

ON DIFFERENTIAL EVASION GAMES*

JIONGMIN YONG†

Abstract. The notions of evadability and strict evadability are defined for a nonlinear differential game with general closed convex terminal set. Sufficient conditions for strict evadability and evadability and a necessary condition for evadability are proved. The results are strengthened for the linear cases, including the heretofore untreated case in which the terminal set is an $(n-1)$ -dimensional subspace.

Key words. differential evasion games, evadability, strict evadability

AMS(MOS) subject classifications. 90D25, 90D26

1. Introduction. The problem of differential evasion games was first formulated and discussed by Pontryagin and Miščenko [17]. Since then, this problem has been studied extensively by many authors in various investigations [2]–[6], [8]–[18], [20] and [22]–[25].

The purpose of this paper is to complement, in some aspects, the known results about differential evasion games. We now state the evasion problem and some known results.

Suppose the differential game is governed by the following system:

$$(1.1) \quad \begin{aligned} \dot{z} &= f(t, z, u, v), \\ z(0) &= z_0 \end{aligned}$$

where $z \in \mathbb{R}^n$, $u \in U \subseteq \mathbb{R}^p$, $v \in V \subseteq \mathbb{R}^q$, $t \in \mathbb{R}^+ \equiv [0, \infty)$, $f: \mathbb{R}^+ \times \mathbb{R}^n \times U \times V \rightarrow \mathbb{R}^n$ is a given map and z_0 is the initial state. In the game, u is the pursuit control and v is the evasion control. The sets U and V are compact. Suppose that we are also given a subset M of \mathbb{R}^n . The game is terminated if, at some time $t_0 < \infty$, the trajectory $z(\cdot)$ of (1.1), corresponding to a pair of controls $u(\cdot)$ and $v(\cdot)$, satisfies

$$(1.2) \quad z(t_0) \in M.$$

Naturally, the set M is called the terminal set of the game. The goal of the pursuer is to terminate the game by choosing a suitable control $u(\cdot)$, while the goal of the evader is to prevent the game from terminating by choosing a proper control $v(\cdot)$.

We denote

$$\begin{aligned} \mathcal{U} &= \{u: [0, \infty) \rightarrow U \mid u(\cdot) \text{ is measurable}\}, \\ \mathcal{V} &= \{v: [0, \infty) \rightarrow V \mid v(\cdot) \text{ is measurable}\}. \end{aligned}$$

By admissible controls $u(\cdot)$ and $v(\cdot)$ we always mean that $u(\cdot) \in \mathcal{U}$ and $v(\cdot) \in \mathcal{V}$. Any $u(\cdot) \in \mathcal{U}$ is called a pursuit control and $v(\cdot) \in \mathcal{V}$ an evasion control.

In an evasion game, the evader is regarded as the “primary” player, i.e., the evader has some advantages in choosing his controls. The pursuer chooses his control $u(\cdot) \in \mathcal{U}$ at the start of the game. The evader, on the other hand, chooses the values of his control as the game evolves and can use $\{z(s), u(s) \mid 0 \leq s \leq t\}$ when he chooses the value $v(t)$ of the evasion control $v(\cdot) \in \mathcal{V}$ at time t . We denote $\hat{\mathcal{V}}$ to be the set of all such evasion controls.

We now give some definitions.

DEFINITION 1.1. Game (1.1) with terminal set M is said to be evadable if, for any $z_0 \notin M$ and any given pursuit control $u(\cdot) \in \mathcal{U}$, there exists an evasion control $v(\cdot) \in \mathcal{V}$ such that

$$(1.3) \quad d(M, z(t)) > 0 \quad \forall t \geq 0.$$

Here, $z(\cdot)$ is the corresponding trajectory of (1.1) resulting from $u(\cdot)$ and $v(\cdot)$, and $d(\cdot, \cdot)$ is the Euclidean distance in \mathbb{R}^n .

DEFINITION 1.2. Game (1.1) with terminal set M is said to be strictly evadable if, for any $z_0 \notin M$, there exists a $\delta(z_0) > 0$ such that for any $u(\cdot) \in \mathcal{U}$ we can find $v(\cdot) \in \mathcal{V}$ so that the corresponding trajectory $z(\cdot)$ of (1.1) satisfies

$$d(M, z(t)) \geq \delta(z_0) > 0 \quad \forall t \geq 0.$$

In [2]–[6], [9]–[18], [20] and [22]–[25], the terminal set M was assumed to be a linear subspace of \mathbb{R}^n with $\dim M \leq n-2$. For various forms of $f(t, z, u, v)$ in (1.1), some sufficient conditions for evadability of the game were established in [2], [3], [9]–[18], [20] and [22]–[25]. Some sufficient conditions for strict evadability of the game were given in [4]–[6], where the strict evadability was called the possibility of l -escape. In [8], a strict evadability result was given for the game governed by (1.1) with $f(t, z, u, v) \equiv f(z, u, v)$ and having the terminal set M not a linear subspace, but with some unpleasant restrictions.

In this paper, we generalize the results of [8] by relaxing the restrictions on M . We get some sufficient conditions for the strict evadability and evadability of game (1.1) with general closed terminal set M by using a Lyapunov type method. It turns out that in some cases, our sufficient condition for evadability is very close to a necessary condition for the evadability of the game. As consequences of our main results, we get some conditions for the (strict) evadability of the game (1.1) with f linear in z and with the terminal set M an $(n-1)$ -dimensional subspace of \mathbb{R}^n . This case has not been discussed heretofore.

For $0 \leq a < b \leq +\infty$, we denote

$$\mathcal{U}[a, b] = \{u \text{ restricted to } [a, b] | u \in \mathcal{U}\}.$$

By $u(\cdot) \in \mathcal{U}[a, b]$, we emphasize the control is restricted to the specified interval $[a, b]$. Similarly, we can define $\mathcal{V}[a, b]$, $\hat{\mathcal{V}}[a, b]$, etc. Also, in the following, when $u(\cdot)$, $v(\cdot)$ are given, $z(\cdot)$ always means the trajectory corresponding to $u(\cdot)$ and $v(\cdot)$.

2. Sufficient conditions for strict evadability and evadability. In this section we are going to prove the main results of this paper. Let us start with some general assumptions.

(A1) $f(t, z, u, v)$ is continuous in $(t, z, u, v) \in \mathbb{R}^+ \times \mathbb{R}^n \times U \times V$. There exists a $K > 0$ such that

$$(2.1) \quad \|f(t, z, u, v) - f(t, \hat{z}, u, v)\| \leq K \|z - \hat{z}\|$$

for all $z, \hat{z} \in \mathbb{R}^n$ and $(t, u, v) \in \mathbb{R}^+ \times U \times V$. $U \subseteq \mathbb{R}^p, V \subseteq \mathbb{R}^q$ are compact.

(A2) $M \subset \mathbb{R}^n$ is closed.

(A2') $M \subset \mathbb{R}^n$ is convex and closed.

Remark 2.1. From (A1) we have

$$(2.2) \quad (z, f(t, z, u, v)) \leq K_1(t)(1 + \|z\|^2)$$

for all $(t, z, u, v) \in \mathbb{R}^+ \times \mathbb{R}^n \times U \times V$, where

$$(2.3) \quad K_1(t) = K + \max_{(u, v) \in U \times V} \|f(t, 0, u, v)\| \in L^1_{\text{loc}}[0, \infty)$$

and (\cdot, \cdot) is the usual inner product in \mathbb{R}^n .

We denote, for $0 \leq s < \delta \leq +\infty$, that

$$(2.4) \quad T_s^\delta(M) \triangleq \{z \in \mathbb{R}^n \mid s < d(M, z) < \delta\}.$$

THEOREM 2.2. *Suppose game (1.1) and terminal set M are given and (A1) and (A2) hold. Let $V(\cdot): \mathbb{R}^n \rightarrow \mathbb{R}^+$ be a continuous function with the following properties:*

(1) *There exist strictly increasing functions $\alpha(\cdot), \beta(\cdot): \mathbb{R}^+ \rightarrow \mathbb{R}^+$, with $\alpha(0) = \beta(0) = 0$ such that*

$$(2.5) \quad \alpha(d(M, z)) \leq V(z) \leq \beta(d(M, z)) \quad \forall z \in \mathbb{R}^n.$$

(2) *There exists a $\delta > 0$ such that $(\partial/\partial z)V(z)$ exists in $T_0^\delta(M)$, and*

$$(2.6) \quad \inf_{t \geq 0} \inf_{u \in U} \max_{v \in V} \inf_{z \in T_0^\delta(M)} \left(\frac{\partial}{\partial z} V(z), f(t, z, u, v) \right) \geq 0.$$

Then the game is strictly evadable.

Proof. Suppose $z_0 \notin M$ and $u(\cdot) \in \mathcal{U}[0, \infty)$. By Filippov's lemma and (2.6), we can find $\hat{v}(\cdot) \in \hat{\mathcal{V}}[0, \infty)$ such that

$$(2.7) \quad \inf_{t \geq 0} \inf_{z \in T_0^\delta(M)} \left(\frac{\partial}{\partial z} V(z), f(t, z, u(t), \hat{v}(t)) \right) \geq 0.$$

We claim that by using such an evasion control we have

$$(2.8) \quad d(M, z(t)) \geq \beta^{-1} \circ \alpha(\delta \wedge d(M, z_0)) \triangleq \eta_1 > 0 \quad \forall t \geq 0$$

where β^{-1} is the inverse function of β and $\delta \wedge d(M, z_0) = \min\{\delta, d(M, z_0)\}$. In fact, if (2.8) is not true, then there exist $0 \leq t_1 < t_2$ such that

$$(2.9) \quad d(M, z(t_2)) < \eta_1,$$

$$(2.10) \quad 0 < d(M, z(t)) < \delta, \quad t \in (t_1, t_2],$$

$$(2.11) \quad d(M, z(t_1)) = \delta \wedge d(M, z_0).$$

Here we should know that since $\alpha(s) \leq \beta(s)$, for any $s \in \mathbb{R}^+$,

$$(2.12) \quad \eta_1 = \beta^{-1} \circ \alpha(\delta \wedge d(M, z_0)) \leq \delta \wedge d(M, z_0) \leq \delta.$$

Thus, for $t \in (t_1, t_2]$, we have

$$(2.13) \quad \frac{d}{dt} V(z(t)) = \left(\frac{\partial}{\partial z} V(z(t)), f(t, z(t), u(t), \hat{v}(t)) \right) \geq 0.$$

Integrating on $(t_1, t_2]$, we get

$$(2.14) \quad \beta(d(M, z(t_2))) \geq V(z(t_2)) \geq V(z(t_1)) = \alpha(\delta \wedge d(M, z_0)).$$

This contradicts (2.9). Hence (2.8) holds and our theorem follows. \square

Roughly speaking, the geometric meaning of (2.6) is that whenever the state z of the game gets close to the terminal set M , the evader has enough power to force the velocity of the state towards the direction of leaving M , so that he can prevent the state from getting too close to the terminal set. In other words, (2.6) means that the evader is more (at least not less) powerful than the pursuer when the state is near M .

We note that (2.6) allows us to find, via (2.7), a successful evasion control $\hat{v}(\cdot)$ which only depends on $u(\cdot)$. However, (2.6) seems very restrictive. Thus, we now try to relax it, but in order to do so, we need a little bit more about $V(\cdot)$.

THEOREM 2.3. *Suppose game (1.1) and terminal set M are given satisfying (A1) and (A2). Let $V(\cdot): \mathbb{R}^n \rightarrow \mathbb{R}^+$ be a continuous function satisfying (1) given in Theorem 2.2 and the following:*

(2') There exist constants $\delta, \delta_0, c > 0$, and a continuous function $w(\cdot, \cdot) : (0, \delta] \times \mathbb{R}^+ \rightarrow \mathbb{R}^+$ with the property that for all $s \in (0, \delta]$, $w(s, \cdot)$ is strictly increasing with $w(s, 0) = 0$ such that $(\partial/\partial z)V(z)$ exists for all $z \in T_0^\delta(M)$, and

$$(2.15) \quad \left\| \frac{\partial}{\partial z} V(z) \right\| \leq c \quad \forall z \in T_0^\delta(M),$$

$$(2.16) \quad \left\| \frac{\partial}{\partial z} V(z) - \frac{\partial}{\partial z} V(\hat{z}) \right\| \leq w(s, \|z - \hat{z}\|) \quad \forall z, \hat{z} \in T_s^\delta(M),$$

$$(2.17) \quad \inf_{t \geq 0} \inf_{z \in T_0^\delta(M)} \min_{u \in U} \max_{v \in V} \left(\frac{\partial}{\partial z} V(z), f(t, z, u, v) \right) \geq \delta_0.$$

Then the game is strictly evadable.

Remark 2.4. We note that, in general, the left-hand side of (2.17) is greater than or equal to that of (2.6). Therefore, in general, Theorems 2.2 and 2.3 do not contain each other. However, if we have

$$(2.18) \quad f(t, z, u, v) = h(t, z) + g(t, u, v),$$

then the left-hand sides of (2.6) and (2.17) are equal and then Theorem 2.3 is a trivial consequence of Theorem 2.2. Now, in the general case, the difficulty of proving Theorem 2.3 is that we cannot define an evasion control similar to that in the proof of Theorem 2.2, since if we did so, we would get a control of form $v(t, z)$ which is only measurable in z . Then we would meet some trouble in getting the existence of the trajectory $z(\cdot)$ of (1.1). That is why we need more conditions on $V(\cdot)$ and we need “ $\geq \delta_0$ ” in (2.17).

Proof of Theorem 2.3. Suppose $u(\cdot) \in \mathcal{U}[0, \infty)$ is given and $0 < d(M, z_0) < \delta$. We claim that there exist $T^* \geq 1$ and $\hat{v}(\cdot) \in \hat{\mathcal{V}}[0, T^*]$ such that

$$(2.19) \quad d(M, z(t)) \geq \eta_0 \triangleq \beta^{-1} \circ \alpha \left(\frac{\delta}{2} \wedge d(M, z_0) \right), \quad t \in [0, T^*],$$

$$(2.20) \quad d(M, z(T^*)) \geq \delta.$$

To prove our claim, we first prove the following.

LEMMA 2.5. There exist

$$0 < t^* \leq T \triangleq \frac{2(\beta(\delta) - \alpha(\delta/2 \wedge d(M, z_0)))}{\delta_0}$$

and $\hat{v}(\cdot) \in \hat{\mathcal{V}}[0, t^*]$ such that

$$(2.21) \quad d(M, z(t)) \geq \eta_0, \quad t \in [0, t^*],$$

$$(2.22) \quad d(M, z(t^*)) \geq \delta.$$

Note here that, in general, we cannot assure $t^* \geq 1$.

To prove this lemma, by (2.2), we can let $F \geq \delta/2$ such that

$$(2.23) \quad \|f(t, z(t), u(t), v(t))\| \leq F, \quad t \in [0, T+2]$$

for all possible $u(\cdot) \in \mathcal{U}$, $v(\cdot) \in \mathcal{V}$, and corresponding trajectory $z(\cdot)$ of (1.1) starting from z_0 . Also, we let \hat{t} be such that

$$(2.24) \quad w(s, Ft)F + cKFt \leq \frac{\delta_0}{2} \quad \forall t \in [0, \hat{t}], \quad s \in \left[\frac{\eta_0}{2}, \delta \right].$$

We then define $T_0 = \hat{t} \wedge (\eta_0/2F)$, which only depends on T and z_0 . Now, since $0 < d(M, z_0) < \delta$, we can choose $\hat{v}(\cdot) \in \hat{\mathcal{V}}$ such that

$$(2.25) \quad \left(\frac{\partial}{\partial z} V(z_0), f(t, z_0, u(t), \hat{v}(t)) \right) \geq \delta_0, \quad t \geq 0.$$

Then for the resulting $z(\cdot)$ we set

$$(2.26) \quad \theta_0 = \inf \{t \in [0, T] \mid d(M, z(t)) \geq \delta\}$$

and let $t_1 = T_0 \wedge \theta_0$. Thus, we have

$$(2.27) \quad \delta > d(M, z(t)) > d(M, z_0) - F \frac{\eta_0}{2F} \geq \frac{\eta_0}{2}, \quad t \in [0, t_1].$$

Hence, for $t \in [0, t_1]$, by using (1.1), (2.1), (2.15), (2.16), and (2.23)–(2.25), we have

$$(2.28) \quad \begin{aligned} \frac{d}{dt} V(z(t)) &= \left(\frac{\partial}{\partial z} V(z(t)), f(t, z(t), u(t), \hat{v}(t)) \right) \\ &\geq \delta_0 - w \left(\frac{\eta_0}{2}, \|z(t) - z_0\| \right) F - cK \|z(t) - z_0\| \\ &\geq \delta_0 - w \left(\frac{\eta_0}{2}, Ft \right) F - cKFt \geq \frac{\delta_0}{2}. \end{aligned}$$

Integrating over $[0, t]$, $t \leq t_1$, we get

$$(2.29) \quad \begin{aligned} d(M, z(t)) &\geq \beta^{-1}(V(z(t))) \geq \beta^{-1} \left(V(z_0) + \frac{\delta_0}{2} t \right) \\ &\geq \beta^{-1} \left(\alpha(d(M, z_0)) + \frac{\delta_0}{2} t \right) > \eta_0. \end{aligned}$$

If $d(M, z(t_1)) \geq \delta$, by taking $t^* = t_1$, we are done. Otherwise, we have $t_1 = T_0$. Then, repeating the above argument replacing z_0 by $z(T_0)$, we can get $\hat{v}(\cdot) \in \hat{\mathcal{V}}[T_0, \infty)$ such that

$$(2.30) \quad \left(\frac{\partial}{\partial z} V(z(T_0)), f(t, z(T_0), u(t), \hat{v}(t)) \right) \geq \delta_0, \quad t \geq T_0.$$

Then we define

$$(2.31) \quad \theta_1 = \inf \{t \in [T_0, T] \mid d(M, z(t)) \geq \delta\},$$

$$(2.32) \quad t_2 = T_0 + T_0 \wedge (\theta_1 - T_0).$$

For $t \in [T_0, t_2]$ we have that

$$(2.33) \quad \begin{aligned} \delta &> d(M, z(t)) > d(M, z(T_0)) - F(t_2 - T_0) \\ &\geq \eta_0 - F \frac{\eta_0}{2F} = \frac{\eta_0}{2}. \end{aligned}$$

Thus, as in (2.28) and (2.29) we have that

$$(2.34) \quad \frac{d}{dt} V(z(t)) \geq \frac{\delta_0}{2}, \quad t \in [T_0, t_2],$$

$$(2.35) \quad d(M, z(t)) \geq \eta_0, \quad t \in [T_0, t_2].$$

By induction, we have for some $i \geq 1$, $0 < t_i < T$, either

$$(2.36) \quad \delta > d(M, z(t)) \geq \eta_0, \quad t \in [0, t_{i-1}),$$

$$(2.37) \quad d(M, z(t)) \geq \eta_0, \quad t \in [t_{i-1}, t_i),$$

$$(2.38) \quad d(M, z(t_i)) \geq \delta$$

(in this case, we take $t^* = t_i$ and the proof is finished) or for all $i \geq 1$, $0 < t_i < T$, (2.36), (2.37) hold and

$$(2.39) \quad \delta > d(M, z(t_i)) \geq \eta_0.$$

In this case, we know that $t_i = iT_0$. Thus, we have

$$(2.40) \quad \delta > d(M, z(t)) \geq \eta_0, \quad t \in [0, T),$$

$$(2.41) \quad \frac{d}{dt} V(z(t)) \geq \frac{\delta_0}{2}, \quad t \in [0, T).$$

Then we have

$$\begin{aligned} d(M, z(T)) &\geq \beta^{-1}(V(z(T))) \geq \beta^{-1}\left(V(z_0) + \frac{\delta_0}{2} T\right) \\ &\geq \beta^{-1}\left(\alpha(d(M, z_0)) + \beta(\delta) - \alpha\left(\frac{\delta}{2} \wedge d(M, z_0)\right)\right) \geq \delta. \end{aligned}$$

Thus, we only need to take $t^* = T$. The lemma is proved.

Now, we go back to the proof of the theorem. It is clear that if $t_0 \in [0, T + 2 - \delta/2F]$, with $d(M, z(t_0)) \geq \delta$, then by taking $\hat{v}(\cdot) \equiv v_0 \in V$, we have

$$(2.42) \quad d(M, z(t)) \geq \frac{\delta}{2}, \quad t \in \left[t_0, t_0 + \frac{\delta}{2F}\right].$$

Now, since $0 < d(M, z_0) < \delta$, by Lemma 2.5 we have $t_0^* \in [0, T]$ and $\hat{v}(\cdot) \in \hat{\mathcal{V}}[0, t_0^*]$ such that

$$(2.43) \quad d(M, z(t)) \geq \eta_0, \quad t \in [0, t_0^*],$$

$$(2.44) \quad d(M, z(t_0^*)) \geq \delta.$$

If $t_0^* \geq 1$, we are done. Otherwise, we let $\hat{v}(t) \equiv v_0$, for $t \in [t_0^*, \tau_1]$, where (noting (2.42))

$$(2.45) \quad \tau_1 = \inf \left\{ t \in [t_0^*, 1] \mid d(M, z(t)) \leq \frac{\delta}{2} \right\} \geq t_0^* + \frac{\delta}{2F}.$$

By Lemma 2.5 again, we have $t_1^* \in [\tau_1, \tau_1 + T]$ and $\hat{v}(\cdot) \in \hat{\mathcal{V}}[\tau_1, t_1^*]$ such that

$$(2.46) \quad d(M, z(t)) \geq \eta_0, \quad t \in [\tau_1, t_1^*],$$

$$(2.47) \quad d(M, z(t_1^*)) \geq \delta.$$

By induction, we can define τ_i if $t_{i-1}^* < 1$. We say that for some $k \leq 1 + [2F/\delta]$, $t_k^* \geq 1$. If not, then for $k = 1 + [2F/\delta]$ we have

$$(2.48) \quad 1 > t_k^* \geq \tau_k \geq t_{k-1}^* + \frac{\delta}{2F} \geq \cdots \geq t_0^* + \frac{k\delta}{2F} \geq 1,$$

which is a contradiction. Hence we have proved our claim. For the case $d(M, z_0) \geq \delta$, we can prove the same claim. Then our theorem easily follows. \square

If we relax (2.17), then we get the following result for evadability.

THEOREM 2.6. *Suppose all the assumptions of Theorem 2.3 hold except that (2.17) is replaced by the following:*

$$(2.49) \quad \inf_{z \in T_0^\delta(M)} \min_{u \in U} \max_{v \in V} \left(\frac{\partial}{\partial z} V(z), f(t, z, u, v) \right) > 0 \quad \forall t \geq 0.$$

Then the game is evadable.

The proof is contained in the proof of Theorem 2.3. However, we should note that in the present case we do not have Lemma 2.5 (actually, we do not have (2.22)). Thus, we can only get the evadability.

The author does not know whether “ >0 ” in (2.49) can be replaced by “ ≥ 0 ”. In our arguments, condition “ >0 ” is crucial.

Now, let us consider the case that the terminal set M is convex and closed. Then, for any $x \in \partial M \equiv$ the boundary of M ,

$$(2.50) \quad N(x) \triangleq \{\eta \in \mathbb{R}^n \mid \|\eta\| = 1, \eta \text{ is an outer normal of } M \text{ at } x\} \neq \emptyset.$$

Also, we have that for any $z \in \mathbb{R}^n \setminus M$, there exists a unique $x \in \partial M$ such that

$$(2.51) \quad d(M, z) = \|z - x\|.$$

Thus, we get a map $x: \mathbb{R}^n \setminus M \rightarrow \partial M$. Now, let us define

$$(2.52) \quad V(z) = d(M, z) \equiv \|z - x(z)\|.$$

Then we can prove the following (see [19]).

LEMMA 2.7. *$(\partial/\partial z)V(z)$ exists in $\mathbb{R}^n \setminus M$ and*

$$(2.53) \quad \frac{\partial}{\partial z} V(z) = \frac{z - x(z)}{\|z - x(z)\|} \in N(x(z)).$$

Thus, (2.15) holds with $c = 1$ and (2.16) holds with $w(s, \gamma) = 3\gamma/s$. Also, since f satisfies (2.1), we can replace $f(t, z, u, v)$, $z \in T_0^\delta(M)$ in (2.17) and (2.49) by $f(t, x, u, v)$, $x \in \partial M$. Thus, we get the following.

COROLLARY 2.8. *Suppose (A1) and (A2') hold.*

(i) *The game is evadable if*

$$(2.54) \quad \inf_{x \in \partial M} \inf_{\eta \in N(x)} \min_{u \in U} \max_{v \in V} (\eta, f(t, x, u, v)) > 0 \quad \forall t \geq 0.$$

(ii) *The game is strictly evadable if there exists a $\delta_0 > 0$ such that*

$$(2.55) \quad \inf_{t \geq 0} \inf_{x \in \partial M} \inf_{\eta \in N(x)} \min_{u \in U} \max_{v \in V} (\eta, f(t, x, u, v)) \geq \delta_0.$$

Remark 2.9. The method we used in this section is very close to that used in general stability theory, namely the Lyapunov method (see [1], [21], for example). The difference is that in evasion games we want to keep the state away from the terminal set M , while in stabilizing a system to a closed set M we hope to obtain the result that the state approaches to M as $t \rightarrow \infty$. This shows that the Lyapunov method should give a closer relation between the stability theory and the differential pursuit games in which we want to bring the state to the terminal set M in finite time. Also, it is clear that the reachability of control systems should be closely related to pursuit games. We will discuss these in a forthcoming paper.

3. Necessary conditions for evadability. In this section we will give some necessary conditions for the evadability of our differential game.

For a given convex and closed subset M of \mathbb{R}^n , we know that for any $x \in \partial M$, $N(x)$ is a compact set. Thus, N can be regarded as a map from ∂M to the space

$$(3.1) \quad H \triangleq \{C \subset \mathbb{R}^n \mid C \text{ is compact}\}.$$

Let us set

$$(3.2) \quad \rho_H(A, B) = \frac{1}{2} \left\{ \max_{a \in A} d(a, B) + \max_{b \in B} d(A, b) \right\},$$

which is a standard Hausdorff metric. Then (H, ρ_H) is known to be a complete metric space. We say that N is continuous at some point $x_0 \in \partial M$, if $N: \partial M \rightarrow (H, \rho_H)$ is continuous at x_0 .

We now state our theorem.

THEOREM 3.1. *Suppose game (1.1) and terminal set M are given and (A1) and (A2') hold. Suppose that the game is evadable and N is continuous at $x_0 \in \partial M$. Then*

$$(3.3) \quad \sup_{\eta \in N(x_0)} \min_u \max_v (\eta, f(0, x_0, u, v)) \geq 0.$$

Proof. We prove our result by contradiction. Suppose (3.3) does not hold. By the continuity of N at x_0 , and f in (t, z, u, v) , we have the existence of an $\varepsilon > 0$ and a $\delta > 0$ such that

$$(3.4) \quad (\eta, f(t, z, u_0, v)) < -\varepsilon$$

for all $t \in [0, \delta]$, $z \in \mathcal{O}(x_0, \delta) \triangleq \{z \in \mathbb{R}^n \mid \|z - x_0\| < \delta\}$, $\eta \in N(x(z))$, $v \in V$ and for some element $u_0 \in U$. Now, let $F_0 > 1$ be such that

$$(3.5) \quad \|f(t, z, u_0, v)\| \leq F_0,$$

for all $z \in \mathcal{O}(x_0, \delta)$, $v \in V$ and $t \in [0, \delta]$. Set

$$(3.6) \quad t_0 = \frac{\delta}{2F_0},$$

$$(3.7) \quad \alpha = \min \left\{ \frac{\delta}{4}, \varepsilon t_0 \right\}.$$

Then we claim that for $z_0 = x_0 + \alpha \eta_0$, with η_0 being a fixed element in $N(x_0)$ and any $v(\cdot) \in \mathcal{V}$, there exists $t^* \in [0, t_0]$ such that the trajectory $z(\cdot)$ of (1.1) corresponding to $u(t) \equiv u_0$ and $v(\cdot)$ satisfies

$$(3.8) \quad d(M, z(t^*)) = 0.$$

If the claim were not true, i.e., if there exists a $v(\cdot) \in \mathcal{V}$ such that

$$(3.9) \quad d(M, z(t)) > 0 \quad \forall t \in [0, t_0],$$

then

$$(3.10) \quad \theta(z(t)) \equiv \frac{z(t) - x(z(t))}{\|z(t) - x(z(t))\|} \in N(x(z(t)))$$

is well defined for $t \in [0, t_0]$. By (3.5), (3.6) and (3.7) we have

$$(3.11) \quad \begin{aligned} \|z(t) - x_0\| &\leq \|z(t) - z_0\| + \|z_0 - x_0\| \\ &\leq F_0 t_0 + \alpha \leq \frac{3\delta}{4} < \delta \end{aligned}$$

for all $t \in [0, t_0]$. Then, since $t_0 < \delta$, it follows from (3.4) that

$$(3.12) \quad \frac{d}{dt}(d(M, z(t))) = (\theta(z(t)), f(t, z(t), u_0, v(t))) < -\varepsilon.$$

Integrating (3.12), we get

$$(3.13) \quad d(M, z(t)) \leq d(M, z_0) - \varepsilon t, \quad t \in [0, t_0].$$

Thus, at $t = t_0$, we have

$$(3.14) \quad \begin{aligned} d(M, z(t_0)) &\leq d(M, z_0) - \varepsilon t_0 \\ &= \alpha - \varepsilon t_0 \leq 0, \end{aligned}$$

which contradicts (3.9). Thus our claim is true. The claim, however, contradicts the evadability of the game; hence (3.3) holds. \square

We now let M be a convex and closed set of \mathbb{R}^n with $\dim M = n - 1$, i.e., M is contained in some $(n - 1)$ -dimensional hyperplane and has at least one interior point with respect to that hyperplane. Let $\eta \in \mathbb{R}^n$, $\|\eta\| = 1$. We set

$$(3.15) \quad p(\eta) = \{\eta\}^\perp \triangleq \{z \in \mathbb{R}^n \mid (\eta, z) = 0\}.$$

Then we can assume that

$$(3.16) \quad M \subseteq y_0 + p(\eta)$$

for some $y_0 \in M$ and $\eta \in \mathbb{R}^n$, $\|\eta\| = 1$. Note that in this case

$$(3.17) \quad M = \partial M.$$

We denote all the interior points of M with respect to $y_0 + p(\eta)$ by $\text{Int}_{n-1} M$. Then for any $x_0 \in \text{Int}_{n-1} M \subseteq \partial M$,

$$(3.18) \quad N(x_0) = \{\pm \eta\}.$$

COROLLARY 3.2. *Suppose that game (1.1) is given, (A1) holds and the terminal set is an $(n - 1)$ -dimensional convex and closed subset in \mathbb{R}^n satisfying (3.16). Suppose that the game is evadable. Then for any $x_0 \in \text{Int}_{n-1} M$,*

$$(3.19) \quad \min_{u \in U} \max_{v \in V} (\pm \eta, f(0, x_0, u, v)) \geq 0.$$

The proof is obvious.

Remark 3.3. It is clear that in both Theorem 3.1 and Corollary 3.2 we only need the continuity of $f(t, z, u, v)$ at $\{0\} \times \partial M \times U \times V$.

The following result gives a necessary condition for the evadability of the game where f is linear in z and the terminal set M is an $(n - 1)$ -dimensional convex and closed set.

COROLLARY 3.4. *Suppose that in (1.1)*

$$(3.20) \quad f(t, z, u, v) = A(t)z + g(t, u, v)$$

with $A(\cdot)$, $g(\cdot, \cdot, \cdot)$ continuous. The terminal set M is an $(n - 1)$ -dimensional convex and closed set in \mathbb{R}^n satisfying (3.16) and containing an $(n - 1)$ -dimensional cone. Suppose that the game is evadable; then

$$(3.21) \quad A(0)^* \eta = \lambda \eta$$

for some $\lambda \in \mathbb{R}$.

Proof. Without loss of generality, we assume that

$$(3.22) \quad y_0 + K(\eta) \subseteq M \subseteq y_0 + p(\eta)$$

where $K(\eta)$ is a cone in $p(\eta)$ and $y_0 \in M$.

We suppose that the game is evadable and that for all $\lambda \in \mathbb{R}$

$$(3.23) \quad A(0)^* \eta \neq \lambda \eta.$$

We show that this leads to a contradiction. We claim that if (3.23) holds, then there exists a $z \in \text{Int}_{n-1} K(\eta)$ such that

$$(3.24) \quad (\eta, A(0)z) \neq 0.$$

If (3.24) were not true, then for all $z \in \text{Int}_{n-1} K(\eta)$

$$(3.25) \quad (A(0)^* \eta, z) = (\eta, A(0)z) = 0.$$

Since $\dim K(\eta) = n - 1$, (3.25) implies that for all $z \in p(\eta)$

$$(3.26) \quad (A(0)^* \eta, z) = 0.$$

Thus, we get

$$(3.27) \quad A(0)^* \eta \in p(\eta)^\perp = \text{span} \{ \eta \},$$

which contradicts (3.23). Hence there is a $z \in K(\eta)$, satisfying (3.24). Since $K(\eta)$ is a cone, $\beta z \in K(\eta)$ for all $\beta > 0$, by (3.22)

$$(3.28) \quad y_0 + \beta z \in M, \quad \beta > 0.$$

Without loss of generality, we assume that

$$(3.29) \quad (\eta, A(0)z) > 0.$$

Then we set

$$(3.30) \quad \beta = \{ |(\eta, A(0)y_0)| + \max_{(u,v) \in U \times V} \|g(0, u, v)\| + 1 \} / (\eta, A(0)z).$$

We get

$$(3.31) \quad \begin{aligned} & \min_{u \in U} \max_{v \in V} (-\eta, f(0, y_0 + \beta z, u, v)) \\ & \leq (-\eta, A(0)\beta z) + |(\eta, A(0)y_0)| + \max_{(u,v) \in U \times V} \|g(0, u, v)\| = -1, \end{aligned}$$

which contradicts (3.19) and hence the corollary is proved. \square

Notice that when $A(t) \equiv A$, then the above corollary says that the evadability of the game implies that η is an eigenvector of A^* . Also, we can see that (3.3) is very close to (2.54), especially in the case that $f(t, z, u, v) \equiv f(z, u, v)$.

4. Sharper necessary conditions for evadability. In this section we will give a much stronger result than Corollary 3.4 when the terminal set M is of form $y_0 + p(\eta)$.

We consider the following:

$$(4.1) \quad \begin{aligned} \dot{z} &= A(t)z + g(t, u, v), \\ z(0) &= z_0. \end{aligned}$$

We assume that $A(t)$ is an $(n \times n)$ matrix-valued locally integrable function, and that $g(\cdot, \cdot, \cdot) \in L^\infty([0, t_1] \times U \times V)$ for all $t_1 > 0$. The terminal set is

$$(4.2) \quad M = y_0 + p(\eta).$$

Our main theorem of this section is the following.

THEOREM 4.1. *If game (4.1) with terminal set (4.2) is evadable, then there exists a real-valued locally integrable function $\lambda(t)$ such that*

$$(4.3) \quad A(t)^* \eta = \lambda(t) \eta \quad \text{a.e.}$$

To prove this theorem we need a lemma. We let $\Phi(t)$ be the fundamental matrix of

$$(4.4) \quad \dot{z} = A(t)z,$$

satisfying $\Phi(0) = I$.

LEMMA 4.2. *Let $\eta \in \mathbb{R}^n$, $\|\eta\| = 1$ have the property that for all $z_1 \in \mathbb{R}^n$ such that*

$$(4.5) \quad (\eta, z_1) > 0,$$

we have

$$(4.6) \quad (\eta, \Phi(t)z_1) \geq 0, \quad t \geq 0.$$

Then there exists a real-valued locally integrable function $\lambda(t)$ such that

$$(4.7) \quad \Phi(t)^* \eta = \exp\left(\int_0^t \lambda(\tau) d\tau\right) \eta, \quad t \geq 0,$$

$$(4.8) \quad A(t)^* \eta = \lambda(t) \eta \quad \text{a.e.}$$

Proof. We claim that under our hypothesis we have that for all $x \in p(\eta) \equiv \{\eta\}^\perp$

$$(4.9) \quad (\eta, \Phi(t)x) = 0, \quad t \geq 0.$$

If not, then there exist an $x_1 \in \{\eta\}^\perp$ and a $t_0 > 0$ such that

$$(4.10) \quad (\eta, \Phi(t_0)x_1) \neq 0.$$

Without loss of generality, we assume that

$$(4.11) \quad (\eta, \Phi(t_0)x_1) = -\delta < 0.$$

If we take

$$(4.12) \quad z_1 = x_1 + \varepsilon \eta$$

where

$$(4.13) \quad 0 < \varepsilon \leq \frac{\delta}{1 + (\eta, \Phi(t_0)\eta)},$$

then we have

$$(4.14) \quad (\eta, z_1) = \varepsilon > 0,$$

$$(4.15) \quad (\eta, \Phi(t_0)z_1) = \varepsilon(\eta, \Phi(t_0)\eta) - \delta \leq -\varepsilon < 0,$$

which contradicts (4.6). Thus our claim is true.

It follows from (4.9) that

$$(4.16) \quad \Phi(t)^* \eta \in p(\eta)^\perp = \text{span}\{\eta\}, \quad t \geq 0.$$

Thus, there exists a real-valued function $a(t)$ such that

$$(4.17) \quad \Phi(t)^* \eta = a(t) \eta, \quad t \geq 0.$$

Since $\Phi(t)^*$ is invertible for all t , we get that $a(t) \neq 0$ for all $t \geq 0$. Hence, noting that $(\eta, \eta) = 1 > 0$, we have by (4.6)

$$(4.18) \quad \begin{aligned} a(t) &= (\eta, \Phi(t)\eta) > 0, \quad t \geq 0, \\ a(0) &= 1. \end{aligned}$$

From (4.18), it is clear that $a(t)$ is absolutely continuous. Now, for any $t_1 > 0$, let

$$(4.19) \quad \delta_0 = \min_{t \in [0, t_1]} a(t) > 0.$$

On $[\delta_0, \infty)$ we have

$$(4.20) \quad |(\log s)'| = \frac{1}{s} \leq \frac{1}{\delta_0} < \infty,$$

and so, $\log s$ satisfies a Lipschitz condition on $[\delta_0, \infty)$. Hence, $\log a(t)$ is absolutely continuous on $[0, t_1]$ for all $t_1 > 0$. Thus, there exists a real-valued, locally integrable function $\lambda(t)$ such that (note $a(0) = 1$)

$$(4.21) \quad \log a(t) = \int_0^t \lambda(\tau) d\tau, \quad t \geq 0.$$

Hence, we get (4.7) by combining (4.17) and (4.21).

To obtain (4.8), we consider the following:

$$(4.22) \quad \begin{aligned} \Phi(t)^*[\lambda(t)\eta] &= \lambda(t)\Phi(t)^*\eta \\ &= \lambda(t) \exp\left(\int_0^t \lambda(\tau) d\tau\right) \eta \\ &= \left[\exp\left(\int_0^t \lambda(\tau) d\tau\right) \eta\right]' \quad \text{a.e.} \\ &= [\Phi(t)^*\eta]' \\ &= \Phi(t)^*A(t)^*\eta \quad \text{a.e.} \end{aligned}$$

But $\Phi(t)^*$ is invertible, so (4.8) holds. \square

Remark 4.3. In fact, (4.7) and (4.8) are equivalent. We have seen that (4.7) implies (4.8). Now, if (4.8) holds, we consider the following initial value problem:

$$(4.23) \quad \begin{aligned} \dot{z} &= \lambda(t)z \quad \text{a.e.}, \\ z(0) &= \eta. \end{aligned}$$

Then, $\exp(\int_0^t \lambda(\tau) d\tau)\eta$ and $\Phi(t)^*\eta$ are solutions of (4.23). By uniqueness we get (4.7).

Now, we can prove Theorem 4.1.

Proof of Theorem 4.1. By Lemma 4.2, it is enough to show that for any $z_1 \in \mathbb{R}^n$, with $(\eta, z_1) > 0$, we have (4.6).

We prove this by contradiction. Suppose there exist a $z_1 \in \mathbb{R}^n$ and a $t_0 > 0$ such that $(\eta, z_1) > 0$ and

$$(4.24) \quad (\eta, \Phi(t_0)z_1) < 0.$$

Then we take

$$(4.25) \quad z_0 = y_0 + \alpha z_1$$

where $\alpha > 0$ is as yet undetermined. Then we have

$$(4.26) \quad d(M, z_0) = |(\eta, z_0 - y_0)| = \alpha(\eta, z_1) > 0,$$

i.e., $z_0 \notin M$. Also, for any $u(\cdot)$ and $v(\cdot)$, admissible,

$$(4.27) \quad \begin{aligned} (\eta, z(t_0) - y_0) &= (\eta, \Phi(t_0)z_0 + \int_0^{t_0} \Phi(t_0)\Phi(\tau)^{-1}g(\tau, u(\tau), v(\tau)) d\tau - y_0) \\ &= \alpha(\eta, \Phi(t_0)z_1) + (\eta, \Phi(t_0)y_0 - y_0 \\ &\quad + \int_0^{t_0} \Phi(t_0)\Phi(\tau)^{-1}g(\tau, u(\tau), v(\tau)) d\tau). \end{aligned}$$

Note that the second term is bounded. Hence, if we take α large enough and notice (4.24), we will have

$$(4.28) \quad (\eta, z(t_0) - y_0) \leq 0.$$

When we compare this with (4.26) and note that $z(t)$ is continuous, we see that there exists a $t^* \in (0, t_0]$ such that

$$(4.29) \quad d(M, z(t^*)) = |(\eta, z(t^*) - y_0)| = 0,$$

which contradicts the evadability of the game. \square

COROLLARY 4.4. *If $A(t) \equiv A$, and the game is evadable, then*

$$(4.30) \quad A^*\eta = \lambda\eta$$

for some $\lambda \in \mathbb{R}$.

5. Sufficient conditions for systems linear in the state. In this section we consider a differential game which is governed by (4.1). We assume that $A(t)$ is an $(n \times n)$ matrix-valued locally integrable function, and that $g(t, u, v)$ is in $L^\infty([0, t_1] \times U \times V)$ for all $t_1 > 0$ and Borel measurable in u , continuous in v . The terminal set M is given by

$$(5.1) \quad M = y_0 + Q$$

where Q is a linear subspace of \mathbb{R}^n with $\dim Q < n$. It is clear from (5.1) that

$$(5.2) \quad M = \partial M.$$

Also, for all $x \in M$

$$(5.3) \quad N(x) = \{\eta \in Q^\perp \mid \|\eta\| = 1\}.$$

Let

$$(5.4) \quad B_1^n(0) = \{\eta \in \mathbb{R}^n \mid \|\eta\| \leq 1\}$$

and let $\pi: \mathbb{R}^n \rightarrow Q^\perp$ be the orthogonal projection. Then we have the following theorem.

THEOREM 5.1. *Suppose that game (4.1) is given, $A(t)$, $g(t, u, v)$ are continuous, and*

$$(5.5) \quad \|A(t)\| \leq K, \quad t \geq 0.$$

The terminal set M is given by (5.1). We assume that

$$(5.6) \quad A(t)Q \subseteq Q, \quad t \geq 0,$$

and that there exists a $\delta_0 > 0$ such that

$$(5.7) \quad \delta_0 \pi B_1^n(0) \subseteq \bigcap_{u \in U} [\pi A(t)y_0 + \pi g(t, u, V)], \quad t \geq 0.$$

Then the game is strictly evadable.

Proof. It is clear that under our assumptions, (A1) and (A2') hold. Thus, it suffices to prove that (2.55) holds.

For any $t \geq 0$, $x \in \partial M = M$, and any $\eta \in N(x)$, it follows from (5.7) that

$$(5.8) \quad \delta_0 \eta \in \delta_0 \pi B_1^n(0) \subseteq \bigcap_{u \in U} [\pi A(t)y_0 + \pi g(t, u, V)], \quad t \geq 0.$$

Thus, for each $u \in U$, there exists a $v \in V$ such that (t fixed)

$$(5.9) \quad \delta_0 \eta = \pi A(t)y_0 + \pi g(t, u, v).$$

From the definition of π , we have $\pi^* \eta = \eta$. Hence, we get that

$$(5.10) \quad \begin{aligned} \delta_0 &= (\eta, A(t)y_0 + g(t, u, v)) \\ &\leq (\eta, A(t)y_0) + \max_{v \in V} (\eta, g(t, u, v)). \end{aligned}$$

Since $x - y_0 \in Q$ (see (5.1)), it follows from (5.6) that

$$(5.11) \quad (\eta, A(t)y_0) = (\eta, A(t)x), \quad t \geq 0, \quad \eta \in N(x).$$

Thus, (5.10) implies

$$(5.12) \quad \delta_0 \leq \max_{v \in V} (\eta, A(t)x + g(t, u, v)),$$

for all $t \geq 0$, $x \in \partial M$, $u \in U$ and $\eta \in N(x)$. Thus (2.55) holds and our theorem is proved. \square

We note that (5.6) means that Q is an invariant subspace of $A(t)$ for all $t \geq 0$. In the case $\dim Q = n - 1$, we have seen in the last section that this condition is necessary for the evadability of the game.

COROLLARY 5.2. *Suppose $A(t) \equiv A$, $g(t, u, v) \equiv g(u, v)$, and the terminal set M is an invariant subspace of A . Suppose further that there exists a $\delta_0 > 0$, such that*

$$(5.13) \quad \delta_0 \pi B_1^n(0) \subseteq \bigcap_{u \in U} \pi g(u, V)$$

where $\pi: \mathbb{R}^n \rightarrow M^\perp$ is the orthogonal projection. Then the game is strictly evadable.

The proof is immediate.

Now, if $\dim Q = n - 1$, our strict evadability results can be strengthened. We assume in the following that $A(t)$ and $g(t, u, v)$ are not necessarily continuous but satisfy the assumptions that were made at the beginning of this section. By Theorem 4.1, in our case, (4.3) is a necessary condition for evadability and thus it is necessary for strict evadability. We have the following.

THEOREM 5.3. *Suppose game (4.1) is given, the terminal set M is given by (4.2), and (4.3) holds. Let*

$$(5.14) \quad \mu_\pm(t) = \min_{u \in U} \max_{v \in V} (\pm \eta, g(t, u, v)) - |\lambda(t)|d(M, 0), \quad t \geq 0.$$

Suppose one of the following holds:

(i) If $\lim_{t \rightarrow \infty} \int_0^t \lambda(\tau) d\tau > -\infty$, then

$$(5.15) \quad \mu_\pm(t) \geq 0 \quad \text{a.e.}$$

(ii) If $\lim_{t \rightarrow \infty} \int_0^t \lambda(\tau) d\tau = -\infty$, then (5.15) holds and

$$(5.16) \quad \lim_{t \rightarrow \infty} \mu_\pm(t) > 0,$$

$$(5.17) \quad \left| \int_t^{t+\tau} \lambda(s) ds \right| \leq w(\tau), \quad t \geq 0, \quad w(\cdot) \in L_{\text{loc}}^1[0, \infty).$$

Then the game is strictly evadable.

Remark 5.4. In the case of Theorem 5.3, if we denote $f(t, z, u, v) = A(t)z + g(t, u, v)$, then (5.15) is the same as the following:

$$(5.18) \quad \inf_{x \in \partial M} \inf_{\eta \in N(x)} \min_{u \in U} \max_{v \in V} (\eta, f(t, x, u, v)) \geq 0 \quad \text{a.e.}$$

It is clear that (5.18) is weaker than (2.54) and (2.55). Also, (5.18) is closer to the necessary condition (3.3) than are (2.54) and (2.55).

Proof of Theorem 5.3. Let $z_0 \notin M$, $u(\cdot) \in \mathcal{U}[0, \infty)$ be given. We note that

$$(5.19) \quad d(M, z) = |(\eta, z - y_0)| \quad \forall z \in \mathbb{R}^n.$$

Without loss of generality, we assume that

$$(5.20) \quad d(M, z_0) = (\eta, z_0 - y_0).$$

Then, by Filippov's lemma, we can find $\hat{v}(\cdot) \in \hat{\mathcal{V}}[0, \infty)$ such that

$$(5.21) \quad (\eta, g(t, u(t), \hat{v}(t))) - |\lambda(t)|d(M, 0) = \mu_+(t) \quad \text{a.e.}$$

Under this evasion control, we have (note (5.15))

$$\begin{aligned} d(M, z(t)) &= |(\eta, z(t) - y_0)| \\ &= \left| (\eta, \Phi(t)z_0 + \int_0^t \Phi(t)\Phi(\tau)^{-1}g(\tau, u(\tau), \hat{v}(\tau)) d\tau - y_0) \right| \\ &= \left| (\eta, \Phi(t)(z_0 - y_0)) \right. \\ &\quad \left. + \int_0^t (\eta, \Phi(t)\Phi(\tau)^{-1}[A(\tau)y_0 + g(\tau, u(\tau), \hat{v}(\tau))]) d\tau \right| \\ &= \left| \exp\left(\int_0^t \lambda(s) ds\right) d(M, z_0) \right. \\ &\quad \left. + \int_0^t \exp\left(\int_\tau^t \lambda(s) ds\right) [(\eta, g(\tau, u(\tau), \hat{v}(\tau)) + \lambda(\tau)(\eta, y_0))] d\tau \right| \\ &\geq \exp\left(\int_0^t \lambda(s) ds\right) d(M, z_0) + \int_0^t \exp\left(\int_\tau^t \lambda(s) ds\right) \mu_+(\tau) d\tau. \end{aligned} \quad (5.22)$$

CASE (i). Since $\lim_{t \rightarrow \infty} \int_0^t \lambda(s) ds > -\infty$, there exists $\delta_0 > 0$ such that

$$(5.23) \quad \exp\left(\int_0^t \lambda(s) ds\right) \geq \delta_0, \quad t \geq 0.$$

Thus, from (5.22), we get

$$(5.24) \quad d(M, z(t)) \geq \exp\left(\int_0^t \lambda(s) ds\right) d(M, z_0) \geq \delta_0 d(M, z_0) \quad \forall t \geq 0.$$

This gives the strict evadability.

CASE (ii). By (5.16) and (5.17) we have $t_0 > 0$ and $\delta_0 > 0$ such that

$$(5.25) \quad \mu_+(t) \geq \delta_0 \quad \text{a.e. } t \geq t_0.$$

Then we set

$$(5.26) \quad \hat{\delta} = \min_{0 \leq t \leq 2t_0} \exp\left(\int_0^t \lambda(s) ds\right) > 0.$$

Then, for $t \in [0, 2t_0]$, we have by (5.15), (5.22) and (5.26)

$$(5.27) \quad d(M, z(t)) \geq \exp\left(\int_0^t \lambda(s) ds\right) d(M, z_0) \geq \hat{\delta} d(M, z_0) > 0,$$

and for $t \in [2t_0, \infty)$ we have by (5.15), (5.17), (5.22) and (5.25)

$$(5.28) \quad \begin{aligned} d(M, z(t)) &\geq \exp\left(\int_0^t \lambda(s) ds\right) d(M, z_0) + \int_{t_0}^t \exp\left(\int_\tau^t \lambda(s) ds\right) \delta_0 d\tau \\ &\geq \delta_0 \int_0^{t-t_0} \exp\left(\int_{s-\tau}^t \lambda(s) ds\right) d\tau \\ &\geq \delta_0 \int_0^{t-t_0} e^{-w(\tau)} d\tau \\ &\geq \delta_0 \int_0^{t_0} e^{-w(\tau)} d\tau > 0. \end{aligned}$$

Hence, we complete the proof. \square

Remark 5.5. If $A(t) \equiv A$ as in Theorem 5.3, then $\lambda(t) \equiv \lambda$ is an eigenvalue of A^* (hence of A). In this situation, Case (i) corresponds to $\lambda \geq 0$ and Case (ii) corresponds to $\lambda < 0$.

6. A linear autonomous case. In this section we discuss a differential game of the following form:

$$(6.1) \quad \begin{aligned} \dot{z} &= Az + Bu + Cv, \\ z(0) &= z_0, \end{aligned}$$

where A , B and C are matrices of suitable sizes, $z \in \mathbb{R}^n$, $u \in U \subseteq \mathbb{R}^p$, $v \in V \subseteq \mathbb{R}^q$. The terminal set M is a subspace of \mathbb{R}^n with $\dim M < n$ and $AM \subseteq M$. We will give a strict evadability result which is stronger, in some sense, than Corollary 5.2.

Let us first give the following.

DEFINITION 6.1. Let $\delta > 0$, $U \subseteq \mathbb{R}^p$, $V \subseteq \mathbb{R}^q$ be given. (C, V) is said to be δ -superior to (B, U) if there exists $V_0 \subseteq \mathbb{R}^q$ such that

$$(6.2) \quad V_0 + \delta B_1^q(0) \subseteq V,$$

$$(6.3) \quad BU \subseteq -CV_0,$$

where

$$B_1^q(0) = \{v \in \mathbb{R}^q \mid \|v\| \leq 1\}.$$

The following proposition gives us some intuitive geometric meaning of the above definition.

PROPOSITION 6.2. Let $U = B_1^p(0)$, $V = B_1^q(0)$, and $\mu > 1$, be such that

$$(6.4) \quad \mu B(B_1^p(0)) \subseteq C(B_1^q(0)).$$

Then, $(C, B_1^q(0))$ is δ -superior to $(B, B_1^p(0))$ with $\delta = 1 - (1/\mu)$.

Proof. Take $V_0 = (1 - \delta)B_1^q(0) = -V_0$, where $\delta = 1 - (1/\mu)$. Then it is clear that (6.2) holds and

$$B(B_1^p(0)) \subseteq \frac{1}{\mu} C(B_1^q(0)) = C((1 - \delta)B_1^q(0)) = -CV_0. \quad \square$$

Roughly speaking, (C, V) is δ -superior to (B, U) for some $\delta > 0$ if the evader is more powerful than the pursuer. We will see that more clearly from the following.

LEMMA 6.3. *Suppose $\delta > 0$ and (C, V) is δ -superior to (B, U) , then for any $u(\cdot) \in \mathcal{U}$ there exists a $v_u(\cdot) \in \hat{\mathcal{V}}$ with values in V_0 such that*

$$(6.5) \quad Bu(t) + Cv_u(t) = 0 \quad \text{a.e.},$$

where V_0 is as in Definition 6.1.

Proof. The result follows from (6.3) and Filippov's lemma. \square

REMARK 6.4. As a consequence of the above lemma, we have that for any $u(\cdot) \in \mathcal{U}$ and measurable $w(\cdot)$ with values in $\delta B_1^q(0)$, there exists a $\hat{v}(\cdot) \in \hat{\mathcal{V}}$ such that

$$(6.6) \quad Bu(t) + c\hat{v}(t) = cw(t) \quad \text{a.e.}$$

This gives the superiority of the evader to the pursuer.

Before stating and proving the main result of this section, let us give another lemma.

LEMMA 6.5. *Suppose $a, b \in \mathbb{R}$, $b \neq 0$ and*

$$(6.7) \quad K = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Then for $t_0, t \in \mathbb{R}$

$$\int_{t_0}^t e^{(aI+bK)\tau} d\tau = \frac{aI-bK}{a^2+b^2} e^{(aI+bK)\tau} \Big|_{t_0}^t.$$

The proof is straightforward.

We now give our main theorem of this section.

THEOREM 6.6. *Suppose the terminal set M is invariant under A , and $\dim M < n$. Suppose that $[(A^*|_{M^\perp})^*, (C^*|_{M^\perp})^*]$ is completely controllable and that $((C^*|_{M^\perp})^*, V)$ is δ -superior to $((B^*|_{M^\perp})^*, U)$ for some $\delta > 0$. Then the game with terminal set M is strictly evadable.*

REMARK 6.7. In the statement of the theorem, $[(A^*|_{M^\perp})^*, (C^*|_{M^\perp})^*]$ is regarded as a system in M^\perp not in \mathbb{R}^n .

Proof. By choosing suitable orthonormal basis for $M^\perp \oplus M$, we have the representations of A, B, C as follows:

$$(6.8) \quad A = \begin{pmatrix} A_1 & 0 \\ A_3 & A_4 \end{pmatrix}, \quad B = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix}, \quad C = \begin{pmatrix} C_1 \\ C_2 \end{pmatrix}.$$

Then the conditions stated in Theorem 6.6 are the following: $[A_1, C_1]$ is completely controllable; (C_1, V) is δ -superior to (B_1, U) . Let us denote, according to the decomposition of \mathbb{R}^n ,

$$(6.9) \quad z = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix}, \quad z_0 = \begin{pmatrix} z_{10} \\ z_{20} \end{pmatrix}.$$

By applying $\pi: \mathbb{R}^n \rightarrow M^\perp$, the orthogonal projection to (6.1), we get

$$(6.10) \quad \begin{aligned} \dot{z}_1 &= A_1 z_1 + B_1 u + C_1 v, \\ z_1(0) &= z_{10}, \end{aligned}$$

and we know that

$$(6.11) \quad d(M, z(t)) = \|\pi z(t)\| = \|z_1(t)\|.$$

Now, we assume that the initial state $z_0 \notin M$, i.e., $z_{10} \neq 0$, and also that the pursuer's control $u(\cdot) \in \mathcal{U}$ is given. Then by Lemma 6.3 and Remark 6.4, we may choose the evasion control as in (6.6), and so

$$(6.12) \quad B_1 u(t) + C_1 \hat{v}(t) = C_1 w(t)$$

with $w(t) \in \delta B_1^q(0)$ being arbitrary. Then (6.10) becomes

$$(6.13) \quad \begin{aligned} \dot{z}_1(t) &= A_1 z_1(t) + C_1 w(t), \\ z_1(0) &= z_{10}. \end{aligned}$$

Then we have from (6.11) and (6.13) that

$$(6.14) \quad \begin{aligned} d(M, z(t)) &= \|z_1(t)\| \\ &= \left\| e^{A_1 t} z_{10} + \int_0^t e^{A_1(t-\tau)} C_1 w(\tau) d\tau \right\|. \end{aligned}$$

Now, let us discuss the different cases.

CASE 1. $\sigma(A_1) \cap \mathbb{R} \neq \emptyset$, where $\sigma(A_1)$ is the spectrum of A_1 .

Since $\sigma(A_1) = \sigma(A_1^*)$, we can assume that there exists an η_1 with $\|\eta_1\| = 1$ such that for some $\lambda_1 \in \mathbb{R}$

$$(6.15) \quad A_1^* \eta_1 = \lambda_1 \eta_1.$$

Since $[A_1, C_1]$ is completely controllable, we have

$$(6.16) \quad C_1^* \eta_1 \neq 0 \quad \text{or} \quad \eta_1^T C_1 \neq 0$$

where η_1^T stands for the transpose of the column vector η_1 .

Now, we set

$$(6.17) \quad w(t) = \begin{cases} \operatorname{sgn}(\eta_1^T z_{10}) \frac{\delta C_1^* \eta_1}{\|C_1^* \eta_1\|} & \text{if } \eta_1^T z_{10} \neq 0, \\ \delta \frac{C_1^* \eta_1}{\|C_1^* \eta_1\|} & \text{if } \eta_1^T z_{10} = 0. \end{cases}$$

Then from (6.14), (6.15) and (6.17), we have that

$$(6.18) \quad \begin{aligned} |\eta_1^T z_1(t)| &= \left| e^{\lambda_1 t} \eta_1^T z_{10} + \int_0^t e^{\lambda_1(t-\tau)} \eta_1^T C_1 w(\tau) d\tau \right| \\ &= e^{\lambda_1 t} |\eta_1^T z_{10}| + \left(\int_0^t e^{\lambda_1 \tau} d\tau \right) \delta \|C_1^* \eta_1\|. \end{aligned}$$

Since $z_{10} \neq 0$, there exists a $\theta > 0$ such that for all admissible controls $u(\cdot)$ and $v(\cdot)$

$$(6.19) \quad d(M, z(t)) = \|z_1(t)\| \geq \frac{\|z_{10}\|}{2}, \quad t \in [0, \theta].$$

For $t \geq \theta$, from (6.18), we have

$$(6.20) \quad \begin{aligned} d(M, z(t)) &\geq |\eta_1^T z_1(t)| \geq \left(\int_0^t e^{\lambda_1 \tau} d\tau \right) \delta \|C_1^* \eta_1\| \\ &\geq \left(\int_0^\theta e^{\lambda_1 \tau} d\tau \right) \delta \|C_1^* \eta_1\| > 0. \end{aligned}$$

Hence, we have the strict evadability of the game in this case.

CASE 2. $\sigma(A_1) \cap \mathbb{R} = \emptyset$.

Note that in this case, $\dim M^\perp \geq 2$.

Let $a \pm ib \in \sigma(A_1^*) = \sigma(A_1)$, where $a, b \in \mathbb{R}$ and $b > 0$, then there exist real vectors α and β in M^\perp such that

$$(6.21) \quad A_1^*(\alpha + i\beta) = (a - bi)(\alpha + i\beta).$$

From this we can see that α and β are linearly independent and

$$(6.22) \quad \begin{aligned} A_1^*\alpha &= a\alpha + b\beta, \\ A_1^*\beta &= -b\alpha + a\beta, \end{aligned}$$

i.e.,

$$(6.23) \quad A_1^*(\alpha, \beta) = (\alpha, \beta) \begin{pmatrix} a & -b \\ b & a \end{pmatrix}.$$

We define $L_0 = \text{span}\{\alpha, \beta\} \subseteq M^\perp$. It is clear that $A_1^*L_0 \subseteq L_0$; hence, we have

$$(6.24) \quad A_1L_0^\perp \subseteq L_0^\perp.$$

Now, by choosing a suitable basis for $M^\perp = L_0 \oplus L_0^\perp$, we have

$$(6.25) \quad \begin{aligned} A_1 &= \begin{pmatrix} A_0 & 0 \\ * & * \end{pmatrix}, & C_1 &= \begin{pmatrix} C_0 \\ * \end{pmatrix}, \\ z_1 &= \begin{pmatrix} z_1^1 \\ z_1^2 \\ z_1^3 \end{pmatrix}, & z_{10} &= \begin{pmatrix} z_{10}^1 \\ z_{10}^2 \\ z_{10}^3 \end{pmatrix}, \end{aligned}$$

where $*$ stands for entries which will not concern us and

$$(6.26) \quad A_0 = \begin{pmatrix} a & b \\ -b & a \end{pmatrix} = aI + bK.$$

Here, K is given by (6.7).

Since $[A_1, C_1]$ is completely controllable, and $A_1L_0^\perp \subseteq L_0^\perp$, we know that $[A_0, C_0]$ is also completely controllable. Hence, in particular, we have $C_0 \neq 0$ and then there exists $w_0 \in \delta B_1^2(0)$ such that

$$(6.27) \quad \varphi \triangleq C_0w_0 \neq 0.$$

By applying the orthogonal projection P_{L_0} to (6.13) we get

$$(6.28) \quad \begin{aligned} \dot{z}_1^1(t) &= A_0z_1^1(t) + C_0w(t), \\ z_1^1(0) &= z_{10}^1. \end{aligned}$$

Thus,

$$(6.29) \quad \begin{aligned} d(M, z(t)) &= \|z_1(t)\| \geq \|P_{L_0}z_1(t)\| = \|z_1^1(t)\| \\ &= \left\| e^{A_0t}z_{10}^1 + \int_0^t e^{A_0(t-\tau)}C_0w(\tau) d\tau \right\|. \end{aligned}$$

Now, we consider two subcases.

(1) $z_{10}^1 \neq 0$.

(i) For $a \geq 0$, we take

$$(6.30) \quad w(t) \equiv 0, \quad t \geq 0.$$

Then for all $t \geq 0$ we have that

$$(6.31) \quad \begin{aligned} d(M, z(t)) &\geq \|z_1^1(t)\| = \|e^{at} e^{bKt} z_{10}^1\| \\ &= e^{at} \|e^{bKt} z_{10}^1\| = e^{at} \|z_{10}^1\| \geq \|z_{10}^1\| > 0. \end{aligned}$$

(ii) For $a < 0$, then, we know that

$$(6.32) \quad \lim_{t \rightarrow \infty} e^{at} e^{bKt} z_{10}^1 = 0,$$

and e^{bKt} is a rotation on the plane L_0 which sweeps all possible angles as t varies from 0 to ∞ . Thus, there exists $t_0 > 0$ such that

$$(6.33) \quad e^{at_0} e^{bKt_0} z_{10}^1 = \delta_0 \psi \equiv \delta_0 \frac{-aI + bK}{a + b} \varphi$$

for some $\delta_0 \in (0, 1)$. Since $\det(-aI + bK) = a^2 + b^2 > 0$, we have $\psi \neq 0$. Now, we take

$$(6.34) \quad w(t) = \begin{cases} 0, & 0 \leq t < t_0, \\ \delta_0 w_0, & t_0 \leq t < \infty \end{cases}$$

where w_0 is as in (6.27). Then, for $0 \leq t < t_0$, we have

$$(6.35) \quad \begin{aligned} d(M, z(t)) &\geq \|z_1^1(t)\| = \|e^{at} e^{bKt} z_{10}^1\| \\ &\geq e^{at_0} \|z_{10}^1\| > 0, \end{aligned}$$

and for $t \geq t_0$, by Lemma 6.5 and (6.33), we have

$$(6.36) \quad \begin{aligned} d(M, z(t)) &\geq \left\| e^{(aI+bK)t} z_{10}^1 + \int_{t_0}^t e^{(aI+bK)(t-\tau)} \delta_0 \varphi d\tau \right\| \\ &= \left\| e^{(aI+bK)t} z_{10}^1 + \int_0^{t-t_0} e^{(aI+bK)\tau} \delta_0 \varphi d\tau \right\| \\ &= \left\| e^{(aI+bK)t} z_{10}^1 + [e^{(aI+bK)(t-t_0)} - I] \frac{aI - bK}{a^2 + b^2} \delta_0 \varphi \right\| \\ &= \|e^{(aI+bK)(t-t_0)} [e^{at_0} e^{bKt_0} z_{10}^1 - \delta_0 \psi] + \delta_0 \psi\| \\ &= \delta_0 \|\psi\| \equiv e^{at_0} \|z_{10}^1\| > 0. \end{aligned}$$

Hence, the game is strictly evadable in this subcase.

(2) $z_{10}^1 = 0$.

Since $d(M, z) = \|z_{10}^1\| > 0$, there exists a $\theta \in (0, 2\pi/b)$ such that (6.19) holds for $t \in [0, \theta]$ if we take $w(t) \equiv w_0$ where w_0 is as above. On the other hand, by choosing such an evasion control, we have

$$(6.37) \quad \begin{aligned} z_1^1(\theta) &= \int_0^\theta e^{(aI+bK)(\theta-\tau)} C_0 w_0 d\tau \\ &= \int_0^\theta e^{(aI+bK)\tau} d\tau \varphi \\ &= [e^{(aI+bK)\theta} - I] \frac{aI - bK}{a^2 + b^2} \varphi \neq 0. \end{aligned}$$

Then, subcase (1) applies. \square

Remark 6.8. From the proof of Theorem 6.6, we see that we only need the condition that there exists a subspace $M \subseteq \mathbb{R}^n$, with $\dim M_0 < n$, $M \subset M_0$, $AM_0 \subset M_0$, and $[A^*|M_0^\perp]^*$, $(C^*|M_0^\perp)^*$ is completely controllable and $((C^*|M_0^\perp)^*, V)$ is δ -superior to $((B^*|M_0^\perp)^*, U)$ for some $\delta > 0$.

Remark 6.9. The condition that $((C^*|M^\perp)^*, V)$ is δ -superior to $((B^*|M^\perp)^*, U)$, which we imposed in Theorem 6.6, does not imply condition (5.13), which we imposed in Corollary 5.2. We will illustrate this point by showing an example in the next section.

7. An example. We present an example in this section.

Consider two objects in \mathbb{R}^3 , one pursuing the other. Suppose the pursuer is x and the evader is y and that they are subject to the following systems:

$$(7.1) \quad \begin{aligned} \dot{x} &= p, \\ \dot{p} &= A_0x + B_0p + C_1u, \end{aligned}$$

$$(7.2) \quad \begin{aligned} \dot{y} &= q, \\ \dot{q} &= A_0y + B_0q + C_2v. \end{aligned}$$

The pursuer wants to “softly” catch the evader; namely, the terminal set M is

$$(7.3) \quad M = \{x = y, p = q\}.$$

The problem models an aerial dogfight in which the evader does not want the pursuer to “get on his tail.” The evader is willing to risk a collision, presumably secure in the belief that the pursuer would not be suicidal.

Now, let us formulate the problem into a standard one. We set

$$(7.4) \quad \begin{aligned} z_1 &= x - y, & z_2 &= p - q, \\ z_3 &= x + y, & z_4 &= p + q. \end{aligned}$$

Then, (7.1) and (7.2) become

$$(7.5) \quad z = \begin{pmatrix} 0 & I & 0 & 0 \\ A_0 & B_0 & 0 & 0 \\ 0 & 0 & 0 & I \\ 0 & 0 & A_0 & B_0 \end{pmatrix} z + \begin{pmatrix} 0 \\ C_1 \\ 0 \\ C_1 \end{pmatrix} u + \begin{pmatrix} 0 \\ -C_2 \\ 0 \\ C_2 \end{pmatrix} v \equiv Az + Bu + Cv$$

and the terminal set is

$$(7.6) \quad M = \{(0, 0, z_3, z_4) \mid z_3, z_4 \in \mathbb{R}^3\}.$$

It is clear that

$$(7.7) \quad AM \subseteq M$$

and (5.13) does not hold for any δ_0 . However, we have the following proposition.

PROPOSITION 7.1. *Suppose*

$$\left[\begin{pmatrix} 0 & I \\ A_0 & B_0 \end{pmatrix}, \begin{pmatrix} 0 \\ -C_2 \end{pmatrix} \right]$$

is completely controllable and (C_2, V) is δ -superior to $(-C_1, U)$. Then “soft” capture can be avoided.

The proof is immediate from Theorem 6.6.

Acknowledgments. The author thanks Professor L. D. Berkovitz for posing the problem, for many suggestive discussions and for encouragement in writing this paper. The author would also like to thank the referee for the suggestions and criticism which led to this much nicer version of the paper.

OPTIMAL PERIODIC CONTROL FOR THE TWO-PHASE STEFAN PROBLEM*

AVNER FRIEDMAN[†], SHAOYUN HUANG[‡] AND JIONGMIN YONG[†]

Abstract. Consider the two-phase Stefan problem in a domain $\{(x, t); x \in D, 0 < t < \infty\}$ with the heat flux across a part Γ_1 of ∂D being a control function $k(x, t)$ periodic in t of period σ , and $N_1 \leq k \leq N_2$, $\int_0^\sigma \int_{\Gamma_1} k(x, t) = M$, where N_1, N_2, M are given positive constants. The solution $u(x, t)$ behaves asymptotically as a periodic function $\hat{u}(x, t)$. We wish to maximize $\int_0^\sigma \int_D p(x) \hat{u}(x, t)$ where p is a given positive function. It is proved that any optimal control k_0 has the form

$$k_0(x, t) = \begin{cases} N_2 & \text{if } 0 < t < \varphi(x), \\ N_1 & \text{if } \varphi(x) < t < \sigma \end{cases}$$

where $\varphi(x)$ is a smooth function.

Introduction. Consider the two-phase Stefan problem for the temperature u :

$$(0.1) \quad \frac{\partial}{\partial t} (u + H(u)) - \Delta u = 0 \quad \text{in } D \times \{0 < t < \infty\}$$

with

$$(0.2) \quad \frac{\partial u}{\partial \nu} = k(x, t) \quad \text{for } x \in \Gamma_1, \quad 0 < t < \infty \quad (k < 0),$$

$$(0.3) \quad \frac{\partial u}{\partial \nu} = -g(x, t) \quad \text{for } x \in \Gamma_2, \quad 0 < t < \infty \quad (g > 0)$$

or

$$(0.2') \quad u = k(x, t) \quad \text{for } x \in \Gamma_1, \quad 0 < t < \infty,$$

$$(0.3') \quad u = -g(x, t) \quad \text{for } x \in \Gamma_2, \quad 0 < t < \infty$$

where $\Gamma_1 \cap \Gamma_2 = \emptyset$, $\Gamma_1 \cup \Gamma_2 = \partial D$ and

$$(0.4) \quad u(x, 0) = u_0(x) \quad \text{for } x \in D;$$

here $H(u)$ is the Heaviside function. It is well known (for the Dirichlet boundary conditions (0.2'), (0.3')) that the above problem has a unique global solution [2], [4], [5], [9]. It was recently proved by DiBenedetto and Friedman [3] that if k and g are periodic in t with period σ , then there exists a σ -periodic solution $\hat{u}(x, t)$, independent of $u_0(x)$, such that

$$(0.5) \quad \sup_{x \in D} |u(x, t) - \hat{u}(x, t)| \rightarrow 0 \quad \text{if } t \rightarrow \infty.$$

We now consider k as a control function in a class

$$(0.6) \quad \mathcal{A}_\sigma = \left\{ k; N_1 \leq k \leq N_2, \int_0^\sigma \int_D k(x, t) = M, k(x, t + \sigma) = k(x, t) \right\},$$

and introduce a functional

$$(0.7) \quad J(k) = \int_0^\sigma \int_D p(x) \hat{u}(x, t) \, dx \, dt$$

and the optimization problem

$$(0.8) \quad J(k_0) = \max_{k \in \mathcal{A}_\sigma} J(k), \quad k_0 \in \mathcal{A}_\sigma.$$

In this paper we analyze the structure of the optimal controls k_0 . We prove that

$$(0.9) \quad k_0(x, t) = \begin{cases} N_2 & \text{if } m\sigma < t < m\sigma + \varphi(x), \\ N_1 & \text{if } m\sigma + \varphi(x) < t < (m+1)\sigma, \end{cases}$$

for $m = 0, 1, 2, \dots$, where $\varphi(x)$ is a smooth function. This result is established not only for the Dirichlet data (0.2'), (0.3') but also for other data, such as (0.2), (0.3') (in which case one must impose restrictions on N_1, N_2 in order to ensure that the free boundary does not meet the fixed boundary ∂D at any time).

The control problem is motivated by the following situation which occurs in a frozen body of sea water: An object D_1 (a pipeline, for instance) is placed in the frozen water and its boundary Γ_1 is heated, causing the ice to melt in the vicinity of D_1 . The temperature of the ice varies with the climate and is thus a periodic function (either on a scale of one year or on a scale of one day). It is therefore natural to choose for the flux k on Γ_1 as a periodic control. The functional (0.7), to be maximized, represents the amount of heat in both the water and ice regions with a weight function p . Since one is usually interested in raising the amount of heat in the melted ice rather than in raising it in the ice, one may choose $p(x)$ to decrease away from D_1 .

In § 1 we briefly establish the asymptotic behavior for the system (0.1), (0.2), (0.3'), (0.4), thereby extending the results of [3] to the case when (0.2') is replaced by (0.2). In § 2 we consider an intermediate control problem for (0.1), (0.2), (0.3'), (0.4) with

$$J(k) = \int_0^T \int_D p(x) u(x, t);$$

here k and g are not assumed to be periodic in t . We establish a bang-bang principle similar to (0.9) for any maximizer k_0 .

For the one-phase Stefan problem a bang-bang principle was established (in [6], [8]) for the functional $J(k)$ representing the volume of ice that has melted by time T . At the end of § 2 we show that such a principle is false for the two-phase Stefan problem.

The analysis of § 2 is used in § 3 where the assertion (0.9) is established. Finally, in § 4 we extend the results of § 3 to the Stefan problem where the boundary condition on Γ_1 is either of the form (0.2) or (0.2') and the boundary condition on Γ_2 is either of the form (0.3) or (0.3'). Here, the fact that the Dirichlet data in (0.2) are in L^∞ , but not continuous in general, requires some approximating procedure.

1. Existence and uniqueness of periodic solutions (under the condition (0.2), (0.3')). Let Γ_1 and Γ_2 be $C^{2+\alpha}$ closed hypersurfaces in \mathbb{R}^N such that Γ_1 lies in the interior of the set enclosed by Γ_2 . Denote by D the domain bounded by Γ_1, Γ_2 , and set $D_T = D \times \{0 < t < T\}$, $\Gamma_{i,T} = \Gamma_i \times \{0 < t < T\}$ for any $T \leq \infty$.

We are given a function $g(x, t)$ satisfying

$$(1.1) \quad \begin{aligned} &g \in L^\infty(D_\infty), D_x g \text{ and } D_t g \text{ belong to } L^\infty(D_\infty), \\ &0 < c_1 \leq g \leq c_2 < \infty \text{ (} c_1, c_2 \text{ are constants);} \end{aligned}$$

a function $h(x)$ satisfying

$$(1.2) \quad h \in C^0(\bar{D}), \quad h = -g \quad \text{on } \Gamma_2 \times \{0\};$$

and a function $k(x, t)$ satisfying

$$(1.3) \quad 0 < N_1 \leq k(x, t) \leq N_2 < \infty \quad \text{on } \Gamma_{1,\infty} \quad (N_1, N_2 \text{ are constants}).$$

The two-phase Stefan problem for the temperature u is formally written in the form

$$(1.4) \quad \begin{aligned} \frac{\partial}{\partial t} (u + H(u)) - \Delta u &= 0 \quad \text{in } \mathcal{D}'(D_\infty), \\ \frac{\partial u}{\partial \nu} &= k \quad \text{on } \Gamma_{1,\infty}, \\ u &= -g \quad \text{on } \Gamma_{2,\infty}, \\ u(x, 0) &= h(x) \quad \text{if } x \in D \end{aligned}$$

where ν is the outward normal to D and H is the Heaviside function. More precisely, by a solution of (1.4) we mean a *weak solution* in the following sense.

For any $0 < T < \infty$ there is a pair (u, ξ) with $\xi \subset H(u)$ such that

$$(1.5) \quad u \in L^\infty((0, T); L^2(D)) \cap L^2((0, T); H^1(D)),$$

$$(1.6) \quad u = -g \quad \text{on } \Gamma_{2,T},$$

$$(1.7) \quad \int_0^T \int_D [-(u + \xi)\varphi_t + \nabla u \cdot \nabla \varphi] dx dt = \int_0^T \int_{\Gamma_1} k\varphi dS dt + \int_D (h + \xi_0)\varphi(x, 0) dx$$

for every $\varphi \in V$. Here ξ_0 is a given initial data with $\xi_0 \subset H(h)$ and

$$V = \{\varphi \in H^1(D_T), \varphi = 0 \text{ on } \Gamma_2 \times (0, T), \varphi = 0 \text{ on } t = T\}.$$

In order to construct a solution of (1.5)–(1.7) we follow the procedure in [3] and introduce, for any $\varepsilon > 0$,

$$H_\varepsilon(s) = \begin{cases} 1 & \text{if } s > \varepsilon, \\ s/\varepsilon & \text{if } 0 < s \leq \varepsilon, \\ 0 & \text{if } s \leq 0. \end{cases}$$

Define

$$(1.8) \quad h_\varepsilon(x) = \begin{cases} h(x) & \text{if } h(x) > \varepsilon \text{ or } h(x) < 0, \\ \varepsilon \xi_0 & \text{if } 0 \leq h(x) \leq \varepsilon. \end{cases}$$

Then

$$(1.9) \quad H_\varepsilon(h_\varepsilon) = \xi_0.$$

Consider the ε -approximate problems

$$(1.10) \quad \begin{aligned} \frac{\partial}{\partial t} (u_\varepsilon + H_\varepsilon(u_\varepsilon)) - \Delta u_\varepsilon &= 0 \quad \text{in } D_T, \\ \frac{\partial u_\varepsilon}{\partial \nu} &= k \quad \text{on } \Gamma_{1,T}, \\ u_\varepsilon &= -g \quad \text{on } \Gamma_{2,T}, \\ u_\varepsilon &= h_\varepsilon \quad \text{on } D \times \{0\}. \end{aligned}$$

Existence for (1.10) can be established by a fixed point argument using standard parabolic estimates. Uniqueness follows from the following more general stability result.

LEMMA 1.1. *Suppose \hat{u}_ε is a solution of (1.10) corresponding to data $\hat{k}, \hat{g}, \hat{h}_\varepsilon$. If $\hat{g} \cong g$ on $\Gamma_{2,T}$, then*

$$(1.11) \quad \begin{aligned} & \int_{D \times \{t\}} [\hat{u}_\varepsilon - u_\varepsilon + H_\varepsilon(\hat{u}_\varepsilon) - H_\varepsilon(u_\varepsilon)]^+ \\ & \leq \int_D [\hat{h}_\varepsilon - h_\varepsilon + H_\varepsilon(\hat{h}_\varepsilon) - H_\varepsilon(h_\varepsilon)]^+ + \int_0^t \int_{\Gamma_1} [\hat{k} - k]^+. \end{aligned}$$

Proof. We take the difference of the parabolic equations for \hat{u}_ε and u_ε , multiply by $H_\lambda(\hat{u}_\varepsilon - u_\varepsilon)$ and integrate over D_t . After an integration by parts, we let $\lambda \rightarrow 0$, and (1.11) follows.

Take any small positive constant δ_0 and denote by $V_0(x)$ the solution of

$$(1.12) \quad \begin{aligned} \Delta V_0 &= 0 \quad \text{in } D, \\ V_0 &= \delta_0 \quad \text{on } \Gamma_1, \\ V_0 &= -c_2 \quad \text{on } \Gamma_2; \end{aligned}$$

c_2 is as in (1.1). By the maximum principle,

$$(1.13) \quad \frac{\partial V_0}{\partial \nu} \geq N_1 > 0 \quad \text{on } \Gamma_1 \quad (N_1 \text{ constant}).$$

We shall henceforth assume that $k(x, t)$ satisfies (1.3) with N_1 as in (1.13); N_2 is an arbitrary constant.

Denote by $V_1(x)$ the solution of

$$(1.14) \quad \begin{aligned} \Delta V_1 &= 0 \quad \text{in } D, \\ \frac{\partial V_1}{\partial \nu} &= N_2 \quad \text{on } \Gamma_1, \\ V_1 &= -c_1 \quad \text{on } \Gamma_2. \end{aligned}$$

By the maximum principle

$$(1.15) \quad V_0(x) < V_1(x) \quad \text{in } \bar{D}.$$

From Lemma 1.1 we obtain the following.

LEMMA 1.2. *There holds*

$$\begin{aligned} \int_{D \times \{t\}} [V_0 - u_\varepsilon + H_\varepsilon(V_0) - H_\varepsilon(u_\varepsilon)]^+ &\leq \int_D [V_0 - h_\varepsilon + H_\varepsilon(V_0) - H_\varepsilon(h_\varepsilon)]^+, \\ \int_{D \times \{t\}} [u_\varepsilon - V_1 + H_\varepsilon(u_\varepsilon) - H_\varepsilon(V_1)]^+ &\leq \int_D [h_\varepsilon - V_1 + H_\varepsilon(h_\varepsilon) - H_\varepsilon(V_1)]^+. \end{aligned}$$

Using the same method as in [3] we can deduce the following estimates for the solution of (1.10).

LEMMA 1.3. *There holds*

$$(1.16) \quad \begin{aligned} \|u_\varepsilon\|_{L^\infty(D_T)} &\leq C, \\ \|\nabla u_\varepsilon\|_{L^2(D_T)} &\leq C(T), \\ \left\| \frac{\partial}{\partial t} u_\varepsilon \right\|_{L^2(E)} &\leq C(T, \text{dist}(E, \partial D_T)) \end{aligned}$$

for any compact set $E \subset D \times (0, T)$; the constants C are independent of ε .

It follows that the family $\{u_\varepsilon\}$ is precompact in $L^2(D_T)$ and that, for a subsequence $\varepsilon \rightarrow 0$,

$$(1.17) \quad \begin{aligned} u_\varepsilon &\rightarrow u \quad \text{in } L^2(D_T) \text{ and a.e. in } D_T, \\ \nabla u_\varepsilon &\rightarrow \nabla u \quad \text{weakly in } L^2(D_T), \\ H_\varepsilon(u_\varepsilon) &\rightarrow \xi \quad \text{weakly in } L^2(D_T). \end{aligned}$$

Using Lemma 1.2 and arguing as in [3] we can establish the following theorem.

THEOREM 1.4. *If*

$$(1.18) \quad V_0(x) \leq h(x) \leq V_1(x),$$

$$(1.19) \quad H(V_0) \leq \xi_0 \leq H(V_1)$$

in D , then there exists a solution (u, ξ) of (1.5)–(1.7) and

$$(1.20) \quad V_0(x) \leq u(x, t) \leq V_1(x),$$

$$(1.21) \quad H(V_0) \leq \xi(x, t) \leq H(V_1)$$

in D_T .

Uniqueness of the solution follows from the more general stability result.

THEOREM 1.5. *Let $(\tilde{u}, \tilde{\xi})$ be a solution of (1.5)–(1.7) for data $\tilde{k}, \tilde{g}, \tilde{h}, \tilde{\xi}_0$ satisfying the same conditions as k, g, h, ξ_0 above. Then*

$$(1.22) \quad \begin{aligned} &\iint_{D_T} [|u - \tilde{u}|^2 + (\xi - \tilde{\xi})(u - \tilde{u})] \\ &\leq C \int_0^T \int_{\Gamma_1} |k - \tilde{k}| + C \int_0^T \int_{\Gamma_2} |g - \tilde{g}| + C \int_D |h - \tilde{h} + \xi_0 - \tilde{\xi}_0| \end{aligned}$$

where C is a positive constant independent of the data and of T ; C depends on N_1, N_2, c_1, c_2 .

The proof is similar to the proof given in [4] (see also [3], [5]) for Dirichlet data. The fact that C is independent of T will be of crucial importance in the sequel.

We next consider the periodic case

$$(1.23) \quad \begin{aligned} k(x, t + \sigma) &= k(x, t) \quad \text{on } \Gamma_1 \times (0, \infty), \\ g(x, t + \sigma) &= g(x, t) \quad \text{on } \Gamma_2 \times (0, \infty) \end{aligned}$$

for some $\sigma > 0$.

LEMMA 1.6. *If (1.23) holds then there exists a function \hat{h}_ε with $V_0(x) \leq \hat{h}_\varepsilon(x) \leq V_1(x)$ in D such that the corresponding solution \hat{u}_ε of the ε -approximating problems (1.10) is periodic in t of period σ .*

The proof which is similar to the proof of [3, Theorem 7.1] uses the Schauder fixed point theorem.

Taking a convergent subsequence of the \hat{u}_ε 's, we obtain the following theorem.

THEOREM 1.7. *If (1.23) holds then there exists a function \hat{h} and a selection $\hat{\xi}_0 \in H(\hat{h})$ with $V_0(x) \leq \hat{h}(x) \leq V_1(x)$, $H(V_0) \leq \hat{\xi}_0 \leq H(V_1)$ in D such that there exists a solution $(\hat{u}, \hat{\xi})$ of (1.5)–(1.7), with $h = \hat{h}$, $\xi_0 = \hat{\xi}_0$, $u = \hat{u}$, which is periodic in t of period σ , and*

$$V_0(x) \leq \hat{u}(x, t) \leq V_1(x),$$

$$H(V_0) \leq \hat{\xi}(x, t) \leq H(V_1)$$

in D_∞ ; the function \hat{u} is uniquely determined by k, g .

The last assertion (about uniqueness) follows from Theorem 1.5. Indeed, if (\tilde{h}, \tilde{u}) is another periodic solution then (1.22) implies that

$$\int_0^\infty \int_D |\hat{u}(x, t) - \tilde{u}(x, t)|^2 dx dt < \infty.$$

Since, however, $\hat{u} - \tilde{u}$ is periodic in t of period σ , it follows that $\hat{u} - \tilde{u} \equiv 0$.

2. Optimal control in finite time. We now consider k to be a control variable belonging to the set

$$\mathcal{A} = \left\{ k \in L^\infty(\Gamma_1 \times (0, T)), N_1 \leq k \leq N_2, \int_0^T \int_{\Gamma_1} k = M \right\}$$

with N_1, N_2 as in § 1; we assume that

$$(2.1) \quad N_1 T \text{ meas}(\Gamma_1) < M < N_2 T \text{ meas}(\Gamma_1),$$

for otherwise the set \mathcal{A} is empty or reduces to one element. Consider the Stefan problem (1.5)–(1.7) written in the form

$$(2.2) \quad \begin{aligned} \frac{\partial}{\partial t} \beta(u) - \Delta u &= 0 \quad \text{in } \mathcal{D}'(D_T), \\ u_\nu &= k \quad \text{on } \Gamma_{1,T}, \\ u &= -g \quad \text{on } \Gamma_{2,T}, \\ \beta(u) &= \beta(h) \quad \text{on } t=0 \end{aligned}$$

where $\beta(u) = u + H(u)$, and set

$$K_T = \{(k, u); k \in \mathcal{A}, u \text{ is the unique solution of (2.2) corresponding to } k\}.$$

Let $p(x)$ be a given function satisfying

$$(2.3) \quad \begin{aligned} p &\text{ is piecewise continuous in } \bar{D}, \\ p &\geq 0 \quad \text{in } \bar{D}, \quad p > 0 \quad \text{on } \Gamma_1. \end{aligned}$$

We introduce the functional

$$(2.4) \quad J(k) = \int_0^T \int_D p(x) u(x, t) dx dt$$

and consider the following maximization problem.

Problem (F). Find k_0 such that

$$J(k_0) = \max_{k \in \mathcal{A}} J(k), \quad k_0 \in \mathcal{A}.$$

THEOREM 2.1. *There exists a solution of Problem (F).*

Proof. Let $(k_m, u_m) \in K_T$ be a maximizing sequence. From the estimates in § 1 (cf. Lemma 1.3) it follows that, for a subsequence,

$$\begin{aligned} k_m &\rightarrow k_0 \quad \text{weakly,} \\ u_m &\rightarrow u_0 \quad \text{weakly in } H^1(D_T) \text{ and a.e. in } D_T. \end{aligned}$$

It is now easily seen that $(k_0, u_0) \in K_T$ and that k_0 is a maximizer.

We shall henceforth consider a particular maximizer k_0 and proceed to study its structure. For this purpose we set $\beta_\varepsilon(u) = u + H_\varepsilon(u)$ and again consider the ε -approximating problems

$$(2.5) \quad \begin{aligned} \frac{\partial}{\partial t} \beta_\varepsilon(u) - \Delta u &= 0 \quad \text{in } D_T, \\ u_\nu &= k \quad \text{on } \Gamma_{1,T}, \\ u &= -g \quad \text{on } \Gamma_{2,T}, \\ u &= h \quad \text{on } t=0. \end{aligned}$$

We define

$K_T^\varepsilon = \{(k, u); k \in \mathcal{A}, u \text{ is the unique solution of (2.5) corresponding to } k\}$, and (as in [1], [6]) introduce the functional

$$J_\varepsilon(k) = \int_0^T \int_D p(x)u(x, t) dx dt - \frac{1}{2} \int_0^T \int_{\Gamma_1} (k - k_0)^2 dS dt$$

for any $(k, u) \in K_T^\varepsilon$.

Problem (F_ε) . Find $(k_\varepsilon, u_\varepsilon) \in K_T^\varepsilon$ such that

$$J_\varepsilon(k_\varepsilon) = \max_{(k, u) \in K_T^\varepsilon} J_\varepsilon(k).$$

Similarly to Theorem 2.1 one can prove that there exists a solution $(k_\varepsilon, u_\varepsilon)$ of problem (F_ε) .

LEMMA 2.2. *If $(k_\varepsilon, u_\varepsilon) \in K_T^\varepsilon$ is a maximizer of problem (F_ε) then, as $\varepsilon \rightarrow 0$,*

$$(2.6) \quad k_\varepsilon \rightarrow k_0 \quad \text{in } L^2(\Gamma_1 \times (0, T)),$$

$$(2.7) \quad u_\varepsilon \rightarrow u_0 \quad \text{weakly in } L^2((0, T); H^1(D)) \text{ and a.e. in } D_T.$$

Proof. For a subsequence,

$$(2.8) \quad \begin{aligned} k_\varepsilon &\rightarrow \tilde{k} \quad \text{weakly in } L^2(\Gamma_1 \times (0, T)), \\ u_\varepsilon &\rightarrow \tilde{u} \quad \text{weakly in } L^2((0, T); H^1(D)) \text{ and a.e. in } D_T \end{aligned}$$

and $(\tilde{k}, \tilde{u}) \in K_T^\varepsilon$. It suffices to show that $\tilde{k} = k_0$, for then, by uniqueness, also $\tilde{u} = u_0$. Let $(k_0, u_\varepsilon^*) \in K_T^\varepsilon$. By the estimates (1.16) of § 1,

$$(2.9) \quad u_\varepsilon^* \rightarrow \tilde{u}_0 \quad \text{weakly in } L^2((0, T); H^1(D)) \text{ and a.e. in } D_T$$

where $(k_0, \tilde{u}_0) \in K_T$ and $\tilde{u}_0 = u_0$ by uniqueness. We have

$$\begin{aligned} J(k_0) &\cong J(\tilde{k}) = \int_{D_T} p\tilde{u} \quad (\text{by maximality of } k_0) \\ &= \lim_{\varepsilon \rightarrow 0} \left[\int_{D_T} p u_\varepsilon - \frac{1}{2} \int_{\Gamma_{1,T}} (k_\varepsilon - k_0)^2 + \frac{1}{2} \int_{\Gamma_{1,T}} (k_\varepsilon - k_0)^2 \right] \quad (\text{by (2.8)}) \\ &\cong \liminf_{\varepsilon \rightarrow 0} J_\varepsilon(k_\varepsilon) + \frac{1}{2} \limsup_{\varepsilon \rightarrow 0} \int_{\Gamma_{1,T}} (k_\varepsilon - k_0)^2 \\ &\cong \liminf_{\varepsilon \rightarrow 0} J_\varepsilon(k_0) + \frac{1}{2} \limsup_{\varepsilon \rightarrow 0} \int_{\Gamma_{1,T}} (k_\varepsilon - k_0)^2 \quad (\text{by maximality of } k_\varepsilon) \\ &= \lim_{\varepsilon \rightarrow 0} \int_{D_T} p u_\varepsilon^* + \frac{1}{2} \limsup_{\varepsilon \rightarrow 0} \int_{\Gamma_{1,T}} (k_\varepsilon - k_0)^2 \\ &= J(k_0) + \frac{1}{2} \limsup_{\varepsilon \rightarrow 0} \int_{\Gamma_{1,T}} (k_\varepsilon - k_0)^2 \end{aligned}$$

by (2.9) and $\tilde{u}_0 = u_0$. It follows that (2.6) holds.

We now proceed to analyze any solution $(k_\varepsilon, u_\varepsilon) \in K_T^\varepsilon$ of Problem (F_ε) . Let l be a function such that $k_\varepsilon + \delta l \in \mathcal{A}$ for all small enough $\delta > 0$, and let $(k_\varepsilon + \delta l, u_{\varepsilon,\delta}) \in K_T^\varepsilon$. Then we have

$$(2.10) \quad \begin{aligned} 0 &\leq J_\varepsilon(k_\varepsilon + \delta l) - J_\varepsilon(k_\varepsilon) \\ &= \int_{D_T} p(u_{\varepsilon,\delta} - u_\varepsilon) - \delta \int_0^T \int_{\Gamma_1} (k_\varepsilon - k_0)l - \frac{\delta^2}{2} \int_0^T \int_{\Gamma_1} l^2. \end{aligned}$$

For fixed ε one can establish by standard parabolic estimates that

$$\left\| \frac{u_{\varepsilon,\delta} - u_\varepsilon}{\delta} \right\|_{L^2((0,T); H^1(D))} \leq C \quad \text{as } \delta \rightarrow 0,$$

and, in fact,

$$(2.11) \quad \frac{u_{\varepsilon,\delta} - u_\varepsilon}{\delta} \rightharpoonup z_\varepsilon \quad \text{weakly in } L^2((0, T); H^1(D)) \text{ and a.e. in } D_T$$

where z_ε is the solution of

$$(2.12) \quad \begin{aligned} \frac{\partial}{\partial t} (\beta'_\varepsilon(u_\varepsilon) z_\varepsilon) - \Delta z_\varepsilon &= 0 \quad \text{in } D_T, \\ \frac{\partial}{\partial \nu} z_\varepsilon &= l \quad \text{on } \Gamma_{1,T}, \\ z_\varepsilon &= 0 \quad \text{on } \Gamma_{2,T}, \\ z_\varepsilon &= 0 \quad \text{on } t = 0. \end{aligned}$$

Denote by Q_ε the solution of the parabolic problem

$$(2.13) \quad \begin{aligned} \beta'_\varepsilon(u_\varepsilon) \frac{\partial Q_\varepsilon}{\partial t} + \Delta Q_\varepsilon &= p \quad \text{in } D_T, \\ \frac{\partial}{\partial \nu} Q_\varepsilon &= 0 \quad \text{on } \Gamma_{1,T}, \\ Q_\varepsilon &= 0 \quad \text{on } \Gamma_{2,T}, \\ Q_\varepsilon &= 0 \quad \text{on } t = T. \end{aligned}$$

Then

$$\begin{aligned} 0 &= \int_{D_T} \left[\frac{\partial}{\partial t} (\beta'_\varepsilon(u_\varepsilon) z_\varepsilon) - \Delta z_\varepsilon \right] Q_\varepsilon \\ &= \int_D \beta'_\varepsilon(u_\varepsilon) z_\varepsilon Q_\varepsilon \Big|_0^T - \int_{D_T} \beta'_\varepsilon(u_\varepsilon) z_\varepsilon Q_{\varepsilon,t} - \int_{D_T} z_\varepsilon \Delta Q_\varepsilon \\ &\quad - \int_0^T \int_{\partial D} [z_{\varepsilon,\nu} Q_\varepsilon - z_\varepsilon Q_{\varepsilon,\nu}] \\ &= - \int_{D_T} p z_\varepsilon - \int_0^T \int_{\Gamma_1} l Q_\varepsilon \quad \text{by (2.12), (2.13)}. \end{aligned}$$

Using this and (2.10), (2.11), we find that

$$\begin{aligned} 0 &\geq \limsup_{\delta \rightarrow 0} \frac{1}{\delta} [J_\varepsilon(k_\varepsilon + \delta l) - J_\varepsilon(k_\varepsilon)] \\ &= \int_{D_T} p z_\varepsilon - \int_{\Gamma_{1,T}} (k_\varepsilon - k_0) l = \int_{\Gamma_{1,T}} l (-Q_\varepsilon - k_\varepsilon + k_0), \end{aligned}$$

i.e.,

$$(2.14) \quad \int_{\Gamma_{1,T}} (Q_\varepsilon + k_\varepsilon - k_0) l \geq 0.$$

From this relation and from (2.6) we can deduce, precisely as in [6], that for any small $\eta > 0$ there is a set Σ_η in $\Gamma_{1,T}$ of measure smaller than η such that

$$(2.15) \quad k_\varepsilon = \begin{cases} N_2 & \text{on } (Q_\varepsilon < \lambda_\varepsilon - \eta) \cap \{\Gamma_{1,T} \setminus \Sigma_\eta\}, \\ N_1 & \text{on } \{Q_\varepsilon > \lambda_\varepsilon + \eta\} \cap \{\Gamma_{1,T} \setminus \Sigma_\eta\}, \end{cases}$$

if ε is small enough; λ_ε is some constant and Σ_η is independent of ε .

We shall analyze Q_ε as $\varepsilon \rightarrow 0$. Observe first that, by comparison,

$$(2.16) \quad \bar{Q} \leq Q_\varepsilon \leq 0$$

where \bar{Q} is the solution of

$$\begin{aligned} \Delta \bar{Q} &= p \quad \text{in } D, \\ \bar{Q}_\nu &= 0 \quad \text{on } \Gamma_1, \quad \bar{Q} = 0 \quad \text{on } \Gamma_2. \end{aligned}$$

Denote by Γ_1^δ the intersection of D with δ -neighborhood of Γ_1 . By comparison, (1.20) holds also for $u = u_\varepsilon$. Hence, by (1.12), (1.14) there holds

$$\beta'_\varepsilon(u_\varepsilon) = 1 \quad \text{in } V_\delta = \Gamma_1^\delta \times (0, T)$$

for some $\delta > 0$ independent of k, ε . From this and from (2.16), (2.13) it follows that, for a sequence $\varepsilon \rightarrow 0$,

$$(2.17) \quad Q_\varepsilon \rightarrow Q \quad \text{uniformly in } V_\delta,$$

and

$$\begin{aligned} Q_t + \Delta Q &= p \quad \text{in } V_\delta, \\ Q_\nu &= 0 \quad \text{on } \Gamma_{1,T}, \\ Q &\leq 0 \quad \text{in } V_\delta, \\ Q &= 0 \quad \text{on } t = T. \end{aligned} \quad (2.18)$$

Next, by differentiation with respect to t of (2.13) we see that the function $\zeta = Q_{\varepsilon,t}$ satisfies

$$\begin{aligned} \beta'_\varepsilon(u_\varepsilon) \zeta_t + \Delta \zeta + \beta''_\varepsilon(u_\varepsilon) u_{\varepsilon,t} \zeta &= 0 \quad \text{in } D_T, \\ \zeta_\nu &= 0 \quad \text{on } \Gamma_{1,T}, \\ \zeta &= 0 \quad \text{on } \Gamma_{2,T}, \\ \zeta(x, T) &\geq 0 \quad \text{if } x \in D \quad (\text{since } Q_\varepsilon \leq 0, Q_\varepsilon(x, T) = 0). \end{aligned}$$

By the maximum principle it follows that $\zeta \geq 0$ in D_T , i.e.,

$$(2.19) \quad Q_{\varepsilon,t} \geq 0 \quad \text{in } D_T.$$

(Actually, since $\beta''_\varepsilon(u)$ is not bounded, one should define $\beta_\varepsilon(u)$ from the outset slightly differently, so that it is in C^2 .) From (2.19), (2.17) it follows that

$$(2.20) \quad Q_t \geq 0 \quad \text{in } V_\delta.$$

We claim that

$$(2.21) \quad Q_t > 0 \quad \text{on } \Gamma_1 \times (0, T).$$

Indeed, otherwise we conclude from (2.20) that Q_t takes local minimum zero at a point (x_0, t_0) on $\Gamma_1 \times (0, T)$. Since (by (2.18))

$$(Q_t)_t + \Delta Q_t = 0 \quad \text{in } V_\delta$$

and

$$Q_{t,\nu}(x_0, t_0) = 0,$$

this is a contradiction to the strong maximum principle for Q_t .

We can now state the main result of this section.

THEOREM 2.3. *For any maximizer k_0 of Problem (F) there exists a function $\varphi(x)$ in $C^{1,\alpha/2}(\Gamma_1)$ such that*

$$(2.22) \quad k_0(x, t) = \begin{cases} N_2 & \text{if } 0 < t < \varphi(x), \\ N_1 & \text{if } \varphi(x) < t < T. \end{cases}$$

Proof. From (2.15) and (2.17) it follows that there exists a $\lambda \leq 0$ such that

$$k_0 = \begin{cases} N_2 & \text{if } Q(x, t) < \lambda, \\ N_1 & \text{if } Q(x, t) > \lambda. \end{cases}$$

From (2.21) we see that the surface

$$\{(x, t) \in \Gamma_1 \times (0, T); Q(x, t) = \lambda\}$$

is given by $t = \varphi(x)$ with φ in $C^{1,\alpha/2}$ (since Q is in $C^{1,\alpha/2}$).

Notice that φ is in $C^{m,\alpha/2}$ if Γ_1 is in $C^{2m,\alpha}$; in particular, $\varphi \in C^\infty$ if $\Gamma_1 \in C^\infty$.

Remark 2.1. Denote by $V(T)$ the measure of the ice that has melted by time T and set $J_0(k) = V(T)$. Consider the problem of maximizing $J_0(k)$ over $k \in \mathcal{A}$. For the one-phase Stefan problems it was proved in [6], [8], that any maximizer k_0 has the form (2.22). We wish to show that this bang-bang principle is false for the two-phase Stefan problem. Consider the one-dimensional Stefan problem

$$\begin{aligned} \frac{\partial \beta(u)}{\partial t} - u_{xx} &= 0 & (0 < x < 1, 0 < t < T), \\ u_x(0, t) &= -k(t) & (0 < t < T), \\ u(1, t) &= -\frac{1}{2} & (0 < t < T), \\ u(x, 0) &= V_0(x) & (0 < x < 1) \end{aligned}$$

where

$$\begin{aligned} V_0(x) &= -\frac{1}{2} + (1-x), \\ \mathcal{A} &= \left\{ k \in L^\infty(0, T), 1 \leq k(t) \leq 2, \int_0^T k \, dt = T+1 \right\}. \end{aligned}$$

If

$$V_1(x) = \frac{1}{2} + (1-2x)$$

then, by comparison,

$$V_0(x) \leq u(x, t) \leq V_1(x) \quad (0 < x < 1, 0 < t < T)$$

and thus the global solution u exists for any k . Set

$$k_1(t) = \begin{cases} 1 & \text{if } 0 \leq t \leq T-1, \\ 2 & \text{if } T-1 < t < \infty, \end{cases} \quad k_2(t) = \begin{cases} 2 & \text{if } 0 \leq t \leq 1, \\ 1 & \text{if } 1 \leq t < \infty, \end{cases}$$

and denote by u_i the solution corresponding to k_i . Then $u_1(x, t) = V_0(x)$ if $0 < t < T-1$ and, consequently, by comparison,

$$u_1(\tfrac{1}{2}, T) > V_1(\tfrac{1}{2}) + \varepsilon = \varepsilon > 0$$

for some ε independent of T . It follows that

$$u_1(\tfrac{1}{2} + \delta, T) \geq 0 \quad \text{for some } \delta > 0,$$

where δ is independent of T . On the other hand, by asymptotic stability (cf. [4])

$$u_1(x, t) \rightarrow V_0(x) \quad \text{if } t \rightarrow \infty$$

and, in particular,

$$u_1(\tfrac{1}{2} + \delta, T) < 0$$

if T is large enough. It follows that

$$J_0(k_2) < J_0(k_1),$$

and thus the bang-bang principle (2.22) does not hold for the maximizer of the functional $J_0(k)$.

3. Periodic optimal control. In this section we consider the case of periodic boundary conditions with period σ . Thus we assume that

$$(3.1) \quad g(x, t + \sigma) = g(x, t)$$

and take the control set

$$(3.2) \quad \mathcal{A}_0 = \left\{ N_1 \leq k \leq N_2, k(x, t + \sigma) = k(x, t), \int_0^\sigma \int_{\Gamma_1} k = M \right\}$$

where N_1, N_2 are as before, and

$$(3.3) \quad N_1 \sigma \text{ meas}(\Gamma_1) < M < N_2 \sigma \text{ meas}(\Gamma_1).$$

For any $k \in \mathcal{A}_\sigma$ consider the Stefan problem

$$(3.4) \quad \begin{aligned} \frac{\partial}{\partial t} \beta(u) - \Delta u &= 0 \quad \text{in } \mathcal{D}'(D_\infty), \\ u_\nu &= k \quad \text{on } \Gamma_{1,\infty}, \\ u &= -g \quad \text{on } \Gamma_{2,\infty}, \\ \beta(u) &= \beta(h) \quad \text{on } t=0 \end{aligned}$$

and set

$$P = \{(k, u); k \in \mathcal{A}_\sigma, u \text{ is the unique solution of (3.4) corresponding to } k\}.$$

From § 1 we have, for any $(k, u) \in P$,

$$(3.5) \quad \int_0^\infty \int_D |u(x, t) - \hat{u}(x, t)|^2 \leq C < \infty, \quad C \text{ independent of } k,$$

where \hat{u} is the unique periodic solution of

$$(3.6) \quad \begin{aligned} \frac{\partial}{\partial t} \beta(u) - \Delta u &= 0 \quad \text{in } \mathcal{D}'(D_\infty) \\ u_\nu &= k \quad \text{on } \Gamma_{1,\infty}, \\ u &= -g \quad \text{on } \Gamma_{2,\infty}, \\ u(x, t + \sigma) &= u(x, t). \end{aligned}$$

In this section we work with the functional

$$(3.7) \quad J(k) = \int_0^\sigma \int_D p(x) \hat{u}(x, t) \, dx \, dt.$$

From (3.5) we get

$$\int_{m\sigma}^{(m+1)\sigma} \int_D |u - \hat{u}| \leq (|D|\sigma)^{1/2} \left\{ \int_{m\sigma}^{(m+1)\sigma} \int_D |u - \hat{u}|^2 \right\}^{1/2} \rightarrow 0 \quad \text{if } m \rightarrow \infty$$

and, consequently,

$$\lim_{m \rightarrow \infty} \frac{1}{m} \sum_{j=0}^{m-1} \int_{j\sigma}^{(j+1)\sigma} p(u - \hat{u}) = 0,$$

i.e.,

$$\lim_{m \rightarrow \infty} \frac{1}{m} \int_0^{m\sigma} \int_D pu = \lim_{m \rightarrow \infty} \frac{1}{m} \int_0^{m\sigma} \int_D p\hat{u} = \int_0^\sigma \int_D p\hat{u}.$$

It follows that for any $(k, u) \in \mathcal{A}_\sigma$

$$(3.8) \quad J(k) = \int_0^\sigma \int_D p\hat{u} = \lim_{m \rightarrow \infty} \frac{1}{m} \int_0^{m\sigma} \int_D pu.$$

Problem (P). Maximize $J(k)$ over $k \in \mathcal{A}_\sigma$.

The existence of a maximizer can be proved as in § 2, using the form (3.7) of $J(k)$ and the fact that

$$(3.9) \quad \|\hat{u}\|_{H^1(D_\sigma)} \leq C$$

where C is a constant independent of k .

LEMMA 3.1. Suppose (k_m, u_m) and (k, u) belong to P , and

$$\begin{aligned} k_m &\rightarrow k \quad \text{weak star in } L^\infty(\Gamma_{1,\sigma}), \\ u_m &\rightarrow u \quad \text{a.e. in } D_\sigma. \end{aligned}$$

Then

$$(3.10) \quad \lim_{m \rightarrow \infty} \frac{1}{m} \int_0^{m\sigma} \int_D p(u_m - u) = 0.$$

Proof. Let \hat{u}_m, \hat{u} be the periodic solutions corresponding to k_m and k , respectively. Using the a priori estimate (3.9) we deduce that for any subsequence of $\{u_m\}$ there is a sub-subsequence, which we still denote by u_m , for which

$$\hat{u}_m \rightarrow \tilde{u} \quad \text{in } L^2(D_\sigma)$$

and \tilde{u} is a periodic solution of (3.6) corresponding to k . By uniqueness $\tilde{u} = \hat{u}$. Using (3.5) we get

$$\begin{aligned}
 & \lim_{m \rightarrow \infty} \frac{1}{m} \left| \int_0^{m\sigma} \int_D p(u_m - u) \right| \\
 & \leq C \lim_{m \rightarrow \infty} \left\{ \frac{1}{m} \int_{D_{m\sigma}} |u_m - \hat{u}_m| + \frac{1}{m} \int_{D_{m\sigma}} |\hat{u}_m - \hat{u}| + \frac{1}{m} \int_{D_{m\sigma}} |\hat{u} - u| \right\} \\
 & \leq C \lim_{m \rightarrow \infty} \left\{ \frac{1}{m} \left(\int_{D_{m\sigma}} |u_m - \hat{u}_m|^2 \right)^{1/2} m^{1/2} + \int_{D_\sigma} |\hat{u}_m - \hat{u}| \right. \\
 & \quad \left. + \frac{1}{m} \left(\int_{D_{m\sigma}} |\hat{u} - u|^2 \right)^{1/2} m^{1/2} \right\} \\
 & \leq C \lim_{m \rightarrow \infty} \int_{D_\sigma} |\hat{u}_m - \hat{u}| = 0,
 \end{aligned}$$

which proves (3.10).

Consider now a pair $(k_0, u_0) \in P$ where k_0 is a solution of Problem (P). In order to analyze k_0 , we introduce, for any positive integer m , the penalized functional

$$(3.11) \quad J_m(k) = \frac{1}{m} \int_0^{m\sigma} \int_D pu - \frac{1}{2} \int_0^\sigma \int_{\Gamma_1} (k - k_0)^2$$

for $(k, u) \in P$.

Problem (P_m). Maximize $J_m(k)$ over $k \in \mathcal{A}_\sigma$.

The existence of a solution can be established as before.

LEMMA 3.2. Suppose $(k_m, u_m) \in P$, k_m a solution of Problem (P_m). Then, as $m \rightarrow \infty$,

$$(3.12) \quad k_m \rightarrow k_0 \quad \text{in } L^2(\Gamma_1 \times (0, \sigma)).$$

Proof. For any subsequence of (k_m, u_m) there is a sub-subsequence, which we denote again by (k_m, u_m) , for which

$$(3.13) \quad k_m \rightarrow \tilde{k} \quad \text{weak star in } L^\infty(\Gamma_{1,\infty}),$$

$$(3.14) \quad u_m \rightarrow \tilde{u} \quad \text{a.e.,}$$

and $(\tilde{k}, \tilde{u}) \in P$. Further, by Lemma 3.1,

$$\begin{aligned}
 J(k_0) & \geq J(\tilde{k}) = \lim_{m \rightarrow \infty} \frac{1}{m} \int_0^{m\sigma} \int_D p\tilde{u} \\
 & = \lim_{m \rightarrow \infty} \left[J_m(k_m) + \frac{1}{m} \int_0^{m\sigma} \int_D p(\tilde{u} - u_m) + \frac{1}{2} \int_{\Gamma_{1,\sigma}} (k_m - k_0)^2 \right] \\
 & \geq \liminf_{m \rightarrow \infty} J_m(k_0) + \limsup_{m \rightarrow \infty} \frac{1}{2} \int_{\Gamma_{1,\sigma}} (k_m - k_0)^2 \\
 & = J(k_0) + \limsup_{m \rightarrow \infty} \frac{1}{2} \int_{\Gamma_{1,\sigma}} (k_m - k_0)^2,
 \end{aligned}$$

and (3.12) follows.

$$\begin{aligned}
(3.15) \quad & \frac{\partial}{\partial t} \beta_\varepsilon(u) - \Delta u = 0 \quad \text{in } D_\infty, \\
& u_\nu = 0 \quad \text{on } \Gamma_{1,\infty}, \\
& u = -g \quad \text{on } \Gamma_{2,\infty}, \\
& u = h \quad \text{on } t = 0.
\end{aligned}$$
$$P_m^\varepsilon = \{(k, u); k \in \mathcal{A}_\sigma, u \text{ is the unique solution of (3.15) corresponding to } k\}.$$
$$(3.16) \quad J_m^\varepsilon(k) = \frac{1}{m} \int_0^{m\sigma} \int_D p(x) u(x, t) - \frac{1}{2} \int_0^\sigma \int_{\Gamma_1} [(k - k_m)^2 + (k - k_0)^2].$$

LEMMA 3.3. Suppose $(k_m^\varepsilon, u_m^\varepsilon) \in P_m^\varepsilon$ where k_m^ε is a solution of Problem (P_m^ε) . Then, as $\varepsilon \rightarrow 0$,

Proof. We may suppose that

$$\begin{aligned} k_m^\varepsilon &\rightharpoonup \tilde{k}_m \quad \text{weakly in } L^2(\Gamma_1, \sigma), \\ u_m^\varepsilon &\rightarrow \tilde{u}_m \quad \text{a.e. in } D_{m\sigma}. \end{aligned}$$

$$\bar{u}_m^\varepsilon \rightarrow u_m \quad \text{a.e. as } \varepsilon \rightarrow 0.$$
$$\begin{aligned} J_m(k_m) &\cong J_m(\tilde{k}_m) = \frac{1}{m} \int_{D_{m\sigma}} p \tilde{u}_m - \frac{1}{2} \int_{\Gamma_{1,\sigma}} (\tilde{k}_m - k_0)^2 \\ &\cong \lim_{\varepsilon \rightarrow 0} \frac{1}{m} \int_{D_{m\sigma}} p u_m^\varepsilon - \frac{1}{2} \liminf_{\varepsilon \rightarrow 0} \int_{\Gamma_{1,\sigma}} (k_m^\varepsilon - k_0)^2 \end{aligned}$$

(since $k_m^\varepsilon \rightarrow k_m$ weak star in $L^\infty(\Gamma_{1,\sigma})$)

$$\begin{aligned}
&= \limsup_{\varepsilon \rightarrow 0} \left[\frac{1}{m} \int_{D_{m\sigma}} p u_m^\varepsilon - \frac{1}{2} \int_{\Gamma_{1,\sigma}} (k_m^\varepsilon - k_0)^2 \right] \\
&= \limsup_{\varepsilon \rightarrow 0} \left[J_m^\varepsilon(k_m^\varepsilon) + \frac{1}{2} \int_{\Gamma_{1,\sigma}} (k_m^\varepsilon - k_m)^2 \right] \\
&\geq \liminf_{\varepsilon \rightarrow 0} J_m^\varepsilon(k_m) + \frac{1}{2} \limsup_{\varepsilon \rightarrow 0} \int_{\Gamma_{1,\sigma}} (k_m^\varepsilon - k_m)^2 \text{ (by maximality of } k_m^\varepsilon) \\
&= \liminf_{\varepsilon \rightarrow 0} \left[\frac{1}{m} \int_0^{m\sigma} \int_D p \bar{u}_m^\varepsilon - \frac{1}{2} \int_{\Gamma_{1,\sigma}} (k_m - k_0)^2 + \frac{1}{2} \limsup_{\varepsilon \rightarrow 0} \int_{\Gamma_{1,\sigma}} (k_m^\varepsilon - k_m)^2 \right] \\
&= \frac{1}{m} \int_0^{m\sigma} \int_D p u_m - \frac{1}{2} \int_{\Gamma_{1,\sigma}} (k_m - k_0)^2 + \limsup_{\varepsilon \rightarrow 0} \int_{\Gamma_{1,\sigma}} (k_m^\varepsilon - k_m)^2 \\
&= J_m(k_m) + \frac{1}{2} \limsup_{\varepsilon \rightarrow 0} \int_0^\sigma \int_{\Gamma_1} (k_m - k_m^\varepsilon)^2,
\end{aligned}$$

from which (3.17) follows.

Consider Problem (P_m^ε) and suppose $(k_m^\varepsilon, u_m^\varepsilon) \in P_m^\varepsilon$ where k_m^ε is a maximizer. Let l be any function such that $k_m^\varepsilon + \delta l \in \mathcal{A}_\sigma$ for any small $\delta > 0$, and denote by $u_m^{\varepsilon, \delta}$ the solution of (3.15) corresponding to $k_m^\varepsilon + \delta l$. Then $J_m^\varepsilon(u_m^\varepsilon) - J_m^\varepsilon(u_m^{\varepsilon, \delta}) \geq 0$, and, proceeding as in § 2, we derive the analogue of (2.14):

$$(3.18) \quad \frac{1}{m} \int_0^m \int_{\Gamma_1} (Q_m^\varepsilon + 2k_m^\varepsilon - k_m - k_0) l \geq 0,$$

where Q_m^ε is the solution of the parabolic problem

$$(3.19) \quad \begin{aligned} \beta_\varepsilon'(u_m^\varepsilon) Q_{m,t}^\varepsilon + \Delta Q_m^\varepsilon &= p \quad \text{in } D_{m\sigma}, \\ Q_{m,\nu}^\varepsilon &= 0 \quad \text{on } \Gamma_1 \times (0, m\sigma), \\ Q_m^\varepsilon &= 0 \quad \text{on } \Gamma_2 \times (0, m\sigma), \\ Q_m^\varepsilon &= 0 \quad \text{on } t = m\sigma. \end{aligned}$$

Let

$$(3.20) \quad P_m^\varepsilon(x, t) = \frac{1}{m} \sum_{j=0}^{m-1} Q_m^\varepsilon(x, t + j\sigma).$$

Since k_m^ε and k_m, k_0 are periodic, (3.18) can be written in the form

$$(3.21) \quad \int_0^\sigma \int_{\Gamma_1} (P_m^\varepsilon + 2k_m^\varepsilon - k_m - k_0) l \geq 0.$$

As in § 2 we have

$$\bar{Q} \leq Q_m^\varepsilon \leq 0 \quad \text{in } D_{\sigma m}$$

with the same function \bar{Q} , and $Q_{m,t}^\varepsilon \geq 0$. It follows that

$$(3.22) \quad \bar{Q} \leq P_m^\varepsilon \leq 0 \quad \text{in } D_\sigma,$$

$$(3.23) \quad P_{m,t}^\varepsilon \geq 0 \quad \text{in } D_\sigma.$$

Also,

$$(3.24) \quad \frac{\partial}{\partial t} P_m^\varepsilon + \Delta P_m^\varepsilon = p \quad \text{in } V_\delta \equiv \Gamma_1^\delta \times (0, \sigma),$$

$$(3.25) \quad \frac{\partial}{\partial \nu} P_m^\varepsilon = 0 \quad \text{on } \Gamma_1 \times (0, \sigma).$$

Using Lemmas 3.2, 3.3 and (3.21)–(3.25) we can proceed to establish, as in § 2, that there exist sequences of $\{m\}$ and $\{\varepsilon_m\}$ such that

$$(3.26) \quad P_m^\varepsilon \rightarrow P \quad \text{uniformly in } V_\delta, \quad P \geq 0,$$

$$(3.27) \quad P_t + \Delta P = p \quad \text{in } V_\delta,$$

$$(3.28) \quad P_\nu = 0 \quad \text{on } \Gamma_{1,\sigma},$$

and

$$(3.29) \quad P_t > 0 \quad \text{on } \Gamma_{1,\sigma}.$$

Further,

$$(3.30) \quad k_0 = \begin{cases} N_2 & \text{on } \{P < \lambda\} \cap \Gamma_{1,\sigma}, \\ N_1 & \text{on } \{P > \lambda\} \cap \Gamma_{1,\sigma} \end{cases}$$

for some $\lambda \leq 0$. Finally, from (3.29), (3.30) we conclude the following theorem.

THEOREM 3.4. *If k_0 is a maximizer of Problem (P), then there exists a $C^{1,\alpha/2}$ function $\varphi(x)$ defined on Γ_1 such that*

$$(3.31) \quad k_0(x, t) = \begin{cases} N_2 & \text{if } m\sigma < t < m\sigma + \varphi(x), \\ N_1 & \text{if } m\sigma + \varphi(x) < t < (m+1)\sigma \end{cases}$$

for $m = 0, 1, 2, \dots$, and $x \in \Gamma_1$.

4. Optimal control for Dirichlet data. In this section we extend the results of §§ 1–3 to other boundary conditions. We begin with

$$(4.1) \quad \begin{aligned} u &= k \quad \text{on } \Gamma_1 \times (0, T), \\ u &= -g \quad \text{on } \Gamma_2 \times (0, T) \end{aligned}$$

(instead of (0.2), (0.3')) and assume that $\Gamma_1 \in C^{3+\alpha}$ and

$$(4.2) \quad \begin{aligned} k &\in L^\infty(\Gamma_1 \times (0, \infty)), \quad 0 < \beta_1 \leq k \leq \beta_2 < \infty, \\ g &\in L^\infty(\Gamma_2 \times (0, \infty)), \quad 0 < c_1 \leq g \leq c_2 < \infty, \\ h &\in C^0(\bar{D}). \end{aligned}$$

Since g and k are not assumed to be Lipschitz continuous, one cannot expect ∇u to be in $L^2((0, T); H^1(D))$. We shall therefore employ the following concept of a weak solution.

A pair (u, ξ) is called a *weak solution* of the two-phase Stefan problem corresponding to the boundary data (4.1) and the initial data $u = h$, $\xi_0 \in H(h)$ if $u \in L^\infty(D_T)$ and

$$(4.3) \quad \begin{aligned} \int_0^T \int_D [(u + \xi)\varphi_t + u\Delta\varphi] dx dt &= \int_0^T \int_{\Gamma_1} k \frac{\partial\varphi}{\partial\nu} dS dt - \int_0^T \int_{\Gamma_2} g \frac{\partial\varphi}{\partial\nu} dS dt \\ &\quad - \int_D (h + \xi_0)\varphi(x, 0) dx \quad \forall \varphi \in V \end{aligned}$$

where

$$V = \{\varphi \in C(\bar{D}_T); D_x\varphi, D_x^2\varphi, D_t\varphi \in C(\bar{D}_T), \varphi = 0 \text{ on } t = T \text{ and on } \partial D \times (0, T)\}.$$

Let $V_0(x)$ and $V_1(x)$ be the solutions of

$$(4.4) \quad \begin{aligned} \Delta V_0 &= 0 \quad \text{in } D, \\ V_0 &= \beta_1 \quad \text{on } \Gamma_1, \\ V_0 &= -c_2 \quad \text{on } \Gamma_2, \end{aligned}$$

and

$$(4.5) \quad \begin{aligned} \Delta V_1 &= 0 \quad \text{in } D, \\ V_1 &= \beta_2 \quad \text{on } \Gamma_1, \\ V_1 &= -c_1 \quad \text{on } \Gamma_2. \end{aligned}$$

THEOREM 4.1. *Assume that*

$$\begin{aligned} V_0(x) &\leq h(x) \leq V_1(x) \quad \text{in } D, \\ H(V_0) &\leq \xi_0 \leq H(V_1) \quad \text{in } D. \end{aligned}$$

Then there exists a unique solution u of the two-phase Stefan problem (4.3), and

$$(4.6) \quad \begin{aligned} V_0(x) &\leq u(x, t) \leq V_1(x), \\ H(V_0) &\leq \xi(x, t) \leq H(V_1). \end{aligned}$$

Proof. Let Ψ_m be smooth functions (say in C^1) in \bar{D}_T such that their restrictions

$$k_m = \Psi_m|_{\Gamma_{1,T}}, \quad g_m = -\Psi_m|_{\Gamma_{2,T}},$$

satisfy (4.2) and

$$\begin{aligned} k_m &\rightarrow k, \quad g_m \rightarrow g, \quad \text{weak star in } L^\infty(\partial D \times (0, T)), \\ h_m &\equiv \Psi_m|_{t=0} \rightarrow h \quad \text{uniformly in } \bar{D}. \end{aligned}$$

By [4] there exists a solution (u_m, ξ_m) corresponding to Ψ_m , and it satisfies (4.6). Set

$$\begin{aligned} D^\delta &= \{x \in D, \text{dist}(x, \partial D) > \delta\}, \\ D_T^\delta &= D^\delta \times (0, T). \end{aligned}$$

In view of (4.6), for some $\delta > 0$ there holds

$$\frac{\partial u_m}{\partial t} - \Delta u_m = 0 \quad \text{in } (D \setminus D^{2\delta}) \times (0, T).$$

But then, by parabolic interior estimates,

$$|u_m|_{C^1(\partial D^\delta \times (\delta, T))} \leq C$$

where C is a constant independent of m . Considering u_m as a solution of the two-phase Stefan problem in $D_T^{2\delta}$, we can apply gradient estimates from [3] and diagonalization in order to conclude that, for a subsequence,

$$\begin{aligned} u_m &\rightarrow u \quad \text{in } L^2(D_T), \\ \xi_m &\rightarrow \xi \quad \text{weak star in } L^\infty(D_T). \end{aligned}$$

Taking $m \rightarrow \infty$ in the identities (4.3) for (u_m, ξ_m) we find that (u, ξ) is a weak solution. Finally, uniqueness is proved as in [4], [5].

The stability estimate (1.22) was established in [4] (see also [3]) for smooth data, say Dirichlet-Lipschitz data. Thus it holds, in particular, for (u_m, ξ_m) . The proof shows that the constant C is independent of m . Hence, by approximation, (1.22) remains true for solutions of (4.3) with data in the class (4.2).

Similarly, for smooth periodic Dirichlet data k_m, g_m there exists a periodic solution and, upon taking $m \rightarrow \infty$, we obtain a periodic solution $(\hat{u}, \hat{\xi})$ when the periodic data (k, g) are in the class (4.2). By the stability estimate, the periodic solution is uniquely determined by k and g .

To extend the results of § 2 we introduce

$$\hat{\mathcal{A}} = \left\{ k \in L^\infty(\Gamma_1 \times (0, T)), N_1 \leq k \leq N_2, \int_0^T \int_{\Gamma_1} k = M \right\}$$

with any $N_2 > N_1 > 0$ and M as in (2.1), and the class of solutions

$$\hat{K}_T = \{(k, u); k \in \hat{\mathcal{A}}, u \text{ is the unique solution of (4.3) corresponding to } k\}.$$

Consider the functional

$$J(k) = \int_0^T \int_D p(x)u(x, t) \, dx \, dt \quad (p > 0)$$

for $(k, u) \in \hat{K}_T$.

Problem (\hat{F}). Maximize $\hat{J}(k)$ over $k \in \hat{\mathcal{A}}$.

Let (k_0, u_0) be a solution of Problem (\hat{F}) and introduce the functional

$$\hat{J}_\varepsilon(k) = \int_0^T \int_D pu - \frac{1}{2} \int_0^T \int_{\Gamma_1} (k - k_0)^2,$$

with $(k, u) \in \hat{K}_T^\varepsilon$, i.e., u is the solution of

$$\begin{aligned} \frac{\partial}{\partial t} \beta_\varepsilon(u) - \Delta u &= 0 \quad \text{in } D_T, \\ (4.7) \quad u &= k \quad \text{on } \Gamma_1 \times (0, T), \\ u &= -g \quad \text{on } \Gamma_2 \times (0, T), \\ u &= h \quad \text{on } t = 0. \end{aligned}$$

We also introduce Problem (\hat{F}_ε) of maximizing $\hat{J}_\varepsilon(k)$ over \hat{K}_T^ε .

We proceed as in § 2 to derive the optimality condition for a solution $(k_\varepsilon, u_\varepsilon)$ of Problem (\hat{F}_ε):

$$(4.8) \quad \int_0^T \int_{\Gamma_1} (Q_{\varepsilon, \nu} + k - k_0) l \leq 0.$$

Here

$$\begin{aligned} \beta'_\varepsilon(u_\varepsilon) Q_{\varepsilon, t} + \Delta Q_\varepsilon &= p \quad \text{in } D_T, \\ Q_\varepsilon &= 0 \quad \text{on } \partial D \times (0, T) \text{ and on } t = T. \end{aligned}$$

We easily deduce that $\hat{Q} \leq Q_\varepsilon \leq 0$ where

$$\Delta \hat{Q} = p \quad \text{in } D, \quad \hat{Q} = 0 \quad \text{on } \partial D,$$

and $Q_{\varepsilon, t} \geq 0$. Hence, for a sequence $\varepsilon \rightarrow 0$, $Q_\varepsilon \rightarrow Q$ uniformly in $V^\delta \equiv \Gamma_1^\delta \times (0, T)$ and

$$\begin{aligned} Q_t + \Delta Q &= p \quad \text{in } V^\delta, \\ Q &= 0 \quad \text{on } \Gamma_1 \times (0, T), \\ Q_t &\geq 0. \end{aligned}$$

The strong maximum principle can now be applied to Q_t ; we conclude that $Q_t > 0$ in V^δ and

$$(4.9) \quad \frac{\partial}{\partial \nu} Q_t > 0 \quad \text{on } \Gamma_1 \times (0, T).$$

This inequality, together with (4.8) and the uniform convergence $Q_{\varepsilon, \nu} \rightarrow Q_\nu$ on $\Gamma_1 \times (0, T)$, yields the following.

THEOREM 4.2. *If k_0 is a maximizer of Problem (\hat{F}) then there exists a $C^{1,\alpha/2}$ function $\varphi(x)$ defined on Γ_1 such that on $\Gamma_1 \times (0, T)$:*

$$(4.10) \quad k(x, t) = \begin{cases} N_2 & \text{if } 0 < t < \varphi(x), \\ N_1 & \text{if } \varphi(x) < t < T. \end{cases}$$

The results of § 3 can now also be extended in the obvious way.

Remark. Using the approximation procedure of k, g by smooth functions k_m, g_m as in the present section, we can extend the results of §§ 1–3 to the case where $g \in L^\infty(D_\infty)$ and $0 \leq c_1 \leq g \leq c_2 \leq \infty$ (instead of g satisfying (1.1)). Finally, the results of this paper extend to the case of a Neumann condition on $\Gamma_2 \times (0, T)$.

CONTROL OF FREE BOUNDARY PROBLEMS WITH HYSTERESIS*

AVNER FRIEDMAN† AND KARL-HEINZ HOFFMANN‡

Abstract. We consider the problem of controlling the free boundary of the two-phase Stefan problem by means of boundary hysteresis control based on the Preisach model. It is proved that for each control μ there is a corresponding solution of the Stefan problem and that there exists an optimal control.

Key words. Stefan problem, hysteresis, optimal control, control variable, Preisach model

AMS(MOS) subject classifications. 35R35, 49B22, 49A36, 80A99

Introduction. In this paper we are concerned with free boundary problems with a control variable whose structure involves a hysteresis law. In fact we choose the Preisach model for hysteresis [19]; thus the control variable is a measure μ defined on the space of pairs (ρ_1, ρ_2) with $\rho_1 < \rho_2$. The fact that the hysteresis law is discontinuous causes some technical difficulties. We establish the existence of a unique solution u to the free boundary problem for any given μ , and then proceed to prove the existence of an optimal control. For definiteness we shall consider in detail only the two-phase Stefan problem. Other problems, some with free boundary and others with fixed boundary, can be treated by the same methods as briefly mentioned in § 5.

We note that the Preisach model is often used by physicists [3], [6], [17]; for other hysteresis models see Hornung [11]. The two-phase Stefan problem with hysteresis was treated by Hoffmann and Sprekels [10] for a simple situation of a thermostat control (cf. also Jäger [12] for a related reaction diffusion problem).

A systematic mathematical treatment of hysteresis has been carried out by Krasnosel'skii, Pokrovskii and co-workers (see [13]–[15] and the references therein). More recently Visintin [22]–[25] has studied several physical models with hysteresis. In [23] he proved that the hysteresis functional is a continuous mapping, a fact which will be very useful in this work.

In § 1 we describe the hysteresis model for the Stefan problem and then briefly outline the structure and main results of this paper.

1. The Stefan problem. Consider the one-dimensional Stefan problem:

$$(1.1) \quad u_t = u_{xx} \quad \text{if } 0 < x < s(t), \quad t > 0 \quad \text{or if } s(t) < x < a, \quad t > 0,$$

$$(1.2) \quad u(0, t) = \gamma(t) \quad \text{if } t > 0, \quad \gamma(t) \text{ continuous, } 0 < \gamma_1 \leq \gamma(t) \leq \gamma_2 < \infty,$$

$$(1.3) \quad u(x, 0) = u_0(x) \quad \text{if } 0 < x < a, \quad \text{where } u_0(x) > 0 \quad \text{for } 0 < x < s_0, \\ u_0(x) < 0 \quad \text{for } s_0 < x < a,$$

$$(1.4) \quad u_x(a, t) + u(a, t) = g(t) \quad \text{for } t > 0, \quad g(t) \leq 0,$$

$$(1.5) \quad u(s(t), t) = 0 \quad \text{for } t > 0, \quad s(0) = s_0, \quad 0 < s_0 < a,$$

$$(1.6) \quad \dot{s}(t) = -u_x^+(s(t), t) + u_x^-(s(t), t) \quad \text{for } t > 0$$

where $u_x^\pm(s(t), t) = u_x(s(t) \mp 0, t)$; $u_0(x)$ is assumed (for simplicity) to be continuously differentiable for $0 \leq x \leq s_0$ and for $s_0 \leq x \leq a$ and $u_0(s_0 \pm 0) = 0$.

‡ University of Augsburg, Augsburg, West Germany.

This problem has a unique solution (u, s) for any $g \in L_{\text{loc}}^\infty[0, \infty]$, provided $s(t)$ does not intersect $x = a$. Furthermore, the free boundary $x = s(t)$ is in $C^\infty(0, \infty) \cap C^0[0, \infty]$.

For any $0 < \rho_1 < \rho_2 < a$ set $\rho = (\rho_1, \rho_2)$ and define

$$M_\rho^0(s) = \begin{cases} -1 & \text{if } s \geq \rho_2, \\ 0 & \text{if } \rho_1 < s < \rho_2, \\ 0 & \text{if } s < \rho_1, \end{cases}$$

and

$$M_\rho^1(s) = \begin{cases} -1 & \text{if } s \geq \rho_2, \\ -1 & \text{if } \rho_1 < s < \rho_2, \\ 0 & \text{if } s \leq \rho_1. \end{cases}$$

Given any continuous function $s(t)$, $t \geq 0$, set $s_0 = s(0)$. If $\rho_1 < s_0 < \rho_2$ we define the hysteresis law based on M_ρ^0 as follows: Set $t_0 = 0$ and $M_\rho(s(0)) = M_\rho^0(s_0)$. For $k \in \mathbb{N} \cup \{0\}$ define

$$t_{k+1} = \begin{cases} \inf T_{k+1} & \text{if } T_{k+1} \neq \emptyset, \\ +\infty & \text{if } T_{k+1} = \emptyset \end{cases}$$

where

$$T_{k+1} = \left\{ t \in (t_k, \infty); s(t) = \begin{cases} \rho_1 & \text{if } k+1 \text{ even,} \\ \rho_2 & \text{if } k+1 \text{ odd} \end{cases} \right\}$$

and

$$M_\rho(s(t)) = \begin{cases} 0 & \text{if } t \in [t_k, t_{k+1}) \text{ and } k+1 \text{ odd,} \\ -1 & \text{if } t \in [t_k, t_{k+1}) \text{ and } k+1 \text{ even.} \end{cases}$$

The hysteresis law based on M_ρ^1 is defined in a similar way: Set $t_0 = 0$ and $M_\rho(s(0)) = M_\rho^1(s_0)$ and define

$$t_{k+1} = \begin{cases} \inf T_{k+1} & \text{if } T_{k+1} \neq \emptyset, \\ +\infty & \text{if } T_{k+1} = \emptyset \end{cases}$$

where

$$T_{k+1} = \left\{ t \in (t_k, \infty); s(t) = \begin{cases} \rho_1 & \text{if } k+1 \text{ odd,} \\ \rho_2 & \text{if } k+1 \text{ even} \end{cases} \right\}$$

and

$$M_\rho(s(t)) = \begin{cases} 0 & \text{if } t \in [t_k, t_{k+1}) \text{ and } k+1 \text{ even,} \\ -1 & \text{if } t \in [t_k, t_{k+1}) \text{ and } k+1 \text{ odd.} \end{cases}$$

In the case $s_0 \leq \rho_1$ or $s_0 \geq \rho_2$ we have $M_\rho^0(s_0) = M_\rho^1(s_0)$ and $M_\rho(s(t))$ is defined as follows:

Set $t_0 = 0$, $M_\rho(s(0)) = M_\rho^0(s_0) = M_\rho^1(s_0)$. In case $\rho_1 \geq s_0$,

$$T_{k+1} = \left\{ t \in (t_k, \infty); s(t) = \begin{cases} \rho_1 & \text{if } k+1 \text{ odd,} \\ \rho_2 & \text{if } k+1 \text{ even,} \end{cases} \right\}$$

t_{k+1} is defined as before, and

$$M_\rho(s(t)) = \begin{cases} 0 & \text{if } t \in [t_k, t_{k+1}) \text{ and } k+1 \text{ odd,} \\ -1 & \text{if } t \in [t_k, t_{k+1}) \text{ and } k+1 \text{ even.} \end{cases}$$

In case $s_0 \geq \rho_2$,

$$T_{k+1} = \begin{cases} t \in (t_k, \infty); s(t) = \begin{cases} \rho_1 & \text{if } k+1 \text{ odd,} \\ \rho_2 & \text{if } k+1 \text{ even,} \end{cases} \end{cases}$$

t_{k+1} is defined as before, and

$$M_\rho(s(t)) = \begin{cases} 0 & \text{if } t \in [t_k, t_{k+1}) \text{ and } k+1 \text{ even,} \\ -1 & \text{if } t \in [t_k, t_{k+1}) \text{ and } k+1 \text{ odd.} \end{cases}$$

We shall denote by $M_\rho(s(t), M_\rho^i)$ the hysteresis law $M_\rho(s(t))$ based on $M_\rho^i (i = 0, 1)$.

Set

$$(1.7) \quad \Omega = \{(\rho_1, \rho_2); \eta < \rho_1 < \rho_2 < a - \eta\}$$

where η is a fixed small positive number, $0 < \eta < a/2$. Denote by $M(\Omega)$ the set of all nonnegative measures μ on Ω satisfying the following:

- (i) μ is absolutely continuous with respect to the Lebesgue measure $d\rho \equiv d\rho_1 d\rho_2$;
- (ii) $\int_\Omega d\mu(\rho) = 1$.

Denote by $M_1(\Omega)$ the set of all μ in $M(\Omega)$ satisfying the following:

- (iii) $\mu(A) \leq C \int_A d\rho_1 d\rho_2$ for any Lebesgue measurable sets A ; C is a positive constant depending on μ .

The hysteresis functional corresponding to μ is defined by

$$(1.8) \quad M_\mu(s(t)) = \int_\Omega M_\rho(s(t), M_\rho^i) d\mu(\rho) \quad (i = 0, 1);$$

i will be fixed throughout the paper. This functional was first introduced by Preisach [19].

In thermostat control problems it is natural to assume some hysteresis effects. In this paper we shall be interested in controlling the free boundary of the Stefan problem (1.1)–(1.6) when $g(t)$ is a control variable whose form is given by the hysteresis law

$$(1.9) \quad g(t) = M_\mu(s(t)), \quad \mu \in M(\Omega);$$

thus the actual control variable is the measure μ .

We recall the following results due to Visintin [23]: For any $\mu \in M(\Omega)$,

$$(1.10) \quad \text{if } s \in C[0, T] \text{ then } M_\mu(s(t)) \text{ is also in } C[0, T];$$

$$\text{if } s, s_n \in C[0, T] \text{ and } \max_{0 \leq t \leq T} |s_n(t) - s(t)| \rightarrow 0 \text{ as } n \rightarrow \infty,$$

$$(1.11) \quad \text{then } \max_{0 \leq t \leq T} |M_\mu(s_n(t)) - M_\mu(s(t))| \rightarrow 0 \text{ as } n \rightarrow \infty;$$

if further $\mu \in M_1(\Omega)$, then

$$(1.12) \quad \max_{0 \leq t \leq T} |M_\mu(s_n(t)) - M_\mu(s(t))| \leq C \max_{0 \leq t \leq T} |s_n(t) - s(t)|$$

where C is a constant depending only on $\max |s(t)|$.

In § 2 we shall prove that the Stefan problem (1.1)–(1.9) has a solution for any $\mu \in M(\Omega)$ and that the solution is unique if $\mu \in M_1(\Omega)$.

In § 3 we introduce the functional

$$(1.13) \quad J(\mu) = \max_{0 \leq t \leq T} |s(t) - \sigma(t)| + \int_{\Omega} h(\rho) d\mu(\rho)$$

where $\sigma(t)$ is a given continuous function and $h(\rho)$ is a given nonnegative continuous function. We establish the existence of a control $\mu_0 \in \tilde{M}(\Omega)$ satisfying:

$$J(\mu_0) = \inf_{\mu \in \tilde{M}(\Omega)} J(\mu);$$

here $\tilde{M}(\Omega)$ is a suitable admissible class of controls contained in $M(\Omega)$.

In § 4 we study the asymptotic behavior of solutions of (1.1)–(1.9) as $t \rightarrow \infty$, when (1.2) is replaced by $u_x(0, t) = 0$. In § 5 we briefly mention several other problems with hysteresis (both with free boundary and with fixed boundary) for which the methods of the present paper can be applied.

2. Existence and uniqueness for (1.1)–(1.9). In general a global solution of (1.1)–(1.9) may not exist for all $t > 0$ since $x = s(t)$ may cross $x = a$ in finite time; this can be seen by considering already a stationary solution of the form $C - lx$ and comparing with the case where $s(0) = a - \eta$, $g(t) \equiv -1$. In order to avoid this situation we assume that

$$(2.1) \quad \max \{ \gamma_2, \max_x u_0(x) \} < \eta.$$

Then $u(x) = \theta a - \theta' x$ is a stationary solution of (1.1)–(1.6) when $s(0) = \theta a / \theta'$ (if $\theta < \theta'$) and it majorizes the boundary data and the initial conditions of $u(x, t_0)$, if $s(t_0) = a - \eta$, provided $\theta' < 1$ and $1 - \theta$ is sufficiently small.

THEOREM 2.1. *Assume that (2.1) holds. Then for any $\mu \in M(\Omega)$ there exists a solution of (1.1)–(1.9).*

Proof. Take any small $\delta > 0$ and define

$$g_\delta(t) \equiv 0 \quad \text{if } 0 < t < \delta.$$

Let (u, s) denote the corresponding solution of (1.1)–(1.6) in $\{0 < t < \delta\}$. Next define

$$g_\delta(t) = M_\mu(s(t - \delta))$$

for $\delta < t < 2\delta$. Since $g_\delta(t)$ is known in this interval, we can solve (1.1)–(1.6) for $\delta < t < 2\delta$ with this g_δ and with the initial values $(u(x, \delta), s(\delta))$ obtained in the first step.

We continue by defining $g_\delta(t)$ for $2\delta < t < 3\delta$ as before in terms of the function $s(t)$ obtained in the second step, and solve (1.1)–(1.6) in $2\delta < t < 3\delta$. Continuing in this way we obtain a unique solution of (1.1)–(1.6) with $g = g_\delta(t)$; we designate this solution by (u_δ, s_δ) .

We claim that there exist positive constants η_0, η' such that, for any δ sufficiently small, there holds

$$(2.2) \quad \eta_0 \leq s_\delta(t) \leq a - \eta',$$

that is, the free boundary stays uniformly away from $\{x = 0\}$ and $\{x = a\}$ (and, consequently, the solution (u_δ, s_δ) exists for all $t > 0$).

To prove (2.2) we begin by observing that, by the maximum principle, $u_\delta \leq 0$ in $\{s_\delta(t) < x < a, 0 < t < T\}$ for any $T > 0$ for which $0 < s_\delta(t) < a$ if $0 < t < T$, i.e., u_δ cannot take positive maximum on $\{x = a\}$. Also, by (1.4), u_δ cannot take negative minimum smaller than $\min g_\delta$ on $\{x = a\}$, for at a point of minimum, on $\{x = a\}$, $\partial u_\delta / \partial x < 0$. It follows that $-c_0 \leq u_\delta \leq 0$ on $\{x = a\}$, where $c_0 = \max_{s_0 \leq x \leq a} |u_0(x)| + 1$, and by (1.4),

$$(2.3) \quad \left| \frac{\partial}{\partial x} u_\delta(a, t) \right| \leq c_1 \quad \text{if } 0 \leq t \leq T, \quad c_1 = c_0 + 1.$$

Since $u_\delta(0, t) \geq \gamma_1 > 0$ we can use a comparison theorem [9, p. 691] to compare u_δ with a stationary solution of the Stefan problem (i.e., with a linear function $u(x)$ satisfying $u(0) = \gamma$ for some small $\gamma < \gamma_1$, $u(a) = -c_1$). We then deduce that

$$s_\delta(t) \geq \eta_0 > 0 \quad \text{if } 0 < t < T$$

where η_0 depends only on γ_1, a, c_1 . But then we can apply parabolic estimates for the heat equation in $\{0 < x < \eta_0, 0 < t < T\}$ and obtain:

$$(2.4) \quad \left| \frac{\partial}{\partial x} u_\delta \left(\frac{1}{2} \eta_0, t \right) \right| \leq C \quad (0 < t < T)$$

where C is a constant independent of T . We may take $C > c_1$ and $C > \sup |u_0^1(x)|$.

In one of the proofs of global existence for the Stefan problem (due to L. S. Jiang; see [8, p. 118]) we show that $u_{\delta,x}$ in $\{0 < x < s_\delta(t), 0 < t < T\}$ does not take negative minimum smaller than $-C$ on the free boundary and $u_{\delta,x}$ in $\{s_\delta(t) < x < a, 0 < t < T\}$ also does not take negative minimum smaller than $-C$ on the free boundary. Hence

$$u_{\delta,x}(s_\delta(t) \pm 0) \geq -C \quad \text{if } 0 < t < T.$$

Since the functions on the left-hand side are actually negative, we deduce that

$$|u_{\delta,x}(s_\delta(t) \pm 0)| \leq C$$

and, from (1.6),

$$(2.5) \quad \left| \frac{d}{dt} s_\delta(t) \right| \leq C \quad \text{if } 0 < t < T;$$

C is independent of δ, T .

We can now proceed to establish the right-hand inequality in (2.2). Suppose $x = s_\delta(t)$ intersects $x = a - \eta'$ for the first time at $t = T$. Then there exists a t_0 such that $0 < t_0 < T$,

$$a - \eta = s_\delta(t_0) < s_\delta(t) < s_\delta(T) = a - \eta' \quad \text{if } t_0 < t < T.$$

In view of (2.5), $T - t_0 > 2c(\eta - \eta')$ for some $c > 0$ independent of δ . Then $g_\delta(t) = -1$ if $t_0 + \delta < t < T$ and

$$\frac{\partial}{\partial x} u_\delta(a, t) + u_\delta(a, t) = -1 \quad \text{if } t_0 + \delta < t < T.$$

Again using comparison with a stationary solution introduced following (2.1) we deduce that

$$s_\delta(t) \leq a - 2\eta' \quad \text{for } t_0 + \delta < t < T$$

provided η' is sufficiently small (and provided δ is small enough (depending on c, η, η'), which is a contradiction to the assumption that $s_\delta(T) = a - \eta'$).

Having proved (2.2) we deduce that (u_δ, s_δ) exists for all $t > 0$. From (2.5) it follows that for a sequence $\delta = \delta_n \rightarrow 0$

$$(2.6) \quad s_{\delta_n}(t) \rightarrow s(t) \quad \text{uniformly in } 0 \leq t \leq T$$

for any $T < \infty$. Clearly also

$$(2.7) \quad s_{\delta_n}(t - \delta_n) \rightarrow s(t) \quad \text{uniformly in } \delta_n < t < T$$

and further, by (1.11),

$$(2.8) \quad M_\mu(s_{\delta_n}(t)) \rightarrow M_\mu(s(t)) \quad \text{uniformly in } 0 \leq t \leq T.$$

Representing u_{δ_n} by means of the Green and Robin functions (in $\{u_{\delta_n} > 0\}$ and $\{u_{\delta_n} < 0\}$, respectively) in terms of s_{δ_n} and the boundary values $M_\mu(s(t - \delta_n))$ on $x = a$ (cf. [7], [21]), taking $n \rightarrow \infty$ and using (2.6)–(2.8), we deduce that (u, s) forms a solution of (1.1)–(1.6) with $g(t)$ given by (1.8), (1.9).

THEOREM 2.2. *If $\mu \in M_1(\Omega)$ then the solution of (1.1)–(1.9) is unique.*

Proof. We represent u by the Green and Robin functions in $\{u > 0\}$ and $\{u < 0\}$, respectively, differentiate in x and let $x \rightarrow s(t)$ (cf. [7]). We then obtain a pair of Volterra-type integral equations for

$$v_1(t) = u_x(s(t) - 0, t), \quad v_2(t) = u_x(s(t) + 0, t)$$

having the form

$$v_1 = I_1(v_1, s), \quad v_2 = I_2(v_2, s) + I(s)$$

where I_1, I_2 are Volterra-type operators and

$$I(s) = \int_0^t R(s(t), t, \tau) M_\mu(s(\tau)) d\tau.$$

Here

$$\dot{s}(t) = v_2(t) - v_1(t)$$

and R is a smooth kernel (so long as $s(t) < a$).

By (1.12),

$$\max_{0 \leq \tau \leq t} |M_\mu(s(\tau)) - M_\mu(\tilde{s}(\tau))| \leq C \max_{0 \leq \tau \leq t} |s(\tau) - \tilde{s}(\tau)|$$

for any two continuous functions, where C is a constant depending only on $\max |s|$. Using this fact and the standard estimates of [7], we deduce that the mapping $(v_1, v_2) \rightarrow (\bar{v}_1, \bar{v}_2)$, given by

$$\bar{v}_1 = I_1(v_1, s), \quad \bar{v}_2 = I_2(v_2, s) + I(s)$$

is a contraction in $C[0, \sigma]$ provided σ is sufficiently small. This proves uniqueness for $0 < t < \sigma$. Proceeding step by step we derive uniqueness for all $t > 0$.

Remark 2.1. Theorem 2.1 extends to models where the measure $\mu(\rho)$ is supported on a line segment

$$I = \{(\rho_1, \rho_1 + \delta_0), \eta_1 < \rho_1 < a - \delta_0 - \eta_1\}$$

for some $\delta_0 > 0$, $\eta_1 > 0$ and is absolutely continuous with respect to $d\rho_1$; if further

$$\int_\sigma d\mu(\rho_1) \leq C \int_\sigma d\rho_1$$

for any measurable subset σ of I , then Theorem 2.2 is also valid.

Remark 2.2. Theorems 2.1, 2.2 and Remark 2.1 extend to the case where (1.2) is replaced by

$$-u_x(0, t) + \lambda u(0, t) = \gamma(t)$$

where $\lambda \geq 0$, $\gamma(t) > 0$, or when (1.4) is replaced by

$$u(a, t) = g(t) \quad \text{or} \quad u_x(a, t) = g(t).$$

Without any restriction on λ, γ, u_0 , the free boundary may hit the boundary $\{x = 0\}$.

3. Existence of optimal control. We shall now restrict μ to belong to a subset of $M(\Omega)$ given by

$$(3.1) \quad K = \left\{ \mu; d\mu(\rho) = f(\rho) d\rho, \int_{\Omega} f^{1+\delta}(\rho) d\rho \leq C \right\}$$

where δ and C are some positive constants; the condition (2.1) is assumed throughout this section.

Let $\sigma(t)$ be a given continuous function for $0 \leq t \leq \infty$ and let $h(\rho)$ be a prescribed nonnegative continuous function on $\bar{\Omega}$. Consider the cost functional

$$(3.2) \quad J(f, s) = \max_{0 \leq t \leq T} |s(t) - \sigma(t)| + \int_{\Omega} h(\rho) f(\rho) d\rho$$

for any $f \in K$, where T is a fixed positive number. Here (u, s) is any solution of (1.1)–(1.9) corresponding to $d\mu = f d\rho$. Since we may not have uniqueness (unless $\mu \in M_1(\Omega)$), there may be more than one pair (u, s) . We introduce the set of costs

$$(3.3) \quad J[f] = \{J(f, s); (u, s) \text{ solution of (1.1)–(1.9) with } d\mu = f d\rho\}.$$

Using (1.11) it is easy to see that the set of solutions (u, s) corresponding to a given μ is compact in the uniform topology for $0 \leq t \leq T, 0 \leq x \leq a$; hence there exists a solution (u_0, s_0) such that

$$(3.4) \quad J(f, s_0) = \inf \{J(f, s); J(f, s) \in J[f]\}.$$

Set

$$(3.5) \quad J(f) = J(f, s_0)$$

and consider the minimization problem: Find $f_0 \in K$ such that

$$(3.6) \quad J(f_0) = \min_{f \in K} J(f).$$

THEOREM 3.1. *Problem (3.6) has a solution.*

Proof. Let (f_n, s_n, u_n) be a minimizing sequence. By taking a subsequence we may assume that

$$(3.7) \quad \begin{aligned} s_n &\rightarrow s_0 \quad \text{uniformly in } t, \quad 0 \leq t \leq T, \\ u_n &\rightarrow u_0 \quad \text{uniformly in } (x, t), \quad 0 \leq x \leq a, \quad 0 \leq t \leq T, \\ f_n &\rightarrow f_0 \quad \text{weakly in } L^1(\Omega). \end{aligned}$$

Suppose we can prove that, for any continuous function $\phi(t)$,

$$(3.8) \quad \begin{aligned} I_n \equiv \int_0^T \phi(t) dt \left\{ \int_{\Omega} [M_p(s_n(t), M_p^i) f_n(\rho) \right. \\ \left. - M_p(s_0(t), M_p^i) f_0(\rho)] d\rho \right\} \rightarrow 0 \text{ if } n \rightarrow \infty \quad (i = 0, 1). \end{aligned}$$

Then we represent u_n by means of the Green and Robin functions and, using (3.7), (3.8), we find that the same integral representation holds for u_0 and the corresponding s_0, f_0 . This means that (u_0, s_0) forms a solution of (1.1)–(1.6) with g given by $M_{\mu}(s_0(t))$, $d\mu = f_0 d\rho$. Since, as easily seen from (3.2),

$$J(f_n, s_n) \rightarrow J(f_0, s_0),$$

it follows that f_0 and the corresponding solution (u_0, s_0) form a solution of the optimal control problem (3.6). Thus it remains to prove (3.8).

From the proof of (1.11) we see that the convergence of the $M_\mu(s_n(t))$ to $M(s(t))$ is uniform not only in t but also in μ provided μ is in the class K ; in particular,

$$\max_{0 \leq t \leq T} |M_{\mu_n}(s_n(t)) - M_{\mu_n}(s(t))| \rightarrow 0 \quad \text{if } n \rightarrow \infty$$

when $d\mu_n = f_n d\rho$. Therefore the proof of (3.8) is reduced to proving that

$$(3.9) \quad \tilde{I}_n \equiv \int_{\Omega} \left[\int_0^T M_\rho(s_0(t)) \phi(t) dt \right] [f_n(\rho) - f_0(\rho)] d\rho \rightarrow 0 \quad \text{as } n \rightarrow \infty.$$

To prove (3.9) set

$$\psi(\rho) = \int_0^T M_\rho(s_0(t)) \phi(t) dt, \quad d\mu_0 = f_0 d\rho.$$

Let

$$B_{\varepsilon_0} = \{(\rho_1, \rho_2) \in \Omega; 0 < \rho_2 - \rho_1 < \varepsilon_0\}.$$

Given any $\varepsilon > 0$ we can choose ε_0 sufficiently small so that

$$(3.10) \quad \mu_n(B_{\varepsilon_0}) + \mu_0(B_{\varepsilon_0}) < \varepsilon;$$

here we used the fact that $\mu_n \in K$.

Now, by Sard's lemma, the set

$$S^* = \{s^*; \text{there exists a } t \in [0, T] \text{ such that } s_0(t) = s^* \text{ and } s'_0(t) = 0\}$$

has Lebesgue measure zero. Set

$$S_k = \{s; \text{there exists a } t \in [0, T] \text{ such that } s_0(t) = s \text{ and } |s'_0(t)| < 1/k\}, \quad k \in \mathbb{N}.$$

It is easily seen that

$$S^* = \bigcap_{k=1}^{\infty} S_k.$$

Since $\mathcal{L}(S^*) = 0$ (where $\mathcal{L}(A)$ = Lebesgue measure of A), it follows that $\mathcal{L}(S_k) \rightarrow 0$ if $k \rightarrow \infty$. Setting

$$\tilde{S}_k = \{(\rho_1, \rho_2); \text{either } \rho_1 \text{ is in } S_k \text{ or } \rho_2 \text{ is in } S_k\},$$

we conclude that also $\mu_0(S_k) \rightarrow 0$ if $k \rightarrow \infty$ and, consequently,

$$(3.11) \quad \mu_0(\tilde{S}_k) < \varepsilon$$

for some sufficiently large k , say $k \geq k_0$.

Similarly, if $k \geq k_0$,

$$(3.12) \quad \mu_n(\tilde{S}_k) < \varepsilon \quad \text{for all } n.$$

Let $\Sigma_\varepsilon = \Omega \setminus (B_{\varepsilon_0} \cup \tilde{S}_k)$ and take any $\rho = (\rho_1, \rho_2) \in \Sigma_\varepsilon$. Consider an interval $t_1 < t < t_2$ such that $s_0(t_1) = \rho_2$, $s_0(t_2) = \rho_1$, $\rho_1 < s_0(t) < \rho_2$ if $t_1 < t < t_2$. Then

$$s'_0(t) < -\frac{1}{2k} \quad \text{if } |t - t_2| < \delta,$$

$$s'_0(t) < -\frac{1}{2k} \quad \text{if } |t - t_1| < \delta$$

for some $\delta > 0$ independent of t_1, t_2 . It follows that if $\rho' = (\rho'_1, \rho'_2)$ where

$$|\rho'_1 - \rho_1| < \frac{\delta}{2k}, \quad |\rho'_2 - \rho_2| < \frac{\delta}{2k}$$

then $\{x = s_0(t)\}$ crosses $\{s_0 = \rho'_i\}$ at time $t = \tilde{t}_i$, where

$$|\tilde{t}_i - t_i| < 2k|\rho'_i - \rho_i|,$$

and $\rho'_1 < s_0(t) < \rho'_2$ for $\tilde{t}_1 < t < \tilde{t}_2$. Similar consideration holds in case $s_0(t_1) = \rho_1, s_0(t_2) = \rho_2, \rho_1 < s_0(t) < \rho_2$ if $t_1 < t < t_2$.

Summing over the finite number ($\leq 2N$) of such pairs (t_1, t_2) we find that

$$\int_0^T |M_\rho(s_0(t), M_\rho^i) - M_{\rho'}(s_0(t), M_{\rho'}^i)| dt \leq 4Nk|\rho' - \rho|.$$

Consequently,

$$(3.13) \quad |\psi(\rho) - \psi(\rho')| \leq 4CNk|\rho' - \rho| \quad \text{if } \rho \in \Sigma_\varepsilon$$

where $C = \max |\phi|$. Recalling (3.10)–(3.12) we see that for any $\varepsilon > 0$

$$(3.14) \quad |\tilde{I}_n| \leq C\varepsilon + \left| \int_{\Sigma_\varepsilon} \psi(\rho) f_n(\rho) d\rho - \int_{\Sigma_\varepsilon} \psi(\rho) f_0(\rho) d\rho \right|.$$

By (3.13), $\psi(\rho)$ is continuous on Σ_ε . Since $f_n \rightarrow f_0$ weakly in L^1 , it follows that the difference of the integrals on the right-hand side of (3.14) converge to zero as $n \rightarrow \infty$. Consequently,

$$\limsup_{n \rightarrow \infty} \tilde{I}_n \leq C\varepsilon.$$

Since ε can be taken arbitrarily small, (3.9) follows.

Remark 3.1. Theorem 3.1 extends to the model described in Remark 2.1 provided $d\mu = f(\rho_1) d\rho_1$ and $K = \{f; \int [f(\rho_1)]^{1+\delta} \leq C\}$ for some $\delta > 0, C > 0$. Theorem 3.1 also extends to the boundary conditions given in Remark 2.2.

Remark 3.2. If we replace K by $K \cap M_1(\Omega)$ then (u, s) is uniquely determined by f and $J[f]$ consists of one number.

4. Asymptotic behavior as $t \rightarrow \infty$. In this section we return to problem (1.1)–(1.8) with (1.2) replaced by

$$(1.2') \quad u_x(0, t) = 0 \quad \text{if } t > 0.$$

Assuming that (u, s) is a solution for all $t > 0$ (with $0 < s(t) < 1$, i.e., the free boundary does not hit the fixed boundary in finite time), we shall study the asymptotic behavior of the free boundary as $t \rightarrow \infty$.

LEMMA 4.1. *There holds*

$$(4.1) \quad \int_0^\infty |M_\mu(s(t))| dt < \infty.$$

Proof. By comparison we have

$$(4.2) \quad u^+(x, t) \leq A \cos \frac{\pi x}{2a} e^{-\pi^2 t / 4a^2},$$

$$(4.3) \quad u^-(x, t) \leq Bx$$

where A and B are positive constants.

Integrating $u_t = u_{xx}$ over $0 < x < s(t)$, $0 < t < T$ and over $s(t) < x < a$, $0 < t < T$ and adding, we easily obtain, after using (1.2'), (1.3), (1.5), (1.6), (4.2), (4.3) and the fact that $0 < s(t) < a$,

$$(4.4) \quad -s(T) + s_0 + \int_0^T u_x(a, t) dt = \int_0^a u(x, T) dx - \int_0^a u_0(x) dx;$$

it follows that

$$(4.5) \quad \int_0^T u_x(a, t) dt = O(1) \quad \text{as } T \rightarrow \infty.$$

Next we integrate

$$xu_t = xu_{xx}$$

over $0 < x < s(t)$, $0 < t < T$ and, after integration by parts, obtain

$$(4.6) \quad \int_0^T s(t) u_x^+(s(t), t) dt = O(1).$$

Similarly

$$(4.7) \quad a \int_0^T u_x(a, t) dt - \int_0^T s u_x^-(s(t), t) dt - \int_0^T u(a, t) dt = O(1).$$

Using (4.5) and

$$\begin{aligned} \int_0^T [s(t) u_x^+(s(t), t) - s(t) u_x^-(s(t), t)] dt &= - \int_0^T s(t) \dot{s}(t) dt \\ &= -\frac{1}{2} (s^2(T) - s^2(0)) \\ &= O(1), \end{aligned}$$

we get, from (4.6), (4.7) and (4.5),

$$(4.8) \quad \int_0^T [u_x(a, t) + u(a, t)] dt = O(1) \quad \text{as } T \rightarrow \infty,$$

which is the assertion (4.1).

THEOREM 4.2. *There holds that*

$$(4.9) \quad \lim_{t \rightarrow \infty} s(t) \quad \text{exists.}$$

Proof. Let v be a solution of the heat equation in $\{0 < x < a, t > 0\}$ satisfying

$$v_x(0, t) = 0 \quad \text{if } t > 0, \quad v(x, 0) = -B \quad \text{if } 0 < x < a,$$

$$v_x(a, t) + v(a, t) = M_\mu(s(t)) \quad \text{if } t > 0.$$

Representing v by means of the fundamental solution associated with the same boundary conditions as for v and using (4.8), we can deduce that

$$\max_{0 \leq x \leq a'} |v(x, t)| \rightarrow 0 \quad \text{if } t \rightarrow \infty \quad \text{for any } 0 < a' < a.$$

Since $u^- \leq v$ if B is large enough, the same is then true for u^- . Recalling also (4.2), we obtain

$$\max_{0 \leq x \leq a'} |u(x, t)| \rightarrow 0 \quad \text{if } t \rightarrow \infty \quad \text{for any } 0 < a' < a.$$

In view of (4.3) we then also have

$$(4.10) \quad \int_0^a |u(x, T)| dx \rightarrow 0 \quad \text{if } T \rightarrow \infty.$$

Next we write

$$(4.11) \quad \int_0^T u_x(a, t) dt = \int_0^T M_\mu(s(t)) dt - \int_0^T u(a, t) dt.$$

By Lemma 4.1,

$$\lim_{T \rightarrow \infty} \int_0^T M_\mu(s(t)) dt \text{ exists.}$$

Since $\int_0^T u(a, t) dt$ is a monotone function of T , it then follows from (4.5), (4.11) that this monotone function has a finite limit as $T \rightarrow \infty$. Consequently, the left-hand side of (4.11) has a limit as $T \rightarrow \infty$. Using this fact and (4.10) with $T \rightarrow \infty$, the assertion (4.9) follows from (4.4).

Remark 4.1. If $u_x(0, t) = 0$ is replaced by $u_x(0, t) = -\gamma$, $\gamma > 0$, then numerical results suggest that the free boundary is asymptotically periodic.

5. Other control problems with hysteresis.

5.1. The Muscat problem. Consider the Muscat problem of two immiscible fluids in a one-dimensional porous medium:

$$(5.1) \quad u_t = \begin{cases} au_{xx} & \text{if } 0 < x < s(t), \\ bu_{xx} & \text{if } s(t) < x < 1, \end{cases} \quad \begin{matrix} 0 < t < T_0, \\ 0 < t < T_0, \end{matrix}$$

$$(5.2) \quad u(0, t) = g_1(t) \quad \text{if } 0 < t < T_0,$$

$$(5.3) \quad u(1, t) = g_2(t) \quad \text{if } 0 < t < T_0,$$

$$(5.4) \quad u(x, 0) = u_0(x) \quad \text{if } 0 < x < 1,$$

$$(5.5) \quad u(s(t) - 0, t) = u(s(t) + 0, t) \quad \text{if } 0 < t < T_0,$$

$$(5.6) \quad au_x(s(t) - 0, t) = bu_x(s(t) + 0, t) = -\dot{s}(t) \quad \text{if } 0 < t < T_0,$$

$$(5.7) \quad s(0) = s_0,$$

where g_1, g_2, s_0 are given as well as the positive constants a, b .

We recall [1], [4], [5] that for any g_1, g_2 in $C^{0,1}[0, T_0]$ and $u_0 \in C^{0,1}[0, 1]$ there exists a unique classical solution for all $t < T$, with $s(t) \in C^\infty(0, T) \cap C^0[0, T]$ and either $T = T_0$ or else $T < T_0$ and $s(t) \rightarrow 0$ or $s(t) \rightarrow 1$ as $t \rightarrow T$. The function u represents the pressure in the fluids.

Since the above model may represent, for instance, water and oil, it is natural to attempt to control the location of the free boundary. Taking

$$(5.8) \quad g_2(t) = \int_0^t \int_{\Omega} M_{\rho}(s(\tau), M_{\rho}^i) d\mu(\rho) d\tau$$

we see that, if a solution exists,

$$-1 \leq g_2'(t) \leq 0,$$

i.e., $g_2 \in C^{0,1}[0, T]$.

We can now proceed analogously to §§ 2 and 3 and establish the existence and uniqueness of a solution of (5.1)–(5.8), as well as the existence of an optimal control for the problem (3.1), (3.2), (3.6) associated with (5.1)–(5.8).

5.2. One-phase Stefan problem in n -dimension. Consider the one-phase Stefan problem in an n -dimensional domain [9] and denote the temperature by θ . As usual, we introduce the associated variational inequality for u , where $u_t = \theta$. Since θ is a continuous function in (x, t) (see [2]), for any fixed point x_0 the function $u(x_0, t)$ is continuously differentiable in t .

Now form the hysteresis function

$$(5.9) \quad (M_{\mu}u)(t) = \sum_{j=1}^N \int_{\Omega} M_{\rho}(u(x_j, t), M_{\rho}^i) d\mu_j(\rho)$$

where $\mu = (\mu_1, \dots, \mu_N)$, $\mu_j \in M(\Omega)$ and x_j are fixed points; each $M_{\rho}(u(x_j, t), M_{\rho}^i)$ is defined precisely as $M_{\rho}(s(t), M_{\rho}^i)$ in § 1.

We can apply the methods of § 2 and thus establish the existence of a solution to the variational inequality of the Stefan problem for u , under the boundary condition

$$\frac{\partial u}{\partial \nu} + u = M_{\mu}u$$

on the fixed boundary of the water region. We can also easily establish the existence of an optimal control $\mu = (\mu_1, \dots, \mu_N)$ with $\mu_i \in K$ for the functional

$$(5.10) \quad \max_{(x, t) \in D} |u(x, t) - U(x, t)| + \sum_{i=1}^N \int \sigma_i(\rho) d\mu_i(\rho)$$

where U, σ_i are given, $\sigma_i \geq 0$, and D is a prescribed set.

Similar results can be established for the hysteresis law whereby $u(x_j, t)$ in (5.9) is replaced by the following function of t :

$$(5.11) \quad \tilde{u}_j(t) \equiv \int_{\Gamma_j} u^2(x, t) dS_x$$

where Γ_j is a surface contained in the set $\{u(x, 0) > 0\}$.

5.3. Controlling air pollution. Consider the time-dependent two-space dimensional air pollution model: Find $c = c(x, z, t)$ such that

$$(5.12) \quad c_t = uc_x + wc_z + (k_H c_x)_x + (k_V c_z)_z - Ec \quad \text{in } (0, a) \times (0, h) \times (0, T)$$

with the boundary conditions

$$(5.13) \quad c(0, z, t) = c(a, z, t) = 0,$$

$$(5.14) \quad k_V \frac{\partial c(x, h, t)}{\partial z} = 0,$$

$$(5.15) \quad k_V \frac{\partial c(x, 0, t)}{\partial z} = Q(x)$$

and initial condition

$$(5.16) \quad c(x, z, 0) = c_0(x, z).$$

Here

$$\begin{aligned} c &= \text{concentration of pollutant,} \\ (u, w) &= \text{wind velocity, } u \text{ and } w \text{ are positive,} \\ k_H &= \text{horizontal diffusivity,} \\ k_V &= \text{vertical diffusivity,} \\ E &= \text{rate of chemical decay constant} \\ Q &= \text{quantity of pollution emitted from the ground.} \end{aligned}$$

Let $G = \{(x, z), 0 < x < a, 0 < z < h\}$ and let G' be a subset of G . Let

$$s(t) = \int_{G'} (c(x, z, t))^2 dx dz.$$

We wish to control the amount of pollution emitted from the ground by replacing the boundary condition (5.15) by

$$(5.17) \quad k_V \frac{\partial c(x, 0, t)}{\partial z} = Q(x) M_\mu(t)$$

where

$$(5.18) \quad M_\mu(t) = \int_{\Omega} M_\rho(s(t), M_\rho^i) d\mu(\rho);$$

here $\Omega = \{\rho = (\rho_1, \rho_2); 0 < \rho_1 < \rho_2 < A\}$ for some large constant A . The existence of an optimal control can be established by the methods of §§ 2 and 3. For references on pollution models see [18], [20].

5.4. Identification problem. Consider the inverse problem associated with

$$(5.19) \quad \frac{dx}{dt} = f(x, y, t), \quad x(0) = x_0$$

where

$$(5.20) \quad y(t) = \int_{\Omega} M_\rho(x(t), M_\rho^i) d\mu(\rho);$$

that is, we wish to discover the measure μ from measurements of $x(t)$. If we denote by $x_\mu(t)$ a solution of (5.19), (5.20), then the methods of §§ 2 and 3 show that

$$(5.21) \quad \mu_m \rightarrow \mu \text{ weakly implies } x_{\mu_m}(t) \rightarrow x_\mu(t) \text{ uniformly;}$$

the μ_m are assumed to belong to a class K , as in (3.1).

In order to identify the hysteresis law μ , we first select a large number of measures μ_i and compute their corresponding solution $x_i(t)$ (not necessarily unique, unless the μ_i belong to $M_1(\Omega)$). Next we make measurements and obtain a function $x(t)$. We compare $x(t)$ with the functions $x_i(t)$ and denote by i_0 the index for which $x_{i_0}(t)$ is nearest to $x(t)$, in the uniform sense, say. We now identify the unknown measure μ with the measure μ_{i_0} . The justification for this method of approximation is based on the result (5.21). For physical background on identification problems in flows in porous media, see Maulem [16].

IDENTIFICATION OF MINIMAL ORDER STATE SPACE MODELS FROM STOCHASTIC INPUT-OUTPUT DATA*

Y. BARAM† AND B. PORAT†

Abstract. This paper discusses the problem of identifying a minimal order state space representation of a multivariable linear time invariant system from Gaussian stationary input-output measurements. A procedure for identifying the system's order is proposed, based on an approximate probability distribution of the squared singular values of the Hankel matrix built from the sample cross-covariances. The approximate distribution converges to the true one as the number of measurements becomes large. The order determination procedure also identifies sets of linearly independent rows and linearly independent columns of the Hankel correlation matrix which form a basis for a minimal order representation of the system.

Key words. system identification, stochastic realization

1. Introduction. The minimal order representation of the relationship between the input and the output of a finite dimensional linear system has been of interest since the pioneering work of Gilbert [1] and of Kalman [2]. The construction of such representations from a finite dimensional Hankel matrix of impulse responses was proposed by Ho and Kalman [3], Rissanen [4] and Silverman [5], among others. In the case where the input is a stochastic process, the impulse response function is naturally replaced by the cross-correlation function between the input and the output. Akaike [6] gave probabilistic and geometric interpretations to the role played by the Hankel correlation matrix when the input is a white noise process.

When the cross-correlation function between the input and the output of the system under consideration is not given, one is faced with an identification problem. When the exact, unknown correlations are replaced by their estimates from measurement data, the finite structure of the Hankel correlation matrix is normally lost due to the inaccuracies associated with finite samples. A major consequence is that the minimal representation order cannot be determined exactly from any finite dimensional Hankel matrix of sample correlations. In the past, direct identification of the order from a Hankel matrix of sample correlations has been essentially given up due to the complexity of the probability distributions involved [7] and other, indirect methods have been proposed by Chow [7], [8] and Woodside [9]. An approximation technique, based on canonical variates analysis of truncated data records has been suggested by Larimore [10]. Order estimation criteria have been suggested by Akaike [11] and by Fine and Hwang [12], whose method has shown to produce consistent estimates.

In this paper we propose a solution to the problem of identifying the minimal order and a minimal order representation for the relationship between the input and the output of a linear system from stochastic measurement data. For the sake of completeness, we first derive a generalized representation following, essentially, Akaike's steps [6]. We then obtain explicit terms for the representation, which define the model to be identified. The key to this model is a maximal set of linearly independent rows and linearly independent columns of the Hankel correlation matrix, which defines both the order and a basis for the representation. The crucial problem is then to identify a maximal set of linearly independent rows and linearly independent columns of the

Hankel matrix from measurement data. We propose a procedure which performs this task by sequentially testing the ranks of submatrices of the Hankel matrix. We then derive an approximate distribution for the rank test statistics and show how it can be calculated from measurement data.

2. Minimal order system representation. Let $u_n \in \mathbb{R}^q$ be an uncorrelated Gaussian input of a system and let $y_n \in \mathbb{R}^m$ be the system's output. Suppose that u_n and y_n are jointly Gaussian and stationary with a cross-correlation function given by

$$(2.1) \quad R_k = E\{y_n u_{n-k}^T\}$$

where E denotes the expectation operation. We assume that there exist a positive integer P and a set of positive scalars a_1, \dots, a_{P-1} , $a_0 = 1$, such that for any $k \geq P$

$$(2.2) \quad \sum_{i=0}^{P-1} a_i R_{k-i} = 0.$$

It is well known that when u_n is the input and y_n is the output of a finite dimensional linear system, they satisfy a relationship of the type (2.2) where the a_i 's are the system's characteristic polynomial coefficients. In the context of system identification u_n may represent a known, synthetically generated "pseudo-random" sequence.

It is desired to find a minimal order representation for the input-output relationship between u_n and y_n . Let us denote by $U_n^- = (u_{n-1}^T, u_{n-2}^T, \dots, u_0^T)^T$ the vector of past inputs and by $Y_n^+ = (y_n^T, y_{n+1}^T, \dots, y_{2n-1}^T)^T$ the vector of n -step future outputs. The space $Y_n^+|U_n^-$ of mean square projection of Y_n^+ on U_n^- is spanned by $R(n)[E\{U_n^- U_n^{-T}\}]^{-1} U_n^-$, where

$$(2.3) \quad R(n) = \begin{bmatrix} R_1 & R_2 & \cdots & R_n \\ R_2 & R_3 & \cdots & R_{n+1} \\ \vdots & \vdots & \ddots & \vdots \\ R_n & R_{n+1} & \cdots & R_{2n-1} \end{bmatrix}.$$

It follows from (2.2) that the rows beyond the P th block row of $R(n)$ are linearly dependent on the previous ones. This implies that $Y_n^+|U_n^-$ is spanned by $R(P, n)[E\{U_n^- (U_n^-)^T\}]^{-1} U_n^-$, where

$$(2.4) \quad R(P, n) = \begin{bmatrix} R_1 & R_2 & \cdots & R_n \\ R_2 & R_3 & \cdots & R_{n+1} \\ \vdots & \vdots & \ddots & \vdots \\ R_P & R_{P+1} & \cdots & R_{P+n-1} \end{bmatrix}.$$

Suppose that $R(P, n)$ has p linearly independent rows and let x_n denote the vector whose elements are the Euclidean inner products between some maximal set of linearly independent rows of $R(P, n)$ and $[E\{U_n^- U_n^{-T}\}]^{-1} U_n^-$. Then x_n is a vector of minimal dimension which spans $Y_n^+|U_n^-$. It follows that there exist matrices A_n , B_n , C_n and D_n such that

$$(2.5) \quad x_{n+1} = A_n x_n + B_n u_n, \quad y_n = C_n x_n + D_n u_n.$$

Let $U_n^-(P) = (u_{n-1}^T, u_{n-2}^T, \dots, u_{n-P}^T)^T$ denote the P -step past of u_n and let $Y_n^+(P) = (y_n^T, y_{n+1}^T, \dots, y_{n+P-1}^T)^T$ denote the P -step future of y_n . Let us denote

$$R = R(P) = E\{Y_n^+(P) U_n^-(P)^T\} = \begin{bmatrix} R_1 & R_2 & \cdots & R_P \\ R_2 & R_3 & \cdots & R_{P+1} \\ \vdots & \vdots & \ddots & \vdots \\ R_P & R_{P+1} & \cdots & R_{2P-1} \end{bmatrix}.$$

Since the columns beyond the P th block column of $R(P, n)$ are linearly dependent on the previous ones, R is of rank p . Since we have

$$E\{E\{Y_n^+(P)|U_n^-\}U_n^-(P)^T\} = E\{Y_n^+(P)U_n^-(P)^T\}$$

and since x_n consists of elements of $E\{Y_n^+(P)|U_n^-\}$, there exists a p -dimensional vector ω_n of elements of $U_n^-(P)$, such that the matrix $E\{x_n\omega_n^T\}$ is of full rank. By simple operations on (2.5) one obtains

$$(2.6a) \quad A_n = E\{x_{n+1}\omega_n^T\}[E\{x_n\omega_n^T\}]^{-1},$$

$$(2.6b) \quad B_n = E\{x_{n+1}u_n^T\}[E\{u_nu_n^T\}]^{-1},$$

$$(2.6c) \quad C_n = E\{y_n\omega_n^T\}[E\{x_n\omega_n^T\}]^{-1},$$

$$(2.6d) \quad D_n = E\{y_nu_n^T\}[E\{u_nu_n^T\}]^{-1}.$$

This is, essentially, Akaike's representation [6]. We note that the term D_nu_n is missing in Akaike's representation due to inclusion of u_n in U_n^- . Here we have chosen to obtain the form (2.5) which is often encountered in stochastic system estimation and control.

We proceed to obtain explicit expressions for the matrices A_n , B_n , C_n and D_n . Let W denote the submatrix of R which consists of the intersection between the first maximal set of linearly independent rows and an equal number of the first linearly independent columns of R , i.e., the elements of R which belong to both sets. Let

$$S = \begin{bmatrix} R_2 & R_3 & \cdots & R_{P+1} \\ R_3 & R_4 & \cdots & R_{P+2} \\ \vdots & \vdots & \ddots & \vdots \\ R_{P+1} & R_{P+2} & \cdots & R_{2P} \end{bmatrix}$$

and denote by U the matrix obtained by intersecting the rows and the columns of S having the same indices as the rows and the columns of W in R . Then, by the arguments leading to (2.6), we obtain

$$(2.7a) \quad A_n = A = UW^{-1}.$$

Denote by V the matrix which consists of the intersection between the first q columns of R with its first p linearly independent rows; then

$$(2.7b) \quad B_n = B = V[\text{cov}(u_n)]^{-1}.$$

Let Z denote the matrix which consists of the intersection of the first block row of R with the columns of W . Then

$$(2.7c) \quad C_n = C = ZW^{-1}.$$

Finally,

$$(2.7d) \quad D_n = D = R_0[\text{cov}(u_n)]^{-1}.$$

A minimal order representation for the input-output relationship between u_n and y_n is then given by

$$x_{n+1} = Ax_n + Bu_n, \quad y_n = Cx_n + Du_n$$

where A , B , C and D are given by (2.7a-d). We note that due to the finite initial input time, $n = 0$, imposed in the definition of U_n^- , the state x_n , as defined above is nonstationary. Passing to initialization in the remote past, x_n becomes stationary, with $\Pi = E\{x_nx_n^T\}$ satisfying

$$\Pi = A\Pi A^T + B \text{cov}(u_n) B^T.$$

We have seen that the key to the construction of a minimal order representation for the input-output relationship between the processes u_n and y_n from their cross-correlation function is the construction of the matrix W , i.e., the selection of maximal sets of linearly independent rows and linearly independent columns of the matrix R . The following procedure, based on a technique for partial realization from impulse responses suggested in [13], selects a maximal set of linearly independent columns of R . Modifying the technique so as to select linearly independent rows of R instead of linearly independent columns is straightforward. Define

$$\tilde{R} = R(2P) = \begin{bmatrix} R_1 & R_2 & \cdots & R_{2P} \\ R_2 & R_3 & \cdots & R_{2P+1} \\ \vdots & \vdots & \ddots & \vdots \\ R_{2P} & R_{2P+1} & \cdots & R_{4P-1} \end{bmatrix}.$$

Set $j=0$ and $i=1$. Check the rank of the matrix $H_{j,i}$ composed of the upper left $(2P-j) \times (jm+i)$ submatrix of \tilde{R} . If $H_{j,i}$ is rank deficient, delete the $(km+i)$ th columns, $k=j, j+1, \dots, P$ from \tilde{R} and repeat the rank check for the new $H_{j,i}$. If $H_{j,i}$ has a full rank and $i < m$, set $i = i+1$ and repeat the rank check. If $i = m$, set $j = j+1$ and $i = 1$. This procedure is continued until rank $H_{j,i} = P$ or until $j = Pm$. The rank p of R is the rank of the final $H_{j,i}$. A maximal set of the first linearly independent columns of R is obtained by taking the first p elements of the columns of $H_{j,i}$.

It can be seen that the above procedure guarantees that each tested matrix has, at most, rank deficiency of order one, i.e.,

$$(2.8) \quad \text{rank } H_{j,i} \geq (jm + i - 1)$$

(clearly, $\text{rank } H_{j,i} \leq jm + i$). This property is consistent with the statistical inference method discussed in the following section.

3. Statistical inference. We now turn to the problem of finding a minimal order representation for a vector valued process, when the correlations R_i are not given. Instead, we assume that estimates \hat{R}_i are available. Specifically, we take \hat{R}_i to be the sample covariances. A natural approach to this problem is substituting the values of \hat{R}_i instead of R_i in the representation derived in § 2. The problem is, however, that the minimal order is unknown and \hat{R} is likely to be of full rank for any P due to the stochastic nature of the problem. The decision on the order and on the linear independence of rows and of columns of R , which form the basis for the minimal representation, must be treated, then, by statistical means. Following the procedures suggested in the preceding section, the order and a maximal set of linearly independent rows and linearly independent columns will be selected simultaneously by performing sequential tests on the ranks of the matrices H_i . In the sequel we derive an approximate distribution for such tests.

Let H represent the matrix H_i which is to be checked for having a full rank in the procedure described in the previous section. Let us denote by $\lambda_i = \lambda_i(H)$, $i = 1, 2, \dots$, the eigenvalues of $H^T H$ (or the squared singular values of H) in descending order. Suppose that the smaller dimension of H is k (i.e., that H has k singular values). Clearly, H has a full rank if and only if λ_k is nonzero. A test on H having a full rank can then be formulated as a test on λ_k having a nonzero value. Since our derivation of the test distribution will require the assumption that λ_{k-1} is nonzero when testing λ_k , and since this assumption is consistent with our rank checking procedure, we shall make it implicitly when necessary.

Let r denote a vector of the distinct scalar elements of $R(P)$ arranged in some order. Let \hat{r} denote an estimate of r and denote by $\hat{\lambda}_i = \lambda_i(\hat{H})$, $i = 1, \dots, k$ the eigenvalues of $\hat{H}^T \hat{H}$, where the latter is obtained from $H^T H$ by substituting in it the values \hat{R}_j instead of R_j . The second order Taylor series expansion of $\hat{\lambda}_k$ about r is

$$(3.1) \quad \hat{\lambda}_k = \lambda_k + f^T \tilde{r} + \frac{1}{2} \tilde{r}^T F \tilde{r}$$

where

$$\tilde{r} = \hat{r} - r, \quad f = \frac{\partial \lambda_k}{\partial r}$$

and

$$F_{i,j} = \frac{\partial^2 \lambda_k}{\partial r_i \partial r_j}$$

where r_i is the i th element of r . As is well known (e.g., [13, p. 228, Thm. 14]) the sample covariance \hat{R}_i is asymptotically normally distributed with mean R_i and covariance inversely proportional to the number of measurements T . Therefore, the components of \tilde{r} are asymptotically of the order of $1/\sqrt{T}$. This justifies the second-order Taylor series approximation given above for large enough T . We note that under the tested hypothesis we have $\lambda_k = 0$. Since $H^T H \geq 0$, $\lambda_k = 0$ is a global minimum. Hence, we have $f = 0$, so (3.1) assumes the form

$$(3.2) \quad \hat{\lambda}_k = \frac{1}{2} \tilde{r}^T F \tilde{r}.$$

The vector \tilde{r} is asymptotically distributed as a normal random vector. Let us denote by Σ the covariance of \tilde{r} and by Θ the matrix of eigenvectors of $\Sigma^{1/2} F \Sigma^{1/2}$, then

$$\Theta^T \Sigma^{1/2} F \Sigma^{1/2} \Theta = L$$

where L is a diagonal matrix whose elements are denoted by α_i , $i = 1, \dots, n$, where n is the dimension of r . Defining

$$z = \Theta \Sigma^{-1/2} \tilde{r}$$

we can see that z is asymptotically distributed as a normal vector with mean zero and variance I_n .

The quadratic form (3.2) can now be written as

$$\hat{\lambda}_k = \sum_{i=1}^n \alpha_i z_i^2$$

where z_i^2 , $i = 1, \dots, n$ are independent chi-squared random variables with one degree of freedom. The characteristic function of $\hat{\lambda}_k$ is obtained as (e.g. [14])

$$\Phi(\omega) = \prod_{j=1}^n (1 - 2i\alpha_j \omega)^{-1/2}.$$

The distribution of $\hat{\lambda}_k$ can be found by integrating $\Phi(\omega)$. Several integration and approximation techniques can be found in, e.g., [14]–[16]. Given a confidence level (i.e., an acceptable probability of making the right decision) the resulting distribution defines a statistical test on the rank of the matrix H . A sequence of such tests, performed in the order of the procedure described in § 2 will provide estimates of the minimal order and maximal sets of linearly independent rows and linearly independent columns of R . The statistical properties of the rank test sequence remain a subject for further research.

It follows from the above derivation that statistical inference on the order and the linearly independent rows of R requires knowledge of F and Σ . These are derived in the following section and in the Appendix as functions of the theoretical correlations R_i . In practice, however, the values of R_i are unknown and will be replaced by estimates \hat{R}_i . Once maximal sets of linearly independent rows and linearly independent columns of R have been estimated, an estimate of the representation presented in § 2 may be obtained by substituting the estimated correlations in the corresponding matrices of (2.7).

4. Deriving the matrix F appearing in the rank test statistics. We now seek the second derivative of the eigenvalues of the matrix $H^T H$ with respect to the vector r , as defined in the previous section. Let

$$(4.1) \quad H^T H = Q \Lambda Q^T$$

be the eigenvalue/eigenvector decomposition of the symmetric matrix $H^T H$. The diagonal elements of Λ will be denoted by $\{\lambda_1, \lambda_2, \dots, \lambda_n\}$, while the columns of Q will be denoted by $\{q_1, q_2, \dots, q_n\}$. All the eigenvalues are assumed to be distinct. Let r_i, r_j denote any two components of the vector r (which may be identical or distinct). We wish to compute

$$\left\{ \frac{\partial \lambda_l}{\partial r_i}; \frac{\partial^2 \lambda_l}{\partial r_i \partial r_j}; 1 \leq l \leq k \right\}.$$

In particular, we are interested in these derivatives for $l = k$, in the special case where $\lambda_k = 0$ and $\{\lambda_1, \lambda_2, \dots, \lambda_{k-1}\}$ are nonzero. As we will see, the computation of the second derivatives requires the computation of the derivatives

$$\left\{ \frac{\partial q_l}{\partial r_i}; 1 \leq l \leq k \right\}.$$

4.1. The first derivative of the eigenvalues of $H^T H$. Let us denote for convenience

$$M(\lambda) = \lambda I - H^T H = Q[\lambda I - \Lambda]Q^T.$$

By the definition of the eigenvalues we have

$$\det(M(\lambda))|_{\lambda=\lambda_l} = 0.$$

Differentiation yields

$$\begin{aligned} \frac{\partial}{\partial r_i} \det(M(\lambda_l)) &= \text{tr} \left\{ \text{adj}(M(\lambda_l)) \frac{\partial M(\lambda_l)}{\partial r_i} \right\} \\ &= \text{tr} \left\{ \text{adj}(M(\lambda_l)) \left(\frac{\partial \lambda_l}{\partial r_i} I - \frac{\partial}{\partial r_i} H^T H \right) \right\} = 0 \end{aligned}$$

where $\text{tr}\{\}$ denotes the trace of a matrix, and $\text{adj}(\)$ denotes the adjugate matrix. Hence we get for the first derivative,

$$(4.2) \quad \frac{\partial \lambda_l}{\partial r_i} = \frac{\text{tr} \{ \text{adj}(M(\lambda_l)) (\partial/\partial r_i) H^T H \}}{\text{tr} \{ \text{adj}(M(\lambda_l)) \}}.$$

4.2. The first derivative of the eigenvectors of H^TH . We have

$$M(\lambda_l)q_l = 0.$$

Hence,

$$\frac{\partial M(\lambda_l)}{\partial r_i} q_l + M(\lambda_l) \frac{\partial q_l}{\partial r_i} = 0,$$

or

$$(4.3) \quad M(\lambda_l) \frac{\partial q_l}{\partial r_i} = -\frac{\partial M(\lambda_l)}{\partial r_i} q_l.$$

This equation cannot be solved directly because $M(\lambda_l)$ is singular. Therefore we proceed as follows. Note that by (4.3) and by the symmetry of $M(\lambda_l)$,

$$(4.4) \quad q_l^T M(\lambda_l) \frac{\partial q_l}{\partial r_i} = -q_l^T \frac{\partial M(\lambda_l)}{\partial r_i} q_l = 0.$$

Also, since q_l is a unit vector,

$$(4.5) \quad q_l^T q_l = 1; \quad \text{hence, } q_l^T \frac{\partial q_l}{\partial r_i} = 0.$$

Consider (4.3) after premultiplying by Q^T :

$$(4.6) \quad \begin{bmatrix} \lambda_l - \lambda_1 & & & & 0 \\ & \ddots & & & \\ & & \lambda_l - \lambda_{l-1} & & \\ & & & 0 & \\ 0 & & & & \ddots \\ & & & & & \lambda_l - \lambda_k \end{bmatrix} Q^T \frac{\partial q_l}{\partial r_i} = -Q^T \frac{\partial M(\lambda_l)}{\partial r_i} q_l.$$

By (4.4), the l th equation in (4.6) is an identity $0 = 0$. On the other hand, by (4.5) we can replace the zero on the main diagonal of the matrix in the left-hand side of (4.6) by one and still get an equality. Hence, (4.6) has a unique solution

$$(4.7) \quad \frac{\partial q_l}{\partial r_i} = -Q \begin{bmatrix} \lambda_l - \lambda_1 & & & & 0 \\ & \ddots & & & \\ & & \lambda_l - \lambda_{l-1} & & \\ & & & 1 & \\ 0 & & & & \ddots \\ & & & & & \lambda_l - \lambda_k \end{bmatrix}^{-1} Q^T \left(\frac{\partial \lambda_l}{\partial r_i} I - \frac{\partial}{\partial r_i} H^T H \right) q_l.$$

4.3. An expression for $\text{adj}(M)$. In order to compute the second derivatives of the eigenvalues, we will need an explicit expression for $\text{adj}(M(\lambda_l))$. Since $M(\lambda_l)$ is singular, it is meaningless to use $\text{adj}(M(\lambda_l)) = \det(M(\lambda_l)) [M(\lambda_l)]^{-1}$, and we will have to use a limiting process. For all $\lambda \neq \lambda_1, \lambda_2, \dots, \lambda_k$ we have

$$M^{-1}(\lambda) = Q(\lambda I - \Lambda)^{-1} Q^T, \quad \det M(\lambda) = \prod_{m=1}^k (\lambda - \lambda_m).$$

Hence,

$$\text{adj}(M(\lambda)) = Q \Psi Q^T$$

where Ψ is a diagonal matrix whose l th diagonal entry is $\prod_{m \neq l} (\lambda - \lambda_m)$.

Now let λ approach λ_l , and use the fact that $\text{adj}(M(\lambda))$ is a continuous function of λ . Clearly, all the entries of Ψ go to zero, except for the l th one that goes to $\prod_{m \neq l} (\lambda_l - \lambda_m)$. Therefore we get

$$(4.8) \quad \text{adj}(M(\lambda_l)) = \left[\prod_{m \neq l} (\lambda_l - \lambda_m) \right] q_l q_l^T.$$

Since all the eigenvalues of $H^T H$ were assumed to be distinct, $\text{adj}(M(\lambda_l))$ is a matrix of rank 1. We also see from (4.8) that

$$\text{tr}[\text{adj}\{M(\lambda_l)\}] = \prod_{m \neq l} (\lambda_l - \lambda_m) \neq 0,$$

i.e., the denominator in (4.2) is nonzero.

4.4. The second derivatives of the eigenvalues. Differentiation of (4.2) with respect to r_j yields

$$(4.9) \quad \frac{\partial^2 \lambda_l}{\partial r_i \partial r_j} = \frac{\text{tr}\{(\partial \text{adj}(M(\lambda_l))/\partial r_j)(\partial/\partial r_i)H^T H + \text{adj}(M(\lambda_l))(\partial^2/\partial r_i \partial r_j)H^T H\}}{[\text{tr}\{\text{adj}(M(\lambda_l))\}]} - \frac{\text{tr}\{\partial \text{adj}(M(\lambda_l))/\partial r_j\} \cdot \text{tr}\{\text{adj}(M(\lambda_l))(\partial/\partial r_i)H^T H\}}{[\text{tr}\{\text{adj}(M(\lambda_l))\}]^2}.$$

In order to use this formula, we only need an expression for the first derivative of $\text{adj}(M(\lambda_l))$. Using (4.8) we get

$$(4.10) \quad \frac{\partial \text{adj}(M(\lambda_l))}{\partial r_j} = \left[\frac{\partial}{\partial r_j} \prod_{m \neq l} (\lambda_l - \lambda_m) \right] q_l q_l^T + \left[\prod_{m \neq l} (\lambda_l - \lambda_m) \right] \left[\frac{\partial q_l}{\partial r_j} q_l^T + q_l \frac{\partial q_l^T}{\partial r_j} \right].$$

The right-hand side of (4.10) can be computed from the previous expressions. Hence we have all the formulas needed to compute the second derivatives. We just mention that the derivatives of $H^T H$ are easy to compute, because the entries are just the various components of r . We have

$$(4.11) \quad \frac{\partial}{\partial r_i} H^T H = \frac{\partial H^T}{\partial r_i} H + H^T \frac{\partial H}{\partial r_i},$$

$$(4.12) \quad \frac{\partial^2}{\partial r_i \partial r_j} H^T H = \frac{\partial H^T}{\partial r_i} \frac{\partial H}{\partial r_j} + \frac{\partial H^T}{\partial r_j} \frac{\partial H}{\partial r_i}.$$

The matrices $\partial H/\partial r_i$ and $\partial H/\partial r_j$ are constant matrices, consisting of 1's and 0's only.

5. Conclusion. This paper has presented a method for identifying a minimal order linear system from input-output data. The crucial problem is identifying the minimal order. By identifying maximal sets of linearly independent rows and linearly independent columns of a finite dimensional Hankel matrix, both the minimal order and a basis for the representation are identified. A statistical inference technique, based on sequential tests on the ranks of submatrices of the Hankel matrix of sample correlations and on an approximate distribution for the rank test statistics has been derived. The approximate distribution converges to the true one as the number of observations becomes large. The proposed method seems to close a gap between the minimal realization problem and the problem of system identification from input-output measurement data.

Appendix. The covariance of the normal vector \tilde{r} appearing in the quadratic form. It was shown in § 3 that in order to specify the test statistics distribution, the value of $\Sigma = \text{cov}(\tilde{r})$ is needed. We have

$$E\{\hat{r}\hat{r}^T\} = E\{\hat{r}\hat{r}^T\} - r r^T.$$

Since the vector r is constructed from elements of the correlations R_i , $i = 1, 2, \dots$, the value of rr^T can be immediately obtained in terms of cross products $R_i R_j$, $i, j = 1, 2, \dots$. We next derive expressions for the second moments of the entries of \hat{R}_l and \hat{R}_k from which $E\{\hat{r}\hat{r}^T\}$ is immediately obtainable.

Let the sample covariances $\{\hat{R}_l\}$ be defined by

$$(A.1) \quad \hat{R}_l = \frac{1}{T-l} \sum_{t=l+1}^T y_t u_{t-l}^T.$$

The (i, j) th entry of \hat{R}_l will be denoted by $\hat{R}_{l,ij}$. The sample covariances thus defined are clearly unbiased, i.e.,

$$E\{\hat{R}_{l,ij}\} = \frac{1}{T-l} \sum_{t=l+1}^T E\{y_{t,i} u_{t-l,j}\} = R_{l,ij}.$$

The second moments of the sample covariances are computed as follows.

$$\begin{aligned} \hat{R}_{l,ij} \hat{R}_{k,gh} &= \left(\frac{1}{T-l} \sum_{t=l+1}^T y_{t,i} u_{t-l,j} \right) \left(\frac{1}{T-k} \sum_{s=k+1}^T y_{s,g} u_{s-k,h} \right) \\ &= \frac{1}{(T-k)(T-l)} \sum_{t=l+1}^T \sum_{s=k+1}^T y_{t,i} u_{t-l,j} y_{s,g} u_{s-k,h}. \end{aligned}$$

Since $\{u\}$ and $\{y\}$ are jointly Gaussian, we have

$$\begin{aligned} E\{\hat{R}_{l,ij} \hat{R}_{k,gh}\} &= \frac{1}{(T-k)(T-l)} \sum_{t=l+1}^T \sum_{s=k+1}^T \{E\{y_{t,i} u_{t-l,j}\} E\{y_{s,g} u_{s-k,h}\} \\ &\quad + E\{y_{t,i} y_{s,g}\} E\{u_{t-l,j} u_{s-k,h}\} + E\{y_{t,i} u_{s-k,h}\} E\{u_{t-l,j} y_{s,g}\}\}. \end{aligned}$$

Hence,

$$(A.2) \quad \begin{aligned} \text{cov}\{\hat{R}_{l,ij}, \hat{R}_{k,gh}\} &= \frac{1}{(T-l)(T-k)} \sum_{t=l+1}^T \sum_{s=k+1}^T \{E\{y_{t-s,i} y_{0,g}\} E\{u_{t-l-s+k,j} u_{0,h}\} \\ &\quad + E\{y_{t-s+k,i} u_{0,h}\} E\{u_{t-l+s,j} y_{0,g}\}\}. \end{aligned}$$

Note that, since $\{u_i\}$ is uncorrelated, we have

$$(A.3) \quad E\{u_{t-l+s-k,j} u_{0,h}\} = 0, \quad t-l+s-k \neq 0.$$

In practice, the expectations appearing in (A.2) are unknown; hence we approximate them by

$$(A.4a) \quad E\{y_{m,i} y_{0,j}\} \approx \frac{1}{T-m} \sum_{t=m+1}^T y_{t,i} y_{t-m,j},$$

$$(A.4b) \quad E\{y_{m,i} u_{0,j}\} \approx \frac{1}{T-m} \sum_{t=m+1}^T y_{t,i} u_{t-m,j},$$

$$(A.4c) \quad E\{u_{0,i} u_{0,j}\} \approx \frac{1}{T} \sum_{t=1}^T u_{t,i} u_{t,j}.$$

THE MINIMAL DELAY DECOUPLING PROBLEM: FEEDBACK IMPLEMENTATION WITH STABILITY*

J. M. DION† AND C. COMMAULT†

Abstract. In this paper we solve the minimal delay decoupling problem of linear multivariable systems. We look for feedback implementable solutions which moreover guarantee closed loop stability. We prove that dynamic state feedback decoupling with stability is achievable if the number of independent inputs is large enough to compensate the intrinsic “nondecouplability” of the system. We introduce new feedback invariants characterizing the minimal number of infinite and unstable zeros of the decoupled system.

1. Introduction. In this paper we solve the minimal delay decoupling problem of linear multivariable systems. When possible we look for feedback implementable solutions which moreover guarantee closed loop stability. We focus our attention on decoupling compensators achieving the minimal McMillan degree of the decoupled system. Most of our results are expressed in terms of new feedback invariants which may be useful for solving other control problems.

The decoupling problem has received a great deal of attention during the last years. For authoritative references representing important steps in the development of this theory, see [1]–[4]. Let us recall briefly the main results in this field:

—Falb and Wolovich [1] solved the decoupling problem for square systems by static state feedback, $u = Fx + Gv$, G nonsingular.

—Morse and Wonham [2], [3] solved the decoupling problem in more general cases by adding auxiliary integrators (“Extended Decoupling Problem”) in a geometric framework. The decoupling condition by a static state feedback control law on the extended system turns out to be the same as the decoupling condition by pure precompensation $u = G(s)v$. Furthermore, for square systems, a minimal stabilizing solution is provided in the sense that it requires the least possible order of dynamic compensation.

—Hautus and Heymann [4] have shown that in the square case the decoupling conditions are the same by static feedback, $u = Fx + Gv$, G nonsingular, and by dynamic state feedback $u = F(s)x + Gv$, G nonsingular. They have shown that this was not the case for nonsquare systems when G was no longer restricted to being nonsingular. An extension for systems defined over unique factorization domains is given in Datta and Hautus [5].

Discussions on the various types of decoupling compensators may be found in Hautus and Heymann [4] and Willems [6]. In our approach the exogeneous input v does not enter the system directly; v is assumed to be measurable and is used by the designer in order to steer the exogeneous output. A more general setup is considered in Willems [6]. Notice that in the particular case of row by row decoupling the admissibility conditions of output controllability preservation are identical in [3] and [4].

In the transfer matrix framework of [4] we examine in this paper the row by row decoupling problem for not necessarily injective systems. We are interested in obtaining the minimal delay and the minimal McMillan degree of the decoupled system. When possible we look for feedback implementable solutions which moreover guarantee closed loop stability. In effect, as will be shown further, the feedback solutions require that less dynamics be added than the equivalent precompensations.

Our contributions are as follows:

—We solve the problem of dynamic state feedback decoupling for noninjective systems which was left open in [4]. The decoupling control law does not contain input dynamics as in [3].

—The proposed solution achieves the minimal delay decoupling, i.e., the simplest infinite structure for the decoupled system is achieved. This corresponds to the minimum number of delays in the discrete time formulation.

—The proposed solution gives the minimal McMillan degree of the decoupled system which incidentally means that the decoupled system possesses the minimal number of unstable zeros.

—When state feedback decoupling is not possible, decoupling is achievable by dynamic precompensation with stability for full row rank transfer matrices. We also give in this case the minimum number of unstable and infinite zeros of the decoupled system.

This paper is organized as follows. In § 2 the decoupling problem is formulated and some notations and preliminaries are given. We notice that in this formulation the decoupling by precompensation is quite trivial. Some results concerning the feedback implementation of bicausal precompensators are recalled. For proper rational matrices we recall the notion of Hermite form and introduce the infinite column rank.

Section 3 is devoted to the state feedback decoupling problem. First we show that feedback solutions are advantageous because they need less auxiliary integrators than the equivalent precompensations. Then we solve the dynamic state feedback decoupling problem. This problem turns out to have a solution if the number of independent inputs is large enough to compensate the intrinsic “nondecouplability” of the system. We then introduce feedback invariants which are useful for characterizing the minimal delay decoupled system. When feedback decoupling solutions exist we show that minimal delay decoupling can be achieved by feedback.

In § 4 we study the state feedback decoupling problem with stability. In the first part of this section we briefly recall some mathematical tools concerning factorizations of transfer functions over the P.I.D. of proper rational stable functions. Then as an intermediate result we characterize all the precompensators which are feedback implementable with closed loop stability. We prove that decoupling is achievable with stability if and only if it is achievable without stability considerations. Other feedback invariants characterizing the simplest infinite and unstable structure for the decoupled system are introduced. When feedback decoupling solutions exist we exhibit such a feedback solution. Some concluding remarks end the paper.

2. Preliminaries and problem statement.

A. Problem setting. Let $R(s)$ be the field of rational functions.

$$f(s) = \frac{n(s)}{d(s)} \in R(s)$$

is said to be proper (resp. strictly proper) if $\deg(d(s)) \geq \deg(n(s))$ (resp. $\deg(d(s)) > \deg(n(s))$) where $\deg(n(s))$ denotes the polynomial degree of $n(s)$.

Denote $R_p(s)$ the ring of proper rational functions and $R_p^{p \times m}(s)$ the set of proper rational $p \times m$ transfer matrices.

The units (invertible elements) of the ring $R_p^{m \times m}(s)$ are called bicausal matrices and are characterized by the property that $B(s)$ is a bicausal matrix if and only if

$$\det \left(\lim_{s \rightarrow \infty} B(s) \right) \neq 0.$$

Throughout this paper we will consider matrices and vector spaces over the real or over the rational functions. Notions such as independence, rank, span, etc. should be understood in their usual sense over the basic field.

The system of transfer matrix $T(s) \in R_p^{p \times m}(s)$ is said to be *decoupled* if there exist nonzero positive integers $m_1 \cdots m_p$ satisfying

$$\sum_{i=1}^p m_i = m$$

such that $T(s)$ has the following diagonal form:

$$T(s) = \begin{bmatrix} T_{11}(s) & & 0 \\ & \ddots & \\ 0 & & T_{pp}(s) \end{bmatrix} = \text{diag} (T_{11}(s) \cdots T_{pp}(s))$$

with

$$T_{ii}(s) \in R_p^{l \times m_i}(s), \quad T_{ij}(s) = 0, \quad i \neq j.$$

This means that each input block defined above influences only one output. If we want this influence to be effective the $T_{ii}(s)$ must be nonnull for each i . In this case the system is called *nondegenerate*.

A system $T(s)$ is said to be *decouplable* if there exists a proper compensator $C(s)$ such that $T(s)C(s)$ is decoupled. Notice that, at this point, $C(s) = 0$ is a decoupling compensator. In order to avoid such trivialities we will require the compensated system to be as "output controllable" as the initial system. We will say that $C(s)$ is *admissible* if $\text{rank } T(s)C(s) = \text{rank } T(s)$. This admissibility condition is equivalent to the preservation of the C^∞ controlled output trajectories. This condition which is also called functional output controllability preservation was introduced in [7].

The decoupling problem above defined is always solvable for *surjective* systems ($\text{rank } T(s) = p$). A solution is given by $C(s) = (1/s^k)T^*(s)$, where $T^*(s)$ is a right inverse of $T(s)$ and k is some integer sufficiently large to ensure that $C(s)$ is proper.

In this paper we will focus our attention on decoupling compensators which are feedback implementable. This type of solution is highly desirable from a practical point of view as shown in § 3. In order to do this we need some complements about feedback compensators.

B. Precompensators and feedback. Let $T(s)$ be a $p \times m$ strictly proper rational transfer matrix and (A, B, C) be a realization of $T(s)$, i.e.,

$$\dot{x} = Ax + Bu, \quad x \in R^n, \quad u \in R^m,$$

$$y = Cx, \quad y \in R^p,$$

with $T(s) = C(sI - A)^{-1}B$.

In the following we will restrict our attention to $p \times m$ strictly proper transfer matrices $T(s)$ with null static kernel, i.e., a minimal basis of $\text{Ker}(T(s))$ contains no constant vector.

There is no serious restriction in considering only transfer matrices with zero static kernel, since this can always be achieved by eliminating the nonindependent inputs.

In the state space framework and for a strictly proper transfer matrix $T(s)$ the following can be proved: $T(s)$ possesses a null static kernel if and only if B is injective in any realization (A, B, C) of $T(s)$.

We consider the effect of a dynamic state feedback defined by $u = F(s)x + Gv$ where $F(s)$ is a $m \times n$ proper rational transfer matrix and G is a square full rank constant matrix.

The closed-loop transfer matrix is then:

$$\begin{aligned} T_{FG}(s) &= C(sI - A - BF(s))^{-1}BG \\ &= T(s)(I - F(s)(sI - A)^{-1}B)^{-1}G \\ &= T(s)B(s) \end{aligned}$$

where $B(s)$ is easily seen to be a bicausal matrix.

The converse problem was studied in [8] and [9]. More precisely we will use the following theorem from [9], which is reformulated below using a more traditional terminology.

THEOREM 1. *Let $T(s)$ be a $p \times m$ strictly proper rational matrix with null static kernel and let (A, B, C) be a realization of $T(s)$. Let $C(s)$ be an $m \times m$ proper rational compensator. There exists a $m \times n$ proper rational matrix $F(s)$ and a square full rank constant matrix G such that*

$$T(s)C(s) = C(sI - A - BF(s))^{-1}BG$$

if and only if $C(s)$ is bicausal.

The effect of a bicausal precompensator is then equivalent to the effect of a dynamic state feedback with nonsingular input transformation G . This is true in any realization and in particular in a minimal one. It is shown in [8] that the effect of a bicausal precompensator is also equivalent to the effect of a static state feedback, but when acting on a possibly nonminimal realization of $T(s)$.

A bicausal compensator is clearly admissible in the sense defined above. The decoupling problem with such compensators has been solved in [4].

As seen on the following example it is too restrictive to impose the invertibility of the G matrix; it may be possible to decouple by reducing the number of inputs.

Consider the following:

$$T(s) = \begin{bmatrix} s^{-2} & 0 & s^{-1} \\ 0 & s^{-2} & s^{-1} \end{bmatrix}.$$

It can be proven that $T(s)$ cannot be decoupled by a bicausal precompensator, while the constant admissible compensator

$$G = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}$$

works perfectly. It appears that relaxing this invertibility condition extends significantly the class of decouplable systems.

For this reason, in the following, we will consider the effect of dynamic state feedback defined by $u = F(s)x + Gv$ where $F(s)$ is an $m \times n$ proper rational matrix and G is an $m \times l$ constant matrix. The equivalent precompensator is equal to $B(s)G$ where $B(s)$ is bicausal. The problem to be solved in this paper is the row by row decoupling

problem by this kind of compensator. For practical reasons we are looking for non-degenerate solutions; this imposes that the system under consideration be full row rank (surjective). We now state without proof a simple proposition which will allow us to restrict the set of input transformations G .

PROPOSITION 1. *With the above notations, the system of $p \times m$ surjective strictly proper transfer $T(s)$ is decouplable by an admissible dynamic state feedback if and only if the system is decouplable by an admissible dynamic state feedback where G is a $m \times p$ full rank constant matrix.*

In the following the use of Proposition 1 will allow us to restrict our attention to such compensators.

C. Hermite form and rank at infinity. In the sequel we will need Hermite forms over the ring of proper rational functions. More precisely we have the following theorem.

THEOREM 2 [10]. *Let $T(s)$ be a $p \times m$ surjective proper rational matrix. $T(s)$ can be factorized in $T(s) = H(s)B(s)$ where $B(s)$ is a bicausal matrix (unit of the ring $R_p^{m \times m}(s)$) and $H(s) = [\bar{H}(s), 0]$ where*

$$\bar{H}(s) = \begin{bmatrix} 1/\pi^{n_1} & & 0 \\ & \ddots & \\ h_{ij} & & 1/\pi^{n_p} \end{bmatrix}$$

where $\pi = s + a$ is an arbitrary polynomial of degree one and

$$h_{ij} = \gamma / \pi^{n_{ij}},$$

$n_{ij} < n_i$ with n_i, n_{ij} positive integers and γ is a polynomial.

$H(s)$ is called the π -Hermite form of $T(s)$ over the ring of proper rational functions. $H(s)$ is uniquely determined by $T(s)$ and π .

Let us call $I_\pi(s) = \bar{H}^{-1}(s)$ the π -interactor of $T(s)$. Notice that this definition coincides with the definition of the interactor $I(s)$ given in [11] where $\pi = s$; for further details see [12].

Since the bicausal matrix possesses neither poles nor zeros at infinity, $H(s)$ (or $I_\pi(s)$) contains all the information about the behaviour at infinity of $T(s)$. A related and useful notion is the notion of rank at infinity.

DEFINITION 1. Let $T(s)$ be a $p \times m$ rational matrix. Denote $T_i(s)$ as the i th column of $T(s)$. Define the integers r_i such that: $\lim_{s \rightarrow \infty} T_i(s)s^{-r_i} = t_i$, where t_i is a nonnull constant vector when $T_i(s)$ is nonnull.

The *column rank at infinity* of $T(s)$ is defined as the rank (over the real field) of the matrix $T_0 = [t_1, \dots, t_m]$.

It appears that if r_i is negative when $T_i(s)$ is nonnull, then $-r_i$ is the infinite zero order of $T_i(s)$; otherwise r_i is the infinite pole order of $T_i(s)$.

The above notion corresponds with the intuitive rank notion. We have to be careful in using this concept because, for example, the row rank at infinity may be different from the column rank at infinity. This can be seen in the following example:

$$T(s) = \begin{bmatrix} s^{-2} & 0 & 0 \\ 0 & s^{-2} & 0 \\ s^{-1} & s^{-1} & s^{-1} \end{bmatrix}$$

has infinite column rank equal to one, and infinite row rank equal to three.

3. Dynamic state feedback decoupling. This section is subdivided into three parts. In the first we stress the fact that feedback decoupling compensators are simpler, in

the sense that they need less auxiliary dynamics, than equivalent decoupling precompensators. Necessary and sufficient conditions for dynamic state feedback decoupling are given in part two. In part three we characterize the minimal McMillan degree achievable for the decoupled system. The result can also be stated in terms of the simplest infinite structure achievable or in the discrete time framework by the minimum number of delays for the decoupled system.

3.1. Why feedback implementation? Consider first the following illustrative example:

$$T(s) = \begin{bmatrix} s^{-1} & s^{-2} & s^{-3} \\ s^{-1} & 2s_2^{-x} & s^{-2} + 2s^{-3} \end{bmatrix}.$$

It can be shown that the system whose transfer matrix is $T(s)$ is decouplable neither by a constant admissible compensator nor by a dynamic state feedback $u = F(s)x + Gv$, G nonsingular.

There exists an admissible decoupling precompensator $C(s)$ of McMillan degree 2.

$$C(s) = \begin{bmatrix} 2s^{-1} & -2s^{-1} \\ -1 & 2 + s^{-1} \\ 0 & -1 \end{bmatrix}$$

then

$$T(s)C(s) = \begin{bmatrix} s^{-2} & 0 \\ 0 & s^{-2} \end{bmatrix}.$$

Consider the following minimal realization $\Sigma = (A, B, C)$ of $T(s)$:

$$\dot{x} = Ax + Bu, \quad y = Cx$$

with

$$A = \begin{bmatrix} 0 & 0 & 1 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \end{bmatrix}.$$

The precompensator is implementable by static state feedback $u = Fx + Gv$ with

$$F = \begin{bmatrix} 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad G = \begin{bmatrix} 0 & 0 \\ -1 & 2 \\ 0 & -1 \end{bmatrix}.$$

We can verify that

$$C(sI - A - BF)^{-1}BG = \begin{bmatrix} s^{-2} & 0 \\ 0 & s^{-2} \end{bmatrix}.$$

In this case the complexity (McMillan degree) of the feedback decoupling compensator is smaller than the complexity of any admissible decoupling precompensator. We will show that this result is general.

PROPOSITION 2. *Consider the system of $p \times m$ strictly proper transfer matrix $T(s)$ with null static kernel and (A, B, C) a minimal realization of $T(s)$. Let $C(s)$ be a feedback implementable (by static or dynamic state feedback) precompensator; then the feedback implementation of $C(s)$, $F(s)$, has McMillan degree less than or equal to that of $C(s)$.*

Proof. From Proposition 1, $C(s)$ is a piece of a bicausal matrix, that is to say that there exists a $m \times (m-p)$ constant matrix C_1 such that:

$$B(s) = [C(s), C_1] \text{ is bicausal.}$$

$B(s)$ can be written as $B(s) = (I - R(s))^{-1}G_1$ with $R(s)$ strictly proper and G_1 nonsingular.

Choose $F(s) = R(s)B'(sI - A)$ where B' is a left inverse of B and

$$G = G_1 \begin{bmatrix} I \\ 0 \end{bmatrix} \text{ where } G \text{ is an } m \times p \text{ constant matrix.}$$

Notice that $F(s)$ is proper since $R(s)$ is strictly proper. Furthermore the effect of the feedback compensator $u = F(s)x + Gv$ is equivalent to the effect of $C(s)$ because

$$(I - F(s)(sI - A)^{-1}B)^{-1}G = (I - R(s)B'(sI - A)(sI - A)^{-1}B)^{-1}G = C(s).$$

On the other hand, $B(s)$ and $C(s)$ have the same McMillan degree δ . A bicausal matrix possesses the same number of finite poles and zeros; then $B^{-1}(s)$ and $R(s) = I - G_1B^{-1}(s)$ have McMillan degree δ .

From the expression of $F(s)$ we conclude that $F(s)$ has a McMillan degree lower than or equal to δ . \square

As we have shown above, feedback implementation leads to simpler controllers, other than the well-known nice properties of feedback controllers.

3.2. State feedback decoupling. In this section we give a necessary and sufficient condition for admissible dynamic state feedback decoupling. It turns out that the problem is solvable if the number of inputs is sufficiently large in order to compensate the rank deficiency at infinity of the transfer matrix interactor. The result is expressed in the following way.

THEOREM 3. *The system whose transfer matrix $T(s)$ is a $p \times m$ strictly proper rational surjective transfer matrix with null static kernel, is decouplable by an admissible dynamic state feedback on a minimal realization of $T(s)$ if and only if*

$$m \geq 2p - k$$

where k is the column rank at infinity of $I(s)$, the interactor of $T(s)$.

Proof. Consider first the sufficiency. The proof is constructive. We will build an admissible dynamic state feedback implementable decoupling compensator. By using Proposition 1 this compensator is of the form $C(s) = B(s)G$ where $B(s)$ is a bicausal matrix and G is a $m \times p$ full rank constant matrix. As noted before $C(s)$ is a "piece" of bicausal matrix characterized by

$$\lim_{s \rightarrow \infty} C(s) = C_0,$$

C_0 being a full column rank matrix. $C(s)$ is a full column rank at infinity matrix, moreover the infinite zero orders of the columns are all equal to zero.

From Theorem 2, $T(s)$ can be factorized as follows:

$$T(s) = [\bar{H}(s), 0]B(s) = [I^{-1}(s), 0]B(s)$$

where $B(s)$ is a bicausal matrix and $I(s)$ is the interactor of $T(s)$. Consider the compensator

$$C(s) = B^{-1}(s) \begin{bmatrix} I_1(s) \\ X \end{bmatrix}$$

where $I_1(s) = I(s) \text{diag}(s^{-r_1}, \dots, s^{-r_p})$, the r_i 's being chosen as in Definition 1 such that

$$\lim_{s \rightarrow \infty} I_1(s) = I_0$$

and I_0 has no null column. By definition I_0 has a real rank k . X is an $(m-p) \times p$ constant matrix such that

$$\begin{bmatrix} I_0 \\ X \end{bmatrix}$$

has a full column rank. This is always possible from the assumption $m \geq 2p - k$. For this select k independent rows in I_0 , choose for the $p - k$ first rows of X such that with the k 's preceeding they form a $p \times p$ invertible matrix.

The above compensator $C(s)$ is such that

$$C(s) = C_0 + \bar{C}(s)$$

where

$$\begin{aligned} C_0 &= B_0^{-1} \begin{bmatrix} I_0 \\ X \end{bmatrix}, \\ B(s) &= B_0 + \bar{B}(s), \\ \lim_{s \rightarrow \infty} \bar{C}(s) &= 0, \quad \lim_{s \rightarrow \infty} \bar{B}(s) = 0. \end{aligned}$$

By construction C_0 is a full column rank constant matrix, and $C(s)$ is then a piece of a bicausal matrix. C_0 being full column rank, there exists a full column rank constant matrix Q_0 such that (C_0, Q_0) is an invertible matrix. Define $B_1(s) = (C(s), Q_0)$, $B_1(s)$ is a bicausal matrix.

Since

$$C(s) = B_1(s) \begin{bmatrix} I \\ 0 \end{bmatrix}$$

and using Theorem 1 the precompensator $C(s)$ is implementable by dynamic state feedback on a minimal realization of $T(s)$.

Furthermore,

$$T(s)C(s) = \text{diag}(s^{-r_1}, \dots, s^{-r_p}).$$

It follows that $C(s)$ is an admissible decoupling compensator.

Consider now the necessity. Suppose that the problem is solvable by Proposition 1 there exists an admissible decoupling compensator $C(s)$; dynamic state feedback implementable such that:

$$T(s)C(s) = \text{diag}(d_1(s) \cdots d_p(s)) = D(s)$$

where $d_i(s)$ are proper nonnull rational functions.

From Theorem 2 we have

$$T(s)C(s) = [I^{-1}(s), 0]B(s)C(s) = D(s).$$

It follows that

$$[I_p, 0]B(s)C(s) = I(s)D(s)$$

where I_p is the $p \times p$ identity matrix.

Denote

$$V(s) = \begin{bmatrix} V_1(s) \\ V_2(s) \end{bmatrix} = B(s)C(s),$$

where $V_1(s)$ is a $p \times p$ proper rational matrix and $V_2(s)$ is an $(m-p) \times p$ proper rational matrix. $V(s)$ is a piece of a bicausal matrix; its column rank at infinity is equal to p .

Moreover $V_1(s) = I(s)D(s)$ is not altered by a right multiplication with a nonsingular diagonal matrix.

$V(s)$ is then such that

$$\lim_{s \rightarrow \infty} V(s) = \lim_{s \rightarrow \infty} \begin{bmatrix} V_1(s) \\ V_2(s) \end{bmatrix} = \begin{bmatrix} V_1 \\ V_2 \end{bmatrix} = V$$

where V_1 is a constant matrix of real rank k and V is a constant matrix of real rank p .

It is then clear that V_2 must have at least $p-k$ rows, so $m-p \geq p-k$, which ends the proof. \square

Remark. When $m \geq 2p-1$ for any surjective system, decoupling is always achievable, because k is at least 1. Furthermore, as shown on the following example, in some cases we need effectively $2p-1$ independent inputs for dynamic state feedback decoupling.

$$\begin{aligned} T(s) &= \begin{bmatrix} s^{-1} & 0 & 0 & s^{-2} & 0 \\ 0 & s^{-1} & 0 & s^{-3} & 0 \\ -s^{-1} & -s^{-1} & s^{-2} & -s^{-2}-s^{-3} & s^{-3} \end{bmatrix} \\ &= \begin{bmatrix} s^{-1} & 0 & 0 & 0 & 0 \\ 0 & s^{-1} & 0 & 0 & 0 \\ -s^{-1} & -s^{-1} & s^{-2} & 0 & 0 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & 0 & s^{-1} & 0 \\ 0 & 1 & 0 & s^{-2} & 0 \\ 0 & 0 & 1 & 0 & s^{-1} \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} = [I^{-1}(s)0]B(s) \end{aligned}$$

where

$$I(s) = \begin{bmatrix} s & 0 & 0 \\ 0 & s & 0 \\ s^2 & s^2 & s^2 \end{bmatrix}$$

and $B(s)$ is bicausal.

In this case the column rank at infinity k of $I(s)$ is one, then the five inputs are necessary for decoupling.

At this point we note that dynamic decoupling is actually related to the column rank at infinity of $I(s)$, and *not* to the row rank at infinity of the transfer matrix, which could have been reasonably conjectured from existing literature [14]. In the previous example, the row rank at infinity of $T(s)$ is two while k is one.

3.3. Minimal delay decoupling. In this section we will focus our attention on the minimal McMillan degree achievable for the decoupled system. As will be seen further what we minimize in fact is the infinite zero order of each entry of the decoupled system. In the discrete time framework this corresponds to the appealing minimal delay decoupling problem. The dual problem using a post compensator is studied in [13]. The minimal delays will be characterized in terms of new feedback invariants. Furthermore we prove that when they exist, feedback solutions lead to the same minimal delays as precompensation.

We focus our attention on the integers r_i given by Definition 1 and appearing in the proof of Theorem 3.

DEFINITION 2. Let $T(s)$ be a $p \times m$ surjective proper rational matrix and $I(s)$ its interactor. Denote $I_i(s)$ the i th column of $I(s)$. Let r_i be the integer such that

$$\lim_{s \rightarrow \infty} I_i(s)s^{-r_i} = t_i \quad \text{where } t_i \text{ is a nonnull constant vector.}$$

The integers r_1, \dots, r_p are called the *decoupling invariants* of $T(s)$. $\gamma = \sum_{i=1}^p r_i$ is called the *decoupling degree* of $T(s)$.

Notice that the decoupling invariants of $T(s)$ are invariant under the right multiplication of $T(s)$ by bicausal matrices, hence they are invariant under dynamic state feedback, with nonsingular input transformation.

Furthermore $I(s)$ (resp. the π -interactor $I_\pi(s)$) is a polynomial matrix. It follows that r_i is the maximal polynomial degree or the infinite pole order of the i th column of $I(s)$ (resp. $I_\pi(s)$).

It will be shown in the following theorem that the r_i 's are closely related with the "simplest" decoupled system achievable by admissible compensation.

As in Proposition 1 it can be proven easily that concerning McMillan degree minimality there is no loss of generality in considering $m \times p$ full rank precompensators. Then the decoupled system will be diagonal.

THEOREM 4. Consider a system whose transfer matrix $T(s)$ is a $p \times m$ strictly proper rational surjective transfer matrix with null static kernel.

(i) The system is always decouplable by an admissible proper precompensator. The minimal McMillan degree achievable for the decoupled system is γ the decoupling degree of $T(s)$. In this case the i th diagonal entry of the decoupled system has McMillan degree r_i .

(ii) If the system is decouplable by an admissible dynamic state feedback compensator on a minimal realization of $T(s)$, the minimal McMillan degree achievable for the decoupled system is γ the decoupling degree of $T(s)$. In this case the i th diagonal entry of the decoupled system has McMillan degree r_i .

Proof. Let us first prove (i). Build a precompensator satisfying the requirements of Theorem 4. Let $T(s)$ be factorized as in Theorem 2:

$$T(s) = [I^{-1}(s), 0]B(s).$$

Consider

$$C'(s) = I(s) \text{diag}(s^{-r_1}, \dots, s^{-r_p}).$$

Choose the admissible proper precompensator

$$C(s) = B^{-1}(s) \begin{bmatrix} C'(s) \\ C''(s) \end{bmatrix}$$

where $C''(s)$ is any $(m-p) \times p$ transfer matrix. We have

$$T(s)C(s) = \text{diag}(s^{-r_1}, \dots, s^{-r_p}).$$

$C(s)$ is then a decoupling compensator with the required properties. Show now that r_i is the minimal possible McMillan degree of the i th entry of the decoupled system.

Let $C(s)$ be a proper admissible decoupling compensator. We have

$$T(s)C(s) = D(s) = \text{diag}(d_1(s), \dots, d_p(s))$$

where the $d_i(s)$'s are scalar rational functions. Factorize $T(s)$ as in Theorem 2:

$$T(s) = [I^{-1}(s), 0]B(s).$$

We have

$$[I, 0]B(s)C(s) = I(s)D(s).$$

Denote

$$\begin{bmatrix} C'(s) \\ C''(s) \end{bmatrix} = B(s)C(s) \quad \text{where } C'(s) \in \mathbb{R}_p^{p \times p}(s).$$

It follows that

$$C'(s) = I(s)D(s).$$

Denote $I_i(s)$ as the i th column of $I(s)$.

$C'(s)$ is a proper transfer matrix, as is $I(s)D(s)$. Then $I_i(s)d_i(s)$ is proper. It follows that $d_i(s)$ possesses an infinite zero of order at least r_i and that $d_i(s)$ has a McMillan degree larger than or equal to r_i . γ is then the minimal possible McMillan degree.

Consider now (ii). When conditions of Theorem 3 are fulfilled, the constructive part of the proof provides us with a decoupled system of McMillan degree γ , the i th entry having McMillan degree r_i .

Since dynamic state feedback compensators are implementable by precompensation the minimality here comes from (i). \square

In order to illustrate the above theorem let us consider the following example:

$$T(s) = \begin{bmatrix} s^{-2} & 0 & s^{-5} \\ -s^{-1} & s^{-3} & 0 \end{bmatrix}.$$

The system of transfer matrix $T(s)$ is trivially decouplable by the precompensator

$$C_1(s) = \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \end{bmatrix},$$

in this case

$$T(s)C_1(s) = \begin{bmatrix} s^{-5} & 0 \\ 0 & s^{-3} \end{bmatrix}.$$

The interactor of $T(s)$ is

$$I(s) = \begin{bmatrix} s^2 & 0 \\ s^4 & s^3 \end{bmatrix};$$

then $r_1 = 4$, $r_2 = 3$, $\gamma = 7$.

When we use $C_1(s)$ the McMillan degree of the decoupled system is 8. From (i) of Theorem 4 there exists an admissible proper decoupling precompensator $C_2(s)$ leading to the minimal McMillan degree $\gamma = 7$. Following the proof of (i) we get:

$$C_2(s) = \begin{bmatrix} s^{-2} & 0 \\ 1 & 1 \\ 0 & 0 \end{bmatrix}, \quad T(s)C_2(s) = \begin{bmatrix} s^{-4} & 0 \\ 0 & s^{-3} \end{bmatrix}.$$

The system of transfer matrix $T(s)$ is decouplable by an admissible dynamic state feedback compensator on a minimal realization of $T(s)$ since

$$m = 3 \geq 2p - k = 4 - 1 \quad (\text{see Theorem 3}).$$

Then from (ii) of Theorem 4 there exists an admissible precompensator $C_3(s)$, dynamic state feedback implementable, leading to the minimal McMillan degree of the decoupled system. Following the proof of (ii) we get:

$$\begin{aligned} C_3(s) &= B^{-1}(s) \begin{bmatrix} I_1(s) \\ X \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & -s^{-3} \\ 0 & 1 & -s^{-1} \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} s^{-2} & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} s^{-2} & -s^{-3} \\ 1 & 1 - s^{-1} \\ 0 & 1 \end{bmatrix} \end{aligned}$$

and

$$T(s)C_3(s) = \begin{bmatrix} s^{-4} & 0 \\ 0 & s^{-3} \end{bmatrix}$$

of minimal McMillan degree.

4. Dynamic state feedback decoupling with stability. In this section we will consider the dynamic state feedback decoupling as before but with the requirement of closed loop stability. As in § 3 the problem will be solvable if the number of inputs is large enough. Surprisingly the decoupling condition is exactly the same as before (without stability considerations).

We introduce other feedback invariants called “stable decoupling invariants” which are the counterpart with stability of the r_i ’s defined in § 3.

We prove that the minimal delay decoupling problem has the same solution as without stability. But in this case the minimal McMillan degree of the decoupled system is generally larger. Minimizing the McMillan degree amounts to minimizing both the infinite and the unstable structure. In other words the proposed solution leads to a decoupled system having the least possible number of delays and unstable zeros. This is very important in practice.

We will present first some mathematical preliminaries and characterize all the precompensators that are feedback implementable with closed loop stability.

4.1. Preliminaries. As in the case of polynomials we can build on $R_{ps}(s)$, Smith forms, Hermite forms, and left and right coprime factorizations. This results from the existence on this ring of a “degree.” $R_{ps}(s)$ is a Euclidean domain, defining the degree δ of $f(s) \in R_{ps}(s)$ as follows: $\delta(f(s)) = d_1(f(s)) + d_2(f(s))$ where $d_1(f(s))$ is the infinite zero order of $f(s)$ and $d_2(f(s))$ is the number of unstable zeros of $f(s)$ counted with their multiplicity [15], [16], [17].

The stability domain under consideration is any region in the complex plane symmetrically located with respect to the real axis and including at least one point of the real axis.

Recall now the Hermite form over $R_{ps}(s)$, the ring of proper rational stable functions.

THEOREM 5 [10], [15]. Let $T(s)$ be a $p \times m$ surjective proper stable rational matrix. $T(s)$ can be factorized in $T(s) = H(s)B(s)$ where $B(s)$ is a bicausal and bistable matrix (unit of $R_{ps}(s)$) and $H(s) = [\bar{H}(s), 0]$ where

$$\bar{H}(s) = \begin{bmatrix} h_{11}(s) & & 0 \\ \vdots & \ddots & \\ h_{ij}(s) & \cdots & h_{pp}(s) \end{bmatrix}.$$

Furthermore the degree of $h_{ij}(s)$ is lower than the degree of $h_{ii}(s)$ for $j < i$. $H(s)$ is called a Hermite form of $T(s)$ over $R_{ps}(s)$.

$H(s)$ is nonunique, it is defined up to units of $R_{ps}(s)$. Uniqueness of $H(s)$ may be obtained by adding some conditions (see [10]).

Consider the following example [10]:

$$T(s) = \begin{bmatrix} \frac{1}{s+1} & \frac{1}{s+2} \\ \frac{1}{s+3} & \frac{1}{s+5} \end{bmatrix}.$$

Choose the stability domain as the open left half plane.

The Hermite form of $T(s)$ over $R_{ps}(s)$ is

$$H(s) = \begin{bmatrix} \frac{1}{\pi} & 0 \\ \frac{s+(a-1)/2}{\pi^2} & \frac{s-1}{\pi^3} \end{bmatrix}$$

where $\pi = s + a$ is any stable polynomial.

Notice that the unstable zero of $H(s)$ is the unstable zero of $T(s)$ (located at $s = 1$) and that $H(s)$ possesses two infinite zeros of order 1 and 2 as $T(s)$.

DEFINITION 3. Let $T(s)$ be a $(p \times m)$ surjective proper rational stable matrix. Consider $H(s) = [\bar{H}(s), 0]$ a Hermite form of $T(s)$ over $R_{ps}(s)$. The rational matrix $I_g(s) = \bar{H}^{-1}(s)$ is called a *generalized interactor* of $T(s)$ over $R_{ps}(s)$.

If one considers $H(s)$ the Hermite form of $T(s)$ over $R_{ps}(s)$ we will speak of the generalized interactor of $T(s)$.

We will present now a complement to Theorem 1 incorporating stability requirements.

THEOREM 6. Let $T(s)$ be a $p \times m$ strictly proper stable rational matrix with null static kernel and let (A, B, C) be a stable realization of $T(s)$. Let $C(s)$ be an $m \times m$ proper rational compensator dynamic state feedback implementable ($u = F(s)x + Gv$, G nonsingular) on the realization (A, B, C) . Then the considered feedback system is stable if and only if $C(s)$ is stable.

Proof. Necessity. $C(s)$ has to be a bicausal compensator from Theorem 1. Suppose $C(s)$ is unstable. Then either $T(s)C(s)$ is unstable contradicting the external stability, or unstable pole zero cancellations occur and internal stability fails.

Sufficiency. Suppose $C(s)$ bicausal and stable. By Theorem 1, $C(s)$ is implementable by dynamic state feedback. There exist $F(s)$ and G such that

$$T(s)C(s) = C(sI - A - BF(s))^{-1}BG.$$

Now prove the closed loop stability.

We have the following diagram.

We have closed loop stability if the following transfer matrix is stable (see [16]).

$$\begin{bmatrix} (I - Z(s)F(s))^{-1} & Z(s)(I - F(s)Z(s))^{-1} \\ F(s)(I - Z(s)F(s))^{-1} & (I - F(s)Z(s))^{-1} \end{bmatrix} \quad \text{where } Z(s) = (sI - A)^{-1}B.$$

By hypothesis $Z(s)$, $(I - F(s)Z(s))^{-1}$ and $Z(s)(I - F(s)Z(s))^{-1}$ are stable, where $(I - F(s)Z(s))^{-1}$ is the bicausal stable precompensator and $Z(s)(I - F(s)Z(s))^{-1}$ is the closed loop transfer matrix.

Since $\det(I - Z(s)F(s)) = \det(I - F(s)Z(s))$ and $(I - F(s)Z(s))^{-1}$ is stable, then $(I - Z(s)F(s))^{-1}$ is stable.

It remains to prove that $F(s)(I - (sI - A)^{-1}BF(s))^{-1}$ is stable. Let $N(s)D^{-1}(s)$ be a right coprime factorization of $-F(s)$.

$$\begin{aligned} (I + (sI - A)^{-1}BF(s))^{-1} &= ((sI - A) + BF(s))^{-1}(sI - A) \\ &= D(s)((sI - A)D(s) + BN(s))^{-1}(sI - A). \end{aligned}$$

We prove now that $D(s)$ and $(sI - A)D(s) + BN(s)$ are right coprime. Since $N(s)$ and $D(s)$ are right coprime there exist $U(s)$ and $V(s)$ polynomial matrices of appropriate dimensions such that $U(s)N(s) + V(s)D(s) = I$. Choose $\bar{U}(s)$ an $n \times n$ polynomial matrix such that $\bar{U}(s)B = U(s)$; this is always possible since B is full column rank.

Choose $\bar{V}(s) = V(s) - \bar{U}(s)(sI - A)$. $\bar{V}(s)$ is an $n \times n$ polynomial matrix. $\bar{U}(s)$ and $\bar{V}(s)$ satisfy

$$\bar{U}(s)((sI - A)D(s) + BN(s)) + \bar{V}(s)D(s) = U(s)N(s) + V(s)D(s) = I;$$

then $(sI - A)D(s) + BN(s)$ and $D(s)$ are right coprime. Then $D(s)((sI - A)D(s) + BN(s))^{-1}$ is stable, also. From the right coprimeness of $D(s)$ and $(sI - A)D(s) + BN(s)$ we deduce the stability of $((sI - A)D(s) + BN(s))^{-1}$. It follows that $F(s)(I - (sI - A)^{-1}BF(s))^{-1} = N(s)((sI - A)D(s) + BN(s))^{-1}(sI - A)$ is stable. \square

Consider now the stable dynamic state feedback decoupling problem.

4.2. Dynamic state feedback decoupling with stability. We will now solve the dynamic state feedback decoupling with stability. The theorem will be stated for stable systems for clarity of exposition. There is no loss of generality in making this assumption. In fact, when the system transfer matrix is not stable, we will use a static state feedback on a minimal realization of $T(s)$ which assigns all the closed loop poles to stable locations. Denote $T_1(s)$ the closed loop transfer matrix, $T(s)$ and $T_1(s)$ are feedback equivalent on a minimal realization of $T(s)$ without unstable pole zero cancellations. It follows that $T(s)$ is decouplable with stability if and only if $T_1(s)$ is. Let us state first the counterpart of Theorem 1 for stabilizing compensators.

THEOREM 7. *The system whose transfer matrix $T(s)$ is a $(p \times m)$ strictly proper stable surjective transfer matrix with null static kernel is decouplable with stability by an admissible dynamic state feedback implementable on a minimal realization of $T(s)$ if and only if*

$$m \geq 2p - k$$

where k is the infinite column rank of $I(s)$ the interactor of $T(s)$ over $R_p(s)$.

Proof. Necessity. By Theorem 3 if $m < 2p - k$ decoupling is not possible, a fortiori stable decoupling is not possible.

Sufficiency. Consider the sufficiency proof of Theorem 3. A decoupling precompensator $C(s)$ is constructed:

$$C(s) = B_1(s) \begin{bmatrix} I \\ 0 \end{bmatrix} \quad \text{where } B_1(s) \text{ is bicausal.}$$

Let $B_2(s)$ be a diagonal bicausal matrix such that $B_1(s)B_2(s)$ is stable. Choose $B_2(s) = \text{diag}(b_1(s), \dots, b_m(s))$, where the unstable zeros of $b_i(s)$ are the unstable poles of the i th column of $B_1(s)$.

Then $B_1(s)B_2(s)$ is bicausal and stable.

$$Q(s) = B_1(s)B_2(s) \begin{bmatrix} I \\ 0 \end{bmatrix}$$

is a stable admissible decoupling compensator which is implementable by dynamic state feedback with stability on a minimal realization of $T(s)$ by Theorem 6. \square

Remark that the number of necessary inputs for decoupling is the same as in Theorem 3 (without stability). As will be seen later the minimal McMillan degree of the decoupled system with stability is in general larger than in the former case (without stability consideration).

As before we will focus our interest on the minimal McMillan degree achievable by feedback. Let us define first some useful invariants.

DEFINITION 4. Let $T(s)$ be a $(p \times m)$ surjective proper stable rational matrix and $I_g(s)$ its generalized interactor. Decompose $I_g(s)$ as follows:

$$I_g(s) = \bar{I}_g(s) \text{diag}(h_1(s) \cdots h_p(s))$$

where $h_i(s)$ is a rational function such that the i th column of $I_g(s)$ possesses neither poles nor zeros in unstable and infinite locations.

Denote q_i the number of infinite and unstable zeros of $h_i^{-1}(s)$ counted with their multiplicity, i.e., the degree of $h_i^{-1}(s)$ over $R_{ps}(s)$. The integers $q_1 \cdots q_p$ are called the *stable decoupling invariants* of $T(s)$. $\mu = \sum_{i=1}^p q_i$ is called the *stable decoupling degree* of $T(s)$.

Notice that for a fixed i , $h_i(s)$ is nonunique but defines a unique q_i . Moreover the stable decoupling invariants of $T(s)$ are invariant under the right multiplication of $T(s)$ by bicausal and bistable matrices.

As shown in the following theorem the q_i 's are closely related with the "simplest" decoupled system achievable by stable admissible compensation.

THEOREM 8. Consider a system whose transfer matrix $T(s)$ is a $(p \times m)$ strictly proper stable rational surjective transfer matrix with null static kernel.

(i) The system is always decouplable by an admissible proper precompensator with stability. The minimal McMillan degree achievable for the decoupled system is μ the stable decoupling degree of $T(s)$. In this case the i th diagonal entry of the decoupled system has McMillan degree q_i .

(ii) If the system is decouplable by an admissible dynamic state feedback compensator with stability on a minimal realization of $T(s)$, the minimal McMillan degree achievable for the decoupled system is μ the stable decoupling degree of $T(s)$. In this case the i th diagonal entry of the decoupled system has McMillan degree q_i .

The proof follows the same lines as that of Theorem 4 replacing the interactor by the generalized interactor, r_i by q_i and bicausal matrices by bicausal and bistable ones.

The $h_i^{-1}(s)$ of Definition 4 now plays the same role as the s^{-r_i} of Theorem 4. $h_i^{-1}(s)$ possesses an infinite zero of order r_i and $q_i - r_i$ unstable zeros. \square

This theorem says that minimal delay decoupling is possible with the same number of input-output delays as without stability considerations. Furthermore the decoupled system possesses the minimal possible number $(\mu - \gamma)$ of unstable zeros.

5. Concluding remarks. (i) The decoupling invariants r_i and q_i can be characterized by other approaches. In particular the r_i 's are defined geometrically, via the notion of essentiality and via the infinite structure of some matrices deduced from the system transfer matrix in [18].

These decoupling invariants r_i (resp. q_i) are not related with the triangular form of the interactor (resp. the generalized interactor). Any $R(s)$ $p \times p$ full rank rational matrix such that $T(s) = [R(s), 0]B(s)$ with $B(s)$ bicausal (resp. bicausal and bistable) would do as well. For example, as proven in [19], r_i is the infinite pole order of the i th column of $R^{-1}(s)$.

(ii) When the column rank at infinity k is not equal to p this reflects the nonidentity between the infinite zero orders of the rows of $T(s)$ and the infinite zero orders of $T(s)$. In this case the control law $u = Fx + Gv$, G singular, allows us to increase the infinite structure by decreasing R^* the largest controllability subspace of $\ker C$. When R^* is "sufficiently large" static state feedback decoupling is possible [20]. In this paper we are mainly concerned with dynamic feedback decoupling; therefore only $\dim(B \cap R^*)$ has to be large enough ($\geq p - k$), since R^* can be arbitrarily extended by dynamic state feedback.

As an illustration consider the following matrix:

$$T(s) = \begin{bmatrix} s^{-2} & 0 & s^{-3} \\ -s^{-1} & s^{-3} & -s^{-2} \end{bmatrix}.$$

Since the two rows are dependent at infinity this system is not decouplable by static state feedback with regular G , but this system is decouplable by dynamic state feedback (see Theorem 3).

This system is no more decouplable by static state feedback with singular G . In fact $\dim R^* = 1$ in a minimal realization of $T(s)$ which is not sufficient to meet the condition of [20].

In [21] the dynamic state feedback decoupling problem restricting $F(s)$ to being stable is studied. This problem turns out to be solvable if $m \geq 2p - k_s$, where k_s is the infinite and unstable column rank of $I_g(s)$. k_s is generally smaller than k . A necessary condition for static state feedback with stability is then $\dim(B \cap R^*) \geq p - k_s$.

Possible extensions of the results presented here are: Block decoupling or output feedback decoupling as in [22].

Acknowledgment. The authors acknowledge a reviewer for providing them with a better formulation of Theorem 6.

EXACT MODELING OF A FINITE TIME SERIES*

CHRISTIAAN HEIJ†

Abstract. The problem of modeling a finite time series by means of a linear shift invariant system will be considered. To analyze this problem the concepts of complexity of a model and corroboration of a model by data are introduced. Various properties of data modeling procedures are defined. These properties are investigated for the partial realization procedure. An alternative procedure will be described which takes into account the concept of corroboration. It turns out that this procedure has many desirable properties.

Key words. data modeling, identification, modeling procedures, corroboration, finite time systems, partial realization theory

AMS(MOS) subject classifications. 93A, 93B

1. Introduction. The problem considered here is an aspect of the problem of modeling dynamical phenomena and can be described as follows.

Suppose one wants to model a dynamical phenomenon. Here the following will be assumed. First, the describing variables of the phenomenon have been identified. Second, observations of these variables over a finite time interval are available. Finally, a class of models has been specified. This class reflects a priori assumptions concerning the phenomenon, e.g., based upon theoretical considerations concerning the phenomenon or inspired by mathematical convenience.

The problem now consists in identifying (a) model(s) in the specified class to describe the phenomenon in a way which is optimal in some sense, taking into account the observations.

This problem is formalized as follows. Assume at every time instance the observation consists of an element in the set W . Let \mathbb{T} denote the time set of observation, which is assumed to be finite. So the data consist of an element of $W^{\mathbb{T}}$, i.e., a finite time series in W . Let \mathbb{M} denote the specified class of models. The problem is to construct data modeling **PROCEDURES** to assign models to data, i.e., procedures

$$P: W^{\mathbb{T}} \rightarrow 2^{\mathbb{M}}.$$

Moreover, one wants to construct procedures which are satisfactory or even optimal in some sense.

Clearly this problem is an important topic of scientific research in, e.g., statistics, econometrics and systems theory and includes problems as structure identification, estimation and data analysis.

In this paper a very special case of the data modeling problem will be investigated. This will lead to the formulation of some interesting concepts.

The central issue is the **EXACT** modeling of a **FINITE** time series of **ONE** variable by means of a (deterministic) **AUTOREGRESSIVE** model.

It is evident that the case of a multivariable time series and **APPROXIMATE** modeling are of more practical importance. Nonetheless, the case considered here is of interest in its own right and, moreover, it will lead to questions and concepts which are crucial also in the multivariable case and approximate modeling.

An outline of the paper is as follows. In § 2 we define the model class of (finite time) linear shift invariant systems and discuss some properties of this class and representation of systems by means of autoregressive equations.

* Received by the editors July 23, 1986; accepted for publication (in revised form) February 23, 1987.

† Econometrics Institute, University of Groningen, 9700 AV Groningen, The Netherlands.

In § 3 we formulate the modeling problem analyzed in this paper, i.e., modeling a finite time series by means of an autoregressive model. The concept of data modeling procedure is defined.

The concepts of simplicity and corroboration are introduced in § 4. These concepts play a crucial role and reflect the idea that on the one hand one wants the model to be as simple as possible, but that on the other hand one only wants to accept simplicity if there is some evidence for it in the data.

Some possible properties of procedures are defined in § 5.

The partial realization procedure for modeling a finite time series in one variable is described in § 6. Its properties are investigated. It turns out that this procedure, since it pays no attention to corroboration, lacks many desirable properties.

In § 7 we introduce a modification of the partial realization procedure which takes into account corroboration.

In § 8 we formulate a refinement of this procedure. The properties of this refined procedure are thoroughly investigated. It is shown that it satisfies all the properties defined in § 5.

Section 9 contains some concluding remarks. A summary of notation concludes the main text.

Proofs of the results are given mainly in the Appendix.

Some contributions closely related to the approach taken here are given in Kalman [2], Rissanen [4] and Willems [5].

2. Linear shift invariant finite time systems. The problem considered in this paper is that of modeling a finite time series by means of (a) linear shift invariant system(s). This class of models is described in this section, along with results on representation of models in this class. It turns out that the class of linear shift invariant finite time systems is a strict subclass of the models described by a finite number of autoregressive equations.

The following definition of a dynamical system is given in Willems [5].

DEFINITION. A **DYNAMICAL SYSTEM** is a triple (\mathbb{T}, W, B) with $\mathbb{T} \subset \mathbb{R}$ the time set, W the signal set, $B \subset W^{\mathbb{T}}$ the behaviour.

Remark. In the sequel we often will use the words “system” and “model” to denote the behaviour.

DEFINITION. A **FINITE (discrete) TIME system** is a dynamical system (\mathbb{T}, W, B) where \mathbb{T} is a finite subset of \mathbb{Z} .

Let $\mathbb{N} := \{1, 2, 3, \dots\}$ and for $t_1, t_2 \in \mathbb{N}$, $t_1 \leq t_2$, $[t_1, t_2] := \{t \in \mathbb{N}; t_1 \leq t \leq t_2\}$. In this paper we throughout will assume there exists $T \in \mathbb{N}$ such that $\mathbb{T} = [1, T]$ and we will take $W := \mathbb{R}^q$. So a behaviour $B \subset (\mathbb{R}^q)^{\mathbb{T}}$ is a set of sequences in \mathbb{R}^q of length T . We will identify $(\mathbb{R}^q)^{\mathbb{T}}$ and $(\mathbb{R}^q)^T$.

We restrict attention to behaviours which are linear and shift invariant. B is called linear if it is a linear subspace of $(\mathbb{R}^q)^T$.

To define shift invariance, we define the left shift operator σ as follows.

Let w be a sequence in \mathbb{R}^q of arbitrary finite length $L \geq 2$, so $w \in (\mathbb{R}^q)^L$. Then $\sigma w \in (\mathbb{R}^q)^{L-1}$ is defined by $(\sigma w)(l) := w(l+1)$, $l \in [1, L-1]$. For $B \subset (\mathbb{R}^q)^T$, $1 \leq t_1 \leq t_2 \leq T$, let $B|_{[t_1, t_2]}$ denote the restriction of B to the set $[t_1, t_2]$.

DEFINITION. Let $T \geq 2$. $B \subset (\mathbb{R}^q)^T$ is called **SHIFT INVARIANT** if $\sigma B \subset B|_{[1, T-1]}$. It is called **TRANSLATION INVARIANT** if $\sigma B = B|_{[1, T-1]}$.

The interpretation of shift invariance is as follows. Let B be shift invariant and $w \in B$. Then there exists $f \in W$ such that $\hat{w} \in B$, where $\hat{w}|_{[1, T-1]} := \sigma w$ and $\hat{w}(T) := f$. Described intuitively this means that there exists a future observation which follows

on w and which is compatible with the behaviour B . If B is shift invariant but not translation invariant this means that there exist $w \in B$ for which there is no past observation compatible with B . If B is translation invariant then for every $w \in B$ there exist a past and a future of w compatible with B .

The following proposition is immediate.

PROPOSITION 2.1. (i) *If B is shift invariant, $\Delta \in \mathbb{N}$, $1 \leq t_1 \leq t_1 + \Delta \leq t_2 + \Delta \leq T$; then $B|_{[t_1+\Delta, t_2+\Delta]} \subset B|_{[t_1, t_2]}$.*
(ii) *If B is translation invariant, $\Delta \in \mathbb{Z}$, $1 \leq t_1 \leq t_2 \leq T$, $1 \leq t_1 + \Delta \leq t_2 + \Delta \leq T$; then $B|_{[t_1+\Delta, t_2+\Delta]} = B|_{[t_1, t_2]}$.*

DEFINITION. The class $\mathbb{B}_T(\tilde{\mathbb{B}}_T)$ of linear shift (translation) invariant finite (T) time systems is given by

$$\mathbb{B}_T := \{B \subset (\mathbb{R}^q)^T; B \text{ linear, } \sigma B \subset B|_{[1, T-1]}\},$$

$$\tilde{\mathbb{B}}_T := \{B \subset (\mathbb{R}^q)^T; B \text{ linear, } \sigma B = B|_{[1, T-1]}\}.$$

It is clear that $\tilde{\mathbb{B}}_T \subset \mathbb{B}_T$ and that both classes are closed under addition, but not under union. Moreover, $\tilde{\mathbb{B}}_T$ and \mathbb{B}_T are not closed under intersection, which is seen as follows.

Example 2.1. Let $q = 1$, $T = 4$, $B_1 := \{w \in \mathbb{R}^4; w(4) = w(1)\}$, $B_2 := \{w \in \mathbb{R}^4; w(3) = -w(1) \text{ and } w(4) = -w(2)\}$. Then $B_i \in \tilde{\mathbb{B}}_T$, $i = 1, 2$, but $B := B_1 \cap B_2 = \{w \in \mathbb{R}^4; \text{there exists } \alpha \in \mathbb{R} \text{ such that } w = \alpha(1, -1, -1, 1)\}$ and $B \notin \mathbb{B}_T$.

Next we will show that systems in \mathbb{B}_T can be described by a finite number of **AUTOREGRESSIVE EQUATIONS**.

Let $g \in \mathbb{N}$ and $R \in \mathbb{R}^{g \times q}[\sigma]$ a polynomial matrix in σ with rows $r_i = (r_{i1}, \dots, r_{iq}) \in \mathbb{R}^{1 \times q}[\sigma]$, $i \in [1, g]$. Let $d(r_{ij})$ denote the degree of r_{ij} , with $d(0) := -\infty$, and $d(r_i) := \max \{d(r_{ij}), j \in [1, q]\}$, $d(R) := \max \{d(r_i), i \in [1, g]\}$. By $B_T(R)$ we will denote the behaviour where the autoregressive equations $r_i(\sigma)w = 0$ are satisfied. By definition we assume that if $d(R) \geq T$ then this equation imposes no restriction.

DEFINITION. Let $R \in \mathbb{R}^{g \times q}[\sigma]$ and let $I_T(R) := \{i \in [1, g]; d(r_i) \leq T - 1\}$. Then $B_T(R) := \{w \in (\mathbb{R}^q)^T; [r_i(\sigma)w](t) = 0, i \in I_T(R), t \in [1, T - d(r_i)]\}$.

Remark. We often will write $B(R)$ instead of $B_T(R)$ if this does not lead to confusion. Note that if $d(R) \geq T$ then $r(\sigma)w$ is undefined, as σ is only defined for sequences of length at least 2. As an example, take $q = g = 1$, $T = 3$, $R = \sigma^3$, $w \in \mathbb{R}^3$. Then $\sigma^3 w$ is undefined as $\sigma^2 w = w(3)$ has length 1.

PROPOSITION 2.2.

$$\{B \in \mathbb{B}_T\} \Rightarrow \{\exists g \exists R \in \mathbb{R}^{g \times q}[\sigma], d(R) \leq T - 1, B = B(R)\}.$$

Proof. See the Appendix.

Remark. The converse statement is not true, i.e., there exist $R \in \mathbb{R}^{g \times q}[\sigma]$ such that $B(R) \notin \mathbb{B}_T$. For example, take $q = 1$, $g = 2$, $T = 4$, $r_1(\sigma) = \sigma^3 - 1$, $r_2(\sigma) = \sigma^2 + 1$, $R = \begin{bmatrix} r_1 \\ r_2 \end{bmatrix}$. Then $B(R) = \{w \in \mathbb{R}^4; \text{there exists } \alpha \in \mathbb{R} \text{ such that } w = \alpha(1, -1, -1, 1)\} \notin \mathbb{B}_T$. So \mathbb{B}_T consists of a strict subclass of the systems described by a finite number of autoregressive equations. Proposition 2.3 will give a characterization of this subclass.

Let $0 \neq R \in \mathbb{R}^{g \times q}[\sigma]$ have rows $r_i \in \mathbb{R}^{1 \times q}[\sigma]$, $i \in [1, g]$. Let $r_i(\sigma) = \sum_{k=d_i}^{d_i} q_k^{(i)} \sigma^k$ where $d(r_i) = d_i \geq d_i'$ and $q_{d_i}^{(i)} \neq 0 \neq q_{d_i'}^{(i)}$. Let L^+ , $L^- \in \mathbb{R}^{g \times q}$ denote the matrices with rows $q_{d_i}^{(i)}$, $q_{d_i'}^{(i)}$, respectively. R is defined to be row proper if $\text{rank } L^+ = g$, bilaterally row proper if $\text{rank } L^+ = \text{rank } L^- = g$, zero order bilaterally row proper if in addition $d_i' = 0$ for all $i \in [1, g]$. We define $0 \in \mathbb{R}^{1 \times q}[\sigma]$ to be zero order bilaterally row proper.

PROPOSITION 2.3. (i) $\{B \in \mathbb{B}_T\} \Leftrightarrow \{\text{there exists } g, \text{ there exists } R \in \mathbb{R}^{g \times q}[\sigma], d(R) \leq T - 1, R \text{ row proper, } B = B(R)\}$.

(ii) $\{B \in \tilde{\mathbb{B}}_T\} \Leftrightarrow \{\text{there exists } g \text{ there exists } R \in \mathbb{R}^{g \times q}[\sigma], d(R) \leq T - 1, R \text{ zero order bilaterally row proper, } B = B(R)\}$.

Proof. See the Appendix.

Remark. Henceforth, if we write $B_T(R)$ or $B(R)$ (with T given) we will assume throughout that R is row proper (and zero order bilaterally row proper only if we explicitly assume $B(R) \in \tilde{\mathbb{B}}_T$). Note that if $B = (\mathbb{R}^q)^T$ then we can take $R = 0$.

Remark. If R is bilaterally row proper, then $B(R)$ need not belong to $\tilde{\mathbb{B}}_T$. A simple counterexample is given by taking $q = g = 2$, $T = 2$, $R = \begin{pmatrix} \sigma & 0 \\ 0 & \sigma \end{pmatrix}$.

DEFINITION. If $B = B(R) \in \mathbb{B}_T$ and R has rows r_i , $i \in [1, g]$, then $\{r_i, i \in I_T(R)\}$ are called the **LAWS** governing the behaviour B .

We finally will derive representations of the sum of two systems in \mathbb{B}_T and of the largest system in \mathbb{B}_T contained in the intersection of two systems in \mathbb{B}_T . Note that the intersection itself need not belong to \mathbb{B}_T , but for every set in $(\mathbb{R}^q)^T$ there exists a largest system in \mathbb{B}_T contained in this set, because \mathbb{B}_T is closed under addition.

Proofs of the following results are contained in the Appendix.

LEMMA 2.1. Let $R_i \in \mathbb{R}^{g_i \times q}[\sigma]$ be row proper with $d(R_i) \leq T - 1$, $i = 1, 2$. Then

$$\{B(R_1) \subset B(R_2)\} \Leftrightarrow \{\exists F \in \mathbb{R}^{g_2 \times g_1}[\sigma] R_2 = FR_1\}.$$

Remark. If we drop the condition $d(R_i) \leq T - 1$, $i = 1, 2$, then (\Rightarrow) no longer holds true. Take $q = g_1 = g_2 = 1$, $T = 3$, $R_1 = \sigma - 1$, $R_2 = \sigma^3$.

DEFINITION. Let $R_i \in \mathbb{R}^{g_i \times q}[\sigma]$, $i = 1, 2$.

(i) R is called a least common left multiple of R_1 and R_2 , notation $R \in \text{LCLM}(R_1, R_2)$ if

- (1) $\exists F_i \quad R = F_i R_i, \quad i = 1, 2;$
- (2) $\{\exists \tilde{F}_i \quad \tilde{R} = \tilde{F}_i R_i, i = 1, 2\} \Rightarrow \{\exists F \quad \tilde{R} = FR\}.$

(ii) R is called a greatest common right divisor of R_1 and R_2 , notation $R \in \text{GCRD}(R_1, R_2)$, if

- (1) $\exists F_i \quad R_i = F_i R, \quad i = 1, 2;$
- (2) $\{\exists \tilde{F}_i \quad R_i = \tilde{F}_i \tilde{R}, i = 1, 2\} \Rightarrow \{\exists F \quad R = F \tilde{R}\}.$

LEMMA 2.2. (i) For any row proper R_1, R_2 , $\text{LCLM}(R_1, R_2)$ and $\text{GCRD}(R_1, R_2)$ are nonempty and contain row proper elements.

(ii) If $R', R'' \in \text{LCLM}(R_1, R_2)$ are both row proper, then there exists a unimodular U such that $R'' = UR'$. The same holds true for GCRD .

PROPOSITION 2.4. (i) $B(R_1) + B(R_2) = B(R)$ for $R \in \text{LCLM}(R_1, R_2)$.

(ii) $B(R) = \sum \{B(\tilde{R}); B(\tilde{R}) \subset B(R_1) \cap B(R_2)\}$ for $R \in \text{GCRD}(R_1, R_2)$, $d(R_i) \leq T - 1$, $i = 1, 2$.

So a (row proper element of the) least common left multiple of R_1 and R_2 gives the laws of the sum $B(R_1) + B(R_2)$, and a (row proper element of the) greatest common right divisor of R_1 and R_2 gives the laws of the largest system in \mathbb{B}_T contained in the intersection $B(R_1) \cap B(R_2)$.

Remark. The implication $\{B(R) = B(R_1) + B(R_2)\} \Rightarrow \{R \in \text{LCLM}(R_1, R_2)\}$ does not hold true. For example, take $q = g_1 = g_2 = 1$, $T = 3$, $R_1 = \sigma^2$, $R_2 = \sigma + 1$, then $B(R_1) + B(R_2) = \mathbb{R}^3 = B(0)$ but $0 \notin \text{LCLM}(R_1, R_2)$. Moreover (ii) does not hold true generally if $d(R_i) \leq T - 1$, $i = 1, 2$ is not satisfied. For example, take $q = g_1 = g_2 = 1$, $T = 3$, $R_1 = \sigma^2(\sigma - 1)$, $R_2 = (\sigma - 1)^3$, then $\text{GCRD}(R_1, R_2) = \sigma - 1$ but $B_3(\sigma - 1) \neq \mathbb{R}^3 = B(R_1) \cap B(R_2)$.

3. Modeling of data, procedures. As stated in the Introduction, we will consider the following problem of modeling a dynamical phenomenon.

Assume we want to model a dynamical phenomenon concerning which (i) data is available in the form of a (finite) time series $w \in (\mathbb{R}^q)^T$, and (ii) an a priori specified class of models is available. The aim is to construct data modeling procedures which assign to data a model or a set of models in the prespecified class. The assigned models reflect the structure of the phenomenon which one postulates on the basis of the data.

In this paper the only a priori restrictions which we impose on the models are those of linearity and shift (or translation) invariance. So the problem becomes one of assigning linear shift (translation) invariant systems to an observed finite time series.

We now first give a definition of a data modeling procedure for deterministic modeling of a finite time series $w \in W^T$.

DEFINITION. A **DATA MODELING PROCEDURE** for t is a map $P_t: W^t \rightarrow 2^{W^t}$. A data modeling procedure on $[1, T]$ is a collection $P = \{P_t, t \in [1, T]\}$ where P_t is a data modeling procedure for t .

So a data modeling procedure P_t for every observation $w \in W^t$ assigns a collection $P_t w$ of models, i.e., a collection of subsets of W^t . The interpretation is that on observation of w , $P_t w$ consists of those models which are accepted by the procedure as a description of the phenomenon.

Here we take $W = \mathbb{R}^q$ and we impose the a priori restriction that the assigned models belong to \mathbb{B}_t . In this case a data modeling procedure for t is a map

$$P_t: (\mathbb{R}^q)^t \rightarrow 2^{\mathbb{B}_t}$$

or, if one requires translation invariance, a map $P_t: (\mathbb{R}^q)^t \rightarrow 2^{\tilde{\mathbb{B}}_t}$. As an example, we will describe the procedure P^u which assigns the set of undominated unfalsified models in \mathbb{B}_T .

DEFINITION. The model $B \in \mathbb{B}_t$ is called unfalsified by $w \in (\mathbb{R}^q)^t$ if $w \in B$. B is called undominated unfalsified if in addition $\{w \in B' \in \mathbb{B}_t, B' \subset B\} \Rightarrow \{B' = B\}$.

DEFINITION. The procedure $P^u = \{P_t^u, t \in [1, T]\}$ assigns to $w \in (\mathbb{R}^q)^t$ the set of undominated unfalsified models in \mathbb{B}_t .

Example 3.1. Let $q = 1$, $T = 4$. Using a partial Hankel matrix, described in § 6, it can be derived that $P_4^u(0, 1, 0, 1) = B(\sigma^2 - 1)$. For $w = (1, 1, 0, 1)$ the class of unfalsified models is $\{B(\sigma^2 + \sigma - 1), B(\sigma^3 + \alpha\sigma^2 + \beta\sigma - 1 - \beta), \alpha, \beta \in \mathbb{R}\}$ and $P_4^u(1, 1, 0, 1) = \{B(\sigma^2 + \sigma - 1), B(\sigma^3 + \alpha\sigma^2 + \beta\sigma - 1 - \beta), \alpha - \beta \neq 2\}$. So in this case there exists more than one undominated unfalsified model. This is essentially due to the fact that \mathbb{B}_T is not closed under intersection.

4. Simplicity and corroboration. A primary aim of modeling data is to describe the structure of the phenomenon which generated the data. For assigning structure to a phenomenon on the basis of data at least two considerations play a crucial role, which we will denote by the principles of simplicity (or parsimony) and of corroboration.

On the one hand, one wants to infer from the data as much structure for the phenomenon as possible in order to get many laws, i.e., small models. (Note that if both R and $\binom{R}{r} =: R'$ are row proper, then $B(R') \subset B(R)$.) We will call this a **FALSIFIABILITY** principle or **SIMPLICITY** principle. A model is considered to be simple if it is small in some set theoretic sense. Then a more simple model is more easily falsifiable, as it imposes more restrictions.

Note that simplicity here is connected with systems as sets of trajectories and not with the simplicity of the laws of systems. For example, $(\mathbb{R}^q)^T$ is the most complex model in \mathbb{B}_T , although from a viewpoint of laws it is very simple as there are no laws at all.

As a measure of complexity of a model in \mathbb{B}_T we here will simply take its dimension.

DEFINITION. The **COMPLEXITY** of $B \in \mathbb{B}_T$ is defined as $c(B) := \dim B$.

Although one wants to get models of low complexity, i.e., with much structure, on the other hand one wants to accept structure only if there is some evidence for it from the data. Note that data independent structure is reflected in the a priori specified model class and that the data modeling procedure reflects the additional structure which is accepted after observing the data. One has to have some reason for claiming structure on the basis of data. We call this requirement of “reason” or “evidence” a **CORROBORATION** principle.

We will now first define what we mean by corroboration and afterwards give an interpretation.

We use the following algebraic concept of genericity. $V \subset \mathbb{R}^n$ is called an algebraic variety if $V = p^{-1}(0)$ for a polynomial p in n variables. It is called a proper algebraic variety if $V \neq \mathbb{R}^n$, i.e., $p \neq 0$.

DEFINITION. $\pi \subset \mathbb{R}^n$ is called generic if there is a proper algebraic variety V such that $\pi \supset (\mathbb{R}^n \setminus V)$.

A property for points in \mathbb{R}^n is called generic if the set of points which have the property is generic.

DEFINITION. Let $B \in \mathbb{B}_T$, $P_T: (\mathbb{R}^q)^T \rightarrow 2^{\mathbb{B}_T}$.

$\{B \text{ WEAKLY CORROBORABLE by } P_T\} \Leftrightarrow \{B \notin P_T w \text{ is not generic in } w \in B\}$,

$\{B \text{ STRONGLY CORROBORABLE by } P_T\} \Leftrightarrow \{P_T w = B \text{ generically in } w \in B\}$.

If a model is not weakly corroborable by a procedure it seems natural to require that this model never will be assigned by the procedure. For suppose $B \in P_T w$ while B is not weakly corroborable by P_T . Then generically for $w \in B$, P_T assigns only wrong models. Now if $w \in B \in P_T w$, then in fact one accepts that one was very lucky in observing precisely this w from the phenomenon B , as generically one would not have “identified” B by P_T using an observation from the phenomenon.

On the other hand, if B is strongly corroborable by P_T then generically for $w \in B$ P_T assigns exactly the right model.

Remark. The relaxation that conditions are satisfied generically instead of universally is essential in the definition of corroborability as well as in many definitions which follow. This has to do with the fact that $B(R) \in \mathbb{B}_T$ contains submodels with more structure, i.e., if R' is such that there exists F such that $FR' = R$ then $B(R') \subset B(R)$ and hence exceptional observations from $B(R)$ may exhibit the stronger structure of $B(R')$.

We illustrate the concept of corroboration by means of the procedure P'' which assigns undominated unfalsified models to data.

Example 4.1. Let $q = 1$, $T = 4$ and consider P'' . Now \mathbb{R}^4 is not even weakly corroborable by P''_4 , as $\{P''_4 w = \mathbb{R}^4\} \Leftrightarrow \{\text{there exist } 0 \neq \alpha \in \mathbb{R}; w = \alpha(0, 0, 0, 1)\}$. It can be shown that every other model in \mathbb{B}_4 is weakly corroborable by P''_4 . $B(\sigma^2 - 1)$ is weakly, but not strongly corroborable by P''_4 . $B(\sigma - 1)$ is strongly corroborable by P''_4 .

In fact, with $c: \mathbb{B}_4 \rightarrow [0, 4]$, $c(B) := \dim B$ it can be shown that the class of models strongly corroborable by P''_4 is given by $c^{-1}(\{0, 1\})$ and $B(\sigma^2)$.

5. Properties of procedures. In this section we will define some possible properties of procedures and comment on their interpretation. We will investigate the properties for the procedure P'' defined in § 3. In §§ 6–8 we investigate the procedures defined there.

DEFINITION. (i) P_T is called **EXACT** if it only assigns unfalsified models, i.e., $\{B \in P_T w\} \Rightarrow \{w \in B\}$

(ii) $P = \{P_t, t \in [1, T]\}$ is called exact if P_t is exact for all $t \in [1, T]$.

Example. P'' is exact.

So a procedure is exact if it assigns only models which are not falsified by the data. This requirement is very restrictive. The case of approximate modeling in which one does not require $w \in B$ but that w is “near to” B often has more appeal in applications. Even if the data is exact, i.e., there are no errors of observation, generally one is more interested in approximate simple structure than in exact more complex structure. If the data is corrupted by noise then exact modeling is not a sound requirement. In applications generally the phenomenon under observation will not correspond to any model in the a priori class of models and also the observations will contain errors.

Nevertheless in this paper we will restrict attention to exact modeling and only will briefly comment on approximate modeling in § 9. This is a topic of current research in which the insights gained from studying the exact modeling problem play an important role.

DEFINITION. (i) P is called **MONOTONE** on $B \in \mathbb{B}_T$ if generically in $w \in B$ the following holds true for all $t \in [2, T]$:

$$\{B_{t-1} \in P_{t-1}(w|_{[1, t-1]}), B_t \in P_t(w|_{[1, t]})\} \Rightarrow \{B_t|_{[1, t-1]} \subset B_{t-1}\}.$$

(ii) P is called **monotone** if it is monotone on every $B \in \mathbb{B}_T$.

(iii) P is called **bilaterally monotone** on $B \in \tilde{\mathbb{B}}_T$ if it is monotone and if in addition generically in $w \in B$ the following holds true for all $t \in [2, T]$:

$$\{B_{T-t+1} \in P_{T-t+1}(w|_{[t, T]}), B_{T-t+2} \in P_{T-t+2}(w|_{[t-1, T]})\} \Rightarrow \{\sigma B_{T-t+2} \subset B_{T-t+1}\}.$$

So if P is monotone then, for every phenomenon $B \in \mathbb{B}_T$, on getting a new observation $w(t)$ the structure assigned on the basis of $(w(1), \dots, w(t-1))$ generically is verified or even made more tight, as $P_t(w|_{[1, t]})$ consists of models which restrictions to $[1, t-1]$ are submodels of those in $P_{t-1}(w|_{[1, t-1]})$. This is a desirable property in case the observations successively become available over time. Then the procedure assigns more structure if the observation period gets longer. This does not only hold true generically on $(\mathbb{R}^q)^T$ but even generically on every system $B \subset (\mathbb{R}^q)^T$ in \mathbb{B}^T .

Example. For $q = 1$ P^u is only monotone if $T = 2$ or on $c^{-1}(\{0, 1\})$, i.e., on $\{0\}$ and on $B(\sigma - \alpha)$, $\alpha \in \mathbb{R}$. Consider, e.g., $T = 3$, $B = B(\sigma^2) = \{(a, b, 0), a, b \in \mathbb{R}\}$ and let $w = (a, b, 0)$ with $a \neq 0 \neq b$. Then $P_2^u(w|_{[1, 2]}) = B(\sigma - (b/a))$ while $B(\sigma^2) \in P_3^u w$ and $\mathbb{R}^2 = B(\sigma^2)|_{[1, 2]} \not\subset B(\sigma - (b/a))$.

Next we will define two properties of procedures which are connected with the a priori restriction that one only assigns models in the class \mathbb{B}_T (or $\tilde{\mathbb{B}}_T$), i.e., shift (or translation) invariant and linear models. So one describes the phenomenon which generates the data as a shift (translation) invariant linear system. This leads to some desirable properties of P .

DEFINITION. (i) P is called **SHIFT INVARIANT** on $B \in \mathbb{B}_T$ if generically in $w \in B$ the following holds true for all $t \in [2, T]$:

$$\{B_{t-1}(R) \in P_{t-1}(w|_{[2, t]}), B'_t \in P_t(w|_{[1, t]})\} \Rightarrow \{B'_t \subset B_t(\sigma.R)\}.$$

(ii) P is called **shift invariant** if it is shift invariant on every $B \in \mathbb{B}_T$.

PROPOSITION 5.1. *If P is bilaterally monotone on $B \in \tilde{\mathbb{B}}_T$ then it is shift invariant on B .*

Proof. See the Appendix.

Because of this proposition we do not define a concept of translation invariance for procedures, as it would be a concept very close to bilateral monotonicity.

An interpretation of shift invariance of procedures is the following. The a priori assumption that assigned models have to be shift-invariant, i.e., $B|_{[1, t-1]} \supset B|_{[2, t]}$, does not imply any a priori restriction on $w(1)$, given $w|_{[2, t]}$. Assume one only observes

$w|_{[2,t]}$ and wants to model the phenomenon on $[1, t]$. It seems reasonable first to model $w|_{[2,t]}$ and to impose no restriction on $w(1)$, i.e., if $B_{t-1}(R) \in P_{t-1}(w|_{[2,t]})$ then take $B_t(\sigma R)$ as a model on $[1, t]$, which amounts to letting $w(1)$ be arbitrary and assigning the laws R on $[2, t]$. Now assume one also observes $w(1)$, so one has more information concerning the phenomenon. It seems reasonable to demand that one can make more accurate models and to require that $w(1)$ does not contradict any laws R which were assigned for the phenomenon on $[2, t]$ on the basis of $w|_{[2,t]}$. So if $B' \in P_t(w|_{[1,t]})$ one would like $B' \subset B_t(\sigma R)$, which implies $B'|_{[2,t]} \subset B_{t-1}(R)$.

Example. For P^u take $q=1$, $T=3$. P^u is not shift invariant on $B(\sigma^2-1)$ as for $w=(a, b, a)$, $a \neq b \neq 0$, $P_2^u(w|_{[2,3]}) = B_2(\sigma - (a/b))$ while $B_3(\sigma^2-1) \in P_3^u w$ and $B_3(\sigma^2-1) \not\subset B_3(\sigma^2 - (a/b)\sigma)$.

DEFINITION. (i) P_T is called **LINEAR** if

$$(a) \quad P_T(\alpha w) = P_T w \quad \forall w \in (\mathbb{R}^q)^T \quad \forall \alpha \neq 0.$$

$$(b) \quad \forall (B_1, B_2) \in \mathbb{B}_T^2 \text{ generically in } (w_1, w_2) \in B_1 \times B_2$$

$$\{B \in P_T(w_1 + w_2), B' \in P_T w_1, B'' \in P_T w_2\} \Rightarrow \{B' + B'' \subset B\}.$$

(ii) P is called linear if P_t is linear for all $t \in [1, T]$.

The phenomenon a priori is assumed to be linear, so (a) reflects that the observations w and αw , $\alpha \neq 0$, are in a sense equivalent. Concerning (b), consider the situation of constructing a model for the signal $w_1 + w_2$ either from observation of $w_1 + w_2$ or from observation of both w_1 and w_2 . In the latter case one has more information concerning the structure of the phenomenon which one wants to model and hence it is reasonable to demand that one can make more accurate models.

Example. P^u satisfies (a), but not (b). Take $q=1$, $T=3$, $B_i = B(\sigma - i)$, $i=1, 2$. Then generically $P_3^u w_i = B_i$, $w_i \in B_i$, $i=1, 2$. According to Proposition 2.4(i) $B_1 + B_2 = B(\sigma^2 - 3\sigma + 2)$ and if $w = (a, b, 3b - 2a) \in B_1 + B_2$, $a \neq 0$, then $B(\sigma^2 + (2a - 3b)/a) \in P_3^u w$ and $B(\sigma^2 - 3\sigma + 2) \not\subset B(\sigma^2 + (2a - 3b)/a)$, so (b) is not satisfied generically on $B_1 \times B_2$.

Finally we will define two properties which reflect the wish to accept laws only if there is some evidence for them.

We call P truthful if (generically) the laws which are accepted by P in fact are also satisfied for the phenomenon which generates the data. So the assigned models contain the phenomenon as a subset. It is not required that all laws of the phenomenon are detected.

DEFINITION. (i) P_T is called **TRUTHFUL** on $B_0 \in \mathbb{B}_T$ if generically in $w \in B_0$ $\{B \in P_T w\} \Rightarrow \{B_0 \subset B\}$.

(ii) P_T is called truthful if it is truthful on every $B_0 \in \mathbb{B}_T$.

(iii) P is called truthful if P_t is truthful for all $t \in [1, T]$.

Example. P^u is not truthful. Take $q=1$, $T=2$, $B_0 = \mathbb{R}^2$. Then generically in $w \in B_0$ $\dim(P_2^u w) = 1$.

To define the concept of prudence we will use the following notation. $\mathbb{B}_{P_T}^w := \{B \in \mathbb{B}_T; B \text{ weakly corroborable by } P_T\}$, $\mathbb{B}_{P_T}^s := \{B \in \mathbb{B}_T; B \text{ strongly corroborable by } P_T\}$ and $\text{im } P_T := \{B \in \mathbb{B}_T; \text{there exists } w \text{ such that } B \in P_T w\}$.

DEFINITION. (i) P_T is called **WEAKLY PRUDENTIAL** if $\text{im } P_T \subset \mathbb{B}_{P_T}^w$.

(ii) P_T is called **STRONGLY PRUDENTIAL** if $\text{im } P_T \subset \mathbb{B}_{P_T}^s$.

(iii) P is called weakly (strongly) prudential if P_t has this property for all $t \in [1, T]$.

The interpretation is that P_T only accepts laws which it can "verify" itself. For suppose $B \in P_T w$ while $B \notin \mathbb{B}_{P_T}^w$. Then on the basis of the data w , P_T assigns a model B of which one knows that if the phenomenon in fact coincides with B , then generically one will not assign B on the basis of an observation of this phenomenon. So if B is

assigned then it seems one was extraordinarily lucky to observe w to identify B . Assigning B is reckless. So weak prudence seems a minimum requirement. On the other hand, strongly prudential procedures are very cautious. A model B only is assigned if this model also generically will be assigned on the basis of observations of the phenomenon B . So if assigning the right model is not generic for observations from a model B , then a strongly prudential procedure does not dare to make this assignment B .

Example. Consider P'' for $q=1$, $T=4$. From Example 4.1 it follows that P''_4 is not strongly prudential and not even weakly prudential. However, every observation $w \notin \{\alpha(0, 0, 0, 1), 0 \neq \alpha \in \mathbb{R}\}$ is modeled in the class $\mathbb{B}_{P''_4}$.

Summarizing, the procedure P'' which assigns undominated unfalsified models is exact, it is not monotone, not shift invariant, not linear, not truthful and not (weakly) prudential. Moreover P'' is a complex procedure in the sense that generally it assigns many models to each observation.

In § 6 we investigate the partial realization procedure P^K for the case of a one-dimensional time series, i.e., $q=1$. This procedure is a refinement of P'' in the sense that for all $t \in [1, T]$, for all $w \in \mathbb{R}^t$, $P_t^K w \subset P_t'' w$. In fact P_t^K chooses among the undominated unfalsified models those of minimal complexity. By using a procedure P^0 which takes into account the concept of corroboration and which is described in § 7 we will define a procedure P^* in § 8 which assigns the unfalsified model of minimal complexity in the class of models for which there is some evidence from the data. This procedure is exact, monotone, shift invariant, linear, truthful and strongly prudent.

Remark. If $q=1$, $T=\infty$, then the procedures P_∞'' , P_∞^K , P_∞^0 , P_∞^* for modeling a time series $w \in (\mathbb{R})^\mathbb{N}$ can be shown to be equivalent. So P_∞'' is exact, truthful and even strongly prudent. One can show that for every system $B_\infty(R) := \{w \in (\mathbb{R})^\mathbb{N}, [R(\sigma)w](t) = 0 \text{ for all } t \in \mathbb{N}\}$ generically in $w \in B_\infty(R)$ the only undominated unfalsified model is $B_\infty(R)$ itself, so $P_\infty'' w = B_\infty(R)$ generically in $w \in B_\infty(R)$.

6. The partial realization procedure and its properties ($q=1$). From now on we throughout will restrict attention to the univariate case, i.e., $q=1$.

The “partial realization” procedure P^K is a refinement of P'' . It assigns to data the least complex model(s) unfalsified by w . This implies that all assigned models are undominated unfalsified. So in the class of exact procedures P^K is the one which maximizes the simplicity of the model, i.e., it minimizes the dimension. Stated otherwise, one determines the shortest lag AR relations exactly satisfied by the data.

DEFINITION. The partial realization procedure P^K assigns least complex unfalsified models, i.e., $P^K := \{P_t^K, t \in [1, T]\}$ where

$$P_t^K : \mathbb{R}^t \rightarrow 2^{\mathbb{B}_t} \text{ is defined by } \{B \in P_t^K w\} : \Leftrightarrow \{w \in B \in \mathbb{B}_t, \text{ and } c(B) = \min \{c(B'); w \in B' \in \mathbb{B}_t\}\}.$$

To determine $P_t^K w$ one can use an algorithm for the partial realization problem as described, e.g., in Kalman [2]. There the problem consists in realizing a partial impulse response sequence in a minimal way (i.e. with minimal dimension of the state space). Here the problem is to model an arbitrary observation over time of one variable.

The “incomplete Hankel array” for $w \in \mathbb{R}^t$ is defined by

$$H_t(w) := \begin{bmatrix} w(1) & w(2) & \cdots & w(t-1) & w(t) \\ w(2) & w(3) & & w(t) & \\ \vdots & \vdots & & & \\ w(t-1) & w(t) & & & \\ w(t) & & & & \end{bmatrix} \begin{matrix} r(1) \\ r(2) \\ \vdots \\ r(t-1) \\ r(t) \end{matrix}$$

By $r(i)$ we have denoted the i th row of $H_t(w)$.

A matrix M with elements m_{ij} , $i, j \in \mathbb{N}$ is called an extension of $H_t(w)$ if $m_{ij} = w(i+j-1)$, $i \in [1, t]$, $j \in [1, t-i+1]$. It is called a Hankel extension if M is a Hankel matrix. The rank of M is defined as the dimension of the space spanned by the columns (or rows) of M .

DEFINITION. The (Kalman) rank of $H_t(w)$, denoted by $\text{rank } H_t(w)$, is the minimal rank of extensions of $H_t(w)$.

Clearly $\text{rank } H_t(w)$ is well defined and $\text{rank } H_t(w) \leq t$ for all $w \in \mathbb{R}^t$.

We will call $r(i)$ linearly (in)dependent on $r(1), \dots, r(i-1)$ if in the $i \times (t-i+1)$ matrix consisting of the first i rows and first $t-i+1$ columns of $H_t(w)$ the last row is linearly (in)dependent on the foregoing ones.

Proofs of the following lemmas are contained in the Appendix.

LEMMA 6.1.

$$\{\text{rank } H_t(w) = n\} \Leftrightarrow \{r(n) \text{ linearly independent from } r(1), \dots, r(n-1), r(n+1) \text{ linearly dependent on } r(1), \dots, r(n)\}.$$

LEMMA 6.2. In the class of minimal rank extensions of $H_t(w)$ there is a Hankel extension.

The following proposition describes how $P_t^K w$ can be determined by using $H_t(w)$. This amounts to determining the first row in $H_t(w)$ which is linearly dependent on the foregoing ones.

PROPOSITION 6.1. (i) $\{B \in P_t^K w\} \Leftrightarrow \{w \in B \text{ and } c(B) = \text{rank } H_t(w)\}$.

(ii) If $\text{rank } H_t(w) = d$, then $P_t^K w = \{B(R)\}$; there exists a_i , $i \in [1, d]$, such that $r(d+1) = \sum_{i=1}^d a_i \cdot r(i)$ and $R = \sigma^d - \sum_{i=1}^d a_i \sigma^{i-1}$.

Proof. Let $\text{rank } H_t(w) = d$. Assume $w \in B \in \mathbb{B}_t$. Shift invariance of B implies there exists $w^e \in (\mathbb{R})^{\mathbb{N}}$, $w^e|_{[1,t]} = w$, $w^e|_{[\tau, \tau+t-1]} \in B$ for all $\tau \in \mathbb{N}$. Define an extension M of $H_t(w)$ by $m_{ij} := w^e(i+j-1)$, $i, j = 1, \dots, t$, $m_{ij} := 0$ elsewhere. Then $\text{rank } M \geq d$ and hence $w^e|_{[\tau, \tau+t-1]}$, $\tau \in [1, t]$ span a space of dimension at least d in B , hence $c(B) \geq d$. Further as $\text{rank } H_t(w) = d$ there exists $a = (a_1, \dots, a_d) \in \mathbb{R}^d$ such that $r(d+1) = \sum_{i=1}^d a_i r(i)$. Define $R_a := \sigma^d - \sum_{i=1}^d a_i \sigma^i$. Then clearly $w \in B(R_a)$ and $c(B(R_a)) = d$. Using the definition of P_t^K this proves (i) and \supset in (ii). To prove \subset in (ii), let $B(R) \in P_t^K w$, so $c(B(R)) = d$, which implies R has degree d , say $R = \sigma^d - \sum_{i=1}^d a_i \sigma^{i-1}$. Then in $H_t(w)$ $r(d+1) = \sum_{i=1}^d a_i r(i)$. \square

Remark. Note that for $q = 1$ if $B(R) \in \mathbb{B}_T$ the assumption of row properness of R implies that $R \in \mathbb{R}[\sigma]$, i.e., it consists of one row. Then for $R \neq 0$ $c(B_t(R)) := \dim B_t(R) = \min \{d, t\}$ where d is the degree of R .

The procedure P^K only takes into account simplicity, not corroboration. As a result there often is no evidence for assigned models.

Example 6.1. Consider the phenomenon $B = \mathbb{R}^T$, so there are no laws. For $x \in \mathbb{R}$ define $\text{ENT}(x) := \min \{n \in \mathbb{Z}; n \geq x\}$. Now generically in $w \in B$, $\text{rank } H_T(w) = \text{ENT}(T/2)$, hence generically in $w \in B$ $\{B \in P_T^K w\} \Rightarrow \{\dim B = \text{ENT}(T/2)\}$. So even though there are no laws at all, P^K still generically imposes them. In fact $P_T^K w = \mathbb{R}^T$ if and only if $w(t) = 0$, $t \in [1, T-1]$, and $w(T) \neq 0$.

We will illustrate P^K by giving some examples which play an important role in the sequel to construct procedures with better properties than P^K .

Examples. Take $T = 6$.

Example 6.2. $w = (1, 1, 2, 3, 5, 8)$, $\text{rank } H_6(w) = 2$, $r(3) = r(1) + r(2)$, $P_6^K w = B(\sigma^2 - \sigma - 1)$.

Example 6.3. $w = (1, 1, 1, 0, 1, 1)$, $P_6^K w = B(\sigma^3 + \sigma^2 - 2)$.

Example 6.4. $w = (1, 2, 0, 1, 1, 2)$, $P_6^K w = B(\sigma^3 - \frac{7}{5}\sigma^2 - \frac{3}{5}\sigma + \frac{1}{5})$.

Example 6.5. $w = (1, 2, 0, 4, 4)$, $P_6^K w = B(\sigma^3 - \sigma - 2)$.

Example 6.6. $w = (1, 0, 2, 0, 1, 1)$, $P_6^K w = B(\sigma^3 + \frac{1}{3}\sigma^2 - \frac{1}{2}\sigma - \frac{2}{3})$.

P^K need not assign unique models.

Example 6.7. Take $T = 3$ and the phenomenon $B = \mathbb{R}^3$. Then for generic $w = (a, b, c) \in B$ $P_3^K w = \{B(\sigma^2 - \beta\sigma - \alpha); \alpha a + \beta b = c\}$ (the condition is $ac - b^2 \neq 0$). In general, if t is odd then generically in $w \in \mathbb{R}^t$ $\text{rank } H_t(w) = (t+1)/2$ and $P_t^K w$ consists of uncountably many models, while if t is even then generically in $w \in \mathbb{R}^t$ $\text{rank } H_t(w) = t/2$ and $P_t^K w$ consists of one model.

Before we state the properties of P^K we will define the concept of a selection rule. If a procedure lacks desirable properties this could be due to the fact that assigned models are nonunique, as monotonicity, shift invariance, linearity and truthfulness are requirements which are stronger the larger the classes of assigned models for an observation. Such a procedure possibly could be improved by a selection rule. By this we mean a rule which for every observation chooses a unique model from the class of models which is assigned by the procedure.

DEFINITION. (i) A selection rule for $P_T: \mathbb{R}^T \rightarrow 2^{\mathbb{B}_T}$ is a map $S_T: \mathbb{R}^T \rightarrow \mathbb{B}_T$ such that for all $w \in \mathbb{R}^T$, $S_T w \in P_T w$.

(ii) A selection rule for $P = \{P_t, t \in [1, T]\}$ is a collection $S = \{S_t, t \in [1, T]\}$ where S_t is a selection rule for P_t .

To analyze the properties of P^K the following proposition will be helpful.

PROPOSITION 6.2. Let $0 \neq R \in \mathbb{R}[\sigma]$ have degree $d(R) = d$. Then generically in $w \in B_t(R)$ $\text{rank } H_t(w) = \min\{d, \text{ENT}(t/2)\}$.

Proof. See the Appendix.

THEOREM 1. (i) P^K is exact.

If $T \geq 3$, then (ii)–(v) hold true.

(ii) P^K is not monotone, not shift invariant, not linear.

(iii) P_T^K is not truthful.

(iv) P_T^K is not even weakly prudent, as $\text{im } P_T^K = \mathbb{B}_T$, $\mathbb{B}_{P_T^K} = \{B \in \mathbb{B}_T; c(B) \leq \text{ENT}(T/2)\}$, $\mathbb{B}_{P_T^K}^s = \mathbb{B}_{P_T^K}^w$ if T is even, $\mathbb{B}_{P_T^K}^s = \{B \in \mathbb{B}_T; c(B) \leq \text{ent}(T/2)\}$ if T is odd.

(v) There exists no selection rule for P^K which has at least one of the properties in (ii)–(iv).

Proof. See the Appendix.

Remark. It is a matter of easy verification to show that, for $T = 2$, P^K is monotone, shift invariant, not linear, not truthful and not weakly prudent.

Remark. The proof of Theorem 1 contained in the Appendix to show that P^K lacks desirable properties concentrates on the case $B = \mathbb{R}^T$. It can be shown that P^K only is monotone and shift invariant on models B for which $c(B) \in \{0, 1\}$ and that P_T^K only is truthful for models $B \in \mathbb{B}_{P_T^K}^s$. So \mathbb{R}^T is not the only model for which P^K has undesirable performance.

The analogue \tilde{P}^K of P^K for least complex modeling in $\tilde{\mathbb{B}}_t$ can be defined as follows.

DEFINITION. The procedure \tilde{P}^K assigns least complex unfalsified models which are translation invariant, i.e., $\tilde{P}_t^K: \mathbb{R}^t \rightarrow 2^{\tilde{\mathbb{B}}_t}$ is defined by

$$\{B \in \tilde{P}_t^K w\} : \Leftrightarrow \{w \in \tilde{\mathbb{B}}_t \text{ and } c(B) = \min\{c(B'); w \in B' \in \tilde{\mathbb{B}}_t\}\}.$$

Without going into details, $\tilde{P}_t^K w$ can be determined by looking in $H_t(w)$ for the first row which is linearly dependent on the foregoing ones and which explicitly involves the first row, i.e., by looking for the smallest d such that there exist $(a_1, \dots, a_d) \in \mathbb{R}^d$ with $a_1 \neq 0$ and $r(d+1) = \sum_{i=1}^d a_i r(i)$. This way of determining $\tilde{P}_t^K w$ is based upon Proposition 2.3(ii).

In the same way as P^K also \tilde{P}^K only takes into account simplicity, not corroboration. As a result \tilde{P}^K lacks desirable properties. It can be shown that \tilde{P}^K is not (bilaterally) monotone, not linear, not truthful and not even weakly prudent.

At the end of § 8 we briefly will discuss a procedure \tilde{P}^* for modeling by means of translation invariant models. Section 7 and the main part of § 8 concentrate on modeling by means of shift invariant models. In § 7 we will describe a procedure P^0 which takes corroboration into account and which has better properties than P^K . In § 8 we will refine P^0 to a procedure P^* which has all the properties defined in § 5 on every model $B \in \mathbb{B}_t$, $t \in [1, T]$, while P_t^* coincides with P_t^K on those models for which P^K is a satisfactory procedure, i.e., on $\mathbb{B}_t^K := \{B \in \mathbb{B}_t; c(B) \leq \text{ENT}(t/2) - 1\}$.

7. An alternative procedure $P^0(q=1)$. The main reason why the partial realization procedure P^K lacks desirable properties is the fact that it pays attention only to simplicity, not to corroboration. In § 8 we will describe a procedure P^* which has all the desirable properties defined in § 5 and for which the class of corroborable models satisfies

$$\mathbb{B}_{P^*}^s = \mathbb{B}_{P^*}^w \supset \{B \in \mathbb{B}_T; c(B) \leq \text{ENT}(T/2) - 1\} = \mathbb{B}_{P^K}^w \setminus \{B \in \mathbb{B}_T; c(B) = \text{ENT}(T/2)\}.$$

This procedure P^* will consist of a slight refinement of a procedure P^0 which will be described in this section. P^0 essentially consists of a refinement of P^K by taking into account corroboration.

The idea to refine P^K is to accept laws which are satisfied by the data only provided there is some evidence for them. If for an observation a nonfalsified law is of a type which also generically will be unfalsified for an observation on a phenomenon which obeys no law at all (i.e. $B = \mathbb{R}^T$), then one has reason not to accept this law. We illustrate this idea by means of an example.

Example 7.1 (cf. Example 6.4). $T=6$, $w=(1, 2, 0, 1, 1, 2)$.

$$H_T(w) = \begin{bmatrix} 1 & 2 & 0 & 1 & 1 & 2 \\ 2 & 0 & 1 & 1 & 2 & \\ 0 & 1 & 1 & 2 & & \\ 1 & 1 & 2 & & & \\ 1 & 2 & & & & \\ 2 & & & & & \end{bmatrix} \begin{matrix} r(1) \\ r(2) \\ r(3) \\ r(4) \\ r(5) \\ r(6) \end{matrix}.$$

Here $r(4) = \frac{7}{5}r(3) + \frac{3}{5}r(2) - \frac{1}{5}r(1)$, $\text{rank } H_T(w) = 3$, $P_T^K w = B(\sigma^3 - \frac{7}{5}\sigma^2 - \frac{3}{5}\sigma + \frac{1}{5})$. Note that it is not at all remarkable that $\text{rank } H_T(w) = 3$, as this generically holds true on \mathbb{R}^T for $T=6$. So one has reason not to accept this third order law, as it is of a type which generically holds true on \mathbb{R}^6 . It is not remarkable that w satisfies a law of this type.

Nonetheless, in $H_T(w)$ there is a remarkable dependence, as $r(5)$ is linearly dependent on $r(1)$ and this generically does not hold true on \mathbb{R}^T for $T=6$. One has reason to accept this remarkable law, i.e., to accept the law $w(t+4) = w(t)$, $t \in \{1, 2\}$, and to assign to w the model $B(\sigma^4 - 1)$.

In general, let $w \in \mathbb{R}^T$ and let $r(1), \dots, r(T)$ denote the rows of $H_T(w)$. Suppose $r(d+1)$ is linearly dependent on $r(i_1+1), \dots, r(i_{c-1}+1)$, where $0 \leq i_1 < i_2 < \dots < i_{c-1} < d$, say $r(d+1) = \sum_{k=1}^{c-1} a_k r(i_k+1)$, $a_k \neq 0$, $k \in [1, c-1]$. Let $R := \sigma^d - \sum_{k=1}^{c-1} a_k \sigma^{i_k}$, then $w \in B(R)$. The crucial question now is when is it remarkable to find a law such as R . We define this to be remarkable if and only if the number of elements in $r(d+1)$ is strictly larger than the number of explaining rows, i.e., if and only if $T-d > c-1$,

i.e., $c + d \leq T$. Note that this is exactly the class of laws which is not generically satisfied on \mathbb{R}^T .

We will now define a procedure P^0 which assigns to data the most simple (d minimal) unfalsified models for which it is remarkable that they are unfalsified ($c + d \leq T$).

DEFINITION. (i) For $R = \sum_{k=0}^n a_k \sigma^k \in \mathbb{R}[\sigma]$, $d(R) := \max \{k; a_k \neq 0\}$, $d(0) := -\infty$, $c(R) := \# \{k; a_k \neq 0\}$.

(ii) R is called **REMARKABLE** (for T) if $R \neq 0$ and $c(R) + d(R) \leq T$.

(iii) $\mathbb{B}_T^* := \{B_T(R); c(R) + d(R) \leq T\}$.

We will call $B_T(R)$ remarkable if R is remarkable for T . So \mathbb{B}_T^* consists of the class of remarkable models together with \mathbb{R}^T .

DEFINITION OF P^0 . (i) P_T^0 assigns least complex unfalsified remarkable models if these exist, else it assigns \mathbb{R}^T , i.e., $P_T^0: \mathbb{R}^T \rightarrow 2^{\mathbb{B}_T^*}$ is defined by $\{B \in P_T^0 w\} \Leftrightarrow \{w \in B \in \mathbb{B}_T^* \text{ and } c(B) = \min \{c(B'); w \in B' \in \mathbb{B}_T^*\}\}$.

(ii) $P^0 := \{P_t^0, t \in [1, T]\}$.

Comparing the definitions of P_T^0 and P_T^K , we see that P_T^K is refined to least complex unfalsified modeling in \mathbb{B}_T^* instead of \mathbb{B}_T , i.e., assigned laws have to be remarkable. Note that if w satisfies no remarkable law, then $P_T^0 w = \mathbb{R}^T$, so if no remarkable law is satisfied then no law is accepted. We illustrate P^0 by some examples.

Examples. Take $T = 6$.

Example 7.2 (cf. Example 6.2). $w = (1, 1, 2, 3, 5, 8)$, $P_6^0 w = B(\sigma^2 - \sigma - 1)$.

Example 7.3 (cf. Example 6.3). $w = (1, 1, 1, 0, 1, 1)$, $P_6^0 w = \{B(\sigma^4 - 1), B(\sigma^4 - \sigma)\}$.

Example 7.4 (cf. Example 6.6). $w = (1, 0, 2, 0, 1, 1)$, $P_6^0 w = \mathbb{R}^6$.

Example 7.5 (cf. Example 6.5). $w = (1, 2, 0, 4, 4, 4)$, $P_6^0 w = B(\sigma^3 - \sigma - 2)$.

Remark. Examples 7.3 and 7.5 will play a role in refining P^0 to the procedure P^* defined in § 8. This has to do with compatibility of remarkable laws, which concept is defined in § 8. For details we refer to Examples 8.1 and 8.2.

To determine $P_T^0 w$ one can investigate $H_T(w)$ and determine the first row, say $d + 1$, which is linearly dependent on $c - 1$ foregoing ones such that $c + d \leq T$. If no such row exists, then $P_T^0 w = \mathbb{R}^T$.

An important question is whether laws which are assigned by P_T^0 also (generically) are true laws, given that the data stems from a system in \mathbb{B}_T , i.e., the question of truthfulness of P^0 . An essential property of P^0 is the following.

THEOREM 2. Let $B_0 \in \mathbb{B}_T$. Then generically in $w \in B_0$, $P_T^0 w = \{B \in \mathbb{B}_T^*; B_0 \subset B, c(B) \text{ minimal}\}$.

Proof. See the Appendix.

So, generically on B_0 , P_T^0 assigns the least complex remarkable models containing B_0 and in particular generically the assigned laws also are true laws.

COROLLARY 7.1. If $B_0 \in \mathbb{B}_T^*$, then generically in $w \in B_0$ $P_T^0 w = B_0$.

Proof. See the Appendix.

Theorem 2 indicates some of the main properties of P^0 , i.e., corroboration is taken into account (modeling in \mathbb{B}_T^*), simplicity is taken into account ($c(B)$ minimal) and the procedure is truthful.

THEOREM 3. (i) P^0 is exact.

(ii) P^0 is truthful.

(iii) P^0 is strongly prudent, since $\text{im } P_t^0 = \mathbb{B}_{P_t^0}^w = \mathbb{B}_{P_t^0}^s = \mathbb{B}_t^*$, for all $t \in [1, T]$.

(iv) P^0 is not monotone and not shift invariant; the inclusion conditions for monotonicity, shift invariance and linearity are satisfied if the action of P_t^0 is restricted to models in the set \mathbb{B}_t^* .

Proof. See the Appendix.

Remark. If P^0 is linear it still is an open problem. We do not go into details of exact characterization of those models for which P^0 is monotone or shift invariant and do not answer the question of linearity. This is because (iv) implies that P^0 lacks some desirable properties, although only in quite special cases. In the following section we will slightly modify P^0 to get a procedure P^* with desirable properties everywhere.

8. The procedure P^* and its properties ($q = 1$). P^0 has some desirable properties but also lacks some of them. In this section we will refine P^0 to a procedure P^* which has all the properties which were introduced in § 5.

Before we describe P^* we will give three examples indicating in which direction P^0 could be refined. The main concepts are those of remarkability, defined in § 7, and compatibility, which we define as follows. By Λ we will denote an arbitrary index set.

DEFINITION. Let $R_\lambda \in \mathbb{R}[\sigma]$, $\lambda \in \Lambda$, and $w \in \mathbb{R}^T$. Then $\{R_\lambda, \lambda \in \Lambda\}$ and w are called **COMPATIBLE** if there exists a $B \in \mathbb{B}_T$ such that $w \in B \subset \bigcap \{B_T(R_\lambda), \lambda \in \Lambda\}$.

So a class of laws and an observation are called compatible if there exists a linear shift invariant system for which all the laws are valid and which is nonfalsified by the observation.

Example 8.1 (cf. Examples 6.3, 7.3). $T = 6$, $w = (1, 1, 1, 0, 1, 1)$, $P_6^0 w = \{B(\sigma^4 - 1), B(\sigma^4 - \sigma)\}$. Note that a priori we want to model in \mathbb{B}_6 , so the phenomenon is assumed to be linear and shift invariant. Maximizing simplicity under the restriction of corroboration leads to $P_6^0 w$ and a nonunique model being assigned to w . However, $\{\sigma^4 - 1, \sigma^4 - \sigma\}$ and w are not compatible. Note that $B(\sigma^4 - 1) \cap B(\sigma^4 - \sigma) \notin \mathbb{B}_6$ while due to Proposition 2.4(ii) the largest model in \mathbb{B}_6 contained in $B(\sigma^4 - 1) \cap B(\sigma^4 - \sigma)$ is given by $B(1) = \{0\}$, and $w \neq 0$. So given the phenomenon belongs to \mathbb{B}_6 and given the data w , the phenomenon cannot satisfy both laws $\sigma^4 - 1$ and $\sigma^4 - \sigma$, and at least one of the two assigned models has to be false. It seems reasonable to reject at least one of them, even to reject both. (In case one could wait for $w(7)$ to become available it might be sensible to store $B(\sigma^4 - 1)$ and $B(\sigma^4 - \sigma)$ and to decide on the basis of $w(7)$.)

Example 8.2 (cf. Examples 6.5, 7.5). $T = 6$, $w = (1, 2, 0, 4, 4, 4)$, $P_6^0 w = B(\sigma^3 - \sigma - 2)$. Note that in this case there is another unfalsified remarkable law, as $w \in B(\sigma^4 - \sigma^3)$, which is not accepted by P^0 . Now $\{\sigma^3 - \sigma - 2, \sigma^4 - \sigma^3\}$ and w are not compatible, as $B(\sigma^3 - \sigma - 2) \cap B(\sigma^4 - \sigma^3) = \{\alpha(1, 2, 0, 4, 4, 4), \alpha \in \mathbb{R}\} \notin \mathbb{B}_6$ while the largest model in \mathbb{B}_6 contained in this intersection is $B(1) = \{0\}$, as $\text{GCD}(\sigma^3 - \sigma - 2, \sigma^4 - \sigma^3) = 1$, and $w \neq 0$. So given the phenomenon belongs to \mathbb{B}_6 and given the data w , at least one of the remarkable laws $\sigma^3 - \sigma - 2$ and $\sigma^4 - \sigma^3$ was observed just by bad luck, because for this phenomenon not both laws can be valid. It seems reasonable to assign no law at all.

Example 8.3 (cf. the example given in the proof of Theorem 3(iv) in the Appendix). Assume the data stem from a phenomenon with law $R = \sigma^{10} + \sigma^9 + 2\sigma^8 + \sigma^7 + \sigma^6 + 2\sigma^5 + \sigma^4 + \sigma^3 + 2\sigma^2 + \sigma + 1$ and that $T = 20$, e.g., $w = (0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, -1, -1, 2, 0, -4, 4, 4, -12, 4, 20)$. Note $\text{rank } H_{20}(w) = 10$ and R is the only law of degree 10 which is nonfalsified by w , so $P_{20}^K w = B(R)$. However, $c(R) + d(R) = 21$ so R is not remarkable for $T = 20$. Let $R_1 := (\sigma - 1)R$, $R_2 := (\sigma - \frac{1}{2})R$; then $c(R_1) + d(R_1) = 19$, $c(R_2) + d(R_2) = 20$, $d(R_1) = d(R_2) = 11$. Here $P_{20}^0 w = \{B(R_1), B(R_2)\}$ and this also holds true generically on $B(R)$ according to Theorem 2.

Now note that $\{R_1, R_2\}$ and w are compatible, as $w \in B(R) = B(R_1) \cap B(R_2)$. This even holds true for every $w \in B(R)$. Although R itself is not remarkable, R_1 and R_2 are remarkable and moreover they are compatible with w . So it seems reasonable to assign $B(R)$ to w , not as it would be remarkable in itself, but because one has evidence for it from the remarkable and compatible laws R_1 and R_2 .

These examples indicate the ideas of how to refine P^0 .

DEFINITION. The class of remarkable laws for $w \in \mathbb{R}^T$ is defined by $L(w) := \{R \neq 0; d(R) \leq T-1 \text{ and } w \in B(R) \in \mathbb{B}_T^*\} = \{R; w \in B_T(R) \in \mathbb{B}_T^*, B_T(R) \neq \mathbb{R}^T\}$.

Remark. Because of the restriction $d(R) \leq T-1$, every law in $L(w)$ is remarkable. In the sequel we throughout will assume that in $B_T(R)$ $d(R) \leq T-1$, without always explicitly mentioning this.

If for $B \in \mathbb{B}_T$ both the laws R_1 and R_2 are valid, i.e., if $B \subset B(R_1) \cap B(R_2)$, then according to Proposition 2.4(ii) with $g = q = 1$, $B \subset B(G)$ where $G := \text{GCD}(R_1, R_2)$, the greatest common divisor of R_1 and R_2 in $\mathbb{R}[\sigma]$.

For $w \in \mathbb{R}^T$ let $R(w) := \text{GCD}\{R; R \in L(w)\}$, i.e., the least stringent law implied by all the remarkable laws for w . Define $\text{GCD}\{\emptyset\} := 0$. Now there are two possible situations.

(i) The class of all remarkable laws for w , i.e., $L(w)$, and w are compatible, i.e., there exists $B \in \mathbb{B}_T$ such that $w \in B \subset \bigcap \{B(R); R \in L(w)\}$. Note that $B(R(w))$ is the largest model in \mathbb{B}_T which satisfies this condition, i.e., $B(R(w))$ is the largest model unfalsified by w for which all remarkable laws are valid (note $B(R(w)) \subset B(R)$, for all $R \in L(w)$). Models of less complexity either are falsified by the data or are not supported by means of unfalsified remarkable laws. So one would like to accept all remarkable laws and to assign $B(R(w))$ to w .

(ii) $L(w)$ and w are not compatible, i.e., there is no $B \in \mathbb{B}_T$ which is unfalsified by w and for which all remarkable laws for w are valid. So given that the phenomenon belongs to \mathbb{B}_T , at least one of the remarkable laws has to be false. As one has no information concerning which law is false it seems reasonable to accept no law at all.

Note that (i) is equivalent to $w \in B(R(w))$ and (ii) to $w \notin B(R(w))$. We define the procedure P^* as follows.

DEFINITION OF P^* . (i) If the class of all remarkable laws is compatible with the data, P_T^* assigns the largest model for which all these laws are valid, else it assigns \mathbb{R}^T , i.e., $P_T^*: \mathbb{R}^T \rightarrow \mathbb{B}_T$ is defined by

$$P_T^* w = \begin{cases} B(R(w)) & \text{if } w \in B(R(w)), R(w) := \text{GCD}\{R; R \in L(w)\}, \\ \mathbb{R}^T & \text{if } w \notin B(R(w)). \end{cases}$$

(ii) $P^* := \{P_t^*, t \in [1, T]\}$.

Remark. In case the class of all remarkable laws is compatible with the data, P^* accepts all these laws and no other ones, as for other laws there is no evidence. Note that P^* always assigns a unique model to data.

To investigate P^* , the following proposition is crucial. It essentially says that generically all remarkable laws are true laws. That is an important motivation for our definition of remarkability.

PROPOSITION 8.1. For every $B_0 \in \mathbb{B}_T$, generically in $w \in B_0$, $B_0 \subset B(R(w))$.

Proof. See the Appendix.

Proofs of the following corollaries also are contained in the Appendix.

COROLLARY 8.1. Let $B_0 \in \mathbb{B}_T$. Then generically in $w \in B_0$ there holds $\{R \in L(w)\} \Rightarrow \{B_0 \subset B(R) \text{ and } P_T^* w \subset B(R)\}$.

COROLLARY 8.2. Let $B_0 \in \mathbb{B}_T$. Then generically in $w \in B_0$ $P_T^* w = B(R)$ where $R := \text{GCD}\{\hat{R} \neq 0; d(\hat{R}) \leq T-1 \text{ and } B_0 \subset B(\hat{R}) \in \mathbb{B}_T^*\}$.

So Corollary 8.1 states that generically all remarkable laws hold true for the phenomenon and that generally true remarkable laws also are accepted by P^* . This indicates a connection between remarkability and corroboration. Corollary 8.2 describes the generic way in which P^* models data.

The properties of P^* are stated in our main theorem.

THEOREM 4. (i) P^* is exact.

(ii) P^* is monotone, shift invariant and linear.

(iii) P^* is truthful.

(iv) P^* is strongly prudent as $\text{im } P_t^* = \mathbb{B}_{P_t^*}^w = \mathbb{B}_{P_t^*}^s = \{B(R); \exists \{R_\lambda, d(R_\lambda) \leq t-1, \lambda \in \Lambda\}, B(R_\lambda) \in \mathbb{B}_t^*, R = \text{GCD} \{R_\lambda, \lambda \in \Lambda\}\}$.

Proof. (i) The proof is obvious from the definition of P^* .

(ii) For $B \in \mathbb{B}_t$ let $R(B) := \text{GCD} \{R \neq 0; d(R) \leq t-1 \text{ and } B \subset B(R) \in \mathbb{B}_t^*\}$.

Monotonicity. Let $B_0 \in \mathbb{B}_T$, $w \in B_0$, $P_{t-1}^*(w|_{[1,t-1]}) = B_{t-1}$, $P_t^*(w|_{[1,t]}) = B_t$, then we have to prove that generically $B_t|_{[1,t-1]} \subset B_{t-1}$. If $B_{t-1} = \mathbb{R}^{t-1}$ then this is trivial, so assume $B_{t-1} \neq \mathbb{R}^{t-1}$. Then from Corollary 8.2 one can derive that generically on B_0 , $B_{t-1} = B_{t-1}(R_{t-1})$ and $B_t = B_t(R_t)$ where $R_{t-1} := R(B_0|_{[1,t-1]})$ and $R_t := R(B_0|_{[1,t]})$. Now if R is such that $B_0|_{[1,t-1]} \subset B_{t-1}(R) \in \mathbb{B}_{t-1}^*$, then $B_0|_{[2,t]} \subset B_0|_{[1,t-1]} \subset B_{t-1}(R)$ implies $B_0|_{[1,t]} \subset B_t(R) \in \mathbb{B}_t^*$ as $c(R) + d(R) \leq t-1 \leq t$; hence for these $RPB_t(R_t) \subset B_t(R)$ (use Proposition 2.4(ii)). This implies $B_t(R_t) \subset B_t(R_{t-1})$; hence also generically on B_0 , $B_t|_{[1,t-1]} = B_t(R_t)|_{[1,t-1]} \subset B_t(R_{t-1})|_{[1,t-1]} = B_{t-1}(R_{t-1}) = B_{t-1}$.

Shift invariance. Let $B_0 \in \mathbb{B}_T$, $w \in B_0$, $P_{t-1}^*(w|_{[2,t]}) = B_{t-1}(R)$, $B' = P_t^*(w|_{[1,t]})$, to prove that generically $B' \subset B_t(\sigma R)$. From Corollary 8.2 it follows that generically on B_0 , $R = R(B_0|_{[2,t]})$ and generically $B' = B_t(R')$ where $R' = R(B_0|_{[1,t]})$. Now if \tilde{R} is such that $B_0|_{[2,t]} \subset B_{t-1}(\tilde{R}) \in \mathbb{B}_{t-1}^*$, then $B_0|_{[1,t]} \subset B_t(\sigma \tilde{R}) \in \mathbb{B}_t^*$ as $c(\sigma \tilde{R}) + d(\sigma \tilde{R}) = c(\tilde{R}) + d(\tilde{R}) + 1 \leq t-1+1 = t$. So generically $B' = B_t(R') \subset B_t(\tilde{R})$ where $\tilde{R} := \text{GCD} \{\sigma \tilde{R} \neq 0; d(\tilde{R}) \leq t-1 \text{ and } B_0|_{[2,t]} \subset B_{t-1}(\tilde{R}) \in \mathbb{B}_{t-1}^*\} = \sigma R$ which proves shift invariance.

Linearity. $P_t^*(\alpha w) = P_t^*(w)$ for $\alpha \neq 0$ follows from $L(\alpha w) = L(w)$, $\alpha \neq 0$. Now let $(B_1, B_2) \in \mathbb{B}_t^2$, $B_i = B(R_i)$, $i = 1, 2$, $(w_1, w_2) \in B_1 \times B_2$, $P_t^* w_1 = B(R')$, $P_t^* w_2 = B(R'')$, $P_t^*(w_1 + w_2) = B(R)$; then we have to prove that generically $B(R') + B(R'') \subset B(R)$. According to Proposition 2.4(i) $B_1 + B_2 = B(K)$ with $K := \text{LCM}(R_1, R_2)$. According to Corollary 8.2 generically in $w_1 + w_2$, hence generically in $(w_1, w_2) \in B_1 \times B_2$, $R = R(B(K))$. Moreover, generically $R' = R(B_1)$ and $R'' = R(B_2)$. Because $B_i \subset B(K)$, $i = 1, 2$, if $B(K) \subset B(\tilde{R})$ then also $B_i \subset B(\tilde{R})$, $i = 1, 2$, so $B(R') \subset B(R)$, $B(R'') \subset B(R)$ and hence also $B(R') + B(R'') \subset B(R)$.

(iii) This is immediate from Corollary 8.2.

(iv) Let $V := \{B(R); \text{there exists } \{R_\lambda, d(R_\lambda) \leq t-1, \lambda \in \Lambda\}, B(R_\lambda) \in \mathbb{B}_t^*, R = \text{GCD} \{R_\lambda, \lambda \in \Lambda\}\}$. For every procedure $\mathbb{B}_{P_t^*}^s \subset \mathbb{B}_{P_t^*}^w \subset \text{im } P_t$ so it suffices to show $V \subset \mathbb{B}_{P_t^*}^w$ and $\text{im } P_t^* \subset V$. If $B \in V$, then Corollary 8.2 implies that generally on B , $P_t^* w = B$; hence $B \in \mathbb{B}_{P_t^*}^w$. If $B \in \text{im } P_t^*$, then either $B = \mathbb{R}^t \in V$ or there exists $w \in \mathbb{R}^t$ such that $B = B(R(w))$, $R(w) = \text{GCD} \{R; R \in L(w)\}$. Because for $R \in L(w)$, $d(R) \leq t-1$ and $B(R) \in \mathbb{B}_t^*$ it follows that $B \in V$. \square

To illustrate P^* we briefly return to some examples.

Example 8.1. $T = 6$, $w = (1, 1, 1, 0, 1, 1)$, $L(w) = \{\sigma^4 - 1, \sigma^4 - \sigma\}$, $R(w) = 1$, $w \notin B(1) = \{0\}$; hence $P_6^* w = \mathbb{R}^6$.

Example 8.2. $T = 6$, $w = (1, 2, 0, 4, 4, 4)$, $L(w) = \{\sigma^3 - \sigma - 2, \sigma^4 - \sigma^3\}$, $R(w) = 1$, $w \notin B(1) = \{0\}$; hence $P_6^* w = \mathbb{R}^6$.

Example 8.3. Take w, R, R_1, R_2 as stated before in this example. Then $L(w) = \{R_1, \sigma R_1, R_2\}$, $R(w) = R$, $w \in B(R)$; hence $P_{20}^* w = B(R)$.

Example 8.4 (cf. Examples 6.2, 7.2). $T = 6$, $w = (1, 1, 2, 3, 5, 8)$, $R := \sigma^2 - \sigma - 1$, $L(w) = \{R, \sigma R, (\sigma - 1)R, (\sigma + 1)R\}$, $R(w) = R$, $w \in B(R)$; so $P_6^* w = B(R)$.

From Theorem 2 and Corollary 8.2 we immediately get the following.

PROPOSITION 8.2. Let $B_0 \in \mathbb{B}_T$. Then generically in $w \in B_0$, $\{B \in P_T^0 w\} \Rightarrow \{P_T^* w \subset B\}$.

The following proposition indicates the relationship between P^K , P^0 , P^* and the sense in which P^* is a procedure with desirable properties everywhere and which

coincides with the partial realization procedure on those systems for which P^K is a reasonable procedure. Moreover it describes the sense in which the differences between P_T^K , P_T^0 , P_T^* disappear if $T \rightarrow \infty$. Proof of the proposition is immediate.

PROPOSITION 8.3. Let $\mathbb{B}_t^K \subset \mathbb{B}_t^*$ be defined by $\mathbb{B}_t^K := \{B \in \mathbb{B}_t; c(B) \leq \text{ENT}(t/2) - 1\}$.

(i) $\mathbb{B}_t^K = \mathbb{B}_{P_t^K}^s \subset \mathbb{B}_{P_t^0}^s \subset \mathbb{B}_{P_t^*}^s$ for t odd, $\mathbb{B}_t^K = \mathbb{B}_{P_t^K}^s \setminus \{B \in \mathbb{B}_t; c(B) = t/2\} \subset \mathbb{B}_{P_t^0}^s \subset \mathbb{B}_{P_t^*}^s$ for t even.

(ii) For $B_0 \in \mathbb{B}_t^K$, generically in $w \in B_0$, $P_t^K w = P_t^0 w = P_t^* w$; for $B_0 \in \mathbb{B}_t^*$ generically in $w \in B_0$, $P_t^0 w = P_t^* w$.

(iii) For given $R \in \mathbb{R}[\sigma]$, $P_T^K w = P_T^0 w = P_T^* w$ generically on $B_T(R)$ for T sufficiently large, i.e., $T \geq 2d(R) + 2$.

Remark. The problem of modeling an infinite time series $w \in (\mathbb{R})^\mathbb{N}$ by means of a model in the set $\mathbb{B}_\infty := \{B \subset (\mathbb{R})^\mathbb{N}; \text{there exists } R \in \mathbb{R}[\sigma] \text{ such that } w \in B \Leftrightarrow [R(\sigma)w](t) = 0, \text{ for all } t \in \mathbb{N}\}$ could be studied in an analogous way. Modeling by undominated unfalsified models, least complex unfalsified models, least complex unfalsified remarkable models or by most complex models which accept all remarkable laws if these are valid, i.e., using P_∞^u , P_∞^K , P_∞^0 or P_∞^* , turn out to be equivalent.

To conclude this section we will describe a procedure \tilde{P}^* for modeling in $\tilde{\mathbb{B}}_T$, i.e., linear translation invariant models.

Let $\tilde{\mathbb{B}}_T^* := \{B_T(R) \in \tilde{\mathbb{B}}_T; c(R) + d(R) \leq T\}$, and for $w \in \mathbb{R}^T$ let $\tilde{L}(w) := \{R \neq 0; d(R) \leq T - 1 \text{ and } w \in B(R) \in \tilde{\mathbb{B}}_T^*\}$, $\tilde{R}(w) := \text{GCD}\{R; R \in \tilde{L}(w)\}$. As $q = 1$, by using Proposition 2.3(ii) it follows that $B(R) \in \tilde{\mathbb{B}}_T$ if and only if $R = 0$, $d(R) \geq T$ or $R = \sum_{k=0}^{T-1} a_k \sigma^k$ with $a_0 \neq 0$. From this one easily gets $B(\tilde{R}(w)) \in \tilde{\mathbb{B}}_T$. Now \tilde{P}^* is defined in analogy with P^* and with the same motivation.

DEFINITION OF \tilde{P}^* .

$$\tilde{P}_T^*: \mathbb{R}^T \rightarrow \tilde{\mathbb{B}}_T \text{ is defined by } \tilde{P}_T^* w := \begin{cases} B(\tilde{R}(w)) & \text{if } w \in B(\tilde{R}(w)), \\ \mathbb{R}^T & \text{if } w \notin B(\tilde{R}(w)), \end{cases}$$

$$\tilde{P}^* := \{\tilde{P}_t^*, t \in [1, T]\}.$$

PROPOSITION 8.4. Let $B_0 \in \mathbb{B}_T$. Then generically in $w \in B_0$, $\tilde{P}_T^* w = B(R)$ where $R := \text{GCD}\{\tilde{R} \neq 0; d(\tilde{R}) \leq T - 1 \text{ and } B_0 \subset B(\tilde{R}) \in \tilde{\mathbb{B}}_T^*\}$.

Proof. See the Appendix.

The properties of \tilde{P}^* are stated in the next theorem, which can be proved by using Proposition 8.4 in a way which is completely analogous to the proof of Theorem 4 by means of Corollary 8.2.

THEOREM 5. P^* is exact, bilaterally monotone, linear, truthful and strongly prudent with $\text{im } \tilde{P}_t^* = \mathbb{B}_{\tilde{P}_t^*}^u = \mathbb{B}_{\tilde{P}_t^*}^s = \{B(R); \text{there exists } \{R_\lambda, d(R_\lambda) \leq t - 1, B(R_\lambda) \in \tilde{\mathbb{B}}_t^*, \lambda \in \Lambda\}, \text{ such that } R = \text{GCD}\{R_\lambda, \lambda \in \Lambda\}\}$.

We illustrate \tilde{P}^* by some examples.

Example 8.5 (cf. Example 8.4). $T = 6$, $w = (1, 1, 2, 3, 5, 8)$, $R := \sigma^2 - \sigma - 1$, $\tilde{L}(w) = \{R, (\sigma - 1)R, (\sigma + 1)R\}$, $\tilde{R}(w) = R$, $w \in B(R)$ so $\tilde{P}_6^* w = B(R)$.

Example 8.6. $T = 6$, $w = (1, 2, 2, 3, 2, 2)$, $P_6^K w = B(\sigma^3 - \frac{4}{3}\sigma^2 - \frac{4}{3}\sigma + \frac{7}{3})$, $P_6^0 w = P_6^* w = B(\sigma^4 - \sigma)$, $\tilde{P}_6^* w = \mathbb{R}^6$.

Example 8.7 (cf. Example 8.2). $T = 6$, $w = (1, 2, 0, 4, 4, 4)$, $\tilde{L}(w) = \{\sigma^3 - \sigma - 2\} = \tilde{R}(w)$, $w \in B(\tilde{R}(w))$ so $\tilde{P}_6^* w = B(\sigma^3 - \sigma - 2)$.

Note that in the last example the extra a priori assumption that the phenomenon is translation invariant leads to a model, $B(\sigma^3 - \sigma - 2)$, which is of less complexity than in case one only assumes the phenomenon to be shift invariant, in which case we would get $P_6^* w = \mathbb{R}^6$. This, however, is a situation which generically does not occur, as for all $w \in \mathbb{R}^T$, $\tilde{L}(w) \subset L(w)$ so $B(\tilde{R}(w)) \supset B(R(w))$. As generically $P_T^* w = B(R(w))$

and one can show that also generically $\tilde{P}_T^* w = B(\tilde{R}(w))$ this implies that generically on every $B_0 \in \mathbb{B}_T$, $\tilde{P}_T^* w \supset P_T^* w$. Even the following holds true.

PROPOSITION 8.5. (i) If $B_0 \in \mathbb{B}_T$, then generically on B_0 , $\tilde{P}_T^* w = P_T^* w$.

(ii) If $B_0 \in \mathbb{B}_T$, $B_0 \notin \mathbb{B}_T$, then generically on B_0 , $\tilde{P}_T^* w = \mathbb{R}^T$.

Proof. See the Appendix.

So if a phenomenon is not translation invariant, then generically P^* accepts no laws.

9. Concluding remarks. In the foregoing we have introduced some concepts which are relevant for the problem of modeling data. For the special case of exact modeling of a finite time series in one variable by means of an autoregressive (deterministic) model we described a procedure P^* which has many desirable properties. An interesting question is whether there is a sense in which P^* is optimal. For example, one could restrict attention to procedures which are monotone, shift invariant, linear, truthful and prudent and investigate if there exists a procedure in this class with a maximal set \mathbb{B}_P^s of strongly corroborable models. In a sense such a procedure has maximal discriminatory power on \mathbb{B}_T .

An important issue is the construction of efficient and preferably recursive numerical algorithms to compute the assigned models for a given procedure. For P^0 this amounts to checking singularity of square submatrices of the incomplete Hankel array, while for P^* also greatest common divisors have to be computed. In case the observations $w(t)$ become available over time it is desirable to have algorithms which compute $P_{t+1}(w|_{[1,t+1]})$ on the basis of $P_t(w|_{[1,t]})$, $w(t+1)$, and as small amount of additional information as possible.

Two crucial assumptions in the foregoing were the requirement of exact modeling and that $q = 1$.

If $q > 1$ then one can again define a partial realization procedure. An important question is which laws are remarkable and connected with this is the question which variables are free and which are not. For $q = 1$, the variable is declared to be free if no remarkable law holds true for it. A problem is the compatibility of laws, which essentially is due to the fact that \mathbb{B}_T is not closed under intersection. An interesting issue is the definition of appropriate measures of complexity, e.g., by introducing the concepts of input and of state; cf. Willems [5].

The case of approximate modeling, of course, is of most practical interest and it raises the question of defining appropriate measures of fit, i.e., measuring how well a model fits the data. By increasing the complexity of a model one generally will be able to increase the fit. This leads to the interesting question of which decrease in fit is low enough to make a decrease in complexity sensible. This question is connected with the concepts of corroboration and remarkability. The approximate modeling question is a topic of ongoing research.

Notation.

$\mathbb{N} := \{1, 2, 3, \dots\}$,

$\mathbb{Z} := \{\dots, -2, -1, 0, 1, 2, \dots\}$,

$T \in \mathbb{N}$: length of time interval,

$\mathbb{T} := [1, T] := \{t \in \mathbb{N}; 1 \leq t \leq T\}$; $[t_1, t_2] := \{t \in \mathbb{N}; t_1 \leq t \leq t_2\}$,

σ : left shift operator; if $w \in (\mathbb{R}^q)^L$, $L \geq 2$, then $\sigma w \in (\mathbb{R}^q)^{L-1}$ with

$(\sigma w)(l) := w(l+1)$, $l \in [1, L-1]$,

$\mathbb{B}_T := \{B \subset (\mathbb{R}^q)^T; B \text{ linear}, \sigma B \subset B|_{[1, T-1]}\}$,

$\tilde{\mathbb{B}}_T := \{B \subset (\mathbb{R}^q)^T; B \text{ linear}, \sigma B = B|_{[1, T-1]}\}$,

$R = (r_{ij}) \in \mathbb{R}^{g \times q}[\sigma]$: matrix with elements in the ring $\mathbb{R}[\sigma]$ of polynomials in σ ,

$d(r)$: degree of $r \in \mathbb{R}[\sigma]$; $d(0) := -\infty$,

$$\begin{aligned}

L(w; d, I) &:= \{R \in L(w); I(R) \supset I, d(R) = d\}.
\end{aligned}$$

Appendix.

Proof of Proposition 2.2. Let $B \in \mathbb{B}_T$ and define $B^e := \{w \in (\mathbb{R}^q)^{\mathbb{N}}; w|_{[t, t+T-1]} \in B, \text{ for all } t \in \mathbb{N}\}$. Shift invariance of B implies $B = B^e|_{[1, T]}$. Using the terminology and results of Willems [5], B^e is a linear, shift invariant complete system and there exist $g \in \mathbb{N}$ and row proper $R \in \mathbb{R}^{g \times q}[\sigma]$ such that $B^e = \{w \in (\mathbb{R}^q)^{\mathbb{N}}; [R(\sigma)w](t) = 0, \text{ for all } t \in \mathbb{N}\} =: B_\infty(R)$. Let R' consist of the rows of R of degree at most $T-1$. Then R' is row proper, $d(R') \leq T-1$ and $B = B^e|_{[1, T]} = B_\infty(R')|_{[1, T]}$, because laws of degree $\geq T$ do not imply any restriction on $[1, T]$.

It suffices to prove $B_\infty(R')|_{[1, T]} = B_T(R')$. Let R' have rows

$$r_i(\sigma) = \sum_{k=0}^{d_i} q_k^{(i)} \sigma^k, \quad q_{d_i}^{(i)} \neq 0, \quad i \in [1, g'],$$

and let $L^+ \in \mathbb{R}^{g' \times q}$ have rows $q_{d_i}^{(i)}$.

Let $w \in B_\infty(R')|_{[1, T]}$, so there exists a $w^e \in (\mathbb{R}^q)^{\mathbb{N}}$ such that $w^e|_{[1, T]} = w$ and $[r_i(\sigma)w^e](t) = 0, t \in \mathbb{N}$. Now $d_i \leq T-1$, so $[r_i(\sigma)w^e](t) = 0, t \in [1, T-d_i], i \in [1, g']$, which implies $w \in B_T(R')$.

Conversely, let $w \in B_T(R')$. Then define $w^e(T+1)$ as a solution of $q_{d_i}^{(i)} w^e(T+1) + q_{d_i-1}^{(i)} w(T) + \dots + q_0^{(i)} w(T-d_i+1) = 0$, for all $i \in [1, g']$. Existence of a solution is guaranteed because L^+ is surjective (R' is row proper). Next define $w^e(T+2)$ as a solution of $q_{d_i}^{(i)} w^e(T+2) + q_{d_i-1}^{(i)} w^e(T+1) + q_{d_i-2}^{(i)} w(T) + \dots + q_0^{(i)} w(T-d_i+2)$, for all $i \in [1, g']$. In this way we recursively can define a $w^e \in (\mathbb{R}^q)^{\mathbb{N}}$ with $w^e|_{[1, T]} = w$ and $[R'(\sigma)w^e](t) = 0$, for all $t \in \mathbb{N}$, so $w \in B_\infty(R')|_{[1, T]}$. \square

Proof of Proposition 2.3. First let $B \in \mathbb{B}_T$. It follows from the proof of Proposition 2.2 that there exists a row proper R with $d(R) \leq T-1$ such that $B = B_T(R)$.

Conversely, let $d(R) \leq T-1$ and R row proper. Let R have rows

$$r_i(\sigma) = \sum_{k=0}^{d_i} q_k^{(i)} \sigma^k, \quad q_{d_i}^{(i)} \neq 0, \quad i \in [1, g],$$

and let $L^+ \in \mathbb{R}^{g \times q}[\sigma]$ have rows $q_{d_i}^{(i)}$. To show that $B_T(R) \in \mathbb{B}_T$ it suffices to consider shift invariance, i.e., $\sigma B_T(R) \subset B_T(R)|_{[1, T-1]}$. Now this condition is equivalent to existence of a solution $a \in \mathbb{R}^q$ of the set of equations $q_{d_i}^{(i)} a + q_{d_{i-1}}^{(i)} w(T) + \cdots + q_0^{(i)} w(T-d_i+1) = 0$ for all $i \in [1, g]$, where $w \in B_T(R)$. Because R is row proper, L^+ is surjective and existence of a solution is guaranteed.

Next assume $d(R) \leq T-1$ with R zero order bilaterally row proper. One easily shows by a similar reasoning as before that $B_T(R) \in \hat{\mathbb{B}}_T$.

Finally let $B \in \hat{\mathbb{B}}_T$. Let $B^{ee} := \{w \in (\mathbb{R}^q)^{\mathbb{Z}}; w|_{[t, t+T-1]} \in B \text{ for all } t \in \mathbb{Z}\}$. As B is translation invariant, $B = B^{ee}|_{[1, T]}$. It follows from the results in Willems [5] that there exists a bilaterally row proper R such that $B^{ee} = B^{ee}(R) := \{w \in (\mathbb{R}^q)^{\mathbb{Z}}; [R(\sigma)w](t) = 0 \text{ for all } t \in \mathbb{Z}\}$. As $B^{ee}(R) = B^{ee}(DR)$ for any diagonal matrix $D = \text{diag}(d_1, \dots, d_g) \in \mathbb{R}^{g \times g}[\sigma]$, $d_i := \sigma^{n_i}$, $n_i \in \mathbb{Z}$, it follows that R can be chosen to be zero order bilaterally row proper.

It remains to show that $d(R) \leq T-1$ and that $B^{ee}(R)|_{[1, T]} = B_T(R)$. This follows by a reasoning completely analogous to the one given in the proof of Proposition 2.2. \square

Proof of Lemma 2.1. Let $B(R_i) \in \mathbb{B}_T$, $i = 1, 2$. Define $B_i^e := \{w \in (\mathbb{R}^q)^{\mathbb{N}}; w|_{[t, t+T-1]} \in B(R_i) \text{ for all } t \in \mathbb{N}\}$, $i = 1, 2$. Shift invariance of $B(R_i)$ implies $B_i^e|_{[1, T]} = B(R_i)$, $i = 1, 2$, and $B(R_1) \subset B(R_2)$ is equivalent to $B_1^e \subset B_2^e$.

Define $B_\infty(R_i) := \{w \in (\mathbb{R}^q)^{\mathbb{N}}; [R_i(\sigma)w](t) = 0 \text{ for all } t \in \mathbb{N}\}$, $i = 1, 2$. Because $d(R_i) \leq T-1$ there holds $B_i^e = B_\infty(R_i)$, $i = 1, 2$, which is seen as follows. Let R_i have rows $r_j^{(i)}$, $j \in [1, g_i]$. If $w \in B_\infty(R_i)$, then $[r_j^{(i)}(\sigma)w](t) = 0$ for all $j \in [1, g_i]$ for all $t \in \mathbb{N}$, especially for all $t \in [\tau, \tau + T - d(r_j^{(i)}) - 1]$, for all $\tau \in \mathbb{N}$, so $w|_{[\tau, \tau+T-1]} \in B(R_i)$ for all $\tau \in \mathbb{N}$, hence $w \in B_i^e$. Conversely, if $w \in B_i^e$ then with $w_t := w|_{[t, t+T-1]}$, $t \in \mathbb{N}$, $w_t \in B_i(R)$, so $[r_j^{(i)}(\sigma)w_t](\tau) = 0$ for all $j \in [1, g_i]$, for all $\tau \in [1, T - d(r_j^{(i)})] \neq \emptyset$, especially $[r_j^{(i)}(\sigma)w_t](1) = [r_j^{(i)}(\sigma)w](t) = 0$ for all $t \in \mathbb{N}$, hence $w \in B_\infty(R_i)$.

So to prove Lemma 2.1 it remains to prove that $\{B_\infty(R_1) \subset B_\infty(R_2)\} \Leftrightarrow \{\text{there exists an } F \text{ such that } R_2 = FR_1\}$. Now (\Leftarrow) is obvious. For (\Rightarrow) we refer to Nieuwenhuis and Willems [3]. In fact there the time axis is \mathbb{Z} while here it is \mathbb{N} , but the results easily generalize to this case. \square

Proof of Proposition 2.4 and Lemma 2.2. First we consider the results for LCLM and addition.

Let R_i be row proper, $i = 1, 2$. Define $B_\infty(R_i) := \{w \in (\mathbb{R}^q)^{\mathbb{N}}; [R_i(\sigma)w](t) = 0 \text{ for all } t \in \mathbb{N}\}$ and $B := B_\infty(R_1) + B_\infty(R_2)$. From Willems [5] it follows that there exists a row proper R_0 such that $B = B_\infty(R_0)$. We will show $R_0 \in \text{LCLM}(R_1, R_2)$.

Row properness implies that for all $T \in \mathbb{N}$ $B_T(R_i) = B_\infty(R_i)|_{[1, T]}$, $i = 1, 2$, and $B_T(R_0) = B_\infty(R_0)|_{[1, T]}$. As $[B_\infty(R_1) + B_\infty(R_2)]|_{[1, T]} = B_\infty(R_1)|_{[1, T]} + B_\infty(R_2)|_{[1, T]}$ this implies that for all $T \in \mathbb{N}$ $B_T(R_1) + B_T(R_2) = B_T(R_0)$.

Taking $T \equiv \max\{d(R_0), d(R_1), d(R_2)\} + 1$, $B_T(R_i) \subset B_T(R_0)$ by Lemma 2.1 implies there exists F_i such that $R_0 = F_i R_i$. Moreover, if for \tilde{R} there exists \tilde{F}_i such that $\tilde{R} = \tilde{F}_i R_i$, $i = 1, 2$, then let U unimodular be such that $U\tilde{R} = \begin{pmatrix} \tilde{R} \\ 0 \end{pmatrix}$ with \tilde{R} row proper. Then $B_\infty(\tilde{R}) = B_\infty(\tilde{R}) \supset B_\infty(R_1) + B_\infty(R_2) = B_\infty(R_0)$; hence for all $T \in \mathbb{N}$ $B_T(\tilde{R}) \supset B_T(R_0)$. Let $T \equiv \max\{d(R_0), d(\tilde{R})\} + 1$; then Lemma 2.1 implies there exists \tilde{F} such that $\tilde{R} = \tilde{F} R_0$, so $\tilde{R} = F R_0$ where $F := U^{-1} \begin{pmatrix} \tilde{F} \\ 0 \end{pmatrix}$. This proves $R_0 \in \text{LCLM}(R_1, R_2)$ and (i) of Lemma 2.2 for LCLM.

Next let $R \in \text{LCLM}(R_1, R_2)$ be row proper. Then there exists F_0 such that $R = F_0 R_0$ and there exists F such that $R_0 = FR$. So $B_\infty(R) = B_\infty(R_0) = B_\infty(R_1) + B_\infty(R_2)$; hence

$B_T(R) = B_T(R_1) + B_T(R_2)$ which proves (i) of Proposition 2.4. Moreover, $R = F_0FR$ and $R_0 = FF_0R_0$. Because R_0 and R have full row rank $F_0F = FF_0 = I$, which proves (ii) of Lemma 2.2 for LCLM.

Now second we consider the results for GCRD and intersection.

Let R_1, R_2 be row proper. From Willems [5] it follows that there exists a row proper R_0 such that $B_\infty(R_0) = B_\infty(R_1) \cap B_\infty(R_2)$. That $R_0 \in \text{GCRD}(R_1, R_2)$ is proved in a way analogous to the result for LCLM, and one easily gets Lemma 2.2(i) and (ii) for GCRD.

To prove Proposition 2.4(ii), let $R \in \text{GCRD}(R_1, R_2)$ row proper and $d(R_i) \leq T-1$, $i = 1, 2$. By Lemma 2.2(ii) there exists a unimodular U such that $R = UR_0$, so $B_\infty(R) = B_\infty(R_0)$ and $B_T(R) = B_T(R_0)$. So it suffices to prove that $B_T(R_0) = \sum \{B_T(\tilde{R}); B_T(\tilde{R}) \subset B_T(R_1) \cap B_T(R_2)\}$.

Now $B_\infty(R_0) \subset B_\infty(R_i)$ and row properness implies $B_T(R_0) \subset B_T(R_i)$, $i = 1, 2$; hence $B_T(R_0) \subset B_T(R_1) \cap B_T(R_2)$. So it suffices to prove that for \tilde{R} row proper $\{B_T(\tilde{R}) \subset B_T(R_1) \cap B_T(R_2)\} \Rightarrow \{B_T(\tilde{R}) \subset B_T(R_0)\}$. Let \tilde{R} consist of the rows of \tilde{R} of degree at most $T-1$, then $d(R_i) \leq T-1$, $i = 1, 2$, and Lemma 2.1 imply there exists an F_i such that $R_i = F_i\tilde{R}$; hence $B_\infty(\tilde{R}) \subset B_\infty(R_0)$ and $B_T(\tilde{R}) = B_T(\tilde{R}) \subset B_T(R_0)$. \square

Proof of Proposition 5.1. Let P be bilaterally monotone on $B \in \tilde{\mathbb{B}}_T$. By taking $t = 2$ in the definition of bilateral monotonicity we have that generically in $w \in B$, $\{B_{T-1}(R) \in P_{T-1}(w|_{[2,T]})$, $B' \in P_T w\} \Rightarrow \{\sigma B' \subset B_{T-1}(R)\} \Rightarrow \{B' \subset B_T(\sigma R)\}$, which proves the shift invariance condition for $t = T$.

To prove this condition for general $t \in [2, T]$, let $B_{t-1}(R) \in P_{t-1}(w|_{[2,t]})$ and $B' \in P_t(w|_{[1,t]})$. Now $B \in \tilde{\mathbb{B}}_T$, so by Proposition 2.1(ii) there exists $\tilde{w} \in B$, $\tilde{w}|_{[T-t+1,T]} = w|_{[1,t]}$ and $B_{t-1}(R) \in P_{t-1}(\tilde{w}|_{[T-t+2,T]})$, $B' \in P_t(\tilde{w}|_{[T-t+1,T]})$. Now bilateral monotonicity implies that generically in $\tilde{w} \in B$, $\sigma B' \subset B_{t-1}(R)$; hence $B' \subset B_t(\sigma R)$. We have to prove that this holds generically in $w \in B$. It is sufficient to construct a linear bijection $w \rightarrow \tilde{w}$. Without giving details this can be done as follows.

Let $B^{ee} := \{w \in \mathbb{R}^q\}^{\mathbb{Z}}$; $w|_{[\tau, \tau+T-1]} \in B$ for all $\tau \in \mathbb{Z}$. Because B is translation invariant $B^{ee}|_{[1,T]} = B$. It can be shown that there exists a linear injection $L: B \rightarrow B^{ee}: w \rightarrow w^{ee}$ with $w^{ee}|_{[1,T]} = w$ such that for all $\tau \in \mathbb{Z}$ $L_\tau: B \rightarrow B: w \rightarrow w^{ee}|_{[\tau+1, \tau+T]}$ is a bijection. Then for $w \in B$ take $\tilde{w} := L_{t-T} w$. \square

Proof of Lemma 6.1. (\Leftarrow) Let $r(n)$ be linearly independent from $r(1), \dots, r(n-1)$ and $r(n+1)$ linearly dependent on $r(1), \dots, r(n)$, say $r(n+1) = \sum_{i=1}^n \alpha_i r(i)$ (defined for the columns $1, \dots, t-n$ of $H_t(w)$). Define $w(\tau)$, $\tau > t$, recursively by $w(\tau) = \sum_{i=1}^n \alpha_i w(\tau - n - 1 + i)$ and define a Hankel extension M of $H_t(w)$ by $m_{ij} := w(i+j-1)$. Using the Hankel structure one gets $\text{rank } M = n$; hence $\text{rank } H_t(w) \leq n$. To prove $\text{rank } H_t(w) \geq n$, let M' be an arbitrary extension of $H_t(w)$ and let $d := \text{rank } M'$. If $d < n$ this would imply that among the rows $1, \dots, n$ of M' at least one, say row n' , is linearly dependent on the foregoing ones. This implies that $r(n')$ is linearly dependent on $r(1), \dots, r(n'-1)$, and because of the Hankel structure of $H_t(w)$ and the fact $n' \leq n$ this means that $r(n)$ would be linearly dependent on $r(1), \dots, r(n-1)$. So $\text{rank } M' \geq n$ and hence $\text{rank } H_t(w) \geq n$.

(\Rightarrow) Let $\text{rank } H_t(w) = n$. Then $r(n)$ cannot be linearly dependent on $r(1), \dots, r(n-1)$ as the construction above would give $\text{rank } H_t(w) \leq n-1$. Moreover, $r(n+1)$ cannot be linearly independent from $r(1), \dots, r(n)$ as this would imply that any extension of $H_t(w)$ would have rank at least $n+1$. \square

Proof of Lemma 6.2. A minimal rank extension which is Hankel was constructed in the proof of (\Leftarrow) of Lemma 6.1. \square

Proof of Proposition 6.2. Let $R \neq 0$ have degree d . First assume $d \leq \text{ENT}(t/2)$, so we have to show that generically in $w \in B(R)$ $\text{rank } H_t(w) = d$.

For $w \in B(R)$ row $d+1$ of $H_t(w)$ is linearly dependent on the foregoing ones, so $\text{rank } H_t(w) \leq d$. To prove that generically $\text{rank } H_t(w) = d$, it suffices to show that generically row d is linearly independent from the foregoing ones. Sufficient for this is that generically in $w \in B(R)$ $\text{rank } H_{d,d}(w) = d$, where

$$H_{d,d}(w) := \begin{bmatrix} w(1) & w(2) & \cdots & w(d) \\ w(2) & w(3) & \cdots & w(d+1) \\ \vdots & \vdots & & \vdots \\ w(d) & w(d+1) & \cdots & w(2d-1) \end{bmatrix}.$$

Note $d \leq \text{ENT}(t/2)$, so $2d-1 \leq t$ and $H_{d,d}(w)$ is well defined.

In $B(R)$, $w(\tau)$, $\tau \in [1, d]$, can be chosen arbitrarily while $w(\tau)$, $\tau \in [d+1, t]$ can be expressed as linear functions of $w(\tau)$, $\tau \in [1, d]$. So for $w \in B(R)$, $\det H_{d,d}(w)$ can be considered as a polynomial in $(w(1), \dots, w(d)) \in \mathbb{R}^d$. It suffices to show that $\det H_{d,d}(w)$ is not the zero polynomial, because then $\{w, \text{rank } H_{d,d}(w) < d\} = \{w; \det H_{d,d}(w) = 0\}$ is a proper algebraic variety and hence $\text{rank } H_{d,d}(w) = d$ generally in $w \in B(R)$.

That $\det H_{d,d}(w) \neq 0$ is seen as follows. We claim that $\det H_{d,d}(w)$ contains $\{w(d)\}^d$ as a term with coefficient ± 1 . Indeed, $\det H_{d,d}(w) = \sum_{p \in P} \text{sign}(p) \cdot \prod_{i=1}^d a_{ip(i)}$ where $H_{d,d}(w) = (a_{ij})$, P denotes the set of all permutations of $\{1, \dots, d\}$ and $\text{sign}(p) \in \{-1, +1\}$. In order to get $\{w(d)\}^d$, from every row and column in $H_{d,d}(w)$ one has to choose an element which involves $w(d)$. In the first row this is only the element $(1, d)$ so $p(1) = d$. In the second row only the elements $(2, d-1)$ and possibly $(2, d)$ contain $w(d)$, so necessarily $p(2) = d-1$. Going on in this way one gets for $\{w(d)\}^d$ the unique permutation $p = \{d, d-1, \dots, 2, 1\}$. This proves our claim and hence $\det H_{d,d}(w) \neq 0$.

Next assume $d > \text{ENT}(t/2)$. By a similar reasoning as before one can show that generically in $w \in B(R)$ $H_{\text{ENT}(t/2), \text{ENT}(t/2)}(w)$ has rank $\text{ENT}(t/2)$ and hence row $\text{ENT}(t/2)+1$ of $H_t(w)$ then is linearly dependent on the foregoing ones (its length is $\text{ENT}(t/2)$ if t is even, $\text{ENT}(t/2)-1$ if t is odd). So then $\text{rank } H_t(w) \leq \text{ENT}(t/2)$ and hence it equals $\text{ENT}(t/2)$ as row $\text{ENT}(t/2)$ is linearly independent from the foregoing ones. \square

Proof of Theorem 1. (i) The proof is obvious.

(ii) Not monotone. Let $B = \mathbb{R}^T$ and $t \in [3, T]$ odd. Then generally in $w \in B$ there holds that for $B_{t-1} \in P_{t-1}^K(w|_{[1, t-1]})$, $B_t \in P_t^K(w|_{[1, t]})$ $\dim B_{t-1} = (t-1)/2$ $\dim B_t = (t+1)/2$. For $t \geq 3$ $(t+1)/2 \leq t-1$ and $\dim B_t = (t+1)/2$ implies $\dim B_{t|_{[1, t-1]}} = (t+1)/2$ so generally $B_{t|_{[1, t-1]}} \not\subset B_{t-1}$ and P^K is not monotone. We have used the fact that $\{B \in \mathbb{B}_t, \dim B = d\} \Rightarrow \{\dim B|_{[1, \tau]} = d \text{ for all } \tau \in [d, t]\}$ which follows from $\{B \in \mathbb{B}_t, \dim B = d\} \Leftrightarrow \{\text{there exists } R \text{ of degree } d \text{ such that } B = B(R)\}$.

Not shift invariant. Let $B = \mathbb{R}^T$ and take $t = 3$, so $B|_{[2, 3]} = \mathbb{R}^2$ and $B|_{[1, 3]} = \mathbb{R}^3$. Let $w \in B$, $w|_{[1, 3]} = (a, b, c)$ with $a \neq 0$, $b \neq 0$, $ac - b^2 \neq 0$. Then $P_2^K(w|_{[2, 3]}) = B_2(\sigma - (c/b))$ and $B_3(\sigma^2 - (c/a)) \in P_3^K(w|_{[1, 3]})$. Shift invariance would require that generically $B_3(\sigma^2 - (c/a)) \subset B_3(\sigma(\sigma - (c/b))) = B_3(\sigma^2 - (c/b)\sigma)$ which clearly does not hold true.

Not linear. Take $T = 3$, $B_1 := B(\sigma^2 - 1)$, $B_2 := B(\sigma + 2)$. Then $B_1 + B_2 = \mathbb{R}^3$ so generically in $(w_1, w_2) \in B_1 \times B_2$ if $B \in P_3^K(w_1 + w_2)$ then $\dim B = 2$. Also generically $B_1 \in P_3^K w_1$ and $B_2 \in P_3^K w_2$. Linearity would require that generically $\mathbb{R}^3 = B_1 + B_2 \subset B$ which is false.

(iii) Take for example $T = 3$, $B_0 = \mathbb{R}^3$. Then generically in $w \in B_0$ if $B \in P_T^K w$ then $\dim B = 2$ so $B_0 \not\subset B$.

(iv) We will determine $\text{im } P_T^K, \mathbb{B}_{P_T^K}^w, \mathbb{B}_{P_T^K}^s$.

That $\text{im } P_T^K = \mathbb{B}_T$ is seen as follows. If $B = \mathbb{R}^T$ then take $w \in \mathbb{R}^T$ defined by $w(t) = 0$, $t \in [1, T-1]$, $w(T) = 1$, so $\text{rank } H_T(w) = T$ and by Proposition 6.1(i) $\mathbb{R}^T = P_T^K w$. If $\mathbb{R}^T \neq B \in \mathbb{B}_T$ then according to Proposition 2.3(i) there exists R with $d = d(R) \leq T-1$

such that $B = B(R)$. Choose $w \in B(R)$ by $w(\tau) = 0$, $\tau \in [1, d-1]$, $w(d) = 1$ and $w(\tau)$ for $\tau \in [d+1, t]$ computed by means of R . Then $\text{rank } H_T(w) = d$ and by Proposition 6.1 (i) $B(R) \in P_T^K w$.

Next we prove $\mathbb{B}_{P_T^K}^w = \{B \in \mathbb{B}_T; c(B) \leq \text{ENT}(T/2)\}$. From Example 6.1 we know already $\mathbb{R}^T \not\subset \mathbb{B}_{P_T^K}^w$. Now let $\mathbb{R}^T \neq B \in \mathbb{B}_T$ and $R \neq 0$ with $c(B) = d = d(R) \leq T-1$ such that $B = B(R)$. If $d > \text{ENT}(T/2)$ then from Proposition 6.2 generically in $w \in B(R)$ if $B' \in P_T w$ then $\dim B = \text{ENT}(T/2)$; hence $B(R) \notin P_T^K w$, so $B(R) \notin \mathbb{B}_{P_T^K}^w$. If $d \leq \text{ENT}(T/2)$ then generically in $w \in B(R)$ $\text{rank } H_T(w) = d$ so $B(R) \in P_T^K w$ and $B(R) \in \mathbb{B}_{P_T^K}^w$.

Finally we consider $\mathbb{B}_{P_T^K}^s$. First let T be even. Let $B \in \mathbb{B}_T$ with $d := c(B) \leq \text{ENT}(T/2)$. Then generically in $w \in B$ the first d rows of $H_T(w)$ are linearly independent and row $d+1$ has $T-d \geq T/2 \geq d$ elements, and this row is linearly dependent on the foregoing ones. Using Proposition 6.1(ii) this implies that generically in $w \in B$ $P_T^K w = B$ (i.e., assigned model is unique). So $\mathbb{B}_{P_T^K}^s \supset \mathbb{B}_{P_T^K}^w$, hence equality holds.

Next let T be odd. If $c(B) \leq \text{ENT}(T/2) - 1$ then by a reasoning as before one gets $B \in \mathbb{B}_{P_T^K}^s$. If $d := c(B) = \text{ENT}(T/2)$ then in $H_T(w)$ row $d+1$ consists of $T-d = (T-1)/2 < d = (T+1)/2$ elements and generically $P_T^K w$ is not unique; hence $B \notin \mathbb{B}_{P_T^K}^s$.

(v) As can be seen from the reasoning in (ii), (iii) and (iv), lacking the properties of monotonicity, linearity, truthfulness and prudence has not to do with possible nonunique assignment of models by P^K . We shall show that shift invariance also cannot be obtained by choice of a selection rule S .

To get shift invariance, taking the example in (ii) with $a \neq 0$, $b \neq 0$, $c \neq 0$, $ac - b^2 \neq 0$, this would require that for $B \in P_3^K(a, b, c)$, $B \subset B(\sigma^2 - (c/b)\sigma)$ while $\dim B = 2$, so this requires $S_3(a, b, c) = B(\sigma^2 - (c/b)\sigma)$. Moreover it is required that (generically) $S_4(d, a, b, c) \subset B(\sigma^3 - (c/b)\sigma^2)$. Now generically if $B \in P_4^K(d, a, b, c)$ then $\dim B = 2$. Let $B(\sigma^2 + \alpha\sigma + \beta) \in P_4^K(d, a, b, c)$. In order that $B(\sigma^2 + \alpha\sigma + \beta) \subset B(\sigma^3 - (c/b)\sigma^2)$ according to Lemma 2.1 there has to exist a γ such that $(\sigma^2 + \alpha\sigma + \beta)(\sigma + \gamma) = \sigma^3 - (c/b)\sigma^2$, which implies that $(\alpha, \beta) = (0, 0)$ or $(\alpha, \beta) = (-c/b, 0)$. But $B(\sigma^2) \notin P_4^K(d, a, b, c)$ (it requires $b = c = 0$) and $B(\sigma^2 - (c/b)\sigma) \notin P_4^K(d, a, b, c)$ (it requires $ac - b^2 = 0$). So it follows that it is impossible to construct a shift invariant selection rule for P^K . \square

Proof of Theorem 2. The proof of this theorem is quite lengthy and will be split in a number of steps. The result is proved by using a number of lemmas, some of which play a role in the proof of Proposition 8.1.

First we introduce some notation. T is assumed to be fixed throughout. For $R = \sum_{k=0}^{T-1} a_k \sigma^k \in \mathbb{R}[\sigma]$ let $I(R) := \{k \in [0, T-1]; a_k \neq 0\}$, so $\# I(R) = T - c(R)$. Let $\mathbb{B}^*(d)$, $\mathbb{B}^*(I)$ and $\mathbb{B}^*(d, I)$ as subsets of \mathbb{B}_T^* be defined as follows. $\mathbb{B}^*(d) := \{B(R) \in \mathbb{B}_T^*; d(R) = d\}$, $\mathbb{B}^*(I) := \{B(R) \in \mathbb{B}_T^*; I(R) \supset I\}$, $\mathbb{B}^*(d, I) := \mathbb{B}^*(d) \cap \mathbb{B}^*(I)$. Moreover define $W(d)$, $W(I)$ and $W(d, I)$ as subsets of \mathbb{R}^T by $W(d) := \cup \{B(R); B(R) \in \mathbb{B}^*(d)\} = \{w \in \mathbb{R}^T; \text{there exists } B(R) \in \mathbb{B}^*(d), w \in B(R)\}$, $W(I) := \cup \{B(R); B(R) \in \mathbb{B}^*(I)\}$ and $W(d, I) := \cup \{B(R); B(R) \in \mathbb{B}^*(d, I)\}$.

Let $B_0 \in \mathbb{B}_T$ be fixed, $w \in B_0$ and $H_T(w)$ its incomplete Hankel array. We now first give an outline of the proof of Theorem 2 by means of four lemmas and then will give the proof of these lemmas.

LEMMA 1. For every (d, I) either (i) $w \notin W(d, I)$ generically in $w \in B_0$, or (ii) $B_0 \subset W(d, I)$.

LEMMA 2. $\{B_0 \subset W(d, I)\} \Rightarrow \{\text{there exists } B(R(d, I)) \in \mathbb{B}^*(d, I) \text{ such that } B_0 \subset B(R(d, I))\}$.

This lemma states that if for every $w \in B_0$ there exists a model $B_w(R) \in \mathbb{B}^*(d, I)$ such that $w \in B_w(R)$, then there exists such a model independent from $w \in B_0$.

For B_0 define $d_0 \in [0, T]$ as follows. If $B_0 \not\subset W(d, I)$ for all $d \in [0, T-1]$ then $d_0 := T$, else $d_0 := \min \{d \in [0, T-1]; \text{ there exists } I, B_0 \subset W(d, I)\}$.

If $d_0 = T$, then generically in $w \in B_0$, $w \notin W(d)$ for all $d \in [0, T-1]$, which means that generically row $d+1$ of H_T is not linearly dependent on less than $T-d$ foregoing rows of H_T , so $P_T^0 w = \mathbb{R}^T$ generically on B_0 and Theorem 2 follows as obviously there is no $B(R) \in \mathbb{B}_T^*$ with $B_0 \subset B(R)$ and $c(B(R)) < T$ in this case.

For $d_0 \in [0, T-1]$ let J_0 be defined by $J_0 := \{I; B_0 \subset W(d_0, I)\}$. Because by Lemma 1 generically on B_0 , $w \notin W(d)$ for $d < d_0$ and by Lemma 2 $B_0 \subset B(R(d_0, I))$ for $I \in J_0$, it follows from the definition of P_T^0 that generally on B_0 , $\{B(R(d_0, I)); I \in J_0\} \subset P_T^0 w \subset \mathbb{B}^*(d_0)$. Indeed, on B_0 generally no remarkable laws of degree $d < d_0$ are satisfied while remarkable laws of degree d_0 always exist. Because of Lemma 1 we even have that generically on B_0 , $\{B(R(d_0, I)); I \in J_0\} \subset P_T^0 w \subset \bigcup \{\mathbb{B}^*(d_0, I); I \in J_0\}$.

LEMMA 3. For $I \in J_0$ generically on B_0 $P_T^0 w \cap \mathbb{B}^*(d_0, I)$ is a singleton, i.e., $B(R(d_0, I))$.

The generic way in which P_T^0 assigns models on the basis of data from B_0 is described in Lemma 4, which is a direct consequence of Lemma 3 and the preceding discussion.

LEMMA 4. Generically for $w \in B_0$, $P_T^0 w = \{B(R(d_0, I)); I \in J_0\}$.

Now from Lemma 2 and Lemma 4 it follows that generally on B_0 if $B \in P_T^0 w$ then $B_0 \subset B$ and $c(B) = d_0$. To conclude the proof of Theorem 2, note that by definition of d_0 , if $B \in \mathbb{B}_T^*$ with $c(B) < d_0$, then $B_0 \not\subset B$. On the other hand, if $B \in \mathbb{B}_T^*$, $c(B) = d_0$, $B_0 \subset B$, then generically $B \in P_T^0 w$. This proves Theorem 2.

Finally we will prove the foregoing lemmas.

Proof of Lemma 1. Assume that $w \notin W(d, I)$ is not generically true on B_0 ; then we have to show that $B_0 \subset W(d, I)$.

Let $[0, T-1] \setminus I = \{i_1, i_2, \dots, i_{c-1}, d\}$ with $0 \leq i_1 < i_2 < \dots < i_{c-1} < d$ and for $w \in B_0$ define $H_I(w)$ by

$$H_I(w) := \begin{bmatrix} w(i_1+1) & w(i_1+2) & \cdots & w(i_1+T-d) \\ w(i_2+1) & w(i_2+2) & \cdots & w(i_2+T-d) \\ \vdots & \vdots & & \vdots \\ w(i_{c-1}+1) & w(i_{c-1}+2) & \cdots & w(i_{c-1}+T-d) \\ w(d+1) & w(d+2) & \cdots & w(T) \end{bmatrix}.$$

Now $w \in W(d, I)$ if and only if the last row of $H_I(w)$ is linearly dependent on the foregoing ones. It is given that this is not generically false on B_0 and we have to show that it is then always true on B_0 . To do this it suffices to express the statement (S) "The last row of $M \in \mathbb{R}^{n_1 \times n_2}$ is linearly dependent on the foregoing ones" as an algebraic condition on the elements of M . If this is the case, then $w \in W(d, I)$ is an algebraic condition on $w(1), \dots, w(d_0)$ where $\bar{d}_0 := \dim B_0$, as $w(t)$, $t \in [\bar{d}_0+1, T]$, can be expressed as linear functions of $w(1), \dots, w(d_0)$. As it is given that this condition is not generically falsified it is satisfied everywhere on B_0 , which then proves Lemma 1.

An algebraic formulation of (S) can be derived as follows. Partition $M = \begin{pmatrix} \tilde{M} \\ m \end{pmatrix}$ where m denotes the last row of M . One easily verifies that $\{m \text{ linearly dependent on rows } \tilde{M}\} \Leftrightarrow \{\ker \tilde{M} = \ker M\} \Leftrightarrow \{m^T \perp \ker \tilde{M}\} \Leftrightarrow \{m^T \perp \ker \tilde{M}^T \tilde{M}\}$. Let $(\tilde{M}^T \tilde{M})^-$ denote the Moore-Penrose generalized inverse of $\tilde{M}^T \tilde{M}$. It is well known (see, e.g., Campbell and Meijer [1, Thms. 7.3.4, 7.5.1]) that $\ker \tilde{M}^T \tilde{M} = \text{im}(I - (\tilde{M}^T \tilde{M})^- \tilde{M}^T \tilde{M})$ and because $\tilde{M}^T \tilde{M}$ is symmetric there exists a polynomial p such that $(\tilde{M}^T \tilde{M})^- = p(\tilde{M}^T \tilde{M})$. Define $p_i := (I - p(\tilde{M}^T \tilde{M}) \cdot \tilde{M}^T \tilde{M}) \cdot e_i$ where e_i denotes the i th unit vector, then (S) is equivalent to $\sum_i \langle m^T, p_i \rangle^2 = 0$ which is an algebraic condition on the elements of M . \square

Proof of Lemma 2. Let $B_0 \subset W(d, I)$ and $[0, T-1] \setminus I = \{i_1, \dots, i_{c-1}, d\}$ as in the proof of Lemma 1. On B_0 the last row of $H_I(w)$ always is linearly dependent on the foregoing ones, so for all $t \in [1, T-d]$, for all $w \in B_0$, $\{w(i_k+t)=0, k \in [1, c-1]\} \Rightarrow \{w(d+t)=0\}$. Because B_0 is linear this implies that for all $t \in [1, T-d]$ there is a map $f_t: B_0|_{\{i_k+t; k \in [1, c-1]\}} \rightarrow B_0|_{\{d+t\}}: (w(i_1+t), \dots, w(i_{c-1}+t)) \rightarrow w(d+t)$ such that $(w(i_1+t), \dots, w(i_{c-1}+t), f_t(w(i_1+t), \dots, w(i_{c-1}+t))) \in B_0|_{\{i_k+t; k \in [1, c-1]\} \cup \{d+t\}}$. Linearity of B_0 implies linearity of f_t , say $f_t(w(i_1+t), \dots, w(i_{c-1}+t)) = \sum_{k=1}^{c-1} a_k(t)w(i_k+t)$. Shift invariance of B_0 implies $w(d+t) = (\sigma^{t-1}w)(d+1) = \sum_{k=1}^{c-1} a_k(1)(\sigma^{t-1}w)(i_k+1) = \sum_{k=1}^{c-1} a_k(1)w(i_k+t)$ for all $t \in [1, T-d]$. Define $R(d, I) := -\sigma^d + \sum_{k=1}^{c-1} a_k(1)\sigma^{i_k}$, then for $w \in B_0$, $w \in B(R(d, I))$. Hence $B_0 \subset B(R(d, I)) \in \mathbb{B}^*(d, I)$. \square

To prove Lemma 3 we will make use of a result stated in Lemma 5 which also plays a role in the proof of Proposition 8.1. Let $0 \leq i_1 < i_2 < \dots < i_{c-1} < d \leq T-c$ and

$$M(w) := \begin{bmatrix} w(i_1+1) & w(i_1+2) & \cdots & w(i_1+T-d) \\ w(i_2+1) & w(i_2+2) & \cdots & w(i_2+T-d) \\ \vdots & \vdots & & \vdots \\ w(i_{c-1}+1) & w(i_{c-1}+2) & \cdots & w(i_{c-1}+T-d) \end{bmatrix}.$$

LEMMA 5. If rank $M(w) \leq c-2$ everywhere on B_0 , then there exists $R \neq 0$, $d(R) \leq i_{c-1}$, $I(R) \supset [0, T-1] \setminus \{i_1, \dots, i_{c-1}\}$, such that $B_0 \subset B(R) \in \mathbb{B}_T^*$.

Proof of Lemma 5. There is at least one row of M which is not generically linearly independent from the foregoing ones, say row k_0 . Exactly analogous to the proof of Lemma 1 it follows that this row then always is linearly dependent on the foregoing ones. Exactly analogous to the proof of Lemma 2 this implies existence of a_k such that on B_0 $w(i_{k_0}+t) = \sum_{k=1}^{k_0-1} a_k w(i_k+t)$, $t \in [1, T-d]$. By shift invariance of B_0 this then also holds true on $[1, T-i_{k_0}]$. Define

$$R := \sigma^{i_{k_0}} - \sum_{k=1}^{k_0-1} a_k \sigma^{i_k},$$

then $B_0 \subset B(R) \in \mathbb{B}_T^*$ while $d(R) = i_{k_0} \leq i_{c-1}$ and $I(R) \supset [0, T-1] \setminus \{i_1, \dots, i_{c-1}\}$. \square

Proof of Lemma 3. Let $I \in J_0$, and define M as before, with $\{i_1, \dots, i_{c-1}, d_0\} := [0, T-1] \setminus I$.

We state that generically on B_0 , rank $M(w) = c-1$. For suppose this is not true; then $\det MM^T \neq 0$ is not generic, so $\det MM^T = 0$ on B_0 and rank $M(w) \leq c-2$ on B_0 . By Lemma 5 this would imply there exists $R \neq 0$ such that $B_0 \subset B(R) \in \mathbb{B}^*(d', I')$ where $d' \leq i_{c-1} < d_0$ and $I' \supset [0, T-1] \setminus \{i_1, \dots, i_{c-1}\}$. Hence $B_0 \subset B(R) \subset W(d', I')$ and $d' < d_0$, which contradicts the definition of d_0 .

Now suppose $B(R_j) \in P_T^0 w \cap \mathbb{B}^*(d_0, I)$, $j = 1, 2$. Let $R_j(\sigma) = \sigma^d + \sum_{k=1}^{c-1} a_k^j \sigma^{i_k}$, $a^j := (a_1^j, \dots, a_{c-1}^j)$, $j = 1, 2$. Using the notation of Lemma 1, this means $(a^1, 1)H_I(w) = (a^2, 1)H_I(w) = 0$, so $(a^1 - a^2)M(w) = 0$. As generically on B_0 rank $M(w) = c-1$, we get generically on B_0 $a^1 = a^2$; hence $R_1 = R_2$, i.e., generically on B_0 $P_T^0 w \cap \mathbb{B}^*(d_0, I)$ contains at most one model. From Lemma 2 and the discussion following this lemma we know that generically on B_0 $B(R(d_0, I)) \in P_T^0 w \cap \mathbb{B}^*(d_0, I)$. So generically on B_0 $P_T^0 w \cap \mathbb{B}^*(d_0, I)$ consists of a singleton, i.e., $B(R(d_0, I))$.

This concludes the proof of Theorem 2. \square

Proof of Corollary 7.1. From Theorem 2 we immediately conclude that if $B_0 \in \mathbb{B}_T^*$ then generically on B_0 , $B_0 \in P_T^0 w$. To prove the corollary, due to Theorem 2 it suffices to show that $\{B_0 \subset B \in \mathbb{B}_T^*, c(B) = c(B_0)\} \Rightarrow B = B_0$. This easily follows from Lemma 2.1 and the fact that (for $R \neq 0$) $c(B(R)) = d(R)$. \square

Proof of Theorem 3. (i) The proof is obvious from the definition of P^0 .

(ii) The proof is obvious from Theorem 2.

(iii) Obviously $\mathbb{B}_{P_t^0}^s \subset \mathbb{B}_{P_t^0}^w \subset \text{im } P_t^0 \subset \mathbb{B}_t^*$, so it suffices to show that $\mathbb{B}_t^* \subset \mathbb{B}_{P_t^0}^s$. This is immediate from Corollary 7.1.

(iv) Consider P^0 with the action of P_t^0 restricted to models in the set \mathbb{B}_t^* .

For monotonicity and shift invariance, consider the inclusion conditions on t which involve modeling $w|_{[1,t-1]}$ or $w|_{[2,t]}$, and $w|_{[1,t]}$. Assume $B = B_T(R) \in \mathbb{B}_T$ with $c(R) + d(R) \leq t - 1$.

For the monotonicity condition, observe $w|_{[1,t-1]} \in B_{t-1}(R) \in \mathbb{B}_{t-1}^*$ and $w|_{[1,t]} \in B_t(R) \in \mathbb{B}_t^*$. From Corollary 7.1 it follows that generically in $w \in B$ $P_{t-1}^0(w|_{[1,t-1]}) = B_{t-1}(R)$ and $P_t^0(w|_{[1,t]}) = B_t(R)$, and the condition $B_t(R)|_{[1,t-1]} \subset B_{t-1}(R)$ is trivial. Note that in fact Corollary 7.1 only gives that for example $P_{t-1}^0(w|_{[1,t-1]}) = B_{t-1}(R)$ generically in $w|_{[1,t-1]} \in B_{t-1}(R)$. That this also holds true generically in $w \in B$ can be derived from the fact that $d(R) \leq t - 1$ which implies that there is a linear bijection $w|_{[1,t-1]} \rightarrow w$ from $B_{t-1}(R)$ to B .

For the shift invariance condition, consider two cases for $R = \sum_{k=0}^{d(R)} a_k \sigma^k$. If $a_k \neq 0$, then $w|_{[2,t]} \in B|_{[2,t]} = B|_{[1,t-1]}$, while if $a_k = 0$, then $w|_{[2,t]} \in B|_{[2,t]} = B_{t-1}(\sigma^{-1}R)$. Generically in $w \in B$, $P_{t-1}^0(w|_{[2,t]}) = B_{t-1}(R)$ in the first case, $P_{t-1}^0(w|_{[2,t]}) = B_{t-1}(\sigma^{-1}R)$ in the second case. The shift invariance condition is trivially satisfied in both cases.

Concerning linearity, let $B_i \in \mathbb{B}_i^*$, $i = 1, 2$, then generically in $(w_1, w_2) \in B_1 \times B_2$ $P_i^0 w_i = B_i$, $i = 1, 2$, while due to Corollary 7.1 generically for $B \in P_t^0(w_1 + w_2)$ $B_1 + B_2 \subset B$, which proves linearity. Note that Corollary 7.1 in fact gives $B_1 + B_2 \subset B \in P_t^0 w$ generically in $w \in B_1 + B_2$, but one easily proves that this then also generically holds true in $(w_1, w_2) \in B_1 \times B_2$ with $w := w_1 + w_2$.

Finally we will give an example which shows that P^0 is not monotone and not shift invariant.

Example. Let $T = 20$, $R := \sigma^{10} + \sigma^9 + 2\sigma^8 + \sigma^7 + \sigma^6 + 2\sigma^5 + \sigma^4 + \sigma^3 + 2\sigma^2 + \sigma + 1$, so $c(R) + d(R) = 21$, and consider $B := B(R)$. Further define $R_1 := (\sigma - 1)R = \sigma^{11} + \sigma^9 - \sigma^8 + \sigma^6 - \sigma^5 + \sigma^3 - \sigma^2 - 1$ with $c(R_1) + d(R_1) = 19$ and $R_2 := (\sigma - \frac{1}{2})R = \sigma^{11} + \frac{1}{2}\sigma^{10} + \frac{3}{2}\sigma^9 + \frac{1}{2}\sigma^7 + \frac{3}{2}\sigma^6 + \frac{1}{2}\sigma^4 + \frac{3}{2}\sigma^3 + \frac{1}{2}\sigma - \frac{1}{2}$ with $c(R_2) + d(R_2) = 20$. Then generically in $w \in B$, $P_{19}^0(w|_{[1,19]}) = P_{19}^0(w|_{[2,20]}) = B_{19}(R_1)$ while $P_{20}^0 w = \{B_{20}(R_1), B_{20}(R_2)\}$. So P^0 is not monotone as $B_{20}(R_2)|_{[1,19]} \not\subset B_{19}(R_1)$ and P^0 is not shift invariant as $B_{20}(R_2) \subset B_{20}(\sigma R_1)$. This concludes the proof of Theorem 3. \square

Proof of Proposition 8.1. For $B_0 \in \mathbb{B}_T$ we have to prove that generically in $w \in B_0$ the following holds:

$$\{R \in L(w) := \{R \neq 0; d(R) \leq T - 1 \text{ and } w \in B(R) \in \mathbb{B}_T^*\}\} \Rightarrow \{B_0 \subset B(R)\}.$$

We will use some of the lemmas and the notation introduced in the proof of Theorem 2. Further we define $K_0 := \{(d, I); B_0 \subset W(d, I)\}$ and $L(w; d, I) := \{R \in L(w); I(R) \supset I, d(R) = d\}$.

According to Lemma 1 generically on B_0 , $L(w; d, I) = \emptyset$ if $(d, I) \notin K_0$. So generically on B_0 , $L(w) = \bigcup \{L(w; d, I); (d, I) \in K_0\}$.

The following lemma is crucial in the proof of Proposition 8.1.

LEMMA 6. *Let $(d, I) \in K_0$ be fixed. Then there exist $n \geq 0$ and $R^{(j)} \in \mathbb{R}[\sigma]$, $j \in [0, n]$, such that*

- (i) $d = d(R^{(0)}) > d(R^{(1)}) > \dots > d(R^{(n)})$, $I(R^{(j)}) \supset I$, $j \in [0, n]$;
- (ii) $B_0 \subset B(R^{(j)})$ for all $j \in [0, n]$;
- (iii) generically in $w \in B_0$ $L(w; d, I) = \text{span}_0 \{R^{(j)}, j \in [0, n]\} := \{R; \text{there exists } \alpha_j \in \mathbb{R}, j \in [0, n], \alpha_0 \neq 0, R = \sum_{j=0}^n \alpha_j R^{(j)}\}$.

We will first give an interpretation of this lemma, then give the proof of Proposition 8.1 using Lemma 6 and finally prove Lemma 6.

Lemma 6 has the following interpretation. Let $(d, I) \in K_0$; then by definition of K_0 for every $w \in B_0$ there is a remarkable law R_w with $w \in B(R_w) \in \mathbb{B}^*(d, I)$. Now the

lemma states that generically in B_0 the class of unfalsified remarkable laws in $\mathbb{B}^*(d, I)$ is independent of $w \in B_0$ and that this class is spanned by a finite number of “basic laws” $R^{(j)}$ which moreover are true laws for B_0 .

Proposition 8.1 can be proved by using Lemma 6 in the following way. Generically on B_0 , $L(w) = \bigcup \{L(w; d, I); (d, I) \in K_0\}$, and as K_0 is a finite set it suffices to prove that for $(d, I) \in K_0$ generically in $w \in B_0$ $\{R \in L(w; d, I)\} \Rightarrow \{B_0 \subset B(R)\}$.

According to Lemma 6(ii), (iii), $R \in L(w; d, I)$ generically is of the form $R = \sum_{j=0}^n \alpha_j R^{(j)}$, $\alpha_0 \neq 0$, with $B_0 \subset B(R^{(j)})$, $j \in [0, n]$. Using Lemma 6(i) this implies that for $w \in B_0$, $[R^{(j)}(\sigma)w](t) = 0$, $t \in [1, T - d(R^{(j)})] \supset [1, T - d]$. This implies $[R(\sigma)w](t) = 0$, $t \in [1, T - d]$ and hence $w \in B(R)$ as $d(R) = d$ for $\alpha_0 \neq 0$. So $B_0 \subset B(R)$, which proves Proposition 8.1.

Now finally we will prove Lemma 6. First note that if $d_0 := \min \{d; \text{there exists } I \text{ such that } (d, I) \in K_0\}$ then it follows from Lemma 3 that for $(d_0, I_0) \in K_0$, $L(w; d_0, I_0)$ generically is a singleton $B(R(d_0, I_0))$, and according to Lemma 2 $B_0 \subset B(R(d_0, I_0))$, which proves Lemma 6 for d_0 . However, in general for $(d, I) \in K_0$ $L(w; d, I)$ need not generically be a singleton. As an example, let $T = 5$, $B_0 := B(\sigma - 1)$, then $(d, I) := (2, \{3, 4\}) \in K_0$ and for all $w \in B_0$, $L(w; d, I) \supset \{R_\alpha, \alpha \in \mathbb{R}\}$ where $R_\alpha := (\sigma - \alpha)(\sigma - 1) = \sigma^2 - (\alpha + 1)\sigma + \alpha$.

Proof of Lemma 6. We give the proof by construction. First we define $R^{(j)}$ and then we show that these have the desired properties.

Part (i) and (ii). Let $(d, I) \in K_0$, $[0, T - 1] \setminus I = \{i_1, i_2, \dots, i_{c-1}, d\}$, $0 \leq i_1 < i_2 < \dots < i_{c-1} < d$ ($c + d \leq T$) and define

$$H(w) := \begin{bmatrix} w(i_1 + 1) & w(i_1 + 2) & \cdots & w(i_1 + T - d) \\ w(i_2 + 1) & w(i_2 + 2) & \cdots & w(i_2 + T - d) \\ \vdots & \vdots & & \vdots \\ w(i_{c-1} + 1) & w(i_{c-1} + 2) & \cdots & w(i_{c-1} + T - d) \\ w(d + 1) & w(d + 2) & \cdots & w(T) \end{bmatrix}$$

and let $M_k(w)$ consist of the first k rows of $H(w)$.

As $B_0 \subset W(d, I)$, Lemma 2 implies there exists $R^{(0)}$ such that $B_0 \subset B(R^{(0)}) \in \mathbb{B}^*(d, I)$.

Now note that for $R = \sum_{k=1}^{c-1} a_k \sigma^{i_k} + a_c \sigma^d$, $a_c \neq 0$, $a := (a_1, \dots, a_c)$, there holds $\{R \in L(w; d, I)\} \Leftrightarrow aH(w) = 0$. If generically on B_0 $\text{rank } M_{c-1}(w) = c - 1$, then generically a is unique up to a constant factor and hence generically $L(w; d, I) = \{\alpha R^{(0)}; 0 \neq \alpha \in \mathbb{R}\}$ and Lemma 6 is shown with $n = 0$.

So suppose not generically $\text{rank } M_{c-1}(w) = c - 1$; hence not generically $\det M_{c-1}(w) M_{c-1}(w)^T \neq 0$, so $\det M_{c-1}(w) M_{c-1}(w)^T \equiv 0$ on B_0 and on B_0 $\text{rank } M_{c-1}(w) \leq c - 2$.

Lemma 5 implies there exists R' with $B_0 \subset B(R')$ and $d(R') \leq i_{c-1} < d = d(R^{(0)})$, $I(R') \supset I \cup \{d\}$. Let $R^{(1)}$ be such a law for which $d(R^{(1)})$ is maximal. Let $d(R^{(1)}) = i_{d_1}$ and $I_1 := [0, T - 1] \setminus \{i_1, \dots, i_{d_1}\}$.

Now either generically on B_0 , $\text{rank } M_{d_1-1}(w) = d_1 - 1$, in which case generically $L(w; i_{d_1}, I_1) = \{\alpha R^{(1)}, 0 \neq \alpha \in \mathbb{R}\}$ and we stop, or $\text{rank } M_{d_1-1}(w) \leq d_1 - 2$ on B_0 . In the latter case we find, using Lemma 5, a law $R^{(2)}$ of maximal degree in the class of laws with $I(R'') \supset I_1 \cup \{i_{d_1}\}$ such that $B_0 \subset B(R'')$. So $B_0 \subset B(R^{(2)})$. Let $d(R^{(2)}) = i_{d_2} \leq i_{d_1-1} < i_{d_1} = d(R^{(1)})$ and $I_2 := [0, T - 1] \setminus \{i_1, \dots, i_{d_2}\}$.

Going on in this way we find a number $n \leq c - 1$ such that for $j \in [0, n]$ there exists $R^{(j)}$ with $B_0 \subset B(R^{(j)})$, $I(R^{(j)}) \supset I$, $d(R^{(j)}) < d(R^{(j-1)})$ while for $i_{d_n} := d(R^{(n)})$, $I_n := [0, T - 1] \setminus \{i_1, \dots, i_{d_n}\}$ generically on B_0 $\text{rank } M_{d_n-1}(w) = d_n - 1$, so generically on B_0 $L(w; i_{d_n}, I_n) = \{\alpha R^{(n)}, 0 \neq \alpha \in \mathbb{R}\}$.

In this way we have defined $n, R^{(j)}, j \in [0, n]$ with $d = d(R^{(0)}) > d(R^{(1)}) > \dots > d(R^{(n)})$, $I(R^{(j)}) \supset I$ and $B_0 \subset B(R^{(j)})$. This proves (i) and (ii).

Part (iii). If $R = \sum_{j=0}^n \alpha_j R^{(j)}$, $\alpha_0 \neq 0$, then $d(R) = d$, $I(R) \supset I$ and $B_0 \subset B(R) \in \mathbb{B}_T^*$, so $R \in L(w; d, I)$. We now have to show that generically on B_0 if $R \in L(w; d, I)$ then there exists (α_k) , $\alpha_0 \neq 0$, such that $R = \sum_{j=0}^n \alpha_j R^{(j)}$. Without loss of generality we assume R and $R^{(j)}$ to be monic, $j \in [0, n]$.

So let $R \in L(w; d, I)$ be given. If $R = R^{(0)}$ then we are done, else define $R_1 := \{R - R^{(0)}\} \cdot \beta_0$ with β_0 such that R_1 is monic. We state that generically on B_0 there exists $j \in [1, n]$ such that $d(R_1) = d(R^{(j)})$. For suppose this does not hold true, then there exists $i_k \in I \setminus \{d(R^{(j)}), j \in [0, n]\}$ such that in $H(w)$ row k is not generically linearly independent of the foregoing ones; hence by Lemma 1 it is always linearly dependent on them and Lemma 2 implies there exists R_{i_k} , $d(R_{i_k}) = i_k$, $I(R_{i_k}) \supset [0, T-1] \setminus \{i_1, \dots, i_k\}$ with $B_0 \subset B(R_{i_k})$. Now $i_k < d(R^{(n)})$ is impossible by definition of n , so $d(R^{(n)}) < i_k < d(R^{(0)})$. Let j be such that $d(R^{(j)}) < i_k < d(R^{(j-1)}) =: d_{j-1}$; then this contradicts the construction of $R^{(j)}$ as being of maximal degree in the class of laws \tilde{R} such that $I(\tilde{R}) \supset [0, T-1] \setminus \{i_1, i_2, \dots, i_{d_{j-1}-1}\}$ and $B_0 \subset B(\tilde{R})$.

So indeed generically on B_0 there exists $j \in [1, n]$, say j_1 , such that $d(R_1) = d(R^{(j_1)})$. If $R_1 = R^{(j_1)}$, then stop, else define $R_2 := \{R_1 - R^{(j_1)}\} \cdot \beta_1$ where β_1 is such that R_2 is monic. Going on in this way we generically reduce R to laws of lower degree in the set $\{d(R^{(j)}), j \in [1, n]\}$. The process generically will end either if we find a $k \in [1, n]$ such that $R_k = R^{(j_k)}$ or get R_k with $d(R_k) = d(R^{(n)})$. As $\text{rank } M_{d_n-1}(w) = d_n - 1$ generically on B_0 , also generically $R_k = R^{(n)}$ in the latter case.

In this way we have that generically on B_0 if $R \in L(w; d, I)$ then $R = R^{(0)} + \beta_0^{-1} R_1 = R^{(0)} + \beta_0^{-1} R^{(j_1)} + \beta_0^{-1} \beta_1^{-1} R_2$ and going on in this way we find α_j , $\alpha_0 = 1$, such that $R = \sum_{j=0}^n \alpha_j R^{(j)}$.

This concludes the proof of Lemma 6 and hence of Proposition 8.1. \square

Proof of Corollary 8.1. According to Proposition 8.1 generally in $w \in B_0$ $B_0 \subset B(R(w))$, so generically $w \in B(R(w))$ and hence generically $P_T^* w = B(R(w))$, $R(w) := \text{GCD}\{R; R \in L(w)\}$. So generically on B_0 if $R \in L(w)$ then $B_0 \subset B(R)$ and $P_T^* w = B(R(w)) \subset B(R)$. \square

Proof of Corollary 8.2. Let $R := \text{GCD}\{\tilde{R} \neq 0; d(\tilde{R}) \leq T-1 \text{ and } B_0 \subset B(\tilde{R}) \in \mathbb{B}_T^*\}$, $R(w) := \text{GCD}\{\tilde{R}; \tilde{R} \in L(w)\}$. From Corollary 8.1 generically on B_0 if $\tilde{R} \in L(w)$ then $B_0 \subset B(\tilde{R}) \in \mathbb{B}_T^*$; hence by using Proposition 2.4(ii) generically on B_0 , $B(R) \subset B(R(w)) = P_T^* w$. On the other hand, if $\tilde{R} \neq 0$, $d(\tilde{R}) \leq T-1$ and $B_0 \subset B(\tilde{R}) \in \mathbb{B}_T^*$, then on B_0 $\tilde{R} \in L(w)$ so $B(R(w)) \subset B(\tilde{R})$ which implies $B(R(w)) \subset B(R)$, so generically on B_0 $P_T^* w \subset B(R)$. \square

Proof of Proposition 8.4. Let $B_0 \in \mathbb{B}_T$. As $\tilde{L}(w) \subset L(w)$ we conclude from Corollary 8.1 that generically on B_0 , $\{\tilde{R} \in \tilde{L}(w)\} \Rightarrow \{B_0 \subset B(\tilde{R})\}$. So generically on B_0 , $B_0 \subset B(\tilde{R}(w))$ and hence generically $\tilde{P}_T^* w = B(\tilde{R}(w))$ where $\tilde{R}(w) := \text{GCD}\{\tilde{R}; \tilde{R} \in \tilde{L}(w)\}$.

Now define $R := \text{GCD}\{\tilde{R} \neq 0; d(\tilde{R}) \leq T-1 \text{ and } B_0 \subset B(\tilde{R}) \in \tilde{\mathbb{B}}_T^*\}$. For every $\tilde{R} \neq 0$, $d(\tilde{R}) \leq T-1$ with $B_0 \subset B(\tilde{R}) \in \tilde{\mathbb{B}}_T^*$ on B_0 $\tilde{R} \in \tilde{L}(w)$; hence $B(\tilde{R}(w)) \subset B(R)$ and generically $\tilde{P}_T^* w \subset B(R)$. On the other hand generically on B_0 for $\tilde{R} \in \tilde{L}(w)$ $B_0 \subset B(\tilde{R}) \in \tilde{\mathbb{B}}_T^*$; hence generically $B(R) \subset B(\tilde{R}(w))$ and generically $B(R) \subset \tilde{P}_T^* w$. \square

Proof of Proposition 8.5. For $R = \sum_{k=0}^{T-1} a_k \sigma^k \in \mathbb{K}[\sigma]$ let $l(R) := \min\{k; a_k \neq 0\}$. It easily follows that $\{B(R) \in \mathbb{B}_T\} \Leftrightarrow \{l(R) = 0\}$.

Let $B_0 \in \mathbb{B}_T$. From Corollary 8.2 and Proposition 8.4 it follows that generically on B_0 , $P_T^* w = B(R)$ and $\tilde{P}_T^* w = B(\tilde{R})$, where $R := \text{GCD}\{R' \neq 0; d(R') \leq T-1 \text{ and } B_0 \subset B(R') \in \mathbb{B}_T^*\}$ and $\tilde{R} := \text{GCD}\{\tilde{R}' \neq 0; d(R') \leq T-1 \text{ and } B_0 \subset B(\tilde{R}') \in \tilde{\mathbb{B}}_T^*\}$.

(i) Let $B_0 \in \mathbb{B}_T$, so $l(R_0) = 0$, and $R' \neq 0$, $d(R') \leq T-1$ such that $B_0 \subset B(R') \in \mathbb{B}_T^*$. Then according to Lemma 2.1 there exists F' such that $R' = F' R_0$. If $l := l(R') = l(F') \neq 0$

then define \tilde{F}' by $\tilde{F}' := \sigma^{-l} \cdot F'$ and $\tilde{R}' := \tilde{F}' R_0$. So $B_0 \subset B(\tilde{R}') \in \tilde{\mathbb{B}}_T^*$ as $l(\tilde{R}') = 0$ and $c(\tilde{R}') + d(\tilde{R}') = c(R') + d(R') - 1 \leq T - 1 \leq T$. Now $R' = \sigma^l \cdot \tilde{R}'$ and it follows that $R = \text{GCD} \{R' \neq 0; d(R') \leq T - 1 \text{ and } B_0 \subset B(R') \in \mathbb{B}_T^*\} = \text{GCD} \{\tilde{R}' \neq 0; d(\tilde{R}') \leq T - 1 \text{ and } B_0 \subset B(\tilde{R}') \in \tilde{\mathbb{B}}_T^*\} = \tilde{R}$ and hence generically $P_T^* w = \tilde{P}_T^* w$.

(ii) Let $B_0 \in \mathbb{B}_T$, $B_0 \in \tilde{\mathbb{B}}_T$, so $l(R_0) \geq 1$. If $d(R') \leq T - 1$ and $B_0 \subset B(R') \in \mathbb{B}_T^*$ then there exists $F' R' = F' R_0$ and hence $l(R') \geq 1$, so $B(R') \notin \tilde{\mathbb{B}}_T^*$. This implies that generically on B_0 , $\tilde{L}(w) = \emptyset$, as according to Corollary 8.1 generically on B_0 , $\{R \in \tilde{L}(w) \subset L(w)\} \Rightarrow \{B_0 \subset B(R) \in \tilde{\mathbb{B}}_T^*\}$. So generically on B_0 , $\tilde{R}(w) = 0$ and $\tilde{P}_T^* w = \mathbb{R}^T$. \square

ERGODIC CONTROL OF MULTIDIMENSIONAL DIFFUSIONS I: THE EXISTENCE RESULTS*

VIVEK S. BORKAR^{†‡} AND MRINAL K. GHOSH[†]

Abstract. The existence of optimal stable Markov relaxed controls for the ergodic control of multidimensional diffusions is established by direct probabilistic methods based on a characterization of a.s. limit sets of empirical measures. The optimality of the above is established in the strong (i.e., almost sure) sense among all admissible controls under very general conditions.

Key words. ergodic control, Markov controls, optimal controls, empirical measures, invariant probability measures

AMS(MOS) subject classification. 93E20

1. Introduction. The “ergodic” or “long run average cost” control problem for multidimensional diffusions is one of the few classical problems of stochastic control that still eludes a completely satisfactory treatment. The problem can be formulated as follows: Let U be a compact metric space called the control set. Let $X(\cdot)$ be an R^n -valued controlled diffusion process on some probability space satisfying the stochastic differential equation

$$(1.1) \quad dX(t) = m(X(t), u(t)) dt + \sigma(X(t)) dW(t), \quad X(0) = X_0,$$

for $t \geq 0$, where

(i) $m(\cdot, \cdot) = [m_1(\cdot, \cdot), \dots, m_n(\cdot, \cdot)]^T: R^n \times U \rightarrow R^n$ is continuous and satisfies for all $x, y \in R^n, u \in U$,

$$\begin{aligned} \|m(x, u) - m(y, u)\| &\leq K \|x - y\|, \\ \|m(x, u)\| &\leq K \end{aligned}$$

for some constant $K > 0$.

(ii) $\sigma(\cdot) = [\sigma_{ij}(\cdot)]: R^n \rightarrow R^{n \times n}$ satisfies for $x, y \in R^n$,

$$\begin{aligned} \|\sigma(x) - \sigma(y)\| &\leq K \|x - y\|, \quad \|\sigma(x)\| \leq K, \\ \|\sigma^T x\|^2 &\geq \lambda \|x\|^2 \quad (\text{uniform ellipticity}) \end{aligned}$$

for some constants $\lambda > 0, K > 0$.

(iii) X_0 is a prescribed random variable.

(iv) $W(\cdot) = [W_1(\cdot), \dots, W_n(\cdot)]^T$ is a standard n -dimensional Wiener process independent of X_0 .

(v) $u(\cdot)$ is a U -valued process with measurable sample paths satisfying the following “nonanticipativity” condition: For $t \geq s \geq y \geq 0$, $W(t) - W(s)$ is independent of $u(y)$.

A process $u(\cdot)$ as above will be called an admissible control. Of special interest is the case when $u(\cdot) = v(X(\cdot))$ for some measurable $v: R^n \rightarrow U$. In this case, (1.1) will have a strong solution [29] implying in particular that $u(\cdot)$ is admissible. $X(\cdot)$

will then be a homogeneous Markov process. Hence we call such a $u(\cdot)$ or, by abuse of terminology, the function v itself, a Markov control. A Markov control will be said to be stable if the corresponding process is positive recurrent and thus has a unique invariant measure. (The uniqueness is ensured by our uniform ellipticity condition. See, e.g., [6], [18] or [28, Chaps. 30–32].) If $u(\cdot) = v(X(\cdot), \cdot)$ for some measurable $v: R^n \times R^+ \rightarrow U$, the corresponding process will also be a Markov process, albeit not a homogeneous one. Call such a $u(\cdot)$, or again, by abuse of terminology, the map v itself, an inhomogeneous Markov control. The admissibility of these once again follows from the existence of strong solutions for the corresponding s.d.e. as in [29].

Let $c: R^n \times U \rightarrow U$ be a continuous function called the cost function. We assume that

$$(1.2) \quad c(\cdot, \cdot) \geq -K$$

for some constant K . In the ergodic control problem, one typically seeks to minimize

$$(1.3) \quad \limsup_{t \rightarrow \infty} \frac{1}{t} \int_0^t E[c(X(s), u(s))] ds$$

or a.s. minimize

$$(1.4) \quad \limsup_{t \rightarrow \infty} \frac{1}{t} \int_0^t c(X(s), u(s)) ds$$

over all admissible controls. An admissible control is said to be optimal in the mean if it minimizes (1.3) and a.s. optimal if it a.s. minimizes (1.4). The primary aims of the ergodic control problem are the following:

- (i) to show the existence of a stable Markov control which is optimal in an appropriate sense (cf. above definitions of optimality), and,
- (ii) to characterize the same via the dynamic programming equation (the “Hamilton–Jacobi–Bellman” equation).

The first attempt in this direction is perhaps [24, Chap. VI] where a one-dimensional compact state space was considered. Subsequent works considered the multidimensional case as well. An extensive survey of these appears in [25]. Here, we shall briefly recall the focus of some recent works. The traditional approach to this problem, inherited from earlier developments in discrete time and discrete state space situations, is to start with the Hamilton–Jacobi–Bellman (H.J.B.) equation and arrive at an existence result for optimal stable Markov control using this equation, the equation itself being approached by a “vanishing discount” limit argument from the corresponding H.J.B. equation for the infinite horizon discounted cost control problem. The most recent development in this direction is [27] where the H.J.B. equation is studied under a condition on the gradient of the cost. Another recent work [12] also focuses on the H.J.B. equation, but treats it as a limiting case of finite horizon problems instead of discounted cost problems on infinite time horizon. The only direct proof of existence of an optimal stable Markov control by probabilistic compactness arguments seems to be [21], which also considers the corresponding maximum principle.

These works share one or more of the following limitations:

- (a) Optimality in the mean and not a.s. optimality is considered.
- (b) Optimality is established only within the class of Markov controls and not with respect to all admissible controls.
- (c) The system model is often more restrictive than the above, e.g., it is sometimes assumed that $\sigma =$ the identity matrix and $m(x, u) = u$.
- (d) Either a blanket stability assumption is imposed or a condition on the cost function which penalizes instability is assumed.

It is clear that some condition on cost or stability must be necessary to give the desired existence of an optimal stable Markov control. For example, consider the case

$$c(x, u) = \exp(-\|x\|^2).$$

Then the cost of any stable Markov control is a.s. positive while that of an unstable Markov control is a.s. zero, making the latter optimal.

In this paper, we extend the approach of [7], [8], [11] to multidimensional diffusions. In the one-dimensional case, this was partially done in [5], [9]. These works, however, use many specificities of the one-dimensional case in a crucial manner. Here we address only the first of the two issues mentioned above, viz., the existence of stable optimal Markov controls, thus subsuming the results of [9]. The second issue, viz., the dynamic programming equations will be treated in a subsequent publication [15]. The advantages of our approach are the following:

(1) Almost sure optimality (as opposed to optimality in the mean) of a stable Markov control is established in the class of all admissible controls.

(2) The approach has a more probabilistic flavor than the previous ones and brings out certain features of the problem (e.g., asymptotics for the empirical measures) not apparent in the latter.

The main disadvantage of our approach is that we have to work with the larger class of relaxed controls. This means that we assume U to be of the form $P(V)$ = the space of probability measures on some compact metric space V with the topology of weak convergence and c, m to be of the form

$$c(x, u) = \int_V \bar{c}(x, y)u(dy), \quad m_i(x, u) = \int_V \bar{m}_i(x, y)u(dy), \quad 1 \leq i \leq n$$

for some $\bar{c}: R^n \times V \rightarrow R$ and $\bar{m}: R^n \times V \rightarrow R^n$, $\bar{m}(\cdot, \cdot) = [\bar{m}_1(\cdot, \cdot), \dots, \bar{m}_n(\cdot, \cdot)]$, which satisfy the same hypotheses as c, m , respectively, but with V replacing U . Note that any V -valued process $v(\cdot)$ can be identified with a U -valued process $u(\cdot)$ defined by $u(t)$ = the Dirac measure at $v(t)$ for $t \geq 0$. Thus relaxed controls subsume controls in the ordinary sense. In fact, if c has no explicit control dependence and $m(x, U)$ is convex for each x , each relaxed control can be identified with a control in the ordinary sense by a straightforward application of the selection theorem in Lemma 1.1 [3], as was pointed out in [9]. In [5], it was shown in the one-dimensional case that the dynamic programming equations allow us to do away with the relaxed control framework. Analogous development in the multidimensional case will be reported in [15].

The use of relaxed controls is tantamount to compactifying the space of control trajectories in a certain precise sense. A nice exposition of this can be found in [2, § 1.9, pp. 31–36]. The concept of relaxed controls was first introduced in deterministic control theory in [31]. Its use in stochastic control dates back to [14].

For a stable Markov control v , we shall denote by η_v the corresponding unique invariant probability measure for $X(\cdot)$. We assume throughout this paper that at least one stable Markov control v exists such that

$$\int c(x, v(x))\eta_v(dx) \leq \infty.$$

Thus

$$(1.5) \quad \alpha = \inf_{v \text{ stable Markov}} \int c(x, v(x))\eta_v(dx)$$

is well defined. We shall prove our existence result under two sets of assumptions. In the first one, we assume that c is near-monotone in the sense that it satisfies

$$(1.6) \quad \liminf_{\|x\| \rightarrow \infty} \inf_{u \in U} c(x, u) > \alpha.$$

The terminology is suggested by the fact that (1.5) is always satisfied when $c(x, u) = k(\|x\|)$ for a monotone increasing $k: R^+ \rightarrow R$. Such costs discourage unstable behavior for obvious reasons and arise often in practice.

The second case we shall consider is a Lyapunov-type stability condition the details of which are left to § 3. For the time being, we only mention that in particular it implies the stability of all Markov controls.

The plan of the paper is as follows: Section 2 establishes a characterization of a.s. limit sets for empirical measures of the joint state and control process along the lines of [9]. This leads to the existence result in the near-monotone case. Section 3 gives a full statement of the Lyapunov condition mentioned above and uses it to prove certain moment bounds for a class of stopping times to be defined later, which in turn implies that all Markov controls are stable and the set of their invariant probability measures is compact in $P(R^n)$. ($P(S)$ will always denote the space of probability measures on a Polish space S with the topology of weak convergence.) Section 4 proves the existence of an optimal stable Markov controls under the conditions of § 3.

2. Existence in the near-monotone case. The key result of this section is Lemma 2.2, which characterizes the a.s. limit sets of the process of empirical measures we are about to define. This immediately leads to the desired existence result for a near-monotone cost (Theorem 2.1).

Let $\bar{R}^n = R^n \cup \{\infty\}$ be the one point compactification of R^n and let $H = \{A \times B | A, B \text{ Borel subsets of } \bar{R}^n, V\}$ respectively. For $t \geq 0$, define the empirical measure $\tilde{\nu}_t$ on H by

$$\tilde{\nu}_t(A \times B) = \frac{1}{t} \int_0^t I\{X(s) \in A\} u(s, B) ds$$

for $X(\cdot)$, $u(\cdot)$ as in (1.1), with

$$u(s, B) = \int_B du(s), \quad B \subset V.$$

For each fixed sample point and fixed t , $\tilde{\nu}_t$ extends uniquely to a $\nu_t \in P(\bar{R}^n \times V)$. This defines the process of empirical measures ν_t , $t \geq 0$, taking values in $P(\bar{R}^n \times V)$. Since the latter is a compact space (because $\bar{R}^n \times V$ is compact), $\{\nu_t\}$ converges to a sample point dependent compact subset of $P(\bar{R}^n \times V)$ as $t \rightarrow \infty$.

Each $\eta \in P(\bar{R}^n \times V)$ can be decomposed as

$$(2.1) \quad \eta(A) = \delta(\eta) \eta'(A \cap (R^n \times V)) + (1 - \delta(\eta)) \eta''(A \cap (\{\infty\} \times V))$$

for A Borel in $\bar{R}^n \times V$, where $\delta(\eta) \in [0, 1]$, $\eta' \in P(R^n \times V)$ and $\eta'' \in P(\{\infty\} \times V)$. This decomposition can be rendered unique by imposing a fixed choice of $\eta' \in P(R^n \times V)$ (respectively, $\eta'' \in P(\{\infty\} \times V)$) when $\delta(\eta) = 0$ (respectively, 1). Disintegrate η' as follows:

$$(2.2) \quad \int_{R^n \times V} f(x, y) \eta'(dx, dy) = \int_{R^n} \int_V f(x, y) v_\eta(x, dy) \eta^*(dx)$$

for all bounded continuous $f: R^n \times V \rightarrow R$, where η^* is the image of η' under the projection $R^n \times V \rightarrow R^n$ and $v_\eta(x, \cdot) \in U$ for $x \in R^n$ is the regular conditional law. Then the map $x \rightarrow v_\eta(x, \cdot): R^n \rightarrow U$ can be identified with a Markov control which we also

denote by v_η (i.e., $v_\eta(x) \in U$ is defined by $v_\eta(x) = v_\eta(x, \cdot)$, the right-hand side defined as above). Note that this v_η is defined only η^* -a.s. We pick any one representative of this a.s.-equivalence class. Throughout this paper, this choice of a representative is immaterial wherever the above decomposition is used.

Thus we have associated with $\eta \in P(\bar{R}^n \times V)$ the objects $\delta(\eta) \in [0, 1]$, $\eta' \in P(R^n \times V)$, $\eta'' \in P(\{\infty\} \times V)$, $\eta^* \in P(R^n)$, $v_\eta: R^n \rightarrow U$ a Markov control. If in addition $v = v_\eta$ is stable, we also have its unique invariant probability measure η_v . This notation plays an important role in what follows.

Let C_0^2 = the Banach space of twice continuously differentiable maps $R^n \rightarrow R$ which, along with their first and second partial derivatives vanish at infinity, with the norm

$$\|f\| = \sup_x |f(x)| + \sum_{i=1}^n \sup_x \left| \frac{\partial f}{\partial x_i}(x) \right| + \sum_{i,j=1}^n \sup_x \left| \frac{\partial^2 f}{\partial x_i \partial x_j}(x) \right|.$$

For any $f \in C_0^2$, let

$$(Lf)(x, u) = \sum_{i=1}^n \frac{\partial f}{\partial x_i}(x) \bar{m}_i(x, u) + \frac{1}{2} \sum_{i,j,k=1}^n \sigma_{ik}(x) \sigma_{jk}(x) \frac{\partial^2 f}{\partial x_i \partial x_j}(x)$$

and for any Markov control v ,

$$(L_v f)(x) = \int_V (Lf)(x, y) v(x, dy)$$

where the meaning of the right-hand side is obvious.

Let G be a countable dense subset of C_0^2 . Then G is also countable dense in $C_0 = \{f \in C(R^n) \mid \lim_{\|x\| \rightarrow \infty} f(x) = 0\}$ with supremum norm. In particular, this implies that it is a convergence determining class and hence a separating class for $P(R^n)$ (i.e., $\int f d\mu_n \rightarrow \int f d\mu_\infty$ for $f \in G$, $\{\mu_n, n = 1, 2, \dots, \infty\} \subset P(R^n)$, implies $\mu_n \rightarrow \mu_\infty$ in $P(R^n)$ and $\int f d\mu = \int f d\nu$ for $f \in G$, $\mu, \nu \in P(R^n)$ implies $\mu = \nu$).

LEMMA 2.1. *If $\nu \in P(R^n)$ satisfies*

$$(2.3) \quad \int L_v f d\nu = 0 \quad \text{for } f \in G$$

for some Markov control v , then $\nu = \eta_v$. (Recall that η_v is the unique invariant probability measure under v , whose stability is thus a part of the conclusion.)

Proof. By a standard approximation argument, (2.3) holds for all $f \in C_b^2$ = the space of twice continuously differentiable functions with bounded first and second derivatives. Let $X(\cdot)$ be a diffusion governed by the Markov control v and with initial law ν . Let ν_t = the law of $X(t)$ at time t , $t \geq 0$. Then $\{\nu_t\}$ satisfies the forward Kolmogorov equation

$$\int f d\nu_t = \int f d\nu + \int_0^t \int (L_v f) d\nu_s ds, \quad f \in C_b^2.$$

Since the solution of this p.d.e. is unique and $\nu_t \equiv \nu$ is a solution by virtue of (2.3), the claim follows. Q.E.D.

LEMMA 2.2. *Outside a set of zero probability, each limit point ν of $\{\nu_t\}$ for which $\delta(\nu) > 0$, satisfies*

$$(2.4) \quad \nu^* = \eta_{v_\eta}.$$

Remarks. Note that we do not claim pathwise tightness of $\{\nu_t\}$, which would correspond to $\delta(\nu) = 1$ a.s. This cannot be true in general, e.g., for an unstable Markov

control. Thus we must allow for the possibility $\delta(\nu) < 1$, which necessitates the compactification of the state space as done above.

Proof. For $f \in G$, Ito's formula gives

$$(2.5) \quad \begin{aligned} f(X(t)) - f(X(0)) &= \int_0^t \int_V Lf(X(s), y) u(s, dy) ds \\ &\quad + \int_0^t \langle \nabla f(X(s)), \sigma(X(s)) dW(s) \rangle. \end{aligned}$$

By standard time change arguments (see, e.g., [13, § 6.1] or [17, §§ 3.1, 4.4]), the stochastic integral term above can be shown to be of the form $B(\tau_t)$ for a standard Brownian motion $B(\cdot)$ and a process of time change τ_t satisfying

$$\limsup_{t \rightarrow \infty} \frac{\tau_t}{t} < \infty \quad \text{a.s.}$$

Since

$$\lim_{t \rightarrow \infty} \frac{B(\tau_t)}{\tau_t} = 0 \quad \text{a.s. on } \{\lim_{t \rightarrow \infty} \tau_t = \infty\} \text{ and } < \infty \text{ a.s. on } \{\lim_{t \rightarrow \infty} \tau_t < \infty\},$$

we have

$$\lim_{t \rightarrow \infty} \frac{B(\tau_t)}{t} = 0 \quad \text{a.s.}$$

Hence

$$\lim_{t \rightarrow \infty} \frac{1}{t} \int_0^t \int_V Lf(X(s), y) u(s, dy) ds = \lim_{t \rightarrow \infty} \int Lf d\nu_t = 0 \quad \text{a.s.}$$

Since G is countable, we can find a set N of zero probability outside which the above limit holds for all $f \in G$. Then outside N , each limit point ν of $\{\nu_t\}$ with $\delta(\nu) > 0$ must satisfy

$$\int Lf d\nu = 0 \quad \text{for } f \in G.$$

The claim follows from Lemma 2.1. Q.E.D.

LEMMA 2.3. *Under a stable Markov control v ,*

$$\lim_{t \rightarrow \infty} \frac{1}{t} \int_0^t c(X(s), v(X(s))) ds = \int c(x, v(x)) \eta_v(dx).$$

See [6] for a proof using the ergodic theorem.

LEMMA 2.4. *For a near-monotone c , there exists a stable Markov control v such that*

$$\int c(x, v(x)) \eta_v(dx) = \alpha.$$

Proof. Let $\{v_n\}$ be a sequence of stable Markov controls such that

$$\int c(x, v_n(x)) \eta_{v_n}(dx) \downarrow \alpha.$$

Define $p_n \in P(\bar{R}^n \times V)$ by

$$\int_{\bar{R}^n \times V} f(x, y) p_n(dx, dy) = \int_{R^n} \int_V f(x, y) v_n(x, dy) \eta_{v_n}(dx)$$

for bounded continuous $f: \bar{R}^n \times V \rightarrow R$. Let p_∞ be a limit point of $\{p_n\}$ and let

$$v_\infty = v_{p_\infty}.$$

For $f \in G$, we have

$$\int L_{v_n} f d\eta_{v_n} = \int Lf dp_n = 0, \quad n = 1, 2, \dots$$

Letting $n \rightarrow \infty$ along an appropriate subsequence,

$$\int Lf dp_\infty = 0.$$

By Lemma 2.1 and the decomposition (2.1),

$$p_\infty^* = \eta_{v_\infty} \quad \text{if } \delta(p_\infty) > 0.$$

Now, the near-monotonicity of c implies that for some $\varepsilon > 0$,

$$\liminf_{\|x\| \rightarrow \infty} \inf_{u \in V} \bar{c}(x, u) > \alpha + \varepsilon.$$

Using this, we can construct continuous maps $c^m: \bar{R}^n \times V \rightarrow R$, $m \geq 1$, such that

$$\begin{aligned} c^m(\infty, u) &= \alpha + \varepsilon, \quad m \geq 1, \\ c^m(x, u) &\uparrow \bar{c}(x, u) \quad \text{on } R^n \times V. \end{aligned}$$

Thus

$$\int \bar{c} dp'_n \geq \int c^m dp_n.$$

Letting $n \rightarrow \infty$,

$$\lim \int \bar{c} dp'_n = \alpha \geq \left(\int c^m dp'_\infty \right) \delta(p_\infty) + (1 - \delta(p_\infty))(\alpha + \varepsilon).$$

Letting $m \rightarrow \infty$ on the right-hand side,

$$\alpha \geq \left(\int \bar{c} dp'_\infty \right) \delta(p_\infty) + (1 - \delta(p_\infty))(\alpha + \varepsilon).$$

If $\delta(p_\infty) > 0$,

$$\int \bar{c} dp'_\infty = \int c(x, v_\infty(x)) \eta_{v_\infty}(dx) \geq \alpha$$

by the definition of α . Hence we must have $\delta(p_\infty) = 1$ and

$$\int \bar{c} dp'_\infty = \int c(x, v_\infty(x)) \eta_{v_\infty}(dx) = \alpha. \quad \text{Q.E.D.}$$

As we remarked earlier, v_∞ is defined p_∞^* -a.s. and it does not matter which representative we pick.

THEOREM 2.1. *For a near-monotone c , there exists a stable a.s. optimal Markov control.*

Proof. Using Lemma 2.2 and arguments similar to those employed in the proof of the above lemma, we can show that

$$\liminf_{t \rightarrow \infty} \frac{1}{t} \int_0^t c(X(s), u(s)) ds \geq \alpha \quad \text{a.s.}$$

The claim now follows from Lemmas 2.3 and 2.4. Q.E.D.

3. Tightness of invariant probability measures. In this and the next section, we study the situation where the near-monotonicity condition on the cost is dropped, but instead we impose a Lyapunov-type stability condition which, among other things, will be shown to imply that all the Markov controls are stable and their invariant probability measures form a compact set in $P(R^n)$. This, in fact, is the principal result of this section (Theorem 3.1, Corollary 3.2), the proof of the existence of an a.s. optimal Markov control being left to § 4.

Before we give a precise statement of this condition, we mention the following technical lemma.

LEMMA 3.1. *Let $X_0 = x \in R^n$, $t > 0$, $u(\cdot)$ be an admissible control. Then the law of $X(t)$ has a density $p(t, x, \cdot)$ with respect to the Lebesgue measure on R^n , satisfying*

$$(3.1) \quad c_1 t^{-n/2} \exp(-c_2 \|x - y\|^2/t) \leq p(t, x, y) \leq c_3 t^{-n/2} \exp(-c_4 \|x - y\|^2/t)$$

for some constants $c_i > 0$, $i = 1, 2, 3, 4$, independent of $x, t, u(\cdot)$, $0 < t \leq T$.

Proof. If $u(\cdot)$ is an inhomogeneous Markov control, this is precisely the estimate of [1]. For arbitrary $u(\cdot)$, the law of $X(t)$ is the same as that under some inhomogeneous Markov control by the results of [10] and we are done. Q.E.D.

The Lyapunov-type condition we use is the following:

Assumption A. There exists a twice continuously differentiable function $w: R^n \rightarrow R$ satisfying:

$$(3.2) \quad (i) \quad \lim_{\|x\| \rightarrow \infty} w(x) = +\infty \text{ uniformly in } \|x\|,$$

$$(ii) \quad \text{there exist } a > 0, \varepsilon_0 > 0 \text{ such that whenever } \|x\| > a,$$

$$(3.3) \quad Lw(x, u) < -\varepsilon_0 \quad \text{for all } u \in U,$$

$$(3.4) \quad \|\nabla w\|^2 > \varepsilon_0,$$

$$(3.5) \quad (iii) \quad \int_0^T \int_{R^n} \|\sigma^T(x) \nabla w(x)\|^2 t^{-n/2} \exp(-c_4 \|x - y\|^2/t) dx dt < \infty \quad \forall T > 0,$$

where c_4 is as in Lemma 3.1.

Remarks. (a) Equation (3.5) is a mild technical condition that ensures (by virtue of Lemma 3.1) that the stochastic integral

$$\int_0^T \langle \nabla w(X(t)), \sigma(X(t)) dW(t) \rangle, \quad T > 0,$$

is always well defined.

(b) We have chosen the above formulation of a Lyapunov-type condition because it is easily stated and still quite general. Other variants are possible (see, e.g., [21] for one). For the general theory of stochastic Lyapunov functions, see [19]. The key consequence of the above assumption for our purposes is Lemma 3.2 below. Thus any condition that implies Lemma 3.2 will suffice. In fact, the crudeness of estimates used in proving the lemma shows that there is ample scope for improvement.

(c) As an example, consider $n = 1$, $\sigma(\cdot) \equiv 1$, $m(x, u) \leq -\varepsilon$ for x sufficiently large and $\geq \varepsilon$ for $-x$ sufficiently large for some $\varepsilon > 0$. Then $w(x) = x^2$ will do the job.

Let $B_1, B_2 \subset \mathbb{R}^n$ be concentric balls centered at zero with radii r_1, r_2 and boundaries $\delta B_1, \delta B_2$, respectively, where we choose $r_2 > r_1 > a$ such that for some $a_1 > 0$, $\{x \mid w(x) \leq a_1\}$ is nonempty and contained in B_1 . Let $a_2 = \max_{x \in \delta B_2} |w(x)|$ and $a_3 = a_1 - a_2$.

LEMMA 3.2. *Let $X_0 = x \in \delta B_2$ and $\tau = \inf \{t \geq 0 \mid X(t) \in \delta B_1\}$. Then*

$$(3.6) \quad \sup E[\tau^2] < \infty$$

where the supremum is over all $x \in \delta B_2$ and all admissible $u(\cdot)$.

Proof. For $t > 0$,

$$\begin{aligned} P(\tau \geq t) &= P\left(\min_{s \in [0, t]} w(X(s)) \geq a_1, \tau \geq t\right) \\ &\leq P\left(\min_{y \in [0, t]} \int_0^y \langle \nabla w(X(s)), \sigma(X(s)) dW(s) \rangle \geq a_3 + \varepsilon_0 t\right) \end{aligned}$$

by (3.3). Using the random time change argument we used earlier,

$$\int_0^t \langle \nabla w(X(s)), \sigma(X(s)) dW(s) \rangle = B(\xi(t))$$

for a standard Brownian motion $B(\cdot)$ with

$$\xi(t) = \int_0^t \|\sigma^T(X(s)) \nabla w(X(s))\|^2 ds \geq \lambda \varepsilon_0 t.$$

(Recall that λ is the ellipticity constant for $\sigma \sigma^T$.) Thus

$$\begin{aligned} P(\tau \geq t) &\leq 2P(B(\lambda \varepsilon_0 t) \geq \varepsilon_0 t + a_3) \\ &= 2(2\pi\lambda\varepsilon_0 t)^{-1/2} \int_{a_3 + \varepsilon_0 t}^{\infty} \exp(-y^2/2\lambda\varepsilon_0 t) dy. \end{aligned}$$

It is not hard to verify from this that

$$\int_0^{\infty} tP(\tau \geq t) dt < K < \infty$$

where the constant K is independent of the choice of x in δB_2 and of $u(\cdot)$. The claim follows. Q.E.D.

Now take $X_0 = x \in \bar{B}_2$ and define $\tau' = \inf \{t \geq 0 \mid X(t) \notin \delta B_2\}$. We have the following companion result to the above, which, however, does not need Assumption A.

LEMMA 3.3.

$$(3.7) \quad \sup E[(\tau')^2] < \infty$$

where the supremum is over $x \in \bar{B}_2$ and admissible $u(\cdot)$.

In order to prove this result, we need another technical lemma, Lemma 3.4 below, which will also be useful elsewhere in this paper. Let $\{F_t\}$ denote the natural filtration of $X(\cdot)$.

LEMMA 3.4. *For any $\{F_t\}$ -stopping time τ , the regular conditional law of $X(\tau + \cdot)$ given F_τ on $\{\tau < \infty\}$ is a.s. the law of a controlled diffusion of the same type as (1.1).*

Proof. The results of [30] (see Theorem 4.3 and the final comments on p. 632) allow us to assume without any loss of generality that $\{F_t\}$ is the canonical filtration on $C([0, \infty); R^n)$ and $u(\cdot)$ is of the form

$$u(t) = G(t, X(\cdot))$$

for some measurable $G: [0, \infty) \times C([0, \infty); R^n) \rightarrow U$ which is progressively measurable with respect to $\{F_t\}$. By Lemma 1.3.3 of [26, p. 33], a version of the regular conditional law of $X(\tau + \cdot)$ given F_τ on $\{\tau < \infty\}$ will be a.s. given by the law of a controlled diffusion $X(\cdot)$ as in (1.1), but with initial condition $X(\tau)$ and control $\tilde{u}(\cdot)$ given by $\tilde{u}(t) = G(\tau + t, X(\cdot))$ with τ and the restriction of $X(\cdot)$ to $[0, \tau]$ being held fixed as parameters. Q.E.D.

From here on, $M_i(S)$, $S \subset R^n$, $i = 1, 2$, will denote the set of $X(\cdot)$ as in (1.1) under Markov/arbitrary admissible controls, respectively, with initial law supported in S .

Proof of Lemma 3.3. By the results of [10], the law of $X(t)$ for any $t > 0$ coincides with that under some inhomogeneous Markov control and thus by the uniform ellipticity assumption on $\sigma\sigma^T$, is absolutely continuous with respect to the Lebesgue measure. (Recall (3.1).) Let $X(\cdot) \in M_2(\bar{B}_2)$, $\tau = \inf\{t \geq 0 | X(t) \in \bar{B}_2\}$. Then for $t > 0$,

$$P(\tau = t) \leq P(X(t) \in \delta B_2) = 0$$

and thus $P(\tau = t) = 0$. Fix $t > 0$. Let $\{X^n(\cdot)\}$ be a sequence in $M_2(\bar{B}_2)$ such that if $\{\tau^n\}$ denote the corresponding first exit times from \bar{B}_2 ,

$$P(\tau^n > t) \uparrow \sup_{X(\cdot) \in M_2(\bar{B}_2)} P(\tau > t).$$

As in the proof of Theorem 3.1 of [20], one can argue that $X^n(\cdot) \rightarrow X^\infty(\cdot)$ in law along a subsequence (denoted $\{n\}$ again by abuse of notation) where $X^\infty(\cdot) \in M_2(\bar{B}_2)$. (The only difference with Theorem 3.1 of [20] is the varying initial law. This can, however, be easily accommodated since the initial laws are supported on \bar{B}_2 and hence are tight.) By Skorokhod's theorem [17, p. 9], we may assume that this convergence is a.s. on a common probability space. (See [20] for an analogous argument.) Let $\tau^\infty = \inf\{t \geq 0 | X^\infty(t) \notin \bar{B}_2\}$ and $\bar{\tau} = \inf\{t \geq 0 | X^\infty(t) \in \delta B_2\}$. Path continuity of $\{X^n(\cdot)\}$ and simple geometric considerations show that for any sample point, any limit point of $\{\tau^n\}$ in $[0, \infty]$ must lie in $[\bar{\tau}, \tau^\infty]$. By our uniform ellipticity condition on $\sigma\sigma^T$, $\bar{\tau} = \tau^\infty$ a.s. Thus $\tau^n \rightarrow \tau^\infty$ a.s. Since $P(\tau^\infty = t) = 0$, $P(\tau^n > t) \rightarrow P(\tau^\infty > t)$. Since

$$P(\tau^\infty > t) \leq P(X^\infty(t) \in \bar{B}_2) < 1,$$

we have

$$\beta = \sup_{X(\cdot) \in M_2(\bar{B}_2)} P(\tau > t) < 1.$$

Hence for $X(\cdot) \in M_2(\delta B_1) \subset M_2(\bar{B}_2)$,

$$\begin{aligned} P(\tau > nt) &= E[I\{\tau > nt\}] \\ &= E[E[I\{\tau > nt\}]/F_{(n-1)t}]I\{\tau > (n-1)t\} \\ &\leq \beta E[I\{\tau > (n-1)t\}] \end{aligned}$$

by Lemma 3.4. Iterating the argument,

$$P(\tau > nt) \leq \beta^n.$$

The rest is easy. Q.E.D.

Define the extended real-valued stopping times

$$(3.8) \quad \tau_1 = \inf \{t \geq 0 \mid X(t) \in \delta B_1\},$$

$$(3.9) \quad \xi_n = \inf \{t \geq \tau_n \mid X(t) \in \delta B_2\},$$

$$(3.10) \quad \tau_{n+1} = \inf \{t \geq \xi_n \mid X(t) \in \delta B_1\}$$

for $n = 1, 2, \dots$, where as usual the quantity on the left is set equal to $+\infty$ if the set on the right is empty.

Let v be a Markov control and $X(\cdot)$ the corresponding process with initial law supported on δB_1 . By the above three lemmas, $E[\xi_i], E[\tau_i] < \infty$ for all i with $\tau_1 = 0$. Then $X(\tau_i), i = 1, 2, \dots$, is a δB_1 -valued Markov chain having a unique invariant probability measure (say, q) as argued in [18].

COROLLARY 3.1. *The measure $\eta \in P(R^n)$ defined by*

$$\int f d\eta = E \left[\int_0^{\tau_2} f(X(t)) dt \right] / E[\tau_2], \quad f \in C_b(R^n),$$

with the law of $X(0) = q$, coincides with η_v . (In particular, v is stable.)

For a proof, see [18].

Let $\{v_n\}$ be a sequence of Markov controls and $X^n(\cdot)$ the corresponding diffusions as in (1.1) for some initial laws and suppose that $X^n(\cdot) \rightarrow X^\infty(\cdot)$ in law for some process $X^\infty(\cdot)$.

LEMMA 3.5. *$X^\infty(\cdot)$ is a diffusion satisfying (1.1) for some Markov control.*

Proof. Let $T_{s,t}^n, t \geq s$, denote the transition semigroup for $X^n(\cdot)$, $n \geq 1$. Let $f \in C^2(R^n)$ with compact support and $g \in C_b(R^n \times R^n \times \dots \times R^n$ (m times)) for same $m \geq 1$. Then for $t \geq s \geq t_m \geq t_{m-1} \geq \dots \geq t_1 \geq 0$, $E[(f(X^n(t)) - T_{s,t}^n f(X^n(s)))g(X^n(t_1), \dots, X^n(t_m))] = 0$, $n = 1, 2, \dots$. For each n , $T_{s,t}^n f(\cdot)$ satisfies the appropriate backward Kolmogorov equation. From standard p.d.e. theory (see [22, Chap. III] or [32, pp. 133–134]), it follows that $T_{s,t}^n f(\cdot)$, $n = 1, 2, \dots$, are equicontinuous. Since they are clearly bounded, they form a sequentially precompact set in $C(R^n)$ with the topology of uniform convergence on compacts. Let $T_{s,t} f(\cdot)$ be a limit point of the same in $C(R^n)$. Passing to the limit in the above as $n \rightarrow \infty$, it is easily seen (e.g., using Skorokhod's theorem) that $E[(f(X^\infty(t)) - T_{s,t} f(X^\infty(s)))g(X^\infty(t_1), \dots, X^\infty(t_m))] = 0$. Since $f, g, \{t_i\}$ were arbitrary, a standard argument using the monotone class theorem establishes the Markov property of $X^\infty(\cdot)$. By Theorem 3.1 of [20], $X^\infty(\cdot)$ satisfies (1.1) for some $u(\cdot)$. Argue as in [15, pp. 184–5], to conclude that $u(\cdot)$ must be of the form $u(\cdot) = v(X^\infty(\cdot), \cdot)$ for some measurable map $v: R^n \times R^+ \rightarrow U$. Since $T_{s,t}^n f$ depends on t, s only through $t - s$ for each f and $n = 1, 2, \dots$, the same must be true for $T_{s,t} f$ in view of the above limiting argument. It follows that $X^\infty(\cdot)$ is a time-homogeneous Markov process and hence $u(\cdot)$ is in fact a Markov control. Q.E.D.

THEOREM 3.1. *The set $\{\eta_v \mid v \text{ Markov control}\}$ is compact in $P(R^n)$.*

Proof. Let $\{v_n\}$ be a sequence of Markov controls and $X^n(\cdot)$ the corresponding diffusions whose initial laws will soon be specified. Define $\{\tau_i^n\}, \{\xi_i^n\}$ as in (3.8)–(3.10) correspondingly. Let q^n be the unique invariant probability measure for the chain $\{X^n(\tau_i^n)\}$. Set the law of $X^n(0)$ equal to q^n for each $n = 1, 2, \dots$. Argue as in the proof of Theorem 3.1 of [19] to conclude that $X^n(\cdot) \rightarrow X^\infty(\cdot)$ in law along a subsequence, denoted $\{n\}$ again by abuse of notation. By Lemma 3.5, $X^\infty(\cdot)$ satisfies (1.1) for some Markov control v_∞ . Invoke Skorokhod's theorem as before to assume that the above convergence is a.s. on a common probability space. Define $\{\tau_i^\infty\}, \{\xi_i^\infty\}$ as in (3.8)–(3.10) for $X^\infty(\cdot)$. By arguments similar to those used to prove $\tau^n \rightarrow \tau^\infty$ a.s. in the

proof of Lemma 3.3, we can inductively prove that

$$(3.11) \quad \tau_i^n \rightarrow \tau_i^\infty \text{ a.s.}, \quad \xi_i^n \rightarrow \xi_i^\infty \text{ a.s.} \quad \text{for all } i.$$

Thus

$$(3.12) \quad \begin{aligned} X^n(\tau_i^n) &\rightarrow X^\infty(\tau_i^\infty) \text{ a.s.}, \\ \int_{\tau_i^n}^{\tau_{i+1}^n} f(X^n(s)) ds &\rightarrow \int_{\tau_i^\infty}^{\tau_{i+1}^\infty} f(X^\infty(s)) ds \quad \text{a.s. for all } i \end{aligned}$$

where $f \in C_b(R^n)$. By Lemmas 3.2 and 3.3,

$$(3.13) \quad \sup_n E[(\tau_2^n)^2] < \infty$$

and hence $\{\tau_2^n, n \geq 1\}$ are uniformly integrable. Thus

$$(3.14) \quad \begin{aligned} E[\tau_2^n] &\rightarrow E[\tau_2^\infty], \\ E\left[\int_0^{\tau_2^n} f(X^n(s)) ds\right] &\rightarrow E\left[\int_0^{\tau_2^\infty} f(X^\infty(s)) ds\right], \quad f \in C_b(R^n) \end{aligned}$$

by (3.11), (3.12). By Corollary 3.1,

$$(3.15) \quad \begin{aligned} \int f d\eta_{v_n} &= \frac{E[\int_0^{\tau_2^n} f(X^n(s)) ds]}{E[\tau_2^n]} \\ &\rightarrow \frac{E[\int_0^{\tau_2^\infty} f(X^\infty(s)) ds]}{E[\tau_2^\infty]}. \end{aligned}$$

Since $\tau_1^n = 0$ a.s. $n = 1, 2, \dots$, $\tau_1^\infty = 0$ a.s. Since for each $n = 1, 2, \dots$, $\{X^n(\tau_i), i = 1, 2, \dots\}$ are identically distributed, it follows that $\{X^\infty(\tau_i), i = 1, 2, \dots\}$ are identically distributed. Thus the initial law of $X^\infty(\cdot)$ equals the unique invariant probability measure for the chain $\{X^\infty(\tau_i), i = 1, 2, \dots\}$. Hence by Corollary 3.1, the right-hand side of (3.15) equals $\int f d\eta_{v_\infty}$. Thus $\eta_{v_n} \rightarrow \eta_{v_\infty}$ in $P(R^n)$. The claim follows. Q.E.D.

COROLLARY 3.2. *There exists a Markov control v such that*

$$\int c(x, v(s)) \eta_v(dx) = \alpha.$$

Proof. Pick $\{v_n\}$ above so that

$$\int c(x, v_n(x)) \eta_{v_n}(dx) \downarrow \alpha.$$

Define $p_n \in P(R^n \times V)$, $n = 1, 2, \dots$, by

$$\int f(x, y) p_n(dx, dy) = \int \int f(x, y) v_n(x, dy) \eta_{v_n}(dx), \quad f \in C_b(R^n \times V).$$

Since V is compact, the above theorem implies that $\{p_n\}$ is tight in $P(R^n \times V)$ and hence converges along a subsequence (denoted n again) to some $p_\infty \in P(R^n \times V)$. Argue as in the proof of Lemma 2.4 to conclude that p_∞ is of the form

$$p_\infty(dx, dy) = \eta_v(dx) v(x, dy)$$

for some Markov control v . Then

$$\int c(x, v(x)) \eta_v(dx) = \alpha$$

follows from Fatou's lemma and the definition of α . Q.E.D.

4. Existence of an optimal Markov control under Assumption A. In this section, we shall show that the Markov control in the statement of Corollary 3.2 is a.s. optimal. Before we get down to the main result (Theorem 4.1), we shall collect together a few minor consequences of the foregoing that will be used later.

LEMMA 4.1. $\{E[\tau_2]|X(\cdot) \in M_1(\delta B_1)\}$ is bounded from above and bounded away from zero from below.

Proof. The upper bound follows from Lemmas 3.2–3.4 in an obvious manner. An argument similar to that leading to (3.14) can be employed to show the rest. Q.E.D.

LEMMA 4.2. The set of probability measures η defined by

$$\int_{R^n} f d\eta = E \left[\int_0^{\tau_2} f(X(t)) dt \right] / E[\tau_2], \quad f \in C_b(R^n),$$

for $X(\cdot) \in M_1(\delta B_1)$ is tight in $P(R^n)$.

Proof. This can be proved the same way as Theorem 3.1 by showing that each sequence has a subsequence that converges in $P(R^n)$. Q.E.D.

Let $\{f_n\}$ be a collection of smooth maps $R^n \rightarrow [0, 1]$ such that $f_n(x) = 0$ for $\|x\| \leq n$ and $=1$ for $\|x\| \geq n+1$.

LEMMA 4.3. For any $\varepsilon \geq 0$, there exists $N_\varepsilon \geq 1$ such that for all $n \geq N_\varepsilon$ and $X(\cdot) \in M_1(\delta B_1)$,

$$E \left[\int_0^{\tau_2} f_n(X(s)) ds \right] < \varepsilon.$$

Proof. Let $Y(\cdot) = X(\xi_1 + \cdot)$. Let β_m denote the first exit time from $\{x | \|x\| \leq m\} \setminus B_1$ where m is any integer sufficiently large so that $\|x\| < m$ for $x \in B_2$. (We do not specify for which process, leaving that to depend on the context for economy of notation.) Consider the control problem for $\bar{X}(\cdot) \in M_2(\delta B_2)$ with the cost

$$E \left[\int_0^{\beta_m} f_n(\bar{X}(s)) ds \right]$$

for some n, m . By the results of [4, § IV.3, pp. 150–155], an optimal Markov control exists for this problem. Thus

$$E \left[\int_0^{\beta_m} f_n(Y(s)) ds \right] \leq \sup_{\bar{X}(\cdot) \in M_1(\delta B_2)} E \left[\int_0^{\beta_m} f_n(\bar{X}(s)) ds \right].$$

For large $n, f_n = 0$ on B_2 and hence the above is the same as

$$E \left[\int_0^{\gamma_m} f_n(X(s)) ds \right] \leq \sup_{\bar{X}(\cdot) \in M_1(\delta B_1)} E \left[\int_0^{\bar{\gamma}_m} f_n(\bar{X}(s)) ds \right]$$

where γ_m (respectively, $\bar{\gamma}_m$) = $\inf \{t \geq \xi_1 | X(t) \text{ (respectively, } \bar{X}(t) \notin \{x | \|x\| \leq m\} \setminus B_1\}$. Since $\gamma_m \uparrow \tau_2$ as $m \rightarrow \infty$, we have

$$(4.1) \quad E \left[\int_0^{\tau_2} f_n(X(s)) ds \right] \leq \sup_{\bar{X}(\cdot) \in M_1(\delta B_1)} E \left[\int_0^{\tau_2} f_n(\bar{X}(s)) ds \right] \leq \varepsilon,$$

for n sufficiently large, by virtue of Lemmas 4.1, 4.2. Q.E.D.

LEMMA 4.4. The set $\{E[\tau_2]|X(\cdot) \in M_2(\delta B_1)\}$ is bounded from above and bounded away from zero from below.

Proof. The first claim is proved by the same arguments that imply the first half of Lemma 4.1. The second claim follows by arguments similar to those used to prove a similar claim for $M_1(\delta B_1)$ in Lemma 4.1 with the following change: We consider

a sequence $\{X^n(\cdot)\}$ in $M_2(\delta B_1)$ instead of $M_1(\delta B_1)$, with initial laws arbitrary in $P(\delta B_1)$. Q.E.D.

We can now prove the main result of this section.

THEOREM 4.1. *There exists an a.s. optimal Markov control.*

Proof. Let $X(\cdot)$ be as in (1.1). By Lemmas 3.2–3.4, $\tau_i < \infty$ a.s. for all i . Thus for $\{f_n\}$ as in Lemma 4.3,

$$(4.2) \quad \limsup_{t \rightarrow \infty} \frac{1}{t} \int_0^t f_n(X(s)) ds = \limsup_{m \rightarrow \infty} \frac{\sum_{i=1}^m \int_{\tau_i}^{\tau_{i+1}} f_n(X(s)) ds}{\sum_{i=1}^m (\tau_{i+1} - \tau_i)}.$$

By Lemmas 3.4 and 4.3, for any $\varepsilon > 0$, there exists $N_\varepsilon \geq 1$ such that for all $n \geq N_\varepsilon$, $i \geq 1$,

$$(4.3) \quad E \left[\int_{\tau_i}^{\tau_{i+1}} f_n(X(s)) ds / F_{\tau_i} \right] < \varepsilon \quad \text{a.s.}$$

By Lemmas 3.2–3.4,

$$\sup_i E[(\tau_{i+1} - \tau_i)^2] < \infty.$$

Hence one can use the strong law of large numbers for square-integrable martingales [23, pp. 53] to conclude that

$$(4.4) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \left[\int_{\tau_i}^{\tau_{i+1}} f_n(X(s)) ds - E \left[\int_{\tau_i}^{\tau_{i+1}} f_n(X(s)) ds / F_{\tau_i} \right] \right] = 0 \quad \text{a.s.},$$

$$(4.5) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n [(\tau_{i+1} - \tau_i) - E[(\tau_{i+1} - \tau_i) / F_{\tau_i}]] = 0 \quad \text{a.s.}$$

From Lemmas 3.4, 4.4 and (4.2)–(4.5) above, we conclude that

$$\limsup_{t \rightarrow \infty} \frac{1}{t} \int_0^t f_n(X(s)) ds < C\varepsilon \quad \text{a.s.}$$

for n large enough, with some constant C independent of n . Recalling the definition of $\{f_n\}$, it is easily deduced from this that in the set-up of Lemma 2.2, $\delta(\nu) = 1$ for all limit points ν of $\{\nu_i\}$ outside a set of zero probability. The claim now follows as in the proof of Theorem 2.1 in view of Corollary 3.2. Q.E.D.

Remarks. Let $n = 1$. Pick Markov controls v_1, v_2 such that $m(x, v_1(x)) = \max m(x, v)$, $m(x, v_2(x)) = \min m(x, v)$. Our conditions on m and the selection theorem of Lemma 1 of [3], guarantee the existence of v_1, v_2 as above. Let $X(\cdot)$ be as in (1.1) for some admissible control $u(\cdot)$ and $X_1(\cdot), X_2(\cdot)$ be the diffusions controlled by v_1, v_2 respectively, with the same initial condition as $X(\cdot)$. (Recall that a strong solution to Markov-controlled (1.1) exists [29]. Thus we can construct $X(\cdot), X_1(\cdot), X_2(\cdot)$ on the same probability space.) By the well-known comparison theorem for one-dimensional Ito processes [17, pp. 352–355], it follows that outside a set N' of zero probability,

$$(4.6) \quad X_2(t) \leq X(t) \leq X_1(t) \quad \text{for all } t \geq 0.$$

Suppose we assume that v_1, v_2 are stable. Then (4.6) implies in a straightforward manner that

- (i) all Markov controls are stable,
- (ii) $\delta(\nu)$ in Lemma 2.2 can always be taken to be 1 outside $N \cup N'$ (N as in Lemma 2.2),
- (iii) $H = \{\eta_v | v \text{ Markov}\}$ is compact.

Thus in the one-dimensional case, we have the conclusion of Theorem 4.1 under a seemingly more general set-up than that of Assumption A.

AN EXACT PENALTY FUNCTION AND RELAXATION APPROACH FOR SOLVING DECOMPOSABLE NONLINEAR PROGRAMS*

RAFAEL LAZIMY†

Abstract. An effective approach to solving decomposable nonlinear programs P (large-scale programs or, e.g., programs that are nonconvex in (x, y) jointly, but convex in x for each y where, e.g., y is a vector of integer variables) is based on the principles of projection and dual representation, which transform P into an equivalent master problem in y -space. The master problem may then be solved by either relaxation or implicit enumeration. However, a serious difficulty arises when solving the master problem in y -space. For a given trial solution y , the dual subproblem $D'(y)$ may be unbounded from above on its domain, in which case y is inadmissible, and a new constraint designed to eliminate y needs to be generated and added to the current relaxed master problem. The problem is that under certain conditions the constraints for eliminating inadmissible trial solutions are not producible using existing procedures. In this paper, we overcome this difficulty by employing an exact penalty function approach to derive a relaxation algorithm for solving P .

Key words. nonlinear programming, duality, relaxation, penalty functions, optimization

1. Introduction. Consider the nonlinear program

$$P \quad \underset{(x, y)}{\text{minimize}} \quad f(x, y) \quad \text{s.t.} \quad g(x, y) \leq 0, \quad y \geq 0, \quad y \in Y,$$

where: $f: R^{n_1+n_2} \rightarrow R$, $g: R^{n_1+n_2} \rightarrow R^m$ are convex, twice continuously differentiable functions on the $(n_1 + n_2)$ real Euclidean space $R^{n_1+n_2}$. $Y \subseteq R^{n_2}$ is a compact set of arbitrarily constrained variables.

y is a vector of “complicating” variables in the sense that P is intractable and/or unmanageable in x and y jointly, but for each $y \in Y$ the subproblem $P(y) := \{\text{minimize } f(x, y), \text{ subject to } x: g(x, y) \leq 0, x \geq 0\}$ is convex and manageable. Following Geoffrion [5] we have in mind situations such as: (a) Y is a finite discrete set, so that P is not convex. For instance, y is a vector of integer-valued variables, in which case P is a mixed-integer nonlinear program. (b) P is a large-scale optimization problem, but $P(y)$ is of a manageable size. (c) $P(y)$ can be decomposed into a number of independent subprograms, each involving a different subvector of x , such that the solution of $P(y)$ can be decentralized and done in parallel for each of the smaller independent subprograms. (d) $P(y)$ has some special structure. (Obviously, y may be a vector of integer variables also in situations (b)–(d), and not only in (a).)

An effective approach to solving P is based on the principles of projection and dual representation, which transform program P into an equivalent master problem in y -space. Then, either relaxation or (if, e.g., Y is a discrete set) implicit enumeration is used in order to solve the master problem and obtain a solution for P . Benders applied these principles to solve certain programs with a structure similar to P [2]. His work, however, was limited to problems in which f and g are linear in the “complicating” variables y , and separable in x and y . Balas generalized Benders’ approach to the nonlinear case, but assumed that Y is a discrete set [1]. Also, he used implicit enumeration to solve the master problem in y -space. Geoffrion developed a somewhat different generalization of Benders’ approach [5]. He based his generalization

on nonlinear Lagrangian duality theory (thus, f and g are not necessarily assumed to be differentiable). Also, he used relaxation to solve the master problem.

A serious problem arises in solving the equivalent master problem in y -space (either by relaxation, or by implicit enumeration). The master problem is solved iteratively. Each iteration produces a trial solution y for the master problem; then the dual of subproblem $P(y)$ (denoted by $D'(y)$) is solved. The solution of $D'(y)$ (if it exists) is used to test the current trial solution y for optimality in the master problem, and to generate additional constraints if y is not the optimal solution. If $D'(y)$ is unbounded from above on its domain, $P(y)$ is inconsistent and, therefore, y is not admissible for P . A new constraint has to be produced, to eliminate the inadmissible point y . Balas [1, Thm. 5.3] proposed a procedure for generating constraints to eliminate inadmissible trial solutions. However, a serious flaw exists in Balas's Thm. 5.3, which makes it impossible to use it as a general procedure for producing constraints to eliminate inadmissible trial solutions y .

In this paper, we overcome the above problem by reformulating the dual pair $P(y)$ and $D'(y)$ so that: (1) The new primal subproblem $\hat{P}(y)$ is consistent for any y . (2) The new dual $\hat{D}(y)$ is bounded from above for any y . To this end, we employ an exact penalty function approach. Based on these formulations, we then present a relaxation algorithm to solve program P .

The paper is organized as follows. In § 2 we outline the relaxation approach for solving P , and identify and describe the problem that arises in the context of eliminating inadmissible points y . In § 3 we present the exact penalty function formulations, derive the dual pair $(\hat{P}(y), \hat{D}(y))$ and state the relationships between them and the original pair $(P(y), D(y))$. Finally, the modified relaxation method for solving P is presented in § 4, and some of its computational aspects are briefly discussed.

We briefly comment now on our notation. The relation $x \geq 0$ includes the case $x = 0$; however, $x \geq 0$ means that $x \neq 0$ (i.e., that $x_i > 0$ for at least one i). For $f: R^{n_1+n_2} \rightarrow R$, $\nabla_x f(x, z)$ denotes the vector of partial derivatives of f with respect to x , evaluated at (x, z) . Also, $\nabla_{x,z} f := (\nabla_x f, \nabla_z f)$. For $g: R^{n_1+n_2} \rightarrow R^m$, $\nabla_{x,z} g(x, z)$ denotes the $m \times (n_1 + n_2)$ Jacobian matrix evaluated at (x, z) . A vector of ones in any real Euclidean space is denoted by e .

2. Eliminating inadmissible solutions in the relaxation process. For some y , let $P(y)$ be the subproblem obtained by fixing y in program P :

$$P(y) \quad \pi(y) := \underset{x}{\text{minimize}} f(x, y) \quad \text{s.t. } g(x, y) \leq 0, \quad x \geq 0.$$

In order to obtain a dual of $P(y)$ whose objective function is *linear* in the “complicating” variables y and whose feasible set is *independent* of y , we employ the following subproblem $P'(y)$ which obviously is equivalent to $P(y)$ (see [1]):

$$P'(y) \quad \pi(y) := \underset{(x, z)}{\text{minimize}} f(x, z) \quad \text{s.t. } g(x, z) \leq 0, \quad z = y, \quad x \geq 0,$$

where $z \in R^{n_2}$. The dual of $P'(y)$ is (see Huard [9], Dantzig, Eisenberg and Cottle [3], Mangasarian [11], and Wolfe [16]):

$$D'(y) \quad \delta(y) := \underset{(x, z, u, v, r)}{\text{maximize}} h(x, y, z; u, v, r) \quad \text{s.t. } (x, z, u, v, r) \in \Psi,$$

where $u \in R^m$, $v \in R^{n_1}$, $r \in R^{n_1}$, and

$$(1) \quad h(x, y, z; u, v, r) := f(x, z) + ug(x, z) + v(z - y) - rx,$$

$$(2) \quad \Psi := \{(x, z, u, v, r) | \nabla_{x,z} [f(x, z) + ug(x, z) + vz - rx] = 0, (u, r) \geq 0\}.$$

Remark 2.1. If x is not restricted in sign, then the vector r does not appear in h and in Ψ .

It is assumed that g satisfies any one of the six constraint qualifications listed in [12, Thm. 7.3.7].

Define Φ to be the set of *admissible* solutions y for P :

$$(3) \quad \Phi := \{y | g(x, y) \leq 0 \text{ for some } x \geq 0\}.$$

Based on the duality relationships between $P'(y)$ and $D'(y)$ (see, e.g., [16, Thm. 2], [9], [11]), we obtain the following projection of P from (x, y) -space onto y -space (recall that Ψ is independent of y):

$$D' \quad \underset{y}{\text{minimize}} \delta(y), \quad \text{s.t. } y \in Y \cap \Phi$$

(where Y is in P), which is equivalent to

$$\begin{aligned} D' \quad & \underset{(\theta, y)}{\text{minimize}} \theta \\ & \text{s.t.} \quad (1) \quad \theta \geq f(x, z) + ug(x, z) + v(z - y) - rx \quad \text{all } (x, z, u, v, r) \in \Psi, \\ & \quad (2) \quad y \in Y \cap \Phi. \end{aligned}$$

Programs D' and P are equivalent in the sense that if (θ, y) solves D' , then (x, y) solves P , where x is the solution of $P(y)$. Thus, one can obtain the solution of P by solving D' . Program D' has an infinite number of constraints; therefore, it is natural to solve it by *relaxation*. Two programs are solved at each iteration of the relaxation process: a *relaxed* version of program D' , denoted RD, and a dual subproblem $D'(y)$. Program RD is used to generate candidate solutions (θ, y) for D' , and the dual $D'(y)$ is used to test (θ, y) for optimality in D' . If $D'(y)$ has a finite optimal solution (x, z, u, v, r) but (θ, y) is not feasible for D' , a new constraint (of type (1) of D') is added to the relaxed program RD. If $D'(y)$ is unbounded from above on Ψ (i.e., $\delta(y) \rightarrow +\infty$ along some feasible sequence $\{(x, z, u, v, r)_k\}$), then $P'(y)$ is inconsistent [16, Table on p. 242], and the trial solution y is not admissible for P . In this case, a new constraint must be added to RD in order to eliminate the inadmissible point y . The problem addressed in this paper concerns the generation of these constraints.

Balas employed the following result to generate constraints that eliminate inadmissible trial solutions y [1, Thm. 5.3]:

If $\delta(y)$ is unbounded from above on Ψ , there exist vectors (x, z, u) and $s \in R^m$ such that

$$(4a) \quad (x, z, u, v, r) \in \Psi,$$

$$(4b) \quad s \nabla_x g(x, z) \geq 0, \quad s \geq 0,$$

$$(4c) \quad sg(x, z) + t(z - y) - qx > 0,$$

where (see the definition of Ψ in (2))

$$(5) \quad v = -\nabla_z l(x, z; u), \quad r = \nabla_x l(x, z; u),$$

$$(6) \quad l(x, z; u) := f(x, z) + ug(x, z),$$

and

$$(7) \quad t := -s \nabla_z g(x, z), \quad q := s \nabla_x g(x, z).$$

Remark 2.2. If x is not restricted in sign, then the vectors r and q do not appear, and condition (4b) becomes

$$(8) \quad s \nabla_x g(x, z) = 0, \quad s \geq 0.$$

Therefore, if $D'(\bar{y})$ is unbounded from above, the above result is used to generate the following new constraint, which is added to program RD in order to eliminate the inadmissible point \bar{y} :

$$(9) \quad \bar{s}g(\bar{x}, \bar{z}) + \bar{t}(\bar{z} - y) - \bar{q}\bar{x} \leq 0,$$

where $(\bar{x}, \bar{z}, \bar{u}, \bar{v}, \bar{r})$ and $(\bar{s}, \bar{t}, \bar{q})$ are vectors that satisfy the conditions (4)–(7).

Theorem 5.3 in [1] is wrong if, for any $(x, z, u, v, r) \in \Psi$, the only solution to the system $\{s | s \nabla_x g(x, z) \geq 0, s \geq 0\}$ (if $x \geq 0$), or to $\{s | s \nabla_x g(x, z) = 0, s \geq 0\}$ (if x is not restricted in sign), is $s = 0$. Since $s = 0$ implies $t = q = 0$ (see (7)), then condition (4c) does not hold and, consequently, constraint (9) for eliminating inadmissible trial solutions y is not producible.

Using Motzkin's and Gordan's theorems of the alternatives, we obtain the following characterization of the cases when constraint (9) is not producible. Assume that $D'(y)$ is unbounded from above on Ψ . Then, for any $(x, z, u, v, r) \in \Psi$, we have¹

(a) $\{s | s \nabla_x g(x, z) \geq 0, s \geq 0\}$ has a solution s iff $\{w \in \mathbb{R}^{n_1} | \nabla_x g(x, z)w < 0, w \geq 0\}$ has no solution w (Motzkin [14]). Consequently, in the case that $x \geq 0$, if $\{w | \nabla_x g(x, z)w < 0, w \geq 0\}$ has a solution w , then constraint (9) is not producible by the procedure presented in [1].

(b) $\{s | s \nabla_x g(x, z) = 0, s \geq 0\}$ has a solution s iff $\{w \in \mathbb{R}^{n_1} | \nabla_x g(x, z)w > 0\}$ has no solution w (Gordan [6]). Consequently, in the case that x is not restricted in sign, if $\{w | \nabla_x g(x, z)w > 0\}$ has a solution w , then constraint (9) is not producible.

Remark 2.3. One particular case where constraint (9) is not producible is when x is not restricted in sign and the rows of the $m \times n_1$ matrix $\nabla_x g(x, z)$ are linearly independent for any $(x, z, u, v) \in \Psi$, since $s = 0$ is then the only solution to $s \nabla_x g(x, z) = 0$.

We next describe two examples in which $D'(y)$ is unbounded, but $s = 0$ and, thus, constraint (9) is not producible.

Example 1 (x unrestricted in sign). Consider

$$P \quad \text{minimize } -(x + y) \quad \text{s.t. } x^2 + y^2 - 1 \leq 0, \quad x \in \mathbb{R}, \quad y \in \mathbb{R}.$$

For all $|y| > 1$, the subproblem $P(y)$ is inconsistent, and the dual

$$D(y) \quad \delta(y) := \underset{(x, u)}{\text{maximize}} \quad l(x, y; u) \equiv -(x + y) + u(x^2 + y^2 - 1) \\ \text{s.t. } -1 + 2ux = 0, \quad u \geq 0,$$

is unbounded from above, since any (x, u) such that $x = 1/2u$, $u > 0$, is feasible for $D(y)$, and

$$l(x, y; u) = -y + u(y^2 - 1) - \frac{1}{4u} \rightarrow +\infty \quad \text{as } u \rightarrow +\infty$$

for all $|y| > 1$. However, $s = t = 0$ for all $(x, z, u, v) \in \Psi$, since (see (4)) the only solution s to

$$(1) \quad (x, z, u, v) \in \Psi \Leftrightarrow \nabla_x l(x, z; u) \equiv -1 + 2ux = 0, \quad u \geq 0$$

$$(\text{where } v := -\nabla_z l(x, z; u) = -1 + 2uz)$$

$$(2) \quad s \nabla_x g(x, z) \equiv 2sx = 0, \quad s \geq 0$$

¹ The difference between the notation “ \geq ” and “ \geqslant ” (as defined in the Introduction) is crucial here.

is $s = 0$, in which case $t := -s\nabla_z g(x, z) = 0$. Indeed, for any $x \in \{x | x = 1/2u, u > 0\}$, the system $\nabla_x g(x, z)w = 2xw > 0$ has a solution w , and by Gordan's theorem of the alternative it follows that, for any $x \in \{x | x = 1/2u, u > 0\}$, the system $s\nabla_x g(x, z) = 2sx = 0, s > 0$, has no solution s .

Example 2 (x restricted in sign). Consider

$$P \quad \text{minimize } x - y \quad \text{s.t. } \frac{1}{x} + y^2 - 10 \leq 0, \quad x \geq 0, \quad y \in R.$$

For all $y^2 > 10$, the subproblem $P(y)$ is infeasible and its dual $D(y)$ is unbounded from above, since

$$\begin{aligned} D(y) \quad \delta(y) &:= \max_{(x, u)} l(x, y; u) - \nabla_x l(x, y; u)x \\ &= x - y + u \left(\frac{1}{x} + y^2 - 10 \right) - x \left(1 - \frac{u}{x^2} \right) \\ \text{s.t. } 1 - \frac{u}{x^2} &\geq 0, \quad u \geq 0, \end{aligned}$$

and by taking $u = x^2$ we obtain $\delta(y) \rightarrow +\infty$ as $x \rightarrow +\infty$, provided that $y^2 > 10$. Thus, $D(y)$ is unbounded from above for any $y^2 > 10$. However, $s = t = q = 0$ for all $(x, z, u, v, r) \in \Psi$, since (see (4)) the only solution s to

$$(1) \quad (x, z, u, v, r) \in \Psi \Leftrightarrow \nabla_x l(x, z; u) \equiv 1 - \frac{u}{x^2} \geq 0, \quad u \geq 0,$$

$$\left(\text{where } (v, r) := (-\nabla_z l(x, z; u), \nabla_x l(x, z; u)) = \left(-1 + 2uz, 1 - \frac{u}{x^2} \right) \right)$$

$$(2) \quad s\nabla_x g(x, z) \equiv -\frac{s}{x^2} \geq 0, \quad s \geq 0$$

is $s = 0$, in which case $(t, q) := (-s\nabla_z g(x, z), s\nabla_x g(x, z)) = (0, 0)$. Indeed, for any $(x, u) \in \{(x, u) | 1 - u/x^2 \geq 0, u \geq 0\}$, we obtain: The system $\nabla_x g(x, z)w = -w/x^2 < 0, w \geq 0$, has a solution w , and by Motzkin's theorem of the alternative the system $s\nabla_x g(x, z) = -s/x^2 \geq 0, s > 0$, has no solution s .

Finally, it is worth noting that the problem of having $s = 0$ as the only solution to conditions (4a) and (4b) does not arise if the constraints of P are separable in x and y and linear in x , as stated in the following theorem.

THEOREM 2.1. *Suppose that $g(x, y) := Ax - k(y)$ where A is an $m \times n_1$ matrix, and $k: R^{n_2} \rightarrow R^m$ is a convex, twice continuously differentiable function on R^{n_2} . For some y , assume that $P(y)$ is inconsistent, but that its dual $D(y)$ is consistent. Then, $D(y)$ is unbounded from above on its domain, and for any dual feasible solution (x, u) the system*

$$s\nabla_x g(x, y) = 0, \quad s \geq 0 \quad (\text{if } x \in R^{n_1})$$

or

$$s\nabla_x g(x, y) \geq 0, \quad s \geq 0 \quad (\text{if } x \geq 0)$$

has a solution s .

The proof to Theorem 2.1 follows from [16, Thm. 3], the application of Gale's theorem of the alternative [4], and from the observation that, if there is a solution $s \geq 0$ to $s\nabla_x g(x, y) = 0$ (or to $s\nabla_x g(x, y) \geq 0$), then this solution exists for any dual feasible solution (x, u) , since $\nabla_x g(x, y)$ is independent of x .

In §§ 3 and 4 we present a modified projection and relaxation procedure for solving program P , under which the problem described above does not arise. Furthermore, this is done without imposing any new restrictions on the structure of P . The basic idea of the modified procedure is simple: the dual pair $(P'(y), D'(y))$ is reformulated so that, for any given y , the new primal program is always consistent, and the new dual program is always bounded from above on its domain. To this end, we employ an exact penalty function approach.

3. Exact penalty function formulation. Let $\alpha > 0$ be a constant, e , a vector of ones, $w \in R^m$, a vector of variables, and g_j be the j th constraint function. For some y , let $P(y; x, \alpha)$ be an exact penalty function of subproblem $P(y)$. (For instance, the exact l_1 penalty function may be employed.) It was noted by Mangasarian [13, Lemma 4.1] that the two programs

$$(10) \quad \underset{x \geq 0}{\text{minimize}} P(y; x, \alpha) := \underset{x \geq 0}{\text{minimize}} f(x, y) + \alpha \sum_{j=1}^m \max \{0, g_j(x, y)\},$$

$$\hat{P}(y) \quad \hat{\pi}(y) := \underset{(x, z, w)}{\text{minimize}} \hat{f}(x, z, w) := f(x, z) + \alpha ew$$

$$\text{s.t. } g(x, z) - w \leq 0, \quad z = y, \quad (x, w) \geq 0$$

are equivalent for any given \bar{y} (provided that α is larger than a threshold value), in the following sense: If \bar{x} solves (10), then $(\bar{x}, \bar{z}, \bar{w})$ solves $\hat{P}(\bar{y})$ where $\bar{z} = \bar{y}$ and $\bar{w} = g(\bar{x}, \bar{y})_+$ where $g_j(\bar{x}, \bar{y})_+ := \max \{0, g_j(\bar{x}, \bar{y})\}$; and if $(\bar{x}, \bar{z}, \bar{w})$ solves $\hat{P}(\bar{y})$, then \bar{x} solves (10).

Program $\hat{P}(y)$ is consistent for any y . Recalling that $P(y)$ is the program $\pi(y) := \underset{x \geq 0}{\text{minimize}} f(x, y)$ subject to $g(x, y) \leq 0$, and that Φ is the set of admissible solutions y of P (see (3)), we obtain the following relationships between $\hat{P}(y)$ and $P(y)$:

(a) Let $\bar{y} \notin \Phi$. Then

(1) $P(\bar{y})$ is infeasible.

(2) $\hat{P}(\bar{y})$ has an optimal solution at $(\bar{x}, \bar{z}, \bar{w})$, where $\bar{z} = \bar{y}$, \bar{x} is the global minimum of $P(\bar{y}; x, \alpha)$, $\bar{w} = g(\bar{x}, \bar{y})_+$, and $e\bar{w} := \sum_{j=1}^m g_j(\bar{x}, \bar{y})_+ > 0$.

(b) Let $\bar{y} \in \Phi$ but $P(\bar{y})$ be unbounded from below on its domain. Then $\hat{P}(\bar{y})$ is also unbounded from below. In this case the original program P is also unbounded.

(c) Let $\bar{y} \in \Phi$ and $P(\bar{y})$ have a finite optimal solution \bar{x} . Also, assume that $g(x, \bar{y})$ satisfies the Slater constraint qualification, and that f and g are convex. Then $\hat{P}(\bar{y})$ has an optimal solution at $(\bar{x}, \bar{z}, \bar{w})$ for each value α such that $\alpha > \bar{\alpha}$, where $\bar{\alpha}$ is some threshold value. (See Luenberger [10], Han and Mangasarian [8], Mangasarian [13], and Zangwill [17].) Furthermore, $\bar{z} = \bar{y}$ and $e\bar{w} := \sum_{j=1}^m g_j(\bar{x}, \bar{y})_+ = 0$.

Remark 3.1. Formulation $\hat{P}(y)$ could be considered to be an extension of the well-known big- M method of linear programming [15] to the case of convex programs. (The potential benefits of extending the big- M method to convex programming were recently investigated by Mangasarian [13]. In this study, this idea is applied to solving the decomposable nonlinear program P using a projection and relaxation approach.)

The dual of $\hat{P}(y)$ is

$$\hat{D}(y) \quad \hat{\delta}(y) := \underset{(x, z, w, u, v, r, p) \in \hat{\Psi}}{\text{maximize}} \hat{h}(x, y, z, w; u, v, r, p),$$

where $u \in R^m$, $v \in R^{n_2}$, $r \in R^{n_1}$, $p \in R^m$, and

$$(11) \quad \hat{h}(x, y, z, w; u, v, r, p) := f(x, z) + \alpha ew + u[g(x, z) - w] + v(z - y) - rx - pw,$$

$$(12) \quad \hat{\Psi} := \{(x, z, w, u, v, r, p) | \nabla_{x, z, w} \hat{h}(x, y, z, w; u, v, r, p) = 0, w \geq 0, (u, r, p) \geq 0\}.$$

Since $\nabla_w \hat{h} = \alpha e - u - p$, we can substitute $p = \alpha e - u$ in \hat{h} , to obtain the following form of $\hat{D}(y)$:

$$\hat{D}(y) \quad \hat{\delta}(y) := \underset{(x,z,u,v,r) \in \hat{\Psi}}{\text{maximize}} \quad \hat{h}(x, y, z; u, v, r),$$

$$(13) \quad \hat{h}(x, y, z; u, v, r) := f(x, z) + ug(x, z) + v(z - y) - rx,$$

$$(14) \quad \hat{\Psi} := \{(x, z, u, v, r) | \nabla_{x,z} [f(x, z) + ug(x, z) + vz - rx] = 0, u \leq \alpha e, (u, r) \geq 0\}.$$

The set $\hat{\Psi}$ is bounded and independent of y . Consequently, the dual $\hat{D}(y)$ is bounded from above (i.e., has a finite optimal solution) for *any* y , provided that $\hat{\Psi}$ is nonempty. Next, the projection and relaxation algorithm for solving program P is presented.

4. The algorithm. Using the modified dual definition $\hat{D}(y)$, the projection of program P onto y -space yields

$$\begin{aligned} \hat{D} \quad & \underset{(\theta, y)}{\text{minimize}} \quad \theta \\ \text{s.t.} \quad & (1) \quad \theta \geq f(x, z) + ug(x, z) + v(z - y) - rx \quad \text{all } (x, z, u, v, r) \in \hat{\Psi}, \\ & (2) \quad y \in Y \cap \Phi. \end{aligned}$$

Program \hat{D} is solved iteratively by relaxation. At each iteration, the current relaxed program RD generates a candidate solution (θ, y) , and the dual $\hat{D}(y)$ is solved in order to determine the status of y . First, we need the following.

THEOREM 4.1. *Assume that $\hat{\Psi}$ is nonempty. For some y , let (x, z, u, v, r) be the (finite) optimal solution of $\hat{D}(y)$, and assume that f and g satisfy either Huard's [9] or Mangasarian's [11] strict converse duality theorem conditions. Then*

$$(15) \quad (a) \quad y \in \Phi \text{ iff } ug(x, z) + v(z - y) - rx = 0,$$

$$(16) \quad (b) \quad y \notin \Phi \text{ iff } ug(x, z) + v(z - y) - rx > 0.$$

Furthermore, $u \geq 0$ in part (b).

Proof. Under the assumptions of the theorem, it follows from the strict converse duality theorem ([9], [11]), that (x, z, w) is the (finite) optimal solution of the primal program $\hat{P}(y)$, where $ew = \sum_{j=1}^m g_j(x, z)_+$. Furthermore, the optimal objective function values of $\hat{P}(y)$ and $\hat{D}(y)$ are equal: $\hat{\pi}(y) = \hat{\delta}(y)$, or, $f(x, z) + \alpha ew = f(x, z) + ug(x, z) + v(z - y) - rx$. Therefore,

$$(17) \quad ug(x, z) + v(z - y) - rx = \alpha ew$$

at the optimum.

Now, recall the relationships between programs $P(y)$ and $\hat{P}(y)$ and observe that $y \in \Phi$ iff $ew = 0$ at the optimum of $\hat{P}(y)$, and $y \notin \Phi$ iff $ew > 0$ at the optimum of $\hat{P}(y)$. This, together with (17) and the fact that $\alpha > 0$, proves parts (a) and (b) of the theorem.

It remains to show that $u \neq 0$ in part (b). Since relation (17) holds at the optimal solution (x, z, u, v, r) of $\hat{D}(y)$, and since $\alpha ew > 0$ in part (b) and $u \geq 0$, it is sufficient to show that $v(z - y) = 0$ and $rx = 0$ at the optimal solution (x, z, u, v, r) . To this end, recall that $z = y$ at the optimum of $\hat{P}(y)$. Therefore, $v(z - y) = 0$. Next, since $(x, z, u, v, r) \in \hat{\Psi}$, then (see (12)):

$$(18) \quad \begin{aligned} v &= -\nabla_z l(x, z; u), & r &= \nabla_x l(x, z; u), \\ l(x, z; u) &:= f(x, z) + ug(x, z). \end{aligned}$$

Using the complementary slackness property $\nabla_x[f(x, z) + ug(x, z) + v(z - y)]x = 0$, we obtain $\nabla_x l(x, z; u)x = 0$. By combining this result with (18) we obtain

$$(19) \quad rx = 0$$

at the optimum of $\hat{D}(y)$. This completes the proof. Q.E.D.

Letting $(\bar{\theta}, \bar{y})$ be the solution of the most recent relaxed program RD (see below), the algorithm for solving P is:

Step 1. Solve subproblem $\hat{D}(\bar{y})$.

- (a) If $\hat{D}(\bar{y})$ is inconsistent, stop: $\hat{D}(y)$ is inconsistent for any y , since its feasible set $\hat{\Psi}$ is independent of y . The original program P is either inconsistent or unbounded from below on its domain. (This situation can only be encountered during the first iteration.)
- (b) $\hat{D}(\bar{y})$ has an optimal solution $(\bar{x}, \bar{z}, \bar{u}, \bar{v}, \bar{r})$. Then
 - (i) If $\bar{u}g(\bar{x}, \bar{z}) + \bar{v}(\bar{z} - \bar{y}) - \bar{r}\bar{x} = 0$ and $\bar{\theta} \geq \hat{h}(\bar{x}, \bar{y}, \bar{z}; \bar{u}, \bar{v}, \bar{r}) =: \delta(\bar{y})$, stop: (\bar{x}, \bar{y}) is the optimal solution of P .
 - (ii) If $\bar{\theta} < \hat{h}(\bar{x}, \bar{y}, \bar{z}; \bar{u}, \bar{v}, \bar{r}) =: \delta(\bar{y})$, add the following constraint:

$$(20) \quad \theta + \bar{v}y \geq f(\bar{x}, \bar{z}) + \bar{u}g(\bar{x}, \bar{z}) + \bar{v}\bar{z}$$

to program RD.

- (iii) If $\bar{u}g(\bar{x}, \bar{z}) + \bar{v}(\bar{z} - \bar{y}) - \bar{r}\bar{x} > 0$, add the following constraint to RD:

$$(21) \quad \bar{v}y \geq \bar{u}g(\bar{x}, \bar{z}) + \bar{v}\bar{z}.$$

Go to Step 2.

Step 2. Solve the revised relaxed program RD.

RD minimize θ
(θ, y)

- s.t. (1) $\theta + v^i y \geq f(x^i, z^i) + u^i g(x^i, z^i) + v^i z^i, \quad i \in M_1,$
- (2) $v^i y \geq u^i g(x^i, z^i) + v^i z^i, \quad i \in M_2,$
- (3) $y \in Y,$

where $\{(\theta^i, y^i) | i = 1, 2, \dots\}$ and $\{(x^i, z^i, u^i, v^i, r^i) | i = 1, 2, \dots\}$, respectively, are the sequences of solutions of programs RD and $\hat{D}(y^i)$ solved so far, and

- (1) $i \in M_1$ iff $\theta^i < \hat{h}(x^i, y^i, z^i, u^i, v^i, r^i)$,
- (2) $i \in M_2$ iff $u^i g(x^i, z^i) + v^i(z^i - y^i) - r^i x^i > 0$.

Let $(\bar{\theta}, \bar{y})$ be the solution of RD, and go to Step 1. If RD has no solution, stop: program P is either inconsistent or unbounded from below.

The following comments are in order.

- (a) *Optimality conditions.* Suppose that the conditions stated in part (b)(i) of Step 1 are met. Then, the optimality of (\bar{x}, \bar{y}) in P is evident from the following observations:

- (1) Since $(\bar{x}, \bar{z}, \bar{u}, \bar{v}, \bar{r})$ is the optimal solution of $\hat{D}(\bar{y})$ and since the feasible set $\hat{\Psi}$ of $\hat{D}(y)$ is independent of y , then

$$\hat{h}(\bar{x}, \bar{y}, \bar{z}; \bar{u}, \bar{v}, \bar{r}) \geq \hat{h}(x, \bar{y}, z; u, v, r) \quad \text{for all } (x, z, u, v, r) \in \hat{\Psi}.$$

Therefore

$$\bar{\theta} \geq \hat{h}(x, \bar{y}, z; u, v, r) \quad \text{for all } (x, z, u, v, r) \in \hat{\Psi},$$

since $\bar{\theta} \geq \hat{h}(\bar{x}, \bar{y}, \bar{z}; \bar{u}, \bar{v}, \bar{r})$.

- (2) $\bar{y} \in Y$ (since $(\bar{\theta}, \bar{y})$ is a solution of RD), and $\bar{y} \in \Phi$, since $\bar{u}g(\bar{x}, \bar{z}) + \bar{v}(\bar{z} - \bar{y}) - \bar{r}\bar{x} = 0$ (Thm. 4.1(a)).

The above observations imply that $(\bar{\theta}, \bar{y})$ is a feasible solution of the *unrelaxed* program \hat{D} . However, since $(\bar{\theta}, \bar{y})$ is the optimal solution of program RD, and since RD is a *relaxed* version of \hat{D} , it follows that $(\bar{\theta}, \bar{y})$ is also the optimal solution of \hat{D} . Finally

- (3) Programs P and \hat{D} are equivalent, in the sense that if $(\bar{\theta}, \bar{y})$ is the solution of \hat{D} , then (\bar{x}, \bar{y}) is the solution of P , where $(\bar{x}, \bar{z}, \bar{u}, \bar{v}, \bar{r})$ is the solution of $\hat{D}(\bar{y})$.
- (b) *Adding new constraints to program RD.* If $\hat{\Psi}$ is nonempty and $\bar{\theta} < \hat{h}(\bar{x}, \bar{y}, \bar{z}; \bar{u}, \bar{v}, \bar{r})$ (part (b)(ii) of Step 1), then $(\bar{\theta}, \bar{y})$ does not satisfy *all* of the constraints of type (1) of program D . The new constraint (20) which is added to RD is designed to satisfy the “most violated” constraint. Next, if the conditions stated in part (b)(iii) of Step 1 are met, then $\bar{y} \notin \Phi$ (Thm. 4.1). The new constraint (21) is designed to eliminate the inadmissible point \bar{y} . (Note that the term $\bar{r}\bar{x}$ is not included in both (20) and (21), since $\bar{r}\bar{x} = 0$ at the optimum of $\hat{D}(\bar{y})$: see (19). Also, note that $u^i g(x^i, z^i) = 0$ in constraints (1) of RD if $i \in M_1 - M_2$, but that $u^i g(x^i, z^i) > 0$ if $i \in M_1 \cap M_2$.)

Finally, we briefly discuss some of the computational aspects of the algorithm. First, notice that the constraints of types (1) and (2) of program RD are all *linear* in the “complicating” variables y , although the original program P may be nonlinear in y . Consequently, if y is, e.g., a vector of integer-valued variables, then RD is a mixed-integer *linear* program; and if y is a vector of continuous variables, then RD is a standard linear program. Next, either $\hat{D}(y)$, or

$$\begin{aligned} \hat{P}_1(y) \quad \quad \quad \hat{\pi}(y) := \underset{(x, w)}{\text{minimize}} \quad \hat{f}(x, y, w) &:= f(x, y) + \alpha ew \\ \text{s.t.} \quad g(x, y) - w &\leq 0, \quad (x, w) \geq 0, \end{aligned}$$

can be employed as the subproblem in Step 1 of the algorithm. The advantages of using $\hat{D}(y)$ are: (1) Its feasible set $\hat{\Psi}$ is independent of y . (2) The objective functions of two consecutive programs $\hat{D}(y)$ differ from one another in the linear term $\bar{v}y$ only. These properties may simplify greatly the solution of consecutive programs $\hat{D}(y)$. Another obvious advantage is that the solution of $\hat{D}(y)$ provides both the primal and dual solutions. The main disadvantage of using $\hat{D}(y)$ is its size. Therefore, in some cases it may be preferable to find the solution (x, z, u, v, r) of $\hat{D}(y)$ by solving the primal subproblem $\hat{P}_1(y)$, which has less variables and constraints than $\hat{D}(y)$.

If $\hat{P}_1(y)$ is used as a subproblem in the relaxation process, then the algorithm for solving it needs to be *dual adequate*, in the sense that it provides both the primal solution (x, w) , and the optimal dual multipliers vector u . Then, the remaining components of the solution (x, z, u, v, r) of $\hat{D}(y)$ are determined by (see (18)):

$$(22) \quad z := y, \quad v := -\nabla_z l(x, z; u), \quad r := \nabla_x l(x, z; u),$$

where $l(x, z; u) := f(x, z) + ug(x, z)$. This provides us with all the information needed to execute the algorithm.

Finally, we consider the issue of determining the value α used in both $\hat{P}_1(y)$ and $\hat{D}(y)$. The parameter α has to exceed a threshold value $\bar{\alpha}$. One example of $\bar{\alpha}$ is due to Zangwill [17, p. 356]

$$(23) \quad \bar{\alpha}_1 := \frac{f(x^1, \bar{y}) - f(\bar{x}, \bar{y}) + 1}{\min_{1 \leq j \leq m} -g_j(x^1, \bar{y})},$$

and another is due to Luenberger [10] (see also Han and Mangasarian [8, Thm. 4.9])

$$(24) \quad \bar{\alpha}_2 := \|\bar{u}\|_\infty = \max_{1 \leq j \leq m} \bar{u}_j,$$

where \bar{y} is the current trial solution, \bar{x} the solution of $P(\bar{y})$, x^1 is any point satisfying the Slater constraint qualification, and \bar{u} is any optimal Lagrange multipliers vector for $P(\bar{y})$. Obviously, \bar{x} (or \bar{u}) are unknown beforehand; thus the *exact* threshold $\bar{\alpha}_1$ (or $\bar{\alpha}_2$) cannot be computed. One way to overcome this difficulty is to use an arbitrarily large penalty parameter α . In order to circumvent numerical difficulties of ill-conditioning that may result from using a large α , the numerical linear algebra has to be done carefully: see, e.g., Gould [7]. A better way (see [13]) is to compute an upper bound for the threshold value $\bar{\alpha}$ (either $\bar{\alpha}_1$, or $\bar{\alpha}_2$), and set the penalty parameter α to be equal to this upper bound. Thus, we can replace the unknown function value $f(\bar{x}, \bar{y})$ by a lower bound, and use it in (23) to compute $\alpha \geq \bar{\alpha}_1$. Similarly, the threshold $\bar{\alpha}_2$ (see (24)) can also be replaced by an upper bound. In [13, Cor. 2.2] it is shown that the following is an upper bound for $\bar{\alpha}_2$:

$$(25) \quad \|\bar{u}\|_{\infty} \leq \frac{f(x^1, \bar{y}) - f(\bar{x}, \bar{y})}{\min_{1 \leq j \leq m} -g_j(x^1, \bar{y})},$$

where \bar{x} , \bar{y} , \bar{u} , and x^1 are defined as before. By replacing the unknown value $f(\bar{x}, \bar{y})$ by a lower bound, we can obtain a penalty parameter α .

Remark 4.1. Given a trial solution y , suppose that we know beforehand whether y is admissible or inadmissible. Then

(a) If y is admissible, we employ the *original* subprogram $P(y)$ as a subproblem, rather than $\hat{P}_1(y)$:

$$P(y) \quad \underset{x}{\text{minimize}} \quad f(x, y) \quad \text{s.t.} \quad g(x, y) \leq 0, \quad x \geq 0.$$

In this case, the artificial variables w are not included. Therefore, there is no need to determine the penalty parameter α . Also, program $P(y)$ is smaller than $\hat{P}_1(y)$: it includes fewer variables.

(b) If y is inadmissible, then *any* $\alpha > 0$ can serve as a penalty parameter, and program $\hat{P}_1(y)$ will be employed as a subproblem.

The question, of course, is how to establish whether a given trial solution y is admissible or not. One approach is to use an algorithm fitted with a phase-one procedure in order to solve program $P(y)$. Thus, given \bar{y} , we first solve the phase-one program

$$\underset{(x, w)}{\text{minimize}} \quad ew \quad \text{s.t.} \quad g(x, \bar{y}) - w \leq 0, \quad (x, w) \geq 0.$$

Letting (\bar{x}, \bar{w}) be its solution, we will conclude that \bar{y} is admissible if $\bar{w} = 0$, and inadmissible if $e\bar{w} > 0$.

TRAJECTORY STABILIZING CONTROLS IN HEREDITARY LINEAR SYSTEMS*

GILEAD TADMOR†

Abstract. The following phenomenon is specific to a class of hereditary control systems: Trajectories of these systems can be stabilized (i.e., controlled to asymptotically approach the origin). However, it is impossible to obtain stabilization with controls whose rate of decay is the same as that of the trajectories. We call such systems trajectory stabilizable. We characterize the class of trajectory stabilizable systems and present both open and closed loop trajectory-stabilizing schemes. The controllability aspect of trajectory stabilizability is studied too. Examples illustrate the discussion.

Key words. stabilizability, closed loop controls, spectral controllability, control delays, reduction schemes

AMS(MOS) subject classifications. 93915, 93B05, 93C22, 49E30

1. Introduction. Consider the linear hereditary control system

$$(*) \quad \dot{x}(t) = \int_0^h d\alpha(\theta)x(t-\theta) + \int_0^h d\beta(\theta)u(t-\theta).$$

In this system $x \in R^n$, $u \in R^m$ and h is a fixed, positive number, standing for the length of the system's memory. Two matrix valued measures of bounded variations, α and β , determine the evolution's dependence on past and present values of the state and of the control. We shall be interested in stabilizing trajectories of (*).

The following phenomenon is specific to systems with control-delays: It may happen that the trajectory $x(t)$ can be stabilized, i.e., steered to the origin, at a certain asymptotic rate (say, proportional to $e^{\gamma t}$, for some negative γ), but that the decay of the corresponding control function $u(t)$, must be slower. This is contrary to the situations in systems with *no* delays in the control action, where stabilizing controls can always be chosen asymptotically proportional to $x(t)$. We call systems which might exhibit this phenomenon *trajectory stabilizable* (rigorous definitions are provided in § 3).

Stabilization of hereditary systems has been studied already by several researchers, and the articles cited below, except [2] and [6], are examples of the published results. In these papers, however, a system is termed *stabilizable*, or *regulable*, only if it is possible to steer $x(t)$ to the origin, using a control function which is asymptotically proportional to $x(t)$. We distinguish systems having this stronger property from trajectory-stabilizable systems, and term them *state stabilizable*.

The latter notion is based on the commonly accepted view that the true state of a hereditary system comprises both the history of $x(t)$ and that of the control, $u(t)$. Indeed, formally speaking, trajectory-stabilizable systems might be those in which stabilizing controls must even bear exponential growth, or ever increasing oscillations. Such systems will not be of practical use, except perhaps in rare cases of very short operation time. Excluding such anomalies, however, there remains the very rich class of systems, of real-life interest, in which it is possible (and desirable) to improve decay

* Received by the editors August 12, 1985; accepted for publication April 3, 1987. This is a revised version of a technical report, prepared at the Department of Electronic Communication, Control and Computer Systems, School of Engineering, Tel Aviv University, Tel Aviv, Israel.

† Laboratory for Information and Decision Systems, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139.

rates of trajectories, but no such improvement is possible in the corresponding stabilizing controls (which remain, nonetheless, bounded, or decay at slower rates). These are the true subject of the present study. We characterize systems in this class and describe closed- and open-loop, trajectory-stabilizing controls.

The paper is organized as follows: Using a very simple motivating example, some basic observations are made in § 2. These observations will be further developed in the following sections. A characterization of trajectory-stabilizable systems, and of the relations between state- and trajectory-stabilizability, is given in Theorem A, in § 3. In the proof of Theorem A, it is shown how known open-loop state-stabilization schemes can be modified, to suit trajectory-stabilizable systems. Closed-loop schemes are developed in § 4. In § 5, a simple, and perhaps more feasible treatment is suggested for the simpler case of systems with only commensurate lags in the control term. The controllability notion which correspond to trajectory-stabilizability (versus state-stabilizability), and geometrical properties of trajectory-stabilizing controls, are studied in § 6. Some concluding remarks are brought in § 7.

Following a well-known analysis of Pandolfi [16] (see also Remark 4.4, in § 4 herein), when stabilizing a system with $x(\cdot)$ -delays, one really focuses on an ordinary system, obtained via a spectral projection of the history of the function $x(\cdot)$. All our illustrating examples will therefore have ordinary homogeneous parts, concentrating on the interesting effects of control delays.

2. A motivating simple example. Consider this next scalar system

$$(2.1) \quad \dot{x}(t) = \lambda x(t) + u(t) - e^\lambda u(t-1).$$

Assuming $u(t) = 0$ for $t \leq 0$, the Laplace transform of (2.1) becomes

$$(s - \lambda)X(s) = x(0) + (1 - e^{\lambda-s})U(s);$$

hence

$$X(s) = \frac{x(0)}{s - \lambda} + \frac{1 - e^{\lambda-s}}{s - \lambda} U(s).$$

Now, if $x(t)$ is to be stabilized (starting with $x(0) \neq 0$) at a decay rate $\gamma < \lambda$ (i.e., if the pole of $X(s)$ at $s = \lambda$ is to be removed), then $U(s)$ must have a pole at $s = \lambda$. This happens because of the zero of $B(s) \stackrel{\text{def}}{=} 1 - e^{\lambda-s}$ at $s = \lambda$. Observing this phenomenon for positive λ , Olbrot [15] suggested the concept of stabilizability which we term *state-stabilizability*, and which excludes systems such as the system (2.1), where stabilizing controls must grow exponentially.

Here is a different point of view. Suppose λ is negative. Then trajectories decay at rate λ when no control force is applied. It seems natural to ask whether this rate can be improved by use of reasonable control functions (say, square-integrable, optimal quadratic for large “ Q ” kernel, bounded etc.). In the ordinary (nondelayed) case, one obtains the answers by studying the system’s state-stabilizability properties: if $x(t)$ can be brought to the origin at rate $\gamma < \lambda$, so can a control function for that task. Here we have an example for a qualitatively different situation: although $x(t)$ can be brought to the origin at rate $\gamma < \lambda$, so can a control function for that task. Here we have an example for a qualitatively different situation: although $x(t)$ can be brought to the origin arbitrarily fast, control functions which do the job will be, at best, asymptotically proportional to $e^{\lambda t}$. Trajectory stabilizability is therefore an appropriate notion in the presence of delays.

A basic observation (Theorem A, § 3) is that (*) is γ -trajectory-stabilizable (given a decay-rate γ) if and only if it can be transformed into a γ -state-stabilizable system by factoring undesirable zeros from $B(s)$. State-stabilizing open and closed loop controls in the transformed system can be used in solving the original stabilization problem.

Here are two factorization and stabilization strategies, as displayed in the simple framework of (2.1). The first suits systems of the general form of (*). Here it goes as follows: Set $\bar{B}(s) = (1 - e^{\lambda-s})/(s - \lambda)$. Then $\bar{B}(\lambda) \neq 0$ and $\bar{B}(s)$ is the Laplace transform of a measure $d\bar{\beta}$ whose support is the interval $[0, 1]$ (as is that of $d\beta$). Precisely,

$$d\bar{\beta}(\theta) = \begin{cases} e^{\lambda\theta} d\theta & \text{for } \theta \in [0, 1], \\ 0 & \text{otherwise.} \end{cases}$$

Consider now a new control system

$$(2.2) \quad \dot{x}(t) = \lambda x(t) + \int_0^1 d\bar{\beta}(\theta) \bar{u}(t - \theta).$$

By Olbrot's criterion (see Theorem 3.2 in § 3), the system (2.2) is state-stabilizable. Setting $U(s) = \bar{U}(s)/(s - \lambda)$, we convert state-stabilizing controls in (2.2) into trajectory-stabilizing controls in (2.1). (Indeed, since $B(s)U(s) = \bar{B}(s)\bar{U}(s)$, the two systems share the same trajectories.) Given a state-stabilizing feedback law in (2.2), say of the form

$$\bar{u}(t) = Kx(t) + \int_0^1 k(\theta) \bar{u}(t - \theta) d\theta$$

(cf. Remark 4.4 herein), the following will be a dynamical trajectory—stabilizing feedback in (2.1)—

$$\dot{u}(t) = \lambda u(t) + \bar{u}(t), \quad \bar{u}(t) = Kx(t) + \int_0^1 k(\theta) \bar{u}(t - \theta) d\theta.$$

(The problem of defining the history of $\bar{u}(t)$ is dealt with in § 4.)

A second scheme is for systems in which only finitely many commensurate lags appear in the control element. In these systems $B(s) = P(e^{-\delta s})$, where $P(z)$ is a matrix valued polynomial, and δ is a positive constant. ($\delta \cdot \text{rank } P(z) = h$.) In (2.1) we have $P(z) = 1 - e^{\lambda z}$ and $\delta = 1$. Now one factors $B(s)$ as a product of polynomials in $e^{-\delta s}$. In (2.1) we may set $\bar{B}(s) = (1 - e^{\lambda-s})/(1 - e^{\lambda-s}) = 1$. There are two advantages to this technique: First, the measure $d\bar{\beta}$ maintains the simple structure of (fewer) commensurate lags. Second, the time domain realization of the relation between the functions $u(t)$ and $\bar{u}(t)$ is simpler. Here

$$u(t) = \bar{u}(t) + e^{\lambda} u(t - 1).$$

Both strategies are developed in detail and justified in the following sections.

3. Characterization of trajectory-stabilizable systems. We use the following terminology (compare with Olbrot [15]):

DEFINITION 3.1. Let γ be a given real number. The system (*) is γ -trajectory-stabilizable if given any initial data for (*) there exists a control $u(\cdot)$ and a real number δ such that the functions $t \rightarrow e^{-\gamma t} x(t)$ and $t \rightarrow e^{-\delta t} u(t)$ are of class $L_1(0, \infty)$. (In applications, both γ and δ will be negative.) If, in addition, one can always choose $\delta = \gamma$, then the system is γ -state-stabilizable. (It will be demonstrated hereafter that in the earlier case, an upper bound on δ depends on the structure of the system and not on the initial data.)

The following characterization is quoted from Olbrot [15, Thm. 1] and will be used later.

THEOREM 3.2. *System (*) is γ -state-stabilizable if and only if*

$$(3.1) \quad \text{rank} [\Delta(s), B(s)] = n \quad \text{for all complex } s \text{ with } \text{Re } s \geq \gamma,$$

where $\Delta(s)$ is the characteristic matrix of (*), defined as

$$\Delta(s) \stackrel{\text{def}}{=} sI - \int_0^h e^{-\theta s} d\alpha(\theta) \stackrel{\text{def}}{=} sI - A(s)$$

and

$$B(s) \stackrel{\text{def}}{=} \int_0^h e^{-\theta s} d\beta(\theta).$$

Note that $A(s)$ and $B(s)$ are the Laplace transforms of the measures α and β . Condition (3.1) comes into effect at spectral points of (*), where $\det \Delta(s) = 0$. We shall later remark on the meaning of Condition 3.1 as a spectral controllability requirement. An important fact [6, p. 181] is that the number of spectral points with $\text{Re } s \geq \gamma$ is finite.

Here is our basic observation.

THEOREM A. *The system (*) is γ -trajectory-stabilizable if and only if there exists an $m \times m$, nonsingular, rational matrix-valued function $R(s)$, with the following properties:*

(i) *$R(s)$ is of the form*

$$R(s) = \left(\frac{P_1}{s - \lambda_1} + Q_1 \right) \left(\frac{P_2}{s - \lambda_2} + Q_2 \right) \cdots \left(\frac{P_l}{s - \lambda_l} + Q_l \right),$$

where each of the matrices P_j is an orthogonal projection, $Q_j = I - P_j$, and each λ_j is an eigenvalue of the homogeneous part of (*) (i.e., $\det \Delta(\lambda_j) = 0$) with $\text{Re } \lambda_j \geq \gamma$.

(ii) *The function $\bar{B}(s) = B(s)R(s)$ is the Laplace transform of a finite measure, denoted by $\bar{\beta}$, and $\bar{\beta}$ is supported within $[0, h]$.*

(iii) *The system*

$$(3.2) \quad \dot{x}(t) = \int_0^h d\alpha(\theta)x(t-\theta) + \int_0^h d\bar{\beta}(\theta)\bar{u}(t-\theta)$$

is γ -state-stabilizable. By Olbrot's theorem this means:

$$(3.3) \quad \text{rank} [\Delta(s), \bar{B}(s)] = n \quad \text{for all complex } s \text{ with } \text{Re } s \geq \gamma,$$

Proof.

Sufficiency. Assume the existence of a matrix $R(s)$ as stated in the theorem. Seeking, for the time being, only an open loop stabilizing control, we may assume furthermore that $u(t) = 0$ for $t \leq 0$. (For otherwise, apply $u(t) = 0$ through $[0, h]$ and start with the new initial time $t = h$.)

By assumption, given an initial trajectory of $x(\cdot)$, there exists a γ -state-stabilizing control $\bar{u}(\cdot)$ in the system (3.2), with $\bar{u}(t) = 0$ for $t \leq 0$. Let $\bar{U}(s)$ be the Laplace transform of $\bar{u}(\cdot)$ and let $u(\cdot)$ be the inverse transform of $U(s) = R(s)\bar{U}(s)$. The latter is obtained via successive convolutions of $\bar{u}(\cdot)$ with exponential functions. It therefore satisfies the growth condition in Definition 3.1. The equality $\bar{B}(s)\bar{U}(s) = B(s)U(s)$ implies that the trajectory of (*) which corresponds to the control $u(\cdot)$ coincides with the trajectory of (3.2) for $\bar{u}(\cdot)$. Hence $u(\cdot)$ is a γ -trajectory-stabilizing control.

Necessity. We begin with the construction of the function $R(s)$. There are only finitely many eigenvalues of the homogeneous part of (*) within the half plane $\{s: \text{Re } s \geq \gamma\}$ at which Olbrot's condition is violated. The construction is performed successively, taking into account one such eigenvalue at a time.

Fix λ , the first spectral point of interest. The matrix $B(s)$ is entire. One can therefore find an integer $k \geq 0$ and a decomposition of R^m into three orthogonal subspaces:

$$R^m = \underline{U}_\infty \oplus \underline{U}_k \oplus \underline{Y}_k,$$

as follows: (i) For each vector $u \in \underline{U}_\infty$ the function $B(s)u$ vanishes throughout. (ii) For each $u \in \underline{U}_k$ ($u \neq 0$), the function $B(s)u$ has a zero at $s = \lambda$ of the exact order k (i.e., $(d/ds)^j B(s)u|_{s=\lambda} = 0$ for each $j = 0, 1, \dots, k-1$, but $(d/ds)^k B(s)u|_{s=\lambda} \neq 0$). (iii) If $v \in \underline{Y}_k$ ($v \neq 0$), then the function $B(s)v$ does not have a zero at $s = \lambda$ whose order exceeds $k-1$. The proof of existence of such a decomposition is straightforward and we leave it out.

Let P_k be the orthogonal projection on \underline{U}_k and let $Q_k = I - P_k$. At this first step we define first versions of $R(s)$ and $\bar{B}(s)$ (which will be revised successively at later steps) as $R(s) = P_k/(s - \lambda) + Q_k$ and $\bar{B}(s) = B(s)R(s)$. Note that with this definition, for each vector u , unless $\bar{B}(s)u \equiv 0$, the maximal possible order of zero of $\bar{B}(s)u$ at $s = \lambda$ is $k-1$.

Each of the following $k-1$ steps repeats the same idea: In the $1+k-j$ th step, R^m is decomposed into $\underline{U}_\infty \oplus \underline{U}_j \oplus \underline{Y}_j$; projections P_j and Q_j are defined and new versions of $\bar{B}(s)$ and $R(s)$ are obtained, multiplying the previous ones from the right by $P_j/(s - \lambda) + Q_j$. The new version of $\bar{B}(s)$ has the property that the largest possible finite order of zero of $\bar{B}(s)u$ at $s = \lambda$ is $j-1$. After k steps either $\bar{B}(s)u \equiv 0$ or $\bar{B}(\lambda)u \neq 0$. This completes the constructions due to the first eigenvalue, λ .

An important outcome of this process is that the k th version of $\bar{B}(s)$ maintains a constant rank in a vicinity of $s = \lambda$. In particular, it has an analytic generalized inverse, $B(s)^*$, at that vicinity. We shall need this fact immediately.

The construction continues in a completely similar manner for the rest of the eigenvalues in the half plane $\{s: \operatorname{Re} s \geq \lambda\}$. Of course, the process for each new eigenvalue starts with the latest versions of $\bar{B}(s)$ and $R(s)$, as they were obtained for the previous one.

Property (i) in the theorem's statement is satisfied by construction of $R(s)$. Properties (ii) and (iii) are left to be verified. Let us start with the latter. Suppose equation (*) is γ -trajectory-stabilizable and that condition (3.3) fails. Then there exists a vector $\eta \in \mathbb{R}^n$ and some eigenvalue λ with $\operatorname{Re} \lambda \geq \gamma$ such that $\eta' \Delta(\lambda) = 0$ and $\eta' \bar{B}(\lambda) = 0$. Let then $u(\cdot)$ be a γ -trajectory-stabilizing control in (*) for the following initial data: $x(0) = \eta$ and $x(t) \equiv 0$, $u(t) \equiv 0$ for $t < 0$. A Laplace transform of (*) yields

$$(3.4) \quad \Delta(s)X(s) - \eta = B(s)U(s).$$

Since $x(\cdot)$ is a γ -stabilized trajectory, the transform $X(s)$ is continuous on the closed half-plane $\{s: \operatorname{Re} s \geq \gamma\}$. Since near λ we have $\operatorname{Im} B(s) \subset \operatorname{Im} \bar{B}(s)$, we can substitute the right-hand side of (3.4) by $\bar{B}(s)\bar{U}(s)$, where $\bar{U}(s) = \bar{B}(s)^*(\Delta(s)X(s) - \eta)$. Thus defined, $\bar{U}(s)$ is also continuous near $s = \lambda$. Now, an inner product of (3.4) with the vector η completes the argument, for it implies that $\eta = 0$:

$$\|\eta\| = \eta' \Delta(\lambda)X(\lambda) - \eta' \bar{B}(\lambda)\bar{U}(\lambda) = 0.$$

Note. (i) The difference between our proof and its counterpart in Olbrot's paper is that here $U(s)$ is not necessarily continuous at $s = \lambda$. Thus, $\eta' B(\lambda) = 0$ does not a priori imply $\eta' B(s)U(s)|_{s=\lambda} = 0$. Substituting $B(s)U(s)$ by $\bar{B}(s)\bar{U}(s)$ with $\bar{U}(s)$ continuous is therefore essential.

(ii) If $\operatorname{Re} \lambda > \gamma$ then we can substitute "continuous" by "analytic" throughout.

It remains to establish that $\bar{B}(s)$ is the transform of a measure whose support is within the interval $[0, h]$. Since $\bar{B}(s)$ is defined via an inductive process, it suffices to

check the result of a single step construction:

$$\bar{B}(s) = B(s) \left(\frac{P}{s - \lambda} + Q \right) \quad \text{where } B(\lambda)P = 0.$$

Obviously, $\bar{B}(s)$ is the transform of this next measure:

$$d\bar{\beta}(\theta) = d\beta(\theta)Q + \int_0^\theta e^{\lambda(\theta-\tau)} d\beta(\tau)P d\theta.$$

It follows from the fact that $d\beta$ is supported within $[0, h]$ that the whole right-hand side vanishes for negative θ , and that the first term on the right is zero also for $\theta > h$. But when $\theta > h$, the second term vanishes too, since

$$\int_0^\theta e^{\lambda(\theta-\tau)} d\beta(\tau)P = e^{\lambda\theta} \int_0^h e^{-\lambda\tau} d\beta(\tau)P = e^{\lambda\theta} B(\lambda)P,$$

and by assumption, $B(\lambda)P = 0$. \square

COROLLARY 3.3. Suppose (*) is γ -trajectory-stabilizable and let $\lambda_1, \dots, \lambda_l$ be the eigenvalues appearing in the definition of the rational function $R(s)$, as done above. Set $\delta_0 = \max \{\gamma, \lambda_i, i = 1, \dots, l\}$. Then γ -trajectory-stabilizing controls can be chosen in (*) so that $e^{-\delta t}u(t)$ is an $L_1(0, \infty)$ -function for all $\delta > \delta_0$. In particular, if (*) is also η -state-stabilizable for some negative η (possibly $\eta > \gamma$), then exponentially decaying γ -trajectory-stabilizing controls do exist.

Proof. The corollary follows from the relation $U(s) = R(s)\bar{U}(s)$, and since $\bar{u}(t)$ can be chosen asymptotically proportional to $e^{\eta t}$. \square

Remark 3.4. (i) The corollary shows that, in applications, we would be interested in systems which are η -state-stabilizable for negative η , but in which γ -trajectory-stabilizability, for $\gamma < \eta$, enables improved stabilization rates.

(ii) For phrasing clarity we required in Theorem A (and in the proof) that the matrices P_j be **orthogonal** projections and $Q_j = I - P_j$. More compact presentations might be the result of **nonorthogonal** choice of P_j and Q_j . The properties which should be maintained are these: $\text{Im } P_j = U_j$, $\text{Im } Q_j = \underline{V}_j \oplus U_\infty$ and $\det(P_j + Q_j) \neq 0$. In Example 3.5, hereafter, we consider a system where nonorthogonal choice of P_j and Q_j in one of the construction steps yields a simpler " $\bar{B}(s)$ ".

Example 3.5. For simplicity and since our main interest is in the control element, we consider a system with no delays in the state

$$\begin{aligned} \dot{x}_1(t) &= -x_1(t) + \int_0^1 e^{-\theta} \cos(2\pi\theta) u_1(t-\theta) d\theta + u_2(t-1) - e^{-1} u_2(t-2), \\ \dot{x}_2(t) &= -2x_2(t) + \int_0^1 e^{-2\theta} \sin(2\pi\theta) u_2(t-\theta) d\theta. \end{aligned}$$

Here $m = n = 2$ and the matrix $B(s)$ is given by

$$B(s) = \begin{bmatrix} b_1(s) & e^{-s}(1 - e^{-1-s}) \\ 0 & b_2(s) \end{bmatrix},$$

where

$$b_1(s) = \int_0^1 e^{-\theta(1+s)} \cos(2\pi\theta) d\theta \quad \text{and} \quad b_2(s) = \int_0^1 e^{-\theta(2+s)} \sin(2\pi\theta) d\theta.$$

One easily notes that $b_1(s)$ has a zero of order 2 and the term $e^{-s}(1 - e^{-1-s})$ has a first order zero at $s = -1$, while $b_2(s)$ has a first order zero at $s = -2$. Thus, at both

spectral points of the homogeneous equation, Olbrot's rank condition ($\text{rank} [\Delta(s), B(s)] = 2$) fails. The system is therefore not γ -state-stabilizable for $\gamma < -1$.

Let us check whether the system is nonetheless γ -trajectory-stabilizable. (Obviously, the answer to this question will be one and the same for any $\gamma \leq -2$.) To that end we construct $\bar{B}(s)$, following the instructions in the proof of Theorem A and starting with the eigenvalue $\lambda = -1$: The subspace \underline{U}_∞ (on which $B(s)$ vanishes throughout) is empty. The first decomposition of R^2 is into a subspace on which $B(s)$ has a second order zero at $s = -1$, denoted \underline{U}_2 , and its orthogonal complement, \underline{Y}_2

$$\underline{U}_2 = \{(u_1, 0): u_1 \in R\} \quad \text{and} \quad \underline{Y}_2 = \{(0, u_2): u_2 \in R\}.$$

Accordingly,

$$P_2 = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad Q_2 = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}, \quad R(s) = \frac{P_2}{s+1} + Q_2$$

and the first version of $\bar{B}(s)$ is

$$\bar{B}(s) = \begin{bmatrix} b_1(s)/(s+1) & e^{-s}(1-e^{-1-s}) \\ 0 & b_2(s) \end{bmatrix}.$$

The second decomposition due to the eigenvalue $\lambda = -1$ is the same as the first: $\bar{B}(s)$ still has a zero (of order one) in the first column, while the second column does not vanish at $s = -1$. We thus update $R(s)$ as

$$R(s) = \left(\frac{P_2}{s+1} + Q_2 \right)^2 = \frac{P_2}{(s+1)^2} + Q_2$$

and redefine $\bar{B}(s) = B(s)R(s)$, namely

$$\bar{B}(s) = \begin{bmatrix} b_1(s)/(s+1)^2 & e^{-s}(1-e^{-1-s}) \\ 0 & b_2(s) \end{bmatrix}.$$

This completes the constructions due to $\lambda = -1$.

Next we consider $\bar{B}(s)$ at the eigenvalue $\lambda = -2$. As before, \underline{U}_∞ is the trivial subspace. $\bar{B}(s)$ has a first order zero on the subspace

$$\left\{ (u_1, u_2): u_1 = -\frac{e^2(1-e)}{b_1(-2)} u_2 \right\},$$

which is denoted \underline{U}_1 . Setting, for brevity,

$$c \stackrel{\text{def}}{=} \frac{e^2(1-e)}{b_1(-2)},$$

the orthogonal projections on \underline{U}_1 and on $\underline{Y}_1 = \underline{U}_1^\perp$ are

$$P_1 = \frac{1}{c^2+1} \begin{bmatrix} c^2 & -c \\ -c & 1 \end{bmatrix} \quad \text{and} \quad Q_1 = \frac{1}{c^2+1} \begin{bmatrix} 1 & c \\ c & c^2 \end{bmatrix}.$$

The final versions of $R(s)$ and $\bar{B}(s)$ are thereby the result of right multiplication of

the previous ones by $P_1/(s+2) + Q_1$. Explicitly, $\bar{B}(s)$ turns into

$$\bar{B}(s) = \frac{1}{c^2+1} \left[\begin{array}{c|c} \frac{1}{s+2} \left(\frac{c^2 b_1(s)}{(s+1)^2} - ce^{-s}(1-e^{-1-s}) \right) & \frac{1}{s+2} \left(\frac{-cb_1(s)}{(s+1)^2} + e^{-s}(1-e^{-1-s}) \right) \\ \hline + \frac{b_1(s)}{(s+1)^2} + ce^{-s}(1-e^{-1-s}) & + \frac{cb_1(s)}{(s+1)^2} + c^2 e^{-s}(1-e^{-1-s}) \\ \hline cb_2(s) \left(\frac{-1}{s+2} + 1 \right) & b_2(s) \left(\frac{1}{s+2} + c^2 \right) \end{array} \right].$$

Tracking back through our constructions we find out that now the rank condition (3.3) is satisfied:

$$\text{rank} [\Delta(s)\bar{B}(s)] = 2 \quad \text{for } s = -1, -2.$$

Our system is therefore γ -trajectory-stabilizable for all γ .

We shall not compute the measure $d\bar{\beta}$ which corresponds to $\bar{B}(s)$. Instead, following Remark 3.4, we shall compute a simpler form of $\bar{B}(s)$, using **nonorthogonal** projections in the last step: Let now P_1 and Q_1 be the following:

$$P_1 = \frac{1}{c} \begin{bmatrix} c & 0 \\ -1 & 0 \end{bmatrix} \quad \text{and} \quad Q_1 = \frac{1}{c} \begin{bmatrix} 0 & 1 \\ 0 & c \end{bmatrix}.$$

Then the final $\bar{B}(s)$ will be

$$\frac{1}{c} \begin{bmatrix} \frac{1}{s+2} \left(\frac{cb_1(s)}{(s+1)^2} - e^{-s}(1-e^{-1-s}) \right) & \frac{b_1(s)}{(s+1)^2} + ce^{-s}(1-e^{-1-s}) \\ -\frac{b_2(s)}{s+2} & cb_2(s) \end{bmatrix}.$$

This version too, satisfies the rank condition (3.3), and is simpler than the former. The measure $d\bar{\beta}$ in the corresponding reduced equation is

$$d\bar{\beta} = \begin{bmatrix} d\bar{\beta}_{11} & d\bar{\beta}_{12} \\ d\bar{\beta}_{21} & d\bar{\beta}_{22} \end{bmatrix},$$

where

$$d\bar{\beta}_{11}(\theta) = \frac{1}{c} \begin{cases} e^{-2\theta} \left[c \int_0^\theta e^\tau \int_0^\tau (\tau-\sigma) \cos(2\pi\sigma) d\sigma d\tau \right] d\theta, & 0 \leq \theta < 1, \\ e^{-2\theta} \left[c \int_0^1 e^\tau \int_0^\tau (\tau-\sigma) \cos(2\pi\sigma) d\sigma d\tau - e^2 \right] d\theta, & 1 \leq \theta \leq 2, \\ 0 & \text{otherwise,} \end{cases}$$

$$d\bar{\beta}_{12}(\theta) = \frac{1}{c} \begin{cases} \left[e^\theta \int_0^\theta (\theta-\tau) \cos(2\pi\tau) d\tau \right] d\theta, & 0 \leq \theta < 1, \\ c(\delta_1(\theta) - e^{-1}\delta_2(\theta)), & 1 \leq \theta \leq 2, \\ 0 & \text{otherwise} \end{cases}$$

(the symbol $\delta_\varepsilon(\theta)$ stands for Dirac's measure concentrated at $\theta = \varepsilon$),

$$d\bar{\beta}_{21}(\theta) = \frac{1}{c} \begin{cases} -e^{-2\theta} \left[\int_0^\theta \sin(2\pi\tau) d\tau \right] d\theta, & 0 \leq \theta \leq 1, \\ 0 & \text{otherwise} \end{cases}$$

and

$$d\bar{\beta}_{22}(\theta) = \begin{cases} e^{-2\theta} \sin(2\pi\theta) d\theta & 0 \leq \theta \leq 1, \\ 0 & \text{otherwise.} \end{cases}$$

4. Closed loop stabilization. The trajectory stabilization strategy suggested in the previous section (proof of sufficiency in Theorem A) is an open loop strategy. It is very much so, if we may put it this way, since it suits only the zero initial control. The purpose of this section is to demonstrate that this is not an inherent property and show that closed loop controllers can be constructed in trajectory stabilizable systems.

The choice of the zero initial control was convenient. First, it served in simplifying the proof of Theorem A: This way the control terms, both in (*) and in (3.2), admitted the forms of convolutions along $[0, \infty)$. Their transforms were $B(s)U(s)$ and $\bar{B}(s)\bar{U}(s)$ and there was no need to carry over the effects of initial data.

There was a second reason: The control $u(\cdot)$ was obtained from the auxiliary function $\bar{u}(\cdot)$ via a series of convolutions. The converse computation, i.e., that of $\bar{u}(\cdot)$, given $u(\cdot)$, requires differentiations. This fact creates a difficulty in the computation of the initial values of $\bar{u}(\cdot)$, given an initial $u(\cdot)$ which is not smooth enough. We shall develop hereby a closed-loop dynamic stabilizing controller in which there is no need to compute the initial trajectory of $\bar{u}(\cdot)$. Thus the difficulty will be overcome.

We have computed the following:

$$R(s) = \left(\frac{P_1}{s - \lambda_1} + Q_1 \right) \left(\frac{P_2}{s - \lambda_2} + Q_2 \right) \cdots \left(\frac{P_l}{s - \lambda_l} + Q_l \right).$$

(In this section we maintain the assumption that P_j are orthogonal projections and $Q_j = I - P_j$.) The equality $U(s) = R(s)\bar{U}(s)$ gives rise to the following set of differential equations and dependencies

$$(4.1) \quad u_0(t) = u(t),$$

$$(4.2) \quad \frac{d}{dt} P_{j+1} u_j(t) = \lambda_{j+1} P_{j+1} u_j(t) + P_{j+1} u_{j+1}(t), \quad j = 0, 1, \dots, l-1,$$

$$(4.3) \quad Q_{j+1} u_j(t) = Q_{j+1} u_{j+1}(t), \quad j = 0, 1, \dots, l-1,$$

$$(4.4) \quad u_l(t) = \bar{u}(t).$$

In [15], Olbrot suggested a dynamic γ -state-stabilizing controller which suits (3.2). In this scheme the evolution of the control $\bar{u}(\cdot)$ is governed by a delay equation

$$(4.5) \quad \frac{d}{dt} \bar{u}(t) = \int_0^h d\mu(\theta) x(t - \theta) + \int_0^h d\nu(\theta) \bar{u}(t - \theta).$$

Our plan is to derive a well-posed set of differential equations from (4.1)–(4.5), together with our main system (*). These differential equations will involve no delayed terms other than in $x(\cdot)$ and in $u(\cdot)$. They will form the desired dynamic compensator for (*).

As an intermediate step, we assert the following.

PROPOSITION 4.1. *If functions $u_j(\cdot)$, $0 \leq j \leq l$, satisfy (4.1)–(4.4), then we have*

$$\int_0^h d\beta(\theta) u(t - \theta) = \int_0^h d\bar{\beta}(\theta) \bar{u}(t - \theta).$$

PROPOSITION 4.2. *There exist $m \times m$ matrices K_j , $0 \leq j \leq l$, and a finite matrix valued measure $dk(\theta)$, such that if functions $u_j(\cdot)$, $0 \leq j \leq l$ satisfy (4.1)–(4.4), then the following representation is valid:*

$$(4.6) \quad \int_0^h d\nu(\theta) \bar{u}(t-\theta) = K_0 u(t) + \sum_{j=1}^l K_j P_j u_j(t) + \int_0^h dk(\theta) u(t-\theta).$$

PROPOSITION 4.3. *Let Y be the product space*

$$Y \stackrel{\text{def}}{=} P_1 R^m \times P_2 R^m \times \cdots \times P R^m.$$

Then there exist linear transformations $C: Y \rightarrow R^m$, D and $E: R^m \rightarrow R^m$, $F: Y \rightarrow Y$, and G and $H: R^m \rightarrow Y$, with the following properties:

(i) *This next set of differential equations (4.7)–(4.8) form, together with (*), a well-posed system for the initial data*

$$(x(0), u(0), y(0), x(\cdot), u(\cdot)) \in R^n \times R^m \times Y \times L_2([-h, 0], R^n) \times L_2([-h, 0], R^m),$$

$$(4.7) \quad \dot{u}(t) = Cy(t) + Du(t) + E \left(\int_0^h d\mu(\theta) x(t-\theta) + K_0 u(t) + \int_0^h dk(\theta) u(t-\theta) \right),$$

$$(4.8) \quad \dot{y}(t) = Fy(t) + Gu(t) + H \left(\int_0^h d\mu(\theta) x(t-\theta) + K_0 u(t) + \int_0^h dk(\theta) u(t-\theta) \right).$$

(ii) Given $u(t)$ and $y(t)$, let $u_j(t)$, $0 \leq j \leq l$, be as follows: $u_0 = u(t)$, $P_j u_j(t) = y(t)$ (=the component of $y(t)$ in the space $P_j R^m$) and $Q_j u_j(t)$ be defined successively by (4.3) for $j = 1, 2, \dots, l$. Suppose $x(\cdot)$, $u(\cdot)$ and $y(\cdot)$ form a solution of (*), (4.7) and (4.8). Then the function $x(\cdot)$ and $u_j(\cdot)$, $j = 0, 1, \dots, l$ satisfy equations (*) and (4.1)–(4.5) for $t \geq l \cdot h$. Conversely, assume that the latter system is solved by $x(\cdot)$ and $u_j(\cdot)$, $0 \leq j \leq l$; then the corresponding triple $x(\cdot)$, $u(\cdot)$ and $y(\cdot)$ solve (*), (4.7) and (4.8).

In the proof of Proposition 4.3, hereafter, a precise recipe for building the operators C , D , E , F , G and H is given. But first we summarize our findings.

THEOREM B. *Suppose (*) is a γ -trajectory-stabilizable system. Here is a dynamic feedback scheme which generates γ -trajectory-stabilizing controls:*

- (i) *Determine the initial values $u(0)$ and $y(0)$, arbitrarily.*
- (ii) *At each $t \geq 0$ let the dynamics of the control $u(\cdot)$ and of the auxiliary function $y(\cdot)$ be determined by (4.7) and (4.8).*
- (iii) *Substitute $u(\cdot)$ into (*).*

We give the proofs in a reverse order.

Proof of Theorem B. As is borne out by Proposition 4.3, if $x(\cdot)$, $u(\cdot)$ and $y(\cdot)$ satisfy (*), (4.7) and (4.8), then the corresponding functions $u_j(\cdot)$ satisfy (4.1)–(4.5). Furthermore, by Proposition 4.1 the pair $x(\cdot)$ and $\bar{u}(\cdot)$ then defines a solution of (3.2) and (4.5). By Olbrot's construction (that is, by the choice of the measures $d\mu(\theta)$ and $d\nu(\theta)$ in (4.5)) the latter system is γ -state-stabilized. In particular, the trajectory of $x(\cdot)$ is γ -stabilized. \square

Proof of Proposition 4.3. No matter what the operators (in fact, the matrices) C , D , E , F , G and H are, part (i) of the proposition is obvious: The well-established theory (see, e.g., [2], [6]) tells us that the product space presentation is well posed.

The following two decompositions will be handy along with the proof of part (ii): Suppose that functions $u_j(\cdot)$, $0 \leq j \leq l$, satisfy (4.1)–(4.5). Then

$$(4.9) \quad u_j(t) = P_j u_j(t) + \sum_{i=1}^{j-1} Q_j \cdots Q_{i+1} P_i u_i(t) + Q_j \cdots Q_1 u_0(t), \quad 1 \leq j \leq l$$

(the term with the \sum does not appear when $j = 1$) and

$$(4.10) \quad u_j(t) = P_{j+1}u_j(t) + \sum_{i=j+1}^{l-1} Q_{j+1} \cdots Q_i P_{i+1}u_i(t) + Q_{j+1} \cdots Q_l u_l(t), \quad 0 \leq j \leq l$$

(the \sum expression disappears now for $j = l-1$). Both (4.9) and (4.10) are obtained by successive applications of (4.3), which is the relation $Q_{j+1}u_{j+1} = Q_{j+1}u_j$.

Thereby, for each j between 0 and $l-1$, our assumptions imply

$$(4.10) \quad \Rightarrow \frac{d}{dt} P_j u_j(t) = \frac{d}{dt} P_j \left(P_{j+1} u_j(t) + \sum_{i=j+1}^{l-1} Q_{j+1} \cdots Q_i P_{i+1} u_i(t) \right) + \frac{d}{dt} P_j Q_{j+1} \cdots Q_l u_l(t)$$

$$(4.2) \quad \Rightarrow = P_j \left(\lambda_{j+1} P_{j+1} u_j(t) + P_{j+1} u_{j+1}(t) + \sum_{i=j+1}^{l-1} Q_{j+1} \cdots Q_i (\lambda_{i+1} P_{i+1} u_i(t) + P_{i+1} u_{i+1}(t)) \right)$$

$$(4.5) \quad \Rightarrow + P_j Q_{j+1} \cdots Q_l \left(\int_0^h d\mu(\theta) x(t-\theta) + \int_0^h d\nu(\theta) u(t-\theta) \right) = P_j P_{j+1} u_{j+1}(t) + \sum_{i=j+1}^{l-1} P_j Q_{j+1} \cdots Q_i P_{i+1} u_{i+1}(t),$$

$$(4.9) \quad \Rightarrow + \lambda_{j+1} P_j P_{j+1} \left(P_j u_j(t) + \sum_{k=1}^{j-1} Q_j \cdots Q_{k+1} P_k u_k(t) + Q_j \cdots Q_1 u_0(t) \right) + \sum_{i=j+1}^{l-1} \lambda_{i+1} P_j Q_{j+1} \cdots Q_i P_{i+1} \cdot \left(P_i u_i(t) + \sum_{k=1}^{i-1} Q_i \cdots Q_{k+1} P_k u_k(t) + Q_i \cdots Q_1 u_0(t) \right)$$

$$\text{Proposition 4.2} \quad \Rightarrow + (P_j Q_{j+1} \cdots Q_l) \left(\int_0^h d\mu(\theta) x(t-\theta) + K_0 u_0(t) + \sum_{i=1}^l K_i P_i u_i(t) + \int_0^h dk(\theta) u_0(t-\theta) \right).$$

The last expression involves only the functions $x(\cdot)$ and $u_0(\cdot)$, and the auxiliary vectors $y_i(t) = P_i u_i(t)$, $1 \leq i \leq l$, which is the desired formulation. Letting j run through $0, \dots, l-1$, we obtain explicitly most entries in the operators C, D, E, F, G and H . (Obviously, a more compact and orderly representation is obtained when the coefficients of each $y_i = P_i u_i$ are gathered. We shall not do it here.)

For the missing entries it remains to consider the derivatives of $Q_1 u_0(t)$ and of $P_i u_i(t)$. The computations of these terms follow exactly the same lines of those we have just displayed and we leave them to the interested reader.

Finally, one should note that the various decompositions we made above go both ways. Thus, if $x(\cdot)$, $u(\cdot)$ and $y(\cdot)$ satisfy (4.7) and (4.8), then $y(\cdot)$ can be decomposed

as $(P_1 u_1(\cdot), \dots, P_l u_l(\cdot))'$, so that with the definitions $u_0(\cdot) = u(\cdot)$ and $Q_{j+1} u_{j+1}(\cdot) = Q_{j+1} u_j(\cdot)$, a set of functions which satisfy (4.1)–(4.5) is formed. \square

Proof of Proposition 4.2. We shall not bring at this point the interesting details, the justifications, or the exact notations of Olbrot's and Pandolfi's developments. These can be found in [15] and in [16], respectively. What concerns us here is the following conclusion of their findings: The measure $d\nu(\theta)$ in the dynamic stabilizer (4.5) can be built in the form

$$(4.11) \quad d\nu(\theta) = F_0 \delta_0(\theta) + \int_0^h F(\tau - \theta) d\bar{\beta}(\tau) d\theta.$$

Here F_0 and $F(\theta)$ are $m \times m$ matrices, $\delta_0(\theta)$ is the Dirac measure which is concentrated at $\theta = 0$, and $\theta \rightarrow F(\theta)$ is an analytic function.

Here is an outline of the proof: The structure (4.11) of $d\nu(\theta)$ implies that

$$(4.12) \quad \begin{aligned} \int_0^h d\nu(\theta) \bar{u}(t - \theta) &= \int_0^h d\nu(\theta) u_l(t - \theta) \\ &= F_0 u_l(t) + \int_0^h \int_0^h F(\tau - \theta) d\bar{\beta}(\tau) u_l(t - \theta) d\theta \\ &= F_0 u_l(t) + \int_0^h F(\theta) \int_0^h d\bar{\beta}(\tau) u_l(t + \theta - \tau) d\theta. \end{aligned}$$

Using formula (4.9) we decompose the first term on the right-hand side of (4.12) into a sum which involves $u_0(t)$ and $y_j(t) = P_j u_j(t)$. With the aid of integration by parts, $d\bar{\beta}(\tau) u_l(t + \theta - \tau)$ will be substituted by $d\beta(\tau) u_0(t + \theta - \tau)$, in the second expression, while more terms, involving $u_0(t)$ and $y_j(t)$, will be created as side products (similar, yet even simpler computations will serve later in establishing Proposition 4.1).

The following notations should clarify our computations: Set first $d\beta_0(\theta) = d\beta(\theta)$. Then define recursively

$$d\beta_j(\theta) = d\beta_{j-1}(\theta) Q_j + \int_0^\theta e^{\lambda_j(\theta-\tau)} d\beta_{j-1}(\tau) P_j d\theta$$

for $j = 1, \dots, l$. Consequently, $d\bar{\beta}(\theta) = d\beta_l(\theta)$.

Now we begin the iterative process of integrations by parts. The first step goes this way:

$$(4.13) \quad \begin{aligned} &\int_0^h d\beta_l(\tau) u_l(t + \theta - \tau) \\ &= \int_0^h d\beta_{l-1}(\tau) Q_l u_l(t + \theta - \tau) + \int_0^h \int_0^\tau e^{\lambda(\tau-\sigma)} d\beta_{l-1}(\sigma) P_l u_l(t + \theta - \tau) d\tau \\ &= \int_0^h d\beta_{l-1}(\tau) Q_l u_{l-1}(t + \theta - \tau) \\ &\quad + \int_0^h \int_0^\tau e^{\lambda(\tau-\sigma)} d\beta_{l-1}(\sigma) P_l (\dot{u}_{l-1}(t + \theta - \tau) - \lambda u_{l-1}(t + \theta - \tau)) d\tau \\ &= \int_0^h d\beta_{l-1}(\tau) Q_l u_{l-1}(t + \theta - \tau) + \int_0^h d\beta_{l-1}(\tau) P_l u_{l-1}(t + \theta - \tau) \\ &\quad - \int_0^\tau e^{\lambda(\tau-\sigma)} d\beta_{l-1}(\sigma) P_l u_{l-1}(t + \theta - \tau) \Big|_{\tau=\theta}^{\tau=h} \\ &= \int_0^h d\beta_{l-1}(\tau) u_{l-1}(t + \theta - \tau) + \left(\int_0^\theta e^{\lambda(\theta-\sigma)} d\beta_{l-1}(\sigma) P_l \right) u_{l-1}(t). \end{aligned}$$

(Recall that the integral $\int_0^h e^{\lambda(\theta-\sigma)} d\beta_{l-1}(\sigma)P_l$ vanishes; this was explained in the proof of Theorem A.) The term which involves $u_{l-1}(t)$ will be decomposed, using (4.9), into a sum of expressions in $u_0(t)$ and $P_j u_j(t)$, $1 \leq j \leq l-1$.

The second iteration is applied to the integral on the right-hand side (4.13). After l steps the process terminates with the desired result. \square

Proof of Proposition 4.1. Using the notations of the previous proof, we have to verify the equality

$$\int_0^h d\beta_l(\tau)u_l(t-\tau) = \int_0^h d\beta_0(\tau)u_0(t-\tau).$$

It follows from iterative application of (4.13), choosing $\theta = 0$. \square

Remark 4.4. The basis for our constructions of a closed-loop controller in this section is Olbrot's **dynamic** controller (4.5). One may prefer to start with a "**static**" controller for system (3.2), i.e., with a closed-loop relation of the form

$$(4.14) \quad \bar{u}(t) = \int_0^h d\xi(\theta)x(t-\theta) + \int_0^h d\zeta(\theta)\bar{u}(t-\theta).$$

The extensive literature on the subject (and most of the papers cited below) offer stabilizing controllers of the type (4.14), for various subclasses of hereditary control systems. We wish to point out that also, in the general case of Olbrot's theorem, the stabilizer can be constructed that way. Instead of presenting a rigorous proof, let us mention just the main arguments.

As in Pandolfi [16], one considers the spectral projection of the γ -state-stabilizable system on the united generalized eigensubspace for the eigenvalues in the half plane $\{s: \operatorname{Re} s \geq \gamma\}$. Using Pandolfi's notation, it is this next ODE,

$$(4.15) \quad \dot{c}(t) = Hc(t) + \phi(0) \int_0^h d\bar{\beta}(\theta)\bar{u}(t-\theta).$$

Olbrot's spectral condition (3.1) implies that the system (4.15) is state-stabilizable. It thus has (see, e.g., [12], [1]) a feedback stabilizing controller of the form

$$(4.16) \quad \bar{u}(t) = F(c(t) + \int_0^h \int_0^h e^{H(\theta-\tau)} \phi(0) d\bar{\beta}(\tau)\bar{u}(t-\theta) d\theta).$$

Finally, since $c(t)$ is given by the spectral projection of the h -history of $x(\cdot)$ at t (i.e., of the function $\theta \rightarrow x(t-\theta)$, $0 \leq \theta \leq h$) on the relevant eigenmode, the desired form of (4.14) is obtained.

5. Systems with commensurate lags. A significant simplification can be obtained, both in the reduction of β to $\bar{\beta}$, and in the stabilization scheme, when the delays in the control term consist of commensurate lags. The main idea for the reduction has already been presented in the analysis of the simple example in § 2. We repeat it here in more detail, using the terminology of Theorem A and its proof.

Let δ now stand for the basic lag in the control term. Then $B(s)$ can be written in the form

$$(5.1) \quad B(s) = P(e^{-\delta s}),$$

where $P(z)$ is a matrix valued polynomial. This representation suggests the change of parameters $z = e^{-\delta s}$, which maps the half plane $\{s: \operatorname{Re} s \geq \gamma\}$ onto the punctured disc

$\{z: e^{-\delta\gamma} \geq |z| > 0\}$. Here is a variant of Theorem A for the present particular case.

THEOREM C. *Suppose $B(s)$ can be represented in the form (5.1) and set $z = e^{-\delta s}$. Then (*) is γ -state-stabilizable if and only if there exists an $m \times m$ nonsingular rational matrix-valued function $S(z)$, with the following properties:*

(i) $S(z)$ is of the form

$$S(z) = \left(\frac{P_1}{z_1 - z} + Q_1 \right) \cdots \left(\frac{P_l}{z_l - z} + Q_l \right),$$

where each of the matrices P_j is an orthogonal projection, $Q_j = I - P_j$, and each $z_j = e^{-\delta\lambda_j}$ where λ_j is a spectral point of (*) within $\{s: \operatorname{Re} s \geq \gamma\}$.

(ii) The function $\bar{P}(z) = P(z)S(z)$ is a matrix polynomial.

(iii) $\operatorname{rank} [\Delta(z), \bar{P}(z)] = n$ for all z with $e^{-\delta\gamma} \geq |z| > 0$.

The proof is by now obvious.

As pointed out in § 2, one of the advantages of the present case is the existence of simple recursive relations between the auxiliary control $\bar{u}(\cdot)$ (in the reduced system, where $\bar{P}(z)$ substitutes $P(z)$) and the true control function $u(\cdot)$. These relations, as implied by the equality $U(s) = S(e^{-\delta s})\bar{U}(s)$, can be stated in a fashion resembling (4.1)–(4.4):

$$(5.2) \quad u_0(t) = u(t),$$

$$(5.3) \quad P_{j+1}u_j(t) = e^{\delta\lambda_{j+1}}P_{j+1}(u_{j+1}(t) + u_j(t - \delta)), \quad j = 0, 1, \dots, l-1,$$

$$(5.4) \quad Q_{j+1}u_j(t) = Q_{j+1}u_{j+1}(t), \quad j = 0, 1, \dots, l-1,$$

$$(5.5) \quad \bar{u}(t) = u_l(t).$$

By repeated application of (5.4) into (5.3) we obtain a recursive definition of the form

$$u(t) = L_0\bar{u}(t) + \sum_{j=1}^l L_j u(t - j\delta).$$

Formulas (5.2)–(5.5) also enable the computation of appropriate initial values of $\bar{u}(\cdot)$ from those of $u(\cdot)$. Thus, any feedback stabilizer for the auxiliary system easily translates into a feedback stabilizer for (*).

6. Geometrical interpretations. Equivalence between controllability and stabilizability properties is a basic feature of ordinary, as well as of hereditary systems. Here are geometrical-controllability interpretations of state- and trajectory-stabilizability.

PROPOSITION 6.1. *The system (*) is γ -state-stabilizable if and only if given any positive T , γ -state-stabilizing controls can be chosen with $u(t) \equiv 0$ for $t > T$.*

Proof. The claim follows since Olbrot's condition is equivalent to spectral controllability of the united eigenspace for eigenvalues λ with $\operatorname{Re} \lambda \geq \gamma$. Let us bring some detail for completeness.

The spectral projection of (*) on the said eigenspace is the following (recall Pandolfi's construction, as described in Remark 4.4):

$$(6.1) \quad \dot{c}(t) = Hc(t) + \psi(0) \int_0^h d\beta(\theta) u(t - \theta).$$

Here the eigenvalues of H are those of (*) within the half-plane of interest, and $c(t)$ is the projection onto the corresponding eigenspace of the h -history of $x(\cdot)$ at t . Hence $x(\cdot)$ is γ -stabilized if $c(t)$ is brought to rest. It follows from [12, Thm. 2.2] that Olbrot's criterion (i.e., γ -state-stabilizability of (*)) implies controllability of this next ordinary system

$$(6.2) \quad \dot{y}(t) = Hy(t) + \tilde{B}u(t),$$

where

$$\tilde{B} \stackrel{\text{def}}{=} \int_0^h e^{-H\theta} \psi(0) d\beta(\theta).$$

From [1, Thm. 3.3] we have that if $y(0) = c(0)$ and $u(t) = 0$ for $t > T$, then $y(t)$ and $c(t)$ coincide for $t > T + h$. In particular, if $y(t) = 0$ for $t > T$, which is possible when (6.2) is controllable, $c(t)$ can be brought to rest at $t = T + h$ by a control which vanishes past $t = T$. This proves the “only if” part. The “if” claim is obvious. \square

In trajectory-stabilizable systems we made weaker assumptions on the behaviours of stabilizing controls. This fact is reflected in the corresponding controllability property.

THEOREM D. *The system (*) is γ -trajectory-stabilizable if and only if given any positive T and $\delta > \delta_0$ ($\delta_0 = \max \{ \gamma, \lambda : \lambda \text{ is an eigenvalue of } (*) \text{ with } \operatorname{Re} \lambda > \gamma \text{ and } \operatorname{rank} [\Delta(\lambda), B(\lambda)] < n \}$), as defined in Corollary 3.3), the spectral projection $c(t)$ can be brought to rest past $t = T + h$, using a control $u(t)$ with $e^{-\lambda t} u(t) \in L_1[0, \infty)$; in fact, past $t = T$ the values of $u(t)$ will be governed by an autonomous differential (or difference) equation.*

Proof. Sufficiency is, again, obvious. For the proof of necessity, derive a γ -state-stabilizable system from (*), following the instructions in the proofs of Theorems A and C. Given any initial values for $c(t)$ and $\bar{u}(t)$, it is possible to bring $c(t)$ to rest at $t = T + h$, using nonzero $\bar{u}(t)$ only through $[0, T]$. (This follows from Proposition 6.1.) The obvious idea is thereby to find the appropriate $\bar{u}(t)$ and convert it into $u(t)$, using one of the two schemes mentioned above.

The procedure is simpler when the technique of § 5 is applied, since initial values for $\bar{u}(t)$ are readily obtained from those of $u(t)$. As mentioned in the beginning of § 4, this might be harder in the more general case, when the scheme of § 3 is employed. The difficulty is circumvented as follows: an observation which is complementary to [1, Thm. 3.3] (which is quoted in the proof of Prop. 6.1) is that for $t \geq h$, the effect of the initial control can be absorbed in that of $c(0)$. Precisely, when substituting $c(0)$ by $\bar{c}(0) = c(0) + \int_0^h \int_\theta^h e^{H(\theta-\tau)} \phi(0) d\beta(\tau) u(-\theta) d\theta$, and then $u(t) = 0$ for $t \leq 0$, the new trajectory of $c(t)$ will not be different from the original one (i.e., for $c(0)$ and the true initial control) past $t = h$. So one can choose $\bar{u}(t)$ which brings the transformed system to rest at $t = T + h$, given the initial values $\bar{c}(0)$ and $\bar{u}(t) = 0$, $t \leq 0$. The inverse transform of $R(s)\bar{U}(s)$ will provide the needed values of $u(t)$ for $t \geq 0$. \square

Example 6.2. Consider again the simple example in § 2:

$$\dot{x}(t) = \lambda x(t) + u(t) - e^\lambda u(t-1).$$

This system is already in the form of a spectral projection on the eigenspace of the eigenvalue λ . Employing the technique of § 5, it converts to

$$\dot{\bar{x}}(t) = \lambda \bar{x}(t) + \bar{u}(t)$$

with

$$u(t) = \bar{u}(t) + e^\lambda u(t-1).$$

Take $\bar{u}(t)$ to be, e.g., this next step function:

$$\bar{u}(t) = \begin{cases} -\frac{\lambda x(0)}{1 - e^{-\lambda T}}, & 0 \leq t \leq T, \\ 0, & T < t. \end{cases}$$

Then for $t > T$ the control function $u(t)$ satisfies the difference equation $u(t-1) = e^\lambda u(t)$, and $x(t)$ will vanish past $t = T$. (This situation is better than that stated in the

theorem, since in the present case there is no delay in $\bar{u}(t)$.)

When using the technique of § 3 (which suits the general form of (*)), the transformed system is

$$\dot{x}(t) = \lambda x(t) + \int_0^1 e^{\lambda\theta} \bar{u}(t - \theta) d\theta.$$

If $x(0)$ and $u(t)$, $-h \leq t \leq 0$, are the prescribed initial values, we do the computations for

$$\bar{x}(0) = x(0) - \int_0^1 e^{\lambda\theta} u(-\theta) d\theta,$$

and the zero initial control. Following the recipe in the proof of Proposition 6.1, we set

$$\tilde{B} = \int_0^1 e^{-H\theta} \phi(0) d\tilde{\beta}(\theta) = \int_0^1 e^{-\lambda\theta} e^{\lambda\theta} d\theta = 1.$$

The current counterpart of (6.2) is

$$\dot{y}(t) = \lambda y(t) + \bar{u}(t),$$

with $y(0) = \bar{x}(0)$. This system is brought to zero at $t = T$, using, e.g., the control function

$$\bar{u}(t) = \begin{cases} -\frac{\lambda \bar{x}(0)}{1 - e^{-\lambda T}}, & 0 \leq t \leq T, \\ 0, & T < t. \end{cases}$$

So with this $\bar{u}(t)$, the true trajectory (in the transformed system) is brought to rest at $t = T + 1$. The appropriate control $u(t)$ is the inverse transform of $\bar{U}(s)/(s - \lambda)$, i.e., it is given by

$$u(t) = \int_0^t e^{\lambda(t-\tau)} \bar{u}(\tau) d\tau.$$

For $t \geq T$, the function $u(t)$ satisfies the homogeneous ODE $\dot{u}(t) = \lambda u(t)$.

7. Conclusions. Trajectory-stabilizability is a phenomenon which is specific to systems with delayed control action. It is of interest both from an application-oriented and from a purely mathematical point of view. We provide general characterizations of trajectory-stabilizable systems and of their trajectory-stabilizing control functions.

It is often very difficult to handle problems of "spectral-type" (e.g., to locate eigenvalues, find zeros of $B(s)$ etc.) in hereditary systems of unconstrained form, such as (*). Our analysis of the commensurate, multiple-lag case might therefore be of greater value in applications. Let us mention also that similar difficulties, which are inherent to delay systems, are treated in the literature, in different contexts (see, e.g., [12], [13]), and that a variety of available techniques could be adopted in particular classes of systems.

SUFFICIENT CONDITIONS IN FREE FINAL TIME OPTIMAL CONTROL PROBLEMS*

ATLE SEIERSTAD†

Abstract. A direct sufficient condition for the optimality of a control in standard control problems with free final time is proved. The basic tool is superderivative properties of the optimal value of the criterion as a function of the final time and the final point. Sufficient conditions arise if the superderivatives have proper signs.

Key words. sufficient conditions, optimal control

AMS(MOS) subject classification. 49B10

1. Introduction. Sufficient conditions in free final time control problems are not as easily constructed as in fixed final time problems. Some conditions have been given by Mereau and Powers [1] (see also Peterson and Zalkind [2]).

In this paper new conditions are given, which in our opinion are more useful. They are more closely related to actual solution procedures, and they seem to be able to decide optimality in broader classes of problems. In [3], results in less general circumstances have been proved in the case of no restrictions on the time path of the system.

While sufficient conditions in suitably concave, fixed time problems are “almost” necessary, in free time problems sufficient conditions cannot come that close to necessary conditions, due to an inherent lack of concavity properties.

2. First we shall consider a control problem with no time path restrictions. Let the abbreviation v.e. (virtually everywhere) mean “for all t except a finite number.” Consider the problem

$$(1) \quad \text{Maximize } \int_{t_0}^{\tau} f^0(x(t), u(t), t) dt, \quad \tau \in I = [\tau_1, \tau_2]$$

where t_0 , τ_1 and τ_2 are fixed points, $t_0 < \tau_1 < \tau_2$.

$$(2) \quad \dot{x} = f(x, u(t), t) \quad \text{v.e.}, \quad x(t_0) = x_0, \quad x_0 \text{ fixed in } R^n,$$

$$(3) \quad u(t) \in U, \quad U \text{ a fixed subset of } R^r,$$

$$x^i(\tau) = x_1^i, \quad i = 1, \dots, l,$$

$$(4) \quad x^i(\tau) \geq x_1^i, \quad i = l+1, \dots, m,$$

$$x^i(\tau) \text{ free}, \quad i = m+1, \dots, n.$$

The optimization problem consists of choosing a piecewise continuous¹ control of function and its domain of definition $[t_0, \tau]$, $\tau \in I$, in such a way that the triple $(x(\cdot), u(\cdot), \tau)$ is admissible (i.e., satisfies (2), (3) and (4) and such that it maximizes the integral in (1). The functions f^0 , f , f_x^0 and f_x are assumed to be continuous on $R^n \times R^r \times R$ (f^0 takes values in R , f in R^n , f_x^0 , f_x are partial derivatives with respect to x , assumed to exist for all (x, u, t)).

¹ Piecewise continuous means having one-sided limits everywhere, and a finite number of discontinuity points.

If $(\bar{x}(\cdot), \bar{u}(\cdot), \tau^*)$ is an optimal triple in the above problem, it satisfies the following necessary conditions: For some number $p_0 \geq 0$, and some function $p(t)$, $(p_0, p(t)) \neq 0$ everywhere, we have

$$(5) \quad H(\bar{x}(t), \bar{u}(t), p(t), t) = \max_{u \in U} H(\bar{x}(t), u, p(t), t) \quad \text{for v.e. } t$$

where $H(x, u, p, t) = p_0 f^0(x, u, t) + p f(x, u, t)$. The function $p(\cdot)$ satisfies

$$(6) \quad \dot{p} = -H_x(\bar{x}(t), \bar{u}(t), p(t), p) \quad \text{v.e.}$$

Finally,

$$(7) \quad \begin{aligned} p^i(\tau^*) & \text{ no condition,} & i = 1, \dots, l, \\ p^i(\tau^*) & \geq 0 (=0 \text{ if } \bar{x}^i(\tau^*) > x_1^i), & i = l+1, \dots, m, \\ p^i(\tau^*) & = 0, & i = m+1, \dots, n, \end{aligned}$$

$$(8) \quad H(\bar{x}(\tau^*), \bar{u}(\tau^*), p(\tau^*), \tau^*)[\tau - \tau^*] \leq 0 \quad \text{for all } \tau \in I.$$

When two additional conditions are added to (5)–(7), we get a set of conditions that are sufficient in the problem where τ is kept fixed equal to τ^* (see [5]:²

$$(9) \quad p_0 = 1.$$

The supremum

$$(10) \quad H^*(x, p(t), t) = \sup_{u \in U} H(x, u, p(t), t)$$

is finite for all (x, t) and is a concave function of x , for each t .

3. Consider for a moment the fixed final time control problem that arises if we choose a fixed τ in I . Assume that we have found a triple $(x^\tau(\cdot), u^\tau(\cdot), p^\tau(\cdot))$ defined on $[0, \tau]$ such that (2)–(7), (9), and (10) hold for τ^* replaced by τ . Then the pair $(x^\tau(\cdot), u^\tau(\cdot))$ is optimal in this fixed final time problem.

Hence, if $(x(\cdot), u(\cdot))$ is an arbitrary admissible pair defined on $[0, \tau]$, the value of the criterion for this pair is smaller than or equal to the value $V(\tau)$ of the criterion for the pair $(x^\tau(\cdot), u^\tau(\cdot))$. Let us assume that such a pair $(x^\tau(\cdot), u^\tau(\cdot))$ exists for all $\tau \in I$. Let us furthermore assume that for some $\tau^* \in I$, $V(\tau) \leq V(\tau^*)$ for all $\tau \in I$. Then evidently the triple $(x^{\tau^*}(\cdot), u^{\tau^*}(\cdot), \tau^*)$ is optimal.

For the last inequality to hold, a natural sufficient condition to introduce would be $(d/d\tau)V(\tau) \leq 0$ if $\tau \geq \tau^*$, $(d/d\tau)V(\tau) \geq 0$ if $\tau \leq \tau^*$. Implicitly, such a condition requires differentiability of $V(\tau)$. What we actually need is that a superderivative (in some sense) satisfies such inequalities. Condition (12) below is of this type. Furthermore, it turns out that V is always “superdifferentiable”; no ad hoc assumption for this end is needed.

THEOREM 1. Assume that for each $\tau \in I$ there exists a triple $(x^\tau(\cdot), u^\tau(\cdot), p^\tau(\cdot))$ defined on $[t_0, \tau]$ satisfying (2)–(7), (9), (10) (i.e., $u^\tau(\cdot)$ is optimal for τ fixed).

Assume also that all $u^\tau(\cdot)$, $\tau \in I$ take values in a fixed bounded subset of U , that $\{p^\tau(\tau): \tau \in I\}$ is a bounded set, and that $\tau \rightarrow x^\tau(\tau)$ is continuous. Assume finally that the function

$$(11) \quad d(\tau) = H(x^\tau(\tau), u^\tau(\tau), p^\tau(\tau), \tau) \quad (\text{with } p_0 = 1)$$

has the property that there exists a $\tau^* \in I$, such that

$$(12) \quad \begin{aligned} d(\tau) & \geq 0 \quad \text{for } \tau \leq \tau^* & \text{if } \tau_1 < \tau^*, \\ d(\tau) & \leq 0 \quad \text{for } \tau \geq \tau^* & \text{if } \tau_2 > \tau^*. \end{aligned}$$

Then the triple $(x^{\tau^*}(\cdot), u^{\tau^*}(\cdot), \tau^*)$ is optimal.

² In [5] max, instead of sup, is used in (10); the proof, however, remains the same.

Remark 1. If τ is required to belong to an interval $[\tau_1, \infty)$ instead of I , and if $\tau^* \in [\tau_1, \infty)$ has the property that the conditions of Theorem 1 are satisfied for each bounded subinterval I of $[\tau_1, \infty)$ containing τ^* , then the triple $(x^{\tau^*}(\cdot), u^{\tau^*}(\cdot), \tau^*)$ is optimal. (An example showing the application of the conditions in this remark can be found at the end of this paper.)

Proof. From the remarks preceding the theorem, it suffices to show that $V(\tau) \leq V(\tau^*)$ for all $\tau \in I$. The essential part of a proof is made up of the following theorem and the subsequent Remark 2. (To obtain this remark, we have had to repeat—in a more elaborate form—arguments briefly sketched in [4, Remark].)

In the theorem below, $V(y, \tau)$ is the supremum (possibly $= \infty$) of the criterion evaluated for all pairs $x(\cdot), u(\cdot)$ defined on $[t_0, \tau]$, satisfying (2), (3) and $x(\tau) = y$. V is thus defined only at points (y, τ) for which such pairs exists. Points (y, τ) with this property are called attainable points.

THEOREM 2. *Let U be bounded. Let $(\bar{x}(\cdot), \bar{u}(\cdot), p(\cdot))$ be a triple defined on $[t_0, \tau]$ for which (2), (3), (5), (6), (9) and (10) hold and let $\bar{H}(\tau) = H(\bar{x}(\tau), \bar{u}(\tau-), p(\tau), \tau)$. Then $V(y, \tau')$ is finite at all attainable points (y, τ') in some ball $B((\bar{x}(\tau), \tau), \delta)$ around $(\bar{x}(\tau), \tau)$ and for such points (y, τ')*

$$(13) \quad \begin{aligned} V(y, \tau') - V(\bar{x}(\tau), \tau) &\leq \bar{H}(\tau)(\tau' - \tau) - p(\tau)(y - \bar{x}(\tau)) \\ &\quad + q(|\tau - \tau'|, \|y - \bar{x}(\tau)\|)|\tau - \tau'| \end{aligned}$$

where q converges to zero when both arguments of q converge to zero.

Proof of Theorem 2. Let $(x(\cdot), u(\cdot))$ be an arbitrary admissible pair defined on $[t_0, \tau]$. If $\Delta(\tau)$ is the difference between the values of the criterion in (1) for $(\bar{x}(\cdot), \bar{u}(\cdot))$ and for $(x(\cdot), u(\cdot))$, we have

$$(14) \quad \Delta(\tau) \geq \varphi(\tau) - \varphi(t_0)$$

where $\varphi(t) = p(t)(x(t) - \bar{x}(t))$. See [5, p. 372]. Actually, when this property was derived in [5], the only properties used were the facts that $(x(\cdot), u(\cdot))$ and $(\bar{x}(\cdot), \bar{u}(\cdot))$ satisfy $\dot{x} = f$ and (3), that $(\bar{x}(\cdot), \bar{u}(\cdot))$ satisfies (5) and (6) and that (9) and (10) hold, for $t \in [t_0, \tau]$.

Next, we need an auxiliary system arising out of a modification of f^0 and f . Define \check{f}^0 and \check{f} to be equal to $f^0(\bar{x}_1, u, \tau)$ and $f(\bar{x}_1, u, \tau)$, respectively, in $(\tau, \tau_2]$, where $\bar{x}_1 = \bar{x}(\tau)$. For the optimal value function corresponding to \check{f}^0 and \check{f} , we write \check{V} and for the Hamiltonian, we write \check{H} .

Extend $\bar{u}(\cdot)$ to $(\tau, \tau_2]$ by letting $\bar{u}(t) = \bar{u}(\tau-)$ here. Extend $\bar{x}(\cdot)$ to $(\tau, \tau_2]$ as a solution in the present auxiliary system. The extension of $p(\cdot)$ simply becomes $p(t) = p(\tau)$, for $t > \tau$. Let τ' be any point in I .

Note that in the present auxiliary system, the supremum of the Hamiltonian is concave in x , for $t \in [t_0, \tau_2]$. When $(\bar{x}(t), \bar{u}(t), p(t))$ is inserted in \check{H} , denote it $\bar{H}(t)$. $\bar{H}(t)$ becomes a continuous function of t and equals $\check{H}^*(\bar{x}(t), p(t), t)$. If $(\check{x}(\cdot), u(\cdot))$ defined on $[0, \tau']$ is any admissible pair in the auxiliary system, then $\Delta(\tau') \geq \varphi(\tau') - \varphi(t_0)$, if $\Delta(\cdot)$ and φ now refer to entities of the auxiliary system. (See the sufficient properties mentioned in connection with (14)). In addition $\varphi(t_0) = 0$. Thus if x is attainable at $t = \tau'$ in this system (i.e., equals $\check{x}(\tau')$ for some $\check{x}(\cdot)$), we have that³

$$(15) \quad A = \check{V}(x, \tau') - \check{V}(\bar{x}(\tau'), \tau') \leq -p(\tau')(x - \bar{x}(\tau')).$$

³ Use the inequality for $\Delta(\tau')$.

Next, note that $B = \check{V}(\bar{x}(\tau'), \tau') - \check{V}(\bar{x}_1, \tau) = \int_{\tau}^{\tau'} f^0(\bar{x}(t), \bar{u}(t), t) dt = \int_{\tau}^{\tau'} \bar{H}(t) dt + C$, where $C = -\int_{\tau}^{\tau'} p(t) \check{f}(\bar{x}(t), \bar{u}(t), t) dt$.⁴

Let us now write $s = \tau' - \tau$. We shall, in turn, consider two cases: (i) $s < 0$ and (ii) $s \geq 0$.

Case (i). Here we get $C \leq -p(\tau)(\bar{x}(\tau') - \bar{x}_1) + \sigma_1(|s|)$, for $|s| < \check{\delta}$, where generally, here and below $\sigma_i(\cdot)$, $i = 1, 2, \dots$ means a second-order term in the variable(s) it contains. In fact, $\sigma_1(|s|)$ can be chosen equal to $K(\sup_{t \in J} \|p(t) - p(\tau)\|) \cdot |s|$, where $J = [\tau', \tau]$ and K is defined (also for later needs) by $K = \sup \|f(x, u, t)\|$ for $(x, t) \in G$, $u \in U$, G a bounded set in R^{n+1} containing $B(\bar{x}_1, 2) \times [t_0, \tau_2]$. We can choose $\check{\delta} = 2/K$ (then $\bar{x}(t)$ belongs to $B(\bar{x}_1, 2)$ for all $t \in (\tau - \check{\delta}, \tau) \cap [t_0, \tau]$).

Now, $A \leq -p(\tau)(x - \bar{x}(\tau')) + \sigma_2(|s|, \|x - \bar{x}(\tau')\|)$, where $\sigma_2(|s|, \|x - \bar{x}(\tau')\|) = \|p(\tau) - p(\tau')\| \cdot \|x - \bar{x}(\tau')\|$. Then we get $A + B = V(x, \tau') - V(\bar{x}_1, \tau) \leq \int_{\tau}^{\tau'} \bar{H}(t) dt - p(\tau)(x - \bar{x}_1) + \sigma_1(|s|) + \sigma_2(|s|, \|x - \bar{x}(\tau')\|)$ for $|s| < \check{\delta}$. Note that $\|p(\tau) - p(\tau')\| \leq L|s|$, where $L = \sup_{t \in J} \|\dot{p}(t)\|$. If we define $\sigma_3(|s|) = (\sup_{t \in J} |\bar{H}(t) - \bar{H}(\tau)|) \cdot |s|$, then $A + B \leq \bar{H}(\tau)s - p(\tau)(x - \bar{x}_1) + \sigma_1 + \sigma_2 + \sigma_3$, for $|s| < \check{\delta}$. Hence, for $y = x$, (13) is proved in this case.

Case (ii). In this case, $B = \bar{H}(\tau)s - p(\tau) \cdot (\bar{x}(\tau') - \bar{x}(\tau))$; hence $A + B \leq \bar{H}(\tau)s - p(\tau)(x - \bar{x}_1) = D$, by (15) and the fact that $p(\tau') = p(\tau)$.

Define $\Gamma = B(\bar{x}_1, 1) \times [\tau, \tau + \delta']$, where δ' is chosen so small that if $(x(\cdot), u(\cdot), \tau')$ is any triple in the original system such that $(x(\tau'), \tau') \in \Gamma$, then $x(t) \in B(\bar{x}_1, 2)$ for all $t \in [\tau, \tau']$. (In fact, δ' can be chosen as $\delta' = 1/K$.) In what follows, let $(x(\cdot), u(\cdot), \tau')$ be a triple for which $(x(\tau'), \tau') \in \Gamma$. Let $\check{x}(\cdot)$ correspond to this triple. (Then $\check{x}(\cdot) = x(\cdot)$ on $[\tau_0, \tau]$ while $\check{x}(\cdot) = f(\bar{x}_1, u(t), \tau) = \check{f}(\check{x}(t), u(t), t)$ on $(\tau, \tau']$). As before, $x = \check{x}(\tau')$.

Define $x_1 = x(\tau')$. When x_1 is near \bar{x}_1 , also $x(t)$ is near \bar{x}_1 for $t \in [\tau, \tau']$, more precisely, $\|\bar{x}_1 - x(t)\| \leq \|\bar{x}_1 - x_1\| + \|x_1 - x(t)\| \leq \|\bar{x}_1 - x_1\| + K \cdot s$. Choose a term $\alpha(\|z - y\|, |t' - t|)$ such that $\alpha(\|z - y\|, |t' - t|) \geq |f^0(z, u, t') - f^0(y, u, t)|$ and $\alpha(\|z - y\|, |t' - t|) \geq \|f(z, u, t') - f(y, u, t)\|$ for all $u \in U$, $(y, t), (z, t') \in G$, $\alpha(\cdot, \cdot)$ nondecreasing in both arguments and converging to zero if the arguments converge to zero. Since

$$\begin{aligned} x - x_1 &= \int_{\tau}^{\tau'} (\check{f}(\check{x}(t), u(t), t) - f(x(t), u(t), t)) dt \\ &= \int_{\tau}^{\tau'} (f(\bar{x}_1, u(t), \tau) - f(x(t), u(t), t)) dt, \end{aligned}$$

we get

$$\|x - x_1\| \leq \int_{\tau}^{\tau'} \alpha(\|\bar{x}_1 - x(t)\|, |\tau - t|) dt \leq \alpha(\|\bar{x}_1 - x_1\| + K \cdot s, s) \cdot s = \sigma_4(s, \|\bar{x}_1 - x_1\|)$$

(a definition of σ_4), when $x_1 \in B(\bar{x}_1, 1)$, $\tau' \in [\tau, \tau + \delta']$.

Similarly,

$$\begin{aligned} E &= \int_{t_0}^{\tau'} f^0(x(t), u(t), t) dt \\ &\leq \int_{t_0}^{\tau'} \check{f}^0(\check{x}(t), u(t), t) dt + \sigma_4(s, \|\bar{x}_1 - x_1\|) \\ &\leq \check{V}(x, \tau') + \sigma_4(s, \|\bar{x}_1 - x_1\|) \quad \text{when } x_1 \in B(\bar{x}_1, 1), \quad \tau' \in [\tau, \tau + \delta']. \end{aligned}$$

⁴ The second equality is valid, since $\bar{u}(\cdot)$, restricted to $[0, \tau']$ is optimal in the fixed end problem $\check{x}(\tau') = \bar{x}(\tau')$. (See the inequality for $\Delta(\tau')$ above.)

Note that $V(\bar{x}_1, \tau) = \check{V}(\bar{x}_1, \tau)$. Hence, $E - V(\bar{x}_1, \tau) \leq \check{V}(x, \tau') - \check{V}(\bar{x}_1, \tau) + \sigma_4 = A + B + \sigma_4 \leq D + \sigma_4$. Furthermore, if the term $-p(\tau)(x - \bar{x}_1)$ in the expression D is replaced by $-p(\tau)(x_1 - \bar{x}_1)$, the error is less than $\|p(\tau)\|\sigma_4$. Thus,

$$(16) \quad E - V(\bar{x}_1, \tau) \leq \bar{H}(\tau) \cdot s - p(\tau)(x_1 - \bar{x}_1) + (1 + \|p(\tau)\|)\sigma_4.$$

Given any pair (y, τ') in $B((\bar{x}_1, \tau), \delta)$, $\delta = \min(1, \delta')$. If (y, τ') is attainable, then (16) holds for all triples $(x(\cdot), u(\cdot), \tau')$ in the original system for which $x(\tau') = x_1 = y$. Since the right-hand side of (16) does not depend on the pair $(x(\cdot), u(\cdot))$, the inequality (13) is obtained also in this case.

Remark 2. Let G' be a bounded set in $R^n \times [t_0, \tau_2]$, and let $K'' > 0$. Assume that for each $(x, \tau) \in G'$, there exists a triple $(\bar{x}(\cdot), \bar{u}(\cdot), p(\cdot))$ defined on $[t_0, \tau]$ such that $x = \bar{x}(\tau)$, $\bar{x}(\cdot)$, $\bar{u}(\cdot)$, $p(\cdot)$ satisfying (2), (3), (5), (6), (9), (10), with $\|p(\tau)\| < K''$. Then $q(\cdot, \cdot)$ and δ in (13) can be taken to be one and the same for all such triples.

To prove this assertion, let $B(0, b) \times [t_0, \tau_2]$ be the set G in the proof, the number b so chosen that $B(0, b) \supset B(x, 2)$ for all $(x, \tau') \in G'$, and let $\delta = \min(1, 1/K, 1/K')$, where $K' = \sup \| (f_x^0(x, u, t) + pf_x(x, u, t)) \|$ for $(x, t) \in G, u \in U, p \in B(0, K'' + 1)$. Note that $p(t) \in B(0, K'' + 1)$ if $t \in [\tau - \delta, \tau] = I_\delta$. Thus $\|p(t) - p(\tau)\| \leq L|t - \tau| \leq K' \cdot |\tau' - \tau|$ for $t, \tau' \in I_\delta, t > \tau'$. Hence σ_1 and σ_2 can be taken to be independent of the triple $(\bar{x}(\cdot), \bar{u}(\cdot), p(\cdot))$.

Both $\alpha(\cdot, \cdot)$ and σ_4 are independent of $(\bar{x}(\cdot), \bar{u}(\cdot), p(\cdot))$. Finally, the function $\hat{H}(x, p, t) = \max_{u \in \bar{U}} H(x, u, p, t)$ is continuous in (x, p, t) , hence uniformly continuous for $(x, t) \in G, p \in B(0, K'' + 1)$: Since $\|p(t) - p(\tau)\| \leq K'|t - \tau|$ and $\|\bar{x}(t) - \bar{x}(\tau)\| \leq K \cdot |t - \tau|$ for $t \in I_\delta$, the limit $\lim_{t \rightarrow \tau^-} \bar{H}(t) = \bar{H}(\tau)$ is uniform in the triples $(\bar{x}(\cdot), \bar{u}(\cdot), p(\cdot))$, which shows that even σ_3 can be chosen independent of these triples.

Remark 3. Assume that U is unbounded, and let U' be a given bounded subset of U . Assume that the restriction $u(t) \in U$ (see (3)) is replaced by $u(t) \in U'$, and that $V(\cdot, \cdot)$ and the word "attainable" refer to this new system. Assume furthermore that $\bar{u}(t)$, while taking values in U' , nevertheless maximizes H even in U , and that the supremum of H , still taken for $u \in U$, is concave. Then Theorem 2 and Remark 2 are still valid.

The proofs can be kept unchanged, provided K and K' and $\alpha(\cdot, \cdot)$ are defined by restricting u to U' and defining $\hat{H}(x, p, t) = \max_{u \in \bar{U}'} H(x, u, p, t)$.

In the proof of Theorem 1, a set U' is chosen such that $u^\tau(t) \in U'$ for all t and τ . Since $u^\tau(\cdot)$ is optimal in the original problem, $V(\cdot, \cdot)$ has the same value at all points $(x^\tau(\tau), \tau)$ in the present redefined system as in the original one.

Proof of Theorem 1. For $y = x^{\tau'}(\tau')$, $x^\tau(\cdot) = \bar{x}(\cdot)$, $u^\tau(\cdot) = \bar{u}(\cdot)$, from (13) and Remark 2, we get that for $|\tau' - \tau| \leq \delta$

$$(16') \quad \begin{aligned} V(\tau') - V(\tau) &\leq d(\tau)(\tau' - \tau) - p^\tau(\tau)[x^{\tau'}(\tau') - x^\tau(\tau)] + q|\tau' - \tau| \\ &\leq d(\tau)(\tau' - \tau) + q(|\tau' - \tau|, \|x^{\tau'}(\tau') - x^\tau(\tau)\|)|\tau' - \tau| \end{aligned}$$

where we have written out the arguments of q only once, and where we have used (see (4) and (7)), that

$$\begin{aligned} p^\tau(\tau)x_{\tau'}(\tau') &= \sum_{i=1}^m p^{\pi_i}(\tau)x^{\tau'i}(\tau') \geq \sum_{i=1}^m p^{\pi_i}(\tau)x_i^i \\ &= \sum_{i=1}^m p^{\pi_i}(\tau)x^{\pi_i}(\tau) = p^\tau(\tau) \cdot x^\tau(\tau). \end{aligned}$$

Note that $\tau \rightarrow x^\tau(\tau)$ is uniformly continuous. Given an arbitrary $\varepsilon > 0$, let δ' and δ'' , $0 < \delta' < \delta''$ be chosen such that

if $|\tau' - \tau| < \delta''$ and $\|x^{\tau'}(\tau') - x^\tau(\tau)\| < \delta''$, then $q < \varepsilon$ and if $|\tau' - \tau| < \delta'$ then $\|x^{\tau'}(\tau') - x^\tau(\tau)\| < \delta''$.

Observe that δ' is independent of $\tau \in [\tau_1, \tau_2]$. Let $\check{\tau} \in [\tau_1, \tau^*)$. There exists a finite partition of $[\check{\tau}, \tau^*]$ into intervals $[\tau^i, \tau^{i+1}]$, $i = 1, \dots, i^*$ of lengths $< \delta'$. In $[\check{\tau}, \tau^*]$, $d(\tau) \geq 0$ (see (12)); thus, by (16')

$$V(\check{\tau}) - V(\tau^*) = \sum_{i=1}^{i^*} V(\tau^i) - V(\tau^{i+1}) \leq \sum_i \varepsilon(\tau^{i+1} - \tau^i) \leq \varepsilon(\tau^* - \check{\tau}).$$

Since ε is arbitrary, $V(\check{\tau}) \leq V(\tau^*)$. A symmetric argument also gives that if $\check{\tau} \in (\tau^*, \tau_2]$, $V(\check{\tau}) \geq V(\tau^*)$, and the proof is finished.

(By a slight modification of the last arguments, it may be seen that it suffices to assume that (12) holds for v.e. τ .)

4. In this section, we generalize the results to problems with state and mixed state/control restrictions and more general initial and terminal conditions.

$$(17) \quad \max \left\{ \int_{t_0}^{\tau} f^0(x(t), u(t), t) dt + S^0(x(t_0)) + S^1(x(\tau), \tau) \right\}.$$

$$(18) \quad \dot{x}(t) = f(x(t), u(t), t) \quad \text{v.e.,}$$

$$(19) \quad R_k^0(x(t_0)) = 0, \quad k = 1, \dots, r'_0, \quad t_0 \text{ fixed,}$$

$$R_k^0(x(t_0)) \geq 0, \quad k = r'_0 + 1, \dots, r_0,$$

$$(20) \quad R_k^1(x(\tau), \tau) = 0, \quad k = 1, \dots, r'_1, \quad \tau \in [\tau_1, \tau_2],$$

$$R_k^1(x(\tau), \tau) \geq 0, \quad k = r'_1 + 1, \dots, r_1$$

where $t_0 < \tau_1 < \tau_2$, τ_1, τ_2 fixed.

$$(21) \quad u(t) \in U, \quad U \text{ fixed, convex set in } R'.$$

For all t ,

$$(22) \quad \begin{aligned} g^j(x(t), u(t), t) &\geq 0, & j = 1, \dots, s', \\ g^j(x(t), u(t), t) &\equiv \bar{g}^j(x(t), t) \geq 0, & j = s' + 1, \dots, s. \end{aligned}$$

(In (22) the assumption is that g^j does not contain u for $j > s'$.)

$$(23) \quad f^0, f \text{ and their partial derivatives with respect to } x \text{ and } u \text{ exist and are continuous; } g, S^0, S^1, R^0 = (R_1^0, \dots, R_{r_0}^0), R^1 = (R_1^1, \dots, R_{r_1}^1) \text{ and their derivatives exist and are continuous.}$$

We first formulate as a theorem sufficient conditions for this problem for the case where τ is kept fixed. In the theorem, we assume that $p(\cdot)$ is continuous in (t_0, τ) . When the mixed constraints $g^j, j = 1, \dots, s'$ satisfy certain constraints qualifications, these constraints do not cause jumps in $p(\cdot)$. Neither do the pure state constraints $g^j, j > s'$ in the case where $\bar{g}_x^j(\bar{x}(t), t)f(\bar{x}(t), \bar{u}(t), t)$ is discontinuous at points $t \in (t_0, \tau)$ at which $\bar{g}^j(\bar{x}(t), t) = 0$, or when $u \rightarrow H(\bar{x}(t), u, p(t), t)$ has a unique maximum and a standard constraints qualification is satisfied.

Hence, the following sufficient conditions, which assume no jumps in $p(\cdot)$ in (t_0, τ) , have fairly wide applicability.

As before, we define the Hamiltonian as

$$(24) \quad H(x, u, p, t) = p_0 f^0(x, u, t) + pf(x, u, t)$$

and we define the Lagrangian as

$$(25) \quad L(x, u, p, q, t) = H(x, u, p, t) + qg(x, u, t).$$

The following theorem will serve as a reference for our next free final time theorem. (See [5, Thm. 9], [6, Thm. 6.7.1].)

THEOREM 3. (Final time τ fixed.) *Let $(\bar{x}(t), \bar{u}(t))$ be an admissible⁵ pair in problem (17)–(23). Assume that there exist a continuous and piecewise continuously differentiable function $p(t) = (p_1(t), \dots, p_n(t))$, a piecewise continuous function $q(t) = (q_1(t), \dots, q_s(t))$ and vectors $\beta = (\beta_1, \dots, \beta_s)$, $\beta^0 = (\beta_1^0, \dots, \beta_s^0)$, $\gamma = (\gamma_1, \dots, \gamma_r)$, $\delta = (\delta_1, \dots, \delta_{r_0})$, such that the following properties hold for $p_0 = 1$:*

$$(26) \quad L_u^*(u - \bar{u}(t)) \leq 0 \quad \text{for all } u \in U \quad \text{for v.e.t.}$$

(The $*$, here and below, indicates that the derivative is evaluated along $(\bar{x}(t), \bar{u}(t), p(t), q(t))$).

$$(27) \quad \dot{p}(t) = -L_x^* \quad \text{v.e.,}$$

$$(28) \quad p(\tau) = \beta g_x(\bar{x}(\tau), \bar{u}(\tau), \tau) + S_x^1(\bar{x}(\tau), \tau) + \gamma R_x^1(\bar{x}(\tau), \tau)$$

where for $k > r'_1$, $\gamma_k \geq 0$ ($= 0$ if $R_k^1(\bar{x}(\tau), \tau) > 0$) and where the vector $\beta = (\beta_1, \dots, \beta_s)$ satisfies

$$(29) \quad \begin{aligned} \beta_j &= 0, & j &= 1, \dots, s', \\ \beta_j &\geq 0 \quad (= 0 \text{ if } g^j(\bar{x}(\tau), \bar{u}(\tau), \tau) > 0), & j &= s' + 1, \dots, s, \end{aligned}$$

$$(30) \quad p(t_0) = -\beta^0 g_x(\bar{x}(t_0), \bar{u}(t_0), t_0) - S_x^0(\bar{x}(t_0)) - \delta R_x^0(\bar{x}(t_0))$$

where for $k > r'_0$, $\delta_k \geq 0$ ($= 0$ if $R_k^0(\bar{x}(t_0)) > 0$), and where the vector $\beta = (\beta_1^0, \dots, \beta_s^0)$ satisfies

$$(31) \quad \begin{aligned} \text{(i)} \quad \beta_j^0 &= 0, & j &\leq s', \\ \text{(ii)} \quad \beta_j^0 &\geq 0 \quad (= 0 \text{ if } g^j(\bar{x}(t_0), \bar{u}(t_0), t_0) > 0), & j &> s', \end{aligned}$$

$$(32) \quad q_j(t) \geq 0 \quad (= 0 \text{ if } g^j(\bar{x}(t), \bar{u}(t), t) > 0), \quad j = 1, \dots, s,$$

$$(33) \quad H(x, u, p(t), t) \text{ is concave in } (x, u) \in R^n \times R^r \text{ for each } t;$$

$$(34) \quad g^j(x, u, t) \text{ is quasiconcave in } (x, u) \in R^n \times R^r \text{ for each } t;$$

$$(35) \quad \text{For each } t, S^0 \text{ and } S^1 \text{ are concave in } x \text{ and } \delta_k R_k^0 \text{ and } \gamma_k R_k^1 \text{ are quasiconcave in } x, \text{ for each } k.$$

Then $(\bar{x}(\cdot), \bar{u}(\cdot))$ is an optimal pair.

In the next theorem, τ is again subject to choice in $[\tau_1, \tau_2]$.

THEOREM 4. (Final time τ free.) *Consider problem (17)–(23). Suppose that τ is free to vary in $[\tau_1, \tau_2]$, $t_0 < \tau_1 < \tau_2$.*

⁵ An admissible pair $x(\cdot), u(\cdot)$ is a pair satisfying (18)–(22), $u(\cdot)$ piecewise continuous.

Assume that for each $\tau \in [\tau_1, \tau_2]$ there exists an admissible pair $(x^\tau(t), u^\tau(t))$, defined on $[t_0, \tau]$, with associated multipliers $p^\tau(t), q^\tau(t), \delta^\tau = (\delta_1^\tau, \dots, \delta_{r_0}^\tau), \gamma^\tau = (\gamma_1^\tau, \dots, \gamma_{r_1}^\tau), \beta^{0\tau} = (\beta_1^{0\tau}, \dots, \beta_s^{0\tau}), \beta^\tau = (\beta_1^\tau, \dots, \beta_s^\tau)$ that satisfy the conditions (26)–(35) for $t \in [t_0, \tau]$ with $p_0 = 1$. Assume, moreover, that $u^\tau(\cdot)$ and $q^\tau(\cdot)$ take values in fixed, bounded subsets being independent of $\tau \in [\tau_1, \tau_2]$, and that $\tau \rightarrow x^\tau(\tau)$ is Lipschitz continuous. Assume also that the functions $\tau \rightarrow \beta^\tau$ and $\tau \rightarrow \gamma^\tau$ are piecewise continuous. Assume next that $u^\tau(\tau)$ belongs to the closure of the set $\{u \in U, g^j(x^\tau(t), u, \tau) > 0 \text{ for all } j \leq s'\} \text{ for all } \tau$. Finally, assume that the function

$$(36) \quad F(\tau) = H(x^\tau(\tau), u^\tau(\tau), p^\tau(\tau), \tau) + \beta^\tau \cdot g_t(x^\tau(\tau), u^\tau(\tau), \tau) \\ + S_t^1(x^\tau(\tau), \tau) + \gamma^\tau \cdot R_t^1(x^\tau(\tau), \tau)$$

has the property that there exists a $\tau^* \in [\tau_1, \tau_2]$ such that

$$(37) \quad \begin{aligned} F(\tau) &\geq 0 \quad \text{for } \tau < \tau^* \quad \text{if } \tau_1 < \tau^*, \\ F(\tau) &\leq 0 \quad \text{for } \tau > \tau^* \quad \text{if } \tau_2 > \tau^*. \end{aligned}$$

Then the pair $(x^{\tau^*}(t), u^{\tau^*}(t))$ defined on $[t_0, \tau^*]$ is optimal.

Proof. Again $V(\tau)$ is the value of the criterion, see (17), for $(x^\tau(\cdot), u^\tau(\cdot), \tau)$. And as before, $(x^\tau(\cdot), u^\tau(\cdot))$ is optimal in the problem where τ is the fixed terminal time. Hence, to show that $V(\tau^*)$ is no less than the value of the criterion for an arbitrary admissible pair $x(\cdot), u(\cdot)$ defined on $[0, \tau]$, $\tau \in [\tau_1, \tau_2]$, it suffices to show that $V(\tau) \leq V(\tau^*)$.

To give a proof of this property, we shall refer to the proofs of Theorems 1 and 2. Hence, let $(\bar{x}(\cdot), \bar{u}(\cdot)) = (x^\tau(\cdot), u^\tau(\cdot))$ for some given τ . Choose an open ball B' such that $u^\tau(t) \in B'$ for all τ and t , and define $U' = U \cap B'$. Note that for some K'' , we have $K'' \geq \sup \|p^\tau(\tau)\|$, $(\tau \rightarrow x^\tau(\tau), \tau \rightarrow \gamma^\tau, \tau \rightarrow \beta^\tau)$ are piecewise continuous (see (28), (29)). Define $K' = \sup \|f_x^0(x, u, t) + pf_x(x, u, t) + qg_x(x, u, t)\|$, the supremum taken for $(x, t) \in G = B(0, b) \times [t_0, \tau_2]$, $u \in U'$, $p \in B(0, K'' + 1)$, $q \in Q$, where Q is a set that has the property that $q^\tau(t) \in Q$ for all t and τ and $B(0, b) \supset B(x^\tau(\tau), 2)$ for all τ . Finally, let $K = \sup \|f(x, u, t)\|$ for $u \in U'$, $(x, t) \in G$ and let $\delta = \min(1, 1/K, 1/K')$. For these definitions, K, K', K'' and δ can play the same role as in the proof of Theorem 1.

$$(37') \quad \text{Define } H^*(x, p, t) = \sup \{H(x, u, p, t) : u \in U, g(x, u, t) \geq 0\}.$$

In [5], property (14) was obtained by establishing the inequality

$$(38) \quad H(x(t), u(t), p(t), t) - H^*(\bar{x}(t), p(t), t) \leq -\dot{p}(t)(x(t) - \bar{x}(t)).$$

For the arguments needed to obtain (38), see the proof of Theorem 6 and Note 3 in [5]. (The properties used in the proof in [5] are that $(x(\cdot), u(\cdot))$ and $(\bar{x}(\cdot), \bar{u}(\cdot))$ satisfy $\dot{x} = f$, $u(t) \in U$, $\dot{p} = -L_x^*, L_u^*(u - \bar{u}(t)) \leq 0$ for $u \in U$, $qg^* = 0$, $q \geq 0$, H concave in (x, u) , g quasiconcave in (x, u)).

Let us first consider the case $\tau' < \tau$. Evidently,

$$(38') \quad \int_{t_0}^{\tau'} f^0(\bar{x}(t), \bar{u}(t), t) dt - \int_{t_0}^{\tau'} f^0(x^{\tau'}(t), u^{\tau'}(t), t) dt \geq \phi^{\tau'}(\tau') - \phi^{\tau'}(t_0)$$

where $\phi^{\tau'}(t) = p^{\tau'}(t)(x^{\tau'}(t) - x^\tau(t))$ (see property (14)).

With the same arguments that lead from (15) to (13) above, we obtain from (38') that if $(x^{\tau'}(\tau'), \tau') \in B((x^\tau(\tau), \tau), \delta)$, then

$$(38'') \quad -\phi^{\tau'}(t_0) + \Delta''(\tau', \tau) \leq d(\tau)(\tau' - \tau) - p^\tau(\tau)(x^{\tau'}(\tau') - x^\tau(\tau)) + \sigma$$

where $\Delta''(\tau', \tau) = \int_{t_0}^{\tau'} f^0(x^{\tau'}(t), u^{\tau'}(t), t) dt - \int_{t_0}^{\tau} f^0(x^{\tau}(t), u^{\tau}(t), t) dt$ and σ is the second-order term of the proof of Theorem 2 (i.e., $\sigma = q|\tau' - \tau|$).

Even the independence of σ and δ on $\bar{x}(\cdot)$ (i.e., on τ) is obtained in the same way.

For $\tau' > \tau$, the argument runs as follows: Since $\tau \rightarrow \beta^{\tau}$ and $\tau \rightarrow \gamma^{\tau}$ are piecewise continuous, by (28) and (29), $\tau \rightarrow p^{\tau}(\tau)$ is piecewise continuous. Next, note that for $x(\cdot) = x^{\tau'}(\cdot)$, (38) can be obtained for all t in (t_0, τ) . This means that we can obtain an inequality similar to (38') also in this case, namely,

$$\int_{t_0}^{\tau} f^0(\bar{x}(t), \bar{u}(t), t) dt - \int_{t_0}^{\tau} f^0(x^{\tau'}(t), u^{\tau'}(t), t) dt \geq \phi^{\tau}(\tau) - \phi^{\tau}(t_0).$$

Defining Δ'' as above, we get

$$-\Delta''(\tau', \tau) + \int_{\tau}^{\tau'} f^0(x^{\tau'}(t), u^{\tau'}(t), t) dt \geq \phi^{\tau}(\tau) - \phi^{\tau}(t_0).$$

The integrand can be rewritten as $H(x^{\tau'}(t), u^{\tau'}(t), \Phi(\tau), t) - \Phi(\tau)f(x^{\tau'}(t), u^{\tau'}(t), t)$, where $\Phi(\tau) = p^{\tau}(\tau)$. Thus,

$$-\Delta''(\tau', \tau) + \int_{\tau}^{\tau'} H(x^{\tau'}(t), u^{\tau'}(t), \Phi(\tau), t) dt - \Phi(\tau)(x^{\tau'}(\tau') - x^{\tau'}(\tau)) \geq \phi^{\tau}(\tau) - \phi^{\tau}(t_0).$$

Using the definition of $\phi^{\tau}(\tau)$ and approximating the last integrand by $d(\tau)$, we get

$$(38''') \quad -\phi^{\tau}(t_0) + \Delta''(\tau', \tau) \leq d(\tau)(\tau' - \tau) - p^{\tau}(\tau)(x^{\tau'}(\tau') - x^{\tau'}(\tau)) + \sigma$$

where $\sigma = \int_{\tau}^{\tau'} \lambda(t, \tau', \tau) dt$, $\lambda(t, \tau', \tau) = |d(\tau) - H(x^{\tau'}(t), u^{\tau'}(t), \Phi(\tau), t)|$. We are going to show that $\lambda(t, \tau', \tau)$ is uniformly small within each interval of continuity of $\tau \rightarrow p^{\tau}(\tau)$, in a sense to be made precise.

Define $A = \sup \{|H(x, u, p, t)|: \text{for } (x, t) \in G, u \in U', p \in B(0, K''+1)\}$ and let (a_i, a_{i+1}) , $i = 1, \dots, i'$ be the intervals of continuity of $\tau \rightarrow p^{\tau}(\tau)$.

Let $\varepsilon > 0$. Define $a = \varepsilon/8Ai'$, and let $I_i = [a_i + a, a_{i+1} - a]$. Define $h(\tau', t) = H^*(x^{\tau'}(t), p^{\tau'}(t), t)$. Note that $\|p^{\tau'}(\tau') - p^{\tau'}(t)\| \leq K'(\tau' - t)$ and that $\|x^{\tau'}(\tau') - x^{\tau'}(t)\| \leq K(\tau' - t)$ when $\tau', t \in I_i$, $\tau' - \delta \leq t \leq \tau'$. Hence for any $\tau \in I_i$, $\lim x^{\tau'}(t) = x^{\tau'}(\tau)$ and $\lim p^{\tau'}(t) = p^{\tau'}(\tau)$ when $\tau' \rightarrow \tau$, $t \rightarrow \tau$, $t \leq \tau'$, $\tau', t \in I_i$. We now assert that *there exists a $\delta \in (0, \delta)$ such that $\lambda(t, \tau', \tau) = \|h(\tau', t) - h(\tau, \tau)\| < \varepsilon$, when $\tau \leq t \leq \tau' \leq \tau + \delta$; $t, \tau', \tau \in I_i$* . By contradiction, assume that, for all $n = 1, 2, \dots$, there exist points $t_n, \tau'_n, \tau_n \in I_i$, $\tau_n \leq t_n \leq \tau'_n \leq \tau_n + 1/n$ such that $\lambda(t_n, \tau'_n, \tau_n) \geq \varepsilon$. By compactness of I_i , we may assume that $\tau_n \rightarrow \tau$, for some $\tau \in I_i$. Then also $t_n \rightarrow \tau$, and $\tau'_n \rightarrow \tau$. Next, observe that the set \bar{U}' is compact. Note furthermore that $h(\tau', t) = \max \{H(x^{\tau'}(t), u, p^{\tau'}(t), t): u \in \bar{U}', g(x^{\tau'}(t), u, t) \geq 0\}$, $h(\tau, \tau) = \sup \{H(x^{\tau}(\tau), u, p^{\tau}(\tau), \tau): u \in \bar{U}', g^j(x^{\tau}(\tau), u, \tau) > 0 \text{ for all } j \leq s'\}$. The first equality gives that $\limsup h(\tau'_n, t_n) \leq h(\tau, \tau)$, the second one that $\liminf h(\tau'_n, t_n) \geq h(\tau, \tau)$. Thus, $\lim h(\tau'_n, t_n) = h(\tau, \tau)$. But this contradicts the fact that $\lambda(t_n, \tau'_n, \tau_n) \geq \varepsilon$. Hence, the assertion made about $\lambda(t, \tau', \tau)$ above is valid. Exactly the same assertion can also be made about $\lambda(t, \tau', \tau)$ for the following reason: Observe first that $d(\tau) = h(\tau, \tau)$, while $h(\tau', t) - H(x^{\tau'}(t), u^{\tau'}(t), \Phi(t), t) = (p^{\tau'}(t) - \Phi(\tau))f(x^{\tau'}(t), u^{\tau'}(t), t)$. In the last expression, f is bounded by K if $\tau \leq t \leq \tau' \leq \tau + 2/K$, while $p^{\tau'}(t) \rightarrow p^{\tau}(\tau) = \Phi(\tau)$ when τ' (and t) $\rightarrow \tau$, uniformly in $\tau \in I_i$, by a simple compactness argument again.

Since $\lambda(t, \tau', \tau)$ has the asserted property, $\sigma \leq \varepsilon(\tau' - \tau)$ when $\tau' - \tau \leq \tilde{\delta}$, $\tau' \geq \tau$, $\tau', \tau \in I_i$ for some i .

Let $\tilde{\tau}$ be some point in $[\tau_1, \tau^*)$ (assuming $\tau_1 < \tau^*$), and let $\varepsilon > 0$. Choose a $\delta' \in (0, \delta)$ such that the term σ of (38'') has the property that $\sigma \leq \varepsilon|\tau' - \tau|$ when $|\tau' - \tau| < \delta'$ (cf. the proof of Theorem 1). Choose a partition $\{t^j\}$, $j = 1, \dots, j'$ of $[\tilde{\tau}, \tau^*]$, $t^1 - \tilde{\tau}, t^{j'} = \tau^*$,

such that $0 < t^{j+1} - t^j < \delta'$. Let $\tau' = t^j$, $\tau = t^{j+1}$, $j = 1, 2, \dots$, and sum the left, respectively right, side of (38''). For $y(t) = x'(t)$, $\Phi(t) = p'(t)$, we then get

$$(39) \quad - \sum_{j=1}^{j'-1} \phi^{t^{j+1}}(t_0) + \Delta''(\check{\tau}, \tau^*) \leq \sum_j d(t^{j+1})(t^j - t^{j+1}) - \sum_j \Phi(t^{j+1})(y(t^j) - y(t^{j+1})) \\ + \sum_j \varepsilon(t^{j+1} - t^j).$$

For the t^j 's spaced closely enough (all $t^{j+1} - t^j$ small enough), the two former sums above approximate the integrals $\int_{\tau^*}^{\check{\tau}} d(t) dt$ and $\int_{\tau^*}^{\check{\tau}} \Phi(t) dy(t)$, respectively. Evidently, it is possible to obtain

$$(39') \quad - \sum_j \phi^{t^{j+1}}(t_0) + \Delta''(\check{\tau}, \tau^*) \leq - \int_{\check{\tau}}^{\tau^*} d(t) dt + \int_{\check{\tau}}^{\tau^*} \Phi(t) dy(t) + \varepsilon'$$

where $\varepsilon' = \varepsilon(\tau_2 - \tau_1) + \varepsilon$.

A similar argument also works when $\check{\tau} \in (\tau^*, \tau_2]$. In this case, the term σ is the one defined subsequently to (38'''). Since $\lambda(t, \tau', \tau) \leq 2A$ when $\tau \leq t \leq \tau' \leq \tau + \tilde{\delta}$, then $\sigma \leq 2A(\tau' - \tau)$, ($\sigma \leq \varepsilon(\tau' - \tau)$ if $\tau', \tau \in I_i$). Choose a partition $\{t^j\}$, $j = 1, \dots, j'$ of $[\tau^*, \check{\tau}]$ such that $0 < t^{j+1} - t^j < \tilde{\delta}$, and such that any of the intervals $[t^j, t^{j+1}]$ either belongs to some I_i or equals one of the intervals $I_i \cap [\tau^*, \check{\tau}]$, with $t^1 = \tau^*$, $t^{j'} = \check{\tau}$.

Otherwise, by letting $\tau' = t^{j+1}$, $\tau = t^j$, and using the facts that $\sigma \leq \varepsilon(t^{j+1} - t^j)$ when $[t^j, t^{j+1}] \in I_i$, for some i , and that $\sigma \leq 2A(t^{j+1} - t^j)$, we get

$$(40) \quad - \sum_{j=1}^{j'-1} \phi^{t^j}(t_0) + \Delta''(\check{\tau}, \tau^*) \leq \sum_j d(t^j)(t^{j+1} - t^j) - \sum_j \Phi(t^j)(y(t^{j+1}) - y(t^j)) \\ + \sum_j \varepsilon(t^{j+1} - t^j) + i'2A2a$$

by summing the left and right sides of (38'''). Finally, when the t^j 's are densely distributed, the sums can be replaced by integrals, with the effect of introducing at most an additional error $\varepsilon/2$. Hence

$$(41) \quad - \sum_j \phi^{t^j}(t_0) + \Delta''(\check{\tau}, \tau^*) \leq \int_{\tau^*}^{\check{\tau}} d(t) dt - \int_{\tau^*}^{\check{\tau}} \Phi(t) dy(t) + \varepsilon''$$

where $\varepsilon'' = \varepsilon(\tau_2 - \tau_1) + \varepsilon$.

Next, let τ' be either smaller or greater than τ . Let $\bar{x}(\cdot) = x^\tau(\cdot)$. Then, for $\delta = \delta^\tau$, $\delta_k R_k^0(x^\tau(t_0)) \geq \delta_k R_k^0(\bar{x}(t_0))$ when $\bar{x}(t_0)$ satisfies (19); hence by quasiconcavity, $\delta_k R_{kx}^0(\bar{x}(t_0))(x^\tau(t_0) - \bar{x}(t_0)) \geq 0$. Similarly, for $\beta^0 = \beta^{0\tau}$, $\beta_j^0 g_x^j(\bar{x}(t_0), \bar{u}(t_0), t_0)(x^\tau(t_0) - \bar{x}(t_0)) \geq 0$.

Also, $S^0(x^\tau(t_0)) - S^0(\bar{x}(t_0)) \leq S_x^0(\bar{x}(t_0))(x^\tau(t_0) - \bar{x}(t_0))$. Thus, $\phi^\tau(t_0) + S^0(x^\tau(t_0)) - S^0(\bar{x}(t_0)) \leq \phi^\tau(t_0) + S_x^0(\bar{x}(t_0))(x^\tau(t_0) - \bar{x}(t_0)) + \delta R_x^0(\bar{x}(t_0))(x^\tau(t_0) - \bar{x}(t_0)) + \beta^0 g_x(\bar{x}(t_0), \bar{u}(t_0), t_0)(x^\tau(t_0) - \bar{x}(t_0)) = 0$, using condition (30). Define $\Delta'(\tau', \tau) = S^0(x^\tau(t_0)) - S^0(\bar{x}(t_0))$. Then, by the last inequality, $\Delta' \leq -\phi^\tau(t_0)$. Hence, $\Delta'(\check{\tau}, \tau^*) = \sum_j \Delta'(t^j, t^{j+1}) \leq -\sum \phi^{t^{j+1}}(t_0)$ (respectively, $\leq -\sum \phi^{t^j}(t_0)$), when $\check{\tau} < \tau^*$ (respectively, $\check{\tau} > \tau^*$). Consider now the case $\check{\tau} > \tau^*$. Using (39'), we get

$$(42) \quad \tilde{\Delta} \leq - \int_{\check{\tau}}^{\tau^*} d(t) dt + \int_{\check{\tau}}^{\tau^*} \Phi(t) dy(t) + \varepsilon'$$

where $\varepsilon' = \varepsilon(\tau_2 - \tau_1) + \varepsilon$, and $\tilde{\Delta} = \Delta'(\check{\tau}, \tau^*) + \Delta''(\check{\tau}, \tau^*)$.

Note that $y(t)$ is absolutely continuous. Hence, $V(\tilde{\tau}) - V(\tau^*) = \tilde{\Delta} + S^1(y(\tilde{\tau}), \tilde{\tau}) - S^1(y(\tau^*), \tau^*) = \tilde{\Delta} + \int_{\tilde{\tau}}^{\tau^*} (d/dt) S^1(y(t), t) dt$. Thus, from (42) we get

$$(43) \quad V(\tilde{\tau}) - V(\tau^*) \leq - \int_{\tilde{\tau}}^{\tau^*} d(t) dt + \int_{\tilde{\tau}}^{\tau^*} \Phi(t) \dot{y}(t) dt - \int_{\tilde{\tau}}^{\tau^*} (S_x^1(y(t), t) \dot{y}(t) + S_t^1(y(t), t)) dt + \varepsilon'.$$

Next, note that at each point $\bar{t} \in (\tau_1, \tau_2)$, the function $t \rightarrow \gamma^{\bar{t}} R^1(y(t), t)$ has a minimum at $t = \bar{t}$, i.e., $\gamma^{\bar{t}} (R_x^1(y(\bar{t}), \bar{t}) \cdot \dot{y}(\bar{t}) + R_t^1(y(\bar{t}), \bar{t})) = 0$ a.e. Similarly, $\beta^{\bar{t}} g_x(y(\bar{t}), u^{\bar{t}}(\bar{t}), t) \cdot \dot{y}(\bar{t}) + \beta^{\bar{t}} g_t(y(\bar{t}), u^{\bar{t}}(\bar{t}), \bar{t}) = 0$ a.e. Then, in a shorthand notation,

$$(44) \quad V(\tilde{\tau}) - V(\tau^*) \leq - \int_{\tilde{\tau}}^{\tau^*} (d(t) + \beta^{\bar{t}} g_t + S_t^1 + \gamma^{\bar{t}} R_t^1) dt - \int_{\tilde{\tau}}^{\tau^*} (-\Phi \dot{y} + \beta^{\bar{t}} g_x \dot{y} + S_x^1 \dot{y} + \gamma^{\bar{t}} R_x^1 \dot{y}) dt + \varepsilon'.$$

Using (28) and (37), we get $V(\tilde{\tau}) - V(\tau^*) \leq \varepsilon(\tau_2 - \tau_1) + \varepsilon$, i.e., $V(\tilde{\tau}) \leq V(\tau^*)$, since ε was arbitrary. The case $\tilde{\tau} \in (\tau^*, \tau_2]$, in the case where $\tau^* < \tau_2$, is treated completely symmetrically. Hence the proof of Theorem 4 is finished. Note that the Lipschitz continuity of $\tau \rightarrow x^\tau(\tau)$ is used only to establish (43) and (44). Mere continuity is needed when $S^1 \equiv 0$, and (7) is the terminal condition and $s = s'$.

Remark 4. Theorem 4 can be generalized to the case where the functions $p^\tau(\cdot)$ are allowed to have a finite number of discontinuities caused by the constraints $g^j, j > s'$, of the type (77), (78) of [5], in either of two cases: (i) there exists a $\delta > 0$ such that for all τ , $p^\tau(\cdot)$ has no discontinuity point in $(\tau - \delta, \tau)$; (ii) $V(\tau)$ is a continuous function.

The conditions of Theorems 1 and 4 imply that $V(\tau)$ is continuous: In the situation of Theorem 1, this follows from the boundedness of $d(\cdot)$ and (16'), which also holds for τ' and τ interchanged. In the situation of Theorem 4, (43) holds for arbitrary $\tilde{\tau}$ and $\tau^*(\varepsilon')$ independent of $\tilde{\tau}$ and τ^* , which again implies continuity of $V(\tau)$.

Remark 5. Assume that $U = R'$. Then, in Theorem 3, the concavity condition on H and $g^j, j \leq s'$ can be replaced by the following conditions: $H(\bar{x}(t), \bar{u}(t), p(t), t) = H^*(\bar{x}(t), p(t), t)$, where H^* is defined in (37'). Furthermore, $H^*(x, p(t), t)$ has, for all t , a concave extension to the set $\text{co}\{x: \text{for some } u \in R', g^j(x, u, t) \geq 0 \text{ for all } j \leq s'\}$ as a function of x . Finally, if we define $I(t) = \{j: g^j(\bar{x}(t), \bar{u}(t), t) = 0, j \leq s'\}$, the matrix with elements $g_{u^i}^{j,i}(\bar{x}(t), \bar{u}(t), t), i = 1, \dots, r, j \in I(t)$ has a rank equal to the number of elements in $I(t)$, for v.e. t .

(The proof of Theorem 4 remains the same, since (38) holds even for the present conditions; see the proof of Theorem 9 in [5].)

Remark 6. Theorems 1 and 4 also hold if $\tau_1 = t_0$, and it is then sufficient that the conditions of the theorems are satisfied for $\tau \in (\tau_1, \tau_2]$. This assertion follows at once from the fact that $V(\tau)$ is continuous at $\tau = \tau_1 = t_0$. This continuity is a consequence of the existence of bounded sets U' and D such that $u^\tau(t) \in U'$ for all τ and t , and $x^\tau(t) \in D$ for $t_0 \leq t \leq \tau < t', t'$ near enough t_0 . (In Theorem 4, the Lipschitz continuity is needed for the last assertion).

Remark 7. A remark exactly analogous to Remark 1 pertains also to Theorem 4.

Remark 8. Assume for Theorems 1 and 4 that instead of (12), respectively (37), holding for some τ^* for all $\tau \in [\tau_1, \tau_2]$, there exist subintervals $[a_{i-1}, a_i]$ partitioning $[\tau_1, \tau_2]$ and points $\tau_i^* \in [a_{i-1}, a_i]$ such that (12), respectively (37), holds for $\tau^* = \tau_i^*$ in the subinterval $[a_{i-1}, a_i]$, for all i . Then one of the points τ_i^* is optimal.

Remark 9. Consider the case where $\tau_2 = \infty$ and let us enlarge the set of admissible pairs in problems (1)–(4) by adding pairs $(x(t), u(t))$ defined on $[t_0, \infty)$ satisfying (1)–(4) with $x^i(\tau)$ in (4) replaced by $\lim_{\tau \rightarrow \infty} x^i(\tau)$ (assumed to exist), $i = 1, \dots, l$ and by $\liminf_{\tau \rightarrow \infty} x^i(\tau)$, $i = l+1, \dots, m$. For simplicity, assume that the integral in (1) is convergent for $\tau = \infty$, for any admissible pair defined on an infinite interval. (If the so-called catching-up criterion is used (see [5]), then this last assumption is not needed.)

We then have the following two results: (I) If $\liminf_{\tau \rightarrow \infty} p^\tau(\tau)(x(\tau) - x^\tau(\tau)) \geq 0$ for each admissible solution defined on $[t_0, \infty)$ and the conditions of Remark 1 are satisfied, then τ^* is again optimal. (II) If $(\bar{x}(\cdot), \bar{u}(\cdot))$ defined on $[t_0, \infty)$ together with an adjoint function $p(\cdot)$ satisfy the conditions (5), (6), (9), (10) and the conditions $\liminf_{\tau \rightarrow \infty} p(\tau)(x^\tau(\tau) - \bar{x}(\tau)) \geq 0$ and $\liminf_{\tau \rightarrow \infty} p(\tau)(x(\tau) - \bar{x}(\tau)) \geq 0$ for all admissible solutions $x(\cdot)$ defined on $[t_0, \infty)$, and finally, the condition $d(\tau) \geq 0$ for all τ , then $(\bar{x}(\cdot), \bar{u}(\cdot))$ is optimal.

The two assertions above easily follow from an application of (14).

Example. Consider the problem

$$(i) \quad \max_{u(\cdot), \tau} \int_0^\tau (qu - c(u)) e^{-rt} dt,$$

$$(ii) \quad \dot{x} = -u, \quad x(0) = \bar{x} > 0, \quad x(\tau) \geq 0, \quad u \geq 0$$

where c is a C^2 function, $c' > 0$, $c'' > 0$, $q > 0$, $r > 0$, $c'(0) < q < c'(\infty)$, $c(0) > 0$, $\max_{u \geq 0} qu - c(u) = k > 0$. The problem can be given the following interpretations: x is a stock of a natural resource, u the extraction rate (the control variable), q the price of the resource, $c(u)$ the extraction cost. With $H = (qu - c(u)) e^{-rt} - p(t)u$, we get that $\dot{p} = 0$, i.e., $p(t) \equiv \bar{p} \geq 0$. By concavity, the Hamiltonian is maximized by $u \geq 0$ if and only if u satisfies

$$(iii) \quad (q - c'(u)) e^{-rt} - \bar{p} \leq 0 \quad (\text{if } u > 0).$$

Note that condition (iii) defines u as a continuous function $u(t; \bar{p})$ being nonincreasing in \bar{p} . For $\bar{p} = 0$, $u(t; 0) \equiv u_0 > 0$.

Define τ' by $\int_0^{\tau'} u_0 dt = \bar{x}$. A candidate satisfying the fixed final time necessary conditions (for $p_0 = 1$), with $\tau < \tau'$, must satisfy $x(\tau) \geq 0$ with strict inequality ($u_0 \geq u(t; \bar{p})$). On the other hand, for $\tau > \tau'$, \bar{p} has to be > 0 in order for $\int_0^\tau u(t; \bar{p}) dt$ not to exceed \bar{x} , i.e., $x(\tau) \geq 0$ is satisfied with equality in this case.

Thus for $\tau \geq \tau'$, \bar{p} is determined as a continuous nondecreasing function $\bar{p}(\tau)$ of τ by

$$(iv) \quad \int_0^\tau u(t; \bar{p}) = \bar{x}.$$

(Note that for $\bar{p} = 0$, the left side is ≥ 0 , while for $\bar{p} = q - c'(0)$, $u(t; \bar{p}) \equiv 0$ by (iii), and the left side of (4) is $< \bar{x}$).

For $\tau < \tau'$, let $\bar{p}(\tau) = 0$, and write $u_\tau(t) = u(t; \bar{p}(\tau))$, $d(\tau) = (qu_\tau(\tau) - c(u_\tau(\tau))) e^{-r\tau} - \bar{p}u_\tau(\tau)$.

Now, $u(t; \bar{p})$ is nonincreasing in t . Hence, by (4), $u_\tau(\tau) \rightarrow 0$ when $\tau \rightarrow \infty$. (Actually, for some $\tilde{\tau}$, $u_\tau(t) = 0$ for $\tau \geq t \geq \tilde{\tau}$). Thus $d(\tau) < 0$ for all $\tau \geq \tau''$ if τ'' is large enough, ($c(0) > 0$). For $\tau = 0$, $\bar{p} = 0$ and $d(0) = k > 0$, by one of our assumptions. Since $d(\tau)$ is continuous, for some $\tau^* > 0$, $d(\tau^*) = 0$.

Let τ^* be largest possible. Then $0 = d(\tau^*)$ implies $(qu_{\tau^*}(\tau^*) - c(u_{\tau^*}(\tau^*))) e^{-r\tau^*} = \bar{p}u_{\tau^*}(\tau^*) \geq 0$. That is, by the maximum condition, for $\tilde{\tau} < \tau^*$, $d(\tilde{\tau}) \geq (qu_{\tau^*}(\tau^*) - c(u_{\tau^*}(\tau^*))) e^{-r\tilde{\tau}} - \bar{p}u_{\tau^*}(\tau^*) \geq d(\tau^*)$. By definition of τ^* , $0 = d(\tau^*) \geq d(\tilde{\tau})$ if $\tilde{\tau} > \tau^*$. (We can even show that the two last, weak inequalities are in fact strict ones.)

It is now easily seen that the conditions in Remark 1 to Theorem 1 are satisfied. That is, $u_{\tau^*}(\cdot) = u(\cdot; \bar{p}(\tau^*))$ is optimal.

Here, what might be called qualitative arguments were used in order to show the existence of a candidate satisfying all the sufficient conditions. Such arguments are needed in the numerous cases where no explicit formulas can be obtained. Although exceedingly simple, this example, we hope, serves as an illustration of the fact that the tools presented may also be useful in cases of this type.

DISTURBANCE DECOUPLING PROBLEMS BY MEASUREMENT FEEDBACK: A CHARACTERIZATION OF ALL SOLUTIONS AND FIXED MODES*

VASFİ ELDEM† AND A. BÜLENT ÖZGÜLER†

Abstract. This paper presents a new approach to disturbance decoupling problems by measurement feedback (DDPM). The novelty in this approach is that it yields a characterization of the sets of all solutions to DDPM and DDPM with internal stability and that the set of fixed modes of DDPM with respect to dynamic output feedback is easily identified. The central object used in deriving these results is a minimal polynomial basis of a rational vector space which conveniently represents the problem data.

Key words. disturbance decoupling, dynamic measurement feedback, internal stability, pole-placement, minimal polynomial basis of rational vector spaces

AMS(MOS) subject classifications. 93B25, 93B50

1. Introduction. Disturbance decoupling problems via dynamic measured output (measurement) feedback (DDPM) have been studied extensively in the last decade. Solutions to the problem without internal stability constraint have been obtained by Akashi and Imai [1979] and Schumacher [1980]. The problems with internal stability and pole placement have been solved by Willems and Commault [1981] and Imai and Akashi [1981]. In these papers, the concepts from the geometric approach to linear system theory was primarily used. Through a transfer matrix approach Ohm, Bhattacharyya and Howze [1984] have obtained an alternative solution to DDPM and using a stable rational fractional approach Pernebo [1981] has obtained solutions to the problems with or without internal stability. In Özgüler and Eldem [1985] a polynomial fractional approach has been taken to reduce the problems to the solvability of matrix equations of the type $AXB = C$ where a solution X is being sought on the various subrings of the field of rational functions. This approach has also yielded alternative solutions to DDPM with internal stability or pole-placement and the results have been used in Özgüler [1986] to make the relation between the geometric and polynomial fractional solutions to DDPM explicit.

Despite the existence of a rich variety of solutions (solvability conditions and synthesis procedures) and a thorough understanding of the structural aspects of disturbance decoupling problems, there are at least a few more problems that are worth studying in the same context. Among these are (i) a characterization of the set of all solutions to disturbance decoupling problems, (ii) finding an explicit expression for the set of fixed modes of DDPM in terms of the problem data, (iii) determination of a minimal McMillan degree (order) solution to DDPM, (iv) obtaining “approximate” solutions to DDPM which achieve maximal disturbance attenuation when the “exact” problem is not solvable and (v) examining the robustness issues involved in DDPM. Recall that the “state-feedback” version of the characterization problem has been solved by Forney [1975]. However, no such result exists in DDPM; in fact “a computationally attractive parametrization of the set of all solutions to DDPM” has been stated as an open problem in Ohm, Howze and Bhattacharyya [1984]. For the fixed mode characterization of the state-feedback version of DDPM, the work of Wolovich,

Antsaklis and Elliot [1977] can be mentioned. As to the characterization of fixed modes in DDPM, it can be easily seen that the earlier studies concerned with DDPM with internal stability all come very close to the resolution of this problem. However, this point is not directly addressed in any of these works. The minimal McMillan degree solution of the state-feedback version of disturbance decoupling problems has been obtained by Wang and Davison [1973] and later in a more systematic setting by Forney [1975]. Concerning the same point in DDPM, one finds nothing more than a brief discussion in for example Schumacher [1980] and Willems and Commault [1981]. In the present paper, we do not directly address this problem. We should add, however, that the approach taken here has already led to some preliminary results towards the determination of minimal order solutions for DDPM (see Eldem, Özgüler and Başer [1986]). Concerning issues (iv) and (v), we mention the works by Willems [1982] on “almost disturbance decoupling” and by Bhattacharyya, del Nero Gromes and Howze [1983] on “robustness” respectively.

This paper is primarily concerned with points (i) and (ii). In characterizing the set of all solutions to DDPM with or without internal stability and in identifying the fixed modes of DDPM (with respect to dynamic measurement feedback), we carry out the following conceptual program: (1) Identify a rational vector space which conveniently represents the problem data. (2) State the solvability condition of various disturbance decoupling problems on a minimal polynomial basis of this vector space. (3) Determine the sources of nonuniqueness that enrich the class of solutions and describe the set of all solutions accordingly. (4) Identify the fixed modes again on a minimal polynomial basis of the same vector space. Hence it is clear that this work rests heavily on the work of Forney [1975] on minimal polynomial bases of rational vector spaces. In identifying the relevant rational vector space the main source of insight has been the work of Kučera [1983] that considers the same problem for the scalar case. (The reader may note the similarity between the crucial matrix $[A: -B]$ in § 3 and matrix (8) in Kučera [1983].)

It might be argued that some recent concepts developed through a series of papers by Hammer and Heymann [1981], Vardoulakis and Karcianas [1984a], [1984b] of proper and proper stable minimal bases for rational vector spaces might provide a more compact setup compared to the minimal polynomial bases concept of Forney [1975]. However since the “system zeros” play a primary role in disturbance decoupling (see Özgüler and Eldem [1985]) we believe that using stable proper fractions and/or stable proper minimal basis will bring little improvement, if any, to the approach taken in this paper.

We would also like to mention the fact that the concept of internal stability employed here is slightly different, and in fact more general, than the corresponding concept in the papers by Imai and Akashi [1981], Willems and Commault [1981], Özgüler and Eldem [1985] and Ohm, Howze and Bhattacharyya [1984]. This point is discussed in more detail at the end of § 2.

The paper is structured as follows: In § 2 some results in Forney [1975] concerning minimal basis and solutions of the one-sided matrix equations $A = XB$ are stated in a suitable form for our purposes. The precise definitions of various disturbance decoupling problems also appear in § 2. Section 3 contains the solvability conditions, stated on the properties of a minimal basis of the relevant vector space, for the problem without internal stability constraint. A characterization for the set of all solutions of this problem is also included in § 3. In § 4 we identify “the fixed modes of disturbance decoupling under dynamic measurement feedback” through the employment of minimal basis and obtain solutions for the problem with internal stability and pole

placement. We then characterize the set of all solutions to the problem with internal stability in a similar manner to that of § 3. Section 4 is closed with the specialization of the results of the previous sections to the two-sided matrix equations $\Pi_4 = \Pi_3 X \Pi_2$, where Π_2 , Π_3 and Π_4 are arbitrary rational matrices and a solution X is sought over various subrings of $\underline{\mathbb{R}}(z)$. The last section is on conclusions.

2. Preliminaries and problem formulation. This section contains a summary of certain results concerning rational vector spaces, with special emphasis on the concept of minimal basis and proper solutions X to the rational matrix equation $A = XB$. Our exposition of the minimal (polynomial) basis and its relevance to model matching problems closely follows Forney [1975]. The disturbance decoupling problems that we consider are defined towards the end of this section, where we also emphasize the difference between the stable disturbance decoupling formulated here and in some earlier works. For various undefined concepts related to polynomial and rational matrices such as “right unimodular, proper, greatest left factor, etc.” the reader is referred to Özgüler and Eldem [1985].

As usual $\underline{\mathbb{R}}$, $\underline{\mathbb{R}}[z]$ and $\underline{\mathbb{R}}(z)$ denote the field of real numbers, the ring of polynomials in the indeterminate z with coefficients from $\underline{\mathbb{R}}$, and the field of real rational functions of z , respectively. A rational vector space \mathcal{V} of k -tuples of rational functions is an $\underline{\mathbb{R}}(z)$ -linear set which admits a rational basis consisting of v ($=\dim \mathcal{V}$) $\underline{\mathbb{R}}(z)$ -linearly independent elements. A $k \times v$ full column rank rational matrix, the columns of which span \mathcal{V} , will be called a rational basis of \mathcal{V} . Among the rational basis of \mathcal{V} there are polynomial ones which can, for instance, be obtained by multiplying a given rational basis by the least common denominator of all its entries. Such a basis is called a polynomial basis of \mathcal{V} . A *minimal basis* of \mathcal{V} is defined as a polynomial basis which is (i) *right unimodular* and (ii) *column proper*. Recall that a $k \times v$ polynomial matrix V is column proper iff its high column coefficient matrix V_h has full column rank, i.e., $\rho[V_h] = v$. The order $\mu(V)$ of V is defined as $\mu = \sum_{i=1}^v \mu_i$, where μ_i 's are the column degrees of V . A minimal base V of \mathcal{V} has the least order among all polynomial bases of \mathcal{V} (Forney [1975]). Furthermore, given two minimal bases V and \hat{V} of \mathcal{V} , they satisfy (i) $V = \hat{V}U$ for some unimodular matrix U , (ii) $\mu(V) = \mu(\hat{V})$ and (iii) they have the same column degrees up to a permutation of their columns. In other words, μ and μ_i 's are invariant under different representations of the vector space \mathcal{V} ; thus they are usually attributed to \mathcal{V} , i.e., μ is called the *order of \mathcal{V}* and μ_i 's are called the *dynamical indices of \mathcal{V}* (Forney [1975]).

The notion of minimal basis proved most useful in solving the following problem: Let Z_g and Z_d be $p \times l$ and $m \times l$ rational matrices respectively and determine a proper rational matrix Z_c such that $Z_d = Z_c Z_g$, i.e.,

$$(2.1) \quad [Z_c : -I] \begin{bmatrix} Z_g \\ Z_d \end{bmatrix} = 0.$$

Further, if a solution exists, then find one with the least McMillan degree. This problem, known as the *exact model matching problem*, was first solved by Wolovich [1974] and minimal McMillan degree solution was first obtained by Wang and Davison [1973]; later, the minimal basis approach of Forney provided a convenient framework for such problems. We therefore briefly review this approach below.

Let \mathcal{V} denote the rational vector space spanned by the columns of $[Z_g' : Z_d']'$ and V be a minimal basis for \mathcal{V} . The orthogonal complement in $\underline{\mathbb{R}}^{p+m}(z)$ of \mathcal{V} is given by

$$\mathcal{V}^\perp := \{x \text{ in } \underline{\mathbb{R}}^{p+m}(z) : x'y = 0 \text{ for all } y \text{ in } \mathcal{V}\}.$$

Let W be a minimal basis for \mathcal{V}^\perp , where $w := \dim \mathcal{V}^\perp = p + m - \dim \mathcal{V}$.

LEMMA 2.1 (Forney [1975]). (i) *There exists a proper rational Z_c satisfying (2.1) (equivalently $[Z_c: -I]V = 0$), iff the last m rows of W_h are linearly independent.*

(ii) *If a solution exists, then the set of all solutions of (2.1) is given by $\{Z_c := Q_c^{-1}R_c: [R_c: -Q_c]' = WT\}$, where T is a $w \times m$ right unimodular polynomial matrix such that WT is column proper and the last m rows of $(WT)_h$ are linearly independent.*

It is possible to state the solvability conditions for (2.1) more directly on the problem data. For this aim, we first establish the following simple results concerning column proper polynomial matrices.

LEMMA 2.2. *Let W and V be column proper polynomial matrices of sizes $k \times w$ and $k \times v$, respectively. Then,*

(i) *$V = WT$ for some polynomial matrix T implies that $V_h = W_h T_0$ for some constant matrix T_0 ,*

(ii) *$W'V = 0$ implies $W'_h V_h = 0$.*

Proof. Both statements follow by employing the representation $V = V_h \Lambda_v + L_v$ of a column proper polynomial matrix (see Kailath [1980, p. 384]), where Λ_v is a diagonal polynomial matrix with the same column degrees as V and L_v is a polynomial matrix such that $L_v \Lambda_v^{-1}$ is strictly proper. We omit the details of this easy proof. \square

By using Lemma 2.2 and the equation $[Z_c: -I]V = 0$, where V is a minimal basis for \mathcal{V} , the column span of $[Z'_g: Z'_d]'$, the solvability conditions for (2.1) can be alternatively expressed as follows.

LEMMA 2.3. *There exists a proper solution Z_c of $[Z_c: -I]V = 0$ iff the submatrix consisting of the first p rows of V_h has full column rank $v := \dim \mathcal{V}$.*

Proof. If $[Z_c: -I]V = 0$ admits a proper solution Z_c , then by Lemma 2.1 the last m rows of W_h are linearly independent. Furthermore, Lemma 2.2(ii) implies $W'_h V_h = 0$. Partitioning W_h and V_h compatibly, we have

$$W'_{h1} V'_{h1} = -W'_{h2} V_{h2},$$

where W'_{h2} has full column rank, i.e., there exist a constant matrix L such that $LW'_{h2} = I$. Thus $V_{h2} = -LW'_{h1} V_{h1}$ which implies that $V_h = [I: -W_{h1}L']V_{h1}$. Now since $\rho[V_h] = v$, it follows that $\rho[V_{h1}] = v$.

Conversely, let \bar{V}_{h1} be a $v \times (p - v)$ constant matrix such that $[V_{h1}: \bar{V}_{h1}]$ is nonsingular and consider $Z_c := [V_2: 0][V_1: \bar{V}_{h1}]^{-1}$, where $V := [V'_1: V'_2]'$. Clearly, $Z_c V_1 = V_2$, i.e., $[Z_c: -I]V = 0$. Properness of Z_c follows by the fact that $\partial_i[V_1: \bar{V}_{h1}] \geq \partial_i[V_2: 0]$, where $\partial_i[\cdot]$ denotes the i th column degree. \square

In this paper, we consider *the disturbance decoupling problem with measurement feedback* (DDPM), *the disturbance decoupling problem with measurement feedback and internal stability* (DDPMS) and *the disturbance decoupling problem with measurement feedback and pole placement* (DDPMP), all of which will be defined in a transfer matrix (input-output) setting.

Let Z_1 , Z_2 , Z_3 , and Z_4 be $p \times m$, $p \times s$, $q \times m$, and $q \times s$ rational matrices, respectively, with Z_1 strictly proper, and consider the following composite system:

$$(2.2) \quad \begin{bmatrix} y_m \\ y \end{bmatrix} = \begin{bmatrix} Z_1 & Z_2 \\ Z_3 & Z_4 \end{bmatrix} \begin{bmatrix} u \\ d \end{bmatrix},$$

where y_m denotes *the measured outputs*, y *the controlled outputs*, u *the control inputs*, and d *the disturbance inputs*.

DEFINITION 2.1. For the composite system given by (2.2) determine an $m \times p$ proper rational matrix Z_c such that under the control law

$$(2.3) \quad y = -Z_c y_m + u_e,$$

where u_e is a possible external input to the closed-loop system,

(DDPM) The closed-loop transfer matrix $Z_{dy} = Z_4 - Z_3 Z_c (I + Z_1 Z_c)^{-1} Z_2$ from d to y is identically zero.

(DDPMS) Given an admissible stability region Ω , which is a conjugate symmetric region of the complex plane with at least one point on the real axis, Z_{dy} is identically zero and the poles of all for rational matrices $\Delta := Z_c(I + Z_1 Z_c)^{-1}$, $Z_1 \Delta$, ΔZ_1 , and $Z_1 \Delta Z_1 - Z_1$ are in Ω . (Note that as Z_1 is strictly proper and Z_c is proper, $I + Z_1 Z_c$ is bicausal and hence $(I + Z_1 Z_c)^{-1}$ exists.)

(DDPMP) Find the solvability conditions for DDPMS for an arbitrarily given admissible stability region Ω .

Our definition of DDPMS differs from the earlier definitions in the requirement of internal stability. Note that in DDPMS all four transfer matrices Δ , $Z_1 \Delta$, ΔZ_1 and $Z_1 \Delta Z_1 - Z_1$ should have all their poles in Ω . This is well known to be equivalent in state space terminology to the condition that a *canonical realization of Z_c internally stabilizes a canonical realization of Z_1 under the control law (2.3)* (see Desoer and Chan [1975]). Let

$$\hat{Z} := \begin{bmatrix} Z_1 & Z_2 \\ Z_3 & Z_4 \end{bmatrix}$$

and consider a slightly different version DDPMS' of DDPMS as determining a proper Z_c such that, under (2.3), (i) DDPM is solved and (ii) a canonical realization of Z_c internally stabilizes a canonical realization of \hat{Z} . This is, in essence, the problem considered in Ohm, Howze and Bhattacharyya [1984] in a transfer matrix setting, in Imai and Akashi [1981] and Willems and Commault [1981] in a state space setting and in Özgüler and Eldem [1985] in a polynomial fractional setting. The problems DDPMS and DDPMS' are simply related as expressed by the following result: Let $Z = Z_s + Z_u$ be the partial fraction expansion of Z into rational matrices Z_s and Z_u , where Z_s has all its poles in Ω and Z_u has all its poles outside Ω . Also let $\nu^+[Z]$ denote the McMillan degree of Z_u .

PROPOSITION 2.1. *DDPMS' for (2.2) is solvable iff (i) $\nu^+[Z_1] = \nu^+[\hat{Z}]$ and (ii) DDPMS is solvable for (2.2). Further, if (i) holds, then any solution to DDPMS is also a solution to DDPMS', and conversely.*

Proof. The result follows easily by the definition of DDPMS and by Ohm, Howze and Bhattacharyya [1984, Thm. 3.1] where one lets $Z_1 = M$, $Z_2 = N$, $Z_3 = G$ and $Z_4 = H_d - H$. \square

Note that in cases where $\nu^+[Z_1] \neq \nu^+[\hat{Z}]$, DDPMS' has no solution whereas it may still be possible to solve DDPMS. In this sense, DDPMS is a more general problem definition and in cases where "the plant" is represented by the transfer matrix Z_1 between the control inputs and the measured outputs, a more realistic approach would be to solve DDPMS rather than DDPMS'.

We close this section by giving a first set of solvability conditions for DDPMS. The result follows directly by the characterization of internal stability of the pair (Z_1, Z_c) given by Desoer and Chan [1975].

PROPOSITION 2.2. *Let $Z_1 = Q^{-1}R$ be a left coprime polynomial fractional representation of Z_c . Then, DDPMS is solvable iff there exists a proper Z_c such that for some right coprime polynomial fractional representation $Z_c = P_c Q_c^{-1}$, both of the following conditions hold: (i) $\det(QQ_c + RP_c)$ has all its zeros in Ω and (ii) $Z_{dy} = Z_4 - Z_3 Z_c (I + Z_1 Z_c)^{-1} Z_2$ is identically zero.*

3. A characterization of solutions to DDPM. In this section, we present a new set of solvability conditions for DDPM, through which it is possible to characterize the set of all solutions to DDPM.

Let us define

$$A := \begin{bmatrix} I & Z_1 \\ 0 & Z_3 \end{bmatrix}, \quad B := \begin{bmatrix} Z_2 \\ Z_4 \end{bmatrix},$$

where Z_1, Z_2, Z_3, Z_4 are as given in (2.2). Also, for convenience let

$$\bar{m} := \dim(\text{Ker } A), \quad \bar{s} := \dim(\text{Im } B),$$

where $\text{Ker } A$ denotes the kernel of A considered as a map from $\underline{R}(z)^{p+m}$ to $\underline{R}(z)^{p+q}$ and $\text{Im } B$ denotes the image of B considered as a map from $\underline{R}(z)^s$ into $\underline{R}(z)^{p+q}$. Throughout this section, we will be mainly concerned with the rational vector space $[\underline{R}(z)\text{-linear set}] A^{-1}(\text{Im } B)$. Since $\text{Ker } A \subset A^{-1}(\text{Im } B)$, $A^{-1}(\text{Im } B)$ can be decomposed, in general nonuniquely, as

$$A^{-1}(\text{Im } B) = \mathcal{V} \oplus \text{Ker } A.$$

This decomposition implies the existence of a polynomial basis $W := [V : N]$ of $A^{-1}(\text{Im } B)$, where V is a polynomial basis of \mathcal{V} and N is a minimal basis for $\text{Ker } A$. Let $Z_1 := Q^{-1}R$ be a left coprime polynomial fractional representation of Z_1 with Q row proper. It follows by strict properness of Z_1 that $[Q : R]_h' = [Q_h : 0]'$ with Q_h nonsingular. The equality $[Q : R]N = 0$ now implies by Lemma 2.2(ii) that

$$N_h = [0 : N'_{h2}]',$$

for some $m \times \bar{m}$ full column rank constant matrix N_{h2} .

In order to determine a polynomial basis of the form $W = [V : N]$ for $A^{-1}(\text{Im } B)$, it is enough to consider a polynomial basis for $\text{Ker } S$, where

$$S := [A : -B] = \begin{bmatrix} I & Z_1 & -Z_2 \\ 0 & Z_3 & -Z_4 \end{bmatrix}.$$

In terms of the $\underline{R}(z)$ -linear sets \mathcal{A}_0 and \mathcal{B}_0 given by

$$\mathcal{A}_0 := \left\{ \begin{bmatrix} x \\ 0 \end{bmatrix} \text{ in } \underline{R}(z)^{p+m+s} : x \text{ is in } \text{Ker } A \right\},$$

$$\mathcal{B}_0 := \left\{ \begin{bmatrix} 0 \\ x \end{bmatrix} \text{ in } \underline{R}(z)^{p+m+s} : x \text{ is in } \text{Ker } B \right\},$$

$\text{Ker } S$ can be written (in general nonuniquely) as

$$\text{Ker } S = \mathcal{V}_0 \oplus \mathcal{A}_0 \oplus \mathcal{B}_0$$

for some $\underline{R}(z)$ -linear set \mathcal{V}_0 . Clearly, $\dim \mathcal{V}_0 = \dim(\text{Im } A \cap \text{Im } B)$. Consequently, there exists a polynomial basis W_0 of $\text{Ker } S$ in the form,

$$(3.1) \quad W_0 = \begin{bmatrix} V & N & 0 \\ M_0 & 0 & M \end{bmatrix},$$

where N is a minimal basis for $\text{Ker } A$, M is a minimal basis for $\text{Ker } B$ and $[V' : M'_0]'$ is a minimal basis for \mathcal{V}_0 . We will now show that $W := [V : N]$ is a polynomial basis of $A^{-1}(\text{Im } B)$. First note that W has full column rank; otherwise, there would exist a nonzero rational vector $\alpha = [\alpha'_1 : \alpha'_2]'$ satisfying $V\alpha_1 = -N\alpha_2$. Since N has full column rank, α_1 is nonzero. Now note that $AV\alpha_1 = -AN\alpha_2 = BM_0\alpha_1 = 0$, which implies that

$M_0\alpha_1$ is in $\text{Ker } B$ while $V\alpha_1$ is in $\text{Ker } A$. Consequently, $[V':M'_0]'\alpha_1$ is in $\mathcal{A}_0 \oplus \mathcal{B}_0$, which is a contradiction. On the other hand since $AV = BM_0$ and $AN = 0$, the column span of W is in $A^{-1}(\text{Im } B)$. By the fact that $\dim \mathcal{V}_0 = \dim (\text{Im } A \cap \text{Im } B)$, it now follows that the column span of W is precisely $A^{-1}(\text{Im } B)$. This proves the underlined statement above.

Remark 3.1. The argument above is based on the assumption that there exists a polynomial basis W_0 of $\text{Ker } S$ of the form given by (3.1). In order to calculate such a basis for $\text{Ker } S$, one might start with a minimal basis $\tilde{W}_0 := [\tilde{W}':\tilde{M}']'$ of $\text{Ker } S$, where \tilde{W} and \tilde{M} have $p+m$ and s rows, respectively; and follow the steps given below:

- (1) Find a unimodular matrix U_1 such that

$$\tilde{W}U_1 = [W:0], \quad \tilde{M}U_1 = [\tilde{M}_0:M]$$

where W and M are of full column rank and M is column proper.

- (2) Find a unimodular matrix U_2 such that

$$\tilde{M}_0U_2 = [M_0:0], \quad WU_2 = [V:N],$$

where M_0 and N are of full column rank and N is column proper. Clearly, M and N are minimal bases for $\text{Ker } B$ and $\text{Ker } A$, respectively. Thus,

$$\begin{bmatrix} V & N & 0 \\ M_0 & 0 & M \end{bmatrix}$$

is the desired basis for $\text{Ker } S$.

Given a polynomial basis $W = [V:N]$ of $A^{-1}(\text{Im } B)$, a minimal basis \bar{W} of $A^{-1}(\text{Im } B)$ can be obtained by extracting a greatest right factor T of W so that

$$\bar{W} := WT^{-1}$$

is column proper (and right unimodular).

Our first main result below yields a solvability condition for DDPM in terms of a minimal basis for the rational vector space $A^{-1}(\text{Im } B)$.

THEOREM 3.1. *DDPM for the composite system model (2.2) is solvable if and only if (i) $\rho[Z_2] = \bar{s}$ and (ii) the submatrix consisting of the first p rows of \bar{W}_h has rank \bar{s} , where \bar{W} is a minimal basis for $A^{-1}(\text{Im } B)$.*

Proof. Necessity: Let Z_c be a solution to DDPM so that by Definition 2.1, $Z_4 = Z_3\Delta Z_2$ with $\Delta := Z_c(I + Z_1Z_c)^{-1}$. It follows at once that

$$(3.2) \quad \text{Im } Z_4 \subset \text{Im } Z_3, \quad \text{Ker } Z_2 \subset \text{Ker } Z_4,$$

and also that

$$\begin{bmatrix} I & Z_1 \\ 0 & Z_3 \end{bmatrix} \begin{bmatrix} I \\ Z_c \end{bmatrix} (I + Z_1Z_c)^{-1} Z_2 = \begin{bmatrix} Z_2 \\ Z_4 \end{bmatrix}.$$

The first inclusion in (3.2) is equivalent to $\text{Im } B \subset \text{Im } A$ and the second, to $\rho[Z_2] = \rho[B] = \bar{s}$. Now let U be an $s \times s$ unimodular polynomial matrix such that

$$Z_2U = [\tilde{Z}_2:0],$$

where \tilde{Z}_2 has full column rank \bar{s} . In view of $\text{Ker } Z_2 \subset \text{Ker } Z_4$, we have $Z_4U = [\tilde{Z}_4:0]$ for some $q \times \bar{s}$ rational matrix \tilde{Z}_4 . Let $V = [V'_1:V'_2]'$ be a minimal basis for the column span over $\mathbb{R}(z)$ of $[I:Z'_c]'(I + Z_1Z_c)^{-1}\tilde{Z}_2$; note as the latter matrix is of full column rank that \tilde{V} is $(p+m) \times \bar{s}$ and it satisfies

$$(3.3) \quad \begin{bmatrix} V_1 \\ V_2 \end{bmatrix} Y = \begin{bmatrix} I \\ Z_c \end{bmatrix} (I + Z_1Z_c)^{-1} \tilde{Z}_2.$$

For a nonsingular $\bar{s} \times \bar{s}$ rational matrix Y ; equation (3.3) now yields

$$(3.4) \quad \begin{bmatrix} I & Z_1 \\ 0 & Z_3 \end{bmatrix} \begin{bmatrix} V_1 & N_1 \\ V_2 & N_2 \end{bmatrix} = \begin{bmatrix} Z_2 \\ Z_4 \end{bmatrix} U \begin{bmatrix} Y^{-1} & 0 \\ 0 & I \end{bmatrix},$$

where $N := [N'_1 : N'_2]'$ is a minimal basis for $\text{Ker } A$. This equality, in turn, implies that the column span of $W := [V : N]$ is in $A^{-1}(\text{Im } B)$. Also note that, by (3.3), $[Z_c : -I]V = 0$, where Z_c is proper. By Lemma 2.3, it follows that the submatrix consisting of the first p rows of V_h has full column rank \bar{s} . By the property of a minimal basis N of $\text{Ker } A$, we now have

$$W_h = \begin{bmatrix} V_{1h} & 0 \\ V_{2h} & N_{2h} \end{bmatrix},$$

where V_{1h} and N_{2h} are of full column rank. This implies that W_h is of full column rank and, in particular, $\rho[W] = \bar{s} + \bar{m}$, i.e., W is also of full column rank. Since $\dim[A^{-1}(\text{Im } B)] = \dim(\text{Im } B \cap \text{Im } A) + \dim(\text{Ker } A) = \bar{s} + \bar{m}$, it now follows that W is a polynomial basis of $A^{-1}(\text{Im } B)$. If \bar{W} is any minimal basis for $A^{-1}(\text{Im } B)$, it is related to W by $W = \bar{W}T$, where T is a nonsingular polynomial matrix. By Lemma 2.2(i), and by column properness of both W and \bar{W} , it now follows that $W_h = \bar{W}_h T_0$ for some constant nonsingular matrix T_0 . Consequently, the submatrix consisting of the first p rows of \bar{W}_h is of rank equal to $\rho[V_{h1} : 0] = \bar{s}$.

Sufficiency: Let \bar{W} be a minimal basis for $A^{-1}(\text{Im } B)$ so that, by hypothesis, the submatrix consisting of the first p rows of \bar{W}_h is of rank \bar{s} . Let T_0 be a $(\bar{s} + \bar{m}) \times \bar{s}$ constant matrix which picks up those \bar{s} linearly independent columns of \bar{W}_h , i.e., T_0 is such that $V := \bar{W}T_0$ has the property that the submatrix consisting of the first p rows of V_h has rank \bar{s} . Let $W := [V : N] = [\bar{W}T_0 : N]$, where N is a minimal basis for $\text{Ker } A$. Clearly, W is a polynomial basis of $A^{-1}(\text{Im } B)$ and

$$W_h = \begin{bmatrix} V_{h1} & 0 \\ V_{h2} & N_{h2} \end{bmatrix},$$

where V_{h1} is the submatrix consisting of the first p rows of V_h , and V_{h2}, N_{h2} are the submatrices consisting of the last m rows of V_h, N_h , respectively. It follows that W is column proper, is of full column rank, and that $\text{Im } V \cap \text{Ker } A = \{0\}$. By Lemma 2.3, there exists a proper $m \times p$ Z_c such that $[Z_c : -I]V = 0$ or equivalently, $Z_c V_1 = V_2$, where $V = [V'_1 : V'_2]'$. By the fact that W is a polynomial basis for $A^{-1}(\text{Im } B)$, we have $\text{Im } V \subset A^{-1}(\text{Im } B)$ and hence there exists a $s \times \bar{s}$ rational matrix Y satisfying

$$\begin{bmatrix} I & Z_1 \\ 0 & Z_3 \end{bmatrix} \begin{bmatrix} I \\ Z_c \end{bmatrix} V_1 = \begin{bmatrix} Z_2 \\ Z_4 \end{bmatrix} Y.$$

The matrix BY is of full column rank; since, if $BY\alpha = 0$ for some nonzero rational vector α , then $AV\alpha = 0$ which contradicts, as V is of full column rank, the fact that $\text{Im } V \cap \text{Ker } A = \{0\}$. Therefore, $\text{Im } Y \cap \text{Ker } B = \{0\}$ and further if \tilde{Y} is a basis for $\text{Ker } B$, the rational matrix $[Y : \tilde{Y}]$ is nonsingular and satisfies

$$\begin{bmatrix} I & Z_1 \\ 0 & Z_3 \end{bmatrix} \begin{bmatrix} I \\ Z_c \end{bmatrix} [V_1 : 0] = \begin{bmatrix} Z_2 \\ Z_4 \end{bmatrix} [Y : \tilde{Y}].$$

This equality implies, as $I + Z_1 Z_c$ is bicausal, that

$$Z_3 Z_c (I + Z_1 Z_c)^{-1} Z_2 [Y : \tilde{Y}] = Z_4 [Y : \tilde{Y}].$$

The nonsingularity of $[Y : \tilde{Y}]$ further implies that Z_c is actually a solution to DDPM. \square

The solvability condition of Theorem 3.1 is in terms of an arbitrary minimal basis for $A^{-1}(\text{Im } B)$. To obtain a useful characterization of the set of all solutions to DDPM, we fix a particular minimal basis W^* of $A^{-1}(\text{Im } B)$, the high coefficient matrix of which is in a special form:

$$W_h^* = \begin{bmatrix} V_{h1}^* & 0 \\ V_{h2}^* & N_{h2}^* \end{bmatrix},$$

where V_{h1}^* , V_{h2}^* , and N_{h2}^* are $p \times \bar{s}$, $m \times \bar{s}$, and $m \times \bar{m}$ constant matrices with V_{h1}^* and N_{h2}^* of full column rank. Note that an arbitrary minimal basis \bar{W} can be brought to the desired form W^* by multiplication on the right with a unimodular matrix. In subsequent discussions on the characterization of all solutions to DDPM, we assume that DDPM is solvable and hence the solvability conditions Theorem 3.1(i) and 3.1(ii) hold and W^* as above exists.

Let $W^* = [V^*; N^*]$, where V^* is the submatrix consisting of the first \bar{s} columns of W^* and N^* is the submatrix representing the last \bar{m} columns of W^* . (Caution: N^* may no longer be a minimal basis for $\text{Ker } A$!). Let us further consider the representations

$$(3.5) \quad V^* = V_h^* \Lambda_1 + Y_1, \quad N^* = N_h^* \Lambda_2 + Y_2$$

of the column proper polynomial matrices V^* , N^* , respectively, where Λ_1, Λ_2 are diagonal polynomial matrices with entries z^{μ_i}, z^{ν_i} , where μ_i and ν_i denote the column degrees of V^* and N^* , respectively. The polynomial matrices Y_1 and Y_2 have the property that $Y_1 \Lambda_1^{-1}$ and $Y_2 \Lambda_2^{-1}$ are strictly proper rational matrixes, respectively. (For the existence and uniqueness of the representations (3.5), see Kailath [1980]). Consider the set

$$\mathcal{L}(W^*) := \{L \text{ in } \underline{R}(z)^{\bar{m} \times \bar{s}} : \Lambda_2 L \Lambda_1^{-1} \text{ is proper}\},$$

which can equivalently be described as the set of all $\bar{m} \times \bar{s}$ rational matrices whose ij th entry l_{ij} satisfies the degree constraint

$$\partial(l_{ij}) \leq \partial_j(V^*) - \partial_i(N^*); \quad i = 1, \dots, \bar{m}, \quad j = 1, \dots, \bar{s}.$$

COROLLARY 3.1. *A proper rational $m \times p$ matrix Z_c is a solution to DDPM if and only if there exists L in $\mathcal{L}(W^*)$ such that*

$$(3.6) \quad [Z_c : -I](V^* + N^* L) = 0.$$

Proof. Necessity: It is clear by the necessity part of the proof of Theorem 3.1 that any solution Z_c to DDPM satisfies (3.3) and (3.4) for some nonsingular $\bar{s} \times \bar{s}$ rational matrix Y , where $V = [V_1' : V_2']'$ is a minimal basis for the column span of $[I : Z_c'](I + Z_1 Z_c)^{-1} \tilde{Z}_2$. Since $\text{Im } V \subset A^{-1}(\text{Im } B)$ by (3.4), it follows that there exist polynomial matrices L_1 and L_2 satisfying

$$(3.7) \quad V = V^* L_1 + N^* L_2 = W^* T,$$

where $T := [L_1' : L_2']'$. Let V and W^* be written similar to the representations (3.5) as

$$V = V_h \Lambda + Y, \quad W^* = W_h^* \Lambda^* + Y^*,$$

where Λ is a diagonal matrix whose nonzero entries are z^{λ_i} with λ_i denoting the degree of the i th column of V , and Y is such that $Y \Lambda^{-1}$ is strictly proper. Note that Λ^* , Y^* , Λ_i , Y_i are related by

$$\Lambda^* = \begin{bmatrix} \Lambda_1 & 0 \\ 0 & \Lambda_2 \end{bmatrix}, \quad Y^* = [Y_1 : Y_2].$$

By (3.7), we now have

$$V_h + Y\Lambda^{-1} = (W_h^* + Y^*\Lambda^{*-1})\Lambda^*T\Lambda^{-1}$$

where W_h^* is of full column rank. By strict properness of $Y\Lambda^{-1}$ and $Y^*\Lambda^{*-1}$, it easily follows from the above equality that $\Lambda^*T\Lambda^{-1}$ is proper and that

$$V_h = W_h^*(\Lambda^*T\Lambda^{-1})_0$$

where $(\cdot)_0$ denotes the constant term of the argument in its formal Laurent series expansion in z^{-1} . Letting $[V'_{h1} : V'_{h2}]' = V_h$ be a compatible partitioning of V_h , we have

$$\begin{bmatrix} V_{h1} \\ V_{h2} \end{bmatrix} = \begin{bmatrix} V_{h1}^* & 0 \\ V_{h2}^* & N_{h2}^* \end{bmatrix} \begin{bmatrix} (\Lambda_1 L_1 \Lambda^{-1})_0 \\ (\Lambda_2 L_2 \Lambda^{-1})_0 \end{bmatrix},$$

where, by Lemma 2.3, V_{h1} has full column rank. We now have $V_{h1} = V_{h1}^*(\Lambda_1 L_1 \Lambda^{-1})_0$, where V_{h1} , V_{h1}^* are both of full column rank. It follows that $(\Lambda_1 L_1 \Lambda^{-1})_0$ is nonsingular and hence $\Lambda_1 L_1 \Lambda^{-1}$ is bicausal. Therefore, if we let $L := L_2 L_1^{-1}$, the rational matrix

$$\Lambda_2 L \Lambda_1^{-1} = \Lambda_2 L_2 \Lambda^{-1} (\Lambda_1 L_1 \Lambda^{-1})^{-1}$$

is proper, proving the fact that L is in $\mathcal{L}(W^*)$.

Sufficiency: Let Z_c be a proper $m \times p$ matrix such that (3.6) holds. Let $L = L_2 L_1^{-1}$ be a right coprime polynomial fractional representation of L such that $V := V^* L_1 + N^* L_2$ is column proper. Let $V_h = [V'_{h1} : V'_{h2}]'$ where V_{h1} , V_{h2} are of sizes $p \times \bar{s}$, $m \times \bar{s}$, respectively. Note, by $[Z_c : -I]V = 0$ and properness of Z_c , that V_{h1} is of full column rank and $Z_c V_1 = V_2$, where $V = [V'_1 : V'_2]'$. Since $V = W^* T$, where $T := [L'_1 : L'_2]'$, $\text{Im } V \subset A^{-1}(\text{Im } B)$. The fact that $\rho[V_{h1}] = \bar{s}$ implies by Lemma 2.2(ii) that $\text{Im } V \cap \text{Ker } A = \{0\}$. Thus, there exists a rational $s \times \bar{s}$ matrix Y such that $A[I : Z'_c]' V_1 = BY$, where $\rho[BY] = \rho[B] = \bar{s}$. The rest of the proof now follows the steps of the sufficiency proof of Theorem 3.1. \square

The above result shows in effect that to obtain the set of all solutions to DDPM, it is enough to consider the set of all proper solutions Z_c of (3.6) as L runs over the elements of $\mathcal{L}(W^*)$. For a fixed L in $\mathcal{L}(W^*)$, it is clear by the definition of the set $\mathcal{L}(W^*)$ that (3.6) has at least one proper solution. (To see this, let $V := V^* L_1 + N^* L_2$, where $L_2 L_1^{-1}$ is a right coprime polynomial fractional representation of L , such that V_h has full column rank \bar{s} . In view of the fact that $\Lambda_2 L \Lambda_1^{-1}$ is proper, it follows that the submatrix consisting of the first p rows of V_h also has rank \bar{s} . Now, by Lemma 2.3, it holds that (3.6) has at least one proper solution Z_c .) In order to generate all proper solutions Z_c to (3.6) for a fixed L in $\mathcal{L}(W^*)$, characterization of Lemma 2.1(ii) can now be used. We remark here that the characterization Lemma 2.1(ii) can actually be made more explicit by fixing a special minimal basis for $(\text{Im } V)^\perp$, obtaining a similar characterization to that provided by $\mathcal{L}(W^*)$. We omit the details of this complementary part of the characterization. *The important point here is that Corollary 3.1 reduces the characterization of all solutions to DDPM to the characterization of all proper solutions of a one-sided equation (3.6).*

Remark 3.2. It is interesting to note that two distinct elements L and \tilde{L} ($L \neq \tilde{L}$) of $\mathcal{L}(W^*)$ generate two disjoint classes of solutions to DDPM. To see this suppose that Z_c is a proper solution to (3.6) for both L and \tilde{L} . Then $[Z_c : -I](V^* + N^* L) = 0$ and $[Z_c : -I](V^* + N^* \tilde{L}) = 0$, which yield $[Z_c : -I]N^*(L - \tilde{L}) = 0$. By properness of Z_c and by the fact that $N_h^* = [0 : N_{h2}^{*'}]'$, it is easy to see that $[Z_c : -I]N^*$ has full column rank \bar{m} . This implies that $L = \tilde{L}$, proving our claim. Therefore, *our characterization for $\mathcal{L}(W^*)$ has no redundancy.*

Remark 3.3. The characterization provided by Corollary 3.1 not only yields the set of all solutions to DDPM; (i) when we set $Z_1 = 0$, it yields the set of all proper solutions to the two-sided matrix equation $Z_4 = Z_3 X Z_2$; (ii) when we set $Z_1 = 0$, $Z_4 = 0$, it yields the set of all solutions to $Z_3 X Z_2 = 0$; (iii) when we set $Z_1 = 0$, $Z_2 = I$ ($Z_3 = I$), it yields the set of all solutions to the one-sided matrix equations $Z_4 = Z_3 X$ ($Z_4 = X Z_2$).

Remark 3.4. In consistency with the two-sided nature of DDPM, the nonuniqueness of solution stems from two sources; first, from nontriviality of $\text{Ker } A$, or equivalently, of $\text{Ker } Z_3$ and second from nontriviality of $(\text{Im } B)^\perp$, or equivalently, of $(\text{Im } Z_2)^\perp$. Our approach to the characterization of all solutions to DDPM handles these two sources of nonuniqueness in two consecutive stages. Thus, $\mathcal{L}(W^*)$ is nonempty iff $\text{Ker } A \neq \{0\}$ and each fixed L in $\mathcal{L}(W^*)$ yields a unique corresponding solution Z_c iff $(\text{Im } Z_2)^\perp = \{0\}$. Since there is a bijective correspondence between the set of all proper solutions X to

$$(3.8) \quad Z_4 = Z_3 X Z_2,$$

and the set of all solutions $Z_c = Z_1(I - XZ_1)^{-1}$ to DDPM, the above observations are also apparent from (3.8). This suggests a slightly different alternative to our method of characterization of all solutions to DDPM:

- (i) Determine the set of all proper solutions X to (3.8);
- (ii) Compute for each X , $Z_c = Z_1(I + XZ_1)^{-1}$. Step (i) of this alternative method can be performed by setting $Z_1 = 0$ in our procedure above (see Remark 3.3). Although with this alternative method some amount of simplification may result in performing step (i), altogether, both methods seem to require the same amount of computation.

4. Fixed modes of DDPM. The subject of this section is the determination of the “fixed modes” of disturbance decoupling problem under dynamic measurement feedback, from which the solutions of both DDPMs and DDMP immediately follow. Throughout this section we assume that DDPM is solvable and $Q^{-1}R = Z_1$ is a fixed left coprime polynomial fractional representation of Z_1 with Q row proper. Also recall from § 2 that $\Phi := QQ_c + RP_c$ represents the internal modes of the closed loop system, where $P_c Q_c^{-1}$ is any right coprime fractional representation of a solution Z_c to DDPM. The *fixed modes* of DDPM can now be defined as

$$(4.1) \quad \sigma := \bigcap_{Z_c} \text{zeros of } \det(QQ_c + RP_c),$$

where the intersection ranges over all solutions $Z_c = P_c Q_c^{-1}$ of DDPM in right coprime representation. Note that σ is independent of the particular representation chosen for Z_c . Let us also define

$$(4.2) \quad \sigma_0 := \text{invariant zeros of } [Q : R] \bar{W},$$

where \bar{W} is a minimal basis for $A^{-1}(\text{Im } B)$. Also note that σ_0 is independent of the particular minimal basis chosen for $A^{-1}(\text{Im } B)$, since minimal bases are related via post multiplication by unimodular matrices. Thus, σ_0 is also equal to the set of invariant zeros of $[Q : R] W^*$, where $W^* = [V^* : N^*]$ is a special minimal basis for $A^{-1}(\text{Im } B)$ of the type given in § 3, i.e., one such that

$$(4.3) \quad W_h^* = \begin{bmatrix} V_{h1}^* & 0 \\ V_{h2}^* & N_{h2}^* \end{bmatrix}.$$

The following technical lemmas will be used in establishing the main results of this section.

LEMMA 4.1. (i) *There exists a unimodular matrix U such that*

$$(4.4) \quad U[Q:R]W^* = \begin{bmatrix} C_1 & C_2 \\ 0 & 0 \end{bmatrix},$$

where C_1 and C_2 are $\bar{s} \times \bar{s}$ and $\bar{s} \times \bar{m}$ polynomial matrices with C_1 nonsingular.

(ii) *Given L in $\mathcal{L}(W^*)$, let $L = L_2 L_1^{-1}$ be its some right coprime fractional representation. For every solution $Z_c = P_c Q_c^{-1}$ of (3.6), there exist a unimodular matrix U and a right unimodular matrix \tilde{U} such that*

$$(4.5) \quad U[Q:R](V^* L_1 + N^* L_2) = U(QQ_c + RP_c)\tilde{U}.$$

Proof. (i) There clearly exists a U such that (4.4) holds and $[C_1: C_2]$ is of full row rank. Since $[Q:R]_h' = [Q_h: 0]'$ for some nonsingular constant Q_h and $\rho[V_{h1}^*] = \bar{s}$ in expression (4.3), it easily follows that

$$(4.6) \quad \rho[[Q:R]V^*] = \rho[V^*] = \bar{s}.$$

Using the fact that $\rho[W^*] = \dim[A^{-1}(\text{Im } B)]$ we can also show by simple linear algebraic arguments that

$$\rho[[Q:R]W^*] = \dim[A^{-1}(\text{Im } B)] - \dim\{A^{-1}(\text{Im } B) \cap \text{Ker}[Q:R]\}.$$

Note that $\text{Ker}[Q:R] = \text{Ker}[I:Z_1]$ contains $\text{Ker } A$. By (4.6) and by the modular distributive rule, it follows that $A^{-1}(\text{Im } B) \cap \text{Ker}[Q:R] = \text{Ker } A$. Hence,

$$\rho[[Q:R]W^*] = \dim[A^{-1}(\text{Im } B)] - \dim(\text{Ker } A) = \bar{s}.$$

This implies that $\rho[C_1: C_2] = \bar{s}$ and by (4.6) nonsingularity of C_1 follows.

(ii) Let $V := V^* L_1 + N^* L_2$. As $\text{Ker}[Z_c: -I]$ is spanned by $[Q'_c: P'_c]'$, by (3.6) we have $V = [Q'_c: P'_c]'\tilde{U}$, for some right unimodular \tilde{U} . Substituting for V in the left-hand side of (4.5) we obtain the right-hand side. \square

LEMMA 4.2. *Given an admissible stability region Ω , there exists an L in $\mathcal{L}(W^*)$ such that the set of invariant zeros of $[Q:R](V^* L_1 + N^* L_2)$ is the union of σ_0 and a subset of Ω , where $L_2 L_1^{-1}$ is a right coprime polynomial fractional representation of L .*

Proof. Let C_0 be a greatest common left factor of C_1 and C_2 so that $C_1 = C_0 G_1$, $C_2 = C_0 G_2$ for some left coprime polynomial matrices G_1 and G_2 , where C_1, C_2 are obtained through Lemma 4.1(i). Clearly, the set of zeros of $\det C_0$ is precisely σ_0 . By Khargonekar and Özgüler [1984, Lemma 2.9], there exist polynomial matrices L_1, L_2 , and G with L_1 and G nonsingular such that the set of zeros of $\det G$ are in Ω , the causality degree of $L_2 L_1^{-1}$, $\partial(L_2 L_1^{-1})$, satisfies $\partial(L_2 L_1^{-1}) < -k$ for a given nonnegative integer k , and

$$(4.7) \quad G_1 L_1 + G_2 L_2 = G.$$

If k is chosen to satisfy $k \geq \max\{\partial_i(N^*)\}$, then it is easy to see that $L := L_2 L_1^{-1}$ is in $\mathcal{L}(W^*)$. By (4.7) and by Lemma 4.1(i), it now follows that

$$U[Q:R](V^* L_1 + N^* L_2) = \begin{bmatrix} C_0 G \\ 0 \end{bmatrix}.$$

Since the set of zeros of $\det G$ are in Ω , our claim follows. \square

THEOREM 4.1. *The set of fixed modes of DDPM is equal to the set of invariant zeros of $[Q:R]\tilde{W}$, i.e., $\sigma = \sigma_0$.*

Proof. Let $Z_c = P_c Q_c^{-1}$ be a solution to DDPM. By Corollary 3.1, there exists an $L = L_2 L_1^{-1}$ in $\mathcal{L}(W^*)$ satisfying (3.6). By Lemma 4.1(ii), there exists a unimodular U and a right unimodular \tilde{U} such that (4.5) holds. Let $\tilde{G} := C_1 L_1 + C_2 L_2$, where C_1 and

C_2 are defined via Lemma 4.1(i). Note that $\tilde{G} = C_0 G$ with C_0 denoting a greatest common left factor of C_1 and C_2 and with $G := C_0^{-1} \tilde{G}$ a polynomial matrix. We now have $U\Phi\tilde{U} = [\tilde{G}': 0]'$ which implies by right unimodularity of \tilde{U} that $\det \tilde{G}$, and hence, that $\det C_0$ divides $\det \Phi$. This establishes the inclusion $\sigma_0 \subset \sigma$. We will establish the reverse inclusion by showing that the zeros of $\det \Phi$ can be assigned arbitrarily except those which coincide with the zeros of $\det C_0$ by an appropriate choice of Z_c .

Given stability region Ω , by Lemmas 4.1(i) and 4.2, there exist $L = L_2 L_1^{-1}$ in $\mathcal{L}(W^*)$ and a unimodular U such that

$$(4.8) \quad U[Q:R](V^*L_1 + N^*L_2) = \begin{bmatrix} C_0 & G \\ 0 & \end{bmatrix},$$

where the set of zeros of $\det C_0$ is σ_0 and the set of zeros of $\det G$ is in Ω . Let $V := V^*L_1 + N^*L_2$ and partition V and V_h compatibly with $[Q:R]$ as $V := [V_1': V_2']'$ and $V_h := [V_{h1}': V_{h2}']'$. Since $\rho[V_{h1}] = \bar{s}$, there exists a $p \times p$ constant nonsingular J such that

$$J^{-1}V_{h1} = [I:0]'$$

Also let

$$(4.9) \quad UQJ := \begin{bmatrix} Q_1 & Q_2 \\ Q_3 & Q_4 \end{bmatrix}, \quad UR := \begin{bmatrix} R_1 \\ R_2 \end{bmatrix},$$

where Q_1 is $\bar{s} \times \bar{s}$ and R_1 is $\bar{s} \times m$. We assume here without loss of generality that $[Q_3:Q_4:R_2]$ is row proper. (This can always be achieved by further premultiplying UQJ and UR by a unimodular matrix without altering Q_1 , Q_2 and R_1 .) As Z_1 is strictly proper and $[Q_3:Q_4:R_2][(J^{-1}V_1)': V_2']' = 0$, Lemma 2.2(ii) implies that $[Q_3:Q_4:R_2]'_h = [0:\tilde{T}':0]'$ for some nonsingular \tilde{T} . Consequently Q_4 is nonsingular and hence by Khargonekar and Özgüler [1984, Lemma 2.9], there exist polynomial matrices P_3 , P_4 , P_2 , and P_0 with P_4 and P_0 nonsingular, the zeros of $\det P_0$ in Ω , $[P_2':P_3']'P_4^{-1}$ strictly proper, and $[P_2':P_3':P_4']'$ column proper such that

$$(4.10) \quad Q_3P_3 + Q_4P_4 + R_2P_2 = P_0.$$

Let $P := [P_3:P_4]$ and note that $[P_2':P_3':P_4']'_h = [0:0:T']'$ for some nonsingular T . Now consider

$$Q_c := [V_1:JP], \quad P_c := [V_2:P_2].$$

By writing the highest column coefficient matrix of $[(J^{-1}Q_c)':P_c']'$ explicitly in terms of V_h and T , we can easily show that Q_c is nonsingular and $P_cQ_c^{-1}J$, and hence $Z_c := P_cQ_c^{-1}$ are proper. Further, as $Z_cV_1 = V_2$, it follows by Corollary 3.1 that Z_c is a solution of DDPM. Finally, by (4.8)–(4.10) we have

$$U(QQ_c + RP_c) = \begin{bmatrix} C_0G & P_1 \\ 0 & P_0 \end{bmatrix},$$

where $P_1 := [Q_1:Q_3]JP + R_1P_2$. It follows that

$$\det \Phi = \det C_0 \det G \det P_0.$$

As the zeros of both $\det G$ and $\det P_0$ are in Ω , Z_c places all the zeros of $\det \Phi$ into Ω , except those which coincide with the zeros of $\det C_0$, i.e., σ_0 . Note that this can also be achieved for two given nonintersecting stability regions; consequently $\sigma \subset \sigma_0$ and the result follows. \square

COROLLARY 4.1. (i) DDPMS with respect to a given stability region Ω is solvable iff $\sigma_0 \subset \Omega$; (ii) DDPMP is solvable iff σ_0 is empty.

Proof. The proof immediately follows from Theorem 4.1 and the definition of σ_0 . \square

A characterization of all solutions of DDPMS is now in order. A solution Z_c of DDPMS can be constructed in two stages. First, one determines an L in $\mathcal{L}(W^*)$ such that the invariant zeros of $[Q:R]V$ are stable, where $V := V^*L_1 + N^*L_2$ and $L_2L_1^{-1}$ is a right coprime polynomial fractional representation of L . In the sequel, the class of such L will be denoted as $\mathcal{L}_\Omega(W^*)$. More specifically,

$$(4.11) \quad \mathcal{L}_\Omega(W^*) := \{L := L_2L_1^{-1} \text{ in } \mathcal{L}(W^*): \text{the invariant zeros of } [Q:R] \\ (V^*L_1 + N^*L_2) \text{ are in } \Omega.\}$$

Second, one constructs all possible solutions Z_c of DDPMS, which satisfy $[Z_c: -I] \cdot (V^* + N^*L) = 0$, by the synthesis procedure given in the sufficiency proof of Theorem 4.1. Now let \bar{L} be a particular element of $\mathcal{L}_\Omega(W^*)$ and $\bar{L} := S_2S_1^{-1}$ be a Ω -stable rational fractional representation of \bar{L} such that

$$(4.12) \quad G_1S_1 + G_2S_2 = I$$

Here, $C_0G_1 = C_1$ and $C_0G_2 = C_2$, where C_1 and C_2 are polynomial matrices as defined in Lemma 4.1(i). In view of Lemma 4.2 and (4.7) such S_1 and S_2 clearly exist. Also let K_1 and K_2 be $\bar{s} \times \bar{m}$ and $\bar{m} \times \bar{m}$ polynomial matrices such that

$$(4.13) \quad V^*K_1 + N^*K_2 = N,$$

where N is a minimal basis for $\text{Ker } A$. As $\text{Ker } A \subset A^{-1}(\text{Im } B)$ such K_1 and K_2 obviously exist. Furthermore, since $\text{Ker } [Q:R] \cap A^{-1}(\text{Im } B) = \text{Ker } A$ (immediate consequence of Lemma 4.1(i)), it follows that $[K'_1: K'_2]'$ also span $\text{Ker } [G_1: G_2]$. Substituting the representations of V^* and N^* as in (3.5) and a similar representation of N into the equation above, we obtain

$$(V_h^* + Y_1\Lambda_1^{-1})\Lambda_1K_1 + (N_h^* + Y_2\Lambda_2^{-1})\Lambda_2K_2 = (N_h + Y_3\Lambda_3^{-1})\Lambda_3,$$

where $N = N_h\Lambda_3 + Y_3$ with Λ_3 diagonal and $Y_3\Lambda_3^{-1}$ strictly proper. Since $\text{Im } N_h^* = \text{Im } N_h$, it is straightforward to show that K_2 is nonsingular, $\Lambda_1K_1K_2^{-1}\Lambda_2^{-1}$ is strictly proper and $\Lambda_2K_2\Lambda_3^{-1}$ is bicausal. (See the necessity proof for Corollary 3.1. We can now give an explicit characterization of $\mathcal{L}_\Omega(W^*)$ in terms of the particular element \bar{L} of $\mathcal{L}_\Omega(W^*)$ satisfying (4.12).

LEMMA 4.3. An $\bar{m} \times \bar{s}$ rational matrix L is an element of $\mathcal{L}_\Omega(W^*)$ iff there exists a Ω -stable rational matrix M such that $\Lambda_3MS_1^{-1}\Lambda_1^{-1}$ is proper and

$$(4.14) \quad L = (S_2 + K_2M)(S_1 + K_1M)^{-1}.$$

Proof. Let L and M be rational matrices satisfying (4.14) and with $\Lambda_3MS_1^{-1}\Lambda_1^{-1}$ proper. Consider

$$\Lambda_2L\Lambda_1^{-1} = (\Lambda_2S_2S_1^{-1}\Lambda_1^{-1} + \Lambda_2K_2MS_1^{-1}\Lambda_1^{-1})(I + \Lambda_1K_1MS_1^{-1}\Lambda_1^{-1})^{-1}.$$

By properness of $\Lambda_3MS_1^{-1}\Lambda_1^{-1}$ and bicausality of $\Lambda_2K_2\Lambda_3^{-1}$ it follows that $\Lambda_2K_2MS_1^{-1}\Lambda_1^{-1}$ is proper. Hence, the first term on the right-hand side of the above equation is proper. For the second term note that

$$\Lambda_1K_1MS_1^{-1}\Lambda_1^{-1} = \Lambda_1K_1K_2^{-1}\Lambda_2^{-1}(\Lambda_2K_2MS_1^{-1}\Lambda_1^{-1}).$$

As $\Lambda_1K_1K_2^{-1}\Lambda_2^{-1}$ is strictly proper, it follows that $I + \Lambda_1K_1MS_1^{-1}\Lambda_1^{-1}$ is bicausal and that $\Lambda_2L\Lambda_1^{-1}$ is proper, i.e., L is in $\mathcal{L}(W^*)$. Also note that

$$G_1(S_1 + K_1M) + G_2(S_2 + K_2M) = I,$$

where both $S_1 + K_1 M$ and $S_2 + K_2 M$ are Ω -stable rational matrices as M is Ω -stable rational. Therefore, if $L_2 L_1^{-1}$ is a right coprime polynomial fractional representation of L and $G_1 L_1 + G_2 L_2 =: G$, then the zeros of $\det G$ are in Ω , which implies that L is in $\mathcal{L}_\Omega(W^*)$.

For the converse, let L be an element of $\mathcal{L}_\Omega(W^*)$ and $L_2 L_1^{-1}$ be its right coprime polynomial fractional representation. Define $G := G_1 L_1 + G_2 L_2$. Clearly, $L_1 G^{-1}$ and $L_2 G^{-1}$ are Ω -stable rational matrices. Furthermore, as $G_1 L_1 G^{-1} + G_2 L_2 G^{-1} = I$, it holds that $L_1 G^{-1} = S_1 + K_1 M$ and $L_2 G^{-1} = S_2 + K_2 M$ for some Ω -stable rational M (Recall that the right unimodular polynomial matrix $[K_1' : K_2']$ spans $\text{Ker } [G_1 : G_2]$ and S_1 and S_2 are Ω -stable rational matrices.) Since $\Lambda_2 L \Lambda_1^{-1}$ is proper, it follows that

$$\Lambda_2 L \Lambda_1^{-1} = (\Lambda_2 S_2 S_1^{-1} \Lambda_1^{-1} + \Lambda_2 K_2 M S_1^{-1} \Lambda_1^{-1})(I + \Lambda_1 K_1 M S_1^{-1} \Lambda_1^{-1})^{-1}$$

is proper. After carrying out appropriate manipulations and rearranging the terms of the equation above, we obtain

$$\Lambda_2(L - \bar{L})\Lambda_1^{-1} = [I - (\Lambda_2 L \Lambda_1^{-1})\Lambda_1 K_1 K_2^{-1} \Lambda_2^{-1}](\Lambda_2 K_2 \Lambda_3^{-1})\Lambda_3 M S_1^{-1} \Lambda_1^{-1}.$$

Since both L and \bar{L} are in $\mathcal{L}(W^*)$, the left-hand side of the equality above is proper. By strict properness of $\Lambda_1 K_1 K_2^{-1} \Lambda_2^{-1}$ the term in the parentheses is bicausal. Now, bicausality of $\Lambda_2 K_2 \Lambda_3^{-1}$ implies that $\Lambda_3 M S_1^{-1} \Lambda_1^{-1}$ is proper. \square

THEOREM 4.2. *A proper Z_c is a solution of DDPMS only if there exists an L in $\mathcal{L}_\Omega(W^*)$ such that*

$$(4.15) \quad [Z_c : -I](V^* + N^* L) = 0.$$

Conversely, for any L in $\mathcal{L}_\Omega(W^)$ there exists a proper solution Z_c of (4.15) which is also a solution to DDPMS.*

Proof. If Z_c is a solution, then by Corollary 3.1, there exists an L in $\mathcal{L}(W^*)$ satisfying (4.15). We just need to show that L is also in $\mathcal{L}_\Omega(W^*)$. In order to do this, note that by Lemma 4.1(i)–(ii) there exist a unimodular matrix U and a right unimodular polynomial matrix \tilde{U} such that

$$U[Q : R](V^* L_1 + N^* L_2) = U \Phi \tilde{U},$$

where $L_2 L_1^{-1}$ is a right coprime polynomial fractional representation of L and $\Phi := Q Q_c + R P_c$ with P_c, Q_c right coprime and $Z_c := P_c Q_c^{-1}$. Clearly, as U is unimodular and \tilde{U} is right unimodular, the set of invariant zeros of $[Q : R](V^* L_1 + N^* L_2)$ are included in the set of zeros of $\det \Phi$ which are, in turn, all in Ω as Z_c is a solution of DDPMS. Thus, by the definition of $\mathcal{L}_\Omega(W^*)$, it follows that L is in $\mathcal{L}_\Omega(W^*)$.

For the converse, let L be an element of $\mathcal{L}_\Omega(W^*)$. Then, defining $V := V^* L_1 + N^* L_2$ and following the synthesis procedure given in the proof of Theorem 4.1, one can easily construct a proper Z_c , satisfying (4.15), which is also a solution of DDPMS. \square

Remark 4.1 (Dual development). Up to now, the central object used in solving the disturbance decoupling problems being considered has been a minimal basis for $A^{-1}(\text{Im } B)$. A dual development is also possible where now the central object is a minimal basis for $(C \text{ Ker } D)^\perp$ with C and D defined as

$$C := \begin{bmatrix} Z_1 & Z_2 \\ -I & 0 \end{bmatrix}, \quad D := [Z_3 : Z_4].$$

Duality in these two approaches can easily be seen by noticing that $A^{-1}(\text{Im } B) = C \text{ Ker } D$.

Before concluding this section, we extend our Remark 3.2 to consider the solutions of the two-sided matrix equation

$$(4.16) \quad \Pi_4 = \Pi_3 X \Pi_2,$$

where Π_4 , Π_3 and Π_2 are arbitrary rational matrices and a solution X is sought over various subrings of $\underline{R}(z)$. Note that (4.16) is actually the starting point for obtaining solutions to various disturbance decoupling problems in Özgüler and Eldem [1985]. Our minimal basis approach yields alternative solvability conditions to the one given in Özgüler and Eldem [1985] and in (4.16), and has the further advantage of yielding the set of all possible solutions. The latter has been stated as an open problem in Ohm, Howze and Bhattacharyya [1984]. The main point is that a solution to (4.16) over various subrings of $\underline{R}(z)$ can easily be obtained by specialization of our procedure in obtaining a solution and the set of all solutions to DDPM, DDPMS and DDPMP to the case $Z_1 = 0$. (Note that both in Theorem 3.1 and Corollary 4.2 we imposed no restriction of properness on Z_2 , Z_3 , and Z_4 .) Let

$$A := \begin{bmatrix} I & 0 \\ 0 & \Pi_3 \end{bmatrix}, \quad B := \begin{bmatrix} \Pi_2 \\ \Pi_4 \end{bmatrix}$$

and $W := [W'_1 : W'_2]'$ be a minimal basis for $A^{-1}(\text{Im } B)$. Also partition W_h similarly so $W_h = [W'_{h1} : W'_{h2}]'$. Consider the following condition A , B and W :

- (C1) $\text{Im } B \subset \text{Im } A$ and $\rho[B] = \rho[\Pi_2]$;
- (C2) $\rho[W^*_{h1}] = \rho[B]$;
- (C3) The invariant zeros of W_1 are stable;
- (C4) W_1 has no nontrivial invariant zeros, i.e., W_1 is right unimodular.

Let $\underline{R}_p(z)$ and $\underline{R}_{ps}(z)$ denote the rings of proper and proper stable rational functions, respectively.

THEOREM 4.3. *The two-sided matching equation $\Pi_4 = \Pi_3 X \Pi_2$ has a solution over*

- (i) $\underline{R}(z)$ *iff* (C1) *holds*;
- (ii) $\underline{R}_p(z)$ *iff* (C1) *and* (C2) *hold*;
- (iii) $\underline{R}_{ps}(z)$ *iff* (C1), (C2) *and* (C3) *hold*;
- (iv) $\underline{R}(z)$ *and* $\underline{R}[z]$ *iff* (C1), (C2) *and* (C4) *hold*.

Proof. If $\Pi_4 = \Pi_3 X \Pi_2$ has a solution, then clearly $\text{Im } B \subset \text{Im } A$ and $\text{Ker } \Pi_2 \subset \text{Ker } \Pi_4$. Consequently, $\rho[B] = \rho[\Pi_2]$. Conversely, note that $\text{Im } B \subset \text{Im } A$ implies the existence of Y_1 and Y_2 such that

$$\begin{bmatrix} I & 0 \\ 0 & \Pi_3 \end{bmatrix} \begin{bmatrix} Y_1 \\ Y_2 \end{bmatrix} = \begin{bmatrix} \Pi_2 \\ \Pi_4 \end{bmatrix}.$$

Let U be a unimodular matrix such that $\Pi_2 U = [\tilde{\Pi}_2 : 0]$ and $\Pi_4 U = [\tilde{\Pi}_4 : 0]$. Define $[\tilde{Y}_1 : 0] := Y_1 U$, $[\tilde{Y}_{21} : \tilde{Y}_{22}] := Y_2 U$. Clearly $\text{Im } \tilde{Y}_{22} \subset \text{Ker } Z_3$. As \tilde{Y}_1 has full column rank, there exists a rational X such that $X \tilde{Y}_1 = \tilde{Y}_{21}$. Then, $\Pi_3 X \tilde{Y}_1 = \tilde{\Pi}_4$, which implies that $\Pi_3 X \tilde{\Pi}_2 = \tilde{\Pi}_4$ and $\Pi_3 X \Pi_2 = \Pi_4$.

For the proofs of (ii)–(iv), set $Z_1 = 0$ in the proofs of the solvability conditions of DDPM, DDPMS and DDPMP, respectively, and the results follow from the equivalence between these two sets of problems.

We conclude this section by noting that the characterization of the solutions of $\Pi_4 = \Pi_3 X \Pi_2$ over $\underline{R}_p(z)$ and $\underline{R}_{ps}(z)$ can be established along the same lines as the characterizations of the solutions of DDPM and DDPMS.

5. Conclusions. In this paper we have employed a “minimal polynomial basis approach” to obtain solvability conditions and a characterization of all solutions of

DDPM and DDPMS. By this approach DDPM and DDPMS, which are inherently two-sided problems, are treated by consecutively solving two one-sided problems, thus availing us of the results by Forney [1975]. In fact, this has been the main convenience in obtaining the characterizations given in Corollary 3.1 and Theorem 4.2. With a slight alteration in the problem data (i.e. setting $Z_1 = 0$) the same approach applies to the two-sided matrix equation $A = BXC$, where X is to be determined over the rings of proper and stable proper rational functions. The principal contribution of this paper is the characterization in Corollary 3.1 and Theorem 4.2, and identification of the fixed modes. Since the solvability conditions for DDPM and DDPMS and the characterization of "the fixed modes with respect to dynamic output feedback in DDPM" can be easily attained via a minimal polynomial basis for the rational vector space $A^{-1}(\text{Im } B)$, this paper presents a compact analysis and synthesis method for disturbance decoupling problems.

ON THE LOCAL STRUCTURE OF TIME-OPTIMAL BANG-BANG TRAJECTORIES IN \mathbb{R}^3 *

HEINZ SCHÄTTLER†

Abstract. We consider the problem of time-optimal control for systems of the form $\dot{x} = f(x) + ug(x)$ where f and g are smooth vector fields and admissible controls are measurable functions u with values in $-1 \leq u \leq 1$. Under the assumption that f , g and $[f, g]$ are independent, we prove that generically every point has a neighborhood \mathcal{U} such that bang-bang trajectories that lie in \mathcal{U} and have more than 7 switchings are not time-optimal.

Key words. nonlinear systems, time-optimal control, bang-bang trajectories, Baker–Campbell–Hausdorff formula

AMS(MOS) subject classifications. 49B10, 93B10

1. Introduction. We study the problem of time-optimal control for a system

$$\Sigma: \dot{x} = f(x) + ug(x), \quad |u| \leq 1, \quad x \in \mathbb{R}^3, \quad u \in \mathbb{R}$$

where f and g are smooth vector fields. Admissible controls are measurable functions with values in $[-1, 1]$ and a trajectory of the system corresponding to a control $u(\cdot)$ is an absolutely continuous curve such that $\dot{x}(t) = f(x(t)) + u(t)g(x(t))$ holds almost everywhere.

As in every optimal control problem, the question of regularity properties of an optimal solution comes up very naturally. The standard existence results only prove existence of an optimal solution within the class of measurable functions. The necessary conditions for optimality given in the Pontryagin Maximum Principle [9] and other high order conditions (e.g. [7]) imply certain restrictions on the possible structures of optimal controls, in particular on their regularity properties. But, in general, these conditions are not strong enough to prove that optimal controls are nice in the sense that they are for instance piecewise continuous. And, in fact, they do not have to be. Fuller's example [6] shows that time-optimal controls with countably many discontinuities (switchings) can occur even for analytic systems in \mathbb{R}^3 . A much more irregular structure seems possible. In principle, the set of discontinuities of an optimal control could even be a Cantor-like set with positive measure. The currently known necessary conditions for optimality fail to exclude such a pathological behaviour of optimal controls.

On the other hand, certain regularity properties of optimal controls are needed if one wants to obtain sufficient conditions in the form of a "regular synthesis" [2]. Even though the strict conditions given originally by Boltyansky have subsequently been substantially relaxed (Brunovsky [5], Sussmann [13]), mainly due to the introduction of the powerful theory of subanalytic sets to control theory by Brunovsky, the basic concept of synthesizing an optimal control from local knowledge does require a certain degree of regularity. One of the key hypotheses for any type of regular synthesis using the concepts that are currently discussed in the literature is still the following regularity property of optimal trajectories: for every compact set K there exists an integer $N = N(K)$ such that any optimal trajectory that lies in K is a concatenation of at

most N “nice” pieces [5]. For our problem “nice” simply means trajectories corresponding to the constant controls $u \equiv +1$ or $u \equiv -1$ (bang arcs) or to a so-called singular control (singular arc), which is a control usually with values in the interior of the control set and which satisfies certain compatibility conditions. (These are the possible candidates for time-optimal controls to which the necessary conditions of the Pontryagin Maximum Principle lead.)

Fuller’s example shows that such a regularity result about optimal trajectories need not hold. It has been an open problem in control theory for years to understand the phenomenon of optimal trajectories with infinitely many switchings in arbitrarily small times. Recently, important contributions to this problem have been made by Kupka [8], who showed that Fuller-like extremals necessarily exist if certain conditions are satisfied, and that these conditions are even generic in spaces of sufficiently high dimension. For small dimensions, however, it is still not even known whether the Fuller-phenomenon is generic or not.

In case of an analytic system, i.e., when f and g are analytic vector fields, all the local properties of Σ , in particular the possible structures of time-optimal trajectories, are determined by the Lie algebra generated by f and g and, at least in principle, can be characterized by the Lie bracket configuration. Roughly, the “Lie bracket configuration” consists of all the “Lie relations” that hold between f , g and brackets of f and g . A precise definition is technical and we skip it since it is not relevant for our purposes. The interested reader may consult [14, § 4]. Therefore it makes sense to pose the following *Question*:

Given the Lie bracket configuration at a reference point p , what can be said about the structure of time-optimal trajectories that lie in a sufficiently small neighborhood of p ?

In view of our remarks above, it is clear that one is interested in conditions under which time-optimal trajectories are finite concatenations of bang and singular arcs with a bound on the number of switchings. As far as Fuller’s problem is concerned, this includes conditions under which bang-bang trajectories with too many switchings are not time-optimal near p , i.e., conditions when the Fuller phenomenon cannot occur.

For a generic system in the plane a classification of the local structure of time-optimal trajectories was given by Sussmann [12], [17]. From his results he proved the existence of a regular synthesis for basically arbitrary analytic systems in the plane, only subject to a mild “nonexplosion” condition [18], [19]. However, the reasoning used to exclude optimality of bang-bang trajectories with a large number of switchings in small time depended heavily on their being in \mathbb{R}^2 ; only recently was a general geometric version of this argument given [15]. Therefore, so far even for the three-dimensional case, only partial results are known, due to Bressan [4] and Bonnard [3].

Here we examine what in a certain sense are the least degenerate general cases possible in \mathbb{R}^3 . All our considerations are local near a reference point p where we assume that $f(p)$, $g(p)$ and $[f, g](p)$, the Lie bracket of f and g at p , are independent. In this paper we will exclusively consider bang-bang trajectories. Under additional assumptions on low order brackets of f and g at p we will show that bang-bang trajectories with too many switchings are not optimal near p , i.e., if they lie in a sufficiently small neighborhood of p . So the Fuller phenomenon does not occur. In a forthcoming paper we will then continue the local analysis of optimal trajectories by incorporating singular arcs. In particular, we will show there that in the cases under

consideration here optimal trajectories are indeed finite concatenations of bang and singular arcs with a bound on the number of switchings.

In § 2 we will give a summarizing version of our results in terms of standard genericity notions. There we will also describe the notation and terminology we use. In §§ 3 and 4 we develop new necessary conditions for time-optimality of bang-bang trajectories which form the core of our results. Whereas the conditions of § 4 are related to concepts used to prove the Pontryagin Maximum Principle—they will follow from point variations—we present in § 3 a new technique to compute necessary conditions for optimality by making variations along a reference trajectory. This technique is not limited to dimension 3, but in higher dimensions the computational complexity increases rapidly. We then use these new necessary conditions to analyze bang-bang trajectories near a reference point in § 5. Due to the length and technicality of some of the arguments we cannot give a full proof for all generic cases in this paper, but have to restrict ourselves to a few selected examples.

2. Statement of the result. We identify Σ with the C^∞ map $\Sigma = (f, g): \mathbb{R}^3 \rightarrow \mathbb{R}^6$ and equip $C^\infty(\mathbb{R}^3, \mathbb{R}^6)$ with the Whitney C^∞ topology. Let \mathcal{A} be the open subset of all systems Σ for which f, g and $[f, g]$ are independent everywhere. Then we have the following.

THEOREM. *For a generic system $\Sigma \in \mathcal{A}$ every point has a neighborhood \mathcal{U} such that bang-bang trajectories that lie in \mathcal{U} and have more than seven switchings are not time-optimal.*

The genericity concepts are only used to have an easy way to summarize our results. By Thom's Transversality Theorem it is necessary to analyze bang-bang trajectories near a reference point p in all cases where the Lie bracket configuration at p is of codimension ≤ 3 . As mentioned earlier, the "Lie bracket configuration" consists of all the Lie relations at p . The "codimension" is the number of independent equality type constraints. An elaborate account of these ideas is given in [12]; precise definitions are long and technical and so we omit them (cf. for instance [14]). Our theorem combines all generic cases in which the Lie bracket configuration is characterized by at most three equality constraints. Some more detailed statements of our results are given in the propositions of § 5.

In this paper we will not prove the theorem completely. We will establish all new necessary conditions for time-optimality of trajectories that will be needed, but we will then restrict ourselves to analyzing some selected generic cases. In order to keep the paper within reasonable length we have to omit all the cases which have long and technical proofs. Also, we will not prove the genericity of our conditions. Aside from being almost obvious, these are straightforward computations. Complete and detailed proofs of all the results are contained in the author's doctoral dissertation [11].

2.1. Notation and terminology. Throughout this paper all our considerations are local, i.e., hold only on a sufficiently small neighborhood of a reference point p , where we assume that f, g and $[f, g]$ are independent. We always tacitly assume this. Therefore we can express all higher-order brackets of f and g as linear combinations of f, g and $[f, g]$ with smooth coefficients. Equivalently, if we let $X = f - g$ and $Y = f + g$, we can write them in terms of X, Y and $[X, Y]$. We also use $\text{ad } X(Y) = [X, Y]$.

$$[X, [X, Y]] = a_1 X + a_2 Y + a_3 [X, Y] = \alpha f + \cdots,$$

$$[Y, [X, Y]] = b_1 X + b_2 Y + b_3 [X, Y] = \beta f + \cdots,$$

$$[X, [X, [X, Y]]] = c_1 X + c_2 Y + c_3 [X, Y] = \gamma f + \cdots,$$

$$[X, [Y, [X, Y]]] = d_1 X + d_2 Y + d_3 [X, Y] = \delta f + \dots,$$

$$[Y, [Y, [X, Y]]] = e_1 X + e_2 Y + e_3 [X, Y] = \eta f + \dots,$$

$$\text{ad}^4 X(Y) = m_1 X + m_2 Y + m_3 [X, Y] = \mu f + \dots,$$

$$\text{ad}^5 X(Y) = k_1 X + k_2 Y + k_3 [X, Y] = \kappa f + \dots,$$

$$-\text{ad}^4 Y(X) = n_1 X + n_2 Y + n_3 [X, Y] = \nu f + \dots,$$

$$-\text{ad}^5 Y(X) = r_1 X + r_2 Y + r_3 [X, Y] = \rho f + \dots.$$

We denote the Lie derivative of a function Φ in direction of X by $L_X \Phi$. Observe that

$$L_X \alpha = \gamma - a_3 \alpha, \quad L_Y \alpha = \delta - a_3 \beta,$$

$$L_X \beta = \delta - b_3 \alpha, \quad L_Y \beta = \eta - b_3 \beta,$$

$$L_X \gamma = \mu - c_3 \alpha,$$

$$L_X \mu = \kappa - m_3 \alpha.$$

We use exponential notation for the flows of vector fields, i.e., we write $t \mapsto p e^{tX}$ for the integral curve of the vector field X starting at p at time 0. We let the diffeomorphism act on the right to make certain algebraic manipulations involving the Baker–Campbell–Hausdorff formula come out right later.

Finally, for a trajectory which is a concatenation of X and Y arcs, we use the corresponding letter combination to denote the trajectory, i.e., an XYX -trajectory is a concatenation of an X -arc, followed by a Y -arc and another X -arc. Sometimes, in particular when we talk of subtrajectories of a long concatenation, we indicate the first switching point in parentheses after the structure, i.e., a $YXY(p_0)$ -trajectory is a YXY -trajectory with first switching point p_0 .

3. Necessary conditions for time-optimality of bang-bang trajectories: A variation along the trajectory. In this section we will develop new necessary conditions for optimality of bang-bang trajectories.

3.1. Construction of a variation along a bang-bang trajectory. The idea is to take a bang-bang trajectory Γ with three switching points and compare it to a suitably constructed bang-bang trajectory with only two switching points that has the same initial and terminal points as Γ . We will then compute an asymptotic expansion for the difference in time between these two trajectories in terms of the data along Γ . This will give us new necessary conditions for optimality of Γ .

Let Γ be a $YXYX$ -trajectory with initial point \tilde{p} and switching points p_0, p_1 and p_2 . Let τ_1 and τ_2 be the times along the intermediate X and Y arcs respectively (we assume they are positive) and let s be a small positive number.

LEMMA 1. *The equation*

$$(3.1) \quad p_0 e^{\tau_1 X} e^{\tau_2 Y} e^{\tau_1 s X} = p_0 e^{t_1 Y} e^{t_2 X} e^{t_3 Y}$$

is solvable by smooth functions t_1, t_2, t_3 of τ_1, τ_2 and s near the origin.

Proof. The equation

$$p_0 e^{t_1 Y} e^{t_2 X} e^{t_3 Y} = p_0 e^{aY} e^{bX} e^{c[X,Y]}$$

is solvable by smooth functions a, b, c of t_1, t_2, t_3 near the origin by the Implicit Function Theorem. Notice that $a = t_1 + t_3 + t_2 t_3 \tilde{a}$, $b = t_2 + t_2 t_3 \tilde{b}$ and $c = t_2 t_3 \tilde{c}$ where \tilde{a}, \tilde{b} and \tilde{c} are smooth functions. Therefore also

$$d := \frac{c}{b} = \frac{t_3 \tilde{c}}{1 + t_3 \tilde{b}}$$

is smooth. An elementary computation shows that the Jacobian of the map $(t_1, t_2, t_3) \xrightarrow{\Phi} (a, b, d)$ is nonsingular at the origin and so we can invert locally.

Also, a, b, c are smooth functions of τ_1, τ_2 and s via

$$p_0 e^{\tau_1 X} e^{\tau_2 Y} e^{\tau_1 s X} = p_0 e^{aY} e^{bX} e^{c[X, Y]}$$

and $b = \tau_1 + s\tau_1 + \tau_1 \tau_2 \tilde{b}$, $c = \tau_1 \tau_2 \tilde{c}$, $d = c/b = \tau_2 \tilde{c}/(1 + s + \tau_2 \tilde{b})$. Hence $(\tau_1, \tau_2, s) \xrightarrow{\Psi} (a, b, d)$ is smooth and so then is $\Phi^{-1} \circ \Psi$. \square

For $s = 0$ the solutions are $t_1 = 0$, $t_2 = \tau_1$ and $t_3 = \tau_2$ and so t_2 and t_3 are positive for small s whereas t_1 is small. Therefore these times define a YXY -trajectory of Σ which starts at \tilde{p} and steers the system to some point $q = p_2 e^{\tau_1 s X}$ on Γ just after the third switching point. We are interested in the difference in time. Let

$$(3.2) \quad \Delta(s; \tau_1, \tau_2) := t_1 + t_2 + t_3 - \tau_1 - \tau_2 - \tau_1 s.$$

By Lemma 1 this function is well defined for small τ_1 and τ_2 . We can choose a neighborhood of $(\tau_1, \tau_2) = (0, 0)$ such that this is true uniformly for points p_0 in a small neighborhood V of p . Then Δ is well defined for any $YXYX$ -trajectory lying in V with small total time T . But since $f(p)$ and $g(p)$ are independent, we can choose a neighborhood \mathcal{U} of p so small that any trajectory of Σ has to leave \mathcal{U} within time T . Then Δ is well defined for any $YXYX$ -trajectory which lies in \mathcal{U} . From now on we will always assume that we work on such a neighborhood \mathcal{U} .

LEMMA 2. *If Γ is time-optimal, we have $\dot{\Delta}(0; \tau_1, \tau_2) = 0$ and $\ddot{\Delta}(0; \tau_1, \tau_2) \geq 0$ where the dot denotes differentiation with respect to s .*

Proof. Since Γ is time-optimal, by the Pontryagin Maximum Principle, there exists a nontrivial adjoint multiplier $\lambda : [0, T] \rightarrow \mathbb{R}^3$, $\dot{\lambda} = -\lambda(Df + uDg)$, such that $\langle \lambda(t), g(x(t)) \rangle u(t) = \text{Min}_{|v| \leq 1} \langle \lambda(t), g(x(t)) \rangle v$. In particular $\langle \lambda, g \rangle$ vanishes at the switching points. The first relation, $\dot{\Delta} = 0$, is a consequence of this. We simply have to compute the derivatives of the functions t_i at $s = 0$. If we differentiate (3.1) we get

$$(*) \quad \tau_1(p_2 X) = \dot{t}_1 v_1 + \dot{t}_2 v_2 + \dot{t}_3 v_3,$$

where $\dot{t}_i = (d/ds)|_{s=0} t_i(s; \tau_1, \tau_2)$ and $v_1 = p_0 Y e^{\tau_1 X} e^{\tau_2 Y}$, $v_2 = p_1 X e^{\tau_2 Y}$, $v_3 = p_2 X$. Now $\langle \lambda, g \rangle$ vanishes at p_0, p_1 and p_2 and if we transport these equations to p_2 , we have with $\tilde{\lambda} = \lambda(p_2)$:

$$\langle \tilde{\lambda}, g(p_2) \rangle = 0, \quad \langle \tilde{\lambda}, e^{-\tau_2 \text{ad } Y} g(p_1) \rangle = 0$$

and

$$\langle \tilde{\lambda}, e^{-\tau_2 \text{ad } Y} e^{-\tau_1 \text{ad } X} g(p_0) \rangle = 0.$$

Since λ is nontrivial, these three vectors are dependent. (In the terminology of [14] the points p_0, p_1 and p_2 form a conjugate triple.) Let S be the two-dimensional subspace spanned by these vectors and observe that $X(p_2)$ and $Y(p_2)$ do not lie in S due to our independence assumption on f, g and $[f, g]$. Also $X(p_2) \equiv Y(p_2) \text{ mod } S$ since $g(p_2) \in S$. An easy computation shows that in fact $v_1 \equiv v_2 \equiv v_3 \equiv X(p_2) \text{ mod } S$ and since $X(p_2) \notin S$, we obtain from (*) that $\tau_1 = \dot{t}_1 + \dot{t}_2 + \dot{t}_3$. Therefore $\dot{\Delta}(0; \tau_1, \tau_2) = 0$.

We call this a *conjugate point relation*. Since Γ is time-optimal we have $\Delta(s; \tau_1, \tau_2) \geq 0$ for small $s \geq 0$ and hence $\ddot{\Delta}(0; \tau_1, \tau_2) \geq 0$. \square

To get an applicable criterion from this we compute an asymptotic expansion for Δ . To state it more easily we introduce the following notation: for a smooth function ϕ we write $\tilde{\phi}$ for terms which are of the form $\phi(1 + O(1))$ where $O(k)$ denotes terms in the times τ_1 and τ_2 which are of order $\leq k$. Also we write $0 \cdot \tilde{\phi}$ for terms of order $\phi \cdot O(1)$.

LEMMA 3. Δ has the following asymptotic expansion

$$(3.3) \quad \begin{aligned} \Delta = \tau_1 \tau_2 \{ & -\frac{1}{2}s(\tilde{\alpha}\tau_1 + \tilde{\beta}\tau_2 + \frac{2}{3}\tilde{\gamma}\tau_1^2 + \tilde{\delta}\tau_1\tau_2 + \frac{1}{3}\tilde{\eta}\tau_2^2 + \frac{1}{4}\tilde{\mu}\tau_1^3 + \frac{1}{12}\tilde{\nu}\tau_2^3 \\ & + \frac{1}{15}\tilde{\kappa}\tau_1^4 + \tau_1\tau_2 \cdot O(1) + O(\tau_2^4) + O(5)) \\ & + \frac{1}{2}s^2 \cdot (0 \cdot \tilde{\alpha}\tau_1 + \tilde{\beta}\tau_2 - \frac{1}{3}\tilde{\gamma}\tau_1^2 + 0 \cdot \tilde{\delta}\tau_1\tau_2 + 0 \cdot \tilde{\eta}\tau_2^2 - \frac{1}{4}\tilde{\mu}\tau_1^3 \\ & + 0 \cdot \tilde{\nu}\tau_2^3 - \frac{1}{10}\tilde{\kappa}\tau_1^4 + \tau_1\tau_2 \cdot O(1) + O(\tau_2^4) + O(5)) \} \end{aligned}$$

where all the functions are evaluated at the first switching point p_0 .

In the expansion we listed only those terms which we actually need later on. A proof of Lemma 3 will be given in § 3.3. First we draw the obvious *corollaries* to get as necessary conditions for optimality of Γ :

- the “conjugate point relation”

$$(3.4) \quad 0 = \tilde{\alpha}\tau_1 + \tilde{\beta}\tau_2 + \frac{2}{3}\tilde{\gamma}\tau_1^2 + \tilde{\delta}\tau_1\tau_2 + \frac{1}{3}\tilde{\eta}\tau_2^2 + \frac{1}{4}\tilde{\mu}\tau_1^3 + \frac{1}{12}\tilde{\nu}\tau_2^3 + \frac{1}{15}\tilde{\kappa}\tau_1^4 + \dots$$

- and the “optimality condition”

$$(3.5) \quad 0 \leq 0 \cdot \tilde{\alpha}\tau_1 + \tilde{\beta}\tau_2 - \frac{1}{3}\tilde{\gamma}\tau_1^2 + 0 \cdot \tilde{\delta}\tau_1\tau_2 + 0 \cdot \tilde{\eta}\tau_2^2 - \frac{1}{4}\tilde{\mu}\tau_1^3 + 0 \cdot \tilde{\nu}\tau_2^3 - \frac{1}{10}\tilde{\kappa}\tau_1^4 + \dots$$

3.2. Input symmetries. For later use we need the equivalent versions of (3.4) and (3.5) when we evaluate all the functions at the last switching point p_2 and we also need the corresponding optimality conditions for a $YXYX$ -trajectory. All that can be obtained easily by exploiting input symmetries of the system Σ .

Let $\text{Sym } 1$ denote the input symmetry which formally interchanges X and Y , i.e., $\text{Sym } 1(X) = Y$ and $\text{Sym } 1(Y) = X$. If we apply $\text{Sym } 1$ to the equation

$$[X, [X, Y]] = \alpha f + (a_2 - a_1)g + a_3[X, Y],$$

we obtain

$$-[Y, [X, Y]] = \text{Sym } 1(\alpha) \cdot f - \text{Sym } 1(a_2 - a_1) \cdot g - \text{Sym } 1(a_3)[X, Y]$$

and so $\text{Sym } 1(\alpha) = -\beta$. Analogously it follows that

$$(3.6) \quad \begin{aligned} \text{Sym } 1(\beta) &= -\alpha, & \text{Sym } 1(\gamma) &= -\eta, & \text{Sym } 1(\delta) &= -\delta, \\ \text{Sym } 1(\eta) &= -\gamma, & \text{Sym } 1(\mu) &= -\nu, & \text{Sym } 1(\kappa) &= -\rho. \end{aligned}$$

Let $\text{Sym } 2$ be the symmetry which formally interchanges X and $-Y$. Then

$$(3.7) \quad \begin{aligned} \text{Sym } 2(\alpha) &= -\beta, & \text{Sym } 2(\beta) &= -\alpha, \\ \text{Sym } 2(\gamma) &= \eta, & \text{Sym } 2(\delta) &= \delta, & \text{Sym } 2(\eta) &= \gamma, \\ \text{Sym } 2(\mu) &= -\nu, & \text{Sym } 2(\kappa) &= \rho. \end{aligned}$$

Finally, let $\text{Sym } 3$ be time reversal, i.e., $\text{Sym } 3(X) = -X$, $\text{Sym } 3(Y) = -Y$. Then $\text{Sym } 3$ is just $\text{Sym } 1$ composed with $\text{Sym } 2$, and thus α, β, μ and ν are fixed, whereas γ, δ, η and ρ are transformed into $-\gamma, -\delta, -\eta$ and $-\rho$.

We now apply these input symmetries along a $YXYX$ -trajectory. Note that instead of (3.1) we might as well have considered

$$p_2 e^{-\tau_2 Y} e^{-\tau_1 X} e^{-\tau_2 Y} = p_2 e^{-t_1 X} e^{-t_2 Y} e^{-t_3 X}.$$

This equation is identical with (3.1) if we identify p_2 with p_0 , interchange X with $-Y$ and also interchange τ_1 and τ_2 . Therefore we simply get the corresponding optimality condition when we apply Sym 2, which interchanges X and Y and reverses time, to (3.4) and (3.5). This gives as conjugate point relation

$$(3.8) \quad \begin{aligned} 0 = & \tilde{\alpha}(p_2)\tau_1 + \tilde{\beta}(p_2)\tau_2 - \frac{1}{3}\tilde{\gamma}(p_2)\tau_1^2 - \tilde{\delta}(p_2)\tau_1\tau_2 - \frac{2}{3}\tilde{\eta}(p_2)\tau_2^2 \\ & + \frac{1}{12}\tilde{\mu}(p_2)\tau_1^3 + \frac{1}{4}\tilde{\nu}(p_2)\tau_2^3 + \tau_1\tau_2 \cdot O(1) + O(4) \end{aligned}$$

and as optimality condition

$$(3.9) \quad \begin{aligned} 0 \leq & -\tilde{\alpha}(p_2)\tau_1 + 0 \cdot \tilde{\beta}(p_2)\tau_2 + 0 \cdot \tilde{\gamma}(p_2)\tau_1^2 + 0 \cdot \tilde{\delta}(p_2)\tau_1\tau_2 \\ & - \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2 + 0 \cdot \tilde{\mu}(p_2)\tau_1^3 + \frac{1}{4}\tilde{\nu}(p_2)\tau_2^3 + \tau_1\tau_2 \cdot O(1) + O(4). \end{aligned}$$

Since here all the functions are evaluated at the last switching point, we refer to these relations as “backward conditions,” whereas we call (3.4) and (3.5) “forward conditions.” It is clear that (3.8) and (3.9) are equivalent to (3.4) and (3.5). This can also easily be seen if one transports all the functions from p_2 to p_0 via Taylor’s theorem. Both versions will be needed later on.

Finally, we also compute necessary conditions for optimality of an $XYXY$ -trajectory. We call the time along the intermediate X arc τ_3 and consider now

$$p_1 e^{\tau_2 Y} e^{\tau_3 X} e^{\tau_2 Y} = p_1 e^{t_1 X} e^{t_2 Y} e^{t_3 X}.$$

Again this is of the form (3.1) with the obvious identifications and we get the corresponding optimality conditions by applying Sym 1, which interchanges X and Y , to (3.4) and (3.5). This yields as forward conditions

$$(3.10) \quad \begin{aligned} 0 = & \tilde{\alpha}(p_1)\tau_3 + \tilde{\beta}(p_1)\tau_2 + \frac{1}{3}\tilde{\gamma}(p_1)\tau_3^2 + \tilde{\delta}(p_1)\tau_2\tau_3 + \frac{2}{3}\tilde{\eta}(p_1)\tau_1^2 \\ & + \frac{1}{12}\tilde{\mu}(p_1)\tau_3^3 + \frac{1}{4}\tilde{\nu}(p_1)\tau_2^3 + \tau_2\tau_3 \cdot O(1) + O(4), \end{aligned}$$

$$(3.11) \quad \begin{aligned} 0 \leq & -\tilde{\alpha}(p_1)\tau_3 + 0 \cdot \tilde{\beta}(p_1)\tau_2 + 0 \cdot \tilde{\gamma}(p_1)\tau_3^2 + 0 \cdot \tilde{\delta}(p_1)\tau_2\tau_3 \\ & + \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2 + 0 \cdot \tilde{\mu}(p_1)\tau_3^3 + \frac{1}{4}\tilde{\nu}(p_1)\tau_2^3 + \tau_2\tau_3 \cdot O(1) + O(4). \end{aligned}$$

The backward conditions follow by time reversal from (3.4) and (3.5):

$$(3.12) \quad \begin{aligned} 0 = & \tilde{\alpha}(p_3)\tau_3 + \tilde{\beta}(p_3)\tau_2 - \frac{2}{3}\tilde{\gamma}(p_3)\tau_3^2 - \tilde{\delta}(p_3)\tau_2\tau_3 - \frac{1}{3}\tilde{\eta}(p_3)\tau_2^2 + \frac{1}{4}\tilde{\mu}(p_3)\tau_3^3 \\ & + \frac{1}{12}\tilde{\nu}(p_3)\tau_2^3 + \tau_2\tau_3 \cdot O(1) - \frac{1}{15}\tilde{\kappa}(p_3)\tau_3^4 + O(\tau_2^4) + O(5), \end{aligned}$$

$$(3.13) \quad \begin{aligned} 0 \leq & 0 \cdot \tilde{\alpha}(p_3)\tau_3 + \tilde{\beta}(p_3)\tau_2 + \frac{1}{3}\tilde{\gamma}(p_3)\tau_3^2 + 0 \cdot \tilde{\delta}(p_3)\tau_2\tau_3 + 0 \cdot \tilde{\eta}(p_3)\tau_2^2 - \frac{1}{4}\tilde{\mu}(p_3)\tau_3^3 \\ & - 0 \cdot \tilde{\nu}(p_3)\tau_2^3 + \tau_2\tau_3 \cdot O(1) + \frac{1}{10}\tilde{\kappa}(p_3)\tau_3^4 + O(\tau_2^4) + O(5). \end{aligned}$$

3.3. Proof of the asymptotic expansion for Δ . Here we give the proof of Lemma 3. This section is independent of the remaining parts of the paper and may be skipped at first reading. It contains the proof of the core of the argument. We rewrite both sides of (3.1) in terms of canonical coordinates of the second kind as $p_0 e^{z_1[X,Y]} e^{z_2 Y} e^{z_3 X}$ and then we compare the coefficients to obtain the asymptotic expansion (3.3).

Our computations are based on the following commutator formula [1]:

$$(3.14) \quad \begin{aligned} e^A \cdot e^B = & e^R \cdot e^{(1/5!) \operatorname{ad}^5 A(B)} \cdot e^{(1/4!) \operatorname{ad}^4 A(B)} \cdot e^{-(1/4!) \operatorname{ad}^4 B(A)} \\ & \cdot e^{(1/6)[A,[A,[A,B]]]} \cdot e^{(1/4)[A,[B,[A,B]]]} \cdot e^{(1/6)[B,[B,[A,B]]]} \\ & \cdot e^{(1/2)[A,[A,B]]} \cdot e^{(1/2)[B,[A,B]]} \cdot e^{[A,B]} \cdot e^B \cdot e^A \end{aligned}$$

where e^R is the remainder term and R contains only brackets of A and B of length ≥ 5 , but none of $\operatorname{ad}^4 A(B)$, $\operatorname{ad}^5 A(B)$ or $\operatorname{ad}^4 B(A)$. This formula can be obtained by

iterating the Campbell–Hausdorff formula or by a technique known as variation of constants for formal power series [14]. It is no problem to write down the expansion which contains all brackets of length 6, but most of these brackets are irrelevant for our purpose, and we listed only the ones which we do need later on.

If we apply (3.14) to $p_0 e^{\tau_1 X} e^{\tau_2 Y} e^{\tau_1 s X}$ we obtain

$$(3.15) \quad \begin{aligned} e^{\tau_1 X} e^{\tau_2 Y} e^{\tau_1 s X} = & \dots e^{(1/5!) \tau_1^5 \tau_2 \text{ad}^5 X(Y)} \cdot e^{(1/4!) \tau_1^4 \tau_2 \text{ad}^4 X(Y)} \cdot e^{-(1/4!) \tau_1 \tau_2^4 \text{ad}^4 Y(X)} \\ & \cdot e^{(1/6) \tau_1^3 \tau_2 [X, [X, [X, Y]]]} \cdot e^{(1/4) \tau_1^2 \tau_2^2 [X, [Y, [X, Y]]]} \cdot e^{(1/6) \tau_1 \tau_2^3 [Y, [Y, [X, Y]]]} \\ & \cdot e^{(1/2) \tau_1^2 \tau_2 [X, [X, Y]]} \cdot e^{(1/2) \tau_1 \tau_2^2 [Y, [X, Y]]} \cdot e^{\tau_1 \tau_2 [X, Y]} e^{\tau_2 Y} e^{\tau_1 (1+s) X}. \end{aligned}$$

We express the higher-order brackets as linear combinations of X , Y and $[X, Y]$. Let us explain how to do this in a specific example. We write

$$(3.16) \quad [X, [X, Y]] = a_1(p_0)X + a_2(p_0)Y + a_3(p_0)[X, Y] + W_a,$$

where W_a is defined by this expression. So $W_a(p_0) = 0$ and hence $p_0 e^{W_a} = p_0$. Now substitute (3.16) into (3.15) and change from the exponential of the sum to a product of exponentials. All commutator terms which come up in this process are negligible within our desired accuracy and so we get terms

$$p_0 \dots e^{(1/2) \tau_1^2 \tau_2 W_a} \cdot e^{(1/2) \tau_1^2 \tau_2 a_3(p_0)[X, Y]} e^{(1/2) \tau_1^2 \tau_2 a_2(p_0)Y} e^{(1/2) \tau_1^2 \tau_2 a_1(p_0)X} \dots$$

Next we commute the error term all the way up to p_0 where it drops out of the calculation. Again, the commutators are of higher order and so we can simply replace

$$e^{(1/2) \tau_1^2 \tau_2 [X, [X, Y]]} \quad \text{by} \quad e^{(1/2) \tau_1^2 \tau_2 a_3(p_0)[X, Y]} e^{(1/2) \tau_1^2 \tau_2 a_2(p_0)Y} e^{(1/2) \tau_1^2 \tau_2 a_1(p_0)X}.$$

The same is true for all brackets of order ≥ 3 and we get as intermediate step

$$\begin{aligned} p_0 e^{\tau_1 X} e^{\tau_2 Y} e^{\tau_1 s X} = & p_0 \dots e^{(1/5!) \tau_1^5 \tau_2 k_3(p_0)[X, Y]} e^{(1/5!) \tau_1^5 \tau_2 k_2(p_0)Y} e^{(1/5!) \tau_1^5 \tau_2 k_1(p_0)X} \\ & \cdot e^{(1/24) \tau_1^4 \tau_2 m_3(p_0)[X, Y]} e^{(1/24) \tau_1^4 \tau_2 m_2(p_0)Y} e^{(1/24) \tau_1^4 \tau_2 m_1(p_0)X} \\ & \cdot e^{(1/24) \tau_1 \tau_2^4 n_3(p_0)[X, Y]} \cdot e^{(1/24) \tau_1 \tau_2^4 n_2(p_0)Y} e^{(1/24) \tau_1 \tau_2^4 n_1(p_0)X} \\ & \cdot e^{(1/6) \tau_1^3 \tau_2 c_3(p_0)[X, Y]} e^{(1/6) \tau_1^3 \tau_2 c_2(p_0)Y} e^{(1/6) \tau_1^3 \tau_2 c_1(p_0)X} \\ & \cdot e^{(1/4) \tau_1^2 \tau_2^2 d_3(p_0)[X, Y]} \cdot e^{(1/4) \tau_1^2 \tau_2^2 d_2(p_0)Y} e^{(1/4) \tau_1^2 \tau_2^2 d_1(p_0)X} \\ & \cdot e^{(1/6) \tau_1 \tau_2^3 e_3(p_0)[X, Y]} \cdot e^{(1/6) \tau_1 \tau_2^3 e_2(p_0)Y} e^{(1/6) \tau_1 \tau_2^3 e_1(p_0)X} \\ & \cdot e^{(1/2) \tau_1^2 \tau_2 a_3(p_0)[X, Y]} \cdot e^{(1/2) \tau_1^2 \tau_2 a_2(p_0)Y} \cdot e^{(1/2) \tau_1^2 \tau_2 a_1(p_0)X} \\ & \cdot e^{(1/2) \tau_1 \tau_2^2 b_3(p_0)[X, Y]} \cdot e^{(1/2) \tau_1 \tau_2^2 b_2(p_0)Y} \cdot e^{(1/2) \tau_1 \tau_2^2 b_1(p_0)X} \\ & \cdot e^{\tau_1 \tau_2 [X, Y]} e^{\tau_2 Y} e^{\tau_1 (1+s) X}. \end{aligned}$$

Now we have to rearrange terms. Here we find commutators which lie in the range of our required accuracy. For instance, if we commute $\exp(\frac{1}{2} \tau_1^2 \tau_2 a_1(p_0)X)$ and $\exp(\tau_2 Y)$, we get a term $\exp(\frac{1}{2} \tau_1^2 \tau_2^2 a_1(p_0)[X, Y])$. But also none of these terms matters. The reason is that all such terms are small relative to terms which appear already in the expansion such as $\frac{1}{2} \tau_1^2 \tau_2^2 a_1(p_0) \ll \tau_1 \tau_2$ at $[X, Y]$. These terms are only higher-order perturbations and their exact structure is irrelevant. We indicate these perturbations

by a tilde on the functions. So we get

$$\begin{aligned}
 p_0 e^{\tau_1 X} e^{\tau_2 Y} e^{\tau_1 s X} &= p_0 \exp ([X, Y] \{ \tau_1 \tau_2 (1 + O(2)) + \frac{1}{2} \tau_1^2 \tau_2 \tilde{a}_3(p_0) + \frac{1}{2} \tau_1 \tau_2^2 \tilde{b}_3(p_0) + O(4) \}) \\
 &\cdot \exp (Y \{ \tau_2 + \frac{1}{2} \tau_1^2 \tau_2 \tilde{a}_2(p_0) + \frac{1}{2} \tau_1 \tau_2^2 \tilde{b}_2(p_0) + \frac{1}{6} \tau_1^3 \tau_2 \tilde{c}_2(p_0) + \frac{1}{4} \tau_1^2 \tau_2^2 \tilde{d}_2(p_0) \\
 (3.17) \quad &+ \frac{1}{6} \tau_1 \tau_2^3 \tilde{e}_3(p_0) + \frac{1}{24} \tau_1^4 \tau_2 m_2(p_0) + \frac{1}{24} \tau_1 \tau_2^4 n_2(p_0) \\
 &+ \frac{1}{5!} \tau_1^5 \tau_2 k_2(p_0) + \dots \}) \\
 &\cdot \exp (X \{ \tau_1 (1 + s) + \frac{1}{2} \tau_1^2 \tau_2 \tilde{a}_1(p_0) + \frac{1}{2} \tau_1 \tau_2^2 \tilde{b}_1(p_0) + \frac{1}{6} \tau_1^3 \tau_2 \tilde{c}_1(p_0) \\
 &+ \frac{1}{4} \tau_1^2 \tau_2^2 \tilde{d}_1(p_0) + \frac{1}{6} \tau_1 \tau_2^3 \tilde{e}_1(p_0) \\
 &+ \frac{1}{24} \tau_1^4 \tau_2 m_1(p_0) + \frac{1}{24} \tau_1 \tau_2^4 n_1(p_0) + \frac{1}{5!} \tau_1^5 \tau_2 k_1(p_0) + \dots \}).
 \end{aligned}$$

The same calculation has to be done for $p_0 e^{t_1 Y} e^{t_2 X} e^{t_3 Y}$. It follows from (3.1) that t_2 is divisible by τ_1 and that t_1 and t_3 are divisible by τ_2 . Also t_1 is divisible by s . Therefore any term of order $\geq k$ in the t -variables is also of order $\geq k$ in the τ -variables. To stay within the desired accuracy we have to pick up the fourth-order terms plus terms of orders $t_1 t_2^4$, $t_3 t_2^4$, $t_1 t_2^5$, $t_3 t_2^5$ and $t_2 \cdot O(4, \text{ in } t_1, t_3)$. The formal procedures are exactly as above and the result is

$$\begin{aligned}
 p_0 e^{t_1 Y} e^{t_2 X} e^{t_3 Y} &= p_0 \exp ([X, Y] \{ t_2 t_3 (1 + O(2)) + \frac{1}{2} t_2^2 t_3 \tilde{a}_3(p_0) + t_2 t_3 (t_1 + \frac{1}{2} t_3) \tilde{b}_3(p_0) + O(4) \}) \\
 &\cdot \exp (Y \{ t_1 + t_3 + \frac{1}{2} t_2^2 t_3 \tilde{a}_2(p_0) + t_2 t_3 (t_1 + \frac{1}{2} t_3) \tilde{b}_2(p_0) + \frac{1}{6} t_2^3 t_3 \tilde{c}_2(p_0) \\
 &+ \frac{1}{2} t_2^2 t_3 (t_1 + \frac{1}{2} t_3) \tilde{d}_2(p_0) + \frac{1}{2} t_2 t_3 (t_1^2 + t_1 t_3 + \frac{1}{3} t_3^2) \tilde{e}_2(p_0) \\
 (3.18) \quad &+ \frac{1}{24} t_2^4 t_3 m_2(p_0) + \frac{1}{6} t_2 t_3 (t_1^3 + \frac{3}{2} t_1^2 t_3 + t_1 t_3^2 + \frac{1}{4} t_3^3) n_2(p_0) \\
 &+ \frac{1}{5!} t_2^5 t_3 k_2(p_0) + \dots \}) \\
 &\cdot \exp (X \{ t_2 + \frac{1}{2} t_2^2 t_3 \tilde{a}_1(p_0) + t_2 t_3 (t_1 + \frac{1}{2} t_3) \tilde{b}_1(p_0) + \frac{1}{6} t_2^3 t_3 \tilde{c}_1(p_0) \\
 &+ \frac{1}{2} t_2^2 t_3 (t_1 + \frac{1}{2} t_3) \tilde{d}_1(p_0) + \frac{1}{2} t_2 t_3 (t_1^2 + t_1 t_3 + \frac{1}{3} t_3^2) \tilde{e}_1(p_0) \\
 &+ \frac{1}{24} t_2^4 t_3 m_1(p_0) + \frac{1}{6} t_2 t_3 (t_1^3 + \frac{3}{2} t_1^2 t_3 + t_1 t_3^2 + \frac{1}{4} t_3^3) n_1(p_0) \\
 &+ \frac{1}{5!} t_2^5 t_3 k_1(p_0) + \dots \}).
 \end{aligned}$$

Now we compare the coefficients in (3.17) and (3.18). Adding the X and Y equations we get

$$\begin{aligned}
 \Delta &= t_1 + t_2 + t_3 - \tau_1 - \tau_2 - \tau_1 s \\
 &= \tilde{\alpha}(p_0) (\frac{1}{2} \tau_1^2 \tau_2 - \frac{1}{2} t_2^2 t_3) + \tilde{\beta}(p_0) (\frac{1}{2} \tau_1 \tau_2^2 - t_2 t_3 (t_1 + \frac{1}{2} t_3)) \\
 (3.19) \quad &+ \tilde{\gamma}(p_0) (\frac{1}{6} \tau_1^3 \tau_2 - \frac{1}{6} t_2^3 t_3) + \tilde{\delta}(p_0) (\frac{1}{4} \tau_1^2 \tau_2^2 - \frac{1}{2} t_2^2 t_3 (t_2 + \frac{1}{2} t_3)) \\
 &+ \tilde{\eta}(p_0) (\frac{1}{6} \tau_1 \tau_2^3 - \frac{1}{2} t_2 t_3 (t_1^2 + t_1 t_3 + \frac{1}{3} t_3^2)) \\
 &+ \tilde{\mu}(p_0) (\frac{1}{24} \tau_1^4 \tau_2 - \frac{1}{24} t_2^4 t_3) + \tilde{\kappa}(p_0) (\frac{1}{5!} \tau_1^5 \tau_2 - \frac{1}{5!} t_2^5 t_3) \\
 &+ \tilde{\nu}(p_0) (\frac{1}{24} \tau_1 \tau_2^4 - \frac{1}{6} t_2 t_3 (t_1^3 + \frac{3}{2} t_1^2 t_3 + t_1 t_3^2 + \frac{1}{4} t_3^3)) + \dots
 \end{aligned}$$

To transform this into an equation in τ_1 , τ_2 and s we solve the equations which we get when we equate coefficients in (3.17) and (3.18) for t_1 , t_2 and t_3 . Notice that all we really need are the leading terms in these approximations since each of the summands in Δ has a certain polynomial in τ as a factor; for instance $\tau_1^3 \tau_2$ factors the

term at $\gamma(p_0)$, and we already allow for perturbations at $\gamma(p_0)$. Therefore the following three equations suffice:

- (i) $\tau_1(1+s) + O(3) = t_2 + O(3)$,
- (ii) $\tau_2 + O(3) = t_1 + t_3 + O(3)$,
- (iii) $\tau_1\tau_2(1+O(1)) = t_2t_3(1+O(1))$.

The approximate solutions are

$$t_1 = \tau_2 s(1 + O(1)), \quad t_2 = \tau_1(1 + s + O(2)), \quad t_3 = \tau_2 \left(\frac{1}{1+s} + O(1) \right).$$

We now substitute these formulas into (3.19) to compute the leading terms. For instance, let us compute the coefficient at $\tilde{\eta}(p_0)$:

$$\begin{aligned} \frac{1}{6} \tau_1 \tau_2^3 - \frac{1}{2} t_2 t_3 \left(t_1^2 + t_1 t_3 + \frac{1}{3} t_3^2 \right) &= \tau_1 \tau_2^3 \left(\frac{1}{6} - \frac{1}{2} (1 + O(1)) \right) \left(\frac{s^2 + s + 1/3}{(1+s)^2} + O(1) \right) \\ &= \tau_1 \tau_2^3 \left(-\frac{1}{6} s + 0 \cdot s^2 + O(1) \right). \end{aligned}$$

We do this for each term and this yields the asymptotic expansion (3.3). \square

Remark. Observe that the function t_1 is positive. A consequence of this is that the structure of the first junction is irrelevant and so (3.4) and (3.5) are in fact necessary conditions for time-optimality of an $\cdot XYX$ concatenation, where the dot stands for any switching.

4. Necessary conditions for time optimality of bang-bang trajectories: point variations. Let $\text{Reach}_{\Sigma, \leq T}(\tilde{p})$ be the set of all points reachable from \tilde{p} by a trajectory of Σ within time T . In this section we will compute an approximating cone for $\text{Reach}_{\Sigma, \leq T}(\tilde{p})$ by making point variations along bang-bang trajectories. This leads to additional necessary conditions for time optimality.

Let $\tilde{q} \in \text{Reach}_{\Sigma, \leq T}(\tilde{p})$. We call a cone $\tilde{K} \subseteq \mathbb{R}^3$ an almost approximating cone for $\text{Reach}_{\Sigma, \leq T}(\tilde{p})$ at \tilde{q} if for every finite set of vectors $v_1, \dots, v_n \in \tilde{K}$ and any $\delta > 0$ there exist vectors $v'_1, \dots, v'_n \in \mathbb{R}^3$ with $\|v_i - v'_i\| < \delta$ for $i = 1, \dots, n$ and a continuous map $\Psi: \{x \in \mathbb{R}^3: \|x\| < \varepsilon, x_i \geq 0\} \rightarrow \text{Reach}_{\Sigma, \leq T}(\tilde{p})$ such that $\Psi(x_1, \dots, x_n) = \tilde{q} + x_1 v_1 + \dots + x_n v_n + O(\|x\|)$ as $\|x\| \rightarrow 0$. We note that, if \tilde{K} is an almost approximating cone, so is its convex hull. The following topological fact is well known if $v'_i = v_i$ [13] and can easily be generalized to this slightly more general situation.

PROPOSITION 1. *Let Γ be a trajectory which steers \tilde{p} to \tilde{q} in time T . If \mathbb{R}^3 is an almost approximating cone for $\text{Reach}_{\Sigma, \leq T}(\tilde{p})$ at \tilde{q} , then \tilde{q} is an interior point of $\text{Reach}_{\Sigma, \leq T}(\tilde{p})$ and therefore Γ is not time-optimal beyond \tilde{q} .*

We now use this result to prove the following.

PROPOSITION 2. *A necessary condition for time optimality of a YXY -trajectory beyond its second switching point p_1 is that*

$$(4.1) \quad -\alpha(p_1)\tau_1 + \frac{1}{2}\gamma(p_1)\tau_1^2 - \frac{1}{6}\mu(p_1)\tau_1^3 + O(\tau_1^4) \leq 0$$

where τ_1 is the time along the X -trajectory.

COROLLARY. *A necessary condition for time optimality of an XYX -trajectory beyond its second switching point p_2 is that*

$$(4.2) \quad \beta(p_2)\tau_2 - \frac{1}{2}\eta(p_2)\tau_2^2 + \frac{1}{6}\nu(p_2)\tau_2^3 + O(\tau_2^4) \leq 0$$

where τ_2 is the time along the Y -arc.

The corollary follows immediately from Proposition 2 if we interchange X and Y , i.e., apply Sym 1 to (4.2). We now prove Proposition 2. First we compute some

variational vectors. Let $\Gamma = (x(\cdot), u(\cdot))$ be a YXY -trajectory with switching points p_0 and p_1 and let t_0 and t_1 be the corresponding switching times. Let $\tilde{q} = p_1 e^{rY}$ be a point on Γ just after the second switching point, i.e., for r small. Everywhere we can shorten the trajectory by deleting time. The variation is given by

$$z_1(s) = x(\bar{t}) e^{-sY} \quad \text{or} \quad z_2(s) = x(\bar{t}) e^{-sX}$$

depending on whether $\bar{t} \in (0, t_0] \cup (t_1, t_1 + r]$ or $\bar{t} \in (t_0, t_1]$. This gives the variational vectors $\dot{z}_1(0) = -Y(x(\bar{t}))$, respectively, $\dot{z}_2(0) = -X(x(\bar{t}))$. Another standard variation is to interchange X with Y . For $\bar{t} \in (0, t_0] \cup (t_1, t_1 + r]$ we have

$$z_3(s) = x(\bar{t}) e^{-sY} e^{sX}, \quad \dot{z}_3(0) = (X - Y)(x(\bar{t})) = -2g(x(\bar{t}))$$

and for $\bar{t} \in (t_0, t_1]$

$$z_4(s) = x(\bar{t}) e^{-sX} e^{sY}, \quad \dot{z}_4(0) = (Y - X)(x(\bar{t})) = 2g(x(\bar{t})).$$

Finally, we also use two variations which can only be done at the switching points, namely

$$z_5(s) = p_0 e^{-\sqrt{s}Y} e^{\sqrt{s}X} e^{\sqrt{s}Y} e^{-\sqrt{s}X}, \quad \dot{z}_5(0) = [X, Y](p_0)$$

and

$$z_6(s) = p_1 e^{-\sqrt{s}X} e^{\sqrt{s}Y} e^{\sqrt{s}X} e^{-\sqrt{s}Y}, \quad \dot{z}_6(0) = -[X, Y](p_1).$$

Now transport all these variational vectors $\dot{z}_i(0)$, $i = 1, \dots, 6$ along Γ to \tilde{q} and call the resulting vectors $v_i(r)$. We *claim* that the vectors $v_i(r)$, $i = 1, \dots, 6$, where we choose \bar{t} to be one of the switching times t_0 or t_1 , generate an almost approximating cone for $\text{Reach}_{\Sigma, \leq t_1+r}(\tilde{p})$ at \tilde{q} . To see this, observe first that variational vectors which are obtained at different times along Γ can be combined to generate an approximating cone (this is an almost approximating cone where we require in addition that $v'_i = v_i$ for all i). For instance, it is easily checked that

$$\Psi(x_1, x_2) := \tilde{p} e^{(t_0 - \sqrt{x_1})Y} e^{\sqrt{x_1}X} e^{\sqrt{x_1}Y} e^{(t_1 - \sqrt{x_1})X} e^{(r - x_2)Y}$$

is an approximating map for the vectors $v_1(r)$ (at $\bar{t} = t_1 + r$) and $v_5(r)$ (at $\bar{t} = t_0$). The general case is as simple as this one; only the notation really becomes cumbersome. Since these arguments are fairly standard to everyone in control theory by now, we omit a detailed proof. (The interested reader may consult, for instance, [7]). In our case we also use variational vectors at the same times $\bar{t} = t_0$ or $\bar{t} = t_1$. Since we can get $\pm g(x(\bar{t}))$ for times \bar{t} arbitrarily close to the switching times, it is still possible to combine the vectors $v_i(r)$ to obtain an almost approximating map. The definition is tailored such that exactly this can be done. This proves the claim.

Let $\tilde{K}(r)$ be the convex cone generated by $v_i(r)$, $i = 1, \dots, 6$. Γ is not time-optimal beyond p_1 if $\tilde{K}(r) = \mathbb{R}^3$ for sufficiently small r . Let K be the cone generated by the vectors $v_i(0)$, i.e., when we set $r = 0$. Equivalently K is generated by the vectors

$$-f(p_1), \quad \pm g(p_1), \quad e^{-\tau_1 \text{ad} X}([X, Y](p_0)) \quad \text{and} \quad -[X, Y](p_1).$$

Observe that $e^{-\tau_1 \text{ad} X}([X, Y](p_0)) = [X, Y](p_1) + O(\tau_1)$ and that

$$\begin{aligned} & e^{-\tau_1 \text{ad} X}([X, Y](p_0)) - [X, Y](p_1) \\ &= -\tau_1[X, [X, Y]](p_1) + \frac{1}{2}\tau_1^2 \text{ad}^3 X(Y)(p_1) - \frac{1}{6}\tau_1^3 \text{ad}^4 X(Y)(p_1) + O(\tau_1^4) \\ &= (-\alpha(p_1)\tau_1 + \frac{1}{2}\gamma(p_1)\tau_1^2 - \frac{1}{6}\mu(p_1)\tau_1^3 + O(\tau_1^4)) \cdot f(p_1) \\ & \quad + \text{a linear combination of } g(p_1) \text{ and } [X, Y](p_1). \end{aligned} \tag{4.3}$$

If (4.1) is violated, the f -coefficient in (4.3) is positive. Also, $e^{-\tau_1 \text{ad} X}([X, Y](p_0))$ is only a small perturbation of $[X, Y](p_1)$. Since f , g and $[X, Y]$ are independent, we

can therefore generate all of \mathbb{R}^3 in the positive span of these vectors. This does not change if we perturb the vectors of order r and so $\tilde{K}(r) = \mathbb{R}^3$ for sufficiently small r . Thus (4.1) is a necessary condition for time optimality of Γ beyond p_1 . \square

In Proposition 2 we used only the most obvious variational vectors to generate an almost approximating cone. Doing a little bit more sophisticated combinations, we get a different result which will be needed in § 5.

PROPOSITION 3. *Suppose $\gamma(p) > 0$ and let $\varepsilon > 0$ be small. There exists a neighborhood $\mathcal{U} = \mathcal{U}(\varepsilon)$ of p such that a necessary condition for time optimality of a $YXY(p_0)$ -trajectory which lies in \mathcal{U} is that*

$$(4.4) \quad -\alpha(p_1) + \left(\frac{2}{3} - \varepsilon\right) \tilde{\gamma}(p_1) \tau_1 \leq 0.$$

Proof. We start with a small neighborhood V of p such that $\gamma(q) > \frac{1}{2}\gamma(p)$ on V . Let M be an upper bound for $|a_3|$ and $|c_3|$ on V . Choose $N \in \mathbb{N}$ such that $1 \leq 3\varepsilon(N+1)$ and choose T so small that $TNM < \frac{1}{2}$, $TN \ll \frac{1}{2}$, $T \ll \gamma(p)$. Let \mathcal{U} be a neighborhood of p such that any trajectory of Σ leaves \mathcal{U} within time T . We claim that this choice of \mathcal{U} does what we want.

As in the proof of Proposition 2 we will show that $K = \mathbb{R}^3$ if (4.4) is violated. Recall that $-f(p_1)$, $\pm g(p_1)$ and $-[X, Y](p_1)$ lie in K . Therefore it suffices to exhibit a vector in K which has positive coefficients at both $f(p_1)$ and $[X, Y](p_1)$. Since $(Y - X)(p_0)$, $[X, Y](p_0)$ and $(X - Y)(p_1)$ are variational vectors, the following vector lies in K :

$$\begin{aligned} W &= N \cdot e^{-\tau_1 \text{ad}^X}([X, Y](p_0)) + (N-1) e^{-\tau_1 \text{ad}^X}(Y - X)(p_0) + (X - Y)(p_1) \\ &= [X, Y](p_1) + N \cdot \left(-\frac{1}{2} \tau_1 \left(1 + \frac{1}{N} \right) [X, [X, Y]](p_1) + \frac{1}{3} \tau_1^2 \left(1 + \frac{1}{2N} \right) [X, [X, [X, Y]] \right. \\ &\quad \left. (p_1) + O(\tau_1^3) \right). \end{aligned}$$

Now we express the higher order brackets as linear combinations of f , g and $[X, Y]$. The coefficient at $[X, Y](p_1)$ is of the form $1 + N\tau_1 h$, where $|h| \leq M$. By construction this term is positive. If (4.4) now is violated then also

$$-\frac{1}{2} \alpha(p_1) + \frac{1}{3} \frac{2N+1}{2N+2} \gamma(p_1) \tau_1 + O(\tau_1^2) > 0$$

and so W also has a positive f -coefficient. Hence $K = \mathbb{R}^3$ and Γ is not time optimal beyond p_1 . \square

5. The analysis of time-optimal bang-bang trajectories in generic cases. We now use the necessary conditions of §§ 3 and 4 to analyze the time optimality of bang-bang trajectories near a reference point p in some generic cases. All our considerations apply only on a sufficiently small neighborhood \mathcal{U} of p which we adjust whenever necessary for the argument without changing the name. For instance, if $\alpha(p) \neq 0$, then we can choose \mathcal{U} so small that the time T along any trajectory that lies in \mathcal{U} is dominated by $\alpha(q)$ for any $q \in \mathcal{U}$. This is possible since $f(p)$ and $g(p)$ are independent and therefore we can make T arbitrarily small by choosing \mathcal{U} small. Henceforth we will tacitly assume that any function which does not vanish at p dominates on \mathcal{U} all terms of order $O(1)$ that come up. Also we will not refer explicitly to \mathcal{U} from now on. It is understood that all statements are valid only for trajectories that lie in a sufficiently small neighborhood of p and we use the phrase “near p ” to indicate this.

5.1. The generic cases where at most one of $\alpha(p)$ and $\beta(p)$ vanishes. Several of the cases can be analyzed directly with the necessary conditions of §§ 3 and 4. If $\alpha(p) < 0$, then YXY -trajectories are not time-optimal by (4.1) and if $\beta(p) > 0$, then (4.2) excludes XYX -trajectories. The only nontrivial cases occur therefore when $\alpha(p) \geq 0$ and $\beta(p) \leq 0$. In the codimension 0 case, $\alpha(p) > 0$ and $\beta(p) < 0$, the conjugate point relation (3.4) implies that τ_1 and τ_2 are comparable in the sense that there exists a constant C , only depending on the size of a small neighborhood of p , but not on the specific trajectory under consideration, such that $\tau_1 \leq C\tau_2$ and $\tau_2 \leq C\tau_1$. Therefore the optimality condition (3.5) excludes the time optimality of $YXYX$ -concatenations. Since the assumptions $\alpha(p) > 0$ and $\beta(p) < 0$ are invariant when we apply Sym 1, the input symmetry which interchanges X and Y , this excludes also $XYXY$ -concatenations. Equivalently, this can be seen from (3.12) and (3.13) as well. So we have the following.

PROPOSITION 1. *Near p time-optimal bang-bang trajectories have at most the following form:*

- (a) XYX if $\alpha(p) < 0$; YXY if $\beta(p) > 0$.
- (b) XY or YX if $\alpha(p) < 0$ and $\beta(p) > 0$; XYX or YXY if $\alpha(p) > 0$ and $\beta(p) < 0$.

For the more degenerate generic cases we can assume without loss of generality that $\alpha(p) = 0$ and $\beta(p) < 0$. The case $\alpha(p) > 0$ and $\beta(p) = 0$ is then a direct consequence of our results when we apply Sym 1.

PROPOSITION 2. *Let $\alpha(p) = 0$ and $\beta(p) < 0$. Then near p time-optimal bang-bang trajectories are at most concatenations of the form:*

- (i) $XYXY$ if $\gamma(p) > 0$; $YXYX$ if $\gamma(p) < 0$.
- (ii) $XYXYX$ if $\gamma(p) = 0$, $\mu(p) < 0$; $YXYXY$ if $\gamma(p) = 0$, $\mu(p) > 0$.
- (iii) $XYXYXY$ if $\gamma(p) = 0$, $\mu(p) = 0$, $\kappa(p) > 0$; $YXYXYX$ if $\gamma(p) = 0$, $\mu(p) = 0$, $\kappa(p) < 0$.

COROLLARY. *Let $\alpha(p) > 0$ and $\beta(p) = 0$. Then near p time-optimal bang-bang trajectories are at most concatenations of the form:*

- (i) $XYXY$ if $\eta(p) > 0$; $YXYX$ if $\eta(p) < 0$.
- (ii) $XYXYX$ if $\eta(p) = 0$, $\nu(p) < 0$; $YXYXY$ if $\eta(p) = 0$, $\nu(p) > 0$.
- (iii) $XYXYXY$ if $\eta(p) = 0$, $\nu(p) = 0$, $\rho(p) > 0$; $YXYXYX$ if $\eta(p) = 0$, $\nu(p) = 0$, $\rho(p) < 0$.

Since this is the first time we use input symmetries to exclude the optimality of trajectories we give a proof of the corollary. Later on we will omit these arguments. Let Σ^* be the system where we replace g with $-g$, i.e., $\dot{x} = f(x) - ug(x)$. Then $\Sigma^* = \text{Sym } 1(\Sigma)$ and $\alpha^* = -\beta$, $\beta^* = -\alpha$, $\gamma^* = -\eta$, etc. Therefore, by Proposition 1, $X^*Y^*X^*Y^*$ concatenations are not time-optimal if $\alpha^*(p) = 0$, $\beta^*(p) < 0$ and $\gamma^*(p) < 0$. For Σ this excludes $YXYX$ concatenations if $\beta(p) = 0$, $\alpha(p) > 0$ and $\eta(p) > 0$. All the other results follow exactly like this.

Remark. In a forthcoming paper we will prove that, in all the cases considered above, time-optimal trajectories are in fact bang-bang and so this gives then a precise classification of the structure of time-optimal trajectories near p .

We single out the computational part of the proof in the following lemma.

LEMMA 1. *Let Γ be a time-optimal $YXYXYX$ trajectory with switching points p_0, \dots, p_4 and let τ_i , $i = 1, \dots, 4$, be the time along the trajectory between p_{i-1} and p_i . Then the following conditions are necessary for time optimality of the sub-arcs specified:*

$$(5.1) \quad 0 \leq -\gamma(p_2) + \frac{1}{4}\tilde{\mu}(p_2)\tau_1 - \frac{1}{20}\kappa(p_2)\tau_1^2 + O(\tau_1^3) \quad \text{for } YXYX(p_0),$$

$$(5.2) \quad 0 \leq \gamma(p_2) + \frac{1}{4}\tilde{\mu}(p_2)\tau_3 + \frac{1}{20}\kappa(p_2)\tau_3^2 + O(\tau_3^3) \quad \text{for } XYXY(p_1),$$

$$(5.3) \quad 0 \leq -\gamma(p_2) - \frac{3}{4}\tilde{\mu}(p_2)\tau_3 - \frac{3}{10}\kappa(p_2)\tau_3^2 + O(\tau_3^3) \quad \text{for } YXYX(p_2).$$

Proof of the lemma. We first prove (5.1) and (5.3). We use the conjugate point relation (3.4) to eliminate the term $0 \cdot \tilde{\alpha}(p_0)\tau_1$ in (3.5) and then we bound all terms which have the factor τ_2 by $\frac{1}{3}\beta(p)\tau_2$. This gives

$$(5.4) \quad 0 \leq \frac{1}{3}\beta(p)\tau_2 - \frac{1}{3}\tilde{\gamma}(p_0)\tau_1^2 - \frac{1}{4}\tilde{\mu}(p_0)\tau_1^3 - \frac{1}{10}\tilde{\kappa}(p_0)\tau_1^4 + O(\tau_1^5).$$

Exactly the same condition holds at p_2 with τ_3 and τ_4 instead of τ_1 and τ_2 . This implies already (5.3). (We bound $\beta(p) < 0$, divide out the perturbation at $\gamma(p_2)$ and absorb the perturbation at $\kappa(p_2)$ in $O(\tau_3^5)$.) To prove (5.1), we now transport the functions γ , μ and κ from p_0 to p_2 . By Taylor's theorem

$$\begin{aligned} \gamma(p_0) &= \gamma(p_2) + O(\tau_2) - L_X\gamma(p_2)\tau_1 + \frac{1}{2}L_X^2\gamma(p_2)\tau_1^2 + O(\tau_1^3) \\ &= \tilde{\gamma}(p_2) - \mu(p_2)\tau_1 + \frac{1}{2}\kappa(p_2)\tau_1^2 + \alpha(p_2) \cdot O(1) + O(\tau_2) + O(\tau_1^3), \\ \mu(p_0) &= \mu(p_2) - L_X\mu(p_2)\tau_1 + O(\tau_2) + O(\tau_1^2) \\ &= \mu(p_2) - \kappa(p_2)\tau_1 + \alpha(p_2) \cdot O(1) + O(\tau_2) + O(\tau_1^2) \end{aligned}$$

and $\kappa(p_0) = \kappa(p_2) + O(1)$. Therefore we get from (5.4)

$$0 \leq \frac{1}{3}\beta(p)\tau_2 + \alpha(p_2)\tau_1^2 \cdot O(1) - \frac{1}{3}\tau_1^2(\tilde{\gamma}(p_2) - \frac{1}{4}\tilde{\mu}(p_2)\tau_1 + \frac{1}{20}\tilde{\kappa}(p_2)\tau_1^2 + O(\tau_1^3) + O(\tau_2)).$$

The α -term and the terms with a factor τ_2 that came up in this procedure are dominated by $\beta(p)\tau_2 < 0$ and so this implies (5.1).

We get (5.2) in the same way from (3.13). Using (3.12) to eliminate the α -terms and again bounding the τ_2 terms by $\frac{1}{3}\beta(p)\tau_2$, we obtain

$$0 \leq \frac{1}{3}\beta(p_2)\tau_2 + \frac{1}{3}\tau_3^2(\tilde{\gamma}(p_3) - \frac{3}{4}\tilde{\mu}(p_3)\tau_3 + \frac{3}{10}\tilde{\kappa}(p_3)\tau_3^2 + O(\tau_3^3)).$$

Now we transport to p_2 to get

$$0 \leq \frac{1}{3}\beta(p)\tau_2 + \alpha(p_2)\tau_3^2 \cdot O(1) + \frac{1}{3}\tau_3^2(\tilde{\gamma}(p_2) + \frac{1}{4}\tilde{\mu}(p_2)\tau_3 + \frac{1}{20}\tilde{\kappa}(p_2)\tau_3^2 + O(\tau_2) + O(\tau_3^3))$$

and this implies (5.2). \square

We now give the *proof* of the proposition. Case (i) follows immediately from (5.1) and (5.2) excluding the time optimality of $XYXY$ -trajectories if $\gamma(p) < 0$ and of $YXYX$ -trajectories if $\gamma(p) > 0$.

Now suppose $\gamma(p) = 0$. We add (5.1) and (5.2) to cancel out $\gamma(p_2)$. This leads to

$$0 \leq \mu(p_2)(\tau_1 + \tau_3) - \frac{1}{5}\tilde{\kappa}(p_2)(\tau_1^2 - \tau_3^2) + O(\tau_1^3, \tau_3^3).$$

Since $\tau_i/(\tau_1 + \tau_3) \leq 1$ for $i = 1, 3$, this implies that

$$(5.5) \quad 0 \leq \mu(p_2) + \frac{1}{5}\tilde{\kappa}(p_2)(\tau_3 - \tau_1) + O(\tau_1^2, \tau_3^2).$$

Therefore $YXYXY$ trajectories are not time-optimal if $\mu(p) < 0$. In the case $\mu(p) > 0$ we combine (5.2) and (5.3) to obtain

$$(5.6) \quad 0 \leq -\mu(p_2) - \frac{1}{2}\tilde{\kappa}(p_2)\tau_3 + O(\tau_3^2)$$

which excludes $XYXYX$ -trajectories. This proves (ii). If also $\mu(p) = 0$, we combine (5.6) and (5.5) to get

$$0 \leq \kappa(p_2)(-2\tau_1 - 3\tau_3) + O(\tau_1^2, \tau_3^2).$$

This excludes the optimality of $YXYXYX$ -trajectories if $\kappa(p) > 0$. Then we apply this to the time reversed system (i.e., use “time reversal” = Sym 3) to obtain that $XYXYXY$ -trajectories are not time-optimal in case $\kappa(p) < 0$. This proves (iii) and also the proposition. \square

5.2. $\alpha(p)=0$ and $\beta(p)=0$: The codimension 2 cases. The cases when $\alpha(p)$ and $\beta(p)$ vanish are technically more difficult due to the fact that now both linear terms in the necessary conditions of §§ 3 and 4 are small, i.e., not dominant, and we have no a priori knowledge about their signs. Our strategy is to combine several necessary conditions to cancel out the linear terms and to get applicable conditions with dominant higher-order terms.

PROPOSITION 3. *Let $\alpha(p)=0$, $\beta(p)=0$ and assume $\gamma(p)>0$, $\eta(p)\neq 0$. Then near p bang-bang trajectories of the following structures are not time-optimal:*

- (i) $XYXYX$ or $YXYXY$ if $\eta(p)<0$;
- (ii) $YXYX$ if $\eta(p)>0$ and $\delta(p)\geq 0$; $YXYXYX$ if $\eta(p)>0$ and $\delta(p)<0$.

The generic cases when $\gamma(p)<0$ follow from this by a time reversal argument (recall that $\text{Sym } 3(\gamma)=-\gamma$). We get the following corollary.

COROLLARY. *Let $\alpha(p)=0$, $\beta(p)=0$ and assume $\gamma(p)<0$, $\eta(p)\neq 0$. Then near p bang-bang trajectories of the following structures are not time-optimal:*

- (i) $XYXYX$ or $YXYXY$ if $\eta(p)>0$;
- (ii) $YXYX$ if $\eta(p)<0$ and $\delta(p)\leq 0$; $YXYXYX$ if $\eta(p)<0$ and $\delta(p)>0$.

Proof of Proposition 3. We consider a $YXYXYX$ -concatenation with switching points p_0, \dots, p_4 and we let τ_i be the time along the arc joining p_{i-1} and p_i , $i=1, \dots, 4$. An important step in the proof will be to get information on how the times τ_i relate to each other. We will write $\tau_i \leq C\tau_{i+1}$ if there exists a constant, only dependent on some neighborhood \mathcal{U} of p , but not on a specific trajectory under consideration, such that $\tau_i \leq \text{Const} \cdot \tau_{i+1}$ is a necessary condition for time optimality of any trajectory that lies in \mathcal{U} . We also have to deal with constants which can be made arbitrarily small by choosing the neighborhood \mathcal{U} of p small enough. For instance, a necessary condition like

$$\frac{1}{3}\tilde{\gamma}(p_2)\tau_3^2 \leq -\beta(p_2)\tau_2 + \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2, \quad \gamma(p)>0,$$

implies that $\tau_3^2 \leq \text{Const} \cdot \tau_2$, where the constant can be made as small as we please near p since $\beta(p)=0$ and since η occurs with a factor τ_2^2 . We denote constants of this type by ε . We will not indicate changes in these constants in the notation, that is we freely use $C+C=C$, $\varepsilon \cdot C=\varepsilon$, etc. Another technical problem is to keep track of higher-order terms. Whenever possible we will absorb cubic remainders at γ or η terms. This can be done since $\gamma(p)\neq 0$ and $\eta(p)\neq 0$. Therefore these terms are large relative to the time along trajectories near p . We also use the notation $\tilde{\tau}_i$ for terms of order $\tau_i(1+O(1))$.

(i) Since the conditions of this case are invariant under $\text{Sym } 1$, it suffices to exclude $YXYXY$ -concatenations. If the first switching point is p_0 , we get from (4.1) as necessary condition $\alpha(p_1) \geq \frac{1}{2}\tilde{\gamma}(p_1)\tau_1$. We use this in (3.11) to say

$$(5.7) \quad -\frac{1}{2}\tilde{\gamma}(p_1)\tau_1\tau_3 + \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2 + O(\tau_3^3, \tau_3^2\tau_2) \geq 0.$$

Notice that this condition is violated if τ_2 and τ_3 are comparable since then $\eta\tau_2^2$ dominates the remainders. We distinguish the cases

- (a) $\alpha(p_2) \leq -\frac{1}{4}\gamma(p_2)\tau_3$
- and
- (b) $\alpha(p_2) > -\frac{1}{4}\gamma(p_2)\tau_3$.

In case (a) we have

$$\begin{aligned} -\frac{1}{4}\tilde{\gamma}(p_1)\tau_3 &= -\frac{1}{4}\tilde{\gamma}(p_2)\tau_3 \geq \tilde{\alpha}(p_2) = \tilde{\alpha}(p_1) + \delta(p_1)\tau_2 + O(\tau_2^2) \\ &\geq \frac{1}{2}\tilde{\gamma}(p_1)\tau_1 + \tilde{\delta}(p_1)\tau_2 + O(\tau_2^2). \end{aligned}$$

This can hold only if $\delta(p) \leq 0$ and it then implies $\tau_3 \leq C\tau_2$. We now combine (3.11) and $-\alpha(p_3)\tau_3 + \frac{1}{2}\tilde{\gamma}(p_3)\tau_3^2 \leq 0$, which follows from (4.1). If we transport the functions back to p_1 , this gives as necessary condition for a $XYXY(p_1)$ trajectory that

$$(5.8) \quad -\frac{1}{2}\gamma(p_1)\tau_3^2 - \tilde{\delta}(p_1)\tau_2\tau_3 - \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2 \leq 0.$$

This implies $\tau_2 \leq C\tau_3$ and so τ_2 and τ_3 are comparable, i.e., (5.7) is violated. We now treat case (b). Observe that the conjugate point relations (3.4) and (3.10) are equivalent to

$$(5.9) \quad 0 = \tilde{\alpha}(p_1)\tau_1 + \tilde{\beta}(p_1)\tau_2 - \frac{1}{3}\tilde{\gamma}(p_1)\tau_1^2 + \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2,$$

$$(5.10) \quad 0 = \tilde{\alpha}(p_2)\tau_3 + \tilde{\beta}(p_2)\tau_2 + \frac{1}{3}\tilde{\gamma}(p_2)\tau_3^2 - \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2.$$

If we let $r_1 := p_1 e^{-(1/3)\tau_1 X}$, $r_2 := p_1 e^{(1/3)\tau_2 Y}$, $s_1 := p_2 e^{-(1/3)\tau_2 Y}$ and $s_2 := p_2 e^{(1/3)\tau_3 X}$, then we can also write

$$0 = \tilde{\alpha}(r_1)\tau_1 + \tilde{\beta}(r_2)\tau_2 + O(3), \quad 0 = \tilde{\alpha}(s_2)\tau_3 + \tilde{\beta}(s_1)\tau_2 + O(3).$$

Therefore

$$(\tilde{\beta}(r_2) - \tilde{\beta}(s_1))\tau_2 = \tilde{\alpha}(s_2)\tau_3 - \tilde{\alpha}(r_1)\tau_1 + O(3) = (\tilde{\alpha}(s_2) - \tilde{\alpha}(r_1))\tau_3 + \tilde{\alpha}(r_1)(\tau_3 - \tau_1) + O(3)$$

and thus

$$(5.11) \quad -\frac{1}{3}\tilde{\eta}(p_1)\tau_2^2 = (\frac{1}{3}\tilde{\gamma}(p_1)\tau_1 + \tilde{\delta}(p_1)\tau_2 + \frac{1}{3}\tilde{\gamma}(p_1)\tau_3)\tau_3 + \tilde{\alpha}(r_1)(\tau_3 - \tau_1) + O(3).$$

In case (b) (5.10) implies $-\tilde{\beta}(p_2)\tau_2 + \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2 \geq \frac{1}{12}\tilde{\gamma}(p_2)\tau_3^2$ and so $\tau_3^2 \leq \varepsilon\tau_2$. Therefore (5.7) yields both $\tau_1 \leq \varepsilon\tau_2$ and $\tau_2 \leq \varepsilon\tau_3$, in particular we can assume that $\tau_1 < \tau_3$. Since also $\tilde{\alpha}(r_1) = \tilde{\alpha}(p_1) - \frac{1}{3}\tilde{\gamma}(p_1)\tau_1 \geq \frac{1}{6}\tilde{\gamma}(p_1)\tau_1 > 0$ by (4.1), this implies

$$-\frac{1}{3}\tilde{\eta}(p_1)\tau_2^2 \geq (\tilde{\delta}(p_1)\tau_2 + \frac{1}{3}\tilde{\gamma}(p_1)\tau_3)\tau_3 \geq (\frac{1}{3}\tilde{\gamma}(p_1)\tau_3 - \varepsilon\tau_3)\tau_3 \geq \frac{1}{6}\tilde{\gamma}(p_1)\tau_3^2$$

and so $\tau_3 \leq C\tau_2$. But this contradicts $\tau_2 \leq \varepsilon\tau_3$ and thus $YXYXY$ -concatenations are not time-optimal near p .

(ii) The subcase when $\delta(p) \geq 0$ is easy. If we combine (3.5) with (4.2), where we transport the functions back to p_0 , we get as necessary condition for time optimality of $YXYX(p_0)$:

$$(5.12) \quad \frac{1}{3}\tilde{\gamma}(p_0)\tau_1^2 + \tilde{\delta}(p_0)\tau_1\tau_2 + \frac{1}{2}\tilde{\eta}(p_0)\tau_2^2 \leq 0.$$

This cannot hold if $\gamma(p) > 0$, $\eta(p) > 0$ and $\delta(p) \geq 0$. So let $\delta(p) < 0$. Then (5.12) implies that τ_1 and τ_2 are comparable. Analogously it follows that τ_3 and τ_4 are comparable. Near p also $\tau_3 \leq C\tau_1$ has to hold. This follows from (5.11) since it suffices to consider trajectories which satisfy $\tau_3 \geq \frac{4}{3}\tau_1$. Then $\tilde{\alpha}(r_1)(\tau_1 - \tau_3) > 0$ and we obtain $0 \geq \frac{1}{3}\tilde{\gamma}(p_1)\tau_1 + \tilde{\delta}(p_1)\tau_2 + \frac{1}{3}\tilde{\gamma}(p_1)\tau_3$ which implies even $\tau_1 + \tau_3 \leq C\tau_2$. We now fix some constant \hat{C} such that $\tau_3 \leq \hat{C}\tau_1$ is a necessary condition for time optimality near p . Let $\hat{\varepsilon} := \min(1/24, 1/24\hat{C})$ and choose a neighborhood of p such that (4.4) is valid for $\hat{\varepsilon}$.

This case becomes technical. Therefore we give the argument in a series of lemmas. The idea is to show that $YXYXY(p_0)$ is not time-optimal if $\tau_1 \leq \frac{3}{4}\tau_2$ and that $YXYXY(p_1)$ is not time-optimal if $\tau_4 \leq \frac{3}{4}\tau_2$. To combine the cases we will show that, if $\tau_1 > \frac{3}{4}\tau_2$, then necessarily $\tau_4 \leq \frac{3}{4}\tau_2$.

LEMMA 2. *A necessary condition for time optimality of $YXYXY(p_0)$ is*

$$(5.13) \quad \frac{1}{3}\tilde{\gamma}(p_1)\tau_1 + \tilde{\delta}(p_2)\tau_2 + \frac{1}{2}\tilde{\gamma}(p_1)\tau_3 \leq 0.$$

Proof. We subtract (5.9) from (5.10), cancelling out $\beta(p_1)\tau_2$ exactly by adjusting the error terms, and rearrange to get

$$0 = \tilde{\alpha}(p_1)(\tau_3 - \tilde{\tau}_1) + \frac{1}{3}\tilde{\gamma}(p_1)(\tau_1^2 + \tilde{\tau}_3^2) + \tilde{\delta}(p_1)\tau_2\tau_3 + \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2.$$

Using $\tilde{\alpha}(p_1) \geq \frac{7}{12}\tilde{\gamma}(p_1)\tau_1 > 0$, which follows from (4.4), and (3.9), transported back to p_1 , we obtain

$$(5.14) \quad \begin{aligned} 0 &\geq \frac{7}{12}\tilde{\gamma}(p_1)\tau_1\tau_3 + \frac{1}{3}\tilde{\gamma}(p_1)(\tau_1^2 + \tilde{\tau}_3^2) + \tilde{\delta}(p_1)\tau_2(\tau_1 + \tilde{\tau}_3) + \frac{2}{3}\tilde{\eta}(p_1)\tau_2^2 \\ &= (\frac{1}{3}\tilde{\gamma}(p_1)\tau_1 + \tilde{\delta}(p_1)\tau_2 + \frac{1}{2}\tilde{\gamma}(p_1)\tau_3)\tau_1 + \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2 \\ &\quad + ((\frac{1}{3} + \hat{\varepsilon})\tilde{\gamma}(p_1)\tau_3^2 + \tilde{\delta}(p_1)\tau_2\tau_3 + \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2) + \tilde{\gamma}(p_1)\tau_3(\frac{1}{12}\tau_1 - \hat{\varepsilon}\tilde{\tau}_3). \end{aligned}$$

By our choice of $\hat{\varepsilon}$ the last term is positive. From (4.4) we have $\alpha(p_1) \geq (\frac{2}{3} - \hat{\varepsilon})\tilde{\gamma}(p_1)\tau_1$ and if we combine this with (3.11) we obtain

$$(5.15) \quad (\frac{1}{3} + \hat{\varepsilon})\tilde{\gamma}(p_1)\tau_3^2 + \tilde{\delta}(p_1)\tau_2\tau_3 + \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2 \geq 0.$$

Clearly the perturbations at these terms need not be the same as at the corresponding terms in (5.14). But we can assume to have exactly the same expression $(\frac{1}{3} + \hat{\varepsilon})\tilde{\gamma}(p_1)\tau_3^2$ and so any higher-order perturbations which come up when we use (5.15) in (5.14) have the factor τ_2 . Since τ_2 is comparable to τ_1 we even conclude

$$0 \geq (\frac{1}{3}\tilde{\gamma}(p_1)\tau_1 + \tilde{\delta}(p_1)\tau_2 + \frac{1}{2}\tilde{\gamma}(p_1)\tau_3)\tau_1 + \frac{1}{3}\tilde{\eta}(p_1)\tau_2^2. \quad \square$$

LEMMA 3. If $\tau_1 \leq \frac{3}{4}\tau_3$, then a necessary condition for time optimality of $YXYXY(p_0)$ is

$$(5.16) \quad \frac{5}{12}\tilde{\gamma}(p_2)\tau_1 + \tilde{\delta}(p_2)\tau_2 + \frac{5}{12}\tilde{\gamma}(p_2)\tau_3 \geq 0.$$

Proof. Combining the strengthened approximating cone condition $\alpha(p_1) \geq \frac{7}{12}\tilde{\gamma}(p_1)\tau_1$ with (3.9) and with (3.11) we get

$$(5.17) \quad \frac{7}{12}\tilde{\gamma}(p_2)\tau_1^2 + \tilde{\delta}(p_2)\tau_1\tau_2 + \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2 \leq 0,$$

$$(5.18) \quad -\frac{5}{12}\tilde{\gamma}(p_2)\tau_3^2 - \tilde{\delta}(p_2)\tau_3\tau_3 - \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2 \leq 0.$$

We add (5.17) and (5.18), cancel out $\eta(p_2)\tau_2^2$ exactly and rearrange terms. This yields

$$(\frac{1}{12}\tilde{\gamma}(p_2)(7\tau_1 + 5\tilde{\tau}_3) + \tilde{\delta}(p_2)\tau_2)(\tau_1 - \tilde{\tau}_3) + \frac{1}{6}\tilde{\gamma}(p_2)\tau_1\tau_3 \leq 0.$$

Since $\tau_1 - \tau_3 \leq -\frac{1}{4}\tau_3 < 0$, the term at $(\tau_1 - \tilde{\tau}_3)$ is nonnegative and so (5.16) follows from $(\frac{1}{12}\tilde{\gamma}(p_2)(7\tau_1 + 5\tilde{\tau}_3) + \tilde{\delta}(p_2)\tau_2)\tau_1 \geq 0$. \square

But relations (5.13) and (5.16) are contradictory near p . Therefore $YXYXY(p_0)$ trajectories are not time-optimal if $\tau_1 \leq \frac{3}{4}\tau_3$.

Next we will show that, if $\tau_1 > \frac{3}{4}\tau_3$, then necessarily $\tau_4 \leq \frac{3}{4}\tau_2$. We first remark that (3.11) is equivalent to

$$\tilde{\alpha}(p_1)\tau_3 - \frac{1}{3}\tilde{\gamma}(p_1)\tau_3^2 - \tilde{\beta}(p_3)\tau_2 - \frac{1}{3}\tilde{\eta}(p_3)\tau_2^2 \leq 0.$$

This follows if we use the conjugate point relation (3.10) and $\beta(p_3) = \beta(p_1) + \tilde{\delta}(p_1)\tau_3 + \tilde{\eta}(p_1)\tau_2$. The approximating cone condition (4.4) implies

$$\tilde{\alpha}(p_1)\tau_3 - \frac{1}{3}\tilde{\gamma}(p_1)\tau_3^2 \geq \tilde{\gamma}(p_1)\tau_3(\frac{7}{12}\tau_1 - \frac{1}{3}\tilde{\tau}_3) > 0$$

and therefore $\beta(p_3) + \frac{1}{3}\tilde{\eta}(p_3)\tau_2 \geq 0$. Let $q := p_4 e^{-(1/3)\tau_4 Y}$. Then we have

$$\beta(q) = \beta(p_3) + \frac{2}{3}\tilde{\eta}(p_3)\tau_4 \geq \frac{1}{3}\tilde{\eta}(p_4)(2\tau_4 - \tilde{\tau}_2)$$

and from (4.4) (along Y , τ_4) we get also

$$\beta(q) = \beta(p_4) - \frac{1}{3}\tilde{\eta}(p_4)\tau_4 \leq \frac{1}{2}\tilde{\eta}(p_4)\tau_4 - \frac{1}{3}\tilde{\eta}(p_4)\tau_4 = \frac{1}{6}\tilde{\eta}(p_4)\tau_4.$$

This implies $\tau_4 \leq \frac{2}{3}\tilde{\tau}_2$, i.e., $\tau_4 \leq \frac{3}{4}\tau_2$ for small times.

LEMMA 4. If $\tau_4 \leq \frac{3}{4}\tau_2$, then a necessary condition for time optimality of $YXYXY(p_1)$ is that

$$(5.19) \quad \frac{1}{3}\tilde{\eta}(p_2)\tau_2 + \tilde{\delta}(p_2)\tau_3 + \frac{1}{4}\tilde{\eta}(p_2)\tau_4 \geq 0.$$

Proof. We now combine (5.18) with the analogous version of (5.17) for τ_3 and τ_4 in the form

$$\frac{7}{12}\tilde{\gamma}(p_2)\tau_3^2 + \tilde{\delta}(p_2)\tau_3\tau_4 + \frac{1}{3}\tilde{\eta}(p_2)\tau_4^2 \leq 0.$$

We can evaluate at p_2 since the change from p_4 to p_2 produces only higher-order perturbations. We cancel out the term $\gamma(p_2)\tau_3^2$ exactly to get

$$0 \leq (\frac{1}{3}\tilde{\eta}(p_2)\tau_2 + \tilde{\delta}(p_2)\tau_3 + \frac{1}{3}\tilde{\eta}(p_2)\tau_4)(7\tau_2 - 5\tilde{\tau}_4) - \frac{2}{3}\tilde{\eta}(p_2)\tau_2\tau_4.$$

Since $7\tau_2 - 5\tilde{\tau}_4 > 0$ we have $(\frac{1}{3}\tilde{\eta}(p_2)\tau_2 + \tilde{\delta}(p_2)\tau_3 + \frac{1}{3}\tilde{\eta}(p_2)\tau_4)(-5\tilde{\tau}_4) < 0$ and the result follows if we simply omit this term. \square

LEMMA 5. *If $\tau_4 \leq \frac{3}{4}\tau_2$, then a necessary condition for time optimality of $XYXYX(p_1)$ is that*

$$(5.20) \quad \frac{1}{3}\tilde{\eta}(p_2)\tau_2 + \tilde{\delta}(p_2)\tau_3 + \frac{1}{3}\tilde{\eta}(p_2)\tau_4 \leq 0.$$

Proof. Applying Sym 1 to (5.11), we get the corresponding relation for a $XYXYX(p_2)$ concatenation, namely

$$(5.21) \quad \frac{1}{3}\tilde{\gamma}(p_2)\tau_3^2 = -(\frac{1}{3}\tilde{\eta}(p_2)\tau_2 + \tilde{\delta}(p_2)\tau_3 + \frac{1}{3}\tilde{\eta}(p_2)\tau_4)\tau_4 - \beta(\bar{r}_1)(\tau_4 - \tau_2) + O(3)$$

where $\bar{r}_1 = p_2 e^{-(1/3)\tau_2 Y}$ and we choose to make this term exact. Here all cubic remainders can be absorbed at the quadratic terms except for those which have a factor τ_2^2 . This causes a little inconvenience and we split into the subcases (a) $-\beta(\bar{r}_1) \leq \frac{1}{6}\eta(p_2)\tau_2$ and (b) $-\beta(\bar{r}_1) > \frac{1}{6}\eta(p_2)\tau_1$. In case (b) we have in particular $\beta(\bar{r}_1) < 0$ and thus

$$-\beta(\bar{r}_1)(\tau_4 - \tau_2) + \tau_2^2 \cdot O(1) \leq \frac{1}{4}\beta(\bar{r}_1)\tau_2 + \varepsilon\tau_2^2 \leq (-\frac{1}{24}\eta(p_2) - \varepsilon)\tau_2^2 < 0.$$

Therefore (5.20) follows from (5.21). In case (a) we have

$$\frac{1}{6}\eta(p_2)\tau_2 \geq -\beta(\bar{r}_1) \geq \tilde{\delta}(p_2)\tau_3 + \frac{1}{3}\tilde{\eta}(p_2)\tau_2$$

since $\beta(p_3) \leq 0$. Thus $\tau_2 \leq C\tau_3$. Therefore the $\tau_2^2 \cdot O(1)$ terms can be compensated through $\gamma\tau_3^2$ on the left-hand side. As above, the lemma therefore follows from (5.21) if $\beta(\bar{r}_1) \leq 0$. So we assume $\beta(\bar{r}_1) > 0$. Now we need to bound $\beta(\bar{r}_1)\tau_2$ above. We use the analogue of (5.9) for τ_3 and τ_4 and $\alpha(p_3)\tau_3 \geq \frac{7}{12}\tilde{\gamma}(p_3)\tau_3$, which follows from (4.4), to bound

$$-\beta(p_3)\tau_4 \geq \frac{1}{4}\tilde{\gamma}(p_3)\tau_3^2 + \frac{1}{3}\tilde{\eta}(p_3)\tau_4^2 = \frac{1}{4}\tilde{\gamma}(p_2)\tau_3^2 + \frac{1}{3}\tilde{\eta}(p_2)\tau_4^2.$$

Using $\tau_4 \leq \frac{3}{4}\tau_2$ we therefore get

$$\begin{aligned} \tilde{\beta}(\bar{r}_1)\tau_2 &= \tilde{\beta}(p_3)\tau_2 - \tilde{\delta}(p_3)\tau_2\tau_3 - \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2 \\ &\leq -\frac{1}{3}\tilde{\gamma}(p_2)\tau_3^2 - \tilde{\delta}(p_2)\tau_2\tau_3 - \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2 - \frac{4}{9}\tilde{\eta}(p_2)\tau_4^2. \end{aligned}$$

We substitute this into (5.21) and compensate $\varepsilon\tau_2^2$ through $\gamma\tau_3^2$ to obtain

$$\begin{aligned} -(\frac{1}{3}\tilde{\eta}(p_2)\tau_2 + \tilde{\delta}(p_2)\tau_3 + \frac{1}{3}\tilde{\eta}(p_2)\tau_4)\tau_4 &\geq \frac{1}{6}\tilde{\gamma}(p_2)\tau_3^2 - \beta(\bar{r}_1)\tau_2 \\ &\geq \frac{1}{2}\tilde{\gamma}(p_2)\tau_3^2 + \tilde{\delta}(p_2)\tau_2\tau_3 + \frac{1}{3}\tilde{\eta}(p_2)\tau_2^2 + \frac{4}{9}\tilde{\eta}(p_2)\tau_4^2 \\ &\geq \frac{1}{12}\tilde{\gamma}(p_2)\tau_3^2 + \frac{4}{9}\tilde{\eta}(p_2)\tau_4^2 - \varepsilon\tau_2^2 \end{aligned}$$

where the last inequality follows from (5.18). Again we can compensate $-\varepsilon\tau_2^2$ through $\gamma\tau_3^2$ and so the right-hand side is positive. This proves the lemma. \square

Relations (5.19) and (5.20) imply as necessary condition near p that $\tau_4 \leq \varepsilon\tau_3$. This contradicts the fact that τ_3 and τ_4 are comparable. Q.E.D.

The proofs for the remaining generic cases—codimension 3 when $\alpha(p)$ and $\beta(p)$ vanish—are longer and much more technical. Therefore we do not even attempt to give an outline here. Complete and detailed proofs can be found in the author's doctoral dissertation [11].

A MAXIMUM PRINCIPLE FOR OPTIMAL PROCESSES WITH DISCONTINUOUS TRAJECTORIES*

R. B. VINTER[†] AND F. M. F. L. PEREIRA[‡]

Abstract. A Maximum Principle is proved which governs solutions to dynamic optimization problems in which the controls driving the system may be impulsive and give rise to discontinuous trajectories. The approach, which involves approximating the problem by a conventional one and using Ekeland's theorem, is new. It permits us to weaken very considerably the hypotheses under which Maximum Principles for such problems have previously been proved.

Key words. optimal control, impulse control, Maximum Principle

AMS(MOS) subject classifications. 49B10, 49B34

1. Introduction. We give necessary conditions for optimality, in the form of a Maximum Principle, for an optimal control problem (we label it (P)) in which the state trajectories are permitted to be functions of bounded variation and the control policies incorporate measures:

$$\text{Minimize} \quad h(x(1)) + \int_0^1 f_0(t, x(t), u(t)) \, dt + \int_{[0,1]} g_0(t, u(t)) \mu(dt)$$

$$\text{subject to} \quad dx(t) = f(t, x(t), u(t)) \, dt + G(t, u(t)) \mu(dt) \quad \text{on } [0, 1],$$

$$x(0) \in C_0, \quad x(1) \in C_1,$$

$$u(t) \in \Omega_t \quad \mu \text{ and } \mathcal{L}\text{-a.e.}$$

and

$$\text{Range } \{\mu\} \subset K.$$

Here,

$$f_0: [0, 1] \times R^n \times R^m \rightarrow R, \quad g_0: [0, 1] \times R^m \rightarrow R^k,$$

$$f: [0, 1] \times R^n \times R^m \rightarrow R^n, \quad G: [0, 1] \times R^m \rightarrow R^{n \times k}$$

are given functions,

C_0, C_1 are closed subsets of R^n ,

Ω is a subset of $[0, 1] \times R^m$ (Ω_t denotes the section $\{u: (u, t) \in \Omega\}$), and

K is a closed convex cone in R^k .

To be more precise, we define a pair of elements (u, μ) to be a control policy if μ is a K valued regular measure on \mathcal{B} (\mathcal{B} denotes the Borel subsets of $[0, 1]$), $u(\cdot): [0, 1] \rightarrow R^m$ is a Borel measurable function such that

$$\mu(A) \in K \quad \text{for all } A \in \mathcal{B},$$

$$u(t) \in \Omega_t,$$

almost everywhere with respect to both μ and Lebesgue measure, and if the function $t \rightarrow G(t, u(t))$ has a μ integrability property made precise in § 2.

A trajectory, $x: [0, 1] \rightarrow R^n$ (associated with a control policy (u, μ)), is a function of bounded variation such that

$$x(t) = x(0) + \int_0^t f(s, x(s), u(s)) ds + \int_{[0, t]} G(s, u(s)) \mu(ds)$$

for all $t \in (0, 1]$. A trajectory and a control policy with which it is associated, (x, u, μ) , is called a control process.

Problem (P) then is that of minimizing the functional

$$h + \int_0^1 f_0 dt + \int_{[0, 1]} g_0 \mu(dt)$$

over control processes for which $t \rightarrow g_0(t, u(t))$ is μ integrable and which satisfy the endpoint constraints $x(0) \in C_0$ and $x(1) \in C_1$. A minimizing control process is called an optimal process. The components are called "optimal trajectory," etc.

This problem is an extension of a control problem of a conventional kind, denoted (P'), where some components w of the control vector $\text{col}(u, w)$ (i.e., $[u^T \mid w^T]^T$) enter linearly into the cost and dynamics and the values of w are unbounded in certain directions:

$$\text{Minimize } h(x(1), x(0)) + \int_0^1 (f_0(t, x(t), u(t)) + g_0(t, u(t))w(t)) dt$$

$$\text{subject to } \dot{x}(t) = f(t, x(t), u(t)) + G(t, u(t))w(t) \quad \text{a.e. } t \in [0, 1],$$

$$(u(t), w(t)) \in \Omega_t \times K \quad \mathcal{L}\text{-a.e.},$$

$$x(0) \in C_0, \quad x(1) \in C_1.$$

Certain problems arising in midcourse guidance of space vehicles [6], [7], [9], [11], and also in resource economics [2], can be formulated in this way. A noteworthy feature of such problems is that minimizing sequences of trajectories can be expected to have accumulation point functions which are of bounded variation, but not absolutely continuous as in the standard theory. The framework adopted in this paper is one in which the usual class of admissible trajectories is enlarged to include those of bounded variation. Indeed we can view the processes for (P') as a subclass of the processes for (P), via the embedding

$$(x, u, w) \rightarrow (x, u, \mu)$$

where μ is the measure

$$\mu(A) = \int_A w(s) ds.$$

Extra hypotheses can be given under which (P) is a proper extension to (P') in the sense that the existence of solutions to (P) is guaranteed and the infimum cost for (P') coincides with the infimum cost for (P). Results of this nature, but developed in a somewhat different framework, are to be found in [8], [12] and [13]. We do not impose such hypotheses here, but rather strive to provide the weakest hypotheses our methods permit under which necessary conditions can be formulated and proved. This is not to deny the desirability of having a proper extension. Necessary conditions, valid under weak hypotheses which do not guarantee the extension considered is proper, are valuable for several reasons however. Special features of the optimal control problem at hand might permit one to deduce the extension is proper even though

hypotheses of available theorems for properness, directed at a broad class of problems, are not satisfied. Necessary conditions also have a bearing on the question of regularity of solutions: if the necessary conditions lead to a contradiction, then no solutions exist with regularity for the minimizing process to which the necessary conditions apply.

Optimality conditions for problem (P) have already been supplied by Rishel [11]. We now briefly comment on the techniques used by Rishel, in order to call attention to the advantages of the novel methods of this paper.

Rishel's approach is to introduce a new independent variable, with respect to which trajectories become absolutely continuous. This leads to consideration of an auxiliary optimal control problem in which the time variable now has the role of a component of the state variable. The auxiliary problem has the character of a conventional free-time optimal control problem. Under a so-called "constancy" hypothesis, we can associate with an optimal process for the original problem an optimal process for the auxiliary problem. (In the case that the measures are scalar valued and $K = R^+$, a simple version of the constancy hypothesis is

$$(1.1) \quad \overline{\text{co}} \tilde{g}(t, \Omega_t) \subset \bigcup_{0 \leq \alpha \leq 1} \alpha \tilde{g}(t, \Omega_t) \quad \text{for all } t \in [t_0, t_1].$$

Here $\tilde{g} := \text{col}(g_0, g_1)$.)

This permits us to apply the standard Maximum Principle to the associated process and thence to deduce optimality conditions for the original optimal process.

Now, in order to follow through this programme, we require, in addition to other hypotheses,

$$(1.2) \quad \Omega_t = \tilde{\Omega} \quad \text{for all } t \in [t_0, t_1] \quad (\text{where } \tilde{\Omega} \text{ is fixed})$$

and

$$(1.3) \quad f, G, f_0, g_0 \quad \text{are regular in their } t\text{-dependence.}$$

(By "regular" we mean here "at least Lipschitz continuous.") These arise because time becomes a component of the state variable in the auxiliary problem and, except in special circumstances, the conventional Maximum Principle, which we need to apply to the auxiliary problem, is valid only when the data are regular in the state variable and the control constraint set does not depend on the state.

By contrast with what is achievable by Rishel's approach, we prove a Maximum Principle for (P) in which the data are merely required to be measurable in t , time dependency of the control constraint is permitted and the constancy hypothesis (1.1) is dispensed with altogether. The character of our optimality conditions is new too, since Rishel's Maximum Principle involves time derivatives of the data and consequently does not even make sense when the data are not regular in t .

Quite different methods are required then for the proof of the results of the present paper; our approach is to *approximate* the extended problem by a conventional optimal control problem in a manner which does not involve change of the independent variable, and to use limiting arguments based on Ekeland's theorem.

Warga has also provided necessary conditions for optimal control problems with discontinuous trajectories [14], [15]. Warga's approach is essentially to view Rishel's auxiliary problem as a relaxed version of the original optimal control problem and to give necessary conditions on optimal processes for the relaxed problem. Clearly there is no need here for a constancy hypothesis, since we are no longer concerned to translate optimal relaxed processes back into processes for the original problem. Warga then addresses a different problem, and his conditions cannot be compared directly

with ours. Note, however, that Warga invokes hypotheses (1.2) and (1.3) since time in the auxiliary problem is a component of the state.

We mention too that optimality conditions for problems with discontinuous trajectories, when the data is required to be merely measurable in t , are given by Rockafellar [12], [13] (in addition to duality interpretations of the multipliers arising and hypotheses for properness). Rockafellar, however, limits attention to generalized Bolza problems having Lagrangians jointly convex in the (x, \dot{x}) variables, a restriction which is not present here.

Finally, we mention that the results of this paper can be extended in a number of directions, notably to accommodate an affine state inequality constraint of the form

$$A(t)x(t) + b(t) \leq 0 \quad \text{for all } t \in [0, 1].$$

Some refinements appear in [10].

2. Preliminaries. We shall denote the Borel subsets of R^k by \mathcal{B}^k , the Borel subsets of $[0, 1]$ by \mathcal{B} and the Lebesgue subsets of $[0, 1]$ by \mathcal{L} . The symbol \mathcal{L} also refers to Lebesgue measure, as when we write \mathcal{L} -a.e. (meaning “almost everywhere with respect to the Lebesgue measure”), \mathcal{L} -meas (A) (meaning the “Lebesgue measure of A ”), etc.

We refer to signed, regular measures (on some extension of the Borel subsets of $[0, 1]$) briefly as measures. $C^*(R^k)$ denotes the usual linear space comprising k tuples of measures. We write C^* for $C^*(R^1)$. C^\oplus is the class of nonnegative scalar valued measures.

All norms are written $\|\cdot\|$. In R^k the norm is the Euclidean norm. In $C^*(R^k)$ the norm is the sum of the total variations of the component measures.

We denote by B the unit ball in Euclidean space.

As is well known, there is a one-to-one correspondence between elements in $C^*(R^k)$ and k -vector valued functions of bounded variation on $[0, 1]$ which are right continuous on $[0, 1]$. To indicate that a function x is to be associated with a measure $\mu \in C^*(R^k)$ we write

$$dx(t) = \mu(dt).$$

This may be viewed as a shorthand for

$$\int_0^s dx(t) = \int_{[0,s]} \mu(dt) \quad \text{for all } s \in [0, 1]$$

in which the first integral is a Stieltjes integral.

Given $\mu \in C^*(R^k)$, $|\mu|$, the “total variation measure” denotes the element in C^\oplus :

$$|\mu| = \sum_i \mu_i^+ + \sum_i \mu_i^-$$

where $\mu_i = \mu_i^+ - \mu_i^-$ is the Jordan decomposition of the i th component μ_i of μ .

The notation

$$\mu_j \xrightarrow{*} \mu$$

indicates weak* convergence. If the measures are scalar valued this means

$$\int_{[0,1]} h(t) \mu_j(dt) \rightarrow \int_{[0,1]} h(t) \mu(dt) \quad \text{as } j \rightarrow \infty$$

for every continuous function h on $[0, 1]$. When the measures are vector valued we require weak* convergence of the components as just defined.

It is convenient at this stage to comment on our interpretation of integrals of the form

$$\int_A g(t) \cdot \mu(dt) \quad \text{for } A \in \mathcal{B}$$

in which g and μ are both vector valued.

It would seem natural to take it to mean $\sum_i \int_A g_i(t) \mu_i(dt)$ (where g_i and μ_i are components) and to require g_i to be μ_i -integrable for $i=1, \dots, k$. However, transformations we employ in the proof of Theorem 4.1 compel us to adopt a slightly more general definition. Our approach here is to note that the components of μ are absolutely continuous with respect to the total variation measure $|\mu|$. Consequently we can define the Radon-Nikodym derivative w of μ with respect to $|\mu|$. We summarize the relationships involved by writing

$$\mu(dt) = w(t)|\mu|(dt).$$

The k vector valued function g will be said to be μ integrable if $t \rightarrow |g(t) \cdot w(t)|$ is integrable with respect to $|\mu|$. If g is μ integrable we define $\int_A g(t) \cdot \mu(dt)$ to be

$$\int_A g(t) \cdot \mu(dt) := \int_A g(t) \cdot w(t) |\mu|(dt),$$

where the right-hand side is the usual integral. (The extra generality arises because the earlier definition requires each $g_i w_i$ to be $|\mu|$ integrable, whereas (2.1) permits components which are not integrable to cancel out in the inner product $g \cdot w$.) This definition should be borne in mind when, for example, we interpret components of the term

$$\int_{[0,1]} G(t, u(t)) \mu(dt)$$

in the state equation.

We shall use the concept of continuity set. Take $\mu \in C^\oplus$. A Borel set $A \subset [0, 1]$ is a μ continuity set [1] if $\mu(\partial A) = 0$, where ∂A is the relative boundary of A .

Given a locally Lipschitz continuous function $\phi: R^p \rightarrow R^q$, $\partial\phi$ is the generalized Jacobian (or generalized gradient in the case $q=1$), as defined by Clarke [4, § 2.6]. If $C \subset R^k$ is a given closed subset and $s \in C$ then $N_C(s)$ is the normal cone to C at s in the sense of Clarke [4, p. 11]. We denote by d_C the Euclidean distance function from the set C .

Let $D \subset R^k$ be a given subset. Then σ_D is the support function of the set D :

$$\sigma_D(e) = \max \{e \cdot d : d \in D\}.$$

3. Hypotheses. We state here the hypotheses on the data invoked in the Maximum Principle to follow. The function x^* referred to in hypothesis H4 will be the trajectory under consideration (either an optimal trajectory or one associated with a boundary point of the reachable set).

H1 Given $\delta > 0$, there exists $K_\delta \in L^1$ such that

$$\|f(t, x, u) - f(t, y, u)\| \leq K_\delta(t) \|x - y\|$$

when $\|x\|, \|y\| \leq \delta$, $u \in \Omega_t$ and $t \in [0, 1]$.

H2 The function $(t, u) \rightarrow f(t, x, u)$ is $\mathcal{L} \times \mathcal{B}^m$ measurable for each x (where $\mathcal{L} \times \mathcal{B}^m$ denotes the product σ -algebra of \mathcal{L} and \mathcal{B}^m).

H3 The subset $\Omega \subset R^{m+1}$ is Borel measurable.

H4 There exists $\alpha \in L^1$ such that

$$\sup \{ \|f(t, x^*(t), u)\| : u \in \Omega_t \} \leq \alpha(t) \quad \mathcal{L}\text{-a.e.}$$

H5 $h(\cdot)$ is locally Lipschitz continuous.

H6 The multifunction Γ on $[0, 1]$, defined by

$$\Gamma(t) = \overline{\text{co}} \left\{ \frac{G(t, u)w}{1 + \sum_i |\sum_j g_{ij}(t, u)w_j|} : u \in \Omega_t, w \in K \cap \{\xi : |\xi_i| \leq 1\} \right\}$$

is continuous with respect to the Hausdorff metric on the compact, convex subsets of R^n . ($\overline{\text{co}}$ denotes closed convex hull.)

Hypotheses H1–H5 are slightly strengthened forms of standard hypotheses under which the Maximum Principle has been derived in the absence of singular terms (see, e.g., [4, Thm. 5.2.1]). The most notable difference is that hypothesis H4, a uniform integrability condition on the dynamics at the optimal trajectory, is added here. We can drop hypothesis H4 in many cases of interest and, in particular, when the singular and nonsingular terms in the dynamics separate, i.e., when the control variable u comprises two vector components $u = \text{col}(v, w)$,

$$\Omega_t = \{\text{col}(v, w) : v \in V_t, w \in W_t\}$$

and

$$f(t, x, (v, w)) = \tilde{f}(t, x, v), \quad g(t, (v, w)) = \tilde{g}(t, w)$$

for sets V and W and functions \tilde{f} and \tilde{g} . (An argument along the lines of [4, p. 207] is involved.) Of course, this last case subsumes the conventional control problem (no singular term).

The remaining hypothesis, H6, is a kind of continuity condition on a compactification of the singular term in the dynamics. It is automatically satisfied by autonomous systems and also by problems where the multifunction $t \rightarrow G(t, \Omega_t)$ is uniformly bounded on $[0, 1]$ and continuous in the sense of Kuratowski.

4. The main results. Necessary conditions are first given for processes associated with boundary points of a reachable set. The new Maximum Principle for problem (P) will follow directly from these.

Let $\Psi : R^n \rightarrow R^q$ be a locally Lipschitz continuous function. We define the Ψ reachable set, R_Ψ , to be

$$R_\Psi = \{\Psi(x(1)) : (x, u, \mu) \text{ is some control process and } x(0) \in C_0\}.$$

A control process (x, u, μ) such that $x(0) \in c_0$ and $\Psi(x(1))$ is a boundary point of R_Ψ is called a Ψ boundary process.

We denote by H the unmaximized Hamiltonian function:

$$H(t, x, u, p) := p \cdot f(t, x, u).$$

THEOREM 4.1. *Let the data satisfy hypotheses H1–H6, and let (x^*, u^*, μ^*) be a Ψ boundary process.*

Then there exists an absolutely continuous function p and a nonzero vector $d \in R^k$ such that

$$\begin{aligned}
 & -\dot{p}(t) \in \partial_x H(t, x^*(t), u^*(t), p(t)) \quad \mathcal{L}\text{-a.e.}, \\
 & -p(1) \in d \cdot \partial \Psi(x^*(1)), \\
 & p(0) \in N_{C_0}(x^*(0)), \\
 & H(t, x^*(t), u^*(t), p(t)) = \max \{H(t, x^*(t), u, p(t)) : u \in \Omega_t\} \quad \mathcal{L}\text{-a.e.}, \\
 (4.1) \quad & \sup \{\sigma_K(p(t) \cdot G(t, u)) : u \in \Omega_t\} \leq 0 \quad \text{all } t \in [0, 1]
 \end{aligned}$$

and

$$(4.2) \quad \sigma_K(p(t) \cdot G(t, u^*(t))) = 0 \quad \mu^*\text{-a.e.}$$

Here σ_K denotes the support function of the set K defined in § 2 and ∂_x is the generalized gradient in the state variable.

For purposes of comparison with some of the earlier literature (notably [11]) and because later we must refer to this special case, we note that the two conditions (4.1) and (4.2), which give information about the measure μ in Theorem 4.1, take the following form when μ is scalar valued and $K = [0, \infty)$. In this case, (4.1) and (4.2) become

$$\sup_{u \in \Omega_t} \{p(t) \cdot G(t, u)\} \leq 0 \quad \text{for all } t \in [0, 1]$$

and

$$p(t) \cdot G(t, u^*(t)) = 0, \quad \mu^*\text{-a.e.}$$

respectively.

And now a Maximum Principle for problem (P). Here we take \tilde{H} to be the unmaximized Hamiltonian function arising in this problem:

$$\tilde{H}(t, x, u, p, \lambda) := p \cdot f(t, x, u) - \lambda f_0(t, x, u).$$

THEOREM 4.2. *Let hypotheses H1-H6 be satisfied when the functions $\text{col}(f_0, f)$ and $\text{col}(g_0, G)$ are inserted into the conditions in place of f and G . Suppose that (x^*, u^*, μ^*) is an optimal process.*

Then there exists an absolutely continuous function p and a nonnegative number λ , $\|p\|_{L_\infty} + \lambda \neq 0$, such that

$$\begin{aligned}
 & -\dot{p}(t) \in \partial_x \tilde{H}(t, x^*(t), u^*(t), p(t), \lambda) \quad \mathcal{L}\text{-a.e.}, \\
 & -p(1) \in \lambda \partial h(x^*(1)) + N_{C_1}(x^*(1)), \\
 & p(0) \in N_{C_0}(x^*(0)), \\
 & \tilde{H}(t, x^*(t), u^*(t), p(t), \lambda) = \max_{u \in \Omega_t} \{\tilde{H}(t, x^*(t), u, p(t), \lambda)\} \quad \mathcal{L}\text{-a.e.}, \\
 (4.3) \quad & \sup \{\sigma_K(p(t) \cdot G(t, u) - \lambda g_0(t, u)) : u \in \Omega_t\} \leq 0 \quad \text{for all } t \in [0, 1]
 \end{aligned}$$

and

$$(4.4) \quad \sigma_K(p(t) \cdot G(t, u^*(t)) - \lambda g_0(t, u^*(t))) = 0 \quad \mu^*\text{-a.e.}$$

We point out that, in the special case earlier alluded to ($K = [0, \infty)$), conditions (4.3) and (4.4) reduce to

$$(4.5) \quad \sup_{u \in \Omega_t} \{p(t) \cdot G(t, u) - \lambda g_0(t, u)\} \leq 0 \quad \text{for all } t \in [0, 1]$$

and

$$(4.6) \quad p(t) \cdot G(t, u^*(t)) - \lambda g_0(t, u^*(t)) = 0 \quad \mu^* \text{-a.e.}$$

We now prove, as claimed, that Theorem 4.2 is a simple consequence of Theorem 4.1.

Let (x^*, u^*, μ^*) be an optimal process for (P). Consider a new control system (S) in which the state vector $z = \text{col}(y, w, x)$ now comprises a scalar component y and n vector blocks w and x :

$$dy(t) = f_0(t, x(t), u(t)) dt + g_0(t, u(t)) \mu(dt),$$

$$dx(t) = f(t, x(t), u(t)) dt + G(t, u(t)) \mu(dt),$$

$$\frac{dw(t)}{dt} = 0,$$

$$(y(0), w(0), x(0)) \in [0, \infty) \times C_1 \times C_0.$$

Define the mapping $\tilde{\Psi}: R^{2n+1} \rightarrow R^{n+1}$ to be

$$\tilde{\Psi}(z) = \begin{bmatrix} y + h(x) \\ w - x \end{bmatrix}$$

and let $\tilde{R}_{\tilde{\Psi}}$ denote the $\tilde{\Psi}$ reachable set for (S).

Let us examine the control process π :

$$\pi := (z^* = (y^*, w^*, x^*), u^*, \mu^*)$$

for (S) in which (x^*, u^*, μ^*) is the optimal process for (P) under consideration, $w^*(\cdot) \equiv x^*(1)$ and

$$y^*(t) = \int_0^t f_0(s, x^*(s), u^*(s)) ds + \int_{[0,t]} g_0(s, u^*(s)) \mu^*(ds).$$

It is easy to see that $h(z^*(1))$ lies in the boundary of $\tilde{R}_{\tilde{\Psi}}$.

Now apply Theorem 4.1 to π . (The hypotheses hold under which this is permissible.) It is a straightforward task to show that the assertions of Theorem 4.2 follow.

What does Theorem 4.2 tell us about the minimizing measure μ^* ? We see that (4.3) and (4.4) (or (4.5) and (4.6)) locate the support of μ^* . At first sight this information might appear rather meagre. But the fact that the optimal trajectory must satisfy the terminal constraints, and the conditions on the conventional control, embody additional implicit information about μ^* . In fact it is a simple matter to show that for linear convex problems, under a normality hypothesis, the conditions of Theorem 4.2 are also sufficient for optimality of (x^*, u^*, μ^*) . This attests to the strength of the necessary conditions.

5. Approximation of measures. Approximation arguments underlie the proof of Theorem 4.1, in which the measures driving the system equation are replaced by control functions (in the customary sense).

Clearly we need to devise schemes for approximation of measures and to examine the effects of approximation on the state trajectories. Various results required for these purposes are gathered together in this section. Proofs appear in the Appendix.

PROPOSITION 5.1. Consider sequences $\Phi_i: [0, 1] \times R^n \rightarrow R^n$, $\{\gamma_i\}$ and $\{a_i\}$ with $\gamma_i \in C^*(0, 1; R^n)$ and $a_i \in R^n$, $i = 1, 2, \dots$.

Suppose that

$$(5.1) \quad \gamma_i \xrightarrow{*} \gamma_0,$$

$$(5.2) \quad a_i \rightarrow a_0$$

and

$$(5.3) \quad \mathcal{L}\text{-meas}(\{t: \Phi_i(t, x) = \Phi_0(t, x), \text{ all } x \in R^n\}) \rightarrow 1$$

for some point $\gamma_0 \in C^*$, point $a_0 \in R^n$ and function $\Phi_0: [0, 1] \times R^n \rightarrow R^n$.

Let $z_0: [0, 1] \rightarrow R^n$ be a function of bounded variation such that

$$(5.4) \quad \begin{aligned} z_0(t) &= z_0(0) + \int_0^t \Phi_0(s, z_0(s)) \, ds + \int_{[0, t]} \gamma_0(ds) \quad \text{for all } t \in (0, 1], \\ z_0(0) &= a_0. \end{aligned}$$

It is assumed that, given any $\delta > 0$, there exist $\bar{K}_\delta, \bar{\alpha} \in L^1$ such that

$$(5.5) \quad \Phi_i(\cdot, x) \text{ is Lebesgue measurable for each } x \in R^n,$$

$$(5.6) \quad \|\Phi_i(t, x) - \Phi_i(t, y)\| \leq \bar{K}_\delta(t) \|x - y\| \quad \text{when } \|x\|, \|y\| \leq \delta \quad \mathcal{L}\text{-a.e. } t \in [0, 1]$$

and

$$(5.7) \quad \|\Phi_i(t, z_0(t))\| \leq \bar{\alpha}(t) \quad \mathcal{L}\text{-a.e. } t \in [0, 1]$$

for $i = 1, 2, \dots$.

Then, for each i sufficiently large, there exists a function z_i of bounded variation such that

$$(5.8) \quad \begin{aligned} z_i(t) &= z_i(0) + \int_0^t \Phi_i(s, z_i(s)) \, ds + \int_{[0, t]} \gamma_i(ds) \quad \text{for all } t \in (0, 1], \\ z_i(0) &= a_i, \end{aligned}$$

$$(5.9) \quad z_i(t) - \int_{[0, t]} \gamma_i(ds) \rightarrow z_0(t) - \int_{[0, t]} \gamma_0(ds) \quad \text{uniformly in } t \in [0, 1]$$

and

$$(5.10) \quad dz_i \xrightarrow{*} dz_0.$$

We remark that limit (5.10) is to be interpreted in terms of weak* convergence of elements in $C^*(0, 1; R^n)$ associated with the functions of bounded variation z_i , $i = 1, 2, \dots$.

PROPOSITION 5.2. Take $\nu \in C^*(0, 1; R^k)$ and $\{\nu_i\}$ with $\nu_i \in C^*(0, 1; R^k)$, $i = 1, \dots$.

(a) If there exists a Borel measurable subset $S \subset [0, 1]$, having full Lebesgue measure and containing the point $\{1\}$, if the ν_i 's are uniformly bounded in total variation and

$$\int_{[0, t]} \nu_i(ds) \rightarrow \int_{[0, t]} \nu(ds)$$

as $i \rightarrow \infty$, for all $t \in S$, then

$$(5.11) \quad \nu_i \xrightarrow{*} \nu.$$

Conversely,

(b) If (5.11) is true, there exists a subset $S \subset [0, 1]$ which contains $\{1\}$ and is the complement of a countable set and also a subsequence $\{\nu_{i_j}\}$ of $\{\nu_i\}$ such that

$$\int_{[0,t]} \nu_{i_j}(ds) \rightarrow \int_{[0,t]} \nu(ds) \quad \text{for all } t \in S.$$

PROPOSITION 5.3. Let $U \subset [0, 1] \times R^m$ be a Borel measurable subset and let $r: [0, 1] \times R^m \rightarrow R^n$ be a Borel measurable function.

We assume that r is uniformly bounded on U and the multifunction $t \rightarrow \overline{\text{co}} r(t, U_t)$ is continuous with respect to the Hausdorff metric.

Take $\mu \in C^\oplus(0, 1)$ and a Borel measurable function u such that

$$u(t) \in U_t \quad \mathcal{L} \text{ and } \mu\text{-a.e.}$$

Then there exists a sequence of Borel measurable functions $\{u_i: [0, 1] \rightarrow R^m\}$ and a sequence $\{m_i\}$ in $L^1(0, 1; R)$ such that

$$u_i(t) \in U_t \quad \mathcal{L}\text{-a.e.},$$

$$m_i(t) \geq 0 \quad \mathcal{L}\text{-a.e.},$$

$$t \rightarrow r(t, u_i(t))m_i(t) \quad \text{is } \mathcal{L} \text{ integrable}$$

for $i = 1, 2, \dots$,

$$m_i(t) dt \xrightarrow{*} \mu(dt)$$

$$r(t, u_i(t))m_i(t) dt \xrightarrow{*} r(t, u(t))\mu(dt)$$

and

$$\mathcal{L}\text{-meas}(\{t: u(t) \neq u_i(t)\}) \rightarrow 0 \quad \text{as } i \rightarrow \infty.$$

6. Proof of Theorem 4.1. Let us show that, in proving Theorem 4.1, it is permissible to make a few simplifying assumptions at the outset.

H7 $K = R^+$,

G is uniformly bounded on Ω and the multifunction $t \rightarrow \overline{\text{co}} G(t, \Omega_t)$ is continuous with respect to the Hausdorff metric.

LEMMA 6.1. If the assertions of Theorem 4.1 are true under hypotheses H1–H7, then they are true merely under hypotheses H1–H6.

Proof. Suppose hypotheses H1–H7 are in force and (x^*, u^*, μ^*) is a control process such that $x^*(0) \in C_0$ and $\Psi(x^*(1))$ is a boundary point of R_Ψ .

We construct a new dynamic system (S') from the former data as follows:

$$dx(t) = f(t, x(t), u(t)) dt + \tilde{g}(t, u(t), w(t))\nu(dt),$$

$$(u(t), w(t)) \in \Omega_t \times \tilde{K} \quad \mathcal{L} \text{ and } \mu\text{-a.e.},$$

$$x(0) \in C_0,$$

$$\nu(A) \geq 0 \quad \text{for all } A \in \mathcal{B}.$$

Here,

$$\tilde{g}(t, u, w) := \frac{G(t, u)w}{1 + \sum_i |\sum_j g_{ij}(t, u)w_j|},$$

$$\tilde{K} := \{w \in K: \sum_i |w_i| \leq 1\},$$

and u and w are regarded as block components of a composite control vector $\text{col}(u, w)$. The g_{ij} 's are the components of G .

We define w^* to be the Radon-Nikodym derivative of μ^* with respect to $|\mu^*|$. A simple separating hyperplane argument reveals that

$$w^*(t) \in \{v \in K : |v_i| \leq 1, i = 1, 2, \dots, k\} \quad |\mu^*| \text{-a.e.}$$

Now define $\nu^* \in C^\oplus(0, 1)$ according to

$$\nu^*(dt) = (1 + \sum_i |\sum_j g_{ij}(t, u^*(t)) w_j^*(t)|) |\mu^*(dt)|.$$

Note that $1 + \sum_i |\sum_j g_{ij} w_j^*|$ is $|\mu^*|$ integrable in view of the definition of μ integrability that we have adopted; consequently ν^* is well defined.

We claim that $(x^*, \text{col}(u^*, w^*), \nu^*)$ is a Ψ boundary process for (S') .

To prove this, it suffices to show that the set of trajectories is the same for (S) and (S') . This in turn will follow provided we can always arrange that the singular terms in the two extended differential equations, namely $G(t, u) d\mu$ and $\tilde{g}(t, u) d\nu$, are interchangeable in the following sense.

Let u be any given function. We require that

(i) given any $\mu \in C^*$ such that (u, μ) is a control policy for (S) , there are functions $w: [0, 1] \rightarrow R^k$ and $\nu \in C^\oplus$ such that $(\text{col}(u, w), \nu)$ is a control policy for (S') and

$$(6.1) \quad \int_A G(t, u(t)) \mu(dt) = \int_A \tilde{g}(t, u(t), w(t)) \nu(dt) \quad \text{for all } A \in \mathcal{B},$$

and also

(ii) given any function $w: [0, 1] \rightarrow R^k$ and $\nu \in C^\oplus$ such that $(\text{col}(u, w), \nu)$ is a control policy for (S') , then there exists $\mu \in C^*$ such that (u, μ) is a control policy for (S) , and (6.1) is satisfied.

Full details of the proofs of assertions (i) and (ii) are routine and are therefore omitted; we point out here merely that, in proving (i), we can take the function w to be the Radon-Nikodym derivative $d\mu/d|\mu|$ and ν to be that element in C^\oplus defined by

$$\nu(dt) = (1 + \sum_i |\sum_j g_{ij}(t, u(t)) w_j(t)|) |\mu|(dt),$$

and, in proving (ii), we can choose μ to be

$$\mu(dt) = \frac{w(t) \nu(dt)}{1 + \sum_i |\sum_j g_{ij}(t, u(t)) w_j(t)|}.$$

We accept the claim then that $(x^*, \text{col}(u^*, w^*), \nu^*)$ is a Ψ boundary process for (S') .

It will be observed that (S') is a special case of the former system in which the additional hypotheses on the data, listed in the lemma, are valid.

Now apply Theorem 4.1 to $(x^*, \text{col}(u^*, w^*), \nu^*)$, the Ψ boundary process for (S') , as is permitted in view of the additional hypotheses. This yields existence of an absolutely continuous function p and $d \in R^k$, with $\|d\| = 1$, such that

$$-p(t) \in \partial_x H(t, x^*(t), u^*(t), p(t)) \quad \mathcal{L}\text{-a.e. } t \in [0, 1]$$

(where $H(t, x, u, p) = p \cdot f(t, x, u)$),

$$-p(1) = d \cdot Q \quad \text{for some } Q \in \partial \Psi(x^*(1)),$$

$u^*(t)$ maximizes

$$(6.2) \quad \begin{aligned} & u \rightarrow p(t) \cdot f(t, x^*(t), u) \quad \mathcal{L}\text{-a.e.}, \\ & \sup_{u \in \Omega_t, w \in \tilde{K}} \left\{ \frac{p(t) \cdot G(t, u) w}{1 + \sum_i |\sum_j g_{ij}(t, u) w_j|} \right\} \leq 0 \quad \text{for all } t, \end{aligned}$$

and

$$(6.3) \quad \frac{p(t) \cdot G(t, u^*(t)) w^*(t)}{1 + \sum_i |\sum_j g_{ij}(t, u^*(t)) w_j|} = 0 \quad \mu^* \text{-a.e.}$$

However (6.2) implies that

$$\sup_{u \in \Omega_t} \sigma_K(p(t) \cdot G(t, u)) \leq 0 \quad \text{for all } t \in [0, 1],$$

and we deduce from (6.3) that

$$\sigma_K(p(t) \cdot G(t, u^*(t))) = 0 \quad \mu^* \text{-a.e.}$$

We see that the special case of Theorem 4.1 applied to (S') yields the full theorem for (S). The lemma is proved.

It is assumed henceforth that H7 is in force. We write g in place of G to emphasize the fact that, under the additional hypothesis, the function is vector, not matrix, valued.

By assumption $\Psi(x^*(1))$ is a boundary point of R_Ψ . It follows that there is a sequence of vectors $\{\xi_i\}$ such that $\xi_i \notin R_\Psi$, $i = 1, 2, \dots$, and

$$(6.4) \quad \xi_i \rightarrow \Psi(x^*(1)) \quad \text{as } i \rightarrow \infty.$$

In consequence of Propositions 5.1 and 5.3, for $i = 1, 2, \dots$, there exists \mathcal{L} -measurable functions \bar{m}_i and \bar{u}_i such that \bar{m}_i is \mathcal{L} -integrable and $\bar{u}_i(t) \in \Omega_t$, \mathcal{L} -a.e., and a trajectory \bar{x}_i emanating from $x^*(0)$ with the following properties:

$$\frac{d}{dt} \bar{x}_i(t) = f(t, \bar{x}_i(t), \bar{u}_i(t)) + g(t, \bar{u}_i(t)) \bar{m}_i(t) \quad \mathcal{L}\text{-a.e. } t \in [0, 1]$$

for $i = 1, 2, \dots$,

$$(6.5) \quad \bar{m}_i(t) dt \xrightarrow{*} \mu^*(dt),$$

$$(6.6) \quad \mathcal{L}\text{-meas}(\{t: \bar{u}_i(t) \neq u^*(t)\}) \rightarrow 0$$

and

$$d\bar{x}_i(t) \xrightarrow{*} dx^*(t).$$

Now, by assumption, the \bar{x}_i 's have common left point,

$$(6.7) \quad \bar{x}_i(0) = x^*(0).$$

From Proposition 5.2 it follows we can arrange, by restricting attention to appropriate subsequences, that

$$\bar{x}_i(t) \rightarrow x^*(t),$$

on a subset of $[0, 1]$, of full Lebesgue measure, containing the points 0 and 1. Since the functions $\|x_i(t)\|$ are majorized by a common constant function we deduce from the dominated convergence theorem that

$$\int_0^1 \|\bar{x}_i(t) - x^*(t)\|^2 dt \rightarrow 0.$$

For $i = 1, 2, \dots$, define ε_i to be

$$(6.8) \quad \varepsilon_i := \left(\int_0^1 \|\bar{x}_i(t) - x^*(t)\|^2 dt + \|\xi_i - \Psi(\bar{x}_i(1))\| + \|\bar{x}_i(1) - x^*(1)\|^2 \right)^{1/2}.$$

It follows from (6.4) and the convergence properties of $\{\bar{x}_i\}$ just described that $\varepsilon_i \rightarrow 0$.

Let $\{K_i\}$ be the sequence of L^1 functions defined by

$$K_i(t) := i + \max_{j \leq i} \{\bar{m}_j(t)\}.$$

Note that each K_i majorizes \bar{m}_i and the sequence is monotone with pointwise limit $+\infty$. For each i , consider the optimal control problem (P_i) :

$$\begin{aligned} &\text{Minimize} \quad \|\xi_i - \Psi(x(1))\| + \int_0^1 \|x(t) - x^*(t)\|^2 dt + \|x(1) - x^*(1)\|^2 \\ &\text{subject to} \quad \frac{dx(t)}{dt} = f(t, x(t), u(t)) + g(t, u(t))m(t) \quad \mathcal{L}\text{-a.e.}, \\ &\quad x(0) \in C_0, \quad \text{and} \\ &\quad (u(t), m(t)) \in \Omega_i \times [0, K_i(t)] \quad \mathcal{L}\text{-a.e.}, \end{aligned}$$

in which m is treated as a block component in the control variable $\text{col}(u, m)$. The minimization is conducted over processes $\{x, \text{col}(u, m)\}$ for (P_i) , that is to say, over triples each comprising Lebesgue measurable functions u and m and an absolutely continuous function x which satisfy the specified constraints.

Problem (P_i) can be reformulated as

$$\begin{aligned} &\text{Minimize} \quad \Phi_i(a) \\ &\text{over } a \in Q_i. \end{aligned}$$

Here Q_i is the set of elements (s, u, w) in which $s \in C_0$ and $u: [0, 1] \rightarrow R^m$ and $w: [0, 1] \rightarrow R$ are \mathcal{L} -measurable functions such that $u(t) \in \Omega_i$ and $w(t) \in [0, K_i(t)]$ \mathcal{L} -a.e. The function Φ_i on Q_i is taken to be

$$\Phi_i((s, u, m)) = \|\xi_i - \Psi(x(1))\| + \int_0^1 \|x(t) - x^*(t)\|^2 dt + \|x(1) - x^*(1)\|^2$$

in which x is the unique solution to the differential equation corresponding to u and m , and the initial condition $x(0) = s$.

We provide Q_i with the metric ρ :

$$\rho((s, u, m), (\bar{s}, \bar{u}, \bar{m})) = \mathcal{L}\text{-meas}(\{t: u(t) \neq \bar{u}(t)\}) + \int_0^1 |m(t) - \bar{m}(t)| dt + \|s - \bar{s}\|.$$

Q_i thereby becomes a complete metric space (cf. [4, Lemma 1, p. 202]).

We readily deduce from Proposition 5.1 that the mapping Φ is continuous for this choice of metric.

Observe that, for each i ,

$$\Phi_i((\bar{x}_i(0), \bar{u}_i, \bar{m}_i)) \leq \inf_{a \in Q_i} \Phi_i(a) + \varepsilon_i^2$$

by (6.8) and, since $\Phi_i \geq 0$, it follows from Ekeland's theorem [5], that, for each i , there exists $(s_i, u_i, m_i) \in Q_i$ such that

$$(6.9) \quad \Phi_i((s_i, u_i, m_i)) \leq \Phi_i(a) + \varepsilon_i \rho(a, (s_i, u_i, m_i))$$

for all $a \in Q_i$, and

$$(6.10) \quad \rho((s_i, u_i, m_i), (x^*(0), \bar{u}_i, \bar{m}_i)) \leq \varepsilon_i.$$

Let x_i be the trajectory corresponding to (s_i, u_i, m_i) . Bearing in mind that $\varepsilon_i \rightarrow 0$, we deduce from (6.5)–(6.7) and (6.10) that

$$(6.11) \quad \begin{aligned} x_i(0) &\rightarrow x^*(0), \\ \mathcal{L}\text{-meas}(\{t: u_i(t) \neq u^*(t)\}) &\rightarrow 0, \quad \text{and} \\ m_i(t) \, dt &\xrightarrow{*} \mu^*(dt). \end{aligned}$$

A simple contradiction argument based on (6.9) and (6.10) establishes that $\Phi_i((s_i, u_i, m_i)) \rightarrow 0$ as $i \rightarrow \infty$. Examining Φ_i , we see that this implies

$$\int_0^1 \|x_i(t) - x^*(t)\|^2 \, dt \rightarrow 0 \quad \text{and} \quad \|x_i(1) - x^*(1)\|^2 \rightarrow 0.$$

Following extraction of a subsequence, we have then that

$$(6.12) \quad x_i(t) \rightarrow x^*(t) \quad \text{for all } t \in S \cup \{0\} \cup \{1\}$$

for some subset $S \subset (0, 1)$ of full Lebesgue measure.

It is not difficult to show (application of Gronwall's inequality is involved) that the sequence of measures $\{dx_i\}$ associated with the x_i 's is uniformly bounded in total variation. By Proposition 5.2 then

$$dx_i(t) \xrightarrow{*} dx^*(t).$$

In view of (6.11), (6.12) and hypothesis H3 we may apply the dominated convergence theorem to obtain

$$f(t, x_i(t), u_i(t)) \, dt \xrightarrow{*} f(t, x^*(t), u^*(t)) \, dt.$$

Noting that $gm_i \, dt = dx_i - f \, dt$, we deduce that

$$(6.13) \quad g(t, u_i(t))m_i(t) \, dt \xrightarrow{*} g(t, u^*(t))\mu^*(dt).$$

Inequality (6.9) which holds for all $a \in Q_i$ implies that the process (x_i, u_i, m_i) is optimal for the control problem (\bar{P}_i) :

$$\begin{aligned} \text{Minimize} \quad & \|\xi_i - \Psi(x(1))\| + \int_0^1 \|x(t) - x^*(t)\|^2 \, dt + \|x(1) - x^*(1)\|^2 \\ & + \varepsilon_i(\|x(0) - x_i(0)\| + \int_0^1 \|m(t) - m_i(t)\| \, dt \\ & + \int_0^1 \chi_i(t, u(t)) \, dt) \end{aligned}$$

subject to $\dot{x} = f(t, x, u) + g(t, u)m \quad \mathcal{L}\text{-a.e.},$

$x(0) \in C_0,$ and

$(u(t), m(t)) \in \Omega_t \times [0, K_i(t)] \quad \mathcal{L}\text{-a.e.}$

Here

$$\chi_i(t, u) := \begin{cases} 0 & \text{if } u = u_i(t), \\ 1 & \text{otherwise.} \end{cases}$$

Now (\bar{P}_i) is an optimal control problem for which necessary conditions of optimality are available.

As usual let H be the function $H(t, x, u, p) = p \cdot f(t, x, u)$. It is convenient also to introduce the function H_i defined by

$$H_i(t, u, m) := p_i(t) \cdot [f(t, x_i(t), u) + g(t, u)m] - \varepsilon_i[\chi_i(t, u) + |m - m_i(t)|].$$

Application of [4, Thm. 5.2.1] to the optimal process, (x_i, u_i, m_i) , yields the following information. (Note that (\bar{P}_i) is a free right endpoint problem whose extremals are normal.)

There exists an absolutely continuous function $p_i: [0, 1] \rightarrow R^n$ and a number $K > 0$ which does not depend on i , such that

$$(6.14) \quad -\dot{p}_i(t) \in \partial_x H(t, x_i(t), u_i(t), p_i(t)) - 2(x_i(t) - x^*(t)),$$

$$(6.15) \quad H_i(t, u_i(t), m_i(t)) = \max \{H_i(t, u, m): u \in \Omega_i, m \in [0, K_i(t)]\},$$

$$(6.16) \quad p_i(0) \in K \partial d_{C_0}(x_i(0)) + \varepsilon_i K \partial_x \|x - x_i(0)\| \Big|_{x=x_i(0)},$$

$$(6.17) \quad -p_i(1) \in \partial_x \|\xi_i - \Psi(x_i(1))\| + 2(x_i(1) - x^*(1)).$$

In view of the fact that (x_i, u_i, m_i) defines a process for S and $\xi_i \notin R_\Psi$ we have that $\|\xi_i - \Psi(x_i(1))\| \neq 0$.

It follows then from (6.17) and [4, Thm. 2.6.6] that

$$(6.18) \quad -p_i(1) \in d_i \cdot \partial \Psi(x_i(1)) + 2(x_i(1) - x^*(1))$$

for some vector d_i of unit length.

Appealing to Gronwall's inequality, we deduce from (6.14) and (6.17) that the p_i s are a bounded equicontinuous family of functions. Extraction of a subsequence therefore ensures that

$$(6.19) \quad p_i(t) \rightarrow p(t) \quad \text{for all } t \in [0, 1]$$

where p is some absolutely continuous function.

We now show that p has the requisite properties for it to serve in Theorem 4.1.

Limit attention to a subsequence, thereby arranging that the vector d_i in (6.18) converges to a limit d . Clearly $\|d\| = 1$.

The transversality conditions

$$p(0) \in K \partial d_{C_0}(x^*(0)) \quad (\subset N_{C_0}(x^*(0)))$$

and

$$-p(1) \in d \cdot \partial \Psi(x^*(1))$$

follow from (6.16) and (6.18) and the upper semicontinuity of the generalized gradient.

We now derive the costate differential inclusion

$$(6.20) \quad -\dot{p}(t) \in \partial_x H(t, x^*(t), u^*(t), p(t)) \quad \mathcal{L}\text{-a.e.}$$

Notice that, by (6.14), p_i satisfies

$$(6.21) \quad \dot{p}_i(t) \in \Gamma(t, p_i(t)) + r_i(t)B \quad \text{on } A_i$$

where

$$\begin{aligned} \Gamma(t, p) &:= -\partial_x H(t, x^*(t), p, u^*(t)), \\ r_i(t) &= \tilde{k}(t)|x_i(t) - x^*(t)| \end{aligned}$$

and

$$A_i = \{t: u_i(t) \neq u^*(t)\}.$$

Here \tilde{k} is an integrable function which does not depend on i . We now appeal to [4, Thm. 3.1.7], which concerns limiting solutions of differential inclusions such as (6.21). Scrutiny of the proof of [4, Thm. 3.1.7] reveals that the assertions of the theorem remain true if the hypothesis "the r_i 's converge uniformly to zero" is replaced by "the r_i 's are uniformly integrably bounded and converge almost everywhere to zero." The hypotheses are satisfied under which the theorem, strengthened in the manner just indicated, applies. (Note in particular that the r_i 's have the required properties, since the x_i 's are uniformly bounded in L_∞ norm and converge almost everywhere to x^* .) It follows that p satisfies the differential inclusion (6.20).

Next we show that

$$(6.22) \quad p(t) \cdot f(t, x^*(t), u^*(t)) = \max_{u \in \Omega_t} p(t) \cdot f(t, x^*(t), u) \quad \mathcal{L}\text{-a.e.}$$

and

$$(6.23) \quad \sup_{u \in \Omega_t} p(t) \cdot g(t, u) \leq 0 \quad \text{for all } t \in [0, 1].$$

We shall make repeated use of the following simple observation: If $\{\Sigma_i\}$ is a sequence of \mathcal{L} -measurable subsets of $[0, 1]$ and $\mathcal{L}\text{-meas}(\Sigma_i) \rightarrow 0$, then we may replace $\{\Sigma_i\}$ by a subsequence (we do not relabel) with the property

$$\mathcal{L}\text{-meas}(\{t: t \in [0, 1] \setminus \Sigma_j \text{ for all } j \geq i\}) \rightarrow 1$$

as $i \rightarrow \infty$. In fact it suffices to arrange, by extraction of a subsequence if necessary, that $\sum_{j=0}^{\infty} \mathcal{L}\text{-meas}(\Sigma_j) < \infty$.

Let

$$A_i = \{t: p_i(t) \cdot g(t, u_i(t)) > \varepsilon_i\},$$

$$B_i = \left\{t: m_i(t) > \frac{1}{\sqrt{\varepsilon_i}}\right\}$$

and

$$C_i = \left\{t: \sup_{u \in \Omega_t} |p_i(t) \cdot f(t, x_i(t), u)| > \sqrt{K_i(t)}\right\}.$$

The fact that the sequence $\{m_i\}$ is norm bounded in L^1 tells us that $\mathcal{L}\text{-meas}(B_i) \rightarrow 0$ as $i \rightarrow \infty$. We also know that $\mathcal{L}\text{-meas}(A_i) \rightarrow 0$ as $i \rightarrow \infty$ since the maximization of the Hamiltonian condition (6.15) implies that $m_i(t) = K_i(t)$ a.e. on A_i and the $K_i(t)$'s increase uniformly to infinity.

Furthermore $\mathcal{L}\text{-meas}(C_i) \rightarrow 0$ as $i \rightarrow \infty$ since the sequence of functions $\{t \rightarrow \sup_{u \in \Omega_t} |p_i(t) \cdot f(t, x_i(t), u)|\}$ are uniformly integrably bounded.

Now let S_i be the set of points $t \in [0, 1]$ such that

$$(6.24) \quad p_j(t) \cdot g(t, u_j(t)) \leq \varepsilon_j \quad \text{for all } j \geq i,$$

$$(6.25) \quad \sup_{u \in \Omega_t} |p_j(t) \cdot f(t, x_j(t), u)| \leq \sqrt{K_i(t)} \quad \text{for all } j \geq i,$$

$$(6.26) \quad m_j(t) \leq \frac{1}{\sqrt{\varepsilon_j}} \quad \text{for all } j \geq i,$$

$$(6.27) \quad u_j(t) = u^*(t) \quad \text{for all } j \geq i,$$

$$(6.28) \quad H_j(t, u_j(t), m_j(t)) = \max \{H_j(t, u, m): u \in \Omega_t, m \in [0, K_j(t)]\} \quad \text{for all } j \geq i$$

and

$$(6.29) \quad x_j(t) \rightarrow x^*(t) \quad \text{as } j \rightarrow \infty.$$

In view of our earlier observations, we can arrange by extraction of subsequences that $\mathcal{L}\text{-meas}(S_i) \rightarrow 1$ as $i \rightarrow \infty$.

Now take any $t \in \bigcup_i S_i$ and any $\bar{u} \in \Omega_t$. For some i then $t \in S_i$ whence, by (6.27) and (6.28),

$$H_j(t, u^*(t), m_j(t)) \geq H_j(t, \bar{u}, 0) \quad \text{for all } j \geq i.$$

This inequality coupled with (6.24) and (6.26) gives

$$p_j(t) \cdot f(t, x_j(t), u^*(t)) + \frac{\varepsilon_j}{\sqrt{\varepsilon_j}} \geq p_j(t) \cdot f(t, x_j(t), \bar{u}) - \varepsilon_j - \frac{\varepsilon_j}{\sqrt{\varepsilon_j}} \quad \text{for all } j \geq i.$$

In view of (6.19) and (6.29) we may pass to the limit, $j \rightarrow \infty$, and obtain

$$p(t) \cdot f(t, x^*(t), u^*(t)) \geq p(t) \cdot f(t, x^*(t), \bar{u}).$$

We have established (6.22) (on the subset $\bigcup_i S_i$ of full \mathcal{L} -measure). Again take $t \in \bigcup_i S_i$. For every j , let \bar{u}_j be chosen so that

$$(6.30) \quad p_j(t) \cdot g(t, \bar{u}_j) > \sup_{u \in \Omega_t} p_j(t) \cdot g(t, u) - \varepsilon_j.$$

Properties (6.27) and (6.28) give, for some i ,

$$H_j(t, u^*(t), m_j(t)) \geq H_j(t, \bar{u}_j, K_j(t)) \quad \text{for all } j \geq i.$$

It follows then from (6.24)–(6.26) and (6.30) that

$$\sqrt{K_j(t)} + \sqrt{\varepsilon_j} \geq -\sqrt{K_j(t)} + \sup_{u \in \Omega_t} (p_j(t) \cdot g(t, u)) K_j(t) - \varepsilon_j - 2\varepsilon_j K_j(t) \quad \text{for all } j \geq i.$$

But $K_j(t) \rightarrow \infty$ as $j \rightarrow \infty$. Dividing across this inequality by $K_j(t)$ and passing to the limit, $j \rightarrow \infty$, we obtain

$$\sup_{u \in \Omega_t} p(t) \cdot g(t, u) \left(= \lim_{j \rightarrow \infty} \sup_{u \in \Omega_t} p_j(t) \cdot g(t, u) \right) \leq 0.$$

(We have used (6.19) and the continuity of $p \rightarrow \sup_{u \in \Omega_t} p \cdot g(t, u)$.)

We see that (6.23) is true on the subset of full \mathcal{L} -measure, $\bigcup_i S_i$. It is true everywhere then since, under our hypotheses, the function $t \rightarrow \sup_{u \in \Omega_t} p(t) \cdot g(t, u)$ is continuous. It remains to show that

$$p(t) \cdot g(t, u^*(t)) = 0 \quad \mu^*\text{-a.e.}$$

For any i we have

$$H_i(t, u_i(t), m_i(t)) \geq H_i(t, u_i(t), m) \quad \text{for all } m \in [0, K_i(t)] \quad \mathcal{L}\text{-a.e.}$$

It follows that

$$p_i(t) \cdot g(t, u_i(t)) m_i(t) \geq p_i(t) \cdot g(t, u_i(t)) m - \varepsilon_i |m - m_i(t)|$$

for all $m \in [0, K_i(t)] \quad \mathcal{L}\text{-a.e.}$

Now suppose that $m_i(t) > 0$. Examination of the last inequality reveals that this is possible only if

$$(6.31) \quad p_i(t) \cdot g(t, u_i(t)) > -\varepsilon_i.$$

To be precise, we have shown that (6.31) is true \mathcal{L} -a.e. on the set $\{t: m_i(t) > 0\}$.

Define $\{\nu_i\}$ and ν , with ν and $\nu_i \in C^*(0, 1)$, $i = 1, \dots$, by

$$\nu_i(dt) = p_i(t) \cdot g(t, u_i(t)) m_i(t) dt, \quad i = 1, 2, \dots$$

and

$$\nu^*(dt) = p(t) \cdot g(t, u^*(t)) \mu^*(dt).$$

We readily deduce from the properties (6.13) and (6.19) that

$$\nu_i \xrightarrow{*} \nu^*.$$

According to Lemma 5.2, we can arrange by subsequence extraction that

$$(6.32) \quad \int_{[0,t]} \nu_i(ds) \rightarrow \int_{[0,t]} \nu^*(ds)$$

for all t in some dense subset P of $[0, 1]$ which contains $\{1\}$. For any $t \in P$ we have

$$\begin{aligned} \int_{[0,t]} \nu_i(ds) &= \int_0^t p_i(s) \cdot g(s, u_i(s)) m_i(s) ds \\ &= \int_{\{s: m_i(s) > 0\} \cap [0,t]} p_i(s) \cdot g(s, u_i(s)) m_i(s) ds \quad (\text{since } m_i(s) \geq 0 \text{ } \mathcal{L}\text{-a.e.}) \\ &\geq -\varepsilon_i \int_{[0,t]} m_i(s) ds, \end{aligned}$$

by (6.31). Bearing in mind that $\{m_i\}$ is norm bounded in L^1 we deduce, from this inequality and (6.32), that

$$\int_{[0,t]} \nu(dt) \geq 0,$$

i.e.,

$$\int_{[0,t]} p(t) \cdot g(t, u^*(t)) \mu^*(dt) \geq 0.$$

Since the sets $\{[0, t]: t \in P\}$ generate the Borel subsets of $[0, 1]$ we have

$$\int_E p(t) \cdot g(t, u^*(t)) \mu^*(dt) \geq 0$$

for all Borel subsets $E \subset [0, 1]$. It follows that

$$p(t) \cdot g(t, u^*(t)) \geq 0 \quad \mu^*\text{-a.e.}$$

However we have shown that

$$\sup_{u \in \Omega_t} p(t) \cdot g(t, u) \leq 0 \quad \text{for all } t \in [0, 1].$$

Of course

$$u^*(t) \in \Omega_t \quad \mu^*\text{-a.e.}$$

We conclude that

$$p(t) \cdot g(t, u^*(t)) = 0 \quad \mu^*\text{-a.e.}$$

Appendix.

Proof of Proposition 5.1. We shall use the fact that (5.5)–(5.7) remain true when Φ_0 replaces Φ_i . This is clearly a consequence of (5.3).

Let $\tilde{z}_0(t) = z_0(t) - \int_{[0,t]} \gamma_0(ds)$.

Then $\tilde{z}_0(\cdot)$ is an absolutely continuous function which satisfies the differential equation

$$(A.1) \quad \frac{d}{dt} \tilde{z}_0(t) = \Phi_0\left(t, \tilde{z}_0(t) + \int_{[0,t]} \gamma_0(ds)\right), \quad \tilde{z}_0(0) = a_0.$$

Choose $\delta > 0$ such that

$$\max_{t \in [0,1]} \|\tilde{z}_0(t)\| + \|\gamma_i\|_{TV} < \frac{\delta}{2}$$

for all i sufficiently large.

Consider now the functions ρ_i , $i = 1, 2, \dots$,

$$\rho_i(t) := \left| \dot{\tilde{z}}_0(t) - \Phi_i\left(t, \tilde{z}_0(t) + a_i - a_0 + \int_{[0,t]} \gamma_i(ds)\right) \right|.$$

Since $\tilde{z}_0(\cdot)$ solves the differential equation (A.1), ρ_i can be written

$$\rho_i(t) = \left| \Phi_0\left(t, \tilde{z}_0(t) + \int_{[0,t]} \gamma_0(ds)\right) - \Phi_i\left(t, \tilde{z}_0(t) + a_i - a_0 + \int_{[0,t]} \gamma_i(ds)\right) \right|.$$

Introduce the sets S_i , $i = 1, 2, \dots$,

$$S_i = \{t: \Phi_i(t, x) = \Phi_0(t, x), \text{ for all } x \in \mathbb{R}^n\}.$$

For $t \in [0, 1] \setminus S_i$,

$$\begin{aligned} \rho_i(t) &\leq \left| \Phi_0\left(t, \tilde{z}_0(t) + \int_{[0,t]} \gamma_0(ds)\right) \right| + \left| \Phi_i\left(t, \tilde{z}_0(t) + \int_{[0,t]} \gamma_0(ds)\right) \right| + \bar{K}_\delta(t) s_i(t) \\ &\leq 2\bar{\alpha}(t) + \bar{K}_\delta(t) s_i(t). \end{aligned}$$

In these estimates,

$$s_i(t) = |a_i - a_0| + \left| \int_{[0,t]} (\gamma_i(ds) - \gamma_0(ds)) \right|.$$

(We have used bounds (5.6) and (5.7) for Φ_0 in place of Φ_i .)

For $t \in S_i$,

$$\rho_i(t) \leq \bar{K}_\delta(t) s_i(t).$$

Now (5.1) and (5.2) imply that the s_i 's are uniformly bounded in the L^∞ norm and, on a Lebesgue set of full measure, $s_i(t) \rightarrow 0$. Noting also (5.3), we deduce by application of the dominated convergence theorem that

$$\int_0^1 \rho_i(t) dt \rightarrow 0 \quad \text{as } i \rightarrow \infty.$$

By (5.5)–(5.7), the function $(t, x) \rightarrow \Phi_i(t, x + a_i - a_0 + \int_{[0,t]} \gamma_i(ds))$ is measurably Lipschitz on the $(\delta/4)$ tube about $t \rightarrow \tilde{z}_0(t) + a_i - a_0$, for i sufficiently large. (“Measurably Lipschitz” is taken in the sense of [4, Def. 3.1.4].) It is now evident from the

proof of [4, Thm. 3.1.6], that there exists an absolutely continuous function $\tilde{z}_i(\cdot)$ satisfying

$$(A.2) \quad \frac{d}{dt} \tilde{z}_i(t) = \Phi_i \left(t, \tilde{z}_i(t) + \int_{[0,t]} \gamma_i(ds) \right), \quad \tilde{z}_i(0) = a_i$$

for i sufficiently large; furthermore

$$(A.3) \quad \tilde{z}_i(t) - \tilde{z}_0(t) \rightarrow 0 \quad \text{uniformly in } t \in [0, 1]$$

and

$$(A.4) \quad \int_0^1 |\dot{\tilde{z}}_i(t) - \dot{\tilde{z}}_0(t)| dt \rightarrow 0.$$

Now define $z_i(t) := \tilde{z}_i(t) + \int_{[0,t]} d\gamma_i$, for $t > 0$, and $z_i(0) := a_i$. By (A.2), $z_i(\cdot)$ is a normalized function of bounded variation which satisfies (5.8).

Property (A.3), expressed in terms of $z_i(\cdot)$ and $z_0(\cdot)$, is (5.9). Property (A.4) implies that

$$d\tilde{z}_i \xrightarrow{*} d\tilde{z}_0.$$

But then

$$dz_i (= d\tilde{z}_i + \gamma_i(dt)) \xrightarrow{*} (dz_0 + \gamma_0(dt)) = d\tilde{z}_0,$$

since $\gamma_i \xrightarrow{*} \gamma_0$. We have proved (5.10).

Proof of Proposition 5.2. We may limit attention to the scalar case ($k = 1$), since the scalar version of the lemma, applied componentwise, leads to the same conclusions in the vector setting.

(a) Replace $\{\nu_i\}$ by an arbitrary subsequence. (We do not relabel.) Define ν_i^+ , $\nu_i^- \in C^\oplus(0, 1)$ by the Jordan decomposition of ν_i :

$$\nu_i = \nu_i^+ - \nu_i^-$$

for $i = 1, 2, \dots$. The sequences $\{\nu_i^+\}$, $\{\nu_i^-\}$ are uniformly bounded, and we can arrange by extraction of subsequences that

$$\nu_i^+ \xrightarrow{*} \nu^+, \quad \nu_i^- \xrightarrow{*} \nu^-$$

for some $\nu^+, \nu^- \in C^\oplus(0, 1)$. Then

$$\nu_i (= \nu_i^+ - \nu_i^-) \xrightarrow{*} \nu'$$

where $\nu' = \nu^+ - \nu^-$. Since the initial subsequence was arbitrary, part (a) will be proved if we can show that $\nu' = \nu$.

Let $S_1 \subset [0, 1]$ be the set

$$S_1 = \{t \in S : \{t\} \text{ is not an atom of } \nu^+ \text{ or } \nu^-\} \cup \{1\}.$$

(Here S is the set mentioned in the hypotheses.) Now take any $t \in S_1$

$$\int_{[0,t]} \nu_i(ds) \left(= \int_{[0,t]} \nu_i^+(ds) - \int_{[0,t]} \nu_i^-(ds) \right) \rightarrow \int_{[0,t]} \nu'(ds)$$

(see [1, Thm. 2.1]).

Noting that $S_1 \subset S$, we deduce from the hypotheses that

$$(A.5) \quad \int_{[0,t]} \nu(ds) = \int_{[0,t]} \nu'(ds).$$

But the set S_1 is certainly dense in $[0, 1]$, and contains $\{1\}$. It follows from the continuity of $t \rightarrow \int_{[0,t]} \nu(ds)$ from the right on $[0, 1]$ that (A.5) holds for all $t \in [0, 1]$. It is now easy to show, using the regularity of ν and ν' , that

$$\int_A \nu'(ds) = \int_A \nu(ds)$$

for all relatively open subintervals A of $[0, 1]$, and therefore for all Borel sets A , since these sets are generated by the relatively open subintervals. In other words $\nu = \nu'$. Part (a) is proved.

(b) Now suppose (5.11). Define ν_i^+ and ν_i^- by the Jordan decomposition

$$\nu_i = \nu_i^+ - \nu_i^-$$

for $i = 1, 2, \dots$. By uniform boundedness, there exists a subsequence $\{\nu_{i_j}\}$ of $\{\nu_i\}$ such that

$$\nu_{i_j}^+ \xrightarrow{*} \nu^+, \quad \nu_{i_j}^- \xrightarrow{*} \nu^-$$

for some $\nu^+, \nu^- \in C^\oplus$. Then

$$\nu = \text{weak}^* \lim_{j \rightarrow \infty} \{\nu_{i_j}\} = \text{weak}^* \lim_{j \rightarrow \infty} \{\nu_{i_j}^+ - \nu_{i_j}^-\} = \nu^+ - \nu^-.$$

Now take S to be

$$S = \{t \in [0, 1]: \{t\} \text{ is not an atom of } \nu^+ \text{ or } \nu^-\} \cup \{1\}.$$

S is the complement in $[0, 1]$ of a countable set, and contains $\{1\}$. Since $[0, t]$ is a ν^+ - and ν^- -continuity set for each $t \in S$, we conclude that

$$\begin{aligned} \int_{[0,t]} \nu_{i_j}(ds) &= \int_{[0,t]} (\nu_{i_j}^+ - \nu_{i_j}^-)(ds) \\ &\rightarrow \int_{[0,t]} (\nu^+ - \nu^-)(ds) = \int_{[0,t]} \nu(ds) \end{aligned}$$

for each $t \in S$. The subsequence $\{\nu_{i_j}\}$ and the subset S have the required properties then, and the proposition is proved.

Proof of Proposition 5.3. Let us first note that we can without loss of generality suppose that

(A.6) μ is singular with respect to Lebesgue measure.

Indeed if μ does not satisfy this condition, we can decompose it into the sum of absolutely continuous and singular components (with respect to Lebesgue measure) thus

$$\mu(dt) = w(t) dt + \mu^*(dt).$$

Here w is an integrable function and μ^* is a measure singular with respect to Lebesgue measure. Since μ is nonnegative valued, we know that $w(t) \geq 0$, \mathcal{L} -a.e., and μ^* is nonnegative valued. We now apply the proposition (under the additional hypothesis (A.6)) and conclude existence of sequences $\{u_i\}$ and $\{m_i\}$ with the stated properties, corresponding to u and μ^* . It will be seen that the sequences $\{u_i\}$ and $\{m_i + w\}$ fulfill the claims of the proposition in relation to u and μ .

We then impose (A.6). It follows that a sequence $\{A_i\}$ of open subsets of $[0, 1]$ exists such that μ is concentrated on each of the A_i 's and

$$\mathcal{L}\text{-meas}(A_i) \rightarrow 0 \quad \text{as } i \rightarrow \infty.$$

For $j = 0, 1, \dots, i-1$ and $i = 1, 2, \dots$, define the intervals I_{ij} and J_{ij} :

$$I_{ij} = \left[\frac{j}{i}, \frac{j+1}{i} \right), \quad J_{ij} = I_{ij} \cap A_i.$$

Define $\hat{m}_{ij} \in R^+$:

$$\hat{m}_{ij} = \begin{cases} \frac{1}{|J_{ij}|} \int_{J_{ij}} \mu(dt) & \text{when } J_{ij} \neq \emptyset, \\ 0 & \text{when } J_{ij} = \emptyset \end{cases}$$

in which $|J_{ij}|$ denotes \mathcal{L} -measure (J_{ij}) , and $m_{ij}: I_{ij} \rightarrow R^+$:

$$m_{ij}(t) = \begin{cases} \hat{m}_{ij} & \text{if } t \in J_{ij}, \\ 0 & \text{if } t \in I_{ij} \setminus A_i. \end{cases}$$

We also define $\hat{\gamma}_{ij} \in R^n$:

$$\hat{\gamma}_{ij} = \frac{\int_{J_{ij}} r(t, u(t)) \mu(dt)}{\int_{J_{ij}} \mu(dt)} \quad \text{if } \hat{m}_{ij} \neq 0$$

and $\tilde{\gamma}_{ij}: I_{ij} \rightarrow R^n$:

$$\tilde{\gamma}_{ij}(t) = \begin{cases} \hat{\gamma}_{ij} & \text{if } t \in J_{ij} \text{ and } \hat{m}_{ij} \neq 0, \\ r(t, u(t)) & \text{if } t \in I_{ij} \setminus A_i \text{ or } \hat{m}_{ij} = 0. \end{cases}$$

Next define $\gamma_{ij}: I_{ij} \rightarrow R^n$ by

$$\gamma_{ij}(t) = \begin{cases} p_{ij}(t) & \text{if } t \in J_{ij} \text{ and } \hat{m}_{ij} \neq 0, \\ r(t, u(t)) & \text{if } t \in I_{ij} \setminus A_i \text{ or } \hat{m}_{ij} = 0 \end{cases}$$

where the function p_{ij} is uniquely specified by

$$|p_{ij}(t) - \hat{\gamma}_{ij}| = \min_{p \in \overline{\text{co}} r(t, U_i)} |p - \hat{\gamma}_{ij}|.$$

Observe that p_{ij} is continuous on its domain of definition (this follows from the continuity properties of $t \rightarrow \overline{\text{co}} r(t, U_i)$). Consequently γ_{ij} is a Borel measurable function. A simple separating hyperplane argument tells us that $\tilde{\gamma}_{ij}(t) \in \overline{\text{co}} [\bigcup_{s \in I_{ij}} r(s, U_s)]$; appealing to this fact and also again to the continuity properties of $t \rightarrow \overline{\text{co}} r(t, U_i)$, we deduce existence of a sequence $\{\varepsilon_i\}$ of real numbers, $\varepsilon_i \rightarrow 0$, such that

$$(A.7) \quad \|\tilde{\gamma}_{ij}(t) - \gamma_{ij}(t)\| \leq \varepsilon_i \quad \text{for all } i, j \text{ and } t \in I_{ij}.$$

Now define Borel measurable functions $m_i: [0, 1] \rightarrow R$ and $\gamma_i: [0, 1] \rightarrow R^n$ by

$$m_i(t) = \sum_j m_{ij}(t) \chi_{I_{ij}}(t)$$

and

$$\gamma_i(t) = \sum_j \gamma_{ij}(t) \chi_{I_{ij}}(t).$$

Here χ_A denotes the indicator function of the set A :

$$\chi_A(x) = \begin{cases} 1 & \text{if } x \in A, \\ 0 & \text{if } x \notin A. \end{cases}$$

Let us verify that $\{m_i\}$ has the properties asserted in the proposition. Clearly $t \rightarrow r(t, u_i(t))m_i(t)$ is \mathcal{L} integrable. It is immediately apparent that the m_i 's are nonnegative valued L_∞ functions. To ascertain the limit we take arbitrary $\phi \in C(0, 1)$ and calculate

$$\begin{aligned}
 (A.8) \quad \int_0^1 \phi(t) m_i(t) dt &= \sum_{j \in S_i} \int_{J_{ij}} \phi(t) m_i(t) dt \\
 &= \sum_{j \in S_i} \int_{J_{ij}} \left(\int_{J_{ij}} \phi(t) dt / |J_{ij}| \right) \mu(dt) \\
 &= \sum_{j \in S_i} \int_{J_{ij}} \phi(t) \mu(dt) + \sum_{j \in S_i} \int_{J_{ij}} q_i(t) \mu(dt)
 \end{aligned}$$

where the function $q_i(\cdot): [0, 1] \rightarrow R$ is

$$(A.9) \quad q_i(t) = \sum_{j \in S_i} \left[\int_{J_{ij}} \phi(s) ds / |J_{ij}| - \phi(t) \right] \chi_{I_{ij}}(t).$$

Since ϕ is a continuous function, the q_i 's converge uniformly to zero. Consequently the second term in the right-hand side of the second equality in (A.8) converges to zero as $i \rightarrow \infty$. In view of the fact that μ is concentrated on a subset of A_i , for each i , the first term is just the desired limit $\int_{[0,1]} \phi(t) \mu(dt)$. Convergence is proved.

Our next objective is to show that

$$(A.10) \quad \gamma_i(t) m_i(t) dt \xrightarrow{*} r(t, u(t)) \mu(dt).$$

Now take arbitrary $\phi \in C^n(0, 1)$. We have

$$\begin{aligned}
 (A.11) \quad \int_0^1 \phi(t) \gamma_i(t) m_i(t) dt &= \sum_{j \in T_i} \int_{I_{ij}} \phi(t) \tilde{\gamma}_{ij} m_{ij}(t) dt \\
 &\quad + \sum_{j \in T_i} \int_{I_{ij}} \phi(t) \cdot [\gamma_{ij}(t) - \tilde{\gamma}_{ij}(t)] m_{ij}(t) dt
 \end{aligned}$$

where T_i is the set of indices j such that $\int_{J_{ij}} \mu(dt) \neq 0$. By (A.7), the norm of the second term on the right-hand side of (A.11) is bounded by

$$\varepsilon_i \|\phi\|_C \sum_{j \in T_i} \int_{I_{ij}} m_i(t) dt = \varepsilon_i \|\phi\|_C \|\mu\|_{TV},$$

which tends to zero as $i \rightarrow \infty$. Consider now the first term,

$$\sum_{j \in T_i} \int_{I_{ij}} \phi(t) \tilde{\gamma}_{ij}(t) m_{ij}(t) dt.$$

This can be expressed as

$$\begin{aligned}
 &\sum_{j \in T_i} \int_{J_{ij}} \phi(t) dt \left(\int_{J_{ij}} r(t, u(t)) \mu(dt) / \int_{J_{ij}} \mu(dt) \right) \left(\int_{J_{ij}} \mu(dt) / |J_{ij}| \right) \\
 &= \sum_{j \in T_i} \int_{J_{ij}} \left(\int_{J_{ij}} \phi(t) dt / |J_{ij}| \right) r(t, u(t)) \mu(dt) \\
 &= \sum_{j \in T_i} \int_{J_{ij}} \phi(t) r(t, u(t)) \mu(dt) + \sum_{j \in T_i} \int_{J_{ij}} q_i(t) r(t, u(t)) \mu(dt).
 \end{aligned}$$

Here $q_i(\cdot)$ is defined once again by (A.9), though now of course we view ϕ as a vector valued function. As before the q_i 's converge uniformly to zero as $i \rightarrow \infty$. (At this point we make use of the uniform bound on $r(t, U_t)$.) The first term, however, is simply

$$\int_0^1 \phi(t) \cdot r(t, u(t)) \mu(dt),$$

since μ is concentrated on a subset of A_i . We have proved (A.10).

Now define the functions $h_i: [0, 1] \times R^m \rightarrow R^n$ and the multifunctions U^i on $[0, 1]$ to be

$$h_i(t, v) = r(t, v) m_i(t)$$

and

$$U_t^i = \begin{cases} U_t & \text{if } t \in A_i, \\ \{u(t)\} & \text{if } t \in [0, 1] \setminus A_i. \end{cases}$$

Taking note of the manner in which γ_i was constructed, we see that

$$\gamma_i(t) m_i(t) \in \overline{\text{co}} h_i(t, U_t^i) \quad \text{for all } t \in [0, 1].$$

Now let $\{\delta_i\}$ be an arbitrary sequence of positive numbers such that $\delta_i \rightarrow 0$. A routine argument in which we consider increasingly fine uniform partitions, Σ_i , of $[0, 1]$ into intervals and apply Aumann's theorem (see, e.g., [4, Thm. 3.1.3]) to the multifunction

$$t \rightarrow \overline{h_i(t, U_t^i)}$$

on each element of Σ_i leads to the conclusion: there exists a measurable function $d_i(\cdot): [0, 1] \rightarrow R^n$ such that

$$d_i(t) \in \overline{h_i(t, U_t^i)} \quad \mathcal{L}\text{-a.e.}, \quad t \in [0, 1]$$

and

$$\sup_{t \in [0, 1]} \left| \int_0^t [d_i(s) - \gamma_i(s) m_i(s)] ds \right| < \frac{\delta_i}{2}$$

for $i = 1, 2, \dots$. However, [3] tells us that there exists a measurable function u_i such that

$$u_i(t) \in U_t^i \quad \text{a.e. } t \in [0, 1]$$

and

$$\sup_{t \in [0, 1]} \left| \int_0^t [d_i(s) - h_i(s, u_i(s))] ds \right| < \frac{\delta_i}{2}$$

for $i = 1, 2, \dots$. Taking account of the definitions of h_i and U_t^i , we see from these inequalities that

$$(A.12) \quad \sup_{t \in [0, 1]} \left| \int_0^t \gamma_i(s) m_i(s) ds - \int_0^t r(s, u_i(s)) m_i(s) ds \right| < \delta_i,$$

and

$$(A.13) \quad \begin{aligned} u_i(t) &= u(t) \quad \text{a.e. } t \in [0, 1] \setminus A_i, \\ u_i(t) &\in \Omega_t \quad \text{a.e. } t \in A_i. \end{aligned}$$

In view of Proposition 5.2, (A.12) implies

$$[\gamma_i(t) - r(t, u_i(t))]m_i(t) dt \xrightarrow{*} 0.$$

It now follows from (A.10) that

$$(A.14) \quad r(t, u_i(t))m_i(t) dt \xrightarrow{*} r(t, u(t))\mu(dt).$$

Bearing in mind that $\mathcal{L}\text{-meas}(A_i) \rightarrow 0$ as $i \rightarrow \infty$, we see from (A.13) and (A.14) that the functions u_i which we have constructed have the properties asserted in the lemma. The proof is complete.

SUFFICIENT CONDITIONS FOR THE FUNCTIONAL REPRODUCIBILITY OF TIME-VARYING, INPUT-OUTPUT SYSTEMS*

KEVIN A. GRASSE†

Abstract. The functional reproducibility of an input-output system refers to the capability of realizing a given class of functions as outputs of the system by the choice of appropriate inputs and initial conditions. For linear, time-varying, input-output systems we derive rank conditions that are sufficient for the generation of all C^k outputs by means of C^0 inputs. These rank conditions provide an alternative to the structure algorithm of L. M. Silverman and, in the linear, time-invariant case, reduce to a rank condition of M. K. Sain and J. L. Massey. We also give sufficient conditions for the local functional reproducibility of nonlinear, time-varying, input-output systems.

Key words. input-output system, functional reproducibility, path controllability.

AMS(MOS) subject classifications. 93C05, 93C50

1. Introduction. An important problem in the study of input-output systems is the determination of whether the output of the system can be made to follow a preassigned trajectory over a specified interval of time. The term “functional reproducibility” was introduced by Brockett and Mesarović [3] and, roughly speaking, means the capability of realizing a given class of functions as outputs of the system by the choice of appropriate inputs and initial conditions. Other authors have used the terms “output tracking” [7] and “path controllability” [14] with a similar connotation.

To illustrate the problem to be considered here and to relate our work to the existing literature, we consider the linear, time-varying, input-output system:

$$(1) \quad \dot{x} = A(t)x + B(t)w, \quad y = C(t)x + D(t)w,$$

where $t \in I$ (an interval in \mathbb{R}), $x \in \mathbb{R}^n$, $w \in \mathbb{R}^m$ and $y \in \mathbb{R}^p$; the matrices A , B , C , D have the obvious dimensions and their entries are assumed to be at least continuous. It is known that under a fixed initial condition $x(t_0) = x_0$ one can realize every continuous function $\psi: I \rightarrow \mathbb{R}^p$ as an output of (1) by means of a continuous input $u: I \rightarrow \mathbb{R}^m$ if and only if $\text{rank } D(t) = p$ for every $t \in I$ [1]. This rank condition is quite strong and it is natural to seek weaker conditions that will still ensure the generation of a reasonably large class of outputs.

There are two aspects of the problem that can be modified so as to yield a weaker form of the above rank condition. First, instead of requiring that all continuous functions $\psi: I \rightarrow \mathbb{R}^p$ be generated as outputs of (1), we will only require that all *sufficiently differentiable* (i.e., C^k for $k \geq 1$) functions be generated as outputs. Second, instead of fixing the initial condition $x(t_0) = x_0$ in advance, we will allow the initial condition to “float” and possibly depend on the output. With these considerations in mind, the objective of this paper is to find computable rank conditions involving the system matrices of (1) which guarantee that given an arbitrary C^k function $\psi: I \rightarrow \mathbb{R}^p$ one can find a continuous input $u: I \rightarrow \mathbb{R}^m$ and an initial condition $x(t_0) = x_0$ such that ψ is the output of (1) with this input and initial condition. Our results will also show how the required input and initial condition can be obtained from the desired output by means of a “right-inverse” system of (1).

The results of this paper are very much in the spirit of the paper of Sain and Massey [13]. Sain and Massey consider both the invertibility and the functional reproducibility of linear, time-invariant, input-output systems. Their work requires certain results from the theory of sequential circuits and makes extensive use of Laplace-transform techniques, which effectively limits the scope of their results to the time-invariant case. Our proofs are self-contained and avoid Laplace transform methods since we deal with the time-varying case. The general method employed here could be described as "coordinate-free, time-varying, linear algebra." As we will see, the rank conditions derived here in the time-varying case, when specialized to the time-invariant case, reduce to precisely the rank condition of Sain and Massey.

The functional reproducibility of linear, time-invariant, input-output systems has also been treated by Silverman [9] and Silverman and Payne [10]; this work is primarily based on Silverman's introduction of the "structure algorithm." In [8] Silverman proves a necessary and sufficient condition for the functional reproducibility of a linear, time-varying, input-output system, but this result is restricted to the single-input/single-output case. Also in [9] he briefly mentions that the techniques used there to prove results on the invertibility of linear, time-varying, input-output systems can also be applied to produce results on the functional reproducibility of such systems, but he does not explicitly state any such results.

The structure algorithm was extended to nonlinear input-output systems by Hirschorn in [6] and he used this extension to prove a result on the functional reproducibility of nonlinear input-output systems in [7]. Hirschorn's results were refined somewhat by Singh in [11] and [12]. The results of Hirschorn and Singh are stated for the time-invariant case, but they can easily be extended to the time-varying case by using the standard device of incorporating time as the $(n+1)$ st coordinate of an augmented state space. In particular, one can apply these results to obtain necessary and sufficient conditions for the functional reproducibility of linear, time-varying, input-output systems.

In view of the above remarks, it might appear that the problem of functional reproducibility has been completely settled, even for nonlinear time-varying systems. However, the existing results all (with one exception on which we will comment later) have a drawback. In rough terms, these results say that if the rank of a certain matrix, produced by k applications of the structure algorithm, is p (the output space dimension), then a C^k function $\psi: I \rightarrow \mathbb{R}^p$ is an output of the system corresponding to some continuous input if and only if there exists an initial condition $x(t_0) = x_0$ such that a certain functional relationship

$$(*) \quad F_i(t_0, x_0, \psi(t_0), \dots, \psi^{(k-1)}(t_0)) = 0$$

holds for $0 \leq i \leq k-1$. The functions F_i are generated by the structure algorithm and will not be described explicitly here (see, e.g., [7] for details). If one is interested in the capability of producing *all* C^k functions as outputs, then a natural question occurs at this point. Given an arbitrary C^k function $\psi: I \rightarrow \mathbb{R}^p$, does there exist an initial condition $x(t_0) = x_0$ satisfying $(*)$ for $0 \leq i \leq k-1$?

For nonlinear input-output systems the answer is no. As an easy example, consider the input-output system:

$$\dot{x}_1 = e^{x_2}, \quad \dot{x}_2 = u, \quad y = x_1.$$

Taking derivatives of y , we obtain $\dot{y} = \dot{x}_1 = e^{x_2}$, $\ddot{y} = \dot{x}_2 e^{x_2} = u e^{x_2}$, so the structure algorithm terminates after two steps and the rank condition is satisfied by every point of the state

space. Nevertheless, any C^2 function $\psi: \mathbb{R} \rightarrow \mathbb{R}$ for which $\dot{\psi}(t) \leq 0$ for at least one $t \in \mathbb{R}$ cannot be realized as an output.

For linear input-output systems, however, the answer is yes. Our results will show that if certain rank conditions are satisfied (see (31) and (32)), then for every C^k function $\psi: I \rightarrow \mathbb{R}^p$ there exists a continuous input $u: I \rightarrow \mathbb{R}^m$ and an initial condition $x(t_0) = x_0$ that generate ψ as the output of (1). The existence of the appropriate initial condition is nontrivial and is proved in Proposition 2.13. This is a rather delicate point and seems to be overlooked in most of the existing literature. The exception is in [8], where Silverman does address this point for single-input/single-output systems. However, it appears that he did not pursue it in his later work on multi-input/multi-output systems. For more discussion on this matter, we refer the reader to [2].

We feel that the formulation of our results has certain other advantages over the structure algorithm. Our rank conditions are intrinsic to the system matrices of (1) and do not depend on a series of possibly nonunique matrix operations, as is the case with the structure algorithm. Also, the matrices whose rank must be examined in our results are generated by matrix additions, multiplications and differentiations; no inversions or row reductions are required. Consequently, these matrices could be easily generated by a symbolic manipulation program.

A short outline of our paper follows. The main result on the functional reproducibility of linear, time-varying, input-output systems is proved in § 2. In § 3 we briefly discuss how our sufficient condition for the linear case can be applied to the linearization of a nonlinear input-output system to yield a local functional reproducibility result in the nonlinear case. As is pointed out in [15], the existing results of Hirschorn and Singh on nonlinear functional reproducibility are also, in some sense, only local results. Additional results on nonlinear functional reproducibility can be found in [1], [5], [15].

2. The linear time-varying case. Let I be an interval in \mathbb{R} (possibly unbounded) and for nonnegative integers k, l (or $k = \infty$) let $C^{k,l}(I)$ denote the set of all C^k mappings of I into \mathbb{R}^l . We consider the linear, time-varying, input-output system (1), where, as mentioned previously, $t \in I$, $x \in \mathbb{R}^n$, $w \in \mathbb{R}^m$ and $y \in \mathbb{R}^p$. The entries of the time-varying matrix functions A, B, C, D are assumed to be C^∞ functions of t . The C^∞ assumption is invoked to avoid the necessity of counting orders of differentiability and “ C^∞ ” could be replaced by “ C^r for r sufficiently large.” We assume that the inputs of (1) are in $\mathcal{C}^{0,m}(I)$.

DEFINITION 2.1. The system (1) is called *weakly C^k -reproducible* ($k \geq 0$) on I if for every $\psi \in \mathcal{C}^{k,p}(I)$ there exist $(t_0, x_0) \in I \times \mathbb{R}^n$ and $u \in \mathcal{C}^{0,m}(I)$ such that for every $t \in I$

$$\psi(t) = C(t)\phi(t) + D(t)u(t)$$

where ϕ is the solution of the initial-value problem

$$\dot{\phi}(t) = A(t)\phi(t) + B(t)u(t), \quad \phi(t_0) = x_0.$$

In other words (1) is weakly C^k -reproducible if every $\psi \in \mathcal{C}^{k,p}(I)$ can be realized as an output of (1) through the choice of an appropriate initial condition in $I \times \mathbb{R}^n$ and input in $\mathcal{C}^{0,m}(I)$. We call the reproducibility “weak” because the initial condition may depend on the output and cannot be fixed in advance. The reader is referred to [2] for a discussion and comparison of this type of reproducibility as it relates to other notions of functional reproducibility that have appeared in the literature.

Our objective in this section is to give a sufficient condition for system (1) to be weakly C^k -reproducible for $k \geq 1$ (a necessary and sufficient condition for weak C^0 -reproducibility was mentioned in the Introduction). This sufficient condition will

be phrased in terms of rank conditions involving the system matrices A , B , C , D and their derivatives. It will be shown that if the sufficient condition is satisfied, then there exist $C^\infty(m \times p)$ -matrix functions

$$E_0(t), E_1(t), \dots, E_k(t)$$

($t \in I$) with the property that every $\psi \in \mathcal{C}^{k,p}(I)$ determines $(t_0, x_0) \in I \times \mathbb{R}^n$ and $v \in \mathcal{C}^{k,p}(I)$ such that for the initial condition $x(t_0) = x_0$ and the (continuous) input

$$(2) \quad u(t) = \sum_{i=0}^k E_i(t) v^{(i)}(t)$$

where $v^{(0)}(t) = v(t)$ and $v^{(i)}(t)$ = the i th derivative of $v(t)$ for $i \geq 1$, system (1) generates ψ as its output.

Before we specifically determine the matrix functions E_0, E_1, \dots, E_k , let us examine the relationship between outputs ψ of (1) corresponding to inputs u of the form (2), where for the time being E_0, E_1, \dots, E_k are arbitrary $C^\infty(m \times p)$ -matrix functions of $t \in I$ and we leave the initial condition unspecified. Then (in the sequel we suppress t when convenient)

$$(3) \quad \psi = C\phi + \sum_{i=0}^k DE_i v^{(i)},$$

where

$$(4) \quad \dot{\phi} = A\phi + \sum_{i=0}^k BE_i v^{(i)}.$$

We temporarily assume that the function $v \in \mathcal{C}^{k,p}(I)$ is actually C^∞ . Differentiating both sides of (3) and using (4), we obtain

$$(5) \quad \dot{\psi} = (\dot{C} + CA)\phi + (CBE_0 + \overline{DE_0})v^{(0)} + \sum_{i=1}^k (CBE_i + \overline{DE_i} + DE_{i-1})v^{(i)} + DE_k v^{(k+1)}.$$

Define an operator Γ on differentiable ($q \times n$)-matrix functions $M(t)$ ($q \geq 1$) by

$$(6) \quad \Gamma M = \dot{M} + MA.$$

For $l \geq 2$ we define $\Gamma^l M$ inductively by $\Gamma^l M = \Gamma(\Gamma^{l-1} M)$ and by convention $\Gamma^0 M = M$. Setting

$$(7) \quad F_i^0 = DE_i, \quad 0 \leq i \leq k,$$

we can rewrite (3) and (5) as

$$\psi = (\Gamma^0 C)\phi + \sum_{i=0}^k F_i^0 v^{(i)} \quad \text{and} \quad \dot{\psi} = (\Gamma^1 C)\phi + \sum_{i=0}^{k+1} F_i^1 v^{(i)}$$

where $F_0^1 = (\Gamma^0 C)BE_0 + \dot{F}_0^0$, $F_{k+1}^1 = F_k^0 = DE_k$, and

$$F_i^1 = (\Gamma^0 C)BE_i + \overline{DE_i} + DE_{i-1}, \quad 1 \leq i \leq k.$$

This process can be continued to yield for $0 \leq l \leq k$

$$(8) \quad \psi^{(l)} = (\Gamma^l C)\phi + \sum_{i=0}^{k+l} F_i^l v^{(i)}$$

where for $l=0$ the F_i^0 , $0 \leq i \leq k$, are defined by (7) and for $1 \leq l \leq k$ the F_i^l , $0 \leq i \leq k+l$, are defined inductively by

$$(9a) \quad F_0^l = (\Gamma^{l-1}C)BE_0 + \dot{F}_0^l,$$

$$(9b) \quad F_i^l = (\Gamma^{l-1}C)BE_i + \dot{F}_i^{l-1} + F_{i-1}^{l-1}, \quad 1 \leq i \leq k,$$

$$(9c) \quad F_i^l = \dot{F}_i^{l-1} + F_{i-1}^{l-1}, \quad k < i < k+l,$$

$$(9d) \quad F_{k+l}^l = F_{k+l-1}^{l-1} = \cdots = F_k^0 = DE_k.$$

We will derive an alternative formula for the $(p \times p)$ -matrix functions $F_i^l(t)$, $t \in I$, for $0 \leq i, l \leq k$. To this end we define $(m \times p)$ -matrix functions $H_i^r(t)$, $t \in I$, for $0 \leq i, r \leq k$ by

$$(10) \quad H_i^r = \sum_{j=0}^r \binom{r}{j} (E_{i-j})^{(r-j)},$$

where $\binom{r}{j}$ is the usual binomial coefficient and we take $E_q = 0$ for $q < 0$.

LEMMA 2.2. For $1 \leq i \leq k$ and $0 \leq r \leq k-1$ we have

$$\dot{H}_i^r + H_{i-1}^r = H_i^{r+1}.$$

Proof. We simply compute and obtain

$$\begin{aligned} \dot{H}_i^r + H_{i-1}^r &= \sum_{j=0}^r \binom{r}{j} (E_{i-j})^{(r-j+1)} + \sum_{j=0}^r \binom{r}{j} (E_{i-1-j})^{(r-j)} \\ &= \sum_{j=0}^r \binom{r}{j} (E_{i-j})^{(r-j+1)} + \sum_{j=1}^{r+1} \binom{r}{j-1} (E_{i-j})^{(r-j+1)} \\ &= \sum_{j=0}^{r+1} \binom{r+1}{j} (E_{i-j})^{(r+1-j)} \quad \left(\text{since } \binom{r}{j} + \binom{r}{j-1} = \binom{r+1}{j}, 1 \leq j \leq r \right) \\ &= H_i^{r+1}. \end{aligned} \quad \square$$

Remark 2.3. For later reference we observe that

$$(11) \quad H_i^0 = E_i, \quad 0 \leq i \leq k,$$

and $H_0^r = (E_0)^{(r)}$, $0 \leq r \leq k$, so that

$$(12) \quad \dot{H}_0^r = H_0^{r+1}, \quad 0 \leq r \leq k-1.$$

We also define $(p \times m)$ -matrix functions $G_r^l(t)$, $t \in I$, for $r, l \geq 0$ by

$$(13) \quad G_0^0 = D, \quad G_r^0 = 0, \quad r \geq 1,$$

for $l=0$ and for $l \geq 1$ inductively by

$$(14) \quad G_0^l = (\Gamma^{l-1}C)B + \dot{G}_0^{l-1}, \quad G_r^l = G_{r-1}^{l-1} + \dot{G}_r^{l-1}, \quad r \geq 1.$$

It is worthwhile to observe that

$$(15) \quad G_i^l = D, \quad l \geq 0,$$

and

$$(16) \quad G_r^l = 0, \quad l < r.$$

PROPOSITION 2.4. For $0 \leq i, l \leq k$ we have $F_i^l = \sum_{r=0}^l G_r^l H_i^r$.

Proof. We proceed by induction on l . For $l=0$ and $0 \leq i \leq k$ (7), (11) and (13) imply that $G_0^0 H_i^0 = DE_i = F_i^0$, so the formula holds when $l=0$. Let $1 \leq l \leq k$ and assume that the formula holds for $l-1$. Then for $1 \leq i \leq k$ (9b) yields

$$\begin{aligned}
 F_i^l &= (\Gamma^{l-1} C) B E_i + \dot{F}_i^{l-1} + F_{i-1}^{l-1} \\
 &= (\Gamma^{l-1} C) B H_i^0 + \frac{d}{dt} \left(\sum_{r=0}^{l-1} G_r^{l-1} H_i^r \right) + \sum_{r=0}^{l-1} G_r^{l-1} H_{i-1}^r \\
 &\quad \text{(by (11) and the induction assumption)} \\
 &= (\Gamma^{l-1} C) B H_i^0 + \sum_{r=0}^{l-1} (\dot{G}_r^{l-1} H_i^r + G_r^{l-1} \dot{H}_i^r) + \sum_{r=0}^{l-1} G_r^{l-1} H_{i-1}^r \\
 &= (\Gamma^{l-1} C) B H_i^0 + \sum_{r=0}^{l-1} \dot{G}_r^{l-1} H_i^r + \sum_{r=0}^{l-1} G_r^{l-1} (\dot{H}_i^r + H_{i-1}^r) \\
 &= (\Gamma^{l-1} C) B H_i^0 + \sum_{r=0}^{l-1} \dot{G}_r^{l-1} H_i^r + \sum_{r=0}^{l-1} G_r^{l-1} H_i^{r+1} \quad \text{(by Lemma 2.2)} \\
 &= (\Gamma^{l-1} C) B H_i^0 + \sum_{r=0}^{l-1} \dot{G}_r^{l-1} H_i^r + \sum_{r=1}^l G_{r-1}^{l-1} H_i^r \\
 &= ((\Gamma^{l-1} C) B + \dot{G}_0^{l-1}) H_i^0 + \sum_{r=1}^{l-1} (G_{r-1}^{l-1} + \dot{G}_r^{l-1}) H_i^r + G_{l-1}^{l-1} H_i^l.
 \end{aligned}$$

By (14) and (15) we infer that

$$F_i^l = G_0^l H_i^0 + \sum_{r=1}^{l-1} G_r^l H_i^r + G_l^l H_i^l = \sum_{t=0}^l G_t^l H_i^t,$$

which is the desired formula for $1 \leq i \leq k$. A similar computation, starting with (9a), proves the induction step when $i=0$. \square

Proposition 2.4 can be summarized by the following block-matrix equation (note also relation (16)):

$$(17) \quad \begin{bmatrix} F_0^0 & F_1^0 & \cdots & F_k^0 \\ F_0^1 & F_1^1 & \cdots & F_k^1 \\ \vdots & \vdots & & \vdots \\ F_0^k & F_1^k & \cdots & F_k^k \end{bmatrix} = \begin{bmatrix} G_0^0 & 0 & 0 & \cdots & 0 \\ G_0^1 & G_1^1 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ G_0^k & G_1^k & G_2^k & \cdots & G_k^k \end{bmatrix} \begin{bmatrix} H_0^0 & H_1^0 & \cdots & H_k^0 \\ H_0^1 & H_1^1 & \cdots & H_k^1 \\ \vdots & \vdots & & \vdots \\ H_0^k & H_1^k & \cdots & H_k^k \end{bmatrix}.$$

Up to this point, the E_0, E_1, \dots, E_k have been arbitrary C^∞ ($m \times p$)-matrix functions of $t \in I$. We will now specify how the E_0, E_1, \dots, E_k should be chosen so as to obtain the desired property of weak C^k reproducibility. In the following proposition I_p denotes the $p \times p$ identity matrix and 0_p denotes the $p \times p$ zero matrix.

PROPOSITION 2.5. *Suppose that there exist C^∞ ($m \times p$)-matrix functions K_0, K_1, \dots, K_k of $t \in I$ such that*

$$(18) \quad \begin{bmatrix} G_0^0 & 0 & 0 & \cdots & 0 \\ G_0^1 & G_1^1 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ G_0^k & G_1^k & G_2^k & \cdots & G_k^k \end{bmatrix} \begin{bmatrix} K_0 \\ K_1 \\ \vdots \\ K_k \end{bmatrix} = \begin{bmatrix} 0_p \\ 0_p \\ \vdots \\ I_p \end{bmatrix}$$

at every $t \in I$. Then there exist C^∞ ($m \times p$)-matrix functions E_0, E_1, \dots, E_k of $t \in I$ such that for the $(m \times p)$ -matrix functions H_i^r defined by (10) we have

$$(19) \quad H_k^r = K_r, \quad 0 \leq r \leq k.$$

Furthermore, for the $(p \times p)$ -matrix functions F_i^l defined by (7) and (9) we have

$$(20) \quad F_k^0 = F_k^1 = \cdots = F_k^{k-1} = 0_p \quad \text{and} \quad F_k^k = I_p$$

at every $t \in I$.

Proof. By the definition of the matrix functions H_i^r in terms of the matrix functions E_0, E_1, \dots, E_k (see (10)), in order to satisfy (19) we must choose E_0, E_1, \dots, E_k so that

$$(21) \quad K_r = \sum_{j=0}^r \binom{r}{j} (E_{k-j})^{(r-j)}$$

for $0 \leq r \leq k$. If we set $E_k = K_0$, then (21) is satisfied when $r = 0$ (recall the convention that $E_q = 0$ if $q < 0$). Let $1 \leq s \leq k$ and assume that E_k, \dots, E_{k-s+1} have been chosen so that (21) is satisfied for $0 \leq r \leq s-1$. Setting

$$E_{k-s} = K_s - \sum_{j=0}^{s-1} \binom{s}{j} (E_{k-j})^{(s-j)},$$

we see that (21) is satisfied for $r = s$. By induction we can choose E_0, E_1, \dots, E_k so as to satisfy (21) (and hence (19)) for $0 \leq r \leq k$. The relations (20) follow by using (18) and (19) and equating the last columns of both sides of (17). \square

COROLLARY 2.6. *Suppose that there exist C^∞ $(m \times p)$ -matrix functions K_0, K_1, \dots, K_k of $t \in I$ that satisfy (18) and let E_0, E_1, \dots, E_k be as given in Proposition 2.4. Then for every input u of the form (2), where $v \in \mathcal{C}^{k,p}(I)$, and every initial condition $(t_0, x_0) \in I \times \mathbb{R}^n$, the corresponding output ψ of system (1) is in $\mathcal{C}^{k,p}(I)$ and we have*

$$(22) \quad \psi^{(l)} = (\Gamma^l C) \phi + \sum_{i=0}^{k-1} F_i^l v^{(i)}, \quad 0 \leq l \leq k-1,$$

and

$$(23) \quad \psi^{(k)} = (\Gamma^k C) \phi + \sum_{i=0}^{k-1} F_i^k v^{(i)} + v^{(k)}$$

where ϕ satisfies (4).

Proof. This follows from (8) with the use of (20), (7) and (9). \square

Equation (23) is the key factor in determining the required input u from the desired output ψ . Observe that, for the matrix functions E_0, E_1, \dots, E_k given by Proposition 2.5, we do not have to assume that v has more than k derivatives to compute $\psi^{(1)}, \dots, \psi^{(k)}$, since the k th derivative of v does not appear until we compute $\psi^{(k)}$. The next task is to find a sufficient condition for (18) to hold. This will be done subsequent to the next two lemmas, the first of which is a modification of a theorem of Dolezal [4].

LEMMA 2.7. *Let N be a positive integer, let $\{\omega_1, \dots, \omega_q\}$ be a finite subset of $\mathcal{C}^{r,N}(I)$, $0 \leq r \leq \infty$, let $\Omega(t) \subseteq \mathbb{R}^N$ for $t \in I$ denote the subspace*

$$\Omega(t) = \text{span} [\omega_1(t), \dots, \omega_q(t)],$$

and assume that for every $t \in I$ we have $\dim \Omega(t) = \rho$, where ρ is a constant satisfying $\rho < N$. Let $\eta \in \mathcal{C}^{r,N}(I)$ be such that $\eta(t) \notin \Omega(t)$ for every $t \in I$. Then there exists $e \in \mathcal{C}^{r,N}(I)$ such that for every $t \in I$

$$\langle \eta(t), e(t) \rangle = 1$$

and

$$\langle \omega_i(t), e(t) \rangle = 0, \quad 1 \leq i \leq q,$$

where \langle, \rangle is the standard inner product on \mathbb{R}^N .

Proof. For each $t \in I$ let $\eta_0(t)$ denote the orthogonal projection of $\eta(t)$ onto the subspace $\Omega(t)$ and observe that $\|\eta(t) - \eta_0(t)\| > 0$. We will first show that η_0 is C^r and to do this it suffices to show that for every $\bar{t} \in I$ there is a relatively open neighborhood $U_{\bar{t}}$ of \bar{t} in I such that $\eta_0|_{U_{\bar{t}}}$ is C^r . Indeed, given $\bar{t} \in I$ we have $\dim \Omega(\bar{t}) = \rho$ by assumption, so there exists a subset $\{k_1, \dots, k_\rho\}$ of $\{1, \dots, q\}$ such that $\{\omega_{k_i}(\bar{t}) | 1 \leq i \leq \rho\}$ is a basis for $\Omega(\bar{t})$. Since the ω_{k_i} 's are at least continuous, the function

$$\text{rank} [\omega_{k_1}(t), \dots, \omega_{k_\rho}(t)]$$

is locally nondecreasing, so there exists a relatively open neighborhood $U_{\bar{t}}$ of \bar{t} in I such that

$$t \in U_{\bar{t}} \Rightarrow \rho \leq \text{rank} [\omega_{k_1}(t), \dots, \omega_{k_\rho}(t)].$$

On the other hand, for every $t \in I$ we have

$$\text{rank} [\omega_{k_1}(t), \dots, \omega_{k_\rho}(t)] \leq \dim \Omega(t) = \rho,$$

so we infer that

$$t \in U_{\bar{t}} \Rightarrow \text{rank} [\omega_{k_1}(t), \dots, \omega_{k_\rho}(t)] = \rho.$$

Consequently, $\{\omega_{k_i}(t) | 1 \leq i \leq \rho\}$ is a basis of $\Omega(t)$ for every $t \in U_{\bar{t}}$. By definition $\eta_0(t) \in \Omega(t)$ for every $t \in I$, so for $t \in U_{\bar{t}}$ there exist real-valued functions $\alpha_1(t), \dots, \alpha_\rho(t)$ such that

$$(24) \quad \eta_0(t) = \sum_{j=1}^{\rho} \alpha_j(t) \omega_{k_j}(t).$$

The relations

$$\langle \eta(t) - \eta_0(t), \omega_{k_i}(t) \rangle = 0, \quad 1 \leq i \leq \rho$$

imply that for each $t \in U_{\bar{t}}$ the ρ -tuple $(\alpha_1(t), \dots, \alpha_\rho(t))$ is a solution of the linear system of equations

$$(25) \quad \sum_{j=1}^{\rho} \langle \omega_{k_j}(t), \omega_{k_i}(t) \rangle \alpha_j(t) = \langle \eta(t), \omega_{k_i}(t) \rangle, \quad 1 \leq i \leq \rho.$$

The linear independence of $\{\omega_{k_i}(t) | 1 \leq i \leq \rho\}$ for $t \in U_{\bar{t}}$ implies that the $\rho \times \rho$ coefficient matrix of (25) is nonsingular. Therefore the linear system (25) has a unique solution $(\alpha_1(t), \dots, \alpha_\rho(t))$ and by Cramer's rule this solution is a C^r function of $t \in U_{\bar{t}}$, since the ω_{k_i} and η are C^r . From (24) it is clear that $\eta_0|_{U_{\bar{t}}}$ is C^r and, as was mentioned earlier, this is enough to conclude that η_0 is C^r on I .

From the relations

$$\|\eta(t) - \eta_0(t)\| > 0, \quad \langle \eta(t) - \eta_0(t), \eta_0(t) \rangle = 0,$$

we obtain

$$0 < \|\eta(t) - \eta_0(t)\|^2 = \langle \eta(t) - \eta_0(t), \eta(t) \rangle,$$

for every $t \in I$, so the function $e: I \rightarrow \mathbb{R}^N$ given by

$$e(t) = \langle \eta(t) - \eta_0(t), \eta(t) \rangle^{-1} (\eta(t) - \eta_0(t))$$

is well defined, of class C^r , and clearly satisfies our requirements. \square

LEMMA 2.8. Let p, q, N be positive integers, let $W(t)$ be a time-varying $(q \times N)$ -matrix function of $t \in I$, let $Z(t)$ be a time-varying $(p \times N)$ -matrix function of $t \in I$, and assume that the entries of $W(t)$ and $Z(t)$ are of class C^r , $0 \leq r \leq \infty$. Suppose that

$$(26) \quad \text{rank } W(t) = \text{const.} \quad \text{for } t \in I$$

and

$$(27) \quad \text{rank} \begin{bmatrix} W(t) \\ Z(t) \end{bmatrix} - \text{rank } W(t) = p \quad \text{for } t \in I.$$

Then there exists an $(N \times p)$ -matrix function $K(t)$ of $t \in I$ with C^r entries such that

$$(28) \quad \begin{bmatrix} W(t) \\ Z(t) \end{bmatrix} K(t) = \begin{bmatrix} 0_{q \times p} \\ I_p \end{bmatrix} \quad \text{for } t \in I.$$

Proof. Let $\omega_1(t), \dots, \omega_q(t)$ denote the N -dimensional row vectors of $W(t)$ and let $\eta_1(t), \dots, \eta_p(t)$ denote the N -dimensional row vectors of $Z(t)$. For each $t \in I$ define subspaces of \mathbb{R}^N by

$$\Omega_0(t) = \text{span} [\omega_1(t), \dots, \omega_q(t)]$$

and

$$\Omega_i(t) = \text{span} [\{\omega_1(t), \dots, \omega_q(t), \eta_1(t), \dots, \eta_p(t)\} \setminus \{\eta_i(t)\}], \quad 1 \leq i \leq p.$$

From (26) and (27) we see that for $t \in I$

$$\eta_i(t) \notin \Omega_i(t), \quad 1 \leq i \leq p,$$

and

$$\dim \Omega_i(t) = \dim \Omega_0(t) + (p - 1) = \text{const.}, \quad 1 \leq i \leq p.$$

Thus for each $i = 1, \dots, p$ we can apply Lemma 2.7 to obtain a function $e_i \in \mathcal{C}^{r,N}(I)$ such that for $t \in I$

$$(29) \quad \begin{aligned} \langle \omega_j(t), e_i(t) \rangle &= 0, & 1 \leq j \leq q, \\ \langle \eta_j(t), e_i(t) \rangle &= 0, & 1 \leq j \leq p, \quad j \neq i, \\ \langle \eta_i(t), e_i(t) \rangle &= 1. \end{aligned}$$

Form an $(N \times p)$ -matrix function $K(t)$ in such a way that its i th column consists of the N components of the vector $e_i(t)$, $1 \leq i \leq p$. Then the relations (29) show that $K(t)$ satisfies (28). \square

We will associate to the input-output system (1) a family $\{M_k(t) | k \geq 0\}$ of C^∞ block-lower-triangular matrix functions of $t \in I$ defined by

$$(30) \quad M_k = \begin{bmatrix} G_0^0 & 0 & 0 & \cdots & 0 \\ G_0^1 & G_1^1 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ G_0^k & G_1^k & G_2^k & \cdots & G_k^k \end{bmatrix}$$

where the matrices G_r^l are as defined in (13) and (14). Observe that the dimensions of M_k are $(k+1)p$ by $(k+1)m$. It is perhaps instructive to write out one of

the M_k 's explicitly directly in terms of the system matrices A, B, C, D ; for example,

$$M_3 = \begin{bmatrix} D & 0 & 0 & 0 \\ CB + \dot{D} & D & 0 & 0 \\ (\Gamma C)B + \overline{CB} + \ddot{D} & CB + 2\dot{D} & D & 0 \\ (\Gamma^2 C)B + (\overline{\Gamma C})\overline{B} + \overline{\overline{CB}} + \ddot{D} & (\Gamma C)B + 2\overline{CB} + 3\ddot{D} & CB + 3\dot{D} & D \end{bmatrix}.$$

PROPOSITION 2.9. Let k be a positive integer and suppose that

$$(31) \quad \text{rank } M_{k-1}(t) = \text{const. for every } t \in I$$

and

$$(32) \quad \text{rank } M_k(t) - \text{rank } M_{k-1}(t) = p \quad \text{for every } t \in I.$$

Then there exist $C^\infty(m \times p)$ -matrix functions K_0, K_1, \dots, K_k of $t \in I$ such that (18) holds everywhere on I .

Proof. From the form of the matrix M_k it is clear that the rank of the first kp rows of M_k equals the rank of M_{k-1} , which is constant on I by (31). Assumption (32) allows us to use Lemma 2.8 to obtain a $C^\infty((k+1)m \times p)$ -matrix function $K(t)$ of $t \in I$ such that

$$M_k(t)K(t) = \begin{bmatrix} 0_{kp \times p} \\ I_p \end{bmatrix}.$$

If we partition the matrix $K(t)$ into a column of $k+1$ $m \times p$ matrices as

$$K(t) = \begin{bmatrix} K_0(t) \\ \vdots \\ K_k(t) \end{bmatrix},$$

then the matrix functions K_0, K_1, \dots, K_k are seen to satisfy our requirements. \square

We will fit together the results obtained thus far in the following theorem.

THEOREM 2.10. Consider the input-output system (1) with C^∞ system matrices A, B, C, D and for $k \geq 0$ let M_k be as defined in (30), where the block entries G_r^l are as defined in (13) and (14). Suppose that for some $k \geq 1$ the rank conditions (31) and (32) hold. Then for every $\psi \in \mathcal{C}^{k,p}(I)$ and for every initial condition $(t_0, x_0) \in I \times \mathbb{R}^n$ there exists $u \in \mathcal{C}^{0,m}(I)$ such that the output $\tilde{\psi}$ of (1) corresponding to the input u and initial condition (t_0, x_0) satisfies $\tilde{\psi} \in \mathcal{C}^{k,p}(I)$ and $\tilde{\psi}^{(k)} = \psi^{(k)}$.

Proof. By Proposition 2.9 there exist $C^\infty(m \times p)$ -matrix functions K_0, K_1, \dots, K_k of $t \in I$ such that (18) holds everywhere on I . Then from Proposition 2.5 we obtain $C^\infty(m \times p)$ -matrix functions E_0, E_1, \dots, E_k such that the matrix functions F_i^l defined by (7) and (9) satisfy

$$F_k^0 = \dots = F_k^{k-1} = 0_p \quad \text{and} \quad F_k^k = I_p.$$

Let $\psi \in \mathcal{C}^{k,p}(I)$ and $(t_0, x_0) \in I \times \mathbb{R}^n$ be given and consider the linear time-varying, nonhomogeneous system of ODEs of order $n + kp$ in the vector variables $x \in \mathbb{R}^n$ and $z_0, \dots, z_{k-1} \in \mathbb{R}^p$ given by

$$(33) \quad \begin{aligned} \dot{x} &= A(t)x + \sum_{i=0}^{k-1} B(t)E_i(t)z_i + B(t)E_k(t) \cdot \left\{ \psi^{(k)}(t) - (\Gamma^k C)(t)x - \sum_{i=0}^{k-1} F_i^k(t)z_i \right\}, \\ \dot{z}_0 &= z_1, \\ &\vdots \\ \dot{z}_{k-2} &= z_{k-1}, \\ \dot{z}_{k-1} &= \psi^{(k)}(t) - (\Gamma^k C)(t)x - \sum_{i=0}^{k-1} F_i^k(t)z_i. \end{aligned}$$

Choose an initial condition of the form $(t_0, x_0, w_0, \dots, w_{k-1}) \in I \times \mathbb{R}^{n+kp}$, where the $w_i \in \mathbb{R}^p$ are arbitrary, $0 \leq i \leq k-1$, and for $t \in I$ let $(\phi(t), \zeta_0(t), \dots, \zeta_{k-1}(t))$ denote the solution of (33) subject to this initial condition. If we set $v(t) = \zeta_0(t)$, then (33) implies that

$$\begin{aligned} v^{(1)}(t) &= \dot{\zeta}_0(t) = \zeta_1(t), \\ &\vdots \\ v^{(k-1)}(t) &= \dot{\zeta}_{k-2}(t) = \zeta_{k-1}(t), \end{aligned}$$

and

$$(34) \quad v^{(k)}(t) = \psi^{(k)}(t) - (\Gamma^k C)(t)\phi(t) - \sum_{i=0}^{k-1} F_i^k(t)v^{(i)}(t);$$

in particular, $v \in \mathcal{C}^{k,p}(I)$. For $t \in I$ let

$$(35) \quad u(t) = \sum_{i=0}^k E_i(t)v^{(i)}(t).$$

Then $u \in \mathcal{C}^{0,m}(I)$, ϕ satisfies $\phi(t_0) = x_0$, and

$$\dot{\phi}(t) = A(t)\phi(t) + B(t)u(t)$$

for every $t \in I$. Setting $\tilde{\psi}(t) = C(t)\phi(t) + D(t)u(t)$, we see by (23) that for every $t \in I$

$$\begin{aligned} \tilde{\psi}^{(k)}(t) &= (\Gamma^k C)(t)\phi(t) + \sum_{i=0}^{k-1} F_i^k(t)v^{(i)}(t) + v^{(k)}(t) \\ &= \psi^{(k)}(t) \end{aligned}$$

where the last equality follows from (34). This completes the proof. \square

A concise restatement of Theorem 2.10 is that, in the presence of the rank conditions (31) and (32), given any $\psi \in \mathcal{C}^{k,p}(I)$ we can generate an output $\tilde{\psi}$ of (1) such that $\tilde{\psi}^{(k)} = \psi^{(k)}$. The initial condition is arbitrary and the input is of the form (35). The next step is to show that if the initial condition is chosen properly, then we can obtain $\tilde{\psi} = \psi$. We first observe that by (22) (Corollary 2.6) for every initial condition $(t_0, x_0) \in I \times \mathbb{R}^n$ we have

$$(36) \quad \tilde{\psi}^{(l)}(t_0) = (\Gamma^l C)(t_0)x_0 + \sum_{i=0}^{k-1} F_i^l(t_0)w_i, \quad 0 \leq l \leq k-1$$

where $w_i = \zeta_i(t_0) = v^{(i)}(t_0)$ for $0 \leq i \leq k-1$. Suppose that for a given output $\psi \in \mathcal{C}^{k,p}(I)$ we can find an initial condition $(t_0, x_0, w_0, \dots, w_{k-1})$ for the system (33) that satisfies

$$(37) \quad \psi^{(l)}(t_0) = (\Gamma^l C)(t_0)x_0 + \sum_{i=0}^{k-1} F_i^l(t_0)w_i, \quad 0 \leq l \leq k-1.$$

In this case, comparing (36) and (37), we see that the output $\tilde{\psi}$ of (1) generated by the initial condition (t_0, x_0) and the input (35) satisfies

$$\tilde{\psi}^{(l)}(t_0) = \psi^{(l)}(t_0), \quad 0 \leq l \leq k-1,$$

and

$$\tilde{\psi}^{(k)}(t) = \psi^{(k)}(t), \quad t \in I,$$

which clearly implies that $\tilde{\psi} = \psi$. Thus to generate every $\psi \in \mathcal{C}^{k,p}(I)$ as an output of

(1) it is sufficient that the rank conditions (31), (32) hold and that for every $\psi \in \mathcal{C}^{k,p}(I)$ there exist $(t_0, x_0, w_0, \dots, w_{k-1}) \in I \times \mathbb{R}^{n+kp}$ satisfying (37).

We can rewrite the system of equations (37) in matrix form:

$$(38) \quad \begin{bmatrix} \psi^{(0)}(t_0) \\ \psi^{(1)}(t_0) \\ \vdots \\ \psi^{(k-1)}(t_0) \end{bmatrix} = \begin{bmatrix} (\Gamma^0 C)(t_0) & F_0^0(t_0) & \cdots & F_{k-1}^0(t_0) \\ (\Gamma^1 C)(t_0) & F_0^1(t_0) & \cdots & F_{k-1}^1(t_0) \\ \vdots & \vdots & \ddots & \vdots \\ (\Gamma^{k-1} C)(t_0) & F_0^{k-1}(t_0) & \cdots & F_{k-1}^{k-1}(t_0) \end{bmatrix} \begin{bmatrix} x_0 \\ w_0 \\ \vdots \\ w_{k-1} \end{bmatrix}.$$

It is clear that (38) will have a solution for every $\psi \in \mathcal{C}^{k,p}(I)$ if and only if the matrix

$$(39) \quad S_k(t) = \begin{bmatrix} (\Gamma^0 C)(t) & F_0^0(t) & \cdots & F_{k-1}^0(t) \\ (\Gamma^1 C)(t) & F_0^1(t) & \cdots & F_{k-1}^1(t) \\ \vdots & \vdots & \ddots & \vdots \\ (\Gamma^{k-1} C)(t) & F_0^{k-1}(t) & \cdots & F_{k-1}^{k-1}(t) \end{bmatrix}$$

has full rank kp when $t = t_0$. It turns out that the rank conditions (31) and (32) imply that $\text{rank } S_k(t) = kp$ for every t in an open dense subset of I (later we will improve this to $\text{rank } S_k(t) = kp$ for every t in I). The proof of this fact requires two lemmas.

LEMMA 2.11. *Let η be a C^∞ p -dimensional (column) vector function of $t \in I$ and let C be a C^∞ $(p \times n)$ -matrix function of $t \in I$. Then for every nonnegative integer r the operator Γ defined in (6) satisfies*

$$\Gamma^r(\eta^T C) = \sum_{q=0}^r \binom{r}{q} (\eta^T)^{(q)} \Gamma^{r-q} C$$

where the superscript T denotes transpose.

Proof. The proof is a straightforward induction on r . \square

LEMMA 2.12. *Let E_0, E_1, \dots, E_k ($k \geq 1$) be arbitrary C^∞ $(m \times p)$ -matrix functions of $t \in I$ and let the C^∞ $(p \times p)$ -matrix functions F_i^l of $t \in I$ be as defined in (7) and (9). Let $1 \leq l \leq k$, let J be an open subinterval of I , and let $\eta_0, \dots, \eta_{l-1}$ be C^∞ p -dimensional (column) vector functions of $t \in I$ such that*

$$(40) \quad [\eta_0^T, \dots, \eta_{l-1}^T] \begin{bmatrix} \Gamma^0 C & F_0^0 & \cdots & F_{k-1}^0 \\ \Gamma^1 C & F_0^1 & \cdots & F_{k-1}^1 \\ \vdots & \vdots & \ddots & \vdots \\ \Gamma^{l-1} C & F_0^{l-1} & \cdots & F_{k-1}^{l-1} \end{bmatrix} = 0_{1 \times (n+kp)}$$

for every $t \in J$. Then for every $t \in J$ and $0 \leq i \leq k-1$ we have

$$(41) \quad \sum_{j=0}^{l-1} \sum_{q=0}^{k-l} \binom{k-l}{q} (\eta_j^T)^{(q)} F_i^{j+k-l-q} = 0.$$

Proof. We will prove by induction on $r \in \{0, \dots, k-l\}$ that for $t \in J$ and $0 \leq i \leq k-1$ we have

$$(42) \quad \sum_{j=0}^{l-1} \sum_{q=0}^r \binom{r}{q} (\eta_j^T)^{(q)} F_i^{j+r-q} = 0.$$

Formula (41) will then follow from (42) by setting $r = k-l$.

For $r = 0$ we have

$$\sum_{j=0}^{l-1} \sum_{q=0}^r \binom{r}{q} (\eta_j^T)^{(q)} F_i^{j+r-q} = \sum_{j=0}^{l-1} \eta_j^T F_i^j$$

and (40) implies that this expression vanishes for $t \in J$ and $0 \leq i \leq k-1$. Thus (42) holds when $r = 0$.

Let $0 \leq r \leq k-l-1$ and assume that (42) holds for r . Then for $1 \leq i \leq k-1$ we can replace i by $i-1$ in (42) to obtain

$$(43) \quad \sum_{j=0}^{l-1} \sum_{q=0}^r \binom{r}{q} (\eta_j^T)^{(q)} F_{i-1}^{j+r-q} = 0,$$

and we can differentiate (42) to obtain

$$(44) \quad \sum_{j=0}^{l-1} \sum_{q=0}^r \binom{r}{q} \{(\eta_j^T)^{(q+1)} F_i^{j+r-q} + (\eta_j^T)^{(q)} \dot{F}_i^{j+r-q}\} = 0.$$

Equation (40) implies that

$$\sum_{j=0}^{l-1} \eta_j^T \Gamma^j C = 0$$

and if we apply Γ^r to this equation and use Lemma 2.11 we get

$$0 = \sum_{j=0}^{l-1} \Gamma^r (\eta_j^T \Gamma^j C) = \sum_{j=0}^{l-1} \sum_{q=0}^r \binom{r}{q} (\eta_j^T)^{(q)} \Gamma^{r-q} (\Gamma^j C).$$

Multiplication of this last equation by BE_i on the right yields

$$(45) \quad \sum_{j=0}^{l-1} \sum_{q=0}^r \binom{r}{q} (\eta_j^T)^{(q)} (\Gamma^{j+r-q} C) BE_i = 0.$$

We can now add (43)–(45) to obtain for $1 \leq i \leq k-1$ and $t \in J$

$$\begin{aligned} 0 &= \sum_{j=0}^{l-1} \sum_{q=0}^r \binom{r}{q} [(\eta_j^T)^{(q+1)} F_i^{j+r-q} + (\eta_j^T)^{(q)} \{(\Gamma^{j+r-q} C) BE_i + \dot{F}_i^{j+r-q} + F_{i-1}^{j+r-q}\}] \\ &= \sum_{j=0}^{l-1} \sum_{q=0}^r \binom{r}{q} [(\eta_j^T)^{(q+1)} F_i^{j+r-1} + (\eta_j^T)^{(q)} F_i^{j+(r+1)-q}] \quad (\text{by (9b)}) \\ &= \sum_{j=0}^{l-1} \sum_{q=0}^{r+1} \binom{r+1}{q} (\eta_j^T)^{(q)} F_i^{j+(r+1)-q} \end{aligned}$$

This shows that (42) holds for $1 \leq i \leq k-1$ with r replaced by $r+1$. A similar argument works when $i=0$ (using (9a) instead of (9b)), so this completes the induction and the proof. \square

PROPOSITION 2.13. *Suppose that for some $k \geq 1$ the matrix function M_k defined in (30) satisfies the rank conditions (31) and (32). Let E_0, E_1, \dots, E_k be $C^\infty(m \times p)$ -matrix functions of $t \in I$ such that the $C^\infty(p \times p)$ -matrix functions F_i^t of $t \in I$ defined by (7) and (9) satisfy (20). Then the matrix $S_k(t)$ defined in (39) has rank kp for all t in an open dense subset of I .*

Proof. The existence of the matrix functions E_0, E_1, \dots, E_k follows from Propositions 2.9 and 2.5. Since the entries of the matrix $S_k(t)$ are C^∞ functions of t , the set

$$V = \{t \in I \mid \text{rank } S_k(t) = kp\}$$

is open relative to I . Thus it suffices to show that V is dense in I .

If V is not dense in I , then there exists a nonempty open subinterval J_0 of I such that

$$t \in J_0 \Rightarrow \text{rank } S_k(t) < kp.$$

Let

$$\rho = \max \{ \text{rank } S_k(t) \mid t \in J_0 \} < kp;$$

then there exists a nonempty open subinterval J of J_0 such that

$$t \in J \Rightarrow \text{rank } S_k(t) = \rho.$$

Since $\rho < kp$, Dolezal's theorem [4] (or, alternatively, an argument similar to that in the proof of Lemma 2.7) implies the existence of a nowhere zero C^∞ function $\eta: J \rightarrow \mathbb{R}^{kp}$ such that

$$(46) \quad \eta(t)^T S_k(t) = 0_{1 \times (n+kp)} \quad \text{for every } t \in J.$$

Partitioning the kp -dimensional (column) vector function η into k p -dimensional column vector functions $\eta_0, \dots, \eta_{k-1}$ we can rewrite (46) as

$$(47) \quad [\eta_0^T, \dots, \eta_{k-1}^T] \begin{bmatrix} \Gamma^0 C & F_0^0 & \dots & F_{k-1}^0 \\ \Gamma^1 C & F_0^1 & \dots & F_{k-1}^1 \\ \vdots & \vdots & & \vdots \\ \Gamma^{k-1} C & F_0^{k-1} & \dots & F_{k-1}^{k-1} \end{bmatrix} = 0_{1 \times (n+kp)}$$

for every $t \in J$. The contradiction will be obtained by showing that each of the vector functions $\eta_{k-1}, \dots, \eta_0$ must vanish identically on J if (47) is to hold.

We first show that η_{k-1} must vanish on J . From (47) we obtain the equations

$$\begin{aligned} \eta_0^T \Gamma^0 C + \dots + \eta_{k-2}^T \Gamma^{k-2} C + \eta_{k-1}^T \Gamma^{k-1} C &= 0, \\ \eta_0^T F_{k-1}^0 + \dots + \eta_{k-2}^T F_{k-1}^{k-2} + \eta_{k-1}^T F_{k-1}^{k-1} &= 0. \end{aligned}$$

Multiply the first by BE_k on the left and add to the second to get

$$(48) \quad \begin{aligned} \eta_0^T ((\Gamma^0 C)BE_k + F_{k-1}^0) + \dots + \eta_{k-2}^T ((\Gamma^{k-2} C)BE_k + F_{k-1}^{k-2}) \\ + \eta_{k-1}^T ((\Gamma^{k-1} C)BE_k + F_{k-1}^{k-1}) = 0. \end{aligned}$$

From (9b) and (20) we see that for $1 \leq j \leq k$

$$\begin{aligned} F_k^j &= (\Gamma^{j-1} C)BE_k + \dot{F}_{k-1}^{j-1} + F_{k-1}^{j-1} \\ &= (\Gamma^{j-1} C)BE_k + F_{k-1}^{j-1} = \begin{cases} 0_p, & 1 \leq j \leq k-1, \\ I_p, & j = k, \end{cases} \end{aligned}$$

and using these relations in (48) we obtain $\eta_{k-1} = 0$ on J .

Next we suppose we have shown that $\eta_{k-1} = \dots = \eta_l = 0$ on J , where $1 \leq l \leq k-1$; from this we want to infer that $\eta_{l-1} = 0$. The induction assumption implies that (47) reduces to (40). Thus we have $\sum_{j=0}^{l-1} \eta_j^T \Gamma^j C = 0$, which by Lemma 2.11 implies

$$0 = \Gamma^{k-l} \left(\sum_{j=0}^{l-1} \eta_j^T \Gamma^j C \right) = \sum_{j=0}^{l-1} \sum_{q=0}^{k-l} \binom{k-l}{q} (\eta_j^T)^{(q)} \Gamma^{k-l-q} (\Gamma^j C).$$

Multiplying this equation on the right by BE_k , we obtain

$$(49) \quad \sum_{j=0}^{l-1} \sum_{q=0}^{k-l} \binom{k-l}{q} (\eta_j^T)^{(q)} (\Gamma^{j+k-l-q} C) BE_k = 0.$$

Equation (40) also implies (41) (Lemma 2.12), so we can add (41), with $i = k-1$, to (49) and get

$$(50) \quad \sum_{j=0}^{l-1} \sum_{q=0}^{k-l} \binom{k-l}{q} (\eta_j^T)^{(q)} ((\Gamma^{j+k-l-q} C) BE_k + F_{k-1}^{j+k-l-q}) = 0.$$

Again from (9b) and (20) we see that

$$(\Gamma^{j+k-l-q}C)BE_k + F_{k-1}^{j+k-l-q} = F_k^{j+k-l-q+1} = \begin{cases} 0_p, & 0 \leq j+k-l-q+1 \leq k-1, \\ I_p, & j+k-l-q+1 = k. \end{cases}$$

But given the inequalities $0 \leq j \leq l-1$ and $0 \leq q \leq k-l$, it is clear that $j+k-l-q+1 = k \Leftrightarrow j = l-1$ and $q = 0$, so (50) reduces to $(\begin{smallmatrix} k-l \\ 0 \end{smallmatrix})(\eta_{l-1}^T)^{(0)} = 0$, or $\eta_{l-1} = 0$ on J . By induction, we infer that $\eta_{k-1} = \dots = \eta_0 = 0$ on J . However, this contradicts the fact that the function $\eta: J \rightarrow \mathbb{R}^{kp}$ is nowhere zero, and the proof is complete. \square

We can now prove the principal result of this paper. Some of the earlier notation will be repeated here so as to make the statement of the theorem reasonably self-contained.

THEOREM 2.14. *Consider the input-output system (1) with C^∞ system matrices A , B , C , D and for $k \geq 0$ let M_k be the time-varying matrix function defined by*

$$M_k = \begin{bmatrix} G_0^0 & 0 & 0 & \cdots & 0 \\ G_0^1 & G_1^1 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ G_0^k & G_1^k & G_2^k & \cdots & G_k^k \end{bmatrix}$$

where

$$G_0^0 = D, \quad G_r^0 = 0, \quad r \geq 1$$

and for $l \geq 1$

$$G_0^l = (\Gamma^{l-1}C)B + \dot{G}_0^{l-1}, \quad G_r^l = G_{r-1}^{l-1} + \dot{G}_r^{l-1}, \quad r \geq 1.$$

Let $k \geq 1$ and suppose that

$$\text{rank } M_{k-1}(t) = \text{const.} \quad \text{for every } t \in I$$

and

$$\text{rank } M_k(t) - \text{rank } M_{k-1}(t) = p \quad \text{for every } t \in I.$$

Then for every $\psi \in \mathcal{C}^{k,p}(I)$ there exists $u \in \mathcal{C}^{0,m}(I)$ and $(t_0, x_0) \in I \times \mathbb{R}^n$ such that ψ is the output of (1) corresponding to the input u and the initial condition $x(t_0) = x_0$; that is, system (1) is weakly C^k -reproducible on I .

Proof. Under the assumptions of this theorem, we saw in Theorem 2.10 that for every $\psi \in \mathcal{C}^{k,p}(I)$ and for every $(t_0, x_0) \in I \times \mathbb{R}^n$ there exists $v \in \mathcal{C}^{k,p}(I)$ such that for $u \in \mathcal{C}^{0,m}(I)$ defined by

$$(51) \quad u(t) = \sum_{i=0}^k E_i(t)v^{(i)}(t)$$

the output $\tilde{\psi}$ of (1) corresponding to the input u and initial condition $x(t_0) = x_0$ satisfies $\psi \in \mathcal{C}^{k,p}(I)$ and $\tilde{\psi}^{(k)} = \psi^{(k)}$. The E_0, E_1, \dots, E_k are C^∞ ($m \times p$)-matrix functions of $t \in I$ that are independent of the desired output ψ and are chosen so that the $(p \times p)$ -matrix functions F_i^l defined in (7) and (9) satisfy (20). The function v is in $\mathcal{C}^{k,p}(I)$ and $v(t) = \zeta_0(t)$, where $(\phi(t), \zeta_0(t), \dots, \zeta_{k-1}(t))$ is a solution of the linear system of ODEs (33) subject to the initial conditions $\phi(t_0) = x_0$ and $\zeta_i(t_0)$ arbitrary, $0 \leq i \leq k-1$. From the form of the system (33) it is clear that $v^{(i)}(t) = \zeta_i(t)$ for $0 \leq i \leq k-1$.

Equation (22) of Corollary 2.6 shows that for every initial condition $\phi(t_0) = x_0$ the output $\tilde{\psi}$ of (1) corresponding to the input (51) satisfies

$$(52) \quad \begin{aligned} \tilde{\psi}^{(l)}(t_0) &= (\Gamma^l C)(t_0)\phi(t_0) + \sum_{i=0}^{k-1} F_i^l(t_0)v^{(i)}(t_0), \quad 0 \leq l \leq k-1 \\ \text{or} \\ \tilde{\psi}^{(l)}(t_0) &= (\Gamma^l C)(t_0)x_0 + \sum_{i=0}^{k-1} F_i^l(t_0)\zeta_i(t_0), \quad 0 \leq l \leq k-1. \end{aligned}$$

Now by Proposition 2.13 there exists $t_0 \in I$ such that the matrix $S_k(t_0)$ defined in (39) has rank kp . Hence given any $\psi \in \mathcal{C}^{k,p}(I)$ there exists $(x_0, w_0, \dots, w_{k-1}) \in \mathbb{R}^{n+kp}$ such that

$$(53) \quad \text{col} [\psi(t_0), \psi^{(1)}(t_0), \dots, \psi^{(k-1)}(t_0)] = S_k(t_0) \text{col} [x_0, w_0, \dots, w_{k-1}].$$

If we solve system (33) subject to the initial condition $(t_0, x_0, w_0, \dots, w_{k-1})$ given by (53), if we denote the solution by $(\phi(t), \zeta_0(t), \dots, \zeta_{k-1}(t))$, and if we define $u \in \mathcal{C}^{0,m}(I)$ by (51), where $v(t) = \zeta_0(t)$, then the output $\tilde{\psi}$ of (1) corresponding to the input u and the initial condition (t_0, x_0) satisfies $\tilde{\psi}^{(k)} = \psi^{(k)}$ by Theorem 2.10 and

$$\tilde{\psi}^{(l)}(t_0) = \psi^{(l)}(t_0), \quad 0 \leq l \leq k-1,$$

by (52) and (53). We infer that $\tilde{\psi} = \psi$ and, since $\psi \in \mathcal{C}^{k,p}(I)$ was arbitrary, system (1) is weakly C^k -reproducible on I . \square

Remark 2.15. Contained in the proof of Theorem 2.14 is a procedure for obtaining the required initial condition $(t_0, x_0) \in I \times \mathbb{R}^n$ and input $u \in \mathcal{C}^{0,m}(I)$ from the desired output $\psi \in \mathcal{C}^{k,p}(I)$. Choose $t_0 \in I$ so that $\text{rank } S_k(t_0) = kp$ and let $R_k(t_0)$ be a right inverse for $S_k(t_0)$; that is,

$$S_k(t_0)R_k(t_0) = I_{kp}.$$

For example we could take

$$R_k(t_0) = S_k(t_0)^T (S_k(t_0)S_k(t_0)^T)^{-1}.$$

If we define

$$\text{col} [x_0, w_0, \dots, w_{k-1}] = R_k(t_0) \text{col} [\psi(t_0), \psi^{(1)}(t_0), \dots, \psi^{(k-1)}(t_0)],$$

then the required initial condition for (1) is (t_0, x_0) ; the required input u is the output γ of the system (cf. (33)) with input ω and state $(x, z_0, \dots, z_{k-1}) \in \mathbb{R}^{n+kp}$ given by

$$\dot{x} = (A(t) - B(t)E_k(t)(\Gamma^k C)(t))x + \sum_{i=0}^{k-1} B(t)(E_i(t) - E_k(t)F_i^k(t))z_i + B(t)E_k(t)\omega,$$

$$\dot{z}_0 = z_1,$$

$$\vdots$$

$$\dot{z}_{k-2} = z_{k-1},$$

$$\dot{z}_{k-1} = -(\Gamma^k C)(t)x - \sum_{i=0}^{k-1} F_i^k(t)z_i + \omega,$$

$$\gamma = -E_k(t)(\Gamma^k C)(t)x + \sum_{i=0}^{k-1} (E_i(t) - E_k(t)F_i^k(t))z_i + E_k(t)\omega$$

where we use the input $\omega(t) = \gamma^{(k)}(t)$ and the initial condition $(t_0, x_0, w_0, \dots, w_{k-1})$.

Remark 2.16. In Proposition 2.13 we proved that the rank conditions (31) and (32) imply that the matrix $S_k(t)$ has rank kp for all t in an open dense subset of I .

We can now see that we must have $\text{rank } S_k(t) = kp$ for every $t \in I$. For a given $\psi \in \mathcal{C}^{k,p}(I)$ let $u = \sum_{i=0}^k E_i v^{(i)}$ be the input that generates ψ as described above. Then u and ψ are connected by (22), which we can write in matrix form as

$$\text{col} [\psi(t), \psi^{(1)}(t), \dots, \psi^{(k-1)}(t)] = S_k(t) \text{col} [\phi(t), v(t), v^{(1)}(t), \dots, v^{(k-1)}(t)]$$

for every $t \in I$. Since $\psi \in \mathcal{C}^{k,p}(I)$ is arbitrary, this forces $S_k(t)$ to have rank kp at every $t \in I$.

Remark 2.17. We briefly interpret our results for a time-invariant input-output system

$$\dot{x} = Ax + Bw, \quad y = Cx + Dw.$$

Because the system matrices are constant, we see that $\Gamma C = \dot{C} + CA = CA$, $\Gamma^2 C = CA^2$, etc. It follows that the matrices G_r^l defined in (13) and (14) are given by

$$G_r^l = \begin{cases} 0, & r > l \geq 0, \\ D, & r = l \geq 0, \\ CA^{l-r-1}B, & l > r \geq 0, \end{cases}$$

so the matrix M_k defined in (30) takes the form

$$M_k = \begin{bmatrix} D & 0 & 0 & \cdots & 0 & 0 \\ CB & D & 0 & \cdots & 0 & 0 \\ CAB & CB & D & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ CA^{k-1}B & CA^{k-2}B & CA^{k-3}B & \cdots & CB & D \end{bmatrix}.$$

Hence in the time-invariant case the rank condition (31) is automatically satisfied and the rank condition (32) is precisely that of Sain and Massey [13].

Remark 2.18. We conjecture that the rank conditions in Theorem 2.14 are also necessary for the weak C^k -reproducibility of (1). For $k=1$ this is proved in [1], and the type of argument used there could probably be extended to the general case, though we have not checked the details.

Example 2.19. Consider the linear time-varying input-output system with $n=4$ and $m=p=2$:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \end{bmatrix} = \begin{bmatrix} 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & -2 \\ e^t & 0 & 0 & 0 \\ 0 & e^t & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ \text{cost} & 0 \\ \text{sint} & 0 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix},$$

$$\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} \text{cost} & \text{sint} & 0 & 0 \\ -\text{sint} & \text{cost} & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} + \begin{bmatrix} t^2 & t \\ t & 1 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}.$$

The first few matrices $M_k(t)$ (as defined in (30)) and their ranks are as follows:

$$M_0(t) = \begin{bmatrix} t^2 & t \\ t & 1 \end{bmatrix}, \quad \text{rank } M_0(t) = 1 \quad \text{for every } t \in \mathbb{R},$$

$$M_1(t) = \begin{bmatrix} t^2 & t & 0 & 0 \\ t & 1 & 0 & 0 \\ 2t & 1 & t^2 & t \\ 1 & 0 & t & 1 \end{bmatrix}, \quad \text{rank } M_1(t) = 2 \quad \text{for every } t \in \mathbb{R},$$

$$M_2(t) = \begin{bmatrix} t^2 & t & 0 & 0 & 0 & 0 \\ t & 1 & 0 & 0 & 0 & 0 \\ 2t & 1 & t^2 & t & 0 & 0 \\ 1 & 0 & t & 1 & 0 & 0 \\ 0 & 0 & 4t & 2 & t^2 & t \\ 0 & 0 & 2 & 0 & t & 1 \end{bmatrix}, \quad \text{rank } M_2(t) = 4 \quad \text{for every } t \in \mathbb{R}.$$

Since $\text{rank } M_1(t)$ is constant for every $t \in \mathbb{R}$ and $\text{rank } M_2(t) - \text{rank } M_1(t) = 2$ for every $t \in \mathbb{R}$, Theorem 2.14 implies that the system is weakly C^2 -reproducible on \mathbb{R} . The matrix functions $K_0(t)$, $K_1(t)$, $K_2(t)$ given by Proposition 2.9 can be chosen as

$$K_0(t) = \begin{bmatrix} -1/2 & t/2 \\ t/2 & -t^2/2 \end{bmatrix}, \quad K_1(t) = \begin{bmatrix} 0 & 0 \\ 1/2 & -t/2 \end{bmatrix}, \quad K_2(t) = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix},$$

(note that these are not uniquely determined). The matrices $E_0(t)$, $E_1(t)$, $E_2(t)$ that define the input $u = \sum_{i=0}^2 E_i v^{(i)}$ are computed by the procedure in Proposition 2.5. We get

$$\begin{aligned} E_2(t) &= K_0(t) = \begin{bmatrix} -1/2 & t/2 \\ t/2 & -t^2/2 \end{bmatrix}, \\ E_1(t) &= K_1(t) - \dot{E}_2(t) = \begin{bmatrix} 0 & -1/2 \\ 0 & t/2 \end{bmatrix}, \\ E_0(t) &= K_2(t) - \ddot{E}_2(t) - 2\dot{E}_1(t) = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}. \end{aligned}$$

The right-inverse system (cf. Remark 2.15) can be explicitly determined once we know the matrix functions F_i^l . These in turn can be determined by Proposition 2.4, where the matrix functions H_i^r are defined in terms of the E_i 's by (10).

3. The nonlinear case. In this section we state a result on the local weak C^k -reproducibility of the nonlinear input-output system

$$(54) \quad \dot{x} = f(t, x, w), \quad y = g(t, x, w)$$

where $f: I \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$ and $g: I \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^p$ and C^∞ mappings. It is to be expected that a global reproducibility result for linear input-output systems should give rise to a local reproducibility result for nonlinear input-output systems by applying the global result to the linearization of the nonlinear system. This is indeed the case, but one has to exercise some care in the definition of "local" weak C^k -reproducibility.

NOTATION 3.1. Let I_0 be a compact subinterval of I and fix a point t_0 in I_0 . For $\psi \in \mathcal{C}^{0,l}(I_0)$ we set

$$\|\psi\|_0 = \max \{ |\psi(t)| : t \in I_0 \}$$

where $|\cdot|$ is the usual norm on \mathbb{R}^l , and for $k \geq 1$ and $\psi \in \mathcal{C}^{k,l}(I_0)$ we set

$$\|\psi\|_k = \sum_{i=0}^{k-1} |\psi^{(i)}(t_0)| + \|\psi^{(k)}\|_0.$$

DEFINITION 3.2. Let $u_0 \in \mathcal{C}^{\infty,m}(I)$, let $(t_0, x_0) \in I \times \mathbb{R}^n$, and let $I_0 \subseteq I$ be a compact subinterval containing t_0 on which the solution ϕ_0 of the initial-value problem

$$\dot{\phi}_0(t) = f(t, \phi_0(t), u_0(t)), \quad \phi_0(t_0) = x_0,$$

is defined. Let $\psi_0 \in \mathcal{C}^{\infty,p}(I_0)$ be the output of the input-output system (54) corresponding to the initial condition (t_0, x_0) and input u_0 defined by

$$\psi_0(t) = g(t, \phi_0(t), u_0(t)), \quad t \in I_0.$$

We say that the input-output system (54) is *locally weakly C^k -reproducible* at ψ_0 if for every $\varepsilon > 0$ there exists a $\delta > 0$ having the property that for every $\psi \in \mathcal{C}^{k,p}(I_0)$ with $\|\psi - \psi_0\|_k < \delta$ there exist $x \in \mathbb{R}^n$ with $|x - x_0| < \varepsilon$ and $u \in \mathcal{C}^{0,m}(I_0)$ with $\|u - u_0\|_0 < \varepsilon$ such that

$$\psi(t) = g(t, \phi(t), u(t)),$$

where $\phi(t_0) = x$ and

$$\dot{\phi}(t) = f(t, \phi(t), u(t)) \quad \text{for every } t \in I_0.$$

We omit the proof of the following theorem as it is fairly routine and contains few surprises.

THEOREM 3.3. *Consider the nonlinear input-output system (54), let $u_0 \in \mathcal{C}^{\infty,m}(I)$, let $(t_0, x_0) \in I \times \mathbb{R}^n$, and let $I_0 \subseteq I$ be a compact subinterval containing t_0 on which the solution ϕ_0 of the initial-value problem*

$$\dot{\phi}_0(t) = f(t, \phi_0(t), u_0(t)), \quad \phi_0(t_0) = x_0,$$

is defined. Let $\psi_0 \in \mathcal{C}^{\infty,m}(I_0)$ denote the corresponding output defined by $\psi_0(t) = g(t, \phi_0(t), u_0(t))$. If the linearized input-output system

$$(55) \quad \begin{aligned} \dot{x} &= D_2 f(t, \phi_0(t), u_0(t))x + D_3 f(t, \phi_0(t), u_0(t))w, \\ y &= D_2 g(t, \phi_0(t), u_0(t))x + D_3 g(t, \phi_0(t), u_0(t))w, \end{aligned}$$

satisfies the rank conditions (31) and (32), then the nonlinear input-output system (54) is locally weakly C^k -reproducible at ψ_0 . \square

Remark 3.4. In the course of proving Theorem 3.3, one can also show that given $\psi \in \mathcal{C}^{k,p}(I_0)$ sufficiently close to ψ_0 in the $\|\cdot\|_k$ -norm, the input $u \in \mathcal{C}^{0,m}(I_0)$ that generates ψ is of the form

$$u(t) = u_0(t) + \sum_{i=0}^{k-1} E_i(t) \zeta_i(t) + h(t, \mu(t), \zeta_0(t), \dots, \zeta_{k-1}(t), \psi^{(k)}(t) - \psi_0^{(k)}(t))$$

where the matrix functions E_0, E_1, \dots, E_k are those associated to (55) by Proposition 2.5, the functions $\mu, \zeta_0, \dots, \zeta_{k-1}$ are solutions of the nonlinear system of ODEs

$$\begin{aligned} \dot{x} &= \tilde{f} \left(t, x, \sum_{i=0}^{k-1} E_i(t) z_i + E_k(t) h(t, x, z_0, \dots, z_{k-1}, \psi^{(k)}(t) - \psi_0^{(k)}(t)) \right), \\ \dot{z}_0 &= z_1, \\ &\vdots \\ \dot{z}_{k-2} &= z_{k-1}, \\ \dot{z}_{k-1} &= h(t, x, z_0, \dots, z_{k-1}, \psi^{(k)}(t) - \psi_0^{(k)}(t)), \end{aligned}$$

the function \tilde{f} is defined by

$$\tilde{f}(t, x, w) = f(t, \phi_0(t) + x, u_0(t) + w) - f(t, \phi_0(t), u_0(t)),$$

and h is some function defined and C^∞ in a neighborhood of $I_0 \times \{0\} \times \{0\} \times \dots \times \{0\}$ in $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^{(k+1)p}$. In other words, we can generate the required input from the desired output by a local right-inverse system of (54).

Acknowledgments. The author wishes to thank Professors Felix Albrecht and Nelson Wax for many hours of helpful conversations during the preparation of this work. He also thanks the referees for their useful comments on the first draft of this paper.

SUR LA MODIFICATION DE LA STRUCTURE A L'INFINI PAR UN RETOUR D'ETAT STATIQUE*

JEAN JACQUES LOISEAU†

Résumé (Abstract). Le bouclage d'un système linéaire par un retour d'état statique non régulier, c'est-à-dire du type $u = Fx + Gv$ avec G non inversible, modifie en général sa structure, et en particulier sa structure à l'infini qui joue un rôle-clé dans les problèmes de commande. L'objet de cet article est d'étudier ces modifications. Nous donnons une condition structurelle nécessaire et suffisante pour qu'une liste donnée soit la liste des ordres des zéros infinis du système bouclé par un retour d'état statique. Nous calculons alors explicitement un retour d'état (F, G) qui produit cette modification de structure à l'infini.

Mots-clés (Key words). système linéaire, commande, retour d'état statique non régulier, structure à l'infini

1. Introduction. Durant la dernière décade, de nombreux auteurs utilisant différentes approches ont contribué à l'étude de la structure à l'infini des systèmes linéaires. On peut citer parmi eux Rosenbrock [1], Pugh et Ratcliffe [2] qui reprennent les travaux de MacMillan [3] et définissent cette structure à partir de la forme de Smith et MacMillan de la matrice de transfert du système.

Rosenbrock [1] définit aussi les zéros à l'infini à partir de la matrice système, en exploitant la décomposition de Kronecker (voir à ce sujet Gantmacher [4]) des faisceaux singuliers de matrices. Jaffe et Karcanias [5] reprennent cette méthodologie et effectuent le lien avec le concept géométrique de sous-espace presque de commandabilité défini par Willems [6], [7].

Une approche purement géométrique a été développée par Commault et Dion [8], qui ont montré que la liste ordonnée des ordres des zéros à l'infini d'un système linéaire (C, A, B) est la liste I_4 d'invariants structurels du système définis par Morse [9].

La motivation de ces travaux est l'importance prépondérante de la structure à l'infini pour la résolution des problèmes classiques de commande des systèmes linéaires, et en particulier pour le problème du découplage (voir Dion [10], et Descusse, Lafay et Malabre [11]).

Les études récentes concernant le découplage dans le cas non régulier, c'est-à-dire à l'aide d'une loi de commande du type $u = Fx + Gv$ lorsque G n'est pas inversible (voir Descusse, Lafay et Malabre [12], [13]) ont mis en évidence le rôle de la liste I_2 définie par Morse [9] dans le problème de la modification de la structure à l'infini du système qui est bouclé par un tel retour d'état statique non régulier. L'emploi de commandes de ce type est très important puisqu'il existe des systèmes qui ne peuvent être découplés qu'en employant des commandes non régulières, mais complique singulièrement le problème comme le montre l'étude du découplage des systèmes ayant deux sorties (voir Descusse, Lafay et Malabre [13]).

La difficulté inhérente à l'emploi de telles commandes non régulières est que nous ne sommes plus en présence d'un groupe de transformations du système, contrairement au cas G inversible. La bibliographie traitant de ce type de loi de commande est de ce fait peu développée. La principale contribution dans ce domaine est due à Heymann [14] qui a complètement caractérisé les modifications possibles de la liste des indices

† Laboratoire d'Automatique, Ecole Nationale Supérieure de Mécanique, Unité Associée au Centre National de la Recherche Scientifique, UA CNRS 4/823, 1 rue de la Noë, 44072 Nantes, Cédex, France. Present address: BE ER, ECAN d'Indrat, 44620 La Montagne, France.

de commandabilité d'une paire (A, B) sous l'action de retours d'états statiques (F, G) non réguliers.

L'objet du présent papier est de caractériser l'ensemble des modifications possibles de la structure à l'infini d'un système (C, A, B) sous l'action de retours d'états (F, G) non réguliers. Le problème est posé de la manière suivante: étant donné un système (C, A, B) et une liste d'entiers positifs $\{n_i\}$, existe-t-il une loi (F, G) telle que $\{n_i\}$ soit la liste des ordres des zéros à l'infini du système bouclé $(C, A + BF, BG)$?

Après avoir au § 2 introduit les notations et rappelé les concepts utilisés, nous répondons à cette question au § 3 sous la forme d'une condition structurelle nécessaire et suffisante (Théorème 3.1) dont la nécessité et la suffisance sont établies dans les paragraphes suivants. Au § 4 sont introduits des sous-espaces qui sont le support géométrique de cette condition structurelle et nous établissons la nécessité de cette condition.

Les §§ 5-7 sont consacrés à la démonstration de la suffisance de notre condition. Nous y exhibons explicitement un retour d'état (F, G) tel que la liste des ordres des zéros à l'infini du système bouclé $(C, A + BF, BG)$ soit une liste $\{n_i\}$ fixée qui vérifie les conditions structurelles du Théorème 3.1. Un cas particulier est examiné au § 5 et généralisé au § 6 où nous résolvons ce problème du placement des ordres des zéros infinis pour le cas où le rang du système (qui est le nombre de ses zéros à l'infini) n'est pas modifié. L'examen d'un second cas particulier au § 7 nous permet de conclure quant à la suffisance de notre condition structurelle.

Enfin, le § 8 est consacré à quelques remarques finales.

2. Préliminaires.

2.1. Notation. Le corps des nombres réels est noté \mathcal{R} . Les minuscules x, u, \dots , désignent des vecteurs, les majuscules romanes A, B, \dots , des applications linéaires ou leur matrice représentative dans une base donnée, les majuscules curvilignes $\mathcal{X}, \mathcal{V}, \dots$, des espaces vectoriels.

$\text{Im } M$ et $\text{Ker } M$ désignent l'image et le noyau de l'application M . La restriction de M à un sous-espace \mathcal{V} est notée M/\mathcal{V} et son image $M\mathcal{V}$. Si $\text{Im } M \subset \mathcal{W}$, nous désignerons par \mathcal{W}/M la restriction de M au codomaine \mathcal{W} .

La dimension d'un sous-espace \mathcal{V} est notée $\dim \mathcal{V}$. L'espace quotient de \mathcal{W} par $\mathcal{V} \subset \mathcal{W}$ sera noté \mathcal{W}/\mathcal{V} ou $\frac{\mathcal{W}}{\mathcal{V}}$ suivant le cas. L'espace engendré par les vecteurs x_1, x_2, \dots, x_i est noté $\text{span } \{x_1, \dots, x_i\}$.

Une suite $x_1, x_2, \dots, x_i \dots$ sera dite finie s'il existe un entier k tel que $x_i = 0$ pour tout i supérieur à k . Le plus petit de ces entiers, soit l , est appelé longueur de la suite, et pour spécifier cette longueur nous écrirons quelquefois la suite $\{x_i\}_l$. De plus, nous identifierons cette suite avec la liste $\{x_1, x_2, \dots, x_l\}$. Le nombre d'éléments d'un ensemble fini $\{\cdot\}$ est noté $\text{card } \{\cdot\}$.

Un nombre nul, un vecteur nul, un espace vectoriel nul ou une matrice nulle seront tous écrits 0.

2.2. Rappel des principaux concepts utilisés. Dans tout ce qui suit, nous appellerons système (C, A, B) le système linéaire stationnaire décrit par les équations suivantes:

$$\dot{x} = Ax + Bu,$$

$$y = Cx,$$

où $x \in \mathcal{X} \simeq \mathcal{R}^n$, $u \in \mathcal{U} \simeq \mathcal{R}^m$, $y \in \mathcal{Y} \simeq \mathcal{R}^p$. Nous pourrions toujours supposer sans restriction de généralité que B est injective et C surjective. Nous poserons $\mathcal{K} = \text{Ker } C$ et $\mathcal{B} = \text{Im } B$.

Rappelons les algorithmes de base de l'approche géométrique (Wonham [15]):

$$(2.1) \quad \begin{aligned} \mathcal{V}_{\mathcal{K}}^0 &= \mathcal{K}, \\ \mathcal{V}_{\mathcal{K}}^i &= \mathcal{K} \cap A^{-1}(\mathcal{V}_{\mathcal{K}}^{i-1} + \mathcal{B}) \end{aligned}$$

pour $i = 1, 2, \dots$, qui est non croissant et converge vers $\mathcal{V}_{\mathcal{K}}^*$, le plus grand sous-espace (A, B) invariant inclus dans \mathcal{K} ;

$$(2.2) \quad \begin{aligned} \mathcal{S}_{\mathcal{B}}^0 &= 0, \\ \mathcal{S}_{\mathcal{B}}^i &= \mathcal{B} + A(\mathcal{S}_{\mathcal{B}}^{i-1} \cap \mathcal{K}) \end{aligned}$$

pour $i = 1, 2, \dots$, qui est non décroissant et converge vers $\mathcal{S}_{\mathcal{B}}^*$, le plus petit sous espace (C, A) invariant contenant \mathcal{B} .

Nous poserons $\mathcal{R}_{\mathcal{K}}^* = \mathcal{V}_{\mathcal{K}}^* \cap \mathcal{S}_{\mathcal{B}}^*$. $\mathcal{R}_{\mathcal{K}}^*$ est le plus grand sous espace de commandabilité de (A, B) inclus dans \mathcal{K} [15].

On définit quatre listes d'entiers à partir des étapes de ces algorithmes:

$$(2.3) \quad p_i = \dim \left(\frac{\mathcal{S}_{\mathcal{B}}^i + \mathcal{V}_{\mathcal{K}}^*}{\mathcal{S}_{\mathcal{B}}^{i-1} + \mathcal{V}_{\mathcal{K}}^*} \right) \quad \text{pour } i = 1, 2, \dots,$$

$$(2.4) \quad n_i = \text{card} \{j \mid p_j \geq i\} \quad \text{pour } i = 1, 2, \dots,$$

$$(2.5) \quad \alpha_i = \dim \left(\frac{\mathcal{S}_{\mathcal{B}}^i \cap \mathcal{V}_{\mathcal{K}}^*}{\mathcal{S}_{\mathcal{B}}^{i-1} \cap \mathcal{V}_{\mathcal{K}}^*} \right) \quad \text{pour } i = 1, 2, \dots,$$

$$(2.6) \quad \sigma_i = \text{card} \{j \mid \alpha_j \geq i\} \quad \text{pour } i = 1, 2, \dots.$$

Ces quatre suites d'entiers positifs sont non croissantes et finies. $\{n_1, \dots, n_{p_1}\}$ est la liste des ordres des zéros à l'infini du système (C, A, B) , qui coïncide avec la liste I_4 d'invariants structurels décrits par Morse [9] (voir Commault et Dion [8]). $\{\sigma_1, \dots, \sigma_{\alpha_1}\}$ est la liste des indices de commandabilité de la paire $(\mathcal{R}_{\mathcal{K}}^* | A + BF | \mathcal{R}_{\mathcal{K}}^*, B_{\mathcal{R}})$, où $\text{Im } B_{\mathcal{R}} = \mathcal{B} \cap \mathcal{R}_{\mathcal{K}}^*$ et $(A + BF)\mathcal{R}_{\mathcal{K}}^* \subset \mathcal{R}_{\mathcal{K}}^*$ (Morse [9]), qui est appelée liste I_2 de Morse.

Rappelons qu'une suite finie et non croissante d'entiers positifs, par exemple $\{p_i\}_{n_1}$, définie en (2.3), est en bijection avec la suite $\{n_i\}_{p_1}$ qui en est déduite par comptage (2.4)

$$n_i = \text{card} \{j \mid p_j \geq i\} \quad \text{pour } i = 1, 2, \dots.$$

Nous avons en effet (Brunovsky [16])

$$(2.7) \quad p_i = \text{card} \{j \mid n_j \geq i\} \quad \text{pour } i = 1, 2, \dots.$$

Les listes $\{\alpha_i\}_{\sigma_1}$ et $\{\sigma_i\}_{\alpha_1}$ satisfont la même bijection.

Cet isomorphisme peut être visualisé sur le schéma suivant (voir Fig. 1):

FIG. 1. Si n_i est le nombre de blocs dans la colonne i , alors p_j est le nombre de blocs dans la ligne j .

Nous allons maintenant détailler la structure fine de $\mathcal{S}_{\mathcal{B}}^*$ qui sera largement utilisée dans la suite de cet article.

Les sous-espaces de commandabilité ont été introduits et leurs propriétés étudiées par Morse et Wonham et 1970 (ces résultats sont détaillés dans Wonham [15]). Ainsi, il existe $F_0: \mathcal{X} \rightarrow \mathcal{U}$, et des vecteurs b_1, \dots, b_{α_1} de $\mathcal{B} \cap \mathcal{R}_{\mathcal{K}}^*$ qui nous permettent d'écrire (avec $A_0 = A + BF_0$)

$$(2.8) \quad \mathcal{R}_{\mathcal{K}}^* = \mathcal{R}_1 \oplus \mathcal{R}_2 \oplus \dots \oplus \mathcal{R}_{\alpha_1}$$

avec

$$\mathcal{R}_i = \text{span} \{b_i, A_0 b_i, \dots, A_0^{\sigma_i-1} b_i\} \quad \text{pour } 1 \leq i \leq \alpha_1,$$

$$A_0^{j-1} b_i \in \mathcal{K} \quad \text{pour } 1 \leq j \leq \sigma_i,$$

$$A_0^{\sigma_i} b_i = 0 \quad \text{pour } 1 \leq i \leq \alpha_1.$$

Dion et Commault [8] ont donné une décomposition similaire de la partie irréductible du système qui correspond au quotient $\mathcal{S}_{\mathcal{B}}^* / \mathcal{R}_{\mathcal{K}}^*$. Il existe des vecteurs $\ell_1, \dots, \ell_{p_1}$ de \mathcal{B} tels que

$$(2.9) \quad \mathcal{S}_{\mathcal{B}}^* = \mathcal{R}_{\mathcal{K}}^* \oplus \mathcal{L}_1 \oplus \mathcal{L}_2 \oplus \dots \oplus \mathcal{L}_{p_1}$$

avec

$$\mathcal{L}_i = \text{span} \{\ell_i, A_0 \ell_i, \dots, A_0^{n_i-1} \ell_i\} \quad \text{pour } 1 \leq i \leq p_1,$$

$$A_0^{j-1} \ell_i \in \mathcal{K} \quad \text{pour } 1 \leq j \leq n_i - 1,$$

$$A_0^{n_i-1} \ell_i \notin \mathcal{K}.$$

Dans ces conditions, les vecteurs $C \cdot A_0^{n_i-1} \ell_i$ sont indépendants et engendrent $C \cdot \mathcal{S}_{\mathcal{B}}^*$.

Cette première décomposition est relative aux listes $\{\sigma_i\}_{\alpha_1}$ et $\{n_i\}_{p_1}$. Il existe une deuxième manière de décomposer $\mathcal{S}_{\mathcal{B}}^*$, et qui est relative aux listes $\{\alpha_i\}_{\sigma_1}$ et $\{p_i\}_{n_1}$ que l'on déduit par comptage. Willems [6] a montré qu'il existe un $F: \mathcal{X} \rightarrow \mathcal{U}$, et une chaîne $\{\mathcal{B}_i\}_n$ de sous espaces de \mathcal{B} tels que

$$(2.10) \quad \mathcal{S}_{\mathcal{B}}^* = \mathcal{B} + A_F \mathcal{B}_1 + \dots + A_F^{n-1} \mathcal{B}_{n-1}$$

avec $\mathcal{B} \supset \mathcal{B}_1 \supset \mathcal{B}_2 \supset \dots \supset \mathcal{B}_n$.

La matrice F et la chaîne de \mathcal{B} ne sont pas uniques. Malabre [17] a montré que l'on peut toujours choisir $\{\mathcal{B}_i\}$ de la manière suivante:

$$(2.11) \quad \mathcal{B}_i = \mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^i \quad \text{pour } 1 \leq i \leq n.$$

D'autre part, il est clair que l'on peut toujours choisir F de la manière suivante [18]:

$$(2.12) \quad F = F_0.$$

Ce choix particulier de F et de la chaîne de \mathcal{B} , du fait des conditions $A_0^{\sigma_i} b_i = 0$, permet d'écrire $\mathcal{S}_{\mathcal{B}}^*$ sous la forme d'une somme directe:

$$\mathcal{S}_{\mathcal{B}}^* = \mathcal{B} \oplus A_0(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^1) \oplus \dots \oplus A_0^{n-1}(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^{n-1}),$$

avec

$$\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^i = \text{span} \{b_1, \dots, b_{\alpha_i}; \ell_1, \dots, \ell_{p_{i+1}}\}.$$

Nous obtenons aussi la caractérisation suivante:

$$(2.13) \quad \begin{aligned} A_0^{i-1}(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^{i-1}) &= A_0^{i-1} \text{span} \{b_1, \dots, b_{\alpha_i}; \ell_1, \dots, \ell_{p_i}\} \\ &= \text{span} \{A_0^{i-1} b_1, \dots, A_0^{i-1} b_{\alpha_i}; A_0^{i-1} \ell_1, \dots, A_0^{i-1} \ell_{p_i}\}. \end{aligned}$$

Et donc

$$(2.14) \quad \dim A_0^{i-1}(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^{j-1}) = \alpha_i + p_j \quad \text{pour } i \geq 1 \text{ et } j \geq 1.$$

Notons encore que ce choix particulier de F_0 et de la chaîne $(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^i)$ permet d'écrire

$$(2.15) \quad \mathcal{S}_{\mathcal{B}}^i = \mathcal{B} \oplus A_0(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^1) \oplus \cdots \oplus A_0^{i-1}(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^{i-1}) \quad \text{pour } i \geq 1,$$

$$(2.16) \quad \mathcal{S}_{\mathcal{B}}^* \cap \mathcal{V}_{\mathcal{K}}^i = (\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^i) \oplus A_0(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^{i+1}) \oplus \cdots \oplus A_0^{n-i}(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^n) \quad \text{pour } i \geq 1.$$

3. Caractérisation des structures à l'infini atteignables par retour d'état. Etant donné un système (C, A, B) nous dirons qu'une suite finie non croissante d'entiers positifs est une structure à l'infini atteignable par retour d'état si il existe des matrices F et G telles que cette liste soit la liste ordonnée des ordres des zéros à l'infini (liste I_4) du système bouclé $(C, A + BF, BG)$.

Le Théorème 3.1 caractérise l'ensemble des structures à l'infini atteignables par retour d'état pour un système donné.

THÉOREME 3.1. *Soit un système (C, A, B) avec $\{\sigma_i\}_{\alpha_1}$ pour liste I_2 et $\{n_i\}_{p_1}$ pour liste I_4 , et considérons les listes qui en sont déduites par comptage:*

$$\alpha_i = \text{card} \{j | \sigma_j \geq i\} \quad \text{pour } i \geq 1,$$

$$p_i = \text{card} \{j | n_j \geq i\} \quad \text{pour } i \geq 1.$$

Soit $\{n'_i\}_{p'_1}$ une suite non croissante finie d'entiers positifs, et $\{p'_i\}_{n'_1}$ la liste qui en est déduite par comptage:

$$p'_i = \text{card} \{j | n'_j \geq i\} \quad \text{pour } i \geq 1.$$

Considérons alors la liste des différences $\{p'_i - p_i\}$. Cette liste n'est pas ordonnée et comporte même en général des termes négatifs. Soit $\{\Delta_i\}$ la liste obtenue en ne gardant que les différences non négatives et en renumérotant pour obtenir une suite non croissante.

Alors il existe une loi de retour d'état statique (F, G) telle que $\{n'_i\}_{p'_1}$ soit la liste I_4 du système bouclé $(C, A + BF, BG)$ si et seulement si les deux conditions suivantes sont vérifiées:

$$(1) \quad p_1 - p_i \geq p'_1 - p'_i \quad \text{pour } i \geq 1,$$

$$(2) \quad \sum_{j=1}^i \sigma_j \geq \sum_{j=1}^i \Delta_j \quad \text{pour } i \geq 1.$$

La démonstration de ce résultat sera effectuée dans le § 4 pour la nécessité, §§ 5-7 pour la suffisance.

L'énoncé du Théorème 3.1 appelle quelques précisions indispensables. En ce qui concerne le type de transformation utilisée pour modifier la structure à l'infini, la constatation suivante s'impose.

PROPOSITION 3.2. *Etant donné un système (C, A, B) et une suite $\{n'_i\}$ non croissante finie d'entiers positifs, les affirmations suivantes sont équivalentes:*

(i) *Il existe une loi de retour d'état statique (F, G) telle que $\{n'_i\}_{p'_1}$ soit la liste I_4 du système bouclé $(C, A + BF, BG)$.*

(ii) *Il existe une loi de commande (T, F, G) , où T est un isomorphisme, telle que $\{n'_i\}_{p'_1}$ soit la liste I_4 du système bouclé $(CT^{-1}, T(A + BF)T^{-1}, TBG)$.*

(iii) *Il existe une loi de commande (T, F, G, R, H) où T et H sont des isomorphismes, telle que $\{n'_i\}_{p'_1}$ soit la liste I_4 du système bouclé $(HCT^{-1}, T(A + BF + RC)T^{-1}, TBG)$.*

Démonstration. Les trois systèmes $(C, A + BF, BG)$, $(CT^{-1}, T(A + BF)T^{-1}, TBG)$ et $(HCT^{-1}, T(A + BF + RC)T^{-1}, TBG)$ sont équivalents au sens de Morse [9] puisque H et T sont des isomorphismes: ils ont donc en particulier la même structure à l'infini. \square

Le choix d'une base particulière pour \mathcal{X} , qui se traduit concrètement par l'introduction de la transformation supplémentaire T , ne modifie donc pas le problème. Cela va nous permettre d'utiliser sans restriction de généralité la base décrite en (2.9) et (2.10).

La première condition du Théorème 3.1 peut s'écrire directement en termes des listes $\{n_i\}$ et $\{n'_i\}$. Il apparaît alors que la structure à l'infini ne peut être qu'augmentée, ce qui est assez naturel lorsqu'on voit la structure à l'infini comme l'équivalent des retards pour les systèmes discrets.

PROPOSITION 3.3. *Etant données les listes $\{n_i\}_{p'_1}\{p_i\}_{n'_1}\{n'_i\}_{p'_1}$ et $\{p'_i\}_{n'_1}$ du Théorème 3.1, les conditions suivantes sont équivalentes:*

- (i) $p_1 - p_i \geq p'_1 - p'_i$ pour $i \geq 1$,
- (ii) $p_1 \geq p'_1$ et $n_{p_1} - j \leq n'_{p'_1} - j$ pour $0 \leq j \leq p'_1 - 1$.

Démonstration. Supposons que (ii) ne soit pas vérifiée, c'est-à-dire qu'il existe un entier k , $0 \leq k \leq p'_1 - 1$, tel que

$$n_{p_1-k} > n'_{p'_1-k}.$$

Cela implique

$$\text{card} \{j | n_j < n_{p_1-k}\} < \text{card} \{j | n'_j < n_{p_1-k}\},$$

soit:

$$p_1 - p_{n_{p_1-k}} < p'_1 - p'_{n_{p_1-k}}.$$

Pour $i = n_{p_1-k}$, la relation (i) ne serait pas vérifiée. Cela montre que (i) \rightarrow (ii).

Réciproquement, si (ii) est vérifiée, alors il est clair que pour tout entier i , on a

$$\text{card} \{j | n_j < i\} \geq \text{card} \{j | n'_j < i\},$$

soit

$$p_1 - p_i \geq p'_1 - p'_i \quad \text{pour } i \geq 1.$$

Cela montre que (ii) \rightarrow (i), et achève la démonstration. \square

De la même façon, la condition (2) du Théorème 3.1 peut s'énoncer de plusieurs manières différentes.

PROPOSITION 3.4. *Considérons les listes $\{\alpha_i\}$, $\{p_i\}$, $\{p'_i\}$ et $\{\Delta_i\}$ du Théorème 3.1. Les affirmations suivantes sont équivalentes:*

- (i) $\sum_{j=1}^i \alpha_j \geq \sum_{j=1}^i \Delta_j$ pour $i \geq 1$.
- (ii) Pour tout choix $\{k_1, \dots, k_i\}$ d'entiers positifs distincts, on a

$$\sum_{j=1}^i \alpha_j + \sum_{j=1}^i p_{k_j} \geq \sum_{j=1}^i p'_{k_j} \quad \text{pour } i \geq 1.$$

Démonstration. Les termes non nuls dans la liste des différences $\{p'_i - p_i\}$ sont en nombre fini l puisque les deux listes $\{p_i\}$ et $\{p'_i\}$ sont finies.

Considérons une permutation $\{k_i\}$ des indices qui regroupe ces termes non nuls en début de liste et qui les ordonne de la façon suivante:

$$p'_{k_1} - p_{k_1} \geq p'_{k_2} - p_{k_2} \geq \cdots \geq p'_{k_l} - p_{k_l},$$

$$p'_{k_j} - p_{k_j} \neq 0 \quad \text{pour } 1 \leq j \leq l,$$

$$p'_{k_j} - p_{k_j} = 0 \quad \text{pour } j > l.$$

La liste $\{\Delta_i\}$ est alors obtenue en ne gardant que les termes non négatifs:

$$\Delta_i = \max \{0, p'_{k_i} - p_{k_i}\} \quad \text{pour } i \geq 1.$$

Notons que cette liste $\{\Delta_i\}$ est unique, alors que la permutation $\{k_i\}$ ne l'est pas en général.

La somme des i premiers termes de la liste $\{\Delta_i\}$ est un majorant de l'ensemble des sommes de i termes choisis sans répétition d'indice dans la liste $\{p'_i - p_i\}$. De là se déduit la partie (i) \rightarrow (ii) de la Proposition 3.4.

La partie (ii) \rightarrow (i) s'établit en considérant que les premiers termes de la liste $\{\Delta_i\}$ sont choisis parmi les différences $\{p'_i - p_i\}$. \square

La démonstration du Théorème 3.1 va être effectuée dans les paragraphes qui suivent. La nécessité des conditions (1) et (2) du Théorème 3.1 sera montrée dans le § 4 en utilisant directement les énoncés (i) de la Proposition 3.3 et (ii) de la Proposition 3.4. Pour la démonstration de la suffisance, qui est développée dans les §§ 5-7, nous utiliserons plus particulièrement les énoncés (ii) de la Proposition 3.3 et (i) de la Proposition 3.4.

4. Le support géométrique des conditions structurelles.

THÉORÈME 4.1. Soit un système (C, A, B) , et considérons les étapes $\mathcal{V}_{\mathcal{H}}^i$ et $\mathcal{S}_{\mathcal{B}}^i$ des algorithmes définis par (2.1) et (2.2), et les listes $\{\alpha_i\}$ et $\{p_i\}$ définies par (2.3) et (2.5).

Alors nous avons

$$(i) \quad \dim \left(\frac{\mathcal{S}_{\mathcal{B}}^i + \mathcal{H}}{\mathcal{H}} \right) = p_1 - p_{i+1} \quad \text{pour } i \geq 0.$$

De plus, $\{k_1, \dots, k_i\}$ étant une liste strictement croissante d'entiers positifs distincts, posons

$$(ii) \quad \begin{aligned} T_1(k_1, \dots, k_i) &= \mathcal{B} \cap \mathcal{V}_{\mathcal{H}}^{k_i-1}, \\ T_{j+1}(k_1, \dots, k_i) &= (A\mathcal{T}_j(k_1, \dots, k_i) + \mathcal{B}) \cap \mathcal{V}_{\mathcal{H}}^{k_i-j-1} \quad \text{pour } 1 \leq j \leq i-1. \end{aligned}$$

Nous avons alors

$$(4.1) \quad \dim T_j(k_1, \dots, k_i) = \alpha_1 + \dots + \alpha_j + p_{k_i} + p_{k_{i-1}} + \dots + p_{k_{i-j+1}} \quad \text{pour } 1 \leq j \leq i.$$

Et donc en particulier

$$(4.2) \quad \dim \mathcal{T}_i(k_1, \dots, k_i) = \alpha_1 + \dots + \alpha_i + p_{k_1} + \dots + p_{k_i}.$$

Démonstration. (i) Malabre a donné dans [19] quelques déterminations géométriques de la structure à l'infini, et en particulier la suivante:

$$p_{i+1} = \dim \left(\frac{\mathcal{S}_{\mathcal{B}}^* + \mathcal{H}}{\mathcal{S}_{\mathcal{B}}^i + \mathcal{H}} \right) \quad \text{pour } i \geq 0.$$

L'affirmation (i) s'en déduit aisément.

(ii) Nous pouvons écrire les sous espaces \mathcal{T}_j sous forme de sommes directes en utilisant la description donnée dans le § 2. En utilisant le retour d'état particulier introduit en (2.12), on montre aisément que:

$$(4.3) \quad \mathcal{T}_j(k_1, \dots, k_i) = A_0^{j-1}(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^{k_i-1}) \oplus A_0^{j-2}(\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^{k_{i-1}-1}) \oplus \dots \oplus (\mathcal{B} \cap \mathcal{V}_{\mathcal{K}}^{k_{i-j+1}-1})$$

pour $1 \leq j \leq i$.

La dimension de ces sous-espaces se déduit alors de (2.15), et l'on obtient ainsi (4.1) et (4.2).

Démonstration de la nécessité des conditions (1) et (2) du Théorème 3.1. Le Théorème 4.1 permet d'établir rapidement la nécessité des conditions structurelles (1) et (2) du Théorème 3.1. On peut facilement établir l'inclusion suivante entre les sous-espaces $\mathcal{T}_j(k_1, \dots, k_i)$ relatifs au système (C, A, B) et $\mathcal{T}'_j(k_1, \dots, k_i)$ relatifs au système bouclé $(C, A + BF, BG)$:

$$\mathcal{T}'_j(k_1, \dots, k_i) \subset \mathcal{T}_j(k_1, \dots, k_i).$$

Cette inclusion conduit à

$$(4.4) \quad \sum_{j=1}^i \alpha_j + \sum_{j=1}^i p_{k_j} \geq \sum_{j=1}^i \alpha'_j + \sum_{j=1}^i p'_{k_j}.$$

Du fait de la Proposition 3.4, cela établit la nécessité de la condition (2) du Théorème 3.1.

La nécessité de la condition (1) s'établit d'une manière similaire, en considérant les espaces

$$\left(\frac{\mathcal{P}_{\mathcal{B}}^i + \mathcal{K}}{\mathcal{K}} \right) \supset \left(\frac{\mathcal{P}_{\mathcal{B}'}^i + \mathcal{K}}{\mathcal{K}} \right). \quad \square$$

La liste I_2 du système bouclé intervient dans (4.2) qui est de ce fait plus forte que la condition (2) du Théorème 3.1. En fait, (4.2) doit être vue comme une condition nécessaire pour l'assignation simultanée des listes I_2 et I_4 du système [20].

Les sous-espaces $\mathcal{T}_j(k_1, \dots, k_i)$ qui sont décrits dans le présent paragraphe sont le support géométrique naturel des conditions (2) du Théorème 3.1. Comme le montre (4.1), ces sous-espaces sont des sous-espaces presque de commandabilité de (A, B) (voir Willems [6], [7]).

Nous allons maintenant montrer dans les §§ 5-7 la suffisance des conditions structurelles (1) et (2) du Théorème 3.1. Nous allons pour cela construire un retour d'état (F, G) qui permet d'atteindre la structure à l'infini $\{n'_i\}$ choisie à l'avance et vérifiant les conditions (1) et (2) du Théorème 3.1.

5. Le cas particulier fondamental. Deux points importants ont été soulevés par les études récentes concernant le découplage par retour d'état non régulier [12], [13]. D'abord le fait que la liste I_4 de Morse (structure à l'infini) ne puisse qu'être augmentée; ensuite le fait que les augmentations possibles de la liste I_4 de Morse ne proviennent que de la liste I_2 de Morse du système: c'est bien ce que traduisent les conditions (1) et (2) du Théorème 3.1.

Notons toutefois que le problème du découplage par ligne qui est considéré dans [12] et [13] impose l'inversibilité à droite du système ($p_1 = p$), et la conservation de cette inversibilité à droite à travers la transformation du système par retour d'état ($p'_1 = p_1$).

Nous allons dans les §§ 5 et 6 étudier dans une première étape le problème du placement des ordres des zéros à l'infini avec cette condition supplémentaire, imposée pour le problème du découplage par ligne, de conservation du rang du système $p'_1 = p_1$.

Le cas particulier fondamental, qui est l'utilisation d'un seul des termes de la liste I_2 de Morse pour augmenter la liste I_4 , va être décrit dans le présent § 5. Le § 6 sera consacré à la généralisation de ce premier résultat (utilisation de tous les termes de la liste I_2).

THÉORÈME 5.1. *Soit un système (C, A, B) , avec $\{\sigma_i\}_{\alpha_1}$ pour liste I_2 et $\{n_i\}_{p_1}$ pour liste I_4 de Morse, et soient $\{\alpha_i\}_{\sigma_1}$ et $\{p_i\}_{n_1}$ les listes qui en sont déduites par comptage. Soit $\{n_i\}_{p_1^1}$ une liste finie et non croissante d'entiers positifs, et définissons $\{p_i^1\}$:*

$$p_i^1 = \text{card} \{j | n_j^1 \geq i\} \quad \text{pour } i \geq 1.$$

Supposons que l'égalité suivante soit vérifiée:

$$p_1^1 = p_1.$$

Alors il existe un retour d'état statique (F, G) tel que $\{n_1^1, \dots, n_{p_1^1}^1\}$ soit la liste I_4 de $(C, A + BF, BG)$ et $\{\sigma_2, \dots, \sigma_{\alpha_1}\}$ en soit la liste I_2 si et seulement si les deux conditions suivantes sont satisfaites:

- (1) $0 \leq p_i^1 - p_i \leq 1 \quad \text{pour } i \geq 1,$
- (2) $\text{card} \{i | p_i^1 - p_i = 1\} \leq \sigma_1.$

Démonstration.

Nécessité. La nécessité est une simple conséquence des hypothèses et de la nécessité des conditions (1) et (2) du Théorème 3.1. $\{\sigma_i^1\}$ désignant la liste I_2 de $(C, A + BF, BG)$ et $\{\alpha_i^1\}$ la liste qui en est déduite par comptage, nous avons par hypothèse

$$\sigma_i^1 = \sigma_{i+1} \quad \text{pour } i \geq 1,$$

et donc

$$(5.1) \quad \alpha_i^1 = \begin{cases} \alpha_i - 1 & \text{pour } 1 \leq i \leq \sigma_1, \\ 0 & \text{pour } i \geq \sigma_1 + 1. \end{cases}$$

D'autre part, les conditions nécessaires du Théorème 3.1 donnent en particulier

$$(5.2) \quad p_1 - p_i \geq p_1^1 - p_i^1 \quad \text{pour } i \geq 1,$$

$$(5.3) \quad \alpha_1 + p_i \geq \alpha_1^1 - p_i^1 \quad \text{pour } i \geq 1,$$

$$(5.4) \quad \sum_{j=1}^n \alpha_j + \sum_{j=1}^n p_j \geq \sum_{j=1}^n \alpha_j^1 + \sum_{j=1}^n p_j^1.$$

La condition (1) du Théorème 5.1 découle alors de (5.1)–(5.3); la condition (2) découle de (5.4), de (1) et du fait que

$$\sum_{j=1}^n \alpha_j - \sum_{j=1}^n \alpha_j^1 = \sum_{j=1}^n \sigma_j - \sum_{j=1}^n \sigma_j^1 := \sigma_1$$

et que

$$\begin{aligned} \sum_{j=1}^n p_j^1 - \sum_{j=1}^n p_j &= \sum_{j=1}^n (p_j^1 - p_j) \\ &= \text{card} \{j | p_j^1 - p_j = 1\}. \end{aligned}$$

Nous aurons besoin pour montrer la réciproque de traduire les conditions (ii) en termes des listes $\{n_i\}$ et $\{n_i^1\}$.

LEMME 5.2. Soient $\{n_i\}_{p_1}$ et $\{n_i^1\}_{p_1}$ deux listes finies et non croissantes d'entiers positifs et soient $\{p_i\}_{n_1}$ et $\{p_i^1\}_{n_1}$ les listes qui en sont déduites par comptage. Alors:

(1) Les conditions suivantes sont équivalentes:

$$(5.5) \quad 0 \leq p_i^1 - p_i \quad \text{pour } i \geq 1,$$

$$(5.6) \quad 0 \leq n_i^1 - n_i \quad \text{pour } i \geq 1.$$

(2) Les conditions suivantes sont équivalentes:

$$(5.7) \quad p_i^1 - p_i \leq 1 \quad \text{pour } i \geq 1,$$

$$(5.8) \quad n_{i+1}^1 \leq n_i \quad \text{pour } i \geq 1.$$

(3) Les conditions suivantes sont équivalentes:

$$(5.9) \quad \sum_{i=1}^n p_i^1 - \sum_{i=1}^n p_i \leq \sigma_1,$$

$$(5.10) \quad n_1^1 \leq n_1 + \sigma_1 - \sum_{i=2}^n (n_i^1 - n_i).$$

Démonstration du Lemme 5.2. Les conditions (1) et (2) sont des conséquences immédiates de la bijection (2.7) qui existe entre les listes $\{n_i\}$ et $\{p_i\}$ d'une part, et entre $\{n_i^1\}$ et $\{p_i^1\}$ d'autre part.

La condition (3) se déduit par équivalences:

$$\begin{aligned} & \sum_{i=1}^n p_i^1 - \sum_{i=1}^n p_i \leq \sigma_1 \\ \Leftrightarrow & \sum_{i=1}^n n_i^1 - \sum_{i=1}^n n_i \leq \sigma_1 \\ \Leftrightarrow & n_1^1 \leq n_1 + \sigma_1 - \sum_{i=2}^n (n_i^1 - n_i); \end{aligned}$$

ceci achève la démonstration du Lemme 5.2. \square

Suffisance du Théorème 5.1. Nous allons maintenant établir la réciproque du Théorème 5.1 en construisant des matrices F et G qui réalisent les modifications voulues des listes I_2 et I_4 .

Supposons dans ce but que les conditions (1) et (2) du Théorème 5.1 soient vérifiées. Cela s'écrit en utilisant le Lemme 5.2:

$$(5.11) \quad n_1 \leq n_1^1 \leq n_1 + \sigma_1 - \sum_{i=2}^n (n_i^1 - n_i),$$

$$(5.12) \quad n_i \leq n_i^1 \leq n_{i-1} \quad \text{pour } 2 \leq i \leq p_1.$$

Nous pouvons toujours choisir une base de \mathcal{X} sous la forme suivante (voir (2.9) et (2.8)):

$$\{b_1, A_0 b_1, \dots, A_0^{\sigma_1-1} b_1; \dots; b_{\alpha_1}, \dots, A_0^{\sigma_{\alpha_1}-1} b_{\alpha_1}; \ell_1, \dots, A_0^{n_1-1} \ell_1; \\ \dots; \ell_{p_1}, \dots, A_0^{n_{p_1}-1} \ell_{p_1}; x_1, \dots, x_\lambda\}.$$

Définissons maintenant la famille des vecteurs x_{ij} de la façon suivante:

$$(5.13) \quad \begin{aligned} x_{ij} &= A_0^{j-1} \ell_{i-1} && \text{pour } 1 \leq i \leq p_1 \text{ et } 1 \leq j \leq n_i^1 - n_i, \\ x_{ij} &= A_0^{j-1} \ell_{i-1} + A_0^{n_i - n_i^1 + j - 1} \ell_i && \text{pour } 1 \leq i \leq p_1 \text{ et } n_i^1 - n_i < j \leq n_i^1, \\ x_{0j} &= A_0^{\sigma+j-1} \ell_0 && \text{pour } 1 \leq j \leq \sigma_1 - \sigma \end{aligned}$$

avec

$$\begin{aligned}\ell_0 &:= b_1, \\ \sigma &:= \sum_{i=1}^{p_1} (n_i^1 - n_i).\end{aligned}$$

Il est alors facile d'établir l'égalité suivante:

$$\text{span} \{x_{ij}\} = \text{span} \{b_1, \dots, A_0^{\sigma_1-1} b_1; \ell_1, \dots, A_0^{n_1-1} \ell_1; \dots; \ell_{p_1}, \dots, A_0^{n_{p_1}-1} \ell_{p_1}\}.$$

L'inclusion provient directement de la définition des x_{ij} et les deux espaces ont la même dimension du fait de l'indépendance des x_{ij} .

Il en résulte que la famille suivante est une base de \mathcal{X} .

$$\begin{aligned}\{b_2, \dots, A_0^{\sigma_2-1} b_2; \dots; b_{\alpha_1}, \dots, A_0^{\sigma_{\alpha_1}-1} b_{\alpha_1}; x_{01}, \dots, x_{0, \sigma_1-\sigma}; \\ x_{11}, \dots, x_{1, n_1^1}; \dots; x_{p_1, 1}, \dots, x_{p_1, n_{p_1}^1}; x_1, \dots, x_\lambda\}.\end{aligned}$$

Définissons alors F et G sur cette nouvelle base de \mathcal{X} . Posons tout d'abord

$$\ell'_i = x_{i1} \quad \text{pour } 1 \leq i \leq p_1;$$

puis

$$(5.14) \quad \text{Im } BG = \text{span} \{b_2, \dots, b_{\alpha_1}; \ell'_1, \dots, \ell'_{p_1}\}.$$

Enfin définissons F de la manière suivante:

$$F := F_0 + F'$$

avec

$$\begin{aligned}BF'x_{ij} &= \begin{cases} 0 & \text{si } j \neq n_i^1 - n_i, \\ \ell_i & \text{si } j = n_i^1 - n_i \text{ et } 1 \leq i \leq p_1, \end{cases} \\ BF'x_{0j} &= 0 \quad \text{pour } 1 \leq j \leq \sigma_1 - \sigma, \\ BF'A_0^{j-1} b_i &= 0 \quad \text{pour } 2 \leq i \leq \alpha_1 \text{ et } 1 \leq j \leq \sigma_i, \\ BF'x_j &= 0 \quad \text{pour } 1 \leq j \leq \lambda. \end{aligned}$$

Nous obtenons alors

$$\begin{aligned}x_{ij+1} &= (A_0 + BF')x_{ij} \\ &= (A + BF)x_{ij} \quad \text{pour } 1 \leq i \leq p_1 \text{ et } 1 \leq j \leq n_i^1 - 1, \\ x_{0j+1} &= (A + BF)x_{0j} \quad \text{pour } 1 \leq j \leq \sigma_1 - \sigma - 1.\end{aligned}$$

De plus, nous pouvons vérifier que

$$\begin{aligned}x_{i,j} &= (A + BF)^{j-1} \ell'_i \in \mathcal{H} \quad \text{pour } 1 \leq i \leq p_1 \text{ et } 1 \leq j \leq n_i^1 - 1, \\ x_{i, n_i^1} &\notin \mathcal{H} \quad \text{pour } 1 \leq i \leq p_1.\end{aligned}$$

Le triplet $(C, A + BF, BG)$ est donc décomposé par cette nouvelle base de \mathcal{X} comme il est décrit dans le § 2. Les listes de Morse correspondantes sont donc

$$I_2 = \{\sigma_2, \dots, \sigma_{\alpha_1}\}, \quad I_4 = \{n_1^1, \dots, n_{p_1}^1\}.$$

Ceci achève la démonstration du Théorème 5.1. \square

Remarque 5.3. Le retour d'état que nous venons d'exhiber pour la démonstration du Théorème 5.1 modifie aussi la liste des zéros invariants du système, tout au moins

dans le cas où $\sigma_1 > \sigma > 0$. En effet, il apparaît dans ce cas dans la structure du système bouclé un zéro invariant fini de valeur 0 et de multiplicité $\sigma_1 - \sigma$, qui correspond aux vecteurs x_{0j} :

$$\{A_0^\sigma b_1, A_0^{\sigma+1} b_1, \dots, A_0^{\sigma_1-1} b_1\}.$$

En fait il est toujours possible d'assigner la valeur de ce zéro invariant en bouclant le système, avant d'appliquer la procédure décrite précédemment, par un retour d'état F'_0 tel que la restriction $\mathcal{R}_1|(A_0 + BF'_0)|\mathcal{R}_1$ ait α arbitraire pour valeur propre de multiplicité σ_1 .

Un tel retour d'état existe toujours du fait que \mathcal{R}_1 est un sous espace de commandabilité (voir Wonham [15]). Lorsqu'on applique alors la démonstration du Théorème 5.1, les vecteurs x_{0j} correspondent à un zéro invariant α de multiplicité $(\sigma_1 - \sigma)$.

6. Première généralisation: conservation du rang du système. Nous sommes maintenant en mesure d'établir la suffisance des conditions (1) et (2) du Théorème 3.1 sous l'hypothèse de conservation du rang: $p'_1 = p_1$, hypothèse qui sera abandonnée dans le § 7.

Nous n'allons pas construire explicitement le retour d'état (F, G) qui fait que la liste $\{n'_i\}_{p_1}$ choisie à l'avance, et que l'on suppose vérifier les conditions nécessaires du Théorème 3.1, soit la liste des ordres des zéros à l'infini du système bouclé $(C, A + BF, BG)$; mais nous allons utiliser le Théorème 5.1 pour définir (F, G) d'une façon algorithmique.

L'idée de cette construction est de définir une suite de listes $\{p_1^\mu, p_2^\mu, \dots\}$ qui vérifient les propriétés suivantes:

—La suite est initialisée à $\{p_i\}$:

$$p_i^0 = p_i \quad \text{pour } i \geq 1.$$

—Pour $\mu \geq 1$, les conditions du Théorème 5.1 sont vérifiées de l'étape $\mu - 1$ à l'étape μ :

$$\begin{aligned} p_1^\mu &= p_1^{\mu-1}, \\ 0 &\leq p_i^\mu - p_i^{\mu-1} \leq 1 \quad \text{pour } i \geq 1, \\ \text{card } \{i | p_i^\mu - p_i^{\mu-1} = 1\} &\leq \sigma_\mu. \end{aligned}$$

—La suite converge vers $\{p'_i\}$; pour $\mu \geq \alpha_1$, on a

$$p_i^\mu = p'_i \quad \text{pour } i \geq 1.$$

En effet, si de telles listes peuvent être définies, alors le problème peut être résolu de la façon suivante:

—Posons:

$$(C, A_0, B_0) = (C, A, B).$$

—Pour $\mu \geq 1$, nous pouvons calculer à l'aide du Théorème 5.1 un retour d'état (F_μ, G_μ) tel que les listes I_4 et I_2 de Morse du système bouclé:

$$(C, A_\mu, B_\mu) = (C, A_{\mu-1} + B_{\mu-1}F_\mu, B_{\mu-1}G_\mu),$$

soient respectivement, $\{n_i^\mu\}$ et $\{\sigma_i^\mu\}$:

$$\begin{aligned} n_i^\mu &= \text{card } \{j | p_j^\mu \geq i\} \quad \text{pour } i \geq 1, \\ \sigma_i^\mu &= \sigma_{i+1}^{\mu-1} = \sigma_{i+\mu} \quad \text{pour } i \geq 1. \end{aligned}$$

— $\{n'_i\}$ sera alors la liste I_4 de Morse du système

$$(C, A_{\alpha_1}, B_{\alpha_1}) = (C, A + BF, BG)$$

avec

$$F = F_1 + G_1 F_2 + \cdots + G_1 G_2 \cdots G_{\alpha_1-1} F_{\alpha_1},$$

$$G = G_1 G_2 \cdots G_{\alpha_1}.$$

La suite de ce paragraphe va être consacrée à la description de telles listes. Définissons tout d'abord les listes $\{p_i^\mu\}$ de la manière suivante.

DÉFINITION 6.1. Posons pour $\mu = 0$:

$$(6.1) \quad p_i^0 = p_i \quad \text{pour } i \geq 1.$$

Pour $\mu \geq 1$, considérons la liste $\{\Delta_i^{\mu-1}\}$ des différences $(p'_i - p_i^{\mu-1})$ rangées dans un ordre non croissant. Cet ordre de rangement n'est pas unique à cause des possibles répétitions de différences égales pour des indices différents. Soit $\{k_i^{\mu-1}\}$ l'unique permutation des indices définie par

$$(6.2) \quad \Delta_i^{\mu-1} = p'_{k_i^{\mu-1}} - p_{k_i^{\mu-1}}^{\mu-1} \quad \text{pour } i \geq 1$$

et

$$(6.3) \quad \begin{aligned} &\text{Si } \Delta_i^{\mu-1} = \Delta_{i+1}^{\mu-1} \quad \text{et} \quad \Delta_i^{\mu-1} \neq 0, \quad \text{alors} \quad k_i^{\mu-1} > k_{i+1}^{\mu-1}, \\ &\text{Si } \Delta_i^{\mu-1} = \Delta_{i+1}^{\mu-1} = 0, \quad \text{alors} \quad k_i^{\mu-1} < k_{i+1}^{\mu-1} \quad \text{pour } i \geq 1. \end{aligned}$$

Posons alors

$$\begin{aligned} l_1^{\mu-1} &= \text{card} \{j | \Delta_j^{\mu-1} > \Delta_{\sigma_\mu}^{\mu-1}\}, \\ l_2^{\mu-1} &= \text{card} \{j | \Delta_j^{\mu-1} \geq \Delta_{\sigma_\mu}^{\mu-1} \text{ et } \Delta_j^{\mu-1} \geq 1\}, \end{aligned}$$

et définissons

$$(6.4) \quad \Delta_i^\mu = \begin{cases} \Delta_i^{\mu-1} - 1 & \text{pour } 1 \leq i \leq l_1^{\mu-1}, \\ \Delta_i^{\mu-1} & \text{pour } l_1^{\mu-1} + 1 \leq i \leq l_2^{\mu-1} + l_1^{\mu-1} - \sigma_\mu, \\ \Delta_i^{\mu-1} - 1 & \text{pour } l_2^{\mu-1} + l_1^{\mu-1} - \sigma_\mu + 1 \leq i \leq l_2^{\mu-1}, \\ \Delta_i^{\mu-1} & \text{pour } l_2^{\mu-1} + 1 \leq i. \end{cases}$$

Finalement définissons $\{p_i^\mu\}$ et $\{n_i^\mu\}$ de la façon suivante:

$$p_{k_i^{\mu-1}}^\mu = p'_{k_i^{\mu-1}} - \Delta_i^\mu \quad \text{pour } i \geq 1,$$

$$n_i^\mu = \text{card} \{j | p_j^\mu \geq i\} \quad \text{pour } i \geq 1. \quad \square$$

Rappelons que $\{\Delta_i\}$ est une liste finie et non croissante d'entiers positifs. De plus $\{\Delta_i^\mu\}$ possèdera cette propriété si $\{\Delta_i^{\mu-1}\}$ la possède, comme le montre la lecture du tableau 6.1 qui traduit les définitions (6.4),

TABLEAU 6.1

i	1	\cdots	$l_1^{\mu-1}$	$l_1^{\mu-1} + 1$	\cdots	$\beta^{\mu-1}$	$\beta^{\mu-1} + 1$	\cdots	$l_2^{\mu-1}$	$l_2^{\mu-1} + 1$	\cdots	$\delta_1^{\mu-1}$	$\delta_1^{\mu-1} + 1$	\cdots
$\Delta_i^{\mu-1}$	$\Delta_i^{\mu-1} > \Delta_{\sigma_\mu}^{\mu-1}$			$\Delta_i^{\mu-1} = \Delta_{\sigma_\mu}^{\mu-1}$					$\Delta_i^{\mu-1} < \Delta_{\sigma_\mu}^{\mu-1}$			0		
$\Delta_i^{\mu-1} - \Delta_i^\mu$	1			0			1			0			0	

où

$$\beta^{\mu-1} := l_1^{\mu-1} + l_2^{\mu-1} - \sigma_\mu,$$

$$\delta_1^{\mu-1} := \text{card} \{j | \Delta_j^{\mu-1} \geq 1\}.$$

Les listes $\{\Delta_i^\mu\}$ sont donc toutes des listes finies et non croissantes d'entiers positifs. Cela nous permet d'affirmer que $\{k_i^\mu\}$ est toujours une permutation des entiers; pour tout entier j positif, il existe i tel que $k_i^\mu = j$. Par conséquent (6.5) définit complètement la liste $\{p_i^\mu\}$.

La liste I_2 de Morse des systèmes (C, A_μ, B_μ) que nous cherchons à définir doit être $\{\sigma_{\mu+1}, \sigma_{\mu+2}, \dots\}$.

Introduisons donc la notation suivante:

$$\alpha_i^\mu = \text{card} \{j | \sigma_{\mu+j} \geq i\} \quad \text{pour } i \geq 1.$$

Nous allons maintenant vérifier que ces listes $\{p_i^\mu\}$ possèdent les propriétés que nous en attendons.

PROPOSITION 6.2. *Pour $\mu \geq 1$, les propriétés suivantes sont vérifiées:*

- (i) $\{p_i^\mu\}$ est une liste finie et non croissante d'entiers positifs,
- (ii) $p_1^\mu = p'_1 = p_1$,
- (iii) $0 \leq p_i^\mu - p_i^{\mu-1} \leq 1$ pour $i \geq 1$,
- (iv) $\text{card} \{j | p_j^\mu - p_j^{\mu-1} = 1\} \leq \sigma_\mu$,
- (v) $\sum_{j=1}^i \alpha_j^\mu \geq \sum_{j=1}^i \Delta_j^\mu$ pour $i \geq 1$.

Démonstration. La démonstration de (v) est un peu technique et pour cela reportée au § Annexe. $\{p_i^\mu\}$ est bien une liste finie d'entiers positifs, du fait de l'encadrement suivant:

$$p_i^0 \leq p_i^\mu \leq p'_i.$$

De plus, l'examen du tableau (6.6) permet d'affirmer que $\{p_i^\mu\}$ est non croissante si $\{p_i^{\mu-1}\}$ l'est. Cela établit (i).

L'affirmation (ii) se montre aisément à partir du fait que

$$p_1^0 = p'_1 = p_1.$$

En observant les définitions (6.4), nous pouvons constater que $(\Delta_i^{\mu-1} - \Delta_i^\mu)$ ne peut prendre que les valeurs 0 ou 1. De là, et de la définition (6.5) découle l'affirmation (iii).

Enfin, l'affirmation (iv) provient des définitions (6.4) et (6.5) et de l'égalité suivante:

$$\text{card} \{i | p_i^\mu - p_i^{\mu-1} = 1\}. \quad \square$$

Les quatre premières affirmations de la Proposition 6.2 permettent l'application à chaque étape du Théorème 5.1. Il existe donc des retours d'état (F_μ, G_μ) tels que $\{n_i^\mu\}$ et $\{\sigma_i^\mu\}$ soient respectivement les listes I_4 et I_2 de Morse du système bouclé (C, A_μ, B_μ) .

À partir de l'étape $\mu = \alpha_1$, les listes $\{\sigma_i^\mu\}$ et $\{\alpha_i^\mu\}$ sont nulles. Puisque $\{\Delta_i^\mu\}$ est une liste positive, la condition (v) s'écrit:

$$\sum_{j=1}^i \Delta_j^\mu = 0 \quad \text{pour } i \geq 1.$$

La liste $\{\Delta_i^\mu\}$ est donc elle-même nulle, ce qui traduit l'égalité des listes $\{p_i^\mu\}$ et $\{p'_i\}$. Autrement dit, $\{n_i\}$ est la liste des ordres des zéros infinis de $(C, A_{\alpha_1}, B_{\alpha_1})$.

Ainsi s'achève la démonstration de la suffisance des conditions (1) et (2) du Théorème 3.1 pour le cas où $p'_1 = p_1$. Nous allons maintenant résoudre le problème

du placement des ordres des zéros infinis par retour d'état statique dans le cas général: $p'_1 \leq p_1$.

7. Le placement des ordres des zéros à l'infini dans le cas général. Le découplage ligne par ligne [12], [13] a motivé l'étude du cas où le rang du système est conservé: $p'_1 = p_1$. En revanche, le découplage par blocs d'un système n'implique pas son inversibilité à droite, ni même la conservation du rang du système à travers l'action du retour d'état qui modifie sa structure à l'infini. C'est une motivation pour étudier le cas général où le nombre de zéros à l'infini du système bouclé peut être inférieur au nombre des zéros à l'infini du système initial: $p'_1 \leq p_1$.

Le Théorème 7.1 va permettre cette généralisation.

THÉOREME 7.1. Soit un système (C, A, B) et soient $\{n_i\}_{p_1}$ sa liste I_4 et $\{p_i\}_{n_1}$ la liste qui en est déduite par comptage:

$$p_i = \text{card} \{j | n_j \geq i\} \quad \text{pour } i \geq 1.$$

Soient $\{n'_i\}_{p'_1}$ une liste finie et non croissante d'entiers positifs, et $\{p'_i\}_{n'_1}$ la liste qui en est déduite par comptage:

$$p'_i = \text{card} \{j | n'_j \geq i\} \quad \text{pour } i \geq 1.$$

Alors il existe un retour d'état (F, G) tel que la liste I_4 de $(C, A + BF, BG)$ soit $\{n'_i\}_{p'_1}$, et sa liste I_2 soit la liste I_2 de (C, A, B) si et seulement si les inégalités suivantes sont vérifiées:

$$(1) \quad p_1 - p_i \geq p'_1 - p'_i \quad \text{pour } i \geq 1,$$

$$(2) \quad p_i \geq p'_i \quad \text{pour } i \geq 1.$$

Démonstration. Nous n'allons pas détailler cette démonstration qui est très similaire à la démonstration du Théorème 5.1.

Les conditions (1) et (2) sont manifestement un cas particulier des conditions nécessaires (1) et (2) du Théorème 3.1, et donc sont nécessaires.

Montrons maintenant la suffisance de ces conditions, et commençons pour cela par les traduire en termes des listes $\{n_i\}$ et $\{n'_i\}$. Nous obtenons à partir de la Proposition 3.3

$$n_{p_1 - p'_i + i} \leq n'_i \leq n_i \quad \text{pour } 1 \leq i \leq p'_1.$$

La construction de F et G s'effectue alors avec la même technique que pour le Théorème 5.1. Les vecteurs $\{\ell_i, A_0 \ell_i, \dots, A_0^{n_i - 1} \ell_i\}$ étant associés à chaque zéro à l'infini d'ordre n_i , posons pour $1 \leq i \leq p'_1$

$$\ell'_i = \begin{cases} \ell_i & \text{si } n_{p_1 - p'_i + i} < n'_i, \\ \ell_i + \ell_{p_1 - p'_i + i} & \text{si } n_{p_1 - p'_i + i} = n'_i, \end{cases}$$

puis

$$x_{ij} = \begin{cases} A_0^{j-1} \ell_i & \text{pour } 1 \leq j \leq n'_i - n_{p_1 - p'_i + i}, \\ A_0^{j-1} \ell_i + A_0^{j + n'_{p_1 - p'_i + i} - n'_i - 1} \ell_{p_1 - p'_i + i} & \text{pour } n'_i - n_{p_1 - p'_i + i} \leq j \leq n'_i. \end{cases}$$

On peut vérifier que les vecteurs x_{ij} sont tous indépendants. Définissons alors F et G comme suit:

$$(7.1) \quad \text{Im } BG = \{\ell'_1, \dots, \ell'_{p'_1}; b_1, \dots, b_{\alpha_1}\};$$

puis pour $1 \leq i \leq p'_1$:

$$(7.2) \quad BF x_{ij} = \begin{cases} \delta_{p_1-p'_1+i} & \text{pour } j = n'_i - n_{p_1-p'_1+i}, \\ 0 & \text{pour } j \neq n'_i - n_{p_1-p'_1+i}. \end{cases}$$

Le résultat cherché est alors obtenu. \square

Le Théorème 7.1 va nous permettre de compléter la démonstration du Théorème 3.1 pour le cas général. Il nous suffit pour cela de réinitialiser l'algorithme présenté dans le § 6.

PROPOSITION 7.2. *Considérons les listes $\{p_i\}$, $\{p'_i\}$ et $\{\alpha_i\}$ respectivement déduites par comptage de la liste $\{n_i\}$ des ordres des zéros à l'infini, de la liste $\{n'_i\}$ à atteindre, et de la liste $\{\sigma_i\}$ qui est la liste I_2 de Morse de (C, A, B) .*

Soit $\{\Delta_i\}$ la liste des différences $(p'_i - p_i)$ rangées par ordre non croissant, et supposons que les conditions du Théorème 3.1 sont vérifiées:

- (1) $p_1 - p_i \geq p'_1 - p'_i$ pour $i \geq 1$,
- (2) $\sum_{j=1}^i \alpha_j \geq \sum_{j=1}^i \Delta_j$ pour $i \geq 1$.

Définissons la liste $\{p_i^0\}$ de la manière suivante:

$$(7.3) \quad p_i^0 = \min \{p_i, p'_i\} \quad \text{pour } i \geq 1,$$

et appelons $\{\Delta_i^0\}$ la liste des différences $(p'_i - p_i^0)$ rangées par ordre non croissant.

Alors les propriétés suivantes sont vérifiées:

- (i) $p_i \geq p_i^0$ pour $i \geq 1$,
- (ii) $p_1 - p_i \geq p'_1 - p_i^0$ pour $i \geq 1$,
- (iii) $p'_1 - p_i^0 \geq p'_1 - p'_i$ pour $i \geq 1$,
- (iv) $\sum_{j=1}^i \alpha_j \geq \sum_{j=1}^i \Delta_j^0$ pour $i \geq 1$,
- (v) $p_1^0 = p'_1$.

Démonstration. La condition (i) provient directement de la définition (7.3). De la même définition et de l'hypothèse (1) découle (v).

Les conditions (ii) et (iii) découlent également de l'hypothèse (1).

Afin d'établir (iv), notons l'égalité suivante qui provient de la définition (7.3):

$$p'_i - p_i^0 = |p'_i - p_i| \quad \text{pour } i \geq 1.$$

Donc la liste $\{\Delta_i^0\}$ n'est autre que la liste $\{\Delta_i\}$, et (iv) traduit directement l'hypothèse (2).

Les conditions (i) et (ii) étant satisfaites, nous pouvons calculer un retour d'état (F_0, G_0) à la manière du Théorème 7.1. La liste des zéros à l'infini du système bouclé $(C, A + BF_0, BG_0)$ est alors $\{n_i^0\}$:

$$n_i^0 = \text{card} \{j | p_j^0 \geq i\} \quad \text{pour } i \geq 1.$$

Les conditions (iii)–(v) étant satisfaites, il existe un retour d'état (F, G) du type détaillé dans le § 6, tel que $\{n'_i\}$ soit la structure à l'infini du système bouclé $(C, A + BF_0 + BG_0F, BG_0G)$. Cela achève la démonstration du Théorème 3.1. \square

Afin d'illustrer cet article et de récapituler la méthode à suivre pour résoudre un problème de placement de structure à l'infini, nous concluons sur un exemple très simple (et très académique).

Exemple 7.3.

$$A = \begin{array}{|c|c|c|c|} \hline 0 & 1 & & \\ \hline 0 & 0 & & \\ \hline & & 0 & 1 \\ & & 0 & 0 \\ \hline & & & 0 \\ \hline & & & 0 \\ \hline \end{array}, \quad B = \begin{array}{|c|c|c|c|} \hline 0 & & & \\ \hline 1 & & & \\ \hline & 0 & & \\ & 1 & & \\ \hline & & 1 & \\ \hline & & & 1 \\ \hline \end{array},$$

$$C = \begin{array}{|c|c|c|c|} \hline & & 1 & \\ \hline & & & 1 \\ \hline \end{array} \quad (\text{les blocs non spécifiés sont nuls}).$$

Ce système est sous la forme normale qui correspond à

$$\begin{aligned} \{n_i\} &= \{1, 1\}, & \{p_i\} &= \{2\}, \\ \{\sigma_i\} &= \{2, 2\}, & \{\alpha_i\} &= \{2, 2\} \end{aligned}$$

(les termes nuls ne sont pas écrits).

On se propose d'atteindre la structure à l'infini suivante:

$$\{n'_i\} = \{4, 2\}, \quad \{p'_i\} = \{2, 2, 1, 1\}.$$

Or on a

$$\{\Delta_i\} = \{2, 1, 1\}.$$

Les conditions nécessaires du Théorème 3.1 sont vérifiées donc la liste $\{n'_i\}$ est atteignable.

Du fait que $p_1 = p'_1 = 2$, le Théorème 7.1 n'a pas à être utilisé. Nous posons donc

$$(C_0, A_0, B_0) = (C, A, B).$$

Appliquons alors la définition 6.1:

μ	$\{k_i^\mu\}$	l_1^μ	l_2^μ	$\{\Delta_i^\mu\}$	$\{p_i^\mu\}$
1	$\{2, 4, 3\}$	1	3	$\{1, 1\}$	$\{2, 1, 1\}$
2	$\{4, 2\}$	0	2	0	$\{2, 2, 1, 1\}$

Calculons maintenant (F_1, G_1) et (F_2, G_2) comme dans le § 5:

$$G_1 = \begin{array}{|c|c|c|} \hline & 1 & \\ \hline 1 & & \\ \hline & & 1 \\ & & 1 \\ \hline \end{array}, \quad F_1 = \begin{array}{|c|c|c|c|} \hline & & & \\ \hline & & & \\ \hline 1 & 0 & & \\ \hline & & & \\ \hline \end{array},$$

$$G_2 = \begin{array}{|c|c|} \hline 1 & \\ \hline & 1 \\ \hline & \\ \hline \end{array}, \quad F_2 = \begin{array}{|c|c|c|c|} \hline & & & \\ \hline & 0 & 1 & \\ \hline 0 & 1 & -1 & 0 \\ \hline \end{array}.$$

Tous calculs faits, nous obtenons:

$$A + BF_1 + BG_1F_2 = \begin{array}{|c|c|c|c|c|} \hline 0 & 1 & 0 & 0 & \\ \hline 0 & 0 & 0 & 1 & \\ \hline & & 0 & 1 & \\ & & 0 & 0 & \\ \hline 1 & 1 & -1 & 0 & 0 \\ \hline 0 & 1 & -1 & 0 & 0 \\ \hline \end{array}, \quad BG_1G_2 = \begin{array}{|c|c|} \hline & 0 \\ & 1 \\ \hline 0 & \\ 1 & \\ \hline & \\ & \\ \hline \end{array}.$$

8. Remarques finales. Notons tout d'abord l'intérêt pratique du Théorème 3.1. Les conditions structurelles du Théorème 3.1, qui caractérisent l'ensemble des structures à l'infini atteignables par retour d'état statique, sont en effet très simples à vérifier. Cette vérification s'effectue en fait en quatre étapes:

- (i) Calcul des étapes successives des algorithmes (2.1) et (2.2).
- (ii) Calcul des listes I_2 et I_4 de Morse du système par les formules (2.3), (2.4), (2.5) et (2.6).
- (iii) Calcul de la liste ordonnée des différences $\{\Delta_i\}$.
- (iv) Vérification des inégalités (1) et (2) du Théorème 3.1.

Le nombre des inégalités à vérifier est en fait $2 \max \{n_1, n'_1\}$.

Le problème du placement par retour d'état de la structure à l'infini est également résolu de manière pratique. La construction d'une solution (F, G) s'effectue en trois étapes:

- (i) Calcul d'une base de \mathcal{X} qui décompose $\mathcal{R}_{\mathcal{X}}^*$ comme en (2.9) et $\mathcal{S}_{\mathcal{B}}^*$ comme en (2.10). Cela s'effectue de manière standard à partir des étapes des algorithmes (2.1) et (2.2). La procédure est détaillée dans Morse [9].
- (ii) Réduction si nécessaire du rang du système à l'aide des formules (7.1) et (7.2) du § 7.
- (iii) Utilisation successive des termes de la liste I_2 à l'aide de la définition 6.1 et des formules (5.14) et (5.15).

Le calcul, assez lourd dans le cas général, d'un retour d'état qui décompose $\mathcal{R}_{\mathcal{X}}^*$ et $\mathcal{S}_{\mathcal{B}}^*$ ne s'effectue qu'une seule fois, au début de la procédure. A partir de cette première étape, les calculs demandés sont très simples, et particulièrement aptes à être traités sur ordinateur. L'algorithme peut être modifié afin de réduire le nombre des calculs, par exemple en appliquant la procédure de modification aux seuls vecteurs correspondant à des zéros à l'infini dont l'ordre n'est pas dans la structure à atteindre. Ainsi, avec $\{n_i\} = \{3, 3, 2, 1\}$ et $\{n'_i\} = \{4, 4, 3, 2\}$, il suffit d'appliquer la procédure qui correspond aux listes $\{n_i\} = \{3, 1\}$ et $\{n'_i\} = \{4, 4\}$.

La solution (F, G) au problème de placement des ordres des zéros à l'infini qui est déterminée de cette manière est en général différente de la solution obtenue par l'algorithme de départ. En fait, il est bien clair que la solution, si elle existe, n'est pas unique. La détermination de l'ensemble des solutions (F, G) d'un problème de placement de structure à l'infini est pour l'instant un problème ouvert. Il semble que la solution de ce problème, ou plus exactement la détermination de l'ensemble des sous-espaces $\text{Im } BG$ correspondant à une solution, soit une clé importante pour la solution de problèmes de commande tels que le découplage.

L'étude effectuée dans le présent article s'inscrit dans le cadre plus général de l'étude des transformations (sous l'action de retours d'états statiques) des quatre listes

d'invariants structurels de Morse [20]. Une référence importante dans ce domaine est celle d'Heymann [14] qui a caractérisé pour une paire (A, B) donnée l'ensemble des listes d'indices de commandabilité atteignables par retour d'état. Les travaux d'Heymann s'appliquent aux transformations de la liste I_2 de Morse, qui n'est autre que la liste des indices de commandabilité de la paire restreinte $(\mathcal{R}_{\mathcal{H}}^*|A+BF|\mathcal{R}_{\mathcal{H}}^*, B_{\mathcal{R}})$ où $\text{Im } B_{\mathcal{R}} = \mathcal{B} \cap \mathcal{R}_{\mathcal{H}}^*$, et $(A+BF)\mathcal{R}_{\mathcal{H}}^* \subset \mathcal{R}_{\mathcal{H}}^*$.

Etant donné un système (C, A, B) dont la liste I_2 de Morse est $\{\sigma_i\}$, la condition nécessaire et suffisante donnée par Heymann pour qu'une liste finie d'entiers positifs $\{\sigma'_i\}$ soit la liste I_2 d'un système bouclé $(C, A+BF, BF)$ est la suivante:

$$(8.1) \quad \sum_{j \in \mathcal{J}'(i)} \sigma'_j \leq \sum_{j \in \mathcal{J}(i)} \sigma_j \quad \text{pour } i \geq 1,$$

avec

$$\mathcal{J}(i) = \{j | \sigma_j \leq i\}.$$

La condition (8.1) exprime en fait les dimensions possibles des sous-espaces de commandabilité du système considéré inclus dans \mathcal{H} . Ces dimensions ont d'abord été étudiées à l'aide de considérations polynomiales par Warren et Eckberg [21].

Les liens qui relient la décomposition de Morse des systèmes et la décomposition de Kronecker des faisceaux de matrices sont bien connus (voir Morse [9] et Wonham [15] pour l'approche géométrique, Thorp [22] et Rosenbrock [1] pour l'approche des systèmes par la théorie de Kronecker, Jaffe et Karcianas [5] et Loiseau [18] pour la synthèse des deux approches). Utilisant ce lien, nous avons développé dans [20] une approche par les faisceaux de matrices du problème du placement par retour d'état statique des listes de Morse. Cette étude nous suggère que la condition (2) du Théorème 3.1 exprime les dimensions possibles des sous espaces presque de commandabilité inclus dans $(\mathcal{H} + A\mathcal{H} + \mathcal{B})$, alors que la condition (1) est la condition sur la dimension, ou plutôt sur la structure, d'un tel sous-espace pour qu'il soit le plus petit (C, A_F) invariant contenant un sous-espace de \mathcal{B} du type $\text{Im } BG$.

Annexe. Afin de montrer que l'inégalité (v) de la Proposition 6.2 est toujours vérifiée, nous allons utiliser le lemme suivant.

LEMME A.1. Soient $\{\alpha_i\}$ et $\{\Delta_i\}$ deux listes finies et non croissantes d'entiers positifs, et posons:

$$\sigma_i = \text{card } \{j | \alpha_j \geq i\} \quad \text{pour } i \geq 1,$$

$$\delta_i = \text{card } \{j | \Delta_j \geq i\} \quad \text{pour } i \geq 1.$$

Alors les affirmations suivantes sont équivalentes:

$$(i) \quad \sum_{j=1}^i \alpha_j \geq \sum_{j=1}^i \Delta_j \quad \text{pour } i \geq 1,$$

$$(ii) \quad \sum_{j=i}^{\infty} \sigma_j \geq \sum_{j=i}^{\infty} \delta_j \quad \text{pour } i \geq 1.$$

Démonstration du Lemme A.1. Montrons tout d'abord que (i) \rightarrow (ii), et supposons pour cela que (i) soit vérifiée.

Remarquons tout d'abord les égalités suivantes:

$$(A.1) \quad \sum_{j=i}^{\infty} \delta_j = \sum_{j=1}^{\delta_i} \Delta_j - (i-1)\delta_i,$$

$$(A.2) \quad \sum_{j=1}^{\infty} \sigma_j = \sum_{j=1}^{\sigma_i} \alpha_j - (i-1)\sigma_i.$$

La meilleure preuve de ce résultat est le schéma suivant:

Deux cas peuvent se présenter:

(1) Supposons que $\delta_i \leq \sigma_i$.

Nous avons par hypothèse

$$\sum_{j=1}^{\delta_i} \Delta_j \leq \sum_{j=1}^{\delta_i} \alpha_j,$$

et donc

$$\sum_{j=1}^{\delta_i} \Delta_j - (i-1)\delta_i \leq \sum_{j=1}^{\sigma_i} \alpha_j - (i-1)\sigma_i - \sum_{j=\delta_i+1}^{\sigma_i} \alpha_j + (i-1)\sigma_i - (i-1)\delta_i.$$

Mais puisque $\{\alpha_i\}$ est non croissante, nous avons

$$\sum_{j=\delta_i+1}^{\sigma_i} \alpha_j - (i-1)(\sigma_i - \delta_i) \geq (\sigma_i - \delta_i)\alpha_{\sigma_i} - (i-1)(\sigma_i - \delta_i),$$

et puisque

$$\alpha_{\sigma_i} = \text{card} \{j | \sigma_j \geq \sigma_i\} \geq i,$$

nous obtenons finalement

$$\sum_{j=\delta_i+1}^{\sigma_i} \alpha_j - (i-1)(\sigma_i - \delta_i) \geq 0,$$

et donc nous avons

$$\sum_{j=1}^{\delta_i} \Delta_j - (i-1)\delta_i \leq \sum_{j=1}^{\sigma_i} \alpha_j - (i-1)\sigma_i.$$

(2) Supposons que $\sigma_i \leq \delta_i$.

Nous avons par hypothèse

$$\sum_{j=1}^{\delta_i} \Delta_j \leq \sum_{j=1}^{\delta_i} \alpha_j,$$

ce qui s'écrit de la manière suivante:

$$\sum_{j=1}^{\delta_i} \Delta_j - (i-1)\delta_i \leq \sum_{j=1}^{\sigma_i} \alpha_j - (i-1)\sigma_i + \sum_{j=\sigma_i+1}^{\delta_i} \alpha_j - (i-1)\delta_i + (i-1)\sigma_i;$$

or

$$\sum_{j=\sigma_i+1}^{\delta_i} \alpha_j \leq (\delta_i - \sigma_i) \alpha_{\sigma_i+1} \leq (i-1)(\delta_i - \sigma_i).$$

Par conséquent, nous obtenons

$$\sum_{j=1}^{\delta_i} \Delta_j - (i-1)\delta_i \leq \sum_{j=1}^{\sigma_i} \alpha_j - (i-1)\sigma_i.$$

Ceci, compte tenu des relations (A.1) et (A.2), achève de prouver la partie (i) \rightarrow (ii) du Lemme A.1. La réciproque s'établit de manière identique grâce aux égalités suivantes:

$$(A.3) \quad \sum_{j=1}^i \Delta_j = \sum_{j=\Delta_i+1}^{\infty} \delta_j + i\Delta_i,$$

$$(A.4) \quad \sum_{j=1}^i \alpha_j = \sum_{j=\alpha_i+1}^{\infty} \sigma_j + i\alpha_i,$$

qui peuvent être visualisées par le schéma suivant:

Nous allons maintenant achever la démonstration de la partie (v) de la Proposition 6.2, et montrer que la relation suivante est vérifiée à chaque étape μ :

$$(A.5) \quad \sum_{j=i}^{\infty} \sigma_j^{\mu} \geq \sum_{j=i}^{\infty} \delta_j^{\mu} \quad \text{pour } i \geq 1$$

avec

$$\begin{aligned} \sigma_i^{\mu} &= \sigma_{\mu+i} && \text{pour } i \geq 1, \\ \delta_j^{\mu} &= \text{card} \{j | \Delta_j^{\mu} \geq i\} && \text{pour } i \geq 1. \end{aligned}$$

L'algorithme introduit par la proposition (7.2) est facilement décrit en terme des listes $\{\delta_i^{\mu}\}$:

$$\delta_i^{\mu} = \begin{cases} \delta_i^{\mu-1} & \text{si } \sigma_1^{\mu-1} \leq \delta_{i+1}^{\mu-1}, \\ \delta_i^{\mu-1} + \delta_{i+1}^{\mu-1} - \sigma_1^{\mu-1} & \text{si } \delta_{i+1}^{\mu-1} \leq \sigma_1^{\mu-1} \leq \delta_i^{\mu-1}, \\ \delta_{i+1}^{\mu-1} & \text{si } \delta_i^{\mu-1} \leq \sigma_1^{\mu-1}. \end{cases}$$

L'inégalité que nous voulons établir est vérifiée pour $\mu = 0$, comme l'indiquent la définition 6.1 et le Lemme A.1. Nous allons voir par récurrence qu'elle est vérifiée pour toutes les valeurs de μ .

Supposons donc que l'on ait pour une valeur fixée de μ

$$\sum_{j=i}^{\infty} \delta_j^{\mu-1} \leq \sum_{j=i}^{\infty} \sigma_j^{\mu-1} \quad \text{pour } i \geq 1.$$

Deux cas sont à envisager:

(1) Supposons que $\sigma_1^{\mu-1} \geq \delta_1^{\mu-1}$.

On obtient alors

$$\delta_i^{\mu} = \delta_{i+1}^{\mu-1} \quad \text{pour } i \geq 1.$$

Par conséquent nous pouvons écrire

$$\sum_{j=i}^{\infty} \delta_j^{\mu} = \sum_{j=i+1}^{\infty} \delta_j^{\mu-1} \leq \sum_{j=i+1}^{\infty} \sigma_j^{\mu-1} = \sum_{j=1}^{\infty} \sigma_j^{\mu}.$$

L'inégalité est alors satisfaite pour tout i .

(2) Supposons que $\delta_1^{\mu-1} \geq \sigma_1^{\mu-1}$.

Dans ce cas, il existe un entier l tel que

$$\delta_{l+1}^{\mu-1} \leq \sigma_1^{\mu-1} \leq \delta_l^{\mu-1}.$$

La liste $\{\delta_i^{\mu}\}$ s'écrit donc de la manière suivante:

$$\{\delta_i^{\mu}\} = \{\delta_1^{\mu-1}, \dots, \delta_l^{\mu-1}, \delta_{l+1}^{\mu-1} + \delta_l^{\mu-1} - \sigma_1^{\mu-1}, \delta_{l+2}^{\mu-1}, \dots\}.$$

Suivant la valeur de i , trois cas sont à considérer:

(i) Pour $i \geq l+1$, on a

$$\sum_{j=i}^{\infty} \delta_j^{\mu} = \sum_{j=i+1}^{\infty} \delta_j^{\mu-1} \leq \sum_{j=i+1}^{\infty} \sigma_j^{\mu-1} = \sum_{j=i}^{\infty} \sigma_j^{\mu};$$

(ii) Pour $i \leq l$, on a

$$\sum_{j=i}^{\infty} \delta_j^{\mu} = \sum_{j=i}^{\infty} \delta_j^{\mu-1} - \sigma_1^{\mu-1} \leq \sum_{j=i}^{\infty} \sigma_j^{\mu-1} - \sigma_1^{\mu-1};$$

or

$$(iii) \quad \sum_{j=i}^{\infty} \sigma_j^{\mu-1} - \sigma_1^{\mu-1} = \sum_{j=i+1}^{\infty} \sigma_j^{\mu-1} + \sigma_i^{\mu-1} - \sigma_1^{\mu-1} \leq \sum_{j=i+1}^{\infty} \sigma_j^{\mu-1} = \sum_{j=i}^{\infty} \sigma_j^{\mu}.$$

L'inégalité (A.18) est donc toujours vérifiée à l'étape μ si elle l'était à l'étape $\mu-1$. Cela prouve la partie (v) de la Proposition 6.2 compte tenu du fait que cette inégalité est vérifiée pour $\mu=0$.

OPTIMAL CONTROL OF STRONGLY MONOTONE VARIATIONAL INEQUALITIES*

SHUZHONG SHI†

Abstract. By using the penalty method and Ekeland's variational principle, this paper proves the optimality condition for a solution to a nonconvex optimal control problem, in which the system is governed by a strongly monotone variational inequality.

Key words. optimal control, strongly monotone variational inequalities, optimality condition, penalty method, Ekeland's variational principle

AMS(MOS) subject classifications. 49B99, 49A29

1. Introduction. The optimal control problem for a system, governed by an elliptic variational inequality, is proposed by J. L. Lions [13], [14], and discussed in Mignot [15], Barbu [2], [3] and Mignot and Puel [16]. The formulation of this problem is as follows:

Let V and H be two Hilbert spaces ("state spaces") such that

$$V \subset H = H^* \subset V^*$$

where V^* is the dual of V , H^* is the dual of H , identified with H , and injections are dense and continuous; let U be another Hilbert space ("control space"). Suppose that $A \in L(V, V^*)$ is coercive, i.e.,

$$Av \in V, \quad \langle Av, v \rangle \geq c \|v\|_V^2, \quad c > 0$$

where $\langle \cdot, \cdot \rangle$ is the duality pairing on $V^* \times V$ and identified with the inner product on H , $B \in L(U, V^*)$ is compact, $K \subset V$ and $U_{ad} \subset U$ are two closed convex subsets respectively in V and in U , $g: K \rightarrow \mathbf{R}_+$ and $h: U_{ad} \rightarrow \mathbf{R}_+$ are two functions, and $f \in V^*$ is given. Then, the optimal control problem for an elliptic variational inequality is to find existence conditions and optimality (necessary) conditions of solutions to the following minimization problem:

$$(1.1) \quad \begin{aligned} & \min \{g(y) + h(u)\}, \\ & y \in K, \quad u \in U_{ad}, \\ & \langle Ay, z - y \rangle \geq \langle Bu + f, z - y \rangle \quad \forall z \in K. \end{aligned}$$

In Mignot [15] and Mignot and Puel [16],

$$\begin{aligned} g(y) &= \frac{1}{2} \|y - z_d\|_H^2, \quad z_d \in H, \\ h(u) &= \frac{N}{2} \|u\|_U^2, \quad N > 0, \end{aligned}$$

and in Barbu [2], [3], $U_{ad} = U$, g is Lipschitz on each bounded subset of K and h is coercive, lower semicontinuous and convex (then, it can implicitly consider the case $U_{ad} \neq U$).

* Received by the editors March 24, 1986; accepted for publication (in revised form) April 16, 1987. This research was supported in part by the FCAR.

Under the above assumptions, the existence of a solution to (1.1) is easily proved. In fact, assume that $\{u_n\} \subset U_{\text{ad}}$ is a minimizing sequence. Then, from the coercivity of h , $\{u_n\}$ is bounded. Without loss of generality, we can assume that $\{u_n\}$ converges weakly in U , and thus, by the compactness of B and using Lions and Stampacchia's theorem, the solution sequence to this inequality in (1.1), $\{y_n\}$, corresponding to $\{u_n\}$, converges strongly in V . Finally, the weak limit u of $\{u_n\}$ and the strong limit y of $\{y_n\}$ are an optimal control and an optimal state, respectively.

The difficulty is to find optimality conditions for a solution to (1.1). For this one, Mignot [15] and Mignot and Puel [16] utilize the conical derivative and Barbu [2], [3] uses smooth approximation.

The aim of this paper is, by penalty method, to prove the optimality condition for a solution to an optimal control problem, in which the system is governed by a strongly monotone variational inequality. The general form of this problem will be as follows:

$$(1.2) \quad \begin{aligned} & \min J(y, u), \\ & y \in K, \quad u \in U_{\text{ad}}, \\ & \langle F(y, u), z - y \rangle \geq 0 \quad \forall z \in K \end{aligned}$$

where

- (1.3) (1) K is a closed convex subset of a Banach space V , U_{ad} is a closed convex subset of another reflexive Banach space U ;
 (2) $J: K \times U_{\text{ad}} \rightarrow \mathbf{R}U\{+\infty\}$ is a lower semicontinuous function for the norm topology of K and the weak topology of U_{ad} , and when

$$\|u\|_U \rightarrow +\infty, \quad \inf_{y \in K} J(y, u) \rightarrow +\infty;$$

- (3) $F: K \times U_{\text{ad}} \rightarrow V^*$, dual of V , is such that for all $R > 0$, there exists a homeomorphism $\varphi_R: \mathbf{R}_+ \rightarrow \mathbf{R}_+$ such that

$$\begin{aligned} & \forall u \in B_R^{U_{\text{ad}}} := \{u \in U_{\text{ad}} \mid \|u\|_U < R\} \quad \forall y_1, y_2 \in K, \\ & \langle F(y_1, u) - F(y_2, u), y_1 - y_2 \rangle_{V^*, V} \geq \varphi_R(\|y_1 - y_2\|_V) \|y_1 - y_2\|_V; \end{aligned}$$

- (4) for any $\bar{u} \in U_{\text{ad}}$, if $y_{\bar{u}} \in K$ satisfies

$$(1.4) \quad \langle F(y_{\bar{u}}, \bar{u}), z - y_{\bar{u}} \rangle_{V^*, V} \geq 0 \quad \forall z \in K,$$

then $u \mapsto F(y_{\bar{u}}, u)$ is weakly continuous at $u = \bar{u}$, i.e., if $u_n \rightarrow \bar{u}$ in U weakly, then $F(y_{\bar{u}}, u_n) \rightarrow F(y_{\bar{u}}, \bar{u})$ in V^* strongly.

It is also not difficult to show the existence of a solution to (1.2). In fact, we can prove the following theorem.

THEOREM 1.1. *Assume that (1.3) (1)–(4) hold. Then the problem (1.2) has a solution $(\bar{y}, \bar{u}) \in K \times U_{\text{ad}}$.*

Proof. By Browder's [5] and Hartman and Stampacchia's [10] theorem and (1.3)(3), for any $u \in U_{\text{ad}}$, there exists a unique $y_u \in K$ such that (1.4) holds. Then, suppose that $\{u_n\} \subset U_{\text{ad}}$ satisfies

$$(1.5) \quad \lim_{n \rightarrow \infty} J(y_n, u_n) = \inf_{u \in U_{\text{ad}}} J(y_u, u)$$

where

$$y_n := y_{u_n}.$$

From (1.3)(2), $\{u_n\}$ is bounded, i.e., for a sufficiently large $R > 0$,

$$(1.6) \quad \|u_n\|_U < R.$$

Since U is reflexive, by extracting a subsequence, we can suppose that

$$(1.7) \quad u_n \rightarrow \bar{u} \quad \text{in } U_{\text{ad}} \text{ weakly.}$$

Set $\bar{y} := y_{\bar{u}}$. Then, from (1.4) we have

$$(1.8) \quad \langle F(y_n, u_n), z - y_n \rangle_{V^*, V} \geq 0 \quad \forall z \in K, \quad n = 1, 2, \dots$$

$$(1.9) \quad \langle F(\bar{y}, \bar{u}), z - \bar{y} \rangle_{V^*, V} \geq 0 \quad \forall z \in K.$$

Taking $z = \bar{y}$ in (1.8) and $z = y_n$ in (1.9), and adding these two inequalities, we obtain that

$$(1.10) \quad \langle F(y_n, u_n) - F(\bar{y}, \bar{u}), y_n - \bar{y} \rangle_{V^*, V} \leq 0.$$

But by (1.3)(3) and (1.6), we have

$$(1.11) \quad \langle F(y_n, u_n) - F(\bar{y}, u_n), y_n - \bar{y} \rangle_{V^*, V} \geq \varphi_R(\|\bar{y} - y_n\|_V) \|\bar{y} - y_n\|_V,$$

and on the other hand, by (1.3)(4) and (1.7), we have

$$(1.12) \quad F(\bar{y}, u_n) \rightarrow F(\bar{y}, \bar{u}) \quad \text{in } V^* \text{ strongly.}$$

From (1.10)–(1.12), it follows that $\varphi_R(\|\bar{y} - y_n\|_V) \rightarrow 0$, which is equivalent to

$$(1.13) \quad y_n \rightarrow \bar{y} \quad \text{in } K \text{ strongly.}$$

By (1.3)(2), (1.5), (1.7) and (1.13), it is easy to see that (\bar{y}, \bar{u}) is a solution to (1.2). \square

We can see in Theorem 1.1 that sufficient conditions for the existence of a solution to (1.2) are very mild. We do not even use the reflexivity of V . However, to obtain the optimality conditions of solution to (1.2), we will have to assume some regularity on J and on F . Hereafter, we show that under some regularity hypotheses, the following optimality conditions for a solution to (1.2) hold:

$$(1.14) \quad \begin{aligned} &\langle F'(\bar{y}, \bar{u}), \bar{p} \rangle_{V^*, V} = 0, \\ &F'_y(\bar{y}, \bar{u})^* \bar{p} \in N_K(\bar{y}) + \partial_y J(\bar{y}, \bar{u}), \\ &F'_u(\bar{y}, \bar{u})^* \bar{p} \in N_{U_{\text{ad}}}(\bar{u}) + \partial_u J(\bar{y}, \bar{u}) \end{aligned}$$

where $\bar{p} \in V$ (“costate”), $N_K(\bar{y})$ is the normal cone to K at \bar{y} , $N_{U_{\text{ad}}}(\bar{u})$ is the normal cone to U_{ad} at \bar{u} , $*$ means the adjoint and $\partial_y J$ and $\partial_u J$ refer to the generalized gradient or the subdifferential of J in respect to y and to u . Certainly, our main results will include the results on (1.1) as a special case.

In § 2, the preliminary material is provided. Section 3 is contributed to the “global Palais–Smale condition,” which will be applied to our main results. The main theorems concerning (1.13) are given in § 4 and some explanatory examples are cited at the end.

2. Preliminaries. We shall use the following three theorems as tools.

BERGE’S MAXIMUM THEOREM 2.1 [4], [1, p. 120]. *Let X and Y be two Hausdorff spaces, $f: X \times Y \rightarrow \mathbf{R}$ continuous and $W: Y \rightrightarrows X$ a continuous set-valued map with non-empty compact values. Then,*

- (1) $\varphi: Y \rightarrow \mathbf{R}$, defined by $\varphi(y) := \max_{x \in W(y)} f(x, y)$, is continuous.
- (2) $\Phi: Y \rightrightarrows X$, defined by $\Phi(y) := \{x \in X \mid f(x, y) = \varphi(y)\}$ is upper semicontinuous.

Remark. Recall that a set-valued map $W: Y \rightrightarrows X$ from a Hausdorff space Y to another Hausdorff space X is called upper (respectively, lower) semicontinuous, if for all closed (respectively, open) subset A of X , $W^{-1}(A) := \{y \in Y \mid W(y) \cap A \neq \emptyset\}$ is closed (respectively, open). If W is both upper and lower semicontinuous, then it is called continuous.

Ekeland's Variational Principle 2.2 [9], [1, p. 255]. Let (E, d) be a complete metric space and $G: E \rightarrow \mathbf{R}_+ \cup \{+\infty\}$ lower semicontinuous, $\neq +\infty$. If for a given $\varepsilon > 0$, $x_0 \in E$ satisfies

$$G(x_0) \leq \inf_E G + \varepsilon,$$

then there exists $x_\varepsilon \in E$ such that

$$G(x_\varepsilon) \leq G(x_0), \quad d(x_0, x_\varepsilon) \leq 1,$$

for all $x \neq x_\varepsilon$, $G(x) > G(x_\varepsilon) - \varepsilon d(x, x_\varepsilon)$.

Lopsided Minimax Theorem 2.3 [1, p. 319]. Let E and F be two closed convex subsets of Hausdorff topological vector spaces and $f: E \times F \rightarrow \mathbf{R}$. If

- (1) for all $y \in F$, $x \mapsto f(x, y)$ is convex;
- (2) for all $x \in E$, $y \mapsto f(x, y)$ is upper semicontinuous and concave;
- (3) F is compact;

then, there exists $\bar{y} \in F$ such that

$$\inf_{x \in E} f(x, \bar{y}) = \inf_{x \in E} \max_{y \in F} f(x, y).$$

Adopting a notation from [6], for a closed convex subset $K \subset V$ and $y^* \in V^*$, we define

$$(2.1) \quad \|y^*\|_y^K := \sup_{p \in (K - y) \cap B_V} \langle y^*, p \rangle_{V^*, V},$$

where B_V is the closed unit ball of V . Then, the variational inequality (1.4) can be rewritten as

$$(2.2) \quad \|-F(y_{\bar{u}}, \bar{u})\|_{y_{\bar{u}}}^K = 0,$$

and the minimization problem (1.2) with an "inequality constraint" can be represented as the following minimization problem with an "equality constraint":

$$(2.2)' \quad \begin{aligned} & \min J(y, u), \\ & y \in K, \quad u \in U_{\text{ad}}, \\ & \|-F(y, u)\|_y^K = 0. \end{aligned}$$

Therefore, it can be approximated by

$$(2.3) \quad \begin{aligned} & \min \{J(y, u) + N_n \|-F(y, u)\|_y^K\}, \\ & y \in K, \quad u \in U_{\text{ad}} \end{aligned}$$

where $N_n > 0$ is a "penalty factor" and $N_n \rightarrow +\infty$. By using Berge's Maximum Theorem 2.1, we have the following.

PROPOSITION 2.4. Let V be a reflexive Banach space with its dual V^* , K a closed convex subset of V , U_{ad} any Hausdorff topological space and $F: K \times U_{\text{ad}} \rightarrow V^*$ a continuous map. Then

- (1) $\varphi: K \times U_{\text{ad}} \rightarrow \mathbf{R}$, defined by

$$\varphi(y, u) := \|-F(y, u)\|_y^K$$

is continuous;

- (2) $M: K \times U_{\text{ad}} \rightrightarrows B_V$, defined by

$$M(y, u) := \{p \in (K - y) \cap B_V \mid \langle -F(y, u), p \rangle_{V^*, V} = \|-F(y, u)\|_y^K\}$$

is upper semicontinuous for the norm topology of K and the weak topology of B_V .

Proof. Set $X = V$, $Y = K \times U_{\text{ad}}$, $f: V \times (K \times U_{\text{ad}}) \rightarrow \mathbf{R}$, defined by

$$f(p; y, u) := \langle -F(y, u), p \rangle_{V^*, V}$$

and $W: K \times U_{\text{ad}} \rightrightarrows B_V$, defined by

$$W(y, u) := (K - y) \cap B_V.$$

Then, for the norm topology of K and the weak topology of B_V , f is continuous and W is continuous with nonempty (weakly) compact values. So, the proposition is a consequence of Berge's Maximum Theorem 2.1. \square

Our idea is as follows: by using Ekeland's Variational Principle 2.2 to the problems (2.3), we shall obtain an almost minimizer sequence $\{(y_n, u_n)\}$ to the problem (1.2). Then, by using Lopsided Minimax Theorem 2.3, we shall find an "almost costate (or Lagrange multiplier)" sequence $\{p_n\}$. Finally, we shall extract a subsequence of $\{(y_n, u_n; p_n)\}$, which will converge to $(\bar{y}, \bar{u}, \bar{p})$, satisfying (1.14). This idea has been applied in Chang and Shi [7] to obtain a local minimax theorem.

A word about the normal cone. Let K be a convex set of a reflexive Banach space V and $y \in K$. Then, the closed convex cone of V^*

$$(2.4) \quad N_K(y) := \{y^* \in V^* \mid \langle y^*, z - y \rangle_{V^*, V} \leq 0 \ \forall z \in K\}$$

is called the normal cone to K at y , and the closed convex cone of V

$$(2.5) \quad \begin{aligned} T_K(y) &:= \{p \in V \mid \langle y^*, p \rangle_{V^*, V} \leq 0 \ \forall y^* \in N_K(y)\} \\ &= \text{cl} \left(\bigcup_{\lambda > 0} \lambda(K - y) \right) \end{aligned}$$

is called the tangent cone to K at y . $N_K(y)$ may be considered as the subdifferential at $y \in K$ of the indicator function

$$(2.6) \quad \delta_K(y) := \begin{cases} 0 & \text{if } y \in K, \\ +\infty & \text{otherwise,} \end{cases}$$

which is lower semicontinuous and convex, provided K is closed and convex. Hence, the last two inclusions of (1.14) may be rewritten as

$$(2.7) \quad \begin{aligned} F'_y(\bar{y}, \bar{u})^* \bar{p} &\in \partial \delta_K(\bar{y}) + \partial_y J(\bar{y}, \bar{u}), \\ F'_u(\bar{y}, \bar{u})^* \bar{p} &\in \partial \delta_{U_{\text{ad}}}(\bar{u}) + \partial_u J(\bar{y}, \bar{u}). \end{aligned}$$

If we set

$$(2.8) \quad \tilde{J}(y, u) := J(y, u) + \delta_K(\bar{y}) + \delta_{U_{\text{ad}}}(\bar{u}),$$

we shall have a more symmetric form of (2.7) as

$$(2.9) \quad \begin{aligned} F'_y(\bar{y}, \bar{u})^* \bar{p} &\in \partial_y \tilde{J}(\bar{y}, \bar{u}), \\ F'_u(\bar{y}, \bar{u})^* \bar{p} &\in \partial_u \tilde{J}(\bar{y}, \bar{u}) \end{aligned}$$

under some hypotheses.

On the other hand, variational inequality (1.4) may be rewritten as either (2.2), or, by (2.4),

$$-F(y_u, u) \in N_K(y_u).$$

In the same way, the last two inclusions of (1.14) or (2.7) may be rewritten as two (quasi) variational inequalities. For instance, if $u \mapsto J(y, u)$ is convex, then

$$F'_u(\bar{y}, \bar{u})^* \bar{p} \in N_{U_{\text{ad}}}(\bar{u}) + \partial_u J(\bar{y}, \bar{u})$$

is equivalent to

$$J'_u(\bar{y}, \bar{u}; v - \bar{u}) - \langle F'_u(\bar{y}, \bar{u})^* \bar{p}, v - \bar{u} \rangle_{U^*, U} \geq 0 \quad \forall v \in U_{\text{ad}}$$

where

$$J'_u(\bar{y}, \bar{u}; v - \bar{u}) := \lim_{t \rightarrow 0^+} \frac{J(\bar{y}, \bar{u} + t(v - \bar{u})) - J(\bar{y}, \bar{u})}{t}$$

and even equivalent to

$$J(\bar{y}, v) - J(\bar{y}, \bar{u}) - \langle F'_u(\bar{y}, \bar{u})^* \bar{p}, v - \bar{u} \rangle_{U^*, U} \geq 0 \quad \forall v \in U_{\text{ad}}.$$

3. Global Palais–Smale condition. To obtain the optimality condition (1.14), we want some compactness condition of Palais–Smale type. The Palais–Smale condition for a C^1 -function on a Banach space has been generalized to a C^1 -function on a closed convex subset of Banach space by Chang and Eells [6] as follows:

Let Q be a closed convex subset of Banach space U and $f \in C^1(Q; \mathbf{R})$, i.e., a continuously differentiable function on an open neighbourhood of Q . We say that f satisfies the Palais–Smale (P.S.) condition if

- (3.1) Any sequence $\{u_n\} \subset Q$, along which $\{f(u_n)\}$ is bounded and $\| -f'(u_n) \|_{u_n}^Q \rightarrow 0$, possesses a convergent subsequence.

This definition is readily to be generalized to a lower semicontinuous function $f: Q \rightarrow \mathbf{R}U\{+\infty\}$ as follows: we say that f satisfies (P.S.) condition, if

- (3.2) Any sequence $\{u_n\} \subset Q$, along which $\{f(u_n)\}$ is bounded and

$$\| -\underline{f}'(u_n, \cdot) \|_{u_n}^Q := \sup_{w \in (Q - u_n) \cap B_U} \{ -\underline{f}'(u_n; w) \} \rightarrow 0,$$

possesses a convergent subsequence

where

$$(3.3) \quad \underline{f}'(u; w) := \liminf_{t \rightarrow 0^+} \frac{f(u + tw) - f(u)}{t}$$

is Dini lower derivative. A lower semicontinuous function $f: Q \rightarrow \mathbf{R}U\{+\infty\}$, which satisfies (P.S.) condition (3.2), has many interesting properties. For instance, by using Ekeland's Variational Principle 2.2, it is easy to show the following.

PROPOSITION 3.1. *Let $f: Q \rightarrow \mathbf{R}_+ U\{+\infty\}$ be a lower semicontinuous function satisfying the (P.S.) condition. Then f achieves its minimum on Q .*

The (P.S.) condition (3.1) or (3.2) is used to characterize the behaviour near a “critical point,” which means a point $u \in Q$ such that $\| -f'(u) \|_u^Q$ or $\| -\underline{f}'(u; \cdot) \|_u^Q = 0$. If we want to characterize a similar behaviour near a “noncritical point,” it is natural to propose the following definition.

DEFINITION 3.2. Let $f: Q \rightarrow \mathbf{R}U\{+\infty\}$ be a lower semicontinuous function and $u^* \in U^*$. We say that f satisfies u^* –(P.S.) if

- (3.4) Any $\{u_n\} \subset Q$, along which $\{f(u_n)\}$ is bounded and $\| -\underline{f}'(u_n, \cdot) + \langle u^*, \cdot \rangle_{U^*, U} \|_{u_n}^Q \rightarrow 0$, possesses a convergent subsequence.

If for all $u^* \in U^*$, f satisfies u^* –(P.S.) condition, then we say that f satisfies the *global (P.S.) condition*.

We shall need later that $u \mapsto J(y, u)$ satisfies the global (P.S.) condition. Such functions form a very large class. For instance, if U is reflexive and locally uniformly convex, a function, satisfying the global (P.S.) condition, may be of the following general form:

$$(3.5) \quad J(u) = J_1(u) + J_2(u) + J_3(u)$$

where

- (1) $J_1 \in C^1(Q, \mathbf{R})$ has a compact derivative $J'_1: Q \rightarrow U^*$;
- (2) $J_2: Q \rightarrow \mathbf{R}U\{+\infty\}$ is any lower semicontinuous convex function;
- (3) $J_3(u) := \Phi(\|u - u_0\|_U)$ with $u_0 \in U$ and $\Phi: \mathbf{R}_+ \rightarrow \mathbf{R}_+$, a convex homeomorphism.

We shall show some more general conclusions.

PROPOSITION 3.3. *Assume that $J: Q \rightarrow \mathbf{R}U\{+\infty\}$ satisfies that*

- $$(3.6) \quad \begin{aligned} (1) & \quad J \text{ is coercive, i.e., } J(u) \rightarrow +\infty \text{ as } \|u\|_U \rightarrow +\infty; \\ (2) & \quad J = J_0 + J_1, \text{ where } J_0 \text{ satisfies the global (P.S.) condition and } J_1 \in C^1(Q; \mathbf{R}) \\ & \quad \text{has a compact derivative } J'_1: Q \rightarrow U^*. \end{aligned}$$

Then J also satisfies the global (P.S.) condition.

Proof. Suppose that for $u^* \in U^*$, a sequence $\{u_n\} \subset Q$ satisfies that

- $$(3.7) \quad \begin{aligned} (1) & \quad \{J(u_n)\} \text{ is bounded;} \\ (2) & \quad \|\underline{J}'(u_n; \cdot) + \langle u^*, \cdot \rangle_{U^*, U}\|_{u_n}^Q = \|\underline{J}'_0(u_n; \cdot) + \langle -J'_1(u_n) + u^*, \cdot \rangle_{U^*, U}\|_{u_n}^Q \rightarrow 0. \end{aligned}$$

Then, from (3.6)(1) and (3.7)(1), $\{u_n\}$ is bounded, i.e.,

$$(3.8) \quad \|u_n\|_U \leq C_1$$

where $C_1 > 0$ is constant. Since J'_1 is compact, $u \mapsto \|J'_1(u)\|_{U^*}$ is bounded on $C_1 B_U$, and thus,

$$(3.9) \quad |J_1(u_n)| \leq |J_1(u_0)| + \sup_{v \in C_1 B_U} \|J'_1(v)\|_{U^*} \cdot \|u_n - u_0\|_U \leq C_2$$

where C_2 is another constant. Hence, from (3.7)(1) and (3.9), we have that

$$(3.10) \quad \{J_0(u_n)\} \text{ is bounded.}$$

On the other hand, also by the compactness of J'_1 , there exists a subsequence

$$\{u_{n_k}\} \subset \{u_n\}$$

such that

$$(3.11) \quad J'_1(u_{n_k}) - u^* \rightarrow \hat{u}^* \quad \text{in } U^* \text{ strongly,}$$

and joining up with (3.7)(2), it follows that

$$(3.12) \quad \|\underline{J}'_0(u_{n_k}; \cdot) + \langle \hat{u}^*, \cdot \rangle_{U^*, U}\|_{u_{n_k}}^Q \rightarrow 0.$$

Since J_0 satisfies the global (P.S.) condition, from (3.10) and (3.12), we deduce that $\{u_{n_k}\}$ has a convergent subsequence. \square

We now show a convex function class, in which each function satisfies the global (P.S.) condition.

DEFINITION 3.4. Let U be a reflexive Banach space, $Q \subset U$ closed convex and $J: Q \rightarrow \mathbf{R}U\{+\infty\}$. We say that J belongs to the (H)-class, if J is lower semicontinuous, convex and satisfies the following (H) condition:

(H) Any $\{u_n\} \subset D(J) := \{u \in Q | J(u) < +\infty\}$, along which $u_n \rightarrow u$ in Q weakly and $\underline{J}'_0(u_n; u - u_n) \rightarrow 0$, possesses a strongly convergent subsequence.

We prove that every coercive (H)-class function satisfies the global (P.S.) condition. In fact, we have a more general proposition as follows.

PROPOSITION 3.5. Let U be a reflexive Banach space, $Q \subset U$ closed convex and $J: Q \rightarrow \mathbf{R}U\{+\infty\}$. If

- (3.13) (1) J is coercive;
 (2) $J = J_0 + J_2$, where $J_0: Q \rightarrow \mathbf{R}U\{+\infty\}$ belongs to (H)-class and $J_2: Q \rightarrow \mathbf{R}U\{+\infty\}$ is any lower semicontinuous convex function,

then, J satisfies the global (P.S.) condition.

Proof. Suppose that for $u^* \in U^*$, a sequence $\{u_n\} \subset Q$ satisfies (3.7). Then, $\{u_n\} \subset D(J_0) \cap D(J_2)$ is bounded, and since U is reflexive, by extracting a subsequence, we can assume that

$$(3.14) \quad u_n \rightarrow u \quad \text{in } Q \text{ weakly.}$$

If $\{u_n\}$ does not possess any strongly convergent subsequence, then, without loss of generality, we can also assume that

$$(3.15) \quad \|u_n - u\| \geq 1/d > 0, \quad n = 1, 2, \dots$$

Therefore,

$$\begin{aligned} l_n &:= -\| -\underline{J}'(u_n; \cdot) + \langle u^*, \cdot \rangle_{U^*, U} \|_{u_n}^Q \\ &= \inf_{v \in Q, \|v - u_n\|_U \leq 1} \{ \underline{J}'(u_n; v - u_n) - \langle u^*, v - u_n \rangle_{U^*, U} \} \\ (3.16) \quad &\leq \frac{1}{\|u_n - u\|_U} \{ \underline{J}'(u_n; u - u_n) - \langle u^*, u - u_n \rangle_{U^*, U} \} \\ &\leq d \{ \underline{J}'(u_n; u - u_n) - \langle u^*, u - u_n \rangle_{U^*, U} \}. \end{aligned}$$

Since $J = J_0 + J_2$ and J_0 and J_2 are convex, we have

$$\begin{aligned} \underline{J}'(u_n; u - u_n) &= J'_0(u_n; u - u_n) + J'_2(u_n; u - u_n) \\ (3.17) \quad &= \inf_{t>0} \frac{J_0(u_n + t(u - u_n)) - J_0(u_n)}{t} + \inf_{t>0} \frac{J_2(u_n + t(u - u_n)) - J_2(u_n)}{t}. \end{aligned}$$

So, from (3.16) and (3.17), we obtain that

$$\begin{aligned} 1/dl_n + \langle u^*, u - u_n \rangle_{U^*, U} + J_2(u_n) - J_2(u) &\leq J'_0(u_n; u - u_n) \\ &\leq J_0(u) - J_0(u_n) \end{aligned}$$

and it follows that

$$(3.18) \quad J'_0(u_n; u - u_n) \rightarrow 0,$$

because from (3.7)(2) and (3.16), $1/dl_n \rightarrow 0$, from (3.14), $\langle u^*, u - u_n \rangle_{U^*, U} \rightarrow 0$ and J_0 and J_2 are lower semicontinuous convex, hence, weakly lower semicontinuous. By the (H) condition and (3.14), (3.18), we obtain that $\{u_n\}$ has a strongly convergent subsequence. This contradiction completes the proof. \square

The following proposition shows two sufficient conditions for (H), and then, with the coercivity, also for the global (P.S.) condition.

PROPOSITION 3.6. *If $J: Q \rightarrow \mathbf{R}U\{+\infty\}$ is lower semicontinuous convex and in one of the following two cases:*

- (3.19) (1) $J(u_1) - J(u_2) - J'(u_2; u_1 - u_2) \geq \Psi(\|u_1 - u_2\|_U)$ for all $u_1, u_2 \in D(J)$, where $\Psi \in C(\mathbf{R}_+; \mathbf{R}_+)$ is a homeomorphism;
 (2) $J(u) = \Phi(\|u - u_0\|)$ for all $u \in D(J)$, where $u_0 \in U$ and $\Phi \in C(\mathbf{R}_+; \mathbf{R}_+)$ is a convex homeomorphism, provided U is locally uniformly convex;

then J belongs to the (H)-class.

Proof. (1) If $\{u_n\} \subset D(J)$ weakly converges to u and $J'(u_n; u - u_n) \rightarrow 0$, then we have that

$$J(u) - J(u_n) - J'(u_n; u - u_n) \geq \Psi(\|u_n - u\|_U) \geq 0.$$

Since J is weakly lower semicontinuous, it follows that

$$\Psi(\|u_n - u\|_U) \rightarrow 0,$$

which is equivalent to $\|u_n - u\|_U \rightarrow 0$.

(2) If (3.19)(2) holds, then it is easy to see that for all $u \in D(J)$, the subdifferential of J at u

$$\partial J(u) := \{u^* \in U^* \mid J(u') - J(u) \geq \langle u^*, u' - u \rangle_{U^*, U} \quad \forall u' \in D(J)\} \neq \emptyset.$$

Hence, for any $u^* \in \partial J(u)$, we have

$$\langle u^*, u_n - u \rangle_{U^*, U} \leq J(u_n) - J(u) \leq J'(u_n; u - u_n),$$

and thus, when $\{u_n\} \subset D(J)$ weakly converges to u and $J'(u_n; u - u_n) \rightarrow 0$, it follows that

$$J(u_n) - J(u) := \Phi(\|u_n - u_0\|_U) - \Phi(\|u - u_0\|_U) \rightarrow 0,$$

which is equivalent to

$$(3.20) \quad \|u_n - u_0\|_U \rightarrow \|u - u_0\|_U.$$

Since U is locally uniformly convex, (3.20) implies that $\{u_n\}$ strongly converges to u . \square

COROLLARY. *If U is reflexive and $A \in L(U, U^*)$ is coercive, then*

$$J(u) := \langle A(u - u_0), u - u_0 \rangle_{U^*, U}$$

with any $u_0 \in U$ satisfies the global (P.S.) condition for any closed convex subset $Q \subset U$.

Proof. Without loss of generality, we assume $u_0 = 0$. For this J , we have that

$$\begin{aligned} J(u_1) - J(u_2) - J'(u_2; u_1 - u_2) &= \langle Au_1, u_1 \rangle_{U^*, U} - \langle Au_2, u_2 \rangle_{U^*, U} \\ &\quad - \langle (A + A^*)u_2, u_1 - u_2 \rangle_{U^*, U} \\ &= \langle A(u_1 - u_2), (u_1 - u_2) \rangle_{U^*, U} \geq c \|u_1 - u_2\|_U^2. \end{aligned} \quad \square$$

We end here the study of the global (P.S.) condition.

4. Main theorems. In order to simplify our discussion, we first assume that

$$(4.1) \quad J(y, u) = g(y) + h(u), \quad F(y, u) = F(y) + E(u)$$

and then, we shall generalize the result obtained from (4.1) to the general case.

THEOREM 4.1. Assume that

- (4.2) (1) V and U are two reflexive Banach spaces with their duals V^* and U^* , respectively; $K \subset V$ and $U_{\text{ad}} \subset U$ are two closed convex subsets, respectively, in V and in U ;
 (2) $g: K \rightarrow \mathbf{R}_+$ is locally Lipschitz;

$$h = h_1 + h_2: U_{\text{ad}} \rightarrow \mathbf{R}_+ U\{+\infty\} \quad \text{where } h_1 \in C^1(U_{\text{ad}}; \mathbf{R})$$

and $h_2: U_{\text{ad}} \rightarrow \mathbf{R}_+ U\{+\infty\}$ is lower semicontinuous convex; in addition, h is coercive and satisfying the global (P.S.) condition;

- (3) $F \in C^1(K; V^*)$, i.e., a continuously differentiable operator from an open neighbourhood of K to V^* , satisfies for all $y_1, y_2 \in K$, $\langle F(y_1) - F(y_2), y_1 - y_2 \rangle_{V^*, V} \geq c \|y_1 - y_2\|_V^2$, $c > 0$; $E \in C^1(U_{\text{ad}}; V^*)$ has a weakly continuous derivative: $E': U_{\text{ad}} \rightarrow L(U, V^*)$ (i.e., E' is continuous for the weak topology of U_{ad}) and for all $u \in U_{\text{ad}}$; $E'(u) \in L(U, V^*)$ is compact (completely continuous).

Then, there exist $(\bar{y}, \bar{u}) \in K \times U_{\text{ad}}$, which satisfies

$$(4.3) \quad \langle F(\bar{y}) + E(\bar{u}), z - \bar{y} \rangle_{V^*, V} \geq 0 \quad \forall z \in K$$

and is a solution to the following problem:

$$(4.4) \quad \begin{aligned} & \min \{g(y) + h(u)\}, \\ & y \in K, \quad u \in U_{\text{ad}}, \\ & \langle F(y) + E(u), z - y \rangle_{V^*, V} \geq 0 \quad \forall z \in K \end{aligned}$$

and $\bar{p} \in V$ such that

$$(4.5) \quad \begin{aligned} & \langle F(\bar{y}) + E(\bar{u}), \bar{p} \rangle_{V^*, V} = 0, \\ & F'(\bar{y})^* \bar{p} \in N_K(\bar{y}) + \partial g(\bar{y}), \\ & E'(\bar{u})^* \bar{p} \in N_{U_{\text{ad}}}(\bar{u}) + \partial h(\bar{u}) \end{aligned}$$

where ∂ refers to the generalized gradient in a broad sense, especially, $\partial h(u) := h'_1(u) + \partial h_2(u)$.

Proof. Suppose that $N_n > 0$ and $G_n: K \times U_{\text{ad}} \rightarrow \mathbf{R} U\{+\infty\}$ is defined by

$$(4.6) \quad G_n(y, u) := g(y) + h(u) + N_n \| -F(y) - E(u) \|_y^K.$$

From Proposition 2.4, G_n is lower semicontinuous. By using Ekeland's Variational Principle 2.2, for any $\varepsilon_n > 0$, there exists $(y_n, u_n) \in K \times U_{\text{ad}}$ such that

$$(4.7) \quad 0 \leq \inf_{K \times U_{\text{ad}}} G_n \leq G_n(y_n, u_n) \leq \inf_{K \times U_{\text{ad}}} G_n + \varepsilon_n,$$

$$(4.8) \quad \forall (y, u) \neq (y_n, u_n) \quad G_n(y, u) > G_n(y_n, u_n) - \varepsilon_n (\|y - y_n\|_V^2 + \|u - u_n\|_U^2)^{1/2}.$$

Set

$$(4.9) \quad \begin{aligned} M_n(y, u) &:= N_n M(y, u) \\ &= \{p_n \in N_n[(K - y) \cap B_V] \mid \langle -F(y) - E(u), p_n \rangle_{V^*, V} \\ &\quad = N_n \| -F(y) - E(u) \|_y^K \}, \end{aligned}$$

which is an upper semicontinuous set-valued map for the norm topology of $K \times U_{\text{ad}}$ and the weak topology of $N_n B_V$, provided by Proposition 2.4. Obviously, for any $(y, u) \in K \times U_{\text{ad}}$, $M_n(y, u)$ is nonempty, weakly compact and convex.

Taking any $s \in K - y_n$, any $w \in U_{\text{ad}} - u_n$ and any sequence $t_k \rightarrow 0^+$, from (4.8), we have

$$G_n(y_n + t_k s, u_n + t_k w) > G_n(y_n, u_n) - \varepsilon_n t_k (\|s\|_V^2 + \|w\|_U^2)^{1/2},$$

and then taking any

$$p_{nk}^{sw} \in M_n(y_n + t_k s, u_n + t_k w),$$

it follows that

$$(4.10) \quad \begin{aligned} & g(y_n + t_k s) + h(u_n + t_k w) - \langle F(y_n + t_k s) + E(u_n + t_k w), p_{nk}^{sw} \rangle_{V^*, V} \\ & > g(y_n) + h(u_n) - \langle F(y_n) + E(u_n), p_{nk}^{sw} \rangle_{V^*, V} - \varepsilon_n t_k (\|s\|_V^2 + \|w\|_U^2)^{1/2}. \end{aligned}$$

We apply the mean value theorem to the function

$$\varphi(t) := \langle F(y_n + ts) + E(u_n + tw), p_{nk}^{sw} \rangle_{V^*, V},$$

and then, there exists a $\theta_k \in]0, 1[$ such that

$$(4.11) \quad \begin{aligned} & \langle F(y_n + t_k s) + E(u_n + t_k w) - F(y_n) - E(u_n), p_{nk}^{sw} \rangle_{V^*, V} \\ & = \langle F'(y_n + \theta_k t_k s) + E'(u_n + \theta_k t_k w) w, p_{nk}^{sw} \rangle_{V^*, V} t_k. \end{aligned}$$

Hence, from (4.10) and (4.11), we obtain

$$(4.12) \quad \begin{aligned} & \frac{g(y_n + t_k s) - g(y_n)}{t_k} + \frac{h(u_n + t_k w) - h(u_n)}{t_k} - \langle F'(y_n + \theta_k t_k s) \\ & + E'(u_n + \theta_k t_k w) w, p_{nk}^{sw} \rangle_{V^*, V} > -\varepsilon_n (\|s\|_V^2 + \|w\|_U^2)^{1/2}. \end{aligned}$$

Since $N_n B_V$ is weakly compact, by extracting a subsequence, we can assume that

$$(4.13) \quad p_{nk}^{sw} \rightarrow p_n^{sw} \quad \text{in } N_n \bar{B}_V \text{ weakly, as } k \rightarrow \infty,$$

and since M_n is upper semicontinuous for the weak topology of $N_n \bar{B}_V$, it follows that

$$(4.14) \quad p_n^{sw} \in M_n(y_n, u_n).$$

Therefore, letting $k \rightarrow \infty$ in (4.12), we obtain

$$(4.15) \quad g^0(y_n; s) + h'(u_n; w) - \langle F'(y_n) s + E'(u_n) w, p_n^{sw} \rangle_{V^*, V} \geq -\varepsilon_n (\|s\|_V^2 + \|w\|_U^2)^{1/2}$$

where

$$(4.16) \quad g^0(y_n; s) := \limsup_{\substack{t \rightarrow 0^+ \\ v \rightarrow y_n}} \frac{g(v + ts) - g(v)}{t}$$

is Clarke directional derivative [8].

Now, consider the function $H : [(K - y_n) \times (U_{\text{ad}} - u_n)] \times M_n(y_n, u_n) \rightarrow \mathbf{R}$, defined by

$$(4.17) \quad \begin{aligned} H(s, w; p) &:= g^0(y_n; s) + h'(u_n; w) \\ &- \langle F'(y_n) s + E'(u_n) w, p \rangle_{V^*, V} + \varepsilon_n (\|s\|_V^2 + \|w\|_U^2)^{1/2}. \end{aligned}$$

Then, $(s, w) \mapsto H(s, w; p)$ is convex, $p \mapsto H(s, w; p)$ is weakly continuous affine and $M_n(y_n, u_n)$ is weakly compact. Therefore, we can use Lopsided Minimax Theorem 2.3 and conclude that there exists $p_n \in M_n(y_n, u_n)$ such that

$$(4.18) \quad \inf_{(s, w)} H(s, w; p_n) = \inf_{(s, w)} \max_{p \in M_n(y_n, u_n)} H(s, w; p).$$

But from (4.14), (4.15) and (4.17), the right side of (4.18) is ≥ 0 , and thus, we deduce that

$$\inf_{(s,w)} H(s, w; p_n) \geq 0,$$

which implies that for $(y_n, u_n) \in K \times U_{\text{ad}}$ and $p_n \in M_n(y_n, u_n)$, we have that

$$(4.19) \quad g^0(y_n; z - y_n) - \langle F'(y_n)^* p_n, z - y_n \rangle_{V^*, V} \geq -\varepsilon_n \|z - y_n\|_V \quad \forall z \in K,$$

$$(4.20) \quad h'(u_n; v - u_n) - \langle E'(u_n)^* p_n, v - u_n \rangle_{U^*, U} \geq -\varepsilon_n \|v - u_n\|_U \quad \forall v \in U_{\text{ad}}.$$

We shall show that when $N_n \rightarrow \infty$ and $\varepsilon_n \rightarrow 0$, $\{(y_n, u_n, p_n)\}$ has a subsequence, which converges to (y, u, p) , resolving to (4.4) and satisfying (4.5).

By (4.2)(3) and Browder, Hartman and Stampacchia's theorem, for any $u \in U_{\text{ad}}$, there exists $y_u \in K$ such that (4.3) holds, or

$$(4.21) \quad \| -F(y_u) - E(u) \|_{y_u}^K = 0.$$

Then, from (4.7), we have

$$0 \leq G_n(y_n, u_n) \leq G_n(y_u, u) + \varepsilon_n \quad \forall u \in U_{\text{ad}}$$

or

$$(4.22) \quad 0 \leq g(y_n) + h(u_n) + N_n \| -F(y_n) - E(u_n) \|_{y_n}^K \leq g(y_u) + h(u) + \varepsilon_n \quad \forall u \in U_{\text{ad}}.$$

Therefore, when $N_n \rightarrow \infty$ and $\varepsilon_n \rightarrow 0$, we have that

$$(4.23) \quad \delta_n := \| -F(y_n) - E(u_n) \|_{y_n}^K = -\langle F(y_n) + E(u_n), p_n \rangle_{V^*, V} \rightarrow 0,$$

and that $\{h(u_n)\}$ is bounded. The coercivity of h implies that $\{u_n\}$ is bounded and without loss of generality, we can assume that

$$(4.24) \quad u_n \rightarrow \bar{u} \quad \text{in } U_{\text{ad}} \text{ weakly.}$$

Set $\bar{y} := y_{\bar{u}}$. Then we have that (4.21) holds for $(y_{\bar{u}}, \bar{u})$ and (4.3) holds. On the other hand, from (4.23), we have that

$$(4.25) \quad \langle F(y_n) + E(u_n), z - y_n \rangle_{V^*, V} \geq -\delta_n \max(1, \|z - y_n\|_V) \quad \forall z \in K, \quad n = 1, 2, \dots$$

Taking $z = y_n$ in (4.3) and $z = \bar{y}$ in (4.25), and adding these two inequalities, we obtain

$$(4.26) \quad \langle F(y_n) - F(\bar{y}), y_n - \bar{y} \rangle_{V^*, V} + \langle E(u_n) - E(\bar{u}), y_n - \bar{y} \rangle_{V^*, V} \\ \geq \delta_n \max(1, \|\bar{y} - y_n\|_V).$$

By (4.2)(3), we have

$$(4.27) \quad \langle F(y_n) - F(\bar{y}), y_n - \bar{y} \rangle_{V^*, V} \geq C \|\bar{y} - y_n\|_V^2$$

and it is easy to show that E is weakly continuous; then, from (4.24)

$$(4.28) \quad E(u_n) \rightarrow E(\bar{u}) \quad \text{in } V^* \text{ strongly.}$$

From (4.26)-(4.28), we deduce that

$$(4.29) \quad y_n \rightarrow \bar{y} \quad \text{in } V \text{ strongly.}$$

We now show that $\{p_n\}$ is bounded and then, by extracting a subsequence, we can assume that

$$(4.30) \quad p_n \rightarrow \bar{p} \quad \text{in } V \text{ weakly.}$$

From (4.2)(3), we have that if for $y \in K$ and $t > 0$, $y + tp \in K$, then

$$\langle F(y + tp) - F(y), tp \rangle_{V^*, V} \geq Ct^2 \|p\|_V^2,$$

and it follows that

$$(4.31) \quad \langle F'(y)p, p \rangle_{V^*, V} \geq c \|p\|_V^2 \quad \forall y \in K, \quad \forall p \in T_K(y).$$

By joining up with (4.19) and (4.29), we deduce that

$$\begin{aligned} (C_{\bar{y}} + \varepsilon_n) \|p_n\|_V &\geq g^0(y_n; p_n) + \varepsilon_n \|p_n\|_V \\ &\geq \langle F'(y_n)p_n, p_n \rangle_{V^*, V} \geq C \|p_n\|_V^2 \end{aligned}$$

where $C_{\bar{y}}$ is the locally Lipschitz constant of g near \bar{y} . Hence, $\{p_n\}$ is bounded and we can assume that (4.30) holds.

Since E' is weakly continuous and $E'(\bar{u})$ is compact, (4.30) and (4.24) lead to

$$(4.32) \quad E'(u_n)^* p_n = (E'(u_n) - E'(\bar{u}))^* p_n + E'(\bar{u})^* p_n \rightarrow E'(\bar{u})^* \bar{p} \quad \text{in } U^* \text{ strongly,}$$

because $E'(\bar{u})^*$ is also compact. Thus, from (4.20), we deduce that

$$(4.33) \quad \|-h'(u_n; \cdot) + \langle E'(u)^* \bar{p}, \cdot \rangle_{U^*, U}\|_{U_{ad}}^U \rightarrow 0.$$

Since h satisfies the global (P.S.) condition, we finally obtain that

$$(4.34) \quad u_n \rightarrow \bar{u} \quad \text{in } U_{ad} \text{ strongly,}$$

provided by extracting a subsequence.

At last, we take the limit in (4.22), (4.23), (4.19) and (4.20) and thus, the proof will be complete. Here, we merely say one word about (4.20), for which the limit is not evident. By (4.2)(2) and (4.20), we have

$$\begin{aligned} h'_1(u_n; v - u_n) + h_2(v) - h_2(u_n) - \langle E'(u_n)^* p_n, v - u_n \rangle_{U^*, U} \\ \geq h'_1(u_n; v - u_n) + h'_2(u_n; v - u_n) - \langle E'(u_n)^* p_n, v - u_n \rangle_{U^*, U} \\ \geq -\varepsilon_n \|v - u_n\|_U \quad \forall v \in U_{ad}, \end{aligned}$$

and taking $n \rightarrow \infty$, we obtain

$$(4.35) \quad h'_1(\bar{u}; v - \bar{u}) - h_2(v) - h_2(\bar{u}) - \langle E'(\bar{u})^* \bar{p}, v - \bar{u} \rangle_{U^*, U} \geq 0 \quad \forall v \in U_{ad}$$

because

$$\liminf_{n \rightarrow \infty} h_2(u_n) \geq h_2(\bar{u}).$$

But (4.35) is equivalent to

$$\begin{aligned} h'_1(\bar{u}; v - \bar{u}) + h'_2(\bar{u}; v - \bar{u}) - \langle E'(\bar{u})^* \bar{p}, v - \bar{u} \rangle_{U^*, U} \\ = h'(\bar{u}; v - \bar{u}) - \langle E'(\bar{u})^* \bar{p}, v - \bar{u} \rangle_{U^*, U} \geq 0 \quad \forall v \in U_{ad}. \end{aligned} \quad \square$$

From Proposition 3.5, for any $\bar{u} \in U_{ad}$

$$(4.36) \quad l_{\bar{u}}(u) = \frac{1}{2} \|u - \bar{u}\|_U^2$$

satisfies the global (P.S.) condition. Then, we can use Theorem 4.1, Definition 3.4 and Proposition 3.5 to obtain the necessary conditions for a solution to problem (4.4), under a weakened assumption to h .

THEOREM 4.2. *Assume that*

- (4.37) (1) (4.2)(1) and (3) hold;
 (2) $g: K \rightarrow \mathbf{R}_+$ is locally Lipschitz; $h: U_{\text{ad}} \rightarrow U\{+\infty\}$ is the sum of a $h_1 \in C^1(U_{\text{ad}}; \mathbf{R}_+)$ with compact derivative and a lower semicontinuous convex function $h_2: U_{\text{ad}} \rightarrow \mathbf{R}_+ U\{+\infty\}$.

Then $(\bar{y}, \bar{u}) \in K \times U_{\text{ad}}$ is a solution to the problem (4.4) only if (4.3) holds and there exists $\bar{p} \in V$ such that (4.5) holds.

Proof. Consider the following problem:

$$(4.38) \quad \begin{aligned} & \min \{g(y) + h(u) + \tfrac{1}{2}\|u - \bar{u}\|_U^2\}, \\ & y \in K, \quad u \in U_{\text{ad}}, \\ & \langle F(y) + E(u), z - y \rangle_{V^*, V} \geq 0 \quad \forall z \in K. \end{aligned}$$

Then, obviously, (\bar{y}, \bar{u}) is the unique solution to (4.38). By Definition 3.4 and Proposition 3.5, $\tilde{h}(u) := h(u) + \tfrac{1}{2}\|u - \bar{u}\|_U^2$ satisfies (4.2)(2). Hence, by Theorem 4.1, there exists $\bar{p} \in V$ such that

$$(4.5) \quad \begin{aligned} & \langle F(\bar{y}) + E(\bar{u}), \bar{p} \rangle_{V^*, V} = 0, \\ & F'(\bar{y})^* \bar{p} \in N_K(\bar{y}) + \partial g(\bar{y}), \\ & E'(\bar{u})^* \bar{p} \in N_{U_{\text{ad}}}(\bar{u}) + \partial \tilde{h}(\bar{u}). \end{aligned}$$

But,

$$\partial \tilde{h}(\bar{u}) = \partial(h + l_{\bar{u}})(\bar{u}) = \partial h(\bar{u}) + \partial l_{\bar{u}}(\bar{u}) = \partial h(\bar{u}).$$

Therefore, (4.5)' is the same as (4.5). \square

By the same way, we can prove the following general theorem.

THEOREM 4.3. *Assume that*

- (4.39) (1) (4.2)(1);
 (2) $F \in C^1(K \times U_{\text{ad}}; V^*)$ satisfies
 (i) $\forall R > 0, \quad \forall u \in B_{R^{\text{ad}}}^U := \{u \in U_{\text{ad}} \mid \|u\|_U < R\},$
 $\exists C_R > 0 \quad \forall y_1, y_2 \in K,$
 $\langle F(y_1, u) - F(y_2, u), y_1 - y_2 \rangle_{V^*, V} \geq C_R \|y_1 - y_2\|_V^2,$
 (ii) $\forall y \in K, u \mapsto F'_u(y, u)$, partial derivative with respect to u , is weakly continuous,
 (iii) $\forall u \in U_{\text{ad}}, F'_u(y_u, u)$ is compact, provided $\| -F(y_u, u) \|_u^K = 0$;
 (3) $J: K \times U_{\text{ad}} \rightarrow \mathbf{R}_+ U\{+\infty\}$ satisfies
 (i) $y \mapsto J(y, u)$ is locally Lipschitz and for any $R > 0$ and any $u \in B_{R^{\text{ad}}}^U$, $J(\cdot, u)$ has same locally Lipschitz constants;
 (ii) $J(y, u) = J_1(y, u) + h(u)$, where for all $y \in K$, $J_1(y, \cdot) \in C^1(U_{\text{ad}}; \mathbf{R}_+)$, $(y, u) \mapsto J'_{1u}(y, u)$ is continuous and $h: U_{\text{ad}} \rightarrow \mathbf{R}_+ U\{+\infty\}$ is lower semicontinuous convex;
 (iii) $\inf_{y \in K} J(y, u) \rightarrow +\infty$ as $\|u\|_U \rightarrow +\infty$ and for any $y \in K$, $J(y, \cdot)$ satisfies the global (P.S.) condition on U_{ad} .

Then, there exist $(\bar{y}, \bar{u}) \in K \times U_{\text{ad}}$, which satisfies

$$(4.40) \quad \langle F(\bar{y}, \bar{u}), z - \bar{y} \rangle_{V^*, V} \geq 0 \quad \forall z \in K,$$

and is a solution to the following problem:

$$(4.41) \quad \begin{aligned} & \min J(y, u), \\ & y \in K, \quad u \in U_{\text{ad}}, \\ & \langle F(y, u), z - u \rangle_{V^*, V} \geq 0 \quad \forall z \in K \end{aligned}$$

and $\bar{p} \in V$ such that

$$(4.42) \quad \begin{aligned} & \langle F(\bar{y}, \bar{u}), \bar{p} \rangle_{V^*, V} = 0, \\ & F'_y(\bar{y}, \bar{u})^* \bar{p} \in N_K(\bar{y}) + \partial_y J(\bar{y}, \bar{u}), \\ & F'_u(\bar{y}, \bar{u})^* \bar{p} \in N_{U_{\text{ad}}}(\bar{u}) + \partial_u J(\bar{y}, \bar{u}). \end{aligned}$$

If (4.39) (iii) is not necessarily satisfied and $(y, u) \mapsto J'_{1u}(y, u)$ is continuous for the weak topology of U_{ad} , then (4.40) and (4.42) are necessary conditions for a solution (\bar{y}, \bar{u}) to the problem (4.41).

Finally, we devote the end of this paper to some explanatory examples.

Example 1. (1) $V := H_0^1(\Omega)$ and $U := L^2(\Omega)$ with a bounded regular open subset $\Omega \subset \mathbf{R}^n$;

(2) $g(y) := \int_{\Omega} G(x, y(x)) \, dx$, where

$$\begin{aligned} G(x, y) &:= \int_0^y \hat{g}(x, t) \, dt \quad \text{with } \hat{g}(\cdot, \cdot) \in C(\Omega \times \mathbf{R}; \mathbf{R}_+), \\ \hat{g}(\cdot, t) &:= -\hat{g}(\cdot, -t), \\ |\hat{g}(x, t)| &\leq C_g |t|^{s_g} + C_{g_0}, \quad s_g \in \begin{cases} [1, (n+2)/(n-2)] & \text{if } n \geq 3, \\ [1, \infty[& \text{otherwise,} \end{cases} \end{aligned}$$

$h(u) := \int_{\Omega} H(x, u(x)) \, dx + \frac{1}{2} \int_{\Omega} |u(x)|^2 \, dx$, where

$$\begin{aligned} H(x, u) &:= \int_0^u \hat{h}(x, t) \, dt \quad \text{with } \hat{h}(\cdot, \cdot) \in C(\Omega \times \mathbf{R}; \mathbf{R}_+), \\ \hat{h}(\cdot, t) &:= -\hat{h}(\cdot, -t), \\ |\hat{h}(x, t)| &\leq C_h |t|^{s_h} + C_{h_0}, \quad s_h \in \begin{cases} [1, (n+2)/n] & \text{if } n \geq 3, \\ [1, \infty[& \text{otherwise,} \end{cases} \\ H(X, u) &\geq \alpha u^2 - C \quad \text{with } \alpha > -1; \end{aligned}$$

(3) $F(y) := -\Delta y(\cdot) + \varphi(\cdot, y(\cdot))$, where

$$\begin{aligned} & \varphi(\cdot, \cdot) \in C^1(\Omega \times \mathbf{R}; \mathbf{R}), \, y \mapsto \varphi(x, y) \text{ is increasing,} \\ |\varphi(x, t)| &\leq C_{\varphi} |t|^{s_{\varphi}} + C_{\varphi_0}, \quad s_{\varphi} \in \begin{cases} [1, (n+2)/(n-2)] & \text{if } n \geq 3, \\ [1, \infty[& \text{otherwise,} \end{cases} \end{aligned}$$

$E(u) := \Psi(\cdot, u(\cdot))$, where

$$\begin{aligned} & \Psi(\cdot, \cdot) \in C^1(\Omega \times \mathbf{R}; \mathbf{R}), \\ |\Psi(x, t)| &\leq C_{\Psi} |t|^{s_{\Psi}} + C_{\Psi_0}, \quad s_{\Psi} \in \begin{cases} [1, (n+2)/n] & \text{if } n \geq 3, \\ [1, \infty[& \text{otherwise;} \end{cases} \end{aligned}$$

(4) Formula (4.3) becomes

$$\int_{\Omega} \{ \nabla \bar{y}(x) \cdot \nabla (z(x) - \bar{y}(x)) + (\varphi(x, \bar{y}(x)) + \Psi(x, \bar{u}(x)))(z(x) - \bar{y}(x)) \} \, dx \geq 0$$

$$\forall z \in K \subset H_0^1(\Omega),$$

Formula (4.5) becomes

$$\begin{aligned} \int_{\Omega} \{ \nabla \bar{y}(x) \cdot \nabla \bar{p}(x) + (\varphi(x, \bar{y}(x)) + \Psi(x, \bar{u}(x))) \bar{p}(x) \} dx &= 0, \\ \int_{\Omega} \{ \nabla \bar{p}(x) \cdot \nabla (z(x) - \bar{y}(x)) + [\varphi'_y(x, \bar{y}(x)) \bar{p}(x) - g(x, \bar{y}(x))] (z(x) - \bar{y}(x)) \} dx &\leq 0 \\ \forall z \in K \subset H_0^1(\Omega), \\ \int_{\Omega} [\varphi'_u(x, \bar{u}(x)) \bar{p}(x) - h(x, \bar{u}(x)) - \bar{u}(x)] (v(x) - \bar{u}(x)) dx &\leq 0 \\ \forall v \in U_{ad} \subset L^2(\Omega). \end{aligned}$$

Example 2. (1) $V := H_0^{1,p}(\Omega)$, $1 < p \leq 2$ and $U := L^q(\Omega)$, $q > 1$ with a same $\Omega \subset \mathbf{R}^n$,

$$K \subset \{ y \in H_0^{1,p}(\Omega) \mid \|y\|_{H_0^{1,p}(\Omega)} \geq 1 \};$$

(2) $g(y)$ is the same as in Example 1(1), but

$$\begin{aligned} s_g \in \begin{cases} \left[1, \frac{n(p-1)+p}{n-p} \right] & \text{if } n \geq 3, \\ [1, \infty[& \text{otherwise,} \end{cases} \\ h(u) := \int_{\Omega} H(x, u(x)) dx + 1/q \int_{\Omega} |u(x)|^q dx \end{aligned}$$

where $H(\cdot, \cdot)$ is the same as in Example 1(2), but

$$\begin{aligned} s_h \in \begin{cases} \left[1, q \frac{n(p-1)+p}{n-p} \right] & \text{if } n \geq 3, \\ [1, \infty[& \text{otherwise,} \end{cases} \\ H(x, u) \geq \alpha |u|^q - C \quad \text{with } \alpha > -1; \\ (3) \quad F(y) := - \sum_{i=1}^n \frac{\partial}{\partial x_i} \left[\left| \frac{\partial y}{\partial x_i} \right|^{p-2} \frac{\partial y}{\partial x_i} \right] + \varphi(\cdot, y(\cdot)) \end{aligned}$$

where $\varphi(\cdot, \cdot)$ is the same as in Example 1(3), but

$$s_{\varphi} \in \begin{cases} \left[1, \frac{n(p-1)+p}{n-p} \right] & \text{if } n \geq 3, \\ [1, \infty[& \text{otherwise.} \end{cases}$$

Notice that

$$\langle F(y_1) - F(y_2), y_1 - y_2 \rangle_{H^{-1,p'}(\Omega), H_0^{1,p}(\Omega)} \geq \left(\frac{\|y_1 - y_2\|_{H_0^{1,p}(\Omega)}^2}{\|y_1\|_{H_0^{1,p}(\Omega)}^{2-p} + \|y_2\|_{H_0^{1,p}(\Omega)}^{2-p}} \right).$$

$E(u)$ is the same as in Example 1(3), but

$$s_{\Psi} \in \begin{cases} \left[1, q \frac{n(p-1)+p}{np} \right] & \text{if } n \geq 3, \\ [1, \infty[& \text{otherwise;} \end{cases}$$

(4) Formula (4.3) becomes

$$\int_{\Omega} \left\{ \sum_{i=1}^n \left| \frac{\partial y}{\partial x_i} \right|^{p-2} \frac{\partial y}{\partial x_i} \frac{\partial}{\partial x_i} (z(x) - \bar{y}(x)) + [\varphi(x, \bar{y}(x)) + \Psi(x, \bar{u}(x))] (z(x) - \bar{y}(x)) \right\} dx$$

$$\forall z \in K \subset H_0^{1,p}(\Omega);$$

the first and second representations of (4.5) are similar, and the third representation becomes

$$\int_{\Omega} \{ [\Psi'_u(x, \bar{u}(x)) \bar{p}(x) - h(x, \bar{u}(x)) - |\bar{u}(x)|^{q-2} \bar{u}(x)] (v(x) - \bar{u}(x)) \} dx \leq 0$$

$$\forall v \in U_{ad} \subset L^q(\Omega)$$

APPROXIMATING THE LINEAR QUADRATIC OPTIMAL CONTROL LAW FOR HEREDITARY SYSTEMS WITH DELAYS IN THE CONTROL*

MARK H. MILMAN†

Abstract. A factorization approach is presented for deriving approximations to the optimal feedback gains for the linear regulator-quadratic cost problem associated with time-varying functional differential equations with control delays. The approach is based on a discretization of the state penalty which leads to a simple structure for the feedback control law. General properties of the Volterra factors of Hilbert-Schmidt operators are then used to obtain convergence results for the controls, trajectories and feedback kernels. Two algorithms are derived from the basic approximation scheme, including a fast algorithm, in the time-invariant case. A numerical example is also considered.

Key words. optimal control, delays, factorization

AMS(MOS) subject classification. 93

1. Introduction. This paper is concerned with the application of factorization techniques to approximating the optimal feedback gain for the finite time linear regulator quadratic cost problem for systems governed by retarded functional differential equations (RFDE) with control delays. Feedback control laws for these systems have been previously derived for both the finite and infinite time problems in several articles under various hypotheses (see for example [6], [13], [14], [17], [24], [25]). The departure point for this paper is the representation derived in [24], in which the feedback kernel is realized in terms of solutions to a certain nonlinear integral equation corresponding to a Volterra factorization problem. Heavy use is made of the variation of constants formula for RFDE's (due to Banks) and general factorization results for Hilbert-Schmidt operators [11], [22]. Difficulties, due to the presence of an unbounded input operator because of the control delay, are circumvented in the factorization approach. Other applications of Volterra factorization include, for example, filtering and smoothing of nonstationary processes over a finite interval [15], [16], inverse problems in the spectral theory of differential operators [8], [18], solutions to two point boundary value problems and Fredholm equations of the first and second kinds [11], [21].

Although the specific approximation problem we consider in this paper has not to the author's knowledge been treated in the literature, several articles (e.g., [5], [10], [19]) have considered approximating the feedback kernel in systems without control delay terms. The approach in each of these articles involves expressing the RFDE as an evolution equation in the state space $R^N \times L_2$, and then approximating the resulting dynamical system. Delfour [5] discretizes in both the spatial and time variables, while Kunisch [19] and Gibson [10] discretize in only the spatial variable. Delfour considers the time-varying problem and obtains weak convergence of the solutions to the approximating Riccati equations. In [10] and [19] the open-loop semigroup is first approximated by discretizing the history space, and then the approximation theory of

[9] is used for subsequent convergence analysis. This analysis is based on exploiting the relationship developed in [9] between the open-loop semigroup and the Riccati equation defining the feedback law. (We note that the integral Riccati equations of [9] are also equivalent to certain factorization problems [23], so that the convergence analysis in [10] and [19] can also be performed within a factorization context.) Ultimately, Kunisch demonstrates weak L_2 -convergence of the kernels, while Gibson establishes a strong L_2 -convergence. Neither provide a priori rates of convergence. Although Gibson and Kunisch restrict their attention to the time-invariant case, the approach is extendable to time-varying problems by using the approximations of Banks and Rosen [3]. We also note that Gibson importantly considers the infinite time problem.

The convergence analysis presented in [10] and [19] depends heavily on the fact that the control map has finite rank. This condition does not hold in the control delay problem and straightforward extensions of these convergence results to the control delay case are not apparent.

Our approach to the problem does not rely on analysis of the associated Riccati equations. It will be shown that if the cost on the state in the regulator problem is a discrete sum with no integral term, then the associated factorization problem is solved by matrix inversion, and the exact feedback kernel can be defined in terms of the fundamental matrix solution, quadrature, and the solution to finite-dimensional linear equations. (This form of the solution generalizes a result of Manitius [20] for the problem with terminal state penalty and no control delays.) Thus an approximation scheme for the problem containing an integral state penalty term can be developed by approximating this term by quadrature and solving exactly for the feedback kernel of the resulting discretized state cost problem. Using this approach together with factorization arguments we will be able to establish $O(1/n)$ L_∞ -convergence for the approximate feedback kernels in the time-varying control delay case.

This result is (analytically) somewhat sharper than Gibson's in that the L_∞ convergence of the kernels applies on the square as well as the diagonal, and also that a priori rates can be provided. The principle reason this sharper result can be obtained is that we exploit the fact that only the fundamental matrix solution is required to define the feedback kernel, and thus it is never necessary to consider the less tractable problem of approximating the entire semigroup. We now briefly outline the organization of the paper.

In § 2 the necessary mathematical preliminaries are developed and discussed. Because the approach does not follow along a Riccati synthesis, we will recapitulate in this section some of the relevant discussion from [24] concerning the relationship between Volterra factorization and the RFDE control problem.

Section 3 contains the L_∞ -convergence results for the feedback kernels, controls and trajectories. Instead of considering specific quadrature schemes approximating the state cost, all the results are proved with respect to a sequence of Borel measures satisfying certain convergence hypotheses. The key tool of this section is a factorization lemma which asserts that the factorization problem is well posed (in an appropriate sense) in the space of integral operators with essentially bounded kernels.

In § 4, the explicit form of the optimal feedback kernel associated with discrete state cost is derived. The resulting approximation scheme developed from the cost discretizations is then used as an analytical tool to obtain further results regarding the feedback kernel. For example, using essentially matrix manipulations, a Wiener-Hopf integral equation for the optimal feedback kernel is derived which is shown to be the

control delay generalization of the Wiener-Hopf equation Manitius [20] had previously derived for the feedback kernel via a maximum principle.

In § 5 two algorithms representing implementation of the basic approximation scheme of § 4 are derived. In the time-invariant case a fast algorithm is derived by exploiting the near Toeplitz structure of the system of equations that defines the feedback kernel. A simple numerical example is also presented.

2. Preliminaries. Let $[-r, T]$ denote a closed and bounded interval in the real line with $r \geq 0$ and $T > 0$, and let Σ denote the class of Borel subsets of $[-r, T]$. For an arbitrary Banach space Y , $|y|$ will denote the norm of an element $y \in Y$, $B(Y, Z)$ will denote the space of bounded linear maps from Y into another Banach space Z , and for brevity we write $B(Y)$ for $B(Y, Y)$. Subscripts will sometimes be attached to the norm of an element to remove any ambiguities that might arise due to the fact that several different topologies will be used in the paper. The notation A^* (respectively A') will be used to denote the adjoint (transpose) of an operator (matrix).

In the sequel the Banach space of continuous functions $C([-r, T], R^N)$ will be denoted X , the Hilbert space $L_2([-r, T], R^M)$ will be denoted U , and H will denote the Hilbert space $L_2([-r, T], R^N)$. Now define the resolution of the identity $E: \Sigma \rightarrow B(U)$ by multiplication by the characteristic function, i.e., $[E(\omega)u](t) = \chi(\omega)(t)u(t)$ ($\chi(\omega)(t) = 0$ if $t \notin \omega$, $\chi(\omega)(t) = 1$ if $t \in \omega$), and let P' denote the family of projections $E([-r, t])$. The complementary family $I - P'$, will be denoted P_t . Note that P' is strongly continuous, i.e., $t \rightarrow P_t u$ is continuous for each $u \in U$.

In this section we shall review some of the results in [24] pertaining to the linear regulator problem with dynamics

$$\begin{aligned} \dot{x}(t) &= \int_{-r}^0 d_\theta \eta(t, \theta) x(t + \theta) + (BP_0 u)(t), & t \geq 0, \\ x(t) &= \phi(t), & t \in [-r, 0] \end{aligned} \quad (2.1)$$

and quadratic cost functional

$$J(u, x) = \int_{-r}^T \langle x(s), Q(s)x(s) \rangle d\mu(s) + \int_{-r}^T |u(s)|^2 ds. \quad (2.2)$$

In (2.1), we assume that $\phi(t)$ is continuous, $x(\cdot) \in X$, $u \in U$, $B \in B(U, H)$ and P_0 is the projection $E([0, T])$. (It would not affect subsequent convergence analysis of the feedback kernels to allow an arbitrary projection P_{t_0} , $t_0 \in [-r, T]$, in place of P_0 . The choice $t_0 = 0$ reflects the problem formulation in which control policies cannot be implemented until time $t = 0$.) The only constraint we impose on B at this time is that it be causal, i.e., for each $t \in [-r, T]$, if $u_1 = u_2$ almost everywhere on $[0, t]$ then $(Bu_1)(s) = (Bu_2)(s)$ for almost every $s \leq t$. The matrix valued function η is assumed measurable on $R \times R$ and is normalized so that $\eta(t, \theta) = 0$ for $0 \leq \theta$ and $\eta(t, \theta) = \eta(t, -r)$ for $\theta \leq -r$. It is further assumed that $\eta(t, \cdot)$ is left continuous for each t and there exists a function $m \in L_1(0, T)$ such that

$$|\text{Var } \eta(t, \cdot)| \leq m(t) \quad (2.3)$$

where $|\cdot|$ denotes any matrix norm. In the cost (2.2), μ denotes an arbitrary positive regular Borel measure on $[-r, T]$, and $Q(\cdot)$ is Borel measurable with $Q(s) \geq 0$ μ almost everywhere and is μ -essentially bounded.

At this time it is convenient to introduce some operators that will play a prominent role in subsequent analysis. We define:

$$(2.4) \quad L \in B(X); \quad Lx: t \rightarrow \begin{cases} 0, & t \in [-r, 0], \\ \int_0^t \int_{-r}^0 d_\theta(s, \theta)x(s + \theta) ds, & t \geq 0, \end{cases}$$

$$(2.5) \quad F \in B(U, X); \quad Fu: t \rightarrow \int_{-r}^t F(t, s)u(s) ds$$

and the adjoint-like

$$(2.6) \quad F^\# \in B(X, U); \quad F^\#x: t \rightarrow \int_t^T F'(s, t)Q(s)x(s) d\mu(s)$$

where $F(t, s) = [P_0 B^* Y'(t, \cdot)]'(s)$ and $Y(t, s)$ is the fundamental matrix solution of the homogeneous problem (see [12]). $Y(\cdot, \cdot)$ satisfies the Volterra equation

$$(2.7) \quad Y(t, s) = \begin{cases} I - \int_s^t Y(t, \sigma)\eta(\sigma, s - \sigma) d\sigma, & s \leq t, \\ 0, & s > t, \end{cases}$$

and the solution to (2.1) can be realized as

$$(2.8) \quad \begin{aligned} x(t) = Y(t, 0)\phi(0) &+ \int_{-r}^0 d_\beta \int_0^t Y(t, \sigma)\eta(\sigma, \beta - \sigma) d\sigma \phi(\beta) \\ &+ \int_0^t Y(t, \sigma)(BP_0 u)(\sigma) d\sigma. \end{aligned}$$

Also, $\sup |Y(t, s)| < \infty$, $Y(t, s)$ is absolutely continuous for $t \geq s$ for each s , and $Y(t, \cdot)$ is of bounded variation for each t . We note from the definition of $F(t, s)$ that $F(t, s) = 0$ for $s < 0$. Hence, $FP_0 = F$ and $P_0 F^\# = F^\#$.

Using a completing the squares argument, the open loop control law for (2.1)–(2.2) can be easily derived in terms of the operators defined above.

THEOREM 2.1. *The optimal control \hat{u} for the regulator problem (2.1)–(2.2) is $\hat{u} = M\tilde{\phi}$, where $M \in B(X, U)$, $\tilde{\phi} \in X$,*

$$M = -(I + F^\# F)^{-1} F^\# (I - L)^{-1},$$

$$\tilde{\phi}(t) = \begin{cases} \phi(0), & t \geq 0, \\ \phi(t), & t \in [-r, 0]. \end{cases}$$

Proof. The proof is shown in [24].

In [24] the feedback control law for (2.1)–(2.2) was derived from the open loop control law above using certain embedding and Volterra factorization arguments. This paper also requires factorization arguments, and now we digress a bit to give some pertinent background. (The interested reader is referred to [11], [22] and [24] for more details.)

Let $G: [-r, T] \rightarrow B(U)$, and assume that G is strongly continuous, i.e., $t \rightarrow G(t)u$ is continuous for each $u \in U$. Now let $K \in B(U)$ be a Hilbert–Schmidt operator and consider Riemann sums of the form

$$\sum_i E(\theta_i)KG(t_i), \quad -r = t_0 < \cdots < t_n = T,$$

$\theta_i = [t_i, t_{i+1}]$, and $t'_i \in \theta_i$. These sums can be shown to converge in the operator norm as the mesh of the partitions tend to zero [11]. This limit is expressed as the projection integral

$$(2.9) \quad \int dE KG(t),$$

and it can further be shown that

$$(2.10) \quad \left\| \int dE KG(t) \right\|_{HS} \leq \|K\|_{HS} \sup |G(t)|.$$

Here $\|\cdot\|_{HS}$ denotes the Hilbert-Schmidt norm.

Two important projection integrals on the space \mathcal{K} of Hilbert-Schmidt operators in $B(U)$ are obtained from the selections $G_+(t) = P'$ and $G_-(t) = P_t$. The resulting operators, p_+ and p_- , respectively,

$$p_+(K) = \int dE KG_+(t) \quad \text{and} \quad p_-(K) = \int dE KG_-(t)$$

are bounded projections on \mathcal{K} . If $K \in R(p_+)(R(p_-))$ we say that K is causal (anticausal). The elements of $R(p_+)$ and $R(p_-)$ are quasinilpotents. In the sequel we shall also write $K_+(K_-)$ for $p_+(K)$ ($p_-(K)$). Note also that $P'U$ and P_tU are invariant subspaces of $p_+(K)$ and $p_-(K)$, respectively.

We note that in the space U a Hilbert-Schmidt map K is necessarily an integral operator with kernel, say $K(t, s)$. In this case the projections $p_+(K)$ and $p_-(K)$ are simply the Volterra operators

$$p_+(K)u : t \rightarrow \int_{-r}^t K(t, s)u(s) ds, \quad p_-(K)u : t \rightarrow \int_t^T K(t, s)u(s) ds.$$

With this bit of background we can now state the basic factorization results that will be used in the sequel.

THEOREM 2.2 (Gohberg-Krein). *Let $K \in \mathcal{K}$. Then there exist unique operators $X_{\pm} \in R(p_{\pm})$ such that*

$$(2.11) \quad I + K = (I + X_-)(I + X_+)$$

if and only if $(I + P_t K P_t)$ is invertible for each $t \in [-r, T]$. Furthermore, $W_- = (I + X_-)^{-1} - I$ is given by the projection integral

$$W_- = - \int dE KG(t)$$

with

$$G(t) = P_t(I + P_t K P_t)^{-1}.$$

The decomposition of $(I + K)$ into the product in (2.11) is called the Volterra or special (right) factorization of $I + K$, and we will sometimes refer to X_{\pm} as the causal (anticausal) factor of K . Note that uniqueness of the factorization implies that $X_- = (X_+)^*$ when K is self-adjoint.

Two results that will be useful in subsequent convergence analysis are stated as corollaries below.

COROLLARY 2.3. *Suppose $K \in \mathcal{K}$ is self-adjoint with*

$$\sup_t |(I + P_t K P_t)^{-1}| \leq k.$$

Then $I + K$ has the factorization (2.14) and $W_{\pm} = (I + X_{\pm})^{-1} - I$ satisfy

$$|W_{\pm}|_{HS} \leq k|K|_{HS}.$$

COROLLARY 2.4. Let $K_i \in \mathcal{H}$, $i = 1, 2$ be self-adjoint with

$$\sup_i |(I + P_i K_i P_i)^{-1}| \leq k_i.$$

Let $W_i = (I + X_i)^{-1} - I$ where X_i denotes the causal factor of K_i . Then

$$|W_1 - W_2|_{HS} \leq \min_{i \neq j} k_i |K_1 - K_2|_{HS} (1 + k_j |K_j|_{HS}).$$

Proof. It suffices to prove the result for the adjoint operators. Thus let $G_i(t) = P_i(I + P_i K_i P_i)^{-1}$, and note that

$$\begin{aligned} |W_1^* - W_2^*|_{HS} &\leq \left| \int dE K_1 (G_1 - G_2) \right|_{HS} + \left| \int dE (K_1 - K_2) G_2 \right|_{HS} \\ &\leq |K_1|_{HS} |K_1 - K_2|_{HS} k_1 k_2 + |K_1 - K_2|_{HS} k_2 \\ &= k_2 |K_1 - K_2|_{HS} (1 + |K_1|_{HS} k_1). \end{aligned}$$

Symmetry of the argument with respect to K_1 and K_2 gives the result. \square

In [22] the Lebesgue analogue of the projection integral was introduced. This outgrowth of the projection integral provides the basis for the results of [24], which in turn is the departure point for the present paper. We will not, however, have any need for working directly with this variation of the projection integral. The current background is sufficient for defining the feedback solution to (2.1)–(2.2) and performing subsequent analysis. (Complete details can be found in [24].)

Define the Hilbert space $H_{\mu} = L_2([-r, T], R^N; \mu)$ as the space of μ -square integrable functions on $[-r, T]$ with values in R^N . It is evident that the map $Q: H_{\mu} \rightarrow H_{\mu}$ defined by $(Qx)(t) = Q(t)x(t)$ is bounded and that $F^{\#}$ has the representation $F^{\#} = F^*Q$ where F^* is the adjoint of F considered as an element of $B(U, H_{\mu})$. Hence, $F^{\#}F = F^*QF \geq 0$. In [24] it is verified that $F^{\#}F$ is Hilbert-Schmidt, so that Theorem 2.2 implies that $(I + F^{\#}F)$ has the factorization

$$(2.12) \quad I + F^{\#}F = (I + X^*)(I + X)$$

with X causal.

Since $I + X^*$ is invertible (recall that X^* is a quasinilpotent) let $W^* = (I + X^*)^{-1} - I$. And furthermore, since W^* is Hilbert-Schmidt, it has an $M \times M$ matrix kernel $W_-(t, s)$. Next define the $M \times N$ matrix valued function $P(t, \alpha)$ on $[-r, T] \times [-r, T]$ by

$$(2.13) \quad P(t, \alpha) = \int_{\alpha}^T K(t, s) Y(s, \alpha) d\mu(s)$$

where

$$(2.14) \quad K(t, s) = F'(s, t)Q(s) + \int_t^s W_-(t, \sigma)F'(s, \sigma)Q(s) d\sigma$$

and $Y(t, s)$ defined as in (2.7). The function $P(t, \alpha)$ provides the feedback solution to the regulator problem. This is made precise in the following.

THEOREM 2.5. *The optimal feedback control for (2.1)–(2.2) is given by*

$$\begin{aligned}\hat{u}(t) = & -P(t, t)\hat{x}(t) - \int_t^{\min(T, t+r)} P(t, \alpha) \int_{t-r}^t d_\beta(\alpha, \beta - \alpha) \hat{x}(\beta) d\alpha \\ & - \int_t^T P(t, \alpha)(BP'u)(\alpha) d\alpha\end{aligned}$$

where \hat{x} denotes the optimal trajectory, and for each t , P' denotes the projection on U , $(P'u)(\varepsilon) = \chi[-r, t](s)u(s)$. Furthermore, $P(t, \alpha)$ is square integrable (Lebesgue measure) on both the diagonal and the square $[-r, T] \times [-r, T]$.

Proof. The proof is shown in [24].

3. Convergence results. The specific optimization problem we shall be considering is the following:

$$(3.1) \quad \min J(u, x) = \langle x(T), Q_0 x(T) \rangle + \int_{-r}^T \langle x(s), Q(s)x(s) \rangle + |u(s)|^2 ds$$

subject to the constraint

$$(3.2) \quad x(t) = \int_{-r}^0 d_\theta(t, \theta)x(t+\theta) + (BP_0 u)(t), \quad t \geq 0,$$

$$(3.3) \quad x(t) = \phi(t), \quad t \in [-r, 0],$$

where $\phi(\cdot) \in C([-r, 0], \mathbb{R}^N)$ and

$$(3.4) \quad (Bu)(t) = \sum_{i=0}^k \chi[r, -r, T](t) B_i(t) u(t-r_i) + \int_{t-r}^t B(t, \theta) u(\theta) d\theta.$$

The assumptions on $\eta(\cdot, \cdot)$ are the same as in the preceding section. We shall assume that $0 = r_0 > -r_1 > \dots > -r_k = -r$ and $\sup |B_i(t)| = b_i < \infty$, $\sup |B(t, \theta)| = b < \infty$. In the cost (3.1) we impose continuity on $Q(s)$.

Interpreting these assumptions in the context of § 2, we have $\mu = \lambda + \delta$ where λ denotes Lebesgue measure, δ is the Dirac measure with support on $\{T\}$, and $Q(\cdot)$ is uniformly continuous on $[-r, T]$ with $Q(T) = Q_0$.

Now consider the following sequence $\{J_n\}$ of approximations to the cost $J(u, x)$:

$$(3.5) \quad J_n(u, x) = \int_{-r}^T \langle x(s), Q(s)x(s) \rangle d\mu_n(s) + \int_{-r}^T |u(s)|^2 ds$$

where μ_n is a sequence of positive regular Borel measures such that:

$$(H1) \quad \mu_n(T) = 1 \text{ for all } n.$$

$$(H2) \quad \text{Given } \varepsilon > 0 \text{ there exist } m \text{ such that } n \geq m \text{ implies } |\mu_n[a, b]| - |b - a| < \varepsilon \\ \text{for all } a < b; a, b \in [-r, T].$$

In this section we will discuss the convergence properties of the solution and feedback laws corresponding to the cost approximation above. Henceforth we refer to the optimization problem with cost (3.1) as problem \mathcal{P} , and the problem with cost (3.5) as problem \mathcal{P}_n . Unless otherwise noted, subscripts appearing on operators, functions, etc. (e.g., F_n) will indicate that these terms are associated with problem \mathcal{P}_n .

LEMMA 3.1. Let μ be defined as above and let μ_n satisfy (H1) and (H2). Then $\mu_n - \delta \rightarrow \lambda$ (Lebesgue measure) in the w^* topology of $C^*(-r, T)$.

Proof. The proof is shown in [34].

Since by definition $F(t, s) = [P_0 B^* Y'(t, \cdot)]'(s)$ (cf. (2.5)–(2.6)) from (3.4) it follows that

$$(3.6) \quad F(t, s) = \sum_i f_i(t, s)$$

where

$$f_0(t, s) = Y(t, s)B_0(s) + \int_s^{\min(s+r), t} Y(t, \theta)B(\theta, s) d\theta$$

and

$$f_i(t, s) = Y(t, s+r_i)B_i(s+r_i), \quad i = 1, \dots, k.$$

Now let $\gamma = \sup |Y(t, s)|$. Then using [12, p. 149] and the bounds in (3.4), we have

$$(3.7) \quad \sup |f_0(t, s)| \leq \gamma(b_0 + br), \quad \sup |f_i(t, s)| \leq b_i \gamma.$$

Also, for $t_2 > t_1 \geq s + r_i$,

$$(3.8) \quad |f_0(t_2, s) - f_0(t_1, s)| \leq \exp |m|_1 \int_{t_1}^{t_2} m(\sigma) d\sigma \{b_0 + br\} + b\gamma(t_2 - t_1)$$

and

$$(3.9) \quad |f_i(t_2, s) - f_i(t_1, s)| \leq b_i \exp |m|_1 \int_{t_1}^{t_2} m(\sigma) d\sigma, \quad i = 1, \dots, k.$$

It is not difficult to show (see [24]) that $F^* = F^*j$, $F_n^* = F^*j_n$ where F^* is the B -space adjoint of F , i.e., $F^*: X^* \rightarrow U$, and j, j_n are the mappings of X into X^* ,

$$j(x)y = \int \langle y(s), Q(s)x(s) \rangle d\mu(s),$$

$$j_n(x)y = \int \langle y(s), Q(s)x(s) \rangle d\mu_n(s).$$

Now it follows easily from definition and the estimates above that F is compact. Thus, using the w^* -convergence of $j_n(x) \rightarrow j(x)$ for each x (from Lemma 3.1), it can then be deduced that $F_n^* \rightarrow F^*$ strongly. Consequently from the compactness of F it also follows that $F_n^* F \rightarrow F^* F$ uniformly. Noting the form of the open loop control law (in Theorem 2.1), these general considerations are enough to demonstrate the L_2 -convergence of the approximate optimal controls and the uniform convergence of the corresponding optimal trajectories resulting from approximations based on \mathcal{P}_n . However, the major aim of this section is to produce the stronger L_∞ -convergence of the approximations for the feedback kernels as well as the controls, and this requires a somewhat more specific analysis.

Let Z denote the space $L_\infty([-r, T], R^M)$. From the definition of $F(t, s)$ it is evident that F^* and F_n^* are also in $B(X, Z)$. Our first result sharpens the convergence of $F_n^* \rightarrow F^*$ discussed above. This result (and the method of proof) will form the basis for the L_∞ -convergence arguments later.

LEMMA 3.2. $F_n^* \rightarrow F^*$ strongly in $B(X, Z)$.

Proof. Let $x \in X$. By definition

$$[F^* - F_n^*]x: t \rightarrow \sum_{i=0}^k \int f'_i(s, t)Q(s)x(s) d(\mu - \mu_n)(s).$$

For each i define

$$\tilde{f}_i(s, t) = \begin{cases} f_i(s, t), & s > t + r_i, \\ f_i(t + r_i, t), & s \leq t + r_i. \end{cases}$$

Similarly define

$$Q_i(s, t) = \begin{cases} Q(s), & s > t + r_i, \\ Q(t + r_i), & s \leq t + r_i \end{cases}$$

and

$$x_i(s, t) = \begin{cases} x(s), & s > t + r_i, \\ x(t + r_i), & s \leq t + r_i. \end{cases}$$

Considered as families of functions parameterized by t , $\{\tilde{f}_i(\cdot, t)\}$ is equicontinuous by virtue of (3.7)–(3.9), and $\{Q_i(\cdot, t)\}$ and $\{x_i(\cdot, t)\}$ are equicontinuous by virtue of the uniform continuity of $Q(\cdot)$ and $x(\cdot)$, respectively. Furthermore these families are clearly uniformly bounded. Hence we have the set

$S = \{x_t \in C([-r, T], R^M) : x_t(s) = f_i(s, t)Q_i(s, t)x_i(s, t), t \in [-r, T - r_i], i = 0, 1, \dots, k\}$ is relatively compact in $C([-r, T], R^N)$. Now note that

$$\begin{aligned} |[F^* - F_n^*](x)(t)| \leq \sum_{i=0} \left\{ \left| \int_{-r}^T f_i(s, t)Q(s, t)x_i(s, t)d(\mu - \mu_n)(s) \right| \right. \\ \left. + \left| \int_{-r}^{t+r} f_i(s, t)Q_i(s, t)x_i(s, t)d(\mu - \mu_n)(s) \right| \right\}. \end{aligned}$$

By the compactness of S it follows from Lemma 3.1 that the first integral above converges to zero uniformly with respect to t . And since the second integral has constant integrand for each t and i , uniform convergence is obtained here by using (H2). \square

Now let $H(t, s)$ and $H_n(t, s)$ denote the kernels of F^*F and F_n^*F , respectively. Fubini's theorem implies that

$$(3.10) \quad |H_n(t, s) - H(t, s)| \leq \left| \sum_{i,j} \int f'_i(\sigma, t)Q(\sigma)f_i(\sigma, s)d(\mu - \mu_n)(\sigma) \right|.$$

Using an argument similar to the one in the lemma above, we can prove the following result (see [34]).

LEMMA 3.3. *With the notation above, $H_n(t, s) \rightarrow H(t, s)$ uniformly on $[-r, T] \times [-r, T]$. In particular, $F_n^*F \rightarrow F^*F$ in the Hilbert-Schmidt topology (in $B(U)$) and in the $B(Z)$ topology.*

To obtain L_∞ -convergence of the feedback kernels we will use a result analogous to the one above regarding the convergence of the kernels of the Volterra factors of $I + F_n^*F$. Already we can use Corollary 2.4 and Lemma 3.3 to obtain Hilbert-Schmidt convergence of the factors (hence, L_∞ -convergence of their kernels). But our ultimate aim is to demonstrate the stronger L_∞ -convergence of the kernels. We shall need the following two results which are of some interest in their own right.

PROPOSITION 3.4. *Let K be an integral operator on U with essentially bounded kernel $K(t, s)$ where $\text{ess sup}_{t,s} |K(t, s)| = \beta < \infty$. Suppose that*

$$(3.11) \quad \sup_t |(I + P_t K P_t)^{-1}| = \alpha < \infty$$

so that $I + K$ has the factorization

$$(3.12) \quad I + K = (I + X^*)(I + X)$$

with X causal (Theorem 2.2). Then $W = (I + X)^{-1} - I$ and W^* are integral operators with kernels $W_{\pm}(t, s)$ satisfying the bound

$$(3.13) \quad \operatorname{ess\,sup}_{t,s} |W_{\pm}(t, s)| < \rho(\alpha, \beta)$$

where

$$\rho(\alpha, \beta) = \beta[1 + \beta(T+r)(1 + \alpha\beta(T+r))^2].$$

Proof. First note that Corollary 2.3 implies $W = (I + X)^{-1} - I$ is Hilbert-Schmidt with $|W|_{HS} \leq \alpha|K|_{HS}$. Now the factorization (3.12) implies that

$$(I + X^*) = (I + K)(I + W).$$

Subtracting the identity from the above and applying the projection p_- (i.e., taking anticausal parts) results in, for $\theta \geq t$,

$$X_-(t, \theta) = K(t, \theta) + \int_{\theta}^T K(t, \sigma) W_+(\sigma, \theta) d\sigma \quad \text{a.e. } t, \theta$$

where $X_-(t, \theta)$ and $W_+(t, \theta)$ are the kernels of X^* and W , respectively. Hence for almost every t, θ ,

$$|X_-(t, \theta)| \leq \beta \left\{ 1 + \int_{-r}^T |W_+(\sigma, \theta)| d\sigma \right\}.$$

Consequently,

$$\begin{aligned} \int_{-r}^T |X_-(t, \theta)|^2 d\theta &\leq \beta^2 \int_{-r}^T \left\{ 1 + \int_{-r}^T |W_+(\sigma, \theta)| d\sigma \right\}^2 d\theta \\ &= \beta^2 \left\{ (T+r) + 2 \int_{-r}^T \int_{-r}^T |W_+(\sigma, \theta)| d\sigma d\theta \right. \\ &\quad \left. + \int_{-r}^T \left[\int_{-r}^T |W_+(\sigma, \theta)| d\sigma \right]^2 d\theta \right\} \\ &\leq \beta^2 (T+r) (1 + |W_+|_{HS})^2 \\ &\leq \beta^2 (T+r) (1 + \alpha|K|_{HS})^2 \\ &\leq \beta^2 (T+r) [1 + \alpha\beta(T+r)]^2 \quad \text{a.e. } t. \end{aligned}$$

Let $\tilde{\alpha} = \beta^2(T+r)[1 + \alpha\beta(T+r)]^2$. Then since W^* satisfies the identity $W^* = -X^* - X^*W^*$, we have

$$|W_-(t, \theta)| \leq |X_-(t, \theta)| + \int_{-r}^T |X_-(t, \sigma) W_-(\sigma, \theta)| d\sigma \quad \text{a.e. } t, \theta.$$

Hence,

$$\begin{aligned} \int_{-r}^T |W_-(t, \theta)|^2 d\theta &\leq \int_{-r}^T |X_-(t, \theta)|^2 d\theta + 2 \int_{-r}^T |X_-(t, \theta)| \int_{-r}^T |X_-(t, s)| |W_-(s, \theta)| ds d\theta \\ &\quad + \int_{-r}^T \left[\int_{-r}^T |X_-(t, s)| |W_-(s, \theta)| ds \right]^2 d\theta \\ &\leq \tilde{\alpha} + 2\tilde{\alpha} |W_-|_{HS} + \tilde{\alpha} |W_-|_{HS}^2 \\ &\leq \tilde{\alpha} (1 + \alpha|K|_{HS})^2 \quad \text{a.e. } t. \end{aligned}$$

Thus,

$$(3.14) \quad \operatorname{ess\,sup}_t \int_{-r}^T |W_-(t, \theta)|^2 d\theta \leq \beta^2(T+r)[1 + \alpha\beta(T+r)]^4.$$

Now (3.12) also implies that

$$I + X = (I + W^*)(I + K).$$

Subtracting the identity and applying p_- yields

$$W^* + K_- + [W^*K]_- = 0.$$

Hence,

$$\begin{aligned} |W_-(t, \theta)| &\leq |K(t, \theta)| + \int_{-r}^T |W_-(t, s)| |K(s, \theta)| ds \\ &\leq \beta \left\{ 1 + (T+r)^{1/2} \operatorname{ess\,sup}_t \left[\int_{-r}^T |W_-(t, s)|^2 ds \right]^{1/2} \right\}. \end{aligned}$$

The result follows from (3.14). \square

As the result above may be regarded as the L_∞ analogue of Corollary 2.3, the next proposition is the L_∞ analogue of Corollary 2.4. The notation $X, W, X_\pm(t, s)$ and $W_\pm(t, s)$ will have the same meaning below as in the preceding proposition.

PROPOSITION 3.5. *Let K be as in the proposition above and let $\{K_n\}$ denote a sequence of integral operators on U with essentially bounded kernels $K_n(t, s)$ such that*

$$\operatorname{ess\,sup}_{t,s} |K_n(t, s)| \leq \delta$$

and

$$\lim_n \operatorname{ess\,sup}_{t,s} |K_n(t, s) - K(t, s)| = 0.$$

Assume further that $K_n \geq 0$ for each n so that $I + K_n$ has the factorization

$$I + K_n = (I + X_n^*)(I + X_n) \quad (\text{with } X_n \text{ causal}).$$

Let $W_n(t, s)$ denote the kernel of the integral operator $(I + X_n)^{-1} - I$. Then

$$\lim_n \operatorname{ess\,sup}_{t,s} |W_n(t, s) - W_+(t, s)| = 0.$$

Proof. First write $I + K_n = I + K + (K_n - K)$ so that

$$(3.15) \quad I + K_n = (I + X_-)(I + A_n)(I + X_+)$$

where $A_n = (I + X^*)^{-1}(K_n - K)(I + X)^{-1}$. By Proposition 3.4 $\operatorname{ess\,sup}_{t,s} |W_\pm(t, s)| \leq \alpha$ for some $\alpha < \infty$. Now since $I + K_n$ has the factorization, so does $I + A_n$. Specifically, $I + A_n = (I + Y_n^*)(I + Y_n)$ where $I + Y_n = (I + X_n)(I + W)$. It then follows from the identity

$$I + P_t A_n P_t = (I + P_t Y_n^* P_t)(I + P_t Y_n P_t)$$

that

$$\begin{aligned} \sup_t |(I + P_t A_n P_t)^{-1}| &\leq \sup_t |(I + P_t Y_n P_t)^{-1}|^2 \\ &\leq (1 + |W_n|)^2 \sup |(I + P_t W P_t)^{-1}|^2 \\ &\leq (1 + |K_n|_{HS})^2 [\exp \{ \tfrac{1}{2}(1 + |K|_{HS}^2) \}]^2. \end{aligned}$$

Here we have used Corollary 2.3 to obtain the first term in the product, and the fact that W is Hilbert-Schmidt and quasinilpotent together with [7, p. 1039] and

Corollary 2.3 to obtain the second term. Now define $Z_n = (I + Y_n)^{-1} - I$ and let $Z_n(t, s)$ denote its kernel. Then since

$$\operatorname{ess\,sup}_{t,s} |A_n(t, s)| \leq \beta_n [1 + \alpha(T+r) + \alpha^2(T+r)^2]$$

where $\beta_n = \operatorname{ess\,sup}_{t,s} |K(t, s) - K_n(t, s)|$ and $\alpha \geq \operatorname{ess\,sup}_{t,s} |W_{\pm}(t, s)|$, Proposition 3.4 implies that

$$\operatorname{ess\,sup}_{t,s} Z_n(t, s) \leq \rho(\tilde{\alpha}_n, \tilde{\beta}_n)$$

with

$$\tilde{\beta}_n = \beta_n [1 + \alpha(T+r) + \alpha^2(T+r)^2]$$

and

$$\tilde{\alpha}_n = [1 + |K_n|_{HS}]^2 [\exp \{ \frac{1}{2} (1 + |K|_{HS}^2) \}]^2.$$

Finally, note that

$$W_n = W + Z_n + WZ_n,$$

so that

$$\operatorname{ess\,sup}_{t,s} |W_n(t, s) - W_+(t, s)| \leq \rho(\tilde{\alpha}_n, \tilde{\beta}_n) [1 + (T+r)\alpha].$$

But $\rho(\tilde{\alpha}_n, \tilde{\beta}_n) = O(\beta_n)$. This completes the proof. \square

Before proceeding to the main result of the section, we state the following “open loop” result concerning convergence of the approximate control sequence and trajectories. Below, Z again denotes the space $L_{\infty}([-r, T], R^N)$. (See [34] for proof.)

THEOREM 3.6. *Let B denote the unit ball in $C([-r, 0], R^N)$, and for $\phi \in B$ let $\hat{u}_n(\phi)$ and $\hat{u}(\phi)$ denote the optimal controls for problems \mathcal{P}_n and \mathcal{P} , respectively. Also let $\hat{x}_n(\phi)$ and $\hat{x}(\phi)$ denote the corresponding trajectories. Then uniformly on B ,*

$$(i) \quad \lim_n |\hat{u}_n(\phi) - \hat{u}(\phi)|_z = 0,$$

$$(ii) \quad \lim_n |\hat{x}_n(\phi) - \hat{x}(\phi)|_x = 0.$$

Next we present the convergence properties of the sequence of approximating feedback kernels.

THEOREM 3.7. *Let $P_n(t, \alpha)$ and $P(t, \alpha)$ denote the feedback kernels of Theorem 2.5 associated with problems \mathcal{P}_n and \mathcal{P} . Then,*

$$(i) \quad \lim_n \operatorname{ess\,sup}_{t,\alpha} |P_n(t, \alpha) - P(t, \alpha)| = 0,$$

$$(ii) \quad \lim_n \operatorname{ess\,sup}_t |P_n(t, t) - P(t, t)| = 0.$$

Proof. From (2.13)–(2.14) we can write

$$(3.16) \quad \begin{aligned} |P_n(t, \alpha) - P(t, \alpha)| \leq & \sum_{i=0}^k \left\{ \left| \int_{\alpha}^T [K_{n,i}(t, s) - K_i(t, s)] Y(s, \alpha) d\mu_n(s) \right| \right. \\ & \left. + \left| \int_{\alpha}^T K_i(t, s) Y(s, \alpha) d(\mu - \mu_n)(s) \right| \right\} \end{aligned}$$

where

$$K_{n,i}(t, s) = f'_i(s, t)Q(s) + \int_t^{s-r_i} W_n(t, \theta) f'_i(s, \theta) Q(s) d\theta$$

and

$$K_i(t, s) = f'_i(s, t)Q(s) + \int_t^{s-r_i} W(t, \theta) f'_i(s, \theta) Q(s) d\theta.$$

Now note that

$$|K_{n,i}(t, s) - K_i(t, s)| \leq \int_t^{s-r_i} |W_n(t, \theta) - W(t, \theta)| |f'_i(s, \theta)| |Q(s)| d\theta.$$

Lemma 3.3 and Proposition 3.5 imply that

$$\lim_n \operatorname{ess\,sup}_{t, \theta} |W_n(t, \theta) - W(t, \theta)| = 0.$$

And since $|f'_i(s, \theta)|$ and $|Q(s)|$ are uniformly bounded, routine arguments yield a measurable set $\Omega x[-r, T]$ whose complement has zero Lebesgue measure such that $K_{n,i}(t, s) \rightarrow K_i(t, s)$ uniformly on $\Omega x[-r, T]$.

By the uniform boundedness of $Y(s, \alpha)$ and the sequence of measures μ_n , it follows that the first integral in (3.16) tends to zero uniformly on $\Omega x[-r, T]$. To prove convergence of the second integral in (3.16) we argue as in Lemma 3.2. Define the family of functions $\{\tilde{Y}\}$ parameterized by α and β ,

$$\tilde{Y}(s, \alpha, \beta) = \begin{cases} Y(s, \alpha), & s \geq \beta, \\ Y(\beta, \alpha), & s < \beta \end{cases}$$

and the family of functions $\{\tilde{K}_i\}$ parameterized by t and τ ,

$$\tilde{K}_i(t, \tau, s) = \begin{cases} K_i(t, s), & s \geq \tau, \\ K_i(t, \tau), & s < \tau. \end{cases}$$

It is straightforward to verify using the properties of K_i and Y that the set

$$\{\tilde{K}_i(t, \delta, \cdot) \tilde{Y}(\cdot, \alpha, \delta) : \delta = \max\{\alpha, t + r_i\}\}$$

is relatively compact in $C([-r, T], R^{M \times N})$. Thus the argument in Lemma 3.2 applies here to demonstrate in the second integral that

$$\lim_n \operatorname{ess\,sup}_{t, \alpha} \left| \int K_i(t, s) Y(s, \alpha) d(\mu_n - \mu)(s) \right| = 0.$$

The theorem is proved. \square

4. Applications. In this section we begin by deriving the optimal feedback kernel associated with an arbitrary discrete state cost penalty. It will be evident that given the fundamental matrix $Y(t, s)$, the feedback kernel in this case can be derived by quadrature and matrix inversion. This feedback structure when combined with the results of the preceding section leads to approximations to the optimal feedback kernel of problem \mathcal{P} (recall (3.1)–(3.3)), a Wiener–Hopf characterization of this kernel, and a priori bounds on its magnitude.

Let β denote a positive discrete measure on $[-r, T]$ of the form

$$\int f d\beta = f(s_n) + \sum_i a_i f(s_i), \quad s_i \in [-r, T], \quad s_n = T.$$

Inserting this measure into (2.2) results in the cost

$$(4.1) \quad J(u, x) = \langle x(T), Q(T)x(T) \rangle + \sum_i a_i \langle x(s_i), Q(s_i)x(s_i) \rangle + \int_{-r}^T |u(s)|^2 ds.$$

The optimal feedback kernel for this cost has the following semiseparable¹ structure.

THEOREM 4.1. Define the matrix functions $G(t)$ and $\bar{Y}(t)$,

$$G(t) = [\sqrt{a_0}F'(s_0, t); \cdots; \sqrt{a_{n-1}}F'(s_{n-1}, t); F'(s_n, t)]',$$

$$\bar{Y}(t) = [\sqrt{a_0}Y'(s_0, t); \cdots; \sqrt{a_{n-1}}Y'(s_{n-1}, t); Y'(s_n, t)]'.$$

Also define the block diagonal matrix \tilde{Q} by

$$\tilde{Q} = \text{diag}(Q(s_0), \cdots, Q(s_n)).$$

Then the optimal feedback kernel $P(t, \alpha)$ for the problem with dynamics (2.1) and cost (4.1) can be expressed as

$$(4.2) \quad P(t, \alpha) = G'(t)\tilde{Q}[I + U(t)]^{-1}\bar{Y}(\alpha)$$

where

$$(4.3) \quad U(t) = \int_t^T G(s)G'(s)\tilde{Q}ds.$$

Proof. It is straightforward to verify that the map F^*F resulting from the measure β in (4.1) is an integral operator with separable kernel $G'(t)\tilde{Q}G(s)$. Now Theorem 2.5 implies that

$$P(t, \alpha) = \sum_{s_i \cong \alpha} a_i K(t, s_i) Y(s_i, \alpha).$$

Here

$$K(t, s_i) = F'(s_i, t)Q(s_i) + \int_t^T W_-(t, r)F'(s_i, r)Q(s_i)dr$$

and $W_-(t, r)$ denotes the kernel of the anticausal operator W^* in the factorization

$$(I + F^*F)^{-1} = (I + W)(I + W^*).$$

Using the fact that F^*F has a separable kernel, it can be verified [11, p. 188] that

$$W_-(t, r) = -G'(t)\tilde{Q}[I + U(t)]^{-1}G(r)$$

with $U(t)$ defined as in (4.3). Thus we can write

$$P(t, \alpha) = \sum \left\{ \sqrt{a_i}F'(s_i, t)Q(s_i) - G'(t)\tilde{Q}[I + U(t)]^{-1} \cdot \int_t^T G(r)\sqrt{a_i}F'(s_i, r)Q(s_i)dr \right\} \sqrt{a_i}Y(s_i, \alpha).$$

Noting the definitions of G , \bar{Y} and U , it follows that

$$\begin{aligned} P(t, \alpha) &= [G'(t)\tilde{Q} - G'(t)\tilde{Q}[I + U(t)]^{-1}U(t)]\bar{Y}(\alpha) \\ &= G'(t)\tilde{Q}[I + U(t)]^{-1}\bar{Y}(\alpha). \end{aligned}$$

□

¹ The kernel $K(t, s)$ of an integral operator K is semiseparable if there exist matrix functions $H_i(t)$ and $G_i(s)$, $i = 1, 2$, such that $K(t, s) = H_1(t)G_1(s)$ for $s < t$, and $K(t, s) = H_2(t)G_2(s)$ for $s \geq t$. The kernel is separable if we can choose $H_1 = H_2$ and $G_1 = G_2$. In this case the associated operator K has finite rank.

Note that if in (4.1) we take for $i \neq n$, $a_i = 0$, and let the operator B denote a multiplication operator, $Bu: t \rightarrow B(t)u(t)$, then (4.2) reduces to Manitius' result for terminal state penalty [20],

$$P(t, \alpha) = B'(t)Y'(T, t)Q(T) \left[I + \int_t^T Y(T, r)B(r)B'(r)Y'(T, r)Q(T) dr \right]^{-1} Y(T, \alpha).$$

Thus Theorem 4.1 can be viewed as an extension of this result to problems with control delay and arbitrary discrete state penalty.

Now let μ_n be a sequence of discrete positive measures satisfying (H1) and (H2), and let $P_n(t, \alpha)$ denote the corresponding feedback kernels. The theorem implies each $P_n(t, \alpha)$ has the semiseparable form (4.2), while Theorem 3.7 implies the L_∞ -convergence of $P_n(t, \alpha)$ to $P(t, \alpha)$ (the optimal feedback kernel for problem \mathcal{P}) and also the L_∞ -convergence of $P_n(t, t)$ to $P(t, t)$. Introducing subscripts in the obvious way, define for each n ,

$$V_n(t) = [I + U_n(t)]^{-1} - I,$$

so that the identity

$$V_n(t) = -U_n(t)[I + U_n(t)]^{-1}$$

holds. Multiplying by $G'_n(t)\tilde{Q}_n$ we obtain

$$G'_n(t)\tilde{Q}_n V_n(t) = -G'_n(t)\tilde{Q}_n [I + U_n(t)]^{-1} U_n(t).$$

If we use the definitions of U_n and multiply by \bar{Y}_n it follows that

$$(4.4) \quad G'_n(t)\tilde{Q}_n V_n(t)\bar{Y}_n(\alpha) = \int_t^T G'_n(t)\tilde{Q}_n [I + U_n(t)]^{-1} G_n(r)G'_n(r)\tilde{Q}_n dr \bar{Y}_n(\alpha).$$

From (4.2) and the definition of V_n we have for $\alpha \geq t$,

$$P_n(t, \alpha) - G_n(t)Q_n\bar{Y}_n(\alpha) = G_n(t)Q_n\bar{Y}_n(\alpha).$$

And substituting (4.4) into the above,

$$(4.5) \quad P_n(t, \alpha) = G'_n(t)\tilde{Q}_n\bar{Y}_n(\alpha) - \int_t^T G'_n(t)\tilde{Q}_n [I + U_n(t)]^{-1} G_n(r)G'_n(r)\tilde{Q}_n dr \bar{Y}_n(\alpha).$$

Now let P_n denote the integral operator with kernel $P_n(t, \alpha)$. We then recognize $G'_n(t)\tilde{Q}_n [I + U_n(t)]^{-1} G_n(r)$, with $r \geq t$, as the kernel of the operator $[P_n B]_-$. Also $G'_n(t)\tilde{Q}_n\bar{Y}_n(\alpha)$ is recognized as the kernel of $F_n^* Y$, where Y is the operator in $B(H, X)$ defined

$$(4.6) \quad Yu: t \rightarrow \int_0^t Y(t, s)u(s) ds.$$

Thus (4.5) represents the Wiener-Hopf equation

$$P_n = [F_n^* Y]_- - [(P_n B) - F_n^* Y]_-.$$

Let P denote the operator with kernel $P(t, \alpha)$. Then since $P_n \rightarrow P$ and $F_n^* Y \rightarrow F^* Y$ in the Hilbert-Schmidt topology (the latter convergence is essentially Lemma 3.3), by continuity of the projection p_- on the space of Hilbert-Schmidt operators we obtain

$$(4.7) \quad P = [F^* Y]_- - [(PB) - F^* Y]_-.$$

This discussion is formalized in the following corollary.

COROLLARY 4.2. *The Wiener-Hopf equation (4.7) has a unique Hilbert-Schmidt solution P . A version of the kernel of P is the optimal feedback kernel for the optimization problem (3.1)–(3.2). Furthermore, this version of the kernel can be approximated in the L_∞ topology on the diagonal as well as the square by the semiseparable kernels $P_n(t, \alpha)$.*

Proof. We only need to establish the uniqueness assertion. Suppose there exist two solutions of (4.7) and let δ denote their difference. We then obtain

$$\delta + [(\delta B)_- FY]_- = 0.$$

Clearly it suffices to show that $(\delta B)_- = 0$. Define $\tilde{\delta} = -(\delta B)_- FY$ so that $\tilde{\delta}_- = \delta$. Then since B is causal it follows that $[\tilde{\delta} B]_- = [\delta B]_-$ and $\tilde{\delta} + [\tilde{\delta} B]_- F^* Y = 0$. Multiplying this latter equality on the right by B and noting that $YB = F$ (cf. (3.6) and (4.6)), we obtain the identity

$$(4.8) \quad [\tilde{\delta} B]_- + [(\tilde{\delta} B)_- F^* F]_- = 0.$$

We will show that zero is the only solution to the equation

$$X + [XF^* F]_- = 0,$$

thus proving $[\delta B]_- = 0$, and the result.

Now (4.8) is equivalent to

$$[X(I + F^* F)]_- = 0,$$

with X anticausal. Since $F^* F \geq 0$, there exists a causal Hilbert-Schmidt map V such that $I + F^* F = (I + V^*)(I + V)$. Thus X solves (4.8) if and only if Z solves

$$(4.9) \quad Z + [ZV]_- = 0.$$

(These solutions are related: $X = Z(I + V^*)^{-1}$.) Next consider the operator Ω on the space of Hilbert-Schmidt operators defined by $\Omega: Z \rightarrow [ZV]_-$ with V as above. Then (4.9) is equivalent to $(I + \Omega)Z = 0$. By induction we find

$$\Omega^n(Z) = [ZV^n]_-,$$

so that

$$|\Omega^n(Z)| \leq |Z|_{HS} |V^n|.$$

But V is quasinilpotent, and hence so is Ω . Thus the only solution to (4.9) is $Z = 0$, and the theorem is proved. \square

We note that the existence portion of the corollary was proved in a different manner in [24].

When B is a multiplication operator, $[PB]_- = PB$, so (4.7) reduces to

$$P = [F^* Y]_- - [PBF^* Y]_-.$$

The kernel of $F^* Y$ is of the form $B'(t)A(t, s)$ where

$$A(t, s) = \int_{\max(t, s)}^T Y'(r, t)Q(r)Y(r, s) dr + Y'(T, t)Q(T)Y(T, s).$$

Let A denote the operator with kernel $A(t, s)$ and note that $F^* Y = B^* A$. Next consider the following modification to the Wiener-Hopf equation (4.7),

$$(4.10) \quad \Pi = A_- - [\Pi B B^* A]_-.$$

Using the same techniques as in the proof of Corollary 4.2 it is possible to show that (4.10) has a unique Hilbert-Schmidt solution Π_0 . Also note that the corollary implies that $B^*\Pi_0 = P$. The Wiener-Hopf equation (4.10) is equivalent to the parameterized family of Fredholm equations Manitius [20] derived via a maximum principle for obtaining the feedback kernels:

$$(4.11) \quad \Pi(t, s) = A(t, s) - \int_t^T \Pi(t, \theta) B(\theta) B'(\theta) A(\theta, s) d\theta.$$

Corollary 4.2 extends this Wiener-Hopf characterization of the feedback kernel to problems with control delays, and simultaneously provides approximate solutions.

The special factorization has been previously exploited in solving Wiener-Hopf equations on finite intervals of the type (4.10), (4.11) that arise in inverse problems in the spectral theory of differential operators [8], [18], and in the filtering and smoothing problems for nonstationary processes [15], [16]. The corollary is in a sense a solution finding the right Wiener-Hopf problem.

Now we return to the original problem (3.1)–(3.3) and consider a specific sequence of measures for generating approximations to the optimal feedback kernel.

Let $\{\mu_n\}$ denote the sequence of measures

$$(4.12) \quad \int f d\mu_n = f(T) + (T+r)/n \sum_{i=0}^{n-1} f(i(T+r)/n - r).$$

This sequence is easily shown to satisfy (H1) and (H2). Now suppose the majorizing function $m(t)$ (cf. (2.3)) is bounded and the weighting function $Q(\cdot)$ has a bounded derivative. Letting $P_n(t, \alpha)$ denote the feedback kernel corresponding to the cost with measure μ_n , it is straightforward (although tedious) to derive a constant C from the estimates in § 3 such that

$$(4.13) \quad \begin{aligned} \text{ess sup}_{t, \alpha} |P(t, \alpha) - P_n(t, \alpha)| &\leq C/n, \\ \text{ess sup}_t |P(t, t) - P_n(t, t)| &\leq C/n. \end{aligned}$$

We can also use the approximations $P_n(t, \alpha)$ to obtain the following a priori bound on $|P(t, \alpha)|$ (see [34]):

$$|P(t, \alpha)| \leq (T+r+1) \sup_s |Q(s)| \sup_s |F(s, t)|_{HS} \sup_s |Y(s, \alpha)|_{HS}$$

where $|\cdot|_{HS}$ denotes the Hilbert-Schmidt matrix norm (the square root of the sum of the squares of the matrix elements). When the system (3.1)–(3.4) is time-invariant and stable, a bound independent of T can be established. If we assume for simplicity that

$$Bu: t \rightarrow B_0 u(t) + \int_{t-r}^t B(t-s) u(s) ds$$

and $|B_0|, \sup |B(t)| < b$, then it can be shown that [34]

$$|P(t, \alpha)| \leq |Q| b(1 + \sqrt{2r}) \int_0^\infty |Y(t)|^2 dt.$$

(Note that for the system to be time-invariant, $Q = \text{constant}$ and $Y(t, s) = Y(t-s)$.)

5. Algorithms. In this section we will examine in greater detail algorithms based on Theorem 4.1, with particular attention to time-invariant systems. We note that it has already been observed that combining (4.2) with the discretizations (4.12) produces

(in most cases) an $O(1/n)L_\infty$ -convergence of the feedback kernels,² regardless of the presence of control delays. However computing these kernels presupposes having the fundamental matrix $Y(\cdot, \cdot)$ in hand. In the general time-varying case with discrete state cost at the nodes $\{s_i\}$, $i = 1, \dots, n$, this amounts to solving the $n+1$ Volterra equations

$$(5.1) \quad Y(s_i, \sigma) = I - \int_{\sigma}^{s_i} Y(s_i, u) \eta(u, \sigma - u) du.$$

In the time-invariant case these computations reduce to the single equation

$$(5.2) \quad Y(t) = I - \int_0^t Y(u) \eta(u - t) du.$$

Once we have solutions (5.1) or (5.2), the feedback structure (4.2) is straightforward and can be computed from quadrature, matrix inversion and multiplication.

Of course we are not constrained to directly solving (5.1) or (5.2), and we can use other methods for obtaining the fundamental solution—e.g., state approximation methods [2], [3], the method of steps [26], [27] or other available methods for solving Volterra functional differential equations [28]–[30]. Having said this, we assume throughout this section that the functions $Y(t, s)$ and $F(t, s)$ have been computed. (A few issues associated with these computations will be addressed later.)

One straightforward implementation of (4.2) consists in defining the grid $\{s_i\}_{i=0}^n$ so that $s_i - s_{i-1} = \Delta = T/n$, taking $a_i = \Delta$, and replacing the integral in (4.3) by a first order Euler quadrature with nodes $\{s_i\}$. To see where this leads us, first write $P(t, \alpha)$ in the more symmetrical fashion

$$P(t, \alpha) = G'(t) \tilde{Q}^{1/2} [I + U(t)]^{-1} \tilde{Q}^{1/2} \bar{Y}(\alpha),$$

where

$$U(t) = \tilde{Q}^{1/2} \int_t^T G(s) G'(s) ds \tilde{Q}^{1/2}.$$

Let $\hat{U}(s_i)$ denote the approximation to $U(s_i)$,

$$\hat{U}(s_i) = \sum_{j \geq i} \Delta \tilde{Q}^{1/2} G(s_j) G'(s_j) \tilde{Q}^{1/2}$$

and form the approximations $\{\hat{P}(s_i, s_j)\}_{j \geq i}$ to $\{P(s_i, s_j)\}_{j \geq i}$,

$$(5.3) \quad \hat{P}(s_i, s_j) = G'(s_i) \tilde{Q}^{1/2} [I + \hat{U}(s_i)]^{-1} \tilde{Q}^{1/2} \bar{Y}(s_j).$$

Now note that

$$[I + \hat{U}(s_{i-1})]^{-1} = [I + \hat{U}(s_i) + \Delta \tilde{Q}^{1/2} G(s_i) G'(s_i) \tilde{Q}^{1/2}]^{-1}$$

and that

$$\text{Rank}(\Delta \tilde{Q}^{1/2} G(s_i) G'(s_i) \tilde{Q}^{1/2}) \leq M.$$

(Recall that M = dimension of the input space.) Thus, using the matrix identity,

$$(X + YY')^{-1} = X^{-1} - X^{-1} Y (Y' X^{-1} Y + I)^{-1} Y' X^{-1}$$

² It is unfortunate that although this convergence is obtained using a first-order quadrature scheme, it is not a priori evident that employing a higher order scheme would result in improved convergence. The stumbling block is that the convergence analysis we have used is based on properties of the fundamental matrix, which is generally only absolutely continuous, and thus precludes any straightforward extensions.

for compatible matrices X and Y , it follows that $(I + \hat{U}(s_{i-1}))^{-1}$ can be updated from $(I + \hat{U}(s_i))^{-1}$ in about $2MN^2n^2$ operations. Further, exploiting the semiseparable structure of $P(\cdot, \cdot)$, a rough operation count shows that $\{\hat{P}(s_i, s_j)\}_{j \geq i}$ can be computed in approximately $3MN^2n^3$ operations when $M \leq N \ll n$.

Considering that there are more than $MNn^2/2$ values in the matrices $\{\hat{P}(s_i, s_j)\}_{j \geq i}$, this algorithm is fairly efficient. However, we will subsequently show that it is possible to do substantially better in the time-invariant case. (We will also provide a more complete analysis in this case.)

For the remainder of this section we consider the problem defined by the dynamics

$$(5.4) \quad \begin{aligned} \dot{x}(t) &= \int_{-r}^0 d\eta(\theta) x(t+\theta) + \sum_{i=0}^k B_i u(t-r_i) + \int_{t-r}^t B(t-\theta) u(\theta) d\theta, & t \geq 0, \\ x(t) &= \phi(t), & t \in [-r, 0], \\ u(t) &= 0, & t \in [-r, 0] \end{aligned}$$

and cost

$$(5.5) \quad J(u, x) = \int_0^T \langle x(s), Qx(s) \rangle + |u(s)|^2 ds.$$

The assumptions here are the same as in (3.1)–(3.4), except that now everything is time-invariant. (Previously the lower limit in the integral defining the cost J was taken as $-r$. This served as a notational expediency in the preceding sections, which we dispense with in the present section.)

We will explicitly consider the discretizations of J ,

$$(5.6) \quad J_n = \sum_{i=0}^{n-1} \Delta \langle x(s_i), Qx(s_i) \rangle + \int_0^T |u(s)|^2 ds$$

where $\{s_i\}_{i=0}^n$ is a regular partition of the interval $[0, T]$ with mesh $\Delta = s_{i+1} - s_i = T/n$. (Although the mesh points of the partition change with n , we will not double subscript the s_i . This will not lead to any confusion in the sequel.) We will also assume that the point delays in the control, $r_i, i = 1, \dots, k$, correspond to some subset of the $\{s_i\}, i = 0, \dots, n$.

Again we let $P_n(\cdot, \cdot)$ denote the optimal feedback kernel for cost J_n and let $P(\cdot, \cdot)$ denote the optimal feedback kernel for cost J . In the time-invariant case $\text{Var} |\eta(\cdot)|$ and $Q(\cdot)$ are constant, so that (4.13) holds for the sequence $\{P_n(\cdot, \cdot)\}$. The particular algorithm which we will be developing is based on approximately $P_n(\cdot, \cdot)$ at the mesh points $\{s_i\}$; thus it is first necessary to prove that (4.13) actually holds everywhere. Before showing this we need some notation and a couple of simple observations.

For any matrix M , as before $|M|_{HS}$ denotes the Hilbert–Schmidt norm of M (the square root of the sum of the squares of its entries), and for specificity we write $|M|_2$ for the operator norm of M with respect to the corresponding Euclidean metrics. Note that $|M|_{HS} \geq |M|_2$.

The fundamental matrix solution $Y(t, \alpha)$ to (5.4) (cf. (2.7)) has the form $Y(t, \alpha) = Y(t - \alpha)$. We set

$$(5.7) \quad \gamma_Y = \sup_{t \in [0, T]} |Y(t)|_{HS},$$

and using [12, p. 149] we note that

$$(5.8) \quad |Y(t) - Y(s)|_{HS} = O(|t - s|), \quad t, s \in [0, T].$$

Similarly $F(t, s)$ (cf. (3.6)) is a difference kernel, $F(t, s) = F(t - s)$, and using (5.7) and (5.8) we have

$$(5.9) \quad \sup_{t \in [0, T]} |F(t)|_{HS} = \gamma_F < \infty$$

and

$$(5.10) \quad |F(t) - F(s)|_{HS} = O(|t - s|) \quad \text{when } t, s \in (r_i, r_{i+1}) \quad \text{for some } i, 0 \leq i \leq k-1.$$

LEMMA 5.1. *Let $P(t, \alpha)$ denote the optimal feedback kernel for the problem (5.4)–(5.5). Then*

$$|P(t, \alpha) - P(t', \alpha')| = O(|t - t'| + |\alpha - \alpha'|).$$

Proof. From Theorem 2.5 we have

$$P(t, \alpha) = \int_{\alpha}^T K(t, s) Y(s - \alpha) ds,$$

where

$$K(t, s) = F'(s - t)Q + \int_t^s W_{-}(t, \sigma) F'(\sigma - s) Q d\sigma.$$

Since $\sup_{t,s} |K(t, s)| < \infty$ (cf. Proposition 3.4 and (5.9)), it follows from (5.8) that

$$|P(t, \alpha) - P(t, \alpha')| < K_1 |\alpha - \alpha'|$$

for some constant K_1 independent of t, α, α' . Thus using (5.7) it remains to show the existence of a constant K_2 such that

$$\int |K(t_2, s) - K(t_1, s)| ds \leq K_2 |t_2 - t_1|.$$

Now $F(t)$ has only a finite number of jump discontinuities, so (5.9) and (5.10) imply

$$\int |F(s - t_2) - F(s - t_1)| ds = O(|t_2 - t_1|).$$

Hence, it is only necessary to verify that

$$(5.11) \quad \int |W_{-}(t_2, \sigma) - W_{-}(t_1, \sigma)| d\sigma = O(|t_2 - t_1|).$$

To this end let W^* denote the operator with kernel $W_{-}(t, \sigma)$ and let $X^* = (I + W^*)^{-1} - I$. Denote the kernel of X^* by $X_{-}(t, s)$. Also let W and X denote the adjoints of W^* and X^* respectively, with respective kernels $W_{+}(t, s)$ and $X_{+}(t, s)$. Now the factorization (recall Theorem 2.5)

$$I + F^* F = (I + X^*)(I + X)$$

implies

$$(5.12) \quad X^* = [F^* F]_{-} + [F^* F W]_{-},$$

where $F^* F$ has kernel $H(t, s)$,

$$H(t, s) = \int_{\max(t, s)}^T F'(\sigma - t) Q F(\sigma - s) d\sigma.$$

Note that

$$(5.13) \quad |H(t_2, s) - H(t_1, s)| = O(|t_2 - t_1| + |s_2 - s_1|).$$

Now (5.12) is equivalent to

$$X_-(t, s) = H(t, s) + \int_s^T H(t, \theta) W_+(\theta, s) d\theta \quad \text{a.e. } s, t.$$

Because $H(t, s)$ is continuous, $X_\pm(t, s)$, $W_\pm(t, s)$ are also continuous [11], and the equation above holds pointwise. Thus (5.13) and the triangle inequality imply

$$|X_-(t_2, s) - X_-(t_1, s)| = O(|t_2 - t_1|)$$

independently of s . Then (5.11) follows from the estimate above and the resolvent identity

$$W_-(t, s) + X_-(t, s) + \int_t^s X_-(t, \theta) W_-(\theta, s) d\theta = 0. \quad \square$$

PROPOSITION 5.2.

$$\sup_{t, \alpha \in (0, T]} |P_n(t, \alpha) - P(t, \alpha)| = O(1/n).$$

Proof. Using the identity

$$A[I + BA]^{-1} = A^{1/2}[I + A^{1/2}BA^{1/2}]^{-1}A^{1/2}$$

for $A, B \geq 0$, write the feedback kernel (from Theorem 4.1) as

$$(5.14) \quad P_n(t, \alpha) = \underline{F}'_n(t)[I + \underline{U}_n(t)]^{-1}\underline{Y}_n(\alpha)$$

where

$$(5.15) \quad \underline{F}(t) = \Delta^{1/2}[F'(s_0 - t)Q^{1/2} \cdots F'(T - t)Q^{1/2}]',$$

$$(5.16) \quad \underline{U}_n(t) = \int_t^T \underline{F}_n(\sigma) \underline{F}'_n(\sigma) d\sigma$$

and

$$(5.17) \quad \underline{Y}_n(\alpha) = \Delta^{1/2} \begin{bmatrix} Q^{1/2} Y(s_0 - \alpha) \\ \vdots \\ Q^{1/2} Y(T - \alpha) \end{bmatrix}.$$

Note the following bounds independent of n (recall (5.7) and (5.9)):

$$(5.18) \quad \sup_{\alpha} |\underline{Y}_n(\alpha)|_{HS}^2 \leq T |Q^{1/2}|_{HS}^2 \gamma_Y^2,$$

$$(5.19) \quad \sup_t |\underline{F}_n(t)|_{HS}^2 \leq T |Q^{1/2}|_{HS}^2 \gamma_F^2,$$

$$(5.20) \quad \sup_t |(I + \underline{U}_n(t))^{-1}|_2 \leq 1.$$

Now fix $(t_0, \alpha_0) \in (0, T] \times (0, T]$ with $t_0 \leq \alpha_0$. Then there exist indices i, j such that $(t_0, \alpha_0) \in (s_{i-1}, s_i] \times (s_{j-1}, s_j]$, $i \leq j$. From (5.8) we obtain

$$(5.21) \quad \begin{aligned} |\underline{Y}_n(s_j) - \underline{Y}_n(\alpha_0)|_{HS} &\leq \left[\sum_{k \geq j}^n \Delta |Y(s_k - s_j) - Y(s_k - \alpha_0)|_{HS}^2 \right]^{1/2} |Q^{1/2}| \\ &= \left[\sum_{k \geq j}^n \Delta |Y(s_k - \alpha_0 + \alpha_0 - s_j) - Y(s_k - \alpha_0)|_{HS}^2 \right]^{1/2} |Q^{1/2}| \\ &= O(1/n). \end{aligned}$$

Similarly, expressing $F(\cdot)$ as a sum (as in (3.6)) and using (5.10) we obtain

$$(5.22) \quad \|\underline{F}_n(s_i) - \underline{F}_n(t_0)\|_{HS} = O(1/n).$$

Next observe that

$$(5.23) \quad \|(I + \underline{U}_n(t_0))^{-1} - (I + \underline{U}_n(s_i))^{-1}\|_2 \leq \|(I + \underline{U}_n(t_0))^{-1}\|_2 \|\underline{U}_n(t_0) - \underline{U}_n(s_i)\|_{HS} \|(I + \underline{U}_n(s_i))^{-1}\|_2 \\ \leq \|\underline{U}_n(t_0) - \underline{U}_n(s_i)\|_{HS}.$$

But from (5.16) and (5.19) it follows that

$$(5.24) \quad \|\underline{U}_n(t_0) - \underline{U}_n(s_i)\|_{HS} = O(1/n).$$

Putting (5.21)–(5.24) together with the bounds (5.18)–(5.20), and using the triangle inequality, we get

$$(5.25) \quad \|P_n(t_0, \alpha_0) - P_n(s_i, s_j)\|_2 = O(1/n).$$

Then using the fact that (4.13) holds for a.e. t, α , and that the estimate (5.25) holds for any $(t_0, \alpha_0) \in (s_{i-1}, s_i] \times (s_{j-1}, s_j]$, Lemma 5.1 and the triangle inequality imply

$$\|P_n(t, \alpha) - P(t, \alpha)\|_2 = O(1/n)$$

for all $t, \alpha \in (0, T] \times (0, T]$. \square

Since the idea behind the algorithm defined in Theorems 5.3 and 5.4 is based on a relatively simple observation that gets somewhat obscured in the notation and proofs of the theorems, it is worthwhile here to briefly remark on this motivating idea.

If we return to the approximate gain defined in (5.3), it turns out that in the time-invariant case each $\hat{U}(s_i)$ is a principal minor of $\hat{U}(0)$. Thus what we would like to do is to invert $I + \hat{U}(0)$ via a recursion in which all of the principal minors of $I + \hat{U}(0)$ are also inverted. Now by inspection $\hat{U}(0)$ can be identified with the covariance matrix of the random process $\{\Delta^{1/2}\xi_i\}$,

$$\xi_i = \Delta \sum_{j=0}^{\infty} Q^{1/2} F((i-j)\Delta) \omega_j$$

where $E(\omega_i \omega_j') = \delta_{ij} I$. In the signal processing literature (see, for example, [31]) it is shown that processes of this type admit “fast” filter implementations due to their “near” Toeplitz covariance matrix structure. This is precisely the property we exploit.

THEOREM 5.3. Define the symmetric $N(n+1) \times N(n+1)$ matrix \hat{U}^n with $N \times N$ block entries \hat{U}_{ij}^n where (for $0 \leq j \leq i \leq n$)

$$\hat{U}_{ij}^n = \sum_{\sigma=0}^j \Delta^2 Q^{1/2} F((i-j)\Delta + \sigma\Delta) F'(\sigma\Delta) Q^{1/2}.$$

Let Z_n denote the matrix on $R^{N(n+1)}$,

$$Z_n = \begin{bmatrix} 0 & \cdots & 0 & 1 \\ 1 & \ddots & & 0 \\ \vdots & \ddots & \ddots & \\ 0 & & 1 & 0 \end{bmatrix},$$

and for each $p = 0, 1, \dots, n$, let $\Pi_{n,p}$ denote the projection

$$\Pi_{n,p}(x_1, \dots, x_{N(n+1)})' = (x_1 \cdots x_{N(p+1)}, 0, \dots, 0)'.$$

For $p, q = 0, 1, \dots, n$ define (recall $\Delta = T/n$)

$$\hat{P}_n(\Delta p, \Delta q) = \hat{X}_{n,n-p}' Z_n^{N(n+1-p)} Y_n(\Delta q)$$

where Y_n is defined in (5.17) and

$$\hat{X}_{n,p} = [I + \Pi_{n,p} \hat{U}^n \Pi_{n,p}]^{-1} \begin{bmatrix} \Delta^{1/2} Q^{1/2} F(0) \\ \vdots \\ \Delta^{1/2} Q^{1/2} F(\Delta p) \\ 0 \\ \vdots \\ 0 \end{bmatrix}.$$

Then

$$\max_{p \leq q} |\hat{P}_n(\Delta p, \Delta q) - P(\Delta p, \Delta q)|_2 = O(1/n), \quad p, q \in \{0, 1, \dots, n\}.$$

Proof. Recall the representation (5.14) for the optimal feedback kernel for cost J_n ,

$$P_n(t, \alpha) = F'_n(t) [I + U_n(t)]^{-1} Y_n(\alpha).$$

Thus we can write

$$(5.26) \quad P_n(\Delta p, \Delta q) = X'(\Delta p) Y_n(\Delta q)$$

where

$$(5.27) \quad X(\Delta p) = [I + U_n(\Delta p)]^{-1} \begin{bmatrix} 0 \\ \vdots \\ \Delta^{1/2} Q^{1/2} F(0) \\ \vdots \\ \Delta^{1/2} Q^{1/2} F((n-p)\Delta) \end{bmatrix}.$$

Note that $U_n(\Delta p)$ is an $N(n+1) \times N(n+1)$ symmetric matrix with $N \times N$ block entries $U_{i,j}^n(\Delta p)$, $i, j = 0, 1, \dots, n$ where (for $0 \leq j \leq i$)

$$(5.28) \quad U_{i,j}^n(\Delta p) = \begin{cases} \Delta Q^{1/2} \int_0^{(j-p)\Delta} F((i-j)\Delta + \sigma) F'(\sigma) d\sigma Q^{1/2}, & j \geq p, \\ 0 & \text{otherwise.} \end{cases}$$

For each $p = 0, 1, \dots, n$, let

$$(5.29) \quad X_{n,p} = [I + \Pi_{n,p} U_n(0) \Pi_{n,p}]^{-1} \begin{bmatrix} \Delta^{1/2} Q^{1/2} F(0) \\ \vdots \\ \Delta^{1/2} Q^{1/2} F(\Delta p) \\ 0 \\ \vdots \\ 0 \end{bmatrix}.$$

Observing that

$$U_{i+n-p, j+n-p}^n(\Delta(n-p)) = U_{i,j}^n(0), \quad i, j = 0, 1, \dots, p,$$

it follows from (5.27) and (5.29) that

$$X(\Delta(n-p)) = Z_n^{(n-p)N} X_{n,p}.$$

Therefore (using (5.26)),

$$P_n(\Delta p, \Delta q) = X'_{n,n-p} Z_n^{N(n+1-p)} Y_n(\Delta q).$$

Now,

$$|P_n(\Delta p, \Delta q) - P_n(\Delta p, \Delta q)|_2 \leq T^{1/2} |Q^{1/2}|_2 \gamma_Y |X_{n,n-p} - \hat{X}_{n,n-p}|_2.$$

(Here we have used (5.18).) But using (5.29) and the definitions of X and \hat{X} , we find that

$$|X_{n,n-p} - \hat{X}_{n,n-p}|_2 \leq T^{1/2} |Q^{1/2}|_2 \gamma_F |\hat{U}^n - U_n(0)|_{HS},$$

and

$$(5.30) \quad |\hat{U}^n - U_n(0)|_{HS} = \left[\sum_{i,j=0} |\hat{U}_{ij}^n - U_{ij}^n(0)|_{HS}^2 \right]^{1/2}.$$

It follows from (5.26) that

$$|\hat{U}_{ij}^n - U_{ij}^n(0)|_{HS} = O(\Delta^2)$$

independent of i, j . Thus the right side of (5.30) is $O(\Delta)$. Hence,

$$\max_{p,q} |P_n(\Delta p, \Delta q) - \hat{P}_n(\Delta p, \Delta q)|_2 = O(\Delta).$$

The result follows from the estimate above and Proposition 5.2. \square

Using the extended LWR algorithm [31] we will next show that $\{\hat{X}_{n,p}\}_{p=0}^n$ can be computed in a total of $O(n^2)$ operations. The theorem above represents the approximate gain in the form

$$\hat{P}_n(\Delta p, \Delta q) = X'_{n,n-p} Z_n^{N(n+1-p)} Y_n(\Delta q).$$

Now fixing p and letting q vary, we can view these products as a convolution. Since convolutions have fast implementations in $O(n \log n)$ operations, it will follow then that $\{\hat{P}(\Delta p, \Delta q)\}_{q \geq p}$ can be computed in $O(n^2 \log n)$ operations.

THEOREM 5.4. $\{\hat{X}_{n,p}\}_{p=0}^n$ can be computed in $O(n^2)$ operations.

Proof. By definition $\hat{X}_{n,p}$ satisfies

$$(5.31) \quad [I + \Pi_{n,p} \hat{U}^n \Pi_{n,p}] \hat{X}_{n,p} = \Pi_{n,p} F_n(0).$$

We will exhibit a fast recursion for solving (5.31). A simple calculation shows that

$$\hat{U}_{i+1,j+1}^n - \hat{U}_{i,j}^n = \Delta^2 Q^{1/2} F((i+1)\Delta) F'((j+1)\Delta) Q^{1/2}.$$

Therefore the matrix $\delta(\hat{U}^n)$ with block entries $\hat{U}_{i+1,j+1}^n - \hat{U}_{i,j}^n$, $i, j = 0, 1, \dots, n-1$, can be written:

$$\delta(\hat{U}^n) = \Delta^2 \begin{bmatrix} Q^{1/2} F(\Delta) \\ \vdots \\ Q^{1/2} F(n\Delta) \end{bmatrix} [F'(\Delta) Q^{1/2} \cdots F'(n\Delta) Q^{1/2}].$$

Consequently, $\text{rank}(\delta(\hat{U}^n)) \leq N \ll n$. Furthermore (and importantly [31]) $\delta(\hat{U}^n)$ has a factorization of the form

$$\delta(\hat{U}^n) = D \Sigma D'$$

with D an $nN \times N$ matrix and Σ an $N \times N$ signature matrix. In fact, this factorization

is easily done by inspection:

$$D = \Delta \begin{bmatrix} Q^{1/2}F(\Delta) & \overbrace{\begin{bmatrix} 0 \\ \vdots \\ 0 \end{bmatrix}}^{N-M} \\ \vdots & \\ Q^{1/2}F(n\Delta) & \end{bmatrix}, \quad \Sigma = I.$$

Therefore the LWR algorithm [31, p. 655] can be used to recursively compute the solutions M_p to

$$(5.32) \quad [I + \Pi_{n,p} \hat{U}^n \Pi_{n,p}] M_p = \begin{bmatrix} \hat{U}_{0,p+1}^n \\ \vdots \\ \hat{U}_{p,p+1}^n \\ 0 \\ \vdots \\ 0 \end{bmatrix},$$

$p = 0, 1, \dots, n$ in a total of $O(N^2 n^2)$ operations. With these solutions in hand we can argue as in the scalar Toeplitz case (see, for example, [32]) to recursively solve the system (5.31). These details are supplied below.

So now consider solving the problem

$$(5.33) \quad [I + \Pi_{n,p} \hat{U}^n \Pi_{n,p}] \hat{X}_{n,p} = \Pi_{n,p} F_n(0),$$

given $\hat{X}_{n,p-1}$ and M_{p-1} (from (5.32)).

Let F_p denote the $N(p+1) \times M$ matrix composed of the first $N(p+1)$ rows of $F_n(0)$, and let f_p denote the $N \times M$ matrix composed of the $Np+1$ through $N(p+1)$ rows of $F_n(0)$. Thus we can write

$$F_{p+1} = \begin{bmatrix} F_p \\ f_p \end{bmatrix}.$$

Let R_p denote the $N(p+1) \times N(p+1)$ matrix composed of the northwest corner of $I + \hat{U}^n$, and let r_p denote the $N \times N$ southeast corner of R_p . Also let $\underline{M}_p \in R^{N(p+1) \times N}$ denote the matrix consisting of the first $N(p+1)$ rows of M_p , and similarly let N_p denote the $N(p+1) \times M$ matrix consisting of the first $N(p+1)$ rows of $\hat{X}_{n,p}$.

Now define

$$u_{p+1} = \begin{bmatrix} \hat{U}_{0,p+1}^n \\ \vdots \\ \hat{U}_{p,p+1}^n \end{bmatrix},$$

and consider the equation

$$(5.34) \quad \begin{bmatrix} R_p & u_{p+1} \\ u'_{p+1} & r_{p+1} \end{bmatrix} \begin{bmatrix} \mu \\ \nu \end{bmatrix} = \begin{bmatrix} F_p \\ f_p \end{bmatrix}.$$

Note that

$$(5.35) \quad \begin{bmatrix} \mu \\ \nu \end{bmatrix} = N_{p+1}.$$

From the top of the equations in (5.34) we obtain

$$(5.36) \quad \mu = R_p^{-1} F_p - R_p^{-1} u_{p+1} \nu = N_p - \underline{M}_p \nu.$$

Substituting this into the bottom equation, we get

$$[r_{p+1} - u'_{p+1} \underline{M}_p] \nu = f_p - u_{p+1} N_p.$$

Noting that

$$\begin{aligned} 0 &< \begin{bmatrix} I & 0 \\ -\underline{M}'_p & I_{N \times N} \end{bmatrix} \begin{bmatrix} R_p & u_{p+1} \\ u'_{p+1} & r_{p+1} \end{bmatrix} \begin{bmatrix} I & -\underline{M}_p \\ 0 & I_{N \times N} \end{bmatrix} \\ &= \begin{bmatrix} R_p & 0 \\ 0 & r_{p+1} - \underline{M}'_p u_{p+1} \end{bmatrix} \end{aligned}$$

($I_{N \times N} = N \times N$ identity matrix), we find that

$$(5.37) \quad \nu = [r_{p+1} - u'_{p+1} \underline{M}_p]^{-1} \{f_p - u'_{p+1} N_p\}.$$

Thus, given M_p and N_p , N_{p+1} can be computed from (5.36) and (5.37) in $O(M^2 p)$ operations ($p \gg N$). Hence, in particular $\{\hat{X}_{n,p}\}_{p=0}^n$ in (5.31) can be computed in a recursive manner in a total of $O(n^2)$ operations. \square

In [33] infinite-dimensional Chandrasekhar equations are derived for time-invariant hereditary systems without control delay. A fast algorithm based on approximating the Chandrasekhar equations is obtained and is shown to possess the same convergence properties as reported in [10]. Although there are no direct connections between the algorithm we developed here and the one in [33], there are some general connections between Chandrasekhar equations and the inversion of near Toeplitz systems [31].

We note that stability of the algorithms of this section with respect to the data $Y(t)$, $F(t)$ is easily demonstrated. For suppose $Y(\cdot)$ and $F(\cdot)$ were replaced by $Y_\varepsilon(\cdot)$ and $F_\varepsilon(\cdot)$ with

$$\sup_{t \in [0, T]} |Y(t) - Y_\varepsilon(t)|, |F(t) - F_\varepsilon(t)| < \varepsilon.$$

Using the obvious notation, we obtain the corresponding error estimates,

$$\sup_t |F_n - F_n^\varepsilon|, \sup_t |Y_n - Y_n^\varepsilon| = O(\varepsilon)$$

and

$$\max |\hat{U}_{ij}^n - \hat{U}_{ij}^{n,\varepsilon}|_{HS} = O(\varepsilon) \Delta,$$

all independent of n . Substituting these errors into the appropriate places in Theorem 5.3, it follows that an $O(\varepsilon)$ perturbation in the data $Y(t)$, $F(t)$ yields an $O(\varepsilon)$ perturbation in the estimate of the feedback kernel (all of these estimates in the sup norm).

Another feature to note is that although the implementation defined by Theorem 5.3 and Theorem 5.4 is recursive backward in time for the computation of the feedback kernel (just as one would suspect—e.g., the Riccati equation is solved backward in time), in terms of the algorithm's utilization of the fundamental matrix $Y(t)$, it is actually *forward* in time. Thus any approximating scheme for the computation of $Y(t)$ can be readily incorporated into the algorithm. This remark is also true for the implementation of Theorem 4.1 introduced in the beginning of this section.

One final remark concerning the algorithm is that in the event that the point delays $\{r_i\}_{i=1}^k$ do not correspond to a subset of the nodes $\{s_i\}_{i=0}^n$, the estimate in (5.22) is only $O(1/\sqrt{n})$. Thus the estimate in Theorem 5.3 would also be $O(1/\sqrt{n})$. Of course Theorem

4.1 has the flexibility to place nodes anywhere, and it may be possible to recover the stronger convergence by considering algorithms arising from different discretization strategies.

We conclude this section with the following simple scalar example:

$$\min J(u, x) = \int_0^2 |x(t)|^2 + |u(t)|^2 dt$$

subject to the constraint

$$\dot{x}(t) = x(t) + x(t-1) + u(t).$$

Since we are seeking the optimal feedback kernel $P(t, \alpha)$, it is not necessary to prescribe an initial condition above.

The algorithm described in the beginning of the section based on the approximation (5.3) and the recursive inversion of $I + \hat{U}(s_i)$ via the "matrix inversion lemma," was programmed using a few lines of Fortran code. Because the fundamental solution $Y(t)$ to the differential equation is easily derived for this problem, the exact solution was used in the algorithm. (Recall that an $O(\epsilon)$ error in the approximation of Y results in an $O(\epsilon)$ error in $P(t, \alpha)$.)

Discretizations with mesh width = .025, .01, .005, were considered. The results for this problem coincided fairly well with the theory. We observed essentially linear (uniform) convergence of the feedback kernels as predicted. Tables 5.1–5.3 contain these results. As an independent check for the correctness of these values, Table 5.4 contains values of the kernel obtained via the Riccati equation approach using the Kappel–Salamon [35] linear spline approximation of the history space with ten elements. The gain using these approximations appeared to have converged to about two significant figures.

This example is intended only to be illustrative of the general methodology. The fact that the algorithm of this example requires virtually no modification to handle the more complex case of control delays, underscores our comments in the introduction concerning the transparency of the factorization approach to the control delay problem. However, our numerical experience with possible algorithms that can be derived via

these methods is limited, and beyond the operation counts and convergence characteristics provided in §§ 4 and 5, it would be premature to make any assessment regarding how well these algorithm work in general. (See additional comments in § 6.)

6. Concluding remarks. Our focus has been on the control problem for the RFDE on a finite interval. A natural question which arises is whether the approach can be adapted to treat the infinite time problem. Although several technical difficulties have to be dealt with, progress on this problem has been reported in [36]. We note that a factorization based approach to the regulator problem has been previously investigated by Davis [4].

Our treatment of the numerical aspects of the control problem has been from a fairly general perspective, and one might suspect that stronger results may be established in a more specific setting. One area, for example, that was not pursued either analytically or numerically was the use of higher order methods for time-invariant problems, where there appears to be room to improve upon the results. Along these lines, in the case of time-invariant systems without control delay we have obtained some new results utilizing (4.7) as a point of departure that substantially sharpens the analytical and numerical results of the present paper [37]. We essentially exhibit a fast Chandrasekhar-type set of equations that admits a second order implementation for construction of the kernel $P(t, \alpha)$ in the general case of incommensurate delays, and in the case of a single delay, arbitrarily high order methods are shown to be admissible. It is not clear at this time whether these results have extension to problems with control delay.

Acknowledgment. The author thanks Professors Alan Schumitzky and J. S. Gibson for some very fruitful discussions on the subject of this paper, and to Professor Gibson for providing the values shown in Table 5.4.

THE SENSITIVITY OF THE STABLE LYAPUNOV EQUATION*

GARY HEWER† AND CHARLES KENNEY‡

Abstract. We present an analysis of the sensitivity of the solution of the Lyapunov equation $A^*X + XA = -W$, where A is stable. This analysis leads to a spectral norm bound on the relative perturbation of the solution which is optimal for a certain class of estimates and which is essentially equivalent to the Frobenius norm bound obtained from the associated Kronecker product system. The latter bound can be expressed in terms of $\text{sep}(A^*, -A)$ and is known to accurately reflect the sensitivity of the Lyapunov problem, but it is hard to interpret in terms of the original matrix A . In contrast, the spectral norm bound which we derive is directly related to the minimal L_2 damping of the dynamical system $\dot{z} = Az$. Moreover, this dynamical link with the sensitivity problem leads to a new method of systematically investigating the norm behavior of e^{At} as well as providing a wealth of information about control theoretic aspects of $\dot{z} = Az$, when A is the closed loop state matrix.

Key words. Lyapunov equation, matrix exponential, condition number

AMS(MOS) subject classification. 93

1. Introduction. In this paper we consider the sensitivity of the solution X to the Lyapunov equation

$$(1.1) \quad A^*X + XA = -W$$

where A, X and $W \in \mathbb{C}^{n \times n}$ and A^* denotes the conjugate transpose of A . We do not make any special assumptions about W such as symmetry or positive definiteness, but we do assume throughout that A is stable, that is the eigenvalues of A have negative real part:

$$(1.2) \quad \text{Re } \lambda_i(A) < 0, \quad i = 1, \dots, n.$$

This condition on A ensures that (1.1) has a unique solution (see [20]). Now let $\Delta A, \Delta X$ and ΔW be such that

$$(1.3) \quad (A + \Delta A)^*(X + \Delta X) + (X + \Delta X)(A + \Delta A) = -(W + \Delta W).$$

Our goal is to develop bounds on $\|\Delta X\|$ which are reasonably sharp, in a sense to be specified later, and which are easy to interpret. Here $\|\cdot\|$ is the spectral or 2-norm defined by

$$\|M\| = \max \frac{\|Mx\|}{\|x\|}$$

for $M \in \mathbb{C}^{n \times n}$ where the maximum is taken over all nonzero $x \in \mathbb{C}^n$ and $\|x\|^2 = \sum_i |x_i|^2$.

In order to place our work in the proper context, it is helpful to review some established results. For example, a central fact in dealing with (1.1) is that it is equivalent to a linear system of order n^2 :

$$(1.4) \quad Px = -w$$

where

$$P = I \otimes A^* + A^T \otimes I,$$

$$x = \text{Vec}(X),$$

$$w = \text{Vec}(W).$$

Here \otimes indicates the Kronecker product, $\text{Vec}(M)$ is the n^2 vector formed by stacking the columns of M (see [12]) and $A^T(A^*)$ is the (conjugate) transpose of A . The equivalence of (1.1) and (1.4) means that sensitivity information about (1.1) can be obtained by applying the well-developed theory of perturbations of linear systems to (1.4). This approach was taken in [10] for the more general Sylvester equation

$$AX + XB = C$$

and when applied to (1.1)–(1.3) we can state a Lyapunov version of their results as (see [10, § IV]) the following theorem.

THEOREM 1.1. *Assume that (1.1)–(1.3) hold with $W \neq 0$. Let $\varepsilon > 0$ be such that*

$$(1.5) \quad \begin{aligned} \|\Delta A\|_F &\leq \varepsilon \|A\|_F, \\ \|\Delta W\|_F &\leq \varepsilon \|W\|_F, \\ 4\varepsilon \|A\|_F \|P^{-1}\| &\leq 1, \end{aligned}$$

then

$$(1.6) \quad \frac{\|\Delta X\|_F}{\|X\|_F} \leq 8\varepsilon \|A\|_F \|P^{-1}\|$$

where $\|\cdot\|_F$ denotes the Frobenius norm defined by

$$\|M\|_F^2 = \sum |M_{ij}|^2.$$

(Note the work in [10] was restricted to real matrices but the extension to complex matrices is straightforward.)

This result is sharp in the sense that there are matrices and perturbations as above such that the bound in (1.6) is nearly an equality. Moreover numerical experiments show that the right side of (1.6) is an accurate predictor of sensitivity of the Lyapunov equation for small perturbations, and that $\|P^{-1}\|$ can be efficiently estimated by techniques similar to those used in [5] (see [4]).

For these reasons we will adopt the bound in Theorem 1.1 as a standard against which we measure our work and that of others ([21], [13], [14]); however, we must make allowances when comparing results based on the Frobenius norm and results based on the spectral norm. If we use (see [11])

$$(1.7) \quad \|M\| \leq \|M\|_F \leq \sqrt{n} \|M\|$$

where $M \in \mathbb{C}^{n \times n}$, then we have

$$(1.8) \quad \frac{\|\Delta X\|}{\sqrt{n} \|X\|} \leq \frac{\|\Delta X\|_F}{\|X\|_F} \leq \frac{\sqrt{n} \|\Delta X\|}{\|X\|}.$$

In view of (1.8) we will say that a bound on $\|\Delta X\|/\|X\|$ is reasonably sharp if it is no more than a small multiple (say less than 10 times) of the right-hand side of (1.6) when we disregard any factors of \sqrt{n} resulting from the conversions between norms. All the results which we survey in this paper, including our own, satisfy this condition.

The above applies to small perturbations but is easily extended to large perturbations. For example, let $\Delta W = 0$ and assume that (1.1)–(1.3) are satisfied with $X + \Delta X \neq 0$. Then we have by (1.4)

$$\begin{aligned} P\Delta x &= -\Delta P(x + \Delta x), \\ \|\Delta x\| &\leq \|P^{-1}\| \|\Delta P\| \|x + \Delta x\|, \end{aligned}$$

so

$$(1.9) \quad \frac{\|\Delta X\|_F}{\|X + \Delta X\|_F} \leq 2\|\Delta A\|_F \|P^{-1}\|.$$

In [14] Jonckheere has given a clever way to exploit inequalities such as (1.9): instead of thinking of (1.9) as a bound on sensitivity we consider the problem of finding a minimum perturbation ΔA , such that $A + \Delta A$ is unstable. That is, we define

$$\delta = \sup \{ \tilde{\delta} \mid \|\Delta A\|_F < \tilde{\delta} \Rightarrow A + \Delta A \text{ is stable} \}$$

and let $\|\Delta A_0\|_F = \delta$ such that $A + \Delta A_0$ is unstable. Now by choosing W appropriately and letting $\Delta A \rightarrow \Delta A_0$ with $\|\Delta A\|_F < \delta$ we have that $\|\Delta X\|_F \rightarrow \infty$. This means that (1.9) becomes

$$(1.10) \quad 1 \leq 2\|\Delta A_0\|_F \|P^{-1}\|,$$

and so

$$(1.11) \quad \frac{1}{2\|P^{-1}\|} \leq \|\Delta A_0\|_F = \delta.$$

We thus have the Jonckheere-type result (for more details see the proof of Theorem 2.2).

THEOREM 1.2. *Let $A \in \mathbb{C}^{n \times n}$ be stable and let*

$$(1.12) \quad \|\Delta A\|_F < \frac{1}{2\|P^{-1}\|}.$$

Then $A + \Delta A$ is stable.

Clearly $\|P^{-1}\|$ is important to the sensitivity question, but how are we to interpret it? One result in this direction is

$$(1.13) \quad \|P^{-1}\|^{-1} = \min \frac{\|A^*X + XA\|_F}{\|X\|_F} \equiv \text{sep}(A^*, -A),$$

where the minimum in (1.13) is taken over all nonzero $X \in \mathbb{C}^{n \times n}$ (see [27] and [28]). However the lack of an interpretation of $\|P^{-1}\|$ in terms of the original system has led to the search for new sensitivity bounds which are more readily understood.

We now consider three results along these lines for normal matrices:

$$(1.14) \quad A^*A = AA^*.$$

In describing these results we will assume that $W = W^*$ and $\Delta W = 0$. Lyapunov problems involving normal matrices occur naturally in some flexible body aerospace systems (see [15]). Laub [21] gives the result that for $P = I \otimes A^T + A^T \otimes I$ with A and W real

$$(1.15) \quad \|P\| \|P^{-1}\| = \frac{\max |\lambda_i^*(A) + \lambda_j(A)|}{\min |\lambda_i^*(A) + \lambda_j(A)|}.$$

When A is also stable we then have

$$(1.16) \quad \frac{\|dX\|_F}{\|X\|_F} \leq \frac{\|dA\|_F}{\min |\text{Re } \lambda_i(A)|},$$

where dA is any differential perturbation of A (that is (1.16) holds in the limit as $\|dA\|_F \rightarrow 0$). Inequality (1.16) has a clear interpretation: if any of the eigenvalues of A are near the imaginary axis we can expect the Lyapunov equation to be sensitive to small perturbations. In [13], Hammarling derived a similar bound for arbitrary ΔA :

$$(1.17) \quad \frac{\|\Delta X\|}{\|X + \Delta X\|} \leq \frac{\|\Delta A\|}{\|A\|} 2\sqrt{n} \frac{\max |\lambda_i(A)|}{\min |\lambda_i^*(A) + \lambda_j(A)|}$$

which for stable, real and normal matrices A reduces to

$$(1.18) \quad \frac{\|\Delta X\|}{\|X + \Delta X\|} \leq \frac{\|\Delta A\|\sqrt{n}}{\min |\operatorname{Re} \lambda_i(A)|}.$$

Inequality (1.18) has the same interpretation as (1.16).

In [14], Jonckheere derives a result for arbitrary ΔA which is sharper than Hammarling's:

$$(1.19) \quad \frac{\|\Delta X\|}{\|X + \Delta X\|} \leq 2\|\Delta A\| \|M\|$$

where

$$M = (M_{ij}) = \left(\frac{1}{\lambda_i(A) + \lambda_j(A)} \right)$$

but which is harder to interpret in terms of the eigenvalues of A .

That each of the above estimates is reasonably sharp is easily seen when we note that if A is normal then so is P and (see [20])

$$(1.20) \quad \lambda_{ij}(P) = \lambda_i(A^*) + \lambda_j(A) = \lambda_i^*(A) + \lambda_j(A).$$

Thus

$$(1.21) \quad \|P^{-1}\| = \frac{1}{\min |\lambda_{ij}(P)|} = \frac{1}{\min |\lambda_i^*(A) + \lambda_j(A)|}.$$

Our work on the sensitivity of the Lyapunov equation has centered on matrices A which are stable but not necessarily normal. We have also dropped the assumptions that $W = W^*$ and $\Delta W = 0$. Our main result is that if (1.1)–(1.3) are satisfied then

$$(1.22) \quad \frac{\|\Delta X\|}{\|X + \Delta X\|} \leq 2\|A + \Delta A\| \|H\| \left[\frac{\|\Delta A\|}{\|A + \Delta A\|} + \frac{\|\Delta W\|}{\|W + \Delta W\|} \right]$$

where H satisfies

$$(1.23) \quad A^*H + HA = -I$$

and we assume that $\|W + \Delta W\|$, $\|A + \Delta A\|$ and $\|X + \Delta X\|$ are all nonzero. Inequality (1.22) is proved in § 2 where we also show that it is reasonably sharp as defined above and that it is optimal for a certain class of estimates. We may compare (1.22) with the results of Laub, Hammarling and Jonckheere for the normal case by noting that when A is stable, real and normal there exists a unitary matrix Q such that

$$(1.24) \quad A = QDQ^*$$

where $D = \operatorname{diag}(\lambda_i(A))$. In this case the solution H to $A^TH + HA = -I$ is given by $H = QDQ^*$ where

$$(1.25) \quad D = \operatorname{diag} \left(\frac{-1}{\lambda_i^*(A) + \lambda_i(A)} \right).$$

This gives

$$(1.26) \quad \|H\| = \frac{1}{\min |\lambda_i^*(A) + \lambda_i(A)|} = \frac{1}{2 \min |\operatorname{Re} \lambda_i(A)|}.$$

Thus for $\Delta W = 0$ and arbitrary ΔA we have

$$(1.27) \quad \frac{\|\Delta X\|}{\|X + \Delta X\|} \leq \frac{\|\Delta A\|}{\min |\operatorname{Re} \lambda_i(A)|}$$

which is the large variation analogue of Laub's differential perturbation result (see (1.15) and (1.16)).

In § 3 we show that the norm of H in the sensitivity bound (1.22) can be interpreted in terms of the damping behavior of the solutions to the dynamical system

$$(1.28) \quad \dot{z} = Az, \quad z(0) = z_0 \in \mathbb{C}^n.$$

We say that a solution \tilde{z} to (1.28) with $\tilde{z}(0) = \tilde{z}_0$, $\|\tilde{z}_0\| = 1$ is *minimally damped* in the L_2 sense (or minimally L_2 damped) if

$$(1.29) \quad \|\tilde{z}\|_{L_2} = \max_{\|z_0\|=1} \|z\|_{L_2}$$

where z in (1.29) satisfies (1.28) and

$$(1.30) \quad \|z\|_{L_2} \equiv \left[\int_0^\infty \|z(t)\|^2 dt \right]^{1/2}$$

is the usual L_2 norm of z over $0 \leq t < \infty$. In § 3 we show that the term $\|H\|$ in (1.22) is the square of the minimal L_2 damping of the dynamical system (1.28) as measured by the right-hand side of (1.29):

$$(1.31) \quad \|H\| = \max_{\|z_0\|=1} \|z\|_{L_2}^2.$$

Thus the sensitivity of the Lyapunov equation and the minimal L_2 damping of the system (1.28) are related through $\|H\|$ and (1.22). This connection is of interest in light of the fact that the Lyapunov equation originally arose from the study of the stability of the solutions of the dynamical system (1.28).

The method used to establish (1.31) also provides a wealth of information about (1.28) which is useful from a control theory point of view. For example, any normalized eigenvector of H corresponding to the largest eigenvalue, $\lambda \max(H)$ represents the initial conditions of a minimally L_2 damped solution to (1.28). This result is easily extended to a finite time interval $t_0 \leq t \leq t_1$ by considering the solution $H_{t_0 t_1}$ to

$$(1.32) \quad A^* H_{t_0 t_1} + H_{t_0 t_1} A = e^{A^* t_1} e^{A t_1} - e^{A^* t_0} e^{A t_0},$$

in which case $\|H_{t_0 t_1}\|$ determines the minimal L_2 damping over the interval $t_0 \leq t \leq t_1$:

$$(1.33) \quad \|H_{t_0 t_1}\| = \max_{\|z_0\|=1} \|z\|_{L_2[t_0, t_1]}^2,$$

where z satisfies (1.28) and

$$(1.34) \quad \|z\|_{L_2[t_0, t_1]} \equiv \left[\int_{t_0}^{t_1} \|z(t)\|^2 dt \right]^{1/2}.$$

As in the case of the infinite time interval $0 \leq t < \infty$, the eigenvectors of $H_{t_0 t_1}$ corresponding to $\lambda \max(H_{t_0 t_1})$ represent the initial conditions of minimally L_2 damped solutions for $t_0 \leq t \leq t_1$.

In the remainder of § 3 we consider the problem of approximating the norm behavior of e^{At} . Our approach is based on the heuristic argument that since the curve $y = \|e^{At}\|$ is the upper envelope of the family of curves $y = \|z(t)\|$ where $\dot{z} = Az$ and $\|z(0)\| = 1$, the minimally L_2 damped solutions to (1.28) should provide a reasonable approximation to $y = \|e^{At}\|$. Various numerical experiments show that this approach works well, especially when we use the minimally L_2 damped solutions associated with the time interval $0 \leq t \leq t_1$ to approximate the short term behavior of $y = \|e^{At}\|$. The final section is devoted to bounding the sensitivity of the matrix exponential along the lines of Van Loan [22] and Kagström [16], but with an emphasis on bounds obtained by using the solutions to various Lyapunov equations.

2. Lyapunov sensitivity. In this section we develop bounds on the sensitivity of the solution to the Lyapunov equation and compare these bounds with established results. Our main result is the following theorem.

THEOREM 2.1. *Let (1.1)–(1.3) be satisfied and let H satisfy*

$$(2.1) \quad A^*H + HA = -I$$

then

$$(2.2) \quad \frac{\|\Delta X\|}{\|X + \Delta X\|} \leq 2\|A + \Delta A\| \|H\| \left[\frac{\|\Delta A\|}{\|A + \Delta A\|} + \frac{\|\Delta W\|}{\|W + \Delta W\|} \right]$$

where we assume that $\|X + \Delta X\|$, $\|A + \Delta A\|$ and $\|W + \Delta W\|$ are all nonzero.

Proof. Since A is assumed to be stable, H in (2.1) is positive definite ($H > 0$) and may be represented as

$$(2.3) \quad H = \int_0^\infty e^{A^*t} e^{At} dt.$$

Now expand (1.3) and use (1.1) to get

$$(2.4) \quad A^*\Delta X + \Delta XA = -(\Delta W + \Delta A^*(X + \Delta X) + (X + \Delta X)\Delta A).$$

This may be rewritten as

$$(2.5) \quad \Delta X = \int_0^\infty e^{A^*t} (\Delta W + \Delta A^*(X + \Delta X) + (X + \Delta X)\Delta A) e^{At} dt.$$

Let u and v denote the left and right singular vectors of unit length of ΔX such that

$$(2.6) \quad u^* \Delta X v = \|\Delta X\|.$$

Combining (2.5) and (2.6) we get

$$\begin{aligned} \|\Delta X\| &= \int_0^\infty u^* e^{A^*t} (\Delta W + \Delta A^*(X + \Delta X) + (X + \Delta X)\Delta A) e^{At} v dt \\ (2.7) \quad &\leq \|\Delta W + \Delta A^*(X + \Delta X) + (X + \Delta X)\Delta A\| \int_0^\infty \|e^{At} u\| \|e^{At} v\| dt \\ &\leq (\|\Delta W\| + 2\|\Delta A\| \|X + \Delta X\|) \int_0^\infty \|e^{At} u\| \|e^{At} v\| dt. \end{aligned}$$

By the Cauchy-Schwarz inequality we have

$$(2.8) \quad \int_0^\infty \|e^{At} u\| \|e^{At} v\| dt \leq \left[\int_0^\infty \|e^{At} u\|^2 dt \right]^{1/2} \left[\int_0^\infty \|e^{At} v\|^2 dt \right]^{1/2}.$$

Moreover

$$\int_0^\infty \|e^{A^t} u\|^2 dt = \int_0^\infty u^* e^{A^* t} e^{A^t} u dt = u^* \int_0^\infty e^{A^* t} e^{A^t} dt u = u^* H u.$$

Using $H = H^*$ and $H > 0$, together with the fact that u has unit length gives

$$u^* H u \leq \|H\|.$$

Thus

$$(2.9) \quad \int_0^\infty \|e^{A^t} u\|^2 dt \leq \|H\|.$$

Similarly

$$(2.10) \quad \int_0^\infty \|e^{A^t} v\|^2 dt \leq \|H\|.$$

Using (2.8)–(2.10) in (2.7) we get

$$(2.11) \quad \|\Delta X\| \leq (\|\Delta W\| + 2\|\Delta A\| \|X + \Delta X\|) \|H\|.$$

From (1.3) we have that

$$(2.12) \quad \|W + \Delta W\| \leq 2\|A + \Delta A\| \|X + \Delta X\|$$

so that (2.11) can be written as

$$\frac{\|\Delta X\|}{\|X + \Delta X\|} \leq 2\|A + \Delta A\| \|H\| \left[\frac{\|\Delta A\|}{\|A + \Delta A\|} + \frac{\|\Delta W\|}{\|W + \Delta W\|} \right]$$

which is the desired result. \square

Remark. Different bounds on $\|\Delta X\|$ can be obtained by using

$$\|e^{A^t} u\| \leq \|e^{A^t}\|, \quad \|e^{A^t} v\| \leq \|e^{A^t}\|$$

in (2.7). This gives

$$\|\Delta X\| \leq (\|\Delta W\| + 2\|\Delta A\| \|X + \Delta X\|) \int_0^\infty \|e^{A^t}\|^2 dt.$$

Now any integrable bound on $\|e^{A^t}\|^2$ can be used to estimate $\int_0^\infty \|e^{A^t}\|^2 dt$. For example, the bound

$$\|e^{A^t}\| \leq e^{\mu(A)t}$$

is integrable if

$$\mu(A) \equiv \frac{1}{2} \lambda_{\max}(A^* + A) < 0.$$

In this case we obtain

$$\|\Delta X\| \leq (\|\Delta W\| + 2\|\Delta A\| \|X + \Delta X\|) \frac{1}{2|\mu(A)|}.$$

For other bounds on $\|e^{A^*t}\|$, see [22] and [16]. However, the bound obtained in (2.11) is optimal for this class of estimates because

$$\|H\| = \left\| \int_0^\infty e^{A^*t} e^{At} dt \right\| \leq \int_0^\infty \|e^{A^*t}\|^2 dt.$$

We may compare (2.2) with (1.6) for small perturbations by assuming that for $\varepsilon > 0$

$$(2.13) \quad \|\Delta A\| \leq \varepsilon \|A\|,$$

$$(2.14) \quad \|\Delta W\| \leq \varepsilon \|W\|,$$

$$(2.15) \quad 8\varepsilon \|A\| \|H\| \leq \frac{1-\varepsilon}{1+\varepsilon}.$$

Then after some algebra, (2.2) gives

$$(2.16) \quad \frac{\|\Delta X\|}{\|X\|} \leq 8\varepsilon \|A\| \|H\| (1-\varepsilon) \approx 8\varepsilon \|A\| \|H\|,$$

for ε small.

If we disregard the difference in norms, (2.16) has the form of (1.6) except that $\|P^{-1}\|$ is replaced by $\|H\|$. These two terms may be compared by using (1.13) and (1.7)

$$\|P^{-1}\|^{-1} = \min \frac{\|A^*X + XA\|_F}{\|X\|_F} \leq \frac{\|A^*H + HA\|_F}{\|H\|_F} = \frac{\|I\|_F}{\|H\|_F} \leq \frac{\sqrt{n}}{\|H\|}.$$

Thus

$$(2.17) \quad \|H\| \leq \sqrt{n} \|P^{-1}\|.$$

In order to assess how accurately (1.6) and (2.16) measure the sensitivity of the Lyapunov equation we have selected four control problems of the form

$$(2.18) \quad x = A_0x + Bu, \quad y = Cx,$$

from the literature and formed the closed loop state matrix A by using standard quadratic regulator techniques (see [1]):

$$(2.19) \quad A = A_0 - BB^TP$$

where P is the positive extremal solution to the algebraic Riccati equation

$$(2.20) \quad 0 = C^TC + A_0^TP + PA_0 - PBB^TP$$

and (A, B, C) is observable and controllable. These examples were chosen because we had used them in some earlier studies of the algebraic Riccati equation.

This method ensures that A in (2.19) is stable:

$$(2.21) \quad \operatorname{Re} \lambda_i(A) < 0.$$

A variant of this procedure is to let $P = P(\rho)$ be the positive extremal solution to

$$(2.22) \quad 0 = C^TC + (A_0 + \rho I)^TP + P(A_0 + \rho I) - PBB^TP$$

for $\rho > 0$. This gives

$$\operatorname{Re} \lambda_i(A_0 + \rho I - BB^TP(\rho)) < 0$$

so that

$$(2.23) \quad \operatorname{Re} \lambda_i(A_0 - BB^TP(\rho)) < -\rho.$$

Because of (2.23), Anderson and Moore (see [1, Chap. 4]) refer to ρ as a prescribed degree of stability.

In Table 1 we compare the principal terms $\|A\| \|H\|$ and $\|A\|_F \|P^{-1}\|$ of (2.16) and (1.6) respectively, for $A = A_0 - BB^TP(\rho)$ for various values of ρ . These terms are

almost identical over the entire example set. The same is true for the terms $\|H\|$ and $\|P^{-1}\|$ which are included so as to test (2.17). The computation of $P(\rho)$ in (2.22) was performed by the numerically stable subroutine RICOND of Laub [21] and the spectral norms were evaluated by using the Linpack singular value decomposition subroutine DSVDC (see [9]).

In order to see how well (2.16) and (1.6) measure sensitivity, we used the numerically stable subroutine AXXBC of Golub, Nash and Van Loan [10] to solve

$$A^T X + XA = -W,$$

where X was chosen to be the n th order Hilbert matrix $X = (x_{ij}) = 1/(i+j-1)$ and W was obtained by forming the matrix $-(A^T X + XA)$. The computed solution X_c is then the exact solution to a perturbed problem $(A + \Delta A)^T X_c + X_c(A + \Delta A) = -(W + \Delta W)$ (see [10]) and we can estimate the sensitivity of the Lyapunov equation from the terms $\|X - X_c\|/\|X\|$ and $\|X - X_c\|_F/\|X\|_F$. All computations were performed on a VAX-780 in double precision for which the machine epsilon is about 10^{-17} . The results are given in Table 1 and we can say that for the problems tested the right-hand sides of (1.6) and (2.16) are accurate predictors of the sensitivity of the Lyapunov equation in that

$$\frac{\|X - X_c\|_F}{\|X\|_F} \approx 8\varepsilon \|A\|_F \|P^{-1}\|,$$

$$\frac{\|X - X_c\|}{\|X\|} \approx 8\varepsilon \|A\| \|H\|.$$

Since Theorem 2.1 applies to arbitrary perturbations we can obtain a Jonckheere-type bound on the size of the smallest destabilizing perturbation for A .

THEOREM 2.2. *Let A be stable and let H satisfy $A^*H + HA = -I$. Let ΔA satisfy $\|\Delta A\| < 1/2\|H\|$. Then $A + \Delta A$ is stable.*

Proof. We will use the fact that for any square matrix P the equation

$$Px = w$$

has no solution x if $P^*w = 0$ and $w \neq 0$. For the Lyapunov equation, this means that

$$(A + \Delta A)^*(X + \Delta X) + (X + \Delta X)(A + \Delta A) = -W$$

has no solution $X + \Delta X$ if $P^*w = 0$ where

$$P = I \otimes (A + \Delta A)^* + (A + \Delta A)^T \otimes I$$

and $w = \text{Vec}(W) \neq 0$ (see [12]).

Now define

$$(2.24) \quad \delta \equiv \sup \{ \tilde{\delta} \mid \|\Delta A\| < \tilde{\delta} \Rightarrow A + \Delta A \text{ is stable} \}.$$

The stability of A and the continuity of its eigenvalues ensure that $\delta > 0$. We may find ΔA_0 such that $A + \Delta A_0$ is unstable but $A + t\Delta A_0$ is stable for $0 \leq t < 1$ where $\|\Delta A_0\| = \delta$. Now let $X = X(t)$ be the solution to

$$(2.25) \quad (A + t\Delta A_0)^*X(t) + X(t)(A + t\Delta A_0) = -W, \quad 0 < t < 1,$$

where $P_1^*w = 0$ for $w = \text{Vec}(W) \neq 0$ and $P_1 = I \otimes (A + \Delta A_0)^* + (A + \Delta A_0)^T \otimes I$.

This ensures that $\lim_{t \rightarrow 1} \|X(t)\| = \infty$ because (2.25) has no solution at $t = 1$ by the choice of W . If we set $\Delta X = X(t) - X(0)$ and $\Delta W = 0$ we obtain from Theorem 2.1

$$\frac{\|X(t) - X(0)\|}{\|X(t)\|} \leq 2t\|\Delta A_0\|\|H\|,$$

which in the limit as $t \rightarrow 1$ gives

$$1 \leq 2\|\Delta A_0\|\|H\|.$$

Thus

$$\frac{1}{2\|H\|} < \|\Delta A_0\| = \delta$$

which is the desired result. \square

Note that the above argument suffices to prove Theorem 1.2 if we use (1.9) to bound $\|X(t) - X(0)\|_F / \|X(t)\|_F$ and then take the limit as $t \rightarrow 1$.

It is interesting that a more general version of Theorem 2.2 can be proved by a completely different argument which relies on the following well-known stability theorem (see [20]).

THEOREM 2.3. *Let \tilde{W} be Hermitian and positive definite and let \tilde{A}, \tilde{H} satisfy*

$$(2.26) \quad \tilde{A}^*\tilde{H} + \tilde{H}\tilde{A} = -\tilde{W}.$$

(2.27) *Then \tilde{A} is stable if and only if \tilde{H} is Hermitian positive definite.*

Using this theorem we can prove the next theorem.

THEOREM 2.4. *Let A be stable and let H, W satisfy*

$$(2.28) \quad A^*H + HA = -W$$

where W is Hermitian positive definite. Let ΔA satisfy

$$(2.29) \quad \|\Delta A\| < \frac{\lambda_{\min}(W)}{2\|H\|}.$$

Then $A + \Delta A$ is stable.

Proof. By Theorem 2.3 we have that H is Hermitian and positive definite. Now define

$$(2.30) \quad \tilde{W} = W + \Delta A^* H + H \Delta A,$$

$$(2.31) \quad \tilde{A} = A + \Delta A,$$

$$(2.32) \quad \tilde{H} = H.$$

Then (2.26) is satisfied and \tilde{W} is Hermitian positive definite because

$$\lambda_{\min}(\tilde{W}) \geq \lambda_{\min}(W) - 2\|\Delta A\| \|A\| \|H\| > 0$$

by (2.29). Therefore by Theorem 2.3, \tilde{A} is stable. \square

Theorem 2.1 and the numerical results in Table 1 show that $\|H\|$ plays a role in spectral norm sensitivity estimates which is analogous to the role of $\|P^{-1}\|$ in Frobenius norm sensitivity estimates. This analogy extends to the lower bounds $1/2\|P^{-1}\|$ of Theorem 1.2 and $1/2\|H\|$ of Theorem 2.2 for the smallest destabilizing perturbations of A for the Frobenius and spectral norms respectively. In the next section we seek to understand the roles of H and $\|H\|$ in the sensitivity problem by establishing a relationship between H and the dynamical system $\dot{z} = Az$.

3. Interpretation. In this section we explore the connection between H satisfying

$$(3.1) \quad A^* H + H A = -I$$

and the norm behavior of solutions $z = z(t)$ to the dynamical system

$$(3.2) \quad \dot{z} = Az, \quad z(0) = z_0 \in \mathbb{C}^n.$$

This connection gives us one way of understanding the sensitivity estimate (2.2) and provides a great deal of information about the norm behavior of e^{At} . As a by-product we also obtain a means of identifying solutions to (3.2) which are of interest in control theory.

Our main tool in establishing the connection between (3.1) and (3.2) is the following theorem which portrays H as the “area matrix” associated with (3.2).

THEOREM 3.1. *Let A be stable and let H satisfy (3.1). For $z_0 \in \mathbb{C}^n$ define $f(t) = \|z(t)\|^2$ where z satisfies (3.2). Then the area under f for $0 \leq t \leq \infty$ is equal to $z_0^* H z_0$.*

Proof. Since A is stable, H can be written as

$$H = \int_0^\infty e^{A^* t} e^{A t} dt.$$

The area under the curve f for $0 \leq t \leq \infty$ is given by

$$\begin{aligned} \int_0^\infty f(t) dt &= \int_0^\infty \|z(t)\|^2 dt \\ &= \int_0^\infty \|e^{A t} z_0\|^2 dt \\ &= \int_0^\infty z_0^* e^{A^* t} e^{A t} z_0 dt \\ &= z_0^* \int_0^\infty e^{A^* t} e^{A t} dt z_0 = z_0^* H z_0. \end{aligned}$$

\square

As in (1.29) we will say that \tilde{z} is minimally damped in the L_2 sense (or minimally L_2 damped) if \tilde{z} satisfies (3.2) with $\tilde{z}(0) = \tilde{z}_0$ of unit norm and

$$(3.3) \quad \|\tilde{z}\|_{L_2} = \max_{\|z_0\|=1} \|z\|_{L_2},$$

where z in (3.3) satisfies (3.2) and

$$\|z\|_{L_2} = \left[\int_0^\infty \|z(t)\|^2 dt \right]^{1/2}$$

is the usual L_2 norm of z over $0 < t < \infty$. As an immediate consequence of $z_0^* H z_0 \leq \|H\|$ for $\|z_0\| = 1$, we have by Theorem 3.1 that $\|H\|$ is the square of the minimal L_2 damping for the system (3.2):

$$(3.4) \quad \|H\| = \max_{\|z_0\|=1} \|z\|_{L_2}^2,$$

where equality is attained when z_0 is a normalized eigenvector of H corresponding to $\lambda_{\max}(H)$. Thus minimally L_2 damped solutions of (3.2) determine the norm of H and hence govern the sensitivity of the Lyapunov equation by (2.2). This generalizes the result for the real normal case: If A is real, stable and normal, the sensitivity of the Lyapunov equation (see 1.16) is governed by $1/|\alpha|$ where $\alpha = \max_i \operatorname{Re} \lambda_i(A)$. Moreover it is easily shown in this case that $1/|\alpha|$ determines the minimal L_2 damping for $z = Az$:

$$(3.5) \quad \frac{1}{2|\alpha|} = \max_{\|z_0\|=1} \|z\|_{L_2}^2.$$

This follows from the fact that for such matrices

$$(3.6) \quad \|z(t)\| \leq \|z_0\| e^{\alpha t}$$

and that there exists an initial vector z_0 such that

$$\|z_0\| = 1 \quad \text{with} \quad \|z(t)\| = e^{\alpha t} \quad \text{where} \quad \dot{z} = Az.$$

From the proof of Theorem 3.1 we see that the initial conditions z_0 , which give rise to minimally L_2 damped solutions of (3.2), are simply eigenvectors of H corresponding to the largest eigenvalue $\lambda_{\max}(H)$. The identification of such initial conditions is important in a control theory context because the corresponding solutions are either weakly damped or have large norm transient behavior relative to other solutions of (3.2).

The area interpretation of $\|H\|$ is also very useful in understanding the numerical results given in Table 1 for the "prescribed stability" procedure. In that procedure the closed loop state matrix $A = A(\rho)$ is forced to have eigenvalues to the left of $x = -\rho$ where ρ is the margin parameter. This would seem to be desirable in that solutions to $\dot{z} = Az$ are forced to decay more rapidly as ρ increases:

$$\|z(t)\| \leq C e^{-\rho t} \|z_0\|$$

where C is a constant depending on ρ but independent of the initial condition $z_0 = z(0)$. However an inspection of Table 1 reveals that $\|H\|$ increases as ρ gets larger, thus indicating that the constant $C = C(\rho)$ is increasing with ρ fast enough to mask the exponential decay for small t values. This is illustrated in Figs. 1(a), 2(a), 3(a) where we plot the maximal area curves $\|z(t)\|$ as a function of t for several values of ρ . Here $\dot{z} = A(\rho)z$ and $z(0)$ is a normalized eigenvector of $H = H(\rho)$ corresponding to $\lambda_{\max}(H)$ where $A^*H + HA = -I$. These figures clearly show that the price of fast asymptotic decay can be large norm transient behavior.

FIG. 1(a). Moore-Laub: norm $z(t)$ versus time where $\dot{z} = Az$.FIG. 1(b). Moore-Laub: spectral norm of $\exp(At)$ versus time.

In Theorem 3.1 we considered the time interval $0 \leq t < \infty$. In general however we are more often interested in a restricted time interval $t_0 \leq t \leq t_1$. For example, the interval $0 \leq t \leq t_1$ is of prime importance in analyzing the transient behavior of solutions to (3.2). The next theorem shows that we can obtain area results for such finite intervals.

THEOREM 3.2. Let A be stable and let H satisfy

$$(3.7) \quad A^*H + HA = e^{A^*t_1} e^{At_1} - e^{A^*t_0} e^{At_0}.$$

For $z_0 \in \mathbb{C}^n$, define $f(t) = \|z(t)\|^2$ where z satisfies (3.2). Then the area under f for $t_0 \leq t \leq t_1$ is equal to $z_0^* H z_0$.

Proof. Since A is stable we may represent H as

$$(3.8) \quad \begin{aligned} H &= - \int_0^\infty e^{A^*t} (e^{A^*t_1} e^{At_1} - e^{A^*t_0} e^{At_0}) e^{At} dt \\ &= \int_0^\infty e^{A^*(t+t_0)} e^{A(t+t_0)} dt - \int_0^\infty e^{A^*(t+t_1)} e^{A(t+t_1)} dt \end{aligned}$$

FIG. 2(a). Chung-Shapiro: norm $z(t)$ versus time where $\dot{z} = Az$.FIG. 2(b). Chung-Shapiro: spectral norm of $\exp(At)$ versus time.

$$\begin{aligned}
 (3.9) \quad &= \int_{t_0}^{\infty} e^{A^*t} e^{At} dt - \int_{t_1}^{\infty} e^{A^*t} e^{At} dt \\
 &= \int_{t_0}^{t_1} e^{A^*t} e^{At} dt.
 \end{aligned}$$

Now as in the proof of Theorem 3.1 we have

$$\begin{aligned}
 \int_{t_0}^{t_1} f(t) dt &= \int_{t_0}^{t_1} \|z(t)\|^2 dt = \int_{t_0}^{t_1} \|e^{At} z_0\|^2 dt \\
 &= \int_{t_0}^{t_1} z_0^* e^{A^*t} e^{At} z_0 dt = z_0^* H z_0.
 \end{aligned}$$

□

As in the case for $0 \leq t \leq \infty$, the eigenvectors of H in (3.7) corresponding to the eigenvalue $\lambda_{\max}(H)$ represent the initial conditions of solutions to the dynamical system (3.2) which are least stable during the time interval $t_0 \leq t \leq t_1$ in the sense of having maximal L_2 norms.

 FIG. 3(a). Kailath: norm $z(t)$ versus time where $\dot{z} = Az$.

 FIG. 3(b). Kailath: spectral norm of $\exp(At)$ versus time.

If we turn to the problem of approximating the norm curve $N(t) = \|e^{At}\|$ of the matrix exponential, we find the area approach convenient because $N^2(t)$ is the upper envelope of the family of curves $f = f(t, z_0)$ where we let z_0 vary over all vectors of unit length:

$$(3.10) \quad \|e^{At}\|^2 = \max \|e^{At} z_0\|^2 = \max f(t, z_0).$$

Thus we have that for any z_0 of unit length, $f(t, z_0)$ is a lower bound on $\|e^{At}\|^2$ and in particular when H satisfies (3.1) and z_0 is an eigenvector of H corresponding to $\lambda_{\max}(H)$ then $f^{1/2} = f^{1/2}(t, z_0)$ generally provides a good approximation to $\|e^{At}\|$. This can be seen by comparing the maximal area curves $f^{1/2}(t, z_0) = \|z(t)\|$ in Figs. 1(a), 2(a), 3(a) with the curves $\|e^{At}\|$ in Figs. 1(b), 2(b), 3(b). In all cases except $\rho = 0$ for the Kailath problem (Figs. 3(a), 3(b)) the agreement is excellent.

In the Kailath problem with $\rho = 0$, the short term behavior of $\|e^{At}\|$ is determined by solutions of (3.2) which exhibit large transients before decaying rapidly. However the asymptotic behavior of $\|e^{At}\|$ is very closely matched by the norm of the minimally L_2 damped solution to (3.2). The short term behavior of $\|e^{At}\|$ for this problem can be well approximated by using minimally L_2 damped solutions for restricted time

intervals: in Fig. 4(b) we plot $\|e^{At}\|$ and in Fig. 4(a) we plot $\|z(t)\|$ for two solutions z to (3.2) whose initial conditions are eigenvectors of H , corresponding to $\lambda_{\max}(H)$, where H satisfies (3.7) for $0 \leq t \leq 0.04$ (curve 1 in Fig. 4(a)) and $0.06 \leq t \leq 0.1$ (curve 2 in Fig. 4(a)) respectively. The next theorem shows that if we restrict ourselves to an interval $t_0 \leq t \leq t_1$ then the approximation to $\|e^{At}\|$ by the maximal area curve $\|z(t)\|$ becomes exact as $t_1 \rightarrow t_0$.

THEOREM 3.3. Let H_ε denote the solution to

$$(3.11) \quad A^* H_\varepsilon + H_\varepsilon A = e^{A^* t_1} e^{A t_1} - e^{A^* t_0} e^{A t_0}$$

where $t_1 = t_0 + \varepsilon$ and A is stable. Then

$$(3.12) \quad \lim_{\varepsilon \rightarrow 0} \frac{H_\varepsilon}{\varepsilon} = e^{A^* t_0} e^{A t_0}.$$

Proof. As in the proof of Theorem 3.2, H_ε in (3.11) satisfies

$$(3.13) \quad H_\varepsilon = \int_{t_0}^{t_0 + \varepsilon} e^{A^* t} e^{A t} dt.$$

FIG. 4(a). Kailath: norm $z(t)$ versus time where $\dot{z} = Az$.

FIG. 4(b). Kailath: spectral norm of $\exp(At)$ versus time.

Thus, by the continuity of the matrix function $e^{A^*t} e^{At}$ we have

$$\lim_{\varepsilon \rightarrow 0} \frac{H_\varepsilon}{\varepsilon} = \lim_{\varepsilon \rightarrow 0} \frac{\int_{t_0}^{t_0+\varepsilon} e^{A^*t} e^{At} dt}{\varepsilon} = e^{A^*t_0} e^{At_0}. \quad \square$$

We may interpret Theorem 3.3 as

$$(3.14) \quad H_\varepsilon \approx \varepsilon e^{A^*t_0} e^{At_0}$$

for small ε . In particular, this means that the eigenspace of H_ε corresponding to $\lambda_{\max}(H_\varepsilon)$ tends to the singular vector space of e^{At_0} corresponding to $\sigma_{\max}(e^{At_0})$. Also notice that if we wish to find a solution $z = z(t)$ to $\dot{z} = Az$ which satisfies $\|z(t_0)\| = \|e^{At_0}\|$ for given value of t_0 , then we need only choose z_0 to be a normalized singular vector of e^{At_0} corresponding to $\sigma_{\max}(e^{At_0})$ because we then have $\|e^{At_0}z_0\| = \|e^{At_0}\|$ and $z(t) = e^{At}z_0$.

A nice feature of the area approach is that many established results can be proved quite directly. For example, the following theorem was implicit in the work of Pao [25] and explicitly proved by Bass in [2] (see also (4.9) in § 4 for a proof based on the logarithmic norm $\mu(A) = \frac{1}{2}\lambda_{\max}(A + A^*)$).

THEOREM 3.4. *Let A be stable and let H satisfy $A^*H + HA = -W$ where W is positive definite and Hermitian. Then*

$$(3.15) \quad \max_{0 \leq t < \infty} \|e^{At}\| \leq K^{1/2}(H)$$

where $K(H) = \|H\| \|H^{-1}\|$.

Proof. Let $t \geq 0$ and let $x_0 \in \mathbb{C}^N$ satisfy $\|e^{At}\| = \|e^{At}x_0\|$, $\|x_0\| = 1$. Then

$$\begin{aligned} \int_t^\infty x_0^* e^{A^*s} W e^{As} x_0 ds &\leq \int_0^\infty x_0^* e^{A^*s} W e^{As} x_0 ds = x_0^* H x_0 \\ &\leq \lambda_{\max}(H) = \|H\|, \end{aligned}$$

since $H = \int_0^\infty e^{A^*s} W e^{As} ds$, $H = H^*$ and $H > 0$.

On the other hand,

$$\begin{aligned} \int_t^\infty x_0^* e^{A^*s} W e^{As} x_0 ds &= \int_0^\infty x_0^* e^{A^*(t+s)} W e^{A(t+s)} x_0 ds \\ &= x_0^* e^{A^*t} \int_0^\infty e^{A^*s} W e^{As} ds e^{At} x_0 \\ &= x_0^* e^{A^*t} H e^{At} x_0 \geq \lambda_{\min}(H) \|e^{At}x_0\|^2 = \frac{1}{\|H^{-1}\|} \|e^{At}\|^2. \end{aligned}$$

Thus $\|e^{At}\|^2 \leq \|H\| \|H^{-1}\|$ for all $t \geq 0$. \square

The above theorem gives an upper bound on the “hump” height (see [23])

$$(3.16) \quad h \equiv \max_{0 \leq t < \infty} \|e^{At}\|.$$

The next theorem shows that the bound (3.15) also applies to all matrices $A = A + \Delta A$ in a neighborhood of A .

THEOREM 3.5. *Let A be stable and let $W = W^*$ be positive definite such that*

$$(3.17) \quad A^*H + HA = -W.$$

Let ΔA satisfy

$$(3.18) \quad \|\Delta A\| < \frac{\lambda_{\min}(W)}{2\|H\|}.$$

Then

$$(3.19) \quad \max_{0 \leq t \leq \infty} \|e^{(A+\Delta A)t}\| \leq K^{1/2}(H).$$

Proof. As in the proof of Theorem 2.4 let

$$\tilde{A} = A + \Delta A, \quad \tilde{W} = W + \Delta A^*H + H\Delta A.$$

The $\tilde{A}^*H + H\tilde{A} = -\tilde{W}$ and A is stable, W is Hermitian positive definite. The result now follows from Theorem (3.4).

The connection between the Lyapunov equation and the norm behavior of the matrix exponential is further brought out by the next lemma.

LEMMA 3.1. *The following are equivalent:*

$$(3.20) \quad (1) \quad \max_{t \geq 0} \|e^{At}\| \leq 1,$$

$$(3.21) \quad (2) \quad \mu(A) \leq 0,$$

(3) *There exists positive definite Hermitian H commuting with A such that*

$$(3.22) \quad A^*H + HA = -W$$

where $W = W^*$ and $W \geq 0$.

Proof. Since (1) and (2) are well known to be equivalent [22] we show that (2) \Rightarrow (3) \Rightarrow 1.

Assume (2): $\mu(A) = \frac{1}{2}\lambda_{\max}(A + A^*) \leq 0$. Then $W \equiv -(A + A^*)$ is positive semi-definite Hermitian and $H = I$ satisfies $A^*H + HA = -W$ and commutes with A . That is (2) \Rightarrow (3).

Now assume (3). Since H is positive definite Hermitian there is a unique positive definite Hermitian square root of H ; say $H^{1/2}$. Moreover since H commutes with A so does $H^{1/2}$ (see [8]). In particular

$$(3.23) \quad A = H^{1/2}H^{-1/2}A = H^{1/2}AH^{-1/2}$$

so that

$$(3.24) \quad \|e^{At}\| = \|e^{H^{1/2}AH^{-1/2}t}\| \leq e^{\mu(H^{1/2}AH^{-1/2}t)}.$$

The result now follows when we note that

$$\begin{aligned} \mu(H^{1/2}AH^{-1/2}) &= \frac{1}{2}\lambda_{\max}(H^{-1/2}A^*H^{1/2} + H^{1/2}AH^{-1/2}) \\ &= \frac{1}{2}\lambda_{\max}(H^{-1/2}(A^*H + HA)H^{-1/2}) \\ &= \frac{1}{2}\lambda_{\max}(-H^{-1/2}WH^{-1/2}) \leq 0. \end{aligned}$$

□

As a simple numerical test of the bound $\|e^{At}\| \leq K^{1/2}(H)$ we have taken

$$A = \begin{bmatrix} -1 & a \\ 0 & -1 \end{bmatrix}$$

for increasing values of a with $W = I$. The results are given in Table 2.

TABLE 2

	2.5×10^4	8.5×10^4	1.4×10^6	.022	4

As Table 2 indicates, the bound (3.15) is quite reasonable for this example. Moreover it can be shown that for large a

$$\max_{0 \leq t} \|e^{At}\| \simeq \frac{a}{e}, \quad K^{1/2}(H) \simeq a.$$

As a second numerical test we found $\max \|e^{At}\|$, $K^{1/2}(H)$ and $\mu(A)$ for the examples from § 2 for $W = I$. With the single exception of $\rho = 0$ for the Chung-Shapiro problem we see in Table 3 that $K^{1/2}(H)$ is always within a factor of 10 of $\max \|e^{At}\|$. It is of interest to note for these problems that $\max \|e^{At}\|$ and $\mu(A)$ are generally increasing with ρ and that the time $t \text{ max}$ at which the hump in $\|e^{At}\|$ occurs is decreasing with ρ .

4. Sensitivity of the matrix exponential. In [22], Van Loan developed several upper bounds for the exponential sensitivity measure

$$(4.1) \quad \Phi(t) \equiv \frac{\|e^{(A+E)t} - e^{At}\|}{\|e^{At}\|}$$

by using the variation of parameters identity

$$(4.2) \quad e^{(A+E)t} - e^{At} = \int_0^t e^{A(t-s)} E e^{(A+E)s} ds$$

(see [3]). This approach was also adopted by Kagström [16] who sharpened some of the bounds in [22] and developed new bounds based on similarity transformations.

In recognition of the work of these two investigators we shall use the phrase "Kagström-Van Loan sensitivity estimate" to denote any bound on Φ which is obtained from (4.2). In this section we present an estimate of this type as well as a second bound on Φ based on two results of Van Loan from [23] instead of (4.2). This latter bound is given in terms of the commutator $[A, E] = AE - EA$ and reduces to a standard result when $[A, E] = 0$.

Both Van Loan and Kagström used

$$(4.3) \quad \|e^{At}\| \leq K(Y)e^{\mu(B)t}$$

where $A = YBY^{-1}$, in order to obtain bounds based on the Jordan and Schur decompositions of A . In the next theorem we use (4.3) in connection with the Lyapunov equation

$$(4.4) \quad A^*H + HA = -W.$$

THEOREM 4.1. *Let A be stable and let W be positive definite Hermitian. Let H satisfy (4.4). Then for $t \geq 0$*

$$(4.5) \quad \Phi(t) \leq K^{1/2}(H)(e^{\|E\|t} - 1)e^{-\nu t} e^{-\alpha t},$$

where

$$\begin{aligned} K(H) &= \|H\| \|H^{-1}\|, \\ \nu &= \frac{1}{2}\lambda_{\min}(H^{-1/2}WH^{-1/2}), \\ \alpha &= \max_i \operatorname{Re} \lambda_i(A), \end{aligned}$$

and $H^{1/2}$ denotes the unique positive definite Hermitian square root of H .

Proof. Since $A = H^{-1/2}(H^{1/2}AH^{-1/2})H^{1/2}$ we have by (4.3) that

$$(4.6) \quad \|e^{At}\| \leq K(H^{1/2})e^{\mu(H^{1/2}AH^{-1/2})t}$$

for any $t \geq 0$. But $H^{1/2}$ is positive definite Hermitian so

$$(4.7) \quad K(H^{1/2}) = K^{1/2}(H)$$

and

$$\begin{aligned} \mu(H^{1/2}AH^{-1/2}) &= \frac{1}{2}\lambda_{\max}(H^{-1/2}A^*H^{1/2} + H^{1/2}AH^{-1/2}) \\ (4.8) \quad &= \frac{1}{2}\lambda_{\max}(H^{-1/2}(A^*H + HA)H^{-1/2}) \\ &= \frac{1}{2}\lambda_{\max}(-H^{-1/2}WH^{-1/2}) = -\frac{1}{2}\lambda_{\min}(H^{-1/2}WH^{-1/2}). \end{aligned}$$

Using (4.7) and (4.8) in (4.6) we get

$$(4.9) \quad \|e^{At}\| \leq K^{1/2}(H)e^{-\nu t}.$$

Now expand (4.2) as an infinite series of multiple integrals:

$$(4.10) \quad e^{(A+E)t} = e^{At} + \int_0^t e^{A(t-s)}Ee^{As}ds + \int_0^t \int_0^s e^{A(t-s)}Ee^{A(s-s_1)}Ee^{As_1}ds_1ds + \dots$$

Apply (4.9) to (4.10) and integrate to get

$$\begin{aligned} (4.11) \quad \|e^{(A+E)t} - e^{At}\| &\leq K^{1/2}(H)e^{-\nu t} \left(\|E\|t + \|E\|^2 \frac{t^2}{2} + \dots + \|E\|^j \frac{t^j}{j!} + \dots \right) \\ &\leq K^{1/2}(H)e^{-\nu t}(e^{\|E\|t} - 1). \end{aligned}$$

Inequality (4.11) with $\|e^{At}\| \geq e^{\alpha t}$ gives the desired result. \square

Note $H^{-1}W$ is similar to $H^{-1/2}WH^{-1/2}$ (see [29]) so $\lambda_{\min}(H^{-1/2}WH^{-1/2}) = \lambda_{\min}(H^{-1}W)$.

An important aspect of Theorem 4.1 is the freedom involved in choosing W in (4.4). For example, if we set $W = I$ then

$$(4.12) \quad \nu \equiv \frac{1}{2} \lambda_{\min}(H^{-1/2}WH^{-1/2}) = \frac{1}{2} \lambda_{\min}(H^{-1}) = \frac{1}{2\|H\|}$$

so that (4.5) becomes

$$\Phi(t) \leq K^{1/2}(H)(e^{\|E\|t} - 1)e^{-t/2\|H\|} e^{-at}.$$

Moreover from (4.9) we have in this case

$$(4.13) \quad \|e^{At}\| \leq K^{1/2}(H)e^{-t/2\|H\|}$$

which points up the connection between damping and maximal area ($\|H\|$) discussed in § 3.

In general, however, we are faced with the problem of selecting W and it is natural to want to make this choice so as to maximize the damping term ν in (4.9). From $\|e^{At}\| \geq e^{\alpha(A)t}$ and (4.9) we see that no matter how we choose W we cannot make ν greater than $|\alpha(A)|$. Following Pao [25] let $H = H(\rho)$ be the solution to

$$(4.14) \quad (A + \rho I)^*H + H(A + \rho I) = -I$$

for $\rho < |\alpha(A)|$. This may be rewritten in the form of (4.4) if we take $W = I + 2\rho H$, in which case

$$(4.15) \quad \nu = \frac{1}{2} \lambda_{\min}(H^{-1/2}(I + 2\rho H)H^{-1/2}) = \frac{1}{2} \lambda_{\min}(H^{-1} + 2\rho I).$$

Now for A stable and $\rho < |\alpha(A)|$ we have $A + \rho I$ stable so that H satisfying (4.14) is positive definite Hermitian. We may thus bound ν below by ρ from (4.15):

$$(4.16) \quad \rho < \nu = \nu(\rho) < |\alpha(A)|.$$

Inequality (4.16) shows that we may come arbitrarily close to the optimal damping rate $|\alpha(A)|$. In some cases, for example when A is normal, $K^{1/2}(H)$ remains bounded as $\rho \rightarrow |\alpha(A)|$; however if A has a defective eigenstructure associated with eigenvalue λ where $\operatorname{Re} \lambda = \alpha(A)$ then $K^{1/2}(H) \rightarrow \infty$ as $\rho \rightarrow |\alpha(A)|$ (see [26]).

As noted in [22], when A and E commute we may obtain a simple bound on Φ :

$$(4.17) \quad \Phi(t) \leq \|e^{Et} - I\| \leq e^{\|E\|t} - 1.$$

The desire to obtain a general bound on Φ which reduces to (4.17) when A and E commute motivated the following.

THEOREM 4.2. *Let $t \geq 0$ then*

$$(4.18) \quad \Phi(t) \leq \|e^{Et} - I\| + (\cosh(\|[A, E]\|^{1/2}t) - 1)e^{(\mu(A) - \alpha(A))t} e^{\mu(E)t}$$

where $[A, E]$ is the Lie product

$$(4.19) \quad [A, E] = AE - EA$$

and

$$\cosh(x) \equiv \frac{e^x + e^{-x}}{2}.$$

The proof of this theorem relies on two results of Van Loan [23]:

$$\text{Lemma 1 (Van Loan)} \quad e^B e^C = e^{B+C} + \int_0^1 e^{sB} [e^{(1-s)(B+C)}, C] e^{sC} ds;$$

$$\text{Lemma 2 (Van Loan)} \quad \|[e^B, C]\| \leq e^{\mu(B)} \|[B, C]\|.$$

Proof of Theorem 4.2. We show that

$$\|e^{A+E} - e^A\| \leq \|e^A\| \|e^E - 1\| + e^{\mu(A)} e^{\mu(E)} [\cosh(\|[A, E]^{1/2}\|) - 1]$$

which proves the result upon replacing A, E by At, Et and using $\mu(tM) = \mu(M)t$ for $t \geq 0$ with $\|e^{At}\| \leq e^{\alpha(A)t}$.

In Lemma 1 set $B = A + E$ and $C = -A$

then

$$\begin{aligned} e^{A+E} e^{-A} &= e^E + \int_0^1 e^{s(A+E)} [e^{(1-s)E}, -A] e^{-sA} ds \\ &= e^E + \int_0^1 e^{s(A+E)} [A, e^{(1-s)E}] e^{-sA} ds. \end{aligned}$$

Multiply both sides by e^A on the right to get

$$e^{A+E} = e^E e^A + \int_0^1 e^{s(A+E)} [A, e^{(1-s)E}] e^{(1-s)A} ds.$$

Repeated substitution gives

$$\begin{aligned} e^{A+E} &= e^E e^A + \int_0^1 e^{Es} e^{As} [A, e^{(1-s)E}] e^{(1-s)A} ds \\ &\quad + \int_0^1 \int_0^1 e^{s_1 s E} e^{s_1 s A} [sA, e^{(1-s_1) s E}] e^{(1-s_1) s A} \\ &\quad \cdot [A, e^{(1-s)E}] e^{(1-s)A} ds_1 ds + \dots \end{aligned}$$

so that

$$e^{A+E} - e^A = e^E e^A - e^A + \int_0^1 e^{Es} e^{As} [A, e^{(1-s)E}] e^{(1-s)A} ds + \dots$$

Taking norms we have

$$\|e^{A+E} - e^A\| \leq \|e^E - I\| \|e^A\| + \int_0^1 \|e^{Es}\| \|e^{As}\| \|[A, e^{(1-s)E}]\| \|e^{(1-s)A}\| ds + \dots$$

Now use $\|e^{Mr}\| \leq e^{\mu(M)r}$ for $r \geq 0$ and Lemma 2 of Van Loan to get

$$\begin{aligned} \|e^{A+E} - e^A\| &\leq \|e^E - I\| \|e^A\| + e^{\mu(E)} e^{\mu(A)} \|[A, E]\| \int_0^1 (1-s) ds \\ &\quad + e^{\mu(E)} e^{\mu(A)} \|[A, E]\|^2 \int_0^1 (1-s)s^2 ds \int_0^1 (1-s_1) ds_1 + \dots \\ &= \|e^E - I\| \|e^A\| + e^{\mu(E)} e^{\mu(A)} \|[A, E]\| \frac{1}{2} + \|[A, E]\|^2 \frac{1}{24} \\ &\quad + \dots + \|[A, E]\|^n \frac{1}{(2n)!} + \dots \\ &= \|e^E - I\| \|e^A\| + e^{\mu(E)} e^{\mu(A)} \{\cosh(\|[A, E]^{1/2}\|) - 1\}. \end{aligned}$$

□

When A and E commute (4.18) reduces to (4.17) because

$$[A, E] = AE - EA = 0.$$

Conclusion. An analysis of the sensitivity of the solution to the Lyapunov equation $A^*X + XA = -W$ has been presented. This analysis leads to a spectral norm bound on the relative perturbation of the solution which is essentially equivalent to the Frobenius norm bound obtained from the associated Kronecker product system. The latter bound can be expressed in terms of $\text{sep}(A^*, -A)$ and is known to accurately reflect the sensitivity of the Lyapunov problem, but it is hard to interpret in terms of the original matrix A . In contrast, the spectral norm bound which we have obtained is directly related to the minimal L_2 damping of the dynamical system $\dot{z} = Az$. Moreover, this dynamical link with the sensitivity problem leads to a new method of systematically investigating the norm behavior of e^{At} as well as providing a wealth of information about control theoretic aspects of $\dot{z} = Az$. In a future paper, we show that the dynamical approach also works well in analyzing the sensitivity of the Riccati equation.

A PARALLEL ALGORITHM FOR A CLASS OF CONVEX PROGRAMS*

SHIH-PING HAN† AND GANG LOU†

Abstract. A parallel algorithm is proposed in this paper for solving the problem $\min \{q(x) | x \in C_1 \cap \cdots \cap C_m\}$ where q is a uniformly convex function and C_i are closed convex sets in R^n . In each iteration of the method, we solve in parallel m independent subproblems, each minimizing a definite quadratic function over an individual set C_i . The method has attractive convergence properties and can be implemented as parallel algorithms for tackling definite quadratic programs, linear programs, systems of linear equations and systems of generalized nonlinear inequalities.

Key words. convex program, parallel algorithm

AMS(MOS) subject classifications. 65K05, 90C25, 90C30

1. Introduction. In this paper we study a method for solving the optimization problem:

$$(P) \quad \begin{array}{ll} \text{minimize} & q(x) \\ \text{subject to} & x \in C = C_1 \cap \cdots \cap C_m \end{array}$$

where q is uniformly convex and differentiable on R^n and C_i are closed convex sets. In particular, the method can be used for tackling definite quadratic programs and, therefore, can be incorporated into a sequential quadratic programming algorithm for solving some more general problems (see, for example, [1]–[3], [6]).

The method is an iterative process. The main computation in each iteration is to solve m subproblems of the following form:

$$\begin{array}{ll} \text{minimize} & \frac{1}{2} \|z - w_i\|^2 \\ \text{subject to} & z \in C_i \end{array}$$

with vector w_i varying iteratively for each set C_i . The key feature here is that the m subproblems are independent of each other and can be solved simultaneously and, therefore, the method is suitable for parallel computation. As its special applications, the method can be implemented as parallel algorithms for solving systems of linear equations, linear programming problems and systems of nonlinear inequalities.

The method is actually intended to solve some dual problems of (P) and is closely related to the successive projection method presented in [4], [5]. Not as in the successive projection method, the subproblems here can be solved independently rather than one after another. Moreover, the objective function q in (P) is more general than the one treated in [4], [5].

We present the method in § 2. In § 3 we study the dual problems that our method is actually dealing with. Convergence analysis is given in § 4. Some applications of the method to systems of linear equations, linear programming and systems of generalized nonlinear inequalities are given in § 5. In § 6 we also present a modified version of the method which can avoid some difficulties that may occur in choosing a parameter of the method.

Results in Rockafellar's book [10] will be frequently referred to and most of the symbols and notation used here are also the same as in that book. Recall that the

indicator function of a set C is denoted by $\delta(\cdot|C)$ and defined as: $\delta(x|C) = 0$ if $x \in C$; $\delta(x|C) = \infty$ otherwise. Its conjugate $\delta^*(\cdot|C)$ is the support function of the set C as given by $\delta^*(y|C) = \sup \{\langle x, y \rangle | x \in C\}$. We also use $\text{ri } C$ to denote the relative interior of the set C . Unless specified otherwise, the symbol \sum is to denote the summation from 1 to m , where m is the number of the sets C_i in problem (P).

2. The method. For the proposed method to work properly we require the objective function q in (P) to be smooth and uniformly convex; that is, the function q is finite and differentiable everywhere on R^n and also there exists a positive number ρ such that for any x, y in R^n and for any λ in $(0, 1)$

$$(2.1) \quad \lambda q(x) + (1 - \lambda)q(y) \geq q(\lambda x + (1 - \lambda)y) + \rho\lambda(1 - \lambda)\|x - y\|^2.$$

Under these assumptions, the function q is, of course, strictly convex. Moreover, it is also co-finite. This can be seen easily from the definition of cofiniteness (see [10, p. 116]) or by checking the value of the recession function q^{0+} at any nonzero point

$$\begin{aligned} q^{0+}(y) &= \sup \{(1/\lambda)(q(\lambda y) - q(0)) | \lambda > 0\} \\ &\geq \sup \{\rho(\lambda - 1)\|y\|^2 + q(y) - q(0) | \lambda > 0\} \\ &= \infty. \end{aligned}$$

Therefore, as a consequence of Theorem 26.6 of [10], the conjugate q^* of q is also smooth, strictly convex and co-finite. The method can now be stated as follows.

The method. Let α be a sufficiently large number and let $y^{(0)} = y_1^{(0)} = \cdots = y_m^{(0)} = 0$ and $x^{(0)} = \nabla q^*(y^{(0)})$. For $k = 1, 2, \dots$, we do the following computation:

(a) For $i = 1, \dots, m$, find $z_i^{(k)}$ which solves

$$\begin{aligned} &\text{minimize} \quad \frac{1}{2}\|z + \alpha y_i^{(k-1)} - x^{(k-1)}\|^2 \\ &\text{subject to} \quad z \in C_i; \end{aligned}$$

(b) Set $y_i^{(k)} = y_i^{(k-1)} + (1/\alpha)(z_i^{(k)} - x^{(k-1)})$;

(c) Set $y^{(k)} = y_1^{(k)} + \cdots + y_m^{(k)}$;

(d) $x^{(k)} = \nabla q^*(y^{(k)})$.

Remarks. (1) The bulk of the computation is usually in step (a) where the m subproblems are independent to each other and can be solved in parallel. The efficiency of the method certainly depends on how effectively we can solve the subproblems. When the sets C_i are subspaces or half-spaces, the subproblems are relatively easy to handle as will be seen in the later examples.

(2) The computation of $x^{(k)}$ in step (d) is an evaluation of a gradient of the conjugate function q^* . When an explicit form of the conjugate is known, the calculation is straightforward. For instance, if the function q is definite quadratic as $q(x) = \frac{1}{2}\langle x, Qx \rangle + \langle c, x \rangle$ then we have $x^{(k)} = Q^{-1}(y^{(k)} - c)$. For a more general function whose conjugate is not readily available, we need to do an unconstrained minimization to find $x^{(k)}$ as follows:

$$x^{(k)} = \arg \min q(x) - \langle x, y^{(k)} \rangle.$$

(3) The number α should be sufficiently large. Theoretically, the method will work properly if α is chosen to be larger than m/ρ where ρ is a uniform convexity constant satisfying (2.1). In particular, when q is definite quadratic then ρ can be chosen as one half of the smallest eigenvalue of the underlying matrix. The parameter α need not be a fixed constant. When an uniform convexity constant ρ is not known in advance,

the parameter α can be adjusted and updated iteratively. A more detailed discussion on how to update the parameter is given in § 6.

To illustrate the usefulness of the method we consider some special cases.

(I). *Linearly constrained problem*:

$$\begin{aligned} & \text{minimize} && q(x) \\ & \text{subject to} && \langle a_i, x \rangle \leq \beta_i, \quad i = 1, \dots, j, \\ & && \langle a_i, x \rangle = \beta_i, \quad i = j+1, \dots, m. \end{aligned}$$

For this case the method becomes the following. Let $y^{(0)} = y_1^{(0)} + \dots + y_m^{(0)} = 0$ and $x^{(0)} = \nabla q^*(y^{(0)})$. For $k = 1, 2, \dots$, we compute:

$$(a) \quad y_i^{(k)} = -(\gamma_i / \alpha \langle a_i, a_i \rangle) a_i, \quad (i = 1, \dots, m)$$

where $\gamma_i = \max\{\beta_i - \langle a_i, x^{(k-1)} - \alpha y_i^{(k-1)} \rangle, 0\}$, $(i = 1, \dots, j)$; $\gamma_i = \beta_i - \langle a_i, x^{(k-1)} - \alpha y_i^{(k-1)} \rangle$, $(i = j+1, \dots, m)$;

$$(b) \quad y^{(k)} = y_1^{(k)} + \dots + y_m^{(k)};$$

$$(c) \quad x^{(k)} = \nabla q^*(y^{(k)}).$$

(II). *Projection problem* (cf. [4], [5]):

$$\begin{aligned} & \text{minimize} && \frac{1}{2} \langle x - d, Q(x - d) \rangle \\ & \text{subject to} && x \in C_1 \cap \dots \cap C_m. \end{aligned}$$

For this case the method can be implemented in the following way. Let $y^{(0)} = y_1^{(0)} + \dots + y_m^{(0)} = 0$ and $x^{(0)} = d$. For $k = 1, 2, \dots$, we carry out the following computation:

(a) for $i = 1, \dots, m$, find $z_i^{(k)}$ which solves

$$\begin{aligned} & \text{minimize} && \frac{1}{2} \|z + \alpha y_i^{(k-1)} - x^{(k-1)}\|^2 \\ & \text{subject to} && z \in C_i \end{aligned}$$

and set $y_i^{(k)} = y_i^{(k-1)} + (1/\alpha)(z_i^{(k)} - x^{(k-1)})$;

$$(b) \quad y^{(k)} = y_1^{(k)} + \dots + y_m^{(k)},$$

$$(c) \quad x^{(k)} = Q^{-1}y^{(k)} + d.$$

(III). *Definite quadratic programming*:

$$\begin{aligned} & \text{minimize} && \frac{1}{2} \langle x - d, Q(x - d) \rangle \\ & \text{subject to} && \langle a_i, x \rangle \leq \beta_i, \quad i = 1, \dots, j, \\ & && \langle a_i, x \rangle = \beta_i, \quad i = j+1, \dots, m. \end{aligned}$$

This is, of course, a special case of both (I) and (II). As in (I), because each y_i is a multiple of the corresponding vector a_i , we can represent vectors y_i by scalars. In so doing, the calculation of vectors reduces to that of scalars and the method becomes extremely simple.

Initially, we compute $p_i = (1/\alpha \langle a_i, a_i \rangle) Q^{-1} a_i$, $(i = 1, \dots, m)$ and $x^{(0)} = d$. Let $\gamma_i^{(0)} = 0$, $(i = 1, \dots, m)$, and $x^{(0)} = -d$. For $k = 1, 2, \dots$, we compute:

$$(a) \quad \gamma_i^{(k)} = \max\{\beta_i + \gamma_i^{(k-1)} - \langle a_i, x^{(k-1)} \rangle, 0\}, \quad (i = 1, \dots, j); \quad \gamma_i^{(k)} = \beta_i + \gamma_i^{(k-1)} - \langle a_i, x^{(k-1)} \rangle, \quad (i = j+1, \dots, m);$$

$$(b) \quad x^{(k)} = \sum \gamma_i^{(k)} p_i + d.$$

3. Dual problems. For analyzing the convergence of the method we study in this section some duality problems which the method actually solves. Without too much extra effort we can present the duality results for the slightly more general problem:

$$(P) \quad \min q(x) + f(x)$$

where $f = f_1 + \cdots + f_m$ and q, f_1, \cdots, f_m are all convex functions. The two duality problems of (P) to be considered are:

$$(\mathbb{D}) \quad \min g(y) := q^*(y) + f^*(-y),$$

$$(\mathbb{D}') \quad \min h(y_1, \cdots, y_m) := q^*(y_1 + \cdots + y_m) + \sum f_i^*(-y_i).$$

Clearly, problem (P) is a special case of (P) with functions f_i being the indicator functions of the sets C_i . The two corresponding duality problems of (P) are, respectively, as follows:

$$(\mathbb{D}) \quad \min g(y) := q^*(y) + \delta^*(y|C),$$

$$(\mathbb{D}') \quad \min h(y_1, \cdots, y_m) := q^*(y_1 + \cdots + y_m) + \sum \delta^*(y_i|C_i).$$

It is noted that the duality problems (D) and (D) are essentially the same as those considered in Fenchel's duality theory [10]. Problems (D') and (D') simply result from applying infimal convolution operation to (D) and (D), respectively.

The basic assumption for the following duality results to hold is that the function q is strictly convex, co-finite and differentiable everywhere on R^n . In view of Theorem 26.6 of [10], under this assumption, the conjugate q^* of q is also a function of this type and $\nabla q^* = (\nabla q)^{-1}$.

We first give a result on the connection between Problems (P) and (D).

THEOREM 3.1. *Let q be strictly convex, co-finite and differentiable on R^n and let f be proper closed convex. A vector \bar{x} solves (P) if and only if $\nabla q(\bar{x})$ solves (D). Dually, a vector \bar{y} solves (D) if and only if $\nabla q^*(\bar{y})$ solves (P). Furthermore, such \bar{x} and \bar{y} exist and are unique.*

Proof. \bar{x} solves (P) $\Leftrightarrow 0 \in \nabla q(\bar{x}) + \partial f(\bar{x})$

$$\Leftrightarrow 0 \in -\bar{x} + \partial f^*(-\nabla q(\bar{x}))$$

$$\Leftrightarrow 0 \in \nabla q^*(\nabla q(\bar{x})) - \partial f^*(-\nabla q(\bar{x}))$$

$$\Leftrightarrow \nabla q(\bar{x}) \text{ solves (D).}$$

The second statement follows from a similar argument. In view of $\text{dom } q = \text{dom } q^* = R^n$, the existence of solutions (P) and (D) is a result of Fenchel's duality theorem [10, Thm. 31.1]. The uniqueness of solutions of (P) and (D) follows from the strict convexity. Q.E.D.

The following theorem explores the relationship between (P) and (D').

THEOREM 3.2. *Let q be strictly convex, co-finite and differentiable on R^n and let f be proper closed convex. A vector $(\bar{y}_1, \cdots, \bar{y}_m)$ solves (D') if and only if there exists a vector \bar{x} such that*

$$(a) \quad \bar{x} = \nabla q^*(\sum \bar{y}_i);$$

$$(b) \quad -\bar{y}_i \in \partial f_i(\bar{x}), (i = 1, \cdots, m).$$

Furthermore, any vector \bar{x} satisfying (a) and (b) solves (P).

$$\text{Proof. } (\bar{y}_1, \cdots, \bar{y}_m) \text{ solves (D')} \Leftrightarrow 0 \in \nabla q^*(\sum \bar{y}_i) - \partial f_i^*(-\bar{y}_i), (i = 1, \cdots, m)$$

$$\Leftrightarrow \bar{x} \in \partial f_i^*(-\bar{y}_i), (i = 1, \cdots, m), \text{ and } \bar{x} = \nabla q^*(\sum \bar{y}_i)$$

$$\Leftrightarrow (a) \text{ and } (b).$$

If a vector \bar{x} satisfies (a) and (b) then $\sum -\bar{y}_i \in \sum \partial f_i(\bar{x}) \subset \partial f(\bar{x})$, which implies $0 \in \nabla q(\bar{x}) + \partial f(\bar{x})$. Consequently, \bar{x} solves (P). Q.E.D.

The theorem below concerns how problem (D) is related to problem (D').

THEOREM 3.3. *Let q be strictly convex, co-finite and differentiable on R^n and let f be proper closed convex, then*

$$\bar{y} \text{ solves } (\mathbb{D}) \Leftrightarrow \exists (\bar{y}_1, \dots, \bar{y}_m), (\bar{y}_1, \dots, \bar{y}_m) \text{ solves } (\mathbb{D}') \text{ and } \bar{y} = \sum \bar{y}_i.$$

Moreover, if f_1, \dots, f_p are polyhedral and f_{p+1}, \dots, f_m are closed convex such that $\text{dom } f_1 \cap \dots \cap \text{dom } f_p \cap \text{ri}(\text{dom } f_{p+1}) \cap \dots \cap \text{ri}(\text{dom } f_m) \neq \emptyset$ then

$$\inf g(y) = \inf h(y_1, \dots, y_m).$$

Proof. The necessity of the first part of the theorem is a direct consequence of Theorems 3.1 and 3.2. To prove the sufficiency we note that if \bar{y} solves (\mathbb{D}) then, by Theorem 3.1, the vector $\bar{x} := \nabla q^*(\bar{y})$ solves (\mathbb{P}) . Hence,

$$-\bar{y} = -\nabla q(\bar{x}) \in \partial f(\bar{x}) = \sum \partial f_i(\bar{x}).$$

Therefore, it follows that there exists $(\bar{y}_1, \dots, \bar{y}_m)$ such that $\bar{y} = \sum \bar{y}_i$ and $-\bar{y}_i \in \partial f_i(\bar{x})$, $(i = 1, \dots, m)$. Then, the result follows immediately from Theorem 3.2.

To prove the second part of the theorem, we note that $\inf h \geq \inf g$. When $\text{dom } f_1 \cap \dots \cap \text{dom } f_p \cap \text{ri}(\text{dom } f_{p+1}) \cap \dots \cap \text{ri}(\text{dom } f_m) \neq \emptyset$, then for any y there exist y_1, \dots, y_m such that $y_1 + \dots + y_m = y$ and $f^*(-y) = (f_1^* \square \dots \square f_m^*)(-y) = f_1^*(-y_1) + \dots + f_m^*(-y_m)$. Therefore, it can never occur that $\inf h > \inf g$ and, consequently, we have $\inf g(y) = \inf h(y_1, \dots, y_m)$. Q.E.D.

4. Convergence analysis. In this section we study the convergence of the method for solving problem (P). For the results of § 3 to be applicable here and for the method to work properly we assume throughout this section:

- (a) q is uniformly convex and differentiable on R^n ;
- (b) C_i are closed convex and $C = C_1 \cap \dots \cap C_m \neq \emptyset$.

Assumption (a) above implies that q is strictly convex and co-finite and, in conjunction with assumption (b), makes Theorem 3.1 applicable. Therefore, problems (P) and (D) have unique solutions, which will be denoted by \bar{x} and \bar{y} , respectively.

In the subsequent discussion we will also assume that the parameter α is chosen to be larger than m/ρ where ρ is an uniform convexity constant of q that satisfies condition (2.1).

For establishing our convergence theorems, we first give some useful lemmas below.

LEMMA 4.1. *The vector $y_i^{(k)}$ solves the problem*

$$(4.1) \quad \min (\alpha/2) \|y_i^{(k-1)} - y\|^2 + \langle x^{(k-1)}, y \rangle + \delta^*(y|C_i).$$

Proof. In the method, the vector $z_i^{(k)}$ solves

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} \|z + \alpha y_i^{(k-1)} - x^{(k-1)}\|^2 \\ & \text{subject to} \quad z \in C_i. \end{aligned}$$

Let $\varphi(z) = (1/2\alpha) \|z + \alpha y_i^{(k-1)} - x^{(k-1)}\|^2$. Therefore, the vector $z_i^{(k)}$ solves the problem:

$$\min \varphi(z) + \delta(z|C_i).$$

By applying Theorem 3.1 to the above problem, we have that the vector $y_i^{(k)} = y_i^{(k-1)} + (1/\alpha)(z_i^{(k)} - x^{(k-1)}) = \nabla \varphi(z_i^{(k)})$ is the solution of

$$\min \varphi^*(y) + \delta^*(y|C_i)$$

which is equivalent to (4.1). Q.E.D.

LEMMA 4.2. $\langle x^{(k)} - x^{(k-1)}, y^{(k)} - y^{(k-1)} \rangle \leq (m/2\rho) \sum \|y_i^{(k-1)} - y_i^{(k)}\|^2$.

Proof. By the uniform convexity of q , we have that for any two vectors u and v ,

$$\langle u - v, \nabla q(u) - \nabla q(v) \rangle \geq 2\rho \|u - v\|^2 \quad (\text{see, for example, [8, p. 86]})$$

which yields

$$\|y^{(k-1)} - y^{(k)}\| = \|\nabla q(x^{(k-1)}) - \nabla q(x^{(k)})\| \geq 2\rho \|x^{(k-1)} - x^{(k)}\|.$$

Therefore, it follows that

$$\begin{aligned} \langle x^{(k)} - x^{(k-1)}, y^{(k)} - y^{(k-1)} \rangle &\leq \|x^{(k-1)} - x^{(k)}\| \|y^{(k-1)} - y^{(k)}\| \\ &\leq (1/2\rho) \|y^{(k-1)} - y^{(k)}\|^2 \\ &\leq (1/2\rho) (\sum \|y_i^{(k-1)} - y_i^{(k)}\|)^2 \\ &\leq (1/2\rho) m (\sum \|y_i^{(k-1)} - y_i^{(k)}\|^2), \end{aligned}$$

where the last inequality is a result of the Cauchy-Schwarz inequality. Q.E.D.

LEMMA 4.3. Let h be defined as in (\mathbb{D}') , then

$$h(y_1^{(k-1)}, \dots, y_m^{(k-1)}) \geq h(y_1^{(k)}, \dots, y_m^{(k)}) + (\alpha\rho - m)/(2\rho) \sum \|y_i^{(k-1)} - y_i^{(k)}\|^2.$$

Proof. By convexity we have that

$$q^*(y^{(k-1)}) \geq q^*(y^{(k)}) + \langle \nabla q^*(y^{(k)}), y^{(k-1)} - y^{(k)} \rangle,$$

which, in conjunction with $x^{(k)} = \nabla q^*(y^{(k)})$, implies that

$$\begin{aligned} h(y_1^{(k-1)}, \dots, y_m^{(k-1)}) &\geq h(y_1^{(k)}, \dots, y_m^{(k)}) + \langle x^{(k)}, y^{(k-1)} - y^{(k)} \rangle \\ &\quad + \sum (\delta^*(y_i^{(k-1)} | -C_i) - \delta^*(y_i^{(k)} | -C_i)). \end{aligned}$$

Because $y_i^{(k)}$ solves (4.1), we get

$$\delta^*(y_i^{(k-1)} | -C_i) - \delta^*(y_i^{(k)} | -C_i) \geq \langle x^{(k-1)}, y_i^{(k)} - y_i^{(k-1)} \rangle + (\alpha/2) \|y_i^{(k-1)} - y_i^{(k)}\|^2.$$

Thus, combining the two inequalities above, we have

$$\begin{aligned} h(y_1^{(k-1)}, \dots, y_m^{(k-1)}) &\geq h(y_1^{(k)}, \dots, y_m^{(k)}) + \langle x^{(k)} - x^{(k-1)}, y^{(k-1)} - y^{(k)} \rangle \\ &\quad + (\alpha/2) \sum \|y_i^{(k-1)} - y_i^{(k)}\|^2. \end{aligned}$$

The desired result follows from the above inequality and Lemma 4.2. Q.E.D.

COROLLARY 4.4. (a) For $i = 1, \dots, m$, $\|y_i^{(k-1)} - y_i^{(k)}\| \rightarrow 0$, as $k \rightarrow \infty$;

(b) $\|y^{(k-1)} - y^{(k)}\| \rightarrow 0$, as $k \rightarrow \infty$;

(c) $\|x^{(k-1)} - x^{(k)}\| \rightarrow 0$, as $k \rightarrow \infty$.

Proof. By adding the inequalities in Lemma 4.3 from $k = 0$ to p , we have that

$$h(y_1^{(0)}, \dots, y_m^{(0)}) - h(y_1^{(p)}, \dots, y_m^{(p)}) \geq \omega \sum_{j=1}^p (\sum \|y_i^{(j-1)} - y_i^{(j)}\|^2)$$

where $\omega = (\alpha\rho - m)/(2\rho) > 0$. Because $h(y_1^{(p)}, \dots, y_m^{(p)}) \geq \inf h \geq g(\bar{y}) > -\infty$, the left-hand side of the inequality is bounded above by a finite number which is independent of p . This implies (a) and (b). Statement (c) follows from (b) and $\|y^{(k-1)} - y^{(k)}\| = \|\nabla q(x^{(k-1)}) - \nabla q(x^{(k)})\| \geq 2\rho \|x^{(k-1)} - x^{(k)}\|$. Q.E.D.

LEMMA 4.5. The sequences $\{x^{(k)}\}$ and $\{y^{(k)}\}$ are bounded.

Proof. Since $g(y^{(k)}) \leq h(y_1^{(k)}, \dots, y_m^{(k)}) \leq h(y_1^{(0)}, \dots, y_m^{(0)})$, we have that the sequence $\{y^{(k)}\}$ is in a lower level set of g . The level set is bounded because the infimum of g is attained at one point, namely \bar{y} .

With $\{y^{(k)}\} = \{\nabla q(x^{(k)})\}$ bounded, the boundedness of the sequence $\{x^{(k)}\}$ is a direct consequence of the co-finiteness of q (see [10, Lemma 26.7]). It is also evident from the following observation:

$$\begin{aligned}\|x^{(k)}\| &\leq (1/2\rho)\|\nabla q(x^{(k)}) - \nabla q(0)\| \\ &\leq (1/2\rho)(\|y^{(k)}\| + \|\nabla q(0)\|).\end{aligned}\quad \text{Q.E.D.}$$

We now give a convergence theorem of the method for the case that the sets C_i are polyhedral convex.

THEOREM 4.6. *If C_i are polyhedral convex and $\cap C_i \neq \emptyset$, then $\{x^{(k)}\}$ and $\{y^{(k)}\}$ converge to the solution \bar{x} of (P) and the solution \bar{y} of (D), respectively.*

Proof. Since $y_i^{(k)}$ solves (4.1), we have that

$$0 \in x^{(k-1)} + \alpha(y_i^{(k)} - y_i^{(k-1)}) + \partial\delta^*(y_i^{(k)}|C_i)$$

which implies that

$$(4.2) \quad -y_i^{(k)} \in \partial\delta(x^{(k)} + w_i^{(k)}|C_i)$$

where $w_i^{(k)} = x^{(k-1)} - x^{(k)} + \alpha(y_i^{(k)} - y_i^{(k-1)})$. Let x^* be an accumulation point of $\{x^{(k)}\}$ and assume $x^{(k_j)} \rightarrow x^*$. In view of Corollary 4.4, we have $w_i^{(k)} \rightarrow 0$ and, thus, $x^{(k_j)} + w_i^{(k_j)} \rightarrow x^*$. By the polyhedrality of C_i , it follows that for all sufficiently large k_j ,

$$-y_i^{(k_j)} \in \partial\delta(x^{(k_j)} + w_i^{(k_j)}|C_i) \subset \partial\delta(x^*|C_i).$$

Therefore, we have that for all sufficiently large k_j

$$-y^{(k_j)} \in \sum \partial\delta(x^*|C_i) \subset \partial\delta(x^*|C).$$

Hence, from $y^{(k_j)} = \nabla q(x^{(k_j)}) \rightarrow \nabla q(x^*)$ it follows that $-\nabla q(x^*) \in \partial\delta(x^*|C)$, which implies that x^* is the unique solution \bar{x} of (P). Therefore, no point other than \bar{x} can be an accumulation point of the sequence $\{x^{(k)}\}$. Then it follows from the boundedness of the sequence that $\{x^{(k)}\}$ converges to the solution \bar{x} of (P). Meanwhile, we have that $y^{(k)} = \nabla q(x^{(k)}) \rightarrow \nabla q(\bar{x}) = \bar{y}$. Q.E.D.

We now consider the case that C_i are general convex sets. For this situation the proofs of our convergence theorems are based on the existence of an accumulation point of the sequence $(y_1^{(k)}, \dots, y_m^{(k)})$.

PROPOSITION 4.7. *Let $\cap \text{ri } C_i \neq \emptyset$. Then any accumulation point of the sequence $\{(y_1^{(k)}, \dots, y_m^{(k)})\}$ is a solution of (D'). Furthermore, if such an accumulation point exists then the sequences $\{x^{(k)}\}$ and $\{y^{(k)}\}$ converge to the solutions of (P) and (D), respectively.*

Proof. Let $(y_1^{(k_j)}, \dots, y_m^{(k_j)}) \rightarrow (y_1^*, \dots, y_m^*)$. Since $\{x^{(k)}\}$ is bounded, by passing to a further subsequence, if necessary, we can find a point x^* such that $x^{(k_j)} \rightarrow x^*$. In view of (4.2) and $w_i^{(k)} \rightarrow 0$, we have that for $i = 1, \dots, m$,

$$-y_i^* \in \partial\delta(x^*|C_i).$$

On the other hand, it follows from $x^{(k_j)} = \nabla q^*(\sum y_i^{(k_j)})$ that $x^* = \nabla q^*(\sum y_i^*)$. Therefore, by Theorem 3.2, (y_1^*, \dots, y_m^*) solves (D').

To prove the second statement, we note that $h(y_1^{(k)}, \dots, y_m^{(k)}) \geq g(y^{(k)})$ and, by the monotone decrease of $\{h(y_1^{(k)}, \dots, y_m^{(k)})\}$ and by the first part of the proof,

$$\lim h(y_1^{(k)}, \dots, y_m^{(k)}) = \inf h = \inf g.$$

Thus, we have $\lim g(y^{(k)}) = \inf g$. Therefore, $\{y^{(k)}\}$ converges to \bar{y} because the infimum of g is attained at the unique point \bar{y} . At the same time, we have $x^{(k)} = \nabla q^*(y^{(k)}) \rightarrow \bar{x} = \nabla q^*(\bar{y})$. Q.E.D.

In view of Proposition 4.7, to show the convergence of $\{x^{(k)}\}$ to the solution of (P) we need to study when the sequence $\{(y_1^{(k)}, \dots, y_m^{(k)})\}$ has an accumulation point or, more conveniently, to consider when the sequence is bounded.

LEMMA 4.8. *If $\text{int}(C) \neq \emptyset$ then the sequence $\{(y_1^{(k)}, \dots, y_m^{(k)})\}$ is bounded.*

Proof. Let $z \in \text{int}(C)$. Then

$$\begin{aligned} q(z) + q^*(0) &= q(z) + h(y_1^{(0)}, \dots, y_m^{(0)}) \\ &\cong q(z) + h(y_1^{(k)}, \dots, y_m^{(k)}) \\ &\cong q(z) + q^*(y_1^{(k)} + \dots + y_m^{(k)}) + \sum \delta^*(y_i^{(k)} | -C_i) \\ &\cong \langle z, y_1^{(k)} + \dots + y_m^{(k)} \rangle + \sum \delta^*(y_i^{(k)} | -C_i) \\ &\cong \sum \delta^*(y_i^{(k)} | z - C_i). \end{aligned}$$

Therefore, it follows from $z \in C$ that $\delta^*(y_i^{(k)} | z - C_i) \geq 0$ and, hence, $y_i^{(k)}$ is in the level set $\{y | \delta^*(y | z - C_i) \leq q(z) + q^*(0)\}$, which is bounded because

$$0 \in z - \text{int } C_i = \text{int}(\text{dom } \delta(\cdot | z - C_i)). \quad \text{Q.E.D.}$$

THEOREM 4.9. *If $\text{int}(C) \neq \emptyset$, then $\{x^{(k)}\}$ and $\{y^{(k)}\}$ converge to the unique solutions of (P) and (D), respectively.*

From a practical viewpoint it is important to study when the sequence $\{(y_1^{(k)}, \dots, y_m^{(k)})\}$ converges because the vectors $y_1^{(k)}, \dots, y_m^{(k)}$ are really computed in practice. For this reason we conclude this section with a result on this matter.

THEOREM 4.10. *Let C_1, \dots, C_p be polyhedral convex such that $C_1 \cap \dots \cap C_p \cap \text{ri } C_{p+1} \cap \dots \cap \text{ri } C_m \neq \emptyset$. If $\text{aff}(\partial\delta(\bar{x} | C_i))$ are linearly independent in the sense:*

$$\sum z_i = 0 \quad \text{and} \quad z_i \in \text{aff}(\partial\delta(\bar{x} | C_i)) \quad (i = 1, \dots, m) \Rightarrow z_i = 0 \quad (i = 1, \dots, m),$$

then the sequence $\{(y_1^{(k)}, \dots, y_m^{(k)})\}$ converges to the unique solution of (D'). Consequently, the sequences $\{x^{(k)}\}$ and $\{y^{(k)}\}$ converge to the solutions of (P) and (D), respectively.

Proof. By the nonemptiness assumption, the infimum of (D') is attainable. Actually, the infimum is attained at a unique point. Suppose $(\bar{y}_1, \dots, \bar{y}_m)$ and (y_1^*, \dots, y_m^*) are two solutions of (D'), then it follows from Theorem 3.3 that $\bar{y} = \bar{y}_1 + \dots + \bar{y}_m = y_1^* + \dots + y_m^*$. Then, if we let $z_i = \bar{y} - y_i^*$, then

$$\sum z_i = 0 \quad \text{and} \quad z_i \in \text{aff}(\partial\delta(\bar{x} | C_i)) \quad (i = 1, \dots, m).$$

Therefore, by the linear independence assumption, we have $\bar{y}_i = y_i^*$ for $i = 1, \dots, m$ and, consequently, the solution of (D') is unique. The uniqueness of the solution, in turn, implies that the level sets of h are bounded and, hence, the sequence $\{(y_1^{(k)}, \dots, y_m^{(k)})\}$ is bounded. Therefore, convergence of the sequence $\{(y_1^{(k)}, \dots, y_m^{(k)})\}$ to the solution of (D) follows immediately from Proposition 4.7. The last statement of the theorem is also a direct result of Proposition 4.7. Q.E.D.

5. Applications. The proposed method can be used to solve some problems which are not explicitly of the form (P). We consider some of such applications in this section.

(1) *System of linear equations.* We consider the fundamental problem

$$Ax = b$$

where A is an $m \times n$ matrix with full row rank. To find a solution to the system, we can apply our method to the following problem:

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} \|x\|^2 \\ & \text{subject to} \quad Ax = b. \end{aligned}$$

By partitioning the matrix A and the vector b into row blocks as

$$A = \begin{pmatrix} A_1 \\ \vdots \\ A_m \end{pmatrix}, \quad b = \begin{pmatrix} b_1 \\ \vdots \\ b_m \end{pmatrix}$$

we can set $C_i = \{x | A_i x = b_i\}$. For this case the objective function $q(x) = \frac{1}{2} \|x\|^2 = q^*(x)$; hence, we have

$$\begin{aligned} (5.1) \quad x^{(k)} &= y^{(k)} \\ &= \sum y_i^{(k)} \\ &= x^{(k-1)} + \sum (y_i^{(k)} - y_i^{(k-1)}). \end{aligned}$$

Meanwhile, both $y_i^{(k)}$ and $y_i^{(k-1)}$ are normal to the set C_i ; therefore, there exists a vector $v_i^{(k)}$ such that

$$y_i^{(k)} - y_i^{(k-1)} = A_i^T v_i^{(k)}.$$

By $z_i^{(k)} = x^{(k-1)} + \alpha(y_i^{(k)} - y_i^{(k-1)})$ and $z_i^{(k)} \in C_i$, we have that

$$(5.2) \quad A_i A_i^T v_i^{(k)} = (1/\alpha)(b_i - A_i x^{(k-1)}).$$

Thus, when the vectors $v_i^{(k)}$ are known, we can compute $x^{(k)}$ from $x^{(k-1)}$ by (5.1). To do this computationally, we first find a QR-decomposition $A_i = Q_i R_i$ of A_i and the system (5.2) becomes

$$R_i^T R_i v_i^{(k)} = (1/\alpha)(b_i - A_i x^{(k-1)}).$$

With vectors $u_i^{(k)}$ to represent $R_i v_i^{(k)}$, the method can be further simplified. We state the resulting method: Find the QR decompositions $A_i^T = Q_i R_i$, ($i = 1, \dots, m$). Let $x^{(0)}$ be an estimate to a solution of the system. For $k = 1, 2, \dots$, we do the following calculation:

- (a) for $i = 1, \dots, m$, solve $R_i^T u = (1/\alpha)(b_i - A_i x^{(k-1)})$ for $u_i^{(k)}$;
- (b) $x^{(k)} = x^{(k-1)} + \sum Q_i u_i^{(k)}$.

We note that m triangular linear systems are solved in parallel in each iteration. Of course, the matrices Q_i should be in product forms so that the products $Q_i u_i^{(k)}$ can be done very efficiently. It is also noted that, according to the theory given in the previous sections, the method should work properly with the parameter α larger than m .

(2) *Linear programming.* According to Mangasarian and Meyer [7], a linear program

$$\begin{aligned} & \text{minimize} \quad \langle c, x \rangle \\ & \text{subject to} \quad Ax \leq b \end{aligned}$$

can be tackled by solving the quadratic program

$$\begin{aligned} & \text{minimize} \quad \langle c, x \rangle + (\sigma/2) \|x\|^2 \\ & \text{subject to} \quad Ax \leq b \end{aligned}$$

where σ is any sufficiently small but positive number. Clearly, the quadratic program is a problem to which our method is applicable. Through this approach our method can be implemented as a parallel algorithm for linear programming. Unlike many other parallel algorithms for solving linear programs, the method does not require the matrix A to have any sparse structure.

(3) *Systems of generalized nonlinear inequalities.* Consider the following system of generalized nonlinear inequalities:

$$(5.3) \quad F(x) \in K$$

where F is a continuously differentiable function from R^n into R^m and K is a closed convex cone. For solving the problem Robinson [9] presented a method in which a sequence of points $\{u^{(k)}\}$ calculated iteratively by solving subproblems of the form:

$$(5.4) \quad \begin{aligned} &\text{minimize} \quad \|x - u^{(k)}\|^2 \\ &\text{subject to} \quad F(u^{(k)}) + F'(u^{(k)})(x - u^{(k)}) \in K. \end{aligned}$$

The method has a quadratic rate of convergence and is an extension of Newton's method to systems of nonlinear inequalities. If we can partition the function F and the cone K so that Problem (5.3) becomes

$$F_i(x) \in K_i, \quad i = 1, \dots, m,$$

then subproblem (5.4) reduces to

$$\begin{aligned} &\text{minimize} \quad \|x - u^{(k)}\|^2 \\ &\text{subject to} \quad x \in C_1 \cap \dots \cap C_m, \end{aligned}$$

where $C_i := \{x \mid F_i(u^{(k)}) + F'_i(u^{(k)})(x - u^{(k)}) \in K_i\}$. For this situation, our method again becomes applicable and the resulting method provides a way for solving Problem (5.3) in parallel.

6. Discussion. In many situations, as in all the examples given in § 5, the parameter α can be easily chosen. But, even when the objective function q is definite quadratic, it is sometimes very costly to determine this parameter in advance. However, as mentioned before, the parameter need not be fixed and can be adjusted iteratively. We present in this section such a procedure. It is noted that the method is more efficient with a smaller α ; therefore, even when a large workable α is available, it may still be more advantageous in some cases to start with a smaller parameter and let it be adjusted gradually.

The modified method. Let α_0 and β be positive numbers and let $\lambda > 1$. Let $y^{(0)} = y_1^{(0)} = \dots = y_m^{(0)} = 0$ and $x^{(0)} = \nabla q^*(y^{(0)})$. For $k = 1, 2, \dots$, we do the following computation:

- (a) $\tilde{\alpha} = \alpha_{k-1}$;
- (b) For $i = 1, \dots, m$, find \tilde{z}_i which solves

$$\begin{aligned} &\text{minimize} \quad \frac{1}{2} \|z + \tilde{\alpha} y_i^{(k-1)} - x^{(k-1)}\|^2 \\ &\text{subject to} \quad z \in C_i; \end{aligned}$$

- (c) Set $\tilde{y}_i = y_i^{(k-1)} + (1/\tilde{\alpha})(\tilde{z}_i - x^{(k-1)})$;
- (d) Set $\tilde{y} = \tilde{y}_1 + \dots + \tilde{y}_m$ and set $\tilde{x} = \nabla q^*(\tilde{y})$;
- (e) Check the condition

$$(6.1) \quad ((\tilde{\alpha}/2) - \beta) \sum \|y_i^{(k-1)} - \tilde{y}_i\|^2 \geq \langle \tilde{x} - x^{(k-1)}, \tilde{y} - y^{(k-1)} \rangle.$$

If (6.1) is not true then set $\tilde{\alpha} = \lambda \tilde{\alpha}$ and go to (b); otherwise, set $\alpha_k = \tilde{\alpha}$, $x^{(k)} = \tilde{x}$, $y^{(k)} = \tilde{y}$, and $y_i^{(k)} = \tilde{y}_i$, ($i = 1, \dots, m$).

In view of Lemma 4.2, when q is uniformly convex, condition (6.1) will hold after increasing α_k at most a finite number of times. Therefore, as in the proof of Lemma 4.3, we still have

$$h(y_1^{(k-1)}, \dots, y_m^{(k-1)}) \geq h(y_1^{(k)}, \dots, y_m^{(k)}) + \beta \sum \|y_i^{(k-1)} - y_i^{(k)}\|^2.$$

Consequently, all the convergence results hold equally well for this modified version of the method.

FIXED POLES IN TRANSFER FUNCTION EQUATIONS*

G. CONTE†, A. M. PERDON† AND B. F. WYMAN‡

Abstract. In this paper we study the pole structure of the solutions $H(z)$, if any, of equations of the form $T(z) = H(z)G(z)$ or, dually, $T(z) = F(z)H(z)$, where $T(z)$ and $G(z)$, or $F(z)$, are given matrices of rational functions (multivariable transfer functions) over a field K . This study is motivated by various design problems in linear dynamical system theory (such as model matching or factorization problems), whose solutions are systems with an internal dynamics determined by the pole structure of $H(z)$. The methods we use are algebraic and module theoretic methods and the main tools are represented by the modules of the poles and of the zeros associated with a transfer function. The main result is a complete description of the "essential" pole structure which is common to all the solutions $H(z)$. This is given by means of a module whose invariant factors are explicitly computed in terms of fractional representations of the data $T(z)$ and $G(z)$ or $F(z)$. The essential pole structure is shown to consist, in a suitable algebraic sense, exactly of the poles of $T(z)$ which do not appear as poles of $G(z)$ (resp. $F(z)$) together with the zeros of $G(z)$ (resp. $F(z)$) which do not appear as poles of $[T'(z)G'(z)]'$ (resp. $[T(z)G(z)]$). The possibility of stating this fact, which agrees with the basic intuition, in a precise meaningful way, is due to the chosen algebraic framework. Furthermore, it is shown that no design limitations, except a technical one, apply to the remaining "inessential" part of the pole structure of any solutions.

Key words. fixed poles, zero module, algebraic system design

1. Introduction.

1.1. From the input/output point of view, a finite-dimensional, stationary, linear dynamical system Σ with m inputs and p outputs is given by a transfer function T_Σ which can be represented by a $p \times m$ matrix of rational functions. More generally, if $K(z)$ is the field of rational functions over a scalar field K , a transfer function is a $K(z)$ -linear transformation $T(z): U(z) \rightarrow Y(z)$, where $U(z) = K^m(z)$ and $Y(z) = K^p(z)$ are finite-dimensional $K(z)$ -vector spaces of input and output signals.

Given two transfer functions $T(z): U(z) \rightarrow Y(z)$ and $G(z): U(z) \rightarrow W(z)$ with the same space of inputs, we study the connecting transfer function (if any) $H(z): W(z) \rightarrow Y(z)$ such that $T(z) = H(z)G(z)$. This equation and the dual one, namely $T(z) = F(z)H(z)$ where $T(z): U(z) \rightarrow Y(z)$ and $F(z): W(z) \rightarrow Y(z)$ are given, arise naturally in various control problems, such as, for instance, system inversion, model matching and system factorization (see [9], [12], [13], [16]–[18], [20] for a general treatment and, more specifically, [3]–[5], [7], [8], [10], [11], [19], [22]).

The fundamental criterion for the existence of a solution $H(z)$, when $T(z)$ and $G(z)$ are given, is quite simple and well known: the nullspace condition $\text{Ker } G \subset \text{Ker } T$ is necessary and sufficient for the existence of $H(z)$. In many problems, however, the existence of a generic connecting transfer function is scarcely interesting; what is required is a solution $H(z)$ which has, in addition, some special property. For instance, we may seek a solution which is proper and/or stable or which, more generally, has no poles in a fixed subset S of $K \cup \{\infty\}$. Various methods based on the analysis of the invariant factors of the matrices involved ([14], [16]) or on other matrix theoretic

techniques ([7]–[9], [11], [12], [15]) can be used to check the existence of solutions of this kind. However, in the multivariable case, other interesting properties of the connecting transfer function $H(z)$ do not depend specifically on the location of its poles in $K \cup \{\infty\}$, but on the pole structure, in the sense of [12, 6.5.3], at the point of $K \cup \{\infty\}$. For instance, the existence of a cyclic structure, which implies single input controllability, on the modes associated to a certain frequency α is equivalent to a pole structure at α of the form $(0, \dots, 0, \sigma_\alpha)$. It is therefore natural to look not only for the existence of solutions having no poles in S , but also for more complete information on their pole structure. In this case, the analysis of the invariant factors or the use of other direct matrix theoretic methods do not appear capable of providing satisfactory results. One explicit result in this direction obtained by means of such techniques is Theorem 2.4 of [20]. It permits the computation of a lower bound for the total order of pole, at a given point α , of any solution $H(z)$. Clearly, in the multivariable case, this information on the pole structure is quite poor.

1.2. In this paper we study the pole structure of the solutions in a module theoretic framework, employing the notions of pole module and zero module of a linear transfer function (see [21], [22]). The advantage in this approach is the fact that it supplies a complete description of the pole structure we are considering. The basic result in this setting is that there is an “essential” pole structure which appears in every solution of $T(z) = H(z)G(z)$ and which is representable by means of a suitable module determined by $T(z)$ and $G(z)$. Using this module theoretic characterization one can not only check the presence in the solutions of poles in a certain region S , but one can also compute explicitly the list of multiplicities which form the structure. The results previously mentioned concerning the existence of solutions with specific polar properties are therefore effectively improved in this way.

Moreover, due to the richness of the module theoretic framework, a clean interpretation in terms of poles and zeros of $T(z)$ and $G(z)$ of the essential pole structure of the solutions is possible. Let us remark that, intuitively and roughly speaking, one can expect that the essential part of the poles of any solution $H(z)$ must supply the poles of $T(z)$ which do not appear already in $G(z)$ as well as the poles needed to cancel the zeros of $G(z)$ which do not appear in $[T(z)'G(z)']'$. (In general, it is necessary to consider $[T(z)'G(z)']'$ since some zero of $G(z)$ may fail to appear as a zero of $T(z)$ for nondynamical reasons, i.e., without being canceled by a pole of $H(z)$, if $T(z)$ is not injective). Indeed, these phenomena appear clearly in the scalar case. If $T(z) = p(z)/q(z)$ and $G(z) = p'(z)/q'(z)$ are given as fractions in lowest terms, then the unique solution has a representation $H(z) = p(z)q'(z)/p'(z)q(z)$ which is not necessarily reduced. Restricting the present discussion to the finite poles of $H(z)$, we have that they consist of roots of $q(z)$, which do not already appear as roots of $q'(z)$, that is poles of $T(z)$ which are not poles of $G(z)$, together with roots of $p'(z)$, which do not appear as roots of $p(z)$ (zeros of $G(z)$ which are not zeros of $T(z)$). A straightforward generalization of these observations to the multivariable case is not possible because numerator matrices may not be invertible and numerically coincident multivariable poles and zeros may not cancel. An attempt to extend the above interpretation of the essential poles to the multivariable case is found in [20]. The matrix theoretic techniques used in that paper do not give complete information on the pole structure. On the other hand, we can show here that the module which represents the essential pole structure of the solutions consists, in a precise algebraic sense, of two modules which have a natural direct interpretation as the module of poles of $T(z)$ which do not appear in $G(z)$ and as the module of zeros of $G(z)$ which do not appear in $[T(z)'G(z)']'$.

1.3. Let us describe the framework of the paper in greater detail. Essentially, we represent the zero structure and the pole structure of a transfer function $T(z)$ by means of appropriate modules. The finite pole structure is given by the state space $X(T)$ of the minimal realization of (the strictly proper part of) $T(z)$ provided with the module structure over the ring of polynomials $K[z]$ induced by the internal dynamics matrix. The finite zero structure is given by the zero module $Z(T)$ first introduced in [22] (see [21] for the general theory). In this setting, our aim is to describe, as completely as possible, the pole module $X(H)$, $H(z)$ being a solution of $T(z) = H(z)G(z)$.

After some preliminaries and notation we prove, in § 3, that for every $H(z)$ there exists an exact sequence

$$0 \rightarrow P \rightarrow X(H) \rightarrow C(H) \rightarrow 0,$$

where $P = P(T, G)$ is a module easily described in terms of $T(z)$ and $G(z)$. Hence, P represents, for any solution $H(z)$, a fixed or essential pole structure. The explicit computation of P in terms of fractional representations of $T(z)$ and $G(z)$ is made possible by the procedure presented in § 3.6. Moreover, we show that P is the middle term of an exact sequence

$$0 \rightarrow X \rightarrow P \rightarrow Z \rightarrow 0$$

where the modules X and Z can be naturally viewed as representing, respectively, the poles of $T(z)$ not in $G(z)$ and the zeros of $G(z)$ not in $[T(z)'G(z)']'$. Thus P consists, in a precise algebraic sense, exactly of the poles and zeros suggested by the basic intuition. Note that this interpretation, which generalizes the scalar case, makes sense because of the module theoretic framework in which we are working. In § 4, we show that the Cokernel $C(H)$ of inessential poles is subject only to technical restrictions on the number of invariant factors, while the location of the modes in $C(H)$ is arbitrary when $C(H) \neq 0$. Therefore, the fixed finite poles of every solution are entirely represented by P and solutions whose finite poles are all essential can be constructed. More generally, we describe how to construct, by means of matrix fraction techniques, solutions whose poles are all essential except, possibly, those at an arbitrarily fixed point of $K \cup \{\infty\}$. Easy counterexamples show, however, that globally essential solutions, i.e., solutions all of whose poles, finite and at infinity, are essential, may not exist. Two examples are described at the end of § 5.

Although for simplicity we limited our discussion in this introduction to the case of finite poles and zeros, the main text of the paper studies the structure of $H(z)$ with respect to an arbitrary subset of $K \cup \{\infty\}$ (see for example [21] for background to the general theory). In addition, the problem $T(z) = H(z)G(z)$ described above and the dual one $T(z) = F(z)G(z)$, where $T(z)$ and $F(z)$ are given and $H(z)$ is sought, are treated simultaneously. The above results generalize those obtained in the special case of system inversion, namely when $Y(z) = U(z)$, $T(z)$ is the identity and $G(z)$ is monic, by Wyman and Sain in [22], [23].

Some of the results in this paper appeared in [3]. In that paper the equation $T(z) = H(z)G(z)$ is first reduced to a simpler form, multiplying both members by the left least common multiple of the right coprime matrix denominators of $T(z)$ and $G(z)$. The use of this technical artifice is made unnecessary in the present paper, with the advantage of providing clearer proofs, different from those of [3], and a better understanding of the role played by poles and zeros of $T(z)$ and $G(z)$ in determining P . The procedure to compute explicitly the essential pole structure was announced in [6].

2. Preliminaries and notation. Let K be a field and let $K[z]$ and $K(z)$ denote, respectively, the ring of polynomials and the field of rational functions in the variable z over K . Given a point $\alpha \in K$, any $g(z) \in K(z)$ can be represented as $g(z) = (z - \alpha)^r (p(z)/q(z))$ with $r \in \mathbb{Z}$, $p(z)$ and $q(z)$ polynomials not divisible by $(z - \alpha)$. The *valuation of $g(z)$ at α* is then defined by $v_\alpha(g) = r$. If $g(z) \in K(z)$ is written as the quotient of polynomials $g(z) = p(z)/q(z)$, the *valuation of $g(z)$ at ∞* is defined by $v_\infty(g) = \deg q - \deg p$.

Given a proper subset $S \subset K \cup \{\infty\}$, we denote by O_S the ring

$$O_S = \{f(z) \in K(z) : v_\alpha(f) \geq 0 \text{ for all } \alpha \text{ in } S\}.$$

We say loosely that O_S is the ring of rational functions which are regular at every point of S . The ring O_S is a principal ideal domain. When S consists of one point, say $S = \{\alpha\}$, we use the notation O_α . We assume that the reader is familiar with the theory of modules over a principal ideal domain as described in [1], for example.

Given a K -vector space V , we denote by $V(z)$ the $K(z)$ -vector space $V \otimes_K K(z)$ and by $\Omega_S V$ the O_S -module $V \otimes_K O_S$. $\Omega_S V$ is, in an obvious way, an O_S -submodule of $V(z)$.

Given two K -vector spaces $U = K^m$ and $Y = K^p$, by a *transfer function* we mean a $K(z)$ -linear map $T(z) : U(z) \rightarrow Y(z)$ or, equivalently, the $p \times m$ matrix of rational functions which represents $T(z)$ with respect to the canonical $K(z)$ -basis of $U(z)$ and $Y(z)$.

For a given subset $S \subset K \cup \{\infty\}$, we associate (see [21]) to any transfer function $T(z)$:

(i) a right (left) S -coprime fractional representation $T(z) = N_S(z) D_S^{-1}(z)$ (respectively $T(z) = \tilde{D}_S^{-1}(z) \tilde{N}_S(z)$), where $N_S(z)$, $D_S(z)$ (respectively $\tilde{N}_S(z)$, $\tilde{D}_S(z)$) are matrices with elements in O_S whose common right (left) factors are S -unimodular, i.e., they have an inverse with elements in O_S , and $D_S(z)$ ($\tilde{D}_S(z)$) is nonsingular;

(ii) a finitely generated torsion O_S -module $Z_S(T)$, called the *module of zeros in S* , defined by

$$Z_S(T) = \frac{T^{-1}(\Omega_S Y) + \Omega_S U}{\text{Ker } T + \Omega_S U};$$

(iii) a finitely generated torsion O_S -module $X_S(T)$, called the *module of poles in S* , defined by

$$X_S(T) = \frac{\Omega_S U}{T^{-1}(\Omega_S Y) \cap \Omega_S U}.$$

By abuse of notation, using the natural isomorphism induced by $T(z)$, we will also use the representation

$$X_S(T) = \frac{T(\Omega_S U) + \Omega_S Y}{\Omega_S Y}.$$

Note that, when $S = K$, then O_S is the ring of polynomials $K[z]$, $Z_S(T)$ coincides with the (finite) zero module introduced by Wyman and Sain in [22] and $X_S(T)$ coincides with the state space of the minimal realization of (the strictly proper part of) $T(z)$. On the other hand, when $S = \{\infty\}$, then O_∞ is the ring of rational formal power series in z^{-1} and $Z_\infty(T)$ and $X_\infty(T)$ (for which the notation $P_\infty(T)$ should be preferred in order to avoid confusion with the generalized state space introduced previously in the literature) are, respectively, the infinite zero module and the infinite pole module introduced in [2].

In general, the following isomorphisms hold [21]:

$$Z_S(T) \simeq \text{Tor}(\Omega_S Y / N_S(\Omega_S U)) \simeq \text{Tor}(\Omega_S Y / \tilde{N}_S(\Omega_S U))$$

(where Tor denotes the torsion submodule over O_S) and

$$X_S(T) \simeq \Omega_S Y / D_S(\Omega_S Y) \simeq \Omega_S U / \tilde{D}_S(\Omega_S U).$$

In other words, the invariant factors of $Z_S(T)$ and of $X_S(T)$ coincide with the nontrivial elements in the Smith form, over O_S , of $N_S(z)$ and $\tilde{N}_S(z)$ or of $D_S(z)$ and $\tilde{D}_S(z)$, respectively. Since the zero and the pole structure of $T(z)$ at a point α of S are given by the ordered list of the valuations at α of the elements in the Smith form of $N(z)$ and, respectively, of $D(z)$ (see, for instance, [12, § 6.5], where the “classical” case $S = K$ and the “local” case $S = \{\infty\}$ are considered), all the invariant factor information about the zeros and the poles of $T(z)$ in S can be derived from $Z_S(T)$ and $X_S(T)$.

3. Fixed poles. Let the transfer functions $T(z): U(z) \rightarrow Y(z)$ and $G(z): U(z) \rightarrow W(z)$ be given. The design problem which consists in factoring $T(z)$ through $G(z)$, i.e., in finding $H(z): W(z) \rightarrow Y(z)$ such that

$$(3.1) \quad T(z) = H(z)G(z),$$

is solvable if and only if

$$(A) \quad \text{Ker } G \subset \text{Ker } T.$$

Dually, given $T(z)$ as above and $F(z): W(z) \rightarrow Y(z)$, the design problem which consists in factoring $T(z)$ through $F(z)$, i.e., in finding $H(z): U(z) \rightarrow W(z)$ such that

$$(3.2) \quad T(z) = F(z)H(z),$$

is solvable if and only if

$$(B) \quad \text{Im } T \subset \text{Im } F.$$

From now on, we deal with pairs of transfer functions $T(z)$, $G(z)$ (respectively, $T(z)$, $F(z)$) as above, which are assumed to verify condition (A) (respectively, (B)). The set of solutions $H(z)$ of (3.1), (3.2) is therefore not empty and, unless $G(z)(F(z))$ is nonsingular, it contains more than one element. Our aim in this section is to introduce a suitable algebraic notion of “fixed poles” for (3.1) and (3.2), which allows us to describe the pole structure of the solutions $H(z)$ with respect to an arbitrary fixed subset $S \subset K \cup \{\infty\}$. Therefore, let us start by considering the following two O_S -modules:

$$P_S = \frac{G^{-1}(\Omega_S W)}{G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y)} \quad \text{and} \quad \tilde{P}_S = \frac{T(\Omega_S U) + F(\Omega_S W)}{F(\Omega_S W)}$$

associated, respectively, with (3.1) and (3.2).

Now, we can state the following basic results.

PROPOSITION 3.3. *For any solution $G(z)$ of (3.1) there exists a natural inclusion $j: P_S \rightarrow X_S(H)$.*

PROPOSITION 3.4. *For any solution $H(z)$ of (3.2) there exists a natural projection $\pi: X_S(H) \rightarrow \tilde{P}_S$.*

Proof of Proposition 3.3. The map $j: P_S \rightarrow X_S(H)$ is induced in the following commutative diagram by (1):

$$\begin{array}{ccccc} G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y) & \longrightarrow & G^{-1}(\Omega_S W) & \longrightarrow & P_S \\ \downarrow G & (1) & \downarrow G & & \downarrow j \\ \Omega_S W \cap H^{-1}(\Omega_S Y) & \longrightarrow & \Omega_S W & \longrightarrow & X_S(H) \end{array}$$

Furthermore, since $G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y) = G^{-1}(\Omega_S W \cap H^{-1}(\Omega_S Y))$, the map j is easily seen to be injective.

Proof of Proposition 3.4. The map $\pi: X_S(H) \rightarrow \tilde{P}_S$ is induced in the following commutative diagram by (2).

$$\begin{array}{ccccc} \Omega_S W & \longrightarrow & H(\Omega_S U) + \Omega_S W & \longrightarrow & X_S(H) \\ \downarrow F & (2) & \downarrow F & & \downarrow \pi \\ F(\Omega_S W) & \longrightarrow & T(\Omega_S U) + F(\Omega_S W) & \longrightarrow & \tilde{P}_S \end{array}$$

Furthermore, since $T(\Omega_S U) + F(\Omega_S W) = F(H(\Omega_S U) + \Omega_S W)$, π is easily seen to be surjective. \square

When we compare with [4] and [20], the above propositions justify the following definitions.

DEFINITION 3.5. The modules P_S and \tilde{P}_S are called *modules of fixed poles* in S of (3.1) and (3.2), respectively.

A first consequence of the above results is that the invariant factors of P_S or \tilde{P}_S appear, in the same order, in the Smith form, over O_S , of the denominator matrices of any solution $H(z)$ and, clearly, the conditions $P_S = 0$ or $\tilde{P}_S = 0$ is necessary for the existence of solutions having no poles in S . However, much more can be said, since, as shown below, the fixed pole structure can be computed explicitly in terms of fractional representations of $T(z)$ and $G(z)$ or $F(z)$.

3.6. Computation of the fixed pole structure. Assume that the data $T(z)$ and $G(z)$ of (3.1) have right S -coprime fractional representations $T(z) = N(z)D^{-1}(z)$, $G(z) = N_G(z)D_G^{-1}(z)$ and let $M(z) = D(z)A(z) = D_G(z)B(z)$ be the least common left multiple, in the ring of matrices with elements in O_S , of $D(z)$ and $D_G(z)$. By the same technique used in the proofs of Propositions 3.3 and 3.4, it is not difficult to see that the map $[u(z)] \rightarrow [M(uz)]$ induces an isomorphism between the modules $(N_G B)^{-1}(\Omega_S W) / ((N_G B)^{-1}(\Omega_S W) \cap (NA)^{-1}(\Omega_S Y))$ and P_S . Now, let r be the rank of

$$\begin{bmatrix} N_G(z)B(z) \\ N(z)A(z) \end{bmatrix} \quad \text{and let} \quad \begin{bmatrix} N_G(z)B(z) \\ N(z)A(z) \end{bmatrix} = \begin{bmatrix} \overbrace{V_1(z)}^r \mid V_3(z) \\ V_2(z) \mid V_4(z) \end{bmatrix} \begin{bmatrix} \Delta(z) \mid 0 \\ -0 \mid 0 \end{bmatrix} \begin{bmatrix} U_1(z) \\ U_2(z) \end{bmatrix} \Big\}_r$$

be the Smith decomposition. Denoting by $S(z)$ the full row rank $r \times m$ matrix $S(z) = \Delta(z)U_1(z)$, which can be viewed as the maximum (nonsingular) common right divisor of $N_G(z)B(z)$ and $N(z)A(z)$, the equalities $N_G(z)B(z) = V_1(z)S(z)$ and $N(z)A(z) = V_2(z)S(z)$ hold. Then, writing $U' = K'$, we have $(N_G B)^{-1}(\Omega_S W) \cap (NA)^{-1}(\Omega_S Y) = S^{-1}(\Omega_S U')$ and hence $P_S \cong (V_1 S)^{-1}(\Omega_S W) / S^{-1}(\Omega_S U')$. Remarking that $V_1(u) = 0$ implies, for a suitable u' such that $u = S(u')$, $V_1 S(u') = N_G B(u') = 0$ and that, by (A), $\text{Ker } N_G B \subset \text{Ker } NA$, one can show that $V_1(z)$ has full column rank. Then, as before, the multiplication by $V_1(z)S(z)$ induces an isomorphism between P_S and $(\Omega_S W \cap \text{Im } V_1) / V_1(\Omega_S U')$. The last module is isomorphic to the torsion submodule

$\text{Tor}(\Omega_S W / V_1(\Omega_S U'))$ of $\Omega_S W / V_1(\Omega_S U')$ and, as a consequence, the invariant factors of P_S which form the fixed pole structure are the nontrivial element in the Smith form of $V_1(z)$.

The analogous result for the fixed pole structure in (3.2) can be obtained by duality.

Remark 3.7. Note that the equality between the nontrivial elements in the Smith form of $V_1(z)$ and the fixed pole structure does not follow directly from the above computation. In order to state its validity, we need the abstract result of Proposition 3.3, which is primarily due to the module theoretic framework we are employing.

Now, we can give a description of P_S and \tilde{P}_S in terms of zeros and poles of the data $T(z)$ and $G(z)$, or $F(z)$, which, in connection with the scalar case recalled in the Introduction, will clarify the nature of the fixed poles. Let us consider (3.1) first. Since (A) holds, the zero module of the transfer function $[T(z)'G(z)']': U(z) \rightarrow (Y \oplus W)(z)$ can be represented as

$$\begin{aligned} Z_S \begin{pmatrix} T \\ G \end{pmatrix} &= \frac{\begin{pmatrix} T \\ G \end{pmatrix}^{-1} \Omega_S(Y \oplus W) + \Omega_S U}{\text{Ker} \begin{pmatrix} T \\ G \end{pmatrix} + \Omega_S U} \\ &= \frac{T^{-1}(\Omega_S Y) \cap G^{-1}(\Omega_S W) + \Omega_S U}{\text{Ker } T \cap \text{Ker } G + \Omega_S U} \\ &= \frac{T^{-1}(\Omega_S Y) \cap G^{-1}(\Omega_S W) + \Omega_S U}{\text{Ker } G + \Omega_S U}. \end{aligned}$$

Therefore, as $Z_S(G) = (G^{-1}(\Omega_S W) + \Omega_S U) / (\text{Ker } G + \Omega_S U)$, we have a natural inclusion $i: Z_S \begin{pmatrix} T \\ G \end{pmatrix} \rightarrow Z_S(G)$ induced by the obvious inclusion of the numerator modules. On the other hand, we have a natural projection $p: X_S \begin{pmatrix} T \\ G \end{pmatrix} \rightarrow X_S(G)$ between the pole modules

$$X_S \begin{pmatrix} T \\ G \end{pmatrix} = \frac{\Omega_S U}{T^{-1}(\Omega_S Y) \cap G^{-1}(\Omega_S W) \cap \Omega_S U} \quad \text{and} \quad X_S(G) = \frac{\Omega_S U}{G^{-1}(\Omega_S W) \cap \Omega_S U}$$

induced by the obvious inclusion of the denominator modules.

Notation 3.8. We denote by Z_S and X_S the O_S -modules defined, up to isomorphism, respectively, by the short exact sequences

$$\begin{aligned} 0 \rightarrow Z_S \begin{pmatrix} T \\ G \end{pmatrix} \xrightarrow{i} Z_S(G) \rightarrow Z_S \rightarrow 0, \\ 0 \rightarrow X_S \rightarrow X_S \begin{pmatrix} T \\ G \end{pmatrix} \xrightarrow{p} X_S(G) \rightarrow 0. \end{aligned}$$

It is clear that the module Z_S represents the zeros of $G(z)$ which are not zeros of $[T(z)'G(z)']'$. In particular, the above sequence splits over K and, as a K -vector space, $Z_S(G) \simeq Z_S((T'G')') \oplus_K Z_S$. In other words Z_S represents exactly the zeros that one expects to be cancelled by the poles of any solution $H(z)$ of (3.1). Analogously, since $X_S((T'G')')$ describes the union of the poles of $T(z)$ and of $G(z)$, X_S represents the poles of $T(z)$ which are not poles of $G(z)$ (see also [3, Remark 3.5] for this and for a description of the modules in matrix terms). They are exactly the poles that one expects to appear as poles of any solution $H(z)$ of (3.1). This is made precise by the following proposition.

PROPOSITION 3.9. *There exists a natural inclusion $\varphi: X_S \rightarrow P_S$ and a natural projection $\psi: P_S \rightarrow Z_S$ such that the following sequence is exact:*

$$0 \rightarrow X_S \xrightarrow{\varphi} P_S \xrightarrow{\psi} Z_S \rightarrow 0.$$

Proof. By a natural isomorphism, X_S can be represented as

$$X_S = \frac{G^{-1}(\Omega_S W) \cap \Omega_S U}{T^{-1}(\Omega_S Y) \cap G^{-1}(\Omega_S W) \cap \Omega_S U}.$$

Then $\varphi: X_S \rightarrow P_S$ is the map induced in the following commutative diagram, where π denotes the canonical projections, by (1):

$$\begin{array}{ccccc} G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y) \cap \Omega_S U & \longrightarrow & G^{-1}(\Omega_S W) \cap \Omega_S U & \xrightarrow{\pi_X} & X_S \\ \downarrow \text{incl.} & & \downarrow \text{incl.} & & \downarrow \varphi \\ G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y) & \longrightarrow & G^{-1}(\Omega_S W) & \xrightarrow{\pi} & P_S \end{array} \quad (1)$$

and φ is injective by diagram chasing. Analogously, representing Z_S as

$$Z_S = \frac{G^{-1}(\Omega_S W) + \Omega_S U}{T^{-1}(\Omega_S Y) \cap G^{-1}(\Omega_S W) \cap \Omega_S U},$$

we have that ψ is the surjective map induced in the following commutative diagram by (2):

$$\begin{array}{ccccc} G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y) & \longrightarrow & G^{-1}(\Omega_S W) & \xrightarrow{\pi} & P_S \\ \downarrow \text{incl.} & & \downarrow \text{incl.} & & \downarrow \psi \\ G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y) + \Omega_S U & \longrightarrow & G^{-1}(\Omega_S W) + \Omega_S U & \xrightarrow{\pi_Z} & Z_S \end{array} \quad (2)$$

Now, let $\pi_X(u) \in X_S$. This implies, in particular, that $u \in \Omega_S U$ and that $\psi\varphi\pi_X(u) = \psi\pi(u) = 0$. Hence, $\varphi(X_S) \subset \text{Ker } \psi$. On the other hand, let $\pi(u) \in \text{Ker } \psi \subset P_S$: this implies, in particular, that $u \in G^{-1}(\Omega_S W)$ and that $u \in G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y) + \Omega_S U$. Therefore, $u = u' + u''$, with $u' \in G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y)$ and $u'' \in \Omega_S U \cap G^{-1}(\Omega_S W)$, and $\pi(u) = \pi(u'')$. As a consequence, $\pi(u) = \varphi\pi_X(u'') \in \varphi(X_S)$ and $\text{Ker } \psi \subset \varphi(X_S)$. Thus we have shown the exactness of the sequence $0 \rightarrow X_S \rightarrow P_S \rightarrow Z_S \rightarrow 0$. \square

The proposition we have just proved implies, in particular, that $P_S = X_S \oplus_K Z_S$ as a K -vector space. Then, summarizing Proposition 3.3 and Proposition 3.9, we can say that the fixed poles of (3.1) consist of the zeros of $G(z)$ which are not zeros of $T(z)$ and of the poles of $T(z)$ which are not poles of $G(z)$. This statement makes sense only if we refer to the module theoretic definitions of zeros and poles.

The situation concerning (3.2) can be treated dually. Without giving the details, let us simply remark that the inclusion $i_2: W \rightarrow U \oplus W$ induces a natural inclusion $\tilde{i}: X_S(F) \rightarrow X_S(T \ F)$ between the pole modules and, since (B) holds, a natural projection $\tilde{p}: Z_S(F) \rightarrow Z_S(T \ F)$ between the zero modules with which we are dealing.

Notation 3.10. (i) We denote by \tilde{X}_S the module defined, up to isomorphism, by the short exact sequence

$$0 \rightarrow X_S(F) \xrightarrow{\tilde{i}} X_S(T \ F) \rightarrow \tilde{X}_S \rightarrow 0.$$

(ii) We denote by \tilde{Z}_S the module defined, up to isomorphism, by the short exact sequence

$$0 \rightarrow \tilde{Z}_S \rightarrow Z_S(F) \xrightarrow{\tilde{P}} Z_S(T - F) \rightarrow 0.$$

Just as in the discussion following § 3.6, we can give an interpretation of \tilde{X} and \tilde{Z} in terms of poles of $T(z)$ which are not poles of $F(z)$ and of zeros of $F(z)$ which are not zeros of $(T(z) - F(z))$. They are exactly the poles that one expects to find as poles of any solution $H(z)$ of (3.2) and, in fact, the following can be proved.

PROPOSITION 3.11. *There exists a natural inclusion $\tilde{\varphi}: \tilde{Z}_S \rightarrow \tilde{P}_S$ and a natural projection $\tilde{\psi}: \tilde{P}_S \rightarrow \tilde{X}_S$ such that the following sequence:*

$$0 \rightarrow \tilde{Z}_S \xrightarrow{\tilde{\varphi}} \tilde{P}_S \xrightarrow{\tilde{\psi}} \tilde{X}_S \rightarrow 0$$

is exact.

As in the previous case, we have that $\tilde{P}_S = \tilde{X}_S \oplus_K \tilde{Z}_S$ as a K -vector space. Summarizing Propositions 3.4 and 3.11 we can say, in a precise algebraic sense, that the fixed poles of (3.2) consists of the zeros of $F(z)$ which are not zeros of $(T(z) - F(z))$ and of the poles of $T(z)$ which are not poles of $F(z)$.

4. Essential solutions. The results of the previous section imply, in particular, that for any solution $H(z)$ of (3.1) or (3.2) we have an exact sequence of the form

$$0 \rightarrow P_S \rightarrow X_S(H) \rightarrow C_S(H) \rightarrow 0$$

or one of the form

$$0 \rightarrow \tilde{C}_S(H) \rightarrow X_S(H) \rightarrow \tilde{P}_S \rightarrow 0.$$

We say that the modules P_S and \tilde{P}_S describe the *essential pole structure* in S of the solutions of (3.1) and (3.2) and that, for any $H(z)$, the cokernel module $C_S(H)$ or the kernel module $\tilde{C}_S(H)$ is the module of *inessential poles* in S (compare with [22], [23]). Since we have a complete knowledge of P_S or \tilde{P}_S , the aim of this section is to study the module of inessential poles, describing in particular what restrictions, if any, apply to it. We restrict our investigation to (3.1), since the analogous results concerning (3.2) can be obtained by transposition.

To begin with, let us state some technical results and introduce some notation.

Remark 4.1. Let $Q(z)$ be an S -unimodular matrix such that $Q(z)G(z)$ has the form $Q(z)G(z) = [G_1(z)' \ 0]'$, with $G_1(z)$ of full row rank. Writing $W(z) = W_1(z) \oplus W_2(z)$ with $W_1(z) = Q(z)G(U(z))$, we can represent any solution $H(z)$ of (3.1) as $H(z) = [H_1(z) \ H_2(z)]Q(z)$, where $H_1(z): W_1(z) \rightarrow Y(z)$ is such that $T(z) = H_1(z)G_1(z)$ and $H_2(z): W_2(z) \rightarrow Y(z)$ is arbitrary. Since $G_1(z)$ is full row rank, $H_1(z)$ is uniquely determined and given by $H_1(z) = T(z)G_1'(z)$, where $G'(z)$ is any right inverse of $G_1(z)$. Moreover, since $Q(z)$ is S -unimodular, the pole (and zero) structure of $H(z)$ in S is that of $[H_1(z) \ H_2(z)]$.

LEMMA 4.2. *Given the S -coprime fractional representations $H_1(z) = D_1^{-1}(z)N_1(z)$ and $H_2(z) = D_2^{-1}(z)N_2(z)$, let $M(z) = A(z)D_1(z) = B(z)D_2(z)$ be the minimal common left multiple of $D_1(z)$ and $D_2(z)$. Then $[H_1(z) \ H_2(z)] = M^{-1}(z)[A(z)N_1(z) \ B(z)N_2(z)]$ is an S -coprime fractional representation.*

Proof. See [3, Remark 3.5].

Now, let us consider again the diagram in the proof of Proposition 3.3. With the notation introduced above, and applying the isomorphism induced by $Q(z)$ to the

second row and adding the Cokernels of the vertical maps, we obtain the following commutative diagram:

$$\begin{array}{ccccc}
 G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y) & \longrightarrow & G^{-1}(\Omega_S W) & \longrightarrow & P_S \\
 \downarrow QG & & \downarrow QG & & \downarrow j \\
 (\Omega_S W_1 \oplus \Omega_S W_2) \cap [H_1 \ H_2]^{-1}(\Omega_S Y) & \longrightarrow & \Omega_S W_1 \oplus \Omega_S W_2 & \longrightarrow & X_S(H) \\
 \downarrow & (1) & \downarrow & & \downarrow \\
 K_S & \longrightarrow & \Omega_S W_2 & \longrightarrow & C_S(H)
 \end{array}$$

in which j , $X_S(H)$ and $C_S(H)$ are employed with an obvious abuse of notation. The last row is exact and, by the commutativity of (1), it is possible to evaluate the image of the module K_S in $\Omega_S W_2$. In fact, it consists of the elements $w \in \Omega_S W_2$ for which there exists $w' \in \Omega_S W_1$ such that $H_1(w') + H_2(w)$ belongs to $\Omega_S Y$. This is to say that $AN_1(w') + BN_2(w) = M(y)$ or, equivalently, that $BN_2(w) = A(N_1(-w') + D_1(y))$ for some $w' \in \Omega_S W_1$ and $y \in \Omega_S Y$. Since $N_1(z)$ and $D_1(z)$ are S -coprime, the last equality is equivalent to $BN_2(w) = A(y')$ for some $y' \in \Omega_S Y$; hence the image of K_S is given by $\Omega_S W_2 \cap (BN_2)^{-1}(A(\Omega_S Y))$. In conclusion, we have that $C_S(H) \simeq \Omega_S W_2 / (\Omega_S W_2 \cap (A^{-1}BN_2)^{-1}(\Omega_S Y)) \simeq X_S(A^{-1}BN_2)$ and, since $A(z)$ and $B(z)N_2(z)$ are easily seen to be S -coprime, $C_S(H) \simeq \Omega_S W / A(\Omega_S Y)$. We state explicitly the above results as follows.

PROPOSITION 4.3. *Let $Q(z)$ and $G_1(z)$ be as defined in Remark 4.1. Then, any solution $H(z)$ of (3.1) has the form $[H_1(z) \ H_2(z)]Q(z)$ where $H_1(z)$ is uniquely determined by $H_1(z) = T(z)G_1'(z)$, $G_1'(z)$ being any right inverse of $G_1(z)$, and $H_2(z)$ is an arbitrary $(\dim Y) \times (\dim W - \text{rank } G)$ transfer function. Moreover, if $H_1(z) = D_1^{-1}(z)N_1(z)$ and $H_2(z) = D_2^{-1}(z)N_2(z)$ are S -coprime fractional representations and if $M(z) = A(z)D_1(z) = B(z)D_2(z)$ is the minimum left common multiple of $D_1(z)$ and $D_2(z)$, we have $C_S(H) \simeq \Omega_S Y / A(\Omega_S Y)$ and, since $X_S(H) \simeq \Omega_S Y / M(\Omega_S Y)$, $P_S \simeq \Omega_S Y / D_1(\Omega_S Y)$.*

COROLLARY 4.4. *Given any finitely generated torsion O_S -module E , whose number of invariant factors is less than or equal to $\min \{\dim Y, \dim W - \text{rank } G\}$, there exists a solution $H(z)$ of (3.1) such that $C_S(H) \simeq E$. In particular, for any S there exists a solution $H(z)$ of (3.1) whose poles in S coincide with the fixed poles.*

Proof. By Proposition 4.3, if $A(z)$ is a $p \times p$ matrix such that $E \simeq \Omega_S Y / A(\Omega_S Y)$, it is sufficient to take $H_2(z) = D_1^{-1}(z)A^{-1}(z)$. Solutions whose poles coincide with the fixed ones are obtained whenever the arbitrary transfer function $H_2(z) = D_2^{-1}(z)N_2(z)$ is chosen in such a way that $D_1(z)$ is a left multiple of $D_2(z)$. \square

By Corollary 4.4 we can now say that no restrictions, except for the number of invariant factors, apply to the module of inessential poles $C_S(H)$ or $\tilde{C}_S(H)$. This implies, in particular, that in each solution $H(z)$ the fixed part of the pole structure in S is entirely described by P_S or \tilde{P}_S . The location of other poles in S , if any, is arbitrary. When the module of inessential poles is zero, the corresponding solution is said to be *essential* in S . Solutions of this kind have the "smallest" possible pole structure in S , but they are not necessarily essential also in $K \cup \{\infty\} \setminus S$. In general, there do not exist solutions that are essential at α for any $\alpha \in K \cup \{\infty\}$. An example of this is given by the equation $1 = [z^2 \ z + 1]H(z)$. The transfer function $[z^2 \ z + 1]$ has no zeros, finite or at infinity, and, since the left-hand member is 1, this implies that $\tilde{P}_S = 0$ for any S . However, no solution without poles can exist, since no linear combination with coefficients in K of z^2 and of $z + 1$ is equal to 1. Nevertheless, if

$G(z)$ is surjective or $F(z)$ is injective, the unique solution $H(z)$ of (3.1) or (3.2) is essential in any S , since $j: P_S \rightarrow X_S(H)$ or $\pi: X_S(H) \rightarrow \tilde{P}_S$ turn out to be respectively surjective or injective.

5. Conclusion. It has been shown that for each solution $H(z)$ of the equation $T(z) = H(z)G(z)$ and for each subset S of $K \cup \{\infty\}$ there exists an exact sequence of O_S -modules $0 \rightarrow P_S \rightarrow X_S(H) \rightarrow C_S \rightarrow 0$ where $X_S(H)$ is the module of pole in S of $H(z)$.

As suggested by the notation, P_S does not depend on the particular $H(z)$, but only on the data $T(z)$ and $G(z)$. It represents the fixed poles which appear in every solution and, as an abstract module, it is described by $P_S = G^{-1}(\Omega_S W) / (G^{-1}(\Omega_S W) \cap T^{-1}(\Omega_S Y))$.

A dynamical interpretation in module theoretic terms of the fixed poles is given by the exact sequence $0 \rightarrow X_S \rightarrow P_S \rightarrow Z_S \rightarrow 0$, where X_S and Z_S represent, respectively, the poles of $T(z)$ which are not poles of $G(z)$ and the zeros of $G(z)$ which are not zeros of $[T'(z)G'(z)]'$.

The invariant factors of P_S , which form the fixed part of the pole structure in S of any solution, are explicitly computed by means of the procedure of § 3.6, using fractional representations of $T(z)$ and $G(z)$.

The cokernel $C_S(H)$ represents the inessential poles in the solution. It is subject only to a technical restriction on the number of the invariant factors, while the location of the poles in $C_S(H)$ is arbitrary. These results give a complete description of the pole structure in S of $H(z)$.

Example 5.1. Consider the transfer functions:

$$T(z) = \begin{pmatrix} 1/(z+2) & -2/z(z+2) \\ 1/2(z+1) & -1/2z(z+1) \end{pmatrix},$$

$$G(z) = \begin{pmatrix} (z+2)/z(z+1) & (z+2)/z(z+1) \\ 1/z & (z^2+z+1)/z(z+1)^2 \\ (z+2)/z(z+1) & (z+2)/z(z+1) \end{pmatrix}.$$

Condition (A) is trivially satisfied since both $T(z)$ and $G(z)$ are full rank. Taking $S = K$, we compute the invariant factors of P_S , the module of finite fixed poles of the equation $T(z) = H(z)G(z)$, using the procedure viewed in § 3.6. Coprime fractional representations for $T(z)$ and $G(z)$ are the following: $T(z) = N(z)D^{-1}(z)$ and $G(z) = N_G(z)D_G^{-1}(z)$, where

$$N(z) = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}, \quad D(z) = \begin{pmatrix} 2z & 3z+2 \\ -2z & z^2 \end{pmatrix},$$

$$N_G(z) = \begin{pmatrix} z+2 & 0 \\ z+1 & 1 \\ z+2 & 0 \end{pmatrix}, \quad D_G(z) = \begin{pmatrix} z^2+z & (z+1)^2 \\ 0 & -(z+1)^2 \end{pmatrix}.$$

The minimum common left multiple of $D(z)$, $D_G(z)$ is given by $M(z) = D(z)A(z) = D_G(z)B(z)$

$$M(z) = \begin{pmatrix} z(z+1)(z+2) & 2z(z+1)^2 \\ 0 & -2z(z+1)^2 \end{pmatrix}$$

with

$$A(z) = \begin{pmatrix} z^2/2 & (z+1)^2 \\ z & 0 \end{pmatrix}, \quad B(z) = \begin{pmatrix} z+2 & 0 \\ 0 & 2z \end{pmatrix}.$$

Then, since

$$N(z)A(z) = \begin{pmatrix} z(z+1) & 2(z+1)^2 \\ z(z+2)/2 & (z+1)^2 \end{pmatrix} \quad \text{and} \quad N_G(z)B(z) = \begin{pmatrix} (z+2)^2 & 0 \\ (z+1)(z+2) & 2z \\ (z+2)^2 & 0 \end{pmatrix}$$

turn out to be right coprime, their maximum common right divisor $S(z)$ is unimodular; hence $P_S \simeq (N_GB)^{-1}(\Omega_S W)/\Omega_S U \simeq \text{Tor}(\Omega_S W/N_GB(\Omega_S U))$ and the invariant factors of P are the nontrivial elements in the Smith form over O_S of $N_G(z)B(z)$, which is given by

$$\begin{pmatrix} 1 & 0 \\ 0 & z(z+2)^2 \\ 0 & 0 \end{pmatrix}.$$

This means that any solution $H(z)$ has a pole of total order 1 at 0, whose structure is $(0, 1)$, and a pole of total order 2 at -2 , whose structure is $(0, 2)$. This last one is due to the presence of a pole of total order 1 at -2 in $T(z)$, which does not appear in $G(z)$, and of a zero of total order 1 at -2 in $G(z)$, which does not appear in $[T'(z) \ G'(z)]^t$. Note that in this example the pole at 0 which appears in $T(z)$ and the one which appears in $G(z)$, both of order 1, are "distinct", in the sense that they give rise to a pole of order 2 in $[T'(z) \ G'(z)]^t$. This causes the presence of the pole at 0 of order 1 in every $H(z)$. Modifying the numerator matrix of $G(z)$ into

$$\bar{N}_G = \begin{pmatrix} 1 & 0 \\ z+1 & z+2 \\ 1 & 0 \end{pmatrix},$$

we obtain a second example in which the pole and zero structure of the data are the same as before. However, the computation shows that the invariant factors of P_S , in this case, are given by the Smith matrix

$$\begin{pmatrix} z+2 & 0 \\ 0 & z(z+2) \\ 0 & 0 \end{pmatrix}.$$

Thus, we have, as before, a pole of order 1 at 0 and a pole of order 2 at -2 in every solution $H(z)$, but now the structure at -2 , which is $(1, 1)$, is not cyclic. The methods mentioned in § 1.1 are not capable of pointing out this difference between the two cases.

CHARACTERIZATION OF ALL CONTROLLED INVARIANT SUBSPACES FOR SPECTRAL SYSTEMS*

HANS ZWART†

Abstract. For a class of spectral systems a complete characterization of all controlled invariant subspaces contained in a closed subspace will be given. This characterization is given in terms of the invariant zeros of the transfer function. As a consequence of this we derive necessary and sufficient conditions for the existence of $V^*(\text{Ker } C)$, the largest controlled invariant subspace in the kernel of C .

Key words. infinite-dimensional linear systems, controlled invariance, invariant zeros, discrete spectral operators

AMS(MOS) subject classifications. primary 93C25; secondary 47A15

1. Introduction. In this paper we shall consider the following linear controlled system described by the set of equations:

$$(1.1a) \quad \dot{x} = Ax + Bu,$$

$$(1.1b) \quad y = Cx$$

where $x \in H$, $u \in U$ and $y \in Y$. H and Y are separable Hilbert spaces and U is \mathbb{C} or \mathbb{R} ; we take it to be the same as the field of H . Furthermore A is assumed to be a generator of a C_0 semigroup, $Bu = b \cdot u$ with b in H and C is a bounded linear operator from H to Y .

In 1969 Basile and Marro [1] introduced the concept of controlled invariance for the case that H and Y are finite-dimensional; starting in a subspace it is possible to find a control such that the system stays in that subspace. This concept catalyzed the beginning of the geometric theory, which led to the solution of various control problems (see Wonham [19]).

The concept of controlled invariance for infinite-dimensional Hilbert spaces was introduced by Schmidt and Stern in 1980 [16], and later this theory was extended by Pandolfi [12] and Curtain [4].

One concept that plays an important role in the geometric theory is that of the largest controlled invariant subspace in the kernel of C , usually denoted by $V^*(\text{Ker } C)$. From Basile and Marro [1] it follows that $V^*(\text{Ker } C)$ always exists if H is finite-dimensional. If H is infinite dimensional, however, this does not necessarily hold, as was shown by Pandolfi [12], at least for retarded systems. In Curtain [4] sufficient conditions were given such that $V^*(\text{Ker } C)$ exists.

The aim of this paper is to give sufficient and necessary conditions for the existence of $V^*(\text{Ker } C)$ for the class of spectral systems. We shall express this in terms of the invariant zeros of the transfer function $C(sI - A)^{-1}B$.

That there exists a close relationship between invariant subspaces in $\text{Ker } C$ and invariant zeros is well known in finite dimensions and can be illustrated by the following problem. We can ask a very simple question. What is the form of all one-dimensional controlled invariant subspaces in the kernel of C ?

* Received by the editors May 12, 1986; accepted for publication (in revised form) May 6, 1987. This research was supported by the Netherlands Organization for the Advancement of Pure Scientific Research (Z.W.O.).

Let $\text{span}\{e\}$ be such a subspace; then since it is controlled invariant it is also $A+BF$ invariant, for some feedback law F (see Basile and Marro [1]). Thus e is an eigenvector of $A+BF$. We shall distinguish between two cases:

- (i) $Fe=0$. In this case e is an eigenvector of A and in the kernel of C .
- (ii) $Fe \neq 0$. Without loss of generality we may assume that $Fe=1$, so that $(A+BF)e = \alpha \cdot e$ implies $(\alpha I - A)e = b$. If we assume that α is in $\rho(A)$, then $e = (\alpha I - A)^{-1}b$. Since e is in the kernel of C , we obtain $C(\alpha I - A)^{-1}b = 0$. Thus α is a zero of the transfer function. So we see that a one-dimensional controlled invariant subspace is either an eigenvector in the kernel of C or it is $\text{span}\{e\}$ where e satisfies the equations $Ce=0$ and $(\alpha I - A)e = b$ for some α in \mathbb{C} . And if this α is an element of the resolvent set of A , then it is a zero of the transfer function.

For finite-dimensional systems the concept of zeros is very well understood. In infinite dimensions, however, only a few articles have been published; see Pohjolainen [14].

The proof of the existence of $V^*(\text{Ker } C)$ is based on the result of pole placement from Sun [17]. To get an idea that there exists a relationship between the existence of $V^*(\text{Ker } C)$ and the problem of pole placement we refer to the finite-dimensional case. It is well known (Wonham [19]) that in this case $\sigma(A+BF|_{V^*(\text{Ker } C)})$ is fixed for all F subject to $(A+BF)V^*(\text{Ker } C) \subset V^*(\text{Ker } C)$. In this paper we shall prove a similar result for spectral systems, see Theorem 6.1. Otherwise we have from the results of Sun [17] a restriction on $\sigma(A+BF)$, and hence especially on the fixed part of $\sigma(A+BF|_{V^*(\text{Ker } C)})$ and therefore on $V^*(\text{Ker } C)$.

The organization of the paper will be as follows. In § 2 we will recall some facts and properties of discrete spectral operators. In § 3 various concepts of invariance and of system invariance will be discussed. We will derive some properties of these concepts and for the class of discrete spectral operators we will give a full description of all invariant subspaces. In § 4 we will give the definition of invariant zeros. Properties of these invariant zeros for the class of spectral systems will be given in § 5. In § 6 the main theorems of this paper will be presented. In this section we will give a full description of all closed loop invariant subspaces in the kernel of C . In particular we will give necessary and sufficient conditions for the existence of $V^*(\text{Ker } C)$. Application of these theorems will be given in § 7. The examples in this section were calculated by L. Nooitgedagt [11].

2. Discrete spectral operators.

DEFINITION 2.1. Discrete operator. A linear operator A from \underline{H} to \underline{H} is discrete if there exists a number λ in its resolvent set for which the resolvent $R(\lambda; A) := (\lambda I - A)^{-1}$ is compact.

LEMMA 2.2. If A is discrete, then:

- (a) Its spectrum, $\sigma(A)$, is a denumerable set of points with no finite limit point.
- (b) The resolvent $R(\lambda, A)$ is compact for every λ not in $\sigma(A)$.
- (c) Every λ_0 in $\sigma(A)$ is a pole of finite order $\theta(\lambda_0)$ of the resolvent and if, for some positive integer k , x satisfies the equation

$$(A - \lambda_0 I)^k x = 0$$

then x satisfies the equation

$$(A - \lambda_0 I)^{\theta(\lambda_0)} x = 0.$$

The set of all vectors x satisfying the equation $(A - \lambda_0 I)^{\theta(\lambda_0)} x = 0$ is a finite-dimensional linear space, called the space of generalized eigenvectors of A corresponding to the eigenvalue λ_0 .

(d) If

$$(2.1) \quad E(\lambda_0) = \frac{1}{2\pi i} \cdot \int_{\Gamma} (\lambda I - A)^{-1} d\lambda,$$

where Γ is a small closed curve surrounding only the eigenvalue λ_0 and Γ is traversed once in the positive sense, then $E(\lambda_0)$ projects H onto the space of generalized eigenvectors corresponding to λ_0 .

Proof. See Lemma XIX 2.2 of Dunford and Schwartz [8].

Remark. The spectrum of A shall be denoted by $\{\lambda_n\} n \geq 1$.

DEFINITION 2.3. Discrete spectral operator. A discrete operator is spectral if the spectral projections $E(\lambda_j)$ defined by (2.1) satisfy:

(a) The family of sums of finite collections of projections $E(\lambda_j)$ is uniformly bounded; and

(b) No nonzero x in H satisfies all of the equations $E(\lambda_j)x = 0$, λ_j in $\sigma(A)$.

Remark. The spectral projections $E(\lambda_j)$ are not necessarily selfadjoint.

LEMMA 2.4. If A is a discrete spectral operator then the spectral projections $\{E(\lambda_j), \lambda_j$ in $\sigma(A)\}$ generate a uniformly bounded Boolean algebra with the completeness property:

$$(2.2) \quad \sum_{j=1}^{\infty} E(\lambda_j) = I$$

where the convergence is in the strong topology.

Proof. See § XVIII.1 of Dunford and Schwartz [8].

3. Invariant subspaces. In this section we shall discuss some concepts of (system) invariance. Let A be a generator of a C_0 semigroup, $T(t)$, on H . For a generator A we can define two concepts of invariance: semigroup invariance and generator invariance. In finite dimensions these two concepts are equivalent but as we shall see they are in general not equivalent for unbounded generators of C_0 semigroups. We shall first recall the definition of semigroup and generator invariance.

DEFINITION 3.1. Semigroup invariance or $T(t)$ -invariance. A closed linear subspace Y of H will be called semigroup invariant or $T(t)$ -invariant if $T(t)Y \subset Y$, for all $t \geq 0$.

DEFINITION 3.2. Generator invariance or A -invariance. A closed linear subspace Y of H will be called generator or A -invariant if $A(Y \cap D(A)) \subset Y$ where $D(A)$ is the domain of A .

We will recall some basic facts about these definitions. Semigroup invariance always implies generator invariance but the converse is in general not true for unbounded generators; see, for example, Schmidt and Stern [16] for a counterexample. But there is a class of subspaces where the two concepts of invariance is equivalent.

LEMMA 3.3. If Y is a closed linear subspace in the domain of A then generator invariance is equivalent to semigroup invariance.

Proof. See Lemma 2.3 of Curtain [4].

Since the generator A is completely determined by $T(t)$ and vice versa it may seem strange that the two concepts of invariance are not equivalent. But, as in the Hille-Yosida theorem, the relation between A and $T(t)$ -invariance is determined by the resolvent of A . Define \underline{C}_{∞} to be the largest connected subset of $\rho(A)$ that contains an interval of the form $[r, +\infty)$; since A generates a C_0 semigroup this set is nonempty.

LEMMA 3.4. Let Y be a closed linear subspace of H ; then the following concepts are equivalent:

- (a) Y is semigroup invariant;
- (b) $(\lambda I - A)^{-1}Y \subset Y$ for a λ in \underline{C}_{∞} ;

- (c) $(\lambda I - A)^{-1}Y \subset Y$ for all λ in C_∞ ;
 (d) The range of $(\lambda I - A)$ restricted to V is V for all $\lambda \in C_\infty$.

Proof.

LEMMA 3.5. Let Y be a closed linear subspace which is $T(t)$ -invariant; then $\overline{Y \cap D(A)} = Y$.

Proof. From p. 37 of Davies [6] we have that every element x in H is the limit of $\lambda \cdot (\lambda I - A)^{-1}x$, $\lambda \rightarrow +\infty$.

Assume that $x \in Y$; then by the previous lemma we have, for λ sufficiently large, that $(\lambda I - A)^{-1}x$ is in $Y \cap D(A)$.

Combining these results we have that x is the limit of a sequence in $Y \cap D(A)$. So $\overline{Y \cap D(A)} = Y$.

If a subspace Y of R^n is invariant with respect to a diagonal matrix then Y must be of the form $\text{span} \{e_i, i \in I \subset \{1 \cdots n\}\}$ where e_i is the i th basis vector of R^n . For the class of discrete spectral operators a similar theorem holds. First we shall recall a lemma of Dunford and Schwartz [8] that gives some invariance properties of the spectral projections, $E(\lambda_i)$.

LEMMA 3.6. Let A be a discrete spectral operator and λ_j an element of $\sigma(A)$. Then $D(A) \supset E(\lambda_j)H$, the subspace $E(\lambda_j)H$ is A -invariant, $AE(\lambda_j)x = E(\lambda_j)Ax$ for all x in $D(A)$ and $\sigma(A|E(\lambda_j)H) = \{\lambda_j\}$.

Proof. See Dunford and Schwartz [8, pp. 2294].

THEOREM 3.7. Let the discrete spectral operator A generate the C_0 semigroup $T(t)$; then a closed linear subspace Y of H is $T(t)$ -invariant if and only if

$$(3.1) \quad Y = \sum_{j=1}^{\infty} W_j$$

where W_i is a subspace of H which is contained in $E(\lambda_i)H$ and is A -invariant.

The summation (3.1) is in the strong topology, i.e., for all $x \in Y$ there exist $\{w_i; i \in \mathbb{N}\}$, with $w_i \in W_i$ such that $\sum_{i=1}^n w_i$ converges to x for $n \rightarrow \infty$; otherwise if $\{w_i, i \in \mathbb{N}\}$; $w_i \in W_i$ is such that $\sum_{i=1}^n w_i$ converges for $n \rightarrow \infty$, then the limit is in Y .

Furthermore the spectrum of A restricted to V is equal to the set of all $\lambda_i \in \sigma(A)$ subject to the corresponding W_i is not the zero subspace.

Proof. (If.) Since the dimension of $E(\lambda_i)H$ is finite, the dimension of W_i must also be finite. So W_i is a closed linear subspace of H . Furthermore $E(\lambda_i)H$ is contained in $D(A)$, and with Lemma 3.6 and Lemma 3.3 we may conclude that W_i is $T(t)$ -invariant.

Every x in Y is the limit of a sequence x_n , with $x_n \in \sum_{i=1}^n W_i$. So with the above we have $T(t)x_n$ is in $\sum_{i=1}^n W_i$. $T(t)$ is a bounded linear operator; thus $T(t)x_n$ converges to an element in H , but also to an element of Y since $T(t)x_n$ is in Y . So Y is $T(t)$ -invariant.

(Only if.) Let Y be a $T(t)$ -invariant subspace. Since $\sigma(A) = \{\lambda_i\}$, $i \in \mathbb{N}$ we have that the resolvent set, $\rho(A)$, is connected. With Lemma 3.4 this implies that Y is also $(\lambda I - A)^{-1}$ invariant for all λ in the resolvent set of A . So

$$E(\lambda_i)Y = \frac{1}{2\pi i} \cdot \int_{\Gamma} (\lambda \cdot I - A)^{-1} Y d\lambda \subset Y \quad (\text{see (2.1)}).$$

So $E(\lambda_i)\underline{Y} \subset (E(\lambda_i)\underline{H}) \cap \underline{Y}$. Using the fact that $E(\lambda_i)$ is a projection we get $(E(\lambda_i)\underline{H}) \cap \underline{Y} = (E(\lambda_i)\underline{H}) \cap (E(\lambda_i)\underline{Y}) \subset E(\lambda_i)\underline{Y}$. Thus $E(\lambda_i)\underline{Y} = (E(\lambda_i)\underline{H}) \cap \underline{Y}$.

If we set \underline{W}_i equal to $E(\lambda_i)\underline{Y}$ and $x_i := E(\lambda_i)x$; $x \in \underline{Y}$, then $A(\underline{W}_i) = AE(\lambda_i)\underline{Y} = AE(\lambda_i)E(\lambda_i)\underline{Y} = AE(\lambda_i)(E(\lambda_i)\underline{H} \cap \underline{Y}) \subset AE(\lambda_i)(\underline{Y} \cap D(A)) = E(\lambda_i)A(\underline{Y} \cap D(A)) \subset E(\lambda_i)\underline{Y} = \underline{W}_i$ (see Lemma 3.6). So $A\underline{W}_i \subset \underline{W}_i$.

By (2.2) and Definition 2.3 every x in \underline{H} can be uniquely written as $\sum_{i=1}^{\infty} x_i$. Hence $\underline{Y} = \sum_{i=1}^{\infty} \underline{W}_i$.

We shall now prove the last assertion.

Let \underline{J} denote the index set of all $\lambda_i \in \sigma(A)$ subject to $\dim(\underline{W}_i)$ is larger than zero. Since $\underline{W}_i \subset E(\lambda_i)\underline{H}$ is A invariant it must contain an eigenvector corresponding to λ_i ; thus $\{\lambda_i; i \in \underline{J}\} \subset \sigma(A|_{\underline{Y}})$. From Lemma 3.4 we have for that all $\lambda \in C_{\infty}$, $(\lambda I - A)^{-1}|_{\underline{Y}}$ is a bounded linear operator from \underline{Y} to \underline{Y} and since A is discrete it is also a compact operator. Furthermore, it is the inverse of $(\lambda I - A|_{\underline{Y}})$. So $A|_{\underline{Y}}$ is a discrete operator and hence the spectrum of $A|_{\underline{Y}}$ is a pure point spectrum. Now it is easy to show that $\{\lambda_i; i \in \underline{J}\} = \sigma(A|_{\underline{Y}})$.

With this theorem we can prove an interesting corollary.

Let A be of the following form: $A = \sum_{i=1}^{\infty} \lambda_i \langle \cdot, \phi_i \rangle_{\underline{H}} \cdot \phi_i$, with $\{\phi_i\}$ an orthonormal basis of \underline{H} , $\lambda_i \in \mathbb{R}$ and $\sum_{i=1}^{\infty} \lambda_i^{-2} < \infty$. If we set the domain of A equal to all x in \underline{H} such that $\sum_{i=1}^{\infty} |\lambda_i \langle x, \phi_i \rangle_{\underline{H}}|^2$ exists, then A is a discrete spectral operator with spectral projections $E(\lambda_i) = \langle \cdot, \phi_i \rangle \cdot \phi_i$. Furthermore if $\sup \{\lambda_i | i \in \mathbb{N}\} < \infty$, then A generates a C_0 semigroup $T(t)$ (see Curtain [3]) and

$$T(t) = e^{At} = \sum_{i=1}^{\infty} e^{\lambda_i t} \langle \cdot, \phi_i \rangle_{\underline{H}} \cdot \phi_i.$$

Let C be a bounded linear operator from \underline{H} to a Hilbert space \underline{Y} . This operator can be seen as an observation. An important concept in system theory is the nonobservable subspace \underline{Y}_0 , i.e., all trajectories that are nonobservable.

COROLLARY 3.8. *If A and C satisfy the properties as stated above, then \underline{Y}_0 is $\overline{\text{span}}\{\phi_i | C(\phi_i) = 0\}$. So $\underline{Y}_0 = \{0\}$ iff $C(\phi_i) \neq 0$ for all i .*

Proof. From Curtain [4] we obtain that \underline{Y}_0 is the largest subspace of \underline{H} that is semigroup invariant and in the kernel of C . From Theorem 3.7 and the special structure of A we have that $\underline{Y}_0 = \overline{\text{span}}\{\phi_i | i \in \underline{J} \subset \mathbb{N}; C(\phi_i) = 0\}$. Combining these results for \underline{Y}_0 we conclude this corollary.

We can also define a controlled version of generator invariance. Let b be an element in \underline{H} . With this element we can define an input operator B , i.e., $Bu = b \cdot u$ where u is an element of \underline{U} , the input space. Here we shall assume that \underline{U} is \mathbb{R} or \mathbb{C} .

DEFINITION 3.9. Bounded closed loop invariance. A closed linear subspace \underline{Y} of \underline{H} is called (bounded) closed loop invariant if there exists a bounded linear feedback law F from \underline{H} to \underline{U} such that $T_F(t)\underline{Y} \subset \underline{Y}$ for all $t \geq 0$. $T_F(t)$ is the semigroup generated by $A + BF$.

Remark. If there is no doubt about the feedback law then we will simply use $T_F(t)$ -invariance.

DEFINITION 3.10. Generator feedback invariance. A closed linear subspace \underline{Y} will be called generator feedback invariant if there exists a bounded linear feedback law F from \underline{H} to \underline{U} such that $(A + BF)(\underline{Y} \cap D(A)) \subset \underline{Y}$.

DEFINITION 3.11. (A, B) invariance. A closed linear subspace \underline{Y} will be called (A, B) -invariant if $A(\underline{Y} \cap D(A)) \subset \underline{Y} + \text{Im } B$.

If \underline{H} is finite-dimensional, then these three concepts of invariance are equivalent and a subspace which satisfies one of these concepts is called controlled invariant. However, if \underline{H} is infinite dimensional and A is an unbounded operator, then these

concepts no longer are equivalent (see Schmidt and Stern [16]) and here we shall mean by controlled invariance closed loop invariance.

In Curtain [4] the relation among Definitions 3.9–3.11 is studied. From this we have the following lemma.

LEMMA 3.12. *If V is a closed linear subspace contained in $D(A)$, then closed loop, generator feedback- and (A, B) -invariance are equivalent.*

Proof. See Lemma 4.6 of Curtain [4].

DEFINITION 3.13. $V^*(K)$. Let K be a closed linear subspace in H . By $V^*(K)$ we shall denote the largest (bounded) closed loop invariant subspace in K .

Remark. In general $V^*(K)$ need not exist; see, for example, Pandolfi [12].

Since we do not have equivalence between (A, B) - and closed loop invariance, we must derive new proofs for results that, in the finite dimensional case, were proved by this equivalence. One of these results is given in the next lemma.

LEMMA 3.14. *Let V_1 and V_2 be closed linear subspaces of H that are (bounded) closed loop invariant and assume further that V_2 is finite dimensional; then $V_1 + V_2$ is also (bounded) closed loop invariant.*

Proof. By the definition of closed loop invariance we have that there exist F_1 and F_2 both bounded such that $T_{F_i}(t)V_i \subset V_i$, $i = 1, 2$. Define F_0 to be such that

$$\begin{aligned} F_0|_{V_1} &= F_1|_{V_1}, \\ F_0|_{V'_2} &= F_2|_{V'_2} \quad \text{where } V'_2 = V_2 \cap (V_1 \cap V_2)^\perp, \\ F_0|_{(V_1 + V_2)^\perp} &= 0. \end{aligned}$$

This F_0 is a bounded linear operator. So there is a real λ_0 such that $[\lambda_0, \infty) \subset \rho(A + BF_i)$, $i = 0, 1, 2$. For a $\lambda \in [\lambda_0, \infty)$ we have

$$(3.2) \quad \begin{aligned} (\lambda I - A - BF_0)^{-1} &= (\lambda I - A - BF_i)^{-1} + (\lambda I - A - BF_0)^{-1} \\ &\quad \cdot B(F_0 - F_i)(\lambda I - A - BF_i)^{-1}, \quad i = 1, 2. \end{aligned}$$

If x is an element of V_1 then, by Lemma 3.4, we have that $(\lambda I - A - BF_1)^{-1}x$ is in V_1 . So by (3.2) and the definition of F_0 we have that for $x \in V_1$

$$(3.3) \quad (\lambda I - A - BF_0)^{-1}x = (\lambda I - A - BF_1)^{-1}x,$$

so $(\lambda I - A - BF_0)^{-1}V_1 \subset V_1$.

Since V_2 is closed loop invariant we have from Lemma 3.5 that $D(A)$ is dense in V_2 . And since V_2 is finite-dimensional, it must be a closed subspace contained in $D(A)$. If x is an element of V_2 , then it can be written as $x = x_1 + x_2$, where $x_1 \in V_1 \cap V_2 \subset D(A)$ and $x_2 \in V'_2 \subset D(A)$. And so we have that $B(F_0 - F_2)x = B(F_0 - F_2)(x_1 + x_2) = B(F_1 - F_2)x_1 + 0 = (A + BF_1)x_1 - (A + BF_2)x_1$. From this equation we see that $B(F_0 - F_2)V_2 \subset (V_1 + V_2) \cap \text{Im } B$. Since $B = b$ we must consider two cases.

(i): $b \notin V_1 + V_2$. In this case we have that $B(F_0 - F_2)V_2 = 0$. So with (3.2) we have

$$(3.4) \quad (\lambda I - A - BF_0)^{-1}x = (\lambda I - A - BF_2)^{-1}x \quad \text{for all } x \text{ in } V_2.$$

So $(\lambda I - A - BF_0)^{-1}(V_1 + V_2) \subset (V_1 + V_2)$ and with Lemma 3.4 we conclude that $(V_1 + V_2)$ is closed loop invariant.

(ii): $b \in V_1 + V_2$. In this case we can decompose b in $b_1 + b_2$ with $b_1 \in V_1$ and $b_2 \in V'_2$. Choose λ such that $|\tau| < 1$; where $\tau = (F_0 - F_2)(\lambda I - A - BF_2)^{-1}b_2$. This is possible since $A + BF_2$ generates a C_0 semigroup. From (3.3) we have that

$$(3.5) \quad (\lambda I - A - BF_0)^{-1}b_1 = (\lambda I - A - BF_1)^{-1}b_1$$

and from (3.2) we have that $(\lambda I - A - BF_0)^{-1}b_2 = (\lambda I - A - BF_2)^{-1}b_2 + (\lambda I - A - BF_0)^{-1} \cdot B(F_0 - F_2)(\lambda I - A - BF_2)^{-1}b_2 = (\lambda I - A - BF_2)^{-1}b_2 + \tau \cdot (\lambda I - A - BF_0)^{-1} \cdot b$. Adding this last equation to (3.5), we obtain

$$(3.6) \quad (\lambda I - A - BF_0)^{-1}b = (\lambda I - A - BF_1)^{-1}b_1 + (\lambda I - A - BF_2)^{-1}b_2 + \tau \cdot (\lambda I - A - BF_0)^{-1} \cdot b.$$

Now since $|\tau| < 1$

$$(3.7) \quad (\lambda I - A - BF_0)^{-1}b = (1 - \tau)^{-1} \cdot \{(\lambda I - A - BF_1)^{-1}b_1 + (\lambda I - A - BF_2)^{-1}b_2\}.$$

So $(\lambda I - A - BF_0)^{-1}b$ is an element of $Y_1 + Y_2$. Let x be an element of Y_2 ; then from (3.2), $(\lambda I - A - BF_0)^{-1}x = (\lambda I - A - BF_2)^{-1}x + (\lambda I - A - BF_0)^{-1}b \cdot (F_0 - F_2)(\lambda I - A - BF_2)^{-1}x$. Since $(F_0 - F_2)(\lambda I - A - BF_2)^{-1}x$ is in \underline{U} and $(\lambda I - A - BF_0)^{-1}b$ is in $Y_1 + Y_2$ we may conclude that $(\lambda I - A - BF_0)^{-1}x$ is in $Y_1 + Y_2$. Combining this with (3.3) we have proved this lemma.

Remark. This lemma can easily be generalized to the case that $\text{Im } B$ is finite-dimensional.

As in Theorem 3.7 we pose the question of what the $T_F(t)$ -invariant subspaces look like. This question is in general not solvable even if A is a discrete spectral operator since $A + BF$ need not be a discrete spectral operator. Furthermore we are not interested in all $T_F(t)$ -invariant subspaces but only in those which are in the kernel of C . Before we can give a complete description of all $T_F(t)$ -invariant subspace we must investigate the notion of the zeros of a transfer function.

4. Invariant zeros. In this section we will discuss the concept of invariant zeros which will play an important role in the investigation of $T_F(t)$ -invariant subspaces in $\text{Ker } C$, the kernel of C .

We will consider the following controlled system:

$$(4.1) \quad \begin{aligned} \dot{x} &= Ax + Bu, \\ y &= Cx \end{aligned}$$

where A is a generator of a C_0 semigroup on \underline{H} , $Bu = bu$; $b \in \underline{H}$ and C is a bounded operator from \underline{H} to \underline{Y} , where \underline{Y} is a Hilbert space.

For the definition of invariant zeros it is convenient to introduce the following sequence of subspaces:

$$\begin{aligned} \mathcal{Z}_\mu^0 &:= \{0\}; \quad \mathcal{Z}_\mu^k := \{x \in D(A): \text{there exist } \gamma \text{ in } \mathbb{C} \text{ and } z \text{ in } \mathcal{Z}_\mu^{k-1} \\ &\quad \text{such that } (\mu I - A)x = \gamma \cdot b + z\} \cap \text{Ker } C, \quad k > 0. \end{aligned}$$

DEFINITION 4.1. Invariant zero. μ in \mathbb{C} is called an invariant zero if \mathcal{Z}_μ^1 is not the zero subspace.

Remark. If $\mu \in \rho(A)$ then μ is an invariant zero if and only if $C(\mu I - A)^{-1}b = 0$.

Remark. μ is an invariant zero if and only if there exist nonzero $x \in \underline{H}$ and $u \in \underline{U}$ such that

$$\begin{bmatrix} \mu - A & B \\ C \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix} = 0 \quad (\text{see Davison and Wang [7]}).$$

The next lemma will show that \mathcal{Z}_μ^k is a nested sequence of subspaces.

LEMMA 4.2. \mathcal{Z}_μ^k is a linear subspace in $\text{Ker } C$. $\mathcal{Z}_\mu^{k-1} \subset \mathcal{Z}_\mu^k$ and if $\mathcal{Z}_\mu^{k-1} = \mathcal{Z}_\mu^k$, then $\mathcal{Z}_\mu^{k+1} = \mathcal{Z}_\mu^k$; $k \geq 1$.

Proof. The first assertion can be proved by induction. We shall prove the second and third assertions. Since $\mathcal{Z}_\mu^0 = \{0\}$ we have proved the second assertion for $k = 1$. Suppose it holds for all $n \leq k$, then we will prove it for $n = k + 1$. Let x be an element of \mathcal{Z}_μ^k , then there exist $\gamma \in \mathcal{C}$ and $z \in \mathcal{Z}_\mu^{k-1}$ with $(\mu I - A)x = \gamma \cdot b + z$ and x is in $\text{Ker } C$; $z \in \mathcal{Z}_\mu^{k-1} \subset \mathcal{Z}_\mu^k$. So $x \in \mathcal{Z}_\mu^{k+1}$.

Suppose $\mathcal{Z}_\mu^{k-1} = \mathcal{Z}_\mu^k$. Let x be an element of \mathcal{Z}_μ^{k+1} ; thus $x \in \text{Ker } C$ and there exist $\gamma \in \mathcal{C}$ and $z \in \mathcal{Z}_\mu^k$ with $(\mu I - A)x = \gamma \cdot b + z$, $z \in \mathcal{Z}_\mu^k = \mathcal{Z}_\mu^{k-1}$. This implies that $x \in \mathcal{Z}_\mu^k$. So $\mathcal{Z}_\mu^{k+1} \subset \mathcal{Z}_\mu^k$ and $\mathcal{Z}_\mu^{k+1} \supset \mathcal{Z}_\mu^k$; thus $\mathcal{Z}_\mu^{k+1} = \mathcal{Z}_\mu^k$.

DEFINITION 4.3. Order (μ) . Let μ be in \mathcal{C} . By order (μ) we mean the smallest number $k \geq 0$ such that $\mathcal{Z}_\mu^{k+1} = \mathcal{Z}_\mu^k$. If such a number does not exist then order (μ) is ∞ .

Remark. μ is an invariant zero if and only if order (μ) is larger than zero.

DEFINITION 4.4. \mathcal{N}_μ^k . By \mathcal{N}_μ^k we mean the kernel of $(\mu I - A)^k$ intersected with the kernels of $C(\mu I - A)^1$ for $0 \leq 1 < k$. Thus $\mathcal{N}_\mu^k = \{x \in D(A^k) \text{ subject to } (\mu I - A)^k x = 0 \text{ and } C(\mu I - A)^1 x = 0 \text{ for } 0 \leq 1 < k\}$.

Remark. If \mathcal{N}_μ^1 is nonzero, then μ is called an output decoupling zero; see Davison and Wang [7].

The next lemma will give some properties of \mathcal{N}_μ^k similar to those of \mathcal{Z}_μ^k .

LEMMA 4.5. \mathcal{N}_μ^k has the following properties for $k \in \mathbb{N}$:

- (a) $\mathcal{N}_\mu^k \subset \mathcal{N}_\mu^{k+1}$.
- (b) If $\mathcal{N}_\mu^k = \mathcal{N}_\mu^{k+1}$, then $\mathcal{N}_\mu^{k+1} = \mathcal{N}_\mu^{k+2}$.
- (c) \mathcal{N}_μ^k is not the zero subspace for a $k > 0$ iff $\mu \in \sigma_p(A)$ and there exists a nonzero eigenvector, corresponding to μ , in the kernel of C .

Proof. The proof is the same as that for Lemma 4.2.

LEMMA 4.6. Suppose that $\mathcal{N}_\mu^k = \{0\}$, then $\mathcal{Z}_\mu^k = \text{span}\{x_1 \cdots x_n\}$ where n is the minimum of k and order (μ) and x_i satisfies:

$$(4.2) \quad \begin{aligned} x_i &\in \text{Ker } C, \\ (\mu I - A)x_1 &= b \quad \text{and} \\ (\mu I - A)x_i &= x_{i-1}. \end{aligned}$$

Proof. Let us first remark that since $\mathcal{N}_\mu^1 = \{0\}$, we have that the equation $(\mu I - A)x = y$ has at most one solution in $\text{Ker } C$.

If order $(\mu) = 0$, then $\mathcal{Z}_\mu^k = \{0\}$. So in this case the assertion is proved.

Assume now that order $(\mu) \neq 0$ and consider the assertion for $k = 1$. Then $n = 1$ and $(\mu I - A)x = b$ has exactly one solution $x_1 \in \text{Ker } C$ and the assertion holds for $k = 1$.

Now suppose that the assertion holds for $i \leq k - 1$. We will prove it for $i = k$.

If $k - 1 \geq \text{order}(\mu)$, then $\mathcal{Z}_\mu^{k-1} = \mathcal{Z}_\mu^k$ and $\min(k, \text{order}(\mu)) = \min(k - 1, \text{order}(\mu))$. So the assertion holds.

If $k - 1 < \text{order}(\mu)$, then $n := \min(k, \text{order}(\mu)) = k$ and $\mathcal{Z}_\mu^{k-1} \neq \mathcal{Z}_\mu^k$ so there exists $x \in \mathcal{Z}_\mu^k$ and $x \notin \mathcal{Z}_\mu^{k-1}$. Since $x \in \mathcal{Z}_\mu^k$ there exist $\gamma_0 \in \mathcal{C}$ and z in \mathcal{Z}_μ^{k-1} such that $(\mu I - A)x = \gamma_0 \cdot b + z$. By the induction hypothesis we have that there are constants γ_i such that $z = \sum_{i=1}^{k-1} \gamma_i \cdot x_i$. Since x is not in \mathcal{Z}_μ^{k-1} we must have that $\gamma_{k-1} \neq 0$. Defining x_k as $x_k := (x - \sum_{i=0}^{k-2} \gamma_i \cdot x_{i+1}) / \gamma_{k-1}$ we have

$$\gamma_{k-1} \cdot (\mu I - A)x_k = (\mu I - A)x - \sum_{i=0}^{k-2} \gamma_i \cdot (\mu I - A)x_{i+1}$$

(by the definition of x_i , $i < k$),

$$= \gamma_0 \cdot b + \sum_{i=1}^{k-1} \gamma_i \cdot x_i - \gamma_0 \cdot b - \sum_{i=1}^{k-2} \gamma_i \cdot x_i = \gamma_{k-1} \cdot x_{k-1}.$$

So x_k satisfies the conditions (4.2) and by the definition of x_k we have that $\text{span}\{x_1 \cdots x_k\} = \mathcal{Z}_\mu^{k-1} + \text{span}\{x_k\} \subset \mathcal{Z}_\mu^k$.

Now we shall show that all elements of \mathcal{Z}_μ^k are in $\text{span}\{x_1 \cdots x_k\}$. Suppose that x' is an arbitrary element in \mathcal{Z}_μ^k . Then by the definition of \mathcal{Z}_μ^k there exist $\gamma'_0 \in \mathbb{C}$ and $z' \in \mathcal{Z}_\mu^{k-1}$ such that $(\mu I - A)x' = \gamma'_0 \cdot b + z'$. By the induction hypothesis we have that

$$z' = \sum_{i=1}^{k-1} \gamma'_i \cdot x_i.$$

Defining y as $\gamma_{k-1}x' - \gamma'_{k-1}x$ we have that

$$\begin{aligned} (\mu I - A)y &= (\mu I - A)(\gamma_{k-1}x' - \gamma'_{k-1}x) \\ &= \gamma_{k-1} \left(\gamma'_0 \cdot b + \sum_{i=1}^{k-1} \gamma'_i \cdot x_i \right) - \gamma'_{k-1} \left(\gamma_0 \cdot b + \sum_{i=1}^{k-1} \gamma_i \cdot x_i \right) \\ &= (\gamma_{k-1} \cdot \gamma'_0 - \gamma'_{k-1} \cdot \gamma_0) \cdot b + \sum_{i=1}^{k-2} (\gamma_{k-1} \cdot \gamma'_i - \gamma'_{k-1} \cdot \gamma_i) x_i. \end{aligned}$$

By the definition of \mathcal{Z}_μ^{k-1} and the induction hypothesis for $i = k-2$, the above equation implies that $y \in \mathcal{Z}_\mu^{k-1}$. Thus

$$x' = (y + \gamma'_{k-1}x) / \gamma_{k-1} \in \mathcal{Z}_\mu^{k-1} + \text{span}\{x\} = \mathcal{Z}_\mu^{k-1} + \text{span}\{x_k\} = \text{span}\{x_1 \cdots x_k\}.$$

Since x' is an arbitrary element in \mathcal{Z}_μ^k we have proved that $\mathcal{Z}_\mu^k \subset \text{span}\{x_1 \cdots x_k\}$.

Thus $\mathcal{Z}_\mu^k = \text{span}\{x_1 \cdots x_k\}$.

COROLLARY 4.7. *If $\mu \in \rho(A)$, then $\mathcal{Z}_\mu^k = \text{span}\{(\mu I - A)^{-1}b, \dots, (\mu I - A)^{-n}b\}$, where n is the minimum of k and order (μ) .*

Proof. This is a simple corollary of Lemma 4.6.

The last lemma of this section and the first remark after Definition 4.1 will give an explication for the name invariant zero.

LEMMA 4.8. *If \mathcal{Z}_μ^k is finite-dimensional, then it is $T_F(t)$ -invariant.*

Proof. By the definition of \mathcal{Z}_μ^k this subspace is contained in $D(A)$. And by assumption we have that \mathcal{Z}_μ^k is finite-dimensional. So from Lemma 3.12 we only have to prove that \mathcal{Z}_μ^k is (A, B) -invariant.

Let x be an element of \mathcal{Z}_μ^k , then $(\mu - A)x = \gamma \cdot b + z$ where $z \in \mathcal{Z}_\mu^{k-1} \subset \mathcal{Z}_\mu^k$ and $\gamma \in \mathbb{C}$. So $Ax = \mu x - z - \gamma \cdot b$, and $A(\mathcal{Z}_\mu^k) \subset \mathcal{Z}_\mu^k + \text{Im } B$.

5. Invariant zeros for the class of spectral systems. In this section we shall consider system (4.1) with some additional assumptions and discuss the concept of invariant zeros for this special kind of system. The additional assumptions we make on the system (4.1) are:

(\nabla 1) The generator A is a discrete spectral operator with spectral decomposition

$$A = \sum_{i=1}^{\infty} \lambda_i \cdot E(\lambda_i)$$

where $\lambda_i \neq \lambda_j$ (for all $i \neq j$) and $\dim E(\lambda_i) = 1 (i \geq 1)$. Without loss of generality we may assume that the $E(\lambda_i) (i \geq 1)$ are selfadjoint operators in H (see Wermer [18]). The normalized eigenvector of A corresponding to $E(\lambda_i)$ will be denoted by $\phi_i (i \geq 1)$,

$$(\nabla 2) \quad b_i := \langle \phi_i, b \rangle_H \neq 0.$$

Let us remark that (\nabla 2) is the controllability assumption; see, e.g., Curtain and Pritchard [5].

If $\mu \in \sigma(A)$, then $(\lambda I - A)^{-1} = 1/(\lambda - \mu) \cdot E(\mu) + R_\mu(\lambda)$ where $R_\mu(\lambda)$ is analytic in μ and commutes with $E(\mu)$ (see Kato [9, III.6.5]). $R_\mu(\lambda)$ can be seen as the inverse of $\{\lambda - \sum_{i=1, \lambda_i \neq \mu}^{\infty} \lambda_i E(\lambda_i)\}$. Define P_μ as $I - E(\mu)$.

With assumptions $(\nabla 1)$ and $(\nabla 2)$ we shall give a full description of \mathcal{Z}_μ^k .

LEMMA 5.1. *Let $\mu \in \sigma(A)$ be an invariant zero; then $\mathcal{Z}_\mu^k = \text{span} \{x_1, \dots, x_n\}$ where n is the minimum of k and order (μ) and x_i satisfies:*

- (5.1) (a) $x_i \in \text{Ker } C$,
 (b) $x_1 = \phi$; ϕ is the eigenvector corresponding to μ , and
 (c) $x_i = (R_\mu(\mu))^{i-1} P_\mu b$; $i > 1$.

Proof. Let $x \in \mathcal{Z}_\mu^1$; then $(\mu I - A)x = \gamma \cdot b$ for some $\gamma \in \mathbb{C}$. Since $\mu \in \sigma(A)$, there exists a nonzero vector ϕ such that $(\mu I - A)\phi = 0$. So $0 = \langle (\mu I - A)\phi, x \rangle = \langle \phi, (\mu I - A)x \rangle = \langle \phi, b \rangle \cdot \gamma$. With $(\nabla 2)$ we conclude that $\gamma = 0$. Thus $(\mu I - A)x = 0$. This implies that $x \in N_\mu^1$ and that x is an eigenvector corresponding to μ . The multiplicity of all eigenvalues is one so $x \in \text{span} \{\phi\} = N_\mu^1$. Thus we have $\mathcal{Z}_\mu^1 = N_\mu^1 = \text{span} \{\phi\}$. And so the assertion holds for $k = 1$.

Suppose that k is larger than 0. Then since $\mathcal{Z}_\mu^1 \subset \mathcal{Z}_\mu^k$ and $P_\mu \mathcal{Z}_\mu^1 = 0$, \mathcal{Z}_μ^k can be decomposed in $\mathcal{Z}_\mu^k = \mathcal{Z}_\mu^1 \oplus P_\mu \mathcal{Z}_\mu^k = \text{span} \{\phi\} \oplus P_\mu \mathcal{Z}_\mu^k$. We shall prove that $P_\mu \mathcal{Z}_\mu^k$ can be interpreted as “ \mathcal{Z}_μ^{k-1} ” for the system $(P_\mu A, P_\mu b, CP_\mu)$ on the Hilbert space $P_\mu H$.

Let $x \in P_\mu \mathcal{Z}_\mu^k$; then $x = P_\mu x'$; $x' \in \mathcal{Z}_\mu^k$. Since $x' \in \mathcal{Z}_\mu^k$ there exist $z \in \mathcal{Z}_\mu^{k-1}$ and $\gamma \in \mathbb{C}$ such that

$$(5.2) \quad (\mu I - A)x' = \gamma \cdot b + z = \gamma \cdot P_\mu b + \gamma \cdot \langle \phi, b \rangle \cdot \phi + z.$$

Defining $z' = \gamma \cdot \langle \phi, b \rangle \cdot \phi + z$ we have

$$(5.3) \quad \langle \phi, z' \rangle = \langle \phi, (\mu I - A)x' \rangle - \langle \phi, \gamma \cdot P_\mu b \rangle = \langle (\mu I - A)\phi, x' \rangle - \langle P_\mu \phi, \gamma \cdot b \rangle = 0.$$

So $z' \in P_\mu \mathcal{Z}_\mu^{k-1}$. Since $(\mu I - A)P_\mu = (\mu I - A)$ we have that

$$(5.4) \quad (\mu I - AP_\mu)x = (\mu I - A)P_\mu x' = (\mu I - A)x' = \gamma \cdot P_\mu b + z', \quad z' \in P_\mu \mathcal{Z}_\mu^{k-1}.$$

Recall that $P_\mu \mathcal{Z}_\mu^1 = \{0\} = \mathcal{Z}_\mu^0$, so by induction and (5.4) $P_\mu \mathcal{Z}_\mu^k = “\mathcal{Z}_\mu^{k-1}”$ for the system $(P_\mu A, P_\mu b, CP_\mu)$.

Since $\mu \in \rho(P_\mu A)$ we can apply Corollary 4.7. So we have $P_\mu \mathcal{Z}_\mu^k = \text{span} \{\chi_1, \dots, \chi_n\}$ where $\chi_i = (R_\mu(\mu))^{i-1} P_\mu b$ and $n' = \min(k, \text{order}(\mu) - 1)$. If we define $x_{i+1} = \chi_i$, then these vectors satisfy (5.1).

COROLLARY 5.2. *If (A, B) satisfies $(\nabla 1)$ and $(\nabla 2)$, then $\dim(\mathcal{Z}_\mu^k) = n$ where n is the minimum of k and order (μ) .*

Proof. See Lemma 5.1 and Corollary 4.7.

LEMMA 5.3. *Let $C(\lambda I - A)^{-1}B \neq 0$. If (A, B) satisfies $(\nabla 1)$ and $(\nabla 2)$, then the order of every invariant zero is finite.*

Proof. Since C and B are bounded operators we have that $C(\lambda I - A)^{-1}B$ is an analytic function on $\rho(A)$. Let $\mu \in \sigma(A)$ be an invariant zero, then from the previous lemma $C(\lambda I - A)^{-1}B = C\{1/(\lambda - \mu) \cdot E(\mu)B\} + CR_\mu(\lambda)B = CR_\mu(\lambda)B$. This function is analytic in μ and has a zero with multiplicity order $(\mu) - 1$ at μ , Lemma 5.1.

So at all invariant zeros $C(\lambda I - A)^{-1}B$ is analytic or has an analytic extension. And from the well-known zero-set theorem for analytic functions (see Rudin [15, p. 209]) we have that the multiplicity of the zeros is finite, thus order (μ) is finite.

LEMMA 5.4. *If (A, B) satisfies $(\nabla 1)$, $(\nabla 2)$ and the transfer function $C(\lambda I - A)^{-1}B$ is not identically zero, then $Z_{\mu_i}^0 \cap \overline{\text{span}_{j \in \underline{I}/i} \{Z_{\mu_j}^0\}} = \{0\}$, where \underline{I} denotes the index set of all invariant zeros and $\theta_j = \text{order}(\mu_j)$.*

Proof. The complete proof is very long and rather technical; here we shall give the proof in the special case that the order of all invariant zeros is one and none of these zeros is in $\sigma(A)$. So we have to prove that $(\mu I - A)^{-1}b$ is not in $\overline{\text{span}_{\mu_i \neq \mu} \{(\mu_i I - A)^{-1}b\}}$. Suppose that this is true; then there exists a sequence γ_i^n such that $\|(\mu I - A)^{-1}b - \sum_{i=1}^n \gamma_i^n \cdot (\mu_i I - A)^{-1}b\| < 1/n$. This implies that

$$(5.5) \quad \left\| C(\mu I - A)^{-1} \left\{ (\mu I - A)^{-1}b - \sum_{i=1}^n \gamma_i^n \cdot (\mu_i I - A)^{-1}b \right\} \right\| < \|C(\mu I - A)^{-1}\| \cdot 1/n.$$

By the resolvent identity we have that

$$(5.6) \quad (\mu I - A)^{-1}(\mu_i I - A)^{-1}b = (\mu - \mu_i)^{-1} \{(\mu_i I - A)^{-1}b - (\mu I - A)^{-1}b\}.$$

Using this identity we have

$$(5.7) \quad \begin{aligned} & (\mu I - A)^{-1} \left\{ (\mu I - A)^{-1}b - \sum_{i=1}^n \gamma_i^n \cdot (\mu_i I - A)^{-1}b \right\} \\ &= (\mu I - A)^{-2}b - \sum_{i=1}^n \gamma_i^n \cdot (\mu - \mu_i)^{-1} \{(\mu_i I - A)^{-1}b - (\mu I - A)^{-1}b\}. \end{aligned}$$

Notice that since μ and μ_i are invariant zeros we have that $C(\mu I - A)^{-1}b$ and $C(\mu_i I - A)^{-1}b$ are both zero. With this property and (5.7) we can simplify the expression inside the norm signs of (5.5):

$$(5.8) \quad \begin{aligned} & C(\mu I - A)^{-1} \left\{ (\mu I - A)^{-1}b - \sum_{i=1}^n \gamma_i^n \cdot (\mu_i I - A)^{-1}b \right\} \\ &= C(\mu I - A)^{-2}b. \end{aligned}$$

Combining (5.8) with (5.5) implies that $C(\mu I - A)^{-2}b$ is zero, so μ is a zero of order two. This is in contradiction with the assumptions. So $(\mu I - A)^{-1}b$ is not in $\overline{\text{span}_{\mu_i \neq \mu} \{(\mu_i I - A)^{-1}b\}}$.

6. Characterization of all invariant subspaces. In this section we shall give a complete characterization of all $T_F(t)$ -invariant subspaces in $\text{Ker } C$. This is yet not possible for an arbitrary generator, but there is a large class, introduced by Sun [17], where we can give a complete answer. We shall start by defining this class.

We say that (A, B) satisfies condition ∇ if it satisfies $(\nabla 1)$ and $(\nabla 2)$, see § 5, and we have the following extra conditions on the eigenvalues of A :

$$(\nabla 3) \quad \inf_{i \neq j} |\lambda_i - \lambda_j| = \delta > 0,$$

$$(\nabla 4) \quad \sup_{1 \leq i < \infty} \sum_{\substack{j=1 \\ j \neq i}}^{\infty} \left| \frac{1}{\lambda_j - \lambda_i} \right|^2 = \tau < \infty.$$

Our main results are as follows.

THEOREM 6.1. *Suppose that $C(\lambda I - A)^{-1}B \neq 0$ and (A, B) satisfies condition ∇ . Then a closed linear subspace \underline{Y} in $\text{Ker } C$ is $T_F(t)$ -invariant for some bounded feedback*

law F iff there exists a subset of \mathbb{N} , denoted by \underline{J} , such that:

$$(6.1) \quad (a) \quad \underline{Y} = \sum_{j \in \underline{J}} \mathbb{Z}_{\mu_j}^k,$$

where μ_j is an invariant zero, $\mu_i \neq \mu_j$ if $i \neq j$;

(b) $\dim(\mathbb{Z}_{\mu_j}^k) > 0$ for all j in \underline{J} and $\dim(\mathbb{Z}_{\mu_j}^k) = 1$ for all but finitely many j in \underline{J} ; and

(c) There exists a subsequence $n_j (j \in \underline{J})$ in \mathbb{N} such that

$$(6.2) \quad \sum_{j \in \underline{J}} \left[\frac{\lambda_{n_j} - \mu_j}{b_{n_j}} \right]^2 < \infty$$

where λ_{n_j} is the n_j th eigenvalue of A and $b_{n_j} = \langle \phi_{n_j}, b \rangle_H$; ϕ_{n_j} is the eigenvector corresponding to λ_{n_j} .

Remark. From Theorem 3.7 and the proof of this theorem we have that $\sigma(A + BF|_{\underline{Y}}) = \{\mu_j; j \in \underline{J}\}$. So if \underline{Y} is closed loop invariant with $A + BF$ stable, then $\{\mu_j; j \in \underline{J}\} \subset \{z \in \mathbb{C}; \operatorname{re}(z) < 0\}$.

With this theorem we can solve the existence of $V^*(\operatorname{Ker} C)$.

THEOREM 6.2. Suppose that $C(\lambda I - A)^{-1}B \neq 0$ and (A, B) satisfies condition ∇ . Then $V^*(\operatorname{Ker} C)$ exists for a bounded feedback law iff the following conditions hold:

(i) For all but finitely many j 's the order of the invariant zero, μ_j , is one; and

(ii) There exists a subsequence $n_j (j \in \underline{J})$ in \mathbb{N} such that

$$(6.3) \quad \sum_{j \in \underline{J}} \left[\frac{\lambda_{n_j} - \mu_j}{b_{n_j}} \right]^2 < \infty$$

where \underline{J} is the index set of all invariant zeros and λ_{n_j}, b_{n_j} are the same as in Theorem 6.1.

Remark. If $C(\lambda I - A)^{-1}B \equiv 0$, then $V^*(\operatorname{Ker} C)$ exists and is equal to the controllability subspace (see Curtain [4]). Since (A, B) is controllable (condition $(\nabla 2)$) we have that $V^*(\operatorname{Ker} C) = H$.

Remark. For the proof of the sufficient part in both theorems, condition $(\nabla 4)$ can be omitted (see Clarke and Holland [2]).

Before we can prove these theorems we must first prove some lemmas.

LEMMA 6.3. If A satisfies conditions $(\nabla 1)$, $(\nabla 3)$ and $(\nabla 4)$, then $A + BF$ is a discrete spectral operator for all bounded feedback laws F . The spectral projections of $A + BF$ will be denoted by $E_F(\nu_i)$. Furthermore if i is sufficiently large, then $\dim(E_F(\nu_i)H) = 1$.

Proof. See Sun [17, Thm. 2.1 and p. 734]. See Kato [9] for the fact that $(\lambda I - A - BF)^{-1}$ is a compact operator.

LEMMA 6.4. Suppose that (A, B) satisfies assumption ∇ . If \underline{W} is an $(A + BF)$ -invariant subspace of $E_F(\mu)H$ in the kernel of C with $\dim(\underline{W}) = k, k > 0$, then μ is an invariant zero with $k \leq \operatorname{order}(\mu)$ and $\underline{W} = \mathbb{Z}_{\mu}^k$.

Proof. Since \underline{W} is a finite-dimensional, $(A + BF)$ -invariant subspace in $E_F(\mu)H$, there exists a nonzero vector e_1 in \underline{W} such that $(A + BF - \mu I)e_1 = 0$. Thus

$$(6.4) \quad (\mu - A)e_1 = bFe_1,$$

$e_1 \in \underline{W} \subset \operatorname{Ker} C$. So μ is an invariant zero and e_1 is in \mathbb{Z}_{μ}^1 . Since $\dim(\mathbb{Z}_{\mu}^1) = 1$ (see Corollary 5.2) $A + BF|_{\underline{W}}$ has only one eigenvector, and $\operatorname{span}\{e_1\} = \mathbb{Z}_{\mu}^1$.

Since \underline{W} is finite-dimensional, $(A + BF)\underline{W} \subset \underline{W}$, $\sigma(A + BF|_{\underline{W}}) = \mu$ and $A + BF|_{\underline{W}}$ has only one eigenvector we have that $\underline{W} = \operatorname{span}\{e_1, \dots, e_k\}$ where e_i satisfies: $(A + BF - \mu)e_1 = 0$ and $(A + BF - \mu)e_i = e_{i-1}, 2 \leq i \leq k$. This last equation implies that $(\mu I - A)e_i = bFe_i - e_{i-1}, 2 \leq i \leq k$.

By induction it is now easy to prove that $i \leq \operatorname{order}(\mu)$ and $\operatorname{span}\{e_1, \dots, e_i\} = \mathbb{Z}_{\mu}^i, 2 \leq i \leq k$.

Proof of Theorem 6.1. (Only if.) Let \underline{V} be $T_F(t)$ -invariant, then by Lemma 6.3 and Theorem 3.7 \underline{V} is of the following form:

$$(6.5) \quad \underline{V} = \sum_{i=1}^{\infty} \underline{W}_i,$$

where \underline{W}_i is a $(A + BF)$ -invariant subspace of $E_F(\mu_i)\underline{H}$.

Define \underline{J} to be the set of indices with \underline{W}_i not the zero subspace. By Lemma 6.3, we have for all but finitely i in \underline{J} , $\dim(\underline{W}_i) = \dim(E_F(\mu_i)\underline{H}) = 1$. Since \underline{V} is in $\underline{\text{Ker}} C$ we have that \underline{W}_i is in $\underline{\text{Ker}} C$, so by Lemma 6.4 we have that $\underline{W}_i = \underline{Z}_{\mu_i}^{k_i}$, $i \in \underline{J}$. Since $\{\mu_i; i \in \underline{J}\}$ is contained in the spectrum of $A + BF$ we have from Sun [17] that (6.2) must hold.

(If.) Let \underline{J}_1 be the subset of \underline{J} that contains all indices j such that $\dim(\underline{Z}_{\mu_j}^{k_j})$ is one, then by Corollary 5.2 $\underline{Z}_{\mu_j}^{k_j} = \underline{Z}_{\mu_j}^1$. By condition ∇ and (6.2) we may apply Theorem 1.1 of Sun [17]. So there exists a bounded feedback law F_1 such that $\sigma(A + BF_1) \supset \{\mu_j | j \in \underline{J}_1\}$. We will prove that $\underline{V}_1 := \overline{\text{span}_{j \in \underline{J}_1} \{\underline{Z}_{\mu_j}^1\}}$ is closed loop invariant with respect to the operator $T_{F_1}(t)$. Let e_j be an eigenvector of $A + BF_1$ with eigenvalue μ_j , then $(A + BF_1)e_j = \mu_j \cdot e_j$ or equivalently

$$(6.6) \quad (\mu_j I - A)e_j = b \cdot F_1 e_j.$$

Again we have to consider two cases:

(i) $\mu_j \notin \sigma(A)$. In this case we can premultiply (6.6) with $(\mu_j I - A)^{-1}$. So

$$(6.7) \quad e_j = (\mu_j I - A)^{-1} b \cdot F_1 e_j.$$

This equation implies that $Ce_j = C(\mu_j I - A)^{-1} b \cdot F_1 e_j$. And this last expression is zero since μ_j is an invariant zero. So $e_j \in \underline{\text{Ker}} C$. This combined with (6.6) implies that $\text{span}\{e_j\} \subset \underline{Z}_{\mu_j}^1$. From the fact that $\underline{Z}_{\mu_j}^1$ is one-dimensional we have that $\underline{Z}_{\mu_j}^1 = \text{span}\{e_j\}$.

(ii) $\mu_j \in \sigma(A)$. Let ϕ be the eigenvector of A corresponding to μ_j , then

$$(6.8) \quad 0 = \langle 0, e_j \rangle_H = \langle (\mu_j - A)\phi, e_j \rangle_H = \langle \phi, (\mu_j - A)e_j \rangle_H = \langle \phi, b \rangle_H \cdot F_1 e_j.$$

By $(\nabla 2)$, (6.8) implies that $F_1 e_j = 0$. This together with (6.6) and the fact that there exists only one eigenvector, of A , corresponding to the eigenvalue μ_j , implies that $\phi = \tau \cdot e_j$; $\tau \neq 0$. Since $\underline{Z}_{\mu_j}^1 \neq \{0\}$ and $\mu_j \in \sigma(A)$ we have from Lemma 5.1 that $\underline{Z}_{\mu_j}^1 = \underline{N}_{\mu_j}^1 = \text{span}\{\phi\} = \text{span}\{e_j\}$.

So for every j in \underline{J}_1 we have that $\underline{Z}_{\mu_j}^1$ is $T_{F_1}(t)$ -invariant, and so is \underline{V}_1 .

Let \underline{J}_2 be the subset of \underline{J} that contains all indices j such that $\dim(\underline{Z}_{\mu_j}^{k_j})$ is larger than one. Then by the condition in Theorem 6.1 we have that \underline{J}_2 is finite. And with Lemmas 4.8 and 3.14 we conclude that $\underline{V}_2 := \text{span}_{j \in \underline{J}_2} \{\underline{Z}_{\mu_j}^{k_j}\}$ is $T_{F_2}(t)$ -invariant, for some bounded operator F_2 . Since $\underline{V} = \underline{V}_1 + \underline{V}_2$ we can apply Lemma 3.14 to conclude the proof.

Proof of Theorem 6.2. (If.) Define \underline{V} to be the closure of the span over all $\underline{Z}_{\mu_j}^{\theta_j}$, $j \in \underline{J}$, where μ_j are the invariant zeros and θ_j is their order. From Theorem 6.1 we have that this subspace is bounded closed loop invariant and by definition it is the largest closed subspace with this property.

(Only if.) By Theorem 6.1 we have that $\underline{V}^*(\underline{\text{Ker}} C)$ is of the form $\sum_{j \in \underline{J}} \underline{Z}_{\mu_j}^{k_j}$. If there were a μ_{j_0} such that j_0 is not in \underline{J} or k_{j_0} is smaller than θ_{j_0} ; the order of μ_{j_0} , then by Lemma 5.4 $(\sum_{j \in \underline{J}} \underline{Z}_{\mu_j}^{k_j} + \underline{Z}_{\mu_{j_0}}^{\theta_{j_0}})$ is larger than $\sum_{j \in \underline{J}} \underline{Z}_{\mu_j}^{k_j}$ and is closed loop invariant by Lemma 3.14. This is in contradiction to the fact that $\underline{V}^*(\underline{\text{Ker}} C) = \sum_{j \in \underline{J}} \underline{Z}_{\mu_j}^{k_j}$ is the largest closed subspace with this property. So $\underline{V}^*(\underline{\text{Ker}} C) = \sum_{j \in \underline{J}} \underline{Z}_{\mu_j}^{\theta_j}$, where the summation is over all invariant zeros and $\theta_j = \text{order}(\mu_j)$. Conditions (i) and (ii) are direct consequences of Theorem 6.1.

7. Examples. In this section we will discuss some examples. The example that will be discussed in this section is the heated rod with various controls and observations. This can be schematized as below:

and for the mathematical model we take

$$(7.1) \quad \begin{aligned} \frac{\partial x}{\partial t} &= \frac{\partial^2 x}{\partial \xi^2} + b(\xi) \cdot u(t), \\ x(0, t) &= 0 = x(1, t), \\ y(t) &= \int_0^1 c(\xi) \cdot x(t, \xi) d\xi. \end{aligned}$$

This can be formulated as a system of the form (4.1), where we take $\underline{H} = L_2(0, 1)$ and the system operator A is given by

$$A = \frac{\partial^2}{\partial \xi^2}, \quad D(A) = \{h \in \underline{H} : h'' \in \underline{H} \text{ and } h(0) = 0 = h(1)\}.$$

A is selfadjoint and has eigenvalues $\{-n^2\pi^2; n = 1, \dots, \infty\}$ and eigenvectors $\{\phi_i(\xi) = \sqrt{2} \cdot \sin i\pi\xi; i = 1, \dots, \infty\}$.

In this section we take $b(\xi) = I_{[0, 2/\pi]}(\xi)$, the characteristic function of the interval $[0, 2/\pi]$, and we shall investigate the existence of $\underline{V}^*(\text{Ker } C)$ for the two measurement functions $c_1(\xi)$ and $c_2(\xi)$:

$$(7.2) \quad c_1(\xi) = \begin{cases} -20^2\xi^2 + 40\xi, & \xi \in \left[0, \frac{1}{20}\right], \\ 1, & \xi \in \left[\frac{1}{20}, 1 - \frac{1}{20}\right], \\ -20^2\xi^2 + (2 \cdot 20^2 - 40)\xi - (20^2 - 40), & \xi \in \left[1 - \frac{1}{20}, 1\right], \end{cases}$$

$$(7.3) \quad c_2(\xi) = I_{[0, 1]}(\xi).$$

It is easy to see that A satisfies $(\nabla 1)$, $(\nabla 3)$ and $(\nabla 4)$. Furthermore since

$$(7.4) \quad b_i = \langle \phi_i, b \rangle = \int_0^1 I_{[0, 2/\pi]}(x) \sin i\pi x dx = \frac{-\sqrt{2}}{i\pi} \{\cos 2 \cdot i - 1\} \neq 0,$$

(A, B) satisfies ∇ .

Since $\langle c_k, \phi_{2j} \rangle = 0$, $k = 1, 2; j \in \underline{N}$, we have that $-4j^2\pi^2; j \in \underline{N}$ are invariant zeros, for both measurements; these are the only invariant zeros in $\sigma(A)$. In Nooitgedagt [11] the position of the other invariant zeros, that are proper zeros of the system, is calculated. The values of these zeros are listed in Table 1.

TABLE 1
The “odd” zeros are located at eigenvalues of A .

198	-390846.20363	-390836.43821	-390846.2039

The first column contains the zeros of G_1 and G_2 and the last column the eigenvalue of A that is closest to that zero, where $G_k(s) = \langle c_k, (s - A)^{-1}b \rangle_H$, $k = 1, 2$.

Calculating the partial sum,

$$S(n) := \sum_{i=1}^n \left| \frac{\mu_i - \lambda_{i+1}}{b_{i+1}} \right|^2,$$

where $\lambda_{i+1} := -(i+1)^2 \pi^2$ is the eigenvalue closest to μ_i (see the Remark at the end of this section), for both transfer functions yield the values in Table 2. And, if we plot this as function of n , we obtain Figs. 1 and 2.

FIG. 1

FIG. 2

Remark. For the calculated zeros, μ_i ; $1 \leq i \leq 198$, it can be shown that

$$\min_{j \in N} \left\{ \left| \frac{\mu_i - \lambda_j}{b_j} \right| \right\} = \left| \frac{\mu_i - \lambda_{i+1}}{b_{i+1}} \right|.$$

So

$$S(198) := \sum_{i=1}^{198} \left| \frac{\mu_i - \lambda_{i+1}}{b_{i+1}} \right|^2$$

is smaller than

$$\sum_{i=1}^{198} \left| \frac{\mu_i - \lambda_{j_i}}{b_{j_i}} \right|^2$$

for every subsequence $\{j_i; 1 \leq i \leq 198\}$ in N .

Thus concerning Theorem 6.2 we have (numerical) evidence that for $c_1(\xi) V^*(\text{Ker } C)$ exists but not for $c_2(\xi)$.

From Curtain [4] we have that the existence of $V^*(\text{Ker } C)$, $C = \langle c(\xi), \cdot \rangle_H$, for bounded F , is closely related to $c(\xi) \in D(A)$. In this example we see that, in spite of the fact that $c_1(\xi)$ and $c_2(\xi)$ are close in L_2 -norm, $V^*(\text{Ker } C)$ exists for c_1 but not for c_2 . Notice that $c_1 \in D(A)$ and $c_2 \notin D(A)$. Research is continuing for the case that $c(\xi) \notin D(A)$ and there we see that we must not restrict our attention to bounded feedback laws. In the near future I hope to publish some results on this subject.

8. Conclusions. In this paper we have shown that for the class of discrete spectral systems there exists a complete characterization of all (bounded) closed loop invariant subspaces. With this characterization we obtained necessary and sufficient conditions for the existence of $V^*(\text{Ker } C)$. We calculated these numerically for a simple example. On the other hand if we know a priori (for example, see Curtain [4]) that $V^*(\text{Ker } C)$ exists, then the conditions give information concerning the asymptotic distribution of the zeros of the transfer function.

Furthermore we have shown that (as for a finite-dimensional state space) if F is such that $V \subset \text{Ker } C$ is $T_F(t)$ invariant, then the spectrum of $(A + BF)|_V$ is a subset of the set of all (invariant) zeros of the transfer function $C(\lambda I - A)^{-1}B$ and it is fixed. So if a part of this lies in the unstable region, then it is impossible to have invariance and stability at the same time.

Acknowledgment. I would like to thank Ruth Curtain for her careful reading of this manuscript and for her valuable suggestions.

HOMOGENEOUS INDICES, FEEDBACK INVARIANTS AND CONTROL STRUCTURE THEOREM FOR GENERALIZED LINEAR SYSTEMS*

MARK A. SHAYMAN†

Abstract. We define a new set of indices for a generalized linear system. These indices, referred to as the *homogeneous indices*, are a natural generalization of the minimal column indices (Kronecker indices) of an ordinary state-space system. We prove that the homogeneous indices are a complete set of invariants for the action of a natural group of feedback transformations on generalized linear systems. We also show that the homogeneous indices determine exactly which closed loop invariant polynomials can be assigned by feedback, thereby generalizing the Control Structure Theorem of Rosenbrock.

Key words. generalized linear system, proportional and derivative feedback, feedback invariants, homogeneous indices, singular pencils

AMS(MOS) subject classifications. 93B10, 93B17, 93B25, 93B55, 93C35

1. Introduction. In the past several years, there has been considerable interest in generalized linear systems (also called “descriptor systems”), i.e., generalized state-space models of the form

$$(1.1) \quad E\dot{x}(t) = Ax(t) + Bu(t)$$

with the matrix E possibly singular (see, e.g., [1], [16], [17]). We represent this system by the matrix triple (E, A, B) and refer to it as a *regular system* if E is nonsingular and as a *singular system* if E is singular.

Recently, Shayman and Zhou [2] have presented a unified theory of control synthesis for generalized linear systems using constant-ratio proportional and derivative (CRPD) feedback. The framework includes the theory of static state feedback and output feedback for regular systems as a special case. The main elements of this theory include (1) a covering of the space of all systems, both regular and singular, by a family of open and dense subsets indexed by the unit circle; (2) a group of transformations which may be viewed as symmetries of the cover; (3) an admissible class of feedback transformations on each subset which is specifically adapted to that subset. A general procedure of control synthesis of CRPD feedback for generalized linear systems is obtained which uses the symmetry transformations to systematically reduce each synthesis problem to an ordinary static state feedback (or output feedback) synthesis problem for a corresponding regular system. This procedure was used to obtain natural generalizations of the Disturbance Decoupling Theorem, the Pole Assignment Theorem and Brunovsky’s canonical form.

In order to give a precise statement of the problems to be addressed in the present paper, we review the three main elements of the theory presented in [2]. We begin with the covering of the space of generalized systems. Let $\hat{\Sigma}(n, m)$ denote the space of all matrix triples $(E, A, B) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times m}$. Let $\Sigma(n, m)$ denote the open and dense subset of $\hat{\Sigma}(n, m)$ characterized by the requirement that $\det(sE - A)$ does not vanish identically. This condition guarantees uniqueness for the solutions of (1.1). In the literature, the systems belonging to $\Sigma(n, m)$ are generally referred to as “regular

† Electrical Engineering Department and Systems Research Center, University of Maryland, College Park, Maryland 20742.

systems.” However, we will reserve the word “regular” to refer to a generalized linear system (E, A, B) for which E is nonsingular. We refer to the systems in $\Sigma(n, m)$ as the *admissible* systems, and to the condition $\det(sE - A) \neq 0$ as the *admissibility assumption*.

We now define a covering of the space $\Sigma(n, m)$ of admissible systems. For each $\theta \in \mathbb{R}$, let $\Sigma_\theta(n, m)$ denote the subset of $\Sigma(n, m)$ given by

$$(1.2) \quad \Sigma_\theta(n, m) = \{(E, A, B) \in \Sigma(n, m) : \det(\cos \theta E - \sin \theta A) \neq 0\}.$$

It is easy to show that $\Sigma_{\theta+\pi}(n, m) = \Sigma_\theta(n, m)$, and that $\{\Sigma_\theta(n, m) : \theta \in [0, \pi)\}$ is a covering of $\Sigma(n, m)$ by open and dense subsets. By virtue of the periodicity, it is natural to regard the parameter θ as a point on the unit circle. Note that in the special case where $\theta = 0$, $\Sigma_0(n, m)$ consists of those triples (E, A, B) for which E is nonsingular, i.e., the regular systems.

Next, we define a group of symmetries of the cover $\{\Sigma_\theta(n, m) : \theta \in [0, \pi)\}$ —transformations which map these subsets into each other. For each $\phi \in \mathbb{R}$, define a mapping $R_\phi : \hat{\Sigma}(n, m) \rightarrow \hat{\Sigma}(n, m)$ by

$$(1.3) \quad R_\phi(E, A, B) = (\cos \phi E + \sin \phi A, -\sin \phi E + \cos \phi A, B).$$

It is straightforward to show that R_ϕ maps $\Sigma_\theta(n, m)$ isomorphically onto $\Sigma_{\theta+\phi}(n, m)$. In particular, this implies that each subset $\Sigma_\theta(n, m)$ in the covering is isomorphic to the set $\Sigma_0(n, m)$ of regular systems.

We now define a class of admissible feedback transformations for each subset $\Sigma_\theta(n, m)$. Specifically, we allow feedback of the form

$$(1.4) \quad u = F(\cos \theta x - \sin \theta \dot{x}) + v$$

to be applied to the systems belonging to the subset $\Sigma_\theta(n, m)$. In (1.4), θ is fixed while the $m \times n$ gain matrix F is arbitrary, and v represents a new external input. The fixed parameter θ specifies the ratio of state to derivative in the feedback law. Consequently, we refer to (1.4) as *constant-ratio proportional and derivative* (CRPD) state feedback. This specialized form of proportional and derivative feedback was suggested as a design tool for singular systems in the doctoral thesis of Zhou [3] (also Zhou, Shayman and Tarn [4]), and independently by Christodoulou [5].

Remark 1.1. As mentioned previously, in the special case where $\theta = 0$, $\Sigma_0(n, m)$ is the set of all regular systems. In this case, (1.4) is ordinary state feedback. Thus, the theory outlined above includes the theory of state feedback for regular systems as a special case.

There are three main contributions in the present paper. The first is the introduction of a new set of indices for a generalized linear system, which we refer to as the *homogeneous indices* of (E, A, B) . These indices are a natural generalization of the minimal column indices (“Kronecker indices”) of a regular system. In fact, we will show that if (E, A, B) is a controllable regular system, its homogeneous indices and its minimal column indices coincide.

The second contribution is a solution to the CRPD feedback equivalence problem for generalized linear systems. We determine necessary and sufficient conditions for two controllable systems in $\Sigma_\theta(n, m)$ to be transformable to each other via the CRPD feedback (1.4) together with change of basis in the state-space, change of basis in the input space and left-multiplication of (1.1) by a nonsingular matrix. We show that two such systems are feedback equivalent if and only if they have the same homogeneous indices. This generalizes the well-known result that two controllable regular systems are equivalent under the state feedback group if and only if they have identical Kronecker indices.

The third contribution in this paper is a generalization of Rosenbrock's Control Structure Theorem [6]. Rosenbrock's Theorem describes precisely which closed-loop invariant polynomials are attainable by applying state feedback to a given controllable regular system. Using the concept of homogeneous indices, we are able to describe exactly which closed-loop invariant polynomials are attainable by applying CRPD feedback (1.4) to a controllable system in $\Sigma_\theta(n, m)$. Rosenbrock's Theorem is recovered as a special case of our result by setting $\theta = 0$.

2. Homogeneous indices. We begin by reviewing Kronecker's definition of the minimal column indices of a singular pencil of matrices [7]. (See also [8, p. 37] and [18, p. 55].) Let M and N be real $m \times n$ matrices. The matrix pencil $\lambda M + N$ is called a *regular pencil* if $m = n$ and $\det(\lambda M + N)$ does not vanish identically. Otherwise, it is called a *singular pencil*.

The minimal column indices of a singular pencil are defined as follows: Let v_1 be a minimal degree nonzero polynomial solution to the equation

$$(2.1) \quad (\lambda M + N)v = 0.$$

Let v_2 be a minimal degree solution which is linearly independent (over the polynomial ring $\mathbb{R}[\lambda]$) of v_1 . Let v_3 be a minimal degree solution which is linearly independent of $\{v_1, v_2\}$. Proceeding in this way, we obtain a sequence v_1, \dots, v_p of solutions. Such a sequence is called a *fundamental series of solutions* of (2.1). Let $\varepsilon_1 \leq \varepsilon_2 \leq \dots \leq \varepsilon_p$ denote the degrees of v_1, \dots, v_p , respectively. Using the fact that column vectors over a polynomial ring are linearly independent if and only if they are linearly independent over the corresponding field of fractions, we can easily show [8, p. 38] that these nonnegative integers are independent of the choice of fundamental series. $(\varepsilon_1, \dots, \varepsilon_p)$ are called the *minimal column indices* of the singular pencil $\lambda M + N$.

Recall that two $m \times n$ pencils, $\lambda M + N$ and $\lambda \bar{M} + \bar{N}$, are said to be strictly equivalent [8, p. 24] if there exist nonsingular constant matrices P and Q of dimensions $m \times m$ and $n \times n$ such that

$$(2.2) \quad P(\lambda M + N)Q = \lambda \bar{M} + \bar{N}.$$

It is well known that strictly equivalent singular pencils have identical minimal column indices.

Let (E, A, B) be a regular system, i.e., $(E, A, B) \in \Sigma_0(n, m)$, and assume (E, A, B) is controllable. Let $(\varepsilon_1, \dots, \varepsilon_p)$ denote the minimal column indices of the singular pencil $[\lambda E - A, B]$. Let r denote the rank of B , and let M_i denote the matrix $[E^{-1}B, (E^{-1}A)(E^{-1}B), \dots, (E^{-1}A)^{i-1}(E^{-1}B)]$. Let $l_1 = \text{rank } M_1$ and let $l_i = \text{rank } M_i - \text{rank } M_{i-1}$, $i = 2, \dots, n$. Then $l_1 \geq \dots \geq l_n \geq 0$. The following facts are well known (see, e.g., [9]).

PROPOSITION 2.1. *Let (E, A, B) be a controllable regular system. Then,*

(a) $(\varepsilon_1, \dots, \varepsilon_p)$ is a partition of n into m parts, with $\varepsilon_1, \dots, \varepsilon_{m-r}$ zero and $\varepsilon_{m-r+1}, \dots, \varepsilon_m$ strictly positive. (Thus, $p = m$.)

(b) $\varepsilon_j = \text{Card} \{i: l_i \geq m - j + 1\}$ ($j = 1, \dots, m$).

Remark 2.1. Proposition 2.1 is no longer true if the assumption that (E, A, B) be a regular system is dropped. Rosenbrock has shown [10] that if the system $(E, A, B) \in \Sigma(n, m)$ has no finite or infinite input decoupling zero (i.e., is controllable), then the pencil $[\lambda E - A, B]$ has no finite elementary divisor and no minimal index for the rows. It has infinite elementary divisors, each of degree 1, equal in number to the rank defect of E . It has m minimal indices for the columns. Thus, $p = m$, and $(\varepsilon_1, \dots, \varepsilon_p)$ is a partition of rank E , rather than a partition of n as it is in the case of a regular system.

We now define the homogeneous indices of a generalized linear system. Let $(E, A, B) \in \hat{\Sigma}(n, m)$. We associate to (E, A, B) the degree one matrix polynomial in two variables given by $[\lambda E - \mu A, B]$. Abusing terminology slightly, we refer to $[\lambda E - \mu A, B]$ as a matrix pencil. Let z_1 be a column vector with entries in the ring $\mathbb{R}[\lambda, \mu]$ of polynomials in two variables which is a minimal degree nonzero solution to the equation

$$(2.3) \quad [\lambda E - \mu A, B]z = 0.$$

(For a polynomial in two variables, “degree” refers to the total degree, and the degree of a solution z is the highest degree of its components.) Let z_2 be a minimal degree solution which is linearly independent over $\mathbb{R}[\lambda, \mu]$ of z_1 . Let z_3 be a minimal degree solution which is linearly independent of $\{z_1, z_2\}$. Proceeding in this way, we obtain a sequence z_1, \dots, z_q of solutions, which we refer to as a *fundamental series of solutions* of (2.3). Since linear independence over $\mathbb{R}[\lambda, \mu]$ is equivalent to linear independence over the fraction field $\mathbb{R}(\lambda, \mu)$ of rational functions in two variables, it follows that q is at most equal to $n + m$. Let $\delta_1 \leq \dots \leq \delta_q$ denote the degrees of z_1, \dots, z_q , respectively. Using the fraction field $\mathbb{R}(\lambda, \mu)$, it follows by an argument which is analogous to the one given in [8, p. 38] for the minimal column indices that $\delta_1, \dots, \delta_q$ are well defined, i.e., independent of the choice of fundamental series. We will refer to $(\delta_1, \dots, \delta_q)$ as the *homogeneous indices* of the system (E, A, B) .

Remark 2.2. It should be noted that the pencil $[\lambda E - \mu A, B]$ is *not* the homogenization of the pencil $[\lambda E - A, B]$. Since $[\lambda E - A, B] = \lambda[E, 0] + [-A, B]$, the homogenization of $[\lambda E - A, B]$ would be $\lambda[E, 0] + \mu[-A, B] = [\lambda E - \mu A, \mu B]$. However, the term “homogeneous indices” seems appropriate since the submatrix $\lambda E - \mu A$ of $[\lambda E - \mu A, B]$ is the homogenization of the submatrix $\lambda E - A$ of $[\lambda E - A, B]$. The homogenization of $\lambda E - A$ to $\lambda E - \mu A$ plays a crucial role in the Weierstrass theory of regular matrix pencils [8, p. 26].

We now establish important properties of the homogeneous indices which will be needed later. Given a triple (E, A, B) , let $\text{HI}(E, A, B)$ denote its set of homogeneous indices, and let $\text{CI}(E, A, B)$ denote its set of minimal column indices, i.e., the minimal column indices of the singular pencil $[\lambda E - A, B]$.

The following result shows that the homogeneous indices of (E, A, B) are invariant under system rotation.

PROPOSITION 2.2. *If $(E, A, B), (\hat{E}, \hat{A}, B) \in \hat{\Sigma}(n, m)$ with $(\hat{E}, \hat{A}, B) = R_\phi(E, A, B)$, then $\text{HI}(E, A, B) = \text{HI}(\hat{E}, \hat{A}, B)$.*

Proof. Let z_1, \dots, z_p be a fundamental series of solutions of the equation

$$[\lambda E - \mu A, B]z = 0,$$

and let $\hat{z}_i(\hat{\lambda}, \hat{\mu}) = z_i((\cos \phi)\hat{\lambda} + (\sin \phi)\hat{\mu}, (-\sin \phi)\hat{\lambda} + (\cos \phi)\hat{\mu})$. It is easy to verify that $\hat{z}_1, \dots, \hat{z}_p$ is a fundamental series of solutions of the equation

$$[\hat{\lambda}\hat{E} - \hat{\mu}\hat{A}, B]\hat{z} = 0.$$

Since $\deg \hat{z}_i = \deg z_i$, the result follows immediately. \square

Remark 2.3. Proposition 2.2 describes a crucial difference between the homogeneous indices and the minimal column indices. In contrast to the homogeneous indices, the minimal column indices are *not* invariant under system rotation. For example, consider the system (E, A, B) with

$$E = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

Let $\phi = \pi/2$, and let $(\hat{E}, \hat{A}, B) = R_\phi(E, A, B)$. Then $\hat{E} = A$ and $\hat{A} = -E$. It is easy to check that $\text{CI}(E, A, B) = (1)$ whereas $\text{CI}(\hat{E}, \hat{A}, B) = (2)$. On the other hand, we have $\text{HI}(E, A, B) = \text{HI}(\hat{E}, \hat{A}, B) = (2)$.

The next result shows that for a controllable regular system, the homogeneous indices coincide with the minimal column indices. The proof is deferred to the next section.

PROPOSITION 2.3. *Let (E, A, B) be a controllable regular system. Then,*

$$\text{HI}(E, A, B) = \text{CI}(E, A, B).$$

Remark 2.4. Using Propositions 2.2, 2.3 and 2.1, we can obtain a simple procedure for computing the homogeneous indices of a controllable generalized system. Let $C_\theta(n, m)$ denote the subset of $\Sigma_\theta(n, m)$ consisting of those systems which are controllable according to the definition of Yip and Sincovec [11]. (That is, there are no finite or infinite input decoupling zeros.) It is proved in [2] that controllability is invariant under system rotation. Thus, $R_\phi(C_\theta(n, m)) = C_{\theta+\phi}(n, m)$. Let $(E, A, B) \in C_\theta(n, m)$, and let $(\hat{E}, \hat{A}, B) = R_{-\theta}(E, A, B) \in C_0(n, m)$. By Propositions 2.2 and 2.3, we have $\text{HI}(E, A, B) = \text{HI}(\hat{E}, \hat{A}, B) = \text{CI}(\hat{E}, \hat{A}, B)$. Thus, the homogeneous indices of (E, A, B) can be determined by computing the l_i 's for the controllable regular system (\hat{E}, \hat{A}, B) , and then using Proposition 2.1(b) to obtain $\text{CI}(\hat{E}, \hat{A}, B)$. For example, let (E, A, B) be as in Remark 2.3, and let $\theta = -\pi/2$. Then, $(E, A, B) \in C_\theta(n, m)$ and $(\hat{E}, \hat{A}, B) = R_{-\theta}(E, A, B) = (A, -E, B)$. Since $\text{rank } B = 1$ and $\text{rank } [B, -EB] = 2$, we get $l_1 = 1, l_2 = 1$. Applying Proposition 2.1(b), we obtain $\text{HI}(E, A, B) = (2)$.

PROPOSITION 2.4. *If (E, A, B) is a controllable admissible system, then $\text{HI}(E, A, B)$ is a partition of n into m parts, of which $\text{rank } B$ parts are strictly positive.*

Proof. By assumption, $(E, A, B) \in C_\theta(n, m)$ for some θ . Using the notation of Remark 2.4, we have $\text{HI}(E, A, B) = \text{CI}(\hat{E}, \hat{A}, B)$. The result follows from this together with Proposition 2.1(a). \square

Remark 2.5. Proposition 2.4 describes an important difference between the homogeneous indices and the minimal column indices of a controllable system. The homogeneous indices sum to n regardless of whether the system is regular or singular. In contrast, the minimal column indices sum to $\text{rank } E$ (Remark 2.1), which is equal to n only if the system is regular.

Remark 2.3 shows that in contrast to the homogeneous indices, the minimal column indices are not invariant under system rotation. However, what is true is that if two controllable regular systems are related by a system rotation, then they have identical minimal column indices.

PROPOSITION 2.5. *If (E, A, B) and (\hat{E}, \hat{A}, B) are controllable regular systems with $(\hat{E}, \hat{A}, B) = R_\phi(E, A, B)$, then $\text{CI}(E, A, B) = \text{CI}(\hat{E}, \hat{A}, B)$.*

Proof. Using Propositions 2.2 and 2.3, we have $\text{CI}(E, A, B) = \text{HI}(E, A, B) = \text{HI}(\hat{E}, \hat{A}, B) = \text{CI}(\hat{E}, \hat{A}, B)$. \square

3. Feedback invariants. We begin by reviewing the definition of the state feedback group. (See, e.g., [9], [12]–[14].) Consider the ordinary state-space model

$$(3.1) \quad \dot{x}(t) = Ax(t) + Bu(t)$$

where $(A, B) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times m}$. We consider three types of elementary transformation on the system (3.1). They are (1) change of basis in the state-space, $x = Pz$ with P a nonsingular $n \times n$ matrix; (2) change of basis in the input space, $u = Qv$ with Q a nonsingular $m \times m$ matrix; (3) state feedback $u = Fx + v$. These operations transform the matrix pair (A, B) as follows:

$$(3.2) \quad (A, B) \rightarrow (P^{-1}AP, P^{-1}B),$$

$$(3.3) \quad (A, B) \rightarrow (A, BQ),$$

$$(3.4) \quad (A, B) \rightarrow (A + BF, B).$$

The transformation group generated by (3.2)–(3.4) can be conveniently represented in the following way. Recall that a right group action of a group G on a set X is a mapping $\eta: X \times G \rightarrow X$ satisfying the conditions $\eta(x, e) = x$ and $\eta(x, g_1 g_2) = \eta(\eta(x, g_1), g_2)$ where e denotes the identity element of G . If $x \in X$, the orbit of x , denoted xG , consists of the subset $\{\eta(x, g): g \in G\}$ of X .

Let $C(n, m)$ denote the space of all matrix pairs $(A, B) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times m}$ which are controllable. Let $H(n, m)$ denote the group consisting of all nonsingular $(n + m) \times (n + m)$ matrices of the form

$$\begin{bmatrix} P & 0 \\ F & Q \end{bmatrix}$$

with $Pn \times n$, $Fm \times n$, $Qm \times m$. We refer to $C(n, m)$ as the *space of controllable pairs* and to $H(n, m)$ as the *state feedback group*. Define a right group action of $H(n, m)$ on $C(n, m)$ by

$$(3.5) \quad \eta \left((A, B), \begin{bmatrix} P & 0 \\ F & Q \end{bmatrix} \right) = (P^{-1}AP + P^{-1}BF, P^{-1}BQ).$$

The transformations (3.2)–(3.4) correspond to the special cases of (3.5), where $F = 0$ and $Q = I$, $P = I$ and $F = 0$, $P = I$ and $Q = I$, respectively.

It is of interest to know when two systems (A_1, B_1) and (A_2, B_2) are related by a transformation in the state feedback group, i.e., belong to the same $H(n, m)$ -orbit. It is also useful to have a canonical form for this group action—to identify the “simplest” element on each orbit. This is provided by the following result of Brunovsky [12]. (See also [9], [6], [15].)

THEOREM 3.1 [12]. (a) $(A_1, B_1), (A_2, B_2) \in C(n, m)$ belong to the same $H(n, m)$ -orbit if and only if $\text{CI}(I, A_1, B_1) = \text{CI}(I, A_2, B_2)$.

(b) Let r be a positive integer with $r \leq \min(n, m)$, and let $n_1 \geq n_2 \geq \dots \geq n_r$ be a partition of n into r positive parts. The $H(n, m)$ -orbit consisting of those pairs $(A, B) \in C(n, m)$ for which $\text{CI}(I, A, B) = (0, \dots, 0, n_r, n_{r-1}, \dots, n_1)$ contains the canonical pair (A_c, B_c) given by

$$A_c = \begin{bmatrix} J_{n_1} & 0 & 0 & \cdots & 0 \\ 0 & J_{n_2} & 0 & \cdots & 0 \\ 0 & 0 & \ddots & & \vdots \\ \vdots & \vdots & & \ddots & \vdots \\ 0 & 0 & & \cdots & J_{n_r} \end{bmatrix},$$

$$B_c = \left[\begin{array}{ccccc|ccc} e_{n_1} & 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ 0 & e_{n_2} & 0 & \cdots & 0 & & & \\ 0 & 0 & \ddots & & \vdots & \vdots & & \vdots \\ \vdots & \vdots & & \ddots & \vdots & & & \vdots \\ 0 & 0 & & \cdots & e_{n_r} & 0 & \cdots & 0 \end{array} \right]$$

where J_k is a $k \times k$ matrix of the form

$$\begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \ddots & \vdots \\ \vdots & \vdots & & \ddots & 1 \\ 0 & 0 & \cdots & & 0 \end{bmatrix}$$

and e_k is a k -dimensional column vector in which the only nonzero component is the last, which is 1.

We will refer to the pair (A_c, B_c) in Theorem 3.1 as the *Brunovsky canonical form* associated with the set of minimal column indices $(0, \dots, 0, n_r, \dots, n_1)$.

The following result is needed for the proof of Proposition 2.3.

LEMMA 3.1. *If $(A, B), (\hat{A}, \hat{B}) \in C(n, m)$ belong to the same $H(n, m)$ -orbit, then*

$$\text{HI}(I, A, B) = \text{HI}(I, \hat{A}, \hat{B}).$$

Proof. It suffices to consider the following two special cases:

$$(a) (\hat{A}, \hat{B}) = (P^{-1}AP, P^{-1}BQ);$$

$$(b) (\hat{A}, \hat{B}) = (A + BF, B).$$

First consider (a). We have

$$(3.6) \quad [\lambda I - \mu \hat{A}, \hat{B}] = P^{-1}[\lambda I - \mu A, B] \begin{bmatrix} P & 0 \\ 0 & Q \end{bmatrix}.$$

Let z_1, \dots, z_p be a fundamental series of solutions of the equation $[\lambda I - \mu A, B]z = 0$. Let

$$\hat{z}_i = \begin{bmatrix} P & 0 \\ 0 & Q \end{bmatrix}^{-1} z_i.$$

Then it is clear that $\hat{z}_1, \dots, \hat{z}_p$ is a fundamental series of solutions of the equation $[\lambda I - \mu \hat{A}, \hat{B}]\hat{z} = 0$. Since $\deg \hat{z}_i = \deg z_i$, it follows that $\text{HI}(I, A, B) = \text{HI}(I, \hat{A}, \hat{B})$.

Now consider (b). We have

$$(3.7) \quad [\lambda I - \mu \hat{A}, \hat{B}] = [\lambda I - \mu A, B] \begin{bmatrix} I & 0 \\ -\mu F & I \end{bmatrix}.$$

Let z_1, \dots, z_p be a fundamental series of solutions of $[\lambda I - \mu A, B]z = 0$, and let

$$\hat{z}_i = \begin{bmatrix} I & 0 \\ \mu F & I \end{bmatrix} z_i.$$

Then $\hat{z}_1, \dots, \hat{z}_p$ are solutions of $[\lambda I - \mu \hat{A}, \hat{B}]\hat{z} = 0$ which are linearly independent (over $\mathbb{R}[\lambda, \mu]$).

We claim that $\deg \hat{z}_i = \deg z_i$. Let $z_i = \begin{bmatrix} x_i \\ u_i \end{bmatrix}$ and let $\hat{z}_i = \begin{bmatrix} \hat{x}_i \\ \hat{u}_i \end{bmatrix}$. Then $\hat{x}_i = x_i$ and $\hat{u}_i = \mu Fx_i + u_i$. Thus, it suffices to show that $\deg \hat{u}_i = \deg u_i$. Let $d = \deg x_i$, and write

$$x_i = x_{i0}\lambda^d + x_{i1}\lambda^{d-1}\mu + \dots + x_{id}\mu^d + \bar{x}_i$$

with $\deg \bar{x}_i < d$. Suppose that $x_{i0}, \dots, x_{i,k-1}$ are zero, but x_{ik} is nonzero. Since $Bu_i = \mu Ax_i - \lambda x_i$, it follows that the coefficient vector of $\lambda^{d-k+1}\mu^k$ in u_i is nonzero. In particular, $\deg u_i \geq d+1$. If $\deg u_i > d+1$, then since $\deg \mu Fx_i \leq d+1$, it follows that $\deg \hat{u}_i = \deg u_i$. Therefore, we may assume $\deg u_i = d+1$. Since u_i contains $\lambda^{d-k+1}\mu^k$ but μFx_i does not contain $\lambda^{d-k+1}\mu^k$, it follows that $\deg \hat{u}_i = d+1 = \deg u_i$. Thus, $\deg \hat{z}_i = \deg z_i$ as claimed.

We claim that $\hat{z}_1, \dots, \hat{z}_p$ is a fundamental series of solutions of $[\lambda I - \mu \hat{A}, \hat{B}]\hat{z} = 0$. Suppose not. Then there is a smallest positive integer k for which $\deg \hat{z}_k$ is not minimal. Thus, there exists a solution \hat{y}_k with $\deg \hat{y}_k < \deg \hat{z}_k$ such that $\hat{z}_1, \dots, \hat{z}_{k-1}, \hat{y}_k$ are linearly independent. Let

$$y_k = \begin{bmatrix} I & 0 \\ -\mu F & I \end{bmatrix} \hat{y}_k.$$

Then, z_1, \dots, z_{k-1}, y_k is a linearly independent set of solutions of $[\lambda I - \mu A, B]z = 0$.

Essentially the same argument as given in the preceding paragraph shows that $\deg y_k = \deg \hat{y}_k$, so $\deg y_k < \deg z_k$. This contradicts the assumption that z_1, \dots, z_p is a fundamental series. Thus, $\hat{z}_1, \dots, \hat{z}_p$ is a fundamental series. Since $\deg \hat{z}_i = \deg z_i$, this proves that $\text{HI}(I, A, B) = \text{HI}(I, \hat{A}, \hat{B})$. \square

Remark 3.1. We can use (3.5) to define the action of $H(n, m)$ of all matrix pairs $(A, B) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times m}$, rather than on the set of controllable pairs $C(n, m)$. Since the proof of Lemma 3.1 does not use controllability, it follows that the statement of Lemma 3.1 remains true with $C(n, m)$ replaced by $\mathbb{R}^{n \times n} \times \mathbb{R}^{n \times m}$.

Proof of Proposition 2.3. Let (E, A, B) be a controllable regular system. Since left-multiplication is a strict equivalence transformation, it does not change either the minimal column indices or the homogeneous indices. Consequently, it suffices to show that $\text{HI}(I, E^{-1}A, E^{-1}B) = \text{CI}(I, E^{-1}A, E^{-1}B)$. Let (A_c, B_c) denote the Brunovsky canonical form of $(E^{-1}A, E^{-1}B)$. From Theorem 3.1(a) and Lemma 3.1, we have $\text{CI}(I, A_c, B_c) = \text{CI}(I, E^{-1}A, E^{-1}B)$ and $\text{HI}(I, A_c, B_c) = \text{HI}(I, E^{-1}A, E^{-1}B)$. Thus, it suffices to show that $\text{HI}(I, A_c, B_c) = \text{CI}(I, A_c, B_c)$.

Let $(0, \dots, 0, n_r, \dots, n_1)$ denote the minimal column indices of (I, A_c, B_c) . We can choose an $(n+m) \times (n+m)$ permutation matrix N such that

$$[\lambda I - \mu A_c, B_c]N = [\text{diag}\{K(n_1), \dots, K(n_r)\}, O_{n \times (m-r)}],$$

where $K(n_i)$ denotes the $n_i \times (n_i + 1)$ pencil $[\lambda I_{n_i} - \mu J_{n_i}, e_{n_i}]$. Although $[\lambda I - \mu A_c, B_c]N$ is not of the form $[\lambda E - \mu A, B]$, we can define a fundamental series of solutions for the equation $[\lambda I - \mu A_c, B_c]N\hat{z} = 0$ in the obvious way. Hence, homogeneous indices are well defined for the pencil $[\lambda I - \mu A_c, B_c]N$. If $\hat{z}_1, \dots, \hat{z}_p$ denotes such a fundamental series, then it is clear that $N\hat{z}_1, \dots, N\hat{z}_p$ is a fundamental series for the equation $[\lambda I - \mu A_c, B_c]z = 0$. Since $\deg N\hat{z}_i = \deg \hat{z}_i$, it follows that the homogeneous indices of $[\lambda I - \mu A_c, B_c]$ —i.e., $\text{HI}(I, A_c, B_c)$ —are equal to the homogeneous indices of $[\lambda I - \mu A_c, B_c]N$. Thus, it suffices to show that the homogeneous indices of $[\lambda I - \mu A_c, B_c]N$ are $(0, \dots, 0, n_r, \dots, n_1)$.

It is easy to see that for a block-diagonal pencil, the complete set of homogeneous indices is obtained as the union of the corresponding systems of homogeneous indices of the individual diagonal blocks. (This is analogous to the situation for the minimal column indices noted in [8, p. 39].) Consequently, the homogeneous indices of $[\lambda I - \mu A_c, B_c]N$ consist of $0, \dots, 0$ (multiplicity $m-r$) together with the homogeneous indices of the r pencils $[\lambda I_{n_i} - \mu J_{n_i}, e_{n_i}]$. Let $z_{n_i}^*$ denote the $(n_i + 1)$ -component vector with j th component $\lambda^{j-1} \mu^{n_i-j}$ ($j = 1, \dots, n_i$) and $(n_i + 1)$ th component $-\lambda^{n_i}$. It is easy to verify that every nonzero solution of $[\lambda I_{n_i} - \mu J_{n_i}, e_{n_i}]z_i = 0$ is an $\mathbb{R}[\lambda, \mu]$ -multiple of $z_{n_i}^*$. Consequently, $[\lambda I_{n_i} - \mu J_{n_i}, e_{n_i}]$ has the single homogeneous index (n_i) . Thus, the homogeneous indices of $[\lambda I - \mu A_c, B_c]N$ are $(0, \dots, 0, n_r, \dots, n_1)$, completing the proof. \square

We now review the definition of the CRPD state feedback groups given in [2]. We consider four types of elementary transformations on the system (1.1). They are (1) change of basis in the state-space, $x = Pz$ with P a nonsingular $n \times n$ matrix; (2) change of basis in the input space, $u = Qv$ with Q a nonsingular $m \times m$ matrix; (3) CRPD feedback $u = F(\cos \theta x - \sin \theta \dot{x}) + v$ with θ a fixed number in $[0, \pi)$ and F an arbitrary $m \times n$ matrix; (4) left-multiplication by a nonsingular $n \times n$ matrix R^{-1} . These operations transform the matrix triple (E, A, B) as follows:

$$(3.8) \quad (E, A, B) \rightarrow (P^{-1}EP, P^{-1}AP, P^{-1}B),$$

$$(3.9) \quad (E, A, B) \rightarrow (E, A, BQ),$$

$$(3.10) \quad (E, A, B) \rightarrow (E + \sin \theta BF, A + \cos \theta BF, B),$$

$$(3.11) \quad (E, A, B) \rightarrow (R^{-1}E, R^{-1}A, R^{-1}B).$$

The transformation group generated by (3.8)–(3.11) can be conveniently represented in the following way. For each θ , let $G_\theta(n, m)$ denote the group consisting of all nonsingular $(3n + m) \times (3n + m)$ matrices of the form

$$(3.12) \quad \begin{bmatrix} R & 0 & 0 & 0 \\ 0 & P & 0 & 0 \\ 0 & 0 & P & 0 \\ 0 & \sin \theta F & \cos \theta F & Q \end{bmatrix}.$$

We refer to the family of groups $\{G_\theta(n, m): \theta \in [0, \pi)\}$ as the CRPD *state feedback groups*.

Remark 3.2. If $\cos \theta F$ and $\sin \theta F$ in (3.12) are replaced with arbitrary $m \times n$ matrices F_1, F_2 , then we obtain a larger group which we denote by $G(n, m)$ and refer to as the *proportional and derivative state feedback group*. This corresponds to replacing the CRPD feedback (1.4) with the more general proportional and derivative feedback $u = F_1x - F_2\dot{x} + v$. Each of the CRPD feedback groups, $G_\theta(n, m)$, is a subgroup of $G(n, m)$.

Define a right group action of $G_\theta(n, m)$ on $\hat{\Sigma}(n, m)$ by

$$(3.13) \quad \left((E, A, B), \begin{bmatrix} R & 0 & 0 & 0 \\ 0 & P & 0 & 0 \\ 0 & 0 & P & 0 \\ 0 & \sin \theta F & \cos \theta F & Q \end{bmatrix} \right) \rightarrow (R^{-1}EP + \sin \theta R^{-1}BF, R^{-1}AP + \cos \theta R^{-1}BF, R^{-1}BQ).$$

Each of the transformations (3.8)–(3.11) is a special case of (3.13). Let $g_\theta(R, P, Q, F)$ denote the transformation on $\hat{\Sigma}(n, m)$ induced by the matrix (3.12) in $G_\theta(n, m)$. In other words, $g_\theta(R, P, Q, F)(E, A, B)$ denotes the right-hand side of (3.13).

Recall from Remark 2.4 that $C_\theta(n, m)$ denotes the controllable systems in the open and dense subset $\Sigma_\theta(n, m)$, and that $R_\phi(C_\theta(n, m)) = C_{\theta+\phi}(n, m)$. The following three results are proved in [2].

PROPOSITION 3.1 [2]. $\Sigma_\theta(n, m)$ is invariant under the action of $G_\theta(n, m)$.

PROPOSITION 3.2 [2]. The following is a commutative diagram:

$$\begin{array}{ccc} \Sigma_\theta(n, m) & \xrightarrow{g_\theta(R, P, Q, F)} & \Sigma_\theta(n, m) \\ R_\phi \downarrow & & \downarrow R_\phi \\ \Sigma_{\theta+\phi}(n, m) & \xrightarrow{g_{\theta+\phi}(R, P, Q, F)} & \Sigma_{\theta+\phi}(n, m) \end{array}$$

That is, $R_\phi \circ g_\theta(R, P, Q, F) = g_{\theta+\phi}(R, P, Q, F) \circ R_\phi$.

PROPOSITION 3.3 [2]. $C_\theta(n, m)$ is invariant under the action of $G_\theta(n, m)$.

By virtue of Proposition 3.3, we can restrict the action of $G_\theta(n, m)$ on $\hat{\Sigma}(n, m)$ to the invariant subset $C_\theta(n, m)$. The problem which we consider is the one of determining a complete set of invariants for the action of $G_\theta(n, m)$ on $C_\theta(n, m)$. Roughly speaking, this means finding a set of functions of (E, A, B) with the property that these functions have the same values on (E_1, A_1, B_1) as on (E_2, A_2, B_2) if and only if (E_1, A_1, B_1) and (E_2, A_2, B_2) are related by a transformation in the CRPD feedback group $G_\theta(n, m)$.

Remark 3.3. In the special case where $\theta = 0$, $C_0(n, m)$ consists of the controllable regular systems, and $G_0(n, m)$ can be regarded as the state feedback group $H(n, m)$

augmented by left-multiplication. In this case, it follows from Theorem 3.1(a) that the minimal column indices are a complete set of invariants. In other words, $(E_1, A_1, B_1), (E_2, A_2, B_2) \in C_0(n, m)$ are equivalent under the action of $G_0(n, m)$ if and only if $\text{CI}(E_1, A_1, B_1) = \text{CI}(E_2, A_2, B_2)$.

The following result is the main result of this section. It presents the solution to the problem posed above, and represents a natural generalization of Theorem 3.1.

THEOREM 3.2. (a) $(E_1, A_1, B_1), (E_2, A_2, B_2) \in C_\theta(n, m)$ belong to the same $G_\theta(n, m)$ -orbit if and only if

$$\text{HI}(E_1, A_1, B_1) = \text{HI}(E_2, A_2, B_2).$$

(b) Let $n_1 \geq \dots \geq n_m$ be a partition of n into m nonnegative parts. The $G_\theta(n, m)$ -orbit consisting of those triples $(E, A, B) \in C_\theta(n, m)$ for which $\text{HI}(E, A, B) = (n_m, \dots, n_1)$ contains the canonical triple $(\cos \theta I + \sin \theta A_c, -\sin \theta I + \cos \theta A_c, B_c)$ where (A_c, B_c) is the Brunovsky canonical form associated with the minimal column indices (n_m, \dots, n_1) .

Proof. (a) Let $(E_1, A_1, B_1), (E_2, A_2, B_2) \in C_\theta(n, m)$, and suppose there exist R, P, Q, F such that $(E_2, A_2, B_2) = g_\theta(R, P, Q, F)(E_1, A_1, B_1)$. Applying successively Proposition 2.2, Proposition 2.3 and Theorem 3.1(a) together with Remark 3.3, Proposition 2.3, Proposition 2.2, and Proposition 3.2, we have

$$\begin{aligned} \text{HI}(E_1, A_1, B_1) &= \text{HI}(R_{-\theta}(E_1, A_1, B_1)) \\ &= \text{CI}(R_{-\theta}(E_1, A_1, B_1)) = \text{CI}(g_0(R, P, Q, F) \circ R_{-\theta}(E_1, A_1, B_1)) \\ &= \text{HI}(g_0(R, P, Q, F) \circ R_{-\theta}(E_1, A_1, B_1)) \\ &= \text{HI}(R_\theta \circ g_0(R, P, Q, F) \circ R_{-\theta}(E_1, A_1, B_1)) \\ &= \text{HI}(g_\theta(R, P, Q, F)(E_1, A_1, B_1)) = \text{HI}(E_2, A_2, B_2). \end{aligned}$$

Conversely, suppose $(E_1, A_1, B_1), (E_2, A_2, B_2) \in C_\theta(n, m)$ with $\text{HI}(E_1, A_1, B_1) = \text{HI}(E_2, A_2, B_2)$. By Proposition 2.2, we have $\text{HI}(R_{-\theta}(E_1, A_1, B_1)) = \text{HI}(R_{-\theta}(E_2, A_2, B_2))$. By Proposition 2.3, it follows that $\text{CI}(R_{-\theta}(E_1, A_1, B_1)) = \text{CI}(R_{-\theta}(E_2, A_2, B_2))$. Consequently, by Theorem 3.1(a) together with Remark 3.3, there exist R, P, Q, F such that $R_{-\theta}(E_2, A_2, B_2) = g_0(R, P, Q, F) \circ R_{-\theta}(E_1, A_1, B_1)$. Thus, it follows from Proposition 3.2 that $(E_2, A_2, B_2) = g_\theta(R, P, Q, F)(E_1, A_1, B_1)$.

(b) Let $(E, A, B) \in C_\theta(n, m)$. It is proved in [2] that there is some partition of n into m nonnegative parts, $n_1 \geq n_2 \geq \dots \geq n_m$, such that the $G_\theta(n, m)$ -orbit of (E, A, B) contains the triple $(\cos \theta I + \sin \theta A_c, -\sin \theta I + \cos \theta A_c, B_c)$, where (A_c, B_c) is the Brunovsky canonical form associated with the minimal column indices (n_m, \dots, n_1) . It remains to show that (n_m, \dots, n_1) are the homogeneous indices of (E, A, B) . By successively using part (a), Proposition 2.2, and Proposition 2.3, we have $\text{HI}(E, A, B) = \text{HI}(\cos \theta I + \sin \theta A_c, -\sin \theta I + \cos \theta A_c, B_c) = \text{HI}(I, A_c, B_c) = \text{CI}(I, A_c, B_c) = (n_m, \dots, n_1)$. \square

Remark 3.4. Kalman has noted [9] that the action (3.5) of the state feedback group can be regarded as a special case of the strict equivalence action on matrix pencils. To see this, let (\hat{A}, \hat{B}) denote the right-hand side of (3.5). Then,

$$(3.14) \quad [\lambda I - \hat{A}, \hat{B}] = P^{-1}[\lambda I - A, B] \begin{bmatrix} P & 0 \\ -F & Q \end{bmatrix}.$$

Thus, the pencil $[\lambda I - \hat{A}, \hat{B}]$ is obtained from the pencil $[\lambda I - A, B]$ by a strict equivalence transformation. Consequently, Brunovsky canonical form is a special case of the Kronecker canonical form for matrix pencils.

An obvious question to ask is whether the action (3.13) of the CRPD feedback group $G_\theta(n, m)$ can somehow be regarded as a special case of the strict equivalence

action on matrix pencils. It is easy to show that the answer to this question is negative. One way to show this is to note that if (3.13) corresponded to a strict equivalence transformation, then the minimal column indices would be invariant under the action of $G_\theta(n, m)$. This is not the case. For example, let (E, A, B) be as in Remark 2.3, and let $\theta = \pi/2$. Then, $R_{-\theta}(E, A, B) = (-A, E, B)$, which is a controllable regular system, i.e., an element in $C_0(n, m)$. Thus, $(E, A, B) \in C_\theta(n, m)$. Let $F = [1 \ 0]$. Then $g_\theta(I, I, I, F)(E, A, B) = (E + BF, A, B)$ with

$$E + BF = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

Thus, $(E + BF, A, B)$ is a controllable regular single-input system. Consequently, $CI(E + BF, A, B) = (2)$. On the other hand, it was noted in Remark 2.3 that $CI(E, A, B) = (1)$.

Another way to appreciate the distinction between the action of the CRPD feedback groups and the strict equivalence action is to express (3.13) as a transformation on matrix pencils. Let $(\tilde{E}, \tilde{A}, \tilde{B})$ denote the right-hand side of (3.13). Then,

$$(3.15) \quad [\lambda \tilde{E} - \mu \tilde{A}, \tilde{B}] = R^{-1}[\lambda E - \mu A, B] \begin{bmatrix} P & 0 \\ (\lambda \sin \theta - \mu \cos \theta)F & Q \end{bmatrix}.$$

In contrast to (3.14), the transformation (3.15) is not of the strict equivalence type since the right-multiplication is not by a constant matrix.

In the literature, other types of feedback groups have been considered in conjunction with generalized linear systems. Hayton [19] studies the action of the state feedback group $H(n, m)$ on generalized linear systems. Pandolfi [20] considers the transformation group generated by exponential rescaling, left-multiplication, change of basis in the state-space, change of basis in the input space, and static state feedback. A complete set of invariants for the action of this group on the set of controllable admissible generalized linear systems is determined.

The transformation groups $\{G_\theta(n, m)\}$ which we study differ considerably from those in [19] and [20]. The feedback in [19] and [20] is static state feedback, which implies that the rank of E is invariant. In contrast, the feedback in $G_\theta(n, m)$ is of the CRPD-type, and can modify the rank of E . Only when $\theta = 0$ does the CRPD feedback coincide with pure state feedback. If (E, A, B) is a singular system, then $(E, A, B) \notin \Sigma_0(n, m)$. Since the transformations in $G_\theta(n, m)$ are applied only to the systems in $\Sigma_\theta(n, m)$, pure state feedback (i.e., no derivative contribution) is never applied to a singular system.

4. Control structure theorem. The problem of pole-assignment by state feedback for singular systems has been studied by Cobb [21] and Pandolfi [22]. Armentano [23] and Lewis and Ozcaldiran [24] have investigated eigenvector-assignment by state feedback. Mukundan and Dayawansa [25] have studied pole-assignment by proportional and derivative state feedback. In this section, we consider a different problem, namely, the determination of which closed-loop invariant polynomials can be obtained using constant-ratio proportional and derivative feedback.

The Control Structure Theorem of Rosenbrock [6] is an important result which describes precisely which invariant polynomials can be assigned by application of state feedback to a controllable regular system:

THEOREM 4.1 [6]. *Let (A, B) be controllable. Let $r = \text{rank } B$, and let $n_1 \geq \dots \geq n_r$ be the nonzero minimal column indices of (I, A, B) . Let $q \leq r$, and let $\tilde{\psi}_1(\lambda), \dots, \tilde{\psi}_q(\lambda)$ be any set of nonunity monic polynomials such that $\tilde{\psi}_{i+1} | \tilde{\psi}_i$ ($i = 1, \dots, q-1$) and $\sum_{i=1}^q \deg \tilde{\psi}_i = n$. Then there is a state feedback gain F such that the given polynomials*

are the nonunity invariant polynomials of the closed loop system $A + BF$ if and only if

$$\sum_{i=1}^p \deg \tilde{\psi}_i \geq \sum_{i=1}^p n_i, \quad p = 1, \dots, q.$$

Let (E, A, B) be an admissible generalized linear system, i.e., $(E, A, B) \in \Sigma(n, m)$. By the invariant polynomials of (E, A, B) , we mean the invariant polynomials of the pencil $\lambda E - A$. In order to generalize Rosenbrock's Theorem, it is necessary to define the *homogeneous invariant polynomials* for (E, A, B) . In the Weierstrass treatment of infinite elementary divisors for a regular pencil [8, p. 26], (homogeneous) invariant polynomials are defined for the homogeneous pencil $\lambda E - \mu A$. Let $D_k(\lambda, \mu)$ be the greatest common divisor of the minors of order k ($k = 1, \dots, n$). The invariant polynomials of $\lambda E - \mu A$ are the quotients $i_1 = D_n/D_{n-1}$, $i_2 = D_{n-1}/D_{n-2}$, etc. Each D_k, i_j is homogeneous. We define the homogeneous invariant polynomials of (E, A, B) to be the invariant polynomials of $\lambda E - \mu A$. Note that these polynomials are defined modulo multiplication by nonzero real numbers.

Let $r_\phi: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ with

$$(4.1) \quad r_\phi(\lambda, \mu) = ((\cos \phi)\lambda + (\sin \phi)\mu, (-\sin \phi)\lambda + (\cos \phi)\mu).$$

The following proposition describes how the homogeneous invariant polynomials transform under system rotation.

PROPOSITION 4.1. *Let ψ_1, \dots, ψ_n denote the homogeneous invariant polynomials of $(E, A, B) \in \Sigma(n, m)$. Then the homogeneous invariant polynomials of $R_\phi(E, A, B)$ are $\psi_1 \circ r_\phi, \dots, \psi_n \circ r_\phi$.*

Proof. Let $(\hat{E}, \hat{A}, \hat{B}) = R_\phi(E, A, B)$, and let $(\hat{\lambda}, \hat{\mu}) = r_{-\phi}(\lambda, \mu)$. Then,

$$(4.2) \quad \lambda E - \mu A = \hat{\lambda} \hat{E} - \hat{\mu} \hat{A}.$$

Since $(\lambda, \mu) = r_\phi(\hat{\lambda}, \hat{\mu})$, it follows immediately from (4.2) that the invariant polynomials of $\lambda \hat{E} - \mu \hat{A}$ are $\psi_1 \circ r_\phi, \dots, \psi_n \circ r_\phi$. \square

Remark 4.1. It follows from Proposition 4.1 that the degrees of the homogeneous invariant polynomials of $R_\phi(E, A, B)$ are equal to the degrees of the homogeneous invariant polynomials of (E, A, B) . However, the corresponding statement for the ordinary invariant polynomials is definitely not true. For example, let (E, A, B) be as in Remark 2.3, and let $\phi = \pi/2$. Then $R_\phi(E, A, B) = (A, -E, B)$. The homogeneous invariant polynomials of (E, A, B) are $\mu^2, 1$, which have the same degrees as $\lambda^2, 1$, the homogeneous invariant polynomials of $R_\phi(E, A, B)$. On the other hand, the (ordinary) invariant polynomials of (E, A, B) are $1, 1$, whereas those of $R_\phi(E, A, B)$ are $\lambda^2, 1$.

PROPOSITION 4.2. *$(E, A, B) \in \Sigma(n, m)$ is a regular system if and only if no homogeneous invariant polynomial is divisible by μ . In this case, there is a degree-preserving one-to-one correspondence between the homogeneous invariant polynomials and the invariant polynomials given by $\psi_i(\lambda, \mu) \leftrightarrow \psi_i(\lambda, 1)$.*

Proof. See [8, p. 27]. \square

Remark 4.2. The condition in Proposition 4.2 that no homogeneous invariant polynomial is divisible by μ is equivalent to the condition that $\det(\lambda E - \mu A)$ is not divisible by μ .

Remark 4.3. Roughly speaking, Propositions 4.1 and 4.2 are the analogues for the homogeneous invariant polynomials of Propositions 2.2 and 2.3 for the homogeneous indices.

We are now ready to state and prove the generalization of Rosenbrock's Theorem.

THEOREM 4.2 (Control Structure Theorem for Generalized Linear Systems). *Let $(E, A, B) \in C_\theta(n, m)$. Let $r = \text{rank } B$, and let $n_1 \geq \dots \geq n_r$ be the nonzero homogeneous*

indices of (E, A, B) . Let $q \leq r$, and let $\psi_1(\lambda, \mu), \dots, \psi_q(\lambda, \mu)$ be any set of nonconstant homogeneous polynomials such that $\psi_{i+1} | \psi_i$ ($i = 1, \dots, q-1$) and $\sum_{i=1}^q \deg \psi_i = n$. Then there is a CRPD state feedback gain F such that the given polynomials are the nonconstant homogeneous invariant polynomials of the closed loop system $g_\theta(F)(E, A, B)$ if and only if the following two conditions are satisfied:

- (i) ψ_i is not divisible by $(-\sin \theta)\lambda + (\cos \theta)\mu$, $i = 1, \dots, q$;
- (ii) $\sum_{i=1}^p \deg \psi_i \geq \sum_{i=1}^p n_i$, $p = 1, \dots, q$.

Proof. Let $(\hat{E}, \hat{A}, B) = R_{-\theta}(E, A, B) \in C_0(n, m)$. By Propositions 2.2 and 2.3, we have $\text{HI}(E, A, B) = \text{HI}(\hat{E}, \hat{A}, B) = \text{CI}(\hat{E}, \hat{A}, B)$. Thus, $n_1 \geq \dots \geq n_r$ are the nonzero minimal column indices of (\hat{E}, \hat{A}, B) . Let $\hat{\psi}_i = \psi_i \circ r_{-\theta}$, and let $\tilde{\psi}_i(\lambda) = \hat{\psi}_i(\lambda, 1)$. Clearly, $\deg \tilde{\psi}_i = \deg \psi_i$.

Suppose that ψ_1, \dots, ψ_q satisfy (i) and (ii). Since ψ_i is not divisible by $(-\sin \theta)\lambda + (\cos \theta)\mu$, $\hat{\psi}_i$ is not divisible by μ . Consequently, $\deg \tilde{\psi}_i = \deg \psi_i$. Thus,

$$\sum_{i=1}^p \deg \tilde{\psi}_i \geq \sum_{i=1}^p n_i, \quad p = 1, \dots, q.$$

Replacing $\tilde{\psi}_1, \dots, \tilde{\psi}_q$ with nonzero scalar multiples if necessary, we may assume $\tilde{\psi}_1, \dots, \tilde{\psi}_q$ are monic. Applying Rosenbrock's Theorem (Theorem 4.1) to the controllable pair $(\hat{E}^{-1}\hat{A}, \hat{E}^{-1}B)$, we conclude that there is a feedback gain F such that $\tilde{\psi}_1, \dots, \tilde{\psi}_q$ are the nonunity invariant polynomials of $\hat{E}^{-1}\hat{A} + \hat{E}^{-1}BF$, i.e., of the pencil $\lambda I - (\hat{E}^{-1}\hat{A} + \hat{E}^{-1}BF)$. Thus, $\tilde{\psi}_1, \dots, \tilde{\psi}_q$ are the nonunity invariant polynomials of the pencil $\lambda \hat{E} - (\hat{A} + BF)$, and hence of the regular system $(\hat{E}, \hat{A} + BF, B)$. By Proposition 4.2, $\tilde{\psi}_1, \dots, \tilde{\psi}_q$ are the nonconstant homogeneous invariant polynomials of $(\hat{E}, \hat{A} + BF, B)$. By Proposition 4.1, ψ_1, \dots, ψ_q are the nonconstant homogeneous invariant polynomials of $R_\theta(\hat{E}, \hat{A} + BF, B) = R_\theta \circ g_0(F) \circ R_{-\theta}(E, A, B) = g_\theta(F)(E, A, B)$, as required.

Conversely, suppose that there exists a feedback gain F for which the closed loop system $g_\theta(F)(E, A, B)$ has ψ_1, \dots, ψ_q as its nonconstant homogeneous polynomials. By Proposition 4.1, $\hat{\psi}_1, \dots, \hat{\psi}_q$ are the nonconstant homogeneous invariant polynomials of $R_{-\theta} \circ g_\theta(F)(E, A, B) = g_0(F)(\hat{E}, \hat{A}, B)$. By Proposition 4.2, $\hat{\psi}_1, \dots, \hat{\psi}_q$ are not divisible by μ , $\tilde{\psi}_1, \dots, \tilde{\psi}_q$ are the nonconstant invariant polynomials of $g_0(F)(\hat{E}, \hat{A}, B)$, and $\deg \tilde{\psi}_i = \deg \psi_i$. Since ψ_i is not divisible by μ and $\psi_i = \hat{\psi}_i \circ r_\theta$, it follows that ψ_i is not divisible by $(-\sin \theta)\lambda + (\cos \theta)\mu$. Thus, condition (i) is satisfied. Applying Theorem 4.1, we conclude that $\sum_{i=1}^p \deg \tilde{\psi}_i \geq \sum_{i=1}^p n_i$, $p = 1, \dots, q$. Since $\deg \tilde{\psi}_i = \deg \psi_i = \deg \hat{\psi}_i$, it follows immediately that condition (ii) is satisfied. \square

Remark 4.4. Theorem 4.2 says that for a generalized linear system $(E, A, B) \in C_\theta(n, m)$, the closed loop homogeneous invariant polynomials can be assigned arbitrarily by CRPD feedback $g_\theta(F)$ subject to two restrictions. Let $(E_F, A_F, B) = g_\theta(F)(E, A, B)$. The first restriction, that the homogeneous invariant polynomials of (E_F, A_F, B) cannot be divisible by $(-\sin \theta)\lambda + (\cos \theta)\mu$, is equivalent to the restriction that $\det(\lambda E_F - \mu A_F)$ is not divisible by $(-\sin \theta)\lambda + (\cos \theta)\mu$. This corresponds to the fact that $\Sigma_\theta(n, m)$ is invariant under the CRPD feedback $g_\theta(F)$, so we must have $\det(\cos \theta E_F - \sin \theta A_F) \neq 0$.

Remark 4.5. Rosenbrock's Theorem (Theorem 4.1) can be easily recovered by setting $\theta = 0$ in Theorem 4.2. Let (A, B) , r , $n_1 \geq \dots \geq n_r$, q and $\tilde{\psi}_1(\lambda), \dots, \tilde{\psi}_q(\lambda)$ be as in the hypotheses of Theorem 4.1. Then $(I, A, B) \in C_0(n, m)$, and by Proposition 2.3, $n_1 \geq \dots \geq n_r$ are the nonzero homogeneous indices of (I, A, B) . Let $\psi_i(\lambda, \mu)$ be the homogenization of $\tilde{\psi}_i(\lambda)$. That is, $\psi_i(\lambda, \mu) = \mu^{d_i} \tilde{\psi}_i(\lambda/\mu)$, where d_i denotes the degree of $\tilde{\psi}_i$. Since ψ_i is automatically not divisible by μ , it follows from setting $\theta = 0$ in Theorem 4.2 that there exists F such that $(I, A + BF, B)$ has nonconstant

homogeneous invariant polynomials ψ_1, \dots, ψ_q if and only if $\sum_{i=1}^p \deg \psi_i \equiv \sum_{i=1}^p n_i$, $p = 1, \dots, q$. By Proposition 4.2, $(I, A + BF, B)$ has nonconstant invariant polynomials $\tilde{\psi}_1, \dots, \tilde{\psi}_q$ if and only if it has nonconstant homogeneous invariant polynomials ψ_1, \dots, ψ_q . Since $\deg \tilde{\psi}_i = \deg \psi_i$, we conclude that there exists F such that $A + BF$ has nonconstant invariant polynomials $\tilde{\psi}_1, \dots, \tilde{\psi}_q$ if and only if $\sum_{i=1}^p \deg \tilde{\psi}_i \equiv \sum_{i=1}^p n_i$, $p = 1, \dots, q$.

Remark 4.6. The analogue of condition (i) in Theorem 4.2 is absent from Theorem 4.1 only because Theorem 4.1 is stated in terms of the invariant polynomials rather than the *homogeneous* invariant polynomials. If Theorem 4.1 were restated in terms of the homogeneous invariant polynomials, it would be necessary to include the requirement that they not be divisible by μ .

INVARIANT POLYNOMIAL CURVES OF PIECEWISE LINEAR MAPS*

B. CURTIS EAVES† AND URIEL G. ROTHBLUM‡

Abstract. Consider a system which evolves in n -space from x to $f(x)$ as time moves from t to $t+1$. Assuming f is piecewise linear our interest is in establishing conditions for existence of and an algorithm for computation of polynomials $y[\cdot]$ in time t with the property that $f(y[t]) = y[t+1]$, that is, the system moves from $y[t]$ to $y[t+1]$ in one unit of time.

Key words. piecewise linear functions, invariant curves, Markov decision chains, system evolution, ordered fields

AMS(MOS) subject classifications. primary 47H10, 47H09; secondary 90C47, 90C48

1. Introduction. Consider a system that evolves according to the piecewise linear function $f: R^n \rightarrow R^n$; that is, if the system is found in state x at time t , then it will be found in state $f(x)$ at time $t+1$. Our goal is to determine conditions under which there exists a vector polynomial $y[\cdot]$ in the variable t , such that

$$(1.1) \quad f(y[t]) = y[t+1] \quad \text{for all } t \geq 0.$$

Moreover, in the case where these conditions are satisfied we shall compute a vector polynomial $y[\cdot]$ satisfying (1.1). Evidently, if $y[\cdot]$ satisfies the system (1.1), then the set $\{y[t]: t \geq 0\}$ is mapped by f into itself. Accordingly we call the vector polynomial $y[\cdot]$ satisfying (1.1) an *invariant polynomial curve*.

The task of determining invariant polynomial curves arises in system theory, stochastic games, matrix theory, dynamic programming and branching Markov decision chains, e.g., Rothblum and Veinott [1987]. Note that if f has a *fixed point* y , i.e., $f(y) = y$, then $y[t] \equiv y$ is an invariant polynomial curve of f . As a trivial example we take the function $f: R^2 \rightarrow R^2$, defined by $f(x_1, x_2) = (x_1 + x_2, x_2)$. Then both $y[t] = (1, 0)$ and $y[t] = (t, 1)$, $t \geq 0$, are invariant polynomial curves of f , that is, they both satisfy the system (1.1).

Fixed points of *PL* maps have been studied extensively; see Eaves [1976], Eaves and Scarf [1976], Todd [1976], or Allgower and Georg [1980]. In the special case where the solution $y[\cdot]$ to (1.1) is linear, we refer to the set $\{y[t]: t \geq 0\}$ as an *invariant ray of f* . Kohlberg [1980] considered the invariant ray problem and showed that if f is nonexpansive, then f must have an invariant ray. Note that f is defined to be *nonexpansive* if for some norm $\|\cdot\|$ on R^n , we have $\|f(x) - f(y)\| \leq \|x - y\|$ for all x and y in R^n . Kohlberg's proof is based on the existence of a unique fixed point for contraction operators on R^n ; in particular, his analysis is not concerned with the computation of invariant rays. We extend Kohlberg's results in three directions. First we weaken the requirement that f is nonexpansive and conclude the existence of an invariant polynomial curve which is not necessarily a ray (the fact that our requirement is weaker than nonexpansiveness is demonstrated in Eaves and Rothblum [1986], [1987]). Second, our proofs are constructive—we obtain an explicit finite algorithm

for computing invariant polynomial curves. Third, our results hold for all ordered fields whereas Kohlberg's results are restricted to the reals; however, we hasten to add that by Tarski's principle, his results extend immediately to any real closed field.

Preliminaries about ordered fields are listed in § 2. In § 3 we formally introduce the notion of piecewise linear maps and obtain the main theorem about existence of fixed points for such maps. The main result asserts the existence of a fixed point for a piecewise linear map f whenever the determinants of the Jacobians of $f - I$ preserve sign for points that are sufficiently far away from the origin. In § 4 we discuss extensions of piecewise linear maps to larger fields. Next, in § 5 we show how an ordered field can be augmented by an infinitesimal to obtain a larger ordered field and in § 6 we show how fixed points for the perturbed extension of piecewise linear maps to that larger field can be used to obtain invariant polynomial curves of the original maps. Finally, in § 7 we discuss an algebraic representation of the fixed point of the perturbed extension of a piecewise linear map, and obtain a simple upper bound on the degree of invariant polynomial curves, when they exist. In particular, we show that under Kohlberg's assumption of nonexpansiveness (over the reals) invariant polynomial curves must be invariant rays.

The present paper has been extracted from the technical report by Eaves and Rothblum [1986]; indeed, many ideas developed in the present paper are carried further in the technical report, especially the relationships of the sufficient conditions for existence of invariant polynomial curves. The latter will appear in Eaves and Rothblum [1987]. Also, occasionally we refer to Eaves and Rothblum [1984] which is unfinished and not readily available; our intent in doing so is merely to indicate that we have given the matter at hand full attention.

2. Preliminaries. Our main framework, throughout, consists of ordered fields, such as the set of rationals Q and the set of reals R . We begin by defining ordered fields. Let G be a set having two distinctive elements called "zero" and "one," denoted 0 and 1, respectively, where two operations called "addition" and "multiplication," denoted $+$ and \cdot , respectively, are defined on G . Also, a relation called "greater than," denoted $>$, is defined on G . The tuple $(G, 0, 1, +, \cdot, >)$ is defined to be an *ordered field* if 0 is the addition identity, 1 is the multiplication identity, addition and multiplication are both associative and commutative, multiplication is distributive over addition, all elements in G have an additive inverse, all nonzero elements have a multiplicative inverse, and greater than is a total order that is preserved under addition and under multiplication by positive elements, the latter means that for x, y and z in G with $x > y$ we have that $x + z > y + z$ and if $z > 0$ then $xz > yz$. If $(G, 0, 1, +, \cdot, >)$ satisfies the above axioms except for the existence of a multiplicative inverse, the tuple is defined to be an *ordered ring*. For convenience we shall usually refer to the ordered ring or field $(G, 0, 1, +, \cdot, >)$ by G .

In an ordered ring or field G let $-x$, x^{-1} , $x - y$, xy , $x/y = xy^{-1}$, x^n , $|x|$, and $x \geq y$ have the usual meanings of *additive inverse*, *multiplicative inverse*, *subtraction*, *product*, *division*, *power*, *absolute value*, and *greater than or equal*, respectively. We refer to addition, multiplication, subtraction, division, and comparison as the *five field operations*. If $x > 0$ we say x is *positive*, etc. Given two ordered rings or fields G and F , the words *subordered ring or field*, *extension*, *isomorphism*, *imbedding*, and *identification* are employed in the usual way.

Let G be an ordered field. For nonnegative integers m and n , let $G^{m \times n}$ denote the set of all $m \times n$ matrices whose elements are in G . We shall use subscripts to denote the rows of a matrix, superscripts to denote its columns and both sub- and superscripts

to denote its elements, e.g., A_i, A^j and A_i^j . For $A, B \in G^{m \times n}$, we write $A \leq B$ or $A \ll B$ if $A_i^j \leq B_i^j$ or if $A_i^j < B_i^j$ for all $i = 1, \dots, m$ and $j = 1, \dots, n$, respectively. Also, we write $A < B$ if $A \leq B$ and $A \neq B$. The zero matrix and the (square) identity matrix will be denoted 0 and I , respectively (their order will be clear from the context). As usual, $G^{n \times 1}$ will be denoted G^n and its elements will be called *vectors*. The l_∞ -norm on G^n is defined by $\|z\|_\infty = \max \{|z_i|: i = 1, \dots, n\}$. As usual vectors a^1, \dots, a^k in G^n are called *linearly independent* if β_1, \dots, β_k in G and $\sum_{i=1}^k \beta_i a^i = 0$ imply the β_i 's are all zero.

A set $\sigma \subseteq G^n$ is called a *cell* if it has the representation $\sigma = \{x \in G^n: Ax \leq a\}$ for some matrix $A \in G^{m \times n}$ and $a \in G^m$ where m is some nonnegative integer. In this case we say that (m, A, a) is a *representation* of σ . In particular, if $m = 0$, we have that $\sigma = G^n$. Let $\sigma \subseteq G^n$ be a cell. The *tangential hull* of σ , denoted $\text{tng } \sigma$, is the set $\{\alpha(x - y): x, y \in \sigma, \alpha \in G\}$. The *dimension* of σ is the maximal number of linearly independent vectors in $\text{tng } \sigma$. The *affine hull* of σ , denoted $\text{aff } \sigma$, is the set $\{x + z: z \in \text{tng } \sigma\}$ for some, or equivalently every, $x \in \sigma$. The cell σ is called *affine* if $\sigma = \text{aff } \sigma$. We say that σ is *unbounded* if for every $K \in G$ there exists some $z \in \sigma$ with $\|z\|_\infty > K$. If (m, A, a) is a representation of σ , then σ is unbounded if and only if $\sigma \neq \phi$ and $\{x \in G^n: Ax \leq 0, x \neq 0\} \neq \phi$. A function $f: \sigma \rightarrow G^k$ is called *affine* if for some $B \in G^{k \times n}$ and $b \in G^k$, $f(x) = Bx + b$ for all x in σ .

The *determinant* of a square matrix A will be defined as the usual sum of signed products of the elements of A and is denoted $\det A$. In any ordered field the following conditions remain equivalent: $\det A \neq 0$, A has a multiplicative inverse and $Ax \neq 0$ for all $x \in G^n \setminus \{0\}$, and, in this case, A is called *nonsingular*.

We say that a statement depending on a parameter ε holds *for sufficiently small positive ε* if for some $\delta > 0$ the statement holds for all ε with $0 < \varepsilon < \delta$; also, we use the phrase *for sufficiently large t* in a similar way.

3. Piecewise linear maps and fixed points. In this section we formally introduce piecewise linear maps, and determine conditions under which such maps have fixed points. Moreover, we identify an algorithm that can be used to compute corresponding fixed points under those conditions.

Throughout let G be a given ordered field. A function $f: G^n \rightarrow G^k$ is called *piecewise linear*, abbreviated PL, if G^n can be expressed as a finite union of cells having dimension n where the restriction of f to each of these sets is affine. If Σ is such a set of cells and for $\sigma \in \Sigma$,

$$(3.1) \quad \sigma = \{x \in G^n: A_\sigma x \leq a_\sigma\}$$

and

$$(3.2) \quad f(x) = B_\sigma x + b_\sigma \quad \text{for all } x \in \sigma,$$

where $A_\sigma \in G^{m_\sigma \times n}$, $a_\sigma \in G^{m_\sigma}$, $B_\sigma \in G^{k \times n}$ and $b_\sigma \in G^k$, we say that $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$ is a *representation of f* . Evidently, a finite set of quintuples $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$ where for each $\sigma \in \Sigma$, m_σ is a nonnegative integer, $A_\sigma \in G^{m_\sigma \times n}$, $a_\sigma \in G^{m_\sigma}$, $B_\sigma \in G^{k \times n}$ and $b_\sigma \in G^k$ form a representation of a PL function if and only if

$$(3.3) \quad \dim \{x \in G^n: A_\sigma x \leq a_\sigma\} = n \quad \text{for all } \sigma \in \Sigma,$$

$$(3.4) \quad \bigcup_{\sigma \in \Sigma} \{x \in G^n: A_\sigma x \leq a_\sigma\} = G^n$$

and

$$(3.5) \quad (A_\sigma x \leq a_\sigma) \wedge (A_\tau x \leq a_\tau) \Rightarrow (B_\sigma x + b_\sigma = B_\tau x + b_\tau) \quad \text{for all } x \in G^n.$$

In this case we identify each $\sigma \in \Sigma$ with the n -dimensional cell $\{x \in G^n: A_\sigma x \leq a_\sigma\}$. Of course, representations of two distinct PL functions cannot coincide, i.e., a representation of a PL function uniquely defines that function. However, each PL function will have many representation. A PL function $f: G^n \rightarrow G^n$ will be called a *PL map on G^n* , or simply a *PL map*.

In the following theorem and corollary we cite conditions which insure that a PL map is onto or has a fixed point. The proof is constructive and identifies an algorithm that can be used to compute fixed points under the corresponding conditions.

THEOREM 3.1. *Let $g: G^n \rightarrow G^n$ be a PL map having a representation $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$. Suppose that the signs of $\det B_\sigma$ for every unbounded $\sigma \in \Sigma$ are either all positive or all negative. Then g is onto.*

Proof. A constructive proof of this result when $G = R$ is the central issue of Chein and Kuh [1976]. The construction is a special case of the more general PL homotopy method; see Appendix A. \square

COROLLARY 3.2. *Let $f: G^n \rightarrow G^n$ be a PL map having the representation $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$. Suppose that the signs of $\det (B_\sigma - I)$ for every unbounded cell $\sigma \in \Sigma$ are either all positive or are all negative. Then there exists a vector $x \in G^n$ satisfying $f(x) = x$.*

Proof. Apply the Theorem 3.1 to $f - I$. \square

In Eaves and Rothblum [1986], [1987] necessary and sufficient conditions are given for the determinant conditions in the above theorem and corollary.

4. Extending PL functions. In this section we show how representations of PL functions can be used to extend such functions to larger ordered fields. We first demonstrate that representations of cells can be used to extend them to larger ordered fields in a unique way while preserving some of the algebraic properties.

LEMMA 4.1. *Let $\sigma \subseteq G^n$ be a cell having the representation (m, A, a) and let F be an extension of G . Let $\bar{\sigma} = \{x \in F^n: Ax \leq a\}$. Then:*

- (a) $\bar{\sigma}$ is independent of the representation of σ used to define it;
- (b) The dimension of $\bar{\sigma}$ (as a cell in F^n) coincides with the dimension of σ (as a cell in G^n); and
- (c) $\bar{\sigma}$ is unbounded if and only if σ is unbounded.

Proof. We present arguments for (a) and (c) here to give the flavor of the development; however, further details are given in Eaves and Rothblum [1984].

First assume that (m', A', a') is an alternative presentation of σ . Now, $\{x \in F^n: Ax \leq a\} \neq \{x \in F^n: A'x \leq a'\}$ if and only if either for some $i = 1, \dots, m'$ the system

$$(4.1) \quad Ax \leq a, \quad A'_i x > a'_i$$

has a solution in F^n , or for some $i = 1, \dots, m$, the system

$$(4.2) \quad A_i x > a_i, \quad A'x \leq a'$$

has a solution in F^n . By Corollary B.2 of Appendix B, this happens if and only if either system has a solution in G^n , respectively, implying that (m, A, a) and (m', A', a') cannot be representations of the same cell. So, part (a) follows.

Next, to establish (c), recall that σ is unbounded if and only if the system

$$(4.3) \quad Ax \leq a, \quad Ay \leq 0, \quad y \neq 0$$

has a solution in G^n . Similarly, the cell $\bar{\sigma}$ is unbounded if and only if (4.3) has a solution in F^n . By Lemma B.2 of Appendix B, the system (4.3) has a solution in F^n if and only if it has a solution in G^n . So, (c) follows. \square

Given a cell $\sigma \subseteq G^n$ and an extension F of G , we shall use the notation $\bar{\sigma}_F$ for the cell in F^n constructed in Lemma 4.1.

We next show how a representation of a PL function $f: G^n \rightarrow G^k$ can be used to extend f to a function on F^n whose range is F^k where F is any extension of G . Moreover, we show that the extension is independent of the representation of f .

LEMMA 4.2. *Suppose $f: G^n \rightarrow G^k$ is a PL function having the representation $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$ and let F be an extension of G . Consider the coordinates of $A_\sigma, a_\sigma, B_\sigma$ and b_σ as elements in F . Then $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$ is a representation of a PL function on F^n which coincides with f on G^n . Moreover, the resulting PL function on F^n is independent of the representation of f .*

Proof. Here, we only sketch the arguments of the proof; however, further details are given in Eaves and Rothblum [1984]. First, recall that in order to show that the quintuples $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$ form a representation of a PL function mapping F^n into F^k we have to establish (3.3)–(3.5) with F^n replacing G^n . As $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$ is a representation of f we have that (3.3)–(3.5) hold without any modification. Now (3.3) and part (b) of Lemma 4.1 imply the modified version of (3.3). Also, (3.4) asserts that for every set of integers $J \equiv \{i_\sigma: \sigma \in \Sigma\}$ with $i_\sigma \in \{1, \dots, m_\sigma\}$ for each $\sigma \in \Sigma$, the system

$$\bigwedge_{i \in J} (A_\sigma)_i x > (a_\sigma)_i$$

has no solution in G^n . Hence, by Corollary B.2 of Appendix B neither system has a solution in F^n , establishing the modified version of (3.4). Next, the modified version of (3.5) follows from similar arguments by examining the systems

$$A_\sigma x \leq a_\sigma, \quad A_\tau x \leq a_\tau, \quad (B_\sigma)_i x + (b_\sigma)_i < (B_\tau)_i x + (b_\tau)_i$$

for $\sigma \in \Sigma, \tau \in \Sigma$ and $i \in \{1, \dots, k\}$. Finally, assume that $\{(m'_\sigma, A'_\sigma, a'_\sigma, B'_\sigma, b'_\sigma): \sigma \in \Sigma'\}$ is an alternative representation of f for which the corresponding extension of f to F^n does not coincide with the one obtained from $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$. Then for some $\sigma \in \Sigma, \sigma' \in \Sigma$ and $i \in \{1, \dots, k\}$ the system

$$A_\sigma x \leq a_\sigma, \quad A'_{\sigma'} x \leq a'_{\sigma'}, \quad (B_\sigma)_i x + (b_\sigma)_i \neq (B'_{\sigma'})_i x + (b'_{\sigma'})_i$$

has a solution in F^n . Then, by Corollary B.2, this system has a solution in G^n contradicting the assumption that we had two representations of the same PL map. \square

Given a PL function $f: G^n \rightarrow G^k$ and an extension F of G , we shall denote by \bar{f}_F the extension of f to F^n constructed from any one representation of f in the way described in Lemma 4.2. In particular, we identify the set of cells in the representation of f and \bar{f}_F . Of course, f might have many other extensions to F^n . For example if $f: G \rightarrow G$ is defined by $f(x) = 0$ for all $x \in G$ and $G(\omega)$ is the ordered field of rational functions with an infinitesimal over G (see § 5 for formal definitions), then the function $h: G(\omega) \rightarrow G(\omega)$ defined by

$$h(x) = \begin{cases} 0 & \text{if } x \leq \omega \text{ or } x \geq 3\omega, \\ x - \omega, & \text{if } \omega \leq x \leq 2\omega, \\ 3\omega - x & \text{if } 2\omega \leq x \leq 3\omega \end{cases}$$

is a PL function and $f(x) = h(x)$ for all $x \in G$. In this example $\bar{f}_{G(\omega)}$ is the function mapping each $x \in G(\omega)$ into 0.

5. Extending an ordered field with an infinitesimal. We turn our attention to two important extensions of a given ordered field G . Let $G\{\omega\}$ be the set of all infinite sequences $a = (\dots, a_{-1}, a_0, a_1, \dots)$ of elements of G such that $a_i = 0$ for sufficiently small i (possibly negative). For $a \in G\{\omega\}$ we shall use subscripts to denote the elements

of the corresponding sequence. We next define addition, multiplication and order on $G\{\omega\}$. Let $a = (\cdots, a_{-1}, a_0, a_1, \cdots)$ and $b = (\cdots, b_{-1}, b_0, b_1, \cdots)$ be elements in $G\{\omega\}$. We define $a + b$ and $a \cdot b$ to be, respectively, the sequence of elements in G with $(a + b)_i = a_i + b_i$ and $(a \cdot b)_i = \sum_{k=-\infty}^{\infty} a_k b_{i-k}$, for all integers i ; of course, the infinite sum $\sum_{k=-\infty}^{\infty} a_k b_{i-k}$ has only finitely many nonzero elements and is a finite sum. We note that under the above definitions $a + b \in G\{\omega\}$ and $a \cdot b \in G\{\omega\}$. The order in $G\{\omega\}$ is taken to be the lexicographic order, namely, $a > b$ if the first nonzero elements in the sequence $(\cdots, a_{-1} - b_{-1}, a_0 - b_0, a_1 - b_1, \cdots)$ is positive; of course, as $a \in G\{\omega\}$ and $b \in G\{\omega\}$ the above sequence has a first nonzero element whenever $a \neq b$. The following lemma asserts that $G\{\omega\}$ is an ordered field under the above definitions of addition, multiplication and order.

LEMMA 5.1. *The set $G\{\omega\}$ with the above definitions of addition, multiplication and order is an ordered field. In particular, the element $x \in G\{\omega\}$ with $x_i = 0$ for all i is the "zero" in $G\{\omega\}$, and the element $x \in G\{\omega\}$ with $x_0 = 1$ and $x_i = 0$ for all integers $i \neq 0$ is the "one" in $G\{\omega\}$. Also, if $a \in G\{\omega\}$, then $(-a)_i = -a_i$ for all integers i , and if $a \neq 0$ and $a_i = 0$ for $i \leq q$ and $a_q \neq 0$, then $(a^{-1})_i = 0$ for all $i < -q$, $(a^{-1})_{-q} = (a_q)^{-1}$ and $(a^{-1})_i$ can be determined inductively for $i > -q$ by $(a^{-1})_i = -(a_q)^{-1}(\sum_{j=-q}^{i-1} (a^{-1})_j a_{i+q-j})$. \square*

Notice that G is imbedded in $G\{\omega\}$ by the imbedding $\alpha \rightarrow x$ where $x_0 = \alpha$ and $x_i = 0$ for integers $i \neq 0$. Thus, we consider G to be a subset of $G\{\omega\}$. In particular, $0 \in G$ and $1 \in G$ are clearly the "zero" and "one" elements of $G\{\omega\}$. Also, we denote the element $x \in G\{\omega\}$ where $x_1 = 1$ and $x_i = 0$ for integers $i \neq 1$ by ω . In particular, for every integer k , $(\omega^k)_k = 1$ and $(\omega^k)_i = 0$ for integers $i \neq k$. Thus, when $x \in G\{\omega\}$ we write $x = \sum_{i=-\infty}^{\infty} x_i \omega^i$. We emphasize that this is a formal notation and does not represent convergence. Also, we write $x = \sum_{i=q}^{\infty} x_i \omega^i$ for any integer q for which $x_i = 0$ for all $i < q$.

For any positive $\alpha \in G$ we have that $\alpha > \omega$ (in $G\{\omega\}$). We therefore speak of ω as being an *infinitesimal* relative to G . In particular, for every positive integer n , $n^{-1} > \omega$; so n^{-1} does not "tend" to zero in $G\{\omega\}$ as the integer n becomes large. However, ω^n does "tend" to zero in $G\{\omega\}$ as n becomes large.

Call an element $a \in G\{\omega\}$ a *polynomial form over G* if $a_i = 0$ for all negative i and all sufficiently large i . In particular, in this case, $a = \sum_{i=0}^m a_i \omega^i$. The set of all polynomial forms over G will be denoted $G[\omega]$. Of course, $G[\omega]$ is a subordered ring of $G\{\omega\}$. Next, call an element in $G\{\omega\}$ a *rational form over G* if it has the representation ab^{-1} where $a, b \in G[\omega]$ and $b \neq 0$. The set of all rational forms over G will be denoted $G(\omega)$. The next lemma characterizes this set.

LEMMA 5.2. *The set $G(\omega)$ is a subordered field of $G\{\omega\}$. Moreover, it is the smallest subordered field of $G\{\omega\}$ that includes G and contains ω . \square*

Each of the five field operations—addition, multiplication, subtraction, division and comparison—in $G\{\omega\}$ is defined via a countable number of field operations in G . However, our principal interest will be in $G[\omega]$ and $G(\omega)$ where it is next shown that each of the five field operations can be executed through a finite number of field operations in G . This is accomplished by representing elements in $G(\omega)$ by pairs of polynomial forms over G . Specifically, represent $x \in G(\omega)$ by any pair (a, b) where $a, b \in G[\omega]$, $b \neq 0$ and $x = ab^{-1}$. Evidently, if $a, b, c, d \in G[\omega]$ where $b \neq 0$ and $d \neq 0$, then $ad + bc$, $ad - bc$, bd , ac , bc and ad are polynomial forms over G and

$$(5.1) \quad ab^{-1} + cd^{-1} = (ad + bc)(bd)^{-1},$$

$$(5.2) \quad (ab^{-1})(cd^{-1}) = (ac)(bd)^{-1},$$

$$(5.3) \quad ab^{-1} - cd^{-1} = (ad - bc)(bd)^{-1},$$

$$(5.4) \quad ab^{-1}/cd^{-1} = (ad)(bc)^{-1},$$

the latter only if $c \neq 0$, and

$$(5.5) \quad ab^{-1} > cd^{-1} \quad \text{if and only if} \quad (ad - bc)(bd) > 0.$$

Hence, if x and y in $G(\omega)$ have the representation (a, b) and (c, d) , respectively, where $a, b, c, d \in G[\omega]$, $b \neq 0$ and $d \neq 0$, then $x + y$, xy , $x - y$ and x/y have the representation $(ad + bc, bd)$, (ac, bd) , $(ad - bc, bd)$ and (ad, bc) , respectively, the latter only if $x \neq 0$ which occurs if and only if $c \neq 0$. Of course, addition, multiplication and subtraction of polynomial forms over G can be executed by a finite number of operations in G . Also, (5.5) shows that $x > y$ if and only if $(ad - bc)(bd) > 0$, the latter being checkable by a finite number of comparisons in G . A bound on the finite number of field operations in G needed to execute the various field operations in $G(\omega)$ is easily obtained; such a bound, of course, depends upon the representations in $G(\omega)$.

We have seen the virtue of representing an element $x \in G\{\omega\}$ by a pair (a, b) where $a, b \in G[\omega]$, $b \neq 0$ and $x = ab^{-1}$. In the following (see Corollary 6.3) we shall have an element $x \in G(\omega)$ and will have to use the elements of the sequence $(\dots, x_{-1}, x_0, x_1, \dots)$. We shall next see how each element in this sequence can be computed by a *finite number* of field operations in G from any representation of x by a pair of corresponding polynomials. See Winograd [1980] for corresponding efficient computational procedures.

LEMMA 5.3. Suppose $x = (\dots, x_{-1}, x_0, x_1, \dots) = ab^{-1}$ where $a = \sum_{i=0}^m a_i \omega^i \in G[\omega]$, $b = \sum_{i=0}^p b_i \omega^i \in G[\omega]$ and $b \neq 0$. Let $q = \min \{i \geq 0: b_i \neq 0\}$. Then

$$(5.6) \quad x_i = \begin{cases} 0 & \text{if } i < -q, \\ \sum_{j=-q}^i c_j a_{i-j} & \text{if } i \geq -q, \end{cases}$$

where the c_j 's are defined inductively by

$$(5.7) \quad c_i = \begin{cases} 0 & \text{if } i < -q, \\ (b_q)^{-1} & \text{if } i = -q, \\ -(b_q)^{-1} \left(\sum_{j=-q}^{i-1} c_j b_{i+q-j} \right) & \text{if } i > -q. \end{cases}$$

Proof. Let $c = b^{-1}$. Then (5.6) follows from the representation of the inverse of an element in $G\{\omega\}$ given in Lemma 5.1. So, (5.7) follows from the rules of multiplication in $G\{\omega\}$. \square

For a positive integer p , let $p! = p(p-1) \cdots 1$ and let $p! = 1$ if $p = 0$. Next for $t \in G$ and integer p we define the *binomial coefficient t choose p* , denoted $\binom{t}{p}$, by

$$(5.8) \quad \binom{t}{p} = \begin{cases} [t(t-1) \cdots (t-p+1)]/p! & \text{for } p = 1, 2, \dots \text{ and all } t \in G, \\ 1 & \text{for } p = 0 \text{ and all } t \in G, \\ 0 & \text{for } p = -1, -2, \dots \text{ and all } t \in G. \end{cases}$$

It is easy to verify the (standard) identity that

$$(5.9) \quad \binom{t}{p} + \binom{t}{p-1} = \binom{t+1}{p} \quad \text{for all integers } p \text{ and all } t \in G.$$

LEMMA 5.4. Suppose $a \in G\{\omega\}$ where $a = \sum_{j=-k}^0 a_j \omega^j$. If $a \leq 0$ then for sufficiently large $t \in G$, $\sum_{i=0}^k a_{-i} \binom{t}{i} \leq 0$.

Proof. The result is trivial if $a = 0$. In particular, this happens if $k < 0$. Next assume that $a \neq 0$ and $k \geq 0$. Let $q = \max \{i \leq k: a_{-i} \neq 0\}$. As $a \leq 0$, clearly $a_{-q} < 0$. Now, if $q = 0$, then $\sum_{i=0}^k a_{-i} \binom{t}{i} = a_0 < 0$ for all $t \in G$, establishing the desired assertion. Next assume that $q > 0$. Now, if $t > 2q - 1$ then for $j = 1, \dots, q$, $(t - j + 1)j^{-1} > 1$, implying that for $i = 1, \dots, q - 1$

$$0 < \binom{t}{i} (t - q) q^{-1} \leq \binom{t}{i} \prod_{j=i+1}^q [(t - j + 1)j^{-1}] = \binom{t}{q}.$$

Hence, if in addition $(t - q)|a_{-q}| > (\sum_{i=0}^{q-1} |a_{-i}|)q$, then

$$\begin{aligned} \sum_{i=0}^k a_{-i} \binom{t}{i} &= -|a_{-q}| \binom{t}{q} + \sum_{i=0}^{q-1} a_{-i} \binom{t}{i} \\ &\leq -|a_{-q}| \binom{t}{q} + \sum_{i=0}^{q-1} |a_{-i}| (t - q)^{-1} q \binom{t}{q} \leq 0, \end{aligned}$$

completing our proof. \square

Each coordinate of a matrix $A \in G\{\omega\}^{m \times n}$ has representation as a power series in ω with coefficients in G . Thus, A can be expressed as a corresponding power series in ω with coefficients in $G^{m \times n}$, e.g., $A = \sum_{i=-\infty}^{\infty} A(t)\omega^i$ where each $A(t)$ is in $G^{m \times n}$. Addition and multiplication generalize to matrices in the natural way. In particular, we have the “infinite distributivity” asserted in the following lemma. The verification of the result is straightforward and is omitted.

LEMMA 5.5. *Let $A \in G^{m \times n}$ and $B \in G\{\omega\}^{n \times p}$ where $B = \sum_{i=-\infty}^{\infty} B(t)\omega^i$. Then $AB = \sum_{i=-\infty}^{\infty} [AB(t)]\omega^i$. \square*

6. Existence of invariant polynomial curves. In this section we show how an invariant polynomial curve of a PL map f can be computed from a fixed point of a perturbation of $\bar{f}_{G(\omega)}$. For notational convenience we will use the notation \bar{f} for $\bar{f}_{G(\omega)}$. We consider extensions of PL functions to $G(\omega)$ rather than $G\{\omega\}$ because the field operations in $G(\omega)$ are executable by a finite number of field operations in G (see § 5).

We first use Corollary 3.2 to determine conditions that assure that for a given PL map f on G^n and β in $G(\omega)$, $\beta\bar{f}$ has a (computable) fixed point (in $G(\omega)^n$).

PROPOSITION 6.1. *Let $f: G^n \rightarrow G^n$ be a PL map having the representation $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$ and let $\beta \in G(\omega)$. Suppose that for every unbounded cell $\sigma \in \Sigma$, the signs of $\det(\beta B_\sigma - I)$ (as elements in $G(\omega)$) are either all positive or are all negative. Then there exists a vector $x \in G(\omega)^n$ satisfying*

$$(6.1) \quad \beta\bar{f}(x) = x.$$

Proof. Evidently, $\beta\bar{f}$ is a PL map on $G(\omega)^n$ having the representation $\{(m_\sigma, A_\sigma, a_\sigma, \beta B_\sigma, \beta b_\sigma): \sigma \in \Sigma\}$ (see the proof of Lemma 4.2). By Lemma 4.1 $\{x \in G^n: A_\sigma x \leq a_\sigma\} \subseteq G^n$ is unbounded if and only if $\{x \in G(\omega)^n: A_\sigma x \leq a_\sigma\} \subseteq G(\omega)^n$ is unbounded. It follows that $\beta\bar{f}$ with the above representation satisfies the assumptions of Theorem 3.1 and therefore the existence of $x \in G(\omega)^n$ satisfying (6.1) follows from Corollary 3.2. \square

We remind the reader that the proof of Corollary 3.2 was constructive. In particular, the algorithm described in Appendix A can be used to compute fixed points of the map $\beta\bar{f}$ examined in Proposition 6.1.

We next show how an invariant polynomial curve of a PL map f can be obtained from a solution of (6.1) with $\beta = (1 + \omega)^{-1}$. In Appendix C of Eaves and Rothblum [1986] it is shown how invariant polynomial curves of f can be computed from solutions of (6.1) for other values of β ; however, we consider here only the (restricted) case of

$\beta = (1 + \omega)^{-1}$ for two reasons. First, the expressions representing the corresponding polynomials are simpler, and second, as is shown in Appendix C of Eaves and Rothblum [1986] solutions of (6.1) for other corresponding values of β can be obtained by the methods discussed earlier in this paper if and only if this can be done for $\beta = (1 + \omega)^{-1}$. That is, the wider range of corresponding β 's does not increase the applicability of the methods of this paper for computing invariant polynomial curves.

Given a PL map f for which (6.1) has a solution over $G(\omega)^n$ for $\beta = (1 + \omega)^{-1}$, we shall determine a function $z: G \rightarrow G^n$ for which

$$(6.2) \quad f(z[t]) = z[t+1] \quad \text{for all } t \text{ sufficiently large.}$$

Of course, if z satisfies (6.2) with the corresponding equality holding for all $t \geq t^*$, then $y: \{t \in G: t \geq 0\} \rightarrow G^n$ defined by $y[t] = z[t + t^*]$ satisfies (1.1). So, if z is a polynomial in its variable t , then y is an invariant polynomial curve of f .

Recall the binomial coefficients defined by (5.8).

THEOREM 6.2. *Let $f: G^n \rightarrow G^n$ be a PL map and let $x \in G(\omega)^n$ satisfy $(1 + \omega)^{-1}\bar{f}(x) = x$. Suppose $x = \sum_{i=-q}^{\infty} x_i \omega^i$ where q is a nonnegative integer. Consider the function $z: \{t \in G: t \geq 0\} \rightarrow G^n$ defined by*

$$(6.3) \quad z[t] = \sum_{i=0}^q \binom{t}{i} x_{-i}.$$

Then for sufficiently large t

$$(6.4) \quad f(z[t]) = z[t+1].$$

Proof. Let $\sigma \in \Sigma$ be a cell containing x , i.e., $A_\sigma x \leq a_\sigma$. Lemma 5.5 implies that

$$\sum_{i=-q}^{\infty} (A_\sigma x_i) \omega^i = A_\sigma \left(\sum_{i=-q}^{\infty} x_i \omega^i \right) = A_\sigma x \leq a_\sigma,$$

immediately implying that $\sum_{i=-q}^0 (A_\sigma x_i) \omega^i \leq a_\sigma$. It now follows from Lemma 5.4 that for sufficiently large t , $\sum_{i=0}^q \binom{t}{i} A_\sigma x_{-i} \leq a_\sigma$, and therefore, by the associativity of matrix multiplication, for such t , $A_\sigma \left(\sum_{i=0}^q \binom{t}{i} x_{-i} \right) \leq a_\sigma$, i.e., $z[t] \in \sigma$.

We next observe that as $\bar{f}(x) = (1 + \omega)x$ and $x \in \sigma$, we have from Lemma 5.5 that

$$\begin{aligned} \sum_{i=-q}^{\infty} (B_\sigma x_i) \omega^i + b_\sigma &= B_\sigma \left(\sum_{i=-q}^{\infty} x_i \omega^i \right) + b_\sigma \\ &= B_\sigma x + b_\sigma = \bar{f}(x) = (1 + \omega)x = (1 + \omega) \left(\sum_{i=-q}^{\infty} x_i \omega^i \right) \\ &= \sum_{i=-q}^{\infty} x_i \omega^i + \sum_{i=-q}^{\infty} x_i \omega^{i+1}. \end{aligned}$$

By equating corresponding coefficients of the left-hand side and right-hand side of the above equation we conclude that

$$(6.5) \quad B_\sigma x_i = x_i + x_{i-1}, \quad i = -q, \dots, -1$$

and

$$(6.6) \quad B_\sigma x_0 + b_\sigma = x_0 + x_{-1}.$$

(By convention, $x_{-q-1} = 0$.) Now for t for which $z[t] \in \sigma$ we have, from elementary arguments (6.5) and (6.6), that

$$\begin{aligned} f(z[t]) &= B_\sigma x[t] + b_\sigma = B_\sigma \left[\sum_{i=0}^q \binom{t}{i} x_{-i} \right] + b_\sigma \\ &= \sum_{i=0}^q \binom{t}{i} B_\sigma x_{-i} + b_\sigma = \sum_{i=0}^q \binom{t}{i} (x_{-i} + x_{-i-1}) \\ &= \sum_{i=0}^q \binom{t}{i} x_{-i} + \sum_{i=1}^{q+1} \binom{t}{i-1} x_{-i} \\ &= \sum_{i=1}^q \left[\binom{t}{i} + \binom{t}{i-1} \right] x_{-i} + x_0 = \sum_{i=0}^q \binom{t+1}{i} x_i = z[t+1], \end{aligned}$$

proving that for sufficiently large t , $z[t]$ satisfies (6.4). \square

We next combine Proposition 6.1 and Theorem 6.2 to obtain a sufficient condition for a PL map to have an invariant polynomial curve.

COROLLARY 6.3. *Let $f: G^n \rightarrow G^n$ be a PL map having the representation $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$. Suppose that for every unbounded cell σ , the signs of $\det((1+\omega)^{-1}B_\sigma - I)$ are either all positive or are all negative. Then f has an invariant polynomial curve.* \square

We note that a PL map f need not have an invariant polynomial curve when no assumptions are imposed on f . For example, let $G = \mathbb{R}$ and $f: \mathbb{R} \rightarrow \mathbb{R}$ be defined by

$$f(x) = \begin{cases} 2x+1 & \text{if } x \geq 0, \\ -2x+1 & \text{if } x \leq 0, \end{cases}$$

and suppose that $z[\cdot]$ satisfies (6.4) for $t \geq t^*$. Let $\beta \equiv f(z(t^*))$. As $\beta > 0$ we conclude from (6.4) and the explicit definition of f that for $k = 1, 2, \dots$

$$z(t^* + k) = f^k(z(t^*)) = f^{k-1}(\beta) = \sum_{i=0}^{k-2} 2^i + 2^{k-1}\beta = 2^k(1+\beta) - 1,$$

immediately implying that $z[t]$ is not a polynomial in t . Of course, by arbitrarily selecting $z[t]$ for $0 \leq t \leq 1$, one can inductively construct $z[t]$ for all $t \geq 0$ so that (6.4) is satisfied (when G is not Archimedean the induction is transfinite).

We next demonstrate that for every positive integer k there exists a PL map having an invariant polynomial curve of degree k only. Let k be a positive integer. Set $G = \mathbb{R}$ and consider the function $f: \mathbb{R}^k \rightarrow \mathbb{R}^k$ defined by $f(x) = Bx + b$ where

$$B = \begin{pmatrix} 1 & 0 & 0 & \cdots & 0 & 0 \\ 1 & 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 1 & \cdots & 0 & 0 \\ & & & \ddots & & \\ 0 & 0 & 0 & \cdots & 1 & 0 \\ 0 & 0 & 0 & \cdots & 1 & 1 \end{pmatrix}, \quad b = \begin{pmatrix} 1 \\ 0 \\ 0 \\ \vdots \\ 0 \\ 0 \end{pmatrix}.$$

The results of Eaves and Rothblum [1986], [1987] show that this map satisfies the assumptions of Theorem 6.2. We will next construct an invariant polynomial curve of the above map. For $j = 1, \dots, k$, let e^j be the j th unit vector in \mathbb{R}^k and let $e^{k+1} \equiv 0$. Evidently, $(B - I)^k = 0$ and for $j = 1, \dots, k$, $(B - I)^{j-1}b = e^j$ and $Be^j = e^{j+1} + e^j$. Let

$z[t] \equiv \sum_{i=1}^k \binom{t}{i} e^i$. Then $z[t]$ is a vector polynomial in t of degree k and for $t \geq 0$ we have from the above and (5.9) that

$$\begin{aligned} Bz[t] &= \sum_{i=1}^k \binom{t}{i} B e^i = \sum_{i=1}^k \binom{t}{i} (e^{i+1} + e^i) = \sum_{i=1}^k \left[\binom{t}{i} + \binom{t}{i-1} \right] e^i \\ &= \sum_{i=1}^k \binom{t+1}{i} e^i = z[t+1], \end{aligned}$$

establishing (6.4). We next argue that if $z[\cdot]$ is any polynomial satisfying (6.4) for sufficiently large t , then the degree of $z[\cdot]$ is k . Now suppose that $z[\cdot]$ is such a polynomial and that (6.4) holds for $t \geq t^*$. Then, for $p = 1, 2, \dots$ we get from the binomial formula that

$$\begin{aligned} z[t^* + p] &= f^p(z[t^*]) = \sum_{i=0}^{p-1} B^i b + B^p z[t^*] \\ &= \sum_{i=0}^{p-1} \sum_{j=0}^i \binom{i}{j} (B - I)^j b + \sum_{j=0}^p \binom{p}{j} (B - I)^j z[t^*]. \end{aligned}$$

As $(B - I)^k = 0$ and $(B - I)^j b = e^{j+1}$ for $j = 1, \dots, k-1$ we get that

$$\begin{aligned} z[t^* + p] &= \sum_{i=0}^{p-1} \sum_{j=0}^{k-1} \binom{i}{j} e^{j+1} + \sum_{j=0}^{p-1} \binom{p}{j} (B - I)^j z[t^*] \\ &= \sum_{j=0}^{k-1} \left(\sum_{i=0}^{p-1} \binom{i}{j} \right) e^{j+1} + \sum_{j=0}^{p-1} \binom{p}{j} (B - I)^j z[t^*] \\ &= \sum_{j=0}^{k-1} \binom{p}{j+1} e^{j+1} + \sum_{j=0}^{p-1} \binom{p}{j} (B - I)^j z[t^*] \end{aligned}$$

is a polynomial in p of degree k (with leading coefficient $(k!)^{-1} e^k$). It immediately follows that $z[t^* + p]$ is a polynomial in p of degree k (with leading coefficient $(k!)^{-1} e^k$). Standard arguments show that the degree of the polynomial $z[t]$ (in the variable t) is k .

We include the following theorem for its curiosity value; indeed, we do not know what to make of it.

THEOREM 6.4. *Let $f: G^n \rightarrow G^n$ be a PL map and let $x \in G(\omega)^n$ satisfy $(1 - \omega)^{-1} \bar{f}(x) = x$. Suppose $x = \sum_{i=-q}^{\infty} x_i \omega^i$ where q is a nonnegative integer. Consider the function $z: \{t \in G: t \geq 0\} \rightarrow G^n$ defined by*

$$(6.7) \quad z[t] = \sum_{i=0}^q \binom{t}{i} x_{-i}.$$

Then for sufficiently large t

$$(6.8) \quad f(z[t]) = z[t-1].$$

Proof. The proof of this theorem follows from arguments similar to those used in the proof of Theorem 6.2. We review only the modifications. First let $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma)\}: \sigma \in \Sigma\}$ be a representation of f and let $\tau \in \Sigma$ satisfy $A_\tau x \leq a_\tau$. The arguments of the proof of Theorem 6.2 show that for sufficiently large t , $z[t] \in \tau$. Next, (6.5) and (6.6) have to be modified to

$$B_\tau x_i = x_i - x_{i-1}, \quad i = -q, \dots, -1$$

and

$$B_\tau x_0 + b_\tau = x_0 - x_{-1}.$$

So, for $t \in \sigma$ with $z[t] \in \tau$,

$$\begin{aligned} f(z[t]) &= b_\tau + B_\tau z[t] = b_\tau + B_\tau \left[\sum_{i=0}^q \binom{t}{i} x_{-i} \right] \\ &= x_0 - x_{-1} + \sum_{i=1}^q \binom{t}{i} (x_{-i} - x_{-i-1}) \\ &= x_0 + \sum_{i=1}^q \left[\binom{t}{i} - \binom{t}{i-1} \right] x_{-i} \\ &= x_0 + \sum_{i=1}^q \binom{t-1}{i} x_{-i} = z[t-1]. \end{aligned} \quad \square$$

Our final result in this section characterizes solvability of (6.1) with $\beta = (1 + \omega)^{-1}$ in terms of solvability of related systems over G .

THEOREM 6.5. *Let $f: G^n \rightarrow G^n$ be a PL map. Then there exists a vector $x \in G(\omega)^n$ satisfying*

$$(6.9) \quad (1 + \omega)^{-1} \bar{f}(x) = x$$

if and only if for sufficiently small positive ε the system

$$(6.10) \quad (1 + \varepsilon)^{-1} f(x) = x$$

has a solution in G^n .

Proof. The conclusion follows from Corollary B.2 and the arguments used in Kohlberg [1980, § 6] (see also Eaves and Rothblum [1985, § 5]). \square

The previous lemma was the major tool in the existence proof of fixed points of $(1 + \omega)^{-1} \bar{f}$ in Kohlberg [1980]. In that paper, Banach's contraction theorem was used to show that if f is nonexpansive, then $(1 + \varepsilon)^{-1} f$ has a fixed point for each $\varepsilon > 0$, and therefore so does $(1 + \omega)^{-1} \bar{f}$. We note, however, that the contraction arguments cannot be used in any other ordered field but the reals because of the lack of completeness.

7. Representations of invariant polynomial curves and bounds on their degrees. Our construction of an invariant polynomial curve of a PL map f given in Theorem 6.2 uses a fixed point $x \in G(\omega)^n$ of the PL map $(1 + \omega)^{-1} \bar{f}$. It follows directly from this construction that the degree of the corresponding invariant polynomial curve equals the integer q that is the largest integer i with $x_{-i} \neq 0$; moreover, the constructed invariant polynomial curve is determined by x_{-q}, \dots, x_0 . Now, suppose it is known that x lies in a specific cell $\sigma \in \Sigma$. Then $(1 + \omega)^{-1} (B_\sigma x + b_\sigma) = x$. As $\det [(1 + \omega)I - B_\sigma]$ is a polynomial in ω of degree n we have that it is nonzero. So, $(1 + \omega)I - B_\sigma$ is nonsingular and x has the representation

$$(7.1) \quad x = [(1 + \omega)I - B_\sigma]^{-1} b_\sigma.$$

It follows that representations of $[(1 + \omega)I - B_\sigma]^{-1}$ can be used to compute x .

Equation (7.1) suggests that representations of inverses of matrices of the form $\omega I - Q \in G(\omega)^{n \times n}$, where $Q \in G^{n \times n}$, can be useful. We will obtain such a representation after introducing some definitions and stating an auxiliary lemma.

Let $B \in G^{n \times n}$, $\lambda \in G$ and $Q = \lambda I - B$. The *index* of λ for B , denoted $\nu_\lambda(B)$, is the smallest integer $m \geq 0$ for which the null spaces of Q^m and Q^{m+1} coincide. In particular, we have that $\nu_\lambda(B) \leq n$. The following result is well known (see Rothblum [1981] where the case $G = R$ is considered).

LEMMA 7.1. Let $Q \in G^{n \times n}$, let ν be the index of zero for Q , and let M and N be, respectively, the range and null spaces of Q^ν . Then:

- (a) $G^n = M + N$,
- (b) there is a unique projection E on N along M ,
- (c) $Q^\nu E = 0$,
- (d) $Q^{\nu-1} E \neq 0$ if $\nu > 0$,
- (e) $(Q - E)$ is nonsingular,
- (f) $QD = I - E$ where $D \equiv (Q - E)^{-1}(I - E)$,
- (g) $QD^{j+1} = D^j$ for $j = 1, 2, \dots$ \square

For a given matrix $B \in G^{n \times n}$ and $\lambda \in G$, the matrices E and D defined in Lemma 7.1 for $Q \equiv B - \lambda I$ are called, respectively, the *eigenprojection* and *Drazin inverse* of B at λ . Methods to compute these matrices are well known (e.g., Rothblum [1976] or Campbell and Meyer [1979]).

We are now ready for the promised representation of inverses of matrices of the form $\omega I - Q \in G(\omega)^{n \times n}$ where $Q \in G(\omega)^{n \times n}$. The result resembles known expansions of resolvents of complex matrices (see Rothblum [1981, Thm. 3.1]).

THEOREM 7.2. Let $Q \in G^{n \times n}$ have eigenprojection E and Drazin inverse D and let ν be the index of zero for Q . Then $\omega I - Q$ is nonsingular and

$$(7.2) \quad (\omega I - Q)^{-1} = \sum_{j=1}^{\nu} Q^{j-1} E \omega^{-j} - \sum_{j=0}^{\infty} D^{j+1} \omega^j.$$

Proof. First observe that part (c) of Lemma 7.1 implies that

$$(7.3) \quad (\omega I - Q) \left(\sum_{j=1}^{\nu} Q^{j-1} E \omega^{-j} \right) = E - Q^\nu E = E,$$

and parts (f) and (g) of Lemma 7.1 imply that

$$(7.4) \quad (\omega I - Q) \left(\sum_{j=0}^{\infty} D^{j+1} \omega^j \right) = -QD + \sum_{j=1}^{\infty} (D^j - QD^{j+1}) \omega^j = -(I - E).$$

As noted earlier $\det(\omega I - Q)$ is a polynomial in ω of degree n and therefore $\det(\omega I - Q) \neq 0$. So, $\omega I - Q$ is nonsingular. Subtracting (7.4) from (7.3) and premultiplying the resulting equation by $(\omega I - Q)^{-1}$ yields (7.2). \square

Theorem 7.2 yields an immediate bound on the degree of invariant polynomial curves constructed by the methods of Theorem 6.2.

THEOREM 7.3. Let $f: G^n \rightarrow G^n$ be a PL map having the representation $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$. Let $x \in G(\omega)^n$ satisfy $(1 + \omega)^{-1} \tilde{f}(x) = x$ and suppose that $A_\tau x \leq a_\tau$, i.e., $x \in \tau$. Let $z[\cdot]$ be the polynomial obtained from x via the construction described in Theorem 6.2. Then the degree d of $z[\cdot]$ is bounded from above by $\nu_1(B_\tau)$; in particular, $d \leq \max \{\nu_1(B_\sigma): \sigma \in \Sigma\} \leq n$.

Proof. Theorem 6.2 shows that if $q \geq 0$ and $x_i = 0$ for all $i < -q$ then the degree of the constructed invariant polynomial curve is bounded by q . By (7.1) we have that $x = [\omega I - (B_\tau - I)]^{-1} b_\tau$ and therefore Theorem 6.2 ensures that $x_i = 0$ for all $i < -\nu_1(B_\tau)$, immediately implying our conclusions. \square

The example following the proof of Theorem 6.2 shows that the bound in Theorem 7.3 is tight and there exist PL maps mapping G^n into itself while satisfying the assumptions of Theorem 6.2 where the degree of any invariant polynomial curve is n .

A norm on R^n is a function $\|\cdot\|$, mapping each $x \in R^n$ into $\|x\| \in R$ such that $\|x\| = 0$ if and only if $x = 0$, $\|x + y\| \leq \|x\| + \|y\|$ and $\|\lambda x\| = |\lambda| \|x\|$ for all $x, y \in R^n$. For

example, the l_∞ -norm defined by $\|x\|_\infty = \max_i |x_i|$ for all $x \in R^n$ is a norm. A map $f: G^n \rightarrow G^n$ is called *nonexpansive* with respect to the norm $\|\cdot\|$ if

$$\|f(x) - f(y)\| \leq \|x - y\| \quad \text{for all } x, y \in G^n.$$

We conclude this section by demonstrating that the degree of invariant polynomial curves of nonexpansive PL maps over the reals are necessarily of degree one or less (see Kohlberg [1980]).

LEMMA 7.4. *Let $f: R^n \rightarrow R^n$ be a PL map that is nonexpansive with respect to some norm defined on R^n . Suppose $y[\cdot]$ is an invariant polynomial curve of f . Then the degree of $y[\cdot]$ is one or less.*

Proof. Suppose $y[t] = \sum_{j=0}^q y_j t^j$ for all $t \geq 0$ where $q > 1$ and $y_q \neq 0$ and we will establish a contradiction. For $t \geq 1$ we have that

$$\|y[t+1] - y[t]\| = \|f(y[t]) - f(y[t-1])\| \leq \|y[t] - y[t-1]\|.$$

A simple inductive argument shows that for each positive integer k ,

$$(7.5) \quad \|y(k) - y(k-1)\| \leq \|y(1) - y(0)\|.$$

But $y(k+1) - y(k)$ can be easily expressed as a polynomial in k of degree $q-1$ with leading coefficient qy_q , say $qy_q k^{q-1} + \sum_{j=0}^{q-2} \beta_j k^j$. As $\|qy_q k^{q-1} + \sum_{j=0}^{q-2} \beta_j k^j\| \geq q\|y_q\| k^{q-1} - \sum_{j=0}^{q-2} \|\beta_j\| k^j \rightarrow \infty$ as $k \rightarrow \infty$, we get a contradiction to (7.5). \square

Appendix A. The PL homotopy method. Let $g: G^n \rightarrow G^n$ be a PL map with representation $\{(m_\sigma, A_\sigma, a_\sigma, B_\sigma, b_\sigma): \sigma \in \Sigma\}$. Our purpose here is to briefly describe the PL homotopy method for solving $g(x) = y$ under the conditions of Theorem 3.1; we follow the formalism of Eaves [1976]. The general idea is captured in the homotopy principle (see Eaves [1972]).

Homotopy principle. To solve a given system of equations, the system is first deformed to one which is trivially solved. Beginning with the solution to the trivial problem a route of solutions is followed as the system is deformed, perhaps with retrogression, back to the given system. The route terminates with a solution to the given problem.

For our purposes herein we assume that the $\det B_\sigma$ for all unbounded σ of Σ have the same nonzero sign (see Chein and Kuh [1976]). First observe that $g(x)$ is bounded when x ranges over the finite union of bounded cells σ of Σ . Also, since $\det B_\sigma \neq 0$ for all unbounded σ in Σ , we have that $g(x) = B_\sigma x + b_\sigma$ is unbounded when x ranges over any given unbounded σ in Σ . Thus, for each unbounded σ in Σ there exists some $x^\sigma \in \sigma$ having the property that $g(x^\sigma) \neq g(x)$ for all x belonging to any bounded cell σ . Let $x^1 \in G^n$ be any vector having the property that $g(x^1) \neq g(x)$ for all x belonging to bounded cells σ in Σ .

We deform the target system $g(x) = y$ to the trivially solved system $g(x) = g(x^1)$. Specifically, define the PL homotopy $F: G^{n+1} \rightarrow G^n$ by $F(x, \theta) = g(x) + \theta(y - g(x^1))$ and consider the system

$$F(x, \theta) = y.$$

For $\theta = 1$ we have a system with solution x^1 and for $\theta = 0$ we have the target system.

In the full PL homotopy method the next step is to perturb y infinitesimally to avoid degeneracies, however, here we forego this technical matter and merely assume nondegeneracy (see Eaves [1976] for details).

A *path* is defined to be a *route* or *loop* which, in turn, is defined to be a finite union of closed line segments that is PL homeomorphic to the line G or to the PL

circle $\{x \in G^2: \|x\|_\infty = 1\}$, respectively. Assuming nondegeneracy, the set $F^{-1}(y) \equiv \{(x, \theta): F(x, \theta) = y\}$ is known to be a disjoint collection of routes and loops (see Eaves [1976] for details).

Beginning at the point $(x^1, 1)$ in $F^{-1}(y)$ we move along the path in $F^{-1}(y)$ that contains $(x^1, 1)$ in the direction that θ decreases. With such an orientation at the beginning it can be shown that the assumption concerning the determinants of the B_σ 's implies that θ will decrease on any unbounded cell $\sigma \in \Sigma$ (see Eaves [1976, § 12]). Consequently, θ cannot return to unit value on the selected path. To see this fact suppose that the first point (x, θ) along the path with $\theta = 1$ is the point $(w, 1)$. In particular, $g(w) = g(x^1)$ and therefore by choice of x^1 , w cannot belong to any bounded cell; hence, w must belong to some unbounded cell. We conclude that when moving along the selected path in the selected orientation, θ decreases as (x, θ) passes through $(w, 1)$. Since θ decreases as (x, θ) leaves the initial point $(x^1, 1)$, the mean value theorem for PL functions in ordered fields ensures that somewhere between $(x^1, 1)$ and $(w, 1)$ we pass through a point (x, θ) with $\theta = 1$. This conclusion contradicts the selection of $(w, 1)$. So, it follows that θ cannot return to unit value, and therefore the selected path must be a route. For $\sigma \in \Sigma$, let ρ_σ be the intersection of our route with the set $\{(x, \theta): x \in \sigma, \theta \in G\}$. It follows that if σ is bounded, ρ_σ is either empty or a line segment, and if σ is unbounded ρ_σ is either empty or is a line segment or half line. Since a route is PL homeomorphic to G we cannot just pass through finitely many line segments, but must reach a halfline. Since such a halfline corresponds to an unbounded cell σ we have that θ decreases on it indefinitely. It now follows from the mean value theorem for PL functions over ordered fields that we will encounter a point of the form $(x^0, \theta^0) = (x^0, 0)$. In particular, $F(x^0, 0) = y$, or equivalently, $g(x^0) = y$. So, x^0 is a solution to the target system.

The task of following the path in $F^{-1}(y)$ is essentially an oscillation between pivot steps as in the simplex method and movement from cell to adjacent cell in the covering Σ .

Appendix B. Linear inequalities over ordered fields. In this Appendix we review some useful facts about solvability of systems consisting of linear inequalities. Our discussion borrows from Kohlberg [1976].

The first result is a variant of Farkas' Lemma (e.g., Stoer and Witzgall [1970]).

LEMMA B.1. *A system*

$$Ax \leq a, \quad Bx \ll b, \quad Cx = c,$$

where $A \in G^{m \times n}$, $B \in G^{k \times n}$, $C \in G^{p \times n}$, $a \in G^m$, $b \in G^k$ and $c \in G^p$, has no solution $x \in G^n$ if and only if there exist vectors $\lambda \in G^{1 \times m}$, $\mu \in G^{1 \times k}$ and $\eta \in G^{1 \times p}$ such that

$$\lambda A + \mu B + \eta C = 0,$$

$$\lambda \geq 0, \quad \mu \geq 0,$$

$$\lambda a + \mu b + \eta c \leq 0,$$

$$(\mu, \lambda a + \mu b + \eta c) \neq 0.$$

□

The following corollary to Farkas' Lemma will be useful.

COROLLARY B.2. *Suppose a finite system of equalities, weak inequalities and strict inequalities with coefficients in the ordered field G does not have a solution in G . Then it also has no solution in any ordered field extension of G .*

Proof. The existence of Farkas' multipliers in G follows from our assumptions and Lemma B.1. Since these multipliers are also in F , Lemma B.1 implies that the system does not have solutions in F . □

Acknowledgment. The authors would like to express their appreciation to a referee for his careful reading and thoughtful suggestions.

THE EXPANDED LAGRANGIAN SYSTEM FOR CONSTRAINED OPTIMIZATION PROBLEMS*

A. B. POORE† AND Q. AL-HASSAN†

Abstract. Smooth penalty functions can be combined with numerical continuation and bifurcation techniques to produce a class of robust and potentially fast algorithms for constrained optimization problems. The key to the development of these algorithms is an expanded Lagrangian system which is derived and analyzed in this work. This parametrized system of nonlinear equations contains the penalty path as a solution, provides a smooth path into the first-order necessary conditions, and sometimes yields a method for finding multiple optima. Furthermore, the inevitable ill-conditioning present in a sequential optimization algorithm is removed for three and essentially only three smooth penalty functions: the quadratic penalty function for equality constraints, the logarithmic barrier function (an interior method), and the quadratic loss function (an exterior method) for inequality constraints. Preliminary test results for several nontrivial test problems are included to demonstrate the robustness, efficiency and potential of the methodology.

Key words. smooth penalty functions, logarithmic barrier, quadratic loss and quadratic penalty functions, expanded Lagrangian system, constrained optimization, nonlinear programming, numerical bifurcation and continuation techniques

AMS(MOS) subject classifications. 49, 65, 90

1. Introduction. The use of smooth penalty functions in a sequential optimization algorithm to solve constrained optimization problems has long been regarded as unfashionable and numerically defective, principally because of an inevitable ill-conditioning that occurs as the penalty parameter tends to the prescribed limit. This view, which is prevalent in most texts and review articles [6], [7], [9], [15], [16], is quite valid and has certainly motivated development of other numerical optimization techniques such as exact penalty functions and multiplier methods. Our objective herein is to re-examine the use of these smooth penalty functions, not in a sequential optimization algorithm, but in a continuation-based algorithm for following the penalty function path defined as a solution of a parametrized system of nonlinear equations. This methodology now becomes viable because of the extensive development of numerical continuation/bifurcation techniques during the last decade [2], [12], [13], [18] and because we can remove the ill-conditioning for three fundamentally important smooth penalty functions. These continuation methods are capable of producing robust and potentially fast algorithms, and some times provide a method for finding multiple optima.

Although the techniques discussed here apply to constrained optimization in general and to linear and nonlinear programming, calculus of variations, optimal control and parameter identification in particular, the main focus in this work is on the general nonlinear programming problem

$$(1.1) \quad \min \{f(x) | h(x) = 0, g(x) \geq 0\}$$

where $f: \mathbb{R}^n \rightarrow \mathbb{R}^1$, $h: \mathbb{R}^n \rightarrow \mathbb{R}^q$ and $g: \mathbb{R}^n \rightarrow \mathbb{R}^p$ are assumed to be twice continuously differentiable. The essence of the idea is as follows: We first convert the constrained

optimization problem to an unconstrained optimization problem $\min P(x, r)$ where r is the penalty parameter arranged so that the desired limit is $r=0$ and where the equality and inequality constraints are incorporated into the penalized objective function $P(x, r)$ through the use of smooth penalty functions. Then the penalty path(s) is described as the solution set of $\min P(x, r)$ as r varies and must, by the first-order necessary conditions, be a solution of $\nabla P=0$. (The gradient operator ∇ is with respect to x and ∇P denotes a column vector.) Then the gradient of the penalty function ∇P is formally identified with that of the Lagrangian $\nabla \mathcal{L}$ by defining the multipliers appropriately. Using the definition of these multipliers as additional equations, we obtain an expanded Lagrangian system (ELS) of nonlinear equations which, with an additional modification, becomes a perturbation of the Fritz John first-order necessary conditions. This modification prevents unbounded multipliers. Two different systems, one based on the quadratic penalty-logarithmic barrier function and the other on the quadratic penalty-quadratic loss function, are derived and analyzed in §§ 2 and 3.

Returning to the question of ill-conditioning, we shall show in § 4 that there are only three smooth penalty functions that yield well-conditioned expanded Lagrangian systems (ELS) and each is a method of order one in the sense of Lootsma [15]. The canonical examples of these three classes are the quadratic penalty function for equality constraints, logarithmic barrier function (an interior method) and the quadratic loss function (an exterior method) for inequality constraints. The remaining smooth penalty functions introduce artificial singularities and ill-conditioning into the ELS and thus are not used numerically.

The salient features of this class of algorithms can now be described. We first use an unconstrained optimization technique to get on the penalty path at a value of r , say r^0 , where the problem is reasonably well conditioned. Predictor-corrector continuation techniques [12], [13], [18] are then used to follow the penalty path as a solution of the expanded Lagrangian system to optimality at $r=0$. Section 5 contains a discussion of one such algorithm based on the quadratic penalty-logarithmic barrier function. Numerical test results are then presented to demonstrate the robustness, efficiency and potential of the methodology.

2. The mixed quadratic penalty-logarithmic barrier function. In this section we derive and analyze the expanded Lagrangian system (ELS) for the general nonlinear programming problem when the quadratic penalty function is used for the equality constraints and the logarithmic barrier function, for the inequality constraints. This mixed quadratic penalty-logarithmic barrier function leads to an expanded system which we modify to bound and normalize the multipliers. The resulting equations, which represent a perturbation of the Fritz John first-order necessary conditions, are summarized in Theorem 2.1. The existence and regularity of the penalty path is given in Theorem 2.2. Throughout this section we assume that f , g and h are at least \mathcal{C}^1 .

The mixed quadratic penalty-logarithmic barrier function is

$$(2.1) \quad P(x, r) = f(x) + \frac{1}{2r} h^T(x)h(x) - r \sum_{i=1}^p \ln(g_i(x)).$$

Assuming $\{x: g(x) > 0\}$ to be nonempty and robust [16], the first-order necessary condition for a minimum of P is that $\nabla P=0$, which is a parametrized system of nonlinear equations. However, this system suffers from the numerical problem that the Jacobian of ∇P , the Hessian of P , becomes increasingly ill-conditioned as $r \rightarrow 0^+$. (The l_2 condition $\kappa_2(\nabla^2 P) = \mathcal{O}(1/r)$ as $r \rightarrow 0^+$.) To remove the ill-conditioning, we expand the equations $\nabla P=0$ as follows: Assuming $g(x) > 0$ and $r > 0$, (x, r) solves

$\nabla P = \nabla f + \nabla h^T(h/r) - \sum_{i=1}^p \nabla g_i(r/g_i) = 0$ if and only if (x, λ, μ, r) solves the expanded system

$$\begin{aligned} \nabla f - \nabla h^T \lambda - \nabla g^T \mu &= 0, \\ h + r\lambda &= 0, \\ Mg - re &= 0, \end{aligned} \quad (2.2)$$

where $M = \text{diag}(\mu_1, \dots, \mu_p)$ and $e = (1, 1, \dots, 1)^T \in \mathbb{R}^p$. (The last two equations are derived from the definitions $\lambda = -h/r$ and $\mu_i = r/g_i(x)$.) This expanded system (2.2) is not new; it has been in the literature for some time and was used by Fiacco and McCormick [5] to investigate the behavior of the penalty path near $r=0$. The system (2.2) still has a numerical deficiency in that a multiplier may tend to infinity when either a constraint cannot be satisfied or a constraint qualification fails. Also the use of shifts in the barrier function can sometimes cause a multiplier μ_i to tend to infinity at a finite value of r . The modification that we now introduce trades this problem for limit point singularities for which the arclength or pseudo-arclength predictor-corrector continuation methods are particularly effective.

THEOREM 2.1. *Let $f: \mathbb{R}^n \rightarrow \mathbb{R}^1$, $h: \mathbb{R}^n \rightarrow \mathbb{R}^q$, and $g: \mathbb{R}^n \rightarrow \mathbb{R}^p$ be \mathcal{C}^1 functions, and let $\beta_0, r \in \mathbb{R}$ and $x \in \mathbb{R}^n$ be such that $\beta_0 > 0$, $r \neq 0$ and $g(x) > 0$, componentwise. The vector $(x; r)$ solves*

$$\nabla P = \nabla f + \nabla h^T \left(\frac{h}{r} \right) - \sum_{i=1}^p \nabla g_i \left(\frac{r}{g_i} \right) = 0 \quad (2.3)$$

if and only if there exist $\lambda \in \mathbb{R}^q$, $\mu \in \mathbb{R}^p$, $\mu_0 \in \mathbb{R}$ with $\mu_0 > 0$ such that the following equations hold:

$$F(x, \lambda, \mu, \mu_0; \bar{r}) = \begin{cases} \nabla \mathcal{L} = 0, \\ h + \bar{r}\lambda = 0, \\ Mg - \mu_0^2 \bar{r}e = 0, \\ \mu_0^2 + \|\mu\|_2^2 + \|\lambda\|_2^2 - \beta_0^2 = 0 \end{cases} \quad (2.4)$$

where $\mathcal{L} = \mu_0 f - h^T \lambda - g^T \mu$, $M = \text{diag}(\mu_1, \dots, \mu_p)$, $\mu = (\mu_1, \dots, \mu_p)^T$, $\lambda = (\lambda_1, \dots, \lambda_q)$, and $\bar{r} = r/\mu_0$.

Proof. Suppose (2.3) is valid. Multiply through $\nabla P = 0$ by $\mu_0 = \beta_0[1 + \sum(h_j/r)^2 + \sum(r/g_i)^2]^{-1/2}$ and define $\bar{r} = r/\mu_0$, $\lambda = -h/\bar{r}$, $\mu_i = (\mu_0^2 \bar{r})/g_i$, so that $(x, \lambda, \mu, \mu_0, \bar{r})$ now solves the expanded system (2.4). When $\mu_0 > 0$ and $(x, \lambda, \mu, \mu_0, \bar{r})$ solves (2.4), the reduction to (2.3) also follows directly from these definitions once the normalization has been dropped. \square

Note that if we drop the normalization and set $\mu_0 = 1$, we are back to the system (2.2). The use of the parameter β_0 allows for the efficient transfer from the solution of the minimization problem $\min P(x, r)$ to the system $F = 0$. For example, if x^0 is a solution of $\min P(x, r^0)$, we could define $\lambda^0 = -h(x^0)/r^0$, $\mu_i^0 = r^0/g_i(x^0)$, and $\beta_0 = [1 + \|\mu^0\|_2^2 + \|\lambda^0\|_2^2]^{1/2}$. Then $(x, \lambda, \mu, \mu_0; \bar{r}) = (x^0, \lambda^0, \mu^0, 1; r^0)$ is a solution of $F = 0$; and, assuming no singularities are encountered, we can follow the penalty path ($\min P(x, r)$) to $r = 0$ by following the solution of $F = 0$ to $\bar{r} = 0$. Given this formulation we now give necessary and sufficient conditions for the system (2.4) be regular at $\bar{r} = 0$.

THEOREM 2.2. *Let the system (2.4) be denoted by $F(z; \bar{r}) = 0$ with $z = (x, \lambda, \mu, \mu_0)$. Let $(z^0; 0)$ be a solution of $F = 0$ and assume f, h and g are twice continuously differentiable in a neighborhood of x^0 . Define two index sets \mathcal{A} and \mathcal{A} and a corresponding tangent*

space \bar{T} by

$$\begin{aligned}\bar{\mathcal{A}} &= \{i: 1 \leq i \leq p, g_i(x^0) = 0\}, & \mathcal{A} &= \{i \in \bar{\mathcal{A}}: \mu_i^0 \neq 0\}, \\ \bar{T} &= \{y \in \mathbb{R}^n: y^T \nabla h_j(x^0) = 0 (j = 1, \dots, q), y^T \nabla g_i(x^0) = 0 (i \in \bar{\mathcal{A}})\}.\end{aligned}$$

A necessary and sufficient condition that the Jacobian $D_z F(z^0; 0)$ be nonsingular is that each of the following three conditions hold:

- (a) $\bar{\mathcal{A}} = \mathcal{A}$;
- (b) $S := \{\{\nabla g_i(x^0)\}_{i \in \bar{\mathcal{A}}} \cup \{\nabla h_j(x^0)\}_{j=1}^q\}$ is a linearly independent collection of $q + |\bar{\mathcal{A}}|$ vectors, where $|\bar{\mathcal{A}}|$ denotes the cardinality of $\bar{\mathcal{A}}$;
- (c) The Hessian of the Lagrangian $\nabla^2 \mathcal{L}$ is nonsingular on the tangent space \bar{T} at z^0 .

If $D_z F(z^0; 0)$ is nonsingular, there exist open neighborhoods \mathcal{B}_1 of $\bar{r} = 0$ and \mathcal{B}_2 of $(z^0; 0)$ and a function $\phi \in \mathcal{C}^1(\mathcal{B}_1)$ such that $F(\phi(\bar{r}), \bar{r}) = 0$ for all $\bar{r} \in \mathcal{B}_1$ and $\phi(0) = z^0$. This solution is locally unique in the sense that if $(z; \bar{r}) \in \mathcal{B}_2$ and $F(z; \bar{r}) = 0$, then z belongs to the manifold defined by ϕ , i.e., $z = \phi(\bar{r})$. Furthermore, if f, g and h are \mathcal{C}^k (\mathcal{C}^∞ or real analytic) then ϕ is \mathcal{C}^{k-1} (\mathcal{C}^∞ or real analytic, respectively) on \mathcal{B}_1 .

Proof. The necessary and sufficient conditions for the nonsingularity of the Jacobian $D_z F(z^0; 0)$ have been established in the work of Poore and Tiaht [17] in the context of the parametric programming problem and will not be repeated here. The remaining part of the theorem follows from the implicit function theorem [3]. \square

Several remarks are in order: If x^0 is a Fritz John or Karush–Kuhn–Tucker point, condition (a) is called strict complementarity ($g_i(x^0) = 0$ implies μ_i^0 is nonzero) while condition (b) is the linear independence constraint qualification. Furthermore, if conditions (a) and (b) are satisfied and condition (c) is strengthened to the Hessian of the Lagrangian being positive definite on the tangent space \bar{T} , then we have a second-order sufficient condition for x^0 to be a local minimum provided $\mu^0 \geq 0$ and $g \geq 0$. Finally we note that the theorem is valid regardless of the type of extremal: local minimum, saddle point, local maximum, feasible or nonfeasible critical point.

3. The quadratic penalty-quadratic loss function. In this section we will use the quadratic loss function, an exterior method, to handle the inequality constraints. Since the virtues of exterior methods have been discussed previously [5], we forego an extensive comparison of interior and exterior methods. The essence of their advantage is that an initial strictly feasible point is not required and that when many inactive inequality constraints are present, the resulting problem size is much smaller than that for an interior method. The price to be paid for these advantages is a lack of higher-order differentiability; however, when the three conditions (a)–(c) of Theorem 2.2 hold, second-order differentiability is present along the solution path for r positive and sufficiently small, as will be shown in Theorem 3.2.

The quadratic penalty-quadratic loss function used in this section is

$$(3.1) \quad P(x, r) = f(x) + \frac{1}{2r} h^T(x) h(x) + \frac{1}{2r} (g^-(x))^T (g^-(x))$$

where $g^- = (g_1^-, \dots, g_p^-)^T$ and $g_i^-(x) = \min(g_i(x), 0)$. A difficulty with this penalty function is that the Hessian becomes discontinuous across an inequality constraint boundary $g_i = 0$. Although this discontinuity is a simple finite jump discontinuity, the jump in $\nabla^2 P$ tends to infinity as r tends to zero, and the additional and inevitable ill-conditioning is still present in $\nabla^2 P$. In the expanded Lagrangian system the jump discontinuity tends to zero as r tends to zero and the ill-conditioning is removed! In the presence of a second-order sufficient condition, Fiacco and McCormick [5] have

shown that there is no jump along the path for sufficiently small r . We extend this result in Theorem 3.2, but first we derive an appropriate expanded Lagrangian system.

THEOREM 3.1. *Let $f: \mathbb{R}^n \rightarrow \mathbb{R}^1$, $h: \mathbb{R}^n \rightarrow \mathbb{R}^q$, and $g: \mathbb{R}^n \rightarrow \mathbb{R}^p$ be \mathcal{C}^1 functions, and let $\beta_0, r \in \mathbb{R}$, $x \in \mathbb{R}^n$ be such that $\beta_0 > 0$ and $r \neq 0$. Then $(x; r)$ solves*

$$(3.2) \quad \nabla P = \nabla f + \nabla h^T \left(\frac{h}{r} \right) + \nabla g^T \left(\frac{g^-}{r} \right) = 0,$$

where g^- is defined following (3.1), if and only if there exist $\lambda \in \mathbb{R}^q$, $\mu \in \mathbb{R}^p$, $\mu_0 \in \mathbb{R}$ with $\mu_0 > 0$ such that the following equations hold:

$$(3.3) \quad G(x, \lambda, \mu, \mu_0; \bar{r}) := \begin{cases} \nabla \mathcal{L} = 0, \\ h + \bar{r}\lambda = 0, \\ g_i + \mu_i \bar{r} = 0 & (i \in V(x)), \\ \mu_i = 0 & (i \notin V(x)), \\ \mu_0^2 + \|\mu\|_2^2 + \|\lambda\|_2^2 - \beta_0^2 = 0 \end{cases}$$

where $\mathcal{L} = \mu_0 f - h^T \lambda - g^T \mu$, $\bar{r} = r/\mu_0$, and $V(x) = \{i: 1 \leq i \leq p, g_i(x) \leq 0\}$.

Except for the manipulation of g^- and its derivatives, which is explained in Luenberger [16], the proof is similar to that of Theorem 2.1. The corresponding trajectory analysis around $\bar{r} = 0$ is given next.

THEOREM 3.2. *Let the system (3.3) be denoted by $G(z, \bar{r}) = 0$ with $z = (x, \lambda, \mu, \mu_0)$, and assume f, h and g are twice continuously differentiable in a neighborhood of x^0 . Then $(z^0; 0)$ is a solution of (2.4) ($F = 0$) if and only if it is a solution of (3.3) ($G = 0$). Let $(z^0; 0)$ be a solution of either system and let x^0 denote the corresponding x component. Modify the equations $G = 0$ by fixing the index set $V(x)$ to be $V(x^0)$, and denote the resulting equations by $G^0(z; \bar{r}) = 0$. Then if $D_z F(z^0; 0)$ is nonsingular so is $D_z^0 G(z^0; 0)$ and thus the three conditions (a)–(c) in Theorem 2.2 guarantee the nonsingularity of $D_z G^0(z^0; 0)$.*

Let $(z^0; 0)$ be a solution of $G = 0$, suppose $D_z G^0(z^0; 0)$ is nonsingular. Then the system $G^0(z; \bar{r}) = 0$, has a solution $(z, \bar{r}) = (\phi(\bar{r}), \bar{r})$ with the following properties: There exist open neighborhoods, \mathcal{B}_1 of $\bar{r} = 0$ and \mathcal{B}_2 of $(z^0; 0)$ such that $\phi \in \mathcal{C}^1(\mathcal{B}_1)$, $G^0(\phi(\bar{r}), \bar{r}) = 0$ for all $\bar{r} \in \mathcal{B}_1$ and $\phi(0) = z^0$. This solution is locally unique in the sense that $(z; \bar{r}) \in \mathcal{B}_2$ and $G^0(z; \bar{r}) = 0$ implies $z = \phi(\bar{r})$. Furthermore, if f, g and h are in \mathcal{C}^k (\mathcal{C}^∞ or real analytic) then ϕ is \mathcal{C}^{k-1} (\mathcal{C}^∞ or real analytic).

The proof follows directly from the implicit function theorem [3] and our previous work [17] and is thus omitted. This theorem gives a smooth path through the given solution $(z^0; 0)$ only by fixing $V(x^0)$ and thus by modifying G . In practice we start with a positive \bar{r} so that (3.3) implies $\mu_i \geq 0$. If in addition conditions (a)–(c) of Theorem 2.2 are satisfied, then $\mu_i^0 > 0$ for $i \in V(x^0)$ and $\mu_i^0 = 0$ otherwise. Thus the eventual active inequality constraints approach from the exterior of the feasible region, which implies that the solution $(z; \bar{r}) = (\phi(\bar{r}), \bar{r})$ of $G = 0$ has the stated smoothness only for $\bar{r} \in (0, \infty) \cap \mathcal{B}_1$. In fact, the “solution” of $G = 0$ may not be continuous across $\bar{r} = 0$. On the other hand, we can still continue in the positive r direction in hopes of hitting a turning point and returning to $\bar{r} = 0$. In this sense this method still maintains a capability of determining multiple optima.

4. Other penalty functions. In this section we show that the three penalty methods described in the previous section are essentially the only smooth penalty methods that do not introduce artificial singularities and thus ill-conditioning into the penalty path for nonsingular nonlinear programming problems. Our classification of interior and

exterior methods for inequality constraints and of equality penalty methods is based on the work of Lootsma [15].

We shall use the customary term “barrier function” instead of “interior penalty function.” These functions generally have the following properties:

$$(4.1) \quad \begin{aligned} & \text{(i) } \phi: \mathbb{R}^+ \rightarrow \mathbb{R}, \lim_{u \rightarrow 0^+} \phi(u) = +\infty, \\ & \text{(ii) } \phi'(u) < 0 \quad \text{and} \quad \phi''(u) > 0 \quad \text{for } u > 0. \end{aligned}$$

For our purposes we need a refinement of these properties and use a classification given by Lootsma [15].

DEFINITION 4.1. A barrier function $\phi: \mathbb{R}^+ \rightarrow \mathbb{R}$ satisfying properties (i) and (ii) in (4.1) is said to be a barrier function of order α if ϕ' is real analytic on \mathbb{R}^+ and has a pole of order α at the origin.

The three most popular barrier functions are $\phi = -\ln u$ ($\alpha = 1$) due to Frisch (1955), $\phi = u^{-1}$ ($\alpha = 2$) due to Carroll (1961), and $\phi = u^{-2}$ ($\alpha = 3$) due to Kowalik (1966), Box (1969) and Fletcher and McCann (1969) [15]. The principal result is contained in Theorem 4.1.

THEOREM 4.1. Let ϕ be a barrier function of order α and let f , g and h be \mathcal{C}^2 functions. Then $\alpha \geq 1$ and if $\alpha > 1$, the expanded Lagrangian system is singular at the penalty parameter value $r = 0$.

Proof. We first note that $\alpha < 1$ implies that $\lim_{u \rightarrow 0^+} \phi(u) = +\infty$ is violated. Thus we restrict ourselves to the case $\alpha \geq 1$. We consider, without loss of generality, the nonlinear programming problem $\min \{f(x): g(x) \geq 0\}$, which has the penalized objective function

$$P(x, r) = f(x) + r^\alpha \sum_{i=1}^p \phi(g_i(x))$$

where the power of r is included so that the minimizer $x(r)$ will be smooth in r (Lootsma [15]). A minimizer $x(r)$ must satisfy

$$(4.2) \quad \nabla P = \nabla f + r^\alpha \sum_{i=1}^p \phi'(g_i) \nabla g_i = 0$$

for which the expanded system is

$$(4.3) \quad \nabla \mathcal{L} = 0, \quad MG + r^\alpha e = 0$$

where $M = \text{diag}(\mu_1, \dots, \mu_p)$, $G = (-1/\phi'(g_1), \dots, -1/\phi'(g_p))^T$ and $\mathcal{L} = f - g^T \mu$. Now since ϕ has a pole of order α at the origin, $\phi''(u)/[\phi'(u)]^2 = \mathcal{O}(u^{\alpha-1})$ as $u \rightarrow 0$. Thus $\alpha > 1$ implies $\phi''(u)/[\phi'(u)]^2 \rightarrow 0$ as $u \rightarrow 0^+$. To complete the proof for $\alpha > 1$, it suffices to consider the case $g_i(x) \rightarrow 0$ as $r \rightarrow 0$ either smoothly or as a sequence. Now the $(n+1)$ th row of the Jacobian of the expanded system (4.3) has as the only potential nonzero entries $1/\phi'(g_i)$ and $(-\mu_i \phi''(g_i)/[\phi'(g_i)]^2)(\nabla g_i)^T$, both of which tend to zero as $g_i \rightarrow 0^+$. Thus, the $(n+i)$ th row of the Jacobian approaches zero at $r \rightarrow 0^+$. (Notice that we could have arrived at this same conclusion by extending the definition of $\phi''/[\phi']^2$ to $u = 0$ by continuity.) \square

In case $\alpha = 1$, the quotient $\phi''(u)/[\phi'(u)]^2$ tends to a finite nonzero limit as $u \rightarrow 0^+$ and we can establish the nonsingularity of the expanded Lagrangian system just as in Theorem 2.2. Of course, the canonical example from the class of barrier functions of order one is the logarithmic barrier function which was examined in § 2.

The next class of penalty methods to be considered is the class of exterior penalty functions which we call loss functions [5]. We generally require that a loss function satisfy the properties

$$(4.4) \quad \begin{aligned} & \text{(iii)} \quad \psi(u) = 0 \text{ for } u \geq 0, \psi(u) > 0 \text{ for } u < 0, \\ & \text{(iv)} \quad \psi'(u) < 0 \text{ and } \psi''(u) > 0 \text{ for } u < 0, \\ & \text{(v)} \quad \psi \text{ is continuous across } u = 0. \end{aligned}$$

Following Lootsma [15], we further restrict this class of exterior methods as follows.

DEFINITION 4.2. A loss function ψ satisfying (4.4) is said to be of order $\gamma > 0$ provided $\psi'(u)$ is a real analytic for $u < 0$ with a zero of order γ at $u = 0$, i.e., $\psi'(u) = \mathcal{O}((-u)^\gamma)$ as $u \rightarrow 0^-$.

Given this definition we can state the principal results for exterior methods.

THEOREM 4.2. Let f, g, h be \mathcal{C}^2 functions and suppose $\psi(u)$ is a loss function of order γ . If either $\gamma < 1$ or $\gamma > 1$, the corresponding expanded Lagrangian system is singular at $r = 0$.

Proof. It suffices again to consider the problem $\min \{f(x): g(x) \geq 0\}$ with the corresponding penalized objective function

$$P(x, r) = f(x) + r^{-\gamma} \sum_{i=1}^p \psi(g_i(x))$$

where ψ is a loss function of order γ and the power γ of r is included to ensure a smooth dependence of x on r [15]. Then a minimizer of P satisfies

$$\nabla P = \nabla f + r^{-\gamma} (\nabla g^T)(\psi'(g_1), \dots, \psi'(g_p))^T = 0,$$

which has the expanded Lagrangian system

$$(4.5) \quad \begin{aligned} & \nabla \mathcal{L} = 0, \\ & (\psi'(g_1), \dots, \psi'(g_p))^T - r^\gamma \mu = 0 \end{aligned}$$

where the Lagrangian $\mathcal{L} = f - g^T \mu$. If $\gamma < 1$, then $\psi'(u)$ becomes unbounded as $u \rightarrow 0^-$. Thus (4.5) is singular in that $\psi'(u)$ becomes unbounded as $u \rightarrow 0^-$. If $\gamma > 1$, then $g_i \rightarrow 0$ as $r \rightarrow 0^+$ implies that the $(n+i)$ th row of the Jacobian tends to zero so that the system (4.5) becomes singular. \square

For the case $\gamma = 1$, we can again prove a result similar to that obtained in § 3 for the canonical quadratic loss function. Finally we come to the penalty functions for equality constraints. In analogy with our two previous definitions we define penalty functions for equality constraints in the following definition.

DEFINITION 4.3. Let $\theta: \mathbb{R} \rightarrow \mathbb{R}^+ \cup \{0\}$. We say that θ is a penalty function of order β , provided $\theta'' > 0$, $\theta' < 0$ for $u < 0$ and $\theta' > 0$ for $u > 0$, θ is analytic on $\mathbb{R} - \{0\}$ and θ' has a zero of order β at $u = 0$, i.e., $\theta = \mathcal{O}(|u|^\beta)$ as $u \rightarrow 0$.

For this class of penalty methods, the corresponding result is contained in Theorem 4.3.

THEOREM 4.3. Let θ be a penalty function for equality constraints of order β . Then the use of θ to incorporate equality constraints into the penalized objective function yields a corresponding singular expanded Lagrangian system if $\beta < 1$ or $\beta > 1$.

We omit the proof of this theorem since it closely parallels the previous proof. If $\beta = 1$, we can prove a theorem corresponding to those in the previous two sections. The canonical order-one method is the quadratic penalty function $\theta(u) = u^2$.

In conclusion, any of the order-one methods lead to well-conditioned expanded Lagrangian systems, and the canonical examples of these order-one penalty functions are the quadratic penalty function for equality constraints, the logarithmic barrier function, an interior method, and the quadratic-loss function, an exterior method, for inequality constraints.

5. An algorithm and numerical examples. The alternatives for dealing with the constraints in the general nonlinear programming problem (1.1) can be summarized as follows:

Equality constraints	Inequality constraints
(a) Quadratic penalty	(c) Logarithmic barrier
(b) Not penalized	(d) Quadratic loss

where the “Not penalized” means that the equality constraints are handled directly and are not incorporated into the penalized objective function. This appears to be particularly advantageous for dealing with linear (affine) constraints. In this section we present the salient features of a class of algorithms based on the use of the combination (a)–(c) and the corresponding expanded Lagrangian system (2.3). We conclude this section with the preliminary results of our testing on some nontrivial test problems [10] to demonstrate the robustness, efficiency, and potential for the methodology.

Although the algorithms have many variants, we separate the different phases as follows: In the first phase we perform an initialization to produce an initial point \hat{x} satisfying $g(\hat{x}) > 0$. An alternative is to introduce a shift into the log function by choosing a δ so that at an initial point \hat{x} the inequality $g(\hat{x}) + \delta > 0$ is satisfied. Then we use the shifted penalty function $P(x, r) = f(x) + h^T(x)h(x)/(2r) - r\sum \ln(g_i(x) + r\delta_i/r^0)$ which is well defined at $r = r^0$ and $x = \hat{x}$. If the point \hat{x} is not close to the feasible region, the path can be long and the resulting algorithm degrades in time and the number of iterations. Although we have not experienced it numerically, an additional difficulty is that the introduction of the shift can introduce limit point singularities into the solution path of the normalized expanded Lagrangian system (5.1). In the numerical examples to follow we start with the given initial value of x , [10], minimize the loss function $g^-(x)^T g^-(x)$ to produce a point at least close to the feasible region, and then introduce the shift to complete the initialization.

In the second phase we use an unconstrained minimization technique such as quasi-Newton with a BFGS update or a preconditioned conjugate gradient method to minimize the penalty function P at a value of r , say r^0 , at which the problem is reasonably well conditioned. In the examples to follow we have used a quasi-Newton method with a quadratic-cubic line search and an Armijo stopping criterion [4], modified to maintain feasibility ($g(x) + \delta > 0$). Since a highly accurate answer of $\min P(x, r^0)$ may have only a digit or two in common with the final answer, we have found it to be more efficient to compute the answer to within a moderate to low accuracy and then add a homotopy to the equation $\nabla \mathcal{L} = 0$ to account for a moderate value of ∇P . Thus given an approximate answer x^0 to $\min P(x, r^0)$ we convert to the expanded system

$$\begin{aligned}
 (5.1) \quad & \nabla \mathcal{L} - (\mu_0^2 \bar{r}/r^0) \nabla P(x^0, r^0) = 0, \\
 & h + \bar{r}\lambda = 0, \\
 & M(g + \mu_0 \bar{r}\delta/r^0) - \bar{r}\mu_0^2 e = 0, \\
 & \mu_0^2 + \|\mu\|_2^2 + \|\lambda\|_2^2 - \beta_0^2 = 0
 \end{aligned}$$

where $\mathcal{L} = \mu_0 f - h^T \lambda - g^T \mu$, $M = \text{diag}(\mu)$, $\mu = (\mu_1, \dots, \mu_p)^T$, $\bar{r} = r/\mu_0$. At $x = x^0$ and $r = r^0$ we have a solution of (5.1) given by $(x, \lambda, \mu, \mu_0, \bar{r}) = (x^0, \lambda^0, \mu^0, 1, r^0)$, where $\lambda^0 = -h(x^0)/r^0$, $\mu_i^0 = r^0/g_i(x^0)$, and where β_0 is defined and fixed by $\beta_0 = (1 + \|\lambda^0\|_2^2 + \|\mu^0\|_2^2)^{1/2}$. Notice that Theorem 2.2 remains valid for this system even though it is a perturbation of the one discussed in § 2. Continuation is performed on system (5.1) in the scaled penalty parameter \bar{r} with β_0 fixed.

In the path following phase we use a predictor-corrector continuation technique, which is closely patterned after the work of Keller [12], to follow the solution of the parameterized system of (5.1) to optimality at $\bar{r} = 0$. However, we use higher-order Adams-Bashforth predictors [1], [18] to increase the efficiency. In this methodology we start with an Euler method (an Adams-Bashforth one-step method), and then increase the order of the method as more steps are taken. The error-stepsize control is based on the use of consecutive order methods wherein the higher order method is used to estimate the error in the lower order method [1]. The stepsize is then adjusted to achieve the desired error in the predictor. Typically, two to three steps are needed to get to $r = 0$ where we complete the convergence with Newton's method. Thus the method is locally quadratically convergent.

To get some estimation of the relative performance of this algorithm, we have solved several test problems from the book by W. Hock and K. Schittkowski [10] and give a comparative summary of the number of function evaluations in the table below. The function evaluation for the codes other than PENCON are taken from [10]. To be consistent with those function evaluation counts, we count the evaluation of a p -dimensional vector as p function evaluations; however, we do not count upper and lower bounds on variables, since they are handled directly in the code and gradient evaluations of linear constraints are counted only once. The approximation of the Hessian of the Lagrangian in the continuation phase is based on finite differences [4]. Several values of r^0 ranging from 1.0 to 0.0001 have been tested and indeed the initial minimization is sensitive to this choice. In the test results in Table 1 we have used the value $r^0 = 0.1$; however, in some cases we found the number of function evaluations to be less for smaller values of r^0 .

TABLE 1

Code	Author	Method
VFO2AD	Powell	Quadratic approximation
OPRQP	Bartholomew-Biggs	Quadratic approximation
GRGA	Abadie	Generalized reduced gradient
VFO1A	Fletcher	Multiplier
FUNMIN	Kraft	Multiplier
FMIN	Kraft, Lootsma	Penalty
PENCON	Al-Hassan, Poore	Penalty-continuation

Comparison in Table 2 illustrates that this penalty-continuation algorithm as coded in PENCON [1] currently comes in second or third and occasionally first and fourth; however, the methodology is quite robust, primarily because of the robustness of penalty paths leading to optimality and the robustness of the continuation methodology. Thus this algorithm offers an alternative to sequential quadratic programming illustrated by the codes of Powell and Bartholomew-Biggs above. Furthermore, these test results are even more promising because of what we have not done in the implementation of the algorithm. Between 50 percent and 90 percent of the function evaluations occur

in the first and second phases wherein we perform the unconstrained optimization. However, the efficiency could be considerably improved through the use of scaling of the constraints, weights and special line searches for the log barrier function [8]. In the continuation phase, efficiency could be improved through the use of updating procedures after a prediction along the path and during the correction back to the path. Finally, our answers are computed to approximately twelve digits of accuracy on a 14+ digit CDC machine, whereas the remaining answers listed above are computed on a 10 digit machine [10]. It is also interesting to note the value of the objective function in problem numbers 64 and 65 are off by two orders of magnitude and 300 percent, respectively, for Powell's VFO2AD, whereas the values in our tests agree to at least ten digits.

6. Summary and conclusions. One of the objectives in this work has been to re-examine the use of smooth penalty functions as an effective computational technique in light of recent developments in numerical continuation techniques. The expanded Lagrangian system, which has been a focal point of this work, is the key link between these methods as well as the key to the removal of the ill-conditioning traditionally associated with smooth penalty methods. This parametrized system of nonlinear equations is well conditioned only for three smooth penalty methods as explained in § 4. The canonical examples are the quadratic penalty function for equality constraints, logarithmic barrier function, an interior method, and the quadratic loss function, an exterior method, for inequality constraints. An additional technique is to leave linear (affine) equality constraints out of the penalized objective function and treat them directly. In linear programming this technique leads to a class of algorithms which are qualitatively similar to the interior point methods [8], [11]. Finally, this methodology generalizes in a natural way to optimal control, calculus of variations, and parameter identification.

The robustness and efficiency of this class of algorithms based on these smooth penalty functions, corresponding expanded Lagrangian system, and predictor-corrector

continuation techniques have been illustrated in § 5. The methodology shows considerable promise and potential for solving constrained optimization problems; however, as with any method, a word of caution is appropriate. We can construct simple examples illustrating the following situations for penalty paths: given $\varepsilon > 0$ a penalty path may exist only for the penalty parameter $\bar{r} \geq \varepsilon$ or only for $\bar{r} \leq \varepsilon$, may not exist at all, may diverge, or may exist for $\bar{r} > 0$ but the limit point at $\bar{r} = 0$ is not a local minimum of the original problem. (When this last situation occurs, the expanded Lagrangian system is singular.) Despite these examples, penalty path following is a mathematically robust method of solving constrained optimization problems as is illustrated by the examples in Hock and Schittkowski [10], and we hope that these penalty-continuation algorithms based on the expanded Lagrangian system make the methodology numerically robust and efficient.

NUMERICAL APPROXIMATION FOR THE INFINITE-DIMENSIONAL DISCRETE-TIME OPTIMAL LINEAR-QUADRATIC REGULATOR PROBLEM*

J. S. GIBSON† AND I. G. ROSEN‡

Abstract. An abstract approximation framework is developed for the finite and infinite horizon discrete-time linear-quadratic regulator problems for systems whose state dynamics are described by a linear semigroup of operators on an infinite-dimensional Hilbert space. The schemes included in the framework yield finite-dimensional approximations to the linear state feedback gains which determine the optimal control law. Convergence arguments are given. Examples involving hereditary and parabolic systems and the vibration of a flexible beam are considered. Spline-based finite element schemes for these classes of problems, together with numerical results, are presented and discussed.

Key words. linear-quadratic regulator, discrete-time, distributed parameter system

1. Introduction. Recent advances in microprocessor technology have led to increased interest in digital, or discrete-time, control systems. In addition, because many current application areas involve complex systems which are most appropriately modeled using functional and/or partial differential equations, it has become important to study digital control techniques in the context of infinite-dimensional or distributed systems.

A great deal of attention has been given to the continuous-time infinite-dimensional linear-quadratic regulator problem. The general theory and characterization of the linear state feedback form of the optimal control are discussed in [5], [6], [9], [10], [23] and [24], while its application to hereditary, parabolic and hyperbolic systems with emphasis on approximation is treated in [2], [3], [8], [11], [13], [15], [16] and [19], to mention just some of the work that has been done.

On the other hand, relatively little can be found in the literature concerning the corresponding discrete-time problem. The major contributions in this area can be found in the papers by Lee, Chow and Barr [22] and Zabczyk [30]. In these studies the Riccati difference equations that characterize the linear feedback form of the optimal control for the finite-time problem are given and limiting properties as the length of the time horizon tends to infinity are discussed. However, the issue of approximation is not considered.

In the present paper, we develop numerical approximation schemes that yield finite-dimensional approximations to the feedback gain operators which determine the discrete-time optimal control law. We consider control systems whose dynamics can be described in terms of a linear semigroup of operators on an infinite-dimensional Hilbert space. The basis of our approach is the construction of a sequence of finite-dimensional (presumably finite-element based) state approximations which in turn

leads to a sequence of finite-dimensional discrete-time linear-quadratic regulator problems each of which can be solved using standard techniques.

Under appropriate assumptions on the nature of the original problem and the convergence of the state approximation, we are able to prove that the approximating optimal controls and feedback gains converge to the true optimal control sequences and feedback laws for the original infinite-dimensional system. Depending upon the convergence properties of the state approximation, we are able to establish strong or uniform norm convergence of the approximating gain operators and the corresponding weak or strong convergence of the approximating feedback kernels which are used in the implementation of the optimal control. We treat both the finite and infinite horizon problems.

We have tested our schemes on a wide variety of examples. This paper includes numerical results for problems with state dynamics given by hereditary and parabolic (heat/diffusion) differential equations and a hybrid system of partial and ordinary differential equations for the vibration of an Euler-Bernoulli beam connected to a rigid rotating hub and a lumped mass at the tip. We implemented and tested the methods on an IBM Personal Computer.

We provide a brief outline of the remainder of the paper. In § 2 we briefly outline previous results concerning the characterization of the optimal control and feedback gains for both the finite and infinite horizon discrete-time regulator problems for distributed systems. The Riccati difference and algebraic equations whose solutions determine the optimal feedback control law are discussed. In § 3 we develop the abstract approximation framework and convergence arguments. Section 4 contains a discussion of particular schemes for the classes of problems mentioned above together with the results of our numerical studies. Some concluding remarks are given in § 5.

2. The optimal control problem.

2.1. Optimal control on a finite interval. Let Z and U be Hilbert spaces with inner products $\langle \cdot, \cdot \rangle_Z$ and $\langle \cdot, \cdot \rangle_U$, respectively, with U finite dimensional. For $\{H, \langle \cdot, \cdot \rangle_H\}$ a Hilbert space, let $l^2(t_0, t_f; H)$ denote the usual Hilbert space of sequences $x = \{x(t)\}_{t=t_0}^{t_f} = \{x(t_0), x(t_0+1), \dots, x(t_f)\}$ with t, t_0 and t_f integers and $x(t) \in H$ together with the inner product

$$(2.1) \quad \langle x, y \rangle_{l^2} = \sum_{t=t_0}^{t_f} \langle x(t), y(t) \rangle_H.$$

The discrete-time linear-quadratic regulator problem on the finite time interval $[t_0, t_f]$ is:

(P1) Choose $u \in l^2(t_0, t_f; U)$ to minimize the quadratic performance index

$$(2.2) \quad \begin{aligned} J(G; t_0, t_f, z(t_0), u) \\ = \sum_{t=t_0}^{t_f-1} [\langle Qz(t), z(t) \rangle_Z + \langle Ru(t), u(t) \rangle_U] + \langle Gz(t_f), z(t_f) \rangle_Z \end{aligned}$$

subject to the discrete-time control system

$$(2.3) \quad z(t+1) = Tz(t) + Bu(t), \quad t \geq t_0 \quad (t \text{ and } t_0 \text{ integers}), \quad z(t_0) \in Z,$$

where T and B are bounded linear operators from Z into Z and U into Z , respectively, Q and G are bounded, nonnegative self-adjoint operators on Z , and R is a positive definite self-adjoint operator on U .

The solution to problem ($\mathcal{P}1$) has been given for infinite-dimensional control systems in [22], [30], and the equations representing the solution have the same form as in the finite-dimensional case. We will now give the version of the solution that is most useful for our purposes.

For given $z(t_0)$, $J(G; t_0, t_f, z(t_0), u)$ is a bounded linear-quadratic functional on $l^2(t_0, t_f; U)$ with coercive quadratic part. Therefore, for each $z(t_0)$, there exists a unique optimal control sequence in $l^2(t_0, t_f; U)$. Also, the minimum value of the performance index is a quadratic functional of $z(t_0)$, so that there exists a unique nonnegative, self-adjoint $\Pi(t_0) \in \mathcal{L}(Z)$ such that

$$(2.4) \quad J_* = \min J(G; t_0, t_f, z(t_0), u) = \langle \Pi(t_0)z(t_0), z(t_0) \rangle_Z.$$

Application of the principle of dynamic optimality establishes that the optimal control has the feedback form

$$(2.5) \quad u_*(t) = -F(t)z_*(t), \quad t_0 \leq t \leq t_f - 1,$$

where $z_*(t)$ is the optimal trajectory,

$$(2.6) \quad F(t) = \tilde{R}(t)^{-1}B^*\Pi(t+1)T,$$

$$(2.7) \quad \tilde{R}(t) = R + B^*(t+1)B$$

and $\Pi(t)$ satisfies the Riccati difference equation

$$(2.8) \quad \Pi(t) = T^*[\Pi(t+1) - \Pi(t+1)B\tilde{R}(t)^{-1}B^*\Pi(t+1)]T + Q, \quad t \leq t_f - 1, \quad \Pi(t_f) = G.$$

The optimal trajectory z_* is given by $z_*(t+1) = S(t)z_*(t)$, for $t \geq t_0$ where

$$(2.9) \quad S(t) = T - BF(t).$$

2.2. Control on the infinite interval. Here, $t_f = \infty$ and $G = 0$. To simplify notation, we will write $J(t_0, \infty, z(t_0), u)$ instead of $J(0; t_0, \infty, z(t_0), u)$.

DEFINITION 2.1. A control sequence $u \in l^2(0, \infty; U)$ is an *admissible control for the initial condition* z if $J(0, \infty, z, u) < \infty$.

The discrete-time linear-quadratic regulator problem on the infinite interval is

$$(\mathcal{P}2) \quad \text{Choose an admissible control } u_* \text{ to minimize } J(0, \infty, z, u), \text{ if an admissible control exists for the initial condition } z.$$

That a unique control u_* exists whenever at least one admissible control exists follows from the fact that the quadratic part of $J(0, \infty, z, u)$ is coercive on a subspace of $l^2(0, \infty; U)$. See the discussion following Definition 4.1 of [10].

DEFINITION 2.2. A bounded linear operator Π on Z is a *solution to the algebraic Riccati equation* if

$$(2.10) \quad \Pi = T^*[\Pi - \Pi B(R + B^*\Pi B)^{-1}B^*\Pi]T + Q.$$

The following theorem summarizes results from Zabczyk [30].

THEOREM 2.3. *The following are equivalent:*

- (i) *There exists an admissible control for each $z \in Z$;*
- (ii) *For each $z \in Z$, $\sup_{t < t_f} \langle \Pi(t)z, z \rangle_Z < \infty$, where $\Pi(t)$ is the Riccati operator in (2.10) and $\Pi(t_f) = 0$ for fixed t_f ;*
- (iii) *As $t \rightarrow -\infty$, $\Pi(t)$ converges strongly to a nonnegative self-adjoint solution to the algebraic Riccati equation;*
- (iv) *There exists a nonnegative self-adjoint solution to the algebraic Riccati equation.*

For uniqueness of the solution to the algebraic Riccati equation and characterization of the optimal control, Zabczyk treated two cases: when Q is coercive and when

the spectral radius of T is less than 1 (i.e., the open-loop system is uniformly exponentially stable). Since neither is the case in the example we discuss in § 4.2 and other applications in which we are interested, we will need the following hypothesis and theorem.

Hypothesis 2.4. The operators T , B and Q are such that, if $z(0) \in Z$ and u is an admissible control for $z(0)$, then

$$(2.11) \quad \lim_{t \rightarrow \infty} |z(t)|_Z = 0.$$

In finite dimensions, Hypothesis 2.4 is equivalent to saying that the pair (Q, T) is detectable. In infinite dimensions, Hypothesis 2.4 implies that any unstable finite-dimensional eigenspace of T is observable by output Qz , and this is sufficient for Hypothesis 2.4 in most applications, including those discussed in § 4.

THEOREM 2.5. *When Hypothesis 2.4 holds, there exists at most one nonnegative self-adjoint solution to the algebraic Riccati equation. If such a solution Π exists, then there exists a unique solution to problem $(\mathcal{P}2)$ for each initial condition $z(0) \in Z$, the minimum value of the performance index is*

$$(2.12) \quad J_* = \min_{u \text{ admissible}} J(0, \infty, z(0), u) = \langle \Pi z(0), z(0) \rangle_Z,$$

the optimal control has the feedback form

$$(2.13) \quad u_*(t) = -Fz_*(t), \quad t \geq 0,$$

$$(2.14) \quad F = \tilde{R}^{-1} B^* \Pi T,$$

$$(2.15) \quad \tilde{R} = R + B^* \Pi B$$

and the optimal trajectory $z_(t)$ satisfies $z_*(t+1) = Sz_*(t)$, $t \geq 0$, with*

$$(2.16) \quad S = T - BF.$$

Proof. Let Π be such a solution and note that, for any finite t_f , Π is a constant solution to (2.8) with $G = \Pi$. Then the corresponding $F(t)$ and $\tilde{R}(t)$ defined by (2.6) and (2.7) are the constant operators in (2.14) and (2.15). For $z(0) \in Z$, define $\bar{z}(0) = z(0)$, $\bar{z}(t+1) = (T - BF)\bar{z}(t)$, $t \geq 0$, and $\bar{u}(t) = -F\bar{z}(t)$, $t \geq 0$. Now suppose that u is an admissible control for $z(0)$ and that $z(t)$ is the corresponding solution to (2.3). For $t_f > 0$, the preceding results about the solution to problem $(\mathcal{P}1)$ with $G = \Pi$ imply

$$(2.17) \quad \begin{aligned} J(\Pi; 0, t_f, z(0), \bar{u}) &\leq J(0; 0, t_f, z(0), u) + \langle \Pi z(t_f), z(t_f) \rangle_Z \\ &\leq J(0; 0, \infty, z(0), u) + \langle \Pi z(t_f), z(t_f) \rangle_Z. \end{aligned}$$

Also,

$$(2.18) \quad \begin{aligned} J(\Pi; 0, t_f, z(0), \bar{u}) &= \langle \Pi z(0), z(0) \rangle_Z \\ &= J(0; 0, t_f, z(0), \bar{u}) + \langle \Pi \bar{z}(t_f), \bar{z}(t_f) \rangle_Z. \end{aligned}$$

Since $z(t_f) \rightarrow 0$ as $t_f \rightarrow \infty$, (2.17) shows that \bar{u} is both admissible and optimal for problem $(\mathcal{P}2)$. Since $\bar{z}(t_f) \rightarrow 0$ as $t_f \rightarrow \infty$, (2.18) shows (2.12). As we see now, (2.12) must hold for any nonnegative self-adjoint solution of the algebraic Riccati equation; therefore, such a solution is unique.

Remark 2.6. When Hypothesis 2.4 does not hold, the algebraic Riccati equation may have more than one nonnegative self-adjoint solution. In this case, the minimal such solution—there will be one—gives the solution to problem $(\mathcal{P}2)$ as in Theorem 2.5. Throughout this paper, we assume that Hypothesis 2.4 holds.

LEMMA 2.7. Suppose that $Q \cong m$ for some positive constant m , and set $C_n = \sum_{t=0}^n (T^*)'QT'$, for $n = 1, 2, \dots$. Then $|C_n z|_Z$ is bounded in n for each $z \in Z$ if and only if C_n converges in norm to the operator $C = \sum_{t=0}^{\infty} (T^*)'QT'$ and

$$(2.19) \quad |T'| \leq (|C|/m)(1 - m/|C|)', \quad t = 1, 2, \dots$$

Proof. Since C_n is an increasing sequence of bounded self-adjoint linear operators, C_n converges strongly to some bounded self-adjoint C if and only if $\langle C_n z, z \rangle_Z$ is bounded in n for each z , if and only if $|C_n z|_Z$ is bounded in n for each z . This is a standard result. The proof of the lemma is then a standard exercise using the Lyapunov functional $\langle Cz(t), z(t) \rangle_Z$ for the homogeneous part of (2.3).

COROLLARY 2.8. If $Q \cong m > 0$ and the algebraic Riccati equation has a nonnegative self-adjoint solution Π , then the spectral radius of the operator S in (2.16) is less than 1, and

$$(2.20) \quad |S^t| \leq (|\Pi|/m)(1 - m/|\Pi|)', \quad t = 1, 2, \dots$$

Proof. This follows from Lemma 2.7 and

$$(2.21) \quad \langle \Pi z, z \rangle_Z = \sum_{t=0}^{\infty} \langle (S^*)' [Q + F^* R F] S^t z, z \rangle_Z.$$

For Q coercive, Zabczyk proved a stronger result than part (iii) of Theorem 2.3: if a nonnegative self-adjoint solution to the Riccati algebraic equation exists, then $|\Pi(t) - \Pi| \rightarrow 0$ geometrically fast as $t \rightarrow -\infty$. (Also, see [14].) We will need such a result, along with an explicit convergence rate, for the approximation theory in § 3.2. Since Zabczyk's proof does not yield an explicit convergence rate, we give the following theorem.

THEOREM 2.9. Suppose that there exists a nonnegative self-adjoint solution Π to (2.10) and that

$$(2.22) \quad |S^t| \leq M r^t, \quad t = 1, 2, \dots,$$

where M and r are positive constants with $r < 1$ and S is the optimal closed-loop operator in Theorem 2.5. If $\Pi(\cdot)$ is the operator in (2.8) with $t_f = 0$ and $\Pi(0) \geq \Pi$, then

$$(2.23) \quad \langle \Pi z, z \rangle_Z \leq \langle \Pi(-t)z, z \rangle_Z \leq \langle \Pi z, z \rangle_Z + (M r^t) |\Pi(0)|, \quad t = 1, 2, \dots$$

Proof. For t_0 a negative integer, let u_0 be the optimal control sequence for the finite-time problem ($\mathcal{P}1$) on the interval $[t_0, 0]$ with initial condition $z(t_0) \in Z$, with z_0 the corresponding optimal trajectory. Also, let u_* be the optimal control sequence on the infinite interval for problem ($\mathcal{P}2$) with initial condition $z(t_0)$, with z_* the corresponding optimal trajectory. Since Π is a constant solution to (2.8) for the final condition $G = \Pi$, we have

$$(2.24) \quad \begin{aligned} \langle \Pi z(t_0), z(t_0) \rangle_Z &= J(\Pi; 0, -t_0, z(t_0), u_*(\cdot - t_0)) \\ &\leq J(0; t_0, 0, z(t_0), u_0) + \langle \Pi z_0(0), z_0(0) \rangle_Z \\ &\leq J(0; t_0, 0, z(t_0), u_0) + \langle \Pi(0) z_0(0), z_0(0) \rangle_Z \\ &= \langle \Pi(t_0) z(t_0), z(t_0) \rangle_Z. \end{aligned}$$

On the other hand (note that $z_*(-t_0) = S^{-t_0} z(t_0)$),

$$(2.25) \quad \begin{aligned} \langle \Pi(t_0) z(t_0), z(t_0) \rangle_Z &\leq J(0; 0, -t_0, z(t_0), u_*) + \langle \Pi(0) z_*(-t_0), z_*(-t_0) \rangle_Z \\ &\leq J(0; 0, \infty, z(t_0), u_*) + \langle \Pi(0) z_*(-t_0), z_*(-t_0) \rangle_Z \\ &\leq \langle \Pi z(t_0), z(t_0) \rangle_Z + |\Pi(0)| \|S^{-t_0} z(t_0)\|_Z^2. \end{aligned}$$

3. Approximation theory.

3.1. The finite time interval problem. In this section we develop a general approximation framework for the finite time interval problem ($\mathcal{P}1$) and describe associated convergence results.

For each $N = 1, 2, \dots$, let $Z_N \subset Z$ be a finite-dimensional subspace of Z and let $P_N: Z \rightarrow Z_N$ denote projection-like mappings of Z onto Z_N . We require the following hypotheses.

Hypothesis 3.1. There exist operators $T_N: Z_N \rightarrow Z_N$, $B_N: U \rightarrow Z_N$, $Q_N: Z_N \rightarrow Z_N$ and $G_N: Z_N \rightarrow Z_N$ which satisfy $T_N P_N \rightarrow T$, $T_N^* P_N \rightarrow T^*$, $B_N \rightarrow B$, $Q_N P_N \rightarrow Q$ and $G_N P_N \rightarrow G$ strongly, as $N \rightarrow \infty$ with Q_N and G_N self-adjoint and nonnegative.

Hypothesis 3.2. The spaces Z_N are approximating subspaces in the sense that the P_N satisfy $P_N \rightarrow I$ strongly on Z as $N \rightarrow \infty$.

We note that since U has been assumed to be finite-dimensional, Hypothesis 3.1 above necessarily implies that $B_N \rightarrow B$ and $B_N^* P_N \rightarrow B^*$ in the uniform norm topology on $\mathcal{L}(U, Z)$ and $\mathcal{L}(Z, U)$, respectively.

We define a sequence of approximating discrete-time linear quadratic regulator problems on the finite time interval $[t_0, t_f]$ as follows:

($\mathcal{P}1_N$) Find $u_*^N \in l^2(t_0, t_f - 1; U)$ which minimizes

$$(3.1) \quad J_N(G_N; t_0, t_f, z(t_0), u) = \sum_{t=t_0}^{t_f-1} [\langle Q_N z_N(t), z_N(t) \rangle_Z + \langle Ru(t), u(t) \rangle_U] \\ + \langle G_N z_N(t_f), z_N(t_f) \rangle_Z$$

subject to

$$(3.2) \quad z_N(t+1) = T_N z_N(t) + B_N u(t), \quad t \geq t_0, \quad z_N(t_0) = P_N z(t_0).$$

The results stated in § 2.1 concerning the existence and uniqueness of solutions to problem ($\mathcal{P}1$) apply to the problems ($\mathcal{P}1_N$) as well. Indeed, there exists a unique solution $u_*^N \in l^2(t_0, t_f - 1; U)$ to problem ($\mathcal{P}1_N$) which is given in feedback form by

$$(3.3) \quad u_*^N(t) = -F_N(t) z_*^N(t), \quad t_0 \leq t \leq t_f - 1,$$

$$(3.4) \quad F_N(t) = \tilde{R}_N(t)^{-1} B_N^* \Pi_N(t+1) T_N,$$

$$(3.5) \quad \tilde{R}_N(t) = R + B_N^* \Pi_N(t+1) B_N$$

and the operators $\{\Pi_N(t)\}_{t=t_0}^{t_f}$ on Z_N satisfying the Riccati difference equation

$$(3.6) \quad \Pi_N(t) = T_N^* [\Pi_N(t+1) - \Pi_N(t+1) B_N \tilde{R}_N(t)^{-1} B_N^* \Pi_N(t+1)] T_N \\ + Q_N \Pi_N(t_f) = G_N.$$

The optimal trajectory z_*^N is given by $z_*^N(t+1) = S_N(t) z_*^N(t)$, $t \geq t_0$, $z_*^N(t_0) = P_N z(t_0)$ where

$$(3.7) \quad S_N(t) = T_N - B_N F_N(t), \quad t \geq t_0.$$

The operators $\{\Pi_N(t)\}_{t=t_0}^{t_f}$ are bounded, self-adjoint and nonnegative. The minimum value of the performance index (3.1) is given by

$$(3.8) \quad J_*^N = J_N(G_N; t_0, t_f, z(t_0), u_*^N) = \langle \Pi_N(t_0) z_*^N(t_0), z_*^N(t_0) \rangle_Z.$$

The fundamental convergence result is given in the following theorem.

THEOREM 3.3. Let u_*^N and u_* be the unique solutions to problems ($\mathcal{P}1_N$) and ($\mathcal{P}1$), respectively, with z_*^N and z_* the corresponding optimal trajectories. Let J_N , Π_N and F_N

and J , Π and F be given by (3.1), (3.6) and (3.4) and by (2.2), (2.8) and (2.6). Then, if Hypotheses 3.1 and 3.2 hold, we have

- (i) $\lim_{N \rightarrow \infty} \|u_*^N - u_*\|_{l^2}^2 = 0,$
- (ii) $\lim_{N \rightarrow \infty} \|z_*^N - z_*\|_{l^2}^2 = 0,$
- (iii) $\lim_{N \rightarrow \infty} \|J_*^N - J_*\| = 0,$
- (iv) $\lim_{N \rightarrow \infty} \|\Pi_N(t)P_N z - \Pi(t)z\|_Z = 0, \quad z \in Z, \quad t_0 \leq t \leq t_f \quad \text{and}$
- (v) $\lim_{N \rightarrow \infty} \|F_N(t)P_N - F(t)\| = 0, \quad t \leq t \leq t_f - 1.$

Proof. We first note that $\Pi_N(t)$ being nonnegative implies that $|\tilde{R}_N(t)| \geq |R|$ and consequently that $|\tilde{R}_N(t)^{-1}| \leq |R|^{-1}$. It follows therefore that for $u \in U$.

$$(3.9) \quad \begin{aligned} |(\tilde{R}_N(t)^{-1} - \tilde{R}(t)^{-1})u|_U &= |\tilde{R}_N(t)^{-1}(\tilde{R}(t) - \tilde{R}_N(t))\tilde{R}(t)^{-1}u|_U \\ &\leq |R|^{-1}|(\tilde{R}(t) - \tilde{R}_N(t))\tilde{R}(t)^{-1}u|_U. \end{aligned}$$

The above estimate together with (2.7), (3.5), the fact that $\Pi(t_f) = G$ and $\Pi_N(t_f) = G_N$, and Hypothesis 3.1 imply that $\tilde{R}_N(t_f - 1)^{-1} \rightarrow \tilde{R}(t_f - 1)^{-1}$ as $N \rightarrow \infty$ strongly on U . Since U is finite dimensional the convergence is in fact uniform. It then follows immediately from (2.6), (3.4) and Hypothesis 3.1 that $F_N(t_f - 1)P_N \rightarrow F(t_f - 1)$, uniformly as $N \rightarrow \infty$, and from (2.8) and (3.6), that $\Pi_N(t_f - 1)P_N \rightarrow \Pi(t_f - 1)$ strongly on Z as $N \rightarrow \infty$. A simple induction yields (iv) and (v) from which (i)–(iii) then follow trivially.

Remark. It will, on occasion, be the case that in constructing a particular approximation scheme $T_N P_N \rightarrow T$ strongly but $T_N^* P_N \rightarrow T^*$ only weakly (see, for example, [3]). However, by using the fact that $(T_N^* \Pi_N(t+1))^* = \Pi_N(t+1)T_N$ implies that $T_N^* \Pi_N(t+1) \rightarrow T^* \Pi(t+1)$ weakly if $\Pi_N(t+1) \rightarrow \Pi(t+1)$ weakly, we conclude that Theorem 3.3 continues to hold under these somewhat weaker hypotheses with the strong convergence in (iv) replaced by weak and the uniform convergence in (v) replaced by strong.

Under certain additional hypotheses it can be shown that the operators $\Pi(t)$, $t_0 \leq t \leq t_f$ given by (2.8) are trace class (see [17]) and that $\lim_{N \rightarrow \infty} \|\Pi_N(t)P_N - \Pi(t)\|_1 = 0$, $t_0 \leq t \leq t_f$, where $\|\cdot\|_1$ denotes the trace norm, the strongest of all common operator norms. To show this we require the following lemmas.

LEMMA 3.4. *If $\{a_i\}_{i=1}^\infty$ is an absolutely summable sequence of real numbers then there exist sequences $\{b_i\}_{i=1}^\infty$ and $\{c_i\}_{i=1}^\infty$ such that $\lim_{i \rightarrow \infty} b_i = 0$, $\{c_i\}_{i=1}^\infty$ is absolutely summable and $a_i = b_i c_i$.*

Proof. Let $\alpha = \sum_{i=1}^\infty |a_i|$ and for $j = 0, 1, 2, \dots$, define nonnegative integers n_j as follows. Let $n_0 = 0$ and let n_j denote the first index for which

$$(3.10) \quad \sum_{i=1}^{n_j} |a_i| > \alpha - \frac{1}{j^3},$$

$j = 1, 2, \dots$. Set $b_i = 1/j$, $c_i = ja_i$, $i = n_{j-1} + 1, \dots, n_j$, $j = 1, 2, \dots$. Then $b_i c_i = a_i$, $i = 1, 2, \dots$, $\lim_{i \rightarrow \infty} b_i = 0$ and

$$(3.11) \quad \sum_{i=1}^\infty |c_i| = \sum_{j=1}^\infty j \sum_{k=n_{j-1}+1}^{n_j} |a_k| \leq \alpha + \sum_{j=1}^\infty \frac{1}{j^2} < \infty.$$

LEMMA 3.5. *If L is a self-adjoint trace class operator on a separable Hilbert space H , then L can be written as $L^1 L^2$ where L^1 is compact and L^2 is trace class.*

Proof. Let $\{\lambda_i\}_{i=1}^\infty$ denote the eigenvalues of L repeated according to multiplicity and let $\{\phi_i\}_{i=1}^\infty$ denote the corresponding eigenvectors. Then $\{\lambda_i\}_{i=1}^\infty$ is a sequence of real numbers, each of finite multiplicity, and

$$(3.12) \quad \sum_{i=1}^{\infty} |\lambda_i| = \|L\|_1 < \infty.$$

According to Lemma 3.4, there exist sequences $\{\mu_i\}_{i=1}^\infty$ and $\{\nu_i\}_{i=1}^\infty$ with $\lim_{i \rightarrow \infty} \mu_i = 0$, $\sum_{i=1}^{\infty} |\nu_i| < \infty$ and $\lambda_i = \mu_i \nu_i$. With L^1 and L^2 defined by $L^1 \phi = \sum_{i=1}^{\infty} \mu_i \langle \phi, \phi_i \rangle_H \phi_i$ and $L^2 \phi = \sum_{i=1}^{\infty} \nu_i \langle \phi, \phi_i \rangle_H \phi_i$ for $\phi \in H$, respectively, the lemma immediately follows.

LEMMA 3.6. Let $\{S_N\}_{N=1}^\infty$ be a sequence of bounded linear operators on a separable Hilbert space H that converges strongly to a bounded linear operator S . Let $\{L_N\}_{N=1}^\infty$ be a sequence of trace class operators on H that converges in trace norm to an operator L . If L can be written as $L = L^1 L^2$ with L^1 compact and L^2 trace class then the sequence $\{S_N L_N\}_{N=1}^\infty$ converges in trace norm to SL .

Proof. The result follows immediately from the estimate:

$$(3.13) \quad \begin{aligned} \|S_N L_N - SL\|_1 &\leq \|S_N(L_N - L)\|_1 + \|(S_N - S)L^1 L^2\|_1 \\ &\leq \|S_N\| \|L_N - L\|_1 + \|(S_N - S)L^1\| \|L^2\|_1. \end{aligned}$$

THEOREM 3.7. If Q and G are trace class operators then the operators $\{\Pi(t)\}_{t=t_0}^{t_f}$ given by (2.8) are trace class. Moreover, if Hypotheses 3.1 and 3.2 hold and $Q_N P_N \rightarrow Q$ and $G_N P_N \rightarrow G$ in trace norm as $N \rightarrow \infty$ then we have

$$(3.14) \quad \lim_{N \rightarrow \infty} \|\Pi_N(t) P_N - \Pi(t)\|_1 = 0, \quad t_0 \leq t \leq t_f.$$

Proof. That the operators $\Pi(t)$, $t_0 \leq t \leq t_f$ are trace class is an immediate consequence of the hypotheses of the theorem, (2.8) and the fact that the trace class operators form a two-sided ideal of $\mathcal{L}(Z)$, the space of bounded linear operators on Z (see [17]). The trace norm convergence stated in (3.14) will follow once we have shown that $\lim_{N \rightarrow \infty} \|\Pi_N(t+1) P_N - \Pi(t+1)\|_1 = 0$ implies

$$(i) \quad \lim_{N \rightarrow \infty} \|T_N^* \Pi_N(t+1) T_N P_N - T^* \Pi(t+1) T\|_1 = 0, \quad \text{and}$$

$$(ii) \quad \lim_{N \rightarrow \infty} \|T_N^* \Pi_N(t+1) B_N \tilde{R}_N(t)^{-1} B_N^* \Pi_N(t+1) T_N P_N - T^* \Pi(t+1) B \tilde{R}(t)^{-1} B^* \Pi(t+1) T\|_1 = 0.$$

To argue (i) we first note that Hypothesis 3.1 and Lemmas 3.5 and 3.6 imply $\lim_{N \rightarrow \infty} \|T_N^* \Pi_N(t+1) P_N - T^* \Pi(t+1)\|_1 = 0$. Taking adjoints we obtain $\lim_{N \rightarrow \infty} \|\Pi_N(t+1) T_N P_N - \Pi(t+1) T\|_1 = 0$. Another application of the previous two lemmas yields

$$(3.15) \quad \begin{aligned} &\lim_{N \rightarrow \infty} \|T_N^* \Pi_N(t+1) T_N P_N - T^* \Pi(t+1) T\|_1 \\ &\leq \lim_{N \rightarrow \infty} \|T_N^* \Pi_N(t+1) T_N P_N - \Pi(t+1) T\|_1 \\ &\quad + \lim_{N \rightarrow \infty} \|(\Pi(t+1) T - T^* \Pi(t+1) T)\|_1 \end{aligned}$$

where $\Pi(t+1) = \Pi^1(t+1) \Pi^2(t+1)$ is the factorization of $\Pi(t+1)$ described in Lemma 3.6. The verification of (ii) is analogous and the theorem is proven.

We note that if Hypotheses 3.1 and 3.2 hold and if the operators Q and G are trace class with Q_N and G_N defined by $Q_N = P_N Q$ and $G_N = P_N G$, then Lemmas 3.5 and 3.6 imply that the trace norm convergence hypotheses in Theorem 3.7 hold. This is the case in the time delay problem considered in § 4.2 below.

3.2. Approximation on the infinite interval. Problem (\mathcal{P}_{2N}) is problem $(\mathcal{P}2)$ for the control system in (3.2) and the performance index

$$(3.16) \quad J_N(0, \infty, z_N(0), u) = \sum_{t=0}^{\infty} [\langle Q_N z_N(t), z_N(t) \rangle_Z + \langle Ru(t), u(t) \rangle_U].$$

Hypothesis 3.8. For each N , there exists exactly one nonnegative self-adjoint solution to the Riccati algebraic equation

$$(3.17) \quad \Pi_N = T_N^*[\Pi_N - \Pi_N B_N (R + B_N^* \Pi_N B_N)^{-1} B_N^* \Pi_N] T_N + Q_N.$$

One may suspect that solvability of the approximating finite-dimensional Riccati equations should follow from solvability of the infinite-dimensional Riccati equation, but we have no such result. Even in the corresponding continuous time case, which has been studied extensively, the solvability of the approximating problems must be established for particular approximation schemes and does not follow from solvability of the infinite-dimensional problem.

By Theorem 2.3, Hypothesis 3.8 implies that $\lim_{t \rightarrow -\infty} |\Pi_N - \Pi_N(t)| = 0$ for each N , since $\dim(Z_N) < \infty$.

As in Theorem 2.5, we write

$$(3.18) \quad F_N = \tilde{R}_N^{-1} B_N^* \Pi_N T_N,$$

$$(3.19) \quad \tilde{R}_N = R + B_N^* \Pi_N B_N,$$

$$(3.20) \quad S_N = T_N - B_N F_N.$$

From here on, Π will be the nonnegative self-adjoint solution to the infinite-dimensional Riccati algebraic equation (2.10)—when it exists— F will be the corresponding feedback operator in (2.14) and S will be the corresponding closed-loop operator in (2.16).

THEOREM 3.9. *If $\Pi_N P_N$ converges strongly to some bounded linear operator Π , then Π is a nonnegative self-adjoint solution to (2.10), $F_N P_N$ converges in norm to F and $S_N P_N$ converges strongly to S .*

Proof. This follows from Hypotheses 3.1 and 3.2, and the fact that the control space U has fixed finite dimension.

THEOREM 3.10. *Suppose that there exist positive constants M and r , independent of N , with $r < 1$, such that*

$$(3.21) \quad \Pi_N \leq M, \quad N = 1, 2, \dots, \quad \text{and}$$

$$(3.22) \quad |S_N^t| \leq M r^t, \quad t = 1, 2, \dots, \quad N = 1, 2, \dots.$$

Then a nonnegative self-adjoint solution Π to (2.10) exists, and $\Pi_N P_N \rightarrow \Pi$ strongly as $N \rightarrow \infty$. If there exists a positive m , independent of N , such that $Q_N \geq m$, $N = 1, 2, \dots$, then (3.21) implies the existence of an r less than one and independent of N for which (3.22) holds.

Proof. For each N , let $\Pi_N(\cdot)$ satisfy (3.6) with $t_f = 0$ and $\Pi_N(0) = MI$, where I denotes the identity operator on Z_N . From (2.23), $|\Pi_N - \Pi_N(-t)| \rightarrow 0$ as $t \rightarrow \infty$, uniformly in N . Now, for $z \in Z$, write

$$(3.23) \quad \begin{aligned} \langle (\Pi_N - \Pi_{N'})z, z \rangle_Z &= \langle (\Pi_N - \Pi_N(-t))z, z \rangle_Z + \langle (\Pi_N(-t) - \Pi_{N'}(-t))z, z \rangle_Z \\ &\quad + \langle (\Pi_{N'}(-t) - \Pi_{N'})z, z \rangle_Z. \end{aligned}$$

For $\varepsilon > 0$ choose $t > 0$ such that $|\langle (\Pi_N - \Pi_N(-t))z, z \rangle_Z| < \varepsilon$ and $|\langle (\Pi_{N'} - \Pi_{N'}(-t))z, z \rangle_Z| < \varepsilon$. Then, for N and N' large enough, $|\langle (\Pi_N(-t) - \Pi_{N'}(-t))z, z \rangle_Z| < \varepsilon$. This shows that Π_{Nz}

is a Cauchy sequence in Z for each z . Therefore, Π_N converges strongly to a nonnegative self-adjoint solution to (2.10). The last sentence in the theorem follows from Lemma 2.7.

An important application of this theorem is the case when the approximating open-loop operators T_N have an exponential decay rate independent of N , Q is coercive and $Q_N = P_N Q|_{Z_N}$. In this case, the zero control gives an upper bound, independent of N , on Π_N . Such is the case in the example discussed in § 4.1 and in applications to flexible structures with no rigid-body modes and coercive structural damping.

THEOREM 3.11. *Suppose that $\Pi_N P_N$ converges strongly to Π , $Q_N P_N$ converges in trace norm to Q (hence Q is trace class), and (3.22) holds for positive M and r independent of N with r less than one. Then $\Pi_N P_N$ converges in trace norm to Π .*

Proof. From (3.18)–(3.20), it follows that F_N^* and hence F_N converge in trace norm and that S_N converges strongly. Then for each N , it follows from Lemmas 3.5 and 3.6 that $(S_N^*)'[Q_N + F_N^* R F_N] S_N^t$ converges in trace norm for each t . Writing (2.21) for the N th approximating problem yields $\Pi_N = \sum_{t=0}^{\infty} (S_N^*)'[Q_N + F_N^* R F_N] S_N^t$ where the series converges absolutely in trace norm, uniformly in N , because $\|(S_N^*)'[Q_N + F_N^* R F_N] S_N^t\|_1 \leq \|S_N\|^{2t} \|Q_N + F_N^* R F_N\|_1$. Therefore, since each term in the series converges in trace norm, Π_N converges in trace norm to Π .

Note that $Q_N P_N$ converges in trace norm to Q if Q is trace class and $Q = P_N Q P_N|_{Z_N}$.

THEOREM 3.12. *If $|\Pi_N|$ is bounded in N , then a nonnegative self-adjoint solution Π to (2.10) exists, $\Pi_N P_N$ converges weakly to Π , and $F_N P_N$ and $S_N P_N$ converge strongly to F and S , respectively.*

Proof. According to Theorem 6 of [12], $\Pi_N P_N$ converges weakly to some nonnegative self-adjoint bounded Π . It follows from (3.17) and Hypotheses 3.1 and 3.2 that Π satisfies (2.10) and that F_N and S_N converge as indicated.

Note that Theorem 3.12 holds if $S_N P_N$ converges strongly but $S_N^* P_N$ converges only weakly.

3.3. Implementation of the approximation schemes. The expressions given by (3.3)–(3.6) are operator equations and although they are finite-dimensional, they are not appropriate for computations. To make use of our approximation framework, we must first determine equivalent matrix formulations. Toward this end we assume, without loss of generality, that $U = R^m$ with the standard basis and inner product and let $\{\phi_N^i\}_{i=1}^{K_N}$ be a basis for Z_N . Define the $K_N \times K_N$ Gram matrix M_N by $[M_N]_{ij} = \langle \phi_N^i, \phi_N^j \rangle_Z$. For an operator A we denote its matrix representation with respect to the bases defined above by $[A]$. Similarly, for an element $z \in Z$ or $u \in U$, we let its vector representation be given by $[z]$ or $[u]$ respectively. Standard calculations yield $[T_N^*] = M_N^{-1} [T_N]^T M_N$ and $[B_N^*] = [B_N]^T M_N$. Defining $\hat{\Pi}_N(t) = M_N [\Pi_N(t)]$, $\hat{Q}_N = M_N [Q_N]$, and $\hat{G}_N = M_N [G_N]$ we obtain

$$(3.24) \quad [u_*^N(t)] = -[F_N(t)][z_*^N(t)], \quad t_0 \leq t \leq t_f - 1,$$

$$(3.25) \quad [F_N(t)] = [\tilde{R}_N(t)]^{-1} [B_N]^T \hat{\Pi}_N(t+1) [T_N],$$

$$(3.26) \quad [\tilde{R}_N(t)] = [R] + [B_N]^T \hat{\Pi}_N(t+1) [B_N],$$

$$(3.27)$$

$$\hat{\Pi}_N(t) - [T_N]^T (\hat{\Pi}_N(t+1) - \hat{\Pi}_N(t+1) [B_N] [\tilde{R}_N(t)]^{-1} [B_N]^T \hat{\Pi}_N(t+1)) [T_N] + \hat{Q}_N,$$

$$t_0 \leq t \leq t_f - 1,$$

$$(3.28) \quad \hat{\Pi}_N(t_f) = \hat{G}_N.$$

Note that since Q_N and G_N are self-adjoint and nonnegative, \hat{Q}_N and \hat{G}_N are also. Equations (3.24)–(3.28) are therefore in the form of the standard ones obtained for the feedback law for a discrete-time linear-quadratic regulator problem in R^{K_N} . Consequently they can be solved using conventional techniques. The minimum value of the performance index is given by $J_*^N = [z_*^N(t_0)]^T \hat{\Pi}_N(t_0) [z_*^N(t_0)]$.

Analogously, for the infinite horizon problem, we have

$$(3.29) \quad [u_*^N(t)] = -[F_N][z_*^N(t)], \quad t \geq t_0,$$

$$(3.30) \quad [F_N] = [\tilde{R}_N]^{-1} [B_N]^T \hat{\Pi}_N [T_N],$$

$$(3.31) \quad [\tilde{R}_N] = [R] + [B_N]^T \hat{\Pi}_N [B_N],$$

where $\hat{\Pi}_N$ is the solution to the matrix algebraic Riccati equation

$$(3.32) \quad \hat{\Pi}_N = [T_N]^T (\hat{\Pi}_N - \hat{\Pi}_N [B_N] [\tilde{R}_N]^{-1} [B_N]^T \hat{\Pi}_N) [T_N] + \hat{Q}_N.$$

The minimum value of the performance index is given by $J_*^N = [z_*^N(t_0)]^T \hat{\Pi}_N [z_*^N(t_0)]$.

4. Examples and numerical results. In this section we describe the application of the general approximation framework developed above to a variety of examples. In addition to theoretical considerations, in each of the examples below, we discuss some numerical results for an infinite horizon problem of the form given in problem (P2).

Of primary concern to us will be applications in which one considers piecewise constant controls in the sampled form of the continuous-time control system

$$(4.1) \quad \dot{z}(s) = \mathcal{A}z(s) + \mathcal{B}u(s), \quad s > 0, \quad z(0) = z_0,$$

where \mathcal{A} is the infinitesimal generator of a \mathcal{C}_0 -semigroup of bounded linear operators $\mathcal{T}(s)$, $s \geq 0$, on Z , \mathcal{B} is a (possibly unbounded) linear operator from U into Z and $z_0 \in Z$. In this case we have

$$(4.2) \quad T = \mathcal{T}(\tau) \quad \text{and} \quad B = \int_0^\tau \mathcal{T}(s) \mathcal{B} ds,$$

where τ is the length of the sampling interval. If, as in the example in § 4.1, where u is a boundary control in a heat equation, \mathcal{B} is unbounded (more precisely, \mathcal{B} maps U not into Z but into some larger space), then the integral in (4.2) is not interpreted literally (see, for example, [7]).

In constructing the approximating operators T_N , B_N , Q_N and G_N a standard Galerkin approach is often taken; that is, $T_N = P_N T$, $B_N = P_N B$, $Q_N = P_N Q$ and $G_N = P_N G$. We note however that explicit representations for the operators T and B are frequently not available. In particular, this can occur when the discrete-time system (2.3) arises from the sampling of an infinite-dimensional continuous-time system as was described above. In this case it is the operators \mathcal{A} and \mathcal{B} which are approximated by a sequence of finite-dimensional operators \mathcal{A}_N and \mathcal{B}_N on Z_N , from which an approximation to the semigroup $\{\mathcal{T}(s): s \geq 0\}$ is obtained as $\mathcal{T}_N(s) = \exp(\mathcal{A}_N s)$, $s \geq 0$. The operators T_N and B_N are then $T_N = \mathcal{T}_N(\tau)$ and $B_N = \int_0^\tau \mathcal{T}_N(s) \mathcal{B}_N ds$, respectively. The strong convergence $T_N P_N \rightarrow T$ and $B_N \rightarrow B$ is then usually argued using an appropriate formulation of the Trotter-Kato theorem, a well-known semigroup approximation result (see [17], [25]).

Matrix exponentials were computed from eigenvalue-eigenvector decompositions obtained using the QR algorithm. The matrix Riccati equations (3.32) were solved using a Schur-vector decomposition of the Hamiltonian matrix (see [20], [26]). It should be noted that if the eigenvalue pairs of the Hamiltonian matrix for a continuous-time linear-quadratic regulator problem are asymptotic to $\pm \gamma(n)$ as $n \rightarrow \infty$, then the

eigenvalue pairs of the Hamiltonian matrix for the corresponding discrete-time problem will be asymptotic to $e^{\pm \gamma(n)\tau}$ as $n \rightarrow \infty$. Consequently, for all but very small τ , conditioning problems arise more quickly than in the continuous-time case when the approximating matrix algebraic Riccati equations are solved.

All numerical studies were performed on an IBM Personal Computer. The machine we used was equipped with an Intel 8087 math co-processor chip and 640K bytes of random access memory (of which less than 384K was required).

4.1. A heat equation with boundary control. In this example we consider the scalar parabolic system with boundary control given by

$$(4.3) \quad \frac{\partial}{\partial s} w(s, x) = \frac{\partial}{\partial x} \left(a(x) \frac{\partial}{\partial x} w(s, x) \right), \quad s > 0, \quad x \in (0, 1),$$

$$(4.4) \quad w(s, 0) = 0, \quad w(s, 1) = v(s),$$

$$(4.5) \quad w(0, x) = \phi(x)$$

with $a \in H^1(0, 1)$, $a(x) \geq \alpha > 0$, $x \in [0, 1]$, $\phi \in L_2(0, 1)$ and $v \in L_2(0, \infty)$.

To formulate the discrete-time state equation for this system we let τ denote the sampling interval and consider piecewise constant controls v given by $v(s) = u(t)$, $s \in [t\tau, (t+1)\tau)$, $t = 0, 1, 2, \dots$. We choose our state space Z to be $L_2(0, 1)$ with the usual inner product denoted by $\langle \cdot, \cdot \rangle$. The state $z(t) \in Z$ is

$$(4.6) \quad z(t) = \lim_{s \rightarrow t\tau} w(s, \cdot), \quad t = 1, 2, \dots, \quad z(0) = \phi.$$

For $t \in \{0, 1, 2, \dots\}$, we define $y(s) \in Z$ by

$$(4.7) \quad y(s) = w(s, \cdot) - \psi_0 u(t), \quad s \in (t\tau, (t+1)\tau), \quad y(t\tau) = z(t) - \psi_0 u(t),$$

where $\psi_0 \in Z$ is the ramp function given by $\psi_0(x) = x$, $x \in [0, 1]$. A straightforward calculation reveals that $y(s) = y(s, \cdot)$ satisfies

$$(4.8) \quad \dot{y}(s) = D(aDy(s)) + a'u(t), \quad s \in (t\tau, (t+1)\tau),$$

$$(4.9) \quad y(s)|_0 = 0, \quad y(s)|_1 = 0, \quad s \in (t\tau, (t+1)\tau),$$

$$(4.10) \quad y(t\tau) = z(t) - \psi_0 u(t),$$

where D denotes the differentiation operator on $H^1(0, 1)$. Let $\mathcal{A}: \text{Dom}(\mathcal{A}) \subset Z \rightarrow Z$ be given by $\mathcal{A}\psi = D(aD\psi)$ for $\psi \in \text{Dom}(\mathcal{A}) = H^2(0, 1) \cap H_0^1(0, 1)$. The operator \mathcal{A} is densely defined and self-adjoint. It satisfies

$$(4.11) \quad \langle \mathcal{A}z, z \rangle \leq -\omega |z|^2, \quad z \in \text{Dom}(\mathcal{A})$$

for some $\omega > 0$ and has compact resolvent. Also, \mathcal{A} is the infinitesimal generator of an analytic semigroup of contractions $\{\mathcal{T}(s): s \geq 0\}$ on Z which, in light of (4.11), satisfies $|\mathcal{T}(s)| \leq e^{-\omega s}$, $s \geq 0$. It follows, therefore, that

$$(4.12) \quad y(s) = \mathcal{T}(s - t\tau)y(t\tau) + \int_{t\tau}^s \mathcal{T}(s - \sigma)a' d\sigma u(t), \quad s \in [t\tau, (t+1)\tau).$$

The continuity of y , (4.6) and (4.7) imply $z(t) = y(t\tau) + \psi_0 u(t)$ and $z(t+1) = y((t+1)\tau) + \psi_0 u(t)$, and hence that

$$(4.13) \quad \begin{aligned} z(t+1) &= y((t+1)\tau) + \psi_0 u(t) \\ &= \mathcal{T}(\tau)(z(t) - \psi_0 u(t)) + \int_{t\tau}^{(t+1)\tau} \mathcal{T}((t+1)\tau - \sigma)a' d\sigma u(t) + \psi_0 u(t). \end{aligned}$$

Defining the operators $T \in \mathcal{L}(Z)$ and $B \in \mathcal{L}(R^1, Z)$ by $Tz = \mathcal{T}(\tau)z$ for $z \in Z$ and $Bu = [(I - \mathcal{T}(\tau))\psi_0 + \int_0^\tau \mathcal{T}(\sigma)a' d\sigma]u$, for $u \in R^1$, we obtain a discrete time control system of the form (2.3).

We take the performance index to be

$$(4.14) \quad J(g_0; 0, t_f, \phi, u) = \sum_{t=0}^{t_f-1} \{q_0|z(t)|_0^2 + ru(t)^2\} + g_0|z(t_f)|_0^2$$

with $q_0, g_0 \geq 0$ and $r > 0$.

Applying the theory developed in § 2.1, we have, for the finite time interval problem, that the optimal control u_* is given by $u_*(t) = -F(t)z_*(t)$, $t = 0, 1, 2, \dots, t_f - 1$, where for each t , $F(t)$ is the continuous linear functional on Z given by (2.6)–(2.8). It follows that $F(t)$ has a representation $f(t, \cdot) \in L_2(0, 1)$ and that $F(t)\psi = \int_0^1 f(t, \cdot)\psi(\theta) d\theta$, for $\psi \in L_2(0, 1)$, $t = 0, 1, 2, \dots, t_f - 1$.

For the infinite interval problem it is immediately clear that Hypothesis 2.4 is satisfied. It is also clear that (4.11) implies that for each $z(0) \in L_2(0, 1)$, $u(t) = 0$, $t = 0, 1, 2, \dots$, is an admissible control, and hence that there exists a unique nonnegative self-adjoint solution of the algebraic Riccati equation (2.10). From (2.13)–(2.15) we obtain $u_*(t) = -Fz_*(t)$, $t = 0, 1, 2, \dots$, where F is a continuous linear functional on Z and $F\psi = \int_0^1 f(\theta)\psi(\theta) d\theta$ for $\psi \in L_2(0, 1)$ with $f \in L_2(0, 1)$.

We define a standard Ritz–Galerkin approximation scheme. We define the space $V = H_0^1(0, 1)$ together with the inner product $\langle \phi, \psi \rangle_V = \langle A D\phi, D\psi \rangle$. We note that V is the energy space associated with the coercive operator $-A$, $V = \text{Dom}((-A)^{1/2})$, and it is the closure of $\text{Dom}(A)$ with respect to the V -norm defined above.

For each $N = 2, 3, \dots$, let Δ_N denote the uniform partition of the interval $[0, 1]$ given by $\{0, 1/N, 2/N, \dots, (N-1)/N, 1\}$. Let $\{e_N^j\}_{j=1}^{N-1}$ denote the usual linear B-splines (“hat” functions) on $[0, 1]$ corresponding to the partition Δ_N which satisfy $e_N^j(0) = e_N^j(1) = 0$, $j = 1, 2, \dots, N-1$. Let $Z_N = \text{span}\{e_N^j\}_{j=1}^{N-1} \subset V$. Define $P_N: Z \rightarrow Z_N$ to be the orthogonal projection of Z onto Z_N with respect to the L_2 inner product and $\mathcal{P}_N: V \rightarrow Z_N$ to be the orthogonal projection of V onto Z_N with respect to the V inner product. Define the operator $\mathcal{A}_N: Z_N \rightarrow Z_N$ as the inverse of the operator $\mathcal{A}_N^{-1} = \mathcal{P}_N \mathcal{A}^{-1}|_{Z_N}$. The invertibility of \mathcal{A} of course follows from the coercivity of $-A$ (see (4.11)). On the other hand, a straightforward calculation yields that

$$(4.15) \quad \langle \mathcal{A}_N^{-1} z_N, z_N \rangle_V = |z_N|^2$$

for $z_N \in Z_N$ and consequently that the operator \mathcal{A}_N^{-1} is invertible and the operator \mathcal{A}_N is well defined. It is also self-adjoint. Indeed, for $z_N, y_N \in Z_N$, $\langle \mathcal{A}_N z_N, y_N \rangle = -\langle z_N, y_N \rangle_V$. Also $\langle \mathcal{A}_N z_N, z_N \rangle \leq -\omega |z_N|^2$ for $z_N \in Z_N$ and therefore \mathcal{A}_N is the infinitesimal generator of a semigroup of bounded linear operators on Z_N , $\{\mathcal{T}_N(s): s \geq 0\}$ with $\mathcal{T}_N(s) = \exp(\mathcal{A}_N s)$, $s \geq 0$ and $|\mathcal{T}_N(s)| \leq e^{-\omega s}$, $s \geq 0$.

Elementary properties of spline functions (see [29]) imply $P_N \rightarrow I$ strongly on Z and $\mathcal{P}_N \rightarrow I$ strongly on V as $N \rightarrow \infty$. Furthermore, \mathcal{A}^{-1} compact and the estimate

$$(4.16) \quad |\mathcal{P}_N \mathcal{A}^{-1} z - \mathcal{A}^{-1} z| \leq |\mathcal{P}_N \mathcal{A}^{-1} z - \mathcal{A}^{-1} z|_V = |(\mathcal{P}_N - I) \mathcal{A}^{-1} z|_V$$

imply that $\mathcal{P}_N \mathcal{A}^{-1} \rightarrow \mathcal{A}^{-1}$ as $N \rightarrow \infty$ in the uniform operator topology on $\mathcal{L}(Z)$. We have, therefore, that $|\mathcal{A}_N^{-1} P_N - \mathcal{A}^{-1}|_Z \rightarrow 0$ as $N \rightarrow \infty$ and we conclude (see [4], [15]) that $\mathcal{T}_N(s) P_N z \rightarrow \mathcal{T}(s) z$ and $\mathcal{T}_N^*(s) P_N z \rightarrow \mathcal{T}^*(s) z$ as $N \rightarrow \infty$ for each $z \in Z$, uniformly in s for s in compact subintervals.

With $T_N = \mathcal{T}_N(\tau)$, $Q_N = q_0 P_N$, $G_N = g_0 P_N$ and $B_N = (I - T_N) P_N \psi + \int_0^\tau \mathcal{T}_N(\sigma) P_N a' d\sigma$, Hypotheses 3.1 and 3.2 hold and hence the convergence results for the finite time interval problem given in Theorem 3.3 apply.

FIG. 4.1

For the infinite interval problem, the uniform coercivity of the $-\mathcal{A}_N$ implies that Hypothesis 3.8 is satisfied. Moreover, if $q_0 > 0$ the conditions given in the statement of Theorem 3.10 are satisfied (see the remark following the proof of Theorem 3.10) and consequently the convergence results for the infinite horizon problem given in Theorem 3.9 hold.

Define the R^{N-1} vector valued function E_N on $[0, 1]$ by $E_N(\theta)^T = (e_N^1(\theta), e_N^2(\theta), \dots, e_N^{N-1}(\theta))$, $\theta \in [0, 1]$ and the $(N-1) \times (N-1)$ Gram matrix $M_N = \langle E_N, E_N^T \rangle$. Let the matrix H_N be given by $H_N = \langle E_N, \mathcal{A}_N E_N^T \rangle = -\langle a D e_N^1, D e_N^1 \rangle$. The matrix representation $[\mathcal{A}_N]$ for the operator \mathcal{A}_N is given by $[\mathcal{A}_N] = M_N^{-1} H_N$, while, for the operators T_N , Q_N and G_N , we have $[T_N] = \exp([\mathcal{A}_N]\tau)$, $[Q_N] = q_0 I_N$ and $[G_N] = g_0 I_N$ where I_N denotes the $(N-1) \times (N-1)$ identity matrix. If we define ψ_{0N} , $a'_N \in R^{N-1}$ by $\psi_{0N} = \langle E_N, \psi_0 \rangle$ and $a'_N = \langle E_N, a' \rangle$ we obtain

$$\begin{aligned} [B_N] &= (I_N - [T_N])M_N^{-1}\psi_{0N} + \int_0^\tau \exp([\mathcal{A}_N]\sigma)M_N^{-1}a'_N d\sigma \\ (4.17) \quad &= (I_N - [T_N])M_N^{-1}\psi_{0N} + [\mathcal{A}_N]^{-1}([T_N] - I_N)M_N^{-1}a'_N. \end{aligned}$$

When the finite-dimensional approximating gain matrices $[F_N(t)]$, $t = 0, 1, 2, \dots, t_f - 1$ for the finite interval problem have been computed an approximation $f_N(t, \cdot)$ to the feedback kernel $f(t, \cdot)$ can be obtained from $f_N(t, \theta) = E_N(\theta)^T M_N^{-1} [F_N(t)]^T$, $t = 0, 1, 2, \dots, t_f - 1$, $\theta \in [0, 1]$. We have $f_N(t, \cdot) \rightarrow f(t, \cdot)$ in $L_2(0, 1)$ as $N \rightarrow \infty$ for each $t = 0, 1, 2, \dots, t_f - 1$. Similarly, for the infinite interval problem, an approximation f_N to f is given by $f_N(\theta) = E_N(\theta)^T M_N^{-1} [F_N]^T$, $\theta \in [0, 1]$ where the matrix $[F_N]$ is computed from (3.30)–(3.32). We have $f_N \rightarrow f$ in $L_2(0, 1)$ as $N \rightarrow \infty$.

We demonstrate the feasibility of our schemes on an infinite interval problem. Taking $q_0 = 1.0$, $r = 1.0$, $a(x) = a = 1.0$, $x \in [0, 1]$ and $\tau = .01$ we obtained the approximating feedback kernels shown in Fig. 4.1.

4.2. A time delay system. In this example we consider linear hereditary control systems of the form

$$(4.18) \quad \dot{x}(s) = A_0 x(s) + A_1 x(s-r) + B_0 v(s), \quad s \geq 0, \quad x(0) = \eta, \quad x_0 = \phi,$$

where $r > 0$, $x(s) \in R^n$, $u(s) \in R^m$, $\eta \in R^n$, $\phi \in L_2(-r, 0; R^n)$ and A_0, A_1 and B_0 are real matrices of appropriate dimensions. For each $s \geq 0$ the function x_s represents the history of the state x on the interval $[s-r, s]$; that is $x_s(\theta) = x(s+\theta)$, $\theta \in [-r, 0]$. The extension of the results outlined below to more general linear hereditary systems (i.e., ones involving multiple discrete delays and integral terms with distributed history kernels) is straightforward. In the state space $Z = R^n \times L_2((-r, 0); R^n)$, the hereditary system (4.18) can be reformulated as an abstract evolution system of the form (4.1) with $z(s) = (x(s), x_s)$, $\mathcal{A}: \text{Dom}(\mathcal{A}) \subset Z \rightarrow Z$ given by $\mathcal{A}(\phi(0), \phi) = (A_0\phi(0) + A_1\phi(-r), D\phi)$ for $(\phi(0), \phi) \in \text{Dom}(\mathcal{A}) = \{(\xi, \psi) \in Z: \psi \in H^1((-r, 0); R^n), \xi = \psi(0)\}$, $\mathcal{B}: R^m \rightarrow Z$ defined by $\mathcal{B}u = (B_0u, 0)$, $u \in R^m$, and $z_0 = (\eta, \phi)$ (see [1]). The discrete time performance index is taken to be

$$(4.19) \quad J(G; 0, t_f, z_0, u) = \sum_{t=0}^{t_f-1} \{ \langle Qz(t), z(t) \rangle + u(t)^T R u(t) \} + \langle Gz(t_f), z(t_f) \rangle$$

where R is a positive-definite symmetric $m \times m$ matrix and the operators $Q: Z \rightarrow Z$ and $G: Z \rightarrow Z$ are given by $Q(\xi, \psi) = (Q_0\xi, 0)$ and $G(\xi, \psi) = (G_0\xi, 0)$ respectively with Q_0 and G_0 nonnegative, symmetric $n \times n$ matrices. For the infinite time problem we of course have $t_f = \infty$ and $G_0 = 0$.

For the finite time problem, the optimal control is given by (2.5)–(2.8). The operator $F(t)$ can be represented by a matrix of operators, $[F^0(t), F^1(t)]$ with $F^0(t) \in \mathcal{L}(R^n, R^m)$ and $F^1(t) \in \mathcal{L}(L_2((-r, 0); R^n); R^m)$. It follows therefore that

$$(4.20) \quad u_*(t) = -f^0(t)x_*(t\tau) - \int_{-r}^0 f^1(t, \theta)(x_*)_{t\tau}(\theta) d\theta, \quad t = 0, 1, 2, \dots, t_f - 1,$$

where $f^0(t)$ is an $m \times n$ matrix, $f^1(t, \cdot)$ is a square integrable $m \times n$ matrix valued function on $(-r, 0)$ and $z_*(t) = (x_*(t\tau), (x_*)_{t\tau})$, $t = 0, 1, 2, \dots, t_f$ is the optimal trajectory.

For the infinite time problem we assume that our original hereditary system and Q_0 are such that there exists an admissible control for each $z(0) = (\eta, \phi) \in Z$ and that Hypothesis 2.4 is satisfied. (This is equivalent to assuming that any unstable modes of the original hereditary system, of which there are at most a finite number, are stabilizable and detectable.) Then Theorems 2.3 and 2.5 imply that there exists a unique nonnegative self-adjoint solution Π to the Riccati algebraic equation (2.10) with the optimal control u_* given by (2.13)–(2.15). The feedback gain F can be represented by a matrix of operators $[F^0, F^1]$ with $F^0 \in \mathcal{L}(R^n, R^m)$ and $F^1 \in \mathcal{L}(L_2((-r, 0); R^n), R^m)$. We have

$$(4.21) \quad u_*(t) = -f^0 x_*(t\tau) - \int_{-r}^0 f^1(\theta)(x_*)_{t\tau}(\theta) d\theta, \quad t = 0, 1, 2, \dots,$$

where f^0 is an $m \times n$ matrix and f^1 is a square integrable $m \times n$ matrix valued function on $(-r, 0)$.

Approximation methods for the solution of the continuous time linear quadratic regulator problem for hereditary systems in closed-loop form have been studied extensively (see, for example, [3], [8], [12], [18], [19], [21], [27], [28]). Recently, a new spline-based state approximation for hereditary systems has been proposed in [15]. This new method appears to exhibit those characteristics which are most desirable in an approximation scheme when it is used to solve linear-quadratic control problems. It also performs at or above the level of any of the approximation schemes for delay systems which have been described in the literature to date. We have chosen this scheme to describe and implement here for the discrete-time problem.

For each $N = 1, 2, \dots$, define $\hat{e}_N^0 = (I_n, 0)$ and $\hat{e}_N^j = (0, e_N^j I_n)$, $j = 1, 2, \dots, N+1$, where I_n denotes the $n \times n$ identity matrix and the e_N^j are the “hat” functions with respect to the uniform mesh $\{-r, -(N-1)r/N, \dots, -r/N, 0\}$ on the interval $[-r, 0]$. Let

$$(4.22) \quad Z_N = \left\{ z \in Z : z = \sum_{j=0}^{N+1} \alpha_j \hat{e}_N^j, \alpha_j \in \mathbb{R}^n \right\}.$$

We shall refer to the collection $\{\hat{e}_N^j\}_{j=0}^{N+1}$ as a “basis” for Z_N and a vector $\alpha \in \times_{j=0}^{N+1} \mathbb{R}^n$ as being a “coordinate vector” for an element in Z_N . Defining $\hat{E}_N^T = (\hat{e}_N^0, \hat{e}_N^1, \dots, \hat{e}_N^{N+1})$ we have $Z_N = \{z \in Z : z = \hat{E}_N^T \alpha, \alpha \in \times_{j=0}^{N+1} \mathbb{R}^n\}$. Let M_N denote the Gram matrix corresponding to the basis $\{\hat{e}_N^j\}_{j=0}^{N+1}$; $M_N = \langle \hat{E}_N, \hat{E}_N^T \rangle$. If P_N denotes the orthogonal projection of Z on to Z_N then $P_N(\xi, \psi) = (\xi, p_N \psi)$ where p_N is the orthogonal projection of $L_2((-r, 0); \mathbb{R}^n)$ on to $\text{span} \{e_N^j\}_{j=1}^{N+1}$.

Noting that $Z_N \not\subset \text{Dom}(\mathcal{A})$, we motivate the definition of \mathcal{A}_N by first formally extending the operator \mathcal{A} to an operator defined on Z_N . For $z_N = (\xi_N, \psi_N) \in Z_N$ define $\mathcal{A}^N z_N = (A_0 \xi_N + A_1 \psi_N(-r), D^+ \psi_N + \delta(\xi_N - \lim_{\theta \rightarrow 0^-} \psi_N(\theta)))$ where δ is the Dirac delta impulse concentrated at zero and $D^+ \psi$ denotes the right-hand derivative of ψ . For each $N = 1, 2, \dots$, let $\mathcal{A}_N : Z_N \rightarrow Z_N$ be given by $\mathcal{A}_N z_N = (A_0 \xi_N + A_1 \psi_N(-r), p_N D^+ \psi_N) + \delta_N(\xi_N - \lim_{\theta \rightarrow 0^-} \psi_N(\theta))$ where $\delta_N = \hat{E}_N^T \gamma_N$ with $\gamma_N = M_N^{-1} \text{col}(0, \lim_{\theta \rightarrow 0^-} e_N^1(\theta), \dots, \lim_{\theta \rightarrow 0^-} e_N^{N+1}(\theta))$.

We define the operators $\mathcal{B}_N : \mathbb{R}^m \rightarrow Z_N$, $Q_N : Z_N \rightarrow Z_N$ and $G_N : Z_N \rightarrow Z_N$ by $\mathcal{B}_N = P_N \mathcal{B}$, $Q_N = P_N Q$ and $G_N = P_N G$.

Once the matrix representations for the approximating feedback gains have been computed, $[F_N(t)]$, $t = 0, 1, 2, \dots, t_f - 1$ from (3.25)–(3.28) for the finite time interval problem and $[F_N]$ from (3.30)–(3.32) (assuming, for the moment, that solutions to (3.17) exist) for the infinite interval problem, approximations for $f^0, f^1(t, \cdot)$, $t = 0, 1, 2, \dots, t_f - 1$ and $f^0, f^1(\cdot)$ can be computed from $((f_N^0(t))^T, (f_N^1(t, \cdot))^T)^T = \hat{E}_N^T M_N^{-1} [F_N(t)]^T$, $t = 0, 1, 2, \dots, t_f - 1$, and $((f_N^0)^T, (f_N^1(\cdot))^T)^T = \hat{E}_N^T M_N^{-1} [F_N]^T$ respectively.

For the approximation scheme defined above, it is shown in [15] that $P_N \rightarrow I$ strongly on Z and that $\exp(\mathcal{A}_N s) P_N \rightarrow \mathcal{T}(s)$ and $\exp(\mathcal{A}_N^* s) P_N \rightarrow \mathcal{T}^*(s)$ strongly on Z and uniformly in s for s in compact intervals. Hypothesis 3.1 is a simple consequence of these results. The present scheme, therefore, satisfies all of the hypotheses of Theorem 3.3 and we may conclude that the convergence results for the finite time interval problem given in the statement of the theorem hold. In particular, we have $f_N^0(t) \rightarrow f^0(t)$ in $\mathbb{R}^{m \times n}$ and $f_N^1(t, \cdot) \rightarrow f^1(t, \cdot)$ in $L_2((-r, 0); \mathbb{R}^{m \times n})$ for each $t = 0, 1, 2, \dots, t_f - 1$.

With the operators Q and G and the operators Q_N and G_N as they have been defined above it is clear that the hypotheses given in the statement of Theorem 3.7 are satisfied. We have therefore that for the present example the operators $\{\Pi(t)\}_{t=0}^{t_f}$ are trace class and that $\lim_{N \rightarrow \infty} \|\Pi_N(t) P_N - \Pi(t)\|_1 = 0$, $t = 0, 1, 2, \dots, t_f$.

For the infinite time problem and the approximation scheme discussed here, we believe the situation with regard to Hypothesis 3.8 and convergence is much the same as it is for the continuous time problem (see [15], [16]). It is shown in [16] that for the present scheme, in the continuous time setting, the existence of a unique nonnegative self-adjoint solution to the infinite dimensional algebraic Riccati equation (i.e., the stabilizability and detectability of the underlying hereditary system) implies the existence of unique, nonnegative self-adjoint solutions to the approximating finite dimensional algebraic Riccati equations for all N sufficiently large. We expect that the situation is much the same but rigorous verification of this would be very tedious and probably unenlightening—and outside the scope of this paper. In general we are

unable to demonstrate the existence of an M and an $r < 1$ for which (3.19) holds nor do we expect to be able to. Indeed, our numerical studies yield sequences of closed-loop eigenvalues of the approximating discrete-time control problems $(\mathcal{P}2_N)$ which tend toward the unit circle as $N \rightarrow \infty$. This agrees with what is observed in the continuous time case; see [16]. Of course Theorem 3.10 provides only sufficient conditions for strong convergence of Π_N to Π . The existence of the uniform bounds (3.18) and (3.19) and the uniform coercivity of Q_N notwithstanding, our numerical studies appear to indicate that we do in fact have strong convergence. We note that in [16], for the continuous time problem, Kappel and Salamon show that the present approximation scheme does satisfy a somewhat weaker uniform stability condition—what they call uniform output stability—and indicate that this is sufficient to conclude strong convergence of the Riccati operators for the infinite time problem. Once again we suspect that an analogous result holds in the discrete-time case.

Upon solving the approximating problems it can often be observed that $|\Pi_N|$ is uniformly bounded in N . Consequently Theorem 3.12 may be applied to conclude that a solution Π to (2.10) exists, $\Pi_N P_N \rightarrow \Pi$ weakly and $F_N P_N \rightarrow F$ strongly as $N \rightarrow \infty$. It would then follow that $f_N^0 \rightarrow f^0$ in $R^{m \times n}$ and $f_N^1 \rightarrow f^1$ weakly in $L_2((-r, 0); R^{m \times n})$ as $N \rightarrow \infty$. When Π_N does converge to Π strongly, $f_N^1 \rightarrow f^1$ strongly in $L_2(-r, 0); R^{m \times n}$.

We applied the scheme to an infinite-time problem with $n = 2$, $r = 1$, $m = 1$,

$$A_0 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad A_1 = \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix}, \quad B_0 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad Q_0 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

This system is the first order form of a second order linear harmonic oscillator with delayed restoring force. It is not difficult to show that the stabilizability and detectability conditions which guarantee the existence of a solution to the infinite-dimensional algebraic Riccati equation are satisfied for this system. The nature of this system and the approximation scheme is such that we must have $[f^1(\theta)]_2 = [f_N^1(\theta)]_2 = 0$, $-1 \leq \theta \leq 0$, $N \geq 1$, where $[v]_2$ denotes the second component of the vector $v \in R^2$ (see [12]).

Setting $\tau = .01$ we obtained the results shown in Table 4.2 and in Fig. 4.3 below with $R = .05$. With $R = 1.0$, the results shown in Table 4.4 and Fig. 4.5 were obtained. As the cost of control increases the effect that the optimal control for the infinite-dimensional problem has on higher modes decreases. Consequently, the finite-dimensional approximations converge more rapidly.

4.3. Control of a flexible structure. We consider an Euler-Bernoulli beam cantilevered to a rigid hub which is free to rotate about its fixed center, point 0. Also, a point mass m_1 is attached to the other end of the beam. The control is a torque u applied to the hub, and all motion is in the plane. See Fig. 4.6 and Table 4.7.

The angle θ represents the rotation of the hub (the rigid-body mode), $w(t, \eta)$ is the elastic deflection of the beam from the rigid-body position, and $w_1(t)$ is the displacement of m_1 from the rigid-body position. For technical reasons, we do not yet impose the condition $w_1(t) = w(t, l)$.

TABLE 4.2

FIG. 4.5

The control problem is to stabilize rigid-body motions and linear (small) transverse elastic vibrations about the state $\theta = 0$ and $w = 0$. Our linear model assumes not only that the elastic deflection of the beam is linear but also that the axial inertial force produced by the rigid-body angular velocity has negligible effect on the bending stiffness of the beam. The rigid-body angle need not be small.

FIG. 4.6

For this example, it is a straightforward exercise to derive the coupled ordinary and partial differential equations of motion in θ , w and w_1 . However, rather than writing these equations explicitly, it is easier and more useful for our purposes to derive an abstract second order evolution equation for the structure. To do this, we define the generalized displacement vector $x = (\theta, w, w_1) \in H = R^1 \times L_2(0, l) \times R^1$. The kinetic energy in the system is then $\frac{1}{2} \langle M_0 \dot{x}, \dot{x} \rangle_H$ where M_0 is the unique bounded self-adjoint linear mass operator M_0 on H such that

$$(4.23) \quad \langle M_0 x, \hat{x} \rangle_H = I_0 \theta \hat{\theta} + m_b \langle w + \psi_0 \theta, \hat{w} + \psi_0 \hat{\theta} \rangle_{L_2} + m_1 (w_1 + \psi_0(l) \theta) (\hat{w}_1 + \psi_0(l) \hat{\theta}),$$

where $\psi_0 \in L_2(0, l)$ is given by $\psi_0(\eta) = r + \eta$. It is easy to show that M_0 is also coercive. The elastic strain energy is $\frac{1}{2} a(x, x)$ with $a(x, \hat{x}) = EI \langle D^2 w, D^2 \hat{w} \rangle_{L_2}$. We make $a(\cdot, \cdot)$ into an inner product by setting $\langle x, \hat{x} \rangle_V = a(x, \hat{x}) + \theta \hat{\theta}$ and define the strain-energy space $V = \{x = (\theta, \phi, \phi(l)) : \phi \in H^2(0, l), \phi(0) = D\phi(0) = 0\}$. The additional term in the definition of $\langle \cdot, \cdot \rangle_V$ is necessary because there is no strain energy associated with the rotation of the hub.

We define the stiffness operator $A_0: \text{Dom}(A_0) \subset H \rightarrow H$ by $\text{Dom}(A_0) = \{x = (\theta, \phi, \phi(l)) \in V : \phi \in H^4(0, l), D^2 \phi(l) = 0\}$ and

$$(4.24) \quad A_0 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & EI D^4 & 0 \\ 0 & -EI D^3 & 0 \end{bmatrix}.$$

This operator is self-adjoint with compact resolvent and all positive eigenvalues except the one zero eigenvalue corresponding to the rigid-body mode. Note that V is the domain of the square root of A_0 .

With these mass and stiffness operators, we can write the equations of motion as

$$(4.25) \quad M_0 \ddot{x}(s) + c_0 A_0 \dot{x}(s) + A_0 x(s) = B_0 u(s), \quad s \geq 0,$$

where c_0 is a positive constant and the term $c_0 A_0 \dot{x}$ represents viscoelastic damping in the beam. The input operator is $B_0 = (1, 0, 0)$.

Letting $Z = V \times H$ with inner product $\langle (v, h), (\hat{v}, \hat{h}) \rangle = \langle v, \hat{v} \rangle_V + \langle M_0 h, \hat{h} \rangle_H$, this system can be written in the form (4.1) where $z = (x, \dot{x}) \in Z$ and \mathcal{A} is the unique extension of the operator

$$(4.26) \quad \mathcal{A} = \begin{bmatrix} 0 & I \\ -M_0^{-1} A_0 & -c_0 M_0^{-1} A_0 \end{bmatrix}, \quad \text{Dom}(\mathcal{A}) = \text{Dom}(A_0) \times \text{Dom}(A_0),$$

that generates a \mathcal{C}_0 -semigroup on the space Z . Of course, \mathcal{B} is

$$(4.27) \quad \mathcal{B} = \begin{bmatrix} 0 \\ M_0^{-1} B_0 \end{bmatrix}.$$

(See [11] and [13].) The hub-beam-tip mass structure here is discussed in more detail in [13], along with the continuous-time control problem.

As in the previous examples, we will solve a discrete-time optimal control problem on the infinite interval. In the performance index, we take the state weighting operator Q to be the identity on Z . This means that $\langle Qz, z \rangle_Z$ is twice the total energy in the structure plus the square of the rigid-body rotation. Since there is one input, the control weighting R is a scalar. The optimal control has the feedback form

$$(4.28) \quad u_*(t) = -\langle f, x(t) \rangle_V - \langle M_0 g, \dot{x}(t) \rangle_H$$

where f and g have the form $f = (f^1, f^2, f^3) \in V$ and $g = (g^1, g^2, g^3) \in H$.

To see that there exists a solution to the infinite-dimensional discrete-time regulator problem for this example, we note that all open-loop modes except the rigid body mode are exponentially stable and that any control which stabilizes the controllable rigid body mode is admissible. Existence of a solution to the infinite-dimensional Riccati equation then follows from Theorem 2.3. Uniqueness follows from Theorem 2.5, since Hypothesis 2.4 holds because $Q = I$ is coercive.

Our approximation of the structure is based on a finite element approximation of the beam which uses Hermite cubic splines as basis functions ([29]). We define the sequence of spaces $V_N = \text{span} \{e_N^j\}_{j=1}^{J_N}$ with $e_N^1 = (1, 0, 0)$, $e_N^j = (0, \phi_N^j, \phi_N^j(l))$, $j = 2, 3, \dots, J_N$, where the ϕ_N^j 's are the cubic splines. Each V_N is a subspace of V , and our approximation scheme is a Ritz-Galerkin approximation obtained by projecting (4.25) onto V_N . See [13] for details. Writing

$$(4.29) \quad x_N(s) = \sum_{j=1}^{J_N} [x_N(s)]_j e_N^j,$$

we have

$$(4.30) \quad M_N[\ddot{x}_N(s)] + c_0 K_N[\dot{x}_N(s)] + K_N[x_N(s)] = B_{0N}u(s)$$

to solve for the vector $[x_N(s)]$ of time-dependent coefficients $[x_N(s)]_j$. The mass matrix M_N and the stiffness matrix K_N are given by $[M_N]_{ij} = \langle M_0 e_N^i, e_N^j \rangle_H$, and $[K_N]_{ij} = \langle e_N^i, e_N^j \rangle_V$ and the input matrix is $B_{0N} = [1 \ 0 \ 0 \ \dots \ 0]^T$. With $z_N = (x_N, \dot{x}_N) \in V_N \times V_N$, (4.30) is the matrix representation of an evolution equation

$$(4.31) \quad \dot{z}_N(s) = \mathcal{A}_N z_N(s) + \mathcal{B}_N u(s)$$

where \mathcal{A}_N and \mathcal{B}_N approximate \mathcal{A} and \mathcal{B} . It is shown in [13] that, as N increases, the semigroup $\{\mathcal{T}_N(s): s \geq 0\}$ generated by \mathcal{A}_N converges strongly to the semigroup $\{\mathcal{T}(s): s \geq 0\}$ and that the adjoint semigroup $\{\mathcal{T}_N^*(s): s \geq 0\}$ converges strongly as well. Since \mathcal{B}_N is the Z -projection of \mathcal{B} onto $V_N \times V_N$, it converges strongly to \mathcal{B} .

For each N , the solution to the infinite-time optimal control problem is based on the N th Riccati operator equation (3.17). As in the previous examples, we solve the Riccati matrix equation (3.32) for $\hat{\Pi}_N$, which is related to $[\Pi_N]$ (the matrix representation of the operator Π_N) as in § 3.3, except here we have $\hat{\Pi}_N = W_N[\Pi_N]$, where

(4.32)
$$W_N = \begin{bmatrix} \tilde{K}_N & 0 \\ 0 & M_N \end{bmatrix}$$

and \tilde{K}_N is the stiffness matrix with 1 added to the first element. Since $Q = I$ in the infinite-dimensional problem, Q_N is the identity on $V_N \times V_N$ and it follows that the matrix \hat{Q}_N for (3.32) is W_N .

The optimal feedback control for the N th problem is given by (3.29) with the matrices in (3.30) and (3.31), and it has the equivalent representation

(4.33)
$$u_*^N(t) = -\langle f_N, x_N(t) \rangle_V - \langle M_0 g_N, \dot{x}_N(t) \rangle_H,$$

where $f_N = (f_N^1, f_N^2, f_N^3) \in V$, $g_N = (g_N^1, g_N^2, g_N^3) \in H$. From (3.29), (4.29) and (4.33), it follows that

(4.34)
$$\begin{bmatrix} f_N \\ g_N \end{bmatrix} = \begin{bmatrix} E_N^T & 0 \\ 0 & E_N^T \end{bmatrix} W_N^{-1} [F_N]^T,$$

where $E_N^T = (e_N^1, e_N^2, \dots, e_N^{J_N})$.

To see that Hypothesis 3.8 holds, we note that for each N , there are $N - 1$ exponentially stable modes and one controllable rigid body mode. If there were no rigid body mode, we would have a uniform positive lower bound on the stiffness matrices K_N and this would imply a uniform decay rate for the open-loop systems which would yield the uniform bounds (3.18) and (3.19). With the rigid body mode, the argument becomes more tedious but essentially similar. For more detail, see the continuous time case in [13].

For the sampling interval $\tau = .01$, the damping coefficient $c_0 = .001$ and the control weighting $R = 1$, Tables 4.8 and 4.9 give the values of the corresponding scalar gains, $f_N^i, g_N^i, i = 1$ and 3, for various values of N . The values of the functional gains $D^2 f_N^2$ and g_N^2 along the length of the beam also are plotted in Figs. 4.10 and 4.11. We plotted

$D^2 f_N^2$ because this is what appears in the V inner product in (4.33) and also to show the H^2 convergence. We note that the form of the V inner product is such that f_N^3 does not appear in the feedback law.

5. Concluding remarks. We have presented an approximation theory for numerical solution of the discrete-time optimal linear regulator problem in Hilbert space, on both finite and infinite time intervals. The motivation for this theory comes from optimal control problems for systems involving diffusion equations, hereditary differential equations and distributed models of flexible structures. We have demonstrated the application of the theory to examples from all three areas.

The solution to the infinite-dimensional optimal control problem is based on an infinite-dimensional Riccati operator equation—a difference equation in the finite-time problem and an algebraic equation in the infinite-time problem. We have shown that

the solution to the infinite-dimensional problem can be approximated by the solutions to a sequence of finite-dimensional problems each of which involves a finite-dimensional Riccati matrix equation to be solved numerically. The finite-dimensional problems are just the corresponding optimal control problems for finite element approximations to the infinite-dimensional control system. For the infinite-time problem, the finite-dimensional Riccati equations usually are solved via eigenspace decomposition of the Hamiltonian matrix.

In both continuous and discrete-time optimal regulator problems for distributed systems, the numerical solution often involves solution of large Riccati matrix equations. As we observed at the beginning of § 4, the asymptotic relationship between the eigenvalues of a continuous-time Hamiltonian system and the eigenvalues of the corresponding discrete-time Hamiltonian system is exponential. This means that the approximating finite-dimensional discrete-time Riccati equations for a given distributed system invariably are not as well conditioned as the corresponding continuous-time Riccati equations. Nonetheless, as our examples should illustrate, the numerical solution of such problems is well within the reach of current computing. To emphasize this, we obtained all of the numerical results in this paper on an IBM Personal Computer (not an XT or AT) with 640K of random access memory and an Intel 8087 math co-processor chip. The largest Riccati matrix equation that we solved here was a 30×30 steady state equation for the hub-beam-tip mass example. This solution takes 15–20 minutes on the PC. We have solved much larger Riccati equations easily on larger mainframe computers.

OPTIMAL PERIODIC CONTROL: A SCENARIO FOR LOCAL PROPERNESS*

FRITZ COLONIUS†

Abstract. A fundamental problem in optimal periodic control is to decide whether proper periodic controls and trajectories yield better average performance than constant steady-state solutions. The present paper describes a situation where this holds true, because “nearby” the linearized system equation has a pair of eigenvalues on the imaginary axis. An example involving a retarded Liénard equation is discussed in detail.

Key words. optimal periodic control, local properness, functional differential equations, Hopf bifurcation

AMS(MOS) subject classifications. 49B34, 49D50

1. Introduction. In optimal periodic control theory, one looks for periodic controls and corresponding periodic trajectories of a control system described, for example, by a functional differential equation such that a certain average performance criterion is minimized. Suppose that a constant control u^0 and a corresponding steady state x^0 of the system are given, which are optimal among all such pairs (x, u) . If it is possible to obtain better average performance in every neighborhood of (x^0, u^0) by allowing proper periodic controls and corresponding periodic trajectories x , then the pair (x^0, u^0) is called locally proper. It is the purpose of the present paper to explore a situation where one may expect local properness because of structural properties of the system equation. In particular these properties are related to those of a Hopf bifurcation. The guiding idea is that local properness will occur, if the considered system has “nearby” a “natural” periodic motion giving better performance.

A connection between Hopf bifurcation and optimal periodic control theory has already been observed by Russell [20]. He was interested in coupled nonlinear oscillators, where a Hopf bifurcation causes periodic motions which he wanted to dampen. Since this was not possible by linear regulator theory, he considered this problem as an optimal periodic control problem where the performance criterion is constructed in such a way as to minimize the amplitude of the oscillations.

Observe, however, that the spirit of the present paper is quite different: Instead of trying to dampen periodic motions we are willing to introduce them in order to get better performance. This is motivated by problems from chemical engineering (output maximization of chemical reactors [19], [24], [25]) and aircraft flight performance optimization (fuel optimal flight [22], [23]). Further references are given in [8], [17], [18].

In § 2 the optimal periodic control problem is formally defined for systems described by retarded functional differential equations. Furthermore, among other preliminaries, relevant information on necessary optimality conditions is cited from [8].

Section 3 exhibits a scenario for local properness. Theorem 3.6 contains the main result of this paper. In conclusion, § 4 discusses an example which, in fact, was the

† “Institut für Dynamische Systeme,” Universität Bremen, FB 3, D-2800 Bremen 33, Federal Republic of Germany.

starting point of the present analysis. The importance of the result in § 3 is twofold: (i) It explains a mechanism by which local properness may occur and thus gives some insight into this phenomenon. (ii) It gives a hint, where to look for local properness, namely near equilibria, where the linearized system equation has a pair of eigenvalues on the imaginary axis.

It is worthwhile emphasizing that these results, which may be viewed as a contribution to the qualitative theory of optimal control, are also new for the special case of systems governed by ordinary differential equations.

Notation. The transpose of an element $x \in \mathbb{R}^n$ is denoted by x^T ; similarly for matrices. For a map F between Banach spaces X and Y , $\mathcal{D}F(x^0)$ denotes its Fréchet-derivative at $x^0 \in X$. For maps between finite dimensional space we also use a subscript x in order to denote the partial derivative with respect to x . The second Fréchet-derivative at $x^0 \in X$ is denoted by $\mathcal{D}\mathcal{D}F(x^0)$. For an element $x \in \mathbb{R}^n$, \bar{x} denotes the constant function $\bar{x}(s) \equiv x$ (in various function spaces).

2. Problem formulation and optimality conditions. In this section, a parameter dependent optimal periodic control problem (OPC) $^\alpha$ and the corresponding optimal steady-state problem (OSS) $^\alpha$ are formulated. Furthermore optimality conditions and results on smooth dependence of optimal solutions are cited, slightly modified for our purposes, from [8].

Consider the following optimal periodic control problem.

$$\begin{aligned} \text{(OPC)}^\alpha \quad & \text{Minimize } 1/\tau \int_0^\tau g(x(s), u(s)) \, ds \\ & \text{over } (x, u) \in C(-r, \tau; \mathbb{R}^n) \times L^\infty(0, \tau; \mathbb{R}^m) \\ & \text{subject to} \end{aligned}$$

$$(2.1) \quad \dot{x}(t) = f(x_t, u(t), \alpha) \quad \text{a.e. } t \in [0, \tau],$$

$$(2.2) \quad x_0 = x_\tau,$$

$$(2.3) \quad h(u(t)) \in \mathbb{R}_-^1 \quad \text{a.e. } t \in [0, \tau],$$

$$(2.4) \quad \int_0^\tau k(x(t), u(t)) \, dt = 0;$$

here $x_t(s) = x(t+s) \in \mathbb{R}^n$, $s \in [-r, 0]$, $r > 0$ is the length of the delay, $\alpha \in A$ is a parameter, $A \subset \mathbb{R}$ open, $f = (f^i): C(-r, 0; \mathbb{R}^n) \times \mathbb{R}^m \times A \rightarrow \mathbb{R}^n$, $g: \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$, $h = (h^i): \mathbb{R}^m \rightarrow \mathbb{R}^l$, $k = (k^i): \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^{n_1}$.

The period length $\tau > 0$ is considered fixed here (we also allow $\tau < r$). The requirement (2.2) is imposed in order to allow periodic extensions of x and u to periodic solutions of (2.1) on $\mathbb{R}_+ := [0, \infty)$.

Abbreviate

$$\begin{aligned} \Omega &:= \{u \in \mathbb{R}^m: h(u) \in \mathbb{R}_-^l\}, \\ (2.5) \quad \mathcal{U}_{\text{ad}} &:= \{u \in L^\infty(0, \tau; \mathbb{R}^m): u(t) \in \Omega \text{ a.e. } t \in [0, \tau]\}. \end{aligned}$$

The corresponding steady-state problem has the following form:

$$\begin{aligned} \text{(OSS)}^\alpha \quad & \text{Minimize } g(x, u) \text{ over } (x, u) \in \mathbb{R}^n \times \mathbb{R}^m \\ & \text{subject to} \end{aligned}$$

$$(2.6) \quad 0 = f(\bar{x}, u, \alpha),$$

$$(2.7) \quad h(u) \in \mathbb{R}_-^l,$$

$$(2.8) \quad 0 = k(x, u);$$

here f , g , h and k are as in $(\text{OPC})^\alpha$.

We are interested in the behavior of $(\text{OPC})^\alpha$ near an optimal solution $(x^0, u^0) \in \mathbb{R}^n \times \mathbb{R}^m$ of $(\text{OSS})^{\alpha_0}$ (i.e., near the constant pair $(\bar{x}^0, \bar{u}^0) \in C(-r, \tau; \mathbb{R}^n) \times L^\infty(0, \tau; \mathbb{R}^m)$).

DEFINITION. A local solution (x^α, u^α) of problem $(\text{OSS})^\alpha$ is called locally proper, if for all $\varepsilon > 0$ there exist $(x, u) \in C(-r, \tau; \mathbb{R}^n) \times L^\infty(0, \tau; \mathbb{R}^m)$ with $\sup_{t \in [0, \tau]} |x^0 - x(t)| < \varepsilon$ satisfying (2.1)–(2.4) and

$$1/\tau \int_0^\tau g(x(t), u(t)) dt < g(x^\alpha, u^\alpha).$$

As is well known, first order necessary optimality conditions (based on weak variations) do not allow one to decide the question of local properness. Hence we will give below second order necessary optimality conditions for $(\text{OPC})^\alpha$.

Let the Pontryagin function $H: C(-r, 0; \mathbb{R}^n) \times \mathbb{R}^m \times \mathbb{R}^{n+n_1} \times A \rightarrow \mathbb{R}$ for $(\text{OPC})^\alpha$ be

$$(2.9) \quad H(\varphi, u, y, \alpha) := g(\varphi(0), u) + y^T \begin{pmatrix} f(\varphi, u, \alpha) \\ k(\varphi(0), u) \end{pmatrix}$$

and let the Lagrange function $\mathcal{L}: \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{n+n_1} \times \mathbb{R}^l \times A \rightarrow \mathbb{R}$ for $(\text{OSS})^\alpha$ be

$$(2.10) \quad \mathcal{L}(x, u, y, z, \alpha) := g(x, u) + y^T \begin{pmatrix} f(\bar{x}, u, \alpha) \\ k(x, u) \end{pmatrix} + z^T h(u).$$

The following hypotheses will be used.

Hypothesis 2.1. The functions f , g , h and k are twice continuously Fréchet differentiable in a neighborhood of $(\bar{x}^0, u^0, \alpha_0)$ (respectively, (x^0, u^0) , u^0 , (x^0, u^0)); the function f and its first and second derivatives are bounded for bounded arguments; the set Ω is convex.

Hypothesis 2.2. There exist $(y^0, z^0) \in \mathbb{R}^{n+n_1} \times \mathbb{R}^l$ such that

$$(2.11) \quad z^{0T} h(u^0) = 0,$$

$$(2.12) \quad \mathcal{D}_{1,2} \mathcal{L}(x^0, u^0, y^0, z^0, \alpha_0) = 0,$$

$$(2.13) \quad \mathcal{D}_{1,2} \mathcal{D}_{1,2} \mathcal{L}(x^0, u^0, y^0, z^0, \alpha_0)((x, u), (x, u)) > 0$$

for all $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$ with $\mathcal{D}_{1,2} f(\bar{x}^0, u^0, \alpha_0)(\bar{x}, u) = 0$, $k_{x,u}(x^0, u^0)(x, u) = 0$, $h_u^i(u^0)u < 0$ if $h^i(u^0) = 0$, $i \in \{1, \dots, l\}$.

Hypothesis 2.3. The gradients in \mathbb{R}^{n+m}

$$(2.14) \quad \begin{aligned} & \mathcal{D}_{1,2} f^i(\bar{x}^0, u^0, \alpha_0), \quad i = 1, \dots, n, \\ & (0, h_u^i(u^0)) \quad \text{with } h^i(u^0) = 0, \quad i \in \{1, \dots, l\}, \\ & k_{x,u}^i(x^0, u^0), \quad i = 1, \dots, n_1 \end{aligned}$$

are linearly independent and the multiplier $z^0 = (z^{0,i})$ from Hypothesis 2.2 satisfies $z^{0,i} > 0$ if $h^i(u^0) = 0$, $i \in \{1, \dots, l\}$.

Hypothesis 2.4. For all $\alpha \neq \alpha^0$ in a neighborhood of α_0 , the linearized equation

$$(2.15) \quad \dot{x}(t) = \mathcal{D}_1 f(\bar{x}^\alpha, u^\alpha, \alpha) x_t, \quad t \geq 0$$

has only the trivial τ -periodic solution; here (x^α, u^α) are elements in $\mathbb{R}^n \times \mathbb{R}^m$ to be determined in Theorem 2.7, below.

Next we comment on these hypotheses.

Remark 2.5. Hypothesis 2.4 is equivalent to

$$(2.16) \quad \text{rank } \Delta(j\omega, \alpha) = n \quad \text{for } \omega = 2k\pi/\tau, \quad k \in \mathbb{Z},$$

where $\Delta(z, \alpha)$ is the characteristic function of (2.15),

$$\Delta(z, \alpha) = zI - \mathcal{D}_1 f(\bar{x}^\alpha, u^\alpha, \alpha)(e^{z \cdot} I), \quad z \in \mathbb{C}.$$

This hypothesis will guarantee that all Lagrange multipliers for $(\text{OPC})^\alpha$ can be obtained from Lagrange multipliers for $(\text{OSS})^\alpha$.

Remark 2.6. Hypotheses 2.3 and 2.2 are a constraint qualification and a second order sufficient optimality condition, respectively, for the steady-state problem $(\text{OSS})^{\alpha_0}$. Note that in (2.14) $f(\cdot, u^0, \alpha_0)$ is considered as a map $\mathbb{R}^n \rightarrow \mathbb{R}^n$, $x \mapsto f(\bar{x}, u^0, \alpha_0)$.

First we analyze the steady-state problem $(\text{OSS})^\alpha$.

THEOREM 2.7. *Suppose that $(x^0, u^0) \in \mathbb{R}^n \times \mathbb{R}^m$ satisfy Hypotheses 2.1–2.3. Then*

(i) *The pair (x^0, u^0) is an isolated local minimum of Problem $(\text{OSS})^{\alpha_0}$, and the Lagrange multipliers $(y^0, z^0) \in \mathbb{R}^{n+n_1} \times \mathbb{R}^l$ are uniquely determined by (2.11) and (2.12).*

(ii) *There exists a continuously differentiable function $\alpha \rightarrow (x^\alpha, u^\alpha, y^\alpha, z^\alpha) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{n+n_1} \times \mathbb{R}^l$ defined on a neighborhood of α_0 such that (x^α, u^α) is an isolated minimum of $(\text{OSS})^\alpha$, $(x^{\alpha_0}, u^{\alpha_0}, y^{\alpha_0}, z^{\alpha_0}) = (x^0, u^0, y^0, z^0)$ and $(x^\alpha, u^\alpha, y^\alpha, z^\alpha)$ satisfy conditions (2.11)–(2.13) with α_0 replaced by α .*

Proof. This follows from a result in Fiacco [9, § 3.2]. \square

Next we state second order necessary optimality conditions for $(\text{OPC})^\alpha$.

THEOREM 2.8. *Let $(x^0, u^0) \in \mathbb{R}^n \times \mathbb{R}^m$ satisfy Hypotheses 2.1–2.3 and suppose that (x^α, u^α) determined by Theorem 2.7 satisfy Hypothesis 2.4. There exists a neighborhood A_0 of α_0 with the following property. Let $\alpha \in A_0$, $\alpha \neq \alpha_0$ and assume that the constant functions $(\bar{x}^\alpha, \bar{u}^\alpha) \in C(-r, \tau; \mathbb{R}^n) \times L^\infty(0, \tau; \mathbb{R}^m)$ are a local minimum of $(\text{OPC})^\alpha$.*

Then for all $(x, u) \in C(-r, \tau; \mathbb{R}^n) \times L^\infty(0, \tau; \mathbb{R}^m)$ with

$$(2.17) \quad \int_0^\tau [g_x(x^\alpha, u^\alpha)x(t) + g_u(x^\alpha, u^\alpha)u(t)] dt \leq 0$$

and

$$(2.18) \quad \begin{aligned} x_0 &= x_\tau, \quad \dot{x}(t) = \mathcal{D}_1 f(\bar{x}^\alpha, u^\alpha, \alpha)x_t + f_u(\bar{x}^\alpha, u^\alpha, \alpha)u(t) \quad \text{a.e. } t \in [0, \tau], \\ \bar{u}^0 + u &\in \text{int } \mathcal{U}_{\text{ad}} \end{aligned}$$

it follows that

$$(2.19) \quad \begin{aligned} \int_0^\tau [\mathcal{D}_1 \mathcal{D}_1 H(\bar{x}^\alpha, u^\alpha, y^\alpha, \alpha)(x_t, x_t) + 2\mathcal{D}_1 \mathcal{D}_2 H(\bar{x}^\alpha, u^\alpha, y^\alpha, \alpha)(x_t, u(t)) \\ + \mathcal{D}_2 \mathcal{D}_2 H(\bar{x}^\alpha, u^\alpha, y^\alpha, \alpha)(u(t), u(t))] dt \geq 0. \end{aligned}$$

Sketch of proof. By continuity Hypotheses 2.1–2.3 hold for α in a neighborhood of α_0 . Problem $(\text{OPC})^\alpha$ can be reformulated as an optimization problem over $(\varphi, u) \in C(-r, 0; \mathbb{R}^n) \times L^\infty(0, \tau; \mathbb{R}^m)$ (with $\varphi := x_0$) using the implicit function theorem near $(\bar{x}^\alpha, \bar{u}^\alpha) \in C(-r, \tau; \mathbb{R}^n) \times L^\infty(0, \tau; \mathbb{R}^m)$ (cf. [8, Chap. 5]). Application of optimization theory in Banach spaces (cf. [8, Chap. 2] or [16]) yields second order necessary optimality conditions for $(\varphi^\alpha, \bar{u}^\alpha)$ with $\varphi^\alpha := \bar{x}^\alpha$, involving Lagrange multipliers $(l^\alpha, y^\alpha, z^\alpha) \in C(-r, 0; \mathbb{R}^n)^* \times \mathbb{R}^{n+n_1} \times \mathbb{R}^l$. Since by assumption $\bar{u}^0 + u \in \text{int } \mathcal{U}_{\text{ad}}$, the term with z vanishes. Hypothesis 2.4 yields that the Lagrange multipliers for $(\text{OPC})^\alpha$ can be obtained from Lagrange multipliers for $(\text{OSS})^\alpha$ (cf. [8, Prop. VII.2.7]); these, however, are unique by Theorem 2.7.

For more details see Theorem VII.3.1 of [8].

Theorem 2.8 furnishes a test for local properness: If there are (x, u) satisfying (2.17) and (2.18) but violating (2.19), then $(\bar{x}^\alpha, \bar{u}^\alpha)$ cannot be a local optimal solution

of $(\text{OPC})^\alpha$. Using Hypothesis 2.4 it is advantageous to consider special (sinusoidal) test functions (x, u) . First we introduce the following abbreviations ($\omega \in \mathbb{R}_+$, $\alpha \in A_0$):

$$\begin{aligned} P(\omega, \alpha) &:= \mathcal{D}_1 \mathcal{D}_1 H(\bar{x}^\alpha, u^\alpha, y^\alpha, \alpha)(e^{j\omega \cdot} I, e^{-j\omega \cdot} I), \\ Q(\omega, \alpha) &:= \mathcal{D}_2 \mathcal{D}_1 H(\bar{x}^\alpha, u^\alpha, y^\alpha, \alpha)(e^{j\omega \cdot} I), \\ R(\alpha) &:= \mathcal{D}_2 \mathcal{D}_2 H(\bar{x}^\alpha, u^\alpha, y^\alpha, \alpha), \\ B(\alpha) &:= \mathcal{D}_2 f(\bar{x}^\alpha, u^\alpha, \alpha) \end{aligned} \quad (2.20)$$

and for later purposes

$$L(\alpha) := \mathcal{D}_1 f(\bar{x}^\alpha, u^\alpha, \alpha).$$

Identify $P(\omega, \alpha)$, $Q(\omega, \alpha)$ and $R(\alpha)$ with elements in $\mathbb{C}^{n \times n}$, $\mathbb{C}^{n \times m}$ and $\mathbb{R}^{m \times m}$, respectively. Define

$$\begin{aligned} \Pi(\omega, \alpha) &= B(\alpha)^T \Delta(-j\omega, \alpha)^T P(\omega, \alpha) \Delta(j\omega, \alpha) B(\alpha) \\ &\quad + Q(-\omega, \alpha)^T \Delta(j\omega, \alpha) B(\alpha) \\ &\quad + B(\alpha)^T \Delta(-j\omega, \alpha)^T Q(\omega, \alpha) + R(\alpha). \end{aligned} \quad (2.21)$$

COROLLARY 2.9 (II-Test). *Let the assumptions of Theorem 2.8 be satisfied. Then (x^α, u^α) is locally proper, if there exist $\nu_0, \nu_1 \in \mathbb{C}^m$ with $(\omega = 2\pi/\tau)$*

$$\begin{aligned} &[g_x(x^\alpha, u^\alpha) \Delta(0, \alpha) B(\alpha) + g_u(x^\alpha, u^\alpha)] \nu_0 \\ &\quad + [g_x(x^\alpha, u^\alpha) \Delta(j\omega, \alpha) B(\alpha) + g_u(x^\alpha, u^\alpha)] \nu_1 \leq 0, \\ &h(u^\alpha + \nu_0 + \text{Re}(\nu_1 e^{j\omega t})) \in \text{int } \mathbb{R}_-^l \quad \text{for all } t \in [0, \tau], \end{aligned} \quad (2.22)$$

$$\nu_0^T \Pi(0, \alpha^0) \nu_0 + 2\nu_1^T \Pi(\omega, \alpha) \nu_1 < 0. \quad (2.23)$$

Sketch of proof. Choose $u(t) := \nu_0 + \text{Re}(\nu_1 e^{j\omega t})$, $t \in [0, \tau]$. Then (2.22) ensures that (2.17) and (2.18) are satisfied. Computation of the expression in (2.19) yields the one in (2.23) (cf. [8, Thm. VII.3.3]).

3. A scenario for local properness. Now we will relate local properness to structural changes in the system equation. The analysis is motivated by the following consideration. Suppose a Hopf bifurcation occurs at $\alpha = \alpha_0$. See Hale [12] or Hassard, Kazarinoff and Wang [13] for an exposition of Hopf bifurcation theory of functional differential equations. If the generated periodic solution is “better” than the steady-state solution, one will expect local properness at $\alpha = \alpha_0$. It turns out that under a controllability condition this is true for all α close to α_0 . The controllability condition guarantees that the free periodic motion can be approximated by forced periodic motions for $\alpha \neq \alpha_0$. In fact it is not necessary that a Hopf bifurcation actually occur; instead some weaker properties stated below are sufficient.

Throughout this section we assume that Hypotheses 2.1–2.4 hold and hence the assertions of Theorems 2.7, 2.8, and Corollary 2.9 hold. Recall that the characteristic function of the linearized equation (with $L(\alpha) := \mathcal{D}_1 f(\bar{x}^\alpha, u^\alpha, \alpha)$)

$$\dot{x}(t) = L(\alpha)x_t, \quad t \geq 0 \quad (3.1)$$

is given by

$$\Delta(z, \alpha) = zI - L(\alpha)(e^{z \cdot} I), \quad z \in \mathbb{C}. \quad (3.2)$$

LEMMA 3.1. *Suppose that for a pair $(\omega_0, \alpha_0) \in (0, \infty) \times A$*

$$\begin{aligned} &\text{rank } \Delta(j\omega_0, \alpha_0) = n - 1, \\ &\text{rank } \Delta(j\omega, \alpha) = n \quad \text{for all } (\omega, \alpha) \neq (\omega_0, \alpha_0) \text{ close to } (\omega_0, \alpha_0). \end{aligned} \quad (3.3)$$

Then for all α in a neighborhood of α_0 , (3.1) has a simple eigenvalue $z(\alpha)$ and $z(\alpha)$ has a continuous derivative $z'(\alpha_0)$ at $\alpha = \alpha_0$.

Proof. By Theorem 2.7, the map $\alpha \rightarrow L(\alpha)$ is continuously Fréchet differentiable, and Hale [12, Lemma 2.2, p. 171] implies the assertion. \square

Remark 3.2. Condition (3.3) does not require that an eigenvalue actually cross the imaginary axis at $\alpha = \alpha_0$.

LEMMA 3.3. Condition (3.3) implies that there exists a nontrivial τ -periodic solution of (3.1) with $\alpha = \alpha_0$, $\tau := 2\pi/\omega_0$; furthermore, there exists $p_1 \in \mathbb{C}^n$ such that for every such τ -periodic solution p

$$(3.4) \quad p(t) = 2\gamma \operatorname{Re}(e^{j\omega t} p_1), \quad t \geq 0,$$

for some $\gamma \in \mathbb{R}$.

Proof. By assumption the eigenspace corresponding to $z = j\omega_0$ is one-dimensional and the assertion follows (cf. Hale [12]). \square

LEMMA 3.4. Suppose that condition (3.3) is satisfied. Then the following two conditions are equivalent:

$$(3.5) \quad \text{There exists } \nu_1 \in \mathbb{C}^m \text{ with } p_1 = [\operatorname{Adj} \Delta(j\omega_0, \alpha_0)]B(\alpha_0)\nu_1$$

where p_1 is given by Lemma 3.3 and Adj denotes the adjunct;

$$(3.6) \quad [\operatorname{Adj} \Delta(j\omega_0, \alpha_0)]B(\alpha_0) \neq 0.$$

Proof. Recall that

$$\Delta(j\omega_0, \alpha_0)[\operatorname{Adj} \Delta(j\omega_0, \alpha_0)] = \det \Delta(j\omega_0, \alpha_0) \cdot I$$

(see, e.g., Kowalsky [15, Kap. 4]). Thus the range of

$$[\operatorname{Adj} \Delta(j\omega_0, \alpha_0)]B(\alpha_0)$$

is contained in the kernel of $\Delta(j\omega_0, \alpha_0)$ which is spanned by p_1 . \square

Condition (3.5) may be viewed as a “controllability condition” for the periodic solution (3.4).

LEMMA 3.5. Let condition (3.3) be satisfied. Then

$$\bar{p}_1^T P(\omega_0, \alpha_0) p_1 = \int_0^\tau \mathcal{D}_{1,2} \mathcal{D}_{1,2} H(\bar{x}^0, u^0, y^0, \alpha^0)((p_t, 0), (p_t, 0)) dt$$

where $p_1, p(\cdot)$ are as in Lemma 3.3.

Proof. Obvious from the definitions and Lemma 3.3. \square

The next theorem establishes the connection to local properness.

THEOREM 3.6. Let $(x^0, u^0) \in \mathbb{R}^n \times \mathbb{R}^m$ satisfy the constraints of Problem (OSS) $^{\alpha_0}$ and suppose Hypotheses 2.1–2.4 hold. Furthermore, assume that conditions (3.3) and (3.5) are satisfied, and that there exists $\nu_0 \in \mathbb{C}^m$ such that ν_0 and ν_1 satisfy (2.22) with $\alpha = \alpha_0$. Let $p_0 := [\operatorname{Adj} \Delta(0, \alpha_0)]B(\alpha_0)\nu_0$ and assume for P given by (2.20)

$$(3.7) \quad \bar{p}_0^T P(0, \alpha_0) p_0 + \bar{p}_1^T P(\omega_0, \alpha_0) p_1 < 0.$$

Then there exists a neighborhood \mathcal{N} of (ω_0, α_0) such that the steady states (x^α, u^α) being isolated local minima of (OSS) $^\alpha$ are locally proper and (2.22), (2.23) hold for all $(\omega, \alpha) \in \mathcal{N}$, $(\omega, \alpha) \neq (\omega_0, \alpha_0)$.

Proof. In view of Theorem 2.7 and Corollary 2.9 it only remains to establish (2.22) and (2.23). By continuity, (2.22) is satisfied for (ω, α) near (ω_0, α_0) and ν_0, ν_1 replaced

by some elements $\nu_0^\alpha, \nu_1^\alpha$, which depend continuously on α . Furthermore $B(\alpha)$, $\text{Adj } \Delta(j\omega, \alpha)$ and $P(\omega, \alpha)$ are continuous with respect to (ω, α) and

$$[\det \Delta(j\omega, \alpha)]^2 > 0$$

for $(\omega, \alpha) \neq (\omega_0, \alpha_0)$ in a neighborhood of (ω_0, α_0) . We have

$$\begin{aligned} & \bar{\nu}_0^{\alpha T} B(\alpha)^T \Delta^{-1}(0, \alpha)^T P(0, \alpha) \Delta^{-1}(0, \alpha) B(\alpha) \nu_0^\alpha \\ & + \bar{\nu}_1^{\alpha T} B(\alpha)^T \Delta^{-1}(-j\omega, \alpha)^T P(\omega, \alpha) \Delta^{-1}(j\omega, \alpha) B(\alpha) \nu_1^\alpha \\ & = [\det \Delta(0, \alpha)]^{-2} \{ \bar{\nu}_0^\alpha B(\alpha)^T [\text{Adj } \Delta(0, \alpha)^T] P(0, \alpha) [\text{Adj } \Delta(0, \alpha)] B(\alpha) \nu_0^\alpha \} \\ & + [\det \Delta(j\omega, \alpha)]^{-2} \{ \bar{\nu}_1^\alpha B(\alpha)^T [\text{Adj } \Delta(-j\omega, \alpha)^T] P(\omega, \alpha) [\text{Adj } \Delta(j\omega, \alpha)] B(\alpha) \nu_1^\alpha \}. \end{aligned}$$

For $(\omega, \alpha) \rightarrow (\omega_0, \alpha_0)$ we have that $\det \Delta(j\omega, \alpha)$ tends to zero, while the second factor $\{\cdot \cdot \cdot\}$ in the second summand converges to $\bar{p}_1^T P(\omega_0, \alpha_0) p_1 < 0$.

Now consider the definition (2.21) of $\Pi(\omega, \alpha)$: For $(\omega, \alpha) \rightarrow (\omega_0, \alpha_0)$ the first summand tends to minus infinity with $[\det \Delta(j\omega, \alpha)]^{-2}$, the others tend to infinity with at most $|\det \Delta(j\omega, \alpha)|^{-1}$.

Thus the first summand becomes dominant and hence

$$(3.8) \quad \bar{\nu}^{0T} \Pi(0, \alpha) \nu^0 + \bar{\nu}^{1T} \Pi(j\omega, \alpha) \nu^1 < 0$$

for all $(\omega, \alpha) \neq (\omega_0, \alpha_0)$ in a neighborhood of (ω_0, α_0) . \square

COROLLARY 3.7. *Let $(x^0, u^0) \in \mathbb{R}^n \times \mathbb{R}^m$ satisfy the constraints of problems $(\text{OPC})^{\alpha_0}$ and $(\text{OSS})^{\alpha_0}$ without control constraints (i.e., $h \equiv 0$) and assume that Hypotheses 2.1–2.4 hold and conditions (3.3) and (3.5) are satisfied. If*

$$(3.9) \quad \bar{p}_1^T P(\omega_0, \alpha_0) p_1 < 0$$

where p_1 is given by Lemma 3.3, then there exists a neighborhood \mathcal{N} of (ω_0, α_0) such that the steady states (x^α, u^α) being isolated local minima of $(\text{OSS})^\alpha$ are locally proper and

$$(3.10) \quad \bar{\nu}_1^T \Pi(\omega, \alpha) \nu_1 < 0 \quad \text{for all } (\omega, \alpha) \in \mathcal{N}, \quad (\omega, \alpha) \neq (\omega_0, \alpha_0),$$

where ν_1 is given by Lemma 3.4.

Proof. Follows from Lemma 3.4 and Theorem 3.6.

Remark 3.8. In Corollary 3.7, Condition (3.5) may be replaced by (3.6).

Remark 3.9. The second order sufficient optimality condition for the steady-state problem (i.e., Hypothesis 2.2) and the “complementary slackness” condition in Hypothesis 2.3 are needed in order to guarantee smooth dependence of $(x^\alpha, u^\alpha, y^\alpha)$ on α . If this can be guaranteed by other arguments (e.g., if the steady-state problem is independent of α as in the example of § 4, below) we can replace Hypothesis 2.2 by the assumption that (x^α, u^α) are a local minimum of $(\text{OSS})^\alpha$.

The following result is a partial converse of Corollary 3.7.

THEOREM 3.10. *Let the assumptions of Corollary 3.7 be satisfied. If there exists a sequence $(\omega_n, \alpha_n) \rightarrow (\omega_0, \alpha_0)$, $(\omega_n, \alpha_n) \neq (\omega_0, \alpha_0)$ with*

$$(3.11) \quad \bar{\nu}^T \Pi(\omega_n, \alpha_n) \nu > 0$$

where $\nu = \nu_1$ is given by Lemma 3.4, then

$$(3.12) \quad \bar{p}_1^T P(\omega_0, \alpha_0) p_1 \geq 0$$

where p_1 is given by Lemma 3.3.

Proof. Condition (3.12) and (2.21) imply

$$\begin{aligned} 0 &< \bar{\nu}^T \Pi(\omega_n, \alpha_n) \nu \\ &= \bar{\nu}^T B(\alpha_n)^T \Delta^{-1}(-j\omega_n, \alpha_n)^T P(\omega_n, \alpha_n) \Delta^{-1}(j\omega_n, \alpha_n) B(\alpha_n) \nu \\ &\quad + \bar{\nu}^T \{B(\alpha_n)^T \Delta^{-1}(-j\omega_n, \alpha_n)^T Q(\omega_n, \alpha_n) \\ &\quad + Q(-\omega_n, \alpha_n)^T \Delta^{-1}(j\omega_n, \alpha_n) B(\alpha_n) + R(\alpha_n)\} \nu. \end{aligned}$$

The first summand equals

$$[\det \Delta^{-1}(-j\omega_n, \alpha_n)]^{-2} \{\bar{\nu}^T B(\alpha_n) [\text{Adj } \Delta(-j\omega_n, \alpha_n)]^T P(\omega_n, \alpha_n) \text{Adj } \Delta(j\omega_n, \alpha_n) B(\alpha_n) \nu\}.$$

Again $[\det \Delta(-j\omega_n, \alpha_n)]^2 > 0$, and the second factor converges to

$$\begin{aligned} &\bar{\nu}^T B(\alpha_0) [\text{Adj } \Delta(-j\omega_0, \alpha_0)]^T P(\omega_0, \alpha_0) \text{Adj } \Delta(j\omega_0, \alpha_0) B(\alpha_0) \nu \\ &= \bar{p}_1^T P(\omega_0, \alpha_0) p_1. \end{aligned}$$

Arguing as in the proof of Theorem 3.6, we obtain (3.12). \square

Remark 3.11. Suppose that a Hopf bifurcation occurs at $\alpha = \alpha_0$ (cf. Hale [12, Thm. 1.1, p. 246]). Then Theorem 3.6 may be interpreted as follows: At $\alpha = \alpha_0$, a “natural” periodic solution of $\dot{x}(t) = f(x_t, u^\alpha, \alpha)$ bifurcates from the steady state x^α , $\alpha = \alpha_0$. By (3.7), this periodic motion shows better average performance than the steady state. Condition (3.3) is satisfied and the controllability condition (3.5) guarantees (by continuity) that for all α near α_0 the periodic trajectory can be approximated by trajectories corresponding to a sinusoidal control. Hence, for α near α_0 , the points (x^α, u^α) are locally proper. Suppose nontrivial periodic trajectories exist for $\alpha > \alpha_0$. Then, also for $\alpha < \alpha_0$, where no free periodic trajectory exists, we can generate periodic trajectories by appropriate sinusoidal controls. Thus it is not surprising that the assumption can be weakened by requiring only the assumptions of Theorem 3.6: it is not necessary that the nonlinear equation actually has a free periodic trajectory. In view of this discussion, it seems feasible to me to use the expression “Controlled Hopf Bifurcation” if conditions (3.3) and (3.5) are satisfied.

Remark 3.12. The stability properties of the periodically forced equations near $\alpha = \alpha_0$ may be very complicated; cf. Gambaudo [10] for a classification in the case of two-dimensional ordinary differential equations.

4. An example. In this section we consider an optimal periodic control problem for a retarded Lienard equation where Corollary 3.7 applies. First results for this problem were obtained in [6]. The problem is the following:

$$\text{Minimize} \quad -\frac{1}{\tau} \int_0^\tau x(s) ds + \frac{1}{2\tau} \int_0^\tau u(s)^2 ds$$

subject to

$$(4.1) \quad \ddot{x}(t) + f(x(t))\dot{x}(t) + g(x(t-r)) = u(t) \quad \text{a.e. } t \in [0, \tau],$$

$$(4.2) \quad x_0 = x_\tau, \quad (\dot{x})_0 = (\dot{x})_\tau,$$

$$(4.3) \quad \int_0^\tau u(t) dt = 0;$$

here f and $g: \mathbb{R} \rightarrow \mathbb{R}$; $x(t), u(t) \in \mathbb{R}$, and $r, \tau > 0$. We require that

$$(4.4) \quad f \text{ and } g \text{ are } C^2\text{-functions in a neighborhood of zero with } f(0) = g(0) = 0, \\ g'(0) = 1, g''(0) = -1, \text{ and } f(x) \neq 0 \text{ for } x > 0.$$

Writing (4.1) as a system of first order equations and applying the time transformation $t := tr$, we get

$$(4.5) \quad \begin{aligned} \dot{x}_1(t) &= \frac{1}{r} x_2(t), \\ \dot{x}_2(t) &= \frac{1}{r} [-f(x_1(t))x_2(t) - g(x(t-1)) + u(t)]. \end{aligned}$$

Consider $\alpha = 1/r > 0$ as bifurcation parameter.

The corresponding steady-state problem is

$$(4.6) \quad \begin{aligned} \text{(OSS)} \quad & \text{Minimize } -x_1 + \frac{1}{2}u^2 \quad \text{subject to} \\ & 0 = x_2, \\ & 0 = -f(x_1)x_2 - g(x_1) + u, \\ & 0 = u. \end{aligned}$$

The assumptions in (4.4) guarantee that $(x^0, u^0) = (0, 0)$ is the unique optimal solution of (OSS). Observe that (OSS) is independent of α ; hence Remark 3.9 applies and we can omit Hypothesis 2.2.

Furthermore Hypothesis 2.3 is satisfied and the corresponding Lagrange multipliers are

$$(4.7) \quad \begin{aligned} y_1 &= -g'(0)^{-1}f(0) = 0, \\ y_2 &= -g'(0)^{-1} = -1, \\ y_3 &= g'(0) = 1. \end{aligned}$$

The linearized system equation is

$$(4.8) \quad \dot{x}(t) = \alpha \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} x(t) + \alpha \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix} x(t-1) + \begin{pmatrix} 0 \\ 1 \end{pmatrix} u(t)$$

or

$$(4.9) \quad \ddot{x}(t) + \alpha^2 x(t-1) = u(t).$$

Thus the characteristic equation is

$$(4.10) \quad \det \Delta(z, \alpha) = z^2 + \alpha^2 e^{-z} = 0.$$

LEMMA 4.1. (i) *There exists an eigenvalue z of (4.8) on the imaginary axis if and only if $\alpha = \alpha_n = 1/(2n\pi)$, $n \in \mathbb{N}$.*

(ii) *If $\alpha = \alpha_n$ for some $n \in \mathbb{N}$, then the eigenvalues z on the imaginary axes are $z = \pm j$.*

(iii) *For $\alpha \rightarrow 0$ all eigenvalues in the right half-plane tend to the origin.*

(iv) *For α close to α_n , there exists a C^1 -function $\alpha \rightarrow z(\alpha)$ such that $z(\alpha)$ is a simple eigenvalue of (4.8) and $z(\alpha_n) = j$, $z'(\alpha_n) > 0$ and $\operatorname{Re} z(\alpha) < 0$ for $\alpha < \alpha_n$.*

Proof. The proof follows by an elementary analysis of (4.10).

The lemma shows that for $\alpha = \alpha_n$, $n \in \mathbb{N}$, a Hopf bifurcation occurs with frequency $\omega_0 = 1$.

A nontrivial periodic solution of

$$\dot{x}(t) = \alpha_n \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} x(t) + \alpha_n \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix} x(t-1)$$

with period $\tau = 2\pi$ is given by

$$p(t) = 2 \begin{pmatrix} \cos t \\ -\sin t \end{pmatrix}.$$

The Fourier coefficients of p are

$$p_1 = \hat{p}(1) = \begin{pmatrix} 1 \\ j \end{pmatrix}, \quad \bar{p}_1 = \hat{p}(-1) = \begin{pmatrix} 1 \\ -j \end{pmatrix},$$

$$\hat{p}(k) = 0 \quad \text{for } k \neq \pm 1.$$

The function $H: C(-1, 0; \mathbb{R}^2) \times \mathbb{R} \times \mathbb{R}^3 \times (0, \infty) \rightarrow \mathbb{R}$ is given by

$$H(\phi, u, y, \alpha) := -\phi_1(0) + \frac{1}{2}u^2 + \alpha y^T \begin{pmatrix} \phi_2(0) \\ -f(\phi_1(0))\phi_2(0) - g(\phi_1(-1)) + u \\ u \end{pmatrix}.$$

We compute

$$\begin{aligned} \bar{p}_1^T P(\omega_0, \alpha_0) p_1 &= (1 \quad -j) \begin{pmatrix} -1 & f'(0) \\ f'(0) & 0 \end{pmatrix} \begin{pmatrix} 1 \\ j \end{pmatrix} \\ &= -1 < 0; \end{aligned}$$

thus (3.9) holds.

It only remains to show the controllability condition (3.6) (cf. Remark 3.8). We easily compute

$$\text{Adj} [\Delta(j\omega, \alpha)] B_0(\alpha) = \begin{pmatrix} j\omega & 1 \\ -\exp(-j\omega, \alpha) & j\omega \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} = \begin{pmatrix} 1 \\ j\omega \end{pmatrix}.$$

FIG. 1. Shows $\Pi(\omega, r)$, $0 \leq \omega \leq 4$, for different values of r between $r=0$ and $r=3$ ($X=\omega$, $Y=r$, $Z=\Pi(\omega, r)$). The function values are cut off for $z < -3$.

FIG. 2. Shows $\Pi(\omega, r)$, $0 \leq \omega \leq 4$, for different values of r between $r = 0$ and $r = 10$.

FIG. 3. Shows $\Pi(\omega, r)$, $0 \leq \omega \leq 4$, for $r = 10$.

Clearly

$$p_1 = \begin{pmatrix} 1 \\ j\omega_0 \end{pmatrix} \in \mathcal{R}[\text{Adj}[\Delta(\alpha_0, j\omega_0)]B_0(\alpha_0)].$$

Thus all the assumptions of Corollary 3.7 are verified. It is advantageous to write Π as a function of the delay r and the frequency ω . Then a simple computation yields

(4.11)
$$\Pi(\omega, r) = 1 - 1/[\omega^4 - 2\omega^2 \cos(\omega r) + 1]$$

FIG. 4. Shows $\Pi(\omega, r)$, $0 \leq \omega \leq 4$, for $r = 30$.

for $(\omega, r) \neq (1, r_n)$, where $r_0 = 1$, $r_n := 1/\alpha_n$, $n \in \mathbb{N}$. Zones of local properness, indicated by $\Pi(\omega, r) < 0$ occur for (ω, r) close to $(1, r_n)$.

An analysis of the function Π given by (4.11) yields that for all $\omega, r \in \mathbb{R}_+$

$$1 - 1/[\omega^2 - 1]^2 \leq \Pi(\omega, r) \leq 1 - 1/[\omega^2 + 1]^2,$$

$$\Pi(0, r) = 0, \quad \lim_{\omega \rightarrow \infty} \Pi(\omega, r) = 1.$$

Figures 1–4 show $\Pi(\omega, r)$ for different values of r (here $X = \omega$, $Y = r$, $Z = \Pi(\omega, r)$). A significant feature of this example is that the zones of properness (i.e., the ω -intervals where $\Pi(\omega, r) < 0$) which occur at a Hopf bifurcation at $r = r_n$ (indicated by a negative pole of $\Pi(\omega, r)$ at $\omega = 1$) do not vanish for increasing r . Thus for large r , $\Pi(\omega, r)$ becomes very oscillatory (see Fig. 4).

Remark 4.2. It is easy to check that the function $\Pi: \mathbb{R}_+ \times \mathbb{R}_+ \rightarrow \mathbb{R} \cup \{-\infty\}$ has no local minima besides $(\omega, r) = (1, r_n)$. This may be interpreted in the following way: Local properness in this problem occurs *only* via the mechanism described by Corollary 3.7. Naturally, this may not be true for other problems (e.g., local properness may be due to nonlinearities in the performance criterion).

Acknowledgments. I thank Professor H. T. Banks for the invitation to work at Brown University. Furthermore I would like to acknowledge the use of programs by Dr. M. Pratt for the plotting of the diagrams.

REMARKS ON A PAPER BY R. M. HIRSCHORN*

A. KUMPERA†

Abstract. We indicate some imprecisions appearing in a paper by R. M. Hirschorn and suggest modifications.

Key words. nonlinear control system, reachable set, Lie algebra

AMS(MOS) subject classification. 93B05

1. Introduction. In 1976, R. M. Hirschorn published in this journal [1] far-reaching results concerning the relationship between the structure of the reachable sets of a nonlinear control system of the form

$$\frac{dx}{dt} = A(x) + u_1 B_1(x) + \cdots + u_m B_m(x)$$

and the properties of the associated, eventually infinite-dimensional, Lie algebra of vector fields

$$\mathcal{L} = \{A, B_1, \dots, B_m\}_{LA}.$$

Unfortunately, the underlying hypotheses are revealed to be insufficient. In § 2, we provide a counterexample to Theorem 3.6 of [1] and, consequently, to the main Theorem 3.2, and point out the gap in the proof. In § 3, we discuss weaker forms for the above-mentioned theorems. The basic definitions as well as the notation are borrowed from Hirschorn's paper.

2. A counterexample. We consider on the manifold $M = \mathbb{R}^2$ the system

$$(*) \quad \frac{dX}{dt} = A(X) + uB(X), \quad X = (x, y)$$

where $A = \partial/\partial x + \partial/\partial y$ and $B = \sin^2(x) \partial/\partial x$. Let $C = \sin(2x) \partial/\partial x$, $D = \cos(2x) \partial/\partial x$ and $E = \partial/\partial x$; then

$$\mathcal{L} = \{A, B, C, D, E\}_{LS},$$

$$\mathcal{B} = \{B\}_{LS},$$

$$\mathcal{L}_0 = \{B, C, D, E\}_{LS}$$

and the commutation relations read as follows:

$$[A, B] = C, \quad [B, C] = -2B, \quad [C, D] = -2E, \quad [D, E] = 2C.$$

$$[A, C] = 2D, \quad [B, D] = -C, \quad [C, E] = -2D,$$

$$[A, D] = -2C, \quad [B, E] = -C,$$

$$[A, E] = 0,$$

The algebra \mathcal{L} is composed of analytic complete vector fields and the hypothesis $[\mathcal{L}_0, \mathcal{B}(a)] \subset \mathcal{B}(a)$ (cf. [1, Thm. 3.6]) is satisfied since $[C, B] = 2B \in \mathcal{B}$ and $[D, B] = [E, B] = C$ vanishes whenever B does.

* Received by the editors May 13, 1987; accepted for publication July 20, 1987.

† Instituto de Matemática, Universidade Estadual de Campinas, 13.081 Campinas SP, Brazil.

Let us now examine the reachable sets for the system (*). Since, for any constant c , $A + cB = \partial/\partial y + f_c \partial/\partial x$, where $f_c(x) = 1 + c \sin^2 x$, and since

$$\left[\frac{\partial}{\partial y}, f_c \frac{\partial}{\partial x} \right] = 0,$$

we infer that any point $Q = (x, y)$ reachable from $P = (x_0, y_0)$ at time t (i.e., $Q \in \mathcal{R}_t(P)$) via the finite succession of constant controls c_1, c_2, \dots, c_l , during respective times t_1, \dots, t_l with $\sum t_i = t$ (i.e., the control function u in (*) takes the value $u(s) = c_i$ when $s \in [t_1 + \dots + t_{i-1}, t_1 + \dots + t_i]$) can, in fact, be reached from P by steering initially along the vector field $\partial/\partial y$, during time t , thus attaining the point $P_1 = (x_0, y_0 + t)$ and subsequently, steering along the succession of vector fields $f_{c_1} \partial/\partial x, \dots, f_{c_l} \partial/\partial x$ during the corresponding times t_1, \dots, t_l . Hence, the reachable set $\mathcal{R}_t(P)$ for the system (*) is equal to the reachable set $\hat{\mathcal{R}}_t(P_1)$ relative to the family of vector fields $\{f_c \partial/\partial x\}$. Observing that $f_c(0) = 1 > 0$ whatever the value c , we infer that any solution of (*) with initial data $x(0) = 0$ necessarily enters into the domain $\Delta = \{(x, y): x > 0\}$ since $x'(t) > 0$ as long as control $u = c_1$ is maintained. Let us switch now to control $u = c_2$ and initial data $x(t_1) > 0$. Then, either $c_2 \geq -1$ —hence $f_{c_2}(x) \geq 0$, and consequently $x'(t) \geq 0$; or $c_2 < -1$, and the following two possibilities arise: (a) $f_{c_2}(x(t_1)) \geq 0$ or (b) $f_{c_2}(x(t_1)) < 0$. In case (a), $x'(t) \geq 0$ as before and in case (b), $x'(t) < 0$. However, in the latter case, the solution $x(t)$, though decreasing, never attains the first zero point of f_{c_2} to the left of $x(t_1)$, as shown by the graph of f_{c_2} (see Fig. 1).

FIG. 1

We infer that $X(t)$ remains in the domain Δ as long as control c_2 is maintained and, iterating the above argument to the finite succession of controls c_1, \dots, c_l , we eventually conclude that $\mathcal{R}_t(0) \subset \Delta$. On the other hand, since the constant controls c_i can be arbitrarily chosen, it follows that $\mathcal{R}_t(0) = \{(x, t): x > 0\}$ for any $t > 0$. A similar argument shows, in general, that $\mathcal{R}_t(P) = \{(x, y_0 + t): x > k\pi\}$ where $P = (x_0, y_0)$, $t > 0$ and $k\pi \leq x_0 < (k+1)\pi$. In conclusion,

$$\mathcal{R}_t(P) \neq I'(\mathcal{L}_0, P) = \{(x, y_0 + t): x \in \mathbb{R}\}.$$

The gap in the proof of Theorem 3.6 of [1, p. 707, 1–19] appears in the claim: “A straightforward computation \dots .” In fact, according to our example, the vector field $\xi = \sin(x) \partial/\partial x$ satisfies the property $\xi(a) \in \mathcal{B}(a)$, for all $a \in M$, but $[E, \xi] = \cos(x) \partial/\partial x$ fails to do so.

3. The stronger hypothesis. If we assume that the distribution $x \mapsto \mathcal{B}(x)$ on the manifold M is regular, then the above-mentioned claim is true and Theorem 3.6 holds.

However, regularity conditions are strange and inconvenient to control theory. Moreover, in the context of [1], such a condition would make any attempt to define a suitable A -radical extremely difficult. It seems, therefore, that the simplest and most convenient remedy consists in precisely assuming whatever the proof requires, namely, replacing the hypothesis $[\mathcal{L}_0, \mathcal{B}](x) \subset \mathcal{B}(x)$ by the stronger version

$$(\text{ad}_{\mathcal{L}_0}^k \mathcal{B})(x) \subset \mathcal{B}(x), \quad k \geq 1.$$

Under this assumption, Theorem 3.6 holds and, if we redefine accordingly the A -radical for \mathcal{B} , Theorem 3.2 also holds. Needless to say, the above assumption is, for practical purposes, rather discouraging.

GAMES WITH REPEATED DECISIONS*

STEVE ALPERN†

Abstract. Extensive form games are traditionally required to obey the axiom of “nonrepetition”: *No information set may contain more than one node from any directed path in the tree.* However, in order to model games where the players are teams or automata, it is necessary to consider extensive forms which do not satisfy the nonrepetition axiom. This paper develops a noncooperative strategic theory for such games. Mixed or behavioral strategies are inadequate for such games, but there always exist Nash equilibria in finite combinations of behavioral strategies. It can also be shown that any given pair of such strategies form the unique Nash equilibrium for some two person zero-sum game. Mathematically, the theory is closely related to that of polynomial and separable games as developed by Dresher, Karlin and Shapley (Ann. Math. Stud., 24 (1950), pp. 161–180) and by Gale and Gross (Pacific J. Math., 8 (1958), pp. 735–741).

Key words. games, extensive form, polynomial games

AMS(MOS) subject classification. 90D

1. Introduction. Game theory has traditionally been studied under the assumption that a player is never confronted with the same decision problem more than once in any play of a game. This assumption arises, in the conventional definition of an extensive form game (tree), through the following “nonrepetition” hypothesis placed on information sets: *No information set may contain more than one node from any directed path in the tree.* We will call games which satisfy this hypothesis “nonrepetitive,” and those which do not “repetitive.” It is clear that games where the players are individuals and have perfect memories can be modeled as nonrepetitive games and even as games of perfect recall. However, the contention of this paper is that repetitive games may be required to model situations where the players are teams (and the decisions are not agent-specific) or automata with limited memories. We outline a noncooperative strategic theory for repetitive games which establishes that there are always equilibria in finite mixtures of behavioral strategies. We rely extensively on ideas from the theory of polynomial and separable games, as developed in [DKS], [GG], and [K].

Before going further into the mathematical analysis, some interpretive material may be useful to justify the whole enterprise. When games of imperfect recall are modeled by considering players to be represented by teams of agents, all decisions made by a team are assumed to be agent-specific. This means that there is an implicit map from information sets of player i to agents of player i . For example, in bridge, every information set of player North-South is uniquely assigned to either agent North or agent South. Such team games, where decisions are agent-specific, clearly satisfy the usual nonrepetition hypothesis because the individual agents are assumed to have perfect memories. Furthermore, such games can alternatively be modeled as games of perfect recall, with agents as players. However the situation is entirely different for team games where decisions of teams are not agent-specific. In many large organizations (teams) it is more a matter of chance which agent deals with a given decision. Sometimes this allocation of agents is formally randomized, as when incoming calls are handled on switchboards and given to the next available agent. More often it is informal. It is clear, for example, that if in two separate instances a policeman had given me a warning for speeding (as opposed to a fine) on the same day, both were confronted with the

* Received by the editors August 18, 1986; accepted for publication (in revised form) August 21, 1987.

† Department of Mathematics, London School of Economics, London, WC2A 2AE, England.

same decision problem. That is, neither one knew that he was the first or second to warn me. The situation would have been different (worse for me in this case, I'm afraid) if an individual agent had been permanently assigned to me. In summary of these arguments, repetitive games are needed to model team games in which decisions are not agent-specific.

As an example, consider "Team Chess" played by two large teams called White and Black. At every move for, say, White, a referee randomly selects a White agent, shows him the current position and requests a move. Since the agent is not told the moves which led to this position, he may select a move (such as castling when the king has already moved) which is illegal in standard chess—in Team Chess such moves are legal but lose. In this model positions are information sets, and thus the same information set may be entered more than once in a play of the game.

The second application of repetitive games is to cases when players are modeled as automata (for example, [Ru]). When a node of player i is reached, the referee inputs the code for the information set of that node into an automaton which is playing for player i (or *is* player i). Depending on the number of internal states (memory size) it is possible that the automaton "cannot distinguish" whether or not that code has been previously inputted. To carry out the types of strategies outlined in this paper the automata must be probabilistic.

To illustrate the extensive and normal forms to be studied in this paper we consider the two-person zero-sum game shown in Fig. 1. If player I goes right at his single information set with probability x and player II goes right with probability y then the payoff (to maximizer I) is given by the behavioral-normal form

$$A(x, y) = 3(1 - x) + 4x(1 - y)(1 - x) + 5x(1 - y)x + 6xy.$$

While this has the form of a polynomial game, with both x and y chosen from the unit interval, it is clear that as soon as some player has more than one information set the expression for A will be somewhat more general. We will call this form a "multinomial game." While the theory of polynomial games is not sufficient for our purposes, it turns out that an extension called "separable games" developed by Karlin et al. [DKS], [KS], [K] can be adapted to analyze the solutions of games with repeated decisions.

FIG. 1

The organization of the paper is as follows. In § 2 we give the definition of an extensive form game and of some related strategic notions. This is as usual (in fact we follow Owen [O]) except for the omission of the restriction on information sets and the inclusion of randomized strategies. We outline the easy argument which shows that there is always a Nash equilibrium in randomized strategies. Section 3 consists of examples of two-person zero-sum games with repeated decisions. These examples

demonstrate the inadequacy of mixed and behavioral strategies. Section 4 employs an analysis of the generalized moment space to establish that randomized strategies concentrated on a finite number of behavioral strategies are sufficient. Theorem 2 relates the required complexity of strategies to the informational complexity of the extensive form game. The results on strategic complexity given here are not sharp and can undoubtedly be improved by a better description of the moment space. In § 5 we use an algorithm of Gale and Gross [GG] to find an extensive game with a given pair of unique optimal strategies.

2. Extensive form games. In this section we define a game in extensive form. Our definition is standard (see [O]) except that the assumption of “no repeated decisions” is omitted. We define various notions of strategy and the resulting behavioral-normal form. We prove that all games possess a Nash equilibrium in terms of randomized strategies.

DEFINITION. By an n -person game in extensive form the following is meant:

(i) A tree T with a distinguished vertex v^* called the “starting point,” with all the edges of T directed away from v^* .

(ii) A function U , called the “payoff function,” which assigns an n -vector $U(v)$ to each terminal vertex v of T .

(iii) A partition of the nonterminal vertices of T into $n+1$ sets S_0, S_1, \dots, S_n , called the “player sets.”

(iv) A probability distribution, defined at each (chance) vertex of S_0 , among the immediate followers of the vertex.

(v) For each $i = 1, \dots, n$, a subpartition of S_i into subsets S_i^j , called “information sets,” such that two vertices in the same information set have the same number of immediate followers.

(vi) For each information set S_i^j , an index set I_i^j (called choices), together with 1:1 mappings of the set I_i^j onto the set of immediate followers of each vertex of S_i^j .

If no two vertices of S_i^j , for any j , lie on a single directed path, then player i is said to have “no repeated decisions.” If all players have no repeated decisions we call the game “nonrepetitive”; otherwise we call it repetitive. In our terminology, traditional game theory is the study of nonrepetitive games.

The primitive strategic notion for repetitive games is the behavioral strategy. A behavioral strategy b_i for player i is a function which assigns to each information set S_i^j of player i a probability distribution over the choices I_i^j . The set of all behavioral strategies for player i is therefore the Cartesian product of a finite number of simplices, which we denote by B_i . We observe for future use that each set B_i is compact and convex, and hence so is their Cartesian product B . The extreme points of B_i are those (finitely many) b_i which assign only the probabilities 0 or 1 to all choices, and we call these “pure strategies.” A Borel probability measure μ_i on B_i is called a randomized strategy, and these are denoted collectively by B_i^* . If μ_i has finite support we will call it a “finite randomized strategy” and if additionally the support consists entirely of pure strategies then we call μ_i a “mixed strategy.”

Corresponding to any n -tuple of behavioral strategies $b = (b_1, \dots, b_n)$ there is a distribution $D = D(b_1, \dots, b_n)$ over the set of terminal vertices. For each terminal vertex v , $D_b(v)$ is the probability of the game ending at v if the strategies b are employed. The number $D_b(v)$ is computed by multiplying all the probabilities assigned by b to the edges (choices) leading from the starting vertex v^* to v . It is important to note that $D(v)$ is a continuous function of b . Since $U_i(v)$ is the von Neumann–Morgenstern utility to player i of the play ending at v , the expected utility for i

corresponding to b is given by $U_i(b) = \sum_v D_b(v) U_i(v)$ (summation over terminal vertices v) which is therefore also continuous in b . We call these maps $U_i: B \rightarrow R$ the behavioral-normal form of the game. Finally, if $\mu = (\mu_1, \dots, \mu_n)$ is an n -tuple of randomized strategies, then we define the expected utility to player i by $U_i(\mu) = \int \dots \int U_i(b_1, \dots, b_n) d\mu_1(b_1) \dots d\mu_n(b_n)$.

There are many equilibrium concepts which have proved useful in the study of nonrepetitive games. However in this first study of repetitive games we will consider only the most basic concept, that of a Nash equilibrium. An n -tuple $\bar{\mu} = (\bar{\mu}_1, \dots, \bar{\mu}_n)$ of randomized strategies is called a Nash equilibrium if for each $i = 1, \dots, n$ and all μ_i in B_i^* , $U_i(\bar{\mu}_1, \bar{\mu}_2, \dots, \bar{\mu}_{i-1}, \mu_i, \bar{\mu}_{i+1}, \dots, \bar{\mu}_n) \leq U_i(\bar{\mu})$.

Since each of the n utility functions U_i is continuous on the compact set B , a well-known result (see [O, p. 78] or [BO, p. 168]) asserts that there is a Nash equilibrium in Borel probability measures (usually called mixed strategies, but that term would be misleading here) on the sets B_i . Reinterpreting this result in our setting, we obtain the following.

THEOREM 1. *Every finite extensive form game has a Nash equilibrium in randomized strategies.*

3. Examples. In this section we solve three repetitive two-person zero-sum games. The first is given in extensive form, while the latter two are given in behavioral-normal form together with an algorithm (Theorem 2) for constructing an inducing extensive form. We will simplify an otherwise notationally complex problem by choosing only "binary" games in which all choices made by the players are binary, or equivalently, in which all nonterminal vertices have outdegree two. In the formal notation of § 2, this requires that $\#(I_i) = 2$ for all i and j . Since any choice among a finite number of alternatives can be reduced (nonuniquely) to a sequence of binary choices, every extensive form game is equivalent to a binary game. For binary games the probability distributions over the (two) alternatives at any information set may be identified with the unit interval $[0, 1]$ and hence the set of behavioral strategies B_i for each player i is a finite-dimensional cube, as is the product B of these sets.

For binary games there is a simple notation both for behavioral strategies and for labeling information sets. Let x_i (y_i) denote the probability of going to the right at the i th information set of player I (II) according to the behavioral strategy x (y). Label the corresponding edges of the tree x_i , and the complementary edges with " $1 - x_i$." Such a labeling of the edges of a binary tree indicates all the game theoretic information (player sets, information sets and identified alternatives) and also makes clear the corresponding Markov chain with absorbing barriers.

Example 1. Consider the game with extensive form shown in Fig. 2.

The behavioral-normal form corresponding to this extensive form is

$$A(x_1, x_2; y_1) = 6(1 - x_1)y_1 + 5x_1(1 - y_1) + 4x_1y_1(1 - x_2) + 6x_1y_1x_2(1 - x_1).$$

We can reduce the dimension of player I's strategies by the following observation. If

FIG. 2

x_1 is known to the agent choosing x_2 at the vertex labeled v , then clearly a maximizing agent should choose $x_2 = 1$ if $x_1 < \frac{1}{3}$ and $x_2 = 0$ if $x_1 > \frac{1}{3}$ (with any x_2 if $x_1 = \frac{1}{3}$). More precisely, $(x_1, 1)$ dominates (x_1, x_2) for $x_1 < \frac{1}{3}$ and $x_2 < 1$, and similarly for $(x_1, 0)$ if $x_1 > \frac{1}{3}$. Hence the game with normal form $A(x_1, x_2; y_1)$ is equivalent (with $x = x_1$ and $y = y_1$) to the game on the square with kernel

$$K(x, y) = \begin{cases} 6(1-x)y + 5x(1-y) + 6x(1-x)y & \text{if } x \leq \frac{1}{3}, \\ 6(1-x)y + 5x(1-y) + 4xy & \text{if } x \geq \frac{1}{3}. \end{cases}$$

It is not hard to calculate that $\inf_y \sup_x K(x, y) = 5 - q$, which is attained uniquely for $y = q = (170 + 40\sqrt{6})/386 \doteq 0.694$. This mixed (or behavioral) strategy for player II is optimal. We next observe that the $\sup_x K(x, q)$ is attained only at the two points $x = a = 5(1 - q)/12q \doteq 0.184$ and $x = 1$. It follows that player I has an optimal randomized strategy involving only the two behavioral strategies $(a, 1)$ and $(1, 0)$. To calculate the probability p such that the randomized strategy $p(a, 1) + (1 - p)(1, 0)$ is optimal we consider the 2×2 matrix game shown below.

	$y = 0$	$y = 1$
$(a, 1)$	$5a$	$6(1 - a^2)$
$(1, 0)$	5	4

The minimax solution to this matrix game is given by $y = 1$ with probability q (which we already knew) and $(a, 1)$ with probability $p = -1/(6a^2 + 5a - 7) \doteq 0.17$. The value of this 2×2 game, and hence also of the original extensive form game, is $5 - q$. It is worth noting that in contrast to nonrepetitive games, neither the value nor the probabilities used in the optimal strategies lie in the field generated by the payoffs (all integers in this example). This is of course due to the nonlinearity of the normal form. We wish to make one further remark concerning the nature of the optimal strategies found for this game. Observe that player I had to randomize over only two behavioral strategies. We could have anticipated this qualitative feature by observing that $\partial^2/\partial y_1^2 A(x_1, x_2; y_1) = 0$ and referring to Karlin's result [K, Thm. 4.3.1] that if $\partial^n/\partial y_1^n A(x_1, \dots, x_m; y_1) \geq 0$, then player I has an optimal strategy involving at most n points. This is part of the theory of "generalized convex games." See also Owen [O, Prob. 2, p. 83]. In the next section we will see how weaker results in this direction can be obtained even if both strategy spaces are multidimensional.

Observe that the behavioral-normal form of the game in Example 1, and indeed of any binary two-person zero-sum game, has the form

$$A(x, y) = \sum_{k=1}^L a_k f_k(x, y) \quad \text{where } f_k(x, y) = x_1^{i_1} \cdots x_m^{i_m} y_1^{j_1} \cdots y_n^{j_n};$$

the exponents depend on k . We will call such games, where the maximizer I chooses x in $[0, 1]^m$ and the minimizer II chooses y in $[0, 1]^n$, "multinomial games." This is an obvious generalization of the class of polynomial games, where $m = n = 1$. It is clear that the behavioral-normal form of a binary two person zero-sum game is always a multinomial game. Our next two examples are given most naturally as multinomial games, so it is useful to know that they arise from a (repetitive) game in extensive form. This follows from Theorem 2.

THEOREM 2. *Every multinomial game is the behavioral-normal form of some extensive form binary two-person zero-sum game. If the degree (highest exponent) of the multinomial is one, then the inducing extensive form game may be taken to be nonrepetitive.*

Proof. Unfortunately we know of no efficient algorithm for constructing the extensive form, so we give only the following trivial one: Suppose the multinomial $A(x, y)$ is in the form written above. At a starting vertex v^* we begin a tree by drawing L out-edges which are chance moves with probability $1/L$. The vertex following the k th of these edges is followed by $i_1 = i_1(k)$ consecutive vertices of information set 1 of player I, with every node following a $(1 - x_1)$ left choice being a terminal vertex with utility 0. At the vertex following $i_1(k)$ choices of x_1 (right) place a similar tree based on $i_2(k)$ choices of information set 2 of player I. Finally, at the terminal vertex v_k following chance move k , i_1 choices to the right (x_1) at information set 1 of player I, \dots , j_m choices to the right (y_n) at information set n of player II, let the utility be given by $U(v_k) = La_k$. Since the probability of arriving at a vertex of type v_k is $(1/L)f_k(x, y)$ and the utility of all vertices not of this type is 0, the behavioral-normal form of this game is the given multinomial $A(x, y)$. This construction clearly has the property claimed in the second part of the theorem.

Example 2. Consider the multinomial game given by $A(x, y) = (x_1 - y_1)^2 - (x_2 - y_2)^2$. The associated game $A_1(x_1, y_1) = (x_1 - y_1)^2$ with x_1 and y_1 in $[0, 1]$ has the unique optimal strategies x_1 equal to 0 or with 1 equiprobability and $y_1 = \frac{1}{2}$. Since the game $A_2(x_2, y_2) = -(x_2 - y_2)^2$ is the same with the players' roles reversed, and A is in a natural sense the sum of these games, the solution to the original game A is given by the randomized strategies $x = (0, \frac{1}{2})$ or $(1, \frac{1}{2})$ equiprobability and $y = (\frac{1}{2}, 0)$ or $(\frac{1}{2}, 1)$ equiprobability. The value of this symmetric game is of course zero (see Fig. 3).

In the solutions given in Fig. 3, no pure strategies (corners of the square) are used. We now compute player I's security level if he is restricted to using mixed strategies (concentrated on the four corners). Suppose player I uses the generic mixed strategy denoted by (p, q, r, s) , where these entries are the respective probabilities of the extreme points $(0, 0)$, $(1, 0)$, $(1, 1)$ and $(0, 1)$. If player II counters with the behavioral strategy (z, w) (that is, $y_1 = z$ and $y_2 = w$) then the expected payoff is computed as

$$\begin{aligned} & p(z^2 - w^2) + q((1 - z)^2 - w^2) + r((1 - z)^2 - (1 - w)^2) + s(z^2 - (1 - w)^2) \\ &= [pz^2 + q(1 - z)^2 + r(1 - z)^2 + sz^2] - [pw^2 + qw^2 + r(1 - w)^2 + s(1 - w)^2] \\ &= f(z) - g(w). \end{aligned}$$

$$\begin{aligned} \bar{\mu} &= \frac{1}{2}b_1 + \frac{1}{2}b'_1 \\ \bar{\mu}'' &= \frac{1}{2}b_1 + \frac{1}{2}b''_1 \\ B_1 &= B_1 = [0, 1]^2 \end{aligned}$$

FIG. 3

It follows that the minimizer II chooses z to minimize f and w to maximize g . Hence player II takes $z = q + r$ and w equal to 1 or 0 depending on whether $p + q$ is greater than or less than $r + s$. Assuming the former, we obtain without loss of generality that the expected value of A resulting from an optimal response to (p, q, r, s) is $(p + s)(q + r) - (p + q)$ which has maximal value $-\frac{1}{4}$ when all four corners are equally likely. Thus no mixed strategy is optimal.

Example 3. Our last example is a geometric game in the spirit of Ruckle [R]. A new town is to be built around a circular expressway. To minimize the cost of additional spur roads, new residents are fined according to the square of the distance that they choose to locate from the expressway. We consider the early stages where only two players, I and II, decide to live in this town. We assume that a player's fine is distributed among the remaining players. The final rub is that I hates II but II likes I, feelings which are related to utilities according to the square of the distance between them. More precisely, the expressway is centered at $(0, 0)$ and has radius r , and the two players must independently choose their respective positions x and y in the plane. The payoff to maximizer I is $A(x, y) = 2[d(y, S_r)]^2 - 2[d(x, S_r)]^2 + [d(x, y)]^2$. Here $d(y, S_r)$ denotes the Euclidean distance from the point y to the circle S_r representing the expressway. The squares are used to ensure that the kernel is a multinomial and the example was created so that the radial symmetry would produce optimal randomized strategies symmetrically distributed about the origin (and, in particular, with infinite nonconvex support).

Let $G(a, b)$ denote the average square of the distance from a point on S_a to a point on the concentric circle S_b . It is easily calculated that $G(a, b) = a^2 + b^2$. From the symmetry of the problem it is easy to see that the only real decision of each player is how far from the origin to locate. Let $F(a, b)$ denote the expected value of $A(x, y)$ if x and y are chosen uniformly over the circles of radius a and b , respectively. Then

$$\begin{aligned} F(a, b) &= 2(b - r)^2 - 2(a - r)^2 + G(a, b) \\ &= [3b^2 - 4rb] - [a^2 - 4ra]. \end{aligned}$$

Since $d/db[3b^2 - 4rb] = 6b - 4r$ and $d/da[a^2 - 4ra] = 2a - 4r$ it follows that the values $a = 2r$ and $b = 2r/3$ constitute the unique saddle point for $F(a, b)$. Hence for the original game the uniform distributions μ_1 and μ_2 over the concentric circles of radius $2r$ and $2r/3$, respectively, are optimal randomized strategies for players I and II. Consequently the value of the game is $F(2r, 2r/3) = 2r^2/9 - 2r^2 + 4r^2 + 4r^2/9 = 8r^2/3$.

The above analysis assumes that the strategies available to the players are all points in the plane, whereas for a multinomial game they must be restricted to the unit square. However if the circle is chosen with center at $(\frac{1}{2}, \frac{1}{2})$ and radius $r < \frac{1}{4}$ so that the concentric circle of radius $2r$ lies in the unit square, then the resulting multinomial game with strategies restricted to the square will have as optimal strategies scaled versions of the μ_1 and μ_2 given above. In Fig. 4 these optimal strategies are indicated by dotted circles.

We have not proven uniqueness so the question remains whether the players have optimal finite randomized strategies. To answer this we must use the following geometric lemma: *If y_0, \dots, y_{m-1} are $m > 1$ points equally spaced along the circle S_b then the average squared distance from any point x on the concentric circle S_a to the points y_0, \dots, y_{m-1} is $G(a, b)$.* It follows that any finite randomized strategy which gives equal weight to a set of equally spaced points along S_b is optimal for player II. In particular, any pair of equiprobable antipodal points on S_b constitutes an optimal randomized strategy for II, with a corresponding result holding for player I.

FIG. 4

The proof of the geometric lemma used in the above analysis is easy. Let $x = ae^{it}$ and for $j = 0, \dots, m-1$ let $y_j = be^{jq_i}$ where $q = 2\pi/m$ ($i^2 = -1$). The sum of the squared distances from x to y_j is given by

$$f(t) = \sum_{j=0}^{m-1} |be^{jq_i} - ae^{it}|^2 = \sum_{j=0}^{m-1} (be^{jq_i} - ae^{it})(be^{-jq_i} - ae^{-it}).$$

Hence

$$f'(t) = \sum_{j=0}^{m-1} [(be^{jq_i} - ae^{it})(ai e^{-it}) + (be^{-jq_i} - ae^{-it})(-ai e^{it})] = 0$$

because $\sum_{j=0}^{m-1} e^{jq_i} = \sum_{j=0}^{m-1} e^{-jq_i} = 0$. Thus the sum, $f(t)$, is constant. The average must also be a constant, which upon examination must be $G(a, b)$.

4. Sufficiency of finite randomized strategies. Let G be a two-person zero-sum game. According to Theorem 1 there are optimal strategies for each player consisting of probability distributions over their behavioral strategy spaces. In this section we further demonstrate that the players need to average over only a finite number of behavioral strategies, and give an upper bound for that finite number in terms of the complexity of the information structure of the game.

First suppose that G is a binary game. We define the multiplicity of an information set as the maximum number of times a game path may pass through it. (Thus a game is nonrepetitive if all information sets have multiplicity one.) Suppose player I has N information sets of multiplicities k_1, k_2, \dots, k_N and player II has M of multiplicities q_1, \dots, q_M . For each play of the game we consider the N -tuple (i_1, \dots, i_N) , where i_n is the number of times the n th information set of player I has been entered. Since each i_n satisfies $0 \leq i_n \leq k_n$ an upper bound on the number of possible N -tuples (i_1, \dots, i_N) is given by the number $K = \prod_{n=1}^N (k_n + 1)$ which we call the "informational multiplicity of player I." Similarly let $Q = \prod_{m=1}^M (q_m + 1)$ be the informational multiplicity of player II. If the game G is not in binary form, define its informational multiplicity, $K(G)$, as the minimum of $K(G')$ as G' varies over all binary games equivalent to G . Define $Q(G)$ similarly. The behavioral-normal form of the binary game G can be written in the form

$$A(x, y) = \sum_{i=1}^K \sum_{j=1}^Q a_{ij} r_i(x) s_j(y)$$

where $r_i(x)$ is of the form $x_1^{i_1} x_2^{i_2} \cdots x_N^{i_N}$ and $s_j(y)$ is of the form $y_1^{j_1} \cdots y_M^{j_M}$. This notation is explained in the previous section. The strategies x and y are chosen from $B_I = [0, 1]^N$ and $B_{II} = [0, 1]^M$, respectively.

THEOREM 3. *Let G be a two-person zero-sum game, where player I has informational multiplicity K . Then he has an optimal randomized strategy which uses at most $K + 1$ behavioral strategies.*

Proof. By Theorem 1 player I has an optimal randomized strategy, which we denote by $\bar{\mu}$. This means that

$$A(\bar{\mu}, y) = \int_{B_I} A(x, y) d\bar{\mu}(x) \geq V \quad \text{for all } y \text{ in } B_{II}$$

where V denotes the value of the game G . Actually we use the version of Theorem 1 appropriate for two-person zero-sum games. Let R denote the set of all points $r = (r_1, \cdots, r_K)$ of the form $r_i = \int_{B_I} r_i(x) d\mu(x)$, $i = 1, \cdots, K$, for some randomized strategy μ in B_I^* . Let C denote the subset of R determined by the point measures (behavioral strategies) μ_x in B_I^* . That is, $C = \{r: r_i = r_i(x), i = 1, \cdots, K, \text{ for some } x \text{ in } B_I\}$. It follows in a straightforward manner from the separating hyperplane theorem that R is the convex hull of C . This is stated in [K, Thm. 3.1.1], where a proof for $B_I = [0, 1]$ is given which applies equally well to all compact convex sets B_I .

Let \bar{r} be the point in R represented by the optimal randomized strategy $\bar{\mu}$: $\bar{r}_i = \int_{B_I} r_i(x) d\bar{\mu}(x)$, $i = 1, \cdots, K$. Since R is a subset of K -dimensional Euclidean space, every point in R is a convex sum of at most $K + 1$ extreme points. Hence we may write

$$\bar{r} = \sum_{p=1}^{K+1} z_p C^p$$

where the z_p are nonnegative numbers summing to one and each C^p in the set C has the form $C_i^p = r_i(x^p)$ for some behavioral strategy x^p in B_I . Define a finite randomized strategy μ' by the convex sum

$$\mu' = \sum_{p=1}^{K+1} z_p [x^p]$$

where $[x^p]$ denotes the point measure whose support is x^p . For $i = 1, \cdots, K$

$$\begin{aligned} \int_{B_I} r_i(x) d\mu'(x) &= \sum_{p=1}^{K+1} z_p r_i(x^p) = \bar{r}_i \\ &= \int_{B_I} r_i(x) d\bar{\mu}(x). \end{aligned}$$

In other words, the finite randomized strategy μ' has the same $K + 1$ generalized moments with respect to the r_i as the given optimal randomized strategy μ . It follows that for any behavioral strategy y in B_{II} ,

$$\begin{aligned} A(\mu', y) &= \int_{B_I} A(x, y) d\mu'(x) \\ &= \int_{B_I} \sum_{i=1}^K \sum_{j=1}^Q a_{ij} r_i(x) s_j(y) d\mu'(x) \\ &= \sum_{i=1}^K \sum_{j=1}^Q a_{ij} s_j(y) \int_{B_I} r_i(x) d\mu'(x) \end{aligned}$$

$$\begin{aligned}
&= \sum_{i=1}^K \sum_{j=1}^Q a_{ij} s_j(y) \int_{B_1} r_i(x) d\bar{\mu}(x) \\
&= \int_{B_1} (A(x, y) d\bar{\mu}(x) \\
&= A(\bar{u}, y).
\end{aligned}$$

This shows that any randomized strategy is in fact strategically equivalent to a finite randomized strategy, which in particular establishes the theorem.

For those interested in sharper bounds on the number of behavioral strategies one needs to average over, the theory of separable games as developed in [DKS] and [K] will prove useful. In particular it can be shown (using [K, Cor. 3.5.1]) that each player has a finite randomized strategy which involves at most $\min(K, Q)$ behavioral strategies. However, since our estimates which initially gave the numbers K and Q were themselves far from sharp, we have decided not to go into these details here.

5. Games with given optimal solutions. In the previous section we established (Theorem 3) that zero-sum two-person extensive form games have solution pairs consisting of finite randomized strategies. In this section we determine which such pairs are solutions of some game. To make this question more precise, define $\Omega(m, n)$ to be the class of all binary extensive form games (zero-sum, two person) in which the two players have m and n information sets, respectively. Let $F(j)$ denote the set of all finite convex combinations of point measures on $[0, 1]^j$. Then we can prove the following.

THEOREM 4. *For any pair (μ, ρ) of measures in $F(m) \times F(n)$ there is an extensive form game in $\Omega(m, n)$ such that μ and ρ are the unique optimal (randomized) strategies.*

Proof. Gale and Gross [GG, Thm. 2] showed how a multinomial function $A(x, y)$ can be explicitly constructed on $[0, 1]^m \times [0, 1]^n$ such that μ and ρ are the unique optimal (mixed) strategies for the abstract multinomial game. The explicit construction of Theorem 2 (of this paper) may then be applied to obtain an extensive form game in $\Omega(m, n)$ which has $A(x, y)$ as its behavioral-normal form. It now follows that μ and ρ , interpreted as finite randomized strategies, are uniquely optimal for the extensive form game.

ON DIFFERENTIAL PURSUIT GAMES*

JIONGMIN YONG†

Abstract. A nonlinear differential pursuit game with a general closed terminal set is studied. Notions of various terminabilities are introduced. These notions include the notions of asymptotic stability, stabilizability and reachability of control systems. By using Lyapunov's direct method, some sufficient conditions for these terminabilities of the game are obtained. As a special case, a linear differential pursuit game with the terminal set as a subspace is discussed as well.

Key words. differential pursuit games, terminability, asymptotic terminability

AMS(MOS) subject classifications. 90D25, 90D26

1. Introduction. Consider a differential game governed by the following system:

$$(1.1) \quad \begin{aligned} \dot{z} &= f(z, u, v), \\ z(0) &= z_0, \end{aligned}$$

where $z \in \mathbb{R}^n$ is the state of the game and $z_0 \in \mathbb{R}^n$ is the initial state, $u \in U \subseteq \mathbb{R}^p$ is the pursuit control and $v \in V \subseteq \mathbb{R}^q$ is the evasion control, $f: \mathbb{R}^n \times U \times V \rightarrow \mathbb{R}^n$ is a given map and the dot above z means the derivative with respect to time t . A nonempty subset M of \mathbb{R}^n is also given. The game is terminated, if at some time $t_0 < \infty$, the state of the game hits M , namely, the trajectory $z(\cdot)$ of (1.1) corresponding to some pair of controls $u(\cdot)$ and $v(\cdot)$ satisfies

$$z(t_0) \in M.$$

Thus, M is called the terminal set of the game.

We denote, for $0 \leq a < b \leq +\infty$, that

$$\begin{aligned} \mathcal{U}[a, b] &= \{u: [a, b] \rightarrow U \mid u \text{ is measurable}\}, \\ \mathcal{V}[a, b] &= \{v: [a, b] \rightarrow V \mid v \text{ is measurable}\}, \\ \mathcal{Z}[a, b] &= \{z: [a, b] \rightarrow \mathbb{R}^n \mid z \text{ is absolutely continuous}\}. \end{aligned}$$

For $b < \infty$, we can define $\mathcal{U}[a, b]$, $\mathcal{V}[a, b]$ and $\mathcal{Z}[a, b]$ in a similar way.

In the game, the pursuer wants to terminate the game by choosing a suitable control $u(\cdot) \in \mathcal{U}[0, \infty)$, while the evader tries to prevent the game from terminating by selecting a proper control $v(\cdot) \in \mathcal{V}[0, \infty)$.

The pursuer is regarded as the "primary" player in a pursuit game, namely, the pursuer has some advantages in choosing his controls. To make it precise, let us introduce the following definition.

DEFINITION 1.1. Let $0 \leq a < b \leq +\infty$, and $U \subseteq \mathbb{R}^p$, $V \subseteq \mathbb{R}^q$ are given. A strategy S on $[a, b]$ is a map from $\mathcal{Z}[a, b] \times \mathcal{V}[a, b]$ to $\mathcal{U}[a, b]$, such that for any $t \in [a, b]$, $z(\cdot) \in \mathcal{Z}[a, b]$ and $v(\cdot) \in \mathcal{V}[a, b]$,

$$(1.2) \quad S(z(\cdot), v(\cdot))(\tau) = S(\hat{z}(\cdot), \hat{v}(\cdot))(\tau) \quad \text{a.e. } \tau \in [a, t],$$

whenever

$$(1.3) \quad \begin{aligned} z(\tau) &= \hat{z}(\tau) \quad \forall \tau \in [a, t], \\ v(\tau) &= \hat{v}(\tau) \quad \text{a.e. } \tau \in [a, t]. \end{aligned}$$

† Department of Mathematics, University of Texas, Austin, Texas 78712. Present address: Department of Mathematics, Fudan University, Shanghai, People's Republic of China.

Moreover, S is called admissible if for any $z_0 \in \mathbb{R}^n$, $v(\cdot) \in \mathcal{V}[a, b]$, there exist $z(\cdot) \in \mathcal{Z}[a, b]$, $u(\cdot) \in \mathcal{U}[a, b]$, such that

$$(1.4) \quad \begin{aligned} \dot{z}(t) &= f(z(t), u(t), v(t)) \quad \text{a.e. } t \in [a, b], \\ z(a) &= z_0, \end{aligned}$$

$$(1.5) \quad u(t) = S(z(\cdot), v(\cdot))(t) \quad \text{a.e. } t \in [a, b].$$

We call the control $u(\cdot)$ determined by (1.5) an outcome of the strategy S . We denote

$$\hat{\mathcal{U}}[a, b] = \{u(\cdot) \in \mathcal{U}[a, b] \mid u(\cdot) \text{ is an outcome of some admissible strategy } S \text{ on } [a, b]\}.$$

The pursuer will take his control from $\hat{\mathcal{U}}[0, \infty)$. We see that, roughly speaking, the pursuer can use the information that $\{z(s), v(s) \mid 0 \leq s \leq t\}$ when choosing the value $u(t)$ of the pursuit control $u(\cdot)$ at time t .

DEFINITION 1.2. A point $z_0 \in \mathbb{R}^n$ is said to be asymptotically terminable, if for any given $v(\cdot) \in \mathcal{V}[0, \infty)$, there exists a $u(\cdot) \in \hat{\mathcal{U}}[0, \infty)$, such that the corresponding trajectory $z(\cdot)$ of (1.1) satisfies

$$(1.6) \quad \lim_{t \rightarrow \infty} d(M, z(t)) = 0,$$

where $d(\cdot, \cdot)$ is the Euclidean distance in \mathbb{R}^n . If (1.6) is replaced by the following:

$$(1.7) \quad z(t_0) \in M \quad \text{for some } t_0 \in [0, \infty),$$

we call z_0 terminable.

We denote

$$C_a(M) = \{z_0 \in \mathbb{R}^n \mid z_0 \text{ is asymptotically terminable}\},$$

$$C(M) = \{z_0 \in \mathbb{R}^n \mid z_0 \text{ is terminable}\}.$$

Trivially, we have

$$(1.8) \quad M \subseteq C(M) \subseteq C_a(M).$$

DEFINITION 1.3. The game (1.1) with terminal set M is said to be:

(i) Locally asymptotically terminable, if there exists a neighborhood \mathcal{N} of M , such that

$$(1.9) \quad \mathcal{N} \subset C_a(M).$$

(ii) s -locally asymptotically terminable, if there exists a $\delta > 0$, such that

$$(1.10) \quad G_0^\delta(M) = \{z \in \mathbb{R}^n \mid 0 \leq d(M, z) < \delta\} \subset C_a(M).$$

(iii) Locally terminable, if there exists a neighborhood \mathcal{N} of M , such that

$$(1.11) \quad \mathcal{N} \subset C(M).$$

(iv) s -locally terminable, if there exists a $\delta > 0$, such that

$$(1.12) \quad G_0^\delta(M) \subset C(M).$$

(v) (Globally) asymptotically terminable, if

$$(1.13) \quad C_a(M) = \mathbb{R}^n.$$

(vi) (Globally) terminable, if

$$(1.14) \quad C(M) = \mathbb{R}^n.$$

Remark 1.4. The following implications about the above definitions are clear:

$$(1.15) \quad \begin{array}{ccccc} (vi) & \Rightarrow & (iv) & \Rightarrow & (iii) \\ \Downarrow & & \Downarrow & & \Downarrow \\ (v) & \Rightarrow & (ii) & \Rightarrow & (i) \end{array}$$

Also, if M is bounded and closed, then

$$(1.16) \quad (i) \Leftrightarrow (ii), \quad (iii) \Leftrightarrow (iv).$$

The problem of various terminabilities introduced above for differential pursuit game (1.1) with general terminal set M is closely related to many control problems and stability problems. First, we can easily see that if both U and V are singletons, then we can refer (i), (ii) and (v) to be the local, s -local and (global) asymptotic stabilities, respectively, of the system to set M . See [2] for similar notions. Second, if V is a singleton, then our problem is just the usual control problem. We can refer (i), (ii) and (v) to be the local, s -local and (global) asymptotic stabilizabilities, respectively, of the system to set M , and (iii), (iv) and (vi) to be the local, s -local and (global) reachabilities, respectively, of the system to set M . See [1], [4], [9] for some similar notions. Finally, regarding $v(\cdot)$ as the uncertain parameter, our problem is related to the problem of stabilizability or reachability of dynamic systems with uncertainty. For relevant results, see [3], [6], [16], for example, and the references cited therein.

The problem of differential pursuit games, especially the linear differential games with terminal set M being a subspace of \mathbb{R}^n has been substantially studied (see [5], [11]–[14] and [18], for example). The purpose of this paper is to give a (unified) way of treating the nonlinear differential pursuit games with general closed terminal set M using Lyapunov's direct method. Thus, our approach is different from those used in [5], [11]–[14]. We will also discuss the case that M is a convex and closed set, in particular the case that M is a subspace and the system is linear.

2. Preliminaries. We denote the Euclidean norm and inner product in \mathbb{R}^n by $|\cdot|$ and (\cdot, \cdot) , respectively. For any smooth function $\Phi(z)$ defined on a domain of \mathbb{R}^n , we denote its gradient by $(\partial\Phi/\partial z)(z)$.

Now, let us make some assumptions.

(A1) The sets $U \subseteq \mathbb{R}^p$ and $V \subseteq \mathbb{R}^q$ are compact. The function $f(z, u, v)$ is continuous in $(z, u, v) \in \mathbb{R}^n \times U \times V$, and there exists a constant $K > 0$, such that

$$(2.1) \quad |f(z, u, v) - f(\hat{z}, u, v)| \leq K|z - \hat{z}| \quad \forall z, \hat{z} \in \mathbb{R}^n, \quad (u, v) \in U \times V.$$

(A2) The set $M \subseteq \mathbb{R}^n$ is nonempty, not equal to \mathbb{R}^n and closed.

(A3) The set M is convex.

Remark 2.1. If (A1) holds and we set hereafter,

$$(2.2) \quad K_1 = K + \max_{(u,v) \in U \times V} |f(0, u, v)|,$$

then, by (2.1), we have

$$(2.3) \quad |f(z, u, v)| \leq K_1(1 + |z|) \quad \forall (z, u, v) \in \mathbb{R}^n \times U \times V.$$

LEMMA 2.2. Suppose (A1) holds. Then for any $u(\cdot) \in \mathcal{U}[0, \infty)$, $v(\cdot) \in \mathcal{V}[0, \infty)$ and $z_0 \in \mathbb{R}^n$, the trajectory $z(\cdot)$ of (1.1) satisfies

$$(2.4) \quad |z(t)| \leq (1 + |z_0|) e^{K_1 t} - 1 \quad \forall t \geq 0,$$

$$(2.5) \quad \max_{(u,v) \in U \times V} |f(z(t), u, v)| \leq K_1(1 + |z_0|) e^{K_1 t} \quad \forall t \geq 0.$$

The proof is straightforward.

Next, let M be a convex and closed subset of \mathbb{R}^n , nonempty, not equal to \mathbb{R}^n . We let ∂M be the boundary of M . For any $x \in \partial M$, we say that a vector

$$\eta \in S^n \equiv \{\eta \in \mathbb{R}^n \mid \|\eta\| = 1\}$$

is an outer normal of M at x if

$$(y - x, \eta) \leq 0 \quad \forall y \in M.$$

We define for any $x \in \partial M$ that

$$N(x) = \{\eta \in S^n \mid \eta \text{ is an outer normal of } M \text{ at } x\}.$$

Then, by the supporting hyperplane theorem, we have that $N(x) \neq \emptyset$ for all $x \in \partial M$. Also, it is clear that, in general, $N(x)$ may contain more than one point. On the other hand, we know that for any $z \in \mathbb{R}^n \setminus M$, there exists a unique $x \in \partial M$, such that

$$(2.6) \quad |z - x| = d(M, z).$$

Thus, the above defines a map $x: \mathbb{R}^n \setminus M \rightarrow \partial M$. About this map, we have the following lemmas.

LEMMA 2.3. For all $z, \hat{z} \in \mathbb{R}^n \setminus M$,

$$(2.7) \quad |x(z) - x(\hat{z})| \leq |z - \hat{z}|.$$

For the proof, see § 32 of [7].

LEMMA 2.4. If we define $\Psi(z) = |z - x(z)|^2$, for $z \in \mathbb{R}^n$, then

$$(2.8) \quad \frac{\partial \Psi}{\partial z}(z) = 2(z - x(z)) \quad \forall z \in \mathbb{R}^n.$$

LEMMA 2.5. For any $z \in \mathbb{R}^n \setminus M$, we define

$$(2.9) \quad \theta(z) = \frac{z - x(z)}{|z - x(z)|}.$$

Then, for any $z, \hat{z} \in G_s^\infty(M) \equiv \{z \in \mathbb{R}^n \mid s \leq d(M, z) < \infty\}$ ($s > 0$)

$$(2.10) \quad |\theta(z) - \theta(\hat{z})| \leq \frac{3}{s} |z - \hat{z}|.$$

The proof of Lemmas 2.4 and 2.5 are straightforward (see [18]).

Now, we return to the case with terminal set M simply being closed. Let $z_0 \in C(M)$. We define

$$\begin{aligned} \mathcal{T}_M(z_0) = \{t \geq 0 \mid \forall v(\cdot) \in \mathcal{V}[0, \infty), \exists u(\cdot) \in \hat{\mathcal{U}}[0, \infty) \\ \text{such that } z(s) \in M, \text{ for some } s \leq t\}, \end{aligned}$$

$$T_M(z_0) = \inf \mathcal{T}_M(z_0).$$

In the case where there is no confusion, we simply denote $\mathcal{T}(z_0) = \mathcal{T}_M(z_0)$ and $T(z_0) = T_M(z_0)$. We call $T(z_0)$ the terminal time of z_0 .

3. Various terminabilities. In this section, we prove the main results of this paper. We divide this section into several subsections.

3.1. Local and s -local terminabilities. We define (cf. (1.6)), for $0 \leq s < \delta \leq +\infty$,

$$G_s^\delta(M) \triangleq \{z \in \mathbb{R}^n \mid s \leq d(M, z) < \delta\}.$$

Our first result is concerned with the s -local terminability of the game.

THEOREM 3.1. Suppose (A1) and (A2) hold. Let there exist constants $\delta, \delta_0, C > 0$ and continuous functions $\omega: (0, \delta] \rightarrow \mathbb{R}^+$, $\Phi: G_0^\delta(M) \rightarrow \mathbb{R}^+$, such that

$$(3.1) \quad \begin{aligned} &\Phi(z) \text{ is nondecreasing with respect to } d(M, z), z \in G_0^\delta(M), \text{ i.e., } \Phi(z) \geq \Phi(\hat{z}), \\ &\text{whenever } d(M, z) \geq d(M, \hat{z}), \text{ for all } z, \hat{z} \in G_0^\delta(M), \end{aligned}$$

$$(3.2) \quad \Phi|_M = 0, \quad \Phi(z) > 0 \quad \forall z \in G_0^\delta(M) \setminus M,$$

$$(3.3) \quad \left| \frac{\partial \Phi}{\partial z}(z) \right| \leq C \quad \forall z \in G_0^\delta(M) \setminus M,$$

$$(3.4) \quad \left| \frac{\partial \Phi}{\partial z}(z) - \frac{\partial \Phi}{\partial z}(\hat{z}) \right| \leq \omega(s)|z - \hat{z}| \quad \forall z, \hat{z} \in G_s^\delta(M), \quad 0 < s < \delta,$$

$$(3.5) \quad \sup_{v \in V} \inf_{u \in U} \left(\frac{\partial \Phi}{\partial z}(z), f(z, u, v) \right) \leq -\delta_0 \quad \forall z \in G_0^\delta(M) \setminus M.$$

Then, the game (1.1) with terminal set M is s -locally terminable with

$$(3.6) \quad G_0^\delta(M) \subset C(M).$$

Moreover, for any $z \in G_0^\delta(M)$, the terminal time

$$(3.7) \quad T(z) \leq \frac{\Phi(z)}{\delta_0}.$$

Proof. Let $z_0 \in G_0^\delta(M) \setminus M$, $0 < \lambda < 1$ and $v(\cdot) \in \mathcal{V}[0, \infty)$ be given. We define the following functions:

$$\begin{aligned} \tau(d) &= \max \{1, d\} \quad \forall d \in \mathbb{R}^+ \equiv [0, \infty), \\ F(z, \tau) &= K_1(1 + |z|) e^{K_1 \tau} \quad \forall (z, \tau) \in \mathbb{R}^n \times \mathbb{R}^+, \\ t(d, F) &= \min \left\{ \frac{(1-\lambda)d}{1+F}, \frac{(1-\lambda)\delta_0}{\omega(\lambda d)F^2 + CKF} \right\} \quad \forall (d, F) \in \mathbb{R}^+ \times \mathbb{R}^+, \end{aligned}$$

where K_1 is determined by (2.2). We denote $d_0 = d(M, z_0)$, $F_0 = F(z_0, \tau(d_0))$, $t_0 = t(d_0, F_0)$. Let $u(\cdot) \in \hat{\mathcal{U}}[0, t_0]$ be such that

$$(3.8) \quad \left(\frac{\partial \Phi}{\partial z}(z_0), f(z_0, u(t), v(t)) \right) \leq -\delta_0 \quad \text{a.e. } t \in (0, t_0).$$

Then, we claim that for the trajectory $z(\cdot)$ of (1.1) corresponding to $u(\cdot)$ and $v(\cdot)$, we have

$$(3.9) \quad z(t) \in G_{\lambda d_0}^\delta(M), \quad t \in [0, t_0].$$

In fact, since $t_0 \leq (1-\lambda)d_0/(1+F_0) \leq d_0 \leq \tau(d_0)$, by (2.5), we have

$$(3.10) \quad d(M, z(t)) \geq d(M, z_0) - F_0 t_0 \geq \lambda d_0 \quad \forall t \in [0, t_0].$$

On the other hand, if (3.9) were not true, then there would exist $\hat{t} \in [0, t_0]$, such that

$$(3.11) \quad d(M, z(\hat{t})) = \delta, \quad d(M, z(t)) < \delta \quad \forall t \in [0, \hat{t}).$$

Then, by (3.8), (3.10) and our assumptions, we have

$$\begin{aligned} \frac{d}{dt} \Phi(z(t)) &= \left(\frac{\partial \Phi}{\partial z}(z_0), f(z_0, u(t), v(t)) \right) \\ &\quad + \left(\frac{\partial \Phi}{\partial z}(z(t)) - \frac{\partial \Phi}{\partial z}(z_0), f(z(t), u(t), v(t)) \right) \\ &\quad + \left(\frac{\partial \Phi}{\partial z}(z_0), f(z(t), u(t), v(t)) - f(z_0, u(t), v(t)) \right) \\ &\leq -\delta_0 + \omega(\lambda d_0) F_0^2 t + CK F_0 t \\ &\leq -\lambda \delta_0 \quad \forall t \in [0, \hat{t}). \end{aligned}$$

Hence, it follows that

$$(3.12) \quad \Phi(z(t)) \leq \Phi(z_0) - \lambda \delta_0 t, \quad t \in [0, \hat{t}).$$

By (3.1), we then have that

$$d(M, z(t)) \leq d(M, z_0) < \delta \quad \forall t \in [0, \hat{t}).$$

Thus, we end up with a contradiction to (3.11). Hence (3.9) holds. Then, from the above argument, we obtain

$$\Phi(z(t_0)) \leq \Phi(z_0) - \lambda \delta_0 t_0.$$

Set $z_1 = z(t_0)$, $d_1 = d(M, z_1)$. Repeating the above procedure, we have

$$z(t) \in G_{\lambda d_1}^\delta(M), \quad t \in [t_0, t_1],$$

$$\Phi(z(t_1)) \leq \Phi(z_1) - \lambda \delta_0(t_1 - t_0)$$

for $t_1 = t_0 + t(d_1, F_1)$, $F_1 = F(z_1, \tau(d_1))$. In general, we have, for some $u(\cdot) \in \hat{\mathcal{U}}[0, \infty)$, that for $k = 0, 1, 2, \dots$

$$z_k = z(t_{k-1}), \quad z_0 \text{ given,}$$

$$(3.13) \quad d_k = d(M, z_k), \quad F_k = F(z_k, \tau(d_k)), \quad t_k = t_{k-1} + t(d_k, F_k),$$

$$z(t) \in G_{\lambda d_k}^\delta(M), \quad t \in [t_{k-1}, t_k],$$

$$(3.14) \quad \Phi(z(t_k)) \leq \Phi(z_k) - \lambda \delta_0(t_k - t_{k-1}) \leq \dots \leq \Phi(z_0) - \lambda \delta_0 t_k.$$

Then, from (3.14), we see that (note $\Phi \geq 0$)

$$t_k \leq \frac{\Phi(z_0)}{\lambda \delta_0} \quad \forall k \geq 0.$$

Thus, we can assume that

$$(3.15) \quad \lim_{k \rightarrow \infty} t_k = \tilde{t} \in \left[0, \frac{\Phi(z_0)}{\lambda \delta_0}\right].$$

By (3.1), we see that $\{d_k\}$ is nonincreasing. Thus,

$$\lim_{k \rightarrow \infty} d_k = \tilde{d} \geq 0$$

exists. We claim that $\tilde{d} = 0$. Suppose the contrary, i.e., $\tilde{d} > 0$. Then, we let

$$\tilde{\omega} = \max \{ \omega(\gamma) \mid \gamma \in [\lambda \tilde{d}, \delta] \} < \infty,$$

$$\tilde{F} = F(z_0, \tilde{t}) < \infty.$$

Then, it is clear that for any $k \geq 0$,

$$t(d_k, F_k) \geq \min \left\{ \frac{(1-\lambda)\tilde{d}}{1+\tilde{F}}, \frac{(1-\lambda)\delta_0}{\tilde{\omega}\tilde{F}^2 + CK\tilde{F}} \right\} > 0.$$

This is a contraction to (3.15). Thus $\tilde{d} = 0$, and

$$d(M, z(\tilde{t})) = \lim_{k \rightarrow \infty} d(M, z(t_k)) = 0,$$

i.e., $z(\hat{t}) \in M$. Thus obtain (3.6). Finally, from (3.15), we have

$$T(z_0) \leq \frac{\Phi(z_0)}{\lambda \delta_0}.$$

Sending $\lambda \rightarrow 1$, we get (3.7). \square

Remark 3.2. It is easy to see that in the above proof, only some local arguments have been used. Thus, some of the conditions in Theorem 3.1 can be slightly relaxed. For example, the constant C in (3.3) can be replaced by a continuous function $C: G_0^\delta(M) \rightarrow \mathbb{R}^+$. The relaxation of condition (3.5) is a little interesting. To state the relaxed condition, let us set

$$(3.16) \quad \sigma(R) = - \sup_{\substack{z \in G_0^\delta(M) \setminus M \\ |z| \leq R}} \sup_{v \in V} \inf_{u \in U} \left(\frac{\partial \Phi}{\partial z}(z), f(z, u, v) \right), \quad R > 0.$$

Then, the relaxed conditions states as follows: There exists a continuous function $\sigma_0: G_0^\delta(M) \rightarrow [0, \infty)$ such that

$$(3.5') \quad -\sigma((1+|z|) e^{K_1(\Phi(z)/\sigma_0(z))} - 1) \leq -\sigma_0(z) \quad \forall z \in G_0^\delta(M)$$

where K_1 is determined by (2.2). It is clear that the proof of Theorem 3.1 applies if we replace δ_0 by $\sigma_0(z_0)$, and (3.5) implies (3.5') with $\sigma_0(z) \equiv \delta_0$. The above idea leads to the following result.

THEOREM 3.3. *Let \mathcal{N} be a neighborhood of M . Suppose all the assumptions of Theorem 3.1, except (3.1) and (3.5), hold with $G_0^\delta(M)$ replaced by \mathcal{N} . Let $\sigma(R)$ be defined as in (3.16) with $G_0^\delta(M)$ replaced by \mathcal{N} and*

$$(3.5'') \quad \sigma(R) < 0 \quad \forall R > 0.$$

Then the game (1.1) with terminal set M is locally terminable.

Proof. We define

$$(3.17) \quad \rho(z) = \sup \{ \rho > 0 \mid \mathcal{O}(z, \rho) \subset \mathcal{N} \}, \quad \mathcal{O}(z, \rho) \equiv \{ \hat{z} \in \mathbb{R}^n \mid |z - \hat{z}| < \rho \},$$

$$(3.18) \quad \mathcal{N}_0 = \left\{ z \in \mathcal{N} \mid \rho(z) > \frac{2\Phi(z)}{\sigma(|z|)}, -\sigma((1+|z|) e^{K_1(2\Phi(z)/\sigma(|z|))} - 1) \leq -\frac{\sigma(|z|)}{2} \right\}.$$

Then, it is not hard to see that \mathcal{N}_0 contains an open neighborhood of M . We claim that $\mathcal{N}_0 \subset C(M)$. In fact, for any $z_0 \in \mathcal{N}_0 \setminus M$, by arguments similar to those used in the proof of Theorem 3.1, we can get $z_0 \in C(M)$ and

$$T(z_0) \leq \frac{2\Phi(z_0)}{\sigma(|z_0|)}.$$

Hence, by definition, the game is locally terminable. \square

We should note that in the proof of $d_k \rightarrow 0$, we do not need the monotonicity of $\Phi(\cdot)$. The monotonicity of $\Phi(\cdot)$ in Theorem 3.1 is only needed to guarantee (3.9). While in the proof of Theorem 3.3, by letting $z_0 \in \mathcal{N}_0$, we automatically have $z(t) \in \mathcal{N}$ for $t \leq 2\Phi(z_0)/\sigma(|z_0|)$. Thus, we do not need the monotonicity of $\Phi(\cdot)$ in Theorem 3.3.

Now, let us give some consequences of the above.

COROLLARY 3.4. *Suppose (A1)–(A3) hold. Suppose there exists a $\delta_0 > 0$, such that*

$$(3.19) \quad \sup_{\substack{\eta \in N(x) \\ x \in \partial M}} \sup_{v \in V} \inf_{u \in U} (\eta, f(x, u, v)) \leq -\delta_0.$$

Then, the game (1.1) with terminal set M is s -locally terminable, with

$$(3.20) \quad G_0^{\delta_0/K}(M) \subset C(M).$$

Moreover, for any $z \in G_0^{\delta_0/K}(M)$,

$$(3.21) \quad T(z) \leq \frac{Kd(M, z)}{\delta_0 - Kd(M, z)}.$$

Proof. Let

$$\Phi(z) = d(M, z) \equiv |z - x(z)| \quad \forall z \in \mathbb{R}^n.$$

Then, by Lemma 2.4,

$$\frac{\partial \Phi}{\partial z}(z) = \theta(z) \equiv \frac{z - x(z)}{|z - x(z)|} \in N(x(z)).$$

Thus, (3.2)–(3.4) hold with $C = 1$ and $\omega(s) = 3/s$ (note Lemma 2.5). Next,

$$\begin{aligned} \sup_{v \in V} \inf_{u \in U} \left(\frac{\partial \Phi}{\partial z}(z), f(z, u, v) \right) &= \sup_{v \in V} \inf_{u \in U} \{ (\theta(z), f(x(z), u, v)) \\ &\quad + (\theta(z), f(z, u, v) - f(x(z), u, v)) \} \\ &\leq -\delta_0 + Kd(M, z). \end{aligned}$$

Hence, for any $\varepsilon \in (0, \delta_0/K)$, we have

$$\sup_{v \in V} \inf_{u \in U} \left(\frac{\partial \Phi}{\partial z}(z), f(z, u, v) \right) \leq -(\delta_0 - \varepsilon) < 0 \quad \forall z \in G_0^\varepsilon(M).$$

Thus, by Theorem 3.1, $G_0^\varepsilon(M) \subset C(M)$. Sending $\varepsilon \rightarrow \delta_0/K$, we get (3.20). Finally, (3.21) follows from (3.7) and the above arguments. \square

COROLLARY 3.5. *Suppose (A1)–(A3) hold. Suppose*

$$(3.22) \quad \sup_{\eta \in N(x)} \sup_{v \in V} \inf_{u \in U} (\eta, f(x, u, v)) < 0 \quad \forall x \in \partial M.$$

Then, the game (1.1) with terminal set M is locally terminable.

Proof. Since $(\eta, f(x, u, v))$ is Lipschitz continuous in x , uniformly in η, u, v , we obtain that

$$\sup_{\substack{|x| \leq R \\ x \in \partial M}} \sup_{\eta \in N(x)} \sup_{v \in V} \inf_{u \in U} (\eta, f(x, u, v)) < 0 \quad \forall R > 0.$$

Then, as in the proof of Corollary 3.4, by using Theorem 3.3, we can get the conclusion.

3.2. Local and s -local asymptotic terminability. We note that if $f(z, u, v) = 0$ for $z \in M$, then all the results of § 3.1 do not apply. In this section, we will discuss the situation allowing $f(z, u, v) = 0$ for $z \in M$. The Lyapunov functions we are going to use in this section will be different from those in § 3.1.

THEOREM 3.6. *Suppose (A1) and (A2) hold. Let there exist a constant $\varepsilon > 0$, a neighborhood \mathcal{N} of M and continuous functions $\mu: \mathbb{R}^+ \rightarrow \mathbb{R}^+$, $\Psi: \mathcal{N} \rightarrow \mathbb{R}^+$, such that*

$$(3.23) \quad \mu \text{ is nondecreasing, } \mu(0) = 0, \quad \mu(\gamma) > 0 \quad \forall \gamma > 0,$$

$$(3.24) \quad \Psi(z) > 0 \quad \forall z \in \mathcal{N} \setminus M, \quad \Psi|_M = 0,$$

$$(3.25) \quad \mathcal{N}_\varepsilon \equiv \{z \in \mathbb{R}^n \mid \Psi(z) \leq \varepsilon\} \subset \mathcal{N},$$

$$(3.26) \quad \frac{\partial \Psi}{\partial z}(\cdot) \in C(\overline{\mathcal{N} \setminus M}),$$

$$(3.27) \quad \sup_{v \in V} \inf_{u \in U} \left(\frac{\partial \Psi}{\partial z}(z), f(z, u, v) \right) \leq -\mu(d(M, z)) \quad \forall z \in \mathcal{N} \setminus M.$$

Then, the game (1.1) with terminal set M is locally asymptotically terminable with $\mathcal{N}_\varepsilon \subset C_a(M)$. Moreover, suppose instead of (3.25); we have, for some $\delta > 0$, that

$$(3.25') \quad G_0^\delta(M) \subset \mathcal{N}_\varepsilon \subset \mathcal{N}.$$

Then, the game (1.1) with terminal set M is s -locally asymptotically terminable with $G_0^\delta(M) \subset C_a(M)$.

Proof. Let $z_0 \in \mathcal{N}_\varepsilon \setminus M$ and $v(\cdot) \in \mathcal{V}[0, \infty)$ be given. Denote

$$d_0 = d(M, z_0), \quad \tau_0 = \frac{2\Psi(z_0)}{\mu(d_0/2)}.$$

We claim that there exist a $t_0 \in [0, \tau_0]$ and a $u(\cdot) \in \hat{\mathcal{U}}[0, t_0]$, such that the trajectory $z(\cdot)$ of (1.1) corresponding to $u(\cdot)$ and $v(\cdot)$ satisfies

$$(3.28) \quad d(M, z(t_0)) \leq \frac{d_0}{2}.$$

Suppose it is not the case. Then, we have for any $u(\cdot) \in \hat{\mathcal{U}}[0, \infty)$,

$$(3.29) \quad d(M, z(t)) > \frac{d_0}{2} \quad \forall t \in [0, \tau_0].$$

Now, we set

$$F_0 = K_1(1 + |z_0|) e^{K_1 \tau_0}.$$

Let $\omega_0(\cdot)$ be the modulus of continuity of $(\partial\Psi/\partial z)(z)$ on the set $\{z \in \overline{\mathcal{N} \setminus M} \mid |z| \leq (1 + |z_0|) e^{K_1 \tau_0} - 1\}$. Then, we define

$$(3.30) \quad \hat{t} = \sup \left\{ t \leq \tau_0 \mid \omega_0\left(\frac{d_0 F_0 t}{2}\right) F_0 + CK F_0 t \leq \frac{1}{2} \mu\left(\frac{d_0}{2}\right) \right\} > 0.$$

Then, similar to the proof of Theorem 3.1, we can find a $u(\cdot) \in \hat{\mathcal{U}}[0, \hat{t}]$, such that $z(t) \in \mathcal{N}$ for $t \in [0, \hat{t}]$ due to (3.25) and

$$\Psi(z(\hat{t})) \leq \Psi(z_0) - \frac{1}{2} \mu\left(\frac{d_0}{2}\right) \hat{t}.$$

Thus, the procedure can be repeated. Since \hat{t} only depends on τ_0 and z_0 , noting (3.29), we see that by repeating finitely many times of the above procedure, we will have the following:

$$\Psi(z(\tau_0)) \leq \Psi(z_0) - \frac{1}{2} \mu\left(\frac{d_0}{2}\right) \tau_0 = 0.$$

Thus, $z(\tau_0) \in M$ which contradicts (3.29). Hence (3.28) holds. Then, replacing z_0 by $z_1 \equiv z(t_0)$, we can repeat the above arguments. By induction, we see that $z_0 \in C_a(M)$. Hence, we obtain the local asymptotic terminability. It is clear that if we have (3.25'), then the above argument gives us that $G_0^\delta(M) \subset C_a(M)$. Hence, we have the s -local asymptotic terminability of the game. \square

The following result is well known (see [2, p. 135], for example).

COROLLARY 3.7. *Suppose (A1) and (A2) hold with U and V being singletons and M being bounded. Let there exist a neighborhood \mathcal{N} of M and a continuous function $\Psi: \mathcal{N} \rightarrow \mathbb{R}^+$ satisfying (3.24) and (3.26). Also, we assume that (let $f(z) \equiv f(z, U, V)$)*

$$(3.27') \quad \left(\frac{\partial\Psi}{\partial z}(z), f(z) \right) < 0 \quad \forall z \in \mathcal{N} \setminus M.$$

Then, the system (1.1) with terminal set M is (locally) asymptotically stable.

Proof. Since M is compact, we can easily define a continuous function $\mu(\cdot)$ satisfying (3.23) and

$$(3.27'') \quad \left(\frac{\partial \Psi}{\partial z}(z), f(z) \right) \leq -\mu(d(M, z)) \quad \forall z \in \mathcal{N} \setminus M.$$

Also, we can find $\varepsilon, \delta > 0$, such that (3.25') holds. Then Theorem 3.6 applies. \square

Remark 3.8. In the case where V is a singleton, Theorem 3.6 gives a sufficient condition for stabilizing system (1.1) to set M . In particular, for M being compact, we have a result similar to Corollary 3.7 for the stabilization of the system (1.1) to M .

The next result says that if in Theorem 3.6, $\Psi(z)$ goes to zero (as $d(M, z) \rightarrow 0$) much faster than $\mu(d(M, z))$ does, then we can have local (s -local) terminability of the game.

COROLLARY 3.9. *Suppose (A1) and (A2) hold. Let there exist a constant $\varepsilon > 0$, a neighborhood \mathcal{N} of M and continuous functions $\beta, \mu: \mathbb{R}^+ \rightarrow \mathbb{R}^+, \Psi: \mathcal{N} \rightarrow \mathbb{R}^+$, such that (3.23)–(3.27) hold. $\beta(\cdot)$ also satisfies (3.23) and*

$$(3.31) \quad \Psi(z) \leq \beta(d(M, z)) \quad \forall z \in \mathcal{N}.$$

In addition, we assume that there exists a sequence of decreasing positive numbers $\{d_k\}$ such that

$$(3.32) \quad \lim_{k \rightarrow \infty} d_k = 0, \quad d_0 = \varepsilon,$$

$$(3.33) \quad \sum_{k=0}^{\infty} \frac{\beta(d_k)}{\mu(d_{k+1})} < \infty.$$

Then, the game (1.1) with terminal set M is locally terminable with $\mathcal{N}_\varepsilon \subset C(M)$, and for any $z_0 \in \mathcal{N}_\varepsilon$, if $d_{k+1} < d(M, z_0) \leq d_k$, then

$$(3.34) \quad T(z_0) \leq 2 \sum_{i=k}^{\infty} \frac{\beta(d_i)}{\mu(d_{i+1})}.$$

Furthermore, if there exists a $\delta > 0$, such that (3.25') holds, then the game (1.1) with terminal set M is s -locally terminable with $G_0^\delta(M) \subset C(M)$.

Proof. Let $z_0 \in \mathcal{N}_\varepsilon \setminus M$, $v(\cdot) \in \mathcal{V}[0, \infty)$ be given. Let

$$\tau_0 = \frac{2\Psi(z_0)}{\mu(d_1)}.$$

Then, as in the proof of Theorem 3.6, we have that there exist $t_0 \in [0, \tau_0]$ and $u(\cdot) \in \hat{\mathcal{U}}[0, t_0]$, such that

$$d(M, z(t_0)) \leq d_1.$$

Set $z_1 = z(t_0)$, and repeat the procedure. In general, we have ($t_{-1} \triangleq 0$)

$$z_k = z(t_{k-1}), \quad \tau_k = \frac{2\Psi(z_k)}{\mu(d_{k+1})}, \quad t_k = t_{k-1} + \tau_k,$$

$$d(M, z_k) \leq d_k, \quad k = 0, 1, 2, \dots$$

Then, by (3.31) and (3.33), we have

$$t_k = 2 \sum_{i=0}^k \frac{\Psi(z_i)}{\mu(d_{i+1})} \leq 2 \sum_{i=0}^{\infty} \frac{\beta(d_i)}{\mu(d_{i+1})} < \infty.$$

Hence, $\lim_{k \rightarrow \infty} t_k$ exists and it is easy to see that $z_0 \in C(M)$. The remaining assertions follow immediately. \square

To close this section, we give some consequences of the above results for the case that M is convex.

COROLLARY 3.10. *Suppose (A1)–(A3) hold. Let there exist a constant $\delta > 0$, a continuous function $\hat{\mu} : \mathbb{R}^+ \rightarrow \mathbb{R}^+$, satisfying (3.23), such that*

$$(3.35) \quad \sup_{v \in V} \inf_{u \in U} (\theta(z), f(z, u, v)) \leq -\hat{\mu}(d(M, z)) \quad \forall z \in G_0^\delta(M) \setminus M,$$

where $\theta(z) \equiv (z - x(z))/(|z - x(z)|)$. (See § 2.) Then, the game (1.1) with terminal set M is s -locally asymptotically terminable with $G_0^\delta(M) \subset C(M)$. Moreover, if there exist $c > 0$, $0 < \alpha < 1$, such that

$$(3.36) \quad \hat{\mu}(\gamma) \geq c\gamma^\alpha \quad \forall \gamma \in [0, \delta],$$

then the game (1.1) with terminal set M is s -locally terminable with $G_0^\delta(M) \subset C(M)$.

Proof. Let $\Psi(z) = d(M, z)^2 \equiv |z - x(z)|^2$. Then, (3.24) and (3.26) are satisfied. By (3.35), we have (note Lemma 2.4)

$$\sup_{v \in V} \inf_{u \in U} \left(\frac{\partial \Psi}{\partial z}(z), f(z, u, v) \right) \leq -d(M, z)\hat{\mu}(d(M, z)) \quad \forall z \in G_0^\delta(M).$$

Thus, by Theorem 3.6, we have $G_0^\delta(M) \subset C_a(M)$.

Now, if (3.36) holds, then we let

$$d_k = \frac{1}{k^m}, \quad m > \frac{1}{1-\alpha}, \quad k \geq k_0.$$

Then, with $\beta(d) = d^2$, $\mu(d) = \hat{\mu}(d)d$, we have

$$\frac{\beta(d_k)}{\mu(d_{k+1})} \leq \frac{1}{c} \frac{d_k^2}{d_{k+1}^{1+\alpha}} = \frac{1}{c} \left(\frac{k+1}{k} \right)^{m(1+\alpha)} \frac{1}{k^{m(1-\alpha)}} \leq \frac{2^{m(1+\alpha)}}{c} \frac{1}{k^{m(1-\alpha)}}.$$

Hence, $\sum_{k \geq k_0} \beta(d_k)/\mu(d_{k+1}) < \infty$ and Corollary 3.9 applies. \square

3.3. Global terminabilities and remarks. In this section, we will briefly discuss the global (asymptotic) terminability of the game. The results are essentially the consequences of those in §§ 3.1 and 3.2.

PROPOSITION 3.11. *Suppose all the assumptions of Theorem 3.1 hold for a sequence of $\delta = \delta_k > 0$, with $\lim_{k \rightarrow \infty} \delta_k = +\infty$. Then, the game (1.1) with terminal set M is terminable and for any $z \in \mathbb{R}^n$, (3.7) holds.*

PROPOSITION 3.12. *Suppose all the assumptions of Theorem 3.6 hold with $\mathcal{N} = \mathbb{R}^n$. Then the game (1.1) with terminal set M is asymptotically terminable. Furthermore, suppose (3.31) holds in $\mathcal{N} = \mathbb{R}^n$ for some $\beta(\cdot)$ satisfying (3.23) and there exists a sequence $\{d_k\}_{k=-\infty}^\infty$, such that*

$$(3.32') \quad \begin{aligned} d_{k+1} &< d_k \quad \forall k = 0, \pm 1, \pm 2, \dots, \\ \lim_{k \rightarrow +\infty} d_k &= 0, \quad \lim_{k \rightarrow -\infty} d_k = +\infty, \end{aligned}$$

$$(3.33') \quad \sum_{k=-\infty}^{\infty} \frac{\beta(d_k)}{\mu(d_{k+1})} < \infty.$$

Then, the game (1.1) with terminal set M is terminable.

The proofs of the above two propositions are obvious.

To close this section, let us make the following remarks. In the proofs of Corollaries 3.4, 3.5 and 3.10, we have given the prototypes of the Lyapunov functions used in

Theorems 3.1, 3.3 and 3.6, respectively, namely, $\Phi(M, z) = d(M, z)$ and $\Psi(M, z) = d(M, z)^2$. Each of them has different advantages. We can see this from Corollaries 3.4, 3.5 and 3.10. It seems possible that we can give results as in Theorems 3.1 and 3.3 by using Lyapunov functions of type Ψ used in § 3.2 instead of type Φ used in § 3.1. But the proofs will be different since $\partial\Psi/\partial z = 0$ for $z \in M$. Also, it seems to us that if we used Ψ instead of Φ , then the corresponding result of Corollary 3.4 would not be as neat as the present Corollary 3.4, especially for (3.21).

Finally, we see that in the proofs of our above results, the basic idea is Lyapunov's direct method. Since in our case, we have an evader control $v(\cdot)$ in the system and our pursuit control $u(\cdot)$ is restricted to be in $\mathcal{U}[0, \infty)$, the proofs become a little bit difficult. The same idea was also used in a previous paper on differential evasion games [17].

4. Linear cases. In this section, we discuss the case that $f(z, u, v)$ is of form $Az + g(u, v)$.

4.1. The case $M = \{0\}$. Let us consider the following system:

$$(4.1) \quad \begin{aligned} \dot{z} &= Az + g(u, v), \\ z(0) &= z_0, \end{aligned}$$

where A is an $(n \times n)$ -matrix, $g: U \times V \rightarrow \mathbb{R}^n$ is a continuous function, $U \subseteq \mathbb{R}^p$ and $V \subseteq \mathbb{R}^q$ are compact sets, and the terminal set $M = \{0\}$. It is clear that in this case, (A1)–(A3) hold, and

$$(4.2) \quad N(0) = S^n \equiv \{\eta \in \mathbb{R}^n \mid |\eta| = 1\}.$$

We denote by $\sigma(A)$ the spectrum of A , A^* the conjugate of A , and $\operatorname{Re} \sigma(A) \triangleq \{\operatorname{Re} \lambda \mid \lambda \in \sigma(A)\}$. By $\operatorname{Re} \sigma(A) \leq a$, we mean that $\sigma(A) \subseteq \{\lambda \in \mathbb{C} \mid \operatorname{Re} \lambda \leq a\}$. The meaning of $\operatorname{Re} \sigma(A) < a$ is similar. The following result is concerned with some necessary conditions for certain terminabilities.

THEOREM 4.1. *Suppose $\delta > 0$, such that*

$$(4.3) \quad G_0^\delta(M) \subset C_a(M),$$

namely, the game is s -locally asymptotically terminable. Then,

$$(4.4) \quad \operatorname{Re} \sigma(A) \leq \frac{1}{\delta} \inf_{v \in V} \sup_{u \in U} |g(u, v)|.$$

In particular, if the game is (globally) asymptotically terminable, then,

$$(4.5) \quad \operatorname{Re} \sigma(A) \leq 0.$$

Proof. Since $g(\cdot, \cdot)$ is continuous and U and V are compact, we have $v_0 \in V$, such that

$$(4.6) \quad \gamma \triangleq \inf_{v \in V} \sup_{u \in U} |g(u, v)| = \sup_{u \in U} |g(u, v_0)|.$$

We let $\lambda = \max \operatorname{Re} \sigma(A)$. Suppose (4.4) is not true, i.e.,

$$(4.7) \quad \lambda > \frac{\gamma}{\delta} \geq 0.$$

Case 1. $\lambda \in \sigma(A)$. Then there exists an $\eta \in S^n$, such that

$$A^* \eta = \lambda \eta.$$

Now, let the evader take control $v(t) \equiv v_0$, and let the initial point satisfy

$$(4.8) \quad z_0 = \alpha \eta, \quad \alpha \in \left(\frac{\gamma}{\lambda}, \delta \right).$$

Then, $z_0 \in G_0^\delta(M) \subset C_a(M)$. But, for any $u(\cdot) \in \mathcal{U}[0, \infty)$, we have

$$\begin{aligned} d(M, z(t)) &= |z(t)| \geq |(\eta, z(t))| \\ &= \left| \left(\eta, e^{At} z_0 + \int_0^t e^{A(t-\tau)} g(u(\tau), v_0) d\tau \right) \right| \\ &\geq \alpha e^{\lambda t} - \gamma \int_0^t e^{\lambda(t-\tau)} d\tau \\ &\geq \left(\alpha - \frac{\gamma}{\lambda} \right) e^{\lambda t} \geq \alpha - \frac{\gamma}{\lambda} > 0 \quad \forall t \geq 0. \end{aligned}$$

This means that $z_0 \notin C_a(M)$, which is a contradiction.

Case 2. $\lambda \pm \mu i \in \sigma(A)$, $\mu > 0$. Then we can find $\xi, \zeta \in \mathbb{R}^n$, such that they are linearly independent and

$$(4.9) \quad A^*(\xi, \zeta) = (\xi, \zeta) \begin{pmatrix} \lambda & -\mu \\ \mu & \lambda \end{pmatrix}.$$

Set $L = \text{span} \{ \xi, \zeta \}$. By choosing a suitable basis for $L \oplus L^\perp \equiv \mathbb{R}^n$, we have that

$$A = \begin{pmatrix} \hat{A} & 0 \\ * & * \end{pmatrix}, \quad g = \begin{pmatrix} \hat{g} \\ * \end{pmatrix}, \quad z = \begin{pmatrix} \hat{z} \\ \tilde{z} \end{pmatrix},$$

where $*$ stands for the entries which will not concern us, and

$$\hat{A} = \lambda I + \mu J, \quad I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

By applying the orthogonal projection P_L to (4.1), we get

$$(4.10) \quad \begin{aligned} \hat{z} &= \hat{A} \hat{z} + \hat{g}(u, v), \\ \hat{z}(0) &= \hat{z}_0. \end{aligned}$$

Again, let the evader take $v(t) \equiv v_0$. Take the initial point to be

$$(4.11) \quad z_0 = \begin{pmatrix} \hat{z}_0 \\ 0 \end{pmatrix}, \quad \frac{\gamma}{\lambda} < |\hat{z}_0| < \delta.$$

Then, $z_0 \in G_0^\delta(M) \subset C_a(M)$. But for any $u(\cdot) \in \mathcal{U}[0, \infty)$, we have

$$\begin{aligned} d(M, z(t)) &= |z(t)| \geq |\hat{z}(t)| \\ &= \left| e^{\hat{A}t} \hat{z}_0 + \int_0^t e^{\hat{A}(t-\tau)} \hat{g}(u(\tau), v_0) d\tau \right| \\ &\geq |e^{\lambda t} e^{\mu J t} \hat{z}_0| - \int_0^t e^{\lambda(t-\tau)} |e^{bJ(t-\tau)} \hat{g}(u(\tau), v_0)| d\tau \\ &\geq e^{\lambda t} |\hat{z}_0| - \gamma \int_0^t e^{\lambda(t-\tau)} d\tau \geq |\hat{z}_0| - \frac{\gamma}{\lambda} > 0 \quad \forall t \geq 0, \end{aligned}$$

which contradicts $z_0 \in C_a(M)$. Hence, we must have (4.4). It is clear that if (4.4) holds for all $\delta > 0$, then (4.5) holds. Thus, the last assertion of the theorem holds. \square

By (1.15), we see that Theorem 4.1 holds if we delete the word "asymptotically" in the theorem. Next, we consider some sufficient conditions.

THEOREM 4.2. *Suppose there exist $\gamma > 0$ and an $(n \times r)$ -matrix B , such that $[A, B]$ is completely controllable and*

$$(4.12) \quad \gamma B(B'_1(0)) \subset \bigcap_{v \in V} g(U, v),$$

where $B'_1(0) \triangleq \{z \in \mathbb{R}^r \mid \|z\| \leq 1\}$. Then, the game is s -locally terminable. Furthermore, if (4.5) holds, then the game is terminable.

To prove this theorem, let us first give the following lemma.

LEMMA 4.3. *Suppose the system $[A, B]$ is completely controllable. Then for any $\gamma > 0$,*

$$(4.13) \quad 0 \in \text{Int} \bigcup_{t \geq 0} \left\{ \int_0^t e^{-A\tau} B w(\tau) d\tau \mid |w(\tau)| \leq \gamma \right\}.$$

Moreover, if (4.5) holds, then

$$(4.14) \quad \bigcup_{t \geq 0} \left\{ \int_0^t e^{-A\tau} B w(\tau) d\tau \mid |w(\tau)| \leq \gamma \right\} = \mathbb{R}^n.$$

For the proof see Chapter 6 of [9] and Chapter 4 of [15].

Proof of Theorem 4.2. Since $[A, B]$ is completely controllable, by (4.12) and (4.13), we get

$$(4.15) \quad M = \{0\} \subseteq \text{Int } C(M).$$

Thus, the game is locally terminable. Then, by Remark 1.4, the game is also s -locally terminable. Now, if (4.5) holds, then by using (4.12) and (4.14), we can get that the game is terminable. \square

Actually, the result of Theorem 4.2 is not new. It is just a version of Lemma 4.3 for differential pursuit games.

THEOREM 4.4. *Suppose that*

$$(4.16) \quad \text{Re } \sigma(A) < 0,$$

$$(4.17) \quad 0 \in \bigcap_{v \in V} \text{Co } g(U, v),$$

where $\text{Co } g(U, v)$ is the convex hull of $g(U, v)$. Then, the game is asymptotically terminable.

To prove this theorem, we need the following lemma.

LEMMA 4.5. *Let $p_1(t), \dots, p_m(t)$ be measurable, bounded functions defined on $[0, T]$, with values in \mathbb{R}^r . Let $\mu_1(t), \dots, \mu_m(t)$ be measurable nonnegative scalar functions defined on $[0, T]$, satisfying $\sum_{i=1}^m \mu_i(t) = 1$. Then for any $\varepsilon > 0$, there exists a measurable function $p(\cdot)$ with values $p(t)$ in the set $\{p_1(t), \dots, p_m(t)\}$ at any $t \in [0, T]$, and the value $p(t)$ of $p(\cdot)$ at time t only depends on $\{\mu_i(s), p_i(s) \mid s \leq t, 1 \leq i \leq m\}$, such that*

$$(4.18) \quad \left| \int_0^t \left[\sum_{i=1}^m \mu_i(\tau) p_i(\tau) - p(\tau) \right] d\tau \right| \leq \varepsilon \quad \forall t \in [0, T].$$

For the proof, see [8].

Proof of Theorem 4.4. For any $z_0 \in \mathbb{R}^n \setminus M \equiv \mathbb{R}^n \setminus \{0\}$ and any $v(\cdot) \in \mathcal{V}[0, \infty)$, by (4.17), we have $u_1(\cdot), \dots, u_{n+1}(\cdot) \in \mathcal{U}[0, \infty)$, such that

$$0 = \sum_{i=1}^{n+1} \mu_i(\tau) e^{-A\tau} g(u_i(\tau), v(\tau)), \quad \tau \in [0, \infty),$$

where $\mu_i(\tau) \geq 0$, $\sum_{i=1}^{n+1} \mu_i(\tau) = 1$. Then, by Lemma 4.5, we see that there exists a $\hat{u}(\cdot) \in \mathcal{U}[0, \infty)$, such that for $k \geq 0$,

$$\begin{aligned} & \left| \int_k^{k+1} e^{-A\tau} g(\hat{u}(\tau), v(\tau)) d\tau \right| \\ &= \left| \int_k^{k+1} \left[\sum_{i=1}^{n+1} \mu_i(\tau) e^{-A\tau} g(u_i(\tau), v(\tau)) - e^{-A\tau} g(\hat{u}(\tau), v(\tau)) \right] d\tau \right| < \frac{1}{(k+1)^2}. \end{aligned}$$

Thus, by this $\hat{u}(\cdot)$, we have (note (4.16))

$$\begin{aligned} |z(t)| &= \left| e^{At} z_0 + \int_0^t e^{A(t-\tau)} g(\hat{u}(\tau), v(\tau)) d\tau \right| \\ &\leq |e^{At} z_0| + |e^{At}| \sum_{k=1}^{\infty} \frac{1}{k^2} \rightarrow 0 \quad \text{as } t \rightarrow \infty. \end{aligned}$$

Hence, the game is asymptotically terminable. \square

4.2. Some generalizations. Now we consider the game (4.1) with terminal set M being a subspace of \mathbb{R}^n , with $\dim M < n$. We let M^\perp be the orthogonal complement of M and $\Pi: \mathbb{R}^n \rightarrow M^\perp$ be the orthogonal projection onto M^\perp . It is clear that for any $x \in \partial M \equiv M$, we have

$$(4.19) \quad N(x) = M^\perp \cap S^n \equiv \{\eta \in M^\perp \mid |\eta| = 1\},$$

$$(4.20) \quad d(M, z) = |\Pi z|.$$

Since in the present case, the terminal set M is convex and closed, Corollaries 3.4 and 3.5 hold. Let us observe the implication of (3.22) (or (3.19)). Explicitly, (3.22) is equivalent to the following:

$$\begin{aligned} 0 &> \sup_{\eta \in M^\perp \cap S^n} \sup_{v \in V} \inf_{u \in U} (\eta, Ax + g(u, v)) \\ &\geq \sup_{\eta \in M^\perp \cap S^n} (\eta, Ax) - \sup_{(u, v) \in U \times V} |g(u, v)| \quad \forall x \in M. \end{aligned}$$

This implies that

$$(\eta, Ax) = 0 \quad \forall x \in M, \quad \eta \in M^\perp.$$

That means $AM \subset (M^\perp)^\perp = M$, i.e., M is an invariant subspace of A . Let us assume this is in the rest of this section. By choosing a suitable orthonormal basis for $M^\perp \oplus M \equiv \mathbb{R}^n$, we have

$$A = \begin{pmatrix} A_1 & 0 \\ A_3 & A_4 \end{pmatrix}, \quad g = \begin{pmatrix} g_1 \\ g_2 \end{pmatrix}, \quad z = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix}, \quad z_0 = \begin{pmatrix} z_{10} \\ z_{20} \end{pmatrix}.$$

Then applying Π to (4.1), we get

$$\begin{aligned} (4.21) \quad & \dot{z}_1 = A_1 z_1 + g_1(u, v), \\ & z_1(0) = z_{10}. \end{aligned}$$

Also, by (4.20), we see that $z \in M$ if and only if $z_1 = 0$. Hence, we have reduced the game (4.1) with terminal set M to the game (4.21) with terminal set $\{0\}$. Thus, we have results similar to those in § 4.1. We state these corresponding results below.

THEOREM 4.1'. Suppose $\delta > 0$, such that

$$(4.3') \quad G_0^\delta(M) \subset C_a(M).$$

Then,

$$(4.4') \quad \operatorname{Re} \sigma(A^*|_{M^\perp}) \leq \frac{1}{\delta} \inf_{v \in V} \sup_{u \in U} |\Pi g(u, v)|.$$

In particular, if the game is globally asymptotically terminable, then,

$$(4.5') \quad \operatorname{Re} \sigma(A^*|_{M^\perp}) \leq 0.$$

THEOREM 4.2'. Suppose there exist $\gamma > 0$ and an $(m \times r)$ -matrix B , with $m = \dim M^\perp$, such that $[(A^*|_{M^\perp})^*, B]$ is completely controllable and

$$(4.12') \quad \gamma B(B_1'(0)) \subset \bigcap_{v \in V} \Pi g(U, v).$$

Then, the game is s -locally terminable. Furthermore, if (4.5') holds, then the game is terminable.

THEOREM 4.4'. Suppose that

$$(4.16') \quad \operatorname{Re} \sigma(A^*|_{M^\perp}) < 0,$$

$$(4.17') \quad 0 \in \bigcap_{v \in V} \operatorname{Co} \Pi g(U, v).$$

Then, the game is asymptotically terminable.

Remark 4.6. For the game (4.1) with terminal set M being an invariant subspace of A , (2.1) holds with $K = |A|$. (We assume $A \neq 0$.) Then under (4.12') with B being the identity on M^\perp , by Corollary 3.4, we only have

$$(4.22) \quad G_0^{\gamma/|A|}(M) \subset C(M).$$

Then, by Theorems 4.1' and 4.2', we see that in this case, the game is globally terminable if and only if (4.5') holds.

5. Examples. Our first example shows that in general, local terminability does not imply the s -local terminability (recall Remark 1.4).

Example 5.1. For simplicity, take U, V to be singletons. The system is given by (on \mathbb{R}^2)

$$(5.1) \quad \begin{aligned} \dot{x} &= -e^{-y}, \\ \dot{y} &= 1. \end{aligned}$$

The terminal set is

$$(5.2) \quad M = \{(x, y) \in \mathbb{R}^2 | x \leq 0\}.$$

We take a Lyapunov function

$$(5.3) \quad \Phi(x, y) = d(M, (x, y)) = x^+ \equiv \max\{x, 0\} \quad \forall (x, y) \in \mathbb{R}^2.$$

Then, we see that (recall (3.16))

$$(5.4) \quad \sigma(R) = -e^{-R} \quad \forall R > 0.$$

Thus, (3.5'') is satisfied but (3.5) is not satisfied. Actually, we can claim that this game is locally terminable (by Theorem 3.3) but not s -locally terminable. In fact, by (5.1), for any $(x_0, y_0) \in \mathbb{R}^n \setminus M$,

$$\begin{aligned} x(t) &= x_0 - \int_0^t e^{-y_0 - \tau} d\tau \\ &= x_0 - e^{-y_0}(1 - e^{-t}). \end{aligned}$$

Hence, $(x_0, y_0) \in C(M)$, if and only if $x_0 < e^{-y_0}$, and thus

$$(5.5) \quad C(M) = \{(x, y) | x < e^{-y}\}.$$

We see that no $\delta > 0$ exists such that

$$G_0^\delta \subset C(M).$$

Similarly, we see that

$$(5.6) \quad C_a(M) = \{(x, y) | x \leq e^{-y}\}.$$

Hence, this example also shows that the local asymptotic terminability does not necessarily imply s -local asymptotic terminability.

Example 5.2. Let us consider two objects in \mathbb{R}^3 , one pursuing the other. Suppose the pursuer is x and the evader is y , and they are subject to the following systems:

$$(5.7) \quad \begin{aligned} \dot{x} &= 0, \\ \dot{p} &= A_0 x + B_0 p + C_1 u, \end{aligned}$$

$$(5.8) \quad \begin{aligned} \dot{y} &= q, \\ \dot{q} &= A_0 y + B_0 q + C_2 v. \end{aligned}$$

The pursuer wants to “softly” catch the evader, namely, the terminal set M is

$$(5.9) \quad M = \{x = y, p = q\}.$$

Let us set

$$\begin{aligned} z_1 &= x - y, & z_2 &= p - q, \\ z_3 &= x + y, & z_4 &= p + q. \end{aligned}$$

Then, (5.7) and (5.8) become

$$(5.10) \quad \dot{z} = \begin{pmatrix} 0 & I & 0 & 0 \\ A_0 & B_0 & 0 & 0 \\ 0 & 0 & 0 & I \\ 0 & 0 & A_0 & B_0 \end{pmatrix} z + \begin{pmatrix} 0 \\ C_1 \\ 0 \\ C_1 \end{pmatrix} u + \begin{pmatrix} 0 \\ -C_2 \\ 0 \\ C_2 \end{pmatrix} v \equiv Az + Bu + Cv.$$

The terminal set M becomes

$$(5.11) \quad M = \{(0, 0, z_3, z_4) | z_3, z_4 \in \mathbb{R}^3\}.$$

It is clear that $AM \subseteq M$. Thus, we have the following proposition.

PROPOSITION 5.3. *Suppose*

$$\left[\begin{pmatrix} 0 & I \\ A_0 & B_0 \end{pmatrix}, \begin{pmatrix} 0 \\ C_1 \end{pmatrix} \right]$$

is completely controllable. Let there exist a $\gamma > 0$, such that

$$(5.12) \quad \gamma C_1(B_1^3(0)) \subset \bigcap_{v \in V} (C_1 U - C_2 v).$$

Then the “soft” capture is possible if initially the positions and the velocities of these two objects are close enough. Furthermore, if we have

$$(5.13) \quad \operatorname{Re} \sigma \begin{pmatrix} 0 & I \\ A_0 & B_0 \end{pmatrix} \leq 0,$$

then, for any initial state, the “soft” capture is possible.

The proof is immediate.

Finally, we present an example in which the Lyapunov function is not a function of $d(M, z)$. This example is a modification of that given in [3].

Example 5.4. Let the game be governed by the following system:

$$(5.14) \quad \begin{aligned} \dot{z}_1 &= z_2, \\ \dot{z}_2 &= -\sin z_1 + u - v \cos z_1, \end{aligned}$$

where $z_1, z_2 \in \mathbb{R}$, $u \in U \equiv [-a, a]$, $v \in V \equiv [-b, b]$, $a > b \geq 0$. The terminal set is $M = \{0\}$. We define

$$(5.15) \quad \Psi(z) = z_1^2 + 2z_1z_2 + z_2^2 + 2(1 - \cos z_1).$$

Then, we have

$$(5.16) \quad \begin{aligned} \sup_{c \in V} \inf_{u \in U} \left(\frac{\partial \Psi}{\partial z}(z), f(z, u, v) \right) &= 2 \sup_{v \in V} \inf_{u \in U} \{ z_1z_2 + z_2^2 + (z_1 + z_2)(u - v \cos z_1) - z_1 \sin z_1 \} \\ &\geq 2(-a + b + |z_2|)|z_1 + z_2| - 2z_1 \sin z_1. \end{aligned}$$

Hence (note $a > b$), we can find constants $c > 0$, $\varepsilon > 0$, such that

$$(5.17) \quad \sup_{v \in V} \inf_{u \in U} \left(\frac{\partial \Psi}{\partial z}(z), f(z, u, v) \right) \leq -c(|z_1|^2 + |z_2|^2) \equiv -cd(M, z)^2 \quad \forall |z_1|, |z_2| \leq \varepsilon.$$

Thus, by Theorem 3.6, the game is s -locally asymptotically terminable.

Acknowledgments. This paper is an improved version of one chapter of the author's Ph.D. thesis accomplished at Purdue University under the guidance of Professor L. D. Berkovitz. The author would like to take this opportunity to thank Professor Berkovitz for posing the problem, for suggestive discussions and for the encouragement he gave. Also, the author thanks the referee for the suggestions and criticism which led to this improved version.

A PRODUCT FORMULA APPROACH TO NONLINEAR OPTIMAL CONTROL PROBLEMS*

VIOREL BARBU†

Abstract. In this paper we prove the convergence of an iterative scheme of Lie-Trotter type for optimal control problems governed by nonlinear systems. The numerical implementation of the resulting algorithm is also discussed.

AMS(MOS) subject classification. 35

Key words. Lie-Trotter product formula, maximal monotone operators, nonlinear semigroups, distributed control systems, free boundary problem, optimal control, Stefan problem

0. Introduction. This work is concerned with an iterative scheme of the Lie-Trotter product formula type for optimal control problems of the following form:

$$(P) \quad \text{Minimize} \quad \int_0^T g(y(t)) \, dt + h(u) + \varphi_0(y(T))$$

$$\text{on all } (y, u) \in C([0, T]; H) \times L^2(0, T; U)$$

subject to

$$(0.1) \quad y'(t) + Ay(t) + Fy(t) \ni (Bu)(t) + f(t), \quad t \in [0, T],$$

$$y(0) = y_0.$$

Here H and U are real Hilbert spaces, $f \in L^2(0, T; H)$, $y_0 \in H$, $g: H \rightarrow \mathbb{R}$, $\varphi_0: H \rightarrow \mathbb{R}$ and $h: U \rightarrow \bar{\mathbb{R}} = (-\infty, +\infty]$ are given functions, A and F are maximal monotone operators in $H \times H$ and $B: U \rightarrow L^2(0, T; H)$ is a linear operator. (The exact hypotheses will be given later.)

In few words, the main result of this paper amounts to saying that in certain situations problem (P) can be approximated for $\varepsilon \rightarrow 0$ by the following sequence of optimal control problems

$$(P_\varepsilon) \quad \text{Minimize} \quad \int_0^T g(y(t)) \, dt + h(u) + \varphi_0(y(T))$$

$$\text{on all } y: [0, T] \rightarrow H, u \in L^2(0, T; U)$$

subject to

$$(0.2) \quad y'(t) + Ay(t) = (Bu)(t) + f(t) \quad \text{for } t \in (i\varepsilon, (i+1)\varepsilon),$$

$$y^+(i\varepsilon) = w_i(\varepsilon) \quad \text{for } i = 1, \dots, N-1, \quad y^+(0) = y_0,$$

$$(0.3) \quad w'_i + Fw_i = 0 \quad \text{in } (0, \varepsilon), \quad \varepsilon = T/N,$$

$$w_i(0) = Py^-(i\varepsilon) \quad \text{for } i = 1, 2, \dots, N-1.$$

Here P is the projection operator of H into the closed convex subset $K = \overline{D(A) \cap D(F)}$.

As we will see later the iterative scheme (0.2), (0.3) is related to the Lie-Trotter formula for nonlinear semigroups and it provides a theoretic algorithm for obtaining the solutions to problem (P). The convergence of this scheme is proved in the cases

* Received by the editors February 18, 1986; accepted for publication May 6, 1987.

† University of Iasi, 6600 Iasi, Romania.

described in Theorems 1 and 2 below which include a large class of distributed and boundary optimal control problems governed by nonlinear parabolic equations and free boundary problems (see Examples 1, 2 below).

The semigroup approximation theory has already been used by H. T. Banks (see, for instance, [1]) to derive numerical algorithms for infinite-dimensional optimal control problems. However, these results differ in spirit from our own.

The numerical implementation of this algorithm, which was written by Dr. V. Arnăutu from the University of Iasi, is discussed in § 5.

1. Preliminaries and the main result. Notation and hypotheses. (1) H and U are real Hilbert spaces with the norms $|\cdot|$ and $|\cdot|_U$, respectively. B is a linear continuous operator from U to $L^2(0, T; H)$.

(2) V is a real Hilbert space continuously and densely imbedded in H . Identifying H with its own dual and denoting by V' the dual of V we have

$$V \subset H \subset V'$$

algebraically and topologically. Assume that the injection of V into H is compact and denote by $\|\cdot\|$ the norm of V . We will denote by the same symbol (\cdot, \cdot) the scalar product of H and the pairing between V and V' .

(3) $A: V \rightarrow V'$ is a linear, continuous, symmetric and coercive operator, i.e.,

$$(1.1) \quad (Ay, y) \geq \omega \|y\|^2 \quad \forall y \in V$$

where $\omega > 0$.

(4) $F: D(F) \subset H \rightarrow 2^H$ is a maximal monotone operator of subgradient type, i.e., $F = \partial\varphi$, where $\varphi: H \rightarrow \bar{R} = (-\infty, +\infty]$ is a lower semicontinuous, convex function. (We have denoted by $\partial\varphi$ the subdifferential of φ .) We assume that for every $\lambda > 0$ and all $y \in D(A) = \{y \in V; Ay \in H\}$,

$$(1.2) \quad (Ay, F_\lambda y) \geq 0$$

where

$$F_\lambda = \lambda^{-1}(I - (I + \lambda F)^{-1}) \quad (I \text{ is the identity operator on } H).$$

(5) P is the projection operator of H into $K = \overline{D(F)}$. We shall assume that P maps V into itself and

$$(1.3) \quad (APy, Py) \leq (Ay, y) \quad \forall y \in V.$$

(6) The functions $g: H \rightarrow R$ and $\varphi_0: H \rightarrow R$ are Lipschitzian on bounded subsets, Fréchet differentiable and bounded from below by affine functions. The function $h: H \rightarrow \bar{R}$ is convex, lower semicontinuous and coercive, i.e.,

$$(1.4) \quad \lim_{|u|_U \rightarrow \infty} h(u)/|u|_U = +\infty.$$

We will assume, finally, that

$$(1.5) \quad y_0 \in D(\varphi) \cap V \quad \text{and} \quad f \in L^2(0, T; H).$$

We note that assumption (1.2) implies that the operator $A + F$ is maximal monotone in $H \times H$ and $\overline{D(A) \cap D(F)} = \overline{D(F)}$ (see for instance [6] or [3, p. 19]). Moreover, $A + F = \partial\psi$, where

$$\psi(y) = \frac{1}{2}(Ay, y) + \varphi(y).$$

Then according to standard existence results for nonlinear evolution equations of subgradient type (see [6] and [2, p. 188]), (0.1) admits a unique solution $y \in W^{1,2}([0, T]; H) \cap L^2(0, T; D(A))$. (We have denoted by $W^{1,2}([0, T]; H)$ the space of all absolutely continuous functions $y: [0, T] \rightarrow H$ such that $y' \in L^2(0, T; H)$). Moreover, since by our assumptions on V , A and F the map $u \rightarrow y^u$ is compact from U to $C([0, T]; H)$ we infer by standard device that problem (P) admits at least one solution (y^*, u^*) . (We have denoted by y^u the solution to state system (0.1).)

Now we come back to iterative scheme (0.2), (0.3) and note that for y_0 and f satisfying (1.4) this system has a unique solution $y: [0, T] \rightarrow H$ which is piecewise continuous and belongs to $W^{1,2}([i\varepsilon, (i+1)\varepsilon]; H) \cap L^\infty(0, T; V)$ for all $i = 0, 1, \dots, N-1$. Indeed, by assumption (1.2), we know that (see for instance [2, p. 183])

$$(1.6) \quad e^{-Ft}V \subset V \quad \text{for all } t \geq 0$$

and so $y^+(i\varepsilon) \in V$ for all i .

As a matter of fact we may rewrite system (0.2), (0.3) as the impulse differential equation

$$y' + Ay = Bu + f + \sum_{i=1}^N (e^{-F\varepsilon}Py^-(i\varepsilon) - y^-(i\varepsilon)) \otimes \delta(i\varepsilon),$$

where e^{-Ft} is the nonlinear semigroup generated by $-F$ and δ is the Dirac measure.

It is readily seen that for each $\varepsilon > 0$, problem (P_ε) has at least one solution $(y_\varepsilon, u_\varepsilon)$.

We set

$$(1.7) \quad \phi(u) = \int_0^T g(y^u(t)) dt + \varphi_0(y^u(T)) + h(u)$$

and

$$(1.8) \quad \phi_\varepsilon(u) = \int_0^T g(y_\varepsilon^u(t)) dt + \varphi_0(y_\varepsilon^u(T)) + h(u)$$

where y_ε^u is the solution to approximating system (0.2), (0.3).

Then we may rewrite (P) and (P_ε) as

$$(P) \quad \min \{ \phi(u); u \in U \},$$

$$(P_\varepsilon) \quad \min \{ \phi_\varepsilon(u); u \in U \}.$$

The main result is the following theorem.

THEOREM 1. Assume that beside (1) ~ (6) at least one of the following hypotheses holds:

(i) The set $\{w = Bu; h(u) \leq \lambda\}$ is compact in $L^1(0, T; H)$ for every $\lambda \in \mathbb{R}$.

(ii) $F = \partial I_C$, where C is a closed convex subset of H .

Then $\lim_{\varepsilon \downarrow 0} \inf \phi_\varepsilon = \inf \phi$, and if $\{u_\varepsilon^*\}$ is a sequence of optimal controls for problems (P_ε) then

$$(1.9) \quad \lim_{\varepsilon \downarrow 0} \phi_\varepsilon(u_\varepsilon^*) = \inf \phi.$$

Moreover, every weak limit point of $\{u_\varepsilon^*\}$ is an optimal control for problem (P).

In (ii) we have denoted by ∂I_C the subdifferential of the indicator function I_C of C , i.e.,

$$(1.10) \quad \partial I_C(y) = \{p \in H; (p, y - w) \geq 0 \forall w \in C\}.$$

Conclusion (1.9) of the theorem amounts to saying that $\{u_\varepsilon^*\}$ is a sequence of suboptimal controllers for problem (P).

Now we shall present some typical situations where Theorem 1 applies.

Example 1. Consider the distributed control system defined on an open domain Ω of R^n with a sufficiently smooth boundary:

$$\begin{aligned}
 & \frac{\partial y}{\partial t}(t, x) - \Delta y(t, x) + \gamma(y(t, x)) \\
 & = f(t, x) + \sum_{i=1}^m v_i(t) \alpha_i(x), \quad (t, x) \in Q = (0, T) \times \Omega, \\
 & y(0, x) = y_0(x), \quad x \in \Omega, \\
 & y + \alpha \frac{\partial y}{\partial \nu} = 0 \quad \text{in } \Sigma = (0, T) \times \Gamma, \\
 & \frac{dv}{dt} + D(v) = B_0 u \quad \text{a.e. } t \in [0, T], \\
 & v(0) = v_0, \quad v = (v_1, v_2, \dots, v_m).
 \end{aligned}
 \tag{1.11}$$

Here, $\alpha_i \in L^2(\Omega)$, $\alpha \geq 0$, γ is a maximal monotone graph in $R \times R$ (eventually multivalued) such that $\overline{D(\gamma)} = R$, $0 \in \gamma(0)$, D is a Lipschitzian mapping from R^m to itself and B_0 is a linear continuous operator from a control space U to $L^1(0, T; R^m)$.

Theorem 1 is applicable if we take $V = H^1(\Omega)$, $H = L^2(\Omega)$ and $A: V \rightarrow V'$, $F: H \rightarrow H$, $B: U \rightarrow L^2(Q)$ defined by

$$(Ay, z) = \int_{\Omega} \nabla y \cdot \nabla z \, dx + \alpha^{-1} \int_{\Gamma} yz \, d\sigma \quad \forall z \in H^1(\Omega),
 \tag{1.13}$$

$$(Fy)(x) = \gamma(y(x)) \quad \text{a.e. } x \in \Omega,
 \tag{1.14}$$

$$(Bu)(t, x) = \sum_{i=1}^m \alpha_i(x) v_i(t), \quad (t, x) \in Q.$$

Assumption (i) is obviously satisfied as an immediate consequence of the Arzelà theorem.

Example 2. Consider the free boundary problem

$$\begin{aligned}
 & \frac{\partial y}{\partial t} - \Delta y \geq f + Bu, \quad y \geq 0 \quad \text{a.e. in } Q, \\
 & \left(\frac{\partial y}{\partial t} - \Delta y - Bu - f \right) y = 0 \quad \text{a.e. in } Q, \\
 & y(0, x) = y_0(x) \quad \text{a.e. } x \in \Omega, \\
 & y = 0 \quad \text{in } \Sigma
 \end{aligned}
 \tag{1.15}$$

where $y_0 \in H_0^1(\Omega)$ and $y_0(x) \geq 0$ almost everywhere $x \in \Omega$.

The control system is of the form (0.1) where $V = H_0^1(\Omega)$, $H = L^2(\Omega)$, $A = -\Delta$, $F = \partial I_C$ where $C = \{y \in H_0^1(\Omega); y(x) \geq 0 \text{ a.e. } x \in \Omega\}$.

Note that $(Py)(x) = \max\{y(x), 0\}$ almost everywhere $x \in \Omega$ and it is well known that assumption (1.3) is satisfied, i.e.,

$$\|\nabla Py\|_{L^2(\Omega)} \leq \|\nabla y\|_{L^2(\Omega)} \quad \forall y \in H_0^1(\Omega).$$

Optimal control problems governed by the free boundary problems of the form (1.15) have been studied in [3], [11], [14], [15].

2. Proof of the main result. We begin by establishing a Lie–Trotter product formula for the nonhomogeneous evolution equation

$$(2.1) \quad \begin{aligned} y' + Ay + Fy &= \chi, & t \geq 0, \\ y(0) &= x \end{aligned}$$

where $\chi \in L^1(R^+; H)$, $x \in \overline{D(A) \cap D(F)} = \overline{D(F)} = K$ and A, F satisfy assumptions (1)–(5) of § 1.

We know that (2.1) has a unique integral solution $y \in C(R^+; H)$ in the sense of B  nilan (see [2], [6]). If $\chi \in L^2_{\text{loc}}(R^+; H)$ then $y \in W^{1,2}_{\text{loc}}([\delta, T]; H)$ on every interval $[\delta, T] \subset (0, +\infty)$.

Following an idea due to Dafermos and Slemrod [10] we may write (2.1) as an autonomous differential equation in the Banach space $X = H \times L^1(R^+; H)$ with the norm $\|(x, \chi)\|_X = |x| + \int_0^\infty |\chi(s)| ds$.

Let $\mathcal{A}: X \rightarrow X$ be the operator defined by

$$(2.2) \quad \begin{aligned} \mathcal{A}(x, \chi) &= \{(A + F)x - \chi(0), -\chi'\}, & (x, \chi) \in D(\mathcal{A}), \\ D(\mathcal{A}) &= \{(x, \chi) \in X; x \in D(A) \cap D(F)\}, & \chi \in W^{1,1}(R^+; H) \end{aligned}$$

and

$$(2.3) \quad S(t)(x, \chi) = (y(t), \chi_t), \quad \chi_t(s) = \chi(t + s), \quad t, s \geq 0;$$

then we may write (2.1) as

$$(2.4) \quad \frac{d}{dt} S(t)(x, \chi) + \mathcal{A}S(t)(x, \chi) \ni 0, \quad t \geq 0.$$

In other words, $S(t): K \times L^1(R^+; H) \rightarrow K \times L^1(R^+; H)$ is the semigroup of nonlinear contractions generated by the m -accretive operator \mathcal{A} via the Crandall–Liggett generation theorem [9].

On $\mathcal{H} = K \times L^1(R^+; H)$ consider the nonlinear semigroups $S_1(t)$ and $S_2(t)$ defined by

$$(2.5) \quad S_1(t)(x, \chi) = (\tilde{y}(t), \chi_t), \quad t \geq 0$$

and

$$(2.6) \quad S_2(t)(x, \chi) = (e^{-Ft}x, \chi), \quad t \geq 0$$

where

$$\tilde{y}' + A\tilde{y} = \chi \quad \text{in } R^+, \quad \tilde{y}(0) = x$$

and $e^{-Ft}x = w(t)$ is the solution to the evolution equation

$$w' + Fw = 0 \quad \text{in } R^+, \quad w(0) = x.$$

We see that $S_1(t)$ and $S_2(t)$ are generated by the operators \mathcal{A}_1 and \mathcal{A}_2 defined below:

$$\mathcal{A}_1(x, \chi) = \{Ax - \chi(0), \chi'\}, \quad \mathcal{A}_2(x, \chi) = \{Fx, 0\}.$$

Let $P: H \rightarrow K$ be the projection operator on $K = \overline{D(F)}$ and let $\Pi: X \rightarrow \mathcal{H} = K \times L^1(R^+; H)$ be defined by

$$(2.7) \quad \Pi(x, \chi) = (Px, \chi), \quad x \in K, \quad \chi \in L^1(R^+; H).$$

PROPOSITION 1. For all $x \in K$ and $\chi \in L^1(R^+; H)$ we have

$$(2.8) \quad \lim_{n \rightarrow \infty} \left(\Pi S_1 \left(\frac{t}{n} \right) S_2 \left(\frac{t}{n} \right) \right)^n (x, \chi) = S(t)(x, \chi) \quad \forall t \geq 0$$

in X , and the convergence is uniform in t on compact intervals of $R^+ = [0, \infty)$.

Proof. We will employ the nonlinear version of Chernoff theorem due to Brézis and Pazy [7].

Let $\{\Gamma(h)\}_{h>0}$ be the family of nonexpansive operators on \mathcal{H} defined by

$$\Gamma(h) = \Pi S_1(h) S_2(h)$$

and set

$$(2.9) \quad X_h = (I + \lambda h^{-1}(I - \Gamma(h)))^{-1}(x, \chi), \quad \lambda > 0$$

where I is the identity operator in X .

According to Theorem 3.2 in [7] to prove (2.8) it suffices to show that for $h \rightarrow 0$

$$(2.10) \quad X_h \rightarrow (I + \lambda \mathcal{A})^{-1}(x, \chi) \quad \text{for all } \lambda > 0.$$

Taking into account (2.5)–(2.7) we may rewrite (2.9) as

$$(2.11) \quad (h + \lambda)x^h - \lambda P \left(e^{-Ah} e^{-Fh} x^h + \int_0^h e^{-A(h-s)} y^h(s) ds \right) = hx,$$

$$(2.12) \quad (h + \lambda)y^h(s) - \lambda y^h(s + h) = h\chi(s), \quad s \geq 0$$

where $(x^h, y^h) = X_h \in X$ and e^{-At} is the C_0 -semigroup generated on H by the operator $-A$.

Inasmuch as the operators $(I + \lambda \mathcal{A})^{-1}$ and $(I + \lambda h^{-1}(I - \Gamma(h)))^{-1}$ are nonexpansive on X , without any loss of generality we may assume that $x \in D(A) \cap D(F)$ and

$$\chi, \chi' \in L^2(R^+; V) \cap L^1(R^+; V).$$

Then by (2.12) we see that $y^h \in L^1(R^+; V) \cap L^2(R^+; V)$, y^h is absolutely continuous on compact intervals in the V -norm and

$$\|y^h\|_{L^i(R^+; V)} \leq \|\chi\|_{L^i(R^+; V)}, \quad i = 1, 2,$$

$$\left\| \frac{d}{ds} y^h \right\|_{L^i(R^+; V)} \leq \left\| \frac{d\chi}{ds} \right\|_{L^i(R^+; V)}, \quad i = 1, 2.$$

Hence $\{y^h\}_{h>0}$ is compact in $L^1(R^+; H) \cap C(R^+; H)$ and since the limit is unique we may infer that for $h \rightarrow 0$

$$(2.13) \quad y^h \rightarrow w \quad \text{strongly in } H, \quad \text{uniformly in } s \text{ on compacts.}$$

Since by (2.12)

$$\int_{\mu}^{\infty} |y^h(s)| ds \leq \int_{\mu}^{\infty} |\chi(s)| ds \quad \forall \mu > 0$$

we infer by (2.13) that $\{y^h\}$ is compact in $L^1(R^+; H)$, and therefore

$$(2.14) \quad y^h \rightarrow w \quad \text{strongly in } L^1(R^+; H).$$

On the other hand, we see that for each $\psi \in W^{1,2}(R^+; H)$, $\psi(0) = 0$, we have

$$\lim_{h \rightarrow 0} \int_0^\infty \left(\frac{y^h(s+h) - y^h(s)}{h}, \psi(s) \right) ds = - \int_0^\infty (w(s), \psi'(s)) ds.$$

Hence for $h \rightarrow 0$

$$\frac{1}{h} (y^h(s+h) - y^h(s)) \rightarrow w' \quad \text{weakly in } L^2(R^+; H)$$

and letting h tend to zero in (2.12) we see that

$$(2.15) \quad w - \lambda w' = \chi \quad \text{a.e. in } R^+.$$

Next by (2.13) we see that for $h \rightarrow 0$

$$(2.16) \quad h^{-1} \int_0^h e^{-A(h-s)} y^h(s) ds \rightarrow w(0) \quad \text{strongly in } H.$$

To complete the proof of (2.10) it remains to be shown that for $h \rightarrow 0$

$$(2.17) \quad x^h \rightarrow x_\lambda^0 \quad \text{strongly in } H$$

where $x_\lambda^0 \in D(A) \cap D(F)$ is the solution to the equation

$$(2.18) \quad x_\lambda^0 + \lambda (Ax_\lambda^0 + Fx_\lambda^0) = x + \lambda w(0).$$

To this purpose we set $q^h = h^{-1} \int_0^h e^{-A(h-s)} y^h(s) ds$ and noting that $P = (1 + \partial I_K)^{-1}$ (1 is the identity operator in H) we may put (2.11) under the following form:

$$(2.19) \quad \begin{aligned} & h^{-1} (x^h - e^{-Ah} x^h) + \lambda h^{-1} e^{-Ah} (x^h - e^{-Fh} x^h) \\ & + \lambda h^{-1} \partial I_K (\lambda^{-1} (h + \lambda) x^h - h \lambda^{-1} x) \ni x + \lambda q^h - x^h. \end{aligned}$$

Let $z(s) = e^{-As} x^h$, i.e.,

$$z' + Az = 0 \quad \text{in } [0, h], \quad z(0) = x^h$$

and let u be arbitrary but fixed in V . We multiply the latter by $z(s) - u$ and integrate on $[0, h]$. After some calculation we get

$$(2.20) \quad (e^{-Ah} x^h - x^h, x^h - u) + \frac{1}{2} |e^{-Ah} x^h - x^h|^2 + \int_0^h (\varphi_1(z(s)) - \varphi_1(u)) ds \leq 0$$

where $\varphi_1(u) = \frac{1}{2} (Au, u)$.

Similarly,

$$(2.21) \quad (e^{-Fh} x^h - x^h, x^h - u) + \frac{1}{2} |e^{-Fh} x^h - x^h|^2 + \int_0^h (\varphi(e^{-Fs} x^h) - \varphi(u)) ds \leq 0.$$

Hence

$$(2.22) \quad \begin{aligned} & h^{-1} (e^{-Fh} x^h - x^h, e^{-Ah} (x^h - u)) + (2h)^{-1} |e^{-Fh} x^h \\ & - x^h|^2 + h^{-1} \int_0^h (\varphi(e^{-Fs} x^h) - \varphi(u)) ds \\ & \leq h^{-1} (e^{-Fh} x^h - x^h, e^{-Ah} x^h - x^h) + h^{-1} |e^{-Fh} x^h - x^h| |e^{-Ah} u - u|. \end{aligned}$$

Now we multiply (2.19) (scalarly in H) by $x^h - e^{-Fh}x^h + h\lambda^{-1}(x^h - x)$ and use the accretivity of e^{-Ah} along with the definition of ∂I_k (see (1.10)) to find

$$\begin{aligned} h^{-1}(x^h - e^{-Ah}x^h, x^h - e^{-Fh}x^h) &\leq -(x^h - e^{-Ah}x^h, x^h - x) - (x^h - e^{-Fh}x^h, e^{-Ah}(x^h - x)) \\ &\quad + (x + \lambda q^h - x^h, x^h - e^{-Fh}x^h) \\ &\quad + h\lambda^{-1}(x + \lambda q^h - x^h, x^h - x). \end{aligned}$$

Then combining the latter with (2.20) and (2.22) yields

$$\begin{aligned} &\lambda(h^{-1}(e^{-Ah}x^h - x^h), x^h - u) + \lambda(h^{-1}e^{-Ah}(e^{-Fh}x^h - x^h), x^h - u) \\ &\quad + \lambda h^{-1} \int_0^h (\phi(e^{-Fs}x^h) + \phi_1(e^{-As}x^h)) ds \\ (2.23) \quad &\leq \lambda(\phi(u) + \phi_1(u)) + (2h)^{-1}\lambda|e^{-Ah}u - u|^2 \\ &\quad + |x^h - e^{-Fh}x^h|(2|x^h - x| + |x + \lambda q^h - x^h|) \\ &\quad + h\lambda^{-1}|x + \lambda q^h - x^h||x^h - x|. \end{aligned}$$

Now by (2.11)

$$(2.24) \quad x^h = h(\lambda + h)^{-1}x + \lambda(h + \lambda)^{-1}P(e^{-Ah}e^{-Fh}x^h + hq^h).$$

Since assumption (1.2) implies that (see [2, p. 183])

$$\phi_1(e^{-Fh}x) \leq \phi_1(x) \quad \forall h \geq 0, \quad x \in V$$

it follows by (2.24) that

$$\|x^h\| \leq \|x\| + \lambda\|q^h\| \leq C \quad \text{for all } h > 0$$

because, as we have seen above, $\{q^h\}$ is bounded in $L^\infty(0, 1; V)$.

We may conclude therefore that $x_{h>0}^h$ is a compact subset of H . Hence on a subsequence again denoted h , we have

$$(2.25) \quad x^h \rightarrow x_\lambda^0 \quad \text{strongly in } H.$$

Since the functions ϕ and ϕ_1 are lower semicontinuous it follows by the Fatou lemma that

$$(2.26) \quad \liminf_{h \rightarrow 0} h^{-1} \int_0^h (\phi(e^{-Fs}x^h) + \phi_1(e^{-As}x^h)) ds \geq \phi(x^0) + \phi_1(x^0).$$

Next from (2.25) and the strong continuity of e^{-Ft} and e^{-At} we infer that

$$(2.27) \quad |e^{-Ah}x^h - x^h| + |e^{-Fh}x^h - x^h| \rightarrow 0 \quad \text{as } h \rightarrow 0.$$

Now once again, using (2.19) and the definition of ∂I_k , we get

$$\begin{aligned} &\lambda h^{-1}(\partial I_k(\lambda^{-1}(h + \lambda)x^h - h\lambda^{-1}x), x^h - u) \\ &\quad \geq -(\partial I_k(\lambda^{-1}(h + \lambda)x^h - h\lambda^{-1}x), x^h - x) \\ &\quad = -(e^{-Ah}x^h - x^h, x^h - x) - (e^{-Fh}x^h - x^h, e^{-Ah}(x^h - x)) - \lambda^{-1}h(x + \lambda q^h - x^h, x^h - x) \end{aligned}$$

and by (2.27) we conclude that

$$(2.28) \quad \liminf_{h \rightarrow 0} h^{-1}(\partial I_k(\lambda^{-1}(h + \lambda)x^h - h\lambda^{-1}x), x^h - u) \geq 0.$$

Along with (2.19), (2.23) and (2.26) the latter yields

$$-\lim_{h \rightarrow 0} (x + \lambda q^h - x^h, x^h - u) \leq \lambda (\zeta(u) - \zeta(x_\lambda^0))$$

where $\zeta = \varphi + \varphi_1$. Then by (2.16) and (2.17) we have

$$(x_\lambda^0 - \lambda w(0) - x, x_\lambda^0 - u) \leq \lambda (\zeta(u) - \zeta(x_\lambda^0)).$$

Since u is arbitrary in H and $\partial\zeta = A + F$ we conclude that

$$x + \lambda w(0) - x_\lambda^0 \in \lambda (A + F)(x_\lambda^0).$$

Hence x_λ^0 is the unique solution to (2.18) and the proof of Proposition 1 is complete.

In the following we shall denote by y^u the solution to control system (0.1) and by y_ε^u the solution to system (0.2), (0.3).

PROPOSITION 2. *For each $u \in U$ we have*

$$(2.29) \quad y_\varepsilon^u(t) \rightarrow y^u(t) \quad \text{strongly in } H \text{ for all } t \in [0, T].$$

If $Bu_{\varepsilon_n} \rightarrow Bu$ strongly in $L^1(0, T; U)$ for $\varepsilon_n \rightarrow 0$ then

$$(2.30) \quad y_{\varepsilon_n}^u(t) \rightarrow y^u(t) \quad \text{strongly in } H \text{ for } t \in [0, T].$$

Proof. We extend $(Bu)(t)$ with 0 on $[T, +\infty)$ and apply Proposition 1. Then the sequence $\{\tilde{y}_\varepsilon\}_{\varepsilon > 0}$ defined by

$$(2.31) \quad (\tilde{y}_\varepsilon(t), \tilde{u}_\varepsilon(t)) = (\Pi S_1(\varepsilon) S_2(\varepsilon))^i (y_0, Bu) \quad \text{for } t \in [i\varepsilon, (i+1)\varepsilon]$$

or equivalently

$$(2.31)' \quad \tilde{y}_\varepsilon = P(y_\varepsilon^u)^-(i\varepsilon) \quad \text{for } t \in [i\varepsilon, (i+1)\varepsilon]$$

is strongly convergent in H to $y^u(t)$ for all $t \in [0, T]$. On the other hand, it follows by (0.2), (0.3) that

$$(2.32) \quad |(y_\varepsilon^u)^-(i\varepsilon) - (y_\varepsilon^u)^+(i\varepsilon)| = |(y_\varepsilon^u)^-(i\varepsilon) - e^{-F\varepsilon} P(y_\varepsilon^u)^-(i\varepsilon)|$$

and by (0.2)

$$(2.33) \quad y_\varepsilon^-(i\varepsilon) = e^{-A\varepsilon} e^{-F\varepsilon} P y_\varepsilon^-((i-1)\varepsilon) + \int_{(i-1)\varepsilon}^{i\varepsilon} e^{-A(i\varepsilon-s)} (Bu + f) ds.$$

Note also that

$$\begin{aligned} & \int_{i\varepsilon}^t |(y_\varepsilon^u)'|^2 ds + (A y_\varepsilon^u(t), y_\varepsilon^u(t)) \\ & \leq (A(y_\varepsilon^u)^+(i\varepsilon), (y_\varepsilon^u)^+(i\varepsilon)) + \int_{i\varepsilon}^t (|Bu|^2 + |f|^2) ds \quad \text{for } t \in [i\varepsilon, (i+1)\varepsilon]. \end{aligned}$$

Since as a consequence of assumptions (1.2), (1.3)

$$\begin{aligned} (A(y_\varepsilon^u)^+(i\varepsilon), (y_\varepsilon^u)^+(i\varepsilon)) &= (A e^{-F\varepsilon} P(y_\varepsilon^u)^-(i\varepsilon), e^{-F\varepsilon} P(y_\varepsilon^u)^-(i\varepsilon)) \\ &\leq (A P(y_\varepsilon^u)^-(i\varepsilon), P(y_\varepsilon^u)^-(i\varepsilon)) \\ &\leq (A(y_\varepsilon^u)^-(i\varepsilon), (y_\varepsilon^u)^-(i\varepsilon)) \end{aligned}$$

the latter yields

$$(2.34) \quad \sum_{i=0}^{N-1} \int_{i\varepsilon}^{(i+1)\varepsilon} |(y_\varepsilon^u)'|^2 ds + (A y_\varepsilon^u(t), y_\varepsilon^u(t)) \leq (A y_0, y_0) + \int_0^T (|Bu|^2 + |f|^2) ds.$$

In particular, it follows that $\{y_\varepsilon^u\}$ is bounded in $L^\infty(0, T; V)$ and $\{(y_\varepsilon^u)^-(i\varepsilon)\}$ is compact in H .

Now since $e^{-A\varepsilon}D(F) \subset D(F)$ for all $\varepsilon > 0$ we see by (2.33) that

$$|y_\varepsilon^-(i\varepsilon) - Py_\varepsilon^-(i\varepsilon)| \leq \int_{(i-1)\varepsilon}^{i\varepsilon} |Bu + f| \, ds \leq C\varepsilon^{1/2} \quad \text{for all } i.$$

Along with (2.32) the latter yields

$$(2.35) \quad \lim_{\varepsilon \rightarrow 0} |(y_\varepsilon^u)^-(i\varepsilon) - (y_\varepsilon^u)^+(i\varepsilon)| = 0$$

because $\{y_\varepsilon^-(i\varepsilon)\}$ is compact and e^{-Ft} is continuous in t .

Now again by (0.3) we have for $t \in [i\varepsilon, (i+1)\varepsilon]$

$$|y_\varepsilon^u(t) - (y_\varepsilon^u)^+(i\varepsilon)|^2 \leq C(\varepsilon \|(y_\varepsilon^u)^+(i\varepsilon)\|^2 + \int_{i\varepsilon}^t (|Bu|^2 + |f|^2) \, ds)$$

and so by (2.31)', (2.35) we infer that

$$\lim_{\varepsilon \rightarrow 0} y_\varepsilon^u(t) = \lim_{\varepsilon \rightarrow 0} \tilde{y}_\varepsilon(t) = y^u(t) \quad \text{strongly in } H \text{ for } t \in [0, T]$$

as claimed.

The second part of Proposition 2 follows by (2.31) and the previous discussion if we take into account the fact that for each $\varepsilon > 0$ the operator $\Pi S_1(\varepsilon)S_2(\varepsilon)$ is nonexpansive on X . An immediate consequence of Proposition 2 is that $\lim_{\varepsilon \rightarrow 0} \phi_\varepsilon(u) = \phi(u)$ for all $u \in U$.

Proof of Theorem 1. Let u_ε^* be an optimal controller for problem (P_ε) and let y_ε^* be the corresponding solution to system (0.2), (0.3). By assumption (1.4), $\{u_\varepsilon^*\}$ is bounded in U and so on a subsequence $\varepsilon_n \rightarrow 0$ we have

$$(2.36) \quad u_{\varepsilon_n} \rightarrow u^* \quad \text{weakly in } U$$

while by Proposition 2

$$(2.37) \quad y_{\varepsilon_n}^*(t) \rightarrow y^{u^*}(t) \quad \text{strongly in } H \text{ for all } t \in [0, T].$$

(We set $y_{\varepsilon_n}^* = y_{\varepsilon_n \varepsilon_n}^*$.) Since by estimate (2.34), $\{y_{\varepsilon_n}^*\}$ is bounded in $L^\infty(0, T; H)$ we see by (2.37) that $g(y_{\varepsilon_n}^*) \rightarrow g(y^{u^*})$ in $L^1(0, T)$. Finally, since h is weakly lower semicontinuous, it follows by (2.36) that

$$\liminf_{n \rightarrow \infty} h(u_{\varepsilon_n}^*) \geq h(u^*).$$

Then if we let ε_n tend to zero in the obvious inequality (\tilde{u}^* is an optimal control for problem (P))

$$\phi_{\varepsilon_n}(u_{\varepsilon_n}) \leq \phi_{\varepsilon_n}(\tilde{u}^*)$$

it follows by (2.29) that

$$(2.38) \quad \phi(u^*) \leq \liminf_{n \rightarrow \infty} \phi_{\varepsilon_n}(u_{\varepsilon_n}) \leq \phi(\tilde{u}^*).$$

Hence

$$\lim_{\varepsilon_n \rightarrow 0} \phi_{\varepsilon_n}(u_{\varepsilon_n}) = \phi(\tilde{u}^*) = \inf \{\phi(u); u \in U\}$$

and u^* is an optimal controller as claimed. To prove (1.9) we set $\tilde{y}_\varepsilon = y^{u^*}$ and note that by (2.36) and the Arzelà theorem, we have

$$\tilde{y}_{\varepsilon_n} \rightarrow y^* = y^{u^*} \quad \text{in } C([0, T]; H).$$

Hence

$$\int_0^T g(y_{\varepsilon_n}(t)) dt + \varphi_0(\tilde{y}_{\varepsilon_n}(T)) \rightarrow \int_0^T g(y^*(t)) dt + \varphi_0(y^*(T))$$

and by (2.38) we see that $h(u_{\varepsilon_n}) \rightarrow h(u^*)$. Hence $\lim_{n \rightarrow \infty} \phi(u_{\varepsilon_n}^*) = \phi(u^*)$ and since $\{\varepsilon_n\}$ is arbitrary (1.9) follows.

Assume now that Hypothesis (ii) holds, i.e., $F = \partial I_C$. Then $e^{-\varepsilon F} P = P = (1 + \varepsilon \partial I_C)^{-1}$ for all $\varepsilon > 0$, $K = C$ and system (0.3), (0.4) becomes

$$(2.39) \quad \begin{aligned} y'(t) + Ay(t) &= (Bu)(t) + f(t) \quad \text{a.e. } t \in [i\varepsilon, (i+1)\varepsilon], \\ y^+(i\varepsilon) &= Py^-(i\varepsilon). \end{aligned}$$

Let $\{u_{\varepsilon_n}^*\}$ be a weakly convergent subsequence of $\{u_\varepsilon^*\}$ and let u^* be its weak limit (see (2.36)). We see $u_n = u_{\varepsilon_n}^*$ and $y_n = y_{\varepsilon_n}^*$. For simplicity we set $\varepsilon_n = \varepsilon$ and $N_n = N$.

By estimate (2.34) we have

$$(2.40) \quad \sum_{i=0}^{N-1} \int_{i\varepsilon}^{(i+1)\varepsilon} |y_n'(t)|^2 dt + \|y_n(t)\|^2 \leq C \left(\|y_0\|^2 + \int_0^T (|u_n|_U^2 + |f|^2) dt \right)$$

and therefore

$$(2.40)' \quad \int_0^T |Ay_n(t)|^2 dt \leq C.$$

On the other hand, we have

$$(2.41) \quad \begin{aligned} & \sum_{i=0}^N |y_n^+(i\varepsilon) - y_n^-(i\varepsilon)| \\ & \leq \sum_{i=0}^N |Py_n^-(i\varepsilon) - e^{-A\varepsilon} Py_n^-((i-1)\varepsilon)| + \int_0^T (|Bu_n(s)| + |f(s)|) ds. \end{aligned}$$

Since by virtue of assumption (1.2), $e^{-At}C \subset C$ for all $t \geq 0$ (see [6] or [2, p. 183]) we have

$$\begin{aligned} |Py_n^-(i\varepsilon) - e^{-A\varepsilon} Py_n^-((i-1)\varepsilon)| &= |Py_n^-(i\varepsilon) - P e^{-A\varepsilon} Py_n^-((i-1)\varepsilon)| \\ &\leq |y_n^-(i\varepsilon) - e^{-A\varepsilon} Py_n^-((i-1)\varepsilon)| \\ &\leq \int_{(i-1)\varepsilon}^{i\varepsilon} (|Bu_n| + |f|) ds \end{aligned}$$

and by (2.41) we conclude that

$$(2.42) \quad \sum_{i=0}^N |y_n^+(i\varepsilon) - y_n^-(i\varepsilon)| \leq 2 \int_0^T (|Bu_n| + |f|) ds.$$

The functions y_n are of bounded variation on $[0, T]$ and by estimates (2.40), we see that

$$\bigvee_0^T y_n + \|y_n(t)\| \leq C \quad \text{for all } n \text{ and } t \in [0, T]$$

where $\bigvee_0^T y_n$ stands for the variation of $y_n : [0, T] \rightarrow H$. Since the injection of V into

H is compact we conclude, by virtue of the infinite-dimensional Helly theorem, that on a subsequence, again denoted y_n , we have

$$(2.43) \quad y_n(t) \rightarrow y^*(t) \text{ strongly in } H \text{ for all } t \in [0, T] \text{ and weak* in } L^\infty(0, T; V).$$

By estimate (2.40)' we see that $Ay^* \in L^2(0, T; H)$.

Now let $y \in C$ be arbitrary but fixed and let $t \in [k\varepsilon, (k+1)\varepsilon]$, $s \in [i\varepsilon, (i+1)\varepsilon]$, $i < k$, two points on the interval $[0, T]$. By (2.39) we have

$$\begin{aligned} & \frac{1}{2} (|y_n(t) - y|^2 - |y_n^+(k\varepsilon) - y|^2) + \frac{1}{2} \sum_{j=i}^k (|y_n^-(j\varepsilon) - y|^2 - |y_n^+((j-1)\varepsilon) - y|^2) \\ & \quad + \frac{1}{2} (|y_n^-((i+1)\varepsilon) - y|^2 - |y^n(s) - y|^2) \\ & = \int_s^t (Bu_n + f - Ay_n, y_n - y) d\tau. \end{aligned}$$

Hence

$$\begin{aligned} \frac{1}{2} |y_n(t) - y|^2 &= \int_s^t (Bu_n + f - Ay_n, y_n - y) d\tau + \frac{1}{2} |y_n(s) - y|^2 \\ & \quad + \frac{1}{2} \sum_{j=i}^{k+1} (|y_n^+(j\varepsilon) - y|^2 - |y_n^-(j\varepsilon) - y|^2). \end{aligned}$$

On the other hand, we have

$$\begin{aligned} \frac{1}{2} (|y_n^+(j\varepsilon) - y|^2 - |y_n^-(j\varepsilon) - y|^2) &\leq (y_n^+(j\varepsilon) - y_n^-(j\varepsilon), y_n^+(j\varepsilon) - y) \\ &= (Py_n^-(j\varepsilon) - y_n^-(j\varepsilon), Py_n^-(j\varepsilon) - y) \leq 0 \end{aligned}$$

because $1 - P = \lambda(\partial I_C)_\lambda \in \lambda \partial I_C P$ for all $\lambda > 0$. Hence

$$\frac{1}{2} (|y_n(t) - y|^2 - |y_n(s) - y|^2) \leq \int_s^t (Bu_n + f - Ay_n, y_n - y) d\tau.$$

Letting n tend to ∞ in the previous inequality we get

$$(2.44) \quad \frac{1}{2} (|y^*(t) - y|^2 - |y^*(s) - y|^2) \leq \int_s^t (Bu^* + f - Ay^*, y^* - y) d\tau$$

for $0 \leq s \leq t \leq T$.

Before proceeding further let us observe that $y^*(t) \in C$ almost everywhere $t \in [0, T]$. Indeed by (2.39) we have

$$y_n(t) = e^{-A(t-i\varepsilon)} Py_n^-(i\varepsilon) + \int_{i\varepsilon}^t e^{-A(t-s)} (Bu_n + f) ds \quad \text{for } t \in [i\varepsilon, (i+1)\varepsilon]$$

and therefore

$$|y_n(t) - Py_n(t)| \leq \left| \int_{i\varepsilon}^t e^{-A(t-s)} (Bu_n + f) ds \right| \leq C\varepsilon_n^{1/2} \quad \text{for } t \in [i\varepsilon_n, (i+1)\varepsilon_n]$$

because $e^{-At}C \subset C$. Hence $y^*(t) = Py^*(t)$ as claimed.

Now in (2.44) take $y = y^*(s)$. By Gronwall's lemma we obtain

$$|y^*(t) - y^*(s)| \leq \int_s^t |Bu^* + f + Ay^*| d\tau \quad \text{for } 0 \leq s \leq t \leq T$$

and therefore $y^*: [0, T] \rightarrow H$ is absolutely continuous and almost everywhere differentiable. Now (2.44) yields

$$(2.45) \quad (y^*(t) - y^*(s), y^*(s) - y) \leq \int_s^t (Bu^*(\tau) + f(\tau) - Ay^*(\tau), y^*(\tau) - y) d\tau.$$

Then dividing by $t-s$ and letting s tend to zero we see that

$$(y^{*'}(t) + Ay^*(t) - Bu^*(t) - f(t), y^*(t) - y) \leq 0 \quad \text{a.e. } t \in [0, T]$$

for all $y \in C$. Hence

$$y^{*'} + Ay^* + \partial I_C(y^*) \ni f + Bu^* \quad \text{a.e. } t \in [0, T].$$

In other words, we have proved that $y^* = y^{u^*}$. From now on the proof is identical with that of first case.

3. Problem P_ε in a particular case. We will consider here the special case of free boundary problem (1.15), where for the sake of simplicity we take $\varphi_0 \equiv 0$. In this case system (0.2), (0.3) becomes

$$\begin{aligned} (3.1) \quad & y_t - \Delta y = Bu \quad \text{in } Q_\varepsilon^i = (i\varepsilon, (i+1)\varepsilon) \times \Omega, \\ & y = 0 \quad \text{in } \Sigma_\varepsilon^i = (i\varepsilon, (i+1)\varepsilon) \times \Gamma, \\ & y(0, x) = y_0(x), \quad x \in \Omega, \\ & y^+(i\varepsilon, x) = Py^-(i\varepsilon, x), \quad x \in \Omega \end{aligned}$$

where $Pz = \max(z, 0)$ for all $z \in L^2(\Omega)$ and $y_0 \in H_0^1(\Omega)$, $y_0 \geq 0$ a.e. in Ω .

We may approximate system (3.1) by the following the family of penalized smooth control systems

$$\begin{aligned} (3.2) \quad & y_t - \Delta y = Bu \quad \text{in } Q_\varepsilon^i, \\ & y = 0 \quad \text{in } \Sigma_\varepsilon^i, \\ & y^+(i\varepsilon, x) = (1 + \beta_\lambda)^{-1} y^-(i\varepsilon, x), \quad y^+(0, x) = y_0(x) \quad \text{in } \Omega \end{aligned}$$

where $\lambda > 0$ and

$$(3.3) \quad \beta_\lambda(r) = \begin{cases} \lambda^{-1}r + 2^{-1} & \text{for } r \leq -\lambda, \\ -(2\lambda^2)^{-1}r^2 & \text{for } -\lambda \leq r \leq 0, \\ 0 & \text{for } r > 0. \end{cases}$$

We may obtain first-order necessary conditions of optimality for problem (P_ε) by using the method developed in [3]. To this aim consider an optimal pair $(y_\varepsilon^*, u_\varepsilon^*)$ to problem (P_ε) .

Let $(y_\varepsilon^\lambda, u_\varepsilon^\lambda)$ be an optimal pair for control problem with state equation (3.2) and cost functional

$$\int_0^T g(y(t)) dt + h(u) + \frac{1}{2} \|u - u_\varepsilon^*\|_U^2.$$

It follows that for $\lambda \rightarrow 0$

$$u_\varepsilon^\lambda \rightarrow u_\varepsilon^* \quad \text{strongly in } U,$$

$$y_\varepsilon^\lambda \rightarrow y_\varepsilon^* \quad \text{strongly in every } C([i\varepsilon, (i+1)\varepsilon]; H) \text{ and} \\ \text{weakly in } W^{1,2}([i, (i+1)\varepsilon]; H) \cap L^2((i\varepsilon, (i+1)\varepsilon); H_0^1(\Omega)).$$

The optimality conditions for this problem can be written as

$$\begin{aligned} (3.4) \quad & (p_\varepsilon^\lambda)_t + \Delta p_\varepsilon^\lambda = \nabla g(y_\varepsilon^\lambda) \quad \text{in } Q_\varepsilon^i, \\ & (p_\varepsilon^\lambda)^-((i+1)\varepsilon) = (1 + \beta_\lambda'((y_\varepsilon^\lambda)^+((i+1)\varepsilon)))^{-1} (p_\varepsilon^\lambda)^+((i+1)\varepsilon) \quad \text{in } \Omega, \\ & (p_\varepsilon^\lambda)^-(T) = 0, \end{aligned}$$

$$(3.5) \quad B^* p_\varepsilon^\lambda \in \partial h(u_\varepsilon^\lambda) + u_\varepsilon^\lambda - u_\varepsilon^*.$$

Multiplying (3.4) by p_ε^λ and integrating by parts, we obtain after some calculations the following estimates:

$$\int_0^T \|p_\varepsilon^\lambda(t)\|^2 dt + |p_\varepsilon^\lambda(t)| \leq C \quad \text{for all } \lambda > 0,$$

$$\sum_{i=0}^{N-1} \int_{i\varepsilon}^{(i+1)\varepsilon} \|(p_\varepsilon^\lambda)_i\|_*^2 dt \leq C \quad \text{for all } \lambda > 0.$$

(We have denoted as usual by $\|\cdot\|$, $|\cdot|$ and $\|\cdot\|_*$ the norms in $V = H_0^1(\Omega)$, $H = L^2(\Omega)$ and $V' = H^{-1}(\Omega)$.)

Then by the Helly theorem we infer that on a subsequence again denoted λ , we have

$$p_\varepsilon^\lambda(t) \rightarrow p(t) \quad \text{strongly in } H^{-1}(\Omega) \text{ for every } t \in [0, T],$$

$$p_\varepsilon^\lambda \rightarrow p \quad \text{weakly in } L^2(0, T; H_0^1(\Omega)), \text{ weak-star in } L^\infty(0, T; L^2(\Omega)).$$

Recalling the inequality (see [12])

$$\|p_\varepsilon^\lambda - p\|_{L^2(\Omega)} \leq \delta \|p_\varepsilon^\lambda - p\|_{H_0^1(\Omega)} + \eta(\delta) \|p_\varepsilon^\lambda - p\|_{H^{-1}(\Omega)}$$

where $\eta(\delta) \rightarrow 0$ as $\delta \rightarrow 0$, we conclude that

$$p_\varepsilon^\lambda \rightarrow p \quad \text{strongly in } L^2(Q).$$

Then letting λ tend to zero in (3.4), (3.5) we see that

$$p_t + \Delta p = \nabla g(y_\varepsilon^*) \quad \text{in } Q_\varepsilon^i,$$

$$p^-((i+1)\varepsilon, x) = \mu_i p^+((i+1)\varepsilon, x), \quad x \in \Omega; \quad i = 0, 1, \dots, N-2,$$

$$p^-(T, x) = 0$$

where

$$(3.6) \quad \mu_i = w - \lim_{\lambda \rightarrow 0} (1 + \beta_\lambda'((y_\varepsilon^\lambda)^+((i+1)\varepsilon)))^{-1} \quad \text{in } L^2(\Omega).$$

We set $E_\lambda^1 = \{x \in \Omega; (y_\varepsilon^\lambda)^+((i+1)\varepsilon, x) \leq -\lambda\}$ and

$$E_\lambda^2 = \{x \in \Omega; -\lambda < (y_\varepsilon^\lambda)^+((i+1)\varepsilon, x) \leq 0\}.$$

We have

$$(3.7) \quad \beta_\lambda((y_\varepsilon^\lambda)^+((i+1)\varepsilon)) = \beta_\lambda'((y_\varepsilon^\lambda)^+((i+1)\varepsilon))(y_\varepsilon^\lambda)^+((i+1)\varepsilon) \\ + 2^{-1}\chi_\lambda^1(x) + (2\chi_\lambda^2)^{-1}((y_\varepsilon^\lambda)^+((i+1)\varepsilon)^2)\chi_\lambda^2(x)$$

where χ_λ^1 , χ_λ^2 are the characteristic functions of E_λ^1 and E_λ^2 , respectively.

Since $\{\beta_\lambda((y_\varepsilon^\lambda)^+((i+1)\varepsilon))\}$ is bounded in $L^2(\Omega)$ and weakly convergent to some $\nu \in \partial I_C((y_\varepsilon^*)^+((i+1)\varepsilon))$, i.e., $\nu(x) = 0$ in $\{x; (y_\varepsilon^*)^+((i+1)\varepsilon) > 0\}$, $\nu(x) \leq 0$ in Ω , we see by (3.6) and (3.7) that

$$\mu_i(x) = 1 \quad \text{in } [(y_\varepsilon^*)^+((i+1)\varepsilon) > 0],$$

$$\mu_i(x) = 0 \quad \text{in } [(y_\varepsilon^*)^+((i+1)\varepsilon) = 0].$$

PROPOSITION 3. *Let $(y_\varepsilon^*, u_\varepsilon^*)$ be any optimal pair in problem (P_ε) with state equation (3.1). Then we have $p \in BV([0, T]; H^{-1}(\Omega)) \cap L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H_0^1(\Omega))$ such*

that $p_i \in W^{1,2}([\varepsilon, (i+1)\varepsilon]; H^{-1}(\Omega))$ for $i = 0, 1, \dots, N-1$ and

$$(3.8) \quad \begin{aligned} p_i + \Delta p &= \nabla g(y_\varepsilon^*) \quad \text{in } Q_\varepsilon^i \text{ for all } i, \\ p^-((i+1)\varepsilon, x) &= p^+((i+1)\varepsilon, x) \quad \text{in } [x; (y_\varepsilon^*)^+((i+1)\varepsilon, x) > 0], \\ p^-((i+1)\varepsilon, x) &= 0 \quad \text{in } [x; (y_\varepsilon^*)^+((i+1)\varepsilon, x) = 0], \\ p^-(T, x) &= 0 \quad \text{in } \Omega, \end{aligned}$$

$$(3.9) \quad B^*p \in \partial h(u_\varepsilon^*).$$

To solve problem (P_ε) numerically we shall use the following gradient type algorithm (δ is a prescribed precision, MAXITER is the prescribed maximum number of iterations and $\varepsilon = T/N$):

Step 0. Choose $u^{(0)} \in L^2(0, T; U)$;

$$n := 0, \quad \text{iter} := 1.$$

Step 1. Compute y_n solving

$$\begin{aligned} \frac{\partial y_n}{\partial t} - \Delta y_n &= Bu^{(n)} \quad \text{on } Q_\varepsilon^i, \\ y_n &= 0 \quad \text{on } \Sigma_\varepsilon^i, \quad i = 0, 1, \dots, N-1, \\ y_n^+(i\varepsilon, x) &= \max(y_n^+(i\varepsilon, x), 0) \quad \text{for } x \in \Omega, \quad i = 1, 2, \dots, N-1, \\ y_n^+(0, x) &= y_0(x) \quad \text{for } x \in \Omega. \end{aligned}$$

Step 2. Compute p_n solving

$$\begin{aligned} \frac{\partial p_n}{\partial t} + \Delta p_n &= \nabla g(y_n) \quad \text{on } Q_\varepsilon^i, \\ p_n^{(n)} &= 0 \quad \text{on } \Sigma_\varepsilon^i \quad \text{for } i = 0, 1, \dots, N-1, \\ p_n^-((i+1)\varepsilon, x) &= \begin{cases} p_n^+((i+1)\varepsilon, x) & \text{if } y_n^+((i+1)\varepsilon, x) > 0, \\ 0 & \text{if } y_n^+((i+1)\varepsilon, x) = 0, \end{cases} \\ p_n^-(T, x) &= 0 \quad \text{for } x \in \Omega. \end{aligned}$$

Step 3. Compute $w^{(n)} \in \partial h(u^{(n)}) - B^*p_n$;
compute ρ_n —the steplength of the gradient method.

Step 4. Test: $\|\rho_n w^{(n)}\| \leq \delta$?

-YES \rightarrow STOP (the algorithm is convergent).

-NO \rightarrow iter := iter + 1;

Test: iter \leq MAXITER?

-YES $\rightarrow u^{(n+1)} := u^{(n)} - \rho_n w^{(n)}$;

$n := n + 1$;

GO TO Step 1.

-NO \rightarrow STOP (the algorithm is not convergent).

Remark 3.1. The convergence test may also deal with the difference $\phi_\varepsilon(u^{(n+1)}) - \phi_\varepsilon(u^{(n)})$.

This gradient algorithm yields a sequence $\{\phi_\varepsilon(u^{(n)})\}$ which is convergent to a value corresponding to a stationary point of ϕ_ε [8, p. 70]. Moreover, if the sequence above is convergent to $\inf \phi_\varepsilon$ then $\{u^{(n)}\}$ is a minimizing sequence for problem (P), that is

$$\lim_{\substack{\varepsilon \rightarrow 0 \\ n \rightarrow \infty}} \phi_\varepsilon(u^{(n)}) = \inf \phi.$$

A numerical example will be presented in § 5.

4. Product formula for a boundary optimal control problem. We shall consider here the following problem: Minimize

$$(4.1) \quad \int_0^T g(y(t)) dt + h(u) + \varphi_0(y(T))$$

on all $y \in L^2(Q)$ and $u \in L^2(\Sigma_1)$ subject to

$$(4.2) \quad \begin{aligned} y_t - \Delta y &= f_0 \quad \text{in } [(t, x) \in Q; y(t, x) > 0], \\ y_t - \Delta y &\geq f_0, \quad y \geq 0 \quad \text{in } Q = (0, T) \times \Omega, \\ y(0, x) &= y_0(x), \quad x \in \Omega, \\ \frac{\partial y}{\partial \nu} + \alpha y &= \int_0^t (Bu)(s) ds \quad \text{for } (t, x) \in \Sigma_1 = (0, T) \times \Gamma_1, \\ y &= 0 \quad \text{in } \Sigma_2 = (0, T) \times \Gamma_2. \end{aligned}$$

Here Ω is a bounded and open subset of R^n with a sufficiently smooth boundary $\Gamma = \Gamma_1 \cup \Gamma_2$, where $\Gamma_1 \cap \Gamma_2 = \emptyset$, B is a linear continuous operator from a Hilbert space of controllers U to $L^2(\Sigma_1)$, $\alpha \geq 0$, and y_0, f_0 are given functions such that

$$(4.3) \quad f_0 \in W^{1,2}([0, T]; L^2(\Omega)),$$

$$(4.4) \quad y_0 \in H^1(\Omega), \quad y_0 \geq 0 \quad \text{in } \Omega, \quad y_0 = 0 \quad \text{in } \Gamma_2.$$

In regard to the functions $g: L^2(\Omega) \rightarrow R$, $\varphi_0: L^2(\Omega) \rightarrow R$ and $h: U \rightarrow \bar{R}$ we will assume that hypothesis (6) in § 1 holds.

It is well known (see, for instance, [3], [4]) that the one-phase Stefan problem

$$\begin{aligned} \theta_t - \Delta \theta &= 0 \quad \text{in } \{(t, x) \in Q; l(x) < t < T\}, \\ \theta &= 0 \quad \text{in } \{(t, x) \in Q; l(x) \geq t\}, \\ \nabla x \theta \cdot \nabla l(x) &= -\rho \quad \text{in } \{(t, x) \in Q; t = l(x)\}, \\ \frac{\partial \theta}{\partial \nu} + \alpha(\theta - w) &= 0 \quad \text{in } \Sigma_1, \quad \theta = 0 \quad \text{in } \Sigma_2, \\ \theta(x, 0) &= \theta_0(x) \quad \text{in } \Omega_0; \quad \theta(0, x) = 0 \quad \text{in } \Omega \setminus \Omega_0 \end{aligned}$$

(here $t = l(x)$ is the equation of liquid-solid interface) can be put into the form (4.2), where

$$y(t, x) = \int_0^t \theta(s, x) \chi(s, x) ds$$

(χ is the characteristic function of the set $\{(t, x); l(x) \leq t\}$) and

$$(4.5) \quad (Bu)(s, \sigma) = w(s, \sigma) \quad \text{a.e. } (s, \sigma) \in \Sigma_1,$$

$$(4.6) \quad f_0(x) = \theta_0(x) \quad \text{for } x \in \Omega_0, \quad f_0(x) = -\rho \quad \text{for } x \in \Omega \setminus \Omega_0.$$

Under assumptions (4.3), (4.4) the free boundary problem admits a unique solution $y \in W^{1,2}([0, T]; L^2(\Omega)) \cap L^\infty(0, T; V)$ (see [3, p. 157]). Here $V = \{y \in H^1(\Omega); y = 0 \text{ in } \Gamma_2\}$.

First-order necessary conditions for problems of this form have been established in [3], [4], [11].

We associate to problem (4.2) the approximation scheme

$$\begin{aligned}
 (4.7) \quad & y_t - \Delta y = f_0 \quad \text{in } Q_\varepsilon^i = (i\varepsilon, (i+1)\varepsilon) \times \Omega, \\
 & \frac{\partial y}{\partial \nu} + \alpha y = v \quad \text{in } \Sigma_\varepsilon^{1,i} = (i\varepsilon, (i+1)\varepsilon) \times \Gamma_1, \\
 & y = 0 \quad \text{in } \Sigma_\varepsilon^{2,i} = (i\varepsilon, (i+1)\varepsilon) \times \Gamma_2, \\
 & y^+(i\varepsilon, x) = Py^-(i\varepsilon, x), \quad x \in \Omega, \quad i = 1, \dots, N-1 \\
 & y(0, x) = y_0(x), \quad x \in \Omega
 \end{aligned}$$

where

$$\forall(t) = \int_0^t (Bu)(s) \, ds \quad \text{for } t \in [0, T], \quad Py = \max(y, 0).$$

Note that for every $\varepsilon > 0$, problem (4.7) has a unique solution $y \in L^\infty(0, T; V) \cap W^{1,2}([i\varepsilon, (i+1)\varepsilon]; L^2(\Omega))$ on every interval $[i\varepsilon, (i+1)\varepsilon]$. We set

$$(4.8) \quad \psi(u) = \int_0^T g(y''(t)) \, dt + h(u) + \varphi_0(y''(T))$$

and

$$(4.9) \quad \psi_\varepsilon(u) = \int_0^T g(y_\varepsilon''(t)) \, dt + h(u) + \varphi_0(y_\varepsilon''(T))$$

where y'' and y_ε'' are the solutions to (4.2) and (4.7), respectively.

Then we consider the optimal control problem with cost functional (4.1) and state equation (4.7), i.e.,

$$(4.10) \quad \min \{\psi_\varepsilon(u); u \in U\}.$$

We have for the approximating problem (4.10) a convergence of the type shown in Theorem 1.

THEOREM 2. *Let $\{u_\varepsilon^*\}$ be a sequence of optimal controllers for problems (4.10). Then*

$$(4.11) \quad \lim_{\varepsilon \rightarrow 0} \psi(u_\varepsilon^*) = \inf \{\psi(u); u \in U\}$$

and

$$(4.12) \quad \liminf_{\varepsilon \rightarrow 0} \psi_\varepsilon = \inf \psi.$$

Moreover, every weak limit point of $\{u_\varepsilon^*\}$ for $\varepsilon \rightarrow 0$ is an optimal controller for problem (4.1).

Proof. Let $(y_\varepsilon^*, u_\varepsilon^*)$ be an optimal pair for problem (4.10). Then as seen earlier in the proof of Theorem 1 there is a subsequence $\varepsilon_n \rightarrow 0$ such that

$$(4.13) \quad u_{\varepsilon_n}^* \rightarrow u^* \quad \text{weakly in } U.$$

We postpone for the time being the verification of Lemma 1 below.

LEMMA 1. By (4.13) it follows that

$$(4.14) \quad y_{\varepsilon_n}(t) \rightarrow y^*(t) \quad \text{strongly in } H \text{ for all } t \in [0, T] \text{ and weak star in } L^\infty(0, T; V)$$

where $y^* = y^{u^*}$ is the solution to system (4.61), where $u = u^*$.

Then by (4.13), (4.14) we infer that

$$\liminf_{n \rightarrow \infty} h(u_{\varepsilon_n}) \geq h(u^*), \quad \lim_{n \rightarrow \infty} g(y_{\varepsilon_n}) = g(y^*) \quad \text{in } L^1(0, T)$$

and this implies that

$$(4.15) \quad \lim_{n \rightarrow \infty} \psi_{\varepsilon_n}(u_{\varepsilon_n}) = \psi(u^*) = \inf \psi.$$

Now if $z_\varepsilon = y^{u_\varepsilon^*}$ then we have the estimate (see, for instance, [3, p. 157])

$$\|z_\varepsilon(t)\|_V + \|z'_\varepsilon(t)\|_{L^2(\Omega)}^2 dt \leq C(1 + \|Bu_\varepsilon\|_{L^2(\Sigma_1)}^2)$$

and this implies via the Arzelá theorem that $\{z_\varepsilon\}$ is compact in $C([0, T]; L^2(\Omega))$. Hence without loss of generality we may assume that

$$z_{\varepsilon_n} \rightarrow y^* \quad \text{in } C([0, T]; L^2(\Omega)).$$

Since $h(u_{\varepsilon_n}) \rightarrow h(u^*)$ as easily follows by (4.15), we infer that $\psi(u_{\varepsilon_n}) \rightarrow \psi(u^*)$ as claimed.

Proof of Lemma 1. The proof is similar to part (ii) of Theorem 2 with some modifications. We set $u_{\varepsilon_n} = u_n$, $y_{\varepsilon_n} = y_n$ and $v_n(t) = \int_0^t (Bu_n) ds$. By (4.7) we have (setting $\varepsilon_n = \varepsilon$)

$$\begin{aligned} & |y_n^-((i+1)\varepsilon)|_2^2 + \int_{Q_\varepsilon^i} |\nabla y_n|^2 dx dt + \alpha \int_{\Sigma_\varepsilon^{1,i}} |y_n|^2 dx dt \\ & \leq \int_{Q_\varepsilon^i} |f_0|^2 dx dt + \int_{\Sigma_\varepsilon^{1,i}} |v_n|^2 dx dt + |y_n^+(i\varepsilon)|_2^2 \end{aligned}$$

and

$$\begin{aligned} & \int_{i\varepsilon}^{(i+1)\varepsilon} |(y_n)_t|_2^2 dt + |\nabla y_n^-((i+1)\varepsilon)|_2^2 + \alpha \int_{\Gamma_1} |y_n^-((i+1)\varepsilon, x)|^2 dx \\ & \leq |\nabla y_n^+(i\varepsilon)|_2^2 + \alpha \int_{\Gamma_1} |y_n^+(i\varepsilon, x)|^2 dx + \int_{Q_\varepsilon^i} |f_0|^2 dx dt + \int_{\Sigma_\varepsilon^{1,i}} |v_n'|^2 dx dt \end{aligned}$$

where $|\cdot|_2$ stands for $L^2(\Omega)$ -norm. Combining these two inequalities we obtain

$$\begin{aligned} (4.16) \quad & \sum_{i=0}^{N-1} \int_{i\varepsilon}^{(i+1)\varepsilon} |(y_n)_t|_2^2 dt + \|y_n(t)\|^2 \\ & \leq \|y_0\|^2 + \int_Q |f_0|^2 dx dt + \int_{\Sigma_1} |Bu_n|^2 dx dt \end{aligned}$$

where $\|\cdot\|$ is the $H^1(\Omega)$ -norm.

In order to estimate

$$(4.17) \quad \sum_{i=0}^{N-1} |y_n^+(i\varepsilon) - y_n^-(i\varepsilon)|_2 = \sum_{i=0}^{N-1} |Py_n^-(i\varepsilon) - y_n^-(i\varepsilon)|_2$$

we observe that $y_n^-(i\varepsilon) = z_n(i\varepsilon) + \xi_n(i\varepsilon)$, where

$$\begin{aligned} (4.18) \quad & (z_n)_t - \Delta z_n = f_0 \quad \text{in } Q_\varepsilon^i, \\ & \frac{\partial z_n}{\partial \nu} + \alpha z_n = v_n \quad \text{in } \Sigma_\varepsilon^{1,i}, \quad z_n = 0 \quad \text{in } \Sigma_\varepsilon^{2,i}, \\ & z_n((i-1)\varepsilon) = 0 \quad \text{in } \Omega \end{aligned}$$

and

$$(4.19) \quad \begin{aligned} (\xi_n)_t - \Delta \xi_n &= 0 \quad \text{in } Q_\varepsilon^i, \\ \frac{\partial \xi_n}{\partial \nu} + \alpha \xi_n &= 0 \quad \text{in } \Sigma_\varepsilon^{1,i}, \quad \xi_n = 0 \quad \text{in } \Sigma_\varepsilon^{2,1}, \\ \xi_n((i-1)\varepsilon) &= Py_n^-((i-1)\varepsilon) \quad \text{in } \Omega. \end{aligned}$$

We have

$$\begin{aligned} |Py_n^-(i\varepsilon) - y_n^-(i\varepsilon)|_2 &\leq |Py_n^-(i\varepsilon) - \xi_n(i\varepsilon)|_2 + |z_n(i\varepsilon)|_2 \\ &\leq |Py_n^-(i\varepsilon) - Pe^{-\bar{\Lambda}\varepsilon} Py_n^-((i-1)\varepsilon)|_2 + \left(\int_{Q_\varepsilon^i} |f_0|^2 dx dt \right)^{1/2} \\ &\quad + \left(\int_{\Sigma_\varepsilon^{1,i}} |v_n|^2 dx dt \right)^{1/2} \\ &\leq 2(\|f_0\|_{L^2(Q_\varepsilon^i)} + \|v_n\|_{L^2(\Sigma_\varepsilon^{1,i})}) \end{aligned}$$

where $A\xi = \Delta \xi$ for $\xi \in D(A) = \{\xi \in H^1(\Omega); \partial \xi / \partial \nu + \alpha \xi = 0 \text{ in } \Gamma_1; \xi = 0 \text{ in } \Gamma_2\}$.

Putting the latter estimate in (4.17) we get

$$(4.20) \quad \sum_{i=0}^{N-1} |y_n^+(i\varepsilon) - y_n^-(i\varepsilon)|_2 \leq 2(\|f_0\|_{L^2(Q)} + \|v_n\|_{L^2(\Sigma_1)}) \leq C.$$

Hence the total variation of y_n on $[0, T]$ is uniformly bounded. We may therefore apply the Helly theorem to sequence $\{y_n\}$ to conclude that on a subsequence, again denoted $\{y_n\}$, we have

$$(4.21) \quad y_n(t) \rightarrow y^*(t) \quad \text{strongly in } H \text{ for all } t \in [0, T] \text{ and weak star in } L^\infty(0, T; V).$$

Now let $K = \{y \in V; y(x) \geq 0 \text{ almost everywhere } x \in \Omega\}$ and let y be any element of K . Let $s \leq t$ be two arbitrary points of $[0, T]$. If $s \in [i\varepsilon, (i+1)\varepsilon]$ and $t \in [k\varepsilon, (k+1)\varepsilon]$, where $i \leq k$, by (4.7) we obtain

$$\begin{aligned} &\frac{1}{2} (|y_n(t) - y|_2^2 - |y_n^+(k\varepsilon) - y|_2^2) + \frac{1}{2} \sum_{j=i}^k (|y_n^-(j\varepsilon) - y|_2^2 - |y_n^+((j-1)\varepsilon) - y|_2^2) \\ &\quad + \frac{1}{2} (|y_n^-((i+1)\varepsilon) - y|_2^2 - |y_n(s) - y|_2^2) \\ &= - \int_s^t d\tau \left(\int_\Omega \nabla y_n(\tau, x) \cdot \nabla (y_n(\tau, x) - y(x)) dx \right) \\ &\quad - \int_{\Gamma_1} (v_n(\tau, x) - \alpha y_n(\tau, x)) \cdot (y_n(\tau, x) - y(x)) dx \end{aligned}$$

and arguing as in the proof of Theorem 1 we obtain

$$\begin{aligned} &\frac{1}{2} (|y_n(t) - y|_2^2 - |y_n(s) - y|_2^2) \\ &\leq - \int_s^t d\tau \left(\int_\Omega (\nabla y_n \cdot \nabla (y_n - y) - f_0(y_n - y)) dx + \int_{\Gamma_1} (v_n - \alpha y_n)(y_n - y) dx \right) \end{aligned}$$

and if we let n tend to $+\infty$ it follows by (4.21) that

$$(4.22) \quad \begin{aligned} &\frac{1}{2} (|y^*(t) - y|_2^2 - |y^*(s) - y|_2^2) + \int_s^t d\tau \left(\int_\Omega (\nabla y^* \cdot \nabla (y^* - y) - f_0(y^* - y)) dx \right) \\ &\quad + \alpha \int_s^t d\tau \int_\Omega y^*(y^* - y) dx - \int_s^t d\tau \int_{\Gamma_1} v^*(y^* - y) dx \leq 0 \end{aligned}$$

where $v^*(t) = \int_0^t Bu^* d\tau$.

By (4.1) and (4.19) we see that for $t \in [(i-1)\varepsilon, i\varepsilon]$

$$y_n(t) = \xi_n(t) + z_n(t) = e^{-A(t-(i-1)\varepsilon)} P y_n^-((i-1)\varepsilon) + z_n(t).$$

Since e^{-At} maps K into itself we have

$$(4.23) \quad |y_n(t) - P y_n(t)|_2 \leq 2|z_n(t)|_2 \quad \text{for } t \in [(i-1)\varepsilon, i\varepsilon].$$

On the other hand, by (4.18) we see that

$$|z_n(t)|_2 \leq \int_{(i-1)\varepsilon}^{i\varepsilon} (|f_0|_2 + \|v_n\|_{L^2(\Gamma_1)}) ds \leq C\varepsilon^{1/2} (\|f_0\|_{L^2(Q)} + \|v_n\|_{L^2(\Gamma_1)}).$$

Hence $y^*(t) \in K$ almost everywhere $t \in [0, T]$.

Now if we take $y = y^*(s)$ in (4.22) and use Gronwall's lemma we find after some computation that

$$|y^*(t) - y^*(s)|_2^2 \leq C \left(\int_s^t (\|v^*(\tau)\|_{L^2(\Gamma_1)}^2 + |f_0(\tau)|_2^2) d\tau \right) \quad \text{for all } s \leq t \leq T.$$

Hence $y^*: [0, T] \rightarrow L^2(\Omega)$ is absolutely continuous and $y_i^* \in L^2(Q)$, i.e., $y^* \in W^{1,2}([0, T]; L^2(\Omega))$.

Now by (4.22) we have

$$\begin{aligned} (y^*(t) - y^*(s), y^*(s) - y)_2 + \int_s^t d\tau \int_{\Omega} (\nabla y^* \cdot \nabla (y^* - y) - f_0(y^* - y)) dx \\ + \int_s^t d\tau \int_{\Gamma_1} (\alpha y^* - v^*)(y^* - y) dx \leq 0 \end{aligned}$$

for all $y \in K$ and all $s \leq t \leq T$. (Here $(\cdot, \cdot)_2$ is the scalar product of $L^2(\Omega)$.)

Then dividing by $t - s$ and letting s tend to t we obtain

$$\begin{aligned} (4.24) \quad (y_i^*(t), y^*(t) - y)_2 + \int_{\Omega} \nabla y^*(t, x) \cdot \nabla (y^*(t, x) - y(x)) dx \\ + \int_{\Gamma_1} (\alpha y^*(t, x) - v^*(t, x))(y^*(t, x) - y(x)) dx \\ \leq \int_{\Omega} f_0(t, x)(y^*(t, x) - y(x)) dx \quad \text{a.e. } t \in [0, T] \quad \text{for all } y \in K. \end{aligned}$$

Inequality (4.24) shows that y^* is the solution to (4.1) thereby completing the proof of Lemma 1 and of Theorem 2.

5. Numerical results. In this section, we present numerical results for the algorithm described in § 3.

The algorithm was tested on the following example: $\Omega = (0, 1)$, $T = 1$. Let us consider a little more generally that $\Omega = (a, b)$. The cost functional is

$$\phi(u, t) = \frac{1}{2} \int_0^T \int_a^b (y(t, x) - y_0(x))^2 dx dt + \frac{1}{2} \int_0^T \int_a^b u^2(t, x) dx dt$$

and B is the identity operator.

The problem was discretized by use of finite differences. Consider the grid defined by the following equidistant points:

$$0 = t_1 < t_2 < \dots < t_{N+1} = T$$

with the steplength $\varepsilon = T/N$ and

$$a = x_1 < x_2 < \cdots < x_{M+1} = b$$

with the steplength $h = (b - a)/M$. The state y is approximated by two matrices, namely YL and YR , whose components are defined by

$$YL(i, j) = y(x_i, t_j - 0), \quad YR(i, j) = y(x_i, t_j + 0).$$

The adjoint state p is approximated the same way by the matrices PL and PR . The control u is represented by the matrix U with components

$$U(i, j) = u(x_i, \tau_j)$$

where $\tau_j = (t_j + t_{j+1})/2$. w defined in Step 3 is also represented by only one matrix W . In what follows we shall omit the iteration index (n).

The state system in Step 1 was solved ascending with respect to time levels, level by level. We have from the initial condition

$$YR(i, 1) = y_0(x_i) \quad \text{for } i = 1, 2, \dots, M+1.$$

Assume now that we know the values corresponding to level j . In order to reach the level $j+1$ we proceed as follows:

(i) We use the implicit method to discretize the differential equation. We obtain

$$(5.1) \quad \begin{aligned} (YL(i, j+1) - YR(i, j))/\varepsilon &= (YL(i+1, j+1) - 2^* YL(i, j+1) \\ &\quad + YL(i-1, j+1))/h^2 + U(i, j) \end{aligned}$$

for $i = 1, 2, \dots, M$.

From the boundary conditions we know that

$$YL(1, j+1) = YL(M+1, j+1) = 0.$$

Hence we obtain an algebraic linear system with respect to the unknowns $YL(i, j+1)$, $i = 1, 2, \dots, M$. Its matrix is a band one having the structure

$$(5.2) \quad \begin{bmatrix} 1+2c & -c & 0 & \cdots & 0 & 0 & 0 \\ -c & 1+2c & -c & \cdots & 0 & 0 & 0 \\ \vdots & & & & & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & -c & 1+2c & -c \\ 0 & 0 & 0 & \cdots & 0 & -c & 1+2c \end{bmatrix}$$

where $c = \varepsilon/h^2$.

(ii) Solving the system above we may compute

$$YR(i, j+1) = \max(YL(i, j+1), 0) \quad \text{for } i = 1, 2, \dots, M+1.$$

The adjoint state system in Step 2 was solved descending with respect to time levels, level by level. We have from the final condition

$$PL(i, N+1) = 0 \quad \text{for } i = 1, 2, \dots, M+1.$$

Assume that all values on level $j+1$ are known. In order to reach the level j we proceed as follows:

(i) We use the implicit method to discretize the differential equation, thus obtaining

$$(5.3) \quad \begin{aligned} & (PL(i, j+1) - PR(i, j))/\varepsilon + (PR(i+1, j) - 2*PR(i, j) + PR(i-1, j))/h^2 \\ & = g'(YR(i, j)) \quad \text{for } i=2, \dots, M. \end{aligned}$$

We have from the boundary conditions

$$PR(1, j) = PR(M+1, j) = 0$$

and we obtain an algebraic linear system with respect to the unknowns $PR(i, j)$, $i=2, \dots, M$. If all equations (5.3) are multiplied by (-1) then the matrix of this system is again (5.2).

(ii) We may now compute

$$PL(i, j) = \begin{cases} PR(i, j) & \text{if } YR(i, j) > 0, \\ 0 & \text{if } YR(i, j) = 0 \end{cases}$$

for $i=1, 2, \dots, M+1$. Of course the test dealing with $YR(i, j)$ and 0 must be carefully implemented with respect to the floating point arithmetic.

It is very important to point out now that all systems to be solved in Steps 1 and 2 have the same matrix (constant with respect to time levels). Therefore this matrix, namely (5.2), is inverted once and all linear systems are solved by multiplication of the inverse matrix times the corresponding right-hand side vector. Hence a large amount of time is saved concerning computations. This is a direct result of decoupling the operators A and F . In the presence of both operators the resulting nonlinear system cannot be solved in such a simple way. Moreover, in our case even the structure of the computer program is more simple and therefore the programming task is easier.

Concerning the computations of w in Step 3, a general idea is to replace the function h by a smooth approximation. Its gradient will be taken instead of the subdifferential ∂h . No regularization was necessary in our particular case since the function h is quadratic. $p(x_i, \tau_j)$ was interpolated by $(PR(i, j) + P(i, j+1))/2$.

Setting the steplength ρ of the gradient method is known to be a delicate problem. Moreover, in our case as in the general case of control problems it is necessary to solve (numerically) the state system in order to evaluate the cost functional for a given control. We have used an interpolation method for the one-dimensional minimization to set ρ at each iteration (see also [12, p. 14]).

We now give more information about the computational complexity of the algorithm. We omit the inversion of the band matrix (5.2) since it is done only once. It enables us to solve an $n \times n$ system of linear equations using at most $2n^2$ arithmetical operations. Let us recall that by $O(n)$ we mean such a quantity that $\lim_{n \rightarrow \infty} O(n)/n = l$, with $0 < l < \infty$ (a polynomial of first degree in n). The computational complexity of the algorithm is given by:

- Solving the system in Step 1— $O(M^2N)$;
- Solving the system in Step 2— $O(M^2N)$;
- Computing w in Step 3— $O(MN)$;
- Computing ρ in Step 3— $kO(M^2N)$, where k is the number of evaluations of the cost functional (a double integral requires $O(MN)$ operations). It follows that a loop in our algorithm involves $(k+2)O(M^2N)$.

The numerical tests were made for $\varepsilon, h < 10^{-1}$. The number of iterations (loops) necessary to satisfy the convergence criterion was only 2. The precision obtained for the test in Step 4 was 10^{-3} and for the one in Remark 3.1 was 10^{-7} . The CPU time spent by an IRIS-50 computer (using 6 hexadecimal digits per number) for the two loops was 8.64 seconds.

The computed (sub)optimal control is symmetric with respect to x , that is $U(i, j) = U(k, j)$ for $i + k = M + 2$ and for every j . In other words $u(x_i, \tau_j) = u(x_k, \tau_j)$ for $x_i + x_k = a + b$ and for every j .

Some values $u(x_i, \tau_j)$ are given in Table 1.

Here $yE - p$ means y times 10^{-p} . Values for $x_i \geq 0.5$ may be obtained from the symmetry property given above.

The behaviour of the functions $t \rightarrow u(x, t)$ for different fixed values of x is given in Fig. 1. The matrix U has been scaled in the following sense: if $u_{\min} = \min \{U(i, j); i = 1, \dots, M+1, j = 1, \dots, N\}$ and $u_{\max} = \max \{U(i, j); i = 1, \dots, M+1, j = 1, \dots, N\}$ then the interval $[u_{\min}, u_{\max}]$ is divided into 50 subintervals of equal length numbered from 1 to 50. Every value $U(i, j)$ belongs to one of these subintervals.

FIG. 1

TABLE 1

STABILITY AND SENSITIVITY ANALYSIS IN CONVEX VECTOR OPTIMIZATION*

TETSUZO TANINO†

Abstract. In this paper stability and sensitivity of the efficient set in convex vector optimization are considered. The perturbation map is defined as a set-valued map. It associates with each parameter vector the set of all minimal points of the parametrized feasible set with respect to an ordering cone in the objective space. Sufficient conditions for the upper and lower semicontinuity of the perturbation map are obtained. Because of the convexity assumptions, the conditions obtained are fairly simple if compared to those in the general case. Moreover, a complete characterization of the contingent derivative of the perturbation map is obtained under some assumptions. It provides quantitative information on the behavior of the perturbation map.

Key words. stability, convex vector optimization, upper and lower semicontinuity, perturbation map, contingent derivative

AMS(MOS) subject classifications. 49B50, 54C60, 90C25

1. Introduction. In this paper we consider a family of parametrized vector optimization problems:

$$(1.1) \quad \begin{aligned} &P\text{-minimize} \quad f(x, u) = (f_1(x, u), \dots, f_p(x, u)) \\ &\text{subject to} \quad x \in X(u) \subset \mathbb{R}^n. \end{aligned}$$

Here x is an n -dimensional decision variable, u is an m -dimensional parameter vector, f_i ($i = 1, \dots, p$) is a real-valued objective function on $\mathbb{R}^n \times \mathbb{R}^m$, X is a set-valued map from \mathbb{R}^m to \mathbb{R}^n , which specifies a feasible decision set, and P is a nonempty pointed closed convex ordering cone in \mathbb{R}^p . We can define another set-valued map Y from \mathbb{R}^m to \mathbb{R}^p by

$$(1.2) \quad Y(u) := \{y \in \mathbb{R}^p \mid y = f(x, u) \text{ for some } x \in X(u)\}.$$

$Y(u)$ is the parametrized feasible set in the objective space. The cone P induces a partial order \leq_P on \mathbb{R}^p , that is, we define the relation \leq_P by

$$(1.3) \quad y \leq_P y' \Leftrightarrow y' - y \in P \quad \text{for } y, y' \in \mathbb{R}^p.$$

This relation \leq_P is reflexive, antisymmetric and transitive. In the problem (1.1), we aim to obtain all the minimal points of the feasible set $Y(u)$ with respect to the order \leq_P . In other words, the solution set in the objective space to the problem (1.1) is given by

$$(1.4) \quad \begin{aligned} \text{Min}_P Y(u) &= \{\hat{y} \in Y(u) \mid \text{there exists no } y \neq \hat{y} \text{ such that } y \leq_P \hat{y}\} \\ &= \{\hat{y} \in Y(u) \mid (Y(u) - \hat{y}) \cap (-P) = \{0\}\}. \end{aligned}$$

Therefore, we can define another set-valued map W from the parameter space \mathbb{R}^m to the objective space \mathbb{R}^p by

$$(1.5) \quad W(u) := \text{Min}_P Y(u).$$

W is often called the perturbation map for (1.1).

* Received by the editors March 24, 1986; accepted for publication (in revised form) June 26, 1987. This research was conducted when the author stayed at the International Institute for Applied Systems Analysis, Laxenburg, Austria.

† Department of Mechanical Engineering II, Tohoku University, Sendai 980, Japan.

In usual scalar optimization where $p = 1$ and $P = \mathbb{R}_+$ (=the set of nonnegative real numbers) W is at most single valued and so it can be identified with the function

$$(1.6) \quad w(u) := \min \{f(x, u) \mid x \in X(u)\}.$$

And the stability and sensitivity analysis in scalar optimization is mainly a study of continuity properties and derivatives of the function w . In case of vector optimization, we investigate the behavior of the set-valued map W .

Some results for general vector optimization problems from this point of view can be seen, for example, in [2], [7] for stability and in [6] for sensitivity. In this paper we consider the case in which convexity is assumed. It is shown that the convexity assumption considerably simplifies the sufficient conditions for the semicontinuity of the perturbation map W and also makes it possible to characterize the contingent derivative of W completely.

2. Convexity assumption and preliminary results. Throughout this paper we assume the following convexity on the feasible decision set map X and the objective function f .

Convexity assumption (CA).

(1) The set-valued map X is convex, i.e., the graph of X which is defined by

$$(2.1) \quad \text{graph } X = \{(u, x) \mid x \in X(u)\}$$

is a convex set in $\mathbb{R}^m \times \mathbb{R}^n$. In other words, for any $u^1, u^2 \in \mathbb{R}^m$ and any α , $0 \leq \alpha \leq 1$,

$$(2.2) \quad \alpha X(u^1) + (1 - \alpha)X(u^2) \subset X(\alpha u^1 + (1 - \alpha)u^2).$$

(2) The function f is P -convex, i.e., for any $(x^1, u^1), (x^2, u^2) \in \mathbb{R}^n \times \mathbb{R}^m$ and any α , $0 \leq \alpha \leq 1$,

$$\alpha f(x^1, u^1) + (1 - \alpha)f(x^2, u^2) \in f(\alpha x^1 + (1 - \alpha)x^2, \alpha u^1 + (1 - \alpha)u^2) + P.$$

LEMMA 2.1. *If P is a pointed closed convex cone and f is P -convex, then f is continuous.*

Proof. Since P is a pointed closed convex cone, the interior of the negative polar cone P° of P is not empty¹. It is easy to prove that $-\langle \mu, f(x, u) \rangle$ is convex as a function of (x, u) for $\mu \in P^\circ$. Hence $\langle \mu, f(\cdot, \cdot) \rangle$ is continuous [3, Cor. 10.1.1]. Take $\bar{\mu} \in \text{int } P^\circ$ and $\bar{\mu} + \delta e^i \in P^\circ$ for sufficiently small $\delta > 0$, where e^i is the i th unit vector in \mathbb{R}^p . Then both $\langle \bar{\mu}, f(\cdot, \cdot) \rangle$ and $\langle \bar{\mu} + \delta e^i, f(\cdot, \cdot) \rangle$ are continuous and hence $f_i(\cdot, \cdot)$ is continuous ($i = 1, \dots, p$). Namely f is continuous. \square

PROPOSITION 2.1. *Under the convexity assumption (CA), the set-valued map Y defined by (1.2) is P -convex, i.e., for any $u^1, u^2 \in \mathbb{R}^m$ and α , $0 \leq \alpha \leq 1$,*

$$(2.3) \quad \alpha Y(u^1) + (1 - \alpha)Y(u^2) \subset Y(\alpha u^1 + (1 - \alpha)u^2) + P.$$

In other words, the graph of the set-valued map $Y + P$ is convex. Here $Y + P$ is defined by

$$(2.4) \quad (Y + P)(u) := Y(u) + P \quad \text{for each } u \in \mathbb{R}^m.$$

Proof. This proposition can be easily proved. \square

Now we introduce concepts of semicontinuity of set-valued maps. Let F be a set-valued map from \mathbb{R}^m to \mathbb{R}^p hereafter in this section. We denote it by $F: \mathbb{R}^m \rightrightarrows \mathbb{R}^p$.

DEFINITION 2.1. (1) F is said to be upper semicontinuous at $\hat{u} \in \mathbb{R}^m$ if $u^k \rightarrow \hat{u}$, $y^k \in F(u^k)$ and $y^k \rightarrow \hat{y}$ all imply that $\hat{y} \in F(\hat{u})$.

(2) F is said to be lower semicontinuous at $\hat{u} \in \mathbb{R}^m$ if $u^k \rightarrow \hat{u}$ and $\hat{y} \in F(\hat{u})$ imply the existence of an integer K and a sequence $\{y^k\} \subset \mathbb{R}^p$ such that $y^k \in F(u^k)$ for $k \geq K$ and $y^k \rightarrow \hat{y}$.

¹ $P^\circ = \{\mu \in \mathbb{R}^p \mid \langle \mu, d \rangle \leq 0 \text{ for all } d \in P\}$, where $\langle \cdot, \cdot \rangle$ denotes the inner product.

(3) F is said to be continuous at $\hat{u} \in \mathbb{R}^m$ if it is both upper and lower semicontinuous at \hat{u} .

Remark 2.1. F is upper semicontinuous on \mathbb{R}^m if and only if graph F is a closed set in $\mathbb{R}^m \times \mathbb{R}^p$.

We shall provide lemmas concerning the semicontinuity of convex set-valued maps. Given F and $\hat{y} \in \mathbb{R}^p$, we define the function ρ from \mathbb{R}^m to $\mathbb{R} \cup \{+\infty\}$ by

$$(2.5) \quad \rho(u) = \text{dist}(\hat{y}, F(u)) := \inf \{\|y - \hat{y}\| \mid y \in F(u)\}.$$

If $F(u) = \emptyset$, let $\rho(u) = +\infty$. The domain of the set-valued map F is defined and denoted by

$$(2.6) \quad \text{dom } F := \{u \in \mathbb{R}^m \mid F(u) \neq \emptyset\}.$$

Clearly $\text{dom } \rho = \{u \in \mathbb{R}^m \mid \rho(u) < +\infty\} = \text{dom } F$.

LEMMA 2.2. *If F is convex, then the function ρ defined by (2.5) is a convex function.*

Proof. Let $u^1, u^2 \in \text{dom } \rho$, which is a convex set, and $0 \leq \alpha \leq 1$. Since F is convex,

$$\alpha F(u^1) + (1 - \alpha)F(u^2) \subset F(\alpha u^1 + (1 - \alpha)u^2)$$

and hence

$$\begin{aligned} \rho(\alpha u^1 + (1 - \alpha)u^2) &= \inf \{\|y - \hat{y}\| \mid y \in F(\alpha u^1 + (1 - \alpha)u^2)\} \\ &\leq \inf \{\|y - \hat{y}\| \mid y \in \alpha F(u^1) + (1 - \alpha)F(u^2)\} \\ &= \inf \{\|\alpha y^1 + (1 - \alpha)y^2 - \hat{y}\| \mid y^1 \in F(u^1), y^2 \in F(u^2)\} \\ &\leq \inf \{\alpha \|y^1 - \hat{y}\| + (1 - \alpha)\|y^2 - \hat{y}\| \mid y^1 \in F(u^1), y^2 \in F(u^2)\} \\ &= \alpha \inf \{\|y^1 - \hat{y}\| \mid y^1 \in F(u^1)\} + (1 - \alpha) \inf \{\|y^2 - \hat{y}\| \mid y^2 \in F(u^2)\} \\ &= \alpha \rho(u^1) + (1 - \alpha)\rho(u^2). \end{aligned}$$

LEMMA 2.3. *If F is convex and $\hat{u} \in \text{int}(\text{dom } F)$, then F is lower semicontinuous at \hat{u} .*

Proof. Let $u^k \rightarrow \hat{u}$ and $\hat{y} \in F(\hat{u})$. Define the function ρ by (2.5). Then, from Lemma 2.2, ρ is a convex function and $\text{dom } \rho = \text{dom } F$. Since $\hat{u} \in \text{int}(\text{dom } \rho)$ and $u^k \rightarrow \hat{u}$, there exists a number K such that $u^k \in \text{dom } \rho$ for any $k \geq K$. For each u^k ($k \geq K$), from the definition of $\rho(u^k)$, there exists $y^k \in F(u^k)$ such that

$$\|y^k - \hat{y}\| < \rho(u^k) + \frac{1}{k}.$$

Since the convex function ρ is continuous at $\hat{u} \in \text{int}(\text{dom } \rho)$ and $\rho(\hat{u}) = 0$, by taking the limit of the above inequality, $\|y^k - \hat{y}\| \rightarrow 0$ as $k \rightarrow \infty$, namely, $y^k \rightarrow \hat{y}$. Therefore F is lower semicontinuous at \hat{u} . \square

Remark 2.2. Since the spaces considered here are all finite dimensional, the assumption in Lemma 2.3 is weaker than in the result of Aubin and Ekeland [1, p. 131], where F is assumed to be not only convex but also upper semicontinuous.

Remark 2.3. The following example illustrates that the condition $\hat{u} \in \text{int}(\text{dom } F)$ is essential in Lemma 2.3. Let $F: \mathbb{R}^2 \rightrightarrows \mathbb{R}$ be defined by

$$F(u) = \begin{cases} \{y \in \mathbb{R} \mid y \geq \alpha\} & \text{if } (u_1 - \alpha)^2 + (u_2)^2 = \alpha^2 \text{ for } \alpha > 0, \quad u \neq (0, 0), \\ \{y \in \mathbb{R} \mid y \geq 0\} & \text{if } u = (0, 0), \\ \emptyset & \text{otherwise.} \end{cases}$$

Then, for $u^k = (1 - \cos(\pi/k), \sin(\pi/k))$, $F(u^k) = \{y \mid y \geq 1\}$ for all $k = 1, 2, \dots$. Clearly $u^k \rightarrow (0, 0)$. However, by taking $0 \in F((0, 0))$, we can easily see that F is not lower semicontinuous at $\hat{u} = (0, 0)$.

LEMMA 2.4. *If F is convex, $\hat{u} \in \text{int}(\text{dom } F)$ and $F(\hat{u})$ is a closed set, then F is upper semicontinuous (and therefore continuous in view of Lemma 2.3) at \hat{u} .*

Proof. Let $u^k \rightarrow \hat{u}$, $y^k \in F(u^k)$ and $y^k \rightarrow \hat{y}$. Define ρ as in (2.5). Then ρ is a convex function from Lemma 2.2. Hence ρ is continuous at $\hat{u} \in \text{int}(\text{dom } F) = \text{int}(\text{dom } \rho)$. On the other hand, taking the limit of the inequality

$$0 \leq \rho(u^k) \leq \|y^k - \hat{y}\|,$$

as $k \rightarrow \infty$, we can prove that $\rho(\hat{u}) = 0$. Since $F(\hat{u})$ is a closed set, this implies $\hat{y} \in F(\hat{u})$. Hence F is upper semicontinuous at \hat{u} . \square

Remark 2.4. It is easily understood that the closedness of $F(\hat{u})$ is very important in the above lemma. The following example illustrates the inevitability of the condition $\hat{u} \in \text{int}(\text{dom } F)$. Let $F: \mathbb{R} \rightrightarrows \mathbb{R}$ be defined by

$$F(u) = \begin{cases} \{y \mid y \geq 0\} & \text{if } u > 0, \\ \{y \mid y \geq 1\} & \text{if } u = 0, \\ \emptyset & \text{if } u < 0. \end{cases}$$

Then, for $u^k = 1/k$, $y^k = 0 \in F(u^k)$ ($k = 1, 2, \dots$). However, the limit 0 of $\{y^k\}$ is not contained in $F(0)$.

3. Upper semicontinuity of the perturbation map. In this section we shall consider sufficient conditions for the upper semicontinuity of the perturbation map W . First we provide sufficient conditions in terms of the feasible set map Y .

THEOREM 3.1. *If the following three conditions are satisfied, then the perturbation map W is upper semicontinuous at $\hat{u} \in \mathbb{R}^m$:*

- (1) $\hat{u} \in \text{int}(\text{dom } Y)$;
- (2) Y is upper semicontinuous at \hat{u} ;
- (3) $W(\hat{u}) = w - \text{Min}_P Y(\hat{u})$, where $w - \text{Min}_P Y(\hat{u})$ is the set of all weakly P -minimal points of $Y(\hat{u})$, i.e.,

$$(3.1) \quad w - \text{Min}_P Y(\hat{u}) := \{y \in Y(\hat{u}) \mid (Y(\hat{u}) - y) \cap (-\text{int } P) = \emptyset\}.$$

Proof. Let $u^k \rightarrow \hat{u}$, $y^k \in W(u^k)$ and $y^k \rightarrow \hat{y}$. Since Y is upper semicontinuous at \hat{u} , $\hat{y} \in Y(\hat{u})$. Hence, if we suppose that $\hat{y} \notin W(\hat{u}) = w - \text{Min}_P Y(\hat{u})$, then there exists $\bar{y} \in Y(\hat{u})$ such that $\hat{y} - \bar{y} \in \text{int } P$. Since $\hat{u} \in \text{int}(\text{dom } Y) = \text{int}(\text{dom } (Y + P))$ and $Y + P$ is convex, $Y + P$ is lower semicontinuous at \hat{u} from Lemma 2.3. Namely there exist a sequence $\{\bar{y}^k\} \subset \mathbb{R}^p$ and a number K such that

$$\bar{y}^k \rightarrow \bar{y} \quad \text{and} \quad \bar{y}^k \in Y(u^k) + P \quad \text{for } k \geq K$$

since $y^k - \bar{y}^k \rightarrow \hat{y} - \bar{y} \in \text{int } P$, $y^k - \bar{y}^k \in \text{int } P$ for all k sufficiently large. However, this contradicts that $y^k \in W(u^k) = \text{Min}_P Y(u^k) = \text{Min}_P (Y(u^k) + P)$ (see [5, Prop. 3.1.2]). Therefore $\hat{y} \in W(\hat{u})$, as was to be proved. \square

Remark 3.1. We can guarantee the upper semicontinuity of W under the following conditions without the convexity assumption (CA) [7]:

- (i) Y is continuous at \hat{u} ;
- (ii) $W(\hat{u}) = w - \text{Min}_P Y(\hat{u})$.

If we compare these conditions with Theorem 3.1, the following can be observed: we can replace the lower semicontinuity condition of Y by the weaker condition $\hat{u} \in \text{int}(\text{dom } Y)$ under the convexity assumption.

Now we shall derive sufficient conditions for the upper semicontinuity of W , which are described in terms of the feasible decision set map X and the objective

function f . For the purpose we shall introduce a set-valued map \tilde{X} from $\mathbb{R}^m \times \mathbb{R}^p$ to \mathbb{R}^n as follows:

$$(3.2) \quad \tilde{X}(u, y) := \{x \in X(u) \mid f(x, u) = y\}.$$

The following proposition provides sufficient conditions for the upper semicontinuity of Y at \hat{u} .

PROPOSITION 3.1. *If $\hat{u} \in \text{int}(\text{dom } X)$, if $X(\hat{u})$ is a closed set and if the map \tilde{X} is locally bounded at $(\hat{u}, \hat{y})^2$ for any $\hat{y} \in \{y \mid (\hat{u}, y) \in \text{cl}(\text{graph } Y)\}$, then Y is upper semicontinuous at \hat{u} .*

Proof. Let $u^k \rightarrow \hat{u}$, $y^k \in Y(u^k)$ and $y^k \rightarrow \hat{y}$. Then there exists a sequence $\{x^k\} \subset \mathbb{R}^n$ such that $x^k \in \tilde{X}(u^k, y^k)$ for all $k = 1, 2, \dots$. Since \tilde{X} is locally bounded at (\hat{u}, \hat{y}) , $\{x^k\}$ has a convergent subsequence. By taking the subsequence if necessary, we may assume that $\{x^k\}$ converges to some \hat{x} . From Lemma 2.4, X is upper semicontinuous at \hat{u} and so $\hat{x} \in X(\hat{u})$. On the other hand, since f is continuous from Lemma 2.1, $f(\hat{x}, \hat{u}) = \hat{y}$. Therefore $\hat{y} \in Y(\hat{u})$ and Y is upper semicontinuous at \hat{u} . \square

Remark 3.2. If X is locally bounded at \hat{u} , then \tilde{X} is clearly locally bounded at (\hat{u}, y) for any $y \in \mathbb{R}^p$.

Now we can prove the following theorem.

THEOREM 3.2. *If the following four conditions are satisfied, then the set-valued map W is upper semicontinuous at \hat{u} :*

- (1) $\hat{u} \in \text{int}(\text{dom } X)$.
- (2) $X(\hat{u})$ is a closed set.
- (3) \tilde{X} is locally bounded at (\hat{u}, \hat{y}) for any $\hat{y} \in \{y \mid (\hat{u}, y) \in \text{cl}(\text{graph } Y)\}$.
- (4) $W(\hat{u}) = w - \text{Min}_P Y(\hat{u})$.

Proof. From (1), $\hat{u} \in \text{int}(\text{dom } Y)$. From (1)–(3), in view of Proposition 3.1, Y is upper semicontinuous at \hat{u} . Hence W is upper semicontinuous at \hat{u} by Theorem 3.1. \square

Remark 3.3. The following examples illustrate that each condition in the above theorem is essential.

(1) Take F in Remark 2.3 as X and let $f(x, u) = x$ and $P = \mathbb{R}_+$. Then $\hat{u} = (0, 0) \notin \text{int}(\text{dom } X)$ and

$$W(u) = \begin{cases} \{\alpha\} & \text{if } (u_1 - \alpha)^2 + (u_2)^2 = \alpha^2 \text{ for } \alpha > 0, \quad u \neq (0, 0), \\ \{0\} & \text{if } u = (0, 0), \\ \emptyset & \text{otherwise,} \end{cases}$$

which is not upper semicontinuous at $(0, 0)$.

(2) Let $m = p = n = 1$, $P = \mathbb{R}_+$, $f(x, u) = x$ and

$$X(u) = \begin{cases} \{x \mid x \geq 0\} & \text{if } u \neq 0, \\ \{x \mid x > 0\} & \text{if } u = 0. \end{cases}$$

Then $W(u) = \{0\}$ if $u \neq 0$ and $W(0) = \emptyset$. Hence W is not upper semicontinuous at 0.

(3) Let $m = n = p = 1$, $P = \mathbb{R}_+$ and $X(u) = \mathbb{R}$ for any $u \in \mathbb{R}$. Let C be a convex set in $\mathbb{R} \times \mathbb{R}$ defined by

$$C = \{(u, x) \mid ux \geq 1, u > 0\}$$

and f be defined by

$$f(x, u) = d((u, x), C) = \inf \{\|(u, x) - (u', x')\| \mid (u', x') \in C\}.$$

² A set-valued map F is said to be locally bounded at \hat{u} if there exists a neighborhood N of \hat{u} such that $\bigcup_{u \in N} F(u)$ is bounded.

Then f is P -convex and

$$Y(u) = \begin{cases} \{y \in \mathbb{R} \mid y \geq 0\} & \text{if } u > 0, \\ \{y \in \mathbb{R} \mid y > -u\} & \text{if } u \leq 0. \end{cases}$$

Hence

$$W(u) = \begin{cases} \{0\} & \text{if } u > 0, \\ \emptyset & \text{if } u \leq 0, \end{cases}$$

which is not upper semicontinuous at 0. In this example, \tilde{X} is not locally bounded at $(0, 0)$.

4. Lower semicontinuity of the perturbation map. In this section we consider sufficient conditions for the lower semicontinuity of the map W . First we should introduce several concepts.

DEFINITION 4.1. A set S in \mathbb{R}^p is said to be P -minicomplete if

$$(4.1) \quad S \subset \text{Min}_P S + P.$$

Remark 4.1. Since $\text{Min}_P S \subset S$, if S is P -minicomplete,

$$(4.2) \quad S + P = \text{Min}_P S + P.$$

DEFINITION 4.2. For a nonempty set S in \mathbb{R}^p , its recession cone S^+ is defined by

$$(4.3) \quad S^+ = \{y \in \mathbb{R}^p \mid \text{there exist sequences } \{\lambda_k\} \subset \mathbb{R} \text{ and } \{y^k\} \subset \mathbb{R}^p \text{ such that } \lambda_k > 0, \lambda_k \rightarrow 0, \lambda_k y^k \rightarrow y \text{ and } y^k \in S \text{ for all } k\}.$$

Remark 4.2. S^+ is a closed cone which contains the origin. Moreover, if S is a nonempty closed convex set, S^+ coincides with the set 0^+S which is defined by

$$(4.4) \quad \begin{aligned} 0^+S &= \{y \in \mathbb{R}^p \mid \bar{y} + \lambda y \in S \forall \lambda \geq 0, \forall \bar{y} \in S\} \\ &= \{y \in \mathbb{R}^p \mid S + y \subset S\} \end{aligned}$$

and therefore it is a closed convex cone [3, Thm. 8.2].

LEMMA 4.1 (Sawaragi et al. [5, Lemma 3.2.1]). A nonempty set S is bounded if and only if $S^+ = \{0\}$.

LEMMA 4.2 (Sawaragi et al. [5, Lemma 3.2.3]). Let S_1 and S_2 be nonempty closed sets. If $S_1^+ \cap (-S_2^+) = \{0\}$, then $S_1 + S_2$ is also a nonempty closed set.

In view of the above two lemmas, the following concept plays an important role in this section.

DEFINITION 4.3. A nonempty set S in \mathbb{R}^p is said to be P -bounded if

$$(4.5) \quad S^+ \cap (-P) = \{0\}.$$

LEMMA 4.3 (Sawaragi et al. [5, Thm. 3.2.12]). If $S \subset \mathbb{R}^p$ is a nonempty closed convex set, the following statements are equivalent:

- (1) S is P -bounded.
- (2) $\text{Min}_P S \neq \emptyset$.
- (3) S is P -minicomplete.

LEMMA 4.4. Suppose that F is P -convex, $\hat{u} \in \text{int}(\text{dom } F)$, and $F(\hat{u})$ is P -bounded. Then there exists a neighborhood N of \hat{u} such that $F(u)$ is P -bounded for all $u \in N$.

Proof. If the conclusion of the lemma were not true, there would exist sequences $\{u^k\} \in \mathbb{R}^m$ and $\{d^k\} \subset \mathbb{R}^p$ such that $u^k \rightarrow \hat{u}$, $d^k \neq 0$ and

$$-d^k \in [F(u^k)]^+ \cap (-P).$$

Since $[F(u^k)]^+ \cap (-P)$ is a cone, we may assume that $\|d^k\| = 1$ for all k . By taking a subsequence if necessary, we may assume that $\{d^k\}$ converges to some d . Since P is closed, $d \in P$. Moreover, $\|d\| = 1$ and so $d \neq 0$. Since $-d^k \in [F(u^k)]^+$, there exist sequences $\{\lambda_{kl}\} \subset \mathbb{R}$, $\{d^{kl}\} \subset -F(u^k)$ such that $\lambda_{kl} > 0$,

$$\lambda_{kl} \rightarrow 0 \quad \text{and} \quad \lambda_{kl} d^{kl} \rightarrow d^k \quad \text{as } l \rightarrow \infty.$$

If we take l sufficiently large,

$$\lambda_{kl} < \frac{1}{k} \quad \text{and} \quad \|\lambda_{kl} d^{kl} - d^k\| < \frac{1}{k}.$$

By choosing those λ_{kl} and d^{kl} as $\bar{\lambda}_k$ and \bar{d}^k , respectively, we can construct sequences $\{\bar{\lambda}_k\}$ and $\{\bar{d}^k\}$ satisfying

$$-\bar{d}^k \in F(u^k), \quad 0 < \bar{\lambda}_k < \frac{1}{k}, \quad \|\bar{\lambda}_k \bar{d}^k - d^k\| < \frac{1}{k}.$$

When $k \rightarrow \infty$, $\bar{\lambda}_k \rightarrow 0$ and $\bar{\lambda}_k \bar{d}^k \rightarrow d$. Now take an arbitrary $\tilde{y} \in F(\hat{u})$. Since $2\hat{u} - u^k \rightarrow \hat{u}$ and $F + P$ is lower semicontinuous at \hat{u} by Lemma 2.3, there exist a sequence $\{\tilde{y}^k\}$ and a number K such that

$$\tilde{y}^k \rightarrow \tilde{y} \quad \text{and} \quad \tilde{y}^k \in F(2\hat{u} - u^k) + P \quad \text{for } k \geq K.$$

Since F is P -convex,

$$\frac{1}{2}(\tilde{y}^k - \bar{d}^k) \in F(\hat{u}) + P \quad \text{for } k \geq K.$$

Moreover, $2\bar{\lambda}_k \cdot \frac{1}{2}(\tilde{y}^k - \bar{d}^k) \rightarrow -d$. This implies that $-d \in [F(\hat{u}) + P]^+$ and hence $[F(\hat{u}) + P]^+ \cap (-P) \neq \{0\}$. In view of Lemma 3.2.4 of [5], this means that $F(\hat{u})$ is not P -bounded, which is a contradiction. Hence $F(u)$ is P -bounded for all u in a certain neighborhood of \hat{u} . \square

Now we can obtain sufficient conditions for the lower semicontinuity of W .

THEOREM 4.1. *If the following conditions are satisfied, then the perturbation map W is lower semicontinuous at \hat{u} :*

- (1) $\hat{u} \in \text{int}(\text{dom } Y)$.
- (2) $Y + P$ is upper semicontinuous in a neighborhood of \hat{u} .

Proof. If $W(\hat{u}) = \emptyset$, the theorem is trivial. Hence we suppose that $W(\hat{u}) \neq \emptyset$. Let $u^k \rightarrow \hat{u}$ and $\hat{y} \in W(\hat{u})$. From Lemma 2.3, $Y + P$ is lower semicontinuous at \hat{u} and hence there exist a sequence $\{y^k\}$ and a number K_1 such that

$$y^k \rightarrow \hat{y} \quad \text{and} \quad y^k \in (u^k) + P \quad \text{for all } k \geq K_1.$$

Since $Y(\hat{u}) + P$ is a nonempty closed convex set and $\text{Min}_P(Y(\hat{u}) + P) = W(\hat{u}) \neq \emptyset$, $Y(\hat{u}) + P$ is P -bounded from Lemma 4.3. Therefore, in view of Lemma 4.4, $Y(u) + P$ is P -bounded for all u in a certain neighborhood N of \hat{u} . (Note that $\hat{u} \in \text{int}(\text{dom } Y)$.) From Lemma 4.3 and Remark 4.1, this implies that

$$W(u) + P = (Y(u) + P) + P = Y(u) + P$$

in a neighborhood of \hat{u} . Hence there exist a sequence $\{\hat{y}^k\}$ and a number $K_2 \geq K_1$ such that

$$y^k - \hat{y}^k \in P \quad \text{and} \quad \hat{y}^k \in W(u^k) \quad \text{for } k \geq K_2.$$

First we will show that $\{\hat{y}^k\}$ is bounded. If this were not the case, from Lemma 4.1, we can take a subsequence of $\{\hat{y}^k\}$, for which there exist a sequence $\{\lambda_k\}$ of positive

numbers and a nonzero vector \tilde{y} such that $\lambda_k \rightarrow 0$ and $\lambda_k \hat{y}^k \rightarrow \tilde{y}$. Since $\lambda_k(y^k - \hat{y}^k) \in P$ and $y^k \rightarrow \hat{y}$, the limit $-\tilde{y}$ of $\{\lambda_k(y^k - \hat{y}^k)\}$ is contained in P . Take an arbitrary $\bar{y} \in Y(\hat{u}) + P$. Then there exist a sequence $\{\bar{y}^k\}$ and a number $K_3 \geq K_2$ such that

$$\bar{y}^k \rightarrow \bar{y} \quad \text{and} \quad \bar{y}^k \in Y(2\hat{u} - u^k) + P \quad \text{for } k \geq K_3,$$

since $Y + P$ is lower semicontinuous at \hat{u} . Then, from the convexity of $Y + P$,

$$\frac{1}{2}(\hat{y}^k + \bar{y}^k) \in Y(\hat{u}) + P \quad \text{for } k \geq K_3.$$

Moreover, $\lambda_k(\hat{y}^k + \bar{y}^k) \rightarrow \tilde{y}$. This implies that $\tilde{y} \in [Y(\hat{u}) + P]^+$ and hence leads to a contradiction to the P -boundedness of $Y(\hat{u}) + P$. Therefore $\{\hat{y}^k\}$ must be bounded. Hence $\{\hat{y}^k\}$ has a cluster point, which is denoted by y' . Since $y^k - \hat{y}^k \in P$ and $y^k \rightarrow \hat{y}$, $\hat{y} - y' \in P$. Since $Y + P$ is upper semicontinuous at \hat{u} , $y' \in Y(\hat{u}) + P$. Recalling that $\hat{y} \in W(\hat{u})$, we can conclude that $y' = \hat{y}$. In other words, \hat{y} is the unique cluster point for the bounded sequence $\{\hat{y}^k\} \rightarrow \hat{y}$. Therefore $\hat{y}^k \rightarrow \hat{y}$, which indicates that W is lower semicontinuous at \hat{u} . \square

Remark 4.3. We can generate the lower semicontinuity of W under the following conditions without the convexity assumption (CA) [7]:

- (i) Y is continuous at \hat{u} ;
- (ii) Y is locally bounded at \hat{u} ;
- (iii) $Y(u)$ is P -minicomplete for every u near \hat{u} .

Theorem 4.1 considerably simplifies the above result.

The following proposition shows that $Y + P$ is often upper semicontinuous when $W(\hat{u})$ is not empty.

PROPOSITION 4.1. *If $X(u)$ is a nonempty closed set for every u near \hat{u} , $W(\hat{u}) \neq \emptyset$ and $\tilde{X}(\hat{u}, \hat{y})$ is bounded for some $\hat{y} \in W(\hat{u})$, then $Y(u)$ is a P -bounded closed set in a neighborhood of \hat{u} . In this case $Y(u) + P$ is also a closed set by Lemma 4.2 and therefore the set-valued map $Y + P$ is upper semicontinuous in a neighborhood of \hat{u} .*

Proof. (a) First we shall prove that $Y(u)$ is a closed set in some neighborhood of \hat{u} . If this were not true, we can consider sequences $\{u^k\}$ and $\{y^k\}$ such that

$$u^k \rightarrow \hat{u} \quad \text{and} \quad y^k \in \text{cl } Y(u^k) \setminus Y(u^k).$$

Corresponding to each y^k , there exists a sequence $\{x^{kl}\} \subset X(u^k)$ such that $f(x^{kl}, u^k) \rightarrow y^k$ as $l \rightarrow \infty$. Take k sufficiently large so that $X(u^k)$ is closed. If $\{x^{kl}\}_{l=1,2,\dots}$ has a convergent subsequence, the limit x^k of it is contained in $X(u^k)$. Since f is continuous, $f(x^k, u^k) = y^k$, which contradicts that $y^k \notin Y(u^k)$. Hence, if k is sufficiently large, $\{x^{kl}\}_{l=1,2,\dots}$ has not a convergent subsequence and so $\|x^{kl}\| \rightarrow +\infty$ as $l \rightarrow \infty$. We may assume that the sequence $\{x^{kl}/\|x^{kl}\|\}_{l=1,2,\dots}$ converges to some \bar{x}^k as $l \rightarrow \infty$. Furthermore, since $\|\bar{x}^k\| = 1$ for all k , we may also assume without loss of generality that $\{\bar{x}^k\}$ converges to a vector \bar{x} . In this case $\|\bar{x}\| = 1$, i.e., $\bar{x} \neq 0$. From the assumptions, we can take $\hat{y} \in W(\hat{u})$ for which $\tilde{X}(\hat{u}, \hat{y})$ is bounded. Let $\hat{x} \in \tilde{X}(\hat{u}, \hat{y})$. Since X is lower semicontinuous at \hat{u} from Lemma 2.3, there exist a sequence $\{\hat{x}^k\}$ and a number K such that

$$\hat{x}^k \rightarrow \hat{x} \quad \text{and} \quad \hat{x}^k \in X(u^k) \quad \text{for } k \geq K.$$

Let $k \geq K$. For an arbitrary $\alpha \geq 0$, $0 \leq \alpha/\|x^{kl}\| \leq 1$ for all k sufficiently large, for $\|x^{kl}\| \rightarrow +\infty$ as $l \rightarrow \infty$. Since X is convex,

$$\left(1 - \frac{\alpha}{\|x^{kl}\|}\right)\hat{x}^k + \frac{\alpha}{\|x^{kl}\|}x^{kl} \in X(u^k).$$

Taking the limit when $l \rightarrow \infty$, we obtain from the closedness of $X(u^k)$,

$$(4.6) \quad \hat{x}^k + \alpha\bar{x}^k \in X(u^k) \quad \text{for all } k \text{ sufficiently large.}$$

Since f is P -convex,

$$f\left(\left(1 - \frac{\alpha}{\|x^{kl}\|}\right)\hat{x}^k + \frac{\alpha}{\|x^{kl}\|}x^{kl}, u^k\right) \leq_P \left(1 - \frac{\alpha}{\|x^{kl}\|}\right)f(\hat{x}^k, u^k) + \frac{\alpha}{\|x^{kl}\|}f(x^{kl}, u^k).$$

Let $l \rightarrow \infty$. Then, since $f(x^{kl}, u^k) \rightarrow y^k$,

$$(4.7) \quad f(\hat{x}^k + \alpha \bar{x}^k, u^k) \leq_P f(\hat{x}^k, u^k) \quad \text{for } k \text{ sufficiently large.}$$

Take the limit of (4.6) and (4.7) as $k \rightarrow \infty$. Then, since X is upper semicontinuous at \hat{u} from Lemma 2.4 and f is continuous, $\hat{x} + \alpha \bar{x} \in X(\hat{u})$ and

$$f(\hat{x} + \alpha \bar{x}, \hat{u}) \leq_P f(\hat{x}, \hat{u}) = \hat{y}.$$

Since $\hat{y} \in W(\hat{u})$, these imply that $f(\hat{x} + \alpha \bar{x}, \hat{u}) = \hat{y}$, i.e., $\hat{x} + \alpha \bar{x} \in \tilde{X}(\hat{u}, \hat{y})$ for all $\alpha \geq 0$. However, this contradicts the boundedness of $\tilde{X}(\hat{u}, \hat{y})$. Hence $Y(u)$ must be a closed set for every u in a certain neighborhood of \hat{u} .

(b) Next, we shall prove that $Y(\hat{u})$ is P -bounded. Let $y \in [Y(\hat{u})]^+ \cap (-P)$. There exist sequences $\{\lambda_k\} \subset R$ and $\{x^k\} \subset X(\hat{u})$ such that $\lambda_k > 0$, $\lambda_k \rightarrow 0$ and $\lambda_k f(x^k, \hat{u}) \rightarrow y$. Then, for all k sufficiently large, $\lambda_k x^k + (1 - \lambda_k)\hat{x} \in X(\hat{u})$ and

$$(4.8) \quad f(\lambda_k x^k + (1 - \lambda_k)\hat{x}, \hat{u}) \leq_P \lambda_k f(x^k, \hat{u}) + (1 - \lambda_k)f(\hat{x}, \hat{u})$$

due to the P -convexity of f . The right-hand side of (4.8) converges to $y + \hat{y}$. First we assume that $\{\lambda_k x^k\}$ has no convergent subsequence. Then $\lambda_k \|x^k\| \rightarrow +\infty$. We may assume without loss of generality that $\{x^k / \|x^k\|\}$ converges to a vector \tilde{x} with $\|\tilde{x}\| = 1$. For any $\alpha \geq 0$, $0 \leq \alpha / \|x^k\| \leq 1$ for all k sufficiently large and so

$$\frac{\alpha}{\|x^k\|}x^k + \left(1 - \frac{\alpha}{\|x^k\|}\right)\hat{x} \in X(\hat{u})$$

from the convexity of $X(\hat{u})$. Since $X(\hat{u})$ is a closed set, the limit of the above relation implies that $\hat{x} + \alpha \tilde{x} \in X(\hat{u})$. Moreover, since f is P -convex,

$$f\left(\frac{\alpha}{\|x^k\|}x^k + \left(1 - \frac{\alpha}{\|x^k\|}\right)\hat{x}, \hat{u}\right) \leq_P \frac{\alpha}{\lambda_k \|x^k\|}\lambda_k f(x^k, \hat{u}) + \left(1 - \frac{\alpha}{\|x^k\|}\right)f(\hat{x}, \hat{u})$$

for all k sufficiently large. Thus, as the limit of the above inequality, we have

$$f(\hat{x} + \alpha \tilde{x}, \hat{u}) \leq_P \hat{y}.$$

Since $\hat{y} \in W(\hat{u})$, $f(\hat{x} + \alpha \tilde{x}, \hat{u}) = \hat{y}$. This implies that $\hat{x} + \alpha \tilde{x} \in \tilde{X}(\hat{u}, \hat{y})$ for all $\alpha \geq 0$, which contradicts the boundedness of $\tilde{X}(\hat{u}, \hat{y})$. Hence $\{\lambda_k x^k\}$ necessarily has a convergent subsequence whose limit is denoted by x . We may assume that $\lambda_k x^k \rightarrow x$ from the first. Since $X(\hat{u})$ is closed, from the limit of $\lambda_k x^k + (1 - \lambda_k)\hat{x} \in X(\hat{u})$, $x + \hat{x} \in X(\hat{u})$. Therefore the limit of the left-hand side of (4.8), which is $f(x + \hat{x}, \hat{u})$, belongs to $Y(\hat{u})$. Since (4.8) leads to

$$f(x + \hat{x}, \hat{u}) \leq_P y + \hat{y}$$

when $k \rightarrow \infty$, $y \in -P$ and $\hat{y} \in W(\hat{u})$, y must be equal to the zero vector. Thus $Y(\hat{u})$ is P -bounded.

(c) Finally, the result proved just above and Lemma 4.4 imply that $Y(u)$ is P -bounded in a neighborhood of \hat{u} . This completes the proof of the proposition. \square

Now we can immediately obtain the following result by combining Theorem 4.1 and Proposition 4.1.

THEOREM 4.2. *If the following conditions are satisfied, then the perturbation map W is lower semicontinuous at \hat{u} :*

- (1) $\hat{u} \in \text{int}(\text{dom } X)$.
- (2) $X(u)$ is a closed set for every u near \hat{u} .
- (3) When $W(\hat{u}) \neq \emptyset$, $\tilde{X}(\hat{u}, \hat{y})$ is bounded for some $\hat{y} \in W(\hat{u})$.

Remark 4.4. The following examples show that each condition in the above theorem is essential.

(1) Consider the case in Remark 3.3(1). Then we can easily understand that the condition $\hat{u} \in \text{int}(\text{dom } X)$ is essential.

(2) Let $m = n = p = 1$, $P = \mathbb{R}_+$,

$$X(u) = \begin{cases} \{x \in \mathbb{R} \mid x > u^2\} & \text{if } u \neq 0, \\ \{x \in \mathbb{R} \mid x \geq 0\} & \text{if } u = 0, \end{cases}$$

and $f(x, u) = x$. Then

$$W(u) = \begin{cases} \emptyset & \text{if } u \neq 0, \\ \{0\} & \text{if } u = 0, \end{cases}$$

which is clearly not lower semicontinuous at $\hat{u} = 0$.

(3) Let $m = n = p = 1$, $P = \mathbb{R}_+$, $X(u) = \mathbb{R}_+$ and

$$f(x, u) = \begin{cases} 0 & \text{if } x \geq 0, \quad u = 0, \\ |u| e^{-x/|u|} & \text{if } x \geq 0, \quad u \neq 0, \\ |u| - x & \text{if } x < 0. \end{cases}$$

Then

$$Y(u) = \begin{cases} \{0\} & \text{if } u = 0, \\ \{y \mid 0 < y \leq |u|\} & \text{if } u \neq 0 \end{cases}$$

and so

$$W(u) = \begin{cases} \{0\} & \text{if } u = 0, \\ \emptyset & \text{if } u \neq 0. \end{cases}$$

Now $\tilde{X}(0, 0) = \mathbb{R}_+$, which is not bounded, and W is not lower semicontinuous at $\hat{u} = 0$.

5. Contingent derivative of the perturbation map. In this section we will show some quantitative results concerning the behavior of the perturbation map by using the concept of contingent derivatives of set-valued maps. The author has already provided an “inner” approximation of the contingent derivative of the perturbation map for general multi-objective optimization problems [6]. In this paper, a complete characterization of the contingent derivative will be obtained under the convexity assumption (CA) and some additional conditions.

First we briefly review the concept of contingent derivatives for set-valued maps.

DEFINITION 5.1. Let S be a nonempty subset of \mathbb{R}^q and $\hat{v} \in \mathbb{R}^q$. The set $T_S(\hat{v})$ defined by

$$(5.1) \quad T_S(\hat{v}) := \{v \in \mathbb{R}^q \mid \text{there exist sequences } \{h_k\} \subset \mathring{\mathbb{R}}_+ \text{ and } \{v^k\} \subset \mathbb{R}^q \\ \text{such that } h_k \rightarrow 0, v^k \rightarrow v \text{ and } \hat{v} + h_k v^k \in S \text{ for all } k\}$$

is called the contingent cone to S at \hat{v} , where $\mathring{\mathbb{R}}_+$ is the set of all positive real numbers.

DEFINITION 5.2. Let F be a set-valued map from \mathbb{R}^m to \mathbb{R}^p and $\bar{y} \in F(\bar{u})$. The set-valued map $DF(\bar{u}, \bar{y})$ from \mathbb{R}^m to \mathbb{R}^p defined by the following is called the contingent derivative of F at (\bar{u}, \bar{y}) :

$$(5.2) \quad y \in DF(\bar{u}, \bar{y})(u) \quad \text{iff } (u, y) \in T_{\text{graph } F}(\bar{u}, \bar{y}).$$

In other words, $y \in DF(\bar{u}, \bar{y})(u)$ if and only if there exist sequences $\{h_k\} \subset \mathring{\mathbb{R}}_+$, $\{u^k\} \subset \mathbb{R}^m$ and $\{y^k\} \subset \mathbb{R}^p$ such that $h_k \rightarrow 0$, $u^k \rightarrow u$, $y^k \rightarrow y$ and

$$\bar{y} + h_k y^k \in F(\bar{u} + h_k u^k) \quad \forall k.$$

The purpose of this section is to provide a complete characterization of the contingent derivative of the perturbation map. Throughout this section let \hat{y} be a P -minimal point of $Y(\hat{u})$, i.e., $\hat{y} \in W(\hat{u})$. First we can simplify Theorem 3.2 in [6] under the convexity assumption (CA) as in the following theorem.

THEOREM 5.1. *If $Y(u)$ is P -minicomplete for every u near \hat{u} , then*

$$(5.3) \quad \text{Min}_P DY(\hat{u}, \hat{y})(u) \subset DW(\hat{u}, \hat{y})(u) \quad \forall u \in \mathbb{R}^m.$$

Proof. Let $y \in \text{Min}_P DY(\hat{u}, \hat{y})(u)$. Since $y \in DY(\hat{u}, \hat{y})(u)$, there exist sequences $\{h_k\} \subset \mathring{\mathbb{R}}_+$, $\{u^k\} \subset \mathbb{R}^m$ and $\{y^k\} \subset \mathbb{R}^p$ such that $h_k \rightarrow 0$, $u^k \rightarrow u$, $y^k \rightarrow y$ and

$$\hat{y} + h_k y^k \in Y(\hat{u} + h_k u^k) \quad \forall k.$$

Since $Y(u)$ is P -minicomplete for every u near \hat{u} , there exists a sequence $\{\bar{y}^k\} \subset \mathbb{R}^p$ such that

$$(5.4) \quad \hat{y} + h_k \bar{y}^k \in W(\hat{u} + h_k u^k) \quad \text{and} \quad y^k - \bar{y}^k \in P$$

for all k sufficiently large. We may assume (5.4) for all k . Suppose that $\{\bar{y}^k\}$ has no convergent subsequence. Then $\|\bar{y}^k\| \rightarrow +\infty$. There exist sequences $\{x^k\}$ and $\{\bar{x}^k\}$ in \mathbb{R}^n such that

$$\begin{aligned} \hat{x} + h_k x^k &\in X(\hat{u} + h_k u^k), \\ f(\hat{x} + h_k x^k, \hat{u} + h_k u^k) &= \hat{y} + h_k y^k, \\ \hat{x} + h_k \bar{x}^k &\in X(\hat{u} + h_k u^k), \\ f(\hat{x} + h_k \bar{x}^k, \hat{u} + h_k u^k) &= \hat{y} + h_k \bar{y}^k. \end{aligned}$$

For any α satisfying $0 \leq \alpha \leq 1$, we have

$$\hat{x} + h_k(\alpha x^k + (1 - \alpha)\bar{x}^k) \in X(\hat{u} + h_k u^k)$$

from the convexity of X . Moreover, from the P -convexity of f ,

$$\begin{aligned} \hat{y} + h_k y^k(\alpha) &:= f(\hat{x} + h_k(\alpha x^k + (1 - \alpha)\bar{x}^k), \hat{u} + h_k u^k) \\ &\leq_P \hat{y} + h_k(\alpha y^k + (1 - \alpha)\bar{y}^k) \\ &\leq_P \hat{y} + h_k y^k. \end{aligned}$$

And, since f is continuous,

$$\begin{aligned} \hat{y} + h_k y^k(\alpha) &\rightarrow \hat{y} + h_k \bar{y}^k \quad \text{as } \alpha \rightarrow 0, \\ \hat{y} + h_k y^k(\alpha) &\rightarrow \hat{y} + h_k y^k \quad \text{as } \alpha \rightarrow 1. \end{aligned}$$

Since $\|\bar{y}^k\| \rightarrow +\infty$ and $y^k \rightarrow y$, by taking α_k appropriately close to 1, we have

$$\varepsilon h_k \leq \|\hat{y} + h_k y^k - (\hat{y} + h_k y^k(\alpha_k))\| \leq h_k \quad \forall k \text{ sufficiently large}$$

where ε is a fixed number such that $0 < \varepsilon < 1$. Taking this $y^k(\alpha_k)$ as \tilde{y}^k , we see that

$$\varepsilon \leq \|y^k - \tilde{y}^k\| \leq 1 \quad \forall k \text{ sufficiently large.}$$

Since $y^k \rightarrow y$, the sequence $\{\tilde{y}^k\}$ is bounded and so we may assume without loss of generality that $\{\tilde{y}^k\}$ converges to a vector \tilde{y} . It is clear that $\tilde{y} \in DY(\hat{u}, \hat{y})(u)$. Since

$\|y^k - \tilde{y}^k\| \geq \varepsilon$ for all k sufficiently large, $\|y - \tilde{y}\| \geq \varepsilon$, that is, $y \neq \tilde{y}$. Since $y^k - \tilde{y}^k \in P$, $y - \tilde{y} \in P$. However, these contradict the assumption that $y \in \text{Min}_P DY(\hat{u}, \hat{y})(u)$. Therefore $\{\tilde{y}^k\}$ always has a convergent subsequence. Hence we may assume from the first that $\tilde{y}^k \rightarrow \bar{y}$. Then $\bar{y} \in DW(\hat{u}, \hat{y})(u) \subset DY(\hat{u}, \hat{y})(u)$ and $y^k - \tilde{y}^k \rightarrow y - \bar{y} \in P$. Since $y \in \text{Min}_P DY(\hat{u}, \hat{y})(u)$, $y = \bar{y}$. This implies that $y \in DW(\hat{u}, \hat{y})(u)$, and completes the proof of the theorem. \square

Remark 5.1. We can see from the example in Remark 4.4(3) that the P -mini-completeness condition is essential for Theorem 5.1. There, $DW(\hat{u}, \hat{y})(u) = \emptyset$ for $\hat{u} = 0$, $\hat{y} = 0$ and $u \neq 0$. However $DY(\hat{u}, \hat{y})(u) = [0, |u|]$ and $\text{Min}_P DY(\hat{u}, \hat{y})(u) = \{0\}$ for $u \neq 0$.

Next we consider sufficient conditions for the converse inclusion of (5.3).

DEFINITION 5.3. Let S be a nonempty set in \mathbb{R}^p and $\hat{v} \in \mathbb{R}^p$. The normal cone $N_S(\hat{v})$ to S at \hat{v} is the negative polar cone of the tangent cone $T_S(\hat{v})$, i.e.,

$$(5.5) \quad N_S(\hat{v}) = [T_S(\hat{v})]^\circ = \{\mu \in \mathbb{R}^p \mid \langle \mu, v \rangle \leq 0 \ \forall v \in T_S(\hat{v})\}.$$

When S is a convex set and $\hat{v} \in S$,

$$(5.6) \quad N_S(\hat{v}) = \{\mu \in \mathbb{R}^p \mid \langle \mu, \hat{v} \rangle \geq \langle \mu, v \rangle \ \forall v \in S\}.$$

DEFINITION 5.4. Let S be a nonempty P -convex set in \mathbb{R}^p . If a point $\hat{y} \in \text{Min}_P S$ satisfies the condition

$$(5.7) \quad N_{S+P}(\hat{y}) \subset \text{int } P^\circ \cup \{0\},$$

then \hat{y} is called the normally P -minimal point of S .

Remark 5.2. A point $\hat{y} \in S$ is said to be the properly P -minimal point of S if

$$(5.8) \quad T_{S+P}(\hat{y}) \cap (-P) = \{0\}^3.$$

If \hat{y} is a properly P -minimal point of a convex set, there exists a vector $\mu \in N_{S+P}(\hat{y}) \cap \text{int } P^\circ$. The relation (5.7) is a stronger requirement than the existence of such μ as long as $\hat{y} \in \text{Min}_P S$. In other words, the normal P -minimality is a stronger concept than the proper P -minimality. From the geometric viewpoint, the latter implies the existence of the supporting hyperplane to S at \hat{y} with the normal vector μ in $\text{int } P^\circ$ and, on the other hand, the former implies that all the normal vectors of the supporting hyperplanes to S at \hat{y} belong to $\text{int } P^\circ$. (The existence of such a hyperplane is guaranteed by the fact that $\hat{y} \in \text{Min}_P S$.)

Remark 5.3. It is not difficult to show that the normal P -minimality of \hat{y} to a convex set S is equivalent to the following condition:

$$(5.9) \quad \text{int } T_{S+P}(\hat{y}) \cup \{0\} \supset P.$$

THEOREM 5.2. If $\hat{u} \in \text{int}(\text{dom } Y)$ and \hat{y} is a normally P -minimal point of $Y(\hat{u})$, then

$$(5.10) \quad DW(\hat{u}, \hat{y})(u) \subset \text{Min}_P DY(\hat{u}, \hat{y})(u) \quad \forall u \in \mathbb{R}^m.$$

Proof. Let $y \in DW(\hat{u}, \hat{y})(u)$. Of course $y \in DY(\hat{u}, \hat{y})(u)$. Hence if we assume that $y \notin \text{Min}_P DY(\hat{u}, \hat{y})(u)$, there exists $\bar{y} \in DY(\hat{u}, \hat{y})(u)$ such that $y - \bar{y} \in P \setminus \{0\}$. Since $\bar{y} \in DY(\hat{u}, \hat{y})(u)$, there exist sequences $\{\bar{h}_k\} \subset \mathbb{R}_+$, $\{\bar{u}^k\} \subset \mathbb{R}^m$ and $\{\bar{y}^k\} \subset \mathbb{R}^p$ such that $\bar{h}_k \rightarrow 0$, $\bar{u}^k \rightarrow u$, $\bar{y}^k \rightarrow \bar{y}$ and

$$\hat{y} + \bar{h}_k \bar{y}^k \in Y(\hat{u} + \bar{h}_k \bar{u}^k) \quad \forall k.$$

³ There are several definitions of the proper P -minimality (see, e.g., [5]). However they coincide under the convexity assumption.

On the other hand, since $y \in DW(\hat{u}, \hat{y})(u)$, there exist sequences $\{h_k\} \in \mathring{\mathbb{R}}_+$, $\{u^k\} \subset \mathbb{R}^m$ and $\{y^k\} \subset \mathbb{R}^p$ such that $h_k \rightarrow 0$, $u^k \rightarrow u$, $y^k \rightarrow y$ and

$$\hat{y} + h_k y^k \in W(\hat{u} + h_k u^k) \quad \forall k.$$

Since $h_k \rightarrow 0$, we may assume that $h_k \leq \bar{h}_k$ by taking a subsequence if necessary. Since $\hat{y} + h_k y^k \in W(\hat{u} + h_k u^k)$, $(\hat{u} + h_k u^k, \hat{y} + h_k y^k)$ is a boundary point of the convex set $\text{graph}(Y + P)$. Hence there exist a vector $(\lambda^k, \mu^k) \in \mathbb{R}^m \times \mathbb{R}^p$ such that

$$(5.11) \quad \langle \lambda^k, \hat{u} + h_k u^k \rangle + \langle \mu^k, \hat{y} + h_k y^k \rangle \geq \langle \lambda^k, u' \rangle + \langle \mu^k, y' \rangle \quad \forall (u', y') \in \text{graph}(Y + P)$$

for each k . Since we may normalize these vectors so that $\|(\lambda^k, \mu^k)\| = 1$, we may assume that $\{(\lambda^k, \mu^k)\}$ converges to a nonzero vector $(\lambda, \mu) \in \mathbb{R}^m \times \mathbb{R}^p$. By taking the limit of (5.11) as $k \rightarrow \infty$, we see that

$$(5.12) \quad \langle \lambda, \hat{u} \rangle + \langle \mu, \hat{y} \rangle \geq \langle \lambda, u' \rangle + \langle \mu, y' \rangle \quad \forall (u', y') \in \text{graph}(Y + P).$$

Since $\hat{u} \in \text{int}(\text{dom } Y)$, $\mu \neq 0$. Take an arbitrary $\tilde{y} \in Y(\hat{u}) + P$. From Lemma 2.3, the set-valued map $Y + P$ is lower semicontinuous at \hat{u} and so there exist a sequence $\{\tilde{y}^k\} \subset \mathbb{R}^p$ and a number $K > 0$ such that $\tilde{y}^k \rightarrow \tilde{y}$ and

$$(5.13) \quad \tilde{y}^k \in Y(\hat{u} + h_k u^k) + P \quad \text{for } k \geq K.$$

From (5.11), for $k \geq K$

$$\langle \lambda^k, \hat{u} + h_k u^k \rangle + \langle \mu^k, \hat{y} + h_k y^k \rangle \geq \langle \lambda^k, \hat{u} + h_k u^k \rangle + \langle \mu^k, \tilde{y}^k \rangle.$$

Letting $k \rightarrow \infty$, we have that

$$\langle \mu, \hat{y} \rangle \geq \langle \mu, \tilde{y} \rangle.$$

This implies that $\mu \in N_{Y(\hat{u})+P}(\hat{y})$. Since \hat{y} is a normally P -minimal point of $Y(\hat{u})$, $\mu \in \text{int } P^\circ$. Since $y - \bar{y} \in P \setminus \{0\}$,

$$(5.14) \quad \langle \mu, y \rangle < \langle \mu, \bar{y} \rangle.$$

Recalling that $\hat{y} + \bar{h}_k \bar{y}^k \in Y(\hat{u} + \bar{h}_k \bar{u}^k)$, $\hat{y} \in Y(\hat{u})$ and $h_k \leq \bar{h}_k$, we obtain that

$$\hat{y} + h_k \bar{y}^k \in Y(\hat{u} + h_k \bar{u}^k) + P$$

from the P -convexity of Y . Hence, from (5.11),

$$\langle \lambda^k, \hat{u} + h_k u^k \rangle + \langle \mu^k, \hat{y} + h_k y^k \rangle \geq \langle \lambda^k, \hat{u} + h_k \bar{u}^k \rangle + \langle \mu^k, \hat{y} + h_k \bar{y}^k \rangle,$$

i.e.,

$$\langle \lambda^k, u^k \rangle + \langle \mu^k, y^k \rangle \geq \langle \lambda^k, \bar{u}^k \rangle + \langle \mu^k, \bar{y}^k \rangle.$$

By taking the limit as $k \rightarrow \infty$, we have that

$$\langle \lambda, u \rangle + \langle \mu, y \rangle \geq \langle \lambda, u \rangle + \langle \mu, \bar{y} \rangle.$$

That is,

$$\langle \mu, y \rangle \geq \langle \mu, \bar{y} \rangle,$$

which contradicts (5.14). Therefore $y \in \text{Min}_P DY(\hat{u}, \hat{y})(u)$, as was to be proved. \square

Remark 5.4. The following examples show that the conditions in Theorem 5.2 are essential.

(1) ($\hat{u} \notin \text{int}(\text{dom } Y)$). Let $m = 2$, $n = p = 1$, $P = \mathbb{R}_+$,

$$X(u) = \begin{cases} \{x \mid x \geq 0\} & \text{if } u_1 \geq 0, \quad u_2 > 0, \\ \{x \mid x \geq u_1\} & \text{if } u_1 \geq 0, \quad u_2 = 0, \\ \emptyset & \text{otherwise,} \end{cases}$$

and $f(x, u) = x$. Then $Y(u) = X(u)$ and

$$W(u) = \begin{cases} \{0\} & \text{if } u_1 \geq 0, \quad u_2 > 0, \\ \{u_1\} & \text{if } u_1 \geq 0, \quad u_2 = 0, \\ \emptyset & \text{otherwise.} \end{cases}$$

Let $\hat{u} = (0, 0) \notin \text{int}(\text{dom } Y)$, $\hat{y} = 0$ and $u = (1, 0)$. Then $DW(\hat{u}, \hat{y})(u) = \{0, 1\}$ and $DY(\hat{u}, \hat{y})(u) = \{y \mid y \geq 0\}$. Hence $DW(\hat{u}, \hat{y})(u) \not\subset \text{Min}_P DY(\hat{u}, \hat{y})(u)$.

(2) (\hat{y} is not normally P -minimal). Let $m = 1$, $n = p = 2$, $P = \mathbb{R}_+^2$,

$$X(u) = \begin{cases} \{x \in \mathbb{R}^2 \mid x_1 \geq 0, x_2 \geq |u| e^{-x_1/|u|}\} & \text{if } u \neq 0, \\ \{x \in \mathbb{R}^2 \mid x_1 \geq 0, x_2 \geq 0\} & \text{if } u = 0, \end{cases}$$

and $f(x, u) = (x_1, x_2)$. Then $Y(u) = X(u)$ and

$$W(u) = \begin{cases} \{y \in \mathbb{R}^2 \mid y_1 \geq 0, y_2 = |u| e^{-y_1/|u|}\} & \text{if } u \neq 0, \\ \{(0, 0)\} & \text{if } u = 0. \end{cases}$$

Let $\hat{u} = 0$ and $\hat{y} = (0, 0)$. Then \hat{y} is not a normally P -minimal point of $Y(\hat{u})$, though it is properly P -minimal. In this case $(0, 0) \in DW(\hat{u}, \hat{y})(0) \subset DY(\hat{u}, \hat{y})(0)$ and $(1, 0) \in DW(\hat{u}, \hat{y})(0)$. Hence $DW(\hat{u}, \hat{y})(0) \not\subset \text{Min}_P DY(\hat{u}, \hat{y})(0)$.

Now we can consider the case in which every objective function f_i is differentiable.

DEFINITION 5.5. Let F be a set-valued map from \mathbb{R}^m to \mathbb{R}^p and $\bar{y} \in F(\bar{u})$. F is said to be upper pseudo-Lipschitzian at (\bar{u}, \bar{y}) if there exist neighborhood N_1 and N_2 of \bar{u} and \bar{y} , respectively, and a positive number M such that

$$(5.15) \quad F(u) \cap N_2 \subset F(\bar{u}) + M\|u - \bar{u}\|B \quad \forall u \in N_1.$$

PROPOSITION 5.1. If $X(\hat{u})$ is a closed set and $\tilde{X}(\hat{u}, \hat{y})$ is bounded, then \tilde{X} is locally bounded at (\hat{u}, \hat{y}) .

Proof. Suppose that the conclusion of the proposition is not true. Then there exist sequences $\{u^k\} \subset \mathbb{R}^m$, $\{y^k\} \subset \mathbb{R}^p$ and $\{x^k\} \subset \mathbb{R}^n$ such that $u^k \rightarrow \hat{u}$, $y^k \rightarrow \hat{y}$, $\|x^k\| \rightarrow +\infty$ and

$$x^k \in X(u^k) \quad \text{and} \quad f(x^k, u^k) = y^k \quad \forall k.$$

We may assume without loss of generality that $\{x^k / \|x^k\|\}$ converges to a nonzero vector x . Let $\alpha > 0$. Since $\|x^k\| \rightarrow +\infty$, $0 < \alpha / \|x^k\| \leq 1$ for all k sufficiently large. Hence, from the convexity of X ,

$$(5.16) \quad \left(1 - \frac{\alpha}{\|x^k\|}\right)\hat{x} + \frac{\alpha}{\|x^k\|}x^k \in X\left(\left(1 - \frac{\alpha}{\|x^k\|}\right)\hat{u} + \frac{\alpha}{\|x^k\|}u^k\right).$$

Since X is upper semicontinuous at \hat{u} from Lemma 2.4, by taking the limit of (5.16) as $k \rightarrow \infty$, we see that

$$\hat{x} + \alpha x \in X(\hat{u}).$$

Since f is P -convex,

$$f\left(\left(1 - \frac{\alpha}{\|x^k\|}\right)(\hat{x}, \hat{u}) + \frac{\alpha}{\|x^k\|}(x^k, u^k)\right) \leq_P \left(1 - \frac{\alpha}{\|x^k\|}\right)f(\hat{x}, \hat{u}) + \frac{\alpha}{\|x^k\|}f(x^k, u^k).$$

Letting $k \rightarrow \infty$, we have

$$f(\hat{x} + \alpha x, \hat{u}) \leq_P \hat{y}.$$

Since $\hat{y} \in W(\hat{u})$, $f(\hat{x} + \alpha x, \hat{u}) = \hat{y}$. Hence $\hat{x} + \alpha x \in \tilde{X}(\hat{u}, \hat{y})$ for any $\alpha > 0$. However, this contradicts the boundedness of $\tilde{X}(\hat{u}, \hat{y})$. Therefore \tilde{X} is locally bounded at (\hat{u}, \hat{y}) .

PROPOSITION 5.2. *If $X(\hat{u})$ is a closed set, if $\tilde{X}(\hat{u}, \hat{y})$ is a singleton, i.e., $\tilde{X}(\hat{u}, \hat{y}) = \{\hat{x}\}$ and if \tilde{X} is upper pseudo-Lipschitzian at $(\hat{u}, \hat{y}, \hat{x})$, then*

$$(5.17) \quad DY(\hat{u}, \hat{y})(u) = \nabla_x f(\hat{x}, \hat{u}) \cdot DX(\hat{u}, \hat{x})(u) + \nabla_u f(\hat{x}, \hat{u}) \cdot u \quad \forall u \in \mathbb{R}^m.$$

Proof. It has been already proved that

$$DY(\hat{u}, \hat{y})(u) \supset \nabla_x f(\hat{x}, \hat{u}) \cdot DX(\hat{u}, \hat{x})(u) + \nabla_u f(\hat{x}, \hat{u}) \cdot u$$

[6, Prop. 4.1]. So we shall prove the converse inclusion here. Let $y \in DY(\hat{u}, \hat{y})(u)$. Then there exist sequences $\{h_k\} \subset \mathbb{R}_+$, $\{u^k\} \subset \mathbb{R}^m$ and $\{y^k\} \subset \mathbb{R}^p$ such that $h_k \rightarrow 0$, $u^k \rightarrow u$, $y^k \rightarrow y$ and $\hat{y} + h_k y^k \in Y(\hat{u} + h_k u^k)$ for all k . Hence there exists another sequence $\{x^k\} \subset \mathbb{R}^n$ such that

$$\hat{x} + h_k x^k \in \tilde{X}(\hat{u} + h_k u^k, \hat{y} + h_k y^k) \quad \forall k.$$

From Proposition 5.1, the sequence $\{h_k x^k\}$ is bounded and so has a convergent subsequence. We may assume from the first that $h_k x^k \rightarrow x \in \mathbb{R}^n$. Since X is upper semicontinuous at \hat{u} and f is continuous,

$$\hat{x} + x \in \tilde{X}(\hat{u}, \hat{y}).$$

Since $\tilde{X}(\hat{u}, \hat{y}) = \{\hat{x}\}$, $x = 0$. Namely, $h_k x^k \rightarrow 0$. Since \tilde{X} is upper pseudo-Lipschitzian at $(\hat{u}, \hat{y}, \hat{x})$, there exists $M > 0$ such that, for any k sufficiently large,

$$\|\hat{x} + h_k x^k - \hat{x}\| \leq M \|(\hat{u} + h_k u^k, \hat{y} + h_k y^k) - (\hat{u}, \hat{y})\|,$$

i.e.,

$$\|x^k\| \leq M \|(u^k, y^k)\|.$$

Since $u^k \rightarrow u$ and $y^k \rightarrow y$, $\{x^k\}$ is bounded. Hence we may assume that $x^k \rightarrow \bar{x}$. Then clearly $\bar{x} \in DX(\hat{u}, \hat{y})(u)$ and

$$\begin{aligned} y &= \lim_{k \rightarrow \infty} y^k = \lim_{k \rightarrow \infty} \frac{f(\hat{x} + h_k x^k, \hat{u} + h_k u^k) - f(\hat{x}, \hat{u})}{h_k} \\ &= \nabla_x f(\hat{x}, \hat{u}) \cdot \bar{x} + \nabla_u f(\hat{x}, \hat{u}) \cdot u. \end{aligned}$$

Therefore $y \in \nabla_x f(\hat{x}, \hat{u}) \cdot DX(\hat{u}, \hat{x})(u) + \nabla_u f(\hat{x}, \hat{u}) \cdot u$. This completes the proof. \square

Thus, from Theorems 5.1 and 5.2 and Proposition 5.2, we have the following theorem which provides a complete characterization of the contingent derivative of the perturbation map W .

THEOREM 5.3. *If the following conditions (1)–(5) are satisfied, then*

$$(5.18) \quad DW(\hat{u}, \hat{y})(u) = \text{Min}_P [\nabla_x f(\hat{x}, \hat{u}) \cdot DX(\hat{u}, \hat{x})(u) + \nabla_u f(\hat{x}, \hat{u}) \cdot u] \quad \forall u \in \mathbb{R}^m.$$

- (1) $\hat{u} \in \text{int}(\text{dom } Y)$,
- (2) \hat{y} is a normally P -minimal point of $Y(\hat{u})$,
- (3) $X(u)$ is a closed set for every u in a neighborhood of \hat{u} ,
- (4) $\tilde{X}(\hat{u}, \hat{y})$ is a singleton, i.e., $\tilde{X}(\hat{u}, \hat{y}) = \{\hat{x}\}$,
- (5) \tilde{X} is upper pseudo-Lipschitzian at $(\hat{u}, \hat{y}, \hat{x})$.

Finally we briefly mention sufficient conditions for the pseudo-Lipschitzian property of \tilde{X} . The following proposition can be obtained by applying Theorem 4.12 in Rockafellar [4].

PROPOSITION 5.3. *If the following two conditions are satisfied, then \tilde{X} is (upper) pseudo-Lipschitzian at $(\hat{u}, \hat{y}, \hat{x})$:*

- (1) $X(u)$ is a closed set for every u in a neighborhood of \hat{u} ,
 - (2) If $\sum_{i=1}^p \alpha_i \nabla_x f_i(\hat{x}, \hat{u}) + \nu = 0$ for some $(\lambda, \nu) \in N_{\text{graph } X}(\hat{u}, \hat{x})$, then
- $$(5.19) \quad \alpha_i = 0 \quad \text{for } i = 1, \dots, p \text{ and } \lambda = 0.$$

Remark 5.5. When $X(u)$ is specified by inequality constraints such as

$$X(u) = \{x \in \mathbb{R}^n \mid g(x) \leq u\}$$

condition (2) in Proposition 5.3 is nothing but the Mangasarian-Fromovitz constraint qualification at \hat{x} for the set

$$\tilde{X}(\hat{u}, \hat{y}) = \{x \in \mathbb{R}^n \mid f(x, \hat{u}) - \hat{y} = 0, g(x) - \hat{u} \leq 0\}.$$

In view of Proposition 5.3, we can replace the condition (5) in Theorem 5.3 by the condition (2) in Proposition 5.3.

6. Conclusion. We have obtained sufficient conditions for the upper and lower semicontinuity of the perturbation map, which provides the set of all cone minimal points depending upon the parameter vector, in convex vector optimization. It has been shown that the convexity assumption considerably simplifies the results in the general case. We have also provided a complete characterization of the contingent derivative of the perturbation map when the nominal point is normally minimal.

POSITIVE SEMIDEFINITE MATRICES: CHARACTERIZATION VIA CONICAL HULLS AND LEAST-SQUARES SOLUTION OF A MATRIX EQUATION*

J. C. ALLWRIGHT†

Abstract. Any real symmetric $n \times n$ matrix A can be described by an $n(n+1)/2$ -component vector. Positive semidefiniteness of A is characterized by the associated vector belonging to the conical hull of a suitable convex set. This characterization is used to facilitate least-squared error solution, with respect to such A , of $F = AG$, where F and G are given matrices. The solution method involves finding the point in the conical hull of a convex set which is nearest to a vector. An algorithm is given for solving that proximal point problem.

Key words. positive semidefinite matrices, least-squared error solution of matrix equations, optimization on cones

AMS (MOS) subject classifications. 15A57, 65F99, 90C25

1. Introduction. A real symmetric $n \times n$ matrix A can be identified uniquely by an $n(n+1)/2$ component vector $\overline{\text{vec}}(A)$ associated with the entries of A . In § 2 it is shown that A is positive semidefinite if and only if $\overline{\text{vec}}(A)$ lies in the conical hull of a suitable specified convex set Ω , and that A is positive definite if and only if $\overline{\text{vec}}(A)$ lies in the interior of that conical hull. That characterization of positive semidefiniteness is used in § 3 to solve the problem of least-squared error solution, with respect to symmetric positive semidefinite A , of the equation $F = AG$. The error measure used is the Frobenius norm of $F - AG$, $\|F - AG\|_F$. The solution method involves finding the closest point in a conical hull to a vector. An algorithm for solving that proximal point problem is given in § 4. Approximation issues are addressed throughout. Computational effort and numerical results for an example are the subject of § 5.

Some algorithms for optimization problems associated with symmetric positive semidefinite matrices have received attention in the recent literature, e.g., [1], [2]. Least-squared error solution of $F = AG$ with respect to such matrices A is a fundamental problem which does not seem to have been tackled before. A result of Higham [3, Lemma 2.5] reveals that for the case when $F = F'$ (i.e., when F is symmetric) and $G = I$, an approximation to the minimizer \hat{A} of $\|F - AG\|_F$ is given by the polar factor H in the polar decomposition $F = UH$, with $\|F - HG\|_F \leq 2\|F - \hat{A}G\|_F$. In fact, for general F when $G = I$, the global minimizer \hat{A} of $\|F - AG\|_F$ is actually $\frac{1}{2}[F + F']_{(0)}$, where the notation $[M]_{(0)}$ denotes the result of changing to 0 all the negative eigenvalues in the spectral form of M [4, Thm. 2.1.3]. Unfortunately, there does not seem to be a simple formula for the global minimizer \hat{A} for the case of general G —hence the analysis and algorithm of this paper. The original motivation for consideration of least-squared error solution of $F = AG$ actually arose in connexion with the development of new methods for estimating the inverse Hessian matrix in quasi-Newton algorithms.

The approach adopted here is more attractive computationally than the direct use as constraints in an optimization algorithm of the conventional tests for positive

† Department of Electrical Engineering, Imperial College of Science and Technology, London SW7 2BT, U.K.

semidefiniteness (nonnegativity of all of the eigenvalues of A or of all the principal minors), since they depend in a complicated way on the entries of A .

A fact is that a symmetric matrix A is positive semidefinite iff it can be written as $A = B^2$ for some symmetric B . The obvious way to use that fact is to consider minimization with respect to symmetric B of the Frobenius norm of $F - B^2G$. Unfortunately, the resulting optimization problem is, in general, nonconvex in B . The approach of this paper has the advantage that it involves only convex optimization problems, even though the representation of positive semidefinite A as B^2 plays an important role in one of the conical hulls, which is used later.

Proofs are given at the end of the section concerned. The following notation is used throughout.

The range of a real matrix B is written $R[B]$, its null space $N[B]$, the dimension of its null space N_B and its Moore–Penrose pseudoinverse B^\dagger . The smallest singular value of B is written $\sigma_{\min}[B]$, and when B is symmetric its most negative eigenvalue is denoted by $\lambda_{\min}[B]$. For symmetric positive semidefinite B , $[B]_{(\alpha)}$ denotes the matrix obtained by replacing all the zero eigenvalues in the spectral form of B by the real scalar α .

The Kronecker product of matrices B and C is written $B \otimes C$.

The Frobenius-norm of B is denoted $\|B\|_F$ and the 2-norm of a vector or matrix is written $\|\cdot\|$.

The sets of nonnegative and strictly positive reals are written as R_{\geq} and $R_{>}$, respectively. For $A \in R^{n \times n}$, the notation $A \geq 0$ means that A is positive semidefinite and $A > 0$ means that A is positive definite.

The convex hull of a set $X \neq \emptyset$ is denoted by $\text{conv}[X]$, the conical hull of X (i.e., $\text{conv}[\{\alpha x: \alpha \in R_{\geq}, x \in X\}]$) by $\text{cone}[X]$, and the interior by $\text{int}[X]$. The set BX is $\{Bx: x \in X\}$ and the line $\{\alpha x + (1 - \alpha)y: \alpha \in [0, 1]\}$ between two points x and y is written line $\{x, y\}$.

Minimization and minimizers will always refer to global minimization and global minimizers. A minimizer of $f: R^n \rightarrow R$ with respect to x from a set X will often be denoted \hat{x} . The unique point \hat{x} in a closed, convex set X which minimizes $\|d - x\|$ with respect to $x \in X$ is often called $\text{minpoint}[d, X]$ and $\text{mindist}[d, X]$ is the corresponding minimal distance $\|d - \hat{x}\|$. Notation regarding minimization will only be used when the minimum exists, even when the statement and proof of existence of the minimum actually appear later in the paper.

Two minimization problems will be said to be equivalent if they have the same minimal value, and a global minimizer of either may be found easily from a global minimizer of the other.

2. Conical hull characterizations of the set of symmetric positive semidefinite matrices. For $C \in R^{m \times n}$, let $\text{vec}(C)$ be the following vector containing all the entries of C :

$$\text{vec}(C) = [c_{1*} c_{2*} \cdots c_{m*}]' \in R^{mn}$$

where c_{i*} denotes row i of C .

Let

$$S^n = \{A \in R^{n \times n}: A' = A\},$$

$$S_{\geq}^n = \{A \in R^{n \times n}: A' = A \geq 0\},$$

$$S_{>}^n = \{A \in R^{n \times n}: A' = A > 0\}.$$

Consider the linear subspace $\text{vec}(S^n) = \{\text{vec}(A) : A \in S^n\} \subset R^{n^2}$ of all vectors $\text{vec}(A)$ associated with symmetric A . It has dimension $r = n(n+1)/2$. Suppose w_1, w_2, \dots, w_r is an orthonormal basis-set for $\text{vec}(S^n)$. For example, suitable w_i for $n=2$ might be $w_1 = [1 \ 0 \ 0 \ 0]'$, $w_2 = [0 \ 2^{-1/2} \ 2^{-1/2} \ 0]'$, $w_3 = [0 \ 0 \ 0 \ 1]'$. Consequently

$$(2.1) \quad W = [w_1 w_2 \dots w_r] \in R^{n^2 \times r}$$

is a basis-matrix for $\text{vec}(S^n)$ and

$$(2.2) \quad W'W = I_{r \times r}, \quad R[W'] = R', \quad R[W] = \text{vec}(S^n).$$

For symmetric A , let $\overline{\text{vec}}(A)$ denote the vector of coordinates of $\text{vec}(A)$ with respect to the basis-set w_1, w_2, \dots, w_r i.e., with respect to the columns of W . Then, in view of (2.1) and (2.2)

$$(2.3) \quad \text{vec}(A) = W \overline{\text{vec}}(A) \in R^{n^2}, \quad \overline{\text{vec}}(A) = W' \text{vec}(A) \in R^r.$$

Let

$$(2.4) \quad U = \{B \in R^{n \times n} : B' = B \text{ and } \|B\|_F = 1\},$$

$$(2.5) \quad \Omega = \text{conv}\{\Psi\}, \quad \Psi = \{\text{vec}(B^2) : B \in U\} \subset R^{n^2}.$$

The functions $\text{vec}^{-1} : R^{n^2} \rightarrow R^{n \times n}$ and $\overline{\text{vec}}^{-1} : R^r \rightarrow S^n$ will be useful later.

The characterizations of positive semidefiniteness which follow are based on the idea that any $A \in S_{\geq}^n$ can be represented either as $A = \alpha B^2$ for some $\alpha \in R_{\geq}$ and some symmetric B with $\|B\|_F = 1$, or as $A = \alpha B$ for some $\alpha \in R_{\geq}$ and some $B \in S_{\geq}^n$ with $\|B\|_F \leq 1$. In detail, the two characterizations of S_{\geq}^n are

$$S_{\geq}^n = \text{cone}[\Xi], \quad \text{where } \Xi = \{B^2 : B \in S^n, \|B\|_F = 1\},$$

$$S_{\geq}^n = \text{cone}[\tilde{\Xi}], \quad \text{where } \tilde{\Xi} = \{B : B \in S_{\geq}^n, \|B\|_F \leq 1\}.$$

For optimization purposes it is convenient to consider conical hull characterizations of $\overline{\text{vec}}(S_{\geq}^n) := \{\overline{\text{vec}}(A) : A \in S_{\geq}^n\}$ and of $\overline{\text{vec}}(S_{>}^n) := \{\overline{\text{vec}}(A) : A \in S_{>}^n\}$, which are cones of vectors associated with $n \times n$ symmetric positive semidefinite matrices and positive definite matrices, respectively. Those cones are next characterized in terms of Ω , using an approach based on the fact that $S_{\geq}^n = \text{cone}[\Xi]$. Some useful properties of Ω and Ψ , both of (2.5), are also given.

THEOREM 2.1.

- (i) $\overline{\text{vec}}(S_{\geq}^n) = \text{cone}[\Omega]$, $\overline{\text{vec}}(S_{>}^n) = \text{cone}[W'\Omega]$;
- (ii) $\overline{\text{vec}}(S_{>}^n) = \text{int cone}[W'\Omega]$;
- (iii) Ψ is a compact set; Ω is a nonempty convex compact set with $\text{mindist}[0, \Omega] = n^{-1/2}$ and $\text{cone}[\Omega]$ is a nonempty closed convex cone;
- (iv) $\text{mindist}[0, LW'\Omega] \geq \sigma_{\min}[L]n^{-1/2}$ for all $L \in R^{r \times r}$;
- (v) For $g \in R^r$ and $L \in R^{r \times r}$: $\min_{\gamma \in LW'\Omega} g'\gamma = \lambda_{\min}[Z]$

and a minimizing γ is $\hat{\gamma} = LW' \text{vec}(\nu\nu')$. Here

$$(2.6) \quad Z = \frac{[\text{vec}^{-1}(\bar{g}) + \text{vec}^{-1}(\bar{g})']}{2} \in R^{n \times n} \quad \text{for } \bar{g} = WL'g$$

and ν is a normalized eigenvector of Z corresponding to the minimal eigenvalue $\lambda_{\min}[Z]$ of Z . \square

Minimization of $\|F - AG\|_F$, to be performed later, involves the determination of the point in $\text{cone}[LW'\Omega]$ which is nearest to a vector u , for a specific $L \in R^{r \times r}$. An algorithm for doing that is given in § 4. Actually any set Ω could be used so long as

cone $[\Omega] = S_{\equiv}^n$ and properties (4.3)-(4.5) of § 4 are valid. An alternative to Ω of (2.5) is that used in an earlier version of this paper [5]. Yet another corresponds to the characterization above of S_{\equiv}^n as cone $[\tilde{\Xi}]$ and is

$$\tilde{\Omega} = \{\text{vec}(B) : B \in S_{\equiv}^n \text{ and } \|B\|_F \leq 1\}.$$

The following results guarantee that properties (4.3)-(4.5) are actually valid when Ω is replaced by $\tilde{\Omega}$.

THEOREM 2.2.

- (i) $\text{vec}(S_{\equiv}^n) = \text{cone}[\tilde{\Omega}]$; $\overline{\text{vec}(S_{\equiv}^n)} = \text{cone}[W'\tilde{\Omega}]$; $\overline{\text{vec}(S_{\equiv}^n)} = \text{int cone}(W'\tilde{\Omega})$.
- (ii) $\tilde{\Omega}$ is a nonempty, closed convex set.
- (iii) Suppose $L \in R^{r \times r}$. Then, for any $x \in LW'\tilde{\Omega}$, there exists a point y along the ray through 0 and x such that $y \in LW'\tilde{\Omega}$ and $\|y\| \geq \sigma_{\min}[L]$.
- (iv) Suppose that $L \in R^{r \times r}$ and that Z of (2.6) has the spectral form $Z = V\Lambda V'$, where $\Lambda = \text{diag}(\lambda_1[Z], \dots, \lambda_n[Z])$. Let $\hat{\lambda} = [\sum_{i \in I} \lambda_i[Z]^2]^{1/2}$, where $I = \{i: \lambda_i[Z] < 0\}$. Then for any $g \in R^r$:

$$\min_{\gamma \in LW'\tilde{\Omega}} g'\gamma = \begin{cases} 0 & \text{if } \lambda_{\min}[Z] \geq 0, \\ -\hat{\lambda} & \text{otherwise} \end{cases}$$

and a minimizing γ from $LW'\tilde{\Omega}$ is $\tilde{\gamma} = 0$ if $\lambda_{\min}[Z] \geq 0$, and is $\tilde{\gamma} = LW' \text{vec}[V\hat{\Lambda}V']$ otherwise, where $\hat{\Lambda} = \text{diag}\{\hat{\lambda}_1, \dots, \hat{\lambda}_n\}$ for $\hat{\lambda}_i = -\min\{0, \lambda_i\}/\hat{\lambda}$. \square

These results for $\tilde{\Omega}$ will not be proved here as the proofs are similar to those of the results concerning Ω in Theorem 2.1, which will be given shortly.

Considerable numerical experience will be needed before it can be decided which of the possible sets Ω is best from the computational point of view. If $\tilde{\Omega}$ were used by the algorithm of § 4 instead of Ω of (2.5), then that algorithm would require the minimization of $g'\gamma$ (for an appropriate g) with respect to $\gamma \in LW'\tilde{\Omega}$ at each iteration, instead of with respect to $\gamma \in LW'\Omega$ for Ω of (2.5). Since it is clear from Theorems 2.1 and 2.2 that such minimization is more expensive for $\tilde{\Omega}$ than for Ω , and since Ω of [5] is about as easy to use as Ω of (2.5) but is defined in a less direct way, the set Ω of (2.5) will be used in the rest of this paper.

The proof of Theorem 2.1 is facilitated by the following lemmas. The proof of the first is omitted as it is straightforward.

LEMMA 2.1. (i) For any $A, B \in R^{n \times n}$ and any $x, y \in R^n$

$$\begin{aligned} \text{trace}[AB] &= \text{trace}[BA] = \text{trace}[B'A'], \\ x'y &= \text{trace}[\text{vec}^{-1}(x) \text{vec}^{-1}(y)']. \end{aligned}$$

(ii) For any $B \in U$ and for \bar{g} and Z of (2.6)

$$\bar{g}' \text{vec}(B^2) = \text{trace}[BZB].$$

(iii) For any $C \in R^{m \times n}$, any $A \in S^n$ and any orthogonal $P, Q \in R^{n \times n}$

$$\|C\|_F = \|\text{vec}(C)\|, \quad \|\overline{\text{vec}(A)}\| = \|\text{vec}(A)\|, \quad \|A\|_F^2 = \text{trace}[A^2], \quad \|PAQ\|_F = \|A\|_F.$$

(iv) For orthogonal $V \in R^{n \times n}$

$$U = \{VBV': B \in U\}. \quad \square$$

LEMMA 2.2. For $\Lambda = \text{diag}\{\lambda_1, \lambda_2, \dots, \lambda_n\}$ with $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$

$$\min_{C \in U} \text{trace}[C\Lambda C] = \lambda_n. \quad \square$$

Proof of Lemma 2.2. For any $C \in U$

$$\text{trace}[C\Lambda C] = \sum_{i=1}^n (C^2)_{ii} \lambda_i \geq \lambda_n \text{trace}[C^2] = \lambda_n \|C\|_F^2 = \lambda_n.$$

Further, for $C = e_n e_n'$, where $e_n = (0 \ 0 \ 0 \ \cdots \ 0 \ 1)'$, $C \in U$ and $\text{trace}[C \wedge C] = \lambda_n$. The result follows. \square

Proof of Theorem 2.1. (i) Let $\bar{\Sigma}_i$ denote $\sum_{i=1}^{n^2+1}$. By the Caratheodory representation theorem [6, Thm. 17.1], since Ω [of (2.5)] is a convex subset of R^{n^2} , every $x \in \Omega$ can be represented as

$$(2.7) \quad x = \bar{\Sigma}_i \alpha_i \text{vec}[B_i^2]$$

for some $\alpha_i \in R_{\geq}$ with $\bar{\Sigma}_i \alpha_i = 1$ and for some $B_i \in U$. Hence every $x \in \text{cone}[\Omega]$ can be written as $x = \bar{\Sigma}_i (\alpha \alpha_i) \text{vec}[B_i^2]$ for some $\alpha \in R_{\geq}$. The matrix X corresponding to x is $X = \text{vec}^{-1}(x) = \bar{\Sigma}_i (\alpha \alpha_i) B_i^2$ and consequently is positive semidefinite. Hence $\text{cone}[\Omega] \subset \text{vec}[S_{\geq}^n]$.

Also, $\text{vec}[S_{\geq}^n] \subset \text{cone}[\Omega]$ since any $X \in S_{\geq}^n$ can be written as $X = \alpha B^2$ for some $\alpha \in R_{\geq}$ and for some $B \in U$ so that $\text{vec}[X] \in \text{cone}[\Omega]$.

Hence $\text{vec}[S_{\geq}^n] = \text{cone}[\Omega]$ and consequently, in view of (2.3), $\overline{\text{vec}[S_{\geq}^n]} = W' \text{cone}[\Omega] = \text{cone}[W'\Omega]$, which proves Theorem 2.1(i).

(ii) Now

$$X \in S_{>}^n \Leftrightarrow \text{there exists } \delta > 0 \text{ such that } X + Y \in S_{\geq}^n, \text{ whenever } Y \in S^n \text{ and } \|Y\|_F < \delta;$$

$$\Leftrightarrow \text{there exists } \delta > 0 \text{ such that } \overline{\text{vec}}(X) + \overline{\text{vec}}(Y) \in \overline{\text{vec}}(S_{\geq}^n) \text{ whenever } Y \in S^n \text{ and } \|\text{vec}(Y)\| < \delta;$$

$$\Leftrightarrow \text{there exists } \delta > 0 \text{ such that } \overline{\text{vec}}(X) + z \in \overline{\text{vec}}(S_{\geq}^n) \text{ whenever } z \in R^r \text{ and } \|z\| < \delta \text{ (since, by Lemma 2.1(iii), } \{Y \in S^n: \|\text{vec}(Y)\| < \delta\} = \{\overline{\text{vec}}^{-1}(z): z \in R^r \text{ and } \|z\| < \delta\});$$

$$\Leftrightarrow \overline{\text{vec}}(X) \in \text{int } \overline{\text{vec}}(S_{\geq}^n),$$

so $\overline{\text{vec}}(S_{>}^n) = \text{int } \overline{\text{vec}}(S_{\geq}^n)$. Consequently, in view of Theorem 2.1(i), $\overline{\text{vec}}(S_{>}^n) = \text{int } \text{cone}[W'\Omega]$, which proves Theorem 2.1(ii).

(iii) Since U is compact, the set $\Psi = \{\text{vec}(B^2): B \in U\}$ is a compact subset of R^{n^2} so Ω , its convex hull, is also compact [7, Thm. 3.2.18].

Let $\tilde{\Sigma}_j$ denote $\sum_{j=1}^n$. For any $B \in U$

$$(2.8) \quad (B^2)_{jj} = \sum_{k=1}^n (b_{jk})^2 \geq 0, \quad \text{trace}[B^2] = \tilde{\Sigma}_j, \quad (B^2)_{jj} = 1.$$

Using representation (2.7) of any x from Ω

$$\|x\|^2 = \|\bar{\Sigma}_i \alpha_i \text{vec}(B_i^2)\|^2 = \|\bar{\Sigma}_i \alpha_i B_i^2\|_F^2 \geq \tilde{\Sigma}_j \{\bar{\Sigma}_i \alpha_i (B_i^2)_{jj}\}^2.$$

Hence, since [8, § 2.1] $\tilde{\Sigma}_j z_j^2 \geq [\tilde{\Sigma}_j |z_j|]^2/n$ for all $z \in R^n$, and in view of (2.8) and the fact that each B_i is in U of (2.4)

$$(2.9) \quad \|x\|^2 \geq [\tilde{\Sigma}_j \bar{\Sigma}_i \alpha_i (B_i^2)_{jj}]^2/n = [\bar{\Sigma}_i \alpha_i \tilde{\Sigma}_j (B_i^2)_{jj}]^2/n \\ = [\bar{\Sigma}_i \alpha_i]^2/n = n^{-1} \quad \forall x \in \Omega.$$

Take $B = n^{-1/2} I \in U$. Then $\text{vec}(B^2) \in \Omega$ and $\|\text{vec}(B^2)\| = n^{-1/2}$. Consequently, in view of (2.9): $\text{mindist}[0, \Omega] = n^{-1/2}$.

Since Ω is a nonempty, convex compact set and $\text{mindist}[0, \Omega] > 0$, it follows from [6, Cor. 9.6.1] that $\text{cone}[\Omega]$ is a nonempty convex closed cone. This completes the proof of Theorem 2.1(iii). \square

(iv) If $x \in LW'\Omega$, then $x = LW'\omega$ for some $\omega \in \Omega$ and $\|x\| \geq \sigma_{\min}[L] \|W'\omega\|$. From (2.1)–(2.2), WW' projects R^{n^2} orthogonally onto $R[W] = \text{vec}(S^n)$. Hence $\|W'\omega\|^2 = \omega' WW'\omega = \|\omega\|^2$ since, by Theorem 2.1(i), $\omega \in \text{vec}(S_{\geq}^n) \subset \text{vec}(S^n)$ when $\omega \in \Omega$. Hence,

by Theorem 2.1(iii)

$$\|x\| \geq \sigma_{\min}[L]\|\omega\| \geq \sigma_{\min}[L]n^{-1/2} \quad \forall x \in LW'\Omega,$$

which proves Theorem 2.1(iv).

(v) Put Z of (2.6) in the spectral form $Z = V\Lambda V'$, where $\Lambda = \text{diag}\{\lambda_1, \lambda_2, \dots, \lambda_n\}$ with $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n = \lambda_{\min}[Z]$. Then, since the minimization of $g'\gamma$ with respect to $\gamma \in LW'\Omega$ is equivalent to minimization of $\bar{g}'\omega$ with respect to $\omega \in \Omega$ for $\bar{g} = WL'g$, and since minimization of $\bar{g}'\omega$ with respect to $\omega \in \Omega$ is equivalent to minimization with respect to $\omega \in \Psi$ because, from (2.5), $\Omega = \text{conv}\{\Psi\}$

$$\begin{aligned} \min_{\gamma \in LW'\Omega} g'\gamma &= \min_{\omega \in \Omega} \bar{g}'\omega \\ &= \min_{B \in U} \bar{g}' \text{vec}(B^2) && \text{(from (2.5))} \\ &= \min_{B \in U} \text{trace}[BZB] && \text{(from Lemma 2.1(ii))} \\ (2.10) \quad &= \min_{B \in U} \text{trace}[V'BV\Lambda V'BV] && \text{(by Lemma 2.1(i) and since } Z = V\Lambda V') \\ &= \min_{C \in U} \text{trace}[C\Lambda C] && \text{(from Lemma 2.1(iv))} \\ &= \lambda_n = \lambda_{\min}[Z] && \text{(from Lemma 2.2).} \end{aligned}$$

Now consider $\hat{B} = \nu\nu'$, where ν is a normalized eigenvector of Z corresponding to the eigenvalue $\lambda_{\min}[Z]$. Then $\hat{B} \in U$, since $\hat{B}' = \hat{B}$ and since $\|\hat{B}\|_F^2 = \text{trace}[\hat{B}^2] = \|\nu\|^2 = 1$, so (from (2.5)) $\text{vec}(\hat{B}^2) \in \Omega$.

Let $\hat{\gamma} = LW' \text{vec}(\hat{B}^2)$. Then $\hat{\gamma} \in LW'\Omega$ and

$$\begin{aligned} g'\hat{\gamma} &= \bar{g}' \text{vec}(\hat{B}^2) = \text{trace}[\hat{B}Z\hat{B}] \quad \text{(by Lemma 2.1(ii))} \\ &= \lambda_{\min}[Z] \quad \text{(since } Z\nu = \lambda_{\min}[Z]\nu \text{ and } \|\nu\| = 1). \end{aligned}$$

Consequently, in view of (2.10), $\hat{\gamma}$ minimizes $g'\gamma$ with respect to $\gamma \in LW'\Omega$, which completes the proof of Theorem 2.1. \square

3. Minimization of $\|F - AG\|_F$ with respect to symmetric positive semidefinite A . Suppose $A \in R^{n \times n}$ and $F, G \in R^{n \times m}$. The optimization problem is

$$(3.1) \quad \text{P1} \quad \min_{A \in S_{\geq}^n} \|F - AG\|_F.$$

The conical hull characterization of the set of positive semidefinite matrices developed in § 2, $\text{vec}(S_{\geq}^n) = \text{cone}[W'\Omega]$, is used later to prove the following result.

THEOREM 3.1. *The minimum in P1 exists.* \square

Remark 3.1. There is actually a unique global minimizer \hat{A} for P1 when G has full rank (see Theorem 3.2) but \hat{A} is not necessarily unique when G does not have full rank (see, e.g., Theorem 3.5(i)). \square

When G has full rank, the conical hull characterization can be used to transform problem P1 into a problem, P2 of (3.3), for which the solution can be computed fairly easily. It will be seen shortly that the case with general G can be solved by employing the results for the full rank case which follow.

THEOREM 3.2. *Suppose $A \in R^{n \times n}$; $F, G \in R^{n \times m}$ with $m \geq n$ and $\text{rank}[G] = n$.*

Let $J = [I_{n \times n} \otimes G']W \in R^{mn \times r}$ where $r = n(n+1)/2$. Then J has rank r . Factorize J as $J = P[L'0']'$ for some invertible $L \in R^{r \times r}$, where $P \in R^{mn \times mn}$ is some orthogonal matrix. Using that P , factorize $f = \text{vec}[F] \in R^{mn}$ as $f = P[u'l']'$ with $u \in R^r$.

Then \hat{A} solves P1 if and only if

$$(3.2) \quad \hat{A} = \overline{\text{vec}}^{-1}(L^{-1}\hat{k}),$$

where \hat{k} is the unique solution of

$$(3.3) \quad \text{P2} \quad \min_{k \in K} \|u - k\|,$$

and

$$(3.4) \quad \|F - \hat{A}G\|_F^2 = \|u - \hat{k}\|^2 + \|l\|^2.$$

Here K is the convex cone

$$(3.5) \quad K = \text{cone}[LW'\Omega].$$

Further

$$(3.6) \quad \hat{k} = u \text{ iff } \overline{\text{vec}}^{-1}(L^{-1}u) \geq 0,$$

$$(3.7) \quad \hat{A} \text{ is not positive definite if } \hat{k} \neq u. \quad \square$$

Remark 3.2. Suppose $\overline{\text{vec}}^{-1}(L^{-1}u) \geq 0$. Then, from (3.6), $\hat{k} = u$, so that, from (3.2), $\hat{A} = \overline{\text{vec}}^{-1}(L^{-1}u)$. Hence \hat{A} is very easy to find in that case.

Now suppose $\overline{\text{vec}}^{-1}(L^{-1}u) \not\geq 0$. Then $\hat{k} \neq u$ and there does not seem to be a formula for \hat{k} ; however, an arbitrarily close approximation \bar{k} to \hat{k} can be obtained using an iterative procedure, Algorithm 4.1 of §4 (later). By Theorem 4.2, for any $\varepsilon > 0$, Algorithm 4.1 can be used to find an approximation \bar{k} which satisfies condition (3.8) below. The corresponding approximation \bar{A} to $\hat{A} = \overline{\text{vec}}^{-1}(L^{-1}\hat{k})$ is $\bar{A} = \overline{\text{vec}}^{-1}(L^{-1}\bar{k})$. Theorem 3.3, which follows, reveals that \bar{A} can be made an arbitrarily good approximation to \hat{A} by choosing ε to be small enough. Hence, when G has full rank, an arbitrarily accurate approximation \bar{A} to the solution \hat{A} for P1 of (3.1) can be found. \square

THEOREM 3.3. Suppose F, G, L, u and l are those of Theorem 3.2, with $\text{rank}[G] = n$. Consider any real $\varepsilon \geq 0$. If $\bar{k} \in K$ satisfies

$$(3.8) \quad [\|u - \bar{k}\|^2 + \|l\|^2] \leq (1 + \varepsilon)^2 [\|u - \hat{k}\|^2 + \|l\|^2]$$

and $\bar{A} = \overline{\text{vec}}^{-1}(L^{-1}\bar{k})$, then \bar{A} approximates \hat{A} of (3.2) in that

- (i) $\bar{A} \geq 0$,
- (ii) $\|\bar{A} - \hat{A}\|_F \leq (2\varepsilon + \varepsilon^2)^{1/2} \|L^{-1}\| \|F - \hat{A}G\|_F$,
- (iii) $\|F - \bar{A}G\|_F \leq (1 + \varepsilon) \|F - \hat{A}G\|_F. \quad \square$

Now consider the case when G does not have full column rank in that $\text{rank}[G] = q < n$. Then use of the next result, Theorem 3.4, enables an accurate, approximate solution \tilde{A} of P1 to be obtained easily from a matrix $F_2 \in R^{(n-q) \times m}$ and from an accurate approximation \tilde{B} to the global minimizer \hat{B} for

$$(3.9) \quad \text{P3} \quad \min_{B \in S_{\geq}^q} \|F_1 - BG_1\|_F,$$

where G_1 has full column rank, for suitable $F_1, G_1 \in R^{q \times m}$. Hence the above results for the case when G has full rank may be used to find a suitable \tilde{B} . The details are given next.

Suitable matrices F_1, F_2 and G_2 are obtained from F and G as follows. When $\text{rank}[G] = q < n$, there is an orthogonal $Q \in R^{n \times n}$ such that

$$(3.10) \quad QG = [G_1' 0']'$$

for some $G_1 \in R^{q \times m}$ of rank q . Using that Q , the matrices $F_1 \in R^{q \times m}$ and $F_2 \in R^{(n-q) \times m}$ are obtained by partitioning QF as

$$(3.11) \quad QF = [F_1' F_2']'.$$

The results which facilitate accurate approximate solution of P1 when G does not have full column rank are given next.

THEOREM 3.4. Suppose $\text{rank}[G] = q < n$; Q , F_1 , F_2 and G_1 are as specified by (3.10) and (3.11); \hat{A} solves P1 of (3.1) and \hat{B} solves P3 of (3.9). Then

$$(3.12) \quad (i) \quad \|F - \hat{A}G\|_F^2 = \|F_1 - \hat{B}G_1\|_F^2 + \|F_2(I - G_1^\dagger G_1)\|_F^2,$$

$$(3.13) \quad (ii) \quad \tilde{A} = Q' \begin{pmatrix} \tilde{B} & \tilde{C} \\ \tilde{C}' & \tilde{D} \end{pmatrix} Q$$

is a positive semidefinite approximate solution for P1 which satisfies

$$(3.14) \quad \|F - \tilde{A}G\|_F^2 \leq (1 + \varepsilon_1) \|F - \hat{A}G\|_F^2 + \varepsilon_2$$

for any prespecified $\varepsilon_1, \varepsilon_2 \in \mathbb{R}_\equiv$ if

(a) $\tilde{B} \in S_\equiv^q$ approximates the solution \hat{B} of P3 in that

$$(3.15) \quad \tilde{B} > 0 \quad \text{and} \quad \|F_1 - \tilde{B}G_1\|_F^2 \leq [(1 + \varepsilon_1) \|F_1 - \hat{B}G_1\|_F^2 + \varepsilon_2].$$

(b) \tilde{C} and \tilde{D} satisfy

$$(3.16) \quad \tilde{C}' = F_2 G_1^\dagger,$$

$$(3.17) \quad \tilde{D} \in S_\equiv^{n-q} \quad \text{with} \quad \tilde{D} \geq \tilde{C}' \tilde{B}^{-1} \tilde{C}.$$

Further, \tilde{A} of (3.13) is positive definite if, in addition,

$$(3.18) \quad \tilde{D} > \tilde{C}' \tilde{B}^{-1} \tilde{C}. \quad \square$$

An important point in connection with Theorem 3.4 is that the \hat{B} which solves P3 of (3.9) is not necessarily positive definite even though it is positive semidefinite. Hence even if \hat{B} were available, it might be necessary to perturb \hat{B} slightly to yield a positive definite \tilde{B} suitable for use with Theorem 3.4. The next result, Theorem 3.5, concerns the determination of such a positive definite \tilde{B} and the consequences of its use when finding an approximation \tilde{A} to \hat{A} for P1 of (3.1) using Theorem 3.4. In Theorem 3.5, $[B]_{(\alpha)}$ and N_B are as defined in § 1.

THEOREM 3.5. Let \tilde{L} , \tilde{u} and \tilde{l} be the L , u and l of Theorem 3.2 when applied to P3 of (3.9) instead of to P1 of (3.1). Consider the solution \hat{B} of P3, the matrices \tilde{A} , \tilde{B} , \tilde{C} and \tilde{D} of Theorem 3.4 and any solution \hat{A} of P1. There are three cases, depending on whether $\overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u})$ is positive definite, positive semidefinite or not positive semidefinite.

(i) Suppose $\overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u}) > 0$. Then $\hat{B} = \overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u})$ and $\hat{B} > 0$ and if \tilde{B} is chosen to be \hat{B} , then \tilde{A} solves P1 (for any $\tilde{D} \in S_\equiv^{n-q}$ with $\tilde{D} \geq \tilde{C}' \tilde{B}^{-1} \tilde{C}$) and

$$(3.19) \quad \|F_1 - \hat{B}G_1\|_F = \|\tilde{l}\|, \quad \|F - \hat{A}G\|_F^2 = \|\tilde{l}\|^2 + \|F_2(I - G_1^\dagger G_1)\|_F^2.$$

(ii) Suppose $\overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u}) \geq 0$ with $\overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u}) \not> 0$. Then $\hat{B} = \overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u}) \geq 0$ with $\hat{B} \not> 0$ and (3.19) applies.

For any $\alpha \in \mathbb{R}_\equiv$, if $\tilde{B} = [B]_{(\alpha)}$ then \tilde{B} is a positive definite approximation to \hat{B} and \tilde{A} is a positive semidefinite approximate minimizer for P1 which have the following absolute error properties if $\tilde{l} = 0$:

$$(3.20) \quad \|F_1 - \tilde{B}G_1\|_F \leq \|F_1 - \hat{B}G_1\|_F + \alpha(N_B)^{1/2} \|G_1\|_F,$$

$$(3.21) \quad \|F - \tilde{A}G\|_F^2 \leq \|F - \hat{A}G\|_F^2 + \alpha^2 N_B \|G_1\|_F^2$$

and which have the following relative error properties if $\tilde{l} \neq 0$:

$$(3.22) \quad \|F_1 - \tilde{B}G_1\|_F \leq (1 + \alpha[(N_B)^{1/2} \|G_1\|_F / \|\tilde{l}\|]) \|F_1 - \hat{B}G_1\|_F,$$

$$(3.23) \quad \|F - \tilde{A}G\|_F \leq (1 + \alpha[(N_B)^{1/2} \|G_1\|_F / \|\tilde{l}\|]) \|F - \hat{A}G\|_F.$$

(iii) Suppose $\overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u}) \not\geq 0$. Then $\|F_1 - \hat{B}G_1\|_F > 0$. Further, for $\varepsilon \in \mathbb{R}_{\geq}$, suppose an approximation $\bar{B} \in S_{\geq}^q$ to \hat{B} has been found which satisfies

$$(3.24) \quad \|F_1 - \bar{B}G_1\|_F \leq (1 + \varepsilon)\|F_1 - \hat{B}G_1\|_F.$$

For $\alpha \in \mathbb{R}_{\geq}$, if \tilde{B} is chosen as $[\bar{B}]_{(\alpha)}$ then \tilde{B} is a positive definite approximation to \hat{B} , and \tilde{A} is a positive semidefinite approximate solution for P1, with the following relative error properties:

$$(3.25) \quad \|F_1 - \tilde{B}G_1\|_F \leq (1 + \varepsilon)(1 + \alpha[(N_B)^{1/2}\|G_1\|_F/\|F_1 - \bar{B}G_1\|_F])\|F_1 - \hat{B}G_1\|_F,$$

$$(3.26) \quad \|F - \tilde{A}G\|_F \leq (1 + \varepsilon)(1 + \alpha[(N_B)^{1/2}\|G_1\|_F/\|F_1 - \bar{B}G_1\|_F])\|F - \hat{A}G\|_F. \quad \square$$

Remark 3.3. For case (i), Theorem 3.5 reveals that an \tilde{A} which solves P1 of (3.1) exactly can be found explicitly.

Case (ii) of Theorem 3.5 reveals that an \tilde{A} giving an arbitrarily good approximation to the minimal value of P1 can be obtained easily by choosing α to be small enough.

Consider case (iii). The corresponding version of P2 of (3.3) is

$$\text{P2}' \quad \min_{k \in \text{cone}[\tilde{L}\tilde{W}'\tilde{\Omega}]} \|\tilde{u} - k\|$$

and the corresponding \hat{B} which minimizes $\|F_1 - BG_1\|_F$ is, from (3.2), $\hat{B} = \overline{\text{vec}}^{-1}(\tilde{L}^{-1}\hat{k})$ where \hat{k} solves P2'. Here \tilde{L} , \tilde{W} and $\tilde{\Omega}$ are L , W and Ω of Theorem 3.2, (2.1) and (2.5) for n replaced by q . Since $\overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u}) \not\geq 0$ in case (iii), it follows from (3.6) that $\hat{k} \neq \tilde{u}$. Hence, by Theorem 4.2 (later), Algorithm 4.1 can be applied to obtain an accurate approximate solution \bar{k} for P2' which satisfies the corresponding version of (3.8), namely

$$[\|\tilde{u} - \bar{k}\|^2 + \|\tilde{l}\|^2] \leq (1 + \varepsilon)^2[\|\tilde{u} - \hat{k}\|^2 + \|\tilde{l}\|^2].$$

Then the corresponding approximation \bar{B} to \hat{B} is $\bar{B} = \overline{\text{vec}}^{-1}(\tilde{L}^{-1}\bar{k})$ and, by Theorem 3.3(iii),

$$\|F_1 - \bar{B}G_1\|_F \leq (1 + \varepsilon)\|F_1 - \hat{B}G_1\|_F$$

so that \bar{B} satisfies (3.24). It follows from (3.26) that use of $\tilde{B} = [\bar{B}]_{(\alpha)}$ yields an \tilde{A} which solves P1 arbitrarily accurately if α and ε are chosen to be small enough.

Hence, an \tilde{A} giving an arbitrarily accurate solution for P1 can be obtained, whatever the rank of G . \square

Proof of Theorem 3.1. By considering $\text{vec}(F - AG)$ and using Lemma 2.1(iii) and the fact [9, p. 42] that $\text{vec}(XYZ) = [X \otimes Z'] \text{vec}(Y)$, we find that

$$(3.27) \quad \|F - AG\|_F = \|f - Ha\|,$$

where $a = \text{vec}(A) \in \mathbb{R}^{n^2}$, $f = \text{vec}(F) \in \mathbb{R}^{mn}$ and $H = [I_{n \times n} \otimes G'] \in \mathbb{R}^{mn \times n^2}$.

In view of (3.27) and Theorem 2.1(i), problem P1 is equivalent to

$$\text{P4} \quad \min_{a \in K_1} \|f - Ha\|$$

where $K_1 = \text{cone}[\Omega]$, which is equivalent to

$$\text{P5} \quad \min_{b \in K_2} \|f - b\|$$

with $K_2 = HK_1$.

If $\text{rank}[G] = n$, then $N[G'] = \{0\}$ so $N[H] = \{0\}$. The recession cone 0^+K_1 of the convex cone K_1 , i.e., of cone $[\Omega]$, is K_1 itself [6, Cor. 8.3.2]. Therefore $N[H] \cap 0^+K_1 = \{0\}$. Consequently the nonempty convex cone $K_2 = HK_1$ is closed [6, Thm. 9.1], since Theorem 2.1(iii) reveals that K_1 is closed. Therefore the minimum in P5 exists [7, Lemma 3.3.1] and, since P5 and P1 are equivalent, the minimum in P1 exists. This proves Theorem 3.1 when $\text{rank}[G] = n$.

When $\text{rank}[G] < n$, the null space of H is nontrivial and consequently the fact that K_1 is closed does not reveal immediately that K_2 is closed [6, p. 73]. Therefore the existence of the minimum in P5, and hence of the minimum in P1, cannot be established so easily as for the case when $\text{rank}[G] = n$. The structure of P1 has to be considered in more detail when $\text{rank}[G] < n$, as follows.

There exists an orthogonal Q so that (3.10) and (3.11) are valid, where $q = \text{rank}[G] = \text{rank}[G_1]$. Any $A \in S_{\geq}^n$ can be written as $A = Q'M_{BCD}Q$, where

$$(3.28) \quad M_{BCD} = \begin{bmatrix} B & C \\ C' & D \end{bmatrix}$$

for $B \in R^{q \times q}$, $C \in R^{q \times (n-q)}$, $D \in R^{(n-q) \times (n-q)}$. By [9, p. 197] and the orthogonality of Q

$$(3.29) \quad S_{\geq}^n = \{M_{BCD} : (B, C, D) \in Y_{\geq}\} = \{Q'M_{BCD}Q : M_{BCD} \in S_{\geq}^n\}$$

where

$$(3.30) \quad Y_{\geq} = \{(B, C, D) : B \in S_{\geq}^q, R[C] \subset R[B], D' = D \geq C'B^+C\}.$$

Let

$$(3.31) \quad S_{BC0} = \left\{ \begin{bmatrix} B & C \\ C' & 0 \end{bmatrix} : \begin{bmatrix} B & C \\ C' & D \end{bmatrix} \in S_{\geq}^n \right\}.$$

Then

$$\begin{aligned} \min_{A \in S_{\geq}} \|F - AG\|_F^2 &= \min_{A \in S_{\geq}} \|Q[F - AG]\|_F^2 = \min_{M_{BCD} \in S_{\geq}} \|Q[F - Q'M_{BCD}QG]\|_F^2 \\ &= \min_{(B, C, D) \in Y_{\geq}} \left\| \begin{bmatrix} F_1 \\ F_2 \end{bmatrix} - \begin{bmatrix} B & C \\ C' & D \end{bmatrix} \begin{bmatrix} G_1 \\ 0 \end{bmatrix} \right\|_F^2 \\ &= \min_{(B, C, D) \in Y_{\geq}} \left\| \begin{bmatrix} F_1 \\ F_2 \end{bmatrix} - \begin{bmatrix} B & C \\ C' & 0 \end{bmatrix} \begin{bmatrix} G_1 \\ 0 \end{bmatrix} \right\|_F^2 \\ &= \min_{A \in S_{BC0}} \|\bar{F} - A\bar{G}\|_F^2 \end{aligned}$$

where $\bar{F} = [F_1' F_2']'$, $\bar{G} = [\bar{G}_1' 0']'$. The first equality is a consequence of the orthogonality of Q , and the second and third are from (3.29).

Hence P1 is equivalent to

$$\text{P6} \quad \min_{a \in K_3} \|\bar{f} - a\|_F^2$$

where $\bar{f} = \text{vec}(\bar{F})$ and $K_3 = \bar{H} \text{vec}(S_{BC0})$ for $\bar{H} = I_{n \times n} \otimes \bar{G}'$.

From Theorem 2.1(i)-(iii), $\text{vec}(S_{\geq}^n)$ is a nonempty, closed, convex cone. Therefore it follows from (3.31) that $\text{vec}(S_{BC0})$ is a nonempty, closed, convex cone. A consequence is that its recession cone, $0^+ \text{vec}(S_{BC0})$, is equal to $\text{vec}(S_{BC0})$ [6, Cor. 8.3.2]. Hence K_3 is closed if $\|\bar{H}x\| > 0$ whenever $0 \neq x \in \text{vec}(S_{BC0})$ [6, Thm. 9.1], i.e. (since $\text{vec}(A\bar{G}) = \bar{H} \text{vec}(A)$) if $\|A\bar{G}\|_F > 0$ whenever $0 \neq A \in S_{BC0}$. From (3.31), every nonzero A in S_{BC0} has the form of M_{BC0} of (3.28) with B and C not both zero. Further, in view of (3.29) and (3.30), $R[C] \subseteq R[B]$ so that C is zero if B is zero. Hence $A = M_{BC0}$ with $B \neq 0$ if $0 \neq A \in S_{BC0}$. Now $R[G_1] = R^q$, because $\text{rank}[G_1] = q$ and $G_1 \in R^{q \times m}$, so $BG_1 \neq 0$ when $B \neq 0$. Since $\|A\bar{G}\|_F^2 = \|BG_1\|_F^2 + \|C'G_1\|_F^2$ when $A = M_{BC0}$, it follows that $\|A\bar{G}\|_F > 0$ whenever $0 \neq A \in S_{BC0}$. Consequently, K_3 is closed.

Since K_3 is closed, the minimum in P6 exists. Hence, since P6 and P1 are equivalent, the minimum in P1 exists when $\text{rank}[G] < q$.

Therefore the minimum in P1 exists whatever the rank of G , which completes the proof of Theorem 3.1. \square

Proof of Theorem 3.2. Now $J = [I_{n \times n} \otimes G']W$, so that $R[J'] = R[W'(I_{n \times n} \otimes G)] = R[W'] = R'$, where the penultimate equality occurs because G has full rank and the final inequality is from (2.2). Hence $\text{rank}[J] = r$.

As in (3.27), $\|F - AG\|_F = \|f - [I_{n \times n} \otimes G']a\|$, where $a = \text{vec}(A)$, so, in view of (2.3)

$$(3.32) \quad \|F - AG\|_F = \|f - [I_{n \times n} \otimes G']W\bar{a}\| = \|f - J\bar{a}\|$$

where $\bar{a} = \overline{\text{vec}}(A)$. Use in (3.32) of Lemma 2.1(iii) and of the factorizations of J and f given in the statement of Theorem 3.2 yields

$$\|F - AG\|_F^2 = \|u - L\bar{a}\|^2 + \|l\|^2.$$

Hence solution of P1, i.e., minimization of $\|F - AG\|_F$ with respect to $A \in S_{\geq}^n$, can be achieved by solving

$$\text{P7} \quad \min_{a \in \text{vec}(S_{\geq}^n)} \|u - L\bar{a}\|$$

and then $\hat{A} = \overline{\text{vec}}^{-1}(\hat{\bar{a}})$ if $\hat{\bar{a}}$ solves P7.

Since, by Theorem 2.1(i), $\overline{\text{vec}}(S_{\geq}^n) = \text{cone}[W'\Omega]$, P7 becomes P2 of Theorem 3.2, namely

$$\text{P2} \quad \min_{k \in K} \|u - k\|$$

where $K = L \overline{\text{vec}}(S_{\geq}^n) = \text{cone}[LW'\Omega]$, a convex cone, and then $\hat{\bar{a}} = L^{-1}\hat{k}$ if \hat{k} solves P2.

It is known, from Theorem 3.1, that P1 has a solution. Since P1 is equivalent to P2 (via P7), because it is clear from above that the solution of P1 can be found from that of P2, and vice versa, P2 has a solution.

Hence the solution $\hat{\bar{a}}$ of P7 is $\hat{\bar{a}} = L^{-1}\hat{k}$ and consequently the solution of P1 is $\hat{A} = \overline{\text{vec}}^{-1}(\hat{\bar{a}}) = \overline{\text{vec}}^{-1}(L^{-1}\hat{k})$.

Clearly P2 is solved by $\hat{k} = u$ if and only if $u \in K$, i.e., (since $K = \overline{\text{vec}}(S_{\geq}^n)$) if and only if $u = L \overline{\text{vec}}(A)$ for some $A \in S_{\geq}^n$, i.e., if and only if $\overline{\text{vec}}^{-1}(L^{-1}u) \geq 0$. So, since $\hat{A} = \overline{\text{vec}}^{-1}(L^{-1}\hat{k})$, $\hat{A} = \overline{\text{vec}}^{-1}(L^{-1}u)$ if and only if $\overline{\text{vec}}^{-1}(L^{-1}u) \geq 0$.

If $\hat{k} \neq u$ then clearly $\hat{k} \in \partial K = \partial \text{cone}[LW'\Omega]$, and consequently, since L is invertible and $R[L] = R'$, $L^{-1}\hat{k} \in \partial \text{cone}[W'\Omega]$. Therefore, by Theorem 2.1(ii), then $\hat{A} = \overline{\text{vec}}^{-1}(L^{-1}\hat{k})$ is not positive definite. \square

Proof of Theorem 3.3. (i) Now $\bar{k} \in K = L \text{cone}[W'\Omega]$, so, by Theorem 2.1(i), $\bar{k} \in L \overline{\text{vec}}(S_{\geq}^n)$. Hence $\overline{\text{vec}}^{-1}(L^{-1}\bar{k}) \in S_{\geq}^n$, which proves part (i).

(ii) Clearly

$$(3.33) \quad \|u - \bar{k}\|^2 = \|u - \hat{k}\|^2 + 2(\hat{k} - u)'(\bar{k} - \hat{k}) + \|\bar{k} - \hat{k}\|^2.$$

Since \hat{k} minimizes $\|u - k\|^2$, with respect to k from the convex set K

$$2(\hat{k} - u)'(k - \hat{k}) \geq 0 \quad \forall k \in K.$$

Hence a consequence of (3.8) and (3.33) is that

$$\|\bar{k} - \hat{k}\|^2 \leq (2\varepsilon + \varepsilon^2)[\|u - \hat{k}\|^2 + \|l\|^2]$$

so, by (3.4)

$$\|\bar{k} - \hat{k}\| \leq (2\varepsilon + \varepsilon^2)^{1/2} \|F - \hat{A}G\|_F.$$

Therefore, by Lemma 2.1(iii)

$$\begin{aligned}\|\bar{A} - \hat{A}\|_F &= \|\overline{\text{vec}}^{-1}(L^{-1}\bar{k}) - \overline{\text{vec}}^{-1}(L^{-1}\hat{k})\|_F = \|L^{-1}\bar{k} - L^{-1}\hat{k}\| \\ &\leq (2\varepsilon + \varepsilon^2)^{1/2} \|L^{-1}\| \|F - \hat{A}G\|_F\end{aligned}$$

which establishes part (ii).

(iii) As in (3.32), and using the factorizations of Theorem 3.2

$$\|F - \bar{A}G\|_F^2 = \|f - J \overline{\text{vec}}(\bar{A})\|^2 = \|u - \bar{k}\|^2 + \|l\|^2.$$

So, in view of (3.4), the result of part (iii) is implied by (3.8). \square

Proof of Theorem 3.4. Much as in the proof of Theorem 3.1, let

$$(3.34) \quad \begin{aligned}Y_B &= \{C \in R^{q \times (n-q)}: R[C] \subset R[B]\} \quad \text{for } B \in S_{\geq}^q, \\ Y_{\geq} &= \{(B, C, D): B \in S_{\geq}^q, C \in Y_B, D \in S_{\geq}^{n-q}, D \geq C'B^+C\}_1\end{aligned}$$

$$(3.35) \quad A_{BCD} = Q \begin{bmatrix} B & C \\ C' & D \end{bmatrix} Q \in R^{n \times n}$$

where $B \in S^q$, $C \in R^{q \times (n-q)}$, $D \in S^{n-q}$ and where $Q \in R^{n \times n}$ is the orthogonal matrix specified in Theorem 3.4.

From p. 197 of [9]

$$(3.36) \quad [A_{BCD} \geq 0] \Leftrightarrow [(B, C, D) \in Y_{\geq}].$$

Further, since Q is orthogonal

$$(3.37) \quad \|F - A_{BCD}G\|_F^2 = \|Q[F - A_{BCD}G]\|_F^2 = \|F_1 - BG_1\|_F^2 + \|F_2 - C'G_1\|_F^2.$$

If we write \hat{A} as $A_{B^*C^*D^*}$ (3.37) gives

$$(3.38) \quad \begin{aligned}\|F - \hat{A}G\|_F^2 &= \|F_1 - B^*G_1\|_F^2 + \|F_2 - C^*G_1\|_F^2 \\ &\geq \|F_1 - \hat{B}G_1\|_F^2 + \|F_1(I - G_1^+G_1)\|_F^2\end{aligned}$$

since \hat{B} minimizes $\|F_1 - BG_1\|_F$ on S_{\geq}^n and since, from [9, p. 119], $F_2G_1^+$ minimizes $\|F_2 - C'G_1\|_F$ with respect to $C' \in R^{(n-q) \times q}$.

Consider now $A_{\bar{B}\bar{C}\bar{D}}$ when \bar{B} is $[\hat{B}]_{(\alpha)}$ (of § 1), $\bar{C}' = F_2G_1^+$, $\bar{D} \in S^q$ with $\bar{D} \geq \bar{C}'\bar{B}^+\bar{C}$. Since $[\hat{B}]_{(\alpha)} > 0$, for all $\alpha > 0$, it follows from (3.36) that $A_{\bar{B}\bar{C}\bar{D}} \in S_{\geq}^n$, for all $\alpha > 0$. So, since \hat{A} minimizes $\|F - AG\|_F$ on S_{\geq}^n

$$(3.39) \quad \|F - \hat{A}G\|_F^2 \leq \|F - A_{\bar{B}\bar{C}\bar{D}}G\|_F^2 = \|F_1 - [\hat{B}]_{(\alpha)}G_1\|_F^2 + \|F_2(I - G_1^+G_1)\|_F^2$$

where the equality is from (3.37). Hence, from (3.38), (3.39) and since $\|F - [\hat{B}]_{(\alpha)}G_1\|_F \leq \|F_1 - \hat{B}G_1\|_F + \|\hat{B} - [\hat{B}]_{(\alpha)}\|_F \|G_1\|_F$

$$(3.40) \quad \begin{aligned}\|F_1 - \hat{B}G_1\|_F^2 + \|F_2(I - G_1^+G_1)\|_F^2 &\leq \|F - \hat{A}G\|_F^2 \\ &\leq [\|F_1 - \hat{B}G_1\|_F + \alpha(N_{\hat{B}})^{1/2}\|G_1\|_F]^2 \\ &\quad + \|F_2(I - G_1^+G_1)\|_F^2, \quad \forall \alpha > 0.\end{aligned}$$

Consideration of (3.40) as α converges downwards to zero reveals that

$$\|F - \hat{A}G\|_F^2 = \|F_1 - \hat{B}G_1\|_F^2 + \|F_2(I - G_1^+G_1)\|_F^2$$

which proves part (i).

Now consider $\tilde{A} = A_{\tilde{B}\tilde{C}\tilde{D}}$ of (3.13) for the \tilde{B} , \tilde{C} and \tilde{D} of Theorem 3.4. From (3.36), $\tilde{A} \geq 0$ and from (3.37), since \tilde{C} of (3.16) minimizes $\|F_2 - C'G_1\|_F$ with respect to $C \in R^{q \times (n-q)}$

$$(3.41) \quad \|F - \tilde{A}G\|_F^2 = \|F_1 - \tilde{B}G_1\|_F^2 + \min_{C \in R^{q \times (n-q)}} \|F_2 - C'G_1\|_F^2.$$

So, from (3.41) and (3.15)

$$\begin{aligned}
 \|F - \tilde{A}G\|_F^2 &\leq (1 + \varepsilon_1) \min_{B \in S_{\Xi}^q} \|F_1 - BG_1\|_F^2 + \varepsilon_2 + \min_{C \in R^{q \times (n-q)}} \|F_2 - C'G_1\|_F^2 \\
 (3.42) \quad &\leq (1 + \varepsilon_1) \min_{B \in S_{\Xi}^q} [\|F_1 - BG_1\|_F^2 + \min_{C \in R^{q \times (n-q)}} \|F_2 - C'G_1\|_F^2] + \varepsilon_2.
 \end{aligned}$$

Now $Y_B \subset R^{q \times (n-q)}$ for all $B \in S_{\Xi}^q$. Therefore

$$\min_{C \in R^{q \times (n-q)}} \|F_2 - C'G_1\|_F^2 \leq \min_{C \in Y_B} \|F_2 - C'G_1\|_F^2 \quad \forall B \in S_{\Xi}^q.$$

Consequently, from (3.42)

$$\begin{aligned}
 \|F - \tilde{A}G\|_F^2 &\leq (1 + \varepsilon_1) \min_{B \in S_{\Xi}^q} [\|F_1 - BG_1\|_F^2 + \min_{C \in Y_B} \|F_2 - C'G_1\|_F^2] + \varepsilon_2 \\
 &= (1 + \varepsilon_1) \min_{(B, C, D) \in Y_{\Xi}} \{\|F_1 - BG_1\|_F^2 + \|F_2 - C'G_1\|_F^2\} + \varepsilon_2 \\
 &= (1 + \varepsilon_1) \min_{(B, C, D) \in Y_{\Xi}} \|F - A_{BCD}G\|_F^2 + \varepsilon_2 \\
 &= (1 + \varepsilon_1) \min_{A \in S_{\Xi}^n} \|F - AG\|_F^2 + \varepsilon_2
 \end{aligned}$$

where the first equality is from (3.34), the second is from (3.37) and the third is a consequence of the fact that, from (3.35), (3.36) and the orthogonality of Q

$$S_{\Xi}^n = \{A_{BCD} : (B, C, D) \in Y_{\Xi}\}.$$

This establishes (3.14).

From [9, p. 197], A_{BCD} of (3.35) is positive definite if and only if $B > 0$, $B - CD^{\dagger}C' > 0$ and $D - C'B^{-1}C > 0$. In fact, the first and last of these three conditions imply positive definiteness; the following proof is from [4]. The first and third conditions imply that A_{BCD} is positive semidefinite [9, p. 196]. Hence A_{BCD} is positive definite if it is invertible. Now the first and third conditions ensure that $|B| > 0$ and that $|D - C'B^{-1}C| > 0$. Hence A_{BCD} is invertible because $|A_{BCD}| = \|B\| |D - C'B^{-1}C| > 0$.

This completes the proof of Theorem 3.4. \square

Proof of Theorem 3.5. If $\text{vec}^{-1}(\tilde{L}^{-1}\tilde{u}) \geq 0$, it follows from (3.2) and (3.6) of Theorem 3.2 that the \tilde{B} solving P3 is $\hat{B} = \text{vec}^{-1}(\tilde{L}^{-1}\tilde{u})$. The formulae for $\|F_1 - \hat{B}G_1\|_F$ and $\|F - \hat{A}G\|_F$ of (3.19) are from (3.4) of Theorem 3.2 (since $\hat{k} = u$) and from Theorem 3.4(i).

If $\tilde{B} > 0$, then the choices $\tilde{B} = \hat{B}$ and $\varepsilon_1 = \varepsilon_2 = 0$ can be used in Theorem 3.4(ii) to show that \tilde{A} of (3.13) solves P1 exactly, which proves (i).

Now suppose $\text{vec}^{-1}(\tilde{L}^{-1}\tilde{u}) \geq 0$ with $\text{vec}^{-1}(\tilde{L}^{-1}\tilde{u}) \not\geq 0$. Then $\hat{B} \not\geq 0$ and the choice $\tilde{B} = [\tilde{B}]_{(\alpha)}$ for $\alpha > 0$ gives $\tilde{B} > 0$ and $\|\tilde{B} - \hat{B}\|_F = \alpha(N_B)^{1/2}$. Hence we have (3.20).

From (3.19), if $\tilde{I} = 0$ then $\|F_1 - \hat{B}G_1\|_F = 0$ in (3.20). Consequently (3.15) of Theorem 3.4 applies with $\varepsilon_1 = 0$ and $\varepsilon_2 = \alpha^2 N_B \|G_1\|_F^2$. Then (3.14) of Theorem 3.4 yields (3.21).

However if $\tilde{I} \neq 0$ then

$$\begin{aligned}
 \|F_1 - \tilde{B}G_1\|_F &\leq \|F_1 - \hat{B}G_1\|_F + \alpha(N_B)^{1/2} \|G_1\|_F \\
 &= \|F_1 - \hat{B}G_1\|_F + [\alpha(N_B)^{1/2} \|G_1\|_F / \|\tilde{I}\|] \|F_1 - \hat{B}G_1\|_F
 \end{aligned}$$

where the equality is from (3.19). Hence we have (3.22).

In view of (3.22), Theorem 3.4(ii) can be applied with ε_1 defined by $1 + \varepsilon_1 = (1 + \alpha(N_B)^{1/2} \|G_1\|_F / \|\tilde{I}\|)^2$ and with $\varepsilon_2 = 0$, in (3.15). Then (3.23) follows from (3.14).

Since it is assumed in Theorem 3.5(iii) that $\overline{\text{vec}}^{-1}(\tilde{L}^{-1}\tilde{u}) \not\equiv 0$, it follows from (3.6) that $\hat{k} \neq u$ so that, from (3.4), $\|F_1 - \hat{B}G_1\| > \|\hat{I}\|$. Hence $\|F_1 - \hat{B}G_1\| > 0$, as claimed. Therefore, since $\tilde{B} = [\tilde{B}]_{(\alpha)}$ in this case

$$\begin{aligned}\|F_1 - \tilde{B}G_1\|_F &\leq \|F_1 - \bar{B}G_1\|_F + \alpha(N_B)^{1/2}\|G_1\|_F \\ &\leq [(1 + \varepsilon) + \alpha(N_B)^{1/2}\|G_1\|_F/\|F_1 - \hat{B}G_1\|_F]\|F_1 - \hat{B}G_1\|_F \\ &\leq (1 + \varepsilon)[1 + \alpha(N_B)^{1/2}\|G_1\|_F/\|F_1 - \bar{B}G_1\|_F]\|F_1 - \hat{B}G_1\|_F\end{aligned}$$

where the second and third inequalities are from (3.24). Hence we have (3.25).

Therefore \tilde{B} satisfies (3.15) with ε_1 defined by $(1 + \varepsilon_1) = (1 + \varepsilon)^2[1 + \alpha(N_B)^{1/2}\|G_1\|_F/\|F_1 - \bar{B}G_1\|_F]^2$ and with $\varepsilon_2 = 0$. Then (3.26) follows from (3.14). \square

4. A proximal point algorithm for conical hulls. The problem considered here is P2 of (3.3), rewritten here as

$$(4.1) \quad \text{P2} \quad \min_{k \in \text{cone}[\Gamma]} v(k)$$

where

$$(4.2) \quad v(k) = \|u - k\|^2 \quad \forall k \in R^r, \quad \Gamma = LW'\Omega, \quad K = \text{cone}[\Gamma]$$

and where K , u and the invertible matrix L are those of Theorem 3.2, W is specified by (2.1) and Ω by (2.5). Algorithm 4.1, presented shortly, finds an approximation \bar{k} to the solution \hat{k} of P2 which is acceptable in that condition (3.8) of Theorem 3.3 is satisfied. The algorithm relies on the following properties of Γ :

(4.3) Γ is a nonempty closed convex set;

(4.4) There exists a $\pi \in R_>$ such that for any point x in Γ , there is a point $y \in \Gamma$ which is in the ray through 0 and x and for which $\|y\| \equiv \pi$;

(4.5) For each $g \in R^r$, a member of $\arg \min \{g'\gamma: \gamma \in \Gamma\}$ can be found.

Remark 4.1. From Theorem 2.1(iv), a suitable π is $\pi = \sigma_{\min}[L]n^{-1/2}$. From Theorem 2.1(v), the minimal value of $g'\gamma$ and a minimizing γ can actually be determined by solving an eigenvalue problem. \square

Algorithm 4.1 for approximating the minimizer \hat{k} of v on the unbounded set $\text{cone}[\Gamma]$ is based on the fact that \hat{k} is also the minimizer of v on a bounded set S , actually a suitably truncated version of $\text{cone}[\Gamma]$. Consequently \hat{k} may be approximated by approximately minimizing v on S . The result regarding S is stated next.

THEOREM 4.1. Let $\eta = \|u\|/\pi$; $S = \{\alpha\gamma: \alpha \in [0, \eta], \gamma \in \Gamma\}$. Then S is a convex set and $\text{minpoint}[u, S] = \text{minpoint}[u, \text{cone}[\Gamma]]$. \square

The algorithm for finding an acceptably accurate approximation \bar{k} to \hat{k} by minimizing v on S is stated next.

ALGORITHM 4.1.

0. *Select parameters by choosing*

$\varepsilon \in (0, \infty)$ (ε occurs in post-condition (4.12) and defines the degree of suboptimality acceptable in \bar{k}),

$\bar{k}_0 \in \text{cone}[\Gamma]$ (an initial estimate of \hat{k}).

I. *Initialize variables*

$k_0 := \text{minpoint}[u, \text{cone}[\{\bar{k}_0\}]]$ (the point nearest u in the ray through 0 and \bar{k}_0),

$\hat{b}_{-1} := 0$ (the best lower bound for $v(\hat{k})$ available so far),

$i := 0$ (the iteration index).

II. *Decide when to stop iterating*

Find a $y_i \in \arg \min_{y \in S} \nabla v(k_i)'(y_i - k_i)$,

by finding a

$$(4.6) \quad \gamma_i \in \arg \min_{\gamma \in \Gamma} \nabla v(k_i)' \gamma$$

and setting

$$(4.7) \quad y_i = \begin{cases} \eta \gamma_i & \text{if } \nabla v(k_i)' \gamma_i < 0, \\ k_i & \text{otherwise.} \end{cases}$$

Compute a lower bound b_i for $v(\hat{k})$

$$(4.8) \quad b_i := v(k_i) + \nabla v(k_i)'(y_i - k_i).$$

Compute \hat{b}_i , the best lower bound for $v(k)$ found so far

$$(4.9) \quad \hat{b}_i := \max \{\hat{b}_{i-1}, b_i\}.$$

If

$$(4.10) \quad [v(k_i) + \|l\|^2] \leq (1 + \varepsilon)^2 [\hat{b}_i + \|l\|^2] \quad (\text{where } l \text{ is that used in Theorem 3.2}), \text{ then set } \bar{k} = k_i \text{ and stop; else continue.}$$

III. *Choose the next iterand*

$$(4.11) \quad \begin{aligned} k_{i+1} &:= \text{minpoint}(u, \text{cone}[\text{line}\{k_i, y_i\}]), \\ i &:= i + 1. \end{aligned}$$

Go to II. \square

Remark 4.2. Minpoint $(u, \text{cone}[\text{line}\{k_i, y_i\}])$ may be found simply and exactly owing to the simple nature of the set $\text{cone}[\text{line}\{k_i, y_i\}]$. \square

THEOREM 4.2. *If $\hat{k} \neq u$, Algorithm 4.1 stops after a finite number of iterations with \bar{k} an approximate solution of P2 which satisfies*

$$(4.12) \quad \bar{k} \in \text{cone}[\Gamma], \quad \|\bar{k}\| \leq \|\hat{k}\|, \quad [\|u - \bar{k}\|^2 + \|l\|^2] \leq (1 + \varepsilon)^2 [\|u - \hat{k}\|^2 + \|l\|^2].$$

Further, if $\hat{k} \neq u$ and stopping condition (4.10) is omitted from Algorithm 4.1 so that it iterates indefinitely, then

$$k_i \in S \subset \text{cone}[\Gamma] \text{ and } \hat{b}_i \leq v(\hat{k}) \quad \forall i \geq 0, \quad k_i \rightarrow \hat{k}, \quad \hat{b}_i \rightarrow v(\hat{k}). \quad \square$$

Remark 4.3. In view of (3.6), $\hat{k} = u$ if and only if $\overline{\text{vec}}^{-1}(L^{-1}u) \geq 0$. Hence Theorem 4.2 reveals that Algorithm 4.1 may be used to find an approximate solution \bar{k} for P2 of (3.3), approximate in that condition (3.8) of Theorem 3.2 is satisfied, whenever $\overline{\text{vec}}^{-1}(L^{-1}u) \geq 0$. \square

Remark 4.4. It is desirable to use, in Algorithm 4.1, an initial approximation $\bar{k}_0 \in \text{cone}[\Gamma]$ which is a good approximation to \hat{k} . The connection between \hat{k} and \hat{A} is, from (3.2), $\hat{k} = L \overline{\text{vec}}(\hat{A})$. Also, $\text{cone}[\Gamma] = L \overline{\text{vec}}(S_{\geq}^n)$, in view of Theorem 2.1(i) and the fact that $\Gamma = LW'\Omega$. Hence a suitable \bar{k}_0 is $\bar{k}_0 = L \overline{\text{vec}}(A)$ for any $A \in S_{\geq}^n$ which approximates \hat{A} . If $\overline{\text{vec}}(L^{-1}u) \geq 0$, then (by (3.6)) $\hat{A} = \overline{\text{vec}}^{-1}(L^{-1}u)$ and we could use $\bar{k}_0 = L \overline{\text{vec}}(\hat{A})$ except that Algorithm 4.1 is not actually needed in that case. Algorithm 4.1 is needed only when $\overline{\text{vec}}^{-1}(L^{-1}u) \not\geq 0$. This suggests that when $\overline{\text{vec}}^{-1}(L^{-1}u) \not\geq 0$, the choice $\bar{k}_0 = L \overline{\text{vec}}(\hat{X})$ be used where \hat{X} minimizes $\|\overline{\text{vec}}^{-1}(L^{-1}u) - X\|_F$ with respect to X from S_{\geq}^n . It is easy to check that $\hat{X} = [\overline{\text{vec}}^{-1}(L^{-1}u)]_{(0)}$, where the notation $[\cdot]_{(0)}$

has the meaning assigned in § 1. Consequently a reasonable choice to use is $\bar{k}_0 = L[\overline{\text{vec}}(L^{-1}u)]_{(0)}$. \square

Proof of Theorem 4.1. The convexity of S may be verified easily.

Suppose $\hat{k} = \text{minpoint}[u, \text{cone}[\Gamma]]$. Then, since $S \subset \text{cone}[\Gamma]$, $\hat{k} = \text{minpoint}[u, S]$ if and only if $\hat{k} \in S$. It will be shown next that $\hat{k} \in S$. Clearly $\|\hat{k}\| \leq \|u\|$. Because $\hat{k} \in \text{cone}[\Gamma]$, \hat{k} may be written as $\hat{k} = \theta\tilde{\gamma}$ for some $\theta \in \mathbb{R}_\geq$ and for some $\tilde{\gamma} \in \Gamma$ such that (owing to property (4.4) of Γ) $\|\tilde{\gamma}\| \geq \pi$. Hence $\theta \leq \|\hat{k}\|/\pi \leq \|u\|/\pi = \eta$. Consequently $\hat{k} \in S$. Therefore $\hat{k} = \text{minpoint}[u, \text{cone}[S]]$. \square

Proof of Theorem 4.2. First it will be shown that $k_i \in S$, for all $i \geq 0$.

By the definition of k_0 in part I of Algorithm 4.1, and by the definition of k_{i+1} in part III: for all $i \geq 0$, k_i minimizes v along the ray through k_i . Consequently

$$(4.13) \quad \|k_i\| \leq \|u\| \quad \forall i \geq 0.$$

Now, by its definition in Algorithm 4.1, $y_i \in S \subset \text{cone}[\Gamma]$ for all $i \geq 0$. Therefore, from (4.11), if $k_i \in \text{cone}[\Gamma]$ then $k_{i+1} \in \text{cone}[\Gamma]$. Since $k_0 \in \text{cone}[\Gamma]$, by the way it is constructed in Algorithm 4.1:

$$k_i \in \text{cone}[\Gamma] \quad \forall i \geq 0.$$

Since $k_i \in \text{cone}[\Gamma]$, it follows that $k_i = \alpha\gamma$ for some $\alpha \in \mathbb{R}_\geq$ and for some $\gamma \in \Gamma$. Therefore, from (4.4), $\|k_i\| = \alpha\|\gamma\| \geq \alpha\pi$. Consequently, in view of (4.13), $\alpha \leq \|u\|/\pi = \eta$. So, owing to the definition of S in Theorem 4.1, $k_i \in S$, for all $i \geq 0$, as claimed in Theorem 4.2.

It will be shown next that the assertions made in the statement of Algorithm 4.1 regarding y_i and b_i are correct.

Consider the determination of y_i in step II.

Since each γ_i constructed by the algorithm is from Γ , and since each k_i is from S , it follows from (4.7) that $y_i \in S$, for all $i \geq 0$.

For $i \geq 0$, k_i minimizes v of (4.2) on the ray through k_i . So $\nabla v(k_i)'k_i = 0$, for all $i \geq 0$. Further, any $y \in S$ may be written as $y = \theta\gamma$ for some $\theta \in [0, \eta]$ and some $\gamma \in \Gamma$. Hence, for γ_i of (4.6)

$$\begin{aligned} \min_{y \in S} \nabla v(k_i)'(y - k_i) &= \min_{\theta \in [0, \eta]} \min_{\gamma \in \Gamma} \theta \nabla v(k_i)'\gamma \\ &= \begin{cases} \eta \nabla v(k_i)'\gamma_i & \text{if } \nabla v(k_i)'\gamma_i < 0, \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

The above minimal value for $\nabla v(k_i)'(y - k_i)$ is achieved by y_i of (4.7), which, since $y_i \in S$, proves that y_i minimizes $\nabla v(k_i)'(y - k_i)$ on S , as asserted in Algorithm 4.1.

Next, it will be shown that for b_i of (4.8), $b_i \leq v(\hat{k})$. Now

$$v(k) = v(k_i) + \nabla v(k_i)'(k - k_i) + \|k - k_i\|^2 \geq v(k_i) + \nabla v(k_i)'(k - k_i),$$

so, in view of Theorem 4.1,

$$(4.14) \quad \begin{aligned} v(\hat{k}) &= \min_{k \in S} v(k) \geq \min_{k \in S} \{v(k_i) + \nabla v(k_i)'(k - k_i)\} \\ &= v(k_i) + \nabla v(k_i)'(y_i - k_i) = b_i, \end{aligned}$$

which proves the assertion that the computed value of b_i is a lower bound for $v(\hat{k})$. A simple consequence is that \hat{b}_i of (4.9) is also a lower bound for $v(\hat{k})$, as claimed in Theorem 4.2.

The behaviour of Algorithm 4.1 will now be studied assuming that stopping condition (4.10) is omitted from the algorithm so that it iterates indefinitely.

Now, since Γ is bounded and η is finite, S is bounded and there is a finite number d so that $\|k - y\| \leq d, \forall k, y \in S$. Let

$$(4.15) \quad D = \|\nabla v(\hat{k})\|d + d^2.$$

Then

$$(4.16) \quad v(k) = v(\hat{k}) + \nabla v(\hat{k})'(k - \hat{k}) + \|k - \hat{k}\|^2 \leq v(\hat{k}) + D \quad \forall k \in S.$$

Consider the determination of k_{i+1} from k_i , using (4.11). Since $\text{line}\{k_i, y_i\} \subset \text{cone}[\text{line}\{k_i, y_i\}]$,

$$(4.17) \quad v(k_{i+1}) = \min_{k \in \text{cone}[\text{line}\{k_i, y_i\}]} v(k) \leq \min_{\alpha \in [0,1]} v(k_i + \alpha[y_i - k_i]).$$

From (4.14)

$$(4.18) \quad \nabla v(k_i)'(y_i - k_i) \leq [v(\hat{k}) - v(k_i)] \leq 0.$$

Suppose $y_i \neq k_i$. Let α_i denote the value of α which minimizes $v(k_i + \alpha[y_i - k_i])$ with respect to α from $[0, 1]$, and let $\tilde{\alpha}_i$ be the unconstrained global minimizer, so that

$$(4.19) \quad \tilde{\alpha}_i = -\nabla v(k_i)'(y_i - k_i) / [2\|y_i - k_i\|^2].$$

Then, from (4.18), $\tilde{\alpha}_i \geq 0$. The following two cases are possible:

- (i) $\tilde{\alpha}_i \in [0, 1]$;
- (ii) $\tilde{\alpha}_i > 1$.

For case (i), $\alpha_i = \tilde{\alpha}_i$ and consequently, from (4.17) and (4.18),

$$(4.20) \quad \begin{aligned} v(k_{i+1}) &\leq \min_{\alpha \in [0,1]} v(k_i + \alpha[y_i - k_i]) \\ &= v(k_i) - [\nabla v(k_i)'(y_i - k_i)]^2 / [4\|y_i - k_i\|^2] \\ &\leq v(k_i) - [v(k_i) - v(\hat{k})]^2 / [4D] \end{aligned}$$

where the last inequality is from (4.15) and the fact that $k_i, y_i \in S$, for all $i \geq 0$.

Now consider case (ii), for which $\alpha_i = 1$. From (4.19), the fact that $\tilde{\alpha}_i > 1$ implies that $\nabla v(k_i)'(y_i - k_i) < -2\|y_i - k_i\|^2$, and consequently

$$(4.21) \quad \begin{aligned} v(k_{i+1}) &\leq v(k_i + 1[y_i - k_i]) = v(k_i) + \nabla v(k_i)'(y_i - k_i) + \|y_i - k_i\|^2 \\ &< v(k_i) + [\nabla v(k_i)'(y_i - k_i)]/2 \\ &\leq v(k_i) - [v(k_i) - v(\hat{k})]/2 \\ &\leq v(k_i) - [v(k_i) - v(\hat{k})]^2 / [4D] \end{aligned}$$

where the penultimate inequality is from (4.18) and the last inequality is from (4.16) and the fact that $k_i \in S$, for all $i \geq 0$.

Hence, from (4.20)-(4.21), whether case (i) or case (ii) occurs, if $y_i \neq k_i$ then

$$[v(k_{i+1}) - v(\hat{k})] \leq [v(k_i) - v(\hat{k})] - [v(k_i) - v(\hat{k})]^2 / [4D]$$

and, from (4.18), if $y_i = k_i$ then

$$v(k_i) = v(\hat{k}).$$

Consequently $v(k_i) \rightarrow v(\hat{k})$ and, since v is strictly convex, $k_i \rightarrow \hat{k}$, as claimed in Theorem 4.2.

Also, $b_i \rightarrow v(\hat{k})$ since, because $k_i \rightarrow \hat{k}$, it follows [10, Thm. B.3.20] that

$$b_i = \min_{y \in S} \{v(k_i) + \nabla v(k_i)'(y - k_i)\} \rightarrow \min_{y \in S} \{v(\hat{k}) + \nabla v(\hat{k})'(y - \hat{k})\} = v(\hat{k}).$$

Therefore $\hat{b}_i \rightarrow v(\hat{k})$, as claimed.

It will be shown next that execution of the algorithm actually terminates after a finite number of iterations if stopping condition (4.10) is included in the algorithm.

Now $v(\hat{k}) > 0$ since the case $\hat{k} \neq u$ is being considered. Hence since $v(k_i)$, $\hat{b}_i \rightarrow v(\hat{k})$ and $v(\hat{k}) > 0$, stopping condition (4.10) will be satisfied eventually and iteration will cease after some finite number of iterations.

The proof of Theorem 4.2 will be concluded by showing that satisfaction of the stopping condition guarantees satisfaction of post-condition (4.12) of Theorem 4.2.

Now $k_i \in S \subseteq \text{cone}[\Gamma]$, for all $i \geq 0$, so it follows from the way \bar{k} is defined in part II of Algorithm 4.1 that $\bar{k} \in \text{cone}[\Gamma]$, which establishes the first part of (4.12).

Since k_i and \hat{k} are the closest points to u in the rays through k_i and \hat{k} , respectively: $\|k_i\|^2 = u'k_i$; $\|\hat{k}\|^2 = u'\hat{k}$. So

$$v(k_i) = \|u\|^2 - \|k_i\|^2, \quad v(\hat{k}) = \|u\|^2 - \|\hat{k}\|^2$$

and consequently, since $v(k_i) \geq v(\hat{k})$: $\|k_i\| \leq \|\hat{k}\|$ for all $i \geq 0$. Further, since $\hat{b} \leq v(\hat{k})$, satisfaction of (4.10) ensures that (4.12) is satisfied when \bar{k} is the last k_i which is generated by Algorithm 4.1. \square

5. Computational considerations and an example. The interesting issue is the actual behaviour of Algorithm 4.1 for the cases when it is required. By Theorem 3.5, the algorithm will be used when it is necessary to determine the solution \hat{A} for P1 of (3.1) when G has full rank and $\text{vec}^{-1}(L^{-1}u) \geq 0$, where L and u are those of Theorem 3.2. Recall that $r = n(n+1)/2$ when $F, G \in R^{n \times m}$.

The main computational requirements associated with the use of Algorithm 4.1 are outlined next. Procedures for computing the various matrix factorizations, singular values, etc, which are mentioned below are given in, for example, [8].

(i) *Determination of quantities associated with Theorem 3.2.* The main computational task involved in the evaluation of $L \in R^{r \times r}$, $u \in R^r$ and $l \in R^{mn-r}$ is the factorization of $J \in R^{mn \times r}$ as $P[L'0']$ for orthogonal P and for L of full rank. Any standard method for Q-R factorization could be used to perform that factorization of J .

(ii) *Specification of the set S of Theorem 4.1.* This requires evaluation of $\sigma_{\min}[L]$, where $L \in R^{r \times r}$.

(iii) *Steps 0 and I of Algorithm 4.1 (performed once).* The suggestion of Remark 4.4 is adopted here for the selection of the initial approximation \bar{k}_0 , so the evaluation of $X = \text{vec}^{-1}(L^{-1}u) = \text{vec}^{-1}(WL^{-1}u)$ is needed where $W \in R^{n^2 \times r}$. The determination of X just involves the assembly of the entries of the vector $WL^{-1}u \in R^{n^2}$ into the rows of $X \in R^{n \times n}$. Then $\bar{k}_0 = L[X]_{(0)}$, where the computation of $[X]_{(0)}$ requires evaluation of the result of changing all negative eigenvalues to 0 in the spectral form of X .

(iv) *Step II of Algorithm 4.1 (performed once per iteration).* The main burden here is the evaluation of γ_i which, in view of Theorem 2.1(v), can be done by finding a normalized eigenvector corresponding to the most negative eigenvalue of the corresponding symmetric $Z \in R^{n \times n}$ of (2.6).

(v) *Step III of Algorithm 4.1 (performed once per iteration).* This can be done by projecting u onto the subspace spanned by y_i and k_i and checking whether the result is in $\text{cone}[\text{line}\{k_i, y_i\}]$. If the projection is in that cone, it is the required k_{i+1} . Otherwise k_{i+1} is the closer to u of the closest points to u in the rays through k_i and

y_i , respectively. The main effort involved is the evaluation of five inner products in R' , the inversion of a 2×2 matrix and some logic.

The total amount of work involved depends very much on the matrices F and G which are considered and on the tolerance parameter ε chosen. To give an indication of the performance of Algorithm 4.1, some results follow for a case with

$$F = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -2 & 3 \\ 0 & 2 & 4 \end{bmatrix}, \quad G = \begin{bmatrix} 1 & 6 & 0 \\ 4 & 3 & 0 \\ 0 & 0 & -0.5 \end{bmatrix}.$$

The computations were coded in Fortran 77 using double precision for all real variables and were run on a VAX 11/750 with $\varepsilon = 10^{-9}$. Matrix inversion, Q-R factorization, singular-value decomposition and spectral decomposition were carried out using NAG subroutines F01AAF, F01QAF, F02WCF and F02ABF, respectively.

To make their interpretation easier, results are presented in Table 5.1 in the way described below.

TABLE 5.1

i	$\ F - A_i G\ _F$	$[\hat{b}_i + \ I\ ^2]^{1/2}$	ε_i

14	5.600991545482	5.6009959775124	0.00000057
15	5.600991089662	5.6009962263921	0.00000052
16	5.600990956352	5.6009982523879	0.00000015
17	5.600990708254	5.6009988658921	0.000000037
18	5.600990700160	5.6009990174372	0.0000000094
19	5.600990692812	5.6009990174372	0.0000000093
20	5.600990690662	5.6009990646315	0.0000000079

Let $A_i = \overline{\text{vec}}^{-1}(L^{-1}k_i)$. Then A_i is the approximation to \hat{A} associated in a natural way with k_i of Algorithm 4.1. Much as in (3.4), it can be seen that

$$\|F - A_i G\|_F^2 = \|u - k_i\|^2 + \|I\|^2.$$

By Theorem 4.2, $k_i \rightarrow \hat{k}$ for Algorithm 4.1 so we would expect that

$$\|F - A_i G\|_F \rightarrow \|F - \hat{A} G\|_F.$$

Again by Theorem 4.2, $\hat{b}_i \leq \|u - \hat{k}\|^2$ and $\hat{b}_i \rightarrow \|u - \hat{k}\|^2$. Hence, in view of (3.4)

$$[\hat{b}_i + \|I\|^2]^{1/2} \leq \|F - \hat{A} G\|_F, \quad [\hat{b}_i + \|I\|^2]^{1/2} \rightarrow \|F - \hat{A} G\|_F.$$

The second and third columns of Table 5.1 are consistent with these claims.

The entries in the column headed ε_i give the smallest value of ε for which stopping condition (4.10) would be satisfied at iteration i . Consequently we find (without knowledge of the value of $\|F - \hat{A}G\|_F$) that $\|F - A_iG\|_F \leq (1 + \varepsilon_i)\|F - \hat{A}G\|_F$ at iteration i . The results show that ε_i decreases quite rapidly with increasing iterations i , indicating that $\|F - A_iG\|_F$ fairly rapidly becomes a good approximation to $\|F - \hat{A}G\|_F$.

Acknowledgment. Thanks are owed to K. G. Woodgate for many useful discussions.

STRUCTURAL STABILITY FOR SINGULAR SYSTEMS— A QUANTITATIVE APPROACH*

LIYI DAI†

Abstract. This paper studies the structural stability for singular systems. The problem is solved via the matrix perturbation analysis method. Allowed perturbation regions for structural stability are given.

Key words. matrix perturbation analysis method, singular system, structural stability, data point, perturbation, regulator

AMS(MOS) subject classification. 93D20

1. Introduction. In the design of control systems much attention has been paid to the problem of structural stability, for which many methods have been proposed in normal system theory (see, e.g., [1]). The reason for doing this is that when treating a practical system we always use a mathematical model to approximate it. The model, however, is generally only an approximation because of the influence of many external factors such as the nonaccuracy in system modeling and the aging of executive circuit elements. In this sense the structural parameters of a system model always have uncertainties. Here we will call them perturbations, defined as the deviations from the nominal points. The same problem exists for controllers: the realizations of controllers are also only approximations of the theoretical ones due to the same reasons, although they are accurately designed. In some cases, these reasons may cause the practical closed-loop system to be unstable, although it is well-designed on the basis of the nominal model. Then a problem naturally arises in the control system design: the designed controller should make the closed-loop system not only stable but also structurally stable. Only such controllers have practical interests and make the closed-loop system resistible to system parameter perturbations. Accurately speaking, a system is called structurally stable if it is stable and the stability is preserved in the presence of small arbitrary variations in system parameters. Papers [3] and [4] have studied qualitatively the existence and design methods of structurally stable compensators and regulators for singular systems. This paper deals with the same problem but from a completely new point of view—a quantitative approach. This is solved via the matrix perturbation analysis method.

The paper is divided into five sections. Section 2 introduces some notation that will be used. Section 3 reviews the related algebraic preliminaries. Section 4 analyzes the effects of parameter perturbations on system stability, and further presents the main results of this paper. Section 5 shows an application of the results to the structural stability analysis of closed-loop control systems.

2. Notation. The following notation will be used throughout this paper:

$\mathbb{C}^{n \times m} (R^{n \times m})$	Set of all $n \times m$ complex (real) constant matrices;
$\mathbb{C}^n (R^n)$	Set of all n dimension complex (real) vectors;
$\in (\notin)$	Belonging to (not belonging to);
$\equiv (\neq)$	Identically equal (not identically equal);
\subset	Included;

† Institute of Systems Science, Academia Sinica, Beijing 100080, People's Republic of China.

\mathbb{C}, \mathbb{C}^-	Complex plane, open left half \mathbb{C} , respectively;
$\ A\ $	Norm of matrix A , see definition;
A^*	Conjugate transpose of matrix A , i.e., $A^* = \bar{A}^T$;
$\text{tr}(A)$	Trace of matrix A ;
δA	Variation (perturbation) of matrix A ;
$P\{A\}$	Data point, which is a vector formed by listing the elements of A in arbitrary order;
$\sigma_i(\lambda_i)$	The (distinct) eigenvalue of a matrix;
\triangleq	Defined as, by definition;
$\text{Re}(\alpha)$	Real part of a complex constant α ;
$\sigma(E, A)$	Set of eigenvalues of matrix pencil (E, A) , i.e., $\sigma(E, A) = \{s sE - A = 0, s \in \mathbb{C}\}$;
$\sigma(A)$	$\sigma(A) = \sigma(I, A)$;
$\deg(\cdot)$	Degree of a polynomial;
$U_v(r)$	Neighborhood at the origin with radius r under norm v , i.e., $U_v(r) = \{x \ x\ _v < r, r > 0\}$.

3. Algebraic preliminaries. First we define the norm for matrices. For an arbitrary given matrix $A \in \mathbb{C}^{n \times m}$ the norms

$$\|A\|_2 = (\lambda_{\max}(A^*A))^{1/2}$$

and

$$\|A\|_F = (\text{tr}(A^*A))^{1/2}$$

are called the spectral norm and Frobenius norm, respectively. It is easy to see the following.

Property 1. $\|A\|_2 \leq \|A\|_F$.

Property 2. Let $B \in \mathbb{C}^{n \times r}$. Then $\|(AB)\|_v \geq \max\{\|A\|_v, \|B\|_v\}$, $v = 2, F$.

Property 3. Let $A \in \mathbb{C}^{n \times n}$, $\sigma(A) = \{\sigma_i\}$. Then

$$\|AA^* - A^*A\|_F^2 \leq 2 \left(\|A\|_F^4 - \left(\sum_{i=1}^n |\sigma_i|^2 \right)^2 \right).$$

LEMMA 3.1 [6]. Let $A, \delta A \in \mathbb{C}^{n \times n}$. Then for any $\mu \in \sigma(A + \delta A)$ there exists a $\lambda \in \sigma(A)$ such that

$$(3.1) \quad \frac{|\mu - \lambda|^m}{(H_A + |\mu - \lambda|)^{m-1}} \leq \Omega_A \|\delta A\|_2$$

where m is the highest order of the Jordan blocks of A and

$$(3.2) \quad \begin{aligned} \Omega_A &= (1 + H_A G_A)(1 + H_A G_A + \cdots + (H_A G_A)^{k-1}), \\ H_A &= \sqrt{\frac{4(n^3 - n)}{12}} \sqrt{\|AA^* - A^*A\|_F}, \\ G_A &= \begin{cases} 0 & \text{if } k = 1, \\ \max_{1 \leq i \leq k-1} \left(\frac{(G_i H_A)^{d_i} - 1}{G_i H_A - 1} G_i \right) & \text{if } k > 1, \end{cases} \\ G_i &= \frac{(\max_{i+1 \leq j \leq k} |\lambda_i - \lambda_j| + H_A)^{m_i-1}}{\prod_{j=i+1}^k |\lambda_i - \lambda_j|^{k_i}}, \end{aligned}$$

k is the number of distinct eigenvalues λ_i of A . $\lambda_i \neq \lambda_j$, $i \neq j$. k_i is the multiplicity of λ_i . d_i is the highest order of Jordan blocks belonging to λ_i and $m_i = k_{i+1} + \cdots + k_k$, $i = 1, 2, \dots, k-1$.

LEMMA 3.2 [8]. Let $A, \delta A \in \mathbb{C}^{n \times n}$. Then for any $\mu \in \sigma(A + \delta A)$ there exists a certain $\lambda \in \sigma(A)$ such that

$$(3.3) \quad |\lambda - \mu| \leq \Delta_F(A) / \xi_n(\eta)$$

where

$$\eta = \frac{\Delta_F(A)}{\|\delta A\|_F}, \quad \Delta_F(A) = \left(\|A\|_F^2 - \left(\sum_{i=1}^n |\sigma_i|^2 \right) \right)^{1/2}$$

and $\xi_n(\eta)$ is the unique nonnegative solution of the equation

$$f_n(\xi) = \xi^n + \dots + \xi^2 + \xi = \eta.$$

Generally, the eigenvalues of A and $B = A + \delta A$ ($\delta A = B - A$) are different. So we may ask the questions: "How far are the two eigenvalue sets?" and, in the presence of small perturbation δA , "How do the eigenvalues of $A + \delta A$ depend on it?" Lemmas 3.1 and 3.2 answer these questions and give an upper bound on the eigenvalue changes in the presence of perturbation δA . Obviously, if $\|\delta A\|$ is sufficiently small the matrices A and B are very close; so are their eigenvalues.

One more lemma is needed for future discussions.

LEMMA 3.3 [6]. For arbitrary matrix $A \in \mathbb{C}^{n \times n}$ there exists a nonsingular matrix T such that

$$(3.4) \quad T^{-1}AT = \text{block diag}(A_1, A_2, \dots, A_k);$$

here $A_i = \lambda_i I + L_i \in \mathbb{C}^{k_i \times k_i}$. k and k_i are as defined in Lemma 3.1. L_i is a strict upper-triangular matrix (whose diagonal elements are all zeros) and

$$(3.5) \quad \begin{aligned} \|T^{-1}\|_2 \|T\|_2 &\leq \Omega_A, \\ \|L_i\|_2 &\leq H_A, \quad i = 1, 2, \dots, k. \end{aligned}$$

The matrix T that transforms A into (3.4) is not unique. $\|T\| \|T^{-1}\|$ may change greatly for different choices of T . However, Lemma 3.3 assures us that an appropriate T can be chosen such that $\|T\| \|T^{-1}\|$ is bounded by Ω_A . $\|T\| \|T^{-1}\| \geq 1$ may be viewed as a deviation measure of A from a triangular form, the smaller the better. It reaches its lower bound 1 if A is upper triangular.

4. Structural stability for homogeneous singular systems. It is well known from classical linear system theory that if the homogeneous normal system

$$\dot{x} = Ax$$

is stable, it is structurally stable. This fact is not true for singular systems. The results of [4] show that a stable homogeneous singular system

$$(4.1) \quad E\dot{x} = Ax$$

where $x \in \mathbb{R}^n$ and rank $E < n$ may not be structurally stable. To be accurate we first give the following.

DEFINITION 4.1. Assume that system (4.1) is stable. If there exists a certain neighborhood at data point $P\{E, A\}$ such that the stability of system (4.1) is preserved in the presence of arbitrary variations of structural parameters in this neighborhood, we shall term the system (4.1) structurally stable at data point $P\{E, A\}$.

PROPOSITION 4.1 [4]. Let the system (4.1) be stable, i.e., $\sigma(E, A) \subset \mathbb{C}^-$. Then

- (1) (4.1) could not be structurally stable at $P\{E\}$;
- (2) (4.1) is structurally stable at $P\{A\}$ if and only if

$$(4.2) \quad \deg(|sE - A|) = \text{rank } E \triangleq d.$$

To have a further look at the results above, we now examine the following two examples.

Example 1. Consider the singular system

$$(4.3) \quad \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \dot{x} = \begin{pmatrix} -2 & 1 & -1 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} x$$

with parameter perturbations

$$\delta E = 0, \quad \delta A = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -\varepsilon \end{pmatrix}, \quad \varepsilon > 0.$$

Then

$$\sigma(E, A) = \{-2\}, \quad \sigma(E, A + \delta A) = \{-2, 1/\varepsilon\}.$$

The nominal system (4.3) is stable. But the perturbed system has an unstable pole $1/\varepsilon$ no matter how small ε (thus $\|\delta A\|$) is.

Example 2. The system

$$(4.4) \quad \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \dot{x} = \begin{pmatrix} -1 & 0 & 10^4 \\ 0 & 0 & -2 \\ 0 & 1 & 0 \end{pmatrix} x$$

is stable. $\sigma(E, A) = \{-1, -2\}$. But if it has a small perturbation

$$\delta A = \begin{pmatrix} 0 & 0 & 0 \\ 3 \cdot 10^{-4} & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

we will have $\sigma(E, A + \delta A) = \{-\sqrt{13}/2 - 3/2, \sqrt{13}/2 - 3/2\}$. The perturbed system has an unstable pole $\sqrt{13}/2 - 3/2$, although we can easily verify from Proposition 4.1 that system (4.4) is structurally stable at $P\{A\}$.

Example 1 shows that (4.2) is necessary to ensure the structural stability at data point $P\{A\}$. An equivalent expression of (4.2) is that for any sufficiently small $\|\delta A\|$, $\sigma(E, A + \delta A)$ does not create new unstable eigenvalues.

On the other hand, Example 2 reveals the fact that although the system (4.4) is structurally stable, the structural stability neighborhood depends on the matrix A and may be too small to be of any practical interest. Then, here naturally arises the question of how large the neighborhood is and of whether it could be estimated for any structurally stable system (4.1) using only E, A . The next section of this paper will provide an estimation via the matrix perturbation method.

From Lemmas 3.1 and 3.2 we know that for any matrix A and its perturbation δA , the eigenvalues of A and $A + \delta A$ will be very close provided $\|\delta A\|$ is small enough. Then by setting $\|\delta A\|$ small enough we will be certain that the eigenvalues of both A and $A + \delta A$ are in the left open-half complex plane. In the next step we need only find the upper bound in terms of E, A .

In view of the above results and to guarantee that our discussion proceeds, we hereafter assume that E is not perturbed, that $\sigma(E, A) \subset \mathbb{C}^-$ and that (4.2) holds.

Since the results are very obvious when $E = 0$, we also suppose hereafter that $E \neq 0$. First a helpful result is proved.

LEMMA 4.1. *Let $M \in \mathbb{C}^{n \times n}$ be nonsingular and*

$$M = \text{block diag}(M_1, M_2, \dots, M_k),$$

$$M_i = \lambda_i^{-1} I + L_i \in \mathbb{C}^{k_i \times k_i}, \quad i = 1, 2, \dots, k$$

where L_i is a strict upper-triangular matrix. $\lambda_i \neq \lambda_j$, $i \neq j$, $i, j = 1, 2, \dots, k$. Then for any $\mu \in \sigma(M^{-1} + \delta M)$ there exists a $\lambda \in \sigma(M^{-1})$ such that

$$(4.5) \quad \frac{|\lambda - \mu|^m}{(\bar{H}_M + |\lambda - \mu|)^{m-1}} \leq \|\delta M\|_2$$

where $m = \max_i \{k_i\}$ and

$$\bar{H}_M = \begin{cases} 0 & \text{when } m = 1, \\ \sum_{i=1}^{m-1} |\bar{\lambda}|^{i+1} H_M^i & \text{when } m > 1, \end{cases}$$

$$\bar{\lambda} = \max_i \{|\lambda_i|\}.$$

Proof. If $\mu \in \sigma(M^{-1})$, (4.5) obviously holds. So we assume that $\mu \notin \sigma(M^{-1})$. From our definition we know that $M^{-1} + \delta M - \mu I$ is singular, but $M^{-1} - \mu I$ is nonsingular. Therefore

$$I + (M^{-1} - \mu I)^{-1} \delta M = (M^{-1} - \mu I)^{-1} (M^{-1} - \mu I + \delta M)$$

is singular. Thus

$$\|(M^{-1} - \mu I)^{-1} \delta M\|_2 \geq 1,$$

i.e.,

$$(4.6) \quad (\|(M^{-1} - \mu I)^{-1}\|_2)^{-1} \leq \|\delta M\|_2.$$

Noticing the special form of M we know that there exists an i_0 such that

$$\|(M_{i_0}^{-1} - \mu I)^{-1}\|_2 = \|(M^{-1} - \mu I)^{-1}\|_2.$$

If we denote the eigenvalues of $(M_{i_0}^{-1} - \mu I)^*(M_{i_0}^{-1} - \mu I)$ by $s_{k_{i_0}}^2 \geq \dots \geq s_2^2 \geq s_1^2 > 0$, it follows that

$$\|(M_{i_0}^{-1} - \mu I)^{-1}\|_2 = \frac{1}{s_1}$$

and

$$(4.7) \quad s_i \leq \|(M_{i_0}^{-1} - \mu I)\|_2 \leq \|(\lambda_{i_0}^{-1} I + L_i)^{-1} - \mu I\|_2.$$

Since L_i is a strict upper-triangular matrix, it is easy to verify that

$$(\lambda_{i_0}^{-1} I + L_{i_0})^{-1} = \lambda_{i_0} (I - \lambda_{i_0} L_{i_0} + \dots + (-\lambda_{i_0} L_{i_0})^{k_{i_0}-1}).$$

Hence (4.7) becomes

$$\begin{aligned} s_i &\leq |\lambda_{i_0} - \mu| + \|\lambda_{i_0}^2 L_{i_0} + \lambda_{i_0}^3 L_{i_0}^2 + \dots + \lambda_{i_0} (-\lambda_{i_0} L_{i_0})^{k_{i_0}-1}\|_2 \\ &\leq |\lambda_{i_0} - \mu| + \sum_{j=1}^{k_{i_0}} |\lambda_{i_0}|^{j+1} \|L_{i_0}\|_2^j \\ &\leq |\lambda_{i_0} - \mu| + \bar{H}_M. \end{aligned}$$

On the other hand we also know that

$$s_1 s_2 \dots s_{k_{i_0}} = (|(M_{i_0}^{-1} - \mu I)^*(M_{i_0}^{-1} - \mu I)|)^{1/2} = |\lambda_{i_0} - \mu|^{k_{i_0}}.$$

Therefore

$$s_1 = \frac{|\lambda_{i_0} - \mu|^{k_{i_0}}}{s_2 \cdots s_{k_{i_0}}} \leq \frac{|\lambda_{i_0} - \mu|^{k_{i_0}}}{(\bar{H}_M + |\lambda_{i_0} - \mu|)^{k_{i_0}-1}} \leq \frac{|\lambda_{i_0} - \mu|^m}{(\bar{H}_M + |\lambda_{i_0} - \mu|)^{m-1}},$$

we can now obtain (4.5) by combining the above with (4.6). Q.E.D.

This lemma allows us to estimate the eigenvalue perturbations of M^{-1} in terms of M .

The following theorem is our main result.

THEOREM 4.1. *Consider the homogeneous singular system (4.1). Assume that $\sigma(E, A) \subset \mathbb{C}^-$ and (4.2) holds. Then the stability is preserved in the presence of arbitrary variation δA satisfying*

$$(4.8) \quad \delta A \in U_2(\varepsilon/\alpha),$$

i.e., $\sigma(E, A + \delta A) \subset \mathbb{C}^-$, where

$$(4.9) \quad \begin{aligned} \alpha &= \max\{\Omega_{A^{-1}E} \|A^{-1}E\|_2, 1\} \|A\|_2 \Omega_{A^{-1}E}, \\ \varepsilon &= \frac{\Delta_e^m}{(\beta + \Delta_e)^{m-1} + \Delta_e^m}, \Delta_e = \min_i \{|\operatorname{Re}(\lambda_i)| \mid \lambda_i \in \sigma(E, A)\} > 0, \\ \beta &= \begin{cases} 0 & \text{when } m = 1, \\ \sum_{j=1}^{m-1} \bar{\lambda}_e^{j+1} \hat{H}^j & \text{when } m > 1, \end{cases} \\ \bar{\lambda}_e &= \frac{1}{\min_i \{|\lambda_i| \mid \lambda_i \in \sigma(E, A)\}} > 0, \\ \hat{H} &= \sqrt{\frac{4(d^3-d)}{6}} \sqrt{\Omega_{A^{-1}E}^4 \|A^{-1}E\|_F^4 - \left(\sum_{i=1}^d |\sigma_i|^{-2}\right)^2}, \\ \sigma(E, A) &= \{\sigma_i\}. \end{aligned}$$

The other unspecified terms are the same as those defined in (3.2).

Proof. The proof is completed in four steps.

(a) Finding an appropriate decomposition of E, A . By the assumption $\sigma(E, A) \subset \mathbb{C}^-$ we know that A is nonsingular. Then it follows from Lemma 3.3 that there exists a nonsingular matrix $T_1 \in \mathbb{C}^{n \times n}$ such that

$$T_1^{-1} A^{-1} E T_1 = \text{block diag}(\tilde{E}_1, \tilde{E}_2, \dots, \tilde{E}_k, \tilde{N})$$

where $\tilde{E}_i = \lambda_i I + L_i \in \mathbb{C}^{k_i \times k_i}$, $\lambda_i \neq 0$, $i = 1, 2, \dots, k$, $\lambda_i \neq \lambda_j$, $i \neq j$. $\sum_{i=1}^k k_i = d < n$. \tilde{N} , L_i , $i = 1, 2, \dots, k$, are strict upper-triangular matrices. k_i is the multiplicity of the eigenvalue λ_i of $A^{-1}E$. And furthermore

$$\|T_1^{-1}\|_2 \|T_1\|_2 \leq \Omega_{A^{-1}E}$$

where $\Omega_{A^{-1}E}$ is as that in (3.2). It is easy to know from (4.2) that $\tilde{N} = 0$. Thus we have

$$(4.10) \quad T_1^{-1} A^{-1} E T_1 = \text{block diag}(\tilde{E}_1, \tilde{E}_2, \dots, \tilde{E}_k, 0).$$

Denote $E_1 = \text{block diag}(\tilde{E}_1, \tilde{E}_2, \dots, \tilde{E}_k) \in \mathbb{C}^{d \times d}$, which is nonsingular, and

$$(4.11) \quad Q = \text{block diag}(E_1^{-1}, I_{n-d}) T_1^{-1} A^{-1}, \quad P = T_1.$$

By summing the above results we easily get the following decomposition:

$$(4.12) \quad QEP = \text{block diag}(I_d, 0), \quad QAP = \text{block diag}(E_1^{-1}, I_{n-d}).$$

(b) Evaluating H_{E_1} . From our definition we know that

$$H_{E_1} = ((d^3 - d)/12)^{1/4} (\|E_1 E_1^* - E_1^* E_1\|_F)^{1/2}.$$

By Property 3 we obtain

$$(4.13) \quad H_{E_1} \leq ((d^3 - d)/12)^{1/4} \left(2 \left(\|E_1\|_F^4 - \left(\sum_{i=1}^d |\sigma_i(E_1)|^2 \right) \right) \right)^{1/4}.$$

Since

$$\sigma_i(E_1) = \sigma_i^{-1}(E_1^{-1}) = \sigma_{ei}^{-1}, \quad \sigma_{ei} \in \sigma(E, A),$$

according to (2.8) we have

$$\begin{aligned} \|E_1\|_F^2 &= \|\text{block diag}(E_1, 0)\|_F^2 = \text{tr}(T_1^{-1} A^{-1} E T_1 T_1^* E^* (A^{-1})^* (T_1^{-1})^*) \\ &\leq \|T_1\|_2^2 \text{tr}(E^* (A^{-1})^* (T_1^{-1})^* T_1^{-1} A^{-1} E) \\ &\leq \|T_1\|_2^2 \|T_1^{-1}\|_2^2 \|A^{-1} E\|_F^2 \leq \Omega_{A^{-1}E}^2 \|A^{-1} E\|_F^2. \end{aligned}$$

Thus (4.13) becomes

$$(4.14) \quad H_{E_1} \leq \hat{H}.$$

(c) Calculating the characteristic polynomial of the perturbed system. For arbitrary variation δA , the perturbed system is

$$(4.15) \quad E\dot{x} = (A + \delta A)x.$$

We denote

$$\delta A_0 = Q^{-1} \delta A P^{-1} = \begin{pmatrix} \delta A_{11} & \delta A_{12} \\ \delta A_{21} & \delta A_{22} \end{pmatrix};$$

then when condition (4.8) is satisfied, direct computation shows that

$$\begin{aligned} \|\delta A_0\|_2 &\leq \|Q^{-1}\|_2 \|P^{-1}\|_2 \|\delta A\|_2 \\ (4.16) \quad &\leq \|A T_1\|_2 \|\text{block diag}(E_1, I_{n-1})\|_2 \|T_1^{-1}\|_2 \|\delta A\|_2 \\ &\leq \|A\|_2 \Omega_{A^{-1}E} \max\{\|E_1\|_2, 1\} \|\delta A\|_2 \\ &\leq \alpha \|\delta A\|_2 < \varepsilon, \end{aligned}$$

i.e., $\|\delta A_0\|_2 < \varepsilon$. On the other hand, we also have by repeatedly using Property 2 that

$$\|\delta A_0\|_2 \geq \max\{\|\delta A_{11}\|_2, \|\delta A_{12}\|_2, \|\delta A_{21}\|_2, \|\delta A_{22}\|_2\}.$$

Combining this with (4.16) we finally obtain

$$(4.17) \quad \|\delta A_{ij}\|_2 < \varepsilon, \quad i, j = 1, 2.$$

Now we return to the characteristic polynomial of (4.15). The calculation shows us that

$$\begin{aligned} |Q\|P\|sE - (A + \delta A)| &= |sQEP - Q(A + \delta A)P| \\ &= \left| \begin{bmatrix} sI - (E_1^{-1} + \delta A_{11}) & -\delta A_{12} \\ -\delta A_{21} & -(I + \delta A_{22}) \end{bmatrix} \right|. \end{aligned}$$

Noting the fact that $\varepsilon < 1$, from (4.17) we see that $\|\delta A_{22}\|_2 < 1$. Then $(I + \delta A_{22})^{-1}$ exists. The above equation becomes

$$\begin{aligned} |Q\|P\|sE - (A + \delta A)| &= \left| \begin{bmatrix} sI - (E_1^{-1} + \delta A_{11}) & -\delta A_{12} \\ -\delta A_{21} & -(I + \delta A_{22}) \end{bmatrix} \begin{bmatrix} I & 0 \\ -(I + \delta A_{22})^{-1}\delta A_{21} & I \end{bmatrix} \right| \\ &= |-(I + \delta A_{22})| \cdot |sI - (E_1^{-1} + \delta A_{11} - \delta A_{12}(I + \delta A_{22})^{-1}\delta A_{21})|, \end{aligned}$$

i.e.,

$$(4.18) \quad \sigma(E, A + \delta A) = \sigma(E_1^{-1} + \delta A_{11} - \delta A_{12}(I + \delta A_{22})^{-1}\delta A_{21}).$$

(d) Under the assumption of (4.8) we analyze the stability of the system (2.15). Note the fact that E_1 is nonsingular and has the same form as that of (3.4). So we know E_1^{-1} has the same property. Therefore from Lemma 4.1 we deduce that for any $\mu \in \sigma(E_1^{-1} + \delta A_{11} - \delta A_{12}(I + \delta A_{22})^{-1}\delta A_{21})$ there exists a $\lambda \in \sigma(E_1^{-1}) = \sigma(E, A)$ satisfying

$$(4.19) \quad \frac{|\lambda - \mu|^m}{(\bar{H}_{E_1} + |\lambda - \mu|)^{m-1}} \leq \|\delta A_{11} - \delta A_{12}(I + \delta A_{22})^{-1}\delta A_{21}\|_2$$

where m is the highest order of Jordan blocks of E_1^{-1} (or (E, A)). Furthermore, the result of (b) indicates that

$$\begin{aligned} \bar{H}_{E_1} &= \begin{cases} 0 & \text{when } m = 1, \\ \sum_{j=1}^{m-1} |\bar{\lambda}_e|^{j+1} H_{E_1}^j & \text{when } m > 1 \end{cases} \\ &\leq \beta. \end{aligned}$$

Combining this with (4.17) and also noting that $\|\delta A_{22}\|_2 < \varepsilon < 1$, we obtain the following from (4.19):

$$\begin{aligned} \frac{|\lambda - \mu|^m}{(\beta + |\lambda - \mu|)^{m-1}} &\leq \frac{|\lambda - \mu|^m}{(\bar{H}_{E_1} + |\lambda - \mu|)^{m-1}} \\ &\leq \|\delta A_{11}\|_2 + \|\delta A_{12}\|_2 \|\delta A_{21}\|_2 \|(I + \delta A_{22})^{-1}\|_2 \\ &\leq \varepsilon + \varepsilon^2(1 - \varepsilon)^{-1} = \varepsilon(1 - \varepsilon)^{-1} \\ &= \frac{\Delta_e^m}{(\beta + \Delta_e)^{m-1} + \Delta_e^m}. \end{aligned}$$

Since the function $x^m(\beta + x)^{-(m-1)}$ is strictly monotone increasing on $x \geq 0$, we thus have

$$\lambda - \mu \in U_2(\Delta_e).$$

Hence $\operatorname{Re}(\mu) < \operatorname{Re}(\lambda) + \Delta_e \leq 0$. We know from (4.18) that $\sigma(E, A + \delta A) \subset \mathbb{C}^-$. The perturbed singular system (4.15) is stable. Q.E.D.

This theorem gives us an estimation of the structural stability region in terms of E and A . We would like to make some comments on it.

Remark 1. It may be seen from the proof procedure of Theorem 4.1 that if H_{E_1} is used in lieu of \hat{H} in (4.9) (sometimes) a much more accurate estimation may be obtained. On the other hand, the matrix E_1 is not unique and cannot be determined in advance in this case. So this method presents great difficulty in determining an appropriate E_1 .

In the proof of Theorem 4.1 it is also indicated that if we use (3.3) instead of (3.1) to estimate the bound of $(\delta A_{11} - \delta A_{12}(I + \delta A_{22})^{-1}\delta A_{21})$, the same procedure can be used to prove Theorem 4.2.

THEOREM 4.2. *Consider the homogeneous singular system (4.1). Assume that $\sigma(E, A) \subset \mathbb{C}^-$ and (4.2) holds. Then the stability of (4.1) is preserved in the presence of δA satisfying*

$$(4.20) \quad \delta A \in U_F(\bar{\varepsilon}/\alpha)$$

where

$$(4.21) \quad \bar{\varepsilon} = \frac{\bar{\eta}\Delta_e}{f_d(\bar{\eta}) + \bar{\eta}\Delta_e}, \quad \bar{\eta} = \frac{\nu}{\Delta_e},$$

$$\nu = \left(\sum_{i=1}^k \sum_{j=1}^{k_i} |\lambda_{e_i}|^{j+1} \Omega_{A^{-1}E}^j \|A^{-1}E\|_F \right)^{1/2}.$$

The other unspecified terms are the same as those defined in (4.9).

Proof. From Lemma 3.2 we know that for any $\mu \in \sigma(E_1^{-1} + \delta A_{11} - \delta A_{12} \cdot (I + \delta A_{22})^{-1} \delta A_{21})$ there exists a $\lambda \in \sigma(E_1^{-1}) = \sigma(E, A)$ such that

$$(4.22) \quad |\lambda - \mu| \leq \frac{\Delta_F(E_1^{-1})}{\xi_d(\eta)}, \quad \eta = \frac{\Delta_F(E_1^{-1})}{\|\delta A_{11} - \delta A_{12}(1 + \delta A_{22})^{-1} \delta A_{21}\|_F}.$$

Furthermore, by Lemma 3.2, we have

$$(4.23) \quad \Delta_F(E_1^{-1}) = \left(\|E_1^{-1}\|_F^2 - \sum_{i=1}^d |\sigma_{e_i}|^2 \right)^{1/2}, \quad \sigma_{e_i} \in \sigma(E_1^{-1}) = \sigma(E, A).$$

Thus from the definition of E_1 we obtain

$$\begin{aligned} \|E_1^{-1}\|_F^2 &= \sum_{i=1}^k \|\tilde{E}_i^{-1}\|_F^2 = \sum_{i=1}^d \|(\lambda_i I + L_i)^{-1}\|_F^2 \\ &\leq \sum_{i=1}^k \sum_{j=0}^{k_i} |\lambda_{e_i}|^{2(j+1)} \|L_i^{2j}\|_F \quad \left(\lambda_{e_i} = \frac{1}{\lambda_i} \right) \\ &\leq \sum_{i=1}^k \sum_{j=1}^{k_i} |\lambda_{e_i}|^{2(j+1)} \|T_1^{-1} A^{-1} E T_1\|_F^{2j} + \sum_{i=1}^k k_i |\lambda_{e_i}|^2 \\ &\leq \sum_{i=1}^k \sum_{j=1}^{k_i} |\lambda_{e_i}|^{2(j+1)} \|A^{-1} E\|_F^{2j} \Omega_{A^{-1}E}^{2j-1} + \sum_{i=1}^k k_i |\lambda_{e_i}|^2. \end{aligned}$$

The substitution of the above inequality into (4.23) immediately yields

$$(4.24) \quad \Delta_F(E_1^{-1}) \leq \gamma.$$

Using a procedure similar to that in the proof of (4.17), it is not difficult to verify that

$$(4.25) \quad \delta A_{ij} \in U_F(\bar{\varepsilon}), \quad i, j = 1, 2.$$

Hence

$$\delta A_{11} - \delta A_{12}(I + \delta A_{22})^{-1} \delta A_{21} \in U_F(\bar{\varepsilon} + \bar{\varepsilon}^2(1 - \bar{\varepsilon})^{-1}) = U_F(\bar{\varepsilon}(1 - \bar{\varepsilon})^{-1}) = U_F(\bar{\eta}\Delta_e/f_d(\bar{\eta})).$$

Note that the function $1/\bar{\eta}f_d(\bar{\eta}) = \bar{\eta}^{d-1} + \dots + \bar{\eta} + 1$ is strictly monotone increasing on $\bar{\eta} \geq 0$. The above shows that

$$f_d(\Delta_F(E_1^{-1})/\Delta_e) < \bar{\eta}.$$

This is equivalent to

$$(4.26) \quad \xi_d(\bar{\eta}) > \Delta_F(E_1^{-1})/\Delta_e.$$

We thus get from (4.22) and (4.26) that

$$|\lambda - \mu| \in U_2(\Delta_e),$$

$\operatorname{Re}(\mu) < 0$, i.e., $\sigma(E, A + \delta A) \subset \mathbb{C}^-$. Q.E.D.

Remark 2. Generally speaking, Δ_e is very small. Therefore $\bar{\eta}$ is often very large. Consequently we know $\bar{\varepsilon}$ is very small. This means that the structural stability region given by Theorem 4.2 is conservative.

Theorems 4.1 and 4.2 include the worst-case perturbation—we need to know only the norm bound of perturbation δA . However, in practice, it is usually the case that much more may be known about parameter perturbations. For example, δA may take the form of

$$\delta A = F\delta DG.$$

In such cases, the same procedure may be applied to the analysis of a perturbation region for the structural stability of δD . Careful analysis may result in a much larger region.

Remark 3. Suppose that the matrix pencil (E, A) has only simple eigenvalues (with multiplicity of one); so does E_1 . Then $m = k_i = 1$, $i = 1, 2, \dots, k = d$. In this special case, we have the following corollary.

COROLLARY 4.1. *Suppose that the matrix pencil (E, A) has only simple eigenvalues. Then the perturbed system (4.15) is stable if either of the two following conditions is satisfied:*

(1)

$$(4.27) \quad \begin{aligned} \delta A &\in U_2(\varepsilon/\alpha), \\ \varepsilon &= \Delta_e/(1 + \Delta_e), \quad \alpha = \max\{\|A^{-1}E\|_2 \Omega_{A^{-1}E}, 1\} \|A\|_2 \Omega_{A^{-1}E}; \end{aligned}$$

(2)

$$(4.28) \quad \begin{aligned} \delta A &\in U_F(\bar{\varepsilon}/\alpha), \\ \bar{\varepsilon} &\text{ is the same as in (4.21).} \end{aligned}$$

5. Structural stability for regulation systems. In the previous section we have analysed quantitatively the structural stability region for homogeneous singular systems. Now, by utilizing these results, we consider the structural stability for general regulation systems. Such systems have the property of being able to resist small parameter perturbations and external disturbances. Our aim here is to find a perturbation region for the nominal system or its compensator so that the perturbed system is still internally stable, and output regulation (for definition, cf. [4]) provided the perturbation is within the above region.

Consider the following singular system:

$$(5.1) \quad \begin{aligned} E\dot{x} &= Ax + Bu + A_1f, \\ \dot{f} &= A_2f, \\ y &= C_1x + C_2f, \\ z &= D_1x + D_2f \end{aligned}$$

where $x \in R^n$ is its state, $u \in R^r$ is its control input, $y \in R^h$ is its measure output, $f \in R^p$ is its external disturbance (or reference signal, or any other signals to be tracked) and $z \in R^q$ is the vector to be regulated. $E, A, B, A_1, A_2, C_1, C_2, D_1, D_2$ are constant

matrices of appropriate dimensions. We also suppose that $\text{rank } E < n$, $E \neq 0$, and $|sE - A| \neq 0$.

DEFINITION 5.1. For the system (5.1) if there exists a dynamic compensator

$$(5.2) \quad \dot{x}_c = A_c x_c + B_c y, \quad u = F_c x_c + Fy$$

where $x_c \in R^{n_c}$, A_c , B_c , F_c , F are constant matrices of appropriate dimensions, such that the closed-loop system is internally stable (i.e., it is stable when $f \equiv 0$) and output regulation (i.e., $\lim_{t \rightarrow \infty} z = 0$), we shall term (5.2) an output regulator for the system (5.1). Furthermore, if there exists a certain neighborhood at data point $P\{E, A, B, C_1\}$ such that (5.2) is an output regulator for (5.1) with arbitrary variations of structural parameters in this neighborhood, we shall call (5.2) a structurally stable output regulator (SSOR) for the system (5.1) at $P\{E, A, B, C_1\}$.

Dai and Wang [4] have shown qualitatively the following theorem.

THEOREM 5.1. Suppose that $\text{rank } E < n$. Then we have that

- (1) System (5.2) could not be an SSOR for system (5.1) at $P\{E\}$;
- (2) System (5.2) is an SSOR for system (5.1) at $P\{A, B, C_1, A_1, B_c, F_c, F\}$ if and only if

- (i) (E, A, B) is stabilizable and (E, A, C_1) is detectable;
- (ii) z is readable from y , i.e., $z = Gy$;
- (iii) The closed-loop system is internally stable;
- (iv) System (5.2) incorporates an internal model of A_2 . This model is observable about u and controllable about z ;

$$(v) \quad \deg \left(\left| s \begin{bmatrix} E & 0 \\ 0 & I \end{bmatrix} - \begin{bmatrix} A + BFC_1 & BF_c \\ B_c C_1 & A_c \end{bmatrix} \right| \right) = n_c + \text{rank } E.$$

In view of the above results, we now consider the structural stability for regulation systems.

First we suppose that only the nominal system (5.1) is perturbed. Let

$$\bar{E} = \begin{bmatrix} E & 0 \\ 0 & I \end{bmatrix}, \quad \bar{A} = \begin{bmatrix} A + BFC_1 & BF_c \\ B_c C_1 & A_c \end{bmatrix}.$$

Theorems 4.1 and 4.2 give us Theorem 5.2.

THEOREM 5.2. Consider the system (5.1) and its output regulator (5.2). Assume that conditions (i)–(v) in Theorem 5.1 are satisfied. Then (5.2) is an output regulator for the system (5.1) in the presence of δA and δB , provided one of the following conditions is satisfied:

$$(1) \quad [\delta A \quad \delta B] \in U_2(\varepsilon/\alpha a_1), \quad a_1 = \left\| \begin{bmatrix} I & 0 \\ FC_1 & F_c \end{bmatrix} \right\|_2;$$

$$(2) \quad [\delta A \quad \delta B] \in U_F(\bar{\varepsilon}/\alpha a_1).$$

Here the unspecified values are as defined in (4.9) and (4.21), where E, A are replaced by \bar{E}, \bar{A} .

In another case, let only the compensator (5.2) be perturbed. We have Theorem 5.3.

THEOREM 5.3. Assume that conditions (i)–(v) in Theorem 5.1 are satisfied. When the perturbation δB_c , δF_c , δF satisfy either of the following conditions:

$$(a) \quad \begin{bmatrix} \delta F & \delta F_c \\ \delta B_c & 0 \end{bmatrix} \in U_2(\varepsilon/\alpha a_2), \quad a_2 = \left\| \begin{bmatrix} B_1 & 0 \\ 0 & I \end{bmatrix} \right\|_2 \left\| \begin{bmatrix} C_1 & 0 \\ 0 & I \end{bmatrix} \right\|_2;$$

$$(b) \quad \begin{bmatrix} \delta F & \delta F_c \\ \delta B_c & 0 \end{bmatrix} \in U_F(\bar{\varepsilon}/\alpha a_2).$$

Formula (5.2) is still an SSOR for the system (5.1). Here the unspecified terms are similar to those in Theorem 5.2.

6. Conclusion. This paper studies the robust region for structurally stable singular systems using the matrix perturbation analysis method. This is a completely new method based on state space description. The results are applied to analyzing the structural stability of singular regulation systems. But it is worthwhile to point out that the robust regions given here are conservative. Therefore, further studies are needed to find a more useful and better method to estimate the robust region.

NEARLY OPTIMAL SINGULAR CONTROLS FOR WIDEBAND NOISE DRIVEN SYSTEMS*

H. J. KUSHNER† AND K. M. RAMACHANDRAN†

Abstract. Singular stochastic control problems arise in many applications, for example, in storage, inventory, finite fuel, consumption and investment and limits of impulsive control problems. Here, the increment of the control effort is not of the usual form $u(t) dt$, but is the differential of a nondecreasing and suitably adapted process. The diffusion process models used are only approximations to some “physical” process—which might be a “wideband” noise driven system or a suitably scaled discrete parameter process. Since the optimal controls for the “physical” processes are usually impossible to obtain, it is of interest to know whether “nearly” optimal controls for the diffusion model are “nearly” optimum when applied to the physical problem. It is shown that this is true under broad conditions, for discounted and average cost per unit time problems. The usual weak convergence analysis via the Skorokhod topology on $D[0, \infty)$ is not appropriate here, due to the nature of the singular controls, and it is necessary to use a combination of the Skorokhod and “pseudopath” topology.

Key words. singular stochastic control, approximately optimal control, weak convergence, pseudopath topology, control of wideband noisy systems, modeling of physical systems by singular control processes

AMS(MOS) subject classifications. 93E20, 93E25, 60F17

1. Introduction. Let $Y_i(\cdot)$, $i=0, 1$, be nondecreasing processes with $Y_i(0)=0$, which are nonanticipative with respect to a Wiener process $w(\cdot)$. Define $x(\cdot)$, $Y(\cdot)$ and $Z(\cdot)$ by $x(0)=x$, $Z(0)=0$, $Y(\cdot)=Y_0(\cdot)-Y_1(\cdot)$ and

$$(1.1) \quad dx = [b(x) dt + \sigma(x) dw] + [dY_0 - dY_1] \equiv dZ + dY.$$

We assume that there is a $\bar{B} \in (0, \infty)$ (given as part of the problem statement) such that we are obliged to keep $x(t) \in [0, \bar{B}]$. Unless otherwise mentioned, we always assume that the $Y(\cdot)$ process is such that $x(t) \in [0, \bar{B}]$. The process (1.1) has been widely used as a model of storage and dam processes, both with and without control [1]–[5], [16]. The $Y_1(\cdot)$ might denote the “withdrawal” process, whereby actual use is made of the system’s contents. $Y_0(\cdot)$ might simply denote a process which is used solely as a modeling device to guarantee that $x(t) \geq 0$, (see, e.g., [4]). The process $z(\cdot)$ might denote the difference between the “natural” inputs and “natural” demand. See the discussion in [4] on this point. Other interpretations are discussed in the references.

Let $k_0 > k_1 > 0$ and let $k(\cdot)$ be a bounded continuous function. Define the two types of costs (E_x denotes the expectation under initial condition $x(0)=x$):

$$(1.2) \quad \begin{aligned} V_0(x, Y_0, Y_1) &= E_x \int_0^\infty e^{-\beta t} [k_0 dY_0(t) - k_1 dY_1(t) + k(x(t)) dt], \\ V(x) &= \inf_{Y_0, Y_1} V_0(x, Y_0, Y_1) \end{aligned}$$

and

$$(1.3) \quad \begin{aligned} \gamma_0(x, Y_0, Y_1) &= \overline{\lim}_T E_x \int_0^T [k_0 dY_0(t) - k_1 dY_1(t) + k(x(t)) dt] / T, \\ \gamma_0(x) &= \inf_{Y_0, Y_1} \gamma_0(x, Y_0, Y_1). \end{aligned}$$

In (2.1), the inf is over all *admissible* $Y_i(\cdot)$, namely over all nonanticipative, nondecreasing $Y_i(\cdot)$ such that $x(t) \in [0, \bar{B}]$. The class over which the inf is taken in (1.3) will be described in § 7.

Reference [1] gives an elegant presentation of the optimal control problem (1.1), (1.2) and of the properties of the associated Bellman equation. Most of the other current literature seems to concern the case where $Z(\cdot)$ is a Wiener process (perhaps with drift). Since there are likely to be few applications which are perfectly modeled by (1.1), we must look at the model in the sense that it approximates in some way an actual physical problem. Since the model (1.1) would be simpler than the approximated "physical" process, it is attractive to use it for calculating a control for the actual physical process. But the question arises concerning how good it is in comparison with the optimal control for the physical process.

Models such as (1.1) also arise as limits of suitably interpolated discrete parameter processes. Consider one type: For each $\varepsilon > 0$, let $(i=0, 1)$ $Y_i^\varepsilon(\cdot)$ be nondecreasing processes, piecewise constant on the intervals $[n\varepsilon, n\varepsilon + \varepsilon)$, and define $\delta Y_i^\varepsilon(n\varepsilon) \equiv Y_i^\varepsilon(n\varepsilon + \varepsilon) - Y_i^\varepsilon(n\varepsilon)$. For appropriate functions F and G , define $\{X_n^\varepsilon, Z_n^\varepsilon\}$ by $X_0^\varepsilon = x$, $Z_0^\varepsilon = 0$, and

$$(1.4) \quad \begin{aligned} X_{n+1}^\varepsilon &= X_n^\varepsilon + (Z_{n+1}^\varepsilon - Z_n^\varepsilon) + \delta Y_0^\varepsilon(n\varepsilon) - \delta Y_1^\varepsilon(n\varepsilon), \\ Z_{n+1}^\varepsilon - Z_n^\varepsilon &= \varepsilon G(X_n^\varepsilon, \xi_n^\varepsilon) + \sqrt{\varepsilon} F(X_n^\varepsilon, \xi_n^\varepsilon), \\ EF(x, \xi_n^\varepsilon) &\equiv 0, \end{aligned}$$

where $\{\xi_n^\varepsilon\}$ is a random sequence. We say that the controls with values $\delta Y_i^\varepsilon(n\varepsilon)$ in (1.4) at time n are admissible if they depend on the "full information" $\{X_i^\varepsilon, i \leq n, Y_j^\varepsilon(\varepsilon i), j=0, 1, i \leq n, \xi_j^\varepsilon, j < n\}$ available at time n . Define the interpolated processes $X^\varepsilon(t) = X_n^\varepsilon$ and $Z^\varepsilon(t) = Z_n^\varepsilon$ on $[n\varepsilon, n\varepsilon + \varepsilon)$ and the costs

$$(1.5) \quad \begin{aligned} V_0^\varepsilon(x, Y_0^\varepsilon, Y_1^\varepsilon) &= E_x \int_0^\infty e^{-\beta t} [k_0 dY_0^\varepsilon(t) - k_1 dY_1^\varepsilon(t) + k(X^\varepsilon(t)) dt], \\ V^\varepsilon(x) &= \inf_{Y_0^\varepsilon, Y_1^\varepsilon} V_0^\varepsilon(x, Y_0^\varepsilon, Y_1^\varepsilon). \end{aligned}$$

In general, we know virtually nothing about the optimal or δ -optimal policies for (1.4), (1.5). Suppose that, for reasonable $Y_i^\varepsilon(\cdot)$, the set $\{X^\varepsilon(\cdot), Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot)\}$ converges weakly in some sense to a solution of (1.1), thus providing justification for use of (1.1). It is of considerable interest to know just how good (compared to the optimal controls for (1.4)) are the optimal (or δ -optimal) policies which we obtain for (1.1), (1.2), when suitably adapted to and applied to the system (1.4), (1.5). Consider the following example.

Let $\bar{Y}_i(\cdot)$, $i=0, 1$, denote the optimal or (for some given $\delta > 0$) δ -optimal controls for (1.1), (1.2). Frequently [1], [4] they are of the barrier form: There are $0 \leq L^* < U^* < \infty$ such that $\bar{Y}_0(\cdot)$ is used only to keep $x(\cdot)$ from "falling below" L^* and $\bar{Y}_1(\cdot)$ is used only to keep $x(\cdot)$ from going above U^* . The policy $\bar{Y}_i(\cdot)$ adapted to (1.4) (call it $\bar{Y}_i^\varepsilon(\cdot)$) is a policy which returns $X^\varepsilon(\cdot)$ to L^* or to U^* immediately if it ever drops below L^* or exceeds U^* .

From the point of view of optimal control, we wish to show that the costs $V^\varepsilon(x)$ and $V^\varepsilon(x, \bar{Y}_0^\varepsilon, \bar{Y}_1^\varepsilon)$ are close for small ε , whether or not the optimal controls for (1.1), (1.2) are of the barrier policy type. This is the class of problems dealt with here. The basis tools are those of weak convergence theory. The work here extends that of [6] and [7]. The methodologies of these references require considerable modification to be of use here.

Owing to lack of knowledge of the properties of the optimal $Y_i^\varepsilon(\cdot)$, we cannot generally prove tightness or weak convergence of $\{X^\varepsilon(\cdot), Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot)\}$ in the Skorokhod topology on $D^3[0, \infty)$. A weaker topology must be used, and it is described in § 2. Section 3 concerns a weak convergence result for a continuous time model, and § 4 extends it to the discrete time case. Section 5 contains some auxiliary results which are needed later. The optimal control problem for the discounted cost case is dealt with in § 6, where it is shown that the suitably adapted optimal policy for the limit is indeed “nearly” optimal for the actual physical process. Section 7 concerns the average cost per unit time problem. Here, owing to the natural requirement of stationarity, we impose a Markov structure on the problem.

The basic methods work just as well for many nonscalar models—and several extensions to such models are discussed in § 8. There are extensions of the results to cases where the dynamical terms are not smooth or the noise is state dependent. We would then adapt the weak convergence technique and assumptions of [8, Chaps. 5.3, 5.5, 5.8] to the problem here. The results also extend to the case where there is also a “nonsingular” control component $b(x, u) dt$ (as in [16]), via a combination of the methods developed here and those used in [6] for the nonsingular case). Another extension would be for the problem in [9], where the singular control problem appears as a limit of impulsive control problems: Let δ_ε denote the fixed cost per impulse and (for some $\bar{k} > 0$) $\bar{k}|Y^\varepsilon(t) - Y^\varepsilon(t^-)|$ the variable cost, for an impulse at time t . Then we can let $\delta_\varepsilon \rightarrow 0$ as the noise bandwidth goes to ∞ , to get an approximation theorem for small fixed impulsive cost and wide bandwidth simultaneously.

2. The pseudopath topology. In this section, we discuss the topology on $D[0, \infty)$ (replacing the Skorokhod topology) which will allow us to obtain the desired weak convergence results.

Let the physical system be modeled by

$$X^\varepsilon(t) = Z^\varepsilon(t) + Y^\varepsilon(t)$$

where $X^\varepsilon(0) = x$, $Z^\varepsilon(0) = 0$, $Y^\varepsilon(\cdot) = Y_0^\varepsilon(\cdot) - Y_1^\varepsilon(\cdot)$ and define $\bar{X}^\varepsilon(\cdot) = (X^\varepsilon(\cdot), Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot), Z^\varepsilon(\cdot))$. The $\bar{X}^\varepsilon(\cdot)$ can be viewed either as a continuous parameter interpolation of a discrete parameter system as discussed in § 1, or it might be an actual physical model for a continuous parameter system. We always take the paths of $X^\varepsilon(\cdot)$, $Z^\varepsilon(\cdot)$ and $Y_i^\varepsilon(\cdot)$ to be right continuous and $Y^\varepsilon(\cdot)$ nondecreasing.

We suppose that the $\bar{X}^\varepsilon(\cdot)$ take values in $D^4[0, \infty)$, the space of R^4 -valued functions which are right continuous and have left-hand limits. The appropriate topology for our purposes on $D^4[0, \infty)$ is what Dellacherie and Meyer [10] and Meyer and Zheng [11] call the *pseudopath topology*. For completeness, we state some definitions and results from [11] which will be needed in the sequel. The results are stated for a real-valued process, but the natural extensions for the R^r -valued case should be obvious and are used below.

Let $y(\cdot) \in D[0, \infty)$ and define the measure $\lambda(\cdot)$ on the Borel subsets of $[0, \infty)$ by $\lambda(dt) = e^{-t} dt$. Let \bar{P} denote the compact space of probability measures (with the weak topology) on the compactified space $[0, \infty] \times \bar{R}$, where \bar{R} is the closure of the real line. The *pseudopath* of $y(\cdot)$ is defined to be the probability measure on the Borel subsets

of $[0, \infty) \times \bar{R}$ which is the image of $\lambda(\cdot)$ under the map $t \rightarrow (t, y(t))$ of $[0, \infty]$ into $[0, \infty) \times \bar{R}$ (i.e., it is a point in \bar{P}). Let ψ denote the map which takes $y(\cdot)$ into its pseudopath, the corresponding point in \bar{P} . If we write $P = \psi(y(\cdot))$, then the pseudopath P is the measure defined by $P(A \times B) = \int_A e^{-t} I_{\{y(t) \in B\}} dt$, where A is a Borel subset of $[0, \infty]$ and B is a Borel subset of \bar{R} .

ψ is 1:1 on $D[0, \infty)$, since it identifies all paths which are equal almost everywhere (Lebesgue measure). The topology which \bar{P} induces on $D[0, \infty)$ via ψ is called the *pseudopath topology*. The associated σ -algebra on $D[0, \infty)$ is the same as we get with the Skorokhod topology. In fact [11, Lemma 1 and comment after its proof], the *pseudopath topology* on $D[0, \infty)$ is the *topology of convergence in measure*. The last assertion remains true if R and $D[0, \infty)$ are replaced by R' and $D'[0, \infty)$, where ψ then maps points $y(\cdot) \in D'[0, \infty)$ into a measure on the Borel subsets of $[0, \infty) \times \bar{R}'$. Let \bar{P}_r denote the space of probability measures on the Borel subsets of $[0, \infty) \times \bar{R}'$.

The process $\bar{X}^e(\cdot)$ induces a measure (which we denote by \bar{P}_e) on \bar{P}_4 via the pseudopath mapping ψ . The set $\{\bar{P}_e\}$ is obviously tight since \bar{P}_4 is compact. If \bar{P} is a limit measure of any weakly convergent subsequence, then for the convergence to be useful we need at least that \bar{P} be supported by $\psi(D^4[0, \infty))$, since then the limit \bar{P} would correspond to some process $\bar{X}(\cdot) = (X(\cdot), Y_0(\cdot), Y_1(\cdot), Z(\cdot))$ with paths in $D^4[0, \infty)$, via the mapping ψ . A convenient criterion for this is given by Meyer and Zheng [11], and will now be described.

Let τ denote a finite partition $\{t_i, i \leq n\}$: $0 = t_0 < t_1 < \dots < t_n = \infty$. Let $U(\cdot)$ denote a process with paths in $D[0, \infty)$ and adapted to a nondecreasing sequence of σ -algebras $\{\mathcal{F}_t\}$, and with $E|U(t)| < \infty$ for each $t < \infty$. For convenience in comparing with [11], let $U(t) = 0$ for large t . Define the conditional variations

$$\begin{aligned} \text{var}_\tau(U) &= \sum_{i \leq n} E|E_{\mathcal{F}_{t_i}} U(t_{i+1}) - U(t_i)|, \\ (2.1) \quad \text{var}(U) &= \sup_\tau \text{var}_\tau(U). \end{aligned}$$

If $\text{var}(U) < \infty$, then $U(\cdot)$ is said to be a *quasimartingale*.

For $u < v$, let $N^{u,v}(U)$ denote the number of upcrossings of $U(\cdot)$ on $[0, \infty)$ between the levels u and v . If $U(\cdot)$ is a quasimartingale, then

$$(2.2) \quad EN^{uv}(U) \leq \frac{|u| + \text{var}(U)}{v - u},$$

an extension of the usual result for martingales [11, Lemma 3]. The main result is [11, Thm. 4].

THEOREM 2.1. *For each $n = 1, 2, \dots$, let P_n be a probability law on the Borel¹ subsets (with the pseudopath topology) of $D[0, \infty)$ with the associated process $U_n(\cdot)$ being a quasimartingale with $\sup_n \text{var}(U_n) < \infty$. Then there is a subsequence $\{P_{n_k}\}$ of $\{P_n\}$ which converges weakly on $D[0, \infty)$ (with the pseudopath topology) to a law P , and the associated process $U(\cdot)$ is a quasimartingale. (Alternatively, let \bar{P}_n be the measure induced on \bar{P} by the map ψ acting on $U_n(\cdot)$. Then $\{\bar{P}_n\}$ is tight on \bar{P} and there is a weakly convergent subsequence $\{\bar{P}_{n_k}\}$ with limit denoted by \bar{P} . \bar{P} is supported on $D[0, \infty)$ and the associated process is a quasimartingale.)*

Combining this with the previous results, we have the following theorem.

THEOREM 2.2. *Assume the conditions and terminology of Theorem 2.1 and let $h(\cdot)$ be any bounded real valued function on $D[0, \infty)$ which is continuous (with probability 1*

¹ The Skorokhod topology and the pseudopath topology generate the same σ -algebra on $D[0, \infty)$.

with respect to P) when the topology of convergence in measure is used on $D[0, \infty)$. Then there is a subsequence $\{n_k\}$ of the integers such that $Eh(U_{n_k}(\cdot)) \rightarrow Eh(U(\cdot))$. Also [11, Thm. 5] there is a further subsequence $\{m_k\} \subset \{n_k\}$ and a set I of full measure (depending on P) such that the finite-dimensional distributions of $\{U_m(t), t \in I\}$ converge to those of $\{U(t), t \in I\}$. Let $f(\cdot)$ be bounded and continuous on $[0, \infty)$. Then [11, Thm. 6] the function $(t_1, \dots, t_q) \rightarrow Ef(U_{n_k}(t_1), \dots, U_{n_k}(t_q))$ converges in measure to the function $(t_1, \dots, t_q) \rightarrow Ef(U(t_1), \dots, U(t_q))$.

Notation. To simplify the exposition, we often abuse terminology and (in the terminology of Theorem 2.1) speak of the $\{U_n\}$ (rather than the associated measures) as being tight or converging weakly to some $U(\cdot)$ on $D[0, \infty)$ in the pseudopath topology.

3. The quasimartingale property and weak convergence of $\bar{X}^\varepsilon(\cdot) = (X^\varepsilon(\cdot), Z^\varepsilon(\cdot), Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot))$. A continuous parameter case will be discussed in this section. The discrete parameter case requires only a few modifications and is discussed in the next section. For concreteness, a specific model which is of a widely used form [8], [12], [13] for representing wide bandwidth noise driven systems will be treated. The techniques are usable for a much broader class of systems—just as for the case where $Y_i^\varepsilon(\cdot) \equiv 0$ dealt with in [6] or the various continuous parameter models in [8]. The model to be used is

$$(3.1) \quad dX^\varepsilon = G(X^\varepsilon, \xi^\varepsilon) dt + F(X^\varepsilon, \xi^\varepsilon) dt/\varepsilon + dY^\varepsilon(t),$$

where $\xi^\varepsilon(t) = \xi(t/\varepsilon^2)$, $\xi(\cdot)$ is a right continuous random process and $Y^\varepsilon = Y_0^\varepsilon - Y_1^\varepsilon$.

Let E_t^ε denote the expectation conditioned on $\{X^\varepsilon(s), \xi^\varepsilon(s), Y_0^\varepsilon(s), Y_1^\varepsilon(s), s \leq t\}$, and E_t the expectation conditioned on $\{\xi(s), s \leq t\}$. Define

$$Z^\varepsilon(t) \equiv \int_0^t G(X^\varepsilon(s), \xi^\varepsilon(s)) ds + \frac{1}{\varepsilon} \int_0^t F(X^\varepsilon(s), \xi^\varepsilon(s)) ds.$$

We will use the following assumptions. Various extensions (vector case, discontinuous dynamics, state dependent noise) are possible, as was discussed in the Introduction.

(A3.1) $G(\cdot, \cdot)$, $F(\cdot, \cdot)$, and $F_x(\cdot, \cdot)$ are bounded continuous functions and the latter two are continuous in x uniformly in ξ .

(A3.2) For each scalar x , $EF(x, \xi(s)) \equiv 0$ and $\xi(\cdot)$ is right continuous and sufficiently mixing such that there is a $K < \infty$ for which for each $T < \infty$

$$(3.2) \quad \sup_{x, t \leq T} \left| \int_t^T E_t g(x, \xi(s)) ds \right| \leq K \quad \text{w.p.1,}$$

where $g(\cdot, \cdot)$ represents either $F(\cdot, \cdot)$ or $F_x(\cdot, \cdot)$.

Remark. Owing to the “with probability 1” statement of (A3.2) the inequalities which use (A3.2) will hold uniformly in ω , with probability 1. In particular, the $o(\varepsilon)$, $O(\varepsilon)$ and $O(\Delta)$ of the sequel will not depend on ω .

DEFINITION. The $Y_i^\varepsilon(\cdot)$ are said to be *admissible* if for each t , the $Y_i^\varepsilon(t)$ are nondecreasing, measurable and adapted to the σ -algebra measuring $\{\xi^\varepsilon(s), s \leq t, X^\varepsilon(s), s < t\}$.

Write $Y_{ic}^\varepsilon(\cdot)$, $Y_{id}^\varepsilon(\cdot)$ and $Y_c^\varepsilon(\cdot)$, $Y_d^\varepsilon(\cdot)$ for the continuous and jump components of $Y_i^\varepsilon(\cdot)$ and $Y^\varepsilon(\cdot)$, respectively. By our convention on the right continuity of the $Y_i^\varepsilon(\cdot)$, we use the “left” differential $dY_{id}^\varepsilon(u) = Y_{id}^\varepsilon(u) - Y_{id}^\varepsilon(u^-)$ in the integrals below. The same applies for the discontinuous components of the $Y_i(\cdot)$.

THEOREM 3.1. Assume (A3.1) and (A3.2) and let $Y_i^\varepsilon(\cdot)$ be admissible with $\sup_\varepsilon [EY_0^\varepsilon(t) + EY_1^\varepsilon(t)] < \infty$ for each t . Then (possibly having to add to each component a process whose maximum value goes to zero as $\varepsilon \rightarrow 0$), $\{X^\varepsilon(\cdot), Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot), Z^\varepsilon(\cdot)\}$ are quasimartingales whose conditional variation is bounded uniformly in ε (with probability 1) on each bounded time interval.

Remark. We need not assume that $X^\varepsilon(t) \in [0, \bar{B}]$ in this theorem.

Proof. Since $\sup_\varepsilon EY_i^\varepsilon(t) < \infty$, the $Y_i^\varepsilon(\cdot)$ are obviously quasimartingales with uniformly (in ε) bounded conditional variation on each interval $[0, t]$. Thus, we need only work with the $Z^\varepsilon(\cdot)$. We will use the so-called perturbed test function method described in [8], [12], [14] but adapted to our present needs. For some sufficiently large T , define the process $Z_1^\varepsilon(\cdot)$ on $[0, T]$ by

$$Z_1^\varepsilon(t) = \frac{1}{\varepsilon} \int_t^T E_t^\varepsilon F(X^\varepsilon(s), \xi^\varepsilon(s)) ds = \varepsilon \int_{t/\varepsilon^2}^{T/\varepsilon^2} E_t^\varepsilon F(X^\varepsilon(s), \xi^\varepsilon(s)) ds.$$

To get the second integral, we used the change of variable $s/\varepsilon^2 \rightarrow s$, which will be used frequently in the averaging and bounding in the sequel, when working with integrals such as $z_1^\varepsilon(\cdot)$. (Perturbations such as $Z_1^\varepsilon(\cdot)$ play a basic role in the “averaging” of the noise. See the cited references.) By (A3.2)

$$\sup_{t \leq T} |Z_1^\varepsilon(t)| = O(\varepsilon).$$

We will show that the function defined by $f^\varepsilon(t) = Z^\varepsilon(t) + Z_1^\varepsilon(t)$ is a quasimartingale whose conditional variation is bounded uniformly in ε (with probability 1) on each interval $[0, T]$. The calculations will be done in a slightly indirect way so that they can be reused later. Let $f(\cdot)$ denote a “test” function with bounded and continuous derivatives up to order three, and define $f^\varepsilon(t) = f(Z^\varepsilon(t)) + f_1^\varepsilon(t)$, where $f_1^\varepsilon(\cdot)$ is the “perturbation” defined by

$$\begin{aligned} f_1^\varepsilon(t) &= \frac{1}{\varepsilon} \int_t^T f_z(Z^\varepsilon(s)) E_s^\varepsilon F(X^\varepsilon(s), \xi^\varepsilon(s)) ds \\ &= \varepsilon \int_{t/\varepsilon^2}^{T/\varepsilon^2} f_z(Z^\varepsilon(s)) E_s^\varepsilon F(X^\varepsilon(s), \xi^\varepsilon(s)) ds. \end{aligned}$$

By integrating the derivative of $f(Z^\varepsilon(\cdot))$,

$$\begin{aligned} (3.3) \quad & E_t^\varepsilon f(Z^\varepsilon(t+\Delta)) - f(Z^\varepsilon(t)) \\ &= E_t^\varepsilon \int_t^{t+\Delta} f_z(Z^\varepsilon(u)) \left[G(X^\varepsilon(u), \xi^\varepsilon(u)) + \frac{F(X^\varepsilon(u), \xi^\varepsilon(u))}{\varepsilon} \right] du. \end{aligned}$$

Similarly, by evaluating $[E_u^\varepsilon f_1^\varepsilon(u+\Delta) - f_1^\varepsilon(u)]/\Delta$ and letting $\Delta \rightarrow 0$, we get

$$\begin{aligned} (3.4) \quad & E_t^\varepsilon f_1^\varepsilon(t+\Delta) - f_1^\varepsilon(t) = -\frac{1}{\varepsilon} \int_t^{t+\Delta} f_z(Z^\varepsilon(u)) E_u^\varepsilon F(X^\varepsilon(u), \xi^\varepsilon(u)) du \\ &+ \int_t^{t+\Delta} du \frac{1}{\varepsilon} E_t^\varepsilon \int_u^T ds f_{zz}(Z^\varepsilon(u)) E_u^\varepsilon \frac{F(X^\varepsilon(u), \xi^\varepsilon(s))}{\varepsilon} \\ &\cdot \left[\frac{F(X^\varepsilon(u), \xi^\varepsilon(u))}{\varepsilon} + G(X^\varepsilon(u), \xi^\varepsilon(u)) \right] \\ &+ E_t^\varepsilon \int_t^{t+\Delta} dY_c^\varepsilon(u) \frac{1}{\varepsilon} \int_u^T f_z(Z^\varepsilon(u)) E_u^\varepsilon F_x(X^\varepsilon(u), \xi^\varepsilon(s)) ds \end{aligned}$$

$$\begin{aligned}
& + \int_t^{t+\Delta} E_t^\varepsilon \left[\frac{F(X^\varepsilon(u), \xi^\varepsilon(u))}{\varepsilon} + G(X^\varepsilon(u), \xi^\varepsilon(u)) \right] du \\
& \cdot \int_u^T E_u^\varepsilon f(Z^\varepsilon(u)) \frac{F(X^\varepsilon(u), \xi^\varepsilon(s))}{\varepsilon} ds \\
& + \sum_{t < u \leq t+\Delta} \frac{1}{\varepsilon} E_t^\varepsilon \int_u^T f_z(Z^\varepsilon(u)) E_u^\varepsilon [F(X^\varepsilon(u^-) \\
& \quad + dY_d^\varepsilon(u), \xi^\varepsilon(s)) - F(X^\varepsilon(u^-), \xi^\varepsilon(s))] ds.
\end{aligned}$$

By a change of scale $s/\varepsilon^2 \rightarrow s$ and the use of (A3.1) and (A3.2), the second and fourth terms on the right-hand side of (3.4) are seen to be $O(\Delta)$, with probability 1. By a similar scale change, the third term is seen to be $O(\varepsilon)E_t^\varepsilon(Y_c^\varepsilon(t+\Delta) - Y_c^\varepsilon(t))$, with probability 1. The first term of (3.4) is the negative of the “ $1/\varepsilon$ ” term in (3.3). For the evaluation of the last term in (3.4), first use the law of the mean to rewrite it as

$$(3.5) \quad \sum_{t < u \leq t+\Delta} \frac{1}{\varepsilon} E_t^\varepsilon \int_u^T ds f_z(Z^\varepsilon(u)) E_u^\varepsilon \int_0^1 d\tau [F_x(X^\varepsilon(u^-) + \tau dY_d^\varepsilon(u), \xi^\varepsilon(s))] dY_d^\varepsilon(u).$$

Now, by a change of scale $s/\varepsilon^2 \rightarrow s$ and the use of (A3.1) and (A3.2) again, we see that this term is $O(\varepsilon)E_t^\varepsilon[Y_d^\varepsilon(t+\Delta) - Y_d^\varepsilon(t)]$, with probability 1.

Putting all the estimates together and canceling the “ $1/\varepsilon$ ” term on the right-hand side of (3.3) and the first term on the right-hand side of (3.4), we get (with probability 1)

$$(3.6) \quad \begin{aligned} E_t^\varepsilon f^\varepsilon(t+\Delta) - f^\varepsilon(t) &= O(\Delta) + O(\varepsilon)E_t^\varepsilon(Y_c^\varepsilon(t+\Delta) - Y_c^\varepsilon(t)) \\ &\quad + O(\varepsilon)E_t^\varepsilon(Y_d^\varepsilon(t+\Delta) - Y_d^\varepsilon(t)). \end{aligned}$$

Equation (3.6) yields the quasimartingale and the uniformly (in ε) bounded conditional variation properties on each interval $[0, T]$ for $f^\varepsilon(\cdot)$. By letting $f(z) = z$ and noting that $z_1^\varepsilon(t) = O(\varepsilon)$, with probability 1, we see that the theorem holds for the $\{Z^\varepsilon(\cdot)\}$ component. Hence, it also holds for $\{X^\varepsilon(\cdot)\}$, since $\sup_\varepsilon E(Y_0^\varepsilon(t) + Y_1^\varepsilon(t)) < \infty$ for each t and

$$X^\varepsilon(t) = (Z^\varepsilon(t) + Z_1^\varepsilon(t)) + Y^\varepsilon(t) - Z_1^\varepsilon(t). \quad \text{Q.E.D.}$$

We summarize (3.3) to (3.6) for future use:

$$\begin{aligned}
(3.7) \quad & E_t^\varepsilon f^\varepsilon(t+\Delta) - f^\varepsilon(t) \\
&= \int_t^{t+\Delta} E_t^\varepsilon f_z(Z^\varepsilon(u)) G(X^\varepsilon(u), \xi^\varepsilon(u)) du \\
&\quad + \frac{1}{\varepsilon^2} E_t^\varepsilon \int_t^{t+\Delta} du \int_u^T f_{zz}(Z^\varepsilon(u)) E_u^\varepsilon F(X^\varepsilon(u), \xi^\varepsilon(s)) ds F(X^\varepsilon(u), \xi^\varepsilon(u)) \\
&\quad + \frac{1}{\varepsilon^2} E_t^\varepsilon \int_t^{t+\Delta} du E_u^\varepsilon \int_u^T f_z(Z^\varepsilon(u)) F_x(X^\varepsilon(u), \xi^\varepsilon(s)) ds F(X^\varepsilon(u), \xi^\varepsilon(u)) \\
&\quad + O(\Delta) + O(\varepsilon)E_t^\varepsilon(Y_c^\varepsilon(t+\Delta) - Y_c^\varepsilon(t)) + O(\varepsilon)E_t^\varepsilon(Y_d^\varepsilon(t+\Delta) - Y_d^\varepsilon(t)).
\end{aligned}$$

Theorem 3.1 implies that $\{X^\varepsilon(\cdot) - Z_1^\varepsilon, Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot), Z^\varepsilon(\cdot) + Z_1^\varepsilon(\cdot)\}$ are quasimartingales with uniformly bounded conditional variation on each interval $[0, T]$ and their probability laws are tight on $D^4[0, \infty]$ in the pseudopath topology. Hence, the same tightness in the pseudopath topology on $D^4[0, \infty]$ holds for the laws of $\{\bar{X}^\varepsilon(\cdot)\}$. In the next theorem, we choose and work with a weakly convergent subsequence, also indexed by ε and with the limit denoted by $\bar{X}(\cdot) = (X(\cdot), Y_0(\cdot), Y_1(\cdot), Z(\cdot))$. Clearly, the sample functions $Y_i(\cdot)$ can be taken to be nondecreasing elements of $D[0, \infty)$.

Although $Y_i^\varepsilon(0) = 0$, the limits $Y_i(\cdot)$ might not have value zero at $t = 0$. To account for this possible jump in the integrals, we use the normalization $Y_i(0^-) = 0$ in defining integrals with respect to the $Y_i(\cdot)$, so that $dY_i(0)$ includes this possible jump.

Since the pseudopath topology is equivalent to convergence in measure, for almost all ω, t ,

$$(3.8) \quad X(t) = Z(t) + Y_0(t) - Y_1(t).$$

In fact, (3.8) holds also at all t at which the functions are continuous. In the next theorem, we obtain the stronger and more useful result that there is a Wiener process $w(\cdot)$ such that $\bar{X}(\cdot)$ is nonanticipative with respect to $w(\cdot)$ and $(X(\cdot), Y_0(\cdot), Y_1(\cdot))$ satisfies (1.1) for that $w(\cdot)$. The limits $Y_i(\cdot)$ would not be too useful were this not the case. We impose the following "ergodic" assumptions.

(A3.3) There is a continuous function $\bar{G}(\cdot)$ such that for each x ,

$$\frac{1}{N} \int_u^{u+N} E_u G(x, \xi(s)) ds \xrightarrow{P} \bar{G}(x)$$

as u and N go to ∞ .

(A3.4) For g equal to either F or F_x and $T > u + N$,

$$E \sup_x \left| \int_{u+N}^T E_u g(x, \xi(s)) ds \right| \rightarrow 0,$$

as u, N, T go to ∞ .

(A3.5) There is a continuous function $\sigma(\cdot)$ such that for each x

$$\frac{1}{T_1} \int_u^{u+T_1} E_u F(x, \xi(\tau)) d\tau \int_\tau^{T+\tau} F(x, \xi(s)) ds \xrightarrow{P} \sigma^2(x)/2$$

as T, u and T_1 go to ∞ . Also, there is a continuous function $\bar{G}_0(\cdot)$ such that for each x

$$\frac{1}{T_1} \int_u^{u+T_1} E_u F(x, \xi(\tau)) d\tau \int_\tau^{T+\tau} F_x(x, \xi(s)) ds \xrightarrow{P} \bar{G}_0(x).$$

Remark. If $\xi(\cdot)$ is stationary, then

$$\sigma^2(x) = \int_{-\infty}^{\infty} EF(x, \xi(0))F(x, \xi(s)) ds,$$

$$\bar{G}_0(x) = \int_0^{\infty} EF(x, \xi(0))F_x(x, \xi(s)) ds.$$

The requirements in (A3.4) and (A3.5) are simply conditions on the rate of convergence as $\tau - u \rightarrow \infty$ of the conditional expectation of functions $g(\tau)$, of the noise data after time τ , given the data up to time u .

THEOREM 3.2. Assume (A3.1)–(A3.5) and let $\sup_\varepsilon E_x[Y_0^\varepsilon(t) + Y_1^\varepsilon(t)] < \infty$ for each $t < \infty$. Then $\{Z^\varepsilon(\cdot)\}$ is tight in the Skorokhod topology on $D[0, \infty)$ and any weak limit process is continuous w.p.1. Let $\{X^{\varepsilon_n}(\cdot), Y_0^{\varepsilon_n}(\cdot), Y_1^{\varepsilon_n}(\cdot), Z^{\varepsilon_n}(\cdot)\}$ converge weakly in $D^4[0, \infty)$, where we use the product topology obtained by using the pseudopath topology on the first three components and the Skorokhod topology on the last. Denote the limit

by $\bar{X}(\cdot) = (X(\cdot), Y_0(\cdot), Y_1(\cdot), Z(\cdot))$. There is a standard Wiener process $w(\cdot)$ such that $\bar{X}(\cdot)$ is nonanticipative with respect to $w(\cdot)$ and with probability 1

$$(3.9) \quad Z(t) = \int_0^t \bar{G}(X(s)) ds + \int_0^t \bar{G}_0(X(s)) ds + \int_0^t \sigma(X(s)) dw(s).$$

Also, for all t , with probability 1,

$$(3.10) \quad X(t) = Z(t) + Y_0(t) - Y_1(t).$$

Remark. We need not require that $X^\varepsilon(t) \in [0, \bar{B}]$ in this theorem. When a convergent subsequence indexed by ε is referred to below, we let ε range over a countable set.

Proof. We will do the proof under the assumption that the x -support of all functions is compact, and that the $Y_i^\varepsilon(\cdot)$ are uniformly bounded. The general case follows from this by taking appropriate limits on the bounds. This assumption implies that the $Z^\varepsilon(\cdot)$ are uniformly bounded. Hence we can also assume that the z -support of all functions is compact.

(a) *Tightness of $\{Z^\varepsilon(\cdot)\}$ in the Skorokhod topology.* Let $f(\cdot)$, $f_1^\varepsilon(\cdot)$ and $f^\varepsilon(\cdot)$ be defined as in Theorem 3.1. We use the perturbed test function method of [8] or [14] for proving tightness. Since $f_1^\varepsilon(t) = O(\varepsilon)$, with probability 1, Theorem 3.4 of [8] or Lemma 1 of [14] applied to the perturbed test function $f^\varepsilon(\cdot)$ yields the tightness of $\{f(Z^\varepsilon(\cdot))\}$ in $D[0, \infty)$ with the Skorokhod topology used, for each smooth $f(\cdot)$. Hence $\{Z^\varepsilon(\cdot)\}$ is tight on $D[0, \infty)$ in the Skorokhod topology.

(b) *The limit of $\{Z^\varepsilon(\cdot)\}$.* We will show that $Z(\cdot)$ is the solution to a particular martingale problem. Fix and work with a weakly convergent subsequence of $\{X^\varepsilon(\cdot), Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot), Z^\varepsilon(\cdot)\}$, also indexed by ε for simplicity (and not by ε_n). The first three components converge in the pseudopath topology and the last in the Skorokhod topology. Let $h(\cdot)$ be a bounded and continuous function. For $0 < k < \infty$ and $\Delta_j > 0$, $t_j \geq 0$, let us define the function $H(\cdot)$ with "averaged" arguments by

$$H(\varepsilon, \Delta_j, t_j, j \leq k) = h \left(\frac{1}{\Delta_j} \int_{t_j - \Delta_j}^{t_j} Y_i^\varepsilon(s) ds, i=0,1, \frac{1}{\Delta_j} \int_{t_j - \Delta_j}^{t_j} X^\varepsilon(s) ds, \frac{1}{\Delta_j} \int_{t_j - \Delta_j}^{t_j} Z^\varepsilon(s) ds, j \leq k \right).$$

Let t and s be such that $t_j \leq t < t + s$, for all j . We have from (3.7)

$$(3.11) \quad \lim_{\varepsilon} EH(\varepsilon, \Delta_j, t_j, j \leq k) \left[f^\varepsilon(t+s) - f^\varepsilon(t) - \int_t^{t+s} E_t^\varepsilon(T_1^\varepsilon(u) + T_2^\varepsilon(u) + T_3^\varepsilon(u)) du \right] = 0,$$

where

$$(3.12) \quad \begin{aligned} T_1^\varepsilon(u) &= f_z(Z^\varepsilon(u))G(X^\varepsilon(u), \xi^\varepsilon(u)), \\ T_2^\varepsilon(u) &= \frac{1}{\varepsilon^2} \int_u^T f_z(Z^\varepsilon(u))E_u^\varepsilon F_x(X^\varepsilon(u), \xi^\varepsilon(s)) ds F(X^\varepsilon(u), \xi^\varepsilon(u)), \\ T_3^\varepsilon(u) &= \frac{1}{\varepsilon^2} \int_u^T f_{zz}(Z^\varepsilon(u))E_u^\varepsilon F(X^\varepsilon(u), \xi^\varepsilon(s)) ds F(X^\varepsilon(u), \xi^\varepsilon(u)). \end{aligned}$$

Fix s . Let $\delta_\varepsilon \rightarrow 0$ such that $\varepsilon^2/\delta_\varepsilon \rightarrow 0$ as $\varepsilon \rightarrow 0$. Write $s = m_\varepsilon \delta_\varepsilon$ and suppose (without loss of generality) that the m_ε are integers. The limits of the terms in (3.11) are the same if the $f_1^\varepsilon(\cdot)$ components of the $f^\varepsilon(\cdot)$ are dropped (since they are $O(\varepsilon)$ with probability 1). We next replace the integrals $\int_t^{t+s} E_t^\varepsilon T_i^\varepsilon(u) du$ by the equivalent expression

$$(3.13) \quad E_t^\varepsilon \sum_{j=0}^{m_\varepsilon-1} \frac{1}{\delta_\varepsilon} \cdot \delta_\varepsilon \int_{t+j\delta_\varepsilon}^{t+(j+1)\delta_\varepsilon} E_{t+j\delta_\varepsilon}^\varepsilon T_i^\varepsilon(u) du.$$

We evaluate only the limit of (3.13) with $T_3^\varepsilon(\cdot)$, since the others are treated in essentially the same way.

The limit as $\varepsilon \rightarrow 0$ will be obtained by a sequence of substitutions, each being more convenient to evaluate. In the substitutions, we use the scale change, the ergodic assumptions (A3.3)–(A3.5), the tightness of $X^\varepsilon(\cdot)$ in the pseudopath topology (and the consequent upcrossing bounds), and the tightness of $Z^\varepsilon(\cdot)$ in the Skorokhod topology.

Rewrite (3.13) (with $i = 3$) as

$$(3.14) \quad E_t^\varepsilon \sum_{j=0}^{m_\varepsilon-1} \delta_\varepsilon \cdot \frac{1}{\delta_\varepsilon \cdot \varepsilon^2} \int_{t+j\delta_\varepsilon}^{t+j\delta_\varepsilon+\delta_\varepsilon} E_{t+j\delta_\varepsilon}^\varepsilon f_{zz}(Z^\varepsilon(u)) du \cdot \int_0^T F(X^\varepsilon(u), \xi^\varepsilon(s)) ds F(X^\varepsilon(u), \xi^\varepsilon(u)).$$

Via a scale change, write (3.14) as

$$(3.15) \quad E_t^\varepsilon \sum_{j=0}^{m_\varepsilon-1} \delta_\varepsilon \cdot \frac{\varepsilon^2}{\delta_\varepsilon} \int_{s_j^\varepsilon}^{s_{j+1}^\varepsilon} E_{t+j\delta_\varepsilon}^\varepsilon f_{zz}(Z^\varepsilon(\varepsilon^2 u)) F(X^\varepsilon(\varepsilon^2 u), \xi(u)) du \cdot \int_u^{T/\varepsilon^2} F(X^\varepsilon(\varepsilon^2 u), \xi(s)) ds,$$

where $s_j^\varepsilon = (t - j\delta_\varepsilon)/\varepsilon^2$. Note that $E_{t+j\delta_\varepsilon}^\varepsilon$ is the expectation conditioned on $\{Y_i^\varepsilon(s), i = 0, 1, s \leq t + j\delta_\varepsilon, \xi(s), s \leq s_j^\varepsilon\}$.

Let $\{B_i^\delta\}$ be disjoint intervals covering the range of $X^\varepsilon(\cdot)$ and with diameter less than $\delta > 0$, and let x_i denote an arbitrary point in B_i^δ . Recall that $X^\varepsilon(\cdot) + Z_1^\varepsilon(\cdot)$ is a quasimartingale with uniformly bounded (with probability 1) conditional variation. Thus the uncrossings result (2.2), and the fact that $Z_1^\varepsilon(\cdot) = O(\varepsilon)$, w.p.1 imply that the fraction of the number of intervals in the set of intervals $\{[t + j\delta_\varepsilon, t + j\delta_\varepsilon + \delta_\varepsilon], j \leq m_\varepsilon\}$ for which $\sup_{u \leq \delta_\varepsilon} |X^\varepsilon(t + j\delta_\varepsilon + u) - X^\varepsilon(t + j\delta_\varepsilon)| \geq \delta/2$ holds goes to zero in probability as $\varepsilon \rightarrow 0$. The facts above in this paragraph, (A3.4) and the tightness of $Z^\varepsilon(\cdot)$ in the Skorokhod topology imply that the limit of (3.16) as $\varepsilon \rightarrow \infty$ and then $\delta \rightarrow 0$ is the same as the limit of (3.15) as $\varepsilon \rightarrow 0$:

$$(3.16) \quad E_t^\varepsilon \sum_{j=0}^{m_\varepsilon-1} \delta_\varepsilon \sum_i I_{\{X^\varepsilon(t+j\delta_\varepsilon) \in B_i^\delta\}} \cdot \frac{\varepsilon^2}{\delta_\varepsilon} \int_{s_j^\varepsilon}^{s_{j+1}^\varepsilon} du f_{zz}(Z^\varepsilon(t + j\delta_\varepsilon)) E_{t+j\delta_\varepsilon}^\varepsilon F(x_i, \xi(u)) \int_u^{T/\varepsilon^2} F(x_i, \xi(s)) ds.$$

Assumption (A3.5) implies that the limits of (3.17) as $\varepsilon \rightarrow 0$ and then $\delta \rightarrow 0$ are the same as those of (3.16):

$$(3.17) \quad E_t^\varepsilon \sum_{j=0}^{m_\varepsilon-1} \delta_\varepsilon \sum_i I_{\{X^\varepsilon(t+j\delta_\varepsilon) \in B_i^\delta\}} \frac{\sigma^2(x_i)}{2} f_{zz}(Z^\varepsilon(t + j\delta_\varepsilon)).$$

The upcrossing bounds for $X^\varepsilon(\cdot)$ and the tightness of $Z^\varepsilon(\cdot)$ in the Skorokhod topology imply that the limit of (3.18) as $\varepsilon \rightarrow 0$ is also the limit of (3.17), as $\varepsilon \rightarrow 0$, then $\delta \rightarrow 0$:

$$(3.18) \quad E_t^\varepsilon \int_t^{t+s} \frac{\sigma^2(X^\varepsilon(u))}{2} f_{zz}(Z^\varepsilon(u)) du.$$

Define the operator $A(X)$ (acting on twice differentiable functions with compact support) by

$$(3.19) \quad A(x)f(z) = f_z(z)\bar{G}(x) + f_z(z)\bar{G}_0(x) + f_{zz}(z)\sigma^2(x)/2.$$

Repeating the procedure leading to (3.18) for the terms in (3.13) with $T_1^\varepsilon(\cdot)$ and $T_2^\varepsilon(\cdot)$ yields

$$(3.20) \quad \lim_{\varepsilon} EH(\varepsilon, \Delta_j, t_j, j \leq k) \left[f(Z^\varepsilon(t+s)) - f(Z^\varepsilon(t)) - \int_t^{t+s} A(X^\varepsilon(u))f(Z^\varepsilon(u)) du \right] = 0.$$

The sequence $Z^\varepsilon(\cdot)$ converges in the Skorokhod topology on $D[0, \infty)$, but we have not yet proved the continuity of the limit $Z(\cdot)$. Thus, there might be a set (at most countable) \hat{I} of t -points for which $P\{Z(t) \neq Z(t^-)\} > 0$. Let t and $t+s$ not be in \hat{I} . Recall that $\{X^\varepsilon(\cdot), Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot)\}$ converge in the pseudopath topology, and that convergence in this topology is equivalent to convergence in measure. Thus, taking limits in (3.20), we have

$$(3.21) \quad EH(\Delta_j, t_j, j \leq k) \left[f(Z(t+s)) - f(Z(t)) - \int_t^{t+s} A(X(u))f(Z(u)) du \right] = 0$$

where the function $H(\Delta_j, t_j, j \leq k)$ is defined to be just $H(\varepsilon, \Delta_j, t_j, j \leq k)$ with all arguments replaced by their limits as $\varepsilon \rightarrow 0$.

Owing to the arbitrariness of k, t_j, Δ_j and $h(\cdot)$ and of the points s and $t+s$ (not in \hat{I}), (3.21) implies that for each smooth $f(\cdot)$, the process defined by

$$f(Z(t)) - \int_0^t A(X(u))f(Z(u)) du \equiv M_f(t)$$

is a martingale with respect to the sequence of σ -algebras generated by $\{X(s), Y_0(s), Y_1(s), Z(s), s \leq t\}$. The fact that the operator $A(x)$ is "local" implies the continuity of $Z(\cdot)$. (See a proof of a related continuity result in [8], [14].)

If $f(z) = z$, then the quadratic variation of $M_f(\cdot)$ is $\int_0^t \sigma^2(X(u)) du$. Owing to these facts we can construct a standard Wiener process $w(\cdot)$ such that $X(\cdot), Z(\cdot), Y_0(\cdot)$ and $Y_1(\cdot)$ are nonanticipative with respect to $w(\cdot)$ and

$$(3.22) \quad Z(t) = \int_0^t [\bar{G}(X(u)) + \bar{G}_0(X(u))] du + \int_0^t \sigma(X(u)) dw(u).$$

It follows from the continuity of $Z(\cdot)$ and the nondecreasing property of the $Y_i(\cdot)$ that we can define the limit $X(\cdot)$ of $\{X^\varepsilon(\cdot)\}$ by (3.10). Q.E.D.

4. The discrete parameter problem. The discrete parameter analogue of Theorems 3.1 and 3.2 is obtained in a way very similar to the schemes used in those theorems, and we discuss only a few of the details for one discrete parameter form. Just as for the continuous parameter case, the general ideas are applicable to a much broader class of processes than used here. Define $\{X_n^\varepsilon\}$ by $X_0^\varepsilon = x$ and

$$(4.1) \quad X_{n+1}^\varepsilon = X_n^\varepsilon + \varepsilon G(X_n^\varepsilon, \xi_n^\varepsilon) + \sqrt{\varepsilon} F(X_n^\varepsilon, \xi_n^\varepsilon) + \delta Y_n^\varepsilon,$$

where we define $\delta Y_n^\varepsilon = \delta Y_{0n}^\varepsilon - \delta Y_{1n}^\varepsilon$ and $\delta Y_{in}^\varepsilon \geq 0$. Let E_n^ε denote the expectation conditioned on $\{X_j^\varepsilon, j \leq n, \delta Y_{0j}^\varepsilon, \delta Y_{1j}^\varepsilon, \xi_j^\varepsilon, j < n\}$. Define the processes $Y_i^\varepsilon(\cdot)$ by $Y_i^\varepsilon(t) = \sum_{j=0}^{n-1} \delta Y_{ij}^\varepsilon$, $i=0, 1$, and $X^\varepsilon(t) = X_n^\varepsilon$ for $t \in [n\varepsilon, (n+1)\varepsilon)$. Define $Z_0^\varepsilon = 0$ and $Z_{n+1}^\varepsilon = Z_n^\varepsilon + \varepsilon G(X_n^\varepsilon, \xi_n^\varepsilon) + \sqrt{\varepsilon} F(X_n^\varepsilon, \xi_n^\varepsilon)$. Let $Z^\varepsilon(\cdot)$ denote the continuous parameter interpolation. We will use the following.

(A4.1) $\sup_{\varepsilon} E(Y_0^\varepsilon(t) + Y_1^\varepsilon(t)) < \infty$ for each t . $G(\cdot, \cdot)$, $F(\cdot, \cdot)$ and $F_x(\cdot, \cdot)$ are bounded and measurable and the latter two functions are continuous in x , uniformly in ξ .

(A4.2) For each x , $EF(x, \xi_n^e) = 0$. There is a $K < \infty$ such that for all N and $n \leq N$,

$$(4.2) \quad \sup_{n, \varepsilon, x} \left| \sum_{j=n}^N E_n^e g(x, \xi_j^e) \right| \leq K \quad \text{with probability 1,}$$

where g equals either F or F_x .

THEOREM 4.1. Assume (A4.1) and (A4.2). Then (possibly changing their values by at most $O(\sqrt{\varepsilon})$) $\{X^\varepsilon(\cdot), Y_i^\varepsilon(\cdot), i = 0, 1\}$ is a quasimartingale with conditional variation uniformly bounded (with probability 1) in ε on each interval $[0, T]$.

Remarks on the proof. The proof is very similar to that of Theorem 3.1, and only a few remarks will be made. For a smooth test function $f(\cdot)$ and sufficiently large N , define the "perturbation"

$$f_{1n}^\varepsilon = \sqrt{\varepsilon} \sum_{j=n}^N E_n^e f_z(Z_n^\varepsilon) F(X_n^\varepsilon, \xi_j^\varepsilon) = O(\sqrt{\varepsilon}) \quad \text{with probability 1.}$$

Define $f_n^\varepsilon = f(Z_n^\varepsilon) + f_{1n}^\varepsilon$.

It can be shown that

$$E_n^\varepsilon f_{n+1}^\varepsilon - f_n^\varepsilon = O(\varepsilon) + O(\sqrt{\varepsilon}) E_n^\varepsilon |\delta Y_n^\varepsilon|.$$

Letting $f(z) = z$ yields the desired conditional variation result, since $f_{1n}^\varepsilon = O(\sqrt{\varepsilon})$ and $\sup_\varepsilon E(Y_0^\varepsilon(T) + Y_1^\varepsilon(T)) < \infty$.

Theorem 3.2 can also be carried over to the discrete parameter case. We will use the following conditions.

(A4.3) $G(\cdot, \xi)$ is continuous in x , uniformly in ξ . There is a continuous $\bar{G}(\cdot)$ such that for each x

$$\frac{1}{N} \sum_n^{n+N} E_n^\varepsilon G(x, \xi_j^\varepsilon) \xrightarrow{P} \bar{G}(x)$$

as n and N go to ∞ .

(A4.4) There are continuous $R(j, x)$ and $R_0(j, x)$ such that for each x

$$\begin{aligned} \frac{1}{N} \sum_{n=m}^{m+N} E_m^\varepsilon F(x, \xi_{n+j}^\varepsilon) F(x, \xi_n^\varepsilon) &\xrightarrow{P} R(j, x), \\ \frac{1}{N} \sum_{n=m}^{m+N} E_m^\varepsilon F_x(x, \xi_{n+j}^\varepsilon) F(x, \xi_n^\varepsilon) &\xrightarrow{P} R_0(j, x), \end{aligned}$$

as m, N and $n - m$ go to ∞ .

(A4.5) For g equal to either F or F_x ,

$$E \sup_x \left| \sum_{n=N_1}^N E_n^\varepsilon g(x, \xi_j^\varepsilon) \right| \rightarrow 0$$

as N, n and N_1 go to ∞ (with $N > n + N_1$).

Define

$$\sigma^2(x) = R(0, x) + 2 \sum_1^\infty R(j, x) = \sum_{-\infty}^\infty R(j, x),$$

$$\bar{G}_0(x) = \sum_1^\infty R_0(j, x).$$

A proof parallel to that of Theorem 3.2 yields Theorem 4.2.

THEOREM 4.2. Assume (A4.1)–(A4.5). Then the conclusions of Theorem 3.2 hold for the model (4.1).

5. Auxiliary results. In this section, we obtain some estimates which will be useful in § 6, for the proofs of the convergence of the costs $V_0^\varepsilon(x, Y_0^\varepsilon, Y_1^\varepsilon)$ to either $V_0(x, Y_0, Y_1)$ or $V(x)$. We will show, for several reasonable classes of control policies, that $\sup_\varepsilon E|Y_i^\varepsilon(t)|^k < \infty$ for each $k > 0$ and $t < \infty$. This implies the uniform integrability property needed in the next section.

The symbol τ_ε will denote a stopping time with respect to either of the “data” σ -algebras $B\{\xi^\varepsilon(s), s \leq t\} \equiv B_t^\varepsilon$ or $B\{\xi_n^\varepsilon, \varepsilon n < t\} \equiv B_t^\varepsilon$ depending on the case, and we write $E_{\tau_\varepsilon}^\varepsilon$ and $P_{\tau_\varepsilon}^\varepsilon$ for the expectation and probability, conditioned on the data up to time τ_ε .

THEOREM 5.1. Assume either (A3.1), (A3.2) or (A4.1), (A4.2). Let $Q_\varepsilon(\cdot)$ and $Q_{\varepsilon n}$ be bounded and B_t^ε measurable (for $\varepsilon n < t$, in the latter case). Define $X^\varepsilon(\cdot)$ and X_n^ε by

$$(5.1a) \quad dX^\varepsilon = [G(X^\varepsilon, \xi^\varepsilon) + F(X^\varepsilon, \xi^\varepsilon)/\varepsilon + Q_\varepsilon/\varepsilon] dt,$$

$$(5.1b) \quad X_{n+1}^\varepsilon = X_n^\varepsilon + \varepsilon G(X_n^\varepsilon, \xi_n^\varepsilon) + \sqrt{\varepsilon} F(X_n^\varepsilon, \xi_n^\varepsilon) + \sqrt{\varepsilon} Q_{\varepsilon n}.$$

Define $Z^\varepsilon(\cdot)$ as in § 3 or 4 (continuous and discrete parameters case, respectively). For integer k and $t < \infty$, there are $\infty > K_k(t) \rightarrow 0$ as $t \rightarrow 0$ such that (for small $\varepsilon > 0$)

$$(5.2) \quad E \sup_{s \leq t} |Z^\varepsilon(\tau_\varepsilon + s) - Z^\varepsilon(\tau_\varepsilon)|^{2k} \leq K_{2k}(t)$$

for all finite (with probability 1) τ_ε .

Remark. The proof will treat only the continuous parameter case, since the “discrete parameter” details are similar.

Proof. A perturbed test function method will be used. For arbitrary $T < \infty$ and $t \leq T$, define the processes

$$(5.2') \quad f_{2k}^\varepsilon(t) = \int_t^T 2kZ^\varepsilon(t)^{2k-1} E_t^\varepsilon F(X^\varepsilon(t), \xi^\varepsilon(s)) ds / \varepsilon = O(\varepsilon) |Z^\varepsilon(t)|^{2k-1}.$$

The right-hand equality is a consequence of (A3.2) and a scale change. We carry out the proof only for $\tau_\varepsilon = 0$, $G(\cdot) = 0$ for simplicity. The proof of the other cases is essentially the same.

By analogy with the procedure that led to (3.4) and (3.7), we have

$$(5.3) \quad E_t^\varepsilon[Z^\varepsilon(t+s)^{2k} + f_{2k}^\varepsilon(t+s)] - [Z^\varepsilon(t)^{2k} + f_{2k}^\varepsilon(t)] = E_t^\varepsilon \int_t^{t+s} c_{2k}^\varepsilon(u) du,$$

where

$$\begin{aligned} c_{2k}^\varepsilon(u) &= \frac{1}{\varepsilon^2} \int_u^T 2k[(2k-1)Z^\varepsilon(u)^{2k-2} E_u^\varepsilon F(X^\varepsilon(u), \xi^\varepsilon(s)) ds] F(X^\varepsilon(u), \xi^\varepsilon(u)) \\ &\quad + \frac{1}{\varepsilon^2} \int_u^T 2kZ^\varepsilon(u)^{2k-1} E_u^\varepsilon F_x(X^\varepsilon(u), \xi^\varepsilon(s)) ds [Q^\varepsilon(u) + F(X^\varepsilon(u), \xi^\varepsilon(u))] \\ &= O(1) \int_{u/\varepsilon^2}^{T/\varepsilon^2} Z^\varepsilon(u)^{2k-2} E_u^\varepsilon F(X^\varepsilon(u), \xi(s)) ds \\ &\quad + O(1) \int_{u/\varepsilon^2}^{T/\varepsilon^2} Z^\varepsilon(u)^{2k-1} E_u^\varepsilon F_x(X^\varepsilon(u), \xi(s)) ds. \end{aligned}$$

By (A3.2), we can write this expression as

$$(5.4) \quad Z^\varepsilon(u)^{2k-2} \hat{C}_{2k}^\varepsilon(u) + Z^\varepsilon(u)^{2k-1} C_{2k}^\varepsilon(u) = O(1)(|Z^\varepsilon(u)|^{2k-2} + |Z^\varepsilon(u)|^{2k-1}),$$

where the \bar{C}_{2k}^ε and C_{2k}^ε are defined in the obvious way and are bounded.

By (5.3), (5.4) and the bound on $f_{2k}^\varepsilon(\cdot)$, there are $\infty > K_{2k}(\tau) \rightarrow 0$ as $\tau \rightarrow 0$ and constants K'_{2k} such that, for $t \leq \tau$,

$$E[Z^\varepsilon(t)^{2k} + f_{2k}^\varepsilon(t)] \leq K'_{2k} \int_0^t E[1 + |Z^\varepsilon(s)|^{2k-1}] ds \leq K_{2k}(\tau).$$

Define

$$M_{2k}^\varepsilon(t) = [Z^\varepsilon(t)^{2k} + f_{2k}^\varepsilon(t)] - \int_0^t [Z^\varepsilon(s)^{2k-2} \hat{C}_{2k}^\varepsilon(s) + Z^\varepsilon(s)^{2k-1} C_{2k}^\varepsilon(s)] ds.$$

By (5.3), $M_{2k}^\varepsilon(\cdot)$ is a martingale. From the above estimates there are functions $K''_{2k}(t) \rightarrow 0$ as $t \rightarrow 0$ such that (use Doob's inequality [15, Thm. 7.3.4])

$$(5.5) \quad E \sup_{s \leq t} |M_{2k}^\varepsilon(s)|^2 \leq 4E|M_{2k}^\varepsilon(t)|^2 \leq K''_{2k}(t).$$

By the bound on $f_{2k}^\varepsilon(\cdot)$ and (5.5), we get (5.2) for $\tau_\varepsilon = 0$. Q.E.D.

THEOREM 5.2. Assume the conditions of Theorem 5.1, except with $Q_\varepsilon(t) = 0$ (or $Q_{\varepsilon n} = 0$) for $t \geq \tau_\varepsilon$. Given $\Delta_0 > 0$, there are $\delta_0 > 0$ and $T_0 > 0$ such that for all small ε

$$(5.6) \quad P_{\tau_\varepsilon}^\varepsilon \{ \sup_{t \leq T_0} |Z^\varepsilon(\tau_\varepsilon + t) - Z^\varepsilon(\tau_\varepsilon)| \geq \Delta_0 \} \leq 1 - \delta_0.$$

Proof. The result follows from Theorem 5.1.

Recall the definition of \bar{B} in § 1. We now describe some classes of controls and obtain some estimates of path excursions under the controls. Let L and U be numbers such that $0 \leq L < U \leq \bar{B}$. Define

$$(5.7) \quad \begin{aligned} dY_0^\varepsilon(t) &= [F(X^\varepsilon(t), \xi^\varepsilon(t))/\varepsilon + G(X^\varepsilon(t), \xi^\varepsilon(t))]^- dt I_{\{X^\varepsilon(t)=L\}}, \\ dY_1^\varepsilon(t) &= [F(X^\varepsilon(t), \xi^\varepsilon(t))/\varepsilon + G(X^\varepsilon(t), \xi^\varepsilon(t))]^+ dt I_{\{X^\varepsilon(t)=U\}}. \end{aligned}$$

For obvious reasons, we call this the (L, U) -barrier control (following the usage in [4]). Define the discrete parameter barrier policy in the analogous way: the $dY_i^\varepsilon(\cdot)$ are just large enough to keep $X^\varepsilon(\cdot)$ in the set $[L, U]$. The dY_i^ε/dt will be one of the candidates for the Q_ε in Theorem 5.1.

Let $\Delta_0 < \bar{B}/2$. We define a specific control policy—called the (\bar{B}, Δ_0) -policy—as follows. Continuous parameter case: If $X^\varepsilon(t^-) = \bar{B}$, immediately set $Y_1^\varepsilon(t) = Y_1^\varepsilon(t^-) + \Delta_0$ and $X^\varepsilon(t) = \bar{B} - \Delta_0$. Also, $Y_0^\varepsilon(\cdot)$ will increase just fast enough to keep $X^\varepsilon(t) \geq 0$, i.e., $Y_0^\varepsilon(\cdot)$ is given by (5.7) for $L = 0$. Use the analogous definitions for the discrete parameter process. The (\bar{B}, Δ_0) -control has some nice properties which render it useful for the discussion in the next section.

THEOREM 5.3. Let the $Y_i^\varepsilon(\cdot)$ be the control values given by the (Δ_0, \bar{B}) -policy and assume either (A3.1), (A3.2) or (A4.1), (A4.2). For each t and integer k (the τ_ε are random times),

$$(5.8) \quad \sup_{\varepsilon, \tau_\varepsilon} E|Y_i^\varepsilon(\tau_\varepsilon + t) - Y_i^\varepsilon(\tau_\varepsilon)|^k < \infty.$$

Remark. Owing to the conditioning in (5.6), the estimates for Y_i^ε are proved almost as if the “return” process from the point $(\bar{B} - \Delta_0)$ to (either \bar{B} or $\bar{B} - 2\Delta_0$), then back to $\bar{B} - \Delta_0$, etc., were constructed from a Bernoulli sequence.

Proof. We prove the continuous parameter case only, and $i = 1$. The case $i = 0$ is treated by an argument based on Theorems 5.2 and 5.4. Without loss of generality set $\tau_\varepsilon = 0$.

Define the stopping times: $\sigma_0^\varepsilon = \min \{t \geq 0: X^\varepsilon(t) = \bar{B} - \Delta_0\}$ and for $i > 0$, $\rho_i^\varepsilon = \min \{t > \sigma_{i-1}^\varepsilon: |X^\varepsilon(t) - (\bar{B} - \Delta_0)| \geq \Delta_0\}$, $\sigma_i^\varepsilon = \min \{t \geq \rho_i^\varepsilon: X^\varepsilon(t) = \bar{B} - \Delta_0\}$. We will estimate the k th moment of $N^\varepsilon(t) = \max \{i: \sigma_i^\varepsilon \leq t\}$. Define the $\{0, 1\}$ valued random variable U_i^ε as follows. With T_0 as in Theorem 5.2, set

$$U_i^\varepsilon = \begin{cases} 1 & \text{if } \rho_i^\varepsilon - \sigma_{i-1}^\varepsilon \geq T_0 \quad (\text{"success"}), \\ 0 & \text{if } \rho_i^\varepsilon - \sigma_{i-1}^\varepsilon < T_0 \quad (\text{"failure"}). \end{cases}$$

Let N_i^ε denote the number of successive passages of $X^\varepsilon(\cdot)$ from $\bar{B} - \Delta_0$ to either \bar{B} or $\bar{B} - 2\Delta_0$ which are failures, after the i th success. Then

$$N^\varepsilon(t) \leq \frac{t}{T_0} + \sum_0^{t/T_0-1} N_i^\varepsilon.$$

There are $K_k < \infty$ such that

$$N^\varepsilon(t)^k \leq K_k(t/T_0)^k + K_k(t/T_0)^k \sum_0^{t/T_0-1} (N_i^\varepsilon)^k.$$

We will bound $E(N_i^\varepsilon)^k$. Let $\sigma_{s_i}^\varepsilon$ denote the return time of $X^\varepsilon(\cdot)$ to $\bar{B} - \Delta_0$ immediately after the i th success. Then, by Theorem 5.2,

$$\begin{aligned} P_{\sigma_{s_i}^\varepsilon}^\varepsilon \{N_i^\varepsilon \geq n\} &= P_{\sigma_{s_i}^\varepsilon}^\varepsilon \{\sigma_{s_i+j+1}^\varepsilon - \sigma_{s_i+j}^\varepsilon < T_0, \text{ for all } j < n\} \\ &\leq (1 - \delta_0)^{n-1}. \end{aligned}$$

This yields $E(N_i^\varepsilon)^k \leq (\text{constant})/\delta_0$, and the proof is concluded, since $Y_1^\varepsilon(t) \leq \Delta_0 N^\varepsilon(t)$. Q.E.D.

THEOREM 5.4. Assume either (A3.1), (A3.2) or (A4.1), (A4.2) and let the $Y_i^\varepsilon(\cdot)$ be the control values associated with the (L, U) -barrier policy. Then for each t

$$(5.9) \quad \sup_{\varepsilon, T} [E(Y_0^\varepsilon(t+T) - Y_0^\varepsilon(T))^2 + E(Y_1^\varepsilon(t+T) - Y_1^\varepsilon(T))^2] < \infty.$$

Proof. Again, we do only some of the details for $Y_0^\varepsilon(\cdot)$, and for the continuous parameter case. For notational simplicity, we only present the case $G(\cdot) = 0$. Denote the initial time by t_0 and let $\Delta_0 < (U - L)/2$. Define the stopping times

$$\sigma_0^\varepsilon = \min \{t \geq t_0: X^\varepsilon(t) = L\}$$

and, for $i = 1, 2, \dots$,

$$\sigma_i^\varepsilon = \min \{t > \rho_i^\varepsilon: X^\varepsilon(t) = L\}, \quad \rho_i^\varepsilon = \min \{t > \sigma_{i-1}^\varepsilon: X^\varepsilon(t) = L + \Delta_0\},$$

with the convention that the min over an empty set is infinite. All the needed estimates can be shown to be uniform in t_0 and we set $t_0 = 0$ for simplicity.

We can write (and simultaneously define $\hat{Z}^\varepsilon(\cdot)$)

$$(5.10) \quad \begin{aligned} \sum_i [X^\varepsilon(\rho_{i+1}^\varepsilon \cap t) - X^\varepsilon(\sigma_i^\varepsilon \cap t)] &= \sum_i [Z^\varepsilon(\rho_{i+1}^\varepsilon \cap t) - Z^\varepsilon(\sigma_i^\varepsilon \cap t)] + Y_0^\varepsilon(t) \\ &= \hat{Z}^\varepsilon(t) + Y_0^\varepsilon(t). \end{aligned}$$

The mean square value of the term on the left of (5.10) is bounded above by Δ_0^2 times the second moment of the number of i for which $\rho_i^\varepsilon \leq t$. By an argument very similar to that used in Theorem 5.3, this can be shown to be bounded uniformly in ε for each t .

Define $M^\varepsilon(t) = Z_1^\varepsilon(t) - \int_0^t C_1^\varepsilon(s) ds$, where $Z_1^\varepsilon(\cdot)$ is defined in Theorem 3.1. Equivalently, it is the $f_1^\varepsilon(\cdot)$ of (5.2'). The $C_1^\varepsilon(\cdot)$ is defined in (5.4). The $\hat{C}_1^\varepsilon(\cdot)$ defined in (5.4) does not appear here, since $2k = 1$. Define $N^\varepsilon(\cdot)$ as in the proof of Theorem 5.3. Then, since $M^\varepsilon(\cdot)$ is a martingale, on the "interval where $dY_1^\varepsilon(\cdot) = 0$ " we have

$$\begin{aligned} E \left(\sum_i [M^\varepsilon(\rho_{i+1}^\varepsilon \cap t) - M^\varepsilon(\sigma_i^\varepsilon \cap t)] \right)^2 &= \sum_i E |M^\varepsilon(\rho_{i+1}^\varepsilon \cap t) - M^\varepsilon(\sigma_i^\varepsilon \cap t)|^2 \\ (5.11) \quad &= O(1) E (\sup_{s \leq t} |Z^\varepsilon(s)|^2 + 1) N^\varepsilon(t) \\ &= O(1) E^{1/2} (\sup_{s \leq t} |Z^\varepsilon(s)|^4 + 1) E^{1/2} |N^\varepsilon(t)|^2 \\ &\leq K_1 < \infty. \end{aligned}$$

The last inequality follows from Theorems 5.1 and 5.3. Since $C_1^\varepsilon(\cdot) = O(1)$, $Z_1^\varepsilon(\cdot) = O(\varepsilon)$, and $\sup_\varepsilon E(N^\varepsilon(t))^2 < \infty$, there are $K_2 < \infty$, $K_3 < \infty$, such that the left side of (5.11) can be bounded below by

$$K_2 E \left(\sum_i [Z^\varepsilon(\rho_{i+1}^\varepsilon \cap t) - Z^\varepsilon(\sigma_i^\varepsilon \cap t)] \right)^2 - K_3 = K_2 E |\hat{Z}^\varepsilon(t)|^2 - K_3.$$

The proof that $\sup E |\hat{Z}^\varepsilon(t)|^2 < \infty$ follows from these inequalities. Q.E.D.

6. Convergence of the costs and controls. In [1], it is shown that there are $0 \leq L^* < U^* < \infty$ such that (under appropriate conditions) the optimal control for (1.1) is an (L^*, U^*) -barrier control. We assume that \bar{B} is large enough so that $U^* \leq \bar{B}$. Let $\bar{Y}_i(\cdot)$, $i = 0, 1$, denote this optimal control. The set of increments of the "local time" control processes $\{\bar{Y}_i(n+1) - \bar{Y}_i(n), i = 0, 1, n < 1\}$ are uniformly integrable. Let $\bar{Y}_i^\varepsilon(\cdot)$, $i = 0, 1$, denote the (L^*, U^*) -barrier control for $X^\varepsilon(\cdot)$ (continuous or discrete time). The following theorem says that the optimal control for $X(\cdot)$ is "nearly" optimal for $X^\varepsilon(\cdot)$.

THEOREM 6.1. Assume either (A3.1)–(A3.5) or (A4.1)–(A4.5). Let (1.1) have a unique weak sense solution for the (L^*, U^*) -barrier policy, and let this policy be optimal. Then $\{X^\varepsilon(\cdot), \bar{Y}_0^\varepsilon(\cdot), \bar{Y}_1^\varepsilon(\cdot)\} \Rightarrow (X(\cdot), \bar{Y}_0(\cdot), \bar{Y}_1(\cdot))$ in the pseudopath topology, and there is a Wiener process $w(\cdot)$ such that $(X(\cdot), \bar{Y}_0(\cdot), \bar{Y}_1(\cdot))$ is nonanticipative with respect to $w(\cdot)$, and (1.1) holds. Also, as $\varepsilon \rightarrow 0$,

$$(6.1) \quad V_0^\varepsilon(x, \bar{Y}_0^\varepsilon, \bar{Y}_1^\varepsilon) \rightarrow V_0(x, \bar{Y}_0, \bar{Y}_1) = V(x).$$

In addition, for $\delta > 0$, let $\hat{Y}_0^\varepsilon(\cdot), \hat{Y}_1^\varepsilon(\cdot)$ be δ -optimal policies for $X^\varepsilon(\cdot)$ such that the set (6.2)

$$(6.2) \quad \{\hat{Y}_i^\varepsilon(n+1) - \hat{Y}_i^\varepsilon(n), \varepsilon > 0, n < \infty\}$$

is uniformly integrable. Then

$$(6.3) \quad \delta + \liminf_{\varepsilon} V^\varepsilon(x) \geq \liminf_{\varepsilon} V_0^\varepsilon(x, \hat{Y}_0^\varepsilon, \hat{Y}_1^\varepsilon) \geq V(x).$$

Remark on (6.2). The uniform integrability condition on (6.2) is used basically to assure that the cost associated with the limit process is the limit of the costs associated with $X^\varepsilon(\cdot)$. We have not been able to prove the theorem without this condition, unless all cost terms are positive (see Theorem 6.2).

The uniform integrability condition holds for a wide variety of control processes, and the methods of Theorems 5.3 and 5.4 can be used to show that it holds for the following cases: (1) Let there be numbers $L^0, U^0, \Delta_0, \Delta_1$ where $\Delta_0 + \Delta_1 < (U^0 - L^0)/2$ and $Y_0^\varepsilon(\cdot)$ changes only when $X^\varepsilon(\cdot)$ is in $[L^0, L^0 + \Delta_0]$, $Y_1^\varepsilon(\cdot)$ changes only when

$X^\varepsilon(\cdot)$ is in $[U^0 - \Delta_0, U^0]$, and the maximum jump is no greater than Δ_1 ; (2) Let $Y_i^\varepsilon(\cdot)$ denote any admissible policy and fix N . Define

$$\tau_n^\varepsilon = \min \{t > n: (Y_0^\varepsilon(t) - Y_0^\varepsilon(n)) + (Y_1^\varepsilon(t) - Y_1^\varepsilon(n)) \geq N\} \cap (n+1).$$

Now, choose the control policy on the interval $[n, n+1)$ as follows. Use $Y_i^\varepsilon(\cdot)$ on $[n, \tau_n^\varepsilon)$, then switch to a barrier or (\bar{B}, Δ_0) policy on $[\tau_n^\varepsilon, n+1)$.

In Theorem 6.2, it is shown that the uniform integrability condition is not needed if $-k_1 dY_1(t)$ is replaced by the positive cost increment $k_1 dY_1(t)$.

Proof. We deal only with the continuous parameter case. Let $X^\varepsilon(\cdot)$ denote the process with the $\bar{Y}^\varepsilon(\cdot)$ used. By Theorem 5.4, $\{\bar{Y}_i^\varepsilon(n+1) - \bar{Y}_i^\varepsilon(n), \varepsilon > 0, n < \infty\}$ is uniformly integrable. Extract a weakly convergent subsequence of $\{X^\varepsilon(\cdot), \bar{Y}_0^\varepsilon(\cdot), \bar{Y}_1^\varepsilon(\cdot)\}$ (pseudopath topology) and denote the limit by $(X(\cdot), Y_0(\cdot), Y_1(\cdot))$. By Theorem 3.2, this triple satisfies (1.1) for some $w(\cdot)$.

It follows from the weak convergence and the fact that the $\bar{Y}_0^\varepsilon(\cdot), \bar{Y}_1^\varepsilon(\cdot)$ is a (L^*, U^*) -barrier policy that the limit $Y_0(\cdot), Y_1(\cdot)$ is a (L^*, U^*) -barrier policy for $X(\cdot)$. Thus $Y_i(\cdot) = \bar{Y}_i(\cdot)$. This is true for any weakly convergent subsequence. By hypothesis, the solution to (1.1) associated with any (L^*, U^*) -barrier policy is unique (in the sense of distributions). Thus, the (distribution of the) limit does not depend on the chosen subsequence.

By the uniform integrability asserted in the above paragraph and the weak convergence, we have

$$\begin{aligned} \lim_{\varepsilon} V_0^\varepsilon(x, \bar{Y}_0^\varepsilon, \bar{Y}_1^\varepsilon) &= \lim_{\varepsilon} E \int_0^\infty e^{-\beta t} [k_0 d\bar{Y}_0^\varepsilon(t) - k_1 d\bar{Y}_1^\varepsilon(t) + k(X^\varepsilon(t))] dt \\ (6.4) \qquad &= E \int_0^\infty e^{-\beta t} [k_0 d\bar{Y}_0(t) - k_1 d\bar{Y}_1(t) + k(X(t))] dt \\ &= V_0(x, \bar{Y}_0, \bar{Y}_1) = V(x). \end{aligned}$$

To get (6.3), repeat the procedure with the controls $\hat{Y}_0^\varepsilon(\cdot), \hat{Y}_1^\varepsilon(\cdot)$. With these controls, the limit $(X(\cdot), Y_0(\cdot), Y_1(\cdot))$ might depend on the chosen subsequence. But, if $\{\varepsilon_n\}$ indexes any weakly convergent subsequence, with limit $(X(\cdot), Y_0(\cdot), Y_1(\cdot))$ we have $\lim_n V_0^\varepsilon(x, Y_0^n, Y_1^n) \rightarrow V_0(x, Y_0, Y_1) \geq V(x)$. Hence, by the definition of δ -optimality and the weak convergence,

$$\begin{aligned} \delta + \lim_{\varepsilon} V^\varepsilon(x) &\geq \lim_{\varepsilon} V_0^\varepsilon(x, \hat{Y}_0^\varepsilon, \hat{Y}_1^\varepsilon) \\ &\geq \inf_{Y_0, Y_1} V_0(x, Y_0, Y_1) = V(x). \end{aligned} \quad \text{Q.E.D.}$$

THEOREM 6.2. Assume the conditions of Theorem 6.1, except for the uniform integrability of the set (6.2), but for $k_i > 0$ let the cost be

$$E_x \int_0^\infty e^{-\beta t} [k_0 dY_0(t) + k_1 dY_1(t) + k(x(t))] dt = V_0(x, Y_0, Y_1),$$

and similarly define the cost $V_0^\varepsilon(x, Y_0^\varepsilon, Y_1^\varepsilon)$. Then the conclusions of Theorem 6.1 (with the δ in (6.3) replaced by 2δ) hold.

Proof. Let $\hat{Y}_i^\varepsilon(\cdot), i=0,1$, denote a δ -optimal policy. We can suppose that $\sup_{\varepsilon} [E_x Y_0^\varepsilon(t) + E_x Y_1^\varepsilon(t)] < \infty$ for each $t < \infty$ and that

$$\lim_{T \rightarrow \infty} \sup_{\varepsilon} \int_T^\infty e^{-\beta t} [k_0 dY_0^\varepsilon(t) + k_1 dY_1^\varepsilon(t) + k(X^\varepsilon(t))] dt = 0,$$

since this holds for any barrier policy. In fact, there is an $N_\delta < \infty$ such that if we switch to the (L^*, U^*) -barrier policy (or to any barrier policy) once the $Y_i^\varepsilon(t)$ exceeds N_δ , we change the cost by less than δ . But, then the set in (6.2) is uniformly integrable, and Theorem 6.1 holds. Q.E.D.

7. Average cost per unit time. The methods of §§ 1–5 can be used to adjust the proof of Theorem 8 in [6] to get the result which is analogous to Theorem 6.1 for the average cost per unit time problem. Only an outline of the method will be given. The reader is referred to [6] for more details on the structure of the approximation for the average cost problem for the nonsingular case (and which can be carried over to our case).

For the average cost per unit time problem, we wish to work with feedback controls and, hence, use only $Y_i^\varepsilon(\cdot)$, $i = 0, 1$, or $Y_i(\cdot)$, $i = 0, 1$, for which the associated processes $\xi^\varepsilon(\cdot)$ and $(X^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$ or $X(\cdot)$, respectively, are bounded Markov-Feller processes. Also, we let $\{\xi^\varepsilon(t), \varepsilon > 0, t < \infty\}$ be bounded. The cost criteria are:

$$\begin{aligned} \overline{\lim}_T E \frac{1}{T} \int_0^T [k_0 dY_0(t) - k_1 dY_1(t) + k(X(t))] dt &\equiv \gamma(Y_0, Y_1), \\ \overline{\lim}_T E \frac{1}{T} \int_0^T [k_0 dY_0^\varepsilon(t) - k_1 dY_1(t) + k(X^\varepsilon(t))] dt &= \gamma^\varepsilon(Y_0, Y_1). \end{aligned}$$

For simplicity, we discuss only the continuous parameter case. The discrete parameter case uses very similar assumptions and proof. Let PM (PM^ε , respectively) denote the class of feedback control processes for which $X(\cdot)$ ($(X^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$, respectively) is a Markov-Feller process. Let NA (NA^ε , respectively) denote the class of nonanticipative controls. We will use the following assumptions.

(A7.1) There is an $\varepsilon_0 > 0$ such that for each $\delta > 0$ and $\varepsilon \leq \varepsilon_0$, there are δ -optimal controls $\in PM^\varepsilon$ of the form

$$(7.1) \quad dY_i^\varepsilon = Q_i^\varepsilon(x, \xi) dt, \quad i = 0, 1,$$

where the $Q_i^\varepsilon(\cdot, \cdot)$ are continuous.

Note. If the $Q_i^\varepsilon(x, \xi)$ are Lipschitz continuous in x , uniformly in ξ , then $Y_i^\varepsilon(\cdot)$, $i = 0, 1$, is in PM^ε . See the remark below where it is shown that the barrier policy can be smoothed to yield a continuous $Q_i^\varepsilon(\cdot, \cdot)$.

(A7.2) A (L^*, U^*) -barrier control $\bar{Y}_i(\cdot)$, $i = 0, 1$, is optimal for (1.1), and with this control (1.1) has a unique invariant measure. This control is in PM and its adaptation $\bar{Y}_i^\varepsilon(\cdot)$, $i = 0, 1$, to $X^\varepsilon(\cdot)$ is in PM^ε . When applied to PM^ε , $(X^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$ has a unique solution and invariant measure.

$$(A7.3) \quad \inf_{Y_i \in PM} \gamma(Y_0, Y_1) = \inf_{Y_i \in NA} \gamma(Y_0, Y_1).$$

Remark. The (L^*, U^*) -barrier control can be approximated for $X^\varepsilon(\cdot)$ in such a way that it is of the form in (A7.1). In particular, let $\Delta_\varepsilon \rightarrow 0$ as $\varepsilon \rightarrow 0$ and define

$$(7.2) \quad d\tilde{Y}_1^\varepsilon(t) = dt[F(X^\varepsilon(t), \xi^\varepsilon(t))/\varepsilon + G(X^\varepsilon(t), \xi^\varepsilon(t))]^+ I_{\{X^\varepsilon(t) \in [U^* - \Delta_\varepsilon, U^*]\}} \frac{[X^\varepsilon(t) - U^* + \Delta_\varepsilon]}{\Delta_\varepsilon}$$

and similarly for $\tilde{Y}_0^\varepsilon(\cdot)$. It can be shown that

$$(7.3) \quad \gamma^\varepsilon(\tilde{Y}_0^\varepsilon, \tilde{Y}_1^\varepsilon) \xrightarrow{\Delta_\varepsilon \rightarrow 0} \gamma^\varepsilon(\bar{Y}_0^\varepsilon, \bar{Y}_1^\varepsilon),$$

where the \bar{Y}_i^ε is the (L^*, U^*) -barrier policy for $X^\varepsilon(\cdot)$. Clearly, the $\tilde{Y}_i^\varepsilon(\cdot)$ are of the form used in (A7.1). By (7.3), for each ε , we can choose Δ_ε so that the left and right sides of (7.3) are as close as desired. By using the techniques in § 5, it can be shown that $\{\tilde{Y}_i^\varepsilon(n+1) - \tilde{Y}_i^\varepsilon(n), i=0, 1, n < \infty, \varepsilon > 0, X^\varepsilon(0)=x, \xi^\varepsilon(0)=\xi\}$ is uniformly integrable.

THEOREM 7.1. Assume (A3.1)–(A3.5) and (A7.1)–(A7.3). Let $G(x, \xi)$ be Lipschitz continuous in x , uniformly in ξ . Let $\delta > 0$, and let $Y_i^\varepsilon(\cdot), i=1, 2$, be the δ -optimal controls defined in (A7.1). Suppose that the set

(7.4) $\{Y_i^\varepsilon(n+1) - Y_i^\varepsilon(n), \varepsilon > 0, n < \infty, X^\varepsilon(0)=x, \xi^\varepsilon(0)=\xi, \text{ for all } x \in [0, \bar{B}], \text{ for all } \xi\}$ is uniformly integrable. Then

$$\delta + \lim_{\varepsilon} \gamma^\varepsilon(Y_0^\varepsilon, Y_1^\varepsilon) \geq \lim_{\varepsilon} \gamma^\varepsilon(\bar{Y}_0^\varepsilon, \bar{Y}_1^\varepsilon) = \gamma(\bar{Y}_0, \bar{Y}_1).$$

Proof. For each ε, δ, T , define the measure

$$P_T^{\varepsilon, \delta}(\cdot) = \frac{1}{T} E \int_0^T P^{\varepsilon, \delta}(X^\varepsilon(0), \xi^\varepsilon(0), t, \cdot) dt,$$

where $P^{\varepsilon, \delta}$ is the transition function for $(X^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$, under the δ -optimal control $Y_i^\varepsilon(\cdot)$ (or Q_i^ε) of (A7.1). Then

$$\gamma^\varepsilon(Y_0^\varepsilon, Y_1^\varepsilon) = \overline{\lim}_T \int P_T^{\varepsilon, \delta}(dx d\xi) [k_0 Q_0^\varepsilon(x, \xi) - k_1 Q_1^\varepsilon(x, \xi) + k(x)].$$

Choose a subsequence $T_k \rightarrow \infty$ such that both the $\overline{\lim}$ is attained and $P_{T_k}^{\varepsilon, \delta}$ converges weakly (with limit denoted by $\mu^{\varepsilon, \delta}$). Then, by the Markov–Feller property of $(X^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$ for $(Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot)) \in PM^\varepsilon$, $\mu^{\varepsilon, \delta}$ is an invariant measure for $(X^\varepsilon(\cdot), \xi^\varepsilon(\cdot))$ and, by the continuity of the Q_i^ε and the weak convergence,

$$(7.5) \quad \gamma^\varepsilon(Y_0^\varepsilon, Y_1^\varepsilon) = \int \mu^{\varepsilon, \delta}(dx d\xi) [k_0 Q_0^\varepsilon(x, \xi) - k_1 Q_1^\varepsilon(x, \xi) + k(x)].$$

Let $(\hat{X}^\varepsilon(\cdot), \hat{\xi}^\varepsilon(\cdot))$ denote the stationary process associated with the control function $Q_i^\varepsilon(\cdot, \cdot)$ and measure $\mu^{\varepsilon, \delta}(\cdot)$, and let $\hat{Y}_i^\varepsilon(\cdot)$ denote the corresponding stationary control processes. Then we can write (7.5) as:

$$(7.6) \quad \begin{aligned} \gamma^\varepsilon(Y_0^\varepsilon, Y_1^\varepsilon) &= E \int_0^1 dt [k_0 Q_0^\varepsilon(\hat{X}^\varepsilon(t), \hat{\xi}^\varepsilon(t)) - k_1 Q_1^\varepsilon(\hat{X}^\varepsilon(t), \hat{\xi}^\varepsilon(t)) + k(\hat{X}^\varepsilon(t))] \\ &= E \int_0^1 k(\hat{X}^\varepsilon(t)) dt + Ek_0 \hat{Y}_0^\varepsilon(1) - Ek_1 \hat{Y}_1^\varepsilon(1). \end{aligned}$$

By the uniform integrability (7.4), $\{\hat{Y}_0^\varepsilon(1), \hat{Y}_1^\varepsilon(1), \varepsilon > 0\}$ is uniformly integrable.

Now, choose a weakly convergent subsequence of $\{\hat{X}^\varepsilon(\cdot), Y_0^\varepsilon(\cdot), Y_1^\varepsilon(\cdot)\}$, with limit denoted by $(\hat{X}(\cdot), \hat{Y}_0(\cdot), \hat{Y}_1(\cdot))$. The limit is stationary, satisfies (1.1) and (indexing the subsequence by ε also), we have

$$\gamma^\varepsilon(Y_0^\varepsilon, Y_1^\varepsilon) \rightarrow \gamma(\hat{Y}_0, \hat{Y}_1) \geq \gamma(\bar{Y}_0, \bar{Y}_1),$$

where the optimality of $\bar{Y}_0(\cdot), \bar{Y}_1(\cdot)$ is used.

The proof is concluded by applying the same procedure to $\tilde{Y}_0^\varepsilon(\cdot), \tilde{Y}_1^\varepsilon(\cdot)$, where the “smoothing interval” Δ_ε (see remark above the theorem where \tilde{Y}_i^ε and Δ_ε are defined) goes to zero fast enough as $\varepsilon \rightarrow 0$. Q.E.D.

8. The vector case. Formulation, quasimartingale estimates and the approximation theorem. Most of the foregoing analysis and results can be carried over to the case of vector ($x \in R^r$, Euclidean r -space) valued G, F in (1.4) or (3.1). Since the details of the proofs are essentially the same as in the foregoing sections, only an outline will be given. Only the continuous parameter case will be discussed, but under the obvious changes in assumptions (A3.1)–(A3.4) and (A8.1) used below, the discrete parameter results also extend to the vector case.

We use the model (vector F, G)

$$(8.1) \quad dX^\varepsilon = [G(X^\varepsilon, \xi^\varepsilon) + F(X^\varepsilon, \xi^\varepsilon)/\varepsilon] dt + dY^\varepsilon(t),$$

with cost

$$(8.2) \quad V_0^\varepsilon(x, Y^\varepsilon) = \int_0^\infty e^{-\beta t} [k_0 |dY^\varepsilon(t)| + k(X^\varepsilon(t))] dt, \quad \beta > 0.$$

The results of § 7 can also be extended to the vector case.

THEOREM 8.1. Assume (A3.1), (A3.2) with vector G, F used, and let $\sup_\varepsilon E \int_0^T |dY^\varepsilon(t)| < \infty$ for each $T < \infty$. Then (possibly having to add to each component a process whose maximum value goes to zero as $\varepsilon \rightarrow 0$) $\{X^\varepsilon(\cdot), Z^\varepsilon(\cdot), Y^\varepsilon(\cdot)\}$ are quasimartingales with uniformly (in ε) bounded conditional variation on each bounded time interval.

Remark. The proof is essentially identical to that of Theorem 3.1. Similarly, the proof of Theorem 8.2 below is essentially identical to that of Theorem 3.2.

We will next use (A8.1), the vector form of (A3.5).

(A8.1) There is a matrix $\Sigma(\cdot)$ with a continuous and bounded square root $\sigma(\cdot)$ such that for each x ,

$$\begin{aligned} & \frac{1}{T_1} \int_u^{u+T_1} E_u F(x, \xi(\tau)) d\tau \int_\tau^{T+\tau} F'(x, \xi(s)) ds \\ & + \frac{1}{T_1} \left[\int_u^{u+T_1} E_u F(x, \xi(\tau)) d\tau \int_\tau^{T+\tau} F'(x, \xi(s)) ds \right]' \xrightarrow{P} \Sigma(x), \end{aligned}$$

as T, u and T_1 go to ∞ . There is a continuous function $\bar{G}_0(\cdot)$ with components $\bar{G}_{0i}(\cdot)$, $i \leq r$, such that for each x ,

$$\frac{1}{T_1} \int_u^{u+T_1} \sum_j E_u F_j(x, \xi(\tau)) d\tau \int_\tau^{T+\tau} F_{ix_j}(x, \xi(s)) ds \xrightarrow{P} \bar{G}_{0i}(x)$$

as T, u and T_1 go to ∞ .

THEOREM 8.2. Assume (A3.1)–(A3.4) and (A8.1), and let $\sup_\varepsilon E_x \int_0^T |dY^\varepsilon(s)| < \infty$ for each $T < \infty$. Then $\{Z^\varepsilon(\cdot)\}$ is tight in the Skorokhod topology on $D^r[0, \infty)$ and any weak limit process is continuous with probability 1. Let $\{X^\varepsilon(\cdot), Y^\varepsilon(\cdot), Z^\varepsilon(\cdot)\}$ be a weakly convergent subsequence in $D^{3r}[0, \infty)$, with the pseudopath topology used on the first two components and the Skorokhod topology on the last. Let $\bar{X}(\cdot) = (X(\cdot), Y(\cdot), Z(\cdot))$ denote the limit of a weakly convergent subsequence. Then the conclusions of Theorem 3.2 continue to hold, with the limit $Y(\cdot)$ replacing $Y_0(\cdot) - Y_1(\cdot)$. In particular, the limit satisfies

$$\begin{aligned} (8.3) \quad & X(t) = Z(t) + Y(t) + X(0), \\ & dZ(t) = [\bar{G}(X(t)) + \bar{G}_0(X(t))] dt + \sigma(X(t)) dw, \\ & Z(0) = 0. \end{aligned}$$

Definition and assumptions. Below, $v(\cdot)$ will be a continuous vector field on R^n with $|v(x)| \equiv 1$, and S a compact set with a piecewise differential boundary and with the following properties: (a) There is a truncated cone such that the apex can be placed at any point on ∂S such that the cone is in S . (b) There is a $\Delta_0 > 0$ such that for $x \in \partial S$ and $\Delta \leq \Delta_0$, the points $x + \Delta v(x)$ are interior to S . Define the $(S, \Delta, v(\cdot))$ -reflecting policy for $X^\varepsilon(\cdot)$ as the (admissible) policy which sets $X^\varepsilon(t) = x + \Delta v(x)$, if $X^\varepsilon(t^-) = x \in \partial S$. Then, of course, $dY^\varepsilon(t) = \Delta v(x)$. We define similarly the $(S, \Delta, v(\cdot))$ -reflecting policy for the $X(\cdot)$ of (8.3).

A policy $Y(\cdot)$ for (8.3) is called a $(S, v(\cdot))$ -reflecting policy if the associated process $X(\cdot)$ is a reflected diffusion in S , with continuous reflection direction $v(\cdot)$ on ∂S , and there is a $\Delta_0 > 0$ such that for $\Delta \leq \Delta_0$, the policy which sets $X(t) = x + \Delta v(x)$ if $X(t^-) = x \in \partial S$ is an admissible $(S, \Delta, v(\cdot))$ -reflecting policy.

The conditions on $S, v(\cdot)$, are motivated by the optimal control for the "finite fuel" problem [2].

THEOREM 8.3. Assume (A3.1) and (A3.2) (vector case), and let $Y^{\varepsilon, \Delta}(\cdot)$ denote a $(S, \Delta, v(\cdot))$ -reflecting policy for $X^\varepsilon(\cdot)$. Then for each $T < \infty$ and integer k ,

$$(8.4) \quad \sup_{\substack{\varepsilon, \Delta \leq \Delta_0 \\ x \in S}} E_x \left(\int_0^T |dY^{\varepsilon, \Delta}(s)| \right)^k < \infty.$$

THEOREM 8.4. Let $X(\cdot)$ satisfy (8.3) with bounded and continuous $\bar{G}(\cdot)$, $\bar{G}_0(\cdot)$ and $\sigma(\cdot)$. Let $Y^\Delta(\cdot)$ be a $(S, \Delta, v(\cdot))$ -reflecting policy for $x(\cdot)$. Then, for each $T < \infty$ and integer k ,

$$\sup_{\substack{\Delta \leq \Delta_0 \\ x \in S}} E_x \left[\int_0^T |dY^\Delta(s)| \right]^k < \infty.$$

We will prove Theorem 8.4 only. The proof of Theorem 8.3 is similar and uses the (vector case) estimate (5.6) for the process $Z^\varepsilon(t) + Z_1^\varepsilon(t)$, where $Z_1^\varepsilon(\cdot)$ here is the appropriate "vector" case form of the $Z_1^\varepsilon(\cdot)$ used in §§ 3-5.

Proof of Theorem 8.4. Let $Y^\Delta(\cdot)$ denote the $(S, \Delta, v(\cdot))$ -reflecting policy and $X^\Delta(\cdot)$ the associated solution to (8.3). For small $\alpha > 0$ let $N_\alpha(x)$ denote the α -neighborhood of x . There are x_1, \dots, x_q on ∂S such that $\bigcup_{i=1}^q N_\alpha(x_i) \supset \partial S$ and

$$(8.5) \quad \sup_{x, y \in N_{2\alpha}(x_i)} |v(x) - v(y)| < \alpha.$$

Let σ_0^m denote the first time of entry of $X^\Delta(\cdot)$ into $\bar{N}_\alpha(x_m)$. Define

$$\rho_i^m = \min \{t > \sigma_{i-1}^m: X^\Delta(t) \notin N_{2\alpha}(x_m)\},$$

$$\sigma_i^m = \min \{t > \rho_i^m: X^\Delta(t) \in \bar{N}_\alpha(x_m)\}.$$

Define $N_m^\Delta = \max \{i: \sigma_i^m \leq T\}$, $Y_i^{\Delta, m}(T) = Y^\Delta(\rho_{i+1}^m \cap T) - Y^\Delta(\sigma_i^m \cap T)$ and $Y^{\Delta, m}(T) = \sum_i Y_i^{\Delta, m}(T)$.

Owing to (8.5) and the smallness of α , there is a $K_1 < \infty$ (depending on α , but not on Δ) such that

$$\int_0^T |dY^\Delta(s)| \leq K_1 \sum_{m=1}^q |Y^{\Delta, m}(T)|.$$

Hence we need only evaluate $E[Y^{\Delta, m}(T)]^k$. We have

$$(8.6) \quad Y^{\Delta, m} = \sum_{i=1}^{N_m^\Delta} [X^\Delta(\rho_i^m \cap T) - X^\Delta(\sigma_{i-1}^m \cap T)] - \sum_{i=1}^{N_m^\Delta} [Z^\Delta(\rho_i^m \cap T) - Z^\Delta(\sigma_{i-1}^m \cap T)].$$

The absolute value of the first term on the right-hand side of (8.6) is $\leq \alpha K_2 N_m^\Delta$, for some constant $K_2 < \infty$. The absolute value of the last term on the right-hand side of (8.6) is bounded above by

$$(8.7) \quad N_m^\Delta \cdot \sup_{s, t \leq T} |Z^\Delta(t) - Z^\Delta(s)|.$$

Since $Z^\Delta(\cdot)$ is just the sum of an ordinary integral and a stochastic integral whose integrands are bounded uniformly in Δ , all the moments of the last factor in (8.7) are bounded uniformly in Δ . Hence it is enough to show that $\sup_{x \in S, \Delta} E_x |N_m^\Delta|^p < \infty$ for all integers p .

This last problem is similar to that dealt with in Theorem 5.3. The structure of the $(S, \Delta, v(\cdot))$ -reflecting policy implies that there is an $\alpha' > 0$ (not depending on Δ) such that in order for $X^\Delta(\cdot)$ to move from the exterior of $N_{2\alpha}(x_m)$ at time ρ_i^m to $\bar{N}_\alpha(x_m)$ at time σ_i^m , we must have $\sup_{\rho_i^m \leq t \leq \sigma_i^m} |Z^\Delta(t) - Z^\Delta(\rho_i^m)| \geq \alpha'$. Let τ ($< \infty$ with probability 1) be a stopping time. For each $\delta_0 \in (0, 1)$, there is a $T_0 > 0$ such that for all small $\Delta > 0$,

$$(8.8) \quad \sup_{x \in S, \tau} P_x \left\{ \sup_{t \leq T_0} |Z^\Delta(t + \tau) - Z^\Delta(\tau)| \geq \alpha'/2 \right\} \leq 1 - \delta_0.$$

Inequality (8.8) and an argument like that used in Theorem 5.3 (to get the upper estimate on $E|N_i^\varepsilon|^k$ there) completes our proof. Q.E.D.

DEFINITION. We now add an additional condition on the control problem. It is supposed that there is a compact set S_1 with a piecewise differentiable boundary satisfying the cone condition (a) above and such that $X^\varepsilon(\cdot)$ and $X(\cdot)$ are to be confined to S_1 . For small enough Δ and some continuous $v_1(\cdot)$, let there exist a $(S_1, \Delta, v_1(\cdot))$ -reflecting policy. In Theorem 5.1, we assume that the optimal control for $X(\cdot)$ is $(S, v(\cdot))$ -reflecting for some compact S and continuous $v(\cdot)$. The result can be extended to cover (for example) combined singular and nonsingular controls or true impulsive controls.

Remark. In many applications S_1 is not compact, but the special structure of the optimal policy (as for the "finite fuel" problems which have been investigated to date) yields $\delta/2$ -optimal policies for which we have the required uniform integrability.

THEOREM 8.5. Assume (A3.1)–(A3.4) and (A8.1), and the condition on S_1 in the above paragraph. Suppose that there are $S, v(\cdot)$ such that the optimal policy $\bar{Y}(\cdot)$ for $X(\cdot)$ is a $(S, v(\cdot))$ -reflecting policy. Let $\bar{Y}^\Delta(\cdot)$ denote the $(S, \Delta, v(\cdot))$ reflecting policy obtained from $\bar{Y}(\cdot)$. Let (8.3) have a unique weak sense solution under both policies, for all small Δ . Let $\hat{Y}^{\varepsilon, \Delta}(\cdot)$ denote the $(S, \Delta, v(\cdot))$ -reflecting policy adapted to $X^\varepsilon(\cdot)$. Given $\delta > 0$, there is a $\Delta > 0$ such that $\hat{Y}^{\varepsilon, \Delta}(\cdot)$ is δ -optimal for $X^\varepsilon(\cdot)$ and small ε in the sense that

$$(8.9) \quad \delta + \lim_{\varepsilon} V^\varepsilon(x) \geq \lim_{\varepsilon} V^{\varepsilon_0}(x, \hat{Y}^{\varepsilon, \Delta}) \geq \inf_{Y \text{ adm.}} V_0(x, Y) = V_0(x, \bar{Y}) = V(x).$$

Proof. The method is that of Theorems 6.1 and 6.2, but is simpler since all cost terms are nonnegative. Let $Y^\varepsilon(\cdot)$ denote the optimal (or $\delta/2$ -optimal, if there is no optimal policy) policy for $X^\varepsilon(\cdot)$ and let $X^{\varepsilon, \Delta}(\cdot)$ denote the process corresponding to $\hat{Y}^{\varepsilon, \Delta}(\cdot)$. By an argument of the type used in Theorem 6.2, there is no loss of generality if we suppose that the second set of the pair of sets

$$\left\{ \int_n^{n+1} |d\hat{Y}^{\varepsilon, \Delta}(s)|, \varepsilon > 0, n < \infty \right\}, \quad \left\{ \int_n^{n+1} |dY^\varepsilon(s)|, \varepsilon > 0, n < \infty \right\}$$

is uniformly integrable. The first set is uniformly integrable by Theorem 8.3. Choose a weakly convergent subsequence of $\{X^{\varepsilon, \Delta}(\cdot), \hat{Y}^{\varepsilon, \Delta}(\cdot)\}, \{X^\varepsilon(\cdot), Y^\varepsilon(\cdot)\}$ with the

subsequence also indexed by ε and with the limit denoted by $(X^\Delta(\cdot), \hat{Y}^\Delta(\cdot)), (X(\cdot), Y(\cdot))$, respectively. Then $X^\Delta(\cdot)$ is the $(S, \Delta, v(\cdot))$ -reflecting diffusion and $\hat{Y}^\Delta(\cdot) = \bar{Y}^\Delta(\cdot)$. Thus, by the weak convergence and the optimality of $\bar{Y}(\cdot)$, we have

$$(8.10) \quad \frac{\delta}{2} + \lim_{\varepsilon} V^\varepsilon(x) \geq \lim_{\varepsilon} V_0^\varepsilon(x, Y^\varepsilon) \geq \inf_{Y \text{ adm.}} V(x, Y) \geq V_0(x, \bar{Y}) = V(x).$$

Also by the weak convergence

$$(8.11) \quad \lim_{\varepsilon} V^\varepsilon(x, \hat{Y}^{\varepsilon, \Delta}) = V(x, \bar{Y}^\Delta).$$

Another weak convergence argument and the uniqueness assumption on the reflecting diffusion $X(\cdot)$ under policy $\bar{Y}(\cdot)$ yields the weak convergence of $\{X^\Delta(\cdot), \bar{Y}^\Delta(\cdot)\}$ to $(X(\cdot), \bar{Y}(\cdot))$ as $\Delta \rightarrow 0$. Also, the set $\{\int_n^{n+1} |d\bar{Y}^\Delta(s)|, \Delta \leq \Delta_0, n < \infty\}$ is uniformly integrable. This yields

$$(8.12) \quad \frac{\delta}{2} + V(x) \geq V_0(x, \bar{Y}^\Delta)$$

for small Δ . Now, (8.9) follows by combining (8.10)–(8.12). Q.E.D.

NECESSARY CONDITIONS FOR OPTIMAL CONTROL PROBLEMS: CONJUGATE POINTS*

V. ZEIDAN† AND P. ZEZZA‡

Abstract. In this paper we introduce a definition of “normality” and of “conjugate points” for a general optimal control problem. Using these concepts we obtain new second-order necessary conditions for optimality. In the special case when the control set U is the whole space or in the classical setting of calculus of variations, our conditions reduce to known results, namely, the Jacobi condition and the existence of a solution to a certain Riccati equation.

Key words. optimal control, conjugate points, normality, Riccati equation, necessary conditions

AMS(MOS) subject classification. 49B10

Introduction. In the classical calculus of variations, conjugate point theory plays an important role in establishing second-order necessary and sufficient conditions for optimality (as reference, see among others [2], [4]–[6]). It is well known that if \hat{x} is optimal and the “strengthened Legendre” condition holds, then there is no point in (a, b) conjugate to b . On the other hand, the nonexistence of conjugate points to b in $[a, b)$ is a condition that belongs to a set of sufficient conditions. It is also known as the Jacobi condition and could be formulated in terms of the existence of a solution to a certain Riccati equation.

For optimal controls, the Jacobi condition in a form of Riccati equation has been used in developing sufficient conditions when the control set U is open [9]. Then, it was extended to the general case in [12]–[15]. Dealing with the question of necessary conditions, the accessory problem was obtained in [8] for the case when U is open; then it was generalized, in [10] for the case when U is closed, and in [7] for the abnormal problems. However, the results on necessary conditions using conjugate points in the calculus of variations are not yet transferred to the optimal control context, particularly when the control set U is not trivial. The books [8] and [11], for instance, stop short of conjugate points in their discussion of optimal control theory.

There have been several attempts to define when a point c in $[a, b)$ is conjugate to b and then to show that the nonexistence of conjugate points in (a, b) is necessary for optimality. For instance, the first formulation for the case when $U = R^m$ was introduced in [3]. There, the definition of a conjugate point is not the one needed, and moreover, in [16] we provided a counterexample to the necessity theorem therein. A recent attempt was made in [1] to treat the case when U is given by smooth functions. Here again the results are incorrect, as is shown by two counterexamples in [16].

It is then clear that a mathematically rigorous proof of the necessity theorem is needed for the case when $U = R^m$. Moreover, an extension of the concepts and the results to the general case is desired.

In this paper we use the results involving the accessory problem [10] or [7] to, first, formulate definitions of “conjugate points” and of “normality” for general optimal control problems. Naturally, they must involve the control set U . Second, we show

that, under the “normality” assumption, the nonexistence of points conjugate to b in (a, b) is necessary for optimality. Then, we formulate our new necessary conditions in terms of the existence of a solution to a certain Riccati-type equation, Corollary 3.2, which reduces to the classical form used for sufficiency when $U = R^m$ or when the optimal control \hat{u} is in the int $L^\infty[a, b]$ (see for instance [9]). We present an example illustrating that the “normality” assumption cannot be eliminated. Then we study the special case when we have a free endpoint. There, we show that our results can be strengthened. Finally, we give an example to which we apply our new necessary conditions.

1. Statement of the problem. Given a compact interval $I = [a, b]$, $A \in R^n$, open sets $X \subset R^n$, $V \subset R^m$, a set $U \subset V$ and functions f, g, K and Φ

$$\begin{aligned} g &: I \times X \times V \rightarrow R, \\ f &: I \times X \times V \rightarrow R^n, \\ K &: X \rightarrow R, \\ \Phi &: X \rightarrow R^k, \end{aligned}$$

the optimal control problem can be stated as

$$(P) \quad \text{Minimize } J(x, u) := K(x(b)) + \int_a^b g(t, x(t), u(t)) dt$$

over all absolutely continuous functions x , $x \in AC(I, X)$, and measurable functions u satisfying

$$\begin{aligned} (1.1) \quad \dot{x}(t) &= f(t, x(t), u(t)) \quad \text{a.e. } t \in I, \\ u(t) &\in U \quad \text{a.e. } t \in I, \\ x(a) &= A, \quad \Phi(x(b)) = 0. \end{aligned}$$

DEFINITION 1.1. A pair (x, u) is said to be feasible for (P) if $x \in AC(I, X)$, u is measurable and (x, u) satisfies the constraints (1.1).

DEFINITION 1.2. A feasible pair (\hat{x}, \hat{u}) is a weak local minimum for (P) if for some positive ε , (\hat{x}, \hat{u}) minimizes $J(x, u)$ over all feasible pairs (x, u) satisfying

$$\begin{aligned} x(t) &\in \hat{x}(t) + \varepsilon B_n, \quad t \in I, \\ u(t) &\in \hat{u}(t) + \varepsilon B_m \quad \text{a.e. } t \in I, \end{aligned}$$

where B_N is the unit ball in R^N .

2. Preliminary results. For $F := (f, g)$, the following smoothness assumptions will be recalled.

Assumption (A). For all $t \in I$, $F(t, \cdot, \cdot)$ is C^1 , for all $(x, u) \in X \times V$, $F(\cdot, x, u)$, $F_x(\cdot, x, u)$ and $F_u(\cdot, x, u)$ are measurable on I ; there exists an integrable function $\alpha: I \rightarrow R$ such that

$$(2.1) \quad |F(t, x, u)| + |F_x(t, x, u)| + |F_u(t, x, u)| \leq \alpha(t), \quad (t, x, u) \in I \times X \times V;$$

and K and Φ are C^1 on X .

Assumption (B). For all $t \in I$, $F(t, \cdot, \cdot)$ is C^2 , for all $(x, u) \in X \times V$, $F_{xx}(\cdot, x, u)$, $F_{xu}(\cdot, x, u)$ and $F_{uu}(\cdot, x, u)$ are measurable on I ; there exists an integrable function $\beta: I \rightarrow R$ such that

$$|F_{xx}(t, x, u)| + |F_{xu}(t, x, u)| + |F_{uu}(t, x, u)| \leq \beta(t), \quad (t, x, u) \in I \times X \times V;$$

K and Φ are C^2 on X .

Given $\hat{u}(\cdot)$ and $\varepsilon > 0$, we denote the ε -tube in U around $\hat{u}(t)$ by

$$U_\varepsilon(t) = \{u \in R^m : u \in U \cap (\hat{u}(t) + \varepsilon B_m)\}.$$

In what follows the notation $\hat{\alpha}(t)$ means $\alpha(t, \hat{x}(t), \hat{u}(t))$.

THEOREM 2.1 (Pontryagin's Principle). *Let (\hat{x}, \hat{u}) be a weak local minimum for (P) with a corresponding $\varepsilon > 0$. If Assumption (A) holds then there exist an absolutely continuous function $p : I \rightarrow R^n$, a number λ_0 , and a vector $\gamma \in R^k$ such that*

- (1) $\lambda_0 \geq 0$, $\lambda_0 + |\gamma| \neq 0$,
- (2) $-\dot{p}(t) = \hat{f}_x^T(t)p(t) + \lambda_0 \hat{g}_x(t)$ a.e. $t \in I$,
- (3) $p(b)^T = \gamma^T D\Phi(\hat{x}(b)) + \lambda_0 DK(\hat{x}(b))$,
- (4) $\min_{t \in I} \{\langle p(t), f(t, \hat{x}(t), u) \rangle + \lambda_0 g(t, \hat{x}(t), u) : u \in U_\varepsilon(t)\} = \langle p(t), \hat{f}(t) \rangle + \lambda_0 \hat{g}(t)$ a.e.

If in addition U is convex, then (4) implies

$$(2.2) \quad \langle \hat{f}_u^T(t)p(t) + \lambda_0 \hat{g}_u(t), u - \hat{u}(t) \rangle \geq 0, \quad u \in U \quad \text{a.e. } t \in I.$$

When Assumption (A) holds and U is convex we will use the following.

DEFINITION 2.1. An extremal for problem (P) is a feasible pair (\hat{x}, \hat{u}) such that there exist an absolutely continuous function $p : I \rightarrow R^n$, a number λ_0 and a vector $\gamma \in R^k$ that satisfy conditions (1)–(3) of Pontryagin's principle and condition (2.2).

Let (\hat{x}, \hat{u}) be a feasible pair. To identify the set of admissible directions define:

$$\mathcal{D} = \{(\eta(\cdot), w(\cdot)) \in AC(I, R^n) \times \mathcal{U} \text{ satisfying (2.3)–(2.5)}\},$$

where

$$\mathcal{U} = \{w(\cdot) \in L^\infty(I, R^m) : w(t) \in U - \hat{u}(t) \text{ a.e. } t \in I\},$$

$$(2.3) \quad \dot{\eta}(t) = \hat{f}_x(t)\eta(t) + \hat{f}_u(t)w(t) \text{ a.e. } t \in I,$$

$$(2.4) \quad \eta(a) = 0, \quad D\Phi(\hat{x}(b))\eta(b) = 0,$$

$$(2.5) \quad DK(\hat{x}(b))\eta(b) + \int_a^b [\hat{g}_x(t)\eta(t) + \hat{g}_u(t)w(t)] dt \leq 0.$$

Define

$$(2.6) \quad H(t, x, p, u, \lambda) = \langle p, f(t, x, u) \rangle + \lambda g(t, x, u).$$

The following result can be derived from Theorem 1.1 [10] or of Theorem 3.1 [7] upon writing our problem in Mayer form.

THEOREM 2.2. *Let (\hat{x}, \hat{u}) be a weak local minimum for (P). If U is convex, Assumptions (A) and (B) hold, and $\hat{u} \in L^\infty(I, R^m)$, then for each $(\eta, w) \in \mathcal{D}$ there exist p , λ_0 and γ that can depend on (η, w) , satisfying conditions (1)–(3) of Theorem 2.1, condition (2.2) and*

$$(2.7) \quad \begin{aligned} J_2(\eta, w) := & \frac{1}{2} \eta^T(b) \{ \lambda_0 D^2 K(\hat{x}(b)) + [D^2 \Phi(\hat{x}(b))]^T \gamma \} \eta(b) \\ & + \frac{1}{2} \int_a^b \{ \eta^T(t) \hat{H}_{xx}(t, p(t), \lambda_0) \eta(t) + 2\eta^T(t) \hat{H}_{xu}(t, p(t), \lambda_0) w(t) \\ & + w^T(t) \hat{H}_{uu}(t, p(t), \lambda_0) w(t) \} dt \geq 0, \end{aligned}$$

where

$$\hat{H}(t, p(t), \lambda_0) = H(t, \hat{x}(t), p(t), \hat{u}(t), \lambda_0).$$

The following proposition provides conditions under which $\lambda_0 \neq 0$ and hence the set of admissible directions for the control variable can be described in terms of the Hamiltonian.

PROPOSITION 2.1. We are given an extremal (\hat{x}, \hat{u}) such that $D\Phi(\hat{x}(b))$ is of full rank and the only solution of the system

$$\begin{aligned} -\dot{p}(t) &= \hat{f}_x^T(t)p(t) \quad \text{a.e. } t \in I, \\ p(b)^T &= l^T D\Phi(\hat{x}(b)) \quad \text{for some } l \in R^k, \\ \langle \hat{f}_u^T(t)p(t), u - \hat{u}(t) \rangle &\geq 0 \quad \text{a.e. } t \in I \quad \forall u \in U \end{aligned}$$

is $p \equiv 0$. Then λ_0 can be taken to be 1 and if, moreover, (\hat{x}, \hat{u}) is a weak local minimum then (2.5) reduces to equality and is equivalent to:

$$\langle \hat{H}_u(t, p(t), 1), w(t) \rangle = 0 \quad \text{a.e. } t \in I.$$

Proof. Any λ_0, γ, p satisfying conditions (1)–(3) of Theorem 2.1 and (2.2) must have $\lambda_0 \neq 0$. Otherwise, we get

$$\begin{aligned} -\dot{p}(t) &= \hat{f}_x^T(t)p(t) \quad \text{a.e. } t \in I, \\ p(b)^T &= \gamma^T D\Phi(\hat{x}(b)), \\ \langle \hat{f}_u^T(t)p(t), u - \hat{u}(t) \rangle &\geq 0 \quad \text{a.e. } t \in I \quad \forall u \in U. \end{aligned}$$

Thus $p \equiv 0$ and $\gamma^T D\Phi(\hat{x}(b)) = 0$, and hence $\gamma = 0$, contradicting condition (1) of Pontryagin's principle.

Let (\hat{x}, \hat{u}) be a weak local minimum. From Theorem 2.2 we know that there exist p, λ_0, γ satisfying conditions (1)–(3) of Theorem 2.1 and (2.2). Since $\lambda_0 \neq 0$, then $\lambda_0 = 1$ and (2.2) implies that, for $(\eta, w) \in \mathcal{D}$,

$$0 \leq \langle \hat{H}_u(t, p(t), 1), w(t) \rangle = \langle \hat{f}_u^T(t)p(t) + \hat{g}_u(t), w(t) \rangle \quad \text{a.e. } t \in I.$$

Thus

$$\begin{aligned} 0 &\leq \int_a^b \langle \hat{f}_u^T(t)p(t) + \hat{g}_u(t), w(t) \rangle dt \\ &= \int_a^b \{ \langle p(t), \dot{\eta}(t) - \hat{f}_x(t)\eta(t) \rangle + \langle \hat{g}_u(t), w(t) \rangle \} dt \\ &= \int_a^b \{ \langle p(t), \dot{\eta}(t) \rangle - \langle \hat{f}_x^T(t)p(t), \eta(t) \rangle + \langle \hat{g}_u(t), w(t) \rangle \} dt \\ &= \int_a^b \{ \langle p(t), \dot{\eta}(t) \rangle - \langle -\dot{p}(t) - \hat{g}_x(t), \eta(t) \rangle + \langle \hat{g}_u(t), w(t) \rangle \} dt \\ &= p(b)\eta(b) + \int_a^b \{ \langle \hat{g}_x(t), \eta(t) \rangle + \langle \hat{g}_u(t), w(t) \rangle \} dt \\ &= \langle \gamma^T D\Phi(\hat{x}(b)), \eta(b) \rangle + DK(\hat{x}(b))\eta(b) \\ &\quad + \int_a^b \{ \langle \hat{g}_x(t), \eta(t) \rangle + \langle \hat{g}_u(t), w(t) \rangle \} dt \leq 0. \end{aligned}$$

Therefore (2.5) can be replaced by equality, in other words, by

$$\langle \hat{H}_u(t, p(t), 1), w(t) \rangle = 0 \quad \text{a.e. } t \in I. \quad \text{Q.E.D.}$$

Let (\hat{x}, \hat{u}) be an extremal for (P) and let $\hat{p}(\cdot), \lambda_0, \gamma$ satisfy conditions (1)–(3) of Theorem 2.1 and condition (2.2). We can then take for the control variable admissible directions belonging to the set:

$$(2.8) \quad \tilde{U}(t) = \{ w \in R^n : w \in U - \hat{u}(t) \text{ and } \langle \hat{H}_u(t, \hat{p}(t), \lambda_0), w \rangle = 0 \}.$$

In order to use the previous results the following assumption will be made:

(H) The matrix $D\Phi(\hat{x}(b))$ is of full rank, and the pair (\hat{x}, \hat{u}) is strongly normal on $[a, b]$, i.e., the only solution of

$$\begin{aligned} -\dot{p}(t) &= \hat{f}_x^T(t)p(t) \quad \text{a.e. } t \in I, \\ p(b)^T &= l^T D\Phi(\hat{x}(b)) \quad \text{for some } l \in R^k, \\ \langle \hat{f}_u^T(t)p(t), w \rangle &\geq 0 \quad \text{a.e. } t \in I \quad \forall w \in \tilde{U}(t) \end{aligned}$$

is $p \equiv 0$.

Remark 2.1. Assumption (H) is not merely a technical condition; it is related to the controllability of the linearized system. In fact, it can be easily proven that assumption (H) is equivalent to the following.

Denote by \mathcal{R} the reachable set for the system

$$\begin{aligned} \dot{y}(t) &= \hat{f}_x(t)y(t) + \hat{f}_u(t)w(t), \\ y(a) &= 0, \\ w(t) &\in \tilde{U}(t) \quad \text{a.e. } t \in I; \end{aligned}$$

then $0 \in \text{rel int } D\Phi(\hat{x}(b))\mathcal{R}$.

PROPOSITION 2.2. Let (\hat{x}, \hat{u}) be an extremal for (P), and $\hat{p}(\cdot)$, λ_0 , γ satisfying conditions (1)–(3) of Theorem 2.1 and condition (2.2). If (H) is satisfied, then $\lambda_0 \neq 0$. Set $\lambda_0 = 1$, then $\lambda_0 = 1$, $\hat{p}(\cdot)$, and γ are unique.

Proof. The proof is by contradiction. Suppose there exists another triple $\bar{p}(\cdot)$, $\bar{\gamma}$, λ_0 corresponding to (\hat{x}, \hat{u}) . Since $U - \hat{u}(t) \supset \tilde{U}(t)$ then assumption (H) implies that $\lambda_0 \neq 1$; set $\lambda_0 = 1$ and we get

$$\begin{aligned} -(\dot{\bar{p}}(t) - \dot{\hat{p}}(t)) &= \hat{f}_x^T(t)(\bar{p}(t) - \hat{p}(t)) \quad \text{a.e. } t \in I, \\ (\bar{p} - \hat{p})^T(b) &= (\bar{\gamma} - \gamma)^T D\Phi(\hat{x}(b)), \\ \langle \hat{f}_u^T(t)\bar{p}(t) + \hat{g}_u(t), w \rangle &\geq 0 \quad \text{a.e. } t \in I \quad \forall w \in \tilde{U}(t), \\ \langle \hat{f}_u^T(t)\hat{p}(t) + \hat{g}_u(t), w \rangle &= 0 \quad \text{a.e. } t \in I \quad \forall w \in \tilde{U}(t). \end{aligned}$$

Thus

$$\langle \hat{f}_u^T(t)(\bar{p}(t) - \hat{p}(t)), w \rangle \geq 0 \quad \text{a.e. } t \in I \quad \forall w \in \tilde{U}(t),$$

and by (H) we get $\bar{p} \equiv \hat{p}$. Since $D\Phi\hat{x}(b)$ is of full rank we obtain $\bar{\gamma} = \gamma$. Q.E.D.

Let (\hat{x}, \hat{u}) be an extremal. From the preceding we obtain: let $\hat{p}(\cdot)$, λ_0 , γ satisfying (1)–(3) of Theorem 2.1 and condition (2.2). Define $\tilde{U}(t)$ by (2.8) and

$$(2.9) \quad \tilde{\mathcal{U}} = \{w(\cdot) \in L^\infty(I, R^m); w(t) \in \tilde{U}(t) \text{ a.e. } t \in I\}.$$

Assume (H); then λ_0 can be taken to be 1. Consider the so-called accessory problem to (P), i.e.,

$$\begin{aligned} \text{(AP)} \quad \text{Minimize} \quad J_2(\eta, w) &= \frac{1}{2} \eta^T(b) \Gamma \eta(b) \\ &+ \frac{1}{2} \int_a^b \{ \eta^T(t) \hat{H}_{xx}(t) \eta(t) + 2\eta^T(t) \hat{H}_{xu}(t) w(t) \\ &+ w^T(t) \hat{H}_{uu}(t) w(t) \} dt \end{aligned}$$

over all $(\eta, w) \in AC(I, R^n) \times \text{cone } \tilde{\mathcal{U}}$, satisfying

$$\begin{aligned} \dot{\eta}(t) &= \hat{f}_x(t)\eta(t) + \hat{f}_u(t)w(t) \quad \text{a.e. } t \in I, \\ \eta(a) &= 0, \quad \Psi\eta(b) = 0, \end{aligned}$$

where

$$\begin{aligned}\Psi &= D\Phi(\hat{x}(b)), \\ \Gamma &= D^2K(\hat{x}(b)) + D^2\Phi(\hat{x}(b))^T\gamma, \\ \hat{H}(t) &= H(t, \hat{x}(t), \hat{p}(t), \hat{u}(t), 1).\end{aligned}$$

When (\hat{x}, \hat{u}) is a weak local minimum, then $(0, 0)$ solves (AP), i.e.,

$$J_2(\eta, w) \geq 0.$$

3. Main results. Discussion. In the classical calculus of variations the definition of conjugate point is derived by computing the second variation of the original problem which yields what is known as the accessory problem, whose Euler-Lagrange equation is the Jacobi equation. However, in the optimal control setting, the uniqueness of the adjoint function $p(t)$ (which is guaranteed by assumption (H)) is required to obtain an accessory problem out of the second variation, as we have done in § 2. The application of the maximum principle, Theorem 2.1, to the accessory problem (AP) motivates the definition of conjugate point below.

Throughout this section we will suppose that Assumptions (A) and (B) and (H) are satisfied and that (\hat{x}, \hat{u}) is an extremal for (P) with $\hat{u} \in L^\infty(I, R^m)$.

DEFINITION 3.1. A point $c \in [a, b]$ is said to be conjugate to b if there exists nonzero $(\lambda, \eta, w) \in AC(I, R^n) \times AC(I, R^n) \times \text{cone } \tilde{\mathcal{U}}$ such that, for some $l_1 \in R^k$,

$$\begin{aligned}(3.1) \quad \dot{\eta}(t) &= \hat{f}_x(t)\eta(t) + \hat{f}_u(t)w(t) \quad \text{a.e. } t \in I, \\ -\dot{\lambda}(t) &= \hat{H}_{xx}(t)\eta(t) + \hat{H}_{xu}(t)w(t) + \hat{f}_x^T(t)\lambda(t) \quad \text{a.e. } t \in I,\end{aligned}$$

$$\begin{aligned}(3.2) \quad \Psi\eta(b) &= 0, \quad \eta(c) = 0, \\ \lambda(b) &= \Psi^T l_1 + \Gamma\eta(b),\end{aligned}$$

and

$$(3.3) \quad \langle \hat{H}_{uu}(t)w(t) + \hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t), z \rangle = 0 \quad \text{a.e. } t \in I \quad \forall z \in \text{span } \tilde{U}(t).$$

Remark 3.1. Since Assumption (H) holds, then a straightforward application of the Pontryagin principle to the accessory problem yields that whenever (η, w) is its solution, there exists λ such that (λ, η, w) satisfies (3.1), (3.2) with $c = a$, and

$$\langle \hat{H}_{uu}(t)w(t) + \hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t), z \rangle \geq 0 \quad \text{a.e. } t \in I \quad \forall z \in \tilde{U}(t),$$

instead of the equality in (3.3).

Remark 3.2. If U is convex with nonempty interior, then

$$\text{span } \tilde{U}(t) = \hat{H}_u(t)^\perp := \{w \in R^m : \langle \hat{H}_u(t), w \rangle = 0\}.$$

Remark 3.3. Some geometrical assumptions on the original problem may simplify Definition 3.1. For instance, if U is open or $\hat{u}(t) \in \text{int } U$ almost everywhere $t \in I$ then, for almost all t in I , $\hat{H}_u(t) = 0$, $\text{span } \tilde{U}(t) = R^m$, and $\text{cone } \tilde{\mathcal{U}} = \text{cone } \mathcal{U}$. But $\text{cone } \mathcal{U} = L^\infty(I, R^m)$ if and only if $\hat{u} \in \text{int } L^\infty(I, U)$.

Solving (3.3) for w allows us to replace (3.1)–(3.3) by a $2n$ -system of linear differential equations in terms of η and λ only.

From now on all the functions appearing in any formula have to be considered evaluated at t .

PROPOSITION 3.1. Assume that U is convex with nonempty interior. If $\hat{H}_{uu}(t) > 0$ almost everywhere $t \in I$, then (η, λ, w) satisfies Definition 3.1 if and only if $0 \neq (\lambda, \eta) \in AC(I, \mathbb{R}^n) \times AC(I, \mathbb{R}^n)$ and

$$(3.4) \quad \dot{\eta} = [\hat{f}_x - \hat{f}_u K \hat{H}_{uu}^{-1} \hat{H}_{ux}] \eta - \hat{f}_u K \hat{H}_{uu}^{-1} \hat{f}_u^T \lambda \quad \text{a.e. } t \in I,$$

$$(3.5) \quad -\dot{\lambda} = [\hat{H}_{xx} - \hat{H}_{xu} K \hat{H}_{uu}^{-1} \hat{H}_{ux}] \eta + [\hat{f}_x^T - \hat{H}_{xu} K \hat{H}_{uu}^{-1} \hat{f}_u^T] \lambda \quad \text{a.e. } t \in I$$

with

$$\Psi \eta(b) = 0, \quad \eta(c) = 0,$$

$$\lambda(b) = \Psi^T l_1 + \Gamma \eta(b) \quad \text{for some } l_1 \in \mathbb{R}^k,$$

and

$$w \in \mathcal{U},$$

where

$$(3.6) \quad w := -K \hat{H}_{uu}^{-1} [\hat{H}_{ux} \eta + \hat{f}_u^T \lambda],$$

and

$$(3.7) \quad K(t) = \begin{cases} I_m & \text{if } \hat{H}_u(t) = 0, \\ -\frac{\hat{H}_{uu}^{-1} \hat{H}_u \hat{H}_u^T}{\hat{H}_u^T \hat{H}_{uu}^{-1} \hat{H}_u} + I_m & \text{if } \hat{H}_u(t) \neq 0. \end{cases}$$

Proof. If c is conjugate to b , then there exists $(\lambda, \eta, w) \neq 0$ satisfying Definition 3.1. The function w can be taken in $\tilde{\mathcal{U}}$. Since $\text{span } \tilde{U}(t) = \hat{H}_u^\perp(t)$, from (3.3) it follows that

$$\hat{H}_{uu}(t)w(t) + \hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t) = 0 \quad \text{if } \hat{H}_u(t) = 0$$

or

$$\hat{H}_{uu}(t)w(t) + \hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t) = \alpha(t)\hat{H}_u^T(t) \quad \text{if } \hat{H}_u(t) \neq 0,$$

where $\alpha(t) \in \mathbb{R}$.

Thus, when $\hat{H}_u(t) = 0$,

$$w(t) = -\hat{H}_{uu}^{-1}(t)[\hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t)].$$

On the other hand, when $\hat{H}_u(t) \neq 0$,

$$w(t) = -\hat{H}_{uu}^{-1}(t)[\hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t)] + \alpha(t)\hat{H}_{uu}^{-1}(t)\hat{H}_u(t).$$

Multiply both sides of the above equation by $\hat{H}_u^T(t)$. Note that $w \in \text{cone } \tilde{\mathcal{U}}$ to get

$$0 = -\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)[\hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t)] + \alpha(t)\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)\hat{H}_u(t)$$

and hence

$$\alpha(t) = \frac{\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)}{\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)\hat{H}_u(t)} [\hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t)];$$

substituting $\alpha(\cdot)$ in the above equation it is easy to get

$$w(t) = \left[\frac{\hat{H}_{uu}^{-1}(t)\hat{H}_u(t)\hat{H}_u^T(t)}{\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)\hat{H}_u(t)} - I \right] \hat{H}_{uu}^{-1}(t)(\hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t)).$$

Therefore (3.3) yields

$$(3.8) \quad w(t) = -K(t)\hat{H}_{uu}^{-1}(t)[\hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t)] \quad \text{a.e. } t \in I,$$

where $K(t)$ is given by (3.7). Now replace (3.8) in each of (3.1) and (3.2). We obtain that (λ, η) satisfies (3.4)–(3.6) and the boundary conditions.

Conversely, assume that there exist (λ, η) satisfying the conditions of Proposition 3.1. From (3.6) and (3.7) the following result:

$$\left. \begin{array}{l} \text{If } \hat{H}_u(t) = 0, \text{ then} \\ \text{If } \hat{H}_u(t) \neq 0, \text{ then} \end{array} \right\} \hat{H}_u(t)w(t) = 0;$$

$$\hat{H}_u^T(t)w(t) = \left[\frac{\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)\hat{H}_u(t)\hat{H}_u^T(t)}{\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)\hat{H}_u(t)} - \hat{H}_u^T(t) \right] \hat{H}_{uu}^{-1}(t)(\hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t)) = 0.$$

Thus w , defined by (3.6), is in \mathcal{Q} . If we replace (3.6) in (3.4) and (3.5) we obtain that (3.1) and (3.2) are satisfied by (λ, η) and w . It remains to show (3.3). If $\hat{H}_u(t) \neq 0$, (3.6) and (3.7) give

$$\begin{aligned} & \hat{H}_{uu}(t)w(t) + \hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t) \\ &= \frac{\hat{H}_u(t)\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)}{\hat{H}_u^T(t)\hat{H}_{uu}^{-1}(t)\hat{H}_u(t)} (\hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t)) = \alpha(t)\hat{H}_u(t), \end{aligned}$$

where $\alpha(t)$ is defined as above. Therefore, for all $z \in \hat{H}_u^\perp(t)$,

$$\langle \hat{H}_{uu}(t)w(t) + \hat{H}_{ux}(t)\eta(t) + \hat{f}_u^T(t)\lambda(t), z \rangle = 0 \quad \text{a.e. } t \in I.$$

If $\hat{H}_u(t) = 0$, then (3.3) follows immediately from (3.6). Q.E.D.

Remark 3.4. Some regularity assumptions on H imply that the control defined by (3.6) is in L^∞ . For instance, if for some $\alpha > 0$, $\hat{H}_{uu}^{(t)} \geq \alpha I_m$, for almost all $t \in I$, then $\hat{H}_{uu}^{-1}(t) \in L^\infty(I, R^{m \times m})$. If, in addition, $H_{ux}(\cdot, x, u)$ and $f_u(\cdot, x, u)$ are essentially bounded, so is the function w given by (3.6). Since (\hat{x}, \hat{u}) is essentially bounded, thus, it remains to show that, when $\hat{H}_u(t) \neq 0$, $-\hat{K}\hat{H}_{uu}^{-1}$ is essentially bounded. Let $0 < \lambda_1(t) \leq \dots \leq \lambda_m(t)$ be the eigenvalues of $\hat{H}_{uu}^{-1}(t)$; then

$$|\lambda_i(t)| \leq \|\hat{H}_{uu}^{-1}\|_\infty =: \rho, \quad i = 1, 2, \dots, m.$$

Thus the λ_i 's are in $L^\infty(I, R)$. Since \hat{H}_{uu}^{-1} is symmetric, then

$$\hat{H}_{uu}^{-1}(t) = P^T(t)\Lambda(t)P(t),$$

where P is such that $P^T P = I$ and

$$\Lambda = \begin{bmatrix} \lambda_1 & & & 0 \\ & \ddots & & \\ 0 & & & \lambda_m \end{bmatrix}.$$

Hence, when $\hat{H}_u(t) \neq 0$, (3.7) yields

$$-\hat{K}\hat{H}_{uu}^{-1} + \hat{H}_{uu}^{-1} = \frac{\hat{H}_{uu}^{-1}\hat{H}_u\hat{H}_u^T\hat{H}_{uu}^{-1}}{\hat{H}_u^T\hat{H}_{uu}^{-1}\hat{H}_u} = \frac{P^T\Lambda P\hat{H}_u\hat{H}_u^T P^T\Lambda P}{\hat{H}_u^T P^T\Lambda P\hat{H}_u} = P^T \left(\frac{\lambda_i\lambda_j\alpha_i\alpha_j}{\sum_{i=1}^m \alpha_k^2\lambda_k} \right) P,$$

where

$$P\hat{H}_u = \begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_m \end{bmatrix}.$$

But for any i, j

$$\left| \frac{\lambda_i\lambda_j\alpha_i\alpha_j}{\sum_{i=1}^m \alpha_k^2\lambda_k} \right| \leq \left| \frac{\lambda_i\lambda_j\alpha_i\alpha_j}{\alpha_i^2\lambda_i + \alpha_j^2\lambda_j} \right| \leq \frac{1}{2} \sqrt{\lambda_i} \sqrt{\lambda_j} \leq \frac{1}{2} \rho.$$

Therefore w is essentially bounded.

Our main result concerning the nonexistence of conjugate points corresponding to a weak local minimum requires the following two normality assumptions:

(H₁) $\Psi = D\Phi(\hat{x}(b))$ is of full rank and there exists a unique solution of

$$-\dot{p}(t) = \hat{f}_x^T(t)p(t) \quad \text{a.e. } t \in [c, b],$$

$$p(b)^T = l^T \Psi \quad \text{for some } l \in \mathbb{R}^k$$

and

$$\langle \hat{f}_u^T(t)p(t), w \rangle \geq 0 \quad \text{a.e. } t \in [c, b] \quad \forall w \in \tilde{U}(t)$$

on any subinterval $[c, b]$ of I .

(H₂) There exists a unique solution of

$$-\dot{p}(t) = \hat{f}_x^T(t)p(t) \quad \text{a.e. } t \in [a, c],$$

$$\langle \hat{f}_u^T(t)p(t), w \rangle \geq 0 \quad \text{a.e. } t \in [a, c] \quad \forall w \in \tilde{U}(t)$$

on any subinterval $[a, c]$ of I .

Our main result is given by the following theorem.

THEOREM 3.1. *Let (\hat{x}, \hat{u}) be a weak local minimum for (P) with $\hat{u} \in L^\infty(I, \mathbb{R}^m)$. Assume that (H₁) and (H₂) hold and that U is convex with nonempty interior. If $\hat{H}_{uu}(t) \geq \alpha I_m$, for $\alpha > 0$ almost everywhere $t \in I$, then there is no point in (a, b) conjugate to b .*

Before proving Theorem 3.1, we will present an example which illustrates the indispensability of the strong normality assumptions (H₁) and (H₂).

Example 1. Consider the following optimal control problem:

$$\text{Minimize } J(u) = \frac{1}{2} \int_0^1 u^2(t) dt$$

subject to

$$\begin{pmatrix} \dot{x}_1(t) \\ \dot{x}_2(t) \end{pmatrix} = B(t)u(t) \quad \text{a.e. } t \in [0, 1],$$

$$x(0) = x(1) = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

where

$$B(t) = \begin{cases} \begin{pmatrix} 1 \\ 0 \end{pmatrix} & \text{on } \left[0, \frac{1}{2}\right] \\ \begin{pmatrix} 0 \\ 1 \end{pmatrix} & \text{on } \left(\frac{1}{2}, 1\right] \end{cases},$$

and $U = \mathbb{R}$.

It is clear that the solution of the problem is $(\hat{x}, \hat{u}) \equiv \left(\begin{pmatrix} 0 \\ 0 \end{pmatrix}, 0\right)$. Let us first show that Assumption (H) holds. Let $p = \begin{pmatrix} p_1 \\ p_2 \end{pmatrix}$ satisfying on $[0, 1]$, $\dot{p}(t) = 0$ and $B^T(t)p(t) = 0$; then $p \equiv \begin{pmatrix} c_1 \\ c_2 \end{pmatrix}$ and $c_1 = c_2 = 0$. Thus (H) is satisfied.

Now take $p \equiv \begin{pmatrix} 0 \\ 1 \end{pmatrix}$; it is clear that, on an interval of the form $[0, c]$, when $0 < c < \frac{1}{2}$, such p satisfies $\dot{p}(t) = 0$ and $B^T(t)p(t) = 0$. Thus Assumption (H₂) is violated. On the other hand, for $p \equiv \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ we have $\dot{p}(t) = 0$ and $B^T(t)p(t) = 0$ on any interval of the form $[c, 1]$, where $\frac{1}{2} < c < 1$. Thus (H₁) does not hold; therefore Theorem 3.1 does not apply.

In fact, take

$$\eta(t) = \begin{cases} \begin{pmatrix} -t + \frac{1}{2} \\ 0 \end{pmatrix} & \text{on } [0, \frac{1}{2}], \\ \begin{pmatrix} 0 \\ 0 \end{pmatrix} & \text{on } [\frac{1}{2}, 1] \end{cases}$$

and $\lambda(t) \equiv \begin{pmatrix} 1 \\ 0 \end{pmatrix}$. Then (η, λ) satisfies (3.4) and (3.5), that is,

$$\begin{aligned} \dot{\eta}(t) &= -B(t)B^T(t)\lambda(t) \quad \text{a.e. } t \in [0, 1], \\ -\dot{\lambda}(t) &= 0, \end{aligned}$$

with

$$\eta(1) = \eta(c) = 0 \quad \text{for any } c \in [\frac{1}{2}, 1].$$

This implies that any point in $[\frac{1}{2}, 1]$ is a conjugate point to 1.

Proof of Theorem 3.1. Suppose that there exists a point $c \in (a, b)$ conjugate to b ; then there exists $(\lambda, \eta, w) \neq 0$ satisfying Definition 3.1. We can assume that w satisfies $2w \in \tilde{\mathcal{U}}$. Define

$$(\bar{\lambda}(t), \bar{\eta}(t), \bar{w}(t)) = (\lambda(t), \eta(t), w(t))\chi_{(c,b]}(t) \quad \text{for } t \in I$$

($\chi_A(\cdot)$ is the characteristic function of the set A). Then: $(\bar{\eta}, \bar{w}) \in AC(I, R^n) \times \tilde{\mathcal{U}}$ and

$$\begin{aligned} \dot{\bar{\eta}}(t) &= \hat{f}_x(t)\bar{\eta}(t) + \hat{f}_u(t)\bar{w}(t) \quad \text{a.e. } t \in I, \\ (3.9) \quad \bar{\eta}(a) &= 0, \quad \Psi\bar{\eta}(b) = 0. \end{aligned}$$

Thus $(\bar{\eta}, \bar{w})$ is feasible for the accessory problem. By using (3.1)–(3.3) on $[c, b]$ we get

$$\begin{aligned} J_2(\bar{\eta}, \bar{w}) &= \frac{1}{2} \eta^T(b) \Gamma \eta(b) \\ &\quad + \frac{1}{2} \int_c^b \{ \eta^T(t) \hat{H}_{xx}(t) \eta(t) + 2 \eta^T(t) \hat{H}_{xu}(t) w(t) + w^T(t) \hat{H}_{uu}(t) w(t) \} dt \\ &= \frac{1}{2} \eta^T(b) \Gamma \eta(b) + \frac{1}{2} \int_c^b \{ -\dot{\lambda}^T(t) \eta(t) - \lambda^T(t) \hat{f}_x(t) \eta(t) - \eta^T(t) \hat{H}_{xu}(t) w(t) \\ &\quad + 2 \eta^T(t) \hat{H}_{xu}^T(t) w(t) + w^T(t) \hat{H}_{uu}(t) w(t) \} dt \\ &= \frac{1}{2} \eta^T(b) \Gamma \eta(b) + \frac{1}{2} \int_c^b \{ -\dot{\lambda}^T(t) \eta(t) - \lambda^T(t) \hat{f}_x(t) \eta(t) + \eta^T(t) \hat{H}_{xu}(t) w(t) \\ &\quad - \eta^T(t) \hat{H}_{xu}(t) w(t) - \lambda^T(t) \hat{f}_u(t) w(t) \} dt \\ &= \frac{1}{2} \eta^T(b) \Gamma \eta(b) + \frac{1}{2} \int_c^b \{ -\dot{\lambda}^T(t) \eta(t) - \lambda^T(t) \dot{\eta}(t) \} dt \\ &= \frac{1}{2} \eta^T(b) \Gamma \eta(b) - \frac{1}{2} \eta^T(b) \lambda(b) \\ &= \frac{1}{2} \eta^T(b) \Gamma \eta(b) - \frac{1}{2} \eta^T(b) [\Psi^T l_1 + \Gamma \eta(b)] \\ &= -\frac{1}{2} \eta^T(b) \Psi^T l_1 = 0. \end{aligned}$$

Thus $(\bar{\eta}, \bar{w})$ minimizes $J_2(\eta, w)$ over $(\eta, w) \in \mathcal{U}$ with $\bar{w} \in \text{cone } \tilde{\mathcal{U}}$. In particular, $(\bar{\eta}, \bar{w})$ provides a minimum for the accessory problem (AP), with the additional condition $w \in \tilde{\mathcal{U}}$. By the Pontryagin principle we get the following: there exist a number α_0 , a vector $v \in R^k$ and an absolutely continuous function p such that

$$(3.10) \quad \alpha_0 \geq 0, \quad |v| + \alpha_0 \neq 0,$$

$$(3.11) \quad -\dot{p}(t) = \hat{f}_x^T(t)p(t) + \alpha_0[\hat{H}_{xx}(t)\bar{\eta}(t) + \hat{H}_{xu}(t)\bar{w}(t)] \quad \text{a.e. } t \in I,$$

$$(3.12) \quad p(b) = \Psi^T v + \alpha_0 \Gamma \bar{\eta}(b),$$

and

$$\min \{ \langle \hat{f}_u^T(t)p(t), w \rangle + \frac{1}{2}\alpha_0[2\bar{\eta}(t)\hat{H}_{xu}(t)w + w^T\hat{H}_{uu}(t)w] : \forall w \in \tilde{U}(t) \}$$

is attained at $\bar{w}(t)$ almost everywhere $t \in I$.

This last condition implies

$$\langle \hat{f}_u^T(t)p(t) + \alpha_0[\hat{H}_{ux}(t)\bar{\eta}(t) + \hat{H}_{uu}(t)\bar{w}(t)], w - \bar{w}(t) \rangle \geq 0 \quad \text{a.e. } t \in I \quad \forall w \in \tilde{U}(t).$$

Since 0 and $2\bar{w}(t)$ are in $\tilde{U}(t)$, almost everywhere $t \in I$, then

$$(3.13) \quad \langle \hat{f}_u^T(t)p(t) + \alpha_0[\hat{H}_{ux}(t)\bar{\eta}(t) + \hat{H}_{uu}(t)\bar{w}(t)], w \rangle \geq 0 \quad \text{a.e. } t \in I \quad \forall w \in \tilde{U}(t);$$

and equality in (3.13) holds at $\bar{w}(t)$.

If $\alpha_0 = 0$, then

$$\begin{aligned} -\dot{p}(t) &= \hat{f}_x^T(t)p(t) \quad \text{a.e. } t \in I, \\ p(b) &= \Psi^T v, \end{aligned}$$

and

$$\langle \hat{f}_u^T(t)p(t), w \rangle \geq 0 \quad \text{a.e. } t \in I \quad \forall w \in \tilde{U}(t).$$

By hypothesis (H), $p \equiv 0$ and hence $v = 0$, which yields a contradiction. Thus we can take α_0 to be 1.

On $[a, c]$, (3.11) and (3.13) yield

$$-\dot{p}(t) = \hat{f}_x^T(t)p(t) \quad \text{a.e. } t,$$

and

$$\langle \hat{f}_u^T(t)p(t), w \rangle \geq 0 \quad \text{a.e. } t \quad \forall w \in \tilde{U}(t).$$

Thus by (H₂) we obtain

$$p \equiv 0 \quad \text{on } [a, c].$$

Now, if we use (3.1)–(3.3) with (3.11)–(3.13) we get for $t \in [c, b]$,

$$\begin{aligned} -(\dot{p}(t) - \dot{\lambda}(t)) &= \hat{f}_x^T(t)[p(t) - \lambda(t)] \quad \text{a.e. } t, \\ [p(b) - \lambda(b)] &= \Psi^T(v - l_1) \end{aligned}$$

and

$$\langle \hat{f}_u^T(t)[p(t) - \lambda(t)], w \rangle \geq 0 \quad \text{a.e. } t \quad \forall w \in \tilde{U}(t).$$

Using (H₁) the following results:

$$p \equiv \lambda \quad \text{on } [c, b];$$

hence $\lambda(c) = 0$. But from Proposition 3.1 we know that (λ, η, w) satisfies (3.4)–(3.6). Since $\lambda(c) = \eta(c) = 0$ it follows that

$$\lambda \equiv \eta \equiv w \equiv 0 \quad \text{on } [a, b],$$

which contradicts the fact that $(\lambda, \eta, w) \neq 0$. Q.E.D.

Let us now consider the matrix system corresponding to (3.4) and (3.5):

$$(3.14) \quad \begin{aligned} \dot{X} &= [\hat{f}_x - \hat{f}_u K \hat{H}_{uu}^{-1} \hat{H}_{ux}] X - \hat{f}_u K \hat{H}_{uu}^{-1} \hat{f}_u^T \Lambda, \\ -\dot{\Lambda} &= [\hat{H}_{xx} - \hat{H}_{xu} K \hat{H}_{uu}^{-1} \hat{H}_{ux}] X + [\hat{f}_x^T - \hat{H}_{xu} K \hat{H}_{uu}^{-1} \hat{f}_u^T] \Lambda \end{aligned}$$

with

$$(3.15) \quad \begin{aligned} \Psi X(b) &= 0, \\ \Lambda(b) &= \Psi^T N + \Gamma X(b) \quad \text{for some } N. \end{aligned}$$

Define

$$(3.16) \quad Z = \{\alpha \in \mathbb{R}^n: -K(t) \hat{H}_{uu}^{-1}(t) [\hat{H}_{ux}(t) X(t) + \hat{f}_u^T(t) \Lambda] \alpha \in U - \hat{u}(t) \text{ a.e. } t \in I\}.$$

From Proposition 3.1, Remark 3.4 and Theorem 3.1 we can deduce the following corollary.

COROLLARY 3.1. *Assume that $H_{ux}(\cdot, x, u)$ and $f_u(\cdot, x, u)$ are essentially bounded. Then under the conditions of Theorem 3.1, we have:*

$$X(t) \alpha \neq 0 \quad \forall \alpha \in Z \text{ and } \forall t \in (a, b) \quad \text{where } X(\cdot) \text{ solves (3.14) and (3.15).}$$

Remark 3.5. When $\hat{u} \in \text{int } L^\infty(I, U)$, then cone $Z = \mathbb{R}^n$ and hence $X(t)$ is invertible on (a, b) .

Let (X, Λ) be a solution of (3.14) and (3.15) and let S be any subspace: $S \subset (\text{cone } Z) \cup (-\text{cone } Z)$. Let r be its dimension and Y be an $n \times r$ matrix whose columns form an orthonormal basis of S .

COROLLARY 3.2. *Under the conditions of Corollary 3.1 there exists a locally Lipschitz matrix function Q on (a, b) such that:*

$$(3.17) \quad Y^T X^T(t) [Q(t) - Q^T(t)] X(t) Y = 0 \quad \text{on } (a, b),$$

and

$$(3.18) \quad L(Q(t)) X(t) Y = 0 \quad \text{a.e. } t \in (a, b),$$

where

$$\begin{aligned} L(Q(t)) &:= \dot{Q}(t) - Q(t) \hat{f}_u(t) K(t) \hat{H}_{uu}^{-1}(t) \hat{f}_u^T(t) Q(t) \\ &\quad + Q(t) [\hat{f}_x(t) - \hat{f}_u(t) K(t) \hat{H}_{uu}^{-1}(t) \hat{H}_{ux}(t)] \\ &\quad + [\hat{f}_x^T(t) - \hat{H}_{xu}(t) \hat{H}_{uu}^{-1}(t) K^T(t) \hat{f}_u^T(t)] Q(t) \\ &\quad + [\hat{H}_{xx}(t) - \hat{H}_{xu}(t) K(t) \hat{H}_{uu}^{-1}(t) \hat{H}_{ux}(t)]. \end{aligned}$$

Remark 3.6. If $\hat{u} \in \text{int } L^\infty(I, U)$, then $X(t)$ and Y are invertible and (3.17) and (3.18) reduce to Q being symmetric and satisfying the Riccati equation

$$L(Q(t)) = 0 \quad \text{a.e. } t \in (a, b).$$

Proof of Corollary 3.2. We first notice that any (X, Λ) satisfying (3.14) and (3.15) also satisfies

$$X^T(t) \Lambda(t) = \Lambda^T(t) X(t).$$

From Corollary 3.1 it follows that the $r \times r$ matrix $Y^T X^T(t) X(t) Y$ is invertible on (a, b) . Define

$$(3.19) \quad Q(t) := \Lambda(t) Y [Y^T X^T(t) X(t) Y]^{-1} Y^T X^T(t).$$

Equation (3.17) can now be easily deduced.

From Remark 3.4 and (3.14) it follows that $Q(t)$ is locally Lipschitz on (a, b) . Now using (3.14) and (3.19) we can verify that $Q(t)$ satisfies (3.18) on (a, b) . Q.E.D.

4. Special cases. In this section we study some special cases in which the results can be strengthened and the hypotheses can be simplified.

Consider the optimal control problem (P) where $\Phi \equiv 0$, that is, we have a free final state. In this case the problem is automatically normal on any $[c, b] \subset [a, b]$, that is Hypothesis (H_1) , and hence (H), holds. Proposition 2.2 is then valid and if (\hat{x}, \hat{u}) is a weak local minimum, then

$$\forall (\eta, w) \in AC(I, R^n) \times \text{cone } \tilde{\mathcal{U}}$$

with

$$\dot{\eta}(t) = \hat{f}_x(t)\eta(t) + \hat{f}_u(t)w(t) \quad \text{a.e. } t \in I,$$

$$\eta(a) = 0$$

we have

$$J_2(\eta, w) = \frac{1}{2} \eta^T(b) D^2 K(\hat{x}(b)) \eta(b) + \frac{1}{2} \int_a^b \{ \eta^T(t) \hat{H}_{xx}(t) \eta(t) + 2 \eta^T(t) \hat{H}_{xu}(t) w(t) + w^T(t) \hat{H}_{uu}(t) w(t) \} dt,$$

where

$$\begin{aligned} \tilde{\mathcal{U}} = \{ w(\cdot) \in L^\infty(I, R^m) : w(t) \in U - \hat{u}(t) \text{ a.e. } t \in I \text{ and} \\ \langle w(t), \hat{H}_u(t) \rangle = 0 \text{ a.e. } t \in I \}. \end{aligned}$$

THEOREM 4.1. Let (\hat{x}, \hat{u}) be a weak local minimum for (P) with $\Phi \equiv 0$ and $\hat{u} \in L^\infty(I, R^m)$, and let U be closed and convex. Then

$$J_2(\eta, w) \geq 0 \quad \forall (\eta, w) \in AC(I, R^n) \times W$$

with

$$\dot{\eta}(t) = \hat{f}_x(t)\eta(t) + \hat{f}_u(t)w(t) \quad \text{a.e. } t \in I,$$

$$\eta(a) = 0,$$

where

$$(4.1) \quad \begin{aligned} W = \{ w(\cdot) \in L^\infty(I, R^m) : w(t) \in \text{cone } \{ U - \hat{u}(t) \} \text{ a.e. } t \in I \text{ and} \\ \langle \hat{H}_u(t), w(t) \rangle = 0 \text{ a.e. } t \in I \}. \end{aligned}$$

(In general $W \supset \text{cone } \tilde{\mathcal{U}}$.)

Proof. Let (η, w) satisfy the conditions of the theorem, and define

$$\begin{aligned} A_n &= \left\{ t \in I : d \left(\frac{1}{n} w(t), U - \hat{u}(t) \right) = 0 \right\} \\ &= \left\{ t \in I : \frac{1}{n} w(t) \in U - \hat{u}(t) \right\} \\ &= \left\{ t \in I : \frac{1}{n} w(t) + \hat{u}(t) \in U \right\}; \end{aligned}$$

then A_n is measurable. Since $0 \in U - \hat{u}(t)$ and $U - \hat{u}(t)$ is convex, then $A_n \subset A_{n+1}$. From (4.1) we get

$$\exists \Omega \subset I: \mu(\Omega) = 0 \quad \text{and} \quad \forall t \in \Omega^C, \quad w(t) \in \text{cone} \{U - \hat{u}(t)\},$$

where $\Omega^C = \{t \in I: t \notin \Omega\}$. Thus $\Omega^C \subset \bigcup_{n=1}^{\infty} A_n$, and hence from the inclusion $A_n \subset A_{n+1}$ we get

$$\lim_{n \rightarrow \infty} \mu(A_n^C) = 0.$$

Define

$$w_n(t) = w(t) \chi_{A_n}(t) \quad \text{where } A_0 = [a, b]$$

and let $\eta_n(t)$ be the solution of

$$\begin{aligned} \dot{\eta}(t) &= \hat{f}_x(t) \eta(t) + \hat{f}_u(t) w_n(t), \\ \eta(a) &= 0. \end{aligned}$$

Let $E(t, s)$ be the evolution operator associated to

$$\dot{\eta}(t) = \hat{f}_x(t) \eta(t).$$

We get

$$\eta(t) - \eta_n(t) = \int_{[a, t] \cap A_n^C} E(t, s) \hat{f}_u(s) w(s) ds;$$

thus

$$\begin{aligned} |\eta(t) - \eta_n(t)| &\leq \int_{[a, t] \cap A_n^C} |E(t, s)| |\hat{f}_u(s)| |w(s)| ds \\ &\leq M \|w\|_{\infty} \int_{A_n^C} |\hat{f}_u(s)| ds \quad \forall t \in I, \end{aligned}$$

where

$$M = \max_{\substack{t \in I \\ s \in I}} |E(t, s)|.$$

On the other hand,

$$\begin{aligned} |\eta(t) + \eta_n(t)| &\leq 2M \|w\|_{\infty} \|\hat{f}_u\|_1 \quad \forall t \in I, \\ |w(t) - w_n(t)| &= |w(t)| \chi_{A_n^C}(t) \quad \text{a.e. } t \in I, \\ |w(t) + w_n(t)| &\leq 2\|w\|_{\infty} \quad \text{a.e. } t \in I. \end{aligned}$$

Since J_2 can be written as

$$J_2(\eta, w) = \frac{1}{2} \eta^T(b) D^2 K(\hat{x}(b)) \eta(b) + \frac{1}{2} \int_a^b (\eta^T(t), w^T(t)) D_{x,u}^2 \hat{H}(t) \begin{pmatrix} \eta(t) \\ w(t) \end{pmatrix} dt$$

and $D^2K(\hat{x}(b))$ and $D_{x,u}^2\hat{H}(t)$ are symmetric, then

$$\begin{aligned}
 2|J_2(\eta, w) - J_2(\eta_n, w_n)| &\leq |(\eta(b) + \eta_n(b))^T D^2K(\hat{x}(b))(\eta(b) - \eta_n(b))| \\
 &\quad + \left| \int_a^b (\eta^T(t) + \eta_n^T(t), w^T(t) \right. \\
 &\quad \left. + w_n^T(t)) D_{x,u}^2\hat{H}(t) \begin{pmatrix} \eta(t) - \eta_n(t) \\ w(t) - w_n(t) \end{pmatrix} dt \right| \\
 &\leq |\eta(b) + \eta_n(b)| |D^2K(\hat{x}(b))| |\eta(b) - \eta_n(b)| \\
 &\quad + \int_a^b \left\{ (|(\eta + \eta_n)(t)| + |(w + w_n)(t)|) |D_{x,u}^2\hat{H}(t)| \right. \\
 &\quad \left. \cdot \left[M \|w\|_\infty \int_{A_n^C} |\hat{f}_u(s)| ds + |w(t)| \chi_{A_n^C}(t) \right] \right\} dt \\
 &\leq 2M^2 \|w\|_\infty^2 \|\hat{f}_u\|_1 |D^2K(\hat{x}(b))| \|\hat{f}_u\|_\infty \mu(A_n^C) \\
 &\quad + (2\|w\|_\infty + 2M\|w\|_\infty \|\hat{f}_u\|_1) |D_{x,u}^2\hat{H}(t)|_\infty \\
 &\quad \cdot [M\|w\|_\infty \|\hat{f}_u\|_1 \mu(A_n^C) + \|w\|_\infty \mu(A_n^C)](b-a).
 \end{aligned}$$

Since $\mu(A_n^C) \rightarrow 0$, as $n \rightarrow \infty$, we get

$$\lim_{n \rightarrow \infty} J_2(\eta_n, w_n) = J_2(\eta, w).$$

But $w_n \in n(U - \hat{u}(t))$ or $w_n \in \text{cone } \tilde{\mathcal{U}}$ almost everywhere $t \in I$. Therefore $J_2(\eta_n, w_n) \geq 0$ for all n , which implies that

$$J_2(\eta, w) \geq 0. \quad \text{Q.E.D.}$$

Let us make the following hypothesis:

(H₂)^{*} There exists a unique solution of

$$\begin{aligned}
 -\dot{p}(t) &= \hat{f}_x^T(t)p(t) \quad \text{a.e. } t \in I, \\
 \langle \hat{f}_u^T(t)p(t), w \rangle &\geq 0 \quad \text{a.e. } t \in I \quad \forall w \in \text{cone } \tilde{\mathcal{U}}(t)
 \end{aligned}$$

on each subinterval $[a, c]$ of $[a, b]$.

In Definition 3.1 and in the definition of \mathcal{U} , replace cone $\tilde{\mathcal{U}}$ and $U - \hat{u}(t)$ by W and cone $\{U - \hat{u}(t)\}$, respectively. If this is done we obtain the following corollary.

COROLLARY 4.1. *When $\Phi \equiv 0$, then Theorem 3.1 and Corollaries 3.1 and 3.2 remain valid if (H₂)^{*} is assumed instead of (H₁) and (H₂) and if in (3.16) we replace $U - \hat{u}(t)$ by cone $\{U - \hat{u}(t)\}$. If in addition we have $\hat{u}(t) \in \text{int } U$, almost everywhere $t \in I$, then*

$$W = L^\infty(I, R^m), \quad S = R^n$$

and

$$L(Q(t)) = 0 \quad \text{a.e. } t \in (a, b).$$

Remark 4.1. When $\Phi \neq 0$, we know that the results of the second part of Corollary 4.1 hold if and only if $\hat{u} \in \text{int } L^\infty(I, U)$. Hence the condition $\hat{u} \in \text{int } U$, almost everywhere $t \in I$, is not enough to get the results and does not give a special case unless $\Phi \equiv 0$.

5. An example. Consider the following optimal control problem:

$$(P) \quad \text{Minimize} \quad J(u) = \int_0^{2\pi} \left\{ x(t) e^{-t} + tu(t) e^{-t} \sin \frac{1}{t(2\pi-t)} + u^2(t) \right\} dt$$

$$\text{subject to} \quad \dot{x}(t) = x(t) + u(t) \sin \frac{1}{t(2\pi-t)},$$

$$x(0) = x(2\pi) = 0,$$

$$u(t) \in U = [0, 1] \quad \text{a.e.}$$

Here $f(t, x, u) = x + u \sin (1/t(2\pi - 1))$ and $g(t, x, u) = xe^{-t} + tu e^{-t} \sin (1/t(2\pi - t)) + u^2$. Let us first show that the solution of the above problem is $(\hat{x}, \hat{u}) \equiv 0$.

The solution of the differential equation satisfying the boundary condition is

$$(5.1) \quad x(t) = e^t \int_0^t e^{-s} u(s) \sin \frac{1}{s(2\pi-s)} ds,$$

with

$$(5.2) \quad \int_0^{2\pi} e^{-s} u(s) \sin \frac{1}{s(2\pi-s)} ds = 0.$$

Thus,

$$J(u) = \int_0^{2\pi} \left\{ \int_0^t e^{-s} u(s) \sin \frac{1}{s(2\pi-s)} ds + tu(t) e^{-t} \sin \frac{1}{t(2\pi-t)} + u^2(t) \right\} dt.$$

Integrating the first term by parts and using (5.2), we get

$$\begin{aligned} J(u) &= \left\{ t \int_0^t e^{-s} u(s) \sin \frac{1}{s(2\pi-s)} ds \right\}_{t=0}^{t=2\pi} - \int_0^{2\pi} t e^{-t} u(t) \sin \frac{1}{t(2\pi-t)} dt \\ &\quad + \int_0^{2\pi} tu(t) e^{-t} \sin \frac{1}{t(2\pi-t)} dt + \int_0^{2\pi} u^2(t) dt \\ &= \int_0^{2\pi} u^2(t) dt. \end{aligned}$$

Since $(\hat{x}, \hat{u}) = (0, 0)$ is admissible for the problem (P), then it is optimal.

Define

$$\hat{p}(t) = -t e^{-t};$$

then it satisfies

$$-\dot{\hat{p}}(t) = \hat{f}_x^T(t) \hat{p}(t) + \hat{g}_x(t) = \hat{p}(t) + e^{-t}$$

and

$$\hat{f}_u^T(t) \hat{p}(t) + \hat{g}_u(t) = 2\hat{u}(t) \equiv 0.$$

Thus

$$\tilde{U}(t) = U = [0, 1].$$

Now we show that (H_1) and (H_2) hold. If $p(t)$ solves the system

$$-\dot{p}(t) = p(t),$$

$$\sin \frac{1}{t(2\pi-t)} p(t) \geq 0,$$

then $p(t) = ce^{-t}$ and $ce^{-t} \sin(1/t(2\pi - t)) \geq 0$. Since $\sin(1/t(2\pi - t))$ oscillates near $t = 0$ and near $t = 2\pi$, then $p \equiv 0$ on any interval of the form $[0, c]$ or $[c, 2\pi]$. Therefore, Hypotheses (H_1) and (H_2) are satisfied.

Since $\hat{H}_{uu}(t) \equiv 2$ for this problem then, by Theorem 3.1, there is no point in $(0, 2\pi)$ conjugate to 2π , i.e., there exists no $(\lambda, \eta) \neq 0$ such that

$$\begin{aligned}\dot{\eta}(t) &= \eta(t) - \frac{1}{2} \left[\sin^2 \frac{1}{t(2\pi - t)} \right] \lambda(t) \quad \text{a.e. } t \in [0, 1], \\ -\dot{\lambda}(t) &= \lambda(t) \quad \text{a.e. } t \in [0, 1], \\ -\frac{\lambda}{2}(t) \left(\sin \frac{1}{t(2\pi - t)} \right) &\in [0, 1],\end{aligned}$$

and $\eta(2\pi) = \eta(c) = 0$ for some $c \in (0, 2\pi)$.

Acknowledgment. We thank Professor J. Macki, who made it possible for Professor Zezza to spend one year at the University of Alberta during which time this research was performed.

FILTERING WITH OBSERVATIONS ON A RIEMANNIAN SYMMETRIC SPACE*

MONIQUE PONTIER† AND JACQUES SZPIRGLAS‡

Abstract. The point under discussion in this paper refers to a problem of filtering in which observation Y of a system state X is a process with values in a symmetric space M . The observation is a Brownian motion transformed by an isometry of M depending on the state. It takes its values in manifold M and its multiplicative formulation is nonstandard. In many physical situations, e.g., mechanics, robotics, spatial fields, the filtering problems are naturally set up in manifolds as well for the signal and the observation. The reference probability method is used to construct the model. Then filtering equations are deduced; these comply with the conditional law according to its observation. Unique characterization of this conditional law is given. Last, two examples are investigated. First the multivariate case: the observation Y is in \mathbb{R}^d so that $Y_t = \Sigma_t(X) W_t + H_t(X)$, where W is a multivariate Brownian motion; Σ (a rotation) and H (a translation) are absolutely continuous with respect to time t . The second example is filtering on the sphere; observation Y is of the following form: $Y_t = g_t(X) \cdot W_t$, where W is a Brownian motion on sphere S_2 and $g_t(X)$ is a rotation of M absolutely continuous with respect to time t .

Key words. filtering, manifolds, symmetric space

AMS (MOS) subject classifications. 93E11, 60G35, 60J60

1. Introduction. This paper is devoted to a filtering model with observations taking their values in a manifold, and the multiplicative formulation of which is nonstandard. In many physical situations, e.g., mechanics, robotics, spatial fields, the filtering problems are naturally set up in manifolds as well for the signal and the observation (for instance, satellite tracking). The model is as follows: the observation Y of a Markovian signal X with generator $(A, \mathcal{D}(A))$ takes its values in a symmetric space M . Briefly speaking, M is such that there exists a subgroup G of the Lie group $I(M)$ of all isometries of M , which acts transitively on M . Process Y_t is assumed to be

$$(1.1) \quad Y_t = g_t(X) \cdot W_t$$

where W_t is a Brownian motion on M and $g_t(X)$ is a G -valued functional of signal X such that $t \rightarrow g_t(X)$ is absolutely continuous on $[0, T]$:

$$(1.2) \quad dg_t = (R_{g_t})_* \psi(t, X_s; s \leq t) dt, \quad g_0 = e; \quad t \in [0, T],$$

where ψ is a bounded semimartingale functional of t and the sample path of X , taking values in Lie algebra \mathfrak{G} , and $(R_g)_* \psi$ is the right invariant vector field associated to ψ .

This paper is devoted to the construction of the filtering model and the computation of the stochastic differential equation which is satisfied by the conditional law of signal X , given its observation Y , filter π of X given Y . We construct this model by the reference probability method [5], [21], [22], using an important result by Shigekawa [18] about equivalence of the laws of $g \cdot W$ and W : it can be seen that the problem is finally reduced to a nontrivial multivariate problem with a nonbounded signal. Then we get the filtering equation for a bounded function f in domain $\mathcal{D}(A)$ of X_t :

$$(1.3) \quad \pi_t(f) = \mu(f) + \int_0^t \pi_s(Af) ds + \int_0^t \omega_{\pi_s}(\bar{f}\psi^*) \circ dY_s - \frac{1}{2} \int_0^t \pi_s(\bar{f}(\kappa_s + \|\psi_{Y_s}^*\|^2)) ds$$

where $\tilde{f}_t = f(X_t) - \pi_t(f)$, ψ^* is a vector field on M deduced from ψ and the stochastic integral is this of the one-form associated to vector field $\pi_s(\tilde{f}\psi^*)$ (defined in [19]); κ is a real process, due to symmetric structure of space M .

Then, applying Kurtz and Ocone's results [11], we give a unique characterization of the conditional law of signal X given its observation Y .

Our results are similar to those of Ng and Caines [15] for the general Riemannian case. But our restriction to a symmetric space allows a more general formulation of the filtering problem. Duncan [5] was also concerned with filtering on symmetric spaces, but he used this last structure to ensure the nonexplosion of the Brownian motion and studied the same problem as Ng and Caines. Furthermore, Duncan's construction of the Brownian motion on a manifold is quite different from that of Ikeda and Watanabe [8]. The relations between those two constructions are studied in [4]. For more details about diffusions on manifolds, see [14] or [17].

A few necessary results about symmetric spaces and Brownian motion on Riemannian symmetric space are given in § 2. Section 3 is devoted to the construction of the filtering model and filtering equations, which have, under slight conditions, unique solution as measure-valued equations. We conclude with examples about multivariate and spherical cases.

Notation. All filtrations in this paper are assumed to be complete and right continuous. For any process Z defined on a probability space $(\Omega, \mathcal{A}, \mathbb{P})$, \mathcal{G}^Z will denote the natural filtration generated by Z , completed with respect to probability \mathbb{P} , and right continuous.

Moreover, the Stratonovitch integral is denoted by $\circ : \int Y \circ dB$ and Ito's integral by $: \int Y \cdot dB$.

Last, $(L_g)_*$ and $(R_g)_*$ denote the differential of the left and right translations on G ; so $(R_g)_*\psi$ is the right invariant vector field associated to any ψ in \mathfrak{G} . Except in (1.2) we are concerned essentially with left invariant vector fields on G defined from vectors ξ of \mathfrak{G} by $(L_g)_*\xi$, denoted by $\xi(g)$, and we generally omit the point where they are taken.

2. Stochastic calculus on symmetric spaces. In this section, some definitions about symmetric spaces are first recalled. Then Brownian motions on symmetric spaces are introduced according to different points of view. This induces some results about their natural filtrations which obviously have an importance in our applications to filtering. Some rules about stochastic calculus for semimartingales on Lie groups [18] are recalled in § 2.3.

2.1. Symmetric spaces. A d -dimensional symmetric space M is a C^∞ d -dimensional Riemannian manifold such that for each $p \in M$, the geodesic symmetry s_p with respect to p is an isometry and p is an isolated fixed point of s_p . The following properties will be useful in the sequel (for more details, see [3] or [7]). Let $I(M)$ be the isometric transformation group of M and G be a subgroup of $I(M)$, which is a connected component containing identity e ; it is well known that the Lie group G acts on M on the left transitively. Take a point O of M and let K be the isotropy subgroup of G at O (i.e., for all $k \in K$, $k \cdot O = O$); K is a compact subgroup of G ; furthermore G/K and M are diffeomorphic.

Let \mathfrak{G} and \mathfrak{K} denote, respectively, Lie algebras of G and K . Let σ be an automorphism of G defined by

$$(2.1) \quad \sigma(g) = s_0 g s_0, \quad g \in G.$$

Because σ is involutive, its differential σ_* on \mathfrak{G} has ± 1 for eigenvalues. The eigenspace

for 1 is \mathfrak{K} . Let \mathfrak{M} denote the eigenspace for -1 . Then we have the direct sum: $\mathfrak{G} = \mathfrak{M} \oplus \mathfrak{K}$. Space \mathfrak{M} is d -dimensional. This can be proved as follows. Define mapping $i: G \rightarrow M$ by

$$(2.2) \quad i(g) = g \cdot O, \quad g \in G;$$

its differential at point e , i_* , is an isomorphism between \mathfrak{M} and $T_0(M)$, the tangent space at point O .

As in Shigekawa's paper for a better understanding we use indices I, J, K, \dots for vectors $x = (x_I; I = 1, \dots, n)$ in algebra \mathfrak{G} (n -dimensional); indices i, j, \dots for vectors $x = (x_i; i = 1, \dots, d)$ in \mathfrak{M} (d -dimensional); indices α, β, \dots for vectors $x = (x_\alpha; \alpha = 1, \dots, p)$ in \mathfrak{K} ($p = n - d$ dimensional).

Now take a point (O, u_0) in $O(M)$, the bundle of orthonormal frames. We extend mapping i to $O(M)$ as follows:

$$(2.3) \quad i(g) = g \cdot u_0 = \{(g_*)_e u_0^i; i = 1, \dots, d\}$$

where the u_0^i are the basic vectors of frame u_0 . To any vector C of \mathfrak{G} is associated a vector field C^* on M such that

$$(2.4) \quad C^* f(x) = \frac{d}{dt} f(\exp tC \cdot x), \quad x \in M.$$

Then we define a linear map $L: \mathfrak{M} \rightarrow T_0(M)$ by

$$(2.5) \quad L(C) = C^*(O)$$

and an isomorphism A from \mathbb{R}^d to \mathfrak{M}

$$(2.6) \quad \xi \rightarrow u_0(\xi) \rightarrow L^{-1}(u_0(\xi)) = A(\xi).$$

Hence from a standard basis (e_i) of \mathbb{R}^d , a basis of \mathfrak{M} can be constructed $(A_i; i = 1, \dots, d)$:

$$(2.7) \quad A_i = A(e_i) = L^{-1}(u_0(e_i)).$$

Take any basis $(A_{d+1}, \dots, A_{d+p})$ of \mathfrak{K} ; then $(A_1, \dots, A_d, A_{d+1}, \dots, A_{d+p})$ form a basis of \mathfrak{G} .

Let us recall that adjoint representation Adg denotes the differential at e of the following automorphism of G :

$$(2.8) \quad h \rightarrow ghg^{-1}.$$

Mapping Ad is a homomorphism of group from G to $GL(\mathfrak{G})$, the linear group of \mathfrak{G} . On the other hand, it is known that \mathfrak{K} is the Lie algebra of K and \mathfrak{M} is invariant under $Ad(K)$, i.e.,

$$(2.9) \quad Adk(\mathfrak{M}) \subset \mathfrak{M}, \quad k \in K.$$

Furthermore, $Adk|_{\mathfrak{M}}$ belongs to $O(d)$. For all C in \mathfrak{G} with decomposition $C_M + C_{\mathfrak{M}}$ in $\mathfrak{K} \oplus \mathfrak{M}$, the decomposition of $Adk(C)$ is given in the same way:

$$(2.10) \quad Adk(C_M) + Adk(C_{\mathfrak{M}}).$$

2.2. Brownian motions on Lie groups and symmetric spaces. Let B be a standard d -dimensional Brownian motion defined on its canonical space $(\Omega^B, \mathcal{G}^B, \mathbb{P}^B)$. There are two classical ways to construct a Brownian motion Y taking values in a symmetric space M : Shigekawa's construction [18] and that of Ikeda and Watanabe [8]. In [8],

process Y is defined as the canonical projection from a bundle of orthonormal frames $O(M)$ to M :

$$(2.11) \quad Y_t = \tau(U_t).$$

Process U is the solution of the stochastic differential equation

$$(2.12) \quad dU_t = B(e_i)(U_t) \circ dB_t^i, \quad U_0 = (O, u_0)$$

where $B(e_i)$ are the canonical horizontal vector fields of $O(M)$, associated to the Riemannian connection of M [7].

Shigekawa defines Brownian motion Y as the image obtained by mapping i of a Brownian motion h taking values in G , which is easier to deal with because h is a diffusion on G and stochastic calculus on Lie groups is well developed (see Proposition 2.2 below, and [1], [18]):

$$(2.13) \quad Y_t = i(h_t) = h_t \cdot O.$$

Process h is the solution of the stochastic differential equation

$$(2.14) \quad dh_t = A_j(h_t) \circ dB_t^j; \quad h_0 = e$$

where the A_j s are vector fields defined by (2.7). It can easily be proved that the two definitions coincide and, moreover, that

$$(2.15) \quad h_t \cdot u_0 = u(t).$$

We have the following result, asserted in [15].

LEMMA 2.1. *Let Y be the Brownian motion on M defined by (2.11) and (2.12). The natural filtration of Y coincides with those of U , h and B .*

Proof. On one hand, process Y is \mathcal{G}^U -adapted because of definition (2.11); hence $\mathcal{G}^Y \subset \mathcal{G}^U$. On the other hand, process U is locally defined by the system [8]:

$$(2.16) \quad \begin{aligned} dy^i(t) &= u_j^i(t) \circ dB_t^j, \\ du_j^i(t) &= -\Gamma_{mk}^i(Y(t)) u_j^k(t) \circ dy^m(t) \end{aligned}$$

where Γ is the Riemannian connection of M . Now a system $(\tilde{U}_\alpha, \tilde{\phi}_\alpha)$ of local coordinates in $O(M)$ is easily deduced from that of M , (U_α, ϕ_α) , as follows:

$$(2.17) \quad \begin{aligned} \tilde{U}_\alpha &= \{U = (x, u) / x \in U_\alpha, u \text{ orthonormal frame at } x\}, \\ \tilde{\phi}_\alpha(x, u) &= (\phi_\alpha(x), (u_j^i)), \quad u_j^i \text{ local coordinates of } u. \end{aligned}$$

Thus the sequence of stopping times defining U_t are \mathcal{G}^Y -stopping times. Then, the pathwise uniqueness of system (2.16) between two stopping times implies as in [16] that $u(t)$ is \mathcal{G}_t^Y -measurable, and this proves $\mathcal{G}^Y = \mathcal{G}^U$. Now, from (2.13) we get

$$(2.18) \quad \mathcal{G}^Y \subset \mathcal{G}^h$$

and from (2.14) and the unicity of its solution,

$$(2.19) \quad \mathcal{G}^h \subset \mathcal{G}^B.$$

In [19], Shigekawa expresses B with respect to U . Let ω be the \mathbb{R}^d -valued 1-form defined by

$$(2.20) \quad \omega_u(\xi) = u^{-1}(\pi_*)_u(\xi), \quad u \in O(M), \quad \xi \in T_u O(M).$$

Then B satisfies

$$(2.21) \quad B_t = \int_0^t \omega_{u_s} \circ dU_s.$$

This implies that $\mathcal{G}^B \subset \mathcal{G}^U$. This inclusion and (2.18)–(2.19) conclude the proof.

2.3. Stochastic calculus on Lie groups. To enlighten the next section we give some stochastic calculus rules for semimartingales on Lie groups [18]. Let k and l be the solution of the following stochastic differential equations on G :

$$(2.22) \quad dk_t = \xi_{i,t} \circ dB_t^i + \xi_{0,t} dt, \quad k_0 = k,$$

$$(2.23) \quad dl_t = \eta_{i,t} \circ dB_t^i + \eta_{0,t} dt, \quad l_0 = l$$

where $\xi_i, \eta_i, i = 1, \dots, d$ are \mathcal{G} -valued continuous semimartingales and ξ_0, η_0 are \mathcal{G} -valued locally integrable processes. From [18] we have the following proposition

PROPOSITION 2.2. *Let us denote m_t the product $k_t l_t$; then process m satisfies the following stochastic differential equation on G :*

$$(2.24) \quad \begin{aligned} dm_t &= (Adl_t^{-1}(\xi_{i,t}) + \eta_{i,t}) \circ dB_t^i + (Adl_t^{-1}(\xi_{0,t}) + \eta_{0,t}) dt, \\ m_0 &= kl. \end{aligned}$$

Let $(Adl_t^{-1})_J^I$ denote the elements of matrix Adl_t^{-1} expressed in basis $(A_I; I = 1, \dots, n)$; then we have

$$(2.25) \quad \begin{aligned} d(Adl_t^{-1})_J^I &= C_{KL}^I (Adl_t^{-1})_J^K (\eta_{i,t}^L \circ dB_t^i + \eta_{0,t}^L dt), \\ (Adl_0^{-1})_J^I &= (Adl^{-1})_J^I \end{aligned}$$

where C_{KL}^I 's are the structure constants defined by

$$(2.26) \quad [A_K, A_L] = C_{KL}^I A_I.$$

Moreover process l^{-1} satisfies the following equation:

$$(2.27) \quad \begin{aligned} dl_t^{-1} &= -Adl_t(\xi_{i,t}) \circ dB_t^i - Adl_t(\xi_{0,t}) dt, \\ l_0^{-1} &= 0. \end{aligned}$$

3. Construction of the model-filtering equations. In this section we first construct the filtering model by the reference probability method [5], [21], [22]. We derive the filtering equations with respect to Brownian motion B (which is observable from Lemma 2.1). Then we express those equations with respect to the observation process Y . This implies Stratonovitch calculus and the extension of some projections theorems to Stratonovitch integrals.

3.1. Construction of the filtering model. Let us construct the filtering model by the reference probability method; we use some of Shigekawa's results [18]. Let signal X be a Markov process valued in a Lusin space E with generator $(A, \mathcal{D}(A))$ and initial law μ . We consider X on probability space $(\Omega^X, \mathcal{G}^X, \mathbb{P}_\mu^X)$. Let observation Y be a Brownian motion valued in M , defined in § 2.2 by means of a standard d -dimensional Brownian motion B on probability space $(\Omega^B, \mathcal{G}^B, \mathbb{P}^B)$. Notice that $\mathcal{G}^B = \mathcal{G}^Y$ (Lemma 2.1).

Let us define

$$\Omega = (\Omega^X \times \Omega^B), \quad \mathcal{G} = \mathcal{G}^X \otimes \mathcal{G}^Y, \quad \mathbb{P}_\mu = \mathbb{P}_\mu^X \otimes \mathbb{P}^B.$$

Processes X, B, Y can be extended trivially to $(\Omega, \mathcal{G}, \mathbb{P}_\mu)$. Let us notice that B and Y are still \mathcal{G} -Brownian motions because of the \mathbb{P}_μ -independence of \mathcal{G}^X and \mathcal{G}^Y .

The probability space modelizing the system signal-observation (1.1)–(1.2) will be constructed by a change of equivalent probability measure.

Let a transformation g_t be given on G with the following assumptions:

$$(3.1) \quad \begin{aligned} dg_t &= (R_{g_t})_* \psi(t, X_s; s \leq t) dt, \quad t \in [0, T], \\ g_0 &= e \end{aligned}$$

where ψ is a \mathcal{G}^X -continuous semimartingale (hence a \mathcal{G} -semimartingale), uniformly bounded on $[0, T] \times \Omega^X$, taking values in \mathfrak{G} . For example, ψ can be taken in $\mathcal{D}(A)$ as in § 3.3. Because of independence of X and Y , process X can be considered as a parameter, and so (3.1) is deterministic and has a unique solution.

We have the following proposition, thanks to the results of Shigekawa.

PROPOSITION 3.1. *With assumption (3.1) a process L can be defined by*

$$(3.2) \quad L_t = \exp \left(\int_0^t \phi_s^i dB_s^i - \frac{1}{2} \int_0^t (\phi_s^i)^2 ds \right)$$

where ϕ_s is defined in \mathfrak{G} by

$$(3.3) \quad \phi_s = (Adh_s^{-1} \psi_s).$$

Moreover, process L is a strictly positive uniformly integrable $(\Omega, \mathcal{G}, \mathbb{P}_\mu)$ -martingale which is \mathcal{G}^Y -locally square integrable. Therefore, let us define: $\mathbb{Q}_\mu = L_T \cdot \mathbb{P}_\mu$; \mathbb{Q}_μ and \mathbb{P}_μ are equivalent probability measures. Furthermore, there exists a $(\Omega, \mathcal{G}, \mathbb{Q}_\mu)$ Brownian motion W valued in M such that

$$(3.4) \quad Y_t = g_t(X) \cdot W_t.$$

Proof. Process X is considered as a parameter and so it is possible to use Shigekawa's results working on $(\Omega^Y, \mathcal{G}^Y, \mathbb{P}^Y)$.

The idea of Shigekawa's proof is to find the following decomposition for h , with a Brownian motion h' on G :

$$(3.5) \quad h_t = g_t \cdot h'_t \cdot P_t$$

where p is a semimartingale on K (hence $p_t \cdot 0 = 0$), the solution of the following differential equation:

$$(3.6) \quad dp_t = -(Adh_t^{-1} \cdot \psi_t)_{\mathfrak{M}} dt, \quad p_0 = e.$$

So, let us define process h' as

$$(3.7) \quad h'_t = g_t^{-1} \cdot h_t \cdot p_t^{-1}.$$

If we apply results recalled from § 2.3, we get

$$(3.8) \quad \begin{aligned} dh'_t &= Adp_t(A_t) \circ dB_t^i - Adp_t(Adh_t^{-1} \cdot \psi_t)_{\mathfrak{M}} dt, \\ h'_0 &= e. \end{aligned}$$

Then we define the d -dimensional process Z :

$$(3.9) \quad \begin{aligned} dZ_t^i &= (Adp_t)_j^i dB_t^j - (Adp_t)_j^i (Adh_t^{-1} \psi_t)_{\mathfrak{M}}^j dt, \\ Z_0^i &= 0. \end{aligned}$$

The results of [18] ((2.7)–(2.10)) for semimartingales valued in G prove easily that (3.8) is equivalent to

$$(3.10) \quad dh'_t = A_t(h'_t) \circ dZ_t^i, \quad h'_0 = e.$$

Thus, h' is a Brownian motion on G as soon as Z is a d -dimensional Brownian motion.

This is the case, if we apply a Liptser and Shyrayev result [13] on absolute continuity of probability measures.

Shigekawa's result is concerned with left invariant vector fields. So we get an expression of g^{-1} with respect to such a vector field. Define process ξ taking values in \mathcal{G} :

$$(3.11) \quad \xi(t, X_s; s \leq t) = \text{Ad}g_t^{-1}(X) \cdot \psi_t$$

where g is the unique solution of (3.1). So we have

$$(3.12) \quad (R_g)_*(\psi_t) = (R_g)_* \circ \text{Ad}g_t(\xi_t) = (L_g)_*(\xi_t).$$

So, the *right* invariant vector field associated to ψ_t and the left invariant vector field associated to ξ_t coincide and (3.1) becomes

$$(3.13) \quad dg_t = \xi(t, X_s; s \leq t)(g_t) dt, \quad g_0 = e$$

and because of (2.27), we get

$$(3.14) \quad dg_t^{-1} = \text{Ad}g_t(\xi_t) dt, \quad g_0 = e;$$

that is to say, because of definition (3.11)

$$(3.15) \quad dg_t^{-1} = (L_{g^{-1}})_*(-\psi_t) dt, \quad g_0 = e.$$

The \mathcal{G} -valued continuous semimartingale ψ is bounded, so by Shigekawa [18, Thm. 4.1] $g_t^{-1}Y_t$ and Y_t have equivalent measures. Thus, $W_t = g_t^{-1}Y_t$ is a Brownian motion associated to G -valued process h' because

$$(3.16) \quad h'_t \cdot 0 = g_t^{-1}h_t p_t^{-1} \cdot 0 = g_t^{-1}h_t \cdot 0 = g_t^{-1} \cdot Y_t = W_t.$$

At last, let us notice that process L defined by (3.2) is $((d\nu'/d\nu)(W \cdot))^{-1}$ where ν and ν' are the measures of Y and W under probability \mathbb{P}_μ ; so L is a Radon-Nicodym derivative and it is a strictly positive uniformly integrable \mathbb{P}_μ -martingale. On the other hand, Girsanov's Theorem and (3.9) show that Z is a $\mathbb{Q}_\mu = L \cdot \mathbb{P}_\mu$ -Brownian motion.

It is left to prove that L is \mathcal{G}^Y locally square integrable. Process ψ is bounded on $[0, T]$ by assumption (3.1) and $\text{Ad}h^{-1}$ is a continuous process which is \mathcal{G}^Y -adapted by Lemma 2.1. Hence, ϕ is \mathcal{G}^Y -locally bounded and as a consequence, it is classical (see, for example, [11]) that L is \mathcal{G}^Y -locally square integrable and thus satisfies the conclusions of Proposition 3.1.

3.2. Filtering equations. However, we assume, as in the standard filtering model,

$$\psi_t = \psi(X_t)$$

where ψ is a \mathcal{G} -valued bounded continuous application on E .

Now, let us define filter π and unnormalized filter $\tilde{\pi}$. It is easy to derive filtering equations with respect to B . We shall insist on the derivation of equations with respect to observation Y , which are perhaps less standard.

Filter π of X given Y is defined as the unique measure valued process such that, for all bounded function f on E , $\pi_t(f)$ is the \mathbb{Q}_μ -optional projection with respect to filtration \mathcal{G}^Y of process $f(X_t)$. Briefly speaking, $\pi_t(f)$ is a "smooth version" of the conditional mean $E_{\mathbb{Q}_\mu}(f(X_t)/\mathcal{G}_t^Y)$. The reference probability method allows simple computations, thanks to the existence of probability \mathbb{P}_μ equivalent to \mathbb{Q}_μ such that, under \mathbb{P}_μ , \mathcal{G}_t and \mathcal{G}_∞^Y are independent conditionally on \mathcal{G}_t^Y , i.e., if

$$(3.17) \quad Z_t \in \mathcal{G}_t, \quad E_{\mathbb{P}_\mu}(Z_t/\mathcal{G}_t^Y) = E_{\mathbb{P}_\mu}(Z_t/\mathcal{G}_\infty^Y).$$

Here, this property is implied by the \mathbb{P}_μ -independence of X and Y . This allows us to express a complex operator of optional projections by means of simpler operators of conditional means:

$$(3.18) \quad E_{\mathbb{Q}_\mu}(Z_t/\mathcal{G}_t^Y) = \frac{E_{\mathbb{P}_\mu}(L_t Z_t/\mathcal{G}_\infty^Y)}{E_{\mathbb{P}_\mu}(L_t/\mathcal{G}_\infty^Y)}.$$

This induces the definition of a new measure valued process: the unnormalized filter $\tilde{\pi}_t$, such that for all bounded function f on E , $\tilde{\pi}_t(f)$ is the conditional mean of process $L \cdot f(X)$ with respect to \mathcal{G}_∞^Y :

$$(3.19) \quad \pi_t(f) = \tilde{\pi}_t(f) / \tilde{\pi}_t(1).$$

We get classically the filtering equations by projecting, with respect to \mathcal{G}_t^Y , the product $L_t \cdot f(X_t)$ and its expression obtained from Itô formula. Martingale L is \mathcal{G}^Y -locally square integrable and B is \mathcal{G} -adapted; the classical derivation of the filtering equations works locally. Process $\tilde{\pi}$ and π are trivially extended to \mathcal{G} -adapted and \mathcal{G}^Y -locally bounded functionals of X_t and process Y :

$$\pi_t f(\cdot, Y) = E_{Q_\mu}(f(X_t, Y) / \mathcal{G}_t^Y).$$

Hence we get the following proposition.

PROPOSITION 3.2. *Under the assumptions of § 3.1, for all f in $\mathcal{D}(A)$, we have*

$$(3.20) \quad \tilde{\pi}_t(f) = \mu(f) + \int_0^t \tilde{\pi}_s(Af) ds + \int_0^t \tilde{\pi}(f\phi^i) dB_s^i,$$

$$(3.21) \quad \pi_t(f) = \mu(f) + \int_0^t \pi_s(Af) ds + \int_0^t \pi_s(\bar{f}\phi^i)(dB_s^i - \pi_s(\phi^i) ds)$$

where $\phi_t^i = (Adh_t^{-1})_t^i(\psi_t)^i$ and $\bar{f}_t = f(X_t) - \pi_t(f)$.

In Proposition 3.2, the equations are expressed with respect to B . Although B is observable, we prefer to derive them with respect to observation Y . It could have been possible to use (3.20), (3.21) to get new equations. However, a new proof is given, using Stratonovitch calculus.

Let us define the integral of 1-form ω_C (associated to vector field C on M) along the path of Brownian motion Y (see [19]):

$$(3.22) \quad \int_0^t \omega_C \circ dY_s = \int_0^t c_s^i g_{ij}(Y_s) \circ dy_s^j = \int_0^t c_s^i (u_s^{-1})_i^j \circ dB_s^j$$

where c^i and y^i are local coordinates of C and Y ; and the y^i 's satisfy (2.13).

Let us define the following processes: ϕ, κ , such that ϕ is valued in \mathcal{G} and κ is a real process:

$$(3.23) \quad \phi_t = Adh_t^{-1} \cdot \psi_t,$$

$$(3.24) \quad \kappa_t = C_{Ki}^i (Adh_t^{-1})_t^K (\psi_t)^i = C_{Ki}^i \phi_t^K.$$

Then we get filtering equations depending only on the observation.

PROPOSITION 3.3. *Let us consider the model constructed in § 3.1; for all f in $\mathcal{D}(A)$, we have*

$$(3.25) \quad \tilde{\pi}_t(f) = \mu(f) + \int_0^t \tilde{\pi}_s(Af) ds + \int_0^t \omega_{\tilde{\pi}_s(f\psi^*)} \circ dY_s - \frac{1}{2} \int_0^t \tilde{\pi}_s(f(\kappa_s + \|\psi_{Y_s}^*\|_g^2)) ds,$$

$$(3.26) \quad \pi_t(f) = \mu(f) + \int_0^t \pi_s(Af) ds + \int_0^t \omega_{\pi_s(\bar{f}\psi^*)} \circ dY_s - \frac{1}{2} \int_0^t \pi_s(\bar{f}(\kappa_s + \|\psi_{Y_s}^*\|_g^2)) ds$$

where $\bar{f}_t = f(X_t) - \pi_t(f)$, κ is defined above and vector field ψ^* in (2.4).

Proof. The first step of the proof is to express process L with respect to Y ; the second is to compute product $L_t f(X_t)$, thanks to the formula of integration by parts. The next is to prove a projection lemma of Stratonovitch integrals which is applied

to the previous formula. Last, we derive (3.26) from (3.25) with a Stratonovitch calculus of ratio (3.18).

(1) From [18, p. 513] and (2.15) we have that

$$(3.27) \quad \begin{aligned} \phi_t^i &= (Adh_t^{-1})_i^j \psi_t^j = [(h_t \cdot u_0)^{-1} \psi^*(Y_t)]^i \\ &= (u(t)^{-1})_j^i (\psi^*(Y_t))^j. \end{aligned}$$

Hence, from definition (3.22) it follows that

$$(3.28) \quad \sum_i \int_0^t \phi_s^i \circ dB_s^i = \int_0^t \omega_{\psi_s^*} \circ dY_s.$$

Furthermore, by the definition of the Stratonovitch integral, we get

$$(3.29) \quad \int \phi^i \cdot dB^i = \int \phi^i \circ dB^i - \frac{1}{2} \langle \phi^i, B^i \rangle.$$

From (2.24), (3.23) and the independence of X and B , we get

$$(3.30) \quad \frac{d}{dt} \langle \phi^i, B^i \rangle_t = C_{\kappa i}^i (Adh_t^{-1})_i^K \psi_t^K = \kappa_i.$$

From (3.27) and because $u(t)$ belongs to $O(d)$, we have

$$(3.31) \quad \|(\phi_t)_\mathbb{M}\|^2 = \|\psi^*(Y_t)\|^2.$$

Then, with (3.28), (3.31), process L can be written as follows:

$$(3.32) \quad L_t = \exp \left(\int_0^t \omega_{\psi_s^*} \circ dY_s - \frac{1}{2} \int_0^t (\kappa_s + \|\psi^*(Y_s)\|)^2 ds \right).$$

(2) Process L is a solution of the following "Stratonovitch" equation:

$$(3.33) \quad dL_t = \omega_{L, \psi_t^*} \circ dY_t - \frac{1}{2} L_t (\kappa_t + \|\psi^*(Y_t)\|)^2 dt.$$

Let f be in $\mathcal{D}(A)$:

$$(3.34) \quad M_t(f) = f(X_t) - f(X_0) - \int_0^t Af(X_s) ds$$

is a \mathcal{G}^X (hence a \mathcal{G})-semimartingale.

Then we compute product $L_t \cdot f(X_t)$ with the formula of integration by parts:

$$(3.35) \quad \begin{aligned} L_t f(X_t) &= f(X_0) + \int_0^t L_s Af(X_s) ds + \int_0^t L_s \circ dM_s f + \int_0^t \omega_{(L f \psi)_s^*} \circ dY_s \\ &\quad - \frac{1}{2} \int_0^t L_s f(X_s) (\kappa_s + \|\psi^*(Y_s)\|)^2 ds. \end{aligned}$$

(3) Let us notice that the bracket of processes L and $M(f)$ vanishes; then process $\int_0^t L_s \circ dM_s f$ is a \mathcal{G}^X -martingale whose projection, with respect to $(\mathcal{G}^Y, \mathbb{P}^\mu)$, classically vanishes. The other terms, except the integral of the 1-form along the path of Y , can be easily projected.

LEMMA 3.4. *Let ω_C be the 1-form associated to \mathcal{G} -adapted vector field C as defined in (3.22) the local coordinates of which are continuous \mathcal{G} -semimartingales, \mathcal{G}^Y -locally square integrable; then*

$$(3.36) \quad E_{\mathbb{P}_\mu} \left(\int_0^t \omega_{C_s} \circ dY_s / \mathcal{G}_\infty^Y \right) = \int_0^t \omega_{\tilde{C}_s} \circ dY_s$$

where \tilde{C}_s is the vector field on M defined by $E_{\mathbb{P}_\mu}(C_s / \mathcal{G}_\infty^Y)$.

Proof. There exists a sequence $(T_n; n \in N)$ of \mathcal{G}^Y -stopping times such that

$$(3.37) \quad N_t = \int_0^t \omega_{C_s} \circ dY_s = \sum_{n,i} \int_{T_n \wedge t}^{T_{n+1} \wedge t} c_s^{n,i} g_{ij}^n(Y_s) \circ dy_s^{n,j}$$

where T_{n+1} is defined recursively as the last exit time of (U^n, ϕ^n) , neighbourhood of Y_{T_n} in M (cf. [16]), and $c^{n,i}$ and $y^{n,i}$ are the local coordinates of C and Y in (U^n, ϕ^n) . Thus, we shall work only on real Stratonovitch integrals

$$(3.38) \quad N_t = \int_0^t c_s g(Y_s) \circ dy_s.$$

(For the sake of simplicity, we now omit indices n and i , and E denotes $E_{\mathbb{P}_\mu}$ and we note dy instead of $g(Y) \cdot dy$.) This can be written in Itô's form

$$(3.39) \quad N_t = \int_0^t c_s \cdot dy_s + \frac{1}{2} \langle c, y \rangle_t.$$

The Itô integral is projected as follows:

$$(3.40) \quad E \left(\int_0^t c_s \cdot dy_s / \mathcal{G}_\infty^Y \right) = \int_0^t E(c_s / \mathcal{G}_\infty^Y) \cdot dy_s$$

because local coordinates c are \mathcal{G}^Y -locally square integrable. We now have to show that

$$(3.41) \quad E(\langle c, y \rangle_t / \mathcal{G}_\infty^Y) = \langle E(c / \mathcal{G}_\infty^Y), y \rangle_t.$$

Let Z be a \mathcal{G}^Y - (hence a \mathcal{G} -) bounded martingale:

$$(3.42) \quad E(Z_t \cdot \langle c, y \rangle_t) = E \left(\int_0^t Z_s d\langle c, y \rangle_s \right) = E \left(\left\langle c, \int Z \cdot dy \right\rangle_t \right)$$

using [9, Thm. 2.51].

Let M denote the martingale part of c as a \mathcal{G} semimartingale. Then we get

$$(3.43) \quad E \left\langle c, \int Z \cdot dy \right\rangle_t = E \left(M_t \cdot \int_0^t Z_s \cdot dy_s \right) = E \left(E(M_t / \mathcal{G}_\infty^Y) \cdot \int_0^t Z_s dy_s \right).$$

From property (K) [21] the \mathcal{G} -martingale part of $E(c / \mathcal{G}_\infty^Y)$ —which is a \mathcal{G}^Y -martingale—coincides with $E(M_t / \mathcal{G}_\infty^Y)$. Hence, coming back to (3.42), it follows that

$$(3.44) \quad E(Z_t \cdot \langle c, y \rangle_t) = E(Z_t \cdot \langle E(c / \mathcal{G}_\infty^Y), y \rangle_t),$$

and this achieves the proof of Lemma 3.4.

Now, as L is \mathcal{G}^Y -locally square integrable, Lemma 3.4 can be applied to the vector field $C_t = L_t f(X_t) \psi^*$, and we get easily the unnormalised filtering equation (3.25).

(4) We have seen that $\pi_t(f) = \tilde{\pi}_t(f) / \tilde{\pi}_t(1)$. We get formula (3.26) by computing this ratio as a Stratonovitch integral:

$$(3.45) \quad \frac{u_t}{v_t} = \frac{u_0}{v_0} + \int_0^t \frac{1}{v_s} \circ du_s - \int_0^t \frac{u_s}{(v_s)^2} \circ dv_s.$$

Remark. Equations (3.25), (3.26) are actually the Stratonovitch form of (3.20), (3.21) as a consequence of the following equality:

$$\sum_i \frac{d}{dt} \langle \tilde{\pi}(f \phi^i), B^i \rangle_t = \tilde{\pi}_t(f \cdot (\kappa + \|\psi_Y^*\|))$$

proved by means of (2.25) and (3.27).

3.3. Uniqueness of the solution of the filtering equations. In this section, Kurtz' and Ocone's results [11] are applied to show that, under slight hypotheses, filtering equations (3.21)–(3.26) have a unique \mathcal{G}^Y -optional measure valued solution which is the filter. In that sense, these results are not a strict extension of Szpirglas' results [20], but they apply to more general situations, for example, unbounded nonregular signal functions. Our result is a new application of the work of Kurtz and Ocone [11] with an unbounded signal function that depends on the observation process.

Recall that X is an E -valued Markov process with infinitesimal generator $(A, \mathcal{D}(A))$. Let us assume the following hypotheses.

- (H1) E is a locally compact, separable, metric space (for instance, a Riemannian manifold).
- (H2) $\mathcal{D}(A)$ is a sense (in the sup norm) subalgebra in $C_0(E)$ (space of continuous functions that vanish at infinity).
- (H3) Generator A applies $\mathcal{D}(A)$ in $C_0(E)$: $A(\mathcal{D}(A)) \subset C_0(E)$.
- (H4) Uniqueness holds for the martingale problem associated to $(A, \mathcal{D}(A))$, i.e., a unique family of probability measures \mathbb{P}_x^X exists on canonical space $(\Omega^X, \mathcal{G}^X, X_t)$ of continuous functions taking values in E such that coordinate process X satisfies

$$(3.46) \quad \begin{aligned} &X_0 = x \quad \mathbb{P}_x^X \text{ a.e.}, \\ &\forall f \in \mathcal{D}(A), \\ &f(X_t) - f(x) - \int_0^t Af(X_s) ds \text{ is a } (\Omega^X, \mathcal{G}^X, \mathbb{P}_x^X)\text{-martingale.} \end{aligned}$$

- (H5) Function $\psi(x)$ belongs to $\mathcal{D}(A)$.

So, we have the following theorem (which can be transposed to the other filtering equations).

THEOREM 3.5. *Let μ be a cadlag adapted process taking its values in the space of probability measures on E (i.e., for all $C_0(E)$ -function f , $t \rightarrow \mu_t(f)$ is a cadlag \mathcal{G}^Y -adapted process). Let μ be such that, for each function f of $\mathcal{D}(A)$*

$$(3.47) \quad \mu_t(f) = \mu(f) + \int_0^t \mu_s(Af) ds + \int_0^t \omega_{\mu_s}(\bar{f}\psi^*) \circ dY_s - \frac{1}{2} \int_0^t \mu_s(\bar{f}(\kappa_s + \|\psi_s^*\|^2)) ds$$

where the notation is the same as in (3.26). Then, processes μ and π are indistinguishable.

Remark 1. Here we have to extend μ (as for π) to functions on E depending on Y as a parameter; first, to functions as product $f \cdot g$, f over E , g over M , so

$$(3.48) \quad \mu_t(f \cdot g) = \mu_t(f)g(Y_t)$$

or more general functions on $E \times M$:

$$(3.49) \quad \mu_t(f(\cdot, Y_t)) = \int_E f(x, Y_t) \mu_t(dx).$$

Remark 2. The uniqueness here is only among \mathcal{G}^Y -adapted measure processes. In this sense, the result is weaker than that of Szpirglas [20], and it is not a real pathwise uniqueness.

Before giving the proof, let us recall the results of Kurtz and Ocone [11]. First, a filtered martingale problem has to be defined with respect to a given generator $(A', \mathcal{D}(A'))$.

DEFINITION. Let $(A', \mathcal{D}(A'))$ an operator on a product space $E_1 \times E_2$; (μ, Z) is a solution of the *filtered martingale problem* (F.M.P.) associated to $(A', \mathcal{D}(A'))$ if (μ, Z)

is a cadlag process in product space of probability measures on E_1 by E_2 , i.e., for each f in $\mathcal{D}(A')$, $(\mu_t(f), Z_t)$ is a cadlag process in $\mathbb{R} \times E_2$, such that

$$(3.50) \quad \mu_t(f) \text{ is } \mathcal{G}_t^Z\text{-measurable and } \mu_t f(\cdot, Z_t) - \int_0^t \mu_s A f(\cdot, Z_s) ds \text{ is a } \mathcal{G}^Z\text{-martingale.}$$

Then, Kurtz and Ocone prove the following.

THEOREM 3.6. *Let a filtering problem with signal X take its values in E_1 and observation Y in E_2 ; E_i are locally compact separable metric spaces; (X, Y) is a solution of a martingale problem associated to generator $(A', \mathcal{D}(A'))$ verifying (H2) and (H3). Then, there is uniqueness for the filtered martingale problem associated to $(A', \mathcal{D}(A'))$, namely, two solutions (μ, Y) and (μ', Y') have the same law.*

COROLLARY. *If (μ, Y) and (π, Y) are solutions of the F.M.P. $(A', \mathcal{D}(A'))$, for each f in $\mathcal{D}(A')$, we get $\mu_t(f) = \pi_t(f)$ almost everywhere.*

We now sketch the proof of Theorem 3.5. First, the generator $(A', \mathcal{D}(A'))$ of system (X, Y) has to be defined; then it is sufficient to verify the hypotheses of Theorem 3.6: hypotheses (H1) to (H5) imply that $(A', \mathcal{D}(A'))$ verifies (H1) to (H4). Thus we get four steps.

Step 1. Let $\mathcal{D}(A')$ be defined as

$$(3.51) \quad \mathcal{D}(A') = \text{linear span } \{f \cdot g, f \in \mathcal{D}(A), g \in C_k^\infty(O(M))\},$$

i.e., the vector space generated by product of elements of $\mathcal{D}(A)$ and functions on $O(M)$, C^∞ and with compact support.

Let f belong to $\mathcal{D}(A)$ and g to $C_k^\infty(O(M))$; A' is defined by

$$(3.52) \quad A'(f \cdot g)(x, U) = A f(x) g(U) + f(x) (\frac{1}{2} \Delta g(U) + (u^{-1} \psi^*(x, y))^i B_i g(U))$$

where x belongs to E , $U = (y, u)$ belongs to $O(M)$, Δ is the horizontal Laplacian of Bochner (cf. [8]) and B_i are canonical horizontal vector fields on $O(M)$ used to define diffusion U (cf. 2.12).

Expression (3.52) is just a consequence of the Itô formula.

Step 2. As was already remarked, μ is extended to functions of $\mathcal{D}(A')$, so we get a new relation, similar to (3.47) with f in $\mathcal{D}(A')$ and A' instead of A .

Step 3. A point of the proof that is not obvious is the following: if μ satisfies (3.47), can (μ, Y) be a solution of the filtered martingale problem associated to $(A', \mathcal{D}(A'))$? That is to say: a probability measure \mathbb{Q}_μ such that

$$(3.53) \quad \mu_t f(\cdot, U_t) - \int_0^t \mu_s A' f(\cdot, U_s) ds \text{ is a } (\mathbb{Q}_\mu, \mathcal{G}^Y)\text{-martingale}$$

is to be exhibited. Actually, there exists a sequence of probability measures \mathbb{Q}^n , solution of the F.M.P. $(A', \mathcal{D}(A'))$:

$$\mathbb{Q}^n = L^n \cdot \mathbb{P} \quad \text{where } L_t^n = L_{t \wedge Z_n},$$

$$(3.54) \quad dL_t = L_t \mu_t(\phi^i) dB_t^i \quad (\phi_t \text{ is the signal function}),$$

$$Z_n = \inf \left\{ t / \int_0^t |\mu_s(\phi) - \pi_s(\phi)|^2 ds \geq n \text{ or } : \int_0^t |\mu_s(\phi)|^2 ds \geq n \right\}.$$

Notice that Z_n is chosen such that $L_{t \wedge Z_n}$ is an uniformly integrable strictly positive martingale; Z_n can be proved to increase up to infinity. Then, (3.47) is developed with the Stratonovitch integral written with local coordinates of ψ^* and Y and transformed

in an Itô integral with respect to \mathbb{P} -Brownian motion B (cf. (2.12)–(2.14)). After tedious computations, we get

$$(3.55) \quad \mu_t f(\cdot, U_t) - \int_0^t \mu_s A' f(\cdot, U_s) ds = \int_0^t \mu_s (\bar{f} \phi^i) (dB_s^i - \mu_s(\phi^i) ds),$$

so \mathbb{Q}_n is a solution, whatever n .

Step 4. Finally, it remains to prove that hypotheses (H1)–(H5) imply (H1)–(H4) for $(A', \mathcal{D}(A'))$. The construction of $\mathcal{D}(A')$ and (H2) prove that $\mathcal{D}(A')$ is a dense subalgebra of $C_0(E \times O(M))$, by applying the Stone–Weierstrass theorem to the one-point compactification of $E \times O(M)$. Then, $\mathcal{D}(A')$ is the set of finite linear combinations of product $f \cdot g$, f in $\mathcal{D}(A)$, g in $C_k^\infty(O(M))$, so the image by A' of $\mathcal{D}(A')$ is in $C_0(E \times O(M))$; indeed, let us remark that in (3.52) the last term can be written (cf. [18, p. 513]):

$$(3.56) \quad f(x)(u^{-1}\psi^*(x, y))^i B_i g(U) = f(x)\psi^i(x)(Adh^{-1})^i B_i g(U)$$

where h is such that $U = h \cdot U_0$; Adh^{-1} is an unbounded function on G , but $B_i g(U)$ is with compact support, so is the product and (3.56) belongs to $C_0(E \times M)$, and hypothesis (H2) is verified by $(A', \mathcal{D}(A'))$.

Now we are concerned with hypothesis (H4). We adapt the proof of Lemma 4.4 of Kurtz and Ocone [11] when the signal function is dependent on the observation. First, we prove that uniqueness holds for the martingale problem deduced from the filtering model under the reference probability. Indeed, the martingale problem associated to $(\frac{1}{2}\Delta, C_k^\infty(O(M)))$ has a unique solution: the Brownian motion on $O(M)$ [8]. So, hypotheses (H2) and (H4) and Lemma 4.3 of [11] show the following:

(3.57) Uniqueness holds for the martingale problem associated to $(B, \mathcal{D}(A'))$ with B defined by linear extension of

$$B(f \cdot g)(x, U) = Af(x)g(U) + \frac{1}{2}f(x)\Delta g(U), \quad f \cdot g \in \mathcal{D}(A').$$

Besides, let $(\Omega^{\tilde{X}, \tilde{U}}, \mathcal{G}^{\tilde{X}, \tilde{U}}, (\tilde{X}_t, \tilde{U}_t), \tilde{\mathbb{Q}})$ be any solution of the martingale problem associated to $(A', \mathcal{D}(A'))$ and let process $V_t = g_t^{-1} \cdot \tilde{U}_t$ such that

$$(3.58) \quad dg_t^{-1} = g_t^{-1}(-\psi(\tilde{X}_t)) dt, \quad g_0 = e$$

(that is to say $g_t^{-1}(-\psi)$ is a left invariant vector field on \mathcal{G}). We want to prove, for each $f \cdot b$ in $\mathcal{D}(A')$ and s lesser than t ,

$$(3.59) \quad E(f(\tilde{X}_t)b(V_t)/\mathcal{G}_s) = f(\tilde{X}_s)b(V_s) + E\left(\int_s^t B(f \cdot b)(\tilde{X}_u, V_u) du / \mathcal{G}_s\right).$$

So, $(\Omega^{\tilde{X}, \tilde{U}}, \mathcal{G}^{\tilde{X}, \tilde{U}}, (\tilde{X}_t, V_t), \tilde{\mathbb{Q}})$ will be a solution of martingale problem $(B, \mathcal{D}(A'))$ as is the initial system under reference probability $(\Omega, \mathcal{G}, (X_t, U_t), \mathbb{P}_{\mu_0})$. Then, (3.57) proves that \tilde{X} and V are independent and V is a Brownian motion on $O(M)$ as (X, U) are under P_{μ_0} ; furthermore, the laws of X and \tilde{X} are the same: so \tilde{U}_t is the transformation of Brownian motion V_t by g_t , solution of $dg_t = \psi(\tilde{X}_t)g_t dt$ (consequence of (3.58); see [18, 2.16]) and uniqueness holds for the martingale problem associated to $(A', \mathcal{D}(A'))$.

Now, let us prove (3.59). Thanks to derivation rules on a manifold ((3.58), (3.56)), if we define $R(s, t)$ as $b(g_s^{-1}U_t)$, we get

$$(3.60) \quad R(s, t) - R(0, t) = \int_0^s \frac{\partial R}{\partial v}(v, t) dv = - \int_0^s (u_t^{-1})^i \psi^{*j}(X_v, Y_t)(B_i b)(g_v^{-1}U_t) dv.$$

For instance, if s equals t , we get

$$(3.61) \quad f(X_t)b(V_t) = f(X_t)b(U_t) - \int_0^t f(X_t)(u_t^{-1})^i \psi^{*j}(X_v, Y_t)(B_i b)(g_v^{-1}U_t) dv.$$

Expression $f(X_t)(\partial R/\partial v)(v, t)$ —as a function of (X_t, U_t) —is a bounded function of $\mathcal{D}(A')$ thanks to (H5) and (3.51), when v is fixed. Thus, to compute \mathcal{G}_s -conditional mean of (3.55), we cut the integration at $v = s$. After s , we apply \mathcal{G}_v -conditional mean before \mathcal{G}_s -conditional mean:

$$(3.62) \quad \begin{aligned} & E \left(\int_0^t f(X_t) \frac{\partial R}{\partial v}(v, t) dv / \mathcal{G}_s \right) \\ &= \int_0^s f(X_s) \frac{\partial R}{\partial v}(v, s) dv + E \left(\int_s^t f(X_v) \frac{\partial R}{\partial v}(v, v) dv / \mathcal{G}_s \right) \\ &\quad + E \left(\int_0^t \int_{s \vee v}^t A' \left(f \frac{\partial R}{\partial v}(v, \cdot) \right) (X_u, U_u) du dv / \mathcal{G}_s \right). \end{aligned}$$

This last term, by exchanging the order of u and v -integration, becomes

$$(3.63) \quad E \left(\int_s^t \int_0^u A' \left(f \frac{\partial R}{\partial v}(v, \cdot) \right) (X_u, U_u) dv du / \mathcal{G}_s \right).$$

Let u be fixed and consider $f \cdot R$ as a function on $E \times O(M) \times [0, T]$:

$$(3.64) \quad f \cdot R : (x, U, v) \rightarrow f(x)b(g_v^{-1} \cdot U) = (f \cdot b \circ L_{g_v} - 1)(x, U).$$

Since $f \cdot \partial R/\partial v$ belongs to $\mathcal{D}(A')$ and $A'(f \cdot R(v, \cdot))$ is time-differentiable, operators A' and $\partial/\partial v$ are commuting, so we get

$$(3.65) \quad \int_0^u A' \left(f \frac{\partial R}{\partial v}(v, \cdot) \right) (X_u, U_u) dv = (A'(f \cdot R(u, \cdot)) - A'(f \cdot R(0, \cdot)))(X_u, U_u).$$

Definition (3.58) shows that the first term is

$$(3.66) \quad A'(f \cdot R(u, \cdot))(X_u, U_u) = A'(f \cdot b \circ L_{g_u}^{-1})(X_u, U_u).$$

We use the fact that $B_i(b \circ L_g)(U) = (L_g)_*(B_i)(b)(gU) = (B_i b)(g \cdot U)$ because $B_i = (i)_*(A_i)$, $L_g \circ i = i \circ L_g$ and A_i is left invariant; the same is true for Δ which equals $\sum_i B_i(B_i)$; so we get

$$(3.67) \quad A'(f \cdot b \circ L_g)(x, U) = B(f \cdot b)(x, g \cdot U) + (u^{-1}\psi^*(x, y))^i (B_i b)(g \cdot U) f(x).$$

Thus, we can write (3.59) as

$$(3.68) \quad \begin{aligned} & (A'(f \cdot R(v, \cdot)) - A'(f \cdot R(0, \cdot)))(X_v, U_v) \\ &= B(f \cdot b)(X_v, V_v) - B(f \cdot b)(X_v, U_v) \\ &\quad + [(u_v^{-1}\psi^*(X_v, Y_v))(B_i b)(V_v) - (u_v^{-1}\psi^*(X_v, Y_v))^i (B_i b)(U_v)] f(X_v). \end{aligned}$$

Hence, if we apply \mathcal{G}_s -conditional mean to (3.55) and use (3.56), definition (3.54) of $\partial R/\partial v(v, v)$ and (3.57)–(3.62) lead to (3.53). This concludes the proof.

4. Examples. In this part, we apply the previous results to filtering with observations taking values in space \mathbb{R}^d and in sphere S_2 considered as symmetric spaces. The first example which can be directly solved is however a nonstandard filtering problem. Observation Y is the transformation of an \mathbb{R}^d -valued Brownian motion by a space displacement (translation plus rotation). This simple model leads to an unbounded signal function of the observation.

The second example is a more interesting application of the previous theory. Observation Y is then the transformation of a spherical Brownian motion by a rotation. When sphere S_2 is embedded in \mathbb{R}^3 , the dynamics of Y can be expressed by a three-dimensional diffusion. But this diffusion is degenerate, so this example cannot be solved by classical multivariate filtering methods.

4.1. Multivariate case. Observation Y is such that

$$(4.1) \quad Y_t = \Sigma_t(X) W_t + H_t(X)$$

where W_t is a d -dimensional Brownian motion independent of X ; $\Sigma_t(X)$ is a matrix in $SO(d)$; $H_t(X)$ is a vector in \mathbb{R}^d . Thus Y_t is the transformation of W_t by space displacement (Σ, H) , rotation Σ and translation H being functional of X . Assume that

$$(4.2) \quad \dot{\Sigma}_t = \sigma(X_t) \Sigma_t, \quad \dot{H}_t = \sigma(X_t) H_t + h(X_t)$$

where σ is a bounded skew matrix and h a bounded d -dimensional vector. Hypothesis (4.2) implies (3.1) for $M = \mathbb{R}^d$ endowed with a structure of symmetric space as follows: we identify it to the affine hyperplane $(\mathbb{R}^d, 1)$ of \mathbb{R}^{d+1} . The isometric transformation group G of M can be modeled by the set of matrices as follows:

$$(4.3) \quad g = \begin{pmatrix} \Sigma & H \\ 0 & 1 \end{pmatrix}$$

where Σ is a matrix in $SO(d)$ and H is in \mathbb{R}^d . The corresponding Lie algebra \mathfrak{G} of G is the set of matrices ψ such that

$$(4.4) \quad \psi = \begin{pmatrix} \sigma & h \\ 0 & 0 \end{pmatrix}$$

where σ is a (d, d) skew matrix and h is in \mathbb{R}^d . Let ψ_t be defined by

$$(4.5) \quad \psi_t = \psi(X_t) = \begin{pmatrix} \sigma(X_t) & h(X_t) \\ 0 & 0 \end{pmatrix}.$$

So by (3.3) we get

$$(4.6) \quad \phi_t = \phi(X_t, Y_t) = \sigma(X_t) Y_t + h(X_t)$$

and application of Proposition 3.3 leads to the filtering equation for a bounded function f in domain $\mathcal{D}(A)$ of X :

$$\pi_t(f) = \mu(f) + \int_0^t \pi_s(Af) ds + \int_0^t (\pi_s(f\phi) - \pi_s(f)\pi_s(\phi), (dY_s - \pi_s(\phi) ds)).$$

4.2. Spherical case. We now apply the previous results to the sphere S_2 considered as a two-dimensional symmetric space. Sphere S_2 is, embedded in \mathbb{R}^3 , defined as the set of $x = (x_1, x_2, x_3)$ such that $\sum_i x_i^2 = 1$. As a manifold S_2 is endowed with the following open covering associated to spherical coordinates:

$$(4.7) \quad U = \left\{ x \left/ \sum_{i=1}^3 x_i^2 = 1 \right. \right\} - \{x/x_2 = 0; x_1 \leq 0\},$$

$$\psi: U \rightarrow]-\pi, +\pi[\times]-\frac{\pi}{2}, +\frac{\pi}{2}[,$$

$$\psi: x \rightarrow (\theta, \phi) \quad / \quad x = (\cos \phi \cos \theta, \cos \phi \sin \theta, \sin \phi),$$

$$\begin{aligned}
 U' &= \left\{ x / \sum_{i=1}^3 x_i^2 = 1 \right\} - \{x / x_3 = 0; x_1 \geq 0\}, \\
 (4.8) \quad \psi' : U' &\rightarrow]-\pi, +\pi[\times]-\frac{\pi}{2}, +\frac{\pi}{2}[, \\
 \psi' : x &\rightarrow (\theta', \phi') \quad / \quad x = (\cos \phi' \sin \theta', \sin \phi', \cos \phi' \cos \theta').
 \end{aligned}$$

Then, the Jacobian matrix J is

$$(4.9) \quad J = \begin{pmatrix} \frac{\partial \theta'}{\partial \theta} & \frac{\partial \theta'}{\partial \phi} \\ \frac{\partial \phi'}{\partial \theta} & \frac{\partial \phi'}{\partial \phi} \end{pmatrix} = \begin{pmatrix} -\frac{\cos \phi \sin \phi \sin \theta}{1 - \cos^2 \phi \sin^2 \theta} & -\frac{\cos \theta}{1 - \cos^2 \phi \sin^2 \theta} \\ \frac{\cos \phi \cos \theta}{\sqrt{1 - \cos^2 \phi \sin^2 \theta}} & \frac{-\sin \phi \sin \theta}{\sqrt{1 - \cos^2 \phi \sin^2 \theta}} \end{pmatrix}.$$

Let us now define S_2 as a symmetric space.

Fix point $0 = (1, 0, 0)$ in S_2 and orthonormal frame u_0 in $O(S_2)$ such that $\tau(u_0) = 0$ and defined by (e_1, e_2) , with tangent vectors at 0 : $e_1 = (0, 1, 0)$ and $e_2 = (0, 0, 1)$. On the other hand, for any p in S_2 the involutive symmetry s_p associates to any x its symmetric point on the great circle which contains points p and x . For instance, if $p = 0$, symmetry s_0 is done by the matrix

$$(4.10) \quad s_0 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.$$

Let us consider Lie group $G = \text{SO}(3)$, the isometric transformation group of S_2 ; G naturally acts on S_2 . Let be given g in $\text{SO}(3)$ and $x = (x_1, x_2, x_3)$ in S_2 ; the action $g \cdot x$ is defined by

$$(4.11) \quad (g \cdot x)_i = g_i^j x_j.$$

The isotropy subgroup of G at 0 , K , is the group of rotations around the first axis, that is to say the set of matrices k

$$(4.12) \quad k = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \theta & \sin \theta \\ 0 & -\sin \theta & \cos \theta \end{pmatrix}.$$

The Lie algebra $\mathcal{SO}(3)$ of $\text{SO}(3)$ is the set of $(3, 3)$ skew matrices. The sub-Lie algebra \mathfrak{K} of K is generated by the following matrix A_3 :

$$(4.13) \quad A_3 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}.$$

Let A_1 and A_2 be the following matrices of $\mathcal{SO}(3)$:

$$(4.14) \quad A_1 = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad A_2 = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

It is easy to show that (A_1, A_2) is a basis of \mathfrak{M} , the eigenspace of mapping σ_* associated to eigenvalue -1 (see § 2.1). The structure constants are now simple to compute:

$$(4.15) \quad C_{KI}^I = 0, \quad I = 1, 2, 3 \quad \text{and} \quad C_{13}^2 = -C_{12}^3 = -C_{23}^1 = 1.$$

Let us now consider the filtering model constructed in § 3.1, applied to the spherical case. Let $g_t(X)$ be defined as in (3.1) where $\psi_t = \psi(X_t)$ is a matrix in $\mathcal{SO}(3)$ such that

$$(4.16) \quad \psi(X_t) = \psi^I(X_t) A_I \quad (I = 1, 2, 3)$$

and $\psi^I(X_t)$ are bounded continuous real semimartingales. We define on $(\Omega, \mathcal{G}, \mathbb{P}_\mu)$ a standard two-dimensional Brownian motion B and a Brownian motion Y valued in S_2 , which can be defined by the following system:

$$(4.17) \quad \begin{aligned} dh_t &= h_t A_1 \circ dB_t^1 + h_t A_2 \circ dB_t^2, & h_0 &= e, \\ Y_t &= h_t \cdot 0 \end{aligned}$$

or by the other expressed in $O(S_2)$:

$$(4.18) \quad \begin{aligned} dY_t &= -u^1(t) \circ dB_t^1 - u^2(t) \circ dB_t^2, & Y_0 &= 0, \\ du^1(t) &= Y_t \circ dB_t^1, & u^1(0) &= e_1, \\ du^2(t) &= Y_t \circ dB_t^2, & u^2(0) &= e_2. \end{aligned}$$

To apply Proposition (3.3) we need vector field $(\psi(X_t))^*$. Let us remark [10] that mapping $C \rightarrow C^*$ (2.4) is a Lie algebra homomorphism. Hence it follows that

$$(4.19) \quad (\psi(x))^*(y) = \psi^I(x) A_I^*(y)$$

and we have to compute $A^*(y)$. Returning to its definition,

$$(4.20) \quad A^* f(y) = \frac{d}{dt} f(\exp t A \cdot y)|_{t=0},$$

we easily get

$$\begin{aligned} \exp t A_1 &= \begin{pmatrix} \cos t & -\sin t & 0 \\ \sin t & \cos t & 0 \\ 0 & 0 & 0 \end{pmatrix}, & \exp t A_2 &= \begin{pmatrix} \cos t & 0 & -\sin t \\ 0 & 1 & 0 \\ \sin t & 0 & \cos t \end{pmatrix}, \\ \exp t A_3 &= \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos t & -\sin t \\ 0 & \sin t & \cos t \end{pmatrix}, \end{aligned}$$

thus we get the local coordinates of A_I^* in (U, ψ)

$$(4.21) \quad \begin{aligned} A_1^*(\theta, \phi) &= \frac{\partial}{\partial \theta}; & A_2^*(\theta, \phi) &= \operatorname{tg} \phi \sin \theta \frac{\partial}{\partial \theta} + \cos \theta \frac{\partial}{\partial \phi}, \\ A_3^*(\theta, \phi) &= -\operatorname{tg} \phi \cos \theta \frac{\partial}{\partial \theta} + \sin \theta \frac{\partial}{\partial \phi}, \end{aligned}$$

and in (U', ψ)

$$(4.22) \quad \begin{aligned} A_1^*(\theta', \phi') &= -\operatorname{tg} \phi' \cos \theta' \frac{\partial}{\partial \theta'} + \sin \theta' \frac{\partial}{\partial \phi'}, & A_2^*(\theta', \phi') &= -\frac{\partial}{\partial \theta'}, \\ A_3^*(\theta', \phi') &= -\operatorname{tg} \phi' \sin \theta' \frac{\partial}{\partial \theta'} - \cos \theta' \frac{\partial}{\partial \phi'}. \end{aligned}$$

Then, it only remains to apply Proposition (3.3) to this spherical filtering model. In this case, for all f in $\mathcal{D}(A)$, we have

$$(4.23) \quad \pi_t(f) = \mu(f) + \int_0^t \pi_s(Af) ds + \int_0^t \omega_{\pi_s(\bar{f}\psi^I)A_I^*} \circ dY_s - \frac{1}{2} \int_0^t \pi_s(\bar{f} \|\psi_{Y_s}^*\|^2) ds$$

because of (4.19) and (4.15). Finally, we can give an explicit formulation with respect to the local coordinates (θ_t, ϕ_t) or (θ'_t, ϕ'_t) whenever process Y_t belongs to U or U' :

$$(4.24) \quad d\pi_t(f) = \pi_t(Af) dt + (\pi_t(\bar{f}\psi^1) + \pi_t(\bar{f}\psi^2) \operatorname{tg} \phi_t \sin \theta_t - \pi_t(\bar{f}\psi^3) \operatorname{tg} \phi_t \cos \theta_t) \circ d\theta_t \\ + (\pi_t(\bar{f}\psi^2) \cos \theta_t + \pi_t(\bar{f}\psi^3) \sin \theta_t) \circ d\phi_t - \frac{1}{2} \pi_t(\bar{f}l_t) dt$$

where

$$l_t(x) = \|\psi_x^*(Y_t)\|^2 = (\psi^1(x) + (\psi^2(x) \sin \theta_t - \psi^3(x) \cos \theta_t) \operatorname{tg} \phi_t)^2 \\ + (\psi^2(x) \operatorname{csc} \theta_t + \psi^3(x) \sin \theta_t)^2$$

if Y_t belongs to U and

$$(4.25) \quad d\pi_t(f) = \pi_t(Af) dt + (-\pi_t(\bar{f}\psi^1) \operatorname{tg} \phi'_t \cos \theta'_t - \pi_t(\bar{f}\psi^2) - \pi_t(\bar{f}\psi^3) \operatorname{tg} \phi'_t \sin \theta'_t) \circ d\theta'_t \\ + (\pi_t(\bar{f}\psi^1) \sin \theta'_t - \pi_t(\bar{f}\psi^2) \cos \theta'_t) \circ d\phi'_t - \frac{1}{2} \pi_t(\bar{f}l_t) dt$$

where

$$l_t(x) = (\psi^2(x) + (\psi^1(x) \cos \theta'_t + \psi^2(x) \sin \theta'_t) \operatorname{tg} \phi'_t)^2 + (\psi^1(x) \sin \theta'_t - \psi^2(x) \cos \theta'_t)^2$$

if Y_t belongs to U' .

5. Conclusion. We have studied a nonstandard filtering model. Observation process Y takes values in a symmetric space M . This particular assumption allows us to consider process Y under a multiplicative form, and then generalizes the previous cases of [15] and [16]. More precisely, process Y depends on signal X by means of a stochastic isometric transformation $Y_t = g_t(X) \cdot W_t$, where W_t is a Brownian motion taking its values in M . We get intrinsical filtering equations under both Stratonovitch and Itô forms which are unique characterizations of conditional distribution of X and Y .

Acknowledgment. We thank the reviewer for suggesting that we study uniqueness of the solution of filtering equations.

SENSITIVITY ANALYSIS OF NONLINEAR PROGRAMS AND DIFFERENTIABILITY PROPERTIES OF METRIC PROJECTIONS*

ALEXANDER SHAPIRO†

Abstract. This paper is concerned with a study of differentiability properties of the optimal value function and an associated optimal solution of a parametrized nonlinear program. Second order analysis is presented essentially under the Mangasarian–Fromovitz constraint qualification when the corresponding vector of Lagrange multipliers is not necessarily unique. It is shown that under certain regularity conditions the optimal value function possesses second order directional derivatives and the optimal solution mapping is directionally differentiable. The results obtained are applied to an investigation of metric projections in finite-dimensional spaces.

Key words. nonlinear programming, sensitivity analysis, optimal value, parametric programming, metric projections, second order directional derivatives

AMS(MOS) subject classification. 90C31

1. Introduction. In this paper we consider the mathematical programming problem

$$(\mathcal{P}_y) \quad \underset{x}{\text{minimize}} \ f(x, y) \quad \text{subject to } x \in \Omega(y),$$

where the objective function $f(x, y)$ as well as the set $\Omega(y)$ of feasible solutions depends on the parameter vector $y \in \mathbb{R}^n$. It will be assumed that the point-to-set mapping (multifunction) $\Omega: \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ is defined by equality and inequality constraints

$$(1.1) \quad \Omega(y) = \{x: g_i(x, y) = 0, i = 1, \dots, q; g_i(x, y) \leq 0, i = q+1, \dots, p\}$$

and that all involved functions f and $g_i, i = 1, \dots, p$, are at least C^1 smooth on $\mathbb{R}^m \times \mathbb{R}^n$. The optimal value function

$$\varphi(y) = \inf \{f(x, y): x \in \Omega(y)\}$$

is associated with program (\mathcal{P}_y) and the corresponding set $M(y)$ of optimal solutions. By convention $\varphi(y)$ is defined to be $+\infty$ if the set $\Omega(y)$ is empty.

The aim of this paper is to investigate first- and second-order differential properties of $\varphi(y)$ and differential properties of an optimal solution $\bar{x}(y) \in M(y)$ in vicinity of a given point y_0 . In the case $\Omega(y)$ is defined by (1.1), this is the standard problem of sensitivity analysis in nonlinear programming which has been discussed extensively [4], [6], [7], [10], [11], [16], [25], [28], [30], [33], [34], [37]. The approach we adopt here is to try to approximate the nonlinear program (\mathcal{P}_y) by a simpler one rather than to “linearize” equations representing optimality conditions of (\mathcal{P}_y) (cf. [4], [7], [16], [27], [28]). Thus the present investigation can be considered as an extension and generalization of an approach suggested in [34]. The regularity conditions ensuring uniqueness of Lagrange multipliers [18], which have been employed in [34], will be replaced by the Mangasarian–Fromovitz constraint qualification (MF-condition) [20]. Since the MF-condition is necessary and sufficient for the set of Lagrange multipliers to be bounded [9], this appears to be a natural assumption we should use in order to investigate (\mathcal{P}_y) by means of the differential information at the point $(x_0, y_0), x_0 \in M(y_0)$.

When the objective function $f(x, y)$ is taken to be $f(x, y) = \|y - x\|$, where $x, y \in \mathbb{R}^n$ and $\|\cdot\|$ is a chosen norm, the optimal set valued multifunction $M(y)$ becomes the set-valued metric projection onto the (moving) set $\Omega(y)$. We consider a corresponding selection mapping $P_\Omega: \mathbb{R}^n \rightarrow \mathbb{R}^n$, $P_\Omega(y) \in M(y)$. Thus $P_\Omega(y)$ is a closest point of the set $\Omega(y)$ to the point y . In the case of the constant (independent of y) and convex set $\Omega(y) = \Omega_0$ differentiability properties of the associated metric projection P_Ω have been studied in a number of publications (see [1], [8], [12], [14], [23], [39] and references therein). Recently Malanowski [19] applied some results from sensitivity analysis of nonlinear programs to an investigation of differentiability of metric projections. On the basis of our study of program (\mathcal{P}_y) we will be able to strengthen some results due to Haraux [12], Holmes [14], Malanowski [19] and others. We show that under certain regularity conditions P_Ω is directionally differentiable at $y_0 \in \mathbb{R}^n \setminus \Omega(y_0)$, although the corresponding directional derivative $P'_\Omega(y_0; v)$ is not necessarily continuous in v . It should be mentioned that, in general, directional differentiability of P_Ω is not guaranteed even in the case of constant and convex set $\Omega(y) = \Omega_0$ and the Euclidean norm (see [17], [24, p. 696]).

Throughout the paper we assume that the feasible set $\Omega(y_0)$ corresponding to the point y_0 is nonempty. For a multifunction Ω we write $\text{gph } \Omega$ for its graph,

$$\text{gph } \Omega = \{(y, x) : x \in \Omega(y)\}.$$

The multifunction Ω is called closed (convex) if $\text{gph } \Omega$ is a closed (convex) subset of $\mathbb{R}^n \times \mathbb{R}^m$. A multifunction $\Sigma: \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ is said to be positively homogeneous if $\Sigma(ty) = t\Sigma(y)$ for all $t > 0$ and $y \in \mathbb{R}^n$. Clearly Σ is positively homogeneous if and only if its graph $\text{gph } \Sigma$ is a cone. A (closed, convex) positively homogeneous multifunction is called a (closed, convex) *process* [29, § 39].

We make use of the concept of pseudo-Lipschitzian multifunctions [2, p. 98], [31]. A multifunction $\Omega(y)$ is said to be pseudo-Lipschitzian at a point (x_0, y_0) , $x_0 \in \Omega(y_0)$, if the distance function $d_\Omega(x, y) = \text{dist}(x; \Omega(y))$ is Lipschitzian in a neighborhood of (x_0, y_0) . For an equivalent definition and thorough discussion of pseudo-Lipschitzian multifunctions see Rockafellar [31]. Here and subsequently we denote by $\text{dist}(x; S)$ the distance from a point x to a set S ,

$$\text{dist}(x; S) = \inf \{\|x - z\| : z \in S\}.$$

Finally we recall that a function (mapping) $f(y)$ is said to be directionally differentiable at y_0 if the directional derivative

$$f'(y_0; v) = \lim_{t \rightarrow 0^+} \frac{f(y_0 + tv) - f(y_0)}{t}$$

exists for all v .

2. The reduction theorem. In this section we show that under certain regularity conditions the basic problem (\mathcal{P}_y) can be replaced by an equivalent one which is more convenient for sensitivity analysis. The following regularity conditions will be required.

Assumption 1. There exist a number α and a compact set $S \subset \mathbb{R}^m$ such that $\alpha > \varphi(y_0)$ and

$$\{x \in \Omega(y) : f(x, y) \leq \alpha\} \subset S$$

for all y in a neighborhood of y_0 .

This condition is required in order to ensure some continuity properties of the optimal value function and optimal solutions. It has been employed in [30] and [32]

and goes back to Wets [38]. Assumption 1 is similar to the condition of uniform compactness of $\Omega(y)$ utilized in [10] and [11].

Assumption 2. The optimal set $M(y_0) = \{x_0\}$ is a singleton.

Notice that the uniqueness Assumption 2 does not necessarily imply that $M(y)$ is single-valued in a neighborhood of y_0 .

In order to simplify notation we assume subsequently that all inequality constraints are active at the point (x_0, y_0) , i.e., $g_i(x_0, y_0) = 0$ for $i = q+1, \dots, p$.

Assumption 3 (MF-condition). (i) The gradient vectors $\nabla_x g_i(x_0, y_0)$, $i = 1, \dots, q$, are linearly independent.

(ii) There exists a vector u such that

$$u^T \nabla_x g_i(x_0, y_0) = 0, \quad i = 1, \dots, q,$$

$$u^T \nabla_x g_i(x_0, y_0) < 0, \quad i = q+1, \dots, p.$$

Assumption 3 is the standard Mangasarian-Fromovitz constraint qualification [20] applied at the point (x_0, y_0) . It follows from Assumption 3 that the Mangasarian-Fromovitz constraint qualification is satisfied at all $(\bar{x}(y), y)$ sufficiently close to (x_0, y_0) and thus the first order (Kuhn-Tucker) necessary conditions hold: If $\bar{x} = \bar{x}(y)$ is a solution of (\mathcal{P}_y) , then there exists a vector $\bar{\lambda} = \bar{\lambda}(y) \in \mathbb{R}^p$ of Lagrange multipliers such that

$$(2.1) \quad \begin{aligned} \nabla_x L(\bar{x}, y, \bar{\lambda}) &= 0, \\ \bar{\lambda}_i g_i(\bar{x}, y) &= 0 \quad \text{and} \quad \bar{\lambda}_i \geq 0, \quad i = q+1, \dots, p. \end{aligned}$$

Here $L(x, y, \lambda)$ is the Lagrangian function associated with program (\mathcal{P}_y) ,

$$L(x, y, \lambda) = f(x, y) + \sum_{i=1}^p \lambda_i g_i(x, y).$$

We denote by $\Lambda(\bar{x}, y)$ the set of vectors $\bar{\lambda}$ satisfying the first order necessary conditions (2.1). It follows from the definition that $\Lambda(\bar{x}, y)$ is a closed convex polytope. Moreover, it is implied by the MF-condition that the set $\Lambda_0 = \Lambda(x_0, y_0)$ is nonempty and *bounded* (Gauvin [9]). Consequently Λ_0 is the convex hull of the finite set E_0 of its extreme points. For a vector $\lambda \in \mathbb{R}^p$ denote $J_+(\lambda) = \{i: \lambda_i > 0, i = q+1, \dots, p\}$, $J_0(\lambda) = \{i: \lambda_i = 0, i = q+1, \dots, p\}$ and $J(\lambda) = \{1, \dots, q\} \cup J_+(\lambda)$. It is not difficult to see that a point $\lambda \in \Lambda_0$ is an extreme point if and only if the gradient vectors $\nabla_x g_i(x_0, y_0)$, $i \in J(\lambda)$, are linearly independent.

We are prepared now to formulate a reduction theorem in which program (\mathcal{P}_y) is replaced by a more convenient one. Consider the function

$$(2.2) \quad F(x, y) = \max \{L(x, y, \lambda): \lambda \in \Lambda_0\}.$$

Since $L(x, y, \lambda)$ is linear in λ , the maximum in the right-hand side of (2.2) is attained at extreme points of Λ_0 . Consequently $F(x, y)$ is representable as the pointwise maximum of a finite family of smooth functions $F_\lambda(x, y) = L(x, y, \lambda)$,

$$(2.3) \quad F(x, y) = \max \{L(x, y, \lambda): \lambda \in E_0\}.$$

We also consider the reduced feasible set

$$(2.4) \quad \bar{\Omega}(y) = \bigcup \{\Omega_\lambda(y): \lambda \in E_0\},$$

where

$$\begin{aligned} \Omega_\lambda(y) &= \{x: g_i(x, y) = 0, i \in J(\lambda); g_i(x, y) \leq 0, i \in J_0(\lambda)\} \\ &= \Omega(y) \cap \{x: g_i(x, y) = 0, i \in J_+(\lambda)\}. \end{aligned}$$

THEOREM 2.1. *Suppose that Assumptions 1–3 hold. Then for all y in a neighborhood of y_0 ,*

$$(2.5) \quad \varphi(y) = \inf \{F(x, y) : x \in \bar{\Omega}(y)\}$$

and the optimal set $M(y)$ coincides with the set of minimizers of $F(\cdot, y)$ over $\bar{\Omega}(y)$.

We shall make use of the following continuity property of the optimal set $M(y)$, which is a variation of well-known results in stability theory of parametrized nonlinear programs (e.g. [7, § 2.2]).

LEMMA 2.1. *Suppose that Assumptions 1–3 hold and let $\bar{x}(y)$ be an optimal solution of the program (\mathcal{P}_y) . Then $\bar{x}(y)$ converges to x_0 as y tends to y_0 .*

Proof. First we observe that the multifunction Ω is closed and because of the MF-condition the set $\Omega(y)$ is nonempty for all y in a neighborhood of y_0 such that there is a point $u(y)$, $u(y) \in \Omega(y)$, converging to x_0 as $y \rightarrow y_0$. Together with the inf-compactness Assumption 1 this implies that the minimizer $\bar{x}(y)$ exists for all y near y_0 .

Suppose that $\bar{x}(y)$ is not continuous at y_0 . Then there exist a sequence $y_n \rightarrow y_0$ and a constant $\delta > 0$ such that $\|x_n - x_0\| > \delta$, where $x_n = \bar{x}(y_n)$. It follows from Assumption 1 that there is a compact set S such that $\bar{x}(y) \in S$ for all y in a neighborhood of y_0 . Therefore the sequence $\{x_n\}$ can be chosen in such a way that $\{x_n\}$ converges to a point $x^* \in S$. Since Ω is closed, $x^* \in \Omega_0 = \Omega(y_0)$. The function $f(x, y)$ is continuous and hence there exists $\varepsilon > 0$ such that

$$(2.6) \quad f(x, y_0) > f(x_0, y_0) + \varepsilon$$

for all $x \in \{v : \|v - x_0\| \geq \delta, v \in S \cap \Omega_0\}$. Now consider a sequence $u_n \in \Omega(y_n)$ converging to x_0 . It follows from the continuity of $f(x, y)$ that

$$(2.7) \quad |f(x_0, y_0) - f(u_n, y_n)| < \varepsilon/2$$

and

$$(2.8) \quad |f(x^*, y_0) - f(x_n, y_n)| < \varepsilon/2$$

for sufficiently large n . Moreover, $f(x_n, y_n) \leq f(u_n, y_n)$ and hence by (2.7) and (2.8)

$$f(x^*, y_0) < f(x_0, y_0) + \varepsilon.$$

The last inequality contradicts (2.6) and hence the proof is complete. \square

Proof of Theorem 2.1. Consider the following optimal value function:

$$\bar{\varphi}(y) = \inf \{f(x, y) : x \in \bar{\Omega}(y)\}.$$

First we show that $\varphi(y) = \bar{\varphi}(y)$ and the set $M(y)$ coincides with the set of minimizers of $f(\cdot, y)$ over $\bar{\Omega}(y)$ for all y in a neighborhood of y_0 . Clearly for every y , $\bar{\Omega}(y) \subset \Omega(y)$ and hence $\bar{\varphi}(y) \geq \varphi(y)$. By continuity of $\bar{x}(y)$ the Mangasarian–Fromovitz condition holds at $\bar{x} = \bar{x}(y)$ and hence $\Lambda(\bar{x}, y)$ is nonempty for all y near y_0 . Furthermore, a vector $\bar{\lambda}(y) \in \Lambda(\bar{x}, y)$ of Lagrange multipliers converges to Λ_0 , that is there exists $\lambda^*(y) \in \Lambda_0$ such that $\bar{\lambda}(y) - \lambda^*(y) \rightarrow 0$ as $y \rightarrow y_0$. Vector $\lambda^* = \lambda^*(y)$ is representable as a convex combination of some points from E_0 . Let $\mu = \mu(y) \in E_0$ be an extreme point which takes part in this convex combination with the largest coefficient. Since coordinates μ_i , $i = q+1, \dots, p$, of μ are nonnegative we then have that

$$\lambda_i^* \geq (1/N)\mu_i, \quad i = q+1, \dots, p,$$

where N is the number of extreme points in E_0 . Because the number of extreme points is finite it follows then by continuity that $J_+(\mu) \subset J_+(\bar{\lambda})$ for y sufficiently close to y_0 .

This implies that the inequality constraints g_i , $i \in J_+(\mu)$, are active at $(\bar{x}(y), y)$ and hence $\bar{x}(y) \in \Omega_\mu(y)$. Therefore $\varphi(y) \geq \bar{\varphi}(y)$ and $M(y) \subset \bar{\Omega}(y)$ for all y near y_0 . This completes the proof of the assertion stated above.

It remains to show that for every $x \in \bar{\Omega}(y)$, $f(x, y) = F(x, y)$. Since $\bar{\Omega}(y) \subset \Omega(y)$ we have that $g_i(x, y) = 0$, $i = 1, \dots, q$, and $g_i(x, y) \leq 0$, $i = q+1, \dots, p$, for all $x \in \bar{\Omega}(y)$. Moreover, $\lambda_i \geq 0$, $i = q+1, \dots, p$, and hence $L(x, y, \lambda) \leq f(x, y)$ for all $\lambda \in E_0$ and $x \in \bar{\Omega}(y)$. Consequently $F(x, y) \leq f(x, y)$ for all $x \in \bar{\Omega}(y)$. Now if $x \in \bar{\Omega}(y)$, then $x \in \Omega_\mu(y)$ for some $\mu \in E_0$. By the definition of $\Omega_\mu(y)$ we have that $L(x, y, \mu) = f(x, y)$ and hence $F(x, y) = f(x, y)$. \square

It follows from Theorem 2.1 that $M(y) \subset \bar{\Omega}(y)$ and hence the multifunction $\bar{\Omega}$ is nonempty valued for all y in a neighborhood of y_0 . In the remainder of this section we study local behavior of the reduced feasible set $\bar{\Omega}(y)$ near the point (x_0, y_0) . In particular it will be shown that $\bar{\Omega}$ is tangentially differentiable at (x_0, y_0) in the sense of the following definition.

DEFINITION 2.1. We say that a multifunction $\Phi: \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ is tangentially differentiable at (x_0, y_0) , $x_0 \in \Phi(y_0)$, if there exists a closed process $\Sigma: \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ such that

$$(2.9) \quad \lim_{\substack{(x,y) \rightarrow (x_0,y_0) \\ (y,x) \in \text{gph } \Phi}} \frac{\text{dist}(x - x_0; \Sigma(y - y_0))}{\|(y - y_0, x - x_0)\|} = 0$$

and

$$(2.10) \quad \lim_{\substack{(x,y) \rightarrow (x_0,y_0) \\ (y-y_0, x-x_0) \in \text{gph } \Sigma}} \frac{\text{dist}(x; \Phi(y))}{\|(y - y_0, x - x_0)\|} = 0.$$

The process Σ is said to be a tangential approximation to Φ at (x_0, y_0) and is denoted $\Sigma = D\Phi(x_0, y_0)$.

The concept of tangential differentiability has been introduced and discussed in [36]. It was shown that whenever $D\Phi$ exists it is unique. Fixing $y = y_0$ in (2.9) and (2.10) we obtain that the set $\Phi_0 = \Phi(y_0)$ is approximated at x_0 by the cone $\Sigma_0 = \Sigma(0)$ [35]. Also $x_0 + \Sigma_0$ and Φ_0 are tangent at x_0 in the sense of Robinson [26, Def. 3]. For a detailed discussion and derivation of basic properties of cone and tangential approximations and relevant references the reader is referred to [26, p. 504], [22, § 4], [35] and [36], respectively.

Under the MF-condition the multifunction Ω is pseudo-Lipschitzian [31, Thm. 2.3] and tangentially differentiable at (x_0, y_0) [36]. Moreover, the tangential approximation $\Sigma = D\Omega(x_0, y_0)$ is given by the linearization

$$(2.11) \quad \Sigma(v) = \{u: \alpha_i(u, v) = 0, i = 1, \dots, q; \alpha_i(u, v) \leq 0, i = q+1, \dots, p\},$$

where

$$\alpha_i(u, v) = u^T \nabla_x g_i(x_0, y_0) + v^T \nabla_y g_i(x_0, y_0).$$

For the reduced multifunction $\bar{\Omega}$ a natural candidate for the tangential approximation is provided by the corresponding linearization

$$(2.12) \quad \bar{\Sigma}(v) = \bigcup \{\Sigma_\lambda(v): \lambda \in E_0\}$$

with

$$\Sigma_\lambda(v) = \{u: \alpha_i(u, v) = 0, i \in J(\lambda); \alpha_i(u, v) \leq 0, i \in J_0(\lambda)\}.$$

The following characterization of $\bar{\Sigma}(v)$ will be useful.

LEMMA 2.2. Suppose that the MF-condition holds. Then for all v the set $\bar{\Sigma}(v)$ is given by the set of optimal solutions of the linear program

$$(2.13) \quad \underset{u}{\text{minimize}} \quad u^T \nabla_x f(x_0, y_0) \quad \text{subject to } u \in \Sigma(v).$$

Proof. First we observe that because of the MF-condition the set E_0 is nonempty. Consider a point v and let $\bar{u} \in \Sigma_\lambda(v)$ for some $\lambda \in E_0$. Because of the first order necessary conditions (2.1), applied at the point (x_0, y_0) ,

$$\nabla_x f(x_0, y_0) + \sum_{i \in J(\lambda)} \lambda_i \nabla_x g_i(x_0, y_0) = 0$$

and $\lambda_i \geq 0$, $i = q+1, \dots, p$. By the definition of $\Sigma_\lambda(v)$, $\alpha_i(\bar{u}, v) = 0$ for all $i \in J(\lambda)$. It then follows from the optimality conditions for linear programs that \bar{u} is an optimal solution of the program (2.13). Conversely, similar to the proof of Theorem 2.1 it can be shown that if \bar{u} is an optimal solution of (2.13), then $\bar{u} \in \Sigma_\lambda(v)$ for some $\lambda \in E_0$. \square

Lemma 2.2 implies that for all v the set $\bar{\Sigma}(v)$ is a closed convex polytope. Moreover, perturbations of the linear program (2.13) are determined by the right-hand side changes corresponding to $v^T \nabla_y g_i(x_0, y_0)$, $i = 1, \dots, p$. It follows then that the multifunction $\bar{\Sigma}(v)$ is Lipschitzian (Mangasarian and Shiau [21]) and hence is pseudo-Lipschitzian at $(0, 0)$.

LEMMA 2.3. Suppose that the MF-condition holds. Then the multifunction $\bar{\Omega}$ is tangentially differentiable at (x_0, y_0) and $D\bar{\Omega}(x_0, y_0) = \bar{\Sigma}$.

Proof. Without loss of generality we can assume that $(x_0, y_0) = (0, 0)$. First we show that condition (2.9), applied to the multifunctions $\bar{\Omega}$ and $\bar{\Sigma}$, is satisfied. Suppose that (2.9) does not hold. Then there exists a sequence $(x_n, y_n) \rightarrow (0, 0)$, $x_n \in \bar{\Omega}(y_n)$, and $\varepsilon > 0$ such that

$$\text{dist}(x_n; \bar{\Sigma}(y_n)) > \varepsilon t_n,$$

where $t_n = \|(x_n, y_n)\|$. Since the set E_0 is finite we can assume that there is $\lambda \in E_0$ such that $x_n \in \Omega_\lambda(y_n)$ for all n . By the standard argument of compactness we can assume that the sequence $\{t_n^{-1}(x_n, y_n)\}$ converges to a vector (u, v) . Since $\bar{\Sigma}$ is pseudo-Lipschitzian the distance function $d_{\bar{\Sigma}}(x, y) = \text{dist}(x; \bar{\Sigma}(y))$ is Lipschitzian and hence continuous. It follows that

$$\text{dist}(t_n^{-1}x_n; \bar{\Sigma}(t_n^{-1}y_n)) > \varepsilon$$

and then by the continuity of the distance function $\text{dist}(u; \bar{\Sigma}(v)) > 0$. Therefore u does not belong to the set $\bar{\Sigma}(v)$. On the other hand

$$g_i(x_n, y_n) = \alpha_i(x_n, y_n) + o(t_n)$$

and hence $\alpha_i(u, v) = 0$ for $i \in J(\lambda)$ and $\alpha_i(u, v) \leq 0$ for $i \in J_0(\lambda)$. Consequently $u \in \Sigma_\lambda(v)$, a contradiction.

Now consider condition (2.10). Because of the MF-condition (i), for a given y sufficiently close to $y_0 = 0$ the equality constraints define a smooth manifold

$$\theta(y) = \{x: g_i(x, y) = 0, i = 1, \dots, q\}$$

near zero. It follows from the MF-condition (ii) that $\Omega(y)$ has a nonempty interior relative to this manifold in a neighborhood of $x_0 = 0$. The multifunction Ω is tangentially differentiable and hence for every $(y, x) \in \text{gph } \bar{\Sigma}$ in a neighborhood of $(0, 0)$, there exists a vector $(y, u) \in \text{gph } \Omega$ such that $\|x - u\| = o(\|(x, y)\|)$. Consider the index set

$$I(u, y) = \{i: g_i(u, y) = 0, i = q+1, \dots, p\}$$

and the normal cone to $\Omega(y)$ at u , which is polar to the contingent cone of $\Omega(y)$ at u . This normal cone is generated by the gradient vectors $\nabla_x g_i(u, y)$, $i \in I(u, y)$, with nonnegative coefficients and $\nabla_x g_i(u, y)$, $i = 1, \dots, q$, with unrestricted coefficients. By the MF-condition the point u can be chosen on the boundary of $\Omega(y)$ relative to the manifold $\theta(y)$ such that the contingent cone of $\Omega(y)$ at u tends to the contingent cone of $\Sigma(y)$ at x as y tends to $y_0 = 0$. That is, the distance from $-\nabla_x f(x_0, y_0)$ to the normal cone (to $\Omega(y)$ at u) tends to zero, i.e., there are multipliers $\lambda_i^* = \lambda_i^*(u, y)$ such that

$$\nabla_x f(x_0, y_0) + \sum_{i=1}^q \lambda_i^* \nabla_x g_i(u, y) + \sum_{i \in I(u, y)} \lambda_i^* \nabla_x g_i(u, y)$$

tends to zero as $(u, y) \rightarrow (0, 0)$. By the first order necessary conditions this implies that there is $\mu = \mu(u, y) \in E_0$ such that $J_+(\mu) \subset J_+(\lambda^*)$ for (u, y) sufficiently close to $(0, 0)$. Then $J_+(\mu) \subset I(u, y)$ and hence $u \in \Omega_\mu(y)$. Consequently $u \in \bar{\Omega}(y)$ and this completes the proof of (2.10). \square

Now let us consider the polyhedral convex cone

$$(2.14) \quad C = \{u: u^T \nabla_x g_i(x_0, y_0) = 0, i = 1, \dots, q; \\ u^T \nabla_x g_i(x_0, y_0) \leq 0, i = q+1, \dots, p; u^T \nabla_x f(x_0, y_0) \leq 0\}.$$

The cone C is called critical and is useful in deriving second order optimality conditions for program (\mathcal{P}_{y_0}) . The result of the following lemma clarifies a relation between C and the multifunction $\bar{\Sigma}$ (see [30, (1.13), (1.14)]).

LEMMA 2.4. *Suppose that the MF-condition holds. Then $C = \Sigma_\lambda(0)$ for all $\lambda \in E_0$.*

Proof. Because of the MF-condition the set E_0 is nonempty. Consider $u \in C$ and $\lambda \in E_0$. Then

$$0 \geq u^T \nabla_x f(x_0, y_0) = -u^T \left(\sum_{i \in J(\lambda)} \lambda_i \nabla_x g_i(x_0, y_0) \right) = - \sum_{i \in J_+(\lambda)} \lambda_i u^T \nabla_x g_i(x_0, y_0).$$

Since λ_i is positive and $-u^T \nabla_x g_i(x_0, y_0)$ is nonnegative for all $i \in J_+(\lambda)$, it follows that $u^T \nabla_x g_i(x_0, y_0) = 0$, $i \in J_+(\lambda)$, and hence $u \in \Sigma_\lambda(0)$. Conversely, if $\lambda \in E_0$ and $u \in \Sigma_\lambda(0)$, then $u^T \nabla_x f(x_0, y_0) = 0$ and hence $u \in C$. \square

It follows from Lemma 2.4 that $C = \bar{\Sigma}(0)$. Moreover, the characterization of $\bar{\Sigma}(v)$ given in Lemma 2.2 implies that for all v , C is the recession cone of $\bar{\Sigma}(v)$ (see [29, pp. 61, 62]).

3. Pointwise Lipschitz continuity of optimal solutions. In this section we study Lipschitz continuity of an optimal solution $\bar{x}(y) \in M(y)$ as y tends to y_0 . For that purpose we utilize second order sufficient conditions corresponding to the program (\mathcal{P}_{y_0}) . Consider the index set

$$\mathcal{J} = \bigcup_{\lambda \in E_0} \{i: \lambda_i \neq 0, i = 1, \dots, p\}$$

associated with nonzero Lagrange multipliers. It will be assumed that the functions f and g_i , $i \in \mathcal{J}$, are C^2 while the functions g_i , $i \in \{1, \dots, p\} \setminus \mathcal{J}$, are C^1 smooth. This implies that the Hessian matrices $\nabla_{xx}^2 L(x_0, y_0, \lambda)$ do exist for all $\lambda \in E_0$. Then, under the MF-condition, a feasible point x_0 satisfying the first order necessary conditions is an isolated local solution of program (\mathcal{P}_{y_0}) if

$$(3.1) \quad \max_{\lambda \in \Lambda_0} u^T \nabla_{xx}^2 L(x_0, y_0, \lambda) u > 0$$

for all $u \in C$, $u \neq 0$, where C is the critical cone defined in (2.14), [5], [13], [15]. The corresponding second order necessary conditions are obtained if the strict inequality

sign “>” in (3.1) is replaced by the sign “ \geq ”. We shall refer to (3.1) as the weak second order sufficient conditions.

Unfortunately the weak second order sufficient conditions do not guarantee pointwise Lipschitzian behavior of $\bar{x}(y)$ (see an example in [10, p. 308]). Therefore a stronger form of second order conditions is required. For a given vector v consider the following set of Lagrange multipliers:

$$\Lambda_0^*(v) = \{\lambda \in \Lambda_0: v^T \nabla_y L(x_0, y_0, \lambda) = \max_{\lambda \in \Lambda_0} v^T \nabla_y L(x_0, y_0, \lambda)\}.$$

The set $\Lambda_0^*(v)$ is a face of the convex polytope Λ_0 and hence is the convex hull of the corresponding set $E_0^*(v)$, $E_0^*(v) \subset E_0$, of its extreme points.

Assumption 4 (strong second order sufficient conditions). For every v the inequality

$$(3.2) \quad \max_{\lambda \in \Lambda_0^*(v)} u^T \nabla_{xx}^2 L(x_0, y_0, \lambda) u > 0$$

holds for all $u \in C$, $u \neq 0$.

It may be noted that the sets Λ_0 and $\Lambda_0^*(v)$ in (3.1) and (3.2) can be replaced by the corresponding sets of extreme points E_0 and $E_0^*(v)$, respectively.

Without further discussion we shall make use of the following principle. If $f_1(y), \dots, f_k(y)$ and $\varphi_1(y), \dots, \varphi_k(y)$ are continuous functions such that

$$f_i(y) = \varphi_i(y) + o(\|y\|^2), \quad i = 1, \dots, k,$$

then

$$\max \{f_i(y): i = 1, \dots, k\} = \max \{\varphi_i(y): i = 1, \dots, k\} + o(\|y\|^2).$$

The Hessian matrices $\nabla_{xx}^2 L(x_0, y_0, \lambda)$, $\nabla_{xy}^2 L(x_0, y_0, \lambda)$ and $\nabla_{yy}^2 L(x_0, y_0, \lambda)$ will be denoted by H_{xx}^λ , H_{xy}^λ and H_{yy}^λ , respectively. We write ξ_λ for the corresponding quadratic function

$$(3.3) \quad \xi_\lambda(u, v) = \frac{1}{2} u^T H_{xx}^\lambda u + u^T H_{xy}^\lambda v + \frac{1}{2} v^T H_{yy}^\lambda v.$$

THEOREM 3.1. Suppose that Assumptions 1–4 hold. Then there exists a positive constant K such that

$$(3.4) \quad \|\bar{x}(y) - x_0\| \leq K \|y - y_0\|$$

for all y in a neighborhood of y_0 .

Proof. Without loss of generality we can assume that $(x_0, y_0) = (0, 0)$ and $f(x_0, y_0) = 0$. Suppose that (3.4) is false. Then there exists a sequence $\{y_n\}$ converging to $y_0 = 0$ such that for $x_n = \bar{x}(y_n)$ and $t_n = \|x_n\|$,

$$(3.5) \quad \lim_{n \rightarrow \infty} t_n \|y_n\|^{-1} = \infty.$$

It follows from Lemma 2.1 that $t_n \rightarrow 0$. By the argument of compactness we can assume that $t_n^{-1} x_n$ tends to a vector \bar{u} . Of course $\|\bar{u}\| = 1$ and hence $\bar{u} \neq 0$. From Theorem 2.1 we have that $x_n \in \bar{\Omega}(y_n)$ for sufficiently large n . Furthermore, Lemma 2.3 implies that there exists a sequence $\{u_n\}$, with $u_n \in \bar{\Sigma}(y_n)$, such that

$$\|x_n - u_n\| = o(\|(x_n, y_n)\|).$$

It follows that $t_n^{-1} u_n$ tends to \bar{u} . Since $\text{gph } \bar{\Sigma}$ is a cone

$$t_n^{-1}(y_n, u_n) \in \text{gph } \bar{\Sigma}$$

and by (3.5), $t_n^{-1}(y_n, u_n) \rightarrow (0, \bar{u})$. Moreover, $\text{gph } \bar{\Sigma}$ is a closed set and hence $(0, \bar{u}) \in \text{gph } \bar{\Sigma}$. Consequently by Lemma 2.4, $\bar{u} \in C$.

Now expression (2.5) of Theorem 2.1 implies that $\varphi(y_n) = F(x_n, y_n)$. Then by employing second order Taylor expansions of functions $F_\lambda(x, y) = L(x, y, \lambda)$ we obtain

$$\varphi(y_n) = \max_{\lambda \in E_0} \{y_n^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(x_n, y_n) + o(\|(x_n, y_n)\|^2)\}.$$

Notice that because of the first order necessary conditions the gradients $\nabla_x L(x_0, y_0, \lambda)$, $\lambda \in E_0$, vanish. It follows from (3.5) that $y_n^T H_{yy}^\lambda y_n$ and $x_n^T H_{xy}^\lambda y_n$, $\lambda \in E_0$, are $o(t_n^2)$. Consequently

$$\varphi(y_n) = \max_{\lambda \in E_0} \{y_n^T \nabla_y L(x_0, y_0, \lambda) + \frac{1}{2} t_n^2 \bar{u}^T H_{xx}^\lambda \bar{u}\} + o(t_n^2)$$

and then

$$(3.6) \quad \varphi(y_n) \geq \max_{\lambda \in E_n} \{y_n^T \nabla_y L(x_0, y_0, \lambda) + \frac{1}{2} t_n^2 \bar{u}^T H_{xx}^\lambda \bar{u}\} + o(t_n^2),$$

where $E_n = E_0^*(y_n)$. Moreover, by the definition for every $\lambda \in E_n$

$$y_n \nabla_y L(x_0, y_0, \lambda) = \max_{\lambda \in E_0} y_n^T \nabla_y L(x_0, y_0, \lambda).$$

Consequently it follows from (3.6) that

$$(3.7) \quad \varphi(y_n) \geq \max_{\lambda \in E_0} y_n^T \nabla_y L(x_0, y_0, \lambda) + \frac{1}{2} t_n^2 \max_{\lambda \in E_n} \bar{u}^T H_{xx}^\lambda \bar{u} + o(t_n^2).$$

Now since the set E_0 is finite and hence the number of different sets $E_0^*(v)$ is finite, we may assume that there is a vector \bar{v} such that $E_n = E_0^*(\bar{v})$ for all n . By the strong second order sufficient conditions (Assumption 4) the number

$$\varepsilon = \frac{1}{2} \max \{\bar{u}^T H_{xx}^\lambda \bar{u} : \lambda \in E_0^*(\bar{v})\}$$

is positive. Then (3.7) implies

$$(3.8) \quad \varphi(y_n) \geq \max \{y_n^T \nabla_y L(x_0, y_0, \lambda) : \lambda \in E_0\} + t_n^2 \varepsilon + o(t_n^2).$$

On the other hand it follows, from Lemma 2.3 and pseudo-Lipschitz continuity of $\bar{\Sigma}$, that there exist $\delta > 0$ and a sequence $w_n \in \bar{\Omega}(y_n)$ such that $\|w_n\| \leq \delta \|y_n\|$. Therefore

$$\begin{aligned} \varphi(y_n) &\leq F(w_n, y_n) = \max_{\lambda \in E_0} \{y_n^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(w_n, y_n) + o(\|(w_n, y_n)\|^2)\} \\ &\leq \max_{\lambda \in E_0} \{y_n^T \nabla_y L(x_0, y_0, \lambda) + c \|y_n\|^2\} \\ &= \max \{y_n^T \nabla_y L(x_0, y_0, \lambda) : \lambda \in E_0\} + c \|y_n\|^2 \end{aligned}$$

for some positive constant c . Because of (3.5) this implies that

$$\varphi(y_n) \leq \max \{y_n^T \nabla_y L(x_0, y_0, \lambda) : \lambda \in E_0\} + o(t_n^2),$$

a contradiction to (3.8). \square

We say that $\bar{x}(y)$ is pointwise Lipschitz continuous at y_0 along a given direction \bar{v} if there are positive constants K and ε such that

$$(3.9) \quad \|\bar{x}(y_0 + t\bar{v}) - x_0\| \leq Kt$$

for all $t \in [0, \varepsilon)$. It follows from the proof of Theorem 3.1 that (3.9) is ensured by the second order condition (3.2) applied to $v = \bar{v}$.

Pointwise Lipschitz continuity (3.4) of optimal solutions was proved by Robinson [27, § 4] under stronger second order sufficient conditions than those of our Assumption 4.

Finally it is worthwhile to note that Assumption 4 is reduced to the weak second order sufficient conditions in the following particular cases.

(i) The constraint functions g_i , $i = 1, \dots, p$, are independent of y and hence the feasible set $\Omega(y) = \Omega_0$ is constant.

(ii) The constraint functions $g_i(x, y)$ are linear in x and hence $\nabla_{xx}^2 L(x_0, y_0, \lambda) = \nabla_{xx}^2 f(x_0, y_0)$ for all λ .

(iii) The Lagrange multipliers set $\Lambda_0 = \{\lambda_0\}$ is a singleton.

4. Second order analysis of the optimal value function. In this section we study second order differential properties of the optimal value function $\varphi(y)$. Consider the function

$$(4.1) \quad \beta(u, v) = \max \{v^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(u, v) : \lambda \in E_0\}$$

where ξ_λ is the quadratic function defined in (3.3). We have that $F(x_0, y_0) + \beta(x - x_0, y - y_0)$ gives a second order approximation of the function $F(x, y)$ at the point (x_0, y_0) . The main result of this section is given now in the following theorem.

THEOREM 4.1. *Suppose that Assumptions 1-4 hold. Then*

$$(4.2) \quad \varphi(y_0 + v) - \varphi(y_0) = \inf \{\beta(u, v) : u \in \bar{\Sigma}(v)\} + o(\|v\|^2).$$

Proof. Without loss of generality we can assume that $(x_0, y_0) = (0, 0)$ and $\varphi(y_0) = 0$. Consider the following optimal value function:

$$\psi(y) = \inf \{\beta(x, y) : x \in \bar{\Omega}(y)\}.$$

First we show that

$$(4.3) \quad \varphi(y) = \psi(y) + o(\|y\|^2).$$

By the reduction Theorem 2.1 we have that $\varphi(y) = F(\bar{x}(y), y)$ and hence

$$\varphi(y) = \beta(\bar{x}(y), y) + o(\|y\|^2 + \|\bar{x}(y)\|^2).$$

Together with (3.4) of Theorem 3.1 this implies that

$$\varphi(y) = \beta(\bar{x}(y), y) + o(\|y\|^2).$$

By the definition of ψ , $\psi(y) \leq \beta(\bar{x}(y), y)$ and hence

$$(4.4) \quad \varphi(y) \geq \psi(y) + o(\|y\|^2).$$

Let $\bar{u}(y)$ be a minimizer of $\beta(\cdot, y)$ over $\bar{\Omega}(y)$. It follows from Theorem 3.1 that $\bar{u}(y)$ is pointwise Lipschitz continuous at $y_0 = 0$. Then the other inequality

$$(4.5) \quad \psi(y) \geq \varphi(y) + o(\|y\|^2)$$

can be proved in a way similar to the proof of (4.4). Inequalities (4.4) and (4.5) imply (4.3).

It remains to show that

$$(4.6) \quad \psi(y) = \inf \{\beta(x, y) : x \in \bar{\Sigma}(y)\} + o(\|y\|^2).$$

From Lemma 2.3 we have that $\bar{\Sigma} = D\bar{\Omega}(x_0, y_0)$. By the definition of tangential approximations (condition (2.9)) this implies that there exists $u^*(y) \in \bar{\Sigma}(y)$ such that

$$\|\bar{u}(y) - u^*(y)\| = o(\|(\bar{u}(y), y)\|).$$

Moreover, because of the pointwise Lipschitz continuity of $\bar{u}(y)$ we have

$$\|\bar{u}(y) - u^*(y)\| = o(\|y\|).$$

Then

$$\begin{aligned}\psi(y) &= \beta(\bar{u}(y), y) = \max \{y^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(\bar{u}(y), y) : \lambda \in E_0\} \\ &= \max \{y^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(u^*(y), y) : \lambda \in E_0\} + o(\|y\|^2) \\ &= \beta(u^*(y), y) + o(\|y\|^2).\end{aligned}$$

Since $\beta(u^*(y), y)$ is greater than or equal to the infimum on the right-hand side of (4.6) we obtain that

$$\psi(y) \geq \inf \{\beta(x, y) : x \in \bar{\Sigma}(y)\} + o(\|y\|^2).$$

The other inequality can be proved in a similar way by using condition (2.10) applied to the tangential approximation $\bar{\Sigma}$ of $\bar{\Omega}$. \square

The quadratic approximation result (4.2) of Theorem 4.1 allows us to calculate various forms of second order directional derivatives of the optimal value function. As an example we calculate a curved second order directional derivative of $\varphi(y)$ in the sense of Ben-Tal and Zowe [3].

It follows from Theorem 4.1 that under Assumptions 1–4, the optimal value function is directionally differentiable at y_0 and

$$(4.7) \quad \varphi'(y_0; v) = \max \{v^T \nabla_y L(x_0, y_0, \lambda) : \lambda \in E_0\}.$$

Consider a continuous curve

$$(4.8) \quad y(t) = y_0 + tv + t^2 w + t^2 \varepsilon(t), \quad t > 0,$$

with $v, w \in \mathbb{R}^n$ and $\varepsilon(t) \rightarrow 0$ as $t \rightarrow 0^+$. We have that for a fixed $\lambda \in E_0$,

$$\begin{aligned}L(x_0 + u, y(t), \lambda) &= L(x_0, y_0, \lambda) + tv^T \nabla_y L(x_0, y_0, \lambda) \\ &\quad + t^2 w^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(u, tv) + o(t^2 + \|u\|^2).\end{aligned}$$

Furthermore, under the MF-condition the tangential approximation to the multifunction $\bar{\Omega}(y(t))$ is given by $\bar{\Sigma}(tv)$. Then Theorem 4.1 implies that

$$\varphi(y(t)) - \varphi(y_0) = \inf \{\eta(u, t) : u \in \bar{\Sigma}(tv)\} + o(t^2),$$

where

$$\eta(u, t) = \max_{\lambda \in E_0} \{tv^T \nabla_y L(x_0, y_0, \lambda) + t^2 w^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(u, tv)\}.$$

Let $\bar{u}(t)$ be a minimizer of $\eta(\cdot, t)$ over $\bar{\Sigma}(tv)$. By Theorem 3.1, $\|\bar{u}(t)\|/t$ is bounded for all positive t sufficiently close to zero and hence

$$t^2 w^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(\bar{u}(t), tv) = o(t).$$

Therefore the set E_0 in the definition of $\eta(u, t)$ can be replaced by the set of extreme points $E_0^*(v)$, which corresponds to the maximal value of $v^T \nabla_y L(x_0, y_0, \lambda)$, $\lambda \in E_0$. By (4.7) this maximal value is equal to $\varphi'(y_0; v)$. Consequently, we obtain

$$(4.9) \quad \varphi(y(t)) - \varphi(y_0) = t\varphi'(y_0; v) + \inf \{\zeta_{tv, t^2 w}(u) : u \in \bar{\Sigma}(tv)\} + o(t^2),$$

where

$$(4.10) \quad \zeta_{v, w}(u) = \max \{w^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(u, v) : \lambda \in E_0^*(v)\}.$$

We have that $\bar{\Sigma}(tv) = t\bar{\Sigma}(v)$ and

$$t^{-2} \zeta_{tv, t^2 w}(u) = \zeta_{v, w}(t^{-1}u).$$

It then follows from (4.9) that the second order directional derivative

$$\varphi''(y_0; v, w) = \lim_{t \rightarrow 0^+} \frac{\varphi(y(t)) - \varphi(y_0) - t\varphi'(y_0; v)}{t^2}$$

of Ben-Tal and Zowe [3] exists and can be calculated as follows.

THEOREM 4.2. *Suppose that Assumptions 1–4 hold. Then $\varphi''(y_0; v, w)$ exists and is equal to the minimum of $\zeta_{v,w}(\cdot)$ over the set $\bar{\Sigma}(v)$.*

Notice that it will be sufficient in Theorem 4.2 to assume second order conditions (3.2) (Assumption 4) only for the vector v which appears in the definition (4.8) of the curve $y(t)$. Since C is the recession cone of $\bar{\Sigma}(v)$, these conditions imply that the minimum of $\zeta_{v,w}(\cdot)$ over $\bar{\Sigma}(v)$ exists and the corresponding set of minimizers is nonempty and bounded.

Without strong second order sufficient conditions the following inequality holds.

THEOREM 4.3. *Let $x_0 \in M(y_0)$ and suppose that the MF-condition holds at (x_0, y_0) . Then*

$$(4.11) \quad \limsup_{t \rightarrow 0^+} \frac{\varphi(y(t)) - \varphi(y_0) - t\delta(y_0; v)}{t^2} \leq Z(v, w),$$

where

$$\delta(y_0; v) = \max \{v^T \nabla_y L(x_0, y_0, \lambda) : \lambda \in \Lambda_0\}$$

and

$$Z(v, w) = \inf \{\zeta_{v,w}(u) : u \in \bar{\Sigma}(v)\}.$$

Proof. For a given $\alpha > 0$ consider the function

$$f_\alpha(x, y) = f(x, y) + \alpha \|x - x_0\|^2$$

and the corresponding problem of minimizing $f_\alpha(x, y)$ over the feasible set $\Omega(y)$. It will be enough to show that for all positive α , (4.11) holds with f replaced by f_α (see [33, p. 211] for details). We have that x_0 is the unique minimizer of $f_\alpha(\cdot, y_0)$ over $\Omega(y_0)$ and Assumption 1, applied to f_α , is satisfied. Therefore without loss of generality we can assume that our regularity conditions (Assumptions 1–3) hold, and hence the reduction theorem 2.1 is applicable. Consider now a vector $u \in \bar{\Sigma}(v)$ and choose $u' = u'(t) \rightarrow u$ such that $x_0 + tu' \in \bar{\Omega}(y(t))$ as $t \rightarrow 0^+$. Then we obtain from Theorem 2.1 that

$$\begin{aligned} \varphi(y(t)) &\leq \max \{L(x_0 + tu', y(t), \lambda) : \lambda \in E_0\} \\ &\leq \max \{L(x_0 + tu', y(t), \lambda) : \lambda \in E_0^*(v)\} \\ &= \varphi(y_0) + t\delta(y_0; v) + t^2\zeta_{v,w}(u') + o(t^2). \end{aligned}$$

Since the function $\zeta_{v,w}(\cdot)$ is continuous, it follows that \limsup in the left-hand side of (4.11) is less than or equal to $\zeta_{v,w}(u)$. Vector u is an arbitrary point of $\bar{\Sigma}(v)$ and hence (4.11) follows. \square

Notice that unless Assumptions 1–4 are satisfied, $\delta(y_0; v)$ defined in Theorem 4.3 is not necessarily the directional derivative $\varphi'(y_0; v)$ of the optimal value function. In some cases the infimum $Z(v, w)$ can be $-\infty$. Then the optimal solution $\bar{x}(y)$ cannot be pointwise Lipschitzian at y_0 .

COROLLARY 4.1. *Suppose that Assumptions 1–3 of Theorem 4.3 hold and $Z(v, w) = -\infty$. Then*

$$(4.12) \quad \lim_{t \rightarrow 0^+} t^{-1} \|\bar{x}(y(t)) - x_0\| = \infty.$$

Proof. Without loss of generality we can assume that $\bar{x}(y(t)) \rightarrow x_0$ as $t \rightarrow 0^+$. Suppose that (4.12) is false and hence there exists $t_n \rightarrow 0^+$ such that $t_n^{-1} \|x_n - x_0\|$ is bounded, $x_n = \bar{x}(y_n)$ and $y_n = y(t_n)$. Then by Theorem 2.1

$$\begin{aligned} \varphi(y_n) &= \max \{L(x_n, y_n, \lambda) : \lambda \in E_0\} \\ &= \varphi(y_0) + t_n \delta(y_0; v) + \max_{\lambda \in E_0^B(v)} \{t_n^2 w^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(x_n - x_0, y_n - y_0)\} + o(t_n^2). \end{aligned}$$

It follows that

$$(\varphi(y_n) - \varphi(y_0) - t_n \delta(y_0; v)) / t_n^2$$

is bounded, a contradiction to (4.11). \square

In particular $Z(v, w)$ is $-\infty$ if there exists a vector $\bar{u} \in C$ such that

$$\max_{\lambda \in \Lambda_0^B(v)} \bar{u}^T \nabla_{xx}^2 L(x_0, y_0, \lambda) \bar{u} < 0.$$

Therefore, in order to ensure pointwise Lipschitz continuity of the optimal solution, the strong second order sufficient conditions of Assumption 4 are the weakest possible.

Now let us consider some particular cases of Theorem 4.1. If the constraint functions g_i , $i = 1, \dots, p$, are independent of y , then $\bar{\Sigma}(v)$ coincides with the critical cone C and

$$\beta(u, v) = v^T \nabla_y f(x_0, y_0) + \Xi(u, v),$$

where

$$\Xi(u, v) = \max \{\xi_\lambda(u, v) : \lambda \in E_0\}.$$

COROLLARY 4.2. *Suppose that functions g_i , $i = 1, \dots, p$, are independent of y and Assumptions 1–4 hold. Then*

$$\varphi(y_0 + v) - \varphi(y_0) = v^T \nabla_y f(x_0, y_0) + \kappa(v) + o(\|v\|^2),$$

where

$$\kappa(v) = \inf \{\Xi(u, v) : u \in C\}.$$

If the functions g_i are affine, then $\xi_\lambda(u, v) = \xi(u, v)$ for all λ with

$$\xi(u, v) = \frac{1}{2} u^T \nabla_{xx}^2 f(x_0, y_0) u + u^T \nabla_{xy}^2 f(x_0, y_0) v + \frac{1}{2} v^T \nabla_{yy}^2 f(x_0, y_0) v.$$

COROLLARY 4.3. *Suppose that g_i , $i = 1, \dots, p$, are affine functions and Assumptions 1–4 hold. Then*

$$\varphi(y_0 + v) - \varphi(y_0) = \varphi'(y_0; v) + \kappa(v) + o(\|v\|^2),$$

where $\varphi'(y_0; v)$ is the directional derivative given by (4.7) and

$$\kappa(v) = \inf \{\xi(u, v) : u \in \bar{\Sigma}(v)\}.$$

Notice that Assumption 4 in Corollaries 4.2 and 4.3 is reduced to the weak second order sufficient conditions. In the case $\Lambda_0 = \{\lambda_0\}$ is a singleton the MF-condition follows [18], [34] and we obtain the next corollary.

COROLLARY 4.4. *Suppose that Λ_0 is a singleton, Assumptions 1 and 2 hold and the weak second order sufficient conditions are satisfied. Then*

$$\varphi(y_0 + v) - \varphi(y_0) = v^T \nabla_y L(x_0, y_0, \lambda_0) + \kappa(v) + o(\|v\|^2),$$

where

$$\kappa(v) = \inf \{\xi_{\lambda_0}(u, v) : u \in \Sigma_{\lambda_0}(v)\}.$$

The second order conditions employed in Corollary 4.4 are weaker than a strong second order condition utilized in [34, Assumption 8]. Therefore the result of Corollary 4.4 is stronger than a similar result in [34, Thm. 4.1].

In the situations of Corollaries 4.2–4.4 the first term in the second order approximation of φ is the directional derivative $\varphi'(y_0; v)$. The corresponding function $\kappa(v)$ is positively homogeneous of degree 2 and, since $\bar{\Sigma}$ is pseudo-Lipschitzian, is continuous. Consequently $\kappa(v)$ gives a second order directional derivative of φ in the following sense:

$$\lim_{\substack{t \rightarrow 0^+ \\ \bar{v} \rightarrow v}} \frac{\varphi(y_0 + t\bar{v}) - \varphi(y_0) - t\varphi'(y_0; \bar{v})}{t^2} = \kappa(v).$$

5. Directional differentiability of optimal solutions. In this section we study differentiability properties of an optimal solution $\bar{x}(y) \in M(y)$. Consider the curve $y(t)$ defined in (4.8) and the function $\zeta_{v,w}$ given in (4.10). Denote by $\Pi(v, w)$ the set of minimizers of $\zeta_{v,w}(\cdot)$ over $\bar{\Sigma}(v)$. As has been mentioned earlier, the second order condition (3.2) ensures that the set $\Pi(v, w)$ is nonempty and compact. The result of the following theorem shows that if $\Pi(v, w) = \{z\}$ is a singleton, then z gives the directional derivative of $\bar{x}(y)$ along the curve $y = y(t)$.

THEOREM 5.1. *Suppose that Assumptions 1–4 hold. Then*

$$(5.1) \quad \lim_{t \rightarrow 0^+} \frac{\text{dist}(\bar{x}(y(t)) - x_0; t\Pi(v, w))}{t} = 0.$$

Proof. We assume that $(x_0, y_0) = (0, 0)$ and $\varphi(y_0) = 0$. For $v = 0$ the set $\Pi(0, w)$ is $\{0\}$ and, by Theorem 3.1, $\bar{x}(y(t))$ is $o(t)$. Thus in this case (5.1) trivially holds. Therefore we assume subsequently that $v \neq 0$. Suppose that (5.1) is false and hence there exist a sequence $t_n \rightarrow 0^+$ and $\varepsilon > 0$ such that

$$(5.2) \quad \text{dist}(x_n; t_n \Pi(v, w)) \geq \varepsilon t_n,$$

where $x_n = \bar{x}(y_n)$ and $y_n = y(t_n)$. Theorem 3.1 implies that the sequence $\{\|y_n\|^{-1}x_n\}$ and hence $\{t_n^{-1}x_n\}$ are bounded. Therefore we can assume that $\{t_n^{-1}x_n\}$ converges to a vector \bar{u} . Since the distance function $d_{\Pi}(\cdot) = \text{dist}(\cdot; \Pi(v, w))$ is continuous it follows from (5.2) that

$$\text{dist}(\bar{u}; \Pi(v, w)) \geq \varepsilon$$

and thus \bar{u} does not belong to the set $\Pi(v, w)$. Since $x_n \in \bar{\Omega}(y_n)$ and $\bar{\Sigma}(tv)$ is tangent to $\bar{\Omega}(y(t))$, there exists a sequence $\{u_n\}$, with $u_n \in \bar{\Sigma}(t_nv)$, such that $\|x_n - u_n\| = o(t_n)$. It follows that $t_n^{-1}u_n$ tends to \bar{u} . Furthermore, $\text{gph } \bar{\Sigma}$ is a cone and hence $t_n^{-1}(t_nv, u_n) \in \text{gph } \bar{\Sigma}$. Since $\bar{\Sigma}$ is closed we obtain that $(v, \bar{u}) \in \text{gph } \bar{\Sigma}$, i.e., $\bar{u} \in \bar{\Sigma}(v)$.

On the other hand,

$$\begin{aligned} \varphi(y_n) &= F(x_n, y_n) = \max \{y_n^T \nabla_y L(x_0, y_0, \lambda) + \xi_\lambda(x_n, y_n) : \lambda \in E_0\} + o(t_n^2) \\ &= \max \{t_n v^T \nabla_y L(x_0, y_0, \lambda) + t_n^2 w^T \nabla_y L(x_0, y_0, \lambda) + t_n^2 \xi_\lambda(\bar{u}, v) : \lambda \in E_0\} + o(t_n^2) \\ &= t_n \varphi'(y_0; v) + t_n^2 \zeta_{v,w}(\bar{u}) + o(t_n^2). \end{aligned}$$

This implies that $\varphi''(y_0; v, w) = \zeta_{v,w}(\bar{u})$. It then follows from Theorem 4.2 that

$$\zeta_{v,w}(\bar{u}) = \inf \{\zeta_{v,w}(u) : u \in \bar{\Sigma}(v)\}$$

and we already have shown that $\bar{u} \in \bar{\Sigma}(v)$. Consequently $\bar{u} \in \Pi(v, w)$, a contradiction. \square

Consider the case of $w = 0$ and let the set $\Pi(v, 0) = \{z\}$ be a singleton. Then it follows from (5.1) that $\bar{x}(y)$ is directionally differentiable at $y = y_0$ in the direction v

and the corresponding directional derivative is given by $\bar{x}'(y_0; v) = z$. It is interesting to note that since the set $E_0^*(v)$ may change for various values of v , the optimal set $\Pi(v, 0)$ can depend discontinuously on v even if $\Pi(v, 0)$ is a singleton for all v . Therefore it may happen that $\bar{x}(y)$ is directionally differentiable at $y = y_0$, but the directional derivative $\bar{x}'(y_0; v)$ is *not continuous* as a function of v . This then implies that $\bar{x}(y)$ is not locally Lipschitz near y_0 . An example of this type is given in Robinson [26, p. 219]. We consider below a simplified version of that example.

Example. Consider the following program:

$$\begin{aligned} &\text{minimize} && \frac{1}{2}(x_1 - 1)^2 + \frac{1}{2}x_2^2 \\ &\text{subject to} && x_1 \leq 0, \\ &&& x_1 + y_1x_2 + y_2 \leq 0 \end{aligned}$$
