I * J$ is the concatenation of I and J (i.e. the multiindex obtained by writing, in order, first the components of I and then those of J).

For any nonnegative integer N , we use $A^{N,\text{hom}}(\mathbf{X})$ to denote the homogeneous component of degree N of $A(\mathbf{X})$, and $A^N(\mathbf{X})$ to denote the sum of the $A^{j,\text{hom}}(\mathbf{X})$ for $j = 0, \dots, N$. The space $A^N(\mathbf{X})$ is embedded as a linear subspace of $A(\mathbf{X})$ but, naturally, it is not a subalgebra. On the other hand, $A^N(\mathbf{X})$ is an algebra if one defines multiplication as in $A(\mathbf{X})$, with the extra proviso that monomials of degree greater than N are set equal to zero. Thus regarded, $A^N(\mathbf{X})$ is the *free nilpotent associative algebra of step $N+1$ in the indeterminates X_0, \dots, X_m* . Then $A^N(\mathbf{X})$ can be identified with the quotient of $A(\mathbf{X})$ by the ideal of all linear combinations of monomials of degree strictly larger than N . The canonical projection from $A(\mathbf{X})$ onto $A^N(\mathbf{X})$ is the *truncation map* τ_X^N . We will write τ^N rather than τ_X^N whenever the context makes it clear which \mathbf{X} is being referred to. Clearly, one can also think of $A^N(\mathbf{X})$ as a quotient of $\hat{A}(\mathbf{X})$. The corresponding truncation map from $\hat{A}(\mathbf{X})$ onto $A^N(\mathbf{X})$ will be denoted by $\hat{\tau}_X^N$ or $\hat{\tau}^N$. The kernels of $\tau^N, \hat{\tau}^N$ are denoted by $A_N(\mathbf{X}), \hat{A}_N(\mathbf{X})$, respectively. In particular, $\hat{A}_0(\mathbf{X})$ is the set of formal power series $\sum_I a_I X_I$ for which $a_\phi = 0$. The *exponential map* is a well defined bijection

$$(3.1) \quad \exp: \hat{A}_0(\mathbf{X}) \rightarrow 1 + \hat{A}_0(\mathbf{X})$$

whose inverse is a map from $1 + \hat{A}_0(\mathbf{X})$ to $\hat{A}_0(\mathbf{X})$ denoted by “log.” If $S \in \hat{A}_0(\mathbf{X})$, then $\exp(S)$ and $\log(1 + S)$ are given by the usual power series.

One can also define $A_k^N(\mathbf{X})$ to be the set of all elements of $A^N(\mathbf{X})$ that are linear combinations of monomials of degree $> k$. Then

$$(3.2) \quad A_k^N(\mathbf{X}) = \tau^N(A_k(\mathbf{X})) = \hat{\tau}^N(\hat{A}_k(\mathbf{X})).$$

The exponential map

$$(3.3) \quad \exp_N: A_0^N(\mathbf{X}) \rightarrow 1 + A_0^N(\mathbf{X})$$

and its inverse \log_N are given, in this case, by power series that are actually finite sums, due to the nilpotency of $A^N(\mathbf{X})$.

The algebras $A(\mathbf{X}), \hat{A}(\mathbf{X}), A^N(\mathbf{X})$ are Lie algebras in the usual way. We let $L(\mathbf{X})$ denote the Lie subalgebra of $A(\mathbf{X})$ generated by X_0, \dots, X_m . An element S of $A(\mathbf{X})$ will be said to be a *Lie element* iff $S \in L(\mathbf{X})$. It is clear that S is a Lie element iff all the homogeneous components of S are Lie elements. Therefore, if we let

$$(3.4) \quad L^{N,\text{hom}}(\mathbf{X}) = L(\mathbf{X}) \cap A^{N,\text{hom}}(\mathbf{X}),$$

we see that $L(\mathbf{X})$ is the direct sum of the $L^{N,\text{hom}}(\mathbf{X})$, $N = 1, 2, 3, \dots$.

The Lie algebra $L(\mathbf{X})$ is spanned by the *formal brackets* of X_0, \dots, X_m . Precisely, we define $\text{Br}(\mathbf{X})$ to be the smallest subset of $L(\mathbf{X})$ that contains X_0, X_1, \dots, X_m and is closed under bracketing. The elements of $\text{Br}(\mathbf{X})$ will be referred to as *brackets* of \mathbf{X} . It is clear that every $B \in \text{Br}(\mathbf{X})$ is homogeneous. (Notice that we have chosen not to define a “bracket” as a formal expression but as an element of $L(\mathbf{X})$ so that, for example, $[[X_0, X_1], [X_0, X_2]]$ and $[[X_1, X_0], [X_2, X_0]]$ are the same element of $\text{Br}(\mathbf{X})$.) Naturally, the elements of $\text{Br}(\mathbf{X})$ are not linearly independent. Several systematic

procedures for singling out subsets of $\text{Br}(\mathbf{X})$ that form bases of $L(\mathbf{X})$ can be found in the literature, cf., for example, [20], [27], but we shall not need those results here.)

We can also define $\hat{L}(\mathbf{X})$ to be the set of all formal sums $\sum_{N=1}^{\infty} S_N$ such that each S_N is in $L^{N,\text{hom}}(\mathbf{X})$, i.e. the set of those elements of $\hat{A}(\mathbf{X})$ all of whose homogeneous components are Lie. The members of $\hat{L}(\mathbf{X})$ will be referred to as *Lie elements* of $\hat{A}(\mathbf{X})$, and they clearly form a Lie subalgebra of $\hat{A}(\mathbf{X})$. The Lie algebras $L(\mathbf{X})$, $\hat{L}(\mathbf{X})$ are known, respectively, as the *free Lie algebra in the indeterminates* X_0, \dots, X_m and the *algebra of Lie series in* X_0, \dots, X_m .

Since $\hat{L}(\mathbf{X}) \subseteq \hat{A}_0(\mathbf{X})$, the exponential map is well defined on $\hat{L}(\mathbf{X})$. The elements of $\hat{A}(\mathbf{X})$ that are of the form $\exp(S)$ for some $S \in \hat{L}(\mathbf{X})$ are the *exponential Lie series* in X_0, \dots, X_m . The set of all such series is denoted by $\hat{G}(\mathbf{X})$. It follows from the Campbell-Hausdorff formula that $\hat{G}(\mathbf{X})$ is a group under multiplication. The exponential map, restricted to $\hat{L}(\mathbf{X})$, is a bijection from $\hat{L}(\mathbf{X})$ onto $\hat{G}(\mathbf{X})$, which will also be denoted by “exp,” while we will use “log” to denote the inverse map.

The group $\hat{G}(\mathbf{X})$ is almost “a Lie group whose Lie algebra is $\hat{L}(\mathbf{X})$,” but it fails to be a true Lie group, since it is infinite-dimensional. However, its truncated versions

$$(3.5) \quad G^N(\mathbf{X}) = \hat{\tau}^N(\hat{G}(\mathbf{X}))$$

are true Lie groups. (As for $\hat{G}(\mathbf{X})$ itself, it is a projective limit of the $G^N(\mathbf{X})$, but we will not make use of this fact.) Each $G^N(\mathbf{X})$ is a connected, simply connected, nilpotent Lie group, with Lie algebra $L^N(\mathbf{X})$, where

$$(3.6) \quad L^N(\mathbf{X}) = \tau^N(L(\mathbf{X})) = \hat{\tau}^N(\hat{L}(\mathbf{X})).$$

The exponential map from $L^N(\mathbf{X})$ to $G^N(\mathbf{X})$ is none other than the restriction of \exp_N to $L^N(\mathbf{X})$ (which is a subset of $A_0^N(\mathbf{X})$). We will therefore also use \exp_N to denote this map. Then \exp_N is a bijection from $L^N(\mathbf{X})$ onto $G^N(\mathbf{X})$, whose inverse map will, as expected, be denoted by \log_N . Then $L^N(\mathbf{X})$ is the *free nilpotent Lie algebra of step $N+1$ in* X_0, \dots, X_m , and we shall refer to the group $G^N(\mathbf{X})$ as the *free nilpotent Lie group of step $N+1$ infinitesimally generated by* X_0, \dots, X_m .

Now suppose that we are given a C^∞ manifold M and an $(m+1)$ -tuple $\mathbf{f} = (f_0, \dots, f_m)$ of C^∞ vector fields on M . Each f_j is therefore a member of $D(M)$, the algebra of all partial differential operators $P: C^\infty(M) \rightarrow C^\infty(M)$. (Here $C^\infty(M)$ denotes the space of C^∞ real-valued functions on M .) There is therefore a well defined *evaluation map*

$$(3.7) \quad \text{Ev}(\mathbf{f}): A(\mathbf{X}) \rightarrow D(M)$$

obtained by “plugging in the f_j for the X_j ,” so that

$$(3.8) \quad \text{Ev}(\mathbf{f}) \left(\sum_I a_I X_I \right) = \sum_I a_I f_I,$$

where, if $I = (i_1, \dots, i_k)$, we write

$$(3.9) \quad f_I = f_{i_1} f_{i_2} \cdots f_{i_k}.$$

The image $\text{Ev}(\mathbf{f})(A(\mathbf{X}))$ will be denoted by $A(\mathbf{f})$. Then $A(\mathbf{f})$ is the subalgebra of $D(M)$ generated by f_0, \dots, f_m . The evaluation map $\text{Ev}(\mathbf{f})$ can be restricted to $L(\mathbf{X})$. The corresponding map, which we will also denote by $\text{Ev}(\mathbf{f})$, is a surjective homomorphism from $L(\mathbf{X})$ onto $L(\mathbf{f})$, where $L(\mathbf{f})$ is the Lie algebra of vector fields generated by f_0, \dots, f_m .

The kernel of $\text{Ev}(\mathbf{f}): A(\mathbf{X}) \rightarrow A(\mathbf{f})$ is the set of all *algebraic identities satisfied by* f_0, \dots, f_m , and we will denote it by $\text{AI}(\mathbf{f})$. Similarly, the kernel of $\text{Ev}(\mathbf{f}): L(\mathbf{X}) \rightarrow L(\mathbf{f})$ is the set of *Lie algebraic identities satisfied by* f_0, \dots, f_m , and we denote it by $\text{LI}(\mathbf{f})$.

If p is a point in M , then we use $D_p(M)$ to denote the set of all partial differential operators at p , i.e. the quotient of $D(M)$ modulo the set of $P \in D(M)$ such that $(P\phi)(p) = 0$ for every $\phi \in C^\infty(M)$. Also, we let $T_p(M)$ denote the tangent space of M at p . We then have the *evaluation at p map* $\text{Ev}_p(\mathbf{f}): A(\mathbf{X}) \rightarrow D_p(M)$ given by $\text{Ev}_p(\mathbf{f})(S) = (\text{Ev}(\mathbf{f})(S))(p)$. The kernel of this map is the set of *algebraic relations among the f_j at p* , and will be denoted by $\text{AR}(\mathbf{f}, p)$. Similarly, $\text{Ev}_p(\mathbf{f})$ maps $L(\mathbf{X})$ to $T_p(M)$. The kernel of this map, denoted by $\text{LR}(\mathbf{f}, p)$, is the set of *Lie algebraic relations* (or, simply, *Lie relations*) among the f_j at p . (For instance, $[X_0, X_1] + X_2$ is a Lie identity satisfied by f_0, f_1, f_2 iff the vector field $[f_0, f_1] + f_2$ vanishes identically. Similarly, $[X_0, X_1] + X_2$ is a Lie relation among the f_j at p iff $[f_0, f_1] + f_2$ vanishes at p .)

The image $\text{Ev}_p(\mathbf{f})(L(\mathbf{X}))$ is precisely the subspace $L(\mathbf{f})(p)$ of $T_p(M)$, where

$$(3.10) \quad L(\mathbf{f})(p) = \{V(p) : V \in L(\mathbf{f})\}.$$

The system \mathbf{f} satisfies the *Lie algebra rank condition* (LARC) at p if $L(\mathbf{f})(p) = T_p(M)$, i.e. if $\text{Ev}_p(\mathbf{f})$ maps $L(\mathbf{X})$ onto $T_p(M)$.

The evaluation maps $\text{Ev}(\mathbf{f}), \text{Ev}_p(\mathbf{f})$ can formally be applied to series S in $\hat{A}(\mathbf{X})$, giving rise to formal infinite sums of partial differential operators (which, if $S \in \hat{L}(\mathbf{X})$, are vector fields). However, if one wishes to make sense of $\text{Ev}(\mathbf{f})(S)$ as a mathematical object in a rigorous way, technical difficulties arise. (For instance, suppose that f_0, f_1 are C^∞ vector fields that satisfy $[f_0, f_1] = f_1$, and S is the Lie series $\sum_{k=0}^{\infty} (-1)^k (\text{ad } X_0)^k(X_1)$. Should the general definition of $\text{Ev}(\mathbf{f})(S)$ be such that, in this particular case, $\text{Ev}(\mathbf{f})(S)$ is the zero series?) Rather than attempt to overcome these difficulties, we shall avoid them, by agreeing to refer to the series $\text{Ev}(\mathbf{f})(S)$ (or $\text{Ev}_p(\mathbf{f})(S)$) *only* as part of purely heuristic discussions which are not expected to be rigorous anyhow, *or* as part of statements that are given a precise mathematical translation. (For instance, the phrase “ $\text{Ev}_p(\mathbf{f})(S)$, applied to a function ϕ , is asymptotic to . . .” will be translated into a collection of inequalities involving only the truncations $\text{Ev}_p(\mathbf{f})(\hat{\tau}^N(S))$, in which only finite sums occur.)

We can also define truncated evaluation maps $\text{Ev}^N(\mathbf{f}), \text{Ev}_p^N(\mathbf{f})$ by restricting $\text{Ev}(\mathbf{f})$ and $\text{Ev}_p(\mathbf{f})$ to $A^N(\mathbf{X})$ or to $L^N(\mathbf{X})$. However, the algebra structure of $A^N(\mathbf{X})$ and the Lie algebra structure of $L^N(\mathbf{X})$ do not turn $A^N(\mathbf{X}), L^N(\mathbf{X})$ into subalgebras of $A(\mathbf{X}), L(\mathbf{X})$. This implies that $\text{Ev}^N(\mathbf{f})$ need not be an algebra homomorphism from $A^N(\mathbf{X})$ to $A(\mathbf{f})$ or from $L^N(\mathbf{X})$ to $L(\mathbf{f})$. Also, the point evaluation maps $\text{Ev}_p^N(\mathbf{f})$ are defined in an obvious way as maps from $A^N(\mathbf{X})$ to $D_p(M)$ and from $L^N(\mathbf{X})$ to $T_p(M)$.

If $\mathcal{E}_p: D(M) \rightarrow D_p(M)$ is the map $Q \rightarrow Q(p)$, then $\text{Ev}_p^N(\mathbf{f}) = \mathcal{E}_p \circ \text{Ev}^N(\mathbf{f})$. We use $\text{AI}^N(\mathbf{f}), \text{LI}^N(\mathbf{f}), \text{AR}^N(\mathbf{f}, p), \text{LR}^N(\mathbf{f}, p)$ to denote, respectively, the kernels of the maps $\text{Ev}^N(\mathbf{f}): A^N(\mathbf{X}) \rightarrow D(M)$, $\text{Ev}^N(\mathbf{f}): L^N(\mathbf{X}) \rightarrow L(\mathbf{f})$, $\text{Ev}_p^N(\mathbf{f}): A^N(\mathbf{X}) \rightarrow D_p(M)$ and $\text{Ev}_p^N(\mathbf{f}): L^N(\mathbf{X}) \rightarrow T_p(M)$. Then $\text{AI}^N(\mathbf{f})$ is the set of *algebraic identities of degree $\leq N$ among the f_i* , and similar self-explanatory names will be used for the other sets $\text{LI}^N(\mathbf{f}), \text{AR}^N(\mathbf{f}, p), \text{LR}^N(\mathbf{f}, p)$. Since, as indicated earlier, Ev^N need not be a homomorphism, the sets $\text{AI}^N(\mathbf{f})$ may fail to be ideals of $A^N(\mathbf{X})$, and the $\text{LI}^N(\mathbf{f})$ need not be ideals of $L^N(\mathbf{X})$. Also, $\text{AR}^N(\mathbf{f}, p)$ can fail to be a subalgebra of $A^N(\mathbf{X})$, and $\text{LR}^N(\mathbf{f}, p)$ may fail to be a Lie subalgebra of $L^N(\mathbf{X})$. (For instance, let $\mathbf{f} = (f_0, f_1, f_2)$, and suppose that $[f_0, f_1](p) = f_1(p)$, and $f_2(p) = 0$. Then $[X_0, X_1] - X_1 \in \text{LR}^2(\mathbf{f}, p)$ and $X_2 \in \text{LR}^2(\mathbf{f}, p)$. If $\text{LR}^2(\mathbf{f}, p)$ were a Lie subalgebra of $L^2(X_0, X_1, X_2)$, it would follow that $[[X_0, X_1], X_2] - [X_1, X_2]$ is in $\text{LR}^2(\mathbf{f}, p)$, i.e. that $[X_1, X_2]$ is in $\text{LR}^2(\mathbf{f}, p)$, since $[[X_0, X_1], X_2] = 0$ in $L^2(X_0, X_1, X_2)$. So $[f_1, f_2](p) = 0$. However, it is easy to construct f_0, f_1, f_2 that satisfy the conditions stated above as well as $[f_1, f_2](p) \neq 0$.)

As in [25], \mathcal{U}_m will denote the set of all functions $u(\cdot)$ whose domain $\text{Dom}(u(\cdot))$ is a compact interval of the form $[0, T]$, such that $u(\cdot)$ takes values in \mathbb{R}^m and is

Lebesgue integrable on $[0, T]$. The time T is the *terminal time* of $u(\cdot)$ and is denoted by $T(u(\cdot))$. If $0 \leq t \leq T(u(\cdot))$, then the restriction of $u(\cdot)$ to $[0, t]$ is denoted by $u^t(\cdot)$. The components of $u(\cdot)$ are $u_1(\cdot), \dots, u_m(\cdot)$, and we write $u_0(t) \equiv 1$.

If we consider the differential equation

$$(3.11) \quad \dot{S} = S \left(X_0 + \sum_{i=1}^{\infty} u_i X_i \right)$$

for an $\hat{A}(\mathbf{X})$ -valued function $t \rightarrow S(t)$, $0 \leq t \leq T(u(\cdot))$, with the initial condition $S(0) = 1$, then the solution is

$$(3.12) \quad S(t) = \sum_I \left(\int_0^t u_I \right) X_I,$$

where $\int_0^t u_I$ is the iterated integral

$$(3.13) \quad \int_0^t u_I = \int_0^t \int_0^{\tau_k} \int_0^{\tau_{k-1}} \cdots \int_0^{\tau_2} u_{i_k}(\tau_k) u_{i_{k-1}}(\tau_{k-1}) \cdots u_{i_1}(\tau_1) d\tau_1 \cdots d\tau_k$$

if $\phi \neq I = (i_1, \dots, i_k)$. (We let $\int_0^t u_\phi = 1$.)

The series $S(T(u(\cdot)))$, with $t \rightarrow S(t)$ given as above, is the *formal power series associated with the control* $u(\cdot)$, and will be denoted by $\text{Ser}(u(\cdot))$. The mapping $\text{Ser}: \mathcal{U}_m \rightarrow \hat{A}(\mathbf{X})$ is injective and, if \mathcal{U}_m is regarded as a semigroup under the operation of concatenation, and $\hat{A}(\mathbf{X})$ is equipped with multiplication, then Ser is a semigroup homomorphism (cf. [25, Lemma 3.1]). Moreover, $\text{Ser}(u(\cdot))$ is always an exponential Lie series (cf. [25, Prop. 3.1]), so that Ser actually takes values in $\hat{G}(\mathbf{X})$. The subsemigroup $\text{Ser}(\mathcal{U}_m)$ of $\hat{G}(\mathbf{X})$ will be denoted by $\hat{S}(\mathbf{X})$. Since Ser is injective, one should think of $\hat{S}(\mathbf{X})$ as being just another way of realizing the control semigroup \mathcal{U}_m , which has the particular advantage of exhibiting \mathcal{U}_m as embedded in a group.

If K is an arbitrary subset of \mathbb{R}^m , then we can consider $\mathcal{U}_m(K)$, the subsemigroup of \mathcal{U}_m whose elements are the K -valued controls. The image of $\mathcal{U}_m(K)$ under Ser will be denoted by $\hat{S}(\mathbf{X}, K)$.

One can also consider the truncated versions of the map Ser and the semigroups $\hat{S}(\mathbf{X})$, $\hat{S}(\mathbf{X}, K)$. The truncation map $\hat{\tau}^N$ maps solutions of (3.11) to solutions of the same equation, regarded now as evolving in $A^N(\mathbf{X})$. Hence, if we let

$$(3.14) \quad \text{Ser}_N(u(\cdot)) = \hat{\tau}^N(\text{Ser}(u(\cdot)))$$

we find that

$$(3.15) \quad \text{Ser}_N(u(\cdot)) = \sum_{|I| \leq N} \left(\int_0^{T(u(\cdot))} u_I \right) X_I.$$

Moreover, $\text{Ser}_N(u(\cdot)) \in G^N(\mathbf{X})$. The sets $\text{Ser}_N(\mathcal{U}_m)$, $\text{Ser}_N(\mathcal{U}_m(K))$ will be denoted by $S^N(\mathbf{X})$, $S^N(\mathbf{X}, K)$, respectively. Clearly, these subsets are subsemigroups of $G^N(\mathbf{X})$. Moreover, $S^N(\mathbf{X})$ is the set of points that can be reached from the identity element of $G^N(\mathbf{X})$ by trajectories of the system

$$(3.16) \quad \dot{S} = \tilde{F}_0^N(S) + \sum_{i=1}^m u_i \tilde{F}_i^N(S),$$

where \tilde{F}_i^N is the restriction to $G^N(\mathbf{X})$ of the linear vector field F_i^N on $A^N(\mathbf{X})$, given by $F_i^N(S) = S X_i$. (It is clear that \tilde{F}_i^N is tangent to $G^N(\mathbf{X})$, and therefore \tilde{F}_i^N is well defined.) The Lie algebra of vector fields generated by F_0^N, \dots, F_m^N is isomorphic to $L^N(\mathbf{X})$ in an obvious way, and therefore acts transitively on $G^N(\mathbf{X})$. From this it

follows, using general results from accessibility theory, that $S^N(\mathbf{X})$ has a nonempty interior relative to $G^N(\mathbf{X})$ and, moreover, this interior is dense in $S^N(\mathbf{X})$. More generally, $S^N(\mathbf{X}, K)$ is the reachable set from the identity corresponding to the system (3.16) with the additional control constraint $(u_1, \dots, u_m) \in K$. The Lie algebra associated with this system is the Lie algebra $\Lambda^N(\mathbf{X}, K)$ generated by the vector fields $u \cdot F^N$, for $u \in K$, where we use the abbreviation $u \cdot F^N$ for $F_0^N + \sum_{i=1}^m u_i F_i^N$. (Recall that $u_0 = 1$.) Then $\Lambda^N(\mathbf{X}, K)$ acts transitively iff

$$(3.17) \quad \text{Aff}(K) = \mathbb{R}^m.$$

Since we are assuming that (3.17) holds, we can conclude that $\Lambda^N(\mathbf{X}, K)$ is indeed transitive. We then have:

LEMMA 3.1. *For every N ,*

$$\emptyset \neq \mathring{S}^N(\mathbf{X}, K) \subseteq S^N(\mathbf{X}, K) \subseteq \text{Clos } \mathring{S}^N(\mathbf{X}, K).$$

(Here “ $\mathring{}$,” and “Clos” mean interior and closure relative to $G^N(\mathbf{X})$.)

The semigroup $S^N(\mathbf{X}, K)$ is the image of $\mathcal{U}_m(K)$ under the map Ser_N . We need nice inverses of this map, i.e. ways of selecting, for $S \in S^N(\mathbf{X}, K)$, a control $u_S(\cdot) \in \mathcal{U}_m(\mathbf{X}, K)$ which “depends smoothly on S ” and is such that $\text{Ser}_N(u_S(\cdot)) = S$. The construction of such inverses was already done in [25]. However, we shall need a slightly stronger result, which we now state.

As in [25], we let Γ be any finite sequence $(\gamma^1, \dots, \gamma^r)$ of points of \mathbb{R}^m , such that $\text{Aff}(\gamma^1, \dots, \gamma^r) = \mathbb{R}^m$. We let \mathbb{R}_+^k denote the set of k -tuples of nonnegative numbers. If $\mathbf{t} = (t_1, \dots, t_k)$ is in \mathbb{R}_+^k , then we define $\{\Gamma, \mathbf{t}\}$ to be the piecewise constant control which is equal to γ^1 during the first t_1 units of time, then to γ^2 during time t_2 , and so on. (This control is well defined even if $k > r$, because we extend the definition of γ^j to all positive integers j , by making $j \rightarrow \gamma^j$ periodic with period r , i.e., we let $\gamma^{r+1} = \gamma^1$, $\gamma^{r+2} = \gamma^2$, and so on.) Any control of the form $\{\Gamma, \mathbf{t}\}$ for some k and some $\mathbf{t} \in \mathbb{R}_+^k$ will be called a Γ -control. If $K \subseteq \mathbb{R}^m$ and Γ consists of elements of K , then Γ will be said to be a K -sequence.

The map $\nu_{k,\Gamma}^N$, defined by $\nu_{k,\Gamma}^N(\mathbf{t}) = \text{Ser}_N(\{\Gamma, \mathbf{t}\})$, takes \mathbb{R}_+^k to $S^N(\mathbf{X})$. Moreover, if Γ is a K -sequence, then $\nu_{k,\Gamma}^N$ maps \mathbb{R}_+^k to $S^N(\mathbf{X}, K)$. If $\mathbf{t}^0 \in \mathbb{R}_+^k$ is such that the differential $d\nu_{k,\Gamma}^N(\mathbf{t}_0)$ has rank equal to the dimension of $G^N(\mathbf{X})$, then the Γ -control $\{\Gamma, \mathbf{t}_0\}$ is said to be N -normal. Clearly, if Γ is a K -sequence and $\{\Gamma, \mathbf{t}_0\}$ is N -normal, then $\nu_{k,\Gamma}^N(\mathbf{t}_0) \in \mathring{S}^N(\mathbf{X}, K)$. Conversely, suppose that $S \in \mathring{S}^N(\mathbf{X}, K)$. We claim that $S = \nu_{k,\Gamma}^N(\mathbf{t}_0)$ for some K -sequence Γ and some N -normal Γ -control $\{\Gamma, \mathbf{t}_0\}$. To see this, observe first that the system (3.16), with the restriction $u \in K$, necessarily has the accessibility property from S , and the same is therefore true for the “backward system” whose trajectories are those of (3.16) run in reverse. It then follows from standard accessibility theory that, if U is any open subset of $G^N(\mathbf{X})$ containing S , then U contains a nonempty open set V such that, for the reverse system, every $S' \in V$ can be reached from S by means of a piecewise constant control. If we apply this with $U = \mathring{S}^N(\mathbf{X}, K)$, we get an open subset V of $\mathring{S}^N(\mathbf{X}, K)$ such that every $S' \in V$ can be steered to S by means of a trajectory of (3.16) that corresponds to a piecewise constant K -valued control. On the other hand, if $S' \in V$ then S' can be reached from the identity element \mathbb{I} of $G^N(\mathbf{X})$ by means of some K -valued control. This control can be approximated by piecewise constant ones. Since V is open, we conclude that some $S' \in V$ is reachable from \mathbb{I} by means of some piecewise constant control. This control is then necessarily of the form $\{\Gamma, \mathbf{t}^0\}$ for some sequence $\Gamma = (\gamma^1, \dots, \gamma^k)$ and some $\mathbf{t}^0 = (t_1^0, \dots, t_k^0) \in \mathbb{R}_+^k$ such that $t_j^0 > 0$ for all j . Since $\text{Aff}(K) = \mathbb{R}^m$, the sequence Γ can be assumed to be such that

$\text{Aff}(\gamma^1, \dots, \gamma^k) = \mathbb{R}^m$. (This may require that some new γ 's be added at the end of Γ , and then the control $\{\Gamma, t^0\}$ has to be continued by assigning positive times t_j to the new γ^j 's. However, the t^j can be taken to be arbitrarily small, and then the new S' will still be in V , since V is open.) We then get a Γ -control $\{\Gamma, t^0\}$ that steers $\mathbb{1}$ to an $S' \in V$, and is such that Γ is a K -sequence and the affine hull of the elements of Γ is \mathbb{R}^m . The proof of [25, Prop. 3.3] then implies that V contains a point S'' which is of the form $\nu_{l\Gamma(t)}^N$ for some l and some N -normal Γ -control $\{\Gamma, t\}$. (The proof of [25, Prop. 3.3] shows that, if $\Gamma = (\gamma^1, \dots, \gamma^r)$ is such that $\text{Aff}(\gamma^1, \dots, \gamma^r) = \mathbb{R}^m$, then an N -normal Γ -control exists. This was shown by choosing an l and a t such that $d\nu_{l\Gamma(t)}^N$ had the largest possible rank $\bar{\rho}$, and then constructing a submanifold M of $G^N(X)$ such that $\dim M = \bar{\rho}$, with the property that all the vector fields in the Lie algebra generated by the \tilde{F}_j^N are tangent to M , from which it follows that $\bar{\rho} = \dim G^N(X)$. The same proof applies if we now choose l, t to be such that $d\nu_{l\Gamma(t)}^N$ has the largest possible rank $\bar{\rho}$ among all l, t such that $\nu_{l\Gamma(t)}^N \in V$. Such an l, t exists because there is some l, t such that $\nu_{l\Gamma(t)}^N \in V$, namely, $l = k$ and $t = t^0$. The conclusion that $\bar{\rho} = \dim G^N(X)$ follows exactly as in [25].) If we now concatenate this N -normal control $\{\Gamma, t\}$ with a piecewise constant control that steers S'' to S , it follows easily that the resulting control is a $\tilde{\Gamma}$ -control for some $\tilde{\Gamma}$, and is N -normal. So, we have shown:

LEMMA 3.2. *Let $K \subseteq \mathbb{R}^m$, and let $S \in G^N(X)$. Then $S \in \hat{S}^N(X, K)$ if and only if there exist*

- (a) *a K -sequence $\Gamma = (\gamma^1, \dots, \gamma^r)$ such that $\text{Aff}(\gamma^1, \dots, \gamma^r) = \mathbb{R}^m$,*
- (b) *a k and a $t \in \mathbb{R}_+^k$ such that $\{\Gamma, t\}$ is N -normal and $\nu_{k\Gamma(t)}^N = S$.*

The existence of “nice local inverses” to the map Ser_N follows easily.

COROLLARY 3.3. *Let $K \subseteq \mathbb{R}^m$, and let $S \in \hat{S}^N(X, K)$. Then there exist:*

- (a) *a K -sequence $\Gamma = (\gamma^1, \dots, \gamma^r)$ such that $\text{Aff}(\gamma^1, \dots, \gamma^r) = \mathbb{R}^m$,*
- (b) *a positive integer k ,*
- (c) *an open subset W of $G^N(X)$ such that $S \in W$,*
- (d) *a real analytic map $\psi: W \rightarrow \mathbb{R}_+^k$, such that*

$$(3.18) \quad \text{Ser}_N(\{\Gamma, \psi(S')\}) = S' \quad \text{for all } S' \in W.$$

The proof is just a straightforward application of the Implicit Function theorem.

The group $\hat{G}(X)$ is the “Lie group” described at the beginning of this section. Formally, an element S of $\hat{G}(X)$ is an exponential of a Lie series in the indeterminates X_0, \dots, X_m , and therefore $\text{Ev}(\mathbf{f})(S)$ is the exponential of a vector field on M , i.e. a map from M to M . If $S \in \hat{S}(X, K)$, then S can be thought of as a control, and $\text{Ev}_p(\mathbf{f})(S)$ is the point of M to which p is steered by this control. Then $\hat{L}(X)$ is the “Lie algebra” of the Lie group $\hat{G}(X)$. Those elements $Z \in \hat{L}(X)$ such that $\text{Ev}_p(\mathbf{f})(Z) = 0$ constitute the “isotropy subalgebra,” and their exponentials are the “isotropy subgroup.” The reachable set from p is $\text{Ev}_p(\mathbf{f})(\hat{S}(X, K))$. The Lie algebra rank condition says that $\hat{G}(X)$ “acts transitively on M near p .” Hence p will be an interior point of the reachable set if the interior of $\hat{S}(X, K)$ intersects the isotropy subgroup.

The preceding formal considerations are not rigorous, because $\hat{G}(X)$ is not a true Lie group and, as explained above, $\text{Ev}(\mathbf{f})$ is not well defined on $\hat{G}(X)$. In order to obtain a rigorous local controllability theorem one has to consider the nilpotent approximations $G^N(X)$ to $\hat{G}(X)$. The $G^N(X)$ are true Lie groups, with Lie algebra $L^N(X)$, and the subsemigroups $S^N(X, K)$ represent the nilpotent approximations to $\hat{S}(X, K)$. Pursuing the analogy with our earlier discussion, we may think of $\text{LR}^N(\mathbf{f}, p)$ as the “isotropy subalgebra” corresponding to the “action” of $G^N(X)$, and of $H^N(\mathbf{f}, p) = \exp_N(\text{LR}^N(\mathbf{f}, p))$ as the “isotropy group.” If N is large enough (so that $\text{Ev}_p^N(\mathbf{f})(L^N(X))$ is the whole tangent space $T_p M$), then the “action” of $G^N(X)$ on M

is transitive. So we might expect to be able to prove that, if the interior of $S^N(\mathbf{X}, K)$ intersects H^N , then p is in the interior of the reachable set from p . Also, it should follow that, if $\dot{S}^N(\mathbf{X}, K) \cap H^N$ contains points reachable from the identity in arbitrarily small time, then (M, \mathbf{f}, K) is STLC from p . However, this reasoning is not valid, since $\text{Ev}^N(\mathbf{f})$ need not be a true Lie algebra homomorphism, $\text{LR}^N(\mathbf{f}, p)$ need not be a Lie subalgebra of $L^N(\mathbf{X})$, and $G^N(\mathbf{X})$ does not really act on M . If $S \in \dot{S}^N(\mathbf{X}, K) \cap H^N(\mathbf{f}, p)$ and we write $S = \exp_N(Z)$, then $\text{Ev}_p^N(\mathbf{f})(Z) = 0$, and so $\text{Ev}_p(\mathbf{f})(Z) = 0$. Therefore $\exp(Z)$ is equal to the identity map plus a series of differential operators that vanish at p . However, there is no reason for $\exp(Z)$ to be the series of a control $u(\cdot)$. What can be said is that $\exp_N(Z) = \text{Ser}_N(u(\cdot))$ for some $u(\cdot)$. But then $\text{Ser}(u(\cdot))$ will not necessarily be equal to $\exp(Z)$, although it will be equal to $\exp(Z)$ up to terms of degree N . So $u(\cdot)$ will not necessarily steer p to p . However, it will steer p to a point q which is close to p . If U is a neighborhood of Z in $L^N(\mathbf{X})$, and $\exp(U)$ is small enough so that $\exp(U) \subseteq S^N(\mathbf{X}, K)$, then one can choose a $u'(\cdot)$ such that $\text{Ser}_N(u'(\cdot)) = \exp_N(Z')$ for each $Z' \in U$. Then the controls $u'(\cdot)$ will steer p to a neighborhood V of q . If U is large enough, then we may expect V to be such that $p \in V$. To make all this rigorous, we have to be able to choose $u'(\cdot)$ in a continuous fashion as a function of Z' . This requires that we confine ourselves to neighborhoods U such that, if $W = \exp(U)$, then there is a map ψ that satisfies the conditions of Corollary 3.3. So we define a *normal neighborhood* of a point $S \in \dot{S}^N(\mathbf{X}, K)$ to be an open subset W of $G^N(\mathbf{X})$ such that there exist Γ, k, ψ for which the conditions of Corollary 3.3 hold. Then Corollary 3.3 simply says that every point of $\dot{S}^N(\mathbf{X}, K)$ has a normal neighborhood. The sufficient condition for STLC from p will then say that, if $\dot{S}^N(\mathbf{X}, K) \cap H^N(\mathbf{f}, p)$ contains points S_i reachable from the identity in arbitrarily small time t_i , then (M, \mathbf{f}, K) is STLC from p , provided that N is sufficiently large, and that these points have normal neighborhoods whose size does not decrease too fast as $t \rightarrow 0$. It will be clear from the proof that it is not necessary to have a lower bound for the size of the neighborhood in all directions, but only in directions transversal to $H^N(\mathbf{f}, p)$. To make this precise, let $\mathcal{E} = (E_1, \dots, E_k)$ be a finite sequence of elements of $L^N(\mathbf{X})$, and let $Z \in L^N(\mathbf{X})$. We define, for $r > 0$

$$(3.19) \quad B_{\mathcal{E}}(Z, r) = \left\{ Z + \sum_{i=1}^k x_i E_i : \sum_{i=1}^k x_i^2 \leq r^2 \right\}.$$

($B_{\mathcal{E}}(Z, r)$ is the \mathcal{E} -ball of radius r and center Z . We will only use this definition for sequences \mathcal{E} such that E_1, \dots, E_k are linearly independent.)

Also, we define a function $T^N : A^N(\mathbf{X}) \rightarrow \mathbb{R}$ by letting $T^N(S)$ be the coefficient of X_0 in S . (In particular, if $S = \text{Ser}_N(u(\cdot))$ for some control $u(\cdot)$, then $T^N(S)$ is the terminal time of $u(\cdot)$.) We then have:

THEOREM 3.4. *Let (M, \mathbf{f}, K) be a control system, and let $p \in M$. Assume that K is a bounded set. Let N be a positive integer, and let $\mathcal{E} = (E_1, \dots, E_n)$ be a sequence of elements of $L^N(\mathbf{X})$ such that $(\text{Ev}_p(\mathbf{f})(E_1), \dots, \text{Ev}_p(\mathbf{f})(E_n))$ is a basis of the tangent space $T_p M$. Assume that there is a sequence of points $S_j, j = 1, 2, \dots$, such that:*

- (i) $S_j \in \dot{S}^N(\mathbf{X}, K) \cap H^N(\mathbf{f}, p)$ for all j ,
- (ii) $T^N(S_j) \rightarrow 0$ as $j \rightarrow \infty$,
- (iii) *If $S_j = \exp_N(Z_j)$, then there are normal neighborhoods W_j of S_j , and a constant $\alpha > 0$, such that*

$$(3.20) \quad \log_N W_j \supseteq B_{\mathcal{E}}(Z_j, \alpha [T^N(S_j)]^N)$$

for all j . Then (M, \mathbf{f}, K) is STLC from p .

Proof. Let $\rho_j = T^N(S_j)$. For each j , choose a K -sequence Γ_j , a positive integer k_j , and a real-analytic map $\psi_j: W_j \rightarrow \mathbb{R}_+^{k_j}$ such that

$$(3.21) \quad \text{Ser}_N(\{\Gamma_j, \psi_j(S)\}) = S$$

whenever $S \in W_j$.

Choose coordinates on a neighborhood \mathcal{N} of p such that p becomes $(0, \dots, 0)$ and the vectors $\text{Ev}_p(\mathbf{f})(E_i)$ are the members e_i of the canonical basis of \mathbb{R}^n . For each control $u(\cdot)$, let $\pi_p(u(\cdot))$ be the point to which $u(\cdot)$ steers p (i.e. $\pi_p(u(\cdot)) = x(T)$, if $u(\cdot)$ is defined on $[0, T]$, and $x(\cdot)$ is the trajectory for $u(\cdot)$ such that $x(0) = p$). Proposition 4.1 of [25] implies that the series $\text{Ev}_p(\mathbf{f})(\text{Ser } u(\cdot))$ gives an asymptotic expansion for $\pi_p(u(\cdot))$ in the following sense: if ϕ is an arbitrary C^∞ function on \mathcal{N} , then there are constants β_ν and times τ_ν such that

$$(3.22) \quad \|\phi(\pi_p(u(\cdot)) - \text{Ev}_p(\mathbf{f})(\text{Ser}_\nu(u(\cdot))))\| < \beta_\nu T(u(\cdot))^{\nu+1}$$

for all ν and all controls $u(\cdot)$ such that $T(u(\cdot)) \leq \tau_\nu$. (Here $\text{Ev}_p(\mathbf{f})(\text{Ser}_\nu(u(\cdot)))$ is a finite sum of partial differential operators evaluated at p , and so $\text{Ev}_p(\mathbf{f})(\text{Ser}_\nu(u(\cdot)))\phi$ is a finite sum of numbers, namely, the results of applying those partial differential operators to ϕ . The result from [25] gives constants β_ν that also depend on a bound A for the controls, but here we are assuming that K is bounded, so that β_ν only depends on ν .)

Inequality (3.22) clearly holds for vector functions as well, so we can apply it to the identity map $\phi: \mathcal{N} \rightarrow \mathcal{N}$. From now on, ϕ denotes this map. Therefore $\phi(\pi_p(u(\cdot))) = \pi_p(u(\cdot))$, and so (3.22) becomes

$$(3.23) \quad \|\pi_p(u(\cdot)) - \text{Ev}_p(\mathbf{f})(\text{Ser}_\nu(u(\cdot)))\| \leq \beta_\nu T(u(\cdot))^{\nu+1}.$$

Now define maps μ_j from the closed unit ball \mathbb{B} of \mathbb{R}^n into M , by

$$(3.24) \quad \mu_j(x_1, \dots, x_n) = \pi_p\left(\left\{\Gamma_j, \psi_j\left(\exp_N\left(Z_j + \alpha\rho_j^N \sum_{i=1}^n x_i E_i\right)\right)\right\}\right).$$

The definition is possible because $Z_j + \alpha\rho_j^N \sum_{i=1}^n x_i E_i$ is in $B_g(Z_j, \alpha\rho_j^N)$, and so its exponential in $A^n(X)$ is in W_j . By construction, $\mu_j(x_1, \dots, x_n)$ is reachable from p , by means of the control

$$(3.25) \quad u_{j,x_1,\dots,x_n}(\cdot) = \left\{\Gamma_j, \psi_j\left(\exp_N\left(Z_j + \alpha\rho_j^N \sum_{i=1}^n x_i E_i\right)\right)\right\}.$$

The truncated series $\text{Ser}_N(u_{j,x_1,\dots,x_n}(\cdot))$ is then

$$\exp_N\left(Z_j + \alpha\rho_j^N \sum_{i=1}^n x_i E_i\right),$$

and so the terminal time $T(u_{j,x_1,\dots,x_n}(\cdot))$ is equal to $T^N(\text{Ser}_N(u_{j,x_1,\dots,x_n}(\cdot)))$, i.e. to

$$\rho_j + \alpha\rho_j^N \sum_{i=1}^n x_i \theta_i,$$

where θ_i is the coefficient of X_0 in E_i . In particular, all the points $\mu_j(x_1, \dots, x_n)$, for $(x_1, \dots, x_n) \in \mathbb{B}$, and fixed j , are reachable from p in time not greater than $\hat{\alpha}\rho_j$, where $\hat{\alpha}$ is some fixed constant which does not depend on j . Since $\rho_j \rightarrow 0$ as $j \rightarrow \infty$, our theorem will be proved if we show that $\mu_j(\mathbb{B})$ contains a neighborhood of p for sufficiently large j .

In view of (3.23), we have

$$(3.26) \quad \left\| \mu_j(x_1, \dots, x_n) - \text{Ev}_p(\mathbf{f}) \left(\exp_N \left(Z_j + \alpha \rho_j^N \sum_{i=1}^n x_i E_i \right) \right) \phi \right\| \leq \beta_N \hat{\alpha}^{N+1} \rho_j^{N+1},$$

provided that j is large enough, so that $\hat{\alpha} \rho_j \leq \tau_N$.

For $Q \in L^N(\mathbf{X})$, define

$$(3.27) \quad \widehat{\text{exp}}_N(Q) = \sum_{k=0}^N \frac{1}{k!} Q^k.$$

(Here we identify $L^N(\mathbf{X})$ with the subspace $\sum_{k=1}^N L^{k, \text{hom}}(\mathbf{X})$, but the powers Q^k are computed in $L(\mathbf{X})$, so that $\widehat{\text{exp}}_N(Q)$ is allowed to contain terms of degree greater than N .) We claim that all the coefficients of the finite series

$$\widehat{\text{exp}}_N \left(Z_j + \alpha \pi_j^N \sum_{i=1}^n x_i E_i \right) - \exp_N \left(Z_j + \alpha \rho_j^N \sum_{i=1}^n x_i E_i \right)$$

are bounded by a fixed constant times ρ_j^{N+1} . To see this, observe first that, if we write

$$(3.28) \quad Z_j = \sum_I z_I^j X_I,$$

then $z_I^j = 0$ for $|I| > N$, and there is a constant c such that $|z_I^j| \leq C \rho_j^{|I|}$ for all j, I . (Here $|I|$ is the length of the multiindex I , i.e. the degree of the monomial X_I . The first assertion follows because $Z_j \in L^N(\mathbf{X})$. The second one holds because $\exp_N(Z_j) = \text{Ser}_N(u_j(\cdot))$ for some K -valued control $u_j(\cdot)$ with terminal time ρ_j . Since the coefficients σ_I of $\text{Ser}(u_j(\cdot))$ are iterated integrals, as shown in (3.12) and (3.13), they satisfy bounds $|\sigma_I^j| \leq \text{constant} \times \rho_j^{|I|}$. Similar bounds then hold for the coefficients of the series $\log(\text{Ser}(u_j(\cdot)))$, and for those of its truncation $Z_j = \hat{\tau}^N(\log(\text{Ser}(u_j(\cdot))))$. The coefficients of $\alpha \rho_j^N \sum_{i=1}^n x_i E_i$ also satisfy a similar bound, since they all contain a factor ρ_j^N , and those of degree $> N$ vanish. So the coefficients of

$$\exp_N \left(Z_j + \alpha \rho_j^N \sum_{i=1}^n x_i E_i \right) \quad \text{and} \quad \widehat{\text{exp}}_N \left(Z_j + \alpha \rho_j^N \sum_{i=1}^n x_i E_i \right)$$

also satisfy these bounds, and then the same is true for those of the difference of these two series. However, the coefficients of this difference vanish whenever $|I| \leq N$. Hence they are bounded by a constant times ρ_j^{N+1} .

It then follows that (3.26) remains valid (possibly with a different constant in the right side) if “ \exp_N ” is replaced by “ $\widehat{\text{exp}}_N$.” Now $\widehat{\text{exp}}_N(Z_j + \alpha \rho_j^N \sum_{i=1}^n x_i E_i)$ can be written out by applying (3.27) and then expanding the powers of $Z_j + \alpha \rho_j^N \sum_{i=1}^n x_i E_i$. This leads to a finite sum of terms of the following five kinds: (i) the term $\alpha \rho_j^N \sum_{i=1}^n x_i E_i$, (ii) powers of Z_j , (iii) products of at least one Z_j factor and at least one $\alpha \rho_j^N \sum_{i=1}^n x_i E_i$, (iv) powers of $\alpha \rho_j^N \sum_{i=1}^n x_i E_i$ other than the first power, (v) the identity.

When evaluated at p , all the terms $\text{Ev}(\mathbf{f})(Z_j^k)$ vanish, because $Z_j \in \text{LR}^N(\mathbf{f}, p)$. The terms of type (iii) are $O(\rho_j^{N+1})$, because Z_j is $O(\rho_j)$. The terms of type (iv) are also $O(\rho_j^{N+1})$. Hence, modulo $O(\rho_j^{N+1})$, only the terms of types (i) and (v) count. So we get the bound

$$(3.29) \quad \left\| \mu_j(x_1, \dots, x_n) - \text{Ev}_p(\mathbf{f}) \left(\mathbb{1} + \alpha \rho_j^N \sum_{i=1}^n x_i E_i \right) \phi \right\| \leq \gamma \rho_j^{N+1}$$

for some constant γ . Then (3.29) implies (using the facts that $\text{Ev}_p(\mathbf{f})(1)\phi = \phi(p) = p = 0$, and $\text{Ev}_p(\mathbf{f})(E_i)\phi = e_i\phi = e_i$)

$$(3.30) \quad \left\| \mu_j(x_1, \dots, x_n) - \alpha \rho_j^N \sum_{i=1}^n x_i e_i \right\| \leq \gamma \rho_j^{N+1}.$$

Let

$$(3.31) \quad \nu_j(x_1, \dots, x_n) = \frac{1}{\alpha \rho_j^N} \mu_j(x_1, \dots, x_n).$$

Then $\mu_j(\mathbb{B})$ contains a neighborhood of 0 if $\nu_j(\mathbb{B})$ does. It follows from (3.30) that

$$(3.32) \quad \|\nu_j(x_1, \dots, x_n) - (x_1, \dots, x_n)\| \leq \text{constant} \times \rho_j.$$

Therefore the ν_j are continuous maps from \mathbb{B} to \mathbb{R}^n that converge uniformly to the identity map of \mathbb{B} as $j \rightarrow \infty$. This implies that $\nu_j(\mathbb{B})$ contains a neighborhood of 0 for large enough j . The proof is then complete.

Theorem 3.4 gives a sufficient condition for local controllability, but not one that is easy to check in practice. The next two sections will be devoted to providing more easily checkable conditions. Here we will just give a simple example that follows directly from Theorem 3.4.

THEOREM 3.5. *Let (M, \mathbf{f}, K) be a control system, and let $p \in M$. Let N be a positive integer such that $\text{Ev}_p(\mathbf{f})(L^N(\mathbf{X})) = T_p M$. Assume that $\hat{S}^N(\mathbf{X}, K)$ contains an element $S = \exp_N(Z)$ such that all the homogeneous components of Z are in $\text{LR}(\mathbf{f}, p)$. Then (M, \mathbf{f}, K) is STLC from p .*

Proof. For each $p > 0$, let $\Delta(\rho)$ be the automorphism of $A(\mathbf{X})$ which sends X_i to ρX_i for $i = 0, \dots, M$. Then $\Delta(\rho)$ gives rise to an automorphism $\hat{\Delta}(\rho)$ of $\hat{A}(\mathbf{X})$, defined by sending a series $S = \sum_{j=0}^{\infty} S_j$, with $S_j \in A^{j, \text{hom}}(\mathbf{X})$ to the series

$$(3.33) \quad \hat{\Delta}(\rho)(S) = \sum_{j=0}^{\infty} \rho^j S_j.$$

Clearly, $\hat{\Delta}(\rho)$ induces an automorphism of $L(\mathbf{X})$, $\hat{L}(\mathbf{X})$, and $\hat{G}(\mathbf{X})$. Moreover, since $\hat{\Delta}(\rho)$ maps $\hat{A}_N(\mathbf{X})$ to $\hat{A}_N(\mathbf{X})$, it induces an automorphism $\Delta^N(\rho)$ of $A^N(\mathbf{X})$ and, in particular, an automorphism of $G^N(\mathbf{X})$ and one of $L^N(\mathbf{X})$.

Moreover, if $0 < \rho \leq 1$, then $\hat{\Delta}(\rho)$ maps $S(\mathbf{X}, K)$ into $S(\mathbf{X}, K)$, and $\Delta^N(\rho)$ maps $S^N(\mathbf{X}, K)$ into $S^N(\mathbf{X}, K)$. (Indeed, if $t \rightarrow S(t)$, $0 \leq t \leq T$, is a solution of (3.11) corresponding to a K -valued control $t \rightarrow u(t) = (u_1(t), \dots, u_m(t))$, then $\tau \rightarrow \hat{\Delta}(\rho)(S(\tau/\rho))$ is a solution of (3.11) on the interval $[0, \rho T]$, corresponding to the control $\tau \rightarrow u(\tau/\rho)$.)

Now suppose that S is an element of $\hat{S}^N(\mathbf{X}, K)$ such that $S = \exp_N(Z)$, where

$$(3.34) \quad Z = \sum_{j=1}^N Z^j, \quad Z^j \in L^{j, \text{hom}}(\mathbf{X}),$$

and $Z \in \text{LR}(\mathbf{f}, p)$. Pick $\mathcal{E} = (E_1, \dots, E_n)$ such that

- (a) the E_i are members of $L^N(\mathbf{X})$,
- (b) each E_i is homogeneous of degree θ_i (with $\theta_i \leq N$),
- (c) $\text{Ev}_p(\mathbf{f})(E_1), \dots, \text{Ev}_p(\mathbf{f})(E_n)$ form a basis of $T_p M$.

Since $S \in \hat{S}^N(\mathbf{X}, K)$, there exists a normal neighborhood W of S . If we let $S_\rho = \Delta^N(\rho)(S)$, $W_\rho = \Delta^N(\rho)(W)$, then W_ρ is a normal neighborhood of S_ρ . Let $\tilde{\alpha} > 0$ be such that $\exp_N(Z + \sum_{i=1}^n y_i E_i) \in W_\rho$ whenever $|y_i| \leq \tilde{\alpha}$. Let $Z_\rho = \Delta(\rho)Z$. Then $\exp_N(Z_\rho + \sum_{i=1}^n \rho^{\theta_i} y_i E_i) \in W_\rho$ whenever $|y_i| \leq \tilde{\alpha}$. Since $\theta_i \leq N$, it follows that

$$(3.35) \quad B_{\mathcal{E}}(Z_\rho, \tilde{\alpha} \rho^N) \subseteq \log_N(W_\rho)$$

whenever $0 < \rho \leq 1$.

Since $Z^j \in L^{j,\text{hom}}(\mathbf{X}) \cap \text{LR}(\mathbf{f}, p)$, it follows that $Z_\rho \in \text{LR}(\mathbf{f}, p)$ for all ρ . Finally, it is clear that $T^N(S_\rho) = \rho c$, where $c = T^N(S)$. Therefore

$$(3.36) \quad B_{\mathcal{G}}(Z_\rho, \alpha[T^N(S)]^N) \subseteq \log_N(W_\rho)$$

for $0 \leq \rho \leq 1$, if $\alpha = \tilde{\alpha}c^{-N}$. So the conditions of Theorems 3.4 hold, and our desired conclusion follows.

The preceding result is too weak for applications. In the following section we will strengthen it in two ways. First, the requirement that each homogeneous component Z^j of Z be a Lie relation at p will be replaced by the weaker condition that Z^j be equal to a Lie relation plus an element of lower degree. Second, the “degree” will be allowed to be a more general one, arising from a one-parameter group of dilations which is not necessarily the family $\{\Delta(\rho): \rho > 0\}$ considered in the proof of Theorem 3.5.

4. Dilations. We now define the concept of a “group of dilations,” and prove a generalization of Theorem 3.5.

If V is a linear space over the reals, a *group of dilations* of V is a mapping $\rho \rightarrow \Delta(\rho)$ that assigns to every real $\rho > 0$ a linear endomorphism $\Delta(\rho): V \rightarrow V$, in such a way that

(DIL1) $\Delta(1) = \text{identity}$,

(DIL2) $\Delta(\rho_1)\Delta(\rho_2) = \Delta(\rho_1\rho_2)$ for all ρ_1, ρ_2 ,

(DIL3) V has a direct sum decomposition

$$(4.1) \quad V = \bigoplus_j V_j$$

such that the subspaces V_j are invariant under the $\Delta(\rho)$, and the action of $\Delta(\rho)$ on each V_j is given by multiplication by ρ_j^α for some $\alpha_j \geq 0$.

The decomposition (4.1) is clearly unique if, in addition, we require that $\alpha_j \neq \alpha_k$ whenever $j \neq k$. In this case, the V_j are referred to as *the homogeneous components of V with respect to Δ* . If $v \in V$ is such that $v \in V_j$ for some j , then v is said to be Δ -homogeneous. If $v \neq 0$, then V_j is uniquely determined by v , and the corresponding α_j is the Δ -degree of v . More generally, any $v \in V$ can be expressed in a unique way as a sum $\sum_j v_j$, $v_j \in V_j$. The Δ -degree of v is the largest α_j such that $v_j \neq 0$, and is denoted by $\deg_\Delta(v)$.

If Δ is a group of dilations of V , then Δ gives rise to groups of dilations Δ^A of $A(V)$, the free associative \mathbb{R} -algebra generated by V (i.e. the tensor algebra over V) and Δ^L of $L(V)$, the free Lie algebra generated by V . In both cases, the new group of dilations consists of automorphism of the algebraic structure, which in addition leave invariant the usual homogeneous components of $A(V)$, $L(V)$ (i.e. the homogeneous components with respect to the groups of dilations induced by $\{\Delta_0(\rho): \rho > 0\}$, where $\Delta_0(\rho): V \rightarrow V$ is multiplication by ρ).

A group of dilations Δ of V will be called *strict* if it has no component of degree zero. If Δ is strict, then Δ^L is also strict, and Δ^A is strict on $A_0(V)$, the set of elements of $A(V)$ with no constant term. (But $\Delta^A(\rho)(1) = 1$ so Δ^A is not strict on $A(V)$.)

We will use $\nu(\Delta)$ to denote the infimum of the degrees of the homogeneous components of Δ . Then $\nu(\Delta) = \nu(\Delta^L)$ for every Δ . If V is finite-dimensional, then the infimum considered above is actually a minimum, and Δ is strict if and only if $\nu(\Delta) > 0$.

In the particular case when $V = L^{1,\text{hom}}(\mathbf{X})$ (i.e. the linear span of X_0, \dots, X_m), we let $\Delta_{1,m}(\rho): V \rightarrow V$ be multiplication by ρ as above. Let Δ be any group of dilations of V . Then Δ gives rise to groups of dilations Δ^A, Δ^L of $A(\mathbf{X})$ and $L(\mathbf{X})$. Any group of dilations of $A(\mathbf{X})$ or of $L(\mathbf{X})$ which arises in this fashion from a strict group of dilations of V will be called an *admissible group of dilations*. (Clearly, a group of dilations $\Delta^\#$ of $L(\mathbf{X})$, is admissible iff $\Delta^\#$ is strict and the $\Delta(\rho)$ are automorphisms which leave the

usual homogeneous components invariant. If $\Delta^\#$ is a group of dilations of $A(X)$, then $\Delta^\#$ is admissible if and only if $\Delta^\#$ consists of automorphisms which leave the usual homogeneous components invariant, and the only elements of $\Delta^\#$ -degree zero are the constants.)

If Δ is a strict group of dilations of $L^{1,\text{hom}}(X)$ —so that Δ gives rise to admissible groups of dilations Δ^A, Δ^L —we will also refer to Δ itself as an admissible group of dilations.

In particular, the groups that arise from $\Delta_{1,m}$, denoted by $\Delta_{1,m}^A, \Delta_{1,m}^L$, are clearly admissible.

If Δ^A is any admissible group of dilations of $A(X)$ as above, arising from a group of dilations Δ of $L^{1,\text{hom}}(X)$, then every $\Delta^A(\rho)$ gives rise in an obvious way to an automorphism $\hat{\Delta}^A(\rho)$ of $\hat{A}(X)$. The $\hat{\Delta}^A(\rho)$ map $\hat{L}(X)$ to $\hat{L}(X)$ and therefore $\hat{G}(X)$ to $\hat{G}(X)$. Since $\Delta^A(\rho)$ maps $A_N(X)$ to $A_N(X)$ for each N , there are induced automorphisms $\Delta^{A,N}(\rho)$ of the algebra $A^N(X)$, which gives rise to automorphisms of the Lie algebra $L^N(X)$ and of the Lie group $G^N(X)$.

We will say that Δ is *compatible with the semigroup $\hat{S}(X, K)$* if

$$(4.2) \quad \hat{\Delta}^A(\rho)\hat{S}(X, K) \subseteq \hat{S}(X, K) \quad \text{for every } \rho \leq 1.$$

Compatibility can be described more directly as follows. The map $\Delta(\rho)$ takes $L^{1,\text{hom}}(X)$ into itself. For $u \in \mathbb{R}^m$, $u = (u_1, \dots, u_m)$, let $X(u) = X_0 + \sum_{i=1}^m u_i X_i$. If $u \in K$, then $\exp(X(u)) \in \hat{S}(X, K)$. Therefore $\hat{\Delta}^A(\rho)(\exp(X(u)))$ must belong to $\hat{S}(X, K)$, if Δ is compatible with $\hat{S}(X, K)$ and $0 < \rho \leq 1$. That is, $\exp(\hat{\Delta}^A(\rho)(X(u))) \in \hat{S}(X, K)$ and so $\exp(\hat{\Delta}^A(\rho)(X(u))) = \text{Ser}(v(\cdot))$ for some $v(\cdot) \in \mathcal{U}_m(K)$. Let T be the terminal time of $v(\cdot)$. Then T cannot equal zero for, if $T = 0$, then we would have $\text{Ser}(v(\cdot)) = 1$, and so $\hat{\Delta}^A(\rho)(X(u)) = 0$, contradicting the fact that $X(u) \neq 0$ and $\hat{\Delta}^A(\rho)$ is an automorphism. It follows from the construction of $\text{Ser}(v(\cdot))$ that the coefficient of X_0 in $\text{Ser}(v(\cdot))$ is precisely T . Moreover, the coefficient of X_0 in $\exp Z$ is the same as the coefficient of X_0 in Z . So

$$(4.3) \quad \hat{\Delta}^A(\rho)(X(u)) = TX_0 + \sum_{i=1}^m \alpha_i X_i,$$

for some choice of $(\alpha_1, \dots, \alpha_m) \in \mathbb{R}^m$. If we let $\beta = \alpha/T$, we see that

$$(4.4) \quad \hat{\Delta}^A(\rho)(X(u)) = TX(\beta).$$

Let $v': [0, T] \rightarrow \mathbb{R}^m$ be such that $v'(t) = \beta$ for $0 \leq t \leq T$. Then $\text{Ser}(v'(\cdot)) = \exp(TX(\beta))$. Since Ser is injective as a map from \mathcal{U}_m into $\hat{G}(X)$, we conclude that $v(\cdot) = v'(\cdot)$. Since $v(\cdot)$ is K -valued, we conclude that $\beta \in K$. Hence $\hat{\Delta}^A(\rho)(X(u))$ is of the form $TX(\beta)$ for some $T > 0$ and some $\beta \in K$. Conversely, if $\{\Delta(\rho)\}$ has the property that $\Delta(\rho)(X(u))$ is of the form $TX(\beta)$ for some $T > 0, \beta \in K$, whenever $0 < \rho \leq 1$ and $u \in K$, then it is easy to see that $\hat{\Delta}^A(\rho)\hat{S}(X, K) \subseteq \hat{S}(X, K)$ whenever $0 < \rho \leq 1$.

To see this, write

$$(4.5) \quad \Delta(\rho)(X(u)) = \sum_{i=0}^m \theta_i(u) X_i$$

for $u \in \mathbb{R}^m$. Then

$$\Delta(\rho)(X_0) = \sum_{i=0}^m \theta_i(0) X_i \quad \text{and} \quad \Delta(\rho)\left(\sum_{j=1}^m u_j X_j\right) = \sum_{i=0}^m [\theta_i(u) - \theta_i(0)] X_i,$$

so that each of the functions $u \rightarrow \theta_i(u) - \theta_i(0)$ is linear. Moreover, $\theta_0(u) > 0$ for every $u \in K$ and, if we define $\beta_i(u) = \theta_i(u)/\theta_0(u)$ for $i = 1, \dots, m$, $u \in \mathbb{R}^m$, $\theta_0(u) \neq 0$, then we have $\beta(u) \in K$ whenever $u \in K$, if $\beta(u) = (\beta_1(u), \dots, \beta_m(u))$. Let $S \in \hat{S}(X, K)$. Then $S = S(T)$, for some $\hat{A}(X)$ -valued function $t \rightarrow S(t)$, $0 \leq t \leq T$, that satisfies

$$(4.6) \quad \dot{S}(t) = S(t) \left(X_0 + \sum_{i=1}^m u_i(t) X_i \right),$$

where the u_i are Lebesgue integrable functions such that $(u_1(t), \dots, u_m(t)) \in K$ for all t . Let $S^\#(t) = \hat{\Delta}^A(\rho) S(t)$. Then

$$(4.7) \quad \begin{aligned} \dot{S}^\#(t) &= S^\#(t) \left(\theta_0(u(t)) X_0 + \sum_{i=1}^m \theta_i(u(t)) X_i \right) \\ &= S^\#(t) \left(\theta_0(u(t)) \left[X_0 + \sum_{i=1}^m \beta_i(u(t)) X_i \right] \right). \end{aligned}$$

Let $\tau(t) = \int_0^t \theta_0(u(s)) ds$. (The integral exists because $u(\cdot)$ is Lebesgue integrable and θ_0 is affine linear.) Since $\theta_0(u(t)) > 0$ for $0 \leq t \leq T$, τ is a strictly increasing function of t . Let $S^*(\tau) = S^\#(t)$, if $\tau = \tau(t)$. Then

$$(4.8) \quad \dot{S}^*(\tau) = S^*(\tau) \left(X_0 + \sum_{i=1}^m v_i(\tau) X_i \right),$$

where the dot now denotes differentiation with respect to τ , and $v_i(\tau) = \beta_i(u(t))$ whenever $\tau = \tau(t)$. The vector-valued function $v(\cdot)$ is Lebesgue integrable. (Notice that $\beta(u(\cdot))$ might fail to be integrable, since we do not know that $\theta_0(\cdot)$ is bounded away from zero. However, $v(\cdot)$ is necessarily integrable because, whenever ϕ is a strictly positive integrable function on $[0, T]$, and $\tau(t) = \int_0^t \phi(s) ds$ for $0 \leq t \leq T$, then the function $g: [0, \tau(T)] \rightarrow \mathbb{R}$ defined by $g(\tau(t)) = f(t)/\phi(t)$ is integrable whenever f is integrable.) Since $(v_1(\tau), \dots, v_m(\tau)) \in K$ for every τ , we see that $S^*(\tau) \in \hat{S}(X, K)$. In particular, since $S^*(\tau(T)) = S^\#(T) = \hat{\Delta}^A(\rho) S$, we see that $\hat{\Delta}^A(\rho) S \in \hat{S}(X, K)$. Therefore $\hat{\Delta}^A(\rho)$ maps $\hat{S}(X, K)$ to $\hat{K}(X, K)$. So we have shown:

LEMMA 4.1. *Let $\Delta = \{\Delta(\rho): 0 < \rho < \infty\}$ be a one-parameter group of dilations of $V = L^{1, \text{hom}}(X)$, and let $\Delta^A, \hat{\Delta}^A$ be the corresponding groups of automorphisms of $A(X), \hat{A}(X)$. Then Δ is compatible with the semigroup $\hat{S}(X, K)$ if and only if $\Delta(\rho) (X_0 + \sum_{i=1}^m u_i X_i)$ is of the form $T(X_0 + \sum_{i=1}^m v_i X_i)$ for some $T > 0$, $(v_1, \dots, v_m) \in K$, whenever $0 < \rho \leq 1$ and $(u_1, \dots, u_m) \in K$.*

If $\hat{\Delta}^A$ is compatible with $\hat{S}(X, K)$ then $\hat{\Delta}^A(\rho)$ gives rise to a map $\Delta_K^{\hat{S}}(\rho): \hat{S}(X, K) \rightarrow \hat{S}(X, K)$ whenever $0 < \rho \leq 1$, and hence to a map $\Delta_K^{\mathcal{U}}(\rho): \mathcal{U}_m(K) \rightarrow \mathcal{U}_m(K)$, since $\mathcal{U}_m(K)$ is identified with $\hat{S}(X, K)$ by means of the bijection Ser. An explicit description of this map follows from the reasoning preceding the statement of Lemma 4.1. If we write

$$(4.9) \quad \Delta(\rho) \left(X_0 + \sum u_i X_i \right) = \sum_{i=0}^m \theta_i^\rho(u) X_i,$$

for $u \in \mathbb{R}^m$, then the control $v(\cdot) = \Delta_K^{\mathcal{U}}(\rho)(u(\cdot))$ that corresponds to a given $u(\cdot) \in \mathcal{U}_m(K)$, defined on an interval $[0, T]$, is obtained from the K -valued map $t \rightarrow \beta^\rho(u(t))$, $0 \leq t \leq T$, by reparametrizing time, using $\tau = \tau(t) = \int_0^t \theta_0^\rho(u(s)) ds$ as the new time parameter. (Here $\beta^\rho(u) = (\beta_1^\rho(u), \dots, \beta_m^\rho(u))$, $\beta_i^\rho(u) = \theta_i^\rho(u)/\theta_0^\rho(u)$.) This explicit description implies, in particular, that $\Delta_K^{\mathcal{U}}(\rho)$ is continuous with respect to some natural topologies on $\mathcal{U}(T)$ (for example, L^1 , pointwise convergence), and that $\Delta_K^{\mathcal{U}}(\rho)$ maps piecewise constant controls to piecewise constant controls. More precisely, if $u(\cdot)$ is a piecewise constant control whose values are u^1, \dots, u^k , on intervals of length

t^1, \dots, t^k , then $\Delta_K^u(\rho)(u(\cdot))$ is piecewise constant with values v^1, \dots, v^k on intervals of length τ^1, \dots, τ^k , where $v^i = \beta^\rho(u^i)$, and $\tau^i = \theta_0^\rho(u^i)t^i$.

This implies, in particular:

LEMMA 4.2. *If Δ is an admissible group of dilations of $L^{1,\text{hom}}(X)$, which is compatible with K , and W is a normal neighborhood of an $S \in \hat{S}^N(X, K)$, then $\Delta^{A,N}(\rho)(W)$ is a normal neighborhood $\Delta^{A,N}(\rho)(S)$ for every $\rho \in (0, 1]$.*

Now suppose that an $(m+1)$ -tuple $\mathbf{f} = (f_0, \dots, f_m)$ of smooth vector fields on a manifold M is given, as well as a point $p \in M$. We can then define $N_0(\mathbf{f}, p)$ to be the smallest integer N such that

$$(4.10) \quad \text{Ev}_p(\mathbf{f})(L^N(\mathbf{X})) = T_p M.$$

If, in addition, an admissible group of dilations Δ on $L^{1,\text{hom}}(\mathbf{X})$ is given, we can also define $\nu_0(\mathbf{f}, p, \Delta)$ to be the largest of the Δ -degrees of all the elements of $L^{N_0(\mathbf{f}, p)}(\mathbf{X})$.

An element Z of $L(\mathbf{X})$ is said to be Δ -neutralized for \mathbf{f} at p if each Δ -homogeneous component Z_j of Z is the sum of an $R_j \in L(\mathbf{X})$ which belongs to $\text{LR}(\mathbf{f}, p)$ and a $Q_j \in L(\mathbf{X})$ such that

$$(4.11) \quad \deg_\Delta(Q_j) < \deg_\Delta(Z_j).$$

Our generalization of Theorem 3.5 is then the following

THEOREM 4.3. *Let (M, \mathbf{f}, K) be a control system, and let $p \in M$. Let Δ be an admissible group of dilations of $L^{1,\text{hom}}(\mathbf{X})$ which is compatible with $\hat{S}(\mathbf{X}, K)$. Let N be a positive integer that satisfies*

$$(4.12) \quad N \geq N_0(\mathbf{f}, p),$$

and

$$(4.13) \quad N\nu(\Delta) \geq \nu_0(\mathbf{f}, p, \Delta).$$

Assume that there exists an element Z of $L^N(\mathbf{X})$ which is Δ -neutralized for \mathbf{f} at p and satisfies $\exp_N(Z) \in \hat{S}^N(X, K)$. Then (M, \mathbf{f}, K) is STLC from p .

Remark. Theorem 3.5 is a particular case of this result. Indeed, to get Theorem 3.5 it suffices to let Δ be the group of dilations defined by $\Delta(\rho)(P) = \rho P$ for $P \in L^{1,\text{hom}}(\mathbf{X})$. A Z that satisfies the condition of Theorem 3.5 is clearly Δ -neutralized for \mathbf{f} at p .

Proof. Let $S \in \hat{S}^N(X, K)$ be such that $S = \exp_N(Z)$, $Z \in L^N(\mathbf{X})$, and Z is Δ -neutralized for \mathbf{f} at p . Let $\mathcal{E} = (E_1, \dots, E_n)$ consist of elements of $L^{N_0(\mathbf{f}, p)}(\mathbf{X})$ which are Δ -homogeneous of degrees $\sigma_1, \dots, \sigma_n$ and are such that the vectors $\text{Ev}_p(\mathbf{f})(E_i)$, $i = 1, \dots, n$ span $T_p M$. (Then, in particular, $\sigma_j \leq \nu_0(\mathbf{f}, p, \Delta)$ for $j = 1, \dots, n$.) Let W be a normal neighborhood of S . Then we can pick a neighborhood W_0 of S and a $\beta > 0$ such that $\exp_N(Z' + \sum_{j=1}^n y_j E_j) \in W$ whenever $\exp_N(Z') \in W_0$ and $|y_j| \leq \beta$ for $j = 1, \dots, n$.

Since Z is Δ -neutralized for \mathbf{f} at p , we can write

$$(4.14) \quad Z = \sum_i Z_i,$$

where the Z_i are elements of $L(\mathbf{X})$, are Δ -homogeneous of degree θ_i (with $\theta_i \neq \theta_j$ if $i \neq j$), and satisfy

$$(4.15) \quad Z_i = R_i + \sum_k Q_{ik},$$

where the Q_{ik} are Δ -homogeneous of degree η_{ik} , the R_i belong to $\text{LR}(\mathbf{f}, p)$, and the η_{ik} satisfy $\eta_{ik} < \theta_i$.

It then follows that the Z_i belong to $L^N(\mathbf{X})$, for we can write $Z = \sum_{j=1}^N Z^j$, with $Z^j \in L^{j,\text{hom}}(\mathbf{X})$, and then each Z^j is a sum of Δ -homogeneous components Z_k^j , which must necessarily belong to $L^{j,\text{hom}}(\mathbf{X})$. The Z_i are then obtained by grouping together all the Z_k^j that have the same Δ -degree, and therefore belong to $L^N(\mathbf{X})$, as stated.

The Q_{ik} can also be assumed to belong to $L^N(\mathbf{X})$. Indeed, suppose that one Q_{ik} was not in $L^N(\mathbf{X})$. Since Q_{ik} is Δ -homogeneous, we must have

$$(4.16) \quad \deg_{\Delta}(Q_{ik}) \geq (N+1) \times \nu(\Delta).$$

On the other hand, we can write

$$(4.17) \quad \text{Ev}_p(\mathbf{f})(Q_{ik}) = \sum_l q_{ikl} \text{Ev}_p(\mathbf{f})(E_l)$$

for appropriate coefficients q_{ikl} . Therefore

$$(4.18) \quad Q_{ik} = R_{ik} + \sum_l q_{ikl} E_l$$

where $R_{ik} \in \text{LR}(\mathbf{f}, p)$. The $q_{ikl} E_l$ are Δ -homogeneous of degree σ_l . Since

$$(4.19) \quad \sigma_l \leq \nu_0(f, p, \Delta) \leq (N+1)\nu(\Delta) \leq \eta_{ik} < \theta_i,$$

we can replace each Q_{ik} that occurs in (4.15) but does not belong to $L^N(\mathbf{X})$ by the sum of the $q_{ikl} E_l$, and add R_{ik} to R_i . This leads to an expression for Z_i for the form (4.15), with all the Q_{ik} in $L^N(\mathbf{X})$.

It then follows that the R_i are in $L^N(\mathbf{X})$ as well. Define

$$(4.20) \quad \tilde{Z}_{\rho} = Z - \sum_{ik} \rho^{\theta_i - \eta_{ik}} Q_{ik}.$$

Then $\exp_N(\tilde{Z}_{\rho}) \in W_0$ if ρ is small enough. Therefore, if ρ is small, W is a normal neighborhood of $\exp_N(\tilde{Z}_{\rho})$ such that

$$(4.21) \quad \exp_N\left(\tilde{Z}_{\rho} + \sum_{i=1}^n y_i E_i\right) \in W$$

whenever $|y_i| \leq \beta$ for $i = 1, \dots, n$. Let $Z_{\rho} = \Delta(\rho)(\tilde{Z}_{\rho})$. Let $W_{\rho} = \Delta(\rho)W$. Then, if ρ is sufficiently small, W_{ρ} is a normal neighborhood of $\exp_N(Z_{\rho})$ such that

$$(4.22) \quad \exp_N\left(Z_{\rho} + \sum_{i=1}^n y_i \rho^{\sigma_i} E_i\right) \in W_{\rho}$$

whenever $|y_i| \leq \beta$ for $i = 1, \dots, n$. Let

$$(4.23) \quad S_{\rho} = \exp_N(Z_{\rho}).$$

Then

$$(4.24) \quad \log_N(W_{\rho}) \supseteq B_{\mathcal{G}}(Z_{\rho}, \beta \rho^{\nu_0(\mathbf{f}, p, \Delta)}).$$

On the other hand, S_{ρ} satisfies

$$(4.25) \quad T^N(S_{\rho}) \leq c \rho^{\nu(\Delta)} \quad \text{for } 0 < \rho \leq 1,$$

for some $c > 0$. (This is because \tilde{Z}_{ρ} is a sum of Δ -homogeneous components, each of which has Δ -degree at least equal to $\nu(\Delta)$, and coefficients that are bounded as $\rho \rightarrow 0$. Therefore all the coefficients of $\Delta(\rho)\tilde{Z}_{\rho}$ are bounded by a constant times $\rho^{\nu(\Delta)}$. In particular, this is true for the coefficient of X_0 , and so (4.25) follows.)

From (4.25) we conclude that

$$(4.26) \quad \rho^{\nu_0(\mathbf{f}, p, \Delta)} \geq \rho^{N\nu(\Delta)} \geq c^{-N} [T^N(S_{\rho})]^N$$

and so

$$(4.27) \quad \log_N (W_\rho) \supseteq B_{\mathcal{G}}(Z_\rho, \alpha [T^N(S_\rho)]^N)$$

if ρ is sufficiently small, and $\alpha = \beta c^{-N}$.

Finally, we have

$$\begin{aligned} Z_\rho &= \Delta(\rho) \tilde{Z}_\rho = \Delta(\rho) \left(\sum_i \left(Z_i - \sum_k \rho^{\theta_i - \eta_{ik}} Q_{ik} \right) \right) \\ &= \sum_i \left[\rho^{\theta_i} Z_i - \sum_k \rho^{\theta_i - \eta_{ik}} \rho^{\eta_{ik}} Q_{ik} \right] \\ &= \sum_i \rho^{\theta_i} \left[Z_i - \sum_k Q_{ik} \right] \\ &= \sum_i \rho^{\theta_i} R_i. \end{aligned}$$

Therefore $Z_\rho \in \text{LR}(\mathbf{f}, p)$. Hence all the hypotheses of Theorem 3.4 are satisfied, and the desired conclusion follows.

5. Invariant elements. Theorem 4.3 says that (M, \mathbf{f}, K) is STLC from p if, for some sufficiently large N , $\hat{S}^N(\mathbf{X}, K)$ contains an element S such that $\log_N(S)$ is Δ -neutralized for \mathbf{f} at p . In order to be able to use this result, we need to know that $\hat{S}^N(\mathbf{X}, K)$ necessarily will contain elements of some very special kind, for then STLC will follow if we hypothesize that these special elements are exponentials of Δ -neutralized members of $L^N(\mathbf{X})$.

To get these “special elements” we exploit a general result about existence of points that are invariant under certain finite groups of pseudoautomorphisms (cf. § 2 for the definition of “pseudoautomorphism”).

Let L be a finite-dimensional, nilpotent Lie algebra over \mathbb{R} , and let G_L be its corresponding connected, simply connected Lie group. Then the exponential map $\exp: L \rightarrow G_L$ is a diffeomorphism onto. Therefore, if $\lambda: L \rightarrow L$ is an arbitray map, then λ gives rise to a map $\tilde{\lambda}: G_L \rightarrow G_L$, defined by letting

$$(5.1) \quad \tilde{\lambda}(\exp(z)) = \exp(\lambda(z)).$$

PROPOSITION 5.1. *Let L be a finite-dimensional, nilpotent Lie algebra over \mathbb{R} , and let G_L be the corresponding connected, simply connected Lie group. Let Λ be a finite group of pseudoautomorphisms of L , and let $\tilde{\Lambda} = \{\tilde{\lambda}: \lambda \in \Lambda\}$ be the group of bijections of G_L induced by Λ . Let S be a nonempty subset of G_L which is closed under multiplication. Suppose that every $\tilde{\lambda} \in \tilde{\Lambda}$ maps S into S . Then S contains an element s such that $\tilde{\lambda}(s) = s$ for all $\lambda \in \Lambda$.*

Proof. Start with an element $s_1 \in S$, and write $s_1 = \exp(b_1)$, where $b_1 \in L$. Let $\Lambda = \{\lambda_1, \dots, \lambda_n\}$, with $\lambda_i \neq \lambda_j$ whenever $i \neq j$. Define s_2 by

$$(5.2) \quad s_2 = \tilde{\lambda}_1(s_1) \tilde{\lambda}_2(s_1) \cdots \tilde{\lambda}_n(s_1).$$

Then $s_2 \in S$, because $\tilde{\lambda}_j(s_1) \in S$ for each j , and S is closed under multiplication. On the other hand, we have

$$(5.3) \quad \tilde{\lambda}_j(s_1) = \exp(\lambda_j(b_1)) \quad \text{for } j = 1, \dots, n.$$

Therefore the Campbell–Hausdorff formula gives

$$(5.4) \quad s_2 = \exp(z_2 + b_2)$$

where

$$(5.5) \quad z_2 = \lambda_1(b_1) + \cdots + \lambda_n(b_1)$$

and $b_2 \in [L]^2$. In view of (5.5), z_2 satisfies $\lambda(z_2) = z_2$ for every $\lambda \in \Lambda$. Assume we have proved, for some k , that there exists an $s_k \in S$ which is of the form $\exp(z_k + b_k)$, with $\lambda(z_k) = z_k$ for all $\lambda \in \Lambda$, and $b_k \in [L]^k$. Then we can define s_{k+1} by

$$(5.6) \quad s_{k+1} = \lambda_1(s_k) \lambda_2(s_k) \cdots \lambda_n(s_k)$$

and conclude from the Campbell-Hausdorff formula that

$$(5.7) \quad s_{k+1} = \exp(z_{k+1} + b_{k+1}),$$

where

$$(5.8) \quad z_{k+1} = \sum_{i=1}^n \lambda_i(z_k + b_k)$$

and b_{k+1} is a linear combination of terms, each of which is a Lie bracket of two or more elements of L of the form $\lambda_j(z_k + b_k)$ for some j . But $\lambda_j(z_k) = z_k$ and, if we let $b_{jk} = \lambda_j(b_k)$, we have $b_{jk} \in [L]^k$, because $b_k \in [L]^k$ and λ is a pseudoautomorphism. So the brackets that appear in b_{k+1} are brackets of two or more terms of the form $z_k + b_{jk}$. Now $[z_k + b_{ik}, z_k - b_{jk}] = [z_k, b_{jk}] + [b_{ik}, z_k] + [b_{ik}, b_{jk}]$, and so $[z_k + b_{ik}, z_k + b_{jk}] \in [L]^{k+1}$. So $b_{k+1} \in [L]^{k+1}$. This proves, by induction, that an $s_k \in S$ of the desired form exists for every k . Since L is nilpotent, we can take k such that $[L]^k = \{0\}$. Then $b_k = 0$, and so, if we let $s = s_k$, the condition that $\lambda(s) = s$ holds for all $\lambda \in \Lambda$.

6. End of the proof of Theorem 2.4. Assume that the conditions of Theorem 2.4 hold. Pick N so large that (4.12) and (4.13) hold. The group Λ obviously induces a group Λ_N of pseudoautomorphisms of the Lie algebra $L^N(\mathbf{X})$. The maps $\tilde{\lambda}$, for $\lambda \in \Lambda_N$, clearly map $\hat{S}^N(\mathbf{X}, K)$ into itself. The set $\hat{S}^N(\mathbf{X}, K)$ is nonempty and closed under multiplication. Proposition 5.1 then implies that $\hat{S}^N(\mathbf{X}, K)$ contains an element $S = \exp_N(Z)$, where $z \in L^N(\mathbf{X})$ is Λ_N -fixed. Then Z is Λ -fixed, and therefore Z is Δ -neutralized for \mathbf{f} at p . Theorem 4.3 then says that (M, \mathbf{f}, K) is STLC from p .

7. Applications. In all the applications discussed here, Λ will be a group obtained from a group of automorphisms Λ_0 of $L(\mathbf{X})$, by adding to it the "time reversal" map. Precisely, let $\mathbb{T}^A: A(\mathbf{X}) \rightarrow A(\mathbf{X})$ be the linear map which sends each monomial $X_{i_1} X_{i_2} \cdots X_{i_k}$ to the "reversed" monomial $X_{i_k} \cdots X_{i_2} X_{i_1}$. Then \mathbb{T}^A is an antiautomorphism of $A(\mathbf{X})$ (i.e. $\mathbb{T}^A(PQ) = \mathbb{T}^A(Q) \mathbb{T}^A(P)$ for all P, Q in $A(\mathbf{X})$). It then follows easily that $\mathbb{T}^A([P, Q]) = [\mathbb{T}^A(Q), \mathbb{T}^A(P)]$, i.e.

$$(7.1) \quad \mathbb{T}^A([P, Q]) = -[\mathbb{T}^A(P), \mathbb{T}^A(Q)],$$

for P, Q in $A(\mathbf{X})$. Then \mathbb{T}^A maps $L(\mathbf{X})$ to $L(\mathbf{X})$, and

$$(7.2) \quad \mathbb{T}(P) = (-1)^{1+k} P \quad \text{for } P \in L^{k, \text{hom}}(\mathbf{X}),$$

where \mathbb{T} denotes the restriction of \mathbb{T}^A to $L(\mathbf{X})$.

It is clear that \mathbb{T} is a pseudoautomorphism of $L(\mathbf{X})$. On the other hand \mathbb{T}^A gives rise in an obvious way to a map $\hat{\mathbb{T}}^A: \hat{A}(\mathbf{X}) \rightarrow \hat{A}(\mathbf{X})$. Clearly, $\hat{\mathbb{T}}^A(P^k) = P^k$ if $P \in A^{1, \text{hom}}(\mathbf{X})$. Therefore

$$(7.3) \quad \hat{\mathbb{T}}^A(\exp P) = \exp P$$

if $P \in A^{1, \text{hom}}(\mathbf{X})$. So, if P_1, \dots, P_k are elements of $L^{1, \text{hom}}(\mathbf{X})$, we have

$$(7.4) \quad \hat{\mathbb{T}}^A(\exp(P_1) \cdots \exp(P_k)) = \exp(P_k) \cdots \exp(P_1).$$

This implies that, if $u(\cdot)$ is a piecewise constant K -valued control, defined on $[0, T]$, then

$$(7.5) \quad \hat{\mathbb{T}}^A(\text{Ser}(u(\cdot))) = \text{Ser}(u^{\text{rev}}(\cdot))$$

where $u^{\text{rev}}(t) = u(T-t)$ for $0 \leq t \leq T$. By an elementary continuity argument, (7.5) holds for all controls $u(\cdot)$. Therefore

$$(7.6) \quad \hat{\mathbb{T}}^A(\hat{S}(\mathbf{X}, K)) = \hat{S}(\mathbf{X}, K).$$

On the other hand, \mathbb{T} gives rise to a map $\hat{\mathbb{T}}: \hat{L}(\mathbf{X}) \rightarrow \hat{L}(\mathbf{X})$, which is obviously equal to the restriction of $\hat{\mathbb{T}}^A$ to $\hat{L}(\mathbf{X})$. If P is any element of $\hat{A}_0(\mathbf{X})$, then $\hat{\mathbb{T}}^A(P^k) = [\hat{\mathbb{T}}^A(P)]^k$ for every k , and therefore

$$(7.7) \quad \hat{\mathbb{T}}^A(\exp(P)) = \exp(\hat{\mathbb{T}}^A(P)).$$

In particular, if $P \in \hat{L}(\mathbf{X})$, we get the equality

$$(7.8) \quad \hat{\mathbb{T}}^A(\exp(P)) = \exp(\hat{\mathbb{T}}(P)),$$

which implies

$$(7.9) \quad \hat{\mathbb{T}}^A(\hat{G}(\mathbf{X})) = \hat{G}(\mathbf{X}).$$

In the terminology of § 2 (cf. especially (2.7)), (7.8) shows that the restriction of $\hat{\mathbb{T}}^A$ to $\hat{G}(\mathbf{X})$ is precisely the map $\mathbb{T}^\# : \hat{G}(\mathbf{X}) \rightarrow \hat{G}(\mathbf{X})$. Hence (7.6) says that $\mathbb{T}^\#$ maps $\hat{S}(\mathbf{X}, K)$ to $\hat{S}(\mathbf{X}, K)$. So we have proved:

LEMMA 7.1. \mathbb{T} is an input symmetry.

Now suppose that Λ_0 is a finite group of *graded* linear maps from $L(\mathbf{X})$ to $L(\mathbf{X})$. (A linear map $\lambda : L(\mathbf{X}) \rightarrow L(\mathbf{X})$ is *graded* if λ maps $L^{j,\text{hom}}(\mathbf{X})$ into $L^{j,\text{hom}}(\mathbf{X})$ for each j .) Then every $\lambda \in \Lambda_0$ commutes with \mathbb{T} . Since \mathbb{T}^2 is the identity map, the set

$$(7.10) \quad \Lambda = \Lambda_0 \cup \{\lambda \mathbb{T} : \lambda \in \Lambda_0\},$$

is a finite group of pseudoautomorphisms. If Λ_0 is a group of input symmetries, then Λ is a group of input symmetries as well. We shall refer to the input symmetry \mathbb{T} as “time reversal,” and to the group Λ defined by (7.10) as “the augmentation of Λ_0 by time reversal.”

Let us call an element of $L(\mathbf{X})$ *totally odd* if all its homogeneous components have odd degree. Then it is clear that the totally odd elements of $L(\mathbf{X})$ are precisely those $P \in L(\mathbf{X})$ that satisfy $\mathbb{T}(P) = -P$. If Λ_0 is a finite group of graded linear maps of $L(\mathbf{X})$, and Λ is its augmentation by time reversal, then the Λ -fixed elements of $L(\mathbf{X})$ are precisely those $P \in L(\mathbf{X})$ that are Λ_0 -fixed and totally odd. So we can conclude from Theorem 2.4 the following:

COROLLARY 7.2. Let (M, \mathbf{f}, K) be a control system, and let $p \in M$. Assume that \mathbf{f} satisfies the LARC at p , and that there exist (a) an admissible group of dilations Δ of $L^{1,\text{hom}}(\mathbf{X})$ which is compatible with $\hat{S}(\mathbf{X}, K)$, (b) a finite group Λ_0 of graded linear maps from $L(\mathbf{X})$ to $L(\mathbf{X})$ that are input symmetries, such that every totally odd Λ_0 -fixed element of $L(\mathbf{X})$ is Δ -neutralized for \mathbf{f} at p . Then (M, \mathbf{f}, K) is STLC from p .

7.1. Symmetric systems. A symmetric system is a family $\mathcal{V} = \{V_i : i \in I\}$ of vector fields on a manifold M , such that for every $i \in I$ there is a $j \in I$ such that $V_j = -V_i$. It is well known that, if a symmetric system satisfies the LARC at p , then the system is STLC from p . For completeness, we show that our theorem implies this result. First, it is clear that we can pick vector fields f_1, \dots, f_m in this family such that the m -tuple (f_1, \dots, f_m) satisfies the LARC at p . Then we can let $f_0 = 0$. Also, we take K to be the set of all points of \mathbb{R}^m of the form $(0, 0, \dots, 0, \pm 1, 0, \dots, 0)$. We let Δ be the group

of dilations such that $\Delta(\rho)(P) = \rho P$ for $P \in L^{1,\text{hom}}(X)$, so that the Δ -degree is just the ordinary degree. We let Λ_0 be the group of automorphisms of $L(X)$ generated by $\lambda_1, \dots, \lambda_m$, where λ_i is the automorphism that takes X_j to X_j for $j \neq i$, and X_i to $-X_i$. Since the λ_i commute, Λ_0 is finite. The Λ_0 -fixed elements of $L(X)$ are those that are linear combinations of brackets where each X_i , $i = 1, \dots, m$, occurs an even number of times. Such a bracket cannot be totally odd unless it contains X_0 . But then, when the bracket is evaluated by plugging in the f_j for the X_j , the result must be zero, because $f_0 = 0$. Hence every totally odd Λ_0 -fixed element of $L(X)$ is actually in $\text{LR}(\mathbf{f}, p)$, and therefore is Δ -neutralized for \mathbf{f} at p . So we can apply Corollary 7.2 and conclude that $\Sigma = (M, \mathbf{f}, K)$ is STLC from p . Since every trajectory of Σ is a trajectory of \mathcal{V} , the small-time local controllability of \mathcal{V} follows.

7.2. The results of Brunovsky, Crouch and Byrnes. In [3], Brunovsky defined an *odd family* $\mathcal{V} = \{V_i: i \in I\}$ of vector fields on a symmetric neighborhood M of 0 to be a family such that for every $i \in I$ there is a $j \in I$ such that $V_j(-x) = -V_i(x)$ for $x \in M$. He then proved that, if \mathcal{V} is odd and satisfies the LARC, then \mathcal{V} is STLC from 0. Crouch and Byrnes [5] provided a coordinate-free generalization of this result. Suppose that $\mathcal{V} = \{V_i: i \in I\}$ is a collection of vector fields on a manifold M , and $p \in M$. Suppose that \mathcal{V} satisfies the LARC at p . Assume that there is a finite group Λ_0 of diffeomorphisms of M such that

- (i) each $\lambda \in \Lambda_0$ maps p to p ,
- (ii) each $\lambda \in \Lambda_0$ maps each V_i to some V_j in the family,
- (iii) the differentials at p of the maps $\lambda \in \Lambda_0$ have no common invariant half space.

The result of [5] then says that \mathcal{V} is small-time locally controllable from p . Brunovsky's theorem is a particular case of this, obtained by letting Λ_0 consist of the identity and the map $\lambda: x \rightarrow -x$. (If $V_j(-x) = -V_i(x)$, and λ_* denotes the differential of λ , so that $\lambda_*(v) = -v$, then λ_* maps V_i to V_j .)

We show that the result of [5] is a particular case of our Corollary 7.2. Let f_1, \dots, f_m be members of the family \mathcal{V} , chosen so that: (i) (f_1, \dots, f_m) satisfies the LARC, (ii) $f_i \neq f_j$ whenever $i \neq j$, (iii) the set $\{f_1, \dots, f_m\}$ is mapped to itself by the maps λ_* , $\lambda \in \Lambda_0$. Let $f_0 \equiv 0$, $\mathbf{f} = (f_0, \dots, f_m)$. Then consider the system (M, \mathbf{f}, K) , where $K = \{0\} \cup \tilde{K}$, and \tilde{K} is the set of all vectors of \mathbb{R}^m of the form $(0, 0, \dots, 0, 1, 0, \dots, 0)$. If $\Sigma = (M, \mathbf{f}, K)$ is STLC from p , then \mathcal{V} is. (Indeed, let q be reachable from p by a trajectory of Σ that corresponds to a piecewise constant $u(\cdot): [0, T] \rightarrow K$. Then q can also be reached by a trajectory that corresponds to a \tilde{K} -valued control, in time $T' \leq T$, by simply eliminating from $u(\cdot)$ all the pieces for which $u(\cdot)$ has the value 0.) The group Λ_0 acts on $L(X)$ for, if $\lambda \in \Lambda_0$, then λ_* permutes the elements of $\{f_1, \dots, f_m\}$, and so we can define an automorphism $g(\lambda)$ of $L(X)$ by

$$(7.11) \quad g(\lambda)(X_0) = X_0$$

and

$$(7.12) \quad g(\lambda)(X_i) = X_j \quad \text{if } \lambda_*(f_i) = f_j.$$

If \mathcal{V} is any element of $L(X)$, it follows from (7.11) and (7.12) that

$$(7.13) \quad \text{Ev}(\mathbf{f})(g(\lambda)(V)) = \lambda_*(\text{Ev}(\mathbf{f})(V)).$$

In particular, this implies that, if V is Λ_0 -fixed, then the vector $\text{Ev}_p(\mathbf{f})(V)$ is invariant under the differentials at p of all the maps $\lambda \in \Lambda_0$. Therefore $\text{Ev}_p(\mathbf{f})(V) = 0$, and so $V \in \text{LR}(\mathbf{f}, p)$.

So, if Δ is any group of dilations whatsoever, all the Λ_0 -fixed elements of $L(X)$ are Δ -neutralized for f at p , and so Σ is STLC from p .

7.3. The Hermes condition and some generalizations. Consider a system

$$(7.14) \quad \dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x), \quad |u_i| \leq 1,$$

and assume that p is an equilibrium point of f_0 , i.e. that $f_0(p) = 0$. We let Λ_0 be the group of automorphisms of $L(X)$ generated by $\sigma_1, \dots, \sigma_m$ and all the $\tilde{\pi}$, $\pi \in S_m$, where: (a) S_m is the group of permutations of $\{1, \dots, m\}$, (b) for $\pi \in S_m$, $\tilde{\pi}$ is the automorphism of $L(X)$ which maps X_0 to X_0 and X_i to $X_{\pi(i)}$ for $i = 1, \dots, m$, (c) σ_i is the automorphism that sends X_j to X_j for $j \neq i$, and X_i to $-X_i$. It is clear that Λ_0 is finite. The Λ_0 -fixed elements are those that are linear combinations of elements of the form $\alpha(B)$, where B is a bracket of X_0, \dots, X_m , and α is the Λ_0 -symmetrization operator, i.e.

$$(7.15) \quad \alpha(V) = \sum_{\lambda \in \Lambda_0} \lambda(V).$$

It is clear that $\alpha(V) = 0$, if $\sigma_i(V) = -V$ for some i . Therefore, $\alpha(B) = 0$ if B is a bracket in which one of the X_i , $i > 0$, appears an odd number of times. Hence, in order to find the Λ_0 -fixed elements, we may limit ourselves to considering the symmetrizations of brackets B where, for $i = 1, \dots, m$, X_i appears an even number of times. For such a B , one may use the symmetrization operator β given by

$$(7.16) \quad \beta(V) = \sum_{\pi \in S_m} \tilde{\pi}(V).$$

Next, let $\theta_1, \dots, \theta_m$ be arbitrary real numbers such that $\theta_i \geq 1$ for $i = 1, \dots, m$. Define $\Delta(\rho)$ by

$$(7.17) \quad \Delta(\rho): (X_0, \dots, X_m) \rightarrow (\rho X_0, \rho^{\theta_1} X_1, \rho^{\theta_2} X_2, \dots, \rho^{\theta_m} X_m).$$

Then Δ is compatible with $\tilde{S}(X, K)$, where $K = \{(u_1, \dots, u_m) : |u_i| \leq 1 \text{ for } i = 1, \dots, m\}$. Then Corollary 7.2 implies that the system is STLC if, whenever B is a bracket with an odd number of X_0 's, and an even number of X_i 's for each $i \in \{1, \dots, m\}$, it follows that every Δ -homogeneous component of $\beta(B)$ is equal, when evaluated at p , to a linear combination of brackets of lower Δ -degree. When the θ_i are different, this condition requires too much, for $\beta(B)$ will in general fail to be homogeneous. So the most interesting case obtains when all the θ_i are equal. Let $1 \leq \theta < \infty$. Define the θ -degree δ_θ of a bracket $B \in \text{Br}(X)$ to be the sum

$$(7.18) \quad \delta_\theta(B) = \delta^0(B) + \theta \sum_{i=1}^m \delta^i(B)$$

where $\delta^i(B)$ is the number of times that X_i occurs in B . Then δ_θ is the degree that arises, in an obvious way, from a group of dilations Δ_θ . We can then apply Corollary 7.2 to get a local controllability theorem involving the group Δ_θ . However, Δ_θ only enters the theorem via the concept of Δ -neutralization, and this concept is unchanged if we multiply all the degrees by a fixed number $\nu > 0$. Hence we can use, instead of δ_θ , the degree $\hat{\delta}_\theta$ defined by $\hat{\delta}_\theta(B) = (1/\theta)\delta_\theta(B)$, i.e.

$$(7.19) \quad \hat{\delta}_\theta(B) = \frac{1}{\theta} \delta^0(B) + \sum_{i=1}^m \delta^i(B).$$

The new definition now has the advantage that $\hat{\delta}_\theta$ also makes sense for $\theta = \infty$, in which case $\hat{\delta}_\infty(B)$ is, simply, the total number of occurrences in B of the X_i for $i = 1, \dots, m$. (But $\hat{\delta}_\infty$ does not arise from an admissible group of dilations.) We can then state the following

THEOREM 7.3. *Consider a system*

$$(7.20) \quad \dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x), \quad x \in M, \quad |u_i| \leq 1,$$

and a point $p \in M$ such that $f_0(p) = 0$. Assume that (f_0, \dots, f_m) satisfies the LARC at p . Assume that there is a $\theta \in [1, \infty]$ such that, whenever $B \in \text{Br}(X)$ is a bracket for which $\delta^0(B)$ is odd and $\delta^1(B), \dots, \delta^m(B)$ are even, then there are brackets C_1, \dots, C_k in $\text{Br}(X)$ such that

$$(7.21) \quad \text{Ev}_p(f)(\beta(B)) = \sum_{i=1}^k \xi_i \text{Ev}_p(f)(C_i)$$

for some $\xi_1, \dots, \xi_k \in \mathbb{R}$, and

$$(7.22) \quad \hat{\delta}_\theta(C_i) < \hat{\delta}_\theta(B) \quad \text{for } i = 1, \dots, k.$$

Then the system (7.20) is STLC from p .

For $\theta < \infty$, this theorem is just the result of applying Corollary 7.2 to our situation, using the group of dilations Δ_θ . To prove the theorem for $\theta = \infty$ we just “take the limit as $\theta \rightarrow \infty$.” Rigorously, this means that, if the hypotheses are satisfied for $\theta = \infty$, then they are also satisfied for some large finite θ . To see this, let us use $S_{k,l}$ to denote the linear span of all the brackets B such that $\delta^0(B) \leq k$ and $\delta^1(B) + \dots + \delta^m(B) \leq l$. If \mathbf{l} is an m -tuple (l_1, \dots, l_m) of nonnegative integers, we define $\tilde{S}_{k,\mathbf{l}}$ to be the linear span of those B 's for which $\delta^0(B) \leq k$, $\delta^1(B) = l_1, \dots, \delta^m(B) = l_m$. Also, we define

$$(7.23) \quad S_{\infty,l} = \bigcup_{k=0}^{\infty} S_{k,l},$$

$$(7.24) \quad \tilde{S}_{\infty,\mathbf{l}} = \bigcup_{k=0}^{\infty} \tilde{S}_{k,\mathbf{l}},$$

and we define spaces $S_{\infty,\mathbf{l}}^{\text{odd}}, \tilde{S}_{\infty,\mathbf{l}}^{\text{odd}}$ in exactly the same way, except that the unions are only taken over odd values of k . We call the m -tuple \mathbf{l} *even* if all its components l_1, \dots, l_m are even. Then the hypothesis of Theorem 7.3 for $\theta = \infty$ says that

$$(7.25) \quad \text{Ev}_p(f)\beta(\tilde{S}_{\infty,\mathbf{l}}^{\text{odd}}) \subseteq \text{Ev}_p(f)(S_{\infty,\|\mathbf{l}\|-1})$$

for all even \mathbf{l} . Pick an \bar{l} such that

$$(7.26) \quad \text{Ev}_p(f)(S_{\infty,\bar{l}}) = T_p M.$$

For $l = 0, 1, \dots, \bar{l}$, pick $k(l)$ such that

$$(7.27) \quad \text{Ev}_p(f)(S_{\infty,l}) = \text{Ev}_p(f)(S_{k(l),l}).$$

Then pick $\theta \in [1, \infty)$ such that $k(l) < \theta$ for $l = 0, \dots, \bar{l}$. We claim that, with this choice of θ , the hypothesis of Theorem 7.3 holds. To see this, let $B \in \tilde{S}_{\infty,\mathbf{l}}^{\text{odd}}$. Assume first that $\|\mathbf{l}\| > \bar{l}$. Then $\text{Ev}_p(f)(B) \in \text{Ev}_p(f)(S_{\infty,\bar{l}})$, so that $\text{Ev}_p(f)(B) \in \text{Ev}_p(f)(S_{k(\bar{l}),\bar{l}})$. Therefore $\text{Ev}_p(f)(B)$ is a linear combination of vectors $\text{Ev}_p(f)(C_i)$, where the C_i are in $S_{k(\bar{l}),\bar{l}}$.

But then

$$(7.28) \quad \hat{\delta}_\theta(C_i) \leq \frac{k(\bar{l})}{\theta} + \bar{l} < \bar{l} + 1 \leq |\mathbf{l}| \leq \hat{\delta}_\theta(B).$$

Next assume that $|\mathbf{l}| \leq \bar{l}$ and \mathbf{l} is even. By (7.25) and (7.27), $\text{Ev}_p(\mathbf{f})(\beta(B))$ is a linear combination of vectors $\text{Ev}_p(\mathbf{f})(C_i)$ with $C_i \in S_{k(\lambda), \lambda}$, where $\lambda = |\mathbf{l}| - 1$. But then

$$(7.29) \quad \hat{\delta}_\theta(C_i) \leq \frac{k(\lambda)}{\theta} + \lambda < \lambda + 1 = |\mathbf{l}| < \hat{\delta}_\theta(B).$$

The proof of Theorem 7.3 is now complete.

Theorem 7.3 contains as a particular case a result for single-input systems was conjectured by H. Hermes and proved by us in [25]. Precisely, the Hermes condition (HC) for a system

$$(7.30) \quad \dot{x} = f(x) + ug(x), \quad |u| \leq 1,$$

at a point p , is the condition that, if B is an arbitrary bracket of f 's and g 's with an even number of g 's, then $B(p)$ is a linear combination of values at p of brackets with fewer g 's. (In particular, by taking $B = f$, we see that the HC implies that $f(p) = 0$.) The result proved in [25] says that, if the system (7.14) satisfies the LARC and the HC at p , then it is STLC from p . If we apply Theorem 7.3 with $m = 1$ (in which case, of course, the symmetrization operator β is just the identity), we obtain a strengthened version of the theorem of [25]. The HC corresponds to $\theta = \infty$ whereas Theorem 7.3 allows other values of θ . Moreover, even if we apply Theorem 7.3 with $\theta = \infty$, the condition that has to be satisfied to get controllability is weaker than the HC, and therefore the resulting controllability theorem is stronger. (The HC demands that *every* bracket with an even number of g 's be neutralized, whereas our result only requires this for brackets with an even number of g 's *and an odd number of f 's*. As will be shown in examples below, these refinements make it possible to handle cases where the HC is insufficient.)

For general m , R. Grossmann [8] states a sufficient condition for controllability, namely, that every bracket where each of the f_i for $i = 1, \dots, m$ occurs an even number of times be expressible, at p , as a linear combination of brackets of lower total degree. This condition amounts to a weaker form of the case $\theta = 1$ of our theorem. (Theorem 7.3 only requires that the symmetrized brackets, which in addition have an odd number of f_0 's, be expressible as linear combination of lower-degree elements.)

7.4. Low order sufficient conditions for systems with a cubic control set. We now illustrate the use of Theorem 7.3 by deriving some sufficient conditions for systems of the form (7.14), in terms of brackets of low degree. Assume that p is an equilibrium point of (7.14), i.e. that $f_0(p) = 0$. Also, assume that (7.14) satisfies the LARC at p . The simplest sufficient condition for STLC is the one obtained from the Pontryagin Maximum Principle, which says that (7.14) is STLC from p if, for every $\varepsilon > 0$, the adjoint equation along the trajectory $t \rightarrow x(t) = p$, $0 \leq t \leq \varepsilon$, has no nontrivial solution $t \rightarrow \lambda(t)$ such that $\langle \lambda(t), f_i(p) \rangle = 0$ for $0 \leq t \leq \varepsilon$. The adjoint equation in this case, written in coordinates, is simply the equation

$$(7.31) \quad \dot{\lambda} = -\lambda A,$$

where A is the Jacobian matrix of f_0 at 0. If $\lambda(\cdot)$ is a solution of (7.31) such that $\langle \lambda(t), f_i(p) \rangle \equiv 0$, then $\langle \lambda(0), A^k f_i(p) \rangle = 0$ for all k . Hence, if the vectors $A^k f_i(p)$ $i = 1, \dots, m$, $k = 0, 1, \dots$ span $T_p M$, there will not exist a $\lambda(\cdot)$ with the desired properties, and so

(7.14) will be STLC from p . Clearly, $A^k f_i(p) = (\text{ad } f_0)^k(f_i)(p)$. Therefore the sufficient condition obtained from the Maximum Principle simply says that (7.14) will be STLC from p if the vectors $(\text{ad } f_0)^k(f_i)(p)$, $i = 1, \dots, m$, $k = 0, 1, \dots$ span $T_p M$. Theorem 7.3 implies a stronger result, namely

PROPOSITION 7.4. *Assume that $f_0(p) = 0$, and the vectors $(\text{ad } f_0)^k(f_i)(p)$, $i = 1, \dots, m$, $k = 0, 1, \dots$, together with the vectors $[f_i, f_j](p)$, $i, j \in \{1, \dots, m\}$, span $T_p M$. Then (7.14) is STLC from p .*

Proof. Our hypotheses imply in particular that (7.14) satisfies the LARC from p . Let $\mu > 0$ be such that the span of the vectors $(\text{ad } f_0)^k(f_i)(p)$, $i \in \{1, \dots, m\}$, $k = 0, 1, \dots$, is actually spanned by vectors of this same form with $k \leq \mu$. Pick θ such that $\mu \leq \theta < \infty$. Then $T_p M$ is spanned by vectors $\text{Ev}_p(\mathbf{f})(B)$, where the B 's are brackets such that $\hat{\delta}_\theta(B) \leq 2$. On the other hand, if C is any bracket with an odd number of X_0 's and an even number of X_i 's for each $i \in \{1, \dots, m\}$, then either $B = X_0$, in which case $\text{Ev}_p(\mathbf{f})(B) = 0$, or $\hat{\delta}_\theta(B) > 2$, in which case $\text{Ev}_p(\mathbf{f})(C)$ is certainly a linear combination of vectors $\text{Ev}_p(\mathbf{f})(B)$ with $\hat{\delta}_\theta(B) < \hat{\delta}_\theta(C)$. Hence the conditions of Theorem 7.3 are satisfied, and (7.14) is STLC from p .

If the sufficient condition of Proposition 7.4 is not satisfied, then it will be necessary to "neutralize" some brackets in order to be able to apply Theorem 7.3. The lowest total degree d where there may exist brackets to be neutralized is $d = 3$. (The case $d = 1$ is disposed of by the assumption that $f_0(p) = 0$.) The only brackets of total degree 3 where X_0 occurs an odd number of times, and each of the other X_i 's an even number of times, are the expressions $[X_i, [X_i, X_0]]$. Symmetrization yields the element

$$(7.32) \quad H = \sum_{i=1}^m [X_i, [X_i, X_0]].$$

We write $h = \text{Ev}(\mathbf{f})(H)$.

If h is "neutralized," in the sense that $h(p)$ is a linear combination of vectors $g_j(p)$, where the g_j are brackets of "lower degree," then that "releases" a whole collection of new brackets. If these brackets now span $T_p M$, then we get controllability again. Exactly which brackets are released by the neutralization of h will depend on how h is neutralized. Suppose that

$$(7.33) \quad h(p) = \sum_{i=1}^m \sum_{k=0}^{\nu} \alpha_{ik} (\text{ad } f_0)^k(f_i)(p) + \sum_{i=1}^m \sum_{j=1}^m \beta_{ij} [f_i, f_j](p)$$

for some choice of coefficients α_{ik}, β_{ij} .

Then, if we choose any θ such that $\theta \geq 1$, $\theta > \nu - 1$, we see that $\text{Ev}_p(\mathbf{f})(H)$ is a linear combination of vectors $\text{Ev}_p(\mathbf{f})(B)$ with $\hat{\delta}_\theta(B) < \hat{\delta}_\theta(H)$. The next value of the total degree d for which there may be brackets B to be neutralized is $d = 5$. And the lowest possible value $\hat{\delta}_\theta(B)$ for such brackets is $2 + (3/\theta)$. If the brackets for which $\hat{\delta}_\theta < 2 + (3/\theta)$ span $T_p M$, the system will be STLC from p . So we get

PROPOSITION 7.5. *Assume that (i) $f_0(p) = 0$, (ii) (7.33) holds for some ν and some choice of coefficients α_{ik}, β_{ij} . Assume that there is a number $\theta \in [1, \infty]$ such that $\theta > \nu - 1$, with the property that the brackets B with $k_1 f_0$'s and $k_2 f_i$'s with $i > 0$ for all k_1, k_2 such that $k_1 + \theta k_2 < 2\theta + 3$, span $T_p M$. Then (7.14) is STLC from p .*

As a simple example, suppose that $h(p) = 0$ or, more generally, that (7.33) holds with $\nu = 1$. Then θ can be chosen to be an arbitrary number in $[1, \infty]$. In particular, we can conclude that the system (7.14) is STLC from p if either (i) $T_p M$ is spanned by all the brackets of total degree ≤ 4 or (ii) $T_p M$ is spanned by all the brackets with $\delta^+ = 1$, $\delta^0 \leq 4$, together with those with $\delta^+ = 2$, $\delta^0 \leq 2$, those with $\delta^+ = 3$ and $\delta^0 \leq 1$,

and those with $\delta^+ = 4$ and $\delta^0 = 0$, or (iii) $T_p M$ is spanned by the brackets with $\delta^+ = 1$, $\delta^0 \leq 5$, together with those with $\delta^+ = 2$, $\delta^0 \leq 2$, and those with $\delta^+ = 3$, $\delta^0 = 0$, or (iv) $T_p M$ is spanned by the brackets with $\delta^+ = 1$, δ^0 arbitrary, together with those with $\delta^+ = 2$, $\delta^0 \leq 2$. (Here, for a bracket B , $\delta^i(B)$ is the number of occurrences of f^i in B , and $\delta^+(B) = \sum_{i=1}^m \delta^i(B)$. The four results stated above are obtained by taking, respectively, $\theta = 1$, $\theta = 1.1$, $\theta = 2.2$, and θ very large.) If (7.33) holds with $\nu = 2$, then we have to choose $\theta > 1$, and so we can conclude that (7.14) is STLC from p if (ii), (iii) or (iv) above hold. If (7.33) holds with $\nu = 3$, then we must choose $\theta > 2$, and we get that (7.14) is STLC from p if (iii) or (iv) hold. Finally, if (7.33) holds with some $\nu \geq 4$, we get small-time local controllability if (iv) holds.

Notice, in particular, that if H is neutralized, in the sense that (7.33) holds for some ν , then this has the effect of unconditionally releasing a number of brackets, namely, all the brackets with $\delta^+ = 2$, $\delta^0 \leq 2$.

Finally, we illustrate the result of Theorem 7.3 in the case $m = 2$, by giving some simple sufficient conditions in terms of brackets up to degree 6. The algebra to be considered here is $L(X_0, X_1, X_2)$. The homogeneous components $L^{j,\text{hom}}(X_0, X_1, X_2)$ have dimensions 3, 3, 8, 18, 48, 116, for $j = 1, 2, 3, 4, 5, 6$, respectively. So there is a total of 196 potentially linearly independent brackets of degree ≤ 6 . After we eliminate those brackets that are totally even, or odd in either X_1 or X_2 , and symmetrize, we are left with exactly eight linearly independent elements to be neutralized, namely, (a) X_0 , (b) H , and (c) six elements $B_1, B_2, B_3, B_4, B_5, B_6$ of degree five, given by

$$(7.34) \quad B_1 = [[X_1, X_2], [[X_1, X_2], X_0]],$$

$$(7.35) \quad B_2 = \sum_{i=1}^2 [X_i, (\text{ad } X_0)^3(X_i)],$$

$$(7.36) \quad B_3 = \sum_{i=1}^2 [[X_0, X_i], [X_0, [X_0, X_i]]],$$

$$(7.37) \quad B_4 = \sum_{i=1}^2 (\text{ad } X_i)^4(X_0),$$

$$(7.38) \quad B_5 = [X_1, [X_1, [X_2, [X_0, X_2]]]] + [X_2, [X_2, [X_1, [X_0, X_1]]]],$$

$$(7.39) \quad B_6 = [[X_0, X_1], [X_2, [X_1, X_2]]] + [[X_0, X_2], [X_1, [X_2, X_1]]].$$

If we apply Theorem 7.3 with $\theta = 1$, we can conclude that our system is STLC from p if the brackets of total degree ≤ 6 span $T_p M$, provided that (i) $f_0(p) = 0$, (ii) $h(p)$ is a linear combination of values at p of brackets of degree < 3 , (iii) each vector $\text{Ev}_p(f)(B_i)$, $i = 1, \dots, 6$, is a linear combination of values at p of brackets of degree < 5 .

7.5. Two single-input examples. We now analyze from the point of view of Theorem 7.3 two examples where the Hermes condition fails to hold but the system is STLC from p .

In [22], G. Stefani discusses an example of a system $\dot{x} = f(x) + ug(x)$ which is STLC from 0 even though (a) the Hermes condition is not satisfied, (b) the first bracket B needed to span the whole tangent space is one where g occurs four times. (This shows that not all brackets that are even in g are obstructions to local controllability.) We will show that Stefani's example fits the framework of our Theorem 7.3, since B is also even in f , and therefore there is no need for it to be neutralized. Stefani's example is the system $\dot{x} = u$, $\dot{y} = x$, $\dot{z} = x^3 y$, in \mathbb{R}^3 , with control constraint $|u| \leq 1$. Then

$g = (1, 0, 0)$, $f = (0, x, x^3y)$. The relevant Lie brackets are as follows:

$$\begin{aligned} [g, f] &= (0, 1, 3x^2y), [f, [g, f]] = (0, 0, 2x^3), \\ [g, [g, f]] &= (0, 0, 6xy), [f, [f, [g, f]]] = 0, \\ [g, [f, [g, f]]] &= [f, [g, [g, f]]] = (0, 0, 6x^2), \\ [g, [g, [g, f]]] &= (0, 0, 6y), \\ [g, [g, [f, [g, f]]]] &= (0, 0, 12x), \\ [g, [g, [g, [f, [g, f]]]] &= (0, 0, 12). \end{aligned}$$

(We omit brackets that vanish or that are trivially expressed in terms of the ones listed here.) In particular, the vectors $g(0)$ and $[g, f](0)$ span a two-dimensional space S . If B is any bracket of f 's and g 's of degree ≤ 5 , then $B(0) \in S$. In particular, if we take $\theta = 1$ in Theorem 7.3, we see that every bracket of degree 3 or 5 is equal, when evaluated at 0, to a linear combination of brackets of lower degree. If we now add the bracket $[g, [g, [g, [f, [g, f]]]]$, which has degree 6, we span the whole space. Notice that, since this bracket is of even total degree, Theorem 7.3 does not require that it be neutralized. Hence Theorem 7.3 implies the fact—proved by Stefani—that this system is STLC from 0.

The preceding example shows that it is possible for controllability to be achieved thanks to the effect of some brackets that are even in g , so that not all such brackets are “obstructions.” We now briefly review another example, already discussed in [25], which shows that a bracket which is even in g may be “neutralized” by a bracket with more g 's but lower total degree. Consider the system $\dot{x} = u$, $\dot{y} = x$, $\dot{z} = x^3 + y^2$, $|u| < 1$. Here $f = (0, x, x^3 + y^2)$ and $g = (1, 0, 0)$. The vectors $g(0)$ and $[f, g](0)$ span a two-dimensional space S , and all the $(\text{ad } f)^k g(0)$, $k \geq 2$, are in S . The vector $[g, [f, g]](0)$ belongs to S . However, $[g, [f, [f, [g, f]]]](0)$ is not in S , so that the Hermes condition fails to hold. On the other hand, $[g, [g, [g, f]]](0)$ is not in S either, and therefore we can apply Theorem 7.3 with $\theta = 1$ and conclude that our system is STLC from 0.

7.6. Polynomial control systems. In [14], V. Jurdjevic studied control problems of the form

$$(7.40) \quad \dot{x} = P(x) + \sum_{i=1}^m u_i b_i, \quad u = (u_1, \dots, u_m) \in K,$$

where the state variable x takes values in \mathbb{R}^n , $P: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a polynomial map each of whose components is homogeneous of degree d , and K is either a cube centered at 0 (the “restricted controls” case) or the whole space \mathbb{R}^m (the “unrestricted case”).

Jurdjevic proved that, if d is odd, then (7.40) is STLC from 0 if and only if $S = \mathbb{R}^n$, where S is the smallest linear subspace of \mathbb{R}^n which is invariant under the map P and contains b_1, \dots, b_m . Moreover, in the unrestricted case it follows that every $x \in \mathbb{R}^n$ can be reached from 0 in time T , for every $T > 0$. We show that this result follows from our general theorem. Actually, we show that it follows from Brunovsky's theorem on odd systems. First we observe that, if d is odd, then (7.40) is an “odd system” in Brunovsky's sense. Therefore, the characterization of small-time local controllability from 0 will follow if we show that the Lie algebra L generated by the vector fields $x \rightarrow P(x)$, $x \rightarrow b_i$, $x \rightarrow -b_i$ satisfies $L(0) = S$.

It follows from the definition of S that, if $x \in S$, then all the vectors b_i belong to S , and so does $P(x)$. Therefore all the members of L are tangent to S , and so $L(0) \subseteq S$. On the other hand, if $Q: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a polynomial map and v is a vector in \mathbb{R}^n , then

the Lie bracket $[v, Q]$, of the constant vector field $x \rightarrow v$ and the vector field $x \rightarrow Q(x)$, is the vector field $x \rightarrow D_v Q(x)$, where $D_v Q(x)$ is the directional derivative of Q at x in the direction of v . In particular, this implies that $(\text{ad } v)^d(P)$ is the constant vector field $x \rightarrow P(v)$. Hence, if we let Σ be set of all vectors v such that the constant vector field $x \rightarrow v$ belongs to L , we see that Σ is invariant under the map P . Therefore $S \subseteq \Sigma$. This implies that $S \subseteq L(0)$, and so $L(0) = S$.

To complete the proof, we must show that, in the unrestricted case, the condition $S = \mathbb{R}^n$ implies that the time T reachable sets are equal to \mathbb{R}^n for all $T > 0$. Assume that $S = \mathbb{R}^n$. Let $T > 0$. Then we already know that there is a neighborhood U of 0 that can be reached in time T . Let $p \in \mathbb{R}^n$. Pick r such that $0 < r < 1$ and $rp \in U$. Let $t \rightarrow x(t)$ be a trajectory such that $x(0) = 0$, $x(r^{1-d}T) = rp$. (Since rp is reachable in time T , $r^{1-d} \geq 1$, and 0 is an equilibrium, it follows that rp is also reachable in time $r^{1-d}T$.) Let $y(t) = r^{-1}x(r^{1-d}t)$ for $0 \leq t \leq T$. Then $y(0) = 0$, $y(T) = p$. Let u_1, \dots, u_m be functions on $[0, r^{d-1}T]$ such that

$$\dot{x}(s) = P(x(s)) + \sum_{i=1}^m u_i(s)b_i \quad \text{for } 0 \leq s \leq r^{d-1}T.$$

Then

$$y(t) = r^d P(x(r^{1-d}t)) + \sum_{i=1}^m r^{-d} u_i(t) b_i,$$

i.e.

$$\dot{y}(t) = P(y(t)) + \sum_{i=1}^m r^{-d} u(t) b_i.$$

Since $t \rightarrow (r^{-d}u_1(t), \dots, r^{-d}u_m(t))$ is an admissible control, it follows that p is reachable from 0 in time T .

7.7. Low order conditions with a general polyhedral control set. Consider a finite sequence $\mathcal{V} = (V_1, \dots, V_m)$ of vector fields on a manifold M . We want conditions for \mathcal{V} to be STLC from a point p . Equivalently, we want to know when the system

$$(7.41) \quad \dot{x} = \sum_{i=1}^m w_i V_i(x), \quad w = (w_1, \dots, w_m) \in J$$

is STLC from p , where J is the set of vectors $(0, 0, \dots, 0, 1, 0, \dots, 0) \in \mathbb{R}^m$.

Let $S_0(\mathcal{V}, p)$ denote the convex hull of the vectors $V_1(p), \dots, V_m(p)$. Let $I_0(\mathcal{V}, p)$ denote the largest subset I of the index set $\{1, \dots, m\}$, such that 0 is a convex combination of the vectors $V_i(p)$, $i \in I$, with strictly positive coefficients. In [24], we proved that, if (7.41) is STLC from p , then $I_0(\mathcal{V}, p)$ has to be nonempty and, moreover, there have to exist indices $i \in I_0(\mathcal{V}, p)$ such that $V_i(p) \neq 0$. The main result of [24] was a sufficient condition for (7.41) to be STLC from p . Let $S_1(\mathcal{V}, p)$ denote the convex hull of the vectors $V_i(p)$, $i \in \{1, \dots, m\}$, $[V_i, V_j](p)$, $i, j \in I_0(\mathcal{V}, p)$. The result of [24] says that, if $S_1(\mathcal{V}, p)$ contains a neighborhood of the origin in the full tangent space $T_p M$, then (7.14) is STLC from p . We now show that this result, as well as some stronger conditions, can be derived from Corollary 7.2.

First, we observe that, instead of (7.41), we can consider the system

$$(7.42) \quad \dot{x} = \sum_{i=1}^m w_i V_i(x), \quad w = (w_1, \dots, w_m) \in K_m,$$

where K_m is the convex hull of J and the vector $(0, 0, \dots, 0)$. (Indeed, let \tilde{J} be the union of J and $\{(0, \dots, 0)\}$. It is clear that, if small-time local controllability holds with J replaced by \tilde{J} , then it holds for the system (7.41). On the other hand, Proposition 2.3 says that \tilde{J} can be replaced by its convex hull as well.)

Let us assume that the origin is an interior point of $S_1(\mathcal{V}, p)$. Also, let us relabel the indices so that $I_0(\mathcal{V}, p) = \{1, \dots, \mu\}$, where $2 \leq \mu \leq m$.

Then we can express 0 as a convex combination

$$(7.43) \quad 0 = \sum_{i=1}^{\mu} \lambda_i V_i(p), \quad \lambda_i > 0, \quad \sum_{i=1}^{\mu} \lambda_i = 1.$$

On the other hand, the hypothesis that 0 is an interior point of $S_1(\mathcal{V}, p)$ implies that: (i) *the vectors $V_1(p), \dots, V_m(p)$, together with the $[V_i, V_j](p)$, for $i = 1, \dots, \mu$; $j = 1, \dots, \mu$ span the tangent space $T_p M$* , (ii) *it is possible to express 0 as a convex combination*

$$(7.44) \quad 0 = \sum_{i=1}^m \alpha_i V_i(p) + \sum_{1 \leq i < j \leq \mu} \beta_{ij} [V_i, V_j](p)$$

where the α_i, β_{ij} are strictly positive, and $\sum \alpha_i + \sum \beta_{ij} = 1$.

(To see that (ii) follows, pick $\delta > 0$ so small that $-\delta Z(p) \in S_1(\mathcal{V}, p)$ whenever $Z = V_i$ for some i or $Z = [V_i, V_j]$ for some $i, j \in \{1, \dots, \mu\}$. Then each $-\delta V_i(p)$, $i \in \{1, \dots, m\}$, can be written as a convex combination of the $V_j(p)$, $j \in \{1, \dots, m\}$, and the $[V_j, V_k](p)$, $j, k \in \{1, \dots, \mu\}$. So 0 can be written as a linear combination of these same vectors in which all the coefficients are nonnegative and the coefficient of $V_i(p)$ is strictly positive. The same is true for $[V_i, V_j](p)$, if $i, j \in \{1, \dots, \mu\}$. If we then add all these expressions and divide by the sum of the coefficients, we obtain an expression of the desired form.)

Now define $f_0 = 0, f_i = \lambda_i V_i$ for $i = 1, \dots, \mu, f_i = \alpha_i V_i$ for $i = \mu + 1, \dots, m$. Consider the system

$$(7.45) \quad \dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x), \quad u = (u_1, \dots, u_m) \in K_m.$$

It is clear that every trajectory of (7.45) is a trajectory of (7.42). Hence it suffices to prove that (7.45) is STLC from p .

To prove that (7.45) is STLC from p , we work with the free Lie algebra $L(X_0, \dots, X_m)$. We let Λ_0 be the group of all automorphisms g_π of $L(X_0, \dots, X_m)$ that are induced by a permutation π of the indices $\{0, \dots, m\}$ that satisfies $\pi(0) = 0, \pi(\{1, \dots, \mu\}) = \{1, \dots, \mu\}$. It is clear that all the g_π are input symmetries. We define dilations $\Delta(p)$ by assigning Δ -degree one to X_0, \dots, X_μ , and Δ -degree δ to $X_{\mu+1}, \dots, X_m$, where δ is some number such that $2 < \delta < 3$.

We now show that all the totally odd Λ_0 -fixed elements of $L(X_0, \dots, X_m)$ are Δ -neutralized for \mathbf{f} at p . Since $f_0(p), \dots, f_m(p)$, and the $[f_i, f_j](p)$ with $i, j \in \{1, \dots, \mu\}$ span $T_p M$, it is clear that $T_p M$ is spanned by the evaluations at \mathbf{f}, p of elements of $L(X_0, \dots, X_m)$ of Δ -degree not greater than δ . Among these, the Λ_0 -fixed elements of Δ -degree one are spanned by X_0 and $X_1 + \dots + X_\mu$. But

$$(7.46) \quad f_0(p) = (f_1 + \dots + f_\mu)(p) = 0,$$

and so these elements are neutralized. The elements of Δ -degree 2 are totally odd and therefore need not be considered. The Λ_0 -fixed elements of Δ -degree δ are spanned by $X_{\mu+1} + \dots + X_m$, and (7.44) shows that $f_{\mu+1}(p) + \dots + f_m(p)$ is equal to the value at p of an element of Δ -degree $< \delta$. Hence Corollary 7.2 can be applied. This completes the proof that the result of [24] is a particular case of Corollary 7.2.

It should be clear from the preceding proof that one can get more sophisticated results by just applying the same method. A detailed analysis of what can be so obtained will be the subject of a future paper. At the moment, we limit ourselves to two examples. In these examples, if $\lambda_1, \dots, \lambda_\mu$ are such that (7.43) holds, we let g_1, g_2 denote the vector fields

$$(7.47) \quad g_1 = \lambda_1 V_1 + \dots + \lambda_\mu V_\mu,$$

$$(7.48) \quad g_2 = \sum_{i=1}^{\mu} \lambda_i^2 (\text{ad } V_i)^2(g_1).$$

(That is, $g_1 = f_1 + \dots + f_\mu$, $g_2 = \sum_{i=1}^{\mu} [f_i, [f_i, g_1]]$.)

Then, if (7.43) holds, the system (7.41) is STLC from p if one of the following conditions holds:

- (I) (a) $g_2(p)$ is a linear combination of the vectors $V_i(p)$, $i \in \{1, \dots, \mu\}$ and the $[V_i, V_j](p)$, $i, j \in \{1, \dots, \mu\}$,
- (b) 0 is a convex combination, with strictly positive coefficients, of the $V_i(p)$, $i \in \{1, \dots, m\}$, the $[V_i, V_j](p)$, $i, j \in \{1, \dots, \mu\}$, and the $[V_i, [V_j, V_k]](p)$, $i, j, k \in \{1, \dots, \mu\}$,
- (c) $T_p M$ is spanned by the $V_i(p)$, $i \in \{1, \dots, m\}$, the $[V_i, V_j](p)$, $i \in \{1, \dots, m\}$, $j \in \{1, \dots, \mu\}$, the $[V_i, [V_j, V_k]](p)$, $i, j, k \in \{1, \dots, \mu\}$, and the $[V_i, [V_j, [V_k, V_l]]](p)$, $i, j, k, l \in \{1, \dots, \mu\}$;
- (II) (a) 0 is a convex combination with strictly positive coefficients of the $V_i(p)$, $i \in \{1, \dots, m\}$ and the $[V_i, V_j](p)$, $i, j \in \{1, \dots, \mu\}$,
- (b) $g_2(p)$ is a linear combination of the $V_i(p)$, $i \in \{1, \dots, m\}$ and the $[V_i, V_j](p)$, $i, j \in \{1, \dots, \mu\}$,
- (c) $T_p M$ is spanned by the $V_i(p)$, $i \in \{1, \dots, m\}$, the $[V_i, V_j](p)$, $i, j \in \{1, \dots, m\}$, the $[V_i, [V_j, V_k]](p)$, where i, j, k are in $\{1, \dots, \mu\}$, and the $[V_i, [V_j, [V_k, V_l]]](p)$, $i, j, k, l \in \{1, \dots, \mu\}$.

To see that (I) implies small-time local controllability from p , we reason as before, but with $3 < \delta < 4$. Condition (c) of (I) says that $T_p M$ is spanned by the brackets of Δ -degree not greater than $1 + \delta$. The Λ_0 -fixed elements of Δ -degree one are spanned by X_0 and $X_1 + \dots + X_\mu$, which are obviously neutralized, since $f_0 \equiv 0$ and (7.43) holds. The Λ_0 -fixed elements of Δ -degree 2 do not matter, because they are totally even. In Δ -degree 3 there is only one Λ_0 -fixed element, namely G_2 , where we let $G_1 = X_1 + \dots + X_\mu$, $G_2 = \sum_{i=1}^{\mu} [X_i, [X_i, G_1]]$. Condition (a) then says that this element is neutralized. In Δ -degree δ there is one Λ_0 -fixed element, namely, $X_{\mu+1} + \dots + X_m$. Condition (b) then says that this element is neutralized. Finally, all the elements of Δ -degree 4 or $1 + \delta$ are totally even, and therefore need not be considered.

To see the sufficiency of (II) we again use the same argument, with δ such that $2 < \delta < 2.5$. Then condition (c) says that $T_p M$ is spanned by evaluations of brackets of Δ -degree not greater than 2δ . The possible Δ -degrees of such brackets are 1, 2, δ , 3, $1 + \delta$, 4, $2 + \delta$ and 2δ . The only Δ -degrees where totally odd brackets occur are 1, δ , 3 and $2 + \delta$. In Δ -degree 1, the Λ_0 -fixed elements are X_0 and $X_1 + \dots + X_\mu$, which are neutralized. In degree δ , the Λ_0 -fixed element is $X_{\mu+1} + \dots + X_m$, which is neutralized by condition (a). In Δ -degree 3, the Λ_0 -fixed element is G_2 , which is neutralized by condition (b). So Corollary 7.2 applies, and small-time local controllability follows.

8. Conclusion. The main implication of the results proven here is that, so far, one method appears to suffice to prove most known small-time local controllability results. It seems to us that this method is still very special, and it should be possible to obtain better results by making a more detailed analysis of the semigroups $S^N(X, K)$.

One important application of the theory developed in this paper is to the problem of High Order Optimality Conditions. Small-time local controllability is a particular instance of this general problem, in which we are concerned with finding sufficient conditions for a particular trajectory (given by $x(t) \equiv p = \text{constant}$) to lie in the interior of the attainable set from p , which is the same as finding necessary conditions for the trajectory to lie on the boundary of the reachable set. The methods of this paper can be used to prove results on the construction of control variations for more general trajectories, and to obtain necessary conditions for optimality. The results will be reported in subsequent papers.

Appendix.

Proof of Proposition 2.3. Clearly, all that needs to be shown is that, if $\tilde{\Sigma}$ is STLC from p , it follows that Σ is STLC_{pc} from p . Suppose that $\tilde{\Sigma}$ is STLC from p . Let $T > 0$. Pick T' such that $0 < T' < T$, and let U be an open set such that $p \in U$ and $U \subseteq \text{Reach}(\tilde{\Sigma}, \leq T', p)$. Shrink U , if necessary, so that $L(f)(q)$ is the full tangent space at q for every $q \in U$. Let $q \in U$. Let \mathcal{F}_{Σ} be the family of vector fields associated with Σ , and let $-\mathcal{F}_{\Sigma} = \{-V : V \in \mathcal{F}_{\Sigma}\}$. Then $L(f) = L(\mathcal{F}_{\Sigma}) = L(-\mathcal{F}_{\Sigma})$. Let \mathcal{H} be the family of restrictions to U of the members of $-\mathcal{F}_{\Sigma}$. Then \mathcal{H} has the AP from q . So there is a nonempty open subset W of U such that every $r \in W$ is reachable from q by an \mathcal{H} -trajectory in time not greater than $T - T'$, so that q is reachable from every $r \in W$ by an \mathcal{F}_{Σ} -trajectory in time not greater than $T - T'$.

Now pick an $r \in W$. Since $W \subseteq U$, r is reachable from p in time τ , for some $\tau \in [0, T']$ by means of a trajectory of $\tilde{\Sigma}$ that corresponds to a control $u(\cdot) : [0, \tau] \rightarrow \tilde{K}$. Then $u(\cdot)$ can be approximated in $L^1([0, \tau], \mathbb{R}^m)$ by a sequence $\{u_n(\cdot)\}$ of piecewise constant K -valued controls. If $x_n(\cdot)$ is the trajectory for $u_n(\cdot)$ such that $x_n(0) = p$, and we let $r_n = x_n(\tau)$, then $r_n \in W$ for sufficiently large n . Therefore W contains a point r' which is reachable from p in time τ by means of a piecewise constant \tilde{K} -valued control. Let $\text{co}(K)$ denote the convex hull of K . Since \tilde{K} is the closure of $\text{co}(K)$, every piecewise constant \tilde{K} -valued control can be approximated in $L^1([0, \tau], \mathbb{R}^m)$ by piecewise constant $\text{co}(K)$ -valued controls. Therefore W must contain a point r'' which is reachable from p in time τ by means of a piecewise constant $\text{co}(K)$ -valued control. Finally, a piecewise constant $\text{co}(K)$ -valued control can be approximated weakly by piecewise constant K -valued controls. Hence W contains a point r''' which is reachable from p in time τ by a piecewise constant K -valued control. So $r''' \in \text{Reach}_{pc}(\Sigma, \leq T', p)$. Since $q \in \text{Reach}_{pc}(\Sigma, \leq (T - T'), r''')$, we conclude that $q \in \text{Reach}_{pc}(\Sigma, \leq T, p)$. Since q was an arbitrary point of U , we see that $U \subseteq \text{Reach}_{pc}(\Sigma, \leq T, p)$. Since U is open, $p \in U$, and T was an arbitrary positive number, it follows that Σ is STLC_{pc} from p .

Acknowledgments. We thank an anonymous referee for very helpful suggestions and remarks. Also, we are especially grateful to Klaus Wagner who read the paper with great care and pinpointed a large number of misprints as well as some mathematical inaccuracies.

MINIMIZING OR MAXIMIZING THE EXPECTED TIME TO REACH ZERO*

D. HEATH†, S. OREY‡, V. PESTIEN§ AND W. SUDDERTH¶

Abstract. We treat the following control problems: the process $X_1(t)$ with values in the interval $(-\infty, 0]$ (or $[0, \infty)$) is given by the stochastic differential equation

$$dX_1(t) = \mu(t) dt + \sigma(t) dW_t, \quad X_1(0) = x_1$$

where the nonanticipative controls μ and σ are to be chosen so that $(\mu(t), \sigma(t))$ remains in a given set \mathcal{S} and the object is to minimize (or maximize) the expected time to reach the origin. The minimization problem had been discussed earlier by Heath, Pestien and Sudderth under various restrictions on the set \mathcal{S} . Here an improved verification lemma is established which is used to solve the minimization and maximization problems for any \mathcal{S} . An application to a portfolio problem is discussed.

Key words. stochastic control, portfolio selection, gambling theory

AMS(MOS) subject classifications. 60G40, 60J60, 93E20

1. Introduction. Consider a real-valued process $\{X_1(t)\}$ given by a stochastic differential equation

$$dX_1(t) = \mu(t) dt + \sigma(t) dW_t, \quad X_1(0) = x_1$$

where $\{W_t\}$ is standard Brownian motion and $\mu(t)$ and $\sigma(t)$ are nonanticipative controls to be chosen so that $(\mu(t), \sigma(t))$ remains in a specified set \mathcal{S} . The problems of minimizing or maximizing the expected time to reach the origin are treated in § 3. The minimization problem has been studied in [9] and [3], though with an exponential change of variables putting the problem on $(0, 1]$. For a more detailed discussion, see Remark 2 in § 3.

The solution of these control problems uses a new refinement of the verification lemma of [9], which is proved in § 2. This result should be of independent interest.

Section 4 deals with a portfolio planning problem which turns out to be a special case of the minimization problem. This portfolio problem was originally solved in [3].

2. Continuous-time stochastic control. The formulation of stochastic control problems given here is adapted from Pestien and Sudderth [9]. Our notation and terminology is the same as theirs, but we consider a more general class of processes and establish a verification lemma more suited to the present applications.

A *continuous-time gambling problem* is a triple (F, Σ, u) where

- (2.1) the *state space* F is Polish (we shall use a Borel subset of ordinary Euclidean space),
- (2.2) the *gambling house* Σ is a mapping which assigns to each $x \in F$ a nonempty collection $\Sigma(x)$ of processes $X = \{X_t, t \geq 0\}$ with state space F such that $X_0 = x$ and X has right-continuous paths with left-limits,
- (2.3) the *utility function* u is a Borel function from F to the real line.

A process $X \in \Sigma(x)$ is said to be *available* at x . Each available X is defined on some probability space (Ω, \mathcal{F}, P) and is adapted to an increasing filtration $(\mathcal{F}_t, t \geq 0)$ of complete sub-sigma fields of \mathcal{F} . The probability space and filtration may depend on X .

A player, starting at position $x \in F$, selects a process $X \in \Sigma(x)$ and receives payoff $u(X)$ defined by

$$(2.4) \quad u(X) = E[\limsup_{t \rightarrow \infty} u(X_t)].$$

The expectation occurring on the right is assumed to be well-defined for every available process X .

The *value function* V is defined by

$$V(x) = \sup \{u(X) : X \in \Sigma(x)\}$$

for every $x \in F$. A process $X \in \Sigma(x)$ is *optimal* at x if

$$u(X) = V(x).$$

From now on we shall require that F be a Borel subset of the Euclidean space \mathbb{R}^d having nonempty interior, and each process $X = \{X_t\}$ under consideration will be an *Ito process* of the form

$$(2.5) \quad X_t = x + \int_0^t \alpha(s) ds + \int_0^t \beta(s) dW_s$$

where $W = \{W_t\}$ is a standard m -dimensional Brownian motion process on (Ω, \mathcal{F}, P) adapted to increasing, right-continuous σ -fields $\{\mathcal{F}_t\}$, and \mathcal{F}_t is independent of $\{W_{t+s} - W_t, s \geq 0\}$. The function $\alpha = \alpha(t, \omega)$ is to be \mathbb{R}^d -valued, progressively measurable, adapted to $\{\mathcal{F}_t\}$ and such that

$$(2.6) \quad \int_0^t |\alpha(s)| ds < \infty \quad \text{a.s. for all } t.$$

The function $\beta = \beta(t, \omega)$ has as values real $d \times m$ matrices, is progressively measurable, adapted to $\{\mathcal{F}_t\}$, and satisfies

$$(2.7) \quad \int_0^t |\beta(s)|^2 ds < \infty \quad \text{a.s. for all } t.$$

For each pair (a, b) , where $a \in \mathbb{R}^d$ is a $d \times 1$ vector and b is a $d \times m$ real-valued matrix, define the differential operator $D(a, b)$ for sufficiently smooth functions $Q : \mathbb{R}^d \rightarrow \mathbb{R}$ by

$$D(a, b)Q(y) = Q_x(y)a + \frac{1}{2} \sum_{i=1}^d \sum_{j=1}^m Q_{x_i x_j}(y)(bb')_{ij}$$

where

$$Q_x(y) = \left(\frac{\partial Q}{\partial x_1}, \dots, \frac{\partial Q}{\partial x_d} \right), \quad Q_{x_i x_j} = \frac{\partial^2 Q}{\partial x_i \partial x_j},$$

and b' is the transpose of b .

We now specify $\Sigma(x)$ by specifying the possible values of α and β . To this end, for each $x \in F$ let $C(x)$ be a nonempty set of pairs (a, b) , where $a \in \mathbb{R}^d$ and b is a real $d \times m$ matrix. (The idea is that $C(x)$ is the set from which a player at state x may choose the value of (α, β) .) Assume also that every available process X is absorbed at the time T_X of its first exit from F° , the interior of F . These conditions define a

function Σ_C on F where $\Sigma_C(x)$ is the collection of all processes X having paths in F and satisfying (2.5), (2.6) and (2.7) together with

$$(2.8) \quad (\alpha(t, \omega), \beta(t, \omega)) \in C(X_t(\omega)) \quad \text{for all } (t, \omega),$$

$$(2.9) \quad (\alpha(t, \omega), \beta(t, \omega)) = (0, 0) \quad \text{for } t \geq T_X(\omega),$$

$$(2.10) \quad C(x) = \{(0, 0)\} \quad \text{for } x \in F - F^\circ.$$

Let Σ be a gambling house such that $\Sigma(x) \subset \Sigma_C(x)$ for every $x \in F$.

The following proposition, which is related to Lemmas 2 and 3 of [9], will be applied in the next two sections.

PROPOSITION. *Let G be an open subset of \mathbb{R}^d which contains F . Suppose $Q: G \rightarrow \mathbb{R}$ and $Q_n: G \rightarrow \mathbb{R}$ for $n = 1, 2, \dots$. Suppose also that each Q_n has continuous second-order derivatives on G and that*

$$(i) \quad \lim_{n \rightarrow \infty} Q_n(x) = Q(x) \quad \text{for every } x \in F.$$

Assume the following conditions for every $x \in F^\circ$ and every $X \in \Sigma(x)$:

(ii) $Q(X) \geq u(X)$ where $Q(X) = E[\limsup_{t \rightarrow \infty} Q(X_t)]$ is assumed to be well-defined.

(iii) There exists a sequence $\{k_n\}$ of nonnegative constants such that $\lim_{n \rightarrow \infty} k_n = 0$ and with probability one, for all n and all $t \geq 0$,

$$D(\alpha(t), \beta(t))Q_n(X_t) \leq k_n.$$

(Here α and β are related to X by (2.5).)

(iv) There exist integrable random variables Z, Y_1, Y_2, \dots such that, for all n and all $t \geq 0$,

$$Z \leq Q_n(X_t) \leq Y_n.$$

Then $Q \geq V$.

The following lemma is the chief tool for the proof of the proposition.

LEMMA. *Suppose $Q: G \rightarrow \mathbb{R}$ has continuous second-order derivatives, $x_0 \in F^\circ$, $X \in \Sigma(x_0)$, and τ is an almost surely finite $\{\mathcal{F}_t\}$ -stopping time. Also assume*

(i) there is a nonnegative constant k such that with probability one, for all $s \geq 0$,

$$D(\alpha(s), \beta(s))Q(X_s) \leq k,$$

(ii) there exist integrable random variables Y and Z such that for all $t \geq 0$,

$$Z \leq Q(X_t) \leq Y.$$

Then

$$EQ(X_\tau) \leq Q(x_0) + kE\tau.$$

Proof. Apply Ito's lemma to write

$$(2.11) \quad Q(X_t) = Q(x_0) - A_t + M_t = Q(x_0) - (kt + A_t) + kt + M_t$$

where

$$A_t = - \int_0^t D(\alpha(s), \beta(s))Q(X_s) ds,$$

$$M_t = \int_0^t Q_x(X_s)\beta(s) dW_s.$$

(Here α and β are related to X by (2.5) and satisfy (2.6) and (2.7).)

Assume without loss of generality that $E\tau < \infty$. Hence,

$$(2.12) \quad EQ(X_\tau) = Q(x_0) + kE\tau + E[M_\tau - (k\tau + A_\tau)].$$

It suffices to show that the final expectation in (2.12) is less than or equal to zero. By condition (i), $-(k\tau + A_\tau) \leq 0$. We will show that $EM_\tau \leq 0$. (Notice that EM_τ is well-defined by the first equality in (2.11) and condition (ii).)

Let T_j be a sequence of stopping times such that $\{M_{t \wedge T_j}, \mathcal{F}_t\}$ is a uniformly integrable martingale for every j and $T_j \rightarrow \infty$ a.s. Let $B_j = [\tau > T_j]$. Then $M_\tau = M_{\tau \wedge T_j}$ on B_j^c , and

$$\begin{aligned} \int_{B_j^c} M_\tau &= \int_{B_j^c} M_{\tau \wedge T_j} = EM_{\tau \wedge T_j} - \int_{B_j} M_{T_j} = 0 - \int_{B_j} [Q(X_{T_j}) + A_{T_j} - Q(x_0)] \\ &\leq \int_{B_j} [-Z + k\tau + Q(x_0)]. \end{aligned}$$

That is,

$$\int_{B_j^c} M_\tau^+ - \int_{B_j^c} M_\tau^- \leq \int_{B_j} [-Z + k\tau + Q(x_0)].$$

Let $j \rightarrow \infty$, and conclude

$$EM_\tau = \int_{\Omega} M_\tau^+ - \int_{\Omega} M_\tau^- \leq \int_{\emptyset} [-Z + k\tau + Q(x_0)] = 0. \quad \square$$

Proof of the proposition. Let $x_0 \in F$ and $X \in \Sigma(x_0)$. By condition (ii) and [9, Lemma 1], it suffices to show

$$(2.13) \quad EQ(X_\tau) \leq Q(x_0)$$

for every almost surely finite stopping time τ .

Assume first that τ is bounded. Then, by the lemma and Fatou's inequality,

$$EQ(X_\tau) \leq \liminf_{n \rightarrow \infty} EQ_n(X_\tau) \leq \lim_{n \rightarrow \infty} Q_n(x_0) + (\lim_{n \rightarrow \infty} k_n)E\tau = Q(x_0).$$

If τ is unbounded, use Fatou's inequality again:

$$EQ(X_\tau) \leq \liminf_{n \rightarrow \infty} EQ(X_{\tau \wedge n}) \leq Q(x_0). \quad \square$$

3. Minimizing or maximizing the expected time to reach zero. The problems described in the Introduction will now be formulated as continuous-time gambling problems in \mathbb{R}^2 . Consider first the problem of minimizing expected time. The first coordinate, x_1 , of the state vector x will correspond to the player's position on $(-\infty, 0]$, while the second coordinate, x_2 , will represent time.

It is convenient to allow negative as well as positive times and define

$$F = \{x \in \mathbb{R}^2: -\infty < x_1 \leq 0\}.$$

Because the object is to minimize expected time, let

$$u(x) = -x_2.$$

Recall the notation from § 2. The interior of F is $F^\circ = (-\infty, 0) \times (-\infty, \infty)$ and by our conventions each available process X will be absorbed at time

$$T = T_X = \inf\{t: X_1(t) = 0\}.$$

In the present example the set $C(x)$ will not depend on x for $x \in F^\circ$. Let $\mathcal{S} \subset \mathbb{R} \times [0, \infty)$,

$$(3.0) \quad C_0 = \left\{ \left(\begin{pmatrix} \mu \\ 1 \end{pmatrix}, \begin{pmatrix} \sigma \\ 0 \end{pmatrix} \right) : (\mu, \sigma) \in \mathcal{S} \right\}$$

and let $C(x) = C_0$ for $x \in F^\circ$. Every $X \in \Sigma_C(x)$ can be specified by stochastic differential equations

$$\begin{aligned} dX_1(t) &= \mu(t) dt + \sigma(t) dW_t, \\ dX_2(t) &= dt, \\ X_1(0) &= x_1, X_2(0) = x_2, \end{aligned} \quad (3.1)$$

where μ and σ are progressively measurable and $(\mu(t), \sigma(t)) \in \mathcal{S}$, $t < T$; and $X_t = X_T$ for $t \geq T$. Note that for every $X \in \Sigma_C(x)$ the second coordinate process $\{X_2(t)\}$ increases deterministically at rate 1 up to time T , and by (2.4) and the definition of u

$$u(X) = -x_2 - ET. \quad (3.2)$$

Now let

$$\begin{aligned} \Sigma(x) &= \{X \in \Sigma_C(x) : u(X) > -\infty\} \\ &= \{X \in \Sigma_C(x) : ET < \infty\}. \end{aligned} \quad (3.3)$$

From (3.2) and (3.3) one sees that

$$V(x_1, x_2) = V(x_1) - x_2 \quad (3.4)$$

where $V(x_1) = V(x_1, 0)$. Furthermore, for $x_1 < y_1 < 0$, a strategy starting at x_1 and minimizing the time to 0 must first minimize the time to y_1 and, having gotten there, minimize the time to 0. This argument leads to $V(x_1) = V(x_1 - y_1) + V(y_1)$. Since V is also continuous and vanishes at the origin, one may conclude

$$V(x_1) = \lambda x_1$$

where $\lambda \geq 0$ depends on \mathcal{S} . (We omit a formal proof because we will not rely on this formula below.)

If in (3.1) $\mu(t) = \mu(X_1(t))$ and $\sigma(t) = \sigma(X_1(t))$, where μ and σ are measurable real-valued functions on $(-\infty, 0)$, we say that X is given by a *stationary Markovian strategy*. For given functions μ and σ then X as defined by (3.1) depends only on the initial conditions, so we may write $u(X) = v(x_1, x_2)$ and from (3.2)

$$v(x_1, x_2) = v(x_1) - x_2 \quad (3.5)$$

where $v(x_1) = v(x_1, 0)$. Now $u(X)$ can be obtained explicitly. Assume for simplicity that μ and σ are piecewise continuous functions, and $\sigma(x_1) \geq \sigma_0 > 0$ for all x_1 . Note that if $\sigma(x_1) \geq \sigma_0 > 0$ and σ and μ are measurable and bounded on compact sets then (3.1) will have a unique weak solution: for μ vanishing this is shown by a time-change argument ([4, Chap. IV, Ex. 4.2]), and for μ not vanishing one uses transformation of drift ([4, Chap. IV, Thm. 4.2]).

By definition $v(x_1)$ is simply the negative of the expected time it takes the diffusion to reach the origin if it is started at x_1 . If $X \in \Sigma(x)$, then T is finite with probability one and $v(x_1)$ is the limit as $M \rightarrow \infty$ of $-v_M(x_1)$, where $v_M(x_1)$ is the expected time to exit the interval $[-M, 0]$. Let us set

$$a(x) = \sigma^2(x).$$

Then v_M is determined by

$$\mu v'_M + \frac{1}{2} a v''_M + 1 = 0, \quad v_M(0) = v_M(-M) = 0.$$

Solving for v'_M and letting $M \rightarrow \infty$ gives

$$v'(x_1) = e^{-B(x_1)} \int_{-\infty}^{x_1} e^{B(z)} \frac{2}{a(z)} dz \quad (3.6)$$

where

$$(3.7) \quad B(x_1) = \int_r^{x_1} \frac{2\mu(y)}{a(y)} dy$$

and r is an arbitrary point in $(-\infty, 0]$. Of course

$$(3.8) \quad v(x_1) = \int_0^{x_1} v'(y) dy.$$

Recall (see, for example, [5]) that the diffusion determined by μ and a has a scale function and speed measure determined respectively by

$$(3.9) \quad dp(x_1) = e^{-B(x_1)} dx_1, \quad dm(x_1) = \frac{2}{a(x_1)} e^{B(x_1)} dx_1.$$

The formulas (3.9) are correct under the same conditions mentioned above for the existence of a unique weak solution. Note first that if p is as in (3.9), $p(X_1(t))$ is a martingale, as can be seen by applying the Ito formula as extended by Krylov [7]. To check the speed measure first consider the case where μ vanishes. Then as remarked above the diffusion can be obtained by a time change of a Brownian motion \tilde{W} , the time change being the inverse of $\phi_t = \int_0^t \sigma^{-2}(\tilde{W}(s)) ds$. Comparing this with the Ito-McKean construction of diffusion we find that the speed measure satisfies $m(dy) = 2\sigma^{-2}(y) dy$, see [2, Thm. 2.123]. When there is drift present consider the drift-free diffusion $Y_t = p(X_1(t))$. From the Ito formula we can read off the diffusion coefficient of Y , hence also the speed measure \tilde{m} for Y and since the speed measure for X_1 is given by $m(dx) = \tilde{m}(p(dx))$ this is now determined and indeed given as in (3.9).

Consider now $\mu(t) \equiv \mu_0$, $\sigma(t) \equiv \sigma_0$, where μ_0 and σ_0 are constants. This will determine a diffusion with $ET < \infty$ if and only if $\mu_0 > 0$, and then

$$(3.10) \quad v(x_1) = \frac{x_1}{\mu_0}$$

which is a special case of (3.6) if $\sigma_0 > 0$ and obvious if $\sigma_0 = 0$.

It is natural, especially in the light of (3.10), to conjecture that an optimal strategy is to choose the drift μ to achieve the supremum

$$M = \sup \{ \mu : (\mu, \sigma) \in \mathcal{S} \text{ for some } \sigma \}.$$

As is explained in Remark 2 below, a similar strategy was proposed by Kelly [6] for certain discrete-time problems. However, these "Kelly strategies" need not be optimal if the set of the possible σ 's is unbounded. The exact criterion for our continuous-time problem involves another quantity

$$I = \inf_{\varepsilon > 0} \sup \{ \mu + \varepsilon \sigma^2 : (\mu, \sigma) \in \mathcal{S} \}.$$

THEOREM 1. *Let $x \in F^\circ$.*

(a) *If $0 < M < \infty$ and $I < \infty$ then $V(x) = x_1/M - x_2$. If in addition $(M, \sigma_0) \in \mathcal{S}$, then the process $X \in \Sigma(x)$ with $\mu(t) \equiv M$ and $\sigma(t) \equiv \sigma_0$ is optimal.*

(b) *If $M \leq 0$ and $I < \infty$ then $V(x) = -\infty$.*

(c) *If $M = \infty$ or $I = \infty$ then $V(x) = -x_2$ (i.e., the origin can be reached in an arbitrarily small expected time.)*

Proof. (a) Let $Q(x) = x_1/M - x_2$. It is clear from (3.5) and (3.10) that $Q \leq V$. It remains to verify that $Q \geq V$. (Once this is done, the final assertion of (a) will follow from (3.5) and (3.10).) This inequality will be proved by applying the proposition of § 2.

For $\delta > 0$, let

$$I(\delta) = \sup \left\{ \mu + \frac{\delta}{2} \sigma^2 : (\mu, \sigma) \in \mathcal{S} \right\},$$

and notice that by condition (a), $I(\delta) < \infty$ for δ sufficiently small. For such δ , let

$$Q^\delta(x) = \frac{e^{x_1 \delta} - 1}{\delta I(\delta)} - x_2.$$

Now verify the conditions of the proposition, with $Q = Q^\delta$ and $Q_n = Q^\delta$ for each n . Condition (i) is automatic and (ii) follows easily. With $k_n = 0$ for each n , it is routine to check that (iii) holds. As to condition (iv), observe that in the formula for $Q^\delta(x)$ the first term on the right is bounded uniformly in x_1 for each fixed δ . So $Q^\delta(X_t)$ is bounded above and below by a constant plus $X_2(t)$, and since $x_2 \leq X_2(t) \leq x_2 + T$ and $X \in \Sigma(x)$ implies that T is integrable, the proposition gives $Q^\delta \geq V$. Finally, because $I(\delta) \rightarrow M$ and $Q^\delta \rightarrow Q$ as $\delta \rightarrow 0$, we have $Q \geq V$.

(b) We reduce the result to (a). Let $\varepsilon > 0$ and consider a new problem based on the set

$$\mathcal{S}_\varepsilon = \mathcal{S} \cup \{(\varepsilon, 0)\}.$$

The quantity corresponding to M for the new problem is $M_\varepsilon = \varepsilon$. Thus part (a) can be applied to obtain the value function

$$V_\varepsilon(x) = \frac{x_1}{\varepsilon} - x_2.$$

Clearly $V(x) \leq V_\varepsilon(x) \rightarrow -\infty$ as $\varepsilon \rightarrow 0$.

(c) If $M = \infty$ the desired conclusion $V(x) = -x_2$ follows easily from (3.10). So assume now that $M < \infty$ and $I = \infty$. Then there exists a sequence (μ_i, σ_i) , with $(\mu_i, \sigma_i) \in \mathcal{S}$, $\sigma_i > 0$, and $\sigma_i \uparrow \infty$ and

$$(3.11) \quad \mu_i \geq -h(a_i)a_i, \quad i = 1, 2, \dots,$$

where $a_i = \sigma_i^2$ and $h(s)$ is a nonnegative function on $[0, \infty)$ which decreases to zero as $s \rightarrow \infty$. Let

$$\sigma(x_1) = \sigma_{i(x_1)}, \quad \mu(x_1) = \mu_{i(x_1)}$$

where i is a function from $(-\infty, 0)$ to the positive integers with $i(x_1)$ increasing rapidly to ∞ as x_1 decreases to $-\infty$. Use (3.6), (3.7) and (3.11) to obtain

$$\begin{aligned} v'(x_1) &= \int_{-\infty}^{x_1} \frac{2}{a(z)} \exp \left(- \int_z^{x_1} \frac{2\mu(y)}{a(y)} dy \right) dz \\ &\geq \int_{-\infty}^{x_1} \frac{2}{a(z)} \exp \left(\int_z^{x_1} h(a(y)) dy \right) dz \\ &\geq \left[\exp \left(\int_{-\infty}^0 h(a(y)) dy \right) \right] \left[\int_{-\infty}^{x_1} \frac{2}{a(z)} dz \right]. \end{aligned}$$

For any $\varepsilon > 0$ we can choose i so that $a(y) = a_{i(y)}$ increases sufficiently fast so that both integrals occurring in the final expression are arbitrarily small. It follows that i can be chosen to make v as small as desired, and then (3.8) gives the desired conclusion. (Notice $T < \infty$ with probability one because $p(-\infty) = -\infty$ by (3.9) and σ is bounded below by σ_1 .) \square

For the maximization problem it seems natural to work on $[0, \infty)$ rather than $(-\infty, 0]$ and to think of maximizing the expected time until bankruptcy occurs. Here is the formal definition of the gambling problem:

$$F = \{x \in \mathbb{R}^2: 0 < x_1 < \infty\},$$

$$u(x) = x_2,$$

$$C(x) = C_0 \quad \text{for } x \in F^\circ$$

where C_0 is given by (3.0),

$$\Sigma(x) = \Sigma_C(x).$$

Then, for $x \in F$ and $X \in \Sigma(x)$,

$$(3.12) \quad u(X) = x_2 + ET$$

where $T = \inf \{t: X_1(t) = 0\}$. As before

$$V(x_1, x_2) = V(x_1) + x_2$$

where

$$V(x_1) = V(x_1, 0).$$

It is natural, as it was for the minimization problem, to conjecture that an optimal strategy will choose μ to achieve

$$M = \sup \{ \mu: (\mu, \sigma) \in \mathcal{S} \text{ for some } \sigma \}.$$

This time the conjecture is essentially correct.

THEOREM 2. *Let $x \in F^\circ$.*

(a) *If $M < 0$, then $V(x) = -x_1/M + x_2$. If in addition $(M, \sigma_0) \in \mathcal{S}$, then the process $X \in \Sigma(x)$ with $\mu(t) \equiv M$ and $\sigma(t) \equiv \sigma_0$ is optimal.*

(b) *If $M \geq 0$, then $V(x) = \infty$.*

Proof. Suppose X is given by a stationary Markov strategy $\mu(t) \equiv \mu_0$, $\sigma(t) \equiv \sigma_0$ where μ_0 and σ_0 are constants. Because we have changed from $(-\infty, 0]$ to $[0, \infty)$, formulas (3.5), (3.10) and (3.12) now imply

$$(3.13) \quad u(X) = \begin{cases} -\frac{x_1}{\mu_0} + x_2 & \text{if } \mu_0 < 0, \\ \infty & \text{if } \mu_0 \geq 0. \end{cases}$$

Part (b) of the theorem is immediate. For (a), let $Q(x) = -x_1/M + x_2$. By (3.13), $Q \leq V$. The reverse inequality will be proved by another application of the proposition of § 2.

Let $\{\beta_n\}$ be a sequence of numbers in the interval $(0, 1)$ which increase up to 1. Define

$$Q_n(x) = \frac{e^{\lambda(\beta_n)x_1} - 1}{\log \beta_n} + x_2 \beta_n^{x_2}$$

where

$$\lambda(\beta) = \frac{-M - \sqrt{M^2 - 2\sigma_0^2 \log \beta}}{\sigma_0^2}$$

and $\sigma_0 > 0$. (The first term on the right-hand side in the definition of $Q_n(x)$ is equal to the expectation of $\int_0^T (\beta_n)^s ds$ for a process $\mu(t) \equiv M$, $\sigma(t) \equiv \sigma_0$ and thus corresponds to a discounted payoff.)

Condition (i) of the proposition is easily verified, and (ii) is obvious because $Q \geq u$. For (iii) let $(a, b) \in C(x)$ where $a = \binom{\mu}{1}$, $b = \binom{\sigma}{0}$ and calculate (with $\beta = \beta_n$)

$$\begin{aligned} D(a, b)Q_n(x) &= \frac{\lambda(\beta) e^{\lambda(\beta)x_1}}{\log \beta} \left(\mu + \frac{1}{2} \lambda(\beta) \sigma^2 \right) + \beta^{x_2} (1 + x_2 \log \beta) \\ &\leq \frac{\lambda(\beta)M}{\log \beta} + \beta^{x_2} (1 + x_2 \log \beta). \end{aligned}$$

The inequality holds because $\mu \leq M$ and $\lambda(\beta) < 0$. Now recall that $X_2(s)$ is an increasing process and (iii) will follow after some calculus. Condition (iv) is an easy consequence of the definition of Q_n together with the facts that $X_1(s) \geq 0$ and $X_2(s) \geq X_2(0)$. \square

Remark 1. Since the set \mathcal{S} is not assumed to be bounded, and the σ with $(\mu, \sigma) \in \mathcal{S}$ are not bounded away from zero, the usual approach via Bellman's equation for the value function V could not be used above. For a continuous time gambling problem as defined in § 2 the Bellman equation can be written in the form

$$(3.14) \quad \sup D(a, b) V(x) = 0$$

where the supremum is taken over all $(a, b) \in C(x)$. For the minimization problem of this section, (3.4) applies and (3.14) becomes

$$(3.15) \quad \sup_{(\mu, \sigma) \in \mathcal{S}} \left[\mu V'(x_1) + \frac{1}{2} \sigma^2 V''(x_1) - 1 \right] = 0.$$

Under condition (c) of Theorem 1 the value function $V(x_1) \equiv 0$ does not satisfy (3.15). Furthermore if $I = \infty$ and $M < \infty$ with $(M, \sigma_0) \in \mathcal{S}$, the function x_1/M does solve (3.15) but does not represent the value function. Under condition (a) of the theorem the value function $V(x_1) = x_1/M$ is a solution of (3.15) but this fact does not follow from standard theorems.

Remark 2. Consider the problem of a process on the interval $0 < \tilde{x}_1 \leq 1$ determined by the equation

$$(3.16) \quad \tilde{X}_1(0) = \tilde{x}_1, d\tilde{X}_1(t) = \tilde{X}_1(t) [\tilde{\mu}(t) dt + \tilde{\sigma}(t) dW_t]$$

where $\tilde{\mu}(t)$, $\tilde{\sigma}(t)$ are nonanticipating controls required to satisfy $(\tilde{\mu}(t), \tilde{\sigma}(t)) \in \tilde{\mathcal{S}}$ and the object is to minimize the expectation of $\tilde{T} = \inf \{t: \tilde{X}_1(t) = 1\}$. This problem reduces to that of Theorem 1 by the change of variables $X_1(t) = \log \tilde{X}_1(t)$. This follows from Ito's formula, and one finds $\mu(t) = \tilde{\mu}(t) - \sigma^2(t)/2$, $\sigma(t) = \tilde{\sigma}(t)$. So one can formulate the theorem to apply to the \tilde{X}_1 process. Note that the role of M is assumed by

$$\tilde{M} = \sup \{ \tilde{\mu} - \tilde{\sigma}^2/2 : (\tilde{\mu}, \tilde{\sigma}) \in \tilde{\mathcal{S}} \}$$

and the role of I is taken by

$$\tilde{I} = \inf_{\varepsilon > 0} \sup \left\{ \tilde{\mu} - \left(\frac{1}{2} - \varepsilon \right) \tilde{\sigma}^2 : (\tilde{\mu}, \tilde{\sigma}) \in \tilde{\mathcal{S}} \right\}.$$

The problem for the \tilde{X}_1 process was considered in [9] and [3] and solved under some restrictions on $\tilde{\mathcal{S}}$. In [9] it was assumed that $\lambda \tilde{\mathcal{S}} \subseteq \tilde{\mathcal{S}}$ for all $\lambda \geq 0$, while in [3] this assumption was needed only for $0 \leq \lambda \leq 1$.

As discussed in [9] and [3] various models lead to the problem on $[0, 1]$. One of these, the "portfolio problem," will be explained in § 4. In [6] Kelly introduced a plan in discrete time based on the criterion of maximizing, at each stage, the expected value of the logarithm. This "Kelly criterion" was further studied by Breiman [1] who

established certain asymptotic optimality properties. Theorem 1 may be interpreted to imply that a continuous time Kelly criterion is in fact optimal under the hypotheses of (a), but not under those of (c).

4. A portfolio problem. Consider the problem of managing a portfolio of stocks, bonds and cash so as to minimize the expected time to reach a given total worth. For a simple model suppose that there is one bond whose price B_t at time t satisfies

$$dB_t = r_B B_t dt,$$

and one stock whose price S_t at time t satisfies

$$dS_t = r_S S_t dt + \sigma_S S_t dW_t$$

where r_B , r_S and σ_S are positive constants and $\{W_t\}$ is a standard Brownian motion. A recent paper by Malliaris [8] explains the use of stochastic differential models in finance and has numerous references to the financial literature. Let $\tilde{X}_1(t)$ be the total fortune of an investor at time t , let $f_S(t)$ be the fraction of that fortune invested in the stock, and let $f_B(t)$ be the fraction invested in the bond. Then \tilde{X}_1 satisfies

$$(4.1) \quad d\tilde{X}_1(t) = \tilde{X}_1(t)[r_S f_S(t) + r_B f_B(t)] dt + \sigma_S f_S(t) dW_t.$$

Let

$$\tilde{S} = \{(\tilde{\mu}, \tilde{\sigma}): \tilde{\mu} = r_S f_S + r_B f_B, \tilde{\sigma} = \sigma_S f_S, f_B \geq 0, f_S \geq 0, f_B + f_S \leq 1\}.$$

Then (4.1) and $\tilde{X}_1(0) = \tilde{x}_1$ are equivalent to (3.16) and $(\tilde{\mu}(t), \tilde{\sigma}(t)) \in \tilde{S}$. We are in the situation of Remark 2 of §3. Theorem 1 applies, and one is in case (a). If $r_B > r_S$ one should obviously take $f_B(t) \equiv 1$. If $r_B \leq r_S$ one finds

$$\tilde{M} = \begin{cases} r_B + \frac{(r_S - r_B)^2}{2\sigma_S^2} & \text{if } r_S \leq r_B + \sigma_S^2, \\ r_S - \frac{\sigma_S^2}{2} & \text{otherwise.} \end{cases}$$

The corresponding optimal policies are given by $f_B = 1 - f_S$ and

$$f_S = \begin{cases} \frac{r_S - r_B}{\sigma_S^2} & \text{if this is less than 1,} \\ 1 & \text{otherwise.} \end{cases}$$

In particular, the Kelly strategy is optimal.

SUPERVISORY CONTROL OF A CLASS OF DISCRETE EVENT PROCESSES*

P. J. RAMADGE†‡ AND W. M. WONHAM†

Abstract. The paper studies the control of a class of discrete event processes, i.e., processes that are discrete, asynchronous and possibly nondeterministic. The controlled process is described as the generator of a formal language, while the controller, or *supervisor*, is constructed from a recognizer for a specified target language that incorporates the desired closed-loop system behavior. The existence problem for a supervisor is reduced to finding the largest *controllable* language contained in a given *legal* language. Two examples are provided.

Key words. discrete event systems, control, automata

1. Introduction. In this paper we study the control of a class of systems broadly known as discrete event processes. The principal features of such processes are that they are discrete, asynchronous and (possibly) nondeterministic. Typical instances include computer networks, flexible manufacturing systems, and the start-up and shut-down procedures of industrial plants.

While numerous practical examples are described in the literature on simulation (see especially Fishman [1978] and Zeigler [1984]), there is at the present time apparently no unifying theory for the control of discrete event processes. Nor is it entirely clear what such a theory ought to encompass. Numerous approaches to the modeling of discrete event processes have appeared in the literature. A general sampling of these could include boolean models (Aveyard [1974]); Petri nets (Peterson [1981]); formal languages (Beauquier and Nivat [1980], Park [1981]); temporal logic (Pnueli [1979], Hailpern and Owicki [1983]); and port automata and flow networks (Milne and Milner [1979], Steenstrup, Arbib and Manes [1981]). All of this work is concerned, in one way or another, with the problem of how to achieve or verify the orderly flow of events; and to this end how to bring together ideas from logic, language and automaton theory. However, while control problems are implicit in much of the work just cited, control-theoretic ideas as such have found little application there. The variety of approaches reflects the diversity of areas in which discrete event processes play an important role. It also indicates that to date no dominant paradigm has emerged upon which a theory of control might be based.

In this article we investigate a simple abstract model of a controlled discrete event process, our main objective being to determine qualitative structural features of the relevant basic control problems. Specifically we take the controlled process to be the generator of a formal language, and study how the recognizer of a specified (target) language may be employed as a controller. In this regard we found suggestive the work of Shaw [1978] and Shields [1979] on flow expressions and path expressions

respectively; while C. A. R. Hoare has recently brought to our attention certain points of similarity with his linguistic approach to concurrent processes in Hoare [1983, Chap. 2]. Nevertheless our definition of “controllable language,” and our main results. (Theorems 7.1 and 10.1) on the existence and structure of controllers are believed to be quite new. Our approach is similar in spirit to some qualitative theories of multivariable control synthesis that have emerged over the last decade in the context of standard dynamic systems (for example, Wonham [1979], Nijmeijer [1983]). The present article is based on Ramadge [1983], and is summarized in Ramadge and Wonham [1984], while earlier versions appeared as Ramadge and Wonham [1982a, b].

The paper is organized as follows. In § 2 we define the class of controlled processes and controllers (*supervisors*) of interest; and in § 3 we discuss various associated formal languages. Sections 4 and 5 develop criteria for the existence of a supervisor for which the corresponding closed-loop controlled system satisfies given linguistic requirements; the main new idea here is that of a *controllable language*. Section 6 introduces the notion of a supervisor that is *proper*, namely *nonblocking* and *nonrejecting*. In § 7 we pose two problems of supervisor synthesis: the Supervisory Marking Problem (SMP) and the Supervisory Control Problem (SCP). Each of these is then shown to be solvable in a *minimally restrictive*, or “optimal,” fashion in the class of proper supervisors, the “optimality” depending on a semilattice property of the relevant classes of languages. Section 8 defines a *projection* (or simplification) of supervisors. The latter, combined with some notions of reduction of languages and recognizers in § 9, leads to our second main result in § 10, the *Quotient Structure Theorem*. According to this, every efficiently constructed supervisor is structurally equivalent to a quotient (i.e., high-level, or lumped, model) of a recognizer of the desired closed-loop generated language. We conclude in §§ 11 and 12 with two simple but practical illustrations.

2. Controlled discrete-event processes.

2.1. Generators. To establish notation we first recall various standard ideas from automaton and language theory (cf. Hopcroft and Ullman [1979]). We define a *generator* to be a 5-tuple

$$\mathcal{G} = (Q, \Sigma, \delta, q_0, Q_m)$$

where Q is the set of *states* q , Σ is the *alphabet* or set of output symbols σ , $\delta: \Sigma \times Q \rightarrow Q$ is the *transition function*, $q_0 \in Q$ is the *initial state* and $Q_m \subset Q$ is a subset of states to be called *marker states*.¹ We always assume that Σ , but not necessarily Q or Q_m , is finite. In general, δ is only a partial function (pfn), meaning that, for each fixed $q \in Q$, $\delta(\sigma, q)$ is defined only for some subset $\Sigma(q) \subset \Sigma$ that depends on q . Formally \mathcal{G} is equivalent to a directed graph with node set Q and an edge $q \rightarrow q'$ labeled σ for each triple (σ, q, q') such that $q' = \delta(\sigma, q)$. Such an edge, or state transition, will be called an *event*.

We interpret \mathcal{G} as a device that starts in q_0 and executes state transitions, i.e., generates a sequence of events, by following its graph. Events are considered to occur spontaneously (no auxiliary forcing mechanism is postulated), asynchronously (i.e., without reference to a clock) and instantaneously. An event is thought of as signaled (to an outside observer, say) by its *label* σ . \mathcal{G} may be nondeterministic in the sense that more than one event may be available for selection at a given node of its graph; however, distinct events at a given node always carry distinct labels.

¹ The terms *generator* and *marker state* are nonstandard, but better suited to our interpretation than, for example, “automaton” and “final state.” Our “generator” is a special case of Harrison’s “transition system” (Harrison [1965]); it will play the role of “plant” in the sense of control theory.

Let Σ^* denote the set of all finite strings s of elements of Σ , including the empty string, 1.² In standard fashion we construct the extended transition function

$$\delta: \Sigma^* \times Q \rightarrow Q \quad (\text{pfn})$$

according to

$$\delta(1, q) = q, \quad q \in Q,$$

and

$$\delta(s\sigma, q) = \delta(\sigma, \delta(s, q))$$

whenever $q' = \delta(s, q)$ and $\delta(\sigma, q')$ are both defined. Any subset of Σ^* is a *language* over Σ . The strings of a language are often called *words*. The language *generated* by \mathcal{G} is

$$L(\mathcal{G}) = \{w: w \in \Sigma^* \text{ and } \delta(w, q_0) \text{ is defined}\}.$$

The language *marked* by \mathcal{G} is

$$L_m(\mathcal{G}) = \{w: w \in L(\mathcal{G}) \text{ and } \delta(w, q_0) \in Q_m\}.$$

We interpret $L(\mathcal{G})$ as the set of all possible finite sequences of events that can occur; while $L_m(\mathcal{G}) \subset L(\mathcal{G})$ is a distinguished subset of these sequences that may be “marked,” or recorded, perhaps representing completed “tasks” (or sequences of tasks) carried out by the physical process that \mathcal{G} is intended to model.³

To conclude this subsection we remark that it is usually convenient to eliminate states of \mathcal{G} that can never be reached (or “accessed”) from q_0 . Namely let

$$Q_{ac} = \{q: \exists w \in \Sigma^*, \delta(w, q_0) = q\},$$

$$Q_{ac,m} = Q_{ac} \cap Q_m,$$

$$\delta_{ac} = \delta|_{(\Sigma \times Q_{ac})}.$$

The *accessible component* of \mathcal{G} , denoted by $Ac(\mathcal{G})$, is then defined to be

$$Ac(\mathcal{G}) = (Q_{ac}, \Sigma, \delta_{ac}, q_0, Q_{ac,m}).$$

A generator \mathcal{G} is *accessible* if $\mathcal{G} = Ac(\mathcal{G})$.

We say that \mathcal{G} is *co-accessible* if every string in $L(\mathcal{G})$ can be completed to a string in $L_m(\mathcal{G})$, i.e.,

$$(\forall w) w \in L(\mathcal{G}) \Rightarrow (\exists s) s \in \Sigma^* \quad \text{and} \quad ws \in L_m(\mathcal{G}).$$

If \mathcal{G} is both accessible and co-accessible it is said to be *trim* (Eilenberg [1974]). It is well known (cf. Eilenberg [1974, § III.5]) that to every language (i.e., subset of Σ^*) there corresponds a trim generator that is essentially unique.

2.2. Controlled discrete event processes. To a generator $\mathcal{G} = (Q, \Sigma, \delta, q_0, Q_m)$ we now adjoin a means of control. That is, \mathcal{G} will play the role of the “plant” (object to be controlled) of standard control theory. For this let $\Sigma_c \subset \Sigma$ be a distinguished subset of the alphabet; we say that an event (σ, q, q') is a *controlled event* if $\sigma \in \Sigma_c$. Let

$$\Gamma = \{0, 1\}^{\Sigma_c}$$

² 1 plays the role of identity of string concatenation, i.e., $1s = s1 = s$.

³ Here there is no implication that generating action halts after the completion of some marked sequence; marked states of \mathcal{G} need not be “final” states.

be the set of all binary assignments to the elements of Σ_c . Each assignment $\gamma \in \Gamma$, i.e., each function

$$\gamma: \Sigma_c \rightarrow \{0, 1\},$$

is a *control pattern*. An event (with label) σ is said to be *enabled by γ* if $\gamma(\sigma) = 1$, or *disabled by γ* if $\gamma(\sigma) = 0$. It is convenient to extend each $\gamma \in \Gamma$ to a map $\gamma: \Sigma \rightarrow \{0, 1\}$ by defining $\gamma(\sigma) = 1$ for each $\sigma \in \Sigma - \Sigma_c$. If $\delta: \Sigma \times Q \rightarrow Q$ is the transition function of \mathcal{G} , we define an augmented transition function

$$\delta_c: \Gamma \times \Sigma \times Q \rightarrow Q \quad (\text{pfn})$$

according to

$$\delta_c(\gamma, \sigma, q) = \begin{cases} \delta(\sigma, q) & \text{if } \delta(\sigma, q) \text{ is defined and } \gamma(\sigma) = 1, \\ \text{undefined} & \text{otherwise.} \end{cases}$$

Formally, the object

$$\mathcal{G}_c = (Q, \Gamma \times \Sigma, \delta_c, q_0, Q_m)$$

is just another generator, constructed from \mathcal{G} by a specification of Σ_c . However, we interpret \mathcal{G}_c as a version of \mathcal{G} that admits external control, as follows. For brevity call “an event labeled σ ” simply “an event σ .” For each fixed $\gamma \in \Gamma$ there is a generator $\mathcal{G}(\gamma)$ formed by deleting from the graph of \mathcal{G} those events σ with $\gamma(\sigma) = 0$, i.e., those events that the control pattern γ disables. Then external control action would consist simply in switching the control pattern through a sequence of elements $\gamma, \gamma', \gamma'', \dots$ in Γ , like switching the pattern of red and green lights in a traffic network. Observe that such control is “permissive” (cf. Peterson [1981]): while disabled events are certainly prevented from occurring, enabled events are not necessarily forced to occur.

A structure \mathcal{G}_c as described above will be called a *controlled discrete event process* (CDEP).

2.3. Example—a primitive CDEP. A user of a resource may be modeled as a deterministic CDEP with three states I (IDLE), R (REQUEST) and U (USE), and with transitions as shown. Here we take (with some change of notation)

$\Sigma = \{\alpha, \beta, \gamma\}$ and $\Sigma_c = \{\beta\}$. The (two) control patterns correspond to evaluations $c = 0$ or $c = 1$ of the control variable c . A transition $R \rightarrow U$ may occur only when $c = 1$.

More interesting examples arise with the concurrent control of several CDEPs; these may then be combined into a single nondeterministic CDEP. At this stage the reader may skip ahead to §§ 11 and 12 for a glance at examples of this type.

2.4. Supervisors. Our objective will be to design a controller that switches control patterns in such a way that a given CDEP, \mathcal{G}_c , as described in § 2.2, behaves in obedience to various constraints. Such a controller will be called a *supervisor*. Formally a supervisor \mathcal{S} is a pair

$$\mathcal{S} = (S, \phi).$$

Here

$$S = (X, \Sigma, \xi, x_0, X_m)$$

is a deterministic automaton with (possibly infinite) state set X , input alphabet Σ , transition (partial) function $\xi: \Sigma \times X \rightarrow X$, initial state x_0 and marker subset $X_m \subset X$; while

$$\phi: X \rightarrow \Gamma$$

is a (total) function that maps supervisor states x into control patterns γ . Thus for each $x \in X$,

$$\gamma := \phi(x) \in \{0, 1\}^{\Sigma_c}.$$

(As before we extend $\phi(x)$ to a map $\phi(x): \Sigma \rightarrow \{0, 1\}$ with $\phi(x)(\sigma) = 1$ for each $\sigma \in \Sigma - \Sigma_c$.) S will always be assumed to be accessible. We call ϕ the *state feedback map*.

In many applications it will be the case that $X_m = X$, i.e., the supervisor plays no auxiliary “marking” role; but the extra generality with $X_m \neq X$ is obtained with little effort.

We interpret S conventionally, as a device that executes a sequence of state transitions (according to ξ) in response to an appropriate input string $w \in \Sigma^*$. Thus we may couple \mathcal{S} to \mathcal{G}_c in a feedback loop by allowing the state transitions of S to be forced by \mathcal{G}_c , and requiring \mathcal{G}_c to be constrained by the successive control patterns determined by the states of S . Formally define the partial function

$$\xi \times \delta_c: \Sigma \times X \times Q \rightarrow X \times Q \quad (\text{pfn})$$

according to

$$(\sigma, x, q) \mapsto (\xi(\sigma, x), \delta_c(\phi(x), \sigma, q)).$$

Thus $(\xi \times \delta_c)(\sigma, x, q)$ is defined iff $\delta(\sigma, q)$ is defined, $\phi(x)(\sigma) = 1$, and $\xi(\sigma, x)$ is defined. This yields the generator

$$(X \times Q, \Sigma, \xi \times \delta_c, (x_0, q_0), X_m \times Q_m).$$

We define the *supervised discrete event process* (SDEP), denoted by $\mathcal{S}/\mathcal{G}_c$, to be the accessible generator⁴

$$(2.1) \quad \mathcal{S}/\mathcal{G}_c = \text{Ac}(X \times Q, \Sigma, \xi \times \delta_c, (x_0, q_0), X_m \times Q_m).$$

From now on we shall assume that $\xi \times \delta_c$ has been extended to strings of Σ^* in the way described in § 2.1 for δ . Of course, so far there is nothing to guarantee that $(X \times Q)_{ac}$ is anything more than the singleton $\{(x_0, q_0)\}$, or that $L(\mathcal{S}/\mathcal{G}_c)$ is any larger than the singleton $\{1\}$ consisting of the empty string alone.

In analogy to the case of \mathcal{G} itself, we wish to interpret the language $L(\mathcal{S}/\mathcal{G}_c)$ generated by $\mathcal{S}/\mathcal{G}_c$ as the set of all possible finite sequences of events that can occur when \mathcal{S} is coupled to \mathcal{G}_c as just described. For this it is necessary to ensure that transitions of S are actually defined whenever they can occur in \mathcal{G} and are enabled by ϕ . To formalize this relationship we shall say that \mathcal{S} is *complete with respect to \mathcal{G}_c* provided the following is true: for all $s \in \Sigma^*$, $\sigma \in \Sigma$ the three conditions

- (i) $s \in L(\mathcal{S}/\mathcal{G}_c)$,
- (ii) $s\sigma \in L(\mathcal{G})$ (i.e., $\delta(s\sigma, q_0)$ is defined),
- (iii) $[\phi \circ \xi(s, x_0)](\sigma) = 1$ (i.e., σ is enabled at $\xi(s, x_0)$), together imply that
- (iv) $s\sigma \in L(\mathcal{S}/\mathcal{G}_c)$ (i.e., $\xi(s\sigma, x_0)$ is defined).

While the definition (2.1) is logically acceptable as it stands, it will be of real value only when it is physically interesting, namely when \mathcal{S} is complete with respect to \mathcal{G}_c .

⁴ The notation is intended to suggest simply that “ \mathcal{G}_c is under supervision by \mathcal{S} ,” no quotient structure is implied!

Before continuing with the general development, the reader might wish to glance at the opening paragraphs of §§ 11 and 12, where two concrete examples of supervisory control problems are provided.

3. Languages of $\mathcal{S}/\mathcal{G}_c$.

3.1. Definitions. Let $L \subset \Sigma^*$. The *closure* of L , denoted by \bar{L} , is the set of all strings that are prefixes of words of L , i.e.,

$$\bar{L} = \{s : s \in \Sigma^* \text{ and } (\exists t) t \in \Sigma^*, st \in L\}.$$

For instance, if $L = \emptyset$ then $\bar{L} = \emptyset$ and if $L \neq \emptyset$ then $1 \in \bar{L}$. A language L is *closed* if $L = \bar{L}$. If \mathcal{G} is any generator then $L(\mathcal{G})$ is closed; if in addition \mathcal{G} is trim then

$$L(\mathcal{G}) = \bar{L}_m(\mathcal{G}).$$

Let \mathcal{G}_c be a CDEP constructed from a generator \mathcal{G} . For simplicity we shall denote \mathcal{G}_c simply by its underlying generator \mathcal{G} . The notation $L(\mathcal{G})$ will henceforth denote the language generated by \mathcal{G} if disabling control action were absent, i.e., all events $\sigma \in \Sigma_c$ were permanently enabled. Similarly we refer to $L_m(\mathcal{G})$ as the *uncontrolled (discrete-event) process language*. Let \mathcal{S} be a supervisor for \mathcal{G} , $L(\mathcal{S}/\mathcal{G})$ the language generated by \mathcal{S}/\mathcal{G} and $L_m(\mathcal{S}/\mathcal{G})$ the language marked by \mathcal{S}/\mathcal{G} . Define the *language controlled by \mathcal{S} in \mathcal{G}* to be

$$(3.1) \quad L_c(\mathcal{S}/\mathcal{G}) := L(\mathcal{S}/\mathcal{G}) \cap L_m(\mathcal{G}).$$

In other words, $L_c(\mathcal{S}/\mathcal{G})$ consists of those (marked) strings of the uncontrolled process language that “survive” in the presence of supervision.

It is clear from the definitions that

$$(3.2) \quad L_m(\mathcal{S}/\mathcal{G}) \subset L_c(\mathcal{S}/\mathcal{G}) \subset L_m(\mathcal{G})$$

and, if \mathcal{G} is trim,

$$(3.3) \quad \bar{L}_m(\mathcal{S}/\mathcal{G}) \subset \bar{L}_c(\mathcal{S}/\mathcal{G}) \subset \bar{L}(\mathcal{S}/\mathcal{G}) [= L(\mathcal{S}/\mathcal{G})] \subset L(\mathcal{G}) = \bar{L}_m(\mathcal{G}).$$

3.2. Examples. Let \mathcal{G} be the generator over $\Sigma = \{\alpha, \beta, \gamma\}$ displayed below.

Then⁵

$$L_m(\mathcal{G}) = (\alpha\gamma^*\beta)^*.$$

We shall consider two different supervisors, each specified by its transition graph, as follows.

⁵ For the notation of regular expressions used here and below see, for example, Hopcroft and Ullman [1979].

This gives for \mathcal{S}/\mathcal{G} the transition graph

It is seen that

$$L(\mathcal{S}/\mathcal{G}) = (\alpha\beta)^*(1 + \alpha\gamma^*),$$

$$L_c(\mathcal{S}/\mathcal{G}) = L(\mathcal{S}/\mathcal{G}) \cap L_m(\mathcal{G}) = (\alpha\beta)^* = L_m(\mathcal{S}/\mathcal{G}).$$

For future reference (§ 6) we note, however, that

$$\bar{L}_c(\mathcal{S}/\mathcal{G}) = (\alpha\beta)^*(1 + \alpha) \subsetneq L(\mathcal{S}/\mathcal{G}).$$

This gives for \mathcal{S}/\mathcal{G} the transition graph

It is seen that

$$L_c(\mathcal{S}/\mathcal{G}) = L_m(\mathcal{G}) = (\alpha\gamma^*\beta)^*.$$

Again for future reference (§ 6), we note that

$$L_m(\mathcal{S}/\mathcal{G}) = (\alpha\beta)^* \subsetneq L_c(\mathcal{S}/\mathcal{G})$$

and

$$\bar{L}_m(\mathcal{S}/\mathcal{G}) \subsetneq \bar{L}_c(\mathcal{S}/\mathcal{G}).$$

4. Marking and control. A supervisor \mathcal{S} performs two essentially independent tasks: marking (as described by $L_m(\mathcal{S}/\mathcal{G})$) and control (as described by $L_c(\mathcal{S}/\mathcal{G})$, $L(\mathcal{S}/\mathcal{G})$). If a given controlled behavior is achievable, then any marking task is simultaneously achievable that is consistent with the controlled behavior.

Without essential loss of generality we assume that the generator \mathcal{G} is trim, namely

$$L(\mathcal{G}) = \bar{L}_m(\mathcal{G}).$$

PROPOSITION 4.1. (i) *For each sublanguage $K \subset L_m(\mathcal{G})$ there exists a complete supervisor \mathcal{S} such that, for \mathcal{S}/\mathcal{G} , we have*

$$L(\mathcal{S}/\mathcal{G}) = L(\mathcal{G}), \quad L_m(\mathcal{S}/\mathcal{G}) = K.$$

(ii) *Let L be a closed sublanguage of $L(\mathcal{G})$. If there exists a complete supervisor \mathcal{S} for which $L(\mathcal{S}/\mathcal{G}) = L$ then for every sublanguage K of $L \cap L_m(\mathcal{G})$ there exists a complete supervisor \mathcal{S}_K such that, correspondingly,*

$$L(\mathcal{S}_K/\mathcal{G}) = L, \quad L_m(\mathcal{S}_K/\mathcal{G}) = K.$$

Before proving Proposition 4.1 we make the (more or less standard) definition: if $L \subset \Sigma^*$, a recognizer \mathcal{M} for L is an accessible generator \mathcal{G} such that $L_m(\mathcal{G}) = L$. While

a recognizer and an accessible generator are formally no different, we interpret a recognizer $\mathcal{M} = (Q, \Sigma, \delta, q_0, Q_m)$ as a device which, like a supervisor, is forced externally by strings in Σ^* ; its action is thus to “recognize” precisely the words of L , regarded as input strings to \mathcal{M} .

Proof of Proposition 4.1. (i) Let $S = (X, \Sigma, \xi, x_0, X_m)$ be a recognizer for K . By adjoining a “dump” state to X , if necessary, we can arrange that $\xi(\sigma, x)$ is defined for all $(\sigma, x) \in \Sigma \times X$. Define

$$\phi : X \rightarrow \{0, 1\}^\Sigma$$

according to

$$\phi(x)(\sigma) = 1, \quad x \in X, \quad \sigma \in \Sigma.$$

It is clear that $\mathcal{S} = (S, \phi)$ has the required properties.

(ii) Let

$$T = (Y, \Sigma, \eta, y_0, Y_m)$$

be a recognizer for K . By adjoining a “dump” state to Y , if necessary, it can be arranged that $\eta(\sigma, y)$ is defined for all $(\sigma, y) \in \Sigma \times Y$. Let

$$\mathcal{S} = (S, \phi), \quad S = (X, \Sigma, \xi, x_0, X)$$

be a complete supervisor for which

$$L(\mathcal{S} / \mathcal{G}) = L.$$

Define the supervisor

$$\mathcal{S}_K = (S', \phi'), \quad S' = (X', \Sigma, \xi', x'_0, X'_m)$$

according to

$$\begin{aligned} X' &= X \times Y, & \xi'(\sigma, x, y) &= (\xi(\sigma, x), \eta(\sigma, y)), \\ x'_0 &= (x_0, y_0), & X'_m &= X \times Y_m, & \phi'(x, y) &= \phi(x). \end{aligned}$$

Since the control action of \mathcal{S}_K is the same as that of \mathcal{S} , it is clear that $L(\mathcal{S}_K / \mathcal{G}) = L$, and obviously $L_m(\mathcal{S}_K / \mathcal{G}) = K$. Also, $\xi'(\sigma, x, y)$ is defined just when $\xi(\sigma, x)$ is defined, so that S_k is complete with respect to \mathcal{G}_c . \square

In this proof our construction merely installs a recognizer that acts as a marking device, either alone in part (i), or “in parallel” with the original supervisor \mathcal{S} in part (ii). This does nothing to change the control action, but might be thought of as a means of recording when words in K have been completed.

5. Controllability. In this section we introduce a definition of controllability that will play a key role in characterizing those languages that can be generated by closed-loop structures $\mathcal{S} / \mathcal{G}$ with a given CDEP \mathcal{G} and a suitable choice of complete supervisor \mathcal{S} .

Let $\mathcal{G} = (Q, \Sigma, \delta, q_0, Q_m)$ be a fixed CDEP. We assume that \mathcal{G} is trim, i.e., $L(\mathcal{G}) = \bar{L}_m(\mathcal{G})$. Write $\Sigma_u = \Sigma - \Sigma_c$, i.e., Σ_u is the set of (labels of) events that cannot be disabled. Let $K \subset \Sigma^*$, $L \subset \Sigma^*$ be arbitrary languages. We say that K is

- (i) *L-closed* if $K = \bar{K} \cap L$,
- (ii) (Σ_u, L) -*invariant* if $\bar{K} \Sigma_u \cap L \subset \bar{K}$,
- (iii) *controllable* if $K \subset L(\mathcal{G})$ and K is $(\Sigma_u, L(\mathcal{G}))$ -invariant i.e., $\bar{K} \Sigma_u \cap L(\mathcal{G}) \subset \bar{K}$.

Recall that \bar{K} is the language consisting of K together with all the prefixes (including the empty word) of words in K . Thus a sublanguage K of L is *L-closed* iff any prefix of K that is a word of L is also a word of K .

The language $\bar{K}\Sigma_u \cap L$ consists of all strings $s' = s\sigma$ where $s' \in L$, $s \in \bar{K}$ and $\sigma \in \Sigma_u$. If we think of L as representing “physically possible behavior,” and \bar{K} as “legally admissible behavior,” then the string $s\sigma$ is a legally admissible string s followed by an uncontrolled symbol σ such that $s\sigma$ is physically possible. K is (Σ_u, L) -invariant precisely when all such strings are legally admissible, i.e., certain instances of uncontrolled behavior are nonetheless legal.

Finally, thinking of $L(\mathcal{G})$ as the uncontrolled process language, i.e., the physically possible uncontrolled behavior of our CDEP, we have that K is controllable if every prefix $s \in \bar{K}$ is physically possible, and every physically possible string $s\sigma$, with $s \in \bar{K}$ and σ uncontrolled, is again in \bar{K} .

The following technical proposition will support our main results (Theorems 6.1, 7.1) on existence of supervisors.

PROPOSITION 5.1. *Let $K_1 \subset L_m(\mathcal{G})$, $K_2 \subset L_m(\mathcal{G})$ and $K_3 \subset L(\mathcal{G})$ with $K_3 \neq \emptyset$. There exists a complete supervisor \mathcal{S} such that for the closed-loop system \mathcal{S}/\mathcal{G} ,*

$$(5.1) \quad L_m(\mathcal{S}/\mathcal{G}) = K_1, \quad L_c(\mathcal{S}/\mathcal{G}) = K_2, \quad L(\mathcal{S}/\mathcal{G}) = K_3,$$

iff

- (i) $K_1 \subset K_2$,
- (ii) $K_2 = K_3 \cap L_m(\mathcal{G})$,
- (iii) K_3 is closed and controllable.

Proof. (Only if). Let the complete supervisor \mathcal{S} satisfy (5.1). Condition (i) follows by (3.2) and (ii) by the definition (3.1) of $L_c(\mathcal{S}/\mathcal{G})$. We have already noted that $L(\mathcal{S}/\mathcal{G}) (= K_3)$ is closed. To show that K_3 is controllable, suppose that $s\sigma \in L(\mathcal{G})$, with $s \in \bar{K}_3 (= K_3 = L(\mathcal{S}/\mathcal{G}))$ and $\sigma \in \Sigma_u$. If $\mathcal{S} = (S, \phi)$ with $S = (X, \Sigma, \xi, x_0, X_m)$ then, in the notation of § 2.4,

$$(x, q) := (\xi \times \delta_c)(s, x_0, q_0)$$

is defined. Since $\sigma \in \Sigma_u$ we have $\phi(x)(\sigma) = 1$, and as $s\sigma \in L(\mathcal{G})$ it follows that $q' := \delta(\sigma, q)$ is defined. Therefore

$$\delta_c(\phi(x), \sigma, q) = q';$$

and because \mathcal{S} is complete with respect to \mathcal{G}_c ,

$$x' := \xi(\sigma, x)$$

is defined. Therefore

$$(\xi \times \delta_c)(\sigma, x, q) = (\xi(\sigma, x), \delta_c(\phi(x), \sigma, q)) = (x', q')$$

is defined, namely

$$s\sigma \in L(\mathcal{S}/\mathcal{G}) = K_3 = \bar{K}_3,$$

so K_3 is controllable.

(If). By Proposition 4.1 it is enough to construct a complete supervisor \mathcal{S} such that $L(\mathcal{S}/\mathcal{G}) = K_3$. For this let $S = (X, \Sigma, \xi, x_0, X)$ be a trim recognizer for K_3 . Since K_3 is closed and S is trim, the marker set of S is X itself, as indicated; and we have that $\xi(s, x_0)$ is defined iff $s \in K_3$. For $x \in X$ let

$$\Sigma_x^0 = \{\sigma : (\exists s) s \in K_3 \text{ and } \xi(s, x_0) = x \text{ and } s\sigma \in L(\mathcal{G}) \text{ and } s\sigma \notin K_3\},$$

$$\Sigma_x^1 = \{\sigma : (\exists s) s \in K_3 \text{ and } \xi(s, x_0) = x \text{ and } s\sigma \in K_3\}.$$

We claim that $\Sigma_x^0 \cap \Sigma_x^1 = \emptyset$. In essence this follows by the fact that S is a trim recognizer for K_3 . Indeed suppose that $\sigma \in \Sigma_x^0 \cap \Sigma_x^1$ with

$$\begin{aligned} s^0 \in K_3, \xi(s^0, x_0) = x, & \quad s^0 \sigma \notin K_3, \\ s^1 \in K_3, \xi(s^1, x_0) = x, & \quad s^1 \sigma \in K_3. \end{aligned}$$

Then

$$\xi(\sigma, x) = \xi(\sigma, \xi(s^0, x_0)) = \xi(s^0 \sigma, x_0)$$

fails to be defined (since $s^0 \sigma \notin K_3$); whereas

$$\xi(\sigma, x) = \xi(\sigma, \xi(s^1, x_0)) = \xi(s^1 \sigma, x_0)$$

must be defined (since $s^1 \sigma \in K_3$): a contradiction.

By controllability of K_3 , $\Sigma_x^0 \subset \Sigma_c$. Let

$$\phi : X \rightarrow \{0, 1\}^\Sigma$$

be any function such that, if $\phi(x) =: \gamma$, then

$$\gamma(\Sigma_x^0) = 0, \quad \gamma(\Sigma_x^1) = 1, \quad \gamma(\Sigma_u - \Sigma_x^1) = 1.$$

It is clear from the claim just proved that such a function ϕ exists.

Now let $\mathcal{S} = (S, \phi)$. It will be shown that $L(\mathcal{S}/\mathcal{G}) = K_3$. By the definition of S , it is clear that $L(\mathcal{S}/\mathcal{G}) \subset K_3$. For the reverse inclusion, we use induction on the length $|s|$ of strings $s \in L(\mathcal{G})$. If $|s| = 1$, i.e., $s = \sigma$ for some $\sigma \in \Sigma$, then

$$\sigma \in \Sigma_{x_0}^1 \quad \text{if } \sigma \in K_3$$

so $\sigma \in L(\mathcal{S}/\mathcal{G})$ if $\sigma \in K_3$. For a language $L \subset \Sigma^*$ write

$$L^{(j)} := \{s : s \in L \text{ and } |s| = j\}, \quad j = 0, 1, 2, \dots,$$

and note that $L = \bigcup_{j=0}^{\infty} L^{(j)}$. Assume for the induction step that

$$L^{(i)}(\mathcal{S}/\mathcal{G}) = K_3^{(i)}, \quad i = 0, 1, \dots, j.$$

Let $s \in L^{(j)}(\mathcal{S}/\mathcal{G})$ and consider the string $s\sigma \in L(\mathcal{G})$. Now $x := \xi(s, x_0)$ is defined, and so $\sigma \in \Sigma_x^0 \cup \Sigma_x^1$; therefore $s\sigma \in K_3$ implies

$$\sigma \in \Sigma_x^1 \text{ and } \xi(\sigma, x) \text{ is defined}$$

implies

$$\phi(x)(\sigma) = 1 \text{ and } \xi(\sigma, x) \text{ is defined}$$

implies

$$s\sigma \in L(\mathcal{S}/\mathcal{G}).$$

Therefore

$$L^{(j+1)}(\mathcal{S}/\mathcal{G}) = K_3^{(j+1)}.$$

It only remains to show that \mathcal{S} is complete with respect to \mathcal{G} . For this let

$$s \in L(\mathcal{S}/\mathcal{G}) = K_3, \quad s\sigma \in L(\mathcal{G}),$$

and

$$[\phi \circ \xi(s, x_0)](\sigma) = 1.$$

Now if $s\sigma \notin K_3$, then we must have

$$\sigma \in \Sigma_{\xi(s, x_0)}^0.$$

But this implies that

$$[\phi \circ \xi(s, x_0)](\sigma) = 0,$$

a contradiction. Hence $s\sigma \in K_3$ and \mathcal{S} is complete. \square

6. Proper supervisors. To specify controlled behavior in a way that is intuitively satisfying, more stringent conditions must be placed on the three languages

$$L_m(\mathcal{S}/\mathcal{G}), \quad L_c(\mathcal{S}/\mathcal{G}), \quad L(\mathcal{S}/\mathcal{G})$$

that describe the closed-loop system \mathcal{S}/\mathcal{G} . We shall say that \mathcal{S} is *nonblocking* if

$$\bar{L}_c(\mathcal{S}/\mathcal{G})[\bar{L}(\mathcal{S}/\mathcal{G}) \cap \bar{L}_m(\mathcal{G})] = L(\mathcal{S}/\mathcal{G})$$

and that \mathcal{S} is *nonrejecting* if

$$\bar{L}_c(\mathcal{S}/\mathcal{G}) = \bar{L}_m(\mathcal{S}/\mathcal{G}).$$

By definition we always have $\bar{L}_c(\mathcal{S}/\mathcal{G}) \subset L(\mathcal{S}/\mathcal{G})$. If \mathcal{S} blocks, i.e., fails to be nonblocking, then there exists a string s generated by \mathcal{S}/\mathcal{G} (i.e., $s \in L(\mathcal{S}/\mathcal{G})$) that can never be completed to a word $st \in L_c(\mathcal{S}/\mathcal{G})$, i.e., $s \notin \bar{L}_c(\mathcal{S}/\mathcal{G})$. In this sense the CDEP may be blocked from ever completing a “task.” This undesirable situation is illustrated by supervisor (i) of § 3.2. Here, for instance, the string $\alpha\gamma \in L(\mathcal{S}/\mathcal{G}) - \bar{L}_c(\mathcal{S}/\mathcal{G})$.

If \mathcal{S} rejects, i.e., fails to be nonrejecting, then there exists a string $s \in \bar{L}_c(\mathcal{S}/\mathcal{G})$ that can be completed to a “task” in $L_c(\mathcal{S}/\mathcal{G})$ but never to a task that is marked, i.e., (say) recorded. By contrast, if $\bar{L}_c(\mathcal{S}/\mathcal{G}) = \bar{L}_m(\mathcal{S}/\mathcal{G})$, so that

$$L_m(\mathcal{S}/\mathcal{G}) \subset L_c(\mathcal{S}/\mathcal{G}) \subset \bar{L}_m(\mathcal{S}/\mathcal{G}),$$

then for every $s \in L_c(\mathcal{S}/\mathcal{G})$ there is some t such that $st \in L_m(\mathcal{S}/\mathcal{G})$, and then $st \in L_c(\mathcal{S}/\mathcal{G})$ as well. In § 3.2 the supervisor (ii) rejects: only strings of the form $(\alpha\beta)^*$ are marked, while $L_c(\mathcal{S}/\mathcal{G}) = (\alpha\gamma^*\beta)^*$ represents the complete set of tasks that may be performed.

A supervisor \mathcal{S} will be said to be *proper* if it is complete, nonblocking and nonrejecting; namely \mathcal{S} is complete and

$$\bar{L}_m(\mathcal{S}/\mathcal{G}) = \bar{L}_c(\mathcal{S}/\mathcal{G}) = L(\mathcal{S}/\mathcal{G}).$$

THEOREM 6.1. *Let $K \subset L_m(\mathcal{G})$, $K \neq \emptyset$.*

(i) *There exists a proper supervisor \mathcal{S} such that $L_m(\mathcal{S}/\mathcal{G}) = K$ iff K is controllable. In that case,*

$$L_c(\mathcal{S}/\mathcal{G}) = L_m(\mathcal{G}) \cap \bar{K}.$$

(ii) *There exists a proper supervisor \mathcal{S} such that $L_c(\mathcal{S}/\mathcal{G}) = K$ iff K is controllable and $L_m(\mathcal{G})$ -closed.*

Proof. (i) K is controllable iff \bar{K} is closed and controllable, iff the triple

$$(K_1, K_2, K_3) := (K, \bar{K} \cap L_m(\mathcal{G}), \bar{K})$$

satisfies conditions (i)–(iii) of Proposition 5.1, iff there exists a complete supervisor \mathcal{S} such that

$$(L_m(\mathcal{S}/\mathcal{G}), L_c(\mathcal{S}/\mathcal{G}), L(\mathcal{S}/\mathcal{G})) = (K, \bar{K} \cap L_m(\mathcal{G}), \bar{K})$$

and this condition means that \mathcal{S} is proper.

(ii) K is controllable and $L_m(\mathcal{G})$ -closed iff the triple

$$(K_1, K_2, K_3) := (K, K, \bar{K})$$

satisfies the conditions of Proposition 5.1, iff there exists a complete supervisor \mathcal{S} such that

$$(L_m(\mathcal{S}/\mathcal{G}), L_c(\mathcal{S}/\mathcal{G}), L(\mathcal{S}/\mathcal{G})) = (K, K, \bar{K}),$$

and again this means that \mathcal{S} is proper. \square

7. Supervisor synthesis problems. Let languages $L_a, L_g \in \Sigma^*$ be given, with

$$\emptyset \neq L_a \subset L_g \subset L_m(\mathcal{G}).$$

We interpret L_g as “legal behavior,” i.e., each word of L_g is a “legal task;” and L_a as “minimal acceptable behavior,” i.e., control of the CDEP \mathcal{G} in such a way that a language smaller than L_a is generated is considered inadequate. We now introduce the

Supervisory Marking Problem (SMP). Construct a proper supervisor \mathcal{S} for \mathcal{G} such that

$$L_a \subset L_m(\mathcal{S}/\mathcal{G}) \subset L_g.$$

Similarly we define the

Supervisory Control Problem (SCP). Construct a proper supervisor \mathcal{S} for \mathcal{G} such that

$$L_a \subset L_c(\mathcal{S}/\mathcal{G}) \subset L_g.$$

If SCP is solvable then by the proof of Theorem 6.1(ii) we can always arrange that $L_m(\mathcal{S}/\mathcal{G}) = L_c(\mathcal{S}/\mathcal{G})$, so that automatically SMP is solvable as well. For a converse to this statement, consider the special but interesting case where L_g is $L_m(\mathcal{G})$ -closed, i.e.,

$$L_g = \bar{L}_g \cap L_m(\mathcal{G}).$$

Then L_g is a sublanguage of $L_m(\mathcal{G})$ with the property that if a string $st \in L_g$ and $s \in L_m(\mathcal{G})$ then also $t \in L_g$. Now if SMP is solvable, the language $L_m(\mathcal{S}/\mathcal{G})$ satisfies

$$L_a \subset L_m(\mathcal{S}/\mathcal{G}) \subset L_g,$$

so that

$$L_a \subset L_m(\mathcal{S}/\mathcal{G}) \subset L_c(\mathcal{S}/\mathcal{G}).$$

Also, since \mathcal{S} is proper,

$$\bar{L}_m(\mathcal{S}/\mathcal{G}) = \bar{L}_c(\mathcal{S}/\mathcal{G})$$

so that

$$L_c(\mathcal{S}/\mathcal{G}) \subset \bar{L}_c(\mathcal{S}/\mathcal{G}) = \bar{L}_m(\mathcal{S}/\mathcal{G}) \subset \bar{L}_g.$$

But $L_c(\mathcal{S}/\mathcal{G}) \subset L_m(\mathcal{G})$ by definition, i.e.,

$$L_c(\mathcal{S}/\mathcal{G}) \subset \bar{L}_g \cap L_m(\mathcal{G}) = L_g.$$

Hence

$$L_a \subset L_c(\mathcal{S}/\mathcal{G}) \subset L_g$$

and so SCP is solvable as well.

When SMP or SCP is solvable, it may be considered desirable that the solution be *minimally restrictive* in the sense that $L_m(\mathcal{S}/\mathcal{G})$ or $L_c(\mathcal{S}/\mathcal{G})$, considered as a sublanguage of $L_m(\mathcal{G})$, be as large as possible, subject to the constraint that it is a sublanguage of L_g . The fact that minimally restrictive solutions are possible in principle is due to a certain semilattice property that we now describe. For this, let $L \subset L(\mathcal{G})$ be an arbitrary sublanguage of $L(\mathcal{G})$. Let

$$C_{\mathcal{G}}(L) := \{K : K \subset L \text{ and } K \text{ is controllable}\},$$

$$F_{\mathcal{G}}(L) := \{K : K \subset L \text{ and } K = \bar{K} \cap L_m(\mathcal{G})\}.$$

Thus $C_{\mathcal{G}}(L)$ (respectively, $F_{\mathcal{G}}(L)$) are the controllable (respectively, $L_m(\mathcal{G})$ -closed) sublanguages of L .

PROPOSITION 7.1. *$C_{\mathcal{G}}(L)$ and $F_{\mathcal{G}}(L)$ are nonempty classes of languages that are closed under arbitrary unions.*

Proof. Let \emptyset be the empty language (i.e., the empty set in Σ^*). Clearly

$$\emptyset \in C_{\mathcal{G}}(L) \quad \text{and} \quad \emptyset \in F_{\mathcal{G}}(L)$$

so $C_{\mathcal{G}}(L)$ and $F_{\mathcal{G}}(L)$ are nonempty classes. If $K_{\alpha} \in C_{\mathcal{G}}(L)$ for α in some index set A , then

$$\bar{K}_{\alpha} \Sigma_u \cap L(\mathcal{G}) \subset \bar{K}_{\alpha}, \quad \alpha \in A.$$

By the definition of closure it follows immediately that

$$\overline{\bigcup_{\alpha} K_{\alpha}} = \bigcup_{\alpha} \bar{K}_{\alpha}.$$

Therefore

$$\begin{aligned} \left(\overline{\bigcup_{\alpha} K_{\alpha}} \right) \Sigma_u \cap L(\mathcal{G}) &= \left(\bigcup_{\alpha} \bar{K}_{\alpha} \right) \Sigma_u \cap L(\mathcal{G}) = \bigcup_{\alpha} (\bar{K}_{\alpha} \Sigma_u) \cap L(\mathcal{G}) \\ &= \bigcup_{\alpha} [\bar{K}_{\alpha} \Sigma_u \cap L(\mathcal{G})] \subset \bigcup_{\alpha} \bar{K}_{\alpha} = \overline{\bigcup_{\alpha} K_{\alpha}}, \end{aligned}$$

and so

$$\bigcup_{\alpha} K_{\alpha} \in C_{\mathcal{G}}(L)$$

as claimed. The proof for $F_{\mathcal{G}}(L)$ is similar. \square

By Proposition 7.1 each of $C_{\mathcal{G}}(L)$, $F_{\mathcal{G}}(L)$ contains a unique supremal element with respect to inclusion, which we denote by

$$\sup C_{\mathcal{G}}(L), \quad \sup F_{\mathcal{G}}(L),$$

respectively. In fact, $C_{\mathcal{G}}(L)$ and $F_{\mathcal{G}}(L)$ are complete subsemilattices of the semilattice of all sublanguages of L , partially ordered by inclusion, and with join operation the union of languages.

On the basis of Theorem 6.1 and Proposition 7.1 we immediately obtain our first main result.

THEOREM 7.1. (i) *SMP is solvable iff*

$$\sup C_{\mathcal{G}}(L_g) \supset L_a.$$

(ii) *SCP is solvable iff*

$$\sup \{C_{\mathcal{G}}(L_g) \cap F_{\mathcal{G}}(L_g)\} \supset L_a.$$

In each case the corresponding supervisor is minimally restrictive. \square

8. Projections of supervisors. Let $\mathcal{S} = (S, \phi)$ and $\hat{\mathcal{S}} = (\hat{S}, \hat{\phi})$ each be supervisors for \mathcal{G} , where as usual

$$S = (X, \Sigma, \xi, x_0, X_m), \quad \phi : X \rightarrow \{0, 1\}^\Sigma,$$

$$\hat{S} = (\hat{X}, \Sigma, \hat{\xi}, \hat{x}_0, \hat{X}_m), \quad \hat{\phi} : \hat{X} \rightarrow \{0, 1\}^\Sigma.$$

We shall say that a (total) function $\pi : X \rightarrow \hat{X}$ is a *projection* from \mathcal{S} to $\hat{\mathcal{S}}$, and write $\pi : \mathcal{S} \rightarrow \hat{\mathcal{S}}$, provided

- (i) $\pi : X \rightarrow \hat{X}$ is surjective,
- (ii) $\pi(x_0) = \hat{x}_0$ and $X_m = \pi^{-1}(\hat{X}_m)$,
- (iii)⁶ $\hat{\xi} \circ (\text{id}_\Sigma \times \pi)(\sigma, x) = \pi \circ \xi(\sigma, x)$ for all (σ, x) where $\xi(\sigma, x)$ is defined,
- (iv) $\hat{\phi} \circ \pi = \phi$.

Under these conditions we shall refer to \hat{S} as the *quotient* of S under π . The situation is displayed in the diagrams⁷ below.

Projections represent very close relationships between supervisors, as expressed in the following. We assume that $\text{id}_\Sigma \times \pi$ is extended to a map $\text{id}_\Sigma \times \pi : \Sigma^* \times X \rightarrow \Sigma^* \times \hat{X}$ in the natural way.

PROPOSITION 8.1. *Let \mathcal{S} be complete with respect to \mathcal{G} , and let $\pi : \mathcal{S} \rightarrow \hat{\mathcal{S}}$ be a projection. Then*

- (i) π is unique,
- (ii) $(L_m, L_c, L)(\mathcal{S}/\mathcal{G}) = (L_m, L_c, L)(\hat{\mathcal{S}}/\mathcal{G})$,
- (iii) $\hat{\mathcal{S}}$ is complete with respect to \mathcal{G} ,
- (iv) \mathcal{S} is nonblocking (respectively, nonrejecting, proper) iff $\hat{\mathcal{S}}$ is nonblocking (respectively, nonrejecting, proper).

Proof. As usual we write

$$\mathcal{S} = (S, \phi), \quad S = (X, \Sigma, \xi, x_0, X_m)$$

and similarly for $\hat{\mathcal{S}}$. Recall that, by definition, both S and \hat{S} are accessible.

- (i) We have $\pi(x_0) = \hat{x}_0$. If $x \in X$ then, since \mathcal{S} is accessible, there is a string $s \in \Sigma^*$ such that $x = \xi(s, x_0)$, so

$$\pi(x) = \pi \circ \xi(s, x_0) = \hat{\xi} \circ (\text{id}_\Sigma \times \pi)(s, x_0) = \hat{\xi}(s, \hat{x}_0)$$

and this formula determines $\pi(x)$ uniquely.

- (ii) Write

$$L = L(\mathcal{S}/\mathcal{G}), \quad \hat{L} = L(\hat{\mathcal{S}}/\mathcal{G}).$$

If $s \in L$ with $|s| = 1$, i.e., $s = \sigma$, then $\phi(x_0)(\sigma) = 1$, and

$$(\xi \times \delta_c)(\sigma, x_0, q_0) = (\xi(\sigma, x_0), \delta_c(\phi(x_0), \sigma, q_0)) = (\xi(\sigma, x_0), \delta(\sigma, q_0))$$

⁶ By definition $\text{id}_\Sigma \times \pi : \Sigma \times X \rightarrow \Sigma \times \hat{X} : (\sigma, x) \mapsto (\sigma, \pi(x))$.

⁷ The symbol \supset means that the left-hand diagram is only “partially commutative,” in the sense of (iii).

is defined; hence $\hat{\phi}(\hat{x}_0)(\sigma) = 1$ and

$$\begin{aligned} (\hat{\xi} \times \delta_c)(\sigma, \hat{x}_0, q_0) &= (\hat{\xi}(\sigma, \hat{x}_0), \delta(\sigma, q_0)) = (\pi \circ \xi(\sigma, x_0), \delta(\sigma, q_0)) \\ &= (\pi \times \text{id}_Q) \circ (\xi \times \delta_c)(\sigma, x_0, q_0) \end{aligned}$$

is defined. This shows that

$$L^{(1)} \subset \hat{L}^{(1)}.$$

By induction on $|s|$ it is readily seen that

$$L^{(j)} \subset \hat{L}^{(j)}, \quad j = 0, 1, \dots,$$

hence $L \subset \hat{L}$.

For the reverse inclusion suppose first that $(\hat{\xi} \times \delta_c)(\sigma, \hat{x}_0, q_0)$ is defined. Then $\sigma \in \hat{L}$ and $\hat{\phi}(\hat{x}_0)(\sigma) = 1$. So

$$\phi(x_0)(\sigma) = (\hat{\phi} \circ \pi(x_0))(\sigma) = \hat{\phi}(\hat{x}_0)(\sigma) = 1.$$

Also

$$\delta(\sigma, q_0) = \delta_c(\hat{\phi}(\hat{x}_0), \sigma, q_0)$$

is defined, so by virtue of completeness $\xi(\sigma, x_0)$ is defined. Therefore

$$(\xi \times \delta_c)(\sigma, x_0, q_0) = (\xi(\sigma, x_0), \delta(\sigma, q_0))$$

is defined, and so $\hat{L}^{(1)} \subset L^{(1)}$. Assuming $\hat{L}^{(i)} \subset L^{(i)}$ ($i = 0, 1, \dots, j$), let $s \in \hat{L}^{(j)}$ and consider $s\sigma \in \hat{L}^{(j+1)}$. Then $s \in L^{(j)}$, so

$$x := (\xi \times \delta_c)(s, x_0, q_0), \quad \hat{x} := (\hat{\xi} \times \delta_c)(s, \hat{x}_0, q_0)$$

are defined, and $\pi(x) = \hat{x}$. By exactly the same argument as before, applied to (x, \hat{x}) in place of (x_0, \hat{x}_0) , we conclude that $s\sigma \in L^{(j+1)}$. So $\hat{L} \subset L$ and $\hat{L} = L$. It is now immediate that

$$L_c(\mathcal{S}/\mathcal{G}) = L(\mathcal{S}/\mathcal{G}) \cap L_m(\mathcal{G}) = L(\hat{\mathcal{S}}/\mathcal{G}) \cap L_m(\mathcal{G}) = L_c(\hat{\mathcal{S}}/\mathcal{G}).$$

Finally,

$$\begin{aligned} s \in L_m(\mathcal{S}/\mathcal{G}) & \\ \text{iff } (\xi \times \delta_c)(s, x_0, q_0) &\in X_m \times Q_m, \\ \text{iff } \xi(s, x_0) \in X_m &\text{ and } s \in L_c(\mathcal{S}/\mathcal{G}), \\ \text{iff } \xi(s, x_0) \in \pi^{-1}(\hat{X}_m) &\text{ and } s \in L_c(\mathcal{S}/\mathcal{G}), \\ \text{iff } \pi \circ \xi(s, x_0) \in \hat{X}_m &\text{ and } s \in L_c(\hat{\mathcal{S}}/\mathcal{G}), \\ \text{iff } \hat{\xi}(s, \hat{x}_0) \in \hat{X}_m &\text{ and } s \in L_c(\hat{\mathcal{S}}/\mathcal{G}), \\ \text{iff } (\hat{\xi} \times \delta_c)(s, \hat{x}_0, q_0) &\in \hat{X}_m \times Q_m, \\ \text{iff } s \in L_m(\hat{\mathcal{S}}/\mathcal{G}). & \end{aligned}$$

(iii) To verify that $\hat{\mathcal{S}}$ is complete with respect to \mathcal{G} , let

$$s \in L(\hat{\mathcal{S}}/\mathcal{G}), \quad s\sigma \in L(\mathcal{G})$$

and

$$(\hat{\phi} \circ \hat{\xi}(s, \hat{x}_0))(\sigma) = 1.$$

Then $s \in L(\mathcal{S}/\mathcal{G})$ by (ii), and

$$\phi \circ \xi(s, x_0)(\sigma) = (\hat{\phi} \circ \pi \circ \xi(s, x_0))(\sigma) = (\hat{\phi} \circ \hat{\xi}(s, \hat{x}_0))(\sigma) = 1.$$

Since \mathcal{S} is complete it follows that $\xi(s\sigma, x_0)$ is defined, hence (because π is a projection) $\hat{\xi}(s\sigma, \hat{x}_0)$ is defined as well, namely $\hat{\mathcal{S}}$ is complete.

(iv) Immediate from (ii) and (iii). \square

9. Efficient supervisor. In this section we give a simple abstract characterization of an “efficiently constructed” supervisor for a given nonempty, controllable and $L_m(\mathcal{G})$ -closed language $K \subset \Sigma^*$. By Theorem 6.1(ii) we know that a proper supervisor $\mathcal{S} = (S, \phi)$ exists such that $K = L_m(\mathcal{S}/\mathcal{G}) = L_c(\mathcal{S}/\mathcal{G})$, so that

$$\bar{K} = L(\mathcal{S}/\mathcal{G}).$$

Furthermore, by the construction used in the proof of Proposition 5.1 (“if” statement), we can arrange that, for a string $s \in \bar{K}$, the state x reached by S is such that, for all $\sigma \in \Sigma_c$,

$$(9.1) \quad \phi(x)(\sigma) = \begin{cases} 0, & s\sigma \notin \bar{K}, \\ 1, & s\sigma \in \bar{K}. \end{cases}$$

On the basis of (9.1) we define an equivalence relation on Σ^* as follows. Strings $s, s' \in \Sigma^*$ are *control-equivalent*, written $s \sim s'$, if for all $\sigma \in \Sigma_c$, $s\sigma \in \bar{K}$ iff $s'\sigma \in \bar{K}$. Thus two strings are control-equivalent if the control action (9.1) immediately following either one is the same for every $\sigma \in \Sigma$.

Recall from automaton theory (for example, Harrison [1965]) that an equivalence relation \mathbf{e} on Σ^* is a *right-congruence* if, whenever $s, s' \in \Sigma^*$ and $s \equiv s' \pmod{\mathbf{e}}$, then for all $t \in \Sigma^*$, $st \equiv s't \pmod{\mathbf{e}}$. Now let $\{\mathbf{e}_\alpha : \alpha \in A\}$ be an arbitrary nonempty family of equivalence relations on Σ^* . Their lattice-theoretic join, written

$$(9.2) \quad \mathbf{e} = \sup \{\mathbf{e}_\alpha : \alpha \in A\},$$

is defined as follows (cf. Szász [1963]): $s \equiv s' \pmod{\mathbf{e}}$ if there exists an integer $k \geq 1$, elements $\alpha_0, \dots, \alpha_k \in A$, and strings $s_1, \dots, s_k \in \Sigma^*$ such that

$$\begin{aligned} s &\equiv s_1 \pmod{\mathbf{e}_{\alpha_0}} \\ s_1 &\equiv s_2 \pmod{\mathbf{e}_{\alpha_1}} \\ &\vdots \\ s_{k-1} &\equiv s_k \pmod{\mathbf{e}_{\alpha_{k-1}}} \\ s_k &\equiv s' \pmod{\mathbf{e}_{\alpha_k}}. \end{aligned}$$

It is easy to check that if, in particular, the \mathbf{e}_α are right-congruences, then so is \mathbf{e} .

The lattice-theoretic ordering of equivalence relations on Σ^* is defined as follows: $\mathbf{e}_1 \leq \mathbf{e}_2$ if, for all $s, s' \in \Sigma^*$, $s \equiv s' \pmod{\mathbf{e}_1}$ implies $s \equiv s' \pmod{\mathbf{e}_2}$; \mathbf{e}_1 is said to be *finer than* \mathbf{e}_2 (or \mathbf{e}_2 is *coarser than* \mathbf{e}_1). Then \mathbf{e} in (9.2) is the finest equivalence relation on Σ^* that is coarser than each \mathbf{e}_α , $\alpha \in A$.

In general, control-equivalence \sim is not a right-congruence. However, if we define $s \equiv s' \pmod{\mathbf{o}}$ if $s = s'$, then trivially \mathbf{o} is a right-congruence and $\mathbf{o} \leq \sim$. It follows from the preceding that the equivalence

$$\approx := \sup \{\mathbf{e} : \mathbf{e} \text{ a right-congruence on } \Sigma^* \text{ and } \mathbf{e} \leq \sim\}$$

exists, and is the coarsest right-congruence on Σ^* that is finer than \sim .

For $s \in \Sigma^*$ let $[s]$ be the equivalence class of $s \pmod{\approx}$. In standard fashion we construct the corresponding automaton, defined on strings in \bar{K} . Let

$$\bar{S} = (\bar{X}, \Sigma, \bar{\xi}, \bar{x}_0, \bar{X}).$$

Here

$$\bar{X} = \{[s] : s \in \bar{K}\}, \quad \bar{x}_0 = [1]$$

(note that $1 \in \bar{K}$ as \bar{K} is nonempty and closed); finally $\bar{\xi}(\sigma, \bar{x}) = \bar{x}'$ if $\bar{x} = [s]$, $s \in \bar{K}$, $s\sigma \in \bar{K}$ and $[s\sigma] = \bar{x}'$; otherwise $\bar{\xi}$ is not defined. Next we define a control law

$$\bar{\phi}: \bar{X} \rightarrow \{0, 1\}^{\Sigma}$$

according to

$$\bar{\phi}(\bar{x})(\sigma) = 0;$$

if $\sigma \in \Sigma_c$, there exists $s \in \bar{K}$ with $[s] = \bar{x}$ and $s\sigma \notin \bar{K}$; otherwise $\bar{\phi}(\bar{x})(\sigma) = 1$. By our construction of \bar{X} , $\bar{\xi}$ and $\bar{\phi}$ are unambiguously determined. We can now define the efficient supervisor

$$\bar{\mathcal{P}} = (\bar{S}, \bar{\phi}).$$

Evidently $\bar{\mathcal{P}}$ is “efficient” in the sense that any automaton \hat{S} , that supports the defined control action (9.1) on each string $s \in \bar{K}$, must have a state structure (right-congruence on Σ^*) at least as fine as that of \bar{S} .

It is easy to see that $\bar{\mathcal{P}}$ is complete, since

$$s \in \bar{K}, [s] = \bar{x}, \bar{\phi}(\bar{x})(\sigma) = 1, s\sigma \in L(\mathcal{G}),$$

implies $s\sigma \in \bar{K}$ and therefore $\bar{\xi}(\sigma, \bar{x})$ is defined. Much as in the proof of Proposition 8.1 it is straightforward to verify that $L(\bar{\mathcal{P}}/\mathcal{G}) = \bar{K} = L(\mathcal{P}/\mathcal{G})$. Finally, as $\bar{X}_m = \bar{X}$,

$$L_m(\bar{\mathcal{P}}/\mathcal{G}) = L(\bar{\mathcal{P}}/\mathcal{G}) \cap L_m(\mathcal{G}) = \bar{K} \cap L_m(\mathcal{G}) = K$$

since K is $L_m(\mathcal{G})$ -closed; so that

$$K = L_m(\bar{\mathcal{P}}/\mathcal{G}) = L_c(\bar{\mathcal{P}}/\mathcal{G})$$

and $\bar{\mathcal{P}}$ is proper. Thus $\bar{\mathcal{P}}$ performs the same control action on \mathcal{G} as the supervisor \mathcal{P} with which we started.

Let $\equiv (\text{mod } \bar{K})$ denote \bar{K} -equivalence on Σ^* : $s \equiv s' (\text{mod } \bar{K})$ if for all $t \in \Sigma^*$, $st \in \bar{K}$ iff $s't \in \bar{K}$. Clearly $\equiv (\text{mod } \bar{K})$ is a right-congruence. Also, if $s \equiv s' (\text{mod } \bar{K})$ then in particular for all $\sigma \in \Sigma_c$, $s\sigma \in \bar{K}$ iff $s'\sigma \in \bar{K}$. It follows that

$$\equiv (\text{mod } \bar{K}) \leq \approx;$$

i.e., for all $s, s' \in \Sigma^*$, $s \equiv s' (\text{mod } \bar{K})$ implies $s \approx s'$. In particular, if $s, s' \in \bar{K}$ and $s \equiv s' (\text{mod } \bar{K})$ then

$$\bar{\xi}(s, \bar{x}_0) = \bar{\xi}(s', \bar{x}_0).$$

We shall refer to the latter property by saying that the automaton \bar{S} is \bar{K} -reduced. By its construction, \bar{S} is also \bar{K} -trim, namely every state of \bar{S} is visited by a word of \bar{K} ; that is, for every $\bar{x} \in \bar{X}$ there is $s \in \bar{K}$ such that $\bar{\xi}(s, \bar{x}_0) = \bar{x}$. In the next section it is shown that any supervisor with these two properties can be projected from a supervisor based on a recognizer for \bar{K} .

10. Quotient structure theorem. We can now prove the second main result of this paper. It states, roughly, that “every efficiently constructed supervisor is a quotient (high-level, or lumped, model) of the desired closed-loop behavior.”

Let $\mathcal{P} = (S, \phi)$ be a complete supervisor for \mathcal{G} . Write $K_1 := L_m(\mathcal{P}/\mathcal{G})$, $K_3 := L(\mathcal{P}/\mathcal{G})$ and assume that S is K_3 -reduced and K_3 -trim. These properties hold for the “efficient” supervisor of the previous section. Finally let

$$\hat{S}^0 = (X^0, \Sigma, \xi^0, x_0^0, X^0)$$

be a trim recognizer for K_3 .

THEOREM 10.1. *Subject to the foregoing hypotheses, there exist a subset $X_m^0 \subset X^0$ and a state feedback map $\phi^0: X^0 \rightarrow \{0, 1\}^\Sigma$ with the following properties:*

(i) *The supervisor*

$$\mathcal{S}^0 := (S^0, \phi^0), \quad S^0 := (X^0, \Sigma, \xi^0, x_0^0, X_m^0)$$

is a complete supervisor for \mathcal{G} with

$$L_m(\mathcal{S}^0/\mathcal{G}) = K_1, \quad L(\mathcal{S}^0/\mathcal{G}) = K_3.$$

(ii) *There is a projection $\pi: \mathcal{S}^0 \rightarrow \mathcal{S}$.*

(iii) *If \mathcal{S} is proper then so is \mathcal{S}^0 .*

Proof. Write

$$S = (X, \Sigma, \xi, x_0, X_m).$$

Let $x^0 \in X^0$. Since \hat{S}^0 is trim there exists $s \in K_3$ such that

$$\xi^0(s, x_0^0) = x^0.$$

Let $\xi(s, x_0) =: x \in X$ and define $\pi: X^0 \rightarrow X$ according to $\pi(x^0) = x$.

To show that π is well-defined, let $t \in K_3$, $\xi^0(t, x_0^0) = x^0$, and let $\xi(t, x_0) =: y \in X$. Since \hat{S}^0 is a recognizer for K_3 and $\xi^0(s, x_0^0) = \xi^0(t, x_0^0)$, we have $s \equiv t \pmod{K_3}$. Since S is K_3 -reduced, $\xi(s, x_0) = \xi(t, x_0)$, i.e., $x = y$.

We claim that π is a projection. First let $x \in X$. Since S is K_3 -trim, there exists $s \in K_3$ such that $\xi(s, x_0) = x$. Let $\xi^0(s, x_0^0) =: x^0$. Then as already shown, $\pi(x^0) = x$, so π is surjective. To verify that π respects ξ^0 , let $\xi^0(\sigma, x^0) = y^0$. We have $x^0 = \xi^0(s, x_0^0)$ for some $s \in K_3$, and then $s\sigma \in K_3$. Since $K_3 = L(\mathcal{S}/\mathcal{G})$, $\xi(s\sigma, \pi(x^0))$ is defined and, as shown already, coincides with $\pi \circ \xi^0(\sigma, x^0)$. To establish that π is a projection it only remains to define $X_m^0 = \pi^{-1}(X_m)$ together with $\phi^0 := \phi \circ \pi$.

It must be shown that $L(\mathcal{S}^0/\mathcal{G}) = K_3$. By the argument used in the proof of Proposition 5.1 it is enough to show that

(i) $(\forall \sigma, x^0)(\exists s)\xi^0(s, x_0^0) = x^0$ and $s\sigma \in L(\mathcal{G})$ and $s\sigma \notin K_3 \Rightarrow \phi^0(x^0)(\sigma) = 0$,

(ii) $(\forall \sigma, x^0)(\exists s)\xi^0(s, x_0^0) = x^0$ and $s\sigma \in K_3 \Rightarrow \phi^0(x^0)(\sigma) = 1$.

For (i), let $\xi^0(s, x_0^0) = x^0$, $s\sigma \in L(\mathcal{G})$, $s\sigma \notin K_3$. Clearly $s \in K_3$. If $\xi(s, x_0) = x$ then, as in the proof of Proposition 5.1, it follows necessarily that $\phi(x)(\sigma) = 0$ and therefore

$$\phi^0(x^0)(\sigma) = (\phi \circ \pi(x^0))(\sigma) = \phi(x)(\sigma) = 0.$$

The proof of (ii) is similar.

To show that \mathcal{S}^0 is complete with respect to \mathcal{G} we note that

$$s \in L(\mathcal{S}^0/\mathcal{G}), \quad s\sigma \in L(\mathcal{G}) \quad \text{and} \quad [\phi^0 \circ \xi^0(s, x_0^0)](\sigma) = 1,$$

iff

$$s \in L(\mathcal{S}/\mathcal{G}), \quad s\sigma \in L(\mathcal{G}) \quad \text{and} \quad [\phi \circ \xi(s, x_0)](\sigma) = 1.$$

But since \mathcal{S} is complete the latter condition implies that $s\sigma \in L(\mathcal{S}/\mathcal{G}) = L(\mathcal{S}^0/\mathcal{G})$.

Finally let $s \in K_3$. Then

$$s \in K_1$$

iff $\xi(s, x_0) \in X_m$ and $\delta(s, q_0) \in Q_m$,

iff $\pi \circ \xi^0(s, x_0^0) \in X_m$ and $\delta(s, q_0) \in Q_m$,

iff $\xi^0(s, x_0^0) \in X_m^0$ and $\delta(s, q_0) \in Q_m$,

iff $s \in L_m(\mathcal{S}^0/\mathcal{G})$.

So $L_m(\mathcal{S}^0/\mathcal{G}) = L_m(\mathcal{S}/\mathcal{G})$. In particular if \mathcal{S} is proper, so is \mathcal{S}^0 . \square

11. Example 1. We consider two users of a single resource, each modeled as in § 2.3, giving the state transition graphs $\mathcal{G}_1, \mathcal{G}_2$ of Fig. 11.1. For \mathcal{G} we take the “shuffle” of $\mathcal{G}_1, \mathcal{G}_2$, namely the process determined by the concurrent actions of \mathcal{G}_1 and \mathcal{G}_2 under the assumption that these actions are asynchronous and independent. This assumption rules out the simultaneous occurrence of an event in \mathcal{G}_1 with an event in \mathcal{G}_2 , but otherwise places no constraint on their joint behavior. The graph of \mathcal{G} is thus as shown in Fig. 11.2. Here the state \odot is both q_0 and (as a singleton) Q_m , while $L_m(\mathcal{G})$ consists of all words over the alphabet

$$\Sigma = \{\alpha_1, \beta_1, \gamma_1, \alpha_2, \beta_2, \gamma_2\}$$

corresponding to paths in the graph that begin and end at \odot .

The objective of supervisory control is to manipulate the binary controls c_1, c_2 in order to satisfy the following synchronization requirements.

(i) *Mutual exclusion:* $\mathcal{G}_1, \mathcal{G}_2$ never simultaneously occupy their respective USE states.

FIG. 11.1. Example 1: Independent CDEPs \mathcal{G}_1 and \mathcal{G}_2 .

FIG. 11.2. Example 1: Shuffle \mathcal{G} of \mathcal{G}_1 and \mathcal{G}_2 .

(ii) *Fair usage*: The USE states of $\mathcal{G}_1, \mathcal{G}_2$ are occupied according to first-come-first-served discipline, namely the index sequence of events β_i must coincide with the index sequence of events α_j .

In practical terms this standard problem could, of course, be solved by a queue; but instead we shall approach it via the ideas of previous sections. However, we defer to a future article the theoretical issue of how conditions like (i) and (ii) may be formalized, simply taking it for granted that from them the “legal” behavior $L_g \subset L_m(\mathcal{G})$ can be explicitly determined. In fact the reader may convince himself that L_g is described by the generator displayed in Fig. 11.3.⁸

By inspection of Fig. 11.3 it is easy to see that L_g is both controllable and $L_m(\mathcal{G})$ -closed. That is,

$$L_g = \sup \{C_{\mathcal{G}}(L_g) \cap F_{\mathcal{G}}(L_g)\}.$$

By Theorem 6.1(ii) there exists a proper supervisor $\mathcal{S} = (S, \phi)$ such that $L_c(\mathcal{S}/\mathcal{G}) = L_g$. As demonstrated in the proof of Proposition 5.1, the state transition diagram for L_g (Fig. 11.3) can serve to define S ; it just remains to identify the state feedback map ϕ . For each state x of S , $\phi(x)$ is a map

$$\phi(x) : \{c_1, c_2\} \rightarrow \{0, 1\},$$

i.e., a binary evaluation of each of the controls c_1, c_2 . So, with reference to Fig. 11.3, it is enough to define

$$\phi(x)(c_1) = \begin{cases} 1 & \text{if an edge labeled } \beta_1 \text{ issues from } x, \\ 0 & \text{otherwise,} \end{cases}$$

and similarly for $\phi(x)(c_2)$. The resulting control patterns are tabulated in Fig. 11.4. The supervisor $\mathcal{S} = (S, \phi)$ then certainly determines

$$L(\mathcal{S}/\mathcal{G}) = \bar{L}_g, \quad L_m(\mathcal{S}/\mathcal{G}) = L_g.$$

We remark that in this example the alternative supervisor

$$\mathcal{S}^\circ = (S^\circ, \phi^\circ)$$

FIG. 11.3. Example 1: Recognizer for L_g .

⁸ Alternatively the generator of Fig. 11.3 could be taken as providing the definition of L_g .

State	x_0	x_1	x_2	x_3	x_4	x_5	x_6	x_7	x_8
ϕ	00	00	10	00	10	01	00	01	00
ϕ°	00	10	10	10	10	01	01	01	01
π	x'_0	x'_1	x'_1	x'_2	x'_2	x'_3	x'_3	x'_4	x'_4

FIG. 11.4. Example 1: Control data for \mathcal{S} , \mathcal{S}° and \mathcal{S}' .

defined by setting $S^\circ = S$, and with ϕ° as tabulated in Fig. 11.4, determines exactly the same language controlled in \mathcal{G} as \mathcal{S} does, namely

$$L(\mathcal{S}^\circ/\mathcal{G}) = L(\mathcal{S}/\mathcal{G}) = \bar{L}_g.$$

To verify this statement note that, for instance, states x_1, x_3 of S are entered only on the occurrence of the event β_1 ; but since β_1 can be immediately followed in \mathcal{G}_1 only by γ_1 , the enablement of β_1 by ϕ° in x_1 and x_3 can have no effect on the language controlled in \mathcal{G} .

It may be left to the reader to verify that \mathcal{S}° is complete with respect to \mathcal{G} . From \mathcal{S}° we construct a new supervisor $\mathcal{S}' = (S', \phi')$ and a projection $\pi: \mathcal{S}^\circ \rightarrow \mathcal{S}'$ as tabulated in Fig. 11.4; the result is displayed in Fig. 11.5. By Proposition 8.1

$$(L_m, L_c, L)(\mathcal{S}'/\mathcal{G}) = (L_m, L_c, L)(\mathcal{S}^\circ/\mathcal{G}),$$

namely control and marking action are preserved. The simplified supervisor \mathcal{S}' has just 5 states and is equivalent, in fact, to a queue (of maximum length 2) that stores events α in order of occurrence and is popped by the corresponding events γ .

12. Example 2. In a manufacturing system we consider two machines M_1, M_2 connected in tandem and separated by a buffer B (Fig. 12.1). Each machine M_i is modeled as a CDEP over the alphabet $\{\alpha_i, \beta_i, \lambda_i, \mu_i\}$ and having binary-valued controls $\{u_i, v_i\}$ (Fig. 12.2). The machine states are IDLE (I), WORKING (W) and DOWN (D).

FIG. 11.5. Example 1: Quotient supervisor \mathcal{S}' .

FIG. 12.1. Example 2: Machines coupled by a buffer.

FIG. 12.2. Example 2: State diagrams of machines.

The control u enables/disables the transition from I to W ($u = 1$ allows M to “accept a workpiece”); while v enables/disables the transition from D to I ($v = 1$ means, when M is in state D , that M is “under repair”). The buffer B has one slot, i.e., is EMPTY (E) or FULL (F); it is not a CDEP but simply an automaton driven by M_1 and M_2 (Fig. 12.3). The system operates as follows. Machine M_1 takes a workpiece (event α_1), and either successfully completes processing and passes the workpiece to the buffer (event β_1); or breaks down and discards the workpiece (event λ_1), but in that case may later be repaired (event μ_1). Machine M_2 operates in the same way, but takes its workpiece from the buffer B , provided one is there.

The problem is to manipulate the controls in order to satisfy the four requirements stated informally below.

- (i) M_1 executes α_1 only if B is in E .
- (ii) M_2 executes α_2 only if B is in F (thereby driving B to E).
- (iii) M_1 cannot execute α_1 while M_2 is in D_2 .
- (iv) If M_1 is in D_1 and M_2 is in D_2 then $v_1 = 0$.

Condition (iv) means that if both machines are down then M_2 must be repaired before M_1 .

As in Example 1, we shall not formalize these requirements or present the details of how the legal language L_g is derived from them, but merely display the result. The language L_g that incorporates requirements (i)–(iv) with the system constraints is generated as shown in Fig. 12.4. The corresponding recognizer defines a supervisor \mathcal{S}° such that $L(\mathcal{S}^\circ/\mathcal{G}) = \bar{L}_g$; the control patterns are tabulated in Fig. 12.6. It can be verified that \mathcal{S}° admits the quotient \mathcal{S} displayed in Fig. 12.5; the required projection is also tabulated in Fig. 12.6. The quotient represents a reduction from 12 states to 6.

FIG. 12.3. Example 2: State diagram of buffer.

FIG. 12.4. Example 2: Recognizer for L_g .

FIG. 12.5. Example 2: Quotient supervisor \mathcal{P} .

x^0	x	u_1	v_1	u_2	v_2
0	0	1	-	0	-
1	0	1*	-	0	-
2	1	0	-	1	-
3	0	1	-	0	-
4	3	0	-	0	1
5	0	1*	-	0	-
6	1	0	-	1*	-
7	2	0	-	-	1
8	3	0	-	0	1
9	4	0	0	0	1
10	5	-	1	0	-
11	5	-	1	0	-

FIG. 12.6. Example 2: Control data for \mathcal{S} and \mathcal{S}^0 . Assignments (*) are determined by consistency for the quotient; entries (-) may be assigned arbitrarily, consistent with the quotient.

As will be shown in a future article, it can actually be obtained directly from two modular “subsupervisors,” of which one is modeled on the buffer, and the other incorporates the logic of breakdown and repair.

13. Conclusion. In this article we have introduced a broad class of controlled discrete event processes together with some general concepts and results relating to their control or “supervision.” Our main conclusion, the Quotient Structure Theorem, is similar in spirit to the Internal Model Principle of regulator theory; it may be roughly paraphrased by saying that “supervisors must be modeled on the task to be accomplished.”

In future articles we shall discuss constructive methods for computing the supremal controllable (or closed controllable) sublanguage of a given language, as well as concrete methods for system specification and supervisor synthesis.

A SIMULTANEOUS ITERATIVE METHOD FOR COMPUTING PROJECTIONS ON POLYHEDRA*

ALFREDO N. IUSEM[†] AND ALVARO R. DE PIERRO[‡]

Abstract. A simultaneous version of Hildreth's iterative algorithm for norm minimization over linear inequalities is presented. Proofs are given showing that the algorithm converges from any starting point to its projection on the linear constraints set in the feasible case and to the nearest least squares solution in the general case.

Key words. projection methods, least squares, quadratic programming

AMS(MOS) subject classifications. 52A05, 65F10, 90C25

1. Introduction. Linearly constrained quadratic optimization problems derived from computing the least element of polyhedra appear in various fields of application and it is not rare to encounter large-scale or even huge-scale problems. Usually the matrix describing the constraints will be sparse, but all too often no special structure pattern is detectable in it. In such cases row-action methods are frequently used. A row action method is an iterative procedure which requires in each step only the current point and one row of the matrix, and performs no transformation on the matrix elements, see Censor [3]. Image reconstruction from projections is an important application of these types of methods, see, e.g., Gordon and Herman [8], Herman and Lent [9].

Hildreth's quadratic programming procedure [11] is a row-action method whose capabilities for solving large-scale problems were numerically demonstrated by Herman and Lent [10].

In order to describe the geometry behind Hildreth's algorithm and our modified version, we start by commenting briefly on the old algorithms by Kaczmarz [12] and Cimmino [4].

These methods were proposed for finding a feasible solution for a system of linear equations, but they can be easily modified for systems of linear inequalities. In such a case, they can be described as follows: Kaczmarz's approach, as presented by Agmon [1] for the inequality case, starts with an arbitrary point and generates the iterates by using the inequalities in a cyclic way and taking as next iterate the orthogonal projection of the current iterate onto the halfspace defined by the current inequality (projecting a point onto a halfspace means projecting it onto the associated hyperplane if the point lies outside the half space and leaving it unmodified otherwise). In Cimmino's method, on the other hand, the current iterate is projected onto all the half spaces and the new iterate is a convex combination of such projections. When the feasible set is nonempty, both algorithms converge from any starting point. Cimmino's method is convergent also in the infeasible case (see [6] and [15]).

Hildreth's method can be seen as a modification of Kaczmarz-Agmon's procedure for the case when the required solution is not just a feasible point but a norm minimizer one. In this case, when the current iterate is outside the halfspace corresponding to the current inequality, the next iterate is its orthogonal projection onto the associated

hyperplane, as in Kaczmarz's method. But when the current point satisfies the constraint the next iterate is its projection onto a hyperplane parallel to the hyperplane defined by the inequality, lying between it and the point itself. The location of such a parallel hyperplane is determined, at each step, by a sequence of dual variables. This sequence guarantees that at each step the current iterate is the orthogonal projection of the starting point onto a perturbed feasible set, defined by translates of the original hyperplanes (i.e. the perturbation acts only upon the right-hand side). When the feasible set is nonempty this sequence of perturbed right-hand sides converges to the original one, and the intermediate minimization property is preserved in the limit.

A proof of convergence can be found in Lent and Censor [13], who give a compact version of Hildreth's method with relaxation and almost-cyclic (instead of cyclic) utilization of the constraints.

Another extension of Hildreth's method was proposed by Bregman [2], who considers the case of minimizing nonquadratic functions. By substituting the orthogonal projections (both onto the original and the perturbed hyperplanes) by the so-called "Bregman projections," he defines an algorithm which converges for a wide class of functions. In [7] it is shown that all strictly convex functions which tend to infinity faster than linearly (i.e. such that $\lim_{\|x\| \rightarrow \infty} (f(x)/\|x\|) = \infty$) belong to that class.

Another view of Hildreth's method is obtained by looking at the sequence of dual variables. In the dual space, Hildreth's method is equivalent to the Successive Over-Relaxation (SOR) algorithm applied to a linear complementarity problem, where the matrix AA' substitutes for the original matrix A and the right-hand side is the original one. See [14] for a description of SOR methods applied to this kind of problem.

In this paper we propose a Cimmino-like relaxed version of Hildreth's method. Each iterate is orthogonally projected onto all the hyperplanes (or its parallel translates, when the constraint is satisfied) and the new iterate is a relaxed convex combination of such projections. Such implementation has two features which make it different from Censor and Lent's version. First, it is appropriate for parallel processing computers, since all the projections of the current iterate can be calculated simultaneously (that is why we call our method "simultaneous"). Second, the convergence of Cimmino's method in the infeasible case is preserved. In our case, the primal sequence converges to a norm minimizing least squares solution, i.e. to the orthogonal projection of the starting point onto the set of points which minimize the sum of the squares of the distances to the halfspaces associated with the inequalities. When the system is feasible, this is just the orthogonal projection of the starting point onto the feasible region.

Convergence in the infeasible case to a well characterized point is an interesting property, since in the applications the feasible set may be empty due to errors associated with the data gathering process, for instance.

At the same time, consideration of the infeasible case produces a rather involved proof, since no easy argument based on Fejér convergence seems available. Also, due to the primal-dual character of the method, we were not able to find a Lyapunov function for the algorithm.

In § 2 we present the algorithm and show some immediate properties, like the linear complementarity between primal and dual variables and the intermediate minimization property of the iterates.

In § 3 we show that the difference between consecutive iterates tends to zero, and that the sequence of the location parameters for the perturbed hyperplanes is bounded. From there, it follows that the sequence of perturbed right-hand sides and finally the sequence of primal iterates are bounded, i.e. they all have convergent subsequences.

In § 4 we prove that all such sequences are indeed convergent; in particular, the sequence of primal iterates converges to the projection of the starting point onto the limit of the perturbed sets, i.e. the feasible set for the system whose right-hand side is the limit of the perturbed right-hand sides. In § 5 such set is identified as the set of weighted least squares solutions if the system is infeasible, or the original feasible set otherwise.

2. The algorithm. Consider the system of inequalities

$$(1) \quad Ax \leq b$$

where A is an $m \times n$ matrix, x and b are n and m vectors respectively.

We introduce first some notation which will be used throughout the paper. If a_i are the rows of A ($a_i \neq 0$ for $1 \leq i \leq m$), let

$$H_i = \{x: \langle a_i, x \rangle = b_i\},$$

$$C_i = \{x: \langle a_i, x \rangle \leq b_i\},$$

$$C = \{x: Ax \leq b\} = \bigcap_{i=1}^m C_i.$$

Let P_i and Q_i be the orthogonal projections onto C_i and H_i , respectively,

$$(2) \quad P_i x = x + \min \left\{ 0, \frac{b_i - \langle a_i, x \rangle}{\|a_i\|^2} \right\} a_i,$$

$$(3) \quad Q_i x = x + \frac{b_i - \langle a_i, x \rangle}{\|a_i\|^2} a_i,$$

where $\langle \cdot, \cdot \rangle$ and $\|\cdot\|$ denote the Euclidean inner product and norm, respectively.

Now the algorithm is defined. Let α be a real number in the open interval $(0, 2)$ and $\lambda_1, \dots, \lambda_m$ be real positive numbers such that $\sum_{i=1}^m \lambda_i = 1$. Take $z^0 = 0$ and $x^0 \in \mathbb{R}^n$ arbitrary. Define

$$(4) \quad x^{k+1} = x^k + \alpha \left(\sum_{i=1}^m \lambda_i c_i^k a_i \right),$$

$$(5) \quad z_i^{k+1} = z_i^k - \lambda_i c_i^k \quad (1 \leq i \leq m),$$

$$(6) \quad c_i^k = \min \left\{ \frac{z_i^k}{\lambda_i}, \frac{b_i - \langle a_i, x^k \rangle}{\|a_i\|^2} \right\}.$$

Next we establish some facts which describe the geometry of the algorithm defined by (4)-(6).

PROPOSITION 1 (nonnegativity of the dual variables). *For any k , $z_i^k \geq 0$ ($1 \leq i \leq m$).*

Proof. True for $k=0$ by definition. From (6) $c_i^k \leq z_i^k / \lambda_i$; then

$$z_i^{k+1} = z_i^k - \lambda_i c_i^k \geq z_i^k - z_i^k = 0. \quad \square$$

Define

$$w_i^k = x^k + c_i^k a_i \quad (1 \leq i \leq m),$$

$$d_i^k = \frac{b_i - \langle a_i, x^k \rangle}{\|a_i\|^2} \quad (1 \leq i \leq m).$$

The w_i^k 's are the "modified projections" whose relaxed convex combination gives the next iterate, i.e.,

$$x^{k+1} = (1 - \alpha)x^k + \alpha \left(\sum_{i=1}^m \lambda_i w_i^k \right).$$

The next proposition shows that w_i^k is the orthogonal projection of x^k onto H_i if $x^k \notin C_i$ or a point in the segment between x^k and its projection onto H_i if $x^k \in C_i$.

PROPOSITION 2. *For all i , $1 \leq i \leq m$ and for all $k \geq 0$, the following statements hold:*

(i) *If $x^k \notin C_i$, then $w_i^k = P_i x^k = Q_i x^k$ and $d_i^k = c_i^k < 0$.*

(ii) *If $x^k \in C_i$, then $0 \leq c_i^k \leq d_i^k$.*

(iii) *$w_i^k \in C_i$.*

(iv) *If $c_i^k \neq d_i^k$, then $c_i^{k+1} \leq 0$.*

Proof. (i) If $x^k \notin C_i$, then $d_i^k < 0$. Since $z_i^k \geq 0$ (Proposition 1) $c_i^k = d_i^k$. From the definitions of w_i^k , P_i and Q_i we get $w_i^k = P_i x^k = Q_i x^k$.

(ii) If $x^k \in C_i$, then $d_i^k \geq 0$ and by Proposition 1, $0 \leq c_i^k \leq d_i^k$.

(iii) Obviously if $c_i^k = d_i^k$. Otherwise $c_i^k = z_i^k / \lambda_i \geq 0$ and $c_i^k < d_i^k$. So

$$\langle a_i, w_i^k \rangle = \langle a_i, x^k \rangle + c_i^k \|a_i\|^2 \leq \langle a_i, x^k \rangle + b_i - \langle a_i, x^k \rangle = b_i.$$

(iv) If $c_i^k \neq d_i^k$, then $c_i^k = z_i^k / \lambda_i \Rightarrow z_i^{k+1} = 0 \Rightarrow c_i^{k+1} \leq 0$. \square

The next lemma is the starting point for our convergence proof, and justifies our calling w_i^k a "modified projection" of x^k : it holds trivially when w_i^k is the projection of x^k onto C_i (case (i) of the proof).

LEMMA 1. $\|x^{k+1} - w_i^{k+1}\| \leq \|x^{k+1} - w_i^k\|$.

Proof. We consider all possible cases for x^{k+1} , w_i^{k+1} , w_i^k .

(i) If $x^{k+1} \notin C_i$, then $w_i^{k+1} = P_i x^{k+1}$ (Proposition 2(ii)). The inequality holds because $P_i x^{k+1}$ is the closest point to x^{k+1} in C_i and $w_i^k \in C_i$ (Proposition 2(iii)).

(ii) If $x^{k+1} \in C_i$ and $w_i^k = Q_i x^k$, then

$$(7) \quad \|x^{k+1} - w_i^k\| = \|x^{k+1} - Q_i x^k\| \geq \|Q_i x^{k+1} - x^{k+1}\|$$

using the closest point property for the projection Q_i . On the other hand $x^{k+1} \in C_i$, so

$$(8) \quad c_i^{k+1} \geq 0 \Rightarrow \|x^{k+1} - w_i^{k+1}\| = c_i^{k+1} \|a_i\| \leq d_i^{k+1} \|a_i\| = \|x^{k+1} - Q_i x^{k+1}\|$$

(Proposition 2(ii)). The result follows from (7) and (8).

(iii) The only remaining case is $x^{k+1} \in C_i$, $w_i^k \neq Q_i x^k$; in this case $w_i^k \neq Q_i x^k \Rightarrow c_i^k \neq d_i^k \Rightarrow c_i^{k+1} = 0$ (Proposition 2(ii) and (iv)) $\Rightarrow x^{k+1} = w_i^{k+1}$. \square

Let

$$\sigma_k = \sum_{i=1}^m \lambda_i (c_i^k)^2 \|a_i\|^2.$$

LEMMA 2.

$$\sigma_{k+1} \leq \sigma_k - \left(\frac{2}{\alpha} - 1 \right) \|x^{k+1} - x^k\|^2.$$

Proof. From Lemma 1,

$$\|x^{k+1} - w_i^{k+1}\|^2 \leq \|x^{k+1} - w_i^k\|^2 = \|x^{k+1} - x^k\|^2 + \|x^k - w_i^k\|^2 - 2\langle x^{k+1} - x^k, w_i^k - x^k \rangle.$$

Multiplying by λ_i and summing on i , (remember that $\sum_{i=1}^m \lambda_i = 1$)

$$\begin{aligned} \sigma_{k+1} &\leq \sigma_k + \|x^{k+1} - x^k\|^2 - 2 \left\langle x^{k+1} - x^k, \sum_{i=1}^m \lambda_i w_i^k - x^k \right\rangle \\ &= \sigma_k + \|x^{k+1} - x^k\|^2 - \frac{2}{\alpha} \|x^{k+1} - x^k\|^2 = \sigma_k - \left(\frac{2}{\alpha} - 1 \right) \|x^{k+1} - x^k\|^2. \quad \square \end{aligned}$$

Now we look at the dual variables z_i^k . The name “dual variables” is justified in the following two propositions.

We define recursively

$$(9) \quad q_i^0 = 0 \quad (1 \leq i \leq m),$$

$$(10) \quad q_i^{k+1} = -c_i^k \|a_i\|^2 + b_i - \langle a_i, x^k \rangle \quad (1 \leq i \leq m).$$

PROPOSITION 3 (Linear complementarity). *For any k , $q_i^k z_i^k = 0$ ($1 \leq i \leq m$).*

Proof. By definition $q_i^{k+1} = -c_i^k \|a_i\|^2 + b_i - \langle a_i, x^k \rangle$ and $z_i^{k+1} = z_i^k - \lambda_i c_i^k$. If $z_i^{k+1} > 0$, $c_i^k \neq z_i^k / \lambda_i \Rightarrow c_i^k = d_i^k \Rightarrow q_i^{k+1} = 0$. On the other hand if $q_i^{k+1} > 0$, $c_i^k \neq d_i^k \Rightarrow c_i^k = z_i^k / \lambda_i \Rightarrow z_i^{k+1} = 0$. \square

PROPOSITION 4. $x^k = x^0 - \alpha A^t z^k$, where “ t ” denotes matrix transposition.

Proof. By induction

$$x^1 = x^0 + \alpha \sum_{i=1}^m \lambda_i c_i^0 a_i = x^0 - \alpha A^t (z^1 - z^0) = x^0 - \alpha A^t z^1.$$

Assuming $x^k = x^0 - \alpha A^t z^k$, then

$$x^{k+1} = x^k + \alpha \sum_{i=1}^m \lambda_i c_i^k a_i = x^k - \alpha A^t (z^{k+1} - z^k),$$

from which the result follows. \square

These two propositions allow us to prove that the algorithm preserves the intermediate optimality property of Hildreth’s algorithm presented in [13].

Define the vector b^k (perturbed right-hand side) as

$$b^k = q^k + Ax^k$$

where q^k are the vectors with components defined by (9) and (10). Construct a sequence of perturbed constraint sets S^k by

$$S^k = \{x: Ax \leq b^k\}.$$

PROPOSITION 5.

$$(i) \quad q_i^k \geq 0 \quad (1 \leq i \leq m).$$

$$(ii) \quad x^k \in S^k.$$

Proof. (i) follows from (6), (9), (10) and (ii) is immediate from part (i) and the definition of S^k . \square

THEOREM 1. x^k is the solution to

$$\min \frac{1}{2} \|x - x^0\|^2 \quad \text{s.t. } x \in S^k.$$

Proof. Since the minimand is convex, the Kuhn–Tucker conditions are sufficient for optimality. They are

$$(11) \quad x - x^0 + A^t \mu = 0,$$

$$(12) \quad \mu_i (\langle a_i, x \rangle - b_i^k) = 0,$$

$$(13) \quad \mu \geq 0,$$

$$(14) \quad Ax \leq b^k.$$

Take $x = x^k$, $\mu = \alpha z^k$. Equation (14) is satisfied by Proposition 5(ii); (11) follows from Proposition 4, (12) from Proposition 3, observing that $Ax^k - b^k = -q^k$, and (13) from Proposition 1. \square

3. Convergence of a subsequence. In order to establish the convergence of the algorithm, we will prove that the sequences $\{c^k\}$, $\{b^k\}$ and $\{x^k\}$ are convergent, with

the limit of the last one being the projection of x^0 onto the feasible set of a perturbed system whose right-hand side is the limit of the sequence $\{b^k\}$. As a first step, we will conclude from Lemma 2 that these sequences are bounded, so they have convergent subsequences.

LEMMA 3. (i) *The sequence $\{c^k\} \subset \mathbb{R}^m$ has a convergent subsequence $c^{k_j} \xrightarrow{j \rightarrow \infty} v$.*

$$(ii) \quad x^{k+1} - x^k \xrightarrow{k \rightarrow \infty} 0.$$

$$(iii) \quad \sum_{i=1}^m \lambda_i c_i^k a_i \xrightarrow{k \rightarrow \infty} 0.$$

$$(iv) \quad \sum_{i=1}^m \lambda_i v_i a_i = 0.$$

Proof. (i) Since $0 < \alpha < 2$, Lemma 2 implies that σ_k is a positive decreasing sequence, hence convergent. It follows that $\{c^k\}$ is bounded. So it has a convergent subsequence.

(ii) $\|x^{k+1} - x^k\|^2 \leq (\alpha/(2-\alpha))(\sigma_k - \sigma_{k+1})$ from Lemma 2. Since $\{\sigma_k\}$ is convergent and $\alpha < 2$, the right-hand side tends to zero.

(iii) From (4)

$$\left\| \sum_{i=1}^m \lambda_i c_i^k a_i \right\|^2 = \frac{1}{\alpha^2} \|x^{k+1} - x^k\|^2 \leq \frac{1}{\alpha(2-\alpha)} (\sigma_k - \sigma_{k+1}) \rightarrow 0.$$

(iv) From (iii), since v is the limit of a subsequence of $\{c^k\}$. \square

From now on, $\{c^{k_j}\}$ will be a convergent subsequence guaranteed by Lemma 3 and v its limit. Let y^* be the vector with components defined by

$$y_i^* = -v_i \|a_i\|^2 \quad (1 \leq i \leq m),$$

and S the set defined by

$$S = \{x: Ax \leq b + y^*\}.$$

PROPOSITION 6.

$$(i) \quad b^{k_j} \xrightarrow{j \rightarrow \infty} b + y^*.$$

$$(ii) \quad S \neq \emptyset.$$

Proof. (i) $b_i^{k_j+1} = -c_i^{k_j} \|a_i\|^2 + b_i - \langle a_i, x^{k_j+1} - x^{k_j} \rangle \xrightarrow{j \rightarrow \infty} y_i^* + b_i$ by Lemma 3(i) and (ii).

(ii) In Linear Programming jargon, since $S^{k_j} \neq \emptyset$ for all j , we have a feasible basis B^{k_j} . The number of bases is finite, so there is one which is feasible for an infinite number of j 's, and hence for the limit of the b^{k_j} 's, which is $b + y^*$. \square

Now that the convergence of the subsequences $\{c^{k_j}\}$ and $\{b^{k_j}\}$ is established, we look at the subsequence $\{x^{k_j}\}$. We will show that it converges to the projection of the starting point x^0 onto S . Observe that S^k and S are convex and so the projections of any point x onto them are well defined (as the closest point to x in the respective sets). Let x^* be the projection of x^0 onto S , \hat{x}^k the projection of x^k onto S and \tilde{x}^k the projection of x^* onto S^k . We will use the following result due to Daniel [5].

THEOREM 2. Let $T = \{u: Au \leq p\}$ and $T' = \{u: Au \leq p'\}$. If T and T' are nonempty, there exists $\gamma \in \mathbb{R}$ depending only on A such that for any $u \in T$ there is a $u' \in T'$ which satisfies

$$\|u - u'\| \leq \gamma \|(p - p')^+\|$$

where the upper plus notation means, for any vector v , $(v^+)_i \equiv \max(0, v_i)$.

Proof. See [5]. \square

LEMMA 4.

- (i) $\|\hat{x}^{k_j} - x^{k_j}\| \xrightarrow{j \rightarrow \infty} 0.$
- (ii) $\|x^{k_j} - x^0\| \xrightarrow{j \rightarrow \infty} \|x^* - x^0\|.$
- (iii) $\|\hat{x}^{k_j} - x^0\| \xrightarrow{j \rightarrow \infty} \|x^* - x^0\|.$

Proof. (i) Use Theorem 2 with $T' = S$, $T = S^{k_j}$, $u = x^{k_j}$. Since \hat{x}^{k_j} is the projection of x^{k_j} onto S , and $x^{k_j} \in S^{k_j}$, if u' is the vector resulting from Theorem 1, $\|\hat{x}^{k_j} - x^{k_j}\| \leq \|x^{k_j} - u'\| \leq \gamma \|(b^{k_j} - b - y^*)^+\| \xrightarrow{j \rightarrow \infty} 0$ by virtue of Proposition 6(i).

(ii) Since $\hat{x}^{k_j} \in S$ and x^* is the projection of x^0 onto S

$$\|x^* - x^0\| \leq \|\hat{x}^{k_j} - x^0\| \leq \|\hat{x}^{k_j} - x^{k_j}\| + \|x^{k_j} - x^0\|.$$

Then for any $\varepsilon > 0$ there exists j_1 such that for $j \geq j_1$

$$(15) \quad \|x^* - x^0\| \leq \|x^{k_j} - x^0\| + \varepsilon \quad \text{because of part (i).}$$

By Theorem 1, $\|x^{k_j} - x^0\| \leq \|x - x^0\| \quad \forall x \in S^{k_j}$. Then

$$\|x^{k_j} - x^0\| \leq \|\tilde{x}^{k_j} - x^0\| \leq \|\tilde{x}^{k_j} - x^*\| + \|x^* - x^0\| \quad \text{since } \tilde{x}^{k_j} \in S^{k_j}.$$

Use Theorem 2 with $T = S$, $T' = S^{k_j}$, $u = x^*$. If u' is the vector in T' guaranteed by the theorem, since \tilde{x}^{k_j} is the projection of x^* onto S^{k_j} , we have $\|\tilde{x}^{k_j} - x^*\| \leq \|u' - x^*\| \leq \gamma \|(b - b^{k_j} + y^*)^+\| \xrightarrow{j \rightarrow \infty} 0$ by Proposition 6(i). So

$$(16) \quad \|x^{k_j} - x^0\| \leq \|x^* - x^0\| + \varepsilon \quad \text{for } j \geq j_2.$$

From (15) and (16) we have that for $j \geq \max\{j_1, j_2\}$

$$\| \|x^{k_j} - x^0\| - \|x^* - x^0\| \| < \varepsilon.$$

(iii) Immediate from (i) and (ii). \square

THEOREM 3. $x^{k_j} \xrightarrow{j \rightarrow \infty} x^*$.

Proof. $\|x^{k_j} - x^*\| \leq \|x^{k_j} - \hat{x}^{k_j}\| + \|\hat{x}^{k_j} - x^*\|.$

The first term of the right-hand side tends to zero by Lemma 4(i). Since $\|\hat{x}^{k_j} - x^0\| \xrightarrow{j \rightarrow \infty} \|x^* - x^0\|$, x^* is the unique closest point to x^0 in S and $\hat{x}^{k_j} \in S$, we conclude that $\hat{x}^{k_j} \xrightarrow{j \rightarrow \infty} x^* \Rightarrow \|\hat{x}^{k_j} - x^*\| \xrightarrow{j \rightarrow \infty} 0$. So $x^{k_j} \xrightarrow{j \rightarrow \infty} x^*$. \square

4. Convergence of the sequence. We will prove now that x^* , the projection of x^0 onto S , is the limit of the whole sequence. We will need four technical lemmas. The complication arises from the fact that x^* may be either inside or outside each of the half spaces and the behaviour of the sequence is different in each case, so that

consideration of each alternative is required. First we show that the difference between consecutive elements of the sequence $\{c^k\}$ tends to 0.

LEMMA 5. $c_i^{k+1} - c_i^k \xrightarrow[k \rightarrow \infty]{} 0$ for $1 \leq i \leq m$.

Proof. From Lemma 3(ii),

$$(17) \quad x^k - x^{k+1} \xrightarrow[k \rightarrow \infty]{} 0.$$

By continuity of the inner product

$$(18) \quad d_i^k - d_i^{k+1} \xrightarrow[k \rightarrow \infty]{} 0 \quad \text{for } 1 \leq j \leq m.$$

Consider the norm defined, for any $x \in \mathbb{R}^n$, as

$$\|x\|_*^2 = \sum_{i=1}^m \lambda_i \|a_i\|^2 x_i^2.$$

From Lemma 2 $\sigma_k = \|c^k\|_*^2$ converges. Since all norms are equivalent in finite dimension $\sum_{i=1}^m |c_i^k|$ converges, so

$$(19) \quad \sum_{i=1}^m (|c_i^k| - |c_i^{k+1}|) \xrightarrow[k \rightarrow \infty]{} 0.$$

Take k_0 big enough so that $\|x^k - x^{k+1}\|$, $|d_i^k - d_i^{k+1}|$ ($i = 1, \dots, m$) and $\|c_i^k| - |c_i^{k+1}||$ ($i = 1, \dots, m$) are less than a given ε for $k > k_0$. Now we consider three cases according to the location of x^k and x^{k+1} with respect to the hyperplane H_i . Let

$$I_1 = \{i: x^k \in C_i \text{ and } x^{k+1} \in C_i\},$$

$$I_2 = \{i: x^k \notin C_i \text{ and } x^{k+1} \notin C_i\},$$

$$I_3 = \{1, \dots, m\} - I_1 - I_2.$$

(i) For $i \in I_2$, $c_i^{k+1} = d_i^{k+1} < 0$, $c_i^k = d_i^k < 0$ from Proposition 2(i). So

$$(20) \quad |c_i^k - c_i^{k+1}| = |d_i^k - d_i^{k+1}| < \varepsilon.$$

Also

$$(21) \quad -\varepsilon < |c_i^k| - |c_i^{k+1}| < \varepsilon.$$

(ii) For $i \in I_3$, since x^k and x^{k+1} are on different sides of H_b we use Proposition 2(i) and (ii) to get

$$(22) \quad |c_i^k| \leq |d_i^k| \leq \frac{\|x^k - Q_i x^k\|}{\|a_i\|} \leq \frac{\|x^k - x^{k+1}\|}{\|a_i\|} \leq \frac{\varepsilon}{\|a_i\|},$$

$$(23) \quad |c_i^{k+1}| \leq |d_i^{k+1}| \leq \frac{\|x^{k+1} - Q_i x^{k+1}\|}{\|a_i\|} \leq \frac{\|x^k - x^{k+1}\|}{\|a_i\|} \leq \frac{\varepsilon}{\|a_i\|}.$$

(iii) From (22) and (23) both $c_i^k - c_i^{k+1}$ and $|c_i^k| - |c_i^{k+1}|$ are arbitrarily small for big enough k and $i \in I_3$. So, using Proposition 2(ii), (19) and (21):

$$(24) \quad \sum_{i \in I_1} (c_i^k - c_i^{k+1}) = \sum_{i \in I_1} (|c_i^k| - |c_i^{k+1}|) \xrightarrow[k \rightarrow \infty]{} 0.$$

But for $i \in I_1$, either $c_i^k \neq d_i^k \Rightarrow c_i^k - c_i^{k+1} \geq 0$ (from Proposition 2(ii) and (iv)) or

$$(25) \quad c_i^k = d_i^k \Rightarrow c_i^k - c_i^{k+1} \geq d_i^k - d_i^{k+1}.$$

Since the right-hand side of (25) tends to 0, it follows from (24) that each term $c_i^k - c_i^{k+1}$ is arbitrarily small for big enough k . \square

We use Lemma 5 to prove some relations between $x^* = \lim_j x^{k_j}$ and $v = \lim_j c^{k_j}$. Let $d^* = (b_i - \langle a_i, x^* \rangle) / \|a_i\|^2$ and $D_i = \{x \in \mathbb{R}^n : \langle a_i, x \rangle < b_i\}$.

LEMMA 6.

- (i) If $x^* \notin C_i$, then $v_i = d_i^* < 0$.
- (ii) If $x^* \in H_i$, then $v_i = 0$.
- (iii) If $x^* \in D_i$, then either $v_i = 0$ or $v_i = d_i^* > 0$.

Proof. (i) Since $x^* \notin C_i$, $d_i^* < 0$ and $x^{k_j} \notin C_i$ for big enough j . So $c_i^{k_j} = d_i^{k_j} < 0$.

Taking limits as $j \rightarrow \infty$ on both sides the result follows.

(ii) Since $x^* \in H_i$, $|d_i^{k_j}| < \varepsilon$ for big enough j and any ε . But by definition $|c_i^{k_j}| \leq |d_i^{k_j}| \Rightarrow$

$$0 = \lim_{j \rightarrow \infty} c_i^{k_j} = v_i.$$

(iii) Since $x^* \in D_i$, $x^{k_j} \in C_i$ for big enough $j \Rightarrow c_i^{k_j} \geq 0 \Rightarrow v_i \geq 0$. Assume $v_i > 0$. We claim that

$$(26) \quad c_i^{k_j} = d_i^{k_j}.$$

Otherwise, by Proposition 2(iv), $c_i^{k_j} \leq 0$; but from Lemma 5 and the definition of v_i , $c_i^{k_j+1}$ is arbitrarily close to $v_i > 0$ for big enough j . Take limits on both sides of (26). \square

Let now $I = \{i : x^* \in D_i, v_i = 0\}$, $J = \{i : x^* \in D_i, v_i \neq 0\}$ (later on it will be shown that $J = \emptyset$).

LEMMA 7. *There exists s such that for $j > s$*

- (a) $c_i^{k_j} = d_i^{k_j}$ for $i \in J$,
- (b) $c_i^{k_j} = 0$ for $i \in I$.

Proof. (a) It follows from (26).

(b) From Lemma 3(i) and Theorem 4, x^{k_j-1} gets arbitrarily close to x^* for big enough j , so $d_i^{k_j-1}$ is arbitrarily close to d_i^* , since $x^* \in D_i$. On the other hand, $c_i^{k_j-1}$ is arbitrarily close to $v_i = 0$ by Lemma 5 and the definition of v_i . It follows that $c_i^{k_j-1} \neq d_i^{k_j-1} \Rightarrow c_i^{k_j} \leq 0$ (Proposition 2(iv)). But $x^* \in D_i \Rightarrow x^{k_j} \in D_i \Rightarrow c_i^{k_j} \geq 0$. So $c_i^{k_j} = 0$ for big enough j . \square

The following lemma is the final piece of the convergence proof. It requires the following elementary proposition, which results from the fact that projections are contractions.

PROPOSITION 7. (i) For any $x, y \in \mathbb{R}^n$, $0 \leq \beta < 2$, $1 \leq i \leq m$,

$$\|(1-\beta)(x-y) + \beta(Q_i x - Q_i y)\| \leq \|x-y\|.$$

(ii) For any $x \in \mathbb{R}^n$, $y \in H_i$, $0 < \beta < 2$, $1 \leq i \leq m$,

$$\|(1-\beta)x + \beta Q_i(x-y)\| \leq \|x-y\|.$$

Proof. (i) It follows easily from (3), expanding the square of the norm.

(ii) From (i), since for $y \in H_i$, $Q_i y = y$. \square

Define now $\varepsilon = \frac{1}{4} \min_i \{\|v_i\| \|a_i\| : v_i \neq 0\}$. Use Lemmas 3(ii) and 5 to find r such that $\|x^{k+1} - x^k\| < \varepsilon$, $|c_i^{k+1} - c_i^k| < \varepsilon / \|a_i\|$ for $k > r$.

LEMMA 8. *Take $k > r$. If x^k generated by the algorithm (4)–(6) satisfies:*

- (a) $\|x^k - x^*\| < \varepsilon$,
- (b) $c_i^k = 0$ for $i \in I$,
- (c) $c_i^k = d_i^k$ for $i \in J$,

then

- (i) $\|x^{k+1} - x^*\| \leq \|x^k - x^*\|$,
- (ii) x^{k+1} satisfies (a), (b) and (c).

Proof. (i) $\|x^{k+1} + x^*\| = \|(x^k - x^*) + \alpha[\sum_{i=1}^m \lambda_i(c_i^k - v_i)a_i]\| \leq \sum_{i=1}^m \lambda_i \|(x^k - x^*) + \alpha[(c_i^k - v_i)a_i]\|$.

Since $\sum_{i=1}^m \lambda_i = 1$, the result is established, provided we show that

$$(27) \quad \|(x^k - x^*) + \alpha[(c_i^k - v_i)a_i]\| \leq \|x^k - x^*\| \quad (1 \leq i \leq m).$$

Consider the following cases:

(I) $x^* \notin C_i$. By Lemma 6(i), $v_i = d_i^* \Rightarrow \|x^* - Q_i x^*\| = |v_i| \|a_i\| > 3\varepsilon$. Since $\|x^k - x^*\| < \varepsilon$, $x^k \notin C_i$. So

$$(28) \quad c_i^k = d_i^k \Rightarrow x^k + c_i^k a_i = Q_i x^k.$$

Also by Lemma 6(i),

$$(29) \quad x^* + v_i a_i = x^* + d_i^* a_i = Q_i x^*.$$

Substitute (28) and (29) into the left-hand side of (27), apply Proposition 7(i) with $\beta = \alpha$ and get the required inequality.

(II) $x^* \in H_i$. By Lemma 6(ii) $v_i = 0$ and $x^* + v_i a_i = Q_i x^*$. If $x^k + c_i^k a_i = Q_i x^k$, apply Proposition 7(i) with $\beta = \alpha$, as before. Otherwise, $x^k \in D_i$ and $0 \leq c_i^k < d_i^k \Rightarrow 0 \leq \alpha(c_i^k/d_i^k) < 2$. Take $\beta = \alpha(c_i^k/d_i^k)$. The left-hand side of (27) becomes

$$\|(1-\beta)x^k + \beta(x^k + d_i^k a_i) - x^*\| = \|(1-\beta)x^k + \beta Q_i x^k - x^*\|.$$

Apply Proposition 7(ii) and get (27).

(III) $x^* \in D_i$, $v_i = 0$. By hypothesis (b), $c_i^k = 0$, and both sides of (27) are equal.

(IV) $x^* \in D$, $v_i \neq 0$. By Lemma 6(iii)

$$(30) \quad v_i = d_i^* \Rightarrow x^* + v_i a_i = Q_i x^*,$$

By hypothesis (c),

$$(31) \quad c_i^k = d_i^k \Rightarrow x^k + c_i^k a_i = Q_i x^k.$$

Substitute (30) and (31) into the left-hand side of (27) and apply Proposition 7(i) with $\beta = \alpha$.

(ii) x^{k+1} satisfies (a) because of part (i). For (b), since $\|x^k - x^*\| < \varepsilon$, $x^k \in D_i \Rightarrow d_i^k > 0$. Since $c_i^k = 0$, by Proposition 2(iv) $c_i^{k+1} \leq 0$. Since x^{k+1} satisfies (a), $x^{k+1} \in D_i \Rightarrow c_i^{k+1} \geq 0$; so $c_i^{k+1} = 0$. For (c), if $c_i^{k+1} \neq d_i^{k+1}$ then by Proposition 2(iv), $c_i^{k+2} \leq 0$. Since $\|x^{k+2} - x^*\| \leq \|x^{k+2} - x^{k+1}\| + \|x^{k+1} - x^k\| + \|x^k - x^*\| \leq 3\varepsilon$, we get $x^{k+2} \in D_i \Rightarrow c_i^{k+2} \geq 0$. So $c_i^{k+2} = 0$. Then

$$(32) \quad |c_i^k| = |c_i^k - c_i^{k+2}| \leq |c_i^k - c_i^{k+1}| + |c_i^{k+1} - c_i^{k+2}| \leq \frac{2\varepsilon}{\|a_i\|}.$$

On the other hand,

$$\begin{aligned} c_i^k \|a_i\| &= \|x^k - Q_i x^k\| \geq \|x^* - Q_i x^k\| - \|x^k - x^*\| \\ &\geq \|x^* - Q_i x^*\| - \|x^k - x^*\| > 4\varepsilon - \varepsilon = 3\varepsilon, \end{aligned}$$

in contradiction with (32). Conclude that $c_i^{k+1} = d_i^{k+1}$. \square

We present now our main convergence result.

THEOREM 4. $x^* = \lim_{k \rightarrow \infty} x^k$.

Proof. Let r and ε be as defined just before Lemma 8. Take j big enough so that $j > s$ as defined in Lemma 7, $k_j > r$ and $\|x^{k_j} - x^*\| < \varepsilon$. Then x^{k_j} satisfies the hypotheses

of Lemma 8, which can be applied recursively for any $k > k_j$. So $\|x^k - x^*\| \leq \|x^{k_j} - x^*\|$ for any $k > k_j$. Since $x^{k_j} \xrightarrow{j \rightarrow \infty} x^*$ the theorem holds. \square

5. Characterization of the set S . Let $F = \{x \in \mathbb{R}^n : \sum_{i=1}^m \lambda_i P_i x = x\}$ and define $f: \mathbb{R}^n \rightarrow \mathbb{R}$ as $f(x) = \sum_{i=1}^m \lambda_i \|x - P_i x\|^2$. In [6] it was shown that F is just the set of minimizers of f and that $F = C$ when $C \neq \emptyset$. The results of §§ 3 and 4 indicate that the point x^* is the projection of x^0 onto the set $S = \{x: Ax \leq b + y^*\}$. We prove here that S is in fact F . So x^* is the closest solution of (1) to x^0 , if (1) is feasible, or the weighted (with the λ_i 's) least squares solution closest to x^0 , if (1) is infeasible.

LEMMA 9. $J = \emptyset$.

Proof. Take $i \in J$. Since $x^k \xrightarrow{k \rightarrow \infty} x^*$, there exists K such that $x^k \in C_i$ for $k > K$. So $c_i^k \geq 0$ for $k \geq K$. Now

$$0 \leq z_i^k = z_i^K - \lambda_i \sum_{j=K}^{k-1} c_i^j \Rightarrow \sum_{j=K}^{k-1} c_i^j \leq \frac{z_i^K}{\lambda_i}.$$

Let k go to infinity. The series converges. So $c_i^k \rightarrow 0$ and $v_i = \lim_{j \rightarrow \infty} c_i^j = 0$. \square

COROLLARY 1. $x^* + v_i a_i = P_i x^*$.

Proof. The second alternative in Lemma 6(iii) is impossible, so $v_i = \min \{0, d_i^*\}$. \square

COROLLARY 2. $x^* \in F$.

Proof. By definition of F , $x^* \in F$ if and only if $x^* = \sum_{i=1}^m \lambda_i P_i x^*$. From Corollary 1, $\sum_{i=1}^m \lambda_i P_i x^* = x^* + \sum_{i=1}^m \lambda_i v_i a_i = x^*$ by Lemma 3(iv). \square

LEMMA 10. (x^*, y^*) is a solution of

$$\begin{aligned} & \min_{x, y} \sum \lambda_i \frac{y_i^2}{\|a_i\|^2}, \\ & \text{s.t.} \begin{cases} Ax \leq b + y, \\ y \geq 0. \end{cases} \end{aligned}$$

Proof. Because of the convexity of the minimand, the Kuhn-Tucker conditions are sufficient for optimality. They are

$$(33) \quad 2 \frac{\lambda_i y_i}{\|a_i\|^2} - \mu - \rho = 0,$$

$$(34) \quad A' \mu = 0,$$

$$(35) \quad \mu_i (\langle a_i, x \rangle - b_i - y_i) = 0, \quad i = 1, \dots, m,$$

$$(36) \quad \rho_i y_i = 0, \quad i = 1, \dots, m,$$

$$(37) \quad Ax - b - y \leq 0,$$

$$(38) \quad \rho \geq 0,$$

$$(39) \quad \mu \geq 0.$$

Take $\rho = 0$, $\mu_i = -(2\lambda_i y_i^* / \|a_i\|^2)$ ($i = 1, \dots, m$), so (33), (36) and (38) are satisfied. In view of Lemmas 6 and 9, $y_i^* = -v_i \|a_i\|^2 \geq 0$. So (39) is satisfied. From Lemma 3(iv), $A' \mu = 0$ and (34) holds. Since $x^* \in S$, (37) holds. Only (35) remains to be checked. If $\mu_i \neq 0$, use Lemmas 6 and 9 to conclude that

$$x^* \notin C_i \Rightarrow v_i = d_i^* = \frac{b_i - \langle a_i, x^* \rangle}{\|a_i\|^2} \Rightarrow \langle a_i, x^* \rangle - b_i - y_i^* = 0. \quad \square$$

Observe that the minimand is strictly convex in y , so y^* is the unique solution for the “ y ” part of the problem.

LEMMA 11. $F = \{x | Ax \leq b + y^*\}$.

Proof. As noted before, F is the set of solutions of the problem $\min_x \sum_{i=1}^m \lambda_i \|P_i x - x\|^2$ (see [6]). Such a problem is equal to

$$\min_x \sum_{i=1}^m \lambda_i \left[\min \left\{ 0, \frac{b_i - \langle a_i, x \rangle}{\|a_i\|^2} \right\} \right]^2 = \min_x \sum_{i=1}^m \frac{\lambda_i}{\|a_i\|^2} [\max \{0, \langle a_i, x \rangle - b_i\}]^2,$$

which is equivalent to

$$\min_y \sum_{i=1}^m \frac{\lambda_i y_i^2}{\|a_i\|^2} \quad \text{s.t. } y_i = \max \{0, \langle a_i, x \rangle - b_i\},$$

or

$$(40) \quad \min_y \sum_{i=1}^m \frac{\lambda_i y_i^2}{\|a_i\|^2} \quad \text{s.t. } \begin{cases} Ax \leq b + y, \\ y \geq 0. \end{cases}$$

So $F = \{x | Ax \leq b + y^0\}$ where y^0 solves the “ y ” part of (40). By Lemma 10, such a y^0 has to be y^* . \square

THEOREM 5. *The sequence $\{x^k\}$ converges to the projection of x^0 onto F (i.e., to the closest point to x^0 in F).*

Proof. Immediate from Lemma 11, remembering that x^* is, by definition, the projection of x^0 onto S . \square

6. Conclusion. Hildreth published his algorithm more than twenty years ago [11] but it was only recently applied for solving huge-scale, sparse problems [10]. In 1980, Lent and Censor [13] gave an extended convergence proof of Hildreth’s method introducing an almost cyclic control and showing that it has an important optimality property. Along the lines of Lent and Censor’s paper, we have modified Hildreth’s algorithm preserving its main characteristics like the optimality property given by our Theorem 5 and obtaining a more general convergence theorem that includes a possibly empty constraint set.

SYMMETRIES IN OPTIMAL CONTROL*

A. J. VAN DER SCHAFT†

Abstract. It is argued that the existence of symmetries may simplify, as in classical mechanics, the solution of optimal control problems. A procedure for obtaining symmetries for the optimal Hamiltonian resulting from the Maximum Principle is given; this avoids the actual calculation of the optimal Hamiltonian. This procedure is based upon the notion of symmetry for the Hamiltonian system with inputs and outputs associated with an optimal control problem.

Key words. optimal control, Hamiltonian system, symmetry, reduction

AMS(MOS) subject classifications. 49A10, 49B10, 58F05, 93C10

1. The Maximum Principle and Hamiltonian systems. Let us consider a smooth nonlinear control system

$$(1) \quad \dot{x} = f(x, u), \quad x \in X, \quad u \in U$$

where f is a smooth mapping. (Smooth always means C^∞ or C^k with k "big enough.") For simplicity of exposition we will take $X = \mathbb{R}^n$ and $U = \mathbb{R}^m$, although X and U may be arbitrary smooth manifolds. (We can even take the input space U to be *state dependent*. Then (x, u) are fiber respecting coordinates for a fiber bundle B over X , instead of coordinates for the product space $X \times U$, see [2], [6], [8].)

Let now $L: X \times U \rightarrow \mathbb{R}$ and $K: X \rightarrow \mathbb{R}$ be smooth functions. We consider the (unrestricted and smooth) Bolza problem of minimizing (with respect to $u(\cdot)$) the cost functional

$$(2) \quad J(x_0, u(\cdot)) = K(x(T)) + \int_0^T L(x(t), u(t)) dt$$

under the constraints

$$(3) \quad \dot{x}(t) = f(x(t), u(t)), \quad x(0) = x_0 \in X.$$

This is called the (finite time) *optimal control problem*. Of course we have to worry about the class of functions $U(x_0)$ from $[0, T]$ to U (which may depend on the initial condition), over which the cost functional is minimized. Since we only want to deal with some *structural* properties of the above optimal control problem, we make the following simplifying assumptions (see also [4]):

1) $U(x_0)$ consists of measurable functions such that $\dot{x} = f(x, u)$ has a well-defined solution for all $t \in [0, T]$ and $x(0) = x_0$.

2) For each $x_0 \in X$ there exists a $u^*(\cdot) \in U(x_0)$ such that

$$(4) \quad J(x_0, u^*(\cdot)) = \min_{u(\cdot) \in U(x_0)} J(x_0, u(\cdot)),$$

($u^*(\cdot): [0, T] \rightarrow U$ is called the *optimal control*).

In order to solve the optimal control problem, the Maximum Principle tells us to introduce the Hamiltonian function $H: X \times \mathbb{R}^n \times U \rightarrow \mathbb{R}$ given by

$$(5) \quad H(x, p, u) := p^T f(x, u) - L(x, u)$$

* Received by the editors October 1, 1984; accepted for publication (in revised form) December 17, 1985.

† Department of Applied Mathematics, Twente University of Technology, 7500 AE Enschede, the Netherlands.

with $p \in \mathbb{R}^n$ the *co-state*, and to consider the following set of differential equations

$$(6a) \quad \dot{x}_i(t) = \frac{\partial H}{\partial p_i}(x(t), p(t), u(t)) = f_i(x(t), u(t)), \quad i = 1, \dots, n,$$

$$(6b) \quad \dot{p}_i(t) = -\frac{\partial H}{\partial x_i}(x(t), p(t), u(t)),$$

with the (mixed) boundary conditions

$$(7) \quad \begin{aligned} x(0) &= x_0, \\ p_i(T) &= -\frac{\partial K}{\partial x_i}(x(T)), \quad i = 1, \dots, n, \end{aligned}$$

where $x(T)$ is the solution at time T of (6a) for $x(0) = x_0$. A necessary condition for a control function $u^* \in U(x_0)$ to be optimal, i.e., satisfying (4), is that for every $t \in [0, T]$

$$(8) \quad H(x^*(t), p^*(t), u^*(t)) = \max_{u \in U} H(x^*(t), p^*(t), u)$$

where $(x^*(\cdot), p^*(\cdot))$ is the solution of (6) with $u(\cdot) = u^*(\cdot)$ and boundary conditions (7). So the Maximum Principle leads us to the following static optimization problem: Find for every $(x, p) \in X \times \mathbb{R}^n$ a $u^* \in U$ such that

$$(9) \quad H(x, p, u^*) = \max_{u \in U} H(x, p, u).$$

Since we assumed U to be \mathbb{R}^m (or a manifold), (9) implies the first order conditions

$$(10) \quad \frac{\partial H}{\partial u_j}(x, p, u^*) = 0, \quad j = 1, \dots, m.$$

Hence the Maximum Principle leads in a natural way to the *system*

$$(11) \quad \begin{aligned} \dot{x}_i &= \frac{\partial H}{\partial p_i}(x, p, u), & i = 1, \dots, n, \\ \dot{p}_i &= -\frac{\partial H}{\partial x_i}(x, p, u), \\ y_j &= \frac{\partial H}{\partial u_j}(x, p, u), & j = 1, \dots, m, \end{aligned}$$

and a necessary condition for $u^*(\cdot)$ to be optimal is that the *outputs* y_j of this system, resulting from $u^*(\cdot)$ and boundary conditions (7), are constant zero.

Now equations (11) form a *Hamiltonian system* as introduced in [2] and developed in [5], [6], [7], [8]. In fact the state space of this Hamiltonian system is $X \times \mathbb{R}^n = \mathbb{R}^{2n}$, with the natural symplectic form $\sum_{i=1}^n dp_i \wedge dx_i$, the input space is $U = \mathbb{R}^m$, and the output space is $Y = \mathbb{R}^m$, with coordinates (y_1, \dots, y_m) . The product space $U \times Y$ has the natural symplectic form $\sum_{j=1}^m dy_j \wedge du_j$. From a geometric point of view equations (11) describe a $(2n + m)$ -dimensional submanifold L of $T(X \times \mathbb{R}^n) \times (U \times Y)$ (the coordinates (x, p, u) parametrize the possible state space evolutions (\dot{x}_i, \dot{p}_i) and outputs y_j). This submanifold has a special structure related to the given symplectic structures on $X \times \mathbb{R}^n$ and $U \times Y$.

Recall the definition of a *Lagrangian submanifold* [1], [8]. A submanifold L of a manifold N with symplectic form ω is Lagrangian if ω restricted to L is zero and $\dim L = \frac{1}{2} \dim N$.

DEFINITION 1 [5], [6], [7], [8]. A Hamiltonian system with state space $\mathbb{R}^n \times \mathbb{R}^n$, input space \mathbb{R}^m and output space \mathbb{R}^m is given by a submanifold $L \subset T(\mathbb{R}^n \times \mathbb{R}^n) \times (\mathbb{R}^m \times \mathbb{R}^m)$ such that

(i) L can be parametrized by the state space variables (x, p) and the input variables u .

(ii) L is a Lagrangian submanifold of $T(\mathbb{R}^n \times \mathbb{R}^n) \times (\mathbb{R}^m \times \mathbb{R}^m)$ with its natural symplectic form $\sum_{i=1}^n (dp_i \wedge dx_i + dp_i \wedge d\dot{x}_i) - \sum_{j=1}^m dy_j \wedge du_j$.

Since L is Lagrangian and satisfies condition (i) there exists a *generating function* $H(x, p, u)$ for L such that L is given by equations (11) [7], [8]. In the optimal control case this generating function $H(x, p, u)$ has the extra property of being affine in the p -variables. We call (11) the Hamiltonian system *associated* with the optimal control problem.

Remark. If X and U are arbitrary manifolds, we have to generalize the definition of the associated Hamiltonian system in the following way. Instead of $\mathbb{R}^n \times \mathbb{R}^n$ we take as state space T^*X , and the space $\mathbb{R}^m \times \mathbb{R}^m$ of inputs and outputs becomes T^*U , where both cotangent bundles are endowed with their natural symplectic forms.

Now we investigate the consequences of imposing the necessary conditions (10) on the associated Hamiltonian system (11). Since the symplectic form $\sum_{i=1}^n (dp_i \wedge dx_i + dp_i \wedge d\dot{x}_i) - \sum_{j=1}^m dy_j \wedge du_j$ is zero restricted to the submanifold L associated with (11), the form $\sum_{i=1}^n (dp_i \wedge dx_i + dp_i \wedge d\dot{x}_i)$ is zero restricted to the subset $L \cap \{y_j = \partial H / \partial u_j = 0, j = 1, \dots, m\}$, and therefore also restricted to the projection V of $L \cap \{y_j = 0, j = 1, \dots, m\}$ onto $T\mathbb{R}^{2n}$. Now if V is a nice $2n$ -dimensional submanifold of $T\mathbb{R}^{2n}$ it follows that V is a *Lagrangian* submanifold of $T\mathbb{R}^{2n}$, $\sum_{i=1}^n (dp_i \wedge dx_i + dp_i \wedge d\dot{x}_i)$. Moreover, if V can be parametrized by the state space variables (x, p) , this implies that V is actually the graph of a Hamiltonian vectorfield on \mathbb{R}^{2n} [1], [8]. The simplest case is where the matrix $(\partial^2 H / \partial u_i \partial u_j)$ has rank m in every solution (x, p, u^*) of (10) (the so-called *nonsingular* case). Then the equations $\partial H / \partial u_j(x, p, u^*) = 0, j = 1, \dots, m$, have locally a unique solution $u^*(x, p)$, and V is locally given as

$$(12) \quad V = \left\{ \left(x, p, \frac{\partial H}{\partial p}(x, p, u^*(x, p)), -\frac{\partial H}{\partial x}(x, p, u^*(x, p)) \right) \mid x \in \mathbb{R}^n, p \in \mathbb{R}^n \right\}.$$

Hence V is locally the graph of the Hamiltonian vector field of the (locally defined) *optimal Hamiltonian* $H^0(x, p) := H(x, p, u^*(x, p))$.

Remark. If $(\partial^2 H / \partial u_i \partial u_j)$ is singular but the rank of the map $\partial H / \partial u(\cdot, \cdot, \cdot)$ from $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m$ to \mathbb{R}^m is equal to m , then the set $(\partial H / \partial u)^{-1}(0)$ is a $2n$ -dimensional submanifold of $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m$. Under certain regularity conditions (see [8]) on the map $(x, p, u) \rightarrow (x, p, \partial H / \partial p(x, p, u), -\partial H / \partial x(x, p, u))$ from $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n$ to $T(\mathbb{R}^n \times \mathbb{R}^n)$ it follows that V is an (immersed) Lagrangian submanifold of $T(\mathbb{R}^n \times \mathbb{R}^n)$. However, since in general V need not be parametrized by the state space variables (x, p) , we generally only obtain a set of *implicit* Hamiltonian differential equations on $\mathbb{R}^n \times \mathbb{R}^n$ [8].

For clarity of exposition we will make the following additional assumptions which will hold throughout the next section:

1) The matrix $(\partial^2 H / \partial u_i \partial u_j)(x, p, u^*)$ is nonsingular in every solution (x, p, u^*) of (10). The solution u^* of (10) is unique and is a smooth mapping $u^*(x, p)$ from $\mathbb{R}^n \times \mathbb{R}^n$ to \mathbb{R}^m .

2) This solution $u^*(x, p)$ is *optimal*, resulting in the optimal Hamiltonian $H^0(x, p) := H(x, p, u^*(x, p))$.

2. Symmetries. Under the simplifying assumptions made before the optimal control problem reduces to the solution of a set of Hamiltonian equations

$$(13) \quad \begin{aligned} \dot{x}_i &= \frac{\partial H^0}{\partial p_i}(x, p), & x(0) &= x_0, \\ \dot{p}_i &= -\frac{\partial H^0}{\partial x_i}(x, p), & p_i(T) &= -\frac{\partial K}{\partial x_i}(x(T)), \end{aligned} \quad i = 1, \dots, n,$$

with $H^0(x, p) = H(x, p, u^*(x, p))$, where $u^*(x, p)$ is the unique solution of

$$(14) \quad \frac{\partial H}{\partial u_j}(x, p, u^*(x, p)) = 0, \quad j = 1, \dots, m.$$

Now solving (13) and (14) is typically a formidable task, and it is worthwhile to look for circumstances which make the solution easier.

If the equations (14) are explicitly solved for $u^*(x, p)$ and if we therefore have an *explicit* expression for $H^0(x, p)$, it is a classical method (in mechanics) to look for *symmetries* of H^0 in order to simplify the solution of (13). (This point was also raised in [3].) Let us introduce some notation. If $F: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ is a smooth function, then we denote the corresponding Hamiltonian vectorfield

$$(15) \quad \dot{x}_i = \frac{\partial F}{\partial p_i}(x, p), \quad \dot{p}_i = -\frac{\partial F}{\partial x_i}(x, p), \quad i = 1, \dots, n$$

by X_F . Moreover if G is another smooth function on $\mathbb{R}^n \times \mathbb{R}^n$, then the *Poisson bracket* $\{F, G\}$ of F and G is defined as

$$(16) \quad \{F, G\} = \sum_{i=1}^n \left(\frac{\partial F}{\partial p_i} \frac{\partial G}{\partial x_i} - \frac{\partial F}{\partial x_i} \frac{\partial G}{\partial p_i} \right).$$

It is easy to see that $\{F, G\} = -\{G, F\}$ and that

$$(17) \quad \{F, G\} = X_F(G).$$

Now the most general definition of an (infinitesimal) symmetry for H^0 is of a Hamiltonian vectorfield X_F satisfying

$$(18) \quad X_F(H^0) = \{F, H^0\} = 0.$$

This implies that $0 = \{F, H^0\} = -\{H^0, F\} = -X_{H^0}(F)$, and hence that F is a *first integral* or *conserved quantity* for (13). Therefore if X_F is a symmetry of H^0 , then F is a first integral for X_{H^0} . Conversely if F is a first integral for X_{H^0} , i.e., $X_{H^0}(F) = 0$, it follows that X_F is a symmetry for H^0 . The existence of such a conserved quantity F for (13) may be used for *reducing* the $2n$ -dimensional set of equations (13) to a $(2n-2)$ -dimensional set. Indeed, suppose that dF nowhere vanishes (this can be relaxed). Then there exists a constant c such that the solution of (13) remains within the submanifold $F^{-1}(c)$. Moreover we may factor out $F^{-1}(c)$ by the integral curves of X_F to obtain a $(2n-2)$ -dimensional manifold. It follows from $X_F(H^0) = 0$ that the equations (13) project to Hamiltonian equations on this reduced manifold. If there are more symmetries available, or a *group* of symmetries, this reduction procedure can be generalized [1]. In general the existence of symmetries for H^0 reduces the solution of (13) to the solution of a *lower-dimensional* set of Hamiltonian equations. (Notice however that our situation is somewhat more complicated than in mechanics, since we do not know the initial conditions of (13), but a mixed set of initial and terminal conditions, see also [4].)

In conclusion, if we have an explicit expression for H^0 the knowledge of symmetries simplifies the solution $x^*(\cdot), p^*(\cdot)$ of (13). Henceforth it also simplifies the construction of the optimal control in open loop form $u^*(t) = u^*(x^*(t), p^*(t))$, or in feedback form $u^*(x^*(t), t) = u^*(x^*(t), p^*(t))$ from the solution $u^*(x, p)$ of (14).

Remark. A symmetry X_F for H^0 may be also profitably used for solving the Hamilton-Jacobi-Bellman equation

$$(19) \quad \begin{aligned} \frac{\partial S}{\partial t}(x, t) &= -\max_u \left(-L(x, u) + \frac{\partial S}{\partial x}(x, t)f(x, u) \right) \\ &= -H^0\left(x, \frac{\partial S}{\partial x}(x, t)\right), \quad S(x, T) = -K(x). \end{aligned}$$

(We have adopted the sign convention from mechanics— S is minus the Bellman value function.) Now (19) defines a flow on the set of Lagrangian submanifolds of $\mathbb{R}^n \times \mathbb{R}^n$. In fact for every t the Lagrangian submanifold is given as $\{(x, p = (\partial S / \partial x)(x, t))\}$. If X_F is a symmetry for H^0 , it follows that the action of X_F commutes with this flow. Explicitly, if the integral flow $X_F(\tau)$ of X_F maps for a *small* and *fixed* τ the Lagrangian submanifold $\{(x, p = (\partial S / \partial x)(x, T))\}$ onto another Lagrangian submanifold $\{(x, p = (\partial R / \partial x)(x))\}$, then $X_F(\tau)$ maps for every $t \in [0, T]$ the Lagrangian submanifold $\{(x, p = (\partial S / \partial x)(x, t))\}$ onto Lagrangian submanifolds $\{(x, p = (\partial R / \partial x)(x, t))\}$ where $R(x, t)$ is the solution of

$$(20) \quad \frac{\partial R}{\partial t}(x, t) = -H^0\left(x, \frac{\partial R}{\partial x}(x, t)\right), \quad R(x, T) = R(x).$$

Therefore instead of solving (19) we may also solve (20) for the maybe easier terminal condition $R(x, T) = R(x)$. In the linear quadratic case (i.e. $F(x, u) = Ax + Bu$, $L(x, u) = \frac{1}{2}x^T Qx + \frac{1}{2}u^T Ru$, and (19) becoming a Riccati equation) this was noted in [10].

Of course in many cases an explicit expression for $u^*(x, p)$ and $H^0(x, p)$ is hard to obtain. However in the author's thesis [8] it was indicated that even *without* explicitly calculating $H^0(x, p)$ we can a priori deduce symmetries for $H^0(x, p)$ by looking for symmetries of the associated Hamiltonian system (11). The same idea was used by Grizzle and Marcus [4] from a different point of view. Let $\dot{x} = f(x, u)$, with $x \in M$ (n -dimensional) and $u \in U$, be a control system. Suppose there exists a vectorfield $G(x)$ on M such that $[G(x), f(x, u)] = 0$ for all $u \in U$ (G is called a symmetry of the control system (cf. [8], [4]). Furthermore suppose that $G(L(x, u)) = 0$ for all $u \in U$ and that $G(K(x)) = 0$. (G is called a symmetry of the optimal control problem, [4].)

Then if G is nowhere zero, M can be locally factored out by the integral curves of G to obtain an $(n-1)$ -dimensional manifold N . It is then shown [4] that the optimal control problem (2) reduces to an optimal control problem defined on this lower dimensional manifold N , and that the optimal control in feedback form can be defined on N . Furthermore this can be generalized from single vectorfields G to a Lie algebra of symmetry vectorfields generated by a symmetry Lie group.

In the sequel it will be shown that this kind of symmetry for the optimal control problem considered in [4] corresponds to a special, although important, type of symmetry for the associated Hamiltonian system and the optimal Hamiltonian $H^0(x, p)$. Furthermore if the end cost function K is *not* invariant under G ($G(K(x)) \neq 0$) it is noted in [4] that the above procedure cannot be followed without modifications, but recourse has to be taken to the same Hamiltonian approach as will be used in this paper. On the other hand the class of symmetries considered in [4] is *enlarged* in [4] by allowing for *feedback* transformations. A feedback $u = \alpha(x, v)$ transforms the

optimal control problem (2) into

$$\min_v K(x(T)) + \int_0^T L(x(t), \alpha(x(t), v(t))) dt$$

under the constraints $\dot{x}(t) = f(x(t), \alpha(x(t), v(t)))$, $x(0) = x_0$. Now a vectorfield G may be a symmetry of this *transformed* optimal control problem without being a symmetry of the original optimal control problem. Such a symmetry G also results in a symmetry of the optimal Hamiltonian but may *not* be obtainable by our approach (although in most cases it will, see the examples). This leads to the question of determining *what* class of symmetries for H^0 can be obtained by our approach and how this class is affected by feedback. This problem is addressed (but not fully solved) in the last part of the paper.

We will now show how we can deduce symmetries for (13) *without* explicitly constructing $H^0(x, p)$ by looking for symmetries of the associated Hamiltonian system (11). Recall the notion of a *prolongation* of a vectorfield or a function. Let S be a vectorfield on M with integral flow S_t (i.e., $(d/dt)S_t(x) = S(S_t(x))$). Then $(S_t)_*: TM \rightarrow TM$ is the integral flow of a vectorfield on TM which we denote by \dot{S} . Let further $F: M \rightarrow \mathbb{R}$, then $\dot{F}: TM \rightarrow \mathbb{R}$ is defined by $\dot{F}(v) = dF(v)$, $v \in TM$.

DEFINITION 2 [5], [7], [8]. Let (11) be a Hamiltonian system given by a Lagrangian submanifold $L \subset T(\mathbb{R}^n \times \mathbb{R}^n) \times (\mathbb{R}^m \times \mathbb{R}^m)$. An (infinitesimal) *symmetry* is a pair of vectorfields (S, S^e) , S a Hamiltonian vectorfield on $\mathbb{R}^n \times \mathbb{R}^n$ and S^e a Hamiltonian vectorfield on $\mathbb{R}^m \times \mathbb{R}^m$, such that the vectorfield (\dot{S}, S^e) on $T(\mathbb{R}^n \times \mathbb{R}^n) \times (\mathbb{R}^m \times \mathbb{R}^m)$ is *tangent* to L , i.e., $(\dot{S}, S^e)(z) \in T_z L$ for all $z \in L$.

A *conservation law* is a pair of functions (F, F^e) , with $F: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ and $F^e: \mathbb{R}^m \times \mathbb{R}^m \rightarrow \mathbb{R}$, such that the function $\dot{F} - F^e: T(\mathbb{R}^n \times \mathbb{R}^n) \times (\mathbb{R}^m \times \mathbb{R}^m) \rightarrow \mathbb{R}$ restricted to L is zero.

Remark. The above definitions are really extensions of the usual definitions of symmetry and conserved quantity for Hamiltonian differential equations, as can be seen as follows. If we forget about inputs and outputs, so if $L \subset T(\mathbb{R}^n \times \mathbb{R}^n)$ is just the graph of a Hamiltonian vectorfield X_H , then \dot{S} being tangent to L means the following. In coordinates \dot{S} is given as $S(x)(\partial/\partial x) + (\partial S/\partial x)(x)\dot{x}(\partial/\partial \dot{x})$ (we forget about indices). Consider now a point $z = (x, X_H(x))$ on L . Elements of $T_z L$ are of the form $(\partial/\partial x) + (\partial X_H(x)/\partial x)(\partial/\partial \dot{x})$. Hence \dot{S} is tangent to L in z if $S(x)(\partial/\partial x) + (\partial S/\partial x)(x)X_H(x)(\partial/\partial \dot{x})$ is a multiple of $(\partial/\partial x) + (\partial X_H(x)/\partial x)(\partial/\partial \dot{x})$. This only happens if $(\partial S/\partial x)(x)X_H(x) = (\partial X_H(x))/(\partial x)S(x)$, or equivalently if the Lie bracket $[S, X_H]$ equals zero. Furthermore, $\dot{F} - F^e = 0$ restricted to L just means that $dF/dt = F^e(y, u)$, with $y_j = \partial H/\partial u_j$, where d/dt is differentiation along the system (13).

As is the case for Hamiltonian *vectorfields*, symmetries and conservation laws for Hamiltonian *systems* are in one-to-one correspondence [5], [8]. In fact if (S, S^e) is a symmetry, then there exists a conservation law (F, F^e) such that $S = X_F$, $S^e = X_{F^e}$, and conversely if (F, F^e) is a conservation law, then (X_F, X_{F^e}) is a symmetry.

We notice that (F, F^e) being a conservation law for (11) can be also succinctly expressed by the equality (see (17))

$$(21) \quad \{H(x, p, u), F(x, p)\} = F^e\left(\frac{\partial H}{\partial u}(x, p, u), u\right) \quad \forall x, p, u$$

where $\{, \}$ means Poisson bracket on $\mathbb{R}^n \times \mathbb{R}^n$.

We now show how symmetries (or conservation laws) for the Hamiltonian system (11) yield symmetries (or conserved quantities) for the optimal Hamiltonian.

THEOREM 3 [8]. Let $(S = X_F, S^e = X_{F^e})$ be a symmetry for (11). Then S is a symmetry for H^0 if $F^e(0, u) = 0$, for all $u \in U$.

Proof. Since (X_F, X_{F^e}) is a symmetry, (21) holds. Therefore

$$\begin{aligned} \{H(x, p, u^*(x, p)), F(x, p)\} &= F^e\left(\frac{\partial H}{\partial u}(x, p, u^*(x, p)), u^*(x, p)\right) \\ &\quad + \sum_{j=1}^m \frac{\partial H}{\partial u_j}(x, p, u^*(x, p))\{u_j^*(x, p), F(x, p)\}. \end{aligned}$$

Since $(\partial H / \partial u_j)(x, p, u^*(x, p)) = 0$, we obtain $\{H^0(x, p), F(x, p)\} = F^e(0, u^*(x, p))$, and hence if $F^e(0, u) = 0$, for all u , $\{H^0(x, p), F(x, p)\} = -S(H^0) = 0$. \square

In conclusion, one can obtain symmetries of H^0 by looking for pairs (F, F^e) satisfying (21) and $F^e(0, u) = 0$. Furthermore, these symmetries may also be useful in finding the solution $u^*(x, p)$ of (14):

THEOREM 4. Let (X_F, X_{F^e}) be a symmetry for (11) with $F^e(0, u) = 0 \ \forall u$. Let $u^*(x, p) = (u_1^*(x, p), \dots, u_m^*(x, p))$ be the solution of (14). Then for $j = 1, \dots, m$

$$(22) \quad \{F(x, p), u_j^*(x, p)\} = \frac{\partial F^e}{\partial y_j}(0, u^*(x, p)).$$

Proof. Differentiate the equalities $(\partial H / \partial u_j)(x, p, u^*(x, p)) = 0$, $j = 1, \dots, m$, with respect to x_k and p_k , $k = 1, \dots, n$:

$$(23) \quad \frac{\partial^2 H}{\partial x_k \partial u_j}(x, p, u^*) + \sum_{i=1}^m \frac{\partial^2 H}{\partial u_i \partial u_j}(x, p, u^*) \frac{\partial u_i^*}{\partial x_k}(x, p) = 0,$$

$$(24) \quad \frac{\partial^2 H}{\partial p_k \partial u_j}(x, p, u^*) + \sum_{i=1}^m \frac{\partial^2 H}{\partial u_i \partial u_j}(x, p, u^*) \frac{\partial u_i^*}{\partial p_k}(x, p) = 0.$$

Furthermore, differentiate

$$\{H(x, p, u), F(x, p)\} = \sum_{k=1}^n \left(\frac{\partial H}{\partial p_k} \frac{\partial F}{\partial x_k} - \frac{\partial H}{\partial x_k} \frac{\partial F}{\partial p_k} \right) = F^e\left(\frac{\partial H}{\partial u}, u\right)$$

with respect to u_j , $j = 1, \dots, m$:

$$(25) \quad \sum_{k=1}^n \left(\frac{\partial^2 H}{\partial u_j \partial p_k} \frac{\partial F}{\partial x_k} - \frac{\partial^2 H}{\partial u_j \partial x_k} \frac{\partial F}{\partial p_k} \right) = \frac{\partial}{\partial u_j} \left(F^e\left(\frac{\partial H}{\partial u}, u\right) \right).$$

Evaluate (25) in the points $(x, p, u^*(x, p))$, and substitute (23) and (24) into (25):

$$(26) \quad - \sum_{k=1}^n \sum_{i=1}^m \frac{\partial^2 H}{\partial u_i \partial u_j} \frac{\partial u_i^*}{\partial p_k} \frac{\partial F}{\partial x_k} + \sum_{k=1}^n \sum_{i=1}^m \frac{\partial^2 H}{\partial u_i \partial u_j} \frac{\partial u_i^*}{\partial x_k} \frac{\partial F}{\partial p_k} = \frac{\partial}{\partial u_j} \left(F^e\left(\frac{\partial H}{\partial u}, u\right) \right)$$

with everything evaluated in $(x, p, u^*(x, p))$. The left-hand side of (26) is equal to

$$(27) \quad \sum_{i=1}^m \frac{\partial^2 H}{\partial u_i \partial u_j}(x, p, u^*) \{F, u_i^*\}(x, p),$$

while the right-hand side of (26) equals

$$\begin{aligned} &\frac{\partial}{\partial u_j} \left(F^e\left(\frac{\partial H}{\partial u}, u\right) \right) \Big|_{u=u^*(x, p)} \\ (28) \quad &= \sum_{i=1}^n \frac{\partial F^e}{\partial y_i} \left(\frac{\partial H}{\partial u}, u \right) \Big|_{u=u^*} \frac{\partial^2 H}{\partial u_j \partial u_i}(x, p, u^*) + \frac{\partial F^e}{\partial u_j} \left(\frac{\partial H}{\partial u}, u \right) \Big|_{u=u^*} \\ &= \sum_{i=1}^n \frac{\partial^2 H}{\partial u_j \partial u_i}(x, p, u^*) \frac{\partial F^e}{\partial y_i}(0, u^*) \end{aligned}$$

since $F^e(0, u) = 0$ implies $\partial F^e / \partial u_j(0, u) = 0$, $j = 1, \dots, m$.

Since $(\partial^2 H / \partial u_i \partial u_j)(x, p, u^*)$ is nonsingular, we obtain (22). \square

Remark. $(\partial F^e / \partial y_j)(0, u^*)$ may also be written as $\{F^e(y, u), u_j\}_{\mathbb{R}^{2m}}(0, u^*)$, with $\{, \}_{\mathbb{R}^{2m}}$ the Poisson bracket on \mathbb{R}^{2m} (given by $\{G(y, u), K(y, u)\}_{\mathbb{R}^{2m}} = \sum_{j=1}^m ((\partial G / \partial y_j)(\partial K / \partial u_j) - (\partial G / \partial u_j)(\partial K / \partial y_j))$). Hence (22) may be rewritten as $\{F, u_j^*\}_{\mathbb{R}^{2n}} = \{F^e, u_j\}_{\mathbb{R}^{2m}}(0, u^*)$.

Therefore, if (F, F^e) is a conservation law with $F^e(0, u) = 0$ the solution of (14) has to belong to the mappings $u^*(x, p)$ whose components satisfy the partial differential equations

$$(29) \quad \{F, u_j^*\} = G_j(u^*), \quad j = 1, \dots, m$$

with $G_j(u^*) = (\partial F^e / \partial y_j)(0, u^*)$.

An important special case of Theorem 3 are the conservation laws (F, F^e) with F^e *identically* zero. The fact that such conservation laws may exist is due to the possible nonminimality of the Hamiltonian system. Indeed, if $F^e = 0$, we obtain

$$(30) \quad \{H(x, p, u), F\} = 0 \quad \forall x, p, u.$$

Hence all integral curves of the Hamiltonian system (11) starting from a fixed initial condition u_0 remain within a submanifold $F^{-1}(c)$, with c a constant, and therefore the system is not “controllable.” Moreover, it follows from (30) that

$$(31) \quad X_F(y_j) = \left\{ F, \frac{\partial H}{\partial u_j}(x, p, u) \right\} = \frac{\partial}{\partial u_j} \{F, H(x, p, u)\} = 0$$

and that

$$(32) \quad [X_{H(x, p, u)}, X_F] = 0 \quad \forall u.$$

(Recall the identity $[X_F, X_G] = X_{\{F, G\}}$ for arbitrary functions F, G on \mathbb{R}^{2n} , [1].) Hence the system is not “observable” and we may factor out the state space by the integral curves of X_F . (It follows from (32) that the vectorfields $X_{H(x, p, u)}$ leave these integral curves invariant.) For a more detailed treatment of these issues we refer to [6], [8]. It follows from Theorem 4 that if $F^e = 0$ then the optimal $u^*(x, p)$ satisfies

$$(33) \quad \{F, u_j^*\} = 0, \quad j = 1, \dots, m.$$

Therefore if we reduce the $2n$ -dimensional state space to a $(2n - 2)$ -dimensional space as sketched above, the optimal $u(x, p)$ also projects to a mapping on this reduced space. The symmetries considered in [4] form a subclass of this special type. Indeed, let the vectorfield G satisfy $[G(x), f(x, u)] = 0$, for all $u \in U$, and $G(L(x, u)) = 0$. Then

$$\begin{aligned} \{H(x, p, u), p^T G(x)\} &= \{p^T f(x, u) - L(x, u), p^T G(x)\} \\ &= p^T \frac{\partial G}{\partial x}(x) f(x, u) - p^T \frac{\partial F}{\partial x}(x, u) G(x) - p^T \frac{\partial L}{\partial x}(x, u) G(x) \\ &= p^T [f(x, u), G(x)] - p^T G(L(x, u)) = 0. \end{aligned}$$

Hence $(p^T G(x), 0)$ is a conservation law for the associated Hamiltonian system, and $p^T G(x)$ is a conserved quantity for the optimal Hamiltonian H^0 . In the physics literature a symmetry with conserved quantity of the form $p^T G(x)$ is called a *geometrical* symmetry (because the symmetry is induced by a vectorfield on the x -space), in contrast to a symmetry with a general conserved quantity $F(x, p)$, which is called a *dynamical* symmetry.

As in the case of Hamiltonian vector fields [1], the treatment of a single symmetry may be extended to *groups* of symmetries. In our context the basic observation in order to do so is the following.

THEOREM 5. Let (F_i, F_i^e) , $i = 1, 2$, be two conservation laws for (11), with $F_i^e(0, u) = 0$, for all u . Then $(\{F_1, F_2\}_{\mathbb{R}^{2n}}, \{F_1^e, F_2^e\}_{\mathbb{R}^{2m}})$ is again a conservation law with $\{F_1^e, F_2^e\}_{\mathbb{R}^{2m}}(0, u) = 0$, for all u . (As before $\{, \}_{\mathbb{R}^{2n}}$ and $\{, \}_{\mathbb{R}^{2m}}$ denote Poisson brackets on \mathbb{R}^{2n} , resp. \mathbb{R}^{2m} .)

Proof. This can be proved by geometric considerations [8], but also by the following explicit calculation. We have $\{H(x, p, u), F_i(x, p)\} = F_i^e((\partial H / \partial u), u)$, $i = 1, 2$. Hence, by Jacobi's identity for the Poisson bracket,

$$\begin{aligned} \{H(x, p, u), \{F_1, F_2\}\} &= \{\{H(x, p, u), F_1\}, F_2\} - \{\{H(x, p, u), F_2\}, F_1\} \\ &= \left\{F_1^e\left(\frac{\partial H}{\partial u}, u\right), F_2\right\} - \left\{F_2^e\left(\frac{\partial H}{\partial u}, u\right), F_1\right\}. \end{aligned}$$

Now

$$\left\{F_1^e\left(\frac{\partial H}{\partial u}, u\right), F_2\right\} = \sum_{j=1}^m \frac{\partial F_1^e}{\partial y_j} \left(\frac{\partial H}{\partial u}, u\right) \left\{\frac{\partial H}{\partial u_j}, F_2\right\},$$

and

$$\begin{aligned} \left\{\frac{\partial H}{\partial u_j}, F_2\right\} &= \frac{\partial}{\partial u_j} \{H, F_2\} = \frac{\partial}{\partial u_j} \left(F_2^e\left(\frac{\partial H}{\partial u}, u\right)\right) \\ &= \frac{\partial F_2^e}{\partial u_j} + \sum_{k=1}^m \frac{\partial F_2^e}{\partial y_k} \frac{\partial^2 H}{\partial u_j \partial u_k}. \end{aligned}$$

Hence

$$\begin{aligned} \{H(x, p, u), \{F_1, F_2\}_{\mathbb{R}^{2n}}\} &= \sum_{j=1}^m \frac{\partial F_1^e}{\partial y_j} \frac{\partial F_2^e}{\partial u_j} - \frac{\partial F_1^e}{\partial u_j} \frac{\partial F_2^e}{\partial y_j} \\ &\quad + \sum_{j=1}^m \sum_{k=1}^m \frac{\partial F_1^e}{\partial y_j} \frac{\partial F_2^e}{\partial y_k} \frac{\partial^2 H}{\partial u_j \partial u_k} - \sum_{j=1}^m \sum_{k=1}^m \frac{\partial F_2^e}{\partial y_j} \frac{\partial F_1^e}{\partial y_k} \frac{\partial^2 H}{\partial u_j \partial u_k} \\ &= \{F_1^e, F_2^e\}_{\mathbb{R}^{2m}}. \end{aligned}$$

Furthermore, $F_i^e(0, u) = 0$ implies $(\partial F_i^e(0, u)) / \partial u_j = 0$, $j = 1, \dots, m$, and hence

$$\{F_1^e, F_2^e\}(0, u) = \sum_j \left(\frac{\partial F_1^e(0, u)}{\partial y_j} \frac{\partial F_2^e(0, u)}{\partial u_j} - \frac{\partial F_1^e(0, u)}{\partial u_j} \frac{\partial F_2^e(0, u)}{\partial y_j} \right) = 0. \quad \square$$

Therefore the mapping $F \mapsto F^e$, given by $\{H(x, p, u), F\} = F^e$, is an algebra morphism from functions on \mathbb{R}^{2n} to \mathbb{R}^{2m} (with respect to the respective Poisson brackets). It also follows from Theorems 4 and 5 that in the case of two conservation laws (F_i, F_i^e) the optimal $u^*(x, p)$ also has to satisfy

$$(34) \quad \{F_1, F_2\}_{\mathbb{R}^{2n}}, u_i^*_{\mathbb{R}^{2n}} = \{F_1^e, F_2^e\}_{\mathbb{R}^{2m}}, u_i^*_{\mathbb{R}^{2m}}(0, u^*).$$

We will now give some illustrative examples of the theory developed above.

Example 1. First we treat the example dealt with in Grizzle and Marcus [4] in our framework. Consider a particle of unit mass in a planar inverse-square-law gravitational field, which has thrusters in the “ x - y ” directions. The equations of motion in rectangular coordinates are given as

$$(\dot{q}_1, \dot{q}_2, \dot{v}_1, \dot{v}_2) = (v_1, v_2, -q_1(q_1^2 + q_2^2)^{-3/2} + u_1, -q_2(q_1^2 + q_2^2)^{-3/2} + u_2) = f(x, u)$$

and are defined on $M = (\mathbb{R}^2 \setminus \{0\}) \times \mathbb{R}^2$ and $U = \mathbb{R}^2$.

Let us take $L(x, u) = \frac{1}{2}(u_1^2 + u_2^2)$. An evident candidate for a symmetry vectorfield on $\mathbb{R}^2 \setminus \{0\}$ is $q_1(\partial/\partial q_2) - q_2(\partial/\partial q_1)$ (infinitesimal rotation). This vectorfield is prolonged to the vectorfield $G = q_1(\partial/\partial q_2) - q_2(\partial/\partial q_1) + v_1(\partial/\partial v_2) - v_2(\partial/\partial v_1)$ on M . Denote $x_1 = q_1$, $x_2 = q_2$, $x_3 = v_1$, $x_4 = v_2$; then the corresponding Hamiltonian function is $p^T G(x) = -p_1 x_2 + p_2 x_1 - p_3 x_4 + p_4 x_3$. Calculation yields

$$\begin{aligned} \{H(x, p, u), p^T G(x)\} &= \{p^T f(x, u) - L(x, u), p^T G(x)\} \\ &= \{p_1 x_3 + p_2 x_4 + p_3(-x_1(x_1^2 + x_2^2)^{-3/2} + u_1) \\ &\quad + p_4(-x_2(x_1^2 + x_2^2)^{-3/2} + u_2) \\ &\quad - \frac{1}{2}u_1^2 - \frac{1}{2}u_2^2, -p_1 x_2 + p_2 x_1 - p_3 x_4 + p_4 x_3\} \\ &= (\text{since the gravitational field is rotation invariant}) \\ &\quad \{p_3 u_1 + p_4 u_2, -p_1 x_2 + p_2 x_1 - p_3 x_4 + p_4 x_3\} \\ &= u_1 p_4 - u_2 p_3. \end{aligned}$$

Furthermore,

$$y_1 = \frac{\partial H}{\partial u_1} = p_3 - u_1, \quad y_2 = \frac{\partial H}{\partial u_2} = p_4 - u_2.$$

Hence,

$$(35) \quad \{H(x, p, u), p^T G(x)\} = u_1(y_2 + u_2) - u_2(y_1 + u_1) = u_1 y_2 - u_2 y_1.$$

Therefore $(F, F^e) = (-p_1 x_2 + p_2 x_1 - p_3 x_4 + p_4 x_3, u_1 y_2 - u_2 y_1)$ is a conservation law for the associated Hamiltonian system satisfying $F^e(0, u) = 0$, for all u . Hence by Theorems 3 and 4

$$\begin{aligned} &\{H(x, p, u^*(x, p)), -p_1 x_2 + p_2 x_1 - p_3 x_4 + p_4 x_3\} = 0, \\ (36) \quad &\{-p_1 x_2 + p_2 x_1 - p_3 x_4 + p_4 x_3, u_1^*(x, p)\} = \frac{\partial F^e}{\partial y_1}(0, u^*) = -u_2^*(x, p), \\ &\{-p_1 x_2 + p_2 x_1 - p_3 x_4 + p_4 x_3, u_2^*(x, p)\} = \frac{\partial F^e}{\partial y_2}(0, u^*) = u_1^*(x, p). \end{aligned}$$

On the other hand, in the Grizzle-Marcus approach one first applies *feedback*

$$(37) \quad \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = (q_1^2 + q_2^2)^{-1/2} \begin{pmatrix} q_1 & q_2 \\ -q_2 & q_1 \end{pmatrix} \begin{pmatrix} w_1 \\ w_2 \end{pmatrix} = \alpha(x, w)$$

(defined on $\mathbb{R}^2 \setminus \{0\}$), transforming $f(x, u)$ into $\tilde{f}(x, w)$, with $w = (w_1, w_2)$ the new inputs. The modified Hamiltonian $\tilde{H}(x, p, w) = p^T \tilde{f}(x, w) - \tilde{L}(x, w)$, with $\tilde{L}(x, w) = L(x, \alpha(x, w)) = \frac{1}{2}w_1^2 + \frac{1}{2}w_2^2$ then satisfies

$$(38) \quad \{\tilde{H}(x, p, w), p^T G(x)\} = 0$$

while

$$(39) \quad \{p^T G(x), w_i^*(x, p)\} = 0, \quad i = 1, 2.$$

Example 2. Consider a mathematical pendulum in space (\mathbb{R}^3) with mass $m = 1$ and length $l = 1$.

Suppose there is a horizontal field by which one can exert a force u_1 in the x -direction and a force u_2 in the y -direction. In spherical coordinates the dynamical equations are

$$(40) \quad \begin{aligned} \ddot{\theta} &= -u_1 \sin \theta + u_2 \cos \theta, \\ \ddot{\phi} &= -g \sin \phi + u_1 \cos \theta \cos \phi + u_2 \sin \theta \cos \phi \end{aligned}$$

with $(\phi, \theta) \in S^2$ (the unit sphere). Therefore the state space is $M = TS^2$ with local coordinates $x_1 = \phi$, $x_2 = \theta$, $x_3 = \dot{\phi}$, $x_4 = \dot{\theta}$. Once more we take $L(x, u) = \frac{1}{2}(u_1^2 + u_2^2)$. The symmetry vectorfield on M is given in local coordinates by $G(x) = (\partial/\partial x_2)$, with corresponding Hamiltonian $p^T G(x) = p_2$. Then

$$\begin{aligned} \{p^T f(x, u) - L(x, u), p^T G(x)\} \\ &= \{p_1 x_3 + p_2 x_4 + p_3(-g \sin x_1 + u_1 \cos x_2 \cos x_1 + u_2 \sin x_2 \cos x_1) \\ &\quad + p_4(-u_1 \sin x_2 + u_2 \cos x_2) - \frac{1}{2}(u_1^2 + u_2^2), p_2\} \\ &= u_1 p_3 \sin x_2 \cos x_1 - u_2 p_3 \cos x_2 \cos x_1 + u_1 p_4 \cos x_2 + u_2 p_4 \sin x_2. \end{aligned}$$

Furthermore

$$(41) \quad \begin{aligned} y_1 &= \frac{\partial H}{\partial u_1} = p_3 \cos x_2 \cos x_1 - p_4 \sin x_2 - u_1, \\ y_2 &= \frac{\partial H}{\partial u_2} = p_3 \sin x_2 \cos x_1 + p_4 \cos x_2 - u_2. \end{aligned}$$

Hence $\{H(x, p, u), p^T G(x)\} = u_1(y_2 + u_2) - u_2(y_1 + u_1) = u_1 y_2 - u_2 y_1$.

So $(p_2, u_1 y_2 - u_2 y_1)$ is a conservation law satisfying the conditions of Theorems 3 and 4. Hence

$$(42) \quad \{H^0, p_2\} = 0,$$

$$(43) \quad \{p_2, u_1^*\} = -u_2^*, \quad \{p_2, u_2^*\} = u_1^*.$$

Of course, this can be easily checked. Setting $y_1 = y_2 = 0$ in (41), one obtains

$$(44) \quad u_1^* = p_3 \cos x_2 \cos x_1 - p_4 \sin x_2, \quad u_2^* = p_3 \sin x_2 \cos x_1 + p_4 \cos x_2$$

in accordance with (43). Furthermore one calculates

$$(45) \quad H^0(x, p) = H(x, p, u^*(x, p)) = p_1 x_3 + p_2 x_4 - p_3 g \sin x_1 + p_3^2 \cos^2 x_1 + p_4^2$$

and hence (42) is satisfied.

We note that this example, although very close to Example 1, *cannot* be treated by the methods of [4]. This is because there does not exist a smooth feedback $u = \alpha(x, w)$ such that $\{\tilde{H}(x, p, w), p_2\} = 0$; the feedback (37) in rectangular coordinates is *not* defined for $\phi = \theta = 0$. (In Example 1 the origin was excluded from the state space!)

In the above case u_1^* and u_2^* can be immediately computed, thanks to the simple form of $L(x, u)$. However suppose $L(x, u) = \frac{1}{4}(u_1^2 + u_2^2)^2$. Then still $\{H(x, p, u), p_2\} = u_1 p_3 \sin x_2 \cos x_1 - u_2 p_3 \cos x_2 \cos x_1 + u_1 p_4 \cos x_2 + u_2 p_4 \sin x_2$ while

$$y_1 = p_3 \cos x_2 \cos x_1 - p_4 \sin x_2 - (u_1^2 + u_2^2)u_1,$$

$$y_2 = p_3 \sin x_2 \cos x_1 + p_4 \cos x_2 - (u_1^2 + u_2^2)u_2.$$

Hence $\{H(x, p, u), p_2\} = u_1(y_2 + u_2(u_1^2 + u_2^2)) - u_2(y_1 + u_1(u_1^2 + u_2^2)) = u_1 y_2 - u_2 y_1$. Consequently $(p_2, u_1 y_2 - u_2 y_1)$ is still a conservation law. Therefore although u_1^* and u_2^* are not so easy to obtain, one knows a priori that (42) and (43) are satisfied. From (43) one obtains

$$(46) \quad \begin{aligned} \frac{\partial^2 u_1^*}{\partial x_2^2} &= \{p_2, \{p_2, u_1^*\}\} = -\{p_2, u_2^*\} = -u_1^*, \\ \frac{\partial^2 u_2^*}{\partial x_2^2} &= \{p_2, \{p_2, u_2^*\}\} = \{p_2, u_1^*\} = -u_2^*. \end{aligned}$$

Consequently as a function of x_2 one knows that u_1^* and u_2^* are of the form $a \sin x_2 + b \cos x_2$, $a, b \in \mathbb{R}$. More generally for any $L(x, u)$ of the form $L(x, u) = h(x_1) \cdot k(\frac{1}{2}(u_1^2 + u_2^2))$, with h and k arbitrary smooth functions, one has

$$\begin{aligned} \{p^T f(x, u) - L(x, u), p_2\} &= u_1 \left(y_2 + h(x_1) \frac{dk}{dz} \left(\frac{1}{2} (u_1^2 + u_2^2) \right) \right) \cdot 2u_2 \\ &\quad - u_2 \left(y_1 + h(x_1) \frac{dk}{dz} \left(\frac{1}{2} (u_1^2 + u_2^2) \right) \right) \cdot 2u_1 \\ &= u_1 y_2 - u_2 y_1. \end{aligned}$$

So again $(p_2, u_1 y_2 - u_2 y_1)$ is a conservation law.

Example 3. We shall show that in the linear-quadratic case there *cannot* exist quadratic conservation laws (F, F^e) with $F^e = 0$, if the system is controllable. Hence the methods of [4] are in this case not applicable. Consider a linear system $\dot{x} = Ax + Bu$ with $L(x, u) = \frac{1}{2}x^T Qx + \frac{1}{2}u^T Ru + u^T Sx$. A linear geometrical symmetry $\dot{x} = Gx$ with G a square matrix corresponds to a quadratic Hamiltonian $p^T Gx$. Calculating,

$$\begin{aligned} \{p^T (Ax + Bu) - \frac{1}{2}x^T Qx - \frac{1}{2}u^T Ru - u^T Sx, p^T Gx\} \\ = -p^T (AG - GA)x + p^T GBu + x^T QGx + u^T SGx. \end{aligned}$$

Now suppose $(p^T Gx, 0)$ is a conservation law. Then

$$(47) \quad AG = GA, \quad GB = SG = 0, \quad QG \text{ skew-symmetric.}$$

The first two equations yield $G(A^k B) = A^k GB = 0$, $k = 0, 1, \dots$. Hence if (A, B) is controllable necessarily $G = 0$! Feedback $u = Fx + Hv$, $\det H \neq 0$, cannot change this situation since $H(x, p, u)$ remains of the same form and (A, B) is controllable if and only if $(A + BF, BH)$ is controllable.

However, there *may* exist linear symmetries with $F^e(y, u) = \frac{1}{2}y^T My + y^T Nu$ (and so $F^e(0, u) = 0$). Consider for example the system $\dot{x} = u$ on \mathbb{R}^n with $L(x, u) = \frac{1}{2}x^T Qx + \frac{1}{2}u^T Ru$, where $Q = Q^T$ and $R = R^T > 0$. The Hamiltonian is $H(x, p, u) = p^T u - \frac{1}{2}x^T Qx - \frac{1}{2}u^T Ru$ and the optimal Hamiltonian is obtained by setting $\partial H / \partial u_j = 0$, which yields $u^* = R^{-1}p$, and hence $H^0(x, p) = \frac{1}{2}p^T R^{-1}p - \frac{1}{2}x^T Qx$.

Let us look at symmetries for $H^0(x, p)$ of the form $p^T Fx$, with F an $n \times n$ -matrix. $\{H^0(x, p), p^T Fx\} = p^T R^{-1} F^T p + x^T Q Fx$, and hence F has to be such that $R^{-1} F^T$ and QF are skew-symmetric. Now $\{H(x, p, u), p^T Fx\} = \{p^T u - \frac{1}{2} x^T Qx - \frac{1}{2} u^T Ru, p^T Fx\} = u^T F^T p - x^T Q Fx = u^T F^T p$. Let us take $F^e(y, u) = y^T Fu$. Since $y = \partial H / \partial u = p - Ru$ we obtain $F^e(y, u) = -u^T R F u + p^T F u$. Because $R^{-1} F^T$, or equivalently, RF has to be skew-symmetric, $F^e(y, u) = p^T F u$, and hence $\{H(x, p, u), p^T Fx\} = y^T F u$.

Remark. This last example shows the close connection of our theory with the original Noether theorem on symmetries of Lagrangian functions. This is further investigated in [9].

One of the most pressing questions is now the following. By looking at conservation laws (F, F^e) , with $F^e(0, u) = 0$, for the associated Hamiltonian system, can we obtain *all* the symmetries for the optimal Hamiltonian, and if not, which subclass of symmetries do we obtain?

The first part of this question is answered as follows. Let the dimension of the codistribution, generated by taking Poisson brackets of the functions $H(x, p, u)$ for each u , be $k \leq 2n$ (for simplicity we assume constant dimensions). Then there are exactly $2n - k$ independent functions K_i such that $\{H(x, p, u), K_i\} = 0$. Furthermore we can arbitrarily choose m independent functions F_i^e on \mathbb{R}^{2n} satisfying $F_i^e(0, u) = 0$ for all u . Hence by Theorem 5 there exist *at most* $\min(m, k)$ independent functions F_i on \mathbb{R}^{2n} , also independent from the functions K_i , such that there exist functions F_i^e on \mathbb{R}^{2m} in such a way that (F_i, F_i^e) are conservation laws for the Hamiltonian system. Hence, in general we do *not* obtain all the symmetries of the optimal Hamiltonian $H^0(x, p)$.

The second part of the question, which subclass of symmetries do we obtain, is much harder. Let X_F be a symmetry for the optimal Hamiltonian, i.e., $X_F(H^0) = \{F, H^0\} = 0$. Then it follows that

$$(48) \quad \{H(x, p, u), F(x, p)\} = F'(x, p, u)$$

with the function F' satisfying

$$(49) \quad F'(x, p, u^*(x, p)) = 0.$$

Now X_F corresponds to a conservation law for the Hamiltonian system if and only if $F'(x, p, u)$ can be written as a function of $y = \partial H / \partial u$ and u , i.e., if there exists a function $F^e : \mathbb{R}^{2m} \rightarrow \mathbb{R}$ such that $F'(x, p, u) = F^e((\partial H / \partial u)(x, p, u), u)$.

PROPOSITION 6. *Let $X_F(H^0) = 0$. Then there exists an $F^e : \mathbb{R}^{2m} \rightarrow \mathbb{R}$ such that (F, F^e) is a conservation law for the associated Hamiltonian system if and only if for every $G : \mathbb{R}^{2n} \rightarrow \mathbb{R}$ such that $(\partial / \partial u_j)\{H(x, p, u), G(x, p)\} = 0$, $j = 1, \dots, m$, it follows that $\{H(x, p, u), F(x, p)\}, G(x, p)\} = 0$.*

Proof. Let $\partial / \partial u_j \{H, G\} = 0$; then equivalently $X_G(y_j) = X_G(\partial H / \partial u_j) = \{\partial H / \partial u_j, G\} = 0$. Also let $\{H(x, p, u), F(x, p)\} = F'(x, p, u)$. Then $\{H(x, p, u), F(x, p)\}, G(x, p)\} = -X_G(F') = 0$, for every such G , implies that $F'(x, p, u)$ only depends on y and u , and hence is of the form $F^e(\partial H / \partial u, u)$. Since $F'(x, p, u^*(x, p)) = 0$, it follows that $F^e(0, u) = 0$. \square

By Theorem 4 it is also a necessary condition for a symmetry X_F of H^0 to be obtainable from a conservation law (F, F^e) that F satisfies equations of the form $\{F, u_i^*\} = G_i(u^*)$. This brings us to another interesting point. If we apply *feedback* $u = \alpha(x, v)$, $v \in \mathbb{R}^m$, with the matrix $\partial \alpha / \partial v$ nonsingular, to the system $\dot{x} = f(x, u)$ and the running cost $L(x, u)$, we obtain

$$(50) \quad \dot{x} = \tilde{f}(x, v) := f(x, \alpha(x, v)), \quad \tilde{L}(x, v) := L(x, \alpha(x, v))$$

resulting in a new Hamiltonian

$$(51) \quad \tilde{H}(x, p, v) = p^T \tilde{f}(x, v) - \tilde{L}(x, v).$$

Now it is clear that

$$(52) \quad \begin{aligned} \max_v \tilde{H}(x, p, v) &= \max_v p^T f(x, \alpha(x, v)) - L(x, \alpha(x, v)) \\ &= \max_u p^T f(x, u) - L(x, u) = \max_u H(x, p, u) = H^0(x, p). \end{aligned}$$

Hence the optimal Hamiltonian $H^0(x, p)$ does not change under feedback, and consequently the symmetries for H^0 remain the same. However the Hamiltonian systems associated respectively to $H(x, p, u)$ and $\tilde{H}(x, p, v)$ are really different. (It is in general not true that by applying feedback $u = \beta(x, p, v)$ to the Hamiltonian system resulting from $H(x, p, u)$ one can obtain the Hamiltonian system corresponding to $\tilde{H}(x, p, v)$.) Consequently the set of conservation laws (F, F^e) for both Hamiltonian systems are in general different. Hence it may happen that for a symmetry X_F of H^0 there exists an F^e such that (F, F^e) is a conservation law for $H(x, p, u)$, while there does *not* exist an \tilde{F}^e such that (F, \tilde{F}^e) is a conservation law for $\tilde{H}(x, p, v)$. Moreover if $u^*(x, p)$ and $v^*(x, p)$ are the optimal controls resulting from maximizing H and \tilde{H} , then there may exist functions G_i such that $\{F, u_i^*\} = G_i(u^*)$, but no functions \tilde{G}_i such that $\{F, v_i^*\} = \tilde{G}_i(v^*)$. The following question is therefore worthwhile to investigate.

Question. Let $H(x, p, u) = p^T f(x, u) - L(x, u)$ be the Hamiltonian of an optimal control problem yielding the optimal Hamiltonian $H^0(x, p) = \max_{u \in \mathbb{R}^m} H(x, p, u)$. Let X_F be a symmetry for H^0 , i.e., $X_F(H^0) = 0$. Does there exist a feedback $u = \alpha(x, v)$, $v \in \mathbb{R}^m$, and a smooth function \tilde{F}^e on \mathbb{R}^{2m} such that (F, \tilde{F}^e) is a conservation law for the Hamiltonian system corresponding to $\tilde{H}(x, p, v) = p^T \tilde{f}(x, v) - \tilde{L}(x, v)$?

If the above question can be answered affirmatively, then in a sense all the symmetries for the optimal Hamiltonian can be recovered from symmetries of an associated Hamiltonian system.

Remark. The above question is also related to the problem of bringing $H(x, p, u)$ into some kind of normal form by feedback transformations $u = \alpha(x, v)$ and state space transformations. If we allow for the *larger* class of transformations $u = \alpha(x, p, v)$ and take the usual assumption that $(\partial^2 H / \partial u_i \partial u_j)$ is nonsingular (say for simplicity negative definite), then the Morse Lemma yields for $H(x, p, u)$ the normal form $\bar{H}(x, p) - \sum_{j=1}^m u_j^2$. Hence we end up with the Hamiltonian system

$$(53) \quad \begin{aligned} \dot{x}_i &= \frac{\partial \bar{H}}{\partial p_i}(x, p), \\ \dot{p}_i &= -\frac{\partial \bar{H}}{\partial x_i}(x, p), \end{aligned} \quad y_j = u_j.$$

In this degenerate case $H^0(x, p) = \bar{H}(x, p)$, and $\{\bar{H}(x, p) - \sum_{j=1}^m u_j^2, F(x, p)\}$ equals a function $F^e((\partial H / \partial u), u)$ if and only if $\{\bar{H}, F\} = 0$. It would be interesting to extend the Morse Lemma to the smaller class of transformations $u = \alpha(x, v)$.

Acknowledgments. I would like to thank Jessy Grizzle and Steve Marcus for some conversations, which stimulated me in extending the original observations made in [8] to the present paper. Also I would like to thank Henk Nijmeijer for his help in the proof of Theorem 4.

PATHWISE NONLINEAR FILTERING FOR NONDEGENERATE DIFFUSIONS WITH NOISE CORRELATION*

M. H. A. DAVIS† AND M. P. SPATHOPOULOS†

Abstract. We consider the filtering problem of calculating $E[f(x_t)|y_s, s \leq t]$ where x_t is a nondegenerate diffusion process on a finite dimensional manifold with given generator and $y_t = \int_0^t h(x_s) ds + w_t^0$ is a real valued observation process. w_t^0 is a scalar Brownian motion whose correlation with x_t is specified by a given vector field Z . It is shown that this filtering problem is robust, i.e., the estimates for x_t can be calculated separately for each observation sample path y_t .

Key words. nonlinear filtering, noise correlation, conditional densities, Markov process, extended generator, stochastic differential equation, manifold, horizontal lifting

AMS(MOS) subject classifications. 93E11, 60H20, 60J60

Introduction. This paper concerns the nonlinear filtering problem of calculating recursively estimates $E[f(x_t)|y_s, 0 \leq s \leq t]$, where x_t is a Markov process on a manifold M and y_t is a real-valued observation process, with possible correlation between the respective "noises." The main set-up of this paper is the following:

The signal process x_t is an A -diffusion process on the manifold M where A is a given nondegenerate second-order differential operator. The scalar observation process y_t is given by the following equation:

$$(0.1) \quad dy_t = h(x_t) dt + dw_t^0.$$

Here w^0 is a standard Brownian motion (BM). Finally, the possible correlation between the signal and the observation process noise is specified by a given vector field Z on M (see (2.1) below).

In Part I a pathwise solution is obtained when the signal is given by the stochastic differential equation¹

$$(0.2) \quad df(x_t) = L_0 f(x_t) dt + L_i f(x_t) \circ dw_t^i, \quad x_0 = x$$

where $L_0, L_i, i = 1, \dots, d$ are C^∞ vector fields, and $w_t^i, i = 1, \dots, d$ are independent scalar BM. It is supposed that there are functions $a_i(\cdot), i = 1, 2, \dots, d$ such that

$$\langle w^i, w^0 \rangle_t = \int_0^t a_i(x_s) ds.$$

It is known [9] that the unconditional distribution $u(t, x) = E[f(x(t, x, w))]$ of the "signal" flow $x = x(t, x, w)$ of diffeomorphisms constructed by (0.2) is obtained by solving the heat equation

$$\frac{\partial u(t, x)}{\partial t} = Au(t, x), \quad \lim_{\substack{t \downarrow 0 \\ p \rightarrow x}} u(t, p) = f(x)$$

where A is the extended generator of the diffusion process x_t given by $A = L_0 + \frac{1}{2} \sum_{i=1}^d L_i^2$.

¹ In (0.2) and throughout the paper, the Einstein summation convention is used. Stochastic integrals written $\sigma_t \circ dw_t^i$ are Stratonovich integrals whereas those written $\sigma_t dw_t^i$ are Ito integrals.

The main result of the “pathwise” theory of nonlinear filtering is that it is possible to compute the conditional distribution of x_t given $\{y_s, 0 \leq s \leq t\}$, in terms of the solution of another heat equation whose coefficients depend on the observation sample path $\{y_s, 0 \leq s \leq t\}$, i.e. a heat equation of the form

$$\frac{\partial U(t, x)}{\partial t} = A_t^\gamma U(t, x), \quad \lim_{\substack{t \downarrow 0 \\ p \rightarrow x}} U(t, p) = f(x),$$

where A_t^γ is a sample-path dependent generator to be computed. In Part I we compute this generator for the above correlated noise case. These results are a slight generalization of those in [2]; they are included here for completeness.

However, this formulation is quite restrictive. Given a nondegenerate generator A on a manifold M of dimension d it is not always possible to find d independent BM such that equation (0.2) generates an A -diffusion process on $M(d)$. This only can be done if $M(d)$ is parallelizable (for example, S^k is parallelizable only for $k = 1, 3, 7$). In general, $n > d$ BM will be required for this, where we only know an upper bound of n which is $2d + 1$ (Whitney’s imbedding theorem). So, there is no systematic way to calculate the d vector fields in equation (0.2).

Therefore if instead of the equation (0.2) an A -diffusion process is given on a manifold $M(d)$, a different set-up will be required.

In Part II we tackle the nonlinear filtering problem when the signal is an A -diffusion process on the manifold $M(d)$, the observation is given by the same equation (0.1) and the noise correlation is represented by a vector field Z .

Given a generator A , an A diffusion can be obtained on M using the “lifting” technique. Motivated by this technique, we find that lifting the signal and the observation equation on the orthonormal frame bundle $O(M)$ of M we can use the same approach as in Part I to derive a pathwise solution on $O(M)$. Then the projection of this solution on M will be the required pathwise solution of our problem under the new formulation. In Part II we find the pathwise solution on $O(M)$ and we calculate the generator \tilde{A}_t^γ on $O(M)$. Then we calculate the projection, A_t^γ , of this generator \tilde{A}_t^γ on M which corresponds to a pathwise solution of the problem on M . Thus the frame bundle, horizontal lifting etc. disappear in the formulation of the final result (Theorem 2.4).

Our main result, Theorem 2.4, involves apparently rather restrictive conditions: *nondegenerate diffusions* and *one-dimensional observations*. As regards nondegeneracy, we remark that theory in Part I covers a wide class of degenerate signal processes, so long as they are given in differential equation form (1.2). When the signal is specified only by its generator, we require nondegeneracy in order to apply the horizontal lifting technique. There is in fact little general theory available for handling degenerate diffusions specified in this form (cf. Stroock and Varadhan [15]).

The theory extends to vector-valued observations when there is no noise correlations ($Z = 0$) but generally not otherwise. As pointed out in [1] and [2] the pathwise method fails if the noise vector fields Z_i corresponding to vector observations $\{y_t^i, i = 1, \dots, m\}$ do not commute.

The reason for this is that although a decomposition of the type (2.11) is still possible, ξ_t is now given by the SDE

$$df(\xi_t(x)) = Z_i f(\xi_t(x)) \circ dy_t^i, \quad \xi_0(x) = x.$$

Stochastic flow theory tells us that $\xi_t(\cdot)$ is almost surely a diffeomorphism, but no continuous dependence on $\{y_t^1, \dots, y_t^m\}$ can be expected; see [10].

It is argued in [1], [2] that pathwise filtering theory is the only theory with any relevance to practical applications, since such applications involve sample paths which are a null set in any "almost sure" theory. The purpose of this paper is to see how far the pathwise theory will go, and the result is that it can be extended to certain cases where the signal is not originally specified in terms of SDE's.

PART I

1.1. The signal and observation equations. For notational consistency with Part II below, the signal process is here denoted r_t , and its generator \tilde{A} . Thus the filtering problem is given by the observation equation

$$(1.1) \quad dy_t = h(r_t) dt + dw_t^0$$

where y_t is the real valued observed process and the signal process r_t is the solution of the stochastic differential equation

$$(1.2) \quad df(r_t) = L_0 f(r_t) dt + L_j f(r_t) \circ dw_t^j, \quad j = 1, \dots, d, \quad f \in C^\infty(N).$$

The process r_t evolves on a σ -compact, connected C^∞ manifold N of dimension n , and L_0, L_1, \dots, L_d are C^∞ vector fields on N . r_0 has a given distribution ν , and w^1, \dots, w^d are independent scalar Brownian motions. We assume r_t has infinite lifetime. To allow possible correlation between the signal noise (w^1, \dots, w^d) and the observation noise w^0 , we suppose there are C^∞ functions a_1, \dots, a_d such that

$$(1.3) \quad \langle w^i, w^0 \rangle_t = \int_0^t a_i(r_s) ds.$$

The corresponding Ito form of (1.2) is

$$df(r_t) = \tilde{A}f(r_t) dt + d\tilde{M}_t^f$$

where $\tilde{A} = L_0 + \frac{1}{2} \sum_{i=1}^d L_i^2$ is the extended generator of r_t and

$$\tilde{M}_t^f := f(r_t) - f(0) - \int_0^t \tilde{A}f(r_s) ds = \int_0^t L_i f(r_s) dw_s^i.$$

Clearly

$$\langle M_t^f, w_t^0 \rangle = \int_0^t \sum_i^d a_i(r_s) L_i f(r_s) ds = \int_0^t \tilde{Z}f(r_s) ds$$

where \tilde{Z} is the vector field

$$(1.4) \quad \tilde{Z}(r) = \sum_{j=1}^d a_j(r) L_j(r).$$

PROPOSITION 1.1. *If (1.3) holds, then $\sum_{i=1}^d a_i^2(r) \leq 1$ for all $r \in N$ except a set of potential zero for r_t .*

Proof. If M_1, M_2 are continuous local martingales and $H_i \in L_2(\langle M_i \rangle)$ $i = 1, 2$, then inequality VII 54.3 from [5] states that

$$\left| \int_0^t H_1 H_2 d\langle M_1, M_2 \rangle \right| \leq \left(\int_0^t H_2^2 d\langle M_2, M_2 \rangle \right)^{1/2} \left(\int_0^t H_1^2 d\langle M_1, M_1 \rangle \right)^{1/2}.$$

Taking

$$H_1 = 1, \quad H_2 = 1, \quad M_1 = \int_0^t a_i(r_s) dw_s^i, \quad M_2 = w_t^0,$$

we have

$$\left| \sum_i \int_0^t a_i^2(r_s) ds \right| \leq t^{1/2} \left(\sum_i \int_0^t a_i^2(r_s) ds \right)^{1/2}$$

or

$$\sum_i \int_0^t a_i^2(r_s) ds \leq t$$

i.e.

$$\int_0^t \left(\sum_i a_i^2(r_s) - 1 \right) ds \leq 0.$$

The conclusion follows, since this holds for all t and starting points r_0 . We shall make the following assumption.

ASSUMPTION 1.1.

$$(1.5) \quad \sum_i a_i^2(r) < 1 \quad \text{for all } r \in N.$$

This essentially means that w_t^0 always contains some “fresh” noise. As pointed out in [12] the above assumption is a nondegeneracy hypothesis, which is crucial for the Zakai equation to have a nice solution. If it is not satisfied, the conditional law of x_t given $\mathcal{Y}_t = \sigma(y, s \leq t)$ may not have a density w.r.t. Lebesgue measure. Let

$$u_t^y(f) := E[f(r_t) | \mathcal{Y}_t].$$

It is convenient to calculate an unnormalized form σ_t of u_t^y so that u_t^y is then given by

$$u_t^y(f) = \sigma_t(f) / \sigma_t(1)$$

where “1” denotes the function $1(r) = 1$. $\sigma_t(f)$ satisfies the Zakai equation

$$(1.6) \quad d\sigma_t(f) = \sigma_t(\tilde{A}f) dt + \sigma_t(\tilde{D}f) dy_t$$

where

$$(1.7) \quad \tilde{D} := \tilde{Z} + h.$$

To get the appropriate form of the Kallianpur–Striebel formula for this problem, we introduce a measure P_0 via the Girsanov transformation

$$\frac{dP_0}{dP} = \exp \left(- \int_0^T h(r_s) dw_s^0 - \frac{1}{2} \int_0^T h^2(r_s) ds \right)$$

and for $i = 1, \dots, d$ define

$$(1.8) \quad dv^i := dw^i + a_i(r_t)h(r_t) dt.$$

Then, under P_0 ,

- (i) y_t and v_t^i , $i = 1, \dots, d$ are BM's;
- (ii) v_t^i, v_t^j are independent for $i \neq j$;
- (iii) $\langle v^i, y \rangle_t = \int_0^t a^i(r_s) ds$.

Now project the v^i onto y , i.e., define

$$(1.9) \quad \tilde{b}_t^i := v_t^i - \int_0^t a_i(r_s) dy_s.$$

Then

$$\langle \tilde{b}^i, y \rangle_t = 0$$

and

$$\langle \tilde{b} \rangle_t = \int_0^t (I - a(r_s) a'(r_s)) ds$$

where

$$[\langle \tilde{b} \rangle_t]_{i,j} = \langle \tilde{b}^i, \tilde{b}^j \rangle_t,$$

$a' = (a'_1, \dots, a'_d)$ and $I = d \times d$ identity matrix.

Since $\sum_i a_i^2(r) < 1$ the matrix $I - a(r)a'(r)$ is positive definite and can be factored into a product of positive definite matrices $\tilde{\Delta}(r)\tilde{\Delta}'(r)$. Defining

$$(1.10) \quad b_t := \int_0^t \tilde{\Delta}^{-1}(r_s) d\tilde{b}_s,$$

we find that $\langle b \rangle_t = It$ and $\langle b^i, y \rangle_t = 0$ i.e., b^1, \dots, b^d, y are (under measure P_0) independent standard BM's. We now express the signal equation (1.2) as a stochastic differential equation driven by b_t and y_t . From (1.2) and (1.8)

$$(1.2') \quad df(r_t) = \hat{Y}_0 f(r_0) dt + L_t f(r_t) \circ dv_t^i$$

where

$$\hat{Y}_0 := L_0 - h\tilde{Z}.$$

Since (1.9) involves Ito integrals, we express (1.2') in Ito form as

$$df(r_t) = \left(\hat{Y}_0 f + \frac{1}{2} \sum L_i^2 f \right) dt + L_t f dv_t^i.$$

When we use (1.9) and (1.10), this becomes

$$(1.2'') \quad df(r_t) = \left(\hat{Y}_0 f + \frac{1}{2} \sum L_i^2 f \right) dt + Y_j f db^j + \tilde{Z} f dy$$

where \tilde{Z} is given by (1.4), and in vector notation the Y_j are given by

$$Y := \tilde{\Delta}' L.$$

Transforming back to Stratonovich integrals in (1.2''), we finally obtain

$$(1.11) \quad df(r_t) = Y_0 f(r_t) dt + \tilde{Z} f(r_t) \circ dy_t + Y_j f(r_t) \circ db_t^j$$

where

$$Y_0 = L_0 - h\tilde{Z} - \frac{1}{2} \left[\sum_i \tilde{\delta}_i^j L_j \tilde{\delta}_i^k + a^j L_j a^k \right] L_k, \quad \tilde{\Delta} = (\tilde{\delta}_k^n)$$

$$\left(= \hat{Y}_0 + \frac{1}{2} \sum (L_i^2 - Y_i^2) - \frac{1}{2} \tilde{Z}^2 \right).$$

Equation (1.11) is the key formula for the filtering problem, as it expresses r_t in the form of an equation driven by the observation process y_t and the other "inputs" b^1, \dots, b^d which are independent of y . The next task is to decompose (1.11) in such a way that the dependence of r_t and y is explicitly brought out. This is done by the Doss-Sussmann technique as in [2], [10].

1.2. The KS formula and the associated multiplicative functional. Let $\tilde{\zeta}_t(r) = \tilde{\zeta}(t, r)$ denote the flow of the vector field \tilde{Z} , i.e., the unique solution of the equation

$$\frac{d}{dt}f(\tilde{\zeta}_t(r)) = \tilde{Z}f(\tilde{\zeta}_t(r)), \quad f \in C^\infty(N), \quad \tilde{\zeta}_0(r) = r.$$

This is a diffeomorphism for all $t \geq 0$. Define

$$\tilde{\xi}_t(r) := \tilde{\zeta}_{y_t}(r).$$

As is easily checked, $\tilde{\xi}_t(r)$ is the solution of

$$d\tilde{\xi}_t(r) = \tilde{Z}(\tilde{\xi}_t(r)) \circ dy_t$$

and obviously $\tilde{\xi}_t(r)$ is a.s. a diffeomorphism for all $t \geq 0$. Now consider the equation

$$(1.12) \quad df(\eta_t) = \tilde{\xi}_t^{-1} Y_0 f(\eta_t) dt + \tilde{\xi}_t^{-1} Y_j f(\eta_t) \circ db_t^j$$

where $\tilde{\xi}_{t*}: T_p(N) \rightarrow T_q(N)$, ($q = \tilde{\xi}_t(p)$) is the differential map and $\tilde{\xi}_t^*(f) := f \circ \tilde{\xi}_t$.

The equation has a unique solution $\eta_t = \eta_t(r)$. Applying the extended Ito formula [10], we get

$$(1.13) \quad r_t(r) = \tilde{\xi}_t \circ \eta_t(r) = \tilde{\zeta}(y_t, \eta_t).$$

The representation (1.12), (1.13) describes the behaviour of r_t conditioned on y under P_0 . Recall that the map $\tilde{\xi}_t^{-1}$ is parametrized by y and that y, b are independent. Thus, conditioned on y, η_t is a diffusion process whose differential generator is

$$(1.14) \quad \tilde{A}_t^* = \tilde{\xi}_t^{-1} Y_0 + \frac{1}{2} \sum_{i=1}^d (\tilde{\xi}_t^{-1} Y_i)^2$$

and for each $t > 0$, r_t is diffeomorphically related to η_t by (1.13).

THEOREM 1.1. *The conditional distribution $u_t^y(f)$ of r_t given \mathcal{Y}_t is given by*

$$(1.15) \quad u_t^y(f) = \frac{\sigma_t(f)}{\sigma_t(1)}$$

where

$$(1.16) \quad \sigma_t(f) = \langle \tilde{T}_{0,t}^y(\tilde{B}_{y_t} f), \nu \rangle.$$

In (1.16), $\tilde{T}_{0,t}^y$ is a semigroup whose extended generator is

$$(1.17) \quad \begin{aligned} \tilde{A}_t^y &= \exp(\tilde{H}_{y_t}) \tilde{A}_t^* \exp(-\tilde{H}_{y_t}) - \frac{1}{2} \tilde{\xi}_t^*(\tilde{D}h), \\ \tilde{B}_t &:= \exp\left(\int_0^t \tilde{\xi}_u^* h(r) du\right) \tilde{\xi}_t^* f(r) \end{aligned}$$

and

$$\tilde{H}_t := \int_0^t \tilde{\xi}_s^* h(r) ds.$$

Proof. We know from a standard formula of conditional expectations that $\sigma_t(f)$ is given in terms of the measure P_0 by

$$\sigma_t(f) := E_0 \left[f(r_t) \exp \left(\int_0^t h(r_s) dy_s - \frac{1}{2} \int_0^t h^2(r_s) ds \right) \middle| \mathcal{Y}_t \right].$$

It is immediate from (1.11) that

$$(1.18) \quad d\langle h(r), y \rangle_t = \tilde{Z}h(r_t) dt$$

and hence the Stratonovich version of this is

$$(1.19) \quad \sigma_t(f) = E_0 \left[f(r_t) \exp \left(\int_0^t h(r_s) \circ dy_s - \frac{1}{2} \int_0^t \tilde{D}h(r_s) ds \right) \middle| \mathcal{Y}_t \right]$$

where \tilde{D} is given by (1.7).

Now since $r_t = \tilde{\xi}_t \circ \eta_t(r)$ and η_t is a functional of the independent processes y_t and $b_t^i = (b_t^1, \dots, b_t^d)$, we can express (1.19) in the form

$$(1.20) \quad \sigma_t(f) = E^b \left(\tilde{\xi}_t^* f(\eta_t) \exp \left(\int_0^t \tilde{\xi}_s^* h(\eta_s) \circ dy_s - \frac{1}{2} \int_0^t \tilde{\xi}_s^* \tilde{D}(\eta_s) ds \right) \right)$$

where E^b means integration over the sample space measure for b_t (=Wiener measure on $C([0, T]; \mathbb{R}^n)$). This is the KS formula for the correlated noise problem. In order to get it in robust form, we need to calculate the stochastic integral in (1.20) as an explicit functional of y .

Introduce the function

$$(1.21) \quad \tilde{H}_y(r) = \tilde{H}(y, r) := \int_0^y \tilde{\xi}_s^* h(r) ds,$$

and calculate $\tilde{H}(y_t, r_t)$ using the Ito formula and (1.13). This gives

$$(1.22) \quad \tilde{H}(y_t, r_t) = \int_0^t h(r_s) \circ dy_s + \int_0^t (\tilde{\xi}_s^{-1} Y_0) \tilde{H}_{y_s}(\eta_s) ds + \int_0^t (\tilde{\xi}_s^{-1} Y_j) \tilde{H}_{y_s}(\eta_s) \circ db_s^j.$$

The stochastic integral with respect to b^j in (1.22) can be reexpressed in Ito form in the standard way using (1.12). Do this and introduce the notation

$$(1.23) \quad Y_j^* := \tilde{\xi}_s^{-1} Y_j, \\ \tilde{B}_{y_t} f(r) := \exp \left(\int_0^{y_t} \tilde{\xi}_u^* h(r) du \right) \tilde{\xi}_{y_t}^* f(\dot{r}).$$

Then using (1.23) in (1.20) gives

$$(1.24) \quad \sigma_t(f) = E[\tilde{B}_{y_t} f(\eta_t) \tilde{a}_t^0(y)]$$

where

$$(1.25) \quad \tilde{a}_t^0(y) := \exp \left[- \int_0^t Y_j^* \tilde{H}_{y_u}(\eta_u) db_u^j - \frac{1}{2} \int_0^t \sum (Y_j^*)^2 \tilde{H}_{y_u}(\eta_u) du \right. \\ \left. - \int_0^t Y_0^* \tilde{H}_{y_u}(\eta_u) du - \frac{1}{2} \int_0^t \xi_u^* \tilde{D}h(\eta_u) du \right].$$

For each $y \in C$, $\tilde{a}_t^0(y)$ is a multiplicative functional (m.f.) of η_t and hence the formula

$$\tilde{T}_{s,t}^y f(\eta) = E_{s,\eta}[f(\eta_t) \tilde{a}_t^s(y)]$$

defines a semigroup of operators on $B(N)$ in terms of which (1.24) becomes

$$\sigma_t(f) = \langle \tilde{T}_{0,t}^y \tilde{B}_{y_t} f, \nu \rangle.$$

We can thus compute $\sigma_t(f)$ by solving the forward equation corresponding to $\tilde{T}_{0,t}^y$ involving $(\tilde{A}_t^y)^*$ where \tilde{A}_t^y is the extended generator of $\tilde{T}_{0,t}^y$ (as defined in (31) of [3]).

We now calculate \tilde{A}_t^y by factoring $\tilde{a}_t^0(y)$ as follows:

$$\begin{aligned} \tilde{a}_t^0(y) = & \exp \left[- \int_0^t Y_j^* \tilde{H}_{y_u}(\eta_u) db_u^j - \frac{1}{2} \int_0^t \sum (Y_j^* \tilde{H}_{y_u}(\eta_u))^2 du \right] \\ & \times \exp \left[\frac{1}{2} \int_0^t \sum (Y_j^* \tilde{H}_{y_u}(\eta_u))^2 du - \frac{1}{2} \int_0^t \sum (Y_j^*)^2 \tilde{H}_{y_u}(\eta_u) du \right. \\ & \left. - \int_0^t Y_0^* \tilde{H}_{y_u}(\eta_u) du - \frac{1}{2} \int_0^t \tilde{\xi}_u^* \tilde{D}h(\eta_u) du \right]. \end{aligned}$$

Since the first term corresponds to a Girsanov type m.f. and the second to a Feynman-Kac type m.f. it follows [2] that

$$\tilde{A}_t^y f = [\tilde{A}_t^* f - \sum Y_j^* \tilde{H}_{y_t} Y_j^* f] + (\frac{1}{2} \sum (Y_j^* \tilde{H}_{y_t})^2 - \tilde{A}_t^* \tilde{H}_{y_t} - \frac{1}{2} \tilde{\xi}_t^* \tilde{D}h) f$$

where \tilde{A}_t^* is the generator of η_t , i.e.,

$$\tilde{A}_t^* = Y_0^* + \frac{1}{2} \sum_{j=1}^d (Y_j^*)^2.$$

In [2] it has been proved that

$$e^g \tilde{A} e^{-g} = \tilde{A} - \sum (L_j g) L_j - \tilde{A} g + \frac{1}{2} \sum (L_j g)^2.$$

When we use the above expression, the generator \tilde{A}_t^y becomes

$$\tilde{A}_t^y = e^{\tilde{H}_{y_t}} \tilde{A}_t^* e^{-\tilde{H}_{y_t}} - \frac{1}{2} \tilde{\xi}_t^* (\tilde{D}h)$$

which is equation (1.17) and the proof is completed.

PART II

2.1. Problem formulation. We consider the filtering problem where now the “signal” process x_t is a diffusion process on the manifold $M(d)$ with a given nondegenerate extended generator A . By this we mean that for all $f \in C^\infty(M)$

$$M_t^f := f(x_t) - f(x_0) - \int_0^t A f(x_s) ds$$

is a local martingale. In local coordinates A is given as

$$A f(x) = \frac{1}{2} a^{ij}(x) \frac{\partial^2 f}{\partial x_i \partial x_j}(x) + b^i(x) \frac{\partial f}{\partial x_i}(x), \quad f \in C^\infty(M)$$

and $a^{ij}(x) q_i q_j > 0$ for all x and $q = (q_i) \in \mathbb{R}^d - \{0\}$.

We assume that x_t has infinite lifetime. This is true if $M(d)$ is compact; conditions under which it holds for noncompact M are discussed by Elworthy [8].

The observation process is given by the following equation:

$$dy_t = h(x_t) dt + dw_t^0.$$

Since the joint process (x_t, w_t^0) is a Hunt process, we know from results in [3] that the joint variation $\langle M^f, w^0 \rangle_t$ must take the form

$$\langle M^f, w^0 \rangle_t = \int_0^t Z f(x_s, w_s^0) ds$$

for some function Zf , and it is shown in [3] that the map $f \rightarrow Zf(x, w^0)$ is a derivation, i.e., satisfies the Leibnitz rule, except perhaps on (x, w) sets of potential zero.

For later development it is necessary to assume that Zf does not depend on w^0 . Then Z is a derivation on M , i.e., $(f \rightarrow Zf(x)) \in T_x(M)$. If we further assume that $Zf(x)$ varies smoothly with x , then Z is a vector field. Thus a natural formulation of the idea of noise correlation is to suppose that a C^∞ vector field Z is given such that

$$(2.1) \quad \langle M^f, w^0 \rangle_t = \int_0^t Zf(x_s) ds.$$

We write Z in local coordinates as

$$(2.2) \quad Z = \bar{a}^i(x) \frac{\partial}{\partial x_i}.$$

Finally, we assume that Z is complete, i.e.

$$\zeta_t(x) \text{ is defined for all } t > 0$$

where $\zeta_t(x)$ is the flow of Z .

2.2. Construction of the process x_t, w_t^0 by horizontal lifting. We use the horizontal lifting technique described in § 5.4 of Ikeda and Watanabe [9] to which the reader is referred for complete details. We summarize briefly here, beginning with some preliminary definitions from differential geometry.

Let M be a C^∞ -manifold and let $\mathcal{X}(M)$ denote the set of vector fields on M . By an *affine connection* ∇ we mean a rule which associates to every $X \in \mathcal{X}(M)$ a linear mapping $\nabla_X : \mathcal{X}(M) \rightarrow \mathcal{X}(M)$ having the following properties:

- (i) $\nabla_X Y$ is bilinear in X and Y ,
- (ii) $\nabla_{fX+gY} = f\nabla_X + g\nabla_Y$,
- (iii) $\nabla_X(fY) = f\nabla_X Y + (Xf)Y$.

The operator ∇_X is called covariant differentiation with respect to X . The components of the connection ∇ are defined as the functions $\{\Gamma_{jk}^i(x)\}$ such that in local coordinates

$$\nabla_{\partial_i} \partial_j = \Gamma_{ij}^k(x) \frac{\partial}{\partial x_k} \quad \left(\partial_i = \frac{\partial}{\partial x_i} \right).$$

An affine connection is called symmetric if $\Gamma_{ij}^k = \Gamma_{ji}^k$. In local coordinates $\nabla_X Y$ may be expressed as

$$\nabla_X Y = \left[X^i(x) \frac{\partial}{\partial x_i} Y^k(x) + \Gamma_{ij}^k(x) X^i(x) Y^j(x) \right] \frac{\partial}{\partial x_k}$$

where

$$X = X^i(x) \frac{\partial}{\partial x_i} \quad \text{and} \quad Y = Y^i(x) \frac{\partial}{\partial x_i}.$$

For I an interval of the real line, let $c : I \ni t \rightarrow c(t) \in M$ be a smooth curve in M , and let $X(t) \in T_{c(t)}(M)$ for $t \in I$. $X(t)$ is said to be parallel along c (with respect to ∇) if

$$\frac{d}{dt} X^i(t) + \Gamma_{kj}^i(c(t)) X^j(t) \frac{dc^k(t)}{dt} = 0, \quad t \in I.$$

For $t_0, t_1 \in I$, $t_0 \leq t_1$, $X(t_1)$ is uniquely determined from $X(t_0)$ and we say that $X(t_1)$ is obtained from $X(t_0)$ by *parallel displacement* along the curve $c(t)$. A C^∞ -manifold is called *Riemannian* if a tensor field $g = (g_{ij})$ of type $(0, 2)$ is given on M such that

- (i) g is symmetric, i.e., $g_{ij}(x) = g_{ji}(x)$,

(ii) g is positive definite, i.e., $g_{ij}(x)q^i q^j > 0$ for all x and $q \in R^d$, $q \neq 0$.
 g is called the Riemannian metric. It defines an inner product on each tangent space $T_x(M)$ by

$$\langle X, Y \rangle = g_{ij}(x) X^i Y^j.$$

An affine connection $\nabla = \{\Gamma_{ij}^k\}$ is said to be compatible with the Riemannian metric g if the inner product is preserved during a parallel displacement of tangent vectors. There exists a unique symmetric affine connection compatible with g , and this is the so-called *Riemannian connection*.

Given the second order operator A on M , we can define a Riemannian metric g on $M(d)$ by

$$g_{ij} = (a^{ij})^{-1} \quad (\text{i.e. } g^{ij} = a^{ij}).$$

Let $G(x) := (a^{ij}(x))$. Then $M(d)$ is a Riemannian manifold.

The components of the corresponding Riemannian connection, called Christoffel symbols, are given by

$$(2.3) \quad \Gamma_{ij}^k = \frac{1}{2} \left[\frac{\partial}{\partial x_i} g_{mj} + \frac{\partial}{\partial x_j} g_{im} - \frac{\partial}{\partial x_m} g_{ij} \right] g^{km}.$$

Now let us introduce the bundle of orthonormal frames on M . By an orthonormal frame $e = [e_1, e_2, \dots, e_d]'$ at x we mean an orthonormal base of $T_x(M)$. Then $O(M)$ is defined as the collection of all orthonormal frames at all points $x \in M$:

$$O(M) := \{r = (x, e) : x \in M, e \text{ is a frame at } x\}$$

and in local coordinates

$$r = (x^i, e_j^i) \in R^d \times R^{d(d+1)/2}$$

where

$$e_j = e_j^i \frac{\partial}{\partial x_i}, \quad j = 1, \dots, d,$$

and since e_i 's are orthonormal in $T_x(M)$

$$g_{kl} e_i^k e_j^l = \delta_j^i \quad ^2$$

or equivalently

$$\sum_{m=1}^d e_m^i e_m^j = g^{ij}(x) = a^{ij}(x).$$

An element β of the orthogonal group $O(d)$ acts on $O(M)$ by

$$(2.4) \quad T_\beta(x, e) = (x, e\beta)$$

where $e\beta = [(e\beta)_1, (e\beta)_2, \dots, (e\beta)_d]'$ is an orthonormal frame at x defined by

$$(e\beta)_j = \beta_j^i e_i, \quad j = 1, \dots, d.$$

Therefore $O(M)$ is a principal fibre bundle over M with the structural group $O(d)$.

The Riemannian connection of M determines a splitting of the tangent bundle to $O(M)$ into vertical and horizontal components. For each $r \in O(M)$

$$H_r = \left\{ X = a^i \left(\frac{\partial}{\partial x_i} \right)_x - \Gamma_{kl}^i(x) e_j^l a^k \frac{\partial}{\partial e_j^i}; \quad (a^i) \in R^d \right\},$$

² By δ_q^{μ} we mean the Kronecker delta.

the *horizontal subspace*, is a linear subspace of $T_r(O(M))$ which is independent of the choice of local coordinates (x^i, e_j^i) .

A vector field X on $O(M)$ is called horizontal if $X(r) \in H_r$ for each $r \in O(M)$. Let π denote the projection map $\pi: O(M) \rightarrow M$ and let $d\pi: TO(M) \rightarrow TM$ denote its differential map. Then given $X \in \mathcal{X}(M)$, there exists a unique $\tilde{X} \in \mathcal{X}(O(M))$ such that \tilde{X}_r is the horizontal lift of $\tilde{X}_{\pi(r)}$ for all $r \in O(M)$. \tilde{X} is called the horizontal lift of X and in local coordinates is given by

$$\tilde{X} = X^i(x) \frac{\partial}{\partial x_i} - \Gamma_{ij}^q(x) X^j(x) e_p^i \frac{\partial}{\partial e_p^q} \quad \text{if } X = X^i(x) \frac{\partial}{\partial x_i}.$$

Similarly, given a smooth curve $c(t)$ on M , the curve $\tilde{c}(t)$ on $O(M)$ is called a horizontal lift of c if (a) $(d\tilde{c}/dt)(t)$ is horizontal and (b) $\pi(\tilde{c}(t)) = c(t)$. Then the curve $\tilde{c}(t)$ is given by $\tilde{c}(t) = (c(t), e(t))$ where the e 's are parallel translated along $c(t)$. Finally we can define the system of the canonical horizontal vector fields $\{L_1, \dots, L_d\}$ such that L_j is the horizontal lift of $e_j \in T_x(M)$ for all $r = (x, e)$. L_j may be expressed as

$$(2.5) \quad L_j = e_j^i \frac{\partial}{\partial x_i} - \Gamma_{kt}^q e_j^k e_p^t \frac{\partial}{\partial e_p^q}.$$

Let us now return to the filtering problem as formulated in § 2.1.

ASSUMPTION 2.1. $\bar{a}(x)\bar{a}'(x) < G(x)$.

Remark. In R^n , $g_{ij} = \delta_{ij}$, $\Gamma_{ij}^q = 0$ and the above inequality corresponds to $aa' < I$, which was the assumption introduced in Part I.

The process (x_t, w_t^0) can be constructed by the "horizontal lifting" technique. The following result is proved in [9].

THEOREM 2.1. In Part I, take $N = O(M)$, L_i , $i = 1, \dots, d$ the canonical horizontal vector fields and let L_0 be the horizontal lift of the vector field

$$\bar{b} = \bar{b}^i(x) \frac{\partial}{\partial x_i}, \quad \bar{b}^i = b^i + \frac{1}{2} g^{ij} \Gamma_{ij}^i.$$

If we define $r(t)$ by (1.2) then $x_t = \pi(r_t)$ is a diffusion process on M with extended generator A .

Remarks. The diffusion $r_t = r(t, r, w)$ on $O(M)$ is the flow of diffeomorphisms defined by

$$(2.5') \quad dr(t) = L_i(r(t)) \circ dw^i + L_0(r(t)) dt, \quad r(0) = r.$$

Let $\tilde{A} = L_0 + \frac{1}{2} \sum_{i=1}^d L_i^2$ be the generator of the diffusion process $r(t)$. One has to show that this corresponds to the horizontal lift of the generator A , i.e., $d\pi(\tilde{A}) = A$. To show this, we take $f(r_t) = f(x_t, e_t) \equiv f(x_t)$ and prove that $\tilde{A}f(x_t) \equiv Af(x_t)$. In [9] it is proved that

$$\frac{1}{2} d\pi \left[\sum_{i=1}^d L_i^2 f \right] = \frac{1}{2} \sum_{i=1}^d L_i(L_i f(x_t)) = \frac{1}{2} \left[a^{ij} \frac{\partial f}{\partial x_i} \frac{\partial f}{\partial x_j} - g^{ij} \Gamma_{ij}^i \frac{\partial f}{\partial x_i} \right]$$

so finally we have

$$d\pi(\tilde{A}) = d\pi(L_0) + \frac{1}{2} \left[\sum_{i=1}^d L_i^2 \right] = \bar{b} + \frac{1}{2} \left[a^{ij} \frac{\partial}{\partial x_i} \frac{\partial}{\partial x_j} - g^{ij} \Gamma_{ij}^i \frac{\partial}{\partial x_i} \right] = A.$$

The Markov property of x_t is a consequence of the fact that $x(t, T_\beta r, w) = x(t, r, w\beta)$ and the remark that $w\beta$ is another d -dimensional Wiener process. Therefore, the probability law of $x(\cdot, T_\beta r, w)$ is independent of $\beta \in O(d)$, i.e., depends only on $x = \pi(r)$.

We have constructed x_t in terms of d -dimensional BM(w^1, \dots, w^d). We now have to construct a BM w_t^0 such that (2.1) holds.

LEMMA 2.1. *Augment w^1, \dots, w^d with a further independent BM w^{d+1} . Then we can choose a BM w^0 s.t. $d\langle w^i, w^0 \rangle_t = \gamma^i(r_t) dt$ where $\gamma^i(r)$ $i = 1, \dots, d$ are any real-valued measurable functions satisfying*

$$\sum_{i=1}^d (\gamma^i(r))^2 \leq 1 \quad \text{for all } r.$$

Proof. Define

$$(2.6) \quad w_t^0 = \sum_{i=1}^d \int_0^t \gamma^i(r_s) dw_s^i + \int_0^t \theta_s dw_s^{d+1}$$

where

$$\theta_s = \left[1 - \sum_{i=1}^d (\gamma^i(r_s))^2 \right]^{1/2}.$$

THEOREM 2.2. *Let w^0 be a BM defined by (2.6) where $\gamma^i(r)$ is given by*

$$(2.7) \quad \gamma^i(r) = (e^{-1})_j^i \bar{a}^j(x)$$

and (e^{-1}) denotes the inverse of the matrix $e = (e_j^i)$. Then $\langle M^f, w^0 \rangle_t = \int_0^t Zf(x_s) ds$ where Z is the given vector field $Z(x) = \bar{a}^i(x)(\partial/\partial x_i)$ $i = 1, \dots, d$.

Proof. Since $df(r_t) = L_0 f(r_t) dt + L_i f(r_t) \circ dw_t^i$, it follows that

$$d\langle M^f, w^0 \rangle_t = L_i f(r_t) d\langle w^i, w^0 \rangle_t.$$

Now if $f: M \rightarrow R$ then

$$L_j f(r_t) = e_j^i \frac{\partial f(x_t)}{\partial x_i}$$

which implies that

$$d\langle M^f, w^0 \rangle_t = e_j^i \frac{\partial f(x_t)}{\partial x_i} \gamma^j(r) dt = e_j^i \frac{\partial f(x)}{\partial x_i} (e^{-1})_k^j \bar{a}^k(x) dt$$

and since

$$(e)(e^{-1}) = I \Rightarrow e_j^i (e^{-1})_k^j = \bar{\delta}_k^i$$

we conclude that

$$d\langle M^f, w^0 \rangle_t = \bar{a}^k(x) \frac{\partial f(x)}{\partial x_k} dt$$

or

$$\langle M^f, w^0 \rangle_t = \int_0^t Zf(x, ds).$$

Remark. The function $\gamma^i(r)$ is an intrinsically defined function, i.e. independent of local coordinates, as can easily be proved. (A similar function appears at the end of § 5.2 of [9]). The inequality $\sum_{i=1}^d (\gamma^i(r))^2 < 1$ is satisfied according to Corollary 2.2 below.

LEMMA 2.2. *Given the vector field $Z = \bar{a}^i(x)(\partial/\partial x_i)$ on $M(d)$, then the horizontal lift \tilde{Z} with respect to the Riemannian connection can be expressed as*

$$\tilde{Z}(r) = \gamma^i(r)L_i$$

with γ^i given by (2.7).

Proof. Using (2.5) and (2.7) in the above expression, we take

$$\begin{aligned}\tilde{Z}(r) &= \bar{a}^i(e^{-1})^j_i e_j^k \frac{\partial}{\partial x_k} - \bar{a}^i(e^{-1})^j_i \Gamma_{kl}^q e_j^k e_p^l \frac{\partial}{\partial e_p^q} \\ &= \bar{a}^i \frac{\partial}{\partial x_i} - \Gamma_{kl}^q \bar{a}^k e_p^l \frac{\partial}{\partial e_p^q}\end{aligned}$$

which is by definition the horizontal lift of Z .

DEFINITION 2.1. For $f \in C^\infty(O(M))$ we denote by \tilde{M}^f the martingale

$$\tilde{M}_t^f = f(r_t) - f(r_0) - \int_0^t \tilde{A}f(r_s) ds.$$

Then if $f: M \rightarrow \mathbb{R}$, $M_t^f \equiv \tilde{M}_t^f$.

LEMMA 2.3. *Let $\bar{a}(x) = (\bar{a}_1(x), \dots, \bar{a}_d(x))'$ and $G(x) = (a^{ij}(x))$. Then under our problem formulation structure the following inequality holds for all $x \in M$ except a set of potential zero for x_i , independently of Assumption 2.1 above.*

$$G(x) - \bar{a}(x)\bar{a}'(x) \geq 0.$$

Proof. Let $x_t = \pi(r_t)$ where r_t denotes the solution of (2.5') with arbitrary r_0 . Since $\langle M_t^f, w_t^0 \rangle = \int_0^t Zf(x_s) ds$ inequality VII. 54.3 of [5] becomes

$$\left| \int_0^t H_1 H_2 Zf(x_s) ds \right| \leq \left[\int_0^t H_1^2 ds \right]^{1/2} \left[\int_0^t H_2^2 d\langle M_t^f, M_t^f \rangle \right]^{1/2}$$

and taking $H_1 = Zf(x_s)$, $H_2 = 1$ we have

$$\left| \int_0^t (Zf(x_s))^2 ds \right| \leq \left[\int_0^t (Zf(x_s))^2 ds \right]^{1/2} [\langle M_t^f, M_t^f \rangle]^{1/2},$$

which implies that

$$(2.8) \quad \int_0^t (Zf(x_s))^2 ds \leq \langle M^f, M^f \rangle_t \quad \forall t.$$

From [3] it is known that

$$(2.9) \quad \langle M^f, M^f \rangle_t = \int_0^t \Delta_A^{ff}(x_s) ds$$

where

$$\Delta_A^{fg} = A(fg) - fAg - gAf.$$

Therefore using (2.8) and (2.9), we have

$$\int_0^t |Zf(x_s)|^2 ds \leq \int_0^t \Delta_A^{ff}(x_s) ds$$

and since in local coordinates

$$\Delta_A^f(x) = a^{ij}(x) \frac{\partial f(x)}{\partial x_i} \frac{\partial f(x)}{\partial x_j} = \nabla f'(x) G(x) \nabla f(x),$$

$$Zf(x) = \bar{a}^i(x) \frac{\partial f(x)}{\partial x_i} = \bar{a}'(x) \nabla f(x),$$

we conclude that

$$\int_0^t \nabla f'(x_s) \bar{a}(x_s) \bar{a}'(x_s) \nabla f(x_s) ds \leq \int_0^t \nabla f'(x_s) G(x_s) \nabla f(x_s) ds \quad \forall t$$

or

$$\int_0^t (G(x_s) - \bar{a}(x_s) \bar{a}'(x_s)) ds \geq 0 \quad \text{for all } t.$$

The result follows.

COROLLARY 2.1. $I - \gamma\gamma' \geq 0$ up to sets of potential zero.

Proof. From Lemma 2.3

$$G - \bar{a}\bar{a}' \geq 0$$

and since $ee' = G$, rearranging, we obtain

$$I - (e^{-1}) \bar{a}\bar{a}'(e^{-1})' \geq 0$$

or equivalently

$$I - \gamma\gamma' \geq 0.$$

Remark. Since $\langle \tilde{M}^f, w^0 \rangle_t = \int_0^t \tilde{Z}f(r_s) ds$, working as in Lemma 2.3 on $O(M)$ we can also conclude that $I - \gamma\gamma' \geq 0$ up to sets of potential zero.

COROLLARY 2.2. If $G - \bar{a}\bar{a}' > 0$ then $I - \gamma\gamma' > 0$.

Proof. Follows directly from Corollary 2.1.

2.3. The generator A_t^y . With the above construction done Part I can be applied, i.e. we have a pathwise filter for r_t given \mathcal{Y}_t .

Our objective is to show that there is a pathwise filter for x_t on M involving only “downstairs” objects. First consider the following lemma.

LEMMA 2.4. Given a curve $x(t)$ on M , consider two horizontal lifts $\tilde{c}_1(t)$ and $\tilde{c}_2(t)$ of the curve $x(t)$, with $\tilde{c}_2(0) = T_\beta \tilde{c}_1(0)$ for some $\beta \in O(d)$ (see (2.4)). Then for all $t \geq 0$

$$(2.10) \quad \tilde{c}_2(t) = T_\beta \tilde{c}_1(t).$$

Proof. The parallel translating of e 's along the curve $x(t)$, in local coordinates, is given by

$$\frac{de_a^i(t)}{dt} = -\Gamma_{kj}^i(x_t) e_a^j(t) \frac{dx^k}{dt}(t),$$

$$x^i(0) = x^i,$$

$$e_a^i(0) = e_a^i.$$

Obviously the rotation of the initial frame e_a^i does not affect the above equation, and therefore both sides of (2.10) satisfy the same differential equation.

In Part I take $N = O(M)$, L_i , $i = 1, \dots, d$ the canonical horizontal vector fields, L_0 as given in Theorem 2.1, $h(r) \equiv h(x)$ $a(r) = \gamma(r)$, $\tilde{Z}(r)$ the horizontal lift of the vector field Z and $r = (x, e) \in O(M)$ where $\pi(r) = x \in M$.

Then the signal equation becomes

$$df(r_t) = Y_0 f(r_t) dt + \tilde{Z}f(r_t) \circ dy_t + Y_j f(r_t) \circ dw_t^j, \quad j = 1, \dots, d$$

where

$$Y_0 = L_0 - h\tilde{Z} - \frac{1}{2} \left[\sum_i \tilde{\delta}_i^j L_j \tilde{\delta}_i^k + \gamma^j L_j \gamma^k \right] L_k, \quad Y = \tilde{\Delta}' L, \quad \tilde{\Delta} \tilde{\Delta}' = I - \gamma \gamma'.$$

The matrix $I - \gamma \gamma'$ is positive definite and can be factorized into the product $\tilde{\Delta} \tilde{\Delta}'$ since according to Corollary 2.2 $I - \gamma \gamma' > 0$. Let $\Delta \Delta' := G - \bar{a} \bar{a}'$. Clearly $\tilde{\Delta} \tilde{\Delta}' = (e^{-1}) \Delta \Delta' (e^{-1})'$.

By decomposing the signal equation we have

$$(2.11) \quad r_t = \tilde{\xi}_t \circ \eta_t(r) = \tilde{\zeta}(y_t, \eta_t)$$

where

$$d\tilde{\xi}_t = \tilde{Z}(\tilde{\xi}_t) \circ dy_t$$

and $\eta_t(r)$ is the diffusion process

$$d\eta_t = \tilde{\xi}_t^{-1} Y_0 f(\eta_t) dt + \tilde{\xi}_t^{-1} Y_j f(\eta_t) \circ dw_t^j, \quad \eta_0 = r$$

whose differential generator is

$$\tilde{A}_t^* = \tilde{\xi}_t^{-1} Y_0 + \frac{1}{2} \sum_{i=1}^d (\tilde{\xi}_t^{-1} Y_i)^2.$$

The process $\eta_t(r)$ has a unique solution up to some explosion time τ . Recall that $\tilde{\zeta}_t(r)$ is defined for all t since the vector field Z is assumed to be complete. Then if $r_t(r)$ is defined for all t , $\eta_t(r)$ is also defined for all t since from (2.11)

$$\eta_t(r) = \tilde{\zeta}(-y_t, r_t(r)).$$

Thus we conclude that, if the signal equation has no explosion and the vector field Z is complete, then $\tau = \infty$.

Since $\tilde{\zeta}_t(r) = \tilde{\zeta}(t, r)$ is the flow of the horizontal vector field \tilde{Z} on $O(M)$, it follows that $\tilde{\zeta}_t$ is the horizontal lift of the curve ζ_t on M (i.e., the flow of the vector field Z on M). Thus $\tilde{\xi}_t = \tilde{\zeta}_{y_t}$ is the horizontal lift of the curve ξ_t on M .

It is quite straightforward to conclude that in local coordinates

$$\tilde{\xi}_t^{-1}(x, e) = (\tilde{\xi}_t^{-1}(x, e)^k, \tilde{\xi}_t^{-1}(x, e)^r_s) = (\xi_t^{-1}(x)^k, e_s^r(t))$$

where the $e_s^r(t)$ are parallel translated along the curve $\xi_t^{-1}(x)$ and therefore

$$\frac{\partial \tilde{\xi}_t^{-1}(x, e)^k}{\partial e_p^q} = 0.$$

Since $\tilde{\xi}_t$ is a diffeomorphism on $O(M)$, $\tilde{\xi}_t^{-1} L_j \in \mathcal{H}(O(M))$, it is given in local coordinates by

$$(2.12) \quad \begin{aligned} L_j^* f(l) &:= (\tilde{\xi}_t^{-1} L_j(x)) f(l) \\ &= e_j^i \frac{\partial \tilde{\xi}_t^{-1}(x)^k}{\partial x_i} \frac{\partial f}{\partial l_k} \\ &\quad + \left[e_j^i \frac{\partial \tilde{\xi}_t^{-1}(x, e)^r_s}{\partial x_i} - \Gamma_{k\mu}^q(x) e_j^k e_p^\mu \frac{\partial \tilde{\xi}_t^{-1}(x, e)^r_s}{\partial e_p^q} \right] \frac{\partial f}{\partial e_s^r(l)} \\ &\quad \forall f \in C^\infty(\pi^{-1}(U_l(M))), \quad l = \xi_t^{-1}(x), \quad e_s^r(l) = \tilde{\xi}_t^{-1}(x, e)^r_s. \end{aligned}$$

THEOREM 2.3. $x_t := \pi(\eta_t)$ is a diffusion process on M with generator

$$(2.13) \quad A_t^* = \frac{1}{2} [a^{k\mu}(x) - \bar{a}^k(x) \bar{a}^\mu(x)] \frac{\partial^*}{\partial x_k} \frac{\partial^*}{\partial x_\mu} + \left[\frac{1}{2} \sum_m \frac{\partial \delta_m^p(x)}{\partial x_j} \delta_m^j(x) - \frac{1}{2} \frac{\partial \bar{a}^p(x)}{\partial x_k} \bar{a}^k(x) + b^p(x) - h(x) \bar{a}^p(x) \right] \frac{\partial^*}{\partial x_p}$$

where by $\partial^*/\partial x_k$ we mean

$$\xi_t^{-1} \frac{\partial}{\partial x_k} = \frac{\partial \xi_t^{-1}(x)^a}{\partial x_k} \frac{\partial}{\partial l_a} = \left[\frac{\partial \xi_t(x)^a}{\partial x_k} \right]^{-1} \frac{\partial}{\partial l_a},$$

$$x = \xi_t(l).$$

Proof. $\eta_t(\eta) = (\eta(t, \eta, w))$ is the solution of the stochastic differential equation

$$(2.14) \quad d\eta(t) = (\tilde{\xi}_t^{-1} Y_j)(\eta(t)) \circ dw^j(t) + (\tilde{\xi}_t^{-1} Y_0)(\eta(t)) dt, \quad \eta(0) = \eta,$$

i.e., $\eta(t, \eta, w)$ is the flow of diffeomorphisms on $O(M)$ corresponding to the vector fields $\tilde{\xi}_t^{-1} Y_j$, $j = 1, \dots, d$ and the drift vector field $\tilde{\xi}_t^{-1} Y_0$. Let $B = d\pi(\tilde{\xi}_t^{-1} Y_0)$.

It has been proved [14] that in local coordinates (2.14) is equivalent to

$$dx^i(t) = \tilde{\delta}_k^m(\eta_t) e_m^j(t) \frac{\partial \xi_t^{-1}(x)^i}{\partial x_j} \circ dw^k(t) + B^i(x_t) dt,$$

$$de_s^r(t) = -\Gamma_{\mu\mu}^q(x_t) \tilde{\delta}_i^m(\eta_t) e_m^k(t) e_p^\mu(t) \frac{\partial \tilde{\xi}_t^{-1}(x, e)_s^r}{\partial e_p^q} \circ dw^i(t) + \tilde{\delta}_i^m(\eta_t) e_m^j(t) \frac{\partial \tilde{\xi}_t^{-1}(x, e)_s^r}{\partial x_j} \circ dw^i(t) - \Gamma_{m\mu}^r(x_t) B^m(x_t) e_s^\mu(t) dt$$

$$i = 1, \dots, d, \quad r, s = 1, \dots, d,$$

$$x^i(0) = x^i,$$

$$e_s^r(0) = e_s^r.$$

$$B^i(x_t) = \left[b^k(x_t) + \frac{1}{2} g^{\mu j}(x_t) \Gamma_{\mu j}^k(x_t) - h(x_t) \bar{a}^k(x_t) - \frac{1}{2} \sum_m \frac{\partial \delta_m^k(x_t)}{\partial x_j} \delta_m^j(x_t) - \frac{1}{2} \Gamma_{\mu j}^k(x_t) \sum_m \delta_m^\mu(x_t) \delta_m^j(x_t) - \frac{1}{2} \bar{a}^j(x_t) \frac{\partial \bar{a}^k(x_t)}{\partial x_j} - \frac{1}{2} \Gamma_{\mu j}^k(x_t) \bar{a}^\mu(x_t) \bar{a}^j(x_t) \right] \frac{\partial \xi_t^{-1}(x)^i}{\partial x_k},$$

$$\Delta \Delta' = G - \bar{a} \bar{a}',$$

$$\Delta = (\delta_k^n)$$

and $n(t) = (x^i(t), e_s^r(t))$. That the solution $\eta(t)$ lies on $O(M)$ if $\eta(0) \in O(M)$ is clear since $\tilde{\xi}_t^{-1} Y_j$ is a vector field on $O(M)$.

A stochastic curve $x(t) = (x^i(t))$ on M is defined by $x(t) = \pi(\eta(t))$. The curve $x(t)$ in M depends on the choice of the initial frame e at x .

It follows that

$$(2.15) \quad x(t, T_\beta \eta, w) = x(t, \eta, w\beta), \quad t \in [0, \infty), \quad \beta \in O(d)$$

where $w\beta = (w(t)\beta)$ is another d -dimensional Wiener process. Indeed according to Lemma 2.4, since $\tilde{\xi}_t^{-1}(x, e\beta) = (\tilde{\xi}_t^{-1}(x, e))(\beta)$ it can be shown [14] that

$$\left[\frac{\partial \tilde{\xi}_t^{-1}(x, e\beta)_s^r}{\partial e_p^a} \right] = (\beta)' \left[\frac{\partial \tilde{\xi}_t^{-1}(x, e)_s^r}{\partial e_p^a} \right] (\beta)$$

and thus this matrix remains orthogonally equivalent³ after the rotation of the initial frame. The above matrices are of dimension $d \times d$ for r, s fixed. Similarly

$$\left| \frac{\partial \tilde{\xi}_t^{-1}(x, e\beta)_s^r}{\partial x_j} \right| = \left| \frac{\partial \tilde{\xi}_t^{-1}(x, e)_s^r}{\partial x_j} \right| (\beta)$$

where now the above matrix is of dimension $d \times 1$ for r, s fixed. The functions $\tilde{\delta}_k^m(t)$ are independent of any rotation of the initial frame, since they represent intrinsic functions given by the equation $\tilde{\Delta}\tilde{\Delta}' = I - \gamma\gamma'$ where γ is an intrinsic function. The drift term $B^i(x_t)$ is independent of the frame e . Therefore (2.15) follows at once.

Hence the probability law of $x(\cdot, T_\beta\eta, w)$ is independent of $\beta \in O(d)$ and depends only on $x = \pi(\eta)$. We denote it by P_x . It is now easy to deduce the strong Markov property of the system $[P_x]$ from that of $\eta(\cdot, \eta, w)$.

Thus, as in Theorem 2.1, there will be a diffusion process $x_t = \pi(\eta_t)$ on M having as extended generator $A_t^* = d\pi(\tilde{A}_t^*)$.

Taking $f: M \rightarrow R$, we can find the generator $A_t^* = d\pi(\tilde{A}_t^*)$ as in Theorem 2.1. After extensive calculations it has been shown [14] that A_t^* is given by (2.13) and this completes the proof.

With reference to KS formula (1.20) it is evident that the conditional distribution σ_t is entirely determined by the law of the "downstairs" process $x_t = \pi(\eta_t)$. This observation leads to the main result.

THEOREM 2.4. *The conditional distribution $u_t^y(f)$ of the A -diffusion process x_t given \mathcal{Y}_t is given by*

$$u_t^y(f) = \frac{\sigma_t(f)}{\sigma_t(1)}$$

where

$$\sigma_t(f) = \langle T_{0,t}^y(B_{y_t}f), \nu \rangle;$$

$T_{0,t}^y$ is a semigroup whose extended generator is

$$A_t^y = e^{H_{y_t}} A_t^* e^{-H_{y_t}} - \frac{1}{2} \xi_t^*(Dh), \quad D = Z + h,$$

$$B_t := \exp \left(\int_0^t \xi_u^* h(x) du \right) \xi_t^* f(x),$$

$$H_t := \int_0^t \xi_s^* h(x) ds.$$

Proof. According to Theorem 1.1, Part I, the associated generator \tilde{A}_t^y on $O(M)$ will be given by

$$\tilde{A}_t^y = e^{\tilde{H}_{y_t}} \tilde{A}_t^* e^{-\tilde{H}_{y_t}} - \frac{1}{2} \tilde{\xi}_t^*(\tilde{D}h)$$

where

$$\tilde{H}_t(r) = \int_0^t \tilde{\xi}_s^* h(r) ds \quad \text{and} \quad \tilde{B}_t = \exp \left(\int_0^t \tilde{\xi}_u^* h(r) du \right) \tilde{\xi}_t^* f(r).$$

³ $O(d)$ -equivalent in Ikeda and Watanabe's terminology [9].

But since $h(r) \equiv h(x)$, we conclude that

$$\tilde{H}_{y_t}(r) \equiv H_{y_t}(x).$$

Taking $f: M \rightarrow R$ the generator $A_t^y = d\pi(\tilde{A}_t^y)$ will be given by

$$A_t^y = e^{H_{y_t}} d\pi(\tilde{A}_t^*) e^{-H_{y_t} - \frac{1}{2}\xi_t^*(Dh)}$$

and

$$B_t = \exp\left(\int_0^t \xi_u^* h(x) du\right) \xi_t^* f(x),$$

which completes the proof.

2.4. Concluding remarks. The problem of pathwise nonlinear filtering for non-degenerate diffusions on manifolds with noise correlation has been studied. Two different models for the diffusion processes have been considered. The first concerned diffusions constructed as solutions of stochastic differential equations on manifolds. The second concerned diffusions given by their extended generator. In both cases scalar observation processes with possible correlation with the signal processes have been considered.

In Theorem 2.4 the smoothness assumptions can be weakened considerably. Thus in Part I it is only necessary to consider C^1 vector fields L_i and C^1 function a_i . Similarly in Part II the coefficients $a^j(x)$ of the generator A must be C^1 so that the connections Γ_{ij}^k can be defined, and the "noise" vector field Z must be C^1 .

Finally, some remarks on manifold-valued *observations*. These were first studied by Duncan [6]. There the stochastic differential equations in the tangent bundle are formulated and solved by using the notation of parallelism of vectors along a curve. Recently Ng and Caines [11] have considered the same problem by the use of the strong solutions of the SDE for the state and observation processes in the orthonormal frame bundles to give a direct derivation of the Zakai equation. In [13] Pontier and Szpirglas show that the filtration of the manifold-valued observation coincides with that of another process taking values in Euclidean space R^n , thus reducing the problem to the classical Zakai equation. A similar approach could possibly be used to extend our results to, say, observations on the circle but of course observations on higher-dimensional manifolds will meet the geometric obstructions mentioned in the introduction. A pathwise theory of filtering manifold valued observations (with no noise correlation) is developed in [16]. It is worth mentioning that in none of the above references is any form of noise correlation considered.

Acknowledgment. We are grateful to a referee who discovered an error in an earlier version of this paper.

IDENTIFIABILITY UNDER APPROXIMATION FOR AN ELLIPTIC BOUNDARY VALUE PROBLEM*

KARL KUNISCH† AND L. W. WHITE‡

Abstract. Necessary and sufficient conditions for identifiability of the diffusion coefficient in Galerkin approximations to a two point boundary value problem are derived for various choices of Galerkin subspaces. The results are further used to investigate output least squares identifiability and output least squares stability of the diffusion coefficient.

Key words. parameter identifiability, stability of output least squares problem, boundary value problem, Galerkin approximation

AMS(MOS) subject classification. 34A55

1. Introduction. In this note we consider the following boundary value problems:

$$(1.1) \quad \begin{aligned} -(au_x)_x + cu &= f \quad \text{in } (0, 1), \\ u_x(0) &= u_x(1) = 0. \end{aligned}$$

Let $I = (0, 1)$ and $f \in L^2(I)$. Recall that if $a \in H^1(I)$ with $a(x) \geq \alpha > 0$ and $c \in L^2(I)$ with $c(x) \geq c > 0$ a.e., then there exists a unique solution $u = u(a)$ of (1.1) in $H^2(I)$. We are concerned with the identification of the coefficient a , given information of the solution $u(a)$ and in particular we will study the injectivity of the mapping $a^M \rightarrow u^N(a^M)$ where a^M is some approximation to a and u^N an approximation to u . At first we describe the problem in a more general context.

Let $\mathcal{C}: H^2(I) \rightarrow Z$ be a continuous linear operator from the solution space to the observation space Z describing the type of available information of the state u . To determine the coefficient corresponding to an observation $z \in Z$ of the system that is modeled by (1.1), the following output least squares formulation is used frequently:

$$(1.2) \quad \underset{Q_{ad}}{\text{minimize}} \quad |\mathcal{C}u(a) - z|_Z^2.$$

Here the set Q_{ad} of admissible parameters is chosen such that the existence of a solution of (1.2) is guaranteed.

For example, if n observations $\{z_k\}_{k=1}^n$ taken at the points $\{x_k\}_{k=1}^n$ are available, we may take $Z = \mathbb{R}^n$ with $\mathcal{C}: H^2(I) \rightarrow \mathbb{R}^n$ defined by $\mathcal{C}u = \{u(x_k)\}_{k=1}^n$. In this case (1.2) becomes

$$(1.3) \quad \underset{Q_{ad}}{\text{minimize}} \quad \sum_{k=1}^n |u(x_k; a) - z_k|^2.$$

Alternatively one might have distributed observations $z \in L^2(I)$, or using the data $\{z_k\}_k$ at $\{x_k\}_{k=1}^n$ one might want to obtain a function $z \in L^2(I)$ either by interpolation or

least squares regression; for \mathcal{C} we would then take $\mathcal{C}u = u$ and the optimization problem becomes

$$(1.4) \quad \underset{Q_{\text{ad}}}{\text{minimize}} \quad |u(a) - z|_{L^2}^2.$$

In either case an appropriate choice for Q_{ad} would be

$$Q_{\text{ad}} = \{a \in H^1: a(x) \geq \alpha > 0, |a|_{H^1} \leq \gamma\},$$

with $\gamma > \alpha$, [6].

Defining the attainable set $\mathcal{V} = \{\mathcal{C}u(a): a \in Q_{\text{ad}}\}$, one may view the optimization problem (1.2) as having two parts:

- (i) given $z \in Z$, find z_{proj} , the projection of z on \mathcal{V} ,
- (ii) given z_{proj} , find $\bar{a} \in Q_{\text{ad}}$ such that $\mathcal{C}u(\bar{a}) = z_{\text{proj}}$.

Assuming the existence of z_{proj} , the uniqueness of z_{proj} depends on the geometry of \mathcal{V} . In (ii) there exists an \bar{a} such that $\mathcal{C}u(\bar{a}) = z_{\text{proj}}$ by definition of Q_{ad} . The question of uniqueness of such an \bar{a} arises and it is guaranteed if $\Phi: a \rightarrow \mathcal{C}u(a)$ is injective at \bar{a} . Injectivity of Φ at \bar{a} is called *identifiability* of a at \bar{a} . The above mentioned uniqueness problems are rather involved in general, see, e.g., [2], [7, Appendix], and [11] for a hyperbolic equation.

When solving (1.2) on a computer it is necessary to replace (1.1)–(1.2) by a finite dimensional problem. This is done by approximating both the solutions of (1.1) and the set Q_{ad} by functions from finite dimensional function spaces. A finite dimensional version of the minimization problem (1.2) is then solved to obtain an estimate for the unknown coefficient a (compare e.g., [1], [5]). Again the existence and uniqueness questions analogous to the two steps (i) and (ii) above can be considered.

The main purpose of this investigation is the study of the uniqueness for the finite dimensional analogue of (ii). If for a chosen approximation of a by a^M the mapping $a^M \rightarrow u^N(a^M)$ is injective at \bar{a}^M , then a is called *identifiable under approximation* at \bar{a}^M . The related question for parabolic equations in dimension one has been treated in [4].

Our results below indicate that the injectivity of $a^M \rightarrow u^N(a^M)$ depends upon certain rank conditions that imply compatibility conditions upon the spaces used to approximate the coefficient a and the solution $u(a)$. It will be seen that a may be identifiable under approximation without the known sufficient conditions for identifiability of a in (1.1) being satisfied [9]. The results here, although depending on the choice of Neumann boundary conditions, can easily be adapted to different boundary conditions.

In § 2 we formulate the discrete problems and give general conditions for identifiability under approximation. In § 3 we examine several concrete examples and obtain necessary and sufficient conditions for identifiability under approximation for these cases. Identifiability will be guaranteed if there is a sufficient amount of movement in the coefficients of the basis element expansion for the approximate solution u^N , where u^N depends on the parameter a^M in question. On the other hand, if the parameter a^M is assumed to be known over those parts of the domain where u^N is stationary, then it can still be identifiable over the remaining parts of the domain $(0, 1)$.

Section 4 is devoted to the problem of continuous dependence of the solution of the discretized version of (1.3) or (1.4) on the observation z and Q_{ad} . Sufficient conditions for output least squares identifiability (OLSI) [2] and output least squares stability (OLS-stability) [3] are given.

Finally, in § 5 we report the findings of a numerical experiment that supports the practical relevance of our results.

2. Basic results. To approximate (1.2) by the standard finite element method [10], let $\{B_i\}_{i=0}^N$ and $\{\phi_j\}_{j=1}^M$ be sets of linearly independent functions defined on I with $B_i \in H^1(I)$ and ϕ_j piecewise continuous. Let $A^M = \text{span}\{\phi_j : j = 1, \dots, M\}$ and $H^N = \text{span}\{B_i : i = 0, \dots, N\}$. Setting

$$\tilde{u}^N = \sum_{i=0}^N \mu_i B_i \quad \text{and} \quad a^M = \sum_{j=1}^M a_j^M \phi_j,$$

we have upon integration by parts of (1.1) with u replaced by u^N :

$$\sum_{i=0}^N \mu_i \langle a B_{i,x}, B_{k,x} \rangle + \sum_{i=0}^N \mu_i \langle c B_i, B_k \rangle = \langle f, B_k \rangle \quad \text{for } k = 0, \dots, N,$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product in L^2 . Replacing a by a^M it follows that

$$\sum_{i=0}^N u_i \sum_{j=1}^M a_j^M \langle \phi_j B_{i,x}, B_{k,x} \rangle + \sum_{i=0}^N \mu_i \langle c B_i, B_k \rangle = \langle f, B_k \rangle \quad \text{for } k = 0, \dots, N.$$

Rearranging the summations in this last expression, we arrive at

$$(2.1) \quad \sum_{j=1}^M a_j^M \sum_{i=0}^N \langle \phi_j B_{i,x}, B_{k,x} \rangle \mu_i + \sum_{i=0}^N \langle c B_i, B_k \rangle \mu_i = \langle f, B_k \rangle \quad \text{for } k = 0, \dots, N.$$

We now make the following definitions: H_j and K are $(N+1) \times (N+1)$ matrices with the (i, k) th elements given by

$$(H_j)_{i,k} = \langle \phi_j B_{i,x}, B_{k,x} \rangle \quad \text{and} \quad (K)_{i,k} = \langle c B_i, B_k \rangle,$$

for $i, k = 0, \dots, N; j = 1, \dots, M$. Similarly $\tilde{f} \in \mathbb{R}^{N+1}$, $\tilde{\mu} \in \mathbb{R}^{N+1}$ and $\tilde{a}^M \in \mathbb{R}^M$ are given by

$$(\tilde{f})_k = \langle f, B_k \rangle, \quad (\tilde{\mu})_i = \mu_i, \quad (\tilde{a}^M)_j = a_j^M.$$

With this notation (2.1) becomes

$$(2.2) \quad \sum_{j=1}^M a_j^M H_j \tilde{\mu} + K \tilde{\mu} = \tilde{f},$$

where we used the symmetry of H_j and K . Thus we obtain a mapping $\tilde{a}^M \rightarrow \tilde{\mu}(\tilde{a}^M)$ from \mathbb{R}^M into \mathbb{R}^{N+1} or, equivalently, $a^M \rightarrow u^N(a^M)$, $a^M = \sum_{j=1}^M a_j^M \phi_j$, from A^M to H^N , that is well defined as long as $\sum_{j=1}^M a_j^M H_j + K$ is invertible. For example, if $c \geq 0$ and $\{B_{i,x}\}_{i=0}^N$ are linearly independent, then $\sum_{j=1}^M a_j^M H_j + K$ is invertible for all

$$\tilde{a}^M \in \mathcal{A} = \left\{ \tilde{a}^M \in \mathbb{R}^M : \sum_{j=1}^M (a^M)_j \phi_j > 0 \quad \text{on } I \right\}.$$

Similarly, if $c \geq c > 0$ as assumed throughout, then again $\sum a_j^M H_j + K$ is invertible for all $\tilde{a}^M \in \mathcal{A}$.

We now define identifiability of $\tilde{a}^M = \text{col}(a_1^M, \dots, a_k^M)$ in (2.2).

DEFINITION 2.1. The parameter $\tilde{a}^M \in \mathcal{A}$ in (2.2) is called identifiable if $\tilde{b} \in \mathcal{A}$ and $\tilde{\mu}(\tilde{a}^M) = \tilde{\mu}(\tilde{b}^M)$ implies $\tilde{a}^M = \tilde{b}^M$.

For a specific choice of approximation of a in (1.1) by a^M , we say that a is identifiable under approximation at a^M if a^M is identifiable.

THEOREM 2.1. *Let $\{\phi_j\}_{j=1}^M$ and $\{B_i\}_{i=0}^N$ be linearly independent, $c(x) \geq c > 0$ and $\tilde{a}^M \in \mathcal{A}$. Then $\tilde{a}^M \in A$ is identifiable if and only if the vectors $\{H_j \tilde{\mu}(\tilde{a}^M)\}_{j=1}^M$ are linearly independent.*

Proof. Using (2.2), linear independence of $H_j \tilde{\mu}(\tilde{a}^M)$ clearly implies identifiability of \tilde{a}^M . Conversely assume that there exists a nontrivial vector $(\alpha_1, \dots, \alpha_M) \in \mathbb{R}^M$ with

$$(2.3) \quad \sum_{j=1}^M \alpha_j H_j \tilde{\mu}(\tilde{a}^M) = 0.$$

Then $\sum_{j=1}^M (a_j^M - \varepsilon \alpha_j) \phi_j > 0$ for some sufficiently small $\varepsilon > 0$ and \tilde{a}_1^M given by $(\tilde{a}_1^M)_j = a_j^M - \varepsilon \alpha_j$ satisfies $\tilde{a}_1^M \in \mathcal{A}$. Multiplying (2.3) by ε and subtracting it from (2.2), we find that $\tilde{\mu}(\tilde{a}^M) = \tilde{\mu}(\tilde{a}_1^M)$. This ends the proof.

Since $H_j: \mathbb{R}^{N+1} \rightarrow \mathbb{R}^{N+1}$, for $j = 1, \dots, M$, we have the following:

COROLLARY 2.1. *If $M > N + 1$, then \tilde{a}^M in (2.2) is not identifiable.*

COROLLARY 2.2. *If $\tilde{\mu}(\tilde{a}^M) \in \text{Ker}(H_j)$ for some $j = 1, \dots, M$, then \tilde{a}^M is not identifiable.*

Proof. If $\tilde{\mu}(\tilde{a}^M) \in \text{Ker}(H_j)$ then the set $\{H_j \tilde{\mu}(\tilde{a}^M)\}_{j=1}^M$ is linearly dependent and the result follows from Theorem 2.1.

Remark 2.1. Corollary 2.2 should be compared with the condition $|u_x| \geq k_1 > 0$ which is known to be a sufficient condition for identifiability of a in the infinite dimensional problem (1.1) [9].

DEFINITION 2.2. The coordinates $\{\tilde{a}_{j_k}^M\}_{k=1}^{\hat{M}}$, $\hat{M} \leq M$, of the parameter vector $\tilde{a}^M \in \mathcal{A}$ are called identifiable if $\tilde{b}^M \in \mathcal{A}$, $\tilde{\mu}(\tilde{a}^M) = \tilde{\mu}(\tilde{b}^M)$ and $\tilde{a}_{j_k}^M = \tilde{b}_{j_k}^M$ for all $j \neq j_k$, $k = 1, \dots, \hat{M}$ imply $\tilde{a}^M = \tilde{b}^M$.

PROPOSITION 2.1. *The coordinates $\{\tilde{a}_{j_k}^M\}_{k=1}^{\hat{M}}$ of $\tilde{a}^M \in \mathcal{A}$ are identifiable if and only if the vectors $\{H_{j_k} \tilde{\mu}(\tilde{a}^M)\}_{k=1}^{\hat{M}}$ are linearly independent.*

The proof is obvious from that of Theorem 2.1.

3. Several examples. In this section we consider several concrete examples and determine their identifiability properties. We point out that here we use N to denote the number of subintervals of I and N and M of the previous section are a function of this N .

Case 1. Let I be partitioned into N subintervals of length $1/N$. For $i = 0, \dots, N$ define the linear spline basis functions

$$(3.1) \quad B_i(x) = \begin{cases} Nx - i + 1, & \frac{i-1}{N} \leq x \leq \frac{i}{N}, \\ -Nx + i + 1, & \frac{i}{N} \leq x \leq \frac{i+1}{N}, \\ 0, & \text{otherwise,} \end{cases}$$

and for $j = 1, \dots, N$ the 0th order splines

$$(3.2) \quad \phi_j(x) = \begin{cases} 1, & \frac{j-1}{N} \leq x \leq \frac{j}{N}, \\ 0, & \text{otherwise.} \end{cases}$$

Thus N and M of the previous section are both N here.

We approximate the solution u of (1.1) by linear splines and the coefficient a by constant splines. It is straightforward to compute the $(N+1) \times (N+1)$ matrices H_j , $j=1, \dots, N$:

$$H_j = N \begin{pmatrix} & & & j-1 & j & & & \\ & & & \vdots & \vdots & & & \\ & & & & & & & \\ 0 & & & & & & & 0 \\ & \ddots & & & & & \ddots & \\ & & 0 & & 0 & & & \\ \vdots & & & 1 & -1 & & \cdot & \cdots j-1 \\ \vdots & & & -1 & 1 & & \cdot & \cdots j \\ & & 0 & & 0 & & & \\ & \ddots & & & & \ddots & & \\ 0 & & & & & & & 0 \end{pmatrix}.$$

Let $\tilde{\mu} = \tilde{\mu}(\tilde{a}^M) = \text{col}(\mu_0, \dots, \mu_N)$ with $\tilde{a}^M \in \mathcal{A}$. Then

$$H_j \tilde{\mu} = N \begin{pmatrix} 0 \\ \vdots \\ 0 \\ \mu_{j-1} - \mu_j & \cdots j-1 \\ -\mu_{j-1} + \mu_j & \cdots j \\ 0 \\ \vdots \\ 0 \end{pmatrix}.$$

Now set $\beta_j = \mu_j - \mu_{j-1}$ for $j=1, \dots, N$. To study the linear independence of the vectors $\{H_j \tilde{\mu}\}_{j=1}^N$, note that

$$(H_1 \tilde{\mu}, \dots, H_N \tilde{\mu}) = NB$$

where B is the $(N+1) \times N$ matrix

$$B = \begin{pmatrix} -\beta_1 & 0 & \cdots & 0 \\ \beta_1 & -\beta_2 & & \\ 0 & \beta_2 & & \\ \vdots & & \ddots & \\ 0 & & & -\beta_{N-1} \\ & & & \beta_{N-1} & -\beta_N \\ & & & & \beta_N \end{pmatrix}.$$

LEMMA 3.1. *The vectors $\{H_j \tilde{\mu}\}_{j=1}^N$ are linearly independent if and only if $\beta_i \neq 0$ for all $i=1, \dots, N$.*

Proof. It is easily shown that B is row equivalent [8] to

$$\tilde{B} = \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & & \\ \vdots & & \ddots & \\ 0 & & & 0 & 1 \\ 0 & & & & 0 \end{pmatrix},$$

provided $\beta_i \neq 0$ for all i and $\{H_j \tilde{\mu}\}_{j=1}^N$ are linearly independent in this case. Conversely, if $\beta_i = 0$ for some i , then the column rank of B is less than N and linear dependence of $\{H_j \tilde{\mu}\}_{j=1}^N$ follows.

THEOREM 3.1. *In Case 1, \tilde{a}^M is identifiable, if and only if $\mu_i(\tilde{a}^M) \neq \mu_{i-1}(\tilde{a}^M)$ for all $i = 1, \dots, N$.*

PROPOSITION 3.1. *The coordinates $\{\tilde{a}_{j_k}^M\}_{k=1}^{\hat{M}}$ of \tilde{a}^M are identifiable if and only if $\mu_{j_k}(\tilde{a}^M) \neq \mu_{j_k-1}(\tilde{a}^M)$ for all $k = 1, \dots, \hat{M}$.*

The interpretation of this result is that the parameter \tilde{a}^M can only be identified at coordinates where the corresponding solution is nonstationary.

Case 2. Let N be even and let I be partitioned into subintervals of length $1/N$. The functions B_i , $i = 0, \dots, N$, are taken as in (3.1). Here, however, we define the functions ϕ_j for $j = 1, \dots, N/2$ by

$$\phi_j(x) = \begin{cases} 1, & \frac{2(j-1)}{N} \leq x \leq \frac{2j}{N}, \\ 0, & \text{otherwise.} \end{cases}$$

Thus M of § 2 is $N/2$ now. We find in this case that the $(N+1) \times (N+1)$ matrices H_j , for $j = 1, \dots, N/2$ are given by

$$H_j = N \begin{pmatrix} 0 & & & & 0 \\ & 1 & -1 & & 1 \\ & -1 & 2 & -1 & \\ & & 0 & -1 & 1 \\ 0 & & & & 0 \end{pmatrix},$$

where the first entry of the nontrivial submatrix is in the $2j-2, 2j-2$ position of H_j . With $\tilde{\mu} = \tilde{\mu}(\tilde{a}^M) = \text{col}(\mu_0, \dots, \mu_N)$ as before, we have

$$(H_1 \tilde{\mu}, \dots, H_{N/2} \tilde{\mu}) = NB$$

where the $(N+1) \times N/2$ -matrix B is given by

$$B = \begin{pmatrix} -\beta_1 & 0 & & 0 \\ \beta_1 - \beta_2 & 0 & & \\ \beta_2 & -\beta_3 & & \\ 0 & \beta_3 - \beta_4 & \cdots & \\ & \beta_4 & & \\ & 0 & & 0 \\ & & & \beta_{N-1} \\ & & & \beta_{N-1} - \beta_N \\ & 0 & & \beta_N \end{pmatrix},$$

and $\beta_i = \mu_i - \mu_{i-1}$ for $i = 1, \dots, N$.

The collection of vectors $\{H_j \tilde{\mu}\}_{j=1}^{N/2}$ is linearly independent if and only if $\text{rank}(B) = N/2$.

LEMMA 3.2. *In Case 2 the vectors $\{H_j \tilde{\mu}\}_{j=1}^{N/2}$ are linearly independent if and only if $\beta_{2i-1} \neq 0$ or $\beta_{2i} \neq 0$ for $i = 1, \dots, N/2$.*

Proof. The rank of the matrix B is equal to the rank of \tilde{B} where

$$\tilde{B} = \begin{pmatrix} \beta_1 & 0 & & 0 \\ \beta_2 & 0 & & 0 \\ 0 & \beta_3 & & 0 \\ 0 & \beta_4 & \cdots & 0 \\ & 0 & & \beta_{N-1} \\ 0 & 0 & & \beta_N \end{pmatrix}.$$

From this and the fact that the dimension of the column space of a matrix is equal to the rank of that matrix, the result follows.

THEOREM 3.2. *In Case 2, \tilde{a}^M is identifiable if and only if $\mu_{2i-1} \neq \mu_{2i-2}$ or $\mu_{2i} \neq \mu_{2i-1}$ for $i = 1, \dots, (N/2)$.*

Case 3. Let I be partitioned into N subintervals of length $1/N$. Again we take the functions B_i , $i = 0, \dots, N$ to be those defined in (3.1). Further we set $\phi_i = B_i$, $i = 0, \dots, N$. Thus M of § 2 is $N+1$ here and both ϕ_j and B_j are linear splines defined on the same mesh. In this case the structure of the $(N+1) \times (N+1)$ matrices $\{H_j\}_{j=0}^N$ is slightly more complicated than in Cases 1 and 2. These matrices are now given as follows:

$$H_0 = \frac{N}{2} \begin{pmatrix} 1 & -1 & & 0 \\ -1 & 1 & & 0 \\ & & & \\ & 0 & & 0 \end{pmatrix},$$

with the first entry in the $(0, 0)$ -element. For $j = 1, \dots, N-1$ we have

$$H_j = \frac{N}{2} \begin{pmatrix} 0 & & 0 & & 0 \\ & 1 & -1 & 0 & \\ 0 & -1 & 2 & -1 & 0 \\ & 0 & -1 & 1 & \\ 0 & & 0 & & 0 \end{pmatrix},$$

where the first entry of the nontrivial submatrix appears in the $(j-1, j-1)$ position of H_j . Finally

$$H_N = \frac{N}{2} \begin{pmatrix} 0 & & 0 \\ & 1 & -1 \\ 0 & -1 & 1 \end{pmatrix},$$

where the first nonzero entry occurs in the $N-1, N-1$ element.

To investigate the linear independence of $\{H_j \tilde{\mu}\}_{j=0}^N$, note that

$$(H_0 \tilde{\mu}, \dots, H_N \tilde{\mu}) = \frac{N}{2} B,$$

where the $(N+1) \times (N+1)$ matrix B is given by

$$B = \begin{pmatrix} -\beta_1 & -\beta_1 & & 0 & 0 \\ \beta_1 & \beta_1 - \beta_2 & & 0 & 0 \\ 0 & \beta_2 & \dots & 0 & 0 \\ \vdots & \vdots & & -\beta_{N-1} & 0 \\ 0 & 0 & & \beta_{N-1} - \beta_N & -\beta_N \\ & & & \beta_N & \beta_N \end{pmatrix},$$

and $\beta_i = \mu_i - \mu_{i-1}$ for $i = 1, \dots, N$. Performing row operations on B , we find that B is equivalent to

$$\tilde{B} = \begin{pmatrix} \beta_1 & \beta_1 & 0 & 0 & 0 \\ 0 & \beta_2 & \beta_2 & 0 & 0 \\ \vdots & 0 & \beta_3 & \vdots & \vdots \\ 0 & 0 & 0 & \beta_{N-1} & 0 \\ & & & \beta_N & \beta_N \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

We then see that B has rank less or equal to N and therefore we have

THEOREM 3.3. *In Case 3, $\tilde{a}^M \in \mathcal{A}$ is not identifiable.*

If one decreases the number of ϕ_j 's in Case 3, then it is reasonable to expect that sufficient and necessary conditions for the identifiability of \tilde{a}^M in the spirit of Cases 1 and 2 can be obtained. We verify this next for a particular choice of N and M . Moreover, in § 5 we present a numerical experiment which tends to support this contention.

Case 4. Let I be partitioned into $2N$ subintervals of length $1/2N$. We choose the functions B_i for $i = 0, \dots, 2N$ as

$$B_i(x) = \begin{cases} 2Nx - i + 1, & \frac{i-1}{2N} \leq x \leq \frac{i}{2N}, \\ -2Nx + i + 1, & \frac{i}{2N} \leq x \leq \frac{i+1}{2N}, \\ 0, & \text{otherwise.} \end{cases}$$

For the functions ϕ_j we take

$$\phi_j(x) = \begin{cases} Nx - j + 1, & \frac{j-1}{N} \leq x \leq \frac{j}{N}, \\ -Nx + j + 1, & \frac{j}{N} \leq x \leq \frac{j+1}{N}, \\ 0, & \text{otherwise,} \end{cases}$$

for $j=0, \dots, N$; thus M of § 2 is $N+1$. The $(2N+1) \times (2N+1)$ -matrices $\{H_j\}_{j=0}^N$ are given as follows:

$$H_0 = \frac{N}{2} \left(\begin{array}{ccc|ccc} 3 & -3 & 0 & & & \\ -3 & 4 & -1 & & & 0 \\ 0 & -1 & 1 & & & \\ \hline & & & & & \\ & 0 & & & & 0 \end{array} \right),$$

with 3 in the $(0,0)$ element,

$$H_j = \frac{N}{2} \left(\begin{array}{ccc|ccc|ccc} & & & & 0 & & & & \\ \hline & & & & & & & & \\ & 1 & -1 & 0 & 0 & 0 & & & \\ & -1 & 4 & -3 & 0 & 0 & & & \\ 0 & 0 & -3 & 6 & -3 & 0 & 0 & & \\ & 0 & 0 & -3 & 4 & -1 & & & \\ & 0 & 0 & 0 & -1 & 1 & & & \\ \hline & & & & 0 & & & & \end{array} \right),$$

where the first entry of the nontrivial submatrix occurs in the $2(i-1), 2(j-1)$ -element and

$$H_N = \frac{N}{2} \left(\begin{array}{ccc|ccc} & 0 & & & 0 & & \\ \hline & & & & & & \\ & & & & 1 & -1 & 0 \\ & 0 & & & -1 & 4 & -3 \\ & & & & 0 & -3 & 3 \end{array} \right).$$

Let $\tilde{\mu} = \tilde{\mu}(\tilde{a}^M) = \text{col}(\mu_0, \dots, \mu_{2N})$. To investigate the linear independence of $\{H_j \tilde{\mu}\}_{j=0}^N$ we put $\beta_i = \mu_i - \mu_{i-1}$ for $i=1, \dots, 2N$ and observe that

$$(H_0 \tilde{\mu}, \dots, H_N \tilde{\mu}) = \frac{N}{2} B$$

where the $(2N+1) \times (N+1)$ matrix B is given by

$$B = \left(\begin{array}{ccc|ccc|ccc|ccc} -3\beta_1 & -\beta_1 & 0 & & & & & & & & \\ 3\beta_1 - \beta_2 & \beta_1 - 3\beta_2 & 0 & & & & & & & & \\ \beta_2 & 3\beta_2 - 3\beta_3 & -\beta_3 & & & & & & & & \\ 0 & 3\beta_3 - \beta_4 & \beta_3 - 3\beta_4 & & & & & & & & \\ & \beta_4 & 3\beta_4 - 3\beta_5 & & & & & & & & \\ & 0 & 3\beta_5 - \beta_6 & \dots & & & & & & & \\ & & \beta_6 & & & & & & & & \\ & & 0 & & & & & & & & \\ & & & & & & & & & & \\ & & & & & & 0 & & & & \\ & & & & & & -\beta_{2N-3} & & & & \\ & & & & & & \beta_{2N-3} - 3\beta_{2N-2} & & & 0 & \\ & & & & & & 3\beta_{2N-2} - 3\beta_{2N-1} & & & -\beta_{2N-1} & \\ & & & & & & 3\beta_{2N-1} - \beta_{2N} & & & \beta_{2N-1} - 3\beta_{2N} & \\ & & & & & & \beta_{2N} & & & 3\beta_{2N} & \end{array} \right)$$

Performing row operations on B , we obtain a matrix \tilde{B} which has the same rank as B and is given by

$$\tilde{B} = \begin{pmatrix} 3\beta_1 & \beta_1 & 0 & & 0 & 0 \\ \beta_2 & 3\beta_2 & 0 & & & \\ 0 & 3\beta_3 & \beta_3 & & & \\ & \beta_4 & 3\beta_4 & & & \\ & 0 & 3\beta_5 & \dots & & \\ & & \beta_6 & & 0 & \\ & & 0 & & \beta_{2N-3} & 0 \\ & & & & 3\beta_{2N-2} & 0 \\ & & & & 3\beta_{2N-1} & \beta_{2N-1} \\ & 0 & 0 & 0 & \beta_{2N} & 3\beta_{2N} \end{pmatrix},$$

which is of dimension $2N \times (N+1)$. The vectors $H_j \tilde{\mu}$ are linearly independent if $\text{rank}(\tilde{B}) = N+1$.

THEOREM 3.4. *In Case 4, if $\mu_{2i-1} \neq \mu_{2i-2}$ or $\mu_{2i} \neq \mu_{2i-1}$ for all $i = 1, \dots, N$ and $(\mu_{2i-1} - \mu_{2i-2})(\mu_{2i} - \mu_{2i-1}) \neq 0$ for some $i = 1, \dots, N$, where $\tilde{\mu} = \tilde{\mu}(\tilde{a}^M)$, then $\tilde{a}^M \in \mathcal{A}$ is identifiable.*

Proof. Let $\tilde{\alpha} = \text{col}(\tilde{\alpha}_0, \dots, \tilde{\alpha}_N) \in \mathbb{R}^{N+1}$ and $\tilde{B}\tilde{\alpha} = 0$. Choose i_1 such that $\beta_{2i_1-1} \cdot \beta_{2i_1} \neq 0$. Then $\alpha_{i_1-1} = \alpha_{i_1} = 0$. Further $\alpha_i = 0$ for all other i , since $\beta_{2i-1} \neq 0$ or $\beta_{2i} \neq 0$. This implies linear independence of the columns of \tilde{B} and thus of B . Theorem 3.1 then implies the result.

THEOREM 3.5. *In Case 4, if $\mu_1 - \mu_0 = \mu_2 - \mu_1 = 0$ or $\mu_{N-1} - \mu_{N-2} = \mu_N - \mu_{N-1} = 0$ or $\mu_{2i-1} - \mu_{2i-2} = \mu_{2i} - \mu_{2i-1} = \mu_{2i+1} - \mu_{2i} = \mu_{2i+2} - \mu_{2i+1} = 0$ for some $i = 2, \dots, N-2$, where $\tilde{\mu} = \tilde{\mu}(\tilde{a})$ then $\tilde{a}^M \in \mathcal{A}$ is not identifiable.*

Proof. Under the assumptions of the theorem the column-rank of \tilde{B} is not maximal and this implies the result.

Remark 3.1. Four consecutive zeros in the β_i 's do not necessarily imply nonidentifiability, provided the zeros start with an even index and are not at the "beginning" or "end" of the sequence $\{\beta_i\}$; in particular $\beta_{2i} = \beta_{2i+1} = \beta_{2i+2} = \beta_{2i+3} = 0$ with $2 \leq i < N-2$ does not imply nonidentifiability. For example let $N = 5$, $\beta_1 = \beta_2 = \beta_3 = \beta_8 = \beta_9 = \beta_{10} = 1$ and $\beta_4 = \beta_5 = \beta_6 = \beta_7 = 0$. Then $\{H_j \tilde{\mu}\}$, $j = 0, \dots, N$, with $\beta_i = \mu_i - \mu_{i-1}$, are linearly independent. Choosing μ_0 and \tilde{a}^M , we can thus calculate μ_i , $i = 1, \dots, 2N$ and \tilde{f} such that \tilde{a}^M is identifiable and $\beta_{2i} = \dots = \beta_{2i+3} = 0$.

Remark 3.2. The conditions of Theorems 3.1–3.4 are conditions on the variation of adjacent $\mu_i(\tilde{a}^M)$ -values. If this variation is sufficient, the identifiability of \tilde{a}^M is guaranteed. The results indicate that the larger the difference between the dimension of the state space approximation and the dimension of the parameter space approximation is, the more likely it is that identifiability of the approximated coefficient holds. In [9] identifiability of a in (1.1) is studied under various conditions on the sign of u_x and u_{xx} . The most general condition implying identifiability of a is $\inf_I \max(|u_x|, u_{xx}) > 0$. Clearly one can construct examples where this condition is not met but identifiability under approximation, e.g., according to one of the Cases 1–4, of \tilde{a}^M holds.

4. Two stability concepts. In this section we discuss the application of two concepts of stability to the finite dimensional output least squares problem

$$(P_M^N) \quad \text{minimize } |u^N(a^M) - z|_{L^2}^2 \text{ over } C,$$

where C is a convex and closed subset of

$$Q_{\text{ad}}^M = \left\{ a^M = \sum_{j=1}^M a_j^M \phi_j; a_j^M \in \mathbb{R}, a^M(x) \geq \alpha > 0, |a^M|_{H^1} \leq \gamma \right\},$$

and $u^N(a^M) = \sum_{i=0}^N \mu_i B_i$, with $\text{col}(\mu_0, \dots, \mu_N) = \tilde{\mu}$ satisfying (2.2). The existence of a minimum a_*^M of (P_M^N) can easily be argued. The reason for introducing the set $C \subset Q_{\text{ad}}^M$ here is that for the first stability concept, uniqueness of solutions of (P_M^N) is required and this cannot be guaranteed over all of Q_{ad}^M . Here we consider H^1 -smooth approximating coefficients, some remarks on L^∞ approximations are given further below. We investigate the continuous dependence of a_*^M on z and also on Q_{ad}^M when dealing with the second stability concept. For $C \subset Q_{\text{ad}}^M$ let $\mathcal{V}(C) = \{u^N(a^M); a^M \in C\}$ denote the attainable set.

DEFINITION 4.1 [2]. The parameter a^M in (2.2) is called output least squares identifiable (OLSI) by (P_M^N) over $C \subset Q_{\text{ad}}^M$, if there exists a neighborhood $\tilde{\mathcal{V}}$ of $\mathcal{V}(C)$ such that for every $z \in \tilde{\mathcal{V}}$ the problem (P_M^N) has a unique solution a_*^M depending continuously on z .

Let $\mathcal{A}_{\text{inj}} \subset Q_{\text{ad}}^M$ be such that $\{H_j \tilde{\mu}(\tilde{a}^M)\}$ is linearly independent for every $a^M = \sum_{j=1}^M (\tilde{a}^M)_j \phi_j \in \mathcal{A}_{\text{inj}}$. As examples for such sets we can take neighborhoods in Q_{ad} of points of identifiability in the sense of § 2.

THEOREM 4.1. *Let \mathcal{A}_{inj} be as just described. Then a^M in (2.2) is OLSI by (P_M^N) over every closed convex subset C of \mathcal{A}_{inj} , provided that $\text{diam } C$ is sufficiently small and z is sufficiently close to the $\mathcal{V}(C)$. Moreover, the unique solution Q_*^M of (P_M^N) depends Lipschitz-continuously on z .*

Proof. By [2, Thm. 4] it suffices to show that $a^M \rightarrow u^N(a^M)$ is twice continuously Fréchet differentiable with $a^M \rightarrow u_{a^M}^N(a^M)$ injective on C . This is equivalent to the existence of continuous first and second order derivatives of $\tilde{a}^M \rightarrow \tilde{\mu}(\tilde{a}^M)$ with \tilde{a}^M such that $\sum_{j=1}^M (\tilde{a}^M)_j \phi_j = a^M \in \mathcal{A}_{\text{inj}}$ and injectivity of $\tilde{\mu}_{\tilde{a}^M}(\tilde{a}^M)$ for every $a^M \in C$. Let $\tilde{\mu}_{\tilde{a}^M}(\tilde{a}^M; \tilde{h}) = \tilde{\eta}$ and $\tilde{\mu}_{\tilde{a}^M \tilde{a}^M}(\tilde{a}; \tilde{h}, \tilde{k}) = \tilde{\xi}$ be the first, resp. second, derivative in directions \tilde{h} and (\tilde{h}, \tilde{k}) . Then

$$(4.1) \quad \tilde{\eta} = -L^{-1}(\Sigma h_j H_j \tilde{\mu}(\tilde{a}^M))$$

and

$$(4.2) \quad \tilde{\xi} = -L^{-1}(\Sigma k_j H_j \tilde{\eta} + \Sigma h_j H_j \tilde{\mu}_{\tilde{a}^M}(\tilde{a}^M; \tilde{k})),$$

where $L = \Sigma \tilde{a}_j^M H_j + K$ and $\tilde{h} = \text{col}(h_1, \dots, h_M)$, $\tilde{k} = \text{col}(k_1, \dots, k_M)$, and the continuity assumptions follow. The injectivity of $\tilde{\mu}_{\tilde{a}^M}(\tilde{a}^M)$ is guaranteed by linear independence of $\{H_j \tilde{\mu}(\tilde{a}^M)\}$; this ends the proof.

To describe the second notion of stability, we consider the case $C = Q_{\text{ad}}^M$:

$$(P_M^N)_w \quad \text{minimize } |u^N(a^M) - z|^2 \text{ over } Q_{\text{ad}}^M.$$

We study continuous dependence of local solutions of $(P_M^N)_w$ on $w = (z, \alpha, \gamma) \in W$, where $W = H^0 \times \mathbb{R} \times \mathbb{R}$. Here W is endowed with the Hilbert-space product norm. We always assume $0 < \alpha < \gamma$, so that Q_{ad}^M is not empty and solutions of (2.2) and $(P_M^N)_w$ exist.

DEFINITION 4.2 [2]. The parameter a^M is called output least squares (OLS)-stable in Q_{ad}^M at the local solution a_0^M of $(P_M^N)_{w^0}$, $w^0 \in W$, if there exists a neighborhood $V(w^0)$ of w^0 in W , a neighborhood $V(a_0^M)$ of a_0^M in H^1 and a constant κ , such that for all $w = (z, \alpha, \gamma) \in V(w^0)$ there exists a local solution a_w^M of $(P_M^N)_w$ with $a_w^M \in V(a_0^M)$ and for all local solutions $a_w^M \in V(a_0^M)$ of $(P_M^N)_w$ we have

$$|a_w^M - a_{w^0}^M|_{H^1} \leq \kappa |w - w^0|_W^{1/2}.$$

Remark 4.1. In comparing OLSI to OLS-stability we observe the following differences: OLSI requires uniqueness of the solutions of the minimization problem, whereas for OLS-stability, uniqueness is not required, with continuity being checked at each local solution. If OLSI holds, then the solutions depend on the observations in a Lipschitz continuous way, whereas OLS-stability only guarantees Hölder continuous dependence. Further, OLSI requires continuous dependence of the solutions on the observation only, whereas OLS-stability involves continuous dependence on the observations as well as on the admissible set Q_{ad} .

Output least squares stability is proved by techniques that guarantee stability of solutions of abstract optimization problems with respect to perturbations in the problem data, see [3] and the references given there. Let $A^M = \text{span}\{\phi_j\}_{j=1}^M$ and let $F(a^M)$ be the Lagrange functional associated with (P_M^N) :

$$F(a^M) = |u^N(a^M) - z|^2 - \lambda^* g(a^M),$$

where $\lambda^* \in C^* \times \mathbb{R}$ and

$g: A^M \times W \rightarrow C^* \times \mathbb{R}$ is given by

$$g(a^M, w) = (\alpha - a^M, |a^M|_{H^1}^2 - \gamma^2), \quad w = (z, \alpha, \gamma).$$

Note that $a^M \in Q_{\text{ad}}^M(w)$ if and only if $g(a^M, w) \in \hat{K} = C_- \times \mathbb{R}_-$, with C_- and \mathbb{R}_- the natural negative cones in $C(I)$ and \mathbb{R} . We shall frequently drop the index w and write $g(a^M)$ and Q_{ad}^M for $g(a^M, w)$ and $Q_{\text{ad}}^M(w)$.

THEOREM 4.2. *Let $A^M = \text{span}\{\phi_j\}_{j=1}^M$ be such that it contains the constant functions, let $(z^0, \alpha^0, \gamma^0) = w^0 \in W$ with $0 < \alpha^0 < \gamma^0$ and let $a_0^M = \sum_{j=1}^M (\tilde{a}_0^M)_j \phi_j$ be a local solution of $(P_M^N)_{w^0}$. If $\{H_j \tilde{\mu}(\tilde{a}_0^M)\}_{j=1}^M$ are linearly independent vectors in \mathbb{R}^{N+1} and $|u^N(a_0^M) - z|$ is sufficiently small, then a^M is OLS-stable in $Q_{\text{ad}}^M(w^0)$ at the local solution a_0^M of $(P_M^N)_{w^0}$.*

For the proof of this theorem the following lemma on the regularity of the constraint set Q_{ad}^M will be required; its proof is quite similar to that of Lemma 4.2 in [3] but will be included for the sake of completeness.

LEMMA 4.1. *Let A^M contain the constant functions. Then every $a^M \in Q_{\text{ad}}^M$ is a regular point, i.e., $0 \in \text{int}\{g(a^M) + \mathcal{R}(g_{a^M}(a^M)) - \hat{K}\} \subset C \times \mathbb{R}$, where \mathcal{R} denotes the range of the mapping $g_{a^M}(a^M)$.*

Proof of Lemma 4.1. We need to show that

$$(4.3) \quad \begin{aligned} 0 &\in \text{int}\{g(a^M) + g_{a^M}(a^M)A^M - C_- \times \mathbb{R}_-\} \\ &= \text{int}\{\alpha - a^M - h^M + C_+, |a^M|_{H^1}^2 - \gamma^2 + 2\langle a^M, h^M \rangle_{H^1} + \mathbb{R}_+ : h^M \in A^M\}, \end{aligned}$$

where we used that $g_{a^M}(a^M)h^M = (-h^M, 2\langle a^M, h^M \rangle_{H^1})$. Let $(\phi, r) \in C \times \mathbb{R}$ with $|(\phi, r)|_{C \times \mathbb{R}} < \delta$ and $\delta > 0$ to be chosen sufficiently small. Note that $\phi - \min \phi \in C_+$ and $\min \phi \in A^M$. In view of the first component in (4.3) we decompose ϕ as

$$\phi = \alpha - a^M - (\alpha - a^M - \min \phi) + \phi - \min \phi$$

and therefore $\phi \in \alpha - a^M - A^M + C_+$. As for the second component in (4.3) observe that

$$\begin{aligned} |a^M|_{H^1}^2 - \gamma^2 + 2\langle a^M, \alpha - a^M - \min \phi \rangle_{H^1} &= -|a^M|_{H^1}^2 + 2\langle a^M, \alpha - \min \phi \rangle_{H^1} - \gamma^2 \\ &\leq \alpha^2 - \gamma^2 + 2\delta |a^M|_{H^1}. \end{aligned}$$

Thus, for δ sufficiently small one can choose $\tilde{r} \in \mathbb{R}_+$ such that

$$r = |a^M|_{H^1}^2 - \gamma^2 + 2\langle a^M, \alpha - a^M - \min \phi \rangle_{H^1} + \tilde{r}$$

and, since (ϕ, r) was arbitrary, a^M is shown to be a regular point.

Proof of Theorem 4.2. We apply results on the stability of abstract optimization problems as summarized in [3, § 3]. Due to the fact that $a^M \rightarrow |u^N(a^M) - z^0|^2$ and $a^M \rightarrow g(a^M, w^0)$ are twice continuously differentiable at a_0^M and since the point $a_0^M \in Q_{ad}^M$ is a regular point, it suffices to establish a lower bound on the second derivative of F at \tilde{a}_0^M . Let $\eta = u_{a^M}^N(a_0^M; h^M)$ and $\xi = u_{a^M, a^M}^N(a_0^M; h^M, h^M)$ for $h^M \in A^M$. Then

$$\begin{aligned} F_{a^M, a^M}(a_0^M; h^M, h^M) &= \langle u^N(a_0^M) - z, \xi \rangle_{H^0} + |\eta|_{H^0}^2 - 2\lambda |h^M|_{H^1}^2 \\ &\geq -|u^N(a_0^M) - z|_{H^0} |\xi|_{H^0} + |\eta|_{H^0}^2 - 2\lambda |h^M|_{H^1}^2, \end{aligned}$$

where $\lambda \leq 0$ is the Lagrange multiplier associated with the norm constraint. In view of (4.1), (4.2), the finite dimensionality of A^M , and the linear independence of $\{H_j \tilde{\mu}(\tilde{a}_0^M)\}_{j=1}^M$ it follows that there exist constants c_1 and c_2 such that

$$F_{a^M, a^M}(a_0^M; h^M, h^M) \geq -c_1 |u^N(a_0^M) - z|_{H^0} |h^M|_{H^1}^2 + c_2 |h^M|_{H^1}^2,$$

so that for $|u^N(a_0^M) - z|$ sufficiently small there exists a constant c_3 with

$$F_{a^M, a^M}(a_0^M; h^M, h^M) \geq c_3 |h^M|_{H^1}^2,$$

from which the result follows [3, Thms. 3.2, 3.3].

Remark 4.2. If $Q_{ad}^M \subset L^\infty$ only and $|a^M|_{H^1} \leq \gamma$ is replaced by $|a^M|_{L^\infty} \leq \gamma$ in the definition of Q_{ad}^M , then again one can show existence of solutions of (P_N^M) and Theorem 4.1 holds with obvious modifications. The results leading to Theorem 4.2 need yet to be generalized to handle the nondifferentiable L^∞ -norm constraint.

5. Numerical results. In this section we present some results of a numerical experiment to estimate the coefficient a in (1.1) given observations z of u . To solve (1.2) with $\mathcal{C} = I$, we consider (2.2) which defines a mapping $\tilde{a}^M \rightarrow \tilde{\mu}(\tilde{a}^M)$ for $\tilde{a}^M \in \mathcal{A}$, and the finite dimensional minimization problems

$$(5.1) \quad \text{minimize} \int_0^1 \left(\sum_{i=0}^N \mu_i(\tilde{a}^M) B_i - z \right)^2 dx.$$

For our experiments we imposed no constraints on $\tilde{a}^M \in \mathbb{R}^M$, although $\tilde{\mu}(\tilde{a}^M)$ is not well defined for some \tilde{a}^M . The basis functions ϕ_j and B_i were chosen as linear spline functions with equidistant grid on $(0, 1)$. As data z we took the values of a solution of (1.1) by choosing the coefficient a and the observation $z(x) = u(x) = x^2(1-x)^2$, and calculating $f = u - (au_x)_x$ from it. Using this f , we then compute $\tilde{\mu}$ from (2.2) as we solve (5.1). For the minimization the Newton-Raphson algorithm was used.

In our calculations (see Figs. 1–10) $N = 10$ represents the number of subintervals used in the linear spline approximation for the solution of (1.1). Thus the dimension of the approximation space for the solution is 11. Further NBI is the number of subintervals of I that determine the linear spline approximation of a ; the dimension of the approximation space for a is NBI + 1. A necessary condition for identifiability of \tilde{a}^M is thus NBI + 1 \leq 11, see Corollary 2.1. We show calculations for NBI = 4, 5, 6, 8–11, for the choice of $a(x) = 1 + x$. In the first five cases good results are obtained. Note that NBI = 5 and $N = 10$ is a special case of Theorem 3.4. In the case NBI = 10, \tilde{a}^M is not identifiable by Theorem 3.3. Numerically this is reflected by the appearance of oscillations as NBI approaches 10 from below, see the graphs for NBI = 9, 10, 11. The start-up value for the minimization routine was chosen as $\tilde{a}_0^M \equiv 2$. We point out that a different scaling of the axes in the various paths was utilized. We also show the graphs for $u^N(a^M)$, when $N = 10$ and NBI = 9, 10, 11. The graphs for the approximating solutions for NBI = 4, 5, 6, 8 are indistinguishable from NBI = 9.

NEARLY OPTIMAL STATE FEEDBACK CONTROLS FOR STOCHASTIC SYSTEMS WITH WIDEBAND NOISE DISTURBANCES*

HAROLD J. KUSHNER† AND W. Runggaldier‡

Abstract. Much of optimal stochastic control theory is concerned with diffusion models. Such models are often only idealizations (or limits in an appropriate sense) of the actual physical process, which might be driven by a wide band-width (not white) process or be a discrete parameter system with correlated driving noises. Optimal or nearly optimal controls, derived for the diffusion models, would not normally be useful, or even of much interest, if they were not also “nearly optimal” for the physical system that the diffusion approximates. It turns out that, under quite broad conditions, the “nearly optimal” controls for the diffusions do have this desired robustness property and are “nearly optimal” for the physical (say wideband noise driven) process, even when compared to controls that can depend on all the (past) driving noise. We treat the problem over a finite time interval, as well as the average cost per unit time problem. Extensions to discrete parameter systems, and to systems stopped on first exit from a bounded domain, are also discussed. Weak convergence methods provide the appropriate analytical tools.

Key words. optimal stochastic control, wideband noise disturbance, approximately optimal control, weak convergence for diffusions

AMS(MOS) subject classifications. 93E20, 93E25, 60F05, 60J60

1. Introduction. The paper is concerned with “approximately optimal” controls for a wide variety of systems driven by wide band-width noise, and their discrete parameter counterparts. Consider a system of the type

$$(1.1) \quad \dot{x}^\varepsilon = F_\varepsilon(x^\varepsilon, \xi^\varepsilon, u^\varepsilon), \quad x \in R^r, \text{ Euclidean } r\text{-space},$$

where $\xi^\varepsilon(\cdot)$ is a wide band-width noise process (the band-width $\rightarrow \infty$ as $\varepsilon \rightarrow 0$), and the cost is

$$(1.2) \quad R^\varepsilon(u^\varepsilon) = E \int_0^{T_1} k(x^\varepsilon(s), u^\varepsilon(s)) ds$$

for some $T_1 < \infty$. When we wish to emphasize the control, we write the solution to (1.1) as $x^\varepsilon(u^\varepsilon, \cdot)$.

For the moment (and loosely speaking) suppose that (1.1) is “close” to a controlled diffusion process, modeled by (1.3), in the sense that if $u^\varepsilon(\cdot)$ is a sequence of “nice” controls for (1.1), then there is a control $u(\cdot)$, and a corresponding controlled diffusion $x(u, \cdot)$ defined by (1.3), such that as $\varepsilon \rightarrow 0$, $x^\varepsilon(u^\varepsilon, \cdot) \Rightarrow x(u, \cdot)$, where \Rightarrow denotes weak convergence (see the next section). Let $\bar{u}(\cdot)$ denote an optimal control for the limit diffusion (1.3), and $\bar{u}^\delta(\cdot)$ a “smooth” δ -optimal control, where $\delta > 0$.

$$(1.3) \quad dx = \bar{b}(x, u) dt + \sigma(x) dw.$$

Now apply $\bar{u}^\delta(\cdot)$ to (1.1). Under fairly broad conditions, it is shown that

$$(1.4) \quad \inf_{u \in RC^\varepsilon} R^\varepsilon(u) \geq R^\varepsilon(\bar{u}^\delta) - \delta$$

for small $\varepsilon > 0$, where RC^ε are the admissible (relaxed) controls for (1.1) (see § 3). Since $\bar{u}^\delta(\cdot)$ is only a function of x and t , it would be considerably simpler than an optimal control for (1.1).

The methods also work well for the discrete parameter case

$$(1.5) \quad x_{n+1}^\varepsilon = x_n^\varepsilon + \varepsilon F_\varepsilon(x_n^\varepsilon, \xi_n^\varepsilon, u_n).$$

The $\{\xi_n^\varepsilon\}$ and $\xi^\varepsilon(\cdot)$ can be state dependent, and there are straightforward extensions to the discounted cost problem, to the problem where the process is stopped on first exit from a set, to the impulsive control problem, and to the average cost per unit time case.

The basic technique is that of weak convergence theory [1], [2], [3], which will be seen to provide a very natural and relatively simple basis for results of the type presented here. The relevant background results are listed in § 2. In § 3 the problem on a finite interval $[0, T_1]$ for a form of (1.1) is set up, and the assumptions stated. For convenience in dealing with the weak convergence, as well as to minimize detail and the number of hypotheses, we work with relaxed controls. The relevant estimates and approximations (the "chattering" lemma, etc.) are also stated in § 3. In § 4, the results for the finite interval are proved. Section 5 concerns the discrete parameter case. The average cost per unit time problem is in § 6, and extensions are discussed in § 8.

A related problem is discussed by Blankenship and Papanicolaou in [4] and Bensoussan and Blankenship in [5]. They deal with the particular nondegenerate system

$$(1.6) \quad \begin{aligned} dx^\varepsilon &= f(x^\varepsilon, y^\varepsilon, u) dt + \sqrt{2} dw, \\ \varepsilon dy^\varepsilon &= g(x^\varepsilon, y^\varepsilon, u) dt + \sqrt{2\varepsilon} dB, \end{aligned}$$

where $w(\cdot)$ and $B(\cdot)$ are mutually independent standard Wiener processes. The technique in [4], [5] concerns an asymptotic expansion of the Bellman equation associated with the optimal control of (1.6). These expansions are hard to carry out, and rely heavily on various nondegeneracy properties associated with (1.6). In a "linear-quadratic" problem, they show that applying the optimal control for the limit problem to the prelimit problem gives a cost increase of $O(\varepsilon)$. There is negligible overlap in methodology with the ideas here. We can treat (1.6) if $g(\cdot)$ does not depend on $u(\cdot)$.

The results in [4], [5] seem to require an analytical approach, rather than our purely probabilistic approach. The methods used here seem quite simple in comparison, and cover a broader collection of problems. Expansions of the value functions do not seem to be obtainable by our methods. On the other hand, we can show, for many typical problem formulations, that the optimal or δ -optimal control for the limit system is a good (nearly optimal) control for the system which is driven by wide band-width noise. Such robustness is an important part of the statement of the control problem. In fact, the optimal or nearly optimal controls for diffusion models would not usually be of interest, were they also not good controls for the actual physical system which is "idealized" by the diffusion model. The general ideas carry over to more general spaces (e.g., to measure valued processes).

2. Weak convergence. Let $C^r[0, \infty)$ denote the space of R^r -valued continuous functions with the sup norm topology on bounded intervals, and let $D^r[0, \infty)$ denote the space of R^r -valued functions which are right continuous and have left-hand limits. Endow $D^r[0, \infty)$ with the Skorohod topology [2]. Our processes (except for the discrete parameter case) have values in C^r , but it is easier to prove tightness in D^r , and then to show that all limits are continuous.

Let \bar{F}_t^ε denote the minimal σ -algebra over which $\{x^\varepsilon(s), \xi^\varepsilon(s), s \leq t\}$ is measurable, and let E_t^ε denote expectation conditioned on \bar{F}_t^ε . Let $f(\cdot)$ be progressively measurable with respect to $\{\bar{F}_t^\varepsilon\}$. We say that $f(\cdot)$ is in $D(\hat{A}^\varepsilon)$, the domain of the operator \hat{A}^ε and $\hat{A}^\varepsilon f = g$ if for each $T < \infty$

$$\begin{aligned} \sup_{t \leq T} E|g(t)| &< \infty, \quad E|g(t+\delta) - g(t)| \rightarrow 0 \quad \text{as } \delta \downarrow 0, \quad \text{each } t, \\ \sup_{\substack{T \geq t \\ \delta > 0}} E \left| \frac{E_t^\varepsilon f(t+\delta) - f(t)}{\delta} - g(t) \right| &< \infty, \\ \lim_{\delta \downarrow 0} E \left| \frac{E_t^\varepsilon f(t+\delta) - f(t)}{\delta} - g(t) \right| &\rightarrow 0 \quad \text{each } t. \end{aligned}$$

If $f(\cdot) \in D(\hat{A}^\varepsilon)$ then ([3], [6])

$$(2.1) \quad f(t) - \int_0^t \hat{A}^\varepsilon f(s) ds \quad \text{is a martingale}$$

and

$$(2.2) \quad E_t^\varepsilon f(t+s) - f(t) = \int_t^{t+s} E_t^\varepsilon \hat{A}^\varepsilon f(u) du.$$

The following condition for tightness in $D'[0, \infty)$ ([3, Thm. 3.4]) is a sufficient condition for a criterion of Aldous and Kurtz [2]. Let \hat{C}_0 denote the continuous real valued functions on R^r with compact support, and \hat{C}_0^k the subset of functions all of whose mixed partial derivatives of order up to k are continuous.

THEOREM 0. Let $x^\varepsilon(\cdot)$ have paths in $D'[0, \infty)$ and let

$$(2.3) \quad \lim_{K \rightarrow \infty} \lim_{\varepsilon} P\{\sup_{t \leq T} |x^\varepsilon(t)| \geq K\} = 0, \quad \text{each } T < \infty.$$

For each $f(\cdot) \in \hat{C}_0^\infty$ and $T < \infty$ let there be a sequence $f^\varepsilon(\cdot) \in D(\hat{A}^\varepsilon)$ such that either (i) or (ii) below hold. Then $\{x^\varepsilon(\cdot)\}$ is tight in $D'[0, \infty)$.

(i) For each $T < \infty$, $\{\hat{A}^\varepsilon f^\varepsilon(t), \varepsilon > 0, t \leq T\}$ is uniformly integrable and for each $\alpha > 0$

$$(2.4) \quad \lim_{\varepsilon} P\{\sup_{t \leq T} |f^\varepsilon(t) - f(x^\varepsilon(t))| \geq \alpha\} = 0.$$

(ii) Equation (2.4) holds and for each $T < \infty$ there is a random variable $B_T^\varepsilon(f)$ such that

$$(2.5) \quad \sup_{t \leq T} |\hat{A}^\varepsilon f^\varepsilon(t)| \leq B_T^\varepsilon(f), \quad \lim_{K \rightarrow \infty} \lim_{\varepsilon} P\{B_T^\varepsilon(f) \geq K\} = 0.$$

Consider a discrete parameter case

$$x_{n+1}^\varepsilon = x_n^\varepsilon + F_\varepsilon(x_n^\varepsilon, \xi_n^\varepsilon).$$

Let \bar{F}_n^ε denote the minimal σ -algebra over which $\{x_i^\varepsilon, \xi_{i-1}^\varepsilon, i \leq n\}$ is measurable, with E_n^ε denoting the associated conditional expectation. We say that $f(\cdot) \in D(\hat{A}^\varepsilon)$ if it is constant on each $[n\varepsilon, (n+1)\varepsilon)$ interval, $f(n\varepsilon)$ is \bar{F}_n^ε -measurable, and $\sup_n E|f(n\varepsilon)| < \infty$. Then we define

$$\hat{A}^\varepsilon f(n\varepsilon) = [E_n^\varepsilon f((n+1)\varepsilon) - f(n\varepsilon)]/\varepsilon,$$

and the discrete parameter analogues of Theorem 0 and (2.1), (2.2) hold. In particular for $f \in D(\hat{A}^\varepsilon)$,

$$E_n^\varepsilon f((n+m)\varepsilon) - f(n\varepsilon) = \varepsilon \sum_{i=n}^{n+m-1} E_n^\varepsilon \hat{A}^\varepsilon f(i\varepsilon).$$

Let $M(\infty)$ denote the collection of measures $\{m(\cdot)\}$ on the Borel subsets of $U \times [0, \infty)$, where U is compact and $m([0, t] \times U) = t$, for all $t \geq 0$. We will be working with weak convergence of a sequence of $M(\infty)$ -valued random variables. Write $(m, f) = \int f(s, \alpha) m(ds \times d\alpha)$. We say that $m_n \rightarrow 0$ if $(m, f) \rightarrow 0$ for each continuous $f(\cdot)$ with compact support. When we say that $m_n(\cdot) \Rightarrow m(\cdot)$ for a sequence of random measures, we always mean weak convergence in $M(\infty)$.

3. Assumptions and relaxed controls. We adopt a particular noise model, which is a standard way of modeling wide band-width noise. The model can readily be generalized, since only a few properties of the processes are used. The model is convenient also because the relevant weak convergence results can be easily referred to. A control $u(\cdot)$ for (1.1) is said to be *admissible* if it takes values in U , a compact set, and it is progressively measurable with respect to the σ -algebras $\sigma\{\xi^\varepsilon(s), s \leq t\} \equiv F_t^\varepsilon$.

A random measure $m(\cdot)$ with values in $M(\infty)$ is said to be an *admissible relaxed control* if $\iint_0^t f(s, \alpha) m(ds \times d\alpha) \equiv (f, m)_t$ is progressively measurable with respect to $\{F_t^\varepsilon\}$ for each bounded continuous $f(\cdot)$. If $m(\cdot)$ is admissible, then there is a measure valued "derivative" function of (ω, t) with value $m_t(\cdot)$ at time t such that for smooth $f(\cdot)$

$$\int f(s, \alpha) m(ds \times d\alpha) = \int dt \int f(s, \alpha) m_s(d\alpha),$$

and $m_t(\cdot)$ is (weakly) progressively measurable in the sense that $\int_0^t ds \int f(s, \alpha) m_s(d\alpha)$ is progressively measurable. We sometimes write the derivative function as m_\cdot . Let AC^ε and RC^ε denote the class of admissible and admissible relaxed controls, respectively, for (1.1).

Assumption A1. $\xi^\varepsilon(t) = \xi(t/\varepsilon^2)$, where $\xi(\cdot)$ is a stationary zero mean process which is either (a) strongly mixing,¹ right continuous and bounded, with the mixing rate function $\phi(\cdot)$ satisfying $\int_0^\infty \phi^{1/2}(s) ds < \infty$ or (b) stationary Gauss-Markov with an integrable correlation function (which thus must go to zero exponentially).

Assumption A2. $F_\varepsilon(x, \xi, u) = b(x, u) + \tilde{b}(x, \xi) + g(x, \xi)/\varepsilon$, where $E\tilde{b}(x, \xi) = Eg(x, \xi) = 0$ under A1(a), and $\tilde{b}(x, \xi) = g(x)\xi$, $\tilde{b}(x, \xi) = b(x)\xi$ under A1(b), $k(\cdot, \cdot)$ is bounded and continuous, and $b(\cdot, \cdot)$, $\tilde{b}(\cdot, \cdot)$, $g(\cdot, \cdot)$ are continuous. The derivative $g_x(\cdot, \xi)$ is continuous (in x, ξ). Also $b(\cdot, \alpha)$ satisfies a linear growth condition and a Lipschitz condition in x , uniformly in $\alpha \in U$. Under A1(a), $\tilde{b}(\cdot, \xi)$, $g(\cdot, \xi)$, $g_x(\cdot, \xi)$ satisfy the same uniform Lipschitz and growth condition, and under A1(b), $\tilde{b}(\cdot)$, $g(\cdot)$ and $g_x(\cdot)$ do.

Define

$$\begin{aligned} \{a_{ij}(x)\} &= \int_{-\infty}^{\infty} Eg(x, \xi(t))g'(x, \xi(0)) dt = a(x), \\ \bar{b}_i(x, u) &= b_i(x, u) + \int_0^\infty E \sum_j g_{i,x_j}(x, \xi(t))g_j(x, \xi(0)) dt, \quad i \leq r. \end{aligned}$$

Assumption A3. Suppose that $\{a_{ij}(\cdot)\}$ has a Lipschitz continuous square root $\sigma(\cdot)$.

For the problem on $[0, T_1]$, the boundedness condition on $k(\cdot, \cdot)$ can be replaced by a polynomial growth condition. For the average cost per unit time problem, the stability methods and assumptions of § 7 can be used for the same purpose.

¹ That is, for $A \in \sigma(\xi(v), v \leq s)$, $B \in \sigma(\xi(v), v \geq s+t)$, $\sup_{A,B} |P(B|A) - P(B)| \leq \phi(s)$.

The weak convergence and existence (of an optimal control) arguments are easier if one works with relaxed controls. It is convenient to work with relaxed controls on $[0, \infty)$. If the control problem is of interest on $[0, T_1]$ only, then define $u(\cdot)$ or $m(\cdot)$ in any admissible way on $[T_1, \infty)$.

Admissible controls for (1.3) or (3.1) below. An *admissible control* for (1.3) is any U -valued function $u(\cdot)$ which is nonanticipative with respect to $w(\cdot)$. An *admissible relaxed control* for (1.3) or (3.1) below is any $M(\infty)$ valued random variable $m(\cdot)$ such that for any collection $\{f_\beta(\cdot)\}$ of bounded continuous functions $f_\beta(\cdot)$, and each $t > 0$, $\{\int_0^t f_\beta(s, \alpha) m(ds \times d\alpha)\}$ is independent of $\{w(t+s) - w(t), s > 0\}$. If $m(\cdot)$ is an admissible relaxed control then there is a $(\omega, t$ -dependent) measure $m_t(\cdot)$ on the Borel sets of U such that

$$\int_0^t \int f(s, \alpha) m(ds \times d\alpha) = \int_0^t ds \int f(s, \alpha) m_s(d\alpha), \quad t < \infty$$

for each bounded and continuous $f(\cdot)$ and almost all ω . When working with (1.3) or (3.1), we assume that $\bar{b}(\cdot)$ and $\sigma(\cdot)$ have the continuity, growth and Lipschitz conditions ascribed to $b(\cdot)$ and $\sigma(\cdot)$ in A1-A3. Let AC and RC denote the class of admissible and admissible relaxed controls, respectively. The classes of admissible controls are defined as they are because we wish to avoid working explicitly with feedback controls. Our processes are uniquely defined for any admissible control.

THEOREM 1. *Let $m(\cdot)$ be an admissible relaxed control (with respect to a Wiener process $w(\cdot)$). Then there exists a nonanticipative solution to*

$$(3.1) \quad dx = dt \int \bar{b}(x, \alpha) m_t(d\alpha) + \sigma(x) dw, \quad x(0) = x$$

and

$$(3.2) \quad E \sup_{t \leq T} |x(t)|^2 \leq K[1 + |x|^2],$$

where K depends only on T and on the growth rates and Lipschitz constants on $\bar{b}(\cdot)$ and $\sigma(\cdot)$.

Define $\{x_n^\Delta\}$ by $x_0^\Delta = x_1^\Delta = x$ and for $n \geq 1$,

$$(3.3) \quad x_{n+1}^\Delta = x_n^\Delta + \int_{n\Delta-\Delta}^{n\Delta} ds \int \bar{b}(x_n^\Delta, \alpha) m_s(d\alpha) + \sigma(x_n^\Delta)[w(n\Delta + \Delta) - w(n\Delta)].$$

Define $x^\Delta(\cdot)$ to be the piecewise constant interpolation (interval Δ) of $\{x_n^\Delta\}$. Then there is a $K_\Delta \rightarrow 0$ as $\Delta \rightarrow 0$ (and depending only on T and on the Lipschitz and growth constants) such that

$$(3.4) \quad E \sup_{t \leq T} |x^\Delta(t) - x(t)|^2 \leq K_\Delta(1 + |x|^2)$$

(K_Δ does not depend on $m(\cdot)$).

Let $m^n(\cdot) \Rightarrow \bar{m}(\cdot)$, where the $m^n(\cdot)$ are admissible with respect to some Wiener process, and let $x^n(\cdot)$ satisfy (3.1) with $m(\cdot) = m^n$. Then $(x^n(\cdot), m^n(\cdot)) \Rightarrow (x(\cdot), \bar{m}(\cdot))$ where $x(\cdot), \bar{m}(\cdot)$ satisfy (3.1) for some Wiener process $w(\cdot)$ and $m(\cdot)$ is admissible with respect to $w(\cdot)$.

Proof. The existence and uniqueness proof for the relaxed control case follows the same (standard) lines as when an admissible control $u(\omega, t)$ is used, and is discussed by Fleming [7] and Fleming and Nisio [8]. The proofs of the estimates (3.2), (3.4) also follow the classical lines. To get the weak convergence in the last paragraph, it

is sufficient to work with the discrete parameter case (3.3), in view of the uniformity (in $m(\cdot)$) of K and K_Δ . But the result is obvious for the discrete parameter case, owing to the continuity of $\bar{b}(\cdot, \cdot)$ and the Lipschitz conditions and linear growth conditions. QED

For (3.1), define

$$(3.5) \quad R(m) = E \int_0^{T_1} \int k(x(s), \alpha) m_s(d\alpha) ds,$$

where $x(\cdot)$ corresponds to $m(\cdot)$ via (3.1). We *sometimes* write the solution to (1.3) or (3.1) as $x(u, \cdot)$ or $x(m, \cdot)$.

THEOREM 2. *In the class of admissible relaxed controls for (3.1), there is an optimal control.*

Proof. The theorem follows from Theorem 1. Simply choose a weakly convergent subsequence $m^\delta(\cdot)$, $\delta \rightarrow 0$, such that $R(m^\delta) \rightarrow \inf_{m \in RC} R(m) \equiv \bar{R}$. Denote the limit of $\{x(m^\delta, \cdot), m^\delta(\cdot)\}$ by $(x(\bar{m}, \cdot), \bar{m}(\cdot))$. Then by Theorem 1, $\bar{m}(\cdot)$ is admissible for some Wiener process $w(\cdot)$ and $(x(\bar{m}, \cdot), \bar{m}(\cdot), w(\cdot))$ solves (3.1). By the weak convergence,

$$E \int_0^{T_1} \int k(x^\delta(s), \alpha) m^\delta(ds \times d\alpha) \rightarrow E \int_0^{T_1} \int k(x(s), \alpha) \bar{m}(ds \times d\alpha) = \bar{R} = R(\bar{m}).$$

QED

Since we wish to show (in the following sections) that any smooth and nearly optimal feedback control for (1.3) is a nearly optimal control of (1.1) for small $\varepsilon > 0$, it is important to know that there is a smooth nearly optimal control for (1.3). This is shown in the next two theorems.

The chattering lemma.

THEOREM 3. *For each $\delta > 0$, there is a piecewise constant admissible control $u^\delta(\cdot)$ for (1.3) such that*

$$R(u^\delta) \leq \inf_{m \in RC} R(m) + \delta.$$

Remark. A proof is in [7], [8]. We only give a rough outline of the construction. Let $\bar{m}(\cdot)$ be an optimal admissible relaxed control. Let $u_1^\rho, \dots, u_k^\rho$ be a ρ -grid in U . Define A_1^ρ by $A_1^\rho = \{\alpha \in U: |\alpha - u_1^\rho| \leq \rho\}$. For $k \geq n > 1$, define

$$A_n^\rho = \{\alpha \in U: |\alpha - u_n^\rho| \leq \rho\} - \bigcup_i^{n-1} A_i^\rho.$$

For $\Delta > 0$ and $i \geq 0$, define

$$\tau_{in}^{\Delta\rho} = \int_{i\Delta}^{i\Delta+\Delta} \bar{m}_s(A_s^\rho) ds,$$

the total integrated time that the optimal relaxed control "takes values" in the set A_n^ρ in the time interval $[i\Delta, i\Delta + \Delta)$. Define the piecewise constant admissible control $\tilde{u}^\delta(\cdot)$ by $\tilde{u}^\delta(t) = u_0^\rho$ for $t \leq \Delta$, where u_0^ρ is any value in U ; in general, set $\tilde{u}^\delta(t) = u_n^\rho$ on

$$\left[(i+1)\Delta + \sum_{l=1}^{n-1} \tau_{il}^{\Delta\rho}, (i+1)\Delta + \sum_{l=1}^n \tau_{il}^{\Delta\rho} \right], \quad i \geq 0, \quad n \leq k.$$

Then, for small ρ and Δ , $\tilde{u}^\delta(\cdot)$ satisfies our needs, even though the intervals of constancy are random.

We can also get a control whose intervals of constancy are nonrandom. Let $\Delta_1 > 0$ be such that $\Delta/\Delta_1 \equiv \bar{k}$ is a large integer, and write $k_{ii}^{\Delta\rho} = [\tau_{ii}^{\Delta\rho}/\Delta_1]$. Then define $\hat{u}^\delta(\cdot)$ as $\tilde{u}^\delta(\cdot)$ was defined but with $k_{ii}^{\Delta\rho}\Delta_1$ replacing $\tau_{ii}^{\Delta\rho}$, and on the nonassigned set, simply set $\hat{u}^\delta(t) = u_0^\rho$, where u_0^ρ is any value in U . For small Δ_1 , Δ and ρ , and large \bar{k} , $\hat{u}^\delta(\cdot)$ also satisfies our needs.

THEOREM 4. *For each $\delta > 0$, there is a piecewise constant (in t) and locally Lipschitz continuous in x (uniformly in t) control $\bar{u}^\delta(\cdot)$ such that $\bar{u}^\delta(t) = \bar{u}^\delta(x(i\Delta), i\Delta)$ for $t \in [i\Delta, i\Delta + \Delta]$*

$$R(\bar{u}^\delta) \leq \inf_{m \in RC} R(m) + \delta.$$

Proof. Fix $\delta > 0$. By the previous theorem, we can find a $\Delta > 0$ and an admissible control $u^\delta(\cdot)$, constant on each interval $[i\Delta, i\Delta + \Delta)$, and such that

$$R(u^\delta) \leq \inf_{m \in RC} R(m) + \delta/4.$$

By examining the imbedded Markov chain $\{x(i\Delta), i\Delta \leq T_1\}$, we see that there is an admissible control $\hat{u}^\delta(t)$ which is piecewise constant and has the form $\hat{u}^\delta(t) = \hat{u}^\delta(x(i\Delta), i\Delta)$ for $t \in [i\Delta, i\Delta + \Delta)$ for some function $\hat{u}^\delta(x, t)$, and is such that

$$R(\hat{u}^\delta) \leq R(u^\delta) + \delta/4.$$

In fact we can suppose that the $\hat{u}^\delta(t)$ take only a finite number of values u_1, \dots, u_k , where k might depend on δ but not otherwise on Δ . Let $x(\cdot)$ denote the process corresponding to the control $\hat{u}^\delta(\cdot)$. Define $B_l^i = \{x: \hat{u}^\delta(x, i\Delta) = u_l\}$. There are open sets \tilde{B}_l^i with smooth boundaries (say, unions of a finite number of spheres) and whose closures are disjoint and such that $(\partial B$ denotes the boundary of the set $B)$

$$(3.6) \quad \begin{aligned} P\{x(i\Delta) \in \partial \tilde{B}_l^i\} &= 0 \quad \text{for all } i, l, \quad i\Delta \leq T_1, \\ \sum_{i=0}^{T_1/\Delta-1} P\left\{x(i\Delta) \in \bigcup_l (B_l^i \Delta \tilde{B}_l^i)\right\} &\leq \frac{\delta}{4T_1} \left[1 + \sup_{x, \alpha} |k(x, \alpha)|\right]. \end{aligned}$$

For each i , define $\tilde{u}^\delta(x, i\Delta)$ to equal u_l on \tilde{B}_l^i , and use any locally Lipschitz continuous interpolation for $x/\in \cup_l \tilde{B}_l^i$. Thus the costs with use of $\hat{u}^\delta(\cdot)$ (on one hand) and use (on the other hand) of $\tilde{u}^\delta(x, i\Delta)$ for $t \in [i\Delta, i\Delta + \Delta)$ and each i differ by at most $\delta/2$. In fact the latter control and $\hat{u}^\delta(\cdot)$ differ on a set whose probability is less than the right side of (3.6). QED

4. Weak convergence of and approximation of the optimal controls for $x^\varepsilon(\cdot)$. In this section we work with the control problem on $[0, T_1]$ and prove (Theorem 5) that the weak limit of any (weakly convergent) sequence of admissible relaxed control for (4.1) is an admissible relaxed control for (3.1) and that the corresponding costs converge. Then, in Theorem 6, we show that any smooth “nearly optimal” feedback control for (3.1) also is “nearly optimal” for (4.1) for small ε .

Let $\delta_\varepsilon \rightarrow 0$, and let $\hat{m}^\varepsilon(\cdot)$ be a δ_ε -optimal admissible relaxed control for the process defined by

$$(4.1) \quad \dot{x}^\varepsilon = \int b(x^\varepsilon, \alpha) m_t(d\alpha) + \tilde{b}(x^\varepsilon, \xi^\varepsilon) + g(x^\varepsilon, \xi^\varepsilon)/\varepsilon,$$

with cost function (3.5). For convenience, we define all $m(\cdot)$ on $[0, \infty)$. In the analysis below it is convenient (but not necessary) to have $\int b(x^\varepsilon(t), \alpha) m_t(d\alpha)$ right continuous (in order to be able to readily evaluate \hat{A}^ε). Owing to the Lipschitz condition and to

the continuity and growth conditions, for each ε we can suppose (w.l.o.g.) that $\hat{m}_t^\varepsilon(\cdot)$, is, in fact, constant on intervals $[i\Delta_\varepsilon, i\Delta_\varepsilon + \Delta_\varepsilon)$ for small enough Δ_ε .

Define L^m , the infinitesimal operator of $x(m, \cdot)$ defined by (3.1), by

$$L^m f(x) = f'_x(x) \int \bar{b}(x, \alpha) m_t(d\alpha) + \frac{1}{2} \sum_{ij} f_{x_i x_j}(x) a_{ij}(x).$$

THEOREM 5. Assume A1–A3. Then $\{x^\varepsilon(\hat{m}^\varepsilon, \cdot), \hat{m}^\varepsilon(\cdot)\}$ is tight in $D^r[0, \infty) \times M(\infty)$. Let $(x^\varepsilon(\hat{m}^\varepsilon, \cdot), \hat{m}^\varepsilon(\cdot)) \Rightarrow (x(\hat{m}, \cdot), \hat{m}(\cdot))$. There is a $w(\cdot)$ such that $\hat{m}(\cdot)$ is admissible with respect to $w(\cdot)$ and

$$(4.2) \quad dx = dt \int \bar{b}(x, \alpha) \hat{m}_t(d\alpha) + \sigma(x) dw.$$

Also

$$\begin{aligned} R^\varepsilon(\hat{m}^\varepsilon) &= E \int_0^{T_1} \int k(x^\varepsilon(s), \alpha) \hat{m}^\varepsilon(ds \times d\alpha) \\ &\rightarrow E \int_0^{T_1} \int k(x(s), \alpha) \hat{m}(ds \times d\alpha) = R(\hat{m}). \end{aligned}$$

Proof. We first work with a truncated system, since tightness is easier to prove if the $x^\varepsilon(\cdot)$ paths are all bounded (see e.g. [3, Chap. 3.3 or 4.6.4] or [9]). Let $q_N(\cdot)$ be a twice continuously differentiable function satisfying $q_N(x) = 1$ for $|x| \leq N$, $q_N(x) = 0$ for $|x| \geq N+1$ and $q_N(x) \in [0, 1]$ for all x . Define $b_N(x, \alpha) = b(x, \alpha)q_N(x)$, $g_N(x, \xi) = g(x, \xi)q_N(x)$, etc., and let $x^{\varepsilon, N}(\cdot)$ denote the \sim solution to (4.1) corresponding to the use of b_N , \tilde{b}_N , g_N , and $\hat{m}^\varepsilon(\cdot)$.

Part 1. Tightness of $\{x^{\varepsilon, N}(\cdot)\}$. Since $U \times [0, t_1]$ is compact for each $t_1 < \infty$, $\{\hat{m}^\varepsilon(\cdot)\}$ is tight in $M(\infty)$. To prove the tightness of $\{x^{\varepsilon, N}(\cdot)\}$, we use the first order perturbed test function method of [3, Chap. 3] (see also [9]). Let $f(\cdot) \in \hat{C}_0^2$. Then (write x for $x^{\varepsilon, N}(t)$ for convenience)

$$\hat{A}^\varepsilon f(x) = f'_x(x) \left[\int b_N(x, \alpha) \hat{m}_t^\varepsilon(d\alpha) + \tilde{b}_N(x, \xi^\varepsilon(t)) + g_N(x, \xi^\varepsilon(t)) / \varepsilon \right].$$

For arbitrary $T < \infty$ and for $t \leq T$, define $f_1^\varepsilon(t) = f_1^\varepsilon(x^{\varepsilon, N}(t), t)$, where

$$\begin{aligned} f_1^\varepsilon(x, t) &= \int_t^T f'_x(x) E_t^\varepsilon g_N(x, \xi^\varepsilon(s)) ds / \varepsilon \\ &= \varepsilon \int_{t/\varepsilon^2}^{T/\varepsilon^2} f'_x(x) E_t^\varepsilon g_N(x, \xi(s)) ds. \end{aligned}$$

Under A1(a), $f_1^\varepsilon(t) = O(\varepsilon)$. Under A1(b), $f_1^\varepsilon(t) = O(\varepsilon)|\xi^\varepsilon(t)|$. In either case

$$\sup_{t \leq T} |f_1^\varepsilon(t)| \xrightarrow{P} 0 \quad \text{as } \varepsilon \rightarrow 0.$$

We have

$$\begin{aligned} \hat{A}^\varepsilon f_1^\varepsilon(t) &= -f'_x(x^{\varepsilon, N}(t)) g_N(x^{\varepsilon, N}(t), \xi^\varepsilon(t)) / \varepsilon \\ &\quad + \frac{1}{\varepsilon} \int_t^T ds [f'_x(x^{\varepsilon, N}(t)) E_t^\varepsilon g_N(x^{\varepsilon, N}(t), \xi^\varepsilon(s))]'_x x^{\varepsilon, N}(t). \end{aligned}$$

Define $f^\varepsilon(t) = f(x^{\varepsilon,N}(t)) + f_1^\varepsilon(t)$. Then, writing x for $x^{\varepsilon,N}(t)$, using the above results and a scale change $s/\varepsilon^2 \rightarrow s$,

$$\begin{aligned}
 \hat{A}^\varepsilon f^\varepsilon(t) = & f'_x(x) \int b_N(x, \alpha) \hat{m}_t^\varepsilon(d\alpha) + f'_x(x) \tilde{b}_N(x, \xi^\varepsilon(t)) \\
 & + \int_{t/\varepsilon^2}^{T/\varepsilon^2} ds E_t^\varepsilon[f'_x(x) g_N(x, \xi(s))]'_x g_N(x, \xi^\varepsilon(t)) \\
 & + \varepsilon \int_{t/\varepsilon^2}^{T/\varepsilon^2} ds E_t^\varepsilon[f'_x(x) g_N(x, \xi(s))]'_x \\
 & \cdot \left[\int b_N(x, \alpha) \hat{m}_t^\varepsilon(d\alpha) + \tilde{b}_N(x, \xi^\varepsilon(t)) \right].
 \end{aligned}
 \tag{4.3}$$

Under A1(a), the second and third terms in (4.3) are $O(1)$. Under A1(b), they are $O(1)[1 + |\xi^\varepsilon(t)|^2]$. Under A1(a), the last term is $O(\varepsilon)$, and under A1(b) it is $O(\varepsilon)[1 + |\xi^\varepsilon(t)|^2]$. In either case the conditions of Theorem 0 hold. Hence $\{x^{\varepsilon,N}(\cdot)\}$ is tight in $D'[0, \infty)$.

Part 2. The martingale problem satisfied by the limit. Let ε index a weakly convergent subsequence with limit denoted by $x^N(\cdot)$, $\hat{m}(\cdot)$; i.e., $\{x^{\varepsilon,N}(\cdot), \hat{m}^\varepsilon(\cdot)\} \Rightarrow (x^N(\cdot), \hat{m}(\cdot))$. There is an (ω, t) -measurable $\hat{m}_t(\cdot)$ such that $\hat{m}_t(U) = 1$ and

$$\int_0^t \int f(s, \alpha) \hat{m}_s(d\alpha) ds = \int_0^t \int f(s, \alpha) \hat{m}(ds \times d\alpha)$$

for each continuous $f(\cdot)$. This is a consequence of the fact that $\hat{m}\{A \times [0, t]\}$ is absolutely continuous for each Borel A , uniformly in ω , A , which implies that the (measurable) limit

$$\lim_{\Delta} [\hat{m}\{A \times [0, t]\} - \hat{m}\{A \times [0, t - \Delta]\}] / \Delta \equiv \hat{m}_t(A)$$

exists for a.a. (ω, t) for each Borel A .

Define L_N^m as L^m was defined, but with the use of \bar{b}_N and g_N instead of \bar{b} and \bar{g} . Let $f(\cdot) \in \hat{C}_0^2$ and define $M_f^N(\cdot)$ by

$$M_f^N(t) = f(x^N(t)) - f(x(0)) - \int_0^t L_N^m f(x^N(s)) ds.$$

We next show that $M_f^N(\cdot)$ is a martingale with respect to $B^N(t) \equiv \sigma\{x^N(s); \hat{m}(A \times [0, s]), \text{Borel } A, s \leq t\}$.

We know that $x^N(\cdot)$ has paths in $D'[0, \infty)$, but we have not yet proved that the paths are in $C'[0, \infty)$. There are at most a countable set of t -points such that $P\{x^N(\cdot)$ is discontinuous at $t\} > 0$. Denote this set by $\mathcal{T} = \{\tau_i\}$. In what follows, until continuity is established, the t_i , t , $t + s$ do not take values in \mathcal{T} . Let $h(\cdot)$ be bounded and continuous and let $t_i < t < t + s$. Let q_1 and q_2 be arbitrary integers and $k_j(\cdot)$ arbitrary bounded and continuous functions. By (2.1), (2.2), and a change of scale ($s/\varepsilon^2 \rightarrow s$) for one of the terms, we have

$$\begin{aligned}
 & Eh(x^{\varepsilon,N}(t_i), (k_j, \hat{m}^\varepsilon)_{t_i}, i \leq q_1, j \leq q_2) \\
 & \cdot \left\{ f(x^{\varepsilon,N}(t+s)) - f(x^{\varepsilon,N}(t)) + f_1^\varepsilon(t+s) - f_1^\varepsilon(t) \right.
 \end{aligned}$$

$$\begin{aligned}
(4.4) \quad & - \int_t^{t+s} \int f'_x(x^{\varepsilon,N}(\tau)) b_N(x^{\varepsilon,N}(\tau), \alpha) \hat{m}^\varepsilon(d\tau \times d\alpha) \\
& - E_t^\varepsilon \int_t^{t+s} f'_x(x^{\varepsilon,N}(\tau)) \tilde{b}_N(x^{\varepsilon,N}(\tau), \xi^{\varepsilon,N}(\tau)) d\tau \\
& - \int_t^{t+s} d\tau E_\tau^\varepsilon \int_{\tau/\varepsilon^2}^{T/\varepsilon^2} [f'_x(x^{\varepsilon,N}(\tau)) g_N(x^{\varepsilon,N}(\tau), \xi(v))]'_x g_N(x^{\varepsilon,N}(\tau), \xi^\varepsilon(\tau)) dv \\
& + \text{terms which go to 0 in mean as } \varepsilon \rightarrow 0 \Big\} = 0.
\end{aligned}$$

Owing to (2.1) and (2.2), (4.4) holds with or without the E_t^ε term on the right-hand side. Recall that $(f, m)_t \equiv \int_0^t \int f(s, \alpha) m(ds \times d\alpha)$.

Now take limits ($\varepsilon \rightarrow 0$) in (4.4) and use Skorohod imbedding ([10, Thm. 3.1.1]). The imbedding allows us to define the probability space so that the weak convergence becomes w.p.l. in the topology of the space $D'[0, \infty) \times M(\infty)$. We use the imbedding without changing the notation, where convenient. The f_1^ε terms in (4.4) disappear as $\varepsilon \rightarrow 0$. Also by the weak convergence and Skorohod imbedding,

$$\begin{aligned}
\int_t^{t+s} \int b_N(x^{\varepsilon,N}(\tau), \alpha) \hat{m}^\varepsilon(d\tau \times d\alpha) & \rightarrow \int_t^{t+s} \int b_N(x^N(\tau), \alpha) \hat{m}(d\tau \times d\alpha), \\
(k_j, \hat{m}^\varepsilon)_t & \rightarrow (k_j, \hat{m})_t,
\end{aligned}$$

w.p.l., uniformly on each finite interval. Next consider the second integral term in (4.4). We will show that

$$(4.5) \quad \lim_{\varepsilon} E \left| \int_t^{t+s} E_t^\varepsilon \tilde{b}_N(x^{\varepsilon,N}(\tau), \xi^\varepsilon(\tau)) d\tau \right| = 0.$$

Since $\{x^{\varepsilon,N}(\cdot)\}$ is tight in $D'[0, \infty)$ it is essentially a right equicontinuous set in the following sense. Given $\rho > 0$ and $T < \infty$, there is a compact set $\Omega_\rho \subset D'[0, T]$ such that

$$P\{x^{\varepsilon,N}(\cdot) \in \Omega_\rho\} \geq 1 - \rho.$$

For $y(\cdot) \in D'[0, T]$, define $w_y[a, b] = \sup\{|y(s) - y(t)| : s, t \in [a, b]\}$ and define

$$w'_y(\delta) = \inf_{\substack{\{t_i\} \\ q}} \max_{i \leq q} w_y[t_i, t_{i+1}],$$

where $0 = t_0 < \dots < t_q = T$ and $t_{i+1} - t_i \geq \delta$. Then [1, p. 116]

$$(4.6) \quad \lim_{\delta} \sup_{y(\cdot) \in \Omega_\rho} w'_y(\delta) = 0.$$

Because of this “equirightcontinuity” characterization, to get the limit (4.5) it is sufficient to evaluate

$$\begin{aligned}
& \lim_{\Delta \downarrow 0} \overline{\lim}_{\varepsilon} E \left| \int_t^{t+s} E_t^\varepsilon \tilde{b}_N(x^{\varepsilon,N}(\tau - \Delta), \xi^\varepsilon(\tau)) d\tau \right| \\
& \leq \lim_{\Delta \downarrow 0} \overline{\lim}_{\varepsilon} E \left| \int_t^{t+s} E_{\tau-\Delta}^\varepsilon \tilde{b}(x^{\varepsilon,N}(\tau - \Delta), \xi^\varepsilon(\tau)) d\tau \right| \equiv \lim_{\Delta \downarrow 0} \overline{\lim}_{\varepsilon} K_\Delta^\varepsilon.
\end{aligned}$$

There are constants C_N and C'_N depending only on N such that, under A1(a)

$$|E_{\tau-\Delta}^\varepsilon \tilde{b}(x^{\varepsilon,N}(\tau - \Delta), \xi^\varepsilon(\tau))| \leq C_N \phi(\Delta/\varepsilon^2),$$

and under A1(b)

$$|E_{\tau-\Delta}^{\varepsilon} \tilde{b}(x^{\varepsilon, N}(\tau-\Delta), \xi^{\varepsilon}(\tau))| \leq C'_N [\exp -\lambda \Delta / \varepsilon^2] |\xi^{\varepsilon}(\tau-\Delta)|,$$

where $\phi(\cdot)$ is the mixing rate A1(a) for $\xi(\cdot)$, and $\exp -\lambda t$ is a bound on the norm of the correlation matrix (under A1(b)). Thus, under A1(a), $\lim_{\varepsilon} K_{\Delta}^{\varepsilon} = 0$ for each $\Delta > 0$. Under A1(b) $K_{\Delta}^{\varepsilon} \leq O(\exp -\lambda \Delta / \varepsilon^2) \int_t^{t+s} |\xi^{\varepsilon}(\tau)| d\tau$. Thus (4.5) holds.

By a very similar technique we can show that, as $\varepsilon \rightarrow 0$, the double integral term in the brackets in (4.4) converges (in mean) to

$$(4.7) \quad \int_t^{t+s} d\tau \int_0^{\infty} E[f'_x(x^N(\tau))g_N(x^N(\tau), \xi(s))]'_x g_N(x^N(\tau), \xi(0)) ds.$$

The expectation in (4.7) is over the $\xi(\cdot)$ only. The $x^N(\tau)$ is considered to be a fixed parameter when taking the expectation. This last limit result is, in fact, a special case of [3, Thm. 5.11]. Thus

$$(4.8) \quad \begin{aligned} & Eh(x^N(t_i), (k_j, \hat{m})_{t_i}, i \leq q_1, j \leq q_2) \\ & \cdot \left[f(x^N(t+s)) - f(x^N(t)) - \int_t^{t+s} L_N^{\hat{m}} f(x^N(\tau)) d\tau \right] = 0. \end{aligned}$$

Since $q_1, q_2, h(\cdot)$ and the $k_j(\cdot)$, t_i, t, s are arbitrary (with $t_i, t, t+s \notin \mathcal{T} = \{\tau_i\}$), the assertion that the $M_f^N(\cdot)$ are $\{B^N(t)\}$ martingales is proved.

It follows from the fact that $x^N(\cdot)$ solves the martingale problem in $D'[0, \infty)$ associated with the local operator $L_N^{\hat{m}}$ that $x^N(\cdot)$ has continuous paths w.p.l.

Part 3. Representation of the limit. Define $\sigma_N(x) = \sigma(x)q_N(x)$. Since the $M_f^N(\cdot)$ are martingales with respect to $B^N(t)$, there is a standard Wiener process $w^N(\cdot)$ (augmenting the probability space if necessary, via the addition of an independent Wiener process if $a(\cdot)$ is degenerate) such that $w^N(t)$ is $B^N(t)$ adapted, $x^N(\cdot)$ is nonanticipative with respect to $w^N(\cdot)$ and

$$(4.9) \quad dx^N = dt \int \bar{b}_N(x^N, \alpha) \hat{m}_t(d\alpha) + \sigma_N(x^N) dw^N.$$

Also, since $w^N(\cdot)$ is $B^N(t)$ adapted, the $\hat{m}(A \times [0, t])$ and $\hat{m}_t(A)$ are nonanticipative with respect to $w^N(\cdot)$. Hence $\hat{m}(\cdot)$ is an admissible relaxed control for the problem with coefficients \bar{b}_N, σ_N .

We now let $N \rightarrow \infty$ and use a "piecing together" argument to get the representation (4.2).

The last assertion of the theorem follows from the weak convergence $(x^{\varepsilon}(\cdot), \hat{m}^{\varepsilon}(\cdot)) \Rightarrow (x(\cdot), \hat{m}(\cdot))$, and the continuity of the process $x(\cdot)$. QED

Remark. With a simpler proof (not requiring working with $\{\hat{m}^{\varepsilon}(\cdot)\}$) we have the following. Let $u(\cdot)$ be a (time-dependent) feedback control which is continuous in x , uniformly in t on each bounded (x, t) set, and for which the martingale problem associated with (1.3) has a unique solution. Then $x^{\varepsilon}(u, \cdot) \Rightarrow x(u, \cdot)$. Also $R^{\varepsilon}(u) \rightarrow R(u)$.

THEOREM 6. Assume A1–A3. Let $\delta > 0$. For the feedback control $\bar{u}^{\delta}(\cdot)$ of Theorem 4 on any Lipschitz continuous (uniformly in t) δ -optimal control $\bar{u}^{\delta}(\cdot)$ for $x(\cdot)$, we have

$$(4.10) \quad \lim_{\varepsilon} [R^{\varepsilon}(\bar{u}^{\delta}) - \inf_{m \in RC^{\varepsilon}} R^{\varepsilon}(m)] \leq \delta.$$

Proof. By the weak convergence argument of Theorem 5, $x^{\varepsilon}(\bar{u}^{\delta}, \cdot) \Rightarrow x(\bar{u}^{\delta}, \cdot)$ and $R^{\varepsilon}(\bar{u}^{\delta}) \rightarrow R(\bar{u}^{\delta})$. The theorem follows from this since

$$R^{\varepsilon} \in (\hat{m}^{\varepsilon}) \rightarrow R(\hat{m}) \geq \inf_{m \in RC} R(m) \geq R(\bar{u}^{\delta}) - \delta. \quad \text{QED}$$

5. The discrete parameter case. An advantage of the weak convergence point of view is that the discrete parameter case can be treated in almost the same way as the continuous parameter case.

Let the system be given by

$$(5.1) \quad x_{n+1}^{\varepsilon} = x_n^{\varepsilon} + \varepsilon \int b(x_n^{\varepsilon}, \alpha) m_n(d\alpha) + \varepsilon \tilde{b}(x_n^{\varepsilon}, \xi_n) + \sqrt{\varepsilon} g(x_n^{\varepsilon}, \xi_n),$$

where $\{\xi_n\}$ satisfies the discrete parameter form of A1(a) or A1(b) and the conditions on $g(\cdot)$, $b(\cdot)$, $\tilde{b}(\cdot)$ and $k(\cdot)$ in A2–A3 hold. Also, assume that the discrete parameter relaxed control $m_n(\cdot)$ depends on $\{\xi_{j-1}, x_j, j \leq n\}$ only. For any admissible relaxed control $m(\cdot)$ for (3.1), define the infinitesimal operator L^m by (which implicitly defines $\bar{b}(\cdot)$ and $\sigma(\cdot)$)

$$(5.2) \quad \begin{aligned} L^m f(x) &= f'_x(x) \int b(x, \alpha) m_t(d\alpha) + \frac{1}{2} \sum_{-\infty}^{\infty} E[f'_x(x) g(x, \xi_n)]'_x g(x, \xi_0) \\ &\equiv f'_x(x) \int \bar{b}(x, \alpha) m_t(d\alpha) + \frac{1}{2} \sum_{i,j} f_{x_i x_j}(x) a_{ij}(x). \end{aligned}$$

The discrete parameter case can easily be put into the framework of the last section. The optimal policy for the discrete parameter case would not usually be “relaxed,” but it is convenient to represent it as a relaxed control, since the limit controls might be relaxed. Define $x^{\varepsilon}(\cdot)$ by $x^{\varepsilon}(t) = x_n^{\varepsilon}$ on $[n\varepsilon, (n+1)\varepsilon)$, and define $m(\cdot)$ by

$$(5.3) \quad m(A \times [0, t]) = \varepsilon \sum_{n=0}^{[t/\varepsilon]-1} m_n(A) + \varepsilon(t - \varepsilon[t/\varepsilon])m_{[t/\varepsilon]}(A).$$

Let $\delta_{\varepsilon} \rightarrow 0$ and let $\hat{m}^{\varepsilon}(\cdot)$ be a δ_{ε} -optimal control for (5.1).

THEOREM 7. *Under the conditions of this section, Theorems 5 and 6 hold for the discrete parameter case.*

Remark. The proof is nearly identical to that of Theorems 5 and 6. One uses the discrete parameter versions (in [3]) of the theorems which were cited to that reference and the definition of $\hat{A}^{\varepsilon}f(n\varepsilon)$ and E_n^{ε} given in § 2.

6. Average cost per unit time. In this section, $(x^{\varepsilon}(\cdot), \xi^{\varepsilon}(\cdot))$ will be a Markov–Feller process with a stationary transition function when the control is of the feedback form $u(x, \xi)$, and $\xi(\cdot)$ is a Markov–Feller process. Let PM denote the class of U -valued functions of x for which (1.3) has a unique (weak sense) solution for each initial condition, and let PM^{ε} denote the class of U -valued continuous functions of (x, ξ) for which the corresponding $(x^{\varepsilon}(\cdot), \xi^{\varepsilon}(\cdot))$ is a Markov–Feller process (e.g., PM^{ε} includes all U -valued locally Lipschitz continuous functions). We work with (6.1), the same system dealt with in the previous section.

$$(6.1) \quad \dot{x}^{\varepsilon} = b(x^{\varepsilon}, u) + \tilde{b}(x^{\varepsilon}, \xi^{\varepsilon}) + g(x^{\varepsilon}, \xi^{\varepsilon})/\varepsilon.$$

Let SR denote the class of stationary admissible relaxed controls for (3.1) such that for each $m(\cdot) \in SR$, there is a process $x(m, \cdot)$ where the pair $(x(m, \cdot), m(\cdot))$ is stationary, and define SR^{ε} analogously for (6.1). When writing $\inf_{m \in SR} F(x(\cdot))$ for some function $F(\cdot)$, we infimize the functional values over these *stationary pairs* $(x(m, \cdot), m(\cdot))$.

The cost function (for a relaxed admissible control) is

$$\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T \int Ek(x^{\varepsilon}(t), \alpha) m_t(d\alpha) dt \equiv \gamma^{\varepsilon}(m)$$

and, for a feedback control,

$$\overline{\lim}_T \frac{1}{T} \int_0^T Ek(x^\varepsilon(t), u(x^\varepsilon(t), \xi^\varepsilon(t))) dt \equiv \gamma^\varepsilon(u).$$

We define the costs $\gamma(u)$ and $\gamma(m)$ for the controlled diffusion $x(\cdot)$ in the analogous way.

It is convenient to start our analysis with some additional assumptions. They will be discussed and sufficient conditions given for them in the next section.

Conditions C1-C4 hold in very many cases of interest. C1 and C3 are basically uniform (in the control) recurrence conditions. They certainly hold if the $x^\varepsilon(t)$ are confined to a compact set. But, more generally, if the system has a stability property for large $|x|$, then it can often be exploited to get C1 and C3. See § 7.3. Also, a nearly optimal stabilizing control for (1.3) is often a stabilizing control for (6.1).

Condition C1. There is $\varepsilon_0 > 0$ such that for each $\delta > 0$, there are continuous δ -optimal controls $u^{\varepsilon, \delta}(\cdot, \cdot) \in PM^\varepsilon$ such that $\{x^\varepsilon(u^{\varepsilon, \delta}, t), t < \infty, \varepsilon \leq \varepsilon_0\}$ is tight in R^r .

Condition C2. For each $\delta > 0$, there is a continuous δ -optimal control $\bar{u}^\delta(\cdot)$ in PM for (1.3) for which (1.3) has a unique invariant measure $\mu^\delta(\cdot)$, and such that $\bar{u}^\delta(\cdot) \in PM^\varepsilon$ for small ε .

Condition C3. For the $\bar{u}^\delta(\cdot)$ in C2, $\{x^\varepsilon(\bar{u}^\delta, t), t < \infty, \varepsilon > 0\}$ is tight in R^r .

Condition C4.

$$\inf_{u \in PM} \gamma(u) = \inf_{m \in SR} \gamma(m).$$

Theorem 8 says that if $\bar{u}^\delta(\cdot)$ is a δ -optimal control for the diffusion, then its use with the $x^\varepsilon(\cdot)$ gives a nearly (3δ) -optimal result for small ε .

THEOREM 8. Assume A1-A3 and C1-C4. Then for each $\delta > 0$, and small ε ,

$$(6.2) \quad \gamma^\varepsilon(\bar{u}^\delta) \leq \inf_{u \in PM^\varepsilon} \gamma^\varepsilon(u) + 3\delta.$$

Proof. Fix $\delta > 0$. $\bar{u}^\delta(\cdot)$ will be the function defined in C2, and $u^{\varepsilon, \delta}(\cdot)$ will be the function defined in C1. Let $P^{\varepsilon, \delta}(x, \xi, t, \cdot)$ denote the transition function for the Markov-Feller process $(x^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$, under the control $u^{\varepsilon, \delta}(\cdot)$. Define the measures

$$P_T^{\varepsilon, \delta}(\cdot) = \frac{1}{T} E \int_0^T P^{\varepsilon, \delta}(x^\varepsilon(0), \xi^\varepsilon(0), t, \cdot) dt,$$

where the average E is over the possibly random initial condition $(x^\varepsilon(0), \xi^\varepsilon(0))$. Then

$$(6.3) \quad \gamma^\varepsilon(u^{\varepsilon, \delta}) = \overline{\lim}_T \int P_T^{\varepsilon, \delta}(dx \times d\xi) k(x, u^{\varepsilon, \delta}(x, \xi)).$$

Let $\xi^\varepsilon(t)$ take values in R^k , and let $M(0)$ denote the set of probability measures on R^{r+k} with the weak topology. By (C1), the set of $M(0)$ -valued measures $\{P_T^{\varepsilon, \delta}(\cdot), T < \infty\}$ is in a compact set in $M(0)$. It follows from Benes [11] that the limit of any weakly convergent (in the topology of $M(0)$) subsequence is an invariant measure for $(x^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$, with the control $u^{\varepsilon, \delta}(\cdot)$ used.

Let $T_n \rightarrow \infty$ be a sequence such that it yields the $\overline{\lim}_T$ in (6.3) and also $P_{T_n}^{\varepsilon, \delta}(\cdot)$ converges weakly to an invariant measure $\mu^{\varepsilon, \delta}(\cdot)$ for $(x^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$. Thus

$$\gamma^\varepsilon(u^{\varepsilon, \delta}) = \int k(x, u^{\varepsilon, \delta}(x, \xi)) \mu^{\varepsilon, \delta}(dx \times d\xi).$$

Let $(\hat{x}^\varepsilon(\cdot), \hat{\xi}^\varepsilon(\cdot))$ denote a stationary process corresponding to the invariant measure $\mu^{\varepsilon, \delta}(\cdot)$.

Write the control $u^{\varepsilon, \delta}(\cdot)$ for $(\hat{x}^\varepsilon(\cdot), \hat{\xi}^\varepsilon(\cdot))$ in the form of a relaxed control, which we call $m^{\varepsilon, \delta}(\cdot)$, with derivative $m_t^{\varepsilon, \delta}(\cdot)$. Let $m^{\varepsilon, \delta}$ denote the measure valued process which is the time derivative of $m^{\varepsilon, \delta}(\cdot \times [0, t])$; i.e., the process with value $m_t^{\varepsilon, \delta}(\cdot)$ at time t . Then the pair (state, relaxed control derivative) of processes $(\hat{x}^\varepsilon(\cdot), m^{\varepsilon, \delta})$ is stationary. Alternatively, for any sequence $\{t_i\}$ and set of increasing numbers $\{s_i\}$, the distributions of $\{\hat{x}^\varepsilon(t + t_i), m^{\varepsilon, \delta}(\cdot \times [s_j + t, s_{j+1} + t]), i, j\}$ do not depend on t .

By the stationarity, we can write

$$(6.4) \quad \gamma^\varepsilon(u^{\varepsilon, \delta}) = E \int_0^1 dt \int k(\hat{x}^\varepsilon(t), \alpha) m_t^{\varepsilon, \delta}(d\alpha).$$

By C1, the collection of invariant measures $\{\mu^{\varepsilon, \delta}(\cdot), \varepsilon > 0\}$ lies in a compact set in $M(0)$. Thus, by Theorem 5, $\{\hat{x}^\varepsilon(\cdot), m^{\varepsilon, \delta}(\cdot)\}$ is tight in $D^r[0, \infty) \times M(\infty)$. Let ε index a weakly convergent subsequence with limit $(\hat{x}^\delta(\cdot), m^\delta(\cdot))$. The limit is of the form (4.2), with the admissible $m^\delta(\cdot)$ replacing the $\hat{m}(\cdot)$ there. Let m^δ denote the measured-valued process which is the time derivative of $m^\delta(\cdot \times [0, t])$ (with value $m_t^\delta(\cdot)$ at time t). By the stationarity of $(x^\varepsilon(\cdot), m^{\varepsilon, \delta})$, the limit pair (state, relaxed control derivative) $(\hat{x}^\delta(\cdot), m^\delta)$ is also stationary, and by the weak convergence

$$(6.5) \quad \gamma^\varepsilon(u^{\varepsilon, \delta}) \rightarrow E \int_0^1 dt \int k(\hat{x}^\delta(t), \alpha) m_t^\delta(d\alpha).$$

Owing to the stationarity of $(\hat{x}^\delta(\cdot), m^\delta)$, the right side of (6.5) equals

$$(6.6) \quad \gamma(m^\delta) = \lim \frac{1}{T} E \int_0^T dt \int k(\hat{x}^\delta(t), \alpha) m_t^\delta(d\alpha).$$

We now apply $\bar{u}^\delta(\cdot)$ to $(x^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$. Define $\tilde{P}_T^{\varepsilon, \delta}(\cdot)$ as $P_T^{\varepsilon, \delta}(\cdot)$ was defined, but with $(x^\varepsilon(\bar{u}^\delta(\cdot), \cdot), \xi^\varepsilon(\cdot))$ used. Choose $T_n \rightarrow \infty$ such that $\tilde{P}_{T_n}^{\varepsilon, \delta}(\cdot) \Rightarrow \tilde{\mu}^{\varepsilon, \delta}(\cdot)$, an invariant measure for $(x^\varepsilon(\bar{u}^\delta(\cdot), \cdot), \xi^\varepsilon(\cdot))$, and such that

$$\gamma^\varepsilon(\bar{u}^\delta) = \lim_n \int \tilde{P}_{T_n}^{\varepsilon, \delta}(dx \times d\xi) k(x, \bar{u}^\delta(x)).$$

Let $(\tilde{x}^\varepsilon(\cdot), \tilde{\xi}^\varepsilon(\cdot))$ denote the stationary process corresponding to the invariant measure $\tilde{\mu}^{\varepsilon, \delta}(\cdot)$ and control $\bar{u}^\delta(\cdot)$.

By C3, $\{\tilde{\mu}^{\varepsilon, \delta}(\cdot), \varepsilon > 0\}$ lies in a compact set in $M(0)$. Then, by Theorem 5, $\{\tilde{x}^\varepsilon(\cdot)\}$ is tight in $D^r[0, \infty)$. Let ε index a weakly convergent subsequence with limit $\tilde{x}^\delta(\cdot)$, and control $\bar{u}^\delta(\cdot)$. Then $\tilde{x}^\delta(\cdot)$ is stationary and is, in fact, the unique stationary process of the form (1.3) corresponding to the control $\bar{u}^\delta(\cdot)$. We have, by Theorem 5,

$$(6.7) \quad \gamma^\varepsilon(\bar{u}^\delta) = E \int_0^1 k(\tilde{x}^\varepsilon(t), \bar{u}^\delta(\tilde{x}^\varepsilon(t))) dt \rightarrow E \int_0^1 k(\tilde{x}^\delta(t), \bar{u}^\delta(\tilde{x}^\delta(t))) dt = \gamma(\bar{u}^\delta).$$

Also by the definition of $\bar{u}^\delta(\cdot)$ and C4,

$$(6.8) \quad \begin{aligned} \gamma(\bar{u}^\delta) &\leq \inf_{u \in PM} \gamma(u) + \delta, \\ \inf_{u \in PM} \gamma(u) &= \inf_{m \in SR} \gamma(m) \leq \gamma(m^\delta). \end{aligned}$$

The theorem follows from inequalities (6.8) and the convergence in (6.5), (6.7). QED

7. On Conditions C1–C4.

7.1. On Condition C4. Let there be an optimal (average cost per unit time) policy $\bar{u}(\cdot)$ in PM for (1.3) and such that the associated diffusion $\bar{x}(\cdot)$ has a unique invariant

measure which we denote by $\mu^{\bar{u}}(\cdot)$. Let the potential

$$C(x) = \int_0^\infty E_x[k(\bar{x}(s), \bar{u}(\bar{x}(s))) - \bar{\gamma}] ds$$

and constant $\bar{\gamma}$ satisfy the Bellman equation

$$(7.1) \quad \bar{\gamma} = \min_{u \in U} [L^u C(x) + k(x, u)].$$

See [12] for one set of conditions guaranteeing this. Let $m(\cdot) \in SR$, with the associated stationary process $x(m, \cdot) \equiv x^m(\cdot)$ and stationary measure $\mu^m(\cdot)$, where $x^m(\cdot)$ satisfies (4.2) for $\hat{m}(\cdot) = m(\cdot)$. Suppose that for any such $m(\cdot)$ with finite $\gamma(m)$,

$$(7.2) \quad \int |C(x)| \mu^m(dx) < \infty.$$

Then (7.1) implies that for any $T < \infty$

$$\bar{\gamma} T \leq EC(x^m(T)) - EC(x^m(0)) + E \int_0^T \int k(x^m(t), \alpha) m_t(d\alpha) dt.$$

Then, by the stationarity of $x^m(\cdot)$, $\bar{\gamma} \leq \gamma(m)$, and C4 holds. A sufficient condition for (7.2) will be given in § 7.3 below.

7.2. On Condition C2. We use results from [13], where the system $\dot{x} = \bar{b}(x, u)$ was assumed to have a stability property, uniformly in $u(\cdot) \in PM$. Write $\bar{b}(x, u) = B(x) + \hat{B}(x, u)$, where $B(\cdot)$ and $\hat{B}(\cdot)$ satisfy the conditions on $b(\cdot)$ in A2, and $\hat{B}(\cdot)$ and $\sigma(\cdot)$ are bounded, $k(\cdot, \cdot)$ is bounded and continuous, and $\{a_{ij}(x)\}$ is uniformly positive definite and satisfies A3. The model is such that the stabilizing effects of $B(\cdot)$ overpower the effects of $\hat{B}(x, u)$ for large $|x|$. This, together with the positive definiteness, will essentially guarantee C2. To quantify the stability property for large $|x|$, let there be a twice continuously differentiable function $V(\cdot)$ such that $0 \leq V(x) \rightarrow \infty$ as $|x| \rightarrow \infty$ and, for some compact set K and $\beta > 0$, $L^u V(x) \leq -\beta$, for $x \notin K$ and all $u(\cdot) \in PM$. (L^u is the differential generator of (1.3).) Let there be $c > 0$, $\alpha > 0$, $q(x) \geq 0$ such that $L^u V^2(x) \leq c - q(x)$, where $\inf_x q(x)/V(x) \geq \alpha$. Typically $V(\cdot)$ would be a Lyapunov function for the system $\dot{x} = B(x)$; e.g., if $B(x) = Ax$ where A is stable and for $Q > 0$, P can be defined by $A'P + PA = -Q$, and we use the Lyapunov function $x'Px = V(x)$. Note that our c and $V(x)$ are called c_2 and $W_1(x)$ in [13].

Under the above conditions, Theorems 3.1, 4.2, 4.3 and the proof of [13, Thm. 4.4] imply the following facts: To any $u(\cdot) \in PM$, there is a unique invariant measure $\mu^u(\cdot)$ for (1.3) and $\{\mu^u(\cdot), u(\cdot) \in PM\}$ is in a compact set in $M(0)$; let $u^\delta(\cdot)$ be a $\delta/2$ -optimal control in PM , smooth or not, and let

$$(7.3) \quad u^n(x) \rightarrow u^\delta(x) \text{ in } L_1(R^r), \quad u^n(\cdot) \in PM.$$

Then for each Borel set A , $\mu^{u^n}(A) \rightarrow \mu^{u^\delta}(A)$ and

$$(7.4) \quad \int k(x, u^n(x)) \mu^{u^n}(dx) \rightarrow \int k(x, u^\delta(x)) \mu^{u^\delta}(dx).$$

These facts imply that for any given $\delta/2$ -optimal $u^\delta(\cdot)$, there is a locally Lipschitz continuous $\bar{u}^\delta(\cdot)$ such that

$$\gamma(\bar{u}^\delta) - \gamma(u^\delta) \leq \delta/2.$$

Reference [13] uses a convexity condition (A3 there) on the set $\{\bar{b}(x, U), k(x, U)\}$ and on U . But, this convexity condition was used only to prove the existence of an optimal control. The smooth $\delta/2$ -optimal control always exists.

7.3. On the assumption (7.2). Again, we use results of [13]. Let $C(\cdot)$ satisfy (7.1) and assume the conditions of § 7.2. Then [13, proof of Lemma 5.1],

$$|C(x)| \leq K(1 + V(x))$$

for some $K < \infty$ (our $C(x)$ is called $V^u(x)$ in [13]). Adapting the proof of [13, Lemma 5.1] to our “relaxed” control case and using the c and α of § 7.2, we get for *any* $M < \infty$ and relaxed control $m(\cdot)$,

$$c \geq \lim_{t \rightarrow \infty} \int_0^t \alpha E \min [M, V(x^m(s))] dt.$$

By the stationarity, the integral equals $\alpha E \min [M, V(x^m(0))]$. Since M is arbitrary and c does not depend on $m(\cdot)$, (7.2) holds.

7.4. On Conditions C1, C3. Under a suitable stability condition on the limit system $x(\cdot)$, both C1 and C3 can be shown via a perturbed Lyapunov function method. In particular, we use some of the results of [3, Chap. 6.6] and [14]. We use the form $b(x, u) = B(x) + \hat{B}(x, u)$ and

$$(7.5) \quad \dot{x}^\varepsilon = B(x) + \hat{B}(x, u) + \tilde{b}(x, \xi^\varepsilon) + g(x, \xi^\varepsilon)/\varepsilon$$

and A2, A3, A1(a). Assume that $B(\cdot)$ and $\hat{B}(\cdot)$ satisfy the conditions on $b(\cdot)$ in A2. Analogous results can be obtained under A1(b), via the method in [3, Chap. 6.8]. We require the existence of a Lyapunov function $V(\cdot)$ satisfying certain inequalities. In applications, the assumptions are essentially equivalent to $B(\cdot)$ strongly dominating the effects of the other terms for large $|x|$.

We begin with an adaptation of a perturbed Lyapunov function method of [14], but with a simpler perturbation. Let $V(\cdot)$ be a twice continuously differentiable nonnegative function such that $V(x) \rightarrow \infty$ as $|x| \rightarrow \infty$ and D1–D4 hold. The K below are constants.

Condition D1. There are $\alpha > 0$, $c < \infty$, such that

$$V'_x(x)B(x) \leq -\alpha V(x) + c \quad \text{and} \quad |V'_x(x)\hat{B}(x, u)|/V(x) \rightarrow 0 \text{ as } |x| \rightarrow \infty;$$

Condition D2. $|V'_x(x)g(x, \xi)| + |V'_x(x)\tilde{b}(x, \xi)| \leq K(1 + V(x))$;

Condition D3. $|(V'_x(x)q(x))'_x p(x)| \leq K(1 + V(x))$, for the pairs

$$q(\cdot) = \tilde{b}(\cdot), p(\cdot) = B(\cdot), \hat{B}(\cdot), \tilde{b}(\cdot) \text{ and } g(\cdot) \quad \text{and}$$

$$q(\cdot) = g(\cdot), p(\cdot) = B(\cdot), \hat{B}(\cdot), \tilde{b}(\cdot);$$

Condition D4. $||V'_x(x)g(x, \xi)|'_x g(x, \xi)|/V(x) \rightarrow 0$ as $|x| \rightarrow \infty$.

Define $V_1^\varepsilon(t) = V_1^\varepsilon(x^\varepsilon(t), t)$, where

$$(7.6) \quad V_1^\varepsilon(x, t) = \int_t^\infty V'_x(x)E_t^\varepsilon \tilde{b}(x, \xi^\varepsilon(s)) ds + \frac{1}{\varepsilon} \int_t^\infty V'_x(x)E_t^\varepsilon g(x, \xi^\varepsilon(s)) ds.$$

By a change of scale $s/\varepsilon^2 \rightarrow s$ and A1(a), D2, we get that the first term is $O(\varepsilon^2)[1 + V(x)]$ and the second is $O(\varepsilon)[1 + V(x)]$. Define the perturbed Lyapunov function $V^\varepsilon(t) = V(x^\varepsilon(t)) + V_1^\varepsilon(t)$. Then (write for $x^\varepsilon(t)$ and \dot{x}^ε for $\dot{x}^\varepsilon(t)$, where convenient)

$$\hat{A}^\varepsilon V(x) = V'_x(x)[B(x) + \hat{B}(x, u) + \tilde{b}(x, \xi^\varepsilon(t)) + g(x, \xi^\varepsilon(t))/\varepsilon],$$

$$\hat{A}^\varepsilon V_1^\varepsilon(x, t) = -V'_x(x)\tilde{b}(x, \xi^\varepsilon(t)) - \frac{1}{\varepsilon} V'_x(x)g(x, \xi^\varepsilon(t))$$

$$+ \int_t^\infty ds [V'_x(x)E_t^\varepsilon \tilde{b}(x, \xi^\varepsilon(s))]'_x \dot{x}^\varepsilon$$

$$+\frac{1}{\varepsilon} \int_t^\infty ds [V'_x(x) E_t^\varepsilon g(x, \xi^\varepsilon(s))]'_x \dot{x}^\varepsilon.$$

By using the scale change $s/\varepsilon^2 \rightarrow s$, A1(a) and D1 to D4, we get that there is a function $h(x) \geq 0$ such that $h(x)/V(x) \rightarrow 0$ as $|x| \rightarrow \infty$ and such that

$$(7.7) \quad \hat{A}^\varepsilon V^\varepsilon(t) \leq -\alpha V(x^\varepsilon(t)) + h(x^\varepsilon(t)).$$

By the bound on $V_1^\varepsilon(x, t)$ below (7.6), we can write (for small $\varepsilon > 0$)

$$(7.8) \quad \hat{A}^\varepsilon V^\varepsilon(t) \leq -\frac{\alpha}{2} V^\varepsilon(x^\varepsilon(t)) + c_1,$$

for some $c_1 < \infty$. Inequality (7.8) yields, for some $c_2 < \infty$,

$$(7.9) \quad EV^\varepsilon(t) \leq e^{-\alpha t/2} EV^\varepsilon(0) + c_2.$$

Now use the bound on $V^\varepsilon(x, 0)$ obtained from the estimates below (7.6) to get that (for some $\varepsilon_0 > 0$)

$$\sup_{\varepsilon_0 \leq \varepsilon, t} EV(x^\varepsilon(t)) < \infty,$$

which yields C1 and C3.

By using the method and conditions in [3, Chap. 6.8], the conditions D1–D4 can be weakened. In particular, $V'_x(x)B(x) \leq -\alpha V(x) + c$ can be replaced by the condition that $V'_x(x)B(x) \leq -\alpha < 0$ for large $|x|$, and some $\alpha > 0$.

8. Extensions. Extensions of the results in §§ 4 to 6 to all the standard control problem formulations are quite possible. Here, we mention only a few possibilities.

8.1. Stopping times. Let G be a bounded open set with a piecewise differentiable boundary, and define

$$R^\varepsilon(m) = E \int_0^{\tau^\varepsilon(m)} ds \int k(x^\varepsilon(s), \alpha) m_s(d\alpha),$$

$$\tau^\varepsilon(m) = \inf \{t: x^\varepsilon(t) \notin G\},$$

where $x^\varepsilon(\cdot)$ is the solution to (4.1) which corresponds to m . Define $R(m)$, the cost for (3.1) in a similar way, with $\tau(m) = \inf \{t: x(t) \notin G\}$.

In extending Theorem 5 to this case, only two problems arise. First, is $\sup_\varepsilon E_x \tau^\varepsilon(m^\varepsilon) < \infty$ for the various sequences $\{m^\varepsilon(\cdot)\}$ which are used? Second, if $(x^\varepsilon(\cdot), m^\varepsilon(\cdot)) \Rightarrow (x(\cdot), m(\cdot))$, do the exit times also converge? The answers are affirmative under broad conditions, certainly if $\{a_{ij}(x)\}$ is uniformly positive definite in G . We discuss the questions in the simple case where $\xi^\varepsilon(\cdot)$ is Markov and bounded.

Suppose that there are $\delta > 0$ and $\rho > 0$ such that

$$(8.1) \quad \inf_{\substack{x \in G \\ m \in RC}} P_x \{x(m, t) \notin N_\delta(G), \text{ some } t \leq T\} \geq \rho,$$

where $N_\delta(G)$ is a δ -neighborhood of G and P_x denotes the probability given the initial condition x . Then it follows that there is a $\rho_1 > 0$ such that for any sequence of $m^\varepsilon(\cdot) \in RC^\varepsilon$

$$(8.2) \quad \liminf_{\varepsilon} \inf_{\xi, x \in G} P_{x, \xi} \{x^\varepsilon(m^\varepsilon, t) \notin G, \text{ some } t \leq 2T\} \geq \rho_1.$$

where $P_{x, \xi}$ denotes the probability given the initial conditions x, ξ .

Suppose that (8.2) is false. Then there are $\varepsilon \rightarrow 0$, and (bounded) initial conditions $x_\varepsilon \in G$ and ξ_ε , such that

$$(8.3) \quad \lim_{\varepsilon} P_{x_\varepsilon, \xi_\varepsilon} \{x^\varepsilon(m^\varepsilon, t) \in G, \text{ some } t \leq 2T\} = 0.$$

There is a subsequence (indexed by ε) and $m(\cdot) \in RC$ such that $\{x^\varepsilon(m^\varepsilon, \cdot), m^\varepsilon(\cdot)\} \Rightarrow \{x(m, \cdot), m(\cdot)\}$. Then (8.3) is contradicted by (8.1). It follows from (8.2) that there is an $\varepsilon_0 > 0$ such that

$$\sup_{\varepsilon_0 \geq \varepsilon \geq 0} E_{x, \xi} \tau^\varepsilon(m) < \infty, \quad x \in G, \xi.$$

In the nondegenerate case, if $\{x^\varepsilon(m^\varepsilon, \cdot), m^\varepsilon(\cdot)\} \Rightarrow (x(m, \cdot), m(\cdot))$, then the exit times also converge. This follows from the weak convergence and the fact that $x(m, \cdot)$ crosses the boundary of G indefinitely often in $[\tau(m), \tau(m) + \Delta]$, for any $\Delta > 0$.

8.2. State dependent noise. The results of §§ 4 to 6 can be extended to the case where the evolution of $\xi^\varepsilon(\cdot)$ depends on $x^\varepsilon(\cdot)$ or $\{\xi_n^\varepsilon\}$ depends on $\{x_n^\varepsilon\}$. The technique is a combination of the control "representation" results of this paper, and the weak convergence methods of the state dependent noise or singular perturbations sections of [3]. The main problems concern, as before, tightness and the representation of the limit as a particular control problem.

One particular case in [3] concerns Markov $(x_n^\varepsilon, \xi_{n-1}^\varepsilon)$, where if x_n^ε is fixed at x , the $\{\xi_n^\varepsilon\}$ is a Markov process with a unique invariant measure (see e.g., [3, Chap. 5.8.3]). Systems such as (1.6), or the wide band-noise driven forms can also be treated if the $g(\cdot)$ there does not depend on u .

THE OBSERVATION SPACE AND REALIZATIONS OF FINITE VOLTERRA SERIES*

P. E. CROUCH† AND P. C. COLLINGWOOD‡

Abstract. In this paper we extend the results on the theory of realizations of finite Volterra series by exploiting the structural properties of the observation space. In general, two distinct minimal realizations of a finite Volterra series may be constructed, one based on the properties of the observation space and the other based on the properties of the Lie algebra. Both these realizations display the canonical structure found earlier for such systems. The results given here also yield information on the observation algebra generated by functions in the observation space, just as previous work gave information on the Lie algebra. As an application, the structure found here is applied to the finite-dimensional filtering problem for these systems.

1. Introduction. In the paper by Crouch [2], some fundamental properties of systems with finite Volterra series were worked out. In this paper, we present some further structure for these systems. The main aspect under consideration is the observation space, introduced for nonlinear systems, to deal with problems concerning observability. We restrict our definitions in this paper to linear analytic systems of the form

$$(1) \quad \begin{aligned} \dot{x} &= f(x) + \sum_{i=1}^m u_i g_i(x), & x \in M, \\ y_i &= h_i(x), & 1 \leq i \leq p, \quad x(0) = x_0, \quad f(x_0) = 0 \end{aligned}$$

where M is a real analytic manifold, f, g_1, \dots, g_m are analytic vector fields on M , and h_1, \dots, h_p are analytic functions on M ; however, most concepts are generalizable to smooth systems. The observation space denoted \mathcal{H} is the smallest vector space of functions on M which contains h_1, \dots, h_p and is closed under the Lie derivative by the vector fields f, g_1, \dots, g_m . In general, \mathcal{H} is infinite-dimensional. We denote the Lie derivative of a function h by a vector field X by $L_X h$ and define $L_X^k(h) = L_X(L_X^{k-1}(h))$, $L_X^1(h) = L_X(h)$. We let \mathcal{A} denote the algebra over \mathbb{R} generated by \mathcal{H} under the operations of pointwise multiplication, addition and scalar multiplication. \mathcal{A} is called the observation algebra. Let \mathcal{L} denote the Lie algebra generated by the vector fields f, g_1, \dots, g_m , and let $[X, Y]$ denote the Lie bracket of vector fields X and Y .

For many problems in nonlinear systems theory the object of primary importance has been the Lie algebra \mathcal{L} . However, as stated above for questions concerning observability, the vector space \mathcal{H} seems to be the correct geometric/algebraic object to consider, especially for analytic systems—see Hermann and Krener [6]. Further use of \mathcal{H} has been made in realization theory (see Hijab [7] and Fliess and Kupka [8]). In estimation theory, some use has been made of the algebra \mathcal{A} , Hijab [7]. Further

use has been made of certain subspaces of \mathcal{H} and distributions orthogonal to them, Gauthier and Bornard [13], Aeyels [14] and Nijmeijer [15], to obtain canonical representations of systems with specific observability properties.

The main aim of this paper is to exploit \mathcal{H} and \mathcal{A} to obtain further structural properties of systems with finite Volterra series. In § 2 we begin by making some comments on the definitions used when referring to properties of system (1). Then, because of their connection with later work, we review two results. The first is a little-recognized result of Fliess [16] concerning the local structure of the algebra \mathcal{A} . The second result gives necessary and sufficient conditions for a system (1) to have an input-output map represented by a finite Volterra series. This result sharpens that obtained by Hijab [7] and Fliess and Kupka [8] for bilinear systems.

In § 3 we recall the canonical form for realizations of finite Volterra series obtained in Crouch [2] using the machinery of graded vector spaces. In order to distinguish this canonical form from others introduced in the works cited above, and motivated by the polynomial nature of these realizations, we refer to this canonical form as the graded polynomial form, or g.p.f. We then define the graded controllable polynomial form, or g.c.p.f., and show that the minimal realizations of finite Volterra series obtained in Crouch [2] are indeed in g.c.p.f. A system in g.c.p.f. is defined with the aid of a finite set of integers, such that any two minimal realizations of a finite Volterra series, both of which are in g.c.p.f., have the same set of integers. These integer invariants coincide with those introduced in Crouch [2].

In § 4 the graded observable polynomial form, or g.o.p.f., is defined. It is shown, by utilizing the structure of \mathcal{H} , that minimal realizations of finite Volterra series can be constructed which are in g.o.p.f. This canonical form differs substantially from the one appearing in Nijmeijer [15]. The g.o.p.f. is defined with the aid of another set of integer invariants which are not related to the observability indices introduced in Nijmeijer [15]. Even for minimal realizations of the same finite Volterra series, the two sets of integer invariants defined here need not coincide, but they do coincide for systems with finite Volterra series consisting of a single term.

It is easily verified from the structure of the g.o.p.f. that the observation algebra \mathcal{A} is a polynomial algebra. However, we show that this result is true for any minimal system in g.p.f. and in particular for a minimal system in g.c.p.f.

In § 5 we consider the estimation problem for a system with finite Volterra series driven by white noise, and use the results obtained in the previous sections to obtain a better description of the estimation algebra in this case.

Some of the constructions, using the observation space as detailed here, were obtained simultaneously by Kupka [12], but it is made clear there that the main aim is to give alternative proofs of some results in Crouch [2]. It is important to understand that we regard many of the results obtained here as complementary to the results in Crouch [2], and we therefore compare and contrast the two constructions where possible.

Since this paper was written, further work on the two canonical forms has been developed (Crouch and Collingwood [19] and Collingwood [20]). The structure of the observation algebra also helped motivate the new and innovative work by Bartosiewicz [21] and [22].

2. Preliminary properties of the observation space. In dealing with system (1) we need to use concepts of controllability, observability and minimality, which have been worked out for nonlinear systems (see, for example, Sussmann and Jurdjevic [9], and Hermann and Krener [6]). A minimal system is defined as one which is orbit minimal

and observable. For analytic systems, orbit minimality is equivalent to the controllability rank condition

$$\mathcal{L}(x) = \{X(x); X \in \mathcal{L}\} = T_x M, \quad x \in M,$$

where $T_x M$ is the tangent space to M at x . This is in turn equivalent to accessibility of the system; that is, the reachable set has nonempty interior in M from every initial state. Let \mathcal{S} be the ideal of \mathcal{L} generated by the vector fields

$$\begin{aligned} ad^k f(g_i), \quad k \geq 0, \quad 1 \leq i \leq m, \\ ad^k f(g) = [f, ad^{k-1} f(g)], \quad ad^1 f(g) = [f, g]. \end{aligned}$$

Since we assume $f(x_0) = 0$, we have $\mathcal{S}(x) = \mathcal{L}(x)$ for all $x \in M$. Thus the controllability rank condition is equivalent to $\mathcal{S}(x) = T_x M$ for all $x \in M$. This in turn implies strong accessibility of the system, that is, that the reachable set at time $T > 0$ has nonempty interior in M from every initial state. Thus, in our situation, we are dealing with strictly autonomous systems.

For the sake of simplicity, we shall refer a system which satisfies the controllability rank condition as controllable rather than by the more traditional terms accessible or weakly controllable. Similarly, we shall refer to a system which satisfies the observability rank condition

$$d\mathcal{H}(x) = \{dh(x); h \in \mathcal{H}\} = T_x^* M, \quad x \in M$$

and $T_x^* M$ is the cotangent space to M at x , as observable, rather than by the usual term weakly observable. In general, a system may satisfy the observability rank condition and fail to be observable in the usual sense. With the definitions above, a controllable and observable system need not be minimal in general. So when minimality is required this will be explicitly stated. As a matter of interest, it is proved in Crouch [2], that a controllable and observable system as defined here, which has a finite Volterra series, is indeed minimal. This mitigates the terminology used here to some extent.

Before we give the first result of this section, we quote the following lemma whose proof is a simple exercise in differentiation (see Collingwood [20]).

LEMMA 1. For $i = 1, 2$ let

$$\begin{aligned} \dot{x}_i &= f^i(x_i) + \sum_{j=1}^m u_j g_j^i(x_i), \quad x_i \in \mathbb{R}^{n_i}, \quad x_i(0) = \bar{x}_i, \\ \sum_i \quad y_k &= h_k^i(x_i), \quad 1 \leq k \leq p \end{aligned}$$

be two systems with the same input-output map. Let $\mathcal{H}_i, i = 1, 2$ be the observation spaces, and $\mathcal{L}_i, i = 1, 2$ the Lie algebras for systems $\sum_i, i = 1, 2$, respectively, and let $t \rightarrow x_i^u(t)$ $i = 1, 2$ denote the solutions of the respective equations subject to the same input functions $u_j(t)$. Then

(i) If \sum_2 is controllable, there is a unique linear surjection $\beta: \mathcal{H}_1 \rightarrow \mathcal{H}_2$ satisfying

$$\beta(\phi)(x_2^u(t)) = \phi(x_1^u(t))$$

for all $\phi \in \mathcal{H}_1$, and trajectories x_i^u , when both sides are defined.

(ii) If \sum_2 is observable, there is a unique Lie algebra homomorphism $\lambda: \mathcal{L}_1 \rightarrow \mathcal{L}_2$, satisfying

$$\lambda(f^1) = f^2 \quad \text{and} \quad \lambda(g_i^1) = g_i^2, \quad 1 \leq i \leq m.$$

We give a proof of the following result, originally obtained in Fliess [16], because of the more geometric flavor and its intimate relation with subsequent results, especially Theorem 4.

THEOREM 1 (Fliess [16]). *Given a controllable and observable system (1), then about any state $x_0 \in \mathbb{R}^n$, there exists a coordinate chart (U, ϕ) , $\phi(x_0) = 0$, $\phi: U \rightarrow V \subset \mathbb{R}^n$, such that in the resulting coordinates $z_1 \cdots z_n$ on V , the system's observation space contains all of the coordinate functions $z \rightarrow z_i$, $1 \leq i \leq n$.*

Proof. Since the system is observable, it satisfies the observability rank condition $d\mathcal{H}(x) = T_x^*M$, $x \in M$, and so there exists functions $\phi_1 \cdots \phi_n \in \mathcal{H}$, such that $d\phi_1(x) \cdots d\phi_n(x)$ span T_x^*M for each $x \in U$, a neighborhood of x_0 . It follows that the map $x \rightarrow \phi(x) = (\phi_1(x), \dots, \phi_n(x)) = (z_1 \cdots z_n) = z$ is a diffeomorphism from U onto some open subset $V \subset \mathbb{R}^n$. Define vector fields and functions on V by

$$\begin{aligned} F(z) &= \phi_* f(\phi^{-1}(z)), & G_i(z) &= \phi_* g_i(\phi^{-1}(z)), \\ H_i(z) &= h_i \circ \phi^{-1}(z). \end{aligned}$$

This defines a system on V

$$\begin{aligned} \dot{z} &= F(z) + \sum_{i=1}^m u_i G_i(z), & z &\in V, \quad z(0) = \phi(x_0), \\ (2) \quad y_i &= H_i(z), & 1 &\leq i \leq p, \end{aligned}$$

which has the same input-output map as system (1). Since both systems are clearly controllable on U and V , respectively, by Lemma 1 we have

$$h \circ \phi^{-1}(z(t)) = \beta(h)(z(t)) = h(x(t))$$

for $h \in \mathcal{H}$, where $t \rightarrow x(t)$ and $t \rightarrow z(t)$ are the solutions of systems (1) and (2), respectively, and defined where $z(t)$ is defined.

Denote by $\psi: V \rightarrow \mathbb{R}^n$ the analytic map $z \rightarrow (\phi_1 \circ \phi^{-1}(z), \dots, \phi_n \circ \phi^{-1}(z)) = (\beta(\phi_1)(z), \dots, \beta(\phi_n)(z))$. Now $\beta(\phi_i)(z(t)) = \phi_i(x(t))$ $1 \leq i \leq n$, so we have $\psi(z(t)) = z(t)$, when $z(t)$ is defined. Since system (2) is controllable on V , the reachable set of system (2) from $z = \phi(x_0)$ contains an open subset of V . Thus, ψ is the identity map on an open subset of V , and hence by analyticity it is the identity map on the whole of V . It follows that $\beta(\phi_i)(z) = z_i$ on V and hence $z \rightarrow z_i$ is in the observability space of system (2) for $1 \leq i \leq n$. \square

Note that if in the situation above the observation space also contains the constant functions then the algebra \mathcal{A} in the coordinates $z_1 \cdots z_n$, is simply $\mathbb{R}[z_1 \cdots z_n]$, the ring of polynomials in $z_1 \cdots z_n$. We show later that this happens globally for minimal realizations of finite Volterra series.

We now turn attention to the problem of establishing conditions under which an analytic system (1) has an input-output map described by a finite Volterra series. We use the technique of Hijab [7] and Fliess and Kupka [8], and although the result is not particularly innovative given the works above and Crouch [2], Fliess [17] and [18], we include its proof as an introduction to the structure of the observation space.

THEOREM 2. *Give a controllable system (1), then its input-output map has a finite Volterra series of length $N \geq 1$ if and only if both of the following conditions hold:*

- (i) \mathcal{H} is a finite-dimensional space;
- (ii) There exists a sequence of subspaces

$$\begin{aligned} \mathcal{H}^k &\subset \mathcal{H}, \quad 0 \leq k \leq N+1, \quad \mathcal{H}^{N+1} = \{0\}, \quad \mathcal{H}^0 = \mathcal{H}, \\ 0 &\subset \mathcal{H}^N \subset \mathcal{H}^{N-1} \subset \cdots \subset \mathcal{H}^1 \subset \mathcal{H}, \end{aligned}$$

such that

- (a) \mathcal{H}^N consists of the constant functions
- (b) $L_{g_i} \mathcal{H}^k \subset \mathcal{H}^{k+1}$, $L_f \mathcal{H}^k \subset \mathcal{H}^k$, $0 \leq k \leq N$, $1 \leq i \leq m$.

Proof. Necessity: If the system has a finite Volterra series then it is realizable by a bilinear system (Brockett [23]) in the form

$$\dot{z} = Az + \sum_{i=1}^m u_i(N_i z + b_i), \quad z(0) = 0, \quad z \in \mathbb{R}^J,$$

$$u_i = c'_i z \quad 1 \leq i \leq p.$$

Moreover, since the system (1) is controllable, we may suppose that there is an analytic map $\phi: M \rightarrow \mathbb{R}^J$, such that given any $h \in \mathcal{H}$, there exists an affine function \bar{h} on \mathbb{R}^J , such that $h = \bar{h} \circ \phi$. Since the space of affine functions on \mathbb{R}^J is finite-dimensional, we see that condition (i) is satisfied. As in Lemma 3.1 of Crouch [2] the last Volterra kernel $W_N(t, \sigma_1 \cdots \sigma_N)(x_0)$, viewed as a function $W_N(t, \sigma_1 \cdots \sigma_N)(x)$ is a constant for each $t, \sigma_1 \cdots \sigma_N$. Thus, the coefficients of the parameters $t, \sigma_1 \cdots \sigma_N$ and their powers, viewed as functions on M , are constant, and not all zero. These coefficients, which are elements of \mathcal{H} , are given by the following expressions, Fliess [18], Crouch [2]:

$$L_{ad}^{k_0}_{f^{(g_{i_1})}} L_{ad}^{k_1}_{f^{(g_{i_2})}} \cdots L_{ad}^{k_{N-1}}_{f^{(g_{i_N})}} L_f^{k_N}(h_j), \quad 1 \leq i_j \leq m, \quad 1 \leq j \leq p, \quad k_i \geq 0.$$

However, by repeated use of the formula

$$L_{ad(X)(Y)}(h) = L_X L_Y(h) - L_Y L_X(h),$$

we see that the linear span of the functions above is the same as the linear span of the functions

$$L_f^{k_0} L_{g_{i_1}} L_f^{k_1} L_{g_{i_2}} \cdots L_{g_{i_N}} L_f^{k_N}(h_j).$$

Let \mathcal{O}^r be the subspace of \mathcal{H} spanned by the functions

$$L_f^{k_0} L_{g_{i_1}} L_f^{k_1} L_{g_{i_2}} \cdots L_{g_{i_r}} L_f^{k_r}(h_j),$$

$k_i \geq 0$, $1 \leq j \leq p$, $1 \leq i_j \leq m$, and set, for $0 \leq r \leq N$,

$$\hat{\mathcal{H}}^r = \mathcal{O}^N + \mathcal{O}^{N-1} + \cdots + \mathcal{O}^r, \quad \hat{\mathcal{H}}^{N+1} = \{0\}.$$

By the arguments above $\mathcal{O}^N = \hat{\mathcal{H}}^N$ is spanned by the constant functions, and it is clear that

$$L_f \hat{\mathcal{H}}^r \subset \hat{\mathcal{H}}^r, \quad L_{g_i} \hat{\mathcal{H}}^r \subset \hat{\mathcal{H}}^{r+1}, \quad 1 \leq i \leq m, \quad 0 \leq r \leq N.$$

Thus condition (ii) of the theorem is satisfied with $\hat{\mathcal{H}}^r = \mathcal{H}^r$, $0 \leq r \leq N+1$.

Sufficiency: Select complementary subspaces \mathcal{O}^j such that $\mathcal{H}^{j+1} + \mathcal{O}^j = \mathcal{H}^j$, $0 \leq j \leq N$, $\mathcal{O}^N = \mathcal{H}^N$. Thus $L_f \mathcal{O}^j \subset \mathcal{H}^j$, $L_{g_i} \mathcal{O}^j \subset \mathcal{H}^{j+1}$. Let $\phi_1^r \cdots \phi_n^r$ be a basis of \mathcal{O}^r for $N \geq r \geq 0$, and let $z_r(t)$ denote the vector $(\phi_1^r(x(t)), \cdots, \phi_n^r(x(t)))$ where $x(t)$ is the solution of system (1). We obtain by differentiation

$$\frac{d}{dt} \phi_j^r(x(t)) = L_f \phi_j^r(x(t)) + \sum_{i=1}^m u_i L_{g_i} \phi_j^r(x(t)).$$

Thus, using the above properties, we obtain

$$(3) \quad \frac{d}{dt} z_r(t) = \sum_{j=r}^N A_j^r z_j(t) + \sum_{j=r+1}^N \sum_{i=1}^m u_i B_{ij}^r z_j(t)$$

for appropriate matrix coefficients A_j^r , B_{ij}^r with $B_{ij}^N = A_j^N = 0$. Also, since $h_i \in \mathcal{H}$ there exist vectors c_{ij} such that

$$(4) \quad h_i(x(t)) = \sum_{r=1}^N c'_{ir} z_r(t).$$

Clearly we may set $z_N(t) \equiv 1 = \phi^N$ the basis element of \mathcal{H}^N . Writing equations (3) and (4) in matrix form we obtain

$$\frac{d}{dt} \begin{bmatrix} z_N \\ z_{N-1} \\ z_{N-2} \\ \vdots \\ z_0 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & \cdots & 0 \\ A_N^{N-1} & A_{N-1}^{N-1} & 0 & \cdots & 0 \\ A_N^{N-2} & A_{N-1}^{N-2} & A_{N-2}^{N-2} & & 0 \\ \vdots & \vdots & & \ddots & \\ A_0^0 & & & & A_0^0 \end{bmatrix} \begin{bmatrix} z_N \\ z_{N-1} \\ z_{N-2} \\ \vdots \\ z_0 \end{bmatrix} + \sum_{i=1}^m u_i \begin{bmatrix} 0 & & & & \\ B_{iN}^{N-1} & 0 & & & \\ B_{iN}^{N-2} & B_{iN-1}^{N-2} & 0 & & \\ \vdots & \vdots & \ddots & \ddots & \\ B_{iN}^0 & & & B_{i1}^0 & 0 \end{bmatrix} \begin{bmatrix} z_N \\ z_{N-1} \\ z_{N-2} \\ \vdots \\ z_0 \end{bmatrix},$$

$$y_i(t) = \sum_{r=1}^N c'_{ir} z_r(t), \quad 1 \leq i \leq p.$$

This system evidently has a finite Volterra series of length N , for any initial state. \square

The bilinear realizations we obtain in the proof of this result are in general not minimal, and it is the structure of the minimal realizations that we consider next.

3. Graded polynomial forms for realizations of finite Volterra series. In order to define the canonical forms for systems with finite Volterra series, as constructed in Crouch [2], we must introduce some notation and results from the theory of graded vector spaces, and polynomial functions on them. All the results may be found in Goodman [4].

A graded vector space consists of a vector space \mathbb{R}^n , and a specified direct sum decomposition of \mathbb{R}^n

$$\mathbb{R}^n = \mathbb{R}^{n_1} \oplus \mathbb{R}^{n_2} \oplus \cdots \oplus \mathbb{R}^{n_N}$$

where $\sum_{i=1}^N n_i = n$. We represent a vector $x \in \mathbb{R}^n$ as the compound vector (x_1, x_2, \dots, x_N) with $x_{n_i} \in \mathbb{R}^{n_i}$. If it is necessary to refer to the components of a vector x_i , we shall denote them as x_i^j , $1 \leq j \leq n_i$.

The role of each subspace is differentiated by the introduction of a dilation $\delta_t: \mathbb{R}^n \rightarrow \mathbb{R}^n$

$$\delta_t(x_1 \cdots x_N) = (tx_1, \dots, t^N x_N).$$

We refer to N as the order of the graded vector space. We say that a polynomial function h on \mathbb{R}^n is homogeneous of degree k if $h \circ \delta_t(x) = t^k h(x)$ for each $x \in \mathbb{R}^n$. The vector space of all homogeneous polynomials of degree k will be denoted by Q^k . A vector field X on \mathbb{R}^n , with polynomial coefficients, is said to be homogeneous of degree m , $0 \leq m \leq N$, if for each $k \geq 0$ and each $h \in Q^k$, $L_X(h) \in Q^{k-m}$. We set $Q^k = 0$ for each $k < 0$. The vector space of all homogeneous vector fields of degree m will be denoted by P^m . We set

$$V^m = P^N \oplus P^{N-1} \oplus \cdots \oplus P^m, \quad C^m = Q^m \oplus Q^{m-1} \oplus \cdots \oplus Q^0.$$

A one form ω on \mathbb{R}^n , with polynomial coefficients, is said to be homogeneous of degree m , if for each k , $0 \leq k \leq N$ and each $X \in P^k$, $\omega(X) \in Q^{m-k}$. We may represent the space of all closed one forms on \mathbb{R}^n , homogeneous of degree m by dQ^m . Let Z^k be the space of constant vector fields in P^k , and W^k the space of constant one forms, homogeneous of degree k . Z^k is spanned by $\partial/\partial x_k^i$ and W^k is spanned by dx_k^i , $1 \leq i \leq n_k$. If $h \in C^m$ and $X \in V^k$ then $L_X(h) \in C^{m-k}$, which may be expressed in the form $dC^m(V^k) \subset C^{m-k}$.

The following sequence of facts are readily verifiable using the definitions above:

$$(5) \quad P^j = \bigoplus_{k=j}^N (Q^{k-j} \otimes Z^k), \quad 1 \leq j \leq N, \quad P^0 = \bigoplus_{k=1}^N (Q^k \otimes Z^k),$$

$$(6) \quad V^j = \bigoplus_{k=j}^N (C^{k-j} \otimes Z^k), \quad 1 \leq j \leq N, \quad V^0 = \bigoplus_{k=1}^N (C^k \otimes Z^k),$$

$$(7) \quad dQ^j \subset \bigoplus_{k=1}^j (Q^{j-k} \otimes W^k), \quad dC^j \subset \bigoplus_{k=1}^j (C^{j-k} \otimes W^k),$$

$$(8) \quad Q^k \otimes P^m \subset P^{m-k}, \quad Q^k \otimes Q^m \subset Q^{k+m},$$

$$(9) \quad [P^k, P^m] \subset P^{m+k}, \quad [V^k, V^m] \subset V^{m+k}.$$

Example 1. If $\mathbb{R}^3 = \mathbb{R} \oplus \mathbb{R}^2$ is a graded vector space of order $N=3$, $n_1=1$, $n_2=2$, $n_3=0$, then we may express $x \in \mathbb{R}^3$ as (x_1^1, x_2^1, x_2^2) . It follows that $x_2^2 + x_2^1 x_1^1 \in C^3$, while $x_2^2 \in Q^2$ and $x_2^1 x_1^1 \in Q^3$. $(x_1^1)^2 \partial / \partial x_1^1 + x_2^1 \partial / \partial x_2^1 \in P^0$ and $\partial / \partial x_1^1 \in P^1$.

Example 2. If $\mathbb{R}^3 = \mathbb{R} \oplus \mathbb{R} \oplus \mathbb{R}$ is a graded vector space of order $N=3$, $n_1=1$, $n_2=1$, $n_3=1$, then we may express $x \in \mathbb{R}^3$ as (x_1^1, x_2^1, x_3^1) . It follows that $x_3^1 \in Q^3$, $\partial / \partial x_1^1 + x_2^1 \partial / \partial x_3^1 \in P^1$ and $(x_1^1)^2 \partial / \partial x_2^1 + (x_2^1 + (x_1^1)^3) \partial / \partial x_3^1 \in V^0$, while $x_2^1 \partial / \partial x_3^1 \in P^1$ and $(x_1^1)^2 \partial / \partial x_2^1 + (x_1^1)^3 \partial / \partial x_3^1 \in P^0$.

Example 3. If $\mathbb{R}^2 = \mathbb{R} \oplus \mathbb{R}$ is a graded vector space of order $2=N$, $n_1=n_2=1$ we may express $x \in \mathbb{R}^2$ as $x = (x_1^1, x_2^1)$. Thus $x_2^1 \in Q^2$, $\partial / \partial x_1^1 \in P^1$ and $(x_1^1)^2 \partial / \partial x_2^1 \in P^0$.

Consider the following system on \mathbb{R}^n :

$$(10) \quad \begin{aligned} \dot{x} &= F(x) + \sum_{i=1}^m u_i G_i(x), \quad x \in \mathbb{R}^n, \quad x(0) = 0, \\ y_i &= H_i(x), \quad 1 \leq i \leq p. \end{aligned}$$

If \mathbb{R}^n is a graded vector space of (order N) we say that the system is in graded polynomial form (g.p.f.) if $F \in V^0$, $G_i \in V^1$, $1 \leq i \leq m$, and $H_i \in C^N$, $1 \leq i \leq p$, relative to the graded structure described above. With the aid of the identities (6) we may write a system (10) in g.p.f. using the coordinates (x_1, \dots, x_N) , as

$$(11) \quad \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \vdots \\ \dot{x}_N \end{bmatrix} = \begin{bmatrix} A_1 x_1 + a_1 \\ A_2 x_2 + a_2(x_1) \\ \vdots \\ A_N x_N + a_N(x_1 \cdots x_{N-1}) \end{bmatrix} + \sum_{i=1}^m u_i \begin{bmatrix} b_{i1} \\ b_{i2}(x_1) \\ \vdots \\ b_{iN}(x_1 \cdots x_{N-1}) \end{bmatrix} \begin{bmatrix} x_1(0) \\ x_2(0) \\ \vdots \\ x_N(0) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix},$$

$$y_i = H_i(x_1 \cdots x_N).$$

Here $a_j(x_1 \cdots x_{j-1})$ represents a vector in \mathbb{R}^{n_j} with components in C^j , $b_{ij}(x_1 \cdots x_{j-1})$ represents a vector in \mathbb{R}^{n_j} with components in C^j , and $H_i(x_1 \cdots x_N)$ belong to C^N .

We claim that any system (10), in g.p.f., has an input-output map described by a finite Volterra series of length not greater than N . To show this, let $\mathcal{H}^i = \mathcal{H} \cap C^{N-i}$, $0 \leq i \leq N$ where \mathcal{H} is the observation space of the system. Since \mathcal{H} is comprised of polynomial functions in C^N , \mathcal{H} is a finite-dimensional vector space as required in (i) of Theorem 2. Since $\mathcal{F} \in V^0$, and $G_i \in V^1$, we see that the sequence of subspaces \bar{H}^i defined above satisfies the conditions (ii)(b) of Theorem 2. In case $\bar{\mathcal{H}}^N = \mathcal{H} \cap C^0$ is nonempty condition (ii)(a) is also satisfied, and the system has a Volterra series of length N . The length of the Volterra series, in the case where $\bar{\mathcal{H}}^N$ is empty, is equal to the smallest integer k such that $\bar{\mathcal{H}}^k$ contains the constant functions.

It follows that the graded polynomial form defined here is exclusively used to describe realizations of finite Volterra series. Note that in the definition relating to system (10) we have not required that $F(0)=0$, but this can be imposed very easily. Note also that there is no loss of generality in assuming that $x(0)=0$, since a change of coordinates ensuring this leaves the graded structure invariant.

We now consider the structure of the Lie algebra of a system in g.p.f. If \mathcal{R}^1 is the subspace of \mathcal{L} spanned by the vector fields $ad^k f(g_i)$, $k \geq 0$, $1 \leq i \leq m$, for a general system (1), and \mathcal{S} is the ideal of \mathcal{L} generated by \mathcal{R}^1 we make the following inductive definitions. $\mathcal{S}^1 = \mathcal{S}$, $\mathcal{S}^m = [\mathcal{S}^1, \mathcal{S}^{m-1}]$ and $\mathcal{R}^m = [\mathcal{R}^1, \mathcal{R}^m]$. In Theorem 3.2 of Crouch [2], it is shown that a minimal realization of a finite Volterra series of length N has an ideal \mathcal{S} , which is nilpotent, and $\mathcal{S}^{N+1} = \{0\}$.

It follows that $\mathcal{R}^{N+1} = \{0\}$ and for $1 \leq i \leq N$

$$\mathcal{S}^i = \mathcal{R}^N + \mathcal{R}^{N-1} + \dots + \mathcal{R}^i.$$

Assuming the system (10), defined on a graded vector space of order N , is in g.p.f. we may define the subspaces $\bar{\mathcal{S}}^i = \mathcal{S} \cap V^i$ of \mathcal{S} for $1 \leq i \leq N+1$. From the relation (9) we deduce that $\bar{\mathcal{S}}^i$ is in fact a sequence of ideals of \mathcal{S} such that $\bar{\mathcal{S}}^i / \bar{\mathcal{S}}^{i+1}$ is an abelian Lie algebra with $\bar{\mathcal{S}}^{N+1} = \{0\}$, and

$$\bar{\mathcal{S}}^N \subset \bar{\mathcal{S}}^{N-1} \subset \dots \subset \bar{\mathcal{S}}^2 \subset \bar{\mathcal{S}}^1.$$

It follows that \mathcal{S} is also a nilpotent Lie algebra (see Humphreys [24]), and in fact we have $\mathcal{S} = \mathcal{S}^1 = \bar{\mathcal{S}}^1 = \mathcal{S} \cap V^1$, $\mathcal{S}^i = (\bar{\mathcal{S}}^1)^i = (\mathcal{S} \cap V^1)^i \subset \mathcal{S}^i \cap V^i \subset \mathcal{S} \cap V^i = \bar{\mathcal{S}}^i$ for $1 \leq i \leq N$. Hence $\mathcal{S}^{N+1} \subset \bar{\mathcal{S}}^{N+1} = \{0\}$. Thus the Lie algebra of system (10) in g.p.f. has the same structure as the Lie algebra in a minimal realization of a finite Volterra series.

To state the main result of Crouch [2] we introduce another definition. We say a realization of a finite Volterra series of length N defined on a graded vector space \mathbb{R}^n of order N is in graded controllable polynomial form (g.c.p.f.) if it is in g.p.f. and

$$(12) \quad V^i(0) = \mathcal{S}^i(0), \quad 1 \leq i \leq N$$

where $V^i(0)$ and $\mathcal{S}^i(0)$ are the subspaces of $T_0\mathbb{R}^n = \mathbb{R}^n$ spanned by the corresponding Lie algebras of vector fields evaluated at $x=0$.

From this definition we see that the dimensions n_i of the subspaces \mathbb{R}^{n_i} in the graded vector space are related to the structure of the system by the relation

$$n_i = \text{Dim } \mathcal{S}^i(0) - \text{Dim } \mathcal{S}^{i+1}(0).$$

In particular, since the dimension of $\mathcal{S}^i(x)$, $x \in \mathcal{M}$ is the same for any minimal realization of a finite Volterra series; any two minimal realizations of the same finite Volterra series of length N both in g.c.p.f. must be defined on the same graded vector space $\mathbb{R}^n = \mathbb{R}^{n_1} \oplus \mathbb{R}^{n_2} \oplus \dots \oplus \mathbb{R}^{n_N}$. In particular the integers n_i , $1 \leq i \leq N$ are invariants, and coincide with those integer invariants introduced in Crouch [2].

Of course, the existence of minimal realizations of finite Volterra series in g.c.p.f. has not yet been established. This is, however, one of the main results in Crouch [2].

THEOREM 3 (Crouch [2]). *A finite Volterra series which has a realization in the form of system (1), where $f + \sum_{i=1}^m \alpha_i g_i$, $\alpha_i \in \mathbb{R}$, are complete vector fields, is also realizable by a minimal system in graded controllable polynomial form. In particular, the state space of a minimal realization is a Cartesian space \mathbb{R}^n for some $n > 0$.*

We now single out some special properties of realizations of finite Volterra series in g.p.f. which are useful in subsequent sections.

LEMMA 2. *If system (10) is a realization of a finite Volterra series of length N , which is in g.c.p.f. the Lie algebra \mathcal{S} contains vector fields of the form*

$$(13) \quad \frac{\partial}{\partial x_i^j} + \sum_{k>i}^m r_k^m(x_1 \dots x_{k-i}) \frac{\partial}{\partial x_k^m}, \quad 1 \leq i \leq N, \quad 1 \leq j \leq n_i$$

with $r_k^m \in C^{k-i}$.

Proof. Since the system is in g.c.p.f., $\mathcal{S}^i(0)/\mathcal{S}^{i+1}(0) = V^i(0)/V^{i+1}(0)$, $1 \leq i \leq N$, which by property (6) is isomorphic to \mathbb{R}^{n_i} , we may select vector fields $X_i^j \in \mathcal{S}^i$ such that their image in $\mathcal{S}^i(0)/\mathcal{S}^{i+1}(0)$ is $\partial/\partial x_i^j$ for $i \leq j \leq n_i$. Since $X_i^j \in \mathcal{S}^i \subset V^i$ it follows that it has the form given in expression (13), \square

Notice that the above result shows that we may replace the condition in (12) by the condition

$$V^i(x) = \mathcal{S}^i(x), \quad x \in \mathbb{R}^n, \quad 1 \leq i \leq N.$$

In particular, $T_x \mathbb{R}^n = \mathbb{R}^n = V^1(x) = \mathcal{S}(x)$ for $x \in \mathbb{R}^n$, so a system (10) in g.c.p.f. with $F(0) = 0$ is controllable.

LEMMA 3. *Let \sum_i , $i = 1, 2$ be two minimal realizations of the same input-output map, each in g.p.f. on a graded vector space \mathbb{R}^n of order N , and let $\Phi: \mathbb{R}^n \rightarrow \mathbb{R}^n$ be the state space isomorphism as guaranteed by Sussmann [10]. Then Φ is a polynomial mapping.*

Proof. We use the notation of Lemma 1 with $M^{n_i} = \mathbb{R}^n$, $i = 1, 2$. Thus $\Phi(x_1^u(t)) = x_2^u(t)$ for all inputs u and $t \geq 0$. Let \sum_1' be the system whose dynamics are those of \sum_1 with outputs $y_i = \Phi^i(x_1)$, $1 \leq i \leq n$, and let \sum_2' be the system whose dynamics are those of \sum_2 with outputs $y_i = x_2^i$, $1 \leq i \leq n$. Both \sum_1' and \sum_2' are therefore minimal realizations of the same input-output map. Thus, as shown in Crouch [2],

$$L_{X_1} L_{X_2} \cdots L_{X_k}(\phi) = 0$$

for all $X_i \in \mathcal{S}_2 \subset \mathcal{L}_2$, $\phi \in \mathcal{H}_2$, $k \geq N+1$, relative to \sum_2' . In particular, since \sum_1' and \sum_2' are also isomorphic,

$$L_{Y_1} L_{Y_2} \cdots L_{Y_k}(\psi) = 0$$

for all $Y_i \in \mathcal{S}_1 \subset \mathcal{L}_1$, $\psi \in \mathcal{H}_1$, $k \geq N+1$. We may now set $\psi = \Phi^i$, $1 \leq i \leq n$, so arguing as in Crouch [2], or Collingwood [20], we see that each Φ^i is a polynomial function. Thus Φ is a polynomial mapping. \square

The isomorphism Φ in Lemma 3 must also be such that Φ^{-1} is also a polynomial mapping, as is easily observed by interchanging the roles of \sum_1 and \sum_2 . Thus, the state space isomorphisms intertwining minimal realizations of finite Volterra series, in g.p.f., have a very special structure. We exploit this fact in the next section.

4. Graded observable polynomial forms for realizations of finite Volterra series. In this section we construct minimal realizations of finite Volterra series, in g.p.f. based on the structure of the observation space \mathcal{H} . We first make the principal definition. A realization of a finite Volterra series of length N , defined on a graded vector space \mathbb{R}^n of order N , is said to be in graded observable polynomial form (g.o.p.f.) if it is in g.p.f. and

$$(14) \quad dC^{N-k}(0) = d\hat{\mathcal{H}}^k(0), \quad 0 \leq k \leq N-1$$

where $dC^k(0)$ and $d\hat{\mathcal{H}}^k(0)$ are the subspaces of $T_0^* \mathbb{R}^n = \mathbb{R}^n$ spanned by the corresponding spaces of one forms evaluated at $x = 0$. $\hat{\mathcal{H}}^k$ as defined in Theorem 2, is the subspace of \mathcal{H} spanned by all functions of the form

$$L_{f^{k_0}} L_{g_{i_1}} L_{f^{k_1}} L_{g_{i_2}} \cdots L_{g_{i_r}} L_{f^{k_r}}(h_j) \quad \text{for } 1 \leq j \leq p, \quad k_i \geq 0, \quad 1 \leq i_j \leq m \text{ and } k \leq r \leq N.$$

Recalling the property (7) we see that if the graded vector space in the above definition is expressed as

$$\mathbb{R}^n = \mathbb{R}^{m_1} \oplus \mathbb{R}^{m_2} \oplus \cdots \oplus \mathbb{R}^{m_N}$$

then the dimensions m_i are related to the system by the equations

$$m_{N-i+1} = \text{Dim } d\hat{\mathcal{H}}^{i-1}(0) - \text{Dim } d\hat{\mathcal{H}}^i(0).$$

In particular, since the dimension of $d\hat{\mathcal{H}}^i(x)$, $x \in M$ is the same for any minimal realization of a finite Volterra series (see Crouch [2]); any two minimal realizations of a finite Volterra series of length N , both in g.o.c.f., must be defined on the same graded vector space. In particular, the integers m_i , $1 \leq i \leq N$ are invariants.

Our next result shows that minimal realizations of finite Volterra series in g.o.p.f. do in fact exist.

THEOREM 4. *A finite Volterra series that has a realization in the form of system (1), where $f + \sum_{i=1}^m \alpha_i g_i$, $\alpha_i \in \mathbb{R}$ are complete vector fields, is also realizable by a minimal system in graded observable polynomial form. The observation space of the system in this representation contains all the coordinate functions.*

Proof. Using standard realization theory as in Sussmann [10], we may assume that we are given a minimal realization of the finite Volterra series, with length N , represented by the system (1) in which the vector fields are complete. As in Crouch [2], we may assume that the state space is $\mathbb{R}^N = M$. By observability $d\mathcal{H}(x) = T_x^* M$ for each $x \in M$, where $x \rightarrow d\mathcal{H}(x)$ is the distribution in the cotangent bundle $d\mathcal{H}(x) = \{dh(x); h \in \mathcal{H}\}$. We select a basis for $d\mathcal{H}(x_0)$ as follows. Let $\phi_{N-1}^1 \cdots \phi_{N-1}^{m_{N-1}} \in \hat{\mathcal{H}}^{N-1} = \mathcal{O}^{N-1}$, as defined in Theorem 2, be such that $d\phi_{N-1}^1(x_0) \cdots d\phi_{N-1}^{m_{N-1}}(x_0)$ is a basis for $d\hat{\mathcal{H}}^{N-1}(x_0)$. Define the basis inductively, by completing the basis for $d\hat{\mathcal{H}}^k(x_0)$, to a basis for $d\hat{\mathcal{H}}^{k-1}(x_0)$ using elements $\phi_{k-1}^1 \cdots \phi_{k-1}^{m_{N-1-k+1}} \in \mathcal{O}^{k-1}$ such that $d\phi_{k-1}^1(x_0) \notin d\hat{\mathcal{H}}^k(x_0)$, $d\phi_{k-1}^1(x_0) \cdots d\phi_{k-1}^{m_{N-1-k+1}}(x_0)$ are linearly independent and together with $d\hat{\mathcal{H}}^k(x_0)$ span $d\hat{\mathcal{H}}^{k-1}(x_0)$.

It is shown in Proposition 4.6 of Crouch [2] that $d\hat{\mathcal{H}}^k(x)$ are constant-dimensional distributions on M for $N-1 \geq k \geq 0$. In fact, if $S \subset \text{Diff}(M)$ is the connected Lie transformation group of M with Lie Algebra \mathcal{S} , by controllability S acts transitively on M and if $\gamma \in S$, $d\phi \in d\hat{\mathcal{H}}^r$ then $\gamma^* d\phi(\gamma(x_0)) = d\phi(x_0) + \omega(x_0)$ where $\omega(x_0) \in d\hat{\mathcal{H}}^{r+1}(x_0)$. Since γ^* is an isomorphism, one deduces that $d\phi_{N-1}^i(x)$ span $d\hat{\mathcal{H}}^{N-1}(x)$ for all $x \in M$, $1 \leq i \leq m_1$. Similarly, an inductive argument shows that $d\phi_k^1(x), \dots, d\phi_k^{m_{N-k}}(x)$ span $d\hat{\mathcal{H}}^k(x)$ for each k , and in particular for $k=0$, when $d\hat{H}^0(x) = T_x^* M$.

We now differentiate these elements of \mathcal{H} along solutions of (1), to construct the desired realization. In particular

$$\frac{d}{dt} \phi_j^k(x(t)) = L_f \phi_j^k(x(t)) + \sum_{i=1}^m u_i L_{g_i} \phi_j^k(x(t)).$$

Since $\phi_j^k \in \hat{\mathcal{H}}^j$, $L_f \phi_j^k \in \hat{\mathcal{H}}^j$, $L_{g_i} \phi_j^k \in \hat{\mathcal{H}}^{j+1}$ and $d\phi_{N-1}^1(x), \dots, d\phi_j^{m_{N-j}}(x)$ span $d\hat{\mathcal{H}}^j(x)$ there exist analytic functions F_j^k, G_{ij}^k such that

$$L_f \phi_j^k(x) = F_j^k(\phi_{N-1}^1(x), \dots, \phi_j^{m_{N-j}}(x)),$$

$$L_{g_i} \phi_j^k(x) = G_{ij}^k(\phi_{N-1}^1(x), \dots, \phi_{N-1}^{m_{N-1}}(x)).$$

Moreover, since $h_i \in \mathcal{H}$ for $1 \leq i \leq p$, there exist analytic functions \hat{h}_i such that

$$h_i(x) = \hat{h}_i(\phi_{N-1}^1(x), \dots, \phi_0^{m_N}(x)).$$

We now set $\hat{x}_r(t) = (\phi_{N-r}^1(x(t)), \dots, \phi_{N-r}^{m_{N-r}}(x(t))) = (\hat{x}_r^1(t), \dots, \hat{x}_r^{m_r}(t))$, and let \hat{f}_r represent the vector with components F_{N-r}^k , $1 \leq k \leq m_r$ and \hat{g}_{ir} represent the vector with components $G_{i,N-r}^k$, $1 \leq k \leq m_r$. It now follows that we have the following representation

for system (1):

$$(15) \quad \begin{bmatrix} \dot{\hat{x}}_1 \\ \dot{\hat{x}}_2 \\ \vdots \\ \dot{\hat{x}}_N \end{bmatrix} = \begin{bmatrix} \hat{f}_1(\hat{x}_1) \\ \hat{f}_2(\hat{x}_1, \hat{x}_2) \\ \vdots \\ \hat{f}_N(\hat{x}_1, \dots, \hat{x}_N) \end{bmatrix} + \sum_{i=1}^m u_i \begin{bmatrix} \hat{g}_{i1} \\ \hat{g}_{i2}(\hat{x}_1) \\ \vdots \\ \hat{g}_{iN}(\hat{x}_1, \dots, \hat{x}_{N-1}) \end{bmatrix} \begin{bmatrix} \hat{x}_1 \in \mathbb{R}^{m_1} \\ \hat{x}_2 \in \mathbb{R}^{m_2} \\ \vdots \\ \hat{x}_N \in \mathbb{R}^{m_n} \end{bmatrix},$$

$$y_i = \hat{h}_i(\hat{x}_1, \dots, \hat{x}_N).$$

Since each component $F_j^k(\phi_{N-1}^1(x), \dots, \phi_j^{m_{N-j}}(x))$ of \hat{F}_{N-j} lies in $\hat{\mathcal{H}}^j$, and $\phi_j^k(x) \in \hat{\mathcal{H}}^j$, viewed as outputs of system (1), they give rise to Volterra series of length at most $N-j$. Thus, with respect to the graded structure defined by system (15)

$$\mathbb{R}^n = \mathbb{R}^{m_1} \oplus \mathbb{R}^{m_2} \oplus \dots \oplus \mathbb{R}^{m_n},$$

we see that $F_j^k(\hat{x}_1, \dots, \hat{x}_{N-j}) \in C^{N-j}$. Similarly, $G_{ij}^k(\hat{x}_1 \dots \hat{x}_{N-j+1}) \in C^{N-j+1}$ and $\hat{h}_i(\hat{x}_1, \dots, \hat{x}_N) \in C^N$. Thus system (15) is in g.p.f. with respect to the graded structure.

The Jacobian of the map $\Phi: M \rightarrow \mathbb{R}^n$ defined by $\Phi(x) = (\phi_{N-1}^1(x), \dots, \phi_0^{m_N}(x))$ has by construction full rank at each point $x \in M$. It follows that system (15) is a complete, controllable, and observable realization of the original Volterra series on the range of Φ . However, as in Corollary 3.8 of Crouch [2], any such realization is also minimal, so the range of Φ must be \mathbb{R}^n , and system (15) is the desired minimal realization of the Volterra series in g.p.f.

By mimicking the proof of Theorem 1, it is clear that the observation space of system (15) also contains all the coordinate functions $\hat{x} \rightarrow \hat{x}_j^i$, $1 \leq i \leq m_j$. In particular $d\hat{\mathcal{H}}^k(\Phi(x_0))$ is spanned by $d\hat{x}_1^1 \dots d\hat{x}_{N-k}^{m_{N-k}}$ and so condition (14) is satisfied, showing that the system is also in g.o.p.f. Finally, we claim that we may assume that $\Phi(x_0) = 0$ without affecting any of the above results. But this is clear since it contains the constant functions so we may modify each basis function ϕ_j^k to obtain the desired result. \square

An immediate corollary of this result is that the observation algebra of the realization (15) obtained above is equal to $\mathbb{R}[\hat{x}_1^1 \dots \hat{x}_N^{m_N}]$. However, this result is true more generally, as we now demonstrate.

LEMMA 4. *If system (15) is a realization of a finite Volterra series of length N , which is in g.o.p.f., the observation algebra \mathcal{H} contains functions of the form*

$$(16) \quad \hat{x}_i^j + S_i^j(\hat{x}_1^1 \dots \hat{x}_{i-1}^{m_{i-1}}), \quad 1 \leq i \leq N, \quad i \leq j \leq m_i$$

where $S_i^j \in C^i$.

Proof. Since the system is in g.o.p.f.

$$d\hat{\mathcal{H}}^{N-i}(0)/d\hat{\mathcal{H}}^{N-i+1}(0) = dC^i(0)/dC^{i-1}(0), \quad 1 \leq i \leq N,$$

which by property (7) is isomorphic to \mathbb{R}^{m_i} . We may select one form $d\phi_j^i \in d\hat{\mathcal{H}}^{N-i}$ such that their image in $d\hat{\mathcal{H}}^{N-i}(0)/d\hat{\mathcal{H}}^{N-i+1}(0)$ is dx_i^j for $1 \leq j \leq m_i$. But since $d\phi_j^i \in d\hat{\mathcal{H}}^{N-i} \subset dC^i$ the expression in (16) follows immediately. \square

From Lemma 4 one deduces immediately that any system in g.o.p.f. has an observation algebra equal to $\mathbb{R}[\hat{x}_1^1 \dots \hat{x}_N^{m_N}]$. This result and the remark following the proof of Theorem 4 may be viewed as a restatement of a similar result obtained in Fliess [16], although the result there is only local. Note also that Lemma 4 shows that in the definition of g.o.p.f., equation (14) may be replaced by $dC^{N-k}(x) = d\hat{\mathcal{H}}^k(x)$, $0 \leq k \leq N-1$, $x \in M$, and in particular for $k=0$ $dC^N(x) = d\hat{\mathcal{H}}^0(x) = d\mathcal{H}(x)$. Thus, a system in g.o.p.f. is always observable.

We now sharpen the result obtained above to show that any minimal system in g.p.f. has a polynomial observation algebra. Note first that if the two systems Σ_1 and

Σ_2 in Lemma 1 are minimal realizations of the same finite Volterra series, and $\mathcal{A}_1, \mathcal{A}_2$ are the observation algebras generated by the observation spaces \mathcal{H}_1 and \mathcal{H}_2 respectively, then the state space isomorphism Φ , guaranteed by Sussmann [10], induces an isomorphism of \mathcal{H}_1 and \mathcal{H}_2 and hence \mathcal{A}_1 and \mathcal{A}_2 . In the case when both systems are g.p.f., however, Lemma 3 shows that Φ has a particularly nice structure which we now exploit.

THEOREM 5. *The observation algebra of a minimal realization of a finite Volterra series in graded polynomial form is the ring of polynomials $\mathbb{R}[x_1 \cdots x_n]$ in the state coordinates $(x_1 \cdots x_n)$.*

Proof. Construct a minimal realization of the finite Volterra series in g.o.p.f. as in Theorem 4 with state $(z_1 \cdots z_n) \in \mathbb{R}^n$. Let ϕ be the state space isomorphism $\phi: \mathbb{R}^n \rightarrow \mathbb{R}^n$ $\phi(x_1 \cdots x_n) = (z_1 \cdots z_n) = z$. If $\mathcal{A} \subset \mathbb{R}[x_1 \cdots x_n]$ is the observation algebra of the original system, by the previous remarks we see that ϕ induces an isomorphism β_ϕ of \mathcal{A} onto $\mathbb{R}[z_1 \cdots z_n]$. By Lemma 3 ϕ is a polynomial mapping with a polynomial inverse. Thus, there exist $q_i \in \mathbb{R}[z_1 \cdots z_n]$ such that $q_i(z) = x_i, 1 \leq i \leq n$.

Now $(\beta_\phi)^{-1}(q_i)(x) = q_i(\phi(x)) = q_i(z) = x_i$ where $(\beta_\phi)^{-1}(q_i) \in \mathcal{A}$. Thus \mathcal{A} contains all the coordinate functions $x_1 \cdots x_n$. Since it also contains the constant functions we see that $\mathcal{A} = \mathbb{R}[x_1 \cdots x_n]$ as claimed. \square

A somewhat stronger intermediate result is given in Collingwood [20].

From Theorems 3 and 4, we see that given a finite Volterra series of length N , we may construct minimal realizations in g.c.p.f. and g.o.p.f., on graded vector spaces of order N , characterized by two sets of integers $n_1 \cdots n_N$, and $m_1 \cdots n_N$, respectively, where for $1 \leq i \leq N$

$$\begin{aligned} n_i &= \text{Dim } (\mathcal{S}^i(0)/\mathcal{S}^{i+1}(0)), \\ m_i &= \text{Dim } (d\hat{\mathcal{H}}^{N-i}(0)/d\hat{\mathcal{H}}^{N-i+1}(0)). \end{aligned}$$

One naturally asks whether these two sets of integers are identical. In general, they are not, and this is demonstrated in Examples 4 and 5 below. However, for Volterra series consisting of a single term (denoted homogeneous Volterra series in Crouch [2]), the two sets of integers are identical. Indeed, referring to § 4.4 of Crouch [2], we see that

$$\begin{aligned} m_i &= \text{Dim } (d\hat{\mathcal{H}}^{N-i}(0)/d\hat{\mathcal{H}}^{N-i+1}(0)) = \text{Dim } (d\mathcal{O}^{N-i}(0)) \\ &= \text{Dim } \mathcal{R}^i(0) = \text{Dim } (\mathcal{S}^i(0)/\mathcal{S}^{i+1}(0)) = n_i. \end{aligned}$$

In general, a system in g.p.f. which is simultaneously in g.o.p.f. and g.c.p.f. so that $n_i = m_i, 1 \leq i \leq N$, will be said to be in graded symmetric polynomial form (g.s.p.f.).

Example 4.

$$\begin{aligned} (17) \quad \dot{x}_1 &= u, & x_1(0) &= 0, \\ \dot{x}_2 &= (x_1)^2, & x_2(0) &= 0, \\ \dot{x}_3 &= x_2, & x_3(0) &= 0, \\ y &= x_3 + x_2 x_1. \end{aligned}$$

The graded structure of this system is exhibited in Example 1 with

$$(x_1, x_2, x_3) = (x_1^1, x_2^1, x_2^2) \in \mathbb{R} \oplus \mathbb{R}^2.$$

That is $N = 3, n_1 = 1, n_2 = 2, n_3 = 0$.

If $f = (x_1)^2 \partial / \partial x_2 + x_2 \partial / \partial x_3$, $g_1 = \partial / \partial x_1$ we compute $g_2 = [g_1, f] = 2x_1 \partial / \partial x_2$, $g_3 = [g_1, g_2] = 2\partial / \partial x_2$, $g_4 = [g_3, f] = 2\partial / \partial x_3$, $g_5 = [g_2, f] = 2x_1 \partial / \partial x_3$, $[g_1, g_5] = 2\partial / \partial x_3$, and

all other brackets vanish. It follows that $\mathcal{S}^3(0)=0$, $\mathcal{S}^2(0)=\text{Span}\{\partial/\partial x_3, \partial/\partial x_2, x_1\partial/\partial x_3\}=\mathbb{R}^2$, $\mathcal{S}^1(0)=\text{Span}\{\mathcal{S}^2(0), \partial/\partial x_1, x_1\partial/\partial x_2\}$, and so the system is in g.c.p.f.

If we set $h_1=x_3+x_2x_1$ we compute $h_2=L_f h_1=x_2+(x_1)^3$, $h_3=L_{g_1} h_1=x_2$, $h_4=L_f h_2=(x_1)^2$, $3h_4=L_{g_1} h_2=3(x_1)^2$, $h_4=L_f h_3=(x_1)^2$, $h_5=L_{g_1} h_4=2x_1$, $h_6=L_{g_1} h_5=2$, and all other Lie derivatives are zero. It follows that $\mathcal{H}=\text{Span}\{x_3+x_2x_1, x_2, x_1(x_1)^2, (x_1)^3, 1\}$, $\mathcal{H}^3=\text{span}\{1\}$, $\mathcal{H}^2=\text{Span}\{1, x_1\}$, $\mathcal{H}^1=\text{Span}\{1, x_1, x_2, (x_1)^2\}$. Thus, $\text{Dim } d\mathcal{H}^0(0)/d\mathcal{H}^1(0)=1$, $\text{Dim } d\mathcal{H}^1(0)/d\mathcal{H}^2(0)=1$, $\text{Dim } d\mathcal{H}^2(0)/d\mathcal{H}^3(0)=1$. Thus, system (17) is not in g.o.c.f., but is observable and hence, minimal. Note that although \mathcal{H} does not contain x_1, x_2 and x_3 , the algebra \mathcal{A} generated by \mathcal{H} does.

Example 5.

$$(18) \quad \begin{aligned} \dot{z}_1 &= u, & z_1(0) &= 0, \\ \dot{z}_2 &= (z_1)^2, & z_2(0) &= 0, \\ \dot{z}_3 &= z_2 + (z_1)^3 + z_2 u, & z_3(0) &= 0, \\ y &= z_3. \end{aligned}$$

The graded structure of this system is exhibited in Example 2 with $(z_1, z_2, z_3) = (x_1^1, x_1^2, x_1^3) \in \mathbb{R} \oplus \mathbb{R} \oplus \mathbb{R}$. That is $N=3$, $n_1=n_2=n_3=1$. Note however that there is a state space isomorphism intertwining systems (17) and (18) defined by

$$z_1 = x_1 = 1/2 h_5(x), \quad z_2 = h_3(x) = x_2, \quad z_3 = x_3 + x_2 x_1 = h_1(x).$$

Thus, systems (17) and (18) are both minimal realizations of the same finite Volterra series, and in particular, the calculations in Example 4 demonstrate that system (18) is in g.o.p.f. but not in g.c.p.f. Note that in this case, $\mathcal{H}=\text{Span}\{z_3, z_2, z_1, (z_1)^2, (z_1)^3, 1\}$, giving an example of Theorem 4.

Example 6.

$$\begin{aligned} \dot{x}_1 &= u, & x_1(0) &= 0, \\ \dot{x}_2 &= (x_1)^2, & x_2(0) &= 0, \\ y &= x_2. \end{aligned}$$

This system is minimal and has a Volterra series consisting of a single second order term. $\mathcal{S}^2(0)=\text{Span}\{\partial/\partial x_2\}$, $\mathcal{S}^1(0)=\text{Span}\{\partial/\partial x_2, x_1\partial/\partial x_2, \partial/\partial x_1\}$, $\mathcal{H}^2=\text{Span}\{1\}$, $\mathcal{H}^1=\text{Span}\{1, x_1\}$, $\mathcal{H}^0=\mathcal{H}=\text{Span}\{1, x_1, x_2, (x_1)^2\}$. Consequently, the system is in g.s.p.f., on the graded vector space of order $N=2$, $\mathbb{R}^2=\mathbb{R} \oplus \mathbb{R}$, $m_1=m_2=n_1=n_2=1$.

5. An application to algebraic estimation theory. Consider the stochastic system given in Ito form by

$$(19) \quad \begin{aligned} dx &= f(x) dt + g(x) dw, & x &\in \mathbb{R}^n, \\ dy &= h(x) dt + dv, & y &\in \mathbb{R} \end{aligned}$$

where $\{w\}$ and $\{v\}$ are independent Brownian motions and suppose that we wish to estimate some real-valued function (or statistic) $\psi(x(t))$ using the information contained in the observations process $Y(t)=\{y(s); 0 \leq s \leq t\}$. It is well known (and indeed, many excellent texts and surveys on the subject, including those of Kallianpur [25], Davis and Marcus [26] and Marcus [27], exist) that if $\hat{\psi}$ is the minimum variance, or least-squares, estimator of ψ , then there are several methods available for the calculation of $\hat{\psi}$. Here we focus our attention on only one of these algorithms, namely the recursive scheme based on the evolution equation of the unnormalized conditional density as

derived by Zakai [11], Mortensen [28] and Duncan [29]. Thus, we obtain $\hat{\psi}$ by solving the system (again in Ito form)

$$\begin{aligned} d\rho(t, x) &= \bar{F}(\rho(t, x)) dt + G(\rho(t, x)) dy, \quad \rho(0) = p_0, \\ (20) \quad \hat{\psi}(t) &= E(\psi(x(t)) | \mathcal{Y}(t)) \\ &= \int_{\mathbb{R}^n} \psi(x) \rho(t, x) dx \left[\int_{\mathbb{R}^n} \rho(t, x) dx \right]^{-1} = C_\psi(\rho), \end{aligned}$$

where \bar{F} and G are the differential operators on $C_0^\infty(\mathbb{R}^n)$ defined by

$$\begin{aligned} \bar{F}(\phi)(x) &= \frac{1}{2} \sum_{i,j=1}^n \frac{\partial^2}{\partial x_i \partial x_j} (g_i(x) g_j(x) \phi(x)) - \sum_{i=1}^n \frac{\partial}{\partial x_i} f_i(x) \phi(x), \\ G(\phi)(x) &= h(x) \phi(x), \end{aligned}$$

$f_i, g_i, 1 \leq i \leq n$ are the components of the vector fields f, g of (19) and $\mathcal{Y}(t)$ is the σ field generated by $Y(t)$. ($C_0^\infty(\mathbb{R}^n)$ is the space of smooth functions on \mathbb{R}^n with compact support.) While giving a complete solution to this filtering problem, the system described by (20) remains unsatisfactory from the point of view of applications since it has the structure of a stochastic partial differential equation. In an attempt to circumvent this problem, the concept of a finite dimensionally computable (f.d.c.) recursive statistic has been introduced. A prime objective of algebraic estimation theory is the determination of conditions under which such statistics exist.

If ψ is such a f.d.c. statistic then by definition, there is a stochastic system driven by the observations process $\{y(t)\}$ and evolving on a finite dimensional manifold, say M , which has as output the desired optimal estimate $\hat{\psi}$. For technical reasons (specifically to alleviate problems with coordinate transformations) such a system is usually described in terms of the Fisk-Stratonovich integral and thus takes the form

$$\begin{aligned} (21) \quad dz &= a(z) dt + b(z) \circ dy, \quad z(0) = z_0, \\ \hat{\psi}(t) &= c(z(t)) \end{aligned}$$

with a, b vector fields and c a real valued function on M . Now, it is reasonable, and natural, to assume that whatever data record generates the estimate, the two systems (20) and (21) should respond in the same way; thus we can think of (20) and (21) as being realizations of the same input-output map. By appealing to the Sussmann [30] and Doss [31] construction of a pathwise solution to a stochastic differential equation, and by transforming (20) into the equivalent (F-S) form we see that the underlying deterministic systems

$$\begin{aligned} (22) \quad \frac{\partial \rho}{\partial t} &= F(\rho) + uG(\rho), \quad \rho(0) = p_0, \\ \hat{\psi}(t) &= C_\psi(\rho) \end{aligned}$$

and

$$\begin{aligned} (23) \quad \frac{dz}{dt} &= a(z) + ub(z), \quad z(0) = z_0, \\ \hat{\psi} &= c(z) \end{aligned}$$

where now $F = \bar{F} - \frac{1}{2}h^2$, are also realizations of the same input-output map. Moreover, Hijab [32] has shown that (21) can be taken to be “minimal” in the sense that the corresponding system (23) is minimal. This means that we can apply the techniques used in the proof of Lemma 1 provided there is sufficient analytic structure on the state space of (22). For instance, if it contains a subspace D invariant under the (semi)-flow generated by X , for all $X \in \{F, G\}_{\text{L.A.}}$, the Lie algebra generated by F and G , and every time-analytic input produces a time-analytic output, we conclude as in Brockett [1] that there should be a homomorphism between the system Lie algebras of (22) and (23), giving a necessary condition for the existence of f.d.c. statistics. Clearly, some of the ideas used to derive this homomorphism principle are of an ad hoc nature, but the work of Hijab [33] and Michael and Chaleyat-Maurel [34], among others, has done much to place it on a more rigorous footing. Moreover, such a homomorphism can be readily found in the case that (19) is linear, and the central theme of algebraic estimation theory is its construction for more general systems.

Unfortunately, the bulk of the available evidence suggests that for most systems this approach will ultimately prove to be fruitless and, as for example, in the analysis of cubic sensor problems, preliminary Lie algebraic calculations and predictions are usually borne out by later probabilistic calculations (Hazewinkel, Marcus and Sussmann [35]). We hope to point the way towards the reasons for this paucity by applying the results of the previous sections to the system (19) under the additional assumption that the underlying deterministic system, corresponding to the equivalent (F-S) form of (19),

$$(24) \quad \begin{aligned} \dot{x} &= \hat{f}(x) + ug(x), & x(0) &= x_0, \quad x \in \mathbb{R}^n, \\ y &= h(x), \end{aligned}$$

with $\hat{f} = f - \frac{1}{2}(dg/dx)g$, is a minimal system in g.p.f. Our arguments are designed to show that there are deep connections between the estimation algebra (i.e., the Lie algebra $\Lambda \triangleq \{F, G\}_{\text{L.A.}}$) corresponding to (19) and the Weyl algebra, W_n , of all differential operators on \mathbb{R}^n with polynomial coefficients. The significance of this observation derives from Hazewinkel and Marcus' [5] result that the only homomorphisms between W_n and a Lie algebra of vector fields are trivial, suggesting, via the above arguments, that if $\Lambda \equiv W_n$, then (19) will have no f.d.c. statistics.

We shall concentrate on the following aspect of the problem. After some manipulation, it is possible to rewrite the generator F as

$$F = \frac{1}{2}L_g^{*2} + L_{\hat{f}}^* - \frac{1}{2}h^2$$

where $\phi \rightarrow L_X^*(\phi)$ is the formal adjoint (w.r.t. the L_2 inner product) of the Lie derivative operator L_X , from which it is clear that if (19) or (24) are polynomial systems on \mathbb{R}^n , $\Lambda \subset W_n$ always. However, there is the important special case, namely if (19) or (21) is linear, for which $\Lambda \neq W_n$ and it is natural to ask therefore if we can determine any other cases for which $\Lambda \neq W_n$. We show that this is equivalent to showing that Λ is not identical to an associated tensor algebra.

As in the previous sections, we denote by \mathcal{L} , \mathcal{I} , and \mathcal{H} the Lie algebra, ideal and observation space of system (24), and denote by \mathcal{L}^* the Lie algebra of differential operators generated by $L_{\hat{f}}^*$ and L_g^* . Let \mathcal{I}^* denote the ideal of \mathcal{L}^* generated by L_g^* . Finally, if F is a Lie algebra of differential operators on $C_0^\infty(\mathbb{R}^n)$, let $E(F)$ denote its enveloping algebra, which we may identify with the algebra of operators on $C_0^\infty(\mathbb{R}^n)$ comprised of repeated finite compositions of operators in F .

The following result follows immediately from these definitions and the identity $[L_X^*, h] = -L_X h$ for smooth vector fields X and smooth functions h viewed as multiplication operators on $C_0^\infty(\mathbb{R}^n)$.

LEMMA 5. $\Lambda \subset \mathbb{R}F + E(\{(\mathcal{H} + 1) \otimes (\mathcal{S}^* + 1)\}_{\text{L.A.}}) \triangleq \Omega$.

Therefore, for polynomic systems (19) we have $\Lambda \subset \Omega \subset W_n$, and so Λ can fail to equal W_n in two ways, Λ may fail to equal Ω , and Ω may fail to equal W_n . The aim of this section is to show that under appropriate conditions systems with finite Volterra series always satisfy $\Omega = W_n$. The following result, the proof of which involves a lot of tedious calculations performed in Collingwood [20], establishes that the Ito correction term $-\frac{1}{2}(dg/dx)g$ does not affect the definition of graded (symmetric) polynomial form.

LEMMA 6. *System (24) is a minimal realization of a finite Volterra series in g.p.f. (g.s.p.f.) if and only if the following system has the same property with respect to the same graded vector space.*

$$\begin{aligned}\dot{x} &= f(x) + ug(x), & x(0) &= x_0, \quad x \in \mathbb{R}^n, \\ y &= h(x).\end{aligned}$$

From this result we see that there is no ambiguity involved if we refer to the (stochastic) system (19) as being in g.p.f.

We may now state the main result of this section.

THEOREM 6. *Given a stochastic system (19) in g.p.f., such that the corresponding deterministic system (24) is minimal and in g.c.p.f., then the estimation algebra satisfies*

$$\Lambda \subset \Omega = W_n.$$

Proof. By Theorem 5 we may assume that the observation algebra of system (24) is $\mathbb{R}[x_1 \cdots x_n]$. Moreover, since system (24) is in g.p.f., $L_g^* = -L_g$ and $L_f^* = -L_f - \text{div}(f)$. Now $c = \text{div}(f) = \text{trace}(\text{diag}(A_1 \cdots A_N))$, where A_1, \dots, A_N are the matrices occurring in the representation of \hat{f} as a vector field on the graded vector space (of order N), as given in (11). Consequently, we may write $F = -L_f + \frac{1}{2}L_g^2 - \frac{1}{2}h^2 - c$, $G = h$. Since the operator consisting of multiplication by a constant commutes with Λ , we ignore the term c in the expression for F . Moreover, \mathcal{S}^* coincides with \mathcal{S} , when viewed as a space of differential operators. Since \mathcal{H} contains constant functions, we may rewrite the expression for Ω as

$$\Omega = \mathbb{R}F + E(\{\mathcal{H} \otimes (\mathcal{S} + 1)\}_{\text{L.A.}}).$$

Since we assume that system (24) is in g.c.p.f., by Lemma 2 we may assume that \mathcal{S} contains the vector fields of the form

$$\partial/\partial x_i + \sum_{j>i} r_i^j(x_1 \cdots x_{j-i})\partial/\partial x_j$$

where r_i^j are polynomials. Since Ω clearly contains $E(\mathcal{H}) = \mathbb{R}[x_1 \cdots x_n]$ and $E(\mathcal{H}) \otimes \mathcal{S}$, it also contains $\partial/\partial x_1, \dots, \partial/\partial x_n$. Thus, Ω contains the generators of W_n and hence $\Omega = W_n$ as required since $F \in W_n$ also. \square

Theorem 6 shows that the algebraic estimation problem, in the case of systems with finite Volterra series, rests on the inclusion

$$\Lambda \subset E(\{\mathcal{H} \otimes (\mathcal{S} + 1)\}_{\text{L.A.}}).$$

There seems to be considerable evidence suggesting that systems (19) in g.p.f. with

Volterra series of length greater than one satisfy $\Lambda = W_n$. Although this would imply the nonexistence of finite-dimensional filters, it may have significance for attempts to obtain approximate filters, based on a stochastic version of the approximation procedure outlined in Crouch [3].

A CONSTRUCTIVE ALGORITHM FOR SENSITIVITY OPTIMIZATION OF PERIODIC SYSTEMS*

TRYPHON T. GEORGIOU† AND PRAMOD P. KHARGONEKAR‡

Abstract. In a recent paper (A. Feintuch, P. P. Khargonekar and A. Tannenbaum, *On the sensitivity minimization problem for linear time-varying periodic systems*, this Journal, 24 (1986), pp. 1076–1085), the problem of weighted sensitivity optimization was considered for linear, discrete-time, periodic time-varying systems. Here we present a constructive algorithm for solving this problem.

Key words. sensitivity minimization, periodic systems, Hankel matrix extension problems

AMS(MOS) subject classifications. 93B50, 30D50

1. Introduction. Zames formulated the weighted sensitivity optimization problem in his seminal paper [14]. Since then, this problem has been thoroughly investigated for linear time-invariant systems by many researchers. We refer the interested reader to the recent survey paper of Francis and Doyle [7] for a good exposition and a complete bibliography. Feintuch and Francis [5] considered this and related problems for linear time-varying systems. Our work is motivated by the recent paper [6] of Feintuch, Khargonekar and Tannenbaum where the problem of weighted sensitivity optimization for linear, discrete-time, periodic time-varying systems is considered. In [6] a formula for minimal weighted sensitivity was derived and the existence of an optimal controller was established. Motivated by possible applications to multirate sampled data systems, here we present a constructive algorithm for the computation of optimal controllers. Our algorithm is based on a simple new way of solving the one step extension problem for finite rank block Hankel matrices. The one-step extension problem for general Hankel operators has been investigated in the masterful work of Adamjan, Arov and Krein [1]. The interested reader is also referred to the recent book [12] by Power for certain related extension problems.

In [10], Khargonekar, Poolla and Tannenbaum showed that to any p -output, m -input, N -periodic, causal, linear, discrete-time system, one can associate a pN -output, mN -input causal linear *time-invariant* system with transfer function $P(z)$ such that $P(\infty)$ is (block) *lower triangular*. Indeed, lower triangularity is closely related to causality. Feintuch, Khargonekar and Tannenbaum [6] showed that the weighted sensitivity minimization problem of Zames [14] for periodic systems can be reduced to the following problem: Given a $pN \times mN$ transfer matrix $T(z)$ with no poles on the unit circle, find

$$(1.1) \quad \mu = \inf \{ \|T(z) - V(z)\|_{\infty} : V(z) \text{ is analytic in the complement of the open unit disc including } \infty \text{ and } V(\infty) \text{ is block lower triangular} \}.$$

This reduction is accomplished using coprime factorizations, Youla parametrization of all stabilizing controllers, and inner-outer factorizations. (There exist good algorithms for these factorizations, e.g., see Doyle [4], Khargonekar and Sontag [11], Vidyasagar [13], and the references cited there.)

A formula for μ in (1.1) was given by Feintuch, Khargonekar and Tannenbaum [6]. This formula shows that μ is the maximum of the norms of N Hankel operators. Our paper is devoted to a constructive algorithm to obtain $V(z)$ to solve (1.1) for the special case of rational $T(z)$. This algorithm combined with techniques for coprime and inner-outer factorizations gives a complete constructive algorithm for obtaining optimal controllers for weighted sensitivity minimization of periodic systems.

2. Main results. It has been shown by Feintuch, Khargonekar and Tannenbaum [6] that the weighted sensitivity minimization of Zames [14] for N -periodic linear time-varying finite-dimensional plants can be reduced to the following *best approximation* problem: Given a (possibly unstable) rational $pN \times mN$ matrix $T(z)$, find

$$(1.1) \quad \mu = \inf \{ \|T(z) - V(z)\|_\infty : V(z) \text{ with entries in } RH_\infty^{pN \times mN} \text{ such that } V(\infty) \text{ is lower block triangular} \}.$$

It is assumed that $T(z)$ has no poles on the unit circle. Here RH_∞ denotes the space of all rational functions with real coefficients which are analytic in the complement of the open unit disc (including infinity). Each $pN \times mN$ matrix is considered as an $N \times N$ square matrix with $p \times m$ block entries. The key constraint here is that $V(\infty)$ is required to be block lower triangular. (This corresponds to causality; see [6].) A formula for μ was given by Feintuch, Khargonekar and Tannenbaum [6] and it was also shown that a $V(z)$ achieving the minimum exists. Our main result is to give a *constructive algorithm* to obtain $V(z)$ which in turn can be used to obtain the optimal controller. We should also note that a solution to this problem will also be a key step in solving the general H^∞ -optimization problem of Doyle [4] in the setting of periodic systems.

Let

$$T(z) = \sum_{j=-\infty}^{\infty} \gamma_j z^{-j}$$

be the Fourier series expansion of $T(z)$ (which converges on an open set containing the unit circle). We are seeking a function

$$V(z) = \sum_{j=0}^{\infty} v_j z^{-j}$$

in $RH_\infty^{pN \times mN}$ such that v_0 is lower $(p \times m)$ -block triangular and $\|T - V\|_\infty$ is minimized. Our solution is to first obtain v_0 with the required constraint, and then obtain the rest of $V(z)$ using Glover's algorithm [9].

From the work of Adamjan, Arov and Krein [1] we know that

$$\inf_{\tilde{V}} \|T(z) - v_0 - \tilde{V}(z)\|_\infty$$

where $\tilde{V}(z) = \sum_{j=1}^{\infty} v_j z^{-j}$ is in $z^{-1}RH_\infty^{pN \times mN}$, is equal to the norm of the Hankel operator.

$$\Gamma_e = \begin{bmatrix} D & \gamma_{-1} & \gamma_{-2} & \cdots \\ \gamma_{-1} & \gamma_{-2} & \gamma_{-3} & \cdots \\ \gamma_{-2} & \gamma_{-3} & \gamma_{-4} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix} \quad \text{where } D = \gamma_0 - v_0.$$

The operator Γ_e is thought of as a bounded linear operator acting between the Hilbert spaces of square summable one-sided sequences-denoted by h_2 :

$$\Gamma_e : h_2^{mN} \rightarrow h_2^{pN}.$$

This result is the matrix version of the Nehari problem. In case $T(z) - v_0$ is a rational matrix valued function, a constructive procedure to obtain a rational $\tilde{V}(z)$ minimizing $\|T(z) - v_0 - \tilde{V}(z)\|_\infty$ is given by Glover [9], and Ball and Ran [2]. Thus, we only need to consider a one-step extension problem for the finite-rank Hankel operator given by the matrix $\Gamma = [\gamma_{1-j-k}]_1^\infty$. We want to determine an "extension" D in $R^{pN \times mN}$, subject to the given constraint that the upper block triangular part of D is specified, so that $\|\Gamma_e\|$ is minimized. In the process of solving the generalized Nehari problem, Adamjan, Arov and Krein [1] have provided a solution to a one-step extension problem for block Hankel operators. However their solution does not seem to lend itself either to an easily computable scheme in the case of finite-rank Hankel operators, or to a procedure dealing with the case where D is partially specified as is required in our case.

It is a standard result in realization theory (see the book by Fuhrmann [8]) that if Γ is a finite-rank Hankel operator, then there exists a triple of matrices (F, G, H) , where F is square $n \times n$ (n being the smallest such integer possible), H is $pN \times n$, and G is $n \times mN$, such that the entries γ_{-k} admit a factorization

$$(2.1) \quad \gamma_{-k} = HF^{k-1}G, \quad k = 1, 2, \dots$$

Moreover, this induces a factorization of Γ into a product OR , where

$$R = \begin{bmatrix} G & FG & F^2G & \dots \end{bmatrix} : h_2^{mN} \rightarrow R^n : (u_i : i = 0, 1, \dots) \rightarrow \sum_{i=0}^{\infty} F^i Gu_i,$$

and

$$O = \begin{bmatrix} H \\ HF \\ HF^2 \\ \vdots \end{bmatrix} : R^n \rightarrow h_2^{pN} : x \rightarrow (HF^i x : i = 0, 1, \dots),$$

are bounded linear maps. These are the usual *reachability* and *observability* maps and, because of minimality, are surjective and injective respectively. In view of this factorization, Γ_e is given by

$$(2.2) \quad \Gamma_e = \begin{bmatrix} D & HR \\ OG & OFR \end{bmatrix}.$$

Let P, Q, Σ, Δ be defined as follows:

$$(2.3) \quad P := RR^*, \quad Q := O^*O, \quad \Sigma := P^{1/2}, \quad \Delta := Q^{1/2},$$

where $(\)^{1/2}$ denotes the "Hermitian square root of," and $(\)^*$ denotes the "adjoint of." Also define the following *finite matrix*.

$$H_e := \begin{bmatrix} D & H\Sigma \\ \Delta G & \Delta F\Sigma \end{bmatrix}.$$

We now have the following proposition.

PROPOSITION 2.4. *With the above notation $\|\Gamma_e\| = \|H_e\|$.*

Proof. Define

$$U := \begin{bmatrix} I_{mN} & 0 \\ 0 & R^*\Sigma^{-1} \end{bmatrix} : R^{mN} + R^n \rightarrow R^{mN} + h_2^{mN},$$

$$V := \begin{bmatrix} I_{pN} & 0 \\ 0 & \Delta^{-1}O^* \end{bmatrix} : R^{pN} + h_2^{pN} \rightarrow R^{pN} + R^n,$$

where I_k denotes the $k \times k$ identity matrix. (That the indicated inverses exist follows easily from the fact that \mathbf{R} is surjective and $\mathbf{0}$ is injective.) It is easily seen that

$$\pi_{\mathbf{R}^*} := \mathbf{R}^*(\mathbf{R}\mathbf{R}^*)^{-1}\mathbf{R} : h_2^{mN} \rightarrow h_2^{mN}$$

is the orthogonal projection onto the range of \mathbf{R}^* , and that

$$\pi_{\mathbf{0}} := \mathbf{0}(\mathbf{0}^*\mathbf{0})^{-1}\mathbf{0}^* : h_2^{pN} \rightarrow h_2^{pN}$$

is the orthogonal projection onto the range of $\mathbf{0}$. It is now straightforward to verify that

$$(2.5a) \quad \mathbf{U}\mathbf{U}^* = I_{mN} + \pi_{\mathbf{R}^*},$$

$$(2.5b) \quad \mathbf{U}^*\mathbf{U} = I_{mN+n},$$

$$(2.5c) \quad \mathbf{V}^*\mathbf{V} = I_{pN} + \pi_{\mathbf{0}},$$

$$(2.5d) \quad \mathbf{V}\mathbf{V}^* = I_{pN+n}.$$

We now prove that $\Gamma_e = \mathbf{V}^*H_e\mathbf{U}^*$. Note first that $H_e = \mathbf{V}\Gamma_e\mathbf{U}$. Then

$$\begin{aligned} \mathbf{V}^*H_e\mathbf{U}^* &= \mathbf{V}^*\mathbf{V}\Gamma_e\mathbf{U}\mathbf{U}^* \\ &= \begin{bmatrix} I_{pN} & 0 \\ 0 & \pi_{\mathbf{0}} \end{bmatrix} \begin{bmatrix} D & H\mathbf{R} \\ \mathbf{0}G & \mathbf{0}F\mathbf{R} \end{bmatrix} \begin{bmatrix} I_{mN} & 0 \\ 0 & \pi_{\mathbf{R}^*} \end{bmatrix} \\ &= \begin{bmatrix} D & H\mathbf{R}\pi_{\mathbf{R}^*} \\ \pi_{\mathbf{0}}\mathbf{0}G & \pi_{\mathbf{0}}\mathbf{0}F\mathbf{R}\pi_{\mathbf{R}^*} \end{bmatrix}. \end{aligned}$$

But $\pi_{\mathbf{0}}\mathbf{0} = \mathbf{0}$, and $\mathbf{R}\pi_{\mathbf{R}^*} = \mathbf{R}[\mathbf{R}^*(\mathbf{R}\mathbf{R}^*)^{-1}\mathbf{R}] = \mathbf{R}$. Consequently,

$$\mathbf{V}^*H_e\mathbf{U}^* = \begin{bmatrix} D & H\mathbf{R} \\ \mathbf{0}G & \mathbf{0}F\mathbf{R} \end{bmatrix} = \Gamma_e.$$

Finally, from (2.5b) and (2.5d) it follows that

$$\|\Gamma_e\| = \|H_e\|,$$

and this completes the proof. \square

Thus, our original problem has now become: *Obtain D subject to the original constraints, so that it minimizes $\|H_e\|$.* Note that the entries of H_e are now finite matrices, and moreover, the quantities Σ, Δ can be obtained from (F, G, H) by first computing P and Q as solutions to the following Lyapunov equations (see [9]):

$$(2.6a) \quad P = FPF^* + GG^*,$$

$$(2.6b) \quad Q = F^*QF + H^*H,$$

and then taking the Hermitian square roots of P and Q (see (2.3)). Below, we focus on how to explicitly compute such a D , given F, G, H, Σ, Δ .

Therefore, our problem has now been reduced to obtain a $pN \times mN$ matrix D whose $(p \times m)$ -block entries above the main diagonal are completely specified by γ_0 , and which minimizes

$$\|H_e\| = \left\| \begin{bmatrix} D & H\Sigma \\ \Delta G & \Delta F\Sigma \end{bmatrix} \right\|.$$

Let D be represented by

$$D = \begin{bmatrix} x_{11} & d_{12} & d_{13} & \cdots & d_{1N} \\ x_{21} & x_{22} & d_{23} & \cdots & d_{2N} \\ \vdots & \vdots & \vdots & & \vdots \\ x_{N1} & x_{N2} & x_{N3} & \cdots & x_{NN} \end{bmatrix},$$

where the entries indicated are $p \times m$ matrices, the d 's being specified by γ_0 and the x 's representing the entries to be filled in. Define

$$\begin{aligned}\hat{H}_e &:= \begin{bmatrix} \Delta G & \Delta F \Sigma \\ D & H \Sigma \end{bmatrix}, \\ L_k &:= \begin{bmatrix} I_{n+kp} & 0 \\ 0 & 0 \end{bmatrix}, \\ R_k &:= \begin{bmatrix} 0 & 0 \\ 0 & I_{n+km} \end{bmatrix}.\end{aligned}$$

We now have the following proposition.

PROPOSITION 2.7. $\mu = \max \{ \|L_1 \hat{H}_e R_{N-1}\|, \dots, \|L_N \hat{H}_e R_0\| \}$.

The matrix $L_K \hat{H}_e R_{N-k}$ is the *top right* $(n+km) \times (n+Nm-km)$ submatrix of \hat{H}_e . Note that $L_k \hat{H}_e R_{N-k}$, for $k=0, 1, \dots, N$ are all the maximal rectangular submatrices of \hat{H}_e whose entries do not depend on the variables x . (It will be seen that the norm of $L_0 \hat{H}_e R_N$ is equal to the norm of $L_N \hat{H}_e R_0$, and this is why only one of the two appears in the expression of the above proposition.) The proof is based on the following very important result—see the book by Power [12] and also [3] for a proof of this result.

LEMMA 2.8 (Parrott, Davis–Kahan–Weinberger). *Consider the block matrix*

$$M(X) = \begin{bmatrix} C & A \\ X & B \end{bmatrix},$$

where A, B, C, X are matrices of compatible dimensions. Then

$$\alpha = \inf_X \|M(X)\| = \max \left\{ \|(C \ A)\|, \left\| \begin{pmatrix} A \\ B \end{pmatrix} \right\| \right\}.$$

Moreover, the above infimum is attained by the choice

$$(2.9) \quad X = -BA^*(\alpha^2 I - AA^*)^{-1}C.$$

In case the indicated inverse does not exist, then this should be interpreted as a pseudo-inverse. Also, in [3], one can find a description of all possible choices for X that attain this infimum.

Proof of Proposition 2.7. By the results of Adamjan, Arov and Krein [1], as we mentioned earlier, it follows that

$$\mu = \inf_{x_{ik}} \|\Gamma_e\|.$$

From Proposition 2.4 we now have that

$$\mu = \inf_{x_{ik}} \|H_e\| = \inf_{x_{ik}} \|\hat{H}_e\|,$$

where the last equality follows from the unitary equivalence of H_e and \hat{H}_e . By repeated application of Lemma 2.8 we now have that

$$\begin{aligned}\mu &= \max \{ \|(L_N \hat{H}_e R_0)\|, \inf_{\substack{x_{j1}, \dots, x_{jj} \\ 1 \leq j \leq N-1}} \|(L_{N-1} \hat{H}_e R_N)\| \} \\ &\quad \vdots \\ &= \max \{ \|(L_N \hat{H}_e R_0)\|, \dots, \|L_2 \hat{H}_e R_{N-2}\|, \inf_{x_{11}} \|L_1 \hat{H}_e R_N\| \} \\ &= \max \{ \|(L_N \hat{H}_e R_0)\|, \|(L_{N-1} \hat{H}_e R_1)\|, \dots, \|(L_0 \hat{H}_e R_N)\| \}.\end{aligned}$$

A final point to be noted is that the first and the last term of the above expression are equal. We have

$$\|(L_N \hat{H}_e R_0)\| = \left\| \begin{pmatrix} \Delta F \Sigma \\ H \Sigma \end{pmatrix} \right\| = \left\| \begin{pmatrix} H \Sigma \\ \Delta F \Sigma \end{pmatrix} \right\|.$$

But

$$\mathbf{V}^* \begin{bmatrix} H \Sigma \\ \Delta F \Sigma \end{bmatrix} \Sigma^{-1} \mathbf{R} = \begin{bmatrix} H \mathbf{R} \\ 0 F \mathbf{R} \end{bmatrix} = \Gamma,$$

and

$$\mathbf{V} \mathbf{V}^* = I_{n+pN} \quad \text{and} \quad \Sigma^{-1} \mathbf{R} \mathbf{R}^* \Sigma = I_n.$$

Consequently, $\|L_N \hat{H}_e R_0\| = \|\Gamma\|$. It follows similarly that $\|L_0 \hat{H}_e R_N\| = \|\Gamma\|$, and this completes the proof. \square

It can be readily shown that the matrices

$$L_k \hat{H}_e R_{N-k}, \quad k = 1, \dots, N,$$

are directly related to the operators $A_k, k = 1, \dots, N$ respectively, of Feintuch, Khargonekar and Tannenbaum [6], and that in fact they have equal norms. Thus, in Proposition 2.7, we have a formula for the optimal sensitivity μ , that is equivalent to the one given in [6]. But, in addition to that, the sequence of steps (2.9) in the proof of the Proposition 2.7 leads to the following procedure to obtain a $V(z)$ that solves the problem (1.1).

ALGORITHM.

1. Obtain a minimal realization (F, G, H) of the negative Fourier coefficients $(\gamma_k: k \leq -1)$ of $T(z)$; i.e., (F, G, H) satisfy (2.1).

2. Obtain P, Q by solving Lyapunov equations (2.6a) and (2.6b) and find their Hermitian square roots Σ, Δ , respectively.

3₁. Select x_{11} using (2.9) to minimize $\|L_1 \hat{H}_e R_N\|$. Note that in $L_1 \hat{H}_e R_N$, the only variable is x_{11} and the rest of $L_1 \hat{H}_e R_N$ is completely specified.

3₂. Select (x_{21}, x_{22}) to minimize $\|L_2 \hat{H}_e R_N\|$. Note that $L_2 \hat{H}_e R_N$ contains x_{11}, x_{21}, x_{22} as the only variables. In this step x_{11} obtained in step 3₁ is used. Again (2.9) is used to select (x_{21}, x_{22}) .

3_j. Select $(x_{j1}, x_{j2}, \dots, x_{jj})$ to minimize $\|L_j \hat{H}_e R_N\|$ for $j = 3, 4, \dots, N$, where the entries x_{k1}, \dots, x_{kk} , for $1 \leq k \leq j-1$ have already been determined at the previous steps. This is done by applying (2.9) to the corresponding submatrices of $L_j \hat{H}_e R_N$.

4. Let $v_0 = \gamma_0 - D$. Now using techniques of Glover [9] obtain

$$\tilde{V}(z) = \sum_{i=1}^{\infty} v_i z^{-i}$$

such that

$$\mu = \|T(z) - v_0 - \tilde{V}(z)\|_{\infty}.$$

For this last step, see also Ball and Ran [2]. Then $V(z) = v_0 + \tilde{V}(z)$ is a solution to (1.1).

We would like to note that only the elements of D are calculated by recursively applying (2.9) $(N-1)$ times. After obtaining D , the procedure of Glover [9] or Ball and Ran [2] can be used to obtain $V(z)$.

THE MAXIMUM PRINCIPLE FOR OPTIMAL CONTROL OF DIFFUSIONS WITH PARTIAL INFORMATION*

U. G. HAUSSMANN†

Abstract. We derive necessary conditions for the optimal control of a system that satisfies an Ito equation with control entering the drift term. The control is a function of a noise corrupted observation of the state, and the cost is the expectation of an integral and a final term. The robust form of the Zakai equation from nonlinear filtering is used to compute the variation of the cost due to a strong or "needle" variation of a control. This gives rise to an explicit formula for the adjoint process, much as in the case with complete information.

Key words. maximum principle, optimal control, partial information, stochastic differential equation, Zakai equation, nonlinear filtering

AMS(MOS) subject classification. 49B60

1. Introduction. Necessary conditions, satisfied by solutions of the problem,

$$(1.1) \quad \min \{J(u): u \in \mathcal{U}\},$$

$$(1.2) \quad J(u) = E \left\{ \int_0^T l(t, X_t, u(t, Y)) dt + c(X_T) \right\},$$

$$(1.3) \quad dX_t = f(t, X_t, u(t, Y)) dt + \sigma(t, X_t) dw_t, \quad X_0 = x_0,$$

$$(1.4) \quad dY_t = h(t, X_t) dt + d\tilde{w}_t, \quad Y_0 = 0,$$

have recently been given by Bensoussan [3]. The control u may depend only on Y , not X . In addition to the uniform ellipticity of $\sigma(t, x)\sigma(t, x)'$ (here σ' is the transpose of σ), he assumed much differentiability and boundedness of the functions l, c, f, σ and h as well as convexity and compactness of the set of control points U . In this work we relax most of these hypotheses thus including the linear regulator. The more difficult problem when constraints are included will be attacked elsewhere. We point out also that the method (of strong variations) cannot be extended to allow σ to depend on the control. Bensoussan [3] used the (stochastic) Zakai equation of nonlinear filtering to define the state of the separated problem and then he applied the method of weak variations to obtain the necessary conditions. The improvement here stems from using weak solutions of the robust (nonstochastic) form of the Zakai equation (Hausmann [7]), from using strong variations, and from finding an explicit representation for the adjoint process.

An attempt on this problem was made by Kushner [9], Hausmann [5], Elliott [4], Arkin and Saksonov [1], where in posing the control problem, the control u is taken to be adapted to a filtration which may be smaller than that generated by the joint process (X, Y) . Unfortunately in the work of Kushner [9] and of Arkin and Saksonov [1] this filtration must be specified a priori, i.e. independently of the control u , and hence *cannot* be the one generated by Y . This difficulty does not arise in Hausmann [5] or Elliott [4], but in those works no representation of the adjoint process is given, so again the result is not a viable maximum principle. Additionally

† Mathematics Department, University of British Columbia, Vancouver, Canada V6T 1Y4.

in these last two works σ must be nonsingular, and in the work of Elliott no state constraints are admitted and the method is inherently incapable of treating them.

In § 2 we give a precise formulation of the problem and we summarize the results from filtering theory which will be used in the sequel. In § 3 we compute the variation in J due to a variation in u , and in § 4 we apply this calculation to derive the maximum principle. We also relate this result to that of Bensoussan [3], and we interpret the adjoint process in terms of the value function. Finally as an example we consider the linear regulator.

The results established here were reported in Haussmann [6].

2. Formulation of the problem. We say that a function $f: \mathcal{X} \times \mathcal{Y} \rightarrow \mathcal{Z}$, where $\mathcal{X}, \mathcal{Y}, \mathcal{Z}$ are subsets of Euclidean spaces, is *locally uniformly continuously differentiable in x* if $f(\cdot, y)$ is continuously differentiable for each y , and for (x, y) in a compact set C , the modulus of continuity of $x \rightarrow f_x(x, y)$ depends only on C .

The following hypotheses are assumed. U is a Borel set in some Euclidean space, and \mathcal{B}^n is the family of Borel sets of \mathbf{R}^n .

(A₁) $f: [0, T] \times \mathbf{R}^n \times U \rightarrow \mathbf{R}^n$ is Borel measurable, continuous in u for each (t, x) , locally uniformly continuously differentiable in x , and for some constant K_1 ,

$$(1 + |x| + |u|)^{-1} |f(t, x, u)| + |f_x(t, x, u)| \leq K_1;$$

(A₂) $\sigma: [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}^n \otimes \mathbf{R}^m$ is Borel measurable, locally uniformly continuously differentiable in x , and for some K_2 ,

$$|\sigma(t, x)| + |\sigma_x(t, x)| \leq K_2;$$

(A₃) $h: [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}^d$ is Borel measurable, locally uniformly continuously differentiable in x , and for some K_3 ,

$$(1 + |x|)^{-1} |h(t, x)| + |h_x(t, x)| \leq K_3;$$

(A₄) $l: [0, T] \times \mathbf{R}^n \times U \rightarrow \mathbf{R}$ is Borel measurable, continuous in u for each (t, x) , locally uniformly continuously differentiable in x , and for some constants $q \geq 1, K_4$,

$$|l(t, x, u)| + |l_x(t, x, u)| \leq K_4(1 + |x|^q + |u|^q);$$

(A₅) $c: \mathbf{R}^n \rightarrow \mathbf{R}$ is continuously differentiable and for some K_5 ,

$$|c(x)| + |c_x(x)| \leq K_5(1 + |x|^q);$$

(A₆) P_0 is a probability measure on $(\mathbf{R}^n, \mathcal{B}^n)$ such that for some $\bar{q} > q + 1$,

$$\int |x|^{\bar{q}} P_0(dx) < \infty.$$

We use the following notation:

c_x is the vector $(c_{x_i}) = (\partial c / \partial x_i)$,

h^i, σ^{ij} are the components of h, σ ,

h_x is the matrix $(h_x)^{ij} = h_{x_j}^i$,

σ_x is the tensor $(\sigma_x)^{ijk} = \sigma_{x_k}^{ij}$,

$\mathcal{C}(0, T; \mathbf{R}^k)$ is the space of continuous functions $[0, T] \rightarrow \mathbf{R}^k$,

$\{\mathcal{G}_t^k\}$ is the canonical Borel filtration on $\mathcal{C}(0, T; \mathbf{R}^k)$,

$\|y\|_t = \sup \{|y(s)|: s \leq t\}$.

An *admissible control* is a function u

$$u: [0, T] \times \mathcal{C}(0, T; \mathbf{R}^d) \rightarrow U$$

which is Borel measurable, $\{\mathcal{G}_t^d\}$ adapted, and for which there exists a constant K_u such that $|u(t, y)| \leq K_u(1 + \|y\|_t)$. We write \mathcal{U} for the set of all admissible controls.

For the underlying probability space we take the canonical space of (x_0, w, Y) where (w, Y) is a standard Brownian motion on $\mathbf{R}^m \times \mathbf{R}^d$ and x_0 is an independent random variable with distribution P_0 . Hence

$$\Omega = \mathbf{R}^n \times \mathcal{C}(0, T; \mathbf{R}^m) \times \mathcal{C}(0, T; \mathbf{R}^d),$$

$$\mathcal{F} = \mathcal{B}^n \otimes \mathcal{G}_T^m \otimes \mathcal{G}_T^d,$$

$$P = P_0 \times P_w^m \times P_w^d,$$

where P_w^k is the Wiener measure on $\mathcal{C}(0, T; \mathbf{R}^k)$. The generic element ω of Ω is denoted by

$$\omega = (\xi, \zeta, \eta).$$

For $u \in \mathcal{U}$, $x \in \mathbf{R}^n$, $s \in [0, T]$, let X^u denote the unique strong solution of

$$(2.1) \quad \begin{aligned} dX_t &= f(t, X_t, u(t, Y)) dt + \sigma(t, X_t) dw_t, \quad t \geq 0, \\ X_0 &\sim P_0 \end{aligned}$$

and let X^{usx} denote the unique strong solution of

$$(2.1)' \quad \begin{aligned} dX_t &= f(t, X_t, u(t, Y)) dt + \sigma(t, X_t) dw_t, \quad t \geq s, \\ X_s &= x. \end{aligned}$$

Moreover, for $\eta \in \mathcal{C}(0, T; \mathbf{R}^d)$, let $X^{u\eta sx}$ be the unique strong solution of

$$(2.2) \quad \begin{aligned} dX_t &= f(t, X_t, u(t, \eta)) dt + \sigma(t, X_t) dw_t, \quad t \geq s, \\ X_s &= x. \end{aligned}$$

Note that $X_t^u(\omega) = X_t^{u0\xi}(\omega)$ P -a.s., and $X_t^{usx}(\omega) = X_t^{u\eta sx}(\omega)$ P -a.s.

From Girsanov's theorem it now follows that if

$$(2.3) \quad Z_t^u = \exp \left\{ \int_0^t h(r, X_r^u) \cdot dY_r - \frac{1}{2} \int_0^t |h(r, X_r^u)|^2 dr \right\},$$

and if $dP^u := Z_T^u dP$, then (X^u, Y) is a solution of (1.3), (1.4) on $(\Omega, \mathcal{F}, P^u)$, i.e., is a weak solution of (1.3), (1.4)—which moreover is unique in law. In addition,

$$J(u) = E^u \left\{ \int_0^T l(t, X_t^u, u(t, Y)) dt + c(X_T^u) \right\},$$

i.e.,

$$(2.4) \quad J(u) = E \left\{ Z_T^u \left[\int_0^T l(t, X_t^u, u(t, Y)) dt + c(X_T^u) \right] \right\}$$

where E^u denotes expectation on $(\Omega, \mathcal{F}, P^u)$. So the problem becomes

$$(2.5) \quad \min \{J(u): u \in \mathcal{U}\}$$

where J is defined by (2.4), (2.3) and (2.1).

Later we shall also require the density

$$Z_t^{usx} := \exp \left\{ \int_s^t h(r, X_r^{usx}) \cdot dy_r - \frac{1}{2} \int_s^t |h(r, X_r^{usx})|^2 dr \right\}$$

on (Ω, \mathcal{F}, P) . Again note that

$$Z_t^u(\omega) = Z_t^{u0\xi}(\omega) \quad P\text{-a.s.}$$

and that $Z_t^{u0\xi}(\omega)$ is in fact constant as a function of ξ P -a.s. (n.b. $\omega = (\xi, \zeta, \eta)$).

In what follows we shall use some concepts from differential equations for which we now introduce some notation. Let $H = L^2(R^n)$ with inner product $\langle v, g \rangle$. Define

$$H^1 := \{v \in H : \partial_i v \in H, i = 1, \dots, n\}$$

where ∂_i is the distributional derivative with respect to x_i (and ∂_0 with respect to t). Let H^{-1} be the dual of H^1 with the pairing (v, g) , $v \in H^{-1}$, $g \in H^1$. The norm in H is written as $|\cdot|_H$ and in H^1 as $\|\cdot\|$, i.e.,

$$\|v\|^2 = |v|_H^2 + \sum_{i=1}^n |\partial_i v|_H^2.$$

Then define

$$W(0, T) := \left\{ v \in L^2(0, T; H^1) : \frac{dv}{dt} \in L^2(0, T; H^{-1}) \right\}.$$

Note that dv/dt is the distributional derivative of $t \rightarrow v(t) \in H^1$ —for details cf. Bensoussan [2].

Let us use the convention that repeated indices are to be summed. Then define $a(t, x) = \sigma(t, x)\sigma(t, x)'$, where $'$ denotes transpose,

$$a_t^{ij} : x \rightarrow a^{ij}(t, x),$$

$$b_t^{u\eta i} : x \rightarrow f^i(t, x, u(t, \eta)) - \frac{1}{2} a^{ij}(t, x) \partial_j [\eta(t) \cdot h(t, x)] - \frac{1}{2} \partial_j a^{ij}(t, x),$$

$$h_t : x \rightarrow h(t, x),$$

$$\partial_0 h_t : x \rightarrow \partial_0 h(t, x) \quad (\text{when this is a function}),$$

$$F_t^{\mu\eta} : x \rightarrow l(t, x, u(t, \eta)) \exp [\eta(t) \cdot h(t, x)],$$

$$\eta_t = \eta(t).$$

It will be useful to impose temporarily an additional hypothesis.

(H)(i) $h \in C^{1,2}((0, T) \times \mathbf{R}^n)$ and there exist constants K_0, α with $\alpha > 0$ such that for all $t \in [0, T]$, $x \in \mathbf{R}^n$, $u \in U$

$$|f(t, x, u)| + |\sigma(t, x)| + |h(t, x)| + |\partial_0 h(t, x)| + \sum |\partial_i h(t, x)| + \sum |\partial_i \partial_j h(t, x)| \leq K_0,$$

$$a(t, x) \leq \alpha I,$$

$$|c|_H < \infty$$

for each $u \in \mathcal{U}$ and any compact $C \subset \mathcal{C}(0, T; \mathbf{R}^d)$

$$\sup_{\eta \in C} \int_0^T |l(t, \cdot, u(t, \eta))|_H^2 dt < \infty.$$

(H)(ii) P_0 has a density p_0 with compact support.

Now we can define, for each $t \in [0, T)$, $u \in \mathcal{U}$, $\eta \in \mathcal{C}(0, T; \mathbf{R}^d)$ a bilinear form on H^1 :

$$\begin{aligned} \mathcal{A}_t^{u\eta}(\mu, v) = & -\frac{1}{2}\langle a_t^{ij}\partial_i\mu, \partial_jv \rangle + \langle b_t^{u\eta i}\partial_i\mu, v \rangle + \frac{1}{2}\langle \partial_i(\eta_i \cdot h_t) a_t^{ij}\mu, \partial_jv \rangle \\ & - \langle [\partial_i(\eta_i \cdot h_t) b_t^{u\eta i} + \eta_i \cdot \partial_0 h_t + \frac{1}{2}|h_t|^2]\mu, v \rangle. \end{aligned}$$

The following results are established in Haussmann [7]. Let $\mathcal{F}_t^y = \{\phi, \mathbf{R}^n \times \mathcal{C}(0, T; \mathbf{R}^m)\} \otimes \mathcal{G}_t^d$ be the σ -algebra generated by $\{Y_s: 0 \leq s \leq t\}$, and let G be a measurable function

$$G: [0, T] \times \mathbf{R}^n \times \mathcal{C}(0, T; \mathbf{R}^d) \rightarrow \mathbf{R}$$

such that for any compact set C

$$(2.6) \quad \sup_{\eta \in C} \int_0^T \int_{\mathbf{R}^n} |G(t, x, \eta)|^2 dx dt < \infty.$$

PROPOSITION 2.1. Assume (A_1) – (A_6) and (H) . Let $u \in \mathcal{U}$ and write $G_t^\eta(x) = G(t, x, \eta)$. Then

(a) for each $\eta \in \mathcal{C}(0, T; \mathbf{R}^d)$ there exists a unique $\mu^{u\eta} \in W(0, t)$ such that

$$(2.7) \quad \left(\frac{d\mu_s^{u\eta}}{ds}, v \right) + \mathcal{A}_s^{u\eta}(\mu_s^{u\eta}, v) + \langle G_s^\eta \exp(\eta_s \cdot h_s), v \rangle = 0, \quad v \in H^1, \quad 0 \leq s \leq t,$$

$$\mu_t^{u\eta} = c \exp(\eta_t \cdot h_t);$$

(b) for almost all x

$$\mu_s^{uY(\omega)}(x) = E \left\{ c(X_t^{usx}) Z_t^{usx} + \int_s^t G_r^{Y(\omega)}(X_r^{usx}) Z_r^{usx} dr \middle| \mathcal{F}_T^Y \right\} (\omega) \exp[Y_s(\omega) \cdot h_s(x)];$$

(c) for each $\eta \in \mathcal{C}(0, T; \mathbf{R}^d)$ there exists a unique $\psi^{u\eta} \in W(0, T)$ such that

$$(2.8) \quad \left(\frac{d\psi_t^{u\eta}}{dt}, v \right) - \mathcal{A}_t^{u\eta}(v, \psi_t^{u\eta}) = 0 \quad \forall v \in H^1, \quad t \geq 0,$$

$$\psi_0^{u\eta} = p_0;$$

(d) $\rho_t^{uY(\omega)}(\cdot) := \psi_t^{uY(\omega)}(\cdot) \exp[Y_t(\omega) \cdot h_t(\cdot)]$ is an unnormalised conditional density of $X_t^u | \mathcal{F}_t^Y$.

Proof. In Haussmann [7, Cor. 2.1, Cor. 3.2 and Thm. 3.4] the result is established under the added hypothesis that

$$(2.9) \quad \sup_{\eta \in C} |G(t, x, \eta)| \leq K(1 + |x|^q).$$

Note that Corollary 3.1 as stated is false: in fact ν must be continuous and this hypothesis must be added throughout. Since we have $\partial_i \partial_j h$ bounded, then we can avoid (2.9) as follows. We take $c = 0$, since the quoted result covers the case $c \neq 0$, $G = 0$. Recalling that $\omega = (\xi, \zeta, \eta)$ and $Y(\omega) = \eta$ a.s. we have from Haussmann [7] that

$$\begin{aligned} \mu_s^{u\eta}(x) &= E \left\{ \int_s^t G_r^\eta(X_r^{usx}) Z_r^{usx} dr \middle| \mathcal{F}_T^Y \right\} (\omega) e^{\eta_s \cdot h_s(x)} \quad \text{a.s.} \\ &= E^\eta \int_s^t G_r^\eta(X_r^{u\eta sx}) e^{\delta_r(\eta)} dr \end{aligned}$$

provided G is also bounded. Here E^η is expectation under P^η , a measure obtained from P by a Girsanov transformation, and $X^{u\eta sx}$ satisfies

$$(2.10) \quad \begin{aligned} dX &= [f(t, X, u(t, \eta)) - a(t, X) \nabla_x (\eta_t \cdot h_t(X))] dt + \sigma(t, X) d\bar{w}, \quad t \geq s, \\ X_s &= x, \end{aligned}$$

where \bar{w} , Y are independent Brownian motions under P^η . Moreover,

$$(2.11) \quad \begin{aligned} \delta_r(\eta) &= \eta_r \cdot h_r(X_r^{u\eta sx}) - \int_s^r [\eta_\theta \cdot \partial_\theta h_\theta(X_\theta^{u\eta sx}) + \tilde{L}_\theta^\eta(\eta_\theta \cdot h_\theta)(X_\theta^{u\eta sx}) \\ &\quad + \frac{1}{2} |h_\theta(X_\theta^{u\eta sx})|^2] d\theta, \\ \tilde{L}_\theta^\eta \phi(x) &= \frac{1}{2} a_\theta^{ij}(x) \partial_i \partial_j \phi(x) + f(\theta, x, u(\theta, \eta)) \cdot \nabla \phi(x) - \frac{1}{2} |\sigma(\theta, x)' \nabla \phi(x)|^2, \end{aligned}$$

so that

$$\sup_{\eta \in C} \sup_{u, r, x} |\delta_r(\eta)| \leq K < \infty,$$

with K depending only on C and K_0 , cf. (H).

Suppose now that G is not bounded. Let

$$G_m(t, x, \eta) = \begin{cases} G(t, x, \eta) & \text{if } |G(t, x, \eta)| \leq m, \\ G(t, x, \eta) \frac{m}{|G(t, x, \eta)|} & \text{otherwise.} \end{cases}$$

Then G_m is bounded, $|G_m| \uparrow |G|$. If we write $\mu_s^{m\eta}(x)$ for $\mu_s^{u\eta}(x)$ when G_m is used, then as in Haussmann [7, Thm. 3.2] it follows that $|\mu_s^{m\eta} - \mu_s^{u\eta}|_H \rightarrow 0$ for each η in $\mathcal{C}(0, T; \mathbb{R}^d)$. Let $\rho \in H$ be a probability density. Then

$$\langle \mu_s^{m\eta}, \rho \rangle \rightarrow \langle \mu_s^{u\eta}, \rho \rangle$$

and

$$\langle \mu_s^{m\eta}, \rho \rangle = E^\eta \int_s^t G_{mr}^\eta(X_r^{u\eta sp}) e^{\delta_r(\eta, \rho)} dr$$

where $\delta_r(\eta, \rho)$ is defined by (2.11) with $X^{u\eta sx}$ replaced by $X^{u\eta sp}$ where $X^{\mu\eta sp}$ is the unique solution of (2.10) with initial distribution

$$X_s \sim \rho(x) dx.$$

Since $|G_m^\eta(\cdot)| \uparrow |G^\eta(\cdot)|$ a.e. ($dt dx$), and since $X^{u\eta sp}$ under P^η has a density $p_r^\eta(x)$ in $L^2(s, T; H^1)$, then $|G_{mr}^\eta(X_r^{u\eta sp}) e^{\delta_r(\eta, \rho)}| \leq |G_r^\eta(X_r^{u\eta sp})| e^K$ and recalling (2.6) we have

$$E^\eta \int_s^t |G_r^\eta(X_r^{u\eta sp})| dr = \int \int |G_r^\eta(x) p_r^\eta(x) dx dr| < \infty.$$

Hence, by the above and the dominated convergence theorem,

$$\begin{aligned} \langle \mu_s^{u\eta}, \rho \rangle &= \lim_m \langle \mu_s^{m\eta}, \rho \rangle \\ &= \lim_m E^\eta \int_s^t G_{mr}^\eta(X_r^{u\eta sp}) e^{\delta_r(\eta, \rho)} dr \\ &= E^\eta \int_s^t G_r^\eta(X_r^{u\eta sp}) e^{\delta_r(\eta, \rho)} dr \\ &= \left\langle E^\eta \int_s^t G_r^\eta(X_r^{u\eta sx}) e^{\delta_r(\eta)} dr, \rho \right\rangle \end{aligned}$$

$$= \left\langle E \left\{ \int_s^t G_r^\eta(X_r^{usx}) Z_r^{usx} dr \middle| \mathcal{F}_T^Y \right\} (\omega) e^{\eta_s \cdot h_s(x)}, \rho \right\rangle.$$

Since the probability densities form a total set in H then the result follows.

We add that, from the usual energy estimates, it follows that for $i = 1, \dots, n$

$$(2.12) \quad \int_0^t |\partial_i \mu_s^{u\eta}|^2 ds \leq K \left\{ |c e^{\eta_i \cdot h_i}|_H^2 + \int_0^t \left| G_s^\eta e^{\eta_s \cdot h_s} \right|_H^2 ds \right\}.$$

3. Strong variations. Let \hat{u} be a solution of (2.5). For s, ε fixed such that $0 \leq s \leq s + \varepsilon \leq T$, a *strong variation* (corresponding to (s, ε)) is an element $u \in \mathcal{U}$ such that

$$u(t, \eta) = \hat{u}(t, \eta), \quad t \notin [s, s + \varepsilon].$$

In this section we study the resultant perturbation of J , i.e., $J(u) - J(\hat{u})$.

We begin with some definitions. Let $\hat{\Phi}_t^{sx}$ be the fundamental matrix solution of

$$(3.1) \quad dz_t = f_x(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) z_t dt + \sigma_x^{(i)}(t, \hat{X}_t^{sx}) z_t dw^i, \quad t \geq s$$

where \hat{X}_t^{sx} is the solution of (2.1)' with $u = \hat{u}$ and $\sigma^{(i)}$ is the i th column of σ . Hence each column of $\hat{\Phi}_t^{sx}$ satisfies (3.1) and $\hat{\Phi}_s^{sx} = I$ a.s. Assume (H) and let $\hat{\mu}^\eta$ be the function $\mu^{u\eta}$ of Proposition 2.1(a) with $u = \hat{u}$, with $G(t, x, \eta) = l(t, x, \hat{u}(t, \eta))$ and with terminal condition at $t = T$. With $\hat{Z}_t = Z_t^{\hat{u}}$ and $\hat{X}_t = X_t^{\hat{u}}$ it follows from Proposition 2.1(b) and (2.4) that

$$(3.2) \quad \begin{aligned} J(\hat{u}) &= EE \left\{ c(\hat{X}_T) \hat{Z}_T + \int_0^T l(t, \hat{X}_t, \hat{u}(t, Y)) \hat{Z}_t dt \middle| \mathcal{F}_T^Y \vee \hat{X}_0 \right\} \\ &= E \hat{\mu}_0^Y(\hat{X}_0) \\ &= E \langle \hat{\mu}_0^Y, p_0 \rangle. \end{aligned}$$

We now set $\hat{v}_t^\eta = \hat{\mu}_t^\eta \exp(-\eta_t \cdot h_t)$. Observe that $\hat{\mu}_t^\eta$, hence \hat{v}_t^η , depends on the past of η through \hat{u} and on the future through the dynamics (2.7). Our aim is to compute $E\{\partial \hat{v}_s^Y(x) | \mathcal{F}_s^Y\}$ where ∂v is the vector with components $\partial_i v$ for $v \in H^1$.

LEMMA 3.1. Assume (A₁)–(A₆) and (H). For each s and almost all x

$$(3.3) \quad \begin{aligned} E\{\partial \hat{v}_s^Y(x) | \mathcal{F}_s^Y\} &= E \left\{ \left[c_x(\hat{X}_T^{sx}) \hat{\Phi}_T^{sx} + \int_s^T l_x(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) \hat{\Phi}_t^{sx} dt \right. \right. \\ &\quad \left. \left. + \left(c(\hat{X}_T^{sx}) + \int_s^T l(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) dt \right) \right. \right. \\ &\quad \left. \left. \cdot \int_s^T h_x^i(t, \hat{X}_t^{sx}) \hat{\Phi}_t^{sx} (dY_t^i - h^i(t, \hat{X}_t^{sx}) dt) \right] \hat{Z}_T^{sx} \middle| \mathcal{F}_s^Y \right\} \quad \text{a.s.} \end{aligned}$$

Note that the right side of (3.3) is defined for all x and equals $\hat{q}_s(x)$, where (n.b. $\hat{E} = E^{\hat{u}}$)

$$(3.4) \quad \begin{aligned} \hat{q}_s(x) &= \hat{E} \left\{ c_x(\hat{X}_T^{sx}) \hat{\Phi}_T^{sx} + \int_s^T l_x(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) \hat{\Phi}_t^{sx} dt \right. \\ &\quad \left. + \left[c(\hat{X}_T^{sx}) + \int_s^T l(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) dt \right] \int_s^T h_x^i(t, \hat{X}_t^{sx}) \hat{\Phi}_t^{sx} d\tilde{w}_t^i \middle| \mathcal{F}_s^Y \right\}. \end{aligned}$$

Proof. From Proposition 2.1(b) we have for almost all x

$$\hat{v}_s^Y(x) = E \left\{ c(\hat{X}_T^{sx}) \hat{Z}_T^{sx} + \int_s^T l(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) \hat{Z}_t^{sx} dt \middle| \mathcal{F}_T^Y \right\} \quad \text{P-a.s.,}$$

so that

$$E\{\hat{v}_s^Y(x) | \mathcal{F}_s^Y\} = E\left\{\left[c(\hat{X}_T^{sx}) + \int_s^T l(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) dt\right] \hat{Z}_T^{sx} \middle| \mathcal{F}_s^Y\right\} \quad P\text{-a.s.}$$

Now fix χ in \mathbf{R}^n and let z_t^{sx} be the solution of (3.1) with $z_s^{sx} = \chi$. A standard computation, linearization of (2.2), shows that for any compact set C

$$\sup_{\omega} E\{\|\hat{X}^{s(x+\chi)} - \hat{X}^{sx}\|_T^2 | \mathcal{F}_T^Y\} = O(|\chi|^2)$$

and

$$(3.5) \quad \sup_{\{\omega: \eta \in C\}} \sup_{s \leq t \leq T} E\{|\hat{X}_t^{s(x+\chi)} - \hat{X}_t^{sx} - z_t^{sx}|^2 | \mathcal{F}_T^Y\} = o(|\chi|^2).$$

Set

$$\bar{Z}_t = \hat{Z}_t^{s(x+\chi)} - \hat{Z}_t^{sx} \left[1 + \int_s^t h_x^i(r, \hat{X}_r^{sx}) \cdot z_r^{sx} dY_r^i - \int_s^t h^i(r, \hat{X}_r^{sx}) h_x^i(r, \hat{X}_r^{sx}) \cdot z_r^{sx} dr \right].$$

Then

$$\begin{aligned} d\bar{Z}_t &= \bar{Z}_t h(t, \hat{X}_t^{s(x+\chi)}) \cdot dY_t + \hat{Z}_t^{sx} [h^i(t, \hat{X}_t^{s(x+\chi)}) - h^i(t, \hat{X}_t^{sx}) - h_x^i(t, \hat{X}_t^{sx}) \cdot z_t^{sx}] dY_t^i \\ &\quad + \hat{Z}_t^{sx} \left[\int_s^t h_x^i(r, \hat{X}_r^{sx}) \cdot z_r^{sx} dY_r^i - \int_s^t h^i(r, \hat{X}_r^{sx}) h_x^i(r, \hat{X}_r^{sx}) \cdot z_r^{sx} dr \right] \\ &\quad \cdot [h(t, \hat{X}_t^{s(x+\chi)}) - h(t, \hat{X}_t^{sx})] \cdot dY_t^i. \end{aligned}$$

Now (3.5), Gronwall's lemma and the fact that for all $q < \infty$, $E\{\|\hat{Z}^{sx}\|_T^q\} < \infty$ by the Burkholder inequality (since h is bounded), imply that

$$\sup_t E|\bar{Z}_t|^2 = o(|\chi|^2).$$

It follows that

$$\begin{aligned} E\{\hat{v}_s^Y(x+\chi) | \mathcal{F}_s^Y\} &= E\{\hat{v}_s^Y(x) | \mathcal{F}_s^Y\} \\ &\quad + E\left\{\left[c_x(\hat{X}_T^{sx}) z_T^{sx} + \int_s^T l_x(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) \cdot z_t^{sx} dt \right. \right. \\ &\quad \left. \left. + \left[c(\hat{X}_T^{sx}) + \int_s^T l(t, \hat{X}_t^{sx}, \hat{u}(t, Y)) dt\right] \right. \right. \\ &\quad \left. \left. \cdot \left[\int_s^T h_x^i(t, \hat{X}_t^{sx}) \cdot z_t^{sx} dY_t^i \right. \right. \right. \\ &\quad \left. \left. \left. - \int_s^T h^i(t, \hat{X}_t^{sx}) h_x^i(t, \hat{X}_t^{sx}) \cdot z_t^{sx} dt\right] \right] \hat{Z}_T^{sx} \middle| \mathcal{F}_s^Y\right\} + R \quad \text{a.s.} \end{aligned}$$

where $E|R| = o(|\chi|)$. But

$$z_t^{sx} = \hat{\Phi}_t^{sx} \chi.$$

So for almost all x , $E\{\hat{v}_s^Y(x) | \mathcal{F}_s^Y\}$ is differentiable in x with derivative $\hat{q}_s(x)$.

It remains to show that

$$\partial E\{\hat{v}_s^Y(x) | \mathcal{F}_s^Y\} = E\{\partial \hat{v}_s^Y(x) | \mathcal{F}_s^Y\} \quad \text{a.s.}$$

Since \hat{v}_s^Y is in H^1 for almost all s , then $\partial \hat{v}_s^Y$ is in $L^2(\mathbf{R})$, i.e., for each i

$$\lim_{\chi \rightarrow 0} \|\chi^{-1}[\hat{v}_s^Y(x + \chi e_i) - \hat{v}_s^Y(x)] - \partial_i \hat{v}_s^Y(x)\|_{L^2(\mathbf{R}^n)} = 0 \quad \text{a.s.}$$

from whence it follows that $\partial \hat{v}_s^Y(x)$ is (x, ω) measurable, and for a suitable subsequence $\{\chi_n\}$ converging to zero we have for almost all x

$$\chi_n^{-1}[\hat{v}_s^Y(x + \chi_n e_i) - \hat{v}_s^Y(x)] \rightarrow \partial_i \hat{v}_s^Y(x) \quad \text{a.s.}$$

But calculations of the kind used above show that, for some $p > 1$,

$$\sup_x E\{|\chi^{-1}[\hat{v}_s^Y(x + \chi e_i) - \hat{v}_s^Y(x)]|^p | \mathcal{F}_s^Y\} < \infty \quad \text{a.s.,}$$

i.e., we have uniform integrability. Since the conditional expectation $E\{\cdot | \mathcal{F}_s^Y\}$ is in this case integration with respect to a measure $P_y(\cdot)$ for y in $\mathcal{C}(0, s; \mathbf{R}^d)$, then Lebesgue's theorem shows that, for almost all s and almost all x ,

$$\lim E\{\chi^{-1}[\hat{v}_s^Y(x + \chi e_i) - \hat{v}_s^Y(x)] | \mathcal{F}_s^Y\} = E\{\partial_i \hat{v}_s^Y(x) | \mathcal{F}_s^Y\} \quad \text{a.s.}$$

The result follows.

Although the above result is only given for $u = \hat{u}$, it holds for any u in \mathcal{U} . We write $\nu_s^{uY}(x)$, $q_s^u(x)$, Φ_t^{usx} correspondingly. Now without assuming (H) $q_s^u(x)$ is still well defined by

$$(3.4)' \quad \begin{aligned} q_s^u(x) = E^u \left\{ c_x(X_T^{usx}) \Phi_T^{usx} + \int_s^T l_x(t, X_t^{usx}, u(t, Y)) \Phi_t^{usx} dt \right. \\ \left. + \left[c(X_T^{usx}) + \int_s^T l(t, X_t^{usx}, u(t, Y)) dt \right] \int_s^T h_x^i(t, X_t^{usx}) \Phi_t^{usx} d\tilde{w}_t^i \middle| \mathcal{F}_s^Y \right\}. \end{aligned}$$

In preparation for the main result we establish two lemmata.

LEMMA 3.2. Assume (A₁)–(A₆). Then there exists a constant K_6 such that for all u in \mathcal{U}

$$|q_s^u(x)| \leq K_6(1 + |x|^q + \|y\|_s^q).$$

Moreover K_6 depends only on K_1, \dots, K_5, K_u, q and T .

Proof. This follows readily from (3.4)'.

With \bar{u} in \mathcal{U} define

$$(3.6) \quad u_{\varepsilon s}(t, y) = \begin{cases} \bar{u}(t, y) & \text{if } s \leq t < s + \varepsilon, \\ \hat{u}(t, y) & \text{otherwise.} \end{cases}$$

Then $u_{\varepsilon s}$ is a strong variation. Wherever the superscript $u_{\varepsilon s}$ appears we replace it by ε .

LEMMA 3.3. Assume (A₁)–(A₆). For any $M < \infty$,

$$\lim_{\varepsilon \rightarrow 0} \sup_{0 \leq s \leq T} \sup_{\|y\|_s \leq M} 1_{\{|x| \leq M\}}(\omega) |q_s^\varepsilon(x) - \hat{q}_s(x)| = 0 \quad \text{a.s.}$$

Proof. Let $\bar{X}_t = X_t^{\varepsilon sx} - \hat{X}_t^{sx}$, and suppress the superscript sx . Then

$$\begin{aligned} d\bar{X}_t = & [f(t, X_t^\varepsilon, u^\varepsilon(t, Y)) - f(t, \hat{X}_t, u^\varepsilon(t, Y))] dt \\ & + [f(t, \hat{X}_t, \bar{u}(t, Y)) - f(t, \hat{X}_t, \hat{u}(t, Y))] 1_{[s, s+\varepsilon)}(t) dt \\ & + [\sigma(t, X_t^\varepsilon) - \sigma(t, \hat{X}_t)] dw_t \end{aligned}$$

so that, by (A₁), (A₂) and Gronwall's inequality, for any $p < \infty$

$$(3.7) \quad \begin{aligned} E\{\|\bar{X}\|_T^p | \mathcal{F}_s^Y\} & \leq KE \left\{ \varepsilon^{p-1} \int_s^{s+\varepsilon} |f(t, \hat{X}_t, \bar{u}(t, Y)) - f(t, \hat{X}_t, \hat{u}(t, Y))|^p dt \middle| \mathcal{F}_s^Y \right\} \\ & \leq \varepsilon^p K(1 + |x|^p + \|Y\|_s^p) \quad \text{a.s.} \end{aligned}$$

where the last inequality follows from (A₁) and

$$(3.8) \quad E\{\|\hat{X}\|_T^p | \mathcal{F}_s^Y\} \leq K(1 + |x|^p + \|Y\|_s^p) \quad \text{a.s.}$$

and where the constant K may change from line to line, but is independent of s , ω , ε (it may depend on p , K_1 , K_2 , \dots , K_5 , q , $\bar{K}(=K_{\bar{u}})$, $\hat{K}(=K_{\hat{u}})$). We also have for any $p < \infty$

$$\sup_{\varepsilon, s, x, \omega} E\{\|\Phi^\varepsilon\|_T^p | \mathcal{F}_s^Y\} < \infty.$$

Let $\bar{\Phi}_t = \Phi_t^\varepsilon - \hat{\Phi}_t$ and let $\sigma^{(i)}$ be the i th column of σ . Then

$$\begin{aligned} d\bar{\Phi}_t &= f_x(t, X_t^\varepsilon, u_t^\varepsilon)\bar{\Phi}_t dt + \sigma_x(t, X_t^\varepsilon)\bar{\Phi}_t dw_t \\ &\quad + [f_x(t, X_t^\varepsilon, \hat{u}) - f_x(t, \hat{X}_t, \hat{u})]\hat{\Phi}_t dt + [\sigma_x^{(i)}(t, X_t^\varepsilon) - \sigma_x^{(i)}(t, \hat{X}_t)]\hat{\Phi}_t dw_t^i \\ &\quad + [f_x(t, X_t^\varepsilon, u^\varepsilon) - f_x(t, X_t^\varepsilon, \hat{u})]\hat{\Phi}_t dt. \end{aligned}$$

Proceeding as in (3.7) it follows that

$$\begin{aligned} (3.9) \quad E\{\|\bar{\Phi}\|_T^p | \mathcal{F}_s^Y\} &\leq K[\varepsilon^p + \sqrt{I_1} + \sqrt{I_2}], \\ I_1 &= E\left\{\int_s^T |f_x(t, X_t^\varepsilon, \hat{u}) - f_x(t, \hat{X}_t, \hat{u})|^{2p} dt \middle| \mathcal{F}_s^Y\right\}, \\ I_2 &= E\left\{\int_s^T |\sigma_x(t, X_t^\varepsilon) - \sigma_x(t, \hat{X}_t)|^{2p} dt \middle| \mathcal{F}_s^Y\right\}. \end{aligned}$$

Consider I_1 . For any $N < \infty$ set

$$A_{\varepsilon N} = \{\omega: \|X^\varepsilon\|_T > N\} \cup \{\omega: \|\hat{X}\|_T > N\} \cup \{\omega: \|Y\|_T > N\};$$

then by (3.7), (3.8)

$$P\{A_{\varepsilon N} | \mathcal{F}_s^Y\} \leq K(1 + |x|^2 + \|Y\|_s^2)/N^2.$$

Moreover by the local uniformly continuous differentiability of f , we have that for ω not in $A_{\varepsilon N}$, $\delta > 0$, there exists η_N such that

$$|f_x(t, X_t^\varepsilon, \hat{u}) - f_x(t, \hat{X}_t, \hat{u})|^{2p} < \delta T^{-1}$$

if $|X_t^\varepsilon - \hat{X}_t| < \eta_N$. Let $B_{\varepsilon N} = \{\omega: \|X^\varepsilon - \hat{X}\|_T \geq \eta_N\}$. By (3.7)

$$P\{B_{\varepsilon N} | \mathcal{F}_s^Y\} \leq \varepsilon^2 K(1 + |x|^2 + \|Y\|_s^2)/\eta_N^2.$$

From the uniform bound on f_x it follows that

$$(3.10) \quad I_1 \leq K\left(\frac{1}{N^2} + \frac{\varepsilon^2}{\eta_N^2}\right)(1 + |x|^2 + \|Y\|_s^2) + \delta.$$

Since I_2 satisfies a similar inequality, then it follows from (3.9) that

$$(3.11) \quad \limsup_{\varepsilon \rightarrow 0} \sup_s \sup_{|x| \leq M} 1_{\{\|Y\|_s \leq M\}} E\{\|\Phi^\varepsilon - \hat{\Phi}\|_T^p | \mathcal{F}_s^Y\} = 0.$$

The boundedness and convergence of X^ε , Φ^ε , and an argument of the kind used for I_1 but applied to

$$E\left\{\int_s^T |l_x(t, X_t^\varepsilon, \hat{u}) - l_x(t, \hat{X}_t, \hat{u})|^{2p} dt \middle| \mathcal{F}_s^Y\right\},$$

now show that for any $p < \infty$

$$\sup_s \sup_{|x| \leq M} 1_{\{\|Y\|_s \leq M\}} E \left\{ \left| c_x(X_T^\varepsilon) \Phi_T^\varepsilon - c_x(\hat{X}_T) \hat{\Phi}_T + \int_s^T [l_x(t, X_t^\varepsilon, u^\varepsilon(t, Y)) \Phi_t^\varepsilon - l_x(t, \hat{X}_t, \hat{u}(t, Y)) \hat{\Phi}_t] dt \right|^p \middle| \mathcal{F}_s^Y \right\}$$

converges to 0 with ε . Similarly

$$\sup_s \sup_{|x| \leq M} 1_{\{\|Y\|_s \leq M\}} E \left\{ \left| c(X_T^\varepsilon) - c(\hat{X}_T) + \int_s^T [l(t, X_t^\varepsilon, u^\varepsilon(t, Y)) - l(t, \hat{X}_t, \hat{u}(t, Y))] dt \right|^p \middle| \mathcal{F}_s^Y \right\}$$

also converges to 0 with ε . The terms

$$\int_s^T [h_x^i(t, X_t^\varepsilon) \Phi_t^\varepsilon - h_x^i(t, \hat{X}_t) \hat{\Phi}_t] dY_t^i, \\ \int_s^T [h_x^i(t, X_t^\varepsilon) \Phi_t^\varepsilon h^i(t, X_t^\varepsilon) - h_x^i(t, \hat{X}_t) \hat{\Phi}_t h^i(t, \hat{X}_t)] dt$$

are treated by the same methods.

We turn now to Z_T^ε . Write ζ^ε for $\log Z_T^\varepsilon$. Then

$$P\{|Z_T^\varepsilon - \hat{Z}_T| > \delta \mid \mathcal{F}_s^Y\} \leq P\{\hat{\zeta}^\varepsilon > N \mid \mathcal{F}_s^Y\} + P\{|\exp(\zeta^\varepsilon - \hat{\zeta}^\varepsilon) - 1| > \delta e^{-N} \mid \mathcal{F}_s^Y\} \\ \leq N^{-2} E \left\{ \int_s^T |h(t, \hat{X}_t)|^2 dt \middle| \mathcal{F}_s^Y \right\} + P\{|\hat{\zeta}^\varepsilon - \zeta| > \delta_N \mid \mathcal{F}_s^Y\}$$

where $\delta_N = \log(1 + \delta e^{-N})$. But

$$P\{|\zeta^\varepsilon - \hat{\zeta}^\varepsilon| > \delta_N \mid \mathcal{F}_s^Y\} \leq P\{\zeta^\varepsilon - \hat{\zeta}^\varepsilon > \delta_N \mid \mathcal{F}_s^Y\} + P\{\hat{\zeta}^\varepsilon - \zeta^\varepsilon > \delta_N \mid \mathcal{F}_s^Y\} \\ \leq 2\delta_N^{-2} E \left\{ \int_s^T |h(t, X_t^\varepsilon) - h(t, \hat{X}_t)|^2 dt \middle| \mathcal{F}_s^Y \right\}.$$

Hence $Z_T^\varepsilon \rightarrow \hat{Z}_T$ in measure uniformly in s, x for $|x| \leq M, \|Y\|_s \leq M$. The linear bound on h implies that for some $p'' > 1$

$$\sup_{\varepsilon, s} \sup_{|x| \leq M} 1_{\{\|Y\|_s \leq M\}} E\{|Z_T^\varepsilon|^{p''} \mid \mathcal{F}_s^Y\} < \infty.$$

Hence for $1 < p' < p''$

$$\lim_{\varepsilon \rightarrow 0} \sup_s \sup_{|x| \leq M} 1_{\{\|Y\|_s \leq M\}} E\{|Z_T^\varepsilon - Z_T|^{p'} \mid \mathcal{F}_s^Y\} = 0.$$

Repeated application of Hölder's inequality now proves the lemma (cf. (3.3), (3.4), (3.4)').

Let us emphasize that the above continuity is independent of, hence uniform with respect to, (H). Similar but somewhat easier calculations establish

COROLLARY 3.1. $\hat{q}_s(\cdot)$ is a.s. continuous.

We are now in a position to present the main result of this section. Define

$$g_t^u(x) = l(t, x, u(t, Y)) + \hat{q}_t(x) \cdot f(t, x, u(t, Y)).$$

THEOREM 3.1. Assume (A₁)–(A₆) and (H). Then

$$J(u_{\varepsilon s}) - J(\hat{u}) = \hat{E} \int_s^{s+\varepsilon} [g_t^{\bar{u}}(\hat{X}_t) - \hat{g}_t(\hat{X}_t)] dt + o(\varepsilon).$$

Proof. With $u = u_{\varepsilon s}$ define $\bar{\mu}_t^{\varepsilon\eta} = \mu_t^{\varepsilon\eta} - \hat{\mu}_t^\eta$. Recall that $\mu_t^{\varepsilon\eta}$ is the solution of (2.7) on $[0, T]$ with $G_t^\eta(x) = l(t, x, u_{\varepsilon s}(t, \eta))$. Then from (2.7) for $v \in H^1$

$$\bar{\mu}_t^{\varepsilon\eta} = 0 \quad \text{if } t \geq s + \varepsilon,$$

$$(3.12) \quad \left(\frac{d\bar{\mu}^{\varepsilon\eta}}{dt}, v \right) + \hat{\mathcal{A}}_t^\eta(\bar{\mu}_t^{\varepsilon\eta}, v) + (\mathcal{A}_t^{\bar{u}\eta} - \hat{\mathcal{A}}_t^\eta)(\mu_t^{\varepsilon\eta}, v) \\ + \langle [l(t, \cdot, \bar{u}(t, \eta)) - l(t, \cdot, \hat{u}(t, \eta))] e^{\eta_i \cdot h_i}, v \rangle = 0 \quad \text{if } s < t \leq s + \varepsilon,$$

$$(3.13) \quad \left(\frac{d\bar{\mu}^{\varepsilon\eta}}{dt}, v \right) + \hat{\mathcal{A}}_t^\eta(\bar{\mu}_t^{\varepsilon\eta}, v) = 0 \quad \text{if } t \leq s.$$

If we write Δf for $f(t, x, \hat{u}(t, \eta)) - f(t, x, u(t, \eta))$, then

$$(\mathcal{A}_t^{\bar{u}\eta} - \hat{\mathcal{A}}_t^\eta)(\mu_t^{\varepsilon\eta}, v) = \langle \Delta f^i [\partial_i \mu_t^{\varepsilon\eta} - \partial_i(\eta_i \cdot h_i) \mu_t^{\varepsilon\eta}], v \rangle \\ = \langle \Delta f^i \partial_i \mu_t^{\varepsilon\eta} e^{\eta_i \cdot h_i}, v \rangle.$$

Recall that $u = u_{\varepsilon s}$ and for $\phi \in \mathcal{U}$ set

$$\tilde{g}_t^{\phi\eta}(x) = l(t, x, \phi(t, \eta)) + \partial \nu_t^{\varepsilon\eta}(x) \cdot f(t, x, \phi(t, \eta)), \\ \tilde{g}_t^\phi(x) = E\{\tilde{g}_t^{\phi Y}(x) | \mathcal{F}_t^Y\} = l(t, x, \phi(t, Y)) + q_t^\varepsilon(x) \cdot f(t, x, \phi(t, Y))$$

and write $\Delta \tilde{g}_t^\eta(x) = \tilde{g}_t^{u\eta}(x) - \tilde{g}_t^{\hat{u}\eta}(x)$, $\Delta \tilde{g}_t(x) = \bar{g}_t^u(x) - \bar{g}_t^{\hat{u}}(x)$. Then (3.12) can be written as

$$(3.12)' \quad \left(\frac{d\bar{\mu}^{\varepsilon\eta}}{dt}, v \right) + \hat{\mathcal{A}}_t^\eta(\bar{\mu}_t^{\varepsilon\eta}, v) + \langle \Delta \tilde{g}_t^\eta e^{\eta_i \cdot h_i}, v \rangle = 0 \quad \text{if } s < t \leq s + \varepsilon.$$

We now want to apply Proposition 2.1(b) to (3.12)' with $t = s + \varepsilon$, $c = 0$, and $G_t^\eta = \Delta \tilde{g}_t^\eta$. Since $\hat{\mu}_t^\eta$ satisfies (2.12), since f is bounded and since c, l satisfy (A₄) and (H), then $\Delta \tilde{g}_t^\eta$ satisfies (2.6), and hence

$$(3.14) \quad J(u_{\varepsilon s}) - J(\hat{u}) = E\langle \bar{\mu}_0^{\varepsilon Y}, p_0 \rangle \\ = E\langle \bar{\mu}_s^{\varepsilon Y}, \hat{\rho}_s^Y e^{-Y_s \cdot h_s} \rangle \\ = E\left\langle E\left\{ \int_s^{s+\varepsilon} \Delta \tilde{g}_t^Y(\hat{X}_t^{sx}) \hat{Z}_t^{sx} dt \middle| \mathcal{F}_T^Y \right\}, \hat{\rho}_s^Y \right\rangle \\ = E\left\langle E\left\{ \int_s^{s+\varepsilon} \Delta \tilde{g}_t(\hat{X}_t^{sx}) dt \hat{Z}_T^{sx} \middle| \mathcal{F}_s^Y \right\}, \hat{\rho}_s^Y \right\rangle \\ = E\left\{ \int_s^{s+\varepsilon} \Delta \tilde{g}_t(\hat{X}_t) dt \hat{Z}_T \right\}$$

where the first equality comes from Proposition 2.1(b), the second from the fact that (2.8), satisfied by $\hat{\psi} = \hat{\rho} e^{-Y \cdot h}$ with $u = \hat{u}$, and (3.13) are adjoint, hence the solutions

have constant inner product, and the third comes from (3.12)' and Proposition 2.1(b), plus the fact that $\bar{\mu}_{s+\varepsilon}^{\varepsilon\eta} = 0$. For the fourth note that $\hat{\rho}_s^Y$ is \mathcal{F}_s^Y measurable, and

$$\begin{aligned} E\{\Delta\tilde{g}_t^Y(\hat{X}_t^{sx})\hat{Z}_t^{sx}|\mathcal{F}_t^Y\} &= E\{\Delta\tilde{g}_t^Y(\hat{X}_t^{sx})\hat{Z}_t^{sx}|\mathcal{F}_s^Y\} \\ &= E\{E\{\Delta\tilde{g}_t^Y(\hat{X}_t^{sx})|\mathcal{F}_t\}\hat{Z}_t^{sx}|\mathcal{F}_s^Y\} \\ &= E\{E\{\Delta\tilde{g}_t(\hat{X}_t^{sx})|\mathcal{F}_t\}\hat{Z}_t^{sx}|\mathcal{F}_s^Y\} \\ &= E\{\Delta\tilde{g}_t(\hat{X}_t^{sx})\hat{Z}_t^{sx}|\mathcal{F}_s^Y\} \\ &= E\{\Delta\tilde{g}_t(\hat{X}_t^{sx})\hat{Z}_T^{sx}|\mathcal{F}_s^Y\} \end{aligned}$$

since $\Delta\tilde{g}_t(\hat{X}_t^{sx})$ is \mathcal{F}_t measurable. The last equality follows from

$$\begin{aligned} (3.15) \quad & \langle E\{\Delta\tilde{g}_t(\hat{X}_t^{sx})\hat{Z}_T^{sx}|\mathcal{F}_s^Y\}, \hat{\rho}_s^Y \rangle = E\{\Delta\tilde{g}_t(\hat{X}_t)\hat{Z}_T\hat{Z}_s^{-1}|\mathcal{F}_s^Y, \hat{X}_s = x\}, \hat{\rho}_s^Y\} \\ &= E\{E\{\Delta\tilde{g}_t(\hat{X}_t)\hat{Z}_T\hat{Z}_s^{-1}|\mathcal{F}_s^Y \vee \hat{X}_s\}\hat{Z}_s|\mathcal{F}_s^Y\} \\ &= E\{E\{\Delta\tilde{g}_t(\hat{X}_t)\hat{Z}_T\hat{Z}_s^{-1}|\mathcal{F}_s^Y \vee \mathcal{F}_s^{\hat{X}}\}\hat{Z}_s|\mathcal{F}_s^Y\} \\ &= E\{\Delta\tilde{g}_t(\hat{X}_t)\hat{Z}_T|\mathcal{F}_s^Y\} \end{aligned}$$

since \hat{X}_s given \mathcal{F}_s^Y is conditionally Markovian and since \hat{Z}_s is $\mathcal{F}_s^Y \vee \mathcal{F}_s^{\hat{X}}$ measurable.

As the final step we shall replace q_t^ε by \hat{q}_t on the right side of (3.14). Note that

$$(3.16) \quad E\{\Delta\tilde{g}_t(\hat{X}_t)\hat{Z}_T\} = E\{1_{\{\|\hat{X}\|_T \leq M\}}1_{\{\|Y\|_T \leq M\}}\Delta\tilde{g}_t(\hat{X}_t)\hat{Z}_T\} + R_t^M$$

where

$$\begin{aligned} |R_t^M| &\leq \int_{A_M} K(1 + \|\hat{X}\|_T^{q+1} + \|Y\|_T^q) d\hat{P}, \\ A_M &= \{\omega: \|\hat{X}\|_T > M\} \cup \{\omega: \|Y\|_T > M\}. \end{aligned}$$

Hypotheses (A₁)–(A₆) imply that the integrand on the right above is integrable and that $\hat{P}(A_M) \rightarrow 0$ so that $\|R^M\|_T \rightarrow 0$ uniformly with respect to the constants in (H). Now Lemmas 3.2, 3.3 and (3.16) imply that

$$E\{\Delta\tilde{g}_t(\hat{X}_t)\hat{Z}_T\} = E\{\Delta\tilde{g}_t(\hat{X}_t)\hat{Z}_T\} + o(1),$$

so the theorem follows.

We emphasize that $o(\varepsilon)$ in the theorem is *uniform* in the data satisfying (A₁)–(A₅) with the same K_1, \dots, K_5 and in P_0 in $\mathcal{P}(K) := \{P = \int |x|^q dP \leq K\}$. We use this remark to eliminate (H). Let us also define the Hamiltonian and the adjoint process p . Recall that ' is transpose and $\hat{E} = E^{\hat{a}}$.

$$(3.17) \quad H(t, x, u, p) = p \cdot f(t, x, u) - l(t, x, u),$$

$$\begin{aligned} (3.18) \quad & p'_s(\omega) = -\hat{q}_s^{Y(\omega)}(\hat{X}_s(\omega)) \\ &= -\hat{E}\left\{c_x(\hat{X}_T)\hat{\Phi}_T^s + \int_s^T l_x(t, \hat{X}_t, \hat{u}(t, Y))\hat{\Phi}_t^s dt \right. \\ & \quad \left. + \left[c(\hat{X}_T) + \int_s^T l(t, \hat{X}_t, \hat{u}(t, Y)) dt\right] \int_s^T h_x^i(t, \hat{X}_t)\hat{\Phi}_t^s d\tilde{w}_t^i \middle| \mathcal{F}_s\right\} \end{aligned}$$

where $\hat{\Phi}_t^s = \hat{\Phi}_t^{s\hat{X}}$ is the fundamental matrix solution of

$$(3.19) \quad dz_t = f_x(t, \hat{X}_t, \hat{u}(t, Y))z_t dt + \sigma_x^{(i)}(t, \hat{X}_t)z_t d\tilde{w}_t^i, \quad t \geq s,$$

with $\hat{\Phi}_s^s = I$. Note that in (3.18) conditioning on \mathcal{F}_s is equivalent to conditioning on $\mathcal{F}_s^Y \vee \hat{X}_s$.

COROLLARY 3.2. Assume (A₁)–(A₆). Then

$$(3.20) \quad J(u_{\varepsilon s}) - J(\hat{u}) = -\hat{E} \int_s^{s+\varepsilon} [H(t, \hat{X}_t, \bar{u}(t, Y), p_t) - H(t, \hat{X}_t, \hat{u}(t, Y), p_t)] dt + o(\varepsilon).$$

Proof. We may assume that P_0 has compact support.¹ Choose $f^n, \bar{\sigma}^n, \bar{h}^n, c^n, l^n$ which satisfy (A₁)–(A₆) with the same constants K_1, \dots, K_5, q , such that

$$f^n(t, x, u) = f(t, x, u) \quad \text{if } |x| \leq n, \quad |u| \leq n,$$

$$l^n(t, x, u) = l(t, x, u) \quad \text{if } |x| \leq n, \quad |u| \leq n,$$

$$c^n(x) = c(x) \quad \text{if } |x| \leq n,$$

$$\bar{h}^n(t, x) = \begin{cases} h(t, x) & \text{if } |x| \leq n, \quad 0 \leq s \leq T, \\ 0 & \text{if } s \notin [0, T]. \end{cases}$$

Let $\beta_n(t)$ be a smooth positive function, support in $\{|t| \leq 1/n\}$, such that $\int \beta_n dt = 1$ and let $\bar{\beta}_n(x) = \prod_{i=1}^n \beta_n(x_i)$. Let

$$h^n(t, x) = \int_{-\infty}^{\infty} \int_{\mathbf{R}^n} \beta_n(t-s) \bar{\beta}_n(x-\xi) \bar{h}^n(s, \xi) d\xi ds,$$

$$dX_t^{nu} = f^n(t, X_t^{nu}, u(t, Y)) dt + \sigma^n(t, X_t^{nu}) d\bar{w}_t + n^{-1} d\bar{w}_t$$

where the initial Ω has been enlarged to $\mathbf{R}^n \times \mathcal{C}(0, T, \mathbf{R}^{2m}) \times \mathcal{C}(0, T; \mathbf{R}^d)$ and \bar{w} is an independent Brownian motion. Using the locally uniform differentiability of h , we can show that for any compact C in \mathbf{R}^n , $\sup_{x \in C} |h^n(\cdot, x) - h(\cdot, x)| \rightarrow 0$ in $L^1(dt)$, hence in measure. Similarly for h_x^n . Also for any u in $\mathcal{U} f^n(t, x, u(t, \eta)) \rightarrow f(t, x, u(t, \eta))$ for each (t, x, η) as $n \rightarrow \infty$. Then f^n , etc. can be chosen so that (H) is satisfied with $\alpha = n^{-2}$.

If we write $\hat{X}_t^n, \hat{\Phi}_t^{sxn}, \hat{Z}_t^{sxn}$ correspondingly and if (H)(ii) is satisfied, then by Theorem 3.1

$$(3.21) \quad J^n(u_{\varepsilon s}) - J^n(\hat{u}) = -E \left\{ \hat{Z}_T^n \int_s^{s+\varepsilon} [H^n(t, \hat{X}_t^n, \bar{u}(t, Y), p_t^n) - H^n(t, \hat{X}_t^n, \hat{u}(t, Y), p_t^n)] dt \right\} + o(\varepsilon).$$

¹ Given P_0 in $\mathcal{P}(K)$, set $P_0^N(\cdot) = k_N P_0(\cdot \cap \{|x| \leq N\})$ where k_N is a normalization constant, $k_N \downarrow 1$. If $J_x(u)$ is the cost corresponding to $X_0 = x$, it can be shown that

$$J^N(u) - J(u) = \int (k_N 1_{\{|x| \leq N\}} - 1) J_x(u) P_0(dx) \rightarrow 0$$

as $N \rightarrow \infty$, uniformly in P in $\mathcal{P}(K)$ and uniformly in the data satisfying (A₁), \dots , (A₅) with the same constants K_1, \dots, K_5 . The term

$$\hat{E} \int_s^{s+\varepsilon} H(t, \hat{X}_t, u(t, y), p_t) dt,$$

cf. (3.20), is treated similarly.

As remarked above, $o(\varepsilon)$ will be uniform in n , so to prove the result we must pass to the limit in (3.21). Since (A_1) – (A_6) are satisfied uniformly in n , then for any $p < \infty$

$$E\{\|\hat{X}^n - \hat{X}\|_T^p + \|X^{nu} - X^u\|_T^p\} \rightarrow 0,$$

and for any compact C in \mathbf{R}^n

$$(3.22) \quad \sup_{x \in C} E\{\|\hat{X}^{nsx} - \hat{X}^{sx}\|_T^p | \mathcal{F}_s^Y\} \rightarrow 0 \quad \text{a.s.},$$

$$(3.23) \quad \sup_n \sup_{x \in C} E\{\|\hat{X}^{nsx}\|_T^p | \mathcal{F}_s^Y\} < \infty \quad \text{a.s.}$$

We shall need similar results for most of the other data. Observe that by (3.23) and (A_3)

$$(3.24) \quad \sup_{x \in C} \sup_n E\left\{\int_s^T |h^n(t, \hat{X}_t^{nsx})|^q dt \middle| \mathcal{F}_s^Y\right\} < \infty \quad \text{a.s.}$$

Moreover if Q^y stands for the product measure $dt \times dP_y$, where P_y is the conditional of $P | \mathcal{F}_s^Y$ (which in this case is a probability measure for each $y \in \mathcal{C}(0, s; \mathbf{R}^d)$), then for any $\varepsilon > 0$, $\delta > 0$

$$\begin{aligned} \sup_{x \in C} Q^y\{ |h^n(t, \hat{X}_t^{nsx}) - h(t, \hat{X}_t^{sx})| > \varepsilon \} &\leq 2\delta T + Q^y\left\{ \sup_{x \in C'} |h^n(t, x) - h(t, x)| > \varepsilon \right\} \\ &\leq (2T + 1)\delta, \end{aligned}$$

for n sufficiently large by the uniform convergence in measure of $h^n \rightarrow h$. Here we take n large enough that by (3.22)

$$\sup_{x \in C} P_y\{\|\hat{X}^{nsx} - \hat{X}^{sx}\|_T > 1\} < \delta,$$

and we take $C' = \{x: |x| \leq M\}$, where M is so large that

$$\sup_{x \in C} P_y\{\|\hat{X}^{sx}\|_T > M - 1\} < \delta.$$

Hence

$$(3.25) \quad \sup_{x \in C} E\left\{\int_s^T |h^n(t, \hat{X}_t^{nsx}) - h(t, \hat{X}_t^{sx})|^p dt \middle| \mathcal{F}_s^Y\right\} \rightarrow 0 \quad \text{a.s.}$$

Since (A_1) , (A_2) , (A_3) hold uniformly in n , then there exist $p'' > p' > 1$ such that

$$(3.26) \quad \sup_{x \in C} \sup_n E\{(\hat{Z}_T^{nsx})^{p''} | \mathcal{F}_s^Y\} < \infty \quad \text{a.s.},$$

and

$$(3.27) \quad \sup_{x \in C} E\{|\hat{Z}_T^{nsx} - \hat{Z}_T^{sx}|^{p'} | \mathcal{F}_s^Y\} \rightarrow 0 \quad \text{a.s.}$$

The result (3.27) follows from (3.26) and (3.25) with $p = 2$. The same arguments also show that

$$\sup_n E(Z_T^{nu})^{p''} < \infty,$$

$$E|Z_T^{nu} - Z_T^u|^{p'} \rightarrow 0,$$

whence it follows easily that the left side of (3.21) converges to that of (3.20).

From (3.24), (3.25), (3.26), (3.27) and similar results involving $h_x^n, c^n, c_x^n, l^n, l_x^n, \Phi^{nsx}$ it can be shown that $\hat{q}_s^n(x) \rightarrow \hat{q}_s(x)$ a.s. uniformly in x in C . Corollary 3.1 now implies that for each s $\hat{q}_s^n(\hat{X}_s^n) \rightarrow \hat{q}_s(\hat{X}_s)$ in probability. Lemma 3.2 then implies that the integral on the right side of (3.21) converges to that of (3.20).

Let us finally eliminate (H)(ii). The above convergence is uniform in P_0 in $\mathcal{P}(K)$ with support in a fixed compact set. Now set $p_0^m(x) = \int \beta_m(|x-y|)P_0(dy)$. Since P_0 has support in $\{|x| \leq N\}$ then $\text{supp } p_0^m \subset \{|x| \leq N+1\}$ and hence (H) is satisfied. Moreover by Fubini's theorem

$$J^m(u) = \int J_x(u) \int \beta_m(|x-y|)P_0(dy) dx \rightarrow \int J_y(u)P_0(dy) = J(u)$$

since $J_x(u)$ is continuous in x . Since also for u in \mathcal{U}

$$\hat{E} \left\{ \int_s^{s+\varepsilon} H(t, \hat{X}_t, u(t, Y), p_t) dt \mid \hat{X}_0 = x \right\}$$

is continuous in x , then the result follows and the corollary is established.

4. The main result. We are now in a position to derive a maximum principle.

THEOREM 4.1. Assume (A₁)–(A₆). If $\hat{u} \in \mathcal{U}$ is a solution of (1.1)–(1.4), then for almost all t

$$\hat{E}\{H(t, \hat{X}_t, \hat{u}(t, Y), p_t) \mid \mathcal{F}_t^Y\} = \max_{u \in U} \hat{E}\{H(t, \hat{X}_t, u, p_t) \mid \mathcal{F}_t^Y\} \quad \text{a.s.}$$

Proof. We begin by defining a countable class of variations. We write $\tilde{\mathcal{U}}_s$ for $L^1(\mathcal{C}(0, T; \mathbf{R}^d), \mathcal{G}_s^d, P_w^d; U)$, the integrable functions mapping $(\mathcal{C}(0, T; \mathbf{R}^d), \mathcal{G}_s^d)$ into U ; then $\tilde{\mathcal{U}}_s$ is separable. Let \mathcal{V} be a countable, dense subset of $\tilde{\mathcal{U}}_T$ such that each element is a bounded function, and define the measurable map

$$i_s: (\mathcal{C}(0, T; \mathbf{R}^d), \mathcal{G}_s^d) \rightarrow (\mathcal{C}(0, T; \mathbf{R}^d), \mathcal{G}_T^d)$$

by $(i_s \eta)(t) = \eta(t \wedge s)$ where $t \wedge s = \min\{t, s\}$. Now $\mathcal{V} \circ i_s$ is a countable dense subset of $\tilde{\mathcal{U}}_s$ (cf. Haussmann [8]), and

$$\bar{\mathcal{U}} := \{u \in \mathcal{U}: u(t, \eta) = v \circ i_t(\eta), v \in \mathcal{V}\}$$

is a countable subset of \mathcal{U} . We shall only consider strong perturbations of the form $u_{\varepsilon s}$ with \bar{u} in $\bar{\mathcal{U}}$, cf. (3.6). Since $\hat{E}|H(t, \hat{X}_t, \bar{u}(t, Y), p_t)| < \infty$ then there is a null set $N(\bar{u})$ such that for $s \notin N(\bar{u})$

$$(4.1) \quad \frac{d}{ds} \int_0^s \hat{E}H(t, \hat{X}_t, \bar{u}(t, Y), p_t) dt = \hat{E}H(s, \hat{X}_s, \bar{u}(s, Y), p_s).$$

We set

$$N = \bigcup_{u \in \bar{\mathcal{U}}} N(\bar{u}) \cup N(\hat{u});$$

then N is a null set.

From Corollary 3.2 we have

$$(4.2) \quad 0 \geq -J(u_{\varepsilon s}) + J(\hat{u}) = \int_s^{s+\varepsilon} [H(t, \hat{X}_t, \bar{u}(t, Y), p_t) - H(t, \hat{X}_t, \hat{u}(t, Y), p_t)] dt + o(\varepsilon),$$

so that when we divide (4.2) by $\varepsilon > 0$ and take the limit as $\varepsilon \rightarrow 0$, then according to (4.1) we have for $s \notin N$

$$0 \geq \hat{E}\{H(s, \hat{X}_s, u(s, Y), p_s) - H(s, \hat{X}_s, \hat{u}(s, Y), p_s)\}$$

for all u in $\mathcal{V} \circ i_s$, hence for all u in $\tilde{\mathcal{U}}_s$ by the denseness of $\mathcal{V} \circ i_s$ in $\tilde{\mathcal{U}}_s$ and by the continuity in u of f and l . It follows as usual (cf. Kushner [9]) that the inequality is preserved when $\hat{E}\{\cdot\}$ is replaced by $\hat{E}\{\cdot | \mathcal{F}_s^Y\}$. This establishes the theorem.

Let us investigate, in a nonrigorous way, the adjoint process. As we saw in the proof of Lemma 3.1 $E\{\hat{p}_s^Y(x) | \mathcal{F}_s^Y\} := V_s^Y(x)$ is the expected cost to go given the past observations and the present state x . Now observe that (cf. (3.18))

$$p'_s = -\hat{q}_s^Y(\hat{X}_s) = -\nabla V_s^Y(\hat{X}_s) \quad \text{a.s.},$$

so as usual the adjoint process is the negative of the gradient of the value function (given the past observations).

On the other hand, if we consider the separated problem as was done in Bensoussan [3], we have

$$\begin{aligned} & \min \{ \mathcal{J}(u) : u \in \mathcal{U} \}, \\ & \mathcal{J}(u) = E_w^d \left\{ \int_0^T \langle l(t, \cdot, u(t, Y)), \rho_t^u \rangle dt + \langle c, \rho_T^u \rangle \right\}, \\ (4.3) \quad & d\rho_t^u = L_t^{u*} \rho_t^u dt + \rho_t^u h_t \cdot dY_t, \quad \rho_0^u = p_0, \end{aligned}$$

where p_0 is the density of P_0 (assumed to exist) and L_t^{u*} is the formal adjoint of

$$L_t^u = \frac{1}{2} a^{ij}(t, \cdot) \partial_i \partial_j + f^i(t, \cdot, u(t, Y(\omega))) \partial_i.$$

Now the optimal cost to go, given the present state ρ and past observation Y , is

$$\tilde{V}_s^Y(\rho) = E_w^d \left\{ \int_s^T \langle l(t, \cdot, \hat{u}(t, Y)), \hat{\rho}_t \rangle dt + \langle c, \hat{\rho}_T \rangle \middle| \mathcal{G}_s^d \right\}$$

where $\hat{\rho}_t$ satisfies (4.3) for $t \geq s$ with u replaced by \hat{u} and with initial condition $\hat{\rho}_s = \rho$. As is readily verified, $\tilde{V}_s^Y(\rho) = \langle V_s^Y, \rho \rangle$ so that the gradient of the value function \tilde{V}_s^Y is (represented by) V_s^Y . But for the separated problem we now define the Hamiltonian

$$\tilde{H}(t, \rho, u, \tilde{p}) = -\langle l(t, \cdot, u), \rho \rangle + \tilde{p}(L_t^{u*} \rho)$$

(\tilde{p} is a functional) so that

$$\begin{aligned} \tilde{H}(t, \rho, u, -\nabla \tilde{V}_t^Y) &= -\langle l(t, \cdot, u), \rho \rangle - \langle V_t^Y, L_t^{u*} \rho \rangle \\ &= -\langle l(t, \cdot, u) + L_t^u V_t^Y, \rho \rangle \\ &= \langle H(t, \cdot, u, p_t), \rho \rangle - \phi_t^Y \end{aligned}$$

where

$$\phi_t^Y = -\frac{1}{2} \langle a_t^{ij} \partial_i \partial_j V_t^Y, \rho \rangle$$

is independent of u . Since

$$\hat{E}\{H(t, \hat{X}_t, u(t, Y), p_t) | \mathcal{F}_t^Y\} = \langle H(t, \cdot, u(t, Y), p_t), \hat{\rho}_t \rangle,$$

then it follows from Theorem 4.1 that

$$\tilde{H}(t, \hat{\rho}_t, \hat{u}(t, Y), \tilde{p}_t) = \max_{u \in U} \tilde{H}(t, \hat{\rho}_t, u, \tilde{p}_t),$$

with $\tilde{p}_t = -\nabla \tilde{V}_t^Y = -\langle V_t^Y, \cdot \rangle$, i.e., the maximum principle holds for the separated problem and the adjoint is the negative of the gradient of the value function.

As an example let us now consider the linear regulator:

$$\begin{aligned} \min \{J(u): u \in \mathcal{U}\}, \\ J(u) = E \left\{ \int_0^T [X_t' M(t) X_t + u_t' N(t) u_t] dt + X_T' D X_T \right\}, \\ dX_t = [A(t) X_t + B(t) u_t] dt + \sigma(t) dw_t, \quad X_0 = x_0, \\ dY_t = H(t) X_t dt + d\tilde{w}_t, \quad Y_0 = 0 \end{aligned}$$

where \mathcal{U} is the set of admissible controls (cf. § 2, with $U = \mathbb{R}^m$). As usual A, B, σ, H, M, N are bounded matrix valued functions of t , and $N(t), M(t), D$ are symmetric with $N(t)$ positive definite and the other two semidefinite. In order that the optimal control, which is a stochastic integral with respect to dY , be in \mathcal{U} we shall assume $H(\cdot)$ to have bounded variation.

Here the Hamiltonian is given as

$$H(t, x, u, p) = p'(A(t)x + B(t)u) - (x'M(t)x + u'N(t)u),$$

so that according to Theorem 4.1, if \hat{u} is optimal, then

$$(4.4) \quad \hat{u}(t, Y) = \frac{1}{2} N(t)^{-1} B(t)' \hat{E}(p_t | \mathcal{F}_t^Y)$$

where

$$(4.5) \quad \begin{aligned} p_t = -2 \left[\Phi(T, t)' D \hat{X}_T + \int_t^T \Phi(s, t)' M(s) \hat{X}_s ds \right] \\ - \left[\hat{X}_T' D \hat{X}_T + \int_t^T (\hat{X}_s' M(s) \hat{X}_s + \hat{u}_s' N(s) \hat{u}_s) ds \right] \int_t^T \Phi(t, s)' H(s)' d\tilde{w} \end{aligned}$$

with

$$\frac{d\Phi}{ds}(s, t) = A(s)\Phi(s, t), \quad \Phi(t, t) = I.$$

We must now give a more explicit representation of \hat{u} , i.e., we must put $\hat{E}(p_t | \mathcal{F}_t^Y)$ into a more usable form. We allow ourselves to be inspired by the linear regulator with complete observation to guess that \hat{u} is linear in the state \hat{X}_t , or at least in $m_t = \hat{E}(\hat{X}_t | \mathcal{F}_t^Y)$, i.e.,

$$(4.6) \quad \hat{u}(t, Y) = K(t) m_t,$$

$$(4.7) \quad dm_t = [A(t) + B(t)K(t)]m_t dt + R(t)H(t)'[dY_t - H(t)m_t dt],$$

$$(4.8) \quad \frac{dR}{dt} - A(t)R - RA(t)' + RH(t)'H(t)R - \sigma(t)\sigma(t)' = 0.$$

If we assume that x_0 is normally distributed, $N(m_0, R_0)$, then the parameters m_0, R_0 give the initial conditions for m_t, R_t . If K is bounded, then it follows that

$$\begin{aligned} m_t &= \phi(t, 0)m_0 + \int_0^t \phi(t, s)R_s H_s' dY_s \\ &= \phi(t, 0)m_0 + R_t H_t' Y_t - \int_0^t \psi(t, s)Y_s ds \end{aligned}$$

for some locally bounded functions ϕ, ψ , because H is absolutely continuous and ϕ, R are differentiable. Hence \hat{u} as given by (4.6) is in \mathcal{U} .

Let $\tilde{\Phi}(s, t)$ be the fundamental matrix solution of

$$\frac{dx}{dt} = (A + BK)x$$

and let $\Psi(s, t)$ be that of

$$\frac{dx}{dt} = \tilde{A}x$$

where

$$\tilde{A} = \begin{bmatrix} A + BK - RH'H & RH'H \\ BK & A \end{bmatrix}.$$

It follows that

$$(4.9) \quad \begin{aligned} d \begin{pmatrix} m \\ \hat{X} \end{pmatrix} &= \tilde{A} \begin{pmatrix} m \\ \hat{X} \end{pmatrix} dt + \begin{pmatrix} RH' & 0 \\ 0 & \sigma \end{pmatrix} d \begin{pmatrix} \tilde{w} \\ w \end{pmatrix}, \\ \begin{pmatrix} m_s \\ \hat{X}_s \end{pmatrix} &= \Psi(s, t) \begin{pmatrix} m_t \\ \hat{X}_t \end{pmatrix} + \int_t^s \Psi(s, \theta) \begin{pmatrix} R_\theta H'(\theta)' & 0 \\ 0 & \sigma(\theta) \end{pmatrix} d \begin{pmatrix} \tilde{w} \\ w_\theta \end{pmatrix}. \end{aligned}$$

Now using (4.9) we can compute

$$\begin{aligned} \hat{E}(p_t | \mathcal{F}_t) &= -2 \left\{ \Phi(T, t)' D(0 \ I) \Psi(T, t) + \int_t^T \Phi(s, t)' M_s(0 \ I) \Psi(s, t) ds \right. \\ &\quad + \int_t^T \Phi(s, t)' H_s' H_s R_s(I \ 0) \Psi(T, s)' ds \begin{pmatrix} 0 \\ I \end{pmatrix} D(0 \ I) \Psi(T, t) \\ &\quad + \int_t^T \int_t^s \Phi(\theta, t)' H_\theta' H_\theta R_\theta(I \ 0) \Psi(s, \theta)' d\theta \begin{pmatrix} 0 \\ I \end{pmatrix} M_s(0 \ I) \Psi(s, t) ds \\ &\quad + \int_t^T \int_t^s \Phi(\theta, t)' H_\theta' H_\theta R_\theta(I \ 0) \Psi(s, \theta)' d\theta \\ &\quad \left. \cdot \begin{pmatrix} I \\ 0 \end{pmatrix} K_s' N_s K_s(0 \ I) \Psi(s, t) ds \right\} \begin{pmatrix} m_t \\ \hat{X}_t \end{pmatrix}. \end{aligned}$$

Since

$$\tilde{A} \begin{pmatrix} I \\ I \end{pmatrix} = \begin{pmatrix} I \\ I \end{pmatrix} (A + BK), \quad \Psi(s, t) \begin{pmatrix} I \\ I \end{pmatrix} = \begin{pmatrix} I \\ I \end{pmatrix} \tilde{\Phi}(s, t),$$

we have

$$(4.10) \quad \begin{aligned} \hat{E}(p_t | \mathcal{F}_t^Y) &= -2 \left\{ \Phi(T, t)' D \tilde{\Phi}(T, t) + \int_t^T \Phi(s, t)' M(s) \tilde{\Phi}(s, t) ds \right. \\ &\quad \left. + \int_t^T \Phi(s, t)' H(s)' H(s) R_s(I \ 0) Q_s \begin{pmatrix} I \\ I \end{pmatrix} \tilde{\Phi}(s, t) ds \right\} m_t \end{aligned}$$

where

$$\begin{aligned} Q_s &= \Psi(T, s)' \begin{pmatrix} 0 \\ I \end{pmatrix} D \Psi(T, s) + \int_s^T \Psi(\theta, s)' \begin{pmatrix} 0 \\ I \end{pmatrix} M(\theta) (0 \ I) \Psi(\theta, s) ds \\ &\quad + \int_s^T \Psi(\theta, s)' \begin{pmatrix} I \\ 0 \end{pmatrix} K(\theta)' N(\theta) K(\theta) (I \ 0) \Psi(\theta, s) ds, \end{aligned}$$

so that Q satisfies

$$\frac{d}{ds}Q_s = -\tilde{A}(s)'Q_s - Q_s\tilde{A}(s) - \begin{pmatrix} K(s)'N(s)K(s) & 0 \\ 0 & M(s) \end{pmatrix},$$

$$Q_T = \begin{pmatrix} 0 & 0 \\ 0 & D \end{pmatrix}.$$

Let us write

$$Q_s \begin{pmatrix} I \\ I \end{pmatrix} = q_s;$$

then

$$\frac{dq}{ds} = -\tilde{A}'(s)q - q(A(s) + B(s)K(s)) - \begin{pmatrix} K(s)'N(s)K(s) \\ M(s) \end{pmatrix},$$

and if $q = (q_1', q_2')'$ then

$$\frac{dq_1}{ds} = -(A + BK - RH'H)'q_1 - K'B'q_2 - q_1(A + BK) - K'NK,$$

$$\frac{dq_2}{ds} = -H'HRq_1 - A'q_2 - q_2(A + BK) - M,$$

$$q_1(T) = 0, \quad q_2(T) = D.$$

We observe that if

$$(4.11) \quad B'(t)q_2(t) = -N(t)K(t)$$

then $q_1(\cdot) = 0$, and if $q_2(s)$ is symmetric then

$$\frac{dq_2}{ds} = -A(s)'q_2 - q_2A(s) + K(s)'N(s)K(s) - M(s), \quad q_2(T) = D.$$

Let us write this solution as $P(s)$. Then the second term in (4.10) is zero since $q_1 = 0$, and

$$\hat{E}(p_t | \mathcal{F}_t^Y) = -2P(t)m_t,$$

so (4.4) holds if $K(t) = -N(t)^{-1}B(t)'P(t)$. Moreover, this K is bounded on $[0, T]$ and (4.11) does hold! Hence the control

$$\hat{u}(t, Y) = -N(t)B(t)'P(t)m_t$$

does satisfy the necessary conditions for optimality.

OPTIMAL HANKEL NORM MODEL REDUCTIONS AND WIENER-HOPF FACTORIZATION I: THE CANONICAL CASE*

JOSEPH A. BALL† AND ANDRÉ C. M. RAN‡

Abstract. We consider the problem for discrete time systems of approximating a given stable rational matrix function $K(z) = \sum_{j=1}^{\infty} K_j z^{-j}$ of McMillan degree n by a function $\hat{K}(z) + H(z)$, where \hat{K} has McMillan degree $l < n$ and H is antistable; we include the case $l=0$ in which we then take $\hat{K}=0$. The minimum possible L^∞ -norm (on the unit circle) of the error $\|K - \hat{K} - H\|_{L^\infty}$, or equivalently the minimum possible spectral norm of the induced Hankel matrix $\|\mathcal{H}_{K-\hat{K}}\|$, is known to be equal to the $(l+1)$ st singular value $\sigma_{l+1}(K)$ of the Hankel matrix $\mathcal{H}_K = [K_{i+j-1}]_{i,j}$. Assume $\sigma_{l+1}(K) < \sigma_l(K)$ and choose the number σ to satisfy $\sigma_{l+1}(K) < \sigma < \sigma_l(K)$; if $l=0$, the condition is simply $\sigma_1(K) = \|\mathcal{H}_K\| < \sigma$. We give an explicit linear fractional map parametrization of the class of all functions $\hat{K} + H$ as above which satisfy $\|K - \hat{K} - H\|_{L^\infty} \leq \sigma$. The coefficients of the linear fractional map are completely determined by the matrices A, B, C in a realization $K(z) = C(zI - A)^{-1}B$ for $K(z)$ and the observability and controllability gramians for the discrete time system (A, B, C) . The analogous results for continuous time systems are derived by a linear fractional change of variable; in this way we recover some recent results of Glover. The basic idea is to use the Grassmannian approach of Ball and Helton to reduce the problem to one of spectral factorization; this in turn can be solved by the geometric factorization principle of Bart, Gohberg, Kaashoek and van Dooren. Known applications include sensitivity minimization in H^∞ control theory and model reduction for linear systems.

Key words. McMillan degree, Lyapunov equation, controllability and observability gramian, singular values, shift invariant subspace representation

AMS(MOS) subject classifications. 93B25, 93B40, 93C35

1. Introduction. We suppose that $K(z)$ is a given strictly proper stable rational $p \times q$ matrix function of McMillan degree n which is analytic on the unit circle. Here we mean "stable" in the sense of discrete time systems, so all poles of K are assumed to be in the open unit disk. We assume that we know a realization

$$K(z) = C(zI_n - A)^{-1}B$$

for K ; here A, B and C are matrices of sizes $n \times n$, $n \times q$ and $p \times n$, respectively, and the spectrum $\sigma(A)$ of A is in the open unit disk.

The model reduction problem that comes up in many engineering applications is that of approximating K by a stable rational matrix function \hat{K} of McMillan degree $l < n$. It is usually desired (see [10], [8] and the references there) to obtain the best approximation in the sense of minimizing the Hankel norm $\|K - \hat{K}\|_{\mathcal{H}}$, where $\|F\|_{\mathcal{H}}$ is the spectral norm of the block Hankel matrix $\mathcal{H}_F = [F_{i+j-1}]_{i,j}$, $j = 1, 2, \dots$ associated with F (where $F(z) = \sum_{i=1}^{\infty} F_i z^{-i}$). Here the block Hankel matrix is considered as an operator from l_q^2 to l_p^2 (where l_r^2 is the space of norm-square-summable \mathbb{C}^r -valued sequences). It is known (see [1] for the scalar case and [10] and [3] for the matrix case) that

$$(1.1) \quad \inf \{ \|K - \hat{K}\|_{\mathcal{H}} : \hat{K} \text{ stable with McMillan degree } \leq l \} = \sigma_{l+1}(K),$$

where $\sigma_1(K) \geq \sigma_2(K) \geq \dots \geq \sigma_n(K)$ are the singular values of \mathcal{H}_K . The singular values of \mathcal{H}_K are alternatively characterized as the square roots of the eigenvalues of the product $\hat{P}\hat{Q}$ of the controllability gramian

$$\hat{P} = \sum_{k=0}^{\infty} A^k B B^* A^{*k}$$

and the observability gramian

$$\hat{Q} = \sum_{k=0}^{\infty} A^{*k} C^* C A^k$$

for the discrete time system (A, B, C) (see [8]). The gramians \hat{P} and \hat{Q} can also be defined as the unique solutions of the Lyapunov equations

$$(1.2) \quad \hat{P} - A\hat{P}A^* = BB^*,$$

$$(1.3) \quad \hat{Q} - A^*\hat{Q}A = C^*C.$$

The approximation result (1.1) has an equivalent formulation in the frequency domain. To describe this we now introduce some notation and terminology for function spaces on the unit circle. For F any function defined on the unit circle, let $\|F\|_{L^\infty} = \sup \{\|F(z)\| : |z| = 1\}$. The space $L_{p \times q}^\infty$ is the set of all measurable $p \times q$ matrix functions F with $\|F\|_{L^\infty} < \infty$. The subspace $H_{p \times q}^\infty$ is the set of all $F \in L_{p \times q}^\infty$ with bounded analytic continuation to the unit disk (the antistable functions).

Denote by $H_{p \times q}^\infty(l)$ the (nonconvex) subset of $L_{p \times q}^\infty$ consisting of all functions H of the form $\hat{K} + H_1$, where \hat{K} is a stable rational $p \times q$ matrix function of McMillan degree at most l and $H_1 \in H_{p \times q}^\infty$. Then an equivalent frequency domain version of (1.1) is

$$(1.1') \quad \inf \{\|K - H\|_{L^\infty} : H \in H_{p \times q}^\infty(l)\} = \sigma_{l+1}(K).$$

For $l = 0$ this amounts to the matrix version of Nehari's theorem [11]; this special case is also relevant to the sensitivity minimization problem in H^∞ control theory (see, e.g. [7] and the references there).

Various authors (see [10], [8] and the references there) have derived algorithms for computing an $H_0 \in H_{p \times q}^\infty(l)$ for which the infimum in (1.1') is achieved, that is, for which

$$(1.4) \quad \|K - H_0\|_{L^\infty} = \sigma_{l+1}(K).$$

In [3] a (degenerate) linear fractional map is produced which parametrizes the set of all $F = K - H_0 \in K + H_{p \times q}^\infty(l)$ that satisfy (1.4). Computation of this map and a starting point for many of the algorithms mentioned above involves a knowledge of the singular value decomposition of \mathcal{H}_K . Glover [8] was the first to obtain a complete parametrization of the set of all solutions directly from the matrices A, B, C , but in the continuous time setting.

In this paper we obtain a result analogous to that of Glover's for the discrete time as well as continuous time setting, but for a slightly modified (and easier) problem. From (1.1') it is clear that for a given tolerance $\sigma > 0$, the smallest integer l for which there is an $F \in K + H_{p \times q}^\infty(l)$ such that $\|F\|_{L^\infty} \leq \sigma$ is the first l for which $\sigma \geq \sigma_{l+1}(K)$. In this paper we assume that a tolerance σ is chosen so that $\sigma_l(K) > \sigma > \sigma_{l+1}(K)$ if $l \geq 1$, or $\sigma > \|\mathcal{H}_K\| = \sigma_1(K)$ if $l = 0$. We then give explicit formulas (in terms of the matrices A, B, C and the controllability and observability gramians \hat{P} and \hat{Q} given by (1.2) and (1.3)) for a linear fractional map which can be used to parametrize the

set of all $F \in K + H_{p \times q}^\infty(I)$ satisfying $\|F\|_{L^\infty} \leq \sigma$. The existence of such a map was already established in [3] for a general $\sigma > 0$; the form of the map is somewhat simpler when one assumes $\sigma_l(K) > \sigma > \sigma_{l+1}(K)$ (or $\sigma > \sigma_1(K)$). The precise result for discrete time is as follows.

THEOREM 1. *Suppose $K(z) = C(zI_n - A)^{-1}B$ is a rational $p \times q$ matrix function with all poles in the open unit disk and of McMillan degree n . Let $\sigma_1(K) \geq \sigma_2(K) \geq \dots \geq \sigma_n(K)$ denote the Hankel singular values of K and choose the positive number σ and the integer l so that $\sigma_l(K) > \sigma > \sigma_{l+1}(K)$ if $l \geq 1$, or $\sigma > \sigma_1(K)$ if $l = 0$. Then there is a rational $(p+q) \times (p+q)$ matrix function*

$$\theta(z) = \begin{bmatrix} \theta_{11}(z) & \theta_{12}(z) \\ \theta_{21}(z) & \theta_{22}(z) \end{bmatrix}$$

such that any matrix function $F = K - H$ where $H \in H_{p \times q}^\infty(I)$ and $\|F\|_{L^\infty} \leq \sigma$ has a representation

$$(1.5) \quad F(z) = (\theta_{11}(z)G(z) + \theta_{12}(z))(\theta_{21}(z)G(z) + \theta_{22}(z))^{-1}$$

for a matrix function $G \in H_{p \times q}^\infty$ such that $\|G\|_{L^\infty} \leq 1$; the function F uniquely determines the function G . Conversely, if $G \in H_{p \times q}^\infty$ with $\|G\|_{L^\infty} \leq 1$, then (1.5) defines a function F with $\|F\|_{L^\infty} \leq \sigma$ of the form $F = K - H$ for a matrix function $H \in H_{p \times q}^\infty(I)$. Moreover, F is rational if and only if G is rational and $\sigma^{-1}F(z)$ is isometric for $|z| = 1$ if and only if $G(z)$ is isometric for $|z| = 1$.

Assume that the matrix A is invertible and has spectrum in the unit disk. Then the matrix function $\theta(z)$ can be given explicitly in the following way. Let \hat{P} and \hat{Q} be the controllability and observability gramians given by (1.2) and (1.3). Set $Z = (I - \sigma^{-2}\hat{Q}\hat{P})^{-1}$ and let c be the $(p+q) \times (p+q)$ Hermitian matrix

$$c = \begin{bmatrix} I_p - \sigma^{-2}CA^{-1}\hat{P}ZA^{*-1}C^* & -CA^{-1}Z^*B \\ -B^*ZA^{*-1}C^* & -\sigma^2I_q - B^*Z\hat{Q}B \end{bmatrix}.$$

Then it develops that c has p positive and q negative eigenvalues, so there is a $(p+q) \times (p+q)$ matrix

$$e = \begin{bmatrix} e_{11} & e_{12} \\ e_{21} & e_{22} \end{bmatrix}$$

such that

$$c^{-1} = e \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} e^*.$$

Then the matrix function $\theta(z)$ can be taken to be

$$\theta(z) = \{I + \underline{C}(zI - A)^{-1}\underline{B}\}e$$

where

$$\underline{A} = \begin{bmatrix} A & -\sigma^{-2}BB^*A^{*-1} \\ 0 & A^{*-1} \end{bmatrix}, \quad \underline{B} = \begin{bmatrix} 0 & B \\ ZA^{*-1}C^* & Z\hat{Q}B \end{bmatrix}$$

and

$$\underline{C} = \begin{bmatrix} C & \sigma^{-2}C\hat{P} \\ 0 & -\sigma^{-2}B^*A^{*-1} \end{bmatrix}.$$

Equivalently, the block entries $\theta_{ij}(z)$ ($1 \leq i, j \leq 2$) of $\theta(z)$ are expressed as

$$(1.6) \quad \theta_{11}(z) = e_{11} + C(zI_n - A)^{-1}(\sigma^{-2}\hat{P}ZA^{*-1}C^*e_{11} + Z^*Be_{21}),$$

$$(1.7) \quad \theta_{12}(z) = e_{12} + C(zI_n - A)^{-1}(\sigma^{-2}\hat{P}ZA^{*-1}C^*e_{12} + Z^*Be_{22}),$$

$$(1.8) \quad \theta_{21}(z) = e_{21} - \sigma^{-2}B^*A^{*-1}(zI_n - A^{*-1})^{-1}(ZA^{*-1}C^*e_{11} + Z\hat{Q}Be_{21}),$$

and

$$(1.9) \quad \theta_{22}(z) = e_{22} - \sigma^{-2}B^*A^{*-1}(zI_n - A^{*-1})^{-1}(ZA^{*-1}C^*e_{12} + Z\hat{Q}Be_{22}).$$

Our basic approach to the proof of Theorem 1 is to use the Grassmannian and invariant subspace approach from [3] to reduce the computation of the matrix θ to the computation of a signed spectral factorization. The signed spectral factorization problem is as follows. Since we are given a realization for the function $K(z)$, we easily derive a realization $Y_-(z) = D_- + C_-(zI - A_-)^{-1}B_-$ for the rational matrix function

$$Y_-(z) = \begin{bmatrix} I_p & K(z) \\ 0 & \sigma I_q \end{bmatrix}.$$

The problem is to find explicitly a rational matrix function $X_+(z) = D_+ + C_+(zI - A_+)^{-1}B_+$ which is analytic and invertible on the closed unit disk such that

$$X_+^*(z) \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} X_+(z) = Y_-^*(z) \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} Y_-(z)$$

where in general $F^*(z) := F(\bar{z}^{-1})^*$. In short, the problem is that of computing a signed spectral factorization from a known signed antispectral factorization of the matrix function

$$W(z) := Y_-^*(z) \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} Y_-(z).$$

This problem can be solved by the geometric state space approach to Wiener-Hopf factorization developed by Bart, Gohberg and Kaashoek [5] (see also [6]). In this context the controllability and observability gramians are identical (up to trivial scalar factors) to the angle operators needed to describe the key subspaces in the construction of [5]. The hypotheses that the matrix A is invertible is needed only to insure that the matrix function θ is analytic and invertible at ∞ . Similar formulas hold if A is not invertible where in this case θ also has a polynomial part; in the continuous time case this issue does not arise. We do not pursue this point here.

In § 2 of the paper we prove Theorem 1 by the method sketched above. In § 3 we derive the analogous results for continuous time systems by a linear fractional change of variable. It is also possible to get the formulas for the continuous time case directly by the same reduction to a signed spectral factorization problem as was done in § 2 for the discrete time case, but with the left half plane playing the role of the unit disk; this is the approach in [4].

As mentioned above, Theorem 1 parallels results of Glover [8] for continuous time systems. In practice, one is interested only in the stable part \hat{K} of an optimal L^∞ -approximant $H = \hat{K} + H_1$ ($H_1 \in H_{p \times q}^\infty$) from $H_{p \times q}^\infty(I)$. Then \hat{K} is an optimal approximant to K in the Hankel norm but not in the L^∞ -norm. The paper of Glover goes on to give estimates of the L^∞ -norm of $K - \hat{K}$ in terms of the Hankel singular values $\sigma_j(K)$ for $j \geq l + 1$. We have nothing to add here to this aspect of the problem.

Also as mentioned above, the paper of Glover actually handles (for continuous time systems) the more complicated situation where one chooses $\sigma = \sigma_{l+1}(K)$. This case can also be handled by our approach, but involves more involved invariant subspace representations (see [2]) and factorization problems (see [9]). We plan to deal with this topic in a future report.

Finally we remark that our results apply equally well to nonrational functions $K(z)$ which have a realization $K(z) = C(zI - A)^{-1}B$ for bounded operators A, B, C with the spectrum of A in the open unit disk (discrete time) or left half plane (continuous time).

2. The model reduction problem. Our starting point to the model reduction problem discussed in the Introduction is the invariant subspace approach to the problem found in [3]. We summarize the results from there which we need here as follows. We denote by H_{p+q}^2 the Hardy space of \mathbb{C}^{p+q} -valued norm square integrable functions on the unit circle with vanishing negative Fourier coefficients.

THEOREM 2.1 (see [3]). *Let $K = \sum_{j=1}^{\infty} K_j z^{-j}$ be a rational $p \times q$ matrix function with no poles on the unit circle. Let $\sigma_1(K) \geq \sigma_2(K) \geq \cdots \geq \sigma_n(K)$ be the singular values of the Hankel matrix operator $\mathcal{H}_K: l_q^2 \rightarrow l_p^2$ with block matrix representation*

$$[\mathcal{H}_K] = [K_{i+j-1}]_{i,j=1,2,\dots}$$

Then

$$\inf \{ \|K - H\|_{L^\infty} : H \in H_{p \times q}^\infty(l) \} = \sigma_{l+1}(K).$$

Moreover, if the numbers σ and l are chosen so that $\sigma_l(K) > \sigma > \sigma_{l+1}(K)$ if $l \geq 1$ ($\sigma > \sigma_1(K)$ if $l = 0$), then there is a rational $(p+q) \times (p+q)$ matrix function

$$\theta(z) = \begin{bmatrix} \theta_{11}(z) & \theta_{12}(z) \\ \theta_{21}(z) & \theta_{22}(z) \end{bmatrix}$$

such that any function $F = K - H$ where $H \in H_{p \times q}^\infty(l)$ and $\|F\|_{L^\infty} \leq \sigma$ must have a representation

$$(2.1) \quad F(z) = (\theta_{11}(z)G(z) + \theta_{12}(z))(\theta_{21}(z)G(z) + \theta_{22}(z))^{-1}$$

for a matrix function $G \in H_{p \times q}^\infty$ such that $\|G\|_{L^\infty} \leq 1$. Conversely, if $G \in H_{p \times q}^\infty$ with $\|G\|_{L^\infty} \leq 1$, then (2.1) defines a function F with $\|F\|_{L^\infty} \leq \sigma$ of the form $F = K - H$ for a matrix function $H \in H_{p \times q}^\infty(l)$. Moreover, F is rational if and only if G is rational and $\sigma^{-1}F(z)$ is isometric for $|z|=1$ if and only if $G(z)$ is isometric for $|z|=1$. The matrix function $\theta(z)$ can be chosen to be any matrix function satisfying the two conditions

$$(2.2) \quad \theta^*(z) \begin{bmatrix} I_p & 0 \\ 0 & -\sigma^2 I_q \end{bmatrix} \theta(z) = \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix}$$

and

$$(2.3) \quad \theta H_{p+q}^2 = \begin{bmatrix} I_p & K \\ 0 & I_q \end{bmatrix} H_{p+q}^2.$$

Thus the proof of Theorem 1 in the Introduction will be complete once we show how to construct a rational matrix function which satisfies (2.2) and (2.3). The following lemma reduces the problem to a signed spectral factorization problem.

LEMMA 2.2. Suppose K is a rational $p \times q$ matrix function. Then a rational $(p+q) \times (p+q)$ matrix function θ exists which satisfies (2.2) and (2.3) if and only if the matrix function

$$(2.4) \quad W(z) = \begin{bmatrix} I_p & 0 \\ K^*(z) & I_q \end{bmatrix} \begin{bmatrix} I_p & 0 \\ 0 & -\sigma^2 I_q \end{bmatrix} \begin{bmatrix} I_p & K(z) \\ 0 & I_q \end{bmatrix}$$

has a signed spectral factorization

$$(2.5) \quad W(z) = X^*(z) \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} X(z)$$

(where X is analytic and invertible on the closed unit disk \bar{D}). If this is the case, then the rational matrix function θ defined by

$$(2.6) \quad \theta(z) = \begin{bmatrix} I_p & K(z) \\ 0 & I_q \end{bmatrix} X(z)^{-1}$$

satisfies (2.2) and (2.3).

Proof. If X is any rational $(p+q) \times (p+q)$ matrix function and θ is defined by (2.6), one easily checks that the factorization (2.2) is equivalent to the factorization (2.5), and that the subspace condition (2.3) is equivalent to the subspace condition

$$X^{-1}H_{p+q}^2 = H_{p+q}^2.$$

But this holds for a rational matrix function X if and only if X is analytic and invertible on the closed unit disk \bar{D} . In this way we see that (2.5) is a signed spectral factorization for W if and only if θ satisfies (2.2) and (2.3), where θ and W are related via (2.4) and (2.6). \square

The next lemma describes $X(z)^{-1}$ in case $K(z) = C(zI - A)^{-1}B$ in terms of A , B and C .

LEMMA 2.3. Suppose $K(z) = C(zI - A)^{-1}B$ where $\sigma(A) \subset D \setminus \{0\}$ and $W(z)$ is given by (2.4). Let P and Q be the unique solutions of the Lyapunov equations

$$(2.7) \quad A(\sigma^2 P)A^* - (\sigma^2 P) = BB^*$$

and

$$(2.8) \quad A^*QA - Q = C^*C.$$

Then $W(z)$ has a signed spectral factorization if and only if the matrix $I - QP$ is invertible.

When this is the case, the factor $X(z)$ for a signed spectral factorization

$$W(z) = X^*(z) \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} X(z)$$

is computed as follows. Set $Z = (I - QP)^{-1}$ and let c be the $(p+q) \times (p+q)$ matrix

$$(2.9) \quad c = \begin{bmatrix} I + CA^{-1}PZA^{*-1}C^* & -CA^{-1}Z^*B \\ -B^*ZA^{-1*}C^* & -\sigma^2 I + B^*ZQB \end{bmatrix}.$$

Then c is Hermitian with p positive and q negative eigenvalues, and so has a factorization

$$(2.10) \quad c = d^* \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} d$$

for an invertible $(p+q) \times (p+q)$ matrix d . Then the spectral factor $X(z)$ for $W(z)$ in this case is given by

$$(2.11) \quad X(z) = d \left\{ \begin{bmatrix} I_p & 0 \\ 0 & I_q \end{bmatrix} + \begin{bmatrix} CP \\ \sigma^{-2} B^* A^{*-1} \end{bmatrix} Z(zI - A^{*-1})^{-1} [A^{*-1} C^*, -QB] \right\}$$

with inverse given by

$$(2.12) \quad X(z)^{-1} = \left\{ \begin{bmatrix} I_p & 0 \\ 0 & I_q \end{bmatrix} - \begin{bmatrix} CP \\ \sigma^{-2} B^* A^{*-1} \end{bmatrix} (zI - A^{*-1})^{-1} Z [A^{*-1} C^*, -QB] \right\} d^{-1}.$$

Proof. First we find a realization for $W(z)$ using (2.4). Obviously

$$\begin{bmatrix} I_p & K(z) \\ 0 & I_q \end{bmatrix} = \begin{bmatrix} I_p & 0 \\ 0 & I_q \end{bmatrix} + \begin{bmatrix} C \\ 0 \end{bmatrix} (zI - A)^{-1} [0, B],$$

and hence

$$\begin{bmatrix} I_p & 0 \\ K^*(z) & I_q \end{bmatrix} = \begin{bmatrix} I_p & 0 \\ -B^* A^{*-1} C^* & I_q \end{bmatrix} - \begin{bmatrix} 0 \\ B^* A^{*-1} \end{bmatrix} (zI - A^{*-1})^{-1} [A^{*-1} C^*, 0].$$

Multiplying realizations as on page 6 of [5] we arrive at the following realization for $W(z)$:

$$W(z) = \tilde{D} + \tilde{C}(zI - \tilde{A})^{-1} \tilde{B}$$

where

$$(2.13) \quad \begin{aligned} \tilde{A} &= \begin{bmatrix} A^{*-1} & A^{*-1} C^* C \\ 0 & A \end{bmatrix}, & \tilde{B} &= \begin{bmatrix} A^{*-1} C^* & 0 \\ 0 & B \end{bmatrix}, \\ \tilde{C} &= \begin{bmatrix} 0 & C \\ -B^* A^{*-1} & -B^* A^{*-1} C^* C \end{bmatrix}, & \tilde{D} &= \begin{bmatrix} I_p & 0 \\ -B^* A^{*-1} C^* & -\sigma^2 I_q \end{bmatrix}. \end{aligned}$$

If we set $\tilde{A}^x = \tilde{A} - \tilde{B} \tilde{D}^{-1} \tilde{C}$, then

$$(2.14) \quad \tilde{A}^x = \begin{bmatrix} A^{*-1} & 0 \\ -\sigma^{-2} B B^* A^{*-1} & A \end{bmatrix}.$$

Let \mathcal{M} be the spectral subspace of \tilde{A} corresponding to the open unit disk, and \mathcal{M}^x the spectral subspace of \tilde{A}^x corresponding to the exterior of the unit disk. Then, according to Theorem 1.5 in [5], there exists a Wiener-Hopf factorization of $\tilde{D}^{-1} W(z)$ of the form

$$(2.15) \quad \tilde{D}^{-1} W(z) = X_-(z) X_+(z)$$

where $X_+(z)$ is analytic and invertible on the closed unit and $X_-(z)$ is analytic and invertible on the exterior of the unit disk, if and only if \mathbb{C}^{2n} has the direct sum decomposition

$$(2.16) \quad \mathbb{C}^{2n} = \mathcal{M} \dot{+} \mathcal{M}^x.$$

Moreover the factors $X_-(z)$ and $X_+(z)$ can be given explicitly as

$$X_-(z) = I_{p+q} + \tilde{D}^{-1} \tilde{C}(zI - \tilde{A})^{-1} (I - \Pi) \tilde{B}$$

and

$$(2.17) \quad X_+(z) = I_{p+q} + \tilde{D}^{-1} \tilde{C} \Pi (zI - \tilde{A})^{-1} \tilde{B}$$

where Π is the projection onto \mathcal{M}^x along \mathcal{M} . From the formula

$$[I + C(zI - A)^{-1} B]^{-1} = I - C(zI - A + BC)^{-1} B,$$

we see from this that

$$(2.18) \quad \begin{aligned} X_+(z)^{-1} &= I_{p+q} - \tilde{D}^{-1} \tilde{C} \Pi (zI - \tilde{A} + \tilde{B} \tilde{C} \Pi)^{-1} \tilde{B} \\ &= I_{p+q} - \tilde{D}^{-1} \tilde{C} (zI - \tilde{A}^x)^{-1} \Pi \tilde{B}. \end{aligned}$$

We next analyze what the direct sum condition (2.15) means for our particular case. From the upper triangular form of \tilde{A} in (2.13) and the hypothesis $\sigma(A) \subset D$ (so $\sigma(A^{*-1}) \subset \mathbb{C} \setminus \bar{D}$), we see that the spectral subspace for \tilde{A} for the exterior of the closed unit disk $\mathbb{C} \setminus \bar{D}$ is $\text{Im} \begin{bmatrix} I \\ 0 \end{bmatrix}$. The spectral subspace \mathcal{M} for A corresponding to D is then completely determined by the following two conditions:

- (i) $\mathcal{M} \dot{+} \text{Im} \begin{bmatrix} I \\ 0 \end{bmatrix} = \mathbb{C}^{2n}$, and
- (ii) $\tilde{A} \mathcal{M} \subset \mathcal{M}$.

The first condition forces \mathcal{M} to have the form $\mathcal{M} = \text{Im} \begin{bmatrix} Q \\ I \end{bmatrix}$ for some $n \times n$ matrix. The second condition then means that for each $x \in \mathbb{C}^n$ there exists a $y \in \mathbb{C}^n$ such that

$$\begin{bmatrix} A^{*-1} & C^*C \\ 0 & A \end{bmatrix} \begin{bmatrix} Q \\ I \end{bmatrix} x = \begin{bmatrix} Q \\ I \end{bmatrix} y.$$

From the second row we get $y = Ax$. From the first row we then get

$$A^{*-1}Qx + A^{*-1}C^*Cx = QAx.$$

Since this identity must hold for all $x \in \mathbb{C}^n$, we see that Q must satisfy the Lyapunov equation (2.8); note that the solution of (2.8) is unique since A and A^{*-1} have disjoint spectra.

In a similar way, from the lower triangular form of \tilde{A}^x in (2.14), we see that the spectral subspace for \tilde{A}^x corresponding to D is $\text{Im} \begin{bmatrix} 0 \\ I \end{bmatrix}$. Then the spectral subspace \mathcal{M}^x for \tilde{A}^x corresponding to $\mathbb{C} \setminus \bar{D}$ must satisfy

- (i') $\mathcal{M}^x \dot{+} \text{Im} \begin{bmatrix} 0 \\ I \end{bmatrix} = \mathbb{C}^{2n}$, and
- (ii') $\tilde{A}^x \mathcal{M}^x \subset \mathcal{M}^x$.

This leads to the conclusion that \mathcal{M}^x has the form $\mathcal{M}^x = \text{Im} \begin{bmatrix} I \\ P \end{bmatrix}$ where P is the unique solution of the Lyapunov equation (2.7). The direct sum condition (2.16) is easily seen to be equivalent to the invertibility of the $2n \times 2n$ matrix $\begin{bmatrix} I & Q \\ P & I \end{bmatrix}$. From the factorization

$$\begin{bmatrix} I & Q \\ P & I \end{bmatrix} = \begin{bmatrix} I & Q \\ 0 & I \end{bmatrix} \begin{bmatrix} I - QP & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ P & I \end{bmatrix},$$

we see that this in turn is equivalent to the invertibility of $I - QP$. We now conclude that the Wiener-Hopf factorization (2.15) exists if and only if $I - QP$ is invertible, where P and Q are the unique solutions of the respective Lyapunov equations (2.7) and (2.8).

To convert the Wiener-Hopf factorization (2.15) to the desired signed spectral factorization (2.5), we use the symmetry $W = W^*$ of W together with the uniqueness of Wiener-Hopf factorization. More precisely, if the normalization

$$X_-(\infty) = \begin{bmatrix} I_p & 0 \\ 0 & I_q \end{bmatrix} = X_+(\infty)$$

is imposed, then the factors $X_+(z)$ and $X_-(z)$ in the Wiener-Hopf factorization are uniquely determined; indeed if $\tilde{D}^{-1}W(z) = X'_-(z)X'_+(z)$ were another such factorization, then $X'_-(z)^{-1}X_-(z) = X'_+(z)X_+(z)^{-1}$ would be analytic on the whole complex plane with value I_{p+q} at ∞ , and hence would be identically equal to I_{p+q} by Liouville's Theorem. For our case, $W(z) = \tilde{D}X_-(z)X_+(z)$ where $W(z) = W^*(z)$, and hence we also have $W(z) = X_+^*(z)X_-^*(z)\tilde{D}^*$. This yields the factorization

$$\tilde{D}^{-1}W(z) = \tilde{D}^{-1}X_+^*(z)X_-^*(z)\tilde{D}^*.$$

Evaluating at ∞ yields $I = \tilde{D}^{-1}X_+(0)^*X_-(0)^*\tilde{D}^*$, so $X_+(0)^{*^{-1}}\tilde{D} = [\tilde{D}^{*-1}X_-(0)^{*^{-1}}]^{-1}$. Then we rewrite the above factorization as

$$(2.19) \quad \tilde{D}^{-1}W(z) = X'_-(z)X'_+(z)$$

where

$$X'_-(z) = \tilde{D}^{-1}X_+^*(z)X_+(0)^{*^{-1}}\tilde{D}$$

and

$$X'_+(z) = \tilde{D}^{*-1}X_-(0)^{*^{-1}}X_-^*(z)\tilde{D}^*.$$

Note that X'_- is analytic and invertible on $\mathbb{C} \setminus D$ with $X'_-(\infty) = I$ and similarly X'_+ is analytic and invertible on \bar{D} with $X'_+(\infty) = I$. Thus the factorization (2.19) is another normalized Wiener-Hopf factorization for $\tilde{D}^{-1}W(z)$. By the uniqueness mentioned above we necessarily have $X'_-(z) = X_-(z)$. Thus the factorization (2.15) has the form

$$(2.20) \quad W(z) = X_+^*(z)X_+(0)^{*^{-1}}\tilde{D}X_+(z).$$

If we evaluate this expression on the unit circle, we see that the matrix $c := X_+(0)^{*^{-1}}\tilde{D}$ is Hermitian with p positive and q negative eigenvalues and hence has a signed Cholesky factorization

$$c = d^* \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} d$$

for some matrix d . If we set

$$(2.21) \quad X(z) = dX_+(z),$$

then

$$W(z) = X^*(z) \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix} X(z)$$

is our desired signed spectral factorization.

It remains only to compute the explicit formulas for c , $X(z)$ and $X(z)^{-1}$ in the statement of the lemma. A straightforward computation shows that the projection Π of \mathbb{C}^{2n} onto

$$\mathcal{M}^x = \text{Im} \begin{bmatrix} I \\ P \end{bmatrix} \quad \text{along} \quad \mathcal{M} = \text{Im} \begin{bmatrix} Q \\ I \end{bmatrix}$$

is given by

$$\Pi = \begin{bmatrix} I \\ P \end{bmatrix} Z[I, -Q]$$

where we have set $Z = (I - QP)^{-1}$.

We identify $\text{Im } \Pi$ with \mathbb{C}^n via the map $S: \mathbb{C}^n \rightarrow \text{Im } \Pi$ given by

$$S = \begin{bmatrix} I \\ P \end{bmatrix},$$

with inverse $S^{-1}: \text{Im } \Pi \rightarrow \mathbb{C}^n$ given by

$$S^{-1} = [I \ 0] | \text{Im } \Pi.$$

Rewrite (2.17) and (2.18) as

$$(2.22) \quad X_+(z) = I_{p+q} + \tilde{D}^{-1} \tilde{C} \Pi S (zI - S^{-1} \Pi \tilde{A} \Pi S)^{-1} S^{-1} \tilde{B}$$

and

$$(2.23) \quad X_+(z)^{-1} = I_{p+q} - \tilde{D}^{-1} \tilde{C} S (zI - S^{-1} \Pi \tilde{A}^x \Pi S)^{-1} S^{-1} \Pi \tilde{B}.$$

Use (2.13) and (2.8) to compute

$$\begin{aligned} S^{-1} \Pi \tilde{A} \Pi S &= S^{-1} \Pi \tilde{A} S = Z[I, -Q] \begin{bmatrix} A^{*-1} & A^{*-1} C^* C \\ 0 & A \end{bmatrix} \begin{bmatrix} I \\ P \end{bmatrix} \\ &= Z[A^{*-1}, A^{*-1} C^* C - QA] \begin{bmatrix} I \\ P \end{bmatrix} \\ &= ZA^{*-1} + Z[QA - A^{*-1} Q]P - ZQAP \\ &= ZA^{*-1} Z^{-1}. \end{aligned}$$

From (2.13) we get

$$(2.24) \quad \begin{aligned} \tilde{D}^{-1} \tilde{C} S &= \begin{bmatrix} I_p & 0 \\ -\sigma^{-2} B^* A^{*-1} C^* & -\sigma^{-2} I_q \end{bmatrix} \begin{bmatrix} CP \\ -B^* A^{*-1} - B^* A^{*-1} C^* CP \end{bmatrix} \\ &= \begin{bmatrix} CP \\ \sigma^{-2} B^* A^{*-1} \end{bmatrix} \end{aligned}$$

and

$$(2.25) \quad \begin{aligned} S^{-1} \Pi \tilde{B} &= Z[I, -Q] \begin{bmatrix} A^{*-1} C^* & 0 \\ 0 & B \end{bmatrix} \\ &= Z[A^{*-1} C^*, -QB]. \end{aligned}$$

From (2.14) we get

$$(2.26) \quad \begin{aligned} S^{-1} \Pi \tilde{A}^x S &= S^{-1} \tilde{A}^x S \\ &= [I \ 0] \begin{bmatrix} A^{*-1} & 0 \\ -\sigma^{-2} B B^* A^{*-1} & A \end{bmatrix} \begin{bmatrix} I \\ P \end{bmatrix} \\ &= A^{*-1}. \end{aligned}$$

From (2.23)

$$\begin{aligned} X_+(0)^{-1} &= I_{p+q} + \tilde{D}^{-1} \tilde{C} S (S^{-1} \Pi \tilde{A}^x \Pi S)^{-1} S^{-1} \Pi \tilde{B} \\ &= I_{p+q} + \begin{bmatrix} CP \\ \sigma^{-2} B^* A^{*-1} \end{bmatrix} A^* Z[A^{*-1} C^*, -QB]. \end{aligned}$$

We compute

$$\begin{aligned}
 c &= X_+(0)^{*^{-1}} \tilde{D} \\
 &= \left\{ I_{p+q} + \begin{bmatrix} CA^{-1} \\ -B^*Q \end{bmatrix} Z^* A [PC^*, \sigma^{-2}A^{-1}B] \right\} \begin{bmatrix} I_p & 0 \\ -B^*A^{*-1}C^* & -\sigma^2I_q \end{bmatrix} \\
 &= \begin{bmatrix} I_p & 0 \\ -B^*A^{*-1}C^* & -\sigma^2I_q \end{bmatrix} \\
 &\quad + \begin{bmatrix} CA^{-1} \\ -B^*Q \end{bmatrix} Z^* A [PC^* - \sigma^{-2}A^{-1}BB^*A^{*-1}C^*, -A^{-1}B].
 \end{aligned}$$

Use (2.7) to then get

$$c = \begin{bmatrix} I_p & 0 \\ -B^*A^{*-1}C^* & -\sigma^2I_q \end{bmatrix} + \begin{bmatrix} CA^{-1} \\ -B^*Q \end{bmatrix} Z^* A [A^{-1}PA^{*-1}C^*, -A^{-1}B].$$

Write

$$c = \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix}$$

and get from this

$$\begin{aligned}
 c_{11} &= I_p + CA^{-1}Z^*PA^{*-1}C^*, \\
 c_{12} &= -CA^{-1}Z^*B, \\
 c_{21} &= -B^*A^{*-1}C^* - B^*QZ^*PA^{*-1}C^* \\
 &= -B^*[I + ZQP]A^{*-1}C^* \\
 &= -B^*ZA^{*-1}C^*
 \end{aligned}$$

and

$$c_{22} = -\sigma^2I_q + B^*QZ^*B = -\sigma^2I_q + B^*ZQB,$$

which agrees with (2.9). Finally, formulas (2.11) and (2.12) follow by plugging the expressions (2.24), (2.25), (2.26), (2.27) into (2.21), (2.22), (2.23), and the lemma follows. \square

We are now in position to complete the proof of Theorem 1 in the Introduction.

Proof of Theorem 1. By Theorem 2.1 and Lemma 2.2, the matrix function

$$\theta(z) = \begin{bmatrix} I_p & K(z) \\ 0 & I_q \end{bmatrix} X(z)^{-1}$$

satisfies all the requirements of Theorem 1 if the factorization (2.5) is a signed spectral factorization for the matrix function $W(z)$ defined by (2.4). We assume that $K(z) = C(zI - A)^{-1}B$ where the $n \times n$ matrix A has spectrum in D . Suppose that P and Q are the unique solutions of the Lyapunov equations (2.7) and (2.8). Then $\hat{P} := -\sigma^2P$ and $\hat{Q} := -Q$ solve (1.2) and (1.3), and hence are the controllability and observability gramians for the system associated with the above realization of $K(z)$. Therefore $I_n - QP = I_n - \sigma^{-2}\hat{Q}\hat{P}$ is invertible if and only if σ is not one of the Hankel singular values $\sigma_j(K)$ of K . Then by Lemma 2.3, $W(z)$ has a signed spectral factorization as in (2.5) where $X(z)^{-1}$ is given by (2.12). We may write

$$\begin{bmatrix} I_p & K(z) \\ 0 & I_q \end{bmatrix}$$

in realization form as

$$\begin{bmatrix} I_p & K(z) \\ 0 & I_q \end{bmatrix} = \begin{bmatrix} I_p & 0 \\ 0 & I_q \end{bmatrix} + \begin{bmatrix} C \\ 0 \end{bmatrix} (zI_n - A)^{-1} [0, B].$$

We then multiply transfer functions as, e.g., [5, p. 6] to obtain

$$\theta(z) = \begin{bmatrix} I_p & K(z) \\ 0 & I_q \end{bmatrix} X(z)^{-1} = \{I + \underline{C}(zI_{2n} - \underline{A})^{-1} \underline{B}\} d^{-1}$$

where

$$\underline{A} = \begin{bmatrix} A & -\sigma^{-2}BB^*A^{*-1} \\ 0 & A^{*-1} \end{bmatrix}, \quad \underline{B} = \begin{bmatrix} 0 & B \\ ZA^{*-1}C^* & Z\hat{Q}B \end{bmatrix}$$

and

$$\underline{C} = \begin{bmatrix} C & \sigma^{-2}C\hat{P} \\ 0 & -\sigma^{-2}B^*A^{*-1} \end{bmatrix}.$$

We may use the Lyapunov equation (1.2) to rewrite \underline{A} as

$$\underline{A} = \begin{bmatrix} A & \sigma^{-2}(A\hat{P} - \hat{P}A^{*-1}) \\ 0 & A^{*-1} \end{bmatrix}$$

from which we get

$$(zI_{2n} - \underline{A})^{-1} = \begin{bmatrix} (zI_n - A)^{-1} & \sigma^{-2}(zI_n - A)^{-1}(A\hat{P} - \hat{P}A^{*-1})(zI_n - A^{*-1})^{-1} \\ 0 & (zI_n - A^{*-1})^{-1} \end{bmatrix}.$$

We compute first

$$(zI_{2n} - \underline{A})^{-1} \underline{B} = \begin{bmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{bmatrix}$$

where

$$\begin{aligned} x_{11} &= \sigma^{-2}(zI_n - A)^{-1}(A\hat{P} - \hat{P}A^{*-1})(zI_n - A^{*-1})^{-1}ZA^{*-1}C^*, \\ x_{12} &= (zI_n - A)^{-1}B + \sigma^{-2}(zI_n - A)^{-1}(A\hat{P} - \hat{P}A^{*-1})(zI_n - A^{*-1})^{-1}Z\hat{Q}B, \\ x_{21} &= (zI_n - A^{*-1})^{-1}ZA^{*-1}C^*, \\ x_{22} &= (zI_n - A^{*-1})^{-1}Z\hat{Q}B. \end{aligned}$$

Now we compute

$$\underline{C}(zI_{2n} - \underline{A})^{-1} \underline{B} = \begin{bmatrix} y_{11} & y_{12} \\ y_{21} & y_{22} \end{bmatrix}$$

where

$$\begin{aligned} y_{11} &= Cx_{11} + \sigma^{-2}C\hat{P}x_{21} \\ &= \sigma^{-2}C(zI_n - A)^{-1}(A\hat{P} - \hat{P}A^{*-1})(zI_n - A^{*-1})^{-1}ZA^{*-1}C^* \\ &\quad + \sigma^{-2}C\hat{P}(zI_n - A^{*-1})^{-1}ZA^{*-1}C^* \\ &= \sigma^{-2}C(zI_n - A)^{-1}\{A\hat{P} - \hat{P}A^{*-1} + (zI_n - A)\hat{P}\}(zI_n - A^{*-1})^{-1}ZA^{*-1}C^* \\ &= \sigma^{-2}C(zI_n - A)^{-1}\hat{P}ZA^{*-1}C^* \end{aligned}$$

and

$$\begin{aligned}
 y_{12} &= Cx_{12} + \sigma^{-2}C\hat{P}x_{22} \\
 &= C(zI_n - A)^{-1}B + \sigma^{-2}C(zI_n - A)^{-1}(A\hat{P} - \hat{P}A^{*-1})(zI_n - A^{*-1})^{-1}Z\hat{Q}B \\
 &\quad + \sigma^{-2}C\hat{P}(zI_n - A^{*-1})^{-1}Z\hat{Q}B \\
 &= C(zI_n - A)^{-1}B + \sigma^{-2}C(zI_n - A)^{-1}\{A\hat{P} - \hat{P}A^{*-1} + (zI_n - A)\hat{P}\}(zI_n - A^{*-1})^{-1}Z\hat{Q}B \\
 &= C(zI_n - A)^{-1}B + \sigma^{-2}C(zI_n - A)^{-1}\hat{P}Z\hat{Q}B \\
 &= C(zI_n - A)^{-1}(I + \sigma^{-2}\hat{P}Z\hat{Q})B.
 \end{aligned}$$

Noting that $I + \sigma^{-2}\hat{P}Z\hat{Q} = I + PZQ = I + PQZ^* = ((I - PQ) + PQ)Z^* = Z^*$, we obtain that

$$y_{12} = C(zI_n - A)^{-1}Z^*B.$$

Further,

$$\begin{aligned}
 y_{21} &= -\sigma^{-2}B^*A^{*-1}x_{21} \\
 &= -\sigma^{-2}B^*A^{*-1}(zI_n - A^{*-1})^{-1}ZA^{*-1}C^*,
 \end{aligned}$$

and finally,

$$\begin{aligned}
 y_{22} &= -\sigma^{-2}B^*A^{*-1}x_{22} \\
 &= -\sigma^{-2}B^*A^{*-1}(zI_n - A^{*-1})^{-1}Z\hat{Q}B.
 \end{aligned}$$

If we now write d^{-1} in block form

$$d^{-1} = \begin{bmatrix} e_{11} & e_{12} \\ e_{21} & e_{22} \end{bmatrix},$$

then

$$\theta(z) = \begin{bmatrix} \theta_{11}(z) & \theta_{12}(z) \\ \theta_{21}(z) & \theta_{22}(z) \end{bmatrix}$$

where

$$\begin{aligned}
 \theta_{11} &= e_{11} + y_{11}e_{11} + y_{12}e_{21}, & \theta_{12} &= e_{12} + y_{11}e_{12} + y_{12}e_{22}, \\
 \theta_{21} &= e_{21} + y_{21}e_{11} + y_{22}e_{21}, & \theta_{22} &= e_{22} + y_{21}e_{12} + y_{22}e_{22}.
 \end{aligned}$$

Substitution of the above expressions for y_{ij} into these expressions for θ_{ij} now yield formulas (1.6)–(1.9). This completes the proof of Theorem 1. \square

3. The continuous time case. In this section we consider the continuous time analogue of the above results; this is the setting of Glover's original paper [8]. These results were obtained in [4] directly by reducing to a signed spectral factorization problem as in § 1 but with the left half plane in place of the unit disk; here we simply reduce to the discrete time case by a linear fractional change of variable. We suppose that we are given a stable rational $p \times q$ matrix function of McMillan degree n which is analytic on the imaginary $j\omega$ axis with $G(\infty) = 0$; for the present continuous time setting, “stable” means that G has no poles in the right half plane $\{s: \operatorname{Re} s > 0\}$. Thus $G(s)$ may be realized as

$$G(s) = C(sI - A)^{-1}B$$

where A , B , C are matrices of sizes $n \times n$, $n \times q$ and $p \times n$, respectively, and where the spectrum of A lies in the open left half plane.

The symbol $H_{p \times q}^{\infty+}$ now denotes the class of $p \times q$ matrix functions analytic in the right half plane and uniformly bounded there; $H_{p \times q}^{\infty-}$ is the analogous class for the left half plane. For l a nonnegative integer, we let $H_{p \times q}^{\infty-}(l)$ denote the class of functions $\hat{G} + F$ where \hat{G} has McMillan degree l and $F \in H_{p \times q}^{\infty-}$. We now let $L_{p \times q}^{\infty}$ denote the class of measurable uniformly bounded functions K on the imaginary axis with norm

$$\|K\|_{L^{\infty}} = \sup_{-\infty < w < \infty} \|K(jw)\|.$$

We also introduce the Hardy spaces H_q^{2-} for the left half plane and H_q^{2+} for the right half plane of \mathbb{C}^q -valued functions and the Lebesgue space L_q^2 of \mathbb{C}^q -valued functions which are norm square integrable on the jw axis.

The problem to be considered in this section is that of approximating a given stable rational matrix function $G(s) = C(sI - A)^{-1}B$ by functions $K(s) \in H_{p \times q}^{\infty-}(l)$ in L^{∞} -norm. From the earlier work of [1], [10] and [3] translated to the continuous time setting by a linear fractional change of variable, it is known that

$$\inf \{\|G - K\|_{L^{\infty}} : K \in H_{p \times q}^{\infty-}(l)\} = \sigma_{l+1}(G)$$

where $\sigma_{l+1}(G)$ is the $(l+1)$ st Hankel singular value of G . The Hankel singular values $\sigma_1(G) \geq \sigma_2(G) \geq \dots \geq \sigma_n(G) > 0$ can be defined for the continuous time case as the square roots of the eigenvalues $\lambda_i(\hat{P}\hat{Q})$ of the product of the controllability gramian

$$\hat{P} := \int_0^{\infty} \exp(At)BB^* \exp(A^*t) dt$$

and the observability gramian

$$\hat{Q} := \int_0^{\infty} \exp(A^*t)C^*C \exp(At) dt.$$

Equivalently, they can be defined as the singular values $\sigma_i(\mathcal{H}_G)$ of the Hankel operator $\mathcal{H}_G : L_q^2(0, \infty) \rightarrow L_q^2(0, \infty)$ defined by

$$(3.1) \quad \mathcal{H}_G : v(t) \rightarrow \int_0^{\infty} C \exp(A(t+\tau))Bv(\tau) d\tau$$

(see [8]). With σ and l chosen so that $\sigma_l(G) > \sigma \geq \sigma_{l+1}(G)$ (or $\sigma \geq \sigma_1(G)$ if $l=0$), there is again a linear fractional map parametrization for the set of all $K \in H_{p \times q}^{\infty-}(l)$ satisfying $\|G - K\|_{L^{\infty}} \leq \sigma$. The form of the linear fractional map simplifies considerably if $\sigma \neq \sigma_{l+1}(G)$. Glover [8] was the first to give formulas for the coefficients of the linear fractional map directly in terms of the matrices A, B, C appearing in the realization of G . The result for the present continuous time setting is as follows.

THEOREM 3.1. *Suppose $G(s) = C(sI - A)^{-1}B$ is a stable rational $p \times q$ matrix function of McMillan degree n , and that the number σ and the integer l are chosen to satisfy $\sigma_l(G) > \sigma > \sigma_{l+1}(G)$ or $\sigma > \sigma_1(G)$ if $l=0$. Then there is a rational $(p+q) \times (p+q)$ matrix function*

$$\theta(s) = \begin{bmatrix} \theta_{11}(s) & \theta_{12}(s) \\ \theta_{21}(s) & \theta_{22}(s) \end{bmatrix}$$

such that a matrix function $\hat{F} \in L_{p \times q}^{\infty}$ is of the form $\hat{F} = G - K$ for some $K \in H_{p \times q}^{\infty-}(l)$ with $\|F\|_{L^{\infty}} \leq \sigma$ if and only if

$$\hat{F}(s) = (\theta_{11}(s)H(s) + \theta_{12}(s))(\theta_{21}(s)H(s) + \theta_{22}(s))^{-1}$$

for some $H \in H_{p \times q}^{\infty-}$ with $\|H\|_{L^{\infty}} \leq 1$. The function \hat{F} uniquely determines the function H .

Moreover, \hat{F} is rational if and only if the corresponding H is rational, and $(1/\sigma)\hat{F}(jw)$ is isometric for all real w if and only if $H(jw)$ is isometric for all real w . The matrix function $\theta(s)$ is given by

$$\theta(s) = \begin{bmatrix} I_p & 0 \\ 0 & \sigma^{-1}I_q \end{bmatrix} + \underline{C}(sI - \underline{A})^{-1}\underline{B}$$

where

$$(3.2) \quad \underline{A} = \begin{bmatrix} A & -\sigma^{-2}BB^* \\ 0 & -A^* \end{bmatrix},$$

$$(3.3) \quad \underline{B} = \begin{bmatrix} 0 & \sigma^{-1}B \\ ZC^* & \sigma^{-1}Z\hat{Q}B \end{bmatrix},$$

$$(3.4) \quad \underline{C} = \begin{bmatrix} C & \sigma^{-2}C\hat{P} \\ 0 & -\sigma^{-2}B^* \end{bmatrix}.$$

Equivalently, the block entries $\theta_{ij}(s)$ ($i, j = 1, 2$) are given by

$$(3.5) \quad \theta_{11}(s) = I_p + \sigma^{-2}C(sI - A)^{-1}\hat{P}ZC^*,$$

$$(3.6) \quad \theta_{12}(s) = \sigma^{-1}C(sI - A)^{-1}Z^*B,$$

$$(3.7) \quad \theta_{21}(s) = -\sigma^{-2}B^*(sI + A^*)^{-1}ZC^*,$$

$$(3.8) \quad \theta_{22}(s) = \sigma^{-1}I_q - \sigma^{-3}B^*(sI + A^*)^{-1}Z\hat{Q}B.$$

Here \hat{P} and \hat{Q} are the controllability and observability gramian, respectively, associated with the realization $G(s) = C(sI - A)^{-1}B$, and $Z = (I - \sigma^{-2}\hat{Q}\hat{P})^{-1}$.

The controllability and observability gramians \hat{P} and \hat{Q} alternatively arise as the unique solutions of the Lyapunov equations

$$(3.9) \quad A\hat{P} + \hat{P}A^* = -BB^*,$$

$$(3.10) \quad A^*\hat{Q} + \hat{Q}A = -C^*C,$$

(see [8]).

The linear fractional map in Glover's solution [8] has a different form from that given in Theorem 3.1. Any linear fractional map of the form

$$H \rightarrow (\theta_{11}H + \theta_{12})(\theta_{21}H + \theta_{22})^{-1}$$

can be represented in the equivalent form

$$(3.11) \quad H \rightarrow H_{11} + H_{12}H(I - H_{22}H)^{-1}H_{21}$$

where

$$\begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = \begin{bmatrix} \theta_{12}\theta_{22}^{-1} & \theta_{11} - \theta_{12}\theta_{22}^{-1}\theta_{21} \\ \theta_{22}^{-1} & -\theta_{22}^{-1}\theta_{21} \end{bmatrix}.$$

When this is done for the case where θ_{11} , θ_{12} , θ_{21} , θ_{22} are given by (3.5)–(3.8), one obtains by a straightforward but tedious computation

$$(3.12) \quad \begin{aligned} H_{11}(s) &= \sigma^{-2}C\hat{P}(sI + Z(A^* + \sigma^{-2}\hat{Q}A\hat{P}))^{-1}Z\hat{Q}B + C(sI - A)^{-1}B, \\ H_{12}(s) &= I + \sigma^{-2}C\hat{P}(sI + Z(A^* + \sigma^{-2}\hat{Q}A\hat{P}))^{-1}ZC^*, \\ H_{21}(s) &= \sigma I + \sigma^{-1}B^*(sI + Z(A^* + \sigma^{-2}\hat{Q}A\hat{P}))^{-1}Z\hat{Q}B, \\ H_{22}(s) &= \sigma^{-1}B^*(sI + Z(A^* + \sigma^{-2}\hat{Q}A\hat{P}))^{-1}ZC^*. \end{aligned}$$

The parametrization of the errors $G - \hat{G} - F$ given by (3.11) and (3.12) agrees with Glover's parametrization of the approximants $\hat{G} + F$ ([8, Cor. 8.6], interpreted for the case $\sigma_{l+1}(G) < \sigma < \sigma_l(G)$ or $\sigma_1(G) < \sigma$ if $l = 0$).

Proof of Theorem 3.1. As is well known and is easily checked, the map $s \rightarrow z(s) = (1+s)/(1-s)$ maps the left half plane conformally onto the unit disk with inverse $z \rightarrow s(z) = (z-1)/(z+1)$. Thus, if $F = F(s)$ is in the Hardy space $H_{p \times q}^\infty(l)$ for the left half plane, then $\tilde{F}(z) := F(s(z)) = F((z-1)/(z+1))$ is in the corresponding space $H_{p \times q}^\infty(l)$ for the unit disk, and conversely, if $K(z) \in H_{p \times q}^\infty(l)$ for the unit disk, then $K'(s) = K(z(s)) = K((1+s)/(1-s))$ is in the space $H_{p \times q}^\infty(l)$ for the left half plane.

Now suppose $G(s) = C(sI - A)^{-1}B$ is a rational matrix function as in Theorem 3.1. In addition to $\sigma(A) \subset \{s: \operatorname{Re} s < 0\}$, we assume $-1 \notin \sigma(A)$; this hypothesis can be avoided by using a different linear fractional change of variables. Then we set $\tilde{G}(z) = G(s(z))$ and note that $\tilde{G}(z) = \tilde{D} + \tilde{C}(zI - \tilde{A})\tilde{B}$, where

$$(3.13) \quad \tilde{D} = C(I - A)^{-1}B,$$

$$(3.14) \quad \tilde{C} = \sqrt{2}C(I - A)^{-1},$$

$$(3.15) \quad \tilde{B} = \sqrt{2}(I - A)^{-1}B,$$

$$(3.16) \quad \tilde{A} = (I + A)(I - A)^{-1}.$$

The extra assumption that $-1 \notin \sigma(A)$ implies that \tilde{A} is invertible; also $\sigma(\tilde{A}) \subset D$ since A has spectrum in the left half plane. Thus we can apply the formulas in Theorem 1 to $\tilde{G}(z)$ in place of $K(z)$. Assume that the number σ is such that $\sigma_{l+1}(\tilde{G}) < \sigma < \sigma_l(\tilde{G})$ (or simply $\sigma_1(\tilde{G}) < \sigma$ if $l = 0$). We shall see later that the singular values $\sigma_i(\tilde{G})$ for the discrete time Hankel matrix $\mathcal{H}_{\tilde{G}}$ are identical with the singular values $\sigma_i(G)$ for the continuous time Hankel operator \mathcal{H}_G given by (3.1). Let

$$\tilde{\theta}(z) = \begin{bmatrix} \tilde{\theta}_{11}(z) & \tilde{\theta}_{12}(z) \\ \tilde{\theta}_{21}(z) & \tilde{\theta}_{22}(z) \end{bmatrix}$$

be the matrix function associated with \tilde{G} and σ as in Theorem 1. Thus

$$(3.17) \quad \tilde{\theta}(z) = \{I_{p+q} + \tilde{C}(zI - \tilde{A})^{-1}\tilde{B}\}\tilde{\theta}(\infty)$$

where

$$(3.18) \quad \tilde{A} = \begin{bmatrix} \tilde{A} & -\sigma^{-2}\tilde{B}\tilde{B}^*\tilde{A}^{*-1} \\ 0 & \tilde{A}^{*-1} \end{bmatrix},$$

$$(3.19) \quad \tilde{B} = \begin{bmatrix} 0 & \tilde{B} \\ \tilde{Z}\tilde{A}^{*-1}\tilde{C}^* & \tilde{Z}\tilde{Q}\tilde{B} \end{bmatrix},$$

$$(3.20) \quad \tilde{C} = \begin{bmatrix} \tilde{C} & \sigma^{-2}\tilde{C}\tilde{P} \\ 0 & -\sigma^{-2}\tilde{B}^*\tilde{A}^{*-1} \end{bmatrix}.$$

Here \tilde{P} and \tilde{Q} are solutions of the discrete time Lyapunov equations

$$(3.21) \quad \tilde{P} - \tilde{A}\tilde{P}\tilde{A}^* = \tilde{B}\tilde{B}^*,$$

$$(3.22) \quad \tilde{Q} - \tilde{A}^*\tilde{Q}\tilde{A} = \tilde{C}^*\tilde{C}$$

and $\tilde{Z} = (I - \sigma^{-2}\tilde{Q}\tilde{P})^{-1}$. The result of Theorem 1 then is that \tilde{F} satisfies

$$\sup \{\|\tilde{F}(z)\|: |z| = 1\} \leq \sigma$$

and

$$\tilde{F} \in \tilde{G} + H_{p \times q}^\infty(l)$$

if and only if \tilde{F} has the form

$$\tilde{F}(z) = T_{\tilde{\theta}(z)}(\tilde{H}(z))$$

for some $\tilde{H} \in H_{p \times q}^\infty$ with $\|\tilde{H}\|_\infty \leq 1$ (sup norm on the unit circle), where in general we define

$$T_\theta(X) = (\theta_{11}X + \theta_{12})(\theta_{21}X + \theta_{22})^{-1}$$

if

$$\theta = \begin{bmatrix} \theta_{11} & \theta_{12} \\ \theta_{21} & \theta_{22} \end{bmatrix}.$$

If we make the change of variable $z \rightarrow z(s)$ and define

$$\theta(s) = \tilde{\theta}(z(s)), \quad G(s) = \tilde{G}(z(s)) \quad \text{and} \quad F(s) = \tilde{F}(z(s)),$$

we see from this that $\theta(s) = \tilde{\theta}(z(s))$ is as desired in Theorem 3.1. It remains only to use (3.13)–(3.22) to compute $\theta(s)$ explicitly in terms of the original A , B , C and continuous time controllability and observability gramians \hat{P} and \hat{Q} .

We first convert the discrete time gramians \tilde{P} , \tilde{Q} to the continuous time gramians \hat{P} , \hat{Q} . From (3.15) and (3.16), the Lyapunov equation (3.21) is equivalent to

$$\tilde{P} - (I + A)(I - A)^{-1}\tilde{P}(I - A^*)^{-1}(I + A^*) = 2(I - A)^{-1}BB^*(I - A^*)^{-1}$$

or

$$(I - A)\tilde{P}(I - A^*) - (I + A)\tilde{P}(I + A)^* = 2BB^*.$$

This collapses to

$$A^*\tilde{P} + \tilde{P}A^* = -B^*B.$$

From (3.9) we see that the discrete time controllability gramian \tilde{P} is identical to the continuous time controllability gramian \hat{P} . Similarly, using (3.14) and (3.16) we see that (3.22) collapses to

$$A^*\tilde{Q} + \tilde{Q}A = -C^*C,$$

so $\tilde{Q} = \hat{Q}$. Thus $\tilde{Z} = (I - \sigma^{-2}\tilde{Q}\tilde{P})^{-1} = (I - \sigma^{-2}\hat{Q}\hat{P})^{-1} = Z$ as well.

The matrix function $\theta(s)$ is determined by the conditions in Theorem 3.1 only up to a constant J -unitary right factor ($J = \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix}$). By using this freedom we can arrange that

$$\theta(\infty) = \begin{bmatrix} I_p & 0 \\ 0 & \sigma^{-1}I_q \end{bmatrix}.$$

Thus with this normalization $\theta(s)$ is given by

$$\theta(s) = \tilde{\theta}(z(s))\tilde{\theta}(z(\infty))^{-1} \begin{bmatrix} I_p & 0 \\ 0 & \sigma^{-1}I_q \end{bmatrix}$$

where

$$\tilde{\theta}(z(s)) = \left[I_{p+q} + \tilde{C} \left(\frac{1+s}{1-s} I - \tilde{A} \right)^{-1} \tilde{B} \right] \tilde{\theta}(\infty).$$

Thus

$$\tilde{\theta}(z(\infty)) = [I_{p+q} - \tilde{C}(I + \tilde{A})^{-1}\tilde{B}]\tilde{\theta}(\infty).$$

Compute next

$$\begin{aligned}
 \tilde{\theta}(z(s)) - \tilde{\theta}(z(\infty)) &= \tilde{C} \left[\left(\frac{1+s}{1-s} I - \tilde{A} \right)^{-1} + (I + \tilde{A})^{-1} \right] \tilde{B} \tilde{\theta}(\infty) \\
 &= \tilde{C} \left(\frac{1+s}{1-s} I - \tilde{A} \right)^{-1} \left[I + \tilde{A} + \frac{1+s}{1-s} I - \tilde{A} \right] (I + \tilde{A})^{-1} \tilde{B} \tilde{\theta}(\infty) \\
 &= \frac{2}{1-s} \tilde{C} \left(\frac{1+s}{1-s} I - \tilde{A} \right)^{-1} (I + \tilde{A})^{-1} \tilde{B} \tilde{\theta}(\infty) \\
 &= 2 \tilde{C} (s(I + \tilde{A}) + (I - \tilde{A}))^{-1} (I + \tilde{A})^{-1} \tilde{B} \tilde{\theta}(\infty) \\
 &\quad \cdot 2 \tilde{C} (I + \tilde{A})^{-1} (sI - (\tilde{A} - I)(\tilde{A} + I)^{-1})^{-1} (I + \tilde{A})^{-1} \tilde{B} \tilde{\theta}(\infty).
 \end{aligned}$$

Thus

$$\begin{aligned}
 \theta(s) &= \begin{bmatrix} I_p & 0 \\ 0 & \sigma^{-1} I_q \end{bmatrix} + 2 \tilde{C} (I + \tilde{A})^{-1} (sI - (\tilde{A} - I)(\tilde{A} + I)^{-1})^{-1} (I + \tilde{A})^{-1} \\
 &\quad \cdot \tilde{B} [I_{p+q} - \tilde{C} (I + \tilde{A})^{-1} \tilde{B}]^{-1} \begin{bmatrix} I_p & 0 \\ 0 & \sigma^{-1} I_q \end{bmatrix}.
 \end{aligned}$$

We thus see that

$$\theta(s) = \begin{bmatrix} I_p & 0 \\ 0 & \sigma^{-1} I_q \end{bmatrix} + \underline{C} (sI - \underline{A})^{-1} \underline{B},$$

where

$$(3.23) \quad \underline{A} = (\tilde{A} - I)(\tilde{A} + I)^{-1},$$

$$(3.24) \quad \underline{B} = \sqrt{2} (I + \tilde{A})^{-1} \tilde{B} [I_{p+q} - \tilde{C} (I + \tilde{A})^{-1} \tilde{B}]^{-1} \begin{bmatrix} I_p & 0 \\ 0 & \sigma^{-1} I_q \end{bmatrix}$$

and

$$(3.25) \quad \underline{C} = \sqrt{2} \tilde{C} (I + \tilde{A})^{-1}.$$

The computation of \underline{A} is aided by noting from the definition (3.15) of \tilde{A} and the Lyapunov equation (3.18) that \tilde{A} can be block-diagonalized.

$$(3.26) \quad \tilde{A} = \begin{bmatrix} \tilde{A} & \sigma^{-2} \tilde{A} \hat{P} - \sigma^{-2} \hat{P} \tilde{A}^{*-1} \\ 0 & \tilde{A}^{*-1} \end{bmatrix} = \begin{bmatrix} I & -\sigma^{-2} \hat{P} \\ 0 & I \end{bmatrix} \begin{bmatrix} \tilde{A} & 0 \\ 0 & \tilde{A}^{*-1} \end{bmatrix} \begin{bmatrix} I & \sigma^{-2} \hat{P} \\ 0 & I \end{bmatrix}.$$

From (3.16) it is immediate that

$$(\tilde{A} - I)(\tilde{A} + I)^{-1} = \underline{A}$$

and

$$(\tilde{A}^{*-1} - I)(\tilde{A}^{*-1} + I)^{-1} = -\underline{A}^*.$$

Thus from this, (3.23) and (3.26) we get

$$\begin{aligned}
 \underline{A} &= \begin{bmatrix} I & -\sigma^{-2} \hat{P} \\ 0 & I \end{bmatrix} \begin{bmatrix} \underline{A} & 0 \\ 0 & -\underline{A}^* \end{bmatrix} \begin{bmatrix} I & \sigma^{-2} \hat{P} \\ 0 & I \end{bmatrix} \\
 &= \begin{bmatrix} \underline{A} & \sigma^{-2} \underline{A} \hat{P} + \sigma^{-2} \hat{P} \underline{A}^* \\ 0 & -\underline{A}^* \end{bmatrix} \\
 &= \begin{bmatrix} \underline{A} & -\sigma^{-2} \underline{B} \underline{B}^* \\ 0 & -\underline{A}^* \end{bmatrix}
 \end{aligned}$$

where we used (3.9) for the last step. This verifies the formula (3.2) for \underline{A} .

We next compute \underline{B} from (3.24). To do this we must compute

$$\tilde{B}[I_{p+q} - \tilde{C}(I + \tilde{A})^{-1}\tilde{B}]^{-1} = [I - \tilde{B}\tilde{C}(I + \tilde{A})^{-1}]^{-1}\tilde{B} = (I + \tilde{A})[I + \tilde{A} - \tilde{B}\tilde{C}]^{-1}\tilde{B}.$$

From (3.19) and (3.20) we get

$$\tilde{B}\tilde{C} = \begin{bmatrix} 0 & -\sigma^{-2}\tilde{B}\tilde{B}^*\tilde{A}^{*-1} \\ Z\tilde{A}^{*-1}\tilde{C}^*\tilde{C} & \sigma^{-2}Z\tilde{A}^{*-1}\tilde{C}^*\tilde{C}\hat{P} - \sigma^{-2}Z\hat{Q}\tilde{B}\tilde{B}^*\tilde{A}^{*-1} \end{bmatrix}.$$

Thus, from 3.18

$$\tilde{A} - \tilde{B}\tilde{C} = \begin{bmatrix} \tilde{A} & 0 \\ -Z\tilde{A}^{*-1}\tilde{C}^*\tilde{C} & x_{22} \end{bmatrix}$$

where (by using (3.21) and (3.22))

$$\begin{aligned} x_{22} &= \tilde{A}^{*-1} - \sigma^{-2}Z\tilde{A}^{*-1}\tilde{C}^*\tilde{C}\hat{P} + \sigma^{-2}Z\hat{Q}\tilde{B}\tilde{B}^*\tilde{A}^{*-1} \\ &= Z[(I - \sigma^{-2}\hat{Q}\hat{P})\tilde{A}^{*-1} + \sigma^{-2}(\hat{Q}\tilde{A} - \tilde{A}^{*-1}\hat{Q})\hat{P} + \sigma^{-2}\hat{Q}(\hat{P}\tilde{A}^{*-1} - \tilde{A}\hat{P})] \\ &= Z[\tilde{A}^{*-1} - \sigma^{-2}\tilde{A}^{*-1}\hat{Q}\hat{P}] \\ &= Z\tilde{A}^{*-1}Z^{-1}. \end{aligned}$$

Therefore

$$\begin{aligned} \tilde{A} - \tilde{B}\tilde{C} &= \begin{bmatrix} \tilde{A} & 0 \\ -Z\tilde{A}^{*-1}\tilde{C}^*\tilde{C} & Z\tilde{A}^{*-1}Z^{-1} \end{bmatrix} \\ &= \begin{bmatrix} I & 0 \\ 0 & Z \end{bmatrix} \begin{bmatrix} \tilde{A} & 0 \\ -\tilde{A}^{*-1}\tilde{C}^*\tilde{C} & \tilde{A}^{*-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & Z^{-1} \end{bmatrix} \\ &= \begin{bmatrix} I & 0 \\ 0 & Z \end{bmatrix} \begin{bmatrix} \tilde{A} & 0 \\ \hat{Q}\tilde{A} - \tilde{A}^{*-1}\hat{Q} & \tilde{A}^{*-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & Z^{-1} \end{bmatrix} \\ &= \begin{bmatrix} I & 0 \\ 0 & Z \end{bmatrix} \begin{bmatrix} I & 0 \\ \hat{Q} & I \end{bmatrix} \begin{bmatrix} \tilde{A} & 0 \\ 0 & \tilde{A}^{*-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ -\hat{Q} & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & Z^{-1} \end{bmatrix} \end{aligned}$$

and

$$I + \tilde{A} - \tilde{B}\tilde{C} = \begin{bmatrix} I & 0 \\ Z\hat{Q} & Z \end{bmatrix} \begin{bmatrix} I + \tilde{A} & 0 \\ 0 & I + \tilde{A}^{*-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ -\hat{Q} & Z^{-1} \end{bmatrix},$$

so

$$(I + \tilde{A} - \tilde{B}\tilde{C})^{-1} = \begin{bmatrix} I & 0 \\ Z\hat{Q} & Z \end{bmatrix} \begin{bmatrix} (I + \tilde{A})^{-1} & 0 \\ 0 & (I + \tilde{A}^{*-1})^{-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ -\hat{Q} & Z^{-1} \end{bmatrix}.$$

We finally conclude that

$$\begin{aligned} \tilde{B}[I_{p+q} - \tilde{C}(I + \tilde{A})^{-1}\tilde{B}]^{-1} \\ = (I + \tilde{A}) \begin{bmatrix} I & 0 \\ Z\hat{Q} & Z \end{bmatrix} \begin{bmatrix} (I + \tilde{A})^{-1} & 0 \\ 0 & (I + \tilde{A}^{*-1})^{-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ -\hat{Q} & Z^{-1} \end{bmatrix} \tilde{B}. \end{aligned}$$

From (3.24), plugging in (3.16) we therefore get

$$\underline{B} = \sqrt{2} \begin{bmatrix} I & 0 \\ Z\hat{Q} & Z \end{bmatrix} \begin{bmatrix} \frac{1}{2}(I - A) & 0 \\ 0 & \frac{1}{2}(I + A^*) \end{bmatrix} \begin{bmatrix} I & 0 \\ -\hat{Q} & Z^{-1} \end{bmatrix} \tilde{B} \begin{bmatrix} I_p & 0 \\ 0 & \sigma^{-1}I_q \end{bmatrix}.$$

Substituting (3.19) for \tilde{B} and (3.14)–(3.16) for \tilde{A} , \tilde{B} , \tilde{C} , we get

$$\begin{aligned} \underline{B} &= \sqrt{2} \begin{bmatrix} \frac{1}{2}(I-A) & 0 \\ \frac{1}{2}Z[\hat{Q}(I-A) - (I+A^*)\hat{Q}] & \frac{1}{2}Z(I+A^*)Z^{-1} \end{bmatrix} \\ &\quad \cdot \begin{bmatrix} 0 & \sqrt{2}\sigma^{-1}(I-A)^{-1}B \\ \sqrt{2}Z(I+A^*)^{-1}C^* & \sqrt{2}\sigma^{-1}Z\hat{Q}(I-A)^{-1}B \end{bmatrix} \\ &= \begin{bmatrix} 0 & \sigma^{-1}B \\ ZC^* & \sigma^{-1}Z\hat{Q}B \end{bmatrix}, \end{aligned}$$

which verifies (3.3). To verify formula (3.4) for \underline{C} , plug (3.20) and (3.26) into (3.25) to get

$$\underline{C} = \sqrt{2} \begin{bmatrix} \tilde{C} & \sigma^{-2}\tilde{C}\hat{P} \\ 0 & -\sigma^{-2}\tilde{B}^*\tilde{A}^{*-1} \end{bmatrix} \begin{bmatrix} I & -\sigma^{-2}\hat{P} \\ 0 & I \end{bmatrix} \begin{bmatrix} (I+\tilde{A})^{-1} & 0 \\ 0 & (I+\tilde{A}^{*-1})^{-1} \end{bmatrix} \begin{bmatrix} I & \sigma^{-2}\hat{P} \\ 0 & I \end{bmatrix}.$$

Now substituting (3.14)–(3.16), we get

$$\begin{aligned} \underline{C} &= \begin{bmatrix} 2C(I-A)^{-1} & 2\sigma^{-2}C(I-A)^{-1}\hat{P} \\ 0 & -2\sigma^{-2}B^*(I+A^*)^{-1} \end{bmatrix} \\ &\quad \cdot \begin{bmatrix} I & -\sigma^{-2}\hat{P} \\ 0 & I \end{bmatrix} \begin{bmatrix} \frac{1}{2}(I-A) & 0 \\ 0 & \frac{1}{2}(I+A^*) \end{bmatrix} \begin{bmatrix} I & \sigma^{-2}\hat{P} \\ 0 & I \end{bmatrix} \\ &= \begin{bmatrix} C(I-A)^{-1} & \sigma^{-2}C(I-A)^{-1}\hat{P} \\ 0 & -\sigma^{-2}B^*(I+A^*)^{-1} \end{bmatrix} \begin{bmatrix} I-A & -\sigma^{-2}(A\hat{P}+\hat{P}A^*) \\ 0 & I+A^* \end{bmatrix} \\ &= \begin{bmatrix} C & \sigma^{-2}C(I-A)^{-1}[-A\hat{P}-\hat{P}A^*+\hat{P}(I+A^*)] \\ 0 & -\sigma^{-2}B^* \end{bmatrix} \\ &= \begin{bmatrix} C & \sigma^{-2}C\hat{P} \\ 0 & -\sigma^{-2}B^* \end{bmatrix}. \end{aligned}$$

This verifies formula (3.4).

It remains only to check that (3.5)–(3.8) follow from (3.2)–(3.4). But this is easily seen by using the diagonalization of \underline{A} derived from the Lyapunov equation (3.9)

$$\begin{aligned} \underline{A} &= \begin{bmatrix} A & \sigma^{-2}A\hat{P}+\sigma^{-2}\hat{P}A^* \\ 0 & -A^* \end{bmatrix} \\ &= \begin{bmatrix} I & -\sigma^{-2}\hat{P} \\ 0 & I \end{bmatrix} \begin{bmatrix} A & 0 \\ 0 & -A^* \end{bmatrix} \begin{bmatrix} I & \sigma^{-2}\hat{P} \\ 0 & I \end{bmatrix} \end{aligned}$$

and then multiplying out. We leave the details to the reader. \square

ITERATIVE METHODS FOR LARGE CONVEX QUADRATIC PROGRAMS: A SURVEY*

Y. Y. LIN† AND J.-S. PANG‡

Abstract. In this paper, we give a state-of-the-art review of many iterative methods for solving large convex quadratic programs. We attempt to classify several of the more basic methods in two categories, within each of which a unified iterative scheme will be introduced and its convergence analyzed. Hybrid iterative methods (such as the proximal point algorithm and a diagonalization scheme) that make use of the more basic schemes will also be described. The results of an extensive computer experimentation which is aimed at comparing the relative performance of the various methods will be reported and discussed. Finally, several important topics which require future research will be highlighted.

Key words. iterative methods, quadratic programs, linear complementarity problem, matrix splitting, duality

AMS(MOS) subject classifications. 90C20, 90C33

1. Introduction.

1.1. Foreword. Convex quadratic programming is an old and important topic in mathematical programming. Its countless applications appear in diverse areas of engineering, mathematical, physical, social and management sciences. In addition, quadratic programs are central to many algorithms for solving nonlinear programming problems.

Over the years, a large number of methods have been developed for solving convex quadratic programs. These methods can be divided into two categories: finite methods and iterative methods. Finite methods solve a given program by some kind of pivoting procedures and terminate in finite time. On the other hand, iterative methods generate an infinite sequence which converges to a limit point that solves the program. In general, finite methods are effective for small-to-medium sized problems, but tend to become less efficient and uneconomical as the problem size increases. This is due to two reasons. One is the fact that round-off errors accumulate very rapidly and often lead to numerical difficulties. The other is the huge computer storage required which places a severe limit on the size of the problem being solved. Iterative methods, on the other hand are immune from these two handicaps because they (i) are self-correcting and (ii) operate on the input data only. As a result, they are capable of preserving any data sparsity and thus are particularly attractive for solving large-scale sparse problems.

Our principal objective in this paper is twofold: (i) to undertake a comprehensive survey of the most commonly used and (in our view) most promising iterative methods for solving large-scale sparse convex quadratic programs (we refer to [44] for a survey of finite methods for solving general convex quadratic programs); and (ii) to perform and report the numerical results of an extensive computer experimentation comparing the relative performance of the methods. Based on the results obtained, we shall make some general comments on each individual method with regard to its strength and drawbacks.

1.2. Review of literature. Among the earliest iterative methods proposed for solving convex quadratic programs is the one by Hildreth [27]. In present-day language,

* Received by the editors September 25, 1985, and in revised form March 4, 1986. This research was based on work supported by the National Science Foundation under grant ECS-8407240.

† School of Management, The University of Texas at Dallas, Richardson, Texas 75083-0688.

Hildreth's procedure may be described as the projected (point) Gauss-Seidel method applied to an equivalent linear complementarity formulation of the given quadratic program. The relaxation method proposed by Agmon [2], Motzkin and Schoenberg [37] for solving a system of linear inequalities is related to Hildreth's procedure and actually appears before the latter.

Hildreth's algorithm was published in the 1950s. It was not until 1971 that Cryer [17] proposed the first successive overrelaxation (SOR) method for minimizing a strictly convex quadratic function over the nonnegative orthant. Subsequently, Cottle, Golub and Sacher [15] extended Cryer's method to a block version; Cottle and Goheen [14] further extended Cryer's method to include box constraints. In [8], Cea and Glowinski proposed a related block SOR scheme. (Many more references on similar SOR methods may be found in the cited articles.) In [31], Mangasarian proposed a general iterative scheme for solving the symmetric linear complementarity problem and improved on the convergence results obtained previously by Cryer, Cottle and others. Subsequently, Mangasarian [32], [34] discussed how a SOR method can be applied to solve separable strictly convex quadratic programs and linear programs. Based on a penalty function approach, Han and Mangasarian [24] proposed an SOR scheme for solving a nonseparable strictly convex quadratic program. Most recently, Lin and Cryer [30] proposed an alternating direction implicit algorithm for the solution of (symmetric) linear complementarity problems arising from free boundary problems. The numerical results reported in [30] show that the alternating direction implicit algorithm is significantly faster than the SOR algorithms.

Motivated by the works of Mangasarian [31], Ahn [3], Aganagic [1] and others, Pang [43] introduced a fundamental iterative scheme for solving the linear complementarity problem. The scheme is based on the classical notion of matrix splittings in numerical analysis. Specialization of the scheme to a strictly convex quadratic program was discussed in [45], [46] where some necessary and sufficient conditions for convergence were established.

Separately, Lent and Censor [28] extended Hildreth's original algorithm and developed an almost cyclic SOR algorithm for a strictly convex quadratic program. The accompanying paper by Herman and Lent [26] described an application of the Lent-Censor extension of Hildreth's algorithm. Another recent application of Hildreth's original algorithm was documented in Bachem and Korte [6]. In [28], the authors pointed out the connection between Hildreth's algorithm and the relaxation method of Agmon [2], Motzkin and Schoenberg [37]. Lent and Censor classified the extended Hildreth algorithm as a row-action method [9]. The term "row-action" refers to the notion that the constraints of the (quadratic) program are acted upon one row at a time.

More recently, Cottle et al. [13] described a Lagrangian relaxation algorithm for solving a constrained matrix problem formulated as a strictly convex quadratic program over the transportation polytope. (See also [38].) An earlier paper by Cottle and Pang [16] discussed the solution of the same problem by an SOR scheme. (See also Cottle [12].) In [46], a convergence result on the Lagrangian relaxation scheme of Cottle et al. was established.

The iterative methods mentioned above can be classified as either (i) LCP (i.e. linear complementarity problem) based, or (ii) dual based. The LCP-based iterative methods solve a given quadratic program via an equivalent linear complementarity formulation. These methods have their origin in the solution of systems of linear equations [40], [53]. The fundamental scheme proposed in Pang [43] is a unification of many of the LCP-based methods. The dual-based iterative methods, on the other

hand, solve a given program via its (Lagrangian) dual program. A typical dual method operates by maximizing the dual function using a certain periodic basis or gradient-type ascent iterative procedure. For certain types of problems, the LCP and the dual formulations are the same.

Many of the iterative methods for solving a general convex quadratic program require a strictly convex objective function. An iterative scheme, proposed recently by Shiau [52], is an exception. Shiau's scheme was designed to solve a linear complementarity problem and proved to be convergent in the case of an asymmetric positive semidefinite matrix. In particular, it is applicable to the linear complementarity problem arising from a convex quadratic program. No computational result concerning this application is available, however. (Incidentally, Shiau's scheme is rather similar to the Frank-Wolfe 1957 procedure [21] for quadratic programs.) A third approach to deal with the convex, but not strictly convex case is to rely on the proximal point algorithm [50], [51]. Ha [23] discussed this idea in his Ph.D. dissertation and showed how it leads to certain decomposition methods for block structured convex quadratic programs. The main idea of the proximal point approach is to first strongly convexify the (quadratic) objective function before applying an inner iterative scheme to the strongly convexified subprograms. Specialized to a linear objective function, the proximal point approach provides an effective iterative procedure for solving large, sparse linear programs which may prove to be a practical alternative to the well-known simplex method and/or many of its variants. Mangasarian's iterative method for linear programs [34] is closely related to the proximal point approach (see Cheng's dissertation [10] for more details).

In recent years, there have been several proposals [18], [39], [54] which attempt to incorporate an iterative scheme in a finite method for solving convex quadratic programs with box constraints. The central idea is to use an iterative method for systems of linear equations (like SOR or conjugate gradient) to carry out the fundamental step of equation solving in a pivoting or active-set method. Under exact arithmetic and suitable stopping rule for the inner scheme, the overall method remains finitely convergent. At present, it is not clear how such an iterative active-set method (as it is called in [39]) can be applied to large-scale problems with general linear constraints. (It should be pointed out that although in theory, any strictly convex quadratic program can be transformed into one with box constraints, the transformation is not suitable for large programs with sparse data. This will be explained in more detail later.)

1.3. Organization. The remainder of this paper is divided into 5 sections. Section 2 contains 3 subsections. In § 2.1, we review a fundamental iterative scheme for solving the symmetric linear complementarity problem. In § 2.2, we state several convergence results of the fundamental scheme. Section 2.3 deals with the issue of error bounds of an approximate solution to the linear complementarity problem. In § 3.1, we discuss the specialization of the iterative scheme of § 2.1 to a separable strictly convex quadratic program and point out how separability is crucial. Section 3.2 deals with the nonseparable case. There, the Han-Mangasarian approach as well as a diagonalization algorithm is described. In § 3.3, we explain how the proximal point algorithm can be applied to a convex quadratic program. Section 4 is concerned with the dual-based iterative methods for solving a strictly convex quadratic program. In § 4.1, we define the dual function and summarize several of its key properties. In § 4.2, we introduce a unified dual ascent method. Section 4.3 explains how the method specializes in two important cases. In § 4.4, we state two convergence results for the dual ascent method of § 4.2.

In § 4.5, we refine the analysis of § 4.3 and discuss two related extensions. In the fifth section, we report the computational experience we have gathered with the various methods surveyed in the previous sections. We divide our discussion into the separable (§ 5.1) and the nonseparable (§ 5.2) case. Numerical results are presented from which observations are drawn. Finally, in the sixth and last section, we point out several issues that are not treated in this survey but which are important and deserve attention.

2. Iterative methods for symmetric LCP's.

2.1. A fundamental scheme. The close connection between a convex quadratic program and a linear complementarity problem is well recognized. Indeed, many iterative methods for (strictly) convex quadratic programs can be derived from a certain basic algorithm for solving the LCP with a symmetric matrix. In this section, we shall explain this fundamental iterative scheme for the LCP and present various convergence results related to it.

Consider the general linear complementarity problem of finding a vector x in R^n such that

$$(2.1.1) \quad w = q + Mx \geq 0, \quad x \geq 0 \quad \text{and} \quad x^T w = 0$$

where q and M are a given n -vector and an n by n matrix, respectively. We shall assume that the matrix M is *symmetric*. Under this symmetry assumption, the LCP (2.1.1) becomes the Karush-Kuhn-Tucker optimality conditions of the quadratic program over the nonnegative orthant:

$$(2.1.2) \quad \begin{aligned} &\text{minimize} \quad f(x) = q^T x + \frac{1}{2} x^T M x \\ &\text{subject to} \quad x \geq 0. \end{aligned}$$

If in addition, M is positive semidefinite, then the quadratic objective function $f(x)$ is convex. In this case, the two problems (2.1.1) and (2.1.2) are completely equivalent. As we shall see, the objective function $f(x)$ plays a crucial role in the convergence results of the basic iterative scheme for solving the LCP (2.1.1).

It is well known that many iterative methods for systems of linear equations can be uniformly described in terms of matrix splittings [40], [53]. Based on the same notion, we introduce a fundamental iterative scheme for solving the LCP (2.1.1). Specifically, let

$$M = B + C$$

be a splitting of the matrix M .

BASIC ALGORITHM. Let x^0 be an arbitrary nonnegative vector. In general, given $x^k \geq 0$, we generate x^{k+1} (which is assumed to exist) as a solution to the linear complementarity subproblem

$$(2.1.3) \quad w = q + Cx^k + Bx \geq 0, \quad x \geq 0 \quad \text{and} \quad x^T w = 0.$$

Terminate if some stopping rule is satisfied.

The above algorithm is very general. In practice, the matrix B should be chosen so that each subproblem (2.1.3) has at least one solution which is easily computable.

An example of such a choice is the standard (point) SOR-splitting where

$$(2.1.4) \quad B = L + D/\omega \quad \text{and} \quad C = U + (1 - 1/\omega)D$$

with D , L and U being the diagonal, strictly lower triangular and strictly upper triangular parts of M , respectively, and with ω being a given scalar satisfying $0 < \omega < 2$. If M has positive diagonals, then under the splitting (2.1.4), the basic algorithm generates the SOR sequence $\{x^k\}$ where

$$(2.1.5) \quad x_i^{k+1} = \max \left\{ 0, x_i^k - \left(\frac{\omega}{M_{ii}} \right) \left(q_i + \sum_{j < i} M_{ij} x_j^{k+1} + \sum_{j \geq i} M_{ij} x_j^k \right) \right\}, \quad i = 1, \dots, n.$$

The latter iteration (2.1.5) is precisely Cryer's 1971 method [17]. In a similar fashion, if M is partitioned in blocks (M_{ij}) and if D , L and U are accordingly defined, then the splitting (2.1.4) leads to a block SOR scheme in which each subproblem (2.1.3) decomposes into smaller sub-subproblems which, typically, can be solved much more easily than the original LCP (2.1.1).

2.2. Convergence results. In this subsection, we give several convergence results pertaining to the basic algorithm. All these results depend crucially on the symmetry assumption of M . (There are a number of results available for the asymmetric LCP [43], [45]. However, they do not seem directly applicable to convex quadratic programs.) Proofs will be omitted but can be found in the references.

We denote the splitting $M = B + C$ by the pair (B, C) . We say that the splitting (B, C) is *regular* if $B - C$ is positive definite. Notice that the SOR splitting (2.1.4) is regular if M is symmetric with positive diagonals and if $0 < \omega < 2$. We shall assume that the matrix B is such that each linear complementarity subproblem (2.1.3) has a solution. In the terminology of linear complementarity theory [41], such a B is referred to as a *Q-matrix*. If B is a *Q-matrix*, the splitting (B, C) is called a *Q-splitting*. Throughout the analysis that follows, except for the implicit understanding that each iterate x^{k+1} is well defined and easily computable, we leave open the question of how the computation of x^{k+1} should be carried out.

The first result states that under the mere assumption of symmetry on M , any accumulation point of a sequence $\{x^k\}$ generated by the basic algorithm with a regular *Q-splitting* (B, C) is a solution to the LCP (2.1.1).

THEOREM 2.2.1. *Let M be a symmetric matrix and (B, C) a regular *Q-splitting* of M . Then, for any $x^0 \geq 0$, any accumulation point of the sequence $\{x^k\}$ produced by the basic algorithm solves (2.1.1).*

Notice that Theorem 2.2.1 does not assert the existence of an accumulation point. For such a point to exist, it is sufficient for the sequence $\{x^k\}$ to be bounded. Conditions ensuring such boundedness consequence are given in the next result.

THEOREM 2.2.2. *Let M , B and C be as given in Theorem 2.2.1. If the two conditions below hold:*

- (A) *the quadratic function $f(x) = q^T x + \frac{1}{2} x^T M x$ is bounded below for $x \geq 0$;*
- (B) *the homogeneous LCP $[x \geq 0, Mx \geq 0 \text{ and } x^T M x = 0]$ has $x = 0$ as the unique solution,*

then any sequence $\{x^k\}$ generated by the basic algorithm is bounded.

It is well known from quadratic programming theory that if a quadratic objective function is bounded below on a polyhedral set, then it achieves its minimum there (see [19], [21]). In particular, assumption (A) implies that the quadratic program (2.1.2) has an optimal solution which must necessarily solve the LCP (2.1.1) by the

symmetry of M . Thus, the existence of a solution to (2.1.1) is implicit in condition (A). Moreover, (A) holds if and only if the matrix M is copositive (i.e. $x^T Mx \geq 0$ for all $x \geq 0$) and the implication below holds:

$$[x \geq 0 \text{ and } x^T Mx = 0] \text{ implies } q^T x \geq 0$$

(see [19] for a proof). In general, the existence of a solution to the LCP (2.1.1) does not imply (A).

Condition (B), on the other hand, is related to the boundedness of the solution set to the LCP (2.1.1). Indeed, it is not difficult to show that (B) holds if and only if for all vectors q , the LCP (2.1.1) has a (possibly empty) bounded solution set. Obviously, if M is strictly copositive (i.e. $x^T Mx > 0$ for all $x \geq 0$), then condition (B) holds trivially. Moreover, according to the discussion above, condition (A) also holds for all vectors q .

We say that a Q -splitting (B, C) of M is *weakly convergent* if for all vectors q and all initial $x^0 \geq 0$, any sequence $\{x^k\}$ generated by the basic algorithm contains at least one accumulation point; moreover, any such point is a solution to the LCP (2.1.1). (Notice that this notion of weak convergence is a global one in the sense that it applies to all constant vectors q .) We have just proven that if M is a symmetric strictly copositive matrix, then any regular Q -splitting of M is weakly convergent. As a matter of fact, the converse of this statement is also true and is made precise in the next theorem.

THEOREM 2.2.3. *Let M be a symmetric matrix. If M is strictly copositive, then any regular Q -splitting of M is weakly convergent. Conversely, if M has a regular Q -splitting that is weakly convergent, then M is strictly copositive.*

Specializing Theorem 2.2.3 to an SOR method, we obtain the following.

COROLLARY 2.2.1. *Let M be symmetric with positive diagonals. Then the SOR splitting (2.1.4) of M is weakly convergent for all $0 < \omega < 2$ if and only if M is strictly copositive.*

Remark. A similar result can be stated for a block SOR method.

Corollary 2.2.1 resembles the Ostrowski–Reich theorem in numerical analysis [40], [53]. The latter theorem states that for the system of linear equations $[Mx = p]$, if M is symmetric with positive diagonals, then the sequence $\{x^k\}$ generated by the (point) SOR method is convergent for any x^0 and all $0 < \omega < 2$ if and only if M is positive definite. There are several differences however. An obvious one is the notion of convergence involved. In the case of a system of linear equations, the entire sequence of iterates converges; whereas in the case of the LCP, the convergence is in terms of subsequences. (Incidentally, the latter kind of convergence is very common in nonlinear programming algorithms.) In [45], Pang raised the question of whether for the LCP (2.1.1), the convergence of the SOR sequence (cf. (2.1.5)) can be characterized by the positive definiteness of M , just like the Ostrowski–Reich result. It is easy to see that positive definiteness of M implies the convergence of the SOR sequence. Unfortunately, the converse is false. To explain this, we quote a convergence result which is a much simplified version of Theorem 2.1 in [46].

THEOREM 2.2.4. *Let M be a symmetric nondegenerate matrix (i.e. all principal minors of M are nonzero). Suppose that M has positive diagonal entries. Then the following statements are equivalent:*

- (i) *For any $x^0 \geq 0$, the SOR sequence $\{x^k\}$ (2.1.5) is convergent for all $0 < \omega < 2$ and all vectors q ;*
- (ii) *M is strictly copositive;*
- (iii) *M is copositive.*

Since there are obviously symmetric nondegenerate copositive matrices that are not positive definite, it follows that the convergence of the SOR sequence (2.1.5) does not necessarily imply the positive definiteness of M .

In several important applications of the LCP (2.1.1) to convex quadratic programs, the matrix M is, in addition to being symmetric, positive semidefinite but not definite. In this case, condition (B) of Theorem 2.2.2 will fail to hold. Thus, Theorem 2.2.2 becomes inapplicable. However, we have the following convergence result.

THEOREM 2.2.5. *Let M be a symmetric positive semidefinite matrix and let (B, C) be a regular Q -splitting of M . Then, for any initial vector $x^0 \geq 0$, the sequence $\{x^k\}$ generated by the basic algorithm is uniquely defined. Moreover, the following three statements are equivalent:*

- (A) *the quadratic function $f(x) = q^T x + \frac{1}{2} x^T M x$ is bounded below for $x \geq 0$;*
- (B) *the LCP (2.1.1) has a solution;*
- (C) *for any initial vector $x^0 \geq 0$, the sequence $\{Mx^k\}$ converges to some vector Mz and z solves the LCP (2.1.1).*

Notice that Theorem 2.2.5 does not assert the convergence of the sequence $\{x^k\}$. As a matter of fact, it remains an open question to determine if $\{x^k\}$ is bounded under the assumptions of Theorem 2.2.5. (More specifically, the question is: Let M , B and C be as given in Theorem 2.2.5. Does condition (A) or (B) imply that the sequence $\{x^k\}$ is bounded?) The next result shows that $\{x^k\}$ is indeed bounded if a Slater constraint qualification holds for the LCP (2.1.1). This result was first proved by Mangasarian [31] for his iterative scheme under a slightly weaker assumption on the matrix M . Basically, the additional Slater condition (together with the properties of M) ensures that the (quadratic) function $f(x)$ has bounded level sets. From this, the boundedness of $\{x^k\}$ follows easily.

THEOREM 2.2.6. *Let M be a symmetric positive semidefinite matrix. Let (B, C) be a regular Q -splitting of M . If there exists a vector x so that*

$$(2.2.1) \quad q + Mx > 0,$$

then for any $x^0 \geq 0$, the (uniquely defined) sequence $\{x^k\}$ generated by the basic algorithm is bounded, and thus has an accumulation point. Moreover, any such point solves the LCP (2.1.1) and the sequence $\{Mx^k\}$ converges.

Remark. The constraint qualification (2.2.1) implies assumption (A) of Theorem 2.2.5 but not conversely. It should also be pointed out that (2.2.1) bears little relationship to assumption (B) in Theorem 2.2.2. In particular, Theorem 2.2.6 is not a special case of Theorem 2.2.2.

2.3. A posteriori error bounds. In practical implementation, an iterative method terminates when a suitable stopping rule is satisfied. A commonly used rule for the LCP (2.1.1) is the following one:

$$(2.3.1) \quad \|\min(x^k, q + Mx^k)\| \leq \varepsilon$$

where $\|\cdot\|$ denotes a vector norm, x^k is the iterate being tested and ε is a given tolerance. The rule is justified on the observation that a vector x^* solves (2.1.1) if and only if

$$\|\min(x^*, q + Mx^*)\| = 0.$$

A question naturally arises, namely, if x^k is the (approximate) solution obtained at the termination of an iterative method under the rule (2.3.1), how close is x^k to an exact solution x^* of (2.1.1)? In other words, can one bound the error $\|x^k - x^*\|$ in terms of the quantity $\|\min(x^k, q + Mx^k)\|$? The result below gives an affirmative answer

to this question under a positive definiteness assumption on M . For a proof, see [47] where similar results for more general problems are established.

THEOREM 2.3.1. *Let M be a symmetric positive definite matrix with least eigenvalue α and let x^* be the (unique) solution to (2.1.1). Let x be an arbitrary vector. Then the following two error bounds hold:*

$$(2.3.2) \quad \|x - x^*\|_2 \leq ((\|M\|_2 + 1)/\alpha) \|\min(x, q + Mx)\|_2$$

and

$$(2.3.3) \quad \frac{\|x - x^*\|_2}{\|x^*\|_2} \leq \text{cond}(M)(\|M\|_2 + 1) \frac{\|\min(x, q + Mx)\|_2}{\|(-q)_+\|_2}$$

where $\text{cond}(M)$ denotes the condition number of M and $(-q)_+ = \max(0, -q)$. (It is assumed that $(-q)_+ \neq 0$ in (2.3.3).)

Remark. If $(-q)_+ = 0$, then $x^* = 0$ is the unique solution to (2.1.1).

The product $\text{cond}(M)(\|M\|_2 + 1)$ in (2.3.3) plays the same role as the condition number in a system of linear equations. Indeed, for the system $[Mx = p]$ where M is nonsingular, the bound

$$(2.3.4) \quad \frac{\|x - M^{-1}p\|}{\|M^{-1}p\|} \leq \text{cond}(M) \frac{\|p - Mx\|}{\|p\|}$$

is well known [40]. Thus, in (2.3.3), the relative error $\|x - x^*\|_2/\|x^*\|_2$ is bounded in terms of the relative residual $\|\min(x, q + Mx)\|_2/\|(-q)_+\|_2$ just like (2.3.4). Similarly, in (2.3.2), the absolute error $\|x - x^*\|_2$ is bounded in terms of the absolute residual $\|\min(x, q + Mx)\|_2$.

In [36], Mangasarian and Shiau have derived error estimates similar to (2.3.2) and (2.3.3) for the LCP (2.1.1) with a positive semidefinite matrix M . Among other things, they give an example to show that in this case, the quantity $\|\min(x, q + Mx)\|_2$ cannot be used as a measure of error. Instead, an alternative residual is needed. However, the bounding constants in the Mangasarian-Shiau error expressions do not appear as easily computable as those in Theorem 2.3.1. The reader is referred to Mangasarian [33] for related results.

3. LCP-based iterative methods for QP's.

3.1. The separable case. Consider the strictly convex quadratic program (QP)

$$(3.1.1) \quad \begin{aligned} &\text{minimize} && f(x) = q^T x + \frac{1}{2} x^T D x \\ &\text{subject to} && Ax \geq b, \quad Cx = d \end{aligned}$$

where the matrix D is symmetric and positive definite. Throughout the discussion, we shall assume that the program (3.1.1) is feasible. By the assumed property on D , it follows that (3.1.1) has a unique optimal solution which we denote by x^* . The Karush-Kuhn-Tucker optimality conditions for (3.1.1) are

$$(3.1.2a) \quad 0 = q + Dx - A^T y - C^T z,$$

$$(3.1.2b) \quad u = -b + Ax \geq 0, \quad y \geq 0, \quad u^T y = 0,$$

$$(3.1.2c) \quad 0 = -d + Cx,$$

which define a “mixed” LCP with matrix M and vector p given by

$$(3.1.3) \quad M = \begin{bmatrix} D & -A^T & -C^T \\ A & 0 & 0 \\ C & 0 & 0 \end{bmatrix} \quad \text{and} \quad p = \begin{bmatrix} q \\ -b \\ -d \end{bmatrix}.$$

The word "mixed" here refers to the equations in (3.1.2a) and (3.1.2c) and the related fact that the variables x and z are unrestricted in sign. For simplicity, we shall call (3.1.2) an LCP with data (3.1.3) and leave out the word "mixed."

In theory, one could apply the basic algorithm of § 2 to the LCP (3.1.2). However, there are serious considerations. One is the fact that the matrix in (3.1.3) is not symmetric. This immediately invalidates all the convergence results of § 2. (The results for the asymmetric LCP are too restrictive to be useful here, unfortunately.) Second, the zero blocks in (3.1.3) make an algorithm like the point SOR method inapplicable. As a result, one is led to seek for alternative LCP formulation(s).

One such formulation can be derived as follows. From (3.1.2a), we solve for x in terms of y and z , obtaining

$$(3.1.4) \quad x = -D^{-1}q + D^{-1}A^T y + D^{-1}C^T z.$$

Substitution of (3.1.4) into (3.1.2b) and (3.1.2c) yields

$$(3.1.5a) \quad u = -b - AD^{-1}q + AD^{-1}A^T y + AD^{-1}C^T z \geq 0, \quad y \geq 0, \quad u^T y = 0,$$

$$(3.1.5b) \quad 0 = -d - CD^{-1}q + CD^{-1}A^T y + CD^{-1}C^T z,$$

which form a ("mixed") LCP defined by the matrix

$$(3.1.6) \quad \begin{bmatrix} AD^{-1}A^T & AD^{-1}C^T \\ CD^{-1}A^T & CD^{-1}C^T \end{bmatrix}.$$

The latter matrix is obviously symmetric. Moreover, it is positive semidefinite but in general not positive definite. Therefore the basic algorithm of § 2 and its convergence results (Theorem 2.2.5 in particular) can be applied to (3.1.5). By backward substitution, (3.1.4) will then produce an (approximate) solution to the original QP (3.1.1). As a special case, one obtains an SOR scheme for solving (3.1.1).

There is a major drawback in the formulation (3.1.5); namely, it involves the inverse of the matrix D . For large-scale problems with sparse data, this inverse could easily destroy the practicality of the approach. Consequently, the formulation (3.1.5) is recommended for QP's with a separable objective function (i.e. with a diagonal D) or for programs where the creation of the matrix (3.1.6) will not cause computer storage difficulties. Observe that in the separable case, the computation of x from y and z in (3.1.4) is trivial.

Two practical points should be mentioned with regard to the implementation of an SOR scheme to (3.1.5). First, (3.1.5b) should be treated as an equation and the variables z unrestricted. In particular, no projection on the nonnegative orthant is required for the z variables (cf. (2.1.5)). Second, for large-scale sparse problems, it is not advisable to form the matrix (3.1.6) explicitly. This is because any sparsity structure could easily be destroyed in the formation of (3.1.6). As explained in [32], it is possible to implement the SOR scheme in such a way that any sparsity or structural properties of the data can be maintained and taken advantage of.

In what follows, we give two convergence results for the basic algorithm of § 2 applied to the LCP (3.1.5). The first result (Theorem 3.1.1) is a specialization of Corollary 2.2.1 and concerns an SOR method. Its proof can be found in [45]. The second result (Theorem 3.1.2) follows from Theorem 2.2.5 and applies to an arbitrary regular Q -splitting of the matrix (3.1.6). Its proof can be found in [46].

THEOREM 3.1.1. *Let D be a symmetric positive definite matrix. Suppose that the matrix A is nonvacuous. Then the (point) SOR splitting of the matrix (3.1.6) is weakly convergent for all $0 < \omega < 2$ if and only if the matrix C has linearly independent rows and there exists a vector x such that $Ax > 0$ and $Cx = 0$.*

THEOREM 3.1.2. *Let D be a symmetric positive definite matrix. Let (G, H) be any regular Q -splitting of the matrix (3.1.6). For any initial (y^0, z^0) with $y^0 \geq 0$, the (uniquely defined) sequence $\{(y^k, z^k)\}$ generated by the basic algorithm applied to (3.1.5) induces a corresponding sequence of iterates $\{x^k\}$ via (3.1.4); namely,*

$$x^k = -D^{-1}q + D^{-1}A^T y^k + D^{-1}C^T z^k \quad \text{for all } k.$$

The following two statements are equivalent:

(D) *for any (y^0, z^0) with $y^0 \geq 0$, the induced sequence $\{x^k\}$ converges to the unique solution of the program (3.1.1);*

(E) *the program (3.1.1) is feasible, or equivalently, solvable.*

As in Theorem 2.2.5, Theorem 3.1.2 does not assert the convergence of the sequence $\{(y^k, z^k)\}$. In order for the latter sequence to be bounded and thus to have the subsequential convergence property, it is sufficient for the matrix C to have linearly independent rows and for a Slater constraint qualification to hold; see [31], [32] for details (cf. also Theorems 2.2.6 and 3.1.1).

3.2. The nonseparable case. As we have pointed out, the formulation (3.1.5) is useful mainly in the separable case. In the sequel, we describe two approaches used to deal with the nonseparable case. One approach is due to Han and Mangasarian [24] who derive it using an exact penalty function theory. The other approach transforms the nonseparable problem into a sequence of separable ones to which the methodology of § 3.1 is applicable.

Consider the quadratic program (3.1.1) and its Karush–Kuhn–Tucker conditions (3.1.2). Observe that if γ is such that $\gamma D - I$ is nonsingular then (3.1.2) is equivalent to

$$(3.2.1a) \quad 0 = (\gamma D - I)q + (\gamma D - I)Dx - (\gamma D - I)A^T y - (\gamma D - I)C^T z,$$

$$(3.2.1b) \quad u = -b - \gamma Aq - A(\gamma D - I)x + \gamma A A^T y + \gamma A C^T z \geq 0, \quad y \geq 0, \quad u^T y = 0,$$

$$(3.2.1c) \quad 0 = -d - \gamma Cq - C(\gamma D - I)x + \gamma C A^T y + \gamma C C^T z.$$

The latter conditions (3.2.1a,b,c) define a mixed LCP with matrix

$$(3.2.2) \quad \begin{bmatrix} (\gamma D - I)D & -(\gamma D - I)A^T & -(\gamma D - I)C^T \\ -A(\gamma D - I) & \gamma A A^T & \gamma A C^T \\ -C(\gamma D - I) & \gamma C A^T & \gamma C C^T \end{bmatrix},$$

which is obviously symmetric. Han and Mangasarian [24] proposed the application of the point SOR method to the formulation (3.2.1). They showed that for $\gamma \geq 1/\rho$ where $\rho > 0$ is the least eigenvalue of D , the matrix (3.2.2) is symmetric positive semidefinite and that if $\gamma > 1/\rho$, the problem (3.2.1) has a solution $(\bar{x}(\gamma), \bar{y}(\gamma), \bar{z}(\gamma))$ such that $\bar{x}(\gamma) = x^*$ where x^* is the unique solution of the program (3.1.1). We remark that if $\gamma > 1/\rho$ and if the matrix $\begin{pmatrix} A \\ C \end{pmatrix}$ has linearly independent rows, then the matrix (3.2.2) is positive definite.

The following gives a convergence result for the (point) SOR method applied to (3.2.1). Its proof can be found in [46].

THEOREM 3.2.1. *Let D be a symmetric positive definite matrix with least eigenvalue $\rho > 0$. Suppose that $\begin{pmatrix} A \\ C \end{pmatrix}$ has no vanishing rows. Fix $\gamma > 1/\rho$. Then for any $\omega \in (0, 2)$ and any initial vector (x^0, y^0, z^0) with $y^0 \geq 0$, the sequence of iterates $\{(x^k, y^k, z^k)\}$ generated by the (point) SOR method applied to (3.2.1) is uniquely defined. Moreover, the following two statements are equivalent:*

(F) for any $\omega \in (0, 2)$ and any initial vector (x^0, y^0, z^0) with $y^0 \geq 0$, the sequence $\{(x^k, y^k, z^k)\}$ is such that $\{x^k\}$ converges to the unique solution x^* of (3.1.1) and that $\{A^T y^k + C^T z^k\}$ converges to some vector $A^T y^* + C^T z^*$ where (x^*, y^*, z^*) solves (3.2.1);

(E) same as the one in Theorem 3.1.2.

As in Theorem 3.1.2, Theorem 3.2.1 does not assert the convergence of the sequence $\{(y^k, z^k)\}$. In order for this to happen, a linear independence property of the matrix $\begin{pmatrix} A \\ C \end{pmatrix}$ as well as a Slater constraint qualification need to hold. See [24] for details.

With regard to the practical implementation of the (point) SOR method applied to (3.2.1), we point out that the inverse of D is absent in the formulation (3.2.1). Moreover, as in the case of (3.1.5), it is not recommended, for large-scale sparse problems, to form the matrix (3.2.2) explicitly. Indeed, the method should (and can) be implemented to take full advantage of any sparsity structure that the data might have.

The other approach used to deal with the program (3.1.1) with a nonseparable D is based on a scheme which, in recent years, has been recognized as an effective algorithm for solving variational inequalities (Ahn and Hogan [4], Pang and Chan [48]) as well as convex programs (Feijou and Meyer [20]). The central idea is to transform (3.1.1) into a sequence of separable quadratic programs. Specifically, let us write

$$(3.2.3) \quad D = G + H$$

where G and H denote, respectively, the diagonal and off-diagonal parts of D . The following is a detailed description of the method that we have termed the diagonalization algorithm.

DIAGONALIZATION ALGORITHM. Let x^0 be a feasible solution to (3.1.1). In general, given x^k feasible, solve the (separable) subprogram

$$(3.2.4) \quad \begin{aligned} &\text{minimize} && \frac{1}{2}x^T Gx + (q + Hx^k)^T x \\ &\text{subject to} && \text{same constraints as (3.1.1)} \end{aligned}$$

and let $x^{k+1/2}$ denote the unique optimal solution. Define $d^k = x^{k+1/2} - x^k$. Perform the one-dimensional search over θ :

$$(3.2.5) \quad \begin{aligned} &\text{minimize} && f(x^k + \theta d^k) \\ &\text{subject to} && x^k + \theta d^k \text{ feasible to (3.1.1)} \end{aligned}$$

and let θ^k be the unique minimizer. Set $x^{k+1} = x^k + \theta^k d^k$. Terminate if some appropriate stopping rule is satisfied.

It should be pointed out that since the objective function $f(x)$ is quadratic, the one-dimensional search problem (3.2.5) is trivial and can be carried out exactly. The vector $x^{k+1/2}$ can be obtained by an SOR scheme or any appropriate method. The following result establishes the convergence of the above algorithm.

THEOREM 3.2.2. *Let D be a symmetric positive definite matrix. Suppose that the feasible set of the program (3.1.1) is nonempty and compact. Then for any initial x^0 which is feasible to (3.1.1), the sequence $\{x^k\}$ generated by the diagonalization algorithm converges to the unique optimal solution x^* of (3.1.1).*

A detailed proof of Theorem 3.2.2 can be found in [20] where the algorithm was stated for general convex objective functions. (See also [29].) In what follows, we sketch the essential ideas underlying the proof. To begin, let F denote the feasible set of (3.1.1). The sequences $\{x^k\}$, $\{x^{k+1/2}\}$ and $\{x^{k+1}\}$ are contained in the compact set F and hence have convergent subsequences $\{x^k\}_K$, $\{x^{k+1/2}\}_K$ and $\{x^{k+1}\}_K$ with limits \bar{x} , \tilde{x} and x' respectively. Since $f(x^{k+1}) \leq f(x^k)$ for all k , the sequence $\{f(x^k)\}$ is

monotonically nonincreasing and bounded below by $f(x^*)$. Thus $\{f(x^k)\}$ converges and $f(\bar{x}) = f(x')$. The rest of the proof consists of showing that \bar{x} is in fact the optimal solution of (3.1.1), and this is done by contradiction. Once this is established, the desired convergence of $\{x^k\}$ follows because the program (3.1.1) has a unique optimal solution by the positive definiteness of D . See the cited references for more details.

Remark. According to [20], a weaker version of Theorem 3.2.2 holds if D is symmetric and positive semidefinite. In this case, the sequence of objective values $\{f(x^k)\}$ converges to the optimum value $f(x^*)$ and the sequence of gradient vectors $\{\nabla f(x^k)\}$ converges to $\nabla f(x^*)$. However, one can not conclude that $\{x^k\}$ converges to x^* .

Notice that Theorem 3.2.2 requires a compactness assumption on the feasible set of the program (3.1.1). The next result shows that if the splitting (3.2.3) is regular, i.e., if $G - H$ is positive definite, then a modified version of the diagonalization algorithm is convergent, regardless of whether the feasible region is compact.

THEOREM 3.2.3. *Let D be a symmetric positive definite matrix. Suppose that the program (3.1.1) is feasible and that $G - H$ is positive definite. For a given x^0 feasible to (3.1.1), let $\{x^k\}$ be such that x^{k+1} is the (unique) solution of the subprogram (3.2.4). Then the sequence $\{f(x^k)\}$ is monotonically nonincreasing and $\{x^k\}$ converges to the unique solution x^* of (3.1.1).*

We sketch the proof of Theorem 3.2.3. First of all, the positive definiteness of $G - H$ implies that for all k ,

$$f(x^{k+1}) - f(x^k) \leq -\frac{1}{2}\alpha \|x^{k+1} - x^k\|_2^2 \leq 0$$

where α is some positive number less than the least eigenvalue of $G - H$. Thus, the sequence $\{f(x^k)\}$ is monotonically nonincreasing and bounded below by $f(x^*)$. Thus $\{f(x^k)\}$ converges. Consequently, $\|x^{k+1} - x^k\|_2 \rightarrow 0$. By a similar manipulation, we may deduce

$$f(x^*) - f(x^k) \leq -\frac{1}{2}\alpha \|x^* - x^k\|_2^2.$$

Thus, the sequence $\{x^k\}$ is bounded. From here on, the desired convergence of $\{x^k\}$ follows from a routine argument.

It is not difficult to show that a necessary and sufficient condition for $G - H$ to be positive definite is that $\|G^{-1/2}DG^{-1/2}\|_2 < 1$. Moreover it has been shown (see [48] e.g.) that if D is symmetric and strictly diagonally dominant, then the latter norm condition holds. Consequently, for such a D , the modified diagonalization algorithm without the one-dimensional search (3.2.5) produces a sequence convergent to the desired solution of (3.1.1).

3.3. The convex case. In this subsection, we discuss the proximal point algorithm applied to the quadratic program (3.1.1), where the matrix D is assumed to be symmetric and positive semidefinite. In general, the proximal point algorithm can solve a variational inequality problem with a monotone operator [50] as well as a general convex program [51]. The central idea of the algorithm is to create a sequence of strongly convexified subprograms, which are solved by certain (iterative) methods like the ones discussed in the previous sections. An attractive feature of this approach is that the subproblems become numerically more stable and error bounds (such as those in § 2.3) can be derived.

Specifically, given an iterate x^k (which may not be feasible to (3.1.1)), let x^{k+1} be an “approximate” solution to the quadratic subprogram

$$\begin{aligned} (3.3.1) \quad & \text{minimize} \quad \frac{1}{2}x^T(D + c_k I)x + (q - c_k x^k)^T x \\ & \text{subject to} \quad \text{same constraints as (3.1.1)} \end{aligned}$$

where c_k is a given positive scalar. Notice that (3.3.1) has a strongly convex objective function. (Strong convexity is equivalent to strict convexity for a quadratic function.) Also, the iterate x^{k+1} is not required to be feasible to (3.1.1). (For example, if (3.3.1) is solved by an iterative scheme like SOR and if x^{k+1} is the iterate obtained at termination, then x^{k+1} is in general, not a feasible vector.) In [50], Rockafellar proposed two criteria under which the sequence $\{x^k\}$ will converge. These two rules are

$$(3.3.2) \quad \|x^{k+1} - z^{k+1}\| \leq \varepsilon_k, \quad \varepsilon_k > 0, \quad \sum_{k=0}^{\infty} \varepsilon_k < \infty$$

and

$$(3.3.3) \quad \|x^{k+1} - z^{k+1}\| \leq \delta_k \|x^{k+1} - x^k\|, \quad \delta_k > 0, \quad \sum_{k=0}^{\infty} \delta_k < \infty,$$

where z^{k+1} denotes the exact solution of (3.3.1) and $\{\varepsilon_k\}$ and $\{\delta_k\}$ are two given sequences of tolerance. Observe that if $\{x^k\}$ is bounded, then (3.3.3) implies (3.3.2).

The following gives a convergence result of the above proximal point algorithm. Its proof can be found in [50], where a much more general version was established.

THEOREM 3.3.1. *Let D be a symmetric positive semidefinite matrix. Let $\{x^k\}$ be a sequence of vectors generated by the proximal point algorithm under the rule (3.3.2). Suppose that the sequence $\{c_k\}$ is bounded. Then $\{x^k\}$ is bounded if and only if the program (3.1.1) is solvable. If $\{x^k\}$ is bounded, then it converges to a vector x^* that solves (3.1.1). Finally, suppose that D is symmetric positive definite, that $\{c_k\}$ is non-increasing and converges to zero and that the rule (3.3.3) holds. Then, if $\{x^k\}$ is bounded, the convergence of $\{x^k\}$ to x^* is superlinear, i.e.,*

$$\lim_{k \rightarrow \infty} \frac{\|x^{k+1} - x^*\|}{\|x^k - x^*\|} = 0.$$

When the proximal point algorithm is used in conjunction with an inner iterative scheme to solve (3.3.1), a question naturally arises, namely, how can one terminate the inner iterations so that the rule (3.3.2) or (3.3.3) will be satisfied? To phrase this question in slightly more general terms, consider a strictly convex QP in the form (3.1.1) where D is symmetric and positive definite. (Note that (3.3.1) is strictly convex.) The question becomes: Given an $\varepsilon < 0$, if x is an iterate obtained in an iterative scheme for solving (3.1.1), how can one ensure that $\|x - x^*\| \leq \varepsilon$ with x^* being the optimum solution of (3.1.1)? The answer to this question relies on the kind of a posteriori error bounds described in § 2.3. Specifically, we need two things. First, we need a suitable quantity similar to $\|\min(x, q + Mx)\|$ for the LCP (2.1.1) in order to stop the iterations. Second, we need to be able to bound the error $\|x - x^*\|$ in terms of the chosen quantity (just like (2.3.2) or (2.3.3)). Based on the equivalent formulation (3.1.4) and (3.1.5), we propose the following measure. Let y and z be two arbitrary vectors and let x be defined from y and z according to (3.1.4). It seems reasonable to use the quantity

$$r(y, z) = \|(\min(y, -b - AD^{-1}q + AD^{-1}A^T y + AD^{-1}C^T z), \\ -d - CD^{-1}q + CD^{-1}A^T y + CD^{-1}C^T z)\|$$

as a measure of error. Indeed, the vector x defined by (3.1.4) solves (3.1.1) if and only if $r(y, z) = 0$. Since most iterative methods for solving (3.1.1) do produce the vectors y and z , we may use something like $r(y, z) \leq \delta$ as a stopping rule for the iterations. The following result (drawn from [47]) shows how $\|x - x^*\|$ is bounded by $r(y, z)$.

THEOREM 3.3.2. *Let D be a symmetric positive definite matrix. Suppose that the matrix $E = \begin{pmatrix} A \\ C \end{pmatrix}$ has linearly independent rows. If x is the vector defined by (3.1.4) for an arbitrary (y, z) , then*

$$(3.3.4) \quad \|x - x^*\|_2 \leq \text{cond}(D)\beta \|ED^{-1}E^T + I\|_2 r(y, z),$$

$$(3.3.5) \quad \frac{\|x - x^*\|_2}{\|x^*\|_2} \leq \text{cond}(D)\beta \|ED^{-1}E^T + I\|_2 \|E\|_2 \frac{r(y, z)}{\|e\|_2},$$

where β is the inverse of the least singular value of the matrix E and e is the vector $\begin{pmatrix} b \\ d \end{pmatrix}$ which is assumed to be nonzero.

Remark. The linear independence assumption of the matrix E ensures that the constant β is positive.

Referring to the comments made at the end of § 2.3, we point out that the linear independence assumption on the matrix E is essential for the bounds (3.3.4) and (3.3.5) to hold. Indeed, without this assumption, the quantity $r(y, z)$ can not be used as a measure of error. In this case, an alternative measure is needed. We refer to [36] for more details.

4. Dual-based iterative methods.

4.1. Background. Consider a strictly convex quadratic program of the form

$$(4.1.1) \quad \begin{aligned} &\text{minimize} \quad f(x) = q^T x + \frac{1}{2} x^T D x \\ &\text{subject to} \quad Ax = b, \quad x \in X \end{aligned}$$

where D is a symmetric positive definite matrix and X is a polyhedral set. Throughout the discussion, we assume that the QP (4.1.1) is feasible. As a result, (4.1.1) has a unique optimal solution which we denote by x^* . The constraints of (4.1.1) have the following features. The set X contains the “easy-to-handle” constraints (e.g. simple bounds) or is itself the Cartesian product of several sets of such nature. The equation “ $Ax = b$ ” consist of the “complicating” constraints. Notice that an implicit assumption in the formulation (4.1.1) is that all the complicating constraints are equalities. (The set X may contain both inequalities and equalities, however.) A consequence of the formulation (4.1.1) is that its (Lagrangian) dual program becomes unconstrained:

$$(4.1.2) \quad \text{maximize } d(y): y \text{ unrestricted}$$

where $d(y)$ is the (Lagrangian) dual function

$$(4.1.3) \quad d(y) = \min_{x \in X} q^T x + \frac{1}{2} x^T D x + y^T (b - Ax).$$

(If there are inequalities among the complicating constraints, the dual program (4.1.2) will have some variables restricted to be nonnegative. This case will be discussed in more detail later.)

In the following result, we summarize several key properties of the dual function and some basic relationships between the primal program (4.1.1) and its dual (4.1.2). See [49] for proofs.

PROPOSITION 4.1.1. *Let D be a symmetric positive definite matrix. Suppose that the program (4.1.1) is feasible. Then the following statements hold:*

(i) *For each y , there exists a unique $x(y)$ in X such that*

$$d(y) = q^T x(y) + \frac{1}{2} x(y)^T D x(y) + y^T (b - Ax(y));$$

(ii) *The dual function $d(y)$ is continuously differentiable and*

$$\nabla d(y) = b - Ax(y);$$

(iii) If y^* is a vector of optimal Lagrange multipliers associated with the equalities $Ax = b$, then y^* solves the dual program (4.1.2). Moreover, such a y^* must exist and

$$d(y^*) = f(x^*)$$

(in particular, there is no duality gap);

(iv) Conversely, if \bar{y} solves the dual program (4.1.2), then $x(\bar{y}) = x^*$.

Remark. For a given y , the vector $x(y)$ as defined in Proposition 4.1.1(i) is in general not primal feasible. It is so if and only if it is optimal.

4.2. A unified dual ascent method. A dual ascent method solves the primal program (4.1.1) by generating a sequence of dual vectors $\{y^k\}$ (which induces the sequence of primal vectors $\{x(y^k)\}$) through the maximization of the dual function $d(y)$. The generation of $\{y^k\}$ is as follows. The initial y^0 is arbitrary. In general, given y^k , choose a search direction δ^k . Define $y^{k+1} = y^k + \theta^k \delta^k$ where θ^k is such that

$$d(y^{k+1}) = \max_{\theta} d(y^k + \theta \delta^k).$$

Since

$$d(y^k + \theta \delta^k) = \min_{x \in X} f(x) + (y^k)^T(b - Ax) + \theta(\delta^k)^T(b - Ax),$$

it follows that the search for θ^k can be achieved by solving the subprogram

$$(4.2.1) \quad \begin{aligned} &\text{minimize} && f(x) + (y^k)^T(b - Ax) \\ &\text{subject to} && (\delta^k)^T(b - Ax) = 0 \text{ and } x \in X \end{aligned}$$

and by letting θ^k be an optimal Lagrange multiplier of the constraint $(\delta^k)^T(b - Ax) = 0$. The subprogram (4.2.1) is clearly feasible (and thus solvable). Indeed, the unique minimizer of (4.2.1) is the vector $x(y^{k+1})$.

The constraint $(\delta^k)^T(b - Ax) = 0$ in (4.2.1) represents an aggregation of the complicating constraints $Ax = b$. Thus, one may interpret the above dual ascent method as solving a sequence of simplified subproblems each of which has the same objective function as the given program (4.1.1), but modified by a Lagrangian term involving the complicating constraints and their corresponding multipliers, and also having all the complicating constraints aggregated into a single one by a certain vector δ^k . The following description summarizes how the dual ascent method is implemented in practice.

DUAL ALGORITHM. Let y^0 be arbitrary. In general, given y^k , generate δ^k . Solve the subproblem (4.2.1). Let $x(y^{k+1})$ be the (unique) minimizer and let θ^k be an optimal Lagrange multiplier of the aggregated constraint $(\delta^k)^T(b - Ax) = 0$. Set $y^{k+1} = y^k + \theta^k \delta^k$. Terminate if some stopping rule is satisfied.

Observe that $x(y^{k+1})$ is obtained as a by-product of the method and no extra effort is required for its computation.

There are many choices for the aggregation vector δ^k . The following are two large families of such choices: (i) Periodic basis ascent—there is a basis of vectors $\{v^1, \dots, v^m\}$ (where m is the number of constraints in $Ax = b$) such that (a) $\delta^k \in \{v^1, \dots, v^m\}$ for each k and (b) there exists an integer l ($\geq m$) such that for all $k \geq 0$, $\{v^1, \dots, v^m\} \subseteq \{\delta^{k+1}, \dots, \delta^{k+l}\}$ and (ii) Gradient-type ascent— $\delta^k = H^k(b - Ax(y^k))$ where H^k is some symmetric matrix. (Recall that $\nabla d(y^k) = b - Ax(y^k)$ from Proposition 4.1.1(ii).) Periodic basis ascent methods include the cyclic coordinate ascent method [13], [38] which has $l = m$ and the basis $\{v^1, \dots, v^m\}$ consisting of the coordinate

vectors. The latter method amounts to the relaxation of the complicating constraints one at a time. Gradient-type ascent methods include the steepest ascent method which has H^k equal to the identity matrix, many quasi-Newton methods [22], [23] as well as the conjugate gradient method with restart that has

$$(4.2.2) \quad H^k = \begin{cases} I & \text{if } k \equiv 0 \pmod{N}, \\ I + \delta^{k-1}(\nabla d(y^k) - \nabla d(y^{k-1})^T) / \nabla d(y^{k-1})^T \nabla d(y^{k-1}) & \text{otherwise,} \end{cases}$$

where N is some positive integer not exceeding m . Under (4.2.2), the vector δ^k is given by

$$(4.2.3) \quad \delta^k = \begin{cases} \nabla d(y^k) & \text{if } k \equiv 0 \pmod{N}, \\ \nabla d(y^k) + \frac{\nabla d(y^k)^T (\nabla d(y^k) - \nabla d(y^{k-1}))}{\nabla d(y^{k-1})^T \nabla d(y^{k-1})} \delta^{k-1} & \text{otherwise,} \end{cases}$$

which is the Polak-Ribiere-Polyak conjugate gradient formula [5]. The integer N denotes the number of iterations after which the method is restarted with the steepest ascent direction.

4.3. Two special cases. Before discussing the convergence of the dual algorithm, we discuss two special instances in which the algorithm is expected to be particularly attractive. One is the case where the program (4.1.1) is separable and the set X consists of simple upper and lower bounds. In this case, each subproblem (4.2.1) is a singly constrained strictly convex separable QP with simple bounds on the variables. As such, it can be solved by a very simple one-dimensional search routine which we briefly outline below (see [13], [7], [25] for more details). Consider a typical subprogram written in the form

$$(4.3.1) \quad \begin{aligned} &\text{minimize} \quad \sum_{i=1}^n q_i x_i + \frac{1}{2} \sum_{i=1}^n c_i x_i^2 \\ &\text{subject to} \quad \sum_{i=1}^n p_i x_i = t, \quad a_i \leq x_i \leq b_i \text{ all } i \end{aligned}$$

where $c_i > 0$ all i . The (Lagrangian) dual program of (4.3.1) is

$$(4.3.2) \quad \text{maximize } d(r): r \text{ unrestricted}$$

where

$$(4.3.3) \quad d(r) = \min_{\substack{a_i \leq x_i \leq b_i \\ \text{all } i}} \left\{ \sum_{i=1}^n (q_i - r p_i) x_i + \frac{1}{2} \sum_{i=1}^n c_i x_i^2 \right\} + r t.$$

For each fixed r , the unique $\{x_i(r)\}$ minimizing (4.3.3) is given by

$$x_i(r) = \min \{b_i, \max \{a_i, -(q_i - r p_i) / c_i\}\}.$$

According to the remark following Proposition 4.1.1, the maximization of $d(r)$ is equivalent to the search of a r^* such that $\sum_{i=1}^n p_i x_i(r^*) = t$. Since each $x_i(r)$ is a one-dimensional piecewise linear function in r , the function $h(r) = \sum_{i=1}^n p_i x_i(r) - t$ is piecewise linear in r . Thus, the search for the desired r^* is easy to carry out. The so-obtained $\{x_i(r^*)\}$ is then the solution to (4.3.1). In the cited references, several strategies to enhance the practical efficiency of the search process are described.

The other instance in which the dual algorithm is potentially attractive is when the objective function $f(x)$ in (4.1.1) is partially separable (i.e. when the matrix D is

block diagonally structured) and the set X is the Cartesian product of lower-dimensional sets. Specifically, assume that the matrix D is block diagonal with diagonal blocks D_i of order n_i by n_i ($i = 1, \dots, m$) and X is equal to $\prod_{i=1}^m X_i$ where each X_i is in R^{n_i} . Under this setting, each subproblem (4.2.1) may be written in the form

$$(4.3.4) \quad \begin{aligned} & \text{minimize} \quad \sum_{i=1}^m g_i^T x_i + \frac{1}{2} \sum_{i=1}^m x_i^T D_i x_i \\ & \text{subject to} \quad \sum_{i=1}^m p_i^T x_i = t, \quad x_i \in X_i \quad (i = 1, \dots, m). \end{aligned}$$

The dual program of (4.3.4) is of the form (4.3.2) with

$$(4.3.5) \quad d(r) = \min \left\{ \sum_{i=1}^m (g_i - r p_i)^T x_i + \frac{1}{2} \sum_{i=1}^m x_i^T D_i x_i : x_i \in X_i \text{ all } i \right\}.$$

For a fixed r , the minimization in (4.3.5) decomposes into m subminimizations ($i = 1, \dots, m$)

$$(4.3.6) \quad \begin{aligned} & \text{minimize} \quad (g_i - r p_i)^T x_i + \frac{1}{2} x_i^T D_i x_i \\ & \text{subject to} \quad x_i \in X_i. \end{aligned}$$

With r as the parameter, the latter problem (4.3.6) becomes a parametric quadratic program which can be solved for example, by the parametric principal pivoting algorithm (see [11], [42]). This parametric algorithm will compute the (unique) solution $x_i(r)$ to (4.3.6) for each value of r . As before, the maximization of $d(r)$ can be achieved by finding a suitable r^* such that $\sum_{i=1}^m p_i^T x_i(r^*) = t$. In this fashion, one obtains a decomposition scheme for solving (4.3.4) which by its definition, occurs as a typical subproblem in the dual algorithm for solving the original QP (4.1.1). We refer to [22], [23] for other uses of the dual approach as a decomposition strategy for large convex QP's.

4.4. Convergence results. In this subsection, we discuss the convergence of the dual algorithm introduced in § 4.2. First of all, observe that if $\{y^k\}$ is the sequence of (dual) vectors generated by the algorithm, then $d(y^{k+1}) \geq d(y^k)$. Thus, the sequence $\{y^k\}$ lies in the level set

$$\{y: d(y) \geq d(y^0)\}.$$

The following result characterizes the boundedness of such a set.

PROPOSITION 4.4.1. *Let D be a symmetric positive definite matrix. Assume that the program (4.1.1) is feasible. Then the dual function $d(y)$ in (4.1.3) has bounded level sets if and only if there exists a neighborhood N of the vector b such that for each vector b' in N , the perturbed system*

$$Ax = b', \quad x \in X$$

is consistent. In particular, if $d(y)$ has bounded level sets, then A must have linearly independent rows.

The proof of Proposition 4.4.1 follows from Corollary 14.2.2 in [49].

In general, if the dual function is assumed to have bounded level sets, then the proof of convergence of the dual algorithm is rather routine. In the next result, we establish the convergence of the dual cyclic coordinate ascent and the dual steepest ascent methods under no such bounded-level-set assumption. Its proof can be found in Lin [29].

THEOREM 4.4.1. *Let D be a symmetric positive definite matrix. Assume that the program (4.1.1) is feasible. Suppose that the sequence of aggregation vectors $\{\delta^k\}$ is chosen according to either a periodic basis ascent method or a gradient-type ascent method where the matrices $\{H^k\}$ are uniformly positive definite on the range space of A , i.e. there exist constants $\alpha > \beta > 0$ such that for all integers k and vectors y*

$$(4.4.1) \quad \alpha \|Ay\|_2^2 \geq y^T A^T H^k A y \geq \beta \|Ay\|_2^2.$$

Then the sequence of primal vectors $\{x(y^k)\}$ converges to the unique solution x^ of (4.1.1). In particular, the conclusion holds for the dual cyclic coordinate ascent method and the dual steepest ascent method.*

Remark. Since the matrix A is not assumed to have full row rank, the condition (4.4.1) is in general less stringent than the requirement that the $\{H^k\}$ are uniformly positive definite on the entire space.

A detailed proof of Theorem 4.4.1 can be found in Lin [29]. In what follows, we sketch the main ideas underlying the proof. First of all, write $x^k = x(y^k)$. It can then be shown that

$$d(y^{k+1}) - d(y^k) \geq \frac{1}{2}\gamma \|x^{k+1} - x^k\|_2^2$$

where γ is some positive number smaller than the least eigenvalue of D . Thus, the sequence $\{d(y^k)\}$ is monotonically nondecreasing and bounded above by $d(y^*)$, where y^* is a maximizer of the dual function $d(y)$. Consequently, $\|x^{k+1} - x^k\| \rightarrow 0$. By a similar manipulation, we may obtain

$$d(y^*) - d(y^k) \geq \frac{1}{2}\gamma \|x^* - x^k\|_2^2,$$

from which the boundedness of $\{x^k\}$ follows. The rest of the proof consists of verifying that any accumulation point of $\{x^k\}$ is in fact an optimal solution of (4.1.1). Since (4.1.1) has a unique optimal solution x^* , the desired convergence of $\{x^k\}$ follows.

There are several versions of the conjugate gradient method for unconstrained optimization [5]; each depends on the particular formula used to define the search direction δ^k . We choose the Polak-Ribiere-Polyak formula (4.2.3) because, reportedly, it seems to yield better performance than other formulas. Considered as a gradient-type ascent method, the H^k matrix (cf. (4.2.2)) defining (4.2.3) does not seem to satisfy condition (4.4.1) easily. For this reason, we state a separate convergence result for the dual conjugate gradient method with restart.

THEOREM 4.4.2. *Let D be a symmetric positive definite matrix. Assume that the program (4.1.1) is feasible. Let the sequence of aggregation vectors $\{\delta^k\}$ be chosen according to formula (4.2.3). Then the sequence of primal vectors $\{x(y^k)\}$ produced by the dual algorithm converges to the unique solution x^* of (4.1.1).*

The proof of Theorem 4.4.2 resembles that of Theorem 4.4.1. The only difference lies in the way to establish the (primal) feasibility of an accumulation point of $\{x^k\}$. The details can be found in Lin [29].

4.5. Two extensions. In § 4.3, we have explained how the separability of the objective function together with the box structure of the set X can facilitate the solution of the subproblems (4.2.1), and thereby increase the attraction of the dual algorithm. In the case of a nonseparable objective (and with the same box structured X), the diagonalization algorithm described in § 3.2 can be used to reduce the program (4.1.1) to a sequence of separable ones to which the specialized dual algorithm is applicable. In what follows, we describe an alternate approach to reduce a nonseparable strictly convex quadratic program to a separable strictly convex quadratic program.

Consider the program (4.1.1) where D is symmetric positive definite with least eigenvalue $\rho > 0$. We may write

$$D = \delta I + G^T G$$

where $0 < \delta < \rho$ and G is a nonsingular matrix. Then, obviously, (4.1.1) is equivalent to

$$(4.5.1) \quad \begin{aligned} &\text{minimize} && q^T x + \frac{1}{2} \delta x^T x + \frac{1}{2} y^T y \\ &\text{subject to} && Ax = b, \quad Gx = y, \quad x \in X. \end{aligned}$$

The latter program (4.5.1) has a strictly convex separable objective. (Incidentally, the equivalence between (4.5.1) and (4.1.1) is well known and is valid even if $\delta = 0$. For $\delta = 0$, the objective in (4.5.1) is not strictly convex, however. This lack of strict convexity could invalidate the convergence results of the iterative methods for solving (4.5.1).)

The formulation (4.5.1) depends on two things: the knowledge of the least eigenvalue of D (or at least a lower bound) and the factorization of the matrix $D - \delta I$. (Recall that the Han-Mangasarian approach for nonseparable QP's also requires a similar quantity γ which is like the inverse of the δ above.) If both δ and the factorization are readily available, then (4.5.1) could turn out to be a useful formulation as some of the iterative schemes for the separable case can be applied. If only δ is known, it is still possible to implement a certain dual periodic basis ascent method as well as the dual conjugate gradient method with restart without the explicit knowledge of the matrix G . See [29] for details of how this is done. Finally, if an extensive amount of effort is required for the computation of δ , then it is not advisable to use the formulation (4.5.1).

To end our discussion on the dual methods, consider a general convex quadratic program:

$$(4.5.2) \quad \begin{aligned} &\text{minimize} && f(x) = q^T x + \frac{1}{2} x^T D x \\ &\text{subject to} && Ax = b, \quad Cx \geq d, \quad x \in X \end{aligned}$$

where D is symmetric positive semidefinite. The equalities $Ax = b$ as well as the inequalities $Cx \geq d$ express the complicating constraints. By adding slack variables to the inequality constraints, we obtain

$$(4.5.3) \quad \begin{aligned} &\text{minimize} && f(x) = q^T x + \frac{1}{2} x^T D x \\ &\text{subject to} && Ax = b, \quad Cx - v = d, \quad x \in X, \quad v \geq 0. \end{aligned}$$

Notice that in terms of the variables (x, v) jointly, the objective function in (4.5.3) is not strictly convex (even if D is positive definite). As a result of this lack of strict convexity, there is no guarantee that a straightforward application of a dual algorithm is necessarily convergent. In order to solve (4.5.3) by a dual approach, one may apply the proximal point algorithm described in § 3.3 to generate a sequence of strongly convex subprograms of the form

$$\begin{aligned} &\text{minimize} && (q - c_k x^k)^T x - c_k (v^k)^T v + \frac{1}{2} x^T (D + c_k I) x + \frac{1}{2} c_k v^T v \quad (c_k > 0) \\ &\text{subject to} && \text{same constraints as (4.5.3)} \end{aligned}$$

and then solve each subprogram by an appropriate dual algorithm. An exception arises when D is positive definite. In this case, the dual cyclic coordinate method (which corresponds to the relaxation of the complicating constraints one at a time) can be applied directly to (4.5.2) despite the presence of the inequalities $Cx \geq d$. (In particular,

the use of the proximal point algorithm becomes unnecessary.) Indeed, let us assume that D is symmetric positive definite. The dual of (4.5.2) is

$$(4.5.4a) \quad \text{maximize } d(y, z): y \text{ unrestricted and } z \geq 0$$

where

$$(4.5.4b) \quad d(y, z) = \min_{x \in X} \{q^T x + \frac{1}{2}x^T D x - y^T(b - Ax) - z^T(-d + Cx)\}.$$

Due to the simple restriction on the z -variables (and no restriction on the y -variables), it is apparent how the cyclic coordinate ascent method can be applied to maximize $d(y, z)$. In practice, the resulting method can be implemented in the primal space (cf. the description of the dual algorithm in § 4.2) and it produces a sequence of primal variables $\{x^k\}$ converging to the (unique) solution of (4.5.2).

The formulation (4.5.4) also helps to explain the technical difficulty involved in a direct application of a dual method (other than the dual cyclic coordinate ascent method) to (4.5.2) and consequently, why the formulation (4.5.3) is needed. The bottleneck is the presence of the nonnegativity restriction on the z -variables. In this regard, [55] might be useful. This is a topic that requires further study.

5. Computational study.

5.1. Separable case. In the last three sections, we have described many iterative methods for solving large convex quadratic programs. From a practical point of view, it is important to know how these methods perform and compare to one another. In this section, we report the numerical results of an extensive computer experimentation with the methods. Data of the test problems were randomly generated and all the computations were performed on an IBM 4381 computer at the University of Texas at Dallas. The computer codes were written in Fortran double precision.

Four sets of experiments were performed. In the first set of experiments, we consider a separable strictly convex QP of the form (4.1.1) with X being the nonnegative orthant and D a positive diagonal matrix. Three methods were tested: (i) an SOR method applied to the following equivalent mixed symmetric LCP formulation:

$$\begin{aligned} x &= -D^{-1}q + D^{-1}y + D^{-1}A^T z \geq 0, \quad y \geq 0, \quad y^T x = 0, \\ 0 &= -b - AD^{-1}q + AD^{-1}y + AD^{-1}A^T z, \end{aligned}$$

(ii) the dual cyclic coordinate ascent method and (iii) the dual conjugate gradient ascent method with restart. The following termination criteria were used in all 3 methods:

$$(5.1.1) \quad \max(\|\min(x^k, y^k)\|_\infty, \|-b + Ax^k\|_\infty) \leq 10^{-6}.$$

In the SOR method, a sequence $\{(y^k, z^k)\}$ is generated; this then defines the iterates $\{x^k\}$ according to the equation

$$x^k = -D^{-1}q + D^{-1}y^k + D^{-1}A^T z^k.$$

The so-generated sequence $\{x^k\}$ is then tested for termination under the rule (5.1.1). In the two dual methods, a sequence $\{(x^k, z^k)\}$ is generated with the property that x^k is the unique solution to the subproblem

$$\begin{aligned} &\text{minimize } q^T x + \frac{1}{2}x^T D x + (z^k)^T(b - Ax) \\ &\text{subject to } x \geq 0. \end{aligned}$$

Thus, with $y^k = q + Dx^k - A^T z^k$, it holds that $\min(x^k, y^k) = 0$. Hence, the rule (5.1.1) reduces to

$$(5.1.2) \quad \|-b + Ax^k\|_{\infty} \leq 10^{-6},$$

which is simply a test of primal feasibility of the iterate x^k .

We ran the methods on 2 sets of test problems, one with $n = 500$ and the other $n = 1000$ (n is the dimension of the x -vector). In the first set of problems ($n = 500$), three values of m (the number of rows in the matrix A) were chosen: these are $m = 40, 80, 160$. For each value of m , different densities of the matrix A were tested (5%, 8%, 11% and 14%). In the second set of problems ($n = 1000$), m was set to be 50, 100 and 200 and the densities of A were 2%, 4%, 6%, 8% and 10%. The results are summarized in Tables 1 and 2. As it is well known, the SOR method is very sensitive to the relaxation parameter. For each individual problem, we ran the method with different values of the parameter (ranging from 1.0 to 1.9 with an increment of 0.1 each run) and picked out the best ω value. The column for the SOR method in Tables 1 and 2 gives the result pertaining to the best ω value. In the two dual methods, we have used the one-dimensional search technique described in § 4.3 to solve each singly constrained subproblem. The specific implementation of the search routine follows that explained in [13].

The results of Tables 1 and 2 pertain to problems where the matrix A has no specific structure and is not extremely sparse. We have compared the two dual methods (under the stopping rule (5.1.2)) on some constrained matrix problems of the type discussed in [13]. The latter problems are of the form (5.1.1) where A is the node-arc incidence matrix of a bipartite graph. Such a matrix A has the following characteristics: (i) all entries are 0 or 1, (ii) it has many times more columns than rows and (iii) it is extremely sparse. For example, if the two groups of nodes in the bipartite graph each have M nodes, then the matrix A is of order $2M \times M^2$ and its density is $1/M$. So for M equal to 50 or more, the density of A will be less than 2%. We should point out

TABLE 1
Separable with $Ax = b$.

that for this set of test problems, the fact that all nonzero entries of A are 1's can be fully taken advantage of by the dual cyclic coordinate method but does not seem to have a large impact in the dual conjugate gradient method. The results are contained in Table 3.

From the results in Tables 1, 2 and 3, the following observations are apparent:

(i) For problems with very sparse matrix A , the dual cyclic coordinate ascent method stands out as the clear winner;

(ii) For problems with not-so-sparse matrix A (say with density of 5% or more), the dual conjugate gradient method tends to be most preferable, followed by the LCP-SOR method and the dual cyclic coordinate method; the distinction between the latter two methods does not seem very significant;

(iii) For problems with a matrix A of even higher density (say 10% or more), the relative attractiveness of the dual cyclic coordinate method tends to decrease rather rapidly;

(iv) For very large problems with extremely sparse matrix A (like the last two problems in Table 3), the dual conjugate gradient method becomes highly inefficient.

100 × 100	9	9.98	59	133.00

We should point out that in terms of computer storage requirement, the 3 methods are roughly equal.

Our next set of experiments is concerned with a separable strictly convex quadratic program of the form

$$(5.1.3) \quad \begin{aligned} &\text{minimize} && q^T x + \frac{1}{2} x^T D x \\ &\text{subject to} && Ax \geq b \quad \text{and} \quad x \geq 0 \end{aligned}$$

where D is a positive diagonal matrix. Two methods are tested: (i) an LCP-SOR method and (ii) the dual cyclic coordinate method. The termination criteria used is similar to (5.1.1). The results are summarized in Table 4. As in Tables 1 and 2, the columns in Table 4 pertaining to the LCP-SOR method report the best output among a set of ten different test values of the relaxation parameter.

We have also tested the proximal point algorithm used in conjunction with the dual conjugate gradient algorithm as explained in § 4.4. The results are not as good as either method in Table 4. Furthermore, there seems to be some erratic behavior in the convergence of the proximal point algorithm when the density of the matrix A exceeds 10%. We do not fully understand the reason for this.

We observe that the two methods in Table 4 are fairly compatible in all cases, with the dual cyclic coordinate method slightly outperforming the LCP-SOR algorithm. In the case of a low-density matrix A , this observation is consistent with that drawn earlier from Tables 1, 2 and 3. However, in the case of a less-sparse matrix A , the reason why the dual cyclic coordinate method still performs somewhat better is not completely clear to us.

5.2. Nonseparable case. Our third set of experiments is concerned with a nonseparable strictly convex quadratic program of the form (4.1.1) where the set X is the nonnegative orthant and the matrix D is symmetric diagonally dominant. Four methods

were tested: (i) the Han–Mangasarian penalty function approach, (ii) the modified (no-line-search) diagonalization algorithm with the dual conjugate gradient algorithm as an inner routine, (iii) the same diagonalization algorithm with the dual cyclic coordinate algorithm as an inner routine and (iv) the dual conjugate gradient algorithm applied to the formulation (4.5.1). The density of the matrix D was set at 4.2% and its order at 500×500 . The termination criteria used in all 4 methods is the satisfaction of the Karush–Kuhn–Tucker optimality conditions within a prescribed tolerance. More specifically, if x^k is an approximate primal solution and if λ^k is an approximate multiplier for the constraint $Ax = b$, then (x^k, λ^k) is considered acceptable if

$$(5.2.1) \quad \varepsilon_k = \max (\| \min (q + Dx^k - A^T \lambda^k, x^k) \|_\infty, \| b - Ax^k \|_\infty) \leq 10^{-5}.$$

In the two diagonalization methods tested, another termination criterion was used to stop the inner iterations. Since a dual method was used as an inner scheme, satisfactory primal feasibility was chosen as the (inner) stopping rule. Specifically, if x^k is the current iterate that defines the subproblem (cf. (3.2.4))

$$(5.2.2) \quad \begin{aligned} & \text{minimize} \quad \frac{1}{2} x^T G x + (q + H x^k)^T x \\ & \text{subject to} \quad \text{same constraints as (4.1.1)} \end{aligned}$$

where G and H are, respectively, the diagonal and off-diagonal parts of D , then a vector x^{k+1} obtained by the dual algorithm of § 4.2 applied to (5.2.2) is considered an acceptable solution if

$$(5.2.3) \quad \| b - A x^{k+1} \|_\infty \leq \varepsilon_k^2$$

where ε_k is defined in (5.2.1). We term (5.2.3) a progressive termination rule in the sense that the accuracy in the solution of each subprogram (5.2.2) depends on the quality of the iterate x^k : the closer x^k is to satisfying the overall stopping rule (5.2.1) for the outer iterations, the more accurately the corresponding subproblem (5.2.2) is solved. Presumably, the advantage of the rule (5.2.3) is that when x^k is far from satisfying (5.2.1), some unnecessary inner iterations can be saved.

The results of this set of experiments are reported in Table 5. The entries there require explanation. First of all, in the Han–Mangasarian method, there are two parameters which will affect its performance. One is the γ value (cf. (3.2.1)) that defines the LCP formulation to which an SOR method is applied. The other is the relaxation parameter in the SOR scheme. We have generated the matrix D so that its least eigenvalue is no less than one. Different values of γ (which is required to be greater than the reciprocal of the least eigenvalue of D) were tested, and for each γ , different ω were experimented. The results in Table 5 pertain to the best γ and ω values obtained. In the dual conjugate gradient method applied to (4.5.1), there is the parameter δ which affects the performance of the method. Again, different values of δ were tested and the best results were reported in Table 5. Finally, the columns (# of iterations) in the two diagonalization methods report the numbers of outer as well as total inner iterations.

From the experience we have gathered on this set of problems, the following conclusions can be drawn:

(i) The diagonalization method seems to be the clear winner among the methods tested. Depending on the density of the A matrix, either the dual cyclic coordinate or the dual conjugate gradient method may be used as an inner routine to solve the subproblems;

(ii) Both the Han-Mangasarian approach and the dual approach applied to the (4.5.1) formulation are very sensitive to the respective parameters γ and δ . Although no formal connection can yet be established, our feeling is that these two parameters relate like reciprocals of one another. As far as performance is concerned, we conjecture that the closer γ is to the reciprocal of the least eigenvalue of D , the better the Han-Mangasarian approach will become. A similar conjecture can be made with respect to δ ;

(iii) The density of the matrix D is not expected to have a significant influence on the above two conclusions.

Our last set of experiments is concerned with a nonseparable strictly convex QP of the form (5.1.3), where the matrix D is symmetric and diagonally dominant. The specification of D is the same as in the previous set of problems. Two methods were tested: (i) the Han-Mangasarian penalty function approach and (ii) the modified (no-line-search) diagonalization scheme with the dual cyclic coordinate method as an inner subroutine. The results are summarized in Table 6. Again, the diagonalization algorithm consistently outperforms the Han-Mangasarian approach.

5.3. Additional runs. Responding to the comments of a referee, we have performed some additional experiments whose outputs are summarized in Tables 7 and 8. Table 7 solves a separable strictly convex quadratic program of the form (4.1.1) and extends Tables 1 and 2 to problems of much larger size. The objective of this set of runs is to (further) demonstrate the ability of the three basic methods for solving large problems. Table 8 solves the same type of quadratic programs as Tables 1, 2 and 7. It tests the three methods under different stopping accuracies. (Tables 1, 2 and 7 are all obtained under the termination rules (5.1.1) and (5.1.2) with an $\varepsilon = 10^{-6}$ accuracy.) The referee believes that the LCP-SOR method will outperform the other two methods when ε is large. The results in Table 8 do not support this belief. In our view, it is the sparsity

of the data that determines the relative efficiency of the respective methods, regardless of the termination accuracy.

6. Conclusion. In this paper, we have reviewed a wide variety of iterative methods for solving large convex quadratic programs and reported our computational experience with many of them. Although the problems solved in the experiments are all randomly generated and may not be considered as most general convex QP's, they are broad enough to be indicative of the relative performance of the various methods. In particular, the conclusions drawn from the tables in § 5 are expected to be valid for a typical QP arising from practice. (Recall that those conclusions are all relative to the methods being tested.)

There are a number of issues that we have either barely touched upon or completely ignored. These issues are important and deserve further investigation. Among them, we name the following four: (i) the effect of conditioning, (ii) the convex but not strictly convex program, (iii) acceleration of the reported methods and (iv) the issue of parallelism. In what follows, we briefly discuss each one of these points.

The problem of conditioning has always been an important issue in a traditional numerical method (such as the SOR algorithm) for solving systems of linear equations. To the best of our knowledge, very little research has been done to treat ill-conditioned quadratic programs by iterative methods. The thesis [54] discusses how certain preconditioning schemes can be incorporated in an iterative active-set method for solving box-constrained strictly convex QP's. (See also [39].) The two papers [36], [47] discuss how error bounds can be obtained in terms of a suitably defined condition number of a strictly convex QP and/or LCP (cf. Theorems 2.3.1 and 3.3.2). Except for these few references, we are not aware of other work done on this important topic. At this juncture, we should mention an experience of ours having to do with an attempt to solve a symmetric LCP with the following (positive definite) matrix

$$\begin{bmatrix} 6 & -4 & 1 & & & & \\ -4 & 6 & -4 & 1 & & & \\ 1 & -4 & 6 & -4 & 1 & & \\ & \ddots & \ddots & \ddots & \ddots & \ddots & \\ & & 1 & -4 & 6 & -4 & 1 \\ & & & 1 & -4 & 6 & -4 \\ & & & & 1 & -4 & 6 \end{bmatrix}$$

by an SOR scheme. (This LCP arises from a least-square concave regression problem in statistics.) For a problem of size 50×50 , the SOR scheme fails to terminate under the rule (2.3.1) with $\varepsilon = 10^{-5}$ in 8,000 iterations. We regard this as a failure for the method. (As expected, the above matrix is very poorly conditioned.)

From a theoretical as well as practical point of view, the issue of applying an iterative method to a convex, but not strictly convex, QP is far from being satisfactorily resolved. At the present time, the proximal point algorithm and the recent iterative scheme of Shiau [52] are the only two applicable approaches. However, very little experience is available on their practical performance. (In a private communication, Olvi Mangasarian informed us that he has some encouraging results with the proximal point algorithm for solving very large linear programs.) We feel that extensive studies are urgently needed to resolve this important issue.

Although very little is formally documented, it is generally believed that many commonly used iterative methods, including those reviewed in this paper, have a linear rate of convergence. The following question naturally arises: Is it possible to accelerate

some of these existing methods or to develop methods with better rate of convergence? The recent paper [30] represents the only contribution that is known to us. We feel that this question is important and requires further study.

Finally, as parallel computers are becoming more and more readily available, it is natural to think for parallel iterative schemes for QP's. The recent paper [35] represents the first contribution on this subject. We expect more activities to follow.

LOCAL CONTROLLABILITY AND INFINITESIMAL GENERATORS OF SEMIGROUPS OF SET-VALUED MAPS*

HALINA FRANKOWSKA†

Abstract. We study the semigroup properties of reachable sets of a differential inclusion

$$x' \in F(x)$$

using the derivative of the set-valued map which associates to each initial state the set of solutions. The results are applied to the local controllability problem.

Key words. differential inclusion, local controllability, reachable set, derivative of solution with respect to initial condition, derivative of a set-valued map, generalized tangent cone, Clarke's tangent cone

AMS(MOS) subject classifications. 49A34, 49A50, 93B05

1. Introduction. In this paper we study the problem of local controllability of a system governed by a differential inclusion

$$(1) \quad x' \in F(x)$$

where F is a set-valued map from \mathbb{R}^n into the subsets of \mathbb{R}^n .

A particular case of (1) is the parametrized system (also called "control system")

$$(2) \quad x' = f(x, u(t)), \quad u(t) \in U \text{ is measurable}$$

where U is a given set; then F is defined by

$$F(x) = \{f(x, u) : u \in U\}.$$

Let $\xi \in \mathbb{R}^n$, $T > 0$ be given. Denote by $S_T(\xi)$ the set of solutions to (1) starting at ξ and defined on the time interval $[0, T]$. The reachable set to (1) at time T from ξ is denoted by $R(T, \xi)$, i.e.

$$R(T, \xi) = \{x(T) : x \in S_T(\xi)\}.$$

The system (1) is called *locally controllable* around ξ at time $T > 0$ if

$$(3) \quad \xi \in \text{Int } R(T, \xi).$$

Under quite general assumptions (boundness and upper semicontinuity of F) the necessary condition for local controllability of (1) at ξ for small $T > 0$ is

$$0 \in \overline{\text{co}} F(\xi)$$

(the closed convex hull of $F(\xi)$), i.e., ξ has to be a weak equilibrium of the map F .

The purpose of this paper is to provide a sufficient condition for (3) when ξ is an equilibrium of F , i.e., when $0 \in F(\xi)$.

We use the techniques of nonsmooth analysis and differential inclusions to answer this question in the following way:

We consider an adequate concept of tangent cone $C_{S_T(\xi)}^{U,V}(\xi)$ to the set of solutions $S_T(\xi)$ at the constant trajectory ξ and prove a kind of an Open Mapping Principle, which states that (3) follows from the "surjectivity" condition

$$(4) \quad \{w(T) : w \in C_{S_T(\xi)}^{U,V}(\xi)\} = \mathbb{R}^n$$

(we specify in § 3 the definition of $C_{S_T(\xi)}^{U,V}(\xi)$ and prove an abstract version of (4)).

How can (4) be verified? In the case when ξ is an equilibrium we proceed in the following way:

* Received by the editors July 10, 1984, and in revised form October 2, 1985.

† CEREMADE, Université de Paris-Dauphine, 75775 Paris, France.

Under a Lipschitzianity assumption, the differential inclusion (1) may be replaced by a "linear" approximation (along the solutions) around the equilibrium and we prove that if the linearized system is locally controllable at zero so does the initial system.

We have to explain now what do we mean by approximating a set-valued map. Set-valued analogues of linear operators are closed convex processes, i.e., set-valued maps whose graph are closed convex cones. We consider the set-valued derivative $CF(\xi, 0)$ associated with Clarke's tangent cone to graph of F at¹ $(\xi, 0)$. The set-valued mapping $CF(\xi, 0)$ is a closed convex process. We prove that if F is Lipschitzian, then (4) holds when the reachable set to the inclusion

$$(5) \quad w' \in \text{co } F(\xi) + CF(\xi, 0)w, \quad w(0) = 0,$$

at time T contains zero in its interior.

We proceed by investigating the analogies with the single-valued smooth case when the differential equation

$$x' = f(x), \quad x(0) = \xi,$$

has a unique solution, which can be written $r(t, \xi)$. The maps $r(t, \xi)$ form a semigroup in the sense that

$$r(0, \xi) = \xi, \quad r(t+s, \xi) = r(t, r(s, \xi)),$$

and f is the *infinitesimal generator* of this semigroup in the sense that

$$f(\xi) = \frac{\partial}{\partial t} r(t, \xi) \Big|_{t=0}.$$

Furthermore, the derivative of $r(t, \cdot)$ with respect to the initial condition is given by the formula

$$\frac{\partial}{\partial \xi} r(t, \xi)(\eta) = w(t)$$

where w is the solution to the linearized differential equation

$$w'(t) = f'(r(t, \xi))w(t), \quad w(0) = \eta.$$

This still holds true in the set-valued case (we have to replace the derivatives by intermediate derivatives for the statements below to hold true). We shall prove essentially that:

- (a) The set-valued map F is the infinitesimal generator to the semigroup $R(t, \cdot)$ and $F(\xi)$ is the derivative of $t \rightarrow R(t, \xi)$ at zero in the direction 1.
- (b) The "derivative" of $\xi \rightarrow S_T(\xi)$ at a solution $x(\cdot)$ of (1) in the direction η is the set of solutions of

$$(6) \quad w'(t) \in dF(x(t), x'(t))(w(t)), \quad w(0) = \eta.$$

This is a property which is the key to solving the local controllability problem in a straightforward way. This motivates not only the title of this paper but also provides some new properties of the reachable sets and the sets of solutions to differential inclusions studied by many authors (see, for example, Aubin and Cellina [2], Hermes [17], Clarke [10], Haddad [16], Castaing and Valadier [8], Olech [21]). (See Aubin and Cellina [2] for an exhaustive bibliography on the subject.)

¹ Recall that the graph of the derivative of a differential map f at point a is the tangent space to the graph of f at the point $(a, f(a))$. Hence a natural way to extend the concept of derivative of a set-valued map F at a point $(a, b) \in \text{graph}(F)$ is to use the set-valued map $DF(a, b)$ whose graph is a tangent cone to graph (F) at (a, b) . (In this paper we use Clarke's intermediate tangent cone: see § 2 for a precise definition.)

The main difficulty we overcome in the paper is that we do not assume that the set-valued map F has convex values. For this reason the reachable sets of (1) are not necessarily closed.

The semigroup of closed reachable sets generated by control systems and, more generally, by dynamical systems without uniqueness were studied by Bushaw [7], Roxin [25], [26], Kloeden [18], [19]. These authors considered the topological properties of such semigroups.

We investigate the differentiability properties (a), (b) of the set-valued maps R and S_T in § 2. In § 3 we prove an Open Mapping Principle and derive from it a sufficient condition for the local controllability of (1). This result is applied in § 4 to prove that the local controllability of the linearized system (5) implies the local controllability of (1). The proofs of several results of this section are given in § 6. We provide some applications in § 5.

2. Differentiability of solutions with respect to initial conditions. Let $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a set-valued map. A function $x \in W^{1,1}(0, T)$ (Sobolev space) is called a solution to the differential inclusion

$$(1) \quad x' \in F(x)$$

if and only if $x'(t) \in F(x(t))$ almost everywhere in $[0, T]$.

Remark. Let us assume that F can be parametrized in the following way for all $x \in \mathbb{R}^n$

$$F(x) = \{f(x, u): u \in U\}$$

where U is a compact metric space and $f: \mathbb{R}^n \times U \rightarrow \mathbb{R}^n$ is a continuous function. Let $x \in W^{1,1}(0, T)$ be a solution to the differential inclusion (1). By a Filippov result (see Aubin and Cellina [2, p. 91]) there exists a measurable control u (a Lebesgue measurable function $u: [0, T] \rightarrow U$) such that $x'(t) = f(x(t), u(t))$ a.e. in $[0, T]$. So we can replace (1) by the control system

$$(2) \quad x'(t) = f(x(t), u(t)), \quad u(t) \in U \text{ is a measurable control.}$$

This can be done for example when F is continuous in the Hausdorff metric and has nonempty convex compact images (see Aubin and Cellina [2, p. 73]).

We recall that, in general, a set-valued map F cannot be parametrized in a way keeping the regularity of F . For instance, when F has compact images and is Lipschitzian in the Hausdorff metric, in general, there does not exist a parametrization of F as described above with f Lipschitzian in the first variable. It seems to be still an open question even in the case when F has convex images. A partial answer to it is given in Le Donne and Marchi [20], where F is parametrized in a Lipschitzian way with the set of parameters U being a compact (nonmetrizable) space.

The control system with feedback

$$x' = f(x, u), \quad u \in U(x)$$

can be reduced to the differential inclusion (1) by setting $F(x) = \{f(x, u): u \in U(x)\}$. Observe that when f is Lipschitzian and U has compact images and is Lipschitzian in the Hausdorff metric then the set-valued map F also has compact images and is Lipschitzian in the Hausdorff metric.

We denote by B the closed unit ball.

Several results of this paper are based on the following:

THEOREM 2.0 (Filippov). *Let V be a subset of \mathbb{R}^n and let $F: V \rightrightarrows \mathbb{R}^n$ be a Lipschitzian set-valued map with closed nonempty images. Then for all $\varepsilon > 0$ there exists a $K > 0$ such*

that for all $y \in W^{1,1}(0, T)$ satisfying $y([0, T]) + \varepsilon B \subset V$ and

$$\rho_F(y) := \int_0^T \text{dist}(y'(t), F(y(t))) dt \leq \varepsilon/K$$

there exists a solution x of (1) satisfying

$$x(0) = y(0), \quad \|x' - y'\|_{L^1(0,T)} \leq K\rho_F(y).$$

For the proof see Filippov [12], Aubin and Cellina [2, p. 120].

We denote by $S_T(\xi)$ the set of all solutions to the differential inclusion (1) defined on the time interval $[0, T]$ and starting at ξ .

Existence theorems imply the nonemptiness of $S_T(\xi)$ under several combinations of assumptions (see, for instance, Aubin and Cellina [2, Chaps. 2, 4], Antosiewicz and Cellina [1], Bressan [6], Olech [21]).

DEFINITION 2.1. The set

$$R(t, \xi) := S_T(\xi)(t) = \{x(t) : x \in S_T(\xi)\}$$

where $t \in [0, T]$ is called the *reachable set* at time t from the initial condition ξ .

The reachable sets satisfy the semigroup property. Namely if $R(t, \xi) \neq \emptyset$ for all $t \in [0, T]$ then

$$(2.2) \quad \begin{aligned} (i) \quad & R(0, \xi) = \xi, \\ (ii) \quad & R(t+s, \xi) = R(t, R(s, \xi)) \quad \text{if } t+s \leq T. \end{aligned}$$

We wish next to define the derivative of the map $t \rightarrow R(t, \xi)$ at $t=0$ in the direction 1. By analogy with the single-valued case, this derivative will be called the infinitesimal generator of the semigroup.

DEFINITION 2.3. Let X, Y be Banach spaces and $G: X \rightrightarrows Y$ be a set-valued map, Lipschitzian at $x, y \in G(x)$. By $dG(x, y)$ we denote the set-valued map from X into Y defined by

$$v \in dG(x, y)(u) \text{ if and only if } \lim_{h \rightarrow 0^+} \text{dist} \left(v, \frac{G(x+hu) - y}{h} \right) = 0.$$

The map $dG(x, y)$ is called the intermediate derivative of G at (x, y) .

Remark. We assume in Definition 2.3 that whenever $G(x+hu) = \emptyset$ then $\text{dist}(v, (G(x+hu) - y)/h) = +\infty$. When G is a single-valued function, Fréchet differentiable at x_0 , then the intermediate derivative of G at the point $(x_0, G(x_0)) \in \text{graph } G$ is equal to the derivative of G .

Remark. The graph of the map $dG(x, y)$ is the so-called intermediate tangent cone to $\text{graph}(G)$ at (x, y) (see Frankowska [13], where the definition of intermediate tangent cone to an arbitrary set is given).

DEFINITION 2.4. Let $R(t, \cdot)$ be a family of set-valued maps satisfying the semigroup properties (2.2), Lipschitzian in t . We say that the map

$$\xi \rightarrow d_t R(0, \xi)(1)$$

from \mathbb{R}^n into itself is the *infinitesimal generator* of the semigroup R .

As for the single-valued case the question arises whether a given set-valued map $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is the infinitesimal generator of the semigroup R . The answer is positive when F is continuous bounded with compact convex values.

THEOREM 2.5. *Let $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a bounded set-valued map with compact values and $\xi \in \text{Int Dom}(F)$. Then*

- (i) *If F is upper semicontinuous at ξ , then $d_t R(0, \xi)(1) \subset \text{co } F(\xi)$.*
- (ii) *If F is continuous on a neighborhood of ξ , then $F(\xi) \subset d_t R(0, \xi)(1)$.*
- (iii) *If F is locally Lipschitzian on a neighborhood of ξ , then $d_t R(0, \xi) = \text{co } F(\xi)$.*

Proof. If $v \in d_t R(0, \xi)(1)$ for all $h > 0$ there exists $x_h \in S_h(\xi)$ such that $x_h(h) \in R(h, \xi)$ and $\lim_{h \rightarrow 0+} (x_h(h) - \xi)/h = v$.

Since F is bounded for some $M > 0$ and all $h > 0$ we have

$$|x_h(t) - \xi| \leq tM \quad \text{for } t \in [0, h].$$

By the upper semicontinuity of F and the above inequality, for all $\varepsilon > 0$ there exists $h > 0$ such that

$$F(x_h(t)) \subset F(\xi) + \varepsilon B \quad \text{for all } t \in [0, h].$$

Thus

$$\frac{1}{h}(x_h(h) - \xi) = \frac{1}{h} \int_0^h x'_h(t) dt \in \frac{1}{h} \int_0^h (\text{co } F(\xi) + \varepsilon B) dt.$$

Since $\text{co } F(\xi) + \varepsilon B$ is a closed convex subset the mean-value theorem (see for instance Aubin and Cellina [2, p. 21]) implies that

$$\frac{x_h(h) - \xi}{h} \in \text{co } F(\xi) + \varepsilon B$$

and thus that $v \in \text{co } F(\xi) + \varepsilon B$. Since ε is arbitrary we have proved (i).

(ii) By a theorem of Filippov (see Filippov [12] and Aubin and Cellina [2, p. 112]) for all $\xi \in \text{Int Dom}(F)$ and $v \in F(\xi)$ there exists $T > 0$ and $x \in S_T(\xi)$ satisfying $x'(0) = v$. Therefore, the sequence $(x(h) - \xi)/h$ converges to v when $h \rightarrow 0+$. Hence, $v \in d_t R(0, \xi)(1)$.

(iii) By the Filippov-Ważewski relaxation theorem (see, for example, Aubin and Cellina [2, p. 124] or Clarke [10, p. 117]) for all small $T > 0$, $W^{1,1}(0, T)$ -solutions of (1) are dense in the set of $W^{1,1}(0, T)$ -solutions of the relaxed inclusion in the metric of uniform convergence. This and inclusions (i), (ii) end the proof. \square

COROLLARY 2.6. *If F is continuous, with compact values, $F(\xi)$ is convex and $\xi \in \text{Int Dom}(F)$ then*

$$d_t R(0, \xi)(1) = F(\xi).$$

As in the case of ordinary differential equations, we need to study the differentiability of the solution map with respect to initial conditions.

Consider the solution map $S_T: \mathbb{R}^n \rightrightarrows W^{1,1}(0, T)$ and the intermediate derivative $dS_T(\xi, z)(\eta)$ of S_T at point (ξ, z) in the direction η .

THEOREM 2.7. *Assume that F has closed graph and choose $z \in S_T(\xi)$. If the map F is Lipschitzian on an open neighborhood of $z([0, T])$, then*

$$\{w \in W^{1,1}(0, T): w'(t) \in dF(z(t), z'(t))w(t), w(0) = \eta\} \subset dS_T(\xi, z)(\eta).$$

Moreover if for almost all $t \in [0, T]$ and for all $u \in \mathbb{R}^n$

$$(2.8) \quad dF(z(t), z'(t))(u) = \left\{ v: \liminf_{h \rightarrow 0+} \text{dist} \left(v, \frac{F(z(t) + hu) - z'(t)}{h} \right) = 0 \right\}$$

(for example when $\text{graph}(F)$ is convex) then we have an equality in the last inclusion.

To prove the theorem we need the following

LEMMA 2.9. *Let F be a set-valued map of closed graph and $L^1(0, T)$ -functions*

$$[0, T] \ni t \rightarrow \alpha_i(t) = (x_i(t), y_i(t)) \in \text{graph } F, \quad i = 1, 2, \dots,$$

$$[0, T] \ni t \rightarrow \phi(t) = (u(t), v(t)) \in \mathbb{R}^n \times \mathbb{R}^n,$$

be given. We assume that for a sequence $h_i \rightarrow 0+$ the following holds true

$$(2.10) \quad \lim_{i \rightarrow \infty} \text{dist} \left(v(t), \frac{F(x_i(t) + h_i u(t)) - y_i(t)}{h_i} \right) = 0 \quad \text{a.e. in } [0, T].$$

If F is Lipschitzian around $\bigcup_i x_i([0, T])$ then there exists a sequence $v_i \in L^1(0, T; \mathbb{R}^n)$ converging to v in $L^1(0, T)$ such that for all large i

$$y_i(t) + h_i v_i(t) \in F(x_i(t) + h_i u(t)) \quad \text{a.e. in } [0, T].$$

Proof. Let L denote the Lipschitz constant of F . For all natural number k set

$$V_{i,k}(t) = \frac{F(x_i(t) + h_i u(t)) - y_i(t)}{h_i} \cap \left(v(t) + \frac{1}{k} B \right),$$

$$U_{i,k}(t) = \frac{F(x_i(t) + h_i u(t)) - y_i(t)}{h_i} \cap L \|u(t)\| B,$$

$$M_{i,k} = \{t \in [0, T]: V_{i,k}(t) \neq \emptyset\},$$

$$W_{i,k}(t) = \begin{cases} V_{i,k}(t) & \text{if } t \in M_{i,k}, \\ U_{i,k}(t) & \text{otherwise.} \end{cases}$$

Since the graph of F is closed and F is L -Lipschitzian around $\bigcup_i x_i([0, T])$ for all k and all large i the set-valued map $[0, T] \ni t \rightarrow W_{i,k}(t)$ has nonempty closed values and is measurable. Moreover, for all k and almost all $t \in [0, T]$, $V_{i,k}(t) \neq \emptyset$ when i is sufficiently large.

Fix k . By a measurable selection theorem (see for instance, Wagner [30]) for all large i there exists a measurable selection $v_{i,k}(t) \in W_{i,k}(t)$.

From the definition of $W_{i,k}(t)$ we obtain

$$\|v_{i,k}(t) - v(t)\| \leq 1/k \quad \text{if } t \in M_{i,k},$$

$$\|v_{i,k}(t)\| \leq L \|u(t)\| \quad \text{otherwise.}$$

Observe that for all large i

$$y_i(t) + h_i v_{i,k}(t) \in F(x_i(t) + h_i u(t)) \quad \text{a.e.,}$$

$$\|v_{i,k}(t)\| \leq \|v(t)\| + \frac{1}{k} + L \|u(t)\| \quad \text{a.e.}$$

Let $i_0 = 0$. Using the induction arguments and (2.10) we define for all $k \geq 1$ numbers $i_k > i_{k-1}$ such that for all $i > i_k$ the Lebesgue measure

$$\mu(M_{i,k+1}) \geq T - 1/k$$

and set for all $i_{k-1} < i \leq i_k$, $t \in [0, T]$

$$v_i(t) = v_{i,k}(t).$$

It is clear that v_i satisfy all the requirements of our lemma. \square

Proof of Theorem 2.7. If $w \in dS_T(\xi, z)(\eta)$ then for all $h > 0$ there exist $w_h \in W^{1,1}(0, T)$ such that

$$z + hw_h \in S_T(\xi + h\eta),$$

$$\lim_{h \rightarrow 0+} w_h = w \quad \text{in } W^{1,1}(0, T).$$

Thus $w(0) = \eta$ and

$$(2.11) \quad z'(t) + hw'_h(t) \in F(z(t) + hw_h(t)) \quad \text{a.e.},$$

$$(2.12) \quad \lim_{h \rightarrow 0+} w_h = w \quad \text{in } C([0, T]).$$

$$(2.13) \quad \text{For a subsequence } \{h_i\} \text{ converging to zero } \lim_{i \rightarrow \infty} w'_{h_i}(t) = w'(t) \quad \text{a.e.}$$

Let L denote the Lipschitz constant of F . Then by (2.11) for almost all t and for all small $h > 0$ we have

$$\begin{aligned} \text{dist} \left(w'(t), \frac{F(z(t) + hw(t)) - z'(t)}{h} \right) &\leq \text{dist} \left(w'_h(t), \frac{F(z(t) + hw_h(t)) - z'(t)}{h} \right) \\ &\quad + \|w'_h(t) - w'(t)\| + L\|w_h(t) - w(t)\| \\ &= \|w'_h(t) - w'(t)\| + L\|w_h(t) - w(t)\|. \end{aligned}$$

This and (2.12), (2.13) imply that under assumption (2.8)

$$w'(t) \in dF(z(t), z'(t))w(t) \quad \text{a.e.}$$

i.e.,

$$dS_T(\xi, z)(\eta) \subset \{w \in W^{1,1}(0, T): w'(t) \in dF(z(t), z'(t))w(t), w(0) = \eta\}.$$

To prove the opposite inclusion we shall show that if

$$\begin{aligned} w'(t) &\in dF(z(t), z'(t))w(t) \quad \text{for almost all } t \in [0, T], \\ w(0) &= \eta, \end{aligned}$$

then for all sequence $h_i > 0$ converging to zero there exists a sequence w_i converging to w in $W^{1,1}(0, T)$ such that $z + h_i w_i \in S_T(\xi + h_i \eta)$.

Consider a sequence $h_i > 0$ converging to zero. By Lemma 2.9 applied to $x_i = z$, $y_i = z'$, $u = w$, $v = w'$ there exists a sequence v_i converging to w' in $L^1(0, T)$ and such that for all i

$$(2.14) \quad z'(t) + h_i v_i(t) \in F(z(t) + h_i w(t)) \quad \text{a.e.}$$

For all $t \in [0, T]$ set

$$\pi_i(t) = \eta + \int_0^t v_i(\tau) d\tau,$$

and observe that

$$\begin{aligned} w - \pi_i &\text{ converges to zero in } C(0, T), \\ \pi'_i &\text{ converges to } w' \text{ in } L^1(0, T). \end{aligned}$$

By Lipschitzian character of F and (2.14) for a constant L and all large i we have

$$\text{dist}((z' + h_i \pi'_i)(t), F((z + h_i \pi_i)(t))) \leq L h_i \|w(t) - \pi_i(t)\|.$$

By the Filippov Theorem 2.0 for a constant M and for all large i there exists $x_i \in S_T(\xi + h_i \eta)$ satisfying

$$\|x'_i - z' - h_i \pi'_i\|_{L^1(0,T)} \leq M h_i \|w - \pi_i\|_{L^1(0,T)}.$$

Set

$$w_i = (x_i - z)/h_i.$$

Then $z + h_i w_i \in S_T(\xi + h_i \eta)$ and w_i converges to w in $W^{1,1}(0, T)$. \square

Remark. The set-valued map $dF(x, y)$ has a closed graph. Moreover if F has convex images on a neighborhood of x then $dF(x, y)$ has convex images. Indeed, if $v, v^1 \in dF(x, y)(u)$ then for all $h > 0$ there exist sequences v_h, v_h^1 converging to v, v^1 as $h \rightarrow 0+$, respectively, such that

$$y + h v_h \in F(x + h u), \quad y + h v_h^1 \in F(x + h u).$$

By convexity for all $\lambda \in [0, 1]$, $y + h(\lambda v_h + (1 - \lambda)v_h^1) \in F(x + h u)$ and therefore $\lambda v + (1 - \lambda)v^1 \in dF(x, y)(u)$. Since λ is arbitrary in $[0, 1]$ the proof follows.

3. The local controllability problem. Let $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a set-valued map, $\xi \in \mathbb{R}^n$ and $R(T, \xi)$ denote the reachable set from ξ at time T of the differential inclusion

$$(1) \quad x' \in F(x).$$

We seek to know whether $\xi \in \text{Int } R(T, \xi)$. If it holds true then we say that (1) is *locally controllable around ξ at time T* .

Our first result concerns a necessary condition for local controllability.

THEOREM 3.1. *Assume that a set-valued map F from \mathbb{R}^n into itself is bounded and upper semicontinuous at a point $\xi \in \mathbb{R}^n$. If the system (1) is locally controllable around ξ for all small time $T > 0$ then*

$$0 \in \overline{\text{co}} F(\xi)$$

(the closed convex hull of $F(\xi)$).

Proof. If $0 \notin \overline{\text{co}} F(\xi)$ then there exists $p \in S^{n-1}$ such that

$$\inf_{u \in F(\xi)} \langle p, u \rangle > 0.$$

Since F is upper semicontinuous at ξ there exists $\beta > 0$ such that

$$\inf \{ \langle p, u \rangle : u \in F(x), x \in \xi + \beta B \} \geq 0.$$

Let $M > 0$ be such that the image of F is contained in the ball MB . If $T \leq \beta/M$ then we have for all $x \in S_T(\xi)$

$$x([0, T]) \subset \xi + MTB \subset \xi + \beta B$$

and therefore

$$\langle p, x(T) \rangle = \langle p, \xi \rangle + \int_0^T \langle p, x'(t) \rangle dt \geq \langle p, \xi \rangle.$$

But this means that $\xi \notin \text{Int } R(T, \xi)$. \square

Remark. Consider the relaxed differential inclusion

$$x' \in \text{co } F(x)$$

and let $R^{\text{co}}(T, \xi)$ denote its reachable set from ξ at time T . When F has compact images and is Lipschitzian, the relaxation theorem (see, for example, Aubin and Cellina

[2, p. 124] or Clarke [10, p. 117]) implies that $\text{Int cl } R(T, \xi) = \text{Int } R^{\text{co}}(T, \xi)$. Hence the local controllability of the relaxed inclusion around ξ implies that the *closure* of the reachable set $R(T, \xi)$ contains ξ in its interior, $\xi \in \text{Int cl } R(T, \xi)$, i.e. that (1) is “almost” locally controllable around ξ .

We shall study next sufficient conditions for local controllability around the point of weak (or strong) equilibrium.

For this we shall use an Open Mapping Principle. We recall

DEFINITION 3.2 (of Clarke’s tangent cone). Let E be a Banach space, K be a subset of E and x be a point in the closure \bar{K} of K . We say that v belongs to $C_K(x)$ (Clarke’s tangent cone to K at x) if and only if for all sequence $x_i \in K$, $h_i > 0$ converging to x and zero, respectively, we can find a sequence $v_i \in E$ converging to v such that $x_i + h_i v_i \in K$.

The set $C_K(x)$ is a closed convex cone (see Clarke [10]).

For studying the local controllability problem we need several weaker topologies on E . This is why we shall adapt Definition 3.2 to our case.

DEFINITION 3.3. Let U, V, E be Banach spaces and $E \subset U$, $E \subset V$. We assume that the topology of E is stronger than the ones of U and V . Let K be a subset of E and let $x \in \bar{K}^U$ (the closure of K in U). We say that $w \in C_K^{U,V}(x)$ if and only if for all sequence $x_i \in K$ converging to x in the space U there exists a constant $m = m(w)$ such that for all sequence $h_i > 0$ converging to zero we can find a sequence $w_i \in E$ converging to w in the space V , verifying for all large i

$$x_i + h_i w_i \in K, \quad \|w_i\|_E \leq m.$$

The set $C_K^{U,V}(x)$ is a convex cone. Moreover,

$$C_K^{E,E}(x) = C_K(x) \subset C_K^{U,V}(x).$$

We denote by $\|\cdot\|_W, \|\cdot\|_C$ the usual norms of $W^{1,1}(0, T)$, $C(0, T)$, respectively.

THEOREM 3.4. Let $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a set-valued map with closed graph. If one of the following two assumptions holds true:

- (i) ξ is a weak equilibrium of F , i.e. $0 \in \overline{\text{co}} F(\xi)$, F is bounded, Lipschitzian on a neighborhood of ξ and $\{w(T): w \in C_{S_T(\xi)}^{C,C}(\xi)\} = \mathbb{R}^n$;
 - (ii) ξ is an equilibrium of F , i.e. $0 \in F(\xi)$, and $\{w(T): w \in C_{S_T(\xi)}^{W,C}(\xi)\} = \mathbb{R}^n$;
- then (1) is locally controllable around ξ at time T .

To prove the above theorem we shall use the following:

OPEN MAPPING PRINCIPLE 3.5. Let E, U, V be Banach spaces $E \subset U \subset V$, K be a closed subset of E and $x_0 \in \bar{K}^U$ (the closure of K in U). Let A be a continuously differentiable map from a neighborhood of K in V into \mathbb{R}^q . If

$$A'(x_0)C_K^{U,V}(x_0) = \mathbb{R}^q,$$

then

$$A(x_0) \in \text{Int } A(K).$$

The proof of this result is given at the end of the section.

Proof of Theorem 3.4. Since $\text{graph}(F) := \{(x, y): y \in F(x), x \in \mathbb{R}^n\}$ is a closed subset of \mathbb{R}^{2n} the set $K := S_T(\xi)$ is closed in $W^{1,1}(0, T)$. By Filippov–Ważewski’s relaxation theorem (see [10, p. 117]) the constant trajectory ξ belongs to the closure of K in the metric $\|\cdot\|_C$. If (i) holds use the open mapping principle with $E = W^{1,1}(0, T)$, $U = V = C(0, T)$ and $A: V \rightarrow \mathbb{R}^n$ defined by $Aw = w(T)$. If (ii) holds set $U = W^{1,1}(0, T)$ and E, V, A as in (i). \square

Remark. As in § 2 we can associate with Clarke's tangent cone $C_{\text{graph}(F)}(\xi, 0)$ the derivative $CF(\xi, 0)$ and we can prove that if ξ is an equilibrium then any solution of the "sublinearization"

$$(3.6) \quad w' \in CF(\xi, 0)(w), \quad w(0) = 0,$$

belongs to $C_{S_T(\xi)}(\xi) \subset C_{S_T(\xi)}^{w,C}(\xi)$. Thus the controllability of (3.6) around zero at time T implies the controllability of (1) around ξ at time T . In the next section we shall improve this result taking a larger sublinearization.

Proof of the open mapping principle. We assume for a moment that $A(x_0)$ does not belong to $\text{Int } A(K)$ and we shall derive a contradiction. Then for all $n \geq 1$ there exists $y_n \in R^q \setminus A(K)$ such that

$$\|A(x_0) - y_n\| \leq 1/2n^2.$$

Since $x_0 \in \bar{K}^U$ by continuity of A there exist $x_0^n \in K$ such that x_0^n converges to x_0 in U and $\|A(x_0^n) - A(x_0)\| \leq 1/n^2$. By Ekeland's variational principle applied to the function $x \rightarrow \|A(x) - y_n\|$ on the complete subset K of E (see Ekeland [11], Aubin and Ekeland [4, p. 255]) there exist $x_n \in K$ such that

$$(3.7) \quad \begin{aligned} \text{(i)} \quad & \|A(x_n) - y_n\| + \frac{1}{n} \|x_n - x_0^n\|_E \leq \|A(x_0^n) - y_n\| \leq \frac{1}{n^2}, \\ \text{(ii)} \quad & \text{for all } x \in K \quad \|A(x_n) - y_n\| \leq \|A(x) - y_n\| + \frac{1}{n} \|x_n - x\|_E. \end{aligned}$$

By (i) we know that x_n converges to x_0 . Introduce a function $f: V \rightarrow \mathbb{R}$ by

$$f(v) := \|A(v) - y_n\|.$$

By assumptions $A(x_n) - y_n \neq 0$. Let us set

$$p_n = \frac{A(x_n) - y_n}{\|A(x_n) - y_n\|} \in S^{q-1}.$$

Then

$$f'(x_n) = A'(x_n)^* p_n.$$

S^{q-1} being a compact, we can take a subsequence p_{n_i} converging to some $p \in S^{q-1}$. Let $w \in C_K^{U,V}(x_0)$ be such that $A'(x_0)w = -p$. From now on we set $x_i = x_{n_i}$, $p_i = p_{n_i}$, $y_i = y_{n_i}$. Since A is Fréchet differentiable on a neighborhood of x_i in V , for all $i > 0$ there exists $\eta_i > 0$ such that for all $v \in V$ of $\|v\|_V \leq \eta_i$

$$(3.8) \quad \|A(x_i + v) - y_i\| - \|A(x_i) - y_i\| \leq \langle p_i, A'(x_i)v \rangle + \frac{1}{n_i} \|v\|_V.$$

Let $m > 1$ be the constant associated with w and $\{x_i\}$ by Definition 3.3. Consider any sequence $h_i \in]0, \eta_i/m[$ converging to zero.

Then there exists a sequence $w_i \in E$ converging to w in V such that

$$(3.9) \quad \|w_i\|_E \leq m, \quad x_i + h_i w_i \in K.$$

Setting $x = x_i + h_i w_i$ in (3.7)(ii) and using (3.8), (3.9) we obtain

$$\begin{aligned} -\frac{m}{n_i} & \leq \frac{1}{h_i} (\|A(x_i + h_i w_i) - y_i\| - \|A x_i - y_i\|) \\ & \leq \langle p_i, A'(x_i) w_i \rangle + \frac{m}{n_i}. \end{aligned}$$

Since A' is continuous at x_0 and w_i converges to w in V , we obtain by passing to the limit in the last inequality when $i \rightarrow \infty$

$$\langle p, A'(x_0)w \rangle \geq 0$$

which contradicts the choice of w and achieves the proof. \square

4. Controllability through set-valued linearization. In this section we shall provide an application of the results of § 3. We recall first

DEFINITION 4.1. Let $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a set-valued map, Lipschitzian on a neighborhood of a point x_0 , $y_0 \in F(x_0)$. We denote by $CF(x_0, y_0)$ the set-valued map from \mathbb{R}^n into \mathbb{R}^n defined by

$$v \in CF(x_0, y_0)(u) \quad \text{if and only if} \quad \limsup_{\substack{(x,y) \rightarrow (x_0,y_0) \\ (x,y) \in \text{graph } F \\ h \rightarrow 0+}} \text{dist} \left(v, \frac{F(x+hu) - y}{h} \right) = 0.$$

If F is a single-valued function continuously differentiable at x_0 , then $y_0 = F(x_0)$ and $CF(x_0, y_0)$ is equal to the Fréchet derivative to F at x_0 .

The graph of the set-valued map $CF(x_0, y_0)$ is the tangent cone (of Clarke) to graph (F) at (x_0, y_0) . Thus it is a closed convex cone. We recall

DEFINITION 4.2. A set-valued map $\mathcal{A}: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is called a closed convex process if its graph is a closed convex cone.

So $CF(x_0, y_0)$ is a closed convex process satisfying

$$\text{graph } CF(x_0, y_0) \subset \text{graph } dF(x_0, y_0).$$

Assume that ξ is an equilibrium and consider the first order approximation of (1) at $(\xi, 0)$

$$(4.3) \quad w' \in F(\xi) + CF(\xi, 0)w, \quad w(0) = 0.$$

From now on we write l.c. for locally controllable.

THEOREM 4.4. Assume that F has compact images and is Lipschitzian on a neighborhood of an equilibrium ξ . Then the inclusion (1) is l.c. around ξ at time $T > 0$ if the inclusion (4.3) is l.c. around zero at time T .

Observe that l.c. of the inclusion (4.3) implies implicitly that for all $x \in \mathbb{R}^n$, $CF(\xi, 0)(x) \neq \emptyset$, i.e. $\text{Dom } CF(\xi, 0) = \mathbb{R}^n$. By the Robinson-Ursescu theorem (see Robinson [23], Ursescu [29], Aubin and Ekeland [4, p. 132]) the set-valued map $CF(\xi, 0)$ is Lipschitzian. Using the proof of the Filippov-Ważewski relaxation theorem (see Clarke [10, p. 117]) one can verify that the set of solutions on $[0, T]$ to the inclusion (4.3) is dense with respect to the metric of uniform convergence on $[0, T]$ in the set of solutions on $[0, T]$ to the relaxed inclusion

$$(4.5) \quad w' \in \text{co } F(\xi) + CF(\xi, 0)w, \quad w(0) = 0.$$

On the other hand if (4.3) is l.c. around zero at time T , so is (4.5). For this reason instead of Theorem 4.4 we shall prove a stronger:

THEOREM 4.6. Assume that F has compact images and is Lipschitzian on a neighborhood of an equilibrium ξ . Then the inclusion (1) is l.c. around ξ at time $T > 0$ if the inclusion (4.5) is l.c. around zero at time T .

To prove Theorem 4.6 we need several lemmas. For the reader's convenience we first state all of them. Their proofs are provided in § 6.

The first lemma is a kind of bang-bang principle for the points around zero (for the bang-bang in the linear case, see, for example, Olech [22]).

LEMMA 4.7. Let $\mathcal{A}: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a closed convex process and $Y \subset \mathbb{R}^n$ be a nonempty convex compact set. Assume that for some $T > 0$ the inclusion

$$(4.8) \quad x' \in \mathcal{A}(x) + Y, \quad x(0) = 0,$$

is l.c. around zero at time T . Then there exists a finite subset $U \subset Y$ of extremal points of Y such that the inclusion

$$(4.9) \quad x' \in \mathcal{A}(x) + \text{co } U, \quad x(0) = 0,$$

is l.c. around zero at time T .

The second lemma is a technical result we need here.

LEMMA 4.10. Let U be a finite subset of \mathbb{R}^n , $0 \in U$, and $T > 0$ be given. Then there exists a constant C depending only on $\text{co } U$ such that for all measurable subset $A \subset [0, T]$ and $a \in \int_A \text{co } U$, we can find a selection $\alpha(t) \in U$ satisfying

$$a = \int_A \alpha(t) dt, \quad \int_A \|\alpha(t)\| dt \leq C \|a\|.$$

The third lemma is related to the sufficient conditions for the local controllability from § 3.

LEMMA 4.11. Assume that F satisfies all the assumptions of Theorem 4.6. Let $U \subset F(\xi)$ be a finite set, $0 \in U$. Then any solution $w \in W^{1,1}(0, T)$ of the inclusion

$$(4.12) \quad w' \in \text{co } U + CF(\xi, 0)w, \quad w(0) = 0,$$

belongs to $C_{S_T(\xi)}^{w,C}(\xi)$.

Proof of Theorem 4.6. The set-valued map $CF(\xi, 0)$ is a closed convex process and $\text{co } F(\xi)$ is a nonempty convex compact set. By Lemma 4.7 there exists a finite set $U \subset F(\xi)$ such that the inclusion (4.12) is l.c. around zero at time T . The set $U \cup \{0\}$ satisfies the assumptions of Lemma 4.11. Thus

$$0 \in \text{Int} \{w(T): w \in C_{S_T(\xi)}^{w,C}(\xi)\}.$$

But this is equivalent to the condition (ii) of Theorem 3.4. The proof is complete. \square

We state next a theorem which allows us to replace the right-hand side of (4.5) by a closed convex process.

Consider the closed convex cone generated by $\text{co } F(\xi)$

$$L = \text{cl} \{\lambda w: \lambda \geq 0; w \in \text{co } F(\xi)\}$$

(L is the tangent cone of convex analysis to $\text{co } F(\xi)$ at zero) and define a set-valued map $\mathcal{A}: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ by

$$\mathcal{A}(x) = \text{cl} (CF(\xi, 0)x + L).$$

PROPOSITION 4.13. If $\text{Dom } CF(\xi, 0) = \mathbb{R}^n$ then the map \mathcal{A} defined as above is a closed convex process.

Proof. By the Robinson–Ursescu theorem the map $CF(\xi, 0)$ is Lipschitzian. So is the map \mathcal{A} . Moreover \mathcal{A} has closed images. It implies that graph \mathcal{A} is closed. Since the graph of the set-valued map $x \rightarrow CF(\xi, 0)x + L$ is a convex cone so is graph \mathcal{A} .

THEOREM 4.14. Assume that F has compact images and is Lipschitzian on a neighborhood of an equilibrium ξ . Then inclusion (4.5) is l.c. around zero at time $T > 0$ if and only if the reachable set to the inclusion

$$(4.15) \quad x' \in \text{cl} (CF(\xi, 0)x + L), \quad x(0) = 0,$$

at time T is equal to \mathbb{R}^n .

This theorem follows from a more general lemma.

LEMMA 4.16. *Let $\mathcal{B}: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a closed convex process and Y be a convex compact subset of \mathbb{R}^n , $0 \in Y$. For all $x \in \mathbb{R}^n$ set*

$$\mathcal{A}(x) = \text{cl} \{ \mathcal{B}(x) + \lambda w : \lambda \geq 0, w \in Y \}.$$

Then the inclusion

$$(4.17) \quad x' \in \mathcal{B}(x) + Y, \quad x(0) = 0,$$

is l.c. around zero at time $T > 0$ if and only if the reachable set to the inclusion

$$(4.18) \quad x' \in \mathcal{A}(x), \quad x(0) = 0,$$

at time T is equal to \mathbb{R}^n .

Proof. Observe that for all $x \in \mathbb{R}^n$, $\mathcal{B}(x) + Y \subset \mathcal{A}(x)$. Thus the reachable set to (4.17) at time T is contained in the reachable set to (4.18) at time T . On the other hand, graph \mathcal{A} is a cone. Hence the reachable sets to (4.18) are also cones. Thus the l.c. of (4.17) around zero at time T implies that the reachable set to (4.18) at time T is equal to \mathbb{R}^n . Assume next that the reachable set to (4.18) at time T is the whole space. For all $x \in \mathbb{R}^n$ set

$$G(x) = \mathcal{B}(x) + Y.$$

Because $\text{Dom } \mathcal{A} = \mathbb{R}^n$ then $\text{Dom } \mathcal{B} = \mathbb{R}^n$ and by the Robinson-Ursescu theorem \mathcal{B} is Lipschitzian on \mathbb{R}^n . Therefore

$$(4.19) \quad \begin{aligned} &G \text{ is Lipschitzian on } \mathbb{R}^n, \quad 0 \in G(0), \\ &\text{graph } G \text{ is convex and closed.} \end{aligned}$$

This implies that the intermediate derivative $dG(0, 0)$ has a convex graph. Because $0 \in Y$, graph \mathcal{B} is a cone contained in graph G . This implies that

$$(4.20) \quad \text{graph } \mathcal{B} \subset \text{graph } dG(0, 0).$$

Since 0 belongs to $\mathcal{B}(0)$, we also have

$$(4.21) \quad \{ \lambda w : \lambda \geq 0, w \in Y \} \subset dG(0, 0)(0).$$

Since graph $dG(0, 0)$ is a closed convex cone we finally obtain by (4.20), (4.21) that for all $x \in \mathbb{R}^n$

$$(4.22) \quad \mathcal{A}(x) \subset dG(0, 0)x.$$

Let $S_T(0)$ denote the set of all solutions on $[0, T]$ to the inclusion

$$x' \in G(x), \quad x(0) = 0.$$

The set $S_T(0) \subset W^{1,1}(0, T)$ is convex. Therefore the Clarke tangent cone $C_{S_T(0)}(0)$ is equal to the tangent cone of convex analysis to $S_T(0)$ at zero (see, for example, Aubin and Ekeland [4, p. 407]). It implies that

$$(4.23) \quad dS_T(0, 0)(0) = C_{S_T(0)}(0).$$

By (4.19) G and $z \equiv 0$ satisfy all the assumptions of Theorem 2.7. This and (4.22) together yield

$$\begin{aligned} dS_T(0, 0)(0) &= \{ w \in W^{1,1}(0, T) : w'(t) \in dG(0, 0)w(t), w(0) = 0 \} \\ &\supset \{ x \in W^{1,1}(0, T) : x'(t) \in \mathcal{A}(x(t)), x(0) = 0 \}. \end{aligned}$$

Since the reachable set at time T to (4.18) is the whole space, using the last relation and (4.23) we obtain

$$\{w(T): w \in C_{S_T(0)}(0) = \mathbb{R}^n\}.$$

But $C_{S_T(0)}(0) \subset C_{S_T(0)}^{w,C}(0)$ and we complete the proof by Theorem 3.4(ii). \square

Remark. Necessary and sufficient conditions for the controllability of closed convex processes were recently studied by J. P. Aubin, C. Olech and the author in a forthcoming paper [5].

Remark. To simplify the matter we have assumed in Theorems 4.4, 4.6 and 4.14 that F has compact values. This assumption can be weakened. Namely it is sufficient for F to have closed (not necessarily bounded) images. The proofs will require a small modification based on density arguments and Filippov's Theorem 2.0.

Remark. One must pay attention to the high sensitivity that the derivative $CF(\xi, 0)$ inherits from the properties of the Clarke tangent cone. As an example, consider the closed unit ball B in \mathbb{R}^2 and the set $A = B \cup \{0\} \times [1, +\infty]$. Then, although the set A is larger than B we have

$$C_B(0, 1) = \mathbb{R} \times \mathbb{R}_-, \quad C_A(0, 1) = \{0\}.$$

When a similar thing happens to $CF(\xi, 0)$ it is often more appropriate (when it is possible) to consider a smaller differential inclusion

$$x' \in Q(x)$$

having the property

$$(\xi, 0) \in \text{graph } Q \subset \text{graph } F.$$

The local controllability of a "smaller" inclusion then will imply the local controllability of the inclusion (1).

The following example illustrates this remark.

Example. Consider the control system in \mathbb{R}^2

$$x' = u, \quad u \in [-1, 1],$$

$$y' = xv, \quad v \in [-1, 1].$$

Then $F(x, y) = [-1, 1] \times [-|x|, |x|]$. The direct computation of $CF(0)$ gives then $CF(0)(x) = \mathbb{R} \times \{0\}$ for all $x \in \mathbb{R}^n$ and $F(0) = \text{co } F(0) = [-1, 1] \times 0$.

The inclusion

$$w' \in CF(0)w + \text{co } F(0), \quad w(0) = 0,$$

is not l.c. at any time T . But for any $v_0 \in [-1, 1]$, $v_0 \neq 0$ the linear system

$$x' = u, \quad y' = xv_0,$$

is controllable.

5. Some applications.

5.1. The parametrized case. We show here how to derive from Theorem 4.6 a result on local controllability of parametrized systems, without assuming too much regularity. Let U be a compact metric space and let $f: \mathbb{R}^n \times U \rightarrow \mathbb{R}^n$ be a continuous

function. Assume that for some $(\xi, \bar{u}) \in \mathbb{R}^n \times U$, $f(\xi, \bar{u}) = 0$ and for some $L, \beta > 0$ and all $u \in U$, $f(\cdot, u)$ is L -Lipschitzian on $\xi + \beta B$ and

$$\frac{\partial f}{\partial x}(\cdot, \bar{u}) \text{ is continuous at } \xi.$$

Consider the control system

$$(5.1) \quad x' = f(x, u(t)), \quad u(t) \in U \text{ is measurable, } x(0) = \xi.$$

We wish to study the local controllability of system (5.1) at a given time T .

Set $F(x) = \{f(x, u) : u \in U\}$. By Aubin and Cellina [2, p. 91] the set of solutions of the control system (5.1) defined on the time interval $[0, T]$ coincides with $S_T(\xi)$. Moreover F has compact images and is Lipschitzian on $\xi + \beta B$, ξ being an equilibrium. Therefore, we can apply the results of § 4 to the control system (5.1).

THEOREM 5.2. *If the system*

$$x' = \frac{\partial f}{\partial x}(\xi, \bar{u})x + v, \quad v \in \text{co } f(\xi, U), \quad x(0) = 0,$$

is l.c. around zero at time T then the system (5.1) is l.c. around ξ at time T .

Proof. By Lemma 4.7 there exist a finite subset $U_1 \subset U$ such that for all $u, v \in U_1$, $u \neq v$, $f(\xi, u) \neq f(\xi, v)$ and the system

$$x' \in \frac{\partial f}{\partial x}(\xi, \bar{u})x + \text{co } f(\xi, U_1), \quad x(0) = 0,$$

is l.c. around zero at time T . It is not restrictive to assume that $\bar{u} \in U_1$. Indeed, if $f(x, \bar{u}) = f(x, u)$ for some $u \in U_1$ we can replace U_1 by $U_1 \cup \{\bar{u}\} \setminus \{u\}$.

Thus we may assume that $U = U_1$. We set then $F(x) = f(x, U)$. A simple computation then gives

$$CF(\xi, 0) = \frac{\partial f}{\partial x}(\xi, \bar{u})$$

and by Theorem 4.6 we complete the proof. \square

The above theorem generalizes a result of Yorke [32].

5.2. An example of controllability of a control system nondifferentiable in the parameter. Consider the following system in \mathbb{R}^2

$$(5.3) \quad x' = x - y + x\sqrt{u} + u, \quad y' = x + yu, \quad u \in [0, 1].$$

The point $(x, y) = 0$ is an equilibrium. The corresponding control is $\bar{u} = 0$. The linearized system from Theorem 5.2 can be written in the form

$$(5.4) \quad w' = Aw + Bu, \quad u \in U$$

where

$$A = \begin{pmatrix} 1 & -1 \\ 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad U = [0, 1].$$

The rank of A is equal to $\text{rg } A = 2$ and the transposed matrix A^* has no real eigenvalues. By a result of Saperstone and Yorke [27] the linear system (5.4) is l.c. around zero at some time $T > 0$.

Therefore

$$\liminf_j \hat{\Phi}_j|_D \cong \int_{D_{\varepsilon'}} r_K(\bar{z}(\tau), \bar{\chi}(\tau), \bar{\chi}'(\tau)) d\tau - \varepsilon''' M(\gamma_3 + \gamma_4) + \nu.$$

Let $\bar{\varepsilon} > 0$. Then for our fixed K and ε' such that

$$-(\gamma_2 - \gamma_1 M)\varepsilon' < \frac{\bar{\varepsilon}}{5}$$

we can choose, in order,

$$\varepsilon''' M(\gamma_3 + \gamma_4) < \frac{\bar{\varepsilon}}{5},$$

$$\varepsilon'' M < \frac{\bar{\varepsilon}}{5},$$

$$K\delta' \gamma_{K\varepsilon''} m(D_{\varepsilon'}) < \frac{\bar{\varepsilon}}{5},$$

$$-\delta'(\gamma_2 - \gamma_1 M)m(D_{\varepsilon'}) < \frac{\bar{\varepsilon}}{5}.$$

Hence,

$$\liminf_j \hat{\Phi}_j|_D \cong \int_{D_{\varepsilon'}} r_K(\bar{z}(\tau), \bar{\chi}(\tau), \bar{\chi}'(\tau)) d\tau - \bar{\varepsilon}.$$

Since K and ε' were arbitrary,

$$\begin{aligned} \liminf_j \hat{\Phi}(z_j, \chi_j, \alpha_j^{-1})|_D &\cong \int_D r(\bar{z}(\tau), \bar{\chi}(\tau), \bar{\chi}'(\tau)) d\tau - \bar{\varepsilon} \\ &= \hat{\Phi}(\bar{z}, \bar{\chi}, \bar{\alpha}^{-1})|_D - \bar{\varepsilon}. \end{aligned}$$

Therefore,

$$(3.6) \quad \liminf_j \hat{\Phi}(z_j, \chi_j, \alpha_j^{-1})|_D \cong \hat{\Phi}(\bar{z}, \bar{\chi}, \bar{\alpha}^{-1})|_D.$$

Let us define an x^* such that

$$x^*(\bar{z}(\tau)) = \bar{\chi}(\tau), \quad \tau \notin D.$$

Then x^* (or more precisely, its equivalence class) belongs to \mathcal{B} . What we wish to show is that x^* and \bar{x} are equivalent and that from $\bar{\chi}$ we can construct an $\tilde{x} \in \mathcal{A}_{M\bar{\theta}}(\bar{x})$ so that (3.6) implies a corresponding result for the $\Phi(x_j)$ and $\Phi(\bar{x})$. Firstly let us show the equivalence of x^* and \bar{x} . The function \bar{z} represents the original time variable t . We want to show that $x^*(\bar{z}(\tau)) = \bar{x}(\bar{z}(\tau))$ for almost all $\tau \notin D$ since the times $z(\tau)$, $\tau \in D$, correspond to the singular part of dx^* .

Fix $\varepsilon > 0$; then there exists an open set $A \subset T$ with $m(A) < \varepsilon$ such that $A \supset \bigcup_{j=1}^{\infty} z_j(D_j) \cup \bar{z}(D)$ where $D_j = \{\tau: z'_j(\tau) = 0\}$. Since $(z_j, \chi_j) \rightarrow (\bar{z}, \bar{\chi})$ uniformly, for every $\delta > 0 \exists k$ such that for $j \geq k$

$$|z_j(\tau) - \bar{z}(\tau)| < \delta \quad \text{and} \quad |\chi_j(\tau) - \bar{\chi}(\tau)| < \delta \quad \forall \tau.$$

But on $T \setminus A$, \bar{z}^{-1} and \bar{z}_j^{-1} , $j = 1, 2, \dots$ exist since we have $\bar{z}'(\tau) = 1$ when $\bar{z}(\tau) \in T \setminus A$ and $z'_j(\tau) = 1$ when $z_j(\tau) \in T \setminus A$. We will then have for $j \geq k$ and $t \in T \setminus A$

$$(3.7) \quad |z_j^{-1}(t) - \bar{z}^{-1}(t)| < \delta.$$

For a (Lebesgue) measurable subset $A \subset [0, T]$ we denote by $\mu(A)$ its Lebesgue measure. Then for all measurable $A \subset [0, T]$

$$(6.6) \quad \int_A U = \int_A \text{co } U = \mu(A) \text{co } U,$$

(see for example Olech [22]). The set $\text{ext co } U \subset U$ of extremal points of $\text{co } U$ is finite. Because $0 \in \text{co } U$ there exists a finite family $\{K_i\}_{i=1}^m$ of subsets $K_i \subset \text{ext co } U$ such that for all i , $0 \notin \text{co } K_i$ and $\bigcup_{i=1}^m \text{co } (K_i \cup \{0\}) = \text{co } U$. Set $U_i = K_i \cup \{0\}$. Then

$$(6.7) \quad \bigcup_{i=1}^m \text{co } U_i = \text{co } U.$$

For all i , zero is a vertex of the polyhedra $\text{co } U_i$. Thus there exist $C_1 > 0$ and $p_i \in S^{n-1}$, $i = 1, \dots, m$ such that for all i

$$(6.8) \quad \sup_{\substack{y, z \in \text{co } U_i \\ y \neq 0}} \left\{ \frac{\|z\|}{\|y\|} : \langle z, p_i \rangle \geq \langle y, p_i \rangle \right\} \leq C_1.$$

Set $C = (2n-1)C_1$. We claim that C is the constant we are looking for. Indeed fix a measurable set $A \subset [0, T]$ and $a \in \int_A \text{co } U$. Then $\int_A U_i = \mu(A) \text{co } U_i$ and by (6.6), (6.7) $\int_A \text{co } U = \bigcup_{i=1}^m \int_A U_i$. Thus for some i_0 , $a \in \int_A U_{i_0} = \mu(A) \text{co } U_{i_0}$. By (6.8)

$$\sup_{z \in \text{co } U_{i_0}} \{ \|z\| : \langle z, p_{i_0} \rangle \geq \langle a, p_{i_0} \rangle \} \leq C_1 \|a\|.$$

A lemma of Frankowska-Olech [14] implies the existence of $\bar{\alpha}(t) \in U_{i_0}$ such that

$$\int_A \bar{\alpha}(t) dt = a, \quad \int_A \|\bar{\alpha}(t)\| dt \leq (2n-1)C_1 \|a\| = C \|a\|.$$

Set

$$\alpha(t) = \begin{cases} \bar{\alpha}(t) & \text{if } t \in A, \\ 0 & \text{otherwise.} \end{cases}$$

Then $\alpha(t) \in U_{i_0} \subset U$ and α is the required function.

Proof of Lemma 4.12. Let $w \in W^{1,1}(0, T)$ be a solution to the inclusion 4.12 and let $u, v \in L^1(0, T)$ be such that for almost all $t \in [0, T]$

$$(6.9) \quad \begin{aligned} w'(t) &= u(t) + v(t), \\ u(t) &\in \text{co } U, \\ v(t) &\in CF(\xi, 0)(w(t)). \end{aligned}$$

Let $x_i \in S_T(\xi)$ be a sequence converging in $W^{1,1}(0, T)$ to the constant trajectory ξ and $h_i \in]0, 1]$ be a sequence converging to zero.

Because $0 \in \text{co } U$, for all i

$$(6.10) \quad h_i u(t) \in \text{co } U.$$

By Lemma 2.9 there exist $v_i \in L^1(0, T)$ such that for all large i

$$(6.11) \quad x'_i(t) + h_i v_i(t) \in F(x_i(t) + h_i w(t)) \quad \text{a.e. in } [0, T],$$

$$(6.12) \quad \lim_{i \rightarrow \infty} v_i = v \quad \text{in } L^1(0, T).$$

Assume for a moment that there exist $y_i \in W^{1,1}(0, T)$ such that:

$$(6.13) \quad y_i(0) = \xi,$$

$$(6.14) \quad \text{for a constant } M \text{ independent of } \{h_i\} \text{ and for all large } i, \|y'_i - x'_i\|_{L^1} \leq Mh_i,$$

$$(6.15) \quad (y_i - x_i)/h_i \rightarrow w \quad \text{uniformly on } [0, T],$$

$$(6.16) \quad \lim_{i \rightarrow \infty} \frac{1}{h_i} \int_0^T \text{dist}(y'_i(t), F(y_i(t))) dt = 0.$$

Then we can apply the Filippov Theorem 2.0 to deduce the existence of M_1 independent of h_i and $z_i \in S_T(\xi)$ such that $(z_i - x_i)/h_i \rightarrow w$ uniformly on $[0, T]$ and for all large i , $\|z'_i - x'_i\|_{L^1} \leq M_1 h_i$. But this yields $w \in C_{S_T(\xi)}^{w, C}(\xi)$.

Therefore it remains to construct functions y_i as described above. We proceed in two steps.

Step 1. We construct here functions $\alpha_i(t) \in U$, $i = 1, 2, \dots$ such that for a constant $C > 0$ and all $i \geq 1$

$$(6.17) \quad \mu\{t \in [0, T]: \alpha_i(t) \neq 0\} \leq Ch_i,$$

$$(6.18) \quad \lim_{i \rightarrow \infty} \sup_{t \in [0, T]} \frac{1}{h_i} \left\| \int_0^t (\alpha_i(\tau) - h_i u(\tau)) d\tau \right\| = 0.$$

Because $\|x'_i\|_{L^1} \rightarrow 0$ there exist $\varepsilon_i \rightarrow 0+$ such that for

$$A_i = \{t: \|x'_i(t)\| \leq \varepsilon_i\}.$$

we have

$$(6.19) \quad \lim_{i \rightarrow \infty} \mu(A_i) = T.$$

Fix i and let $q = q(i)$ be an integer satisfying

$$(6.20) \quad q \geq \frac{2T}{h_i^2} \sup_{e \in U} \|e\| + 1.$$

Denote by I_j the interval

$$\left[\frac{j-1}{q} T, \frac{j}{q} T \right], \quad j = 1, \dots, q.$$

By Lemma 4.10 and (6.10) there exist a constant \bar{C} independent of h_i and functions $\alpha^j(t) \in U$ such that for all j

$$(6.21) \quad \int_{I_j \cap A_i} \alpha^j(t) dt = \int_{I_j \cap A_i} h_i u(t) dt,$$

$$(6.22) \quad \int_{I_j \cap A_i} \|\alpha^j(t)\| dt \leq \bar{C} \left\| \int_{I_j \cap A_i} h_i u(t) dt \right\|.$$

Set

$$\alpha_i(t) = \begin{cases} \alpha^j(t) & \text{if } t \in I_j \cap A_i, \\ 0 & \text{if } t \in [0, T] \setminus A_i, \end{cases}$$

and let $\delta = \min \{\|e\|: e \in U \setminus \{0\}\} > 0$. By (6.22)

$$\begin{aligned} \delta \mu\{t: \alpha_i(t) \neq 0\} &\leq \int_0^T \|\alpha_i(t)\| dt = \sum_{j=1}^q \int_{I_j \cap A_i} \|\alpha^j(t)\| dt \\ &\leq \bar{C} \sum_{j=1}^q h_i \int_{I_j} \|u(t)\| dt = \bar{C} h_i \|u\|_{L^1}. \end{aligned}$$

Thus for a constant C independent of h_i , inequality (6.17) holds true. By (6.21) for all $t \in [0, T]$ and some $j = j(t)$

$$\begin{aligned} \left\| \int_0^t \alpha_i(\tau) d\tau - \int_0^t h_i u(\tau) d\tau \right\| &\leq \int_{I_j} (\|\alpha_i(\tau)\| + h_i \|u(\tau)\|) d\tau + h_i \int_{[0,t] \setminus A_i} \|u(\tau)\| d\tau \\ &\leq 2 \sup_{e \in U} \|e\| T/q + h_i \int_{[0,t] \setminus A_i} \|u(\tau)\| d\tau \end{aligned}$$

and (6.19), (6.20) imply (6.18).

Step 2. We define here the required functions y_i . Let L be the Lipschitz constant of F . Since $\alpha_i(t) \in U \subset F(\xi)$ for all large i there exist $\gamma_i \in L^1(0, T)$ satisfying

$$(6.23) \quad \gamma_i(t) \in F(x_i(t)),$$

$$(6.24) \quad \|\gamma_i(t) - \alpha_i(t)\| \leq L \|x_i(t) - \xi\|.$$

For all $t \in [0, T]$ set

$$(6.25) \quad y_i'(t) = \begin{cases} \gamma_i(t) & \text{if } \alpha_i(t) \neq 0, \\ x_i'(t) + h_i v_i(t) & \text{otherwise,} \end{cases}$$

and

$$y_i(t) = \xi + \int_0^t y_i'(\tau) d\tau.$$

By (6.17)

$$\begin{aligned} \|y_i' - x_i'\|_{L^1} &\leq h_i \|v_i\|_{L^1} + \int_{\{t: \alpha_i(t) \neq 0\}} \|\gamma_i(t) - x_i'(t)\| dt \\ &\leq h_i (\|v_i\|_{L^1} + 2C \sup \{\|e\|: e \in F(x_i(t))\}). \end{aligned}$$

Therefore $\{y_i\}$ satisfy (6.13), (6.14). Furthermore for all i, t

$$\begin{aligned} y_i(t) - x_i(t) &= \int_0^t (y_i' - x_i')(\tau) d\tau \\ &= \int_0^t h_i v_i(\tau) d\tau + \int_{[0,t] \cap \{\tau: \alpha_i(\tau) \neq 0\}} (\gamma_i - x_i' - h_i v_i)(\tau) d\tau \\ &= \int_0^t (h_i v + \alpha_i)(\tau) d\tau + h_i \int_0^t (v_i - v)(\tau) d\tau \\ &\quad + \int_{[0,t] \cap \{\tau: \alpha_i(\tau) \neq 0\}} [(\gamma_i - \alpha_i)(\tau) - (x_i' + h_i v_i)(\tau)] d\tau. \end{aligned}$$

Note that $\|x_i'(\tau)\| \leq x/\varepsilon_i$ a.e. on $\{\tau: \alpha_i(\tau) \neq 0\}$. Thus using (6.24), (6.12) and (6.17) we obtain

$$y_i(t) - x_i(t) = \int_0^t (h_i v + \alpha_i)(\tau) d\tau + o(t, h_i)$$

where $o(t, h_i)/h_i \rightarrow 0$ uniformly on $[0, T]$. Thus relations (6.18) and (6.9) imply (6.15).

By the Lipschitzianity of F for all large i

$$(6.26) \quad \text{dist}(y_i'(t), F(y_i(t))) \leq \text{dist}(y_i'(t), F(x_i(t) + h_i w(t))) + L \|y_i(t) - x_i(t) - h_i w(t)\|.$$

By (6.11), (6.25), (6.23) and Lipschitzian nature of F

$$\begin{aligned} & \int_0^T \text{dist}(y'_i(t), F(x_i(t) + h_i w(t))) dt \\ &= \int_{\{t: \alpha_i(t) \neq 0\}} \text{dist}(\gamma_i(t), F(x_i(t) + h_i w(t))) dt \\ &\leq Lh_i \int_{\{t: \alpha_i(t) \neq 0\}} \|w(t)\| dt. \end{aligned}$$

By (6.26), (6.17), (6.15) and the last inequality we obtain (6.16) and end the proof of the lemma. \square

Note added in proof. During the revision of this article, I became aware of a recent work by Soviet mathematicians Polovinkin and Smirnov who (in a book in preparation) use a similar approach to the variational equations of Theorem 2.7.

Acknowledgments. The author wishes to thank St. Łojasiewicz, Jr. for useful remarks and wishes to acknowledge the comments of the unknown referee which helped to correct and improve the presentation of this paper.

THE STRUCTURE OF TIME-OPTIMAL TRAJECTORIES FOR SINGLE-INPUT SYSTEMS IN THE PLANE: THE C^∞ NONSINGULAR CASE*

H. J. SUSSMANN†

Abstract. For single-input C^∞ systems in the plane, in which the control enters linearly, we prove, if the system is suitably nondegenerate, that the time-optimal trajectories are finite concatenations of “bang-bang” and singular arcs, with local bounds on the number of switchings.

Key words. time-optimal control, two-dimensional systems, regular synthesis

AMS(MOS) subject classifications. 93C10, 93B15, 93B20

1. Introduction. The purpose of this paper is to prove local bounds on the number of switchings for arbitrary optimal control problems in the plane, of the form

$$(1.1) \quad \dot{x} = F(x) + uG(x), \quad |u| \leq 1,$$

$$(1.2) \quad \text{minimize } \int L(x(t)) dt,$$

where the vector fields F , G and the scalar function L are of class C^∞ , $L(x) > 0$ for all x , and some additional nondegeneracy conditions are satisfied.

In a subsequent paper [Su 7], these results will be applied to obtain a complete description of the structure of optimal trajectories for real analytic problems *without any extra requirements*. Finally, in the third article of this series, the results on optimal trajectories will be used to prove existence of a regular synthesis for real analytic problems (cf. [Su 8]).

Our work is part of a general program of research, initiated by Boltyanskii in his paper [Bo], and later pursued by Brunovsky (cf. [Br 1], [Br 2]), this author [Su 1]–[Su 6], and Baytman [Ba].

The goal of this program is to prove the existence of a regular synthesis for large classes of optimal control problems. A precise definition of “regular synthesis” will be given in [Su 8], when we state and prove our existence theorem. But the intuitive idea is quite simple: a “regular synthesis” for an optimal control problem with target point \bar{p} is, roughly, a feedback control law that steers to \bar{p} every point from which \bar{p} can be reached, that satisfies certain “piecewise smoothness” conditions, and that is “extremal,” in the sense that every trajectory satisfies the Maximum Principle.

Boltyanskii proved in [Bo] that a “regular synthesis” in his sense is necessarily optimal, thereby generalizing the classical result that, when the whole space is smoothly covered by trajectories that satisfy the necessary conditions for optimality, then these trajectories are optimal. This leads naturally to the question: when does a regular synthesis exist? or, equivalently: when is there an optimal feedback which is “piecewise smooth” in some appropriate sense? In [Br 1], Brunovsky proved an existence theorem for a very special class of systems (time-optimal problems for linear systems with a normality condition and polyhedral control constraints), but his work introduced a fundamental idea: the use of the theory of subanalytic sets. It has now become clear that, modulo minor technical restrictions, the use of subanalytic sets makes it possible to reduce the problem of proving the existence of a regular synthesis to the problem

of *trajectory analysis*. Roughly speaking, a *finite-dimensional reduction* (FDR) of an optimal control problem is a family \mathcal{F} of trajectories which is parametrized by a finite-dimensional parameter, and which is *sufficient* (i.e. every optimal trajectory is in \mathcal{F}) or at least *weakly sufficient* (i.e. whenever there is an optimal trajectory from p to q , then there is an optimal trajectory $\gamma \in \mathcal{F}$ that goes from p and q). It turns out that, whenever an FDR exists and some other technical hypotheses hold, the existence of a regular synthesis follows. (This will be shown in full generality in [Su 6]. However, for the case that concerns us here, of problems of the form (1.1), (1.2) in the plane, a self-contained presentation will be given in [Su 8].)

The main problem then becomes that of carrying out the trajectory analysis for particular classes of systems, so as to prove the existence of an FDR. This had been done, so far, for several types of problems, all of whom shared the feature of not giving rise to singular controls. (Examples:

(a) various types of problems where all optimal controls are necessarily bang-bang, as in Brunovsky [Br 1]–[Br 3], Sussmann [Su 2], [Su 4],

(b) classical calculus of variations problems with a nondegenerate Lagrangian, as outlined in [Su 2],

(c) linear problems with quadratic cost, as in Brunovsky [Br 3], Sussmann [Su 5].)

The present work constitutes the first step in the direction of extending the theory to the case where singular controls appear. We prove that, for systems (1.1), (1.2), with the properties stated above, the required FDR's are possible. With the exception of certain "degenerate cases," we show that every point p in the state space has a neighborhood U such that every optimal trajectory in U is a finite concatenation of bang-bang and singular pieces, with a fixed finite bound on the number of pieces. This shows that, at least locally, there is a finite-dimensional sufficient family. In one of the "degenerate cases" we prove a weaker result, namely, that every p has a neighborhood U with the property that, whenever $q_1 \in U$ can be reached from $q_0 \in U$ by an optimal trajectory in U , then q_1 can be optimally reached in U from q_0 by a bang-bang trajectory, with a fixed bound on the number of switchings. In the other "degenerate cases" no such conclusion is true but, fortunately, when the system is real analytic, it is still possible to prove the existence of a regular synthesis. So we end up proving the existence of a regular synthesis for *all* systems (1.1), (1.2), with F , G , L analytic and $L > 0$, with no extra hypotheses whatsoever (except for the technical requirement that there be no trajectory that goes to ∞ with finite cost).

This paper, and its sequel [Su 7], deal exclusively with the time-optimal case. Only in [Su 8], where the existence of a regular synthesis is proved, do we return to the general situation, which turns out to be easily reduced to the time-optimal one (because we can reparametrize the trajectories using cost, rather than time, as the parameter, so that (1.1), (1.2) becomes a time-minimization problem with a modified F , G).

The paper is organized as follows: In § 2 we introduce some basic definitions and notations. In § 3 we review the Maximum Principle, we study properties of conjugate points, and we study the optimal trajectories near "ordinary points" p (i.e., points where F and G are independent, and where G and $[F, G]$ are independent). In § 4 and § 5 we prove some lemmas, and in § 6 we study the optimal trajectories near certain nonordinary points (called "good nonordinary points"), with the exception of one type of such points (called "antiturnpike points") which are studied in § 7. For suitably nondegenerate smooth problems, our results give a complete description of the optimal trajectories, except in the neighborhood of certain "branch points." In [Su 7] we will show that in the real analytic case the branch points can be handled as well.

The main results of this paper are Theorems 3.8, 3.9, 3.13, 6.1, 6.2, 6.3 and 6.4, which give a complete description of the optimal trajectories in regions where the system is sufficiently nondegenerate.

Our work partially overlaps with Baytman's book [Ba]. Baytman proved existence of a regular synthesis for a class of smooth systems, without using the theory of subanalytic sets. However, he has to make various nondegeneracy assumptions which, in particular, fail to be satisfied for arbitrary analytic systems.

2. Basic definitions. Throughout this paper, we use \mathbb{R} to denote the real line and \mathbb{R}^n to denote n -dimensional Euclidean space. Points in \mathbb{R}^n are always thought of as *column vectors*.

We use $]a, b[$, $[a, b]$ to denote, respectively, the open and the closed intervals with end points a, b . The self-explanatory notations $]a, b[$, $[a, b]$ are used for half-open, half-closed intervals.

A *curve* in \mathbb{R}^n is a continuous map $\gamma: I \rightarrow \mathbb{R}^n$, where I is some real interval. We use the symbol "Dom" for "domain" so that, for instance, if $\gamma: I \rightarrow \mathbb{R}^n$ is a curve, then $\text{Dom}(\gamma) = I$. The symbol " \upharpoonright " denotes "restriction." (Examples: $\gamma \upharpoonright J$ is the restriction of the curve γ to the subinterval J of $\text{Dom}(\gamma)$; if X is a vector field on an open set $U \subseteq \mathbb{R}^n$, and if $V \subseteq U$, V open, then $X \upharpoonright V$ is the restriction of X to V .)

In this paper, M always denotes an open subset of \mathbb{R}^2 . (More generally, M could also be taken to be an arbitrary two-dimensional smooth manifold.)

A C^∞ *chart* in M is a pair $(U, (\xi, \eta))$, where U is an open subset of M , and ξ, η are C^∞ real-valued functions on U that satisfy

(2.1.i) the mapping $Q: p \rightarrow (\xi(p), \eta(p))$ is one-to-one on U , and

(2.1.ii) the Jacobian matrix of the map Q is nonsingular at every point $p \in U$.

When $(U, (\xi, \eta))$ is a chart, then Q establishes a bijection between U and some open set $\tilde{U} \subseteq \mathbb{R}^2$. By means of this bijection, we can identify each point $p \in U$ with the pair (x, y) of its coordinates relative to the chart. We will often do so. The chart $(U, (\xi, \eta))$ will be called *analytic* if the functions (ξ, η) are real analytic.

If $\varepsilon > 0$, $\delta > 0$, we write

$$(2.1.a) \quad \mathcal{R}(\varepsilon, \delta) = \{(x, y): |x| < \varepsilon, |y| < \delta\}.$$

A chart $(U, (\xi, \eta))$ will be called *rectangular* if $\tilde{U} = \mathcal{R}(\varepsilon, \delta)$ for some ε, δ . If, in addition, $\varepsilon = \delta$, then $(U, (\xi, \eta))$ is a *square chart*. We say that $(U, (\xi, \eta))$ is *centered at* p if $\xi(p) = \eta(p) = 0$. We write

$$(2.1.b) \quad Sq(\varepsilon) = \mathcal{R}(\varepsilon, \varepsilon).$$

A C^∞ *vector field* on an open subset U of \mathbb{R}^2 is a C^∞ \mathbb{R}^2 -valued function on U . We use $\mathcal{V}(U)$ to denote the set of all C^∞ vector fields on U . Also, we use $C^\infty(U)$ to denote the class of all C^∞ real-valued functions on U . It is well known that each $X \in \mathcal{V}(U)$ gives rise to a *first order differential operator from $C^\infty(U)$ to $C^\infty(U)$* . As is customary, we will also use X to denote this operator so that, if $\alpha \in C^\infty(U)$, then $X\alpha$ is also a function, defined by

$$(2.2) \quad (X\alpha)(p) = \lim_{\varepsilon \rightarrow 0} \frac{\alpha(p + \varepsilon X(p)) - \alpha(p)}{\varepsilon}.$$

If $(U, (\xi, \eta))$ is a chart, and we identify U with \tilde{U} as above, then each vector field $X \in \mathcal{V}(U)$ can be written in a unique way as a linear combination

$$(2.3) \quad X = \alpha \partial_x + \beta \partial_y,$$

where ∂_x, ∂_y are the vector fields with components $(1, 0), (0, 1)$, respectively (i.e., the differential operators usually denoted by $\partial/\partial x, \partial/\partial y$), and α, β are C^∞ functions of the variables x, y , for $(x, y) \in \tilde{U}$. The functions α, β are the *components of X relative to the chart $(U, (\xi, \eta))$* . We always think of X as a column-valued function with components α, β . We then use DX to denote the matrix

$$(2.4) \quad DX = \begin{pmatrix} \partial_x \alpha & \partial_y \alpha \\ \partial_x \beta & \partial_y \beta \end{pmatrix}.$$

The *Lie-bracket* of two vector fields X, Y is the vector field $[X, Y]$ that corresponds to the differential operator

$$(2.5) \quad [X, Y] = XY - YX.$$

Equivalently, $[X, Y]$ can be computed relative to a coordinate chart by

$$(2.6) \quad [X, Y] = (DY) \cdot X - (DX) \cdot Y.$$

Throughout the paper, F and G are two fixed vector fields in $\mathcal{V}(M)$. We let Σ denote the control system

$$(2.7) \quad \dot{p} = F(p) + uG(p), \quad |u| \leq 1, \quad p \in M.$$

A *control* is a measurable function $u(\cdot): [a, b] \rightarrow [-1, 1]$, where $[a, b]$ is some bounded closed interval. We use \mathcal{U} to denote the class of all controls. Naturally, if $u(\cdot): [a, b] \rightarrow [-1, 1]$ is a control, then $\text{Dom}(u(\cdot)) = [a, b]$. A *trajectory of Σ* for a control $u(\cdot)$ is an absolutely continuous curve $\gamma: \text{Dom}(u(\cdot)) \rightarrow M$ which satisfies the equation

$$(2.8) \quad \dot{\gamma}(t) = F(\gamma(t)) + u(t)G(\gamma(t))$$

for almost every $t \in \text{Dom}(u(\cdot))$. The set of all trajectories of Σ will be denoted by $\text{Traj}(\Sigma)$.

Notice that, by definition, the domain $\text{Dom}(\gamma)$ of a $\gamma \in \text{Traj}(\Sigma)$ is necessarily a compact interval $[a, b]$. We use $\text{In}(\gamma)$ to denote $\gamma(a)$, i.e. the *initial point* of γ , and $\text{Term}(\gamma)$ to denote the *terminal point* $\gamma(b)$ of γ . Also, $T(\gamma)$ denotes $b - a$, i.e., the *time along γ* .

If $\gamma \in \text{Traj}(\Sigma)$, we say that γ is *time-optimal* if $T(\gamma) \leq T(\gamma')$ for every $\gamma' \in \text{Traj}(\Sigma)$ such that $\text{In}(\gamma) = \text{In}(\gamma')$, $\text{Term}(\gamma) = \text{Term}(\gamma')$. We use $\text{Opt}^1(\Sigma)$ to denote the set of all time-optimal $\gamma \in \text{Traj}(\Sigma)$. (The superscript 1 refers to the fact that time-optimal trajectories minimize the integral $\int L dt$, where the Lagrangian L is equal to 1. More generally, we will use $\text{Opt}^L(\Sigma)$ to denote the trajectories of Σ which are optimal for the cost functional $\int L$.)

If M' is an open subset of M , then the system Σ can be restricted to M' . This restriction is denoted by $\Sigma \upharpoonright M'$. Then $\text{Traj}(\Sigma \upharpoonright M')$ is the set of all trajectories of the restriction, i.e. the set of all $\gamma \in \text{Traj}(\Sigma)$ which are entirely contained in M' .

If $u_1(\cdot): [a, b] \rightarrow [-1, 1]$ and $u_2: [b, c] \rightarrow [-1, 1]$ are controls, we use $u_2 * u_1$ to denote the control defined on $[a, c]$ by

$$(2.9) \quad (u_2 * u_1)(t) = \begin{cases} u_1(t) & \text{for } t \in \text{Dom}(u_1(\cdot)), \\ u_2(t) & \text{for } t \in \text{Dom}(u_2(\cdot)). \end{cases}$$

(This control is called the *concatenation* of u_1 and u_2 .)

If $\gamma_1: [a, b] \rightarrow M$, $\gamma_2: [b, c] \rightarrow M$ are trajectories for $u_1(\cdot)$, $u_2(\cdot)$ such that $\gamma_1(b) = \gamma_2(b)$, then $\gamma_2 * \gamma_1$ is the trajectory

$$(2.10) \quad (\gamma_2 * \gamma_1)(t) = \begin{cases} \gamma_1(t) & \text{for } t \in \text{Dom}(\gamma_1), \\ \gamma_2(t) & \text{for } t \in \text{Dom}(\gamma_2). \end{cases}$$

Notice that $u_2 * u_1$ is only defined if $\max(\text{Dom}(u_1(\cdot))) = \min(\text{Dom}(u_2(\cdot)))$, and that, for $\gamma_2 * \gamma_1$ to be defined, it is necessary that, in addition, $\text{Term}(\gamma_1) = \text{In}(\gamma_2)$. Notice also the order: $\gamma_2 * \gamma_1$ is the trajectory obtained by following first γ_1 , and then γ_2 .

We write

$$(2.11.a) \quad X = F - G,$$

$$(2.11.b) \quad Y = F + G,$$

so that

$$(2.12.a) \quad F = \frac{1}{2}(Y + X),$$

$$(2.12.b) \quad G = \frac{1}{2}(Y - X).$$

If V is an arbitrary vector field, we use $t \rightarrow \Phi^V(t, p)$ to denote the integral curve of V which goes through p at time $t = 0$. We also write

$$(2.13) \quad \Phi_t^V(p) = \Phi^V(t, p).$$

The family of maps Φ_t^V will be referred to as the *flow* of V .

We use $\text{Traj}(X)$ to denote the set of all trajectories of Σ which correspond to the constant control $u(\cdot)$ whose value is equal to -1 . Therefore $\gamma \in \text{Traj}(X)$ iff γ is a trajectory of Σ which is an integral curve of X . (Notice that γ cannot possibly be a *maximal* integral curve of X , because $\text{Dom}(\gamma)$ must be a compact interval.) Equivalently, $\gamma \in \text{Traj}(X)$ iff $\gamma = \Phi^X(\cdot, p)|J$ for some $p \in M$ and some compact interval J . We define $\text{Traj}(Y)$ in a similar way, using the control $u = 1$ rather than $u = -1$. Elements of $\text{Traj}(X)$, $\text{Traj}(Y)$ will be called *X-trajectories* and *Y-trajectories*, respectively.

We need symbols to refer to more complicated trajectory types. If $\mathcal{C}_1, \dots, \mathcal{C}_N$ are collections of trajectories, we write $\mathcal{C}_1 * \dots * \mathcal{C}_N$ to denote the set of all concatenations $\gamma = \gamma_1 * \dots * \gamma_N$, where, for each $i \in \{1, \dots, N\}$, either $\gamma_i \in \mathcal{C}_i$ or γ_i is trivial. (A trivial trajectory is one whose domain is a single point. Thus, for instance, a concatenation $\gamma_1 * \gamma_2 * \gamma_3$ with γ_2 trivial is the same as the concatenation $\gamma_1 * \gamma_3$.) That is, $\mathcal{C}_1 * \dots * \mathcal{C}_N$ consists of all concatenations $\gamma_1 * \dots * \gamma_N$, with $\gamma_i \in \mathcal{C}_i$, with any number of γ_i 's allowed to be absent. If $\mathcal{C}_1 = \dots = \mathcal{C}_N = \mathcal{C}$, we will simply write \mathcal{C}^N for $\mathcal{C}_1 * \dots * \mathcal{C}_N$, so that \mathcal{C}^N is the set of all concatenations of at most N trajectories in \mathcal{C} .

If ξ_1, \dots, ξ_N are symbols for trajectory types, then we will write $\text{Traj}(\xi_1 * \dots * \xi_N)$ for $\text{Traj}(\xi_1) * \dots * \text{Traj}(\xi_N)$. (The elements of $\text{Traj}(\xi_1 * \dots * \xi_N)$ are called $\xi_1 * \dots * \xi_N$ -trajectories.) If $\xi_1 = \dots = \xi_N = \xi$, then we write ξ^N for $\xi_1 * \dots * \xi_N$. (Notice that, with these conventions, $\text{Traj}(\xi^N)$ and $[\text{Traj}(\xi)]^N$ denote the same class of trajectories.) If $\xi = \xi_1 * \dots * \xi_N$, then a *strict ξ -trajectory* is a ξ -trajectory that is not an η -trajectory for any symbol η obtained from $\xi_1 * \dots * \xi_N$ by deleting one or more ξ_i 's. We use $\text{Traj}_s(\xi)$ to denote the set of all strict ξ -trajectories. (Example: $\text{Traj}(\xi^4)$ is the disjoint union of the sets $\text{Traj}_s(\xi^i)$, $i = 0, 1, 2, 3, 4$.)

If ξ_1, \dots, ξ_N are trajectory type symbols, the symbol $\xi_1 \vee \dots \vee \xi_N$ will stand for a trajectory that is of one of the types ξ_1, \dots, ξ_N . That is

$$\text{Traj}(\xi_1 \vee \dots \vee \xi_N) = \text{Traj}(\xi_1) \cup \dots \cup \text{Traj}(\xi_N).$$

The following examples illustrate our notational conventions:

(a) An $X * Y * X * Y$ -trajectory is a concatenation of at most four pieces, of which the first and third are Y -trajectories and the second and fourth are X -trajectories;

however, any one, or any two, or any three of these pieces may be missing, and all four of them may even be missing, so that a trivial trajectory is in $\text{Traj}(X * Y * X * Y)$;

(b) An $(X \vee Y)^4$ -trajectory is a bang-bang trajectory with at most three switchings;

(c) A strict $(X \vee Y)^4$ -trajectory is a bang-bang trajectory with exactly three switchings;

(d) a strict $Z * (X \vee Y) * Z$ -trajectory is a concatenation of exactly three pieces, the first and third of which are in $\text{Traj}(Z)$, while the middle one is either an X -trajectory or a Y -trajectory (Z -trajectories will be defined later);

(e) There do not exist strict $X * X$ -trajectories, because $\text{Traj}(X * X) = \text{Traj}(X)$.

Now let \mathcal{C} be any set of trajectories. We write

$$(2.14) \quad \mathcal{C}^\infty = \bigcup_{N=1}^{\infty} \mathcal{C}^N.$$

A *bang-bang trajectory* is a trajectory which corresponds to a control $u(\cdot)$ such that $|u(t)| = 1$ for all t . A *regular bang-bang trajectory* is one that is a finite concatenation of X - and Y -trajectories. Therefore the set of regular bang-bang trajectories is precisely $[\text{Traj}(X \vee Y)]^\infty$.

If $\mathcal{C} \subseteq \text{Traj}(\Sigma)$, and U is a subset of M , we call \mathcal{C} *sufficient on U* if

$$(2.15) \quad \text{Opt}^1(\Sigma \upharpoonright U) \subseteq \mathcal{C}^\infty,$$

i.e., if every time-optimal trajectory in U is a finite concatenation of pieces that belong to \mathcal{C} . We call \mathcal{C} *boundedly sufficient on U* if there is an integer $N > 0$ such that

$$(2.16) \quad \text{Opt}^1(\Sigma \upharpoonright U) \subseteq \mathcal{C}^N,$$

i.e., if every time-optimal trajectory γ in U is a concatenation of a finite number $\nu(\gamma)$ of pieces which belong to \mathcal{C} , and if there is a finite upper bound, independent of γ , for the numbers $\nu(\gamma)$.

If $T > 0$, $\mathcal{C} \subseteq \text{Traj}(\Sigma)$, we use $\mathcal{C}[\leq T]$ to denote the set of all $\gamma \in \mathcal{C}$ such that $T(\gamma) \leq T$. We say that \mathcal{C} is *finite-time boundedly sufficient on U* if for every $T > 0$ there is an integer $N = N(T)$, $N > 0$, such that

$$(2.17) \quad \text{Opt}^1(\Sigma \upharpoonright U)[\leq T] \subseteq \mathcal{C}^N$$

(i.e., the integer $\nu(\gamma)$ considered above is allowed to depend on γ , but only through $T(\gamma)$).

Also, if \mathcal{C} , U are as before, we will call \mathcal{C} *weakly sufficient on U* if, whenever $q_0 \in U$, $q_1 \in U$ and $\gamma \in \text{Opt}^1(\Sigma \upharpoonright U)$ steers q_0 to q_1 , then there exists a $\gamma' \in \mathcal{C}$ that is also time-optimal, steers q_0 to q_1 , and is contained in U . We call \mathcal{C} *weakly boundedly sufficient on U* if there is an N such that \mathcal{C}^N is weakly sufficient on U .

3. The maximum principle, conjugate points, ordinary points. An *admissible pair* for the system Σ is a pair $(u(\cdot), \gamma)$, such that $u(\cdot) \in \mathcal{U}$ and γ is a trajectory corresponding to $u(\cdot)$. We use $\text{Adm}(\Sigma)$ to denote the set of admissible pairs.

Suppose $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$. A *variational vector field along $(u(\cdot), \gamma)$* is a vector-valued absolutely continuous function $v(\cdot): \text{Dom}(\gamma) \rightarrow \mathbb{R}^2$ that satisfies the equation

$$(3.1) \quad \dot{v}(t) = ((DF)(\gamma(t)) + u(t)(DG)(\gamma(t)))v(t).$$

Equation (3.1) is called the *variational equation along $(u(\cdot), \gamma)$* . It is a (time-varying) linear homogeneous system of two ordinary differential equations for the two components of the vector-valued function $v(\cdot)$, with coefficients that are continuous functions of t . Therefore (3.1) has one and only one solution $v(\cdot)$ for any initial

condition $v(t_0) = v_0$ ($t_0 \in \text{Dom}(\gamma)$, $v_0 \in \mathbb{R}^2$). We let $\text{VVF}(u(\cdot), \gamma)$ denote the set of all variational vector fields along $(u(\cdot), \gamma)$. So $\text{VVF}(u(\cdot), \gamma)$ is a two-dimensional linear space over \mathbb{R} .

The variational equation is stated in terms of a particular choice of coordinates. The following lemma shows that $\text{VVF}(u(\cdot), \gamma)$ is really a “coordinate free object” (i.e., that we can think of a variational vector field along γ as a map $v(\cdot)$ such that $v(t)$ is a tangent vector to M at $\gamma(t)$ for each t).

LEMMA 3.1. *Let $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$, and let $v(\cdot): \text{Dom}(\gamma) \rightarrow \mathbb{R}^2$ be absolutely continuous. Then $v(\cdot)$ is a variational vector field along $(u(\cdot), \gamma)$ if and only if there is an $\varepsilon > 0$, and a map*

$$\Gamma: [0, \varepsilon] \times \text{Dom}(\gamma) \rightarrow M$$

such that:

- (i) $s \rightarrow \Gamma(s, t)$ is of class C^1 for each fixed $t \in \text{Dom}(\gamma)$;
- (ii) $t \rightarrow \Gamma(s, t)$ is a trajectory of Σ corresponding to the control $u(\cdot)$ for each fixed $s \in [0, \varepsilon]$;

(iii) $\Gamma(0, t) = \gamma(t)$ for $t \in \text{Dom}(\gamma)$;

(iv) $v(t) = (d/ds)|_{s=0} \Gamma(s, t)$ for $t \in \text{Dom}(\gamma)$.

Proof. If Γ, ε are such that (i), \dots , (iv) hold, then

$$(3.2) \quad \frac{\partial}{\partial t} \Gamma(s, t) = F(\Gamma(s, t)) + u(t)G(\Gamma(s, t))$$

holds. If we differentiate with respect to s , set $s=0$, and formally interchange the t and s differentiations in the left side of the resulting equation, we get (3.1). The rigorous justification of the interchange of differentiation is carried out by a well-known argument, writing (3.2) as an integral equation, and differentiating under the integral sign. We omit the details.

Conversely, if $v(\cdot) \in \text{VVF}(u(\cdot), \gamma)$, pick an arbitrary C^1 curve $\delta: [0, \varepsilon] \rightarrow M$ such that $\dot{\delta}(a) = v(a)$, where we let $[a, b] = \text{Dom}(\gamma)$. If ε is sufficiently small, it follows from the existence, uniqueness and continuous dependence theorems of O.D.E. theory that there is a Γ for which (i), (ii) and (iii) hold and for which, in addition, $\Gamma(s, 0) = \delta(s)$ for $0 \leq s \leq \varepsilon$. Then, if we let

$$w(t) = \frac{d}{ds} \bigg|_{s=0} \Gamma(s, t),$$

it follows from the part already proved that $w(\cdot) \in \text{VVF}(u(\cdot), \gamma)$. Clearly, $w(a) = v(a)$. Since $v(\cdot) \in \text{VVF}(u(\cdot), \gamma)$ it follows from the uniqueness of solutions of (3.1) that $v(\cdot) = w(\cdot)$. So (iv) holds as well. \square

A *variational covector field* along a $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$ is an absolutely continuous $\lambda(\cdot): \text{Dom}(\gamma) \rightarrow \mathbb{R}_*^2$ that satisfies

$$(3.3) \quad \dot{\lambda}(t) = -\lambda(t)(DF(\gamma(t)) + u(t)DG(\gamma(t)))$$

for almost all $t \in \text{Dom}(\gamma)$. (Here \mathbb{R}_*^2 is the space of *row vectors*.) We let $\text{VVF}^*(u(\cdot), \gamma)$ denote the space of all variational covector fields along $(u(\cdot), \gamma)$. Equation (3.3), like (3.2), appears to depend on a particular choice of coordinates, but the following lemma shows that it is not so, and that the elements of $\text{VVF}^*(u(\cdot), \gamma)$ are covector-valued functions (i.e., $\lambda(t)$ is a cotangent vector at $\gamma(t)$ for each t). The proof is elementary, and we omit it.

LEMMA 3.2. Let $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$, and let $\lambda(\cdot): \text{Dom}(\gamma) \rightarrow \mathbb{R}_*^2$ be absolutely continuous. Then $\lambda(\cdot) \in \text{VVF}^*(u(\cdot), \gamma)$ if and only if the function $t \rightarrow \lambda(t) \cdot v(t)$ is constant for every $v(\cdot) \in \text{VVF}(u(\cdot), \gamma)$. \square

We define $\mathcal{H}: \mathbb{R}_*^2 \times M \times \mathbb{R} \rightarrow \mathbb{R}$ by

$$(3.4) \quad \mathcal{H}(\lambda, p, u) = \lambda \cdot (F(p) + uG(p)).$$

If $\lambda(\cdot) \in \text{VVF}^*(u(\cdot), \gamma)$, $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$, we say that $\lambda(\cdot)$ is *minimizing* if

$$(3.5) \quad \mathcal{H}(\lambda(t), \gamma(t), u(t)) = \min \{ \mathcal{H}(\lambda(t), \gamma(t), u) : -1 \leq u \leq 1 \}$$

for almost all $t \in \text{Dom}(\gamma)$.

The *Maximum Principle* says that, if $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$, and $\gamma \in \text{Opt}^1(\Sigma)$, then there exist: (a) a nontrivial, minimizing $\lambda(\cdot) \in \text{VVF}^*(u(\cdot), \gamma)$ and (b) a constant $\lambda_0 \geq 0$, such that

$$(3.6) \quad \mathcal{H}(\lambda(t), \gamma(t), u(t)) + \lambda_0 = 0$$

for almost all $t \in \text{Dom}(\gamma)$.

If $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$, and $\lambda(\cdot) \in \text{VVF}^*(u(\cdot), \gamma)$, $\lambda_0 \geq 0$, are such that $\lambda(\cdot)$ is nontrivial and minimizing, and (3.6) holds for almost all t , then the 4-tuple

$$(3.7) \quad \Lambda = (u(\cdot), \gamma, \lambda(\cdot), \lambda_0)$$

will be called an *extremal lift* of $(u(\cdot), \gamma)$. (So the Maximum Principle says that every time-optimal trajectory has an extremal lift.)

If Λ is an extremal lift of $(u(\cdot), \gamma)$, and (3.7) holds, we define the *switching function* ϕ_Λ along Λ to be the function $\phi_\Lambda: \text{Dom}(\gamma) \rightarrow \mathbb{R}$ given by

$$(3.8) \quad \phi_\Lambda(t) = \lambda(t) \cdot G(\gamma(t)).$$

Therefore, it is clear that the following holds.

LEMMA 3.3. Let $\Lambda = (u(\cdot), \gamma, \lambda(\cdot), \lambda_0)$ be an extremal lift of the admissible pair $(u(\cdot), \gamma)$. Then:

(a) The switching function ϕ_Λ is continuous on $\text{Dom}(\gamma)$;

(b) If $\phi_\Lambda(t) > 0$ for all t in some interval I , then $u(t) = -1$ for almost all $t \in I$, and therefore $\gamma \upharpoonright I \in \text{Traj}(X)$;

(c) If $\phi_\Lambda(t) < 0$ for $t \in I$, then $u(t) = 1$ for almost all $t \in I$, and therefore $\gamma \upharpoonright I \in \text{Traj}(Y)$.

A $t \in \text{Dom}(\gamma)$ will be said to be a *switching time* for γ if there does not exist an $\varepsilon > 0$ such that $\gamma \upharpoonright ([t - \varepsilon, t + \varepsilon] \cap \text{Dom}(\gamma)) \in \text{Traj}(X \vee Y)$. If t is a switching time for γ , and $p = \gamma(t)$, then we say that p is a *switching point* of γ , or that γ has a *switching* at p .

Lemma 3.3 implies the following.

LEMMA 3.4. If $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$, and $\Lambda = (u(\cdot), \gamma, \lambda(\cdot), \lambda_0)$ is an extremal lift of $(u(\cdot), \gamma)$, then $\phi_\Lambda(t) = 0$ for every switching time t of γ .

Suppose that $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$. Let t_0 belong to $\text{Dom}(\gamma)$, and let $v_0 \in \mathbb{R}^2$. Let us write $v(v_0, t_0, \cdot)$ to denote the unique variational vector field along $(u(\cdot), \gamma)$ whose value at t_0 is v_0 . If $t_0 \in \text{Dom}(\gamma)$ and $t_1 \in \text{Dom}(\gamma)$, we say that t_0 and t_1 are *conjugate along* $(u(\cdot), \gamma)$ if the vectors $v(G(\gamma(t_0)), t_0; t_1)$ and $G(\gamma(t_1))$ are linearly dependent. Notice that conjugacy is a symmetric relation. (If $v(G(\gamma(t_0)), t_0; t_1)$ and $G(\gamma(t_1))$ are linearly dependent, then $v(G(\gamma(t_0)), t_0; t)$ and $v(G(\gamma(t_1)), t_1; t)$ are dependent for all t , and in particular for $t = t_0$, so that $G(\gamma(t_0))$ and $v(G(\gamma(t_1)), t_1; t_0)$ are dependent.) However, it is possible for t_0 and t_2 to be conjugate to a time t_1 without being conjugate to each other. (This can happen if $G(\gamma(t_1)) = 0$.) If t_0 and t_1 are conjugate along $(u(\cdot), \gamma)$, we also say that the points $p_0 = \gamma(t_0)$, $p_1 = \gamma(t_1)$ are conjugate along $(u(\cdot), \gamma)$.

LEMMA 3.5. Let $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$, $\gamma \in \text{Opt}^1(\Sigma)$. Suppose that γ has switchings at p_0 and p_1 . Then p_0 and p_1 are conjugate along $(u(\cdot), \gamma)$.

Proof. Let $\Lambda = (u(\cdot), \gamma, \lambda(\cdot), \lambda_0)$ be an extremal lift of $(u(\cdot), \gamma)$. Let $\gamma(t_i) = p_i$, $i = 0, 1$. Since t_0 and t_1 are switching times for γ , we have

$$\phi_\Lambda(t_0) = \phi_\Lambda(t_1) = 0,$$

i.e.,

$$\lambda(t_0) \cdot G(\gamma(t_0)) = \lambda(t_1) \cdot G(\gamma(t_1)) = 0.$$

By Lemma 3.2, the function $t \rightarrow \lambda(t) \cdot v(G(\gamma(t_0)), t_0; t)$ is constant. So

$$\lambda(t_1) \cdot v(G(\gamma(t_0)), t_0; t_1) = \lambda(t_1) \cdot G(\gamma(t_1)) = 0.$$

Since $\lambda(t_1) \neq 0$, the vectors $v(G(\gamma(t_0)), t_0; t_1)$ and $G(\gamma(t_1))$ are linearly dependent. So t_0 and t_1 are conjugate. \square

The following results will be useful later.

LEMMA 3.6. Let U be the domain of a rectangular coordinate system (ξ, η) with respect to which X has components $(1, 0)$ (i.e. $X = \partial_x$). Let $\gamma_1: [a, b] \rightarrow U$ be a trajectory of Σ , of the form $t \rightarrow (x_1(t), y_1(t))$, such that the function $y_1(\cdot)$ is of class C^1 , and $\dot{y}_1(t) \neq 0$ for all $t \in \text{Dom}(\gamma_1)$. Suppose that $\tau: [a, b] \rightarrow]0, \infty[$ is a function of class C^1 such that, for each $t \in [a, b]$, the point $(x_1(t) + \tau(t), y_1(t))$ belongs to U and is conjugate to $(x_1(t), y_1(t))$ along the X -trajectory joining both points. Suppose that the curve $t \rightarrow (x_1(t) + \tau(t), y_1(t))$, $t \in \text{Dom}(\gamma_1)$ can be reparametrized by a parameter s such that $ds/dt > 0$, in such a way that the reparametrized curve is a trajectory γ_2 of Σ . Let δ_a, δ_b be the unique X -trajectories going from $(x_1(a), y_1(a))$ to $(x_1(a) + \tau(a), y_1(a))$ and from $(x_1(b), y_1(b))$ to $(x_1(b) + \tau(b), y_1(b))$, respectively. Then

$$(3.9) \quad T(\delta_b * \gamma_1) = T(\gamma_2 * \delta_a).$$

Proof. (cf. Fig. 1). Let Y have components (α, β) . Then

$$(3.10.a) \quad F = \frac{1}{2}(\alpha + 1)\partial_x + \frac{1}{2}\beta\partial_y$$

and

$$(3.10.b) \quad G = \frac{1}{2}(\alpha - 1)\partial_x + \frac{1}{2}\beta\partial_y.$$

Let $u(\cdot): [a, b] \rightarrow [-1, 1]$ be a control such that γ_1 is a trajectory for $u(\cdot)$. Then the functions $x_1(\cdot)$, $y_1(\cdot)$ satisfy the differential equations

$$(3.11.a) \quad \dot{x}_1(t) = \frac{1}{2}(\alpha(x_1(t), y_1(t)) + 1) + \frac{u(t)}{2}(\alpha(x_1(t), y_1(t)) - 1),$$

$$(3.11.b) \quad \dot{y}_1(t) = \frac{1 + u(t)}{2}\beta(x_1(t), y_1(t)).$$

Since $\dot{y}_1(t) \neq 0$ for all t , \dot{y}_1 is either > 0 for all t , or < 0 for all t . Let us assume that $\dot{y}_1(t) > 0$ for all $t \in [a, b]$. Then we can reparametrize γ_1 using the y coordinate as a parameter. Let $\tilde{a} = y_1(a)$, $\tilde{b} = y_1(b)$, let $y \rightarrow (\tilde{x}(y), y)$, $\tilde{a} \leq y \leq \tilde{b}$ be the reparametrized curve, and let $y \rightarrow \tilde{t}(y)$ be the time as a function of y . Then

$$\frac{d\tilde{x}}{dy} = \frac{\alpha}{\beta}(\tilde{x}(y), y) + \frac{1 - u(\tilde{t}(y))}{1 + u(\tilde{t}(y))} \cdot \frac{1}{\beta(\tilde{x}(y), y)}$$

and

$$\frac{d\tilde{t}}{dy} = \frac{2}{1 + u(\tilde{t}(y))} \cdot \frac{1}{\beta(\tilde{x}(y), y)}.$$

FIG. 1

Therefore

$$\frac{d}{dy}(\tilde{x}(y) - \tilde{t}(y)) = \frac{\alpha - 1}{\beta}(\tilde{x}(y), y).$$

So

$$(3.12.a) \quad x_1(b) - x_1(a) - T(\gamma_1) = \int_a^b \frac{\alpha - 1}{\beta}(\tilde{x}(y), y) dy.$$

Let $\gamma_2: [a', b'] \rightarrow U$ be of the form $t \rightarrow (x_2(t), y_2(t))$, and let $y \rightarrow (\tilde{x}^*(y), y)$ be γ_2 , reparametrized using y as the parameter. Then, a computation similar to the one leading to (3.12.a) gives

$$(3.12.b) \quad x_2(b') - x_2(a') - T(\gamma_2) = \int_a^b \frac{\alpha - 1}{\beta}(\tilde{x}^*(y), y) dy.$$

The hypothesis that $(x_1(t) + \tau(t), y_1(t))$ and $(x_1(t), y_1(t))$ are conjugate along the X -trajectory joining them implies that

$$\frac{\alpha - 1}{\beta}(\tilde{x}^*(y), y) = \frac{\alpha - 1}{\beta}(\tilde{x}(y), y)$$

for all y . (Because $(\alpha - 1)\beta^{-1}$ is the inverse of the slope of G .) So

$$(3.13) \quad x_1(b) - x_1(a) - T(\gamma_1) = x_2(b') - x_2(a') - T(\gamma_2).$$

Suppose that $x_1(b) \geq x_1(a)$, and that $x_2(b') \leq x_2(a')$. Let $\bar{p}_1 = (x_1(b), y_1(a))$, $\bar{p}_2 = (x_2(b'), y_2(b'))$.

Then

$$(3.14.a) \quad T(\delta_b * \gamma_1) = T(\gamma_1) + x_2(b') - x_1(b)$$

and

$$(3.14.b) \quad T(\gamma_2 * \delta_a) = x_1(b) - x_1(a) + x_2(b') - x_1(b) + x_2(a') - x_2(b') + T(\gamma_2).$$

Therefore (3.13) implies that $T(\delta_b * \gamma_1) = T(\gamma_2 * \delta_a)$. If $x_1(b) \geq x_1(a)$ but $x_2(b') > x_2(a')$, then the term $x_2(a') - x_2(b')$ does not occur in (3.14.b), but we must add $x_2(b') - x_2(a')$ to (3.14.a), so (3.9) still holds. The other cases are similar. So (3.9) is proved if $\dot{y}_1 > 0$ on $[a, b]$. The case when $\dot{y}_1 < 0$ is similar. \square

We now investigate the derivative of the switching function. After a straightforward computation, we get the following.

LEMMA 3.7. *Let $\Lambda = (u(\cdot), \gamma, \lambda(\cdot), \lambda_0)$ be an extremal lift of an admissible $(u(\cdot), \gamma)$. Then the switching function $\phi_\Lambda: \text{Dom}(\gamma) \rightarrow \mathbb{R}$ is of class C^1 , and its derivative is given by*

$$(3.15) \quad \dot{\phi}_\Lambda(t) = \lambda(t) \cdot [F, G](\gamma(t)).$$

The preceding result shows that the Lie bracket of F and G is very important, so we give it a special name. We let

$$(3.16) \quad H = [F, G].$$

Then H can also be expressed in terms of X and Y , using (2.12.a, b). We get

$$(3.17) \quad H = \frac{1}{2}[X, Y].$$

From Lemma 3.7, we get the following.

THEOREM 3.8. *Let $U \subseteq M$ be an open set such that $G(p)$ and $H(p)$ are linearly independent at every $p \in U$. Then*

$$\text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}(X \vee Y)^\infty.$$

Proof. Let $(u(\cdot), \gamma) \in \text{Adm}(\Sigma)$, $\gamma \in \text{Opt}^1(\Sigma \upharpoonright U)$. Let $\Lambda = (u(\cdot), \gamma, \lambda(\cdot), \lambda_0)$ be an extremal lift of $(u(\cdot), \gamma)$.

If $t_0 \in \text{Dom}(\gamma)$ is such that $\phi_\Lambda(t_0) = 0$, then (3.15) implies that

$$(3.18) \quad \dot{\phi}_\Lambda(t_0) = \lambda(t_0) \cdot H(\gamma(t_0)).$$

Since $G(\gamma(t_0))$ and $H(\gamma(t_0))$ are linearly independent, and $\lambda(t_0) \neq 0$, but $\lambda(t_0) \cdot G(\gamma(t_0)) = 0$, it follows that $\dot{\phi}_\Lambda(t_0) \neq 0$.

So all zeros of ϕ_Λ are isolated. Then ϕ_Λ has finitely many zeros, since $\text{Dom}(\gamma)$ is compact. Therefore γ is regular bang-bang. \square

If F and G are independent, then we can be much more precise. Let $\Omega(A)$ be the set of points $p \in M$ such that $F(p)$ and $G(p)$ are independent, and let $\Omega(B)$ be the set of p such that $G(p)$ and $H(p)$ are independent. Then it is clear that $\Omega(A)$ and $\Omega(B)$ are open. An *ordinary point* is a point p which belongs to $\Omega(A) \cap \Omega(B)$.

We can define smooth functions f, g on $\Omega(A)$ by

$$(3.19) \quad H = fF + gG.$$

THEOREM 3.9. *Let $U \subseteq M$ be open, and suppose that $U \subseteq \Omega(A) \cap \Omega(B)$. Then*

$$(3.20) \quad \text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}((X \vee Y)^2).$$

If $f > 0$ throughout U , then

$$(3.21) \quad \text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}(Y * X).$$

If $f < 0$ throughout U , then

$$(3.22) \quad \text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}(X * Y).$$

Proof. Any $\gamma \in \text{Traj}(\Sigma \upharpoonright U)$ is entirely contained in a connected component of U . If U is connected, then $f > 0$ throughout U , or $f < 0$ throughout U . So the last two assertions imply the first one.

We will prove that (3.21) holds if $f > 0$ throughout U . Let $(u(\cdot), \gamma) \in \text{Opt}^1(\Sigma \upharpoonright U)$, and let $\Lambda = (u(\cdot), \gamma, \lambda(\cdot), \lambda_0)$ be an extremal lift. Let t_0 be a time such that $\phi_\Lambda(t_0) = 0$. Then

$$\dot{\phi}_\Lambda(t_0) = \lambda(t_0) \cdot H(\gamma(t_0)) = f(\gamma(t_0))\lambda(t_0) \cdot F(\gamma(t_0))$$

(since $\lambda(t_0) \cdot G(\gamma(t_0)) = 0$).

Since $F(\gamma(t_0))$ and $G(\gamma(t_0))$ are linearly independent, and $\lambda(t_0) \cdot G(\gamma(t_0)) = 0$, we have

$$(3.23) \quad \lambda(t_0) \cdot F(\gamma(t_0)) \neq 0.$$

On the other hand,

$$(3.24) \quad \mathcal{H}(\lambda(t), \gamma(t), u(t)) \leq 0$$

for almost all t (because $\lambda_0 \geq 0$).

So

$$\lambda(t) \cdot F(\gamma(t)) \leq -u(t)\lambda(t) \cdot G(\gamma(t))$$

for almost all t . In particular, we can let $t \rightarrow t_0$, and get

$$(3.25) \quad \lambda(t_0) \cdot F(\gamma(t_0)) \leq 0.$$

Combining this with (3.23) we get

$$(3.26) \quad \lambda(t_0) \cdot F(\gamma(t_0)) < 0.$$

Since $f(\gamma(t_0)) > 0$, we get

$$(3.27) \quad \dot{\phi}_\Lambda(t_0) < 0.$$

This proves that, if t_0 is a switching time for γ , then γ is an X -trajectory for $t < t_0$, and a Y -trajectory for $t > t_0$. So γ cannot have more than one switching, and our conclusion is proved. \square

The conclusion of Theorem 3.9 can also be proved by a different method, which gives some other useful results. We define a 1-form ω in $\Omega(A)$ by

$$(3.28) \quad \langle \omega, F \rangle = 1, \quad \langle \omega, G \rangle = 0.$$

Then, if $\gamma \in \text{Traj}(\Sigma \upharpoonright \Omega(A))$, the time $T(\gamma)$ is the integral of ω along γ . Suppose that

(3.I.a) γ_1 and γ_2 are trajectories of Σ in $\Omega(A)$, going from a point p to a point q ,

(3.I.b) $\gamma_2^{-1} * \gamma_1$ is a simple closed curve whose interior is entirely contained in $\Omega(A)$ (Here γ_2^{-1} is γ_2 run backwards.),

(3.I.c) $\gamma_2^{-1} * \gamma_1$ is oriented counterclockwise, relative to some coordinate system.

Let \mathcal{R} be the region enclosed by $\gamma_2^{-1} * \gamma_1$. Then

$$(3.29) \quad T(\gamma_1) - T(\gamma_2) = \int_{\gamma_2^{-1} * \gamma_1} \omega.$$

By Stokes' Theorem, we get

$$(3.30) \quad T(\gamma_1) - T(\gamma_2) = \iint_{\mathcal{R}} d\omega.$$

On the other hand, we can compute $d\omega$ by the fomula

$$(3.31) \quad \langle d\omega, F \wedge G \rangle = F\langle \omega, G \rangle - G\langle \omega, F \rangle - \langle \omega, [F, G] \rangle$$

and we get (since $\langle \omega, G \rangle$ and $\langle \omega, F \rangle$ are constant functions, and so $F\langle \omega, G \rangle \equiv G\langle \omega, F \rangle \equiv 0$)

$$(3.32) \quad \langle d\omega, F \wedge G \rangle = -\langle \omega, [F, G] \rangle = -f.$$

In the preceding formulas, $F \wedge G$ is the exterior product of F and G . In coordinates, we can express $F \wedge G$ as

$$(3.33) \quad F \wedge G = \Delta_A \partial_x \wedge \partial_y,$$

where

$$(3.34) \quad \Delta_A = \det(F, G).$$

(Here “det” stands for “determinant.” Recall that F and G are column-vector-valued functions on M , and so we can form, for each $p \in M$, the two-by-two matrix with columns $F(p)$, $G(p)$.)

Then

$$(3.35) \quad d\omega = \rho \, dx \wedge dy$$

where ρ is computed by

$$(3.36) \quad \rho = \langle d\omega, \partial_x \wedge \partial_y \rangle = \frac{1}{\Delta_A} \langle d\omega, F \wedge G \rangle,$$

so that

$$(3.37) \quad d\omega = -\frac{f}{\Delta_A} \, dx \wedge dy.$$

Therefore, we have proved the following.

LEMMA 3.10. *Suppose (3.I.a, b, c) hold, and let \mathcal{R} be the region enclosed by $\gamma_2^{-1} * \gamma_1$. Then*

$$(3.38) \quad T(\gamma_1) - T(\gamma_2) = - \iint_{\mathcal{R}} \frac{f}{\Delta_A} \, dx \wedge dy.$$

As a consequence of Lemma 3.10, we get the following.

LEMMA 3.11. *Let U be an open subset of $\Omega(A)$ such that $f(p) > 0$ for p in some dense subset of U . Suppose that U is the domain of some coordinate chart with respect to which $\Delta_A(p) > 0$ for $p \in U$. Then, if γ_1 and γ_2 are trajectories of Σ in U such that $\text{In}(\gamma_1) = \text{In}(\gamma_2)$, $\text{Term}(\gamma_1) = \text{Term}(\gamma_2)$, and that $\gamma_2^{-1} * \gamma_1$ is a simple closed curve oriented counterclockwise whose interior is contained in U , it follows that*

$$(3.39) \quad T(\gamma_1) < T(\gamma_2).$$

Inequality (3.39) also holds if $f < 0$ on a dense set and $\Delta_A < 0$ on U . In the other two cases (i.e., when $f \cdot \Delta_A < 0$ on a dense set) the opposite inequality holds.

Proof. We only consider the first case. (The other ones are similar.) If \mathcal{R} is the region bounded by $\gamma_2^{-1} * \gamma_1$, then $f \geq 0$ on \mathcal{R} , but \mathcal{R} contains points where $f > 0$. So

$$\iint_{\mathcal{R}} \frac{f}{\Delta_A} dx dy > 0.$$

Formula (3.38) then implies (3.39). \square

In order to apply the preceding lemma to prove an extension of Theorem 3.9, we first establish the existence of a particular type of coordinate chart about any point $p \in \Omega(A)$.

LEMMA 3.12. *Let X and Y be smooth vector fields on an open set $M \subseteq \mathbb{R}^2$, and let $p \in M$ be such that $X(p)$ and $Y(p)$ are linearly independent. Then there is a coordinate chart $(U, (\xi, \eta))$, defined on a neighborhood U of p , relative to which X and Y have components $(\alpha, 0)$, $(0, \beta)$, respectively, where α and β are smooth functions on U such that $\alpha > 0$ and $\beta > 0$ throughout U .*

Proof. Let $Q_1(t, s) = \Phi_t^X \Phi_s^Y(p)$. Then Q_1 is a smooth map from some square $\text{Sq}(\varepsilon)$ onto an open set U_1 such that $p \in U$. Moreover, the differential of Q_1 at $(0, 0)$ is nonsingular. So, by taking ε small enough, we may assume that Q_1 is a diffeomorphism. Let $\eta: U_1 \rightarrow \mathbb{R}$ be Q_1^{-1} followed by the map $(t, s) \rightarrow s$. If $q \in U_1$ is of the form $\Phi_{\bar{t}}^X \Phi_{\bar{s}}^Y(p)$, then the integral curve of X through q is the curve $r \mapsto \Phi_{\bar{t}+r}^X \Phi_{\bar{s}}^Y(p)$, and η has the same value \bar{s} at all the points in this curve. Therefore $X\eta \equiv 0$. On the other hand, $\eta(p) = 0$ and $\eta(\Phi_t^Y(p)) = t$ for $|t| < \varepsilon$, so that $Y\eta(p) = 1$. By a similar reasoning, we get a function ξ on some open subset U_2 , such that $p \in U_2$, $\xi(p) = 0$, $X\xi(p) = 1$, and $Y\xi \equiv 0$. The formulas $X\xi(p) = Y\eta(p) = 1$, $X\eta(p) = Y\xi(p) = 0$, imply that the differentials of ξ and η at p are linearly independent. So, if $U \subseteq U_1 \cap U_2$, $p \in U$, and U is sufficiently small, the map $q \mapsto (\xi(q), \eta(q))$ is a diffeomorphism, so that $(U, (\xi, \eta))$ is a chart. The components of X in this chart are $X\xi, X\eta$. Since $X\eta \equiv 0$, we see that X has components $(\alpha, 0)$, for some smooth function α . Since $X\xi(p) = 1$, it follows that $\alpha(p) = 1$. So, by making U smaller, if necessary, we may assume that $\alpha > 0$ throughout U . A similar argument shows that Y has components $(0, \beta)$, and it may be assumed that $\beta > 0$ throughout U . \square

We are now ready to prove a slight generalization of Theorem 3.9.

THEOREM 3.13. *Let $U \subseteq M$ be open, and suppose that $U \subseteq \Omega(A)$, and that $f > 0$ on a dense subset U' of U . Then*

$$(3.40.a) \quad \text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}(Y * X).$$

If, instead, $f < 0$ throughout U' , then

$$(3.40.b) \quad \text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}(X * Y).$$

Proof. We prove the first assertion only. (The second one follows by a similar argument, or can be proved from the first one by interchanging X and Y .) So we assume that $f > 0$ on a dense subset of U .

The first step is to prove that no strict $X * Y$ -trajectory in U can be optimal. Suppose $\gamma: [a, b] \rightarrow U$ is an optimal strict $X * Y$ -trajectory. Let t_0 be the switching time, so that $a < t_0 < b$, $\gamma \upharpoonright [a, t_0]$ is a Y -trajectory, and $\gamma \upharpoonright [t_0, b]$ is an X -trajectory. Pick a coordinate chart $(V, (\xi, \eta))$, centered at $\gamma(t_0)$, and such that X, Y have components $(\alpha, 0)$, $(0, \beta)$, respectively, with $\alpha > 0$, $\beta > 0$ on V . We identify V with its image under (ξ, η) , and we assume that V is a square $\text{Sq}(\varepsilon)$. Then the X -trajectories are horizontal and go from left to right, and the Y -trajectories are vertical and go up. If $\delta > 0$ is small enough, then $\gamma_2 = \gamma \upharpoonright [t_0 - \delta, t_0 + \delta]$ is a strict $X * Y$ -trajectory in V .

Clearly, there is a unique strict $Y * X$ -trajectory γ_1 going from $\gamma(t_0 - \delta)$ to $\gamma(t_0 + \delta)$ in V . The curve $\gamma_2^{-1} * \gamma_1$ is simple, closed, and oriented counterclockwise. Then

$$(3.41) \quad T(\gamma_1) - T(\gamma_2) = - \iint_{\mathcal{R}} \frac{f}{\Delta_A} dx dy,$$

where \mathcal{R} is the rectangular region enclosed by $\gamma_2^{-1} * \gamma_1$. Since $\Delta_A > 0$ on U (because $\Delta_A = \alpha\beta$), and $f \geq 0$ on U , but \mathcal{R} contains at least one point where $f > 0$, we see that $T(\gamma_1) < T(\gamma_2)$. So γ_2 is not optimal. Therefore γ is not optimal, which is a contradiction. This completes the first step.

We now let $\gamma \in \text{Opt}^1(\Sigma \upharpoonright U)$ be arbitrary. Let t_0 be an arbitrary interior point of $\text{Dom}(\gamma)$, and pick a chart $(V, (\xi, \eta))$ as above. Also, pick $\delta > 0$ such that $\gamma \upharpoonright [t_0 - \delta, t_0 + \delta]$ is entirely contained in V . Then it may happen that

(i) $\gamma \upharpoonright [t_0 - \delta, t_0 + \delta] \in \text{Traj}(X \vee Y)$.

If (i) does not happen, then $\xi(\gamma(t_0 + \delta)) > \xi(\gamma(t_0 - \delta))$ and $\eta(\gamma(t_0 + \delta)) > \eta(\gamma(t_0 - \delta))$. Therefore the point $\gamma(t_0 + \delta)$ lies strictly above and strictly to the right of $\gamma(t_0 - \delta)$. Let $\gamma_2^* = \gamma \upharpoonright [t_0 - \delta, t_0 + \delta]$, and let γ_1^* be the unique strict $Y * X$ -trajectory in V going from $\gamma(t_0 - \delta)$ to $\gamma(t_0 + \delta)$. Let E be the set of points $\gamma_1^*(t)$, for $t \in \text{Dom}(\gamma_1^*)$. Then E is compact. If $\gamma_2^*(s) \in E$ for all $s \in \text{Dom}(\gamma_2^*)$, then it is easy to see that $\gamma_2^* = \gamma_1^*$, i.e., that

(ii) $\gamma \upharpoonright [t_0 - \delta, t_0 + \delta] \in \text{Traj}(Y * X)$.

If (ii) is not true, then there must be a $t \in [t_0 - \delta, t_0 + \delta]$ such that $\gamma_2^*(t) \notin E$. The set of such t is open in $[t_0 - \delta, t_0 + \delta]$, and does not contain the endpoints $t_0 - \delta, t_0 + \delta$, because $\gamma(t_0 - \delta)$ and $\gamma(t_0 + \delta)$ are in E . So there is a maximal interval $[t_1, t_2] \subseteq [t_0 - \delta, t_0 + \delta]$ such that $\gamma_2^*(t) \notin E$ for $t_1 < t < t_2$. Then $\gamma_2^*(t_1) \in E$ and $\gamma_2^*(t_2) \in E$. Let $\gamma_2 = \gamma_2^* \upharpoonright [t_1, t_2]$. If $\gamma_1^*(s_i) = \gamma_2^*(t_i)$ for $i = 1, 2$, let $\gamma_1 = \gamma_1^* \upharpoonright [s_1, s_2]$. Then γ_1 and γ_2 go from the same initial point to the same terminal point. Moreover, γ_1 and γ_2 have no points in common other than the endpoints, because $\gamma_2(t) \notin E$ for $t_1 < t < t_2$, but γ_1 is entirely contained in E . So $\gamma_2^{-1} * \gamma_1$ is a simple closed curve oriented counterclockwise. Exactly as in the first step, we conclude that $T(\gamma_1) < T(\gamma_2)$, so that γ_2 is not optimal, and then γ is not optimal. This contradiction arose from assuming that neither (i) nor (ii) hold.

So we have proved that, if t_0 is any interior point of $\text{Dom}(\gamma)$, then there is a $\delta > 0$ for which (i) or (ii) holds. Then it follows easily that, if J is a compact subinterval of the interior of $\text{Dom}(\gamma)$, then $\gamma \upharpoonright J$ is regular bang-bang. Since we know that $\gamma \upharpoonright J$ cannot have a strict $X * Y$ piece, it follows that $\gamma \upharpoonright J \in \text{Traj}(Y * X)$. From this it follows immediately that $\gamma \in \text{Traj}(Y * X)$. \square

We conclude this section with the definition of a new function which makes it possible to compute f as a quotient of determinants. We let

$$(3.42) \quad \Delta_B = \det(G, H).$$

Then we have

$$\Delta_B = \det(G, fF + gG)$$

so that

$$\Delta_B = f \det(G, F) = -f \Delta_A.$$

Therefore

$$(3.43) \quad f = -\frac{\Delta_B}{\Delta_A}.$$

The determinants Δ_A , Δ_B can also be expressed in terms of X and Y . The result is

$$(3.44) \quad \Delta_A = \frac{1}{2} \det(X, Y),$$

$$(3.45) \quad \Delta_B = \frac{1}{4} \det(Y - X, [X, Y]).$$

4. Barriers. Let $U \subseteq M$ be a connected open set. A *barrier* in U is a subset B of U such that

- (4.I.a) B is a smooth, one-dimensional, connected, relatively closed submanifold of U ,
- (4.I.b) $U - B$ has exactly two connected components,
- (4.I.c) one of the components of $U - B$, which we denote by U^+ , has the property that, at each $p \in B$, each of the vectors $X(p)$, $Y(p)$ is either tangent to B or points into U^+ .

LEMMA 4.1. *Let $U \subseteq M$ be open and connected. Let $B \subseteq U$ be a barrier in U , and let U^+ be the connected component of $U - B$ with the property described in (4.I.c). Let U^- be the other connected component of $U - B$. Then every trajectory $\gamma \in \text{Traj}(\Sigma \upharpoonright U)$ is a concatenation of at most three pieces $\gamma_1, \gamma_2, \gamma_3$, such that $\gamma_1(t) \in U^-$ for all $t \in \text{Dom}(\gamma_1)$, $t \neq \max \text{Dom}(\gamma_1)$, γ_2 is entirely contained in B , and $\gamma_3(t) \in U^+$ for all $t \in \text{Dom}(\gamma_3)$, $t \neq \min \text{Dom}(\gamma_3)$.*

Proof. Step 1: We prove that there is no integral trajectory γ of X or of Y that goes from a point $p \in B$ to a $q \in U^-$. Suppose γ is such a trajectory for, say, X . Let $\gamma(t_0) = p_0$, $\gamma(t_1) = p_1$. Let $\bar{t} \in [t_0, t_1]$ be the largest t such that $\gamma(t) \in B$. (Here we use the fact that B is closed.) Then $\gamma(t) \in U^-$ for $\bar{t} < t \leq t_1$. Pick a vector field X^* , on a neighborhood W of $\gamma(\bar{t})$, such that $X^*(q)$ points into U^+ for each $q \in B \cap W$. For each $\varepsilon > 0$, let γ_ε denote the integral curve of $\varepsilon X^* + X$ such that $\gamma_\varepsilon(\bar{t}) = \gamma(\bar{t})$. Pick a $\delta > 0$, $\delta < t_1 - \bar{t}$, such that $\gamma|[\bar{t}, \bar{t} + \delta]$ is entirely contained in W . Then by the continuous dependence on parameters for solutions of ordinary differential equations, the curve γ_ε is defined on $[\bar{t}, \bar{t} + \delta]$, and $\gamma_\varepsilon(t) \in W$ for $t \in [\bar{t}, \bar{t} + \delta]$, if $0 < \varepsilon < \varepsilon_0$, provided that ε_0 is small enough. Moreover, $\gamma_\varepsilon(t) \rightarrow \gamma(t)$ as $\varepsilon \rightarrow 0$. We claim that, if $0 < \varepsilon < \varepsilon_0$, then $\gamma_\varepsilon|[\bar{t}, \bar{t} + \delta]$ is entirely contained in U^+ . Indeed, if there is a $t \in [\bar{t}, \bar{t} + \delta]$ such that $\gamma_\varepsilon(t) \in U^-$, then this t is contained in a maximal open interval $]a, b[\subseteq [\bar{t}, \bar{t} + \delta]$ such that $\gamma_\varepsilon(]a, b[) \subseteq U^-$. Then $\gamma_\varepsilon(a) \in B$. Since $\dot{\gamma}_\varepsilon(a) = (\varepsilon X^* + X)(\gamma_\varepsilon(a))$, and $X(\gamma_\varepsilon(a))$ points to U^+ or is tangent to B , while $X^*(\gamma_\varepsilon(a))$ points to U^+ , we have

$$\gamma_\varepsilon(a + s) \in U^+ \quad \text{for } s > 0, s \text{ near } 0.$$

This contradicts the fact that $\gamma_\varepsilon(\tau) \in U^-$ for $\tau \in]a, b[$. So no t can exist for which $\gamma_\varepsilon(t) \in U^-$. On the other hand, if $\gamma_\varepsilon(t) \in B$, and if $t > \bar{t}$, then $\gamma_\varepsilon(t - s) \in U^-$ for small $s > 0$. Since we already know that no point of $\gamma_\varepsilon|[\bar{t}, \bar{t} + \delta]$ can be in U^- , it follows that $\gamma_\varepsilon(t) \in U^+$ for $t \in]\bar{t}, \bar{t} + \delta]$.

If we now let $\varepsilon \rightarrow 0$, we find that $\gamma(\bar{t} + \delta) \in B \cup U^+$. But this contradicts the fact that $\gamma(\bar{t} + \delta) \in U^-$.

Step 2: It follows easily from Step 1 that, if γ is an arbitrary regular bang-bang trajectory of Σ such that $\gamma(t_0) \in B$ for some t_0 , then $\gamma(t) \in B \cup U^+$ for all $t \geq t_0$, $t \in \text{Dom}(\gamma)$.

Step 3: Let $\gamma \in \text{Traj}(\Sigma \upharpoonright U)$, and let $t_0 \in \text{Dom}(\gamma)$ be such that $\gamma(t_0) \in B$. If γ corresponds to a control $u(\cdot): \text{Dom}(\gamma) \rightarrow [-1, 1]$, then $u(\cdot)$ is the weak limit of regular bang-bang controls $u_n(\cdot)$ with the same domain. Let γ_n be the corresponding trajectories, which satisfy $\gamma_n(t_0) = \gamma(t_0)$. Then $\gamma_n(t) \in B \cup U^+$ for $t \geq t_0$, by Step 2. Letting $n \rightarrow \infty$, we conclude that $\gamma(t) \in B \cup U^+$ for $t \geq t_0$.

Step 4: Let $\gamma \in \text{Traj}(\Sigma \upharpoonright U)$, and let $t_0 \in \text{Dom}(\gamma)$ be such that $\gamma(t_0) \in B$. Let γ^{-1} be γ run backwards, i.e., $\gamma^{-1}(t) = \gamma(-t)$, for $-t \in \text{Dom}(\gamma)$. Then γ^{-1} is a trajectory of Σ' , where Σ' is the system obtained from Σ by changing X, Y into $-X, -Y$. The set B is also a barrier in U for the new system, except that now U^- plays the role of U^+ . Since $\gamma^{-1}(-t_0) \in B$, it follows from Step 3 that $\gamma^{-1}(s) \in B \cup U^-$ for $s \geq t_0$, $s \in \text{Dom}(\gamma^{-1})$. Therefore $\gamma(t) \in B \cup U^-$ for $t \leq t_0$, $t \in \text{Dom}(\gamma)$.

Step 5: Let $\gamma \in \text{Traj}(\Sigma \upharpoonright U)$. If γ never goes through B , then γ is entirely contained in U^- or in U^+ , and the desired conclusion holds. If γ goes through B , let t_0 be the infimum, and let t_1 be the supremum, of the set of those $t \in \text{Dom}(\gamma)$ such that $\gamma(t) \in B$. Then $\gamma(t_0) \in B$ and $\gamma(t_1) \in B$. Since $\gamma(t_0) \in B$, it follows from Step 3 that $\gamma(t) \in B \cup U^+$ for $t > t_0$. Therefore $\gamma(t) \in U^+$ for $t > t_1$. Since $\gamma(t_1) \in B$, it follows that $\gamma(t) \in B \cup U^-$ for $t \leq t_1$. So $\gamma(t) \in U^-$ for $t < t_0$. If $t_0 \leq t \leq t_1$, then $\gamma(t) \in B \cup U^+$ and $\gamma(t) \in B \cup U^-$, so $\gamma(t) \in B$.

Summarizing: $\gamma(t) \in U^-$ for $t < t_0$, $\gamma(t) \in B$ for $t_0 \leq t \leq t_1$, and $\gamma(t) \in U^+$ for $t > t_1$. This is precisely the desired conclusion. \square

5. A lemma. We now prove a lemma that excludes certain types of switchings. We consider the following situation:

- (5.I.a) γ is a strict $X * Y$ - or $Y * X$ -trajectory, with a switching at a point q_0 ,
- (5.I.b) the vectors $X(q_0), Y(q_0)$ are linearly dependent, but point in opposite directions.

We want to conclude from these conditions that γ cannot be time-optimal. Let us first observe that such a conclusion cannot possibly be arrived at using solely the Maximum Principle. Indeed, a γ for which (5.I.a) and (5.I.b) hold may very well satisfy the Maximum Principle. For a simple example, suppose that X and Y satisfy (5.I.b), and that, in addition, the vectors $X(q_0)$ and $[X, Y](q_0)$ are linearly independent (i.e., that $G(q_0)$ and $H(q_0)$ are independent). Pick $\bar{\lambda} \in \mathbb{R}_*^2$ such that $\bar{\lambda} \neq 0$ but $\bar{\lambda} \cdot G(q_0) = 0$. Let γ be the concatenation of (a) the curve $t \rightarrow \Phi_t^Y(q_0)$, $-\delta \leq t \leq 0$, and (b) the curve $t \rightarrow \Phi_t^X(q_0)$, $0 \leq t \leq \delta$, where $\delta > 0$ is small. Let $\lambda(\cdot)$ be the unique variational covector along γ for which $\lambda(0) = \bar{\lambda}$. For $t > 0$, the derivative of $t \rightarrow \lambda(t) \cdot G(\gamma(t))$ is $t \rightarrow \lambda(t) \cdot [X, G](\gamma(t))$, i.e., $t \rightarrow \lambda(t) \cdot H(\gamma(t))$. In particular, the limit of this derivative at $t = 0$ is $\bar{\lambda} \cdot H(q_0)$. Similarly, the derivative for $t < 0$ also equals $\lambda(t) \cdot H(\gamma(t))$, which goes to $\bar{\lambda} \cdot H(q_0)$ as $t \rightarrow 0^-$. In view of our hypothesis that $H(q_0)$ and $G(q_0)$ are independent, we can conclude that $\bar{\lambda} \cdot H(q_0) \neq 0$. By changing $\bar{\lambda}$ to $-\bar{\lambda}$, if necessary, we may assume that $\bar{\lambda} \cdot H(q_0) > 0$. Then $\lambda(t) \cdot G(\gamma(t)) > 0$ for $t > 0$, and $\lambda(t) \cdot G(\gamma(t)) < 0$ for $t < 0$, as long as t is sufficiently close to 0. By making δ smaller, we may assume that $\lambda(t) \cdot G(\gamma(t)) > 0$ for all $t \in]0, \delta]$, $\lambda(t) \cdot G(\gamma(t)) < 0$ for all $t \in [-\delta, 0[$. Then the Hamiltonian $u \rightarrow \mathcal{H}(\lambda(t), \gamma(t), u)$ is minimized by $u = -1$ if $t > 0$, and by $u = 1$ if $t < 0$. So, if we let $u(t) = -1$ for $0 < t \leq \delta$, $u(t) = 1$ for $-\delta \leq t < 0$, we see that γ is a trajectory that corresponds to $u(\cdot)$, that $\lambda(\cdot)$ is a variational covector along $(u(\cdot), \gamma)$, and that $\lambda(\cdot)$ is nontrivial and minimizing. The value of the Hamiltonian along $(u(\cdot), \gamma, \lambda(\cdot))$ is $\mathcal{H}(\lambda(t), \gamma(t), u(t)) = \lambda(t) \cdot X(\gamma(t))$ for $t > 0$, and $\mathcal{H}(\lambda(t), \gamma(t), u(t)) = \lambda(t) \cdot Y(\gamma(t))$ for $t < 0$. Since $\gamma \upharpoonright [0, \delta] \in \text{Traj}(X)$, we see that $\mathcal{H}(\lambda(t), \gamma(t), u(t))$ is constant for $0 \leq t \leq \delta$. When $t = 0$, we get $\mathcal{H}(\lambda(0), \gamma(0), u(0)) = \bar{\lambda} \cdot F(q_0) = 0$ (since $F(q_0)$ and $G(q_0)$ are linearly dependent, and $\bar{\lambda} \cdot G(q_0) = 0$ but $G(q_0) \neq 0$). So \mathcal{H} vanishes along $\lambda(\cdot), \gamma, u(\cdot)$ for $t \geq 0$. A similar argument establishes that \mathcal{H} also vanishes for $t \leq 0$. So, if we let $\lambda_0 = 0$, all the conditions of the Maximum Principle hold.

The preceding remarks show that one can construct examples of trajectories γ for which (5.I.a) and (5.I.b) hold, but which satisfy the Maximum Principle. The fact that such a γ cannot be optimal is, therefore, a “high-order optimality condition.”

Actually, we will only prove our desired conclusion under an extra hypothesis, namely, that

- (5.I.c) the X - and Y -trajectories through q_0 have a tangency of finite order at q_0 .

We suspect that (5.I.c) is not really needed, but our proof does require it. In any case, notice that (5.I.c) is no restriction at all in the analytic case because, if (5.I.c) is violated, then the X - and Y -trajectories through q_0 must coincide (as sets) but be oriented in opposite directions, so that it is completely obvious that γ cannot be optimal.

LEMMA 5.1. *If (5.I.a, b, c) hold, then γ is not time-optimal.*

Proof. (cf. Fig. 2). We may assume that $\gamma \in \text{Traj}(X * Y)$. (The other case is identical.) Let $[a, b] = \text{Dom}(\gamma)$, and let $t_0 \in]a, b[$ be such that $\gamma(t_0) = q_0$.

Pick a square coordinate chart $(U, (\xi, \eta))$, of radius ε , and centered at q_0 , such that $X = \partial_x$ relative to these coordinates. Then $Y = \alpha \partial_x + \beta \partial_y$ on U , where α, β are smooth functions that satisfy

(5.1) $\alpha(0, 0) < 0, \quad \beta(0, 0) = 0.$

By making ε smaller, if necessary, we may assume that $\alpha < 0$ throughout U . Then, by making a larger, if necessary, we may assume that $\gamma|_{[a, t_0]}$ is entirely contained

FIG. 2

in U . Let

$$(5.2) \quad t \rightarrow (x(t), y(t)), \quad a \leq t \leq t_0$$

be the expression of $\gamma| [a, t_0]$ relative to our coordinates. Then

$$(5.3) \quad \dot{x}(t) = \alpha(x(t), y(t)) < 0,$$

so that $\gamma| [a, t_0]$ is entirely contained in the half-square $\{(x, y) \in U: x > 0\}$. The hypothesis that the Y -trajectory through q_0 does not have an infinite-order tangency with the X -trajectory says that some derivative of $y(\cdot)$ is nonzero at t_0 . If we let k be the smallest integer such that

$$(5.4) \quad \frac{d^k y}{dt^k}(t_0) \neq 0,$$

then $y(\cdot)$ has the Taylor expansion

$$(5.5) \quad y(t) = \rho(t - t_0)^k + O(|t - t_0|^{k+1})$$

for $t \leq t_0$, where

$$(5.6) \quad \rho = \frac{1}{k!} \frac{d^k y}{dt^k}(t_0).$$

After making the change of coordinates $(x, y) \rightarrow (x, -y)$, if necessary, we may assume that the sign of ρ is $(-1)^k$, so that $y(t) > 0$ for $t < t_0$, t near t_0 . By making a even larger, if necessary, we may assume that

$$(5.7) \quad y(t) > 0 \quad \text{for } a \leq t < t_0.$$

On the other hand, we have

$$(5.8) \quad \dot{y}(t) = \beta(x(t), y(t))$$

and so, for $j \geq 1$:

$$(5.9) \quad \frac{d^j y}{dt^j}(t) = (Y^{j-1} \beta)(x(t), y(t)).$$

Therefore $k = \nu + 1$, where ν is the first integer j such that $(Y^j \beta)(q_0) \neq 0$. A simple computation shows that

$$(5.10) \quad Y^j \beta = \alpha^j (\partial_x^j \beta) + \sum_{0 \leq i < j} \psi_{ij} \cdot \partial_x^i \beta$$

for suitable functions ψ_{ij} . Since $\alpha(q_0) < 0$, this implies that ν is also the first integer j such that $(\partial_x^j \beta)(q_0) \neq 0$, and that

$$(5.11) \quad \rho = \frac{1}{k!} \alpha(q_0)^\nu (\partial_x^\nu \beta)(q_0).$$

Since ρ has sign $(-1)^{\nu+1}$, it follows that

$$(5.12) \quad \partial_x^\nu \beta(q_0) < 0.$$

We now pick a $t_1 \in [a, t_0[$, such that $x(t_1) < b - t_0$. Then the point $(x(t_1), 0)$ is in $\gamma| [t_0, b]$, and $(x(t_1), 0) = \gamma(t_2)$ for some t_2 . (Actually, $t_2 = t_0 + x(t_1)$.) We let $\gamma_1 = \gamma| [t_1, t_0]$, $\gamma_2 = \gamma| [t_0, t_2]$. Also, we let γ_3 denote the vertical segment from $(x(t_1), y(t_1))$ to $(x(t_1), 0)$. We let $\mathcal{P}(t_1)$ denote the closed region bounded by γ_1 , γ_2 and γ_3 .

The function β has the Taylor expansion

$$(5.13) \quad \beta(x, y) = \beta(x, 0) + O(|y|)$$

for (x, y) near 0. Therefore, we have

$$(5.14) \quad \beta(x, y) = \frac{x^\nu}{\nu!} (\partial_x^\nu \beta)(q_0) + O(|x|^{\nu+1}) + O(|y|).$$

Since the curve γ_1 satisfies $\dot{x}(t_0) = \alpha(0, 0) \neq 0$, and

$$(5.15) \quad y(t) = \rho(t - t_0)^{\nu+1} + O(|t - t_0|^{\nu+2}),$$

we see that, as $(x, y) \rightarrow 0$ along $\mathcal{P}(t_1)$, we have $y = O(x^{\nu+1})$. Hence

$$(5.16) \quad y = O(x^{\nu+1}) \quad \text{as } (x, y) \rightarrow 0 \text{ along } \mathcal{P}(t_1).$$

So, if we restrict ourselves to $\mathcal{P}(t_1)$, the Taylor expansion for β becomes

$$(5.17) \quad \beta(x, y) = \frac{x^\nu}{\nu!} (\partial_x^\nu \beta)(q_0) + O(x^{\nu+1}).$$

On the other hand, the derivative $\partial_x \beta$ satisfies

$$(5.18) \quad \partial_x \beta(x, y) = \partial_x \beta(x, 0) + O(|y|),$$

i.e.,

$$(5.19) \quad \partial_x \beta(x, y) = \frac{x^{\nu-1}}{(\nu-1)!} (\partial_x^\nu \beta)(q_0) + O(|x|^\nu) + O(|y|);$$

so that, if we restrict ourselves to $\mathcal{P}(t_1)$, we get

$$(5.20) \quad \partial_x \beta(x, y) = \frac{x^{\nu-1}}{(\nu-1)!} (\partial_x^\nu \beta)(q_0) + O(x^\nu).$$

Combining (5.17) and (5.20) we get

$$(5.21) \quad \beta(x, y) = \frac{x}{\nu} (\partial_x \beta)(x, y) [1 + O(x)]$$

as $(x, y) \rightarrow 0$, $(x, y) \in \mathcal{P}(t_1)$.

It is clear that

$$(5.22) \quad \Delta_A = \frac{1}{2} \beta,$$

$$(5.23) \quad \Delta_B = \frac{1}{4} ((\alpha - 1)(\partial_x \beta) + \beta(\partial_x \alpha)).$$

Using (5.21), we get

$$(5.24) \quad \Delta_B = \frac{1}{4} \left(\alpha - 1 + \frac{x}{\nu} \partial_x \alpha (1 + O(x)) \right) (\partial_x \beta),$$

i.e.,

$$(5.25) \quad \Delta_B = \frac{1}{4} (\alpha - 1 + O(x)) \partial_x \beta,$$

always for $(x, y) \rightarrow 0$, $(x, y) \in \mathcal{P}(t_1)$.

Now choose t_1 so small that the $O(x)$ of formula (5.25) is dominated by $\alpha - 1$ (recall that $\alpha < 0$ on U), and that the $O(x^{\nu+1})$, $O(x^\nu)$ that appear in the right sides

of (5.17), (5.20) are actually dominated by the lower order terms that precede them. Then (since $\partial_x^\nu \beta(q_0) < 0$), we see that, if $\mathcal{P}(t_1)^0 = \mathcal{P}(t_1) - \{q_0\}$:

$$(5.II) \quad \beta < 0 \text{ and } \partial_x \beta < 0 \text{ throughout } \mathcal{P}(t_1)^0,$$

and that

$$(5.III) \quad \Delta_A < 0 \text{ and } \Delta_B > 0 \text{ throughout } \mathcal{P}(t_1)^0.$$

Therefore $\mathcal{P}(t_1)^0 \subseteq \Omega(A)$, and f is well defined on $\mathcal{P}(t_1)^0$. Since $f = -\Delta_B/\Delta_A$, we conclude that

$$(5.IV) \quad f > 0 \text{ throughout } \mathcal{P}(t_1)^0.$$

At any point q of γ_3 , the vector $Y(q)$ points to the left (because $\alpha < 0$) and down (because $\beta < 0$ on $\mathcal{P}(t_1)^0$). Therefore the tangent vector $-\partial_y$ to γ_3 is a convex combination of $X(q)$ and $Y(q)$. So γ_3 is, after a suitable reparametrization, a trajectory of Σ . Moreover, the curve $\gamma_2 * \gamma_1$ is also a trajectory of Σ , and $\gamma_3^{-1} * \gamma_2 * \gamma_1$ is a simple closed curve, oriented counterclockwise.

Since $f > 0$ and $\Delta_A < 0$ in the region enclosed by $\gamma_3^{-1} * (\gamma_2 * \gamma_1)$, we are almost in a situation where Lemma 3.11 applies. If we could apply it, we would conclude that

$$(5.26) \quad T(\gamma_3) < T(\gamma_2 * \gamma_1).$$

(Naturally, the roles of the γ_1 , γ_2 of the statement of Lemma 3.11 are played by $\gamma_2 * \gamma_1$ and γ_3 , respectively.) The reason why Lemma 3.11 cannot actually be applied as it stands is that, in Lemma 3.11, it was required that the curves γ_1 , γ_2 , and the region enclosed by them, be entirely contained in $\Omega(A)$. Here this condition does not hold, because $q_0 \notin \Omega(A)$. However, it is a very simple matter to modify the argument so as to be able to apply Lemma 3.11 and conclude that (5.26) holds. Pick t'_1 between t_1 and t_0 , and let $\gamma_{t'_1}$ be the concatenation of: (a) $\gamma \upharpoonright [t_1, t'_1]$, (b) the vertical segment from $(x(t'_1), y(t'_1))$ to $(x(t'_1), 0)$, suitably reparametrized so that it becomes a trajectory of Σ , and (c) the X -trajectory from $(x(t'_1), 0)$ to $(x(t_1), 0)$. Now Lemma 3.11 can be applied rigorously, and we get

$$(5.27) \quad T(\gamma_3) < T(\gamma_{t'_1}).$$

Another application of Lemma 3.11 shows that, if $t'_1 < t'' < t_0$, then $T(\gamma_{t'_1}) < T(\gamma_{t''})$. If we let $t''_1 \rightarrow t_0$, we get $T(\gamma_{t'_1}) \leq T(\gamma_2 * \gamma_1)$. So (5.26) holds.

Since $\gamma_2 * \gamma_1$ is a piece of γ , we conclude from (5.26) that γ is not optimal. \square

Remark 5.1. Suppose that (5.I.a, b) hold, and that γ is actually a strict $X * Y$ -trajectory. Let \mathcal{R} denote the open region bounded by the curves $t \rightarrow \Phi_t^Y(q_0)$, $t < 0$, and $t \rightarrow \Phi_t^X(q_0)$, $t > 0$. Hypothesis (5.I.c) was only used in the proof of Lemma 5.1 to conclude that $f > 0$ on \mathcal{R} . Therefore the conclusion of Lemma 5.1 is still true if (5.I.c) does not hold, as long as $f > 0$ on \mathcal{R} .

6. Nonordinary arcs. We now study the time-optimal trajectories in the neighborhood of certain arcs which consist entirely of points p such that $\Delta_A(p) = 0$ or $\Delta_B(p) = 0$. Recall that a point $p \in M$ is called an *ordinary point* if both $\Delta_A(p)$ and $\Delta_B(p)$ are nonzero. A *nonordinary point* is therefore a point p where the function $\Delta_A \cdot \Delta_B$ vanishes. A *nonordinary arc* is a smooth one-dimensional connected embedded submanifold S of M , with the property that every $p \in S$ is nonordinary. An *isolated nonordinary arc* (henceforth abbreviated as INOA) is a nonordinary arc S with the property that there

is a U such that

- (6.I.a) U is an open, connected subset of M ,
- (6.I.b) $U - S \subseteq \Omega(A) \cap \Omega(B)$,
- (6.I.c) S is a relatively closed subset of U .

If U is such that (6.I.a, b) hold, then $U - S$ has at most two connected components. However, $U - S$ might be connected. (Example: let U be an annulus, and let S be a segment joining the inner and outer boundaries of U .) In any case, one can always make U smaller, and assume that, in addition to (6.I.a, b, c), a further condition holds, namely,

- (6.I.d) $U - S$ has exactly two connected components.

An INOA S will be called *regular* if it satisfies the following three conditions:

- (6.II.a) Each of the vector fields X, Y is either everywhere tangent to S or nowhere tangent to S ,
- (6.II.b) each of the functions Δ_A, Δ_B is either identically zero on S or nowhere zero on S ,
- (6.II.c) if X and Y are everywhere tangent to S , then each of the vector fields $X, Y, Y - X$ is either identically zero on S or never zero on S .

Suppose that S is a regular INOA. Let U be such that (6.I) hold. In view of (6.II.a) it is clear that, if either X or Y is everywhere tangent to S , then S is a barrier in U . Also, if both X and Y are nowhere tangent to S , then it may happen that

- (6.III) for each $p \in S$, the vectors $X(p), Y(p)$ point to opposite sides of S ,

or that $X(p)$ and $Y(p)$ point to the same side of S for all p . In the latter case, the submanifold S is a barrier in U . Hence a regular INOA is either a barrier in U or an arc for which (6.III) holds. (In the latter case, S will be called a *nonbarrier regular* INOA.)

THEOREM 6.1. *Let S be a regular INOA which is a barrier in U for some U for which (6.I) hold. Then every time-optimal trajectory in U is bang-bang with at most four switchings.*

Proof. Let U^+, U^- be the connected components of $U - S$, labelled in such a way that, for each $p \in S$, each of the vectors $X(p), Y(p)$ either is tangent to S or points into U^+ . Then Lemma 4.1 implies that every trajectory of $\Sigma \upharpoonright U$ is a concatenation $\gamma_3 * \gamma_2 * \gamma_1$ of at most three pieces such that, if $\text{Dom}(\gamma_i) = [a_i, b_i]$ (so that $b_1 = a_2, b_2 = a_3$), then $\gamma_1 \upharpoonright [a_1, b_1[$ is contained in U^- , $\gamma_3 \upharpoonright [a_3, b_3]$ is contained in U^+ , and γ_2 is contained in S .

Now suppose that γ is time-optimal. Since U^- is entirely contained in $\Omega(A) \cap \Omega(B)$, Theorem 3.9 implies that γ_1 is bang-bang with at most one switching. A similar conclusion holds for γ_3 . As for γ_2 , let us first observe that this piece can only occur if at least one of the vector fields X, Y is everywhere tangent to S . If only one of X, Y is everywhere tangent to S , then γ_2 is bang-bang with no switchings. If both X and Y are everywhere tangent to S , then (6.II.c) implies, first of all, that X is either always zero on S , or never zero on S . In the former case, γ_2 must be a Y -trajectory, and so γ_2 is bang-bang with no switchings. A similar conclusion follows if Y vanishes everywhere on S . So we need only consider the case when both X and Y are nonzero everywhere on S . In this case, if there is some $p \in S$ such that $X(p)$ and $Y(p)$ have

opposite directions, it follows that $X(p)$ and $Y(p)$ have opposite directions for all $p \in S$. But then it is clear that γ_2 must be an $X \vee Y$ -trajectory. Finally, we must consider the case when, for all $p \in S$, the vectors $X(p)$ and $Y(p)$ are nonzero, tangent to S , and positive multiples of each other. In this case, (6.II.c) says that either $X(p) = Y(p)$ for all $p \in S$, or $X(p) \neq Y(p)$ for all $p \in S$. If $X \equiv Y$ on S , then $\gamma_2 \in \text{Traj}(X)$. If $X(p) \neq Y(p)$ for all $p \in S$, then either $X(p)$ is shorter than $Y(p)$ for all $p \in S$, or it is longer for all $p \in S$. In the former case, γ_2 must be a Y -trajectory whereas, in the latter case, γ_2 has to be an X -trajectory. So we have shown that, in all possible cases, $\gamma_2 \in \text{Traj}(X \vee Y)$.

So γ is bang-bang with at most four switchings (namely: one switching for each of γ_1, γ_3 , and, possibly, the switchings at a_2 and b_2). \square

We now study what happens when (6.III) holds. Let U_X, U_Y be the connected components of $U - S$, labelled in such a way that, if V is either X or Y , and $p \in S$, then $V(p)$ points into U_V . The function f is well defined and nowhere vanishing on $U_X \cup U_Y$ (because $U_X \cup U_Y \subseteq \Omega(A) \cap \Omega(B)$).

Since U_X and U_Y are connected, we have three possibilities:

(6.IV.a) $f > 0$ throughout $U_X \cup U_Y$, or $f < 0$ throughout $U_X \cup U_Y$,

(6.IV.b) $f < 0$ on U_X and $f > 0$ on U_Y ,

(6.IV.c) $f > 0$ on U_X and $f < 0$ on U_Y .

The case when (6.IV.a) holds is easy to dispose of.

THEOREM 6.2. *Let S be a nonbarrier regular INOA, and let U be such that (6.I), (6.III) and (6.IV.a) hold. Then every time-optimal trajectory in U is bang-bang with at most one switching.*

Proof. Since S is a regular INOA, it satisfies (6.II.b). Therefore the function Δ_A either vanishes identically on S , or vanishes nowhere on S . Suppose first that Δ_A never vanishes on S . Then U is entirely contained in $\Omega(A)$. So the hypothesis of Theorem 3.13 holds, and we can conclude that

$$\text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}(X \vee Y)^2.$$

Now suppose that $\Delta_A \equiv 0$ on S . Let us consider the case when $f > 0$ on $U_X \cup U_Y$. (The case when $f < 0$ on $U_X \cup U_Y$ is similar.) Let $\gamma \in \text{Opt}^1(\Sigma \upharpoonright U)$. Let I_X, I_Y denote the subsets of $\text{Dom}(\gamma)$ that consist of all t such that $\gamma(t) \in U_X, \gamma(t) \in U_Y$, respectively. Then I_X, I_Y are relatively open subsets of $\text{Dom}(\gamma)$.

Let $\mathcal{F}_X, \mathcal{F}_Y$ denote the sets of connected components of I_X, I_Y , respectively. Suppose that $J \in \mathcal{F}_Y$. If $J =]a, b[$ for some a, b , then $\gamma(a) \in S$ and $\gamma(b) \in S$. Since $\gamma \upharpoonright J$ is entirely contained in U_Y , and $f > 0$ on U_Y , we can conclude from Thm. 3.9 that $\gamma \upharpoonright J$ is an X -trajectory, or a Y -trajectory, or an X -trajectory followed by a Y -trajectory. On the other hand, it is not possible for $\gamma \upharpoonright]a, a + \delta[$ to be an X -trajectory for any $\delta > 0$ (because X points into U_X , and $\gamma \upharpoonright J$ is contained in U_Y). Similarly, it is not possible for $\gamma \upharpoonright]b - \delta, b[$ to be a Y -trajectory. So we have reached a contradiction. Therefore no $J \in \mathcal{F}_Y$ can be an open interval. This shows that \mathcal{F}_Y consists of at most two intervals, and that each of these intervals contains one of the endpoints of $\text{Dom}(\gamma)$.

Now let $J \in \mathcal{F}_X$. Suppose that $J =]a, b[$. Exactly as above, we conclude that $\gamma(a) \in S$, that $\gamma(b) \in S$, and that $\gamma \upharpoonright J$ is an X -trajectory, or a Y -trajectory, or an X -trajectory followed by a Y -trajectory. If $\gamma \upharpoonright J$ were an X -trajectory, then γ would leave S at $\gamma(a)$ and enter U_X , but it would never be able to return to S (since $X(p)$ points into U_X for each $p \in S$). But this would contradict the fact that $\gamma(b) \in S$. Similarly, we also reach a contradiction if $\gamma \upharpoonright J$ is a Y -trajectory. Therefore $\gamma \upharpoonright J$ is an X -trajectory followed by a Y -trajectory. Choose $c \in]a, b[$ such that $\gamma \upharpoonright]a, c[$ is an X -trajectory and

that $\gamma|_{[c, b[}$ is a Y -trajectory. We now show that a and b cannot be switching times of γ . Suppose a were a switching time for γ . Then $\gamma(a)$ and $\gamma(c)$ would have to be conjugate along γ . Let $t \mapsto v(t)$ denote the variational vector field along γ such that $v(a) = G(\gamma(a))$. Since $G(\gamma(a)) = \frac{1}{2}(Y(\gamma(a)) - X(\gamma(a)))$, and $\Delta_A(\gamma(a)) = 0$, the vector $G(\gamma(a))$ must equal $\rho X(\gamma(a))$, for some ρ . Moreover, ρ must be nonzero, because $G(\gamma(a)) \neq 0$. If we let v' denote the variational vector field along γ such that $v'(a) = X(\gamma(a))$, then our preceding remarks show that $v(t) = \rho v'(t)$ for all $t \in \text{Dom}(\gamma)$. On the other hand, since $\gamma|_{[a, c]} \in \text{Traj}(X)$, we have $v'(t) = X(\gamma(t))$ for $t \in [a, c]$. In particular, $v'(c) = X(\gamma(c))$. Since $\gamma(a)$ and $\gamma(c)$ are conjugate along γ , the vectors $G(\gamma(c))$ and $v(c)$ are linearly dependent. Since $v(c) = \rho v'(c) \neq 0$, we have an equality $G(\gamma(c)) = \rho' X(\gamma(c))$ for some $\rho' \in \mathbb{R}$. Since $Y = X + 2G$, we conclude that $Y(\gamma(c))$ is a multiple of $X(\gamma(c))$, and therefore it follows that $\Delta_A(\gamma(c)) = 0$. But this contradicts the facts that $\gamma(c) \in U_X$, and $U_X \subseteq \Omega(A)$. So a cannot be a switching time for γ . A similar reasoning shows that b is not a switching time either.

Now suppose that $\min \text{Dom}(\gamma) < a$. Since γ does not have a switching at a , and $\gamma|_{[a, c]} \in \text{Traj}(X)$, it follows that $\gamma|_{[a - \delta, a]} \in \text{Traj}(X)$ for some $\delta > 0$. Since $X(\gamma(a))$ points into U_X , it follows that $\gamma(t) \in U_Y$ for $a - \delta \leq t < a$. Let J' be the connected component of I_Y such that $[a - \delta, a] \subseteq J'$. Then $J' \in \mathcal{F}_Y$ and so, as was shown before, J' must contain an endpoint of $\text{Dom}(\gamma)$. So $J' = \text{Dom}(\gamma) \cap] - \infty, a[$. The curve $\gamma|_{J'}$ is an X -trajectory, or a Y -trajectory, or an X -trajectory followed by a Y -trajectory. Since $\gamma|_{[a - \delta, a]} \in \text{Traj}(X)$, we conclude that $\gamma|_{(\text{Dom}(\gamma) \cap] - \infty, a])} \in \text{Traj}(X)$. Therefore $\gamma|_{(\text{Dom}(\gamma) \cap] - \infty, c])} \in \text{Traj}(X)$. This conclusion was arrived at under the assumption that $a > \min \text{Dom}(\gamma)$, but it is obviously true if $a = \min \text{Dom}(\gamma)$. Similarly, we can conclude that $\gamma|_{[c, \infty[\cap (\text{Dom}(\gamma))} \in \text{Traj}(Y)$.

We have therefore established that, if there is some interval $J \in \mathcal{F}_X$ which is open, then $\gamma \in \text{Traj}(Y * X)$.

Now suppose there is a $J \in \mathcal{F}_X$ which is not open. If $J = [a, b]$ then, necessarily, $J = \text{Dom}(\gamma)$ (because J is a connected component of I_X , and so J is relatively open in $\text{Dom}(\gamma)$). But then Theorem 3.9 implies that $\gamma \in \text{Traj}(Y * X)$. Now suppose that $J = [a, b[$. Then $a = \min \text{Dom}(\gamma)$, and $\gamma(b) \in S$. Theorem 3.9 implies that $\gamma|_{[a, b]} \in \text{Traj}(Y * X)$. If $\gamma|_{[a, b]}$ is a strict $Y * X$ -trajectory, with switching at a time $c \in]a, b[$, then the conjugate point argument used before shows that γ cannot have a switching at b , and that $\gamma|_{([c, \infty[\cap (\text{Dom}(\gamma))}]$ is a Y -trajectory. Therefore $\gamma \in \text{Traj}(Y * X)$, if $\gamma|_{[a, b]}$ is a strict $Y * X$ -trajectory.

If $\gamma|_{[a, b]}$ is not a strict $Y * X$ -trajectory, then $\gamma|_{[a, b]} \in \text{Traj}(X \vee Y)$. The possibility that $\gamma|_{[a, b]} \in \text{Traj}(X)$ is excluded, because $\gamma|_{[a, b]} \subseteq U_X$, and $\gamma(b) \in S$. So $\gamma|_{[a, b]} \in \text{Traj}(Y)$. Hence we have shown that, if $J \in \mathcal{F}_X$ and $J = [a, b[$, then $\gamma \in \text{Traj}(Y * X)$, except possibly if $\gamma|_J \in \text{Traj}(Y)$. Similarly, if $J \in \mathcal{F}_X$ and $J =]a, b[$, then $\gamma \in \text{Traj}(Y * X)$, except possibly in the case when $\gamma|_J \in \text{Traj}(X)$.

Now suppose that $\gamma \notin \text{Traj}(Y * X)$. Then one and only one of the following can happen:

- (6.V.i) \mathcal{F}_X is empty,
- (6.V.ii) \mathcal{F}_X consists of exactly one interval J , of the form $[\min \text{Dom}(\gamma), b[$, such that $\gamma|_J \in \text{Traj}(Y)$,
- (6.V.iii) \mathcal{F}_X consists of exactly one interval J , of the form $]a, \max \text{Dom}(\gamma)]$, such that $\gamma|_J \in \text{Traj}(X)$,
- (6.V.iv) \mathcal{F}_X consists of exactly two intervals of the form $J_1 = [\min \text{Dom}(\gamma), b[$, and $J_2 =]a, \max \text{Dom}(\gamma)]$ (with $b \leq a$), such that $\gamma|_{J_1} \in \text{Traj}(Y)$, and that $\gamma|_{J_2} \in \text{Traj}(X)$.

Suppose that \mathcal{F}_X is empty. Since \mathcal{F}_Y consists of at most two intervals, and each of these must contain an endpoint of γ , we see that γ is a concatenation of at most three pieces $\gamma_1, \gamma_2, \gamma_3$, such that $\text{Dom}(\gamma_i) = \text{Clos } J_i, J_i \in \mathcal{F}_Y$, for $i = 1, 3$. But then γ_2 must be entirely contained in S . Since $\dot{\gamma}_2(t)$ is a convex combination of $X(\gamma_2(t))$ and $Y(\gamma_2(t))$, and these vectors are multiples of each other and not tangent to S , it follows that $\dot{\gamma}_2(t) = 0$ for $t \in \text{Dom}(\gamma_2)$. So $\text{Dom}(\gamma_2)$ must be reduced to a single point. Therefore, if \mathcal{F}_Y consists of two intervals, then these intervals must be of the form $[\min \text{Dom}(\gamma), a[$ and $]a, \max \text{Dom}(\gamma)]$, for some interior point a of $\text{Dom}(\gamma)$, such that $\gamma(a) \in S$. By Theorem 3.9, $\gamma|((\text{Dom } \gamma) \cap]-\infty, a])$ is a $Y * X$ -trajectory. Since $\gamma|[\min \text{Dom}(\gamma), a[$ is contained in U_Y , there cannot be a piece $\gamma| [a - \delta, a]$ which is a Y -trajectory. So $\gamma|[\min \text{Dom}(\gamma), a]$ is an X -trajectory. Similarly, $\gamma|[a, \max \text{Dom}(\gamma)]$ is a Y -trajectory. Therefore $\gamma \in \text{Traj}(Y * X)$. If \mathcal{F}_Y consists of one interval only, then one shows as before that γ cannot contain a piece that is contained in S , and therefore one can also conclude that $\gamma \in \text{Traj}(Y * X)$. Finally, the case when $\mathcal{F}_Y = \emptyset$ is impossible, since it would imply that γ is entirely contained in S .

Summarizing, we have shown that, if \mathcal{F}_X is empty, then $\gamma \in \text{Traj}(Y * X)$. If $\gamma \notin \text{Traj}(Y * X)$ then, as indicated earlier, one of (6.V) hold. Moreover, we now know that (6.V.i.) cannot hold. Suppose (6.V.ii) holds. Let J, b be as in the statement of (6.V.ii). Then $\gamma| [b, \max \text{Dom}(\gamma)]$ is a time-optimal trajectory in U whose corresponding \mathcal{F}_X is empty. So we can apply what we have proved so far to this curve, and conclude that $\gamma| [b, \max \text{Dom}(\gamma)] \in \text{Traj}(Y * X)$. Therefore $\gamma \in \text{Traj}(Y * X * Y)$. We claim that γ cannot contain a switching from a Y - to an X -trajectory. Indeed, such a switching cannot occur at a point in $U_X \cup U_Y$, because $f > 0$ on $U_X \cup U_Y$ (cf. Theorem 3.9). Moreover, it cannot occur at a point $p \in S$, because $X(p)$ and $Y(p)$ are dependent and point in opposite directions, and so Lemma 5.1 applies. (The statement of Lemma 5.1 requires the extra hypothesis that, at p , the X - and Y -trajectories have a tangency of finite order. However, this hypothesis was only used to conclude that $f > 0$ on the region \mathcal{R} described in Remark 5.1. As explained in Remark 5.1, the conclusion of Lemma 5.1 still holds without the extra hypothesis, if we know that $f > 0$ on \mathcal{R} . Also, in our case, it is clear that $\mathcal{R} \subseteq U_Y$, and so $f > 0$ on \mathcal{R} .) So the switching from Y to X is excluded, and it follows that $\gamma \in \text{Traj}(Y * X)$.

If (6.V.iii) holds, then one proves in exactly the same way that $\gamma \in \text{Traj}(Y * X)$. Finally, if (6.V.iv) holds, then the restriction γ' of γ to $[b, \max \text{Dom}(\gamma)]$ is a time-optimal trajectory for which (6.V.ii) holds, and so $\gamma' \in \text{Traj}(Y * X)$. So $\gamma \in \text{Traj}(Y * X * Y)$. Exactly as before, the Y - to X -switching is excluded, and so $\gamma \in \text{Traj}(Y * X)$.

This completes the proof that $\text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}(Y * X)$, if $f > 0$ throughout $U_X \cup U_Y$. Similarly, if $f < 0$ on $U_X \cup U_Y$, it follows that $\text{Opt}^1(\Sigma \upharpoonright U) \subseteq \text{Traj}(X * Y)$. The proof of Theorem 6.2 is now complete. \square

We now consider the case when (6.IV.b) holds. A regular INOA S for which there is a U such that (6.I), (6.III) and (6.IV.b) hold will be said to be *of the turnpike type*. If, in addition, the function Δ_A never vanishes on S , then S will be called a *turnpike* (cf. Fig. 3).

THEOREM 6.3. *Let S be a regular INOA of the turnpike type. Let U be such that (6.I), (6.III) and (6.IV.b) hold. Then every time-optimal trajectory γ in U is a concatenation $\gamma_1 * \gamma_2 * \gamma_3$ of at most three pieces, such that γ_1 and γ_3 are in $\text{Traj}(X \vee Y)$, and that γ_2 is entirely contained in S . If S is not a turnpike, then every $\gamma \in \text{Opt}^1(\Sigma \upharpoonright U)$ is bang-bang with at most one switching (i.e., the γ_2 piece cannot occur).*

Proof. Exactly as in the proof of Theorem 6.2, let I_X be the set of those $t \in \text{Dom}(\gamma)$ such that $\gamma(t) \in U_X$, and let \mathcal{F}_X be the set of connected components of I_X . Define

The proof of Theorem 6.4 will be given in § 7.

We conclude this section with a corollary summarizing much of the information that we have just obtained. Let us say that p is a *near-ordinary point* if it is an ordinary point, or it belongs to a regular INOA S which, if it is of the antiturnpike type, is nondegenerate. We define a *Z-trajectory* to be a nontrivial trajectory γ of Σ entirely contained in $\text{Clos } S$ for some regular INOA S that is a turnpike.

COROLLARY 6.5. *Let p be a near ordinary point. Then p has a neighborhood U such that*

$$\text{Opt}^1(\Sigma \upharpoonright U) \subseteq [\text{Traj}(X \vee Y \vee Z)]^5.$$

Proof. If S is a barrier in U for some U for which (6.I) hold, then the conclusion follows from Theorem 6.1. If S is nonbarrier, then (6.III) holds. Let U be such that (6.I) hold. If (6.IV.a) holds, then we get the desired conclusion from Theorem 6.2. If S is of the turnpike type, then we can use Theorem 6.3. Finally, if S is of the antiturnpike type, then we use Theorem 6.4. \square

7. Nondegenerate antiturnpikes. In this section we prove Theorem 6.4. We assume that

- (7.I) S is a nondegenerate regular INOA of the turnpike type (i.e. a regular INOA for which (6.III) holds, and for which there exist a U such that (6.I) and (6.IV.c) hold, and a $k \geq 0$ such that (6.VI.a) or (6.VI.b) holds).

We pick a fixed U for which (6.I) and (6.IV.c) hold. Also, we fix a $k \geq 0$ for which either (6.VI.a) or (6.VI.b) holds, and we assume, without loss of generality, that it is actually (6.VI.a) that holds.

We first prove a local result. Pick a point $p \in S$. Since (6.III) holds, we know in particular that $X(p)$ is not tangent to S . So we can find a neighborhood $W(p)$ of p which is the domain of a square coordinate chart such that, if we use x, y to denote the coordinates, then

- (7.II.a) $W(p)$ is identified, via the coordinates, with the square,
 (7.1) $\text{Sq}(\varepsilon(p)) = \{(x, y) : |x| < \varepsilon(p), |y| < \varepsilon(p)\}$ for some $\varepsilon(p) > 0$,
 (7.II.b) $W(p) \subseteq U$,
 (7.II.c) p has coordinates $(0, 0)$,
 (7.II.d) $S \cap W(p) = \{(x, y) \in \text{Sq}(\varepsilon(p)) : x = 0\}$,
 (7.II.e) $X \upharpoonright W(p) = \partial_x$.

Let

$$(7.2) \quad Y = \alpha \partial_x + \beta \partial_y$$

be the expression of Y in our coordinates. Since $X(p)$ and $Y(p)$ point to opposite sides of S , we must have $\alpha(0, 0) < 0$ and therefore we may assume (after making $\varepsilon(p)$ smaller, if needed) that $\alpha < 0$ throughout $W(p)$. A simple computation shows that

$$(7.3) \quad \Delta_A = \frac{1}{2}\beta$$

and that

$$(7.4) \quad \Delta_B = \frac{1}{4}((\alpha - 1)(\partial_x \beta) - (\partial_x \alpha)\beta).$$

Let σ be the function

$$(7.5) \quad \sigma(q) = \frac{\beta(q)}{4(\alpha(q) - 1)},$$

so that $\sigma(q)$ is equal to one quarter of the slope of $G(q)$.

Let us write $q_1 \sim q_2$ if q_1, q_2 are points in $W(p)$ lying in the same X -trajectory (i.e., having the same y coordinate) and are conjugate along it. Then $(x_1, y_1) \sim (x_2, y_2)$ if and only if

$$(7.6.a) \quad y_1 = y_2$$

and

$$(7.6.b) \quad \sigma(x_1, y_1) = \sigma(x_2, y_2).$$

We now study the solutions of (7.6). Let

$$(7.7) \quad \zeta(x_1, x_2, y) = \sigma(x_1, y) - \sigma(x_2, y).$$

Then the study of the solutions of (7.6) is obviously equivalent to that of the solutions of

$$(7.8) \quad \zeta(x_1, x_2, y) = 0.$$

First observe that

$$(7.9) \quad \partial_x \sigma = \Delta_B.$$

It follows from (7.II.d), (7.II.b) and (6.I.b) that $\Delta_B \neq 0$ at all points $(x, y) \in W(p)$ such that $x \neq 0$. Therefore, if we fix any y , the function $x \rightarrow \sigma(x, y)$ is strictly monotonic for x in each of the intervals $]-\varepsilon(p), 0[,]0, \varepsilon(p)[$. So (7.7) has no solutions x_1, x_2, y for which $x_1 \neq x_2$ but they are both ≥ 0 , or both ≤ 0 . So all we have to do is study the solutions of (7.7) for which $x_1 < 0 < x_2$.

Since (7.9) holds, we have, for $i = 1, 2, \dots$

$$(7.10) \quad \partial_x^i \sigma = X^{i-1} \Delta_B.$$

Therefore, in view of (6.VI.a), we can write

$$(7.11) \quad \sigma(x, y) = \sigma(0, y) + \frac{x^{k+1}}{(k+1)!} (X^k \Delta_B)(0, y) + x^{k+2} \xi(x, y)$$

where ξ is a smooth function. This gives

$$(7.12) \quad \zeta(x_1, x_2, y) = \frac{x_1^{k+1} - x_2^{k+1}}{(k+1)!} (X^k \Delta_B)(0, y) + x_1^{k+2} \xi(x_1, y) - x_2^{k+2} \xi(x_2, y).$$

Since $\xi(x_2, y) - \xi(x_1, y)$ vanishes when $x_2 = x_1$, we can write

$$(7.13) \quad \xi(x_2, y) = \xi(x_1, y) + (x_2 - x_1) \eta(x_1, x_2, y),$$

where η is smooth. Therefore we have

$$(7.14) \quad \zeta(x_1, x_2, y) = (x_1 - x_2) \tilde{\zeta}(x_1, x_2, y)$$

where

$$(7.15) \quad \tilde{\zeta}(x_1, x_2, y) = \frac{1}{(k+1)!} \left(\sum_{i=0}^k x_1^i x_2^{k-i} \right) (X^k \Delta_B)(0, y) + O((|x_1| + |x_2|)^{k+1}).$$

Hence the solutions of $\zeta = 0$ for which $x_1 \neq x_2$ are exactly the solutions of $\tilde{\zeta} = 0$. We consider two cases:

(7.III.i) Δ_A has different signs on opposite sides of S , and

(7.III.ii) Δ_A has the same sign on both sides of S .

If (7.III.i) holds, then β has opposite signs on the two sides of S , and so $\sigma(x_1, y)\sigma(x_2, y) < 0$ whenever $x_1 < 0 < x_2$. (Recall that $\alpha - 1 < 0$.) Hence $\sigma(x_1, y) = \sigma(x_2, y)$ is impossible if $x_1 < 0 < x_2$, and we conclude that there are no solutions of $\zeta(x_1, x_2, y) = 0$ for which $x_1 < 0 < x_2$.

Now suppose that (7.III.ii) holds. Since $f = -\Delta_B/\Delta_A$, and f has opposite signs on the two sides of S , the function Δ_B must change sign on the y axis. This requires, in particular, that k be odd. But then $k > 0$, and so

$$(7.16) \quad \tilde{\zeta}(0, 0, y) = 0.$$

Define a function μ by

$$(7.17) \quad \mu(x, \rho, y) = \tilde{\zeta}(x, \rho x, y).$$

Then μ is well defined and smooth for $(x, y) \in \text{Sq } \frac{1}{2}\varepsilon(p)$, $|\rho| < 2$.

We have

$$(7.18) \quad \mu(x, \rho, y) = \frac{x^k}{(k+1)!} \nu(x, \rho, y),$$

where

$$(7.19) \quad \nu(x, \rho, y) = \left(\sum_{i=0}^k \rho^{k-i} \right) (X^k \Delta_B)(0, y) + O(|x|).$$

Since k is odd, we have

$$(7.20) \quad \nu(0, -1, y) = 0.$$

On the other hand, $\rho = -1$ is a simple zero of the polynomial

$$(7.21) \quad \sum_{i=0}^k \rho^{k-i} = \frac{\rho^{k+1} - 1}{\rho - 1}$$

and so

$$(7.22) \quad \frac{\partial \nu}{\partial \rho}(0, -1, y) \neq 0.$$

By the Implicit Function theorem, there exists a $\delta(p)$ such that $0 < \delta(p) < \frac{1}{2}\varepsilon(p)$, and that there is a smooth function $\rho: \text{Sq}(\delta(p)) \rightarrow \mathbb{R}$ such that

$$(7.23.a) \quad \rho(0, y) = -1 \quad \text{for } |y| < \delta(p),$$

that

$$(7.23.b) \quad |\rho(x, y)| < 2 \quad \text{for } (x, y) \in \text{Sq}(\delta(p))$$

and that

$$(7.24) \quad \nu(x, \rho(x, y), y) = 0 \quad \text{for } (x, y) \in \text{Sq}(\delta(p)).$$

Let us make $\delta(p)$ smaller, if necessary, and assume that

$$(7.25) \quad \rho(x, y) \leq -\frac{1}{2} \quad \text{for } (x, y) \in \text{Sq}(\delta(p)).$$

Let $\psi: \text{Sq}(\delta(p)) \rightarrow \mathbb{R}$ be given by

$$(7.26) \quad \psi(x, y) = x\rho(x, y).$$

Then

$$(7.27) \quad |\psi(x, y)| < \varepsilon(p)$$

and

$$(7.28) \quad x \cdot \psi(x, y) < 0 \quad \text{for } (x, y) \in \text{Sq}(\delta(p)), \quad x \neq 0.$$

It is clear that

$$(7.29) \quad \tilde{\zeta}(x, \psi(x, y), y) = 0.$$

So, for each $(x, y) \in \text{Sq}(\delta(p))$ such that $x \neq 0$, the point $(\psi(x, y), y)$ lies in the same X -trajectory as (x, y) , and is conjugate to (x, y) along this trajectory. We claim that, conversely, if $(x_1, y) \sim (x_2, y)$, and if $x_1 < 0 < x_2$, and $(x_i, y) \in \text{Sq}(\delta(p))$ for $i = 1, 2$, then $x_1 = \psi(x_2, y)$ and $x_2 = \psi(x_1, y)$. To prove this, simply observe that, since $\Delta_B(x, y) \neq 0$ for $0 < x < \varepsilon(p)$, the function $x \rightarrow \sigma(x, y)$, $0 < x < \varepsilon(p)$ is strictly monotonic on $]0, \varepsilon(p)[$ (in view of (7.9)), and so the equation $\sigma(x, y) = \sigma(x_1, y)$ has at most one solution $x \in]0, \varepsilon(p)[$. Since $0 < \psi(x_1, y) < \varepsilon(p)$, and $\sigma(\psi(x_1, y), y) = \sigma(x_1, y)$, the facts that $\sigma(x_2, y) = \sigma(x_1, y)$ and $0 < x_2 < \delta(p)$ imply that $x_2 = \psi(x_1, y)$. The proof that $x_1 = \psi(x_2, y)$ is similar.

We now summarize what we have proved. Let $\delta(p)$ be as above if (7.III.ii) holds. If (7.III.i) holds, let $\delta(p) = \varepsilon(p)$. We have shown that

- (7.IV.a) If (7.III.i) holds, then there are no solutions (x_1, x_2, y) of (7.8) such that $|x_i| < \delta(p)$, $|y| < \delta(p)$ and that $x_1 \neq x_2$,
- (7.IV.b) if (7.III.ii) holds, then there is a smooth function $\psi: \text{Sq}(\delta(p)) \rightarrow]-\varepsilon(p), \varepsilon(p)[$ such that (7.28) holds and that, if $|x_i| < \delta(p)$, $|y| < \delta(p)$, then x_1, x_2, y satisfy (7.8) if and only if $x_1 = x_2$ or $x_1 = \psi(x_2, y)$.

We now prove, using (7.IV), that no strict $Y * X * Y$ -trajectory in $\text{Sq}(\delta'(p))$ can be time-optimal, if $0 < \delta'(p) \leq \delta(p)$, and $\delta'(p)$ is small enough. To prove this, we let $\delta'(p)$ be a number that satisfies $0 < \delta'(p) \leq \delta(p)$, plus an extra condition that will be stated later, and we suppose that γ is a strict $Y * X * Y$ -trajectory in $\text{Sq}(\delta'(p))$, and that γ is time-optimal. We will reach a contradiction. If (7.III.i) holds, then this is quite easy. Indeed, if q_1 and q_2 are the points where the switchings of γ occur, then it is clear that $q_1 \neq q_2$ but $q_1 \sim q_2$. If $q_i = (x_i, \bar{y})$, $i = 1, 2$, then (x_1, x_2, \bar{y}) satisfies (7.8), and $x_1 \neq x_2$. By (7.IV.a), this is a contradiction. (Hence we may take, e.g., $\delta'(p) = \delta(p)$.)

We now consider the other case, namely, when (7.III.ii) holds. We let γ , the q_i , x_i , \bar{y} be as above, and we let t_i be such that $\gamma(t_i) = q_i$. Clearly, we may assume that $t_1 < t_2$. Then we have $x_1 < 0 < x_2$, and $x_2 = \psi(x_1, \bar{y})$. Let Q be the open set

$$(7.30) \quad Q = \{(x, y) \in \text{Sq}(\delta(p)) : |\psi(x, y)| < \delta(p)\}.$$

Then $(x_1, \bar{y}) \in Q$. Let $K: Q \rightarrow Q$ be the map

$$(7.31) \quad K(x, y) = (\psi(x, y), y).$$

Let $\gamma_1 = \gamma|_{[t_1 - \theta, t_1]}$, where $\theta > 0$ is so small that γ_1 is entirely contained in Q , and that γ_1 never intersects the y axis. Let

$$(7.32) \quad \tilde{\gamma}_2 = K \circ \gamma_1.$$

Then $\gamma_1(t) \sim \tilde{\gamma}_2(t)$ for all $t \in [t_1 - \theta, t_1]$. If we prove that, after a suitable reparametrization, $\tilde{\gamma}_2$ becomes a trajectory γ_2 of Σ , which is not bang-bang, then we will have reached a contradiction. (Indeed: let $\hat{\gamma}$ be the concatenation $\gamma_2 * \hat{\gamma}_1$, where $\hat{\gamma}_1$ is the X -trajectory from $\gamma_1(t_1 - \theta)$ to $K(\gamma_1(t_1 - \theta))$. Then Lemma 3.6 implies that

$$(7.33) \quad T(\gamma \upharpoonright [t_1 - \theta, t_2]) = T(\hat{\gamma}).$$

Since γ is time-optimal, we conclude that $\hat{\gamma}$ is time-optimal, which is a contradiction, because γ_2 is a piece of $\hat{\gamma}$, which is not bang-bang but is contained in $\Omega(A) \cap \Omega(B)$.)

So in order to reach a contradiction, we must show that $\tilde{\gamma}_2$ can be reparametrized so as to produce a trajectory of Σ which is not bang-bang. This will follow if we prove that, for each $t \in [t_1 - \theta, t_1]$, the vector $\dot{\tilde{\gamma}}_2(t)$ is a strict convex combination of $X(\tilde{\gamma}_2(t))$ and $Y(\tilde{\gamma}_2(t))$. Since we are assuming that (7.III.ii) holds, we may assume, without loss of generality, that $\beta(x, y) > 0$ for all $(x, y) \in \text{Sq}(\delta(p))$, $x \neq 0$. If K_* denotes the differential of the map K , we must show that $K_*(\gamma_1(t)) \cdot Y(\gamma_1(t))$ is a strict convex combination of $X(\tilde{\gamma}_2(t))$ and $Y(\tilde{\gamma}_2(t))$, for $t \in [t_1 - \theta, t_1]$. Since $\beta(q) > 0$ and $\alpha(q) < 0$ for all $q \in \text{Sq}(\delta(p))$, this conclusion will follow if we show that, for $q \in Q$, the vector $K_*(q) \cdot Y(q)$ has strictly positive components. Clearly:

$$(7.34) \quad K_*(q) \cdot Y(q) = \begin{bmatrix} (\partial_x \psi)(q) & (\partial_y \psi)(q) \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \alpha(q) \\ \beta(q) \end{bmatrix}.$$

Since $\psi(0, y) = 0$, it is clear that $(\partial_x \psi)(0, 0) = 0$. On the other hand, it follows easily from the definition of ψ that $(\partial_x \psi)(0, 0) = -1$. Since $\alpha(p) < 0$, there is an r such that $0 < r \leq \delta(p)$ and that the function

$$(7.35) \quad q \rightarrow ((\partial_x \psi) \cdot \alpha + (\partial_y \psi) \cdot \beta)(q)$$

is strictly positive on $\text{Sq}(r)$. We now take this r to be $\delta'(p)$. Then $K_*(q) \cdot Y(q)$ is a strict convex combination of $X(K(q))$ and $Y(K(q))$ for all $q \in Q \cap \text{Sq}(\delta'(p))$. As explained above, this shows that γ is not time-optimal.

We now let $\delta'(p)$ be such that $0 < \delta'(p) \leq \delta(p)$, and that no strict $Y * X * Y$ -trajectory in $\text{Sq}(\delta'(p))$ is time-optimal. We want to analyze the structure of an arbitrary time-optimal trajectory γ in $\text{Sq}(\delta'(p))$. First, it is clear that γ cannot contain a strict $Y * X * Y$ piece. Therefore, if $J \subseteq \text{Dom}(\gamma)$ is a maximal interval such that $\gamma \upharpoonright J$ is an X -trajectory, it follows that either

$$(7.V.a) \quad J \text{ contains one of the endpoints of } \text{Dom}(\gamma), \text{ or}$$

$$(7.V.b) \quad J = [t_1, t_2], \text{ and one of the points } \gamma(t_1), \gamma(t_2) \text{ is in } S.$$

If (7.V.b) holds, then the points $\gamma(t_1), \gamma(t_2)$ satisfy $\gamma(t_1) \sim \gamma(t_2)$, $\gamma(t_1) \neq \gamma(t_2)$. If we let $\gamma(t_i) = (x_i, y)$, then either $x_1 = 0$ or $x_2 = 0$. Moreover, $x_1 \neq x_2$, and $\sigma(x_1, y) = \sigma(x_2, y)$. But then we have reached a contradiction, because (7.IV) clearly implies that no solution (x_1, x_2, y) of (7.8) can satisfy $x_1 \neq x_2$ but be such that $x_1 = 0$ or $x_2 = 0$.

So (7.V.b) cannot hold.

We conclude that, if γ is a time-optimal trajectory in $\text{Sq}(\delta'(p))$, then $\gamma = \gamma_3 * \gamma_2 * \gamma_1$, where γ_1 and γ_3 are X -trajectories, and γ_2 contains no X -trajectory. We now have to determine the structure of those time-optimal trajectories γ that contain no X -trajectory. Suppose γ has this property. Let J be a maximal subinterval of $\text{Dom}(\gamma)$ such that $\gamma \upharpoonright J$ is a Y -trajectory. Let $J = [t_1, t_2]$. Since Y always points to the same side of S , it is not possible for both $\gamma(t_1)$ and $\gamma(t_2)$ to be in S . If $\gamma(t_i) \notin S$, then t_i must be an endpoint of $\text{Dom}(\gamma)$. (Otherwise there would be a $\theta > 0$ such that $\gamma \upharpoonright [t_i - \theta, t_i + \theta]$ is entirely contained in $\Omega(A) \cap \Omega(B)$, and therefore belongs to

$\text{Traj}((X \vee Y)^2)$. Since γ contains no X -trajectory, it follows that $\gamma|_{[t_i - \theta, t_i + \theta]}$ is a Y -trajectory, contradicting the maximality of J .) So γ is a concatenation $\gamma_3 * \gamma_2 * \gamma_1$, where γ_1 and γ_3 are Y -trajectories, and γ_2 contains no X - or Y -trajectory. Then it follows that γ_2 is entirely contained in S . If γ_2 is nontrivial then it follows, in particular, that S is an arc where Δ_A never vanishes. (Otherwise, since S is a regular INOA, we would have $\Delta_A \equiv 0$ on S . So, if $q \in S$, the vectors $X(q)$ and $Y(q)$ are linearly dependent and have opposite directions. Therefore no convex combination of $X(q)$ and $Y(q)$ can be tangent to S at q , unless it equals zero. So no nontrivial trajectory of Σ can be contained in S .) So β never vanishes on $\{(x, y) \in \text{Sq}(\delta(p)) : x = 0\}$, and therefore β never vanishes on $\text{Sq}(\delta(p))$. So f is well defined on $\text{Sq}(\delta(p))$. Since S is of the antiturnpike type, we have

$$(7.36.a) \quad f(x, y) > 0 \quad \text{for } x > 0,$$

$$(7.36.b) \quad f(x, y) < 0 \quad \text{for } x < 0.$$

It is easy to see that, if $\tau_1 < \tau_2$, $\tau_i \in \text{Dom}(\gamma_2)$, and $\tau_2 - \tau_1$ is small enough, then there is a $Y * X$ -trajectory $\tilde{\gamma}_2$ that goes from $\gamma_2(\tau_1)$ to $\gamma_2(\tau_2)$ and is entirely contained in $\text{Sq}(\delta(p))$. Then $\tilde{\gamma}_2(t) \in \{(x, y) : x > 0\}$ for t in the interior of $\text{Dom}(\tilde{\gamma}_2)$. If $\beta > 0$ on $\text{Sq}(\delta(p))$, then the curve $\gamma_2^{-1} * \tilde{\gamma}_2$ is oriented counterclockwise, and $f > 0$ in the interior on the region \mathcal{R} it encloses. Therefore we can apply Lemma 3.10 and conclude that $T(\tilde{\gamma}_2) < T(\gamma_2)$. If $\beta < 0$ on $\text{Sq}(\delta(p))$, then $\tilde{\gamma}_2^{-1} * \gamma_2$ is oriented counterclockwise, and therefore Lemma 3.10 again implies that $T(\tilde{\gamma}_2) < T(\gamma_2)$. In either case, γ_2 is not optimal, and we have reached a contradiction. So γ_2 is actually trivial, and γ is a Y -trajectory.

So we have shown that, if γ is a time-optimal trajectory in $\text{Sq}(\delta'(p))$, then it follows that $\gamma \in \text{Traj}(X * Y * X)$. That is, we have shown the following.

LEMMA 7.1. *Let S be a nondegenerate regular INOA of the antiturnpike type. Suppose that there is a $k \geq 0$ for which (6.VI.a) holds. Then for every $p \in S$ there exists an open arc $S'(p) \subseteq S$, containing p , for which there is a $\delta'(p) > 0$ with the property that, if*

$$(7.37) \quad V(p) = \{\Phi_i^X(q) : q \in S'(p), |t| < \delta'(p)\},$$

*then every time-optimal trajectory in $V(p)$ is an $X * Y * X$ -trajectory.*

Using Lemma 7.1, it is now easy to conclude the proof of Theorem 6.4. Let S satisfy the hypotheses of Lemma 7.1. For each p , pick an $S'(p)$ and a $\delta'(p)$ with the property of Lemma 7.1, and define $V(p)$ by (7.37). Make $\delta'(p)$ smaller, if necessary, so that $V(p) \subseteq U$. Let

$$(7.38) \quad U_0 = \bigcup \{V(p) : p \in S\}.$$

Then U_0 is open, and $S \subseteq U_0 \subseteq U$. Let $\gamma \in \text{Traj}(\Sigma|_{U_0})$, and suppose that γ is time-optimal. Then, locally, γ is contained in the sets $V(p)$, and therefore γ is regular bang-bang. We now claim that γ cannot contain a strict $Y * X * Y$ piece. Indeed, suppose that γ_1 is a strict $Y * X * Y$ -trajectory that is contained in U_0 and is time-optimal. Let t_1, t_2 be the switching times, labelled so that $t_1 < t_2$. Let $\tilde{\gamma}_1 = \gamma_1|_{[t_1, t_2]}$. Then $\tilde{\gamma}_1$ is contained in η , where η is the maximal integral curve of $X|_U$ such that $\eta(t_1) = \gamma_1(t_1)$. It follows from Theorem 3.9 that $\tilde{\gamma}_1$ must intersect S at some point q . (Otherwise, since $U_0 \subseteq U$ and $U - S \subseteq \Omega(A) \cap \Omega(B)$, we would conclude that $\tilde{\gamma}_1$ is contained in $\Omega(A) \cap \Omega(B)$ and therefore that $\gamma_1|_{[t_1 - \theta, t_2 + \theta]}$ is also contained in $\Omega(A) \cap \Omega(B)$ for some $\theta > 0$. But then Theorem 3.9 would imply that $\gamma_1|_{[t_1 - \theta, t_2 + \theta]}$ is not time-optimal, and therefore γ_1 would not be time-optimal either.)

Since $U - S$ has two connected components, and $X(p)$ points towards the same component of $U - S$ for all $p \in S$, it is clear that there is at most one time $\bar{t} \in \text{Dom}(\eta)$ such that $\eta(\bar{t}) \in S$. Since $\eta(t) = q$ for some $t \in [t_1, t_2]$, we conclude that there is a unique $\bar{t} \in \text{Dom}(\eta)$ such that $\eta(\bar{t}) \in S$, and that this \bar{t} satisfies $t_1 \leq \bar{t} \leq t_2$, and $\eta(\bar{t}) = q$.

If q' is any point on η , it is clear that $q' \in U_0$ if and only if $|\tau| < \delta'(p)$ for some $p \in S$ such that $q \in S'(p)$, where $\tau \in \mathbb{R}$ is the unique time such that $q' = \Phi_\tau^X(q)$. From this it follows easily that there is a $p \in S$ such that $\tilde{\gamma}_1$ is contained in $V(p)$. Then $\gamma_1|_{[t_1 - \theta, t_2 + \theta]}$ is contained in $V(p)$ for sufficiently small $\theta > 0$. But then γ_1 is not time-optimal, since $V(p)$ satisfies the conclusion of Lemma 7.1.

So γ is regular bang-bang, and it does not contain any strict $Y * X * Y$ piece. Therefore γ is an $X * Y * X$ -trajectory. This completes the proof of Theorem 6.4. \square

ASYMPTOTICALLY EFFICIENT SELF-TUNING REGULATORS*

T. L. LAI† AND C. Z. WEI‡

Abstract. This paper studies the problem of adaptive regulation of linear systems with white-noise disturbances. The apparent dilemma between the control objective and the need of information for parameter estimation is resolved by occasional use of white-noise probing inputs and by a reparametrization of the model. Insights into the question concerning how often and when such probing inputs should be introduced are provided by the concept of "asymptotic efficiency," which quantifies the asymptotically minimal cost due to parameter ignorance, or equivalently, due to the infeasibility of using the optimal regulator that assumes knowledge of the system parameters. Asymptotically efficient adaptive regulators are constructed by making use of certain basic properties of adaptive predictors involving recursive least squares for the reparametrized model.

Key words. adaptive control, linear systems, least squares identification, self-tuning, probing inputs, asymptotic efficiency

AMS(MOS) subject classifications. Primary 62L20, 93E20; secondary 60G42, 93E10

1. Introduction. We study herein the problem of efficient adaptive control for the linear system

$$(1.1) \quad y_n = \alpha_1 y_{n-1} + \cdots + \alpha_p y_{n-p} + \beta_1 u_{n-d} + \cdots + \beta_q u_{n-d-q+1} + \varepsilon_n,$$

where the y 's represent outputs and the u 's represent inputs at various times and the ε 's represent random disturbances. We assume that $\{\varepsilon_n\}$ is a martingale difference sequence with respect to an increasing sequence of σ -fields $\{\mathcal{F}_n\}$ (i.e., ε_n is \mathcal{F}_n -measurable and $E(\varepsilon_n | \mathcal{F}_{n-1}) = 0$ for all n) such that

$$(1.2) \quad \sup_n E(|\varepsilon_n|^\gamma | \mathcal{F}_{n-1}) < \infty \quad \text{a.s. (almost surely) for some } \gamma > 2.$$

Moreover, assume that $\beta_1 \neq 0$ and that the polynomials

$$(1.3) \quad A(s) = s^p - \alpha_1 s^{p-1} - \cdots - \alpha_p \quad \text{and} \quad B(s) = \beta_1 s^{q-1} + \beta_2 s^{q-2} + \cdots + \beta_q$$

have all zeros inside the unit circle.

An important problem in the literature is how to choose the inputs u_i , on the basis of current and past observations $y_i, y_{i-1}, u_{i-1}, \dots$, to regulate the outputs, say, such that $\sum_{i=1}^N y_{i+d}^2$ is minimized in some sense, at least in the long run as $N \rightarrow \infty$. Although one may in principle use a Bayesian approach, putting a prior distribution on the unknown parameters and applying dynamic programming when the disturbances ε_n are independent and identically distributed (i.i.d.) with a known common distribution (say for example, normal) and when a fixed horizon N is given, the dynamic programming equations are prohibitively difficult to handle, both computationally and analytically (cf. [1]).

A much more practical approach is that of the *self-tuning regulator*, proposed by Åström and Wittenmark [2]. This "self-tuning" idea is to start by considering the case where the system parameters are known, for which the optimal controller can be

* Received by the editors April 8, 1985; accepted for publication (in revised form) March 11, 1986. This work was supported by the National Science Foundation, and in the case of the first author, also by the Army Research Office and the John Simon Guggenheim Foundation.

† Department of Statistics, Columbia University, New York, New York 10027.

‡ Department of Mathematics, University of Maryland, College Park, Maryland 20742.

explicitly found by the separation principle, and then to substitute the system parameters in the optimal controller by their least squares estimates. To fix the ideas, consider first the case of unit delay (i.e., $d = 1$). Here the optimal controller assuming known parameters is given by

$$(1.4) \quad u_n = -(\alpha_1 y_n + \cdots + \alpha_p y_{n-p+1} + \beta_2 u_{n-1} + \cdots + \beta_q u_{n-q+1}) / \beta_1,$$

or equivalently, by the equation

$$(1.4') \quad \theta' \varphi_n = 0,$$

where $\theta = (\alpha_1, \dots, \alpha_p, \beta_1, \dots, \beta_q)'$ and $\varphi_n = (y_n, \dots, y_{n-p+1}, u_n, \dots, u_{n-q+1})'$. Letting $\theta_n = (\hat{\alpha}_{1,n}, \dots, \hat{\alpha}_{p,n}, \hat{\beta}_{1,n}, \dots, \hat{\beta}_{q,n})' = (\sum_1^n \varphi_i \varphi_i')^{-1} \sum_1^n \varphi_i y_{i+1}$ be the least squares estimate of θ based on $\varphi_1, y_2, \dots, \varphi_n, y_{n+1}$, the self-tuning regulator that assumes no prior knowledge of the parameters is given by

$$(1.5) \quad u_n = -(\hat{\alpha}_{1,n-1} y_n + \cdots + \hat{\alpha}_{p,n-1} y_{n-p+1} + \hat{\beta}_{2,n-1} u_{n-1} + \cdots + \hat{\beta}_{q,n-1} u_{n-q+1}) / \hat{\beta}_{1,n-1},$$

or implicitly by

$$(1.5') \quad \theta'_{n-1} \varphi_n = 0.$$

As is well known, θ_i can be determined for $i > \tau = \inf \{n: \sum_1^n \varphi_i \varphi_i' \text{ is nonsingular}\}$ by the recursive algorithm

$$(1.6a) \quad \theta_i = \theta_{i-1} + (y_{i+1} - \theta'_{i-1} \varphi_i) P_i \varphi_i,$$

$$(1.6b) \quad P_i = P_{i-1} - P_{i-1} \varphi_i \varphi_i' P_{i-1} / (1 + \varphi_i' P_{i-1} \varphi_i),$$

noting that $P_i^{-1} = P_{i-1}^{-1} + \varphi_i \varphi_i'$ and therefore $P_n = (\sum_1^n \varphi_i \varphi_i')^{-1}$ for $n \geq \tau$ (cf. [3]).

When the random disturbances are i.i.d. normal with mean 0 and variance $\sigma^2 > 0$, the least squares estimate θ_i is the same as the maximum likelihood estimator of θ . Thus, in this case, the self-tuning regulator (1.5) is simply the maximum likelihood estimator of the (unobservable) optimal controller (1.4) at every stage. While (1.5) may well represent one's best approximation to (1.4), how good the approximation is depends on how much information there is to estimate θ . A basic issue concerning this self-tuning approach is, therefore, whether there is enough information for adequately estimating θ . If there is not enough information, then perhaps one should use some inputs to probe the system for more information, instead of adhering to a poorly estimated version of (1.4'). While the use of white-noise perturbations to improve parameter estimation and the future controls is a well-known idea (cf. [2]), it remains an open problem concerning how often such probing inputs should be introduced. We provide an answer to this problem herein, making use of the concept of *asymptotic efficiency*, introduced in [4], of adaptive regulators.

If we use the (unrealizable) optimal regulator (1.4) that assumes knowledge of θ , then the outputs are $y_i = \varepsilon_i$. In view of this, we define the "regret," at stage n , of a sequence of inputs $\{u_i\}$ to be

$$(1.7) \quad R_n = \sum_1^n (y_i - \varepsilon_i)^2$$

(cf. [4]). An input sequence is called "globally convergent" if

$$(1.8) \quad \lim_{n \rightarrow \infty} R_n / n = 0 \quad \text{a.s.}$$

As shown in [4], considerable insight into how rapidly the convergence in (1.8) can occur, or equivalently, how small can the order of magnitude for the regret R_n be, is

provided by studying the following auxiliary Bayes problem in which β_1 is assumed known.

Suppose that in addition to (1.3), the polynomials

$$(1.9) \quad B(s) = \beta_1 s^{q-1} + \cdots + \beta_q \text{ and } \alpha_1 s^{p-1} + \cdots + \alpha_p \text{ are relatively prime,}$$

and that the random disturbances ε_n are i.i.d. normal with mean 0 and variance $\sigma^2 > 0$. Assume that β_1 is known, and let

$$(1.10) \quad \lambda = -\beta_1^{-1}(\alpha_1, \cdots, \alpha_p, \beta_2, \cdots, \beta_q)'$$

have a truncated normal prior distribution π , which is the restriction of a normal distribution with mean 0 and covariance matrix $\sigma_0^2 I_h$ to the stability region defined by (1.3), where $h = p + q - 1$ and I_h denotes the $h \times h$ identity matrix. Define the $(p + q - 1)$ -dimensional vector

$$(1.11) \quad \psi_n = (y_n, \cdots, y_{n-p+1}, u_{n-1}, \cdots, u_{n-q+1})'$$

and let $z_{n+1} = y_{n+1} - \beta_1 u_n$. Letting $\lambda_{n-1}^* = E_\pi[\lambda | \psi_1, z_2, \cdots, \psi_{n-1}, z_n]$ be the Bayes estimate of λ , it is noted in [4] that for any choice of the input sequence $\{u_i\}$

$$(1.12) \quad E_\pi \left\{ \sum_{i=1}^n (u_i - \lambda' \psi_i)^2 \right\} \geq E_\pi \sum_{i=1}^n \{(\lambda_{i-1}^* - \lambda)' \psi_i\}^2.$$

Restricting to input sequences $\{u_i\}$ that are globally convergent and that satisfy the growth condition

$$(1.13) \quad u_n^2 = O(n^\delta) \quad \text{for some } 0 < \delta < 1,$$

it is shown in [4] that for such input sequences

$$(1.14) \quad \beta_1^2 \sum_{i=1}^n \{(\lambda_{i-1}^* - \lambda)' \psi_i\}^2 \sim \sigma^2 h \log n \quad \text{a.s.,}$$

and therefore, by Fatou's Lemma and (1.12),

$$(1.15) \quad E_\pi \left\{ \sum_{i=1}^n (y_{i+1} - \varepsilon_{i+1})^2 \right\} = \beta_1^2 E_\pi \left\{ \sum_{i=1}^n (u_i - \lambda' \psi_i)^2 \right\} \geq (\sigma^2 h + o(1)) \log n.$$

In view of (1.12), (1.14) and (1.15), an input sequence $\{u_i\}$ is called "asymptotically efficient" in [4] if its regret is asymptotically no larger than the order $\sigma^2 h \log n$. More generally, without any distributional assumptions on the unobservable ε_n and without assuming any prior knowledge of β_1 and the other parameters, [4] provides the following definition of asymptotically efficient regulators.

DEFINITION. Consider the linear system (1.1) with $d = 1$ and such that $\beta_1 \neq 0$ and (1.3), (1.9) hold, and in which $\{\varepsilon_n\}$ is a martingale difference sequence satisfying (1.2). Let $v = \limsup_{n \rightarrow \infty} E(\varepsilon_n^2 | \mathcal{F}_{n-1})$. A sequence of inputs $\{u_n\}$ is said to be asymptotically efficient if

$$(1.16) \quad \limsup_{n \rightarrow \infty} R_n / \log n \leq v(p + q - 1) \quad \text{a.s.}$$

The construction of asymptotically efficient self-tuning regulators is given in § 3 below. This construction involves a refinement of the method developed in [5] for

constructing adaptive control schemes whose regrets satisfy the weaker conclusion

$$(1.17) \quad \limsup_{n \rightarrow \infty} R_n / \log n < \infty \quad \text{a.s.},$$

but in the more general setting of colored noise (i.e., where the ε_n in (1.1) is a finite moving average of martingale differences).

It is interesting to compare the definition (1.8) of global convergence with (1.17) and with the definition (1.16) of asymptotic efficiency, and to review in this connection some recent results on adaptive control of the linear system (1.1). By making use of stochastic approximation techniques instead of least squares to estimate the unknown θ in (1.4'), Goodwin, Ramadge and Caines [6] showed that the resultant rule is globally convergent, without any stability assumption on the polynomial $A(s)$ and even for the more general setting of colored noise. Their fundamental work opened an active area of research during the past few years. In particular, Sin and Goodwin [7] established the global convergence of an alternative control rule that involves a hybrid between stochastic approximation and recursive least squares. In another direction, Caines and Lafontaine [8], and Chen and Caines [9], proposed the introduction of white noise perturbations into the control algorithm of Goodwin et al. [6] to persistently excite the system. They showed that this approach of "continually disturbed control" leads to strongly consistent estimates by the method of least squares or by stochastic approximation, although the resultant control rule is no longer globally convergent. Subsequently, Becker, Kumar and Wei [10] showed that without introducing white noise perturbations, the parameter estimates in the original algorithm of Goodwin et al. [6] converge to a limit which is a random multiple of θ and which differs from θ with strictly positive probability. A survey of these and other results has been provided by Kumar [11].

Although these recent developments have established the global convergence of adaptive regulators that are generated by stochastic approximation recursions (i.e., having scalar gains), it remains an unsettled problem whether the classical least squares recursions also lead to globally convergent schemes which may even have better rates of convergence than those generated by stochastic approximation. After all, the least squares method coincides with the asymptotically efficient method of maximum likelihood for parameter estimation in the case where the ε_n are i.i.d. normal with mean 0 and variance σ^2 . It is therefore natural to expect that the self-tuning regulator (1.5) should be nearly optimal when there is adequate information to estimate θ . However, if the information content for estimating θ remains consistently low, then there is no guarantee that the self-tuning equation (1.5') would eventually be a good approximation to (1.4') and the self-tuning idea may not work (cf. [4]).

In [5], under the stability assumption (1.3) but in the more general setting of colored noise that is assumed to be a.s. bounded, we proposed a simple criterion for deciding at every stage, on the basis of the observed data, whether there is adequate information to estimate θ . When the data show inadequate information, instead of adhering rigidly to the self-tuning equation to determine the output u_n , we proposed to introduce white-noise perturbations to improve the information content of the design. We showed in [5] that the number of these perturbations up to stage n is kept within $O(\log n)$ and that the regret R_n of the regulator satisfies (1.17), which is much stronger than the global convergence property (1.8).

In the present setting of white noise, we show in this work that by a refinement of the algorithm used in [5] the property (1.17) can be further sharpened to (1.16), which gives the "best constant" for the left-hand side of (1.17). Central to this refinement

are the reparametrization of (1.1) as

$$(1.18) \quad y_{n+1} = \beta_1(u_n - \lambda' \psi_n) + \varepsilon_{n+1}$$

and the use of least-squares-type recursions estimating λ instead of the recursions (1.6) estimating θ , where λ and ψ_n are defined in (1.10) and (1.11).

Suppose that β_1 in (1.18) is known, and assume that the ε_n are i.i.d. normal with mean 0 and variance $v > 0$. Then the Bayes estimate λ_{i-1}^* of λ with respect to the truncated normal prior distribution π is asymptotically equivalent to the least squares estimate $\hat{\lambda}_{i-1}$ (cf. [4]), and in view of (1.12), (1.14) and (1.15), an asymptotically optimal order for the regret R_n is $v(p+q-1) \log n$, as given in (1.16). Without assuming β_1 to be known and without any distributional assumptions on ε_n , we show in § 3 how to construct a consistent estimate of β_1 and how to “self-tune” the reparametrized model (1.18) to attain the asymptotically optimal order $v(p+q-1) \log n$ for R_n .

Section 2 develops certain basic lemmas that will be needed in the sequel. Section 4 extends the methods and results of § 3 to the case of general delay.

2. Preliminary lemmas. A basic tool in §§ 3 and 4 is the following asymptotic property, proved in [4, Thm. 2], of adaptive predictors in the regression model (1.18).

LEMMA 1. *Suppose that in the regression model (1.18), $\{\varepsilon_n\}$ is a martingale difference sequence with respect to an increasing sequence of σ -fields $\{\mathcal{F}_n\}$ such that (1.2) holds, and that u_n and ψ_n are \mathcal{F}_n -measurable, ψ_n and λ being $h \times 1$ vectors. Assume that $\beta_1 \neq 0$ and that*

$$(2.1) \quad \lambda_{\min} \left(\sum_1^n \psi_i \psi_i' \right) \rightarrow \infty \quad \text{and} \quad \psi_n' \left(\sum_1^n \psi_i \psi_i' \right)^{-1} \psi_i \rightarrow 0 \quad \text{a.s.}$$

Let b_n be \mathcal{F}_n -measurable such that $b_n \rightarrow \beta_1$ a.s. For $i > \tau = \inf \{n: \sum_1^n \psi_i \psi_i' \text{ is nonsingular}\}$, define the recursions

$$(2.2a) \quad \lambda_i = \lambda_{i-1} + (u_i - b_i^{-1} y_{i+1} - \lambda_{i-1}' \psi_i) P_i \psi_i,$$

$$(2.2b) \quad P_i^{-1} = P_{i-1}^{-1} + \psi_i \psi_i'.$$

Let

$$(2.3) \quad e_{n+1} = y_{n+1} - b_n(u_n - \lambda'_{n-1} \psi_n)$$

be the prediction error of the \mathcal{F}_n -measurable predictor $\hat{y}_{n+1} = b_n(u_n - \lambda'_{n-1} \psi_n)$ of y_{n+1} . Then

$$(2.4) \quad \sum_{\tau+1}^n (e_{i+1} - \varepsilon_{i+1})^2 + \beta_1^2 (\lambda_n - \lambda)' P_n^{-1} (\lambda_n - \lambda) \\ \leq \{ \limsup_{i \rightarrow \infty} E(\varepsilon_i^2 | \mathcal{F}_{i-1}) + o(1) \} \log \det \left(\sum_1^n \psi_i \psi_i' \right) + o \left(\sum_1^n (u_i - \lambda' \psi_i)^2 \right) \quad \text{a.s.}$$

Remark. In (2.1) and the sequel, we use λ_{\min} and λ_{\max} to denote the minimum and maximum eigenvalues of a symmetric matrix. For the special case $b_i = \beta_1$ for all i , the recursions (2.2) coincide with the recursions defining the least squares estimates of λ in the model (1.18) when β_1 is known (cf. (1.6)). In general, without assuming β_1 to be known, we replace β_1 in these least squares recursions by consistent estimates b_i , and this leads to (2.2).

The next three lemmas are on the asymptotic behavior of the linear system (1.1) in which $\beta_1 \neq 0$ and (1.3) holds. Let

$$Y_n = (y_n, \dots, y_{n-p+1})', \quad U_n = (u_n, \dots, u_{n-q+2})', \\ A = \begin{pmatrix} \alpha_1 & \dots & \alpha_{p-1} & \alpha_p \\ & I_{p-1} & & 0 \end{pmatrix}, \quad B = \begin{pmatrix} -\beta_2/\beta_1 & \dots & -\beta_q/\beta_1 \\ & I_{q-2} & & 0 \end{pmatrix}.$$

While the above definition assumes that $q \geq 2$, define $U_n = u_n$ and $B = 0$ in the case $q = 1$. Likewise set $Y_n = y_n$ and $A = 0$ when $p = 0$. By (1.1),

$$(2.5) \quad \begin{aligned} Y_n &= A Y_{n-1} + \left(\sum_{j=1}^q \beta_j u_{n-d-j+1} + \varepsilon_n, 0, \dots, 0 \right)', \\ U_n &= B U_{n-1} - \beta_1^{-1} \left(\sum_{j=0}^p \alpha_j y_{n+d-j} + \varepsilon_{n+d}, 0, \dots, 0 \right)' \quad \text{where } \alpha_0 = -1. \end{aligned}$$

Regarding a $k \times k$ matrix H as a linear operator, define $\|H\| = \sup_{\|x\|=1} \|Hx\| = \lambda_{\max}^{1/2}(H'H)$. By (1.3), there exist $0 < \rho < 1$ and $C > 0$ such that $\|A^n\| \leq C\rho^n$ and $\|B^n\| \leq C\rho^n$ for all n , and therefore (2.5) implies the following (cf. [12, p. 361]).

LEMMA 2. For $n > m$,

$$(i) \quad \|Y_n\| \leq C\rho^{n-m} \|Y_m\| + C \sum_{i=0}^{n-m-1} \rho^i \left\{ |\varepsilon_{n-i}| + \sum_{j=1}^q |\beta_j| |u_{n-d-i-j+1}| \right\},$$

$$(ii) \quad \|U_n\| \leq C\rho^{n-m} \|U_m\| + C|\beta_1|^{-1} \sum_{i=0}^{n-m-1} \rho^i \left\{ |\varepsilon_{n+d-i}| + \sum_{j=0}^p |\alpha_j| |y_{n+d-i-j}| \right\}.$$

Consequently, there exists $D > 0$ such that for all $n > \nu > m$,

$$(iii) \quad \sum_{i=\nu}^n \|Y_i\|^2 \leq D \left\{ (\rho^{\nu-m} \|Y_m\|)^2 + \sum_{i=m+1}^n \varepsilon_i^2 + \sum_{i=m+2-d-q}^{n-d} u_i^2 \right\},$$

$$(iv) \quad \sum_{i=\nu}^n \|U_i\|^2 \leq D \left\{ (\rho^{\nu-m} \|U_m\|)^2 + \sum_{i=m+1}^n \varepsilon_{i+d}^2 + \sum_{i=m+1-d-p}^{n+d} y_i^2 \right\}.$$

As an immediate application of Lemma 2 (i), we have the following.

LEMMA 3. Let c_n be a nondecreasing sequence of positive constants such that $c_n \rightarrow \infty$. Suppose that $u_n = O(c_n)$ and $\varepsilon_n = O(c_n)$ a.s. Then $y_n = O(c_n)$ a.s.

LEMMA 4. Suppose that $\{\varepsilon_n\}$ is a martingale difference sequence with respect to $\{\mathcal{F}_n\}$ such that $\sup_n E(e^{\gamma|\varepsilon_n|} | \mathcal{F}_{n-1}) < \infty$ for some $\gamma > 0$. Then $\varepsilon_n = O(\log n)$ a.s.

Proof. Taking $b > 1/\gamma$, note that

$$\sum_{n=1}^{\infty} P\{|\varepsilon_n| \geq b \log n | \mathcal{F}_{n-1}\} \leq \left(\sup_n E(e^{\gamma|\varepsilon_n|} | \mathcal{F}_{n-1}) \right) \sum_1^{\infty} n^{-\gamma b} < \infty.$$

Hence, by the conditional Borel-Cantelli lemma (cf. [13, p. 55]), $P\{|\varepsilon_n| < b \log n \text{ for all large } n\} = 1$. \square

LEMMA 5. Let $\{c_n\}, \{c_n^*\}$ be nondecreasing sequences of positive numbers such that

$$(2.6) \quad c_n^* \rightarrow \infty, \quad c_{n+d}^* = O(c_n^*), \quad c_n / c_n^* \rightarrow \infty.$$

Suppose that

$$(2.7) \quad |u_n| \leq c_n \quad \text{and} \quad \varepsilon_n = O(c_n^*) \quad \text{a.s.}$$

Let $n_0 < n_0 + m_0 < n_1 < \dots < n_i < n_i + m_i < n_{i+1} < \dots$ be positive integer-valued random variables such that

$$(2.8) \quad m_i / \log c_{n_i} \rightarrow \infty \quad \text{a.s.}$$

Letting $I = \cup_i \{n_i + 1, \dots, n_i + m_i\}$, suppose that

$$(2.9) \quad \sup_{n \in I} |u_n| / c_n^* < \infty \quad \text{a.s.}$$

(i) If $b > 1/|\log \rho|$, then

$$(2.10) \quad \max \{ \|Y_n\| / c_n^* : n_i + b \log c_{n_i} \leq n \leq n_i + m_i + d \} = O(1) \quad \text{a.s.}$$

(ii) Let $\psi_n = (y_n, \dots, y_{n-r}, u_{n-1}, \dots, u_{n-s})'$. Suppose that for some $K > 0$, with probability 1

$$(2.11) \quad |u_n| \leq \min \{c_n, K\|\psi_n\|\} \quad \text{for all large } n \notin I,$$

$$(2.12) \quad |y_{n+d} - \varepsilon_{n+d}| \chi\{K\|\psi_n\| < c_n \text{ and } n \notin I\} = o(c_n),$$

where χ_A denotes the indicator function of an event A , i.e., $\chi_A(\omega) = 0$ if $\omega \notin A$ and $\chi_A(\omega) = 1$ if $\omega \in A$. Then $\psi_n = o(c_n)$ a.s., and consequently, with probability 1,

$$(2.13) \quad |u_n| \leq K\|\psi_n\| < c_n \quad \text{for all large } n \notin I.$$

Proof. (i) By Lemma 3, $\|Y_{n_i}\| = O(c_{n_i})$ a.s. Since $\rho^b < e^{-1}$,

$$(2.14) \quad \|Y_{n_i}\| \rho^{b \log c_{n_i}} \rightarrow 0 \quad \text{a.s.}$$

From (2.7), (2.9), (2.14) and Lemma 2(i) (where we set $m = n_i$), (2.10) follows.

(ii) By restricting to an event with probability 1, we can assume that (2.7) and (2.12) hold everywhere (instead of a.s.). Given $\delta > 0$ sufficiently small so that

$$(2.15) \quad \delta K(r+s+1) < 1 \quad \text{and} \quad C|\beta_1|^{-1}(1-\rho)^{-1} \left(1 + \sum_{j=0}^p |\alpha_j|\right) \delta < 1,$$

we can choose by (2.12) and (2.7) sufficiently large T_0 so that for all $T \geq T_0$,

$$(2.16) \quad n_T + m_T < n \leq n_{T+1} \quad \text{and} \quad K\|\psi_n\| < c_n \Rightarrow |y_{n+d}| \leq \delta^2 c_n.$$

We now prove by induction on n that

$$(2.17) \quad |u_n| \leq \delta c_n \quad \text{and} \quad |y_{n+d}| \leq \delta^2 c_n$$

for all n satisfying $n_T + \frac{1}{3}m_T \leq n \leq n_{T+1}$, provided that $T (\geq T_0)$ is sufficiently large, as specified below.

By (i), (2.6) and (2.9), (2.17) holds for $n_T + \frac{1}{3}m_T \leq n \leq n_T + m_T$, provided that $T \geq T_0$ is sufficiently large. Now take $\nu \geq n_T + m_T$ with $\nu < n_{T+1}$, and assume that (2.17) holds for all $(n_T + \frac{1}{3}m_T \leq) n \leq \nu$. Since

$$\begin{aligned} K\|\psi_{\nu+1}\| &\leq K\{|y_{\nu+1}| + \dots + |y_{\nu+1-r}| + |u_\nu| + \dots + |u_{\nu+1-s}|\} \\ &\leq K(r+s+1)\delta c_\nu \quad \text{by induction hypothesis,} \\ &< c_{\nu+1} \quad \text{by (2.15),} \end{aligned}$$

it then follows from (2.16) that

$$(2.18) \quad |y_{\nu+1+d}| \leq \delta^2 c_{\nu+1}.$$

By (2.6) and (2.7), when T is sufficiently large,

$$(2.19) \quad |\varepsilon_n| \leq \delta^2 c_n \quad \text{for all } n \geq n_T.$$

From Lemma 2(ii) (with $m = n_T + \lceil \frac{1}{2}m_T \rceil$ and T sufficiently large), (2.15), (2.18), and the induction hypothesis, it then follows that $|u_{\nu+1}| \leq \delta c_{\nu+1}$. This shows that (2.17) also holds for $n = \nu + 1$.

We have therefore shown that $u_n \chi_{\{n \notin I\}} = o(c_n)$. By (2.6) and (2.9), $u_n \chi_{\{n \in I\}} = o(c_n)$. Hence $u_n = o(c_n)$. Since $\varepsilon_n = o(c_n)$, it then follows from Lemma 2(i) that $y_n = o(c_n)$. Therefore $\psi_n = o(c_n)$. \square

Lemma 5 provides a useful technical device for the analysis of the control rules developed in the next two sections, where the inputs will be truncated by c_n and white-noise probing signals will be used to excite the system at stages $n \in I$.

The following lemma provides consistent estimation of the parameters of the linear system (1.1) in the presence of “occasional excitation” in the inputs. Define

$$(2.20) \quad \varphi_n = (y_{n+d-1}, \dots, y_{n+d-p}, u_n, \dots, u_{n-q+1})', \quad \theta = (\alpha_1, \dots, \alpha_p, \beta_1, \dots, \beta_q)',$$

and rewrite (1.1) as the regression model

$$(2.21) \quad y_{n+d} = \theta' \varphi_n + \varepsilon_{n+d}.$$

LEMMA 6. Consider the linear system (1.1) in which $\{\varepsilon_n\}$ is a martingale difference sequence satisfying (1.2). Let τ be a (finite) stopping time and let $n_1 < n_1 + m_1 < \dots < n_i < n_i + m_i < n_{i+1} < \dots$ be nonrandom positive integers such that

$$(2.22) \quad \lim_{i \rightarrow \infty} m_i = \infty \quad \text{and} \quad \limsup_{i \rightarrow \infty} m_i / m_{i-1} < \infty.$$

Let $I = \{1, \dots, \tau\} \cup (\cup_{i=1}^{\infty} \{n_i + 1, \dots, n_i + m_i\})$, and let $\#_n$ denote the number of elements in I that are $\leq n$. Defining φ_n and θ as in (2.20), suppose that for $n \in I$

$$(2.23) \quad u_n \text{ is a random variable independent of } y_n, \varphi_{n-d}, \dots, \varphi_1 \\ \text{such that } u_n \text{ has mean 0, variance } V > 0 \text{ and } |u_n| \leq M.$$

Assume that $\liminf_{n \rightarrow \infty} E(\varepsilon_n^2 | \mathcal{F}_{n-1}) > 0$ a.s. and that

$$(2.24) \quad \|\varphi_n\| = O(c_n) \quad \text{a.s.,}$$

where $\{c_n\}$ is a nondecreasing sequence of positive constants satisfying (2.8) and

$$(2.25) \quad c_n \rightarrow \infty, c_n \sim c_{n+1} \quad \text{and} \quad \log c_n = O(\log \#_n).$$

Then

$$(2.26) \quad \liminf_{n \rightarrow \infty} \lambda_{\min} \left(\sum_{t \in I, t \leq n} \varphi_t \varphi_t' \right) / \#_n > 0 \quad \text{a.s.}$$

Moreover, defining the least squares estimate

$$(2.27) \quad \theta_n^* = \left(\sum_{t \in I, t \leq n} \varphi_t \varphi_t' \right)^{-1} \left(\sum_{t \in I, t \leq n} \varphi_t y_{t+d} \right)$$

based only on (φ_t, y_{t+d}) with $t \in I$, we have

$$(2.28) \quad \theta_n^* - \theta = O((\log \#_n)^{1/2} / \#_n^{1/2}) \quad \text{a.s.,}$$

and therefore $\theta_n^* \rightarrow \theta$ a.s.

Proof. In view of (2.21), we can apply Theorem 1 of [14] to conclude that

$$(2.29) \quad \theta_n^* - \theta = O \left(\left\{ \log \lambda_{\max} \left(\sum_{t \in I, t \leq n} \varphi_t \varphi_t' \right) \right\}^{1/2} / \lambda_{\min}^{1/2} \left(\sum_{t \in I, t \leq n} \varphi_t \varphi_t' \right) \right) \quad \text{a.s.}$$

By (2.24),

$$\lambda_{\max} \left(\sum_{t \in I, t \leq n} \varphi_t \varphi_t' \right) \leq \sum_{t \in I, t \leq n} \|\varphi_t\|^2 = O(c_n^2 \#_n) \quad \text{a.s.,}$$

and therefore

$$\log \lambda_{\max} \left(\sum_{t \in I, t \leq n} \varphi_t \varphi_t' \right) = O(\log \#_n) \quad \text{a.s.}$$

by (2.25). Hence (2.28) follows from (2.29) if it can be shown that (2.26) holds.

To prove (2.26), first note by (1.2) that

$$(2.30) \quad \sum_{t \in I, t \leq n} \varepsilon_t^2 = \sum_{t \in I, t \leq n} E(\varepsilon_t^2 | \mathcal{F}_{t-1}) + o(\#_n) = O(\#_n) \quad \text{a.s.}$$

(cf. [14, p. 157]). Let $I^* = \cup_i \{n_i + [\frac{1}{2}m_i], \dots, n_i + m_i\}$. Since $\sup_{t \in I} |u_t| \leq M$, it then follows from Lemma 2(iii) (with $m = n_i + d + q$, $v = n_i + [\frac{1}{2}m_i]$) and (2.30), (2.24), (2.8) that

$$\sum_{t \in I^*, t \leq n} \|\varphi_t\|^2 = \sum_{i: n_i \leq n} \sum_{t=n_i + [\frac{1}{2}m_i]}^{\min\{n_i + m_i, n\}} \|\varphi_t\|^2 = O(\#_n) \quad \text{a.s.}$$

In view of this, (2.22), (2.23) and the assumption that $\liminf_{n \rightarrow \infty} E(\varepsilon_n^2 | \mathcal{F}_{n-1}) > 0$ a.s., we can apply Theorem 5 and Corollary 2 of [12] to conclude that

$$(2.31) \quad \liminf_{n \rightarrow \infty} \lambda_{\min} \left(\sum_{t \in I^*, t \leq n} \varphi_t \varphi_t' \right) / \#_n > 0 \quad \text{a.s.},$$

which implies (2.26). \square

Remark. Instead of using the stochastic projection theory of [12] as in the preceding proof, we can apply Corollary 2 of [15] on excitation properties to derive (2.31). However, the same proof as above using the stochastic projection theory of [12] can also be used to prove the following stronger result than (2.26): For $r \geq 0$ define

$$(2.32) \quad \varphi_{n,r} = (\varphi_n', u_{n+1}, \dots, u_{n+r})'.$$

Then

$$(2.33) \quad \liminf_{n \rightarrow \infty} \lambda_{\min} \left(\sum_{t \in I, t \leq n \text{ and } t \equiv j \pmod{d}} \varphi_{t,r} \varphi_{t,r}' \right) / \#_n > 0 \quad \text{a.s.}$$

for $j = 0, \dots, d-1$. We will make use of (2.33) in § 4.

3. An asymptotically efficient input sequence in the case of unit delay. In this section we consider the case $d = 1$ first for bounded ε_n and then extend the result to the unbounded case. We will assume that $\{\varepsilon_n\}$ is a martingale difference sequence satisfying (1.2) and

$$(3.1) \quad \liminf_{n \rightarrow \infty} E(\varepsilon_n^2 | \mathcal{F}_{n-1}) > 0 \quad \text{a.s.}$$

Suppose that the ε_n are bounded with probability 1. This implies that the optimal input sequence (assuming known parameters), defined by (1.4) and with outputs $y_n = \varepsilon_n$, is bounded a.s. (Lemma 2(ii)). We therefore restrict the inputs u_n within $[-c_n, c_n]$ such that

$$(3.2) \quad c_n \sim \log \log n.$$

This implies by Lemma 3 that (2.24) holds.

A basic idea in our construction of asymptotically efficient regulators is the introduction of white-noise probing inputs to obtain strongly consistent estimates, as in Lemma 6. Let $\varphi_n = (y_n, \dots, y_{n-p+1}, u_n, \dots, u_{n-q+1})'$, $V_n = \sum_1^n \varphi_i \varphi_i'$ and define

$$(3.3) \quad \tau = \inf \{n: V_{n-1} \text{ is nonsingular and } \hat{\beta}_{1,n-1} \neq 0\},$$

where $\hat{\beta}_{1,t}$ is the least squares estimate of β_1 based on $\varphi_1, y_2, \dots, \varphi_t, y_{t+1}$ as in (1.5). Let $\rho > 1$, $\delta > 0$ and take positive integers n_i and m_i such that

$$(3.4) \quad n_i = \exp \{i^\rho (1 + o(1))\},$$

$$(3.5) \quad m_i \sim (\log i)^\delta.$$

Let

$$(3.6) \quad I = \{1, \dots, \tau\} \cup \left(\bigcup_{i=1}^{\infty} \{n_i + 1, \dots, n_i + m_i\} \right)$$

be the set of stages when white-noise probing inputs are introduced. Thus, at stage $n \in I$, the input u_n satisfies (2.23) with $d = 1$. Let $\#_n$ be the number of probing inputs up to stage n (i.e., $\#_n$ = number of elements in I that are $\leq n$). Then from (3.4) and (3.5),

$$(3.7) \quad \#_n \sim (\log n)^{1/\rho} (\rho^{-1} \log \log n)^\delta \left(\sim \sum_{i: n_i \leq n} m_i \right).$$

By (3.2), (3.5) and (3.7), conditions (2.8), (2.22) and (2.25) also hold. Define the least squares estimate θ_n^* based only on probing inputs as in (2.27), and modify the estimate as follows to ensure a nonzero estimate of β_1 : Set $\tilde{\theta}_{\tau-1} = \theta_{\tau-1}^*$ and define for $n \geq \tau$

$$(3.8) \quad \begin{aligned} \tilde{\theta}_n &= \theta_n^* && \text{if } \beta_{1,n}^* \neq 0, \\ &= \tilde{\theta}_{n-1} && \text{if } \beta_{1,n}^* = 0. \end{aligned}$$

Since $\beta_1 \neq 0$, it follows from Lemma 6 that

$$(3.9) \quad \tilde{\theta}_n - \theta = O((\log \#_n)^{1/2} / \#_n^{1/2}) \quad \text{a.s.}$$

Another key idea in the construction of asymptotically efficient regulators is the reparametrization of (1.1) in the form $y_{t+1} = \beta_1(u_t - \lambda' \psi_t) + \varepsilon_{t+1}$, where λ and ψ_t are defined in (1.10) and (1.11). Making use of the consistent estimates $\tilde{\theta}_t = (\tilde{\alpha}_{1,t}, \dots, \tilde{\alpha}_{p,t}, \tilde{\beta}_{1,t}, \dots, \tilde{\beta}_{q,t})'$ and noting that $\tilde{\beta}_{1,t} \neq 0$, define

$$(3.10) \quad \tilde{\lambda}_t = -\tilde{\beta}_{1,t}^{-1}(\tilde{\alpha}_{1,t}, \dots, \tilde{\alpha}_{p,t}, \tilde{\beta}_{2,t}, \dots, \tilde{\beta}_{q,t})'$$

as an auxiliary estimate of $\lambda = -\beta_1^{-1}(\alpha_1, \dots, \alpha_p, \beta_2, \dots, \beta_q)'$ and conclude from (3.9) that

$$(3.11) \quad \tilde{\lambda}_t - \lambda = O((\log \#_t)^{1/2} / \#_t^{1/2}) \quad \text{a.s.}$$

Although the auxiliary estimates $\tilde{\lambda}_t$ are strongly consistent, they are not asymptotically efficient since they only use a small (albeit well designed or excited) subset of the observations. Nevertheless, because of their strong consistency, they can be used to provide diagnostic checks on other estimators. One such estimator, introduced in Lemma 1, is defined recursively for $t \geq \tau$ by

$$(3.12a) \quad \lambda_t = \lambda_{t-1} + (u_t - \tilde{\beta}_{1,t-1}^{-1} y_{t+1} - \lambda'_{t-1} \psi_t) P_t \psi_t,$$

$$(3.12b) \quad P_t^{-1} = P_{t-1}^{-1} + \psi_t \psi_t', \quad \left(P_{\tau-1} = \left(\sum_{i=1}^{\tau-1} \psi_i \psi_i' \right)^{-1}, \lambda_{\tau-1} = \tilde{\lambda}_{\tau-1} \right),$$

and in turn suggests the adaptive regulator $\lambda'_{n-1} \psi_n$ at stage $n \notin I$. The adaptive choice, given in (3.13) below, between $\lambda'_{n-1} \psi_n$ and $\tilde{\lambda}'_{n-1} \psi_n$ yields an asymptotically efficient (as defined by (1.16)) sequence of self-tuning regulators. This is the content of the next theorem.

THEOREM 1. Consider the linear system (1.1) with $d = 1$ and $\beta_1 \neq 0$ and such that the stability assumption (1.3) holds. Suppose that $\{\varepsilon_n\}$ is a martingale difference sequence such that (1.2), (3.1) hold and $\sup_n |\varepsilon_n| < \infty$ a.s. Defining I by (3.3)–(3.6), introduce probing inputs (2.23) at stages $n \in I$. Let $\{c_n\}$ be a nondecreasing sequence of positive numbers satisfying (3.2). Define the auxiliary estimates $\tilde{\lambda}_t$ of λ by (3.8)–(3.10) and the recursive estimates λ_t by (3.12), where λ and ψ_t are given in (1.10) and (1.11). Let $A > 0$, and let $\#_n$ be the number of probing inputs up to stage n . For $n \notin I$, define

$$(3.13) \quad u_n = \begin{cases} (-c_n) \vee (\lambda'_{n-1} \psi_n \Lambda c_n) & \text{if } |(\lambda_{n-1} - \tilde{\lambda}_{n-1})' \psi_n| \leq A \#_n^{-1/2} (\log \#_n) \|\psi_n\|, \\ (-c_n) \vee (\tilde{\lambda}'_{n-1} \psi_n \Lambda c_n) & \text{otherwise,} \end{cases}$$

where \vee and Λ denote maximum and minimum respectively. The regret R_n of this input sequence $\{u_n\}$ satisfies (1.16).

Proof. Since $|u_n| \leq c_n$ and $\sup_n |\varepsilon_n| < \infty$ a.s., it follows from Lemma 3 that $\|\varphi_n\| = O(c_n)$ a.s. and therefore

$$(3.14) \quad \|\psi_n\| = O(c_n) \quad \text{a.s.}$$

Since ψ_i is a subvector of φ_i , $\lambda_{\min}(\sum_1^n \psi_i \psi_i') \geq \lambda_{\min}(\sum_1^n \varphi_i \varphi_i')$ and therefore by Lemma 6 (see (2.26)),

$$(3.15) \quad \liminf_{n \rightarrow \infty} \lambda_{\min} \left(\sum_1^n \psi_i \psi_i' \right) / \#_n > 0 \quad \text{a.s.}$$

By (3.2), (3.7), (3.14) and (3.15),

$$(3.16) \quad \psi_n' \left(\sum_1^n \psi_i \psi_i' \right)^{-1} \psi_n \leq \|\psi_n\|^2 / \lambda_{\min} \left(\sum_1^n \psi_i \psi_i' \right) \rightarrow 0 \quad \text{a.s.}$$

and

$$(3.17) \quad \sum_{i \in I, i \leq n} (u_i - \lambda' \psi_i)^2 = O(c_n^2 \#_n) = o(\log n) \quad \text{a.s.}$$

Define

$$(3.18) \quad \begin{aligned} z_n &= \lambda'_{n-1} \psi_n \quad \text{if } |(\lambda_{n-1} - \tilde{\lambda}_{n-1})' \psi_n| \leq A \#_n^{-1/2} (\log \#_n) \|\psi_n\|, \\ &= \tilde{\lambda}'_{n-1} \psi_n \quad \text{otherwise.} \end{aligned}$$

From (3.7), (3.11) and (3.18), it follows that for $0 < \eta < 1/(2\rho)$,

$$(3.19) \quad z_n = \lambda' \psi_n + O((\log n)^{-\eta} \|\psi_n\|) \quad \text{a.s.}$$

By (3.19), with probability 1, $|z_n| \leq (\|\lambda\| + 1) \|\psi_n\|$ for all large n . Moreover, note that $u_n = (-c_n) \vee (z_n \wedge c_n)$ for $n \notin I$ and that $y_{n+1} - \varepsilon_{n+1} = \beta_1(u_n - \lambda' \psi_n)$. Hence, by (3.19),

$$|y_{n+1} - \varepsilon_{n+1}| \chi\{(\|\lambda\| + 1) \|\psi_n\| < c_n, n \notin I\} = O((\log n)^{-\eta} \|\psi_n\|) = o(c_n) \quad \text{a.s., by (3.14).}$$

Therefore, by Lemma 5(ii),

$$(3.20) \quad \begin{aligned} 1 &= P\{|u_n| < c_n \text{ for all large } n \notin I\}. \\ &= P\{u_n = z_n \text{ for all large } n \notin I\}. \end{aligned}$$

Let $e_{n+1} = y_{n+1} - \tilde{\beta}_{1,n-1}(u_n - \lambda'_{n-1} \psi_n) = \beta_1(u_n - \lambda' \psi_n) - \tilde{\beta}_{1,n-1}(u_n - \lambda'_{n-1} \psi_n) + \varepsilon_{n+1}$. We now show that with probability 1

$$(3.21) \quad \beta_1 |u_n - \lambda' \psi_n| \leq |e_{n+1} - \varepsilon_{n+1}| \quad \text{for all large } n \notin I.$$

By (3.20), $u_n = z_n$ for all large $n \notin I$, with probability 1. If $u_n = \lambda'_{n-1} \psi_n$, then $e_{n+1} - \varepsilon_{n+1} = \beta_1(u_n - \lambda' \psi_n)$. If $u_n = z_n \neq \lambda'_{n-1} \psi_n$, then by (3.18), $u_n = \tilde{\lambda}'_{n-1} \psi_n$ and

$$\begin{aligned} |u_n - \lambda'_{n-1} \psi_n| &> A \#_n^{-1/2} (\log \#_n) \|\psi_n\| \\ &> (\log \#_n)^{1/3} |(\tilde{\lambda}_{n-1} - \lambda)' \psi_n| \quad \text{for all large } n, \text{ by (3.11),} \end{aligned}$$

and therefore

$$|u_n - \lambda' \psi_n| = |(\tilde{\lambda}_{n-1} - \lambda)' \psi_n| < (\log \#_n)^{-1/3} |u_n - \lambda'_{n-1} \psi_n|,$$

implying (3.21) since $\tilde{\beta}_{1,n-1} \rightarrow \beta$ a.s.

Since $\log \det(\sum_1^n \psi_i \psi_i')$ is the sum of logarithms of the eigenvalues of $\sum_1^n \psi_i \psi_i'$, it follows from (3.14) that

$$(3.22) \quad \begin{aligned} \log \det \left(\sum_1^n \psi_i \psi_i' \right) &\leq (p+q-1) \log \left(\sum_1^n \|\psi_i\|^2 \right) \\ &\leq (p+q-1)(1+o(1)) \log n \quad \text{a.s.} \end{aligned}$$

In view of (3.16), Lemma 1 is applicable. From Lemma 1 and (3.21), (3.22), it follows that with probability 1, for all large n ,

$$(3.23) \quad \beta_1^2 \sum_{i \in I, i \leq n} (u_i - \lambda' \psi_i)^2 \leq (v + o(1))(p + q - 1) \log n + o\left(\sum_{i=1}^n (u_i - \lambda' \psi_i)^2\right).$$

From (3.17) and (3.23), the desired conclusion (1.16) follows since

$$R_n = \sum_{i=0}^{n-1} (y_{i+1} - \varepsilon_{i+1})^2 = \beta_1^2 \sum_{i=0}^{n-1} (u_i - \lambda' \psi_i)^2. \quad \square$$

We now extend Theorem 1 to the general case where the random disturbances ε_n need not be bounded a.s. To consider the unbounded case, we strengthen the assumption (1.2) into

$$(3.24) \quad \sup_n E(e^{\gamma|\varepsilon_n|} | \mathcal{F}_{n-1}) < \infty \quad \text{a.s. for some } \gamma > 0.$$

This includes the important example where the ε_n are i.i.d. with mean 0, variance $\sigma^2 > 0$ and a finite moment generating function. The truncation sequence $\{c_n\}$ given by (3.2) is too small for this setting. For example, when the ε_n are i.i.d. normal, it follows easily from the Borel-Cantelli lemma that

$$\limsup_{n \rightarrow \infty} |\varepsilon_n| / (2 \log n)^{1/2} = \sigma \quad \text{a.s.}$$

We therefore take a larger truncation sequence c_n such that

$$(3.25) \quad c_n \sim c_{n+1}, \quad c_n / \log n \rightarrow \infty \quad \text{but } c_n = o((\log n)^\alpha) \text{ for all } \alpha > 1.$$

With this choice of c_n , in order that condition (2.8) still holds, we replace the growth condition (3.5) on m_i by

$$(3.26) \quad m_i \sim i^\delta \quad \text{for some } 0 < \delta < \rho - 1.$$

Note that if $n_j \leq n < n_{j+1}$, where n_j is given in (3.4), then

$$(3.27) \quad \#_n \sim \sum_{i=1}^j m_i \sim (1 + \delta)^{-1} j^{1+\delta} \sim (1 + \delta)^{-1} (\log n)^{(1+\delta)/\rho} = o(\log n).$$

While it was easy to prove (3.16) in the case of bounded ε_n , we cannot use the same argument for the present unbounded setting since $\#_n = o(\log n)$ a.s. by (3.27) but $c_n / \log n \rightarrow \infty$. We shall show that, under the additional coprimality assumption (1.9), the ψ_n in fact have the persistent excitation property

$$(3.28) \quad \liminf_{n \rightarrow \infty} n^{-1} \lambda_{\min} \left(\sum_{i=1}^n \psi_i \psi_i' \right) > 0 \quad \text{a.s.}$$

THEOREM 2. *Suppose that we replace the a.s. boundedness assumption on $\{\varepsilon_n\}$ in Theorem 1 by (3.24), the condition (3.2) on $\{c_n\}$ by (3.25), and the condition (3.5) on m_i by (3.26). Then under the additional assumption (1.9), the conclusion of Theorem 1 still holds.*

Proof. Let $c_n^* = \log n (= o(c_n))$ by (3.25). By (3.24) and Lemma 4, $\varepsilon_n = O(c_n^*)$ a.s. Moreover, by (3.25)–(3.27), (2.8), (2.22) and (2.25) still hold. Define z_n as in (3.18) and note that (3.19) still holds with $0 < \eta < (1 + \delta)/(2\rho)$. The same argument as in Theorem 1 shows that (3.14) and (3.20) still hold.

From (1.18), (3.19) and (3.20), it follows that with probability 1

$$(3.29) \quad y_{n+1} = \varepsilon_{n+1} + O((\log n)^{-\eta} \|\psi_n\|) \quad \text{for all large } n \notin I.$$

By (3.14), (3.25) and Lemma 2, there exist $K > 0$ and $0 < a < 1$ such that with probability 1, for all large n ,

$$(3.30) \quad |u_n| \leq K \left\{ 1 + \sum_{0 \leq i \leq K \log \log n} a^i (|\varepsilon_{n+1-i}| + |y_{n+1-i}|) \right\},$$

$$(3.31) \quad |y_n| \leq K \left\{ 1 + \sum_{0 \leq i \leq K \log \log n} a^i (|\varepsilon_{n-i}| + |u_{n-1-i}|) \right\}.$$

We now show that

$$(3.32) \quad \sum_{i \in I, i \leq n} (u_i - \lambda' \psi_i)^2 = o(\log n) \quad \text{a.s.}$$

Since $|u_i| \leq M$ for $i \in I$ and since $\#_n = O((\log n)^{(1+\delta)/\rho})$ by (3.27), it suffices to show that

$$(3.33) \quad \sum_{i \in I, i \leq n} \|\psi_i\|^2 = o(\log n) \quad \text{a.s.}$$

We first note by (3.24) that

$$\sum_{i=1}^{\infty} \sum_{n_i - m_i < n \leq n_i + m_i} P\{|\varepsilon_n| \geq B \log i | \mathcal{F}_{n-1}\} \leq \left\{ \sup_n E(e^{\gamma|\varepsilon_n|} | \mathcal{F}_{n-1}) \right\} \sum_{i=1}^{\infty} 2m_i i^{-\gamma B} < \infty$$

by choosing B large enough so that $\gamma B > 1 + \delta$. Hence, by the conditional Borel–Cantelli lemma (cf. [13, p. 55]),

$$(3.34) \quad \max_{n_i - m_i < n \leq n_i + m_i} |\varepsilon_n| \leq B \log i \sim (B/\rho) \log \log n_i \quad \text{a.s.}$$

From (3.29) together with (3.14), (3.25) and (3.34), it follows that

$$(3.35) \quad \max_{n_i - m_i < n \leq n_i} |y_n| = O((\log n_i)^{1-\eta/2}) \quad \text{a.s.}$$

From (3.30), (3.34) and (3.35), we then obtain that

$$(3.36) \quad \max_{n_i - m_i/2 \leq n \leq n_i} \|\psi_n\| = O((\log n_i)^{1-\eta/2}) \quad \text{a.s.}$$

Putting (3.36) and (3.34) into (3.29) yields

$$(3.37) \quad \max_{n_i - m_i/2 < n \leq n_i} \|y_n\| = O((\log n_i)^{(1-\eta/2)-\eta}) \quad \text{a.s.}$$

Proceeding inductively in this way, we can show that if $(k-1)\eta > 1$ then

$$(3.38) \quad \max_{n_i - m_i/2^k \leq n \leq n_i} \|\psi_n\| = O(\log \log n_i) \quad \text{a.s.}$$

Since $|u_n| \leq M$ for $n_i < n \leq n_i + m_i$, it then follows from (3.31), (3.34) and (3.38) that

$$(3.39) \quad \max_{n_i < n \leq n_i + m_i} \|\psi_n\| = O(\log \log n_i) \quad \text{a.s.}$$

Therefore with probability 1

$$\sum_{i: n_i \leq n} \left\{ \sum_{r=n_i+1}^{n_i+m_i} \|\psi_r\|^2 \right\} = \sum_{i: n_i \leq n} O(m_i (\log \log n_i)^2) = o(\log n),$$

thus establishing (3.33) and therefore (3.32) also.

In view of (3.32), it remains to prove that

$$(3.40) \quad \beta_1^2 \sum_{i \notin I, i \leq n} (u_i - \lambda' \psi_i)^2 \leq \{v(p+q-1) + o(1)\} \log n \quad \text{a.s.}$$

We can prove this by applying Lemma 1 as in the last two paragraphs of the proof of Theorem 1. To show that Lemma 1 is applicable, we shall prove that (3.16) still holds by establishing the persistent excitation property (3.28) of $\{\psi_n\}$. First, in view of (3.29),

$$(3.41) \quad \sum_{i \notin I, i \leq n} y_{i+1}^2 \leq 2 \sum_{i \notin I, i \leq n} \varepsilon_{i+1}^2 + \sum_{i \notin I, i \leq n} o(\|\psi_i\|^2).$$

From (3.32) and (3.41), it follows that

$$(3.42) \quad \sum_{i=1}^n y_{i+1}^2 \leq 2 \sum_{i=1}^n \varepsilon_{i+1}^2 + o(\log n) + o\left(\sum_{i=1}^n \|\psi_i\|^2\right) = O(n) + o\left(\sum_{i=1}^n \|\psi_i\|^2\right) \quad \text{a.s.}$$

since $\sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n E(\varepsilon_i^2 | \mathcal{F}_{i-1}) + o(n)$ a.s. (cf. [14, p. 157]). By Lemma 2(iv) and (3.42), $\sum_{i=1}^n \|U_i\|^2 = O(n) + o(\sum_{i=1}^n \|\psi_i\|^2)$ a.s., so

$$\sum_{i=1}^n \|\psi_i\|^2 = O(n) + o\left(\sum_{i=1}^n \|\psi_i\|^2\right) \quad \text{a.s.}$$

This shows that $\sum_{i=1}^n \|\psi_i\|^2 = O(n)$ a.s., and therefore by (3.29),

$$(3.43) \quad \sum_{i \notin I, i \leq n} (y_{i+1} - \varepsilon_{i+1})^2 = \sum_{i \notin I, i \leq n} o(\|\psi_i\|^2) = o(n) \quad \text{a.s.}$$

From (3.32) and (3.43), it then follows that $\sum_{i=1}^n (y_{i+1} - \varepsilon_{i+1})^2 = o(n)$ a.s., i.e., $\{u_i\}$ is globally convergent. In view of the coprimality assumption (1.9), the global convergence of $\{u_i\}$ implies the desired persistent excitation property (3.28) for $\{\psi_n\}$, by Corollary 3 of [15]. \square

4. Extensions to the case of general delay. The approach in the preceding section can be readily extended to the case of general d . The key idea is to rewrite (1.1) in the regression form (4.4) below so that we can apply Lemma 1. Since $1 - \alpha_1 z - \cdots - \alpha_p z^p$ and z^d are relatively prime, we can find polynomials $F(z) = 1 + f_1 z + \cdots + f_{d-1} z^{d-1}$ and $G(z) = g_1 + g_2 z + \cdots + g_p z^{p-1}$ such that

$$(1 - \alpha_1 z - \cdots - \alpha_p z^p)F(z) + z^d G(z) = 1;$$

moreover, we can rewrite (1.1) as

$$(4.1) \quad y_{n+d} = g_1 y_n + \cdots + g_p y_{n-p+1} + \gamma_1 u_n + \cdots + \gamma_{q+d-1} u_{n-q-d+2} + \tilde{\varepsilon}_{n+d},$$

where $\gamma_j = \sum_{i+s=j} f_i \beta_s$ ($f_0 = 1$), so $\gamma_1 = \beta_1 \neq 0$, and

$$(4.2) \quad \tilde{\varepsilon}_{n+d} = \varepsilon_{n+d} + f_1 \varepsilon_{n+d-1} + \cdots + f_{d-1} \varepsilon_{n+1} = y_{n+d} - E(y_{n+d} | \mathcal{F}_n)$$

(cf. [6]). Defining

$$(4.3) \quad \begin{aligned} \lambda &= -\beta_1^{-1}(g_1, \cdots, g_p, \gamma_2, \cdots, \gamma_{q+d-1})', \\ \psi_n &= (y_n, \cdots, y_{n-p+1}, u_{n-1}, \cdots, u_{n-q-d+2})', \end{aligned}$$

we can write (4.1) in the form of d regression models: For $j = 0, \cdots, d-1$,

$$(4.4) \quad y_{j+d(t+1)} = \beta_1(u_{j+dt} - \lambda' \psi_{j+dt}) + \tilde{\varepsilon}_{j+d(t+1)}, \quad t = 1, 2, \cdots$$

Example. Consider the linear system

$$(4.5) \quad y_n = \alpha y_{n-1} + \beta u_{n-2} + \varepsilon_n.$$

Here $d = 2$ and we can write (4.5) as

$$(4.6) \quad \begin{aligned} y_{n+2} &= \alpha y_{n+1} + \beta u_n + \varepsilon_{n+2} = \alpha(\alpha y_n + \beta u_{n-1} + \varepsilon_{n+1}) + \beta u_n + \varepsilon_{n+2} \\ &= \alpha^2 y_n + \beta u_n + \alpha \beta u_{n-1} + \tilde{\varepsilon}_{n+2}, \end{aligned}$$

where $\tilde{\varepsilon}_i = \varepsilon_i + \alpha \varepsilon_{i-1}$.

When the system parameters are known, the optimal controller chooses the input u_n at stage n such that $E(y_{n+d}|\mathcal{F}_n) = 0$, and the outputs are $y_i = \tilde{\varepsilon}_i$. We therefore define the “regret,” at stage n , of a sequence of inputs $\{u_i\}$ to be

$$(4.7) \quad R_n(d) = \sum_1^n (y_i - \tilde{\varepsilon}_i)^2.$$

Without assuming any prior knowledge of the system parameters, we now construct an input sequence such that

$$(4.8) \quad \limsup_{n \rightarrow \infty} R_n(d)/\log n \leq \tilde{v}d(p+q+d-2) \quad \text{a.s., where}$$

$$\tilde{v} = \limsup_{n \rightarrow \infty} E(\tilde{\varepsilon}_{n+d}^2|\mathcal{F}_n).$$

Note that (4.8) reduces to (1.16) in the case $d = 1$.

Suppose that the martingale difference sequence $\{\varepsilon_n\}$ is bounded a.s. and satisfies (1.2) and (3.1). As in § 3, we introduce white-noise probing inputs to obtain strongly consistent estimates. For the given d , define φ_n and θ by (2.20). Let $V_n = \sum_1^n \varphi_i \varphi_i'$,

$$(4.9) \quad \tau = \inf \{n: V_{n-d} \text{ is nonsingular and } \hat{\beta}_{1,n-d} \neq 0\},$$

where $\hat{\beta}_{1,t}$ is the least squares estimate of β_1 based on $\{(\varphi_i, y_{i+d}): i \leq t\}$ in the regression model (2.21). With (4.9) replacing (3.3), we can define n_i , m_i and I as in (3.4)–(3.6) and introduce white-noise probing input (2.23) at stage $n \in I$. Define the auxiliary estimates $\tilde{\theta}_n = (\tilde{\alpha}_{1,n}, \dots, \tilde{\alpha}_{p,n}, \tilde{\beta}_{1,n}, \dots, \tilde{\beta}_{q,n})'$ as in (3.8). Since (3.9) still holds by Lemma 6 and since the parameters g_1, \dots, g_p , $\gamma_1 (= \beta_1), \dots, \gamma_{q+d-1}$ of the reparametrized model (4.1) are polynomials in the α 's and β 's (see the preceding example), we can obtain from the auxiliary estimates $\tilde{\theta}_n$ the corresponding strongly consistent estimates $\tilde{\beta}_{1,n} \neq 0$ and $\tilde{\lambda}_n$ such that

$$(4.10) \quad \tilde{\lambda}_n - \lambda = O((\log \#_n)^{1/2} / \#_n^{1/2}) \quad \text{a.s.,}$$

where $\#_n$ is the number of probing inputs up to stage n .

In view of (4.4), the general-delay version of the recursive estimates λ_t introduced in (3.12) is of the following form. For $n = j + dt$ (with $t = 1, 2, \dots$ and $j = 0, \dots, d-1$), let

$$(4.11) \quad P_n^{-1} = \sum_{s=1}^t \psi_{j+ds} \psi_{j+ds}' = \sum_{i \leq n, i \equiv j \pmod{d}} \psi_i \psi_i',$$

and define the estimates of λ recursively by

$$(4.12) \quad \lambda_n = \lambda_{n-d} + (u_n - \tilde{\beta}_{1,n-d}^{-1} y_{n+d} - \lambda'_{n-d} \psi_n) P_n \psi_n.$$

Let $A > 0$. Analogous to (3.13), we define at stage $n \notin I$ the input

$$(4.13) \quad u_n = \begin{cases} (-c_n) \vee (\lambda'_{n-d} \psi_n \Lambda c_n) & \text{if } |(\lambda_{n-d} - \tilde{\lambda}_{n-d})' \psi_n| \leq A \#_n^{-1/2} (\log \#_n) \|\psi_n\|, \\ (-c_n) \vee (\tilde{\lambda}'_{n-d} \psi_n \Lambda c_n) & \text{otherwise.} \end{cases}$$

THEOREM 3. *Consider the linear system (1.1) with $\beta_1 \neq 0$ and such that (1.3) holds. Suppose that $\{\varepsilon_n\}$ is a martingale difference sequence such that (1.2), (3.1) hold and $\sup_n |\varepsilon_n| < \infty$ a.s. Let $\{c_n\}$ be a nondecreasing sequence of positive numbers satisfying (3.2). Then the regret of the input sequence $\{u_n\}$ defined above (by (4.13) for $n \notin I$, and by (2.23) for $n \in I$) satisfies (4.8).*

Proof. Note by (4.2) that for fixed j , $\{\tilde{\varepsilon}_{j+dt}: t \geq 1\}$ is a martingale difference sequence such that $\sup_t E(|\tilde{\varepsilon}_{j+dt}|^\gamma | \mathcal{F}_{j+d(t-1)}) < \infty$ and $\sup_t |\tilde{\varepsilon}_{j+dt}| < \infty$ a.s. By Lemma 3, (3.14) still holds. Moreover, it follows from (4.4) and an argument similar to the proof of Theorem 1 that

$$|y_{n+d} - \tilde{\varepsilon}_{n+d}| \chi\{(\|\lambda\| + 1)\|\psi_n\| < c_n, n \notin I\} = o(c_n) \quad \text{a.s.}$$

Since ψ_n is a subvector of $\varphi_{n-d+1,d}$ defined in (2.32), it follows from (2.33) that

$$\liminf_{n \rightarrow \infty} \lambda_{\min} \left(\sum_{t \leq n, t \equiv j \pmod{d}} \psi_t \psi_t' \right) / \#_n > 0 \quad \text{a.s.}$$

for $j = 0, \dots, d-1$, and therefore $\psi_n' P_n \psi_n \rightarrow 0$ a.s. Hence Lemma 1 can again be applied to each of the d regression models in (4.4), and an argument similar to the proof of Theorem 1 shows that for $j = 0, \dots, d-1$,

$$(4.14) \quad \beta_1^2 \sum_{j+dt \notin I, j+dt \leq n} (u_{j+dt} - \lambda' \psi_{j+dt})^2 \\ \leq (\tilde{v} + o(1))(p + q + d - 2) \log n + o \left(\sum_{i=1}^n (u_i - \lambda' \psi_i)^2 \right),$$

noting that $p + q + d - 2$ is the dimensionality of the vector ψ_n . Clearly (3.17) still holds as before. From (4.14) and (3.17), the desired conclusion (4.8) follows. \square

OPTIMAL CONTROL FOR PARABOLIC VARIATIONAL INEQUALITIES*

AVNER FRIEDMAN†

Abstract. Consider the problem of maximizing a functional that depends on a control function $k(x, t)$ and on the solution $u(x, t)$ of a parabolic variational inequality with k appearing in the data. Necessary conditions are obtained for the maximizers $k_0(x, t)$, and the structure of k_0 is then analyzed. An application to the Stefan problem is given.

Key words. optimal control, parabolic variational inequality, elliptic variational inequality, bang-bang principle, Stefan problem

AMS(MOS) subject classifications. 49A29, 49B22, 35K55

Introduction. Consider a parabolic variational inequality with control $k(x, t)$ appearing either in the inhomogeneous term or in the boundary data. Denote the corresponding solution by $u(x, t)$ and introduce a functional

$$J(k) = \iint F(x, t, u) \, dx \, dt + \iint \Phi(k) \, dx \, dt.$$

Let k_0 be a solution of the problem

$$(0.1) \quad J(k_0) = \max_{k \in \alpha} J(k), \quad k_0 \in \alpha$$

where α is a given class of control functions. We are interested in studying properties of k_0 .

In most control problems for partial differential equations (see [9], [10]) the functional $J(k)$ is differentiable. This is not the case here. For this reason there are difficulties in deriving effective necessary conditions on the maximizers k_0 ; see [1], [11], [12] and the reference given there.

In a recent paper [4] we have treated the case of an elliptic variational inequality under the assumption that

$$(0.2) \quad F_u > 0.$$

Using a comparison argument, we were able to obtain a general simple necessary condition for the maximizing control. This condition yields a bang-bang principle for some classes α . As pointed out in [4], the method does not carry over to parabolic variational inequalities.

In the present paper we use a different method which allows us to treat both elliptic and parabolic variational inequalities; furthermore, the restriction (0.2) is removed.

The method consists in approximating the maximizer (k_0, u_0) with maximizers $(k_\varepsilon, u_\varepsilon)$ of ε -penalized problems which are "smooth." We first obtain necessary conditions of the maximizers k_ε (in § 1) and then use them (in subsequent sections) to find the structure of k_0 .

† Department of Mathematics, Purdue University, West Lafayette, Indiana 47907.

In order to avoid duplication we shall treat in detail only parabolic variational inequalities; elliptic variational inequalities can be treated in precisely the same way.

In case

$$\alpha = \left\{ 0 \leq k \leq M, \int \int k \, dx \, dt = H \right\}$$

where k appears as the nonhomogeneous term, it is shown (in § 2) that in the noncoincidence set of u_0

$$(0.3) \quad k_0 = \begin{cases} M & \text{if } Q < \lambda, \\ 0 & \text{if } Q > \lambda \end{cases}$$

for a suitable solution Q of a parabolic equation.

Other functionals and control sets α are considered in § 3. In § 4 we consider the case where the control appears in the boundary data. An application to the Stefan problem in N -dimension is given in § 5.

We finally remark that the necessary conditions derived in this paper are not sufficient in general.

1. The ε -problem. Let D be a bounded domain in \mathbb{R}^N with C^2 boundary S and set

$$\begin{aligned} D_T &= D \times (0, T), & S_T &= S \times (0, T), \\ \partial_p D_T &= S_T \cup D \times \{0\}, & \partial_{-p} D_T &= S_T \cup D \times \{T\} \end{aligned}$$

for any $T > 0$. We denote points in D_T by (x, t) .

Let $U^0(x, t)$ be a given function satisfying

$$(1.1) \quad \begin{aligned} D_t U^0, D_x^2 U^0 &\in L^\infty(D_T), \\ U^0 &> 0 \quad \text{on } S_T, \quad U^0 \geq 0 \quad \text{on } D \times \{0\}. \end{aligned}$$

Let f be a given function satisfying

$$(1.2) \quad f \in L^p(D_T)$$

where

$$(1.3) \quad p > \frac{N+2}{2}, \quad p \geq 2.$$

We introduce a class α of control functions $k(x, t)$ with the following properties:

$$(1.4) \quad \alpha \text{ is a closed, bounded and convex set in } L^p(D_T).$$

For any $k \in \alpha$ consider the parabolic variational inequality

$$(1.5) \quad \int \int_{D_T} u_t(\psi - u) + \int \int_{D_T} \nabla u \cdot \nabla(\psi - u) \geq - \int \int_{D_T} (f + k)(\psi - u) \quad \forall \psi \in K, \quad u \in K$$

where

$$(1.6) \quad \begin{aligned} K &= \{ \psi; \psi - U^0 \in L^2(0, T; H_0^1(D)), \psi_t \in L^2(0, T; H^{-1}(D)), \\ &\quad \psi(\cdot, 0) = U_0(\cdot, 0), \psi \geq 0 \text{ a.e. in } D_T \}; \end{aligned}$$

here $H^{-1}(D)$ is the dual of $H_0^1(D)$. Notice that $\psi \in C^0([0, T]; H^{-1}(D))$ so that the condition $\psi(\cdot, 0) = U_0(\cdot, 0)$ is meaningful.

We introduce the functional

$$(1.7) \quad J(k) = \iint_{D_T} F(x, t, u) \, dx \, dt + \iint_{D_T} \Phi(k) \, dx \, dt$$

and assume that

$$(1.8) \quad \begin{aligned} &k \rightarrow \iint_{D_T} \Phi(k) \text{ is upper semicontinuous under weak convergence in } L^p(D_T), \\ &\text{i.e., if } k_m \rightarrow k \text{ weakly in } L^p(D_T) \text{ where } k_m, k \in \mathfrak{a} \text{ then} \\ &\iint_{D_T} \Phi(k) \geq \limsup_{k \rightarrow \infty} \iint_{D_T} \Phi(k_m). \end{aligned}$$

We also assume that

$$(1.9) \quad F(x, t, u) \text{ is continuous in } \overline{D_T} \times \mathbb{R}^1.$$

Consider the problem: find k_0 such that

$$(1.10) \quad J(k_0) = \max_{k \in \mathfrak{a}} J(k), \quad k_0 \in \mathfrak{a}.$$

By the general theory of variational inequalities [2], [3], [7], for any $k \in \mathfrak{a}$ there exists a unique solution u of (1.5) and $u, D_x^2 u$ belong to $L^p(D_T)$; hence, by the Sobolev imbedding and (1.3) (cf. [8])

$$(1.11) \quad |u|_{C^\alpha(D_T)} \leq C$$

for some α positive; C and α are independent of k . Take a maximizing sequence k_m and their corresponding solutions u_m such that

$$\begin{aligned} k_m &\rightarrow k_0 \quad \text{weakly in } L^p(D_T), \\ u_m &\rightarrow u_0 \quad \text{in } C^\beta(D_T), \quad 0 < \beta < \alpha. \end{aligned}$$

Then one can easily verify that (1.5) is satisfied for $k = k_0$, $u = u_0$ and that k_0 is a solution of problem (1.10).

Our main purpose is to find necessary conditions for maximizers k_0 . For this we need the additional assumptions:

$$(1.12) \quad F_u(x, t, u) \text{ is continuous in } \overline{D_T} \times \mathbb{R}^1,$$

and $\Phi(k)$ is differentiable, i.e.

$$(1.13) \quad \begin{aligned} &\text{for any } k \in \mathfrak{a} \text{ there exists a function in } L^q(D_T) (1/p + 1/q = 1) \text{ denoted} \\ &\text{by } \Phi'(k) \text{ such that for any } l \in L^p(D_T) \text{ with } k + \delta l \in \mathfrak{a} \text{ if } 0 < \delta < 1 \\ &\text{there holds: } \lim_{\delta \rightarrow 0} 1/\delta \iint_{D_T} [\Phi(k + \delta l) - \Phi(k)] = \iint_{D_T} \Phi'(k) l. \end{aligned}$$

The difficulty in deriving effective necessary conditions on k_0 stems from the fact that the functional $J(k)$ does not have a Frechet derivative (unless the free boundary happens to be smooth). To overcome this difficulty we consider, for any $\varepsilon \in (0, 1)$, the penalized problem

$$(1.14) \quad \begin{aligned} u_t - \Delta u + \beta_\varepsilon(u) &= -(f + k) \quad \text{in } D_T, \\ u &= U^0 \quad \text{on } \partial_p D_T \end{aligned}$$

where $\beta_\varepsilon(s) \in C^\infty(\mathbb{R}^1)$ and

$$(1.15) \quad \begin{aligned} \beta_\varepsilon(s) &\rightarrow 0 \quad \text{if } s > 0, \quad \varepsilon \rightarrow 0, \\ \beta_\varepsilon(s) &\rightarrow -\infty \quad \text{if } s < 0, \quad \varepsilon \rightarrow 0, \\ \beta'_\varepsilon(s) &\geq 0. \end{aligned}$$

Denote by u_ε the unique solution of (1.14) and (following [1]) introduce the functional

$$(1.16) \quad J_\varepsilon(k) = \iint_{D_T} F(x, t, u_\varepsilon) + \iint_{D_T} \Phi(k) - \frac{1}{2} \iint_{D_T} (k - k_0)^2.$$

DEFINITION 1.1. The ε -problem consists in finding a function k_ε satisfying

$$(1.17) \quad J_\varepsilon(k_\varepsilon) = \max_{k \in \mathfrak{a}} J_\varepsilon(k), \quad k_\varepsilon \in \mathfrak{a}.$$

Suppose u_ε is the solution of (1.14) corresponding to a maximizer k_ε . Denote by Q_ε the solution of the parabolic problem

$$(1.18) \quad \begin{aligned} Q_t + \Delta Q - \beta'_\varepsilon(u_\varepsilon)Q &= -F_u(x, t, u_\varepsilon) \quad \text{in } D_T, \\ Q &= 0 \quad \text{on } \partial_{-p}D_T. \end{aligned}$$

LEMMA 1.1. If $k_\varepsilon + \delta l \in \mathfrak{a}$ for any $0 < \delta < \delta_0$ and some $\delta_0 > 0$, then

$$(1.19) \quad \iint_{D_T} (-Q_\varepsilon - \Phi'(k_\varepsilon) + k_\varepsilon - k_0)l \geq 0.$$

Proof. Denote by $u_{\varepsilon,\delta}$ the solution of (1.14) corresponding to $k_\varepsilon + \delta l$. Then

$$(1.20) \quad \begin{aligned} 0 &\geq \overline{\lim}_{\delta \rightarrow 0} \frac{1}{\delta} (J(k_\varepsilon + \delta l) - J(k_\varepsilon)) \\ &= \overline{\lim}_{\delta \rightarrow 0} \iint_{D_T} \frac{1}{\delta} (F(x, t, u_{\varepsilon,\delta}) - F(x, t, u_\varepsilon)) + \iint_{D_T} \Phi'(k_\varepsilon)l - \iint_{D_T} (k_\varepsilon - k_0)l \\ &= I_1 + I_2 + I_3; \end{aligned}$$

the integral in I_1 is equal to

$$\iint_{D_T} F_u(x, t, \tilde{u}_{\varepsilon,\delta}(x, t)) \frac{u_{\varepsilon,\delta} - u_\varepsilon}{\delta}$$

where $\tilde{u}_{\varepsilon,\delta}(x, t)$ lies in the interval with end-points $u_\varepsilon(x, t)$, $u_{\varepsilon,\delta}(x, t)$. Denote by $Q_{\varepsilon,\delta}$ the solution of (1.18) corresponds to $F_u(x, t, \tilde{u}_{\varepsilon,\delta})$. Then $\lim_{\delta \rightarrow 0} Q_{\varepsilon,\delta} = Q_\varepsilon$ uniformly in D_T . Also

$$\lim_{\delta \rightarrow 0} \frac{u_{\varepsilon,\delta} - u_\varepsilon}{\delta} = z \quad \text{uniformly in } D_T$$

where

$$(1.21) \quad \begin{aligned} z_t - \Delta z + \beta'_\varepsilon(u_\varepsilon)z &= -l \quad \text{in } D_T, \\ z &= 0 \quad \text{on } \partial_p D_T. \end{aligned}$$

It follows that

$$\begin{aligned} I_1 &= - \iint_{D_T} [Q_{\varepsilon,t} + \Delta Q_\varepsilon - \beta'_\varepsilon(u_\varepsilon)Q_\varepsilon]z \\ &= \iint_{D_T} [z_t - \Delta z + \beta'_\varepsilon(u_\varepsilon)z]Q = \iint_{D_T} Ql, \quad \text{by (1.21)}. \end{aligned}$$

When we substitute this into (1.20), the assertion (1.19) follows.

LEMMA 1.2. As $\varepsilon \rightarrow 0$

$$(1.22) \quad \begin{aligned} k_\varepsilon &\rightarrow k_0 \quad \text{strongly in } L^p(D_T), \\ u_\varepsilon &\rightarrow u_0 \quad \text{uniformly in } D_T. \end{aligned}$$

This result is due to Barbu [1]. For convenience we recall the proof.

Proof. Denote by u_ε^* the solution of (1.14) corresponding to k_0 . By a standard argument [2], [3]

$$\|\beta_\varepsilon(u_\varepsilon)\|_{L^p(D_T)} \leq C, \quad \|\beta_\varepsilon(u_\varepsilon^*)\|_{L^p(D_T)} \leq C.$$

Hence (1.11) holds for u_ε and u_ε^* . It follows that for any sequence of ε 's there is a subsequence such that

$$\begin{aligned} k_\varepsilon &\rightarrow \tilde{k} \quad \text{weakly in } L^p(D_T), \\ u_\varepsilon &\rightarrow \tilde{u}, \quad u_\varepsilon^* \rightarrow \hat{u} \quad \text{uniformly in } D_T \end{aligned}$$

and

$$\begin{aligned} J_\varepsilon(k_0) &\rightarrow J(k_0), \\ \lim J_\varepsilon(k_\varepsilon) &= J(\tilde{k}) - \frac{1}{2} \lim \iint_{D_T} |k_\varepsilon - k_0|^2. \end{aligned}$$

Since $J_\varepsilon(k_0) \leq J_\varepsilon(k_\varepsilon)$ and $J(k_0) \geq J(\tilde{k})$, it follows that

$$\lim \iint_{D_T} |k_\varepsilon - k_0|^2 = 0.$$

Thus $\tilde{k} = k_0$, $\tilde{u} = u_0$, and (1.22) follows.

2. The bang-bang principle. In this section we take

$$(2.1) \quad \alpha = \left\{ k \in L^\infty(D_T), 0 \leq k \leq M, \iint_{D_T} k = H \right\}$$

where M is such that $M \operatorname{meas}(D_T) > H$, so that α is nontrivial. For simplicity we take

$$(2.2) \quad J(k) = \iint_{D_T} F(x, t, u) \, dx \, dt$$

and assume that

$$(2.3) \quad f \in L^\infty(D_T).$$

We shall use the notation of § 1, and set

$$\Omega_\varepsilon = \{u_\varepsilon > 0\}, \quad \Omega_0 = \{u_0 > 0\}.$$

Let q be the solution of

$$(2.4) \quad -\Delta q = C_0 \quad \text{in } D, \quad q = 0 \quad \text{on } \partial D.$$

Then $q > 0$ in D and, by comparison,

$$-q < Q_\varepsilon < q \quad \text{in } D_T$$

provided

$$C_0 > \sup_{D_T} |F_u(x, t, u_\varepsilon)| \quad \forall \varepsilon \in (0, 1)$$

(recall that $\beta'_\varepsilon(u_\varepsilon) \geq 0$). It follows that

$$(2.5) \quad -C \leq Q_\varepsilon \leq C \quad \text{in } D_T;$$

further

$$(2.6) \quad \text{if } F_u(x, t, u) \geq 0 \quad \text{for } u \geq 0 \quad \text{then } 0 \leq Q_\varepsilon \leq C.$$

Let G be any compact subset of Ω_0 . Then $u_\varepsilon \geq c > 0$ in G if ε is small enough and, consequently, $\beta_\varepsilon(u_\varepsilon) = 0$ in G . It follows that, for a subsequence, $Q_\varepsilon \rightarrow Q$ uniformly in G and $Q_t + \Delta Q = -F_u(x, t, u_0)$ in G . Since G is arbitrary we conclude that, for a subsequence,

$$(2.7) \quad Q_\varepsilon \rightarrow Q \quad \text{uniformly in compact subsets of } \Omega_0,$$

$$(2.8) \quad Q_t + \Delta Q = -F_u(x, t, u_0) \quad \text{in } \Omega_0$$

and

$$(2.9) \quad -C \leq Q \leq C \quad \text{in } \Omega_0.$$

Also, by (2.6) and the strong maximum principle,

$$(2.10) \quad \text{if } F_u(x, t, u) > 0 \text{ for } u > 0 \text{ then } 0 < Q \leq C \text{ in } \Omega_0.$$

THEOREM 2.1. *There exists a constant λ such that*

$$(2.11) \quad \begin{aligned} k_0 &= M \quad \text{a.e. in } \{Q < \lambda\} \cap \Omega_0, \\ k_0 &= 0 \quad \text{a.e. in } \{Q > \lambda\} \cap \Omega_0. \end{aligned}$$

Proof. From Lemma 1.2 it follows that for any $\eta > 0$ there exists a set G_η of measure $< \eta$ such that

$$|k_\varepsilon - k_0| < \eta \quad \text{in } \Omega' \equiv D_T \setminus G_\eta.$$

If we take in Lemma 1.1 l with support in Ω' , then we obtain the inequality

$$\iint_{\Omega'} (Q_\varepsilon + \theta) l \geq 0 \quad \text{where } |\theta| \leq \eta;$$

here $\theta = k_\varepsilon - k_0$ is independent of l .

We can now argue as in Theorem 2.1 of [4] and deduce that there exists a λ_ε such that in Ω'

$$k_\varepsilon = \begin{cases} M & \text{a.e. in } \{Q_\varepsilon < \lambda_\varepsilon - \eta\}, \\ 0 & \text{a.e. in } \{Q_\varepsilon > \lambda_\varepsilon + \eta\}. \end{cases}$$

Since $|\lambda_\varepsilon| \leq C$ (by (2.9)), we may assume that $\lambda_\varepsilon \rightarrow \lambda$ as $\varepsilon \rightarrow 0$.

Let G be any compact subset of Ω_0 and let $G' = \Omega' \cap G$. Then, by (2.7),

$$\{Q_\varepsilon < \lambda_\varepsilon - \eta\} \cap G' \supset \{Q < \lambda - 2\eta\} \cap G'$$

if ε is sufficiently small. It follows that $k_\varepsilon = M$ in $\{Q < \lambda - 2\eta\} \cap G'$, and the same is then true of the limit k_0 . Since η and G are arbitrary we conclude that $k_0 = M$ a.e. in $\{Q < \lambda\} \cap \Omega_0$. Similarly $k_0 = 0$ a.e. in $\{Q > \lambda\} \cap \Omega_0$.

Remark 2.1. If $F_u(x, t, u) \neq 0$ for all $u > 0$ then the set $\{Q = \lambda\}$ has measure zero. Indeed, a.e. on this set $Q_t = 0$ and $\Delta Q = 0$, so that also $F_u(x, t, u(x, t)) = 0$ (by (2.8)).

Notation. By V_δ ($\delta > 0$) we denote δ D -neighborhood of S .

THEOREM 2.2. *Suppose $F_u(x, t, u) > 0$ if $(x, t) \in \bar{D}_T$, $u > 0$. Then (i) $\lambda \geq 0$; (ii) if $\lambda > 0$ then $k_0 = M$ in some set $V_{\delta_0} \times (0, T)$; (iii) if $\lambda > 0$ then $k_0 = M$ a.e. in $D_T \setminus \Omega_0$; (iv) if $f \leq 0$ then $\lambda > 0$.*

Proof. The assertion (i) follows from (2.10). Next, since $U^0 > 0$ on S we have

$$u_\varepsilon \geq c > 0 \quad \text{in } V_{\delta_1} \times (0, T)$$

for some $\delta_1 > 0$, and

$$Q_{\varepsilon,t} + \Delta Q_{\varepsilon} = -F_u(x, t, u_{\varepsilon}) \quad \text{in } V_{\delta_1} \times (0, T).$$

Recalling that $Q_{\varepsilon} = 0$ on S_T , $Q_{\varepsilon} \geq 0$, we can deduce (using the strong maximum principle and parabolic regularity) that in $V_{\delta_2} \times (0, T)$ ($\delta_2 < \delta_1$),

$$(2.12) \quad c_0 d(x, t) \leq Q_{\varepsilon}(x, t) \leq c_1 d(x, t) \quad (0 < c_0 < c_1)$$

where $d(x, t)$ is the distance to the parabolic boundary $\partial V_{\delta_1} \times (0, T) \cup V_{\delta_1} \times \{t = T\}$. The second inequality in (2.12) and Theorem 2.1 yield the assertion (ii).

Suppose next that $\lambda > 0$. If the assertion (iii) is not true, then there exists a $\delta > 0$ and a subset $G \subset (D_T \setminus \Omega_0)$ with positive measure η such that $k_0 < M - \delta$ in G . Let $k_1 = k_0$ in $D_T \setminus G$, $k_1 = k_0 + \delta$ in G . Then the solution u_1 of the variational inequality (1.5) corresponding to k_1 is the same solution u_0 as for k_0 . Notice that η can be chosen arbitrarily small.

Since $\lambda > 0$, by (ii) there is a set G' in Ω_0 such that $k_0 = M$ on G' , and $\text{meas}(G') = \eta$ (if η was chosen small enough). Let $k_2 = k_1$ in $D_T \setminus G'$, $k_2 = M - \delta$ in G' . Then by comparison, the solution u' corresponding to k_2 satisfies: $u' \geq u_0$ and $u' \neq u_0$. It follows that $J(k_2) > J(k_0)$, which is a contradiction since $k_2 \in \alpha$.

To prove (iv) observe that if $\lambda = 0$ then $k_0 = 0$ in Ω_0 and therefore

$$\frac{\partial u_0}{\partial t} - \Delta u_0 = -f \geq 0 \quad \text{in } \Omega_0.$$

We can construct a ball

$$E: |x - \bar{x}|^2 + (t - \bar{t})^2 \leq \alpha$$

in Ω_0 such that ∂E intersect the free boundary at a point (x_0, t_0) which is not the top or bottom points of E . In fact, to construct E we move a plane which has a fixed nonhorizontal direction until it touches $\{u_0 = 0\}$ at some point (x_0, t_0) . Then, by the strong maximum principle, $\nabla_x u_0(x_0, t_0) \neq 0$, contradicting the fact that $\nabla_x u$ (is continuous and) vanishes on the free boundary [3], [7].

Remark 2.2 If $F_u(x, t, u) < 0$ for $(x, t) \in \bar{D}_T$, $u > 0$, then $Q < 0$ in Ω_0 and $\lambda \leq 0$. Further, if $\lambda < 0$ then $k_0 = 0$ in $V_{\delta_0} \times (0, T)$ and $k_0 = 0$ a.e. in $D_T \setminus \Omega_0$. Finally, if $f \leq -M$ then $\lambda < 0$. The proof of these statements is analogous to the proof of Theorem 2.2.

Remark 2.3. Theorems 2.1, 2.2 and Remark 2.2 exhibit the bang-bang nature of the maximizer k_0 .

THEOREM 2.3. *If $f \geq -M$, $F_u(x, t, u) > 0$ for all $(x, t) \in \bar{D}_T$, $u > 0$, then $\text{meas}[\Omega_0 \cap \{k_0 = 0\}] > 0$.*

Proof. If the assertion is not true, then

$$\frac{\partial u_0}{\partial t} - \Delta u_0 = -f - M \quad \text{in } \Omega_0$$

and

$$\frac{\partial u_0}{\partial t} - \Delta u_0 = 0 \geq -f - M \quad \text{a.e. in } D_T \setminus \Omega_0.$$

Thus u_0 is a solution of the parabolic variational inequality with the right-hand side $-f - M$, which is $\leq (-f - k)$ for any $k \in \alpha$. By comparison we conclude that $u_0 \leq u$ for any solution u of (1.5), and clearly $u_0 \neq u$ if $k_0 \neq k$ in Ω_0 . It follows that $J(k_0) < J(k)$ if $k_0 \neq k$ in Ω_0 , a contradiction.

Remark 2.4. Similarly, if $F_u < 0$ and $f \geq 0$ then $\text{meas}[\Omega_0 \cap \{k_0 = M\}] > 0$.

Remark 2.5. The results of this section extend to variational inequalities with any obstacle $\phi(x, t)$; one simply has to work with $\tilde{u} = u - \phi$ and replace f by $\tilde{f} = f - \Delta\phi$. This remark applies as well to the results of the subsequent sections.

Remark 2.6. All the results of this section extend to the case of parabolic operators

$$\frac{\partial}{\partial t} - \sum_{i,j=1}^N a_{ij}(x, t) \frac{\partial^2}{\partial x_i \partial x_j} + \sum_{i=1}^N b_i(x, t) \frac{\partial}{\partial x_i}$$

with $a_{ij} \in C^2$, $b_i \in C^1$; the same is true of the results of the subsequent sections.

Remark 2.7. The results of this section can be extended to the case where $U^0 \geq 0$ on S_T .

3. Generalizations. We begin by extending the results of § 2 to the functional

$$(3.1) \quad J(k) = \sum_{i=1}^m \mu_i \int_D F(x, u(x, t_i)) dx + \iint_{D_T} \Phi(k)$$

where μ_i are given constants and $0 < t_1 < \dots < t_m \leq T$ are given.

Let (k_0, u_0) be a maximizer and let $(k_\varepsilon, u_\varepsilon)$ be a maximizer for the ε -problem. Define Q_ε^i to be the solution of

$$(3.2) \quad \begin{aligned} Q_t + \Delta Q - \beta'_\varepsilon(u_\varepsilon)Q &= 0 \quad \text{in } D_{t_i}, \\ Q(x, t_i) &= F_u(x, u_\varepsilon(x, t_i)) \quad \text{if } x \in D, \\ Q &= 0 \quad \text{on } S_{t_i} \end{aligned}$$

and set

$$(3.3) \quad Q_\varepsilon(x, t) = \sum_{i=1}^m \mu_i Q_\varepsilon^i(x, t) \quad \text{if } (x, t) \in D_{t_i}.$$

Then

$$\begin{aligned} \int_D F_u(x, u_\varepsilon(x, t_i)) z(x, t_i) &= \int_D Q_\varepsilon^i(x, t_i) z(x, t_i) = \iint_{D_{t_i}} (Q_\varepsilon^i z)_t \\ &= \iint_{D_{t_i}} (Q_{\varepsilon,t}^i z + Q_\varepsilon^i z_t) = - \iint_{D_{t_i}} Q_\varepsilon^i L. \end{aligned}$$

Proceeding analogously to Lemma 1.1, we get:

LEMMA 3.1. *If $(k_\varepsilon, u_\varepsilon)$ is a maximizer for the ε -problem corresponding to (3.1) then for any l such that $k_\varepsilon + \delta l \in \mathfrak{a} \forall 0 < \delta < \delta_0$,*

$$\iint_{D_T} (Q^\varepsilon(x, t) - \Phi'(k_\varepsilon) + (k_\varepsilon - k_0))l \geq 0.$$

We can now proceed as in § 2 and prove:

THEOREM 3.2. *Let \mathfrak{a} be given by (2.1). Then for any maximizer (k_0, u_0) for (3.1) there exists a constant λ such that (2.11) holds, where $Q = \lim Q_\varepsilon$ and the Q_ε are given by (3.2), (3.3); the convergence of Q_ε to Q is uniform in compact subsets of Ω_0 .*

Similarly one can extend Theorem 2.2.

Consider next an admissible set

$$(3.4) \quad \mathfrak{a} = \left\{ k \in L^p(D_T), k \geq \delta, \iint_{D_T} k^p(x, t) \leq H \right\}$$

where $\delta > 0$, with functional

$$(3.5) \quad J(k) = \iint_{D_T} F(x, t, u) + \iint_{D_T} k;$$

for simplicity we assume that

$$(3.6) \quad F_u(x, t, u) > 0 \quad \text{if } u > 0.$$

THEOREM 3.3. *For any maximizer k_0 there exists a positive constant μ such that*

$$(3.7) \quad Q - 1 = \mu k_0^{p-1} \quad \text{a.e. in } \Omega_0 \cap \{Q < 1\}.$$

Proof. For the ε -problem we have (cf. [4])

$$(3.8) \quad \begin{aligned} Q_\varepsilon - 1 + k_\varepsilon - k_0 &= -\mu_\varepsilon k_\varepsilon^{p-1} \quad \text{a.e. in } \Omega_\varepsilon \cap \{k_\varepsilon > \delta\}, \\ &\geq 0 \quad \text{a.e. in } \Omega_\varepsilon \cap \{k_\varepsilon = \delta\}, \end{aligned}$$

and $Q_\varepsilon \geq 0$ since $F_u \geq 0$. As in § 2, $Q_\varepsilon \rightarrow Q$ uniformly in compact subsets of Ω_0 , and

$$(3.9) \quad -1 \leq Q_\varepsilon - 1 < -\frac{1}{2} \quad \text{in } (V_{\delta_0} \times (\eta, T)) \setminus G_\varepsilon, \quad \text{meas } G_\varepsilon \rightarrow 0 \quad \text{if } \varepsilon \rightarrow 0,$$

where V_{δ_0} is some δ_0 D -neighborhood of S and η is any positive number; ε is sufficiently small depending on η .

From (3.8), (3.9) and (1.22) it follows that $k_\varepsilon > \delta$ in $(V_{\delta_0} \times (\eta, T)) \setminus G_\varepsilon$ where $\text{meas}(G_\varepsilon) \rightarrow 0$ if $\varepsilon \rightarrow 0$, and $0 < \mu_\varepsilon \leq C$. Integrating the first relation in (3.8) over $(V_{\delta_0} \times (\eta, T)) \setminus G_\varepsilon$, we find that

$$\mu_\varepsilon \iint k_\varepsilon^{p-1} \geq c > 0.$$

Since also $\iint k_\varepsilon^{p-1} \leq C$ for all $k_\varepsilon \in \mathfrak{a}$, we find that $\mu_\varepsilon \geq c > 0$. Hence, for a subsequence, $\mu_\varepsilon \rightarrow \mu$, $0 < \mu < \infty$.

Taking $\varepsilon \rightarrow 0$ in (3.8), (3.7) follows.

Remark 3.1. Theorem 3.1 can be extended to more general $\Phi(k)$ and to other control sets \mathfrak{a} .

Remark 3.2. The results of §§ 2 and 3 can trivially be extended to elliptic variational inequalities. Thus, all the results obtained in [4] are valid also when the condition $F_u > 0$ is dropped.

4. Control on the boundary. In this section we extend the results of the previous sections to problems in which the control occurs on the boundary. For definiteness we take zero initial conditions and Neumann boundary conditions.

Consider the parabolic variational inequality

$$(4.1) \quad \begin{aligned} &\iint_{D_T} u_t(\psi - u) + \iint_{D_T} \nabla u \cdot \nabla(\psi - u) \\ &\geq \iint_{S_T} k(\psi - u) - \iint_{D_T} f(\psi - u) \quad \forall \psi \in K, \quad u \in K \end{aligned}$$

where

$$(4.2) \quad K = \{\psi; \psi \in L^2(0, T; H^1(D)), \psi_t \in L^2(0, T; H^{-1}(D)), \psi(\cdot, 0) = 0, \psi \geq 0 \text{ a.e. in } D_T\}$$

and k is a control variable in the class

$$(4.3) \quad \mathfrak{a} = \left\{ k \in L^\infty(S_T), 0 \leq k \leq M, \iint_{S_T} k = H \right\}.$$

We also introduce the functional

$$(4.4) \quad J(k) = \iint_{D_T} F(x, t, u) + \iint_{S_T} \Phi(k)$$

and consider the problem: Find k_0 such that

$$(4.5) \quad J(k_0) = \max_{k \in \mathfrak{a}} J(k), \quad k_0 \in \mathfrak{a}.$$

We assume that $F(x, t, u)$ satisfies (1.9), (1.12) and that Φ satisfies (1.8), (1.13) with D_T replaced by S_T . We further assume that, for some $\delta_0 > 0$,

$$(4.6) \quad f < 0 \quad \text{in } V_{\delta_0} \times (0, T)$$

where V_δ is a δ D -neighborhood of S .

Let (k_0, u_0) be a solution of (4.5). We introduce the ε -penalized problem

$$(4.7) \quad \begin{aligned} u_t - \Delta u + \beta_\varepsilon(u) &= -f \quad \text{in } D_T, \\ \frac{\partial u}{\partial \nu} &= k \quad \text{on } S_T, \\ u(x, 0) &= 0 \quad \text{if } x \in D. \end{aligned}$$

Denoting by \tilde{u}_ε the solution of (4.7), the corresponding functional for the ε -problem is

$$(4.8) \quad J_\varepsilon(k) = \iint_{D_T} F(x, t, \tilde{u}_\varepsilon) + \iint_{S_T} \Phi(k) - \frac{1}{2} \iint_{S_T} (k_\varepsilon - k_0)^2.$$

Let $(k_\varepsilon, u_\varepsilon)$ be a maximizer for the ε -problem; as in Lemma 1.2, $k_\varepsilon \rightarrow k_0$ strongly in $L^2(S_T)$ and $u_\varepsilon \rightarrow u_0$ uniformly in D_T .

LEMMA 4.1. *If ε is small enough then*

$$(4.9) \quad u_\varepsilon \geq c > 0 \quad \text{in } V_{\delta_0} \times (0, T)$$

for some $c > 0$, $\delta_0 > 0$.

Proof. In the coincidence set of u_0 there holds: $0 \geq -f$, that is $f \geq 0$. In view of (4.6) we conclude that $u_0 > 0$ in $V_{\delta_0} \times (0, T)$. Since further $\partial u_0 / \partial \nu \geq 0$ on S_T , the strong maximum principle shows that $u_0 > 0$ on S_T and, thus, $u_0 \geq 2c > 0$ in $V_{\delta_0} \times (0, T)$. The assertion (4.9) now follows by the uniform convergence of u_ε to u_0 .

Let Q_ε be the solution of

$$(4.10) \quad \begin{aligned} Q_{\varepsilon,t} + \Delta Q_\varepsilon - \beta'_\varepsilon(u_\varepsilon)Q &= -F_u(x, t, u_0) \quad \text{in } D_T, \\ \frac{\partial Q_\varepsilon}{\partial \nu} &= 0 \quad \text{on } S_T, \\ Q_\varepsilon(x, T) &= 0 \quad \text{if } x \in D. \end{aligned}$$

Suppose $k_\varepsilon + \delta l$ is an admissible control for any small $\delta > 0$. Proceeding as in § 2, we deduce that

$$\begin{aligned} 0 &\geq \overline{\lim}_{\delta \rightarrow 0} \frac{1}{\delta} (J_\varepsilon(k_\varepsilon + \delta l) - J_\varepsilon(k_\varepsilon)) \\ &= \overline{\lim}_{\delta \rightarrow 0} \iint_{D_T} F_u(x, t, \tilde{u}_{\varepsilon, \delta}) \frac{u_{\varepsilon, \delta} - u_\varepsilon}{\delta} + \iint_{S_T} \Phi'(k_\varepsilon)l - \iint_{S_T} (k_\varepsilon - k_0)l \\ &= \iint_{S_T} Q_\varepsilon l + \iint_{S_T} \Phi'(k_\varepsilon)l - \iint_{S_T} (k_\varepsilon - k)l. \end{aligned}$$

Thus

$$(4.11) \quad \iint_{S_T} (Q_\varepsilon + \Phi'(k_\varepsilon) - (k_\varepsilon - k))l \leq 0 \quad \text{if } k_\varepsilon + \delta l \in \alpha \quad \forall 0 < \delta < \delta_1.$$

From this we deduce that there is a constant λ_ε and a subset G_ε of S_T of measure $\leq \eta(\varepsilon)$ such that in $S_T \setminus G_\varepsilon$

$$(4.12) \quad k_\varepsilon = \begin{cases} 0 & \text{a.e. on } \{Q_\varepsilon + \Phi'(k_\varepsilon) < \lambda_\varepsilon - \eta(\varepsilon)\}, \\ M & \text{a.e. on } \{Q_\varepsilon + \Phi'(k_\varepsilon) > \lambda_\varepsilon + \eta(\varepsilon)\}, \end{cases}$$

and $\eta(\varepsilon) \rightarrow 0$ if $\varepsilon \rightarrow 0$.

By comparing u_ε with a solution of

$$-\Delta w = C_1 \quad \text{in } D, \quad w_\nu = M \quad \text{on } S$$

where $C_1 > \|f\|_\infty$, we find that

$$(4.13) \quad 0 \leq u_\varepsilon \leq C.$$

Similarly, by comparing Q_ε with a solution of

$$\frac{\partial q}{\partial t} - \Delta q = C_2 \quad \text{in } D_T,$$

$$\frac{\partial q}{\partial \nu} = 0 \quad \text{on } S_T,$$

$$q(x, 0) = q_0,$$

where $C_2 > \sup |F_u|$, we deduce that

$$(4.14) \quad -C \leq Q_\varepsilon \leq C.$$

Making use of Lemma 4.1 and (4.14), we can now go to the limit in (4.12) and deduce:

THEOREM 4.2. *If (k_0, u_0) is a maximizer for (4.5), then there exists a constant λ such that*

$$k_0 = M \quad \text{a.e. in } Q + \alpha_M > \lambda,$$

$$k_0 = 0 \quad \text{a.e. in } Q + \beta_M < \lambda,$$

where $\alpha_M \leq \Phi'(S) \leq \beta_M$ for $0 \leq S \leq M$; in particular, $\alpha_M = \beta_M = 0$ if $\Phi \equiv 0$.

5. An application to the Stefan problem. In this section we consider the Stefan problem in N dimensions, i.e., the problem of melting ice. Given a certain amount of heating energy, we ask: how should we spread it in space and time so as to achieve the largest volume of melted ice? A more precise formulation will be given below. This problem was studied in [5] in case $N = 1$.

Let G (the metal core) be a bounded $C^{2,\alpha}$ domain in \mathbb{R}^N and let E_1 be a domain containing \bar{G} ; set $E = E_1 \setminus \bar{G}$. Let B_R denote a ball of large radius R in \mathbb{R}^N and set $D = B_R \setminus G$.

Physically, E is initially occupied by water and $B_R \setminus E_1$ is occupied by ice at zero temperature. Denote the temperature by θ . Then

$$\theta(x, 0) = h(x) \quad \text{if } x \in E \quad (h > 0)$$

and

$$\theta_t - \Delta \theta = 0 \quad \text{in the water.}$$

On the free boundary $\partial\{\theta > 0\} \cap D_T$ we have $\theta = 0$ as well as the conservation of energy. On the boundary of the core $S \equiv \partial G$

$$(5.1) \quad \frac{\partial \theta}{\partial \nu} = k$$

where ν is the inner normal to ∂G . The left-hand side in (5.1) represents the flux, and k is a control function in the class

$$(5.2) \quad \mathfrak{a} = \left\{ k; k \in L^\infty(S_T), 0 \leq k \leq M, \int \int_{S_T} k = H \right\}.$$

Using the Duvaut transformation

$$u(x, t) = \begin{cases} \int_0^t \theta(x, \tau) d\tau & \text{if } x \in E, \\ \int_{s(x)}^t \theta(x, \tau) d\tau & \text{if } t > s(x), \\ 0 & \text{if } t < s(x) \end{cases}$$

where $t = s(x)$ is the free boundary, one can formally transform the problem into a parabolic variational inequality (for details see [3], [6], [7]):

$$(5.3) \quad \begin{aligned} & \int \int_{D_T} u_t(v - u) + \int \int_{D_T} \nabla u \cdot \nabla(v - u) \\ & \geq \int \int_{S_T} \tilde{k}(v - u) + \int \int_{D_T} f(v - u) \quad \forall v \in K, \quad u \in K \end{aligned}$$

where

$$(5.4) \quad f = \begin{cases} h(x) & \text{if } x \in E, \\ -1 & \text{if } x \in B_R \setminus E, \end{cases}$$

$$(5.5) \quad \tilde{k}(x, t) = \int_0^t k(x, \tau) d\tau$$

and

$$(5.6) \quad K = \{v \in H^1(D_T), v \geq 0 \text{ a.e., } v = 0 \text{ on } \partial B_R \times (0, T), v(\cdot, 0) = 0 \text{ on } D \times \{0\}\}.$$

Using comparison as in [6], [3, p. 87] one can show that if R is chosen sufficiently large (depending on h, M, H, T) then the solution of (5.3) must vanish in a neighborhood of $\partial B_R \times (0, T)$ and, therefore, is independent of the truncating parameter R .

We also have, as in [3], [6], [7], that $u_t \geq 0$ in D_T and $u > 0$ in $\bar{E} \times (0, T)$, and u_t is continuous [3].

The volume of the melted ice at time T is given by

$$\int_D \chi_{\{\theta(x, T) > 0\}} dx = \int_D \chi_{\{u(x, T) > 0\}} dx,$$

which is easily seen (by integrating the variational inequality over $D \times \{T\}$) to be equal to

$$-\int_D u_t(x, T) dx + \text{const.}$$

This functional is not sufficiently regular for our method. We shall therefore average it “slightly,” replacing it by

$$-\frac{1}{h} \int_{T-h}^T \int_D u_t(x, t) dx dt + \text{const.}$$

for any small $h > 0$. Thus the control problem is reduced to minimizing the functional

$$(5.7) \quad J(k) = \int_D u(x, T) dx - \int_D u(x, T_0) dx$$

where $T_0 = T - h$. We shall accordingly replace \mathfrak{a} by

$$(5.8) \quad \mathfrak{a}_{T_0} = \{k \in \mathfrak{a}, k(x, t) = 0 \text{ if } t > T_0\}.$$

Thus the problem is to find k_0 satisfying

$$(5.9) \quad J(k_0) = \min_{k \in \mathfrak{a}_{T_0}} J(k), \quad k_0 \in \mathfrak{a}_{T_0}.$$

Let (k_0, u_0) be a solution of problem (5.9).

Introduce the ε -penalized problem

$$(5.10) \quad \begin{aligned} u_t - \Delta u + \beta_\varepsilon(u) &= f_\varepsilon, \\ u(x, 0) &= u_{0,\varepsilon}(x) \quad \text{if } x \in D, \\ \frac{\partial u}{\partial \nu} &= k \quad \text{on } S_T, \\ u &= 0 \quad \text{on } \partial B_R \times (0, T); \end{aligned}$$

here, as in [3], [6], [7], f_ε is a mollification of f and $u_{0,\varepsilon}$ is a suitably chosen positive function which converges to 0 if $\varepsilon \rightarrow 0$; the functions $\beta_\varepsilon(s)$ are chosen to satisfy

$$(5.11) \quad \begin{aligned} \beta_\varepsilon(s) &= 0 \quad \text{if } s > \varepsilon, \\ \beta'_\varepsilon(s) &= \frac{1}{\varepsilon} \quad \text{if } s < \varepsilon; \end{aligned}$$

notice that $\beta_\varepsilon(0) = -1$. Recall [3], [6] that $\partial u_\varepsilon / \partial t \geq 0$ and thus

$$(5.12) \quad -1 \leq \beta_\varepsilon(u) \leq 0 \quad \text{in } D_T.$$

For the ε -problem the functional is

$$(5.13) \quad J_\varepsilon(k) = J(k) + \frac{1}{2} \iint_{S_T} (k - k_0)^2$$

where the u corresponding to k is the solution of (5.10).

Let $(k_\varepsilon, u_\varepsilon)$ be a minimizer for the ε -problem associated with (5.8), (5.10) and (5.13), (5.7). Denote by Q_ε^T the solution of

$$(5.14) \quad \begin{aligned} Q_t + \Delta Q - \beta'_\varepsilon(u_\varepsilon)Q &= 0 \quad \text{in } D_T, \\ Q_\nu &= 0 \quad \text{on } S_T, \\ Q &= 0 \quad \text{on } \partial B_R \times (0, T), \\ Q(x, T) &= 1 \quad \text{if } x \in D. \end{aligned}$$

Similarly we define $Q_\varepsilon^{T_0}$ and set

$$(5.15) \quad \begin{aligned} \tilde{Q}_\varepsilon &= Q_\varepsilon^T - Q_\varepsilon^{T_0}, \\ W_\varepsilon(x, t) &= \int_t^{T_0} \tilde{Q}_\varepsilon(x, \tau) d\tau. \end{aligned}$$

If $k_\varepsilon + \delta l \in \mathfrak{a}$ for any $0 < \delta < \delta_1$, then proceeding similarly to § 4 we get

$$\iint_{S_{T_0}} \tilde{Q}_\varepsilon \tilde{l} + \iint_{S_{T_0}} (k_\varepsilon - k) l \geq 0$$

where $\tilde{l}(x, t) = \int_0^t l(x, \tau) d\tau$, or

$$(5.16) \quad \iint_{S_{T_0}} (W_\varepsilon + (k_\varepsilon - k)) l \geq 0.$$

Since $u_\varepsilon \geq c > 0$ in $V_{\delta_0} \times (\eta, T)$ where V_{δ_0} is a δ_0 D -neighborhood of S and $\eta > 0$, provided ε is small enough, we deduce, as in § 4, that for a subsequence

$$(5.17) \quad Q_\varepsilon^T \rightarrow Q^T, \quad Q_\varepsilon^{T_0} \rightarrow Q^{T_0} \quad \text{uniformly in } V_{\delta_0} \times (\eta, T_0).$$

LEMMA 5.1. *For any small $\eta > 0$, $\delta_0 > 0$ there exists an $\alpha > 0$ such that*

$$(5.18) \quad Q^T - Q^{T_0} \leq -\alpha \quad \text{in } V_{\delta_0} \times (\eta, T_0).$$

Proof. By the maximum principle $Q_\varepsilon^T(x, T_0) < 1$; hence, by comparison,

$$(5.19) \quad \tilde{Q}_\varepsilon = Q_\varepsilon^T - Q_\varepsilon^{T_0} \leq 0 \quad \text{in } D_{T_0}.$$

Since

$$\frac{\partial}{\partial t} Q_\varepsilon^T + \Delta Q_\varepsilon^T = \beta'_\varepsilon(u_\varepsilon) Q_\varepsilon^T \geq 0,$$

we can compare Q_ε^T with the solution of

$$\begin{aligned} Z_t + \Delta Z &= 0 \quad \text{in } D_T, \\ Z_\nu &= 0 \quad \text{on } S_T, \\ Z &= 0 \quad \text{on } \partial B_R \times (0, T), \\ Z(x, T) &= 0 \quad \text{if } x \in D \end{aligned}$$

and deduce that

$$Q_\varepsilon^T(x, T_0) \leq Z(x, T_0) \leq 1 - \alpha_0 \quad \text{if } x \in D$$

where $\alpha_0 > 0$ is independent of ε . Hence

$$(5.20) \quad \tilde{Q}_\varepsilon(x, T_0) \leq -\alpha_0 \quad \text{if } x \in D.$$

Also

$$\frac{\partial}{\partial t} \tilde{Q}_\varepsilon + \Delta \tilde{Q}_\varepsilon = 0 \quad \text{in } V_{2\delta_0} \times (\eta, T)$$

if ε is small enough (so that $u_\varepsilon \geq c > 0$ in $V_{2\delta_0} \times (\eta, T)$). We compare \tilde{Q}_ε with the solution \tilde{Z} of

$$\frac{\partial}{\partial t} \tilde{Z} + \Delta \tilde{Z} = 0 \quad \text{in } V_{2\delta_0} \times (\eta, T),$$

$$\begin{aligned}\tilde{Z}_\nu &= 0 \quad \text{on } S_{T_0}, \\ \tilde{Z} &= 0 \quad \text{on } (\partial V_{2\delta_0} \cap D) \times (\eta, T), \\ \tilde{Z}(x, T_0) &= -\alpha_0.\end{aligned}$$

When we recall (5.19) and (5.20) it is clear that $\tilde{Q}_\varepsilon \leq \tilde{Z}$. On the other hand, by the maximum principle, $\tilde{Z} \leq -\alpha < 0$ in $V_{\delta_0} \times (\eta, T)$ for some α depending on δ_0 and α_0 . Consequently,

$$(5.21) \quad Q_\varepsilon^T - Q_\varepsilon^{T_0} \leq \tilde{Z} \leq -\alpha \quad \text{in } V_{\delta_0} \times (\eta, T_0)$$

and, taking $\varepsilon \rightarrow 0$, the assertion (5.18) follows.

Set

$$(5.22) \quad W(x, t) = \int_t^{T_0} (Q^T(x, \tau) - Q^{T_0}(x, \tau)) d\tau.$$

From Lemma 5.1 we have that

$$(5.23) \quad W_t(x, t) \geq \alpha \quad \text{in } V_{\delta_0} \times (\eta, T_0).$$

Now, from (5.16) we deduce that there is a subset G_ε of S_T of measure $\leq \delta(\varepsilon)$ such that in $S_T \setminus G_\varepsilon$

$$\begin{aligned}k_\varepsilon &= 0 & \text{if } W_\varepsilon > \lambda_\varepsilon + \eta(\varepsilon), \\ k_\varepsilon &= M & \text{if } W_\varepsilon < \lambda_\varepsilon - \eta(\varepsilon),\end{aligned}$$

and $\delta(\varepsilon) \rightarrow 0$ if $\varepsilon \rightarrow 0$. Going to the limit with $\varepsilon \rightarrow 0$ and proceeding as in § 4 we find that the strong L^2 limit k_0 satisfies:

$$(5.24) \quad \begin{aligned}k_0 &= 0 & \text{if } W > \lambda, \\ k_0 &= M & \text{if } W < \lambda\end{aligned}$$

for some λ . In view of (5.23) we also conclude that

$$(5.25) \quad \begin{aligned}k_0(x, t) &= M & \text{if } 0 < t < \phi(x), \quad x \in S, \\ k_0(x, t) &= 0 & \text{if } \phi(x) < t < T_0, \quad x \in S\end{aligned}$$

for some function $\phi(x)$; further, since W is continuously differentiable on S_{T_0} and W_t is strictly negative, it easily follows that $\phi(x)$ is continuously differentiable about any point x where $\phi(x) > 0$. We have thus proved

THEOREM 5.2. *If (k_0, u_0) is a solution of problem (5.9) then there exists a function $W(x, t)$ defined by (5.22), (5.17) and a continuous function $\phi(x)$ defined for $x \in S$ such that k_0 satisfies (5.24), (5.25); $\phi(x)$ is continuously differentiable on the set $\{\phi > 0\}$.*

We conclude this section by considering the maximum problem for the functional

$$(5.26) \quad J(k) = \iint_{D_T} \theta(x, t) dx dt$$

in the class \mathfrak{a} defined in (5.2); this functional represents the thermal energy of the fluid. Since $\theta = u_t$, we have, up to an additive constant, that

$$(5.27) \quad J(k) = \int_D u(x, T) dx.$$

The maximization problem leads to

$$(5.28) \quad \iint_{S_T} \left[\left(\int_{t_0}^T Q_\varepsilon(x, \tau) d\tau \right) - (k_\varepsilon - k)(x, t) \right] l(x, t) \leq 0$$

if $k_\varepsilon + \delta l \in \alpha$ for all small $\delta > 0$, where Q_ε is the solution of

$$Q_t + \Delta Q - \beta'_\varepsilon(u_\varepsilon)Q = 0 \quad \text{in } D_T,$$

$$Q_\nu = 0 \quad \text{on } S_T,$$

$$Q = 0 \quad \text{on } \partial B_R \times (0, T),$$

$$Q(x, T) = 1 \quad \text{if } x \in D.$$

From this we can deduce, as before, that any maximizer k_0 satisfies (5.24), (5.25), with replaced by the limit (say \tilde{W}) of the functions $\int_{t_0}^T Q_\varepsilon(x, \tau) d\tau$, and $\phi(x)$ is replaced by another continuous function (say $\tilde{\phi}(x)$).

ACAUSAL REALIZATION THEORY, PART I; LINEAR DETERMINISTIC SYSTEMS*

A. J. KRENER†

Abstract. We study acausal linear systems, their controllability and observability properties and the weighting patterns that they realize. A complete classification is given of all minimal real analytic realizations of a given weighting pattern and of all minimal autonomous realizations of a stationary weighting pattern.

Key words. acausal linear systems, controllable and observable on and off, minimal realization

AMS(MOS) subject classifications. 93B20, 34B05, 47A50

1. Introduction. Acausal linear systems theory is concerned with mathematical entities of the form

$$(1.1a) \quad \dot{x} = Ax + Bu,$$

$$(1.1b) \quad V^0 x(t_0) + V^1 x(t_1) = v,$$

$$(1.1c) \quad y = Cx + Du,$$

$$(1.1d) \quad w = W^0 x(t_0) + W^1 x(t_1)$$

where $x(t)$, v , $w \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$ and $y(t) \in \mathbb{R}^p$. The matrices A , B , C , D , V^0 , V^1 , W^0 and W^1 are dimensioned accordingly and A , B , C , D may be bounded measurable functions of t . We refer to $x(t)$ as the *state*, $u(t)$ as the *input* and $y(t)$ the *output* at time t , although t may actually represent a spatial parameter. The vector v is called the *boundary input* and the vector w the *boundary output*. We refer to (1.1) as the acausal system Σ .

We always assume that (1.1a), (1.1b) is a *well-posed problem*, i.e., for every boundary input v and square integrable $u(t)$ there exists a unique solution $x(t)$. In this case (1.1) defines a linear mapping also denoted by Σ .

$$(1.2a) \quad \Sigma: \mathbb{R}^{n \times 1} \times L_2^{m \times 1}[t_0, t_1] \rightarrow \mathbb{R}^{n \times 1} \times L_2^{p \times 1}[t_0, t_1],$$

$$(1.2b) \quad \Sigma: (v, u(t)) \mapsto (w, y(t)).$$

We say that such a mapping is the *input output map* of the acausal system (1.1) or equivalently that the acausal system (1.1) is a *realization* of the input output mapping.

In § 2 we discuss situations where such models naturally arise. Of course (1.1) is a generalization of the usual linear system where $V^0 = W^1 = I$ and $V^1 = W^0 = 0$. Such a system is *causal* because future inputs do not affect past states or outputs. Systems of the form (1.1) do not necessarily have this property, hence the term *acausal*. There are many possible generalizations of (1.1) which are of interest. We shall mention some of these in § 2, but we shall not discuss them in any great depth.

Section 3 is essentially a review of [1] where systems of the form (1.1) were first introduced under the name of *boundary value linear systems*.

In § 4, we exhibit two other processes closely related to $x(t)$ but which are causal in some generalized sense. These processes supply the foundations for the definitions of controllability and observability given in § 5. Also in this section we begin to relate controllability and observability to minimality.

The key results of this paper are found in §§ 6 and 7. The first is a complete classification of all the minimal real analytic realizations of the mapping

$$(v=0, u(\cdot)) \mapsto y(\cdot)$$

induced by (1.1). The second is complete classification of all the minimal autonomous realizations of such maps which are stationary.

Recently Gohberg and Kaashoek [9], [10] have made an excellent study of such systems. Their work is based on completely different concepts of controllability and observability. They do not discuss the question of minimality but treat a different question of irreducibility. At the end of § 5 we give an example that illustrates the differences between their work and ours.

2. Examples and extensions. Acausal systems naturally arise when the independent variable t is spatial rather than temporal. For example, consider a static, approximately horizontal beam, clamped at both ends, which supports a continuously distributed load. We can view this from a system theoretic point of view where the input $u(t)$ is the load density and the output $y(t)$ is the deflection of the beam. ($y(t) > 0$ indicates downward deflection.) The variable t measures length along the beam. The relationship between input and output is given by

$$(2.1) \quad E(t)I(t) \frac{d^4 y}{dt^4} = u(t)$$

where $E(t)$ is the modulus of elasticity and $I(t)$ is the moment of inertia of the cross section. Clamping at both ends imposes boundary conditions on $y(t_0)$, $y(t_1)$, $\dot{y}(t_0)$ and $\dot{y}(t_1)$.

This can be put in state space form (1.1) by letting $x = (x_1, x_2, x_3, x_4) = (y, \dot{y}, \ddot{y}, \dddot{y})$; then

$$\begin{aligned} A &= \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}, & B &= \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1/EI \end{bmatrix}, \\ C &= [1 \ 0 \ 0 \ 0], & D &= [0], \\ V^0 &= \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, & V^1 &= \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}. \end{aligned}$$

A similar example was considered in [2] but with the bending moment as input, which resulted in a second order system.

The acausal nature of this system is apparent, the load at point s affects the deflection at every point t along the beam. One goal of the loading might be to force the beam to assume a desired shape. Such a problem can be cast as a linear quadratic optimal control problem [2].

The boundary condition (1.1) can be used to force $x(t)$ to be *cyclic*, $x(t_0) = x(t_1)$ by letting $V^0 = -V^1$ and $v = 0$. Similarly if $V^0 = V^1$ and $v = 0$ we obtain an *anticyclic* state process $x(t_0) = -x(t_1)$. Such phenomena cannot be modeled by causal systems.

If we drive (1.1) by white Gaussian noise process $u(t)$ and an independent Gaussian boundary value v then we obtain two Gaussian processes $x(t)$ and $y(t)$. If a causal system is so driven, then the state process $x(t)$ is Markov but for most acausal systems the state process is not Markov.

These stochastic systems are a convenient way of representing stochastic processes. We study the associated realization theory in the sequel [4] to this paper. Using this class of models one can formulate and solve various estimation problems for spatially distributed processes [3], [5], [6].

Even processes where the independent variable t is temporal can have an acausal character. These are systems which are anticipatory. There is an intelligent controller who modifies the evolution of the system in order to achieve a desired goal at some future time. This may be on a fixed time interval or over a moving time interval. Most messages are of this type. Before composing the message, the author usually has a fairly clear idea of what the contents should include, and particularly how it should begin and end. Another example is the tracking of an object whose ultimate destination is already known.

Causality is a property of the mapping from inputs $u(\cdot)$ to outputs $y(\cdot)$. Suppose one is studying a system where the inputs and outputs are not known a priori as is frequently the case in network theory. If it is impossible to decide a priori whether the process one wishes to model is causal or not, why restrict a priori to causal models? Besides (1.1), Luenberger's descriptor systems can be used to model acausality [12].

There are numerous extensions of the acausal linear system (1.1) which we will not go into in any depth. A straightforward one is to discretize t or we could let $t_0 = -\infty$ and/or $t_1 = \infty$. A more substantial generalization is to allow t to be a multidimensional variable. Such systems arise in distributed parameter control, image processing, and seismic data processing. It is somewhat surprising considering all the effort that has gone into these areas that one-dimensional acausal systems have not received more study.

Throughout this paper we consider only well-posed systems. This rules out many interesting problems. For example in the stochastic setting, we rule out a pinned Wiener process (Brownian Bridge). Generally we restrict our attention to two point boundary value processes where the solution $x(t)$ of (1.1a) is partially constrained at only two times t_0, t_1 as in (1.1b). But multipoint constrained problems will arise even in this paper. They have wide applicability in many other contexts.

3. Basic facts. Let $\Phi(t, s)$ be $n \times n$ matrix valued function satisfying

$$(3.1a) \quad \frac{\partial}{\partial t} \Phi(t, s) = A(t) \Phi(t, s),$$

$$(3.1b) \quad \Phi(t, t) = I.$$

Since $A(t)$ is assumed to be bounded and measurable, the existence, uniqueness and absolute continuity of $\Phi(t, s)$ follows from standard theorems on ODE's.

The boundary value problem (1.1a), (1.1c) is *well posed* iff the matrix

$$(3.2) \quad F = V^0 + V^1 \Phi(t_1, t_0)$$

is invertible. If this is satisfied then the solution to (1.1a), (1.1b) is given by

$$(3.3) \quad x(t) = \Phi(t, t_0) F^{-1} v + \int_{t_0}^{t_1} G(t, s) B(s) u(s) ds.$$

Green's matrix $G(t, s)$ is given by splicing together two matrix valued functions

$$(3.4a) \quad G(t, s) = \begin{cases} G^0(t, s) & \text{if } t > s, \\ G^1(t, s) & \text{if } s > t \end{cases}$$

along the line $t = s$, where

$$(3.4b) \quad G^0(t, s) = \Phi(t, t_0)F^{-1}V^0\Phi(t_0, s),$$

$$(3.4c) \quad G^1(t, s) = -\Phi(t, t_0)F^{-1}V^1\Phi(t_1, s) = \Phi(t, t_0)F^{-1}(V^0 - I)\Phi(t_0, s).$$

The output $y(t)$ is given by

$$(3.5) \quad y(t) = C(t)\Phi(t, t_0)F^{-1}v + \int_{t_0}^{t_1} W(t, s)u(s) ds$$

where the *weighting pattern* $W(t, s)$ is given by

$$(3.6) \quad W(t, s) = C(t)G(t, s)B(s) + D(t)\delta(t - s).$$

The system (1.1) defines a linear mapping Σ

$$\begin{aligned} \Sigma: \mathbb{R}^{n \times 1} \times L_2^{m \times 1}[t_0, t_1] &\rightarrow \mathbb{R}^{n \times 1} \times L_2^{p \times 1}[t_0, t_1], \\ \Sigma: \begin{pmatrix} v \\ u(\cdot) \end{pmatrix} &\mapsto \begin{pmatrix} w \\ y(\cdot) \end{pmatrix} = \begin{pmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{pmatrix} \begin{pmatrix} v \\ u(\cdot) \end{pmatrix}. \end{aligned}$$

The maps Σ_{11} , Σ_{12} and Σ_{21} are of finite rank since they map from and/or to finite-dimensional vector spaces. The most important part of Σ is the infinite rank part Σ_{22} which maps between the function spaces. The usefulness of the model (1.1) depends ultimately on the fact that it describes an infinite rank mapping in a very concise and tractable fashion.

Suppose we have an integral operator Σ_{22}

$$\begin{aligned} \Sigma_{22}: L_2^{m \times 1}[t_0, t_1] &\rightarrow L_2^{p \times 1}[t_0, t_1], \\ \Sigma_{22}: u(\cdot) &\mapsto y(\cdot) \end{aligned}$$

where

$$y(t) = \int_{t_0}^{t_1} W(t, s)u(s) ds.$$

The system (1.1) is said to be a *realization* of Σ_{22} (or equivalently the kernel $W(t, s)$) if $W(t, s)$ is the *weighting pattern* of (1.1) as given by (3.6). Realization theory (in the deterministic sense) is concerned with the existence and classification of the realizations of $W(t, s)$ and related questions. As an example of such a question consider the adjoint map Σ^* of Σ

$$(3.7a) \quad \Sigma^*: \mathbb{R}^{1 \times n} \times L_2^{1 \times p}[t_0, t_1] \rightarrow \mathbb{R}^{1 \times n} \times L_2^{1 \times m}[t_0, t_1],$$

$$(3.7b) \quad \Sigma^*: (\zeta, \mu(t)) \mapsto (\xi, \nu(t))$$

defined by the equation

$$(3.8) \quad \xi v + \int_{t_0}^{t_1} \nu(t)u(t) dt = \zeta w + \int_0^t \mu(t)y(t) dt$$

for all $(v, u(t))$ and $(\zeta, \mu(t))$. An obvious question is whether Σ^* can be realized by an acausal linear system. As was shown in [1] the following system (given in adjoint

form) does the job. The functions $\lambda(t)$, $\mu(t)$ and $\nu(t)$ are the state, input and output, respectively, ζ denotes the boundary input and ξ the boundary output.

$$(3.9a) \quad \dot{\lambda} = -\lambda A - \mu C,$$

$$(3.9b) \quad \lambda(t_0)M^0 + \lambda(t_1)M^1 = \zeta,$$

$$(3.9c) \quad \nu = \lambda B + \mu D,$$

$$(3.9d) \quad \xi = \lambda(t_0)N^0 + \lambda(t_1)N^1.$$

The boundary matrices are fixed by

$$(3.10) \quad \begin{bmatrix} V^0 & V^1 \\ W^0 & W^1 \end{bmatrix} \begin{bmatrix} -M^0 & -N^0 \\ M^1 & N^T \end{bmatrix} = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}.$$

It is convenient to make a change of coordinates in the space of boundary input values v so that

$$(3.11) \quad F = V^0 + V^1\Phi(t_1, t_0) = I.$$

If V^0 and V^1 satisfy this, then the boundary conditions are in *standard form* and Σ is a *standard realization* of $W(t, s)$. Causal linear systems where $V^0 = I$ and $V^1 = 0$ have boundary conditions in standard form.

Frequently W^0 and W^1 are not explicitly given, but the dual systems can still be determined if one assumes that the dual boundary conditions (3.9c) satisfy the dual of (3.11), i.e.,

$$(3.12) \quad \Phi(t_1, t_0)M^0 + M^1 = I.$$

By equating the upper left blocks of (3.10) and (3.12) we see that

$$(3.13a) \quad M^0 = V^1,$$

$$(3.13b) \quad M^1 = \Phi(t_1, t_0)V^0\Phi(t_0, t_1).$$

These conditions (3.13) are called the *standard dual boundary conditions*.

Notice in the causal case when $V^0 = I$ and $V^1 = 0$, the standard dual boundary conditions are $M^0 = 0$ and $M^1 = I$. Systems with such boundary conditions are said to be *anticausal*, because under time reversal they become causal.

Having computed the standard dual boundary conditions we can in the same way compute the *standard* boundary output equation (1.1d). We assume that

$$(3.14) \quad W^0\Phi(t_0, t_1) + W^1 = I;$$

then this and the lower left block of (3.10) imply that

$$(3.15a) \quad W^0 = \Phi(t_1, t_0)(V^0 - I),$$

$$(3.15b) \quad W^1 = I + \Phi(t_1, t_0)V^1.$$

This normalization has been chosen so that for causal systems $W^0 = 0$ and $W^1 = I$, and the boundary output is $w = x(t_1)$.

It is a simple exercise to verify that for the standard boundary equations (1.1b), (1.1d) the matrix

$$(3.16) \quad \begin{bmatrix} V^0 & V^1 \\ W^0 & W^1 \end{bmatrix}$$

is nonsingular. This means that the boundary inputs and outputs are linearly independent variables. A *standard acausal system* (1.1) is one where the coefficients of the boundary equations (1.1b), (1.1d) satisfy the normalizations (3.11) and (3.14).

As we have seen, (1.1) defines a linear mapping

$$(3.17) \quad \Sigma_{22}: u(t) \mapsto y(t) = \int_{t_0}^{t_1} W(t, s) u(s) ds$$

where

$$(3.18) \quad W(t, s) = C(t)G(t, s)B(s) + D(t)\delta(t - s).$$

A kernel $W(t, s)$ is called *proper* if it is the sum of a bounded measurable term and a Dirac delta term as is (3.18). It is called *strictly proper* if the second term is missing, e.g., $D(t) = 0$. The next theorem is trivial but occasionally useful.

THEOREM 3.1. *A strictly proper $p \times m$ kernel $W(t, s)$ can be realized by an acausal linear system (1.1) iff there exists bounded measurable $p \times n$ and $n \times m$ matrices $C(t)$ and $B(s)$ and $n \times n$ matrices V^0 and V^1 such that*

$$(3.19) \quad V^0 + V^1 = I,$$

$$(3.20) \quad W(t, s) = \begin{cases} C(t)V^0B(s), & t > s, \\ -C(t)V^1B(s), & t < s. \end{cases}$$

Proof. If $C(t)$, $B(s)$, V^0 and V^1 exist then $W(t, s)$ is realized by (1.1) with $A = 0$. On the other hand, if $W(t, s)$ is realized by any acausal system (1.1) then the time dependent change of state coordinates given by $\tilde{x} = \Phi(t_0, t)x$ transforms (1.1) into an acausal system $\tilde{\Sigma}$ where $\tilde{A} = 0$, $\tilde{C}(t) = C(t)\Phi(t, t_0)$ and $\tilde{B}(s) = \Phi(t_0, s)B(s)$. The transformed boundary conditions $\tilde{V}^0 = V^0$ and $\tilde{V}^1 = V^1\Phi(t_1, t_0)$ are in standard form. It is straightforward to verify that $\tilde{\Sigma}$ also realizes $W(t, s)$. Q.E.D.

4. The inward and outward boundary value processes. In general a system of the form (1.1) defines an acausal mapping from $u(\cdot)$ to $y(\cdot)$. The output $y(t)$ at time t depends on the input $u(s)$ at all times $s \in [t_0, t_1]$, not just those $s \in [t_0, t]$ as for causal systems. A natural question to ask is whether there is any causal way of looking at (1.1).

It turns out that a related question is how to view the boundary input condition (1.1c) and the boundary output equation (1.1d). For causal systems the boundary input condition is just $x(t_0) = v$ and the boundary output equation is $w = x(t_1)$. The initial value v can be thought of as the medium which transmits the effects of past controls $u(s)$, $s \in (-\infty, t_0)$ to the state $x(t)$ and output $y(t)$ for $t \in [t_0, t_1]$. The state $x(t)$ and output $y(t)$ can also be determined if w and $u(s)$, $s \in [t, t_1]$ are known. But this is not really an anticausal representation because w depends on v and $u(s)$ for all $s \in [t_0, t_1]$.

We now present a similar interpretation of v and w in the acausal case. We need to introduce moving boundary conditions. Suppose $t_0 \leq \tau_0 \leq \tau_1 \leq t_1$, then define four matrices

$$(4.1a) \quad K^0 = \Phi(\tau_0, t_0)V^0\Phi(t_0, \tau_0),$$

$$(4.1b) \quad K^1 = \Phi(\tau_0, t_0)V^1\Phi(t_1, \tau_1),$$

$$(4.1c) \quad L^0 = \Phi(\tau_1, t_1)W^0\Phi(t_0, \tau_0),$$

$$(4.1d) \quad L^1 = \Phi(\tau_1, t_1)W^1\Phi(t_1, \tau_1).$$

These matrices are functions of τ_0 and τ_1 but for notational simplicity we suppress the arguments. We shall assume that V^0 , V^1 , W^0 and W^1 are in standard form on the interval $[t_0, t_1]$, then it is easy to see that K^0 , K^1 , L^0 and L^1 are in standard form on the interval $[\tau_0, \tau_1]$.

Let $x(t)$ be the solution of (1.1) for some $u(t)$ and v . We define the inward boundary process $k(\tau_0, \tau_1)$ by

$$(4.2) \quad k(\tau_0, \tau_1) = K^0 x(\tau_0) + K^1 x(\tau_1).$$

There are two important points to be made about this process. A simple calculation shows that

$$(4.3) \quad k(\tau_0, \tau_1) = \Phi(\tau_0, t_0)v + \left(\int_{t_0}^{\tau_0} + \int_{\tau_1}^{t_1} \right) G(\tau_0, s)B(s)u(s) ds.$$

We can interpret this as causality in some generalized sense for the mapping $u(\cdot) \mapsto k(\cdot, \cdot)$. Think of the pair $\{\tau_0, \tau_1\}$ as being the present; the past is $[t_0, t_1] \setminus [\tau_0, \tau_1]$ and the future is (τ_0, τ_1) . Then (4.3) says that the present value of $k(\tau_0, \tau_1)$ does not depend on future values of the input $u(\tau)$ for $\tau \in (\tau_0, \tau_1)$.

The second point is that given the present value $k(\tau_0, \tau_1)$ and future values $u(\tau)$, $\tau \in (\tau_0, \tau_1)$ we can compute future values $x(\tau)$ and $y(\tau)$ for $\tau \in (\tau_0, \tau_1)$. This is because the boundary value problem

$$(4.4a) \quad \dot{x} = Ax + Bu, \quad t \in [\tau_0, \tau_1],$$

$$(4.4b) \quad K^0 x(\tau_0) + K^1 x(\tau_1) = k,$$

is well posed, and its solution for given u and v agrees with that of (1.1) on $[\tau_0, \tau_1]$ provided $k = k(\tau_0, \tau_1)$ given by (4.3).

Note that $k(t_0, t_1) = v$ and so v can be thought of as the medium that transmits the effects of $u(s)$ for $s \notin [t_0, t_1]$ to $x(t)$ and $y(t)$ for $t \in [t_0, t_1]$.

If we consider the process $l(\tau_0, \tau_1)$ defined by

$$(4.5) \quad l(\tau_0, \tau_1) = L^0 x(\tau_0) + L^1 x(\tau_1),$$

then

$$(4.6) \quad l(\tau_0, \tau_1) = \Phi(\tau_1, \tau_0)k(\tau_0, \tau_1) + \int_{\tau_0}^{\tau_1} \Phi(\tau_1, s)B(s)u(s) ds.$$

From knowledge of $l(\tau_0, \tau_1)$ and $u(t)$ for $t \in [t_0, t_1] \setminus (\tau_0, \tau_1)$ we can reconstruct $x(t)$ for $t \in [t_0, t_1] \setminus (\tau_0, \tau_1)$ as the solution of the well-posed four point boundary value problem

$$(4.7a) \quad \dot{x} = Ax + Bu, \quad t \in [t_0, t_1] \setminus (\tau_0, \tau_1),$$

$$(4.7b) \quad V^0 x(t_0) + V^1 x(t_1) = v,$$

$$(4.7c) \quad L^0 x(\tau_0) + L^1 x(\tau_1) = l(\tau_0, \tau_1).$$

However the map $u(\cdot) \mapsto l(\cdot, \cdot)$ is not causal in any generalized sense because $l(\tau_0, \tau_1)$ depends on $u(s)$ for all $s \in [t_0, t_1]$.

We have just seen that the inward boundary value process of an acausal system plays a role similar to that of the forward moving state of a causal system. For acausal systems there is also an outward boundary value process which plays the same role as the future jump $x(t_1) - \Phi(t_1, \tau_0)x(\tau_0)$ of the state of a causal process caused by $u(\tau)$ differing from 0 on $[\tau_0, t_1]$.

Given $u(\tau)$ for $\tau \in [\tau_0, \tau_1]$, define $z(\tau)$ and $j(\tau_0, \tau_1)$ by

$$(4.8a) \quad \dot{z} = Az + Bu,$$

$$(4.8b) \quad z(\tau_0) = 0,$$

$$(4.8c) \quad j(\tau_0, \tau_1) = z(\tau_1).$$

The *outward boundary value process* is $j(\tau_0, \tau_1)$ and has two important properties similar to those of $k(\tau_0, \tau_1)$. The first is that

$$j(\tau_0, \tau_1) = \int_{\tau_0}^{\tau_1} \Phi(\tau_1, s) B(s) u(s) ds,$$

so if we think of $\{\tau_0, \tau_1\}$ as the present, $[t_0, t_1] \setminus [\tau_0, \tau_1]$ as the past and (τ_0, τ_1) as the future, then the mapping $u(\cdot) \mapsto j(\tau_0, \tau_1)$ is anticausal. In other words $j(\tau_0, \tau_1)$ does not depend on past values of $u(\tau)$.

The second point is that given the present value $j(\tau_0, \tau_1)$ and past values $u(t)$, $t \in [t_0, t_1] \setminus [\tau_0, \tau_1]$ we can compute past values $x(t)$ and $y(t)$ for $t \in [t_0, t_1] \setminus [\tau_0, \tau_1]$. This is because the solution $x(t)$ of the well-posed four point boundary value problem (4.7a), (4.7b), and

$$(4.7d) \quad -\Phi(\tau_1, \tau_0)x(\tau_0) + x(\tau_1) = j$$

agrees with the solution of (1.1) if $j = j(\tau_0, \tau_1)$ given by (4.8).

We have chosen the letter j for the outward boundary value process because it represents the jump that the state experiences between times τ_0 and τ_1 because of the control $u(t) \neq 0$, $t \in [\tau_0, \tau_1]$.

This suggests another viewpoint on the boundary value v . It is possible that the process $x(t)$ lies on some compactified version of the real line and v is the jump that the state experiences from time t_1 through infinity to time t_0 because of the effects of the control $u(t)$ for $t \notin [t_0, t_1]$.

5. Controllability and observability. Suppose the map $\Sigma: (v, u(\cdot)) \mapsto (w, y(\cdot))$ arises from the state space model (1.1); then it factors into a mapping $(v, u(\cdot)) \mapsto x(\cdot)$ followed by a mapping $x(\cdot) \mapsto (w, y(\cdot))$. It is natural that realization theory be concerned with these factor mappings. The critical issues for the minimality of a realization Σ are whether the first factor is onto and the second is one to one in some sense. In the systems literature this first property is called controllability and the second is called observability. For linear time invariant causal systems any two reasonable definitions of controllability are equivalent. The same holds for any two reasonable definitions of observability. But for time varying and/or nonlinear causal systems there are several nonequivalent definitions whose utility varies with the problem of the moment. Therefore it should come as no surprise that there are at least two useful definitions of both controllability and observability for acausal systems.

The first two definitions relate to the inward boundary value process $k(\tau_0, \tau_1)$.

DEFINITION. The system (1.1) is *controllable off* $[\tau_0, \tau_1]$ if the map

$$(5.1) \quad \{u(t): t \in [t_0, t_1] \setminus [\tau_0, \tau_1]\} \mapsto k(\tau_0, \tau_1) = \left(\int_{t_0}^{\tau_0} + \int_{\tau_1}^{t_1} \right) G(\tau_0, s) B(s) u(s) ds,$$

defined by (4.3) (or equivalently (4.2)) where $v = 0$, is onto.

DEFINITION. The system (1.1) is *observable on* $[\tau_0, \tau_1]$ if the map

$$(5.2) \quad k \mapsto \{y(\tau) = C\Phi(\tau, \tau_0)k: \tau \in [\tau_0, \tau_1]\},$$

defined for $\tau \in [\tau_0, \tau_1]$ by (4.4a), (4.4b) and (1.1c), is 1-1. The control $u(t)$ is assumed to be zero on $[\tau_0, \tau_1]$.

As mentioned before, in a general sense controllability and observability are the two halves of minimality. The next result shows that we are on the right track.

THEOREM 5.1. Let the system (1.1) be a realization of the weighting pattern $W(t, s)$. If there exists τ_0 and τ_1 where $t_0 < \tau_0 < \tau_1 < t_1$ such that (1.1) is controllable off $[\tau_0, \tau_1]$

and observable on $[\tau_0, \tau_1]$, then (1.1) is minimal, i.e., of minimal state dimension among all realizations of $W(t, s)$. Moreover, if $\tilde{\Sigma}$ is any other minimal realization of $W(t, s)$ then $\tilde{\Sigma}$ is also controllable off and observable on $[\tau_0, \tau_1]$.

We defer the proof of this theorem for the moment. To check controllability off $[\tau_0, \tau_1]$ and observability on $[\tau_0, \tau_1]$ we need to compute the Gramians

$$(5.3) \quad \mathcal{C}[\tau_0, \tau_1] = \left(\int_{\tau_0}^{\tau_1} + \int_{\tau_1}^{t_1} \right) G(\tau_0, s) B(s) B^*(s) G^*(\tau_0, s) ds,$$

$$(5.4) \quad \mathcal{O}[\tau_0, \tau_1] = \int_{\tau_0}^{\tau_1} \Phi^*(t, \tau_0) C^*(t) C(t) \Phi(t, \tau_0) dt$$

where $*$ denotes transpose. The following is a standard exercise in linear systems theory; see, for example, Desoer [11] or Brockett [17].

PROPOSITION 5.2. *The system (1.1) is controllable off $[\tau_0, \tau_1]$ iff $\mathcal{C}[\tau_0, \tau_1]$ is positive definite. The system (1.1) is observable on $[\tau_0, \tau_1]$ iff $\mathcal{O}[\tau_0, \tau_1]$ is positive definite.*

Remark. $\mathcal{O}[\tau_0, \tau_1]$ is the observability Gramian of the causal system with the same A and C matrices. Therefore observability on is the same as causal observability.

Proof of Theorem 5.1. Let Σ and $\tilde{\Sigma}$ be realizations of $W(t, s)$. (Σ is given by (1.1) and $\tilde{\Sigma}$ by a similar acausal system with tildes, i.e., \tilde{x} , \tilde{A} , etc.) Since Σ is controllable off $[\tau_0, \tau_1]$, $\mathcal{C}[\tau_0, \tau_1]$ is invertible. Given $k \in \mathbb{R}^n$ define a control $u(t; k)$ with support off (τ_0, τ_1) (i.e., with support in $[t_0, t_1] \setminus (\tau_0, \tau_1)$) by

$$u(t; k) = B^*(t) G^*(\tau_0, t) (\mathcal{C}[\tau_0, \tau_1])^{-1} k.$$

Under (5.1)

$$u(t; k) \mapsto k(\tau^0, \tau^1) = k.$$

If we drive Σ and $\tilde{\Sigma}$ with $u(t; k)$ ($= \tilde{u}(t; k)$) and $v = 0$, $\tilde{v} = 0$, then we obtain $k(\tau_0, \tau_1)$ and $\tilde{k}(\tau_0, \tau_1)$. We have the commuting diagram (Fig. 5.1), which defines a linear mapping

$$T: k(\tau_0, \tau_1) \mapsto \tilde{k}(\tau_0, \tau_1).$$

The outputs $y(t)$ and $\tilde{y}(t)$ of Σ and $\tilde{\Sigma}$ corresponding to $u(t; k)$ must agree. Since the support of $u(t; k)$ is off (τ_0, τ_1) , the output $y(\tau)$ on $[\tau_0, \tau_1]$ is given by (5.2) as a function of $k(\tau_0, \tau_1)$. A similar expression holds for $\tilde{y}(\tau)$ for $\tau \in [\tau_0, \tau_1]$. Therefore we have another commuting diagram (Fig. 5.2). From this we see that the kernel of T is contained in the kernel of the upper right mapping of Fig. 5.2 which is given by (5.2). But this latter kernel is 0 since Σ is observable on $[\tau_0, \tau_1]$.

This shows that the state dimension of $\tilde{\Sigma}$ must be greater than or equal to that of Σ . Hence Σ is minimal. If the dimensions are equal, then T is a linear isomorphism. From this it follows that $\tilde{\Sigma}$ is controllable off and observable on $[\tau_0, \tau_1]$. Q.E.D.

We note for future reference that if Σ is controllable off $[\tau_0, \tau_1]$ but not observable on $[\tau_0, \tau_1]$, the map T is well defined but not necessarily 1-1. Its kernel is contained in the kernel of $\mathcal{O}[\tau_0, \tau_1]$. In particular, for all $t \in [\tau_0, \tau_1]$

$$(5.5) \quad \tilde{C}(t) \tilde{\Phi}(t, \tau_0) T = C(t) \Phi(t, \tau_0).$$

There is an analogous development based on the outward boundary value process $j(\tau_0, \tau_1)$.

DEFINITION. The system (1.1) is *controllable on* $[\tau_0, \tau_1]$ if the map

$$(5.6) \quad \{u(\tau): \tau \in [\tau_0, \tau_1]\} \mapsto j(\tau_0, \tau_1) = \int_{\tau_0}^{\tau_1} \Phi(\tau_1, s) B(s) \dot{u}(s) ds$$

as defined by the system (4.8) is onto.

DEFINITION. The system (1.2) is *observable off* $[\tau_0, \tau_1]$ if the map defined by (4.7a), (4.7b), (4.7d)

$$(5.7) \quad j(\tau_0, \tau_1) \mapsto \{y(t) = C(t)G(t, \tau_1)j(\tau_0, \tau_1) : t \in [t_0, t_1] \setminus (\tau_0, \tau_1)\}$$

is one to one. The control is restricted to be zero off (τ_0, τ_1) .

The associated Gramians are

$$(5.8a) \quad \mathcal{C}[\tau_0, \tau_1] = \int_{\tau_0}^{\tau_1} \Phi(\tau_1, s)B(s)B^*(s)\Phi^*(\tau_1, s) ds,$$

$$(5.8b) \quad \mathcal{O}_{\tau_0, \tau_1} = \left(\int_{t_0}^{\tau_0} + \int_{\tau_1}^{t_1} \right) G^*(t, \tau_1)C^*(t)C(t)G(t, \tau_1) dt.$$

PROPOSITION 5.3. *The system (1.1) is controllable on $[\tau_0, \tau_1]$ iff $\mathcal{C}[\tau_0, \tau_1]$ is positive definite. The system (1.1) is observable off $[\tau_0, \tau_1]$ iff $\mathcal{O}_{\tau_0, \tau_1}$ is positive definite.*

Remark. $\mathcal{C}[\tau_0, \tau_1]$ is the controllability Gramian of the causal system with the same A and B matrices. Therefore controllability on is just causal controllability.

THEOREM 5.4. *Let the system (1.1) be a realization of the weighing pattern $W(t, s)$. If there exists a τ_0 and τ_1 where $t_0 < \tau_0 < \tau_1 < t_1$ such that the system is controllable on $[\tau_0, \tau_1]$ and observable off $[\tau_0, \tau_1]$ then (1.1) is minimal. Moreover if $\tilde{\Sigma}$ is any other minimal realization of $W(t, s)$ then $\tilde{\Sigma}$ is also controllable on and observable off $[\tau_0, \tau_1]$.*

Proof. It is essentially the same as the proof of Theorem 5.1. Let Σ and $\tilde{\Sigma}$ be two realizations of $W(t, s)$. Since Σ is controllable on $[\tau_0, \tau_1]$, $\mathcal{C}[\tau_0, \tau_1]$ is invertible. Given $j \in \mathbb{R}^n$, define a control $u(t; j)$ with support in $[\tau_0, \tau_1]$ by

$$u(t; j) = B^*(t)\Phi^*(\tau_1, t)(\mathcal{C}[\tau_0, \tau_1])^{-1}j;$$

then under (5.6)

$$j \mapsto u(t; j) \rightarrow j(\tau_0, \tau_1) = j.$$

Let $\tilde{j}(\tau_0, \tau_1)$ be the value of the outward boundary value process of $\tilde{\Sigma}$ corresponding to $u(t; j)$. Then we have the commuting diagram (Fig. 5.3), which defines the linear mapping

$$S: j(\tau_0, \tau_1) \mapsto \tilde{j}(\tau_0, \tau_1).$$

The outputs $y(t)$ and $\tilde{y}(t)$ of Σ and $\tilde{\Sigma}$ must agree. Since the support of $u(\tau; j)$ is on $[\tau_0, \tau_1]$, the outputs off (τ_0, τ_1) are functions (5.7) of $j(\tau_0, \tau_1)$, $\tilde{j}(\tau_0, \tau_1)$. Therefore, we have a second commuting diagram (Fig. 5.4). The kernel of S is contained in the kernel of the upper right mapping of Fig. 5.4, given by (5.6). Since Σ is observable off $[\tau_0, \tau_1]$, the latter is zero. Hence S is one to one. The state dimension of $\tilde{\Sigma}$ must be greater than or equal to that of Σ . Hence Σ is minimal. If the dimensions are equal, then S is an isomorphism. From this it follows that $\tilde{\Sigma}$ is controllable on and observable off $[\tau_0, \tau_1]$. Q.E.D.

We note for future reference that if Σ is not controllable on $[\tau_0, \tau_1]$ then the map S can be defined on the range of the map (5.6) which is the range of $\mathcal{C}[\tau_0, \tau_1]$. If Σ is observable off $[\tau_0, \tau_1]$ then on this domain S is 1-1 by the above argument. In particular, for all $s \in [\tau_0, \tau_1]$

$$(5.9) \quad S\Phi(\tau_1, s)B(s) = \tilde{\Phi}(\tau_1, s)\tilde{B}(s).$$

In general the concepts of controllability on and controllability off are independent, i.e., we can construct an example that is one but not the other. A system is *real analytic*

FIG. 5.1

FIG. 5.2

FIG. 5.3

FIG. 5.4

if the matrices A , B , C and D are real analytic functions of t . Of course this includes *autonomous* systems where A , B , C , and D are constant. For real analytic systems, controllability (observability) on implies controllability (observability) off but they are not equivalent.

PROPOSITION 5.5. Suppose (1.1) is a real analytic system and $t_0 < \tau_0 < \tau_1 < t_1$.

(a) If (1.1) is controllable (observable) off some $[\tau_0, \tau_1]$ then it is controllable (observable) off every $[\tau_0, \tau_1]$.

(b) If (1.1) is controllable (observable) on some $[\tau_0, \tau_1]$ then it is controllable (observable) on every $[\tau_0, \tau_1]$.

(c) If (1.1) is controllable (observable) on some $[\tau_0, \tau_1]$ then it is controllable (observable) off every $[\tau_0, \tau_1]$.

Proof. (a) By definition, the Gramian $\mathcal{G}[\tau_0, \tau_1]$ is a real analytic, nonnegative definite matrix valued function of τ_0 and τ_1 . Also it is monotone nonincreasing in $[\tau_0, \tau_1]$, i.e., if $[\sigma_0, \sigma_1] \supseteq [\tau_0, \tau_1]$ then $\mathcal{G}[\sigma_0, \sigma_1] \leq \mathcal{G}[\tau_0, \tau_1]$. Suppose for some τ_0 and τ_1 , $t_0 < \tau_0 < \tau_1 < t_1$, the Gramian $\mathcal{G}[\tau_0, \tau_1]$ is not positive definite then it is also not positive definite for all σ_0 and σ_1 such that $[\sigma_0, \sigma_1] \supseteq [\tau_0, \tau_1]$. For some open set of σ_0 and σ_1 , the determinant of $\mathcal{G}[\sigma_0, \sigma_1]$ is zero. Real analyticity implies it is zero everywhere.

The other parts of (a) and (b) are proved in a similar fashion. (c) Suppose (1.1) is controllable on some $[\tau_0, \tau_1]$; then by (b) it is controllable on every $[\tau_0, \tau_1]$. Suppose it is not controllable off some $[\tau_0, \tau_1]$. Then we can find $0 \neq \lambda \in \mathbb{R}^{1 \times n}$ such that

$$\lambda(\mathcal{G}[\tau^0, \tau^1])\lambda^* = 0.$$

$\mathcal{C}[\tau^0, \tau^1]$ is the sum of two nonnegative definite matrices so λ must annihilate each:

$$\begin{aligned} 0 &= \lambda \int_{t_0}^{\tau_0} G(\tau_0, s) B(s) B^*(s) G^*(\tau_0, s) ds \lambda^* \\ &= \lambda \Phi(\tau_0, t_0) V^0 \Phi(t_0, t_1) \mathcal{C}[t_0, t_1] \Phi^*(t_0, t_1) V^{0*} \Phi^*(\tau_0, t_0) \lambda^*. \end{aligned}$$

Since $\mathcal{C}[t_0, \tau_0]$ is positive definite and $\Phi(t_0, t_1)$ is invertible we observe that

$$0 = \lambda \Phi(\tau_0, t_0) V^0.$$

From the other integral of $\mathcal{C}[\tau^0, \tau^1]$ we derive in a similar fashion that

$$0 = \lambda \Phi(\tau_0, t_0) V^1 \Phi(t_1, t_0).$$

But this implies $\lambda = 0$ for $V^0 + V^1 \Phi(t_1, t_0) = I$.

The other part of (c) is proved similarly. Q.E.D.

While Theorems 5.1 and 5.4 give sufficient conditions for minimality, these conditions are not necessary, as is shown by the following example, similar to one found in [10].

Example 5.6. Let $[t_0, t_1] = [0, 1]$. Consider the acausal system

$$\begin{aligned} \dot{x}_1 &= 0, & x_2(0) + x_1(1) - x_2(1) &= v_1, \\ \dot{x}_2 &= u, & x_2(0) &= v_2, \\ y &= x_1. \end{aligned}$$

It is a simple exercise to verify that this system is controllable and observable off every $[\tau_0, \tau_1]$ but it is not controllable nor observable on any $[\tau_0, \tau_1]$. The Gramians are

$$\begin{aligned} \mathcal{C}[\tau^0, \tau^1] &= \begin{vmatrix} 1 - \tau_1 + \tau_0 & \tau_0 \\ \tau_0 & \tau_0 \end{vmatrix}, & \mathcal{C}[\tau^0, \tau^1] &= \begin{vmatrix} 0 & 0 \\ 0 & \tau_1 - \tau_0 \end{vmatrix}, \\ \mathcal{O}[\tau^0, \tau^1] &= \begin{vmatrix} 1 - \tau_1 & \tau_1 - 1 \\ \tau_1 - 1 & 1 - \tau_1 + \tau_0 \end{vmatrix}, & \mathcal{O}[\tau^0, \tau^1] &= \begin{vmatrix} \tau_1 - \tau_0 & 0 \\ 0 & 0 \end{vmatrix}. \end{aligned}$$

By studying this system we get an understanding of what controllability and observability off $[\tau_0, \tau_1]$ really mean. The boundary conditions allow us to control x_1 in an indirect fashion. For example, to achieve a desired $x(\tau)$, $0 < \tau < 1$, we use the control on $[0, \tau]$ to fix $x_2(\tau)$. We use the control on $[\tau_1, 1]$ to fix $x_2(1)$. The first boundary condition and dynamics imply that $x_1(\tau) = x_2(1)$.

This indirect controllability through the boundary conditions is possible in acausal systems that are controllable off every $[\tau_0, \tau_1]$. Given any $\tau \in (t_0, t_1)$ and any $x^0 \in \mathbb{R}$ there exists a $u(\cdot)$ such that $x(\tau) = x^0$. The controllability off hypothesis implies that the map $u(\cdot) \rightarrow k(\tau, \tau)$ is onto, and it follows immediately from (4.1) and (4.2) that $x(\tau) = k(\tau, \tau)$.

The boundary conditions also allow us to detect jumps or breaks in both state coordinate trajectories even though we can only observe x_1 . For example, if for some unknown reason x_2 jumps at $\tau \in (0, 1)$ ($x_2(\tau^+) - x_2(\tau^-) = j_2$), then this affects $x_1(t)$ through the first boundary condition and we can detect it through $y(t)$.

This indirect observability through the boundary conditions is possible in any system that is observable off every $[\tau_0, \tau_1]$. Given any $\tau \in (t_0, t_1)$ and jump $j = x(\tau^+) - x(\tau^-)$, the mapping $j \rightarrow y(\cdot)$ is one to one. Therefore if we know the time τ of the jump, we can detect it.

The weighting pattern of this system is $W(t, s) = 1$ for all $t, s \in [t_0, t_1]$. From Theorem 3.1 it can be seen that this is a minimal realization of $W(t, s) = 1$. For if Σ is a one-dimensional realization then there exists 1×1 matrices $C(t)$, $B(s)$, V^0 and V^1 such that

$$V^0 + V^1 = 1$$

and

$$1 = C(t)V^0B(s), \quad t > s,$$

$$1 = -C(t)V^1B(s), \quad t < s.$$

The latter equations imply $C(t)$ and $B(s)$ are constant. If one is subtracted from the other we have

$$0 = C(V^0 + V^1)B = CB,$$

so either C or B is zero, a contradiction.

6. Minimal real analytic realizations. In the last section we gave sufficient conditions for minimality. In this one we give necessary and sufficient conditions for a real analytic realization to be minimal within the class of real analytic realizations. We describe how a real analytic realization can be reduced to a minimal real analytic realization, and how minimal real analytic realizations of the same weighting pattern can possibly differ. It may come as a bit of a surprise to readers familiar with causal systems theory that two minimal real analytic realizations can differ by more than a change of coordinates in the state space.

THEOREM 6.1. *Suppose Σ , given by (1.1), is a standard real analytic realization of $W(t, s)$. Σ is a minimal real analytic realization if and only if Σ is controllable and observable off every $[\tau_0, \tau_1]$ and*

$$(6.1) \quad \text{Kernel } \mathcal{O}[t_0, t_1] \subseteq \text{Range } \Phi(t_0, t_1)C[t_0, t_1]\Phi^*(t_0, t_1).$$

Any real analytic realization can be reduced to a minimal real analytic realization. If Σ and $\tilde{\Sigma}$ are two standard minimal real analytic realizations of the same $W(t, s)$, then there exists a real analytic invertible $n \times n$ matrix valued function $R(t)$ such that

$$(6.2a) \quad \tilde{A}(t) = R(t)A(t)R^{-1}(t) + \dot{R}(t)R^{-1}(t),$$

$$(6.2b) \quad \tilde{B}(t) = R(t)B(t),$$

$$(6.2c) \quad \tilde{C}(t) = C(t)R^{-1}(t),$$

$$(6.2d) \quad \tilde{D}(t) = D(t),$$

$$(6.2e) \quad R(t)\Phi(t, s) = \tilde{\Phi}(t, s)R(s),$$

and

$$(6.3a) \quad \mathcal{O}[t_0, t_1](V^0 - R^{-1}(t_0)\tilde{V}^0R(t_0))\Phi[t_0, t_1]\mathcal{G}[t_0, t_1] = 0,$$

$$(6.3b) \quad \mathcal{O}[t_0, t_1](V^1 - R^{-1}(t_0)\tilde{V}^1R(t_1))\mathcal{G}[t_0, t_1] = 0.$$

On the other hand, if Σ is a minimal real analytic realization of $W(t, s)$ and $\tilde{\Sigma}$ satisfies (6.2) and (6.3) for some real analytic invertible $R(t)$, then $\tilde{\Sigma}$ is also a minimal real analytic realization of $W(t, s)$.

Remarks. Condition (6.1) means that any state which is unobservable on $[t_0, t_1]$ must be controllable on $[t_0, t_1]$. Equations (6.2) are the same as those that arise from a time varying change of coordinates $\tilde{x} = R(t)x$, but this is not the whole story because of (6.3). If Σ is both controllable and observable on $[t_0, t_1]$ then (6.3) becomes

$$\tilde{V}^0 = R(t_0)V^0R^{-1}(t_0), \quad \tilde{V}^1 = R(t_0)V^1R^{-1}(t_1).$$

Then (6.2) and (6.3) represent a time varying change of state coordinates $\tilde{x} = R(t)x$ and a corresponding change of coordinates in the space of boundary inputs, $\tilde{v} = R(t_0)v$, so that $\tilde{\Sigma}$ is standard, $\tilde{V}^0 + \tilde{V}^1\tilde{\Phi}(t_1, t_0) = I$. Since $\tilde{\Sigma}$ is standard, (6.3a) and (6.3b) are equivalent.

Proof. Suppose Σ and $\tilde{\Sigma}$ are standard real and analytic realizations of $W(t, s)$. Clearly $D(t) = \tilde{D}(t)$. For simplicity henceforth we assume that $D(t) = 0$. Suppose for some τ_0 and τ_1 , the system Σ is controllable and observable off $[\tau_0, \tau_1]$ and (6.1) is satisfied.

It is convenient to make a time varying change of state coordinate $x_{\text{new}}(t) = \Phi(t_0, t)x_{\text{old}}(t)$ so that in these new coordinates $A(t) = 0$. We make a similar change of coordinates on $\tilde{\Sigma}$ so that $\tilde{A}(t) = 0$. Then $\Phi(t, s) = I$, $\tilde{\Phi}(t, s) = I$ and

$$(6.4a) \quad W(t, s) = C(t)V^0B(s) = \tilde{C}(t)\tilde{V}^0\tilde{B}(s) \quad \text{if } t > s,$$

$$(6.4b) \quad W(t, s) = C(t)(V^0 - I)B(s) = \tilde{C}(t)(\tilde{V}^0 - I)\tilde{B}(s) \quad \text{if } t < s.$$

By real analyticity we conclude that these formulas must hold for all t and s so

$$(6.5) \quad C(t)B(s) = \tilde{C}(t)\tilde{B}(s).$$

Relative to the controllability on and observability on Gramians $\mathcal{C}[t_0, t_1]$ and $\mathcal{O}[t_0, t_1]$, there is a nested family of subspaces of the state space

$$\begin{aligned} \mathbb{R}^n &\supseteq \text{Range}(\mathcal{C}[t_0, t_1]) + \text{Kernel}(\mathcal{O}[t_0, t_1]) \\ &\supseteq \text{Range}(\mathcal{C}[t_0, t_1]) \\ &\supseteq \text{Range}(\mathcal{C}[t_0, t_1]) \cap \text{Kernel}(\mathcal{O}[t_0, t_1]) \supseteq 0. \end{aligned}$$

We can choose coordinates $x = (x_1, x_2, x_3, x_4)$, which respect this flag, i.e.,

$$\text{Range } \mathcal{C}[t_0, t_1] \cap \text{Kernel } \mathcal{O}[t_0, t_1] = \{x: x_i = 0, i = 1, 2, 3\},$$

$$\text{Range } \mathcal{C}[t_0, t_1] = \{x: x_i = 0, i = 1, 2\},$$

$$\text{Range } \mathcal{C}[t_0, t_1] + \text{Kernel } \mathcal{O}[t_0, t_1] = \{x: x_1 = 0\}.$$

This is essentially the Kalman 4 part decomposition of the state space; see Kalman [16] or Desoer [11, p. 187] for more details.

The x_1 and x_3 coordinates are observable and the x_1 and x_2 coordinates are uncontrollable on $[t_0, t_1]$. We make the same change of coordinates in the space of boundary inputs v to ensure that $V^0 + V^1 = I$.

Relative to this partition of x we have that

$$(6.6a) \quad B^*(s) = \begin{pmatrix} 0 & 0 & B_3^*(s) & B_4^*(s) \end{pmatrix},$$

$$(6.6b) \quad C(t) = \begin{pmatrix} C_1(t) & 0 & C_3(t) & 0 \end{pmatrix}.$$

Let d_i be the dimension of x_i ; then $d_1 + d_2 + d_3 + d_4 = n$. Condition (6.1) ensures that $d_2 = 0$.

We make a similar decomposition of the state space of $\tilde{\Sigma}$, $\tilde{x} = (\tilde{x}_1, \tilde{x}_2, \tilde{x}_3, \tilde{x}_4)$ of dimensions $\tilde{d}_1 + \tilde{d}_2 + \tilde{d}_3 + \tilde{d}_4 = \tilde{n}$. Of course \tilde{d}_2 need not be zero.

Relative to this partition of \tilde{x} we have

$$(6.7a) \quad \tilde{B}^*(s) = \begin{pmatrix} 0 & 0 & \tilde{B}_3^*(s) & \tilde{B}_4^*(s) \end{pmatrix},$$

$$(6.7b) \quad \tilde{C}(t) = \begin{pmatrix} \tilde{C}_1(t) & 0 & \tilde{C}_3(t) & 0 \end{pmatrix}.$$

From (6.5), (6.6) and (6.7) we see that

$$(6.8) \quad C_3(t)B_3(s) = \tilde{C}_3(t)\tilde{B}_3(s).$$

We can consider (6.8) as the weighting pattern of a causal system which can be realized on either x_3 or \tilde{x}_3 space. Both these realizations are minimal because the x_3 and \tilde{x}_3 coordinates are both controllable and observable on $[t_0, t_1]$. Hence $d_3 = \tilde{d}_3$.

Now consider the map $T: k(\tau_0, \tau_1) \mapsto \tilde{k}(\tau_0, \tau_1)$ constructed in the proof of Theorem 5.1. Since Σ is controllable off $[\tau_0, \tau_1]$, T is well defined but it need not be one to one. Restricted to the range of $\mathcal{O}[\tau_0, \tau_1]$, it is one to one. The ranks of $\mathcal{O}[\tau_0, \tau_1]$ and $\tilde{\mathcal{O}}[\tau_0, \tau_1]$ are $d_1 + d_3$ and $\tilde{d}_1 + \tilde{d}_3$, respectively. The counting diagram (Fig. 5.2) implies that $d_1 + d_3 \leq \tilde{d}_1 + \tilde{d}_3$. Since $d_3 = \tilde{d}_3$ this implies that $d_1 \leq \tilde{d}_1$.

Next consider the map $S: j(\tau_0, \tau_1) \mapsto \tilde{j}(\tau_0, \tau_1)$ of Theorem 5.4. This is not defined for all $j(\tau_0, \tau_1)$ but only those in the range of $\mathcal{C}[\tau_0, \tau_1]$. On this domain it is one to one. The ranks of $\mathcal{C}[\tau_0, \tau_1]$ and $\tilde{\mathcal{C}}[\tau_0, \tau_1]$ are $d_3 + d_4$ and $\tilde{d}_3 + \tilde{d}_4$, respectively. The commuting diagram (Fig. 5.4) implies that $d_3 + d_4 \leq \tilde{d}_3 + \tilde{d}_4$ and hence $d_4 \leq \tilde{d}_4$.

We have shown that $d_i \leq \tilde{d}_i$ for $i = 1, 2, 3, 4$ so $n \leq \tilde{n}$ and hence Σ is minimal.

Suppose $\Sigma(t, s)$ is any standard real analytic realization of $W(t, s)$; we now show that Σ can be reduced to obtain a lower-dimensional realization of $W(t, s)$ which is controllable and observable off every $[\tau_0, \tau_1]$ and such that (6.1) is satisfied. In this manner we see that if a realization is minimal it is controllable and observable off every $[\tau_0, \tau_1]$, and every state unobservable on $[\tau_0, \tau_1]$ is controllable on $[\tau_0, \tau_1]$.

We assume that we have made the preliminary change of state coordinates so that $A(t) = 0$. Suppose Σ is controllable and observable off every $[\tau_0, \tau_1]$. We decompose the state space relative to the Gramians $\mathcal{C}[t_0, t_1]$ and $\mathcal{O}[t_0, t_1]$ as above.

The x_2 coordinate is irrelevant to the weighting pattern of the system. From (6.6) we have that

$$W(t, s) = \begin{cases} \sum_{i=1,3} \sum_{j=3,4} C_i(t) V_{ij}^0 B_j(s) & \text{if } t > s, \\ -\sum_{i=1,3} \sum_{j=3,4} C_i(t) V_{ij}^1 B_j(s) & \text{if } t < s. \end{cases}$$

Therefore we can delete x_2 and the second boundary condition. The new system satisfies (6.1) so we obtain a new realization of $W(t, s)$, of lower dimension, which is minimal among real analytic realizations.

Suppose Σ is not controllable or not observable off every $[\tau_0, \tau_1]$; then we can reduce it to one that is. We decompose the state space into 4 parts relative to Gramians $\mathcal{C}[\tau_0, \tau_0]$ and $\mathcal{O}[\tau_0, \tau_0]$ for any $t_0 < \tau_0 < \tau_1 < t_1$. We obtain a flag of subspaces

$$\begin{aligned} \mathbb{R}^n &\supseteq \text{Range}(\mathcal{C})_{\tau_0, \tau_1}] + \text{Kernel}(\mathcal{O})_{\tau_0, \tau_1}] \\ &\supseteq \text{Range}(\mathcal{C})_{\tau_0, \tau_1}] \\ &\supseteq \text{Range}(\mathcal{C})_{\tau_0, \tau_1}] \cap \text{Kernel}(\mathcal{O})_{\tau_0, \tau_1}] \supseteq 0. \end{aligned}$$

As before we choose coordinates $x = (x_1, x_2, x_3, x_4)$ which respect this flag and we make the same change of coordinates in the space of boundary values v to keep the system in standard form.

From the choice of coordinates

$$G(t, s)B(s) = V^i B(s) = \begin{bmatrix} 0 \\ 0 \\ * \\ * \end{bmatrix} \quad \text{where } i = 0 \text{ if } t > s \text{ and } i = 1 \text{ if } t < s,$$

and

$$C(t)G(t, s) = C(t)V^i = [* \ 0 \ * \ 0] \quad \text{where } i = 0 \text{ if } t > s \text{ and } i = 1 \text{ if } t < s.$$

Since $V^0 + V^1 = I$ we obtain

$$(6.9a) \quad B(s) = \begin{bmatrix} B_1(s) \\ B_2(s) \\ B_3(s) \\ B_4(s) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ * \\ * \end{bmatrix},$$

$$(6.9b) \quad C(t) = [C_1(t)C_2(t)C_3(t)C_4(t)] = [* \ 0 \ * \ 0],$$

$$(6.9c) \quad V^i B(s) = \begin{bmatrix} V_{13}^i B_3(s) + V_{14}^i B_4(s) \\ V_{23}^i B_3(s) + V_{24}^i B_4(s) \\ V_{33}^i B_3(s) + V_{34}^i B_4(s) \\ V_{44}^i B_3(s) + V_{44}^i B_4(s) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ * \\ * \end{bmatrix},$$

$$(6.9d) \quad \begin{aligned} C(t)V^i &= [C_1(t)V_{11}^i + C_3(t)V_{31}^i; C_1(t)V_{12}^i + C_3(t)V_{32}^i; \\ &\quad C_1(t)V_{13}^i + C_3(t)V_{33}^i; C_1(t)V_{14}^i + C_3(t)V_{34}^i] \\ &= [* \ 0 \ * \ 0]. \end{aligned}$$

We can calculate $W(t, s)$ from (6.9a), (6.9d) as

$$(6.10a) \quad W(t, s) = \begin{cases} C_1(t)V_{13}^0 B_3(s) + C_3(t)V_{33}^0 B_3(s), & t > s, \\ -C_1(t)V_{13}^1 B_3(s) - C_3(t)V_{33}^1 B_3(s), & t < s \end{cases}$$

or from (6.9b), (6.9c) as

$$(6.10b) \quad W(t, s) = \begin{cases} C_3(t)V_{33}^0 B_3(s) + C_3(t)V_{34}^0 B_4(s), & t > s, \\ -C_3(t)V_{33}^1 B_3(s) - C_3(t)V_{34}^1 B_4(s), & t < s. \end{cases}$$

Equation (6.10a) shows that the x_2 and x_4 coordinates are unnecessary to realize $W(t, s)$, so we delete them and the corresponding boundary conditions to obtain a new system which is observable off every $[\tau_0, \tau_1]$. From the first component of (6.9c) we see that $V_{13}^i B_3(s) = 0$ so we can delete the x_1 coordinate and realize $W(t, s)$ by

$$(6.11a) \quad \dot{x}_3 = B_3 u,$$

$$(6.11b) \quad V_{33}^0 x_3(t_0) + V_{33}^1 x_3(t_1) = v_3,$$

$$(6.11c) \quad y = C_3 x_3.$$

This realization is controllable and observable off every $[\tau_0, \tau_1]$. As previously seen, such realizations can be further reduced so that (6.1) holds, thereby obtaining a minimal real analytic realization.

Next we study the relationship between minimal real analytic realizations. Let Σ and $\tilde{\Sigma}$ be two standard minimal real analytic realizations of $W(t, s)$. Hence they are controllable and observable off every $[\tau_0, \tau_1]$ and (6.1) is satisfied. We transform

state coordinates on Σ and $\tilde{\Sigma}$ as in the first part of the proof so that $A(t) = \tilde{A}(t) = 0$ and $x = (x_1, x_3, x_4)$, $\tilde{x} = (\tilde{x}_1, \tilde{x}_3, \tilde{x}_4)$. Because they are minimal $d_i = \tilde{d}_i$, $i = 1, 3, 4$ and $d_2 = \tilde{d}_2 = 0$.

The decomposition of the state space induces a similar decomposition of the boundary value processes, $k = (k_1, k_3, k_4)$, $\tilde{k} = (\tilde{k}_1, \tilde{k}_3, \tilde{k}_4)$, $j = (j_1, j_3, j_4)$ and $\tilde{j} = (\tilde{j}_1, \tilde{j}_3, \tilde{j}_4)$. We consider the maps T and S in more detail. If $k \in \text{kernel } \mathcal{O}[\tau_0, \tau_1]$ then $T(k) = \tilde{k} \in \text{kernel } \tilde{\mathcal{O}}[\tau_0, \tau_1]$, so $\tilde{k} = Tk$ is given by

$$(6.12) \quad \begin{pmatrix} \tilde{k}_1 \\ \tilde{k}_3 \\ \tilde{k}_4 \end{pmatrix} = \begin{pmatrix} T_{11} & T_{13} & 0 \\ T_{31} & T_{33} & 0 \\ T_{41} & T_{43} & T_{44} \end{pmatrix} \begin{pmatrix} k_1 \\ k_3 \\ k_4 \end{pmatrix}.$$

By the commuting diagram (Fig. 5.2) the upper left 2×2 block of T is invertible.

On the other hand S is only defined on the range of $C[\tau_0, \tau_1]$ (i.e. $j = (0, j_3, j_4)$), but it is one to one. So $\tilde{j} = S(0, j_3, j_4)$ is given by

$$(6.13) \quad \begin{pmatrix} \tilde{j}_1 \\ \tilde{j}_3 \\ \tilde{j}_4 \end{pmatrix} = \begin{pmatrix} 0 & S_{13} & S_{14} \\ 0 & S_{33} & S_{34} \\ 0 & S_{43} & S_{44} \end{pmatrix} \begin{pmatrix} 0 \\ j_3 \\ j_4 \end{pmatrix}$$

where the matrix is of rank $d_3 + d_4$.

From (5.5) and (5.9) we have

$$(6.14a) \quad C(t) = \tilde{C}(t)T,$$

$$(6.14b) \quad \tilde{B}(s) = SB(s),$$

so (6.5) becomes

$$(6.15) \quad \tilde{C}(t)TB(s) = \tilde{C}(t)SB(s).$$

If we multiply by $\tilde{C}^*(t)$ and $B^*(s)$ and integrate we obtain

$$(6.16) \quad \tilde{\mathcal{O}}[t_0, t_1](T - S)\mathcal{C}[t_0, t_1] = 0.$$

This implies that $T_{ij} = S_{ij}$ for $i = 1, 3$ and $j = 3, 4$. We define an $n \times n$ matrix R by

$$(6.17) \quad R = \begin{bmatrix} T_{11} & T_{13} & 0 \\ T_{31} & T_{33} & 0 \\ T_{41} & S_{43} & S_{44} \end{bmatrix}.$$

Since $S_{14} = T_{14} = 0$ and $S_{34} = T_{34} = 0$, S_{44} must be invertible for S to be of rank $d_3 + d_4$. The upper left 2×2 block of R is from T , hence is invertible. This shows that R is invertible. Since R agrees with T in rows indexed by 1 and 3, from (6.7b) and (6.14a) we see that

$$(6.18a) \quad C(t) = \tilde{C}(t)R.$$

Since R agrees with S in columns indexed by 3 and 4, from (6.7a) and (6.14b) we see that

$$(6.18b) \quad \tilde{B}(t) = RB(t).$$

From (6.4a) and (6.18), we obtain

$$C(t)V^0B(s) = C(t)R^{-1}\tilde{V}^0RB(s).$$

We multiply on both sides and integrate to obtain

$$(6.19) \quad \mathcal{O}[t_0, t_1](V^0 - R^{-1}\tilde{V}^0R)C[t_0, t_1] = 0.$$

Let $\Phi(t, s)$ and $\tilde{\Phi}(t, s)$ denote the fundamental solutions for Σ and $\tilde{\Sigma}$ in their original state coordinates. Define

$$(6.20) \quad R(t) = \tilde{\Phi}(t, t_0) R \Phi(t_0, t);$$

then it is straightforward but tedious to verify (6.2) and (6.3) from (6.18), (6.19) and (6.20).

On the other hand suppose Σ and $\tilde{\Sigma}$ are two systems related by (6.2) and (6.3). Then if $t > s$ the weighting pattern of $\tilde{\Sigma}$ is given by

$$\begin{aligned} \tilde{W}(t, s) &= \tilde{C}(t) \tilde{\Phi}(t, t_0) \tilde{V}^0 \tilde{\Phi}(t_0, s) \tilde{B}(s) \\ &= C(t) \Phi(t, t_0) V^0 \Phi(t_0, s) B(s) + C(t) \Phi(t, t_0) (V^0 - R^{-1}(t_0) \tilde{V}^0 R(t_0)) \Phi(t_0, s) B(s). \end{aligned}$$

But (6.2a) implies that this second term is zero, so $\tilde{W}(t, s) = W(t, s)$ for $t > s$. A similar calculation holds for $t < s$. Q.E.D.

Suppose Σ is a minimal realization of $W(t, s)$ and we choose state coordinates as before so that $A(t) = 0$ and $x = (x_1, x_3, x_4)$ respects the flag of subspaces associated to $\mathcal{C}[t_0, t_1]$ and $\mathcal{O}[t_0, t_1]$. Since $V^0 + V^1 = I$

$$(6.21a) \quad W(t, s) = \sum_{i=1,3} \sum_{j=3,4} C_i(t) V_{ij}^0 B_j(s) \quad \text{if } t > s,$$

$$(6.21b) \quad W(t, s) = \sum_{i=1,3} \sum_{j=3,4} C_i(t) (V^0 - I)_{ij} B_j(s) \quad \text{if } t < s.$$

Then

$$(6.22a) \quad W(t, s) = W_1(t, s) + W_2(t, s),$$

$$(6.22b) \quad W_1(t, s) = \begin{cases} C_3(t) V_{33}^0 B_3(s), & t > s, \\ C_3(t) (V_{33}^0 - I) B_3(s), & t < s \end{cases}$$

and for all t, s

$$(6.23) \quad W_2(t, s) = C_1(t) V_{13}^0 B_3(s) + C_1(t) V_{14}^0 B_4(s) + C_3(t) V_{34}^0 B_4(s).$$

Each kernel $W_i(t, s)$ defines a mapping

$$u(t) \mapsto y_i(t) = \int_{t_0}^{t_1} W_i(t, s) u(s) ds.$$

The first kernel $W_1(t, s)$ defines a mapping of infinite rank which can be realized on x_3 space. The second kernel $W_2(t, s)$ defines a mapping of finite rank

$$y_2(t) = C_1(t) V_{13}^0 \int_{t_0}^{t_1} B_3(s) u(s) ds + (C_1(t) V_{14}^0 + C_3(t) V_{34}^0) \int_{t_0}^{t_1} B_4(s) u(s) ds.$$

There is an alternate decomposition of $W(t, s)$:

$$(6.24a) \quad W(t, s) = \tilde{W}_1(t, s) + \tilde{W}_2(t, s)$$

where

$$(6.24b) \quad \tilde{W}_1(t, s) = \begin{cases} C_3(t) B_3(s), & t > s, \\ 0, & t < s, \end{cases}$$

$$(6.24c)$$

$$\tilde{W}_2(t, s) = C_1(t) V_{13}^0 B_3(s) + C_1(t) V_{14}^0 B_4(s) + C_3(t) (V_{33}^0 - I) B_3(s) + C_3(t) V_{34}^0 B_4(s).$$

$\tilde{W}_1(t, s)$ is a causal weighing pattern which can be realized on \tilde{x}_3 space. As before, \tilde{W}_1 and \tilde{W}_2 are maps of infinite and finite rank, respectively.

In their excellent study of acausal systems, Gohberg and Kaashoek [9], [10] have introduced the concepts of multicontrollability and multiobservability, which are different generalizations of causal controllability and observability from those discussed above. The following example is a slight modification of one found in [10, § II.1 and illustrates some of the differences between their work and ours.

Example 6.2. Let $[t_0, t_1] = [0, 1]$.

$$\dot{x}_1 = 0, \quad x_2(0) + x_1(1) - x_2(1) = v_1,$$

$$\dot{x}_2 = 0, \quad x_2(0) + x_3(0) - x_3(1) = v_2,$$

$$\dot{x}_3 = u, \quad x_3(0) = v_3,$$

$$y = x_1.$$

Gohberg and Kaashoek associate with an acausal system a sequence of weighting patterns of which $W(t, s)$ given by (3.6) is the first. Relevant to these weighting patterns are the concepts of multicontrollability and multiobservability. This example is a 3 controllable and 3 observable system. They show that such systems are irreducible under similarity and reduction and are characterized up to similarity by their sequence of weighting patterns. They do not discuss minimality.

By our definition this system is not controllable nor observable off any $[\tau_0, \tau_1]$ and (6.1) is not satisfied. Therefore by Theorem 6.1 it is not minimal among real analytic realizations. If we reduce it as described above we arrive at the trivial system of state dimension 0. The weighting pattern (3.6) is $W(t, s) = 0$, but the other weighting patterns of Gohberg and Kaashoek are not all zero.

7. Autonomous and stationary systems. An acausal linear system is *autonomous* if A, B, C, D are constant with respect to t . The transition matrix and Green's matrix are given by

$$(7.1) \quad \Phi(t, s) = e^{(t-s)A},$$

$$(7.2a) \quad G(t, s) = e^{(t-t_0)A} V^0 e^{(t_0-s)A} \quad \text{if } t > s,$$

$$(7.2b) \quad G(t, s) = -e^{(t-t_0)A} V^1 e^{(t_1-s)A} \quad \text{if } t < s.$$

From this it is easy to give alternate tests for controllability and observability.

PROPOSITION 7.1. Let Σ be an autonomous acausal system and $t_0 < \tau_0 < \tau_1 < t_1$:

(a) Σ is controllable on $[\tau_0, \tau_1]$ iff the matrix

$$(7.3a) \quad \mathcal{C} = [B, \dots, A^{n-1}B]$$

is of rank n .

(b) Σ is controllable off $[\tau_0, \tau_1]$ iff the matrix

$$(7.3b) \quad \mathcal{C}^b = [V^0 B, \quad V^1 B, \quad \dots, \quad V^0 A^{n-1} B, \quad V^1 A^{n-1} B]$$

is of rank n .

(c) Σ is observable on $[\tau_0, \tau_1]$ iff the matrix

$$(7.3c) \quad \mathcal{O} = \begin{bmatrix} C \\ \vdots \\ CA^{n-1} \end{bmatrix}$$

is of rank n .

(d) Σ is observable off $[\tau_0, \tau_1]$ iff the matrix

$$(7.3d) \quad \mathcal{O}^b = \begin{bmatrix} CV^0 \\ CV^1 \\ \vdots \\ CA^{n-1}V^0 \\ CA^{n-1}V^1 \end{bmatrix}$$

is of rank n .

(e) Condition (6.1) is satisfied iff

$$(7.3e) \quad \text{Kernel } \mathcal{O} \text{ Range } \mathcal{C}.$$

Proof. Assertion (a) and (c) are well known from the causal theory, and (e) is straightforward. We only prove (b) since the proof of (d) is essentially the same. Suppose (7.3b) fails; then there exists an $1 \times n$ vector $\lambda \neq 0$ such that

$$(7.4) \quad \lambda V^0 A^k B = \lambda V^1 A^k B = 0$$

for any $k \geq 0$ (by Cayley-Hamilton). Hence for any t

$$(7.5) \quad \lambda V^0 e^{At} B = \lambda V^1 e^{At} B = 0.$$

Now for any $t_0 < \tau_0 < \tau_1 < t_1$,

$$(7.6) \quad \begin{aligned} 0 &= \lambda \Phi(t_0, \tau_0)(\mathcal{C})\tau_0, \tau_1[\Phi^*(t_0, \tau_0)\lambda^* \\ &= \int_{t_0}^{\tau_0} \lambda V^0 e^{A(t_0-s)} BB^* e^{A^*(t_0-s)} V^{0*} \lambda^* ds \\ &\quad + \int_{\tau_1}^{t_1} \lambda V^1 e^{A(t_1-s)} BB^* e^{A^*(t_1-s)} V^{1*} \lambda^* ds. \end{aligned}$$

Therefore $\mathcal{C}[\tau_0, \tau_1]$ is not positive definite and the system is not controllable off $[\tau_0, \tau_1]$.

On the other hand, if there exists λ such that (7.6) holds for all $t_0 < \tau_0 < \tau_1 < t_1$, then (7.5) must hold. Differentiating (7.5) yields (7.4). Q.E.D.

Gohberg and Kaashoek [13] have demonstrated that a weighting pattern can have a minimal autonomous realization and a minimal real analytic realization of lower dimension. They showed that the weighting pattern $W(t, s) = 1 - s$ has this property. Their realizations are as follows.

Example 7.2. Let $[t_0, t_1] = [0, 1]$.

$$\begin{aligned} \dot{x}_1 &= 0, & x_2(0) + x_3(0) + x_1(1) - x_2(1) &= v_1, \\ \dot{x}_2 &= x_3, & x_2(0) &= v_2, \\ \dot{x}_3 &= u, & x_3(0) &= v_3, \\ y &= x_1. \end{aligned}$$

The system is controllable off any $[\tau_0, \tau_1]$ but not observable off any $[\tau_0, \tau_1]$, where $0 < \tau_0 < \tau_1 < 1$. Therefore by Theorem 6.1 it is not a minimal realization within the class of real analytic realizations. In fact $W(t, s) = 1 - s$ can also be realized by the following.

Example 7.3. Let $[t_0, t_1] = [0, 1]$.

$$\begin{aligned} \dot{x}_1 &= (1-t)u, & x_1(0) &= v_1, \\ \dot{x}_2 &= (1-t)u, & x_2(1) &= v_2, \\ y &= x_1 - x_2. \end{aligned}$$

This is controllable and observable off every $[\tau_0, \tau_1]$ and (6.1) is satisfied. Hence by Theorem 6.1 this is a minimal real analytic realization of $W(t, s) = 1 - s$. Moreover the other minimal real analytic realizations of $W(t, s)$ are described by this theorem. If one of them were autonomous there would exist an invertible 2×2 matrix $R(t)$ such that for some constant matrices $\tilde{A}, \tilde{B}, \tilde{C}$

$$(7.7a) \quad \tilde{A} = \dot{R}(t)R^{-1}(t),$$

$$(7.7b) \quad \tilde{B} = R(t) \begin{pmatrix} 1-t \\ 1-t \end{pmatrix},$$

$$(7.7c) \quad \tilde{C} = (1 - 1)R^{-1}(t).$$

Without loss of generality we can assume that $R(0) = I$ so $\tilde{B} = (1 \ 1)^*$ and $\tilde{C} = (1 \ -1)$. Equation (7.7b) implies that \tilde{B} is an eigenvector of $R(t)$ with eigenvalue $1/(1-t)$. On the other hand, equation (7.7a) implies that $R(t) = e^{\tilde{A}t}$ and hence $1/(1-t)$ cannot be an eigenvalue of $R(t)$. We conclude that there are no two-dimensional autonomous realizations of $W(t, s) = 1 - s$ but there are two-dimensional real analytic realizations.

We were a bit surprised by these examples for we had conjectured the opposite, namely that the class of autonomous models admitted a self-contained minimal realization theory. Being autonomous is a property of the system and not of the weighting pattern. Therefore we should have expected that we need a "nice" class of weighting patterns to obtain a self-contained minimal realization theory. The stationary weighting patterns are such a class.

A weighting pattern $W(t, s)$ is *stationary* if it is only a function of $t - s$, in abuse of notation $W(t, s) = W(t - s)$. An acausal linear system is *stationary* if it is autonomous and its weighting pattern is stationary. Every autonomous causal system is stationary, and hence the stationary acausal systems generalize the autonomous causal systems. The corollary to the following theorem was first stated in [3]; see also [9], [10].

PROPOSITION 7.4. *A standard autonomous acausal linear system is stationary iff for all $k, l = 0, \dots, n-1$.*

$$(7.8a) \quad CA^k[A, V^0]A^lB = 0,$$

$$(7.8b) \quad CA^k[A, V^1]A^lB = 0$$

where $[A, V^i] = AV^i - V^iA, i = 1, 2$.

Proof. Suppose the system is stationary; then

$$(7.9) \quad Ce^{A(t-t_0)}V^0e^{A(t_0-s)}B = Ce^{A(t+r-t_0)}V^0e^{A(t_0-r-s)}B.$$

If we differentiate this with respect to r at $r = 0$ we obtain

$$(7.10) \quad 0 = Ce^{A(t-t_0)}[A, V^0]e^{A(t_0-s)}B.$$

Differentiation of this with respect to t and s one or more times yields (7.8). The steps are reversible, so the converse holds. Q.E.D.

COROLLARY 7.5. *Suppose Σ is a standard autonomous acausal system which is controllable and observable on $[t_0, t_1]$. Σ is stationary iff*

$$(7.11a) \quad [A, V^0] = 0,$$

$$(7.11b) \quad [A, V^1] = 0.$$

The Gohberg-Kaashoek phenomenon cannot happen for stationary weighting patterns; in other words, a minimal autonomous realization is also a minimal real analytic realization.

THEOREM 7.6. (i) Suppose Σ (1.1) is a standard stationary realization of a stationary weighting pattern $W(t-s)$. Σ is a minimal stationary (equivalently, autonomous) realization iff

$$(7.12a) \quad \text{rank } \mathcal{C}^b = n,$$

$$(7.12b) \quad \text{rank } \mathcal{O}^b = n,$$

$$(7.12c) \quad \text{Kernel } \mathcal{O} \subseteq \text{Range } \mathcal{C}.$$

(ii) A minimal stationary realization is also a minimal real analytic realization.

(iii) Any stationary realization can be modified and reduced to a minimal stationary realization.

(iv) Suppose Σ and $\tilde{\Sigma}$ are stationary minimal realizations of $W(t-s)$ then there exists an invertible constant matrix R such that

$$(7.13a) \quad (A - R^{-1}\tilde{A}R)\mathcal{C} = 0,$$

$$(7.13b) \quad \mathcal{O}(A - R^{-1}\tilde{A}R) = 0,$$

$$(7.13c) \quad \tilde{B} = RB,$$

$$(7.13d) \quad \tilde{C} = CR^{-1},$$

$$(7.13e) \quad \tilde{D} = D$$

and

$$(7.14a) \quad \mathcal{O}(V^0 - R^{-1}\tilde{V}^0R)\mathcal{C} = 0,$$

$$(7.14b) \quad \mathcal{O}(V^1 - R^{-1}\tilde{V}^1R)\mathcal{C} = 0.$$

On the other hand, if Σ is a minimal stationary realization of $W(t-s)$ and $\tilde{\Sigma}$ is an autonomous system related to Σ by (7.13) and (7.14) for some invertible R then $\tilde{\Sigma}$ is also a minimal stationary realization of $W(t-s)$.

Proof. (i) Suppose Σ is an autonomous realization of a stationary weighting pattern which satisfies (7.12); then by Proposition 7.1, Σ is controllable and observable off every $[\tau_0, \tau_1]$ and (6.1) is satisfied. By Theorem 6.1, Σ is a minimal real analytic realization and hence a minimal stationary realization.

Suppose Σ is an autonomous realization of a stationary weighting pattern $W(t-s)$ which does not satisfy (7.12). To show that Σ is not minimal we shall construct a new autonomous realization $\tilde{\Sigma}$ of smaller state dimension which does satisfy (7.12) and hence is minimal. As the reader has seen, the way one obtains a lower-dimensional realization of a weighting pattern is to find an appropriate subspace of the state space which is left invariant by the dynamics. One either restricts to this subspace or quotients by this subspace to reduce the dimension of the state space. In the context of real-analytic systems we have the luxury of making a time varying change of coordinates so that the invariant subspaces are time invariant. In the context of autonomous systems we do not have this option.

The natural subspaces associated with an autonomous system (1.1) are formed from the matrices found in Proposition 7.1, e.g.,

$$(7.15a) \quad \text{Range } \mathcal{C},$$

$$(7.15b) \quad \text{Kernel } \mathcal{O},$$

$$(7.15c) \quad \text{Range } \mathcal{C}^b,$$

$$(7.15d) \quad \text{Kernel } \mathcal{O}^b.$$

The first and second are clearly invariant by definition.

$$(7.16a) \quad A(\text{Range } \mathcal{C}) \subseteq \text{Range } \mathcal{C},$$

$$(7.16b) \quad A(\text{Kernel } \mathcal{O}) \subseteq \text{Kernel } \mathcal{O}.$$

The third and fourth are generally not. It is this latter fact which seems to cause the Gohberg–Kaashoek phenomenon.

Even if the system (1.1) is stationary it is not always true that (7.15b), (7.15d) are A invariant. However, they are nearly so, for (7.8) implies that

$$(7.17a) \quad A(\text{Range } \mathcal{C}^b) \subseteq \text{Range } \mathcal{C}^b + \text{Kernel } \mathcal{O},$$

$$(7.17b) \quad A(\text{Kernel } \mathcal{O}^b \cap \text{Range } \mathcal{C}) \subseteq \text{Kernel } \mathcal{O}^b.$$

The reader with a background in geometric linear control theory recognizes (7.17a) as a form of (A, B) invariance (or controlled invariance) and (7.17b) as a form of (C, A) (or conditioned invariance). For details see [14] and [15].

Let D be a matrix such that

$$(7.18) \quad \text{Range } D = \text{Kernel } \mathcal{O};$$

then by a standard lemma there exists a matrix F such that

$$(7.19) \quad (A + DF) \text{Range } \mathcal{C}^b \subseteq \text{Range } \mathcal{C}^b.$$

Moreover, since (7.16a) holds we can choose F so that

$$(7.20) \quad \text{Kernel } F \supset \text{Range } \mathcal{C}.$$

Let $\tilde{A} = A + DF$; then (7.18) and (7.20) imply that

$$(7.21a) \quad C\tilde{A}^k = CA^k,$$

$$(7.21b) \quad \tilde{A}^k B = A^k B$$

for all k , so for all t, s

$$(7.22a) \quad C e^{\tilde{A}t} = C e^{At},$$

$$(7.22b) \quad e^{\tilde{A}s} B = e^{As} B.$$

Therefore we can modify Σ by replacing A by \tilde{A} and not change the weighting pattern $W(t-s)$.

In this way we obtain another autonomous realization of $W(t-s)$ such that (7.15c) is \tilde{A} invariant. By restricting this system to the subspace of the state space given by (7.15c) we obtain a smaller autonomous realization of $W(t-s)$ which satisfies (7.12a).

The property described by equation (7.17b) is called (C, A) invariance (or conditioned invariance). It is the dual of the property described by (7.17a). If we choose a matrix E such that

$$(7.23) \quad \text{Range } \mathcal{C} = \text{Kernel } E,$$

then it is a standard exercise to show that there exists a matrix G such that

$$(7.24) \quad (A + GE) \text{Kernel } \mathcal{O}^b \subseteq \text{Kernel } \mathcal{O}^b.$$

Moreover, because of (7.16b) we can choose G such that

$$(7.25) \quad \text{Range } G \subset \text{Kernel } \mathcal{O}.$$

If we define $\tilde{A} = A + GE$ then because of (7.23) and (7.25), (7.21) and (7.22) hold. We can replace A by \tilde{A} without changing the weighting pattern. For this new realization (7.15d) is \tilde{A} invariant and we can project it out. The resulting realization satisfies (7.12b).

In this way we obtain a realization satisfying (7.12a), (7.12b); in other words, one that is controllable and observable off every $[\tau_0, \tau_1]$. To reduce this to a realization satisfying (7.12c) we choose coordinates that respect the flag of subspaces

$$\begin{aligned}\mathbb{R}^n &\supseteq \text{Range } \mathcal{C} + \text{Kernel } \mathcal{O} \\ &\supseteq \text{Range } \mathcal{C} \\ &\supseteq \text{Range } \mathcal{C} \cap \text{Kernel } \mathcal{O} \supseteq 0.\end{aligned}$$

In other words, $x = (x_1, x_2, x_3, x_4)^*$ and

$$\begin{aligned}\text{Range } \mathcal{C} + \text{Kernel } \mathcal{O} &= \{x: x_1 = 0\}, \\ \text{Range } \mathcal{C} &= \{x: x_1 = 0, x_2 = 0\}, \\ \text{Range } \mathcal{C} \cap \text{Kernel } \mathcal{O} &= \{x: x_1 = 0, x_2 = 0, x_3 = 0\}.\end{aligned}$$

If we define $B(s) = e^{As}B$ and $C(t) = C e^{At}$ then in these coordinates

$$(7.26a) \quad e^{As}B = B(s) = \begin{bmatrix} 0 \\ 0 \\ B_3(s) \\ B_4(s) \end{bmatrix},$$

$$(7.26b) \quad C e^{At} = C(t) = [C_1(t) \ 0 \ C_3(t) \ 0],$$

and

$$(7.26c) \quad W(t-s) = \begin{cases} \sum_{i=1,3} \sum_{j=3,4} C_i(t-t_0) V_{ij}^0 B_j(t_0-s), & t > s, \\ -\sum_{i=1,3} \sum_{j=3,4} C_i(t-t_0) V_{ij}^1 B_j(t_1-s), & t < s. \end{cases}$$

Hence we can delete the x_2 coordinate and the corresponding boundary input condition without changing $W(t-s)$. This completes the proof of statement (i).

(ii) By (i) a minimal stationary realization must satisfy (7.12). Hence by Theorem 6.1 and Proposition 7.1 it must also be a minimal real analytic realization.

(iii) In the proof of (i) we showed how a stationary realization can be modified and reduced to a realization satisfying (7.12). By Theorem 6.1 such a system is a minimal real analytic realization, hence a minimal stationary realization.

(iv) If Σ is a minimal stationary realization of $W(t-s)$ and $\tilde{\Sigma}$ is an autonomous realization related to Σ by (7.13) and (7.14), then it is easy to verify that $\tilde{\Sigma}$ realizes $W(t-s)$, hence is a minimal stationary realization.

If Σ and $\tilde{\Sigma}$ are two minimal stationary realizations of $W(t-s)$ then by Theorem 6.1 there exists a real analytic matrix valued function $R(t)$ satisfying (6.2) and (6.3). In particular (6.2b) implies that

$$\tilde{B} = R(t)B,$$

so $R(t)$ is constant on $\text{Range } B$. If we differentiate this expression using (6.2a) we obtain

$$\tilde{A}\tilde{B} = R(t)AB.$$

Further differentiations yield

$$(7.27a) \quad \tilde{C} = R(t)\mathcal{C},$$

$$(7.27b) \quad 0 = \dot{R}(t)\mathcal{C}.$$

In a similar fashion repeated differentiations of (6.2c) yield

$$(7.28a) \quad \tilde{\mathcal{O}} = \mathcal{O}R^{-1}(t),$$

$$(7.28b) \quad 0 = \mathcal{O}R^{-1}(t) = -\mathcal{O}\dot{R}^{-1}(t)R(t)R^{-1}(t).$$

Rewrite (6.2a) as

$$(7.29) \quad A - R^{-1}(t)\tilde{A}R(t)R(t)\dot{R}(t)$$

and multiply by \mathcal{C} on the right using (7.27b) to obtain

$$(7.30a) \quad (A - R^{-1}(t)\tilde{A}R(t))\mathcal{C} = 0.$$

We multiply (7.29) by \mathcal{O} on the left and use (7.28b) to obtain

$$(7.30b) \quad \mathcal{O}(A - R^{-1}(t)\tilde{A}R(t)) = 0.$$

If we let $R = R(t_0)$, a constant matrix, then (7.13) follows immediately. Moreover, (6.3a) implies (7.14a) and (7.27a) and (6.3b) imply (7.14b). Q.E.D.

Remark. While minimal stationary realizations are related by (7.13) and (7.14) for some constant matrix R , they can also be related by nonconstant matrices.

Example 7.7. Consider the time varying change of state coordinates $\tilde{x} = R(t)x$ for Example 5.6, where

$$R(t) = \begin{bmatrix} 1 & 0 \\ t & 1 \end{bmatrix}.$$

The new system is given by

$$\dot{\tilde{x}}_1 = 0, \quad \tilde{x}_2(0) + 2\tilde{x}_1(1) - \tilde{x}_2(1) = v_1,$$

$$\dot{\tilde{x}}_2 = \tilde{x}_1 + u, \quad \tilde{x}_2(0) = v_2,$$

$$y = \tilde{x}_1.$$

These two systems are also related by (7.13) and (7.14), where $R = I$.

Recall that an acausal system is *causal* if $V^0 = I$ and $V^1 = 0$ and *anticausal* if $V^0 = 0$ and $V^1 = I$. It is *strictly acausal* if both V^0 and V^1 are invertible.

PROPOSITION 7.8. *Suppose Σ is a standard stationary acausal system which is controllable and observable on $[t_0, t_1]$. The state and boundary space of Σ can be decomposed $x = (x_1, x_2, x_3)$, $v = (v_1, v_2, v_3)$ into a causal part x_1 , anticausal part x_2 , and an acausal part x_3 .*

$$(7.31a) \quad \dot{x}_1 = A_{11}x_1 + B_1u,$$

$$(7.31b) \quad x_1(t_0) = v_1,$$

$$(7.32a) \quad \dot{x}_2 = A_{22}x_2 + B_2u,$$

$$(7.32b) \quad x_2(t_1) = e^{A_{22}(t_1-t_0)}v_2,$$

$$(7.33a) \quad \dot{x}_3 = A_{31}x_1 + A_{32}x_2 + A_{33}x_3 + B_3u,$$

$$(7.33b) \quad V_{33}^0x_3(t_0) + V_{33}^1x_3(t_1) = v_3 - V_{31}^0x_1(t_0) - V_{32}^0x_2(t_0) - V_{31}^1x_1(t_1) - V_{32}^1x_2(t_1).$$

Proof. Consider the flag of subspaces

$$\mathbb{R}^m \supseteq \text{Range } V^1 \supseteq \text{Range } V^0 \cap \text{Range } V^0 \subseteq 0$$

and choose state coordinates that respect this flag $x = (x_1, x_2, x_3)$. In other words,

$$\text{Range } V^1 = \{x: x_1 = 0\},$$

$$\text{Range } V^0 \cap \text{Range } V^1 = \{x: x_1 = 0, x_2 = 0\},$$

$$\text{Range } V^0 = \{x: x_2 = 0\}.$$

We choose the same coordinates on the space of boundary input values v . Since A commutes with V^0 and V^1 it leaves their ranges invariant. Because $V^0 + V^1 e^{A(t_1-t_0)} = I$, V^0 and V^1 also commute hence leave their ranges invariant. This implies that

$$A = \begin{bmatrix} A_{11} & 0 & 0 \\ 0 & A_{22} & 0 \\ A_{31} & A_{32} & A_{33} \end{bmatrix},$$

$$V^0 = \begin{bmatrix} I & 0 & 0 \\ 0 & 0 & 0 \\ V_{31}^0 & V_{32}^0 & V_{33}^0 \end{bmatrix},$$

$$V^1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & e^{A_{22}(t_0-t_1)} & 0 \\ V_{31}^1 & V_{32}^1 & V_{33}^1 \end{bmatrix}$$

where $V_{33}^0 + V_{33}^1 e^{A_{33}(t_1-t_0)} = I$. Q.E.D.

Consider the acausal part of the above system, assuming that the causal state coordinates $x_1(t)$ and anticausal state coordinates $x_2(t)$ are identically zero. This yields an acausal system

$$(7.34a) \quad \dot{x}_3 = A_{33}x_3 + B_3u,$$

$$(7.34b) \quad V_{33}^0 x_3(t_0) + V_{33}^1 x_3(t_1) = v_3,$$

which can also be decomposed into causal, anticausal and acausal parts. The decomposition process can be repeated until the acausal part is strictly acausal. In this way the original system can be decomposed into causal and anticausal parts which feed into causal and anticausal parts through the state differential equations and boundary conditions. The pattern may be repeated several times until it terminates in a strictly acausal system.

The boundary condition (1.1b) of a stationary system is said to be *separable* if $\text{Range } V^0 \cap \text{Range } V^1 = 0$.

COROLLARY 7.9. *Suppose Σ is a standard stationary acausal system which is controllable and observable on $[t_0, t_1[$. If the boundary condition is separable then Σ separates into independent causal and anticausal systems.*

MODELING, STABILIZATION AND CONTROL OF SERIALLY CONNECTED BEAMS*

G. CHEN†¶, M. C. DELFOUR‡, A. M. KRALL† AND G. PAYRE§

Abstract. Many flexible structures consist of a large number of components coupled end to end in the form of a chain. In this paper, we consider the simplest type of such structures which is formed by N serially connected Euler-Bernoulli beams, with N actuators and sensors co-located at nodal points. When these N beams are strongly connected at all intermediate nodes and their material coefficients satisfy certain properties, uniform exponential stabilization can be achieved by stabilizing at one end point of the composite beam.

We use finite elements to discretize the partial differential equation and compute the spectra of these boundary damped operators. Numerical results are also illustrated.

Key words. serially connected beams, actuators and sensors, exponential stabilization

AMS(MOS) subject classifications. 93D15, 73K12, 73K25

1. Introduction. In this paper, we study the stabilization and control of composite beams or serially connected beams as shown in Fig. 1 where beam i , $1 \leq i \leq N$, is represented by the line segment $J_i = [x_{i-1}, x_i]$, $x_{i-1} < x_i$. We assume that each beam is uniform, with constant mass density m_i and flexural rigidity $E_i I_i$, $i = 1, 2, \dots, N$. Each beam satisfies the partial differential equation

$$(1.1) \quad m_i \frac{\partial^2 y}{\partial t^2} + E_i I_i \frac{\partial^4 y}{\partial x^4} = 0 \quad \text{on }]x_{i-1}, x_i[, \quad t > 0,$$

with initial conditions

$$(1.2) \quad y(x, 0) = y_0(x), \quad \frac{\partial y}{\partial t}(x, 0) = y_1(x), \quad 0 \leq x \leq L,$$

and boundary conditions determined by the coupling with neighboring beams.

FIG. 1. Serially connected beams.

Our study is motivated by problems in structural dynamics. Many civil engineering structures such as bridges, and flexural members in large space structures are modeled by beam equations like (1.1). Due to operation, safety and performance considerations, engineers use many “in-span indeterminate conditions” to design those structures. Four basic types of such intermediate conditions have been mentioned in [8, p. II-42]:

- (1.6) Angle guide 

Each of the above “joints” is known to have certain advantages in the design of structures.

The main objective of this paper is to study the suppression of vibration in structures. Our study is motivated by stabilization problems in large flexible space structures. These structures are dynamic in nature and require good designs of active control and passive damping mechanisms. We have observed several proposed designs of a future space station. They all contain flexible truss beam structures, some of which are linked by rotatable joints with damping devices. Those joints serve the important dual purposes of maneuvering and stabilization. Most or perhaps all of them are nonlinear in nature and hard to model mathematically. Linear joint conditions are only simplifications and approximations for those complicated joints. It will take some time before we can actually understand those structures.

For the Euler–Bernoulli beam equation (1.1), the physical meanings of various mathematical quantities are shown below:

y : transverse deflection,

$\frac{\partial y}{\partial t}$: transverse velocity,

$\theta = \frac{\partial y}{\partial x}$: rotation,

$\frac{\partial \theta}{\partial t} = \frac{\partial^2 y}{\partial t \partial x}$: angular velocity,

$\mathbb{M} = -E_i I_i \frac{\partial^2 y}{\partial x^2}$: bending moment,

$\frac{\partial \mathbb{M}}{\partial t} = -E_i I_i \frac{\partial^3 y}{\partial t \partial x^2}$: rate of change of moment,

$\mathbb{V} = -E_i I_i \frac{\partial^3 y}{\partial x^3}$: shear,

$\frac{\partial \mathbb{V}}{\partial t} = -E_i I_i \frac{\partial^4 y}{\partial t \partial x^3}$: rate of change of shear.

At a linear joint x_i , depending on the mechanical design, part or all of the physical variables from x_i^- and x_i^+ achieve equilibrium at x_i , yielding 4 mathematical relations.

The four basic joints (1.3)–(1.6) are the simplest special cases of such mathematical relations. They are known [8] to cause discontinuities (across the joint) in one of the state variables y , θ , \mathbb{M} and \mathbb{V} , and leave the other 3 state variables continuous, particularly, the “dual” (or “complementary”) state variable, as indicated in Table 1.

In the mathematical modeling of controller action at joints, it is natural and reasonable to designate the discontinuity across a joint as the control variable at x_i , because its values can be adjusted—under our command and with different mechanical

TABLE 1

Joint	Discontinuous state variables	Continuous state variables
Rigid support	\mathbb{V}	$y; \theta, \mathbb{M}$
Moment release	θ	$\mathbb{M}; y, \mathbb{V}$
Shear release	y	$\mathbb{V}; \theta, \mathbb{M}$
Angle guide	\mathbb{M}	$\theta; y, \mathbb{V}$

The first state variable in each entry above is the dual variable.

designs—to influence the dynamic response of the structure. For example, let x_i be a rigid support joint with control u_i . Then the intermediate boundary conditions at x_i are given as follows:

$$\begin{aligned} y(x_i^-, t) &= y(x_i^+, t), \\ \frac{\partial y}{\partial x}(x_i^-, t) &= \frac{\partial y}{\partial x}(x_i^+, t) \quad (\text{i.e., } \theta^- = \theta^+), \\ -E_i I_i \frac{\partial^2 y}{\partial x^2}(x_i^-, t) &= -E_{i+1} I_{i+1} \frac{\partial^2 y}{\partial x^2}(x_i^+, t) \quad (\text{i.e., } \mathbb{M}^- = \mathbb{M}^+), \\ E_i I_i \frac{\partial^3 y}{\partial x^3}(x_i^-, t) - E_{i+1} I_{i+1} \frac{\partial^3 y}{\partial x^3}(x_i^+, t) &= u_i(t). \end{aligned}$$

This is just one of the cases to be studied here by us.

Due to the limited scope of this paper, here we will only consider in-span controllers at joints that are rigid supports or angle guides, or combinations. Moment and shear release or other types of joints seem to have different advantages and disadvantages which are currently being investigated. We hope that our paper can motivate further study in this direction.

Our problem is to study the control and stabilization of serially connected beams as described above. We wish to establish a strong form of stabilization—uniform exponential stabilization—with one stabilizer only. This stabilizer, formed by velocity feedback, is considered to be located at one end of the span. Another situation, more practical perhaps, is to consider the stabilizer located at an interior node of the span. This corresponds to a much harder problem and is briefly discussed in § 4.3.

The organization of this paper is as follows.

In § 2 we first recall a fundamental theorem of existence for a second order (in time) hyperbolic equation. A control-theoretic formulation for a vibrating system consisting of a composite clamped beam with N pairs of co-located sensors and actuators is then given.

In § 3, we present the main result of the paper in Theorem 3.1. A special case of this theorem says that N serially connected beams such that

$$(1.7) \qquad m_i \leq m_{i+1}, \quad E_i I_i \geq E_{i+1} I_{i+1}, \quad 1 \leq i < N-1$$

can be uniformly exponentially stabilized with only one sensor and one actuator at the end ($x = L$) of the beam:

$$(1.8) \qquad E_N I_N \frac{\partial^3 y}{\partial x^3}(L, t) - k_{0N} \frac{\partial y}{\partial t}(L, t) = 0, \qquad k_{0N} > 0.$$

Previously, results have been established for exponential stabilization of all of the (finitely many) modes of the finite element model, but none for the continuum model.

In § 4, we discuss various cases, including different conservative left end boundary conditions, a beam with varying mass density and flexural rigidity, and stabilization at an intermediate node.

In § 5, we use the finite element numerical method to compute the spectrum. Some interesting information on the distribution of eigenvalues is illustrated.

Notation. \mathbb{R} will be the field of all real numbers. For $n \geq 1$, \mathbb{R}^n will denote the n -dimensional Euclidean space with norm $|x|$ and inner product $x \cdot y$ for x and y in \mathbb{R}^n . Given a Banach space E , its topological dual will be denoted E' and the duality pairing between an element x^* of E' and x of E by $\langle x^*, x \rangle_{E' \times E}$. Given a continuous linear map L between two Banach spaces E and F , L^* will be the corresponding dual map between F' and E' . Let a and b , $a < b$, be two real numbers and E be a Banach space. $L^p(a, b; E)$ will be the Banach space of all equivalence classes of Lebesgue measurable functions from $[a, b]$ into E which are p -integrable ($1 \leq p < \infty$) or essentially bounded ($p = \infty$). Given a function $y: [a, b] \rightarrow E$, \dot{y} and \ddot{y} will denote the first and second vectorial distribution derivatives of y . $C^m(a, b; E)$ will be the space of m -times boundedly continuously differentiable functions from $[a, b]$ into E . For $m \geq 1$ and an open interval I , $H^m(I)$ will be the Sobolev space of all functions in $L^2(I; \mathbb{R})$ whose first m distributional derivatives belong to $L^2(I; \mathbb{R})$.

2. Control-theoretic formulation of a clamped serially connected beam with N pairs of co-located actuators and sensors. Let V and H be two real Hilbert spaces with norms $\|\cdot\|$ and $|\cdot|$, respectively. Identify the elements of the dual H' of H with those of H and assume that the chains of injection are continuous with dense image

$$(2.1) \quad V \rightarrow H \equiv H' \rightarrow V'.$$

Let $a(t; v, w)$ be a family of bilinear forms on V such that

$$(2.1) \quad V \rightarrow H \equiv H' \rightarrow V'.$$

Let $a(t; v, w)$ be a family of bilinear forms on V such that

$$(2.2) \quad \text{for all } v, w, \quad t \rightarrow a(t; v, w) \text{ is } C^1([0, T]; \mathbb{R}) \quad \text{for all } T > 0,$$

$$(2.3) \quad \text{for all } v, w, \quad a(t; v, w) = a(t; w, v) \quad \text{for all } t \geq 0,$$

$$(2.4) \quad \text{there exists a } \lambda \in \mathbb{R}, \alpha > 0 \quad \text{for all } v, \quad a(t; v, v) + \lambda |v|^2 \geq \alpha \|v\|^2.$$

We let $A(t) \in \mathcal{L}(V, V')$ denote the operator defined by $a(t; v, w)$.

Let

$$(2.5) \quad C: V \rightarrow \mathbb{R}^m \quad (m \geq 1 \text{ an integer})$$

be an arbitrary linear map and $u \in L^2(0, T; \mathbb{R}^m)$, $T > 0$, be a control function. We now consider the controlled system

$$(2.6) \quad A(t)y(t) + \ddot{y}(t) + C^*u(t) = 0, \quad y_0 \in V, \quad y_1 \in H'.$$

This problem is well posed [5] and has a unique solution under appropriate hypotheses on A .

Let the observation be given by

$$(2.7) \quad z(t) = C\dot{y}(t)$$

in a sense to be made clear in (2.14). Let K be an $m \times m$ matrix such that

$$(2.8) \quad \text{there exists a } \beta \geq 0, \quad \text{such that for all } u \in \mathbb{R}^m, \quad Ku \cdot u \geq \beta |u|^2.$$

Define the feedback law

$$(2.9) \quad u(t) = K\dot{z}(t).$$

The resulting closed loop system will be

$$(2.10) \quad A(t)y(t) + C^*KC\dot{y}(t) + \ddot{y}(t) = 0, \quad y(0) = y_0, \quad \dot{y}(0) = y_1.$$

The perturbing term is

$$(2.11) \quad G\dot{y}(t), \quad G = C^*KC \in \mathcal{L}(V, V').$$

The next theorem shows that system (2.10) is well posed.

THEOREM 2.1. (i) *Under the hypotheses on the matrix K , equation (2.10) has a unique solution*

$$(2.12) \quad y \in C([0, T]; V), \quad \dot{y} \in C([0, T]; H), \quad C\dot{y} \in L^2(0, T; \mathbb{R}^m), \quad \ddot{y} \in L^2(0, T; V').$$

(ii) *Let $A(t) \equiv A$, $0 \leq t < \infty$, be autonomous. Then the densely defined closed operator*

$$\mathcal{A} \equiv \begin{bmatrix} 0 & I \\ A & 0 \end{bmatrix}$$

is dissipative with domain $D(\mathcal{A}) = D(A) \oplus V$ and generates a C_0 -semigroup of contractions $\{S(t) | t \geq 0\}$ on $V \oplus H$. The solution y of (2.10) forms a C_0 -semigroup in $V \times H$ defined by

$$(2.13) \quad S(t)(y_0, y_1) = (y(t), \dot{y}(t)), \quad t \geq 0.$$

(iii) *For (y_0, y_1) in $D(\mathcal{A})$,*

$$(2.14)$$

$$y \in C^1([0, T]; V), \quad \dot{y} \in C^1([0, T]; H), \quad C\dot{y} \in C([0, T]; \mathbb{R}^m), \quad \ddot{y} \in C([0, T]; V').$$

Proof. (ii) is a simple consequence of the Lumer-Phillips theorem. (i) is a simple extension of a theorem in [5]. \square

With the preceding formalism in mind, we now consider the control-theoretic formulation of a composite clamped beam with N pairs of co-located sensors and actuators.

Let a beam of length L be made up of N connected beams $[x_{i-1}, x_i]$, $1 \leq i \leq N$. For each i th segment beam the equation is

$$(2.15) \quad m_i \frac{\partial^2 y}{\partial t^2} + E_i I_i \frac{\partial^4 y}{\partial x^4} = 0, \quad x_{i-1} < x < x_i, \quad 1 \leq i \leq N.$$

The beam is clamped at $x = 0$:

$$(2.16) \quad y(0, t) = 0, \quad \frac{\partial y}{\partial x}(0, t) = 0, \quad t > 0.$$

At each interior node x_i , the beam is strongly connected:

$$(2.17) \quad y(x_i^-, t) = y(x_i^+, t), \quad \frac{\partial y}{\partial x}(x_i^-, t) = \frac{\partial y}{\partial x}(x_i^+, t), \quad t > 0,$$

with a point force $u_{0i}(t)$ and a point bending moment $u_{1i}(t)$ applied at x_i :

$$(2.18) \quad \begin{aligned} E_i I_i \frac{\partial^3 y}{\partial x^3}(x_i^-, t) - E_{i+1} I_{i+1} \frac{\partial^3 y}{\partial x^3}(x_i^+, t) &= u_{0i}(t), \\ - \left[E_i I_i \frac{\partial^2 y}{\partial x^2}(x_i^-, t) - E_{i+1} I_{i+1} \frac{\partial^2 y}{\partial x^2}(x_i^+, t) \right] &= u_{1i}(t), \end{aligned} \quad 1 \leq i \leq N-1.$$

At the right end $x_N = L$, a point force $u_{0N}(t)$ and a point bending moment $u_{1N}(t)$ are applied:

$$(2.19) \quad \begin{aligned} E_N I_N \frac{\partial^3 y}{\partial x^3}(L, t) &= u_{0N}(t), \\ -E_N I_N \frac{\partial^2 y}{\partial x^2}(L, t) &= u_{1N}(t), \end{aligned} \quad i = N.$$

Remark 2.2. The intermediate conditions (2.17) and (2.18) signify that the joint at x_i is:

- (i) A rigid support, if $u_{1i}(t) \equiv 0$, but $u_{0i}(t) \neq 0$;
- (ii) An angle guide, if $u_{0i}(t) \equiv 0$, but $u_{1i}(t) \neq 0$;
- (iii) A combination of (i) and (ii), if $u_{0i}(t) \neq 0$ and $u_{1i}(t) \neq 0$.

The above feedback laws (2.18) and (2.19) are realizable as all variables $E_i I_i (\partial^3 y / \partial x^3)$ (=shear) and $E_i I_i (\partial^2 y / \partial x^2)$ (=bending moment) on the left of (2.18) and (2.19) are determinable.

Remark 2.3. The boundary conditions (2.17)–(2.18) are the natural conditions arising from the presence of point forces $u_{0i}(t)$ and point bending moments $u_{1i}(t)$ at each point x_i . In the static case the calculus of variations can be used to show that the solution $y \in H^2(0, L)$ of the boundary value problem

$$\begin{aligned} \frac{\partial^4 y}{\partial x^4}(x) &= 0 \quad \text{on }]x_{i-1}, x_i[, \quad 1 \leq i \leq N, \\ E_i I_i \frac{\partial^3 y}{\partial x^3}(x_i^-) - E_{i+1} I_{i+1} \frac{\partial^3 y}{\partial x^3}(x_i^+) &= u_{0i}, \\ -\left[E_i I_i \frac{\partial^2 y}{\partial x^2}(x_i^-) - E_{i+1} I_{i+1} \frac{\partial^2 y}{\partial x^2}(x_i^+) \right] &= u_{1i}, \quad 1 \leq i \leq N-1, \\ E_N I_N \frac{\partial^3 y}{\partial x^3}(L) &= u_{0N}, \quad \frac{\partial y}{\partial x}(0) = 0, \\ -E_N I_N \frac{\partial^2 y}{\partial x^2}(L) &= u_{1N}, \quad y(0) = 0, \end{aligned}$$

is precisely the function that minimizes the strain energy plus the sum of the potential energy of the external forces u_{0i} and bending moments u_{1i} :

$$U(v) = \sum_{i=1}^N \frac{1}{2} E_i I_i \int_{x_{i-1}}^{x_i} |D^2 v(x)|^2 dx + u_{0i} v(x_i) + u_{1i} Dv(x_i)$$

over all deflection distributions v in $H^2(0, L)$ such that

$$v(0) = 0 \quad \text{and} \quad Dv(0) = 0.$$

The spaces H , V and the operators A and C are

$$(2.20) \quad \begin{aligned} H &= L^2(0, L), \quad V = \{v \in H^2(0, L) | v(0) = 0, Dv(0) = 0\}, \\ \langle Av, w \rangle &= \sum_{i=1}^N E_i I_i \int_{x_{i-1}}^{x_i} D^2 v(x) \cdot D^2 w(x) dx, \\ v \rightarrow Cv &= (C_1 v, C_2 v, \dots, C_N v), \quad C_i v = (v(x_i), Dv(x_i)). \end{aligned}$$

Denote by

$$(2.21) \quad u(t) = (u_1(t), u_2(t), \dots, u_N(t)), \quad u_i(t) = (u_{0i}(t), u_{1i}(t)),$$

the vector of control functions at time t in $(\mathbb{R}^2)^N$. Then the system of equations (2.15) to (2.19) can be rewritten in the following way:

$$(2.22) \quad A(t)y(t) + M\ddot{y}(t) + C^*u(t) = 0,$$

where

$$C^*u(t) = \sum_{i=1}^N C_i^* u_i(t)$$

and $M = M(x)$ is defined by

$$(2.23) \quad M(x) = \sum_{i=1}^N m_i \chi_{J_i}(x),$$

$\chi_{J_i}(x)$ is the characteristic function of the interval

$$J_i = [x_{i-1}, x_i].$$

At each point x_i , $1 \leq i \leq N$, we observe the vector

$$(2.24) \quad z_i(t) = \left(\frac{\partial y}{\partial t}(x_i, t), \frac{\partial^2 y}{\partial x \partial t}(x_i, t) \right), \quad t > 0.$$

The global observation is given by

$$(2.25) \quad z(t) = (z_1(t), z_2(t), \dots, z_N(t)) \in (\mathbb{R}^2)^N$$

and the feedback law is chosen as

$$(2.26) \quad u(t) = Kz(t), \quad K = \text{a } 2N \times 2N \text{ matrix.}$$

By construction

$$(2.27) \quad z(t) = C\dot{y}(t) \quad \text{and} \quad u(t) = KC\dot{y}(t).$$

So finally

$$(2.28) \quad A(t)y(t) + M\ddot{y}(t) + C^*KC\dot{y}(t) = 0.$$

Note that (2.28) differs slightly from (2.10) in Theorem 2.1 due to the presence of M . Nevertheless, the conclusions of Theorem 2.1 remain valid and applicable to our problem, as a straightforward modification will enable the proof to go through without difficulty.

Also note that for (2.28), we use the equivalent norm

$$\|(w, z)\|_{V \times H}^2 = \|w\|_V^2 + \int_0^L M(x)z^2(x) dx.$$

We will restrict our attention to special feedback matrices which are made up of N 2×2 matrices K_i , $1 \leq i \leq N$, along the diagonal. All other entries are zero.

$$(2.29) \quad K = \begin{bmatrix} K_1 & & & & & \\ & \ddots & & & & \\ & & K_2 & & & \\ & & & \ddots & & \\ & & & & K_3 & \\ & & & & & \ddots \\ & & 0 & & & & K_N \end{bmatrix}.$$

The above hypothesis on K amounts to assuming that sensors and actuators are co-located with local feedback.

3. Uniform exponential stabilization of serially connected beams. For the model proposed in the last section, we now wish to find certain feedback matrices K to obtain uniform exponential stabilization.

We assume that the matrices K_i are of the form

$$(3.1) \quad K_i = \begin{bmatrix} k_{0i} & -c_i \\ c_i & k_{1i} \end{bmatrix}, \quad k_{0i} \geq 0, \quad k_{1i} \geq 0, \quad c_i \in \mathbb{R}, \quad 1 \leq i \leq N.$$

It is readily seen that property (2.8) is satisfied, so Theorem 2.1 is applicable.

The next theorem is the main theorem which gives a set of sufficient conditions on the parameters to ensure uniform exponential stabilizability.

THEOREM 3.1. Assume that the $2N \times 2N$ matrix K satisfies (2.29) where the submatrices K_i satisfy (3.1). Also assume that

$$(3.2) \quad m_i \leq m_{i+1}, \quad E_i I_i \geq E_{i+1} I_{i+1} \quad \text{for } 1 \leq i \leq N-1.$$

Let the initial conditions y_0 and y_1 in (1.2) be given in $V \times H$. Furthermore, assume that either of the following occurs:

(i) Case 1.

$$(3.3) \quad \begin{aligned} k_{0N} > 0, \quad k_{1N} \geq 0, \quad c_N = 0, \\ k_{0i} \geq 0, \quad k_{1i} = 0, \quad c_i = 0, \quad 1 \leq i \leq N-1; \end{aligned}$$

(ii) Case 2.

$$(3.4) \quad \begin{aligned} k_{0N} > 0, \quad k_{1N} > 0, \quad c_N \in \mathbb{R} \quad (\text{arbitrary}), \\ k_{0i} \geq 0, \quad k_{1i} = 0, \quad c_i = 0, \quad 1 \leq i \leq N-1. \end{aligned}$$

Then there exist $\mu > 0$, $\omega > 0$ such that for all $(y_0, y_1) \in V \times H$, the energy of the system (2.28) decays uniformly exponentially:

$$\begin{aligned} \frac{1}{2} \sum_{i=1}^N \int_{x_{i-1}}^{x_i} [m_i |\dot{y}(t)|^2 + E_i I_i |D^2 y(t)|^2] dx &\leq \mu e^{-\omega t} \\ &\cdot \frac{1}{2} \sum_{i=1}^N \int_{x_{i-1}}^{x_i} [m_i |y_1|^2 + E_i I_i |D^2 y_0|^2] dx. \end{aligned}$$

Proof. The proof necessitates the construction of a Lyapunov functional and uses energy multipliers (see [1], [4] for similar techniques applied to the wave equation).

Let the Lyapunov functional be

$$v(t) = v(t, y(t), \dot{y}(t)),$$

where (y, \dot{y}) is the solution in § 2 with initial condition $(y_0, y_1) \in D(\mathcal{A})$, satisfying

$$(y, \dot{y}) \in C([0, T]; D(\mathcal{A})) \cap C^1([0, T]; V \times H) \quad \text{for any } T > 0.$$

We wish to show that

$$(3.5) \quad \text{there exists } T' > 0 \text{ such that for } t \geq T', (dv(t)/dt) \leq 0.$$

We proceed stepwise as follows.

(i) *Defining and utilizing the functional $v(t)$.*

On each interval $J_i = [x_{i-1}, x_i]$, $1 \leq i \leq N$, we let

$$(3.6) \quad \begin{aligned} v_i(t) = (1-\varepsilon)t \int_{J_i} [m_i |\dot{y}(x, t)|^2 + E_i I_i |D^2 y(x, t)|^2] dx \\ + \int_{J_i} 2m_i x \dot{y}(x, t) Dy(x, t) dx \quad \text{with } 0 < \varepsilon < 1, \end{aligned}$$

and define

$$(3.7) \quad v(t) = \sum_{i=1}^N v_i(t).$$

If (3.5) can be justified, then there exists some constant $c(T') > 0$, such that

$$(3.8) \quad v(t) \leq v(T') \leq c(T')E(y(0), \dot{y}(0)),$$

where E is the elastic energy norm

$$E(y(t), \dot{y}(t)) = \frac{1}{2} \int_0^L [M(x)|\dot{y}(x, t)|^2 + (EI)(x)|D^2y(x, t)|^2] dx$$

and

$$(EI)(x) = \sum_{i=1}^N E_i I_i \chi_{J_i}(x).$$

It is easy to show that there exists $c > 0$ such that (for T' sufficiently large and $t \geq T'$)

$$(3.9) \quad \left| \int_0^L 2x\dot{y}(x, t)Dy(x, t) dx \right| \leq cE(y(t), \dot{y}(t)).$$

Thus from (3.6)–(3.9) we deduce that

$$(3.10) \quad [(1-\varepsilon)t - c]E(y(t), \dot{y}(t)) \leq c(T')E(y(0), \dot{y}(0)), \quad t \geq T',$$

and consequently, for some $\bar{c}(\bar{T}) > 0$,

$$(3.11) \quad E(y(t), \dot{y}(t)) \leq \bar{c}(\bar{T})E(y(0), \dot{y}(0)), \quad t \geq T = \max \left\{ T', \frac{2c}{1-\varepsilon} \right\}.$$

The energy E is bounded on $[0, \bar{T}]$ and the inequality extends to initial conditions $(y_0, y_1) \in V \times H$, yielding

$$\int_{\bar{T}}^{\infty} E(y(t), \dot{y}(t))^2 dt \leq \bar{c}(T)^2 E(y_0, y_1)^2 \int_{\bar{T}}^{\infty} \left[\frac{1}{(1-\varepsilon)t - c} \right]^2 dt < \infty.$$

A theorem in [7, p. 121] applies, and we conclude that there exist $\mu \geq 1$, $\omega > 0$, such that

$$(3.12) \quad E(y(t), \dot{y}(t)) \leq \mu e^{-\omega t} E(y_0, y_1).$$

This proves uniform exponential stabilizability of the system.

(ii) *Computation of $(d/dt)v_i(t)$.* We want to show that

$$(3.13) \quad \frac{d}{dt} v_i(t) + \int_{J_i} DQ_i(x, t) dx + \int_{J_i} R_i(x, t) dx = 0,$$

with

$$(3.14) \quad \begin{aligned} Q_i(x, t) = & 2E_i I_i (1-\varepsilon)t(\dot{y}D^3y - D\dot{y}D^2y) - m_i x|\dot{y}|^2 \\ & + E_i I_i [2xDyD^3y - 2DyD^2y - x|D^2y|^2] \end{aligned}$$

and

$$(3.15) \quad R_i(x, t) = \varepsilon|\dot{y}|^2 + E_i I_i (2+\varepsilon)|D^2y|^2.$$

Differentiating v_i in (3.6), we get

$$\begin{aligned}\frac{d}{dt} v_i(t) &= \int_{J_i} \{(1-\varepsilon)[m_i|\dot{y}|^2 + E_i I_i |D^2 y|^2] \\ &\quad + 2(1-\varepsilon)t[m_i \dot{y}\ddot{y} + E_i I_i D^2 y D^2 \dot{y}] + 2m_i x[\ddot{y} D y + \dot{y} D \dot{y}]\} dx \\ &= (1-\varepsilon) \int_{J_i} [m_i|\dot{y}|^2 + E_i I_i |D^2 y|^2] dx + 2 \int_{J_i} m_i \ddot{y}[(1-\varepsilon)t\dot{y} + x D y] dx \\ &\quad + 2(1-\varepsilon)t \int_{J_i} E_i I_i D^2 y D^2 \dot{y} dx + \int_{J_i} m_i x D(\dot{y}^2) dx.\end{aligned}$$

On J_i ,

$$m_i \ddot{y} + E_i I_i D^4 y = 0$$

holds, so it can be used to eliminate \ddot{y} . Furthermore,

$$\begin{aligned}D(D^3 y \dot{y}) &= D^3 y D \dot{y} + D^4 y \dot{y}, \\ D(D^2 y D \dot{y}) &= D^3 y D \dot{y} + D^2 y D^2 \dot{y}, \\ D^2 y D^2 \dot{y} - D^4 y \dot{y} &= D(D^2 y D \dot{y} - D^3 y \dot{y});\end{aligned}$$

thus

$$\begin{aligned}(3.16) \quad \frac{d}{dt} v_i(t) &= (1-\varepsilon) \int_{J_i} [m_i|\dot{y}|^2 + E_i I_i |D^2 y|^2] dx - \int_{J_i} 2E_i I_i x D^4 y D y dx \\ &\quad + 2(1-\varepsilon)t E_i I_i \int_{J_i} D[D^2 y D \dot{y} - D^3 y \dot{y}] dx + \int_{J_i} m_i x D(\dot{y})^2 dx.\end{aligned}$$

Also

$$(3.17) \quad x D(\dot{y})^2 = D(x|\dot{y}|^2) - |\dot{y}|^2$$

and

$$(3.18) \quad D[2x(D^3 y D y - \tfrac{1}{2}|D^2 y|^2) - 2D^2 y D y] = 2x D^4 y D y - 3|D^2 y|^2.$$

The substitution of (3.17) and (3.18) in (3.16) yields (3.13)–(3.15).

(iii) *Verification of inequality (3.5).* In view of (3.13), the critical property (3.5) will be verified if we can show that

$$\begin{aligned}(3.19) \quad &\sum_{i=1}^N \left\{ [Q_i(x_i, t) - Q_i(x_{i-1}, t)] + \int_{J_i} R_i(x, t) dx \right\} \\ &= -\frac{d}{dt} \sum_{i=1}^N v_i(t) = -\frac{d}{dt} v(t) \geq 0, \quad t \geq T' .\end{aligned}$$

Since all feedback laws are local we need only verify that

$$\begin{aligned}(3.20) \quad &S_i(t) + \int_{J_i} R_i(x, t) dx \geq 0, \quad 1 \leq i \leq N, \quad t \geq T', \\ &S_0(t) \geq 0,\end{aligned}$$

where

$$\begin{aligned}(3.21) \quad &S_0(t) \equiv -Q_1(0, t), \\ &S_i(t) \equiv Q_i(x_i, t) - Q_{i+1}(x_i, t), \quad 1 \leq i \leq N-1, \\ &S_N(t) = Q_N(x_N, t),\end{aligned}$$

We first deal with the term R_i :

$$R_i(x, t) \cong \varepsilon [m_i |\dot{y}|^2 + E_i I_i |D^2 y|^2].$$

To deal with the Q_i 's we use the decomposition

$$\begin{aligned} Q_{i1}(x, t) &\equiv 2(1 - \varepsilon)t E_i I_i [\dot{y} D^3 y - D\dot{y} D^2 y], \\ Q_{i2}(x, t) &\equiv -m_i x |\dot{y}|^2, \\ Q_{i3}(x, t) &\equiv 2E_i I_i x D\dot{y} D^3 y, \\ Q_{i4}(x, t) &\equiv -2E_i I_i D\dot{y} D^2 y, \\ Q_{i5}(x, t) &\equiv -E_i I_i x |D^2 y|^2; \end{aligned} \quad (3.22)$$

thus

$$Q_i(x, t) = \sum_{j=1}^5 Q_{ij}(x, t). \quad (3.23)$$

Next, for $0 \leq i \leq N$ and $1 \leq j \leq 5$ we define

$$\begin{aligned} S_{ij}(t) &\equiv Q_{ij}(x_i, t) - Q_{i+1,j}(x_i, t), \quad 1 \leq i \leq N-1, \\ S_{0j}(t) &\equiv -Q_{1j}(0, t), \quad S_{Nj}(t) \equiv Q_{Nj}(x_N, t), \quad i = 0 \text{ or } N, \end{aligned} \quad (3.24)$$

and let

$$S_i(t) \equiv \sum_{j=1}^5 S_{ij}(t), \quad 0 \leq i \leq N. \quad (3.25)$$

For each i we compute $S_i(t)$. When $i = 0$, at the left end,

$$S_0(t) = 0. \quad (3.26)$$

For $i = N$, at the right end,

$$\begin{aligned} S_N(t) &= E_N I_N [2(1 - \varepsilon)t \dot{y} + 2x_N D\dot{y}] D^3 y - E_N I_N [2(1 - \varepsilon)t D\dot{y} + 2D\dot{y}] D^2 y \\ &\quad - m_N x_N |\dot{y}|^2 - E_N I_N x_N |D^2 y|^2 \\ &= [2(1 - \varepsilon)t \dot{y} + 2x_N D\dot{y}] [k_{0N} \dot{y} - c_N D\dot{y}] + [2(1 - \varepsilon)t D\dot{y} + 2D\dot{y}] [c_N \dot{y} + k_{1N} D\dot{y}] \\ &\quad - \frac{x_N}{E_N I_N} [c_N \dot{y} + k_{1N} D\dot{y}]^2 - m_N x_N |\dot{y}|^2 \\ &= 2(1 - \varepsilon)t [k_{0N} |\dot{y}|^2 + k_{1N} |D\dot{y}|^2] + D\dot{y} [2x_N (k_{0N} \dot{y} - c_N D\dot{y}) + 2(c_N \dot{y} + k_{1N} D\dot{y})] \\ &\quad - \frac{x_N}{E_N I_N} [c_N \dot{y} + k_{1N} D\dot{y}]^2 - m_N x_N |\dot{y}|^2. \end{aligned}$$

For any $\delta > 0$,

$$|D\dot{y}| \cdot |\dot{y}| \leq \delta^2 |D\dot{y}|^2 + \frac{1}{\delta^2} |\dot{y}|^2.$$

Also, for any $\alpha, \beta \in \mathbb{R}$,

$$(\alpha + \beta)^2 \leq 2(\alpha^2 + \beta^2).$$

Therefore

$$\begin{aligned}
 S_N(t) &\geq 2(1-\varepsilon)t[k_{0N}|\dot{y}|^2 + k_{1N}|D\dot{y}|^2] \\
 &\quad - \left\{ \delta^2 |Dy|^2 + \frac{1}{\delta^2} |(2x_N k_{0N} + 2c_N)\dot{y} + (-2x_N c_N + 2k_{1N})D\dot{y}|^2 \right\} \\
 &\quad - \frac{x_N}{E_N I_N} (c_N \dot{y} + k_{1N} D\dot{y})^2 - m_N x_N |\dot{y}|^2 \\
 &\geq 2(1-\varepsilon)t[k_{0N}|\dot{y}|^2 + k_{1N}|D\dot{y}|^2] \\
 &\quad - \frac{2}{\delta^2} \{ |2x_N k_{0N} + 2c_N|^2 |\dot{y}|^2 + |-2x_N c_N + 2k_{1N}|^2 |D\dot{y}|^2 \} \\
 &\quad - \frac{2x_N}{E_N I_N} \{ c_N^2 |\dot{y}|^2 + k_{1N}^2 |D\dot{y}|^2 \} - m_N x_N |\dot{y}|^2 - \delta^2 |Dy|^2.
 \end{aligned}$$

The last term can be absorbed into $\int_{J_N} R_N dx$ for small δ . If either

$$(3.27a) \quad k_{0N} > 0, \quad c_N = 0, \quad k_{1N} \geq 0, \quad \text{or}$$

$$(3.27b) \quad k_{0N} > 0, \quad c_N \neq 0, \quad k_{1N} > 0$$

then for t large enough, the sum of the remaining terms is nonnegative.

At intermediate nodes, under the assumption that

$$(3.28) \quad k_{0i} \geq 0, \quad c_i = 0, \quad k_{1i} = 0, \quad m_i \leq m_{i+1}, \quad E_i I_i \geq E_{i+1} I_{i+1}, \quad 1 \leq i \leq N-1,$$

we have

$$\begin{aligned}
 S_{i1}(t) &= 2(1-\varepsilon)t\{\dot{y}[E_i I_i D^3 y(x_i^-, t) - E_{i+1} I_{i+1} D^3 y(x_i^+, t)] \\
 &\quad - D\dot{y}[E_i I_i D^2 y(x_i^-, t) - E_{i+1} I_{i+1} D^2 y(x_i^+, t)]\} \\
 &= 2(1-\varepsilon)tk_{0i}|\dot{y}|^2 \geq 0, \\
 S_{i2}(t) &= \frac{1}{2}(-m_i + m_{i+1})x_i|\dot{y}(x_i, t)|^2 \geq 0, \\
 S_{i3}(t) &= 2x_i D\dot{y}(x_i, t)[E_i I_i D^3 y(x_i^-, t) - E_{i+1} I_{i+1} D^3 y(x_i^+, t)] \\
 &= 2x_i D\dot{y}(x_i, t)k_{0i}\dot{y}(x_i, t), \\
 S_{i4}(t) &= 2D\dot{y}(x_i, t)[-E_i I_i D^2 y(x_i^-, t) + E_{i+1} I_{i+1} D^2 y(x_i^+, t)] = 0, \\
 S_{i5}(t) &= x_i[-E_i I_i |D^2 y(x_i^-, t)|^2 + E_{i+1} I_{i+1} |D^2 y(x_i^+, t)|^2] \\
 &= \left(\frac{E_{i+1} I_{i+1}}{E_i I_i} \right) x_i [E_i I_i - E_{i+1} I_{i+1}] |D^2 y(x_i, t)|^2 \geq 0.
 \end{aligned}$$

$S_{i3}(t)$ can be absorbed into $S_{i1}(t)$ and $\int_{J_i} R_i dx$.

So we have shown that (3.19) is satisfied. This concludes the proof of the theorem. \square

An immediate consequence of the uniform exponential stabilizability result above is the exact controllability result (see [6], [9]).

Remark 3.2. Condition (3.2) has an interesting physical interpretation: as

$$\frac{E_{i+1}I_{i+1}}{m_{i+1}} \leq \frac{E_i I_i}{m_i}, \quad i = 1, 2, \dots, N-1,$$

the beam is “more flexible” toward the right end.

4. Miscellaneous discussions: Other cases and boundary conditions.

4.1. Change of the conservative left end condition. The proof of Theorem 3.1 was carried out with the conservative clamped left end condition (2.16). Other types of conservative left end boundary conditions can be used; they are given below:

- (i) $y(0, t) = 0, \quad \frac{\partial^2 y}{\partial x^2}(0, t) = 0$ (simply supported or pinned left end),
- (ii) $\frac{\partial^2 y}{\partial x^2}(0, t) = 0, \quad \frac{\partial^3 y}{\partial x^3}(0, t) = 0$ (free left end),
- (iii) $\frac{\partial y}{\partial x}(0, t) = 0, \quad \frac{\partial^3 y}{\partial x^3}(0, t) = 0$ (shear hinge left end),
- (iv) $\frac{\partial y}{\partial t}(0, t) = 0, \quad \frac{\partial y}{\partial x}(0, t) = 0,$
- (v) $\frac{\partial y}{\partial t}(0, t) = 0, \quad \frac{\partial^2 y}{\partial x^2}(0, t) = 0,$
- (vi) $\frac{\partial^2 y}{\partial t \partial x}(0, t) = 0, \quad \frac{\partial^3 y}{\partial x^3}(0, t) = 0.$

For any of the above, very minor modifications of the proof will enable Theorem 3.1 to go through, and the exponential decay result holds.

Note that for the above boundary conditions, the elastic energy functional E no longer serves as a norm. A new underlying Hilbert space $V \times H$ must be formulated which usually excludes one or two steady states in $H^2 \times L^2$.

4.2. Stabilization at one end for a beam with varying mass density $m(x)$ and flexural rigidity $I(x)E(x)$. Consider the case of a single beam

$$(4.1) \quad m(x) \frac{\partial^2 y}{\partial t^2}(x, t) + \frac{\partial^2}{\partial x^2} \left[E(x) I(x) \frac{\partial^2 y}{\partial x^2}(x, t) \right] = 0, \quad 0 < x < L, \quad t > 0,$$

which is clamped, simply supported or free at the left end $x = 0$. At the right end $x = L$, assume dissipative boundary conditions

$$(4.2) \quad \begin{aligned} (EI y_{xx})_x &= k_{0N} y_t, & k_{0N} &> 0, \\ -EI y_{xx} &= k_{1N} y_{xt}, & k_{1N} &\geq 0. \end{aligned}$$

Under what conditions on $m(x)$ and $E(x)I(x)$ do we have uniform exponential decay

$$(4.3) \quad \begin{aligned} & \frac{1}{2} \int_0^L \left[m(x) \frac{\partial y(x, t)^2}{\partial t} + E(x) I(x) \left(\frac{\partial^2 y(x, t)}{\partial x^2} \right)^2 \right] dx \\ & \leq \frac{1}{2} \mu e^{-\omega t} \int_0^L \left[m(x) \frac{\partial y^2}{\partial t}(x, 0) + E(x) I(x) \left(\frac{\partial^2 y}{\partial x^2}(x, 0) \right)^2 \right] dx \end{aligned}$$

as in § 3?

We return to (3.2). The hypothesis (3.2) seems to signify that the beam (4.1), (4.2) should be more massive and less rigid toward the right end, i.e.,

$$(4.4) \quad m(x_2) \geq m(x_1), \quad E(x_2)I(x_2) \leq E(x_1)I(x_1) \quad \text{for } x_1, x_2 \in [0, L], \quad x_2 > x_1$$

in order for a proof for (4.3) to go through. A closer look indicates otherwise.

An energy identity for (4.1) can be given as

$$\begin{aligned} & \frac{d}{dt} \int_0^L [(1-\varepsilon)t(my^2 + EI|D^2y|^2) + m\eta y Dy] dx \\ &= \{2(1-\varepsilon)t[-D(EID^2y)\dot{y} + EID^2yD\dot{y}] \\ & \quad + \frac{1}{2}m\eta\dot{y}^2 - \eta D(EID^2y)Dy + EID^2y(D\eta Dy + \eta D^2y) - \frac{1}{2}EI|D^2y|^2\}_0^L \\ & \quad + \int_0^L \left\{ \frac{1}{2}[2(1-\varepsilon)m - (Dm\eta + mD\eta)]\dot{y}^2 \right. \\ & \quad \left. + (EI[(1-\varepsilon) - 2D\eta] + \frac{1}{2}D(EI\eta))|D^2y|^2 - EID^2\eta DyD^2y \right\} dx. \end{aligned}$$

Thus if there exist $\varepsilon > 0$, $\delta > 0$ and a twice differentiable function $\eta(x)$ on $[0, L]$ such that

$$\begin{aligned} & \eta(0) = 0, \\ (4.5) \quad & 2(1-\varepsilon)m - (Dm\eta + mD\eta) < -\delta < 0, \\ & EI[(1-\varepsilon) - 2D\eta] + \frac{1}{2}D(EI\eta) < -\delta < 0, \end{aligned}$$

then (4.3) holds. It is easy to see that when $m(x) = \text{constant}$, $E(x)I(x) = \text{constant}$, we can just choose $\eta(x) = 2x$.

Generally, (4.4) is neither necessary nor sufficient for (4.5) to hold.

4.3. Stabilization at an intermediate node. Consider the following situation: two beams are connected at x_1 by a co-located sensor-stabilizer of the rigid support and angle guide type as in Fig. 2.

$$\begin{aligned} & y(x_1^-, t) = y(x_1^+, t), \\ & \frac{\partial}{\partial x} y(x_1^-, t) = \frac{\partial}{\partial x} y(x_1^+, t), \\ (4.6) \quad & E_1 I_1 \frac{\partial^3 y}{\partial x^3}(x_1^-, t) - E_2 I_2 \frac{\partial^3 y}{\partial x^3}(x_1^+, t) = k_0 \frac{\partial y}{\partial t}(x_1, t), \quad k_0 > 0, \\ & - \left[E_1 I_1 \frac{\partial^2 y}{\partial x^2}(x_1^-, t) - E_2 I_2 \frac{\partial^2 y}{\partial x^2}(x_1^+, t) \right] = k_1 \frac{\partial^2 y}{\partial x \partial t}(x_1, t), \quad k_1 > 0. \end{aligned}$$

FIG. 2

At the left end x_0 and the right end x_2 , we assume conservative boundary conditions—clamped, hinged, free, etc. Can stabilizing conditions (4.6) lead to a uniform exponential decay result?

This problem seems to have significant application interest as structural engineers often design stabilizers in the middle of the span.

Preliminary results seem to suggest that exponential decay of energy does not hold in general. This problem is still open and requires a careful investigation.

5. Numerical simulation. We consider a single beam with feedback control at the end point.

The chosen beam is characterized by the following figures (MKSA units):

$$(5.1) \quad \begin{aligned} \gamma &= m(\text{mass density}) = 3.58 \text{ kg/m}, \quad L = 44 \text{ m}, \quad EI = 223.20 \text{ kg} \times \text{m}^3/\text{s}^2 \\ &(\text{m} = \text{meter}, \text{s} = \text{sec}, \text{kg} = \text{kilogram}). \end{aligned}$$

It corresponds to beams encountered in the simulation of large flexible space structures. In our model $N = 1$ and the matrix K_1 is chosen of the form

$$(5.2) \quad K_1 = \begin{bmatrix} \alpha & 0 \\ 0 & \beta \end{bmatrix}, \quad \alpha \geq 0, \quad \beta \geq 0.$$

The beam equation was approximated by the finite element method. The spatial domain $[0, L]$ was divided into nine equal intervals. The approximating function was globally C^1 and its restriction to each interval was a cubic polynomial. There are 4 boundary conditions: the two (clamped) conditions at left end are essential conditions and the two (dissipative) conditions at right end are natural conditions. Thus there are a total of $(2 \cdot 9 + 2) - 2 = 18$ elements with $2 \times 18 = 36$ degrees of freedom.

We let the approximate solution be

$$y^h(x, t) = \sum_{i=1}^{18} a_i(t) \psi_i(x),$$

where $\{\psi_i(x) | 1 \leq i \leq 18\}$ is the global finite element basis just mentioned. We use (2.28):

$$\langle m\ddot{y}^h + Ay^h + C^*K_1C\dot{y}^h, \psi_j \rangle_{V' \times V} = 0 \quad \text{for } 1 \leq j \leq 18.$$

This yields a matrix equation

$$(5.3) \quad M_2\ddot{q} + M_1\dot{q} + M_0q = 0,$$

where

$$q = q(t) = \begin{bmatrix} a_1(t) \\ \vdots \\ a_{18}(t) \end{bmatrix},$$

and M_0, M_1, M_2 are 18×18 matrices with entries

$$\begin{aligned} M_0 &= [m_{ij}^0]_{18 \times 18}, & m_{ij}^0 &= \langle A\psi_i, \psi_j \rangle_{V' \times V} = a(\psi_i, \psi_j), \\ M_1 &= [m_{ij}^1]_{18 \times 18}, & m_{ij}^1 &= \langle C^*K_1C\psi_i, \psi_j \rangle_{V' \times V}, \\ M_2 &= [m_{ij}^2]_{18 \times 18}, & m_{ij}^2 &= \gamma \langle \psi_i, \psi_j \rangle_{V' \times V} = \gamma \langle \psi_i, \psi_j \rangle_{L^2}. \end{aligned}$$

All three matrices are symmetric and nonnegative. M_0 and M_2 are strictly positive definite.

To compute eigenfrequencies, let

$$q(t) = e^{\lambda t} q_0, \quad q_0 = \text{a constant 18-vector},$$

and substitute it in (5.3). We get

$$(\lambda^2 M_2 + \lambda M_1 + M_0) q_0 = 0.$$

Thus the following eigenvalue problem is obtained:

$$\left(\begin{bmatrix} 0 & I \\ -M_2^{-1} M_0 & -M_2^{-1} M_1 \end{bmatrix} - \lambda I_{36 \times 36} \right) \begin{bmatrix} q_0 \\ \lambda q_0 \end{bmatrix} = 0.$$

The 36×36 matrix has 36 eigenvalues. We have computed them and provided some graphs here. Due to numerical truncation, the reader should only pay attention to eigenvalues near the real axis. The ones far away from that axis are spurious. In order to make comparisons, the eigenvalues were also computed from the transcendental equation (by separation of variables) using Newton's method (cf. Fig. 7, to be compared with Fig. 6).

Three patterns of spectrum seem to appear, as shown below (Fig. 3):

Case 1. The boundary conditions are

$$\begin{aligned} EI \frac{\partial^3 y}{\partial x^3}(L, t) &= \alpha \frac{\partial y}{\partial t}(L, t), \quad \alpha > 0, \\ -EI \frac{\partial^2 y}{\partial x^2}(L, t) &= 0. \end{aligned}$$

See Fig. 4. As α is increased, the spectrum seems to move uniformly to the left.

Case 2. The boundary conditions are

$$\begin{aligned} EI \frac{\partial^3 y}{\partial x^3}(L, t) &= 0, \\ -EI \frac{\partial^2 y}{\partial x^2}(L, t) &= \beta \frac{\partial^2 y}{\partial x \partial t}(L, t), \quad \beta > 0. \end{aligned}$$

See Fig. 5. As β becomes larger, the spectrum seems to bend toward the negative real axis.

FIG. 3. Locus of the spectrum of the finite element approximation to the spectrum.

FIG. 4.*: These eigenvalues accompanied with asterisks are spurious in the sense that they distort the real spectral pattern of the damped operator, because by Theorem 3.1, the eigenvalues are uniformly bounded away from the imaginary axis thus they should not bend backward toward the imaginary axis. These are some of the artificial features and difficulties created by finite element discretizations. See also subsequent figures (except Fig. 7). In Figs. 4, 5 and 6, the first $\frac{3}{4}$ of the computed eigenvalues have good accuracy. As a general rule, the accuracy of computed eigenvalues decreases as their moduli increase.

** : These eigenvalues accumulate the largest numerical errors.

Case 3. The boundary conditions are

$$EI \frac{\partial^3 y}{\partial x^3}(L, t) = \alpha \frac{\partial y}{\partial t}(L, t), \quad \alpha > 0,$$
$$-EI \frac{\partial^2 y}{\partial x^2}(L, t) = \beta \frac{\partial^2 y}{\partial x \partial t}(L, t), \quad \beta > 0.$$

See Fig. 6.

OUTPUT TRACKING FOR NONLINEAR SYSTEMS WITH SINGULAR POINTS*

R. HIRSCHORN† AND J. DAVIS†

Abstract. Some of the well-known linear results on output tracking have been generalized to include nonlinear control systems by removing from the state space a codimension one submanifold of "singular points." These points do not exist in the linear case, but in nonlinear tracking applications the system trajectory can begin at or pass through "singular points." The purpose of this paper is to study nonlinear output tracking with singular points.

Key words. nonlinear systems, output tracking, singularities

AMS(MOS) subject classification. 93B05

1. Introduction. In the output tracking problem one tries to control a system so that its output follows or tracks some desired path. For linear systems this problem was first considered by Brockett and Mesarović [1] in 1965. They used an inverse system to generate the required control. Since then a number of approaches to the linear output tracking problem have been explored (cf. [2]–[4]).

For nonlinear control systems the output tracking problem is more difficult but a number of the well-known linear results have been generalized to the nonlinear case (cf. [5]–[9]). To a large extent this has been possible because the methods used by Silverman [3] in the linear case can be generalized provided one removes from the state space a codimension one submanifold of "singular points" which do not exist in the linear case. When the state of the system approaches a singular point the theory breaks down because the control effort typically becomes unbounded. For rigid manipulators the current theory works well [10], but is inadequate when trying to control flexible manipulators. This is partly due to the existence of "singular points" in the state trajectory for the natural tracking problems. The purpose of this paper is to study output tracking with "singular points." In § 2 singular points in the output tracking problem are introduced. In § 3 the main results, Theorem 3.1 and Theorem 3.2 are proved and the use of these results illustrated.

2. Singular points for output tracking. Consider the single-input affine nonlinear system model

$$(2.1) \quad \begin{aligned} \dot{x}(t) &= f(x(t)) + u(t)g(x(t)), & x(0) &= x_0 \in M, \\ y(t) &= h(x(t)) \end{aligned}$$

where M is a connected C^∞ manifold, f and g are C^∞ (smooth) vector fields on M , h is a C^∞ (smooth) function on M , and the controls $u: [0, \infty) \rightarrow \mathbb{R}$ are continuous functions. For each control u let $x(t, u, x_0)$ denote the corresponding solution to the state differential equation (2.1) and let $y(t, u, x_0)$ denote the corresponding output. The reachable set from x_0 for the system model (2.1) is $\mathcal{R}(x_0) = \{x(t, u, x_0) | t \geq 0, u \text{ admissible}\}$. The system is assumed to have the accessibility property (i.e., $\mathcal{R}(x_0)$ has a nonempty interior in M). If this is not the case, one simply replaces M by the appropriate submanifold (cf. [1], [12]).

The output tracking problem is the identification of functions $y_d(t)$ which can appear as outputs for the system (2.1), i.e., $y_d(\cdot) = y(\cdot, u, x_0)$ for some admissible

* Received by the editors October 7, 1985, and in revised form January 3, 1986.

† Department of Mathematics and Statistics, Queen's University, Kingston, Ontario, Canada K7L 3N6.

control u , and the construction of a control u_d for which $y_d(\cdot) = y(\cdot, u_d, x_0)$. To avoid keeping track of degrees of differentiability, y_d is assumed to be infinity differentiable (i.e., C^∞ or smooth).

The basic idea in both linear and nonlinear tracking is to solve for the control, u_d , as a function of the desired output, y_d , and the state, x , of the system. The following example shows how this approach can break down when "singular points" are present.

Example 2.1. Consider the nonlinear system model with state equation

$$(2.2) \quad \begin{aligned} \dot{x}_1(t) &= u(t), & x_1(0) &= 1, \\ \dot{x}_2(t) &= x_1^2(t), & x_2(0) &= 0, \end{aligned}$$

and with output $y(t) = x_2(t)$. Here $\dot{y}(t) = \dot{x}_2(t) = x_1^2(t)$ and $\ddot{y}(t) = 2x_1(t)u(t)$ so that $u(t)$ can be expressed as a function of y and the states. Also $y(0) = 0$ and $y'(0) = 1$ so that a necessary condition for the output of this system to track a desired smooth path y_d (i.e. $y \equiv y_d$) is that $y_d(0) = 0$, $y'_d(0) = 1$. To see that this is sufficient, suppose that $y_d(0) = 0$, $y'_d(0) = 1$ and set $u_d(t, x) = y''_d(t)/2x_1$, a control using state feedback, and $y''_d(t)$ as a feedforward term. Using this control the output y satisfies $y(0) = 0 = y_d(0)$, $y'(0) = 1 = y'_d(0)$ and $y''(t) = 2x_1(t)u_d(t) = 2x_1(t)y''_d(t)/2x_1(t) = y''_d(t)$ for $t \geq 0$. This implies that $y \equiv y_d$.

In particular for $y_d(t) = t + t^2$ one has $y_d(0) = 0$, $y'_d(0) = 1$ and therefore $u_d(t) = y''_d(t)/2x_1(t) = 1/x_1(t)$ should make $y(t)$ "track" $y_d(t)$. Solving (2.2) with $u \equiv u_d$ yields $x_1(t) = (1 + 2t)^{1/2}$ for all $t \geq 0$ and $y(t) = x_2(t) = t + t^2 = y_d(t)$ for all $t \geq 0$. The resulting trajectory $x(t)$ is shown in Fig. 1.1.

FIG. 1.1

Replacing y_d with $y_d(t) = t - t^2$, one has $y_d(0) = 0$, $y'_d(0) = 1$ as required, and the control $u_d(t) = y''_d(t)/2x_1(t) = -1/x_1(t)$ will cause y to track y_d . In particular, solving (2.1), one sees that $x_1(t) = (1 - 2t)^{1/2}$ for $0 \leq t \leq \frac{1}{2}$ and $y(t) = t - t^2 = y_d(t)$ for $0 \leq t < \frac{1}{2}$. There is a problem, however, when $x_1 = 0$, namely $u_d \rightarrow -\infty$ as $x_1 \rightarrow 0$ (or as $t \rightarrow \frac{1}{2}$). Such points will be called "singular points" for the tracking problem. On first consideration, they seem to create a barrier to the state trajectory (see Fig. 1.2).

On the other hand, if $y_d(t) = t - t^2 + t^3/3$ then $y_d(0) = 0$, $y'_d(0) = 1$, and using $u_d(t) = -1$ for all $t \geq 0$ in (2.1) yields $x_1(t) = 1 - t$ for all $t \geq 0$ and $y = x_2(t) = t - t^2 + t^3/3 = y_d(t)$ for all $t \geq 0$. Here the state trajectory has no problem passing through the set of "singular points" (see Fig. 1.3).

FIG. 1.2

FIG. 1.3

When the state trajectory passes through a singular point, extra restrictions are placed on the class of outputs that the system can track. To gain a better understanding of output tracking in the neighborhood of these "singular points" one should study (2.1), where the initial state is a singular point—for example, $x_0 = (0, 1)$. Before doing this a precise definition for singular points will be given.

DEFINITION 2.1. The *relative order* α of the nonlinear system (2.1) is the least nonnegative integer k such that $gf^{k-1}h \neq 0$ on M or $\alpha = \infty$ if $gf^k h \equiv 0$ for all $k \geq 0$.

If $\alpha = \infty$ the input-output corresponding to system (2.1) is essential trivial; that is, varying the control has little effect on the output. In particular, Theorem 3.1 of [5] asserts that when M, f, g, h are real analytic $\alpha = \infty$ implies that $y(t, u, x_0) = y(t, 0, x_0)$ for all $x_0 \in M$ and for all real analytic controls u .

If $\alpha < \infty$ then $gf^{\alpha-1}h \neq 0$ on M and

$$\begin{aligned}
 y(t) &= h(x(t)) \\
 y^{(1)}(t) &= fh(x(t)) \\
 &\vdots \\
 y^{(\alpha-1)}(t) &= f^{\alpha-1}h(x(t)) \\
 y^{(\alpha)}(t) &= f^\alpha h(x(t)) + u(t)gf^{\alpha-1}h(x(t)).
 \end{aligned}
 \tag{2.3}$$

Thus a necessary condition for the system to track y_d is that $y_d(0) = h(x_0)$, $y_d^{(1)}(0) = fh(x_0)$, \dots , $y_d^{(\alpha-1)}(0) = f^{\alpha-1}h(x_0)$. If $gf^{\alpha-1}h(x_0) \neq 0$ then this is sufficient. One can use

$$u_d(t, x) = \frac{y^{(\alpha)}(t) - f^{\alpha-1}h(x)}{gf^{\alpha-1}h(x)}$$

and show $y^{(\alpha)}(t, u_d, x_0) = y_d^{(\alpha)}(t)$ for t in some *nbhd* of 0, and hence that $y(t, u_d, x_0) = y_d(t)$ in view of the initial condition requirements.

In the event that $gf^{\alpha-1}h(x_0) = 0$, higher derivatives of y_d play a role in determining if y_d can be tracked by the system output.

DEFINITION 2.2. A state x_0 is called a *singular point for output tracking* if $gf^{\alpha-1}h(x_0) = 0$.

Remark 2.1. The input-output behavior of a system with singular initial state x_0 can be quite different from that of a linear system or a nonlinear system with a nonsingular initial state. At a nonsingular initial state the input-output map is injective and so an inverse system exists. In particular, suppose that y is the output to the system (2.1) which results from a control u , and the input to the inverse system is set equal to $y^{(\alpha)}$. Then the output of the inverse system will be u (cf. [5]). Thus if $y_d^{(\alpha)}$, the α th derivative of a desired C^∞ output, is used as an input then the inverse system will generate a unique C^∞ function u_d which can be used for forcing the system (2.1) to track y_d . Thus a desired C^∞ output is always generated by a unique C^∞ input. At a singular initial state x_0 one can have a noninvertible input output map (e.g., Example 2.1 and Remark 3.1) and C^∞ outputs which are generated by inputs which are continuous but not differentiable (e.g., Example 3.5).

To facilitate the computation of higher derivatives of y , set $a(x) = f^\alpha h(x)$ and $b(x) = gf^{\alpha-1}h(x)$, so that $a, b \in C^\infty(M)$, the ring of smooth real valued functions on M . Then

$$y^{(\alpha)}(t) = a(x(t)) + u(t)b(x(t))$$

and

$$y^{(\alpha+1)}(t) = \frac{d}{dt}a(x(t)) + u(t)\frac{d}{dt}b(x(t)) + u^{(1)}(t)b(x(t)).$$

As before,

$$\frac{d}{dt}a(x(t)) = fa(x(t)) + uga(x(t)) = [f + u(t)g]a(x(t))$$

where

$$[f + u(t)g]a(x(t)) = (da)_{x(t)}(f(x(t)) + u(t)g(x(t))),$$

and

$$\begin{aligned} \frac{d^2}{dt^2}a(x(t)) &= [f + u(t)g]^2a(x(t)) + \dot{u}(t)ga(x(t)) \\ &= f^2a(x(t)) + u(t)(gfa(x(t)) + fga(x(t))) + u^2(t)g^2a(x(t)) \\ &\quad + \dot{u}(t)ga(x(t)) \\ &= \left(\frac{\partial}{\partial x} \left(\frac{da}{dt}(x(t)) \right) \right) (f(x(t)) + u(t)g(x(t))) + \left(\frac{\partial}{\partial u} \left(\frac{da}{dt}(x(t)) \right) \right) \dot{u}(t). \end{aligned}$$

This leads to the following definitions: for $r_1, \dots, r_k \in R$ set

$$\begin{aligned}
 a_0(x) &\triangleq a(x) \\
 a_1(x, r_1) &\triangleq \left(\frac{\partial}{\partial x} a_0(x) \right) (f(x) + r_1 g(x)) \\
 (2.4) \quad a_2(x, r_1, r_2) &\triangleq \left(\frac{\partial}{\partial x} a_1(x, r_1) \right) (f(x) + r_1 g(x)) + \left(\frac{\partial}{\partial r_1} a_1(x, r_1) \right) r_2 \\
 &\vdots \\
 a_k(x, r_1, \dots, r_k) &\triangleq \left(\frac{\partial}{\partial x} a_{k-1} \right) (f(x) + r_1 g(x)) + \left(\frac{\partial}{\partial r_1} a_{k-1} \right) r_2 + \dots + \left(\frac{\partial}{\partial r_{k-1}} a_{k-1} \right) r_k.
 \end{aligned}$$

Note that for x fixed $a_k(x, r_1, \dots, r_k)$ is a polynomial in r_1, \dots, r_k of degree $\leq k$. It follows that for $x(t) = x(t, u, x_0)$ one has

$$\begin{aligned}
 (2.5) \quad \frac{d^k}{dt^k} a(x(t)) &= a_k(x(t), u(t), u^{(1)}(t), \dots, u^{(k-1)}(t)), \text{ and} \\
 \frac{d^k}{dt^k} b(x(t)) &= b_k(x(t), u(t), u^{(1)}(t), \dots, u^{(k-1)}(t))
 \end{aligned}$$

where $b_k(x, r_1, \dots, r_k)$ is defined as above with $b_0(x) = b(x)$ (i.e., using the recursion formula (2.4)).

It turns out that the number of further restrictions placed on y_d at a singular point x_0 (i.e. $b(x_0) = 0$) depends on how many derivatives of $b(x(t))$ must be taken before $(d^k/dt^k)b(x(t))|_{t=0} \neq 0$. We formalize this in the following definition.

DEFINITION 2.3. The *degree of singularity of a state* $x_0 \in M$, $\beta(x_0)$, is the least nonnegative integer k such that the polynomial $(r_1, \dots, r_k) \rightarrow b_k(x_0, r_1, \dots, r_k)$ is not the zero polynomial, or $\beta(x_0) = \infty$ if $b_k(x_0, r_1, \dots, r_k) = 0$ for all $r_1, \dots, r_k \in R$ and for all $k \geq 0$.

Remark 2.2. When $k < \beta(x_0)$ it follows that $b_k(x_0, r_1, \dots, r_k) = 0$ for all $r_i \in R$. For $k = \beta(x_0)$ there exists $s_1, \dots, s_{\beta(x_0)}$ such that $b_{\beta(x_0)}(x_0, s_1, \dots, s_{\beta(x_0)}) \neq 0$. This means that any sufficiently differentiable control u such that $u^{(k)}(0) = s_{k+1}$ for $0 \leq k \leq \beta(x_0) - 1$ has the property that $(d^k/dt^k)b(x(t, u, x_0))|_{t=0} = b_k(x_0, s_1, \dots, s_k) = 0$ for $k < \beta(x_0)$ and $(d^{\beta(x_0)}/dt^{\beta(x_0)})b(x(t, u, x_0))|_{t=0} = b_{\beta(x_0)}(x_0, s_1, \dots, s_{\beta(x_0)}) \neq 0$. In particular, if x_0 is a singular point the trajectory $t \rightarrow x(t, u, x_0)$ leaves the set of singular points $\{x \in M | b(x) = 0\}$.

Remark 2.3. If x_0 is *not* a singular point then $b_0(x_0) \neq 0$ and the degree of singularity of x_0 is zero.

Example 2.1 (continued). Consider the system described by (2.2). Here $f(x_1, x_2) = (0, x_1^2)$, $g(x_1, x_2) = (1, 0)$, $h(x_1, x_2) = x_2$, $fh(x) = dh_x f(x) = x_1^2$,

$$gh(x) = dh_x g(x) = \begin{bmatrix} 0 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \equiv 0,$$

and

$$ghf(x) = (d(fh))_x g(x) = \begin{bmatrix} 2x_1 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = 2x_1 \neq 0 \quad \text{on } M = \mathbb{R}^2.$$

Thus the relative order of this system is $\alpha = 2$. With the initial condition $x_0 = (1, 0)$ considered previously, $gh(x_0) = 2 \neq 0$ so that the degree of singularity of x_0 is $\beta(x_0) = 0$ and x_0 is not a singular point, and the existing theory on tracking applies. If the system has the initial state $\hat{x}_0 = (0, 1)$ then $gh(\hat{x}_0) = 0$ so that \hat{x}_0 is a singular point. Here

$$\begin{aligned} y^{(\alpha)}(t) &= y^{(2)}(t) = a(x(t)) + u(t)b(x(t)) = f^2h(x) + ugh(x) \\ &= 0 + u(2x_1) \end{aligned}$$

so that $b(x) = 2x_1$. Using (2.3)

$$\begin{aligned} b_0(x) &= b(x) = 2x_1, \\ b_1(x, r_1) &= \left(\frac{\partial}{\partial x} b_0(x) \right) r_1 g(x) = [2 \quad 0] \begin{bmatrix} r_1 \\ 0 \end{bmatrix} = 2r_1, \end{aligned}$$

and at \hat{x}_0 the polynomial $r_1 \rightarrow b_1(\hat{x}_0, r_1) = 2r_1$ is not the zero polynomial while $b_0(\hat{x}_0) = 2(0) = 0$. This means that the degree of singularity of \hat{x}_0 is $\beta(\hat{x}_0) = 1$. Note that at \hat{x}_0 the input output map is not one-to-one as $u(t)$ and $-u(t)$ produce the same output.

For a system with finite relative order (i.e., a nontrivial input-output map) the set of singular points $S = \{x | b(x) = 0\}$ is basically a codimension one submanifold of M . If the system has the accessibility property and if x_0 is a singular point (i.e., $b(x_0) = 0$) then most controls u will steer the system out S . For such a control $b(x(t, u, x_0)) \neq 0$ and one would expect that, for some k , $(d^k/dt^k)b(x(t, u, x_0))|_{t=0} \neq 0$. From Remark 2.2 this implies $\beta(x_0) < \infty$. Also for nonsingular points $\beta(x_0) = 0$. Thus one expects that $\beta(x_0) < \infty$ for all $x \in M$ iff the system is nontrivial (i.e., $\alpha < \infty$). For real analytic systems this is easy to prove.

THEOREM 2.1. *Consider the nonlinear system (2.1) where f , g , h and M are real analytic. Then $\alpha < \infty$ if and only if $\beta(x_0) < \infty$ for all $x_0 \in M$.*

Proof. Suppose that $\beta(x_0) < \infty$ for all $x_0 \in M$. Then $\alpha < \infty$ by definition. Suppose that $\alpha < \infty$ but $\beta(x_0) = \infty$ for some $x_0 \in M$. Then x_0 must be a singular point and thus the real analytic function $x \rightarrow b(x) = gf^{\alpha-1}h(x)$ vanishes at x_0 . Now $b \neq 0$ as $\alpha < \infty$ and by real analyticity the set $\{x \in M | b(x) \neq 0\}$ must be an open dense subset of M . Since (2.1) has the accessibility property the reachable set from x_0 has an open interior in M and thus there exists a real analytic control $u_0(t)$ such that $b(x(t, u_0, x_0)) \neq 0$. If $b^{(k)}(x(t, u_0, x_0))|_{t=0} = 0$ for all $k \geq 0$ (i.e., $\beta(x_0) = \infty$) then the Taylor series for $b(x(t, u_0, x_0))$ is 0 and hence $b(x(t, u_0, x_0)) \equiv 0$, a contradiction. Thus $\beta(x_0) < \infty$ and the proof is complete.

3. Output tracking at a singular point. Suppose that $y(t) = y(x(t, u, x_0))$ is the output of system (2.1) corresponding to the input u . If $\alpha < \infty$ then from (2.3)

$$y^{(k)}(t) = f^k h(x(t)) \quad \text{for } 0 \leq k < \alpha,$$

and a necessary condition for tracking a path $y_d(t)$ is that

$$y_d^{(k)}(0) = f^k h(x_0) \quad \text{for } 0 \leq k < \alpha.$$

It is well known that this is sufficient when x_0 is not a singular point (c.f. [5], [6]) but this is not the case when x_0 is a singular point. For example, the system described by (2.2) with $x_0 = (0, 1)$, a singular point, and $y_d(t) = 1 - t^2$ satisfies the above necessary condition but can never be tracked since $y(t) \geq 0$ for all t and $y^{(2)}(0) = 0$ for all u .

The additional requirements placed on y_d when x_0 is a singular point are easily described. For each $x_0 \in M$ (2.4) defines inductively a sequence of polynomials

$$\{a_k(x_0, r_1, \dots, r_k)\} \quad \text{with } a_0(x_0) = a(x_0) = f^\alpha h(x_0),$$

and

$$\{b_k(x_0, r_1, \dots, r_k)\} \quad \text{with } b_0(x_0) = b(x_0) = gf^{\alpha-1}h(x_0).$$

For $\beta > 0$ consider the mapping

$$F_{x_0}^{\alpha, \beta} : (r_1, \dots, r_\beta) \rightarrow (a_0(x_0), a_1(x_0, r_1), \dots, a_{\beta-1}(x_0, r_1, \dots, r_{\beta-1}), a_\beta(x_0, r_1, \dots, r_\beta) + r_1 b_\beta(x_0, r_1, \dots, r_\beta))$$

of R^β into $R^{\beta+1}$.

THEOREM 3.1. *Consider the nonlinear system (2.1) with $\beta = \beta(x_0) < \infty$. A necessary condition for $y_d \in C^\infty(R)$ to be tracked by the output (using an input which is $(\beta - 1)$ -times differentiable at 0) is that*

$$y_d^{(k)}(0) = f^k h(x_0) \quad \text{for } 0 \leq k < \alpha$$

and $(y_d^{(\alpha)}(0), y_d^{(\alpha+1)}(0), \dots, y_d^{(\alpha+\beta)}(0)) \in \text{Range } F_{x_0}^{\alpha, \beta}$ if $\beta > 0$.

Proof. If $\beta(x_0) = 0$ the proof is immediate. If $\beta(x_0) > 0$ then as in §2

$$y^{(\alpha)}(t) = a(x(t)) + u(t)b(x(t))$$

where

$$a(x) = f^\alpha h(x) \quad \text{and} \quad b(x) = gf^{\alpha-1}h(x),$$

$$\begin{aligned} y^{(\alpha+1)}(t) &= \frac{d}{dt} a(x(t)) + u(t) \frac{d}{dt} b(x(t)) + \left(\frac{d}{dt} u(t) \right) b(x(t)) \\ &= a^{(1)}(x(t)) + u(t)b^{(1)}(x(t)) + u^{(1)}(t)b(x(t)) \\ y^{(\alpha+2)}(t) &= a^{(2)}(x(t)) + u(t)b^{(2)}(x(t)) + 2u^{(1)}(t)b^{(1)}(x(t)) + u^{(2)}(t)b(x(t)) \\ &\vdots \\ y^{(\alpha+k)}(t) &= a^{(k)}(x(t)) + u(t)b^{(k)}(x(t)) + ku^{(1)}(t)b^{(k-1)}(x(t)) + \dots + u^{(k)}(t)b(x(t)) \end{aligned}$$

for $k \geq 0$. Using (2.5) to evaluate $a^{(k)}(x(t))$, $b^{(k)}(x(t))$ and the fact that $b^{(k)}(x(0)) = 0$ for $k < \beta(x_0)$, one sees that

$$\begin{aligned} y^{(\alpha)}(0) &= a_0(x_0) \\ y^{(\alpha+1)}(0) &= a_1(x_0, u(0)) \\ &\vdots \\ y^{(\alpha+\beta(x_0)-1)}(0) &= a_{\beta(x_0)-1}(x_0, u(0), \dots, u^{(\beta(x_0)-2)}(0)) \\ y^{(\alpha+\beta(x_0))}(0) &= a_{\beta(x_0)}(x_0, u(0), \dots, u^{(\beta(x_0)-1)}(0)) \\ &\quad + u(0)b_{\beta(x_0)}(x_0, u(0), \dots, u^{(\beta(x_0)-1)}(0)). \end{aligned}$$

This says that

$$(y_d^{(\alpha)}(0), \dots, y_d^{(\alpha+\beta(x_0))}(0)) \in \text{Range } F_{x_0}^{\alpha, \beta(x_0)}.$$

This completes the proof.

Theorem 3.1 comes close to identifying those functions y_d that can be tracked by the output of a nonlinear system, and by slightly reducing the class of functions defined by Theorem 3.1 a control u_d which generates y_d can be described. In particular, for x_0 fixed, the polynomial

$$(r_1, \dots, r_\beta) \rightarrow b(x_0, r_1, \dots, r_\beta)$$

is nonzero on an open dense subset of R^β , namely $D_{x_0}^\beta = \{(r_1, \dots, r_\beta) \mid b_\beta(x_0, r_1, \dots, r_\beta) \neq 0\}$. Let $F_{x_0}^{\alpha, \beta} \upharpoonright D_{x_0}^\beta$ denote the restriction of $F_{x_0}^{\alpha, \beta}$ to $D_{x_0}^\beta$.

THEOREM 3.2. *Consider the nonlinear system (2.1) with $\beta = \beta(x_0) < \infty$. A sufficient condition for $y_d \in C^\infty(R)$ to be tracked by the output is that*

$$y_d^{(k)}(0) = f^k h(x_0) \quad \text{for } 0 \leq k < \alpha,$$

and

$$(y_d^{(\alpha)}(0), y_d^{(\alpha+1)}(0), \dots, y_d^{(\alpha+\beta)}(0)) \in \text{Range } F_{x_0}^{\alpha, \beta} \upharpoonright_{D_{x_0}^{\beta_0}} \quad \text{for } \beta > 0,$$

where $D_{x_0}^{\beta_0} = \{r \in R^{\beta_0} | b_\beta(x_0, r) \neq 0\} \subseteq R^{\beta_0}$.

Proof. Suppose that $y_d(t)$ is a C^∞ function of t that satisfies the hypothesis of Theorem 3.2. If $\beta(x_0) = 0$ then Theorem 3.2 reduces to Theorem 3.1 of [5]. If $\beta(x_0) > 0$ set $\beta = \beta(x_0)$ and choose $(r_1, \dots, r_\beta) \in D_{x_0}^{\beta_0}$ such that

$$(3.1) \quad (y_d^{(\alpha)}(0), \dots, y_d^{(\alpha+\beta)}(0)) = F_{x_0}^{\alpha, \beta}(r_1, \dots, r_\beta)$$

and $b_\beta(x_0, r_1, \dots, r_\beta) \neq 0$. Let $u_*(t)$ be any smooth control with the property that $u_*^{(k)}(0) = r_{k+1}$ for $0 \leq k \leq \beta - 1$. Set $x_*(t) = x(t, u_*, x_0)$ so that $(d^k/dt^k)b(x_*(t))|_{t=0} = 0$ for $0 \leq k < \beta$ and $(d^\beta/dt^\beta)b(x_*(t))|_{t=0} = b_\beta(x_0, r_1, \dots, r_\beta) \neq 0$. Now choose $\varepsilon > 0$ such that $b(x_*(s)) \neq 0$ for $0 < |s| < \varepsilon$. For each such value of s the system (2.1) with $t_0 = s$, $x_0 = x_*(s)$ and $u(t, x) = (y_d^{(\alpha)}(t) - a(x))/b(x)$ has a smooth solution $x(t) = x(t, u, x_*(s))$. Since $b(x_*(s)) \neq 0$ the initial condition is not a singular point. Thus for $t > s$ the output $y \equiv y_d$, and initially the control is

$$\lim_{t \rightarrow s} u(t, x(t)) = u(s, x(s)) = u(s, x_*(s)) = \frac{y_d^{(\alpha)}(s) - a(x_*(s))}{b(x_*(s))}.$$

The effort here is to show that this method still works when x_0 is singular. By showing that $u(s, x_*(s))$ has a finite limit as s tends to 0 (i.e., as $x_*(s) \rightarrow x_0$), it follows from the continuity of solutions of differential equations with respect to parameters that $u(t, x(t))$ is continuous on $[0, \infty)$ when $\dot{x}(t) = f(x(t)) + u(t, x)g(x(t))$ and $x(0) = x_0$.

To show that $\lim_{s \rightarrow 0^+} u(s, x_*(s))$ has a limit, l'Hôpital's rule is used β times. By definition $\lim_{s \rightarrow 0^+} u(s, x_*(s)) = \lim_{s \rightarrow 0^+} (y_d^{(\alpha)}(s) - a(x_*(s))/b(x_*(s)))$. Here $\lim_{s \rightarrow 0^+} b(x_*(s)) = b(x_0) = b_0(x_0) = 0$ as $\beta > 0$ and from equation (3.1) $y_d^{(\alpha)}(0)$ is the first component of $F_{x_0}^{\alpha, \beta}(r_1, \dots, r_\beta)$. In particular $y_d^{(\alpha)}(0) = a_0(x_0)$ so that $\lim_{s \rightarrow 0^+} y_d^{(\alpha)}(s) - a(x_*(s)) = a_0(x_*(0)) - a(x_*(0)) = a_0(x_0) - a_0(x_0)$. Thus by l'Hôpital's rule

$$\lim_{s \rightarrow 0^+} u(s, x_*(s)) = \lim_{s \rightarrow 0^+} \frac{y_d^{(\alpha+1)}(s) - a^{(1)}(x_*(s))}{b^{(1)}(x_*(s))}$$

(provided the limit on the right exists). The above argument can be repeated. If $\beta > 1$ then $b^{(1)}(x_0) = 0$ and from (3.1) $y_d^{(\alpha+1)}(0) = a_1(x_0, r_1)$ and $a^{(1)}(x_*(0)) = a_1(x_0, u_*(0)) = a_1(x_0, r_1)$ by definition of a_1 . In this way l'Hôpital's rule can be repeated until we attempt to calculate

$$\begin{aligned} \lim_{s \rightarrow 0^+} u(s, x_*(s)) &= \frac{y_d^{(\alpha+\beta)}(0) - a^{(\beta)}(x_*(0))}{b^{(\beta)}(x_*(0))} \\ &= \frac{y_d^{(\alpha+\beta)}(0) - a_\beta(x_0, r_1, \dots, r_\beta)}{b_\beta(x_0, r_1, \dots, r_\beta)}. \end{aligned}$$

From (3.1) $y_d^{(\alpha+\beta)}(0) = a_\beta(x_0, r_1, \dots, r_\beta) + r_1 b_\beta(x_0, r_1, \dots, r_\beta)$ so that $\lim_{s \rightarrow 0^+} u(s, x_*(s)) = r_1 = u_*(0)$. In particular, if one sets

$$u_d(t, x) = \begin{cases} \frac{y_d^{(\alpha)}(t) - a(x)}{b(x)} & \text{for } t > 0, \\ r_1 & \text{for } t = 0, \end{cases}$$

and $x_d(t)$ solves $\dot{x}_d = f(x_d) + u_d g(x_d)$ ($x_d(0) = x_0$), then $u_d(t, x_d(t))$ will be continuous. In fact, the resulting output $y(t)$ has the property that

$$y^{(\alpha)} = a(x_d) + u_d(t, x_d)b(x_d) = a(x_d) + \frac{y_d^{(\alpha)} - a(x_d)}{b(x_d)}b(x_d) = y_d^{(\alpha)},$$

so that $y \equiv y_d$. This completes the proof.

COROLLARY 3.1. *Suppose that $y_d \in C^\infty(R)$ satisfies the hypothesis of Theorem 3.2 so that*

$$(y_d^{(\alpha)}(0), y_d^{(\alpha+1)}(0), \dots, y_d^{(\alpha+\beta)}(0)) = F_{x_0}^{\alpha, \beta}(r_1, r_2, \dots, r_\beta)$$

for (r_1, \dots, r_β) in the open dense subset $D_{x_0}^\beta$ of R^β . Then the output y of system (2.1) can be controlled so that $y \equiv y_d$ by using

$$u_d(t, x) = \begin{cases} r_1 & \text{for } t = 0, \\ \frac{y_d^{(\alpha)}(t) - a(x)}{b(x)} & \text{for } t > 0. \end{cases}$$

Proof. This follows directly from the proof of Theorem 3.2.

COROLLARY 3.2. *Consider the nonlinear system (2.1) with $\beta = \beta(x_0) < \infty$, and suppose that $D_{x_0}^\beta = R^\beta$. Then any $y_d \in C^\infty(R)$ that satisfies the hypothesis of Theorem 3.1 can be tracked.*

Proof. When $D_{x_0}^\beta = R^\beta$ the necessary conditions of Theorem 3.1 and the sufficient conditions of Theorem 3.2 agree.

Remark 3.1. From Theorem 3.2 one can see that the input-output map for the system (2.1) at a singular point will not be 1-1 when $F_{x_0}^{\alpha, \beta} \upharpoonright_{D_{x_0}^\beta}$ fails to be injective.

Example 3.1 (Example 2.1 continued). Consider the system described by (2.2) with $x_0 = (0, 1)$ so that $\alpha = 2$, $\beta = \beta(x_0) = 1$. Here $a(x) \equiv 0$, $b(x) = 2x_1$, $b_0(x) = 2x_1$, $b_1(x, r_1) = 2r_1$ and $a_k \equiv 0$ for all $k \geq 0$. Here

$$F_{x_0}^{\alpha, \beta}(r_1, \dots, r_\beta) = F_{x_0}^{1, 2}(r_1) = (a_0(x_0), a_1(x_0, r_1) + r_1 b_1(x_0, r_1)) = (0, 2r_1^2),$$

$$D_{x_0}^\beta = D_{x_0}^1 = \{r_1 | b_1(x_0, r_1) \neq 0\} = \{r_1 | 2r_1 \neq 0\} = (-\infty, 0) \cup (0, \infty).$$

Theorem 3.1 asserts that a necessary condition to track y_d is that $y_d(0) = 1$, $y_d'(0) = 0$ and $(y_d''(0), y_d'''(0)) \in \text{Range } F_{x_0}^{1, 2} = \{0\} \times R$. Theorem 3.2 asserts that y_d can be tracked if $(y_d''(0), y_d'''(0)) \in \text{Range } F_{x_0}^{1, 2} \upharpoonright_{D_{x_0}^1} = \{0\} \times (R \sim \{0\})$. Thus $y_d(t) = 1 + t^3 z(t)$ can be tracked for all $z \in C^\infty(R)$ with $z(0) \neq 0$, and if y_d can be tracked, then $y_d(t) = 1 + t^3 z(t)$ for $z \in C^\infty(R)$ by Theorem 3.1. Notice that in Example 2.1 in § 2 the trajectory is at a singular point at time $\frac{1}{2}$ when $y_d(t) = t - t^2$ and if $t_0 = \frac{1}{2}$ then $y_d''(t_0) = -2 \notin \text{Range } F_{x_0}^{1, 2}$ (here $x_0 = x(t_0) = x(\frac{1}{2})$). When $y_d(t) = t - t^2 + t^3/3$, then $x(1)$ is singular and for $t_0 = 1$, $y_d''(t_0) = 0$, $y_d'''(t_0) = 2 \neq 0$ as required by Theorem 3.2.

Example 3.2. (This is a nontrivial application of Theorem 3.2). Consider the system (2.1) with $x \in R^3$,

$$f(x) = (x_1 x_2, x_1, x_2 e^{x_1}), \quad g(x) = (x_2^2, 0, 0), \quad h(x) = e^{x_3}.$$

Since the system is to have the accessibility property, let $M = R^3 \sim (\{0, 0\} \times R) = \{(x_1, x_2, x_3) \in R^3 | x_1^2 + x_2^2 \neq 0\}$. By direct computation $gh \equiv 0$, $gfh(x) = x_2^3 e^{x_1 + x_3}$ so that $\alpha = 2$, and $y^{(\alpha)} = y^{(2)} = f^2 h(x) + ugfh(x) = a(x) + ub(x)$ where $a(x) = (x_1 + x_2^2(x_1 + e^{x_1})) e^{x_1 + x_3}$ and $b(x) = x_2^3 e^{x_1 + x_3}$. Thus the set of singular points are those x_0 with $b(x_0) = 0$, i.e., x_2 -coordinate zero.

Let $x_0 = (x_{01}, 0, x_{03})$ be a singular point. To compute $\beta(x_0)$, note that

$$\begin{aligned} b^{(1)}(x(t)) &= \frac{d}{dt}(x_2^3 e^{x_1+x_3}) = 3x_2^2 \dot{x}_2 e^{x_1+x_3} + x_2^3(\dot{x}_1 + \dot{x}_3) e^{x_1+x_3} \\ &= 3x_2^2 x_1 e^{x_1+x_3} + x_2^4(x_1 + x_2 u + e^{x_1}) e^{x_1+x_3} = b_1(x, u) \end{aligned}$$

and thus $b_1(x_0, r_1) = 0$ for all r_1 . Similarly $b_2(x_0, r_1, r_2) = 0$, but $b_3(x_0, r_1, r_2, r_3) = 6x_{01}^3 e^{x_{01}+x_{03}} \neq 0$ since $(0, 0, x_{03}) \notin M$. Thus $\beta(x_0) = 3$ for all singular x_0 . To find the map $F_{x_0}^{\alpha, \beta} = F_{x_0}^{2,3}: R^3 \rightarrow R^4$ one can compute a_0, a_1, a_2 and a_3 at x_0 . Here $a_0(x_0) = x_{01} e^{x_{01}+x_{03}}$, $a_1(x_0, r_1) = 0$, $a_2(x_0, r_1, r_2) = x_{01}^2(1 + 3x_{01} + 3e^{x_{01}}) e^{x_{01}+x_{03}}$, $a_3(x_0, r_1, r_2, r_3) = r_1 b_3(x_0, r_1, r_2, r_3) = 2x_{01}^2 e^{x_{01}+x_{03}}(1 + 4x_{01})r_1$. Thus $F_{x_0}^{2,3}(r_1, r_2, r_3) = (x_{01} e^{x_{01}+x_{03}}, 0, x_{01}^2(1 + 3x_{01} + 3e^{x_{01}}) e^{x_{01}+x_{03}}, 2r_1(1 + 4x_{01})x_{01}^2 e^{x_{01}+x_{03}})$ and since $b_3(x_0, r_1, r_2, r_3) \neq 0$ for all $(r_1, r_2, r_3) \in R^3$, $D_{x_0}^3 = R^3$ and Corollary 3.2 of Theorem 3.2 says that y_d can be tracked by this system if

$$\begin{aligned} y_d(0) &= h(x_0) = e^{x_{03}}, \\ y_d^{(1)}(0) &= fh(x_0) = 0, \end{aligned}$$

and

$$\begin{bmatrix} y_d^{(2)}(0) \\ y_d^{(3)}(0) \\ y_d^{(4)}(0) \\ y_d^{(5)}(0) \end{bmatrix} \in \text{Range } F_{x_0}^{2,3}.$$

If $q_0 = x_{01} e^{x_{01}+x_{03}}$, $q_2 = x_{01}^2(1 + 3x_{01} + 3e^{x_{01}}) e^{x_{01}+x_{03}}$ then this means $y_d^{(2)}(0) = q_0$, $y_d^{(3)}(0) = 0$, $y_d^{(4)}(0) = q_2$ and $y_d^{(5)}(0)$ is free if $1 + 4x_{01} \neq 0$ and is zero if $1 + 4x_{01} = 0$. Thus for $x_0 = (1, 0, -1)$ y_d can be tracked if

$$y_d(0) = e^{-1}, \quad y_d^{(1)}(0) = 0, \quad y_d^{(2)}(0) = 1, \quad y_d^{(3)}(0) = 0, \quad y_d^{(4)}(0) = 4 + 3e.$$

A control function u which works is given by

$$\begin{aligned} u_d(t, x) &= \frac{y_d^{(2)}(t) - a(x)}{b(x)} \\ &= \frac{y_d^{(2)}(t) - (x_1 + x_2^2(x_1 + e^{x_1})) e^{x_1+x_3}}{x_2^3 e^{x_1+x_3}} \quad \text{for } t > 0. \end{aligned}$$

The appropriate limiting initial value is $u_d(0, x_0) = r_1$, where r_1 solves

$$y_d^{(5)}(0) = a_3 + r_1 b_3 = 2r_1(1 + 4x_{01})x_{01}^2 e^{x_{01}+x_{03}} = 10r_1 \quad \text{or} \quad r_1 = \frac{y_d^{(5)}(0)}{10}.$$

Example 3.3. This example illustrates that $y_d \in C^\infty(R)$ does not imply $u_d \in C^\infty(R)$ if x_0 is singular. Consider the system

$$\begin{aligned} \dot{x}_1 &= 1, & a(x) &= x_2, \\ \dot{x}_2 &= -2u, & b(x) &= x_1, \\ \dot{x}_3 &= x_2 + x_1 u, \\ y &= x_3, \end{aligned}$$

where $\alpha = 1$ and $b^{(1)}(x(0)) = \dot{x}_1 = 1$ so that $\beta(x_0) = 1$ for x_0 singular (i.e., $x_0 = (0, x_{02}, x_{03})$). Here $D'_{x_0} = R^2$ so Corollary 3.2 of Theorem 3.2 applies.

If $x_0 = (0, 1, 1)$ then y_d can be tracked if $y_d(0) = 1$, and $(y_d^{(1)}(0), y_d^{(2)}(0)) \in \text{Range } F_{x_0}^{1,1} = \{(1, -r_1) | r_1 \in R\}$ or equivalently, $y_d(0) = 1$ and $y_d^{(1)}(0) = 1$. This means that

$$y_d(t) = 1 + t + \frac{t^3}{3}$$

can be tracked using

$$u_d(t, u) = \begin{cases} r_1 & \text{for } t = t_0 = 0, \\ \frac{y_d'(t) - a(x)}{b(x)} & \text{for } t > 0 \end{cases}$$

where $y_d^{(2)}(0) = 0 = -r_1$. Thus

$$u_d(t, x) = \begin{cases} 0 & \text{for } t = 0, \\ \frac{1 + t^2 - x_2}{x_1} & \text{for } t > 0. \end{cases}$$

In this example the state equations can be solved explicitly to find u as a function of t alone. In fact, solving the state equations with $u = u_d$ yields $x_1(t) = t$, $x_2(t) = -2t^2 \ln t + 1$, $x_3(t) = 1 + t + (t^3/3) = y(t) = y_d(t)$ as required. Here y_d is smooth, and u_d is continuous at $t = 0$ but not differentiable, since

$$u_d(t) = u_d(t, x_d(t)) = \frac{1 + t^2 - x_2(t)}{x_1(t)} = \frac{1 + t^2 + 2t^2 \ln t - 1}{t} = t(1 + 2 \ln t)$$

so

$$\lim_{t \rightarrow 0^+} u_d(t) = 0 = u_d(0, x_0) \quad \text{and} \quad \lim_{t \rightarrow 0^+} u_d^{(1)}(t) = \lim_{t \rightarrow 0^+} (3 + 2 \ln t) = -\infty.$$

Abstract. For the discrete-time linear stochastic systems with unknown coefficients we give an adaptive control by which both strong consistency of the parameter estimates and asymptotic optimality for the tracking system are achieved simultaneously. This is done by disturbing the signal that is to be tracked, and the disturbance consists of a sequence of random vectors with covariance matrices tending to zero. The main result is essentially based on some criteria for consistency of parameter estimate for the system without monitoring, which are also demonstrated in the paper. The existence of adaptive control is also discussed.

Key words. stochastic system, parameter estimate, strong consistency, adaptive tracking, asymptotic optimality

AMS(MOS) subject classification. 93C40

1. Introduction. Since Åström and Wittenmark [1] introduced the self-tuning regulator, much work has been devoted in recent years to the parameter-adaptive control and to the related parameter estimation problem. For the adaptive tracking problem, Goodwin, Ramadge and Caines [15] and Sin and Goodwin [21] have established the global convergence of the system and the asymptotic optimality of the tracking error by use of the stochastic gradient and the modified least squares algorithms, respectively. On the other hand, for linear stochastic systems without monitoring there are different conditions guaranteeing the strong consistency of estimates for the unknown system coefficients by invoking various approaches such as the probabilistic method (Ljung [18], Moore [20], Solo [22]), the ordinary differential equation method (Ljung [19], Kushner and Clark [17]) and the combined treatment (Chen [5], [6], [8]). But the crucial point in these different conditions is almost the same fact—the persistent excitation condition, which means that for the matrix $\sum_{i=1}^n \varphi_i \varphi_i^T$ consisting of the stochastic regressors φ_i the ratio of its maximum to minimum eigenvalues is bounded. Unfortunately, it does not always take place for the system with asymptotically optimal adaptive control given in Goodwin, Ramadge and Caines [15] and Sin and Goodwin [21], as shown in Becker, Kumar and Wei [2].

In order to get the consistent estimate for unknown parameters the adaptive control law is disturbed by a random noise introduced artificially (see Caines and Lafortune [3], Chen [7], Chen and Caines [9]). With such a treatment it turns out that the estimate is strongly consistent but the tracking error differs from its minimal value by an additional term caused by the random noise added to the adaptive control law.

However, all these facts do not mean that there is no adaptive control law forcing the long run average of the tracking errors to be minimal and, at the same time, making the parameter estimate strongly consistent, since the asymptotically optimal adaptive control law is not unique.

In this paper, we first give an adaptive control by which both strong consistency of the estimates and optimality for the tracking system are achieved simultaneously. The main idea is that the asymptotically optimal adaptive control is disturbed by a random vector sequence with vanishing covariance matrices, in contrast to the work of Caines and Lafortune [3], Chen and Caines [9] and Chen [7], where the disturbance

† Institute of Systems Science, Academia Sinica, Beijing, People's Republic of China.

is of constant covariance matrix. As a result the matrix $\sum_{i=1}^n \varphi_i \varphi_i^T$ mentioned above is ill-conditioned; hence no persistent excitation-like condition can be applied to guarantee consistency for estimates. However, recently the authors have obtained some new results (Chen and Guo [10], [11], [12]), establishing the strong consistency of parameter estimates for systems with $\sum_{i=1}^n \varphi_i \varphi_i^T$ ill-conditioned, and it appears that they are suitable to the analysis of the case of adaptive control with vanishing disturbances and make the system asymptotically optimal and the parameter estimates strongly consistent.

2. Statement of the problem. Let (Ω, \mathcal{F}, P) be a probability space with a family $\{\mathcal{F}_n\}$ of nondecreasing sub- σ -algebras. Consider the following stochastic control system:

$$(2.1) \quad y_n + A_1 y_{n-1} + \cdots + A_p y_{n-p} = B_1 u_{n-1} + \cdots + B_q u_{n-q} + w_n + C_1 w_{n-1} + \cdots + C_r w_{n-r}$$

where y_n , u_n and w_n are the m -, l - and m -dimensional output, input and driven noise, respectively, and $p \geq 1$, $q \geq 1$, $y_n = w_n = 0$, $u_n = 0$ for $n < 0$. A_i , B_j , C_k ($i = 1 \dots p$, $j = 1 \dots q$, $k = 1 \dots r$) are the unknown matrices.

Assume that u_n and w_n are \mathcal{F}_n -measurable and

$$(2.2) \quad E(w_n | \mathcal{F}_{n-1}) = 0, \quad E(\|w_n\|^2 | \mathcal{F}_{n-1}) \leq c_0 r_{n-1}^\varepsilon$$

with constants $c_0 > 0$, $\varepsilon \in [0, 1)$ and r_{n-1} defined later on by (2.9).

Let z be the shift-back operator and set

$$(2.3) \quad A(z) = I + A_1 z + \cdots + A_p z^p,$$

$$(2.4) \quad B(z) = B_1 + B_2 z + \cdots + B_q z^{q-1},$$

$$(2.5) \quad C(z) = I + C_1 z + \cdots + C_r z^r,$$

$$(2.6) \quad \theta^T = [-A_1 \cdots -A_p B_1 \cdots B_q C_1 \cdots C_r].$$

Denote by θ_n the n th estimate for θ , and let θ_n be given by

$$(2.7) \quad \theta_{n+1} = \theta_n + \frac{\varphi_n}{r_n} (y_{n+1}^T - \varphi_n^T \theta_n)$$

with

$$(2.8) \quad \varphi_n^T = [y_n^T, y_{n-1}^T, \dots, y_{n-p+1}^T, u_n^T \cdots u_{n-q+1}^T, y_n^T - \varphi_{n-1}^T \theta_{n-1}, \dots, y_{n-r+1}^T - \varphi_{n-r}^T \theta_{n-r}],$$

$$(2.9) \quad r_n = 1 + \sum_{i=1}^n \|\varphi_i\|^2, \quad r_0 = 1.$$

The initial values θ_0 and φ_0 are arbitrarily chosen.

Under reasonable conditions Goodwin, Ramadge and Caines [15] proved the global convergence and asymptotical optimality of the tracking system with u_n defined from

$$(2.10) \quad \theta_n^T \varphi_n = y_{n+1}^*,$$

i.e.,

$$(2.11) \quad \overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \|u_i\|^2 < \infty, \quad \overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \|y_i\|^2 < \infty \quad \text{a.s.}$$

$$(2.12) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n (y_i - y_i^*)(y_i - y_i^*)^T = R \quad \text{a.s.}$$

However, in this case the estimate θ_n may be inconsistent (Becker, Kumar and Wei [2]). It can be easily explained by the following example. Let $y_n^* \equiv 0$ and $\theta_0^T \theta_0 > \theta^T \theta$. Then we have

$$\theta_n^T \varphi_n \equiv 0, \quad \theta_n^T (\theta_{n+1} - \theta_n) = \theta_n^T \frac{\varphi_n}{r_n} y_{n+1}^* \equiv 0;$$

hence

$$\begin{aligned} \theta_n^T \theta_n &= \theta_{n-1}^T \theta_{n-1} + (\theta_n - \theta_{n-1})^T (\theta_n - \theta_{n-1}) \\ &= \theta_0^T \theta_0 + \sum_{i=1}^n (\theta_i - \theta_{i-1})^T (\theta_i - \theta_{i-1}) \geq \theta_0^T \theta_0 > \theta^T \theta. \end{aligned}$$

In order to achieve strongly consistent parameter estimates, Caines and Lafortune [3], Chen [7] and Chen and Caines [9] added a disturbance with covariance matrix $R_1 > 0$ to the reference sequence $\{y_n^*\}$. In this case θ_n tends to θ but the long run average of the tracking errors differs from its minimum value R by an additional term R_1 :

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n (y_i - y_i^*)(y_i - y_i^*)^T = R + R_1 \quad \text{a.s.}$$

It is natural to ask: Is it possible to achieve simultaneously both asymptotic optimality of the adaptive tracking system and the strong consistency of parameter estimates? To answer this question is the topic of the paper.

3. Main result. We first define adaptive control for the tracking system. Let $\{\varepsilon_i\}$ be an m -dimensional i.i.d. sequence which is independent of $\{w_n\}$ with properties $E\varepsilon_i \varepsilon_i^T = I$, $E\|\varepsilon_i\|^5 < \infty$.

Without loss of generality we assume $\mathcal{F}_n = \sigma\{w_i, i \leq n; \varepsilon_j, j \leq n\}$.

Unlike (2.10) we define adaptive control from the equation

$$(3.1) \quad \theta_n^T \varphi_n = y_{n+1}^* + v_n$$

where $\{y_n^*\}$ is a bounded deterministic reference sequence and

$$(3.2) \quad v_1 = 0, \quad v_n = \frac{\varepsilon_n}{\log^{1/8} n} \quad \forall n \geq 2.$$

(The existence of u_n satisfying (3.1) or (2.10) is discussed in Appendix 1.)

The disturbance v_n in (3.1) is designed to have a vanishing covariance matrix in order to make tracking error asymptotically minimal, but for this the system loses the persistent excitation property which is of crucial importance in the analysis of Caines and Lafortune [3], Chen [7] and Chen and Caines [9]. To overcome this difficulty is the main task of the present paper.

We need the following conditions:

(A₁) $C(z) - \frac{1}{2}I$ is strictly positive real;

(A₂) B_1 if of full rank and zeros of $\det B_1^+ B(z)$ lie outside the closed unit disk;

(A₃) $B_1^+ A(z)$ and $B_1^+ B(z)$ are left-coprime and $B_1^+ B_q$ is of full rank;

(A₄) $\{w_i\}$ is a mutually independent sequence with $Ew_i = 0$; $\sup_i E\|w_i\|^{4+\delta} < \infty$ for some $\delta > 0$ and

$$(3.3) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n w_i w_i^T = R > 0 \quad \text{a.s.}$$

THEOREM 1. For system (2.1)–(2.2) let the parameter estimate be given by (2.7)–(2.9) and let the control be defined by (3.1) and (3.2). If conditions A_1 – A_4 are fulfilled, then the tracking system is asymptotically optimal and the estimate is strongly consistent, i.e., (2.11) and (2.12) take place and $\theta_n \xrightarrow{n \rightarrow \infty} \theta$ a.s.

The proof of this theorem is given in § 5. For this we need some criteria for strong consistency of parameter estimate for systems without monitoring.

4. Parameter estimation for systems without monitoring. In contrast to φ_n we define an estimate-free vector φ_n^0 :

$$(4.1) \quad \varphi_n^0 = [y_n^\tau \cdots y_{n-p+1}^\tau, u_n^\tau \cdots u_{n-q+1}^\tau, w_n^\tau \cdots w_{n-r+1}^\tau]^\tau$$

and set

$$(4.2) \quad \xi_n = y_n - w_n - \theta_{n-1}^\tau \varphi_{n-1},$$

$$(4.3) \quad \varphi_n^\xi = [0 \cdots 0, 0 \cdots 0, \xi_n^\tau \cdots \xi_{n-r+1}^\tau]^\tau.$$

Then we have

$$(4.4) \quad \varphi_n = \varphi_n^0 + \varphi_n^\xi,$$

$$(4.5) \quad y_{n+1} = \theta^\tau \varphi_n^0 + w_{n+1},$$

and

$$\begin{aligned} \theta_{n+1} &= \theta_n + \frac{\varphi_n}{r_n} (\varphi_n^{0\tau} \theta + w_{n+1}^\tau - \varphi_n^\tau \theta_n) \\ &= \theta_n + \frac{\varphi_n}{r_n} (\varphi_n^\tau \theta - \varphi_n^{\xi\tau} \theta + w_{n+1}^\tau - \varphi_n^\tau \theta_n); \end{aligned}$$

hence

$$(4.6) \quad \tilde{\theta}_{n+1} = \left(I - \frac{\varphi_n \varphi_n^\tau}{r_n} \right) \tilde{\theta}_n + \frac{\varphi_n \varphi_n^{\xi\tau}}{r_n} \theta - \frac{\varphi_n}{r_n} w_{n+1}^\tau$$

with

$$(4.7) \quad \tilde{\theta}_n = \theta - \theta_n.$$

Let the matrix $\Phi(n, i)$ be recursively defined by

$$(4.8) \quad \Phi(n+1, i) = \left(I - \frac{\varphi_i \varphi_i^\tau}{r_i} \right) \Phi(n, i), \quad \Phi(i, i) = I.$$

Then from (4.6) it follows that

$$(4.9) \quad \tilde{\theta}_{n+1} = \Phi(n+1, 0) \tilde{\theta}_0 + \sum_{j=0}^n \Phi(n+1, j+1) \frac{\varphi_j \varphi_j^{\xi\tau}}{r_j} \theta - \sum_{j=0}^n \Phi(n+1, j+1) \frac{\varphi_j}{r_j} w_{j+1}^\tau,$$

from which we see that the behavior of $\Phi(n, 0)$ is of great importance for consistency of parameter estimates.

LEMMA 1. For the system and algorithm defined by (2.1)–(2.2) and (2.7)–(2.9) if condition A_1 holds, then

$$(4.10) \quad \sum_{n=0}^{\infty} \frac{\|\xi_{n+1}\|^2}{r_n} < \infty \quad \text{a.s.};$$

moreover, if conditions A_2 and A_4 hold and (2.10) or (3.1) is satisfied, then $r_n \rightarrow \infty$, and

$$(4.11) \quad \frac{1}{n} \sum_{i=0}^n \|\xi_{i+1}\|^2 \xrightarrow{n \rightarrow \infty} 0.$$

Proof. In Chen and Caines [9] and Chen [7], (4.10) and (4.11) are proved for v_n with the constant covariance matrix, but they can be verified by the same argument used there. \square

LEMMA 2. For the system and algorithm defined by (2.1)–(2.2) and (2.7)–(2.9) if condition A_1 holds then $\Phi(n, 0) \xrightarrow{n \rightarrow \infty} 0$ implies $\theta_n \xrightarrow{n \rightarrow \infty} \theta$ a.s. for any initial value θ_0 . For the special case of $r = 0$, the converse assertion is also true, i.e., if $\theta_n \xrightarrow{n \rightarrow \infty} \theta$ a.s. for any θ_0 then $\Phi(n, 0) \xrightarrow{n \rightarrow \infty} 0$ a.s.

Proof. The first step is to show

$$(4.12) \quad \sum_{i=0}^{n-1} \frac{\|\Phi(n, i+1)\varphi_i\|^2}{r_i} \leq d$$

for any vector sequence $\{\varphi_n\}$ with $\Phi(n, i)$ and r_n related by (2.9) and (4.8), where d is the dimension of φ_n .

Then by (2.2) and (4.12) we can prove that the last term of (4.9) goes to zero if $\Phi(n, 0) \xrightarrow{n \rightarrow \infty} 0$. Finally, by (4.10) and (4.12) the second term on the right-hand side of (4.9) also converges to zero if $\Phi(n, 0) \xrightarrow{n \rightarrow \infty} 0$. This is just a sketch proof for the first conclusion. For detailed proof we refer to Chen and Guo [12]. The second conclusion can be easily seen from (4.9). \square

LEMMA 3. If $r_n \xrightarrow{n \rightarrow \infty} \infty$, $\overline{\lim}_{n \rightarrow \infty} r_n / r_{n-1} < \infty$ and there exist quantities N_0 and M possibly depending on ω such that

$$(4.13) \quad \frac{\lambda_{\max}^n}{\lambda_{\min}^n} \leq M(\log r_n)^{1/4} \quad \text{a.s.} \quad \forall n \geq N_0;$$

then $\Phi(n, 0) \xrightarrow{n \rightarrow \infty} 0$, where λ_{\max}^n and λ_{\min}^n denote the maximum and minimum eigenvalue of the matrix $\sum_{i=1}^n \varphi_i \varphi_i^T + (1/d)I$ respectively and d denotes the dimension of φ_n .

Proof. We only give a sketch of the proof and refer readers interested in details to Chen and Guo [10], [11].

The key point is to find a function $m(t)$ such that $m(t) \xrightarrow{t \rightarrow \infty} \infty$ and

$$\|\Phi(m(N + k\alpha), m(N + (k-1)\alpha))\| \leq \sqrt{1 - \frac{\beta^2}{c_1 k}} \quad \forall k \geq 1$$

for some $N, \alpha > 0, \beta > 0$ and $c_1 > 0$. If it has been done, then

$$\begin{aligned} \|\Phi(m(N + k\alpha), 0)\| &\leq \prod_{i=1}^k \|\Phi(m(N + i\alpha), m(N + (i-1)\alpha))\| \cdot \|\Phi(m(N), 0)\| \\ &\leq \left[\prod_{i=1}^k \left(1 - \frac{\beta^2}{c_1 i} \right) \right]^{1/2} \xrightarrow{k \rightarrow \infty} 0; \end{aligned}$$

hence $\Phi(n, 0) \xrightarrow{n \rightarrow \infty} 0$ since $\|\Phi(j+1, j)\| \leq 1$ for all j .

It appears that the following defined function can serve as the desired one:

$$m(t) = \max [n: t_n \leq t],$$

$$t_n \triangleq \sum_{i=2}^{n-1} \frac{\|\varphi_i\|^2}{r_i (\log r_i)^{1/4}}. \quad \square$$

Remark 1. Lemma 3 is a purely algebraic result, namely, it is true for any vector sequence $\{\varphi_n\}$, only if $\Phi(n, 0)$, φ_n and r_n are related by (2.9) and (4.8).

Remark 2. There exists an example (see Chen and Guo [13]) showing that Lemma 3 is no longer true if condition (4.13) is replaced by a more general one:

$$\lambda_{\max}^n / \lambda_{\min}^n \leq M(\log r_n)^{1+a}, \quad a > 0.$$

This means that, in order for the estimate given by (2.7) to be consistent, the condition number of $\sum_{i=1}^n \varphi_i \varphi_i^\tau + (1/d)I$ is allowed to diverge at a rate of $(\log r_n)^{1/4}$, but not faster than $(\log r_n)^{1+a}$.

LEMMA 4. Let $\{\varphi_n^1\}$, $\{\varphi_n^2\}$ and $\{\psi_n\}$ be the vector sequence satisfying conditions $\varphi_n^1 = \varphi_n^2 + \psi_n$ and

$$(4.14) \quad \sum_{n=0}^{\infty} \frac{\|\psi_n\|^2}{r_{1n}} < \infty.$$

Then $\Phi_1(n, 0) \xrightarrow{n \rightarrow \infty} 0$ if and only if $\Phi_2(n, 0) \xrightarrow{n \rightarrow \infty} 0$, where by definition

$$\Phi_i(n+1, 0) = \left(I - \frac{\varphi_n^i \varphi_n^{i\tau}}{r_{in}} \right) \Phi_i(n, 0), \quad \Phi_i(0, 0) = I,$$

$$r_{in} = 1 + \sum_{j=1}^n \|\varphi_j^i\|^2, \quad r_{i0} = 1, \quad i = 1, 2.$$

Proof. Without loss of generality we assume that $\|\varphi_0^1\| \neq 1$.

Suppose $\Phi_1(n, 0) \xrightarrow{n \rightarrow \infty} 0$; then from the following chain of equalities:

$$\begin{aligned} \det \Phi_1(n+1, 0) &= \det \prod_{i=0}^n \Phi_1(i+1, i) = \prod_{i=0}^n \det \left(I - \frac{\varphi_i^1 \varphi_i^{1\tau}}{r_{1i}} \right) \\ &= \prod_{i=1}^n \frac{r_{1i-1}}{r_{1i}} (1 - \|\varphi_0^1\|^2) = \frac{1}{r_{1n}} (1 - \|\varphi_0^1\|^2) \end{aligned}$$

we see that $r_{1n} \xrightarrow{n \rightarrow \infty} \infty$.

By (4.14) and the Kronecker lemma we have

$$(4.15) \quad \frac{r_{2n}}{r_{1n}} = \frac{r_{1n} - 2 \sum_{i=1}^n \varphi_i^{1\tau} \psi_i + \sum_{i=1}^n \|\psi_i\|^2}{r_{1n}} \xrightarrow{n \rightarrow \infty} 1$$

and by (4.14)

$$(4.16) \quad \sum_{n=0}^{\infty} \frac{\|\psi_n\|^2}{r_{2n}} < \infty.$$

We immediately verify that

$$\begin{aligned} \Phi_2(n+1, 0) &= \Phi_1(n+1, 0) + \sum_{j=0}^n \Phi_1(n+1, j+1) \frac{\varphi_j^1 \psi_j^\tau}{r_{1j}} \Phi_2(j, 0) \\ &\quad + \sum_{j=0}^n \Phi_1(n+1, j+1) \frac{\psi_j \varphi_j^{2\tau}}{r_{2j}} \Phi_2(j, 0) \\ &\quad + \sum_{j=0}^n \frac{\Phi_1(n+1, j+1) \varphi_j^1}{r_{1j}^{1/2}} \left(\sqrt{\frac{r_{2j}}{r_{1j}}} - \sqrt{\frac{r_{1j}}{r_{2j}}} \right) \frac{\varphi_j^{2\tau} \Phi_2(j, 0)}{r_{2j}^{1/2}}. \end{aligned}$$

By using (4.12) and (4.14)–(4.16) it is not difficult to conclude that $\Phi_1(n, 0) \xrightarrow{n \rightarrow \infty} 0$ implies $\Phi_2(n, 0) \xrightarrow{n \rightarrow \infty} 0$. The converse implication is proved in a similar way. \square

THEOREM 2. For the system and algorithm defined by (2.1)–(2.2) and (2.7)–(2.9) if condition A_1 holds and if $r_n \xrightarrow{n \rightarrow \infty} \infty$,

$$\overline{\lim}_{n \rightarrow \infty} r_n / r_{n-1} < \infty \text{ and } \lambda_{\max}^n / \lambda_{\min}^n \leq M(\log r_n)^{1/4} \quad \forall n \geq N$$

(or $r_n^0 \xrightarrow{n \rightarrow \infty} \infty$, $\overline{\lim}_{n \rightarrow \infty} r_n^0 / r_{n-1}^0 < \infty$ and $\lambda_{\max}^{0n} / \lambda_{\min}^{0n} \leq M(\log r_n^0)^{1/4}$ for all $n \geq N$) with N and M possibly depending on ω , then

$$\theta_n \xrightarrow{n \rightarrow \infty} \theta \quad \text{a.s.}$$

for any initial value, where λ_{\max}^{0n} , λ_{\min}^{0n} denote the maximum and minimum eigenvalue of $\sum_{i=1}^n \varphi_i^0 \varphi_i^{0\tau} + (1/d)I$, respectively, and $r_n^0 = 1 + \sum_{i=1}^n \|\varphi_i^0\|^2$ with φ_n^0 defined by (4.1).

Proof. Since (4.4), (4.10) and Lemma 4 can be applied with $\varphi_n^1 = \varphi_n$, $\varphi_n^2 = \varphi_n^0$ and $\psi_n = \varphi_n^\varepsilon$, hence $\Phi(n, 0) \xrightarrow{n \rightarrow \infty} 0$ if and only if $\Phi_0(n, 0) \xrightarrow{n \rightarrow \infty} 0$, where $\Phi_0(n, 0)$ is defined by (4.8) with φ_n and r_n replaced by φ_n^0 and r_n^0 , respectively. Then the conclusions of the theorem immediately follow from Lemmas 2 and 3. \square

5. Proof of Theorem 1. To begin with we prove the following lemmas.

LEMMA 5. Let $\{v_n\}$ be defined by (3.2) and let $H_N(z) = \sum_{i=0}^{\infty} H_i(N)z^i$ be the matrix series in shift-back operator z , where the matrix coefficients $H_i(N)$ may depend upon ω , but there are constants (independent of ω) $k_1 > 0$ and $k_2 > 0$ such that

$$\|H_i(N)\| \leq k_1 \exp(-k_2 i) \quad \forall i \quad \forall N \geq 0.$$

Then

$$\begin{aligned} \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \sum_{n=1}^N (H_N(z)v_n)(H_N(z)v_n)^\tau \\ = \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \sum_{i=0}^N H_i(N)H_i^\tau(N) \left(\sum_{j=2}^N \frac{1}{\log^{1/4} j} \right). \end{aligned}$$

Proof. See Appendix 2.

LEMMA 6. Let condition A_4 except (3.3) be held and let $H(z) = \sum_{i=0}^{\infty} H_i z^i$ and $G(z) = \sum_{i=0}^{\infty} G_i z^i$ be matrix series in shift-back operator z with $\|H_i\| + \|G_i\| \leq k_1 \exp(-k_2 i)$ for all $i \geq 0$, for some constants $k_1 > 0$, $k_2 > 0$. Then there exists $\gamma \in (0, 1)$ such that for all $l \geq 0$, $m \geq 0$,

$$(5.1) \quad \lim_{N \rightarrow \infty} \frac{1}{N^\gamma} \sum_{n=1}^N (H(z)w_{n+1-l})(G(z)v_{n-m})^\tau = 0 \quad \text{a.s.},$$

$$(5.2) \quad \lim_{N \rightarrow \infty} \frac{1}{N^\gamma} \sum_{n=1}^N (H(z)w_{n+1-l})\eta_n^\tau = 0 \quad \text{a.s.}$$

for any bounded deterministic sequence $\{\eta_n\}$, and

$$(5.3) \quad \overline{\lim}_{N \rightarrow \infty} \frac{1}{N} \sum_{n=1}^N \|H(z)w_{n+1-l}\|^2 < \infty \quad \text{a.s.}$$

Proof. See Appendix 2.

Set

$$(5.4) \quad H_1(z) = [B_1^+ B(z)]^{-1} B_1^+ A(z),$$

$$(5.5) \quad H_2(z) = H_1(z) - [B_1^+ B(z)]^{-1} B_1^+ C(z),$$

$$(5.6) \quad Y_n^* = [y_n^{*\tau} \cdots y_{n-p+1}^{*\tau}, (H_1(z)y_{n+1}^*)^\tau \cdots (H_1(z)y_{n-q+2}^*)^\tau]^\tau$$

and

$$(5.7) \quad Z_n = [v_{n-1}^\tau \cdots v_{n-p}^\tau, (H_1(z)v_n)^\tau \cdots (H_1(z)v_{n-q+1})^\tau]^\tau.$$

In the following, by $\lambda_{\min}(X)$ ($\lambda_{\max}(X)$) we mean the minimum (maximum) eigenvalue of the matrix X ; we have the following.

LEMMA 7. *Under conditions of Theorem 1 if*

$$(5.8) \quad \lim_{N \rightarrow \infty} \lambda_{\min} \left(\frac{\log^{1/4} N}{N} \sum_{n=1}^N (Y_n^* Y_n^{*\tau} + Z_n Z_n^\tau) \right) \neq 0 \quad \text{a.s.}$$

then

$$\theta_n \xrightarrow[n \rightarrow \infty]{} \theta \quad \text{a.s.}$$

Proof. By Theorem 2 we only need to prove $\Phi_0(n, 0) \xrightarrow[n \rightarrow \infty]{} 0$ a.s. From (2.1) we have

$$(5.9) \quad u_n = [B_1^+ B(z)]^{-1} B_1^+ A(z) y_{n+1} - [B_1^+ B(z)]^{-1} B_1^+ C(z) w_{n+1};$$

then by (3.1), (4.2), (5.4), (5.5) and (5.9), φ_n^0 defined by (4.1) can be written as

$$(5.10) \quad \varphi_n^0 = \varphi_n^1 + \psi_n$$

where

$$(5.11) \quad \psi_n = [\xi_n^\tau \cdots \xi_{n-p+1}^\tau, (H_1(z)\xi_{n+1})^\tau \cdots (H_1(z)\xi_{n-q+2})^\tau 0 \cdots 0]^\tau,$$

$$(5.12) \quad \varphi_n^1 = \varphi_n^2 + \varphi_n^3,$$

$$(5.13) \quad \varphi_n^2 = [w_n^\tau \cdots w_{n-p+1}^\tau, (H_2(z)w_{n+1})^\tau \cdots (H_2(z)w_{n-q+2})^\tau, w_n^\tau \cdots w_{n-r+1}^\tau]^\tau,$$

$$(5.14) \quad \varphi_n^3 = [Y_n^{*\tau} + Z_n^\tau, 0 \cdots 0]^\tau.$$

By (4.4), (4.10), similar to (4.15) we have

$$(5.15) \quad \frac{r_n^0}{r_n} = \frac{r_n - 2 \sum_{i=1}^n \varphi_i^\tau \varphi_i^\xi + \sum_{i=1}^n \|\varphi_i^\xi\|^2}{r_n} \xrightarrow[n \rightarrow \infty]{} 1.$$

Then by the Schwarz inequality it follows that

$$\begin{aligned} \sum_{n=0}^{\infty} \frac{\|H_1(z)\xi_{n+1-l}\|^2}{r_n^0} &\leq \sum_{n=0}^{\infty} \frac{1}{r_n^0} \sum_{i=0}^{\infty} \|H_{1i}\| \sum_{i=0}^{\infty} \|H_{1i}\| \cdot \|\xi_{n+1-l-i}\|^2 \\ &\leq k_0 \sum_{i=0}^{\infty} \|H_{1i}\| \sum_{n=0}^{\infty} \frac{\|\xi_{n+1-l-i}\|^2}{r_n^0} < \infty \end{aligned}$$

where the last inequality is obtained because $\xi_i = 0$ for $i < 0$ and the coefficients in $H_1(z) = \sum_{i=0}^{\infty} H_{1i} z^i$ have the estimates $\|H_{1i}\| \leq k_1 \exp(-k_2 i)$, for all $i \geq 0$, ($k_1 > 0$, $k_2 > 0$) by condition A_2 . Thus we have established

$$(5.16) \quad \sum_{n=0}^{\infty} \frac{\|\psi_n\|^2}{r_n^0} < \infty$$

and by Lemma 4 we conclude that $\Phi_0(n, 0) \xrightarrow[n \rightarrow \infty]{} 0$ iff $\Phi_1(n, 0) \xrightarrow[n \rightarrow \infty]{} 0$.

Next, we prove that

$$(5.17) \quad \lim_{N \rightarrow \infty} \lambda_{\min} \left(\frac{\log^{1/4} N}{N} \sum_{n=1}^N \varphi_n^1 \varphi_n^{1\tau} \right) \neq 0 \quad \text{a.s.}$$

If for some $\omega \in \Omega$ (5.17) were not true, then we would find a subsequence of eigenvectors $\begin{bmatrix} \alpha_{N_k} \\ \beta_{N_k} \end{bmatrix}$ for matrix $(\log^{1/4} N_k / N_k) \sum_{n=1}^{N_k} \varphi_n^1 \varphi_n^{1\tau}$ with $N_k \xrightarrow[k \rightarrow \infty]{} \infty$, $\alpha_{N_k} \in R^{mp+lq}$, $\beta_{N_k} \in R^{mr}$ and

$$(5.18) \quad \|\alpha_{N_k}\|^2 + \|\beta_{N_k}\|^2 = 1$$

such that

$$(5.19) \quad (\alpha_{N_k}^\tau, \beta_{N_k}^\tau) \frac{\log^{1/4} N_k}{N_k} \sum_{n=1}^{N_k} \varphi_n^1 \varphi_n^{1\tau} \begin{pmatrix} \alpha_{N_k} \\ \beta_{N_k} \end{pmatrix} \xrightarrow[k \rightarrow \infty]{} 0.$$

Without loss of generality we always assume that this fixed ω does not belong to a possible exceptional set of probability zero. Obviously, α_{N_k} and β_{N_k} would be ω -dependent but not necessarily measurable.

Utilizing Lemma 6 one can easily be convinced of the fact

$$(5.20) \quad \frac{\log^{1/4} N}{N} \sum_{n=1}^N \varphi_n^2 \varphi_n^{3\tau} \xrightarrow[N \rightarrow \infty]{} 0,$$

then (5.19) is reduced to

$$(5.21) \quad (\alpha_{N_k}^\tau, \beta_{N_k}^\tau) \frac{\log^{1/4} N_k}{N_k} \sum_{n=1}^{N_k} \varphi_n^2 \varphi_n^{2\tau} \begin{pmatrix} \alpha_{N_k} \\ \beta_{N_k} \end{pmatrix} \xrightarrow[k \rightarrow \infty]{} 0,$$

$$(5.22) \quad (\alpha_{N_k}^\tau, \beta_{N_k}^\tau) \frac{\log^{1/4} N_k}{N_k} \sum_{n=1}^{N_k} \varphi_n^3 \varphi_n^{3\tau} \begin{pmatrix} \alpha_{N_k} \\ \beta_{N_k} \end{pmatrix} \xrightarrow[k \rightarrow \infty]{} 0.$$

In view of Lemma 6, (5.8) implies

$$(5.23) \quad \lim_{N \rightarrow \infty} \lambda_{\min} \left(\frac{\log^{1/4} N}{N} \sum_{n=1}^N (Y_n^* + Z_n)(Y_n^* + Z_n)^\tau \right) \neq 0.$$

Paying attention to the fact that the last mr elements in φ_n^3 are zeros, by (5.22) and (5.23) we conclude that

$$(5.24) \quad \alpha_{N_k} \xrightarrow[k \rightarrow \infty]{} 0;$$

hence, recalling (5.18) we have

$$(5.25) \quad \|\beta_{N_k}\| \xrightarrow[k \rightarrow \infty]{} 1.$$

Let

$$x_n^1 = [w_n^\tau \cdots w_{n-p+1}^\tau, (H_2(z)w_{n+1})^\tau \cdots (H_2(z)w_{n-q+2})^\tau]^\tau,$$

$$x_n^2 = [w_n^\tau \cdots w_{n-r+1}^\tau]^\tau.$$

Then $\varphi_n^2 = [x_n^1, x_n^2]^\tau$ and (5.21) implies

$$(5.26) \quad \frac{1}{N_k} \sum_{n=1}^{N_k} \|\alpha_{N_k}^\tau x_n^1 + \beta_{N_k}^\tau x_n^2\|^2 \xrightarrow[k \rightarrow \infty]{} 0.$$

Further, we have

$$(5.27) \quad \overline{\lim}_{N \rightarrow \infty} \frac{1}{N} \sum_{n=1}^N \|x_n^1\|^2 < \infty \quad \text{a.s.}$$

by Lemma 6, and

$$(5.28) \quad \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{n=1}^N x_n^2 x_n^{2\tau} = \begin{bmatrix} R & 0 \\ 0 & R \end{bmatrix} > 0$$

by ergodicity.

Thus from (5.24) and (5.26)–(5.28) it follows that

$$\lim_{k \rightarrow \infty} \frac{1}{N_k} \sum_{n=1}^{N_k} \beta_{N_k}^\tau x_n^2 x_n^{2\tau} \beta_{N_k} = 0,$$

which leads to $\beta_{N_k} \xrightarrow{k \rightarrow \infty} 0$ by (5.28). Comparing it with (5.25) we obtain a contradiction, which shows the truth of (5.17). Therefore, there exist $\alpha_0 > 0$, N_0 such that

$$(5.29) \quad \lambda_{\min} \left(\sum_{i=1}^n \varphi_i^1 \varphi_i^{1\tau} \right) \geq \frac{n}{\log^{1/4} n} \alpha_0 \quad \forall n \geq N_0.$$

By (5.12) and Lemma 6 it follows that

$$(5.30) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \|\varphi_i^1\|^2 \geq \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \|w_i\|^2 = \text{tr } R > 0$$

and

$$(5.31) \quad \overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \|\varphi_i^1\|^2 < \infty \quad \text{a.s.}$$

From (5.30) and (5.31) it follows that there are positive quantities $\beta \geq \alpha > 0$ such that

$$(5.32) \quad \alpha n \leq r_{1n} \leq \beta n,$$

which, together with (5.29), yields

$$\lambda_{\max}^{1n} / \lambda_{\min}^{1n} \leq M \log^{1/4} r_{1n} \quad \forall n \geq N_0 \quad \text{with some } M > 0$$

where λ_{\max}^{1n} and λ_{\min}^{1n} denote, respectively, the maximum and minimum eigenvalues of $\sum_{i=1}^n \varphi_i^1 \varphi_i^{1\tau} + (1/\alpha)I$. Then we obtain the required assertion $\Phi_1(n, 0) \xrightarrow{n \rightarrow \infty} 0$ by Lemma 3 and Remark 1. \square

Proof of Theorem 1. Since $\sum_{i=2}^n (v_i v_i^\tau - (1/\log^{1/4} i)I)/i$ is a convergent martingale, by the Kronecker lemma it follows that

$$(5.33) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n v_i v_i^\tau = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=2}^n \frac{1}{\log^{1/4} i} I = 0.$$

Similarly we have

$$(5.34) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n w_i v_{i-1}^\tau = 0.$$

From (3.1) and (4.2) it follows that

$$(5.35) \quad y_{n+1} = \xi_{n+1} + y_{n+1}^* + w_{n+1} + v_n.$$

Then (2.11) and (2.12) follow immediately from (4.11), (5.9), (5.33)–(5.35) and condition A_2 .

Thus we only need to prove $\theta_n \xrightarrow{n \rightarrow \infty} \theta$ a.s. By Lemma 7 it suffices to verify that

$$(5.36) \quad \lim_{N \rightarrow \infty} \lambda_{\min} \left(\frac{\log^{1/4} N}{N} \sum_{n=1}^N Z_n Z_n^\tau \right) \neq 0 \quad \text{a.s.}$$

If (5.36) were not true, then there would exist a subsequence of eigenvectors $\alpha_{N_k} \in R^{mp+lq}$ for matrix $(\log^{1/4} N_k / N_k) \sum_{n=1}^{N_k} Z_n Z_n^\tau$ with $N_k \xrightarrow[k \rightarrow \infty]{} \infty$ and

$$(5.37) \quad \|\alpha_{N_k}\| = 1 \quad \forall k \geq 1$$

such that

$$(5.38) \quad \alpha_{N_k}^\tau \frac{\log^{1/4} N_k}{N_k} \sum_{n=1}^{N_k} Z_n Z_n^\tau \alpha_{N_k} \xrightarrow[k \rightarrow \infty]{} 0.$$

Without loss of generality we suppose $\alpha_{N_k} \xrightarrow[k \rightarrow \infty]{} \alpha$. Write α_{N_k} and α in the component form

$$\alpha_{N_k} = [\alpha_1^\tau(N_k) \cdots \alpha_{p+q}^\tau(N_k)]^\tau, \quad \alpha = [\alpha_1^\tau \cdots \alpha_{p+q}^\tau]^\tau$$

with $\alpha_i(N_k)$, α_i being m -dimensional and $\alpha_{p+j}(N_k)$, α_{p+j} l -dimensional vectors, $i = 1 \cdots p$, $j = 1 \cdots q$.

Set

$$(5.39) \quad \begin{aligned} H_{N_k}(z) &= \alpha_1^\tau(N_k)z + \cdots + \alpha_p^\tau(N_k)z^p \\ &\quad + \alpha_{p+1}^\tau(N_k)H_1(z) + \cdots + \alpha_{p+q}^\tau(N_k)H_1(z)z^{q-1} \\ &\triangleq \sum_{i=0}^{\infty} h_i^\tau(N_k)z^i, \end{aligned}$$

$$(5.40) \quad \begin{aligned} H(z) &= \alpha_1^\tau z + \cdots + \alpha_p^\tau z^p + \alpha_{p+1}^\tau H_1(z) + \cdots + \alpha_{p+q}^\tau H_1(z)z^{q-1} \\ &\triangleq \sum_{i=0}^{\infty} h_i^\tau z^i. \end{aligned}$$

We note that α_{N_k} and hence $H_{N_k}(z)$ may depend on ω , but by condition A₂ and (5.37) it is clear that there are constants $c_1 > 0$, $c_2 > 0$ such that $\|h_i(N_k)\| \leq c_1 \exp(-c_2 i)$ for all $i \geq 0$, for all $k \geq 0$. Then Lemma 5 can be applied, and from (5.38), (5.39) we have

$$\begin{aligned} 0 &= \lim_{k \rightarrow \infty} \frac{\log^{1/4} N_k}{N_k} \sum_{n=1}^{N_k} [\alpha_1^\tau(N_k)v_{n-1} + \cdots + \alpha_p^\tau(N_k)v_{n-p} + \alpha_{p+1}^\tau(N_k)H_1(z)v_n + \cdots \\ &\quad + \alpha_{p+q}^\tau(N_k)H_1(z)v_{n-q+1}]^2 \\ &= \lim_{k \rightarrow \infty} \frac{\log^{1/4} N_k}{N_k} \sum_{n=1}^{N_k} [(\alpha_1^\tau(N_k)z + \cdots + \alpha_p^\tau(N_k)z^p + \alpha_{p+1}^\tau(N_k)H_1(z) + \cdots \\ &\quad + \alpha_{p+q}^\tau(N_k)H_1(z)z^{q-1})v_n]^2 \\ &= \lim_{k \rightarrow \infty} \frac{\log^{1/4} N_k}{N_k} \sum_{n=1}^{N_k} (H_{N_k}(z)v_n)(H_{N_k}(z)v_n)^\tau \\ &= \lim_{k \rightarrow \infty} \frac{\log^{1/4} N_k}{N_k} \sum_{i=0}^{N_k} h_i^\tau(N_k) \sum_{n=2}^{N_k} \frac{1}{\log^{1/4} n} h_i(N_k), \end{aligned}$$

which implies that

$$\lim_{k \rightarrow \infty} \sum_{i=0}^{N_k} \|h_i(N_k)\|^2 = 0$$

and hence $\sum_{i=0}^{\infty} \|h_i\|^2 = 0$ by the dominated convergence theorem; therefore $H(z) = 0$. Setting $z = 0$ and paying attention to the fact that $H_1(0)(= B_1^+)$ is of full row rank we see $\alpha_{p+1}^\tau B_1^+ = 0$ and so $\alpha_{p+1} = 0$. Then it follows directly from (5.40) that

$$(5.41) \quad (\alpha_1^\tau + \alpha_2^\tau z + \cdots + \alpha_p^\tau z^{p-1}) = -(\alpha_{p+2}^\tau + \cdots + \alpha_{p+q}^\tau z^{q-2})H_1(z).$$

In view of condition A_3 , applying Lemma 6.6-1 of Kailath [16] to (5.41) we know that there exists a polynomial with vector coefficients $f(z)$:

$$f(z) = f_1 + f_2 z + \cdots + f_s z^{s-1}, \quad s \geq 1,$$

such that

$$(5.42) \quad (\alpha_{p+2}^\tau + \cdots + \alpha_{p+q}^\tau z^{q-2}) = f^\tau(z) B_1^+ B(z) \\ = (f_1^\tau + \cdots + f_s^\tau z^{s-1})(B_1^+ B_1 + \cdots + B_1^+ B q z^{q-1}).$$

From here it is easy to conclude that $f_i = 0$ ($1 \leq i \leq s$) since $B_1^+ B_q$ is of full rank by condition A_3 , then $\alpha_{p+j} = 0$ by (5.42), and then $\alpha_j = 0$ by (5.41) ($1 \leq j \leq q$, $1 \leq i \leq p$). Thus $\alpha = 0$, and $\alpha_{N_k} \xrightarrow{k \rightarrow \infty} 0$, thus contradicting (5.37). Hence (5.36) holds. \square

6. Concluding discussion. In order to get optimality in both tracking and estimating we have added to $\{y_n^*\}$ a random disturbance with covariance matrix tending to zero, but, intuitively, the disturbance may harm the tracking if time is bounded. However, all assertions of Theorem 1 can remain valid for u_n defined from (3.1) with v_n deleted (i.e. from (2.10)) if the reference signal y_n^* itself is "complicated" enough in the sense that

$$(6.1) \quad \lim_{N \rightarrow \infty} \lambda_{\min} \left(\frac{\log^{1/4} N}{N} \sum_{n=1}^N Y_n^* Y_n^{*\tau} \right) \neq 0.$$

This remark can easily be seen from Lemma 7.

For the single-input and single-output system it is easy to show that for (6.1) it suffices to require condition A_3 and

$$(6.2) \quad \lim_{N \rightarrow \infty} \lambda_{\min} \left(\frac{\log^{1/4} N}{N} \sum_{n=1}^N [y_n^* \cdots y_{n-p-q+1}^*]^\tau [y_n^* \cdots y_{n-p-q+1}^*] \right) \neq 0.$$

Recently, for multidimensional and random $\{y_n^*\}$ we have obtained conditions similar to (6.2) in order that all conclusions of Theorem 1 hold by applying u_n defined from (2.10). It will be published elsewhere.

Appendix 1. Existence of adaptive control.

LEMMA. (1) Let A and B be two matrices of dimensions $m \times n$ and $n \times m$, respectively. Then the following equality takes place

$$\det(I_m + AB) = \det(I_n + BA)$$

where I_n means the $n \times n$ identity matrix.

(2) Provided x_1 and x_2 are independent random variables, then

$$\sup_{a \in R^1} P(x_1 + x_2 = a) \leq \min \left\{ \sup_{a \in R^1} P(x_1 = a), \sup_{a \in R^1} P(x_2 = a) \right\}.$$

Proof. (1) By taking determinants for both sides of the following matrix identity:

$$\begin{bmatrix} I_m & -A \\ 0 & BA + I_n \end{bmatrix} = \begin{bmatrix} I_m & 0 \\ -B & I_n \end{bmatrix} \cdot \begin{bmatrix} I_m + AB & -A \\ 0 & I_n \end{bmatrix} \cdot \begin{bmatrix} I_m & 0 \\ B & I_n \end{bmatrix},$$

the desired equality is immediately verified.

(2) Denote by $F_1(x)$, $F_2(x)$, $F_{12}(x)$ the distributions of x_1 , x_2 , $x_1 + x_2$, respectively. Clearly we have

$$F_{12}(x) = \int_{-\infty}^{\infty} F_1(x-y) dF_2(y)$$

and

$$F_{12}(x+) = \int_{-\infty}^{\infty} F_1((x-y)+) dF_2(y)$$

by the dominated convergence theorem.

Then for any $a \in R^1$

$$\begin{aligned} P(x_1 + x_2 = a) &= F_{12}(a+) - F_{12}(a) = \int_{-\infty}^{\infty} [F_1((a-y)+) - F_1(a-y)] dF_2(y) \\ &= \int_{-\infty}^{\infty} P(x_1 = a-y) dF_2(y) \leq \sup_{a \in R^1} P(x_1 = a) \int_{-\infty}^{\infty} dF_2(y) \\ &= \sup_{a \in R^1} P(x_1 = a). \end{aligned}$$

Similarly, we have

$$P(x_1 + x_2 = a) \leq \sup_{a \in R^1} P(x_2 = a)$$

and thus the desired result follows. \square

THEOREM. Assume $m \leq l$ and $\{w_n\}$ and $\{v_n\}$ are two sequences of mutually independent random vectors and the components of w_n are independent and with continuous distribution functions. Then for any $n \geq 1$ there exists u_n satisfying (3.1) if the initial values are appropriately chosen. Further, this u_n is unique if and only if $m = l$.

Proof. Let $A_{in}, B_{jn}, C_{kn}, i = 1 \cdots p, j = 1 \cdots q, k = 1 \cdots r$ be the matrix components of θ_n , i.e.,

$$\theta_n^\tau = [-A_{1n} \cdots -A_{pn} B_{1n} \cdots B_{qn} C_{1n} \cdots C_{rn}].$$

Set

$$\bar{\theta}_n^\tau = [-A_{1n} \cdots -A_{pn} 0 B_{2n} \cdots B_{qn} C_{1n} \cdots C_{rn}],$$

and

$$\bar{\varphi}_n = [y_n^\tau \cdots y_{n-p+1}^\tau, 0, u_{n-1}^\tau \cdots u_{n-q+1}^\tau, y_n^\tau - \varphi_{n-1}^\tau \theta_{n-1}, \cdots, y_{n-r+1}^\tau - \varphi_{n-r}^\tau \theta_{n-r}]^\tau.$$

Equation (3.1) is equivalent to

$$(A.1) \quad B_{1n} u_n = y_{n+1}^* + v_n - \bar{\theta}_n^\tau \bar{\varphi}_n.$$

First let $m = l$. For this case we only need to prove that B_{1n} is invertible a.s. In fact, if this is true, then from (A.1) u_n is uniquely defined by $u_n = B_{1n}^{-1}(y_{n+1}^* + v_n - \bar{\theta}_n^\tau \bar{\varphi}_n)$, which obviously is \mathcal{F}_n -measurable. (In adaptive tracking cases we take $\mathcal{F}_n \triangleq \sigma\{w_i, v_i, i \leq n\}$.)

From (2.7) and (4.2) we obtain

$$(A.2) \quad B_{1n+1} = B_{1n} + \frac{1}{r_n}(\xi_{n+1} + w_{n+1})u_n^\tau.$$

It is easy to take initial values φ_0, θ_0 such that B_{11} is invertible; for example, take $u_0 = 0$ and B_{10} invertible.

We now inductively prove that B_{1n} is nondegenerate for any $n \geq 0$. Assuming B_{1n} is nonsingular a.s., we show that B_{1n+1} is also. In other words, we need to prove that $P(N) = 0$ implies $P(DN^c) = 0$, where

$$N \triangleq \{\omega \mid \det B_{1n} = 0\}, \quad D \triangleq \{\omega \mid \det B_{1n+1} = 0\}.$$

Suppose that the opposite were true, i.e., $P(N) = 0$, but $P(DN^c) > 0$.

From (A.2) we have

$$\det \left(B_{1n} + \frac{1}{r_n} (\xi_{n+1} + w_{n+1}) u_n^T \right) = 0 \quad \forall \omega \in DN^c$$

but $\det B_{1n} \neq 0$ for $\omega \in DN^c$; hence

$$\det \left(I + \frac{1}{r_n} B_{1n}^{-1} (\xi_{n+1} + w_{n+1}) u_n^T \right) = 0 \quad \forall \omega \in DN^c$$

or

$$\det \left(1 + \frac{1}{r_n} u_n^T B_{1n}^{-1} (\xi_{n+1} + w_{n+1}) \right) = 0 \quad \forall \omega \in DN^c$$

by part (1) of the lemma.

Then we have

$$(A.3) \quad u_n^T B_{1n}^{-1} (\xi_{n+1} + w_{n+1}) = -r_n \quad \forall \omega \in DN^c$$

and consequently,

$$(A.4) \quad u_n^T B_{1n} \neq 0 \quad \forall \omega \in DN^c$$

since $r_n \geq 1$.

We denote by $\alpha_i(\omega)$ and $w_{n+1,i}$ the components of $u_n^T B_{1n}^{-1}$ and w_{n+1} respectively, i.e.,

$$(A.5) \quad u_n^T B_{1n}^{-1} = [\alpha_1(\omega), \dots, \alpha_m(\omega)],$$

$$(A.6) \quad w_{n+1} = [w_{n+1,1}, \dots, w_{n+1,m}]^T.$$

Then from (A.3), (A.5) and (A.6) we have

$$(A.7) \quad \sum_{i=1}^m \alpha_i(\omega) w_{n+1,i} + r_n + u_n^T B_{1n}^{-1} \xi_{n+1} = 0 \quad \forall \omega \in DN^c.$$

From (A.4) and the assumption $P(DN^c) > 0$ we would have some $\alpha_i(\omega)$ and a subset $D_1 \subset DN^c$ such that

$$(A.8) \quad \alpha_i(\omega) \neq 0 \quad \forall \omega \in D_1, \quad P(D_1) > 0.$$

Without loss of generality, we assume $i = 1$, and define the random variable $z(\omega)$:

$$z(\omega) = \begin{cases} \frac{1}{\alpha_1(\omega)} \left[\sum_{i=2}^m \alpha_i(\omega) w_{n+1,i} + r_n + u_n^T B_{1n}^{-1} \xi_{n+1} \right], & \omega \in D_1, \\ 0, & \omega \in D_1^c, \end{cases}$$

which is clearly independent of $w_{n+1,1}$. By part (2) of the lemma, it follows that

$$(A.9) \quad P(w_{n+1,1} + z(\omega) = 0) = 0.$$

However, (A.7) and (A.8) would yield

$$(A.10) \quad P(w_{n+1,1} + z(\omega) = 0) \geq P(D_1) > 0.$$

The contradiction obtained proves $P(DN^c) = 0$, and hence the nonsingularity of $B_{1,n+1}$ a.s.

Now assume $m < l$.

Let

$$B_{1n} \triangleq [\overbrace{B_{1n}^1}^m, \overbrace{B_{1n}^2}^{l-m}]m, \quad u_n^\tau \triangleq [\overbrace{u_n^{1\tau}}^m, \overbrace{u_n^{2\tau}}^{l-m}].$$

From (A.2) we see

$$B_{1n+1}^1 = B_{1n}^1 + \frac{1}{r_n}(\xi_{n+1} + w_{n+1})u_n^{1\tau}.$$

By an argument similar to that given for the $m = l$ case we can prove that B_{1n}^1 is invertible a.s. for any $n \geq 1$ if φ_0, θ_0 are adequately chosen. Then (A.1) is equivalent to

$$(A.11) \quad [I, (B_{1n}^1)^{-1}B_{1n}^2]u_n = (B_{1n}^1)^{-1}(y_{n+1}^* + v_n - \bar{\theta}_n^\tau \bar{\varphi}_n)$$

or

$$u_n^1 + (B_{1n}^1)^{-1}B_{1n}^2u_n^2 = (B_{1n}^1)^{-1}(y_{n+1}^* + v_n - \bar{\theta}_n^\tau \bar{\varphi}_n).$$

Obviously, the solution of (A.11) can be expressed by

$$u_n = \begin{bmatrix} (B_{1n}^1)^{-1}(y_{n+1}^* + v_n - \bar{\theta}_n^\tau \bar{\varphi}_n - B_{1n}^2u_n^2) \\ u_n^2 \end{bmatrix} \quad \text{a.s.}$$

with any $(l-m)$ -dimensional and \mathcal{F}_n -measurable u_n^2 . This means that for the case $m < l$ the control u_n satisfying (3.1) exists but it is not unique. \square

Remark. Recently Caines and Meyn [4] also have shown the existence of u_n satisfying (2.10) for a one-dimensional case but under conditions different from those imposed here.

Appendix 2. Proof of lemmas.

Proof of Lemma 5. Due to the assumption $v_n = 0$ for $n < 0$, we have

$$\begin{aligned} \sum_{h=1}^N (H_N(z)v_n)(H_N(z)v_n)^\tau &= \sum_{i,j=0}^{\infty} H_i(N) \left(\sum_{n=1}^N v_{n-i}v_{n-j}^\tau \right) H_j^\tau(N) \\ &= \sum_{i,j=0}^{\infty} H_i(N) \left(\sum_{n=\max(i,j,1)}^N v_{n-i}v_{n-j}^\tau \right) H_j^\tau(N). \end{aligned}$$

Set

$$S_N(i, j) = \sum_{n=\max(i,j,1)}^N [v_{n-i}v_{n-j}^\tau - \delta_{ij}R_{n-i}],$$

$$R_n = Ev_nv_n^\tau = \begin{cases} \frac{1}{\log^{1/4} n} I, & n > 1, \\ 0, & n \leq 1. \end{cases}$$

Clearly, $S_N(i, j)$ is a martingale and by Burkholder inequality (Chow and Teicher [14]), C_r -inequality and Schwarz inequality we have

$$\begin{aligned} E\|S_N(i, j)\|^{2+\delta/2} &\leq c_1 E \left(\sum_{n=\max(i,j,1)}^N \|v_{n-i}v_{n-j}^\tau - \delta_{ij}R_{n-i}\|^2 \right)^{1+(\delta/4)} \\ &\leq c_1 N^{\delta/4} E \sum_{n=\max(i,j,1)}^N \|v_{n-i}v_{n-j}^\tau - \delta_{ij}R_{n-i}\|^{2+(\delta/2)} \\ &\leq c_2 N^{1+\delta/4} \quad \text{for any } i \geq 0, j \geq 0 \text{ and some } c_1 > 0, c_2 > 0. \end{aligned}$$

From here and the Hölder inequality it follows that for any $\varepsilon > 0$ and

$$\gamma \in \left(\frac{2 + (\delta/4)}{2 + (\delta/2)}, 1 \right),$$

$$\begin{aligned} & P \left\{ \sum_{i,j=0}^{\infty} e^{-k_2(i+j)} \|S_N(i,j)\| > N^{\gamma} \cdot \varepsilon \right\} \\ & \leq \frac{1}{\varepsilon^{2+(\delta/2)} N^{\gamma(2+(\delta/2))}} E \left(\sum_{i,j=0}^{\infty} e^{-k_2(i+j)} \|S_N(i,j)\| \right)^{2+(\delta/2)} \\ & \leq c_3 \frac{1}{N^{\gamma(2+(\delta/2))}} E \sum_{i,j=0}^{\infty} (e^{-k_2(i+j)})^{1+(\delta/4)} \|S_N(i,j)\|^{2+(\delta/2)} \\ & \leq c_4 \cdot \frac{1}{N^{\gamma(2+(\delta/2)) - (1+(\delta/4))}} \quad \text{for any } N \geq 1 \text{ and some constants } c_3 > 0, c_4 > 0. \end{aligned}$$

Then by the Borel–Cantelli lemma we see

$$(A.12) \quad \overline{\lim}_{N \rightarrow \infty} \frac{1}{N^{\gamma}} \left\| \sum_{i,j=0}^{\infty} H_i(N) S_N(i,j) H_j^{\tau}(N) \right\| \leq \lim_{N \rightarrow \infty} \frac{k_1^2}{N^{\gamma}} \sum_{i,j=0}^{\infty} e^{-k_2(i+j)} \|S_N(i,j)\| \xrightarrow{N \rightarrow \infty} 0.$$

Finally, we obtain the desired result

$$\begin{aligned} & \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \sum_{n=1}^N (H_N(z) v_n) (H_N(z) v_n)^{\tau} \\ & = \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \sum_{i,j=0}^{\infty} (H_i(N) S_N(i,j) H_j^{\tau}(N)) \\ & \quad + \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \sum_{i,j=0}^{\infty} H_i(N) \sum_{n=\max(i,j,1)}^N \delta_{ij} R_{n-i} H_j^{\tau}(N) \\ & = \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \sum_{i=0}^N H_i(N) \sum_{n=\max(i,1)}^N R_{n-i} H_i^{\tau}(N) \\ & = \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \left[H_0(N) \sum_{n=1}^N R_n H_0^{\tau}(N) + \sum_{i=1}^N H_i(N) \sum_{n=0}^{N-i} R_n H_i^{\tau}(N) \right] \\ & = \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \left[H_0(N) \sum_{n=1}^N R_n H_0^{\tau}(N) \right. \\ & \quad \left. + \sum_{i=1}^N H_i(N) \left(\sum_{n=1}^N R_n + R_0 - \sum_{n=N-i+1}^N R_n \right) H_i^{\tau}(N) \right] \\ & = \lim_{N \rightarrow \infty} \frac{\log^{1/4} N}{N} \sum_{i=0}^N H_i(N) \sum_{n=1}^N R_n H_i^{\tau}(N). \quad \square \end{aligned}$$

Proof of Lemma 6. Set

$$S_N(i,j) \triangleq \sum_{n=1}^N w_{n+1-l-i} v_{n-m-j}^{\tau}.$$

Similar to the proof of (A.12), one can easily be convinced that

$$\lim_{N \rightarrow \infty} \frac{1}{N^{\gamma}} \sum_{i,j=0}^{\infty} H_i S_N(i,j) G_j^{\tau} = 0,$$

which is tantamount to (5.1).

Clearly, (5.2) can be verified in similar fashion.

By setting $H_N(z) \equiv H(z)$ and $v_n \equiv w_{n+1-l}$ in (A.12) we have

$$\lim_{N \rightarrow \infty} \frac{1}{N^\gamma} \sum_{i,j=0}^{\infty} H_i S_N(i,j) H_j^\tau = 0$$

where

$$S_N(i,j) = \sum_{n=\max(i,j,1)}^N [w_{n-l+1-i} w_{n-l+1-j}^\tau - \delta_{ij} R_{n-l+1-i}]$$

and

$$R_{n-l+1-i} \triangleq E w_{n-l+1-i} w_{n-l+1-i}^\tau.$$

Hence by the uniform boundedness of R_n we have

$$\begin{aligned} & \overline{\lim}_{N \rightarrow \infty} \frac{1}{N} \sum_{n=1}^N \|H(z) w_{n+1-l}\|^2 \\ &= \overline{\lim}_{N \rightarrow \infty} \operatorname{tr} \left[\frac{1}{N} \sum_{n=1}^N (H(z) w_{n+1-l})(H(z) w_{n+1-l})^\tau \right] \\ &= \overline{\lim}_{N \rightarrow \infty} \operatorname{tr} \left[\frac{1}{N} \sum_{i,j=0}^{\infty} H_i S_N(i,j) H_j^\tau + \sum_{i,j=0}^{\infty} H_i \frac{1}{N} \sum_{n=\max(i,j,1)}^N \delta_{ij} R_{n-l+1-i} H_j^\tau \right] \\ &= \overline{\lim}_{N \rightarrow \infty} \operatorname{tr} \sum_{i=0}^{\infty} H_i \frac{1}{N} \sum_{n=\max(i,1)}^N R_{n-l+1-i} H_i^\tau < \infty. \end{aligned}$$

This completes the proof of the lemma. \square

OPTIMAL CONTROL OF A SIGNORINI PROBLEM*

A. BERMUDEZ† AND C. SAGUEZ‡

Abstract. In this paper we present a new method to obtain necessary conditions for optimal control problems of variational inequalities. It uses only techniques of classical convex analysis and is based on a transformation of the original problem into another one involving a linear state equation and nonconvex constraints on the state.

Key words. optimal control, variational inequalities, optimality conditions

AMS(MOS) subject classifications. Primary 49B22, 49A29; secondary 35J85, 35R35

1. Introduction. Optimal control problems for variational inequalities have been considered by many authors (J. L. Lions [5], J. P. Yvon [13], C. Saguez [12], F. Mignot [7], V. Barbu [1], [2]). The main difficulties appearing in such problems are to obtain optimality conditions and efficient numerical algorithms. They are due to the non-differentiability of the mapping giving the state from the control.

For the obstacle problem some results have been given by F. Mignot and J. P. Puel [8] using the conical derivative and by V. Barbu [1] using a penalty method. This last method has also been used in C. Saguez [11] and V. Barbu [2] to deal with parabolic problems.

More recently the authors have introduced a new method (A. Bermudez and C. Saguez [4]) to study optimal control problems of variational inequalities. The main idea is to transform the optimal control problem into another one involving a linear state equation and nonconvex constraints on the state. Optimality conditions are then obtained by analyzing the ones corresponding to this new optimal control problem.

The same transformation has been used by F. Mignot and J. P. Puel [9] to study an optimal control problem of a parabolic variational inequality of the obstacle type. For obtaining optimality conditions they use a regularization technique which needs some difficult a priori estimates.

In this paper we introduce another method which consists of considering two directions along which this optimal control problem is convex and then writing the corresponding optimality conditions.

This method which is quite general is applied to solve a boundary control problem for a variational inequality of Signorini type.

2. The optimal control problem. Let Ω be an open bounded subset of \mathbb{R}^N with smooth boundary Γ . Let f be given in $L^2(\Omega)$.

For $v \in L^2(\Gamma)$ we define $y(v)$ the state of the system as the solution of the variational inequality:

$$(2.1) \quad a(y, Z - y) \cong \int_{\Omega} f(Z - y) \, dx + \int_{\Gamma} v(Z - y) \, d\Gamma \quad \forall Z \in K$$

where a is the bilinear form:

$$(2.2) \quad a(y, Z) = \sum_{i=1}^N \int_{\Omega} \frac{\partial y}{\partial X_i} \frac{\partial Z}{\partial X_i} \, dx + \int_{\Omega} yZ \, dx$$

† Dep. Ecuaciones Funcionales, University of Santiago, Spain.

‡ SIMULOG S.A. Av. du Centre-78182 St. Quentin en Yvelines, France.

and K is given by:

$$(2.3) \quad K = \{Z \in V: Z \geq 0 \text{ a.e. on } \Gamma\}$$

with $V = H^1(\Omega)$.

We denote by A the bounded linear operator from V into V' defined by:

$$(2.4) \quad \langle Ay, Z \rangle = a(y, Z) \quad \forall y, Z \in V$$

where \langle, \rangle represents the duality map between V' and V .

Consider the following cost function:

$$(2.5) \quad J(v) = \int_{\Omega} (y(v) - Z_d)^2 dx + \frac{\nu}{2} \int_{\Gamma} v^2 d\Gamma$$

where Z_d is a given function in $L^2(\Omega)$ and ν a strictly positive real number.

The optimal problem is to find $u \in U_{ad}$ such that

$$(2.6) \quad J(u) \leq J(v) \quad \forall v \in L^2(\Gamma).$$

Existence of a solution of this problem is shown in J. L. Lions [5] by using a compacity method.

3. A regularity result. In this paragraph we show some regularity properties which will be used to obtain optimality conditions.

PROPOSITION 3.1. *If y is the solution of (2.1) there exists η in $L^2(\Gamma)$ such that:*

$$(3.1) \quad \frac{\partial y}{\partial n} + \eta = v \quad \text{on } \Gamma,$$

$$(3.2) \quad \eta \leq 0 \quad \text{on } \Gamma,$$

$$(3.3) \quad \int_{\Gamma} y \eta d\Gamma = 0.$$

Proof. Let y_{ε} be the solution of the penalized problem:

$$(3.4) \quad -\Delta y_{\varepsilon} + y_{\varepsilon} = f \quad \text{in } \Omega, \quad \frac{\partial y_{\varepsilon}}{\partial n} - \frac{1}{\varepsilon} y_{\varepsilon}^{-} = v \quad \text{on } \Gamma.$$

Multiplying the first equation by $-(1/\varepsilon)y_{\varepsilon}^{-}$ and using a Green's formula we obtain:

$$(3.5) \quad \frac{1}{\varepsilon} a(y_{\varepsilon}^{-}, y_{\varepsilon}^{-}) + \frac{1}{\varepsilon^2} \int_{\Gamma} |y_{\varepsilon}^{-}|^2 d\Gamma = -\frac{1}{\varepsilon} \int_{\Omega} f y_{\varepsilon}^{-} dx - \frac{1}{\varepsilon} \int_{\Gamma} v y_{\varepsilon}^{-} d\Gamma$$

from which it follows that:

$$(3.6) \quad \frac{1}{\varepsilon} y_{\varepsilon}^{-} \text{ is bounded in } L^2(\Gamma)$$

and then

$$(3.7) \quad y_{\varepsilon} \text{ is bounded in } H^{3/2}(\Omega) \quad (\text{see J. L. Lions and E. Magenes [6]}).$$

By using the compacity of the inclusion $H^{3/2}(\Omega) \subset H^1(\Omega)$, we deduce from (3.7) the existence of $y \in H^{3/2}(\Omega)$, $\eta \in L^2(\Gamma)$ and a sequence $\{\varepsilon_n\} \rightarrow 0$ such that:

$$(3.8) \quad \{y_{\varepsilon_n}\} \rightarrow y \quad \text{in } H^1(\Omega) \text{ strongly,}$$

$$(3.9) \quad \left\{ -\frac{1}{\varepsilon} y_{\varepsilon_n}^{-} \right\} \rightarrow \eta \quad \text{in } L^2(\Gamma) \text{ weakly,}$$

which implies that:

$$(3.10) \quad \begin{aligned} -\Delta y + y &= f, \\ \frac{\partial y}{\partial n} + \eta &= u, \\ y|_{\Gamma} &\geq 0 \quad \eta \leq 0; \end{aligned}$$

on the other hand we have

$$(3.11) \quad 0 \leq \lim_{n \rightarrow \infty} \left\{ -\frac{1}{\varepsilon} \int_{\Gamma} y_{\varepsilon_n}^- y_{\varepsilon_n} d\Gamma \right\} = \int_{\Gamma} \eta y \leq 0,$$

which finishes the proof. \square

PROPOSITION 3.2. *If u is an optimal control of the problem (2.6) then $u \in H^{1/2}(\Gamma)$.*

Proof. We use a regularization method as in C. Saguez [12], F. Mignot and J. P. Puel [9]. Consider the optimal control problem obtained by replacing the state variational inequality (2.1) by:

$$(3.12) \quad -\Delta y_{\varepsilon}^{\delta} + y_{\varepsilon}^{\delta} = f, \quad \frac{\partial y_{\varepsilon}^{\delta}}{\partial n} + \frac{1}{\varepsilon} \beta^{\delta}(y_{\varepsilon}^{\delta}) = v$$

where

$$(3.13) \quad \beta^{\delta}(r) = \begin{cases} r + \frac{\delta}{2} & \text{if } r \leq -\delta, \\ -\frac{1}{2\delta} r^2 & \text{if } -\delta \leq r \leq 0, \\ 0 & \text{if } r \geq 0, \end{cases}$$

and the cost function by the adapted cost function:

$$(3.14) \quad J_{\varepsilon}^{\delta}(v) = \frac{1}{2} \int_{\Omega} (y_{\varepsilon}^{\delta}(v) - Z_d)^2 dx + \frac{\nu}{2} \int_{\Gamma} v^2 d\Gamma + \frac{1}{2} \int_{\Gamma} (v - u)^2 d\Gamma.$$

It is not difficult to prove that for each $\varepsilon > 0$ there exists an optimal control u_{ε}^{δ} satisfying the following optimality conditions:

$$(3.15) \quad -\Delta y_{\varepsilon}^{\delta} + y_{\varepsilon}^{\delta} = f, \quad \frac{\partial y_{\varepsilon}^{\delta}}{\partial n} + \frac{1}{\varepsilon} \beta^{\delta}(y_{\varepsilon}^{\delta}) = u_{\varepsilon}^{\delta},$$

$$(3.16) \quad a(p_{\varepsilon}^{\delta}, Z) + \frac{1}{\varepsilon} \int_{\Gamma} \beta^{\delta'}(y_{\varepsilon}^{\delta}) p_{\varepsilon}^{\delta} Z d\Gamma = \int_{\Omega} (y_{\varepsilon}^{\delta} - Z_d) Z dx, \quad \forall Z \in V,$$

$$(3.17) \quad p_{\varepsilon}^{\delta} + \nu u_{\varepsilon}^{\delta} + u_{\varepsilon}^{\delta} - u = 0.$$

As in the proof of Proposition 3.1 we can show that:

$$(3.18) \quad y_{\varepsilon}^{\delta}(v) \rightarrow y(v) \quad \text{strongly in } V$$

and then

$$(3.19) \quad \limsup_{\varepsilon \rightarrow 0} J_{\varepsilon}^{\delta}(u_{\varepsilon}^{\delta}) \leq J(u)$$

because

$$(3.20) \quad J_{\varepsilon}^{\delta}(u_{\varepsilon}^{\delta}) \leq J_{\varepsilon}^{\delta}(u).$$

Moreover $\{u_\varepsilon^\delta\}$ is bounded in $L^2(\Gamma)$ then there exists a sequence $\{\varepsilon_n\} \rightarrow 0$ such that:

$$(3.21) \quad u_{\varepsilon_n}^\delta \rightarrow \bar{u} \text{ in } H^{-1/2}(\Gamma) \text{ strongly,}$$

from which it follows that:

$$(3.22) \quad y_{\varepsilon_n}^\delta(u_{\varepsilon_n}^\delta) \rightarrow y(\bar{u}) \text{ strongly in } V.$$

Therefore

$$(3.23) \quad \begin{aligned} \liminf_{n \rightarrow +\infty} J_{\varepsilon_n}^\delta(u_{\varepsilon_n}^\delta) &\geq J(\bar{u}) \frac{1}{2} \int_{\Omega} (\bar{u} - u)^2 \\ &\geq J(u) + \frac{1}{2} \int_{\Omega} (\bar{u} - u)^2 d\Gamma \end{aligned}$$

and then $u = \bar{u}$ by using (3.19).

On the other hand, by taking $Z = p_\varepsilon^\delta$ in (3.16) we can show that $\{p_\varepsilon^\delta\}$ is bounded in V .

If $p \in V$ is a weak limit point, then we deduce from (3.17)

$$p + \nu u = 0$$

which completes the proof. \square

4. Optimality conditions. The main result is the following:

THEOREM 4.1. *If u is an optimal control of the problem (2.6), there exists (y, ξ, q, θ) such that $y \in H^{3/2}(\Omega)$, $\xi \in L^2(\Gamma)$, $q \in H^1(\Omega)$, $\theta \in H^{-1/2}(\Gamma)$:*

$$(4.1) \quad \begin{aligned} -\Delta y + y &= f \quad \text{in } \Omega, \\ \frac{\partial y}{\partial n} + \xi &= u \quad \text{on } \Gamma, \\ y &\geq 0, \quad \xi \leq 0, \quad \int_{\Gamma} y \xi d\Gamma = 0. \end{aligned}$$

$$(4.2) \quad a(q, Z) = \int_{\Omega} (y - Z_d) Z dx + \langle \theta, Z \rangle_{H^{-1/2}(\Gamma) - H^{1/2}(\Gamma)} \quad \forall Z \in H^1(\Omega),$$

$$(4.3) \quad \int_{\Gamma} q \eta d\Gamma = 0 \quad \forall \eta \in \tilde{\mathcal{C}}_\xi \quad \text{with} \quad \int_{\Gamma} \eta y(u, \xi) = 0,$$

$$(4.4) \quad \langle \theta, Z \rangle_{H^{-1/2}(\Gamma) - H^{1/2}(\Gamma)} = 0 \quad \forall Z \in \mathcal{C}_y \quad \text{with} \quad \int_{\Gamma} Z \xi = 0$$

where

$$\tilde{\mathcal{C}}_\xi = \{\eta \in L^2(\Gamma) : \exists t > 0, \xi + t\eta \leq 0\},$$

and

$$(4.5) \quad \begin{aligned} \mathcal{C}_y &= \{Z \in H^{1/2}(\Gamma) : \exists t > 0, y + tZ \geq 0\}, \\ q + \nu u &= 0 \quad \text{on } \Gamma. \end{aligned}$$

Proof. (i) From Proposition 3.1 we deduce that if u is an optimal control then there exists $\xi \in L^2(\Gamma)$ such that (u, ξ) is an optimal control of the following constrained optimal control problem:

$$(4.6) \quad \text{minimizing } G(v, \eta) = \frac{1}{2} \int_{\Omega} (y(v, \eta) - Z_d)^2 dx + \frac{\nu}{2} \int_{\Gamma} v^2 d\Gamma \quad (v, \eta) \in (L^2(\Gamma))^2,$$

$$(4.7) \quad \eta \leq 0, y(v, \eta) \geq 0 \quad \text{on } \Gamma, \quad \int_{\Gamma} y(v, \eta) \eta d\Gamma = 0$$

where $y(v, \eta)$ denotes the solution of the (linear) state equation:

$$(4.8) \quad -\Delta y + y = f, \quad \frac{\partial y}{\partial n} + \eta = v.$$

(ii) Denote by χ_E the indicator function of a set E . Let ψ be the function from $H^1(\Gamma) \times L^2(\Gamma)$ into $(-\infty, \infty]$ given by:

$$(4.9) \quad \psi(Z, \eta) = \chi_C(Z) + \chi_{C^0}(\eta) + \chi_{\{0\}}\left(\int_{\Gamma} Z \eta d\Gamma\right)$$

where $C = \{\phi \in H^1(\Gamma), \phi \geq 0 \text{ a.e. on } \Gamma\}$

C^0 denotes the dual cone of C .

Then ψ is convex with respect to each variable separately, and moreover the problem (4.6)–(4.7) is equivalent to minimizing in the space $(L^2(\Gamma))^2$ the function F given by:

$$(4.10) \quad F(v, \eta) = G(v, \eta) + \psi(y(v, \eta)|_{\Gamma}, \eta).$$

(iii) If (u, ξ) is a minimum for F , then u is a minimum for the following convex function:

$$(4.11) \quad v \in L^2(\Gamma) \rightarrow F(v, \xi) \in (-\infty, \infty],$$

which implies:

$$(4.12) \quad \int_{\Omega} (y(u, \xi) - Z_d) \frac{\partial y}{\partial v}(v, \xi) dx + \nu \int_{\Gamma} uv d\Gamma + \left\langle \theta, \frac{\partial y}{\partial v}(v, \xi) \right\rangle_{H^{-1}(\Gamma)H^1(\Gamma)} = 0 \quad \forall v \in L^2(\Gamma),$$

with

$$(4.13) \quad \theta \in \partial_1 \psi(y(u, \xi)|_{\Gamma}, \xi)$$

because the mapping

$$(4.14) \quad v \in L^2(\Gamma) \rightarrow \frac{\partial y}{\partial v}(v, \xi)|_{\Gamma} \in H^1(\Gamma)$$

is surjective (see A. Bermudez [3]).

Similarly, if (u, ξ) is a minimum for F , then $\eta = 0$ is a minimum for the convex function

$$(4.15) \quad \eta \in L^2(\Gamma) \rightarrow F(u + \eta, \xi + \eta) \in (-\infty, \infty],$$

from which we can deduce the existence of p :

$$(4.16) \quad p \in \partial_2 \psi(y(u, \xi)|_{\Gamma}, \xi)$$

such that

$$(4.17) \quad \nu u + p = 0.$$

By using (4.17) in (4.12) we get

$$(4.18) \quad \int_{\Gamma} p \frac{\partial Z}{\partial n} d\Gamma = \int_{\Omega} (y(u, \xi) - Z_d) Z + \langle \theta, Z|_{\Gamma} \rangle_{H^{-1}(\Gamma)H^1(\Gamma)} \quad \forall Z \in H^{3/2}(\Omega).$$

By Proposition 3.2, we have $u \in H^{1/2}(\Gamma)$. Then (4.17) implies the existence of $q \in H^1(\Omega)$ such that $q|_{\Gamma} = p$ and from (4.18) we deduce $\theta \in H^{-1/2}(\Gamma)$ and

$$(4.19) \quad a(q, Z) = \int_{\Omega} (y(u, \xi) - Z_d) Z + \langle \theta, Z \rangle_{H^{-1/2}(\Gamma)H^{1/2}(\Gamma)} \quad \forall Z \in H^1(\Omega),$$

from which the uniqueness of q follows.

(iv) To prove (4.3)–(4.4) notice first that (4.13) and (4.16) are respectively equivalent to:

$$(4.20) \quad \theta \in \partial \chi_{C \cap [\mathbb{R}\xi]^0}(y(u, \xi))$$

and

$$(4.21) \quad p \in \partial \chi_{C^0 \cap [\mathbb{R}y(u, \xi)]^0}(\xi),$$

which can also be written as follows:

$$(4.22) \quad \begin{aligned} \langle \theta, y(u, \xi) \rangle &= 0, \\ \langle \theta, Z \rangle &\leq 0 \quad \forall Z \in C, \quad \int_{\Gamma} Z \xi d\Gamma = 0, \end{aligned}$$

$$(4.23) \quad \begin{aligned} \int_{\Gamma} p \xi d\Gamma &= 0, \\ \int_{\Gamma} p \eta d\Gamma &\leq 0 \quad \forall \eta \in C^0, \quad \int_{\Gamma} \eta y(u, \xi) d\Gamma = 0. \end{aligned}$$

Finally it is easy to see that (4.22) and (4.23) are equivalent to (4.4) and (4.3), respectively. \square

Remark 4.1. The variational equality (4.12) can be interpreted as follows:

$$(4.24) \quad -\Delta q + q = y - Z_d \quad \text{in } \Omega, \quad \frac{\partial q}{\partial n} = \theta \quad \text{on } \Gamma.$$

Remark 4.2. From the Proposition 2.2 in F. Mignot [7] we have

$$(4.25) \quad \bar{\mathcal{C}}_y = (C^0 \cap [\mathbb{R}y]^0)^0,$$

$$(4.26) \quad \bar{\mathcal{C}}_{\xi} = (C \cap [\mathbb{R}\xi]^0)^0.$$

Therefore (4.20) and (4.21) imply the existence of sequences $\{\theta_n\}$, $\{p_n\}$, $\{\tau_n\}$ and $\{t_n\}$ such that

$$(4.27) \quad \begin{aligned} \{\theta_n\} &\rightarrow \theta \quad \text{in } H^{-1/2}(\Gamma), \quad \{p_n\} \rightarrow p \quad \text{in } H^{1/2}(\Gamma), \\ \tau_n &> 0, \quad t_n > 0, \\ \xi + \tau_n \theta_n &\leq 0, \quad y + t_n p_n \geq 0. \end{aligned}$$

Assume that the sequences $\{\tau_n\}$ and $\{t_n\}$ have strictly positive limit points τ and t , respectively. Then, by taking $\lambda = \max \{1/\tau, 1/t\}$ we deduce

$$(4.28) \quad \alpha = \lambda \xi + \theta \leq 0,$$

$$(4.29) \quad \beta = \lambda y + p \geq 0.$$

Now it is easy to see that the equations (4.1), (4.2), (4.5), (4.28) and (4.29) are nothing other than the first order necessary conditions for $((u, \xi), (\alpha, \beta, \lambda))$ to be a stationary point of the following Lagrangian function associated with the optimization problem (4.6), (4.7):

$$(4.30) \quad \begin{aligned} L((v, \eta), (\gamma, \delta, \mu)) = & \frac{1}{2} \int_{\Omega} (y(v, \eta) - Z_d)^2 dx + \nu \int_{\Gamma} v^2 d\Gamma + \langle y(v, \eta), \gamma \rangle_{H^{1/2}(\Gamma), H^{-1/2}(\Gamma)} \\ & + \int_{\Gamma} \eta \delta d\Gamma - \mu \int_{\Gamma} y(v, \eta) \eta d\Gamma, \end{aligned}$$

under the constraints

$$\gamma \leq 0, \quad \delta \geq 0, \quad \mu \geq 0.$$

Remark 4.3. A direct proof of (4.1), (4.2), (4.5), (4.28) and (4.29), by using some well-known results on existence of Lagrange multipliers, is considered in A. Bermudez and C. Saguez [4]. It requires one to replace the functional space V by another one in which the set K has a nonvoid interior.

Moreover, to get nontrivial optimality conditions a “qualification property” has to be proved. This point, or alternatively, the assumption on the sequences $\{\tau_n\}$ and $\{t_n\}$ we have made in the Remark 4.2, are open problems.

LIPSCHITZ CONTINUITY OF SOLUTIONS OF LINEAR INEQUALITIES, PROGRAMS AND COMPLEMENTARITY PROBLEMS*

O. L. MANGASARIAN† AND T.-H. SHIAU‡

Abstract. It is shown that solutions of linear inequalities, linear programs and certain linear complementarity problems (e.g. those with P -matrices or Z -matrices but *not* semidefinite matrices) are Lipschitz continuous with respect to changes in the right-hand side data of the problem. Solutions of linear programs are *not* Lipschitz continuous with respect to the coefficients of the objective function. The Lipschitz constant given here is a generalization of the role played by the norm of the inverse of a nonsingular matrix in bounding the perturbation of the solution of a system of equations in terms of a right-hand side perturbation.

Key words. linear inequalities, linear programming, linear complementarity problems, Lipschitz continuity, perturbation analysis

AMS (MOS) subject classifications. 15A39, 90C05, 65F35

1. Introduction. The purpose of this work is to show that solutions of linear inequalities, linear programs and certain linear complementarity problems are Lipschitz continuous with respect to changes in the right-hand side of the problem. Speaking in general and in somewhat loose terms, if we denote, by r^1 and r^2 , two distinct right-hand sides, then there exist corresponding solutions x^1 and x^2 such that

$$(1.1) \quad \|x^1 - x^2\| \leq K \|r^1 - r^2\|$$

where the Lipschitz constant K depends only on the matrix defining the problem, but not on the right-hand sides nor the objective function if there is one. A key role in determining the Lipschitz constant K is played by the condition number for linear inequalities, introduced in [11], which is a generalization of the very useful concept of a condition number for a nonsingular square matrix [3]. In [19] Robinson obtained local Lipschitz continuity results for generalized equations which include linear programs, convex quadratic programs and monotone linear complementarity problems. Robinson's Lipschitz constant [19, Thm. 2] involves a bound on the solution set which is assumed to be bounded. By contrast our Lipschitz constants are global, and our solution sets need not be bounded. In [18] Robinson obtained a Lipschitz constant for the perturbation of linear inequalities which is different from our constant (2.5).

We give now a summary of our principal results. Theorem 2.2 deals with a system of linear inequalities and equalities (2.1) and shows that if the system is solvable for right-hand sides r^1 and r^2 , then for each solution x^1 for right-hand side r^1 there exists a solution x^2 for right-hand side r^2 such that (1.1) holds. The Lipschitz constant here plays the same role as the norm of the inverse of a nonsingular matrix does for a system of linear equations. Our Lipschitz constant for the system (2.1) defined by (2.5), is a minor variation of the constant (6) of [11] but is different from Robinson's [18]. Furthermore, the Lipschitz continuity Theorem 2.2 leads in a very elementary way to Theorem 2.2' which is essentially equivalent to Theorem 1 of [11] and to Hoffman's theorem [8], [18] and which gives an estimate of the error in an approximate solution to the systems of linear inequalities and equalities (2.1) in terms of the residual of the

approximate solution and the Lipschitz constant. Again the role played in Theorem 2.2' by the Lipschitz constant is an extension of the same role played by the norm of the inverse of a matrix for a system of linear equations. Computation of the Lipschitz constant (2.5) for the system of linear inequalities and equalities (2.1) is quite difficult, but an important fact is that such a constant exists and is finite. For some special cases such as when we have strongly stable linear inequalities only (that is linear inequalities solvable for all right-hand sides) the Lipschitz constant can be computed by a single linear program as in (2.17) below. By using the Lipschitz constant for linear inequalities and equalities we show in Theorem 2.4 that solutions of linear programs are also Lipschitz continuous with respect to right-hand side perturbations only. Proposition 2.6 shows that our Lipschitz constant (2.20) for the linear program (2.18) is sharper than that of Cook et al. [4, Thm. 5]. By means of a simple example (2.26), we show that solutions of linear programs are *not* Lipschitz continuous with respect to perturbations in the objective function coefficients. Finally in § 3 by using the Lipschitz constant for linear inequalities and equalities we establish in Theorem 3.2 Lipschitz continuity of solutions of linear complementarity problems with respect to right-hand side perturbations that generate unique solutions along the line segment joining perturbed and unperturbed right-hand sides. A simple consequence of this result is Theorem 3.3 which shows that the solution of a linear complementarity problem with a P -matrix (that is a matrix with positive principal minors) is Lipschitz continuous with respect to right-hand side perturbations. Example 3.4 shows that solutions of positive semidefinite linear complementarity problems are not Lipschitz continuous with respect to their right-hand sides. Finally by exploiting the fact that for certain classes of matrices such as Z -matrices (real matrices with nonpositive off-diagonal elements) the linear complementarity problem can be solved as a linear program [10], Lipschitz continuity of solutions of such linear complementarity problems are obtained in Theorem 3.5.

A brief word about notation and some basic concepts employed. For a vector x in the n -dimensional real space R^n , $|x|$ and x_+ will denote the vectors in R^n with components $|x|_i := |x_i|$ and $(x_+)_i := \max\{x_i, 0\}$, $i = 1, \dots, n$, respectively. For a norm $\|x\|_\beta$ on R^n , $\|x\|_{\beta^*}$ will denote the dual norm [9], [16] on R^n , that is $\|x\|_{\beta^*} := \max_{\|y\|_\beta = 1} xy$, where xy denotes the scalar product $\sum_{i=1}^n x_i y_i$. The generalized Cauchy-Schwarz inequality $|xy| \leq \|x\|_\beta \cdot \|y\|_{\beta^*}$, for x and y in R^n , follows immediately from this definition of the dual norm. For $1 \leq p, q \leq \infty$, and $(1/p) + (1/q) = 1$, the p -norm $(\sum_{i=1}^n |x_i|^p)^{1/p}$ and the q -norm are dual norms on R^n [16]. If $\|\cdot\|_\beta$ is a norm on R^n , we shall, with a slight abuse of notation, let $\|\cdot\|_\beta$ also denote the corresponding norm on R^m for $m \neq n$. For an $m \times n$ real matrix A , A_i denotes the i th row, $A_{\cdot j}$ denotes the j th column, $A_I := A_{i \in I}$, and $A_{\cdot J} := A_{\cdot j \in J}$, where $I \subset \{1, \dots, m\}$ and $J \subset \{1, \dots, n\}$. $\|A\|_\beta$ denotes the matrix norm [16], [20] subordinate to the vector norm $\|\cdot\|_\beta$, that is $\|A\|_\beta = \max_{\|x\|_\beta = 1} \|Ax\|_\beta$. The consistency condition $\|Ax\|_\beta \leq \|A\|_\beta \|x\|_\beta$ follows immediately from this definition of a matrix norm. A monotonic norm on R^n is any norm $\|\cdot\|$ on R^n such that for a, b in R^n , $\|a\| \leq \|b\|$ whenever $|a| \leq |b|$ or equivalently if $\|a\| = \||a|\|$ [9, p. 47]. The p -norm for $p \geq 1$ is monotonic [16]. A vector of ones in any real space will be denoted by e . The identity matrix of any order will be denoted by I . The nonnegative orthant in R^n will be denoted by R_+^n . The abbreviation rhs will denote "right-hand side."

2. Linear inequalities and programs. We shall first be concerned with Lipschitz continuity of solutions of the following set of linear inequalities with respect to changes in the right-hand side

$$(2.1) \quad Ax \leq b, \quad Cx = d$$

where b and d are given points in R^m and R^k , respectively, $A \in R^{m \times n}$, that is an $m \times n$ real matrix and $C \in R^{k \times n}$. We shall employ a slight variation of the condition constant introduced in [11, Eq. (6)] for linear inequalities and programs as our Lipschitz constant for the linear inequalities (2.1) and subsequently for the linear program (2.18) and the linear complementarity problem (3.1).

We begin with a simple extension of the fundamental theorem on basic solutions [6, Thm. 2.11] to unrestricted as well as nonnegative variables.

LEMMA 2.1 (Basic solutions). *Let $A \in R^{m \times n}$, $C \in R^{k \times n}$ and $p \in R^n$. The system*

$$(2.2) \quad A^T u + C^T v = p, \quad u \geq 0$$

has a solution $(u, v) \in R^{m+k}$ if and only if it has a basic solution, that is a solution (u, v) such that the rows of $\begin{pmatrix} A \\ C \end{pmatrix}$ corresponding to nonzero components of (u, v) are linearly independent.

Proof. The system (2.2) having a solution (u, v) implies that

$$(2.3) \quad A^T u + \tilde{C}^T v = p, \quad (u, v) \geq 0$$

has a solution where \tilde{C} is obtained from C by multiplying by -1 those rows of C corresponding to negative components of v . It follows from the fundamental theorem on basic solutions [6, Thm. 2.11] that (2.3) has a basic solution and consequently so does (2.2). \square

We proceed now to establish Lipschitz continuity of solutions of (2.1) with respect to right-hand side perturbations. Robinson [18, Cor. 2.2] gives this result with a different Lipschitz constant.

THEOREM 2.2 (Lipschitz continuity of feasible points of linear inequalities and equalities). *Let the linear inequalities and equalities (2.1) have nonempty feasible sets S^1 and S^2 for the right-hand sides (b^1, d^1) and (b^2, d^2) , respectively. For each $x^1 \in S^1$ there exists an $x^2 \in S^2$ closest to x^1 in the ∞ -norm such that*

$$(2.4) \quad \|x^1 - x^2\|_\infty \leq \mu_\beta(A; C) \left\| \begin{pmatrix} b^1 - b^2 \\ d^1 - d^2 \end{pmatrix} \right\|_\beta$$

where $\|\cdot\|_\beta$ is some norm on R^{m+k} and

$$(2.5) \quad \mu_\beta(A; C) := \sup_{u, v} \left\{ \left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\|_{\beta^*} \left| \begin{array}{l} \|uA + vC\|_1 = 1, \quad u \geq 0. \\ \text{Rows of } \begin{pmatrix} A \\ C \end{pmatrix} \text{ corresponding to nonzero} \\ \text{elements of } \begin{pmatrix} u \\ v \end{pmatrix} \text{ are linear independent} \end{array} \right. \right\}.$$

Proof. We note that $\mu_\beta(A; C)$ is finite. For if not, there would exist fixed subsets I and J of $\{1, \dots, m\}$ and $\{1, \dots, k\}$, respectively, and a sequence $\{u_i^I, v_j^J\}$ such that $\{\|u_i^I, v_j^J\|\} \rightarrow \infty$ and the rows of $\begin{pmatrix} A \\ C \end{pmatrix}$ are linearly independent. Hence a subsequence

$$\left\{ \frac{(u_i^I, v_j^J)}{\|u_i^I, v_j^J\|} \right\}$$

converges to (\bar{u}_I, \bar{v}_J) satisfying $\bar{u}_I A_I + \bar{v}_J C_J = 0$, $\|\bar{u}_I, \bar{v}_J\| = 1$, which contradicts the linear independence of the rows of $\begin{pmatrix} A \\ C \end{pmatrix}$.

Now let $x^1 \in S^1$. Choose $x^2 \in S^2$ which is closest to x^1 in the ∞ -norm. Thus x^2 must solve

$$(2.6) \quad \min_x \|x - x^1\|_\infty \quad \text{s.t.} \quad Ax \leq b^2, \quad Cx = d^2$$

which is equivalent to the linear program

$$(2.7) \quad \min_{x, \delta} \delta \quad \text{s.t.} \quad Ax \leq b^2, \quad Cx = d^2, \quad x + e\delta \geq x^1, \quad -x + e\delta \geq -x^1.$$

Hence (x^2, δ^2) and some $(u^2, v^2, r^2, s^2) \in R^{\dot{m}+k+2n}$ satisfy the following Karush-Kuhn-Tucker conditions for (2.7)

$$(2.8) \quad \begin{aligned} Ax^2 &\leq b^2, \quad Cx^2 = d^2, \quad \|x^1 - x^2\|_\infty = \delta^2, \\ u^2(-Ax^2 + b^2) &= 0, \quad r^2(x^2 + e\delta^2 - x^1) = 0, \quad s^2(-x^2 + e\delta^2 + x^1) = 0, \\ -u^2A + v^2C + r^2 - s^2 &= 0, \quad e(r^2 + s^2) = 1, \quad (u^2, r^2, s^2) \geq 0. \end{aligned}$$

Note that if $0 = \delta^2 = \|x^1 - x^2\|_\infty$, then (2.4) is trivially true. So assume that $\delta^2 > 0$. It follows from $\delta^2 > 0$ and $r_j^2(x^2 + e\delta^2 - x^1)_j = 0$ and $s_j^2(-x^2 + e\delta^2 + x^1)_j = 0$ that $r_j^2 s_j^2 = 0$, for $j = 1, \dots, n$. Hence

$$(2.9) \quad -u^2A + v^2C + r^2 - s^2 = 0, \quad e(r^2 + s^2) = 1, \quad r^2 s^2 = 0, \quad (u^2, r^2, s^2) \geq 0.$$

By Lemma 2.1 and $u^2(-Ax^2 + b^2) = 0$ it follows that we may take

$$u^2 = \begin{pmatrix} u_I^2 \\ 0 \end{pmatrix} \geq 0 \quad \text{and} \quad v^2 = \begin{pmatrix} v_J^2 \\ 0 \end{pmatrix}$$

such that the rows of (A_I^J) are linearly independent and $u_I^2(-A_I x^2 + b_I^2) = 0$. Hence (2.9) becomes

$$\|-u_I^2 A_I + v_J^2 C_J\|_1 = \|r^2 - s^2\|_1 = e(r^2 + s^2) = 1, \quad u_I^2 \geq 0,$$

Rows of (A_I^J) linear independent.

Hence by (2.5) we have

$$(2.10) \quad \left\| \frac{u^2}{v^2} \right\|_{\beta^*} \leq \mu_\beta(A; C).$$

We now have

$$(2.11) \quad \begin{aligned} \|x^1 - x^2\|_\infty &= \delta^2 = -b^2 u^2 + d^2 v^2 + x^1(r^2 - s^2) \\ &= -b^2 u^2 + d^2 v^2 + x^1(A^T u^2 - C^T v^2) \\ &= u^2(Ax^1 - b^2 + b^1 - b^1) + v^2(-Cx^1 + d^2 + d^1 - d^1) \\ &\leq u^2(b^1 - b^2) + v^2(d^2 - d^1) \\ &\leq \left\| \frac{u^2}{v^2} \right\|_{\beta^*} \|b^1 - b^2\|_\beta \\ &\leq \mu_\beta(A; C) \left\| \frac{b^1 - b^2}{d^1 - d^2} \right\|_\beta \quad (\text{by (2.10)}). \quad \square \end{aligned}$$

Note that the Lipschitz constant $\mu_\beta(A; C)$ of (2.4) plays the same role as that of the norm of the inverse of a nonsingular matrix of a system of linear equations. This fact can be seen more clearly from the following corollary to Theorem 2.2 applied to systems solvable for all right-hand sides (i.e. strongly stable) systems. Note also that we can get a sharper result by replacing $(b^1 - b^2)$, in (2.4) and (2.11) onward, by $(b^1 - b^2)_+$.

COROLLARY 2.3 (Lipschitz continuity of feasible points of strongly stable linear inequalities). *Let $A \in R^{m \times n}$ and $C \in R^{k \times n}$ be such that*

$$(2.12) \quad \begin{aligned} &\text{Rows of } C \text{ are linearly independent and} \\ &Ax < 0, \quad Cx = 0 \quad \text{has a solution } x. \end{aligned}$$

Then the linear inequalities (2.1) are solvable for all right-hand sides $(b, d) \in R^{m+k}$. For each x^1 in the solution set of (2.1) with right-hand sides (b^1, d^1) , there exists an x^2 in the solution set of (2.1) with right-hand sides (b^2, d^2) such that

$$(2.13) \quad \|x^1 - x^2\|_\infty \leq \bar{\mu}_\beta(A; C) \left\| \begin{matrix} b^1 - b^2 \\ d^1 - d^2 \end{matrix} \right\|_\beta$$

where $\|\cdot\|_\beta$ is some norm on R^{m+k} and

$$(2.14) \quad \bar{\mu}_\beta(A; C) := \max_{(u,v) \in R^{m+k}} \left\{ \left\| \begin{matrix} u \\ v \end{matrix} \right\|_{\beta^*} \mid \begin{matrix} \|uA + vC\|_1 = 1 \\ u \geq 0 \end{matrix} \right\}.$$

Proof. That (2.1) is solvable for any right-hand side (b, d) follows from solving $Cx = d$ for x^d for any given d and then taking as the desired solution $x^d + \lambda \bar{x}$ for sufficiently large positive λ , where \bar{x} solves $Ax < 0$, $Cx = 0$. The rest of the proof of the corollary is similar to the proof of Theorem 2.2, except that u^2 and v^2 are not decomposed into

$$\begin{pmatrix} u_i^2 \\ 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} v_j^2 \\ 0 \end{pmatrix}.$$

The finiteness of $\bar{\mu}_\beta(A; C)$ of (2.14) follows from the boundedness of the feasible region of (2.14). For if it were unbounded, there would exist $\{u^i, v^i\}$ such that $\{\|u^i, v^i\|\} \rightarrow \infty$, and consequently an accumulation point (\bar{u}, \bar{v}) would exist such that

$$(2.15) \quad \bar{u}A + \bar{v}C = 0, \quad \bar{u} \geq 0, \quad (\bar{u}, \bar{v}) \neq 0.$$

This, however, would contradict the linear independence of the rows of C if $\bar{u} = 0$, and if $\bar{u} \neq 0$ would contradict the solvability of $Ax < 0$, $Cx = 0$, because then $0 = \bar{u}Ax + \bar{v}Cx = \bar{u}Ax < 0$. \square

Note that if A is vacuous and C is a nonsingular square matrix, then

$$(2.16) \quad \bar{\mu}_\infty(\phi; C) = \max_{v \in R^k} \{ \|v\|_1 \mid \|vC\|_1 = 1 \} = \|(C^T)^{-1}\|_1 = \|C^{-1}\|_\infty.$$

This was already pointed out in [11, Remark 2]. Note also that (2.14) can be written in the equivalent form

$$(2.14') \quad \bar{\mu}_\beta(A; C) = \max_{(u,v,z) \in R^{m+k+n}} \left\{ \left\| \begin{matrix} u \\ v \end{matrix} \right\|_{\beta^*} \mid \begin{matrix} -z \leq uA + vC \leq z \\ u \geq 0, \quad ez = 1 \end{matrix} \right\}.$$

This is a difficult convex-function maximization problem on a polyhedral set which is closely related to the NP-complete problem of a norm-maximization problem on a polyhedral set for positive integer β^* [12]. However for $\beta^* = \infty$, that is $\beta = 1$, it can be shown, as in [12], that (2.14') is in P. In addition a good bound for $\bar{\mu}_\beta(A; C)$ for any β can be obtained by solving a single linear program [12]. When C is empty and $\beta = \infty$, (2.14') degenerates to the following linear program:

$$(2.17) \quad \bar{\mu}_\infty(A; \phi) = \max_{(u,z) \in R^{m+n}} \{ eu \mid -z \leq uA \leq z, u \geq 0, ez = 1 \}.$$

We note that the Lipschitz constants $\mu_\beta(A; C)$ and $\bar{\mu}_\beta(A; C)$, which play the role of the norm of the inverse of a nonsingular matrix of a system of linear equations, can also be used, just as the norm of the inverse can, to obtain a bound on the error in an approximate solution in terms of the residual. Thus, if we assume for the moment that A is vacuous and that C is $n \times n$ and nonsingular, then $\bar{\mu}_\beta(\phi; C) = \|C^{-1}\|_\infty$ by

(2.16). Thus (2.5) and (2.13) are the extensions to a system of linear inequalities and equalities of the following simple Lipschitz continuity property of $Cx = d$

$$\|x^1 - x^2\|_\infty \leq \|C^{-1}\|_\infty \|d^1 - d^2\|_\infty$$

where $x^1 = C^{-1}d^1$ and $x^2 = C^{-1}d^2$. Since $\|C^{-1}\|_\infty$ can also be used to estimate the error in an approximate solution x to $Cx^1 = d^1$ in terms of its residual $\|Cx - d^1\|_\infty$ as follows:

$$\|x - x^1\|_\infty = \|C^{-1}(Cx - d^1)\|_\infty \leq \|C^{-1}\|_\infty \|Cx - d^1\|_\infty,$$

it follows that the Lipschitz constants $\mu_\beta(A; C)$ and $\bar{\mu}_\beta(A; C)$ can be similarly used to give an estimate on the error in an approximate solution to (2.1) in terms of its residual. In fact this estimate has been given in [11, Thm. 1] and by Hoffman [8], [18] with a different constant. It also follows very easily from Theorem 2.2 above as follows.

THEOREM 2.2' (Error bound for approximate solution of linear inequalities and equalities). *Let the linear inequalities and equalities (2.1) have a nonempty feasible set S^1 for the right-hand side (b^1, d^1) . For each x in R^n there exists an $x^1 \in S^1$ such that*

$$\|x - x^1\|_\infty \leq \mu_\beta(A; C) \left\| \begin{pmatrix} Ax - b^1 \\ Cx - d^1 \end{pmatrix} \right\|_\beta$$

where $\mu_\beta(A; C)$ is defined by (2.5).

Proof. Since for each $x \in R^n$

$$Ax \leq b^1 + (Ax - b^1)_+, \quad Cx = d^1 + (Cx - d^1)$$

it follows by Theorem 2.2 that there exists an $x^1 \in S^1$ such that the conclusion of the theorem holds. \square

A similar error bound holds for strongly stable linear inequalities which is based on (2.13).

It is interesting to note that Theorem 2.2 is stronger than Theorem 2.2' in the sense that the latter follows directly from the former as was demonstrated above, whereas the converse holds with the additional assumption that the norm $\|\cdot\|_\beta$ is a monotonic norm [9], [16]. Thus to obtain Theorem 2.2 from Theorem 2.2', we have from Theorem 2.2' that for each $x^1 \in S^1$ there exists an $x^2 \in S^2$ such that

$$\|x^2 - x^1\|_\infty \leq \mu_\beta(A; C) \left\| \begin{pmatrix} Ax^1 - b^2 \\ Cx^1 - d^2 \end{pmatrix} \right\|_\beta \leq \mu_\beta(A; C) \left\| \begin{pmatrix} b^1 - b^2 \\ d^1 - d^2 \end{pmatrix} \right\|_\beta$$

where the last inequality follows from

$$\begin{aligned} (Ax^1 - b^2)_+ &= (Ax^1 - b^2 + b^1 - b^1)_+ \leq (b^1 - b^2)_+ \leq |b^1 - b^2|, \\ |Cx^1 - d^2| &= |Cx^1 - d^2 + d^1 - d^1| = |d^1 - d^2| \end{aligned}$$

and the monotonicity of the norm $\|\cdot\|_\beta$.

Next we establish the Lipschitz continuity with respect to right-hand side perturbation of solutions of the linear program

$$(2.18) \quad \max_x px \quad \text{s.t.} \quad Ax \leq b, \quad Cx = d$$

where $p \in R^n$ and A, b, C, d are as in (2.1). For the Lipschitz continuity results for linear programs we have to restrict the norms employed to monotonic norms [9], [16] and have to drop $u \geq 0$ from (2.5). Lipschitz continuity results for more general optimization problems are given in [1], [7].

THEOREM 2.4 (Lipschitz continuity of solutions of linear programs with respect to right-hand side perturbation). *Let the linear program (2.18) have nonempty solution sets S^1 and S^2 for right-hand sides (b^1, d^1) and (b^2, d^2) , respectively. For each $x^1 \in S^1$ there exists an $x^2 \in S^2$ such that*

$$(2.19) \quad \|x^1 - x^2\|_\infty \leq \nu_\beta(A; C) \left\| \begin{matrix} b^1 - b^2 \\ d^1 - d^2 \end{matrix} \right\|_\beta$$

where $\|\cdot\|_\beta$ is some monotonic norm on R^{m+k} and

$$(2.20) \quad \nu_\beta(A; C) := \sup_{u, v} \left\{ \left\| \begin{matrix} u \\ v \end{matrix} \right\|_{\beta^*} \left| \begin{matrix} \|uA + vC\|_1 = 1 \\ \text{Rows of } \begin{pmatrix} A \\ C \end{pmatrix} \text{ corresponding to nonzero} \\ \text{elements of } \begin{pmatrix} u \\ v \end{pmatrix} \text{ are linear independent} \end{matrix} \right. \right\}.$$

Proof. Given $x^1 \in S^1$, let

$$A_I x^1 = b_I^1, \quad A_J x^1 < b_J^1$$

where $I \cup J = \{1, 2, \dots, m\}$. Fix any $\bar{x}^2 \in S^2$ and let $I = I_1 \cup I_2$ where

$$I_1 := \{i \in I \mid A_i \bar{x}^2 = b_i^2\}, \quad I_2 := \{i \in I \mid A_i \bar{x}^2 < b_i^2\}.$$

Since $x = \bar{x}^2$ satisfies the system of constraints

$$(2.21) \quad \begin{aligned} & \text{(i)} \quad A_{I_1} x = b_{I_1}^2, \\ & \text{(ii)} \quad A_{I_2} \bar{x}^2 \leq A_{I_2} x, \quad A_{I_2} x \leq b_{I_2}^2, \\ & \text{(iii)} \quad A_J x \leq b_J^2, \quad Cx = d^2, \end{aligned}$$

it follows that (2.21) is nonvacuous. As in Theorem 2.2, let x^2 be a solution of

$$(2.22) \quad \min \|x - x^1\|_\infty \quad \text{s.t. (2.21)}.$$

Since (2.22) is a convex program, x^2 remains optimal after we remove any number of inactive constraints. For each $i \in I_2$, at least one of the two constraints of (2.21)(ii) is inactive because $A_i \bar{x}^2 < b_i^2$. So we can remove one inactive constraint for each $i \in I_2$ thus obtaining

$$(2.23) \quad \|x^2 - x^1\|_\infty = \min \|x - x^1\|_\infty \quad \text{s.t. (2.24)} = \min \|x - x^1\|_\infty \quad \text{s.t. (2.21)}$$

where

$$(2.24) \quad \begin{aligned} & \text{(i)} \quad A_{I_1} x = b_{I_1}^2, \\ & \text{(iia)} \quad A_K \bar{x}^2 \leq A_K x, \\ & \text{(iib)} \quad A_L x \leq b_L^2, \\ & \text{(iic)} \quad A_J x \leq b_J^2, \quad Cx = d^2 \end{aligned}$$

where $K \cup L = I_2$, $K \cap L = \emptyset$. So $I_1 \cup K \cup L \cup J = \{1, 2, \dots, m\}$ and I_1 , K , L and J are all disjoint. On the other hand, since

$$A_K x^1 = b_K^1 - b_K^2 + b_K^2 \geq b_K^1 - b_K^2 + A_K \bar{x}^2,$$

it follows that $x = x^1$ satisfies the following system:

$$(2.24') \quad \begin{aligned} & \text{(i)} \quad A_{I_1} x = b_{I_1}^1, \\ & \text{(iia)} \quad b_K^1 - b_K^2 + A_K \bar{x}^2 \leq A_K x, \\ & \text{(iib)} \quad A_L x \leq b_L^1, \\ & \text{(iic)} \quad A_J x \leq b_J^1, \quad Cx = d^1. \end{aligned}$$

It follows by (2.23), (2.24'), Theorem 2.2 and the norm monotonicity that

$$\begin{aligned} \|x^1 - x^2\|_\infty &\leq \mu_\beta \left\| \begin{pmatrix} -A_K \\ A_L \\ A_J \end{pmatrix}; \begin{pmatrix} A_{I_1} \\ C \end{pmatrix} \right\| \left\| \begin{matrix} -b_K^1 + b_K^2 \\ b_H^1 - b_H^2 \\ d^1 - d^2 \end{matrix} \right\|_\beta \\ &\leq \nu_\beta(A; C) \left\| \begin{matrix} b^1 - b^2 \\ d^1 - d^2 \end{matrix} \right\|_\beta \end{aligned}$$

where $H = I_1 \cup L \cup J$ is the complement of K .

It remains to show that $x^2 \in S^1$. Since $x^1 \in S^1$, we have by the Karush-Kuhn-Tucker optimality conditions that

$$(2.25) \quad A_I^T u_I^1 + C^T v^1 = p \quad \text{for some } u_I^1 \geq 0 \quad \text{and some } v^1.$$

Since both \bar{x}^2 and x^2 satisfy (2.21) it follows that

$$px^2 = u_I^1 A_I x^2 + v^1 C x^2 \geq u_I^1 A_I \bar{x}^2 + v^1 C \bar{x}^2 = p \bar{x}^2$$

and the proof is complete. \square

Remark 2.5. We note that Cook, Gerards, Schrijver and Tardos [4, Thm. 5] have a similar result to Theorem 2.4 for *integer* entries for A but without the equality constraints $Cx = d$. However their Lipschitz constant is bigger than or equal to our Lipschitz constant. In fact their Lipschitz constant $n\Delta(A)$ is only for $\beta = \infty$, where ΔA is the maximum of the absolute values of the determinants of the square submatrices of A . We formalize the relation between the two Lipschitz constants as follows.

PROPOSITION 2.6. *For integer A , $\nu_\infty(A; \phi) \leq n\Delta(A)$.*

Proof. For any u_I for which $\|u_I A_I\|_1 = 1$ and the rows of A_I are linearly independent, we can assume that

$$A_I = [B \quad N]$$

where B is a nonsingular square submatrix.

Let $q := u_I B$, then $\|q\|_1 \leq \|u_I A_I\|_1 = 1$ since $u_I B$ is a subvector of $u_I A_I$. It follows that

$$\|u_I\|_1 = \|(B^T)^{-1} q\|_1 \leq \|(B^T)^{-1}\|_1 \|q\|_1 \leq \|(B^T)^{-1}\|_1 = \max_i \sum_j |h_{ij}|$$

where h_{ij} is the (i, j) entry of B^{-1} [16, p. 22]. Hence

$$h_{ij} = \frac{1}{\det B} (-1)^{i+j} B_{ji}$$

where B_{ij} is the (i, j) cofactor of B which is the determinant of a square submatrix of A . Hence

$$|B_{ji}| \leq \Delta(A).$$

If A is integral $|\det B| \geq 1$ is an integer; hence

$$|h_{ij}| \leq \frac{1}{|\det B|} |B_{ji}| \leq \Delta(A).$$

Consequently,

$$\|u_I\|_1 \leq \|(B^T)^{-1}\|_1 = \max_i \sum_j |h_{ij}| \leq n\Delta(A).$$

Since u_I is arbitrary, we have

$$\nu_\infty(A; \phi) = \sup \{ \|u_I\|_1 \mid \|u_I A_I\|_1 = 1, \text{ rows of } A_I \text{ linear independent} \} \leq n\Delta(A). \quad \square$$

Remark 2.7. Note that it is not true that solutions of linear programs are Lipschitzian with respect to perturbations in the objective function coefficients as evidenced by the following simple example:

$$(2.26) \quad \max (1 + \delta)x_1 + x_2 \quad \text{s.t. } x_1 + x_2 \leq 1, \quad (x_1, x_2) \geq 0.$$

The solution to this problem is:

$$x(\delta) = \begin{cases} (1, 0) & \text{for } \delta > 0, \\ (0, 1) & \text{for } \delta < 0. \end{cases}$$

Hence

$$\lim_{\delta \rightarrow 0+} \frac{\|x(\delta) - x(-\delta)\|}{2\delta} = \infty$$

and hence $x(\delta)$ is not Lipschitzian with respect to δ .

3. Linear complementarity problems. In this section we shall employ the Lipschitz constant $\mu_\beta(A; C)$ developed in Theorem 2.2 for linear inequalities and equalities to obtain a Lipschitz constant for linear complementarity problems with matrices that have positive principal minors [5] or which are hidden Z -matrices [17]. We will show by means of Example 3.4 that solutions of linear complementarity problems with a positive semidefinite matrix are not Lipschitz continuous with respect to right-hand side perturbations.

We consider the linear complementarity problem (M, q) of finding an x in R^n such that

$$(3.1) \quad Mx + q \geq 0, \quad x \geq 0, \quad x(Mx + q) = 0$$

where $M \in R^{n \times n}$ and $q \in R^n$. Note that given $J \subset \{1, \dots, n\}$, any solution of the following system of $2n$ linear inequalities and equalities

$$(3.2) \quad \begin{aligned} M_J x + q_j &\geq 0, & x_j &= 0, & j &\in J, \\ M_J x + q_j &= 0, & x_j &\geq 0, & j &\notin J, \end{aligned}$$

is a solution of (M, q) . For $J \subset \{1, \dots, n\}$ let $Q(J)$ denote the set of all q vectors for which (3.2) has a solution. It is easy to verify that $Q(J)$ is a closed convex cone. In fact it is called a *complementary cone* of (M, q) [14, p. 482]. It is also obvious that $\bigcup Q(J)_{J \subset \{1, \dots, n\}}$ is the set of all q for which (M, q) is solvable. Define

$$(3.3) \quad \sigma_\beta(M) := \max_{J \subset \{1, \dots, n\}} \mu_\beta \left(\begin{pmatrix} -M_J \\ -I_{\bar{J}} \end{pmatrix}; \begin{pmatrix} I_J \\ M_{\bar{J}} \end{pmatrix} \right)$$

where μ_β is defined by (2.5) and \bar{J} is the complement of J in $\{1, \dots, n\}$. We shall prove (Theorem 3.3) that $\sigma_\beta(M)$ will serve as a Lipschitz constant for solutions of (M, q) when M is a P -matrix, that is a matrix with positive principal minors [5], [2], or more generally (Theorem 3.2) for perturbations of q such that the linear complementarity problem is uniquely solvable along the line joining the original q and the perturbed q . We will also establish Lipschitz continuity for solutions of (M, q) when M is a hidden Z -matrix (Theorem 3.5). We begin with a lemma. A related result to this lemma appears in [15].

LEMMA 3.1. *Let q^1 and q^2 be fixed distinct vectors in R^n and let $q(t) := (1-t)q^1 + tq^2$ for $t \in [0, 1]$. Assume that $(M, q(t))$ is solvable for $t \in [0, 1]$. Then there exists a partition $0 = t_0 < t_1 < \dots < t_N = 1$ such that for $1 \leq i \leq N$*

$$(3.4) \quad q(t_{i-1}) \in Q(J_i), \quad q(t_i) \in Q(J_i) \quad \text{for some } J_i \subset \{1, \dots, n\}.$$

Proof. Let

$$T(J) := \{t \mid t \in [0, 1], q(t) \in Q(J)\}$$

for $J \subset \{1, \dots, n\}$. It is easy to see that $T(J)$ is closed and convex and hence it is a closed interval which may degenerate to a single point or to the empty set. Since $(M, q(t))$ is solvable for $t \in [0, 1]$ it follows that

$$[0, 1] \subset \bigcup_{J \subset \{1, \dots, n\}} T(J).$$

Let

$$L := \{[l_1, u_1], \dots, [l_K, u_K]\}$$

be the set of *maximal* intervals in $\{T(J) \mid J \subset \{1, \dots, n\}\}$, that is there is no other interval $T(J)$, $J \subset \{1, \dots, n\}$ that properly contains $[l_i, u_i]$. By removing duplicates from L if needed, we can assume that $[l_i, u_i], \dots, [l_K, u_K]$ are distinct and that $l_i < l_2 < \dots < l_K$. Since each $t \in [0, 1]$ belongs to $T(J)$ (for some $J \subset \{1, \dots, n\}$) which is either in L or contained in some interval of L , we have that

$$[0, 1] \subset \bigcup_{i=1}^K [l_i, u_i].$$

Thus $l_i \leq u_{i-1}$, otherwise (u_{i-1}, l_i) would be an uncovered gap of $[0, 1]$. Also $u_{i-1} < u_i$, otherwise $[l_i, u_i]$ would not be maximal because it would be contained in $[l_{i-1}, u_{i-1}]$.

Hence $l_1 = 0$, $l_{i-1} < l_i \leq u_{i-1} < u_i$ and $u_K = 1$. Let $0 = t_0 < t_1 < \dots < t_N = 1$ be the sorted numbers of $\{l_1, u_1, l_2, u_2, \dots, l_K, u_K\}$ with duplicates removed. Then each interval $[t_{i-1}, t_i]$ is contained in some interval $T(J_i)$ in L and so

$$q(t_{i-1}) \in Q(J_i) \quad \text{and} \quad q(t_i) \in Q(J_i). \quad \square$$

We establish now the Lipschitz continuity of linear complementarity problems with unique solutions along the line segment $q(t) := (1-t)q^1 + tq^2$, $t \in [0, 1]$.

THEOREM 3.2 (Lipschitz continuity of uniquely solvable linear complementarity problems). *Let q^1 and q^2 be points in R^n such that the linear complementarity problem $(M, q(t))$ with $q(t) := (1-t)q^1 + tq^2$ has a unique solution for each $t \in [0, 1]$. Then the unique solutions x^1 of (M, q^1) and x^2 of (M, q^2) satisfy*

$$\|x^1 - x^2\|_\infty \leq \sigma_\beta(M) \|q^1 - q^2\|_\beta$$

where $\sigma_\beta(M)$ is defined by (3.3).

Proof. There exist $0 = t_0 < t_1 < \dots < t_N = 1$ with properties stated in Lemma 3.1. Let $x(t_i)$ be the unique solution of $(M, q(t_i))$. Since for $1 \leq i \leq N$, $q(t_{i-1})$ and $q(t_i)$ belong to $Q(J_i)$ for some $J_i \subset \{1, \dots, n\}$, there exists a solution $y(t_{i-1})$ of $(M, q(t_{i-1}))$ such that by (2.4) and (3.3) it follows that

$$\begin{aligned} \|x(t_i) - y(t_{i-1})\|_\infty &\leq \mu_\beta \begin{pmatrix} -M_{J_i} & I_{J_i} \\ -I_{\bar{J}_i} & M_{\bar{J}_i} \end{pmatrix} \|q(t_i) - q(t_{i-1})\|_\beta \\ (3.5) \qquad &\leq \sigma_\beta(M) (t_i - t_{i-1}) \|q^1 - q^2\|_\beta \end{aligned}$$

where \bar{J}_i is the complement of J_i in $\{1, \dots, n\}$. Summing up for $i = 1, \dots, N$ gives

$$\sum_{i=1}^N \|x(t_i) - y(t_{i-1})\|_\infty \leq \sigma_\beta(M) \|q^1 - q^2\|_\beta.$$

Since $(M, q(t_{i-1}))$ has a unique solution, $y(t_{i-1}) = x(t_{i-1})$. Hence

$$\|x^1 - x^2\|_\infty \leq \sum_{i=1}^N \|x(t_i) - x(t_{i-1})\|_\infty \leq \sigma_\beta(M) \|q^1 - q^2\|_\beta. \quad \square$$

Since for P -matrix M , the linear complementarity problem (M, q) has a unique solution for each $q \in R^n$ [13], the following theorem is an immediate corollary to Theorem 3.2.

THEOREM 3.3 (Lipschitz continuity of solutions of linear complementarity problems with P -matrices). *Let M be a P -matrix. For each q^1 and q^2 in R^n the corresponding unique solutions x^1 and x^2 of (M, q^1) and (M, q^2) , respectively, satisfy*

$$\|x^1 - x^2\|_\infty \leq \sigma_\beta(M) \|q^1 - q^2\|_\beta$$

where $\sigma_\beta(M)$ is defined by (3.3).

The following example shows that solutions of positive semidefinite linear complementarity problems may not be Lipschitzian.

Example 3.4.

$$M = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \quad q^1 = \begin{pmatrix} -\varepsilon \\ 1 \end{pmatrix}, \quad q^2 = \begin{pmatrix} \varepsilon \\ 1 \end{pmatrix}, \quad \varepsilon > 0,$$

$$q(t) = \begin{pmatrix} -\varepsilon + 2\varepsilon t \\ 1 \end{pmatrix}, \quad t_0 = 0, \quad t_1 = \frac{1}{2}, \quad t_2 = 1,$$

$$J_1 = \phi, \quad J_2 = \{1, 2\},$$

$$q(t_0) \text{ and } q(t_1) \text{ are in } Q(J_1) = \{q \in R^2 \mid q_1 \leq 0, q_2 \geq 0\},$$

$$q(t_1) \text{ and } q(t_2) \text{ are in } Q(J_2) = R_+^2,$$

$$y(t_0) = x(t_0) = \begin{pmatrix} 1 \\ \varepsilon - 2\varepsilon t_0 \end{pmatrix} = \begin{pmatrix} 1 \\ \varepsilon \end{pmatrix},$$

$$x(t_2) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

In order to satisfy (3.5), $y(t_1)$ must be $\begin{pmatrix} 0 \\ 0 \end{pmatrix}$. However (3.5) also requires that

$$x(t_1) = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Hence $x(t_1) \neq y(t_1)$ and the proof of Theorem 3.2 fails. In fact, since

$$\lim_{\varepsilon \rightarrow 0} \frac{\|x(t_2) - x(t_0)\|_\infty}{\|q^2 - q^1\|_\infty} = \lim_{\varepsilon \rightarrow 0} \frac{1}{2\varepsilon} = \infty,$$

the solutions of the problem cannot be Lipschitzian.

We conclude by showing that other linear complementarity problems that can be formulated as linear programs [10] have solutions which are Lipschitzian with respect to their right-hand sides as a consequence of Theorem 2.4. In particular if M satisfies the condition of Theorem 2 of [10] with $c = 0$, that is

$$(3.6) \quad MZ_1 = Z_2, \quad rZ_1 + sZ_2 > 0, \quad (r, s) \geq 0$$

for some $n \times n$ Z -matrices Z_1 and Z_2 , and some n -vectors r and s , then a solution to such a linear complementarity problem is obtained by solving the single linear program

$$\min px \quad \text{s.t.} \quad Mx + q \geq 0, \quad x \geq 0$$

where $p = r + M^T s$, and hence p is independent of q . In the terminology of [17], such a matrix M is called a hidden Z -matrix and is a generalization of Z -matrix which

includes such matrices as those with a strictly dominant diagonal, and all matrices of Table 1 in [10] except cases 12 to 14.

THEOREM 3.5 (Lipschitz continuity of solutions of linear complementarity problems with hidden Z -matrices). *Let M be a hidden Z -matrix, that is M satisfies (3.6). For each q^1 and q^2 in R^n for which (M, q^1) and (M, q^2) are solvable, there exist solutions x^1 of (M, q^1) and x^2 of (M, q^2) such as*

$$\|x^1 - x^2\|_\infty \leq \nu_\beta \left(\begin{matrix} M \\ I \end{matrix}; \phi \right) \|q^1 - q^2\|_\beta$$

where $\|\cdot\|_\beta$ is some norm on R^n and ν_β is defined by (2.20).

Proof. By [10], there exist solutions of (M, q^1) and (M, q^2) which are obtained by solving the linear programs

$$\min \{px \mid Mx + q^1 \geq 0, x \geq 0\},$$

$$\min \{px \mid Mx + q^2 \geq 0, x \geq 0\}$$

where p is a fixed vector independent of q^1 and q^2 . The conclusion of the theorem follows immediately from Theorem 2.4. \square

We note that for the case of a strictly diagonally dominant positive definite matrix M , (M, q) is uniquely solvable for each q in R^n , and the Lipschitz continuity of the solution follows also from either Theorem 3.5 or Theorem 3.3.

CHANDRASEKHAR EQUATIONS FOR INFINITE DIMENSIONAL SYSTEMS*

KAZUFUMI ITO[†] AND ROBERT K. POWERS[‡]

Abstract. In this paper we derive the Chandrasekhar equations for linear time invariant systems defined on Hilbert spaces using a functional analytic technique. An important consequence of this is that the solution to the evolutionary Riccati equation is strongly differentiable in time and one can define a “strong” solution of the Riccati differential equation. A detailed discussion on the linear quadratic optimal problem for hereditary differential systems is also included.

Key words. Chandrasekhar equations, Riccati operator, regularity results, infinite dimensional systems

AMS(MOS) subject classification. 49

1. Introduction. The Chandrasekhar equations [14] are an alternative form to the Riccati equations from which the optimal feedback gain operator may be calculated directly. If the system has a small number of inputs and outputs, the Chandrasekhar algorithm offers significant reduction in the computational complexity for determining the optimal feedback gain. As observed in [20], this is much more evident in the infinite dimensional case if the optimal feedback gain operator is calculated numerically using some approximation method. In this case, the number of states grows linearly to the order of approximation.

The purpose of this paper is to derive Chandrasekhar equations for systems defined by evolution equations on Hilbert spaces in which the input and output operators are assumed to be bounded. The form of the Chandrasekhar equations derived immediately implies that the solution of the associated Riccati equation is strongly differentiable in time, and it allows us to define a “strong” solution of the Riccati equation. Another important consequence of this is that the optimal control for the linear quadratic regulator (LQR) problem is continuously differentiable if the initial datum is sufficiently smooth.

The Chandrasekhar equations for infinite dimensional systems have been discussed in [4] and [7] using a Lions-type framework [17]. However, the equations derived in [4] and [7] are satisfied in the distributional sense. In [22], Sorine derived a set of Chandrasekhar equations satisfied in a strong sense for parabolic systems. Sorine’s derivation relied on the analyticity of the semigroup and thus does not apply to general systems. Our approach differs from those above in that it uses an approximation technique. A sequence of approximating optimal control problems is chosen for which the Chandrasekhar equations may be derived as in the finite dimensional case (see [6], [14], and [16]). Convergence is then established and the appropriate equations are shown to be satisfied. In this paper, our considerations are restricted to the LQR problem, but the results are also applicable to the Kalman filtering problem [8].

A number of test computations have been successfully carried out using hereditary differential systems [20] and viscous damped cantilevered Euler-Bernoulli beam equations with tip mass as our model examples. Our expectations on the computational reduction using the Chandrasekhar algorithm were fully realized. Also, see [5] for the numerical approximating scheme for the solution of Chandrasekhar equations in infinite dimensional spaces. We are currently studying the use of the Chandrasekhar algorithm for computing the optimal steady state feedback gain operator combining it with the Kleinman-Newton algorithm. Details of this and other numerical studies will be reported elsewhere.

The contents of the paper are as follows. Section 2 briefly recalls the linear quadratic problem and characterizes the optimal control (see [2], [9], and [17] for a survey of the literature). In § 3 a characterization of the Riccati operator is derived and used to obtain the Chandrasekhar equations. Regularity results for the Riccati operator and optimal control are discussed in § 4. As a specific example we discuss in § 5 the linear quadratic optimal control problem for hereditary differential systems in which the input and output spaces are finite dimensional. Because of the smoothing property of the solution semigroup, results stronger than those of the general problem are obtained.

The notation used in this paper is standard. The symbol $\langle \cdot, \cdot \rangle$ stands for the inner product in a Hilbert space where the underlying space will be understood from the context. Also, $\| \cdot \|$ denotes the norm for elements of a Banach space and for operators between Banach spaces, while $|\cdot|$ denotes the Euclidean norm. The adjoint of a densely defined operator \mathcal{A} from one Hilbert space to another is denoted by \mathcal{A}^* .

2. Riccati equations. Let Z , U , and Y be Hilbert spaces. We consider the evolution equation on Z

$$(2.1) \quad \begin{aligned} \frac{d}{dt}z(t) &= \mathcal{A}z(t) + \mathcal{B}u(t), & t \geq 0, \\ z(0) &= z \in Z \end{aligned}$$

where $u(\cdot)$ is a U -valued, square integrable (control) function and \mathcal{A} is the infinitesimal generator of a strongly continuous semigroup $S(t)$ on Z . The Y -valued (observation) function y is given by

$$(2.2) \quad y(t) = \mathcal{C}z(t), \quad t \geq 0.$$

We assume that $\mathcal{B} \in \mathcal{L}(U, Z)$ and $\mathcal{C} \in \mathcal{L}(Z, Y)$.

For any $T \geq 0$, if u is differentiable almost everywhere on $[0, T]$, $\dot{u} \in L_1(0, T; U)$ and $z \in \mathcal{D}(\mathcal{A})$, then the initial value problem (2.1) has a unique “strong” solution [19, Cor. 2.10] in the sense that z is differentiable almost everywhere (a.e.) on $[0, T]$ with $\dot{z} \in L_1(0, T; Z)$ and (2.1) holds a.e. on $[0, T]$. It follows from Corollary 2.2 in [19] that (2.1) has at most one solution and if it has a solution, this solution is given by

$$(2.3) \quad z(t) = S(t)z + \int_0^t S(t-s)\mathcal{B}u(s) ds,$$

which we shall call the mild solution of (2.1). Moreover, the mild solution satisfies the “weak” differential equation

$$\frac{d}{dt}\langle z(t), x \rangle = \langle z(t), \mathcal{A}^*x \rangle + \langle \mathcal{B}u(t), x \rangle \quad \text{for all } x \in \mathcal{D}(\mathcal{A}^*).$$

Consider the linear quadratic optimal control problem on a finite time interval: for given initial data $z \in Z$, choose the control $u \in L_2(0, T; \mathbb{R}^m)$ that minimizes the cost functional

$$(2.4) \quad J(u, [0, T]) = \int_0^T (\|y(t)\|^2 + \|u(t)\|^2) dt + \langle Gz(T), z(T) \rangle_Z$$

where G is a nonnegative (definite), self-adjoint operator on Z and z is the mild solution to (2.1). The next theorem, which characterizes the optimal control, follows from [2], [9] and [23].

THEOREM 2.1. *The optimal control u^0 of (2.4) is given by*

$$(2.5) \quad u^0(t) = -\mathcal{B}^* \Pi(t) z^0(t), \quad t \geq 0$$

where $\Pi(t)$, $t \leq T$, is strongly continuous on Z . Moreover, $\Pi(t)$ is the unique solution within the class of nonnegative self-adjoint operators for which $\langle \Pi(t)z, z \rangle$ is absolutely continuous for $z \in \mathcal{D}(\mathcal{A})$, and satisfies the “weak differential” Riccati equation

$$(2.6) \quad \frac{d}{dt} \langle \Pi(t)z, z \rangle + 2\langle \mathcal{A}z, \Pi(t)z \rangle - \langle \mathcal{B}^* \Pi(t)z, \mathcal{B}^* \Pi(t)z \rangle + \langle \mathcal{C}z, \mathcal{C}z \rangle = 0, \quad \text{for all } z \in \mathcal{D}(\mathcal{A}).$$

$$\Pi(T) = G$$

If $\mathcal{U}(\cdot, \cdot)$ denotes the perturbed evolution operator of the semigroup $S(t)$ by $-\mathcal{B}\mathcal{B}^*\Pi$, then for $z \in Z$

$$(2.7) \quad \mathcal{U}(s, t)z = S(s-t)z - \int_t^s S(s-\sigma)\mathcal{B}\mathcal{B}^*\Pi(\sigma)\mathcal{U}(\sigma, t)z d\sigma,$$

$\Pi(t)$ satisfies

$$(2.8) \quad \Pi(t)z = S^*(T-t)G\mathcal{U}(T, t)z + \int_t^T S^*(\sigma-t)\mathcal{C}^*\mathcal{C}\mathcal{U}(\sigma, t)z d\sigma$$

and

$$z^0(t) = \mathcal{U}(t, 0)z.$$

3. Chandrasekhar equations. From here on, we assume that $Gz \in \mathcal{D}(\mathcal{A}^*)$ for all $z \in Z$. By the closed graph theorem \mathcal{A}^*G is then a bounded operator on Z . Let us define a bounded self-adjoint operator Q on Z by

$$(3.1) \quad \langle Qx, y \rangle = \langle \mathcal{A}^*Gx, y \rangle + \langle x, \mathcal{A}^*Gy \rangle - \langle \mathcal{B}^*Gx, \mathcal{B}^*Gy \rangle + \langle \mathcal{C}x, \mathcal{C}y \rangle \quad \text{for all } x, y \in Z.$$

The main result of this paper is given in the following theorem.

THEOREM 3.1. *If $\Pi(t)$, $t \leq T$ is the solution to the Riccati equation (2.6), then for $z \in Z$*

$$(3.2) \quad \Pi(t)z = Gz + \int_t^T \mathcal{U}^*(T, s)Q\mathcal{U}(T, s)z ds.$$

Conversely, if $\Pi(t)$ satisfies (3.2) with (2.7), then it satisfies the Riccati equation (2.6).

Proof. If \mathcal{A} is a bounded linear operator on Z , then

$$S(t) = e^{\mathcal{A}t} = \sum_{n=0}^{\infty} \frac{(\mathcal{A}t)^n}{n!}$$

and $t \rightarrow S(t)$ is differentiable in norm. Hence the same arguments as given in [14] for the finite dimensional system allow us to show that the theorem holds for such a case. Consider the Yosida approximation of \mathcal{A} given by

$$\mathcal{A}_\lambda = \lambda \mathcal{A} (\lambda I - \mathcal{A})^{-1} \quad \text{for } \lambda \in \mathbb{R}^+ \cap \rho(\mathcal{A}).$$

Then \mathcal{A}_λ is a bounded linear operator on Z and from Theorem 5.5 in [19]

$$e^{\mathcal{A}_\lambda t} z \rightarrow S(t)z \quad \text{as } \lambda \rightarrow \infty (\text{strongly}), \quad z \in Z$$

uniformly on bounded t -intervals. Note that

$$\mathcal{A}_\lambda^* = \lambda \mathcal{A}^* (\lambda I - \mathcal{A}^*)^{-1}.$$

Indeed, for $x \in \mathcal{D}(\mathcal{A})$ and $y \in Z$

$$\langle \mathcal{A}_\lambda x, y \rangle = \langle \lambda (\lambda I - \mathcal{A})^{-1} \mathcal{A} x, y \rangle = \langle x, \lambda \mathcal{A}^* (\lambda I - \mathcal{A}^*)^{-1} y \rangle.$$

But since $\mathcal{D}(\mathcal{A})$ is dense in Z , this shows that $\mathcal{A}_\lambda^* = \lambda \mathcal{A}^* (\lambda I - \mathcal{A}^*)^{-1}$. Thus Theorem 5.5 in [19] again implies that

$$e^{\mathcal{A}_\lambda^* t} z \rightarrow S^*(t)z, \quad z \in Z$$

uniformly on bounded t -intervals.

Consider the approximate problem $(\mathcal{A}_\lambda, \mathcal{B}, \mathcal{C})$ for which the theorem holds. If $\Pi_\lambda(t)$ and $\mathcal{U}_\lambda(\cdot, \cdot)$ denote the solution of the Riccati equation and the perturbed evolution operator corresponding to the perturbation of $e^{\mathcal{A}_\lambda t}$ by $-\mathcal{B}\mathcal{B}^*\Pi_\lambda(t)$, respectively, then

$$\Pi_\lambda(t)z = Gz + \int_t^T \mathcal{U}_\lambda^*(T, s) Q_\lambda \mathcal{U}_\lambda(T, s)z \, ds \quad \text{for } z \in Z$$

where

$$Q_\lambda = \mathcal{A}_\lambda^* G + G \mathcal{A}_\lambda - G \mathcal{B} \mathcal{B}^* G + \mathcal{C}^* \mathcal{C}.$$

It follows from Theorem 6.1 in Gibson [13] that $\Pi_\lambda(t)$ converges strongly to $\Pi(t)$ for $t \leq T$, and the convergence is uniform on bounded t -intervals. Moreover, statement (6.14) in [13] implies that

$$\mathcal{U}_\lambda(t, s)z \rightarrow \mathcal{U}(t, s)z, \quad z \in Z, \quad 0 \leq s \leq t \leq T$$

where the convergence is uniform in t and s . Hence, for all $x \in Z$

$$\begin{aligned} \langle \Pi(t)x, x \rangle &= \lim_{\lambda \uparrow \infty} \langle \Pi_\lambda(t)x, x \rangle = \langle Gx, x \rangle + \lim_{\lambda \uparrow \infty} \int_t^T \langle Q_\lambda \mathcal{U}_\lambda(T, s)x, \mathcal{U}_\lambda(T, s)x \rangle \, ds \\ (3.3) \quad &= \langle Gx, x \rangle + \lim_{\lambda \uparrow \infty} \int_t^T \{ 2 \langle \mathcal{A}^* G \mathcal{U}_\lambda(T, s)x, J_\lambda \mathcal{U}_\lambda(T, s)x \rangle \\ &\quad + \langle (\mathcal{C}^* \mathcal{C} - G \mathcal{B} \mathcal{B}^* G) \mathcal{U}_\lambda(T, s)x, \mathcal{U}_\lambda(T, s)x \rangle \} \, ds \end{aligned}$$

where $J_\lambda = \lambda (\lambda I - \mathcal{A})^{-1}$, $\lambda \in \rho(\mathcal{A})$. Note that

$$J_\lambda \mathcal{U}_\lambda(T, s)x = (J_\lambda - I) \mathcal{U}(T, s)x + J_\lambda (\mathcal{U}_\lambda(T, s) - \mathcal{U}(T, s))x + \mathcal{U}(T, s)x$$

converges strongly to $\mathcal{U}(T, s)x$ for $s \leq T$ since J_λ converges strongly to the identity operator I on Z (see [19]). Since the integrand appearing in (3.3) is uniformly bound in λ and s , the dominated convergence theorem allows us to obtain that for $x \in Z$

$$\begin{aligned} \langle \Pi(t)x, x \rangle &= \langle Gx, x \rangle + \int_t^T \{2\langle \mathcal{A}^*G\mathcal{U}(T, s)x, \mathcal{U}(T, s)x \rangle \\ &\quad + \langle (\mathcal{C}^*\mathcal{C} - G\mathcal{B}\mathcal{B}^*G)\mathcal{U}(T, s)x, \mathcal{U}(T, s)x \rangle\} ds \\ &= \left\langle \left(G + \int_t^T \mathcal{U}^*(T, s)Q\mathcal{U}(T, s) ds \right) x, x \right\rangle, \end{aligned}$$

which completes the proof of the first statement since the operators appearing in both sides of this equation are self-adjoint. Conversely, suppose that $\Pi(t)$, $t \leq T$ satisfies (3.2). Then $t \rightarrow \Pi(t)x$ is continuously differentiable for $x \in Z$ and

$$\begin{aligned} \frac{d}{dt} \langle \Pi(t)x, y \rangle &= \left\langle \frac{d}{dt} \Pi(t)x, y \right\rangle \\ &= \langle \mathcal{U}(T, t)x, Q\mathcal{U}(T, t)y \rangle \end{aligned}$$

for all $x, y \in Z$. Thus, for $x \in \mathcal{D}(\mathcal{A})$

$$\begin{aligned} \langle Qx, x \rangle - \left\langle \frac{d}{dt} \Pi(t)x, x \right\rangle &= \int_t^T \frac{d}{ds} \langle \mathcal{U}(T, s)x, Q\mathcal{U}(T, s)x \rangle ds \\ &= -2 \int_t^T \langle \mathcal{U}(T, s)(\mathcal{A} - \mathcal{B}\mathcal{B}^*\Pi(s))x, Q\mathcal{U}(T, s)x \rangle ds \\ &= -2 \left[\int_t^T \langle \mathcal{U}(T, s)\mathcal{A}x, Q\mathcal{U}(T, s)x \rangle ds \right. \\ &\quad \left. - \int_t^T \langle \mathcal{U}(T, s)\mathcal{B}\mathcal{B}^*\Pi(s)x, Q\mathcal{U}(T, s)x \rangle ds \right] \\ &= -2 \int_t^T \frac{d}{ds} \langle \Pi(s)\mathcal{A}x, x \rangle ds + \int_t^T \frac{d}{ds} \|\mathcal{B}^*\Pi(s)x\|^2 ds \\ &= -2\langle G, \mathcal{A}x \rangle + \langle \mathcal{B}^*Gx, \mathcal{B}^*Gx \rangle \\ &\quad + 2\langle \Pi(t), \mathcal{A}x \rangle + \langle \mathcal{B}^*\Pi(t)x, \mathcal{B}^*\Pi(t)x \rangle. \end{aligned}$$

By the definition of Q , this implies that $\Pi(t)$ satisfies (2.6). Q.E.D.

Remark 3.2. Important in applications is the case $G \equiv 0$. If this occurs, then $Q = \mathcal{C}^*\mathcal{C}$ and

$$\Pi(t)z = \int_t^T L^*(s)L(s)z ds, \quad z \in Z$$

where $L(s) \equiv \mathcal{C}\mathcal{U}(T, s)$. Define the gain operator by $K(t) = \mathcal{B}^*\Pi(t)$. Then (see Gibson [12])

$$(3.4) \quad \mathcal{U}(T, t)z = S(T-t)z - \int_t^T \mathcal{U}(T, s)\mathcal{B}K(s)S(s-t)z ds, \quad z \in Z$$

and the operators $K(t)$ and $L(t)$ jointly satisfy

$$\begin{aligned} K(t)z &= \int_t^T \mathcal{B}L^*(s)L(s)z ds, \\ L(t)z &= \mathcal{C}S(T-t)z - \int_t^T L(s)\mathcal{B}K(s)S(s-t)z ds \end{aligned}$$

for all $z \in Z$, which are the infinite dimensional Chandrasekhar equations in integral form. Since $K(t)z$ and $L(t)x$ are continuously differentiable for $z \in Z$ and $x \in \mathcal{D}(\mathcal{A})$, $K(t)$ and $L(t)$ also satisfy

$$\frac{d}{dt}K(t)z = -\mathcal{B}^*L^*(t)L(t)z, \quad z \in Z,$$

$$K(T) = 0,$$

$$\frac{d}{dt}L(t)x = -L(t)[\mathcal{A} - \mathcal{B}K(t)]x, \quad x \in \mathcal{D}(\mathcal{A}),$$

$$L(t) = \mathcal{C}.$$

Note that these Chandrasekhar differential equations correspond to those derived for finite dimensional systems [14].

4. Strong differential Riccati equation. An important consequence of (3.2) is the following theorem.

THEOREM 4.1. *If $GZ \subset \mathcal{D}(\mathcal{A}^*)$ and $\Pi(t)$, $t \leq T$, is the solution to the Riccati equation (2.6), then for $z \in \mathcal{D}(\mathcal{A})$, $\Pi(t)z$ is the unique strong solution to the Riccati equation (2.6) in the sense that $\Pi(t)z$ is continuously differentiable on $[0, T]$, $\Pi(t)z \in \mathcal{D}(\mathcal{A}^*)$ for $0 \leq t \leq T$ and the strong differentiable Riccati equation*

$$\left(\frac{d}{dt}\Pi(t) + \mathcal{A}^*\Pi(t) + \Pi(t)\mathcal{A} - \Pi(t)\mathcal{B}\mathcal{B}^*\Pi(t) + \mathcal{C}^*\mathcal{C} \right) z = 0 \quad \text{for all } z \in \mathcal{D}(\mathcal{A}),$$

$$\Pi(T) = G$$

is satisfied on $[0, T]$.

Proof. From (2.6), we have for all $x, y \in \mathcal{D}(\mathcal{A})$

$$\langle \Pi(t)x, \mathcal{A}y \rangle = - \left(\frac{d}{dt} \langle \Pi(t)x, y \rangle + \langle \Pi(t)\mathcal{A}x, y \rangle - \langle \mathcal{B}\Pi(t)x, \mathcal{B}\Pi(t)y \rangle + \langle \mathcal{C}x, \mathcal{C}y \rangle \right).$$

From Theorem 3.1, $\Pi(t)x$ is continuously differentiable for $x \in Z$,

$$\langle \Pi(t)x, \mathcal{A}y \rangle = - \left\langle \left(\frac{d}{dt}\Pi(t) + \Pi(t)\mathcal{A} - \Pi(t)\mathcal{B}\mathcal{B}^*\Pi(t) + \mathcal{C}^*\mathcal{C} \right) x, y \right\rangle$$

for all $x, y \in \mathcal{D}(\mathcal{A})$ and the right-hand side of this expression is defined for all $y \in Z$. Thus, since \mathcal{A} is a densely defined closed operator on Z , this implies that for each $t \leq T$, $\Pi(t)x \in \mathcal{D}(\mathcal{A}^*)$ for $x \in \mathcal{D}(\mathcal{A})$ and

$$\left\langle \left(\frac{d}{dt}\Pi(t) + \mathcal{A}^*\Pi(t) + \Pi(t)\mathcal{A} - \Pi(t)\mathcal{B}\mathcal{B}^*\Pi(t) + \mathcal{C}^*\mathcal{C} \right) x, y \right\rangle = 0$$

$$\text{for all } x \in \mathcal{D}(\mathcal{A}) \quad \text{and} \quad y \in Z,$$

which completes the proof. Q.E.D.

The following lemma is concerned with the strong differentiability of $t \rightarrow \mathcal{U}(t, s)x$ on Z . Here we shall give a proof using the standard constructive argument although it can be considerably simplified using the contraction mapping theorem.

LEMMA 4.2. Suppose that $\mathcal{B}(t)$ is an operator on Z such that for $z \in Z$, $\mathcal{B}(t)z$ is continuously differentiable on $[0, T]$. Then $\mathcal{A} + \mathcal{B}(t)$ generates a perturbed evolution operator $V(t, s)$, of the semigroup $S(t)$ on Z and for $z \in \mathcal{D}(\mathcal{A})$ $V(t, s)z \in \mathcal{D}(\mathcal{A})$, $0 \leq s \leq t \leq T$, $V(t, s)z$ is strongly differentiable in t , and

$$(4.1) \quad \frac{\partial}{\partial t} V(t, s)z = (\mathcal{A} + \mathcal{B}(t))V(t, s)z$$

is satisfied for $0 \leq s \leq t \leq T$. Moreover, the derivative $(\partial/\partial t)V(t, s)z$ for $z \in \mathcal{D}(\mathcal{A})$ is jointly continuous in t and s .

Proof. Consider a class Ω of evolution operators on Z as follows: Ω consists of bounded linear operators $V(t, s)$, $0 \leq s \leq t \leq T$ on Z such that

- (i) $V(s, s) = I$, $V(t, r)V(r, s) = V(t, s)$ for $0 \leq s \leq r \leq t \leq T$;
- (ii) $(t, s) \rightarrow V(t, s)$ is strongly continuous for $0 \leq s \leq t \leq T$;
- (iii) for $z \in \mathcal{D}(\mathcal{A})$, $V(t, s)z \in \mathcal{D}(\mathcal{A})$ is strongly differentiable in t and the derivative $(\partial/\partial t)V(t, s)z$ is strongly continuous in t and s for $0 \leq s \leq t \leq T$.

Note that $V^{(0)}(t, s)z = S(t-s)z$, $z \in Z$ belongs to Ω . Define a sequence of evolution operators $V^{(k)}(t, s)$ by

$$(4.2) \quad V^{(k+1)}(t, s)z = S(t-s)z + \int_s^t S(t-\sigma)\mathcal{B}(\sigma)V^{(k)}(\sigma, s)z d\sigma$$

for $z \in Z$ and $0 \leq s \leq t \leq T$.

It then follows from [9], [19] that

$$V^{(k)}(t, s)z \rightarrow V(t, s)z \quad \text{for } z \in Z \text{ and } 0 \leq s \leq t \leq T$$

where the convergence is uniform in t and s . If $V^{(k)}(t, s)$ belongs to the class Ω , then for $z \in \mathcal{D}(\mathcal{A})$, $\mathcal{B}(t)V^{(k)}(t, s)z$ is continuously differentiable in t and

$$\frac{\partial}{\partial t}(\mathcal{B}(t)V^{(k)}(t, s)z) = \dot{\mathcal{B}}(t)V^{(k)}(t, s)z + \mathcal{B}(t)\frac{\partial}{\partial t}V^{(k)}(t, s)z.$$

It now follows from (4.2) and [15, p. 487] that for $z \in \mathcal{D}(\mathcal{A})$, $V^{(k+1)}(t, s)z$ is continuously differentiable in t and satisfies

$$\frac{\partial}{\partial t}V^{(k+1)}(t, s)z = \mathcal{A}V^{(k+1)}(t, s)z + \mathcal{B}(t)V^{(k)}(t, s)z$$

or

$$(4.3) \quad \begin{aligned} \frac{\partial}{\partial t}V^{(k+1)}(t, s)z &= S(t-s)(\mathcal{A} + \mathcal{B}(t))z + \int_s^t S(t-\sigma)\dot{\mathcal{B}}(\sigma)V^{(k)}(\sigma, s)z d\sigma \\ &\quad + \int_s^t S(t-\sigma)\mathcal{B}(\sigma)\frac{\partial}{\partial \sigma}V^{(k)}(\sigma, s)z d\sigma \quad \text{for } 0 \leq s \leq t \leq T. \end{aligned}$$

Hence, by induction, $V^{(k)}(t, x)z$ belongs to Ω for $k \geq 0$. From (4.3)

$$(4.4) \quad \begin{aligned} &\frac{\partial}{\partial t}V^{(k+1)}(t, s)z - \frac{\partial}{\partial t}V^{(k)}(t, s)z \\ &= \int_s^t S(t-\sigma)\dot{\mathcal{B}}(\sigma)(V^{(k)}(\sigma, s) - V^{(k-1)}(\sigma, s))z d\sigma \\ &\quad + \int_s^t S(t-\sigma)\mathcal{B}(\sigma)\left(\frac{\partial}{\partial \sigma}V^{(k)}(\sigma, s)z - \frac{\partial}{\partial \sigma}V^{(k-1)}(\sigma, s)z\right) d\sigma. \end{aligned}$$

By induction on k one easily verifies the estimate

$$\|V^{(k)}(t, s) - V^{(k-1)}(t, s)\| \leq C_1 M_1^k \frac{(t-s)^k}{k!}$$

where

$$C_1 = \max_{0 \leq s \leq T} \|S(s)\| \quad \text{and} \quad M_1 = \max_{0 \leq s \leq t \leq T} \|S(t-s)\mathcal{B}(s)\|.$$

Since $\mathcal{B}(t)z$ is continuous for each $z \in Z$, $\|\mathcal{B}(t)\|$ is uniformly bounded on $[0, T]$. Thus, from (4.4)

$$\begin{aligned} & \left\| \frac{\partial}{\partial t} V^{(k+1)}(t, s)z - \frac{\partial}{\partial t} V^{(k)}(t, s)z \right\| \\ & \leq C_1 M_2 M_1^k \frac{(t-s)^{k+1}}{(k+1)!} \|z\| + M_1 \int_s^t \left\| \frac{\partial}{\partial \sigma} V^{(k)}(\sigma, s)z - \frac{\partial}{\partial \sigma} V^{(k-1)}(\sigma, s)z \right\| d\sigma \end{aligned}$$

where

$$M_2 = \max_{0 \leq s \leq t \leq T} \|S(t-s)\mathcal{B}(s)\|.$$

By induction on k one obtains

$$\begin{aligned} \left\| \frac{\partial}{\partial t} V^{(k)}(t, s)z - \frac{\partial}{\partial t} V^{(k-1)}(t, s)z \right\| & \leq \frac{(t-s)^k}{(k-1)!} M_2 M_1^{k-1} C_1 \|z\| \\ & \quad + \frac{(t-s)^k}{k!} M_1^k C_1 \|\mathcal{A}z\|. \end{aligned}$$

Hence, $(\partial/\partial t)V^{(k)}(t, s)z$ converges to a function of $C(s, T; Z)$ for $0 \leq s \leq t \leq T$ and $z \in \mathcal{D}(\mathcal{A})$ where the convergence is uniform in t and s . Note that the differential operator $(\partial/\partial t)$ on $C(s, T; Z)$ is closed. These facts, when combined with the convergence of $V^{(k)}(t, s)z$ to $V(t, s)z$ in $C(s, T; Z)$, show that for $z \in \mathcal{D}(\mathcal{A})$ $V(t, s)z$ is continuously differentiable in t , and the derivative is jointly continuous in t and s . Since

$$V(t, s)z = S(t-s)z + \int_s^t S(t-\sigma)\mathcal{B}(\sigma)V(\sigma, s)z d\sigma$$

$$\text{for } z \in Z \quad \text{and} \quad 0 \leq s \leq t \leq T,$$

it now follows from [15, p. 487] that for $z \in \mathcal{D}(\mathcal{A})$, $V(t, s)z \in \mathcal{D}(\mathcal{A})$ and

$$\frac{\partial}{\partial t} V(t, s)z = (\mathcal{A} + \mathcal{B}(t))V(t, s)z$$

for $0 \leq s \leq t \leq T$. Q.E.D.

LEMMA 4.3. *If $GZ \subset \mathcal{D}(\mathcal{A}^*)$ and the initial data $z \in \mathcal{D}(\mathcal{A})$, then the optimal control u^0 to (2.4) is continuously differentiable on $[0, T]$ and*

$$(4.5) \quad \frac{d}{dt} u^0(t) = \mathcal{B}^*(\mathcal{A}^* \Pi(t) + \mathcal{C}^* \mathcal{C})z^0(t).$$

Proof. Since $\mathcal{B}^* \Pi(t)x$ is continuously differentiable for $x \in Z$ on $[0, T]$, it follows from Lemma 4.2 that $z^0(t) = \mathcal{U}(t, 0)z$ is continuously differentiable for $z \in \mathcal{D}(\mathcal{A})$. Thus, from (2.5) u^0 is continuously differentiable on $[0, T]$ and

$$\frac{d}{dt} u^0(t) = -\mathcal{B}^* \left(\frac{d}{dt} \Pi(t)z^0(t) + \Pi(t)\dot{z}^0(t) \right).$$

Equation (4.5) now follows from Theorem 4.1. Q.E.D.

5. Hereditary differential system. In this section we discuss the hereditary differential system

$$(5.1) \quad \begin{aligned} \frac{d}{dt}x(t) &= \int_{-r}^0 d\mu(\theta)x(t+\theta) + Bu(t), \quad t \geq t_0, \\ x(t_0) &= \eta \quad \text{and} \quad x(t_0 + \theta) = \phi(\theta), \quad -r \leq \theta < 0 \end{aligned}$$

where $\mu(\cdot)$ is an $n \times n$ matrix valued function of bounded variation which vanishes at $\theta = 0$ and is left continuous on $(-r, 0)$. Without loss of generality we can assume that for $\theta \geq 0$, $\mu(\theta) = 0$ and for $\theta \leq -r$, $\mu(\theta) = \mu(-r)$. B is an $n \times m$ matrix. The observation y is given by

$$(5.2) \quad y(t) = Cx(t)$$

where C is a $p \times n$ matrix. We will denote by Z the product space $\mathbb{R}^n \times L_2(-r, 0; \mathbb{R}^n)$ in this section. Given an element $z \in Z$, $\eta \in \mathbb{R}^n$ and $\phi \in L_2$ denote the two coordinates of z : $z = (\eta, \phi)$. It is well known [3], [11] that for $(\eta, \phi) \in Z$ and u locally square integrable, (5.1) admits a unique solution $x \in L_2(t_0 - r, T; \mathbb{R}^n) \cap H^1(t_0, T; \mathbb{R}^n)$ for any $T \geq t_0$. If $t_0 = 0$, then (5.1) can be formulated as an evolution equation on Z ,

$$(5.3) \quad \frac{d}{dt}z(t) = \mathcal{A}z(t) + \mathcal{B}u(t), \quad t \geq 0$$

where $z(t) = (x(t), x(t + \cdot)) \in Z$, $t \geq 0$ and $\mathcal{B}u = (Bu, 0) \in Z$ for $u \in \mathbb{R}^m$. The infinitesimal generator \mathcal{A} is then defined by

$$\mathcal{D}(\mathcal{A}) = \{(\eta, \phi) \in Z \mid \eta = \phi(0) \text{ and } \dot{\phi} \in L_2\}$$

and for $(\phi(0), \phi) \in \mathcal{D}(\mathcal{A})$

$$\mathcal{A}(\phi(0), \phi) = \left(\int_{-r}^0 d\mu(\theta)\phi(\theta), \dot{\phi} \right),$$

and generates the strong continuous semigroup $S(t)$: $S(t)(\eta, \phi) = (x(t), x(t + \cdot))$, $t \geq 0$, where x is the solution of (5.1) with $t_0 = 0$ and $u \equiv 0$. Within this framework, the observation equation (5.2) is written as

$$(5.4) \quad y(t) = \mathcal{C}z(t), \quad t \geq 0$$

where $\mathcal{C}(\eta, \phi) = C\eta \in \mathbb{R}^p$ for $(\eta, \phi) \in Z$. Thus the system (5.1)–(5.2) is formulated as the model system (2.1)–(2.2) in which $Z = \mathbb{R}^n \times L_2$, $U = \mathbb{R}^m$ and $Y = \mathbb{R}^p$.

The following lemma (see [10], [21]) gives two important properties of the hereditary differential system which shall be used extensively in the subsequent development.

LEMMA 5.1. (i) If X denotes the Hilbert space $\mathcal{D}(\mathcal{A})$ equipped with the graph norm, then $\int_0^t S(t-s)\mathcal{B}u(s) ds$ is an X -valued function continuous in t for each $u \in L_2(0; T; \mathbb{R}^m)$ and continuous in u for each $t \in [0, T]$.

(ii) If γ is a $p \times n$ matrix-valued function of bounded variation on $[-r, 0]$ and \mathcal{K} denotes an operator defined by $\mathcal{K}(\eta, \phi) = \int_{-r}^0 d\gamma(\theta)\phi(\theta)$ for $(\eta, \phi) \in Z$, then there exists a nondecreasing function $M(\cdot): [0, \infty] \rightarrow \mathbb{R}^+$ such that for $z \in Z$

$$(5.5) \quad \int_0^T |\mathcal{K}S(t)z|^2 dt \leq M(T)\|z\|^2.$$

Remark. In (5.5) the expression $\mathcal{H}S(\dot{t})z$ only makes sense when $z \in \mathcal{D}(\mathcal{A})$. However, because of (ii), we will use the expression $\mathcal{H}S(t)z$, $0 \leq t \leq T$ to denote the function in $L_2(0, T; \mathbb{R}^p)$ which is obtained by a continuous extension of the operator:

$$z \in \mathcal{D}(\mathcal{A}) \rightarrow \mathcal{H}S(t)z \in L_2(0, T; \mathbb{R}^p).$$

Let us consider the linear quadratic optimal control problem: for given $(\eta, \phi) \in Z$ choose the control $u \in L_2(t_0, T; \mathbb{R}^m)$ that minimizes the cost functional

$$(5.6) \quad J(u, [t_0, T]) = \int_{t_0}^T (|Cx(t)|^2 + |u(t)|^2) dt + \langle G_0 x(T), x(T) \rangle_{\mathbb{R}^n}$$

where G_0 is a nonnegative, symmetric matrix on \mathbb{R}^n and $x(\cdot)$ is the solution to (5.1). Note that (5.6) can be equivalently written as

$$J(u, [t_0, T]) = \int_{t_0}^T (|\mathcal{G}z(t)|^2 + |u(t)|^2) dt + \langle Gz(T), z(T) \rangle_Z$$

where G is a nonnegative, self-adjoint operator on Z defined by $G(\eta, \phi) = (G_0\eta, 0) \in Z$ for $(\eta, \phi) \in Z$ and $z(\cdot)$ is given by

$$z(t) = S(t - t_0)(\eta, \phi) + \int_{t_0}^t S(t - s)\mathcal{B}u(s) ds, \quad t \geq t_0.$$

Hence Theorem 2.1 applies to the minimization problem (5.6).

It follows from [13], [24] that if $(y, \psi) \in \mathcal{D}(\mathcal{A}^*)$ then

$$\psi(\theta) - (\mu(\theta) - \mu(-r))^T y \in H^1(-r, 0)$$

and

$$\psi(-r) = (\mu((-r)^+) - \mu(-r))^T y.$$

Obviously $Gz \notin \mathcal{D}(\mathcal{A}^*)$ in general. So, Theorem 3.1 does not apply for (5.6) unless $G_0 = 0$. However, as a result of Lemma 5.1 one can extend the results in §§ 3 and 4 to this case. We will discuss such an extension later and for the present consider the case $G_0 = 0$.

If $G_0 = 0$, then the solution $\Pi(t)$ to the Riccati equation (2.6) is given by

$$(5.7) \quad \Pi(t)z = \int_t^T S^*(\sigma - t)\mathcal{C}^*\mathcal{C}\mathcal{U}(\sigma, t)z d\sigma.$$

Let \mathcal{A}_T be the infinitesimal generator on Z defined by $\mathcal{D}(\mathcal{A}_T) = \mathcal{D}(\mathcal{A})$ and for $\phi \in H^1$

$$\mathcal{A}_T(\phi(0), \phi) = \left(\int_{-r}^0 d\mu^T(\theta)\phi(\theta), \dot{\phi} \right)$$

and let $S_T(t)$ denote the C_0 -semigroup generated by \mathcal{A}_T . Define the structural operator \mathcal{F} on Z by

$$\mathcal{F}(\eta, \phi) = \left(\eta, \int_{-r}^{\theta-} d\mu(\xi)\phi(\xi - \theta) \right) \quad \text{for } (\eta, \phi) \in Z.$$

Then, the following result has been proven by Manitius [18].

THEOREM 5.2.

- (i) $\mathcal{F}S(t) = S_T^*(t)\mathcal{F}$, $\mathcal{F}^*S_T(t) = S^*(t)\mathcal{F}^*$, $t \geq 0$.
- (ii) If $z \in \mathcal{D}(\mathcal{A})$, then $\mathcal{F}z \in \mathcal{D}(\mathcal{A}_T^*)$ and $\mathcal{A}_T^*\mathcal{F}z = \mathcal{F}\mathcal{A}z$.
- (iii) If $z \in \mathcal{D}(\mathcal{A}_T)$, then $\mathcal{F}^*z \in \mathcal{D}(\mathcal{A}^*)$ and $\mathcal{A}^*\mathcal{F}^*z = \mathcal{F}^*\mathcal{A}_Tz$.

Since $\mathcal{C}^* = \mathcal{F}^*\mathcal{C}^*$, it follows from (5.7) and Theorem 5.2 that

$$\Pi(t)z = \mathcal{F}^* \int_t^T S_T(\sigma - t)\mathcal{C}^*\mathcal{C}\mathcal{U}(\sigma, t)z d\sigma.$$

Note that $\mathcal{C}^*y = (C^Ty, 0) \in Z$ for $y \in \mathbb{R}^p$. Thus from (i) of Lemma 5.1 and (iii) of Theorem 5.2, $\Pi(t)z \in \mathcal{D}(\mathcal{A}^*)$ for $z \in Z$. Moreover, since the evolution operator $\mathcal{U}(\sigma, t)$ is jointly continuous for $0 \leq t \leq \sigma \leq T$, $\mathcal{A}^*\Pi(t)z$ is strongly continuous in Z for $z \in Z$, and hence $\Pi(t)\mathcal{A}$ has a bounded extension to all of Z . The next result now follows from Theorem 4.1 and Lemma 4.3 (see [10], [21] for a different derivation of this result).

THEOREM 5.3. *If $G_0 = 0$, then for $z \in Z$, $\Pi(t)z$ is a unique strong solution to the Riccati equation in the sense that $\Pi(t)z$ is continuously differentiable on $[0, T)$, $\Pi(t)z \in \mathcal{D}(\mathcal{A}^*)$ for $0 \leq t \leq T$, and the strong differential Riccati equation*

$$\left(\frac{d}{dt} \Pi(t) + \mathcal{A}^* \Pi(t) + \Pi(t) \mathcal{A} - \Pi(t) \mathcal{B} \mathcal{B}^* \Pi(t) + \mathcal{C}^* \mathcal{C} \right) z = 0 \quad \text{for all } z \in Z$$

is satisfied on $[0, T)$. Moreover, the optimal control $u^0(\cdot)$ to (5.6) is continuously differentiable on $(0, T]$ for $(\eta, \phi) \in Z$.

Proof. From (4.8), if $z = (\eta, \phi) \in \mathcal{D}(\mathcal{A})$, then u^0 is continuously differentiable and

$$\dot{u}^0(t) = \mathcal{B}^*(\mathcal{A}^* \Pi(t) + \mathcal{C}^* \mathcal{C}) z^0(t),$$

$$z^0(t) = \mathcal{U}(t, 0)(\eta, \phi).$$

It has been proven that $\mathcal{A}^*\Pi(t)z$ is strongly continuous in Z for $z \in Z$. So, the theorem follows since $\mathcal{D}(\mathcal{A})$ is dense in Z and $\mathcal{U}(t, 0)$ is continuous on Z for $t \geq 0$. Q.E.D.

Let us turn to the case $G_0 \neq 0$. Consider the λ th approximate problem to (5.6) in which the cost functional is given by

$$(5.8) \quad J^\lambda(u, [t_0, T]) = \int_{t_0}^T (|\mathcal{C}z(t)|^2 + |u(t)|^2) dt + \langle G_\lambda z(T), z(T) \rangle_Z$$

where $G_\lambda = J_\lambda^* G J_\lambda$ and $J_\lambda = \lambda(\lambda I - \mathcal{A})^{-1}$ for $\lambda \in \rho(\mathcal{A})$. Note that $G_\lambda Z \subset \mathcal{D}(\mathcal{A}^*)$ and $G_\lambda \rightarrow G$ in trace norm since G has a finite rank. If $\Pi_\lambda(t)$, $t \leq T$ denotes the solution of the Riccati equation associated with the problem (5.8), then it follows from Theorem 3.1 that

$$\Pi_\lambda(t)z = G_\lambda z + \int_t^T \mathcal{U}_\lambda^*(T, s) Q_\lambda \mathcal{U}_\lambda(T, s) z ds, \quad z \in Z$$

where Q_λ is a self-adjoint operator on Z defined by

$$Q_\lambda = \mathcal{A}^* G_\lambda + G_\lambda \mathcal{A} - G_\lambda \mathcal{B} \mathcal{B}^* G_\lambda + \mathcal{C}^* \mathcal{C}.$$

Such a representation for Q_λ exists since $G_\lambda \mathcal{A}$ can be extended to all Z via (3.1). If we denote the optimal control for the original problem (5.6) by u^0 and the optimal control for the λ th approximate problem (5.8) by u_λ , it follows from [13, pp. 114–115] that u_λ converges strongly to u^0 in $L_2(t_0, T; \mathbb{R}^m)$, and the convergence is uniform in t_0 for $0 \leq t_0 \leq T$.

The following three results are essential to discuss the extension of Theorem 3.1 and Lemma 4.3 to the case when $G_0 \neq 0$.

LEMMA 5.4. *$G\mathcal{A}$ has a bounded extension to all elements $z \in Z$ of the form $z = (\phi(0), \phi)$ with $\phi \in C(-r, 0; \mathbb{R}^n)$ and there exists a nondecreasing function $M(\cdot): [0, \infty) \rightarrow \mathbb{R}^+$ such that for $z \in Z$*

$$(5.9) \quad \int_0^T |G\mathcal{A}S(t)z|^2 dt \leq M(T) \|z\|^2.$$

Proof. For $z = (\phi(0), \phi) \in \mathcal{D}(\mathcal{A})$

$$\begin{aligned} |G\mathcal{A}z| &= \left| G \left(\int_{-r}^0 d\mu(\theta) \phi(\theta), \dot{\phi} \right) \right| = \left| G_0 \int_{-r}^0 d\mu(\theta) \phi(\theta) \right| \\ &\leq |G_0| \int_{-r}^0 |d\mu| \|\phi\|_{C(-r, 0; \mathbb{R}^n)}. \end{aligned}$$

Since $H^1(-r, 0; \mathbb{R}^n)$ is dense in $C(-r, 0; \mathbb{R}^n)$, $G\mathcal{A}$ has the prescribed extension. Upon identifying $G\mathcal{A}$ with \mathcal{H} of Lemma 5.1, (5.9) follows. Q.E.D.

LEMMA 5.5. For $x, y \in Z$

$$\langle G_\lambda \mathcal{A} \mathcal{U}_\lambda(T, t)x, \mathcal{U}_\lambda(T, t)y \rangle \rightarrow \langle G\mathcal{A} \mathcal{U}(T, t)x, \mathcal{U}(T, t)y \rangle \quad \text{in } L_2(t_0, T).$$

Remark. To be precise, Lemma 5.4 only extends $G_\lambda \mathcal{A}$ and $G\mathcal{A}$ to $x = (\phi(0), \phi)$ such that $\phi \in C(-r, 0; \mathbb{R}^n)$. However, as functions in $L_2(t_0, T)$, the inner products may be extended to all Z .

Proof. First note that $\mathcal{U}_\lambda(T, t)z$ converges strongly to $\mathcal{U}(T, t)z$ for $z \in Z$ and the convergence is uniform in t , and that

$$\mathcal{U}_\lambda(T, t)z = S(T-t)z + \int_t^T S(T-s)\mathcal{B}u_\lambda(s) ds$$

where $u_\lambda(\cdot)$ is the optimal control for the λ th approximate (5.8) on the time interval $[t, T]$ with given initial condition $z \in Z$. Since J_λ converges strongly to I as $\lambda \rightarrow \infty$ on $X = \mathcal{D}(\mathcal{A})$, it follows from (i) of Lemma 5.1 and the fact that $u_\lambda \rightarrow u^0$ in $L_2(t, T; \mathbb{R}^m)$ that for $t \leq T$

$$f_\lambda(t) = J_\lambda \int_t^T S(T-s)\mathcal{B}u_\lambda(s) ds$$

converges strongly to

$$f^0(t) = \int_t^T S(T-s)\mathcal{B}u_0 \rightarrow u^0(s) ds$$

in X . Since $\|f_\lambda(t)\|_X$ is uniformly bounded in λ and $t \in [t_0, T]$, by the dominated convergence theorem, $f_\lambda(t)$ converges strongly to $f^0(t)$ in $L_2(t_0, T; X)$. Hence $\langle G\mathcal{A}f_\lambda(t), J_\lambda \mathcal{U}_\lambda(T, t)y \rangle$ converges strongly to $\langle G\mathcal{A}f^0(t), \mathcal{U}(T, t)y \rangle$ in $L_2(t_0, T)$ for $y \in Z$. The remainder of the proof is to show that for $z, y \in Z$

$$(5.10) \quad \langle G\mathcal{A}J_\lambda S(T-t)z, J_\lambda \mathcal{U}_\lambda(T, t)y \rangle \rightarrow \langle G\mathcal{A}S(T-t)z, \mathcal{U}(T, t)y \rangle \quad \text{in } L_2(t_0, T).$$

As in Lemma 5.4, it can be shown that

$$\int_{t_0}^T |G\mathcal{A}J_\lambda S(T-t)z|^2 dt \leq M \|z\|^2, \quad z \in Z,$$

since $\|J_\lambda\|$ is bounded uniformly in λ . The desired result follows from direct applications of the triangle inequality and the dominated convergence theorem.

LEMMA 5.6. There exists a finite rank (\tilde{p}) operator \mathcal{H} on Z and a nonsingular diagonal matrix Λ on $\mathbb{R}^{\tilde{p}}$ such that

$$2\langle G\mathcal{A}z, z \rangle + \langle (\mathcal{C}^* \mathcal{C} - G\mathcal{B}\mathcal{B}^* G)z, z \rangle = \langle \Lambda \mathcal{H}z, \mathcal{H}z \rangle_{\mathbb{R}^{\tilde{p}}} \quad \text{for } z \in \mathcal{D}(\mathcal{A})$$

and \mathcal{H} can be continuously extended to all elements $z \in Z$ of the form $z = (\phi(0), \phi)$ with $\phi \in C(-r, 0; \mathbb{R}^n)$.

Proof. Let X' denote the strong dual space of X . We identify Z with its dual, so that $X \subset Z \subset X'$. If j is the canonical injection from X into Z : $j\phi = (\phi(0), \phi) \in Z$, $\phi \in X$, then j is an embedding from X into Z ; i.e., j is injective and $j(X)$ is dense in Z ; thus it follows from Prop. 4 in [1, p. 65] that j' from Z to X' and $j'j$ from X to X' are embeddings:

$$X \xrightarrow{j} Z \xrightarrow{j'} X'$$

and the bilinear form $(x, y)_{X', X}$ on $X' \times X$ is the unique extension by continuity of the scalar product (x, y) of Z restricted to $Z \times X$. Here (\cdot) stands for dual operators. Let us define an operator $Q \in \mathcal{L}(X, X')$ by

$$Q = \mathcal{A}'G + j'G\mathcal{A} - j'G\mathcal{B}\mathcal{B}^*Gj + j'\mathcal{C}^*\mathcal{C}j.$$

If i is the norm-preserving canonical map from X' into X , then iQ is a self-adjoint operator on X . Indeed,

$$\langle iQx, y \rangle_X = \langle Qx, y \rangle_{X', X} = \langle x, Qy \rangle_{X, X'} = \langle x, iQy \rangle_X.$$

Since G and \mathcal{C} have finite rank, Q has a finite rank, and so iQ does also. Suppose $\text{rank}(iQ) = \tilde{p}$. Then there exists an operator \mathcal{H} on X and a nonsingular diagonal matrix Λ on $\mathbb{R}^{\tilde{p}}$ such that

$$iQz = \mathcal{H}^* \Lambda \mathcal{H}z \quad \text{for all } z \in X = \mathcal{D}(\mathcal{A}).$$

It now follows that for $z \in X$

$$\langle Qz, z \rangle_{X', X} = \langle iQz, z \rangle_X = \langle \mathcal{H}^* \Lambda \mathcal{H}z, z \rangle_X = \langle \Lambda \mathcal{H}z, \mathcal{H}z \rangle_{\mathbb{R}^{\tilde{p}}}.$$

The proof is completed if we note that

$$\langle Qz, z \rangle_{X', X} = 2\langle G\mathcal{A}z, z \rangle_Z + \langle (\mathcal{C}^*\mathcal{C} - G\mathcal{B}\mathcal{B}^*G)z, z \rangle_Z$$

and that from Lemma 5.4 the right-hand side of this equality is continuous on $\phi \in C(-r, 0; \mathbb{R}^n)$. Q.E.D.

The next theorem gives the extension of Remark 3.2 and Theorem 3.1 to the case $G_0 \neq 0$.

THEOREM 5.7. *If $\Pi(t)$, $t \leq T$, is the solution of the Riccati equation (2.6) with $G(\eta, \phi) = (G_0\eta, 0)$ for $(\eta, \phi) \in Z$, then for $z \in Z$*

$$\Pi(t)z = Gz + \int_t^T (\mathcal{H}\mathcal{U}(T, s))^* \Lambda \mathcal{H}\mathcal{U}(T, s)z \, ds$$

where \mathcal{H} and Λ are defined in Lemma 5.6.

Proof. Recall that for $t \leq T$ and $z \in Z$

$$\Pi_\lambda(t)z = G_\lambda z + \int_t^T \mathcal{U}_\lambda^*(T, s)Q_\lambda \mathcal{U}_\lambda(T, s)z \, ds.$$

Since $\Pi_\lambda(t)$, $t \leq T$ converges strongly to $\Pi(t)$, uniformly on bounded t -intervals, for $t \leq T$ and $x, y \in Z$

$$\begin{aligned} \langle \Pi(t)x, y \rangle &= \lim_{\lambda \uparrow \infty} \langle \Pi_\lambda(t)x, y \rangle \\ &= \lim_{\lambda \uparrow \infty} \left(\langle G_\lambda x, y \rangle + \int_t^T \{ \langle \mathcal{A}^* G_\lambda \mathcal{U}_\lambda(T, s)x, \mathcal{U}_\lambda(T, s)y \rangle \right. \\ &\quad \left. + \langle \mathcal{U}_\lambda(T, s)x, \mathcal{A}^* G_\lambda \mathcal{U}_\lambda(T, s)y \rangle \right. \\ &\quad \left. + \langle (\mathcal{C}^*\mathcal{C} - G_\lambda \mathcal{B}\mathcal{B}^*G_\lambda) \mathcal{U}_\lambda(T, s)x, \mathcal{U}_\lambda(T, s)y \rangle \} \, ds \right). \end{aligned}$$

Hence, from Lemma 5.5 and the fact that $\mathcal{U}_\lambda(T, s)z$ converges strongly to $\mathcal{U}(T, s)z$ for $z \in Z$ and the convergence is uniform in s , the dominated convergence theorem allows us to show that for $t \leq T$ and $x, y \in Z$

$$\begin{aligned} \langle \Pi(t)x, y \rangle = & \langle Gx, y \rangle + \int_t^T \{ \langle G\mathcal{A}\mathcal{U}(T, s)x, \mathcal{U}(T, s)y \rangle + \langle \mathcal{U}(T, s)x, G\mathcal{A}\mathcal{U}(T, s)y \rangle \\ & + \langle (\mathcal{C}^*\mathcal{C} - G\mathcal{B}\mathcal{B}^*G)\mathcal{U}(T, s)x, \mathcal{U}(T, s)y \rangle \} ds. \end{aligned}$$

Since $\mathcal{U}(T, t)z \in \mathcal{D}(\mathcal{A})$ for $z \in \mathcal{D}(\mathcal{A})$, it follows from Lemma 5.6 that for $x, y \in \mathcal{D}(\mathcal{A})$

$$(5.11) \quad \langle \Pi(t)x, y \rangle = \langle Gx, y \rangle + \int_t^T \langle \Lambda \mathcal{H}\mathcal{U}(T, s)x, \mathcal{H}\mathcal{U}(T, s)y \rangle ds.$$

But since \mathcal{H} can be continuously extended to all elements z of the form $z = (\phi(0), \phi)$ with $\phi \in C(-r, 0; \mathbb{R}^n)$, it follows from (ii) of Lemma 5.1 and the arguments in the proof of Lemma 5.5 that (5.11) holds for all $x, y \in Z$. Q.E.D.

The following results are concerned with the differentiability of the optimal control $u^0(\cdot)$ of (5.8).

THEOREM 5.8. *For $z \in Z$ the optimal control $u^0(\cdot)$ of (5.8) is absolutely continuous on $[t_0, T]$ with $\dot{u}^0 \in L_2(t_0, T; \mathbb{R}^m)$.*

Proof. It follows from Theorem 4.3 that if $z = (\eta, \phi) \in \mathcal{D}(\mathcal{A})$, then $u_\lambda(\cdot)$ is continuously differentiable on $[t_0, T]$ and is given by

$$\frac{d}{dt} u_\lambda(t) = \mathcal{B}^*(\mathcal{A}^*\Pi_\lambda(t) + \mathcal{C}^*\mathcal{C})\mathcal{U}_\lambda(t, t_0)z.$$

From (2.8)

$$\Pi_\lambda(t)z = S^*(T-t)G_\lambda\mathcal{U}_\lambda(T, t)z + \int_t^T S^*(\sigma-t)\mathcal{C}^*\mathcal{C}\mathcal{U}_\lambda(\sigma, t)z d\sigma \quad \text{for } z \in Z.$$

Note that $G_\lambda Z \subset \mathcal{D}(\mathcal{A}^*)$. Hence, using the same arguments as those in the proof of Lemma 4.3, one can show that $\Pi_\lambda(t)z \in \mathcal{D}(\mathcal{A}^*)$ for $z \in Z$ and $t \leq T$, and moreover, that $\mathcal{A}^*\Pi_\lambda(t)$ is strongly continuous on $[t_0, T]$. Since $\mathcal{U}_\lambda(t, \cdot)$ is strongly continuous on Z , this fact along with the closedness of the differential operator (d/dt) on $C(t_0, T; \mathbb{R}^m)$, shows that for $z \in Z$ $u_\lambda(t)$ is continuously differentiable on $[t_0, T]$. We now note that for $t \leq T$

$$\begin{aligned} \mathcal{B}^*\mathcal{A}^*S^*(T-t)G_\lambda &= \mathcal{B}^*\mathcal{A}^*S^*(T-t)J_\lambda^*GJ_\lambda \\ &= \mathcal{B}^*\mathcal{A}^*S^*(T-t)J_\lambda^*\mathcal{F}^*GJ_\lambda \quad (\text{using } \mathcal{F}^*G = G) \\ &= \mathcal{B}^*\mathcal{A}^*S^*(T-t)\mathcal{F}^*I_\lambda GJ_\lambda \\ &= \mathcal{B}^*\mathcal{F}^*\mathcal{A}_T S_T(T-t)I_\lambda GJ_\lambda \\ &= \mathcal{B}^*\mathcal{A}_T S_T(T-t)I_\lambda GJ_\lambda \quad (\text{using } \mathcal{B}^*\mathcal{F}^* = \mathcal{B}^*) \end{aligned}$$

where $I_\lambda = \lambda(\lambda I - \mathcal{A}_T)^{-1}$, $\lambda \in \rho(\mathcal{A})$ and we have used Theorem 5.2 successively. Since $\mathcal{B}^*(\eta, \phi) = B^T\eta$, the arguments, as in the proof of Lemma 5.4, yield that $\mathcal{B}^*\mathcal{A}_T$ has a bounded extension to all elements $z \in Z$ of the form $z = (\phi(0), \phi)$ with $\phi \in C(-r, 0; \mathbb{R}^n)$ and

$$(5.12) \quad \int_0^T |\mathcal{B}^*\mathcal{A}_T S_T(T-t)z|^2 dt \leq M(T)\|z\|^2$$

for $M(\cdot):[0, \infty) \rightarrow \mathbb{R}^+$ nondecreasing. Hence one obtains

$$\begin{aligned} \frac{d}{dt} u_\lambda(t) &= \mathcal{B}^* \mathcal{A}^* \{S^*(T-t) G_\lambda u_\lambda(T, t) \\ &\quad + \int_t^T S^*(\sigma-t) \mathcal{C}^* \mathcal{C} u_\lambda(\sigma, t) d\sigma\} u_\lambda(t, t_0) z + \mathcal{B}^* \mathcal{C}^* \mathcal{C} u_\lambda(t, t_0) z \\ &= \mathcal{B}^* \mathcal{A}_T S_T(T-t) I_\lambda G J_\lambda u_\lambda(T, t_0) z \\ &\quad + \mathcal{B}^* \mathcal{A}_T \int_t^T S_T(\sigma-t) \mathcal{C}^* \mathcal{C} u_\lambda(\sigma, t_0) z d\sigma + \mathcal{B}^* \mathcal{C}^* \mathcal{C} u_\lambda(t, t_0) z. \end{aligned}$$

Note that $u_\lambda(t, t_0)z$ converges strongly to $u(t, t_0)z$ for $z \in Z$, and the convergence is uniform on $[t_0, T]$. Since I_λ and J_λ converge strongly to the identity operator on Z , $I_\lambda G J_\lambda u_\lambda(T, t_0)z$ converges strongly to $G u(T, t_0)z$ for $z \in Z$. It now follows from (i) of Lemma 5.1 and (5.12) that $\{(d/dt)u_\lambda(\cdot)\}$ is a convergent sequence in $L_2(t_0, T; \mathbb{R}^m)$, which completes the proof when combined with the closedness of the differential operator (d/dt) on $L_2(t_0, T; \mathbb{R}^m)$. Q.E.D.

This last corollary establishes the Chandrasekhar equations for hereditary differential systems.

COROLLARY 5.9. *Define the operator $L(\cdot)$ on Z by $L(t)z = \mathcal{H}u(T, t)z$, $0 \leq t \leq T$ for all $z \in Z$, and the gain operator $K(t) = \mathcal{B}^* \Pi(t)$, $t \leq T$. Then $K(t)z$ and $L(t)x$ are absolutely continuous on $[0, T]$ for $z \in Z$ and $x \in \mathcal{D}(\mathcal{A})$, and they also satisfy*

$$\frac{d}{dt} K(t)z = -\mathcal{B}^* L^*(t) \Lambda L(t)z, \quad z \in Z,$$

$$K(T) = \mathcal{B}^* G$$

and

$$\frac{d}{dt} L(t)x = -L(t)(\mathcal{A} - \mathcal{B}K(t))x, \quad x \in \mathcal{D}(\mathcal{A}),$$

$$L(T)x = \mathcal{H}x.$$

Proof. From (2.7),

$$L(t)\mathcal{B}v = \mathcal{H}S(T-t)\mathcal{B}v - \mathcal{H} \int_t^T S(T-s)\mathcal{B}K(s)u(s, t)\mathcal{B}v ds \quad \text{for } v \in \mathbb{R}^m.$$

Here note that $\mathcal{H}S(\tau)\mathcal{B}v = \mathcal{H}(x(\tau), x(\tau + \cdot))$, $\tau \geq 0$ where x is the homogeneous solution of (5.1) with initial condition $\mathcal{B}v$ and $x \in BV(-r, T; \mathbb{R}^n)$ for any $T \geq 0$. This means that $L(t)\mathcal{B} \in \mathbb{R}^{\tilde{p} \times m}$ exists for each t , and it is not difficult to show that $L(t)\mathcal{B}$ is of bounded variation on $[0, T]$. So $\mathcal{B}^* L^*(\cdot) = (L(\cdot)\mathcal{B})^* \in \mathbb{R}^{m \times \tilde{p}}$. It then follows from Theorem 5.7 that for $z \in Z$

$$K(t)z = \mathcal{B}^* Gz + \int_t^T \mathcal{B}^* L^*(s) \Lambda L(s)z ds,$$

and hence $K(t)z$ is absolutely continuous on $[0, T]$.

Since $\mathcal{H}u(T, t)\mathcal{B} = L(t)\mathcal{B}$ is integrable, it follows from Lemma 5.1 and (3.4) that for $z \in Z$

$$L(t)z = \mathcal{H}S(t-t)z - \int_t^T L(s)\mathcal{B}K(s)S(s-t)z ds,$$

and thus for $z \in \mathcal{D}(\mathcal{A})$, $L(t)z$ is absolutely continuous on $[0, T]$ with square integrable derivative. Q.E.D.

Acknowledgments. The authors would like to thank Professor John A. Burns for motivating this work, and the reviewers, whose comments were most helpful.

ALGEBRAIC RICCATI EQUATION ARISING IN BOUNDARY CONTROL PROBLEMS*

FRANCO FLANDOLI†

Abstract. An algebraic Riccati equation is studied, with application to the optimal control of deterministic and stochastic parabolic systems with boundary control. The control function can act on the boundary through Dirichlet or Neumann conditions.

Key words. algebraic Riccati equation, Dirichlet boundary control, deterministic and stochastic dynamics

AMS(MOS) subject classification. 49A22

1. Introduction. In this paper we are concerned with the optimal control over infinite time horizon of two classes of boundary control systems: the first one is a class of deterministic parabolic systems with boundary control, described by an abstract semigroup model (similar to those considered in [B2] or [L1]) which covers both cases of Dirichlet boundary control and Neumann boundary control; the second one is a class of stochastic parabolic systems with state and control dependent noises, which in a sense generalizes the previous one, along the lines of stochastic systems considered in [I1] (but [I1] is concerned only with the case of distributed controls); also the stochastic model covers both cases of Dirichlet and Neumann boundary control. The work is based on a direct study of a generalized version of the algebraic Riccati equation, connected with the stochastic problem and the deterministic one. The properties obtained include existence, uniqueness, asymptotic behavior for the Riccati equation, synthesis of optimal control, and stability of optimal trajectories. Examples of applications are given in §§ 4.2 and 5.3.

Boundary control problems, above all in the deterministic case, have been extensively studied, in recent years, using analytic semigroups. In particular, the optimal control over finite time horizon of deterministic systems has been studied in [B2], [L2] and [F2]; for similar stochastic problems see [F1], [F3]. A different approach, based on techniques along the lines of [L5], is presented in [S1] and [S2], where problems over infinite time horizon and related algebraic Riccati equations are also considered; in particular, a problem with Neumann boundary control and Dirichlet boundary observation is studied under very general assumptions in [S1], while the case of Dirichlet boundary control and distributed observation (one of the problems studied here) is considered in [S2] assuming stability of the uncontrolled system. We remark that in these works a variational technique is employed.

We present here a different approach from that of [S1] and [S2]: first we use analytic semigroups along the lines of [B2], [L2] and [F2]; second we employ a dynamic programming technique. One of the advantages of this approach is that it allows one to study in an almost unified way the deterministic problem and the stochastic one; in fact the main part of the work, concerning a direct solution to the algebraic Riccati equation, is developed by studying an appropriate Riccati equation which covers the stochastic case as well as the deterministic one. The results on the stochastic problem are new; in the case of the Dirichlet boundary control of determinis-

tic systems, we prove some results on stability of optimal trajectories, and asymptotic behavior of the solution $P(t)$ of a differential Riccati equation (see Theorem 2), which are not included in [S1], [S2], and we prove the existence of a solution P_∞ of the algebraic Riccati equation under the natural assumption of existence of admissible controls.

Following a classical idea of distributed control theory ([L7], [D4]), we derive P_∞ as a limit, as $t \rightarrow \infty$, of $P(t)$; however the usual monotonicity and boundedness results for $P(t)$, which can be proved in a standard way, are not sufficient in the present case. A much stronger convergence of $P(t)$ is needed (see (3.44)) because of the presence of an unbounded operator in the nonlinear term of the Riccati equations (see (1.14) and (3.5)), and in the feedback gain (see (4.1) and (5.1)). To this purpose, the major technical issue to settle is the bound (3.21), which is proved with a technique along the lines of [F2].

The direct solution of the algebraic Riccati equation and the asymptotic behavior of $P(t)$ are the objects of § 3. Synthesis of optimal control, stability of optimal trajectories, and uniqueness of the solution to the algebraic Riccati equation are studied separately in the deterministic case, § 4, and in the stochastic case, § 5 (although with similar methods based on results of § 3). Some examples of applications to concrete boundary control problems are given in § 4.2 and § 5.3; we remark that also the pointwise control of parabolic systems in dimension $n \leq 3$ can be described using the abstract semigroup models (1.1) and (1.8) (see [D2] and [I2]), so that the results of the present paper apply to this problem.

We remark that the assumption of existence of admissible controls (which yields existence of P_∞ and synthesis) is verified for deterministic parabolic systems, with a second order elliptic operator and Dirichlet boundary control, also in the case of unstable free systems, in virtue of recent stabilizability results of [T2] and [L3] (for Neumann boundary control problems see [S1]). As to relations between the present work and stabilizability of boundary control systems, we note also that (assuming detectability) the feedback control (4.1), with the feedback gain involving P_∞ , gives another example of stabilizing boundary control. In the stochastic case stability problems for boundary control systems are new in the literature; in § 5 we extend to this case some typical results of distributed control theory ([I1], [H2]).

We conclude by listing some notation. If X is a Banach (resp. Hilbert) space, then we shall denote its norm by $|\cdot|_X$ (resp. its inner product by $\langle \cdot, \cdot \rangle_X$); if X and Y are Banach spaces, then we shall denote by $L(X, Y)$ the Banach space of all bounded linear operators from X to Y , and by $L(X)$ the space $L(X, X)$.

If X is a Hilbert space and T is a linear operator in X , then we shall denote its domain by $D(T)$, and its adjoint operator (if $D(T)$ is dense in X) by T^* (similar notation if $T \in L(X, Y)$, where X and Y are Hilbert spaces); further, we shall set $\Sigma^+(X) = \{T \in L(X) | T = T^*, \langle Tx, x \rangle_X \geq 0 \text{ for any } x \in X\}$. The domains D_A^γ and $D_{A^*}^\gamma$ will be defined in § 1.1.

Let X be a Banach space, and let $a < b$ be two real numbers; if $p \in [1, \infty[$ then we shall denote by $L^p(a, b; X)$ the Banach space of all functions $f: [a, b] \rightarrow X$ such that $\int_a^b |f(t)|_X^p dt < \infty$ (similarly, with obvious modifications, if $p = +\infty$, and if $b = +\infty$). Further, we shall denote by $C(a, b; X)$ the Banach space of all continuous functions $f: [a, b] \rightarrow X$ (similarly if $b = +\infty$), and we shall set $C^1(a, b; X) = \{f \in C(a, b; X) | (df/dt) \in C(a, b; X)\}$.

Finally, if X and Y are Banach spaces then we shall set $C_s(a, b; L(X, Y)) = \{T(\cdot): [a, b] \rightarrow L(X, Y) | T(\cdot)x \in C(a, b; Y) \text{ for any } x \in X\}$. Similar definitions if $b = +\infty$, and for $C_s(a, b; \Sigma^+(X))$ where X is a Hilbert space.

1.1. Problem formulation and hypotheses. We introduce here the infinite time horizon problems and the related algebraic Riccati equations which are the objects of this paper. We formulate first the deterministic problem, and then the stochastic one.

Let H , U , V be Hilbert spaces; H will be the state space, U the control space, and V the observation space. In order to unify the study of deterministic and stochastic problems, and to use the theory of Hilbert space valued Brownian motions and stochastic integration ([C2], [C3]), it is preferable to assume separability of these Hilbert spaces; moreover this is not restrictive for applications. However, as far as we are concerned with the deterministic case, all results hold in the general case.

Throughout the paper we shall make the following assumption:

- (H1) A is the infinitesimal generator of an analytic semigroup e^{tA} , $t \geq 0$, in H ; $\lambda \geq 0$ is a real number such that $A - \lambda$ is stable, $B \in L(U, D_A^\alpha)$ for some $\alpha \in]0, 1]$, where D_A^α denotes the domain of the fractional power $(\lambda - A)^\alpha$; $C \in L(H, V)$, $N \in \Sigma^+(U)$ and $\langle Nu, u \rangle_U \geq \nu |u|_U^2$ for any $u \in U$ and for some fixed $\nu > 0$.

We remark that the fractional powers $(\lambda - A)^\gamma$ and $(\lambda - A^*)^\gamma$, $\gamma \in \mathbb{R}$, are well defined because $A - \lambda$ is stable ([T1]); we shall denote their domains by D_A^γ and $D_{A^*}^\gamma$, respectively.

In applications to boundary control problems, A is defined by an elliptic operator in a bounded domain of \mathbb{R}^n with homogeneous boundary conditions, and B is the Green mapping of a related elliptic boundary value problem; see Example 1, § 4.2, for more precise definitions. We remark that $\alpha = \frac{1}{4} - \varepsilon$, $\varepsilon > 0$, in the case of second order elliptic operators with Dirichlet boundary conditions, while $\alpha = \frac{3}{4} - \varepsilon$ in the Neumann case ([L1]).

It is well known ([B2], [L1]) that solutions to parabolic boundary value problems can be represented by an abstract semigroup formula involving operators A and B which verify (H1). In the case of problems over infinite time horizon it turns out that the system can be appropriately described by the input-output formula (see Example 1, § 4.2)

$$(1.1) \quad y(t) = e^{tA} y_0 + \int_0^t (A - \lambda) e^{(t-s)A} B u(s) ds$$

where $u(\cdot)$ is the control function and $y(\cdot)$ is the state function. We remark that, given $T > 0$, (1.1) defines a function $y \in L^2(0, T; H)$ for any $u \in L^2(0, T; U)$. To see this, we recall first that analyticity and stability of $e^{t(A-\lambda)}$ imply that, for any $\gamma > 0$, there exists a constant $c(\gamma) > 0$ such that

$$(1.2) \quad |(\lambda - A)^\gamma e^{t(A-\lambda)}|_{L(H)} \leq c(\gamma) e^{-\omega t} / t^\gamma, \quad t > 0,$$

for a suitable constant $\omega > 0$ ([T1, Thm. 3.3.3]); then from (H1) it follows that there exists a constant $c > 0$ such that

$$(1.3) \quad \begin{aligned} |(A - \lambda) e^{tA} B|_{L(U, H)} &= |(\lambda - A)^{1-\alpha} e^{t(A-\lambda)} e^{t\lambda} (\lambda - A)^\alpha B|_{L(U, H)} \\ &\leq c e^{t(\lambda-\omega)} / t^{1-\alpha}, \quad t > 0. \end{aligned}$$

If $u \in L^2(0, T; U)$ then (1.3) and a Young inequality yield $y \in L^2(0, T; H)$ in (1.1).

Given $y_0 \in H$, we will be concerned in § 4 with the following deterministic optimal control problem:

minimize

$$(1.4) \quad J_\infty(u) = \int_0^\infty \{|Cy(t)|_V^2 + \langle Nu(t), u(t) \rangle_U\} dt$$

over all $u \in L^2(0, \infty; U)$, subject to (1.1).

The algebraic Riccati equation arising in this problem is formally (a correct meaning is given by (1.7) below):

$$(1.5) \quad A^*P_\infty + P_\infty A + C^*C - P_\infty(A - \lambda)BN^{-1}B^*(A^* - \lambda)P_\infty = 0;$$

this equation will be studied in § 3, as a particular case of (1.10). In order to give a precise meaning to the nonlinear term of (1.5) we introduce a useful notation. Note that the composition $(A - \lambda)B$ is not well defined in general, while the operator $B^*(A^* - \lambda)$ is well defined on $D(A^*)$, and it can be extended, in a unique way, to a bounded operator from $D_{A^*}^{1-\alpha}$ to U . More precisely,

$$(1.6) \quad \begin{aligned} &\text{there exists a unique } K \in L(D_{A^*}^{1-\alpha}, U) \text{ such that} \\ &Kx = B^*(A^* - \lambda)x \text{ for any } x \in D(A^*). \end{aligned}$$

To see this, it is enough to define $K = -[(\lambda - A)^\alpha B]^*(\lambda - A^*)^{1-\alpha}$, and to note that K is the unique extension because $D(A^*)$ is dense in $D_{A^*}^{1-\alpha}$ ([T1]). Using this notation we can say, for instance, that $P_\infty \in \Sigma^+(H) \cap L(H, D_{A^*}^{1-\alpha})$ is a solution of (1.5) if

$$(1.7) \quad \langle P_\infty x, Ay \rangle_H + \langle Ax, P_\infty y \rangle_H + \langle Cx, Cy \rangle_V - \langle N^{-1}KP_\infty x, KP_\infty y \rangle_U = 0$$

for any $x, y \in D(A)$.

Let us define now the stochastic problem. Assume that (H1) holds, and let X_1 and X_2 be two separable Hilbert spaces. Let $w_1(t)$ and $w_2(t)$, $t \geq 0$, be two independent Brownian motions, defined in a probability space $(\Omega, \mathcal{F}, \mathcal{P})$, with values in X_1 and X_2 respectively; for the definition of Hilbert space valued Brownian motions see [C2]. Let \mathcal{F}_t be the σ -algebra generated by $\{w_1(s), w_2(s); 0 \leq s \leq t\}$; if $0 \leq T < \infty$ (similarly if $T = +\infty$), then we shall denote by $M_w^2(0, T; H)$ the Hilbert space of all strongly measurable stochastic processes $f: [0, T] \times \Omega \rightarrow H$ such that $f(t)$ is \mathcal{F}_t -measurable for any $t \in [0, T]$, and

$$E \int_0^T |f(t)|_H^2 dt < \infty$$

(similarly we define $M_w^2(0, T; U)$ and $M_w^2(0, T; V)$). Further, we shall denote by $C_w(0, T; L^2(\Omega; H))$ the Banach space of all $f \in M_w^2(0, T; H)$ such that $E|f(\cdot)|_H^2$ is a continuous function on $[0, T]$.

Assume that

$$(H2) \quad F_1 \in L(H, L(X_1, H)), \quad F_2 \in L(U, L(X_2, H));$$

then a general class of stochastic parabolic systems with boundary control, and state and control dependent noises, can be described by the following integral equation:

$$(1.8) \quad \begin{aligned} y(t) = & e^{tA}y_0 + \int_0^t (A - \lambda) e^{(t-s)A} Bu(s) ds \\ & + \int_0^t e^{(t-s)A} F_1(y(s)) dw_1(s) + \int_0^t e^{(t-s)A} F_2(u(s)) dw_2(s). \end{aligned}$$

Examples are given in § 5.3 and in [F1]. Similar systems, but with distributed control (i.e. without the term $(A - \lambda)$ in (1.8)), are considered, for instance in [I1]. We remark that, given $T > 0$, if $u \in M_w^2(0, T; U)$ then there exists a unique solution $y \in M_w^2(0, T; H)$ of (1.8). This follows from a standard application ([C2]) of the contraction principle; to this end, the only novelty is due to the first integral term in (1.8), and it is sufficient to note that it defines a stochastic process in $M_w^2(0, T; H)$ for any $u \in M_w^2(0, T; U)$, by virtue of (1.3) and the Young inequality.

In § 5 we shall consider the following optimal control problem:

minimize

$$(1.9) \quad J_{\infty}(u) = E \int_0^{\infty} \{ |Cy(t)|_V^2 + \langle Nu(t), u(t) \rangle_U \} dt$$

over all $u \in M_w^2(0, \infty; U)$, subject to (1.8).

The algebraic Riccati equation arising in this problem is formally (a correct meaning is given by (1.14) below):

$$(1.10) \quad A^*P_{\infty} + P_{\infty}A + C^*C + \phi_1(P_{\infty}) - P_{\infty}(A - \lambda)B\phi_2(P_{\infty})B^*(A^* - \lambda)P_{\infty} = 0$$

where $\phi_1(\cdot)$ and $\phi_2(\cdot)$ are the applications from $\Sigma^+(H)$ to $\Sigma^+(H)$ and $\Sigma^+(U)$, respectively, defined as follows. Let

$$(1.11) \quad W_1 \in \Sigma^+(X_1), \quad W_2 \in \Sigma^+(X_2), \quad W_1 \text{ and } W_2 \text{ trace class operators}$$

be the covariance operators of the Brownian motions $w_1(t)$ and $w_2(t)$, respectively [C2]; then from the properties of trace class operators [K1], and (H2), it follows easily that the applications $\Delta_1(\cdot)$ and $\Delta_2(\cdot)$ defined by

$$(1.12) \quad \begin{aligned} \langle \Delta_1(P)x, y \rangle_H &= \text{trace } F_1(x)^* P F_1(y) W_1, & x, y \in H, \quad P \in \Sigma^+(H), \\ \langle \Delta_2(P)u, v \rangle_U &= \text{trace } F_2(u)^* P F_2(v) W_2, & u, v \in U, \quad P \in \Sigma^+(H), \end{aligned}$$

are well defined and continuous from $\Sigma^+(H)$ to $\Sigma^+(H)$ and $\Sigma^+(U)$, respectively; further, if $P_n x \rightarrow Px$ for any $x \in H$ then $\Delta_i(P_n)x \rightarrow \Delta_i(P)x$ for any $x \in H$ and $i = 1, 2$. Finally, $\phi_1(\cdot)$ and $\phi_2(\cdot)$ are defined by

$$(1.13) \quad \phi_1(P) = \Delta_1(P), \quad \phi_2(P) = (N + \Delta_2(P))^{-1} \quad \text{for any } P \in \Sigma^+(H).$$

A similar problem with distributed control is studied in [11].

Using the operator K , given by (1.6), we can say that $P_{\infty} \in \Sigma^+(H) \cap L(H, D_A^{1-\alpha})$ is a solution to (1.10) if

$$(1.14) \quad \begin{aligned} &\langle P_{\infty}x, Ay \rangle_H + \langle Ax, P_{\infty}y \rangle_H + \langle Cx, Cy \rangle_V + \langle \phi_1(P_{\infty})x, y \rangle_H \\ &\quad - \langle \phi_2(P_{\infty})KP_{\infty}x, KP_{\infty}y \rangle_U = 0 \end{aligned}$$

for any $x, y \in D(A)$.

We remark that (1.5) is a particular case of (1.10), with

$$(1.15) \quad \phi_1(P) = 0, \quad \phi_2(P) = N^{-1} \quad \text{for any } P \in \Sigma^+(H).$$

For this reason we study in § 3 the algebraic Riccati equation (1.10), which covers both the deterministic and the stochastic case. It is to be noted that the direct study of (1.10) does not introduce essential complications with respect to a direct study of (1.5).

2. Preliminaries. We summarize results for (1.1) and (1.8) which are useful in subsequent sections. Hypotheses and notation of § 1.1 are assumed throughout this section.

Let $T > 0$ be given; let us consider the linear mapping

$$(2.1) \quad \mathcal{L} \in L(L^2(0, T; U), L^2(0, T; H))$$

defined by

$$(2.2) \quad \mathcal{L}(u)(t) = \int_0^t (A - \lambda) e^{(t-s)A} Bu(s) ds \quad \text{for a.e. } t \in [0, T],$$

for any $u \in L^2(0, T; U)$. Note that (2.1) follows from (1.3) and a Young inequality. Further (1.3) yields easily

$$(2.3) \quad \mathcal{L} \in L(C(0, T; U), C(0, T; H)).$$

It is useful to introduce an approximation of (2.2); following [Y1], we define the operators

$$(2.4) \quad I_n = n(n - A)^{-1} \quad \text{for any } n \geq \lambda.$$

The following properties hold ([Y1]):

$$(2.5) \quad \begin{aligned} &I_n \in L(H, D(A)), I_n x \rightarrow x \text{ for any } x \in H, \text{ there exists a constant } c > 0 \\ &\text{such that } |I_n|_{L(H)} \leq c, I_n \text{ commutes with } e^{tA}, A, (\lambda - A)^\gamma. \end{aligned}$$

Using the operators I_n we define the approximations $\mathcal{L}_n \in L(C(0, T; U), C(0, T; H))$ of (2.2) by

$$(2.6) \quad \mathcal{L}_n(u)(t) = I_n \mathcal{L}(u)(t) = \int_0^t e^{(t-s)A} (A - \lambda) I_n B u(s) ds,$$

$t \in [0, T]$, for any $u \in C(0, T; U)$ (or also $u \in L^2(0, T; U)$).

LEMMA 1. If $u_n \rightarrow u$ in $C(0, T; U)$ then $\mathcal{L}_n(u_n) \rightarrow \mathcal{L}(u)$ in $C(0, T; U)$; moreover, for any $u \in C(0, T; U)$, we have:

$$(2.7) \quad \mathcal{L}_n(u) \in C(0, T; D(A)) \cap C^1(0, T; H),$$

$$(2.8) \quad \frac{d}{dt} \mathcal{L}_n(u)(t) = A \mathcal{L}_n(u)(t) + (A - \lambda) I_n B u(t), \quad t \in [0, T].$$

Proof. $\mathcal{L}_n(u_n) = I_n \mathcal{L}(u_n)$ by definition; then from (2.3) and (2.5) it follows $\mathcal{L}_n(u_n) \rightarrow \mathcal{L}(u)$ in $C(0, T; H)$. Let $u \in C(0, T; U)$; from the equality

$$\begin{aligned} A \mathcal{L}_n(u)(t) &= (A - \lambda) \mathcal{L}_n(u)(t) + \lambda \mathcal{L}_n(u)(t) \\ &= - \int_0^t (\lambda - A)^{1-\alpha} e^{(t-s)A} (A - \lambda) I_n (\lambda - A)^\alpha B u(s) ds + \lambda \mathcal{L}_n(u)(t), \end{aligned}$$

it follows readily that $\mathcal{L}_n(u) \in C(0, T; D(A))$; similarly one can prove that $\mathcal{L}_n(u) \in C^1(0, T; H)$ and that (2.8) holds. \square

2.1. Deterministic closed loop systems. Let $G(\cdot) \in C_s(0, T; L(H, U))$ be given; we consider the closed loop system (which corresponds to (1.1) with the feedback control $u(t) = -G(t)y(t)$)

$$(2.9) \quad y(t) = e^{tA} y_0 - \int_0^t (A - \lambda) e^{(t-s)A} B G(s) y(s) ds, \quad t \in [0, T],$$

and the approximating system

$$(2.10) \quad y_n(t) = e^{tA} I_n y_0 - \int_0^t e^{(t-s)A} (A - \lambda) I_n B G(s) y_n(s) ds,$$

$t \in [0, T]$ where $y_0 \in H$. From Lemma 1, (1.3) and the contraction principle, Corollary 1 follows immediately.

COROLLARY 1. *There exist unique solutions y and y_n of (2.9) and (2.10), respectively, in $C(0, T; H)$, and $y_n \rightarrow y$ in $C(0, T; H)$. Moreover $y_n \in C(0, T; D(A)) \cap C^1(0, T; H)$ and*

$$(2.11) \quad \begin{aligned} \frac{d}{dt} y_n(t) &= A y_n(t) - (A - \lambda) I_n B G(t) y_n(t), \quad t \in [0, T], \\ y_n(0) &= I_n y_0. \end{aligned}$$

Consider now the case of a constant operator $G \in L(H, U)$ in (2.9) and (2.10). In virtue of Corollary 1, we can define a strongly continuous semigroup $T(t)$ by the integral equation

$$(2.12) \quad T(t) = e^{tA} - \int_0^t (A - \lambda) e^{(t-s)A} B G T(s) ds, \quad t \geq 0$$

(the semigroup property follows by standard arguments, as in [K1]). We define also the approximations $T_n(\cdot) \in C_s(0, \infty; L(H))$ by the equations

$$(2.13) \quad T_n(t) = e^{tA} I_n - \int_0^t e^{(t-s)A} (A - \lambda) I_n B G T_n(s) ds, \quad t \geq 0;$$

note that $T(\cdot)I_n^{-1}$ are analytic semigroups, because they are defined by a bounded perturbation of the analytic semigroup e^{tA} .

PROPOSITION 1. *For any $x \in H$ and $T \geq 0$ we have $T_n(\cdot)x \rightarrow T(\cdot)x$ in $C(0, T; H)$, $T_n(\cdot)x \in C(0, T; D(A)) \cap C^1(0, T; H)$ and*

$$(2.14) \quad \frac{d}{dt} T_n(t)x = (A - (A - \lambda) I_n B G) T_n(t)x, \quad T_n(0)x = I_n x.$$

Moreover, $T(t)$ is an analytic semigroup with generator

$$A_G = (A - \lambda)(1 - BG) - \lambda, \quad D(A_G) = \{x \in H \mid (1 - BG)x \in D(A)\}.$$

Proof. The properties of $T_n(\cdot)$ follow readily from Corollary 1. For the proof of the analyticity of $T(t)$ and of the last part of the proposition, we refer, for instance, to [D2], [L4], or [Z2]. \square

2.2. Stochastic closed loop systems. Let $G \in L(H, U)$ be given. We consider here the stochastic equation

$$(2.15) \quad \begin{aligned} y(t) &= e^{tA} y_0 - \int_0^t (A - \lambda) e^{(t-s)A} B G y(s) ds \\ &\quad + \int_0^t e^{(t-s)A} F_1(y(s)) dw_1(s) - \int_0^t e^{(t-s)A} F_2(G y(s)) dw_2(s), \quad t \geq 0, \end{aligned}$$

which corresponds to (1.8) when the feedback control $u(t) = -G y(t)$ is used. We consider also the approximating equation

$$(2.16) \quad \begin{aligned} y_n(t) &= e^{tA} I_n y_0 - \int_0^t e^{(t-s)A} (A - \lambda) I_n B G y_n(s) ds \\ &\quad + \int_0^t e^{(t-s)A} I_n F_1(y_n(s)) dw_1(s) - \int_0^t e^{(t-s)A} I_n F_2(G y_n(s)) dw_2(s), \quad t \geq 0. \end{aligned}$$

LEMMA 2. Let $T \geq 0$ and $y_0 \in H$ be given. Then there exist unique solutions y and y_n of (2.15) and (2.16) respectively in $C_w(0, T; L^2(\Omega, H))$, $y_n \rightarrow y$ in $C_w(0, T; L^2(\Omega, H))$, and y_n verifies the stochastic differential equation

$$(2.17) \quad \begin{aligned} dy_n(t) &= (A - (A - \lambda)I_n BG)y_n(t) dt + I_n F_1(y_n(t)) dw_1(t) - I_n F_2(Gy_n(t)) dw_2(t), \\ y_n(0) &= I_n y_0. \end{aligned}$$

Moreover y verifies the integral equation

$$(2.18) \quad y(t) = T(t)y_0 + \int_0^t T(t-s)F_1(y(s)) dw_1(s) - \int_0^t T(t-s)F_2(Gy(s)) dw_2(s),$$

where $T(t)$ is the semigroup defined by (2.12).

Proof. It is proved in [C2] that the last two integral terms of (2.15) define continuous linear mappings from $C_w(0, T; L^2(\Omega, H))$ into itself; (2.3) implies that also the first integral term of (2.15) defines a continuous linear mapping in $C_w(0, T; L^2(\Omega, H))$; moreover the same results hold for (2.16). Then a standard application of the contraction principle yields existence and uniqueness of solutions to (2.15) and (2.16) in $C_w(0, T; L^2(\Omega, H))$, and convergence of y_n to y in $C_w(0, T; L^2(\Omega, H))$ (using (2.5)). The regularity of coefficients in (2.16) implies that y_n has a stochastic differential and (2.17) holds, in virtue of [I1, § 2.1]. Finally from (2.17) we have (by using a stochastic Fubini theorem of [C1])

$$(2.19) \quad \begin{aligned} y_n(t) &= T_n(t)I_n y_0 + \int_0^t T_n(t-s)I_n F_1(y_n(s)) dw_1(s) \\ &\quad - \int_0^t T_n(t-s)I_n F_2(Gy_n(s)) dw_2(s), \end{aligned}$$

where $T_n(t)$ is defined by (2.13); (2.19) implies (2.18) as $n \rightarrow \infty$, in virtue of the convergence results of Proposition 1, of the present lemma, and in virtue of (2.5). \square

It is useful to know that the solution to the stochastic “boundary feedback” system (2.15) is also the solution to (2.18), because a large variety of results on systems like (2.18) are already available (see for instance [I1]); in § 5.2 we shall study in this way stability and stabilizability of (2.15) and (1.8), respectively.

3. Direct solution to the Riccati equation. In this section we discuss some properties of the algebraic Riccati equation (1.10), and of the corresponding differential Riccati equation arising in finite time horizon problems. Using the already known results on the differential Riccati equation (§ 3.1) we derive in a standard way a “candidate” solution P_∞ to the algebraic Riccati equation (Proposition 4, § 3.2); however, as we remarked in the introduction, the strong convergence (3.13) is not sufficient in the present situation; then we prove the uniform bounds of § 3.2, which yield the existence and the asymptotic behavior results of § 3.3. The results of this section will be applied in §§ 4 and 5 to the deterministic problem (1.4) and to the stochastic problem (1.9), respectively.

3.1. Review on the differential Riccati equation and the problem over finite time horizon. For proofs and further details concerning the arguments of this subsection we refer to our previous works [F1] and [F2]; similar (and further) results for the deterministic case are to be found in [B2], [L2], [S2]. We restrict the discussion to the stochastic problem; all results, with obvious modifications, hold also in the deterministic case.

Given $T > 0$, $y_0 \in H$, and

$$(3.1) \quad P_0 \in \Sigma^+(H) \cap L(H, D_A^{1-\alpha}),$$

let us consider the problem:

minimize

$$(3.2) \quad J_T(u) = E \int_0^T \{ |Cy(t)|_V^2 + \langle Nu(t), u(t) \rangle_U \} dt + E \langle P_0 y(T), y(T) \rangle_H$$

over all $u \in M_w^2(0, T; U)$, subject to (1.8).

The differential Riccati equation arising in this problem has the form

$$(3.3) \quad \begin{aligned} \frac{dP(t)}{dt} &= A^*P(t) + P(t)A + C^*C + \phi_1(P(t)) \\ &\quad - P(t)(A - \lambda)B\phi_2(P(t))B^*(A^* - \lambda)P(t), \quad t \in [0, T], \\ P(0) &= P_0. \end{aligned}$$

Remark 1. Since y defined by (1.8) is not continuous in mean square, for a general control $u \in M_w^2(0, T; U)$, we have to give a meaning to the term $E \langle P_0 y(T), y(T) \rangle_H$. We recall ([F2, Lemma 3.3]) that (3.1) implies that the operator $(\lambda - A^*)^{((1-\alpha)/2)-\varepsilon} P_0 (\lambda - A)^{((1-\alpha)/2)-\varepsilon}$ has a unique extension $L_\varepsilon \in L(H)$ for any $\varepsilon > 0$. Moreover, for $\varepsilon > 0$ sufficiently small, the operator valued function $(\lambda - A)^{\varepsilon - ((1-\alpha)/2)} (\lambda - A) e^{tA} B = (\lambda - A)^{((1-\alpha)/2)+\varepsilon} e^{tA} (\lambda - A)^\alpha B$ belongs to $L^2(0, T; L(U, H))$; therefore, if y is defined by (1.8), then $(\lambda - A)^{\varepsilon - ((1-\alpha)/2)} y \in C_w(0, T; L^2(\Omega, H))$ for any $u \in M_w^2(0, T; U)$, and for $\varepsilon > 0$ sufficiently small (see also [F1, § 5]). Then, for a fixed $\varepsilon > 0$ sufficiently small, a precise meaning to the term $E \langle P_0 y(T), y(T) \rangle_H$ is given by the expression $E \langle L_\varepsilon - (\lambda - A)^{\varepsilon - ((1-\alpha)/2)} y(T), (\lambda - A)^{\varepsilon - ((1-\alpha)/2)} y(T) \rangle_H$, which is well defined. When the control u is more regular (for instance if $E \int_0^T |u(t)|_U^{(1/\alpha)+\varepsilon} dt < \infty$, $\varepsilon > 0$), so that $y \in C_w(0, T; L^2(\Omega, H))$, this expression reduces to $E \langle P_0 y(T), y(T) \rangle_H$.

PROPOSITION 2. Assume that hypotheses (H1), (H2) and notation of § 1.1 hold, and that (3.1) holds. Then there exists a unique mild solution $P(\cdot) \in C_s(0, T; L(H, D_A^{1-\alpha})) \cap C_s(0, T; \Sigma^+(H))$ of (3.3), in the sense that $P(\cdot)$ verifies the integral equation

$$(3.4) \quad \begin{aligned} P(t) &= e^{tA^*} P_0 e^{tA} + \int_0^t e^{(t-s)A^*} (C^*C + \phi_1(P(s)) \\ &\quad - (KP(s))^* \phi_2(P(s)) KP(s)) e^{(t-s)A} ds, \\ &\quad t \in [0, T], \end{aligned}$$

where K is given by (1.6), or equivalently, the equation

$$(3.5) \quad \begin{aligned} \frac{d}{dt} \langle P(t)x, y \rangle_H &= \langle P(t)x, Ay \rangle_H + \langle Ax, P(t)y \rangle_H + \langle Cx, Cy \rangle_V \\ &\quad + \langle \phi_1(P(t))x, y \rangle_H - \langle \phi_2(P(t))KP(t)x, KP(t)y \rangle_U, \quad t \in [0, T], \\ P(0) &= P_0, \end{aligned}$$

for any $x, y \in D(A)$. Further, there exists a unique optimal control $\bar{u} \in M_w^2(0, T; U)$ for problem (3.2); if (\bar{u}, \bar{y}) is the optimal pair, then

$$(3.6) \quad \bar{u}(t) = -\phi_2(P(T-t))KP(T-t)\bar{y}(t), \quad t \in [0, T].$$

Finally, the following relations hold:

$$(3.7) \quad \langle P(T)y_0, y_0 \rangle_H = J_T(\bar{u}),$$

$$(3.8) \quad \begin{aligned} \langle P(T)y_0, y_0 \rangle_H = J_T(u) - E \int_0^T & |\phi_2^{-1/2}(P(T-t))u(t) \\ & + \phi_2^{1/2}(P(T-t))KP(T-t)y(t)|_U^2 dt \end{aligned}$$

for any $u \in M_w^2(0, T; U)$, y given by (1.8).

This proposition is proved in [F1]; however it could be proved easily using the machinery of the present paper: local and maximal existence and uniqueness for (3.3) follows from a standard application of the contraction principle; the main point of the global existence follows from an a priori estimation for $|(\lambda - A^*)^{1-\alpha}P(t)|_{L(H)}$ which is essentially included in Theorem 1 below, if we replace " $t \geq 0$ " with " $t \in J$ " in every part of Theorem 1, where J is the interval of maximal existence of $P(t)$; the rest of Proposition 2 follows readily from (3.8), which can be proved by evaluating the stochastic differential $d\langle P(T-t)y_n(t), y_n(t) \rangle_H$, where y_n are regular approximations of y along the lines of § 2, and by integrating over $[0, T]$ and taking the limit as $n \rightarrow \infty$.

Remark 2. It is useful for the sequel to recall explicitly the deterministic version of (3.8):

for any $y_0 \in H$, $T > 0$, $P(\cdot)$ mild solution of (3.3) with ϕ_1 and ϕ_2 given by (1.15), and $u \in L^2(0, T; U)$, the relation

$$(3.9) \quad \begin{aligned} \langle P(T)y_0, y_0 \rangle_H = \int_0^T & \{ |Cy(t)|_V^2 + \langle Nu(t), u(t) \rangle_U \} dt + \langle P_0 y(T), y(T) \rangle_H \\ & - \int_0^T |N^{1/2}u(t) + N^{-1/2}KP(T-t)y(t)|_U^2 dt \end{aligned}$$

holds, with y given by (1.1).

We conclude this section with a simple result on monotonicity of $P(t)$. From the arbitrariness of $T > 0$ in Proposition 2, and the uniqueness of solution to (3.3), we have that, under the hypotheses of Proposition 2, there exists a unique mild solution $P(\cdot)$ of (3.3) over $[0, \infty[$. When $P_0 = 0$ the following result holds.

PROPOSITION 3. Assume that the hypotheses of Proposition 2 hold, and let $P(\cdot)$ be the mild solution of (3.3) with $P_0 = 0$. Then $\langle P(T_1)y_0, y_0 \rangle_H \leq \langle P(T_2)y_0, y_0 \rangle_H$ for any $0 \leq T_1 \leq T_2$ and $y_0 \in H$.

Proof. Let $y_0 \in H$ and $T_2 \geq T_1 \geq 0$ be given; let (\bar{u}_2, \bar{y}_2) be the optimal pair of problem (3.2) with $T = T_2$; from (3.7) we have

$$\langle P(T_2)y_0, y_0 \rangle_H = J_{T_2}(\bar{u}_2) = E \int_0^{T_2} \{ |C\bar{y}_2(t)|_V^2 + \langle N\bar{u}_2(t), \bar{u}_2(t) \rangle_U \} dt;$$

then

$$\langle P(T_2)y_0, y_0 \rangle_H \geq E \int_0^{T_1} \{ |C\bar{y}_2(t)|_V^2 + \langle N\bar{u}_2(t), \bar{u}_2(t) \rangle_U \} dt = J_{T_1}(\bar{u}_2);$$

but Proposition 2 (and in particular (3.8)) with $T = T_1$ implies $J_{T_1}(\bar{u}_2) \geq \langle P(T_1)y_0, y_0 \rangle_H$. We conclude $\langle P(T_2)y_0, y_0 \rangle_H \geq \langle P(T_1)y_0, y_0 \rangle_H$. \square

3.2. Uniform bounds. Following a well-known idea of the distributed control theory, we derive a candidate P_∞ for the solution to (1.10) as a limit, as $t \rightarrow +\infty$, of the solution $P(t)$ of (3.3) with $P_0 = 0$. It is useful to introduce the following definition.

DEFINITION 1. Given $y_0 \in H$, we say that $u \in M_w^2(0, \infty; U)$ (resp. $u \in L^2(0, \infty; U)$) is an admissible control for problem (1.9) (resp. (1.4)) if $Cy \in M_w^2(0, \infty; V)$ (resp. $Cy \in L^2(0, \infty; V)$), where y is the corresponding solution of (1.8) (resp. (1.1)).

In the sequel, we shall often assume one of the following hypotheses:

$$(3.10) \quad \begin{array}{l} \text{for any } y_0 \in H \text{ there exists an admissible control} \\ u \in M_w^2(0, \infty; U) \text{ for problem (1.9)} \end{array}$$

(stochastic case);

$$(3.11) \quad \begin{array}{l} \text{for any } y_0 \in H \text{ there exists an admissible control} \\ u \in L^2(0, \infty; U) \text{ for problem (1.4)} \end{array}$$

(deterministic case).

PROPOSITION 4. Assume that (H1), (H2) and (3.10) hold (stochastic case), or that (H1), (1.15) and (3.11) hold (deterministic case); let $P(\cdot)$ be the mild solution of (3.3) over $[0, \infty[$, with $P_0 = 0$. Then

$$(3.12) \quad \sup_{t \geq 0} |P(t)|_{L(H)} < \infty,$$

and consequently there exists an operator $P_\infty \in \Sigma^+(H)$ such that

$$(3.13) \quad P(t)x \rightarrow P_\infty x \quad \text{as } t \rightarrow +\infty \quad \text{for any } x \in H.$$

Proof. We give the proof only in the stochastic case, because the proof in the deterministic case is equal, with obvious formal modifications. Let $y_0 \in H$ and $T > 0$ be given, and let $u \in M_w^2(0, \infty; U)$ be an admissible control; then from Proposition 2 we have

$$\langle P(T)y_0, y_0 \rangle_H \leq J_T(u) = E \int_0^T \{ |Cy(t)|_V^2 + \langle Nu(t), u(t) \rangle_U \} dt \leq J_\infty(u)$$

where $J_\infty(\cdot)$ is defined by (1.9); then $\sup_{T \geq 0} \langle P(T)y_0, y_0 \rangle_H < \infty$, and this implies (3.12) in virtue of the Banach-Steinhaus theorem. (3.13) follows from (3.12), along with Proposition 3 and a standard result on nondecreasing bounded families of selfadjoint operators ([D4]). \square

In the case of distributed control problems this result is sufficient to prove that P_∞ is a solution to the algebraic Riccati equation, and to solve the synthesis. In the present case however we see from (1.14), (3.5), (4.1) and (5.1) that we need some properties like $P_\infty \in L(H, D_{A^*}^{1-\alpha})$ and $KP(t)x \rightarrow KP_\infty x$ for any $x \in H$. To this end the major result is the bound (3.21) below.

Let us introduce the following integral equation for the operator valued function $U(t, s)$, $t \geq s \geq 0$:

$$(3.14) \quad U(t, s) = e^{(t-s)(A-\lambda)} - \int_s^t (A-\lambda) e^{(r-s)(A-\lambda)} B\phi_2(P(r))KP(r)U(t, r) dr$$

formally $U(t, s)$ verifies the differential equation

$$\frac{\partial}{\partial s} U(t, s) = -[A - \lambda - (A - \lambda)B\phi_2(P(s))B^*(A^* - \lambda)P(s)]U(t, s),$$

$$0 \leq s \leq t.$$

$$U(t, t) = 1,$$

We remark that $U(t, s)$ can be defined by other equivalent integral equations, which are more common in some part of the literature; however we choose (3.14) because it can be used more directly than others to derive (3.15) and (3.16) below.

LEMMA 3. Let $P(t)$ be the mild solution of (3.3) over $[0, \infty[$, with $P_0 = 0$. Then for any $t \geq 0$ there exists a unique solution $U(t, \cdot) \in C_s(0, t; L(H))$ to (3.14), and the following integral versions of (3.5) hold:

$$(3.15) \quad P(t) = \int_0^t U^*(t, s) [C^*C + 2\lambda P(s) + (KP(s))^* \phi_2(P(s)) KP(s)] U(t, s) ds,$$

$$(3.16) \quad P(t) = \int_0^t e^{(t-s)(A^*-\lambda)} [C^*C + 2\lambda P(s) + \phi_1(P(s))] U(t, s) ds, \quad t \geq 0.$$

Proof. Let $I_n = n(n - A)^{-1}$ as in § 2; let us consider the approximating equation of (3.14)

$$U_n(t, s) = e^{(t-s)(A-\lambda)} I_n - \int_s^t e^{(t-s)(A-\lambda)} (A-\lambda) \cdot I_n B \phi_2(P(r)) KP(r) U_n(t, r) dr, \quad t \geq s \geq 0.$$

With the notation of Corollary 1, given $t \geq 0$ and $y_0 \in H$, let us set $G(s) = \phi_2(P(t-s)) KP(t-s)$, $y(s) = e^{sA} U(t, t-s)y_0$, $y_n(s) = e^{sA} U_n(t, t-s)$; then y and y_n verify (2.9) and (2.10), respectively, and Corollary 1 applies, yielding the existence of unique solutions $U(t, \cdot)$ and $U_n(t, \cdot)$ in $C_s(0, t; L(H))$, for any $t \geq 0$; further for any $h \in H$ and $t \geq 0$,

$$(3.17) \quad \begin{aligned} U_n(t, \cdot)h &\rightarrow U(t, \cdot)h \text{ in } C(0, t; H), \\ U_n(t, \cdot)h &\in C(0, t; D(A)) \cap C^1(0, t; H), \text{ and} \end{aligned}$$

$$(3.18) \quad \begin{aligned} \frac{\partial}{\partial s} U_n(t, s)h &= -[A - \lambda - (A - \lambda) I_n B \phi_2(P(s)) KP(s)] U_n(t, s)h, \quad 0 \leq s \leq t, \\ U_n(t, t) &= I_n. \end{aligned}$$

Let $h \in H$; since $U_n(t, s)h \in D(A)$, we can use (3.5) with $x = y = U_n(t, s)h$; from (3.5) and (3.18) we have

$$\begin{aligned} &\left\langle \frac{\partial}{\partial s} P(s) U_n(t, s)h, U_n(t, s)h \right\rangle_H \\ &= \frac{\partial}{\partial \sigma} \langle P(\sigma) U_n(t, s)h, U_n(t, s)h \rangle_H \Big|_{\sigma=s} + 2 \operatorname{Re} \left\langle P(s) U_n(t, s)h, \frac{\partial}{\partial s} U_n(t, s)h \right\rangle \\ (3.19) \quad &= 2 \operatorname{Re} \langle P(s) U_n(t, s)h, A U_n(t, s)h \rangle \\ &\quad + \langle [C^*C + \phi_1(P(s)) - (KP(s))^* \phi_2(P(s)) KP(s)] U_n(t, s)h, U_n(t, s)h \rangle \\ &\quad - 2 \operatorname{Re} \langle P(s) U_n(t, s)h, (A - \lambda - (A - \lambda) I_n B \phi_2(P(s)) KP(s)) U_n(t, s)h \rangle \\ &= \langle [C^*C + 2\lambda P(s) + \phi_1(P(s)) + (KP(s))^* \phi_2(P(s)) KP(s)] U_n(t, s)h, U_n(t, s)h \rangle \\ &\quad - 2 \langle K(1 + I_n) P(s) U_n(t, s)h, \phi_2(P(s)) KP(s) U_n(t, s)h \rangle; \end{aligned}$$

integrating on $[0, t]$ with respect to s , and using the convergence (3.17) and (2.5), from (3.19) we have:

$$\begin{aligned} \langle P(t)h, h \rangle &= \int_0^t \langle [C^*C + 2\lambda P(s) + \phi_1(P(s)) \\ &\quad + (KP(s))^* \phi_2(P(s)) KP(s)] U(t, s)h, U(t, s)h \rangle ds. \end{aligned}$$

This implies (3.15) because $P(t)$ is selfadjoint. The proof of (3.16) is similar. \square

THEOREM 1. Assume that (H1), (H2) and (3.12) hold; let $P(\cdot)$ be the mild solution of (3.3) with $P_0 = 0$, and $U(t, s)$, $t \geq s \geq 0$ be the solution to (3.14). Then there exists a constant $c > 0$ such that

$$(3.20) \quad |U(t, s)|_{L(H)} \leq c, \quad t \geq s \geq 0;$$

moreover, for any $\gamma < 1$ there exists a constant $c(\gamma) > 0$ such that

$$(3.21) \quad |(\lambda - A^*)^\gamma P(t)|_{L(H)} \leq c(\gamma), \quad t \geq 0.$$

Proof. Step 1. Let us set $R(t, s) = KP(s)U(t, s)$, for $t \geq s \geq 0$; from (3.14), (3.16) and the evolution property $U(s, r)U(t, s) = U(t, r)$, we have

$$(3.22) \quad U(t, s) = e^{(t-s)(A-\lambda)} - \int_s^t (A-\lambda) e^{(r-s)(A-\lambda)} B \phi_2(P(r)) R(t, r) dr,$$

$$(3.23) \quad R(t, s) = \int_0^s K e^{(s-r)(A^*-\lambda)} (C^*C + 2\lambda P(r) + \phi_1(P(r))) U(t, r) dr,$$

for $0 \leq s \leq t$. From (H1) and (1.13) it follows immediately that $0 \leq \langle \phi_2(P(t))u, u \rangle_U \leq 1/\nu |u|_U^2$, for any $t \geq 0$ and $u \in U$, so that $|\phi_2(P(t))|_{L(U)} \leq 1/\nu$ for any $t \geq 0$; then, from (1.2), (H1) and (3.22), there exists a constant $c_1 > 0$ such that

$$(3.24) \quad |U(t, s)x|_H \leq c_1 e^{-\omega(t-s)} |x|_H + c_1 \int_s^t \frac{e^{-\omega(r-s)}}{(r-s)^{1-\alpha}} |R(t, r)x|_U dr$$

for any $x \in H$ and $t \geq s \geq 0$. Further, from (1.2), (H1), (3.12) and (3.23), there exists a constant $c_2 > 0$ such that

$$(3.25) \quad |R(t, s)x|_U \leq c_2 \int_0^s \frac{e^{-\omega(s-r)}}{(s-r)^{1-\alpha}} |U(t, r)x|_H dr$$

for any $x \in H$ and $t \geq s \geq 0$.

Step 2. If $1 < p \leq \infty$, $p \neq 1/\alpha$, then there exists a constant $k_1(p) > 0$ such that

$$(3.26) \quad |U(t, \cdot)x|_{L^q(0,t;H)} \leq k_1(p) |x|_H + k_1(p) |R(t, \cdot)x|_{L^p(0,t;U)},$$

$$(3.27) \quad |R(t, \cdot)x|_{L^q(0,t;U)} \leq k_1(p) |U(t, \cdot)x|_{L^p(0,t;H)}$$

for any $x \in H$ and $t \geq 0$, where

$$(3.28) \quad q = \begin{cases} p/(1-\alpha p) & \text{if } 1 < p < 1/\alpha, \\ \infty & \text{if } 1/\alpha < p \leq \infty; \end{cases}$$

if $p = 1/\alpha$, then for any $\varepsilon \in]0, \min(\alpha, \omega)[$ there exists a constant $k_2(\varepsilon) > 0$ such that

$$(3.29) \quad |U(t, \cdot)x|_{L^{1/\varepsilon}(0,t;H)} \leq k_2(\varepsilon) |x|_H + k_2(\varepsilon) |R(t, \cdot)x|_{L^{1/\alpha}(0,t;U)},$$

$$(3.30) \quad |R(t, \cdot)x|_{L^{1/\varepsilon}(0,t;U)} \leq k_2(\varepsilon) |U(t, \cdot)x|_{L^{1/\alpha}(0,t;H)},$$

for any $t \geq 0$ and $x \in H$. (3.26) and (3.27), with $1 < p < 1/\alpha$, follow from (3.24) and (3.25), respectively, using a Young inequality ([H1, p. 290]); the case $1/\alpha < p < \infty$ follows readily from the Hölder inequality. As to (3.29) and (3.30), let us note first that, for any $t > 0$, the function

$$\varepsilon \rightarrow \frac{e^{t(-\omega+\varepsilon)}}{t^{1-\alpha+\varepsilon}}$$

is nondecreasing for $\varepsilon \geq 0$ (because it has nonnegative first derivative with respect to ε); then from (3.24) it follows

$$(3.31) \quad |U(t, s)x|_H \leq c_1 e^{-\omega(t-s)}|x|_H + c_1 \int_s^t \frac{e^{(-\omega+\varepsilon)(r-s)}}{(r-s)^{1-\alpha+\varepsilon}} |R(t, r)x|_U dr$$

for any $\varepsilon > 0$, $t \geq 0$ and $x \in H$. If $p = 1/\alpha$ and $0 < \varepsilon < \min(\alpha, \omega)$, then we can apply to (3.31) the above-mentioned Young inequality, and we have (3.29); similarly we can prove (3.30).

Step 3. Let $c_P > 0$ be a constant such that

$$(3.32) \quad |P(t)|_{L(H)} \leq c_P \quad \text{for any } t \geq 0$$

(see (3.12)). From (3.15) we have

$$(3.33) \quad \begin{aligned} & \int_0^t \langle \phi_2(P(s))KP(s)U(t, s)x, KP(s)U(t, s)x \rangle_U \\ & \leq \int_0^t \langle [C^*C + 2\lambda P(s) + \phi_1(P(s)) \\ & \quad + (KP(s))^*\phi_2(P(s))KP(s)]U(t, s)x, U(t, s)x \rangle_H ds \\ & = \langle P(t)x, x \rangle_H \leq c_P|x|_H^2 \quad \text{for any } t \geq 0 \text{ and } x \in H. \end{aligned}$$

Moreover, from (3.32) and (1.12) we have $|\Delta_2(P(s))|_{L(U)} \leq c_3 c_P$ for any $s \geq 0$, and for a suitable constant $c_3 > 0$; then, from definition (1.13), there exists $c_4 > 0$ such that

$$(3.34) \quad \langle \phi_2(P(s))u, u \rangle_U \geq c_4|u|_U^2 \quad \text{for any } s \geq 0 \text{ and } u \in U.$$

(3.33) and (3.34) yield

$$(3.35) \quad \int_0^t |R(t, s)x|_U^2 ds \leq (1/c_4)c_P|x|_H^2 \quad \text{for any } t \geq 0 \text{ and } x \in H.$$

Step 4. Let us start with the uniform bound (3.35), and let us apply repeatedly (3.26) and (3.27), or (3.29) and (3.30) if some exponent p is equal to $1/\alpha$; in a finite number of steps we have (3.20). For instance, in the case of Dirichlet (resp. Neumann) boundary control and second order elliptic operators, it is sufficient to apply (3.26) and (3.27) two times (resp. one time), because $\alpha = \frac{1}{4} - \varepsilon$ (resp. $\alpha = \frac{3}{4} - \varepsilon$) for any $\varepsilon > 0$.

Finally, applying (1.2), (3.32), (3.20) and the Hölder inequality to (3.16), we find (3.21). \square

3.3. Asymptotic behavior and existence for the algebraic Riccati equation. For the sake of simplicity, we prove the strong convergence result (3.38) below under the additional assumption that

$$(3.36) \quad (\lambda - A)^{-1} \text{ is a compact operator.}$$

(3.37) can be proved with a lengthy argument without assuming (3.36); however, (3.36) is verified in boundary control problems, because the operator A is defined by an elliptic operator in a bounded domain of R^n (see Example 1, § 4.2), and consequently (3.36) is not restrictive for applications.

THEOREM 2. *Under hypotheses and notation of Proposition 2, we have*

$$(3.37) \quad P_\infty \in L(H, D_A^{1-\alpha}) \quad \text{and} \quad \langle (\lambda - A^*)^\gamma P(t)x, y \rangle_H \rightarrow \langle (\lambda - A^*)^\gamma P_\infty x, y \rangle_H$$

for any $\gamma < 1$, $x, y \in H$. Further, if (3.36) holds then

$$(3.38) \quad (\lambda - A^*)^\gamma P(t)x \rightarrow (\lambda - A^*)^\gamma P_\infty x \quad \text{for any } x \in H \text{ and } \gamma < 1,$$

and in particular

$$(3.39) \quad KP(t)x \rightarrow KP_\infty x \quad \text{for any } x \in H,$$

where K is defined by (1.6); moreover P_∞ is a solution to (1.10), in the sense that it verifies (1.14), or equivalently that $P_\infty \in \Sigma^+(H) \cap L(H, D_A^{1-\alpha}) \cap L(D(A), D(A^*))$ and

$$(3.40) \quad A^*P_\infty x + P_\infty Ax + C^*Cx + \phi_1(P_\infty)x - (KP_\infty)^*\phi_2(P_\infty)KP_\infty x = 0$$

holds for any $x \in D(A)$. Finally,

$$(3.41) \quad P_\infty \leq \hat{P}_\infty \quad (\text{i.e. } \langle P_\infty x, x \rangle_H \leq \langle \hat{P}_\infty x, x \rangle_H \text{ for any } x \in H)$$

for any solution \hat{P}_∞ of (1.10).

Proof. Let $x \in H$ and $\gamma < 1$ be given; the set $\{(\lambda - A^*)^\gamma P(t)x\}_{t \geq 0}$ is bounded in H , in virtue of (3.21); then, for any sequence $t_n \rightarrow +\infty$, there exists a subsequence t_{n_k} such that

$$(3.42) \quad \lim_{k \rightarrow \infty} \langle (\lambda - A^*)^\gamma P(t_{n_k})x, y \rangle_H = \langle z, y \rangle_H \quad \text{for any } y \in H$$

and for some $z \in H$. But (3.13) implies $\lim_{k \rightarrow \infty} \langle P(t_{n_k})x, (\lambda - A)^\gamma y \rangle_H = \langle P_\infty x, (\lambda - A)^\gamma y \rangle_H$ for any $y \in D_A^\gamma$; then $\langle z, y \rangle_H = \langle P_\infty x, (\lambda - A)^\gamma y \rangle_H$ for any $y \in D_A^\gamma$, whence $P_\infty x \in D_{A^*}^\gamma$ and

$$(3.43) \quad z = (\lambda - A^*)^\gamma P_\infty x.$$

Since z does not depend on t_n and t_{n_k} (because (3.43) holds), (3.37) follows from (3.42) and (3.43).

Let us recall now that $(\lambda - A^*)^{-\varepsilon}$ is compact for any $\varepsilon > 0$ if (3.36) holds ([B1]). If $\gamma + \varepsilon < 1$, then from (3.37) we have that $(\lambda - A^*)^{\gamma+\varepsilon} P(t)x$ converges weakly to $(\lambda - A^*)^{\gamma+\varepsilon} P_\infty x$ for any $x \in H$; then (3.38) follows from the compactness of $(\lambda - A^*)^{-\varepsilon}$, and (3.39) follows from (3.38) and (1.6).

Let us prove that P_∞ verifies (1.14). Let $x, y \in D(A)$ be given. From (3.39) and (3.13) it follows that the right side of (3.5) converges to $\langle P_\infty x, Ay \rangle_H + \langle Ax, P_\infty y \rangle_H + \langle Cx, Cy \rangle_V + \langle \phi_1(P_\infty)x, y \rangle_H - \langle \phi_2(P_\infty)KP_\infty x, KP_\infty y \rangle_U$, whence

$$(3.44) \quad \text{there exists } a_{x,y} = \lim_{t \rightarrow \infty} \frac{d}{dt} \langle P(t)x, y \rangle_H;$$

moreover, from (3.13) we have that

$$(3.45) \quad \text{there exists } \lim_{t \rightarrow \infty} \langle P(t)x, y \rangle_H = \langle P_\infty x, y \rangle_H.$$

In virtue of a simple argument of real analysis, (3.44) and (3.45) yield $a_{x,y} = 0$. This implies that (1.14) holds. Moreover, from (1.14) we have readily $P_\infty \in L(D(A), D(A^*))$ and (3.40).

Finally, let us prove (3.41). We consider first the stochastic case, i.e. we assume that (H1), (H2) and (3.10) hold. Let \hat{P}_∞ be a solution to (1.10), in the sense that \hat{P}_∞ verifies (1.14); then \hat{P}_∞ verifies also (3.5) with $P_0 = \hat{P}_\infty$, i.e. \hat{P}_∞ is the mild solution of (3.3) with $P_0 = \hat{P}_\infty$. Let $y_0 \in H$ be fixed; we define the following feedback control

$$(3.46) \quad \hat{u}(t) = -\phi_2(\hat{P}_\infty)K\hat{P}_\infty \hat{y}(t), \quad t \geq 0.$$

Since \hat{P}_∞ is the mild solution of (3.3) with $P_0 = \hat{P}_\infty$, given $T > 0$, (3.8) holds with

$P(T) = P_0 = \hat{P}_\infty$, and in particular with $u(t) = \hat{u}(t)$; this yields

$$\langle \hat{P}_\infty y_0, y_0 \rangle_H = E \int_0^T \{ |C\hat{y}(t)|_V^2 + \langle N\hat{u}(t), \hat{u}(t) \rangle_U \} dt + E \langle \hat{P}_\infty \hat{y}(T), \hat{y}(T) \rangle_H,$$

whence

$$(3.47) \quad E \int_0^T \{ |C\hat{y}(t)|_V^2 + \langle N\hat{u}(t), \hat{u}(t) \rangle_U \} dt \leq \langle \hat{P}_\infty y_0, y_0 \rangle_H;$$

as $T \rightarrow \infty$ (\hat{u} and \hat{y} are independent on T), (3.47) implies

$$(3.48) \quad J_\infty(\hat{u}) \leq \langle \hat{P}_\infty y_0, y_0 \rangle_H,$$

where $J_\infty(\cdot)$ is defined by (1.9). Given $T > 0$, relation (3.8), when $P(\cdot)$ is the mild solution of (3.3) with $P_0 = 0$, yields

$$(3.49) \quad \langle P(T)y_0, y_0 \rangle_H \leq E \int_0^T \{ |Cy(t)|_V^2 + \langle Nu(t), u(t) \rangle_U \} dt$$

for any $u \in M_w^2(0, T; U)$; as $T \rightarrow \infty$, (3.54) implies

$$(3.50) \quad \langle P_\infty y_0, y_0 \rangle_H \leq J_\infty(u) \quad \text{for any } u \in M_w^2(0, \infty; U).$$

From (3.48), and (3.50) with $u = \hat{u}$ defined by (3.46), we have $\langle P_\infty y_0, y_0 \rangle_H \leq \langle \hat{P}_\infty y_0, y_0 \rangle_H$; this implies (3.41), and the proof of (3.41) is complete in the stochastic case.

In the deterministic case, i.e. when (H1), (1.15) and (3.11) hold, the proof is equal; we point out only the relations which correspond to (3.46), (3.48) and (3.50), because they are useful in § 4. Let \hat{P}_∞ be a solution of (1.5) (in the sense of the present theorem). Given $y_0 \in H$, let \hat{u} be the feedback control defined by

$$(3.51) \quad \hat{u}(t) = -N^{-1}K\hat{P}_\infty \hat{y}(t), \quad t \geq 0;$$

then

$$(3.52) \quad J_\infty(\hat{u}) \leq \langle \hat{P}_\infty y_0, y_0 \rangle_H,$$

where $J_\infty(\cdot)$ is defined by (1.4); moreover, if P_∞ is the solution to (1.5) defined by (3.13), then

$$(3.53) \quad \langle P_\infty y_0, y_0 \rangle_H \leq J_\infty(u) \quad \text{for any } u \in L^2(0, \infty; U). \quad \square$$

4. The deterministic optimal control problem. In this section we apply the results of § 3 (in particular Theorem 2) to the deterministic optimal control problem (1.4). First we solve the synthesis (§ 4.1), and then we give a uniqueness result for the algebraic Riccati equation, and a stability result for the optimal trajectories (§ 4.2). Finally, an example of deterministic boundary control problem is discussed at the end of § 4.2.

4.1. Synthesis.

THEOREM 3. Assume that (H1) and (3.36) hold. Then there exists a solution to the algebraic Riccati equation (1.5) (in the sense of Theorem 2) if and only if (3.11) holds. In this case the results of Theorem 2 hold, and for any $y_0 \in H$ there exists a unique optimal control $\bar{u} \in L^2(0, \infty; U)$ for problem (1.4); moreover, if (\bar{u}, \bar{y}) is the optimal pair and P_∞ is defined by (3.13), then

$$(4.1) \quad \bar{u}(t) = -N^{-1}K P_\infty \bar{y}(t), \quad t \geq 0$$

(K given by (1.6)) and

$$(4.2) \quad \langle P_\infty y_0, y_0 \rangle_H = J_\infty(\bar{u}).$$

Finally, $\bar{u}(\cdot)$ and $\bar{y}(\cdot)$ are analytic functions for $t > 0$, and

$$(4.3) \quad \bar{y}(t) = T(t)y_0, \quad t \geq 0,$$

where $T(t)$ is the analytic semigroup defined by the integral equation

$$(4.4) \quad T(t) = e^{tA} - \int_0^t (A - \lambda) e^{(t-s)A} B N^{-1} K P_\infty T(s) ds, \quad t \geq 0.$$

Proof. If (3.11) holds then P_∞ defined by (3.13) is a solution to (1.5) in virtue of Theorem 2, and the results of Theorem 2 hold; conversely, if \hat{P}_∞ is a solution to (1.5), and $y_0 \in H$ is given, then (3.52) holds, whence \hat{u} (defined by (3.51)) is an admissible control; this proves (3.11).

Given $y_0 \in H$, we can take $\hat{P}_\infty = P_\infty$ in (3.53); then (3.52) and (3.53) imply that (4.2) holds, with $\bar{u} = \hat{u}$ given by (3.51) or equivalently by (4.1); moreover, from (3.53) and (4.2) we see that \bar{u} is an optimal control. It is also unique because $J_\infty(\cdot)$ is a strictly convex functional, by virtue of hypothesis (H1) on N .

Finally, Proposition 1 implies that (4.4) defines an analytic semigroup; (4.3) follows from (4.4), (1.1) and (4.1), and the analyticity of \bar{u} and \bar{y} follows from the analyticity of $T(t)$ and from (4.1) and (4.3). \square

4.2. Stability of optimal trajectories and uniqueness of solution to (1.5). The results of this section extend to boundary control problems some results of [Z1].

We recall that the pair (C, A) is said to be detectable if there exists $S \in L(V, H)$ such that $A - SC$ is stable. The following lemma will be useful in the proof of Theorem 4.

LEMMA 4. Assume that (H1) holds and that (C, A) is detectable. Let $G \in L(H, U)$ be given, and assume that the feedback control $u(t) = -Gy(t)$ is an admissible control (Definition 1) for any $y_0 \in H$; then the trajectories y are exponentially stable for any $y_0 \in H$, and the semigroup $T(t)$ defined by (2.12) is exponentially stable.

Proof. Let $T(\cdot)$ and $T_n(\cdot)$ be defined by (2.12) and (2.13), respectively; let $S \in L(V, H)$ be such that $A - SC$ is stable; then from (2.14) we have

$$(4.5) \quad \begin{aligned} \frac{d}{dt} T_n(t)x &= (A - SC)T_n(t)x + SCT_n(t)x + (SC - A)I_n BGT_n(t)x \\ &\quad + (\lambda - SC)I_n BGT_n(t)x \quad \text{for any } t \geq 0 \text{ and } x \in H \end{aligned}$$

and $T_n(0) = I_n$; then by the variation of constant device we have

$$(4.6) \quad \begin{aligned} T_n(t)x &= e^{t(A-SC)} I_n x + \int_0^t e^{(t-s)(A-SC)} SCT_n(s)x ds \\ &\quad + \int_0^t (SC - A) e^{(t-s)(A-SC)} I_n BGT_n(s)x ds \\ &\quad + \int_0^t e^{(t-s)(A-SC)} (\lambda - SC) I_n BGT_n(s)x ds, \quad t \geq 0, \quad x \in H. \end{aligned}$$

In order to take the limit as $n \rightarrow \infty$ in (4.6) we have to study the limit behavior of the second integral term in (4.6). For any $0 < T \leq \infty$ consider the mapping \mathcal{L}_T on $L^2(0, T; H)$ defined by $\mathcal{L}_T(z)(t) = \int_0^t (SC - A) e^{(t-s)(A-SC)} z(s) ds$, for a.e. $t \in]0, T[$, and for any $z \in L^2(0, T; H)$; since $e^{t(A-SC)}$ is a stable, analytic semigroup, it is known that \mathcal{L}_T is a continuous linear mapping in $L^2(0, T; H)$, for any $0 < T \leq \infty$ (see for instance [D5], [D1] or [L6]), and there exists a constant $c > 0$ such that

$$(4.7) \quad \|\mathcal{L}_T(z)\|_{L^2(0, T; H)} \leq c \|z\|_{L^2(0, T; H)} \quad \text{for any } z \in L^2(0, T; H)$$

and $T \in]0, \infty]$. Therefore, for any fixed $T > 0$, we can take the limit (in the $L^2(0, T; H)$ -topology) in (4.6) as $n \rightarrow \infty$, using also the convergence result of Proposition 1; this yields

$$(4.8) \quad \begin{aligned} T(t)x &= e^{t(A-SC)}x + \int_0^t e^{(t-s)(A-SC)} SCT(s)x \, ds \\ &+ \int_0^t (SC - A) e^{(t-s)(A-SC)} BGT(s)x \, ds \\ &+ \int_0^t e^{(t-s)(A-SC)} (\lambda - SC) BGT(s)x \, ds \end{aligned}$$

for any $t \geq 0$ and $x \in H$. We apply now a Young inequality to the first and the third integral terms of (4.8), and (4.7), with $T = +\infty$, to the second integral term of (4.8); we have

$$(4.9) \quad \begin{aligned} |T(\cdot)x|_{L^2(0, \infty; H)} &\leq c_2|x|_H + c_1|SCT(\cdot)x|_{L^2(0, \infty; H)} + c|BGT(\cdot)x|_{L^2(0, \infty; H)} \\ &+ c_1|(\lambda - SC)BGT(\cdot)x|_{L^2(0, \infty; H)} \end{aligned}$$

for any $x \in H$, where c_1 and c_2 are the norms of $e^{t(A-SC)}$ in $L^1(0, \infty; H)$ and $L^2(0, \infty; H)$, respectively. If u is the feedback control defined by $u(t) = -Gy(t)$, corresponding to the initial trajectory $y(0) = x$, then $y(t) = T(t)x$ and $u(t) = -GT(t)x$ (see (2.12)); since $u(\cdot)$ is assumed to be admissible, this implies $GT(\cdot)x \in L^2(0, \infty; U)$ and $CT(\cdot)x \in L^2(0, \infty; V)$. Therefore, from (4.9) we have

$$(4.10) \quad \int_0^\infty |T(t)x|_H^2 \, dt < \infty \quad \text{for any } x \in H.$$

This implies, by virtue of a result of [D3], that $T(t)$ is a stable semigroup, and also the trajectories $y(t) = T(t)y_0$ are exponentially stable for any $y_0 \in H$. \square

DEFINITION 2. The system (1.1) is said to be exponentially stabilizable if there exists $G \in L(H, U)$ such that (2.12) defines an exponentially stable semigroup $T(t)$.

THEOREM 4. (i) Assume that (H1) and (3.36) hold, and that (C, A) is detectable; then there exists at most one solution of the algebraic Riccati equation (1.5) (in the sense of Theorem 2), and in this case the unique solution is P_∞ defined by (3.13). (ii) Moreover if P_∞ exists, then for any $y_0 \in H$ the optimal control (4.1) of problem (1.4) is a stabilizing control, and, more precisely, system (1.1) is exponentially stabilizable and the optimal trajectories \bar{y} (Theorem 3) are exponentially stable for any $y_0 \in H$.

Proof. Let \hat{P}_∞ be a solution to (1.5); given $y_0 \in H$, let $\hat{u}(\cdot)$ be defined by (3.51). From (3.52) it follows that $\hat{u}(\cdot)$ is an admissible control for problem (1.4); then (3.11) holds, and Theorem 2 implies that P_∞ exists, and

$$(4.11) \quad P_\infty \leq \hat{P}_\infty.$$

Since the optimal control $\bar{u}(\cdot)$ given by (4.1) is an admissible control (and this holds for any $y_0 \in H$), Lemma 4 implies that the optimal trajectories $\bar{y}(\cdot)$ are exponentially stable. This proves part (ii) of the theorem. Taking $P(t) = P_0 = \hat{P}_\infty$ and $u = \bar{u}$, $y = \bar{y}$ in (3.9) (this is possible because \hat{P}_∞ verifies (1.7), and consequently it verifies (3.5) with ϕ_1 and ϕ_2 given by (1.15)), we have

$$(4.12) \quad \langle \hat{P}_\infty y_0, y_0 \rangle_H \leq \int_0^T \{ |\bar{C}\bar{y}(t)|_V^2 + \langle N\bar{u}(t), \bar{u}(t) \rangle_U \} \, dt + \langle \hat{P}_\infty \bar{y}(T), \bar{y}(T) \rangle_H;$$

as $T \rightarrow \infty$, from (4.12) and the stability of $\bar{y}(\cdot)$ we have

$$(4.13) \quad \langle \hat{P}_\infty y_0, y_0 \rangle_H \leq J_\infty(\bar{u}),$$

where $J_\infty(\cdot)$ is defined by (1.4). From (4.11), (4.13) and (4.2) we have $\hat{P}_\infty = P_\infty$, and also the proof of part (i) of the theorem is complete. \square

Finally, applying Theorem 4 to the case $C = 1$, we find that the following classical result ([P1]) holds also for boundary control problems.

COROLLARY 2. *Assume that (H1) and (3.36) hold. Then system (1.1) is stabilizable if and only if for any $y_0 \in H$ there exists a control $u \in L^2(0, \infty; U)$ such that*

$$\int_0^\infty \{|y(t)|_H^2 + |u(t)|_U^2\} dt < \infty,$$

where y is the corresponding solution of (1.1).

We conclude this section by discussing an example of a Dirichlet boundary control problem over infinite time horizon.

Example 1. Let θ be a bounded open domain of R^n with C^∞ boundary Γ , with θ locally on one side of Γ . Let $A(x, D)$ be the elliptic operator

$$(4.14) \quad A(x, D)f = - \sum_{i,j=1}^n D_j a_{ij}(x) D_i f - cf,$$

where $c \in R$, the real coefficients $a_{ij} \in C^\infty(\bar{\theta})$, and

$$\sum_{i,j=1}^n a_{ij}(x) \xi_i \xi_j \geq \eta |\xi|^2 \quad \text{for any } \xi \in R^n, \quad \text{for some } \eta > 0$$

(more general elliptic operators can be considered, but (4.14) simplifies the discussion of Examples 2 and 3 of § 5.3).

We consider the following optimal control problem governed by a parabolic system with boundary control:

minimize

$$(4.15) \quad J_\infty(u) = \int_0^\infty \left\{ \int_\theta y^2 + \int_\Gamma u^2 \right\} dt$$

over all $u \in L^2(0, \infty; L^2(\Gamma))$, subject to the state equation

$$(4.16) \quad \begin{aligned} \frac{\partial y}{\partial t} &= -A(x, D)y \quad \text{in } [0, \infty[\times \theta, \\ y &= u \quad \text{on } [0, \infty[\times \Gamma, \\ y(0, x) &= y_0(x) \quad \text{in } \theta, \end{aligned}$$

where $y_0 \in L^2(\theta)$. Let $\lambda \geq c$; then the elliptic system

$$(4.17) \quad \begin{aligned} (A(x, D) + \lambda)z &= 0 \quad \text{in } \theta, \\ z &= g \quad \text{on } \Gamma, \end{aligned}$$

has a unique solution $z \in H^{1/2}(\theta)$ for any $g \in L^2(\Gamma)$ ([L6, pp. 187-188]) and we can define the Green mapping

$$(4.18) \quad B \in L(L^2(\Gamma), H^{1/2}(\theta)), \quad Bg = z$$

where z is the solution to (4.17). Setting $y_\lambda(t, x) = e^{-\lambda t} y(t, x)$, from (4.16) we have

$$(4.19) \quad \begin{aligned} \frac{\partial y_\lambda}{\partial t} &= -(A(x, D) + \lambda)y_\lambda \quad \text{in } [0, \infty[\times \theta, \\ y_\lambda &= e^{-\lambda t} u \quad \text{on } [0, \infty[\times \Gamma, \\ y_\lambda(0, x) &= y_0(x) \quad \text{in } \theta. \end{aligned}$$

Let A be the linear operator in $L^2(\theta)$ defined by $(Af)(x) = -A(x, D)f(x)$, for any $f \in D(A) = H^2(\theta) \cap H_0^1(\theta)$. A generates an analytic semigroup e^{tA} , $t \geq 0$, in $L^2(\theta)$ ([T1]). Then the solution to (4.19) is given by ([L1])

$$y_\lambda(t) = e^{t(A-\lambda)}y_0 + \int_0^t (A-\lambda) e^{(t-s)(A-\lambda)} B e^{-\lambda s} u(s) ds,$$

whence the solution of (4.16) is given by (1.1). Since $D_A^\alpha = H^{2\alpha}(\theta)$, for any $0 \leq \alpha < \frac{1}{4}$ ([L1]), assumption (H1) on B is verified. The connection between notation of this example and § 1.1 is given by: $H = L^2(\theta)$, $U = L^2(\Gamma)$, $V = L^2(\theta)$, $C = 1$, $N = 1$.

In [L3] or [T2] it is proved that system (4.16) is stabilizable; moreover (C, A) is detectable because C is an isomorphism. Then Theorems 2, 3 and 4 apply to this problem.

5. The stochastic optimal control problem. The results of this section are the stochastic counterpart of the results of § 4. Similar results in the case of distributed control problems are proved in [I1].

Since stability and stabilizability of stochastic boundary control systems appear new arguments in the literature, we devote to them § 5.2.

5.1. Synthesis.

THEOREM 5. Assume that (H1), (H2) and (3.36) hold. Then there exists a solution to the algebraic Riccati equation (1.10) if and only if (3.10) holds. In this case the results of Theorem 2 hold, and for any $y_0 \in H$ there exists a unique optimal control $\bar{u} \in M_w^2(0, \infty; U)$ for problem (1.9); moreover if (\bar{u}, \bar{y}) is the optimal pair and P_∞ is defined by (3.13), then

$$(5.1) \quad \bar{u}(t) = -\phi_2(P_\infty) K P_\infty \bar{y}(t), \quad t \geq 0,$$

$$(5.2) \quad \langle P_\infty y_0, y_0 \rangle_H = J_\infty(\bar{u}),$$

and \bar{y} verifies equation (2.15) with $G = \phi_2(P_\infty) K P_\infty$.

We omit the proof of this theorem because it is an obvious modification of the proof of Theorem 3.

5.2. Stability and stabilizability of stochastic boundary control systems. The results of this section are simple consequences of known results in distributed control theory ([I1], [H2]), and of (2.18). They are useful to prove Lemma 5 and to study Examples 2 and 3 of § 5.3.

We consider only exponential stability, and stabilizability, in mean square.

DEFINITION 3. (i) We say that system (2.15) is exponentially stable in mean square if there exist two constants $c > 0$ and $k > 0$ such that

$$E|y(t)|_H^2 \leq c e^{-kt} |y_0|_H^2 \quad \text{for any } y_0 \in H.$$

(ii) We say that system (1.8) is exponentially stabilizable in mean square if there exists $G \in L(H, U)$ such that the closed loop system (2.15) is exponentially stable in mean square.

Let $y(\cdot)$ be the solution to (2.15); since $y(\cdot)$ is also solution to (2.18) (in virtue of Lemma 2), we can use already available results on equations of the form (2.18); from [I1, Thm. 3.1] we have the following.

PROPOSITION 5. *The following statements are equivalent:*

- (i) *system (2.15) is exponentially stable in mean square;*
- (ii) *$E \int_0^\infty |y(t)|_H^2 dt < \infty$ for any $y_0 \in H$;*
- (iii) *there exists $P \in \Sigma^+(H)$ such that $\langle Px, A_G y \rangle_H + \langle A_G x, Py \rangle_H + \langle \Delta_1(P)x, y \rangle_H + \langle \Delta_2(P)Gx, Gy \rangle_U = -\langle x, y \rangle_H$ for any $x, y \in D(A_G)$, where A_G is defined in Proposition 1, $\Delta_1(\cdot)$ and $\Delta_2(\cdot)$ in (1.12).*

Similarly, from [H2, Thm. 1], we have the following.

PROPOSITION 6. *Assume that the deterministic system (1.1) is exponentially stabilizable (Definition 2, § 4.2) by means of the feedback control $u(t) = -Gy(t)$, and that*

$$(5.3) \quad \left| \int_0^\infty T^*(t) [\Delta_1(I) + G^* \Delta_2(I) G] T(t) dt \right|_H < 1,$$

where $T(t)$ is defined by (2.12), $\Delta_1(\cdot)$ and $\Delta_2(\cdot)$ by (1.12), and I is the identity in H . Then the stochastic system (1.8) is exponentially stabilizable in mean square, by means of the (stochastic) feedback control $u(t) = -Gy(t)$.

In Examples 2 and 3 of § 5.3 we have to prove the existence of an admissible control for any initial trajectory $y_0 \in H$ (assumption (3.10)); in this direction Proposition 6 will be useful, because if (1.8) is exponentially stabilizable in mean square then (3.10) is verified.

5.3. Stability of optimal trajectories and uniqueness of solution to (1.10).

LEMMA 5. *Assume that (H1) and (H2) hold; assume moreover that (C, A) is detectable, and that there exists $S \in L(V, H)$ such that*

$$(5.4) \quad (\text{trace } W_1) |F_1|_{L(H, L(X_1, H))}^2 \int_0^\infty |e^{t(A-SC)}|_{L(H)}^2 dt < 1,$$

where I is the identity in H . Let $G \in L(H, U)$ be given, and assume that the feedback control $u(t) = -Gy(t)$ (y given by (2.15)) is an admissible control for any $y_0 \in H$; then the trajectories $y(\cdot)$ are exponentially stable in mean square for any $y_0 \in H$.

Proof. Let $y_0 \in H$ be given, and let y and y_n be defined by (2.15) and (2.16), respectively; arguing as in the proof of Lemma 4 we find the equation (which corresponds to (4.8))

$$(5.5) \quad \begin{aligned} y(t) &= e^{t(A-SC)} y_0 + \int_0^t e^{(t-s)(A-SC)} SCy(s) ds \\ &\quad + \int_0^t (SC - A) e^{(t-s)(A-SC)} BGy(s) ds + \int_0^t e^{(t-s)(A-SC)} (\lambda - SC) BGy(s) ds \\ &\quad + \int_0^t e^{(t-s)(A-SC)} F_1(y(s)) dw_1(s) - \int_0^t e^{(t-s)(A-SC)} F_2(Gy(s)) dw_2(s) \\ &= \int_0^t e^{(t-s)(A-SC)} F_1(y(s)) dw_1(s) + h(t), \quad t \geq 0, \end{aligned}$$

where we have introduced for simplicity of notation the stochastic process $h(t)$, defined

by (5.5). Let $\varepsilon > 0$; from (5.5) and the inequality $(a+b)^2 \leq (1+\varepsilon)a^2 + (1+1/\varepsilon)b^2$ we have

$$\begin{aligned}
 E|y(t)|_H^2 &\leq (1+\varepsilon)E\left|\int_0^t e^{(t-s)(A-SC)}F_1(y(s))dw_1(s)\right|_H^2 + \left(1+\frac{1}{\varepsilon}\right)E|h(t)|_H^2 \\
 &= (1+\varepsilon)E\int_0^t \text{trace}(e^{(t-s)(A-SC)}F_1(y(s)))^*W_1(e^{(t-s)(A+SC)}F_1(y(s))) \\
 (5.6) \quad &+ \left(1+\frac{1}{\varepsilon}\right)E|h(t)|_H^2 \\
 &\leq (1+\varepsilon)(\text{trace } W_1)|F_1|_{L(H,L(X_1,H))}^2 \int_0^t |e^{(t-s)(A-SC)}|_{L(H)}^2 E|y(s)|_H^2 ds \\
 &+ \left(1+\frac{1}{\varepsilon}\right)E|h(t)|_H^2,
 \end{aligned}$$

where we have used some well-known properties of the trace and of the stochastic integral ([C2]). Let us take $S \in L(V, H)$ such that (5.4) holds, and let us denote by k the constant on the left side of (5.4); if $\varepsilon > 0$ is such that

$$(5.7) \quad (1+\varepsilon)k < 1;$$

then from (5.6) and a Young inequality we have

$$(5.8) \quad E\int_0^\infty |y(t)|_H^2 dt \leq (1+\varepsilon)kE\int_0^\infty |y(t)|_H^2 dt + (1+1/\varepsilon)E\int_0^\infty |h(t)|_H^2 dt.$$

Arguing as in Lemma 4, we have that $h \in M_w^2(0, \infty; H)$; then from (5.8) and (5.7) we have

$$(5.9) \quad E\int_0^\infty |y(t)|_H^2 dt < \infty.$$

Since (5.9) holds for any initial trajectory $y_0 \in H$, from Proposition 5 we have that $y(\cdot)$ is exponentially stable in mean square for any $y_0 \in H$. \square

THEOREM 6. (i) Assume that (H1), (H2) and (3.36) hold, (C, A) is detectable, and (5.4) holds; then there exists at most one solution of the algebraic Riccati equation (1.10), and in this case the unique solution is equal to P_∞ given by (3.13). (ii) If moreover P_∞ exists, then for any $y_0 \in H$ the optimal trajectory \bar{y} of problem (1.9) is exponentially stable in mean square.

We omit the proof because it is an obvious modification of the proof of Theorem 4. Finally, as in § 4.2, we have the following.

COROLLARY 3. Assume that (H1), (H2) and (3.36) hold. Then system (1.8) is exponentially stabilizable in mean square if and only if for any $y_0 \in H$ there exists $u \in M_w^2(0, \infty; U)$ such that

$$E\int_0^\infty \{|y(t)|_H^2 + |u(t)|_U^2\} dt < \infty.$$

This result follows readily from Theorem 6 with $C = 1$; we remark only that (5.4) is verified if we take $S = \mu$ for a sufficiently large $\mu \geq 0$.

We conclude by discussing two examples of stochastic boundary control problems over infinite time horizon.

Example 2. Let $(\Omega, \mathcal{F}, \mathcal{P})$ be a probability space, and let $w(t)$ be a real Brownian motion; with notation and hypotheses of Example 1, we consider the problem of

$$\begin{aligned}
 (5.10) \quad & \text{minimizing} \\
 & J_\infty(u) = E \int_0^\infty \left\{ \int_\theta y^2 + \int_\Gamma u^2 \right\} dt \\
 & \text{over all } u \in M_w^2(0, \infty; L^2(\Gamma)), \quad \text{subject to} \\
 & dy = -A(x, D)y \, dt + c_1 y \, dw(t) \quad \text{in } [0, \infty[\times \theta, \\
 (5.11) \quad & y = u \quad \text{on } [0, \infty[\times \Gamma, \\
 & y(0, x) = y_0(x) \quad \text{in } \theta,
 \end{aligned}$$

where $c_1 \in R$ is a fixed constant. This problem can be studied in the abstract setting of § 1.1 if we put $X_1 = X_2 = R$, $W_1 = 1$, $W_2 = 0$, $F_1(y) = c_1 y$ for any $y \in L^2(\theta)$, and consequently $\phi_1(P) = c_1^2 P$ and $\phi_2(P) = N^{-1}$ for any $P \in \Sigma^+(H)$. Assume that

$$(5.12) \quad c < 0 \text{ (hence } A \text{ stable)} \quad \text{and} \quad -c_1^2/2c < 1,$$

where c is given in (4.14); then the hypotheses of Proposition 6 are verified with $G = 0$; since (C, A) is detectable, we can apply to this example all results of the paper.

In the following example we discuss a problem in which it is possible to avoid the restrictive assumption (5.12).

Example 3. With notation and hypotheses of Example 2 except from (5.12), let us consider the stochastic system with distributed and boundary controls

$$\begin{aligned}
 (5.13) \quad & dy = -A(x, D)y \, dt + c_1 y \, dw(t) + c_2 u_1 \, dt \quad \text{in } [0, \infty[\times \theta, \\
 & y = u_2 \quad \text{on } [0, \infty[\times \Gamma, \\
 & y(0, x) = y_0(x) \quad \text{in } \theta,
 \end{aligned}$$

where u_1 and u_2 are two different controls, and c_2 is a positive constant. Let us consider the problem of minimizing

$$(5.14) \quad J_\infty(u) = E \int_0^\infty \left\{ \int_\theta (y^2 + n_1 u_1^2) + \int_\Gamma n_2 u_2^2 \right\} dt$$

over all pairs $(u_1, u_2) \in M_w^2(0, \infty; L^2(\theta)) \cap M_w^2(0, \infty; L^2(\Gamma))$, subject to (5.13); here n_1 and n_2 are positive real numbers. For “large” n_1 (resp. “small” c_2) we can see (5.13) as a system in which it is possible to implement a distributed control, but its use is strongly penalized by (5.14) (resp. it has a small effect on the system); in a sense, this is a problem controlled “mainly” on the boundary. With $U = L^2(\theta) \times L^2(\Gamma)$, $N \in \Sigma^+(U)$ defined by $N(u_1, u_2) = (n_1 u_1, n_2 u_2)$ for any $(u_1, u_2) \in U$, $\tilde{B} \in L(U, D_A^\alpha)$ defined by $\tilde{B}(u_1, u_2) = (A - \lambda)^{\alpha-1} u_1 + B u_2$ where B is given by (4.18), we see that this problem fits in with the abstract scheme of § 1.1, with \tilde{B} in place of B . Moreover, (5.13) is stable

and hypotheses of Proposition 6 are verified, by taking the feedback control $(u_1, u_2) = (-\mu y, 0)$, for a sufficiently large $\mu \geq 0$ such that $c_1^2/(c_2\mu - c) < 1$. Consequently, the results of the present paper can be applied.

ON THE SUPREMAL CONTROLLABLE SUBLANGUAGE OF A GIVEN LANGUAGE*

W. M. WONHAM† AND P. J. RAMADGE‡

Abstract. The concept of controllable language has been shown to play a basic role in the existence theory of supervisory controls for discrete event processes. In this paper the supremal controllable sublanguage S of a given language L is characterized as the largest fixpoint of a monotone operator Ω . In the case where the languages involved are regular it is shown that the fixpoint S can be computed as the limit of the (finite) sequence $\{K_j\}$ given by $K_{j+1} = \Omega(K_j)$, $K_0 = L$. An effective computational algorithm is developed, and three examples are provided for illustration.

Key words. supervisory control, discrete event process, controllable language

AMS(MOS) subject classification. 93B

1. Introduction. The concept of controllable language was introduced in Ramadge and Wonham [1983], where it was shown to play a basic role in the existence theory of supervisory controls for discrete event processes. In this paper we characterize the supremal controllable sublanguage S of a given language L as the largest fixpoint of a certain operator Ω . In the case where the languages involved are regular we show that the fixpoint S can be computed as the limit of the (finite) sequence of languages K_j given by

$$K_{j+1} = \Omega(K_j), \quad K_0 = L.$$

Three computational examples are provided for illustration.

A summary version of this paper has appeared as Wonham and Ramadge [1984].

We recall here only the facts needed in the development to follow. Let Σ be a (nonempty) finite alphabet of elements σ , and as usual denote by Σ^* the set of all finite strings of elements of Σ , including the empty string 1. A subset $L \subset \Sigma^*$ is a *language* over Σ . A string $s \in L$ is a *word* of L . If $s, s', t \in \Sigma^*$ with $s't = s$, then s' is a *prefix* of s ; thus both 1 and s are prefixes of s . The *closure* of L is the language \bar{L} consisting of all the prefixes of words in L ; thus if $L = \emptyset$ then $\bar{L} = \emptyset$, and if $L \neq \emptyset$ then $1 \in \bar{L}$. Clearly $L \subset \bar{L}$; L is *closed* if $L = \bar{L}$. Let M be a fixed language over Σ and let Σ_0 be a fixed subset of Σ . A language $K \subset \Sigma^*$ is *controllable* (with respect to M and Σ_0) if

$$\bar{K}\Sigma_0 \cap M \subset \bar{K}.$$

In the supervisory control theory of Ramadge and Wonham [1983] this condition has the following interpretation: Σ is an alphabet of “events”; $\Sigma - \Sigma_0$ is the subset of “controlled events” that can be enabled or disabled by a “supervisor”; thus Σ_0 is the subset of “uncontrolled” events that cannot be disabled; in the absence of control, M is the (closed) language generated by an automaton (or generator) \mathcal{G} over the alphabet Σ ; K (in this context) is a specified sublanguage of M ; \mathcal{G} can be controlled by a

‡ Department of Electrical Engineering and Computer Science, Princeton University, Princeton, New Jersey 08544.

supervisor to generate exactly $\bar{K} \subset M$ just when K is controllable, namely strings in M of the form $t\sigma_0$, with $t \in \bar{K}$ and $\sigma_0 \in \Sigma_0$, are again in \bar{K} . In the present article we need not assume until § 6 that M is closed or that $K \subset M$.

Let $L \subset \Sigma^*$ be arbitrary. Then the *supremal controllable sublanguage* of L is the language

$$\sup C(L) := \bigcup \{K : K \subset L \text{ and } K \text{ is controllable}\}.$$

It was shown in Ramadge and Wonham [1983] that $\sup C(L)$ is well defined (although it may be empty), is controllable, and contains every controllable sublanguage of L .

For a very simple instance of these ideas the reader may glance ahead to Example 3 (§ 7.1). Here the events (labelled) α_1, α_2 are controlled (i.e., can be disabled, viz. prevented from occurring) whereas events β are uncontrolled (i.e., are permanently enabled), namely $\Sigma_0 = \{\beta\}$. Let \mathcal{A} be an automaton whose behavior (without disablements) is the language

$$M = \overline{(\alpha_1\beta^2 + \alpha_2)\beta^*}.$$

With respect to M and Σ_0 the language $N := \{\alpha_1\beta^2\}$ is uncontrollable, since $(\alpha_1\beta^2)\beta \in M$ but $(\alpha_1\beta^2)\beta \notin N$. It is easily seen (cf. § 7.1) that $\sup C(N) = \emptyset$. Intuitively, no mechanism that is capable of disabling only α_1 and α_2 could control \mathcal{A} to generate exactly N . If α_1, α_2 are both disabled then \mathcal{A} generates $\{1\} = \sup C(\bar{N})$.

2. A fixpoint characterization of $\sup C(L)$. Let $L, M \subset \Sigma^*$ be two fixed languages, and let Σ_0 be a fixed subset of Σ . Let \mathcal{L} be the set of all languages over Σ (i.e. \mathcal{L} = power set of Σ^*), and define the operator

$$\Omega : \mathcal{L} \rightarrow \mathcal{L}$$

according to

$$(2.1) \quad \Omega(K) = L \cap \sup \{T : T \subset \Sigma^*, T = \bar{T} \text{ and } T\Sigma_0 \cap M \subset \bar{K}\}, \quad K \in \mathcal{L}.$$

It is easy to check (cf. Ramadge and Wonham [1983, proof of Prop. 7.1]) that the condition in $\{ \}$ of (2.1) is closed under arbitrary unions, so Ω is well defined. Of course Ω depends on the fixed elements L, M and Σ_0 .

If $t \in \Sigma^*$ write \bar{t} for $\overline{\{t\}}$, the set of prefixes of the string t . The following alternative description of $\Omega(K)$ will be useful.

LEMMA 2.1.

$$\Omega(K) = \{t : t \in L \text{ and } \bar{t}\Sigma_0 \cap M \subset \bar{K}\}.$$

Proof. Immediate from (2.1). \square

Let $S := \sup C(L)$, the supremal controllable sublanguage of L (with respect to M and Σ_0). We now have the following.

PROPOSITION 2.1. $S = \Omega(S)$ and $S \supset K$ for every K such that $K = \Omega(K)$.

A language K such that $K = \Omega(K)$ is a *fixpoint* of Ω . Thus Proposition 2.1 describes $\sup C(L)$ as the largest fixpoint of Ω . Of incidental interest is the following.

COROLLARY. If $S := \sup C(L)$ then S is L -closed, namely

$$S = \bar{S} \cap L.$$

Proof of Corollary. By Proposition 2.1 we can write

$$S = \Omega(S) = L \cap T$$

for some closed T . Therefore $T \supset \bar{S}$,

$$L \cap T = S \subset L \cap \bar{S} \subset L \cap T,$$

and so $S = L \cap \bar{S}$. \square

Proof of Proposition 2.1. We have that $S \subset L$ and S is controllable, i.e.,

$$\bar{S}\Sigma_0 \cap M \subset \bar{S},$$

so

$$\bar{S} \subset \sup \{T: T = \bar{T} \text{ and } T\Sigma_0 \cap M \subset \bar{S}\},$$

i.e.,

$$S \subset L \cap \bar{S} \subset \Omega(S).$$

To prove the reverse inclusion, let $t \in \Omega(S)$. By Lemma 2.1

$$t \in L \quad \text{and} \quad \bar{t}\Sigma_0 \cap M \subset \bar{S}.$$

If $S' = S \cup \{t\}$ then $S' \subset L$, and

$$\begin{aligned} \bar{S}'\Sigma_0 \cap M &= (\bar{S} \cup \bar{t})\Sigma_0 \cap M \\ &= (\bar{S}\Sigma_0 \cap M) \cup (\bar{t}\Sigma_0 \cap M) \\ &\subset \bar{S} \\ &\subset \bar{S}'. \end{aligned}$$

Therefore $S' \in \mathbf{C}(L)$ and $S' \supset S$. Because S is supremal, $S' = S$, i.e., $t \in S$ and so $\Omega(S) \subset S$. This gives $S = \Omega(S)$, namely S is a fixpoint of Ω .

Now let K be any fixpoint of Ω . It will be shown that $K \subset S$. We have $K \subset L$, and

$$\begin{aligned} K &\subset \sup \{T: T = \bar{T} \text{ and } \bar{T}\Sigma_0 \cap M \subset \bar{K}\} \\ &=: T^+, \quad \text{say.} \end{aligned}$$

It is enough to check that K is controllable. Now since T^+ is closed

$$\bar{K} \subset T^+$$

and since the defining condition in $\{ \}$ is closed under arbitrary unions

$$T^+\Sigma_0 \cap M \subset \bar{K}.$$

Thus

$$\bar{K}\Sigma_0 \cap M \subset \bar{K}$$

and the proof is complete. \square

In view of Proposition 2.1 it is natural to attempt to compute $S = \sup \mathbf{C}(L)$ by iteration of Ω . For this, define the sequence

$$(2.2) \quad \begin{aligned} K_0 &= L, \\ K_{j+1} &= \Omega(K_j), \quad j = 0, 1, \dots \end{aligned}$$

PROPOSITION 2.2. *The (set-theoretic) limit*

$$K := \lim K_j \quad (j \rightarrow \infty)$$

exists and $S \subset K$.

Proof. It is clear that Ω is monotone, i.e., if $A \subset B \subset \Sigma^*$ then $\Omega(A) \subset \Omega(B)$. Then

$$K_1 = \Omega(K_0) \subset L = K_0,$$

and if $K_j \subset K_{j-1}$ we have

$$K_{j+1} = \Omega(K_j) \subset \Omega(K_{j-1}) = K_j.$$

Hence

$$K_0 \supset K_1 \supset K_2 \supset \cdots$$

so that

$$K = \lim K_j = \bigcap_{j=0}^{\infty} K_j$$

exists. Now

$$S = \Omega(S) \subset L = K_0,$$

and $S \subset K_j$ implies

$$S = \Omega(S) \subset \Omega(K_j) = K_{j+1},$$

so $S \subset K$. \square

It is not true in general that $K \subset S$ (see § 4); however, in the regular case, which we discuss next, it is true that $S = K$ and also that our iteration scheme is effective.

3. Computation of $\sup C(L)$ in the regular case. To define the regular case we first recall the definition of Nerode equivalence (e.g., Hopcroft and Ullman [1979, p. 65]). Let $L \subset \Sigma^*$. Strings $s, t \in \Sigma^*$ are *equivalent* (mod L), written

$$s \equiv t \pmod{L} \quad \text{or} \quad s \equiv_L t,$$

if

$$\{s': s' \in \Sigma^* \text{ and } ss' \in L\} = \{t': t' \in \Sigma^* \text{ and } tt' \in L\}.$$

In other words, two strings are equivalent (mod L) if they are each “continuable” in the same ways to form completed words of L . We shall write

$$\|L\| := \text{card}(\Sigma^*/\equiv_L),$$

namely $\|L\|$ is the (possibly denumerable) number of equivalence classes of \equiv_L in Σ^* . For example if $L = \emptyset$ or $L = \Sigma^*$ then any pair of strings are equivalent, so $\|L\| = 1$. If $\Sigma = \{\alpha, \beta\}$ and

$$L = \alpha^* = \{1, \alpha, \alpha\alpha, \dots\},$$

then $\|L\| = 2$; whereas if $\Sigma = \{\alpha, \beta\}$ with

$$L = \{\alpha^n \beta^n; n = 0, 1, 2, \dots\},$$

then $\|L\| = \infty$. Note that an inclusion $K \subset L$ does not imply any particular ordering of the “norms” $\|K\|, \|L\|$.

The language L is *regular* if $\|L\| < \infty$. In that case, it is well known that $\|L\|$ is the minimal cardinality of the state set of an automaton that “recognizes” L ; so $\|L\|$ roughly measures the size of “memory” in L .

We now state the main result of this section.

THEOREM 3.1. *In case the languages L and M are regular, the sequence of languages K_j defined by*

$$K_0 = L, \quad K_{j+1} = \Omega(K_j), \quad j \geq 0$$

converges after a finite number of terms to $S(= \sup C(L))$. Furthermore, S is a regular language, with

$$\|S\| \leq \|L\| \|M\| + 1.$$

For the proof of Theorem 3.1 we shall require the following three lemmas.

LEMMA 3.1. Let $A, B, C \subset \Sigma^*$. Suppose that for all $s, t \in \Sigma^*$ the conditions $s, t \in \bar{C}$; $s \equiv_A t$; $s \equiv_B t$ together imply $s \equiv_C t$. Then

$$\|C\| \leq \|A\| \|B\| + 1.$$

Proof. For each equivalence relation π on Σ^* we write

$$\|\pi\| = \text{card}(\Sigma^*/\pi).$$

If ρ is also an equivalence relation on Σ^* , we say that π refines ρ if, for all $s, t \in \Sigma^*$, $s \equiv t \pmod{\pi}$ implies $s \equiv t \pmod{\rho}$. If π refines ρ then obviously $\|\pi\| \geq \|\rho\|$.

Now define the equivalence relation π on Σ^* according to

$$s \equiv t \pmod{\pi} \quad \text{iff} \quad s \equiv_A t \quad \text{and} \quad s \equiv_B t.$$

Let π_C be the restriction of π to $\bar{C} \subset \Sigma^*$: namely if we identify π with $\Pi \subset \Sigma^* \times \Sigma^*$ then π_C is identified with $\Pi_C = \Pi \cap (\bar{C} \times \bar{C})$. Let ρ denote \equiv_C and let ρ_C denote the restriction of ρ to \bar{C} . Then the hypothesis states that π_C refines ρ_C , so we have

$$\|\rho_C\| \leq \|\pi_C\| \leq \|\pi\| \leq \|A\| \|B\| + 1.$$

The subset $\Sigma^* - \bar{C} \subset \Sigma^*$ is either empty or exactly one equivalence class of ρ , and therefore

$$\|\rho\| \leq \|\rho_C\| + 1 \leq \|A\| \|B\| + 1$$

as claimed. \square

LEMMA 3.2. For $m = 1, 2, \dots$, let

$$\mathcal{L}_m = \{L: L \subset \Sigma^* \text{ and } \|L\| \leq m\}.$$

Then $\text{card}(\mathcal{L}_m) < \infty$.

Proof. In light of the fact about recognizers cited earlier, the lemma states that only a finite number of distinct languages can be defined over a fixed finite alphabet by means of a recognizer of a priori fixed, finite state cardinality m . This conclusion is immediate from the standard description of a finite state recognizer (Hopcroft and Ullman [1979]) and elementary combinatorics. \square

LEMMA 3.3. Let K_j ($j = 0, 1, 2, \dots$) be a sequence of regular languages over Σ , such that

- (i) $K_0 \supset K_1 \supset K_2 \supset \dots$, and
- (ii) there is a finite constant m for which

$$\|K_j\| \leq m$$

for all j .

Then there is an index k such that

$$K_j = K_k, \quad j \geq k.$$

The lemma states that a monotone, “norm”-bounded sequence of regular languages is finitely convergent.

Proof. In the notation of Lemma 3.2 we have by (ii) that $K_j \in \mathcal{L}_m$ for all j . By the finiteness of \mathcal{L}_m there is $K \in \mathcal{L}_m$ such that K occurs in the sequence $\{K_j\}$ infinitely often. The result is then immediate by the monotonicity (i). \square

We are now ready to discuss the computation of $\sup C(L)$. Reverting to the notation of § 2, we make the assumption:

(3.1) The languages L, M are regular.

Our key result is the following.

LEMMA 3.4. For the sequence $\{K_j\}$ defined by (2.2),

$$\|K_j\| \leq \|L\| \|M\| + 1, \quad j \geq 0.$$

Proof. By Lemma 2.1 we have, for $j \geq 1$,

$$\begin{aligned} K_j &= \Omega(K_{j-1}) \\ &= \{t: t \in L \text{ and } t\Sigma_0 \cap M \subset \bar{K}_{j-1}\}. \end{aligned}$$

It will be shown that, for all $i \geq 0$, the conditions

$$(3.2)_i \quad s, t \in \bar{K}_i, \quad s \equiv_L t, \quad s \equiv_M t,$$

together imply

$$(3.3)_i \quad s \equiv t \pmod{K_i}.$$

For this we fix $j \geq 1$ and make the inductive assumption that

$$(3.2)_i \text{ implies } (3.3)_i \text{ for } 0 \leq i < j.$$

Since $K_0 = L$, the assertion for $j = 1$ is trivial. Observe next that if $(3.2)_j$ is true for a pair $s, t \in \Sigma^*$ then, because $K_j \subset K_{j-1}$, we have that $(3.2)_{j-1}$ is also true for s, t ; and therefore $(3.3)_{j-1}$ is true.

For the inductive step assume that $(3.2)_j$ is true for a pair $s, t \in \Sigma^*$, and suppose that $sq \in K_j$ for some $q \in \Sigma^*$. Then

$$sq \in L \text{ and } \overline{sq}\Sigma_0 \cap M \subset \bar{K}_{j-1}.$$

Since $s \equiv_L t$ we have $tq \in L$. Next, suppose t' is a prefix of tq . If t' is a prefix of t then

$$t'\Sigma_0 \cap M \subset \bar{K}_{j-1}$$

because $t \in \bar{K}_j$. If $t' = tp$ for some prefix p of q , and if $tp\sigma \in M$ for some $\sigma \in \Sigma_0$, then $s \equiv_M t$ implies that $sp\sigma \in M$; but sp is a prefix of sq , so that $sp\sigma \in \bar{K}_{j-1}$, namely $sp\sigma r \in K_{j-1}$ for some $r \in \Sigma^*$. By the inductive hypothesis, $s \equiv t \pmod{K_{j-1}}$, so that $tp\sigma r \in K_{j-1}$, namely $tp\sigma \in \bar{K}_{j-1}$. We have now shown that

$$\overline{tq}\Sigma_0 \cap M \subset \bar{K}_{j-1},$$

and so $tq \in K_j$. Thus for $q \in \Sigma^*$,

$$sq \in K_j \text{ implies } tq \in K_j.$$

By symmetry the reverse implication is also true, and therefore $s \equiv t \pmod{K_j}$ as claimed.

We have established that $(3.2)_i$ implies $(3.3)_i$ for all i . We now apply Lemma 3.1 with

$$A = L, \quad B = M, \quad C = K_i$$

and the proof is complete. \square

Finally we are ready for the proof of Theorem 3.1.

Proof of Theorem 3.1. By the proof of Proposition 2.2 the sequence of languages $\{K_j\}$ is monotone decreasing, and by Lemma 3.4 the numerical sequence $\|K_j\|$ is

bounded by $\|L\| \|M\| + 1$. Thus by Lemma 3.3, the sequence K_j is finitely convergent to a limit K . But this implies that K is a fixpoint of Ω . Thus $K \subset S$. The result now follows by Proposition 2.2. \square

4. Counterexamples. It was shown in the previous section that if L and M are regular, then $\sup \mathbf{C}(L) = \bigcap_{j=0}^{\infty} K_j$, i.e., that $\bigcap_{j=0}^{\infty} K_j$ is a fixpoint of the operator Ω . At the moment it remains an open question as to whether this result is also true for more general classes of languages. It is certainly not true for arbitrary languages L, M as the following example illustrates.

4.1. Example 1. Let

$$\begin{aligned}\Sigma &= \{\alpha, \beta, \gamma\}, \quad \Sigma_0 = \{\alpha, \gamma\}, \quad \text{and} \\ L &= \alpha\beta + \alpha\{\gamma^{n+1}\beta\gamma^m : 0 \leq m \leq n, n \geq 0\}, \\ M &= \overline{\alpha\beta + \alpha\gamma\gamma^*\beta\gamma^*}.\end{aligned}$$

An infinite tree recognizer for L is shown in Fig. 4.1. Recalling that

$$\Omega(K_j) = \{t : t \in L \text{ and } \bar{t}\Sigma_0 \cap M \subset \bar{K}_j\}$$

and using Fig. 4.1, we have

$$K_j = \alpha\beta + \alpha\gamma^j\{\gamma^{n+1}\beta\gamma^m : 0 \leq m \leq n, n \geq 0\}.$$

Thus

$$\bigcap_{j=0}^{\infty} K_j = \alpha\beta.$$

FIG. 4.1. Example 1. Tree recognizer for L .

By inspection of Fig. 4.1 it is evident that $\sup C(L) = \emptyset$. Thus

$$\sup C(L) \neq \bigcap_{j=0}^\infty K_j.$$

It was shown in § 3 that if L and M are regular languages, then $\sup C(L)$ is also a regular language. The conclusion may be false, however, if either L or M fails to be regular. This is illustrated in Example 2.

4.2. Example 2. Let

$$\Sigma = \{\alpha, \beta, \gamma\}, \quad \Sigma_0 = \{\alpha, \gamma\}, \quad \text{and}$$

$$L = \alpha\alpha^*\beta\beta^*,$$

$$M = L + \{\alpha^n\beta^{n+1}\gamma: n \geq 1\}.$$

The infinite tree recognizer for M is shown in Fig. 4.2. Recalling that

$$\Omega(L) = \{t: t \in L \text{ and } \bar{t}\Sigma_0 \cap M \subset \bar{L}\}$$

and using Fig. 4.2 we have

$$\Omega(L) = \{\alpha^n\beta^m: 1 \leq m \leq n, n \geq 1\}$$

and

$$\Omega^2(L) = \Omega(L).$$

FIG. 4.2. Example 2. Tree recognizer for M .

Thus in this case

$$\sup \mathbf{C}(L) = \bigcap_{j=1}^{\infty} K_j,$$

but $\sup \mathbf{C}(L)$ is not a regular language.

5. Effective computability of the operator Ω . We return to the case when L and M are regular languages and show that our proposed iteration scheme yields an effective procedure for the computation of $\sup \mathbf{C}(L)$. For this it will be sufficient, in view of Theorem 3.1, to show that the operator Ω can be effectively computed.

We begin by reviewing some results from the theory of regular languages. Recall that a language $K \subset \Sigma^*$ is regular iff there exists a finite automaton

$$\mathcal{A} = (Q, \Sigma, \delta, q_0, Q_m)$$

with

$$K = \{s : s \in \Sigma^* \text{ and } \delta(s, q_0) \in Q_m\}.$$

In this case we write $|\mathcal{A}| = K$. The automaton \mathcal{A} provides an effective means of specifying the regular language K . Henceforth when we say that a regular language $K \subset \Sigma^*$ is given, we shall understand that a finite automaton \mathcal{A} is supplied with $|\mathcal{A}| = K$.

Let $\mathcal{O} : \mathcal{L}^n \rightarrow \mathcal{L}$ be an operator which preserves regularity, i.e., K_1, \dots, K_n regular implies $\mathcal{O}(K_1, \dots, K_n)$ regular. We say that \mathcal{O} is *effectively computable* if from each n -tuple (K_1, \dots, K_n) of regular languages we can effectively construct a finite automaton \mathcal{A} with $|\mathcal{A}| = \mathcal{O}(K_1, \dots, K_n)$. For example it is well known (see e.g., Eilenberg [1974]) that each of the four standard operators: closure, complement, union and intersection, preserves regularity and is effectively computable.

Define $H : \mathcal{L} \rightarrow \mathcal{L}$ by

$$H(K) := \sup \{T : T \subset K \text{ and } T = \bar{T}\}$$

and for fixed $\Sigma_0 \subset \Sigma$ define $B_0 : \mathcal{L} \rightarrow \mathcal{L}$ by

$$B_0(K) := \{w : w \in \Sigma^* \text{ and } w\sigma \in K \text{ for all } \sigma \in \Sigma_0\}.$$

LEMMA 5.1. *The operators H and B_0 preserve regularity and are effectively computable.*

Proof. Let $\mathcal{A} = (Q, \Sigma, \delta, q_0, Q_m)$ be a finite automaton with $|\mathcal{A}| = K$.

(1) If $q_0 \notin Q_m$, then clearly $H(K) = \emptyset$. If $q_0 \in Q_m$, then define

$$X = Q_m,$$

$$x_0 = q_0,$$

$$X_m = X,$$

and $\xi : \Sigma \times X \rightarrow X$ by

$$\xi(\sigma, x) = \begin{cases} \delta(\sigma, x) & \text{if } \delta(\sigma, x) \in Q_m, \\ \text{undefined} & \text{otherwise.} \end{cases}$$

Let

$$\mathcal{B} := (X, \Sigma, \xi, x_0, X).$$

Then

$$\begin{aligned} w \in |\mathcal{B}| & \quad \text{iff } \bar{w} \in |\mathcal{A}|, \\ & \quad \text{iff } w \in H(K). \end{aligned}$$

(2) Let

$$X_m = \{q: q \in Q \text{ and } \delta(\sigma, q) \in Q_m \text{ for all } \sigma \in \Sigma_0\},$$

$$\mathcal{B} = (Q, \Sigma, \delta, q_0, X_m).$$

Then

$$w \in |\mathcal{B}| \quad \text{iff } w\sigma \in |\mathcal{A}| \text{ for all } \sigma \in \Sigma_0,$$

$$\text{iff } w \in B_0(K).$$

□

The following lemma is the key to an effective computation of Ω .

LEMMA 5.2. *For each $K \subset \Sigma^*$*

$$\Omega(K) = L \cap H \cdot B_0(\bar{K} \cup M^c).$$

Proof. For each $K \subset \Sigma^*$

$$\Omega(K) = \{w \mid w \in L \text{ and } \bar{w}\Sigma_0 \cap M \subset \bar{K}\}.$$

Hence

$$\begin{aligned} w \in \Omega(K) & \quad \text{iff } w \in L \text{ and } \bar{w}\Sigma_0 \cap M \subset \bar{K}, \\ & \quad \text{iff } w \in L \text{ and } \bar{w}\Sigma_0 \subset \bar{K} \cup M^c, \\ & \quad \text{iff } w \in L \text{ and } \bar{w} \subset B_0(\bar{K} \cup M^c), \\ & \quad \text{iff } w \in L \text{ and } w \in H \cdot B_0(\bar{K} \cup M^c), \\ & \quad \text{iff } w \in L \cap H \cdot B_0(\bar{K} \cup M^c). \end{aligned}$$

□

Finally we have our desired result.

PROPOSITION 5.1. *The operator Ω is effectively computable.*

Proof. The assertion is immediate from Lemmas 5.1 and 5.2 and the effective computability of closure, complement, union and intersection. □

6. Alternative computation of Ω . In the applications so far considered (Ramadge and Wonham [1983]) the language M is closed (i.e., $M = \bar{M}$) and represents the uncontrolled, “physically possible” behavior of a discrete event process; while $L \subset M$ is the “legal” language describing behavior that is both possible and acceptable. For this special case we present a more efficient computation of the operator Ω . This method will be used in the presentation of examples in § 7.

Recall that for the finite automaton

$$\mathcal{A} = (Q, \Sigma, \delta, q_0, Q_m)$$

the transition function $\delta: \Sigma \times Q \rightarrow Q$ is in general only a partial function, meaning that, for each $q \in Q$, $\delta(\sigma, q)$ is only defined for a subset $\Sigma(q) \subset \Sigma$ that depends on q . We call $\Sigma(q)$ the *active set* at the state q . Define the *empty automaton* over Σ , denoted \emptyset_Σ , by

$$\emptyset_\Sigma := (\emptyset, \Sigma, \emptyset, \emptyset, \emptyset).$$

Clearly $|\emptyset_\Sigma| = \emptyset$.

For the automaton \mathcal{A} define

$$Q_{ac} := \{q: q \in Q \text{ and } \delta(w, q_0) = q \text{ for some } w \in \Sigma^*\},$$

$$Q_{co} := \{q: q \in Q \text{ and } \delta(w, q) \in Q_m \text{ for some } w \in \Sigma^*\}.$$

Q_{ac} is called the *accessible set* of \mathcal{A} and Q_{co} the *coaccessible set* of \mathcal{A} . We say that \mathcal{A} is *accessible* if $Q_{ac} = Q$, *coaccessible* if $Q_{co} = Q$ and *trim* if $Q = Q_{ac} = Q_{co}$.

Let

$$Q_{tr} := Q_{ac} \cap Q_{co}, \quad \delta_{tr} := \delta|(\Sigma \times Q_{tr}).$$

Then the *trim component* of \mathcal{A} is defined by

$$\text{Tr}(\mathcal{A}) := \begin{cases} (Q_{tr}, \Sigma, \delta_{tr}, q_0, Q_{tr}) & \text{if } Q_{tr} \neq \emptyset, \\ \emptyset_{\Sigma} & \text{otherwise.} \end{cases}$$

It is clear that $|\text{Tr}(\mathcal{A})| = |\mathcal{A}|$ (Eilenberg [1974, p. 23]) and that $\text{Tr}(\mathcal{A})$ is effectively constructible.

Now let $\mathcal{A} = (Q, \Sigma, \delta, q_0, Q_m)$ and $\mathcal{B} = (X, \Sigma, \xi, X_0, X_m)$ be trim finite automata with $|\mathcal{B}| \subset |\mathcal{A}|$. We say that \mathcal{B} *refines* \mathcal{A} if

$$\text{for all } s, t \in \overline{|\mathcal{B}|}, \quad \xi(s, x_0) = \xi(t, x_0) \text{ implies } \delta(s, q_0) = \delta(t, q_0).$$

If \mathcal{B} refines \mathcal{A} then it is easily shown that there exists a unique function $h: X \rightarrow Q$ satisfying

$$(6.1) \quad h \cdot \xi(s, x_0) = \delta(s, q_0), \quad s \in \overline{|\mathcal{B}|}.$$

We are now ready to examine the operator Ω . For this let $L, M \subset \Sigma^*$ be regular languages with $L \subset M$ and $M = \bar{M}$, and let K_j be the sequence of regular languages defined by

$$K_0 = L, \quad K_{j+1} = \Omega(K_j), \quad j \geq 0.$$

LEMMA 6.1. *Let*

$$\mathcal{A} = (Q, \Sigma, \delta, q_0, Q), \quad \mathcal{C}_j = (X, \Sigma, \xi, x_0, X_m)$$

be trim automata such that

$$|\mathcal{A}| = M, \quad |\mathcal{C}_j| = K_j,$$

and \mathcal{C}_j refines \mathcal{A} . Let $h: X \rightarrow Q$ be the unique map satisfying (6.1). Then $w \in \Omega(K_j)$ iff $w \in K_j$ and

$$\text{for each } u \in \bar{w}, \quad x = \xi(u, x_0) \text{ implies } \Sigma(h(x)) \cap \Sigma_0 \subset \Sigma(x).$$

Proof. Recall that

$$w \in \Omega(K_j)$$

$$\text{iff } w \in K_j \text{ and } \bar{w}\Sigma_0 \cap M \subset \bar{K}_j,$$

$$\text{iff } w \in K_j \text{ and } (\forall u \in \bar{w}) u\Sigma_0 \cap M \subset \bar{K}_j,$$

$$\text{iff } w \in K_j \text{ and } (\forall u \in \bar{w}) (\forall \sigma \in \Sigma_0) (u\sigma \in M \text{ implies } u\sigma \in \bar{K}_j),$$

$$\text{iff } w \in K_j \text{ and } (\forall u \in \bar{w}) (\forall \sigma \in \Sigma(\delta(u, q_0)) \cap \Sigma_0) u\sigma \in \bar{K}_j,$$

$$\text{iff } w \in K_j \text{ and } (\forall u \in \bar{w}) \Sigma(\delta(u, q_0)) \cap \Sigma_0 \subset \Sigma(\xi(u, x_0)),$$

$$\text{iff } w \in K_j \text{ and } (\forall u \in \bar{w}) (x = \xi(u, x_0) \text{ implies } \Sigma(h(x)) \cap \Sigma_0 \subset \Sigma(x)). \quad \square$$

In view of Lemma 6.1 it is natural to attempt to construct an automaton \mathcal{C}_{j+1} with $|\mathcal{C}_{j+1}| = \Omega(K_j)$ simply by removing those states of \mathcal{C}_j that fail to satisfy the *active event constraint*

$$\Sigma(h(x)) \cap \Sigma_0 \subset \Sigma(x).$$

More formally let \mathcal{A} and \mathcal{C}_j be defined as in Lemma 6.1, let

$$\begin{aligned} X' &= \{x: x \in X \text{ and } \Sigma(h(x)) \cap \Sigma_0 \subset \Sigma(x)\}, \\ X'_m &= X_m \cap X', \end{aligned}$$

and let $\xi': \Sigma \times X' \rightarrow X'$ be the function given by

$$\xi'(\sigma, x) = \begin{cases} \xi(\sigma, x) & \text{if } \xi(\sigma, x) \in X', \\ \text{undefined} & \text{otherwise.} \end{cases}$$

Then define

$$(6.2) \quad \mathcal{C}_{j+1} := \begin{cases} \text{Tr}((X', \Sigma, \xi', x_0, X'_m)) & \text{if } x_0 \in X', \\ \emptyset_{\Sigma} & \text{otherwise.} \end{cases}$$

PROPOSITION 6.1. *Let \mathcal{A} and \mathcal{C}_j be as defined in the statement of Lemma 6.1, and let \mathcal{C}_{j+1} be the automaton defined by (6.2). Then*

$$|\mathcal{C}_{j+1}| = \Omega(K_j) = K_{j+1}$$

and \mathcal{C}_{j+1} refines \mathcal{A} .

Proof.

$$w \in |\mathcal{C}_{j+1}|$$

$$\text{iff } w \in |\mathcal{C}_j| \text{ and } (\forall u \in \bar{w}) \xi(u, x_0) \in X',$$

$$\text{iff } w \in K_j \text{ and } (\forall u \in \bar{w}) x = \xi(u, x_0) \text{ implies } \Sigma(h(x)) \cap \Sigma_0 \subset \Sigma(x),$$

$$\text{iff } w \in \Omega(K_j) \text{ (by Lemma 6.1).}$$

That \mathcal{C}_{j+1} refines \mathcal{A} follows immediately from the fact that \mathcal{C}_j refines \mathcal{A} . \square

It only remains to show that, given trim automata $\mathcal{A} = (Q, \Sigma, \delta, q_0, Q_m)$ and $\mathcal{B} = (Z, \Sigma, \alpha, z_0, Z_m)$ with $|\mathcal{A}| = M$ and $|\mathcal{B}| = L$, we can effectively construct an automaton \mathcal{C}_0 such that $|\mathcal{C}_0| = L$, and \mathcal{C}_0 refines \mathcal{A} .

Define the intersection $\mathcal{A} \cap \mathcal{B}$ of \mathcal{A} and \mathcal{B} by

$$\mathcal{A} \cap \mathcal{B} := (Q \times Z, \Sigma, \langle \delta, \alpha \rangle, (q_0, z_0), Q_m \times Z_m)$$

where $\langle \delta, \alpha \rangle(\sigma, q, z)$ is defined iff both $\delta(\sigma, q)$ and $\alpha(\sigma, z)$ are defined and is given by

$$\langle \delta, \alpha \rangle(\sigma, q, z) = (\delta(\sigma, q), \alpha(\sigma, z)).$$

Clearly $|\mathcal{A} \cap \mathcal{B}| = |\mathcal{A}| \cap |\mathcal{B}|$ (Eilenberg [1974, p. 17]).

PROPOSITION 6.2. *Let \mathcal{A} and \mathcal{B} be as defined above and let $\mathcal{C}_0 = \text{Tr}(\mathcal{A} \cap \mathcal{B})$. Then $|\mathcal{C}_0| = L$ and \mathcal{C}_0 refines \mathcal{A} .*

Proof.

$$|\mathcal{C}_0| = |\mathcal{A}| \cap |\mathcal{B}| = M \cap L = L.$$

For $s, t \in \bar{L}$

$$\langle \delta, \alpha \rangle(s, q_0, z_0) = \langle \delta, \alpha \rangle(t, q_0, z_0)$$

implies

$$\delta(s, q_0) = \delta(t, q_0).$$

Hence \mathcal{C}_0 refines \mathcal{A} . \square

The method of this section has been implemented in Pascal by Lin [1984].

7. Illustrations. The computations in this section are intended mainly to illustrate the result of Theorem 3.1. In the examples that follow, $L \subset M$ and $M = \bar{M}$, and so we employ the computation scheme developed in § 6.

It is often convenient for purposes of computation to represent a finite automaton $\mathcal{A} = (Q, \Sigma, \delta, q_0, Q_m)$ by its transition matrix. This is a finite square matrix Δ whose columns and rows are indexed by the state set of \mathcal{A} and whose entries $\Delta(p, q)$ are the subsets of Σ given by

$$\Delta(p, q) = \{\sigma : \sigma \in \Sigma \text{ and } q = \delta(\sigma, p)\}.$$

7.1. Example 3. Let $\Sigma = \{\alpha_1, \alpha_2, \beta\}$, $\Sigma_0 = \{\beta\}$; and in the notation of regular expressions (Hopcroft and Ullman [1979]) let

$$L = \overline{\alpha_1\beta^2} + \alpha_2\beta^*, \quad M = \overline{(\alpha_1\beta^2 + \alpha_2)}\beta^*.$$

An automaton \mathcal{A} for M (i.e., a trim automaton with $|\mathcal{A}| = M$) is displayed below (\odot denotes the initial state, \cdot denotes marker states).

Note that while the string $\alpha_1\beta^2$ is legal, its successor $\alpha_1\beta^3$ is not; but since $\beta \in \Sigma_0$ this implies $\alpha_1\beta^2 \notin K_1$. Proceeding in this informal manner it is intuitively clear that

$$\sup C(L) = 1 + \alpha_2\beta^*.$$

To verify this by formal computation consider the automaton \mathcal{B} for L shown below.

It is clear that \mathcal{B} refines \mathcal{A} . To the transition matrix of \mathcal{B} we adjoin two columns: one listing $\Sigma(h(x)) \cap \Sigma_0$, the other listing $\Sigma(x)$. This yields the following tableau.¹

	0	1	2	3	4	$\Sigma(h(x)) \cap \Sigma_0$	$\Sigma(x)$
0		α_1			α_2		$\alpha_1\alpha_2$
1			β			β	β
2				β		β	β
3						β	
4					β	β	β

¹ We denote the empty set simply by a blank entry in the tableau.

Since

$$\Sigma(3') \cap \Sigma_0 \not\subset \Sigma(3),$$

we remove state 3 from the tableau and arrange that the resulting automaton is trim. The result (shown below) is an automaton for the language K_1 .

	0	1	2	4	$\Sigma(h(x)) \cap \Sigma_0$	$\Sigma(x)$
$K_1:$	0	α_1		α_2		$\alpha_1 \alpha_2$
	1		β		β	β
	2				β	
	4			β	β	β

$$K_1 = \overline{\alpha_1 \beta} + \alpha_2 \beta^*$$

Iterating this procedure yields the following sequence of tableaux:

	0	1	4	$\Sigma(h(x)) \cap \Sigma_0$	$\Sigma(x)$
$K_2:$	0	α_1	α_2		$\alpha_1 \alpha_2$
	1			β	
	4		β	β	β

$$K_2 = \overline{\alpha_1} + \alpha_2 \beta^*$$

	0	4	$\Sigma(h(x)) \cap \Sigma_0$	$\Sigma(x)$
$K_3:$	0	α_2		$\alpha_1 \alpha_2$
	4	β	β	β

$$K_3 = 1 + \alpha_2 \beta^*$$

Since each state of the last tableau satisfies the active event constraint, our iteration scheme has converged. We conclude that

$$\sup C(L) = 1 + \alpha_2 \beta^*$$

as expected. \square

7.2. Example 4. Consider a simplified version of the example of (Ramadge and Wonham [1983, § 12]), to which the reader is referred for any unexplained terminology below. Two machines M_1 and M_2 are connected in tandem, separated by a buffer B .

The M_i are controlled discrete-event processes (CDEPs) with state diagrams as shown.

Here the defining condition simply maintains the content of the buffer at zero or one (workpiece) at all times. Finally we define

$$L = L_f \cap M.$$

Evidently L_f , and therefore L , are closed.

To compute $\sup C(L)$ we first obtain an automaton for L . By inspection, L_f consists of those strings of Σ^* in which β_1, α_2 occur in strict alternation. An automaton for L_f is therefore as shown below.

To compute an automaton for L we must form the product of the automata for L_f and M . We omit the simple computation, merely displaying the result.

	0E	0F	1E	1F	2E	2F	3E	3F
0E					α_1			
0F			α_2			α_1		
1E	β_2						α_1	
1F		β_2						α_1
2E		β_1						
2F							α_2	
3E				β_1	β_2			
3F						β_2		

initial state: 0E
marker states: all states

Evidently this automaton refines the automaton for M . Hence we can immediately write down the following tableau.

In state I_i , M_i is “idle”; in state W_i it is “working.” The buffer B has a single slot and is modeled by an automaton with the two states E (empty) and F (full).

Initially the system is in state (I_1, I_2, E) . A work cycle $\alpha_1\beta_1$ of M_1 “deposits a workpiece in B ” driving B to F ; M_2 can then begin its work cycle by “removing the workpiece from B ” thereby resetting B to E . The controlled events are α_1, α_2 ; namely $\Sigma_0 = \{\beta_1, \beta_2\}$.

For M we adopt the closure of the shuffle language generated by M_1 and M_2 . M has the automaton displayed below.

To define the legal language L we impose the “safety” requirement determined by the capacity of the buffer. To formalize this let $\sigma \in \Sigma = \{\alpha_1, \beta_1, \alpha_2, \beta_2\}$ and for a string $s \in \Sigma^*$ write

$$|\sigma|(s) = \text{number of occurrences of } \sigma \text{ in } s.$$

Define the “safety language” $L_f \subset \Sigma^*$ according to

$$L_f = \{s: s \in \Sigma^* \text{ and } |\alpha_2|(t) \leq |\beta_1|(t) \leq |\alpha_2|(t) + 1 \text{ for all prefixes } t \text{ of } s\}.$$

	0E	0F	1E	1F	2E	2F	3E	3F	$\Sigma(h(x) \cap \Sigma_0$	$\Sigma(x)$
K_0 :	0E				α_1					α_1
	0F		α_2			α_1				$\alpha_2\alpha_1$
	1E	β_2					α_1		β_2	$\beta_2\alpha_1$
	1F		β_2					α_1	β_2	$\beta_2\alpha_1$
	2E		β_1						β_1	β_1
	2F						α_2		β_1	α_2
	3E			β_1	β_2				$\beta_1\beta_2$	$\beta_1\beta_2$
	3F					β_2			$\beta_1\beta_2$	β_2

Both the states $2F$ and $3F$ fail to satisfy the active event constraint and hence must be removed from the tableau. This yields

	$0E$	$0F$	$1E$	$1F$	$2E$	$2F$	$\Sigma(h(x)) \cap \Sigma_0$	$\Sigma(x)$
$0E$					α_1			α_1
$0F$			α_2					α_2
$1E$	β_2					α_1	β_2	$\beta_2\alpha_1$
$1F$		β_2					β_2	β_2
$2E$		β_1					β_1	β_1
$3E$				β_1	β_2		$\beta_1\beta_2$	$\beta_1\beta_2$

initial state: $0E$

marker states: all states

Since each state of this trim automaton satisfies the active event constraint it is an automaton for $\text{sup } C(L)$. The state transition graph is shown below.

This result is in agreement with Ramadge and Wonham [1983], where our automaton transition graph for $\text{sup } C(L)$ in fact appears as a subgraph of the automaton transition graph of Ramadge and Wonham [1983, Fig. 12.4].

7.3. Example 5. A cat and a mouse are placed in the maze shown in Fig. 7.1, with the cat initially in room 2 and the mouse initially in room 4. Each doorway in the maze must be traversed in the direction indicated and is either for the exclusive use of the cat (displayed as $\neg\uparrow-$) or for the exclusive use of the mouse (displayed as $\neg\downarrow-$). In addition each door, with the exception of c_7 , can be opened or closed as required in order to control the movement of the cat and the mouse.

Our objective is to find the control scheme that permits the cat and the mouse the greatest possible freedom of movement but also guarantees that

- (a) The cat and the mouse never occupy the same room simultaneously;
- (b) It is always possible for the cat and the mouse to return to the initial state, i.e., the state in which the cat is in room 2 and the mouse is in room 4.

Let $\Sigma = \{c_i, m_j: 1 \leq i \leq 7, 1 \leq j \leq 6\}$. We model the movement of the cat in the maze by the automaton \mathcal{G}_c over Σ shown below.

Here state i corresponds to room i and a transition $i \xrightarrow{c_k} j$ corresponds to traversing the door c_k between rooms i and j .

Similarly we model the movement of the mouse in the maze by the automaton \mathcal{G}_m shown below.

Now for our joint model of the cat and the mouse we adopt the automaton \mathcal{G} constructed by shuffling the automata \mathcal{G}_c and \mathcal{G}_m . The states of \mathcal{G} are ordered pairs (i, j) where i is a state of \mathcal{G}_c and j is a state of \mathcal{G}_m , and the transitions of \mathcal{G}_c are either of the form

$$(i, j) \xrightarrow{c_k} (i', j)$$

where $i \xrightarrow{c_k} i'$ is a transition in \mathcal{G}_c , or of the form

$$(i, j) \xrightarrow{m_k} (i, j')$$

FIG. 7.1. Example 5. Maze for cat and mouse.

where $j \rightarrow^{m_k} j'$ is a transition in \mathcal{G}_m . The automaton \mathcal{G} is displayed in Fig. 7.2.² We let $M = |\mathcal{G}|$ and Σ_0 be the set of labels of uncontrolled doors, i.e., $\Sigma_0 = \{c_7\}$.

To construct an automaton for the legal language L we remove those states (i, j) of \mathcal{G} for which $i = j$, and take the trim component of the resultant automaton. Clearly this automaton satisfies constraint (a). To satisfy constraint (b) we must ensure that every state is coaccessible to the state 24. Hence we designate 24 as the only marker state and again take the trim component of the resultant automaton. These computations yield the automaton \mathcal{H} for L shown on the left-hand side of Fig. 7.3.

Having specified M , L and Σ_0 we now proceed to compute $\sup C(L)$. By the construction of \mathcal{H} it is clear that \mathcal{H} refines \mathcal{G} . Hence we can immediately fill in the right-hand columns of Fig. 7.3 to form our initial tableau. Since the states 13 and 31 fail to satisfy the active event constraint, these are removed and we compute the trim component of the remaining automaton. The resultant automaton for K_1 is shown in Fig. 7.4.

It is clear from Fig. 7.4 that K_1 is controllable. Hence $\sup C(L) = K_1$. The automaton for $\sup C(L)$ is displayed by its state transition graph in Fig. 7.5.

Using the results of Ramadge and Wonham [1983] we can now construct a quotient supervisor which synthesizes the language $\sup C(L)$. This is shown in Fig. 7.6. The "optimal" control strategy which this supervisor implements can be summarized as follows. If the cat and the mouse occupy their respective initial rooms, then both are

² For convenience we often abbreviate (i, j) to simply ij , e.g., $(2, 3)$ becomes 23, $(1, 3)$ becomes 13.

FIG. 7.2. Example 5. Shuffled automaton *G*.

given the opportunity to move to a new room, i.e., c_3 and m_5 are open. If the cat leaves room 2, then the mouse is isolated in room 4, i.e., m_5 and c_5 are closed, and the cat is free to roam the rest of the maze. Similarly, if the mouse leaves room 4, then the cat is isolated in room 2, and the mouse is permitted access to those rooms from which it can return to room 4, i.e., rooms 0, 3, 4.

8. Conclusion. The characterization of supremal controllable language given in this paper is both of theoretical interest and provides a basis for computation in the regular case. It would be of considerable interest to find convergence criteria that could be used to extend Theorem 3.1 to broader classes of languages, as well as to study the issue of computational efficiency.

Acknowledgments. It is a pleasure to acknowledge the helpful contributions of Lin Feng and John Thistle to the development of Theorem 3.1.

DUAL TECHNIQUES FOR MINIMAX*

WILLIAM W. HAGER† AND DWAYNE L. PRESLER‡

Abstract. A dual formulation for a convex minimax problem is presented and the notion of reducibility is introduced. For nonconvex problems, Rockafellar's augmented Lagrangian is used to close the duality gap. We show how mathematical programming algorithms can be applied to the minimax problem and we develop a special algorithm for reducible minimax problems.

Key words. minimax, duality, augmented Lagrangians

AMS(MOS) subject classifications. 65K05, 90C30

1. Introduction. A dual minimax problem is formulated and the concept of reducibility is introduced. Since the dual problem may not solve the primal problem when the cost lacks convexity, § 3 develops augmented Lagrangian techniques to bridge the duality gap. In particular, an analogue of Rockafellar's augmented Lagrangian is applied to the minimax problem. Abstractly, the minimax problem is a constrained optimization problem with special structure. In § 4 we show how mathematical programming algorithms such as those in [18] can be embedded into an algorithm to solve the minimax problem. Section 5 presents a special scheme for solving reducible minimax problems. Other algorithms that have been proposed for minimax problems include those in [3], [4], [8], [9], [11]–[14], [20], [21], [24], [26] and [34]. Most of these algorithms are either "primal" in nature or the algorithm addresses problems where the maximization phase of the minimax problem is restricted to a finite set. Our methods, on the other hand, are dual methods derived from an augmented Lagrangian and the maximization can be performed over an infinite set. Another approach to minimax problems utilizes nondifferentiable optimization techniques. This family of methods is described in [23] by Kiwiel and in [32] by Shor. As discussed later, perhaps the algorithm [26] of Murray and Overton is the closest to the approach proposed in § 4. Our algorithm for reducible minimax problems seems to be distinct from other algorithms for the minimax problem.

2. Abstract dual. Given sets X and Y and given a real-valued function f defined on $X \times Y$, we consider the problem

$$(2.1) \quad \underset{x \in X}{\text{minimize}} \quad \underset{y \in Y}{\text{maximum}} \quad f(x, y).$$

In other words, if $\Phi: X \rightarrow \mathbb{R}$ is the real-valued function defined by

$$\Phi(x) = \supremum \{f(x, y): y \in Y\},$$

we are concerned with the problem

$$(2.2) \quad \underset{x \in X}{\text{minimize}} \quad \{\Phi(x): x \in X\}.$$

To derive a dual to (2.1), let us write (2.2) in the form

$$(2.3) \quad \begin{aligned} &\text{minimize } \rho \\ &\text{subject to } \Phi(x) - \rho \leq 0, \quad x \in X, \quad \rho \in \mathbb{R}. \end{aligned}$$

The collection \mathbf{P} of functionals that are nonnegative everywhere on Y is a cone. When g is a functional defined on Y , we write $g \geq 0$ if $g \in \mathbf{P}$. Similarly the relation $g \leq 0$ means that $-g \in \mathbf{P}$. Since $f(x, y) - \rho$ is a real-valued function of y for each fixed $x \in X$, and for each fixed $\rho \in R$, (2.3) can be expressed as follows:

$$(2.4) \quad \text{minimize } \{ \rho: f(x, \cdot) - \rho \mathbf{1}(\cdot) \leq 0, x \in X, \rho \in R \}$$

where $\mathbf{1}: Y \rightarrow R$ is the function defined by $\mathbf{1}(y) = 1$ for every $y \in Y$. That is, $\mathbf{1}$ is identically equal to one on Y .

Let \mathbf{Y} be a normed vector space consisting of functionals defined on Y and suppose that \mathbf{Y} contains $f(x, \cdot) - \rho \mathbf{1}(\cdot)$ for every $x \in X$ and $\rho \in R$. The dual problem associated with (2.4) involves the dual space \mathbf{Y}^* . Given a linear functional $\lambda \in \mathbf{Y}^*$, let $\langle \lambda, p \rangle$ denote the value of λ at p and write $\lambda \geq 0$ if $\langle \lambda, p \rangle \geq 0$ for every $p \in \mathbf{P} \cap \mathbf{Y}$. Then the dual to (2.4) is

$$(2.5) \quad \text{maximize } \{ \mathbf{I}(\lambda): \lambda \in \mathbf{Y}^*, \lambda \geq 0 \}$$

where the dual functional \mathbf{I} is defined by

$$(2.6) \quad \mathbf{I}(\lambda) = \infimum \{ \rho + \langle \lambda, f(x, \cdot) - \rho \mathbf{1}(\cdot) \rangle: x \in X, \rho \in R \}.$$

Since

$$\rho + \langle \lambda, f(x, \cdot) - \rho \mathbf{1}(\cdot) \rangle = \langle \lambda, f(x, \cdot) \rangle + \rho(1 - \langle \lambda, \mathbf{1} \rangle),$$

it follows that $\mathbf{I}(\lambda)$ is $-\infty$ unless $\langle \lambda, \mathbf{1} \rangle = 1$. Moreover, if $\langle \lambda, \mathbf{1} \rangle = 1$, then the dual functional can be expressed

$$\mathbf{I}(\lambda) = \infimum \{ \langle \lambda, f(x, \cdot) \rangle: x \in X \}.$$

Now let us consider the standard question in duality theory: When does there exist a solution to (2.5) and when is the maximum in (2.5) equal to the minimum in (2.2)? Applying [17, Thm. A.1], we have the following.

THEOREM 2.1. *Whenever ρ and x are feasible for (2.3) and λ is feasible for (2.5), we have $\mathbf{I}(\lambda) \leq \rho$. Moreover, if ρ^* and x^* are feasible for (2.3), λ^* is feasible for (2.5), and $\mathbf{I}(\lambda^*) = \rho^*$, then ρ^* and x^* are optimal in (2.3), λ^* is optimal in (2.5), and the complementary slackness condition $\langle \lambda^*, f(x^*, \cdot) \rangle = \rho^*$ holds. On the other hand, suppose that X is a convex subset of a vector space and for each fixed $y \in Y$, $f(x, y)$ is a convex function of $x \in X$. If there exists a ball $\mathbf{B} \subset \mathbf{Y}$ with center at the origin such that*

$$(2.7) \quad \sup_{\phi \in \mathbf{B}} \inf_{x \in X} \sup_{y \in Y} \{ f(x, y) - \phi(y) \} < \infty,$$

then (2.5) has a solution λ^* and

$$\mathbf{I}(\lambda^*) = \inf_{x \in X} \sup_{y \in Y} f(x, y).$$

For illustration, suppose that Y is the finite set $\{1, \dots, m\}$ and let $f_i(x)$ denote the function $f(x, i)$. In this case, both \mathbf{Y} and \mathbf{Y}^* can be identified with R^m , the space of m -tuples of real numbers, and the functional $\langle \cdot, \cdot \rangle$ is the usual dot product in R^m . Hence, the feasibility condition " $\lambda \in \mathbf{Y}^*$, $\lambda \geq 0$, and $\langle \lambda, \mathbf{1} \rangle = 1$ " associated with the dual problem (2.5) is equivalent to saying that $\lambda \in R^m$, $\lambda_i \geq 0$ for $i = 1, \dots, m$, and $\lambda_1 + \dots + \lambda_m = 1$. Observe that in this finite-dimensional framework, assumption (2.7) is satisfied trivially. If both X and the f_i are convex, then Theorem 2.1 tells us that there exists an optimal solution λ^* to (2.5) and

$$\mathbf{I}(\lambda^*) = \inf \left\{ \sum_{i=1}^m \lambda_i^* f_i(x): x \in X \right\} = \inf_{x \in X} \max \{ f_i(x): i = 1, \dots, m \}.$$

For a second illustration, let us consider the case where Y is a compact subset of a normed vector space, \mathbf{Y} is the space of continuous real-valued functions defined on Y , and the norm $\|\cdot\|$ for \mathbf{Y} is defined by

$$\|\phi\| = \text{maximum } \{|\phi(y)|: y \in Y\}.$$

Again (2.7) is satisfied trivially. Furthermore, if Y is an interval $[a, b] \subset \mathbf{R}$, then \mathbf{Y}^* is the space of functions with bounded variation on $[a, b]$ and the complementary slackness condition can be expressed using a Stieltjes integral:

$$(2.8) \quad \int_a^b (f(x^*, y) - \rho^*) d\lambda^*(y) = 0.$$

In the proof of [17, Lemma 5.2], we note that when λ has bounded variation, the inequality $\lambda \geq 0$ is equivalent to saying that $\lambda(y)$ is a nondecreasing function of y . Hence, if ρ^* and x^* are feasible for (2.3) and λ^* is feasible for (2.5), then $f(x^*, y) - \rho^* \leq 0$ for every $y \in Y$ and (2.8) implies that $\lambda^*(\cdot)$ is constant on each subinterval of $[a, b]$ where $f(x^*, \cdot) < \rho^*$.

In many applications, one discovers that a solution pair (ρ^*, x^*) for (2.3) has the property that $f(x^*, y) < \rho^*$ except for y in a finite set $\{y_1, \dots, y_m\} \subset Y$. In this case, the complementary slackness condition (2.8) tells us that $\lambda^*(\cdot)$ is constant on each open interval (y_i, y_{i+1}) and $\lambda^*(y_i^+) \geq \lambda^*(y_i^-)$. If this jump set is known in advance and if we restrict our attention to λ 's which are constant on each interval (y_i, y_{i+1}) , then the dual functional can be expressed

$$I(\lambda) = \inf \left\{ \sum_{i=1}^m \lambda_i f(x, y_i): x \in X \right\}$$

where $\lambda_i = \lambda(y_i^+) - \lambda(y_i^-)$ is the jump at y_i . Generally, the y_i are unknown and the dual functional must be maximized over both the y_i and the λ_i . To summarize, if Y is the interval $[a, b]$, \mathbf{Y} is the space of continuous real-valued functions defined on $[a, b]$, and there exists both a solution ρ^* and x^* to (2.3) and a solution λ^* to (2.5) such that $\rho^* = I(\lambda^*)$ and $f(x^*, y) = \rho^*$ for finitely many y , then the continuous dual problem (2.5) can be replaced by the discrete dual

$$(2.9) \quad \begin{aligned} &\text{maximize } I(\lambda_1, \dots, \lambda_N, y_1, \dots, y_N) \\ &\text{subject to } \lambda_i \geq 0 \quad \text{and} \quad y_i \in Y \quad \text{for } i = 1, \dots, N, \quad \sum_{i=1}^N \lambda_i = 1, \end{aligned}$$

where

$$I(\lambda_1, \dots, \lambda_N, y_1, \dots, y_N) = \inf \left\{ \sum_{i=1}^N \lambda_i f(x, y_i): x \in X \right\}$$

and where N is any integer greater than or equal to the number of y for which $f(x^*, y) = \rho^*$. The optimal λ_i and y_i in (2.9) correspond to the size and the location of the jumps in λ^* . The discrete dual (2.9) will now be studied in a general setting.

The generalized finite sequence space of Charnes, Cooper and Kortanek (see [5]–[7]) is a natural setting for the discrete dual. Let Λ denote a vector space of real-valued functions defined on Y where $\lambda \in \Lambda$ if and only if $\lambda(y) = 0$ for all but a finite number of y in Y . Instead of writing $\lambda(y)$, we write λ_y and we consider λ_y the y th component of λ . Given $\lambda \in \Lambda$, the collection of y in Y for which $\lambda_y \neq 0$ is the

support of λ . In [5] the space Λ is called a *generalized finite sequence space*. Given $\lambda \in \Lambda$, let us define the dual functional

$$I(\lambda) = \inf \left\{ \sum_{y \in Y} \lambda_y f(x, y) : x \in X \right\}.$$

The dual problem is

$$(2.10) \quad \text{maximize } \left\{ I(\lambda) : \lambda \in \Lambda, \lambda \geq 0, \sum_{y \in Y} \lambda_y = 1 \right\}.$$

THEOREM 2.2. *If λ^* is feasible for (2.10), $x^* \in X$, and*

$$(2.11) \quad I(\lambda^*) = \sup \{ f(x^*, y) : y \in Y \},$$

then λ^ is optimal in (2.10), x^* is optimal in (2.2), and $f(x^*, y) = I(\lambda^*)$ for each y in the support of λ^* . Moreover, letting S denote the support of λ^* , we have*

$$(2.12) \quad \min_{x \in X} \max_{y \in S} f(x, y) = \min_{x \in X} \max_{y \in Y} f(x, y).$$

Proof. If the components of λ are nonnegative and sum to 1 and if $\Gamma \subset Y$ is any finite subset which contains the support of λ , then the following relations hold for any $x \in X$:

$$\begin{aligned} I(\lambda) &= \inf \left\{ \sum_{y \in \Gamma} \lambda_y f(z, y) : z \in X \right\} \\ &\leq \sum_{y \in \Gamma} \lambda_y f(x, y) \\ (2.13) \quad &\leq \left(\sum_{y \in \Gamma} \lambda_y \right) \max \{ f(x, y) : y \in \Gamma \} \\ &= \max \{ f(x, y) : y \in \Gamma \} \\ &\leq \sup \{ f(x, y) : y \in Y \} \\ &= \Phi(x). \end{aligned}$$

(The last equality is the definition of $\Phi(x)$.) Hence, $I(\lambda) \leq \Phi(x)$ whenever λ is feasible for (2.10) and $x \in X$. Since $I(\lambda^*) = \Phi(x^*)$ by (2.11), we conclude from (2.13) that λ^* is optimal in (2.10) and x^* is optimal in (2.2). If S is the support of λ^* , then (2.13) also tells us that

$$(2.14) \quad I(\lambda^*) \leq \sum_{y \in S} \lambda_y^* f(x^*, y) \leq \Phi(x^*).$$

But $I(\lambda^*) = \Phi(x^*)$ and the inequalities in (2.14) are equalities. Since $\lambda_y^* > 0$ and $f(x^*, y) \leq \Phi(x^*)$ for every $y \in S$ and since the components of λ^* sum to one, it follows from (2.14) that

$$(2.15) \quad I(\lambda^*) = \Phi(x^*) = f(x^*, y) \quad \text{for every } y \in S.$$

Finally, let us consider (2.12). Relation (2.13) implies that

$$(2.16) \quad I(\lambda^*) \leq \max \{ f(x, y) : y \in S \}$$

for every x in X . Taking the infimum over $x \in X$, (2.16) tells us that

$$(2.17) \quad I(\lambda^*) \leq \inf_{x \in X} \max_{y \in S} f(x, y).$$

Combining (2.15) and (2.17), we have

$$\Phi(x^*) = \max_{y \in S} f(x^*, y) = \min_{x \in X} \max_{y \in S} f(x, y),$$

which completes the proof of (2.12). \square

For any $S \subset Y$, we have the trivial relation

$$\min_{x \in X} \max_{y \in S} f(x, y) \leq \min_{x \in X} \max_{y \in Y} f(x, y).$$

Theorem 2.2 tells us that if the value of the dual problem (2.10) is equal to the value of the primal problem (2.2), then there exists a finite set $S \subset Y$ such that (2.12) holds. Therefore, one strategy for solving the minimax problem (2.1) is to start with a finite set S and adjust it until (2.12) is satisfied. The simplified problem

$$\text{minimize}_{x \in X} \text{maximum}_{y \in S} f(x, y)$$

is often easier to solve than the original problem (2.1). This idea is developed further in § 5. When there exists a finite set S satisfying (2.12), we say that the minimax problem is *reducible*.

How often is a minimax problem reducible? Let us consider the following example:

$$(2.18) \quad \text{minimize}_{x \in R} \text{maximum}_{y \in R} \beta x^2 + 2\alpha xy + y^2.$$

Since the maximum is attained at $y = \alpha x$, the function Φ is given by

$$\Phi(x) = (\alpha^2 + \beta)x^2.$$

When $\alpha^2 + \beta$ is nonnegative, $\Phi(x)$ achieves its minimum at $x = 0$ and when x is 0, the maximizing value of y in (2.18) is $y = 0$. On the other hand, suppose that $S = \{0\}$ and let us consider the restricted minimax problem

$$\text{minimize}_{x \in R} \text{maximum}_{y=0} \beta x^2 + 2\alpha xy - y^2,$$

which is equivalent to

$$\text{minimize}_{x \in R} \beta x^2.$$

For $\beta \geq 0$, the minimum is attained at $x = 0$ while for $\beta < 0$, βx^2 has no minimum. In summary, for $\beta < -\alpha^2$, Φ has no minimum. For $\beta \in [-\alpha^2, 0)$, no set S satisfies (2.12). And for $\beta \geq 0$, the minimax problem is reducible with $S = \{0\}$.

Now suppose that $f: R^2 \rightarrow R$ is an arbitrary twice continuously differentiable function. We assume that there exists a solution x^* to the minimax problem (2.1) and there exists y^* such that

$$f(x^*, y^*) = \text{maximum}_{y \in R} \{f(x^*, y)\}$$

and

$$(2.19) \quad \frac{\partial^2 f}{\partial y^2}(x^*, y^*) < 0.$$

Then for x in a neighborhood of x^* , the implicit function theorem gives us a differentiable function $y(\cdot)$ such that $y(x^*) = y^*$ and

$$(2.20) \quad \frac{\partial f}{\partial y}(x, y(x)) = 0.$$

By (2.19), $y(x)$ is a local maximizer of $f(x, \cdot)$ for x near x^* . Let us assume that $y(x)$ is the global maximizer of $f(x, \cdot)$. Since x^* minimizes $\Phi(x)$, we know that $\Phi''(x^*) \geq 0$. Applying the chain rule to $\Phi(x) = f(x, y(x))$ and utilizing (2.20), it can be shown that

$$(2.21) \quad \frac{\partial^2 \Phi}{\partial x^2}(x^*) = \frac{\partial^2 f}{\partial x^2}(x^*, y^*) - \frac{((\partial^2 f / \partial x \partial y)(x^*, y^*))^2}{(\partial^2 f / \partial y^2)(x^*, y^*)}.$$

If X is restricted to a neighborhood of x^* , then (2.12) holds for $S = \{y^*\}$ provided

$$(2.22) \quad \frac{\partial^2 f}{\partial x^2}(x^*, y^*) > 0.$$

On the other hand, by (2.21), the inequality $\Phi''(x^*) \geq 0$ only guarantees that

$$(2.23) \quad \frac{\partial^2 f}{\partial x^2}(x^*, y^*) \geq \frac{((\partial^2 f / \partial x \partial y)(x^*, y^*))^2}{(\partial^2 f / \partial y^2)(x^*, y^*)}.$$

In other words, relation (2.22) is sufficient for the minimax problem to be reducible when X is a neighborhood of x^* while the fact that x^* minimizes Φ only implies (2.23).

Returning to example (2.18), observe that the range of α and β for which the minimax problem is reducible is larger than the range for which the minimax problem is not reducible. Consequently, if α and β are chosen randomly and if the minimax problem (2.18) has a solution, then the problem is probably reducible. The problem (see [19]) of optimally coating a surface to minimize the maximum reflection associated with incoming waves is an example of a very complicated nonconvex problem that is reducible even though $I(\lambda^*) < \Phi(x^*)$. Based on these observations, we feel that algorithms which search for a set S satisfying (2.12) will apply to a broad class of problems.

Although a general minimax problem is not necessarily reducible, a convex finite-dimensional minimax problem is always reducible. Dem'yanov and Malozemov [13] establish this fact in the following setting: X is a closed convex subset of R^n , Y is a compact subset of R^m , $f(x, y)$ is continuous and continuously differentiable with respect to x on $\tilde{X} \times Y$ where \tilde{X} is an open set containing X , $f(\cdot, y)$ is convex for each $y \in Y$, and there exists a solution to (2.1). One can also establish (2.12) under weaker assumptions using Clarke's result [10, Thm. 2.1] and properties of subgradients found in Rockafellar's book [29]. The analysis of Charnes, Cooper and Kortanek [7] also appears applicable. For completeness, we now derive (2.12) using Theorem 2.1 and results from [29]. First, let us consider the case where Y is a finite set.

LEMMA 2.3. *Suppose that Y is a finite set, X is a nonempty convex subset of R^n , and $f(\cdot, y)$ is convex for each $y \in Y$. If there exists a solution x^* to the primal problem (2.2), then there exists a solution λ^* to the dual problem (2.10) and $I(\lambda^*) = \Phi(x^*)$. Moreover, λ^* can be chosen so that its support has at most $n + 1$ elements.*

(It follows from Theorem 2.2 that under the hypotheses of Lemma 2.3, (2.12) holds for some set S which has at most $n + 1$ elements.)

Proof. By Theorem 2.1 and by the observations that follow the theorem, there exists a solution λ^* to the dual problem (2.10) and $I(\lambda^*) = \Phi(x^*)$. Let m denote the number of elements in Y and assume for convenience that $Y = \{1, \dots, m\}$. The equality $I(\lambda^*) = \Phi(x^*)$ combined with (2.13) tell us that

$$(2.24) \quad I(\lambda^*) = \text{minimum}_{x \in X} \sum_{i=1}^m \lambda_i^* f_i(x) = \sum_{i=1}^m \lambda_i^* f_i(x^*)$$

where $f_i(\cdot)$ denotes $f(\cdot, i)$. Let $\partial f_i(x)$ denote the collection of subgradients of f_i at x .

By [29, Thm. 27.4] and by (2.24), there exists $g_i \in \partial f_i(x^*)$ such that

$$(2.25) \quad \left\langle \sum_{i=1}^m \lambda_i^* g_i, x - x^* \right\rangle \geq 0 \quad \text{for every } x \in X.$$

Define the set $P = \{i \in [1, m]: \lambda_i^* > 0\}$. Since $\lambda^* \geq 0$ and $\lambda_1^* + \cdots + \lambda_m^* = 1$, it follows from [29, Thm. 17.1] that there exists nonnegative scalars μ_i for $i \in P$ such that the support of μ has at most $n+1$ elements,

$$\sum_{i \in P} \mu_i g_i = \sum_{i=1}^m \lambda_i^* g_i \quad \text{and} \quad \sum_{i \in P} \mu_i = 1.$$

Hence, (2.25) yields

$$(2.26) \quad \left\langle \sum_{i \in P} \mu_i g_i, x - x^* \right\rangle \geq 0 \quad \text{for every } x \in X.$$

Again by [29, Thm. 27.4] and by (2.26), we have

$$(2.27) \quad \sum_{i \in P} \mu_i f_i(x^*) = \text{minimum}_{x \in X} \sum_{i \in P} \mu_i f_i(x).$$

The identity $\mathbf{l}(\lambda^*) = \Phi(x^*)$ combined with Theorem 2.2 imply that $f_i(x^*) = \Phi(x^*)$ for every $i \in P$. Since the μ_i sum to one, it follows from (2.27) that

$$\Phi(x^*) = \text{minimum}_{x \in X} \sum_{i \in P} \mu_i f_i(x) = \mathbf{l}(\mu).$$

By Theorem 2.2, μ is a solution to the dual problem. \square

THEOREM 2.4. *Suppose that Y is a nonempty compact subset of a normed space, X is a nonempty compact, convex subset of \mathbb{R}^n , and f is a real-valued function defined on $\overset{\circ}{X} \times Y$ where $\overset{\circ}{X}$ is a relatively open set containing X . If $f(\cdot, y)$ is convex and lower semicontinuous for each y in Y and $f(x, \cdot)$ is continuous for each x in $\overset{\circ}{X}$, then there exists a solution x^* to (2.2), there exists a solution λ^* to (2.10), and $\mathbf{l}(\lambda^*) = \Phi(x^*)$. Moreover, λ^* can be chosen so that its support has at most $n+1$ elements.*

Proof. Let $\{y_1, y_2, \dots\}$ be a dense subset of Y and define $\Phi^N: X \rightarrow \mathbb{R}$ by

$$\Phi^N(x) = \text{maximum} \{f(x, y_i): i = 1, \dots, N\}.$$

Since $f(\cdot, y)$ is lower semicontinuous, Φ^N is lower semicontinuous. Thus the compactness of X guarantees the existence of $x^N \in X$ such that

$$\Phi^N(x^N) = \text{minimum}_{x \in X} \Phi^N(x).$$

In addition, the compactness of X implies that a subsequence of the x^N converges to some $x^* \in X$. By [29, Thm. 10.8] and the assumption that $f(x, \cdot)$ is continuous and $\{y_1, y_2, \dots\}$ is a dense subset of Y , Φ^N converges to Φ uniformly on X . Consequently, we have

$$\Phi(x^*) = \text{minimum} \{\Phi(x): x \in X\}.$$

Referring to Lemma 2.3, there exists a set $Y^N \subset \{y_1, \dots, y_N\}$ where Y^N has at most $n+1$ elements and there exists a corresponding set of nonnegative scalars $\{\lambda_y^N: y \in Y^N\}$ which sum to one and which satisfy the relation

$$(2.28) \quad \text{minimum}_{x \in X} \sum_{y \in Y^N} \lambda_y^N f(x, y) = \Phi^N(x^N).$$

Since the sets Y^N and the scalars λ_y^N lie in compact sets, we can extract convergent subsequences. Assume for convenience that x^N converges to x^* , λ^N converges to λ^* and Y^N converges to Y^* . For any $x \in X$,

$$(2.29) \quad \lim_{N \rightarrow \infty} \sum_{y \in Y^N} \lambda_y^N f(x, y) = \sum_{y \in Y^*} \lambda_y^* f(x, y)$$

since $f(x, \cdot)$ is continuous. Minimizing the left side of (2.29) over $x \in X$ yields

$$\lim_{N \rightarrow \infty} I(\lambda^N) \leq \sum_{y \in Y^*} \lambda_y^* f(x, y)$$

for every $x \in X$. Since $I(\lambda^N)$ is equal to $\Phi(x^N)$ and since $\Phi(x^N)$ approaches $\Phi(x^*)$ as N tends to infinity, we conclude that

$$(2.30) \quad \Phi(x^*) \leq \sum_{y \in Y^*} \lambda_y^* f(x, y)$$

for every $x \in X$. Minimizing the right side of (2.30) over x in X yields the relation $\Phi(x^*) \leq I(\lambda^*)$ and by (2.13), λ^* is a solution to the dual problem (2.10). \square

In Theorem 2.4, we can replace the assumption that X is compact with the assumption that X is closed, however, the existence of x^* is lost.

COROLLARY 2.5. *Suppose that Y is a nonempty compact subset of a normed space, X is a nonempty closed, convex subset of R^n and f is a real-valued function defined on $\hat{X} \times Y$ where \hat{X} is a relatively open set containing X . If $f(\cdot, y)$ is convex and lower semicontinuous for each y in Y and $f(x, \cdot)$ is continuous for each x in \hat{X} , then there exists a solution λ^* to (2.10), and*

$$I(\lambda^*) = \inf_{x \in X} \Phi(x).$$

Moreover, λ^* can be chosen so that its support has at most $n+1$ elements.

Proof. Given an integer N , define the set

$$X^N = \{x \in X: \|x\| \leq N\}$$

where $\|\cdot\|$ is any norm for R^n . We assume that N is large enough that X^N is nonempty. By Theorem 2.4, there exists $\lambda^N \in \Lambda$ such that

$$I^N(\lambda^N) = \text{minimum}_{x \in X^N} \Phi(x)$$

where I^N is defined by

$$I^N(\lambda) = \text{minimum}_{x \in X^N} \sum_{y \in Y} \lambda_y f(x, y)$$

and where the support Y^N of λ^N has at most $n+1$ elements. From (2.10), the components of λ^N are nonnegative and sum to one. Since Y^N and the components of λ^N lie in compact sets, there exists a subsequence of the λ^N which converges to some λ^* . Let Y^* denote the support of λ^* and assume for convenience that the entire sequence $\{\lambda^N\}$ converges to λ^* . For each $x \in X$, the continuity of $f(x, \cdot)$ implies that

$$(2.31) \quad \lim_{N \rightarrow \infty} \sum_{y \in Y^N} \lambda_y^N f(x, y) = \sum_{y \in Y^*} \lambda_y^* f(x, y).$$

We minimize the left side of (2.31) over $x \in X^N$ to obtain

$$(2.32) \quad \lim_{N \rightarrow \infty} I^N(\lambda^N) \leq \sum_{y \in Y^*} \lambda_y^* f(x, y).$$

Minimizing the right side of (2.32) over $x \in X$ yields

$$I(\lambda^*) \geq \lim_{N \rightarrow \infty} I^N(\lambda^N),$$

and since $\Phi(x^N)$ is equal to $I^N(\lambda^N)$, we have

$$I(\lambda^*) \geq \lim_{N \rightarrow \infty} \Phi(x^N) = \inf_{x \in X} \Phi(x).$$

Finally, (2.13) tells us that λ^* is a solution to the dual problem (2.10). \square

3. Augmented Lagrangians. A nonconvex problem often has a duality gap and the value of the dual problem is strictly less than the value of the primal problem. A strategy for bridging this gap emanates from work of Arrow and Solow [1], Hestenes [22], and Powell [28]. The basic idea is to augment the ordinary Lagrangian with a penalty term. To introduce this penalized dual approach, we first consider a finite-dimensional mathematical program with equality constraints:

$$(3.1) \quad \begin{array}{ll} \text{minimize} & f(x) \\ \text{subject to} & h(x) = 0, \quad x \in R^n \end{array}$$

where $f: R^n \rightarrow R$ and $h: R^n \rightarrow R^m$. (Mathematical programs in a Hilbert space setting are studied in [16] and [27].) The ordinary Lagrangian corresponding to (3.1) is $I(\lambda, x) = f(x) + \lambda^T h(x)$. Letting r be a positive scalar and letting $|\cdot|$ denote the Euclidean norm, the augmented Lagrangian corresponding to the penalty term $r|h(x)|^2$ is

$$(3.2) \quad L(\lambda, x) = f(x) + \lambda^T h(x) + r|h(x)|^2.$$

To illustrate the type of results that can be proved about the augmented Lagrangian, we state the following theorem which is extracted from Bertsekas [2]. In stating this theorem, our convention is that the gradient ∇ is a row vector and the gradient ∇h of the vector valued function h is a $m \times n$ matrix with i th row ∇h_i for $i = 1$ to m . Also, we let ∇^2 denote the Hessian matrix of second partial derivatives and the phrase “ x^* is a local minimizer for (3.1)” means that $h(x^*) = 0$ and $f(x^*) \leq f(x)$ whenever $h(x) = 0$ and x is near x^* .

THEOREM 3.1. *Suppose that x^* is a local minimizer for (3.1), both f and h are twice continuously differentiable in a neighborhood of x^* , and the rows of $\nabla h(x^*)$ are linearly independent. If $\lambda = \lambda^*$ is the solution to the equation*

$$(3.3) \quad \nabla f(x^*) + \lambda^{*T} \nabla h(x^*) = 0$$

and $\nabla_x^2 I(\lambda^, x^*)$ is positive definite in the null space of $\nabla h(x^*)$, then there exists a parameter s and a neighborhood N of x^* such that the problem*

$$\text{minimize } \{L(\mu, x): x \in N\}$$

has a unique minimizer $x_{\mu,r}$ whenever $r \geq s$ and $|\lambda^ - \mu| \leq r/s$. Moreover, there exists a constant c , independent of r and μ , such that*

$$(3.4) \quad |x_{\mu,r} - x^*| + |\lambda_{\mu,r} - \lambda^*| \leq c|\mu - \lambda^*|/r$$

where $\lambda_{\mu,r} := \mu + 2rh(x_{\mu,r})$.

Now let us consider the inequality constrained problem

$$(3.5) \quad \begin{array}{ll} \text{minimize} & f(x) \\ \text{subject to} & g(x) \leq 0, \quad x \in R^n \end{array}$$

where $g: R^n \rightarrow R^l$. Rockafellar's augmented Lagrangian (see [30]) is obtained by converting the inequality constraints to equality constraints using slack variables,

forming the augmented Lagrangian corresponding to these equality constraints, and minimizing over the slack variables to obtain

$$(3.6) \quad L(\lambda, x) = f(x) + \sum_{i \in I_+} (\lambda_i g_i(x) + r g_i(x)^2) - \frac{1}{4r} \sum_{i \in I_-} \lambda_i^2$$

where the sets I_+ and I_- are defined by

$$I_+ = \{i \in [1, l]: 2r g_i(x) + \lambda_i \geq 0\} \quad \text{and} \quad I_- = \{i \in [1, l]: 2r g_i(x) + \lambda_i < 0\}.$$

Thus the part of the Lagrangian (3.6) corresponding to indices $i \in I_+$ resembles the equality Lagrangian (3.2) while the part of the Lagrangian corresponding to indices $i \in I_-$ is locally independent of x . Theorem 3.1 also applies to inequality constrained problems since an inequality can be converted to an equality using Valentine's device (see [2] and [33]).

Augmented Lagrangians are now applied to the minimax problem (2.1). Let us consider the case where the set Y connected with the maximization is the integers $\{1, 2, \dots\}$ and at some solution x^* to (2.2), we have

$$f(x^*, i) \geq f(x^*, i+1)$$

for each i . We assume that $f(x^*, i) = \Phi(x^*)$ for $i = 1, \dots, N$ while $f(x^*, i) < \Phi(x^*)$ for $i > N$. Recall from § 2 that the set $S = \{1, \dots, N\}$ is usually the support of a dual multiplier λ^* . If a good estimate for x^* is known, then S is known and, at least locally, x^* is a solution to the equality constrained problem

$$(3.7) \quad \text{minimize } \{\rho: f(x) = \rho \mathbf{1}, x \in X, \rho \in R\}$$

where $\mathbf{1}$ denotes the vector in R^N with every component equal to 1 and $f(x)$ denotes the vector-valued function with i th component $f_i(x)$ equal to $f(x, i)$ for $i = 1, \dots, N$. The corresponding augmented Lagrangian is

$$(3.8) \quad L(\lambda, x, \rho) = \rho + \lambda^T (f(x) - \rho \mathbf{1}) + r |f(x) - \rho \mathbf{1}|^2.$$

In practice, the support set S for the minimax problem is not known, and we must use the inequality constrained formulation

$$\text{minimize } \{\rho: f(x) \leq \rho \mathbf{1}, x \in X, \rho \in R\}.$$

Since this formulation is equivalent to

$$(3.9) \quad \text{minimize } \{\rho: f(x) + z = \rho \mathbf{1}, z \geq 0, x \in X, \rho \in R, z \in R^N\},$$

the analogue of Rockafellar's augmented Lagrangian is

$$(3.10) \quad L(\lambda, x, \rho) = \text{minimum } \{\rho + \lambda^T (f(x) + z - \rho \mathbf{1}) + r |f(x) + z - \rho \mathbf{1}|^2: z \geq 0, z \in R^N\}.$$

Since the extremum in (3.10) is a strictly convex function of z , there exists a unique z which attains the minimum, and by (3.6), the augmented Lagrangian (3.10) can be expressed:

$$L(\lambda, x, \rho) = \rho + \sum_{i \in I_+} \{\lambda_i (f_i(x) - \rho) + r (f_i(x) - \rho)^2\} + \frac{1}{4r} \sum_{i \in I_-} \lambda_i^2$$

where

$$I_+ = \{i \in [1, N]: 2r (f_i(x) - \rho) + \lambda_i \geq 0\} \quad \text{and} \quad I_- = \{i \in [1, N]: 2r (f_i(x) - \rho) + \lambda_i < 0\}.$$

When using an augmented Lagrangian to solve the constrained optimization problem (3.9), we minimize $L(\lambda, x, \rho)$ over x in X and ρ in R to obtain the dual

functional $L(\lambda)$. Then the dual functional is maximized over λ to obtain a solution λ^* to the dual problem

$$\text{maximize } \{L(\lambda): \lambda \in R^N\}.$$

As we will show shortly, the minimum of $L(\lambda, x, \rho)$ over ρ can be computed explicitly. Let $L(\lambda, x)$ denote the partly minimized functional defined by

$$(3.11) \quad L(\lambda, x) = \text{minimum } \{L(\lambda, x, \rho): \rho \in R\}.$$

LEMMA 3.2. *There exists a unique ρ , which attains the minimum in (3.11).*

Proof. Defining the parameter

$$\rho_1 = \text{maximum } \{f_i(x) + \lambda_i/2r: i = 1, \dots, N\},$$

observe that $L(\lambda, x, \rho) = \rho$ plus a constant (independent of ρ) for $\rho \geq \rho_1$. Thus the minimum of $L(\lambda, x, \cdot)$ occurs on the interval $[-\infty, \rho_1]$. By [17, Cor. A6], the derivative of $L(\lambda, x, \rho)$ with respect to ρ is a Lipschitz continuous function of ρ on bounded intervals. Since the second derivative of $L(\lambda, x, \cdot)$ is at least $2r$ on $(-\infty, \rho_1]$, we conclude that $L(\lambda, x, \cdot)$ is strictly convex on $(-\infty, \rho_1]$ and there exists a unique minimum. \square

To compute the minimum for $L(\lambda, x, \cdot)$, we define the parameters

$$\rho_i = f_i(x) + \lambda_i/2r$$

for $i = 1, \dots, N$ and we reindex the components of f and λ so that

$$\rho_1 \geq \rho_2 \geq \dots \geq \rho_N.$$

Since $L(\lambda, x, \cdot)$ is strictly convex on $(-\infty, \rho_1]$, the derivative of $L(\lambda, x, \cdot)$ is monotone increasing (with slope at least $2r$). For ρ between ρ_{j+1} and ρ_j , the derivative of $L(\lambda, x, \cdot)$ is given by

$$(3.12) \quad \frac{d}{d\rho} L(\lambda, x, \rho) = 1 + 2rj\rho - \sum_{i=1}^j (\lambda_i + 2rf_i(x)).$$

With the convention that ρ_{N+1} is $-\infty$, there exists an interval $[\rho_{j+1}, \rho_j]$ where the derivative changes sign. Since $L(\lambda, x, \cdot)$ is a quadratic on this interval, the minimizer ρ^* of the quadratic is easily evaluated:

$$\rho^* = \frac{-1 + \sum_{i=1}^j (\lambda_i + 2rf_i(x))}{2rj}.$$

Since the computer time to sort $f_i(x) + \lambda_i/2r$ into decreasing order is proportional to $N \log_2 N$ (see [25]) while the time to evaluate the derivative (3.12) for $\rho = \rho_1$ through $\rho = \rho_N$ is proportional to N , the computer time required to minimize $L(\lambda, x, \cdot)$ is proportional to $N \log_2 N$.

4. General minimax problems. Now let us return to the minimax problem

$$(4.1) \quad \text{minimize}_{x \in X} \text{maximum}_{y \in Y} f(x, y)$$

where f is a real-valued function defined on $X \times Y$. As demonstrated in the proof of Theorem 2.4, one method to solve the minimax problem is to introduce a set $Y^N \subset Y$ with N elements and to consider the approximation

$$\text{minimize}_{x \in X} \text{maximum}_{y \in Y^N} f(x, y).$$

If $x^N \in X$ has the property that

$$\text{maximum}_{y \in Y^N} f(x^N, y) = \text{minimum}_{x \in X} \text{maximum}_{y \in Y^N} f(x, y)$$

where $Y^1 \subset Y^2 \subset Y^3 \subset \dots$ and the union of Y^N over N is a dense subset of Y , then under the hypotheses of Theorem 2.4, every convergent subsequence of $\{x^N\}$ approaches a solution to (4.1). Moreover, defining $\Phi^N: X \rightarrow R$ by

$$\Phi^N(x) = \text{maximum}_{y \in Y^N} f(x, y),$$

Dem'yanov and Malozemov [13] show that if x^N is an extreme point of Φ^N , then every convergent subsequence of $\{x^N\}$ approaches an extreme point of the function

$$\Phi(x) = \text{maximum}_{y \in Y} f(x, y).$$

Their assumptions are that $X \subset R^n$, $Y \subset R^m$, Y is compact, X is closed and convex, and $f(x, y)$ is continuous and continuously differentiable with respect to x on $\tilde{X} \times Y$ where \tilde{X} is an open set containing X .

The principal difficulty involved with primal algorithms for minimax problems is that the function Φ is almost always nondifferentiable at its minimum. Ways to circumvent this lack of smoothness are developed in the algorithms of Dem'yanov [12] and others. Unlike the primal function, the dual function is usually smooth at the solution to the dual problem. Nonetheless, as we now show, the dual problem can be ill conditioned and algorithms for solving the dual problem must deal with this conditioning. In describing the ill conditioning associated with the dual problem, we assume for simplicity that X is R^n . The dual functional corresponding to Y^N is

$$(4.2) \quad \mathbf{I}(\lambda) = \infimum_{x \in X} \mathbf{I}(\lambda, x)$$

where the Lagrangian $\mathbf{I}: R^N \times R^n \rightarrow R$ is defined by

$$\mathbf{I}(\lambda, x) = \sum_{y \in Y^N} \lambda_y f(x, y).$$

Suppose that $x = x^*$ attains the minimum in (4.2) when $\lambda = \lambda^*$, that $f(x, y)$ is twice continuously differentiable with respect to x for every $y \in Y^N$, and that the Hessian

$$(4.3) \quad \sum_{y \in Y^N} \lambda_y^* \nabla_x^2 f(x^*, y)$$

is positive definite. Since x^* attains the minimum in (4.2) when $\lambda = \lambda^*$, the gradient of the Lagrangian with respect to x is zero at $x = x^*$: $\nabla_x \mathbf{I}(\lambda^*, x^*) = 0$. Since the Hessian (4.3) is nonsingular, the implicit function theorem tells us that for λ near λ^* , there exists an $x(\lambda)$ that satisfies the equation

$$(4.4) \quad \nabla_x \mathbf{I}(\lambda, x(\lambda)) = 0,$$

and by the second order sufficiency condition, $x(\lambda)$ is a local minimizer for $\mathbf{I}(\lambda, \cdot)$. Let us assume that $x(\lambda)$ is also a global minimizer for $\mathbf{I}(\lambda, \cdot)$. By the chain rule and (4.4), we have

$$(4.5) \quad \frac{\partial \mathbf{I}}{\partial \lambda_y}(\lambda) = f(x(\lambda), y) + \nabla_x \mathbf{I}(\lambda, x(\lambda)) \frac{\partial x}{\partial \lambda_y}(x(\lambda), \lambda) = f(x(\lambda), y).$$

Differentiating (4.4) with respect to λ_z yields

$$\frac{\partial x}{\partial \lambda_z}(\lambda) = -\nabla_x^2 \mathbf{I}(\lambda, x(\lambda))^{-1} \nabla_x f(x(\lambda), z)^T,$$

and differentiating (4.5) with respect to λ_z gives us

$$\frac{\partial^2 \mathbf{I}}{\partial \lambda_y \partial \lambda_z}(\lambda) = -\nabla_x f(x(\lambda), y) \nabla_x^2 \mathbf{I}(\lambda, x(\lambda))^{-1} \nabla_x f(x(\lambda), z)^T.$$

Hence, the Hessian of the dual functional has the form

$$\frac{\partial^2 \mathbf{I}}{\partial \lambda^2}(\lambda) = -GF^{-1}G^T$$

where F is the $n \times n$ matrix given by

$$F = \sum_{y \in Y^N} \lambda_y \nabla_x^2 f(x(\lambda), y)$$

and G is the $N \times n$ matrix whose y th row is $\nabla_x f(x(\lambda), y)$ for $y \in Y^N$.

Remember that if λ is feasible in the dual problem, then the components of λ sum to one. If P is a $(N-1) \times N$ matrix whose rows are a basis in R^N for the space orthogonal to the vector with every component equal to one, then the convergence speed of steepest ascent applied to the dual functional is related to the distribution of eigenvalues for the Hessian of \mathbf{I} evaluated in the row space of P . The Hessian of $\mathbf{I}(P^T \mu)$ with respect to μ is given by $-(PG)F^{-1}(PG)^T$. Since PG is $(N-1) \times n$ while the Hessian of \mathbf{I} with respect to μ is $(N-1) \times (N-1)$, we conclude that the Hessian is singular whenever $N-1$ is greater than n , or equivalently, whenever N is greater than $n+1$.

Now consider the strategy of Theorem 2.4 where we introduce a set $Y^N \subset Y$ for which

$$\lim_{N \rightarrow \infty} \inf \{|y - z| : z \in Y^N\} = 0$$

for every $y \in Y$. By its structure, the Hessian of $\mathbf{I}(\lambda)$ is singular whenever the support of λ has more than $n+1$ elements. The convergence speed of numerical schemes (like steepest ascent) for solving the dual problem is governed by the ratio between the absolute largest eigenvalue and the absolute smallest eigenvalue of the Hessian, and as the ratio tends to infinity, the convergence speed approaches zero. If the support of λ has more than $n+1$ elements, then the smallest eigenvalue is zero, the ratio is infinity, and convergence is slow. In other words, asymptotically, it is impractical to maximize the dual functional using say steepest descent (or almost any standard algorithm) when N is large.

The augmented Lagrangian is subject to similar instabilities. For the inequality constrained problem (3.5) and the augmented Lagrangian (3.6), Rockafellar shows in an appropriate setting (see [31]) that

$$(4.6) \quad \frac{\partial^2 \mathbf{L}}{\partial \lambda_+^2}(\lambda^*) = -\nabla g_+(x^*) F_r^{-1} \nabla g_+(x^*)^T, \quad \frac{\partial^2 \mathbf{L}}{\partial \lambda_-^2}(\lambda^*) = -\frac{1}{2r} I, \quad \frac{\partial^2 \mathbf{L}}{\partial \lambda_+ \partial \lambda_-}(\lambda^*) = 0$$

where $\mathbf{L}(\lambda) = \inf \{\mathbf{L}(\lambda, x) : x \in R^n\}$, λ_{\pm} and g_{\pm} denote the components of λ and g corresponding to indices $i \in I_{\pm}$, and

$$F_r = \nabla^2 f(x^*) + \sum_{i \in I_+} (\lambda_i^* \nabla^2 g_i(x^*) + 2r \nabla g_i(x^*)^T \nabla g_i(x^*)).$$

Hence, the Hessian (4.6) is singular when the number of elements in I_+ is greater than n .

Recall that the minimax problem corresponding to Y^N can be written as the inequality constrained problem

$$(4.7) \quad \begin{aligned} &\text{minimize } \rho \\ &\text{subject to } x \in X, \quad \rho \in R, \quad f(x, y) \leq \rho \quad \text{for every } y \in Y^N. \end{aligned}$$

Thus the y th component of g in (3.5) is identified with $f(x, y) - \rho$. Since the independent variables in (4.7) are x and ρ , the primal problem (4.7) is formulated in R^{n+1} when $X \subset R^n$ and the Hessian

$$\frac{\partial^2 L}{\partial \lambda^2}(\lambda^*)$$

is singular when the number of elements in I_+ is greater than $n+1$. Observe that the augmented Lagrangian is better conditioned than the ordinary Lagrangian, since the part of the Hessian corresponding to the second partial derivative with respect to λ_- is a multiple of the identity matrix which is perfectly conditioned. Nonetheless, as N grows, the Hessian can still become singular.

Now let us develop an algorithm to solve the minimax problem. Given $x \in X$, let $y_1(x), y_2(x), \dots$ denote the local maxima of $f(x, \cdot)$ on Y . Our algorithm for solving the minimax problem has two phases. In both phases, we utilize the inequality formulation (4.7). However, in *phase one*, Y^N is a fixed set $\{y_1, \dots, y_N\}$ contained in Y and N is "large." In *phase two*, Y^N has the form $\{y_1(x), \dots, y_N(x)\}$ and N is "small." If $f(x, \cdot)$ has a finite number of local maxima on Y , then the phase two problem

$$(4.8) \quad \begin{aligned} &\text{minimize } \rho \\ &\text{subject to } x \in X, \quad \rho \in R, \quad f(x, y_i(x)) \leq \rho \quad \text{for } i = 1, \dots, N \end{aligned}$$

is usually equivalent to (4.1) for N sufficiently large. Since (4.8) involves tracking the peaks $y_i(\cdot)$, solving (4.8) is more difficult than solving (4.7). Hence, phase two should only be activated when the algorithm applied to (4.8) converges rapidly. For many mathematical programming algorithms, rapid convergence only occurs in a *neighborhood* of an optimum. For this reason, it is more efficient to apply an unsophisticated algorithm to the ill conditioned problem (4.7) generating a starting guess for a fast algorithm that solves (4.8).

Let us now show in detail how an algorithm such as [18, Algorithm 5.2] or any other algorithm with similar structure can be used to solve either (4.7) or (4.8). Each iteration of Algorithm 5.2 has the following steps: A restoration step where the equality and binding inequality constraints are partially satisfied, a multiplier update where an improved approximation to the optimal dual multipliers is generated, an unconstrained minimization step where the augmented Lagrangian is minimized using (for example) several preconditioned conjugate gradient iterations, and an adjustment to the penalty when a minimizer of the augmented Lagrangian has essentially been computed. This algorithm monitors the convergence of the iterations to a Kuhn-Tucker point and typically, both the restoration step and the multiplier update are only activated in a neighborhood of an optimum. In other words, unless the iterations are in a neighborhood of an optimum, Algorithm 5.2 is essentially a preconditioned conjugate gradient method applied to an augmented Lagrangian. In [18] we show that Algorithm 5.2 is globally convergent while the iterations are locally quadratically convergent. When applying Algorithm 5.2 to either (4.7) or (4.8), the following four issues must be considered:

(1) *The initialization of phase one and phase two.* That is, given a guess for a solution to (4.1), what is the corresponding starting guess for the multipliers? Given an approximation to a solution to (4.7), what is the starting guess to (4.8)?

(2) *The addition and deletion of constraints.* After each iteration of an algorithm applied to either (4.7) or (4.8), we must delete "unnecessary" elements from Y^N and we must add "significant" elements to Y^N . The augmented Lagrangian will help to determine which elements to delete and which elements to add.

(3) *The elimination of ρ .* We introduced the parameter ρ to convert the minimax problem into an inequality constrained mathematical program. When applying a mathematical programming algorithm to either (4.7) or (4.8), we would like to eliminate the artificial variable ρ so that the iterations are expressed in terms of x and λ .

(4) *The computation of the gradient of the augmented Lagrangian.* When using the conjugate gradient method or any other gradient-based scheme to minimize the augmented Lagrangian, we need a formula for the gradient of the augmented Lagrangian with respect to x . Clarke's result [10, Thm. 2.1] can be used to compute this gradient.

To begin, let us consider the initialization of phase one. If x_1 is the starting guess in phase one, then in the absence of better information, let Y^N be the maximizers of $f(x_1, \cdot)$ on Y . In other words, $\eta \in Y^N$ if and only if

$$f(x, \eta) = \text{maximum}_{y \in Y} f(x, y).$$

In the absence of better information, the starting guess λ_1 for the multipliers corresponding to the constraint $f(x, y) \leq \rho$ is $\lambda_{1y} = 1/N$ for each $y \in Y^N$. The x starting guess for phase two is simply the final iteration x_k of phase one. To initialize the phase two multipliers, we collapse the components of the phase one multipliers around the nearest peak. That is, in phase one we generate a multiplier λ_k with support Y^N . Given an element y in Y^N , the index $\nu(y)$ of the nearest peak is

$$\nu(y) = \arg \min \{\|y - y_i(x_k)\| : i = 1, 2, \dots\}.$$

When more than one index achieves the minimum, let $\nu(y)$ be any one of them. Then the i th component of λ_1 , the starting guess for phase two, is the sum of the phase one multiplier components that correspond to elements of Y^N closest to $y_i(x_k)$:

$$\lambda_{1i} = \sum_{\substack{y \in Y^N \\ \nu(y)=i}} \lambda_{ky}.$$

Moreover, the starting set Y^N for phase two consists of those $y_i(\cdot)$ for which λ_{1i} is positive.
