

LAGRANGE MULTIPLIERS IN STOCHASTIC PROGRAMMING*

SJUR D. FLÅM†

Abstract. A Fritz John multiplier rule is given for discrete time, finite horizon, stochastic programs. Particular emphasis is placed on constraint qualifications that allow for the application of this rule in normal Lagrange form.

Key words. nonsmooth analysis, constraint qualifications, Kuhn-Tucker conditions

AMS(MOS) subject classification. 49B60

1. Introduction. Finite horizon, stochastic programs typically come in the following general form:

$$(P1) \quad \text{minimize the overall expected cost } \mathbb{E}f(\omega, x_1(\omega), \dots, x_T(\omega))$$

by making, sequentially, at each stage $t = 1, 2, \dots, T$, a decision $x_t(\omega) \in \mathbb{R}^{n_t}$, under imperfect information about the exact state ω of the world. Formally,

$$(1.1) \quad x_t(\cdot) \text{ should be } \Sigma_t\text{-measurable,}$$

where Σ_t , $t = 1, 2, \dots, T$, are known sub-sigma-algebras of a given probability space $(\Omega, \Sigma, \text{Pr})$. Most often, in practice, knowledge about the generic outcome ω in the sample space Ω becomes more refined with the passage of time, or, at least, does not deteriorate. To model such step-wise reduction of uncertainty we naturally assume that

$$(1.2) \quad \Sigma_1 \subset \Sigma_2 \subset \dots \subset \Sigma_T.$$

By way of example, let the information flow be generated by a stochastic process ξ_1, \dots, ξ_T on Ω . Then x_t should depend only on the actual realization of ξ_1, \dots, ξ_t ; i.e., Σ_t is, in this case, the smallest σ -algebra rendering all (possibly vector) variates ξ_1, \dots, ξ_t measurable, and (1.2) holds.

In addition to imposing the informational constraints (1.1) and (1.2), we also require that

$$(1.3) \quad g_t(\omega, x_1(\omega), \dots, x_t(\omega)) \leq 0 \quad \text{almost surely (a.s.) for } t = 1, \dots, T,$$

where $g_t(\cdot, x_1(\cdot), \dots, x_t(\cdot))$ is Σ_t -measurable with values in \mathbb{R}^{m_t} , and inequality (1.3) is understood to hold component-wise.

This completes the heuristic description of the multistage stochastic optimization problem. More formal assumptions are relegated to § 2.

The purpose of this paper is to characterize locally optimal solutions to problem (P1) in terms of the so-called *Lagrange multipliers* or Kuhn-Tucker conditions. It is well known, at least in deterministic programming, that such multipliers serve several ends expediently: They are prominent in optimality conditions, dominate much of stability analysis, play major roles in methods involving duality or decomposition, and are, not to forget, keys to the design of exact penalty functions. Thus, there is ample

motivation for exploring their existence and nature in the context of stochastic programming. However, stochasticity present, the multipliers take on new features; they become random vectors, or they are measures. This has all been clearly brought to the fore by Rockafellar and Wets in a series of papers; see [17]–[19] and the references therein. Much of their analysis is confined to the case when $f(\omega, \cdot)$ and each component of $g_t(\omega, \cdot)$ is convex, with special attention paid to conditions that ensure existence of primal-dual optimal pairs of solutions. Their approach is the min-max theory of Lagrangian saddle-functions, such functions arising naturally from Rockafellar's scheme of conjugate duality and optimization of perturbed criteria [13].

By contrast, we will dispense with convexity assumptions and take existence of a locally optimal solution to (P1) for granted. Our main concern is to identify the precise nature of multipliers, to guarantee their existence, and finally, to provide constraint qualifications that imply that the multiplier rule has the desired normal form.

Our vehicle is the nonsmooth calculus of Clarke [2]. Hiriart-Urruty [7] has already applied this apparatus to 2-stage versions of our problem. He preferred to treat (P1) in its dynamic form and did not explore to what function space the second stage multipliers belong. As a difference, we avoid dynamic programming and instead analyze (P1) in its extended “static” form. The merit of this approach is that a multiplier rule emerges that completely parallels familiar results for deterministic programs.

To invoke the toolkit of nonsmooth calculus we need that *strategies* $x_t(\cdot)$ and *constraint functions* $g_t(\cdot, x_1(\cdot), \dots, x_t(\cdot))$, $t = 1, \dots, T$, belong to specified Banach spaces of measurable functions on $(\Omega, \Sigma, \text{Pr})$. In this regard we choose to steer away from two notable problem versions; namely,

- (i) when $g_t(\cdot, x_1(\cdot), \dots, x_t(\cdot))$, $t = 1, \dots, T$, are essentially bounded, and
- (ii) the case when strategies x_t , and constraints g_t are continuous with (1.3) sharpened to hold for all ω .

The reason for avoiding (i) and (ii) here is threefold. First, we plan to complement the studies of Rockafellar and Wets [17]–[19] by focusing on spaces of perturbations that have more pleasant duality properties than $L^\infty(\Omega)$ and $C(\Omega)$. Thus, [4] and [20] may be regarded as predecessors of this paper. Second, it may often be difficult, or even unnatural, to argue a priori that all g_t (and possibly also x_t) are essentially bounded or continuous on Ω . Frequently, larger spaces such as $L^p(\Omega)$, $1 \leq p < \infty$, are more convenient and realistic. Third, since $L^\infty(\Omega)$ and $C(\Omega)$ are “too small,” we are left with “too many” multipliers. Not only are many of these hard to interpret, but computations may also become very demanding. To illustrate this, consider a closed ball in the continuous dual $L^\infty(\Omega)^*$, large enough to contain all optimal multipliers and relevant approximations of these. Unless the sample space (Ω, Σ) is finite, this ball is neither w^* -metrizable nor w^* -sequentially compact. Then maximizing sequences of multipliers can, in principle, escape our control. The essential difficulty here stems from the fact that $L^\infty(\Omega)$ is either finite-dimensional (trivial case) or nonseparable (interesting case). By contrast, as we will see, all spaces $L^p(\Omega)$, $1 \leq p < \infty$, and some generalizations of these, are very well behaved. Thus, this paper serves both as a warning against the popular, quite common choice $L^\infty(\Omega)$, and as an invitation to consider alternative, more tractable spaces of perturbations.

In all events, we acknowledge that problem (P1) is very challenging when it comes to efficient computation. Even linear, 2-stage versions can often be solved only approximately; see [1] and [10]. Computational concerns are, however, beyond the scope of this paper, which is organized as follows. Section 2 provides some necessary technical prerequisites. Section 3 gives the multiplier rule, and the paper is concluded by briefly addressing the effect of standard constraint qualifications.

2. Preliminaries. This section collects all assumptions that are imposed to make problem (P1) well defined.

2.1. On probability spaces. We require that all σ -algebras $\Sigma_1, \dots, \Sigma_T$, mentioned in (1.1) and (1.2), be *complete*. If some Σ_t is not, it should be completed in the standard way: Include in Σ_t all subsets of Σ_t -measurable zero-sets. This done, we identify measurable functions (or events) that coincide almost surely. We also demand that $\Sigma_1, \dots, \Sigma_T$ be *separable* in the sense that each Σ_t becomes a separable metric space when endowed with the distance function

$$d(A, B) := \Pr(A \setminus B) + \Pr(B \setminus A).$$

2.2. On strategy spaces. First, we require that the decision x_t at stage t belongs to a space X_t of \mathbb{R}^{n_t} -valued, Σ_t -measurable random vectors. Thus, the restriction that strategies should be *nonanticipative* is implicit in our problem formulation. In addition, we insist that X_t be Banach. This amounts possibly to a stronger condition than (1.1). Also, we add here a constraint

$$(2.1) \quad x \in C,$$

where the set $C \subset X_1 \times \dots \times X_T$ is closed and nonempty. The abstract constraint (2.1) typically accounts for fairly tractable restrictions, for instance, upper and lower bounds, that may be imposed in addition to (1.2). We will give no further details on the precise nature of the set C .

2.3. On spaces of perturbations and their duals. The standard (and canonical) way to perturb problem (P1) is to replace (1.3) by

$$(2.2) \quad g_t(\omega, x_1(\omega), \dots, x_t(\omega)) \leq u_t(\omega) \quad \text{a.s. for } t = 1, \dots, T,$$

where the perturbation $u_t(\omega) \in \mathbb{R}^{m_t}$ belongs to some subspace U_t of measurable random vectors. We now proceed to identify an appropriate class of such function spaces U_t . In general, when Σ is a σ -algebra on Ω , denote by $L^o(\Sigma)$ the linear space of all Σ -measurable, real-valued functions on Ω . A linear subspace $\text{OCBF} \subset L^o(\Sigma)$ is said to be an *order continuous Banach foundation space* if there exists a norm $\|\cdot\|$ (making OCBF complete) such that

- (a) $\Theta \in L^o(\Sigma)$, $\Theta' \in \text{OCBF}$, $|\Theta(\omega)| \leq |\Theta'(\omega)|$ almost surely implies $\Theta \in \text{OCBF}$ and $\|\Theta\| \leq \|\Theta'\|$;
- (b) $\Theta'' \geq \Theta'^{n+1}$, $\Theta''(\omega) \downarrow 0$ almost surely and $\Theta'' \in \text{OCBF}$ imply $\lim_{n \rightarrow \infty} \|\Theta''\| = 0$;
- (c) The essential support of the entire space OCBF equals Ω .

Examples include the $L^p(\Omega)$ spaces, $1 \leq p < +\infty$, and their generalization to Orlicz spaces where the Δ_2 -condition holds [6], [10]. Also, when Ω is countable, the spaces ℓ^p , $1 \leq p < +\infty$, and c_o are of this type. Important properties of OCBF-spaces here are the following: *convergence in norm implies convergence in probability*, and *continuous linear functionals are representable as integrands*; that is, for the continuous dual OCBF^* we have

$$\text{OCBF}^* = \{\Theta^* \in L^o(\Sigma): E|\Theta \cdot \Theta^*| < +\infty \text{ for all } \Theta \in \text{OCBF}\}$$

with the action of $\Theta^* \in \text{OCBF}^*$ being defined by $\langle \Theta, \Theta^* \rangle := E\Theta \cdot \Theta^*$. For details see [10]. In the following we will speak of OCBF-spaces whose elements are random vectors in \mathbb{R}^m , say. On such occasions we tacitly assume that the OCBF-space in question arises as the product of m identical OCBF-spaces of real-valued functions. We assume that *the perturbation u_t in (2.2) belongs to an OCBF-space U_t for each $t = 1, \dots, T$* . Note that since $L^\infty(\Omega)$ is not an OCBF-space, this choice is excluded.

2.4. On the constraint functions g_t . A crucial assumption is that each g_t must map $X_1 \times \cdots \times X_t$ into an OCBF-space U_t of \mathbb{R}^{m_t} -valued, Σ_t -measurable random vectors, i.e.,

$$x_1 \in X_1, \dots, x_t \in X_t \Rightarrow g_t(\cdot, x_1(\cdot), \dots, x_t(\cdot)) \in U_t \quad \text{for } t = 1, \dots, T.$$

As an example, suppose $g_t(\omega, z)$ is affinely bounded, i.e.,

$$\|g_t(\omega, z)\| \leq |a_t(\omega) \cdot z + \beta_t(\omega)| \quad \text{a.s.}$$

with $a_t \in L^p(\Omega)$, $X_1 \times \cdots \times X_t \subset L^q(\Omega)$, $1 < p < +\infty$, $1/p + 1/q = 1$, and $\beta_t \in L^1(\Omega)$. Then $U_t = L^1(\Omega)$ would be a suitable choice. We remark that for the measurability of $g_t(\cdot, x_1(\cdot), \dots, x_t(\cdot))$ it suffices that g_t is Σ_t -normal [14].

2.5. On Lipschitz continuity. We assume that the criterion $\text{Ef}(\omega, x(\omega))$ is locally Lipschitz on an open set that contains C . For example, if X is a closed subspace of $L^\infty(\Omega)$ and

$$|f(\omega, x) - f(\omega, x')| \leq k(\omega)|x - x'|$$

for every pair of constant vectors x, x' with $k \in L^1(\Omega)$, then the above assumption holds with Lipschitz constant Ek , see [7, Lemma 3]. We also assume that *each*

$$g_t: X_1 \times \cdots \times X_t \rightarrow U_t, \quad t = 1, \dots, T,$$

is locally Lipschitz continuous on an open set containing C .

3. The multiplier rule. In keeping with the duality scheme of Rockafellar [13], suppose the perturbation $u_t \in U_t$ in (2.2) becomes available only at an extra expense

$$\langle y_t, u_t \rangle := E(y_t \cdot u_t).$$

Here y_t belongs to the dual space $Y_t := U_t^*$ (reflexiveness is not assumed, e.g., $U_t = L^1(\Omega)$, $Y_t = L^\infty(\Omega)$), and y_t should be interpreted as a random, exogenous price regime revealed only at stage t . It is appropriate to contemplate now what kind of measurability u_t and y_t could reasonably enjoy. For this purpose recall that our knowledge about the identity of ω is given, at stage t , only up to Σ_t . That is, we can discern for any event in Σ_t , and *only* such events, whether it has actually happened or not. Also, by assumption, each $g_t(\cdot, x_1(\cdot), \dots, x_t(\cdot))$ is Σ_t -measurable. Thus, when evaluating various perturbations u_t , it is impossible to discriminate between different candidates with finer precision than allowed for by Σ_t . This amounts to having u_t measurable with respect to Σ_t . The price y_t , unveiled in period t and prior to the choice of x_t , should, for the same reason, also be Σ_t -measurable. In summary, the opportunity to procure ourselves with perturbation profiles

$$u := (u_1, \dots, u_T) \in U := U_1 \times \cdots \times U_T$$

at the additional cost $\langle y, u \rangle = \langle y_1, u_1 \rangle + \cdots + \langle y_T, u_T \rangle$, with $y := (y_1, \dots, y_T)$ and $y_t \in Y_t = U_t^*$, leads naturally to the *Lagrangian*

$$L(x, y) := \inf \{ \text{Ef}(x) + \langle y, u \rangle \mid g_t(x_1, \dots, x_t) \leq u_t \in U_t \text{ a.s., } t = 1, \dots, T \}.$$

Trivially, $L(x, y) = -\infty$ if for some t we have $y_t < 0$ on a set of positive measure. Therefore, only nonnegative prices $y_t \geq 0$ almost surely are worthy of further consideration, and then the Lagrangian takes on the familiar form

$$L(x, y) = \text{Ef}(x) + \langle y, g(x) \rangle,$$

where

$$\langle y, g(x) \rangle := \sum_{t=1}^T \langle y_t, g_t(x_1, \dots, x_t) \rangle.$$

The original (primal) problem (P1) can be compactly restated as

$$(P2) \quad \inf_{x \in C} \sup_{y \in Y_+} L(x, y),$$

where Y_+ denotes the nonnegative cone of $Y = Y_1 \times \dots \times Y_T$. Its value $\inf (P2)$ majorizes that of the associate dual problem

$$(D) \quad \sup_{y \in Y_+} \inf_{x \in C} L(x, y).$$

A saddle point (x, y) of L would solve (P2) and (D) optimally with equal values and must necessarily satisfy the *Kuhn–Tucker conditions*:

$$(3.1) \quad 0 = \langle y, g(x) \rangle,$$

$$(3.2) \quad 0 \in \partial_x [L(x, y) + \delta_C(x)],$$

where ∂_x denotes the partial subdifferential of convex analysis and δ_C is the extended indicator of C . y is then called a *Lagrange multiplier* at x . However, when problem (P2) is nonconvex, it is often unrealistic to search for global saddle points. Instead we may have to contend, at best, with local versions of such points. Yet, as we plan to show, it is not wishful thinking to maintain (3.1) and (3.2) with ∂_x signifying the Clarke subdifferential [2]. Indeed, the following result offers close to complete evidence that *local* solutions to (P2) are supported by Lagrange multipliers. For the statement we need the following definition.

DEFINITION. The correspondence $(x, y) \rightarrow \partial_x \langle y, g(x) \rangle$ is said to be *closed* if for every sequence $(x^k, y^k, \nabla^k) \in X \times Y \times \partial_x \langle y^k, g(x^k) \rangle$ where $x^k \rightarrow x$ in norm, and $y^k \rightarrow y$, $\nabla^k \rightarrow \nabla$ in the w^* -topologies, we have $\nabla \in \partial_x \langle y, g(x) \rangle$.

Note in particular that this holds if g is C^1 .

THEOREM 3.1 (Fritz John rule in stochastic programming). *Under the hypothesis of § 2, let x be a locally optimal solution to problem (P2). Suppose that the correspondence $(x, y) \rightarrow \partial_x \langle y, g(x) \rangle$ is closed. Then for every $\delta, \eta > 0$ sufficiently small there exists a nonzero, nonnegative multiplier*

$$(y_0, y_1, \dots, y_T) \in R \times Y_1 \times \dots \times Y_T$$

such that

$$(3.3) \quad y_t(\omega) \cdot g_t(\omega, x_1(\omega), \dots, x_t(\omega)) = 0 \quad \text{a.s.} \quad \text{for } t = 1, \dots, T,$$

and

$$(3.4) \quad 0 \in \partial_x \left[y_0 \operatorname{Ef}(x) + \sum_{t=1}^T \langle y_t, g_t(x_1, \dots, x_t) \rangle + \eta^{-1} \rho(y) d(x) \right],$$

where d denotes the distance function to

$$C_\delta(x) := \{x' \in C : \|x' - x\| \leq \delta\},$$

and ρ is a strict norm on the dual of $R \times U$ such that the ρ -topology on bounded sets coincides with the w^* -topology.

Remark. The role of the parameter δ is to restrict attention to a part $C_\delta(x)$ of C within which x is globally optimal. The other parameter η should be chosen so small that η^{-1} exceeds the Lipschitz constant of the function

$$[\text{Ef}(\cdot, x(\cdot)), g_1(\cdot, x_1(\cdot)), \dots, g_T(\cdot, x_1(\cdot)), \dots, x_T(\cdot)]$$

near x .

The proof of Theorem 3.1 will be simplified if we isolate and divorce some central arguments from their specific context of the theorem. Therefore, we will focus first on the generalized program

$$(P3) \quad \text{minimize } f_0(x) \text{ subject to } f_1(x) \leq 0 \quad \text{and} \quad x \in C,$$

and argue later that problem (P2) is only a special instance of (P3). In (P3) the set C is again a nonempty closed part of some Banach space X , and $f_0: X \rightarrow \mathbb{R}$, $f_1: X \rightarrow U$ are both locally Lipschitz near any point in C . The space U (of perturbations) is normed *separable* (not necessarily complete) and ordered by a relation \leq , defined, as usual, via a closed convex cone U_+ having

$$U_+^* := \{u^* \in U^*: \inf \langle u^*, U_+ \rangle = 0\}$$

as positive dual (polar cone).

We say that a *local solution* x to the generalized program (P3) is *supported by a multiplier* $(y_0, y_1) \in \mathbb{R}_+ \times U_+^*$ if $(y_0, y_1) \neq 0$, $\langle y_1, f_1(x) \rangle = 0$, and

$$(3.5) \quad 0 \in \partial_x [y_0 f_0(x) + \langle y_1, f_1(x) \rangle + \eta^{-1} \rho(y) d(x)],$$

where d is the distance function to

$$C_\delta(x) := \{x' \in C: \|x' - x\| \leq \delta\},$$

$\delta > 0$ being so small that x becomes a global solution to (P3) when restricted to $C_\delta(x)$ instead of C , and η^{-1} is greater than the Lipschitz constant of (f_0, f_1) near x . In (3.5) ρ is, as in (3.4), a strict norm on the dual of $R \times U$ generating the w^* -topology on bounded sets.

THEOREM 3.2 (Fritz John rule). *Under the above hypothesis on (P3) suppose that the correspondence $(x, y_1) \rightarrow \partial_x \langle y_1, f_1(x) \rangle$ is closed. Then every local solution to (P3) is supported by a multiplier.*

Proof. The statement is close to a transcription of Clarke's multiplier rule [2]. He deals, however, with only finitely many explicit restrictions (i.e., U is finite-dimensional). We must therefore carefully arrange the situation so that his method of proof carries over.

The main object is the pointwise maximum function $F: X \rightarrow \mathbb{R}$ defined, for arbitrary fixed parameter $\varepsilon > 0$, by

$$(3.6) \quad F(x') := \max_{y \in M} \langle y, (f_0(x') - f_0(x) + \varepsilon, f_1(x')) \rangle,$$

where $M \subset \mathbb{R} \times U_+^*$ is an appropriate set of multipliers. Specifically, since U is normed separable, there exists, by the Clarkson–Rieffel renorming lemma [9], a *strict* norm ρ_1 on the continuous dual space U^* , which is weaker than the usual dual norm, and such that the ρ_1 -topology on any bounded subset of U^* coincides with the w^* -topology. Now define a strict norm ρ on $\mathbb{R} \times U^*$ by

$$\rho(y_0, y_1) := (y_0^2 + \rho_1(y_1)^2)^{1/2},$$

and let

$$M := \{y \in \mathbb{R} \times U_+^*: \rho(y) \leq 1\}.$$

Note that $y \in M$ implies $\|y\| \leq \beta$ for some uniform bound β . We claim that F , as defined in (3.6), is Lipschitz near any $x' \in C$. Indeed, F being the pointwise maximum of the function family $\langle y, \varphi(\cdot) \rangle$, $y \in M$, with

$$(3.7) \quad \varphi(x') := (f_0(x') - f_0(x) + \varepsilon, f_1(x')),$$

it suffices to show that this family is equi-Lipschitz. That property follows readily from

$$\begin{aligned} |\langle y, \varphi(x') \rangle - \langle y, \varphi(x'') \rangle| &\leq \|y\| \|\varphi(x') - \varphi(x'')\| \\ &= \beta \|\varphi(x') - \varphi(x'')\|, \end{aligned}$$

and the Lipschitz continuity of φ (3.7).

We claim that $F(x') > 0$ for all $x' \in C$ sufficiently near x . In fact, $F(x') \leq 0$ would imply, in the first place, that $f_1(x') \leq 0$, because if $-f_1(x') \notin U_+$, then for some $u^* \in U_+^*$ we have $\langle u^*, -f_1(x') \rangle < 0$, and this contradicts $F(x') \leq 0$. Second, to posit the three conditions: $F(x') \leq 0$, $x' \in C$ is near x , and $f_1(x') \leq 0$, would entail the following contradiction:

$$f_0(x') \leq f_0(x) - \varepsilon.$$

Since x is locally ε -optimal, there exists by Ekeland's variational principle [2], a point x_ε , within $\sqrt{\varepsilon}$ -distance from x , that minimizes

$$F(x') + \sqrt{\varepsilon} \|x' - x_\varepsilon\|$$

over $C_\delta(x)$. Now the distance (function) d to $C_\delta(x)$ can be used for the purpose of exact penalization [2, Prop. 2.4.3]: To wit, x_ε is an *unconstrained* minimum for the function

$$F(x') + \sqrt{\varepsilon} \|x' - x_\varepsilon\| + \eta^{-1} d(x').$$

Therefore, letting B^* denote the closed unit ball in X^* , we have

$$(3.8) \quad 0 \in \partial G(x_\varepsilon) + \sqrt{\varepsilon} B^*,$$

where, using (3.7) and the fact that F is positive near x ,

$$(3.9) \quad G(x') := \max_{y \in M} [\langle y, \varphi(x') \rangle + \eta^{-1} \rho(y) d(x')].$$

We next intend to employ Theorem 2.8.2 of Clarke [2] for the estimation of $\partial G(x')$. For this, observe that the spaces $\mathbb{R} \times U$ and $\mathbb{R}^* \times U^*$ are placed in duality by the natural pairing

$$\langle (r, u), (r^*, u^*) \rangle := rr^* + \langle u, u^* \rangle.$$

Endow M , under this pairing, with the (relative) w^* -topology. Then M , being closed bounded, is compact by the Alaoglu–Bourbaki theorem. Moreover, M is metrizable because U is separable [9]. In particular,

(i) M is sequentially compact.

In addition we observe that

- (ii) the map $\langle y, \varphi(x') \rangle + \eta^{-1} \rho(y) d(x')$, which occurs in (3.9), is w^* -continuous in y on M for every fixed x' ;
- (iii) each function $\langle y, \varphi(x') \rangle + \eta^{-1} \rho(y) d(x')$, $y \in M$, in (3.9) is locally Lipschitz in x' , and the set

$$\{\langle y, \varphi(x') \rangle + \eta^{-1} \rho(y) d(x') : y \in M\}$$

is bounded.

The upshot of (i)–(iii) and the metrizable of M is that Theorem 2.8.2 of Clarke [2] is indeed applicable for the estimation of $\partial G(x_\varepsilon)$. Since $F(x_\varepsilon)$ and $G(x_\varepsilon)$ are positive, any maximizing multiplier $y_\varepsilon \in M$ in (3.6), as well as in (3.9), for $x' = x_\varepsilon$, must satisfy $\rho(y_\varepsilon) = 1$. Moreover, since ρ is strict this y_ε is unique. It follows from (3.8) and (3.9) and the closedness of $(x, y_1) \rightarrow \partial_x \langle y_1, f_1(x) \rangle$ that

$$(3.10) \quad 0 \in \partial_x [\langle y_\varepsilon, \varphi(x_\varepsilon) \rangle + \eta^{-1} d(x_\varepsilon)].$$

Now the arguments of Clarke [2, Thm. 6.1.1] apply verbatim and we contend with a sketch: Let some sequence $\varepsilon(k)$, $k = 1, 2, \dots$, tend downward to 0. Then $x_{\varepsilon(k)} \rightarrow x$, and some subsequence $y_{\varepsilon(k)}$, $k \in K$, will w^* -converge to a point $y \in M$. Since $\rho(y) = 1$ we have $y \neq 0$. Letting $k \in K$ pass to infinity in (3.10) we obtain the desired conclusion. \square

Remarks. It is crucial in the above proof that closed bounded subsets of $Y = U^*$ be w^* -compact and metrizable. For this, it is both necessary and sufficient that the normed space U is separable [9]. In particular, a nonseparable space $U = L^\infty(\Omega)$ does not fit our framework.

Evidently, we can identify ρ with the usual dual norm whenever the latter is strictly convex and U is reflexive. In particular, the proof can be simplified when $U = L^p(\Omega)$, $p \in (1, \infty)$. We wish, however, to accomodate for the nonreflexive space $U = L^1(\Omega)$ as well as c_0 , and then the dual norm is unsuitable.

The case when U equals the space $C(\Omega)$ of continuous functions on a compact set Ω in an Euclidean space, falls under the hypothesis of Theorem 3.2. Thus, in particular, we may give multiplier rules for semi-infinite programming.

Proof of Theorem 3.1. Recall that perturbations u_i in (2.2) are to be selected from an OCBF-space U_i of Σ_i -measurable random vectors in \mathbb{R}^m . The associated convex cone U_{i+} is, of course, the set of all $u_i \in U_i$ such that $u_i \geq 0$ almost surely. Since Σ_i is separable, so is U_i (see [10]) as well as

$$U := U_1 \times \dots \times U_T.$$

The said convex cone U_{i+} is closed because convergence in norm implies convergence in probability. Hence

$$U_+ := U_{1+} \times \dots \times U_{T+}$$

is also closed. Now let $f_0(x) := \text{Ef}(\omega, x(\omega))$,

$$f_1(x) := (g_1(\cdot, x_1(\cdot)), \dots, x_t(\cdot))_{t \in \{1, \dots, T\}}$$

and appeal to Theorem 3.2. \square

Remarks. As in Clarke [2, Thm. 2.7.5] conditions can be given that, when $C = X$, ensure that (3.4) holds almost surely; that is,

$$0 \in \partial_x [y_0 f(\omega, x(\omega)) + \sum_{t=1}^T y_t(\omega) g_t(\omega, x_1(\omega), \dots, x_t(\omega))] \text{ a.s.}$$

By appropriately redefining the cones U_{i+} , $i = 1, \dots, T$, there is no problem in accomodating for equality constraints.

As mentioned, we could design a more direct proof especially adapted to the instance $U = L^p(\Omega)$, $p \in (1, \infty)$. However, the important spaces $L^1(\Omega)$ and c_0 would then call for separate discussion.

4. Constraint qualifications. For the purpose of duality theory, stability analysis, exact penalty methods [5], and the like we need to ensure that the only multiplier

$y = (y_0, y_1, \dots, y_T)$ satisfying (3.3) and (3.4) with $y_0 = 0$, is the origin 0. We then say that the *multiplier rule holds in normal Lagrange form*.

Conditions guaranteeing the existence of Lagrange multipliers have been extensively studied in the literature on programming in Banach spaces: With reference to (P3) [21] offers the following sufficient condition:

$$(4.1) \quad 0 \in \text{int}_U [f'_1(x) T_C x - T_{U_-} f_1(x)]$$

provided $C \subset X$ is closed convex, f_0 is Frechet differentiable, and f_1 is continuously Frechet differentiable. Here $T_C x$ and $T_{U_-} f_1(x)$ denote the usual tangent cone (of convex analysis) of C at x , and $U_- := -U_+$ at $f_1(x)$, respectively. In particular [12], (4.1) would hold if

$$(4.2) \quad x \in \text{int } C \text{ and } f'_1(x) \text{ is surjective,}$$

or if

$$(4.3) \quad \text{there exists } x' \in T_C x \text{ such that } f'_1(x)x' \in \text{int } T_{U_-} f_1(x).$$

These conditions are stringent; however, (4.2) requires that the constraint $x \in C$ is not binding and that $f'_1(x)$ has full rank; (4.3) implies that U_+ has nonempty interior whereas in our context $\text{int } L^p(\Omega)_+ = \emptyset$ for all $p \in [1, \infty)$. Also, it is desirable to avoid the strong differentiability assumption behind (4.1).

For our approach, recall that in smooth deterministic programming, with $C = X$, a minimal hypothesis for existence of Lagrange multipliers is the well-known Mangasarian-Fromowitz (M-F) constraint qualification. In fact, (4.1) is then equivalent to M-F. If, moreover, data are convex, the M-F-qualification reduces to the Slater condition. The M-F-condition has also been taken into the context of nondifferentiable programming [2], [8], [15], and [16]. Our purpose here is twofold: first, we show that the M-F and Slater conditions carry easily over to program (P3), second, that they come naturally in terms of each realization ω , rather than intervening at the level of the functional spaces.

We begin with the *M-F-constraint qualification*, which is most general. According to this there should exist a direction $d = (d_1, \dots, d_T) \in X$ in the *Clarke tangent cone* $T_C(x)$ of C at x such that $g_t(\omega, x_1(\omega), \dots, x_t(\omega)) = 0$ implies

$$g_t^0(\omega, x_1(\omega), \dots, x_t(\omega); d_1(\omega), \dots, d_t(\omega)) < 0 \quad \text{a.s. for } t = 1, \dots, T.$$

Here g_t^0 denotes, for each given ω , the *Clarke directional derivative* of $g_t(\omega, x_1(\omega), \dots, x_t(\omega))$ at the point $(x_1(\omega), \dots, x_t(\omega))$ in the direction $(d_1(\omega), \dots, d_t(\omega))$. We tacitly assume that $g_t(\omega, z)$ is Lipschitz in z almost surely.

PROPOSITION 4.1. *Under the hypothesis of Theorem 3.1 and the M-F-constraint qualification, all multipliers at the local solution x to P have normal form.*

Proof. Suppose not. Then there exists $(y_1, \dots, y_T) \geq 0$, and different from zero, such that (for $\delta, \eta > 0$ sufficiently small)

$$0 \in \partial_x \left[\sum_{t=1}^T \langle y_t, g_t(x) \rangle + \eta^{-1} \|y\| d(x) \right].$$

Consequently,

$$\begin{aligned} 0 &\leq \left[\sum_{t=1}^T \langle y_t, g_t(\cdot) \rangle + \eta^{-1} \|y\| d(\cdot) \right]^0(x; d) \\ &\leq \sum_{t=1}^T \langle y_t, g_t^0(x_1, \dots, x_t; d_1, \dots, d_t) \rangle < 0, \end{aligned}$$

a contradiction. Here, the penultimate inequality follows from two facts: First, the

directional derivative of a sum minorizes the sum of directional derivatives [2, Prop. 2.3.3], and second, the derivative of the distance function in a tangent direction equals zero [2, § 2.4]. \square

Next we discuss the Slater condition.

PROPOSITION 4.2. *Suppose there exists some $\hat{x} \in C$ such that*

$$(4.1) \quad g_t(\omega, \hat{x}_1(\omega), \dots, \hat{x}_t(\omega)) < 0 \quad \text{a.s. for } t = 1, \dots, T,$$

with C and g_1, \dots, g_T being starshaped with respect to \hat{x} . Then the M-F-constraint qualification holds.

Proof. Starshapedness of a set with respect to a point means that the set can be entirely illuminated by a source of light placed at the point in question. Correspondingly, a function is starshaped at a point if and only if its epigraph is starshaped at that point. Select the direction $d := \hat{x} - x$ and note that $g_t(\omega, x_1(\omega), \dots, x_t(\omega)) = 0$ implies, together with (4.1) and the star-shapedness that

$$g_t^0(\omega, x_1(\omega), \dots, x_t(\omega); d_1(\omega), \dots, d_t(\omega)) < 0 \quad \text{a.s.}$$

An appeal to Proposition 4.1 completes the proof. \square

ALGEBRAIC GEOMETRIC ASPECTS OF FEEDBACK STABILIZATION*

SHIVA SHANKAR† AND V. R. SULE‡

Abstract. This paper develops a theory of feedback stabilization for SISO transfer functions over a general integral domain which extends the well-known coprime factorization approach to stabilization. Necessary and sufficient conditions for stabilizability of a transfer function in this general setting are obtained. These conditions are then refined in the special cases of unique factorization domains (UFDs), Noetherian rings, and rings of fractions. It is shown that these conditions can be naturally interpreted geometrically in terms of the prime spectrum of the ring. This interpretation provides a natural generalization to the classical notions of the poles and zeros of a plant.

The set of transfer functions is topologized so as to restrict to the graph topology of Vidyasagar [*IEEE Trans. Automatic Control*, AC-29 (1984), pp. 403–418], when the ring is a Bezout domain. It is shown that stability of a feedback system is robust in this topology when the ring is a UFD.

This theory is then applied to the problem of stabilization of multidimensional systems. The above stabilizability criterion is interpreted geometrically in terms of affine varieties in \mathbb{C}^n when the stability region is the complement of a compact polynomially convex domain Γ . This criterion restricts to the well-known result for two-dimensional systems when Γ is the unit polydisc; it also allows the resolution of an open problem of Guiver [*Multidimensional Systems Theory*, D. Reidel, 1985]. Finally it is shown that while feedback stabilizability is robust, it is not, however, a generic property.

Key words. stabilization, graph topology, unique factorization domain (UFD)

AMS(MOS) subject classifications. 93D15, 93D25, 93B27, 93B25

1. Introduction. In this paper we develop a general theory for feedback stabilization of plants whose transfer functions are described by fractions over a general *integral domain*. This ring theoretic stabilization problem is patterned after Desoer et al. [4], Vidyasagar, Schnider, and Francis [10] and is defined as follows.

1.1. The stabilization problem. Let \mathbf{A} be an integral domain that represents the ring of stable causal SISO transfer functions. Denote by \mathbf{F} the field of fractions of \mathbf{A} consisting of all possible transfer functions. Define the subset \mathcal{F} of $\mathbf{F} \times \mathbf{F}$ as follows:

$$\mathcal{F} = \{(p, c) \in \mathbf{F} \times \mathbf{F} \mid 1 + pc \neq 0\}.$$

For a given transfer function p in \mathbf{F} the *fibre* over p , denoted \mathcal{F}_p , is the set of all transfer functions c for which (p, c) belongs to \mathcal{F} . Note that \mathcal{F}_p is never empty; indeed \mathcal{F}_0 equals \mathbf{F} , and \mathcal{F}_p for every nonzero p is the complement of a singleton in \mathbf{F} .

DEFINITION. The pair (p, c) in \mathcal{F} is said to be *stable* if $(1+pc)^{-1}$, $p(1+pc)^{-1}$, and $c(1+pc)^{-1}$ all belong to the subring \mathbf{A} of \mathbf{F} . In this case c is said to *stabilize* the transfer function p .

THE STABILIZATION PROBLEM. Given p in \mathbf{F} determine the set of all c in the fibre over p that stabilizes p .

Remark. The above “ring theoretic” stabilization problem specializes to the classical input/output stabilization of a dynamical system when \mathbf{A} is a ring of operators on the space of bounded functions (called inputs) to another space of bounded functions

(called outputs); define the map:

$$(1) \quad \begin{aligned} H: \mathcal{F} &\rightarrow \mathbf{F}^{2 \times 2}, \\ (p, c) &\mapsto \begin{bmatrix} (1+pc)^{-1} & -p(1+pc)^{-1} \\ c(1+pc)^{-1} & (1+pc)^{-1} \end{bmatrix}. \end{aligned}$$

The map H represents the input/output map

$$[u_1, u_2]^T \mapsto [e_1, e_2]^T$$

of the *feedback system* $\langle p, c \rangle$ shown in Fig. 1 with p and c denoting the transfer functions of the *plant* and *controller*, respectively, where u_1, u_2 are bounded inputs.

FIG. 1. Feedback system.

The feedback system $\langle p, c \rangle$ is said to be stable if the image $H(p, c)$, belongs to $\mathbf{A}^{2 \times 2}$, in which case c is called a *stabilizing controller* of p .

Note that for some p , the set of c in \mathcal{F}_p that stabilize it could be empty. This situation is more general than those considered in (Desoer et al. [4], Vidyasagar [9]) where the plant is always assumed to have coprime fractions, and because of which the set of stabilizing controllers is always nonempty.

1.2. Motivation. The above ring theoretic stabilization problem is solved in Desoer et al. [4] for those p admitting coprime fractions over the ring \mathbf{A} . Its subsequent extensions by Desoer and Gustavson [3] and Vidyasagar [9] also relied on the existence of coprime fractions for p . Moreover, a basis for the *graph topology* on the set of plants introduced by Vidyasagar [8] to study robustness of stability is defined again via coprime fractions. Thus coprime factorizability is central to the stabilization theory developed so far.

In many engineering situations, for instance multidimensional systems [2], spatially distributed systems (see Kamen [2]) etc., plant transfer functions do not always admit coprime fractions. Thus from these examples, as well as from a theoretical point of view, it is desirable to have a more general theory of stabilization which subsumes the existing theory whenever coprime fractions do indeed exist. It is also important to be able to interpret geometrically this general algebraic theory. For instance, in the case of plants whose transfer functions are fractions of functions holomorphic in some domain in \mathbb{C} , the stabilizability of the plant is determined geometrically in terms of its poles and zeros. This is the case with linear time invariant (LTI) lumped or distributed plants. Similarly, for two-dimensional (2-D) plants it is now well known (Bose [2]) that the stabilizability of the plant depends on whether the pole-zero sets of the plant intersect within the unit bidisc. What then are the geometric objects in general rings (which are the generalizations of the poles and zeros of the above special cases) in terms of which the stabilizability conditions of this more comprehensive theory could be expressed? It is also necessary to topologize the set of plants which will specialize to the graph topology of Vidyasagar in order to study robustness of stability. These considerations motivate the following questions:

(1) What are necessary and sufficient conditions for stabilizability of a plant with fractions over a general integral domain, (a question originally posed by Vidyasagar, Schnider, and Francis [10])? For instance, in the study of 2-D systems by Guiver and Bose [2] existence of rational coprime fractions is also necessary for stabilizability.

(2) How can the above conditions be interpreted in special cases such as Bezout domains, unique factorization domains (UFDs), Noetherian rings, rings of fractions, etc.?

(3) What are the geometric interpretations of the above algebraic criteria?

(4) What is a natural topology on the set of all plants? Is stabilizability robust with respect to this topology? Does the set of stabilizable plants form a dense set in the set of all plants?

(5) How can the above results be interpreted geometrically for the special case of the n -D stabilization problem?

In this paper we answer the above questions for SISO plants. Though we restrict ourselves to the SISO case, more for clarity and for the natural geometric interpretations that can be obtained, the results nevertheless provide a stabilizability theory for a diverse class of linear systems including n -D, distributed, and infinite-dimensional systems. We have recently obtained corresponding algebraic criteria for feedback stability in the MIMO case over integral domains. Its ramifications such as tracking, disturbance rejection, among others, will be reported elsewhere.

1.3. Outline of results. As the main body of the paper is somewhat technical we provide a detailed preview of the main results of this paper. This outline also serves to fix notation. For general background in commutative algebra we refer the reader to Atiyah and McDonald [1]; for algebraic geometry, refer to Hartshorne [6, Chap. 1].

1.3.1. General stabilizability conditions. In § 2.1 we present the following necessary and sufficient condition for stabilizability of a plant with fractions over a general integral domain. Let $p = nd^{-1}$ be a transfer function in \mathbf{F} . Define the following ideal quotients of the principal ideals (n) and (d) :

$$\begin{aligned}\mathbf{a} &= ((n): d) \quad \text{denoted hereafter as } (n: d), \\ \mathbf{b} &= (d: n).\end{aligned}$$

These ideals are independent of the fraction representing p .

One of our principal results is the following theorem (cf. Theorem 2.1.1).

THEOREM 2.1.1'. *The transfer function $p = nd^{-1}$ is stabilizable if and only if the ideals \mathbf{a} and \mathbf{b} are coprime (i.e., $\mathbf{a} + \mathbf{b} = \mathbf{A}$).*

We next consider the interpretation of this result for the following special cases.

(1) The ring \mathbf{A} is a Bezout domain: Here we show that \mathbf{a} and \mathbf{b} are always coprime; hence every transfer function is stabilizable (Corollary 2.1.4).

(2) When \mathbf{A} is a UFD the transfer function p is stabilizable if and only if p has coprime fractions (Corollary 2.1.5).

(3) When \mathbf{A} is a Noetherian ring the stabilizability condition can be directly expressed in terms of the primary decompositions of (n) and (d) (Corollary 2.1.7).

(4) Let \mathbf{A} be a ring of fractions $\mathbf{S}^{-1}\mathbf{B}$ of a ring \mathbf{B} with respect to a multiplicatively closed subset \mathbf{S} of \mathbf{B} . Then the above ideals \mathbf{a} and \mathbf{b} in \mathbf{A} are extensions of ideals \mathbf{I}_a and \mathbf{I}_b in \mathbf{B} , respectively. The stabilizability condition is now as in the following corollary (cf. Corollary 2.1.8).

COROLLARY. *The transfer function p is stabilizable if and only if*

$$(\mathbf{I}_a + \mathbf{I}_b) \cap \mathbf{S} \neq \emptyset.$$

1.3.2. Geometric interpretations. In § 2.2 we discuss the geometric implications of the above results. By “geometric” we mean interpretations in terms of prime ideals of the ring. In the well-known case of linear time invariant (lumped as well as distributed) plants, the set of stable transfer functions is a ring of functions holomorphic in some subset of \mathbb{C} . In such cases the zeros of a stable transfer function correspond to prime ideals of the ring containing the transfer function. Hence for a general ring \mathbf{A} the interpretation of the stabilizability condition in terms of prime ideals of \mathbf{A} is a natural generalization of the interpretation of stabilizability in terms of poles and zeros. This point is developed in Sule [7].

Let $\text{spec } \mathbf{A}$ denote the prime spectrum of the ring \mathbf{A} . For an ideal \mathbf{c} of \mathbf{A} let $V(\mathbf{c}) \subseteq \text{spec } \mathbf{A}$ denote the set of all prime ideals of \mathbf{A} containing \mathbf{c} . Clearly, Theorem 2.1.1 is equivalent to

$$V(\mathbf{a}) \cap V(\mathbf{b}) = \emptyset.$$

We show that when \mathbf{A} is a Noetherian ring $V(\mathbf{a})$ and $V(\mathbf{b})$ can be determined from the algebraic criteria obtained above. Thus in this case the stabilizability condition is interpreted directly in terms of n and d (Corollary 2.1.7) and hence, in light of the above remarks, directly in terms of notions which are generalizations of the poles and zeros of the plant.

We then consider the special case when $\mathbf{A} = \mathbf{S}^{-1}\mathbf{B}$. Define the subset $\Omega \subseteq \text{spec } \mathbf{B}$

$$\Omega = \{\mathbf{p} \in \text{spec } \mathbf{B} \mid \mathbf{p} \cap \mathbf{S} = \emptyset\}.$$

The geometric equivalent of Corollary 2.1.8 is the following.

COROLLARY 2.1.8'. *The transfer function p is stabilizable if and only if*

$$V(\mathbf{I}_a) \cap V(\mathbf{I}_b) \cap \Omega = \emptyset.$$

This is a key result in our development since it is this result that we interpret in the special case of n -D systems in terms of the geometry of affine varieties in \mathbb{C}^n .

1.3.3. Robustness results. In § 2.2 we topologize the set of all transfer functions with the purpose of studying genericity questions. Here we consider the field \mathbf{F} of transfer functions as a quotient space arising from an equivalence relation on $\mathbf{A} \times (\mathbf{A} \setminus \{0\}) := \mathbf{A} \times \mathbf{A}^*$. Hence the natural topology to consider is the quotient topology inherited from a topology (not necessarily the product topology) on $\mathbf{A} \times \mathbf{A}^*$. We show that in the special case of a Bezout domain this is just the well-known graph topology.

For a topological ring \mathbf{A} satisfying additional conditions we show that stability of a feedback system is a robust property in the quotient topology.

1.3.4. Multidimensional stabilization. In § 3 we apply the above theory to obtain necessary and sufficient conditions for stabilizability of n -D plants, as well as study the robustness of stabilizability. This problem belongs to one of the above special cases, namely when the ring \mathbf{A} is a ring of fractions $\mathbf{S}^{-1}\mathbf{B}$ where \mathbf{B} is the polynomial ring in n indeterminates over a subfield \mathbb{K} of \mathbb{C} , denoted $\mathbb{K}[X_1 \cdots X_n]$. We show here that the central issue in geometrically interpreting the stabilizability condition is that of characterizing affine varieties corresponding to prime ideals of \mathbf{B} that do not meet \mathbf{S} . We resolve this problem by showing that such a characterization is possible whenever the complement of the region of stability Γ in \mathbb{C}^n which defines \mathbf{S} is a compact *polynomially convex domain*. This generalises the work of Guiver and Bose in [2] on 2-D systems with Γ being the closed unit bidisc \bar{U}^2 . We also answer a question of Guiver [2, Open Prob. 6].

Next the robustness questions in n -D stabilization are studied by specialising the general theory developed in § 2. From there it follows that the stabilizing feedback is

robust in the quotient topology. On the other hand we show that there exist nonstabilizable plants which remain nonstabilizable under arbitrary small perturbations. From this it follows that the set of stabilizable plants, although open, is not dense in the set of all plants.

Finally we wish to emphasise here that an important feature of our theory is that it is in terms of the ideals \mathbf{a} and \mathbf{b} , which are intrinsic to the transfer function p , i.e., they are invariant with respect to the fraction nd^{-1} representing p . This is in contrast to previous work in this subject where the results are stated in terms of some special (usually coprime) fractional representation of p . Our development could therefore be considered the “coordinate-free” approach to stabilizability theory.

2. General theory. Recall from the Introduction the stabilization problem over an integral domain \mathbf{A} ; namely, given a transfer function p in \mathbf{F} the field of fractions of \mathbf{A} , determine those c in \mathcal{F}_p , the fibre over p , which stabilize p . In the following section we develop necessary and sufficient conditions for the solution of this problem.

2.1. General stabilizability conditions. Since p is an element of the field of fractions of an integral domain it corresponds to an equivalence class of pairs in $\mathbf{A} \times \mathbf{A}^*$, i.e., two fractions nd^{-1} and $n_1d_1^{-1}$ represent the same plant p if and only if $nd_1 = n_1d$. Thus in the following, although we sometimes state results in terms of a particular fraction, we need to show, and we do, that they are independent of this representation of p .

Recall from § 1.3.1 the definitions of the ideals \mathbf{a} and \mathbf{b} of \mathbf{A} denoted, respectively, by $(n:d)$ and $(d:n)$. Observe that these ideals are in fact independent of the fraction representing p . For if $p = nd^{-1} = n_1d_1^{-1}$, then

$$\begin{aligned} x \in (n:d) &\Leftrightarrow xd = kn && \text{for some } k \text{ in } \mathbf{A} \\ &\Leftrightarrow xdd_1 = knd_1 && \text{as } d_1 \text{ is nonzero} \\ &\Leftrightarrow xdd_1 = kn_1d \\ &\Leftrightarrow xd_1 = kn_1 && \text{as } d \text{ is nonzero} \\ &\Leftrightarrow x \in (n_1:d_1); \end{aligned}$$

so $\mathbf{a} = (n:d) = (n_1:d_1)$ and similarly for the ideal \mathbf{b} .

Our main result on stabilizability is the following theorem.

THEOREM 2.1.1. *The transfer function p is stabilizable if and only if the ideal quotients of p are coprime, i.e., $\mathbf{a} + \mathbf{b} = \mathbf{A}$.*

Let $p = nd^{-1}$ be any (fixed) representation of p . Then all the stabilizing transfer functions c of p are of the form

$$c = x_3x_1^{-1},$$

where x_1, x_2, x_3 satisfy

$$(2) \quad nx_1 = dx_2,$$

$$(3) \quad nx_3 = d(1 - x_1).$$

Proof. Suppose $p = nd^{-1}$ is stabilized by $c = at^{-1}$ in \mathcal{F}_p . Then by definition there exist x_1, x_2, x_3 in \mathbf{A} such that

$$(4) \quad (1 + pc)^{-1} = x_1,$$

$$(5) \quad p(1 + pc)^{-1} = x_2,$$

$$(6) \quad c(1 + pc)^{-1} = x_3.$$

First, (4) implies that x_1 is nonzero. Next, (5) $\Leftrightarrow px_1 = x_2$ (substituting from (4)) $\Leftrightarrow nx_1 = dx_2$ which is (2). Now (6) $\Leftrightarrow cx_1 = x_3 \Leftrightarrow ax_1 = tx_3$; i.e., $c = at^{-1} = x_3x_1^{-1}$. Finally, (4) $\Leftrightarrow x_1(1+pc) = 1 \Leftrightarrow x_1 + nx_3d^{-1} = 1$ (as $c = x_3x_1^{-1}$ from above) $\Leftrightarrow dx_1 + nx_3 = d$; i.e., $nx_3 = d(1-x_1)$ which is (3). Thus, from (2) $x_1 \in (d:n) = \mathbf{b}$ and from (3) $(1-x_1) \in (n:d) = \mathbf{a}$. Hence, $1 = x_1 + (1-x_1) \in \mathbf{a} + \mathbf{b}$, i.e., \mathbf{a} and \mathbf{b} are coprime.

Conversely, suppose \mathbf{a} and \mathbf{b} are coprime, i.e., suppose there exists x_1 in \mathbf{b} such that $(1-x_1)$ is in \mathbf{a} . We first claim that there exists a *nonzero* x_1 in \mathbf{b} such that $(1-x_1)$ is in \mathbf{a} . For if $\mathbf{a} \neq \mathbf{A}$, then 1 is not in \mathbf{a} . So if $x_1 = 0$ is the only element in \mathbf{b} for which $1-x_1$ is in \mathbf{a} , then 1 is in \mathbf{a} which is absurd. On the other hand suppose $\mathbf{a} = \mathbf{A}$. Now $\mathbf{b} = (d:n)$ is not the zero ideal as d , which is nonzero, belongs to \mathbf{b} . Then for any x_1 in \mathbf{b} , $1-x_1$ is in \mathbf{a} . So for any nonzero x_1 in \mathbf{b} with $1-x_1$ in \mathbf{a} let x_2 and x_3 be elements in \mathbf{A} such that

$$nx_1 = dx_2, \quad nx_3 = d(1-x_1).$$

Let $c = x_3x_1^{-1}$. Then a simple computation shows that

$$(1+pc)^{-1} = x_1, \quad p(1+pc)^{-1} = x_2, \quad c(1+pc)^{-1} = x_3;$$

i.e., p is stabilized by c . \square

In applications it is of interest to determine whether there exist stabilizing controllers for a given plant which are in \mathbf{A} . We call such a plant *strongly stabilizable*. A necessary and sufficient condition for this follows from the above theorem.

COROLLARY 2.1.2. *Let nd^{-1} be any representation of a stabilizable plant p . Then p is strongly stabilizable by a controller c in \mathbf{A} if and only if*

$$(7) \quad (d) \subseteq ((nc+d)).$$

Proof. From the above theorem it follows that the stabilizing controller of p is given by $c = x_3x_1^{-1}$. Hence, c belongs to \mathbf{A} if and only if $x_3 = cx_1 \Leftrightarrow (nc+d)x_1 = d$ (from (3)). \square

DEFINITION. Let \mathbf{T} be a saturated multiplicatively closed subset of \mathbf{A} . A transfer function is said to be *weakly causal* if it belongs to the subring $\mathbf{T}^{-1}\mathbf{A}$ of \mathbf{F} and to be *strictly causal* if it belongs to the Jacobson radical of $\mathbf{T}^{-1}\mathbf{A}$. The subring $\mathbf{T}^{-1}\mathbf{A}$ will be called a *causal structure* defined by \mathbf{T} .

The above definition is motivated by engineering considerations where a plant is weakly causal if its output at time $t=0$ is dependent on the input for time $t \leq 0$, and is strongly causal if it is dependent on the input for time $t < 0$ (see Bose [2]).

PROPOSITION 2.1.3. *All the stabilizing transfer functions of a strictly causal transfer function are weakly causal.*

Proof. Let $p = nd^{-1}$ be a strictly causal transfer function; i.e., let p belong to \mathbf{j} , the Jacobson radical of $\mathbf{T}^{-1}\mathbf{A}$. Hence n belongs to \mathbf{j} . As every stabilizing transfer function $c = x_3x_1^{-1}$ of p satisfies (2) and (3), it follows that $(1-x_1)$ belongs to \mathbf{j} (as d being a unit in $\mathbf{T}^{-1}\mathbf{A}$ does not). Now if x_1 were not to belong to \mathbf{T} , it then would be in a maximal ideal \mathbf{m} of $\mathbf{T}^{-1}\mathbf{A}$ to which also $(1-x_1)$ belongs. Then $x_1 + (1-x_1) = 1$ would belong to \mathbf{m} , which is absurd. \square

2.1.1. Special cases. We now specialize the above general results, which are valid for arbitrary integral domains, to rings of interest in applications.

1. *Bezout domains.* We show here that Theorem 2.1.1 specializes to the well-known result on stabilization (Vidyasagar, Schnider, and Francis [10]).

COROLLARY 2.1.4. *If \mathbf{A} is a Bezout domain then every transfer function is stabilizable.*

Proof. Recall that in a Bezout domain every finitely generated ideal is principal. So for $p = nd^{-1}$, let $(n, d) = (g)$ for some g in \mathbf{A} where (g) is the smallest ideal that contains both (n) and (d) . Hence $n = n'g$ and $d = d'g$ for some n', d' in \mathbf{A} .

We claim that $(n', d') = \mathbf{A}$. For if not then (n', d') is a proper ideal in \mathbf{A} and hence equals (g') for some g' not a unit. Then (gg') is a principal ideal strictly contained in (g) and which contains (n) and (d) , which is a contradiction.

Clearly $(n') \subseteq (n': d') = (n: d) = \mathbf{a}$; similarly $(d') \subseteq \mathbf{b}$. Hence, $\mathbf{a} + \mathbf{b} = \mathbf{A}$. \square

Remark. In general, even if \mathbf{A} is not a Bezout domain, the above argument shows that if p can be represented by nd^{-1} where (n) and (d) are coprime then p is stabilizable.

2. *Unique factorization domains.* These rings are of interest in distributed systems and n -D problems. For instance the rings $\mathbb{K}[X_1 \cdots X_n]$ and $\mathbb{K}[[X_1 \cdots X_n]]$ are UFDs but not Bezout domains. In this case for $p = nd^{-1}$ there exist relatively prime n' and d' such that $p = n'd'^{-1}$. Then clearly $(n: d) = (n')$ and $(d: n) = (d')$. Hence we have the following corollary.

COROLLARY 2.1.5. *Let \mathbf{A} be a UFD. Then p is stabilizable if and only if*

$$(n') + (d') = \mathbf{A}.$$

Remark. For a general ring \mathbf{A} , it follows from (3) that every stabilizing controller of $p = nd^{-1}$ is of the form $c = x_3x_1^{-1}$ where x_3 and x_1 are elements of the ring \mathbf{A} that satisfy

$$nx_3 + dx_1 = d.$$

In the special case of a UFD if n and d are relatively prime, it follows from (2) and (3) that

$$x_1 = td \quad \text{and} \quad x_3 = ad.$$

Hence the above equation becomes

$$nad + dtd = d,$$

which, as d is nonzero, is equivalent to

$$na + dt = 1.$$

Thus every stabilizing controller c of $p = nd^{-1}$ (n and d relatively prime) is of the form $c = at^{-1}$ where a and t are elements of \mathbf{A} that solve $na + dt = 1$ or equivalently $na + dt = u$, for u a unit in \mathbf{A} .

With reference to the strong stabilizability problem described above we have the following corollary.

COROLLARY 2.1.6. *Let \mathbf{A} be a UFD. Then a stabilizable transfer function $p = n'd'^{-1}$, where n' and d' are relatively prime, is strongly stabilizable by a c in \mathbf{A} if and only if*

$$((n'c + d')) = \mathbf{A}.$$

Proof. From (2) above we get $x_1 = yd'$ for some y in \mathbf{A} (since n' and d' are relatively prime). Hence, from (3) and the fact that $x_3 = cx_1$ (which is equivalent to the strong stabilizability of p) we have $(n'c + d')yd' = d' \Leftrightarrow (n'c + d')$ is a unit. \square

3. *Noetherian rings.* We now consider the case when \mathbf{A} is a Noetherian ring since this ring is of importance to many applications. As there exist many Noetherian rings that are not UFDs this case merits separate treatment.

Consider the primary decompositions of (n) and (d) ,

$$(n) = \bigcap_{i=1}^{m_1} \mathbf{q}_i \quad \text{and} \quad (d) = \bigcap_{j=1}^{m_2} \mathbf{q}'_j,$$

where the indices i and j are ordered such that

$$d \notin \mathbf{q}_i \quad \text{for } i = 1 \cdots k_1 \leq m_1$$

and

$$n \notin \mathbf{q}'_j \quad \text{for } j = 1 \cdots k_2 \leq m_2.$$

Let $\text{rad } \mathbf{q}_i = \mathbf{p}_i$ and $\text{rad } \mathbf{q}'_j = \mathbf{p}'_j$. (Here rad denotes the radical.) In this notation we have the following corollary.

COROLLARY 2.1.7. *Let \mathbf{A} be a Noetherian ring. Then $p = nd^{-1}$ is stabilizable if and only if*

$$\mathbf{p}_i + \mathbf{p}'_j = \mathbf{A} \quad \forall i = 1 \cdots k_1, \quad j = 1 \cdots k_2.$$

Proof. Since \mathbf{a} and \mathbf{b} coprime is equivalent to $\text{rad } \mathbf{a}$ and $\text{rad } \mathbf{b}$ coprime, p is stabilizable if and only if

$$(8) \quad \text{rad } \mathbf{a} + \text{rad } \mathbf{b} = \mathbf{A}.$$

Since for a primary ideal \mathbf{q} and an element x in \mathbf{A}

$$\begin{aligned} \text{rad } (\mathbf{q} : x) &= \text{rad } \mathbf{q} \quad \text{if } x \notin \mathbf{q} \\ &= \mathbf{A} \quad \text{if } x \in \mathbf{q} \end{aligned}$$

we have

$$(9) \quad \text{rad } \mathbf{a} = \text{rad } \bigcap_{i=1}^{m_1} (\mathbf{q}_i : d) = \bigcap_{i=1}^{k_1} \mathbf{p}_i$$

and similarly

$$\text{rad } \mathbf{b} = \bigcap_{j=1}^{k_2} \mathbf{p}'_j.$$

Hence (8) implies that $\mathbf{p}_i + \mathbf{p}'_j = \mathbf{A}$ for all $i = 1 \cdots k_1$ and $j = 1 \cdots k_2$.

Conversely suppose p is not stabilizable. Then the ideal

$$\bigcap_{i=1}^{k_1} \mathbf{p}_i + \bigcap_{j=1}^{k_2} \mathbf{p}'_j \neq \mathbf{A},$$

and hence is contained in some prime ideal \mathbf{p} of \mathbf{A} . Thus, $\bigcap_{i=1}^{k_1} \mathbf{p}_i \subseteq \mathbf{p}$ and $\bigcap_{j=1}^{k_2} \mathbf{p}'_j \subseteq \mathbf{p} \Rightarrow \mathbf{p}_i \subseteq \mathbf{p}$ for some $i \leq k_1$ and $\mathbf{p}'_j \subseteq \mathbf{p}$ for some $j \leq k_2 \Leftrightarrow \mathbf{p}_i + \mathbf{p}'_j \subseteq \mathbf{p}$. \square

Remark. Note that for a different fraction $n'd'^{-1}$ representing the transfer function p the associated prime ideals of (n') and (d') will in general be different from those of (n) and (d) . However, in light of the comment preceding Theorem 2.1.1 the intersections in (9) will be independent of these representations and so will therefore be the condition of the above corollary.

4. Ring of fractions. Now consider the case when \mathbf{A} itself arises as a ring of fractions of some other ring \mathbf{B} , i.e., $\mathbf{A} = \mathbf{S}^{-1}\mathbf{B}$, $\mathbf{S} \subseteq \mathbf{B}$ is a multiplicatively closed subset (not containing 0). This case is of importance to applications and one such application, namely the multidimensional stabilization problem, is considered later in this paper. There \mathbf{B} is the polynomial ring $\mathbb{C}[X_1 \cdots X_n]$ and \mathbf{S} is a set of polynomials whose varieties do not intersect some fixed region Γ in \mathbb{C}^n . We now interpret our basic stabilization theorem in terms of ideals of \mathbf{B} .

Let \mathbf{I}_a and \mathbf{I}_b be ideals of \mathbf{B} such that

$$\mathbf{a} = \mathbf{S}^{-1}\mathbf{I}_a \quad \text{and} \quad \mathbf{b} = \mathbf{S}^{-1}\mathbf{I}_b.$$

Theorem 2.1.1 now translates to the following corollary.

COROLLARY 2.1.8. *The transfer function p is stabilizable if and only if*

$$(10) \quad (\mathbf{I}_a + \mathbf{I}_b) \cap \mathbf{S} \neq \emptyset.$$

Proof. As $\mathbf{a} + \mathbf{b} = \mathbf{S}^{-1}(\mathbf{I}_a + \mathbf{I}_b)$ it follows that

$$\mathbf{a} + \mathbf{b} = \mathbf{A} \Leftrightarrow (\mathbf{I}_a + \mathbf{I}_b) \cap \mathbf{S} \neq \emptyset. \quad \square$$

Note that \mathbf{I}_a and \mathbf{I}_b need not be unique. However, we determine one such pair in terms of a suitable fraction representing p .

Let $p = nd^{-1}$, n, d in $\mathbf{S}^{-1}\mathbf{B}$, i.e., $n = f'h'^{-1}$ and $d = g'h''^{-1}$ for h', h'' in \mathbf{S} . Then $p = nd^{-1} = (f'h''/1)(g'h'/1)^{-1}$. This is well-defined for as h'' is in \mathbf{S} , $h''/1$ is nonzero. Hence $g'/1 = (g'h''^{-1})(h''/1)$ is nonzero, which implies that $g'h'/1$ is nonzero.

Let $f = f'h''$, $g = g'h'$ so that

$$(11) \quad p = (f/1)(g/1)^{-1}.$$

In this notation we have the following proposition.

PROPOSITION 2.1.9. $\mathbf{I}_a = (f: g)$ and $\mathbf{I}_b = (g: f)$ extend to \mathbf{a} and \mathbf{b} , respectively.

Proof. Let $h \in (f: g)$. Then $(g/1)(h/1)$ belongs to the ideal $(f/1)$, which implies that $h/1$ is in \mathbf{a} . (This follows from the representation of p in (11).) Thus $\mathbf{S}^{-1}\mathbf{I}_a \subseteq \mathbf{a}$.

Conversely let a/s be in \mathbf{a} . Then

$$(a/s)(g/1) = (a'/s')(f/1)$$

for some a'/s' in \mathbf{A} . This implies that

$$as' \in (f: g) \Rightarrow as'/(s's) = a/s \in \mathbf{S}^{-1}\mathbf{I}_a,$$

i.e., $\mathbf{a} \subseteq \mathbf{S}^{-1}\mathbf{I}_a$.

The proof for $\mathbf{b} = \mathbf{S}^{-1}\mathbf{I}_b$ is identical. \square

Remark. In the case where \mathbf{B} is a UFD there exist f and g in \mathbf{B} that are relatively prime such that $(f/1)(g/1)^{-1} = p$. Then $\mathbf{I}_a = (f)$ and $\mathbf{I}_b = (g)$. Hence condition (10) is equivalent to

$$(12) \quad p \text{ is stabilizable iff } (f, g) \cap \mathbf{S} \neq \emptyset.$$

Remark. Causal structures in this case will be defined via saturated multiplicatively closed subsets \mathbf{T} of $\mathbf{A} = \mathbf{S}^{-1}\mathbf{B}$ which contain the image of \mathbf{S} under the natural injection $i: \mathbf{B} \rightarrow \mathbf{S}^{-1}\mathbf{B}$. Then $\mathbf{T}^{-1}\mathbf{A}$ will be naturally identified with $\mathbf{T}^{-1}\mathbf{B}$.

2.2. Geometric interpretations. In this section we interpret the above algebraic criteria of stabilizability in concrete geometric terms. Recall from § 1.3.2 that $\text{spec } \mathbf{A}$ denotes the prime spectrum of the ring \mathbf{A} and for an ideal \mathbf{c} in \mathbf{A} , $V(\mathbf{c})$ denotes the subset of $\text{spec } \mathbf{A}$ consisting of all prime ideals that contain \mathbf{c} . Clearly the geometric equivalent of Theorem 2.1.1 is the following corollary.

COROLLARY 2.2.10. *The transfer function p is stabilizable if and only if*

$$V(\mathbf{a}) \cap V(\mathbf{b}) = \emptyset.$$

The equivalents of the above geometric interpretation for the special cases of Bezout domains, UFDs, and Noetherian rings are straightforward. We consider therefore only the case when \mathbf{A} is a ring of fractions $\mathbf{S}^{-1}\mathbf{B}$ and determine the geometric equivalent of Corollary 2.1.8.

Corresponding to the multiplicatively closed subset \mathbf{S} of \mathbf{B} , define

$$\Omega = \{\mathbf{p} \in \text{spec } \mathbf{B} \mid \mathbf{p} \cap \mathbf{S} = \emptyset\}.$$

In this case we have the following corollary.

COROLLARY 2.2.11. *The transfer function p is stabilizable if and only if*

$$V(\mathbf{I}_a) \cap V(\mathbf{I}_b) \cap \Omega = \emptyset.$$

Proof. Assume p stabilizable, which implies by Corollary 2.1.8 that

$$(\mathbf{I}_a + \mathbf{I}_b) \cap \mathbf{S} \neq \emptyset \Rightarrow \mathbf{p} \cap \mathbf{S} \neq \emptyset \quad \text{for all } \mathbf{p} \in V(\mathbf{I}_a + \mathbf{I}_b) \Rightarrow V(\mathbf{I}_a) \cap V(\mathbf{I}_b) \cap \Omega = \emptyset.$$

Conversely suppose p is not stabilizable. Then again by Corollary 2.1.8 $(\mathbf{I}_a + \mathbf{I}_b) \cap \mathbf{S} = \emptyset$, which implies that $\mathbf{S}^{-1}(\mathbf{I}_a + \mathbf{I}_b)$ is a proper ideal in $\mathbf{S}^{-1}\mathbf{B}$. Let \mathbf{m} be a maximal ideal in $\mathbf{S}^{-1}\mathbf{B}$ containing $\mathbf{S}^{-1}(\mathbf{I}_a + \mathbf{I}_b)$. Let \mathbf{p} and \mathbf{i} be the contractions in \mathbf{B} of ideals \mathbf{m} and $\mathbf{S}^{-1}(\mathbf{I}_a + \mathbf{I}_b)$, respectively. Then $(\mathbf{I}_a + \mathbf{I}_b) \subseteq \mathbf{i} \subseteq \mathbf{p}$. Since $\mathbf{p} \cap \mathbf{S} = \emptyset$ and \mathbf{p} belongs to $V(\mathbf{I}_a + \mathbf{I}_b)$, the result follows. \square

Observe that Corollary 2.2.10 requires the determination of the (Zariski) closed subsets $V(\mathbf{a})$ and $V(\mathbf{b})$ in terms of the given data $V(n)$ and $V(d)$. Note that whenever the plant can be represented by a relatively prime fraction nd^{-1} (for instance whenever \mathbf{A} is either a Bezout domain or a UFD) $V(\mathbf{a}) = V(n)$ and $V(\mathbf{b}) = V(d)$. Also in the Noetherian case it is clear from (9) in Corollary 2.1.7 that

$$V(\mathbf{a}) = \bigcup_{i=1}^{k_1} V(\mathbf{p}_i) \quad \text{and} \quad V(\mathbf{b}) = \bigcup_{j=1}^{k_2} V(\mathbf{p}'_j).$$

Thus again $V(\mathbf{a})$ and $V(\mathbf{b})$ are expressed in terms of n and d (i.e., in terms of the primary decompositions of (n) and (d)). Note that similar expressions can be derived for $V(\mathbf{I}_a)$ and $V(\mathbf{I}_b)$ in Corollary 2.2.11 when \mathbf{A} is a ring of fractions of a Noetherian ring \mathbf{B} . However, while in general there does not seem to be such a simple way of expressing $V(\mathbf{a})$ and $V(\mathbf{b})$, we show below that for certain transfer functions which we call *simple* a geometric characterization of $V(\mathbf{a})$ and $V(\mathbf{b})$ is indeed possible.

DEFINITION. A transfer function p is said to be *simple* if it has a representation nd^{-1} with $\text{rad}(n) = (n)$ and $\text{rad}(d) = (d)$. We call such a representation simple.

Remark. This definition is motivated by the fact that in many practical situations transfer functions of plants have simple (i.e., nonrepeated) nonminimum phase poles and zeros. Thus in view of our remarks in § 1.3.2 concerning the prime spectrum of the ring the above definition is a natural generalization of transfer functions with simple poles and zeros. Note that in the special case of a simple n -D plant fg^{-1} described above in subsection 4 of § 2.1, those irreducible factors of the polynomials f and g that do not belong to \mathbf{S} are nonrepeated. In fact it can be shown that in the *quotient topology* defined in the next section simple transfer functions are open and dense in the set of all transfer functions, i.e., most transfer functions are in fact simple.

For such transfer functions we have the following proposition.

PROPOSITION 2.2.12. *Let p have a simple representation nd^{-1} . Define Γ_a and Γ_b to be the families of closed subsets of $\text{spec } \mathbf{A}$ given by*

$$\Gamma_a = \{\psi \mid V(n) \subseteq \psi \cup V(d)\},$$

$$\Gamma_b = \{\theta \mid V(d) \subseteq \theta \cup V(n)\}.$$

Then $V(\mathbf{a})$ and $V(\mathbf{b})$ are the unique minimal elements of Γ_a and Γ_b , respectively.

Proof. First we show that $V(\mathbf{a})$ belongs to Γ_a . So let x be in \mathbf{a} , which implies that $(x)(d) \subseteq (n)$. Hence

$$V(n) \subseteq V(x) \cup V(d) \quad \text{for all } x \in \mathbf{a} \Rightarrow V(n) \subseteq \left(\bigcap_{x \in \mathbf{a}} V(x) \right) \cup V(d) = V(\mathbf{a}) \cup V(d).$$

Thus $V(\mathbf{a})$ belongs to Γ_a .

We claim that if ψ belongs to Γ_a then $V(\mathbf{a}) \subseteq \psi$. For as ψ is closed there exists an ideal \mathbf{i} in \mathbf{A} such that $\psi = V(\mathbf{i})$. Then

$$\begin{aligned} V(n) \subseteq V(\mathbf{i}) \cup V(d) = V(\mathbf{i}(d)) &\Rightarrow \mathbf{i}(d) \subseteq \text{rad}(n) = (n) \quad (\text{as } p \text{ is simple}) \\ &\Rightarrow \mathbf{i} \subseteq (n : d) = \mathbf{a} \Rightarrow V(\mathbf{a}) \subseteq V(\mathbf{i}). \end{aligned}$$

A similar reasoning shows that $V(\mathbf{b})$ is minimal in Γ_b . \square

Thus it clearly follows that the geometric stabilizability condition of Corollary 2.1.10 can now be expressed for simple transfer functions as

$$p \text{ is stabilizable iff } \psi_{\min} \cap \theta_{\min} = \emptyset,$$

where ψ_{\min} and θ_{\min} are minimal elements of the families Γ_a and Γ_b , respectively.

2.3. Robustness of stabilizability. In this section we investigate the robustness of feedback stability over general rings. For this purpose we need a notion of when one transfer function is close to another, i.e., we need to topologize the set of transfer functions. In the special case of a Bezout domain the graph topology defined by Vidyasagar [8] serves this purpose. However, since this topology is defined in terms of coprime fractional representations of the transfer function it cannot be carried over to our more general setting. Our first purpose therefore is to topologize the set of transfer functions in such a way so as to be independent of any choice of fractional representations. This is in keeping with the spirit of this paper as the above developments have been in terms of the ideals \mathbf{a} and \mathbf{b} , which are indeed independent of the representation.

Motivated by the above considerations we topologize the set of transfer functions in this general setting in such a way so as to specialise to the graph topology whenever coprime fractions exist. Our development here is also guided by genericity questions in the multidimensional stabilization problem, which is treated in detail in the next section.

Now let the ring \mathbf{A} be a topological ring (\mathbf{A}, τ_R) . The field of fractions \mathbf{F} arises as a quotient of $\mathbf{A} \times \mathbf{A}^*$ by the equivalence relation \sim where

$$(a, t) \sim (a', t') \quad \text{iff} \quad at' = a't.$$

Consider $\mathbf{A} \times \mathbf{A}$ to be a topological space with some topology τ (not necessarily the product topology). We consider \mathbf{F} to be a topological space with the *quotient topology* τ_q induced by the subspace topology, also denoted by τ , on $\mathbf{A} \times \mathbf{A}^* \subset \mathbf{A} \times \mathbf{A}$, i.e., if

$$(13) \quad \pi: \mathbf{A} \times \mathbf{A}^* \rightarrow \mathbf{F}$$

is the natural projection, then $U \subseteq \mathbf{F}$ is open in τ_q if and only if $\pi^{-1}(U)$ belongs to τ . Our choice of the topology τ on $\mathbf{A} \times \mathbf{A}$ is motivated by genericity questions and is required to satisfy the following conditions. These conditions as well as others that we introduce in this section will be shown to be satisfied in the special case of n -D systems in the next section.

Condition C1. Every element of \mathbf{A} is closed in τ_R .

Condition C2. Let $ay = bx$. Then given a neighborhood $N(x, y)$ of (x, y) (i.e., in τ) there exists a neighborhood $N(a, b)$ of (a, b) such that for all (a', b') in $N(a, b)$; there exists (x', y') in $N(x, y)$ with $a'y' = b'x'$.

Condition C3. The product topology τ_P on $\mathbf{A} \times \mathbf{A}$ is weaker than the topology τ on $\mathbf{A} \times \mathbf{A}$, i.e., $\tau_P \subseteq \tau$.

Remark. Clearly under assumptions C1 and C3, $\mathbf{A} \times \mathbf{A}^*$ is open in $\mathbf{A} \times \mathbf{A}$ with respect to the topology τ . Then Condition C2 is satisfied by the subspace $\mathbf{A} \times \mathbf{A}^*$, i.e., if (a, b) and (x, y) belong to $\mathbf{A} \times \mathbf{A}^*$ then the neighborhoods $N(a, b)$ and $N(x, y)$ in C2 can be chosen to be open subsets of $\mathbf{A} \times \mathbf{A}^*$. We then say that $\mathbf{A} \times \mathbf{A}^*$ satisfies C2.

Remark. It is important to note that τ , in general, is not the product topology τ_P . The open sets of τ_P are usually much too large to allow robustness of stabilizability. This will become clear in the section on n -D systems below.

PROPOSITION 2.3.13. *The mapping π in (13) is open if and only if $\mathbf{A} \times \mathbf{A}^*$ satisfies C2.*

Proof. Suppose π is open. Then given a neighborhood $N(x, y)$ of (x, y) , $\pi N(x, y)$ is open, which implies that $\pi^{-1}\pi N(x, y)$ is open (as \mathbf{F} has the quotient topology).

Let $(a, b) \sim (x, y)$, i.e., $(a, b) \in \pi^{-1}\pi N(x, y)$. As $\pi^{-1}\pi N(x, y)$ is open, there exists a neighborhood $N(a, b)$ of (a, b) contained in $\pi^{-1}\pi N(x, y)$. Hence for all (a', b') in $N(a, b)$ there exists (x', y') in $N(x, y)$ such that $(a', b') \sim (x', y')$, i.e., C2 is satisfied.

Conversely suppose that $\mathbf{A} \times \mathbf{A}^*$ satisfies C2. Let $N \subseteq \mathbf{A} \times \mathbf{A}^*$ be open. We need to show that $\pi^{-1}\pi N$ is open. So let (a, b) be in $\pi^{-1}\pi N$. Clearly there exists (x, y) in N such that $(a, b) \sim (x, y)$. By C2 there exists a neighborhood $N(a, b)$ of (a, b) such that for all (a', b') in $N(a, b)$, there exists (x', y') in N with $(a', b') \sim (x', y')$. Hence $N(a, b) \subseteq \pi^{-1}\pi N$. \square

Remark. Clearly by the above proposition a basis of neighborhoods containing a transfer function p in \mathbf{F} can be obtained as follows.

Let (a, b) in $\mathbf{A} \times \mathbf{A}^*$ belong to $\pi^{-1}p$. Consider the collection πU , where U varies over all basic neighborhoods of (a, b) in $\mathbf{A} \times \mathbf{A}^*$ and (a, b) varying over $\pi^{-1}p$. Then this collection is a basis of neighborhoods about p . Moreover, it follows from C2 that this basis can actually be obtained by fixing any (a, b) in $\pi^{-1}p$.

From this it follows that whenever every p has coprime fractions, the quotient topology on \mathbf{F} is just the graph topology.

We now investigate the following questions:

1. Given a stabilizable transfer function p is there a neighborhood in the quotient topology defined above consisting of stabilizable transfer function?

2. Given such a neighborhood does there exist a controller that stabilizes every transfer function in it?

Consider the topological ring (\mathbf{A}, τ_R) with a topology τ on $\mathbf{A} \times \mathbf{A}$ satisfying the above conditions C1, C2, and C3. Assume further that the following condition holds.

Condition C4. The set of units in \mathbf{A} is open in the topology τ_R .

Under Conditions C1 to C4 we have the following proposition.

PROPOSITION 2.3.14. *Let p in \mathbf{F} be stabilizable. Then there exists a neighborhood of p in the quotient topology such that every transfer function in this neighborhood is stabilizable.*

Proof. Let $p = nd^{-1}$. Then by Theorem 2.1.1 p is stabilizable if and only if there exist x_1, x_2, x_3 in \mathbf{A} such that the following equations hold:

$$nx_1 = dx_2, \quad nx_3 = d(1 - x_1).$$

Observe that $x_1 + (1 - x_1) = 1$ is contained in the open set of units. Hence as \mathbf{A} is a topological ring there exist neighborhoods $N_P(x_2, x_1)$ and $N_P(1 - x_1, x_3)$ of (x_2, x_1)

and $(1 - x_1, x_3)$ in the product topology τ_P such that for all (x'_2, x'_1) in $N_P(x_2, x_1)$ and (x'_4, x'_3) in $N_P(1 - x_1, x_3)$

$$(14) \quad x'_1 + x'_4 = u$$

where u is a unit.

Now choose neighborhoods $N(x_2, x_1)$ and $N(1 - x_1, x_3)$ in the topology τ on $\mathbf{A} \times \mathbf{A}$ such that

$$N(x_2, x_1) \subseteq N_P(x_2, x_1)$$

and

$$N(1 - x_1, x_3) \subseteq N_P(1 - x_1, x_3)$$

which is possible by Condition C3. Given these neighborhoods, by C2 there exists a neighborhood $N(n, d)$ in $\mathbf{A} \times \mathbf{A}^*$ such that for all (n', d') in $N(n, d)$, there exist (x'_2, x'_1) in $N(x_2, x_1)$ and (x'_4, x'_3) in $N(1 - x_1, x_3)$ with

$$n'x'_1 = d'x'_2,$$

$$n'x'_3 = d'x'_4.$$

But by (14) $u^{-1}x'_1 + u^{-1}x'_4 = 1$. Hence multiplying both the above equations by u^{-1} we obtain

$$n'(x'_1u^{-1}) = d'(x'_2u^{-1}),$$

$$n'(x'_3u^{-1}) = d'(1 - x'_1u^{-1}).$$

Hence, $n'd'^{-1}$ is also stabilizable for all (n', d') in $N(n, d)$. \square

While this proposition answers question 1 above, the controller $x_3x_1^{-1}$ of p may not be the same as the stabilizing controller $x'_3x'_1{}^{-1}$ of $n'd'^{-1}$. We answer question 2 in the affirmative in the special case when \mathbf{A} is a UFD satisfying Conditions C1–C4.

THEOREM 2.3.15. *Let \mathbf{A} be a UFD satisfying C1–C4. Suppose c stabilizes a transfer function p in \mathbf{F} . Then there exists a neighborhood of p in the quotient topology such that c stabilizes every plant in it.*

Proof. Let $p = nd^{-1}$ where now n and d are relatively prime. Then from (2) and (3) of Theorem 2.1.1 with these n and d , $c = x_3x_1^{-1}$. Furthermore,

$$x_1 = rd \quad \text{and} \quad 1 - x_1 = sn$$

for some r, s in \mathbf{A} .

By Conditions C3 and C4 there exists a neighborhood $N(n, d)$ of (n, d) in the topology τ on $\mathbf{A} \times \mathbf{A}$ such that for all (n', d') in $N(n, d)$

$$rd' + sn' = u,$$

where u is a unit in \mathbf{A} .

Define

$$x'_1 = rd'u^{-1}, \quad x'_2 = rn'u^{-1}, \quad x'_3 = sd'u^{-1}, \quad \text{and} \quad x'_4 = sn'u^{-1}.$$

Then

$$n'x'_1 = d'x'_2, \quad n'x'_3 = d'(1 - x'_1).$$

Thus $n'd'^{-1}$ is stabilized by $x'_3x'_1{}^{-1} = x_3x_1^{-1} = c$. \square

While the above theorem answers question 2 in the special case of a UFD, the corresponding answer for the general case is not known.

By the above the set of stabilizable transfer functions is open in the quotient topology. Is it also dense in the set of all transfer functions? Although the answer to this is in the affirmative in the case of LTI systems (as is well known), this is not so in the more general setting of this paper. In fact we show in the special case of n -D systems in the next section that there exist nonstabilizable transfer functions with neighborhoods consisting of transfer functions that are also not stabilizable.

For related results regarding the graph topology see Zhu [11].

3. Stabilization of multidimensional systems. In this section we use the above theory to analyse stabilizability of multidimensional systems.

DEFINITION OF THE PROBLEM. With respect to the general formulation of the stabilization problem in the introduction, the problem here is defined as follows:

Let $\mathbf{A} = \mathbf{S}^{-1}\mathbf{B}$ where $\mathbf{B} = \mathbb{K}[X_1 \cdots X_n]$, the polynomial ring in n indeterminates with coefficients in a subfield \mathbb{K} of \mathbb{C} .

Let \mathbf{S} be the multiplicatively closed subset of \mathbf{B} consisting of all polynomials whose (affine) varieties in \mathbb{C}^n do not intersect some fixed compact region $\Gamma \subset \mathbb{C}^n$.

We define a causal structure via closed subsets of Γ as follows:

Let Γ' be some fixed closed subset of Γ .

Let \mathbf{T} be the saturated multiplicatively closed subset of \mathbf{A} consisting of rational functions fg^{-1} such that the variety of f does not intersect Γ' . (Note that the natural injection $i: \mathbf{B} \rightarrow \mathbf{A}$ maps \mathbf{S} into \mathbf{T} ; viz., the remark at the very end of § 2.1.)

Thus this is a special case of the general problem considered in part 4 of § 2.1, namely when \mathbf{A} is a ring of fractions. Also observe that as \mathbf{B} is a UFD so is $\mathbf{S}^{-1}\mathbf{B}$.

The main purpose of this section is to interpret the results developed above in this concrete setting of the polynomial ring $\mathbb{K}[X_1 \cdots X_n]$ in terms of affine varieties in \mathbb{C}^n .

The motivation for considering this special case stems from the 2-D stabilization problem treated by Guiver and Bose in [2, Chap. 3]. In our formulation their problem is as follows:

$\mathbf{B} = \mathbb{C}[X_1, X_2]$, $\Gamma = \bar{U}^2$ the closed unit polydisc in \mathbb{C}^2 . The causal structure is defined by $\Gamma' = (0, 0)$.

They prove that a plant $p = f/g$, f and g in $\mathbb{C}[X_1, X_2]$ is stabilizable if and only if f and g do not have a common zero in \bar{U}^2 . Their proof makes critical use of the fact that f and g , when relatively prime, have a finite number of common zeros (which is not the case for n -D systems, $n > 2$), and that the region Γ defining \mathbf{S} is the unit polydisc.

We on the other hand treat n -D systems for general n and where the region Γ is any arbitrary compact region in \mathbb{C}^n . The motivation for generalizing from 2-D to n -D is clear. Replacing the polydisc \bar{U}^n by an arbitrary compact region Γ follows from applications and is in fact posed as an *open problem* by Guiver in [2, Open Prob. 6].

In the following section we arrive at geometric criteria based on the theory developed in the previous sections and which also allows us to settle this open problem.

3.1. Stabilizability conditions. Consider the n -D transfer function p in \mathbf{F} . Since \mathbf{B} here is a UFD, by the remark following Proposition 2.1.9 p admits a representation $(f/1)(g/1)^{-1}$, where f and g are relatively prime. Then $\mathbf{I}_a = (f)$ and $\mathbf{I}_b = (g)$. Recall also from § 2.2 that Ω is the set of all prime ideals of \mathbf{B} that do not intersect \mathbf{S} . Hence, by Corollary 2.2.11, we have

$$(15) \quad p \text{ is stabilizable iff } V(f, g) \cap \Omega = \emptyset.$$

Since Ω is a set of prime ideals of $\mathbb{K}[X_1 \cdots X_n]$, and since by the Hilbert Nullstellensatz these prime ideals correspond to irreducible varieties in \mathbb{C}^n (as \mathbb{C} is the algebraic closure of \mathbb{K}), we can think of Ω as a collection of irreducible varieties. (As our entire discussion is with respect to the fixed subfield \mathbb{K} of \mathbb{C} , by variety we always mean a \mathbb{K} -variety, i.e., the zero set in \mathbb{C}^n of an ideal in $\mathbb{K}[X_1 \cdots X_n]$.) Now the affine variety of the ideal (f, g) , also denoted $V(f, g)$, is a (finite) union of irreducible varieties as well (corresponding to the minimal primes belonging to the ideal (f, g)). Hence (15) above can be interpreted to mean that none of the irreducible varieties in $V(f, g)$ belongs to Ω considered now as a collection of irreducible varieties.

This interpretation of the stabilizability condition in terms of affine varieties forces on us the need to characterize the irreducible varieties in the collection Ω . In general, since Ω is just a set of prime ideals which do not intersect some given multiplicatively closed subset S , such a characterization may not be possible. However, note that in the above stabilizability problem S arises in a special way, namely as a set of polynomials whose varieties do not intersect some given region $\Gamma \subset \mathbb{C}^n$. For such S we show that a geometric characterization of Ω is indeed possible, and the nature of this characterization is suggested by the following condition.

LEMMA 3.1.16. *Let \mathfrak{p} be a prime ideal in $\mathbb{K}[X_1 \cdots X_n]$. Then*

$$V(\mathfrak{p}) \cap \Gamma \neq \emptyset \Rightarrow \mathfrak{p} \in \Omega.$$

Proof. The proof is obvious. (Here $V(\mathfrak{p})$ is the variety of \mathfrak{p} in \mathbb{C}^n .) \square

The question therefore is: under what conditions on Γ does every \mathfrak{p} in Ω satisfy $V(\mathfrak{p}) \cap \Gamma \neq \emptyset$? Note that for such Γ the stabilizability condition would reduce to the following:

The transfer function $p = fg^{-1}$ (f, g relatively prime) is stabilizable if and only if the varieties $V(f)$ and $V(g)$ do not intersect in Γ .

Remark. Note that as f and g are relatively prime no irreducible component of $V(f)$ coincides with an irreducible component of $V(g)$. Hence, the dimension of every irreducible component of $V(f) \cap V(g)$ is strictly less than $n - 1$. On the other hand as $\text{codimension } V(f) + \text{codimension } V(g) \geq \text{codimension } (V(f) \cap V(g))$ it follows that the dimension of every irreducible component of $V(f) \cap V(g)$ is greater than or equal to $n - 2$. Hence the dimension of every irreducible component of $V(f) \cap V(g)$ equals $n - 2$, i.e., $V(f) \cap V(g)$ is a variety of pure codimension 2.

Thus actually it suffices, as far as the stabilizability condition is concerned, to obtain properties of Γ under which the reverse implication in Lemma 3.1.16 holds for prime ideals of height 2 in Ω .

To repeat, the question now is that if $V(\mathfrak{p}) \cap \Gamma = \emptyset$, then is it true that $\mathfrak{p} \notin \Omega$, i.e., is $\mathfrak{p} \cap S \neq \emptyset$. If this were true then there is a polynomial f in $\mathfrak{p} \cap S$. But

$$f \in S \Rightarrow V(f) \cap \Gamma = \emptyset \quad \text{and} \quad f \in \mathfrak{p} \Rightarrow V(\mathfrak{p}) \subseteq V(f)$$

in which case there is a codimension 1 variety, namely $V(f)$, that contains $V(\mathfrak{p})$ and that does not intersect Γ . This motivates the following.

DEFINITION. A region $\Gamma \subset \mathbb{C}^n$ is said to be *codimension k -convex* if given a codimension k irreducible variety V with $V \cap \Gamma = \emptyset$, there exists a codimension 1 variety V' such that

$$(16) \quad V \subset V' \quad \text{and} \quad V' \cap \Gamma = \emptyset.$$

Remark. If the region Γ is codimension k -convex then clearly for any variety V of pure codimension k with $V \cap \Gamma = \emptyset$ there exists a codimension 1 variety V' such that (16) holds.

We now show that the codimension k -convexity of the region Γ allows the reverse implication in Lemma 3.1.16 for primes of height $n - k$.

PROPOSITION 3.1.17. *Let \mathbf{i} be the ideal in $\mathbb{K}[X_1 \cdots X_n]$ of a pure codimension k variety V in \mathbb{C}^n . Then*

$$(17) \quad V \cap \Gamma = \emptyset \Leftrightarrow \mathbf{i} \cap \mathbf{S} \neq \emptyset \quad \text{iff } \Gamma \text{ is codimension } k\text{-convex.}$$

Proof. That (17) implies codimension k -convexity of Γ is clear. So suppose now that Γ is codimension k -convex. Then given the variety V of the ideal \mathbf{i} with $V \cap \Gamma = \emptyset$, by the remark following the definition above, there exists a codimension 1 variety $V' = V(h)$, where h is a polynomial in $\mathbb{K}[X_1 \cdots X_n]$, such that $V \subset V'$ and $V' \cap \Gamma = \emptyset$. By the Nullstellensatz, h^t belongs to \mathbf{i} for some $t \geq 1$. Since $V' = V(h')$, $V' \cap \Gamma = \emptyset$ implies that h' belongs to $\mathbf{S} \cap \mathbf{i}$. \square

Specialising the above result for $k = 2$ we have the geometric equivalent of the stabilizability result.

THEOREM 3.1.18. *Let Γ be codimension 2-convex. Then the transfer function $p = fg^{-1}$ (where f and g are relatively prime) is stabilizable if and only if*

$$V(f) \cap V(g) \cap \Gamma = \emptyset.$$

The above property of codimension k -convexity of a region Γ is a geometric one. The region Γ , however, defines an algebraic object, namely the multiplicatively closed subset \mathbf{S} of \mathbf{B} . It is therefore natural to expect that this geometric property of Γ is captured by some algebraic property of the ring $\mathbf{S}^{-1}\mathbf{B}$. The next proposition reveals this.

PROPOSITION 3.1.19. *Let Γ be a region in \mathbb{C}^n .*

- (i) *If Γ is codimension k -convex then the following statement holds:*
 (18) *Let \mathbf{p}_f be a prime ideal of height k in $\mathbf{S}^{-1}\mathbf{B}$. Then \mathbf{p}_f is contained in an ideal \mathbf{m}_f of height n .*
 (ii) *Conversely, if Γ is codimension n -convex, then statement (18) implies codimension k -convexity of Γ .*

Proof. (i) Let \mathbf{p} be the contraction of \mathbf{p}_f to \mathbf{B} . Clearly \mathbf{p} is of height k which implies that $V(\mathbf{p})$ is of codimension k . As $\mathbf{p} \cap \mathbf{S} = \emptyset$, by Proposition 3.1.17 $V(\mathbf{p}) \cap \Gamma \neq \emptyset$. So let x be a point in $V(\mathbf{p}) \cap \Gamma$. Then $\mathbf{I}(x)$, the maximal ideal in \mathbf{B} with $V(\mathbf{I}(x)) \supseteq \{x\}$, is of height n containing \mathbf{p} and such that $\mathbf{I}(x) \cap \mathbf{S} = \emptyset$. Let \mathbf{m}_f be the extension in $\mathbf{S}^{-1}\mathbf{B}$ of $\mathbf{I}(x)$. Clearly \mathbf{m}_f is of height n and contains \mathbf{p}_f .

(ii) Now assume that Γ is codimension n -convex. Suppose to the contrary that Γ is not codimension k -convex. Then there exists a prime ideal \mathbf{p} of height k with $V(\mathbf{p}) \cap \Gamma = \emptyset$ and such that for all $f \in \mathbf{p}$, $V(f) \cap \Gamma \neq \emptyset$. This further implies that $\mathbf{p} \cap \mathbf{S} = \emptyset$ and hence that its extension \mathbf{p}_f is a prime ideal in $\mathbf{S}^{-1}\mathbf{B}$. We claim that \mathbf{p}_f is not contained in an ideal of height n . For if \mathbf{m}_f were such a height n ideal containing \mathbf{p}_f then its contraction \mathbf{m} is a maximal ideal in \mathbf{B} with $\mathbf{m} \cap \mathbf{S} = \emptyset$. As \mathbf{m} is of height n and Γ is codimension n -convex, by Proposition 3.1.17 $V(\mathbf{m}) \cap \Gamma \neq \emptyset$. So let $x \in V(\mathbf{m}) \cap \Gamma$. As $V(\mathbf{m})$ is contained $V(\mathbf{p})$, x belongs to $V(\mathbf{p}) \cap \Gamma$ which is a contradiction. \square

Remark. The above proposition has the following important consequence when $\mathbb{K} = \mathbb{C}$. Let Γ be a region in \mathbb{C}^n which is codimension k -convex for all $2 \leq k \leq n$. Then the maximal ideals of $\mathbf{S}^{-1}\mathbb{C}[X_1 \cdots X_n]$ are in one-to-one correspondence with the points of Γ .

We now address the multidimensional stabilization problem considered by Guiver and Bose explained in the beginning of this section.

Here $\mathbf{B} = \mathbb{C}[X_1 \cdots X_n]$, $\Gamma = \bar{U}^n$, the closed unit polydisc and the causal structure is defined by Γ' which is the origin in \mathbb{C}^n . By Theorem 3.1.18 the geometric condition

for stabilizability holds if \bar{U}^n is codimension 2-convex. We now show that in fact \bar{U}^n is codimension k -convex for all $2 \leq k \leq n$.

We make use of the following well-known results (see, for instance, Gunning and Rossi [5]).

T1 (Corollary to Cartan's theorem *B*). Suppose $f_1 \cdots f_k$ are holomorphic functions on a pseudoconvex domain $\Gamma \subset \mathbb{C}^n$ such that the $\{f_i\}$ have no common zeros in Γ . Then there exist holomorphic functions $g_1 \cdots g_k$ such that $\sum f_i g_i = 1$.

T2 (Oka-Weil approximation theorem). Let $\Gamma \subset \mathbb{C}^n$ be a polynomially convex domain. Then any holomorphic function on Γ is uniformly approximable on compact subsets of Γ by polynomials.

PROPOSITION 3.1.20. *The polydisc \bar{U}^n is codimension k -convex for all $2 \leq k \leq n$.*

Proof. Given any variety V with $V \cap \bar{U}^n = \emptyset$, we need to find a polynomial $h \in \mathbb{C}[X_1 \cdots X_n]$ such that $V \subset V(h)$ and $V(h) \cap \bar{U}^n = \emptyset$.

As \bar{U}^n and V are closed subsets (in the \mathbb{C} -topology) there is an open set $W \supset \bar{U}^n$ with $W \cap V = \emptyset$. In fact W can be chosen to be geometrically convex with smooth boundary. Clearly W is also pseudoconvex.

Now let the ideal $\mathbf{I}(V) = (f_1 \cdots f_k)$ be the ideal of the variety V . As $V \cap \bar{U}^n = \emptyset$ the polynomials $\{f_i\}$ do not all vanish at any point in \bar{U}^n . Hence by T1 we can find $g_1 \cdots g_k$, holomorphic on W , such that $\sum f_i g_i = 1$. As W is also polynomially convex, by T2 we can uniformly approximate on the compact set \bar{U}^n , the holomorphic functions $g_1 \cdots g_k$ by polynomials $h_1 \cdots h_k$ so that

$$\sum_{i=1}^k f_i(x) h_i(x) \neq 0 \quad \text{for all } x \in \bar{U}^n.$$

Let $h = \sum f_i h_i$. Clearly $V(h) \cap \bar{U}^n = \emptyset$ and h belongs to $\mathbf{I}(V)$ which implies that $V \subset V(h)$. \square

Thus it follows from the above proposition that the geometric stabilizability condition of Theorem 3.1.18 holds for the n -D stabilization problem described above. Furthermore, if $p = fg^{-1}$ is a stabilizable transfer function with f, g relatively prime in $\mathbb{C}[X_1 \cdots X_n]$ then by the above result there exist h_1, h_2 in $\mathbb{C}[X_1 \cdots X_n]$ such that

$$h_1 f + h_2 g = h \in \mathbf{S}.$$

As h belongs to \mathbf{S} , it is a unit in $\mathbf{A} = \mathbf{S}^{-1}\mathbf{B}$. Hence by the remark following Corollary 2.1.5, a stabilizing controller of p is given by $h_1 h_2^{-1}$.

Consider now the causal structure defined via Γ' , the origin in \mathbb{C}^n ; i.e., let \mathbf{T} be the saturated multiplicatively closed subset of \mathbf{A} consisting of rational functions fg^{-1} such that the variety of f does not contain the origin. By Proposition 2.1.3 all the stabilizing controllers of a strictly causal transfer function are weakly causal. In this case (of n -D systems) we can further conclude that every stabilizable transfer function $p = fg^{-1}$ has a weakly causal controller. This is because if $h_1 f + h_2 g$ is in \mathbf{S} , then by perturbing h_2 (slightly) to h'_2 we can ensure that $h_1 f + h'_2 g$ is still in \mathbf{S} as well as that $h'_2(0) \neq 0$. Then $h_1 h'_2^{-1}$ is in $\mathbf{T}^{-1}\mathbf{A}$ and is therefore a weakly causal controller of p .

In Open Problem 6 in [2] Guiver poses the following question: Given the plant $p = fg^{-1}$ with f, g in $\mathbb{K}[X_1 \cdots X_n]$, is there a stabilizing controller $c = h_1 h_2^{-1}$ with h_1, h_2 also in $\mathbb{K}[X_1 \cdots X_n]$, $\mathbb{K} = \mathbb{R}$ or \mathbb{Q} ? We now answer this question in the affirmative.

THEOREM 3.1.21. *Let $p = fg^{-1}$ be a stabilizable transfer function with f, g relatively prime and in $\mathbb{R}[X_1 \cdots X_n]$. Then there exists a stabilizing controller $c = h_1 h_2^{-1}$ with h_1, h_2 in $\mathbb{Q}[X_1 \cdots X_n]$.*

Proof. As p is stabilizable and as \bar{U}^n is codimension 2-convex the geometric criterion of Theorem 3.1.18 implies that there is a polynomial h belonging to the ideal

$(f, g) \in \mathbb{C}[X_1 \cdots X_n]$ with $V(h) \cap \bar{U}^n = \emptyset$. Consider now the polynomial hh^* in $\mathbb{R}[X_1 \cdots X_n]$ (here h^* denotes the complex conjugate of h). Clearly as $\bar{U}^{n*} = \bar{U}^n$, $V(hh^*) \cap \bar{U}^n = \emptyset$. Equally clearly hh^* belongs to the contraction of the ideal (f, g) to $\mathbb{R}[X_1 \cdots X_n]$. Hence there exist polynomials h_1, h_2 in $\mathbb{R}[X_1 \cdots X_n]$ such that

$$fh_1 + gh_2 = hh^* \in S.$$

As \mathbb{Q} is dense in \mathbb{R} it is possible to perturb h_1 and h_2 to h'_1 and h'_2 in $\mathbb{Q}[X_1 \cdots X_n]$ such that

$$fh'_1 + gh'_2 \in S.$$

Thus, $h'_1 h'^{-1}_2$ is the desired stabilizing controller. \square

Remark. It follows from the above proofs that any compact polynomially convex domain Γ in \mathbb{C}^n is codimension k -convex for all $2 \leq k \leq n$. Hence the geometric stabilizability condition of Theorem 3.1.18 for the case when $\mathbb{K} = \mathbb{C}$ holds for all such Γ . Furthermore, the polydisc \bar{U}^n in Theorem 3.1.21 can be replaced by such Γ which are also symmetric about the real axis.

Note that this is more than what is necessary for the stabilizability problem as it suffices for Γ to be only codimension 2-convex. Thus it is desirable to characterize geometrically such regions. Note that an algebraic characterization of codimension 2-convex regions is available via Proposition 3.1.19.

However, it is *not* possible to replace Γ by any compact region, for instance, by those that are not holomorphically convex (because of Hartog's phenomenon). Thus, even in the 2-D case the above geometric criteria for stabilizability will not hold with the polydisc \bar{U}^2 replaced by a compact annular region. This negatively answers a question raised by Guiver in [2].

3.2. Robustness of stability. We consider here the robustness of stabilizability of n -D systems, i.e., we wish to define a topology on the set of transfer functions \mathbf{F} , the field of fractions of \mathbf{A} (where now $\mathbf{A} = S^{-1}\mathbb{C}[X_1 \cdots X_n]$ and S is the multiplicatively closed subset of \mathbf{B} defined with respect to the polydisc \bar{U}^n) with respect to which Conditions C1 to C4 in § 2.3 are satisfied. This will enable us to carry over the robustness results obtained in the general setting there to the special case of n -D systems here. This is accomplished in a series of steps as follows.

(i) The ring \mathbf{A} here is a topological (in fact, normed) ring with respect to the following norm:

$$\|fg^{-1}\| = \sup_{z \in \bar{U}^n} |f(z)g(z)^{-1}|, \quad fg^{-1} \in \mathbf{A}.$$

Note that this is well defined since fg^{-1} is holomorphic in \bar{U}^n , and is a norm since \bar{U}^n has nonempty interior. It is an easy check that \mathbf{A} is a normed ring under the above norm. Clearly it also follows that if the sequence $f_n g_n^{-1}$ converges to fg^{-1} in this norm topology then the variety $V(f_n)$ converges uniformly to $V(f)$ in \bar{U}^n . \mathbf{A} is Hausdorff being a normed ring; hence C1 is satisfied.

(ii) We now (in the notation of § 2.2) impose a topology τ on $\mathbf{A} \times \mathbf{A}$ such that Condition C2 is satisfied. We describe this topology via a basis of neighborhoods about each (x, y) in $\mathbf{A} \times \mathbf{A}$ as follows:

As \mathbf{A} is a UFD express (x, y) as $h(x', y') = (hx', hy')$ where x', y' in \mathbf{A} are relatively prime. Let $N(h)$, $N(x')$, and $N(y')$ be neighborhoods of h , x' , and y' in the norm topology of \mathbf{A} . Obtain a neighborhood $N(x, y)$ of (x, y) as

$$(19) \quad N(x, y) = \{h''(x'', y'') \mid h'' \in N(h), x'' \in N(x'), y'' \in N(y')\}.$$

The collection $N(x, y)$ obtained this way as $N(h)$, $N(x')$, and $N(y')$ vary over all neighborhoods of h , x' , and y' is a basis for a topology τ on $\mathbf{A} \times \mathbf{A}$. We now show that Condition C2 is satisfied with respect to this topology.

Let (x, y) and (a, b) in $\mathbf{A} \times \mathbf{A}$ satisfy

$$ay = bx.$$

Let $(x, y) = h(x', y')$ and $(a, b) = g(a', b')$, where the pairs (x', y') and (a', b') are each relatively prime. Hence the above equation is equivalent to

$$a'y' = b'x'.$$

Therefore $(a', b') = u(x', y')$ for some (unit) u in \mathbf{A} .

Now let $N(x, y)$ be a given neighborhood of (x, y) specified by neighborhoods $N(h)$, $N(x')$, and $N(y')$ as in (19). (Clearly it suffices to check Condition C2 for such neighborhoods since they form a basis for the topology τ .) Let $N(u)$ be a neighborhood of u . Then

$$N(a', b') = \{u''(x'', y'') \mid u'' \in N(u), x'' \in N(x'), y'' \in N(y')\}$$

is a neighborhood of (a', b') . Let $N(g)$ be a neighborhood of g . Then

$$N(a, b) = \{g''(a'', b'') \mid (a'', b'') \in N(a, b) \text{ and } g'' \in N(g)\}$$

is a neighborhood of (a, b) .

Now let (x'', y'') be in the above given neighborhood $N(x, y)$. Then define

$$(a'', b'') = (gux'', gyy'').$$

Clearly (a'', b'') is in $N(a, b)$ and satisfies $a''y'' = b''x''$. This shows that Condition C2 is satisfied.

(iii) Give $\mathbf{A} \times \mathbf{A}^* \subset \mathbf{A} \times \mathbf{A}$ the subspace topology with respect to τ , also denoted τ . Topologize the set of transfer functions by the quotient topology τ_q via the projection

$$\pi: \mathbf{A} \times \mathbf{A}^* \rightarrow \mathbf{F}.$$

(iv) Clearly from (19) it follows that the product topology τ_p on $\mathbf{A} \times \mathbf{A}$ induced by the norm topology on \mathbf{A} is weaker than the topology τ , i.e., Condition C3 is satisfied.

(v) For any x in \mathbf{A} with $\|x\| < 1$, $1+x$ is a unit in \mathbf{A} . Hence the set of units in \mathbf{A} is open, i.e., C4 is satisfied.

Thus it follows by (i)–(v) above that all the results of § 2.2 on robustness hold in this special case of n -D systems. We therefore have the following theorem.

THEOREM 3.2.22. (1) *Let c be a stabilizing controller of an n -D transfer function p . Then there is a neighborhood of p in the quotient topology τ_q such that every transfer function in this neighborhood is stabilized by the same controller c .*

(2) *Stabilizability is not a generic property of the set of n -D transfer functions.*

Proof. Part (1) follows from the above discussion, i.e., from Theorem 2.3.15.

(2) Consider polynomials $f, g \neq 0$ in $\mathbb{C}[X_1 \cdots X_n]$ such that (a) the singular loci of $V(f)$ and $V(g)$ do not intersect \bar{U}^n ; (b) $V(f)$ and $V(g)$ have a nonempty transversal intersection in \bar{U}^n .

Obviously such f and g exist. Consider the transfer function $p = fg^{-1}$. By the above theory p is not stabilizable. Clearly, there exists a $\delta > 0$ such that for all xx'^{-1} and yy'^{-1} in $S^{-1}\mathbb{C}[X_1 \cdots X_n]$ with

$$|f - xx'^{-1}| < \delta, \quad |g - yy'^{-1}| < \delta,$$

$V(x)$ and $V(y)$ intersect transversally in \bar{U}^n . Then the collection of all such transfer functions $xy'(x'y)^{-1}$ is clearly open in τ_p and therefore in τ_q , and are all non-stabilizable. \square

Remark. We emphasize here once again that the topology τ on $\mathbf{A} \times \mathbf{A}$ is not the product topology τ_P . In fact the robustness result is not valid with respect to τ_P . Actually even more is true, viz., with respect to τ_P every neighborhood of a stabilizable transfer function contains nonstabilizable ones as the following simple argument demonstrates.

Let $p = fg^{-1}$, where f and g are relatively prime be stabilizable, i.e., $V(f)$ and $V(g)$ do not intersect in \bar{U}^n . In the product topology every neighborhood of p will contain transfer functions of the kind $hf(kg)^{-1}$, where hf and kg are relatively prime but where $V(h)$ and $V(k)$ intersect in \bar{U}^n . Such plants are clearly not stabilizable.

Remark. From the above proof it is clear that every neighborhood of an n -D transfer function $p = fg^{-1}$, with f, g relatively prime and such that $V(f) \cap V(g)$ contains points of the boundary of \bar{U}^n but not its interior U^n , contains stabilizable transfer functions. Thus such transfer functions belong to the boundary of the closed subset of nonstabilizable transfer functions and can therefore be perturbed and made stabilizable. A more detailed study of this boundary will appear elsewhere.

Acknowledgments. We are grateful to G. Misra, A. Parameswaran, S. Patkar, and A. R. Shastri for many useful discussions. We would also like to thank a very knowledgeable referee for his comments which led to improvements in the presentation of this paper.

UNBOUNDED SOLUTIONS TO THE LINEAR QUADRATIC CONTROL PROBLEM*

G. DA PRATO[†] AND M. C. DELFOUR[‡]

Abstract. Examples are presented to show that the solution of the operational algebraic Riccati equation can be an unbounded operator for infinite dimensional systems in a Hilbert space even with bounded control and observation operators. This phenomenon is connected to the presence of a continuous spectrum in one of the operators. The object of this paper is to fill up the gap in the classical linear quadratic theory. The key step is the introduction of the set of stabilizable initial conditions. Then a new simple approach to the linear-quadratic problem is presented that provides the connection with the notion of approximate stabilizability for the triplet (A, B, C) .

Key words. linear quadratic, stabilizability, Riccati equation

AMS(MOS) subject classifications. 49A22

1. Introduction. The infinite time, linear quadratic, optimal control theory for infinite-dimensional systems in Hilbert spaces with bounded control and observation operators has been extensively studied (see, for instance, the book by Curtain and Pritchard [1]). Typically, let H (*state space*), U (*control space*), and Y (*observation space*) be three Hilbert spaces. Let $A: D(A) \subset H \rightarrow H$ be the infinitesimal generator of a strongly continuous semigroup e^{tA} and let $B: U \rightarrow H$ and $C: H \rightarrow Y$ be continuous linear operators. The state $x(t)$ at time $t \geq 0$ is given by

$$(1.1) \quad x(t) = e^{tA}h + \int_0^t e^{(t-s)A}Bu(s) ds, \quad t \geq 0,$$

and the cost function by

$$(1.2) \quad J(u, h) = \int_0^\infty \{|Cx(s)|^2 + |u(s)|^2\} ds.$$

Under the standard (A, B, C) stabilizability hypothesis for the triplet (A, B, C) ,

$$(1.3) \quad \forall h \in H, \quad \exists u \in L^2(0, \infty; U) \quad \text{such that } J(u, h) < \infty,$$

it is well known that the corresponding algebraic operator Riccati equation

$$(1.4) \quad A^*P + PA - PBB^*P + C^*C = 0$$

has a minimum positive symmetrical bounded solution \underline{P} ; that is,

$$(1.5) \quad \underline{P}: H \rightarrow H \text{ is linear and continuous (bounded),}$$

$$(1.6) \quad \underline{P}^* = \underline{P} \text{ (symmetry), } \forall h \in H, (\underline{P}h, h) \geq 0 \text{ (positivity),}$$

and for any other solution of (1.4) verifying (1.5) and (1.6)

$$(1.7) \quad \forall h \in H, \quad (Qh, h) \geq (\underline{P}h, h) \text{ (minimality).}$$

The authors have recently constructed examples where the system is not stabilizable, and yet the algebraic Riccati equation has a positive selfadjoint unbounded solution (cf. [2]). This phenomenon is intimately related to the fact that only a dense subset of initial conditions are (A, B, C) stabilizable. This has many interesting implications for infinite-dimensional control systems. For instance, it points out that definitions of stabilizability (here, (A, B, I) stabilizability) that assume the existence of a bounded feedback operator really contain two hypotheses in one: the existence of a feedback operator that stabilizes all initial conditions in H , and the boundedness of this operator. Example 6.1 in § 6 describes a control system that can only be stabilized by an unbounded feedback operator for all initial conditions in H .

The object of this paper is to fill the gap in the theory. Under no stabilizability hypothesis, we a priori define the set Σ of initial states that can be (A, B, C) stabilized and show that it can be given a natural Hilbert space structure. When Σ is dense in the space of initial conditions, we construct the smallest or minimum positive self-adjoint unbounded solution to the algebraic Riccati equation. A new technique is introduced to directly obtain the semigroup associated with the closed loop system and the properties of the feedback operator. If the usual detectability hypothesis is added, we recover that the closed loop system is exponentially stable. Examples are also included to illustrate the theoretical considerations. Extensions to systems with unbounded control and observation operators are possible and will be reported in a forthcoming paper. We felt that it was more instructive to first illustrate the phenomenon and the main features of the theory for the bounded case.

Notation. The space of continuous linear operators from a Hilbert space X to another Hilbert space Y will be denoted by $\mathcal{L}(X; Y)$. When $X = Y$, the cone of continuous linear operators in $\mathcal{L}(X; X)$ verifying conditions (1.5) and (1.6) will be denoted $\Sigma^+(X)$. \mathbf{R} will be the field of all real numbers and \mathbf{N} the set of integers greater than or equal to 1.

2. Problem formulation. Let H, U, Y, A, B , and C be as defined in § 1. Consider the mild solution of the system

$$(2.1) \quad \begin{aligned} x'(s) &= Ax(s) + Bu(s), \quad s \geq 0, \\ x(0) &= h, \end{aligned}$$

and the associated cost function

$$(2.2) \quad J(u, h) = \int_0^\infty \{|Cx(s)|^2 + |u(s)|^2\} ds.$$

A *mild solution* of (2.1) is a continuous function $x: [0, \infty[\rightarrow H$ verifying (1.1). Denote by V the value function

$$(2.3) \quad V(h) = \inf \{J(u, h): u \in L^2(0, \infty; U)\}$$

with domain

$$(2.4) \quad \text{dom } V = \{h \in H: V(h) < \infty\},$$

which will be referred to as the *domain of stabilizability* for the triple (A, B, C) . Observe that under the (A, B, C) stabilizability condition (1.3) $\text{dom } V = H$.

3. An example of unbounded solution to the Riccati equation. Let $H = \ell^2$ be the Hilbert space of all sequences $x = \{x_n\}_{n \in \mathbf{N}}$, with norm

$$(3.1) \quad |x|^2 = \sum_{k=1}^{\infty} x_k^2.$$

Let $\{e_k\}$ be the orthonormal basis in ℓ^2

$$(3.2) \quad (e_k)_n = \delta_{kn}, \quad k \in \mathbf{N}.$$

Define the bounded operators

$$(3.3) \quad Ae_k = \frac{k}{k+1} e_k, \quad Be_k = \frac{\sqrt{2k+1}}{k+1} e_k, \quad k \in \mathbf{N}.$$

Note that their spectra are made up of a point and a continuous part

$$(3.4) \quad \sigma_p(A) = \left\{ \frac{k}{k+1} : k \in \mathbf{N} \right\}, \quad \sigma_c(A) = \{1\},$$

$$(3.5) \quad \sigma_p(B) = \left\{ \frac{\sqrt{2k+1}}{k+1} : k \in \mathbf{N} \right\}, \quad \sigma_c(B) = \{0\}.$$

Associate with A and B the control system

$$(3.6) \quad \begin{aligned} x'(s) &= Ax(s) + Bu(s), \quad s \geq 0, \\ x(0) &= h, \end{aligned}$$

and the cost function

$$(3.7) \quad J(u, h) = \int_0^\infty \{|x(s)|^2 + |u(s)|^2\} ds.$$

Here the observation operator C is the identity operator on H . If the pair (A, B) was stabilizable, there would exist a symmetric positive bounded linear operator P_∞ on H that would be the minimum solution of the algebraic operator Riccati equation

$$(3.8) \quad P_\infty A + A^* P_\infty - P_\infty B B^* P_\infty + I = 0,$$

in the sense of conditions (1.5) and (1.6). Here A , B , and I are diagonal operators, and it is easy to check that the only positive selfadjoint solution to (3.8) is the diagonal unbounded operator

$$(3.9) \quad P_\infty e_k = (k+1) e_k, \quad k \in \mathbf{N}.$$

This means that only initial conditions h in the domain $D(P_\infty^{1/2})$ of $P_\infty^{1/2}$

$$(3.10) \quad \begin{aligned} D(P_\infty^{1/2}) &= \left\{ x \in \ell^2 : \sum_{k=1}^\infty (k+1) x_k^2 < \infty \right\}, \\ P_\infty^{1/2} e_k &= \sqrt{k+1} e_k \end{aligned}$$

can be stabilized, and that for all others

$$(3.11) \quad J(u, h) = \infty, \quad h \notin D(P_\infty^{1/2}).$$

Hence $\text{dom } V = D(P_\infty^{1/2})$ in this example.

The interpretation of this phenomenon is that, for initial conditions $h \notin D(P_\infty^{1/2})$, the corresponding state x cannot be stabilized with a finite energy control u in $L^2(0, \infty; H)$. Yet the closed loop system is given by the operator

$$(3.12) \quad A - B B^* P_\infty = -I,$$

which is exponentially stable in H , and for all h in H the solution x^* of the closed loop system

$$(3.13) \quad \begin{aligned} x'(s) &= [A - B B^* P_\infty] x(s), \quad s \geq 0, \\ x(0) &= h, \end{aligned}$$

is given by $x^*(s) = e^{-s}h$, which belongs to $L^2(0, \infty; H)$, whereas the optimal control u^* is given by

$$(3.14) \quad u^*(s) = -B^*P_\infty x^*(s) = -B^*P_\infty e^{-s}h.$$

So u belongs to $L^2(0, \infty; H)$ if and only if $h \in D(P_\infty^{1/2})$.

Finally, it is useful to note that

$$(3.15) \quad B^*P_\infty e_k = \sqrt{2k+1} e_k, \quad D(B^*P_\infty) = D(P_\infty^{1/2})$$

and that

$$(3.16) \quad BB^*P_\infty e_k = \frac{2k+1}{k+1} e_k, \quad D(BB^*P_\infty) = H.$$

4. Asymptotic behaviour of the solution $P(t)$ to the associated differential operator Riccati equation. It is well known that for any fixed $T > 0$, we can associate with the control problem (2.1)–(2.2) the mild solution $P \in C_s([0, \infty[; \Sigma^+(H))$ of the differential operator Riccati equation

$$(4.1) \quad \begin{aligned} P'(t) &= A^*P(t) + P(t)A - P(t)BB^*P(t) + C^*C \quad \text{in } [0, T], \\ P(0) &= 0. \end{aligned}$$

We say that P in $C_s([0, T]; \Sigma^+(H))$ is a *mild solution* of the Riccati differential equation (4.1) if P verifies the integral equation

$$P(t)x = \int_0^t \{e^{(t-s)A^*} [C^*C - P(s)BB^*P(s)] e^{(t-s)A} x\} ds$$

for all x in H (for example, see Curtain and Pritchard [1] for basic results on existence and uniqueness). We have denoted by $C_s([0, \infty[; \Sigma^+(H))$ the set of all mappings $T: [0, \infty[\rightarrow \Sigma^+(H)$, such that $T(\cdot)x$ is continuous for all $x \in H$.

For each $h \in H$ the function $(P(\cdot)h, h)$ is nondecreasing. Moreover, the following identity holds:

$$(4.2) \quad (P(t)h, h) + \int_0^t |u(s) + B^*P(t-s)x(s)|^2 ds = \int_0^t \{|Cx(s)|^2 + |u(s)|^2\} ds, \quad \forall u \in L_{loc}^2(0, \infty; U).$$

To obtain identity (4.2) fix $t > 0$, multiply both sides of (4.1) evaluated at $t-s$, $t \geq s \geq 0$, by $x(s)$, use (2.1) to eliminate $x'(s)$, and integrate with respect to s from 0 to t .

Define the function

$$(4.3) \quad h \rightarrow \phi(h) = \lim_{t \rightarrow \infty} (P(t)h, h): H \rightarrow [0, \infty].$$

The function ϕ is convex, proper,¹ and lower semicontinuous with domain

$$(4.4) \quad \Sigma = \{h \in H: \phi(h) < \infty\}.$$

LEMMA 4.1. *The following properties are verified:*

- (i) *For all h and k in Σ , $(P(\cdot)h, k)$ is bounded;*
- (ii) *Σ is a vector subspace of H ;*
- (iii) *For all h and k in Σ , the following limit exists*

$$(4.5) \quad \psi(h, k) = \lim_{t \rightarrow \infty} (P(t)h, k).$$

¹ A convex function $f: H \rightarrow [0, \infty]$ is said to be proper if $f(x) < \infty$ for at least one x and $f(x) > -\infty$ for every x (cf. R. T. Rockafellar [7, p. 24]).

Moreover, ψ is a bilinear form on $\Sigma \times \Sigma$ and

$$(4.6) \quad \psi(h, h) = \phi(h), \quad \forall h \in H.$$

Proof. (i) For all h and k in Σ and $t \geq 0$, we have

$$(4.7) \quad |(P(t)h, k)|^2 \leq (P(t)h, h)(P(t)k, k) \leq \phi(h)\phi(k),$$

and the conclusion follows.

(ii) For all h in Σ and λ in \mathbf{R} , $\phi(\lambda h) = \lambda^2 \phi(h)$, and hence $\lambda h \in \Sigma$. For all h and k in Σ

$$(P(t)(h+k), h+k) = (P(t)h, h) + (P(t)k, k) + 2(P(t)h, k)$$

and from (i), $\phi(h+k) \leq [\phi(h)^{1/2} + \phi(k)^{1/2}]^2$. Thus Σ is a linear subspace of H . Part (iii) is an immediate consequence of parts (i) and (ii). \square

Define the following inner product on Σ

$$(4.8) \quad (h, k)_\Sigma = (h, k) + \psi(h, k),$$

which makes it a pre-Hilbert space.

LEMMA 4.2. *The space Σ endowed with the inner product (4.8) is a Hilbert space.*

Proof. It is sufficient to show that Σ is complete with respect to the norm

$$(4.9) \quad |h|_\Sigma = [|h|^2 + \phi(h)]^{1/2}.$$

Let $\{h_n\}$ be a Cauchy sequence in Σ . Then there exists $h \in H$ such that $h_n \rightarrow h$. Moreover, there exists $\lambda \geq 0$ such that

$$(4.10) \quad |h_n|^2 + \phi(h_n) \rightarrow \lambda$$

and

$$(4.11) \quad \phi(h_n) \rightarrow \lambda - |h|^2.$$

By lower semicontinuity of ϕ , we have

$$(4.12) \quad \lambda - |h|^2 = \lim_{n \rightarrow \infty} \phi(h_n) \geq \phi(h),$$

and, by definition of Σ , h belongs to Σ . Finally, for each $\varepsilon > 0$, there exists a positive integer $N(\varepsilon)$ such that

$$|h_n - h_m|_\Sigma^2 = |h_n - h_m|^2 + \phi(h_n - h_m) \leq \varepsilon, \quad \forall m, n \geq N(\varepsilon).$$

As n goes to infinity, we get

$$|h - h_m|^2 + \phi(h - h_m) \leq \varepsilon, \quad \forall m \geq N(\varepsilon),$$

by continuity of the norm in H and lower semicontinuity of ϕ . This shows that $h_n \rightarrow h$ in Σ and completes the proof. \square

We have constructed the space Σ of initial conditions for which the expression $(P(t)h, h)$ has a limit. In general, its closure in H will not be dense, and it will be natural to decompose H as a direct sum

$$(4.13) \quad H = \bar{\Sigma} \oplus \Sigma^\perp,$$

where $\bar{\Sigma}$ is the closure of Σ in H , and Σ^\perp is the orthogonal complement to Σ in H . In the following, we identify the elements of the dual H' of H with those of H . We denote by Σ' the dual of Σ .

PROPOSITION 4.3. Assume that Σ is dense in H . Then there exists a unique linear operator $P_\infty \in \mathcal{L}(\Sigma; \Sigma')$ such that

$$(4.14) \quad \langle P_\infty h, k \rangle_\Sigma = \psi(h, k), \quad \forall h, k \in \Sigma.$$

P_∞ can also be viewed as a closed selfadjoint positive operator on H with dense domain

$$(4.15) \quad D(P_\infty) = \{h \in \Sigma: \psi(h, \cdot) \text{ is continuous in } H\}.$$

We have

$$(4.16) \quad \phi(h) = (P_\infty h, h), \quad \forall h \in D(P_\infty),$$

$$(4.17) \quad \psi(h, k) = (P_\infty h, k), \quad \forall h \in D(P_\infty), \forall k \in H,$$

and the subdifferential of ϕ is given by

$$(4.18) \quad \frac{1}{2}\partial\phi(h) = \begin{cases} P_\infty h, & \text{if } h \in D(P_\infty), \\ \emptyset, & \text{if } h \notin D(P_\infty); \end{cases}$$

that is,

$$\partial\phi(h) = \{p \in H \mid \forall v \in D(P_\infty), \langle p, v \rangle \leq d\phi(h; v)\},$$

where $d\phi(h; v)$ is the Gâteaux semiderivative at h in the direction v .

Moreover, $P_\infty^{1/2}$ is well defined and

$$(4.19) \quad D(P_\infty^{1/2}) = \Sigma = [D(P_\infty), H]_{1/2},$$

where $[X, Y]_{1/2}$ denotes the interpolation space between Y and its dense subspace X (see Lions and Peetre [6] or Lions and Magenes [5] for the theory of interpolation spaces).

Proof. By definition of the inner product on Σ , the symmetrical bilinear form ψ on $\Sigma \times \Sigma$ is continuous, and there exists a unique $P_\infty \in \mathcal{L}(\Sigma; \Sigma')$ such that (4.14) is verified. Moreover, ψ is Σ - H coercive and P_∞ is a self-adjoint operator in H with domain $D(P_\infty)$. Expression (4.18) follows from the fact that ϕ is lower semicontinuous. Hence $\partial\phi(\cdot)$ is maximal monotone on H as a set-valued function. Finally, the positive self-adjoint operator P_∞ has a positive square root $P_\infty^{1/2}$, which is a closed linear operator on H with dense domain $D(P_\infty^{1/2})$, which coincides with Σ . \square

Assume now that Σ is not dense in H , and denote by $\bar{\Sigma}$ the closure of Σ in H . Then we have the following similar result.

COROLLARY. There exists a unique linear operator $P_\infty \in \mathcal{L}(\Sigma; \Sigma')$ such that

$$(4.20) \quad \langle P_\infty h, k \rangle_\Sigma = \psi(h, k), \quad \forall h, k \in \Sigma.$$

P_∞ can also be viewed as a closed selfadjoint positive operator on $\bar{\Sigma}$ with dense domain

$$(4.21) \quad D(P_\infty) = \{h \in \Sigma: \psi(h, \cdot) \text{ is continuous in } \bar{\Sigma}\}.$$

We have

$$(4.22) \quad \phi(h) = (P_\infty h, h), \quad \forall h \in D(P_\infty),$$

$$(4.23) \quad \psi(h, k) = (P_\infty h, k), \quad \forall h \in D(P_\infty), \quad \forall k \in \bar{\Sigma},$$

and the subdifferential of ϕ is given by

$$(4.24) \quad \frac{1}{2}\partial\phi(h) = \begin{cases} P_\infty h, & \text{if } h \in D(P_\infty), \\ \emptyset, & \text{if } h \notin D(P_\infty). \end{cases}$$

Moreover, $P_\infty^{1/2}$ is well defined and

$$(4.25) \quad D(P_\infty^{1/2}) = \Sigma = [D(P_\infty), \bar{\Sigma}]_{1/2}. \quad \square$$

5. Existence of the optimal control and optimal closed loop system. In this section we use the asymptotic properties obtained in § 4 to solve the optimal control problem (2.1)–(2.2). In addition, we study the mapping between the initial conditions and the optimal state and control.

THEOREM 5.1. *The following statements hold:*

(i) *Given any h in H , either $h \notin \Sigma$ and*

$$(5.1) \quad J(u, h) = +\infty, \quad \forall u \in L^2(0, \infty; U) \quad \text{and} \quad V(h) = \phi(h) = +\infty,$$

or $h \in \Sigma$ and there exists a unique optimal control $\hat{u}(\cdot, h)$ in $L^2(0, \infty; U)$ such that

$$(5.2) \quad J(\hat{u}(\cdot, h), h) = V(h) = \phi(h).$$

(ii) *The mapping*

$$(5.3) \quad \Sigma \rightarrow L^2(0, \infty; U), \quad h \rightarrow \hat{u}(\cdot, h)$$

is linear and continuous.

(iii) *Denote by $\hat{x}(\cdot, h)$ the optimal state corresponding to the optimal control $\hat{u}(\cdot, h)$ and set*

$$(5.4) \quad S_\Sigma(t)h = \hat{x}(t, h), \quad t \geq 0, \quad h \in \Sigma.$$

Then $S_\Sigma(\cdot)$ is a strongly continuous semigroup in Σ .

(iv) *Let A_Σ be the infinitesimal generator of $S_\Sigma(\cdot)$. For all $h \in D(A_\Sigma)$, we have that*

$$(5.5) \quad \hat{u}(\cdot, h) \in H^1(0, \infty, U) \quad \text{and} \quad \hat{u}'(\cdot, h) = \hat{u}(\cdot, A_\Sigma h),$$

$$(5.6) \quad C\hat{x}(\cdot, h) \in H^1(0, \infty; Y), \quad \hat{x}'(\cdot, h) = \hat{x}(\cdot, A_\Sigma h), \quad \text{and} \quad D(A_\Sigma) \subset D(A).$$

(v) *For all h in $D(A_\Sigma)$ the map*

$$(5.7) \quad h \rightarrow \hat{u}(0, h) : D(A_\Sigma) \rightarrow U$$

is linear and continuous. Its closure in Σ generates an unbounded linear operator

$$(5.8) \quad K : D(K) \subset \Sigma \rightarrow U \quad \text{such that} \quad D(A_\Sigma) \subset D(K)$$

and

$$(5.9) \quad D(A_\Sigma) = D(A) \cap D(K), \quad A_\Sigma h = Ah + BKh.$$

Moreover, for all h in $D(A_\Sigma)$ and $t \in [0, \infty[$, $\hat{x}(t, h) \in D(A_\Sigma)$,

$$(5.10) \quad A_\Sigma \hat{x}(t, h) = A\hat{x}(t, h) + B\hat{u}(t, h) = [A + BK]\hat{x}(t, h),$$

$$(5.11) \quad \hat{u}(t, h) = K\hat{x}(t, h).$$

(vi) *For all h in $D(A_\Sigma)$,*

$$(5.12) \quad Kh = \lim_{t \rightarrow \infty} -B^*P(t)h,$$

and for all h in Σ and almost all t in $[0, \infty[$

$$\hat{u}(t, h) = K\hat{x}(t, h), \quad \hat{x}(t, h) \in D(K).$$

*When $\bar{\Sigma} = H$ the closure K_∞ of the operator $-B^*P_\infty$ in Σ coincides with K on $D(A_\Sigma)$.*

Proof. (i). By definition of Σ , for all $h \notin \Sigma$ $\lim_{t \rightarrow \infty} (P(t)h, h) = \infty$ and, in view of identity (4.2),

$$(P(t)h, h) \leq J(u, h), \quad \forall u \in L^2(0, \infty; U), \quad \forall t \geq 0.$$

By letting t go to infinity, we obtain (5.1). When $h \in \Sigma$, identity (4.2) yields

$$\phi(h) \leq J(u, h), \quad \forall u \in L^2(0, \infty; U).$$

For each $t > 0$, let (x_t, u_t) be defined by

$$(5.13) \quad \begin{aligned} x_t'(s) &= Ax_t(s) - BB^*P(t-s)x_t(s), \quad \text{in } [0, t], & x_t(0) &= h, \\ u_t(s) &= -B^*P(t-s)x_t(s), \quad \text{in } [0, t]. \end{aligned}$$

The pair (x_t, u_t) is the optimal solution on the interval $[0, t]$. Consider the extension \hat{u}_t of u_t from $[0, t]$ to $[0, \infty[$

$$(5.14) \quad \hat{u}_t(s) = \begin{cases} u_t(s), & \text{if } 0 \leq s \leq t, \\ 0, & \text{if } s > t, \end{cases}$$

and let \hat{x}_t be the corresponding extension of the solution x_t of the state equation on $[0, t]$

$$\hat{x}_t(s) = \begin{cases} x_t(s), & \text{if } 0 \leq s \leq t, \\ 0, & \text{if } s > t. \end{cases}$$

Again by (4.2) and (5.14)

$$(5.15) \quad (P(t)h, h) = \int_0^t \{|Cx_t(s)|^2 + |u_t(s)|^2\} ds \geq \int_0^\infty |\hat{u}_t(s)|^2 ds.$$

Hence for any sequence $\{t_n\}$, $t_n \rightarrow \infty$, the sequence $\{\hat{u}_{t_n}\}$ is bounded in $L^2(0, \infty; U)$. So there exists \hat{u} in $L^2(0, \infty; U)$ and a subsequence of $\{t_n\}$ (still denoted $\{t_n\}$) such that

$$(5.16) \quad \hat{u}_{t_n} \rightarrow \hat{u} \quad \text{in } L^2(0, \infty; U)\text{-weak}.$$

Denote by \hat{x} the solution of

$$(5.17) \quad \hat{x}'(s) = A\hat{x}(s) + B\hat{u}(s), \quad \text{for } s \geq 0, \quad \hat{x}(0) = h.$$

Then for any fixed $T > 0$ and $t_n > T$

$$\hat{u}_{t_n} \rightarrow \hat{u} \quad \text{in } L^2(0, T; U)\text{-weak}, \quad \hat{x}_{t_n} \rightarrow \hat{x} \quad \text{in } L^2(0, T; H)\text{-weak}.$$

For $t_n > T$, however,

$$(P(t_n)h, h) \geq \int_0^T \{|Cx_{t_n}(s)|^2 + |u_{t_n}(s)|^2\} ds$$

and by weak lower semicontinuity

$$\phi(h) \geq \int_0^T \{|C\hat{x}(s)|^2 + |\hat{u}(s)|^2\} ds.$$

As T goes to infinity

$$(5.18) \quad \phi(h) \geq \int_0^\infty \{|C\hat{x}(s)|^2 + |\hat{u}(s)|^2\} ds = J(\hat{u}, h).$$

Combining (5.18) and (5.13) it follows that there exists $\hat{u} = \hat{u}(\cdot, h) \in L^2(0, \infty; U)$ such that

$$J(\hat{u}, h) \leq \phi(h) \leq J(u, h), \quad \forall u \in L^2(0, \infty; U).$$

It follows that $V(h) \leq J(\hat{u}, h) \leq \phi(h) \leq V(h)$. This establishes (5.2). As for the uniqueness of \hat{u} , assume that \hat{u}_1 and \hat{u}_2 are two optimal controls in $L^2(0, \infty; U)$. Then $J(\hat{u}_1, h) = J(\hat{u}_2, h) = V(h)$. So for $\hat{u}_1 \neq \hat{u}_2$

$$\begin{aligned} J((\hat{u}_1 + \hat{u}_2)/2, h) &= \frac{1}{2}[J(\hat{u}_1, h) + J(\hat{u}_2, h)] - J((\hat{u}_1 - \hat{u}_2)/2, h) \\ &= V(h) - J((\hat{u}_1 - \hat{u}_2)/2, h) \leq V(h) - \frac{1}{4}\|\hat{u}_1 - \hat{u}_2\|^2 < V(h), \end{aligned}$$

which contradicts the optimality of \hat{u}_1 and \hat{u}_2 .

(ii) Let \hat{u}_t be defined by (5.13), then

$$(5.19) \quad \|\hat{u}_t\|_{L^2(0, \infty; U)}^2 \leq (P(t)h, h) \leq |h|_{\Sigma}^2.$$

Moreover, since the optimal control is unique, we have proved in part (i) that

$$\lim_{t \rightarrow \infty} \hat{u}_t = \hat{u} \quad \text{in } L^2(0, \infty; U)\text{-weak, for any } h \in \Sigma.$$

We now prove that $\hat{u}_t \rightarrow \hat{u}$ in $L^2(0, \infty; U)$ -strong. By optimality of the pair (x_t, u_t) on $[0, t]$

$$J'(u_t, h) = \inf \{J'(v, h) : v \in L^2(0, \infty; U)\},$$

where

$$J'(v, h) = \int_0^t \{|Cx(s; v)|^2 + |v(s)|^2\} ds.$$

We want to prove that $\lim_{t \rightarrow \infty} J'(u_t, h) = J(\hat{u}, h)$. By definition of the minimizing element u_t on $[0, t]$

$$J'(u_t, h) \leq J'(\hat{u}(\cdot, h), h) = \int_0^t \{|C\hat{x}(s, \hat{u}(\cdot, h))|^2 + |\hat{u}(s, h)|^2\} ds$$

and necessarily

$$\limsup_{t \rightarrow \infty} J'(u_t, h) \leq \int_0^\infty \{|C\hat{x}(s, \hat{u}(\cdot, h))|^2 + |\hat{u}(s, h)|^2\} ds = J(\hat{u}(\cdot, h), h).$$

We have shown in (i) that $\hat{u}_t \rightarrow \hat{u}$ in $L^2(0, \infty; U)$ -weak, and we can show by the same technique that $\{C\hat{x}_t\}$ is bounded in $L^2(0, \infty; Y)$, and that weak subsequences $\{C\hat{x}_{t_n}\}$ converging to some y in $L^2(0, \infty; Y)$ can be extracted as follows:

$$C\hat{x}_{t_n} \rightarrow y, \quad \text{in } L^2(0, \infty; Y)\text{-weak.}$$

By continuity of the state $x(\cdot; u)$ with respect to the control u on a finite time interval $[0, T]$, $T > 0$, the map $u \rightarrow x(\cdot; u) : L^2(0, T; U) \rightarrow L^2(0, T; H)$ is weakly continuous and, finally,

$$u \rightarrow Cx(\cdot; u) : L^2(0, T; U) \rightarrow L^2(0, T; Y)$$

is also weakly continuous. This implies that for all $T > 0$, $y = C\hat{x}(\hat{u}, h)$ in $L^2(0, T; Y)$ and hence in $L^2(0, \infty; Y)$. As a result,

$$\hat{u}_t \rightarrow \hat{u}, \quad \text{in } L^2(0, \infty; U)\text{-weak} \quad \text{and} \quad C\hat{x}_t \rightarrow C\hat{x}, \quad \text{in } L^2(0, \infty; Y)\text{-weak.}$$

The functional

$$(v, y) \rightarrow \int_0^\infty \{|y(s)|^2 + |v(s)|^2\} ds : L^2(0, \infty; U) \times L^2(0, \infty; Y) \rightarrow \mathbf{R}$$

is, however, weakly lower semicontinuous and necessarily

$$\liminf_{t \rightarrow \infty} \int_0^\infty [|C\hat{x}_t|^2 + |\hat{u}_t|^2] ds \geq \int_0^\infty [|C\hat{x}|^2 + |\hat{u}|^2] ds;$$

that is,

$$\liminf_{t \rightarrow \infty} J'(u_t, h) \geq J(\hat{u}, h).$$

Finally,

$$J(\hat{u}, h) \leq \liminf_{t \rightarrow \infty} J'(u_t, h) \leq \limsup_{t \rightarrow \infty} J'(u_t, h) \leq J(\hat{u}, h),$$

and this proves that $\lim_{t \rightarrow \infty} J'(u_t, h) = J(\hat{u}, h)$.

The strong continuity will now be obtained by the following simple computation:

$$\begin{aligned} \|C\hat{x}_t - C\hat{x}\|^2 + \|\hat{u}_t - u\|^2 &= \|C\hat{x}_t\|^2 + \|\hat{u}_t\|^2 + \|C\hat{x}\|^2 + \|\hat{u}\|^2 - 2(C\hat{x}_t, C\hat{x}) - 2(\hat{u}_t, \hat{u}) \\ &= J'(u_t, h) + J(\hat{u}, h) - 2(C\hat{x}_t, C\hat{x}) - 2(\hat{u}_t, \hat{u}). \end{aligned}$$

As t goes to ∞ , $J'(u_t, h) \rightarrow J(u, h)$ and, by weak convergence,

$$(C\hat{x}_t, C\hat{x}) \rightarrow (C\hat{x}, C\hat{x}) = \|C\hat{x}\|^2 \quad \text{and} \quad (\hat{u}_t, \hat{u}) \rightarrow (\hat{u}, \hat{u}) = \|\hat{u}\|^2.$$

So we conclude that

$$\lim_{t \rightarrow \infty} \{\|C\hat{x}_t - C\hat{x}\|^2 + \|\hat{u}_t - u\|^2\} = 2J(\hat{u}, h) - 2[\|C\hat{x}\|^2 + \|\hat{u}\|^2] = 0$$

and that

$$\hat{u}_t \rightarrow \hat{u}, \quad \text{in } L^2(0, \infty; U)\text{-strong} \quad \text{and} \quad C\hat{x}_t \rightarrow C\hat{x}, \quad \text{in } L^2(0, \infty; Y)\text{-strong}.$$

By (5.18) and by the uniform boundedness theorem, it follows that the mapping $h \rightarrow \hat{u}(\cdot, h): \Sigma \rightarrow L^2(0, \infty; U)$ is linear and continuous.

(iii) First, note that, by Bellman's optimality principle, we have $\hat{x}(t, h) \in \Sigma$ for all $h \in \Sigma$ and

$$(5.20) \quad \hat{x}(t+s, h) = \hat{x}(t; \hat{x}(s, h)), \quad \forall t \geq 0, \quad \forall s \geq 0,$$

$$(5.21) \quad V(\hat{x}(t, h)) = \int_t^\infty \{|C\hat{x}(s, h)|^2 + |\hat{u}(s, h)|^2\} ds.$$

Thus $S_\Sigma(t)$ is a linear operator in Σ for all $t \geq 0$. We prove now that $S_\Sigma(t)$ is bounded in Σ . By (5.17) we have

$$(5.22) \quad \hat{x}(t, h) = e^{tA}h + \int_0^t e^{(t-s)A}B\hat{u}(s, h) ds.$$

It follows that for any $T > 0$ there exists $C_T > 0$ such that

$$(5.23) \quad |\hat{x}(t, h)|_H^2 \leq C_T |h|_H^2, \quad 0 \leq t \leq T.$$

Moreover, from (5.21), $\phi(\hat{x}(t, h)) \leq \phi(h)$ and the continuity of $S_\Sigma(t)$ follows. We now prove that $\lim_{t \rightarrow 0} \hat{x}(t, h) = h, \forall h \in \Sigma$. By (5.22) we have $\lim_{t \rightarrow 0} \hat{x}(t, h) = h$ in H . It remains to show that $\hat{x}(t)$ is continuous at $t = 0$ with respect to the seminorm $\phi(h)^{1/2}$. By the linearity of $\hat{x}(\cdot, h)$ and $\hat{u}(\cdot, h)$ in h , we have

$$\phi(\hat{x}(t, h) - h) = \int_0^\infty \{|C\hat{x}(t+s, h) - C\hat{x}(s, h)|^2 + |\hat{u}(t+s, h) - \hat{u}(s, h)|^2\} ds.$$

Since $C\hat{x}(\cdot, h) \in L^2(0, \infty; Y)$ and $\hat{u}(\cdot, h) \in L^2(0, \infty; U)$, we have $\lim_{t \rightarrow 0} \phi(\hat{x}(t, h) - h) = 0$. This proves (iii).

(iv) For any $h \in D(A_\Sigma)$, $\hat{x}(\cdot, h) \in C^1([0, \infty; \Sigma])$ and $\hat{x}'(0, h) = A_\Sigma h$. Denote by $\hat{w}(\cdot) = \hat{u}(\cdot, A_\Sigma h)$ the optimal control corresponding to $A_\Sigma h$. So for all $t > 0$

$$\begin{aligned} \phi \left[\frac{\hat{x}(t, h) - h}{t} - A_\Sigma h \right] &= \int_0^\infty \left\{ \left| \frac{C\hat{x}(t+s, h) - C\hat{x}(s, h)}{t} - C\hat{x}'(s, h) \right|^2 \right. \\ &\quad \left. + \left| \frac{\hat{u}(t+s, h) - \hat{u}(s, h)}{t} - \hat{w}(s) \right|^2 \right\} ds. \end{aligned}$$

As t goes to zero, the first two terms go to zero and necessarily

$$\lim_{t \rightarrow 0} \int_0^\infty \left| \frac{\hat{u}(t+s) - \hat{u}(s)}{t} - \hat{w}(s) \right|^2 ds = 0,$$

which implies $\hat{w} = \hat{u}'$ and $\hat{u} \in H^1(0, \infty; U)$, $\forall h \in D(A_\Sigma)$. By (5.22) we conclude that $h \in D(A)$, and (5.6) follows.

(v) We have shown in (ii) that the map $h \rightarrow \hat{u}(\cdot, h) : \Sigma \rightarrow L^2(0, \infty; U)$ is linear and continuous. In particular,

$$h \rightarrow \hat{u}'(\cdot, h) = \hat{u}(\cdot, A_\Sigma h) : D(A_\Sigma) \rightarrow L^2(0, \infty; U)$$

is also continuous. Hence

$$h \rightarrow \hat{u}(\cdot, h) : D(A_\Sigma) \rightarrow H^1(0, \infty; U)$$

is linear and continuous when $D(A_\Sigma)$ is endowed with the following graph norm topology:

$$\|h\|_{D(A_\Sigma)}^2 = \|h\|_\Sigma^2 + \|A_\Sigma h\|^2.$$

In particular, $\hat{u}(\infty) = 0$, $\hat{u} \in C([0, \infty]; U)$ and the map $h \rightarrow \hat{u}(0, h) : D(A_\Sigma) \rightarrow U$ is linear and continuous. We denote it by K . Equivalently, K is a closed linear unbounded operator from Σ to U with domain

$$D(K) = \{h \in \Sigma : Kh \in U\} \supset D(A_\Sigma).$$

In view of this and identity (5.6)

$$\forall h \in D(A_\Sigma), \quad A_\Sigma h = Ah + B\hat{u}(0, h) = [A + BK]h.$$

Conversely, if $h \in D(A) \cap D(K)$, then

$$A_\Sigma h = Ah + BK h \Rightarrow h \in D(A_\Sigma),$$

and $D(A_\Sigma) = D(A) \cap D(K)$.

(vi) To relate K and the limit of $P(t)$, we go back to formula (4.2) with $h \in \Sigma$, $u = \hat{u}(\cdot, h)$ and $x = \hat{x}(\cdot, h)$:

$$\begin{aligned} (5.24) \quad \langle P(t)h, h \rangle_\Sigma &+ \int_0^t |\hat{u}(s, h) + B^*P(t-s)\hat{x}(s, h)|^2 ds \\ &= \int_0^t \{|C\hat{x}(s, h)|^2 + |\hat{u}(s, h)|^2\} ds. \end{aligned}$$

As t goes to infinity, we obtain

$$\lim_{t \rightarrow \infty} \int_0^t |\hat{u}(s, h) + B^*P(t-s)\hat{x}(s, h)|^2 ds = 0.$$

Setting $P(r) = 0$ for $r \leq 0$, then

$$(5.25) \quad \lim_{t \rightarrow \infty} \int_0^\infty |\hat{u}(s, h) + B^*P(t-s)\hat{x}(s, h)|^2 ds = 0,$$

since

$$\lim_{t \rightarrow \infty} \int_t^\infty |\hat{u}(s, h)|^2 ds = 0.$$

Now repeat the same estimate with $A_\Sigma h$ instead of h and $\hat{x}(\cdot, A_\Sigma h) = \hat{x}'(\cdot, h)$, $\hat{u}(\cdot, A_\Sigma h) = \hat{u}'(\cdot, h)$. Then by the same argument

$$(5.26) \quad \lim_{t \rightarrow \infty} \int_0^\infty |\hat{u}'(s, h) + B^*P(t-s)\hat{x}'(s, h)|^2 ds = 0.$$

Introduce the notation, and use (5.25) and (5.26) as follows:

$$\begin{aligned} v_t(s) &= \hat{u}(s, h) + B^*P(t-s)\hat{x}(s, h), & v_t &\rightarrow 0 \quad \text{in } L^2(0, \infty; U), \\ w_t(s) &= \hat{u}'(s, h) + B^*P(t-s)\hat{x}'(s, h), & w_t &\rightarrow 0 \quad \text{in } L^2(0, \infty; U). \end{aligned}$$

For h in $D(A_\Sigma)$, differentiate (5.24) with respect to t

$$\frac{d}{dt} \langle P(t)h, h \rangle + |\hat{u}(0, h) + B^*P(t)h|^2 + 2 \int_0^t (v_t(s), w_t(s)) ds = |C\hat{x}(t, h)|^2 + |\hat{u}(t, h)|^2.$$

For $t' \geq t$, however,

$$\langle P(t')h, h \rangle - \langle P(t)h, h \rangle \geq 0 \Rightarrow \frac{d}{dt} \langle P(t)h, h \rangle \geq 0,$$

and note that

$$\lim_{t \rightarrow \infty} \int_0^t (v_t(s), w_t(s)) ds = \lim_{t \rightarrow \infty} \int_0^\infty (v_t(s), w_t(s)) ds \rightarrow 0 \quad \text{as } t \rightarrow \infty.$$

Hence

$$\begin{aligned} 0 &\leq \limsup_{t \rightarrow \infty} \frac{d}{dt} \langle P(t)h, h \rangle \leq \limsup_{t \rightarrow \infty} \{|C\hat{x}(t, h)|^2 + |\hat{u}(t, h)|^2\}, \\ 0 &\leq \limsup_{t \rightarrow \infty} |\hat{u}(0, h) + B^*P(t)h|^2 \leq \limsup_{t \rightarrow \infty} \{|C\hat{x}(t, h)|^2 + |\hat{u}(t, h)|^2\}, \end{aligned}$$

and the \liminf are positive. Recall, however, that $C\hat{x}(\cdot, h) \in H^1(0, \infty; Y)$ and $\hat{u}(\cdot, h) \in H^1(0, \infty; U)$, and this implies that $\lim_{t \rightarrow \infty} C\hat{x}(\cdot, h) = 0$ and $\lim_{t \rightarrow \infty} \hat{u}(\cdot, h) = 0$, and the limit of the two terms exists and is equal to 0. So, finally, for all h in $D(A_\Sigma)$ $Kh = \lim_{t \rightarrow \infty} [-B^*P(t)h]$. \square

Remark 5.1. Theorem 5.1 shows that

$$(5.27) \quad V(h) = \phi(h) = V(\hat{x}(0, h)) = \int_0^\infty \{|C\hat{x}(s, h)|^2 + |\hat{u}(s, h)|^2\} ds.$$

Hence $\text{dom } V = \text{dom } \phi = \Sigma$, and Σ coincides with the domain of stabilization of the triple (A, B, C) .

Moreover, by the linearity of $\hat{x}(s, h)$ and $\hat{u}(s, h)$ in h , it follows that

$$(5.28) \quad \psi(h, k) = \int_0^\infty \{(C\hat{x}(s, h), C\hat{x}(s, k)) + (\hat{u}(s, h), \hat{u}(s, k))\} ds, \quad \forall h, k \in \Sigma.$$

6. The algebraic Riccati equation. Recall that we have identified the elements of the dual H' of H with those of H . Our first task is to give a meaning to a solution of the operator algebraic Riccati equation. Let Q be a positive selfadjoint closed linear operator from H to H with a dense domain $D(Q)$. Define

$$(6.1) \quad \Sigma_Q = D(Q^{1/2}) \text{ endowed with its graph norm topology,}$$

$$(6.2) \quad A_Q = A - BB^*Q \text{ on } D(A) \cap D(Q), \text{ and}$$

$$(6.3) \quad \bar{A}_Q = \text{closure of } A_Q \text{ in } \Sigma_Q \text{ (closure of the graph of } A_Q \text{ in } \Sigma_Q \times \Sigma_Q).$$

DEFINITION 6.1. We say that a positive selfadjoint closed linear operator Q with dense domain in H is a solution of the operator algebraic Riccati equation if

- (i) \bar{A}_Q is the infinitesimal generator of a strongly continuous semigroup $\{S_Q(t)\}$ of class C_0 on Σ_Q , and
- (ii) Q verifies the following equation:

$$(6.4) \quad (Qh, Ak) + (Qk, Ah) - (B^*Qh, B^*Qk)_U + (Ch, Ck)_Y = 0, \quad \forall h, k \in D(A) \cap D(Q).$$

DEFINITION 6.2. We say that the triplet (A, B, C) is *approximately stabilizable* (respectively, *stabilizable*) if $\bar{\Sigma} = H$ (respectively, $\Sigma = H$).

Remark 6.1. Note that our definition of approximate stabilizability does not assume the existence of a bounded linear feedback operator. In the literature on the control of infinite dimensional systems, many papers use a definition of stabilizability that assumes the existence of a bounded feedback operator (cf., for instance, Jacobson and Nett [8]). As we will see in Example 6.1, there are simple control systems for which there exists only an unbounded feedback operator, which makes the closed loop system stable for all initial conditions in the state space H . So for infinite dimensional control systems a hypothesis using the existence of a bounded feedback really contains two hypotheses in one. To clarify this question we would have to systematically go over this literature. However, this is not the objective of this paper.

Proposition 6.1. (i) If the triplet (A, B, C) is approximately stabilizable, then the operator P_∞ on H defined by (4.15) is a positive selfadjoint closed linear solution of the operator algebraic Riccati equation (6.4). Moreover, for any other positive selfadjoint closed linear solution Q to (6.4), P_∞ is the minimum solution, that is,

$$(6.5) \quad D(Q^{1/2}) \subset D(P_\infty^{1/2}), \quad \text{and} \quad \forall h \in D(Q), (Qh, h) \geq (P_\infty h, h).$$

(ii) The operator algebraic Riccati equation (6.4) has a positive selfadjoint solution in the sense of Definition 6.1 if and only if the triplet (A, B, C) is approximately stabilizable.

Proof. (i) Recall that from (5.28) for all h and k in $D(A_\Sigma)$

$$\begin{aligned} \langle P_\infty A_\Sigma h, k \rangle &= \int_0^\infty \{(C\hat{x}'(s, h), C\hat{x}(s, k))_Y + (\hat{u}'(s, h), \hat{u}(s, k))_U\} ds, \\ \langle P_\infty h, A_\Sigma k \rangle &= \int_0^\infty \{(C\hat{x}(s, h), C\hat{x}'(s, k))_Y + (\hat{u}(s, h), \hat{u}'(s, k))_U\} ds. \end{aligned}$$

Now $C\hat{x}(\cdot, h)$ and $C\hat{x}(\cdot, k)$ belong to $H^1(0, \infty; Y)$; $\hat{u}(\cdot, h)$ and $\hat{u}(\cdot, k)$ belong to $H^1(0, \infty; Y)$, and their limits as t goes to infinity are 0. Therefore

$$\begin{aligned} \langle P_\infty A_\Sigma h, k \rangle + \langle P_\infty h, A_\Sigma k \rangle &= \int_0^\infty \frac{d}{dt} \{ (C\hat{x}(s, h), C\hat{x}(s, k))_Y + (\hat{u}(s, h), \hat{u}(s, k))_U \} ds \\ &= -(Ch, Ck)_Y - (\hat{u}(0, h), \hat{u}(0, k))_U. \end{aligned}$$

In view of expression (5.10) to (5.12) in Theorem 5.1 we readily obtain (6.4) by specializing to h and k in $D(Q) \cap D(A)$.

Let Q be another positive selfadjoint solution of the operator algebraic Riccati equation (6.4). Then we can rearrange the terms in the following way:

$$\begin{aligned} ([A - BB^*Q]h, Qk) + (Qh, [A - BB^*Q]k) + (B^*Qh, B^*Qk)_U + (Ch, Ck)_Y &= 0, \\ \forall h, k \in D(Q) \cap D(A). \end{aligned}$$

By hypothesis

$$(6.6) \quad (\bar{A}_Q h, Qk) + (Qh, \bar{A}_Q k) + (B^*Qh, B^*Qk)_U + (Ch, Ck)_Y = 0$$

and

$$(B^*Qh, B^*Qk)_U = -[(Ch, Ck)_Y - (Q^{1/2}\bar{A}_Q h, Q^{1/2}k) - (Q^{1/2}h, Q^{1/2}\bar{A}_Q k)].$$

However, $D(Q) \cap D(A) \subset D(\bar{A}_Q)$ and, by linearity and density, the above equation extends to all h and k in $D(\bar{A}_Q)$. In particular, the operator $K_Q = -B^*Q$ has a continuous linear extension $\bar{K}_Q: D(\bar{K}_Q) \subset H \rightarrow U$ such that $D(\bar{K}_Q) \supset D(\bar{A}_Q)$.

For all h in $D(\bar{A}_Q)$,

$$2(\bar{A}_Q S_Q(t)h, Qh) + |B^*Q S_Q(t)h|_U^2 + |C S_Q(t)h|_Y^2 = 0$$

and for all $t \geq 0$

$$|Q^{1/2} S_Q(t)h|^2 + \int_0^t \{ |B^*Q S_Q(s)h|_U^2 + |C S_Q(s)h|_Y^2 \} ds = |Q^{1/2}h|^2.$$

Therefore

$$(6.7) \quad \forall t \geq 0, \quad \forall h \in D(\bar{A}_Q), \quad \int_0^t \{ |u_Q(s)|_U^2 + |C x_Q(s)|_Y^2 \} ds \leq |Q^{1/2}h|^2,$$

where

$$u_Q(s) = -B^*Q x_Q(s) \quad \text{and} \quad x_Q(s) = S_Q(s)h, \quad s \geq 0.$$

Using the monotone increasing property of the integral, inequality (6.7) holds with $t = \infty$ and extends to all h in $D(Q^{1/2})$. Recall that for all h in $\Sigma = D(P_\infty^{1/2})$

$$\int_0^\infty \{ |C\hat{x}(s, h)|^2 + |\hat{u}(s, h)|^2 \} ds = |P_\infty^{1/2}h|^2$$

for the control, and state

$$\hat{u}(s, h) = -B^*Q\hat{x}(s, h) \quad \text{and} \quad \hat{x}(s, h) = S_\Sigma(s)h, \quad s \geq 0.$$

Hence, by minimality of the optimal control $\hat{u}(\cdot, h)$,

$$|P_\infty^{1/2}h|^2 = J(\hat{u}(\cdot, h), h) \leq J(u_Q, h) \leq |Q^{1/2}h|^2$$

and, necessarily, $D(Q^{1/2}) \subset D(P_\infty^{1/2}) = \Sigma$.

(ii) From part (i) we have already established that (6.4) has a positive selfadjoint solution if (A, B, C) is stabilized. Conversely, if Q is a positive selfadjoint solution to the operator algebraic Riccati equation (6.4), then we can repeat the step in part (i) and obtain (6.7), which says that the dense subset $D(\bar{A}_Q)$ of initial conditions is (A, B, C) stabilizable. In particular, $D(\bar{A}_Q) \subset \Sigma$ and $\bar{\Sigma} = H$. \square

Example 6.1. Recall the example in § 3. We have seen that

$$(6.8) \quad H = D(A) = \ell^2, \quad \Sigma = \left\{ h \in \ell^2: \sum_{k=1}^{\infty} (k+1)h_k^2 < \infty \right\}, \quad \bar{\Sigma} = H,$$

$$(6.9) \quad D(P_{\infty}) = \left\{ h \in \ell^2: \sum_{k=1}^{\infty} (k+1)^2 h_k^2 < \infty \right\}, \quad P_{\infty} e_k = (k+1)e_k, \quad k \in \mathbb{N}.$$

Moreover, $D(A_{\Sigma}) = \Sigma$, and K is the closed operator in H

$$(6.10) \quad D(K) = \Sigma, \quad K e_k = \sqrt{2k+1} e_k, \quad k \in \mathbb{N}.$$

The space Σ is the set of all initial conditions that can be stabilized with a finite energy. However, for all h in H

$$(6.11) \quad \int_0^{\infty} |x(s)|_H^2 ds < \infty,$$

and for all h in Σ

$$(6.12) \quad \int_0^{\infty} |x(s)|_{\Sigma}^2 ds = \int_0^{\infty} \{ |x(s)|_H^2 + \langle P_{\infty} x(s), x(s) \rangle_{\Sigma} \} ds \leq c|h|^2.$$

We remark that, in general, the closed loop system is not exponentially stable, as the following example shows.

Example 6.2. Let $H = D(A) = \ell^2$,

$$(6.13) \quad A e_k = 0, \quad B e_k = \frac{1}{k} e_k, \quad C e_k = e_k.$$

Then

$$(6.14) \quad P_{\infty} e_k = k e_k, \quad k \in \mathbb{N},$$

$$(6.15) \quad \Sigma = \left\{ h \in \ell^2: \sum_{k=1}^{\infty} k h_k^2 < \infty \right\}, \quad \bar{\Sigma} = H,$$

$$(6.16) \quad F e_k = (A - B B^* P_{\infty}) e_k = -\frac{1}{k} e_k.$$

Thus F is stable but not exponentially stable both in H and in Σ .

PROPOSITION 6.2. *If the triplet (A, B, C) is approximatively stabilizable and the pair (A^*, C^*) is stabilizable, then*

$$(6.17) \quad \int_0^{\infty} |\hat{x}(t, h)|_H^2 dt < \infty, \quad \text{for all } h \in \Sigma$$

and the triplet (A, B, I) is approximatively stabilizable.

Proof. If (A^*, C^*) is stabilizable, then there exists a minimum positive bounded solution to the Riccati equation

$$(6.18) \quad A Q + Q A^* - Q C^* C Q + I = 0$$

and the closed loop system

$$(6.19) \quad y'(t) = [A^* - C^*CQ]y(t), \quad y(0) = k$$

is L^2 -stable. Denote by $T(t)$ the semigroup associated with the above system. For all h in Σ consider the optimal state $\hat{x}(\cdot, h)$ and control $\hat{u}(\cdot, h)$, then

$$(6.20) \quad \hat{x}'(t, h) = [A^* - C^*CQ]^* \hat{x}(t, h) + QC^*C\hat{x}(t, h) + B\hat{u}(t, h), \quad \hat{x}(0, h) = h$$

and

$$(6.21) \quad \hat{x}(t, h) = T^*(t)h + \int_0^t T^*(t-s)[QC^*C\hat{x}(s, h) + B\hat{u}(s, h)] ds.$$

It follows that

$$\begin{aligned} \|\hat{x}(t; h)\|_{L^2(0, \infty; H)} &\leq \|T^*(\cdot)h\|_{L^2(0, \infty; H)} + \|T^*(\cdot)h\|_{L^2(0, \infty; H)} \|QC^*C\hat{x}(\cdot, h) \\ &\quad + B\hat{u}(\cdot, h)\|_{L^2(0, \infty; H)}. \end{aligned}$$

The right-hand side is finite since T^* is exponentially decreasing, QC^* and B are bounded, and $C\hat{x}(\cdot, h)$ and $\hat{u}(\cdot, h)$ are $L^2(0, \infty; H)$ functions. \square

Remark 6.2. To show the L^2 -stability with respect to the Σ norm, we would have to prove that

$$(6.22) \quad \int_0^\infty \langle P_\infty \hat{x}(t; h), \hat{x}(t, h) \rangle_\Sigma dt = \int_0^\infty \int_t^\infty [|C\hat{x}(s, h)|^2 + |\hat{u}(s, h)|^2] ds dt < \infty.$$

7. A condition for approximative stabilizability. In this section we examine the connection between the (A, B, I) approximative stabilizability and the Hautus condition. We present a set of conditions (Hypothesis 7.1) under which the equivalence is verified (Proposition 7.1). We complete this section with an application of Hypothesis 7.1 to the nerve axon system (Example 7.1).

Hypothesis 7.1. Let A be the infinitesimal generator of an analytic semigroup on H . Denote by $\sigma(A)$ the spectrum of A , and by $\rho(A)$ the resolvent set of A . Assume that the following properties are verified:

- (i) $\sigma(A)$ consists of a convergent sequence $\{\lambda_i\}$ of semisimple² eigenvalues plus the limit point $\lambda_\infty = \lim_{i \rightarrow \infty} \lambda_i$;
- (ii) $\sigma(A) = \sigma^-(A) \cup \sigma^+(A)$, where $\sigma^-(A) = \{\lambda: \operatorname{Re} \lambda < 0\}$ and $\sigma^+(A) = \{\lambda: \operatorname{Re} \lambda > 0\}$. We set $P_+ = 1/(2\pi i) \int_\gamma (\lambda - A)^{-1} d\lambda$, where γ is a suitable curve around $\sigma^+(A)$ and define $P = I - P_+$;
- (iii) Setting $P_i = 1/(2\pi i) \int_{C(\lambda_i, \varepsilon_i)} (\lambda - A)^{-1} d\lambda$, where $C(\lambda_i, \varepsilon_i)$ is a circle in $\rho(A)$, we have $e^{tA}P_+x = \sum_{i=1}^\infty e^{t\lambda_i}P_i x$.

PROPOSITION 7.1. Assume that Hypothesis 7.1 is verified and that $B \in \mathcal{L}(U; H)$. Then the following statements are equivalent:

- (i) The triple (A, B, I) is approximatively stabilizable,
- (ii) $\operatorname{Ker}(B^*) \cap \operatorname{Ker}(A^* - \lambda_i I) = \{0\}$ for all $\lambda_i \in \sigma^+(A)$.

Proof. (i) \Rightarrow (ii). Assume, by contradiction, that (A, B, I) is approximatively stabilizable and that there exists $\lambda \in \sigma(A)$ and h in H , $|h| = 1$, such that $A^*h = \bar{\lambda}h$, $B^*h = 0$. By (A, B, I) approximative stabilizability for any k in Σ there exists a control u in $L^2(0, \infty; U)$ such that the corresponding solution x of (2.1) belongs to $L^2(0, \infty; U)$. Define the function $g(t) = (h, x(t))$. Then g is the solution of the equation

$$g'(t) = \lambda g(t), \quad t \geq 0, \quad g(0) = (h, k) \Rightarrow g(t) = (h, k) e^{\lambda t}, \quad t \geq 0.$$

² An eigenvalue is said to be semisimple if it is an isolated point of the spectrum and a simple pole of the resolvent operator (cf. T Kato [4, p. 41]).

Hence

$$|(h, k)| \int_0^\infty e^{\operatorname{Re} \lambda t} dt = \|g\|_{L^2(0, \infty)} \leq \|h\|_{L^2(0, \infty; U)} < \infty.$$

However,

$$(7.1) \quad \int_0^\infty e^{\operatorname{Re} \lambda t} dt = \infty \Rightarrow \forall k \in \Sigma, \quad (h, k) = 0,$$

and by density of Σ in H , $h = 0$, which is in contradiction with our hypothesis.

(ii) \Rightarrow (i). Let $h \in H$ and $u \in L^2(0, \infty; U)$. We can write the solution of problem (2.1) as

$$(7.2) \quad \begin{aligned} x(t) = & e^{tA} Ph + \int_0^t e^{(t-s)A} P_- Bu(s) ds - \int_t^\infty e^{(t-s)A} P_+ Bu(s) ds \\ & + e^{tA} \left\{ P_+ h + \int_0^\infty e^{-sA} P_+ Bu(s) ds \right\}. \end{aligned}$$

Thus the control u is admissible if and only if $P_+ h + \int_0^\infty e^{-sA} P_+ Bu(s) ds = 0$. Consider now the mapping

$$(7.3) \quad u \rightarrow \gamma(u) = \int_0^\infty e^{-sA} P_+ Bu(s) ds : L^2(0, \infty; U) \rightarrow P_+ H = H_+$$

and its adjoint

$$(7.4) \quad h \rightarrow (\gamma^* h)(s) = B^* e^{-sA^*} h : H_+^* \rightarrow L^2(0, \infty; U).$$

Clearly the triple (A, B, I) is approximatively stabilizable if and only if $\operatorname{Ker}(\gamma^*) = \{0\}$. Now assume that (ii) holds and, by contradiction, that $\operatorname{Ker}(\gamma^*) \neq \{0\}$. In view of Hypothesis 7.1 (iii) for any $h \in \operatorname{Ker}(\gamma^*)$ we have

$$(7.5) \quad B^* e^{-sA^*} h = B^* \sum_{i=1}^\infty e^{-t\lambda_i} P_i^* h = 0,$$

which implies $P_i^* h \in \operatorname{Ker}(B^*)$. Since $P_i^* h \in \operatorname{Ker}(A^* - \lambda_i I)$ (because λ_i is semisimple) we have found a contradiction with (ii). \square

Example 7.1 (The nerve axon system). Let Ω be an open bounded set in \mathbf{R} and consider the system (introduced in [3])

$$(7.6) \quad \begin{aligned} \frac{\partial x_1}{\partial t}(t, \xi) &= \alpha \Delta x_1(t, \xi) + b_{11} x_1(t, \xi) + b_{12} x_2(t, \xi) + \sum_{j=1}^J f_j(t) \phi_j(t, \xi), \\ t > 0, \quad \xi \in \Omega, \\ \frac{\partial x_2}{\partial t}(t, \xi) &= b_{21} x_1(t, \xi) + b_{22} x_2(t, \xi) + \sum_{j=1}^J g_j(t) \psi_j(t, \xi), \quad t > 0, \quad \xi \in \Omega, \\ x_1(0, x) &= h_1(x), \quad \xi \in \Omega, \\ x_2(0, x) &= h_2(x), \quad \xi \in \Omega, \\ x_1(t, \xi) &= 0, \quad x_2(t, \xi) = 0, \quad t > 0, \quad \xi \in \partial\Omega, \end{aligned}$$

where we assume that $\alpha, b_{ij} : \mathbf{R} \rightarrow \mathbf{R}$ are given real numbers, with $\alpha > 0$, $b_{12} b_{21} \neq 0$, and $\phi_1, \dots, \phi_J, \psi_1, \dots, \psi_J \in C(\bar{\Omega})$ are linearly independent functions.

Choose $H = L^2(\Omega) \times L^2(\Omega)$, $U = \mathbf{R}^J \times \mathbf{R}^J$. Setting

$$(7.7) \quad x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad h = \begin{bmatrix} h_1 \\ h_2 \end{bmatrix}, \quad u = \begin{bmatrix} (f_1, \dots, f_J) \\ (g_1, \dots, g_J) \end{bmatrix}, \quad Bu = \begin{bmatrix} \sum_{j=1}^J f_j \phi_j(t, \cdot) \\ \sum_{j=1}^J g_j \psi_j(t, \cdot) \end{bmatrix}$$

and

$$(7.8) \quad b = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix},$$

we can write system (7.6) in the abstract form (2.1). The spectrum $\sigma(A)$ of A consists in two sequences of semisimple eigenvalues $\{\lambda_{\pm}(k)\}_{k \in \mathbf{N}}$ and the accumulation point

$$(7.10) \quad \lambda_{\infty} = b_{22}.$$

The eigenvalues $\lambda_{\pm}(k)$ are defined by

$$(7.11) \quad \lambda_{\pm}(k) = \frac{1}{2}[-\alpha\mu_k + \text{Tr}(b) \pm \sqrt{[-\alpha\mu_k + \text{Tr}(b)]^2 + 4[\alpha\mu_k b_{22} - \det(b)]}],$$

where the μ_k 's are the eigenvalues of the Laplacian with Dirichlet boundary conditions. Now it is easy to check Hypothesis 7.1, so that we can apply Proposition 7.1.

LOCAL CONVERGENCES AND OPTIMAL SHAPE DESIGN*

WENBIN LIU† AND J. E. RUBIO‡

Abstract. Several new concepts dealing with the convergence of convex sets and functionals in various spaces are introduced. Some compactness and lower-semicontinuity results with respect to the convergences are established. Then three general existence results of optimal shapes for variational inequalities are obtained.

Key words. optimal shape design, local convergence, existence theorems, variational convergence, variational inequality

AMS(MOS) subject classification. 49A29

1. Introduction. In [5]–[8] and [11]–[13], some existence results of optimal shape design for partial differential equations and variational inequalities have been established. In that work, the original problem is transformed to establish existence results. However, it is now realized that we can study domain optimization problems directly by introducing some concepts dealing with the convergences in various spaces, and thus establish more general results.

The plan of our paper is as follows. In § 2 we introduce some general results that will be used later, and we treat the local convergences of functionals in various spaces. Then some compactness and lower-semicontinuity results with respect to the convergences are established. In § 3 we introduce and study some new Mosco convergences of closed convex sets in various spaces. Finally, in § 4, as examples of some applications of the new concepts, we establish some general existence results of optimal shapes for variational inequalities, which can cover some results in [5]–[8] and [11]–[13].

2. Notation and preliminaries. In this section, we introduce and prove some results that will be used later.

Let A and B be two subsets of R^m and define δ as follows (see [13]):

$$\delta(A, B) = \max \{ \rho(A, B), \rho(B, A) \}, \quad \text{where } \rho(A, B) = \sup_{x \in A} \inf_{y \in B} \|x - y\|_{R^m}.$$

Then it is well known that δ is a metric on the closed subsets of R^m , the Hausdorff metric. A very useful property is presented in the following theorem.

THEOREM 2.1 ([13]). *Let $\{A_n\}$ be a sequence of closed sets of R^m such that $A_n \subset C$, a bounded closed set of R^m . Then there are a subsequence of $\{A_n\}$, still denoted as $\{A_n\}$, and a closed set $A \subset C$ such that $\delta(A_n, A) \rightarrow 0$.*

By using the metric δ , we can also study the convergence of open sets [13].

DEFINITION 2.1. Let $\{\Omega_n\}$ ($n = 0, 1, \dots$) be a sequence of open sets contained in an open set $C \subset R^m$. We say that $\Omega_n \xrightarrow{C} \Omega_0$ if $\delta(\bar{\Omega}_n, \bar{\Omega}_0) \rightarrow 0$, where $\bar{\Omega}^c \equiv \bar{C} \setminus \Omega$ and \bar{C} is the closure of C in R^m .

It follows from Theorem 2.1 that if $\{\Omega_n\}$ ($n = 1, 2, \dots$), a sequence of open sets in R^m , is contained in C bounded open set of R^m , then there are subsequence of $\{\Omega_n\}$, still denoted as $\{\Omega_n\}$, and a closed F in \bar{C} such that $\delta(\bar{C} \setminus \Omega_n, F) \rightarrow 0$. It is easy to see that $\bar{C} \setminus F$ is open because $\bar{C} \setminus F \subset C$ (note that $\bar{C} \setminus C \subset F$ from Lemma 3.1 [3]) and so $R^m \setminus (\bar{C} \setminus F) = F \cup (R^m \setminus \bar{C})$ is closed. Therefore, there is an open set $\Omega_0 = \bar{C} \setminus F \subset C$ such that $\Omega_n \xrightarrow{C} \Omega_0$.

LEMMA 2.1. Let $\{\Omega_n\}$ ($n=0, 1, \dots$) be a sequence of open sets of R^m , contained in a bounded set of R^m . If $\{\Omega_n\}$ is contained in C , an open set of R^m and $\Omega_n \xrightarrow{C} \Omega_0$, then for any open set $G \Subset \Omega_0$ (that is, \bar{G} is compact and $\bar{G} \subset \Omega_0$), there is $N(G) > 0$ such that $G \subset \Omega_n$ ($n \geq N(G)$) (see the proof of Proposition 3.1 in [13]).

Remark 2.1. We can give another proof for Lemma 2.1 by the fact that $\delta(C \setminus \Omega_n, C \setminus \Omega_0) \geq \rho(x, C \setminus \Omega_0)$ if $x \in G$ and $x \notin \Omega_n$. We also note that C is not necessarily bounded in the above lemma. It follows from this lemma that for any open set $G \Subset \Omega_0$, we find that $N(G) > 0$ such that $G \Subset \Omega_n$ for $n \geq N(G)$ because we find that another open set $G_0 \Subset \Omega_0$ such that $G \Subset G_0$.

We say that the open set sequence $\{\Omega_n\}$ ($n=0, 1, 2, \dots$) has the property G if, for any open set $G \Subset \Omega_0$, there is $N(G) > 0$ such that $G \subset \Omega_n$ ($n \geq N(G)$). Thus, if $\Omega_n \xrightarrow{C} \Omega_0$ ($n=1, 2, \dots$), then $\{\Omega_n\}$ ($n=0, 1, \dots$) has the property G .

It is clear that such a convergence is too weak, as it cannot even guarantee that the Lebesgue measure of Ω_n tends to that of Ω_0 when $\Omega_n \xrightarrow{C} \Omega_0$, and, furthermore, we cannot get much information about $\partial\Omega_0$ from what we know about $\{\partial\Omega_n\}$. So we introduce a stronger convergence.

THEOREM 2.2 ([5], [13]). Let $O_\varepsilon = \{\Omega \text{ open, } \Omega \subset C \text{ a fixed bounded open of } R^m, \text{ and } \Omega \text{ has the } \varepsilon\text{-cone property}\}$ (see [5] and [13]) for some $\varepsilon > 0$. Then O_ε is a compact metric space where the following distance is defined:

$$d_C(A, B) = \delta(A^\varepsilon, B^\varepsilon) + \left(\int_{R^m} |\chi_A - \chi_B| dx \right),$$

where χ_A is the characteristics function of A .

Note that the compactness and the property in Lemma 2.1 for O_ε can be established without introduction of δ (see [5] and [6]).

THEOREM 2.3 ([5]). If $\Omega \in O_\varepsilon$, then it has a Lipschitz boundary and there is an extension operator j_Ω from $H^1(\Omega)$ to $H^1(R^m)$ such that

$$\|j_\Omega u\|_{H^1(R^m)} \leq c \|u\|_{H^1(\Omega)}, \quad \text{for any } u \in H^1(\Omega),$$

where the constant c is independent of Ω .

Remark 2.2. Let C be a fixed open set in R^m with a $W^{r,\infty}$ boundary (see [11]). We can introduce (see [11] and [12]), for $k \geq 1$,

$$O^{k,\infty} \equiv \{T(C); T \in \mathcal{F}^{k,\infty}\},$$

where $\mathcal{F}^{k,\infty} \equiv \{T; T \text{ is a bijective from } R^m \text{ to } R^m \text{ and } I - T, I - T^{-1} \in [W^{k,\infty}(R^m)]^m\}$. It can be shown that for any $k \geq 1$ there is a topology τ on $O^{k,\infty}$, which is finer than the topology given by the distance d_{R^m} in Theorem 2.2, such that any bounded closed sets in $O^{k,\infty}$ are compact in $O^{k-1,\infty}$ (see [11] and [12]). There are some other classes of open sets with topologies finer than that introduced by the distance d_C such that the topology spaces are compact. These classes do not belong to O_ε or $O^{k,\infty}$.

Finally, we introduce some concepts of local convergences that are similar to those in [14] and prove some results on compactness and lower-semicontinuity with respect to the convergences.

DEFINITION 2.2. Assume that $\{\Omega_n\}$ is a bounded set sequence in R^m with the property G and that $u_n \in H^1(\Omega_n)$ for $n=0, 1, 2, \dots$. If the sequence $\{\|u_n\|_{H^1(\Omega_n)}\}$ is bounded and for any open set $G \Subset \Omega_0$, there is $N(G) > 0$ such that $u_n \in H^1(G)$ ($n \geq N$) and $\|u_n - u_0\|_{L^2(G)} \rightarrow 0$ ($\|u_n - u_0\|_{H^1(G)} \rightarrow 0$), then we say that $\{u_n\}$ locally weakly (strongly) converges to u_0 in $H^1(\Omega_0)$, or

$$u_n \xrightarrow{L} u_0 \text{ weakly (strongly) in } H^1(\Omega_0).$$

THEOREM 2.4. *Let $\{\Omega_n\}$ be a sequence of bounded open sets of R^m with the property G and $u_n \in H^1(\Omega_n)$ for $n = 0, 1, \dots$. If for any fixed open set $G \Subset \Omega_0$, the functional $u \rightarrow \int_G h(x, u, \nabla u) dx$ is weakly lower-semicontinuous (l.s.c.) in $H^1(G)$, where h is a nonnegative function measurable on $R^m \times R \times R^m$, then*

$$\int_{\Omega_0} h(x, u_0, \nabla u_0) dx \leq \liminf_{n \rightarrow \infty} \int_{\Omega_n} h(x, u_n, \nabla u_n) dx,$$

if $u_n \xrightarrow{L} u_0$ weakly in $H^1(\Omega_0)$.

Proof. Let $\{G_j\}$ be a sequence of bounded open sets such that $G_j \Subset \Omega_0$, $G_j \subset G_{j+1}$, and $\bigcup_1^\infty G_j = \Omega_0$. Then we see that $\chi_{G_j} \rightarrow \chi_{\Omega_0}$ almost everywhere in R^m . Let $u \xrightarrow{L} u_0$ weakly in $H^1(\Omega_0)$. First, for any fixed G_j , we prove that

$$(2.1) \quad \int_{G_j} h(x, u_0, \nabla u_0) dx \leq \liminf_{n \rightarrow \infty} \int_{G_j} h(x, u_n, \nabla u_n) dx.$$

To this end, let $\{u_{n(k)}\}$, a subsequence of $\{u_n\}$, satisfy

$$\lim_{k \rightarrow \infty} \int_{G_j} h(x, u_{n(k)}, \nabla u_{n(k)}) dx = \liminf_{n \rightarrow \infty} \int_{G_j} h(x, u_n, \nabla u_n) dx.$$

Then we suppose that $u_{n(k)} \rightarrow u_0$ weakly in $H^1(G_j)$ as $\{\|u_n\|_{H^1(\Omega_n)}\}$ is bounded and $u_n \rightarrow u_0$ in $L^2(G_j)$ (note that if $G_j \Subset G$, a bounded open set of R^m , and $u_n \rightarrow u_0$ weakly in $H^1(G)$, then $u_n \rightarrow u_0$ strongly in $L^2(G_j)$ without any assumptions on ∂G_j). So we get (2.1) from the l.s.c. assumption. Next, from Fatou's lemma, we have

$$\begin{aligned} \int_{\Omega_0} h(x, u_0, \nabla u_0) dx &= \int_{\Omega_0} \lim_{j \rightarrow \infty} \chi_{G_j} h(x, u_0, \nabla u_0) dx \\ &\leq \liminf_{j \rightarrow \infty} \int_{G_j} h(x, u_0, \nabla u_0) dx \\ &\leq \liminf_{j \rightarrow \infty} \liminf_{n \rightarrow \infty} \int_{G_j} h(x, u_n, \nabla u_n) dx \\ &\leq \liminf_{j \rightarrow \infty} \liminf_{n \rightarrow \infty} \int_{\Omega_n} h(x, u_n, \nabla u_n) dx \\ &= \liminf_{n \rightarrow \infty} \int_{\Omega_n} h(x, u_n, \nabla u_n) dx, \end{aligned}$$

because for fixed G_j , there is $N > 0$ such that $G_j \subset \Omega_n$ ($n \geq N$) and h is non-negative. \square

COROLLARY 2.1. *Let $\{\Omega_n\}$ ($n = 0, 1, \dots$) be a sequence of bounded open sets in R^m with the property G . Let the nonnegative function h be measurable on $R^m \times R \times R^m$, $h(x, \cdot, \cdot)$ be continuous on $R \times R^m$ and $h(x, t, \cdot)$ be convex. Then*

$$\int_{\Omega_0} h(x, u_0, \nabla u_0) dx \leq \liminf_{n \rightarrow \infty} \int_{\Omega_n} h(x, u_n, \nabla u_n) dx,$$

if $u_n \xrightarrow{L} u_0$ weakly in $H^1(\Omega_0)$.

Proof. It is well known that under the assumption of this corollary, the functional $u \rightarrow \int_G h(x, u, \nabla u) dx$ is weakly l.s.c. in $H^1(G)$ for any fixed bounded open set G in R^m . \square

From Theorem 2.4 we also prove some l.s.c. results in [6] and [14] without the continuity assumption in x , which is restrictive in boundary problems. The following result establishes the weak compactness of the local convergence in H^1 .

THEOREM 2.5. *Let Ω_n be an open set contained in a bounded open set C of R^m for $n=0, 1, \dots$. If $\Omega_n \xrightarrow{c} \Omega_0$, then for any sequence $\{u_n\}$ so that $u_n \in H^1(\Omega_n)$ and $\|u_n\|_{H^1(\Omega_n)} \leq d$, there is a subsequence of $\{u_n\}$, still denoted as $\{u_n\}$, and $u_0 \in H^1(\Omega_0)$, such that $u_n \xrightarrow{L} u_0$ weakly in $H^1(\Omega_0)$.*

Proof. Let G_j ($j=1, 2, \dots$) be the open set such that $G_j \Subset \Omega_0$ for $j=1, 2, \dots$, $G_j \subset G_{j+1}$, and $\bigcup G_j = \Omega_0$. For G_1 there is $\{u_{n_k}^1\}$, a subsequence of $\{u_n\}$, and u_0^1 such that $u_{n_k}^1 \rightarrow u_0^1$ strongly in $L^2(G_1)$, $u_{n_k}^1 \in H^1(\Omega_{n_k}^1)$, $u_0^1 \in H^1(G_1)$, and $\|u_0^1\|_{H^1(G_1)} \leq d$ as $G_1 \Subset \Omega_n$ ($n \geq N(G_1)$) from Lemma 2.1 and Remark 2.1. For G_2 , we also have such $\{u_{n_k}^2\}$, a subsequence of $\{u_{n_k}^1\}$, and u_0^2 such that $u_{n_k}^2 \rightarrow u_0^2$ in $L^2(G_2)$ strongly, $\|u_0^2\|_{H^1(G_2)} \leq d$, and $u_0^2|_{G_1} = u_0^1$, and so on. Let $u_0(x) = u_0^j(x)$ where $x \in G_j$. Then u_0 is well defined and in $L^2(\Omega_0)$, since we have $\|u_0\|_{L^2(G_j)} \leq d$ for any $j=1, 2, \dots$. On the other hand, for any $\varphi \in \mathcal{D}(\Omega_0)$ there is j_0 such that $\varphi \in \mathcal{D}(G_{j_0})$, and thus $\langle \nabla u_0, \varphi \rangle = -\langle \nabla u_j, \varphi \rangle$; that is, $\nabla u_0 = \nabla u_j$ when $x \in G_j$ so that $u_0 \in H^1(\Omega_0)$. Thus put $n_k \equiv n_k^k$ and $u_{n_k} \equiv u_{n_k}^k$ for $k=1, 2, \dots$, and we obtain $u_{n_k} \in H^1(\Omega_{n_k})$ such that $u_{n_k} \in H^1(G_j)$ ($n_k \geq N(G_j)$), $u_{n_k} \rightarrow u_0$ in $L^2(G_j)$ and $\|u_0\|_{H^1(G_j)} \leq d$ for any fixed j . Then for any $G \Subset \Omega_0$ such that $\bar{G} \subset \Omega_0 = \bigcup G_j$, $G \subset G_j$ for a fixed j since $\{G_j\}$ is an open cover of \bar{G} , which is a compact set. Thus, we infer that $u_{n_k} \rightarrow u_0$ strongly in $L^2(G)$. \square

We now turn to the evolution case. Let T be a positive number and the spaces $L^2(0, T; H^1(\Omega))$ be the same as in [9]. For fixed $\theta \geq 0$, let $G^\theta(0, T; H^1(\Omega)) = \{u: u \in L^2(0, T; H^1(\Omega)), t^\theta u' \in L^2(0, T; L^2(\Omega)), \theta \geq 0\}$ with the norm

$$\|u\|_{G^\theta(0, T; H^1(\Omega))} = \left[\int_0^T \|u\|_{H^1(\Omega)}^2 dt + \int_0^T \|t^\theta u'\|_{L^2(\Omega)}^2 dt \right]^{1/2};$$

and let $W(0, T) = \{u \in L^2(0, T; H^1(\Omega)); u' \in L^2(0, T; [H^1(\Omega)]^*)\}$ [9], where $u' = du/dt$ is its vector-valued generalized derivative in [9].

DEFINITION 2.3. Let $\{\Omega_n\}$ ($n=0, 1, \dots$) be a sequence of bounded open sets in R^m with the property G . Let $u_n \in L^2(\kappa, T; H^1(\Omega_n))$ ($\kappa \geq 0$) for $n=0, 1, \dots$. We say that $\{u_n\}$ *locally strongly (weakly) converges* to u_0 in the space $L^2(\kappa, T; H^1(\Omega_0))$, or

$$u_n \xrightarrow{L} u_0 \text{ strongly (weakly) in } L^2(\kappa, T; H^1(\Omega_0)),$$

if $\{\|u_n\|_{L^2(\kappa, T; H^1(\Omega_n))}\}$ is bounded and for any $G \Subset \Omega_0$ there is $N(G) > 0$ such that $u_n \in L^2(\kappa, T; H^1(G))$ after $n \geq N$, and $u_n \rightarrow u_0$ strongly in $L^2(\kappa, T; H^1(G))$ ($L^2(\kappa, T; L^2(G))$).

We now combine the weak compactness and lower-semicontinuity with respect to this convergence in the following theorem.

THEOREM 2.6. *Let $\{\Omega_n\}$ ($n=0, 1, \dots$) be a sequence of bounded open sets in R^m with the property G . Let $\Omega_n \xrightarrow{c} \Omega_0$ and the sequence $\{\|u_n\|_{G^\theta(0, T; H^1(\Omega_n))}\}$ be bounded. Then there are $u_0 \in G^\theta(0, T; H^1(\Omega_0))$ and a subsequence of $\{u_n\}$, still denoted as $\{u_n\}$, such that $u_n \xrightarrow{L} u_0$ weakly in $L^2(\theta\delta, T; H^1(\Omega_0))$ for any fixed $\delta > 0$ and*

$$\int_0^T \int_{\Omega_0} h(t, x, u_0, \nabla u_0) dx dt \leq \liminf_{n \rightarrow \infty} \int_0^T \int_{\Omega_n} h(t, x, u_n, \nabla u_n) dx dt,$$

where h is nonnegative and measurable on $R^+ \times R^m \times R \times R^m$. We suppose that for any fixed $G \Subset \Omega_0$ and $t > 0$, the functional $u \rightarrow \int_G h(t, x, u, \nabla u) dx$ is lower-semicontinuous with respect to $L^2(G)$ convergence in $H^1(G)$.

Proof. By Lions' compactness result in Theorem 5.1 of [10] and a similar method used in the proof of Theorem 2.5, we find that $u_0 \in G^\theta(0, T; H^1(\Omega_0))$ and $u_n \xrightarrow{L} u_0$

weakly in $L^2(\theta\delta, T; H^1(\Omega_0))$ for any $\delta > 0$. Let $\{u_{n_k}\}$ be a subsequence of $\{u_n\}$ such that

$$\lim_{k \rightarrow \infty} \int_0^T \int_{\Omega_{n_k}} h(t, x, u_{n_k}, \nabla u_{n_k}) dx dt = \underline{\lim}_{n \rightarrow \infty} \int_0^T \int_{\Omega_n} h(t, x, u_n, \nabla u_n) dx dt.$$

Then for any $G \Subset \Omega_0$ there is a subsequence of $\{u_{n_k}\}$ (depending on G), still denoted as $\{u_{n_k}\}$, such that $u_{n_k}(t) \rightarrow u_0(t)$ strongly in $L^2(G)$ almost everywhere for $t \in (0, T)$. Therefore, for fixed G ,

$$\int_G h(t, x, u_0, \nabla u_0) dx \leq \underline{\lim}_{n \rightarrow \infty} \int_G h(t, x, u_{n_k}, \nabla u_{n_k}) dx \quad \text{a.e. for } t \in (0, T).$$

Thus, as in the proof of Theorem 2.4,

$$\int_G h(t, x, u_0, \nabla u_0) dx \leq \underline{\lim}_{k \rightarrow \infty} \int_{\Omega_{n_k}} h(t, x, u_{n_k}, \nabla u_{n_k}) dx \quad \text{a.e. for } t \in (0, T).$$

Thus,

$$\begin{aligned} \int_0^T \int_G h(t, x, u_0, \nabla u_0) dx dt &\leq \int_0^T \underline{\lim}_{k \rightarrow \infty} \int_{\Omega_{n_k}} h(t, x, u_{n_k}, \nabla u_{n_k}) dx dt \\ &\leq \underline{\lim}_{k \rightarrow \infty} \int_0^T \int_{\Omega_{n_k}} h(t, x, u_{n_k}, \nabla u_{n_k}) dx dt \\ &= \underline{\lim}_{n \rightarrow \infty} \int_0^T \int_{\Omega_n} h(t, x, u_n, \nabla u_n) dx dt, \end{aligned}$$

due to Fatou's lemma. However, G is any open set such that $G \Subset \Omega_0$. Thus we get our conclusion. \square

Remark 2.3. If $h(t, q, s, p) = h_1(t, q, s)$ and h_1 is nonnegative and continuous with respect to s , then h satisfies all the conditions in Theorem 2.6. On the other hand, if $h(t, q, s, p) = h_2(q, s, p)$, the nonnegative function h_2 is continuous on $R^m \times R \times R^m$, and $h_2(q, s, \cdot)$ is strictly convex in R , then from [14] we see that h satisfies all the conditions in Theorem 2.6.

3. Convergences of convex sets. We now study the convergence of closed convex sets in various spaces. Before doing so, we will first examine a further property of our local convergences, which is important to establish existence of optimal shapes.

3.1. Uniformly absolute continuity. We first note a fact about our local convergences. If $u_n \in H^1(\Omega)$ for $n = 0, 1, \dots$ and $u_n \rightarrow u$ in $H^1(\Omega)$ strongly, then it is known that the sequence of integrals $\{\int_{\Omega} [|u_n|^2 + |\nabla u_n|^2] dx\}$ is uniformly absolutely continuous; that is, for any $\varepsilon > 0$ there is $\delta > 0$ such that

$$\int_E (|u_n|^2 + |\nabla u_n|^2) dx \leq \varepsilon, \quad \text{for } n = 1, 2, \dots \text{ provided } \text{mes}(E) \leq \delta.$$

For our local convergences, however, this is not necessarily true.

Example 3.1. Let $\Omega_0 = \Omega_n = (0, 1)$ for $n = 1, 2, \dots$, $u_0 = 0$, and

$$u_n(t) = \begin{cases} -n/t + 1/n, & 0 < t < 1/n^2 \\ 0 & 1/n^2 \leq t < 1 \end{cases}$$

Then $u_n \xrightarrow{L} u_0$ strongly in $H^1(\Omega_0)$. It is true that $\int_0^{1/n^2} (|u_n|^2 + |\nabla u_n|^2) dt \geq 1$, however.

Because of this, $i_n = \int_{\Omega_n} (\nabla v_n, \nabla u_n) dx$ does not necessarily converge to $i_0 = \int_{\Omega_0} (\nabla v_0, \nabla u_0) dx$, even if $u_n \xrightarrow{L} u_0$ and $v_n \xrightarrow{L} v_0$ strongly in $H^1(\Omega_0)$, and this makes it difficult to establish any existence results for optimal shapes. Thus, we now introduce the following result.

DEFINITION 3.1. Let $u_n \in H^1(\Omega_n)$ for $n = 1, 2, \dots$. We say that $\{u_n\}$ is *uniformly absolutely continuous* (U.A.C.) if

$$\int_{E_n} (|u_n|^2 + |\nabla u_n|^2) dx \rightarrow 0,$$

where the measurable sets $E_n \in \Omega_n$ for $n = 1, 2, \dots$, and $\text{mes}(E_n) \rightarrow 0$. We have a similar definition for $u_n \in L^2(\kappa; T; H^1(\Omega_n))$ ($\kappa \geq 0$); $\{u_n\}$ is U.A.C. if $\int_{\kappa}^T \int_{E_n} [|u_n|^2 + |\nabla u_n|^2] dx dt \rightarrow 0$, where E_n satisfies the same conditions. In the same way, we say that $\{u_n\}$ is *weakly uniformly absolutely continuous* if $\int_{E_n} (|u_n|^2 + |\nabla u_n|^2) dx$ (or $\int_{\kappa}^T \int_{E_n} [|u_n|^2 + |\nabla u_n|^2] dx dt$) is replaced by $\int_{E_n} |u_n|^2 dx$ (or $\int_{\kappa}^T \int_{E_n} |u_n|^2 dx dt$) in the above definition.

Example 3.2. If $\Omega_n \subset C$ and there is an extension operator j_n from $H^1(\Omega_n)$ to $H^1(C)$ ($n = 1, 2, \dots$) such that $\sup_n \|j_n\| < \infty$ [5], where C is a bounded open set of R^m with a Lipschitz boundary, then for any $\{u_n\}$ with $u_n \in H^1(\Omega_n)$ for $n = 1, 2, \dots$, which is locally weakly convergent to an element in $H^1(\Omega_0)$, there is $\{u_{n_k}\}$, a subsequence of $\{u_n\}$, such that it is weakly U.A.C. To see this, we note that $j_{n_k} u_{n_k} \rightarrow u_0$ in $L^2(C)$ strongly (see [1]) and $\int_{E_{n_k}} |u_{n_k}|^2 dx \leq \int_{E_{n_k}} |j_{n_k} u_{n_k}|^2 dx \rightarrow 0$, while $\text{mes}(E_{n_k}) \rightarrow 0$. In fact, we can prove that $\{u_n\}$ itself is weakly U.A.C. To do this, we just note that from Sobolev's embedding results [1] (note that C is bounded), there is $\delta > 0$, $\rho > 1$ such that

$$\left(\int_C |j_n u_n|^{2\rho} dx \right)^{1/2\rho} \leq \delta \|j_n u_n\|_{H^1(C)} \leq \delta \sup_n \|j_n\| \|u_n\|_{H^1(\Omega_n)},$$

so that

$$\int_{E_n} |u_n|^2 dx = \int_{E_n} |j_n u_n|^2 dx \leq \left(\int_C |j_n u_n|^{2\rho} dx \right)^{1/\rho} \left(\int_{E_n} dx \right)^{1-1/\rho}.$$

Thus $\{u_n\}$ is weakly U.A.C.

On the other hand, we can prove a similar conclusion for $\{u_n\}$ with $u_n \in G^\theta(0, T; H^1(\Omega_n))$; that is, $\int_0^T \int_{E_n} u_n^2 dx dt \rightarrow 0$ ($E_n \subset \Omega_n$), provided $\{\|u_n\|_{G^\theta(0, T; H^1(\Omega_n))}\}$ is bounded and $\text{mes}(E_n) \rightarrow 0$, because

$$\begin{aligned} \int_0^T \int_{E_n} u_n^2 dx dt &= \int_0^T \int_{E_n} (j_n u_n)^2 dx dt \\ &\leq \int_0^T \int_C \|j_n u_n\|_{L^{2\rho}(C)}^2 dx dt \text{mes}(E_n)^{1-1/\rho} \\ &\leq \delta \sup_n \|j_n\| \text{mes}(E_n)^{1-1/\rho} \int_0^T \int_{\Omega_n} \|u_n\|_{H^1(\Omega_n)}^2 dx dt. \end{aligned}$$

Finally, we note a useful fact: the operator J_n , $(J_n u)(t, x) = (j_n u(t, \circ))(x)$ is also an extension operator from $G^\theta(0, T; H^1(\Omega_n))$ to $G^\theta(0, T; H^1(C))$ for $n = 1, 2, \dots$, and $\{\|J_n\|\}$ is bounded if j_n is also an extension operator from $L^2(\Omega_n)$ to $L^2(C)$ with $\sup_n \|j_n\|_{\mathcal{L}(L^2(\Omega_n), L^2(C))} < \infty$. To see this, we must note that $J_n u$ is strongly measurable to $t > 0$,

$$\int_0^T \|J_n u\|_{H^1(C)}^2 dt \leq \int_0^T \|j_n\| \|u\|_{H^1(\Omega_n)}^2 dt,$$

and

$$\int_0^T \|t^\theta (j_n u_n)'\|_{L^2(C)}^2 dt \leq \int_0^T \|j_n\|_{\mathcal{L}(L^2(\Omega_n), L^2(C))} \|t^\theta u_n'\|_{L^2(\Omega_n)}^2 dt.$$

Remark 3.1. It can be proved by the integral transform formula that if $\{\Omega_n\}$ is bounded in $O^{k,\infty}(k \geq 1)$ and $\{\|u_n\|_{H^1(\Omega_n)}\}$ is bounded, then $\{u_n\}$ is weakly U.A.C.

3.2. Local Mosco convergence. We now give a definition of the convergence of convex sets in some various spaces, similar to the Mosco convergence in [2].

DEFINITION 3.2. Let $\{\Omega_n\}$ ($n = 0, 1, \dots$) be a sequence of bounded open sets in R^m with the property G . Let K_n be a nonempty closed convex set in $H^1(\Omega_n)$ for $n = 0, 1, \dots$. We say that $\{K_n\}$ *locally Mosco converges* to K_0 in $H^1(\Omega_0)$ (denoted as $K_n \xrightarrow{LM} K_0$ in $H^1(\Omega_0)$), if and only if

- (i) $U \in K_0$, provided there is $\{n_k\}$, a subsequence of $\{n\}$, such that $u_{n_k} \in K_{n_k}$ and $u_{n_k} \xrightarrow{L} u$ weakly in $H^1(\Omega_0)$.
- (ii) For any $u \in K_0$, there are $u_n \in K_n$ ($n = 1, 2, \dots$) such that $u_n \xrightarrow{L} u$ strongly in $H^1(\Omega_0)$, and $\{u_n\}$ is U.A.C.

It is clear that even if $\Omega_n = \Omega_0$, $n = 1, 2, \dots$, this concept is not the same as the Mosco convergence of closed convex sets in [2]. To see this, we take $\Omega_n = \Omega_0 = (0, 1)$ and $K_n = K_0 = \{u \in H^1(\Omega_0); u|_{\partial\Omega_0} \geq 0\}$. Then it follows that K_n Mosco converges to K_0 . It is easy to find $u_n \in K_n$ such that $u_n \xrightarrow{L} -1$ weakly in $H^1(\Omega_0)$, which is not in K_0 .

In the following examples, $O_\varepsilon = \{\Omega: \Omega \text{ open}, \Omega \subset C \text{ a bounded open set of } R^m \text{ with a Lipschitz boundary, } \Omega \text{ has the } \varepsilon\text{-cone property for a fixed } \varepsilon > 0\}$, $\Omega_n \in O_\varepsilon$ ($n = 0, 1, \dots$), and $\Omega_n \rightarrow \Omega_0$ in the distance $d_C(\cdot, \cdot)$.

Example 3.3. Let $K_n = H^1(\Omega_n)$ for $n = 0, 1, \dots$. We prove that $K_n \xrightarrow{LM} K_0$ in $H^1(\Omega_0)$. First, if $u_{n_k} \in K_{n_k}$ and $u_{n_k} \xrightarrow{L} u$ weakly in $H^1(\Omega_0)$, then $u \in H^1(\Omega_0)$. Next, for any $u \in H^1(\Omega_0)$, let j_0 be an extension operator from $H^1(\Omega_0)$ to $H^1(C)$ and $\{u_n\} = \{j_0 u|_{\Omega_n}\}$, which is U.A.C. Then, from $G \subset \Omega_n$ ($n \geq N$) for any fixed $G \Subset \Omega_0$ (see § 2), we see that $u_n \xrightarrow{L} u$ strongly in $H^1(\Omega_0)$.

Example 3.4. Let $K_n = H_0^1(\Omega_n)$ for $n = 0, 1, \dots$. If $u_{n_k} \rightarrow u_0$ with $u_{n_k} \in H^1(\Omega_{n_k})$, it follows that $u_0 \in H_0^1(\Omega_0)$ by passing the limits in $(\chi(\Omega_{n_k}) - 1)u_{n_k} = 0$ and by using the fact that $\chi(\Omega_n) \rightarrow \chi(\Omega_0)$ in $L^2(R^m)$ strongly and $\partial\Omega_0$ is Lipschitz, where \underline{u}_n is the zero extension of u_n on R^m . Let $u \in H_0^1(\Omega_0)$. Then there are $v_n \in \mathcal{D}(\Omega_0)$ such that $v_n \rightarrow u$ strongly in $H_0^1(\Omega_0)$. For any v_i , there is an integer $N_i > 0$ such that $v_i \in H_0^1(\Omega_j)$ ($j \geq N_i$) and $N_{i+1} > N_i$ because v_i has a compact support in Ω_0 . We now take $u_j = v_i$ if $N_i \leq j < N_{i+1}$, where $j = N_1, N_j + 1, \dots$. Then we construct $\{u_n\}$ such that $u_n \in H_0^1(\Omega_n)$ and $u_n \xrightarrow{L} u$ strongly in $H_0^1(\Omega_0)$. We see that $K_n \xrightarrow{LM} K_0$ in $H^1(\Omega_0)$ if we can prove that $\{u_n\}$ obtained above is U.A.C. To this end, we must note that $\{u_n\} \subset \mathcal{D}(\Omega_0)$ and $u_n \rightarrow u$ in $H_0^1(\Omega_0)$ implies that $\underline{u}_n \rightarrow \underline{u}$ in $H_0^1(C)$, where \underline{u} is the zero extension of u on C .

Example 3.5. Let $K_n = \{u: u \in H_0^1(\Omega_n), u \geq 0 \text{ almost everywhere in } \Omega_n\}$ for $n = 0, 1, \dots$. We now prove that $K_n \xrightarrow{LM} K_0$ in $H^1(\Omega_0)$. First, if $u_{n_k} \in K_{n_k}$ and $u_{n_k} \xrightarrow{L} u$, then we see that for any $G \Subset \Omega_0$, $u|_G \geq 0$ so that $u \in K_0$. Next, for any $u \in K_0$, from Example 3.4, there are $u_n \in H_0^1(\Omega_n)$ such that $u_n \rightarrow u$ in $H^1(G)$ strongly for any $G \Subset \Omega_0$ and $\{\|u_n\|_{H^1(\Omega_n)}\}$ is bounded. Let $\underline{u}_n = \max(u_n, 0) \in K_n$. Then from [4], we know that $\underline{u}_n \rightarrow u$ strongly in $H^1(G)$ since $u \geq 0$ and that $\|\underline{u}_n\|_{H^1(\Omega_n)} \leq \|u_n\|_{H^1(\Omega_n)}$. On the other hand, from the inequality

$$\int_{E_n} (|\underline{u}_n|^2 + |\nabla \underline{u}_n|^2) dx \leq \int_{E_n} (|u_n|^2 + |\nabla u_n|^2) dx$$

and the fact that $\{u_n\}$ is U.A.C. (see Ex. 3.4), we see that $\{\underline{u}_n\}$ is U.A.C., also.

By the same method we can prove that $K_n \xrightarrow{LM} K_0$, where $K_n = \{u: u \in H^1(\Omega_n), u \geq \varphi \text{ almost everywhere in } \Omega_n, \Phi \in H^1(R^n)\}$ or $K_n = \{u: u \in H^1(\Omega_n), |u| \leq 1 \text{ almost everywhere in } \Omega_n\}$ for $n = 0, 1, \dots$.

Example 3.6. Let $K_n = \{u: u \in H^1(\Omega_n), \int_{\Omega_n} |\nabla u| dx \leq 1\}$ for $n = 0, 1, 2, \dots$. We prove here that $K_n \xrightarrow{LM} K_0$. First, if $u_{n_k} \xrightarrow{L} u$ weakly in $H^1(\Omega_0)$, then for any $G \Subset \Omega_0$, $u_{n_k} \rightarrow u$ weakly in $H^1(G)$. Thus, $\int_G |\nabla u| dx \leq 1$; that is, $u \in K_0$. Next, for any $u \in K_0$, let $\underline{u} = j_0 u$, where j_0 is an extension operator from $H^1(\Omega_0)$ to $H^1(C)$. We then have

$$\int_{\Omega_n} |\nabla \underline{u}| dx \leq \int_{\Omega_0} |\nabla u| dx + \int_{\Omega_n \setminus (\Omega_n \cap \Omega_0)} |\nabla \underline{u}| dx \leq 1 + \varepsilon_n,$$

where $\varepsilon_n \rightarrow 0$ because $\chi_{\Omega_n} \rightarrow \chi_{\Omega_0}$ strongly in $L^2(R^m)$, as seen before. Let $u_n = \underline{u}_n / 1 + \varepsilon_n \in K_n$, where $\underline{u}_n = \underline{u}|_{\Omega_n}$. Then, we have that $u_n \rightarrow u$ strongly in $H^1(G)$ for any $G \Subset \Omega_0$, and $\{u_n\}$ is U.A.C.

In a similar method, we show that $K_n \xrightarrow{LM} K_0$ in $H^1(\Omega_0)$, where $K_n = \{u: u \in H_0^1(\Omega_n), |\nabla u| \leq 1 \text{ almost everywhere in } \Omega_n\}$ for $n = 0, 1, \dots$.

Remark 3.2. It can easily be proved that the conclusions for Examples 3.3–3.6 still hold if we replace the condition $\{\Omega_n\} \subset O_\varepsilon$ and $\Omega_n \rightarrow \Omega_0$ in the distance d_C , by $\{\Omega_n\} \subset O^{k,\infty}$ and $\Omega_n \rightarrow \Omega_0$ in $O^{k,\infty}$ ($k \geq 1$). We can also prove the conclusions for some other classes of open sets by the fact that $\Omega_n \xrightarrow{L} \Omega_0$ and $\chi_{\Omega_n} \rightarrow \chi_{\Omega_0}$ as $\Omega_n \rightarrow \Omega_0$ (see Remark 2.2).

We now study the evolution case. First, we give the following definition.

DEFINITION 3.3. Let $\{\Omega_n\}$ ($n = 0, 1, \dots$) be a sequence of bounded open sets in R^m with the property G . Let K_n be a nonempty close convex set in the space $L^2(0, T; H^1(\Omega_n))$ for $n = 0, 1, \dots$. We say that $\{K_n\}$ *locally Mosco converges* to K_0 in $L^2(0, T; H^1(\Omega_0))$ (to be denoted as $K_n \xrightarrow{LM} K_0$ in $L^2(0, T; H^1(\Omega_0))$) if

(i) $u \in K_0$ provided there is $\{u_{n_k}\}$, where $\{n_k\}$ is a subsequence of $\{n\}$, such that $u_{n_k} \in K_{n_k}$ and $u_{n_k} \xrightarrow{L} u$ weakly in $L^2(0, T; H^1(\Omega_0))$.

(ii) For any $u \in K_0$, there are $u_n \in K_n$ ($n = 1, 2, \dots$) such that $u_n \xrightarrow{L} u$ strongly in $L^2(0, T; H^1(\Omega_0))$ and $\{u_n\}$ is U.A.C.

Example 3.7. Let $K_n = L^2(0, T; H^1(\Omega_n))$ for $n = 0, 1, \dots$. As in Example 3.3, we can prove that $K_n \xrightarrow{LM} K_0$ in $L^2(0, T; H^1(\Omega_0))$ if we note that there is an extension operator $J: L^2(0, T; H^1(\Omega_0))$ to $L^2(0, T; H^1(R^n))$. To see this, let j_0 be an extension operator from $H^1(\Omega_0)$ to $H^1(C)$ and $(J_0 u)(t, x) = [j_0 u(t, x)](x)$. Then, J_0 is one from $L^2(0, T; H^1(\Omega_0))$ to $L^2(0, T; H^1(R^m))$, as in Example 3.2. We can also prove a similar conclusion for $K_n = L^2(0, T; H_0^1(\Omega_n))$ for $n = 0, 1, 2, \dots$ if we note that $\mathcal{D}((0, T) \times \Omega_0)$ is dense in $L^2(0, T; H_0^1(\Omega_0))$ and $(0, T) \times \Omega_n \xrightarrow{(0, T) \times C} (0, T) \times \Omega_0$ as $\Omega_n \xrightarrow{C} \Omega_0$.

Example 3.8. Let $K_n = \{u: u \in L^2(0, T; H^1(\Omega_n)), u \geq \psi \text{ almost everywhere, where } \psi \text{ is in } L^2(0, T; H^1(R^n))\}$. We now prove that $K_n \xrightarrow{LM} K_0$ in $L^2(0, T; H^1(\Omega_0))$. If $u_n \in K_n$ and $u_n \xrightarrow{L} u$ weakly in $L^2(0, T; H^1(\Omega_0))$, then for any $G \Subset \Omega_0$, $u_n \rightarrow u$ weakly in $L^2(0, T; L^2(G))$. Thus $u \geq \psi$ almost everywhere in $(0, T) \times \Omega_0$; that is, $u \in K_0$. Next, for any $u \in K_0$, let $u_n = \max(J_0 u, \psi)|_{\Omega_n} \in K_n$ for $n = 1, 2, \dots$. Then, for any $G \Subset \Omega_0$, there is $N > 0$ such that $u_n \in L^2(0, T; H^1(G))$ ($n \geq N(G)$) and $u_n \rightarrow u$ strongly in $L^2(0, T; H^1(G))$ because there is $N(G) > 0$ such that $G \subset \Omega_n$ ($n \geq N(G)$). It is clear that $\{u_n\}$ is U.A.C.

In the same way, we can also prove that $K_n \xrightarrow{LM} K_0$, where $K_n = \{u: u \in L^2(0, T; H_0^1(\Omega_n)), u \geq \psi, \psi \leq 0, \psi \in L^2(0, T; H^1(R^m))\}$.

Remark 3.3. For Examples 3.7 and 3.8, we have the same remark as Remark 3.2.

4. Existence of optimal shape design for variational inequalities. In this section, \mathcal{B} will be a class of bounded open sets in R^m , which are contained in a fixed bounded open set. We further suppose that there is an open set C of R^m and a topology τ on

\mathcal{B} , which is finer than the topology given by the distance d_C , such that (\mathcal{B}, τ) is compact in the sense that every sequence in \mathcal{B} has a convergent subsequence. Let K_Ω be a nonempty closed convex set in $H^1(\Omega)$ for any $\Omega \in \mathcal{B}$. For any $u, v \in H^1(\Omega)$, let

$$a(u, v) = \int_{\Omega} [(A(x)\nabla u(x), \nabla v(x))_{R^m} + a(x)u(x)v(x)] dx,$$

$$(f, u) = \int_{\Omega} f(x)u(x) dx,$$

where $A \in [L^\infty(R^m)]^{m \times m}$ is a positive matrix, $a \in L^\infty(R^m)$, $a(x) \geq 0$, and $f \in L^2(R^m)$. We suppose that $a(u, u)$ is uniformly coercive; that is, $a(u - v, u - v) \geq c\|u - v\|_{H^1(\Omega)}^2$ for any $u, v \in K_\Omega$, where the constant c is independent of Ω .

4.1. Existence of optimal shape design for elliptic variational inequalities. We now consider the following optimal shape design problem (OSD):

$$\min_{\Omega \in \mathcal{B}} \int_{\Omega} g(x, u, \nabla u) dx,$$

subject to

$$(4.1) \quad a(u, v - u) \geq (f, v - u), \quad u \in K_\Omega, \text{ for every } v \in K_\Omega,$$

where g is a nonnegative measurable function on $R^m \times R \times R^m$, $g(x, t, \cdot)$ is convex on R^m , and $g(x, \cdot, \cdot)$ is continuous on $R \times R^m$.

We now give a general existence result for the optimal shapes.

THEOREM 4.1. *If $K_{\Omega_n} \xrightarrow{LM} K_{\Omega_0}$ when $\Omega_n \rightarrow \Omega_0$ in the topology τ , then (OSD) has at least one solution.*

Proof. Let $\{\Omega_n\}$ ($n = 1, 2, \dots$) be a minimizing sequence of (OSD) and u_n be the solution of (4.1) on Ω_n . From the condition, we know that there is a subsequence of $\{\Omega_n\}$, still denoted as $\{\Omega_n\}$, and $\Omega_0 \in \mathcal{B}$ such that $\Omega_n \rightarrow \Omega_0$ in the topology τ . Thus $\Omega_n \xrightarrow{C} \Omega_0$ and $\chi_{\Omega_n} \rightarrow \chi_{\Omega_0}$ strongly in $L^1(R^m)$ (so in $L^2(R^m)$). From

$$(4.2) \quad a(u_n, v - u_n) \geq (f, v - u_n), \quad u_n \in K_{\Omega_n}, \text{ for all } v \in K_{\Omega_n},$$

Schwartz's inequality, and the uniform coercivity of $a(\cdot, \cdot)$, we see that there is $M > 0$ such that

$$c\|u_n - v\|_{H^1(\Omega)}^2 \leq a(u_n - v, u_n - v) \leq (M\|v\|_{H^1(\Omega)} + \|f\|_{L^2(R^m)})\|u_n - v\|_{H^1(\Omega)},$$

for any $v \in K_{\Omega_n}$. Let v_0 be a fixed element in K_{Ω_0} and $v_n \xrightarrow{L} v_0$ strongly in $H^1(\Omega_0)$ with $v_n \in K_{\Omega_n}$. We see that $\{\|v_n\|_{H^1(\Omega_n)}\}$ is bounded and thus, by letting $v = v_n$ for $n = 1, 2, \dots$ in the inequalities above, it follows that $\{\|u_n\|_{H^1(\Omega_n)}\}$ is also bounded. By Theorem 2.5, we know that there are $u_0 \in H^1(\Omega_0)$ and a subsequence of $\{u_n\}$, still denoted as $\{u_n\}$, such that $u_n \xrightarrow{L} u_0$ weakly in $H^1(\Omega_0)$. We now show that u_0 is the solution of (4.1) on Ω_0 . To this end, we first note that $u_0 \in K_{\Omega_0}$ because $K_{\Omega_n} \xrightarrow{LM} K_{\Omega_0}$. For the same reason, for any $v \in K_{\Omega_0}$, there are $v_n \in K_{\Omega_n}$ such that $v_n \xrightarrow{L} v$ strongly in $H^1(\Omega_0)$. Next, for any $\varepsilon > 0$ there are $G \Subset \Omega_0$ and $N > 0$ such that $G \Subset \Omega_n$ and $\text{mes}(\Omega_0 \setminus G) + \text{mes}(\Omega_n \setminus G) \leq \varepsilon$ for $n \geq N$ because $\chi_{\Omega_n} \rightarrow \chi_{\Omega_0}$ strongly in $L^2(R^m)$. For such fixed $G \Subset \Omega_0$,

$$(4.3) \quad \lim_{n \rightarrow \infty} \int_G f(u_n - v_n) dx = \int_G (f, u_0 - v) dx,$$

$$(4.4) \quad \lim_{n \rightarrow \infty} \int_G [(A\nabla u_n, \nabla v_n)_{R^m} + au_nv_n] dx = \int_G [(A\nabla u_0, \nabla v)_{R^m} + au_0v] dx,$$

for any $v \in K_{\Omega_0}$, where $u_n \xrightarrow{L} u_0$ weakly, $v_n \xrightarrow{L} v$ strongly in $H^1(\Omega_0)$, and $\{v_n\}$ is U.A.C. We now estimate $j_1 = |\int_{\Omega_n \setminus G} [(A \nabla u_n, \nabla v_n) a u_n v_n] dx|$ and $j_2 = |\int_{\Omega_n \setminus G} f(u_n - v_n) dx|$. We see that j_2 can be arbitrary small since

$$j_2 \leq \|f\|_{L^2(\Omega_n \setminus G)} (\|u_n\|_{L^2(\Omega_n \setminus G)} + \|v_n\|_{L^2(\Omega_n \setminus G)}).$$

From the fact that $\{v_n\}$ is U.A.C. and from the same reasons as above, we also know that j_1 can be arbitrarily small from Schwartz's inequality. Combining (4.3) and (4.4), we get

$$(4.5) \quad \int_{\Omega_0} f(v - u_0) dx = \lim_{n \rightarrow \infty} \int_{\Omega_n} f(v_n - u_n) dx,$$

$$(4.6) \quad \int_{\Omega_0} [(A \nabla u_0, \nabla v) + a u_0 v] dx = \lim_{n \rightarrow \infty} \int_{\Omega_n} [(A \nabla u_n, \nabla v_n) + a u_n v_n] dx.$$

On the other hand, from Corollary 2.1,

$$\int_{\Omega_0} [(A \nabla u_0, \nabla u_0) + a u_0 u_0] dx \leq \lim_{n \rightarrow \infty} \int_{\Omega_n} [(A \nabla u_n, \nabla u_n) + a u_n u_n] dx.$$

Together with (4.5) and (4.6), we infer that, for any $v \in K_{\Omega_0}$,

$$\begin{aligned} (f, u_0 - v) &= \int_{\Omega_0} f(u_0 - v) dx = \lim_{n \rightarrow \infty} \int_{\Omega_n} f(u_n - v_n) dx \\ &\geq \lim_{n \rightarrow \infty} a(u_n, u_n - v_n) \geq a(u_0, u_0 - v). \end{aligned}$$

That is, u_0 is the solution of (4.1) on Ω_0 . To see that Ω_0 is an optimal shape, we only need to use Corollary 2.2, that $u_n \xrightarrow{L} u_0$ weakly in $H^1(\Omega_0)$, and that $\{\Omega_n\}$ is a minimizing sequence of (OSD). \square

COROLLARY 4.1. *Let $\mathcal{B} = O_\varepsilon$ and $\{K_\Omega\}$ in (OSD) be the same as one in Examples 3.3–3.6. Then (OSD) has at least one solution.*

Remark 4.1. If \mathcal{B} is a closed bounded set in $O^{k,\infty}$ ($k \geq 2$) (see § 2) in (OSD), Theorem 4.1 and Corollary 4.1 are still true, from Remarks 2.2. and 3.2.

Remark 4.2. Theorem 4.1 is a very general existence result, and it can be used in some other classes of open sets. Furthermore, we see from the theorem that in many cases (see, e.g., Example 3.3) we still have existence results without assuming the condition that there are uniform extension operators (Theorem 2.3), which was assumed in other works [5]–[7], [13].

4.2. Existence of optimal shape design for evolution variational inequalities. Let \mathcal{B} have the same meaning as above and K_Ω be a nonempty closed convex set in $L^2(0, T; H^1(\Omega))$ for every $\Omega \in \mathcal{B}$. We consider the following evolution optimal shape design problem:

$$(OSE) \quad \min_{\Omega \in \mathcal{B}} \int_0^T \int_{\Omega} h(t, x, u, \nabla u) dx dt,$$

subject to

$$(4.7) \quad \int_0^T (u', v - u) dt + \int_0^T a(u, v - u) dt \geq \int_0^T (f, v - u) dt,$$

$$u(0, x) = \psi(x), \quad u \in K_\Omega \cap W(0, T; H^1(\Omega)) \text{ for any } v \in K_\Omega,$$

where $\psi \in L^2(R^m)$, $f \in L^2(R^{m+1})$, $(u', v) = \langle u', v \rangle_{(H^1(\Omega))^* \times H^1(\Omega)}$, and h satisfies conditions in Theorem 2.6. Furthermore, we suppose that $A(\cdot)$ and $a(\cdot)$ in $a(u, v)$ are continuous on R^m . Thus, we give the following result.

THEOREM 4.2. *If (4.7) has a unique solution for any $\Omega \in \mathcal{B}$ and the solution u_Ω is in $G^0(0, T; H^1(\Omega))$ such that the following uniform boundedness condition holds:*

$$\|u_\Omega\|_{G^0(0, T; H^1(\Omega))} \leq d, \quad \text{where } d \text{ is independent of } \Omega \in \mathcal{B},$$

then (OSE) has at least one solution if $K_{\Omega_n} \xrightarrow{LM} K_{\Omega_0}$ in $L^2(0, T; H^1(\Omega_0))$ as $\Omega_n \rightarrow \Omega_0$ in (\mathcal{B}, τ) .

Proof. We use the same method as in the proof of Theorem 4.1. Let $\{\Omega_n\}$ be a minimizing sequence of (OSE). From Theorem 2.6 and the uniform boundedness condition, we know that there is a subsequence of $\{u_n\}$, still denoted as $\{u_n\}$, and $u_0 \in G^0(0, T; H^1(\Omega_0))$ such that $u_n \xrightarrow{L} u_0$ weakly in $L^2(0, T; H^1(\Omega_0))$, where u_n is the solution of (4.7) on Ω_n . We only need to prove that u_0 is the solution of (4.7) on Ω_0 due to Theorem 2.6. First, by the same method in the proof of Theorem 4.1, we have, for any $v \in K_{\Omega_0}$,

$$(4.8) \quad \int_0^T \int_{\Omega_0} f(u_0 - v) \, dx \, dt = \lim_{n \rightarrow \infty} \int_0^T \int_{\Omega_n} f(u_n - v_n) \, dx \, dt,$$

where $\{v_n\}$ is U.A.C., $v_n \xrightarrow{L} v$ strongly in $L^2(0, T; H^1(\Omega_0))$. Similarly, from Theorem 2.6, Remark 2.1, and Example 3.2,

$$(4.9) \quad \begin{aligned} & \int_0^T \int_{\Omega_0} [(A \nabla u_0, \nabla(u_0 - v)) + a u_0(u_0 - v)] \, dx \, dt \\ & \leq \lim_{n \rightarrow \infty} \int_0^T \int_{\Omega_n} [(A \nabla u_n, \nabla(u_n - v_n)) + a u_n(u_n - v_n)] \, dx \, dt. \end{aligned}$$

We now prove that

$$(4.10) \quad \int_0^T (u'_0, v) \, dt = \lim_{n \rightarrow \infty} \int_0^T (u'_n, v_n) \, dt.$$

To see this, we first note that for any $G \Subset \Omega_0$,

$$\int_0^T \int_G u'_0 v \, dx \, dt = \lim_{n \rightarrow \infty} \int_0^T \int_G u'_n v_n \, dx \, dt,$$

since $u'_n \rightarrow u'_0$ weakly in $L^2(0, T; L^2(G))$ from the fact that $u_n \rightarrow u_0$ in $L^2(0, T; L^2(G))$ strongly and that $\{\|u'_n\|_{L^2(0, T; L^2(G))}\}$ is bounded. Next, we note that for any $\varepsilon > 0$ there are $G \Subset \Omega_0$ and $N > 0$ such that $G \subset \Omega_n$ ($n \geq N$) and $\text{mes}(\Omega_n \setminus G) + \text{mes}(\Omega_0 \setminus G) \leq \varepsilon$ such that

$$\begin{aligned} & \left| \int_0^T \int_{\Omega_n \setminus G} u'_n v_n \, dx \, dt \right| + \left| \int_0^T \int_{\Omega_0 \setminus G} u'_0 v \, dx \, dt \right| \\ & \leq \|u'_n\|_{L^2(0, T; L^2(\Omega_n))} \|v_n\|_{L^2(0, T; H^1(\Omega_n \setminus G))} + \|u'_0\|_{L^2(0, T; L^2(\Omega_0))} \|v\|_{L^2(0, T; H^1(\Omega_0 \setminus G))}, \end{aligned}$$

which can be arbitrarily small if $\text{mes}(\Omega_0 \setminus G)$ is small enough, because $\{v_n\}$ is U.A.C. and $\{\|u_n\|_{G^0(0, T; H^1(\Omega))}\}$ is bounded. So we get (4.10) from

$$\int_0^T (u'_n, v_n) \, dt = \int_0^T \int_{\Omega_n} u'_n v_n \, dx \, dt.$$

Finally, we prove that

$$(4.11) \quad \int_0^T (u'_0, u_0) \, dt \leq \lim_{n \rightarrow \infty} \int_0^T (u'_n, u_n) \, dt.$$

To do this, we note that since $u_n \rightarrow u_0$ strongly in $L^2(0, T; L^2(G))$ for any $G \Subset \Omega_0$ and $\{\|u_n\|_{G^0(0, T; H^1(\Omega_n))}\}$ is bounded, then it follows from Lions' compactness embedding result in [10] that $u_n \rightarrow u_0$ weakly in $W(0, T)$ for any $G \Subset \Omega_0$. On the other hand, $W(0, T)$ is embedded in $C(0, T; L^2(G))$ [9], so $u_n(T, x) \rightharpoonup u_0(T, x)$ weakly in $L^2(\Omega_0)$. Thus (see the proof of Theorem 2.4),

$$\begin{aligned} 2 \int_0^T (u'_0, u_0) dt &= \int_{\Omega_0} u_0^2(T, x) dx - \int_{\Omega_0} \psi^2(x) dx \\ &\leq \liminf_{n \rightarrow \infty} \int_{\Omega_n} u_n^2(T, x) dx - \lim_{n \rightarrow \infty} \int_{\Omega_n} \psi^2(x) dx \\ &= \liminf_{n \rightarrow \infty} \int_{\Omega_n} [u_n^2(T, x) - \psi^2(x)] dx = 2 \liminf_{n \rightarrow \infty} \int_0^T (u'_n, u_n) dt. \end{aligned}$$

Combining (4.8)–(4.11), we infer that u_0 is the solution of (4.7) on Ω_0 . Thus Ω_0 is an optimal shape from Theorem 2.6. \square

COROLLARY 4.2. *Let $\psi = 0$, $f \in C(0, T; H^{-1}(R^n)) \cap L^2(R^{m+1})$ and $f(0) = 0$ in (OSE). Suppose for every fixed $\Omega \in \mathcal{B}$, that there is a constant $\rho > 0$, independent of Ω , such that, for any $v \in K_\Omega$ and $s \geq 0$,*

$$G(s)v + G^*(s)v - G^*(s)G(s)v + (\rho - 1)v \in \rho K_\Omega,$$

where $G(s)$ is the semigroup introduced in [10, p. 294]. Then (OSE) has at least one solution, provided $K_{\Omega_n} \xrightarrow{LM} K_{\Omega_0}$ as $\Omega_n \xrightarrow{\tau} \Omega_0$.

Proof. We only need to note that the uniform boundedness condition holds from the proof of Theorem 9 in [10, p. 294]. \square

Remark 4.3. We have the same remark for Theorem 4.2 and Corollary 4.2 as Remark 4.1.

Another important case where the uniform boundedness condition holds can be found in [3, p. 124]. However, this condition is somewhat restrictive. In some important cases, we can replace it by the common condition that $\{\|u_\Omega\|_{G^0(0, T; H^1(\Omega))}\}$ is bounded.

Before giving further results in this direction, we first give a definition.

DEFINITION 4.1. Let K_Ω be a closed convex set in $H^1(\Omega)$ for any $\Omega \in \mathcal{B}$. We say that $\{K_\Omega\}(\Omega \in \mathcal{B})$ is L^2 -locally closed if for any $\{\Omega_n\} \subset \mathcal{B}$ ($n = 0, 1, \dots$) such that $\Omega_n \xrightarrow{\subseteq} \Omega_0$, we have $u \in K_{\Omega_0}$, provided there are $u_{n_k} \in K_{\Omega_{n_k}}$ satisfying that for any $G \Subset \Omega_0$, there is $N(G) > 0$ such that $u_{n_k} \in L^2(G)$ ($k \geq N$) and $u_{n_k} \rightarrow u$ strongly in $L^2(G)$ (in Definition 3.2(i), we have an additional requirement that $\{\|u_{n_k}\|_{H^1(\Omega_{n_k})}\}$ be bounded).

We note that all $\{K_\Omega\}$ in Examples 3.3–3.6 are L^2 -locally closed.

In the following, $\mathcal{B} = \mathcal{O}_\varepsilon$ and the condition that $u \in K_\Omega \cap W(0, T)$ in (OSE) will be replaced by $u \in K_\Omega \cap G^{1/2}(0, T; H^1(\Omega))$, and we further require that $a(u, v) = a(v, u)$ for any $u, v \in H^1(\Omega)$ to ensure that we can use the existence theorem of solutions for evolution variational inequalities in [3].

THEOREM 4.3. *In (OSE), let $\mathcal{B} = \mathcal{O}_\varepsilon$ and $K_\Omega = \{v \in L^2(0, T; H^1(\Omega)); v(t) \in \underline{K}_\Omega \text{ almost everywhere for } t \in (0, T)\}$, where \underline{K}_Ω is a closed convex set in $H^1(\Omega)$ and $\psi|_\Omega \in \underline{K}_\Omega$ for every $\Omega \in \mathcal{O}_\varepsilon$. Then (OSE) has at least one solution, provided $\{\underline{K}_\Omega\}$ is L^2 -locally closed and $\underline{K}_{\Omega_n} \xrightarrow{LM} \underline{K}_{\Omega_0}$ in $H^1(\Omega_0)$ as $\Omega_n \rightarrow \Omega_0$ in \mathcal{O}_ε .*

Proof. First we note that (OSE) now is the same as

$$(4.12) \quad \min_{\Omega \in \mathcal{O}_\varepsilon} \int_0^T \int_\Omega h(t, x, u, \nabla u) dx dt, \\ \int_0^T [(u'(t), v - u(t)) + a(u(t), v - u(t))] \rho(t) dt \geq \int_0^T (f, v - u(t)) \rho(t) dt,$$

where $u(t) \in \underline{K}_\Omega$ almost everywhere, $u \in G^{1/2}(0, T; H^1(\Omega))$, for any $v \in \underline{K}_\Omega$ and $\rho \in \mathcal{D}(0, T)$, $\rho \geq 0$. From [3] we see that for any $\Omega \in O_\varepsilon$, (4.12) has a unique solution in $G^{1/2}(0, T; H^1(\Omega))$ and that $\{\|u_\Omega\|_{G^{1/2}(0, T; H^1(\Omega))}\}$ is bounded. Suppose $\{\Omega_n\}$ is a minimizing sequence of (OSE) and $\Omega_n \rightarrow \Omega_0 \in O_\varepsilon$. Then we find a subsequence of $\{u_n\}$, still denoted as $\{u_n\}$, and a function u_0 in $G^{1/2}(0, T; H^1(\Omega_0))$ such that $u_n \xrightarrow{L} u_0$ weakly in $L^2(\delta, T; H^1(\Omega_0))$ for any $\delta > 0$, where u_n is the solution of (4.12) on Ω_n for $n = 1, 2, \dots$. Thus for any $G \Subset \Omega_0$, there is a subsequence of $\{u_n\}$, still denoted as $\{u_n\}$, such that $u_n(t) \rightarrow u_0(t)$ strongly in $L^2(G)$ almost everywhere for $t \in (0, T)$. Therefore, as in the proof of Theorem 2.5 in § 2, there is $\{u_{n_k}(t)\}$ ($k = 1, 2, \dots, n$), a subsequence of $\{u_n(t)\}$, such that $u_{n_k}(t) \in \underline{K}_{\Omega_k}$ almost everywhere for $t \in (0, T)$, and for any fixed $G \Subset \Omega_0$, $u_{n_k}(t) \rightarrow u_0(t)$ strongly in $L^2(G)$ almost everywhere for $t \in (0, T)$. Thus $u_0(t) \in \underline{K}_{\Omega_0}$ almost everywhere for $t \in (0, T)$ because of the L^2 -closeness assumption of $\{\underline{K}_\Omega\}$; that is, $u_0 \in K_{\Omega_0}$. We prove that u_0 is the solution of (4.12) on Ω_0 . First, for any $v \in \underline{K}_{\Omega_0}$, there is $v_n \in \underline{K}_{\Omega_n}$ for $n = 1, 2, \dots$ such that $v_n \xrightarrow{L} v$ strongly in $H^1(\Omega_0)$ (thus, $v_n \xrightarrow{L} v$ strongly in $L^2(0, T; H^1(\Omega_0))$) and that $\{v_n\}$ is U.A.C. Next, from the fact that $\{\|u_n\|_{G^{1/2}(0, T; H^1(\Omega_n))}\}$ is bounded, we infer that for any $\delta > 0$, $\{\|u_n\|_{G^0(\delta, T; H^1(\Omega_n))}\}$ is bounded. So, as in the proof Theorem 4.2, we have, from the fact that $\rho \geq 0$ and that ρ has a compact support in $(0, T)$,

$$(4.13) \quad \int_0^T (f, v - u_0) \rho \, dt = \lim_{n \rightarrow \infty} \int_0^T (f, v_n - u_n) \rho \, dt,$$

$$(4.14) \quad \int_0^T a(u_0, u_0 - v) \rho \, dt \leq \varliminf_{n \rightarrow \infty} \int_0^T a(u_n, u_n - v_n) \rho \, dt,$$

for any fixed $v \in \underline{K}_{\Omega_0}$. Next, note $\rho \in \mathcal{D}(0, T)$. Thus we have for any fixed $G \Subset \Omega_0$

$$\begin{aligned} 2 \int_0^T (u'_0, u_0)_{L^2(G)} \rho \, dt &= - \int_0^T \rho' \|u_0\|_{L^2(G)}^2 \, dt \\ &= - \lim_{n \rightarrow \infty} \int_0^T \rho' \|u_n\|_{L^2(G)}^2 \, dt \\ &= \lim_{n \rightarrow \infty} 2 \int_0^T (u'_n, u_n)_{L^2(G)} \rho \, dt, \end{aligned}$$

because $u_n \xrightarrow{L} u_0$ weakly in $L^2(\delta, T; H^1(\Omega_0))$ for any $\delta > 0$. On the other hand, we have uniformly bounded extension operators j_n from $H^1(\Omega_n)$ to $H^1(C)$ (see § 2). From Example 3.2, we know, as $\text{mes}(\Omega_0 \setminus G) \rightarrow 0$,

$$\left| \int_\delta^T \int_{\Omega_0 \setminus G} \rho u'_0 u_0 \, dx \, dt \right| \quad \text{and} \quad \left| \int_\delta^T \int_{\Omega_n \setminus G} \rho u'_n u_n \, dx \, dt \right|$$

can be arbitrarily small for fixed ρ because

$$2 \left| \int_\delta^T \int_{\Omega_n \setminus G} \rho u'_n u_n \, dx \, dt \right| = \left| \int_\delta^T \int_{\Omega_n \setminus G} \rho' u_n^2 \, dx \, dt \right|$$

for a $\delta > 0$. Thus, we infer that

$$(4.15) \quad \int_0^T (u'_0, u_0) \rho \, dt \leq \varliminf_{n \rightarrow \infty} \int_0^T (u'_n, u_n) \rho \, dt.$$

It only remains to prove that

$$(4.16) \quad \int_0^T (u'_0, v) \rho \, dt = \lim_{n \rightarrow \infty} \int_0^T (u'_n, v_n) \rho \, dt.$$

To show this, we note that for any $\delta > 0$, $\{\int_{\delta}^T \|u'_n\|_{L^2(\Omega_n)}^2 dt\}$ is bounded. Thus, $\int_{\delta}^T (u'_0, v) \rho dt = \lim_{n \rightarrow \infty} \int_{\delta}^T (u'_n, v_n) \rho dt$, as before. On the other hand, ρ has a compact support in $(0, T)$, so we get (4.16). We see now that $u_0 \in G^{1/2}(0, T; H^1(\Omega_0))$, and u_0 satisfies (4.12). Thus we know that Ω_0 is an optimal shape from Theorem 2.6. \square

Combining Theorem 4.3 and Examples 3.7 and 3.8, we can easily give many examples about the existence of optimal shapes in the evolution case.

5. Discussion. It seems that we cannot deal with such cases as $K_{\Omega} = \{v \in H^1(\Omega), v|_{\partial\Omega} \geq 0\}$. However, we must realize that the local convergences given in this paper are only some special cases of a general local convergence theory. In further papers we will develop a general local convergence theory, which seems very useful in the studies of domain optimization. We will see that by using some suitable local convergences, we can treat much wider ranges of domain optimization problems.

Acknowledgments. The authors thank the referees for their valuable comments and suggestions.

STABLE SOLUTIONS OF REAL ALGEBRAIC MATRIX RICCATI EQUATIONS*

ANDRÉ C. M. RAN† AND LEIBA RODMAN‡

Abstract. Various stability properties of real symmetric solutions of algebraic matrix Riccati equations with real coefficients are studied. The stability is understood in the sense of robustness, i.e., a solution is stable if, roughly speaking, every nearby equation has a nearby solution.

Key words. Riccati equations, stability, Lipschitz-stability

AMS(MOS) subject classifications. 15A24, 93C35

1. Introduction. We consider the algebraic matrix Riccati equations

$$(1.1) \quad XDC + XA + A^T X - C = 0,$$

where A , D , and C are given $n \times n$ real matrices with $C = C^T$, $D = D^T$, and $D \geq 0$ (we use the notation $X \geq Y$ for real symmetric matrices X and Y to indicate that the difference $X - Y$ is positive semidefinite; the superscript “ T ” stands for the transposed matrix). Only real symmetric solutions X of (1.1) will be considered in this paper. Such solutions, and especially the maximal solution, play a crucial role in the classical quadratic control problems in continuous time (see, e.g., [KS], [Br], [K], or practically any book on linear control systems). In recent years, many new important applications of (1.1) have appeared (we mention only one of them here: H^∞ control; see, e.g., [GGLD], [ZK], and [BC]), and numerical algorithms for finding real symmetric solutions of the algebraic matrix Riccati equation are being developed (see, e.g., [BM], [By], and [L]). Also, real symmetric solutions that are not maximal appear in the optimal feedback control for certain linear quadratic problems (see [T] and [ST]).

In this paper we characterize real symmetric solutions X_0 of (1.1) with various stability properties. We say that a solution X_0 is stable if, roughly speaking, any equation with slightly perturbed coefficients A' , D' , and C' (the perturbed coefficients D' and C' must satisfy the same symmetry conditions as (1.1), i.e., $C' = C'^T$, $D' \geq 0$) will have a real symmetric solution as close as we wish to X_0 . (The precise definitions of various notions of stability are given in §3.) As a byproduct, we also obtain descriptions of stably disconjugate Hamiltonian systems of differential equations $Jx' = Hx$, where $H = H^T$ is a given constant matrix and $J = \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix}$. Often we will assume that the pair (A, D) is *controllable*, i.e., the rank of the $n \times n^2$ matrix $[D \ AD \ \cdots \ A^{n-1}D]$ is n . In the framework of complex matrices (in this case, A^T in (1.1) is replaced by the conjugate transpose A^*), the study of stability properties of Hermitian solutions was done in [RR2]. The approach we take in this paper to stability problems of solutions X_0 of (1.1) is based on reduction to corresponding stability problems of the graph subspace

$$\left\{ \begin{bmatrix} x \\ X_0 x \end{bmatrix} : x \in \mathbb{R}^n \right\}.$$

The graph subspace is M -invariant and J -neutral, where M is the Hamiltonian for (1.1). Various stability properties of such subspaces have been studied in [RR1].

The perturbation and stability properties of the solution of the algebraic Riccati equations have been studied in the literature in a somewhat different framework. Namely, assuming that the coefficients A , D , and C are C^r or analytic functions of a parameter (or several parameters), it can be shown under appropriate hypotheses that certain solutions of the algebraic Riccati equation are again C^r or analytic functions. See [D], [Ro2], and [RR4], where analytic dependence on parameters is assumed, and the main focus is on the stabilizing solution (in [RR4] the C^r -dependence is studied as well), and [Bu], where the C^1 -dependence is assumed (see also the last paragraph in § 3).

The paper is organized as follows. In the next section (which is of a preliminary character), we characterize (1.1) for which there is a real symmetric solution in terms of the canonical form of pair of matrices

$$\begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}, \quad \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}.$$

The main results on stability and Lipschitz stability of real symmetric solutions of (1.1) are described in §§ 3 and 4, respectively. Some properties of stable solutions, particularly in relation to stability of nearby solutions of nearby equations and with isolatedness, are described in § 5. Finally, in the last section we apply these results to characterize stably disconjugate Hamiltonian systems.

We use the following notation and conventions throughout the paper. The spectrum (i.e., the set of eigenvalues, possibly complex) of an $n \times n$ real matrix T is denoted $\sigma(T)$. The algebraic multiplicity of an eigenvalue λ of T is defined to be the dimension of $\text{Ker}(T - \lambda I)^n$ (understood as a subspace in the complex space \mathbb{C}^n), and the geometric multiplicity is $\dim \text{Ker}(T - \lambda I)$. The partial multiplicities of T corresponding to λ are, by definition, the sizes of the Jordan blocks with eigenvalue λ in the Jordan form of T . Finally, $\text{Im } Z = \{Zx : x \in \mathbb{R}^n\} \subset \mathbb{R}^m$ denotes the column space of a real $m \times n$ matrix Z .

2. Existence of real symmetric solutions. A standard approach to the investigation of (1.1) is by introducing the $2n \times 2n$ real matrices

$$(2.1) \quad M = \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}; \quad J = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}.$$

We check that $J = -J^T$ and that $JM = -M^T J$. So $(M, J) \in L_{2n}(-1, -1)$, where we borrow the notation $L_p(-1, -1)$ from [RR1] to designate the set of all ordered pairs (B, H) of $p \times p$ real matrices B and H such that H is invertible, $H = -H^T$, and $HB = -B^T H$. (Observe that p must be even so that $L_p(-1, -1) \neq \emptyset$.) Such pairs (B, H) can be reduced to a canonical form (described, for example, in [DPWZ]) by simultaneous real congruence and similarity, as follows. We denote by $J_q(a)$ the lower triangular $q \times q$ Jordan block with eigenvalue a (which is assumed to be real), and by $J_q\left(\begin{smallmatrix} a & b \\ -b & a \end{smallmatrix}\right)$ the $2q \times 2q$ matrix

$$J_q\left(\begin{smallmatrix} a & b \\ -b & a \end{smallmatrix}\right) = \begin{bmatrix} Z & 0 & \cdots & 0 & 0 \\ I_2 & Z & \cdots & 0 & 0 \\ 0 & I_2 & \ddots & \vdots & \vdots \\ \vdots & \vdots & \ddots & Z & 0 \\ 0 & 0 & \cdots & I_2 & Z \end{bmatrix}, \quad Z = \begin{bmatrix} a & b \\ -b & a \end{bmatrix};$$

here a and b are real numbers with $b \neq 0$, and I_2 denotes the 2×2 identity matrix.

THEOREM 2.1 ([DPWZ], [Th]). *Let $(B, H) \in L_p(-1, -1)$. Then there exists a real invertible matrix S such that the pair $(S^{-1}BS, S^THS) \in L_p(-1, -1)$ decomposes into a simultaneous direct sum*

$$(2.2) \quad S^{-1}BS = \bigoplus_{j=1}^p B_j, \quad S^THS = \bigoplus_{j=1}^p H_j,$$

where $(B_j, H_j) \in L_{p_j}(-1, -1)$ and each pair (B_j, H_j) is one of the following 5 types.

Type 1.

$$B_j = J_{2n_j}(0); \quad H_j = \kappa_j F_{2n_j},$$

where $\kappa_j = \pm 1$ and F_k is the $k \times k$ matrix given by

$$F_k = \begin{bmatrix} 0 & \cdots & 0 & 0 & 1 \\ 0 & & 0 & -1 & 0 \\ 0 & & 1 & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots \\ (-1)^{k-1} & \cdots & 0 & 0 & 0 \end{bmatrix}.$$

Type 2.

$$B_j = J_{2n_j+1}(0) \oplus (-J_{2n_j+1}(0))^T; \quad H_j = \begin{bmatrix} 0 & I_{2n_j+1} \\ -I_{2n_j+1} & 0 \end{bmatrix}.$$

Type 3.

$$B_j = J_{n_j}(a) \oplus (-J_{n_j}(a))^T; \quad H_j = \begin{bmatrix} 0 & I_{n_j} \\ -I_{n_j} & 0 \end{bmatrix},$$

where a is a positive real number.

Type 4.

$$B_j = J_{n_j} \begin{pmatrix} 0 & b \\ -b & 0 \end{pmatrix}; \quad H_j = \kappa_j \begin{bmatrix} 0 & \cdots & 0 & F_{2'}^{n_j} \\ 0 & \cdots & -F_{2'}^{n_j} & 0 \\ \vdots & \ddots & \vdots & \vdots \\ (-1)^{n_j-1} & F_{2'}^{n_j} & \cdots & 0 & 0 \end{bmatrix},$$

where $b > 0$, $\kappa_j = \pm 1$, and $F_2 = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$.

Type 5.

$$B_j = J_{n_j} \begin{pmatrix} a & b \\ -b & a \end{pmatrix} \oplus \left(-J_{n_j} \begin{pmatrix} a & b \\ -b & a \end{pmatrix} \right)^T; \quad H_j = \begin{bmatrix} 0 & I_{2n_j} \\ -I_{2n_j} & 0 \end{bmatrix}.$$

Moreover, the blocks (B_j, H_j) in (2.2) are uniquely determined by (B, H) up to a permutation.

The signs $\kappa_j = \pm 1$ that are attached to partial multiplicities corresponding to the pure imaginary ($\neq 0$) eigenvalues of B and to even partial multiplicities corresponding to the zero eigenvalue of B are also uniquely determined (up to permutation of signs attached to equal partial multiplicities corresponding to the same eigenvalue of B) and form the *sign characteristic* of (B, H) .

We now return to the Riccati equation (1.1) and the matrices (M, J) given by (2.1). The basic existence result is given by the following theorem.

THEOREM 2.2. *Assume that $C = C^T$, $D = D^T \geq 0$, and the pair (A, D) is controllable, i.e., the rank of the $n \times n^2$ matrix $[D \ AD \ \cdots \ A^{n-1}D]$ is n . Then the following statements are equivalent:*

- (i) *there exists a real symmetric solution X of (1.1);*

- (ii) all pure imaginary and zero eigenvalues of M (if any) have only even partial multiplicities and the signs κ_i in the sign characteristic of (M, J) corresponding to the (nonzero) pure imaginary eigenvalues are all -1 , while the sign κ_j attached to the even partial multiplicity m corresponding to the zero eigenvalue is $(-1)^{m/2}$;
- (iii) all pure imaginary and zero eigenvalues of M (if any) have only even partial multiplicities.

The equivalence (i) \Leftrightarrow (iii) in Theorem 2.2 is well known (see [Cu], [LR], and [S]). The implication (ii) \Rightarrow (iii) is evident, and, finally, the implication (i) \Rightarrow (ii) follows from Lemma 2.3 below. The proof of this lemma uses basically known ideas. Close results are found in [Ro1] and [GLR4], but in this form the result of Lemma 2.3 appears to be new.

LEMMA 2.3. Let A , D , and C be real $n \times n$ matrices with $C = C^T$, $D = D^T$, D positive semidefinite and (A, D) controllable. If there is a real matrix $X = X^T$ such that

$$XDX + XA + A^T X - C = 0,$$

then every pure imaginary or zero eigenvalue of

$$M := \begin{pmatrix} A & D \\ C & -A^T \end{pmatrix}$$

has even partial multiplicities, and the signs in the sign characteristic of $(M, \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix})$ corresponding to pure imaginary nonzero eigenvalues are all -1 , while the sign κ_j attached to the partial multiplicity m corresponding to the zero eigenvalue is $(-1)^{m/2}$.

Proof. Let

$$J = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}.$$

We verify that

$$(2.3) \quad \begin{pmatrix} I & 0 \\ -X & I \end{pmatrix} M \begin{pmatrix} I & 0 \\ X & I \end{pmatrix} = \begin{pmatrix} A + DX & D \\ 0 & -(A + DX)^T \end{pmatrix}$$

and

$$(2.4) \quad \begin{pmatrix} I & X \\ 0 & I \end{pmatrix} J \begin{pmatrix} I & 0 \\ X & I \end{pmatrix} = J.$$

Furthermore, let $Z = S^{-1}(A + DX)S$ be the real Jordan form of $A + DX$ (here S is some real invertible matrix). We verify that

$$(2.5) \quad \begin{pmatrix} S^{-1} & 0 \\ 0 & S^T \end{pmatrix} \begin{pmatrix} A + DX & D \\ 0 & -(A + DX)^T \end{pmatrix} \begin{pmatrix} S & 0 \\ 0 & S^{-1T} \end{pmatrix} = \begin{pmatrix} Z & D_0 \\ 0 & -Z^T \end{pmatrix},$$

where $D_0 = S^{-1}DS^{-1T}$ is symmetric and positive semidefinite; and

$$(2.6) \quad \begin{pmatrix} S^T & 0 \\ 0 & S^{-1} \end{pmatrix} J \begin{pmatrix} S & 0 \\ 0 & S^{-1T} \end{pmatrix} = J.$$

It is easily seen that the pair (Z, D_0) is controllable as well. Because of formulas (2.3)–(2.5), we can consider the pair

$$\left(\begin{bmatrix} Z & D_0 \\ 0 & -Z^T \end{bmatrix}, J \right)$$

in place of the original pair (M, J) . Let ib ($b \geq 0$) be a pure imaginary (or zero) eigenvalue of Z . Without loss of generality we can write $Z = Z_1 \oplus Z_2$, where $\sigma(Z_1) = \{\pm ib\}$; $\sigma(Z_2) \cap \{\pm ib\} = \emptyset$. Partition D_0 accordingly as follows:

$$D_0 = \begin{pmatrix} D_{01} & D_{02} \\ D_{02}^T & D_{03} \end{pmatrix}.$$

Apply the following similarity transformation to $\begin{bmatrix} Z & D_0 \\ 0 & -Z^T \end{bmatrix}$:

$$\begin{pmatrix} I & 0 & 0 & -U \\ 0 & I & -U^T & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \begin{pmatrix} Z_1 & 0 & D_{01} & D_{02} \\ 0 & Z_2 & D_{02}^T & D_{03} \\ 0 & 0 & -Z_1^T & 0 \\ 0 & 0 & 0 & -Z_2^T \end{pmatrix} \begin{pmatrix} I & 0 & 0 & U \\ 0 & I & U^T & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \\ = \begin{pmatrix} Z_1 & 0 & D_{01} & \tilde{D}_{02} \\ 0 & Z_2 & \tilde{D}_{02}^T & D_{03} \\ 0 & 0 & -Z_1^T & 0 \\ 0 & 0 & 0 & -Z_2^T \end{pmatrix},$$

where the real matrix U is chosen so that $\tilde{D}_{02} = 0$ (it is easy to see that such choice is possible because $\sigma(Z_1) \cap \sigma(Z_2) = \emptyset$). We verify that

$$\begin{pmatrix} I & 0 \\ V & I \end{pmatrix} J \begin{pmatrix} I & V \\ 0 & I \end{pmatrix} = J,$$

where

$$V = V^T = \begin{pmatrix} 0 & U \\ U^T & 0 \end{pmatrix},$$

and that the pair (Z_1, D_{01}) is controllable.

We have reduced the proof of the lemma to the following situation: either

$$(2.7) \quad M = \begin{bmatrix} \bigoplus_{j=1}^p J_{n_j} \begin{pmatrix} 0 & b \\ -b & 0 \end{pmatrix} & D \\ 0 & \bigoplus_{j=1}^p \left(-J_{n_j} \begin{pmatrix} 0 & b \\ -b & 0 \end{pmatrix} \right)^T \end{bmatrix}$$

(where $b > 0$), or

$$(2.8) \quad M = \begin{bmatrix} \bigoplus_{j=1}^p J_{n_j}(0) & D \\ 0 & \bigoplus_{j=1}^p (-J_{n_j}(0))^T \end{bmatrix}.$$

First, consider the case where M is given by (2.8). Using Lemma 8.4 of [GLR1] or Lemma 3.4 of [GLR2] we verify that the partial multiplicities of M are $2n_1, \dots, 2n_p$. Observe that, for a given real $n \times n$ matrix K , the set \mathcal{V} of all real symmetric positive semidefinite $n \times n$ matrices V such that (K, V) is controllable, is connected (this follows, for example, from the easily verified fact that (K, V) is controllable if and only if the

matrix

$$[I \ K \cdots K^{n-1}] \begin{bmatrix} V & 0 & \cdots & 0 \\ 0 & V & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & V \end{bmatrix} \begin{bmatrix} I \\ K^T \\ \vdots \\ (K^T)^{n-1} \end{bmatrix}$$

is positive definite). Let $K = \bigoplus_{j=1}^p J_{n_j}(o)$. Because of the connectivity of \mathcal{V} , Theorem II.1.1 of [GLR3] implies that the sign characteristic of

$$\left(\begin{bmatrix} K & V \\ 0 & -K^T \end{bmatrix}, \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix} \right)$$

is independent of $V \in \mathcal{V}$ (Theorem II.1.1 of [GLR3] is stated for the framework of complex matrices; however, Proposition 3.3 of [RR1] makes it possible to apply this theorem for the real case as well). Thus, the sign characteristic of (M, J) is the same as that of

$$(2.9) \quad \left(\begin{bmatrix} K & V_0 \\ 0 & -K^T \end{bmatrix}, J \right),$$

where $V_0 = e_1 e_1^T + e_{n_1+1} e_{n_1+1}^T + \cdots + e_{n_1+\cdots+n_{p-1}+1} e_{n_1+\cdots+n_{p-1}+1}^T$. (We denote by e_k the column vector with 1 in the k th position and zeros elsewhere; the dimension of e_k is clear from the context.)

By inspection, we verify that the signs κ_j in the sign characteristic of the pair (2.9) are $(-1)^{n_1}, \dots, (-1)^{n_p}$. (This part of the proof follows the arguments used in the proof of Theorem 4 in [Ro1].)

Consider now the case where M is given by (2.7). Let

$$K = \bigoplus_{j=1}^p J_{n_j} \begin{bmatrix} 0 & b \\ -b & 0 \end{bmatrix} \quad (b > 0).$$

The existence of a Hermitian solution (namely, the zero solution) of the Riccati equation $XXD + XK + K^T X = 0$ implies (in view of the results of [Cu], [LR], and [S]; see also Theorem II.4.3 in [GLR4]) that all the partial multiplicities of M are even. Actually, the proof of Theorem II.4.3 in [GLR4] shows that the partial multiplicities of M corresponding to the eigenvalue $\pm ib$ are $2n_1, \dots, 2n_p$. Theorem 4 in [Ro1] and Proposition I.6.8 in [GLR4] combined tell us that the sign characteristic of the pair

$$\left(i \begin{bmatrix} K & D \\ 0 & -K^T \end{bmatrix}, i \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix} \right)$$

(as defined in, e.g., [GLR4]), for complex matrices selfadjoint in a complex indefinite scalar product, consists entirely of -1 's. Proposition 3.3 in [RR1] implies that all the signs in the sign characteristic of

$$\left(i \begin{bmatrix} K & D \\ 0 & -K^T \end{bmatrix}, i \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix} \right)$$

are -1 's. \square

The conditions (i)–(iii) in Theorem 2.2 are equivalent to the existence of an M -invariant J -Lagrangian subspace (see, e.g., [F], where several other equivalent conditions are stated under the somewhat milder assumption of sign-controllability of (A, D)). In general, given a real matrix N such that $JN = -N^T J$, criteria for existence of an N -invariant J -Lagrangian subspace are given in [CD] (the context in [CD] is

different from ours) and in [RR1]. The criterion given in [RR1] states that there is an N -invariant J -Lagrangian subspace if and only if for every eigenvalue ib ($b > 0$) of N the number of odd partial multiplicities corresponding to ib is even, and the sum of the signs κ_j attached to these odd partial multiplicities is zero. However, the situation in Theorem 2.2 is special (because of the hypotheses that $D \geq 0$ and (A, D) is controllable, which need not be satisfied for a general matrix

$$N = \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}$$

such that $JN = -N^T J$), and therefore the criterion given in Theorem 2.2(ii) for existence of an M -invariant J -Lagrangian subspace also takes a special form.

3. Stable symmetric solutions. We introduce the concept of stable solutions of the algebraic Riccati equation (1.1). It is convenient to first introduce some notation. Let \mathcal{C}_n be the set of all triples of real $n \times n$ matrices (A, C, D) such that $C = C^T$, $D = D^T$; D is positive semidefinite, and the pair (A, D) is controllable. For $(A, C, D) \in \mathcal{C}_n$ let $\chi(A, C, D)$ be the set of real symmetric solutions (possibly an empty set) of the algebraic Riccati equation

$$(3.1) \quad XDX + XA + A^T X - C = 0.$$

A solution $X \in \chi(A, C, D)$ will be called *conditionally stable* if for every $\varepsilon > 0$ there is $\delta > 0$ such that every triple $(A', C', D') \in \mathcal{C}_n$ for which $\chi(A', C', D') \neq \emptyset$ and for which

$$\|A - A'\| + \|C - C'\| + \|D - D'\| < \delta$$

has a solution $X' \in \chi(A', C', D')$ with $\|X' - X\| < \varepsilon$. If the condition $\chi(A', C', D') \neq \emptyset$ is omitted from the above definition, we obtain the definition of an *unconditionally stable* solution X .

A standard approach (also adopted here) to study the solutions X of (3.1) is by way of the graph subspaces

$$(3.2) \quad \mathcal{N}(X) = \text{Im} \begin{bmatrix} I \\ X \end{bmatrix} \subset \mathbb{R}^{2n}.$$

It is easy to see that $\mathcal{N}(X)$ is M -invariant and J -Lagrangian for every real symmetric solution X of (3.1); here

$$(3.3) \quad M = \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}, \quad J = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}.$$

Conversely (see [Cu], [LR], and [S], and also Theorem 2.2), if (A, D) is controllable, then every M -invariant J -Lagrangian subspace is of the form $\text{Im} \begin{bmatrix} I \\ X \end{bmatrix}$ for some real symmetric solution of (3.1).

Next, we need the notion of (un)conditionally stable invariant Lagrangian subspaces, introduced and studied in [RR1]. For subspaces $\mathcal{M}, \mathcal{N} \subset \mathbb{R}^p$, we let $\Theta(\mathcal{M}, \mathcal{N})$ be the *gap metric* defined by

$$\Theta(\mathcal{M}, \mathcal{N}) = \|P_{\mathcal{M}} - P_{\mathcal{N}}\|,$$

where $P_{\mathcal{M}}(P_{\mathcal{N}})$ is the orthogonal projection on $\mathcal{M}(\mathcal{N})$, with respect to the standard inner product

$$\langle (x_1, \dots, x_p)^T, (y_1, \dots, y_p)^T \rangle = \sum_{j=1}^p x_j y_j$$

in \mathbb{R}^p . Let $(B, H) \in L_p(-1, -1)$, and let \mathcal{N} be a B -invariant H -Lagrangian subspace in \mathbb{R}^p . We say that \mathcal{N} is *conditionally stable* if for every $\varepsilon > 0$ there is $\delta > 0$ such that every pair $(B', H') \in L_p(-1, -1)$ with $\|B - B'\| + \|H - H'\| < \delta$ has a B' -invariant H' -Lagrangian subspace \mathcal{N}' with $\Theta(\mathcal{N}, \mathcal{N}') < \varepsilon$ *provided* the set of B' -invariant H' -Lagrangian subspaces is not empty. If this proviso is removed, we obtain the definition of an *unconditionally stable* B -invariant H -Lagrangian subspace \mathcal{N} .

In the following, for a given $m \times m$ real matrix \mathcal{Z} , we denote by $R(\mathcal{Z}, \lambda)$ the root subspace of \mathcal{Z} corresponding to its real eigenvalue λ , and by $R(\mathcal{Z}, a \pm ib)$ the real root subspace of \mathcal{Z} corresponding to the pair of complex conjugate nonreal eigenvalue $a \pm ib$ as follows:

$$R(\mathcal{Z}, \lambda) = \text{Ker}(\mathcal{Z} - \lambda I)^m,$$

$$R(\mathcal{Z}, a \pm ib) = \text{Ker}(\mathcal{Z}^2 - 2a\mathcal{Z} + (a^2 + b^2)I)^m.$$

LEMMA 3.1. *Let $(A, C, D) \in \mathcal{C}_n$, and let*

$$M = \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}, \quad J = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}.$$

Then $X \in \chi(A, C, D)$ is an (un)conditionally stable solution of (3.1) if and only if $\mathcal{N}(X)$ is (un)conditionally stable as an M -invariant J -Lagrangian subspace.

Proof. Clearly, if $\mathcal{N}(X)$ is (un)conditionally stable, then X is an (un)conditionally stable solution of (3.1).

Conversely, assume $\mathcal{N}(X)$ is not (un)conditionally stable. We must prove that X is not (un)conditionally stable. Let X_0 be a real symmetric solution of (3.1) such that $\sigma(A + DX_0)$ lies in the closed left half-plane. (The existence of such X_0 is ensured because $\chi(A, C, D)$ is nonempty; see, e.g., [GLR4]. Note also that X_0 is unique, by Theorem 2.1 and Theorem 3.2 in [RR1].) Furthermore, let

$$\tilde{M} = \begin{bmatrix} A + DX_0 & D \\ 0 & -(A + DX_0)^T \end{bmatrix}.$$

Applying similarity (2.3) (with X replaced by X_0) it is easy to see that the \tilde{M} -invariant J -Lagrangian subspace

$$\mathcal{N}_0 = \text{Im} \begin{bmatrix} I \\ X - X_0 \end{bmatrix}$$

is not (un)conditionally stable.

At this point, it is convenient to separately consider the two concepts of stability. So first assume that \mathcal{N}_0 is not conditionally stable. By Theorem 3.4 of [RR1], we conclude that at least one of three following conditions holds:

- (a) $(0) \neq \mathcal{N}_0 \cap R(\tilde{M}, \lambda_0) \neq R(\tilde{M}, \lambda_0)$ for some real nonzero eigenvalue λ_0 of \tilde{M} such that $\dim \text{Ker}(\tilde{M} - \lambda_0 I) > 1$;
- (b) $\mathcal{N}_0 \cap R(\tilde{M}, \lambda_0)$ is odd-dimensional for some real nonzero eigenvalue λ_0 of \tilde{M} such that $\dim \text{Ker}(\tilde{M} - \lambda_0 I) = 1$ and $R(\tilde{M}, \lambda_0)$ is even-dimensional;
- (c) $0 \neq \mathcal{N}_0 \cap R(\tilde{M}, a_0 \pm ib_0) \neq R(\tilde{M}, a_0 \pm ib_0)$ for some nonreal nonpure imaginary eigenvalues $a_0 \pm ib_0$ ($a_0 \neq 0, b_0 > 0$) of \tilde{M} with geometric multiplicity at least 2.

Observe that since $(\tilde{M}, J) \in L(-1, -1)$ (see also Theorem 3.4 in [RR1]), if any of the conditions (a), (b), or (c) is satisfied for λ_0 or $a_0 \pm ib_0$ as appropriate, then the same condition is satisfied for $-\lambda_0$ or $-a_0 \pm ib_0$. So we can assume $\lambda_0 < 0$ or $a_0 < 0$, as appropriate.

Because of our choice of X_0 , the subspace $R(\tilde{M}, \lambda_0)$, or $R(\tilde{M}, a_0 \pm ib_0)$, is contained in $\text{Im} \begin{bmatrix} I \\ 0 \end{bmatrix}$. In view of the description of stable invariant subspaces for real matrices (see [BGK], [GLR2], or [GLR5]), there is a sequence of real matrices $\{A_m\}_{m=1}^\infty$ such that $A_m \rightarrow A + DX_0$ as $m \rightarrow \infty$ and for every A_m -invariant subspace $\mathcal{N}_m (\subset \mathbb{R}^n)$

$$(3.4) \quad \Theta \left(\begin{bmatrix} \mathcal{N}_m \\ 0 \end{bmatrix}, \mathcal{N}_0 \cap \mathcal{F} \right) \geq \varepsilon_0,$$

where ε_0 is independent of m , and \mathcal{F} is the sum of all root subspaces of \tilde{M} corresponding to the eigenvalues in the open left half-plane. Clearly, $(A_m, 0, D) \in \mathcal{C}_n$ for m large enough and $\chi(A_m, 0, D) \neq \emptyset$. Let

$$(3.5) \quad \tilde{M}_m = \begin{bmatrix} A_m & D \\ 0 & -A_m^T \end{bmatrix}.$$

We claim that for any \tilde{M}_m -invariant J -Lagrangian subspace $\tilde{\mathcal{N}}_m$ the inequality

$$(3.6) \quad \Theta(\tilde{\mathcal{N}}_m, \mathcal{N}_0) \geq \varepsilon_1$$

holds (here, and in the following, we denote by $\varepsilon_1, \varepsilon_2, \dots$ positive constants independent of m). Indeed, if (3.6) were false, then we would have

$$(3.7) \quad \Theta(\tilde{\mathcal{N}}_m \cap \mathcal{F}_m, \mathcal{N}_0 \cap \mathcal{F}) \rightarrow 0 \quad \text{as } m \rightarrow \infty,$$

where \mathcal{F}_m is the \tilde{M}_m -invariant subspace equal to the sum of all root subspaces of \tilde{M}_m corresponding to eigenvalues that converge (as $m \rightarrow \infty$) to the open left half-plane eigenvalues of \tilde{M} . The form (3.5) of \tilde{M} easily implies that

$$\mathcal{F}_m \subset \text{Im} \begin{bmatrix} I \\ 0 \end{bmatrix},$$

(i.e., we can consider $\tilde{\mathcal{N}}_m \cap \mathcal{F}_m$ as an A_m -invariant subspace), and (3.7) clearly contradicts (3.4).

We conclude from (3.6) that every solution $X_m = X_m^T$ of the equation

$$(3.8) \quad YDY + YA_m + A_m^T Y = 0$$

satisfies

$$(3.9) \quad \|X_m - (X - X_0)\| \geq \varepsilon_2.$$

Consider now the equation

$$(3.10) \quad \begin{aligned} & ZDZ + Z(A_m - DX_0) + (A_m - DX_0)^T Z \\ & + X_0 DX_0 - X_0 A_m - A_m^T X_0 = 0. \end{aligned}$$

We easily verify that Y is a symmetric solution of (3.8) if and only if $Y + X_0$ is a symmetric solution of (3.10). Also, $A_m - DX_0 \rightarrow A$ and

$$X_0 DX_0 - X_0 A_m - A_m^T X_0 \rightarrow -C$$

as $m \rightarrow \infty$. Now (3.9) implies that X is not conditionally stable.

Consider now the unconditional stability. So let \mathcal{N}_0 not be unconditionally stable. If $\sigma(\tilde{M}) \cap i\mathbb{R} = \emptyset$, then, in view of Theorem 3.4 of [RR1], we can argue as above to prove that X is not unconditionally stable. It remains to be proved (by the same Theorem 3.4 of [RR1]) that if \tilde{M} has pure imaginary or zero eigenvalues, then there is no unconditionally stable solution X .

It is convenient to reformulate the statement that we will prove in the following form: Given $(A, 0, D) \in \mathcal{C}_n$ with $\operatorname{Re} \sigma(A) \leq 0$, and such that A has pure imaginary or zero eigenvalues. For every $\varepsilon > 0$ find $(A', C', D') \in \mathcal{C}_n$ such that $\|A' - A\| + \|C'\| + \|D' - D\| < \varepsilon$ and $\chi(A', C', D') = \emptyset$. Applying the reductions as in the proof of Lemma 2.3, we can assume without loss of generality that the matrix

$$M := \begin{bmatrix} A & D \\ 0 & A^T \end{bmatrix}$$

is given by (2.7) or (2.8).

First, consider the case where M is given by (2.8). Because of the controllability condition, the top left corner entry d of D is positive. Let $C'(\varepsilon)$ be the $n \times n$ matrix with $-\varepsilon$ in the top left corner and zeros elsewhere, and let

$$M(\varepsilon) = \begin{bmatrix} A & d \\ C'(\varepsilon) & -A^T \end{bmatrix}.$$

Clearly, $(A, C'(\varepsilon), D) \in \mathcal{C}_n$. It is not difficult to check that for $\varepsilon > 0$ the matrix $M(\varepsilon)$ has $2n - 2$ zero eigenvalues (counting multiplicities) and the simple eigenvalues $\pm i\sqrt{\varepsilon d}$. Indeed, by an appropriate similarity, $M(\varepsilon)$ can be reduced to the form

$$\begin{bmatrix} 0 & d & 0 & * \\ -\varepsilon & 0 & & \\ 0 & J_{n_1-1}(0) \oplus \bigoplus_{j=2}^p J_{n_j}(0) & & * \\ 0 & 0 & -J_{n_1-1}(0)^T \oplus \bigoplus_{j=2}^p J_{n_j}^T(0) \end{bmatrix}.$$

By Theorem 2.2, $\chi(A, C'(\varepsilon), D) = \emptyset$ for $\varepsilon > 0$.

Finally, assume M is given by (2.7). Let us first verify that for any positive definite real symmetric matrix

$$\begin{bmatrix} d_1 & d_2 \\ d_2 & d_3 \end{bmatrix}$$

and for any $b > 0$ the 4×4 matrix

$$Q(\varepsilon) = \begin{bmatrix} 0 & b & d_1 & d_2 \\ -b & 0 & d_2 & d_3 \\ -\varepsilon & 0 & 0 & b \\ 0 & -\varepsilon & -b & 0 \end{bmatrix}$$

has four distinct pure imaginary (nonzero) eigenvalues different from $\pm ib$ when $\varepsilon > 0$ is sufficiently close to zero. Indeed, we can assume without loss of generality that $b = 1$; then the characteristic polynomial of $Q(\varepsilon)$ is

$$\lambda^4 + 2\lambda^2(1 + \varepsilon q) + 1 - 2\varepsilon q + \varepsilon^2 r = (\lambda^2 + (1 + \varepsilon q))^2 + \varepsilon^2(r - q^2) - 4\varepsilon q,$$

where

$$q = \frac{1}{2}(d_1 + d_3); \quad r = d_1 d_3 - d_2^2.$$

Since $q > 0$,

$$\varepsilon^2(r - q^2) - 4\varepsilon q < 0 \quad (\text{for } \varepsilon > 0)$$

and

$$(1 + \varepsilon q)^2 > \varepsilon^2(r - q^2) - 4\varepsilon q \quad (\text{for all real } \varepsilon),$$

the conclusion concerning eigenvalues of $Q(\varepsilon)$ follows. We now apply a perturbation similar to that applied in the case M , given by (2.8). Let $C'(\varepsilon)$ be the $n \times n$ matrix with $-\varepsilon$ in the $(1, 1)$ and $(2, 2)$ positions, and zeros elsewhere (here $\varepsilon > 0$). Again, $(A, C'(\varepsilon), D) \in \mathcal{C}_n$, and the matrix

$$M(\varepsilon) = \begin{bmatrix} A & D \\ C'(\varepsilon) & -A^T \end{bmatrix}$$

can be reduced by a suitable similarity to the form

$$\begin{bmatrix} \begin{matrix} 0 & b & d_1 & d_2 \\ -b & 0 & d_2 & d_3 \\ -\varepsilon & 0 & 0 & b \\ 0 & -\varepsilon & -b & 0 \end{matrix} & \begin{matrix} 0 \\ * \\ * \\ 0 \end{matrix} \\ \begin{matrix} 0 \\ 0 \end{matrix} & \begin{matrix} J_{n_1-1} \begin{bmatrix} 0 & b \\ -b & 0 \end{bmatrix} \oplus \bigoplus_{j=2}^p J_{n_j} \begin{bmatrix} 0 & b \\ -b & 0 \end{bmatrix} \\ 0 & -J_{n_1-1} \begin{bmatrix} 0 & b \\ -b & 0 \end{bmatrix}^T \oplus \bigoplus_{j=2}^p -J_{n_j} \begin{bmatrix} 0 & b \\ -b & 0 \end{bmatrix}^T \end{matrix} \end{bmatrix}.$$

Here

$$\begin{bmatrix} d_1 & d_2 \\ d_2 & d_3 \end{bmatrix}$$

is the top left 2×2 corner of D , which is positive definite in view of the controllability condition. Now $M(\varepsilon)$ has simple pure imaginary eigenvalues (when $\varepsilon > 0$ is close to zero), so $\chi(A, C'(\varepsilon), D) = \emptyset$ by Theorem 2.2, and we are done. \square

With the results of Lemma 3.1, the proof of the following descriptions of all stable symmetric solutions of the algebraic Riccati equation is done simply by appealing to Theorem 3.4 of [RR1].

THEOREM 3.2. *Let*

$$(3.11) \quad XDX + XA + A^T X - C = 0$$

be an algebraic Riccati equation with real $n \times n$ matrices A , $C = C^T$, and $D = D^T$ such that D is positive semidefinite and (A, D) is a controllable pair, and let

$$M = \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}.$$

A solution $X = X^T$ (X is a real matrix) of (3.11) is conditionally stable if and only if the following conditions are satisfied:

- (i) $\text{Im} \left[\begin{smallmatrix} I \\ X \end{smallmatrix} \right] \cap R(M, \lambda)$ is either zero or $R(M, \lambda)$ whenever $\lambda \neq 0$ is a real eigenvalue of M with geometric multiplicity greater than 1;
- (ii) $\text{Im} \left[\begin{smallmatrix} I \\ X \end{smallmatrix} \right] \cap R(M, \lambda)$ is an even-dimensional subspace whenever $\lambda \neq 0$ is a real eigenvalue of M of geometric multiplicity 1 and even algebraic multiplicity;
- (iii) $\text{Im} \left[\begin{smallmatrix} I \\ X \end{smallmatrix} \right] \cap R(M, a \pm ib)$ is either zero or $R(M, a \pm ib)$ whenever $a \pm ib$ is a conjugate pair of nonreal nonpure imaginary eigenvalues of M with geometric multiplicity at least 2.

THEOREM 3.3. *In the notation and under the hypotheses of Theorem 3.2, there exists an unconditionally stable real symmetric solution X if and only if M has no pure imaginary*

or zero eigenvalues. If this condition is satisfied, then X is unconditionally stable if and only if it is conditionally stable.

The first part of this theorem also follows from Corollary 3 in [F2].

Of special interest are the maximal solution X_+ and the minimal solution X_- (i.e., X_+ and X_- are real symmetric solutions of (3.11) such that $X_+ - X$ and $X - X_-$ are positive semidefinite for every real symmetric solution X). If the set of real symmetric solutions is nonempty, then X_+ and X_- always exist and are characterized by the properties that $\sigma(A + DX_+)$ lies in the closed left half-plane, and $\sigma(A + DX_-)$ lies in the closed right half-plane (see [K], [KS], [LR], and [S]).

COROLLARY 3.4. *The maximal and minimal solutions X_+ and X_- are conditionally stable. If M has no pure imaginary or zero eigenvalues, then X_+ and X_- are unconditionally stable.*

Actually, in the case where M has no pure imaginary or zero eigenvalues, the solutions X_+ and X_- are unconditionally Lipschitz stable as well (see Theorem 4.2 in the next section).

It is instructive to compare Theorems 3.2 and 3.3 with the results on structural stability of solution of the algebraic Riccati equations proved in [Bu]. A (real symmetric) solution X of (1.1) is called *structurally stable* if the following holds: Given any continuously differentiable functions $A(t)$, $C(t) = C(t)^*$, and $D(t) = D(t)^*$ such that $A(t_0) = A$, $C(t_0) = C$, and $D(t_0) = D$, for $|t - t_0|$ sufficiently small there exists a unique (in a sufficiently small neighborhood of X) solution $X(t)$ of the equation $YD(t)Y + YA(t) + A(t)^T Y - C(t) = 0$, and, moreover, the number of eigenvalues (counted with multiplicities) of $A(t) + D(t)X(t)$ in each of the three regions—open left half-plane, imaginary axis, open right half-plane—coincides with the number of eigenvalues of $A + DX$ in the corresponding region. The crucial difference with our definition of unconditionally stable solutions is that in the case of a structurally stable solution X , the perturbed equation must have a *unique* solution in a neighborhood of X . As proved in [Bu], a solution X is structurally stable if and only if $\sigma(A + DX) \cap \sigma(-A^T - XD) = \emptyset$, i.e., if and only if X is a Lipschitz stable solution (see Theorem 4.2 in the next section). In this connection we point out that an invariant subspace \mathcal{M} of a complex matrix A is Lipschitz stable if and only if every nearby matrix has a unique invariant subspace in a suitable neighborhood of \mathcal{M} (see [RR3] and Theorem 15.5.1 in [GLR5]); no symmetries are assumed here.

4. Lipschitz stability. Consider (3.1) with the usual (in this paper) assumption that $(A, C, D) \in \mathcal{C}_n$. A real symmetric solution X of (3.1) will be called *conditionally Lipschitz stable* if there exist positive constants K, ε such that for every triple $(A', C', D') \in \mathcal{C}_n$ satisfying $\|A - A'\| + \|C - C'\| + \|D - D'\| < \varepsilon$, and with $\chi(A', C', D') \neq \emptyset$ there is a real symmetric X' with the properties that $X'D'X' + X'A' + A'^T X' - C' = 0$ and $\|X - X'\| \leq K(\|A - A'\| + \|C - C'\| + \|D - D'\|)$. If the statement “and with $\chi(A', C', D') \neq \emptyset$ ” is omitted from this definition, we obtain the notion of *unconditionally Lipschitz stable* X .

THEOREM 4.1. *Assume $(A, C, D) \in \mathcal{C}_n$. Then the following statements are equivalent:*

- (i) *there exists a conditionally Lipschitz stable real symmetric solution of (3.1);*
- (ii) *there exists an unconditionally Lipschitz stable real symmetric solution of (3.1);*
- (iii) *the matrix*

$$M := \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}$$

has no pure imaginary or zero eigenvalues.

Proof. Clearly (ii) \Rightarrow (i). Assume that (iii) holds. By Theorem 3.5 of [RR1], there exists an unconditionally Lipschitz stable M -invariant J -Lagrangian subspace \mathcal{N} (as before, $J = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}$). The subspace \mathcal{N} must be of the form $\text{Im} \begin{bmatrix} I \\ X \end{bmatrix}$, where X is a real symmetric solution of (3.1) (cf. the proof of Theorem 2.2). Then X is unconditionally Lipschitz stable, thereby proving (ii).

It remains to be proved that (i) implies (iii). Let X be a conditionally Lipschitz stable solution of (3.1), put

$$\tilde{M} = \begin{bmatrix} I & 0 \\ -X & I \end{bmatrix} \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix} \begin{bmatrix} I & 0 \\ X & I \end{bmatrix} = \begin{bmatrix} A+DX & D \\ 0 & -(A+DX)^T \end{bmatrix} = \begin{bmatrix} \tilde{A} & D \\ 0 & -\tilde{A}^T \end{bmatrix}.$$

Then 0 is a conditionally Lipschitz stable solution of $XDX + X\tilde{A} + \tilde{A}^T X = 0$.

So we can restrict our attention to the case $C = 0$ and the zero solution of

$$(4.1) \quad XDX + XA + A^T X = 0.$$

We assume that A has pure imaginary or zero eigenvalues, and it will be proved that the zero solution of (4.1) is not conditionally Lipschitz stable.

Let $E_1 \geq 0$ and $E_2 < 0$ be $n \times n$ real symmetric matrices such that the $2n \times 2n$ matrix

$$\begin{bmatrix} 0 & E_1 \\ -E_2 & 0 \end{bmatrix}$$

has $2n$ distinct eigenvalues. Consider the Riccati equation

$$(4.2) \quad X(D + \alpha E_1)X + XA + A^T X + \alpha E_2 = 0,$$

for every $\alpha \geq 0$. Put $R(X) = -X(D + \alpha E_1)X - XA - A^T X - \alpha E_2$. Then $R(0) = -\alpha E_2 \geq 0$. By Theorem 2.1 in [RV] it follows that (4.2) has Hermitian solutions, and therefore also has real symmetric solutions. Note in this connection that the controllability of (A, D) implies the controllability of $(A, D + \alpha E_1)$. Let

$$M(\alpha) = \begin{bmatrix} A & D + \alpha E_1 \\ -\alpha E_2 & -A^T \end{bmatrix}$$

be the matrix corresponding to (4.2). Since for large α the matrix $M(\alpha)$ has $2n$ distinct eigenvalues, by a general result on the Jordan structure of a matrix analytically depending on a parameter (see [B], [GLR2]), for $\alpha_0 > 0$ sufficiently small the matrix $M(\alpha)$, $0 < \alpha \leq \alpha_0$, also has $2n$ distinct eigenvalues.

In particular, the number of $M(\alpha)$ -invariant J -Lagrangian subspaces is finite and is independent of α , for $0 < \alpha \leq \alpha_0$. So the number of real symmetric solutions $X(\alpha)$ of (4.2) is also finite and independent of α ($0 < \alpha \leq \alpha_0$). Moreover, the Puiseux expansions of eigenvalues, eigenvectors, and generalized eigenvectors of a matrix depending analytically on a parameter (see [B] and [GLR2]), together with the formula

$$\mathcal{N}(\alpha) = \text{Im} \begin{bmatrix} I \\ X(\alpha) \end{bmatrix},$$

where $\mathcal{N}(\alpha)$ is any $M(\alpha)$ -invariant J -Lagrangian subspace, show that $X(\alpha)$ is given by a fractional power series

$$(4.3) \quad X(\alpha) = \sum_{j=-k}^{\infty} \alpha^{j/p} X_j,$$

for some choice of the p th root $\alpha^{1/p}$ (here k is a nonnegative integer, and X_j are $n \times n$ matrices that may depend on the choice of $\alpha^{1/p}$). Arguing by contradiction, assume

that 0 is a conditionally Lipschitz stable real symmetric solution of (4.1). Then there is $K > 0$ such that for every $\alpha \in (0, \alpha_0]$ there is a solution $\tilde{X}(\alpha)$ of (4.2) satisfying

$$(4.4) \quad \|\tilde{X} - \tilde{X}(\alpha)\| \leq K\alpha.$$

As the number of branches in (4.3) is finite, there will be a sequence $\{\alpha_j\}_{j=1}^\infty$ of positive numbers such that $\lim_{j \rightarrow \infty} \alpha_j = 0$ and $\tilde{X}(\alpha_j)$ belongs to the same branch in (4.3). For this branch (4.4) implies that $k=0$, $X_0 = \tilde{X}$, and $X_1 = \cdots = X_{p-1} = 0$ in (4.3). In particular, $X(\alpha)$ is differentiable at $\alpha=0$ along this branch, and $X'(0) = X_p$. Differentiating equality (4.2) with respect to α and evaluating at $\alpha=0$ gives

$$(4.5) \quad X_p A + A^T X_p = -E_2.$$

We have assumed, however, that A has pure imaginary or zero eigenvalues. Let $i\beta \in \sigma(A)$, and denote by $y \in \mathbb{C}^n$ the corresponding eigenvector. Then we have $Ay = i\beta y$, $y^* A^T = -i\beta y^*$, and (4.5) implies $-y^* E_2 y = 0$, a contradiction with the negative definiteness of E_2 . \square

Using Theorem 4.1, we can now describe the Lipschitz stable real symmetric solutions of (3.1).

THEOREM 4.2. *Assume $(A, C, D) \in \mathcal{C}_n$, and assume that the matrix*

$$M = \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}$$

has no pure imaginary or zero eigenvalues. Then the following statements are equivalent for a real symmetric solution X of

$$(4.6) \quad XDX + XA + A^T X - C = 0:$$

- (i) X is conditionally Lipschitz stable;
- (ii) X is unconditionally Lipschitz stable;
- (iii) $\sigma(A + DX) \cap \sigma(-A^T - XD) = \emptyset$.

Proof. If condition (iii) holds, then the corresponding M -invariant J -Lagrangian subspace $\mathcal{N} = \text{Im} \begin{bmatrix} I \\ X \end{bmatrix}$ is spectral (i.e., sum of root subspaces). Then, clearly, \mathcal{N} is unconditionally Lipschitz stable as an M -invariant J -Lagrangian subspace (even as an M -invariant subspace); so (ii) follows. The implication (ii) \Rightarrow (i) is evident. Finally, assume (i). Let X_0 be the maximal real symmetric solution of (4.6). We have

$$\begin{bmatrix} I & 0 \\ -X_0 & I \end{bmatrix} M \begin{bmatrix} I & 0 \\ X_0 & I \end{bmatrix} = \begin{bmatrix} A + DX_0 & D \\ 0 & -(A + DX_0)^T \end{bmatrix};$$

so without loss of generality we can (and will) assume that $C = 0$ and the spectrum of A lies in the open left half-plane (as $\sigma(M) \cap i\mathbb{R} = \emptyset$, we must have also $\sigma(A) \cap i\mathbb{R} = \emptyset$). Arguing by contradiction, let $\lambda_0 \in \sigma(A + DX) \cap \sigma(-A^T - XD)$, and assume (without loss of generality) that λ_0 lies in the open left half-plane. The corresponding M -invariant subspace $\mathcal{N} = \text{Im} \begin{bmatrix} I \\ X \end{bmatrix}$ is then not a spectral subspace. Let $\mathcal{N}_0 = \text{Im} \begin{bmatrix} I \\ 0 \end{bmatrix}$ and let $P: \mathbb{R}^{2n} \rightarrow \mathbb{R}^n$ be the projection on the first n coordinates (so $P \begin{bmatrix} x \\ y \end{bmatrix} = x$, where $x, y \in \mathbb{R}^n$). The subspace $\mathcal{H} = P(\mathcal{N} \cap \mathcal{N}_0) \subset \mathbb{R}^n$ is clearly A -invariant; moreover, \mathcal{H} is not a spectral subspace for A . Consequently (see [KMR] and [GLR5]), \mathcal{H} is not Lipschitz stable as an A -invariant subspace. So there exists a sequence of real matrices $\{A_p\}_{p=1}^\infty$ such that $A_p \rightarrow A$ as $p \rightarrow \infty$ but

$$(4.6) \quad \lim_{p \rightarrow \infty} \frac{\text{dist}(\mathcal{H}, \text{Inv}(A_p))}{\|A_p - A\|} = \infty,$$

where $\text{Inv}(A_p)$ stands for the set of all real A_p -invariant subspaces, and

$$\text{dist}(\mathcal{H}, \text{Inv}(A_p)) = \inf_{\mathcal{L} \in \text{Inv}(A_p)} \Theta(\mathcal{H}, \mathcal{L})$$

is the distance from \mathcal{H} to $\text{Inv}(A_p)$ in the gap metric. For p large enough, we have $(A_p, 0, D) \in \mathcal{C}_n$, but (4.6) implies

$$\lim_{p \rightarrow \infty} \frac{\text{dist}(X, R(A_p))}{\|A_p - A\|} = \infty,$$

where

$$\text{dist}(X, R(A_p)) = \inf_{Y \in R(A_p)} \|X - Y\|,$$

and $R(A_p)$ stands for the (nonempty) set of real symmetric solutions of the equation $YDY + YA_p + A_p^T Y = 0$. We have obtained a contradiction to the conditional Lipschitz stability of X . \square

The last part of the proof of Theorem 4.2 uses similar ideas to those in the proof of Theorem 4.5 in [RR2].

We conclude this section with an improved version of Theorem 4.9 in [RR2] concerning Lipschitz stable complex Hermitian solutions of the Riccati equation with complex coefficients

$$(4.7) \quad XDX + XA + A^*X - C = 0,$$

where A , D , and C are complex $n \times n$ matrices with $D = D^* \geq 0$, $C = C^*$, and (A, D) controllable. The definitions of conditionally and unconditionally Lipschitz stable Hermitian solutions X of (4.7) are given analogously to the real case (allowing perturbed equations with complex coefficients as well).

THEOREM 4.3. *Assume that $D = D^* \geq 0$, $C = C^*$, and (A, D) controllable.*

There exists an (un)conditionally Lipschitz stable Hermitian solution X of (4.7) if and only if the matrix

$$\begin{bmatrix} A & D \\ C & -A^* \end{bmatrix}$$

has no pure imaginary or zero eigenvalues. In this case a Hermitian solution X of (4.7) is (un)conditionally Lipschitz stable if and only if

$$\sigma(A + DX) \cap \sigma(-A^* - XD) = \emptyset.$$

The proof of Theorem 4.3 is obtained in the same way as the proofs of Theorems 4.1 and 4.2.

5. Further properties of stable solutions of the Riccati equation. In this section we indicate some properties of the stable solutions that follow from Theorems 3.2, 3.3, 4.1, and 4.2. Given the algebraic Riccati equation

$$(5.1) \quad XDX + XA + A^T X - C = 0,$$

with $(A, C, D) \in \mathcal{C}_n$. Denote by \mathcal{S}_{cs} , \mathcal{S}_{us} , and \mathcal{S}_{LS} the classes of conditionally stable, unconditionally stable, and Lipschitz stable real symmetric solutions of (5.1), respectively (by Theorems 4.1 and 4.2, the classes of conditionally and unconditionally Lipschitz stable real symmetric solutions coincide).

COROLLARY 5.1. *We have*

$$\mathcal{S}_{Ls} \subset \mathcal{S}_{us} \subset \mathcal{S}_{cs}.$$

Furthermore, assuming the set of real symmetric solutions of (5.1) is nonempty, we have $\mathcal{S}_{us} = \mathcal{S}_{cs}$ if and only if the matrix

$$M = \begin{bmatrix} A & D \\ C & -A^T \end{bmatrix}$$

has no pure imaginary or zero eigenvalues. The equality $\mathcal{S}_{Ls} = \mathcal{S}_{us}$ holds if and only if every nonreal nonpure imaginary eigenvalue of M with geometric multiplicity 1 has algebraic multiplicity 1, and every nonzero real eigenvalue of M with geometric multiplicity 1 has algebraic multiplicity at most 2.

Next, we show that the stable solutions (with the exception of conditionally stable ones) are persistent in the sense that any sufficiently close solution of a nearby equation is again stable.

COROLLARY 5.2. *Let X_0 belong to one of the classes \mathcal{S}_{Ls} and \mathcal{S}_{us} . Then there exists $\varepsilon > 0$ such that every solution Y_0 of*

$$YD'Y + YA' + A'^TY - C' = 0$$

belongs to the same stability class, provided $(A', C', D') \in \mathcal{C}_n$ and

$$\|A' - A\| + \|C' - C\| + \|D' - D\| + \|Y_0 - X_0\| < \varepsilon.$$

For the conditional stability, this corollary is generally false, as the following example shows.

Example 5.1. Let

$$A = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & -1 \\ 0 & 0 & 0 & -1 \end{bmatrix}, \quad C = 0,$$

and D any 4×4 positive semidefinite Hermitian matrix such that (A, D) is controllable and the $(2, 4)$ entry of D is nonzero. Then the zero solution of $XD'X + XA + A^TX = 0$ is conditionally stable by Theorem 3.2. However, for real $\varepsilon \neq 0$ such that $|\varepsilon|$ is small, the matrix

$$M(\varepsilon) = \begin{bmatrix} A(\varepsilon) & D \\ 0 & -A(\varepsilon)^T \end{bmatrix},$$

where

$$A(\varepsilon) = \begin{bmatrix} 1 & 1 \\ 0 & 1 + \varepsilon \end{bmatrix} \oplus \begin{bmatrix} -1 & -1 \\ 0 & -1 - \varepsilon \end{bmatrix}$$

has geometric multiplicity 1 and algebraic multiplicity 2 corresponding to the eigenvalue 1. By the same Theorem 3.2 the zero solution of $XD'X + XA(\varepsilon) + A(\varepsilon)^TX = 0$ is not conditionally stable (for real $\varepsilon \neq 0$ close to zero).

Our last observation relates the notions of stability with isolatedness of the solutions. A real symmetric solution X_0 of (5.1) is called *isolated* if there is no other real symmetric solution in a sufficiently small neighborhood of X_0 , in other words, if there is $\varepsilon > 0$ such that any real symmetric solution $X \neq X_0$ of (5.1) (if such exists) satisfies the inequality $\|X - X_0\| \geq \varepsilon$. It is easy to see (via the isolatedness properties of M -invariant J -Lagrangian subspaces, see [RR1]) that every conditionally stable real symmetric solution is isolated. The converse is generally not true, as the following example shows.

Example 5.2. Let $A(\varepsilon)$, C , D be as in Example 5.1. Then for fixed real $\varepsilon \neq 0$ with $|\varepsilon|$ small, the zero solution of $XD\dot{X} + XA(\varepsilon) + A(\varepsilon)^T X = 0$ is isolated but not conditionally stable.

The following result describes the situation where every isolated solution is conditionally stable.

COROLLARY 5.3. *Every isolated real symmetric solution of (3.1) is conditionally stable if and only if every real nonzero eigenvalue of M of geometric multiplicity 1 has odd algebraic multiplicity.*

The proof of this corollary follows by combining Theorem 3.2 and the description of isolated real invariant subspaces for real matrices (see [BGK]). Analogous statements concerning the case where every isolated solution is unconditionally stable, or Lipschitz stable, can be given as well. We omit these statements.

6. Disconjugacy of Hamiltonian systems. Consider the linear Hamiltonian equation

$$(6.1) \quad Jx' = Hx,$$

where

$$J = \begin{bmatrix} 0 & -I_n \\ I_n & 0 \end{bmatrix}, \quad H = \begin{bmatrix} A & B^T \\ B & C \end{bmatrix}$$

are constant real matrices and $x = x(t)$, $-\infty < t < \infty$, is an unknown $2n$ -dimensional real vector function. Equation (6.1) is called *disconjugate* if it has no nontrivial solutions $x(t) = \begin{bmatrix} y(t) \\ z(t) \end{bmatrix}$ such that the vector $y(t)$ has zeros at two distinct points. We have the following result (see [C]).

THEOREM 6.1. *Assume that $C = C^T$ is positive semidefinite, $A = A^T$, and (C, B) is controllable. Then (6.1) is disconjugate if and only if the Riccati equation*

$$(6.2) \quad XCX + B^T X + XB + A = 0$$

has real symmetric solutions X .

We say that (6.1) is *stably disconjugate* if there exists $\varepsilon > 0$ such that all equations

$$(6.3) \quad Jx' = \tilde{H}x$$

with real matrices

$$\tilde{H} = \begin{bmatrix} \tilde{A} & \tilde{B}^T \\ \tilde{B} & \tilde{C}^T \end{bmatrix}$$

satisfying $\tilde{C} = \tilde{C}^T$ positive semidefinite, $\tilde{A} = \tilde{A}^T$, and $\|\tilde{A} - A\| + \|\tilde{B} - B\| + \|\tilde{C} - C\| < \varepsilon$ are disconjugate. The criterion for stable disconjugacy is given in the following theorem.

THEOREM 6.2. *Equation (6.1) is stably disconjugate if and only if the matrix*

$$(6.4) \quad \begin{bmatrix} B & C \\ -A & -B^T \end{bmatrix}$$

has no pure imaginary or zero eigenvalues.

Proof. Assume that (6.3) has no pure imaginary eigenvalues. By Theorem 2.2, (6.2) has real symmetric solutions, and this is also true for (6.3) if $\varepsilon > 0$ is small enough. By Theorem 6.1, (6.1) is stably disconjugate.

Conversely, assume that (6.4) has pure imaginary or zero eigenvalues, and that (6.1) is disconjugate. We will show that it is not stably disconjugate. To this end (in view of Theorem 6.1), it is sufficient to exhibit for every $\varepsilon > 0$ real matrices \tilde{A} , \tilde{C} , and \tilde{B} such that $\tilde{C} = \tilde{C}^T$ is positive semidefinite, $\tilde{A} = \tilde{A}^T$, $\|\tilde{A} - A\| + \|\tilde{B} - B\| + \|\tilde{C} - C\| < \varepsilon$, and the equation $X\tilde{C}X + \tilde{B}^TX + X\tilde{B} + \tilde{A} = 0$ has no real symmetric solutions. This can be done by using the same perturbations as in the proof of the unconditional stability part of Lemma 3.1. \square

The theorem can also be easily obtained from Corollary 3 in [F2].

SUFFICIENCY CRITERIA VIA FOCAL POINTS AND VIA COUPLED POINTS*

VERA ZEIDAN†

This paper is dedicated to the memory of W. T. Reid.

Abstract. Considered in this paper is a general quadratic functional $J(\eta)$ with constraints of the form $\eta(a) = D\eta(b) = 0$, where D is an $r \times n$ -matrix ($r \leq n$) and of full rank. It is shown that the nonexistence of focal points to b in $[a, b]$ is equivalent to the existence of a solution to the corresponding Riccati equation with associated boundary conditions. Thus, it is equivalent to the positivity of $J(\eta)$. This result generalizes W. A. Coppel, *Proceedings of the Royal Society of Edinburgh*, 73A, 18, 1974-1975, pp. 271-289; V. B. Haas, *Systems and Control Letters*, 5 (1984), North-Holland, Amsterdam, pp. 55-57; and W. T. Reid, Academic Press, New York, 1972, in which either $D = I$ or 0 is assumed. Moreover, it is proven that the nonexistence of "coupled points with a " in $(a, b]$ is also equivalent to the positivity of $J(\eta)$, proving that for this problem, the notion of a "coupled point with a " is the one searched for to extend that of a "conjugate point to a " from $D = I$ to a general D . Each of these conditions is proved to be sufficient for optimality in the nonlinear calculus of variations problem with fixed initial state but variable final endpoints.

Key words. calculus of variations, focal points, coupled points, Riccati equations, sufficient conditions

AMS(MOS) subject classification. 49B36

1. Introduction. Consider the following functional:

$$J(\eta) = \frac{1}{2} \eta(b)^T \Gamma \eta(b) + \frac{1}{2} \int_a^b \{ \eta^T(s) P(s) \eta(s) + 2 \dot{\eta}^T(s) Q(s) \eta(s) + \dot{\eta}^T(s) R(s) \dot{\eta}(s) \} ds,$$

where $\eta(\cdot)$ is absolutely continuous $\eta: [a, b] \rightarrow \mathbb{R}^n$ and satisfies

$$\eta(a) = 0, \quad D\eta(b) = 0;$$

and $P(\cdot)$, $Q(\cdot)$, and $R(\cdot)$ are given $n \times n$ -matrix functions such that, for all $t \in [a, b]$, $P(t)$ and $R(t)$ are symmetric. The functions P , Q , and R are essentially bounded on $[a, b]$. The matrix Γ is symmetric, and $D \in M_{r \times n}$ ($r \leq n$) is of full rank.

Set

$$\mathcal{D} := D^T (DD^T)^{-1} D;$$

then \mathcal{D} is a *projection*, symmetric, $\mathcal{D}(I - \mathcal{D}) = 0$, and $\mathcal{D}\alpha = 0$ if and only if $D\alpha = 0$. Thus, without loss of generality, the boundary condition $D\eta(b) = 0$ can be replaced by $\mathcal{D}\eta(b) = 0$. Furthermore, due to the boundary conditions on $\eta(b)$, Γ in $J(\eta)$ can be assumed of the form $(I - \mathcal{D})\Gamma(I - \mathcal{D})$.

The Euler-Lagrange equation associated with the problem is

$$(1.1) \quad \frac{d}{dt} [R(t) \dot{\eta}(t) + Q(t) \eta(t)] = Q^T(t) \dot{\eta}(t) + P(t) \eta(t), \quad t \in [a, b] \text{ a.e.}$$

Assume throughout the paper the strengthened Legendre condition, i.e., $R(t) \geq \beta I$, for $t \in [a, b]$ almost everywhere, and for some $\beta > 0$. Then, following Cesari [3], by a solution of (1.1) we mean a function $\eta(\cdot)$ absolutely continuous (AC) for which there

* Received by the editors September 11, 1989, accepted for publication (in revised form) November 27, 1990. The author thanks Consiglio Nazionale delle Ricerche (Italy) and the Natural Sciences and Engineering Research Council of Canada, whose support made this research possible.

† Department of Mathematics, Michigan State University, East Lansing, Michigan 48824.

exists a function $\xi(\cdot) \in AC$ satisfying for $t \in [a, b]$ almost everywhere the *Jacobi system*

$$(1.2) \quad \begin{aligned} \dot{\eta}(t) &= A(t)\eta(t) + B(t)\xi(t), \\ \dot{\xi}(t) &= C(t)\eta(t) - A^T(t)\xi(t), \end{aligned}$$

where

$$A = -R^{-1}Q, \quad B = R^{-1}, \quad C = P - Q^T R^{-1}Q.$$

Since the initial condition of η is fixed, corresponding to \mathbf{b} there is the notion of a *focal point* introduced for the case of smooth data by Kneser in 1898 (see [1] and [16]). Such a point $c \in [a, b]$ is characterized by the existence of a nonzero solution (η, ξ) of (1.2) satisfying

$$(1.3) \quad \eta(c) = \mathcal{D}\eta(b) = 0 \quad \text{and} \quad \langle \eta(b), \xi(b) + \hat{\Gamma}\eta(b) \rangle = 0,$$

where $\hat{\Gamma} = (I - \mathcal{D})\Gamma(I - \mathcal{D})$.

Sufficient conditions for the positivity of $J(\eta)$ are known in terms of the corresponding Riccati equation. See, for instance, [2], where the result is proved for the more general situation, that is, the linear optimal regulator problem. The question of relating focal point theory *directly* to the Riccati equation with a corresponding boundary condition is of theoretical and practical interest. In addition to providing us with a sufficiency criterion in terms of a first-order linear system of ordinary differential equations (1.2), it allows us to see how we can *explicitly* construct a solution to the Riccati equation. Much work has been done in that direction but only for the special case when $\mathcal{D} = 0$ or $\mathcal{D} = I$. In fact, it is shown in [5], [8], and [12] that in those cases the nonexistence of focal points (when $\mathcal{D} = I$ focal points are conjugate points) to \mathbf{b} in $[a, b)$ is equivalent to the existence of a solution to the corresponding Riccati equation and, hence, to the positivity of $J(\eta)$. This is proved by constructing a “conjoined basis” to the Jacobi system in terms of which the solution for the Riccati equation is obtained. On the other hand, it is a well-known fact (when $\mathcal{D} = 0$ see [10] and [12], and for a general \mathcal{D} , see [20]) that the nonexistence of focal points \mathbf{b} in (a, b) is a necessary condition for the nonnegativity of $J(\eta)$. Thus, for $\mathcal{D} = I$ or 0, the gap between necessary and sufficient conditions is as small as possible.

In [7] there is a transformation from a variable endpoint problem to one with a free endpoint. Hence, the Riccati solution to the original problem is given in terms of the one for the free endpoint case. This idea would not work here since $P(b)$ is undefined through that transformation, and thus the boundary condition in (3) of Theorem 2.1 cannot be recaptured.

Recently, in collaboration with Zezza, the author developed in [17]–[19] the notion of a coupled point that is an extension of the focal point to the case of variable endpoint(s). Since the final endpoint of η in the above problem is varying, we have here the notion of a point coupled with \mathbf{a} . To such a point c , corresponds a nonzero solution (η, ξ) of the Jacobi system satisfying

$$\begin{aligned} \eta(\cdot) &\not\equiv \eta(c) \quad \text{on} \quad [c, b] \quad (\text{drop if } c = b) \\ \eta(a) &= \mathcal{D}\eta(c) = 0 \quad \text{and} \quad \left\langle \eta(c), \xi(c) + \hat{\Gamma}\eta(c) + \int_c^b P(s) ds \eta(c) \right\rangle = 0, \end{aligned}$$

where $\hat{\Gamma} = (I - \mathcal{D})\Gamma(I - \mathcal{D})$.

It is shown in [18] and [19] that the nonexistence of points in (a, b) coupled with \mathbf{a} is necessary for the nonnegativity of $J(\eta)$ subject to $\eta(a) = \mathcal{D}\eta(b) = 0$.

This paper focuses on two issues. First, we show that for a general \mathcal{D} , the nonexistence of focal points to \mathbf{b} in $[a, b)$ is equivalent to the existence of a solution

to the corresponding Riccati equation and boundary condition, and hence it is equivalent to the strict positivity of $J(\eta)$ over $\eta(a) = \mathcal{D}\eta(b) = 0$. The proof we employ is of a constructive nature. We show how the nonexistence of focal points to \mathbf{b} in $[a, b]$ produces an *explicit formula* for the solution of the Riccati equation with associated boundary conditions. Thus, we extend the result in [5], [8], and [15] to a general case, i.e., when the right endpoint is restricted to belong to any linear subspace $\mathcal{L} = \ker \mathcal{D}$ of the state space. The second goal is to show that the definition of a coupled point is, in fact, the right one that extends the notion of a focal point to the variable endpoint(s) problem. To accomplish this aim, it is only natural to consider the above problem, that is, the problem with one endpoint *fixed* and the other *varying* on a linear subspace. Then we show that the nonexistence of coupled points to \mathbf{a} also allows us to construct a solution to the corresponding Riccati equation with associated boundary condition, and hence is equivalent to the strict positivity of $J(\eta)$ over $\eta(a) = \mathcal{D}\eta(b) = 0$. This also means that the nonexistence of focal points to \mathbf{b} in $[a, b]$ is equivalent to the nonexistence of coupled points with \mathbf{a} in $(a, b]$. In the last section, we show that the nonexistence of focal points to \mathbf{b} in $[a, b]$, or the nonexistence of coupled points with \mathbf{a} in $(a, b]$ is sufficient for optimality in the nonlinear calculus of variations problem with fixed initial and variable final endpoints. Finally, we provide a numerical example to illustrate the utility of our results.

2. Sufficiency and focal points. Consider the quadratic functional $J(\eta)$ given in the Introduction. The following definition can be found in [1] and [16].

DEFINITION 2.1. A point \mathbf{c} is focal to \mathbf{b} if there exists a nonzero solution (η, ξ) of the Jacobi system

$$(2.1) \quad \begin{aligned} \dot{\eta} &= A\eta + B\xi, \\ \dot{\xi} &= C\eta - A^T\xi, \end{aligned}$$

where $A = -R^{-1}Q$, $B = R^{-1}$, $C = P - Q^TR^{-1}Q$, with

$$(2.2) \quad \eta(c) = \mathcal{D}\eta(b) = 0 \quad \text{and} \quad \langle \eta(b), \xi(b) + \hat{\Gamma}\eta(b) \rangle = 0,$$

where $\hat{\Gamma} = (I - \mathcal{D})\Gamma(I - \mathcal{D})$.

The main goal of this section is to establish the equivalence between the positivity of $J(\eta)$ over $\eta: \eta(a) = \mathcal{D}\eta(b) = 0$ and the nonexistence of focal points to \mathbf{b} in $[a, b]$. This is done by constructing a certain “conjoined basis” (U, V) of (2.1) having a certain property that leads to the construction of a solution to the corresponding Riccati equation.

Following Reid [15], we make the following definition.

DEFINITION 2.2. A pair (U, V) of $n \times n$ -matrix functions on $[a, b]$ is a conjoined basis of the Jacobi system (2.1) if (U, V) solves the Jacobi matrix system, and the columns (U_i, V_i) of (U, V) form a set of linearly independent solutions of (2.1) such that

$$U^TV = V^TU.$$

The following theorem forms the main result of this section.

THEOREM 2.1. *The following are equivalent.*

- (1) *There exists no point in $[a, b]$ focal to \mathbf{b} ,*
- (2) *There exists a conjoined basis (U, V) to (2.1) such that $\det U \neq 0$ on $[a, b]$ and*

$$(I - \mathcal{D})[V(b) + \hat{\Gamma}U(b)] = 0,$$

(3) *There exists a Lipschitz symmetric matrix function $W(\cdot):[a, b] \rightarrow M_{n \times n}$ solution of*

$$\dot{W} + WBW + A^T W + WA - C = 0 \quad \text{for } t \in [a, b] \text{ a.e.,}$$

with

$$(I - \mathcal{D})[W(b) + \hat{\Gamma}] = 0,$$

$$(4) \quad J(\eta) \geq \varepsilon \int_a^b |\dot{\eta}(t)|^2 dt \quad \forall \eta: \eta(a) - D\eta(b) = 0, \quad \text{for some } \varepsilon > 0.$$

Remark. When $\mathcal{D} = I$ or $\mathcal{D} = 0$, Theorem 2.1 reduces to well-known results by Reid [15, Chap. IV, Thm. 7.1]; respectively [15, Chap. IV, Thm. 7.3]. Thus, our result here extends that of Reid to a general setting. Reid has also tackled the case where subspace constraints at both endpoints are allowed. In Chapter IV of [15, Thm. 7.4] he established the relationship between the positivity of the quadratic functional and the corresponding Riccati equation. Here, in Theorem 2.1, we extend his result to also include the focal point theory for the case where the initial endpoint is zero and the final endpoint is constrained to a subspace.

Proof of Theorem 2.1. We will show the following implications: (2) \Rightarrow (3) \Rightarrow (4) \Rightarrow (1) \Rightarrow (2).

(2) \Rightarrow (3): Let (U, V) be the conjoined basis in (2). Since U is invertible on $[a, b]$, define $W = VU^{-1}$. Using $U^T V = V^T U$, we obtain the symmetry of W . It is easily shown that W satisfies the Riccati equation of (3) and $(I - \mathcal{D})[W(b) + \hat{\Gamma}] = 0$.

(3) \Rightarrow (4): Let W be the Lipschitz symmetric function satisfying condition (3). Since $R(t) \geq \beta I$, for $t \in [a, b]$ almost everywhere, then for $0 < \varepsilon \leq \beta/2$, $R_\varepsilon(t) := R(t) - \varepsilon I \geq (\beta/2)I$ for almost all t in $[a, b]$. Consider the Riccati equation in condition (3) with B replaced by $B_\varepsilon = R_\varepsilon^{-1}$. Since $R_\varepsilon \geq (\beta/2)I$ almost everywhere, then $R_\varepsilon^{-1} \in L^\infty[a, b]$ and, hence, by the embedding theorem of differential equations or the continuous dependence on a parameter (see, e.g., Theorem 4.1 in the Appendix of [9]), there exists a Lipschitz symmetric matrix function W_ε satisfying

$$\dot{W}_\varepsilon + W_\varepsilon B_\varepsilon W_\varepsilon + A_\varepsilon^T W_\varepsilon + W_\varepsilon A_\varepsilon - C_\varepsilon = 0 \quad \text{a.e.}$$

with

$$W_\varepsilon(b) = W(b) + \varepsilon I,$$

where $B_\varepsilon = R_\varepsilon^{-1}$, $A_\varepsilon = -R_\varepsilon^{-1}Q$, $C_\varepsilon = P - Q^T R_\varepsilon^{-1}Q$. Let $\eta \neq 0$ be any absolutely continuous function satisfying $\eta(a) = \mathcal{D}\eta(b) = 0$. Then

$$0 = \frac{1}{2} \eta^T(b) W_\varepsilon(b) \eta(b) - \frac{1}{2} \int_a^b \frac{d}{dt} \{ \eta^T(t) W_\varepsilon(t) \eta(t) \} dt$$

and hence

$$\begin{aligned} J(\eta) &= \frac{1}{2} \eta(b)^T (W_\varepsilon(b) + \Gamma) \eta(b) + \frac{1}{2} \int_a^b \{ \eta^T(t) (P(t) - \dot{W}_\varepsilon(t)) \eta(t) \\ &\quad + 2\dot{\eta}^T(t) (Q(t) - W_\varepsilon(t)) \eta(t) + \dot{\eta}^T(t) R(t) \dot{\eta}(t) \} dt \\ &= \frac{1}{2} \eta^T(b) (I - \mathcal{D}) (W_\varepsilon(b) + \Gamma) (I - \mathcal{D}) \eta(b) \\ &\quad + \frac{1}{2} \int_a^b [\eta^T (Q^T - W_\varepsilon) + \dot{\eta}^T R_\varepsilon] R_\varepsilon^{-1} [(Q - W_\varepsilon) \eta + R_\varepsilon \dot{\eta}] dt \\ &\quad + \varepsilon \int_a^b |\dot{\eta}(t)|^2 dt. \end{aligned}$$

Thus, if $J_\varepsilon(\eta)$ is the second term of the last equation, then $J_\varepsilon(\eta) \geq 0$ and

$$J_\varepsilon(\eta) = 0 \quad \text{if and only if} \quad \dot{\eta} = -R_\varepsilon^{-1}(Q - W_\varepsilon)\eta.$$

Since $\eta(a) = 0$, it follows that $J_\varepsilon(\eta)$ is positive definite. Since $(I - \mathcal{D})(W_\varepsilon(b) + \hat{\Gamma}) = \varepsilon(I - \mathcal{D})$, condition (4) holds.

(4) \Rightarrow (1): If there exists a point $c \in [a, b]$ focal to b then there exists $(\eta, \xi) \neq 0$ satisfying (2.1) and (2.2). Define

$$\bar{\eta}(s) = \begin{cases} \eta(s) & \text{on } [c, b] \\ 0 & \text{on } [a, c], \end{cases}$$

then

$$\begin{aligned} J(\bar{\eta}) &= \frac{1}{2} \eta^T(b) \Gamma \eta(b) + \frac{1}{2} \int_c^b \{ \dot{\xi} \cdot \eta + \dot{\eta} \cdot \xi \} dt \\ &= \frac{1}{2} \eta^T(b) \hat{\Gamma} \eta(b) + \frac{1}{2} \xi \cdot \eta|_c^b \\ &= 0, \end{aligned}$$

and hence, using (4), $\bar{\eta} \equiv 0$. Since B is invertible, (2.1) yields $\xi \equiv 0$ on $[c, b]$. Therefore, $(\eta, \xi) \equiv 0$ and we have a contradiction, proving that (1) holds.

Let us define (U_a, V_a) and (U_b, V_b) to be the solutions to the Jacobi matrix system

$$\begin{aligned} \dot{U} &= AU + BV, \\ \dot{V} &= CU - A^T V, \end{aligned} \tag{2.3}$$

with boundary conditions, respectively,

$$\begin{aligned} U_a(a) &= 0, & U_b(b) &= I - \mathcal{D}, \\ V_a(a) &= I, & V_b(b) &= -\hat{\Gamma} - \mathcal{D}. \end{aligned} \quad \text{and}$$

It is easy to see that (U_a, V_a) and (U_b, V_b) satisfy $d/dt[U^T V - V^T U] = 0$ for t in $[a, b]$ almost everywhere. Thus, by using the boundary conditions on (U_a, V_a) and (U_b, V_b) and the fact that $\hat{\Gamma} = (I - \mathcal{D})\Gamma(I - \mathcal{D})$, it results that $U_\alpha^T V_\alpha = V_\alpha^T U_\alpha$, $\alpha = a, b$.

To prove that (1) \Rightarrow (2) the following lemmas will be needed.

LEMMA 2.1. For all $t \in [a, b]$,

$$V_a^T(t) U_b(t) - U_a^T(t) V_b(t) = \text{constant} = U_b(a). \tag{2.4}$$

If, in addition, we assume condition (1) of Theorem 2.1, then $\det U_b(t) \neq 0 \quad \forall t \in [a, b]$ and $\det U_a(b) \neq 0$.

Proof of Lemma 2.1. Using system (2.3) for (U_a, V_a) and (U_b, V_b) , we obtain

$$\frac{d}{dt} [V_a^T(t) U_b(t) - U_a^T(t) V_b(t)] = 0$$

and hence

$$V_a^T(t) U_b(t) - U_a^T(t) V_b(t) = \text{constant} = M.$$

Evaluating $t = a$, we get that $M = U_b(a)$.

If there exists $c \in [a, b]$ and $\alpha (\neq 0) \in \mathbb{R}^n$ such that $U_b(c)\alpha = 0$, define

$$(\eta(t), \xi(t)) = (U_b(t)\alpha, V_b(t)\alpha).$$

Thus, (η, ξ) and c satisfy the Jacobi system (2.1) and (2.2). Moreover, $(\eta, \xi) \neq 0$, since otherwise $(\eta(b), \xi(b)) = ((I - \mathcal{D})\alpha, (-\hat{\Gamma} - \mathcal{D})\alpha) = 0$ and hence, $(I - \mathcal{D})\alpha = 0$ and $\mathcal{D}\alpha = 0$. Therefore, $\alpha = 0$, contradicting $\alpha \neq 0$. Thus, c is focal to b , but this contradicts (1). We have proved that $\det U_b(t) \neq 0$ for all $t \in [a, b]$.

Now, if $\det U_a(b) = 0$, then $U_a(b)\alpha = 0$ for some $\alpha \neq 0$, $\alpha \in \mathbb{R}^n$. Define $(\eta(t), \xi(t)) = (U_a(t)\alpha, V_a(t)\alpha)$. It follows that (2.1) holds, and $\eta(a) = \eta(b) = 0$; i.e., (2.2) is also satisfied for $c = a$. Moreover, $(\eta(a), \xi(a)) = (0, \alpha) \neq 0$ yields $(\eta, \xi) \neq 0$. Therefore, a is focal to b , and a contradiction with (1) is obtained. \square

LEMMA 2.2. *Let*

$$(2.5) \quad \begin{aligned} U(t) &= U_a(t)U_b^{T^{-1}}(a)\mathcal{D} + U_b(t), \\ V(t) &= V_a(t)U_b^{T^{-1}}(a)\mathcal{D} + V_b(t), \end{aligned}$$

then (U, V) satisfies (2.3), $U^T(t)V(t) = V^T(t)U(t)$, $(I - \mathcal{D})(V(b) + \hat{\Gamma}U(b)) = 0$, $\det U(a) \neq 0$ and $\det U(b) \neq 0$.

Proof of Lemma 2.2. Using the definition of (U_a, V_a) , (U_b, V_b) , (2.4), and the invertibility of $U_b(a)$, it results that

$$\begin{aligned} U^T(t)V(t) - V^T(t)U(t) &= \mathcal{D}U_b^{-1}(a)(U_a^T(t)V_b(t) - V_a^T(t)U_b(t)) \\ &\quad + (U_b^T(t)V_a(t) - V_b^T(t)U_a(t))U_b^{T^{-1}}(a)\mathcal{D} \\ &= -\mathcal{D} + \mathcal{D} \\ &= 0. \end{aligned}$$

Since (U_a, V_a) and (U_b, V_b) satisfy (2.3), then so does (U, V) defined by (2.5). Let us calculate

$$\begin{aligned} (I - \mathcal{D})(V(b) + \hat{\Gamma}U(b)) &= (I - \mathcal{D})V_a(b)U_b^{T^{-1}}(a)\mathcal{D} - \hat{\Gamma} \\ &\quad + (I - \mathcal{D})\hat{\Gamma}U_a(b)U_b^{T^{-1}}(a)\mathcal{D} + \hat{\Gamma}. \end{aligned}$$

But, from (2.4) evaluated at $t = b$ we obtain

$$(I - \mathcal{D})V_a(b) + \hat{\Gamma}U_a(b) = (I - \mathcal{D})U_b^T(a);$$

therefore,

$$(I - \mathcal{D})(V(b) + \hat{\Gamma}U(b)) = 0.$$

Note that $U(a) = U_b(a)$, which is invertible. Now we show that $U(b) = U_a(b)U_b^{T^{-1}}(a)\mathcal{D} + (I - \mathcal{D})$ is invertible. If there exists $\alpha (\neq 0) \in \mathbb{R}^n$ with

$$(2.6) \quad U_a(b)U_b^{T^{-1}}(a)\mathcal{D}\alpha = -(I - \mathcal{D})\alpha,$$

then, from (2.4) at $t = b$ we have

$$(I - \mathcal{D})V_a(b) + \hat{\Gamma}U_a(b) + \mathcal{D}U_a(b) = U_b^T(a)$$

and thus

$$\mathcal{D}U_a(b) = \mathcal{D}U_b^T(a),$$

which yields

$$\mathcal{D}U_a(b)U_b^{T^{-1}}(a) = \mathcal{D}.$$

Using this in (2.6), we get $\mathcal{D}\alpha = 0$, but from (2.6) we obtain that $(I - \mathcal{D})\alpha = 0$. Hence $\alpha = 0$ and a contradiction results. Therefore $U(b)$ is invertible. \square

Let us return to the proof of Theorem 2.1.

(1) \Rightarrow (2): From Lemma 2.1 we have $U_b(a)$ invertible. Let (U, V) be defined by (2.5). Using Lemma 2.2, it remains to show that U is invertible on (a, b) . If this is false, then there exists $c \in (a, b)$ and $\alpha \neq 0$ with $U(c)\alpha = 0$, that is,

$$(2.7) \quad U_a(c)U_b^{T^{-1}}(a)\mathcal{D}\alpha = -U_b(c)\alpha.$$

Define

$$(2.8) \quad (\eta(t), \xi(t)) = \begin{cases} (U_a(t)U_b^{T^{-1}}(a)\mathcal{D}\alpha, V_a(t)U_b^{T^{-1}}(a)\mathcal{D}\alpha) & t \in [a, c] \\ -(U_b(t)\alpha, V_b(t)\alpha) & t \in [c, b]. \end{cases}$$

It is clear that η is absolutely continuous with $\eta(a) = \mathcal{D}\eta(b) = 0$. Let us compute $J(\eta)$ by taking into account that (U_a, V_a) and (U_b, V_b) satisfy (2.3). It follows that

$$\begin{aligned} J(\eta) &= \frac{1}{2} \alpha^T \hat{\Gamma} \alpha + \int_a^c \frac{d}{dt} [\alpha^T \mathcal{D} U_b^{-1}(a) V_a^T(t) U_a(t) U_b^{T^{-1}}(a) \mathcal{D} \alpha] dt \\ &\quad + \int_c^b \frac{d}{dt} [\alpha^T U_b^T(t) V_b(t) \alpha] dt. \end{aligned}$$

Using (2.7) we obtain

$$J(\eta) = \frac{1}{2} \alpha^T [-\mathcal{D} U_b^{-1}(a) V_a^T(c) U_b(c) + \mathcal{D} U_b^{-1}(a) U_a^T(c) V_b(c)] \alpha$$

and hence from (2.4) we have

$$(2.9) \quad J(\eta) = -\frac{1}{2} \alpha^T \mathcal{D} \alpha \leq 0.$$

Set

$$h(t) = \begin{cases} U_b^{-1}(t) U_a(t) U_b^{T^{-1}}(a) \mathcal{D} \alpha & t \in [a, c] \\ -\alpha & t \in [c, b]. \end{cases}$$

From (2.7) it results that $h(\cdot)$ is absolutely continuous and $\eta(t) = U_b(t)h(t)$. From the corollary on p. 138 of [15] and the fact that $\eta(a) = 0$, it follows that

$$\begin{aligned} J(\eta) &= \frac{1}{2} \alpha^T \hat{\Gamma} \alpha + \frac{1}{2} h^T(t) U_b^T(t) V^T(t) h(t) \Big|_a^b \\ &\quad + \frac{1}{2} \int_a^b \dot{h}^T(t) U^T(t) R(t) U(t) h(t) dt \\ &= \frac{1}{2} \int_a^b \dot{h}^T(t) U^T(t) R(t) U(t) h(t) dt \geq 0, \end{aligned}$$

since $R(t) > 0$ for all t . Thus, (2.9) gives $\mathcal{D}\alpha = 0$. But from (2.7) and the invertibility of $U_b(c)$ for $c \in [a, b]$, we obtain $\alpha = 0$, which is a contradiction. \square

3. Sufficiency and coupled points. Consider here the same quadratic form as in § 2. In [17]–[19], the notion of coupled points was introduced. It is an extension of that of focal (and conjugate) points to the case of variable endpoint(s). Since the final endpoint $\eta(b)$ is varying in our problem, we have the notion of points coupled with **a**. It has been shown in the above-mentioned references that the nonexistence of points in (a, b) coupled with **a** is a necessary condition for the nonnegativity of the functional

$J(\eta)$ over the constraints $\eta(a) = \mathcal{D}\eta(b) = 0$. It is an important question whether the notion of coupled points exactly replaces in the variable endpoint(s) problem that of focal or conjugate points known for the fixed endpoint(s) case. In this section, we answer this question for the problem studied in the previous sections. We show that the nonexistence of points in $(a, b]$ coupled with \mathbf{a} is equivalent to the positivity of the functional $J(\eta)$ over $\eta(a) = 0 = \mathcal{D}\eta(b)$. This result, combined with that of the previous section, tells us that the nonexistence of points focal to \mathbf{b} in $[a, b]$ is in fact equivalent to the nonexistence of points coupled with \mathbf{a} in $(a, b]$. The approach we use here is analogous to that in § 2. However, the main difficulty resides in showing that the nonexistence of points in $(a, b]$ coupled with b implies condition (2) of Theorem 2.1.

DEFINITION 3.1. A point $c \in (a, b]$ is coupled with \mathbf{a} if there exists a pair $(\eta, \xi) \neq 0$ satisfying the Jacobi system (2.1) with $\eta(\cdot) \neq \eta(c)$ on $[c, b]$ (drop if $c = b$),

$$(3.1) \quad \eta(a) = \mathcal{D}\eta(c) = 0 \quad \text{and} \quad \left\langle \eta(c), \xi(c) + \hat{\Gamma}\eta(c) + \int_c^b P(s) ds \eta(c) \right\rangle = 0,$$

where $\hat{\Gamma} = (I - \mathcal{D})\Gamma(I - \mathcal{D})$.

Remark. When $\mathcal{D} = I$, condition (3.1) reduces to $\eta(a) = \eta(c) = 0$. Moreover, in this case, $\eta(\cdot) \neq \eta(c)$ on $[c, b]$ is trivially satisfied since otherwise $(\eta, \xi) \equiv (0, 0)$ on $[a, b]$. Thus, when $\mathcal{D} \neq I$ and $\eta(c) \neq 0$, the last of (3.1) says that in the definition of a coupled point a certain penalty term $\int_c^b P(s) ds \eta(c)$ should be added to the transversality condition at c .

The following result is the objective of this section.

THEOREM 3.1. *Condition (1) in Theorem 2.1 can be replaced by*

(i) *there exists no point in $(a, b]$ coupled with \mathbf{a} ,*

which is equivalent to

(ii) *there is no $c \in (a, b]$ for which there exists $(\eta, \xi) \neq 0$ satisfying (2.1) on $[a, b]$ and (3.1).*

To prove the theorem we need to study two issues. The first concerns the impact of the strengthened Legendre condition on the problem with “penalized” functional $\tilde{J}([a, t], \eta)$ (see below). Then, we derive important properties of condition (i) of Theorem 3.1.

For $t \in [a, b]$, define

$$\begin{aligned} \tilde{J}([a, t], \eta) := & \frac{1}{2} \eta^T(t) \left(\Gamma + \int_t^b P(s) ds \right) \eta(t) \\ & + \frac{1}{2} \int_a^t \{ \eta^T(s) P(s) \eta(s) + 2 \dot{\eta}^T(s) Q(s) \eta(s) \\ & + \dot{\eta}^T(s) R(s) \dot{\eta}(s) \} ds, \end{aligned}$$

where $\eta: [a, b] \rightarrow \mathbb{R}^n$ is absolutely continuous and satisfies

$$\eta(a) = \mathcal{D}\eta(t) = 0.$$

LEMMA 3.1. *The strengthened Legendre condition yields the existence of $t_0 \in (a, b]$ such that*

$$\tilde{J}([a, t_0], \eta) > 0 \quad \forall \eta \neq 0: \eta(a) = \mathcal{D}\eta(t_0) = 0.$$

Proof of Lemma 3.1. Let β be the positive number satisfying the strengthened Legendre condition. The essential boundedness of $P(\cdot)$ and $Q(\cdot)$ yields the existence of $M > 0$ such that, for $t \in [a, b]$ almost everywhere,

$$\|P(t)\| \leq M, \quad \|Q(t)\| \leq M, \quad \text{for all } t, \quad \left\| \int_a^b P(s) ds \right\| \leq M, \quad \text{and } \|\hat{\Gamma}\| \leq M,$$

where “ $\|\cdot\|$ ” is the matrix 2-norm. Choose $t_0 \in (a, b]$ close enough to a such that

$$-M(t_0 - a)^2 - 4M(t_0 - a) + \beta > 0.$$

Let $\eta(\cdot) \neq 0$: $\eta(a) = \mathcal{D}\eta(t_0) = 0$. We will show that $\tilde{J}([a, t_0], \eta) > 0$. In fact, from the Cauchy-Schwartz inequality it follows that, for all $s \in [a, t_0]$,

$$|\eta(s)| \leq \int_a^{t_0} |\dot{\eta}(\tau)| d\tau \leq (t_0 - a)^{1/2} \left(\int_a^{t_0} |\dot{\eta}(\tau)|^2 d\tau \right)^{1/2}.$$

Thus,

$$\begin{aligned} & \left| \eta^T(t_0) \left(\hat{\Gamma} + \int_{t_0}^b P(s) ds \right) \eta(t_0) + \int_a^{t_0} \{ \eta^T(s) P(s) \eta(s) + 2\dot{\eta}^T(s) Q(s) \eta(s) \} ds \right| \\ & \leq \{ 2M(t_0 - a) + M(t_0 - a)^2 + 2M(t_0 - a) \} \int_a^{t_0} |\dot{\eta}(s)|^2 ds. \end{aligned}$$

Then,

$$\tilde{J}([a, t_0], \eta) > \{-4M(t_0 - a) - M(t_0 - a)^2 + \beta\} \int_a^{t_0} |\dot{\eta}(s)|^2 ds > 0. \quad \square$$

Let (U_a, V_a) be the solution of (2.3) satisfying, as in § 2, $U_a(a) = 0$, and $V_a(a) = I$.

COROLLARY 3.1. *Under the conditions of Lemma 3.1 we have $\det U_a(t_0) \neq 0$, where t_0 is the value in Lemma 3.1, and, for all $\beta \neq 0$: $\mathcal{D}\beta = 0$,*

$$\beta^T \left[V_a(t_0) U_a^{-1}(t_0) + \hat{\Gamma} + \int_{t_0}^b P(s) ds \right] \beta > 0.$$

Proof. If for $\alpha \neq 0$ $U_a(t_0)\alpha = 0$, define on $[a, t_0]$ the functions $(\eta(t), \xi(t)) = (U_a(t)\alpha, V_a(t)\alpha)$. Then (η, ξ) satisfy the Jacobi system (2.1) and $(\eta, \xi) \neq 0$, since $\xi(a) = \alpha \neq 0$. Moreover, $\eta(a) = \eta(t_0) = 0$ and hence, using the Jacobi system,

$$\tilde{J}([a, t_0], \eta) = \eta(t) \cdot \xi(t)|_a^{t_0} = 0.$$

This contradicts Lemma 3.1.

Now, if there exists $\beta \neq 0$: $\mathcal{D}\beta = 0$ and $\beta^T [V_a(t_0) U_a^{-1}(t_0) + \hat{\Gamma} + \int_{t_0}^b P(s) ds] \beta \leq 0$, define on $[a, t_0]$, $(\eta(t), \xi(t)) = (U_a(t) U_a^{-1}(t_0) \beta, V_a(t) U_a^{-1}(t_0) \beta)$. Since $\xi(a) = U_a^{-1}(t_0) \beta \neq 0$, then $(\eta, \xi) \neq 0$. Also, $\eta(a) = \mathcal{D}\eta(t_0) = 0$ and

$$\begin{aligned} \tilde{J}([a, t_0], \eta) &= \frac{1}{2} \beta^T \left[\Gamma + \int_{t_0}^b P(s) ds \right] \beta + \eta(t) \cdot \xi(t)|_a^{t_0} \\ &= \frac{1}{2} \beta^T \left[\hat{\Gamma} + \int_{t_0}^b P(s) ds + V_a(t_0) U_a^{-1}(t_0) \right] \beta \\ &\leq 0. \end{aligned}$$

This contradicts Lemma 3.1. \square

Let us now study the properties of the nonexistence of coupled points.

LEMMA 3.2. *Assume that \mathbf{b} is not coupled with \mathbf{a} , then in the definition of c coupled with a (Definition 3.1) the condition $\eta(\cdot) \neq \eta(c)$ on $[c, b]$ can be eliminated.*

Proof of Lemma 3.2. The result will be proved by contradiction. If there exist $c \in (a, b]$ and $(\eta, \xi) \neq 0$ satisfying (2.1) and (3.1) with $\eta(\cdot) \equiv \eta(c)$ on $[c, b]$, then on $[c, b]$, (2.1) yields

$$\xi(t) = Q(t)\eta(c)$$

and

$$\dot{\xi}(t) = P(t)\eta(c).$$

Thus

$$\xi(b) = \xi(c) + \int_c^b P(s) ds \eta(c)$$

and hence (3.1) becomes

$$\eta(a) = 0 = \mathcal{D}\eta(b) \quad \text{and} \quad \langle \eta(b), \xi(b) + \hat{\Gamma}\eta(b) \rangle = 0,$$

that is, b is coupled with a . Therefore, we obtain a contradiction. \square

Let (U_b, V_b) be the pair as in § 2, that is, the solution of (2.3) with $U_b(b) = I - \mathcal{D}$ and $V_b(b) = -\hat{\Gamma} - \mathcal{D}$.

LEMMA 3.3. *If there exists no $c \in (a, b]$ coupled with a then $\det U_a(t) \neq 0$ on $(a, b]$ and $\det U_b(a) \neq 0$.*

Proof of Lemma 3.3. If for some $c \in (a, b]$ and $\alpha \neq 0$ we have $U_a(c)\alpha = 0$, then $(\eta(t), \xi(t)) = (U_a(t)\alpha, V_a(t)\alpha) \neq 0$ satisfies (2.1) and $\eta(a) = \eta(c) = 0$. This contradicts the hypothesis that no $c \in (a, b]$ is coupled, and hence conjugate to a .

If $U_b(a)\alpha = 0$ for $\alpha \neq 0$, then

$$(\eta(t), \xi(t)) = (U_b(t)\alpha, V_b(t)\alpha)$$

satisfies $\eta(a) = \mathcal{D}\eta(b) = 0$ and $\langle \eta(b), \xi(b) + \hat{\Gamma}\eta(b) \rangle = 0$. Moreover, $(\eta(b), \xi(b)) = ((I - \mathcal{D})\alpha, -\hat{\Gamma}\alpha - \mathcal{D}\alpha) \neq 0$ (otherwise $\alpha = 0$). Thus, we have b coupled with a , and hence a contradiction follows. \square

The following results say that if (i) of Theorem 3.1 holds, then in the definition of a coupled point not only $\eta(\cdot) \neq \eta(c)$ on $[c, b]$ can be removed but the last equality in (3.1) can be replaced by “ \leq .”

LEMMA 3.4. *Assume that there are no points in $(a, b]$ coupled with a , then there exist no $c \in (a, b]$ and $(\eta, \xi) \neq 0$ solution of (2.1) with*

$$\eta(a) = \mathcal{D}\eta(c) = 0 \quad \text{and} \quad \left\langle \eta(c), \xi(c) + \hat{\Gamma}\eta(c) + \int_c^b P(s) ds \eta(c) \right\rangle \leq 0.$$

Proof of Lemma 3.4. From Definition 3.1 and the assumption of Lemma 3.4, we only need to show that the strict inequality above cannot happen. Let us argue by contradiction. Assume there exist $c \in (a, b]$ and $(\eta, \xi) \neq 0$ satisfying system (2.1), $\eta(a) = \mathcal{D}\eta(c) = 0$ and $\langle \eta(c), \xi(c) + \hat{\Gamma}\eta(c) + \int_c^b P(s) ds \eta(c) \rangle < 0$. We can easily see that since $\eta(a) = 0$ and (η, ξ) is nonzero and satisfies (2.1), there exists $\alpha_0 \neq 0$ such that $(\eta(t), \xi(t)) = (U_a(t)\alpha_0, V_a(t)\alpha_0)$. Thus, also $\mathcal{D}U_a(c)\alpha_0 = 0$ and

$$\alpha_0^T U_a^T(c) \left[V_a(c) + \hat{\Gamma}U_a(c) + \int_c^b P(s) ds U_a(c) \right] \alpha_0 < 0.$$

Set $\beta_0 = U_a(c)\alpha_0$. Then from Lemma 3.3 we have $\beta_0 \neq 0$, also $\mathcal{D}\beta_0 = 0$ and

$$\beta_0^T \left[V_a(c)U_a^{-1}(c) + \hat{\Gamma} + \int_c^b P(s) ds \right] \beta_0 < 0.$$

Define

$$\mathcal{A}(t) := V_a(t)U_a^{-1}(t) + \hat{\Gamma} + \int_t^b P(s) ds,$$

then $\mathcal{A}(\cdot)$ is continuous on $(a, b]$. From Corollary 3.1, $\beta^T \mathcal{A}(t_0)\beta > 0$ for all $\beta \neq 0$: $\mathcal{D}\beta = 0$. Since, we know $\beta_0 \mathcal{A}(c)\beta_0 < 0$, there exists $\bar{c} \in (a, b]$ such that $\beta_0^T \mathcal{A}(\bar{c})\beta_0 = 0$. Define on $[a, b]$

$$(\eta(t), \xi(t)) = (U_a(t)U_a^{-1}(\bar{c})\beta_0, \quad V_a(t)U_a^{-1}(\bar{c})\beta_0).$$

We have $\eta(a) = \mathcal{D}\eta(\bar{c}) = 0$, $(\eta, \xi) \neq 0$ because $\beta_0 \neq 0$, and $\langle \eta(\bar{c}), \xi(\bar{c}) + \hat{\Gamma}\eta(\bar{c}) + \int_{\bar{c}}^b P(s) ds \eta(\bar{c}) \rangle = \beta_0^T \mathcal{A}(\bar{c})\beta_0 = 0$. Hence, \bar{c} is coupled with a , which is a contradiction. \square

Now we will provide the proof of the main result of this section.

Proof of Theorem 3.1. From Theorem 2.1 and Lemma 3.2, we only need to prove that condition (4) of Theorem 2.1 implies (ii), and (ii) implies condition (2) of Theorem 2.1. Assume condition (4) of Theorem 2.1. If (ii) is false, there exist $(\eta, \xi) \neq 0$ solution of (2.1) and $c \in (a, b]$ such that

$$\eta(a) = \mathcal{D}\eta(c) = 0 \quad \text{and} \quad \left\langle \eta(c), \xi(c) + \hat{\Gamma}\eta(c) + \int_c^b P(s) ds \eta(c) \right\rangle = 0.$$

Define

$$\bar{\eta}(t) := \begin{cases} \eta(t) & \text{on } [a, c], \\ \eta(c) & \text{on } [c, b]; \end{cases}$$

then $\bar{\eta}(c)$ is absolutely continuous, $\bar{\eta}(a) = \mathcal{D}\bar{\eta}(b) = 0$, and

$$\begin{aligned} J(\bar{\eta}) &= \frac{1}{2} \eta^T(c) \left(\hat{\Gamma} + \int_c^b P(s) ds \right) \eta(c) + \frac{1}{2} \eta(t) \cdot \xi(t) \Big|_a^c \\ &= 0. \end{aligned}$$

Also $\bar{\eta} \neq 0$, since otherwise (2.1) gives that $(\eta, \xi) \equiv 0$ on $[a, c]$ and hence on $[a, b]$. Thus, we have a contradiction with condition (4).

Finally, assume that (ii) holds and let us show that condition (2) of Theorem 2.1 is satisfied. From Lemma 3.3 it follows that $U_b(a)$ is invertible. Thus, define (U, V) by (2.5). Using Lemma 2.2, it only remains to show that U is invertible on (a, b) . Suppose not, then there exist $c \in (a, b)$ and $\alpha \neq 0$ such that $U(c)\alpha = 0$, that is, $U_a(c)U_b^{T^{-1}}(a)\mathcal{D}\alpha = -U_b(c)\alpha$, which is (2.7). Define (η, ξ) exactly as in (2.8),

$$(\eta(t), \xi(t)) = \begin{cases} (U_a(t)U_b^{T^{-1}}(a)\mathcal{D}\alpha, V_a(t)U_b^{T^{-1}}(a)\mathcal{D}\alpha) & t \in [a, c], \\ -(U_b(t)\alpha, V_b(t)\alpha) & t \in [c, b]. \end{cases}$$

Then, computations identical to those that led to (2.9) give that $J(\eta) = -\frac{1}{2}\alpha^T \mathcal{D}\alpha \leq 0$. Now, we know by Lemma 3.3 that U_a is invertible on $(a, b]$. Thus, define

$$\gamma(t) = \begin{cases} U_b^{T^{-1}}(a)\mathcal{D}\alpha & t \in [a, c], \\ -U_a^{-1}(t)U_b(t)\alpha & t \in [c, b], \end{cases}$$

then

$$\eta(t) = U_a(t)\gamma(t).$$

Using the corollary on p. 138 of [11] to compute $J(\eta)$, we get that

$$\begin{aligned} J(\eta) &= \frac{1}{2} \eta^T(b) \hat{\Gamma} \eta(b) + \frac{1}{2} \gamma^T(t) V_a^T(t) U_a(t) \gamma(t) \Big|_a^b \\ &\quad + \frac{1}{2} \int_a^b \dot{\gamma}^T(t) U_a^T(t) R(t) U_a(t) \dot{\gamma}(t) dt \\ &= \frac{1}{2} \gamma^T(b) U_a^T(b) [\hat{\Gamma} U_a(b) + V_a(b)] \gamma(b) \\ &\quad + \frac{1}{2} \int_a^b \dot{\gamma}^T(t) U_a^T(t) R(t) U_a(t) \dot{\gamma}(t) dt. \end{aligned}$$

Since (U_a, V_a) is a principal solution to (2.1) with $\eta(a) = 0$, then Lemma 3.4 means that

$$w^T U_a^T(t) \left[V_a(t) + \hat{\Gamma} U_a(t) + \int_t^b P(s) ds U_a(t) \right] w > 0$$

for all $w \neq 0$ and $t \in (a, b]$ such that $\mathcal{D}U_a(t)w = 0$. In particular, $\gamma^T(b) U_a^T(b) \times [V_a(b) + \hat{\Gamma} U_a(b)] \gamma(b) \geq 0$, since $\mathcal{D}U_a(b) \gamma(b) = 0$. Thus, $J(\eta) \geq 0$. We know that $J(\eta) = -\frac{1}{2} \alpha^T \mathcal{D} \alpha \leq 0$, then $J(\eta) = 0$. Thus, $\mathcal{D} \alpha = 0$ and $\gamma(b) = 0$, that is, $\alpha = 0$. Hence a contradiction follows. \square

4. Application to nonlinear problems. In this section we consider the following general problem of calculus of variations with fixed initial state but variable final endpoints:

$$(V) \quad \text{minimize } I(x) := \gamma(x(b)) + \int_a^b L(t, x(t), \dot{x}(t)) dt,$$

over all absolutely continuous functions $x: [a, b] \rightarrow \mathbb{R}^n$ satisfying

$$x(a) = A, \quad \phi(x(b)) = 0,$$

where $A \in \mathbb{R}^n$, $\phi: \mathbb{R}^n \rightarrow \mathbb{R}^r$ ($r \leq n$), $\gamma: \mathbb{R}^n \rightarrow \mathbb{R}$, and $L: [a, b] \times \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$.

In the special case where $\phi(\cdot)$ is affine ($\phi(y) = y - B$) this problem reduces to the *classical* calculus of variations about which intensive literature can be found (see, for instance, [1], [9], [14], and [16]). Recently, the interest in the problem was renewed, due to its close connection to the optimal control problem [16] and to the multiple integral calculus of variations problem [6]. Two of the main questions that are now the center of attention are the existence of Lipschitz solutions to the classical problem (see [4] and the references therein) and the study of the variable endpoint(s) case (see [12]–[14] and [21], and the references therein). As is the case with the conjugate point theory for the classical setting, we would like to obtain for the variable endpoint(s) problem necessary conditions for optimality that are almost sufficient. In [17]–[19], it is shown that in the variable endpoints case the nonexistence of coupled points with \mathbf{b} in (a, b) is necessary for weak local minimality. On the other hand, given that in (V) the left-hand point $x(a)$ is fixed, it is known (see, for instance, [20]) that the nonexistence of focal points to a in (a, b) is necessary. Using the results of previous sections, we show here that each of these necessary conditions can be strengthened to become sufficient for the weak local optimality in (V).

Let $z(\cdot): [a, b] \rightarrow \mathbb{R}^k$ be in $L^\infty[a, b]$. The *tube* of radius ε about $z(\cdot)$ is defined by $T(z(\cdot); \varepsilon) = \{(t, y) \in [a, b] \times \mathbb{R}^k : |y - z(t)| < \varepsilon\}$. A function $y(\cdot)$ is said to be in $T(z(\cdot); \varepsilon)$ if $(t, y(t)) \in T(z(\cdot); \varepsilon)$ for $t \in [a, b]$ almost everywhere.

DEFINITION 4.1. An absolutely continuous function $\hat{x}(\cdot):[a, b] \rightarrow \mathbb{R}^n$ that satisfies the constraints $\hat{x}(a) = A$, $\phi(\hat{x}(b)) = 0$ is said to be *admissible*. An admissible function $\hat{x}(\cdot)$ is a *weak local minimum* for (V) if there exists $\varepsilon > 0$ such that $I(x) \geq I(\hat{x})$ for all admissible $x(\cdot): (x(\cdot), \dot{x}(\cdot)) \in T(\hat{x}, \hat{x}; \varepsilon)$.

Let $\hat{x}(\cdot)$ be admissible and Lipschitz. We make the following nonrestrictive assumptions on the data.

(i) There exists $\varepsilon > 0$ such that $\gamma(\cdot)$ and $\phi(\cdot)$ are C^2 on the ε -neighborhood of $\hat{x}(b)$, and, for almost all $t \in [a, b]$, $L(t, \cdot, \cdot)$ is C^2 on the ε -neighborhood of $(\hat{x}(t), \dot{\hat{x}}(t))$.

(ii) $L(t, x, v)$ and its derivatives in (x, v) up to second order are integrable along $(\hat{x}, \dot{\hat{x}})$.

(iii) $\nabla_{(x,v)}^2 L(t, \cdot, \cdot)$ is continuous at $(\hat{x}, \dot{\hat{x}})$ uniformly in t , and $\hat{L}_{vx}(t) := L_{vx}(t, \hat{x}(t), \dot{\hat{x}}(t))$ is essentially bounded on $[a, b]$.

Given that we are interested in finding a sufficiency criterion for weak local minimality of a Lipschitz candidate \hat{x} , it is natural to assume that \hat{x} satisfies the necessary conditions for optimality: in particular, the Euler-Lagrange equation:

$$(\mathcal{E}) \quad \frac{d}{dt} \hat{L}_v(t) = \hat{L}_x(t) \quad t \in [a, b] \text{ a.e.},$$

the transversality condition:

there exists a vector $l \in \mathbb{R}^r$ such that

$$(\mathcal{T}) \quad -\hat{L}_v(b) = l^T [\nabla \phi(\hat{x}(b))] + \nabla \gamma(\hat{x}(b)),$$

and the Legendre condition:

$$(\mathcal{L}) \quad \hat{L}_{vv}(t) \geq 0 \quad \text{for } t \in [a, b] \text{ a.e.}$$

Define

$$P(s) := \hat{L}_{xx}(s), \quad Q(s) := \hat{L}_{vx}(s), \quad R(s) := \hat{L}_{vv}(s),$$

$$\Gamma = [\nabla^2 \phi(\hat{x}(b))]^T l + \nabla^2 \gamma(\hat{x}(b)),$$

$$D = \nabla \phi(\hat{x}(b)), \quad \mathcal{D} = D^T (DD^T)^{-1} D,$$

and

$$\hat{\Gamma} = (I - \mathcal{D})\Gamma(I - \mathcal{D}).$$

The second variation corresponding to the problem (V) (see, for instance, [20]) is

$$J(\hat{x}; \eta) = \frac{1}{2} \eta(b)^T \Gamma \eta(b) + \frac{1}{2} \int_a^b \{ \eta^T(s) P(s) \eta(s) + 2 \dot{\eta}^T(s) Q(s) \eta(s) + \dot{\eta}^T(s) R(s) \dot{\eta}(s) \} ds,$$

where $\eta(\cdot):[a, b] \rightarrow \mathbb{R}^n$ is absolutely continuous and satisfies $\eta(a) = \mathcal{D}\eta(b) = 0$.

This functional is exactly of the form considered in the previous sections. Thus, as in §§ 2 and 3, we have the notions of focal points to **b** and coupled points with **a**. In terms of these notions, necessary conditions for optimality in (V) were developed in [18] and [19]. The corresponding sufficiency criterion are given by the following theorem, where $(\mathcal{L})'$ denotes the strengthened Legendre condition.

THEOREM 4.1. Let \hat{x} be a Lipschitz admissible function for (V). Assume that \hat{x} satisfies (\mathcal{E}) , (\mathcal{T}) , and $(\mathcal{L})'$. Then \hat{x} provides a strict weak local minimum for (V) if one of the following conditions holds.

(1) There are no points in $[a, b]$ focal to **b**.

- (2) *There are no points in $(a, b]$ coupled with a .*
 (3) *There exists a Lipschitz symmetric matrix function $W(\cdot)$ solution of*

$$\begin{aligned} \dot{W} + WBW + A^T W + WA - C &= 0 \quad t \in [a, b] \text{ a.e.,} \\ (I - \mathcal{D})[W(b) + \hat{\Gamma}] &= 0, \end{aligned}$$

(where A , B , and C are defined as in § 2).

Proof. From Theorems 2.1 and 3.1, each of the above conditions is equivalent to: there exists $\delta > 0$ such that

$$J(\hat{x}; \eta) \geq \delta \int_a^b |\dot{\eta}(t)|^2 dt \quad \forall \eta: \eta(a) = D\eta(b) = 0.$$

Using [10, Thm. 12.2.7], we can find $\alpha > 0$, $\beta > 0$ such that, for all $\eta: \eta(a) = 0$,

$$(4.1) \quad J(\hat{x}; \eta) + \alpha |D\eta(b)|^2 \geq \beta \int_a^b |\dot{\eta}(t)|^2 dt.$$

Define $M = \min \{\beta/8, \beta/(8(b-a)), \beta/(8(b-a)^2)\}$. Since $\phi(\cdot)$ and $\gamma(\cdot)$ are C^2 in the ε -neighborhood of $\hat{x}(b)$, then there exist $K > 0$, $0 < \varepsilon_1 (\leq \varepsilon)$, such that, for all $x: |x - \hat{x}(b)| < \varepsilon_1$,

$$(4.2) \quad \begin{aligned} \|\nabla^2 \phi(x)^T l - \nabla^2 \phi(\hat{x}(b))^T l\| &< M, \\ \|\nabla^2 \gamma(x) - \nabla^2 \gamma(\hat{x}(b))\| &< M, \\ \|\nabla^2 \phi(x)\| &\leq K, \end{aligned}$$

where $\|\cdot\|$ is any matrix norm. Using the fact that $\nabla^2 L(t, \cdot, \cdot)$ is continuous at $(\hat{x}, \dot{\hat{x}})$ uniformly in t , we can find $\varepsilon_2 (\leq \varepsilon_1)$ such that for all absolutely continuous functions $x(\cdot): (x(\cdot), \dot{x}(\cdot)) \in T(\hat{x}, \dot{\hat{x}}; \varepsilon_2)$ we have

$$(4.3) \quad \|\nabla_{(x,v)}^2 L(t, x(t), \dot{x}(t)) - \nabla_{(x,v)}^2 \hat{L}(t)\| < M \quad \text{a.e.}$$

Set $\varepsilon_0 = \min \{\varepsilon_2, \sqrt{\beta/(\alpha K^2(b-a)^3)}\}$, and take $x(\cdot) (\neq \hat{x})$ be any admissible function for (V) with $(x(\cdot), \dot{x}(\cdot)) \in T(\hat{x}, \dot{\hat{x}}; \varepsilon_0)$. We will show that $I(x) > I(\hat{x})$.

Using $\phi(x(b)) = \phi(\hat{x}(b)) = 0$ and Taylor's expansion we get the following:

$$\begin{aligned} I(x) - I(\hat{x}) &= \gamma(x(b)) + \phi(x(b))^T l - (\gamma(\hat{x}(b)) + \phi(\hat{x}(b))^T l) \\ &\quad + \int_a^b \{L(t, x(t), \dot{x}(t)) - \hat{L}(t)\} dt \\ &= [l^T \nabla \phi(\hat{x}(b)) + \nabla \gamma(\hat{x}(b))](x(b) - \hat{x}(b)) \\ &\quad + \int_a^b (\hat{L}_x(t), \hat{L}_v(t)) \begin{pmatrix} x(t) - \hat{x}(t) \\ \dot{x}(t) - \dot{\hat{x}}(t) \end{pmatrix} dt \\ &\quad + \frac{1}{2} (x(b) - \hat{x}(b))^T (\nabla^2 \phi(x')^T l + \nabla^2 \gamma(x'')) (x(b) - \hat{x}(b)) \\ &\quad + \frac{1}{2} \int_a^b (x^T(t) - \hat{x}^T(t), \dot{x}^T(t) - \dot{\hat{x}}^T(t)) \\ &\quad \cdot \nabla^2 L(t, \tilde{x}(t), \dot{\tilde{x}}(t)) \begin{pmatrix} x(t) - \hat{x}(t) \\ \dot{x}(t) - \dot{\hat{x}}(t) \end{pmatrix} dt, \end{aligned}$$

where x' and x'' are between $x(b)$ and $\hat{x}(b)$, and $(\tilde{x}(\cdot), \dot{\tilde{x}}(\cdot))$ is between $(x(\cdot), \dot{x}(\cdot))$ and $(\hat{x}(\cdot), \dot{\hat{x}}(\cdot))$. Integrating by parts the second term and using conditions (\mathcal{E}) and (\mathcal{T}) , we are left with the last two terms. Since $x(a) = \hat{x}(a) = 0$, Hölder's inequality yields that, for all $s \in [a, b]$

$$(4.4) \quad |x(s) - \hat{x}(s)|^2 \leq (b-a) \int_a^b |\dot{x}(t) - \dot{\hat{x}}(t)|^2 dt.$$

Using the first two inequalities of (4.2)–(4.4), and the definition of M , we obtain

$$I(x) - I(\hat{x}) \geq J(\hat{x}; (x - \hat{x})) - \frac{\beta}{4} \int_a^b |\dot{x} - \dot{\hat{x}}|^2 dt,$$

and from (4.1) it follows that

$$I(x) - I(\hat{x}) \geq \frac{3\beta}{4} \int_a^b |\dot{x} - \dot{\hat{x}}|^2 dt - \alpha |D(x(b) - \hat{x}(b))|^2.$$

We also have

$$\begin{aligned} 0 &= \phi(x(b)) - \phi(\hat{x}(b)) \\ &= \nabla \phi(\hat{x}(b))(x(b) - \hat{x}(b)) + \frac{1}{2} (x(b) - \hat{x}(b))^T \nabla^2 \phi(\bar{x})(x(b) - \hat{x}(b)), \end{aligned}$$

and thus,

$$\begin{aligned} |D(x(b) - \hat{x}(b))|^2 &\leq \frac{K^2}{2} |x(b) - \hat{x}(b)|^4 \\ &\leq \frac{K^2}{2} (b-a)^2 \left(\int_a^b |\dot{x} - \dot{\hat{x}}|^2 \right)^2. \end{aligned}$$

Therefore, using $|\dot{x}(t) - \dot{\hat{x}}(t)|^2 < \varepsilon_0^2 \leq \beta / (\alpha K^2 (b-a)^3)$, it results that

$$I(x) - I(\hat{x}) \geq \frac{\beta}{4} \int_a^b |\dot{x} - \dot{\hat{x}}|^2 dt. \quad \square$$

To illustrate the utility of the previous result we consider the following example.

Example. The question is to find a weak local minimum for the problem

$$\begin{aligned} (\bar{V}) \quad \text{Minimize } I(x) &= \frac{1}{2} x_1^2 \left(\frac{\pi}{4} \right) + \frac{1}{2} x_2^2 \left(\frac{\pi}{4} \right) + x_1^3 \left(\frac{\pi}{4} \right) + x_2^5 \left(\frac{\pi}{4} \right) \\ &\quad + \frac{1}{2} \int_0^{\pi/4} \{x_1^2 + x_2^2 - x_1^3 - x_2^3 - x_1 x_2^2 - x_1^2 x_2\} dt \end{aligned}$$

over all absolutely continuous functions $x(\cdot) = \begin{pmatrix} x_1(\cdot) \\ x_2(\cdot) \end{pmatrix}$ satisfying $x_1(0) = x_2(0) = 0$, $x_1(\pi/4) = x_2(\pi/4)$.

Take $\hat{x}(\cdot) = \begin{pmatrix} x_1(\cdot) \\ x_2(\cdot) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$. We can then easily check that $\hat{x}(\cdot)$ satisfies the Euler-Lagrange equation, and the transversality condition for $l = 0$, as well as the strengthened Legendre condition. To prove that $\hat{x}(\cdot)$ is a weak local minimum for (\bar{V}) we will use Theorem 4.1 with condition (2).

For this problem,

$$\begin{aligned} P(s) &\equiv \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}, \quad Q(s) \equiv 0, \quad R(s) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \\ \Gamma &= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad \text{and} \quad D = (-1, 1). \end{aligned}$$

The Jacobi system is

$$\begin{aligned}\dot{\eta}_1 &= \xi_1, & \dot{\xi}_1 &= -\eta_1, \\ \dot{\eta}_2 &= \xi_2, & \dot{\xi}_2 &= -\eta_2,\end{aligned}$$

whose solution is

$$(4.5) \quad \begin{aligned}\eta_1(t) &= A \sin t + B \cos t, & \xi_1(t) &= A \cos t - B \sin t, \\ \eta_2(t) &= M \sin t + N \cos t, & \xi_2(t) &= M \cos t - N \sin t.\end{aligned}$$

Let us search for the coupled point with 0 in $(0, \pi/4]$.

From Definition (3.1), $c \in (0, \pi/4]$ is coupled with 0 if there exists $(\eta, \xi) \neq 0$ solving (4.5) with $\eta_1(0) = \eta_2(0) = 0$, $\eta_1(c) = \eta_2(c)$, and $\eta_1(c)[\xi_1(c) + \xi_2(c) + 2\eta_1(c) - 2(\pi/4 - c)\eta_1(c)] = 0$. This is equivalent to $B = N = 0$, $A = M$, and $A \sin c = 0$ or $A[\cos c + \sin c(1 + c - \pi/4)] = 0$. But $A \neq 0$, since otherwise $(\eta, \xi) = (0, 0)$. Thus, we must have $\cos c = -\sin c(1 + c - \pi/4)$. However, $c \in (0, \pi/4]$ and hence the last equation cannot happen. Therefore, there exists no $c \in (0, \pi/4]$ coupled with 0, and by Theorem 4.1, $\hat{x} \equiv 0$ is a weak local minimum for (\bar{V}) .

Acknowledgments. The author thanks the conscientious referees, whose comments helped improve the readability of the paper.

PROPERTIES OF ENERGY-MINIMIZING SEGMENTATIONS*

JAYANT SHAH†

Abstract. In Computer Vision, one approach to segmenting an image consists in minimizing an energy functional that is defined over a set of all possible segmentations in terms of penalties for deviations from ideal properties. Studied here are the smoothing properties of such a formulation defined with two parameters, which are the weights associated with the penalty measures. This paper deals with only the one-dimensional case. It is shown that the effect of these parameters is to set *two* local thresholds, one for the intensity gradient and one for the difference between the maximum and the minimum values of image intensity in a region. If one of the thresholds is not exceeded in a region, the region is regarded as uniform and will not be broken up. Thus, low intensity noise and low gradients are filtered out. Conversely, if the image intensity changes rapidly in a region so that both the thresholds are exceeded, the region will be broken up.

Key words. nonconvex minimization, free boundary problem, image segmentation, piecewise smooth approximations

AMS(MOS) subject classification. 35R35

1. Introduction. In Computer Vision, the segmentation problem is the problem of subdividing an image into regions so that in each region, the image properties are relatively uniform. We have been studying the problem by a variational approach. This approach is motivated in part by occasional failures of traditional methods, which are based on either local edge operators or on histogram partitioning and in part by a desire to integrate the preprocessing and postprocessing steps associated with the traditional methods into one global formulation. The general idea is that we should define an energy functional over a set of all possible segmentations in terms of penalty measures that correspond to various desired properties of a good segmentation. Our approach is a modification of one due to Geman and Geman [5] and subsequently developed by Marroquin [6] and by Blake and Zisserman [2]. The particular functional that we have studied is the following:

$$E(f, B) = \mu^2 \int \int_R (f - g)^2 dx dy + \int \int_{R-B} \|\nabla f\|^2 dx dy - \nu |B|$$

where

R is the image domain,

g is the grey level function, $g: R \rightarrow \mathbf{R}_+$,

B denotes the union of region boundaries; thus B is the segmenting curve,

f is the smoothed image which need not be continuous across B ,

$|B|$ = the length of B ,

μ, ν are the weights.

The problem is to find f and B that minimize $E(f, B)$. While the first term imposes penalty for deviation of f from g , the second term forces f to be as smooth as possible. By minimizing the length of the segmenting curve, the third term tries to avoid segmenting the image into too many regions with wildly zigzagging boundaries. Thus the formulation is designed to find a minimal segmentation such that in every region, the image intensity g is approximately constant. The formulation is minimal in the sense that by dropping any one of the three terms, we get $\inf E = 0$: without the first

term, take $f=0$ and B empty; without the second, take $f=g$ and B empty; without the third, take B to be a fine grid of N horizontal lines and vertical lines, segmenting R into tiny squares and f =average of g in each square.

For a fixed segmenting curve B , let f_B denote the minimizer of $E(f, B)$ with respect to f . In the interior of $R - B$, f_B satisfies the equation $\nabla^2 f_B = \mu^2(f_B - g)$. If B is sufficiently regular, say piecewise C^1 , then f_B satisfies the boundary condition $\partial f_B / \partial n = 0$ along B and along the boundary of R . Thus in each component S of $R - B$, f_B is a smoothed version of g . The amount of smoothing depends on μ . $f_B \rightarrow g$ as $\mu|S| \rightarrow \infty$ and $f_B \rightarrow \bar{g}_S$ as $\mu|S| \rightarrow 0$, where \bar{g}_S is the constant function with value equal to the average of g in S . $1/\mu$ may be thought of as the nominal smoothing radius. For reasonably regular curves B , properties of f_B are well understood, and f_B may be calculated easily by methods such as the finite element method combined with a multigrid relaxation procedure. The real problem is to show the existence and regularity of curves B that minimize $E(f_B, B)$. This is a difficult problem, both theoretically and practically, because of nonlinearity and the existence of many local minima. The questions that arise naturally are

1. Is the problem of minimizing $E(f_B, B)$ with respect to B well posed? In particular, does it have a solution that is not too wild, say, a solution that is piecewise C^2 ?

2. Is there a practical algorithm for minimizing $E(f_B, B)$?

3. Is the formulation well suited for solving vision problems? For example, how is the segmenting curve placed? How does it behave in the presence of noise? How should one choose and vary μ and ν in the context of the vision problem?

All of these questions are still open. We have reported in [7] our initial numerical experiments based on steepest gradient descent. We have also extensively analyzed the limiting cases of the formulation, namely, the limit as $\mu \rightarrow \infty$ and the limit as $\mu \rightarrow 0$ in [8]. We have also discussed the nature of singularities of the segmenting curve B . Asymptotic behavior of the model has also been studied by Richardson in [9]. A very deep analysis of the question of the weak existence of the minimizing curve B has been carried out by Ambrosio [1]; De Giorgi, Carriero, and Leaci [4]; and Dal Maso, Morel, and Solimini [3].

In this paper, we begin to study segmentations obtained when μ and ν are arbitrary. Here, we deal only with the one-dimensional case. That is, we assume that R is one-dimensional and B consists of a set of breakpoints.

The existence of a minimizing segmentation in the one-dimensional case is very easy to see. We note that $\inf_{f,B} E(f, B) \leq E(f_\phi, \phi)$ where f_ϕ is the solution of the Neumann problem with B empty. Therefore, there exists a minimizing sequence $\{f_i, B_i\}$ for $E(f, B)$ such that $|B_i| \leq E(f_\phi, \phi)/\nu$. Hence there exists a subsequence $\{B_{i_k}\}$ converging to B^* , with $|B^*| \leq \inf |B_{i_k}|$. Let f_{B^*} satisfy the equation $f_{B^*}'' = \mu^2(f_{B^*} - g)$ in $R - B^*$ and the boundary condition $f_{B^*}' = 0$ at each breakpoint in B^* and at the endpoints of R . Because the elliptic boundary value problem for f_{B^*} is well posed with respect to deformation of B^* , it follows that $E(f_{B^*}, B^*) \leq \lim E(f_i, B_i)$; hence (f_{B^*}, B^*) minimizes $E(f, B)$.

The interesting question in the one-dimensional case is how μ and ν control the segmentation of R . We show that the role of μ and ν may be interpreted as follows. These parameters set, in effect, *two* local thresholds. The smaller the region, the higher are the thresholds for the region. A region in which

- (i) either the maximum intensity gradient is below its threshold,
- (ii) or the difference between the maximum intensity and the minimum intensity is below its threshold,

is regarded as uniform and will not be broken up. In other words, low intensity noise and low gradients will be filtered out. In a region of R where the intensity changes rapidly such that both the thresholds are exceeded, the region will tend to be broken up such that in each piece, $g_{\max} - g_{\min}$ roughly equals its threshold value. Figure 1 illustrates this behavior.

FIG. 1

In § 2, we derive an a priori lower bound on the length of each segment in a minimizing segmentation. From this, we deduce the smoothing properties. We illustrate how the number of segments in a minimizing segmentation varies as we vary μ and ν . In § 3, we derive an upper bound on the segment length to show that the lower bound is qualitatively correct. In the last two sections, we analyze the behavior as $\mu \rightarrow 0$ or $\mu \rightarrow \infty$.

The main technique in deriving these results is obtaining estimates for the reduction in energy due to a single additional cut. Consequently, the upper and lower bounds that we derive hold under much weaker conditions. This allows us to consider segmentations by sets of breakpoints, B , which satisfy conditions

$$(*) \quad \begin{aligned} E(f_B, B) &< E(f_{\tilde{B}}, \tilde{B}) \\ \text{for all } \tilde{B} \subset B \text{ such that } |\tilde{B}| &= |B| - 1 \end{aligned}$$

and

$$(**) \quad \begin{aligned} E(f_B, B) &\leq E(f_{\tilde{B}}, \tilde{B}) \\ \text{for all } \tilde{B} \supset B \text{ such that } |\tilde{B}| &= |B| + 1. \end{aligned}$$

In particular, if B minimizes $E(f_B, B)$, then B satisfies (*) and (**). However, all the conclusions stated above still hold for any B that satisfies (*) and (**), thus indicating that such a set B may already provide an acceptable segmentation.

Notation. For any interval $D \subset R$, define

$$\begin{aligned} \delta_D g &= \max_D g - \min_D g, \\ \text{Lip}_D g &= \begin{cases} \text{Lipschitz constant of } g \text{ in } D & \text{if } g \text{ is Lipschitz,} \\ \infty & \text{otherwise,} \end{cases} \\ \alpha_D &= \max \left\{ \frac{\nu/\mu}{2(\delta_D g)^2}, \frac{\mu\nu}{2(\text{Lip}_D g)^2} \right\}. \end{aligned}$$

2. A lower bound.

THEOREM 1. *Let B be a set of breakpoints satisfying the condition (*). If B is not empty, then the following must hold:*

- (i) $\alpha_R < 1$,
- (ii) for all segments S ,

$$|S| > \frac{1}{\mu} \log \frac{1}{1 - \alpha_R}.$$

Proof. Suppose that B is not empty and satisfied (*). Let S be a segment. Let S' be an adjoining segment. We adopt the notation and the coordinate x as shown in Fig. 2.

FIG. 2

Let B' be the set of breakpoints obtained by removing the breakpoint at P . Integration by parts (see [8, § 6, Lemma]) gives us

$$0 < E(f_{B'}, B') - E(f_B, B) = f_{B'}'(P)[f_B^+(P) - f_B^-(P)] - \nu$$

where the superscripts $+$ and $-$ refer to the values of f_B on the two sides of a breakpoint. Therefore,

$$\nu < \|f_{B'}'\|_{\infty, S \cup S'} |f_B^+(P) - f_B^-(P)|.$$

We need the following lemma.

LEMMA 1. Let $D = [0, a]$ and $g: D \rightarrow \mathbf{R}$ be a bounded function. Let u satisfy $u'' = \mu^2(u - g)$ and $u'(0) = u'(a) = 0$. Then,

$$g_{\min} \leq u(x) \leq g_{\max},$$

$$|u(x) - g(x)| \leq \min \left\{ \delta_D g, \frac{1}{\mu} \text{Lip}_D g \right\},$$

$$|u'(x)| \leq \min \{ 2\mu \delta_D g, \text{Lip}_D g \} (1 - e^{-\mu x}).$$

Proof of Lemma 1. Extend g to all of \mathbf{R} by successive reflections of D . Let g denote also this extension.

Then,

$$u(x) = \frac{\mu}{2} \int_{-\infty}^{\infty} e^{-\mu r} g(y) dy \quad \text{where } r = |y - x|.$$

Therefore,

$$g_{\min} = \frac{\mu}{2} \int_{-\infty}^{\infty} e^{-\mu r} g_{\min} dy \leq u(x) \leq \frac{\mu}{2} \int_{-\infty}^{\infty} e^{-\mu r} g_{\max} dy = g_{\max}.$$

Moreover,

$$|u(x) - g(x)| \leq \frac{\mu}{2} \int_{-\infty}^{\infty} e^{-\mu r} |g(y) - g(x)| dy \leq \min \left\{ \delta_D g, \frac{1}{\mu} \text{Lip}_D g \right\}.$$

Let $g_c = g - c$, where c is some fixed constant. Since $u'(x)$ remains unchanged, if we add a constant to g ,

$$\begin{aligned} u'(x) &= \frac{\mu}{2} \int_{-\infty}^{\infty} \frac{d}{dx} e^{-\mu r} g_c(y) dy \\ &= -\frac{\mu^2}{2} \int_{-\infty}^x e^{-\mu r} g_c(y) dy + \frac{\mu^2}{2} \int_x^{\infty} e^{-\mu r} g_c(y) dy \\ &= -\frac{\mu^2}{2} \int_{-\infty}^0 e^{-\mu(x-y)} g_c(y) dy - \frac{\mu^2}{2} \int_0^x e^{-\mu(x-y)} g_c(y) dy \\ &\quad + \frac{\mu^2}{2} \int_x^{\infty} e^{-\mu(y-x)} g_c(y) dy. \end{aligned}$$

Since $g(-y) = g(y)$,

$$\begin{aligned} u'(x) &= -\frac{\mu^2}{2} \int_0^\infty e^{-\mu(x+y)} g_c(y) dy - \frac{\mu^2}{2} \int_0^x e^{-\mu(x-y)} g_c(y) dy \\ &\quad + \frac{\mu^2}{2} \int_x^\infty e^{-\mu(y-x)} g_c(y) dy \\ &= -\mu^2 e^{-\mu x} \int_0^x (\cosh \mu y) g_c(y) dy + \mu^2 (\sinh \mu x) \int_x^\infty e^{-\mu y} g_c(y) dy. \end{aligned}$$

Setting $c = (g_{\max} + g_{\min})/2$ so that $|g_c| \leq \frac{1}{2}(\delta_D g)$, we get

$$|u'(x)| \leq \mu(1 - e^{-2\mu x})(\delta_D g) \leq 2\mu(1 - e^{-\mu x})(\delta_D g).$$

Setting $c = g(x)$ so that $|g_c(y)| \leq (\text{Lip}_D g)|y - x|$, we get

$$\begin{aligned} |u'(x)| &\leq \mu^2 (\text{Lip}_D g) \left[e^{-\mu x} \int_0^x (\cosh \mu y)(x - y) dy + (\sinh \mu x) \int_x^\infty e^{-\mu y}(y - x) dy \right] \\ &\leq (1 - e^{-\mu x})(\text{Lip}_D g). \end{aligned} \quad \square$$

We continue now with the proof of the theorem. Applying the lemma to each segment of R , we get

$$|f_B^+(P) - f_B^-(P)| \leq \delta_R g.$$

Also,

$$\begin{aligned} |f_B^+(P) - f_B^-(P)| &= |(f_B^+(P) - g(P)) - (f_B^-(P) - g(P))| \\ &\leq \frac{2}{\mu} \text{Lip}_R g. \end{aligned}$$

Applying the lemma to $S \cup S'$, we get

$$\|f_{B'}\|_{\infty, S \cup S'} \leq \min \{2\mu \delta_R g, \text{Lip}_R g\} (1 - e^{-\mu|S|}).$$

Therefore

$$\begin{aligned} \nu &< 2 \min \left\{ \mu(\delta_R g)^2, \frac{1}{\mu} (\text{Lip}_R g)^2 \right\} (1 - e^{-\mu|S|}) \\ &< 2 \min \left\{ \mu(\delta_R g)^2, \frac{1}{\mu} (\text{Lip}_R g)^2 \right\}. \end{aligned}$$

The theorem follows. \square

Since the smallest segment must have length less than or equal to $|R|/|B|$, part (ii) of Theorem 1 may be restated as follows.

COROLLARY 1. *Let B be a nonempty set of breakpoints satisfying the condition (*). Then,*

$$\nu < 2 \min \left\{ \mu(\delta_R g)^2, \frac{1}{\mu} (\text{Lip}_R g)^2 \right\} (1 - e^{-\mu|R|/|B|}).$$

Thus, the (μ, ν) space is laminated by a series of curves, marking regions corresponding to the number of possible breakpoints in a minimizing segmentation as shown in Fig. 3. An upper bound derived in the next section shows that these curves are qualitatively correct in depicting curves with $|B|$ constant.

To see where the actual breakpoints are likely to occur, we have Corollary 2.

COROLLARY 2. *Let D be a connected interval in R . If*

$$\alpha_D > 1 - e^{-\mu|D|/2},$$

then any set of breakpoints satisfying () cannot have more than two breakpoints in D ; that is, D can contain at most one whole segment.*

Proof. Suppose that there are more than two breakpoints in D . Then, apply the theorem to the union of two adjacent segments contained in D in order to get a contradiction. \square

We may think of Corollary 2 as setting local thresholds (that depend on $|D|$) for $\delta_D g$ and $\text{Lip}_D g$. In particular, if

$$\text{either } \delta_D g < \sqrt{\nu/2\mu} \quad \text{or} \quad \text{Lip}_D g < \sqrt{\mu\nu/2},$$

then there cannot be more than two breakpoints in D . That is, low intensity noise and low gradients are filtered out.

3. An upper bound. We now derive an upper bound on the segment length as a function of μ and ν to show that the lower bound in Theorem 1 is reasonable. An upper bound cannot exist in terms of the global quantities $\delta_R g$ and $\text{Lip}_R g$ used in Theorem 1. To see this, just take g to be a step function. If we keep μ fixed and require a breakpoint at the discontinuity of g , then $\nu \rightarrow 0$ as we move the discontinuity closer and closer to one of the endpoints of R . Therefore, to get an upper bound, we have to make some assumptions regarding the profile of g . It is easy to see that with μ and g fixed and g sufficiently general, we get more and more breakpoints as we decrease ν . Corollary 2 indicates that most of these breakpoints will occur in regions of high gradient. Therefore, we derive an upper bound for segments within which g has high gradient everywhere.

THEOREM 2. *Let B be a set of breakpoints satisfying the condition (**). Suppose that g is C^1 in a segment S and $|g'(x)| \geq c$ for all $x \in S$. Then*

$$\mu|S| \leq \psi^{-1}\left(\frac{\mu\nu}{2c^2}\right),$$

FIG. 3. $k = |B|$.

where ψ is a monotonically increasing function: $\lim_{z \rightarrow \infty} \psi(z) = 1$ and $\psi(z) \approx z^3/32$ for small z .

To prove the theorem, we need Lemma 2.

LEMMA 2. Let $D = [0, a]$ and $g : D \rightarrow \mathbf{R}$ be a C^1 function such that $g'(x) \geq 0$ for all $x \in D$. Let u satisfy $u'' = \mu^2(u - g)$ and $u'(0) = u'(a) = 0$. Then $u'(x) \geq 0$ for all $x \in D$.

Proof. Let $v = u'$. Then, v satisfies $v'' - \mu^2(v - g') = 0$, $v(0) = v(a) = 0$. Therefore, v minimizes

$$U(w) = \mu^2 \int_D (w - g')^2 + \int_D |w'|^2$$

subject to the condition $w(0) = w(a) = 0$. Define

$$\tilde{v}(x) = \begin{cases} v(x) & \text{if } v(x) \geq 0, \\ 0 & \text{otherwise.} \end{cases}$$

Then, $U(\tilde{v}) \leq U(v)$ and hence $\tilde{v} = v$. Now let

$$u(x) = u(0) + \int_0^x v \, dx \quad \text{where } u(0) = \frac{v'(0)}{\mu^2} + g(0).$$

Proof of Theorem 2. Choose the coordinate x so that the origin is at one of the end points of S and $g'(x) \geq c$. Let g_1 be the linear function with slope c such that $g_1(0) = g(0)$. Write $g = g_1 + \tilde{g}$. In S , let f_1 satisfy $f_1'' = \mu^2(f_1 - g_1)$, $f_1'|_{\partial S} = 0$, and let \tilde{f} satisfy $\tilde{f}'' = \mu^2(\tilde{f} - \tilde{g})$, $\tilde{f}'|_{\partial S} = 0$. Let $\ell = |S|$. Since $g'_1(x) = c$ and $\tilde{g}'(x) \geq 0$, $f'_1(\ell/2) \geq \tilde{f}'(\ell/2) \geq 0$ by Lemma 2. It is easy to construct f_1 explicitly:

$$f_1(x) = g_1(x) - \frac{c \sinh(x - (\ell/2))}{\mu \cosh(\mu\ell/2)}$$

and

$$f'_1(x) = c - \frac{c \cosh(x - (\ell/2))}{\cosh(\mu\ell/2)}.$$

Therefore,

$$f'_1(\ell/2) \geq c \left[1 - \frac{1}{\cosh(\mu\ell/2)} \right].$$

Let B be a set of breakpoints satisfying (**). Consider introduction of an additional breakpoint, P , at the center of the segment S . Let $B' = B \cup \{P\}$. Let $h = f_{B'} - f_B$. Then h satisfies the equation $h'' = \mu^2 h$ in $S - P$ and the boundary condition $h' = 0$ at the endpoints of S , and $h' = -f'_B$ at P . By solving explicitly for h , we easily obtain

$$h^+(\ell/2) = -h^-(\ell/2) = \frac{1}{\mu} f'_B(\ell/2) \coth(\mu\ell/2)$$

Therefore, the change in energy due to the extra breakpoint

$$\begin{aligned} &= E(f_B, B) - E(f_B, B') \\ &= f'_B(P)[f_B^+(P) - f_B^-(P)] - \nu \\ &= f'_B(P)[h^+(P) - h^-(P)] - \nu \\ &= \frac{2}{\mu} [f'_B(\ell/2)]^2 \coth(\mu\ell/2) - \nu \\ &\leq 0 \quad \text{by the condition (**).} \end{aligned}$$

Therefore

$$\begin{aligned} \nu &\geq \frac{2}{\mu} [f'_B(l/2)]^2 \coth(\mu l/2) \\ &\geq \frac{2}{\mu} [f'_1(l/2)]^2 \coth(\mu l/2) \\ &\geq \frac{2}{\mu} c^2 \psi(\mu l), \end{aligned}$$

where

$$\psi(\mu l) = \frac{8 \sinh^4(\mu l/4)}{\sinh(\mu l)}.$$

To compare the lower bound λ , given by Theorem 1, with the upper bound Λ , given by Theorem 2, assume that g is *linear* in a fixed R . Let

$$\theta = \frac{\mu \nu}{2(g')^2}.$$

Suppose that the minimizing B is not empty so that $\theta < 1$. Then,

$$\lambda = \frac{1}{\mu} \varphi^{-1} \left(\theta \max \left\{ \frac{1}{\mu^2 |R|^2}, 1 \right\} \right) \quad \text{where } \varphi(z) = 1 - e^{-z}.$$

We must consider the following two cases.

Case 1. $\mu \Lambda \rightarrow \infty$.

Note that $\mu \Lambda \rightarrow \infty \Leftrightarrow \mu \lambda \rightarrow \infty \Leftrightarrow \theta \rightarrow 1$. Moreover, $\mu \rightarrow \infty$ as $\theta \rightarrow 1$. We have

$$\lim_{\theta \rightarrow 1} \frac{\lambda}{\Lambda} = \lim_{\theta \rightarrow 1} \frac{\varphi^{-1}(\theta)}{\psi^{-1}(\theta)} = \frac{1}{2}.$$

Case 2. $\mu \Lambda \rightarrow 0$ or $\mu \lambda \rightarrow 0$.

$\mu \Lambda \rightarrow 0 \Leftrightarrow \theta \rightarrow 0$ and $\mu \lambda \approx \sqrt[3]{32\theta}$ when θ is small. In order to estimate $\mu \lambda$, we have to consider two subcases.

Case 2a. $\mu |R| \geq 1$. Then $\mu \lambda = \varphi^{-1}(\theta) \approx \theta$ if θ is small. Hence $\Lambda \rightarrow 0 \Leftrightarrow \lambda \rightarrow 0 \Leftrightarrow \theta \rightarrow 0$; however,

$$0 \leq \lim_{\theta \rightarrow 0} \frac{\lambda}{\Lambda} \leq \lim_{\theta \rightarrow 0} \frac{\theta^{2/3}}{\sqrt[3]{32}} = 0.$$

Case 2b. $\mu |R| \leq 1$. Then

$$\mu \lambda = \varphi^{-1} \left(\frac{\theta}{\mu^2 |R|^2} \right) \approx \frac{\theta}{\mu^2 |R|^2} \quad \text{if } \frac{\theta}{\mu^2 |R|^2} \text{ is small.}$$

Hence $\Lambda \rightarrow 0 \Leftrightarrow \lambda \rightarrow 0 \Leftrightarrow \theta/\mu^3 \rightarrow 0$; but,

$$0 \leq \lim_{\theta/\mu^3 \rightarrow 0} \frac{\lambda}{\Lambda} \leq \lim_{\theta/\mu^3 \rightarrow 0} \frac{1}{\sqrt[3]{32}} \left(\frac{\theta}{\mu^3 |R|^3} \right)^{2/3} = 0.$$

Thus, although both bounds tend to zero simultaneously, the lower bound given by Theorem 1 is too low when g is linear and the segment sizes tend to zero. The reason for this is that in the proof of Theorem 1, we had to use the global estimate δ_{Rg} in place of $\delta_{S \cup S'} g$, because the set of breakpoints B need not be maximal among the sets

satisfying the condition (*), and hence $|S'|$ need not be small when $|S|$ is. However, as $\lambda \rightarrow 0$, $\delta_{S \cup S'} g \rightarrow 0$ if B satisfies (**), and $|g'(x)| \geq c > 0$ for all $x \in R$. We can use the upper bound Λ in this special case to estimate $|S \cup S'|$ and thus estimate $\delta_{S \cup S'} g$. Using this estimate, we can obtain a better lower bound, $\lambda_{\#}$ for segmentations that satisfy (*) and (**) such that $\lambda_{\#}/\Lambda$ is uniformly bounded from above and below by positive constants.

4. Behaviour when μ is small. By Theorem 1, in a nontrivial minimizing segmentation,

$$\max \left\{ \frac{\nu/\mu^2}{2(\delta_R g)^2}, \frac{\nu}{2(\text{Lip}_R g)^2} \right\} < \frac{1}{\mu} (1 - e^{-\mu|S|}) < |S| \leq \frac{|R|}{2}.$$

Hence, as $\mu \rightarrow 0$, we must bound ν/μ^2 in order to have nontrivial segmentations. We thus impose the condition

$$\frac{\nu}{\mu^2} = \nu_0 < |R|(\delta_R g)^2$$

when μ is small. Let

$$E_0(B) = \int_R (g - \bar{g}_B)^2 + \nu_0 |B|,$$

where \bar{g}_B is the piecewise constant function that, in each segment, equals the average value of g in that segment. By expressing f and g as cosine series, it is easy to show that

$$(\#) \quad \frac{E_0(B)}{1 + (\mu^2 |R|^2 / \pi^2)} \leq \frac{1}{\mu^2} E(f_B, B) \leq E_0(B).$$

(See [8, § 4] for a similar estimate when R is two-dimensional.) Consequently, we expect the behavior of $E(f_B, B)$ to be controlled by $E_0(B)$ as $\mu \rightarrow 0$. Notice that E_0 has a well-defined minimum. Like Theorem 1, we have the following lemma.

LEMMA 3. *Let B_0 be a nonempty set of breakpoints such that $E_0(B_0) < E_0(B'_0)$ for all $B'_0 \subset B$ with $|B'_0| = |B_0| - 1$. Then, for every segment S ,*

$$|S| > \frac{\nu_0}{(\delta_R g)^2}.$$

Proof. We proceed as in Theorem 1. Consider a segment S . Let S' be an adjoining segment, meeting S at P . Let $s = |S|$ and $s' = |S'|$. Let a , a' and b be the average values of g in S , S' , and $S \cup S'$, respectively. Note that $b = (as + a's')/(s + s')$. Let $B'_0 = B_0 - \{P\}$. Then

$$\begin{aligned} E_0(B'_0) - E_0(B_0) &= \int_{S \cup S'} (g - b)^2 - \int_S (g - a)^2 - \int_{S'} (g - a')^2 - \nu_0 \\ &= \frac{(a - a')^2 ss'}{s + s'} - \nu_0 \\ &\geq 0. \end{aligned}$$

Therefore,

$$\frac{1}{s} < \frac{1}{s} + \frac{1}{s'} = \frac{s + s'}{ss'} \leq \frac{(a - a')^2}{\nu_0} \leq \frac{(\delta_R g)^2}{\nu_0}.$$

As in Corollary 2, if

$$(\delta_D g)^2 < \frac{\nu_0}{|D|}$$

in a connected interval D , then D cannot contain more than one whole segment of the segmentation that minimizes E_0 . Thus, minimizing of E_0 is akin to the schemes that segment images by partitioning histograms.

For each positive integer k , let $D_k \subset \mathbf{R}^k$ be the subspace corresponding to the sets of k breakpoints that result in segments of length greater than $\nu_0/\{2(\partial_R g)^2\}$. $E(f_B, B)$ and $E_0(B)$ achieve their global minima over the space $D = \Pi_{k \leq k_0} D_k$, where k_0 is a fixed integer. To compare the global minima of $E(f_B, B)$ and $E_0(B)$, we may restrict them to D . $E(f_B, B)$ and $E_0(B)$ are continuous over D , where D has the induced topology from $\Pi_{k \leq k_0} \mathbf{R}^k$ with the standard topology. By $(\#)$, $(1/\mu^2)E(f_B, B)$ converges uniformly to $E_0(B)$ over D . From this, it is easy to see Theorem 3.

THEOREM 3. *Let B_0 be a set of breakpoints belonging to D .*

A. Suppose that B_0 minimizes $E_0(B)$ locally. Then, there exist a sequence of sets $\{B_i\}_{i \geq 1}$ of breakpoints belonging to D and a sequence of numbers $\{\mu_i\}_{i \geq 1}$ such that

- a. $B_i \rightarrow B_0$ and $\mu_i \rightarrow 0$ as $i \rightarrow \infty$,*
- b. B_i minimizes $E(f_B, B)$ locally with $\mu = \mu_i$ and $\nu = \nu_0 \mu^2$,*
- c. $E(f_B, B) \rightarrow E_0(B)$ as $i \rightarrow \infty$.*

B. Conversely, suppose that B_0 does not locally minimize $E_0(B)$. Then there exists a constant μ_0 such that for all $\mu \leq \mu_0$, $E(f_B, B)$ does not achieve its global minimum at B_0 .

By analyzing the convergence of the derivatives of $E(f_B, B)$ and $E_0(B)$ as in [8], it is possible to obtain stronger statements.

5. Behavior when μ is large. By Theorem 1 again, in a nontrivial minimizing segmentation,

$$(\partial_R g)^2 \geq \frac{\nu}{2\mu} \quad \text{and} \quad (\text{Lip}_R g)^2 \geq \frac{\mu\nu}{2}.$$

Hence as $\mu \rightarrow \infty$, we must bound $\mu\nu$. We impose the condition

$$\frac{\mu\nu}{2} = \nu_\infty \leq (\text{Lip}_R g)^2$$

when μ is large. Let

$$E_\infty(B) = \sum_{x \in B} [\nu_\infty - \{g'(x)\}^2].$$

In [7] we show that for a fixed set B of breakpoints and $g \in C^{1,1}(R)$,

$$E(f_B, B) = E(f_\emptyset, \emptyset) + \frac{2}{\mu} E_\infty + O\left(\frac{1}{\mu^2}\right).$$

(This follows easily from Lemma 4 below.) This indicates that as $\mu \rightarrow \infty$, it becomes advantageous to place more and more breakpoints in the vicinity of points where $|g'(x)|$ is maximum. Note however that although $E_\infty(B)$ may have stationary points (where $g'' = 0$), unlike $E_0(B)$, it has no minima unless $\sqrt{\nu_\infty} > \|g'\|_{\infty, R}$. Thus we should expect $|B| \rightarrow \infty$ as $\mu \rightarrow \infty$.

Let $B_{\mu, \nu}$ denotes a set of breakpoints that minimizes $E(f_B, B)$ with fixed μ and ν .

THEOREM 4. *Suppose that $g \in C^{1,1}(R)$. Then, the following hold.*

i. For every $\varepsilon > 0$, there exists a constant $\mu_\varepsilon > 0$ such that for all $\mu > \mu_\varepsilon$ and $\nu = 2\nu_\infty/\mu$,

$$B_{\mu,\nu} \subset \{x: |g'(x)| \geq \sqrt{\nu_\infty} - \varepsilon\}.$$

ii. If $\|g'\|_{\infty,R} > \sqrt{\nu_\infty}$, then

$$|B_{\mu,\nu} \cap \{x: |g'(x)| > \sqrt{\nu_\infty}\}| \rightarrow \infty \quad \text{as } \mu \rightarrow \infty.$$

COROLLARY 3. Let $g \in C^{1,1}(R)$. Instead of assuming that $\mu\nu$ is fixed as $\mu \rightarrow \infty$, fix a positive integer k and suppose that for each μ we choose ν such that $|B_{\mu,\nu}| \leq k$. If $B_{\mu,\nu}$ is nonempty for all μ , then as $\mu \rightarrow \infty$,

$$\frac{\mu\nu}{2} \rightarrow \|g'\|_{\infty,R}^2 \quad \text{and} \quad \lim_{\mu \rightarrow \infty} B_{\mu,\nu} \subset \{x: |g'(x)| = \|g'\|_{\infty,R}\}.$$

Proof of Theorem 4. Let $c = \sqrt{\nu_\infty}$. Let $R_\varepsilon = \{x: |g'(x)| \leq c - \varepsilon/2\}$. Choose μ_0 such that

$$\left(c - \frac{\varepsilon}{2}\right)^2 < \frac{c^2}{1 - e^{-\mu_0|R|}}.$$

By Corollary 2, each connected component of R_ε contains at most two breakpoints of $B_{\mu,\nu}$ for all $\mu \geq \mu_0$. We show now that for sufficiently large μ , the breakpoints in R_ε can occur only at points where $|g'| \geq c - \varepsilon$. Consider a connected component W of R_ε which contains at least one point, P , of $B_{\mu,\nu}$ where $|g'| < c - \varepsilon$. Since W can have at most two points of $B_{\mu,\nu}$, it has an interval containing no breakpoints in which $c - \varepsilon \leq |g'(x)| \leq c - \varepsilon/2$. (This is true even if W contains an endpoint of R .) Let Q be a point in this interval such that $|g'(Q)| = c - 2\varepsilon/3$. We claim that if μ is sufficiently large, we can reduce the energy by removing the cut at P and placing it at Q . We need the following lemma, which is an extension of Lemma 1.

LEMMA 4. Let $D = [0, a]$ and let $g: D \rightarrow \mathbf{R}$ be a $C^{1,1}$ function. Let u satisfy the equation $u'' = \mu^2(u - g)$ in D and the boundary condition $u'(0) = u'(a) = 0$. Then there exists a constant C such that

$$\begin{aligned} \left|u(0) - g(0) - \frac{g'(0)}{\mu}\right| &\leq \frac{1}{\mu} \left[\left(\frac{1}{2} + \mu a\right) e^{-\mu a} \|g'\|_{\infty,D} + \frac{C}{\mu} (\text{Lip}_D g') \right], \\ |u'(x) - g'(x)| &\leq \left(\frac{3}{2} + \mu a\right) e^{-\mu a/2} \|g'\|_{\infty,D} + \frac{C}{\mu} (\text{Lip}_D g'). \end{aligned}$$

Proof of the Lemma. Extend g to all of \mathbf{R} by successive reflections of D . As in the proof of Lemma 1,

$$\begin{aligned} u(x) - g(x) &= \frac{\mu}{2} \int_{-\infty}^{\infty} e^{-\mu|y-x|} [g(y) - g(x)] dy \\ &= \mu e^{-\mu x} \int_0^x (\cosh \mu y) [g(y) - g(x)] dy \\ &\quad + \mu (\cosh \mu x) \int_x^{\infty} e^{-\mu y} [g(y) - g(x)] dy. \end{aligned}$$

Also from the proof of Lemma 1, we have

$$\begin{aligned} u'(x) &= -\mu^2 e^{-\mu x} \int_0^x (\cosh \mu y) [g(y) - g(x)] dy \\ &\quad + \mu^2 (\sinh \mu x) \int_x^{\infty} e^{-\mu y} [g(y) - g(x)] dy. \end{aligned}$$

The required estimates are now obtained by substituting

$$\begin{aligned} g(y) - g(x) &= g'(x)(y-x) + \tilde{g}(y)(y-x)^2 \quad \text{if } 0 \leq y \leq a, \\ |g(y) - g(x)| &\leq a \|g'\|_{\infty, D} \quad \text{if } y \geq a, \end{aligned}$$

where $|\tilde{g}(y)| \leq \text{Lip}_R g'$, and evaluating the integrals. \square

We continue now with the proof of Theorem 4. We may assume that the points P and Q are in the same segment S . Let $s = \varepsilon / (\text{Lip}_R g')$. Note that $|S| \geq s/2$. Choose $\mu_\varepsilon \geq \mu_0$ such that

$$\left(\frac{3}{2} + \frac{\mu_\varepsilon s}{12} \right) e^{-\mu_\varepsilon s/24} \|g'\|_{\infty, R} + \frac{C}{\mu_\varepsilon} (\text{Lip}_R g') \leq \frac{\varepsilon}{12},$$

where C is the constant defined in Lemma 4. Let S' be the other segment with P as one of its endpoints. Let f_0, f_1 , and f_2 be the solutions of the Neumann problem $f'' = \mu^2(f - g)$ in $S \cup S'$, $S \cup S' - \{P\}$, $S \cup S' - \{Q\}$, respectively, with homogeneous boundary conditions. Let $v_i = f_i - g$ for $i = 0, 1, 2$. Then the reduction in energy by moving the cut from P to Q equals

$$f'_0(Q)[v_2^+(Q) - v_2^-(Q)] - f'_0(P)[v_1^+(P) - v_1^-(P)].$$

By Lemma 4,

$$\begin{aligned} |f'_0(Q) - g'(Q)| &\leq \frac{\varepsilon}{12} \\ \left| v_2^\pm(Q) \mp \frac{g'(Q)}{\mu} \right| &\leq \frac{\varepsilon}{12\mu} \\ |f'_0(P)| &\leq |g'(P)| + \frac{\varepsilon}{12} \leq c - \frac{11\varepsilon}{12} \\ |v_1^+(P)| &\leq \frac{1}{\mu} \left(|g'(P)| + \frac{\varepsilon}{12} \right) \leq \frac{1}{\mu} \left(c - \frac{11\varepsilon}{12} \right). \end{aligned}$$

If $|S'| \geq s/2$, then

$$|v_1^-(P)| \leq \frac{1}{\mu} \left(c - \frac{11\varepsilon}{12} \right)$$

by Lemma 4. If $|S'| \leq s/2$, then

$$\|g'\|_{\infty, S'} \leq |g'(P)| + (\text{Lip}_R g') \frac{s}{12} \leq |g'(P)| + \frac{\varepsilon}{12}$$

and hence, by Lemma 1

$$|v_1^-(P)| \leq \frac{1}{\mu} \left(|g'(P)| + \frac{\varepsilon}{12} \right) \leq \frac{1}{\mu} \left(c - \frac{11\varepsilon}{12} \right)$$

again. Therefore

$$\text{Reduction in energy} \geq \frac{2}{\mu} \left(c - \frac{3\varepsilon}{4} \right)^2 - \frac{2}{\mu} \left(c - \frac{11\varepsilon}{12} \right)^2 > 0.$$

To prove part (ii) of the theorem, choose $\alpha > 0$ such that $N = \{x : c + \alpha < |g'(x)| < \|g'\|_{\infty, R}\}$ is not empty. Then, using Lemma 4, show in the same way as in part (i) that for every $\varepsilon > 0$, there exists μ_ε such that for all $\mu > \mu_\varepsilon$, if $I \subset N$ is an interval of length $\geq \varepsilon$, not containing a point of $B_{\mu, \nu}$, we can reduce the energy by placing a cut at the center of I . \square

THE REVENGE OF THE LINEAR SEARCH PROBLEM*

ANATOLE BECK† AND MICAH BECK‡

Abstract. The linear search problem is the name for several problems motivated by the same external reality. At times, the search for a goal can proceed in two (or more) directions. Looking in one direction is at the expense of time and effort, which can be used elsewhere. More specifically, it might actually be moving further from the goal. This is modeled by a physical search along an infinite straight line, where the object of the search might be in either direction. Faced with a (known or unknown) probability distribution, this paper attempts to minimize the expected loss, where the loss is a function of the time of the search and the location of the object. In this variant of the problem, known distributions are dealt with, and the loss function is a known power of the time spent.

Key words. linear search, search games

Introduction. In 1972, the senior author, with the assistance of one of his students, took up the linear search problem under the assumption that the “cost” of each unit of distance increases with the time spent in search [4]. One way of defining the problem is to define the cost function $X_\alpha(x)$ as $\int_{-\infty}^{\infty} (X(x, t))^\alpha dF(t)$, where $x = \{x_i\}_{i=-\infty}^{\infty}$ is a search strategy, and $X(x, t)$ is defined as follows: for t lying between x_{n-1} and x_{n+1} , $X(x, t) = |t| + \sum_{i=-\infty}^n 2|x_i|$, and F is the (known or unknown) distribution of the target. Much has been written on the case where $\alpha = 1$ [1, 2, 3, 5, 6, 7]. Among the values of $\alpha > 1$, $\alpha = 2$ is special. This reflects not only the general mathematical interest in square-summable functions, but also the naive assumption that the function multiplying each new $dF(t)$ (possibly reflecting the degree of impatience) is proportional to the time already spent.

It will be the purpose of this paper to duplicate some of the results of [5] and [6] for the cases $\alpha > 1$ and especially $\alpha = 2$.

1. Definitions and fundamental notion. Let $\alpha > 1$ be arbitrarily fixed for the remainder of the paper and $\beta = \alpha - 1$. We will consider probability distributions F on the real line \mathbb{R} for which the absolute α -moment $M_\alpha = M_\alpha(F) = \int_{-\infty}^{\infty} |t|^\alpha dF(t) < \infty$. F is taken continuous from the left in \mathbb{R}^- , the negative reals, continuous from the right in \mathbb{R}^+ , and thus continuous at 0, for reasons set out in [1]. In [2], we define a *generalized search procedure* as a sequence $\{x_i\}_{i=-\infty}^{\infty}$ with

$$\cdots \leq x_2 \leq x_0 \leq x_{-2} \leq \cdots \leq 0 \leq \cdots \leq x_{-1} \leq x_1 \leq x_3 \leq \cdots.$$

We denote the set of generalized search plans as \mathcal{X}_1 . For each point $t \in \mathbb{R}$, if t lies between x_{n-1} and x_{n+1} , we consider that the search plan x envisions a path beginning at 0 and consisting of the intervals $\cdots, [x_{-2}, x_{-1}], [x_0, x_{-1}], [x_0, x_1], \cdots$, up to the point x_n , followed by the interval between x_n and t . The length of this path is $|t| + 2s_n$, where $s_n = \sum_{i=-\infty}^n |x_i|$. If $\sum_{i=-\infty}^0 |x_i| = \infty$, then $X(x, t) = \infty$, for all $t \in \mathbb{R}$, and x is a very unsatisfactory search procedure. Since the search procedure $y = \{-(-2)^n\}$ yields

$X(x, t) < 9|t|$, for all $t \in \mathbb{R}$, we see that $X_\alpha(y) = \int_{-\infty}^{\infty} X(y, t)^\alpha dF(t) \leq 9^\alpha M_\alpha(F)$. Thus we have at least one strategy giving a finite value for X_α if $M_\alpha < \infty$. On the other hand, $X(x, t) \geq |t|$ for all search procedures x and all $t \in \mathbb{R}$, giving $X_\alpha(x) \geq M_\alpha(F)$ for all search procedures. By [4, Thm. 17], if $M_\alpha(F) < \infty$, then there is a search procedure z such that $X_\alpha(z) \leq X_\alpha(x)$ for all search procedures x . By [4, Thm. 29], if either $\bar{F}^+(0)$ or $\bar{F}^-(0)$ is finite, then there exists a $k \in \mathbb{Z}$ such that all the turning points z_i of z are 0 for $i \leq k$, where

$$\bar{F}^+(0) = \limsup \{(F(t) - F(0))/t \mid t \downarrow 0\}$$

and

$$\bar{F}^-(0) = \limsup \{(F(t) - F(0))/t \mid t \uparrow 0\}.$$

At this point, we will also prove the following lemma.

LEMMA 1.1. *If x is a minimizing search procedure for the distribution F and exponent $\alpha > 0$, then $|x_{n-1}| < |x_{n+1}|$ unless the search has not really begun ($x_n = x_{n+1} = 0$) or is really already over ($|F(x_n) - F(x_{n-1})| = 1$).*

Proof. Assume without loss of generality that $x_n \leq 0$; the other case is similar, mutatis mutandis. If $x_{n-1} = x_{n+1}$, let y be the search procedure

$$\begin{aligned} y_j &= x_j, & \forall j < n, \\ y_j &= x_{j+z}, & \forall j \geq n. \end{aligned}$$

Then $X(y, t) = X(x, t) - 2(|x_n| + |x_{n-1}|)$, $\forall t \notin (x_n, x_{n-1})$. Thus $X_\alpha(y) < X_\alpha(x)$ if $F(x_n) > 0$ or $F(x_{n-1}) < 1$. \square

2. Uniform distribution. We begin with the distribution F , defined by $F'(t) = 1/(b-a)$, for all $a < t < b$, $F'(t) = 0$ elsewhere. If $a > 0$ or $b < 0$, the problem is trivial, so we take $a < 0 < b$. To simplify the notation, we will rewrite the left-hand endpoint of (a, b) as $(-a, b)$ with $a > 0$, and rewrite each search strategy by omitting as turning points all x_i that are 0 or lie outside $[-a, b]$.

THEOREM 2.1. *If $a > b$, then $X_\alpha(x)$ is minimized by $x = \{b, -a\}$. If $a < b$, then $X_\alpha(x)$ is minimized by $\{-a, b\}$.*

We begin with the following lemma.

LEMMA 2.2. *If $0 < a < b$, then*

$$\int_0^a t^\alpha dt + \int_0^b (2a+t)^\alpha dt < \int_0^b t^\alpha dt + \int_0^a (2b+t)^\alpha dt.$$

Proof. We must show that

$$\int_0^b (2a+t)^\alpha - t^\alpha dt < \int_0^a (2b+t)^\alpha - t^\alpha dt,$$

i.e.,

$$\int_0^b \alpha \int_0^{2a} (t+s)^\beta ds dt < \int_0^a \alpha \int_0^{2b} (t+s)^\beta ds dt.$$

Ignoring the common factor α and subtracting the common domain $[0, a] \times [0, b]$, we must show that

$$\int_0^b \int_a^{2a} (t+s)^\beta ds dt < \int_0^a \int_b^{2b} (t+s)^\beta ds dt,$$

i.e.,

$$\begin{aligned} \int_0^b \int_0^a (a+t+s)^\beta ds dt &< \int_0^a \int_0^b (b+t+s)^\beta ds dt \\ &= \int_0^b \int_0^a (b+t+s)^\beta ds dt, \end{aligned}$$

which is clear since $a+t+s < b+t+s$, for all $s, t \in \mathbb{R}$. \square

LEMMA 2.3. *If $0 < a < b < c$, then*

$$\int_0^b t^\alpha dt + \int_0^c (2b+t)^\alpha dt < \int_0^a t^\alpha dt + \int_0^b (2a+t)^\alpha dt + \int_a^c (2a+2b+t)^\alpha dt.$$

Proof. We must show that

$$\int_0^a (2b+t)^\alpha - t^\alpha dt < \int_0^b (2a+t)^\alpha - t^\alpha dt + \int_a^c (2a+2b+t)^\alpha - (2b+t)^\alpha dt,$$

i.e.,

$$\begin{aligned} \int_0^a \int_0^{2b} (s+t)^\beta ds dt &< \int_0^b \int_0^{2a} (s+t)^\beta ds dt + \int_a^c \int_0^{2a} (2b+s+t)^\beta ds dt, \\ \int_a^c \int_0^a (2b+s+t)^\beta ds dt &> a(2b+a)^\beta (c-a) > a(2a+b)^\beta (b-a) > \int_{2a}^{a+b} \int_0^a (s+t)^\beta ds dt, \\ \int_a^c \int_a^{2a} (2b+s+t)^\beta ds dt &> a(2b+2a)^\beta (c-a) > a(2b+a)^\beta (b-a) > \int_{a+b}^{2b} \int_0^a (s+t)^\beta ds dt, \\ \int_0^b \int_0^{2a} (s+t)^\beta ds dt &> \int_0^{2a} \int_0^a (s+t)^\beta ds dt. \end{aligned}$$

Adding the extremes,

$$\begin{aligned} \int_a^c \int_0^{2a} (2b+s+t)^\beta ds dt + \int_0^b \int_0^{2a} (s+t)^\beta ds dt &> \int_0^{2b} \int_0^a (s+t)^\beta ds dt \\ &= \int_0^a \int_0^{2b} (s+t)^\beta ds dt. \end{aligned} \quad \square$$

LEMMA 2.4. *If $0 < b \leq a < c$, then the same conclusion holds as in Lemma 2.3.*

Proof. The inequality

$$\int_0^b t^\alpha dt + \int_0^a (2b+t)^\alpha dt \leq \int_0^a t^\alpha dt + \int_0^b (2a+t)^\alpha dt$$

holds by Lemma 2.2, while

$$\int_a^c (2b+t)^\alpha dt < \int_a^c (2a+2b+t)^\alpha dt. \quad \square$$

COROLLARY 2.5. *If $0 < a < c$ and $0 < b < c$, then the same conclusion holds.*

LEMMA 2.6. *If $0 < a < c \leq b < d$, then*

$$\begin{aligned} \int_0^c t^\alpha dt + \int_0^d (2c+t)^\alpha dt &< \int_0^a t^\alpha dt + \int_0^b (2a+t)^\alpha dt + \int_a^c (2a+2b+t)^\alpha dt \\ &\quad + \int_b^d (2a+2b+2c+t)^\alpha dt. \end{aligned}$$

Proof. Note that

$$\begin{aligned} \int_b^d (2a+2b+2c+t)^\alpha dt &> \int_b^d (2c+t)^\alpha dt, \\ \int_0^c t^\alpha dt - \int_0^a t^\alpha dt &= \int_a^c t^\alpha dt, \end{aligned}$$

and

$$\begin{aligned} \int_a^c (2a+2b+t)^\alpha - t^\alpha dt &= \alpha \int_a^c \int_0^{2a+2b} (s+t)^\beta ds dt \\ &> \alpha \int_a^c \int_{2a+b}^{2a+2b} (s+t)^\beta ds dt + \alpha \int_a^c \int_{2a}^{2a+b} (s+t)^\beta ds dt. \end{aligned}$$

On the other hand,

$$\begin{aligned} \int_0^b (2c+t)^\alpha - (2a+t)^\alpha dt &= \alpha \int_0^b \int_{2a}^{2c} (s+t)^\beta ds dt \\ &= \alpha \int_0^b \int_{2a}^{a+c} (s+t)^\beta ds dt + \alpha \int_0^b \int_{a+c}^{2c} (s+t)^\beta ds dt. \end{aligned}$$

Also,

$$\begin{aligned} \int_a^c \int_{2a+b}^{2a+2b} (s+t)^\beta ds dt &= \int_a^c \int_0^b (2a+b+s+t)^\beta ds dt \\ &> \int_a^c \int_0^b (c+s+t)^\beta ds dt \\ &= \int_0^b \int_{a+c}^{2c} (s+t)^\beta ds dt \end{aligned}$$

and

$$\begin{aligned} \int_a^c \int_{2a}^{2a+b} (s+t)^\beta ds dt &= \int_a^c \int_0^b (2a+s+t)^\beta ds dt \\ &> \int_a^c \int_0^b (a+s+t)^\beta ds dt \\ &= \int_0^b \int_{2a}^{a+c} (s+t)^\beta ds dt. \end{aligned}$$

Adding the first two inequalities gives us

$$\begin{aligned} \int_b^d (2a+2b+2c+t)^\alpha dt + \int_a^c (2a+2b+t)^\alpha dt - \int_a^c t^\alpha dt \\ > \int_b^d (2c+t)^\alpha dt + \alpha \int_a^c \int_{2a+b}^{2a+2b} (s+t)^\beta ds dt + \alpha \int_a^c \int_{2a}^{2a+b} (s+t)^\beta ds dt. \end{aligned}$$

Incorporating the first equality gives us

$$\begin{aligned} \int_b^d (2a+2b+2c+t)^\alpha dt + \int_a^c (2a+2b+t)^\alpha dt + \int_0^a t^\alpha dt \\ > \int_0^c t^\alpha dt + \int_b^d (2c+t)^\alpha dt + \alpha \int_a^c \int_{2a+b}^{2a+2b} (s+t)^\beta ds dt + \alpha \int_a^c \int_{2a}^{2a+b} (s+t)^\beta ds dt. \end{aligned}$$

It remains to show that

$$\int_0^b (2a+t)^\alpha dt > \int_0^b (2c+t)^\alpha dt - \alpha \int_a^c \int_{2a+b}^{2a+2b} (s+t)^\beta ds dt - \alpha \int_a^c \int_{2a}^{2a+b} (s+t)^\beta ds dt,$$

which, by the second equality, means

$$\begin{aligned} \alpha \int_a^c \int_{2a+b}^{2a+2b} (s+t)^\beta ds dt + \alpha \int_a^c \int_{2a}^{2a+b} (s+t) ds dt \\ > \alpha \int_0^b \int_{2a}^{a+c} (s+t)^\beta ds dt + \alpha \int_0^b \int_{a+c}^{2c} (s+t)^\beta ds dt, \end{aligned}$$

which follows from the last two inequalities. \square

Proof of Theorem 2.1. By [4, Thm. 29], there is a minimizing strategy $\{x_i\}$ with $x_i = 0$, for all $i \leq 0$. We cannot have $0 \neq x_1 \in (-a, b)$ and $|x_2| < |x_3|$, since in that case, by either Lemma 2.3 (if $|x_1| < |x_2|$) or Lemma 2.4 (if $|x_1| \geq |x_2|$), the substitution of 0 for x_1 would reduce $X_\alpha(x)$. If $|x_2| > |x_3|$ and $x_4 \in (-a, b)$, then by Lemma 2.6, the substitution of 0 for x_1 and x_2 would reduce $X_\alpha(x)$. Finally, if $|x_2| > |x_3|$ and $x_4 \notin (-a, b)$, the substitution of 0 for x_1 and x_2 , and of the endpoint (either $-a$ or b) of the same sign for x_4 would reduce $X_\alpha(x)$. Thus, in all cases, $X_\alpha(x)$ is not minimized if $0 \neq x_1 \in (-a, b)$. It follows that the first nonzero turning point is one of the endpoints, from which we see at once that the second is the other endpoint. By Lemma 2.2, x_1 must be the endpoint with the smaller absolute value. \square

3. Symmetric distributions. A distribution F is called *symmetric* if $F(x) + F(-x) = 1$, for all $x \in \mathbb{R}$. For these distributions, we take the notational convenience of writing our search strategies with positive entries (i.e., $\{|x_i|\}$ for $\{x_i\}$) with the understanding that the actual turning points alternate in sign. Clearly, x and $-x$ give the same value of X_α .

THEOREM 3.1. *If F is a symmetric distribution, x is a minimizing search strategy, and x_k satisfies $0 < x_k$ and $F(x_k) < 1$, then $x_{k+1} > x_k$.*

Proof. The proof of this theorem is a modification of the proof of Lemma 3.2.

LEMMA 3.2. *On the hypothesis of Theorem 3.1, $x_{k+1} \neq x_k$.*

Proof. Assume that $x_k = x_{k+1}$. Then when the search reaches the $(k+1)$ th turning point, the strategy x calls for crossing back to x_k before searching new territory. However, because of symmetry, the same search effectively can be accomplished without crossing back. More explicitly, define the strategy y by

$$\begin{aligned} y_n &= x_n, & \forall n \leq k, \\ y_n &= x_{n+1}, & \forall n > k. \end{aligned}$$

Note that all turning points after the k th are in the opposite half of \mathbb{R} . Indeed, we see that $X(x, t) = X(y, t)$, for all $|t| \leq x_k$, $X(x, t) = X(y, -t) + 2|x_k|$, for all $|t| > x_k$. Thus $X_\alpha(y) < X_\alpha(x)$, contrary to the minimality of x . \square

Proof of Theorem 3.1. In the proof of Lemma 3.2, we drop the entry x_{k+1} . In this proof, we assume that $x_{k+1} \leq x_k$, which means $x_{k+1} < x_k$. Let j be the largest value of n for which $x_n \leq x_k$. Thus $j \geq k+1$ and is of opposite parity to k . Then $x_k < x_{j+2}$, and we drop all the x_n for $k < n \leq j$. Thus, as before, if $y = (\dots, x_{k-1}, x_k, x_{j+1}, x_{j+2}, \dots)$, all the entries after the k th lie in the opposite half of \mathbb{R} . Then we have

$$\begin{aligned} X_\alpha(x) &= \sum_{n=-\infty}^{k-1} \int_{x_{n-1}}^{x_{n+1}} (2s_n + t)^\alpha dF(t) + \int_{x_{k-1}}^{x_{k+1}} (2s_k + t)^\alpha dF(t) \\ &\quad + \dots + \int_{x_j}^{x_{j+2}} (2s_{j+1} + t)^\alpha dF(t) + \sum_{n=j+2}^{\infty} \int_{x_{n-1}}^{x_{n+1}} (2s_n + t)^\alpha dF(t), \\ X_\alpha(y) &= \sum_{n=-\infty}^{k-1} \int_{x_{n-1}}^{x_{n+1}} (2s_n + t)^\alpha dF(t) + \int_{x_{k-1}}^{x_{j+1}} (2s_k + t)^\alpha dF(t) + \int_{x_k}^{x_{j+2}} (2r_{j+1} + t)^\alpha dF(t) \\ &\quad + \sum_{n=j+2}^{\infty} \int_{x_{n-1}}^{x_{n+1}} (2r_n + t)^\alpha dF(t), \end{aligned}$$

where

$$s_n = \sum_{i=-\infty}^n x_i, \quad \forall n \in \mathbb{Z}, \quad \text{and} \quad r_n = s_k + x_{j+1} + \cdots + x_n < s_n, \quad \forall n > j.$$

Then

$$\begin{aligned} X_\alpha(x) - X_\alpha(y) &= \int_{x_{k-1}}^{x_{k+1}} (2s_k + t)^\alpha dF(t) + \int_{x_{k+1}}^{x_{k+3}} (2s_{k+2} + t)^\alpha dF(t) \\ &\quad + \cdots + \int_{x_{j-2}}^{x_j} (2s_{j-1} + t)^\alpha dF(t) + \int_{x_j}^{x_k} (2s_{j+1} + t)^\alpha dF(t) \\ &\quad + \int_{x_k}^{x_{j+2}} (2s_{j+1} + t)^\alpha dF(t) + \int_{x_k}^{x_{k+2}} (2s_{k+1} + t)^\alpha dF(t) \\ &\quad + \int_{x_{k+2}}^{x_{k+4}} (2s_{k+3} + t)^\alpha dF(t) + \cdots + \int_{x_{j-1}}^{x_{j+1}} (2s_j + t)^\alpha dF(t) \\ &\quad - \int_{x_{k-1}}^{x_k} (2s_k + t)^\alpha dF(t) - \int_{x_k}^{x_{j+1}} (2s_k + t)^\alpha dF(t) \\ &\quad - \int_{x_k}^{x_{j+2}} (2r_{j+1} + t)^\alpha dF(t) + \sum_{n=j+2}^{\infty} \int_{x_{n-1}}^{x_{n+1}} (2s_n + t)^\alpha - (2r_n + t)^\alpha dF(t) \\ &> \int_{x_{k-1}}^{x_{k+1}} (2s_k + t)^\alpha dF(t) + \int_{x_{k+1}}^{x_{k+3}} (2s_k + t)^\alpha dF(t) \\ &\quad + \cdots + \int_{x_{j-2}}^{x_j} (2s_k + t)^\alpha dF(t) + \int_{x_j}^{x_k} (2s_k + t)^\alpha dF(t) \\ &\quad + \int_{x_k}^{x_{j+2}} (2s_{j+1} + t)^\alpha dF(t) + \int_{x_k}^{x_{k+2}} (2s_k + t)^\alpha dF(t) \\ &\quad + \cdots + \int_{x_{j-1}}^{x_{j+1}} (2s_k + t)^\alpha dF(t) - \int_{x_{k-1}}^{x_{k+1}} (2s_k + t)^\alpha dF(t) \\ &\quad - \int_{x_{k+1}}^{x_k} (2s_k + t)^\alpha dF(t) - \int_{x_k}^{x_{j+1}} (2s_k + t)^\alpha dF(t) \\ &\quad - \int_{x_k}^{x_{j+2}} (2r_{j+1} + t)^\alpha dF(t) \\ &= \int_{x_{k+1}}^{x_k} (2s_k + t)^\alpha dF(t) + \int_{x_k}^{x_{j+2}} (2s_{j+1} + t)^\alpha dF(t) \\ &\quad + \int_{x_k}^{x_{j+1}} (2s_k + t)^\alpha dF(t) - \int_{x_{k+1}}^{x_k} (2s_k + t)^\alpha dF(t) \\ &\quad - \int_{x_k}^{x_{j+2}} (2r_{j+1} + t)^\alpha dF(t) - \int_{x_k}^{x_{j+1}} (2s_k + t)^\alpha dF(t) \\ &= \int_{x_k}^{x_{j+2}} (2s_{j+1} + t)^\alpha - (2r_{j+1} + t)^\alpha dF(t) > 0, \end{aligned}$$

contrary to the assumed minimality of $X_\alpha(x)$. \square

4. The triangular distribution. We define the triangular distribution T by the condition that $\dot{T}(t) = 1 - |t|$, for all $-1 < t < 1$, $\dot{T}(t) = 0$, for all $|t| > 1$. The only result in this section is Theorem 4.1.

THEOREM 4.1. *If x is a minimizing search strategy for T , then $x_i < 1$, for all $i \in \mathbb{Z}$.*

Proof. Suppose that k is the least value of n for which $x_n = 1$, i.e., $x = \{x_1, \dots, x_{k-1}, 1, 1, \dots\}$. Let $y = \{x_1, \dots, x_{k-1}, s, 1, 1, \dots\}$. Then

$$\begin{aligned} X_\alpha(x) = \sum_{n=0}^{k-2} \int_{x_{n-1}}^{x_{n+1}} (2s_n + t)^\alpha (1-t) dt + \int_{x_{k-2}}^1 (2s_{k-1} + t)^\alpha (1-t) dt \\ + \int_{x_{k-1}}^1 (2s_{k-1} + 2 + t)^\alpha (1-t) dt \end{aligned}$$

and

$$\begin{aligned} X_\alpha(y) = \sum_{n=0}^{k-2} \int_{x_{n-1}}^{x_{n+1}} (2s_n + t)^\alpha (1-t) dt + \int_{x_{k-2}}^s (2s_{k-1} + t)^\alpha (1-t) dt \\ + \int_{x_{k-1}}^1 (2s_{k-1} + 2s + t)^\alpha (1-t) dt \\ + \int_s^1 (2s_{k-1} + 2s + 2 + t)^\alpha (1-t) dt. \end{aligned}$$

Thus

$$\begin{aligned} X_\alpha(x) - X_\alpha(y) &= \int_s^1 (2s_{k-1} + t)^\alpha (1-t) dt \\ &+ \int_{x_{k-1}}^1 ((2s_{k-1} + 2 + t)^\alpha - (2s_{k-1} + 2s + t)^\alpha) (1-t) dt - \int_s^1 (2s_{k-1} + 2s + 2 + t)^\alpha (1-t) dt \\ &= \int_{x_{k-1}}^1 ((2s_{k-1} + 2 + t)^\alpha - (2s_{k-1} + 2s + t)^\alpha) (1-t) dt \\ &- \int_s^1 ((2s_{k-1} + 2s + 2 + t)^\alpha - (2s_{k-1} + t)^\alpha) (1-t) dt. \end{aligned}$$

By the mean value theorem,

$$(2s_{k-1} + 2 + t)^\alpha - (2s_{k-1} + 2s + t)^\alpha \geq 2\alpha(1-s)(2s_{k-1} + 2s)^\beta > 2\alpha(1-s)(2s_{k-1})^\beta,$$

while

$$(2s_{k-1} + 2s + 2 + t)^\alpha - (2s_{k-1} + t)^\alpha < 4\alpha(1+s)(2s_{k-1} + 2s + 3)^\beta < 8\alpha(2s_{k-1} + 5)^\beta.$$

Hence,

$$X_\alpha(x) - X_\alpha(y) > \alpha(1-s)(2s_{k-1})^\beta(1-x_{k-1})^2 - 4\alpha(2s_{k-1} + 5)^\beta(1-s)^2 > 0,$$

if $1-s$ is sufficiently small, contrary to the assumed minimality of $X_\alpha(x)$. \square

5. The special case $\alpha = 2$. For a symmetric distribution F , define the function H in \mathbb{R}^+ by $H(s) = \int_0^s t dF(t)$. Then for any search plan $x = \{x_n\}_{n=-\infty}^\infty$, we have

$$X_2(x) = \sum_{n=-\infty}^\infty \int_{x_{n-1}}^{x_{n+1}} (2s_n + t)^2 dF(t) = M_2(F) + 4\Delta_1 + 4\Delta_2,$$

where

$$\begin{aligned}
 M_2(F) &= \int_{-\infty}^{\infty} t^2 dF(t) = \sum_{n=-\infty}^{\infty} \int_{x_{n-1}}^{x_{n+1}} t^2 dF(t), \\
 \Delta_1 &= \sum_{n=-\infty}^{\infty} \int_{x_{n-1}}^{x_{n+1}} s_n t dF(t) \\
 &= \sum_{n=-\infty}^{\infty} s_n (H(x_{n+1}) - H(x_{n-1})) \\
 &= \sum_{n=-\infty}^{\infty} \sum_{j=-\infty}^n x_j (H(x_{n+1}) - H(x_{n-1})) \\
 &= \sum_{-\infty < j \leq n} x_j (H(x_{n+1}) - H(x_{n-1})) \\
 &= \sum_{j=-\infty}^{\infty} x_j (2H_{\infty} - H(x_{j-1}) - H(x_j)),
 \end{aligned}$$

where

$$H_{\infty} = \int_0^{\infty} t dF(t) = \frac{1}{2} M_1(F),$$

and

$$\Delta_2 = \sum_{n=-\infty}^{\infty} \int_{x_{n-1}}^{x_{n+1}} s_n^2 dF(t) = \sum_{n=-\infty}^{\infty} s_n^2 (F(x_{n+1}) - F(x_{n-1})).$$

If F is differentiable, then a minimizing search strategy x would satisfy $\partial \Delta / \partial x_k = 0$, for all $k \in \mathbb{Z}$, where $\Delta = \Delta_1 + \Delta_2$. The corresponding formula in the case where $\alpha = 1$ involves only the three turning points x_{k-1} , x_k , and x_{k+1} , thus enabling it to be used easily as a computing tool. For $\alpha = 2$, however, the matter is more complicated; see below:

$$\begin{aligned}
 \frac{\partial \Delta_1}{\partial x_k} &= (2H_{\infty} - H(x_{k-1}) - H(x_k)) - H'(x_k)x_k - H'(x_k)x_{k+1} \\
 &= 2H_{\infty} - H(x_{k-1}) - H(x_k) - x_k F'(x_k)(x_k + x_{k+1}), \\
 \frac{\partial \Delta_2}{\partial x_k} &= \sum_{n=k}^{\infty} 2s_n (F(x_{n+1}) - F(x_{n-1})) + F'(x_k)s_{k-1}^2 - F'(x_k)s_{k+1}^2 \\
 &= \sum_{n=k}^{\infty} 2s_k (F(x_{n+1}) - F(x_{n-1})) + \sum_{n=k}^{\infty} 2(s_n - s_k)(F(x_{n+1}) - F(x_{n-1})) - F'(x_k)(s_{k+1}^2 - s_{k-1}^2) \\
 &= 2s_k (G(x_{k-1}) + G(x_k)) + \sum_{n=k}^{\infty} 2 \sum_{j=k+1}^n x_j (F(x_{n+1}) - F(x_{n-1})) \\
 &\quad - F'(x_k)(s_{k+1} + s_{k-1})(s_{k+1} - s_{k-1}) \\
 &= 2s_k (G(x_{k-1}) + G(x_k)) + 2 \sum_{k < j \leq n} x_j (F(x_{n+1}) - F(x_{n-1})) \\
 &\quad - F'(x_k)(s_{k+1} + s_{k-1})(x_{k+1} + x_k) \\
 &= 2s_k (G(x_{k-1}) + G(x_k)) + 2 \sum_{j=k+1}^{\infty} x_j (G(x_{j-1}) + G(x_j)) - F'(x_k)(s_{k+1} + s_{k-1})(x_{k+1} + x_k),
 \end{aligned}$$

where

$$G(x) = 1 - F(x), \quad \forall x > 0.$$

Thus, our necessary condition becomes

$$\begin{aligned} 0 = \frac{\partial \Delta}{\partial x_k} &= 2H_\infty - H(x_{k-1}) - H(x_k) - x_k F'(x_k)(x_k + x_{k+1}) - (s_{k+1} + s_{k-1}) F'(x_k)(x_k + x_{k+1}) \\ &\quad + 2s_k(G(x_{k-1}) + G(x_k)) + 2 \sum_{j=k+1}^{\infty} x_j(G(x_{j-1}) + G(x_j)) \\ &= 2H_\infty - H(x_{k-1}) - H(x_k) - (s_{k+1} + s_k) F'(x_k)(x_{k+1} + x_k) + 2s_k(G(x_{k-1}) + G(x_k)) \\ &\quad + 2 \sum_{j=k+1}^{\infty} x_j(G(x_{j-1}) + G(x_j)). \end{aligned}$$

Since this is true for all $k \in \mathbb{Z}$,

$$\begin{aligned} 0 = \frac{\partial \Delta}{\partial x_k} - \frac{\partial \Delta}{\partial x_{k+1}} &= H(x_{k+1}) - H(x_{k-1}) - (s_{k+1} + s_k) F'(x_k)(x_{k+1} + x_k) \\ &\quad + (s_{k+2} + s_{k+1}) F'(x_{k+1})(x_{k+2} + x_{k+1}) + 2s_k(G(x_{k-1}) + G(x_k)) \\ &\quad - 2s_{k+1}(G(x_k) + G(x_{k+1})) + 2x_{k+1}(G(x_k) + G(x_{k+1})) \\ &= H(x_{k+1}) - H(x_{k-1}) - (s_{k+1} + s_k) F'(x_k)(x_{k+1} + x_k) \\ &\quad + (s_{k+2} + s_{k+1}) F'(x_{k+1})(x_{k+2} + x_{k+1}) + 2s_k(G(x_{k-1}) - G(x_{k+1})), \end{aligned}$$

which has the advantage that it involves only finitely many values of x_n . We can, in principle, use this formula to calculate x_{k+2} when x_1, \dots, x_{k+1} are known. Actually, the calculation is very delicate, depending on the size of $F'(x_{k+1})$. However, for every choice for x_1 and x_2 , we can generate values for all the other x_n . Thus, what would be a one-dimensional search in the case where $\alpha = 1$ becomes a two-dimensional search for $\alpha = 2$. We will carry out a numerical analysis for the triangular and normal distributions.

6. Numerical approximations. To obtain the turning points for the triangular distribution, we start with the search strategy $(1, 1, 1, 1, \dots)$. In line with Theorem 4.1, we modify $x_1 = 1$ to x_{11} , which satisfies the equation for $\partial \Delta / \partial x_1 = 0$, with $x_0 = 0$ and $x_2 = x_3 = 1$. Then we modify the strategy $(x_{11}, 1, 1, 1, \dots)$ by applying the equation for $\partial \Delta / \partial x_2 = 0$, with $x_1 = x_{11}$ and $x_3 = x_4 = 1$. The solution is called x_{22} , and we then modify x_{11} to x_{21} , using $x_0 = 0$, $x_2 = x_{22}$, and $x_3 = x_4 = 1$. We continue in this way, generating $x_{33}, x_{32}, x_{31}, x_{44}$, etc.

Actually, solving for x_{kj} will give us $x_{kj} = 1$ for quite small values of k and j because of the limitations of the machine, so we alter our algorithm to yield $\delta_{kj} = 1 - x_{kj}$ instead. Then we obtain $\delta_n = \lim_{k \rightarrow \infty} \delta_{kn}$, for all $n \in \mathbb{N}$. This procedure will give us the values shown in Table 1. For $\alpha = 1$,

$$X_1(x) = M_1(T) + \sum_{n=1}^{\infty} s_n((1 - x_{n-1})^2 - (1 - x_{n+1})^2) = M_1(T) + \sum_{n=0}^{\infty} (x_n + x_{n+1})(1 - x_n)^2.$$

Thus, the condition $0 = \partial X_1 / \partial x_n = (1 - x_n)^2 - 2(x_n + x_{n+1})(1 - x_n) + (1 - x_{n-1})^2$ translates as $0 = 3\delta_n^2 - (4 - 2\delta_{n+1}) + \delta_{n-1}^2$. We then seek a sequence $\{\delta_n\}$ satisfying this equation, for all $n \in \mathbb{N}$, and $\delta_0 = 1 - x_0 = 1$. For other values of α , we have

$$\frac{\partial X_\alpha}{\partial x_n} = \sum_{j=n}^{\infty} \int_{x_{j-1}}^{x_{j+1}} (2s_j + t)^\alpha (1 - t) dt - \delta_n((2s_{n+1} + x_n)^\alpha - (2s_{n-1} + x_n)^\alpha),$$

which we wish to equal 0. Thus, we want

$$\begin{aligned}
 0 &= \frac{\partial X_\alpha}{\partial x_n} - \frac{\partial X_\alpha}{\partial x_{n+1}} = \int_{x_{n-1}}^{x_{n+1}} (2s_n + t)^\alpha (1-t) dt - \delta_n ((2s_{n+1} + x_n)^\alpha - (2s_{n-1} + x_n)^\alpha) \\
 &\quad + \delta_{n+1} ((2s_{n+2} + x_{n+1})^\alpha - (2s_n + x_{n+1})^\alpha) \\
 &= \frac{2}{\alpha+1} ((2s_n + x_{n+1})^\alpha (1 + \alpha\delta_{n+1} + 2s_n) \\
 &\quad - (2s_n + x_{n-1})^\alpha (1 + \alpha\delta_{n-1} + 2s_n)) \\
 &\quad - \delta_n ((2s_{n+1} + x_n)^\alpha - (2s_{n-1} + x_n)^\alpha) \\
 &\quad + \delta_{n+1} ((2s_{n+2} + x_{n+1})^\alpha - (2s_n + x_{n+1})^\alpha),
 \end{aligned}$$

where $x_n = 1 - \delta_n$ and $s_n = x_1 + \dots + x_n$, $\forall n \in \mathbb{N}$.

We obtain δ_n for each value of α between 1 and 3 by taking as initial values what we have for $\alpha = 1$ and applying Newton's method until we get the necessary zeroes. The results are found in Table 1.

The normal distribution is more complicated. To avoid the complications of infinitely many turning points, we will use the equations we get from the condition $(\partial\Delta/\partial x_k) - (\partial\Delta/\partial x_{k+1}) = 0$, for all $k \in \mathbb{N}$. Choosing values of x_1 and x_2 with $0 < x_1 < x_2$, we generate x_3, \dots, x_{20} recursively and calculate Δ for those x_1, x_2 for which $0 < x_1 < x_2 < \dots < x_{20} < 10^3$. Table 2 shows a comparison of the turning points for $\alpha = 1, 2$.

H_∞ -CONTROL BY STATE-FEEDBACK FOR PLANTS WITH ZEROS ON THE IMAGINARY AXIS*

CARSTEN SCHERER†

Abstract. Algebraic tests are derived for the suboptimality of some parameter in the H_∞ -optimization problem by state-feedback, where the finite zero structure of the plant is not restricted. As an application of these characterizations, a quadratically convergent algorithm for the computation of the optimal value is presented. The suboptimality tests are based on new solvability criteria for general algebraic Riccati inequalities that are of independent interest.

Key words. H_∞ -optimization, invariant zeros, Riccati inequalities, quadratic convergence

1. Introduction. In the seminal papers [15], [10], [11], and [28], suboptimality tests for the state-feedback H_∞ -problem were derived by making essential use of the bounded real lemma [2]. These characterizations are formulated in terms of the solvability of an algebraic Riccati *equation* (ARE) that contains some perturbation parameter $\varepsilon > 0$. For the so-called regular problem (in the terminology of [23]), this ε -parametrized Riccati equation could be viewed as an unperturbed strict algebraic Riccati *inequality* (ARI). If the plant has, in addition, no zeros on the imaginary axis, we can return to an unperturbed Riccati *equation* [3], [24] whose solvability can be checked algebraically. The ARE-based suboptimality tests allow us to find quadratically convergent algorithms for computing the optimal value [18]. If considering the *singular* problem for a plant without zeros on the imaginary axis, the perturbation technique can be avoided as well. We must replace the Riccati equation by a quadratic matrix inequality as it is known in the theory of singular LQ problems [23]. In fact, the suboptimality criteria boil down to the solvability of a certain reduced-order Riccati equation, which implies that the computational algorithms of [18] are again applicable.

In this paper we provide an algebraic solvability test for general strict Riccati inequalities. This leads directly to a characterization of suboptimality for the regular H_∞ -problem without the need to apply any perturbation technique. In a subsequent paper we show how these results may be generalized to a solution of the H_∞ -problem by output measurement [19].

The paper is structured as follows. In § 2 we give a precise formulation of the regular H_∞ -optimization problem by state-feedback and point out the relation of suboptimality with algebraic Riccati inequalities (Theorem 1). We briefly explain the above-described perturbation methods and the difficulties caused by plant zeros on the imaginary axis. The self-contained § 3 is the core of our whole approach. It contains the derivation of new algebraic conditions which are equivalent to the solvability of a strict algebraic Riccati inequality with a symmetric or positive definite matrix (Theorems 3 and 6). The parameter matrices that define the ARI are in no way restricted. Section 4 consists of the translation of these criteria to the H_∞ -problem. Although this is just a task of matching matrices, we explicitly discuss the influence of the plant zeros on the H_∞ -optimal value and on the design of suboptimal feedbacks. Section 5

is devoted to proposing an algorithm for the computation of the optimal value. Moreover, we investigate the possibility of computing the optimal value by solving certain Hermitian eigenvalue problems.

1b. Notation. We denote by \mathbb{N} the nonnegative integers, by \mathbb{R} and \mathbb{C} the real and complex numbers where \mathbb{C} is partitioned in the usual way as $\mathbb{C}^- \cup \mathbb{C}^0 \cup \mathbb{C}^+$, the open left half-plane, the imaginary axis and the open right half-plane, respectively. The spaces $\mathbb{R}^n, \mathbb{C}^n$ are equipped with the usual Euclidean norm and $\mathbb{R}^{n \times m}, \mathbb{C}^{n \times m}$ with the induced operator norm where all these norms are denoted by $\|\cdot\|$. Any matrix and any subspace appearing in this paper is considered to be *real* if not stated otherwise. In general, the dimensions of (sub)matrices are suppressed and a block in a partitioned matrix which is of no interest is denoted as “*.” Moreover, we use the notation $A|_{\mathcal{J}}$ for the restriction of $A \in \mathbb{R}^{n \times n}$ to any A -invariant subspace \mathcal{J} .

For the subset of symmetric matrices in $\mathbb{R}^{n \times n}$ we use the symbol \mathbb{S}^n . $X > Y$ ($X \geq Y$) means that X and Y are symmetric and $X - Y$ is positive (semi)definite. If \mathcal{S} is any subset of \mathbb{S}^n , S_- is called a (strict) lower bound if $S_- \leq S$ ($S_- < S$) holds for all $S \in \mathcal{S}$. If there exists one (strict) lower bound, there are obviously infinitely many. An important concept is to choose “close” (strict) lower bounds: S_- is called a (strict) lower limit point of \mathcal{S} if S_- is a (strict) lower bound of \mathcal{S} and if there exists a sequence $S_j \in \mathbb{S}^n$ with $S_j \rightarrow S_-$ for $j \rightarrow \infty$. Obviously, there is *at most one* lower limit point and *at most one* strict lower limit point of \mathcal{S} . A matrix $S \in \mathbb{S}^n$ is called positive (negative) on the complex set of vectors $\mathcal{M} \subset \mathbb{C}^n$ if $x^* S x > 0$ ($x^* S x < 0$) holds for all $x \in \mathcal{M} \setminus \{0\}$. Finally, we always identify a system $\dot{x} = Ax + Bu$, $z = Cx + Du$ with the corresponding Rosenbrock matrix

$$S(s) = \begin{pmatrix} A - sI & B \\ C & D \end{pmatrix}.$$

If $H(s)$ is a real rational matrix, we define $\|H(s)\|_{\infty} := \sup_{\omega \in \mathbb{R}} \|H(i\omega)\| \leq \infty$. $\|H(s)\|_{\infty}$ coincides with the L_{∞} -norm if $H(s)$ is proper and has no poles on the imaginary axis. If $H(s)$ is proper and stable, $\|H(s)\|_{\infty}$ is the H_{∞} -norm of $H(s)$.

2. H_{∞} -optimization and Riccati inequalities. The system is described by

$$(1) \quad \begin{aligned} \dot{x} &= Ax + Bu + Gd, & x(0) &= 0, \\ z &= Hx + Eu, \end{aligned}$$

where $x \in \mathbb{R}^n$ is the state, $u \in \mathbb{R}^m$ the control, $d \in \mathbb{R}^r$ the external disturbance, and $z \in \mathbb{R}^k$ the controlled output, and the real matrices A, B, G, H, E are of compatible size.

The H_{∞} -problem by static state-feedback consists of minimizing $\|(H + EF) \times (sI - A - BF)^{-1}G\|_{\infty}$ over all feedback matrices F such that $A + BF$ is stable. Obviously, $(A - sI \ B)$ must be stabilizable. In this paper, we treat only the *regular* problem and hence we assume in addition that E has maximal column. We can then perform the preliminary feedback $u = Fx + v$ with $F := -(E^T E)^{-1} E^T H$ to achieve $E^T (H + EF) = 0$. The subsequent input coordinate change $v = (E^T E)^{-1/2} u$ shows that we can start (just to simplify the formulae) without restriction with the following requirements:

$$(2) \quad (A - sI \ B) \text{ is stabilizable and } E^T (H \ E) = (0 \ I).$$

Apart from § 3, these are the standing assumptions throughout the paper. For any F of correct size, we introduce the notation

$$\mu(F) := \frac{1}{\|(H + EF)(sI - A - BF)G\|_{\infty}^2}$$

under the usual conventions $1/0 = \infty$, $1/\infty = 0$. The feedback matrix F is called *stabilizing* if $A + BF$ is stable. We study in this paper the H_∞ -optimization problem

$$\mu_* = \sup \{ \mu(F) \mid F \text{ is stabilizing} \}.$$

By stabilizability of $(A - sI \ B)$, μ_* is positive but could be infinite. The first step consists of giving algebraic characterizations for some real parameter μ to be *suboptimal* in the sense of $\mu < \mu_*$. If μ is actually suboptimal, we discuss the construction of stabilizing feedbacks F with $\mu < \mu(F)$. Based on the suboptimality criteria, we finally give a fast procedure to compute μ_* . The following suboptimality characterization is easily extracted from [10], [11], [28], and [18] and is contained in [19] as a special case of a fundamental result for the possibly singular problem.

THEOREM 1. *Fix any $\mu > 0$. Then μ is suboptimal if and only if there exists some $P > 0$ with*

$$(3) \quad A^T P + PA + P(\mu GG^T - BB^T)P + H^T H < 0.$$

If $P > 0$ satisfies (3), then $F := -B^T P$ is μ -suboptimal in the sense of $\mu < \mu(F)$.

The parameter μ enters this ARI linearly. This is the simple reason why we do not infimize $\|(H + EF)(sI - A - BF)^{-1}G\|_\infty$ but, equivalently, maximize $\mu(F)$.

If we reformulate that $\mu > 0$ is suboptimal if and only if there exists an $X > 0$ with

$$(4) \quad (-A^T)^T X + X(-A^T) - X(H^T)(H^T)^T X - \mu GG^T + BB^T > 0,$$

we can explain the difficulties caused by the \mathbb{C}^0 -zeros [1] of the system

$$(5) \quad \begin{pmatrix} A - sI & B \\ H & E \end{pmatrix}$$

which coincide, by (2), with the unobservable modes of

$$S(s) := \begin{pmatrix} A - sI \\ H \end{pmatrix}.$$

Fix some $\mu > 0$ and suppose first that $S(s)$ has only unobservable modes in \mathbb{C}^+ , i.e., the system $(-A^T - sI \ H^T)$ is stabilizable. We anticipate Theorem 2 to infer that (4) has a positive definite solution if and only if the Riccati equation

$$(6) \quad (-A^T)^T X + X(-A^T) - X(H^T)(H^T)^T X - \mu GG^T + BB^T = 0$$

is solvable and its stabilizing (maximal) solution X_+ ($\sigma(-A^T - H^T H X_+) \subset \mathbb{C}^-$) is positive definite. These conditions can be checked in an algebraic way: See if the Hamiltonian

$$H(\mu) := \begin{pmatrix} -A^T & -H^T H \\ \mu GG^T - BB^T & A \end{pmatrix}$$

has no eigenvalues in \mathbb{C}^0 . If this is true, compute a real matrix $(T_1^T \ T_2^T)^T$ whose columns form a basis of the stable subspace of $H(\mu)$. Then T_1 is invertible and we must see if the symmetric stabilizing solution $X_+ = T_2 T_1^{-1}$ of the ARE (6) is positive definite (see, e.g., [6, § 7.2]).

General direct solvability criteria for the ARI (4) are only available under the assumption that $S(s)$ has no unobservable modes in \mathbb{C}^0 : There exists a real symmetric solution of the ARI (4) if and only if $H(\mu)$ has no eigenvalues in \mathbb{C}^0 [5]. But even under this restrictive assumption, no characterization of the existence of positive definite solutions is available.

Our whole interest centers around the situation $\sigma(S(s)) \cap \mathbb{C}^0 \neq \emptyset$, where the results of [5] are not applicable. Since it is not possible in this case to infer from the solvability of the ARI (4) the solvability of the ARE (6), we cannot work with Riccati equations instead of Riccati inequalities. The usual technique to overcome these difficulties is to look at the perturbed ARE

$$(7) \quad (-A^T)^T X + X(-A^T) - X((H^T)(H^T)^T + \varepsilon^2 I)X - \mu GG^T + BB^T = 0.$$

Since $(-A^T - sI \ H^T \ \varepsilon I)$ is controllable, it is clear that μ is suboptimal if and only if there exists an $\varepsilon > 0$ such that (7) has a positive definite solution. The main difficulty is the suitable choice of $\varepsilon > 0$. Although this perturbation approach has obvious disadvantages, it provides the starting point for our derivation of direct solvability tests for general strict algebraic Riccati inequalities.

3. Solvability criteria for a strict algebraic Riccati inequality. We derive in this section checkable conditions for the solvability of the Riccati inequality

$$A^T X + XA - XBB^T X + Q > 0$$

with some real symmetric or even positive definite X . Here the data matrices $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times m}$, and $Q \in \mathbb{S}^n$ are completely arbitrary; in particular we do not assume that $(A - sI \ B)$ is controllable or stabilizable. To avoid confusion we stress that all objects introduced in this section are only used here and are independent of those in the rest of the paper.

We decided to investigate this type of ARI instead of the one appearing in H_∞ -theory since our results are somewhat more natural and easier to formulate with respect to the data A, B, Q and since it is more convenient to compare them with those in the literature. In particular we refer the reader to [5], where the most general solvability test for the strict Riccati inequalities appears: If $(A - sI \ B)$ has no uncontrollable modes on the imaginary axis, the ARI (8) has a solution $X \in \mathbb{S}^n$ if and only if the Hamiltonian (9) has no eigenvalues in \mathbb{C}^0 . In this generality the existence of positive definite solutions has not been characterized up to now.

For notational simplicity let us introduce the Riccati map $R: \mathbb{S}^n \rightarrow \mathbb{S}^n$ by

$$X \rightarrow R(X) := A^T X + XA - XBB^T X + Q.$$

If $(A - sI \ B)$ is stabilizable, it is simple to derive the following rather well-known basic results, which will be instrumental in our subsequent considerations.

THEOREM 2. *Suppose that $(A - sI \ B)$ is stabilizable. Then the following three statements are equivalent:*

- (a) $R(X) > 0$ has a solution $X \in \mathbb{S}^n$.
- (b) $R(X) = 0$ has a solution $X_+ \in \mathbb{S}^n$ such that $A - BB^T X_+$ is stable.
- (c) The Hamiltonian matrix

$$(9) \quad \begin{pmatrix} A & -BB^T \\ -Q & -A^T \end{pmatrix}$$

has no eigenvalues on the imaginary axis.

Suppose that one of these conditions holds true. Then the solution X_+ in (b) is unique. This so-called stabilizing solution X_+ has the maximality properties

$$X \in \mathbb{S}^n: R(X) \geq 0 \Rightarrow X \leq X_+ \quad \text{and} \quad R(X) > 0 \Rightarrow X < X_+.$$

Furthermore, there exists a sequence $X_j \in \mathbb{S}^n$ with $R(X_j) > 0$ that converges to X_+ for $j \rightarrow \infty$.

Proof. For a proof of the equivalences we refer to [5]–[7], [16] and stress that there is no need to use (advanced) techniques from symplectic algebra. The statements

about the uniqueness and the maximality of X_+ are combinations of results from [7], [16], and [26]. We note that $R(X) > 0$ implies $X_+ \geq X$. Therefore, $x^T(X_+ - X)x = 0$ yields $X_+x = Xx$, i.e., $x^TR(X_+)x = x^TR(X)x$, which leads to $x = 0$.

We should, however, prove in more detail that X_+ can be approximated by solutions of the strict Riccati inequality. In the case where the Hamiltonian (9) has no eigenvalues in \mathbb{C}^0 , there exists some $\varepsilon_0 > 0$ such that

$$\begin{pmatrix} A & -BB^T \\ -Q + \varepsilon I & -A^T \end{pmatrix}$$

has no eigenvalues in \mathbb{C}^0 for all $\varepsilon \in [0, \varepsilon_0]$. For these ε , there is a unique $X(\varepsilon) \in \mathbb{S}^n$ with $R(X(\varepsilon)) = \varepsilon I > 0$ such that $A - BB^TX(\varepsilon)$ is stable. By maximality, $X(\cdot)$ is nondecreasing for decreasing ε and bounded from above by $X(0)$, i.e., it converges to some X_0 for $\varepsilon \searrow 0$. By $R(X_0) = 0$ and $\sigma(A - BB^TX_0) \subset \mathbb{C}^- \cup \mathbb{C}^0$, we conclude that X_0 coincides with X_+ [26] and we end up with $X(\varepsilon) \rightarrow X_+$ for $\varepsilon \searrow 0$. \square

If $(A - sI \ B)$ is not necessarily stabilizable, the uncontrollable modes of $(A - sI \ B)$ on the imaginary axis pose the main problem [5]. To be able to apply the results in Theorem 2 and to display the zero structure of $(A - sI \ B)$ in \mathbb{C}^0 , it is most helpful to transform $(A - sI \ B)$ with the help of a nonsingular matrix S to

$$(10) \quad A_S := SAS^{-1} = \begin{pmatrix} A_1 & B_1F_2 & B_1F_3 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{pmatrix}, \quad B_S := SB = \begin{pmatrix} B_1 \\ 0 \\ 0 \end{pmatrix}$$

such that $(A_1 - sI \ B_1)$ is stabilizable, $\sigma(A_2) \in \mathbb{C}^0$, and $\sigma(A_3) \in \mathbb{C}^+ [14]$. Then the eigenstructure of A_2 determines the zero structure of the pencil $(A - sI \ B)$ on the imaginary axis. The standard stabilizable subspaces of $(A - sI \ B)$ with respect to \mathbb{C}^- and $\mathbb{C}^- \cup \mathbb{C}^0$, which are denoted as

$$\mathcal{V}^-(A - sI \ B) \quad \text{and} \quad \mathcal{V}^-(A - sI \ B) + \mathcal{V}^0(A - sI \ B),$$

have (with an obvious partition) a nice explicit description in these special coordinates:

$$\mathcal{V}^-(A_S - sI \ B_S) = \{x_2 = 0, x_3 = 0\} \quad \text{and} \quad \mathcal{V}^-(A_S - sI \ B_S) + \mathcal{V}^0(A_S - sI \ B_S) = \{x_3 = 0\}.$$

The matrix Q is transformed to $Q_S := S^{-T}QS^{-1}$ and Q_S is partitioned as A_S . If defining $X \rightarrow R_S(X) := A_S^TX + XA_S - XB_SB_S^TX + Q_S$, the transformation of Q is motivated by

$$S^TR_S(X)S = R(S^TXS),$$

which shows that

$$\{X \in \mathbb{S}^n \mid R(X) > 0\} = S^T\{X \in \mathbb{S}^n \mid R_S(X) > 0\}S.$$

Therefore it is possible as well to characterize the existence of some symmetric or positive definite X with $R_S(X) > 0$.

If we partition $X \in \mathbb{S}^n$ and $R_S(X)$ as Q , we easily compute the blocks of $R_S(X)$ as

$$R_1(X) := A_1^TX_1 + X_1A_1 - X_1B_1B_1^TX_1 + Q_1,$$

$$R_{12}(X) := (A_1 - B_1B_1^TX_1)^TX_{12} + X_{12}A_2 + X_1B_1F_2 + Q_{12},$$

$$R_{13}(X) := (A_1 - B_1B_1^TX_1)^TX_{13} + X_{13}A_3 + X_1B_1F_3 + Q_{13},$$

$$R_2(X) := A_2^TX_2 + X_2A_2 - (F_2 - B_1^TX_{12})^T(F_2 - B_1^TX_{12}) + F_2^TF_2 + Q_2,$$

$$R_{23}(X) := A_2^TX_{23} + X_{23}A_3 - (F_2 - B_1^TX_{12})^T(F_3 - B_1X_{13}) + F_2^TF_3 + Q_{23},$$

$$R_3(X) := A_3^TX_3 + X_3A_3 - (F_3 - B_1^TX_{13})^T(F_3 - B_1^TX_{13}) + F_3^TF_3 + Q_3.$$

Although these formulas look complicated, they exhibit the dependence of the blocks of $R_S(X)$ on those of X . It will turn out to be of great importance that $R_1(X)$ only depends on X_1 and $R_{12}(X)$ only on X_1 and X_{12} . Furthermore, varying X_3 only changes the block $R_3(X)$ in $R_S(X)$. Now we are ready to formulate the main result of this paper.

THEOREM 3. (a) *There exists an $X \in \mathbb{S}^n$ with $R_S(X) > 0$ if and only if there is some $Y \in \mathbb{S}^n$ such that*

$$(11) \quad \sigma(A_1 - B_1 B_1^T Y_1) \subset \mathbb{C}^-, \quad A_1^T Y_1 + Y_1 A_1 - Y_1 B_1 B_1^T Y_1 + Q_1 = 0,$$

$$(12) \quad (A_1 - B_1 B_1^T Y_1)^T Y_{12} + Y_{12} A_2 + Y_1 B_1 F_2 + Q_{12} = 0,$$

$$(13) \quad x^*[Q_2 + F_2^T F_2 - (F_2 - B_1^T Y_{12})^T (F_2 - B_1^T Y_{12})]x > 0$$

hold for any (possibly complex) eigenvector x of A_2 .

(b) *There exists a real symmetric $X > 0$ with $R_S(X) > 0$ if and only if some Y exists as in (a) which satisfies, in addition, $Y_1 > 0$.*

All conditions given in the theorem are verifiable. First, we must test the existence of Y_1 that satisfies (11). By stabilizability of $(A_1 - sI \ B_1)$ and Theorem 2, we need only check whether the Hamiltonian

$$\begin{pmatrix} A_1 & -B_1 B_1^T \\ -Q_1 & -A_1^T \end{pmatrix}$$

has no eigenvalues in \mathbb{C}^0 . If Y_1 exists, it is *unique* and easily determined by computing a basis of the stable eigenspace of this Hamiltonian. Then the Sylvester equation (12) has a *unique* solution Y_{12} . Since A_2 is real, we propose to test (13) in the following way: For any $i\omega \in \sigma(A_2)$ with $\text{Re}(\omega) \geq 0$, we compute a complex matrix E whose columns form a basis of the complex subspace $\{x \in \mathbb{C}^{n_2} \mid (A_2 - i\omega I)x = 0\}$ ($A_2 \in \mathbb{R}^{n_2 \times n_2}$) and check whether $E^*[Q_2 + F_2^T F_2 - (F_2 - B_1^T Y_{12})^T (F_2 - B_1^T Y_{12})]E$ is positive definite. The additional condition in (b) can be verified by determining the smallest eigenvalue of the uniquely determined matrix Y_1 . Obviously, the uncontrollable modes of $(A - sI \ B)$ in \mathbb{C}^+ do not influence these criteria.

The first step in proving Theorem 3 consists of verifying the result for a Lyapunov inequality

$$A^T X + XA + Q > 0$$

in the case where A has only eigenvalues in \mathbb{C}^0 . This is in itself an interesting and (to our knowledge) new result. We not only characterize the existence of solutions but also show that they can even be chosen to be arbitrarily large. The key idea for the proof is to perturb the Lyapunov inequality and to investigate the resulting parametrized ARE for a *controllable* system, for which a well-established theory exists.

THEOREM 4. *Suppose that the matrix $A \in \mathbb{R}^{n \times n}$ has only eigenvalues on the imaginary axis.*

(a) *The inequality $A^T X + XA + Q > 0$ has a real symmetric solution X if and only if for any eigenvector x of A , the quadratic form $x^* Q x$ is positive.*

(b) *If one of the equivalent conditions of (a) holds there exists for any $X_0 \in \mathbb{S}^n$ a solution $X \in \mathbb{S}^n$ of the Lyapunov inequality with $X > X_0$.*

Proof of (a). If X is some solution of the Lyapunov inequality, we deduce from $(A - i\omega I)^* X + X(A - i\omega I) + Q > 0$ for any $\omega \in \mathbb{R}$ immediately the necessity of our condition if choosing $i\omega \in \sigma(A)$.

To prove that this obvious necessary condition is in fact sufficient, we first note that there exists a $\delta > 0$ such that the implication

$$(14) \quad (A - i\omega I)x = 0, \|x\| = 1 \Rightarrow x^*(Q - \delta I)x > 0$$

holds true. Define for this fixed δ the matrix $Q_\delta := Q - \delta I$ and consider the ARE

$$(15) \quad A^T X + X A - \varepsilon^2 X^2 + Q_\delta = 0.$$

We show that this ARE has a solution $X \in \mathbb{S}^n$ for some $\varepsilon > 0$. This implies $A^T X + X A + Q = \delta I + \varepsilon^2 X^2 > 0$, i.e., X solves the Lyapunov inequality as desired.

Since $(A - sI \ \varepsilon I)$ is controllable for $\varepsilon > 0$, there is a real symmetric solution of (15) if and only if the frequency domain inequality

$$I + (\varepsilon I)(i\omega I - A)^{-*} Q_\delta (i\omega I - A)^{-1} (\varepsilon I) \geq 0$$

holds for all $i\omega \in \mathbb{C}^0 \setminus \sigma(A)$ [4]. If defining $H(i\omega) = (i\omega I - A)^{-*} Q_\delta (i\omega I - A)^{-1}$, the Hermitian matrix $I + H(i\omega)$ converges to the identity for $|\omega| \rightarrow \infty$ and thus there exists an ω_0 such that $I + H(i\omega) > 0$ for all $\omega \in \mathbb{R}$ with $|\omega| > \omega_0$. This implies $I + \varepsilon^2 H(i\omega) > 0$ for all $\varepsilon \in [0, 1]$ and $|\omega| > \omega_0$. With the *bounded* set of frequencies $F := \{\omega \in [-\omega_0, \omega_0] \mid i\omega \notin \sigma(A)\}$, we need only prove that

$$\exists \varepsilon \in (0, 1] \quad \forall \omega \in F: \quad (i\omega I - A)^*(i\omega I - A) + \varepsilon^2 Q_\delta \geq 0.$$

Suppose that this statement is not true. Then we can construct sequences $\omega_j \in F$ and $x_j \in \mathbb{C}^n$ with $\|x_j\| = 1$ such that

$$(16) \quad x_j^* (i\omega_j I - A)^* (i\omega_j I - A) x_j < -\frac{1}{j} x_j^* Q_\delta x_j$$

holds for all $j \in \mathbb{N}$. By boundedness, it is possible to extract a subsequence such that x_{j_l} converges to some $x_\infty \neq 0$ and ω_{j_l} to an $\omega_\infty \in [-\omega_0, \omega_0]$ for $l \rightarrow \infty$. From (16) we deduce $(i\omega_{j_l} I - A) x_{j_l} \rightarrow 0$ for $l \rightarrow \infty$ since $x_{j_l}^* Q_\delta x_{j_l}$ is bounded. This shows $(i\omega_\infty I - A) x_\infty = 0$ and, therefore, x_∞ is an eigenvector of A . The inequality (16), however, yields $x_{j_l}^* Q_\delta x_{j_l} \leq 0$ and thus $x_\infty^* Q_\delta x_\infty \leq 0$, a contradiction to (14).

Proof of (b). Suppose that $Z \in \mathbb{S}^n$ satisfies $A^T Z + Z A + Q > 0$. Then there exists some $\delta_0 > 0$ such that $A^T Z + Z A + Q - \delta_0 I$ is still positive definite. Now consider the parametrized ARE

$$AP + PA^T + \delta_0 P^2 - \varepsilon I = 0.$$

By standard LQ theory this equation has for any $\varepsilon > 0$ a unique positive definite solution $P(\varepsilon)$. Considering the corresponding LQ problem shows immediately that $P(\varepsilon)$ is nonincreasing for decreasing values of ε and thus $P_0 := \lim_{\varepsilon \rightarrow 0} P(\varepsilon)$ exists, is positive semidefinite and satisfies $AP_0 + P_0 A^T + \delta_0 P_0^2 = 0$. Since the zero matrix is another solution of the latter ARE and since A has all its eigenvalues in $\mathbb{C}^0 \cup \mathbb{C}^+$, 0 is the *maximal* solution of this equation [26] and hence we obtain $P_0 \leq 0$, i.e., $P_0 = 0$. Therefore there exists an $\varepsilon_0 > 0$ with $P(\varepsilon_0)^{-1} > X_0 - Z$ and, of course, $P(\varepsilon_0)^{-1}$ satisfies $A^T P(\varepsilon_0)^{-1} + P(\varepsilon_0)^{-1} A + \delta_0 I = \varepsilon_0 P(\varepsilon_0)^{-2} > 0$. This implies that $X := P(\varepsilon_0)^{-1} + Z$ satisfies $X > X_0$ and, by the choice of δ_0 , $A^T X + X A + Q > 0$ as desired. \square

Now we are able to prove Theorem 3. The proof of necessity essentially proceeds along the following ideas. We perturb B to some $B(\varepsilon)$ such that $(A - sI \ B(\varepsilon))$ is stabilizable and infer that the ARE $A^T X + X A - X B(\varepsilon) B(\varepsilon)^T X + Q = 0$ has a stabilizing solution $X(\varepsilon)$ for all small $\varepsilon > 0$. Then it is possible to show that the $(1, 1)$ and $(1, 2)$ block of $X(\varepsilon)$ converge to the corresponding blocks Y_1 and Y_{12} , which must be constructed. The nonstrict version of (13) would follow immediately. To verify the strict version of this statement we must, in addition, perturb the constant matrix Q .

Proof of necessity in Theorem 3. Suppose that $X \in \mathbb{S}^n$ satisfies $R_S(X) > 0$. Then we define the submatrices

$$X_p := \begin{pmatrix} X_1 & X_{12} \\ X_{12}^T & X_2 \end{pmatrix}, \quad A_p := \begin{pmatrix} A_1 & B_1 F_2 \\ 0 & A_2 \end{pmatrix}$$

and the perturbations

$$B_p(\varepsilon) := \begin{pmatrix} B_1 & 0 \\ 0 & \varepsilon I \end{pmatrix}, \quad Q_p(\delta) := \begin{pmatrix} Q_1 & Q_{12} \\ Q_{12}^T & Q_2 - \delta I \end{pmatrix}$$

to infer $A_p^T X_p + X_p A_p - X_p B_p(0) B_p(0)^T X_p + Q_p(0) > 0$. By continuity, there exist $\varepsilon_0 > 0$ and $\delta_0 > 0$ such that

$$A_p^T X_p + X_p A_p - X_p B_p(\varepsilon) B_p(\varepsilon)^T X_p + Q_p(\delta_0) > 0$$

holds for all $\varepsilon \in [0, \varepsilon_0]$. Since $(A_p - sI \ B_p(\varepsilon))$ is stabilizable for $\varepsilon > 0$, we can choose $X(\varepsilon)$ to be the largest matrix satisfying

$$(17) \quad A_p^T X(\varepsilon) + X(\varepsilon) A_p - X(\varepsilon) B_p(\varepsilon) B_p(\varepsilon)^T X(\varepsilon) + Q_p(\delta_0) = 0.$$

We partition $X(\cdot)$ according to A_p and note that

$$(18) \quad A_p - B_p(\varepsilon) B_p(\varepsilon)^T X(\varepsilon) = \begin{pmatrix} A_1 - B_1 B_1^T X_1(\varepsilon) & B_1 F_2 - B_1 B_1^T X_{12}(\varepsilon) \\ -\varepsilon^2 X_{12}(\varepsilon)^T & A_2 - \varepsilon^2 X_2(\varepsilon) \end{pmatrix}$$

is stable. By maximality, $X(\cdot)$ is nondecreasing for decreasing $\varepsilon \in (0, \varepsilon_0]$. To prove further properties of $X(\cdot)$, we write (17) blockwise and get

$$(19) \quad A_1^T X_1(\varepsilon) + X_1(\varepsilon) A_1 - X_1(\varepsilon) B_1 B_1^T X_1(\varepsilon) + Q_1 - (\varepsilon X_{12}(\varepsilon))(\varepsilon X_{12}(\varepsilon))^T = 0,$$

$$(20) \quad (A_1 - B_1 B_1^T X_1(\varepsilon))^T X_{12}(\varepsilon) + X_{12}(\varepsilon) (A_2 - \varepsilon^2 X_2(\varepsilon)) + X_1(\varepsilon) B_1 F_2 + Q_{12} = 0,$$

$$(21) \quad A_2^T X_2(\varepsilon) + X_2(\varepsilon) A_2 + \tilde{Q}_2 - \varepsilon^2 X_2(\varepsilon)^2 - (F_2 - B_1^T X_{12}(\varepsilon))^T (F_2 - B_1^T X_{12}(\varepsilon)) = 0$$

after introducing $\tilde{Q}_2 := F_2^T F_2 + Q_2 - \delta_0 I$.

Multiplying (21) with ε^2 shows that $P(\varepsilon) := \varepsilon^2 X_2(\varepsilon)$ satisfies

$$(22) \quad A_2^T P(\varepsilon) + P(\varepsilon) A_2 + \varepsilon^2 \tilde{Q}_2 - P(\varepsilon)^2 = \varepsilon^2 (F_2 - B_1^T X_{12}(\varepsilon))^T (F_2 - B_1^T X_{12}(\varepsilon))$$

for $\varepsilon \in (0, \varepsilon_0]$. We now prove $P(\varepsilon) \rightarrow 0$ for $\varepsilon \rightarrow 0$.

Choose $i\omega \in \sigma(A_2)$ and take an arbitrary Jordan chain $x_{-1} = 0$, $(A_2 - i\omega I)x_j = x_{j-1}$ for $j = 0, \dots, l$. If we multiply (22) from the left with x_j^* and from the right with x_j , we obtain

$$x_{j-1}^* P(\varepsilon) x_j + x_j^* P(\varepsilon) x_{j-1} + \varepsilon^2 x_j^* \tilde{Q}_2 x_j \geq \|P(\varepsilon) x_j\|^2.$$

For $j = 0$, we deduce $P(\varepsilon) x_0 \rightarrow 0$. Suppose now that $P(\varepsilon) x_{j-1} \rightarrow 0$. Then we conclude from $x_j^* P(\varepsilon) x_{j-1} \rightarrow 0$ and $x_{j-1}^* P(\varepsilon) x_j \rightarrow 0$ with the help of this inequality $P(\varepsilon) x_j \rightarrow 0$. By induction this property thus holds for all $j = 0, \dots, l$. Since A_2 has only eigenvalues in \mathbb{C}^0 and the Jordan chain was arbitrary, we conclude $P(\varepsilon) \rightarrow 0$ for $\varepsilon \rightarrow 0$.

Equation (22) hence implies $\varepsilon^2 (F_2 - B_1^T X_{12}(\varepsilon))^T (F_2 - B_1^T X_{12}(\varepsilon)) \rightarrow 0$, and thus

$$(23) \quad B_1^T [\varepsilon X_{12}(\varepsilon)] \rightarrow 0$$

for $\varepsilon \rightarrow 0$.

Recall that $X_1(\varepsilon)$ is nondecreasing for decreasing ε . By (19), $X_1(\varepsilon)$ satisfies the inequality $A_1^T X_1(\varepsilon) + X_1(\varepsilon) A_1 - X_1(\varepsilon) B_1 B_1^T X_1(\varepsilon) + Q_1 \geq 0$ and is hence bounded by the stabilizing solution of the corresponding Riccati equation. Therefore $X_1(\varepsilon)$ converges to some $X_1(0)$ for $\varepsilon \rightarrow 0$. This implies, again by (19), that $\varepsilon X_{12}(\varepsilon)$ is in fact bounded.

Now choose some F with $\sigma(A_1 - B_1 B_1^T X_1(0) + B_1 F) \subset \mathbb{C}^-$. From (20) we deduce the equation

$$\begin{aligned} & (A_1 - B_1 B_1^T X_1(\varepsilon) + B_1 F)^T [\varepsilon X_{12}(\varepsilon)] + [\varepsilon X_{12}(\varepsilon)] A_2 \\ & = -\varepsilon Q_{12} - [\varepsilon X_1(\varepsilon)] B_1 F_2 + [\varepsilon X_{12}(\varepsilon)] [\varepsilon^2 X_2(\varepsilon)] + F^T B_1^T [\varepsilon X_{12}(\varepsilon)]. \end{aligned}$$

The right-hand side converges to 0 and $X \rightarrow (A_1 - B_1 B_1^T X_1(0) + B_1 F)^T X + X A_2$ is, by the choice of F , a bijective map with bounded inverse. This already implies $\varepsilon X_{12}(\varepsilon) \rightarrow 0$ for $\varepsilon \rightarrow 0$. Thus $X_1(0)$ is in fact a *solution* of the ARE $A_1^T X + X A_1 - X B_1 B_1^T X + Q_1 = 0$. Since the stable matrix (18) is similar to

$$\begin{pmatrix} A_1 - B_1 B_1^T X_1(0) & \varepsilon(B_1 F_2 - B_1 B_1^T X_{12}(\varepsilon)) \\ -\varepsilon X_{12}(\varepsilon)^T & A_2 - \varepsilon^2 X_2(\varepsilon) \end{pmatrix}$$

(using the similarity transformation $\begin{pmatrix} \varepsilon & 0 \\ 0 & 1 \end{pmatrix}$), we obtain first $\sigma(A_1 - B_1 B_1^T X_1(0)) \subset \mathbb{C}^- \cup \mathbb{C}^0$. Since the ARI $A_1^T X + X A_1 - X B_1 B_1^T X + Q_1 > 0$ is solvable, the corresponding Hamiltonian has no eigenvalues in \mathbb{C}^0 and thus $A_1 - B_1 B_1^T X_1(0)$ must in fact be stable.

Now it is possible to infer from (20) the convergence of $X_{12}(\varepsilon)$ to the unique solution $X_{12}(0)$ of the linear equation

$$(A_1 - B_1 B_1^T X_1(0))^T X + X A_2 + X_1(0) B_1 F_2 + Q_{12} = 0.$$

For any eigenvector x of A_2 we deduce from (21)

$$x^* [F_2^T F_2 + Q_2 - (F_2 - B_1^T X_{12}(\varepsilon))^T (F_2 - B_1^T X_{12}(\varepsilon))] x \geq \delta_0 x^* x$$

and thus, after taking the limit,

$$x^* [F_2^T F_2 + Q_2 - (F_2 - B_1^T X_{12}(0))^T (F_2 - B_1^T X_{12}(0))] x > 0.$$

If $X > 0$ solves $R_S(X) > 0$, we infer in addition that $X_1 > 0$ satisfies $A_1^T X_1 + X_1 A_1 - X_1 B_1 B_1^T X_1 + Q_1 > 0$ and hence conclude $X_1 < Y_1$, i.e., $Y_1 > 0$. \square

Sufficiency is shown by constructing X blockwise where we exploit the above-described particular structure of the Riccati map. We select some X_1 with $R_1(X) > 0$ for any real symmetric X that has X_1 as its $(1, 1)$ block. X_1 is chosen near Y_1 such that it is possible to find X_{12} and X_2 with $R_{12}(X) = 0$ and $R_2(X) > 0$. For the special blocks $X_{13} = 0$ and $X_{23} = 0$, we can find a large X_3 to make $R_3(X)$ arbitrarily large. Since only $R_3(X)$ is influenced by X_3 , we can force $R_S(X)$ to be positive definite. If Y_1 is positive definite, X_1 can be chosen to be positive definite and if X_2 and X_3 are large enough, X itself becomes positive definite. For later use, we construct a whole sequence $X(j)$ of solutions.

Proof of sufficiency in Theorem 3. According to Theorem 2, there exists a sequence $X_1(j)$ which converges to Y_1 for $j \rightarrow \infty$ and which satisfies $A_1^T X_1(j) + X_1(j) A_1 - X_1(j) B_1 B_1^T X_1(j) + Q_1 > 0$. Without restriction, this sequence can be chosen such that $A_1 - B_1 B_1^T X_1(j)$ is stable for all $j \in \mathbb{N}$. Hence there exists a sequence $X_{12}(j)$ which satisfies

$$(A_1 - B_1 B_1^T X_1(j))^T X_{12}(j) + X_{12}(j) A_2 + X_1(j) B_1 F_2 + Q_{12} = 0$$

for all $j \in \mathbb{N}$ and which necessarily converges to Y_{12} for $j \rightarrow \infty$. Therefore there exists a $j_0 \in \mathbb{N}$ such that $x^* [Q_2 + F_2^T F_2 - (F_2 - B_1^T X_{12}(j))^T (F_2 - B_1^T X_{12}(j))] x$ is positive for all eigenvectors x of A_2 and all $j \geq j_0$. We can apply Theorem 4 to infer the existence of a sequence $X_2(j)$ with

$$A_2^T X_2(j) + X_2(j) A_2 + Q_2 + F_2^T F_2 - (F_2 - B_1^T X_{12}(j))^T (F_2 - B_1^T X_{12}(j)) > 0$$

and

$$(24) \quad jI < X_2(j)$$

for all $j \geq j_0$. Now define

$$X(j) := \begin{pmatrix} X_1(j) & X_{12}(j) & 0 \\ X_{12}^T(j) & X_2(j) & 0 \\ 0 & 0 & X_3(j) \end{pmatrix}$$

with some still unspecified sequence $X_3(j)$. We obtain

$$R_S(X(j)) = \begin{pmatrix} R_1(X(j)) & 0 & R_{13}(X(j)) \\ 0 & R_2(X(j)) & R_{23}(X(j)) \\ R_{13}(X(j))^T & R_{23}(X(j))^T & A_3^T X_3(j) + X_3(j)A_3 + Q_3 \end{pmatrix}.$$

By construction, $R_1(X(j))$ and $R_2(X(j))$ are positive definite. Since $X_3(j)$ only influences the (3, 3) block and since $-A_3^T$ is stable, $R_3(X(j))$ reaches any symmetric matrix if varying $X_3(j)$ in the symmetric matrices, without changing the other blocks of $R_S(X(j))$. In particular we can find for any $j \geq j_0$ a symmetric $X_3(j)$ such that $R_S(X(j))$ is positive definite. This already proves the sufficiency part of (a).

It is even possible to define a sequence $X_3(j)$ with $R_S(X(j)) > 0$ and $R_3(X(j)) > Q_3 + jI$. The inequality $A_3^T X_3(j) + X_3(j)A_3 > jI$ leads to

$$(25) \quad X_3(j) > j \int_0^\infty e^{-A_3^T t} e^{-A_3 t} dt,$$

which shows in particular that $X_3(j)$ is positive definite. If we recall (24) and the fact that $X_1(j)$, $X_{12}(j)$ converge, $X(j)$ is positive definite for all large j (Lemma 14). \square

Until now the results were given with respect to the transformed data A_S , B_S , and Q_S . We want to propose a possibility to reformulate them in a way which is invariant under the transformation $(A, B, Q) \rightarrow (A_S, B_S, Q_S)$.

First, we characterize the existence of $Y \in \mathbb{S}^n$ such that (11) and (12) hold. This is equivalent to saying that $R_S(Y)$ admits the block triangular shape

$$\begin{pmatrix} 0 & 0 & * \\ 0 & * & * \\ * & * & * \end{pmatrix}$$

and the (1, 1) block $A_1 - B_1 B_1^T Y_1$ of $A_S - B_S B_S^T Y$ is stable. Hence $Y \in \mathbb{S}^n$ satisfies (11) and (12) if and only if $x^T R_S(Y) y$ vanishes for $x \in \mathcal{V}^-(A_S - sI \ B_S)$ and $y \in \mathcal{V}^-(A_S - sI \ B_S) + \mathcal{V}^0(A_S - sI \ B_S)$ and the restriction of $(A_S - B_S B_S^T Y)$ to $\mathcal{V}^-(A_S - sI \ B_S)$ is stable.

DEFINITION 5. \mathcal{T} denotes the set of all matrices $Z \in \mathbb{S}^n$ such that $x^T R(Z) y$ vanishes for all $x \in \mathcal{V}^-(A - sI \ B)$, $y \in \mathcal{V}^-(A - sI \ B) + \mathcal{V}^0(A - sI \ B)$ and such that the restriction of $(A - B B^T Z)$ to $\mathcal{V}^-(A - sI \ B)$ is stable.

If \mathcal{T}_S denotes the corresponding set for (A_S, B_S, Q_S) , we easily derive $\mathcal{T} = S^T \mathcal{T}_S S$. The explicit description

$$\mathcal{T}_S = \left\{ \begin{pmatrix} Y_1 & Y_{12} & * \\ Y_{12}^T & * & * \\ * & * & * \end{pmatrix} \in \mathbb{S}^n \mid Y_1, Y_{12} \text{ are the unique matrices that satisfy (11), (12)} \right\}$$

shows that \mathcal{T} is, if nonempty, a linear manifold in \mathbb{S}^n .

Second, we must reformulate (13). For this purpose we search a complex set $\mathcal{E}(A - sI \ B)$ of \mathbb{C}^n -vectors such that all possible second components of $x \in \mathcal{E}(A_S - sI \ B_S)$ are given by all eigenvectors of A_2 . Obviously, $(A_S - i\omega I)x + B_S u = 0$ implies $(A_2 - i\omega I)x_2 = 0$ and $x_3 = 0$. If x_2 satisfies $(A_2 - i\omega I)x_2 = 0$, we may define

$x := (0 \ x_2^* \ 0)^*$ and $u := -F_2 x_2$ to obtain $(A_S - i\omega I)x + B_S u = 0$. Therefore we define for any $\lambda \in \mathbb{C}$ the *complex* subspace

$$\mathcal{V}^\lambda(A - sI \ B) := \{x \in \mathbb{C}^n \mid \exists u \in \mathbb{C}^m : (A - \lambda I)x + Bu = 0\}$$

and easily verify $\mathcal{V}^\lambda(A_S - sI \ B_S) = S\mathcal{V}^\lambda(A - sI \ B)$. Note that $\mathcal{V}^\lambda(A - sI \ B)$ is the whole \mathbb{C}^n if $(A - sI \ B)$ is controllable [12, Hilfssatz 5.3]. Moreover, the second component of $x \in \mathcal{V}^\lambda(A_S - sI \ B_S)$ is nontrivial (and hence an eigenvector of A_2) if and only if $x \notin \mathcal{V}^-(A_S - sI \ B_S)$.

If we now fix some $Y \in \mathcal{T}_S$, we observe $x^* R_S(Y)x = x_2^* [Q_2 + F_2^T F_2 - (F_2 - B_1^T Y_{12})^T (F_2 - B_1^T Y_{12})] x_2$ for any $x \in \bigcup_{\lambda \in \mathbb{C}^0} \mathcal{V}^\lambda(A_S - sI \ B_S)$ and $x^T Y x = x_1^T Y_1 x_1$ for any $x \in \mathcal{V}^-(A_S - sI \ B_S)$. It is not difficult to verify that these quadratic forms are invariant under the transformation $(A, B, Q) \rightarrow (A_S, B_S, Q_S)$. Therefore we are in the position to reformulate the conditions of Theorem 3 in terms of the original data (A, B, Q) .

THEOREM 6. (a) *There exists an $X \in \mathcal{S}^n$ with $R(X) > 0$ if and only if there exists some $Z \in \mathcal{T}$ such that*

$$x^* R(Z)x > 0 \quad \text{for all } x \in \bigcup_{\lambda \in \mathbb{C}^0} \mathcal{V}^\lambda(A - sI \ B) \setminus \mathcal{V}^-(A - sI \ B).$$

(b) *There exists a $X > 0$ with $R(X) > 0$ if and only if there exists some $Z \in \mathcal{T}$ with $x^* R(Z)x > 0$ for all $x \in \bigcup_{\lambda \in \mathbb{C}^0} \mathcal{V}^\lambda(A - sI \ B) \setminus \mathcal{V}^-(A - sI \ B)$ and*

$$x^* Z x > 0 \quad \text{for all } x \in \mathcal{V}^-(A - sI \ B) \setminus \{0\}.$$

If these conditions hold for *one* $Z \in \mathcal{T}$ then they are valid for all other elements $Z \in \mathcal{T}$.

Let us finally take a closer look at the solution set

$$(26) \quad \mathcal{X} := \{X \in \mathcal{S}^n \mid X > 0, R(X) > 0\}$$

if it is nonempty. If $(A - sI \ B)$ is stabilizable, \mathcal{X} has a strict upper bound $X_+ > 0$, which is, in addition, a limit point of \mathcal{X} (Theorem 2). We can extract from the proof of Theorem 3 that \mathcal{X} has in general no upper bound. Instead we could try to find lower bounds of \mathcal{X}^{-1} . If $(A - sI \ B)$ is stabilizable, $P := X_+^{-1}$ is in fact a *strict lower limit point* of \mathcal{X}^{-1} (Theorem 2) and satisfies $AP + PA^T - BB^T + PQP = 0$ with $\sigma(A + PQ) \subset \mathbb{C}^+$. This important result can be generalized without any assumption on $(A - sI \ B)$.

THEOREM 7. *If \mathcal{X} is not empty, it has the strict lower limit point*

$$(27) \quad P := S^{-1} \begin{pmatrix} Y_1^{-1} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} S^{-T},$$

where $Y_1 > 0$ satisfies (11). P is a positive semidefinite solution of

$$AP + PA^T - BB^T + PQP = 0$$

with $\sigma(A + PQ) \subset \mathbb{C}^0 \cup \mathbb{C}^+$, where the eigenvalues of $A + PQ$ in \mathbb{C}^0 are the uncontrollable modes of $(A - sI \ B)$ in \mathbb{C}^0 (counted with multiplicities).

Proof. It is obviously enough to prove these results for $S = I$. We already saw during the proof of the necessity part of Theorem 3 that $R_S(X) > 0$ implies $X_1 < Y_1$ and Lemma 14 shows $P < X^{-1}$. In the sufficiency part, we constructed $X(j)$, which is positive definite and satisfies $R(X(j)) > 0$ for all large j . Moreover, we infer from (24) $X_2(j)^{-1} \rightarrow 0$ and from (25) $X_3(j)^{-1} \rightarrow 0$ for $j \rightarrow \infty$. Since $X_1(j)^{-1}$ converges to Y_1^{-1} and $X_{12}(j)$ is bounded for $j \rightarrow \infty$, we conclude $X(j)^{-1} \rightarrow P$ for $j \rightarrow \infty$ by Lemma 14.

The other properties of P are obvious. \square

Remark. Suppose that \mathcal{T} is positive on $\mathcal{V}^-(A - sI \ B)$, which is weaker than $\mathcal{X} \neq \emptyset$. Since only the blocks $Y_1 > 0$ and Y_{12} are fixed in the above-given explicit description of \mathcal{T} , this set contains positive definite elements, and P as defined by (27) is a lower limit point of

$$\{Z \in \mathcal{T} \mid Z > 0\}.$$

Moreover, P still has all the properties as listed in Theorem 7. It can be shown that P is in fact the *minimal* under all matrices $X \in \mathbb{S}^n$ which satisfy

$$AX + XA^T - BB^T + XQX = 0, \quad \sigma(A + XQ) \subset \mathbb{C}^0 \cup \mathbb{C}^+, \quad X \geq 0.$$

4. Solution of the H_∞ -optimization problem. We recall from § 2 that $\mu > 0$ is suboptimal if and only if (4) has a positive definite solution. Hence we need only translate the results of § 3 to the present situation.

We first formulate a testable suboptimality criterion in special coordinates that gives the best insight into how the optimal value is restricted. As in § 3, there exists a nonsingular S with

$$S^{-T}AS^T = \begin{pmatrix} A_1 & 0 & 0 \\ K_2H_1 & A_2 & 0 \\ K_3H_1 & 0 & A_3 \end{pmatrix}, \quad S^{-T}G = \begin{pmatrix} G_1 \\ G_2 \\ G_3 \end{pmatrix}, \quad S^{-T}B = \begin{pmatrix} B_1 \\ B_2 \\ B_3 \end{pmatrix},$$

$$HS^T = (H_1 \ 0 \ 0)$$

such that (A_1^{-sI}) has only unobservable modes in \mathbb{C}^+ , $\sigma(A_2) \subset \mathbb{C}^0$, and $\sigma(A_3) \subset \mathbb{C}^-$. Moreover, we denote the set of eigenvalues of A_2 with nonnegative real part as $\{i\omega_1, \dots, i\omega_l\}$ and choose, for any $j \in \{1, \dots, l\}$, complex matrices E_j whose columns form a basis of the eigenspace $\{x \in \mathbb{C}^{n_2} \mid (A_2^T - i\omega_j I)x = 0\}$ (where n_2 is the dimension of A_2).

We immediately arrive at the following central result of our paper which is, in fact, just a corollary to Theorem 3.

THEOREM 8. *Suppose $\mu > 0$. Then μ is suboptimal if and only if there exist matrices $X(\mu)$ and $Y(\mu)$ with*

$$(28) \quad A_1X(\mu) + X(\mu)A_1^T + X(\mu)H_1^TH_1X(\mu) + \mu G_1G_1^T - B_1B_1^T = 0,$$

$$(29) \quad \sigma(A_1 + X(\mu)H_1^TH_1) \subset \mathbb{C}^+,$$

$$(30) \quad X(\mu) > 0,$$

$$(31) \quad (A_1 + X(\mu)H_1^TH_1)Y(\mu) + Y(\mu)A_2^T + X(\mu)H_1^TK_2^T + \mu G_1G_2^T - B_1B_2^T = 0,$$

$$(32) \quad E_j^*[(K_2^T + H_1Y(\mu))^T(K_2^T + H_1Y(\mu)) + \mu G_2G_2^T - B_2B_2^T - K_2K_2^T]E_j < 0$$

for all $j \in \{1, \dots, l\}$.

From the discussion in § 3 it is clear how to check all these conditions algebraically. We stress again that $X(\mu)$ and $Y(\mu)$ are, if existent, uniquely determined, which justifies considering them as functions of μ .

To determine the optimal value μ_* , we must find out when one of these conditions fails to hold. It is a central observation that the solution $X(\mu)$ of the parameter-dependent ARE (28) with property (29) is very well understood [18, §§ V, VI]. In particular there exists a formula for the domain of definition of the function $X(\cdot)$: Compute the unique $X(0)$ which exists and is positive definite by $0 < \mu_*$. Then there exists an $X(\mu)$ with (28) and (29) if and only if

$$\mu < \mu_{\max} := \|H_1(sI - A_1 - X(0)H_1^TH_1)^{-1}G_1\|_\infty^{-2} \leq \infty.$$

Moreover, $X(\cdot)$ is analytic on $(-\infty, \mu_{\max})$ with $X'(\mu) \leq 0$ and $X''(\mu) \leq 0$. Therefore

$$Y(\cdot) \text{ is defined and analytic on } (-\infty, \mu_{\max}).$$

In [18, § VIII] we intensively discussed how to find the second critical parameter

$$\mu_{\text{pos}} := \sup\{\mu < \mu_{\max} \mid X(\mu) > 0\},$$

which is related to the restriction (30). The third critical parameter

$$\mu_{\text{neg}} := \sup\{\mu < \mu_{\max} \mid (32) \text{ holds for all } j = 1, \dots, l\}$$

displays the new restricting condition caused by the \mathbb{C}^0 -zeros of the plant. We immediately deduce that

$$\mu_* = \min\{\mu_{\text{pos}}, \mu_{\text{neg}}\}.$$

In § 5 we give an algorithm for computing μ_{neg} . We will clarify in [19] that μ_{neg} equals $\sup\{\|(H + EF)(sI - A - BF)^{-1}G\|_\infty \mid \sigma(A + BF) \cap \mathbb{C}^0 = \emptyset\}$ if $(A - sI \ B)$ is only assumed to be stabilizable with respect to \mathbb{C}^0 . Therefore μ_{neg} may be interpreted as the optimal value of an L_∞ -optimization problem.

Let us briefly discuss how the various plant zeros influence the optimal value. We can assume without restriction that

$$(33) \quad A_1 = \begin{pmatrix} A_1^o & 0 \\ K_1^o H_1^o & A_1^+ \end{pmatrix}, \quad H_1 = (H_1^o \ 0), \quad G_1 = \begin{pmatrix} G_1^o \\ G_1^+ \end{pmatrix}, \quad B_1 = \begin{pmatrix} B_1^o \\ B_1^+ \end{pmatrix},$$

where

$$\begin{pmatrix} A_1^o - sI \\ H_1^o \end{pmatrix}$$

is observable and $\sigma(A_1^+)$ contains the zeros of $S(s)$ in \mathbb{C}^+ . $X(\mu)$ can be partitioned as

$$\begin{pmatrix} X^o(\mu) & X^{o+}(\mu) \\ X^{o+}(\mu)^T & X^+(\mu) \end{pmatrix}$$

and (28), (29) are equivalent to

$$(34) \quad A_1^o X^o(\mu) + X^o(\mu)(A_1^o)^T + X^o(\mu)(H_1^o)^T H_1^o X^o(\mu) + \mu G_1^o (G_1^o)^T - B_1^o (B_1^o)^T = 0,$$

$$(35) \quad \sigma(A_1^o + X^o(\mu)(H_1^o)^T H_1^o) \subset \mathbb{C}^+$$

plus two *linear* equations for $X^{o+}(\mu)$ and $X^+(\mu)$.

The existence of (the unique) $X^o(\mu)$ with (34) and (35) is equivalent to the existence of $X(\mu)$, i.e., to $\mu < \mu_{\max}$. If $\mu > 0$ is suboptimal, $X^o(\mu)$ exists and is positive definite. This part of the conditions is not related to the zeros of $S(s)$ but is in fact due to $H \neq 0$ and the resulting “observable part” of $S(s)$.

If the plant has \mathbb{C}^+ -zeros, the linear equations which determine $X^{o+}(\mu)$ and $X^+(\mu)$ always have unique solutions for $\mu < \mu_{\max}$. The additional condition caused by these zeros, however, is not only $X^+(\mu) > 0$, but the correct restriction is also coupled to $X^o(\mu)$ via $X^{o+}(\mu)$: $X(\mu) > 0$. This is different for the \mathbb{C}^0 -zeros of $S(s)$. Let us partition $Y(\mu)$ as

$$\begin{pmatrix} Y^o(\mu) \\ Y^+(\mu) \end{pmatrix}.$$

By $H_1 Y(\mu) = H_1^o Y^o(\mu)$, (32) is only influenced by $Y^o(\mu)$, which satisfies

$$[A_1^o + X^o(\mu)(H_1^o)^T H_1^o] Y^o(\mu) + Y^o(\mu) A_2^T + X^o(\mu)(H_1^o)^T K_2^T + \mu G_1^o G_2^T - B_1^o B_2^T = 0.$$

Therefore only $X^o(\mu)$ directly influences the right-hand side of (32), which is in particular not affected by the \mathbb{C}^+ -zero structure! Moreover, (32) is not again coupled to $X^o(\mu)$. The \mathbb{C}^- -zeros do not influence the optimal value at all.

We stress that $G_1^o \neq 0$ causes the genuine difficulties in the H_∞ -problem: If G_1^o vanishes (which is equivalent to $\mu_{\max} = \infty$), $X^o(\cdot)$ and $Y^o(\cdot)$ are *constant*, and $X(\mu)$ as well as the right-hand side of (32) are affine in μ .

What can be said for the feedback construction? Motivated by Theorem 1, we translate Theorem 7 to the present situation and include certain obvious smoothness and monotonicity properties inherited from $X(\cdot)$.

THEOREM 9. (a) For $\mu < \mu_{\text{pos}}$, the matrix

$$P(\mu) = S^{-1} \begin{pmatrix} X(\mu)^{-1} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} S^{-T}$$

satisfies $A^T P(\mu) + P(\mu)A + P(\mu)(\mu GG^T - BB^T)P(\mu) + H^T H = 0$ with $\sigma(A + \mu GG^T P(\mu) - BB^T P(\mu)) \subset \mathbb{C}^- \cup \mathbb{C}^0$, where the eigenvalues in \mathbb{C}^0 are the zeros of $S(s)$ in \mathbb{C}^0 (counted with multiplicities). The kernel of $P(\mu)$ is constant and equal to the undetectable subspace of $S(s)$ with respect to \mathbb{C}^+ . The function $\mu \rightarrow P(\mu)$ is analytic on $(-\infty, \mu_{\text{pos}})$ with $P'(\cdot) \geq 0$ and $P''(\cdot) \geq 0$.

(b) For $\mu < \mu_*$, $P(\mu)$ is the strict lower limit point of

$$(36) \quad \{P > 0 \mid A^T P + PA + P(\mu GG^T - BB^T)P + H^T H < 0\}.$$

We extract the existence of a sequence P_j in (36) with $P_j \rightarrow P(\mu)$ for $j \rightarrow \infty$. Let us define the feedbacks $F_j := -B^T P_j$ and $F_\infty := -B^T P(\mu)$. Then any F_j is stabilizing with $\mu < \mu(F_j)$ (Theorem 1). $A + BF_\infty$ is in general *not* stable and $\sigma(A + BF_\infty) = \sigma(A_1 - B_1 B_1^T X(\mu)^{-1}) \cup \sigma(A_2) \cup \sigma(A_3)$ shows that it has precisely the \mathbb{C}^0 -zeros of $S(s)$ as eigenvalues which are not stabilized. These are, however, canceled in the closed-loop transfer matrix and $H(sI - A - BB^T P(\mu))^{-1} G = H_1(sI - A - B_1 B_1^T X(\mu)^{-1}) G_1$ implies $\mu < \mu(F_\infty)$ [18, Thm. 5]. We summarize these observations by saying that the zeros of $S(s)$ on the imaginary axis generally lead to a jump of the optimal value from μ_{pos} to $\min\{\mu_{\text{pos}}, \mu_{\text{neg}}\}$ but only cause *arbitrarily small* additional feedback.

If $S(s)$ has no \mathbb{C}^0 -zeros, the suboptimality of $\mu > 0$ is characterized by the existence of $X(\mu)$ with (28)–(30). This is equivalent to the existence of $P \geq 0$ with $A^T P + PA + P(\mu GG^T - BB^T)P + H^T H = 0$ and $\sigma(A + \mu GG^T P - BB^T P) \subset \mathbb{C}^-$ since P , if it exists, is unique and coincides with $P(\mu)$. Then $F_\infty = -B^T P$ is stabilizing and still satisfies $\mu < \mu(F)$. We have rederived the results of [3], [24] for \mathbb{C}^0 -zero-free plants.

To design suboptimal feedbacks, we stress that it is neither useful nor necessary to solve the full-order strict ARI (4). Fix $\mu < \mu_*$. We need only compute $X(\mu)$ (by solving a reduced-order Riccati equation), $Y(\mu)$ (by solving a reduced-order linear equation) and to find a solution Z of the reduced-order Lyapunov inequality

$$A_2 Z + Z A_2^T + (K_2^T + H_1 Y(\mu))^T (K_2^T + H_1 Y(\mu)) + \mu G_2 G_2^T - B_2 B_2^T - K_2 K_2^T < 0$$

such that

$$X_p := \begin{pmatrix} X(\mu) & Y(\mu) \\ Y(\mu)^T & Z \end{pmatrix}$$

is positive definite. By [18, Thm. 5], it is obvious that

$$F := -B^T S^{-1} \begin{pmatrix} X_p^{-1} & 0 \\ 0 & 0 \end{pmatrix} S^{-T}$$

is stabilizing and yields the nonstrict inequality $\mu \leq \mu(F)$, which suffices for practical purposes.

Let us finally translate the coordinate invariant formulation appearing in § 3 to the H_∞ -problem. Again this proceeds by simple algebraic dualization and we can be succinct. The main motivation for including this reformulation is the possibility to generalize it literally to the situation when E does not have full column rank [19].

We denote the undetectable subspaces of $S(s)$ with respect to \mathbb{C}^+ or \mathbb{C}^0 by

$$\mathcal{S}_+ \quad \text{or} \quad \mathcal{S}_0,$$

respectively. We further introduce

$$\mathcal{S}_\lambda := \left\{ x \in \mathbb{C}^n \mid \exists u \in \mathbb{C}^n : \begin{pmatrix} x \\ 0 \end{pmatrix} = \begin{pmatrix} A - \lambda I \\ H \end{pmatrix} u \right\},$$

which is motivated by the easily verified duality relation $\mathcal{S}_\lambda = \mathcal{V}^{-\bar{\lambda}}(-A^T - sI \ H^T)^\perp$ for any $\lambda \in \mathbb{C}$. Note that \mathcal{S}_λ is trivial if $S(s)$ is observable.

According to the Riccati map

$$R(X, \mu) := AX + XA^T + XH^THX + \mu GG^T - BB^T$$

defined on $\mathbb{S}^n \times \mathbb{R}$, we introduce for any $\mu \in \mathbb{R}$, the set

$$\mathcal{T}(\mu) := \{ Z \in \mathbb{S}^n \mid ((A + ZH^TH)^T \mid \mathcal{S}_+^\perp) \subset \mathbb{C}^+, x^TR(Z, \mu)y = 0 \text{ for } x \in \mathcal{S}_+^\perp, y \in \mathcal{S}_+^\perp + \mathcal{S}_0^\perp \}$$

and clearly obtain the explicit description

$$\mathcal{T}(\mu) = S^T \left\{ \begin{pmatrix} X(\mu) & Y(\mu) & * \\ Y(\mu)^T & * & * \\ * & * & * \end{pmatrix} \in \mathbb{S}^n \mid X(\mu), Y(\mu) \text{ satisfy (28), (29), (31)} \right\} S.$$

THEOREM 10. *The parameter $\mu > 0$ is suboptimal if and only if there exists a $Z \in \mathcal{T}(\mu)$ such that Z is positive on \mathcal{S}_+^\perp and $R(Z, \mu)$ is negative on $\bigcup_{\lambda \in \mathbb{C}^0} \mathcal{S}_\lambda^\perp \setminus \mathcal{S}_+^\perp$.*

We recall the intuitive interpretation of these conditions: $\mathcal{T}(\mu) \neq \emptyset$ means that a certain lower-dimensional Riccati equation has a antistabilizing solution. We can parametrize $\mathcal{T}(\mu)$ by solving this ARE and a reduced-order linear equation. The positivity condition is just the positive definiteness of the ARE solution. The negativity condition expresses the solvability of a certain reduced-order Lyapunov inequality which is built up with the solution of the linear equation.

Remark. Obviously, $\mathcal{T}(\mu)$ is nonempty if and only if $\mu < \mu_{\max}$. Using the explicit formula for μ_{\max} , it is easily seen that

$$\mu_{\max} = \|C(sI + A + ZH^TH)^{-1}G\|_\infty^{-2}$$

holds for any $Z \in \mathcal{T}(0)$.

5. Computation of the optimal value. We use all the objects defined in § 4 and, in addition, introduce for $j \in \{1, \dots, l\}$ the Hermitian-valued analytic functions

$$F_j(\mu) := -E_j^*[(K_2^T + H_1 Y(\mu))^T (K_2^T + H_1 Y(\mu)) + \mu G_2 G_2^T - B_2 B_2^T - K_2 K_2^T] E_j,$$

$$F(\mu) := \text{blockdiag}(F_1(\mu) \cdots F_l(\mu))$$

on $(-\infty, \mu_{\max})$.

For the computation of μ_* , it remains to determine the critical parameter $\mu_{\text{neg}} = \sup \{ \mu < \mu_{\max} \mid F(\mu) > 0 \}$. To apply the general algorithm in [18, § 7], we must prove $F'(\mu) \leq 0$, $F''(\mu) \leq 0$, and $F(0) > 0$. The last inequality is trivial since $\mu = 0$ is suboptimal. The other two properties are indeed verifiable. Since the proof is nontrivial and

allows us to extract an explicit formula for the derivative $F'(\cdot)$, we present it in detail.

THEOREM 11. *The analytic functions $F_j(\cdot)$ satisfy $F_j(0) > 0$ and $F'_j(\mu) \leq 0$ as well as $F''_j(\mu) \leq 0$ for all $\mu \in (-\infty, \mu_{\max})$ and $j = 1, \dots, l$.*

Collection of formulas. Fix $\mu \in (-\infty, \mu_{\max})$. If defining

$$(H(\mu) \ H_B(\mu) \ H_G(\mu)) := H_1(i\omega_j I + A_1 + X(\mu)H_1^T H_1)^{-1}(X(\mu)H_1^T \ B_1 \ G_1),$$

we can compute $F_j(\mu)$ with the help of

$$(K_2^T + H_1 Y(\mu))E_j = (I - H(\mu))K_2^T E_j - \mu H_G(\mu)G_2^T E_j + H_B(\mu)B_2^T E_j$$

and

$$(37) \ F'_j(\mu) = -E_j^* [G_2 - H_G(\mu)^*(K_2^T + H_1 Y(\mu))]^* [G_2 - H_G(\mu)^*(K_2^T + H_1 Y(\mu))] E_j.$$

Proof. To simplify the exposition we first derive several useful formulas. We fix some $j \in \{1, \dots, l\}$ and define

$$L(\mu) := K_2^T + H_1 Y(\mu) \quad \text{as well as} \quad A(\mu) := (A_1 + X(\mu)H_1^T H_1 + i\omega_j I)^{-1}.$$

The differentiation of (28) leads to

$$(A_1 + X(\mu)H_1^T H_1)X'(\mu) + X'(\mu)(A_1 + X(\mu)H_1^T H_1)^T + G_1 G_1^T = 0,$$

$$(A_1 + X(\mu)H_1^T H_1)X''(\mu) + X''(\mu)(A_1 + X(\mu)H_1^T H_1)^T + 2X'(\mu)H_1^T H_1 X'(\mu) = 0.$$

If we add and subtract $i\omega_j X'(\mu)$ in the first and $i\omega_j X''(\mu)$ in the second equation and multiply the resulting equations with $H_1 A(\mu)$ from the left and with $A(\mu)^* H_1^T$ from the right, we get

$$(38) \quad H_1 X'(\mu)A(\mu)^* H_1^T + H_1 A(\mu)X'(\mu)H_1^T = -[H_1 A(\mu)G_1][H_1 A(\mu)G_1]^*,$$

$$(39) \quad \begin{aligned} & H_1 X''(\mu)A(\mu)^* H_1^T + H_1 A(\mu)X''(\mu)H_1^T \\ & = -2H_1 A(\mu)X'(\mu)H_1^T H_1 X'(\mu)A(\mu)^* H_1^T. \end{aligned}$$

Moreover, we differentiate (31) and derive

$$(A_1 + X(\mu)H_1^T H_1)Y'(\mu) + Y'(\mu)A_2^T + X'(\mu)H_1^T L(\mu) + G_1 G_2^T = 0,$$

$$(A_1 + X(\mu)H_1^T H_1)Y''(\mu) + Y''(\mu)A_2^T + X''(\mu)H_1^T L(\mu) + 2X'(\mu)H_1^T H_1 Y'(\mu) = 0.$$

If we multiply the equations for $Y(\mu)$, $Y'(\mu)$, and $Y''(\mu)$ from the right with E_j and from the left with $H_1 A(\mu)$, we obtain by $A_2^T E_j = i\omega_j E_j$

$$(40) \quad H_1 Y(\mu)E_j = -H_1 A(\mu)[X(\mu)H_1^T K_2^T + \mu G_1 G_2^T - B_1 B_2^T]E_j,$$

$$(41) \quad H_1 Y'(\mu)E_j = -H_1 A(\mu)[X'(\mu)H_1^T L(\mu) + G_1 G_2^T]E_j,$$

$$(42) \quad H_1 Y''(\mu)E_j = -H_1 A(\mu)[X''(\mu)H_1^T L(\mu) + 2X'(\mu)H_1^T H_1 Y'(\mu)]E_j.$$

Equation (40) leads to the formula for $L(\mu)E_j$.

Now we compute by explicit differentiation of $F_j(\cdot)$ and exploiting (41)

$$\begin{aligned} F'_j(\mu) &= -(H_1 Y'(\mu)E_j)^* L(\mu)E_j - E_j^* L(\mu)^T (H_1 Y'(\mu)E_j) - E_j^* G_2 G_2^T E_j \\ &= (L(\mu)E_j)^* [H_1 X'(\mu)A(\mu)^* H_1^T + H_1 A(\mu)X'(\mu)H_1^T] L(\mu)E_j \\ &\quad + E_j^* [G_2 (H_1 A(\mu)G_1)^* L(\mu) + L(\mu)^T (H_1 A(\mu)G_1)G_2^T - G_2 G_2^T] E_j. \end{aligned}$$

After an obvious completion of the squares, we infer

$$\begin{aligned} F'_j(\mu) &= (L(\mu)E_j)^*[H_1X'(\mu)A(\mu)^*H_1^T + H_1A(\mu)X'(\mu)H_1^T]L(\mu)E_j \\ &\quad + (L(\mu)E_j)^*[H_1A(\mu)G_1][H_1A(\mu)G_1]^*L(\mu)E_j \\ &\quad - E_j^*[G_2 - L(\mu)^TH_1A(\mu)G_1][G_2 - L(\mu)^TH_1A(\mu)G_1]^*E_j. \end{aligned}$$

Equation (38) leads to the considerable simplification

$$F'_j(\mu) = -E_j^*[G_2 - L(\mu)^TH_1A(\mu)G_1][G_2 - L(\mu)^TH_1A(\mu)G_1]^*E_j,$$

which is the formula for $F'_j(\mu)$ that we must prove and which shows $F'_j(\mu) \leq 0$.

The second derivative of $F_j(\cdot)$ is given by

$$\begin{aligned} F''_j(\mu) &= -(H_1Y''(\mu)E_j)^*L(\mu)E_j - E_j^*L(\mu)^T(H_1Y''(\mu)E_j) \\ &\quad - 2(H_1Y'(\mu)E_j)^*(H_1Y'(\mu)E_j). \end{aligned}$$

We infer from (42)

$$\begin{aligned} F''_j(\mu) &= E_j^*L(\mu)^T[H_1X''(\mu)A(\mu)^*H_1^T + H_1A(\mu)X''(\mu)H_1^T]L(\mu)E_j \\ &\quad + 2E_j^*[Y'(\mu)^TH_1^TH_1X'(\mu)A(\mu)^*H_1^T]L(\mu) \\ &\quad + L(\mu)^TH_1A(\mu)X'(\mu)H_1^TH_1Y'(\mu)]E_j \\ &\quad - 2E_j^*[Y'(\mu)^TH_1^TH_1Y'(\mu)]E_j^*. \end{aligned}$$

Again a completion of the squares and equation (39) lead to

$$\begin{aligned} F''_j(\mu) &= E_j^*L(\mu)^T[-2H_1A(\mu)X'(\mu)H_1^TH_1X'(\mu)A(\mu)^*H_1^T]L(\mu)E_j \\ &\quad - 2E_j^*[Y'(\mu) - X'(\mu)A(\mu)^*H_1^TL(\mu)]^*H_1^TH_1[Y'(\mu) - X'(\mu)A(\mu)^*H_1^TL(\mu)]E_j \\ &\quad + 2E_j^*[X'(\mu)A(\mu)^*H_1^TL(\mu)]^*H_1^TH_1[X'(\mu)A(\mu)^*H_1^TL(\mu)]E_j \\ &= -2E_j^*[Y'(\mu) - X'(\mu)A(\mu)^*H_1^TL(\mu)]^*H_1^TH_1[Y'(\mu) - X'(\mu)A(\mu)^*H_1^TL(\mu)]E_j, \end{aligned}$$

which implies $F''_j(\mu) \leq 0$. \square

Note that we should avoid computing first the whole matrix $Y(\mu)$ and then $F_j(\mu)$. It is further interesting that $H_1(i\omega_j I + A_1 + X(\mu)H_1^TH_1)^{-1}G_1$ is just the value at $i\omega_j$ of that transfer matrix which plays a central role in the computation of μ_{\max} .

Now we can apply all the results of [18, § 7] since they can be proved in completely the same way for Hermitian-valued functions. We summarize the consequences in the following result.

THEOREM 12. *The critical parameter μ_{neg} equals μ_{\max} if and only if $F(\mu)$ is positive semidefinite for all $\mu \in (-\infty, \mu_{\max})$. Otherwise there exists a $\mu_1 \in (0, \mu_{\max})$ with $F(\mu_1) \not\geq 0$. Then μ_{neg} equals the unique value for which $F(\mu_{\text{neg}})$ is positive semidefinite and singular.*

For a given $\mu_{\text{neg}} \leq \mu_j < \mu_{\max}$ there exists a unique $\mu_{j+1} \in [\mu_{\text{neg}}, \mu_j]$ such that $F(\mu_j) + F'(\mu_j)(\mu_{j+1} - \mu_j)$ is positive semidefinite and singular. The inductively defined sequence μ_j converges monotonically from above and quadratically to μ_{neg} .

Literally the same result holds for the function

$$\mu \rightarrow \text{blockdiag}(X(\mu), F_1(\mu), \dots, F_l(\mu))$$

on $(0, \mu_{\max})$, which allows us to directly compute μ_* instead of determining μ_{neg} and μ_{pos} separately.

Finally we show how to characterize that the critical parameters are infinite, interestingly enough, just by simple algebraic inclusions. Moreover, we stress the important consequences of $\mu_{\max} = \infty$ for the computation of μ_* . We recall from [18] that μ_{\max} is infinite if and only if $X(\cdot)$ is affine and then the parameter μ_{pos} can be determined by solving a symmetric eigenvalue problem. In the same sense the computation of μ_{neg} reduces to the solution of a Hermitian eigenvalue problem.

THEOREM 13. (a) $\mu_{\max} = \infty$ if and only if $\text{im}(G)$ is contained in the unobservable subspace of $S(s)$.

(b) $\mu_{\text{pos}} = \infty$ if and only if $\text{im}(G) \subset \mathcal{S}_+$.

(c) $\mu_{\text{neg}} = \infty$ if and only if $\text{im}(G) \subset \bigcap_{\lambda \in \mathbb{C}^0} \mathcal{S}_\lambda$.

In the case of $\mu_{\max} = \infty$ and $\mu_{\text{neg}} < \infty$, μ_{neg} is the unique value μ for which

$$F(0) - \mu \text{ blockdiag}(E_1^*(G_2 G_2^T)E_1 \cdots E_l^*(G_2 G_2^T)E_l)$$

is positive semidefinite and singular.

Proof. (a) and (b) already appear in [18]. In the case of $\mu_{\max} = \infty$, $H_G(\mu)$ vanishes, and (37) implies $F_j(\mu) = -E_j^* G_2 G_2^T E_j$. Therefore, $F(\cdot)$ is affine and μ_{neg} is finite, with the characterization we have to prove, if and only if there is at least one $j \in \{1, \dots, l\}$ such that $E_j^* G_2 G_2^T E_j$ does not vanish.

We prove (c) by replacing the inclusion with the equivalent fact that $G^T \mathcal{S}_\lambda^\perp$ is trivial for all $\lambda \in \mathbb{C}^0$. Moreover, we can assume (without restriction) $S = I$ and (33). With an obvious notation we infer for $\lambda \in \mathbb{C}^0$ by duality:

$$(43) \quad \mathcal{S}_\lambda^\perp = \{((x_1^0)^T (x_1^+)^T x_2^T x_3^T)^T \mid x_1^+ = 0, (-A_2^T - \lambda I)x_2, x_3 = 0\}.$$

Now $\mu_{\text{neg}} = \infty$ implies $\mu_{\max} = \infty$ and hence $G_1^0 = 0$. Furthermore, $G_2^T E_j = 0$ for any $j \in \{1, \dots, l\}$ shows $(A_2^T - i\omega_j I)x_2 = 0 \Rightarrow G_2^T x_2 = 0$. This obviously leads to $G^T \mathcal{S}_\lambda^\perp = \{0\}$. On the other hand, $G^T \mathcal{S}_\lambda^\perp = \{0\}$ for one $\lambda \in \mathbb{C}^0$ already implies $G_1^0 = 0$, i.e., $\mu_{\max} = \infty$. Therefore, $G^T \mathcal{S}_{i\omega_j}^\perp = \{0\}$ leads to $G_2^T E_j = 0$ for all $j \in \{1, \dots, l\}$. \square

In case of $\mu_{\max} = \infty$, this result displays in a very nice way both qualitatively and quantitatively which parts of and how G influences μ_{neg} and thus restricts the optimal value μ_* . For the still simpler situation $H = 0$, we obtain $F(0) = \text{blockdiag}(E_1^* B_2 B_2^T E_1 \cdots E_l^* B_2 B_2^T E_l)$ and there is no need to solve any ARE. A referee drew our attention to the unpublished paper [8], which contains suboptimality tests for the one block H_∞ -problem by output measurement without restrictions on $\mathbb{C}^0 \cup \{\infty\}$ -zeros. The results of [8] are applicable to our problem if and only if H vanishes and then they boil down to $X(\mu) > 0$ and $F(\mu) > 0$, although both the formulation as well as the derivation (in the frequency domain) are completely different from ours. Even for $H \neq 0$ and $\mu_{\max} = \infty$, Theorem 13 extends the results of [8] but the real difficulties, of course, arise for $\mu_{\max} < \infty$.

Appendix. The following result is a simple consequence of the well-known formula for the inverse of a block matrix.

LEMMA 14. (a) If

$$X = \begin{pmatrix} X_1 & X_{12} \\ X_{12}^T & X_2 \end{pmatrix} \in \mathbb{S}^n$$

is positive definite and $X_1^{-1} > P_1$, the following inequalities hold:

$$X^{-1} \geq \begin{pmatrix} X_1^{-1} & 0 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad X^{-1} > \begin{pmatrix} P_1 & 0 \\ 0 & 0 \end{pmatrix}.$$

(b) Suppose that $X_1(j)$ converges to $X_1 > 0$, $X_2(j)^{-1}$ converges to 0, and $X_{12}(j)$ is bounded for $j \rightarrow \infty$. Then

$$X(j) := \begin{pmatrix} X_1(j) & X_{12}(j) \\ X_{12}(j)^T & X_2(j) \end{pmatrix}$$

is positive definite for all large j and

$$\lim_{j \rightarrow \infty} X(j)^{-1} = \begin{pmatrix} X_1^{-1} & 0 \\ 0 & 0 \end{pmatrix}.$$

Acknowledgments. I gratefully acknowledge the support of Siep Weiland from the University of Groningen who wasted many hours for very helpful discussions about the treatment of system zeros on the imaginary axis in the almost disturbance decoupling problem. My thanks also go to the other members of the Systems and Control Group in Groningen (and especially to Professor J. C. Willems) for their kind hospitality.

H_∞ -OPTIMIZATION WITHOUT ASSUMPTIONS ON FINITE OR INFINITE ZEROS*

CARSTEN SCHERER†

Abstract. Explicit algebraic conditions are presented for the suboptimality of some parameter in the H_∞ -optimization problem by output measurement control. Apart from two strict properness conditions, no artificial assumptions restrict the underlying system. In particular, the plant may have zeros on the imaginary axis or at infinity. These suboptimality characterizations are applied to show how to compute the optimal value by quadratically convergent algorithms and to solve the almost disturbance decoupling problem with internal stability.

Key words. H_∞ -optimization, invariant zeros, Riccati inequalities, almost disturbance decoupling

1. Introduction. After Zames introduced the basic motivations for H_∞ -optimization in [41], this problem has attracted much research, and several techniques for its solutions have been proposed. We only want to mention briefly the approaches in the frequency domain using operator theory [8], [9], J -spectral factorization [2], [11], polynomial methods [18], or an all-pass imbedding (including a treatment of the H_∞ -problem at optimality) [20]. The direct solutions of the H_∞ -problem in the state space are primarily based on the bounded real lemma and on ideas from LQ-theory as well as differential games [3]–[5], [14]–[17], [24], [33], [35]. We refer the reader to [8], [9], [5] for rather comprehensive discussions of the historical development.

The paper [5] may be viewed as the breakthrough for the state-space techniques to solve the H_∞ -problem. The suboptimality tests are formulated in terms of the solvability of two indefinite Riccati equations and a coupling condition on their solutions. Some authors tried to remove several artificial assumptions needed in the approach of [5]. In [4] we can find generalized formulae if certain direct feedthrough matrices do not vanish. From a practical point of view, the main restriction results from the hypothesis that the plant cannot have zeros either on the imaginary axis or at infinity. Using tools of the geometric theory, the zero assumption at infinity was removed in [33], and the suboptimality criteria were given in terms of the solvability of two quadratic matrix inequalities and a coupling condition on their solutions. The solutions of these inequalities may be constructed by transforming the system and again solving two reduced-order indefinite Riccati equations. The general problem without any assumption on the zeros on the imaginary axis and at infinity has not been solved up until now.

In [31] we explained the difficulties resulting from the imaginary axis zeros in the regular H_∞ -problem by state feedback: we cannot infer from the solvability of an algebraic Riccati *inequality* (ARI) the solvability of the corresponding algebraic Riccati *equation* (ARE). The same problems arise in the general H_∞ -problem by output feedback. Indeed from the very beginning of the direct state-space approach to the H_∞ -problem [24] it became clear that Riccati *inequalities* could be viewed as a central

tool for studying this problem. In fact new algebraic tests for the solvability of general strict Riccati inequalities lead to a satisfactory solution of the regular state-feedback H_∞ -problem [31].

In this paper these ideas are extended to attack the general H_∞ -optimization problem by output measurement and without assumptions on finite or infinite zeros of the underlying plant. Our approach only refers to a strict version of the bounded real lemma and proceeds, by simple algebraic manipulations, completely in the state space.

The paper is organized as follows. In § 3, we will be able to provide a very short but complete proof of a characterization of suboptimality in terms of the solvability of two Riccati inequalities and a coupling condition on their solutions where the ARIs still depend on an unknown feedback and injection matrix (Theorem 1). We shortly discuss the results appearing in the literature. For a reformulation of this characterization into algebraic tests, we need to transform the system data, which is explained in § 4. Then we show in § 5 how to check the solvability of the feedback-dependent ARI by the solvability of a *fixed* well-defined reduced-order ARI (Theorem 6). An abstract reformulation (Theorem 10) displays how to express the suboptimality directly in terms of the original system matrices. These considerations lead to the solution of the general H_∞ -optimization problem by state feedback. Section 6 is devoted to clarifying how the coupling condition can be checked algebraically, culminating in the solution of the general H_∞ -problem by output measurement (Theorem 14). Section 7 contains the application of these results to the computation of the optimal value by quadratically convergent algorithms. In addition, we display certain special cases for which it may be determined by solving Hermitian eigenvalue problems. Finally, we derive in § 8 the geometric solution of the almost disturbance decoupling problem with stability.

We adopt all the notations from [31]. Moreover, we denote by A^+ the Moore-Penrose inverse of $A \in \mathbb{R}^{n \times m}$. The symbol \mathbb{C}^g is used for any nonempty subset of \mathbb{C} which is symmetric with respect to the real axis.

2. Problem formulation. The system is described by

$$(1) \quad \begin{aligned} \dot{x} &= Ax + Bu + Gd, & x(0) &= 0, \\ y &= Cx + Dd, \\ z &= Hx + Ed, \end{aligned}$$

where $x \in \mathbb{R}^n$ is the state, $d \in \mathbb{R}^r$ is the external disturbance, $u \in \mathbb{R}^m$ is the control, $z \in \mathbb{R}^k$ is the controlled output, and $y \in \mathbb{R}^p$ is the measured output available for control. A *compensator* is any dynamic output-feedback system

$$(2) \quad \begin{aligned} \dot{w} &= Kw + Ly, & w(0) &= 0, \\ u &= Mw + Ny. \end{aligned}$$

This system is identified with

$$C_r(s) = \begin{pmatrix} K - sI & L \\ M & N \end{pmatrix},$$

where, for clarity, the dimension $r \in \mathbb{N} \cup \{0\}$ ($K \in \mathbb{R}^{r \times r}$) appears as an index. The closed-loop system is given by

$$\left(\begin{array}{cc|c} A + BNC - sI & BM & G + BND \\ LC & K - sI & LD \\ \hline H + ENC & EM & END \end{array} \right)$$

with state $\begin{pmatrix} x \\ w \end{pmatrix}$ and initial value 0. Moreover, the compensator $C_r(s)$ is called *stabilizing* if it internally stabilizes the resulting closed-loop system in the sense of

$$\sigma \begin{pmatrix} A + BNC & BM \\ LC & K \end{pmatrix} \subset \mathbb{C}^-.$$

It is well known that a stabilizing controller exists and only if

$$(A - sI \quad B) \text{ is stabilizable and } \begin{pmatrix} A - sI \\ C \end{pmatrix} \text{ is detectable.}$$

Apart from § 4, these are the standing assumptions throughout this paper.

For any stabilizing compensator $C_r(s)$, let $\gamma(C_r(s))$ denote the H_∞ -norm of the controlled closed-loop system. The general H_∞ -problem by output measurement consists of minimizing $\gamma(C_r(s))$ over all stabilizing controllers $C_r(s)$. For the same reasons as in [31], we rather consider the equivalent problem: Maximize

$$\mu(C_r(s)) := \frac{1}{\gamma(C_r(s))^2}$$

over all stabilizing $C_r(s)$ under the usual convention $1/0 = \infty$. We define the optimal value by

$$\mu_{\text{opt}} := \sup \{ \mu(C_r(s)) \mid C_r(s) \text{ is stabilizing, } r \in \mathbb{N} \}.$$

Now we can describe the subjects of the present paper:

- Give checkable (algebraic) conditions for some parameter $\mu > 0$ to be suboptimal in the sense of $\mu < \mu_{\text{opt}}$.
- Find a fast algorithm for computing μ_{opt} .
- Try to determine when μ_{opt} can be computed explicitly or characterize whether μ_{opt} is infinite.

All these problems will find rather satisfactory answers. The only restriction on the plant is that there is no direct feedthrough from u to y (which is easy to handle) and from d to z (which is more difficult to deal with). For techniques to overcome these assumptions we refer the reader to [26]. A particular case has its own interest: The state-feedback H_∞ -problem that is defined by the specification

$$C = I \quad \text{and} \quad D = 0;$$

i.e., the whole state is available for control and it is not directly corrupted by the disturbances.

In the frequency domain [8], [9], the plant (including weighting matrices) is described by the real rational proper matrix $G(s)$ as

$$\begin{pmatrix} z(s) \\ y(s) \end{pmatrix} = \begin{pmatrix} G_{11}(s) & G_{12}(s) \\ G_{21}(s) & G_{22}(s) \end{pmatrix} \begin{pmatrix} d(s) \\ u(s) \end{pmatrix}.$$

In our case the system is only restricted to be internally stabilizable and to have a representation with *strictly* proper matrices $G_{11}(s)$ and $G_{22}(s)$. In the usual frequency domain approach, we first parametrize the set of transfer matrices of all internally stabilized closed-loop systems as

$$\{ T_1(s) + T_2(s)Q(s)T_3(s) \mid Q(s) \text{ real rational, proper, stable} \}$$

with $T_2(s) = (H + EF)(sI - A - BF)^{-1}B$ (for some F satisfying $\sigma(A + BF) \subset \mathbb{C}^-$), $T_3(s) = C(sI - A - JC)^{-1}(G + JD)$ (for some J satisfying $\sigma(A + JC) \subset \mathbb{C}^-$) and some real rational proper stable $T_1(s)$. This step changes the H_∞ -problem to a *model-matching problem*.

If $T_2(\lambda)$ has maximal column rank and $T_3(\lambda)$ has maximal row rank for all $\lambda \in \mathbb{C}^0 \cup \{\infty\}$, it is possible to transform the model-matching problem into the so-called *four block Nehari problem* [9]. The aim of this paper is to overcome these rank assumptions, which imply that the transformation to the four block problem is not possible anymore.

3. Suboptimality and strict algebraic Riccati inequalities. We start by characterizing the suboptimality of some positive μ by the solvability of Riccati inequalities which still depend on some unknown feedback and injection matrix.

THEOREM 1. $\mu > 0$ is suboptimal and only if there exist F and J as well as $P > 0$ and $Q > 0$, which satisfy

$$(3) \quad (A + BF)^T P + P(A + BF) + \mu P G G^T P + (H + EF)^T (H + EF) < 0,$$

$$(4) \quad (A + JC)Q + Q(A + JC)^T + \mu Q H^T H Q + (G + JD)(G + JD)^T < 0,$$

$$(5) \quad \rho(PQ) < \frac{1}{\mu}.$$

If these conditions are satisfied, there exists a stabilizing controller $C_n(s)$ of dimension n with $\mu < \mu(C_n(s))$.

This result has a very nice interpretation. Suppose that F is any matrix such that (3) has a positive definite solution. Then this feedback F yields $\sigma(A + BF) \subset \mathbb{C}^-$ and $\|(H + EF)(sI - A - BF)^{-1}G\|_\infty < 1/\mu$. On the other hand, if F satisfies these last two properties, there exists a $P > 0$, which solves (3). Therefore there exist F and $P > 0$ with (3) if and only if μ is suboptimal for the H_∞ -problem by *static state feedback* for the plant

$$S(s) := \begin{pmatrix} A - sI & B \\ H & E \end{pmatrix}$$

and the disturbance input matrix G .

Dually, the existence of J and $Q > 0$ with (4) is equivalent to the suboptimality of μ for the H_∞ -estimation problem (by linear observers) for the plant

$$T(s) := \begin{pmatrix} A - sI & G \\ C & D \end{pmatrix}$$

and the output Hx to be estimated [23]. However, for $\mu < \mu_{\text{opt}}$ it does not suffice that μ is suboptimal for these two problems separately; we must require the additional coupling condition (5). This constraint can be understood if trying to build a compensator: The controller may be constructed as an estimator for the desired suboptimal control function Fx (which is not implementable) using only the measurements y . The conditions for this estimation to be possible result in (5) [5].

From a practical point of view Theorem 1 is not very useful: It is not clear how to test these conditions in algebraic way without resorting to perturbation techniques which would involve an additional parameter. Moreover, it does not provide any insight into how the \mathbb{C}^0 -zeros of the plants $S(s)$ or $T(s)$ influence the optimal value μ_{opt} . Contrary to the considerations in [27], which stop at this point, this is only a preliminary step in our approach.

Theorem 1 is proved in [27] (and was derived independently for the regular problem in the first version of this paper). Nevertheless, we would like to include a complete and most direct proof which is still much shorter than that in [27] since there will be no need to distinguish between proper and nonproper controllers. Moreover,

we prove the sufficiency part by starting with a compensator which is only a slight modification of that used for the regular problem in [4], [5]; the modification can be easily motivated and the required computations are very simple.

Proof of necessity. Suppose that $\mu > 0$ is suboptimal. Then there exists a stabilizing controller $C_r(s)$ with $\mu < \mu(C_r(s))$. Let us define the abbreviations

$$\begin{aligned} \mathcal{A} &:= \begin{pmatrix} A+BNC & BM \\ LC & K \end{pmatrix}, & \mathcal{B} &:= \begin{pmatrix} G+BND \\ LD \end{pmatrix}, \\ \mathcal{C} &:= (H+ENC \quad EM), & \mathcal{D} &:= END. \end{aligned}$$

By $\sigma(\mathcal{A}) \subset \mathbb{C}^-$ and $\|\mathcal{C}(sI - \mathcal{A})^{-1}\mathcal{B} + \mathcal{D}\|_\infty^2 < 1/\mu$, we can apply the strict version of the bounded real lemma and infer the existence of some $\mathcal{Y} > 0$ with [27], [42]

$$(6) \quad \begin{pmatrix} \mathcal{A}^T \mathcal{Y} + \mathcal{Y} \mathcal{A} + \mathcal{C}^T \mathcal{C} & \mathcal{Y} \mathcal{B} + \mathcal{C}^T \mathcal{D} \\ \mathcal{B}^T \mathcal{Y} + \mathcal{D}^T \mathcal{C} & \mathcal{D}^T \mathcal{D} - (1/\mu)I \end{pmatrix} < 0.$$

It is very simple to see [27] that

$$(7) \quad \mathcal{X} := \frac{1}{\mu} \mathcal{Y}$$

satisfies

$$(8) \quad \begin{pmatrix} \mathcal{A} \mathcal{X} + \mathcal{X} \mathcal{A}^T + \mathcal{B} \mathcal{B}^T & \mathcal{X} \mathcal{C}^T + \mathcal{B} \mathcal{D}^T \\ \mathcal{C} \mathcal{X} + \mathcal{D} \mathcal{B}^T & \mathcal{D} \mathcal{D}^T - (1/\mu)I \end{pmatrix} < 0.$$

Let us now partition

$$\mathcal{X} = \begin{pmatrix} X & X_{12} \\ X_{12}^T & X_2 \end{pmatrix} \quad \text{and} \quad \mathcal{Y} = \begin{pmatrix} Y & Y_{12} \\ Y_{12}^T & Y_2 \end{pmatrix}$$

according to \mathcal{A} . Note that both matrices in (6) and (8) are in fact partitioned into three block rows/columns.

Now we just compute the (1, 1) block of the matrix in (6) to

$$\begin{aligned} & A^T Y + Y A + C^T [N^T B^T Y + L^T Y_{12}^T + N^T E^T H] + [Y B N + Y_{12} L + H^T E N] C \\ & + H^T H + (ENC)^T ENC, \end{aligned}$$

which equals

$$(A+JC)^T Y + Y(A+JC) + H^T H + (ENC)^T (ENC)$$

for $J := BN + Y^{-1} Y_{12} L + Y^{-1} H^T E N$. The (1, 3) of (6) block may be written with the help of J as

$$Y(G+JD) + (ENC)^T (END).$$

By

$$\begin{pmatrix} (ENC)^T (ENC) & (ENC)^T (END) \\ (END)^T (ENC) & (END)^T (END) \end{pmatrix} \geq 0,$$

we immediately infer from (6) the inequality

$$\begin{pmatrix} (A+JC)^T Y + Y(A+JC) + H^T H & Y(G+JD) \\ (G+JD)^T Y & -(1/\mu)I \end{pmatrix} < 0.$$

The Schur complement of the matrix on the left in this inequality with respect to the (2, 2) block is negative definite. If we multiply it with μ we infer that $Q := (\mu Y)^{-1} > 0$ satisfies (4).

Since (8) is dual to (6), there is *no need for any computation* to deduce that $P := (\mu X)^{-1}$ is a *positive definite* solution to (3) for $F := NC + MX_{12}^T X^{-1} + NDG^T X^{-1}$.

By the well-known formula for the inverse of a block matrix, the left upper block of \mathcal{Y}^{-1} is given by $(Y - Y_{12} Y_2^{-1} Y_{12}^T)^{-1}$. Therefore (7) shows $\mu X \geq Y^{-1}$, which clearly leads, by the definition of P and Q , to $\rho(PQ) \leq 1/\mu$. If the inequality is not strict, we can perturb P or Q (e.g., to $P - \varepsilon I$ or $Q - \varepsilon I$, $\varepsilon > 0$) such that these perturbations still satisfy the ARIs (3) or (4) and, in addition, the strict coupling condition (5) becomes true.

Proof of sufficiency and controller construction. Let R_F and R_J denote the left-hand sides of the Riccati inequalities (3) and (4). We assume without restriction

$$(9) \quad Q^{-1} R_J Q^{-1} < \mu R_F.$$

Suppose that this is not valid. Obviously, there exists some matrix $R < 0$ with $Q^{-1} R_J Q^{-1} < \mu R$ and $R_F < \mu R$. Since the ARI $(A + BF)^T X + X(A + BF) + \mu X G G^T X + (H + EF)^T (H + EF) - \mu R < 0$ has the solution $X = P$ and since $A + BF$ is stable, there exists some $\bar{P} < P$ [31] with $(A + BF)^T \bar{P} + \bar{P}(A + BF) + \mu \bar{P} G G^T \bar{P} + (H + EF)^T (H + EF) - \mu R = 0$. The stability of $A + BF$ and $\mu R < 0$ implies $\bar{P} > 0$. We can hence replace P by \bar{P} such that all the hypotheses in the theorem persist to hold and (9) becomes true.

Motivated by the results for the regular problem [4], [5], we introduce the *strictly proper* compensator

$$\begin{aligned} \dot{w} &= (A + \mu G G^T P + \Delta)w + Bu + \tilde{J}((C + \mu D G^T P)w - y), \quad w(0) = 0, \\ u &= Fw \end{aligned}$$

in observer form, where we define

$$\begin{aligned} \tilde{J} &:= (I - \mu Q P)^{-1} J, \\ \Delta &:= -\mu(Q^{-1} - \mu P)^{-1}[(BF)^T P + (EF)^T (H + EF)]. \end{aligned}$$

The only modification consists of the introduction of Δ . The formula for Δ will immediately become clear by the computations shown below.

As usual, we consider the dynamics of the error $e := x - w$, which is clearly given by

$$\dot{e} = (A + \mu G G^T P + \tilde{J}(C + \mu D G^T P) + \Delta)e - ((G + \tilde{J}D)G^T(\mu P) + \Delta)x + (G + \tilde{J}D)d.$$

This leads to the closed-loop system (with state $(x^T e^T)^T$)

$$\left(\begin{array}{cc|c} A + BF - sI & -BF & G \\ -(G + \tilde{J}D)G^T(\mu P) - \Delta & A + \mu G G^T P + \tilde{J}(C + \mu D G^T P) + \Delta - sI & G + \tilde{J}D \\ \hline H + EF & -EF & 0 \end{array} \right),$$

which is again denoted as

$$\begin{pmatrix} \mathcal{A} - sI & \mathcal{B} \\ \mathcal{C} & 0 \end{pmatrix}.$$

We must show that $\sigma(\mathcal{A}) \subset \mathbb{C}^-$ and $\|\sqrt{\mu}\mathcal{C}(sI - \mathcal{A})^{-1}\mathcal{B}\|_\infty < 1$.

To finish the proof, it suffices (by the bounded real lemma [42]) to construct a solution \mathcal{Y} of the strict ARI

$$(10) \quad \mathcal{A}^T \mathcal{Y} + \mathcal{Y} \mathcal{A} + \mathcal{Y} \mathcal{B} \mathcal{B}^T \mathcal{Y} + \mu \mathcal{C}^T \mathcal{C} < 0.$$

Again motivated by the solution of the regular problem [5], we are led to try

$$\mathcal{Y} := \begin{pmatrix} \mu P & 0 \\ 0 & Q^{-1} - \mu P \end{pmatrix},$$

which is positive definite by (5). Let us introduce the abbreviation $Z := Q^{-1} - \mu P$.

Now we just compute the blocks of the left-hand side of (10). The (1, 1) block is immediately seen to be μR_F , which is negative definite. The (2, 1) block is given by

$$\begin{aligned} & -(BF)^T(\mu P) - Z(G + \tilde{J}D)G^T(\mu P) - Z\Delta + Z(G + \tilde{J}D)G^T(\mu P) - \mu(EF)^T(H + EF) \\ & = -\mu(BF)^TP - \mu(EF)^T(H + EF) - (Q^{-1} - \mu P)\Delta, \end{aligned}$$

which just vanishes by the very definition of Δ . We first stress $Z\tilde{J} = Q^{-1}J$ and then compute the (2, 2) block to

$$\begin{aligned} & (A + \mu GG^TP)^TZ + Z(A + \mu GG^TP) + ZGG^TZ + \mu(EF)^T(EF) + \Delta^TZ + Z\Delta \\ & + Q^{-1}JDD^TJ^TQ^{-1} + (C^T + \mu PGD^T)J^TQ^{-1} + ZGD^TJ^TQ^{-1} \\ & + Q^{-1}J(C + \mu DG^TP) + Q^{-1}JDG^TZ, \end{aligned}$$

which is rewritten, by $\mu PGG^TZ + \mu ZGG^TP + ZGG^TZ = Q^{-1}GG^TQ^{-1} - (\mu P)GG^T(\mu P)$, as

$$\begin{aligned} & A^TZ + ZA - (\mu P)GG^T(\mu P) + \Delta^TZ + Z\Delta + \mu(EF)^T(EF) + C^TJ^TQ^{-1} + Q^{-1}JC \\ & + Q^{-1}GG^TQ^{-1} + Q^{-1}JDG^TQ^{-1} + Q^{-1}G(JD)^TQ^{-1} + Q^{-1}JD(JD)^TQ^{-1}. \end{aligned}$$

The definition of Δ shows that $\Delta^TZ + Z\Delta + \mu(EF)^T(EF)$ is equal to

$$-(BF)^T(\mu P) - (\mu P)BF - \mu(H + EF)^T(H + EF) + \mu H^TH.$$

Therefore the (2, 2) block is given by

$$\begin{aligned} & A^TZ + ZA - (\mu P)GG^T(\mu P) - (BF)^T(\mu P) - (\mu P)BF - \mu(H + EF)^T(H + EF) \\ & + (JC)^TQ^{-1} + Q^{-1}(JC) + \mu H^TH + Q^{-1}(G + JD)(G + JD)^TQ^{-1}, \end{aligned}$$

which obviously equals

$$Q^{-1}R_JQ^{-1} - \mu R_F < 0. \quad \square$$

The modification Δ of the standard suboptimal compensator [4], [5] is due to the generality of F and J : We do not need to specify particularly chosen matrices F and J and can define a compensator based on certain solutions of the Riccati *inequalities*. The controller has a simple observer structure with a similar interpretation as discussed in [5]. In completely the same fashion we could also construct a compensator based on the minimal solutions of those Riccati equations that correspond to (3), (4) (which exist since $A + BF$ and $A + JC$ are stable). These solutions still satisfy (5) by minimality.

The question arises of how to test the various conditions of Theorem 1 in an algebraic way. The following results are available in the literature under combinations of the assumptions:

- (a) E has maximal column rank and D has maximal row rank.
- (b) $S(s)$ and $T(s)$ have no invariant zeros in \mathbb{C}^0 (see § 4).

If (b) holds, our characterization may be reformulated as follows [33]: There exist solutions $P \geq 0$, $Q \geq 0$ of the two *quadratic matrix inequalities*

$$\begin{aligned} & \begin{pmatrix} A^TP + PA + \mu PGG^TP + H^TH & PB + H^TE \\ B^TP + E^TH & E^TE \end{pmatrix} \geq 0 \text{ plus rank conditions,} \\ & \begin{pmatrix} AQ + QA^T + \mu QH^THQ + GG^T & QC^T + GD^T \\ CQ + DG^T & DD^T \end{pmatrix} \geq 0 \text{ plus rank conditions,} \end{aligned}$$

which satisfy

$$\rho(PQ) < \frac{1}{\mu}.$$

If both (a) and (b) hold true, the quadratic matrix inequalities can obviously be reduced (by taking the Schur complements with respect to the $(2, 2)$ blocks) to indefinite AREs and we arrive at the results of [4], [5]. If (a) fails to hold, the solutions of the quadratic matrix inequalities may as well be determined by solving two reduced-order indefinite AREs for subsystems of certain transformed versions of $S(s)$ and $T(s)$ [33]. A referee drew our attention to the paper [12] where algebraic tests for suboptimality are derived (in the frequency domain) if (a) and (b) do not necessarily hold true. However, these results are restricted to the one block problem, i.e., $T_2(s)$, $T_3(s)$ as appearing in § 2 must be square and invertible as rational matrices.

The aim of this paper is to remove both assumptions (a) and (b) for the general four block problem as described in § 2. We will generalize the suboptimality criteria we derived in [31] for the regular state-feedback problem ($C = I$, $D = 0$, E has maximal column rank) that are formulated in terms of the Riccati map

$$R(X, \mu) := AX + XA^T + XH^THX + \mu GG^T - (B - XH^TE)(E^TE)^+(B^T + E^THX)$$

and the associated map

$$A(X) := A + XH^TH - (B + XH^TE)(E^TE)^+E^TH,$$

defined on $\mathbb{S}^n \times \mathbb{R}$ and \mathbb{S}^n , respectively. Note that we performed in [31] a preliminary feedback with

$$(11) \quad F := -(E^TE)^+E^TH$$

(motivated by $E^T(H + EF) = 0$) and one easily verifies that $R(X, \mu)$ equals

$$(A + BF)X + X(A + BF)^T + X(H + EF)^T(H + EF)X + \mu GG^T - B(E^TE)^+B^T$$

and $A(X)$ is given by

$$(A + BF) + X(H + EF)^T(H + EF).$$

We already indicate the generalization to the singular problem by using the Moore-Penrose inverse: The two representations of these maps still coincide even if E does not have maximal column rank! The undetectable subspaces and the observability normal form appearing in [31] have their natural generalizations in the corresponding conditionally invariant subspaces and in a modification of Morse's canonical form, which are both thoroughly investigated in geometric control theory.

4. Transformation by restricted coordinate changes. For some arbitrary $(n + k) \times (n + m)$ system

$$S(s) = \begin{pmatrix} A - sI & B \\ H & E \end{pmatrix}$$

and any $\mathbb{C}^g \subset \mathbb{C}$ we denote by [1]

- $\sigma(S(s))$ the set of invariant zeros,
- $\mathcal{V}^g(S(s))$ the largest element under all subspaces $\mathcal{U} \subset \mathbb{R}^n$ for which there exists an F with $(A + BF)\mathcal{U} \subset \mathcal{U}$ and $\mathcal{U} \subset \ker(H + EF)$ such that the restriction of $A + BF$ to \mathcal{U} has only eigenvalues in \mathbb{C}^g .
- $\mathcal{S}^g(S(s))$ the smallest element under all subspaces $\mathcal{U} \subset \mathbb{R}^n$ for which there exists a J with $(A + JH)\mathcal{U} \subset \mathcal{U}$ and $\text{im}(B + JE) \subset \mathcal{U}$ such that $(A + JH)^T|_{\mathcal{U}^\perp}$ has only eigenvalues in \mathbb{C}^g .

We recall the important duality relation

$$\mathcal{S}_g(S(s)) = \mathcal{V}^g(S(s))^T^\perp.$$

For $\mathbb{C}^g = \mathbb{C}$, $\mathbb{C}^g = \mathbb{C}^-$, $\mathbb{C}^g = \mathbb{C}^0$, and $\mathbb{C}^g = \mathbb{C}^+$, we denote the corresponding spaces by replacing g with $*$, $-$, 0 and $+$, respectively. If we choose some \mathbb{C}^g with $\sigma(S(s)) \cap \mathbb{C}^g = \emptyset$, we define (independently of the choice of \mathbb{C}^g)

$$\mathcal{R}^*(S(s)) := \mathcal{V}^g(S(s)) \quad \text{and} \quad \mathcal{N}_*(S(s)) := \mathcal{S}_g(S(s)).$$

Motivated by the results in [31], we introduce for any $\lambda \in \mathbb{C}$ the *complex* subspace

$$\mathcal{V}^\lambda(S(s)) := \left\{ x \in \mathbb{C}^n \mid \exists u \in \mathbb{C}^m : S(\lambda) \begin{pmatrix} x \\ u \end{pmatrix} = 0 \right\}$$

as well as

$$\mathcal{S}_\lambda(S(s)) := \left\{ x \in \mathbb{C}^n \mid \exists u \in \mathbb{C}^{n+m} : \begin{pmatrix} x \\ 0 \end{pmatrix} = S(\lambda) u \right\}$$

and obtain the duality relation

$$\mathcal{S}_\lambda(S(s)) = \mathcal{V}^{\bar{\lambda}}(S(s))^T^\perp.$$

These various subspaces are displayed in the best way using the famous canonical form of Morse [22], which was given for not necessarily strictly proper systems in [1]. This canonical form is derived for the so-called full transformation group consisting of coordinate changes, “state-feedback” and “output-injection” transformations. The orbit of $S(s)$ under this transformation group can be easily described as

$$\left\{ LS(s)R \mid L = \begin{pmatrix} U & J \\ 0 & V \end{pmatrix}, R = \begin{pmatrix} U^{-1} & 0 \\ F & W \end{pmatrix}, U \in \mathbb{R}^{n \times n}, V, W \text{ square and nonsingular} \right\}.$$

The transformation properties $\mathcal{V}^g(LS(s)R) = U\mathcal{V}^g(S(s))$ and $\mathcal{S}_g(LS(s)R) = U\mathcal{S}_g(S(s))$ (where L and R are partitioned and denoted as above) are well known and we easily verify the same relations for the spaces $\mathcal{V}^\lambda(S(s))$ and $\mathcal{S}_\lambda(S(s))$. It will be instrumental to restrict this transformation group to pure *coordinate changes* ($F=0$ and $J=0$) or, since we work with the Euclidean norm in the output space, even to *restricted coordinate changes*: $F=0$, $J=0$; V and W orthogonal. Note that the set of coordinate changes and restricted coordinate changes still form a group.

The structure of the transformed system in the following result cannot be immediately extracted from [22], [1], not even for general coordinate transformations.

THEOREM 2. *The system*

$$S_F(s) := \begin{pmatrix} A + BF - sI & B \\ H + EF & E \end{pmatrix}$$

with F defined by (11) can be transformed by restricted coordinate changes to

$$\tilde{S}(s) = \begin{pmatrix} \tilde{A} - sI & \tilde{B} \\ \tilde{H} & \tilde{E} \end{pmatrix} := \begin{pmatrix} A_1 - sI & J_1 H_2 & 0 & \Sigma_1 \\ B_2 F_1 & A_2 - sI & B_2 & \Sigma_2 \\ H_1 & 0 & 0 & 0 \\ 0 & H_2 & 0 & 0 \\ 0 & 0 & 0 & \Sigma \end{pmatrix}$$

with the following properties:

- (a) Σ is symmetric and nonsingular;
- (b) $\begin{pmatrix} A_2 - \lambda I & B_2 \\ H_2 & 0 \end{pmatrix}$ has maximal row rank for all $\lambda \in \mathbb{C}$;

- (c) $\mathcal{S}_g(\tilde{S}(s)) = \left\{ \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^n \mid x_1 \in \mathcal{S}_g \begin{pmatrix} A_1 - sI \\ H_1 \end{pmatrix} \right\} \text{ for any } \mathbb{C}^g;$
- (d) $\mathcal{S}_\lambda(\tilde{S}(s)) = \left\{ \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{C}^n \mid x_1 \in \mathcal{S}_\lambda \begin{pmatrix} A_1 - sI \\ H_1 \end{pmatrix} \right\} \text{ for all } \lambda \in \mathbb{C}.$

The proof of this transformation result is based on an interesting solvability criterion for a linear equation which has its origin in the solution of the regulator problem (combine Korollar 7.2 with Satz 7.4 in [19]).

LEMMA 3. *Suppose that*

$$\begin{pmatrix} A - \lambda I & B \\ H & 0 \end{pmatrix}$$

of the size $(n+k) \times (n+m)$ has maximal row rank for all $\lambda \in \mathbb{C}$. Given any $M \in \mathbb{R}^{l \times l}$, $R \in \mathbb{R}^{n \times l}$, and $S \in \mathbb{R}^{k \times l}$ ($l \in \mathbb{N}$), there exist X and Y with

$$AX - XM + BY = R, \quad HX = S.$$

Proof of Proposition 2. The singular value decomposition yields orthogonal V, W and a nonsingular $\Sigma = \Sigma^T$ such that VEW equals $\begin{pmatrix} 0 & 0 \\ 0 & \Sigma \end{pmatrix}$. By the choice of F , we obtain

$$\begin{pmatrix} I & 0 \\ 0 & V \end{pmatrix} S_F(s) \begin{pmatrix} I & 0 \\ 0 & W \end{pmatrix} = \begin{pmatrix} \bar{A} - sI & \bar{B} & \bar{\Sigma} \\ \bar{H} & 0 & 0 \\ 0 & 0 & \Sigma \end{pmatrix}.$$

We now transform the strictly proper system

$$\tilde{S}(s) := \begin{pmatrix} \bar{A} - sI & \bar{B} \\ \bar{H} & 0 \end{pmatrix}$$

to Morse's canonical form [22]. If reversing the performed state-feedback and output-injection transformations and repartitioning suitably, the transformed system admits the shape

$$\left(\begin{array}{cc|c} \bar{A}_1 - sI & \bar{J}_1 \bar{H}_2 & 0 \\ \bar{A}_{21} & \bar{A}_2 - sI & \bar{B}_2 \\ \hline \bar{H}_1 & 0 & 0 \\ 0 & \bar{H}_2 & 0 \end{array} \right)$$

such that

$$\begin{pmatrix} \bar{A}_2 - \lambda I & \bar{B}_2 \\ \bar{H}_2 & 0 \end{pmatrix}$$

has maximal row rank for all $\lambda \in \mathbb{C}$. Since we can obviously reverse the coordinate change in the input space without violating these properties, this transformation is possible by general coordinate changes in the state space and output space; we denote the corresponding matrices by \bar{U} and \bar{V} . We clearly have

$$H\bar{U}^{-1} = \bar{V}^{-1} \begin{pmatrix} \bar{H}_1 & 0 \\ 0 & \bar{H}_2 \end{pmatrix}$$

and can decompose \bar{V}^{-1} as

$$\tilde{V}^T \begin{pmatrix} T_1 & 0 \\ T_2 & T_3 \end{pmatrix}$$

with some *orthogonal* \tilde{V} to obtain

$$\tilde{V}H\bar{U}^{-1} = \begin{pmatrix} T_1\bar{H}_1 & 0 \\ T_2\bar{H}_1 & T_3\bar{H}_2 \end{pmatrix}.$$

Therefore $\bar{S}(s)$ can be transformed by *restricted* coordinate changes to

$$(12) \quad \left(\begin{array}{cc|c} \bar{A}_1 - sI & J_1 H_2 & 0 \\ \bar{A}_{21} & \bar{A}_2 - sI & B_2 \\ \hline H_1 & 0 & 0 \\ H_{21} & H_2 & 0 \end{array} \right)$$

and, still,

$$\begin{pmatrix} \bar{A}_2 - \lambda I & B_2 \\ H_2 & 0 \end{pmatrix}$$

has maximal row rank for all $\lambda \in \mathbb{C}$.

At this point apply Lemma 3 to remove H_{21} and to shape \bar{A}_{21} . There exist matrices X and F_1 with

$$\bar{A}_2 X - X(\bar{A}_1 - J_1 H_{21}) + \bar{A}_{21} - B_2 F_1 = 0, \quad H_2 X + H_{21} = 0.$$

If we add the X -right multiple of the second column of (12) to the first one and then the $(-X)$ -left multiple of the first row to the second one (which is just a coordinate change in the state space), we cancel H_{21} and change \bar{A}_{21} to $B_2 F_1$ as desired. Since the block \bar{A}_2 is just transformed to $A_2 := \bar{A}_2 - X J_1 H_2$, condition (b) still holds.

If $S_2(s)$ denotes the system appearing in (b) and n_2 is the dimension of A_2 , the observations $\mathcal{S}_g(S_2(s)) = \mathbb{R}^{n_2}$ (for any \mathbb{C}^g) and $\mathcal{S}_\lambda(S_2(s)) = \mathbb{C}^{n_2}$ (for any $\lambda \in \mathbb{C}$) finish the proof. \square

The main reason for transforming to this special form is property (b) in Theorem 2. As it is known from the theory of almost disturbance decoupling, such a right-invertible system without any zeros has the following very appealing property [39], [36].

THEOREM 4. *If*

$$\begin{pmatrix} A - \lambda I & B \\ H & 0 \end{pmatrix}$$

has maximal row rank for all $\lambda \in \mathbb{C}$, there exists a sequence of feedback matrices F_j such that $A + B F_j$ is stable and

$$\lim_{j \rightarrow \infty} \|H(sI - A - B F_j)^{-1}\|_\infty = 0 \quad \text{as well as} \quad \lim_{j \rightarrow \infty} \int_0^\infty \|H e^{(A + B F_j)t}\|^2 dt = 0$$

hold true.

As noted in § 3, we will work with the Riccati map $R(\cdot, \cdot)$ and with $A(\cdot)$ even if E does not have maximal column rank. It is important to know how these maps behave under restricted coordinate changes. Let U denote the state-transformation matrix in $S(s) \rightarrow \tilde{S}(s)$, i.e., $U(A + BF)U^{-1} = \tilde{A}$. Then we have to transform G as

$$\tilde{G} = \begin{pmatrix} G_1 \\ G_2 \end{pmatrix} := UG.$$

We denote by $\tilde{R}(\cdot, \cdot)$ and $\tilde{A}(\cdot)$ the maps for the transformed data $\tilde{S}(s)$ and \tilde{G} , which are given by

$$\tilde{R}(X, \mu) = \tilde{A}X + X\tilde{A}^T + X\tilde{H}^T\tilde{H}X + \mu\tilde{G}\tilde{G}^T - \tilde{B}(\tilde{E}^T\tilde{E})^+\tilde{B} \quad \text{and} \quad \tilde{A}(X) = \tilde{A} + X\tilde{H}^T\tilde{H}.$$

The following result is verified by computation. The verification exhibits the reason for introducing the notion of restricted coordinate changes: We must make essential use of the orthogonality of *both* transformations in the input space and the output space.

LEMMA 5. *For any $X \in \mathbb{S}^n$ and $\mu \in \mathbb{R}$, the equations $UR(X, \mu)U^T = \tilde{R}(UXU^T, \mu)$ and $UA(X)U^{-1} = \tilde{A}(UXU^T)$ hold true.*

5. H_∞ -optimization by static state feedback. Our aim is to provide reasonable and verifiable characterizations for the set

$$\mathcal{P}_\mu := \{P > 0 \mid \exists F: (A + BF)^T P + P(A + BF) + \mu PGG^T P + (H + EF)^T(H + EF) < 0\}$$

to be nonempty if μ is positive.

The reader should recall the interpretation of the ARI (3) as explained in § 3, which shows that all the results of this section have immediate consequences for the general H_∞ -optimization problem by *static state feedback*. Let us denote its optimal value by

$$\mu_* := \sup \{ \|(H + EF)(sI - A - BF)^{-1}G\|_\infty^{-2} \mid \sigma(A + BF) \subset \mathbb{C}^- \}.$$

As an example, we mention the problem of *maximizing the complex stability radius by feedback*, which is just our H_∞ -optimization problem for $E = 0$ [13].

Remark. From Theorem 6 we extract the following well-known conclusion for the state-feedback H_∞ -problem: In the case where $C = I$ and $D = 0$, the optimal value μ_{opt} for *dynamic* controllers coincides with μ_* .

We define $S(s)$, G , $R(\cdot, \cdot)$, $A(\cdot)$ and the transformed objects $\tilde{S}(s)$, \tilde{G} , $\tilde{R}(\cdot, \cdot)$, $\tilde{A}(\cdot)$ as well as the state transformation matrix U as in § 4, where $\tilde{S}(s)$ has all the properties listed in Theorem 2. If any of the subspaces introduced in § 4 are defined with respect to $S(s)$, we drop the argument.

Our first suboptimality test is one of the central results of this paper.

THEOREM 6. *Suppose $\mu > 0$. Then $\mu < \mu_*$ if and only if the ARI*

$$(13) \quad A_1 X + X A_1^T + X H_1^T H_1 X + \mu G_1 G_1^T - (J_1 \quad \Sigma_1 \Sigma^{-1})(J_1 \quad \Sigma_1 \Sigma^{-1})^T < 0$$

has a positive definite solution.

Therefore $\mu < \mu_*$ can be tested by seeing whether or not a certain reduced-order algebraic Riccati inequality has a positive definite solution. The ARI is written in a suggestive way. If we introduce

$$(14) \quad B_1 := (J_1 \quad \Sigma_1 \Sigma^{-1}),$$

the ARI (13) has a positive definite solution if and only if $\mu > 0$ is suboptimal for the *regular* H_∞ -problem in which the underlying system is given by

$$(15) \quad S_1(s) := \begin{pmatrix} A_1 - sI & B_1 \\ H_1 & 0 \\ 0 & I \end{pmatrix}$$

and G_1 is the disturbance input matrix. This shows the only difference if comparing regular and singular problems: For regular problems, the suboptimality can be tested by looking at an ARI defined in terms of the original system matrices. For singular problems, we must transform the system and test the suboptimality for a certain (regular) subsystem. The reduction to the regular subsystem may be viewed as factoring out the “unproblematic” part of the system, which is constituted by the finite but assignable zeros and by the infinite zero structure (the \mathcal{S}_* -part of the system). The subsystem (15) is determined by the “relevant” part of the plant, which is determined

by the zeros of $S(s)$ (and in particular by those in \mathbb{C}^0 and \mathbb{C}^+) as well as the part of $S(s)$ “outside \mathcal{N}_* ,” which is related to the “observable part” of

$$\begin{pmatrix} A_1 - sI \\ H_1 \end{pmatrix}$$

and due to the nontriviality of H_1 [31, § 4].

Proof. By the very definition of restricted coordinate changes, we can work without restriction with the transformed data $\tilde{S}(s)$, \tilde{G} .

Suppose $\mu < \mu_*$ and choose some F and $X > 0$ with

$$(16) \quad (\tilde{A} + \tilde{B}F)X + X(\tilde{A} + \tilde{B}F)^T + X(\tilde{H} + \tilde{E}F)^T(\tilde{H} + \tilde{E}F)X + \mu\tilde{G}\tilde{G}^T < 0.$$

We now partition

$$X = \begin{pmatrix} X_1 & X_{12} \\ X_{12}^T & X_2 \end{pmatrix}$$

according to \tilde{A} and FX as $\begin{pmatrix} * & * \\ * & * \end{pmatrix}$ according to the column partition of \tilde{B} and the row partition of \tilde{A} . Then we compute the (1, 1) block of the ARI (16) to obtain (recalling $\Sigma = \Sigma^T$)

$$\begin{aligned} & A_1X_1 + X_1A_1^T + J_1H_2X_{12}^T + (J_1H_2X_{12}^T)^T + \Sigma_1\tilde{F} + (\Sigma_1\tilde{F})^T \\ & + X_1H_1^TH_1X_1 + X_{12}H_2^TH_2X_{12}^T + \tilde{F}^T\Sigma^2\tilde{F} + \mu G_1G_1^T < 0. \end{aligned}$$

An obvious completion of the squares delivers

$$\begin{aligned} & A_1X_1 + X_1A_1^T + X_1H_1^TH_1X_1 + \mu G_1G_1^T - J_1J_1^T - \Sigma_1\Sigma^{-2}\Sigma_1 \\ & + (J_1 + X_{12}H_2^T)(J_1 + X_{12}H_2^T)^T + (\Sigma^{-2}\Sigma_1^T + \tilde{F})^T\Sigma^2(\Sigma^{-2}\Sigma_1^T + \tilde{F}) < 0. \end{aligned}$$

This already proves the necessity part.

For the proof of sufficiency it is enough to construct some \tilde{F} with

$$(17) \quad \sigma(\tilde{A} + \tilde{B}\tilde{F}) \subset \mathbb{C}^-$$

and such that the H_∞ -norm of

$$(18) \quad (\tilde{H} + \tilde{E}\tilde{F})(sI - \tilde{A} - \tilde{B}\tilde{F})^{-1}\tilde{G}$$

is smaller than $1/\sqrt{\mu}$.

Now suppose that the ARI (13) has the positive definite solution X_1 . Then there exists some F (e.g., $F := -B_1^TX_1^{-1}$) [31] such that

$$A_1 + B_1F$$

is stable and the inequality

$$(19) \quad \left\| \begin{pmatrix} H_1 \\ F \end{pmatrix} H(s) G_1 \right\|_\infty < \frac{1}{\sqrt{\mu}}$$

holds for $H(s) := (A_1 + B_1F - sI)^{-1}$. Let us partition $F = \begin{pmatrix} F_s \\ F_z \end{pmatrix}$ according to the column partitioning of B_1 in (14).

Exploiting the properties of the structure at infinity, it is possible to approximate the transfer matrix in (19) by (18) in the H_∞ -norm, if \tilde{F} is a suitably chosen feedback

matrix with (17). If the error is small enough, the proof is finished. An obvious feedback transformation of $\tilde{S}(s)$ leads to

$$(20) \quad \begin{pmatrix} A_1 + \Sigma_1 \Sigma^{-1} F_\Sigma - sI & J_1 H_2 & 0 & \Sigma_1 & G_1 \\ 0 & A_2 - sI & B_2 & \Sigma_2 & G_2 \\ H_1 & 0 & 0 & 0 & 0 \\ 0 & H_2 & 0 & 0 & 0 \\ F_\Sigma & 0 & 0 & \Sigma & 0 \end{pmatrix}.$$

According to Lemma 3, there exist X and Y with

$$A_2 X - X(A_1 + B_1 F) - B_2 Y = 0 \quad \text{and} \quad H_2 X = F_j.$$

We now add the X -right multiple of the second column of (20) to the first one and the $(-X)$ -left multiple of the first row of the resulting pencil to its second row (which amounts to a coordinate change for (20) in the state-space). After a suitable feedback to eliminate the $(2, 1)$ block, we obtain

$$\begin{pmatrix} A_1 + B_1 F - sI & J_1 H_2 & 0 & \Sigma_1 & G_1 \\ 0 & \tilde{A}_2 - sI & B_2 & \tilde{\Sigma}_2 & \tilde{G}_2 \\ H_1 & 0 & 0 & 0 & 0 \\ F_j & H_2 & 0 & 0 & 0 \\ F_\Sigma & 0 & 0 & \Sigma & 0 \end{pmatrix}$$

with $\tilde{A}_2 := A_2 - XJ_1 H_2$, $\tilde{\Sigma}_2 := \Sigma_2 - X\Sigma_1$ and $\tilde{G}_2 := G_2 - XG_1$. Therefore

$$\begin{pmatrix} \tilde{A}_2 - \lambda I & B_2 \\ H_2 & 0 \end{pmatrix}$$

still has maximal row rank for all $\lambda \in \mathbb{C}$. By Theorem 4, we can hence construct a sequence $F_2(j)$ such that $\tilde{A}_2 + B_2 F_2(j)$ is stable and

$$(21) \quad \lim_{j \rightarrow \infty} \|H_2 H_j(s)\|_\infty^2 = 0$$

holds for $H_j(s) := (\tilde{A}_2 + B_2 F_2(j) - sI)^{-1}$. A last feedback finally leads to the closed-loop system

$$\left(\begin{array}{cc|c} A_1 + B_1 F - sI & J_1 H_2 & G_1 \\ 0 & \tilde{A}_2 + B_2 F_2(j) - sI & \tilde{G}_2 \\ \hline H_1 & 0 & 0 \\ F_j & H_2 & 0 \\ F_\Sigma & 0 & 0 \end{array} \right).$$

This system is internally stable. Moreover, its transfer matrix equals

$$(22) \quad \begin{pmatrix} H_1 & 0 \\ F_j & H_2 \\ F_\Sigma & 0 \end{pmatrix} \begin{pmatrix} H(s) & -H(s)J_1 H_2 H_j(s) \\ 0 & H_j(s) \end{pmatrix} \begin{pmatrix} G_1 \\ \tilde{G}_2 \end{pmatrix}$$

by the formula for the inverse of a block matrix. Hence we can infer from (19) and (21) that the H_∞ -norm of (22) is less than $1/\sqrt{\mu}$ for some j which is sufficiently large. \square

The proof contains an explicit construction of stabilizing suboptimal feedback matrices which yield a closed-loop system with a block triangular structure. Since we make no *special* choices for the μ -suboptimal feedbacks for the regular H_∞ -subproblem (called F) and the sequence of feedbacks on the infinite zero structure used for the approximation (denoted as $F_2(j)$), it is possible to take into account additional freedom (e.g., pole placement requirements) or simplifications for the construction of these matrices [31], [36].

If we combine Theorem 6 with the results in [31] we conclude:

The optimal value μ_* of the general state-feedback H_∞ -problem for $S(s)$ and G can be computed by a quadratically convergent algorithm. The infinite zeros of $S(s)$ only cause additional *algebraic* effort for transforming $S(s)$ into $\tilde{S}(s)$.

Another technique to construct suboptimal static feedback matrices is to perturb H and E such that the perturbation of E has maximal column rank. Since we want to allow for rather general perturbation schemes, we introduce the following notion.

DEFINITION 7. The family $(0, \infty) \ni \varepsilon \rightarrow (H_\varepsilon \ E_\varepsilon) \in \mathbb{R}^{(k+p) \times (n+m)}$, $p \in \mathbb{N}_0$, is called an *admissible perturbation* of $(H \ E) \in \mathbb{R}^{k \times (n+m)}$ if the following conditions are satisfied:

- (a) $\lim_{\varepsilon \rightarrow 0} (H_\varepsilon \ E_\varepsilon) = \begin{pmatrix} H & E \\ 0 & 0 \end{pmatrix} \in \mathbb{R}^{(k+p) \times (n+m)}$;
- (b) $(H \ E)^T (H \ E) \leq (H_\varepsilon \ E_\varepsilon)^T (H_\varepsilon \ E_\varepsilon)$ for $\varepsilon > 0$;
- (c) E_ε has maximal column rank for $\varepsilon > 0$.

THEOREM 8. Suppose that $P > 0$ satisfies

$$(23) \quad A^T P + P A + H_\varepsilon^T H_\varepsilon + \mu P G G^T P - (P B + H_\varepsilon^T E_\varepsilon)(E_\varepsilon^T E_\varepsilon)^{-1}(E_\varepsilon^T H_\varepsilon + B^T P) < 0$$

for some $\varepsilon > 0$. If defining F by

$$F := -(E_\varepsilon^T E_\varepsilon)^{-1}(E_\varepsilon^T H_\varepsilon + B^T P),$$

P satisfies the ARI (3) and is thus an element of \mathcal{P}_μ . If P is contained in \mathcal{P}_μ , there exists an $\varepsilon > 0$ such that P solves (23).

Proof. According to the different possible representations of the Riccati map as presented in § 4, the ARI (23) can be rearranged to

$$(24) \quad (A + B F)^T P + P(A + B F) + \mu P G G^T P + (H_\varepsilon + E_\varepsilon F)^T (H_\varepsilon + E_\varepsilon F) < 0.$$

The inequality (b) implies $(H + E F)^T (H + E F) \leq (H_\varepsilon + E_\varepsilon F)^T (H_\varepsilon + E_\varepsilon F)$, which yields $P \in \mathcal{P}_\mu$. The convergence property (a) shows that there exists for $P \in \mathcal{P}_\mu$ some F and some $\varepsilon > 0$ for which (24) holds. Since E_ε has maximal column rank by (c), a standard completion of the squares argument leads to the ARI (23). \square

The union of all positive definite solutions of (23) over all $\varepsilon > 0$ therefore coincides with \mathcal{P}_μ . This result allows us to construct a suboptimal feedback matrix by finding a suitable $\varepsilon > 0$, in fact, directly in terms of the system data without any preliminary transformation. In practice, however, the choice of $\varepsilon > 0$ remains as a problem.

From a computational point of view, we arrive at a satisfactory solution of the state-feedback H_∞ -problem. However, we wish as well to have an algebraic characterization (without referring to perturbations) of suboptimality for which no preliminary transformation of the plant is required and which is directly formulated in terms of the original data $S(s)$ and G . Indeed it is possible to generalize the criterion we derived in [31]. We first define the set $\mathcal{T}(\mu)$ (apart from an additional invariance requirement) literally as in [31, § 4].

DEFINITION 9. For any $\mu \in \mathbb{R}$, $\mathcal{T}(\mu)$ is the set of all matrices $Z \in \mathbb{S}^n$ such that

- \mathcal{S}_* is $A(Z)$ -invariant,
- the restriction of $A(Z)^T$ to \mathcal{S}_+^\perp has all its eigenvalues in \mathbb{C}^+ ,
- $x^T R(Z, \mu) y$ vanishes for $x \in \mathcal{S}_+^\perp$ and $y \in \mathcal{S}_+^\perp + \mathcal{S}_0^\perp$.

We stress that $A(Z)\mathcal{S}_* \subset \mathcal{S}_*$ implies $A(Z)^T \mathcal{S}_+^\perp \subset \mathcal{S}_+^\perp$ such that the definition makes sense. Now we can formulate an abstract but algebraically verifiable suboptimality test in terms of the original data matrices.

THEOREM 10. Suppose $\mu > 0$. Then $\mu < \mu_*$ if and only if there exists some $Z \in \mathcal{T}(\mu)$ such that

$$(25) \quad Z \text{ is positive on } \mathcal{S}_+^\perp \text{ and } R(Z, \mu) \text{ is negative on } \bigcup_{\lambda \in \mathbb{C}^0} \mathcal{S}_\lambda^\perp \setminus \mathcal{S}_+^\perp.$$

How do the matrices in $\mathcal{T}(\mu)$ look and how should these conditions be understood? The answer is simple and is motivated by Theorem 6. According to Definition 9, we introduce the set $\mathcal{T}_1(\mu)$ for the Riccati map

$$R_1(X, \mu) := A_1 X + X A_1^T + X H_1^T H_1 X + \mu G_1 G_1^T - B_1 B_1^T,$$

where the underlying system is $S_1(s)$ as defined in (15). By

$$(26) \quad \mathcal{S}_g(S_1(s)) = \mathcal{S}_g \begin{pmatrix} A_1 - sI \\ H_1 \end{pmatrix}$$

for any \mathbb{C}^g or $g = \lambda \in \mathbb{C}$, this is just the linear manifold we discussed intensively in [31]. The following result displays the simple relation of $\mathcal{T}(\mu)$ and $\mathcal{T}_1(\mu)$. Moreover, the combination of Theorem 6 and [31, Thm. 10] with the properties of the quadratic forms appearing in the Lemma 11 proves our abstract suboptimality criterion.

LEMMA 11. It holds that

$$\mathcal{T}(\mu) = U^{-1} \left\{ \begin{pmatrix} Z_1 & Z_{12} \\ Z_{12}^T & Z_2 \end{pmatrix} \in \mathbb{S}^n \mid Z_1 \in \mathcal{T}_1(\mu), Z_{12} \text{ satisfies } J_1 + Z_{12} H_2^T = 0 \right\} U^{-T}.$$

Moreover, if choosing $Z \in \mathcal{T}(\mu)$ and $Z_1 \in \mathcal{T}_1(\mu)$, then

$$\begin{aligned} \{x^* Z x \mid x \in \mathcal{S}_+^\perp\} &= \{x^* Z_1 x \mid x \in \mathcal{S}_+(S_1(s))^\perp\}, \\ \{x^* R(Z, \mu) x \mid x \in \mathcal{S}_\lambda^\perp\} &= \{x^* R_1(Z_1, \mu) x \mid x \in \mathcal{S}_\lambda(S_1(s))^\perp\} \end{aligned}$$

hold for any $\lambda \in \mathbb{C}^0$.

Proof. Lemma 5 and the transformation properties of $\mathcal{S}_g(\cdot)$ for $g = +, 0, \lambda \in \mathbb{C}$ show that we can prove the lemma without restriction for the system $\tilde{S}(s)$ and \tilde{G} . If partitioning any $Z \in \mathbb{S}^n$, $\tilde{A}(Z)$ and $\tilde{R}(Z, \mu)$ as \tilde{A} , we easily compute

$$\tilde{A}(Z) = \begin{pmatrix} A_1 + Z_1 H_1^T H_1 & J_1 H_2 + Z_{12} H_2^T H_2 \\ * & * \end{pmatrix}$$

and the blocks $\tilde{R}_1(Z, \mu)$, $\tilde{R}_{12}(Z, \mu)$, and $\tilde{R}_2(Z, \mu)$ of $\tilde{R}(Z, \mu)$, which are given by

$$\begin{aligned} &A_1 Z_1 + Z_1 A_1^T + Z_1 H_1^T H_1 Z_1 + \mu G_1 G_1^T - \Sigma_1 \Sigma^{-2} \Sigma_1^T - J_1 J_1^T + (J_1 + Z_{12} H_2^T)(J_1 + Z_{12} H_2^T)^T, \\ &(A_1 + Z_1 H_1^T H_1) Z_{12} + Z_{12} A_2^T + Z_1 F_1^T B_2^T + (J_1 + Z_{12} H_2^T) H_2 Z_2 + \mu G_1 G_2^T - \Sigma_1 \Sigma^{-2} \Sigma_2^T, \\ &A_2 Z_2 + Z_2 A_2^T + Z_2 H_2^T H_2 Z_2 - \Sigma_2 \Sigma^{-2} \Sigma_2^T + \mu G_2 G_2^T + Z_{12}^T H_1^T H_1 Z_{12} + B_2 F_1 Z_{12} + Z_{12}^T F_1^T B_2^T, \end{aligned}$$

respectively. The combination of Theorem 2 with (26) implies

$$\mathcal{S}_g^\perp(\tilde{S}(s)) = \left\{ x = \begin{pmatrix} x_1 \\ 0 \end{pmatrix} \mid x_1 \in \mathcal{S}_g(S_1(s))^\perp \right\}$$

for all \mathbb{C}^g or $g = \lambda \in \mathbb{C}$.

We infer that $\tilde{A}(Z)$ leaves $\mathcal{S}_*(\tilde{S}(s))$ invariant if and only if $J_1 H_2 + Z_{12} H_2^T H_2 = 0$, or, since H_2 has maximal row rank, $J_1 + Z_{12} H_2^T = 0$.

Now suppose that $J_1 + Z_{12}H_2^T$ vanishes. Then $\tilde{A}(Z)^T$ is antistable on $\mathcal{S}_+(\tilde{S}(s))^\perp$ if and only if $(A_1 + Z_1H_1^TH_1)^T$ is antistable on $\mathcal{S}_+(S_1(s))^\perp$. Moreover we obviously have $\tilde{R}_1(Z, \mu) = R_1(Z_1, \mu)$. If we choose $x = (x_1^* 0)^* \in \mathcal{S}_+^\perp(\tilde{S}(s))$ and $y = (y_1^* 0) \in \mathcal{S}_+^\perp(\tilde{S}(s)) + \mathcal{S}_0^\perp(\tilde{S}(s))$, we infer $x^TR(Z, \mu)y = x_1^TR_1(Z_1, \mu)y_1$. This already proves the relation of $\mathcal{T}(\mu)$ and $\mathcal{T}_1(\mu)$.

Now take $x = (x_1^* 0)^* \in \mathcal{S}_+^\perp(\tilde{S}(s))$ and $y = (y_1^* 0)^* \in \mathcal{S}_\lambda^\perp(\tilde{S}(s))$ for some $\lambda \in \mathbb{C}^0$. We infer $x^*Zx = x_1^*Z_1x_1$ and $y^TR(Z, \mu)y = y_1^TR_1(Z_1, \mu)y_1$ and just have to note that neither $x_1^*Z_1x_1$ nor $y_1^TR_1(Z_1, \mu)y_1$ depend on the particular choice of $Z_1 \in \mathcal{T}_1(\mu)$ to finish the proof. \square

Remark. Lemma 11 shows that $\mathcal{T}(\mu)$, if nonempty, is a linear manifold in \mathbb{S}^n . Moreover, the positivity/negativity conditions (25) hold for *one* $Z \in \mathcal{T}(\mu)$ if and only if they hold for *all* $Z \in \mathcal{T}(\mu)$. Therefore it suffices to choose one element $Z \in \mathcal{T}(\mu)$ and to verify (25) for this particular Z . This can be done explicitly as explained in [31].

We should recall the following intuitive interpretation of $\mathcal{T}(\mu)$: $\mathcal{T}(\mu)$ is nonempty if and only if a certain reduced-order Riccati equation has a (unique) antistabilizing solution. A parametrization of $\mathcal{T}(\mu)$ is computed by solving this ARE and two (always solvable) linear equations. Positivity of $\mathcal{T}(\mu)$ on \mathcal{S}_+^\perp is related to the positive definiteness of the ARE solution. The negativity of $R(\mathcal{T}(\mu), \mu)$ on $\mathcal{S}_\lambda^\perp \setminus \mathcal{S}_+^\perp$ for all $\lambda \in \mathbb{C}^0$ is related to the solvability of a reduced-order Lyapunov inequality.

Let us introduce the following critical parameters:

$$\begin{aligned} \mu_{\max}: \quad & \mu < \mu_{\max} \Leftrightarrow \mathcal{T}(\mu) \neq \emptyset, \\ \mu_{\text{pos}}: \quad & \mu < \mu_{\text{pos}} \Leftrightarrow \mu < \mu_{\max}, \mathcal{T}(\mu) \text{ is positive on } \mathcal{S}_+^\perp, \\ \mu_{\text{neg}}: \quad & \mu < \mu_{\text{neg}} \Leftrightarrow \mu < \mu_{\max}, R(\mathcal{T}(\mu), \mu) \text{ is negative on } \bigcup_{\lambda \in \mathbb{C}^0} \mathcal{S}_\lambda^\perp \setminus \mathcal{S}_+^\perp, \end{aligned}$$

which obviously lead to

$$\mu_* = \min \{\mu_{\text{pos}}, \mu_{\text{neg}}\}.$$

We can again refer to [31] for the fast computation of all these parameters since they coincide with those for $T_1(\mu)$. Moreover, μ_* coincides with μ_{pos} if $S(s)$ has no invariant zeros on the imaginary axis. Due to the \mathbb{C}^0 -zeros of $S(s)$, the optimal value may jump from μ_{pos} to $\min \{\mu_{\text{pos}}, \mu_{\text{neg}}\}$. In fact, μ_{neg} has its own system theoretic significance.

Remark. Suppose that $(A - sI \ B)$ is stabilizable with respect to \mathbb{C}^0 . Along the lines of our approach to the H_∞ -problem and exploiting [31, Thm. 3(a)], we can prove for any $\mu > 0$ the following equivalences:

$$\begin{aligned} \exists F: \quad & \sigma(A + BF) \cap \mathbb{C}^0 = \emptyset, \quad \mu < \|(H + EF)(sI - A - BF)^{-1}G\|_\infty^{-2} \\ & \Leftrightarrow \\ \exists P \in \mathbb{S}^n: \quad & (A + BF)^TP + P(A + BF) + \mu PGG^TP + (H + EF)^T(H + EF) < 0 \\ & \Leftrightarrow \\ & \mu < \mu_{\text{neg}}. \end{aligned}$$

This implies that μ_{neg} is the optimal value of the L_∞ -optimization problem

$$\sup \{ \|(H + EF)(sI - A - BF)^{-1}G\|_\infty^{-2} \mid \sigma(A + BF) \cap \mathbb{C}^0 = \emptyset \}.$$

Let us conclude this section with an algebraic characterization of $\mu_{\max} = \infty$, $\mu_{\text{pos}} = \infty$, and $\mu_{\text{neg}} = \infty$. By [31, Thm. 13] the following result no longer needs proof.

THEOREM 12. (a) $\mu_{\max} = \infty$ if and only if $\text{im}(G) \subset \mathcal{N}_*(S(s))$. In the case of $\mu_{\max} = \infty$, the parameters μ_{pos} and μ_{neg} can be computed by solving Hermitian eigenvalue problems.

- (b) $\mu_{\text{pos}} = \infty$ if and only if $\text{im}(G) \subset \mathcal{S}_+$.
 (c) $\mu_{\text{neg}} = \infty$ if and only if $\text{im}(G) \subset \bigcap_{\lambda \in \mathbb{C}^0} \mathcal{S}_\lambda$.

6. The solution of the general H_∞ -optimization problem. We have discussed in § 5 how to test algebraically whether or not \mathcal{P}_μ is nonempty. If we introduce

$$\mathcal{Q}_\nu := \{Q > 0 \mid \exists J: (A + JC)Q + Q(A + JC)^T + \nu QH^T H Q + (G + JD)(G + JD)^T < 0\},$$

it is possible by dualization to check $\mathcal{Q}_\nu \neq \emptyset$ in the same way. We have even shown how to compute the critical parameters μ_* and ν_* such that $\mathcal{P}_\mu, \mathcal{Q}_\nu$ are nonempty if and only if $\mu < \mu_*, \nu < \nu_*$. Therefore it remains to verify the coupling condition (5) for $\mu < \min\{\mu_*, \nu_*\}$. If we tried to test this condition directly, we would be confronted with the difficulty of finding *suitable* $P \in \mathcal{P}_\mu$ and $Q \in \mathcal{Q}_\mu$, but is it not clear how to make a concrete choice. At this point the introduction of lower limit as discussed in [31] for general Riccati inequalities proves to be very fruitful. Let $P_1(\mu)$ denote the strict lower limit point of the set of inverses of all positive definite solutions of (13). We stress that it is simple to compute $P_1(\mu)$ by solving one well-defined reduced-order Riccati equation [31, Thm. 9].

THEOREM 13. *For $\mu < \mu_*$, the set \mathcal{P}_μ has a strict lower limit point $P(\mu)$, which is given by*

$$P(\mu) = U^T \begin{pmatrix} P_1(\mu) & 0 \\ 0 & 0 \end{pmatrix} U.$$

Dually, the set \mathcal{Q}_ν has a *computable* strict lower limit point $Q(\nu)$ for $\nu < \nu_*$. This solves our problem: Fix $\mu < \min\{\mu_*, \nu_*\}$. Suppose that $P \in \mathcal{P}_\mu$ and $Q \in \mathcal{Q}_\mu$ satisfy (5). By $P(\mu) < P$ and $Q(\mu) < Q$, we obtain

$$(27) \quad \rho(P(\mu)Q(\mu)) < \frac{1}{\mu}.$$

Now assume (27). There exist sequences $P_j \in \mathcal{P}_\mu$ and $Q_j \in \mathcal{Q}_\mu$ with $P_j \rightarrow P(\mu)$ and $Q_j \rightarrow Q(\mu)$ for $j \rightarrow \infty$. By (27), there exists a sufficiently large j with $\rho(P_j Q_j) < 1/\mu$. We arrive at the central result of this paper.

THEOREM 14. *The positive parameter μ satisfies $\mu < \mu_{\text{opt}}$ if and only if*

$$\mu < \mu_*, \quad \mu < \nu_*, \quad \text{and} \quad \rho(P(\mu)Q(\mu)) < \frac{1}{\mu}.$$

As shown in § 5, the inequalities $\mu < \mu_*$ and $\mu < \nu_*$ can be tested algebraically. Moreover, we recall the detailed investigation of the influence of the various zeros of $S(s)$ and $T(s)$ on both values μ_* and ν_* in [31, § 4]. From the explicit formula for $P(\mu)$ and, dually, for $Q(\mu)$ it is obvious that these matrices are *not influenced by the \mathbb{C}^0 -zeros* of $S(s)$ and $T(s)$, which may be expressed as follows:

The \mathbb{C}^0 -zeros of $S(s)$ and $T(s)$ do not cause additional coupling constraints.

It remains to prove Theorem 13, which is again based on the nice properties of the subsystem of $\tilde{S}(s)$ appearing in Theorem 2(b). In particular we exhibit in Proposition 15 the striking flexibility of the Riccati map defined for a right invertible system without any zeros. Its proof is given in the Appendix.

PROPOSITION 15. *Let*

$$S(\lambda) = \begin{pmatrix} A - \lambda I & B \\ H & 0 \end{pmatrix}$$

have maximal row rank for all $\lambda \in \mathbb{C}$. Then for all $X_0 \in \mathbb{S}^n$ and $R_0 \in \mathbb{S}^n$ there exist an $\varepsilon > 0$ and an $X \in \mathbb{S}^n$ with

$$X > X_0 \quad \text{and} \quad AX + XA^T + XH^T HX - \frac{BB^T}{\varepsilon^2} < R_0.$$

Proof of Theorem 13. We can again assume without restriction that

$$S(s) = \tilde{S}(s) \quad \text{with} \quad F_1 = 0 \quad \text{and} \quad G = \tilde{G}.$$

Choose $P \in \mathcal{P}_\mu$. Take any F such that $X := P^{-1}$ satisfies (16). We proved that the $(1, 1)$ block X_1 of X solves the ARI (13) and we infer by the definition of $P_1(\mu)$ the inequality $P_1(\mu) < X_1^{-1}$. Lemma 14 in [31] shows one part of the claim:

$$P(\mu) := \begin{pmatrix} P_1(\mu) & 0 \\ 0 & 0 \end{pmatrix} < P.$$

Let us now define the admissible perturbation

$$\tilde{H}_\varepsilon := \begin{pmatrix} H_1 & 0 \\ 0 & H_2 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad \tilde{E}_\varepsilon := \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & \Sigma \\ \varepsilon I & 0 \end{pmatrix}$$

and, for notational simplicity, the Riccati map

$$\tilde{R}_\varepsilon(X, \mu) := \tilde{A}X + X\tilde{A}^T + X\tilde{H}_\varepsilon^T \tilde{H}_\varepsilon X + \mu \tilde{G}\tilde{G}^T - \tilde{B}(\tilde{E}_\varepsilon^T \tilde{E}_\varepsilon)^{-1} \tilde{B}^T.$$

According to Theorem 8, it suffices to construct sequences $\varepsilon_j > 0$ and $X(j) > 0$ which satisfy $\tilde{R}_{\varepsilon_j}(X(j), \mu) < 0$ and $X(j)^{-1} \rightarrow P(\mu)$ for $j \rightarrow \infty$. We exploit the obvious relation

$$\tilde{R}_\varepsilon(X, \mu) = \tilde{R}(X, \mu) + \begin{pmatrix} 0 & 0 \\ 0 & -(1/\varepsilon^2)B_2B_2^T \end{pmatrix}$$

and note that we already computed the blocks of $\tilde{R}(X, \mu)$ in the proof of Lemma 11. By the definition of $P_1(\mu)$, we can find a sequence $X_1(j) > 0$ of solutions of the ARI (13) with $X_1(j)^{-1} \rightarrow P_1(\mu)$ for $j \rightarrow \infty$. Moreover, we define $X_{12}(j) \equiv X_{12}$, where X_{12} satisfies $J_1 + X_{12}H_2^T = 0$. If we look at the structure of $\tilde{R}_2(\cdot, \mu) - (1/\varepsilon^2)B_2B_2^T$, we can deduce from Proposition 15 the existence of sequences $\varepsilon_j > 0$ and $X_2(j)$ such that

$$X(j) := \begin{pmatrix} X_1(j) & X_{12} \\ X_{12}^T & X_2(j) \end{pmatrix}$$

is positive definite, $X_2(j)^{-1}$ converges to 0 for $j \rightarrow \infty$, and $\tilde{R}_{\varepsilon_j}(X(j), \mu)$ is negative definite. Again by [31, Lemma 14], we infer $X(j)^{-1} \rightarrow P(\mu)$ for $j \rightarrow \infty$. \square

7. The computation of the optimal value. We have intensively discussed [30], [31] how to compute the critical parameters μ_{pos} , μ_{neg} , and μ_{max} for $(S(s) \ G)$ and those for $(T(s)^T \ H^T)$ denoted as ν_{pos} , ν_{neg} , and ν_{max} .

In § 6 we introduced $P(\cdot)$ on $(-\infty, \mu_*)$ and $Q(\cdot)$ on $(-\infty, \nu_*)$ and proved that we only have to find in addition

$$\mu_{\text{cou}} := \sup \left\{ \mu < \min \{ \mu_*, \nu_* \} \mid \rho(P(\mu)Q(\mu)) < \frac{1}{\mu} \right\}$$

to determine μ_{opt} .

If we combine Theorem 13 with [31, Thm. 9], there exist nonsingular constant matrices S, T with

$$P(\mu) = S^T \begin{pmatrix} X(\mu)^{-1} & 0 \\ 0 & 0 \end{pmatrix} S, \quad X(\mu) > 0, \quad \text{for } \mu < \mu_*$$

and

$$Q(\nu) = T^T \begin{pmatrix} Z(\nu)^{-1} & 0 \\ 0 & 0 \end{pmatrix} T, \quad Z(\nu) > 0, \quad \text{for } \nu < \nu_*.$$

Let us denote the left upper block of ST^T (in an obvious partition) as V . Then we extract from [30, § 7] for $\mu \in (-\infty, \min \{\mu_*, \nu_*\})$ the equivalence

$$\rho(P(\mu)Q(\mu)) < \frac{1}{\mu} \Leftrightarrow \mu V^T Z(\mu)^{-1} V < X(\mu).$$

If we define the analytic function

$$(-\infty, \min \{\mu_*, \nu_*\}) \ni \mu \rightarrow F(\mu) := X(\mu) - \mu V^T Z(\mu)^{-1} V,$$

we obtain

$$\mu_{\text{cou}} = \sup \{ \mu \mid 0 < \mu < \min \{\mu_*, \nu_*\}, F(\mu) > 0 \}.$$

Since $F(0)$ is positive definite and $F'(\mu)$ as well as $F''(\mu)$ are both negative semidefinite for $\mu < \min \{\mu_*, \nu_*\}$ (because both $X(\cdot)$ and $Y(\cdot)$ have these properties), we can literally apply to $F(\cdot)$ the algorithm formulated in [30, § 7] to compute μ_{cou} and then μ_{opt} . As explained in [31, § 5], we can combine the computation of μ_{cou} with that of μ_*, ν_* , which implies that there exists a quadratically convergent algorithm to determine μ_{opt} .

If one of the values μ_{max} or ν_{max} is infinite, $\mu_{\text{pos}}, \mu_{\text{neg}}$ or $\nu_{\text{pos}}, \nu_{\text{neg}}$ can be found by solving linear equations and Hermitian eigenvalue problems [30], [31], and it may happen, depending in particular on V , that $F(\cdot)$ also has simple structural properties which allow the explicit computation of μ_{opt} . If both values are infinite, this can be assured and we summarize the consequences in the following result.

THEOREM 16. $\mu_{\text{max}} = \infty$ if and only if $\text{im}(G) \subset \mathcal{N}_*(S(s))$ and, dually, $\nu_{\text{max}} = \infty$ if and only if $\mathcal{R}^*(T(s)) \subset \ker(H)$. If both values are infinite, there exists a computable square polynomial matrix $P_{\text{cou}}(\mu)$ such that the optimal value is given by

$$\min \{ \mu_*, \nu_* \}$$

if $P_{\text{cou}}(\mu)$ has no zeros in $(0, \min \{ \mu_*, \nu_* \})$ or, otherwise, by

$$\mu_{\text{opt}} = \min \{ \mu \in (0, \min \{ \mu_*, \nu_* \}) \mid \det(P_{\text{cou}}(\mu)) = 0 \}.$$

Proof. We only have to consider the characterization of μ_{opt} in the case of $\mu_{\text{max}} = \infty$ and $\nu_{\text{max}} = \infty$. Then $X(\cdot)$ and $Y(\cdot)$ are both affine and, therefore, $F(\cdot)$ is a real rational function without poles in $(-\infty, \min \{ \mu_*, \nu_* \})$. Let $d(\cdot)$ denote the least common multiple of the denominators of all the elements of $F(\cdot)$ and define the polynomial matrix $P_{\text{cou}}(\mu) := d(\mu)F(\mu)$. We obtain for any $\mu \in (-\infty, \min \{ \mu_*, \nu_* \})$:

$$\det(F(\mu)) = 0 \Leftrightarrow \det(P_{\text{cou}}(\mu)) = 0.$$

The distinction between the following cases finishes the proof. $P_{\text{cou}}(\mu)$ has no zeros in $(0, \min \{ \mu_*, \nu_* \})$: Then $\det(F(\mu))$ does not vanish in this interval. This implies $F(\mu) > 0$ for all $\mu \in (0, \min \{ \mu_*, \nu_* \})$ and thus $\mu_{\text{opt}} = \min \{ \mu_*, \nu_* \}$. There exists a minimal zero μ_0 of $P_{\text{cou}}(\mu)$ in $(0, \min \{ \mu_*, \nu_* \})$: Then $F(\mu)$ is positive definite for $\mu \in (0, \mu_0)$. Hence $F(\mu_0)$ is positive semidefinite and singular. By [30, Prop. 6], $F(\mu)$ cannot be positive definite for $\mu > \mu_0$ and we infer $\mu_{\text{opt}} = \mu_0$. \square

The reader should note the additional simplifications if μ_{pos} and/or ν_{pos} is/are infinite since the functions $P(\cdot)$ and/or $Q(\cdot)$ is/are constant in this case. There is no need to discuss all the details. We just give an interpretation of these results for the model-matching problem introduced in § 2. If one of the matrices $T_2(s)$ or $T_3(s)^T$ has full row rank over $\mathbb{R}(s)$ (the two block problem), either μ_{max} or ν_{max} is infinite. If both matrices have full row rank (the one block problem), the computation of μ_{opt} amounts to the solution of an eigenvalue problem. Theorem 16, however, shows that this may even happen if none of these conditions holds true, i.e., for certain four block problems.

8. Almost disturbance decoupling with stability. Any geometric characterization of $\mu_{\text{opt}} = \infty$ solves the *almost disturbance decoupling problem with \mathbb{C}^- -stability by output measurement* (ADDP). Up until now the ADDP has been treated for *closed* stability sets [37] or the given conditions for the multiple-input multiple-output (MIMO) case are deduced in a rather ad hoc way from single-input single-output (SISO) results without geometric interpretations [21]. Our approach allows us to derive the following new geometric solution of the ADDP in a straightforward manner.

THEOREM 17. μ_{opt} is infinite if and only if

$$(28) \quad \text{im}(G) \subset \mathcal{S}_+(S(s)) \cap \bigcap_{\lambda \in \mathbb{C}^0} \mathcal{S}_\lambda(S(s)),$$

$$(29) \quad \mathcal{V}^+(T(s)) + \sum_{\lambda \in \mathbb{C}^0} \mathcal{V}^\lambda(T(s)) \subset \ker(H),$$

$$(30) \quad \mathcal{V}^+(T(s)) \subset \mathcal{S}_+(S(s)).$$

Proof. If we assume $\mu_{\text{opt}} = \infty$, we obtain (28) from $\mu_* = \infty$, i.e., $\mu_{\text{pos}} = \infty$ and $\mu_{\text{neg}} = \infty$ and Theorem 12. The dual inclusion (29) follows from $\nu_* = \infty$. By $\mu_{\text{pos}} = \infty$ and $\nu_{\text{pos}} = \infty$, the functions $P(\cdot)$ and $Q(\cdot)$ are constant. Therefore $\rho(P(\mu)Q(\mu)) < 1/\mu$ holds for all $\mu \in \mathbb{R}$ if and only if $P(\mu)Q(\mu) = 0$ or $\text{im}(Q(\mu)) \subset \ker(P(\mu))$ are valid for one/all $\mu \in \mathbb{R}$. Theorem 13 together with [31, Thm. 9] implies that the kernel of $P(\mu)$ is given by $\mathcal{S}_+(S(s))$ and, dually, the image of $Q(\mu)$ equals $\mathcal{V}^+(T(s))$. This yields (30). The arguments can be reversed to obtain $\mu_{\text{opt}} = \infty$ from (28), (29), and (30). \square

We should compare this result with the solution of the ADDP for the closed stability set $\mathbb{C}^- \cup \mathbb{C}^0$. The first two conditions differ due to \mathbb{C}^0 -zeros of $S(s)$ and $T(s)$ but the third condition is the same reflecting the earlier statement that the \mathbb{C}^0 -zeros do not cause additional coupling constraints.

The solution of the state-feedback ADDP ($C = I$ and $D = 0$) is contained in the above result: (29) and (30) are automatically satisfied. As it was expected in [21], the relevant space on the right in (28) lies between $\mathcal{S}_+(S(s)) \cap \mathcal{S}_0(S(s)) = \mathcal{V}^-(S(s)) + \mathcal{S}_*(S(s))$ and $\mathcal{S}_+(S(s)) = \mathcal{V}^-(S(s)) + \mathcal{V}^0(S(s)) + \mathcal{S}_*(S(s))$. We stress a simple consequence of our results that cannot be obtained from those in [21]: If $\mu_* = \infty$, it is possible to construct a sequence of *static* stabilizing feedback matrices to approach μ_* .

We finally mention an application of the solution to the ADDP in robust stabilization: As discussed in [16], it is possible to test algebraically whether complete quadratic stabilization is realizable.

Appendix.

Proof of Proposition 15. Since we can decompose any $R_0 \in \mathbb{S}^n$ as $JJ^T - GG^T$, it suffices to prove the result for $R_0 = -GG^T$. Thus we have to show for an arbitrary real $G \in \mathbb{R}^{n \times \times}$ and any $X_0 \in \mathbb{S}^n$:

$$\exists \rho > 0 \quad \exists X > X_0: AX + XA^T + XH^THX - \rho BB^T + GG^T < 0.$$

By Theorem 4, there exist $P > 0$ and F with $(A + BF)^T P + P(A + BF) + PGG^T P + H^T H < 0$. Since

$$(H_\varepsilon \ E_\varepsilon) = \begin{pmatrix} H & 0 \\ 0 & \varepsilon I \end{pmatrix}$$

defines an admissible perturbation of (HE) , we infer from Theorem 8 the existence of some $X > 0$ and ρ_0 with $AX + XA^T + XH^T HX - \rho_0 BB^T + GG^T < 0$. From now on, ρ is always taken out of $[\rho_0, \infty)$ if not specified otherwise. The set

$$\mathcal{X}(\rho) := \{X > 0 \mid AX + XA^T + XH^T HX - \rho BB^T + GG^T < 0\}$$

is nonempty. According to [31, Thm. 9], $\mathcal{X}(\rho)^{-1}$ has a strict lower limit point, which is denoted as $P_\rho \geq 0$ and is, by $\mathcal{X}(\rho) \subset \mathcal{X}(\sigma)$ for $\rho < \sigma$, nonincreasing. Therefore the limit $\lim_{\rho \rightarrow \infty} P_\rho$ exists. If we show that this limit vanishes, we have proved the proposition. Reference [31, Thm. 9] also contains an explicit formula for P_ρ . We transform with some nonsingular S as

$$SAS^{-1} = \begin{pmatrix} A_1 & 0 \\ K_2 H_1 & A_2 \end{pmatrix}, \quad SB = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix}, \quad SG = \begin{pmatrix} G_1 \\ G_2 \end{pmatrix}, \quad HS^{-1} = (H_1 \ 0),$$

such that

$$\begin{pmatrix} A_1 - sI \\ H_1 \end{pmatrix}$$

only has unobservable modes in \mathbb{C}^+ and $\sigma(A_2) \subset \mathbb{C}^0 \cup \mathbb{C}^-$. Then P_ρ is equal to

$$S^T \begin{pmatrix} X_\rho^{-1} & 0 \\ 0 & 0 \end{pmatrix} S,$$

where $X_\rho > 0$ is the unique matrix which satisfies

$$A_1 X_\rho + X_\rho A_1^T + X_\rho H_1^T H_1 X_\rho + G_1 G_1^T - \rho B_1 B_1^T = 0, \quad \sigma(A_1 + X_\rho H_1^T H_1) \subset \mathbb{C}^+.$$

Note that X_ρ is nondecreasing.

Let us define $\Delta_\rho := X_\rho - X_{\rho_0} \geq 0$ and $\tilde{A}_1 := A_1 + X_{\rho_0} H_1^T H_1$. Then it is simple to verify [32] that Δ_ρ satisfies

$$\tilde{A}_1 \Delta_\rho + \Delta_\rho \tilde{A}_1^T + \Delta_\rho H_1^T H_1 \Delta_\rho - (\rho - \rho_0) B_1 B_1^T = 0, \quad \sigma(\tilde{A}_1^T + \Delta_\rho H_1^T H_1) \subset \mathbb{C}^+.$$

Let us now assume $\rho > \rho_0$. Obviously,

$$\begin{pmatrix} \tilde{A}_1 - \lambda I & B_1 \\ H_1 & 0 \end{pmatrix}$$

still has maximal row rank for all $\lambda \in \mathbb{C}$, which implies that $(\tilde{A}_1 - sI \ B_1)$ is controllable. Hence Δ_ρ has no kernel and is in fact positive definite. Moreover, we obtain

$$\tilde{A}_1^T \Delta_\rho^{-1} + \Delta_\rho^{-1} \tilde{A}_1 + H_1^T H_1 - (\rho - \rho_0) \Delta_\rho^{-1} B_1 B_1^T \Delta_\rho^{-1} = 0, \quad \sigma(\tilde{A}_1 - (\rho - \rho_0) B_1 B_1^T \Delta_\rho^{-1}) \subset \mathbb{C}^-.$$

By LQ-theory we deduce for any $x_0 \in \mathbb{R}^{n_1}$ (with n_1 as the dimension of \tilde{A}_1)

$$x_0^T \Delta_\rho^{-1} x_0 = \inf \int_0^\infty \frac{1}{\rho - \rho_0} u(t)^T u(t) + x(t)^T H_1^T H_1 x(t) dt,$$

where we vary F such that $\tilde{A}_1 + B_1 F$ is stable and define $x(\cdot)$, $u(\cdot)$ via $\dot{x}(t) = (\tilde{A}_1 + B_1 F)x(t)$, $x(0) = x_0$, $u(t) = Fx(t)$. Again by Theorem 4, there exists a sequence F_j with $\sigma(\tilde{A}_1 + B_1 F_j) \subset \mathbb{C}^-$ and

$$\int_0^\infty \|H_1 e^{(\tilde{A}_1 + B_1 F_j)t}\|^2 dt \rightarrow 0$$

for $j \rightarrow \infty$. This implies $x_0^T \Delta_\rho^{-1} x_0 \rightarrow 0$ for $\rho \rightarrow \infty$. Since x_0 was arbitrary, we obtain $\Delta_\rho^{-1} \rightarrow 0$ and therefore also $X_\rho^{-1} \rightarrow 0$, i.e., $P_\rho \rightarrow 0$ for $\rho \rightarrow \infty$. \square

Acknowledgments. I would like to thank Siep Weiland from the University of Groningen for reading the first draft of the manuscript and for his never-ending interest in this topic. My thanks also go to all the other members of the Systems and Control Group in Groningen (and especially to Professor J. C. Willems) for their kind hospitality.

BOUNDARY VELOCITY CONTROL OF INCOMPRESSIBLE FLOW WITH AN APPLICATION TO VISCOUS DRAG REDUCTION*

MAX D. GUNZBURGER†, LISHENG HOU‡, AND THOMAS P. SVOBODNY§

Abstract. An optimal boundary control problem for the Navier–Stokes equations is presented. The control is the velocity on the boundary, which is constrained to lie in a closed, convex subset of $H^{1/2}$ of the boundary. A necessary condition for optimality is derived. Computations are done when the control set is actually finite-dimensional, resulting in an application to viscous drag reduction.

Key words. optimal control, Navier–Stokes equations, boundary control, finite element methods, distributed parameter systems

1. Introduction. We are concerned with a constrained optimization problem for steady fluid flow, namely that of computing a boundary value of the velocity that minimizes a volume integral that represents frictional energy dissipation. The constraint is the system of equations for viscous incompressible flow. The boundary value of the velocity, hereupon dubbed the control, is constrained to a closed, convex subset of $\mathbf{H}^{1/2}(\Gamma_c)$, where Γ_c is a portion of the body boundary. Such a constraint is necessary since the control does not appear explicitly in the cost functional. Moreover, we cannot eliminate the control in solving coupled state-adjoint equations. In the present case a minimum principle gives us a variational inequality that couples the system of state and adjoint equations. If we further constrain the control set to be in a finite-dimensional subspace, then we are led to an optimization problem where the feasibility set is the set of vertices of a cube in m -dimensional Euclidean space.

Our choice of the cost functional to be optimized is motivated by the following physical consideration (cf. [9]). If a body with boundary Γ is immersed in a fluid, then the force acting on the body is

$$\mathbf{F} = \int_{\Gamma} \mathbf{T} \cdot \mathbf{n} \, d\Gamma,$$

where \mathbf{T} is the stress tensor and \mathbf{n} is the unit normal vector pointing into the body. If we consider a body moving with rectilinear velocity \mathbf{V} , then a measure of the component of the force in the direction of the velocity is

$$\mathbf{F}_D = \mathbf{F} \cdot \mathbf{V} = \mathbf{V} \cdot \int_{\Gamma} \mathbf{T} \cdot \mathbf{n} \, d\Gamma = \int_{\Gamma} \mathbf{v} \cdot \mathbf{T} \cdot \mathbf{n} \, d\Gamma,$$

where $\mathbf{v} = \mathbf{v}(\mathbf{x}, t)$ is the velocity field of the fluid. If we assume the linear constitutive law, i.e., an expression for stress is given by

$$\mathbf{T} = -p\mathbf{I} + 2\mu\mathbf{D},$$

where p denotes a pressure field and μ the (constant) viscosity of the fluid, and $\mathbf{D} = \mathbf{D}(\mathbf{v}) = \frac{1}{2}(\nabla\mathbf{v} + \nabla\mathbf{v}^T)$ is a symmetric tensor of first-order derivatives of \mathbf{v} , an integration by parts gives

$$\mathbf{F}_D = 2\mu \int_{\Omega} \mathbf{D} : \mathbf{D} \, dx - \int_{\Omega} p(\operatorname{div} \mathbf{v}) \, dx + \mu \int_{\Omega} \mathbf{v} \cdot \nabla(\operatorname{div} \mathbf{v}) \, dx.$$

(We are assuming that the fluid is isotropic, reflected in the fact that the medium itself is described by the scalar quantity μ .) Although this expression for the drag was derived in the context of the ideal conditions mentioned, it seems reasonable to use the right-hand side as a cost functional to be minimized subject to the constraints imposed by the incompressible Navier–Stokes equations. Of course, on this constraint set, the second and third terms on the right-hand side are clearly zero, thus making our cost functional positive. The term to which this functional then reduces is known in the literature as the *dissipation function*; it represents the rate at which heat energy is conducted into the fluid, or equivalently, the rate at which heat is generated by deformations of the velocity field.

We apply our results to the following problem. It is known that for an aerodynamic body moving at uniform velocity, the main contribution to retardation is the frictional force. This force is increased if the boundary layer becomes turbulent. In addition, the body may have to overcome adverse pressure gradients if the boundary layer separates. We want to reduce viscous (skin-friction) drag of an immersed body whose relative velocity with respect to the fluid is fixed (\mathbf{v}_{∞}). In the specific application that is considered at the end, the method of control is the following: we have m disjoint regions (holes) on the surface of the body where we can specify positive (blowing) or negative (sucking) velocities [4]. Of course, the rate of flow at each hole is strictly limited, not only for the obvious reasons, but because too strong a control would change the lift, and the problem would not represent the one posed. On the other hand, the control velocity must dominate pressure gradients. We will assume that the control set is small enough so that the velocity profile at each hole is fixed, and thus the problem reduces to a finite-dimensional control problem.

The numerical approximation is carried out using the finite-element method; a sketch of the procedure as well as a model problem is given at the end. Further details concerning the approximation of such optimization problems as well as the more difficult (from the viewpoint of approximation) unconstrained case, including error estimates, are given in [3]. The authors are presently applying the techniques and algorithms discussed here to other applications, e.g., flows about airfoils.

1.1. Notation. Real k -dimensional Euclidean space is denoted R^k ; R_+^k is the subset with nonnegative coordinates. The domain Ω is a bounded smooth domain in R^2 or R^3 , whose boundary consists of two connected components $\Gamma = \Gamma_e \cup \Gamma_c$. Furthermore, $\Gamma_e = \Gamma_{(1)} \cup \Gamma_{(2)}$, where $\Gamma_{(1)}$ must have an interior, but $\Gamma_{(2)}$ may be empty. Let $\mathbf{H}^m(B)$ be the Hilbert space of R^n -valued functions defined on B whose j th derivatives, $0 \leq j \leq m$ are in $L^2(B)$. The norm in this space will be denoted by $\|\cdot\|_m$. In all cases, boldface indicates vector-valued. We will use the quotient spaces $L_0^2(\Omega) = \{f \in L^2(\Omega) : \int_{\Omega} f \, dx = 0\}$ and $\mathbf{H}_0^{1/2}(G) = \{\mathbf{g} \in \mathbf{H}^{1/2}(G) : \int_G \mathbf{g} \cdot \mathbf{n} \, dG = 0\}$.

$\langle \cdot, \cdot \rangle_X$ will mean the duality pairing on $X' \times X$, while $\langle\langle \cdot, \cdot \rangle\rangle_X$ will mean the inner product in the Hilbert space X .

The matrix $\{\partial u_i / \partial x_j\}$ will be denoted $\nabla \mathbf{u}$. The velocity deformation tensor is $\mathbf{D}(\mathbf{u}) = \frac{1}{2}(\nabla \mathbf{u} + \nabla \mathbf{u}^T)$. We use the forms

$$\begin{aligned} a(\mathbf{u}, \mathbf{v}) &= 2\nu \int_{\Omega} \mathbf{D}(\mathbf{u}) : \mathbf{D}(\mathbf{v}) \, dx \quad \forall \mathbf{u}, \mathbf{v} \in \mathbf{H}^1(\Omega), \\ b(\mathbf{u}, p) &= - \int_{\Omega} p(\operatorname{div} \mathbf{u}) \, dx \quad \forall p \in L_0^2(\Omega), \quad \mathbf{u} \in \mathbf{H}^1(\Omega), \\ c(\mathbf{u}, \mathbf{v}, \mathbf{w}) &= \int_{\Omega} \mathbf{u} \cdot \nabla \mathbf{v} \cdot \mathbf{w} \, dx \quad \forall \mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbf{H}^1(\Omega). \end{aligned}$$

The following estimate, which is a straightforward application of the Hölder and Sobolev inequalities (cf. [11]), will prove to be useful:

$$|c(\mathbf{u}, \mathbf{v}, \mathbf{w})| \leq \begin{cases} \text{const.} \|\mathbf{u}\|_{1/2} \|\mathbf{v}\|_1 \|\mathbf{w}\|_1 \\ \text{const.} \|\mathbf{u}\|_1 \|\mathbf{v}\|_1 \|\mathbf{w}\|_{1/2} \end{cases}.$$

These forms induce the following operators.

$$A : \mathbf{H}^1(\Omega) \rightarrow \mathbf{H}^{-1}(\Omega)$$

defined by

$$\begin{aligned} \langle A\mathbf{u}, \mathbf{v} \rangle &= a(\mathbf{u}, \mathbf{v}), \quad \mathbf{u} \in \mathbf{H}^1(\Omega), \quad \mathbf{v} \in \mathbf{H}_0^1(\Omega), \\ B : \mathbf{H}^1(\Omega) &\rightarrow L_0^2(\Omega) \end{aligned}$$

defined by

$$\begin{aligned} \langle B\mathbf{u}, p \rangle &= b(\mathbf{u}, p), \quad \mathbf{u} \in \mathbf{H}^1(\Omega), \quad p \in L_0^2(\Omega), \\ \overline{B} : L_0^2(\Omega) &\rightarrow \mathbf{H}^{-1}(\Omega) \end{aligned}$$

defined by

$$\langle \overline{B}p, \mathbf{u} \rangle = b(\mathbf{u}, p) \quad \mathbf{u} \in \mathbf{H}_0^1(\Omega), \quad p \in L_0^2(\Omega),$$

and

$$C : \mathbf{H}^1(\Omega) \times \mathbf{H}^1(\Omega) \rightarrow \mathbf{H}^{-1}(\Omega)$$

defined by

$$\langle C(\mathbf{u}, \mathbf{v}), \mathbf{w} \rangle = c(\mathbf{u}, \mathbf{v}, \mathbf{w}), \quad \mathbf{u}, \mathbf{v} \in \mathbf{H}^1(\Omega), \quad \mathbf{w} \in \mathbf{H}_0^1(\Omega).$$

For theorems concerning operators associated with the stationary Navier–Stokes equations, consult [7]. We will use the trace operators

$$\gamma_e : \mathbf{H}^1(\Omega) \rightarrow \mathbf{H}^{1/2}(\Gamma_e), \quad \gamma_c : \mathbf{H}^1(\Omega) \rightarrow \mathbf{H}^{1/2}(\Gamma_c)$$

and $\gamma = \gamma_e \times \gamma_c$. Optimal solutions of the optimization problem will be tagged with asterisks, \mathbf{v}^* , or with hats, $\hat{\mathbf{v}}$.

2. The optimization problem: boundary velocity control with constraints. We recall that we are faced with the problem of minimizing the functional (\mathbf{F}_D) , subject to the constraint

$$-\nu \Delta \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v} + \nabla p = 0$$

$$\nabla \cdot \mathbf{v} = 0$$

and either of the sets of boundary conditions

$$(BVC1) \quad \mathbf{v}|_{\Gamma_e} = \mathbf{v}_\infty, \quad \text{and} \quad \mathbf{v}|_{\Gamma_c} = \mathbf{g},$$

(the Boundary Value Control Problem 1), or

$$(BVC2) \quad \mathbf{v}|_{(\Gamma_1)} = \mathbf{v}_\infty, \quad \mathbf{T}(\mathbf{v}) \cdot \mathbf{n}|_{(\Gamma_2)} = 0, \quad \text{and} \quad \mathbf{v}|_{\Gamma_c} = \mathbf{g},$$

(the Boundary Value Control Problem 2), where the control function \mathbf{g} is to lie in \mathcal{U} , a closed, convex subset of $\mathbf{H}^{1/2}(\Gamma_c)$, and where ν is the kinematic viscosity.

Our program is a straightforward approach to a constrained optimization problem: we investigate existence of optimal solutions, we verify the existence of Lagrange multipliers, and then we derive a minimum principle that couples the Euler–Lagrange equations as necessary conditions for the optimal boundary velocity. The cost functional is given by

$$J(\mathbf{v}) = \frac{\nu}{2} \int_{\Omega} |\nabla \mathbf{v} + \nabla \mathbf{v}^T|^2 dx.$$

2.1. Existence of an optimal solution. Consider the Navier–Stokes equations in the weak form,

$$(2.1) \quad a(\mathbf{v}, \mathbf{w}) + c(\mathbf{v}, \mathbf{v}, \mathbf{w}) + b(\mathbf{w}, p) = 0 \quad \forall \mathbf{w} \in \mathbf{H}_0^1(\Omega)$$

$$(2.2) \quad b(\mathbf{v}, q) = 0 \quad \forall q \in L_0^2(\Omega)$$

$$(2.3) \quad \mathbf{v}|_{\Gamma_c} = \mathbf{g}$$

and either

$$(2.4) \quad \mathbf{v}|_{\Gamma_e} = \mathbf{v}_\infty$$

or

$$(2.5) \quad \mathbf{v}|_{(\Gamma_1)} = \mathbf{v}_\infty \quad \mathbf{T}(\mathbf{v}) \cdot \mathbf{n}|_{(\Gamma_2)} = 0.$$

Always, $\mathbf{v}_\infty \in \mathbf{H}^{1/2}(\Gamma_e)$ (or $\mathbf{v}_\infty \in \mathbf{H}^{1/2}(\Gamma_{(1)})$ in the case of (BVC2)) and, in the case of (BVC1), we assume

$$\int_{\Gamma_c} \mathbf{g} \cdot \mathbf{n} d\Gamma + \int_{\Gamma_e} \mathbf{v}_\infty \cdot \mathbf{n} d\Gamma = 0.$$

We consider the case (BVC1), and for simplicity assume that

$$\int_{\Gamma_e} \mathbf{v}_\infty \cdot \mathbf{n} d\Gamma = 0,$$

so that

$$\int_{\Gamma_c} \mathbf{g} \cdot \mathbf{n} d\Gamma = 0.$$

(Cases (BVC2) and (BVC1) without the above assumption can be treated in similar manner.)

DEFINITION 1. We define the *admissibility set*

$$\mathcal{T}_{\text{ad}} = \{(\mathbf{v}, \mathbf{g}) \in \mathbf{H}^1(\Omega) \times \mathcal{U}(\subseteq \mathbf{H}^{1/2}(\Gamma_c)) : J(\mathbf{v}) < \infty \text{ and there exists } p \in L_0^2(\Omega) \text{ and so that (2.2)–(2.4) and either (2.4) or (2.5) are satisfied}\}.$$

DEFINITION 2. We define an *optimal solution* $(\mathbf{v}^*, \mathbf{g}^*)$ to be one for which $J(\mathbf{v}^*) \leq J(\mathbf{v})$ for any $(\mathbf{v}, \mathbf{g}) \in \mathcal{T}_{\text{ad}}$.

DEFINITION 3. We define a *local minimum* $(\hat{\mathbf{v}}, \hat{\mathbf{g}})$ to be one for which there exists $\epsilon > 0$ such that $J(\hat{\mathbf{v}}) \leq J(\mathbf{v})$ for any $(\mathbf{v}, \mathbf{g}) \in \mathcal{T}_{\text{ad}}$ with $\|\mathbf{v} - \hat{\mathbf{v}}\|_1 < \epsilon$

LEMMA 2.1. *There exists an optimal solution to the above problem.*

Proof. First, note that \mathcal{T}_{ad} is nonempty. This follows from the fact

$$J(\mathbf{v}) \leq \nu \|\mathbf{v}\|_1^2$$

and well-known existence theorems for solutions of stationary Navier–Stokes equations (cf. [1], [8], and [10]). Now let $\mathbf{V}_m = (\mathbf{v}_m, \mathbf{g}_m)$ be a sequence in \mathcal{T}_{ad} such that

$$\lim_{m \rightarrow \infty} J(\mathbf{v}_m) = \inf_{v \in \mathcal{T}_{\text{ad}}} J(\mathbf{v}).$$

By definition of \mathcal{T}_{ad} , $J(\mathbf{v}_m) \leq C_0$, a constant independent of m . On the boundary, $\mathbf{v} = \mathbf{v}_\infty \in \mathbf{H}^{1/2}(\Gamma_e)$, and because of the assumption on Γ_e we have

$$J(\mathbf{v}) \geq c_1 \|\mathbf{v}\|_1^2 - c_2 \|\mathbf{v}\|_1 - c_3$$

(this is a direct consequence of Korn's inequality, cf. [2, p.117]); thus, $\|\mathbf{v}_m\|_1 \leq C_V$. By the trace theorem, $\|\mathbf{g}_m\|_{1/2} \leq C_U$. We therefore have the weak limits

$$\mathbf{v}_m \rightharpoonup \mathbf{v}^* \in \mathbf{H}^1(\Omega), \quad \mathbf{g}_m \rightharpoonup \mathbf{g}^* \in \mathbf{H}^{1/2}(\Gamma_C).$$

Since $\mathbf{H}^1(\Omega)$ imbeds compactly in $\mathbf{L}^2(\Omega)$, we also have the strong limit

$$\mathbf{v}_m \rightarrow \mathbf{v}^* \in \mathbf{L}^2(\Omega).$$

As \mathcal{U} is convex, closed, it is closed in the weak topology, thus $\mathbf{g}^* \in \mathcal{U}$. Next, using the fact that J is bounded, convex, we have that it is weakly lower semicontinuous, and thus $J(\mathbf{v}^*) = \inf_{v \in \mathcal{T}_{\text{ad}}} J(\mathbf{v})$.

Now we must show that the limit \mathbf{v}^* is in the admissible set, \mathcal{T}_{ad} . We first show that \mathbf{v}^* satisfies the boundary conditions. Since

$$\gamma_e v_m = \mathbf{v}_\infty, \quad \gamma_c \mathbf{v}_m = \mathbf{g}_m,$$

we want to show that $\gamma_e \times \gamma_c$ is a weakly closed operator. But it is continuous on $\mathbf{H}^1(\Omega)$ and so it is closed, and thus has a closed graph, and thus by the Hahn–Banach theorem, is weakly closed. Thus

$$\gamma_e \mathbf{v}^* = \mathbf{v}_\infty, \quad \gamma_c \mathbf{v}^* = \mathbf{g}^*.$$

Now we show that the limiting flow is incompressible. The condition

$$b(\mathbf{v}_m, q) = 0, \quad \forall q \in \mathbf{L}^2$$

means that $\mathbf{v}_m \in \ker(B)$ for all m . But since $\ker(B)$ is a closed subspace, it is weakly closed, and so

$$\mathbf{v}^* \in \ker(B) \Rightarrow b(\mathbf{v}^*, q) = 0 \quad \forall q \in L^2(\Omega).$$

It is clear that $a(\mathbf{v}_m, \mathbf{w}) \rightarrow a(\mathbf{v}^*, \mathbf{w})$ for all $\mathbf{w} \in \mathbf{H}^1(\Omega)$. On the other hand, the operator $C(\cdot, \cdot)$ is weak sequentially continuous. To see this, take $\mathbf{w} \in \mathbf{C}_0^\infty(\Omega)$, and consider

$$c(\mathbf{v}_m, \mathbf{v}_m, \mathbf{w}) = -c(\mathbf{v}_m, \mathbf{w}, \mathbf{v}_m) = - \sum_{i,j} \int_{\Omega} v_{mi} \frac{\partial w_j}{\partial x_i} v_{mj} \, dx.$$

Since $(\nabla \mathbf{w})_{ij} \in L^\infty(\Omega)$, and since $\mathbf{v}_m \rightarrow \mathbf{v}^*$ in $\mathbf{L}^2(\Omega)$, we have

$$c(\mathbf{v}_m, \mathbf{v}_m, \mathbf{w}) \rightarrow c(\mathbf{v}^*, \mathbf{v}^*, \mathbf{w}) \quad \forall \mathbf{w} \in \mathbf{C}_0^\infty;$$

but this space is dense in $\mathbf{H}_0^1(\Omega)$, thus

$$A\mathbf{v}_m + C(\mathbf{v}_m, \mathbf{v}_m) \rightarrow A\mathbf{v}^* + C(\mathbf{v}^*, \mathbf{v}^*) \in \mathbf{H}^{-1}.$$

Moreover, $A\mathbf{v}_m + C(\mathbf{v}_m, \mathbf{v}_m) \in R(\overline{B})$ for all m ; but the inf sup condition ([7, p.81]) implies that $R(\overline{B})$ is closed, and thus

$$A\mathbf{v}^* + C(\mathbf{v}^*, \mathbf{v}^*) \in R(\overline{B}),$$

or, in other words, there exists a $p^* \in L_0^2(\Omega)$ such that

$$A\mathbf{v}^* + C(\mathbf{v}^*, \mathbf{v}^*) = -\overline{B}p^*,$$

which completes the proof of existence of an optimal control. \square

2.2. The Lagrange multiplier rule. The idea of the technique of Lagrange multipliers is that the problem of minimizing a functional subject to a constraint can be reduced to the unconstrained minimization of an auxiliary functional, the Lagrangian. Important in applications of convex optimization is the existence of a minimum principle. (The general theory of the parametrized Lagrange multiplier rule is developed in [5, Chap. 1] and [13, Chap. 1].)

We can define a mapping

$$\mathbf{F} : \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathcal{U}_{\text{ad}} \rightarrow \mathbf{H}^{-1}(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{1/2}(\Gamma_e) \times \mathbf{H}^{1/2}(\Gamma_c)$$

by

$$F^1(\mathbf{v}, p, \mathbf{g}) = A\mathbf{v} + C(\mathbf{v}, \mathbf{v}) + \overline{B}p \in \mathbf{H}^{-1}(\Omega)$$

$$F^2(\mathbf{v}, p, \mathbf{g}) = B\mathbf{v} \in L_0^2(\Omega)$$

$$F^3(\mathbf{v}, p, \mathbf{g}) = \gamma_e \mathbf{v} - \mathbf{v}_\infty \in \mathbf{H}^{1/2}(\Gamma_e)$$

$$F^4(\mathbf{v}, p, \mathbf{g}) = \gamma_c \mathbf{v} - \mathbf{g} \in \mathbf{H}^{1/2}(\Gamma_c)$$

For economy, we say $\mathbf{F} : \mathbf{X} \times \mathcal{U} \rightarrow \mathbf{Y}$. Thus, our constraint (2.1)-(2.4) is

$$\mathbf{F} = 0 \in \mathbf{H}^{-1}(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{1/2}(\Gamma_e) \times \mathbf{H}^{1/2}(\Gamma_c)$$

or

$$\mathbf{F} = 0 \in \mathbf{Y}.$$

We say that the set \mathcal{U} has *property C* at $(\hat{\mathbf{v}}, \hat{\mathbf{g}})$ if for any nonzero solution $(\boldsymbol{\xi}, \sigma)$ of the system

$$(2.6) \quad \begin{aligned} -\nu \delta \xi_i + \xi_j \frac{\partial \hat{v}_j}{\partial x_1} - \hat{v}_j \frac{\partial \xi_i}{\partial x_j} + \frac{\partial \sigma}{\partial x_i} &= 0 \\ \nabla \cdot \boldsymbol{\xi} &= 0 \\ \boldsymbol{\xi}|_{\Gamma} &= 0 \end{aligned}$$

we can find $\mathbf{g} \in \mathcal{U}$ such that

$$(2.7) \quad \int_{\Gamma_C} \mathbf{T}(\boldsymbol{\xi}) \cdot \mathbf{n} \cdot (\mathbf{g} - \hat{\mathbf{g}}) d\Gamma < 0.$$

Convention will have it that property C is to hold vacuously if there are no nonzero solutions of (2.6).

Remark. As in [3] we can show that $\mathcal{U} = \mathbf{H}^{1/2}(\Gamma)$ has property C (this is the case where the control is not constrained). This conclusion is seen to be equivalent to the following uniqueness result: If (2.7) is not true, then $\mathbf{T}(\boldsymbol{\xi}) = 0$ and if $\boldsymbol{\xi}$ is a solution to (2.6), then $\boldsymbol{\xi} = 0$.

We will use the notation $D_1 \mathbf{F}(\hat{\mathbf{v}}, \hat{\mathbf{g}}) = D_{(u,p)} \mathbf{F}(\hat{\mathbf{v}}, \hat{p}, \hat{\mathbf{g}}) = \hat{F}$, $\mathbf{W} = (\mathbf{w}, q)$, $\mathbf{Z} = \text{image}(\hat{F})$, $\mathbf{F}(\mathbf{v}, p, \mathcal{U}) = \text{image of the map } \mathbf{g} \rightarrow \mathbf{F}(\mathbf{v}, p, \mathbf{g}), \mathbf{g} \in \mathcal{U}$, $\mathbf{F}(\mathcal{U}) = \mathbf{F}(\hat{\mathbf{v}}, \hat{p}, \mathcal{U})$; note that $\mathbf{F}(\mathcal{U})$ is convex since \mathbf{F} depends linearly on the control.

We are now in a position to state the main result of this section.

THEOREM 1. *Let $(\hat{\mathbf{v}}, \hat{\mathbf{g}})$ be a local minimum (in the sense of Definition 3). Then there exists a nonzero Lagrange multiplier,*

$$\begin{aligned} \mathbb{Z} = (\boldsymbol{\xi}, \sigma, \boldsymbol{\zeta}_e, \boldsymbol{\zeta}_c) &\in [\mathbf{H}^{-1}(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{1/2}(\Gamma_e) \times \mathbf{H}^{1/2}(\Gamma_c)]' \\ &= \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma_e) \times \mathbf{H}^{-1/2}(\Gamma_c) \\ &(\text{or } = \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega) \times (\mathbf{H}_0^{1/2}(\Gamma_{(1)}))' \times (\mathbf{H}_0^{1/2}(\Gamma_c))') \end{aligned}$$

(the dual spaces depend on the specified (BVP)), so that if \mathcal{U} satisfies property C at $(\hat{\mathbf{v}}, \hat{\mathbf{g}})$, then $\hat{\mathbb{Z}}$ solves the variational system

$$(2.8) \quad \langle J'(\hat{\mathbf{v}}), \mathbf{w} \rangle + \langle \hat{\mathbb{Z}}, D_1 \mathbf{F}(\hat{\mathbf{v}}, \hat{\mathbf{g}})(\mathbf{w}, q) \rangle = 0, \quad \forall \mathbf{W} \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega).$$

If property C is not valid then $\hat{\mathbb{Z}}$ is a nonzero solution to

$$(2.9) \quad \langle \hat{\mathbb{Z}}, D_1 \mathbf{F}(\hat{\mathbf{v}}, \hat{\mathbf{g}}) \mathbf{W} \rangle = 0, \quad \forall \mathbf{W} \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega);$$

in either case, $\hat{\mathbb{Z}}$ satisfies the variational inequality

$$(2.10) \quad \langle \hat{\mathbb{Z}}, \mathbf{F}(\hat{\mathbf{v}}, \hat{p}, \mathbf{g}) \rangle \geq 0, \quad \forall \mathbf{g} \in \mathcal{U}.$$

The inequality (2.10) will henceforth be referred to as the *minimum principle*. The Lagrangian for this problem is

$$\begin{aligned} L = J(\mathbf{v}) + \langle \mathbb{Z}, \mathbf{F}(\mathbf{v}, p, \mathbf{g}) \rangle &= a(\mathbf{v}, \mathbf{v}) + a(\mathbf{v}, \boldsymbol{\xi}) + c(\mathbf{v}, \mathbf{v}, \boldsymbol{\xi}) \\ &+ b(\boldsymbol{\xi}, p) + b(\mathbf{v}, \sigma) + \langle \boldsymbol{\zeta}_1, \gamma_e \mathbf{v} - \mathbf{v}_\infty \rangle_{\Gamma} + \langle \boldsymbol{\zeta}_2, \gamma_C \mathbf{v} - \mathbf{g} \rangle_{\Gamma}. \end{aligned}$$

The proof of Theorem 1 will rely on the following result.

THEOREM 2. (Ioffe and Tikhomirov [5]). *In the notation of the foregoing, if*

- (a) \mathbf{X} and \mathbf{Y} are Banach spaces;
- (b) $J \in C^1(\mathbf{X})$, $D_1\mathbf{F}(\mathbf{v}, p) \in C^1(\mathbf{X})$;
- (c) $\mathbf{F}(\mathbf{v}, p, \mathcal{U})$ convex;
- (d) \mathbf{Z} is closed in \mathbf{Y} and has finite codimension;
- (e) some condition of complete regularity holds (for instance, $0 \in \mathbf{Y}$ is an interior point of $\mathbf{Z} + \mathbf{F}(\mathcal{U})$);

then there exists a $\hat{\mathbf{Z}}$ as described in Theorem 1 and satisfying (2.8) and (2.10).

Proof. For the proof see [13, Theorem P, p. 49] or [5, Theorem 3, p. 71, p. 85].

□

Proof of Theorem 1. We wish to apply Theorem 2 to construct a \mathbf{Z} that satisfies (2.8) and (2.10). It is clear that conditions (a), (b), and (c) follow from previous observations. To show condition (d) is true, we show that \hat{F} is Fredholm. If we compute the derivative,

$$\hat{F}(\mathbf{w}, q) = D_1 F(\hat{\mathbf{u}}, \hat{p}, \hat{\mathbf{g}}) \begin{pmatrix} \mathbf{w} \\ q \end{pmatrix} = \begin{pmatrix} A\mathbf{w} + \overline{B}q + C(\hat{\mathbf{u}}, \mathbf{w}) + C(\mathbf{w}, \hat{\mathbf{u}}) \\ B\mathbf{w} \\ \gamma_e \mathbf{w} \\ \gamma_c \mathbf{w} \end{pmatrix}.$$

By the trace theorem, and using the ellipticity of A and the inf sup property for B , we can see (cf. [1], [6], and [7]) that the Stokes operator

$$\begin{pmatrix} A & \overline{B} \\ B & 0 \\ \gamma & 0 \end{pmatrix}$$

is an isomorphism from $\mathbf{H}^1(\Omega) \times L_0^2(\Omega) \rightarrow \mathbf{H}^{-1}(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{1/2}(\Gamma)$. (The last factor in this product of spaces is $\mathbf{H}_0^{1/2}(\Gamma)$ if the velocity is specified on the whole outer boundary, i.e., (BVC1).) We estimate the linear operators $C(\cdot, \hat{\mathbf{u}})$ and $C(\hat{\mathbf{u}}, \cdot)$ as follows. From the estimate

$$|c(\mathbf{w}, \hat{\mathbf{u}}, \boldsymbol{\xi})| \leq \|\mathbf{w}\|_{1/2} \|\hat{\mathbf{u}}\|_1 \|\boldsymbol{\xi}\|_1,$$

we have that $C(\cdot, \hat{\mathbf{u}})$ is continuous from $\mathbf{H}^{1/2}(\Omega)$ into $\mathbf{H}^{-1}(\Omega)$ and thus compact from $\mathbf{H}^1(\Omega)$ into $\mathbf{H}^{-1}(\Omega)$. Likewise, from the estimate

$$|c(\hat{\mathbf{u}}, \mathbf{w}, \boldsymbol{\xi})| \leq \|\hat{\mathbf{u}}\|_1 \|\mathbf{w}\|_1 \|\boldsymbol{\xi}\|_{1/2},$$

we see that $C(\hat{\mathbf{u}}, \cdot)$ is continuous from $\mathbf{H}^1(\Omega)$ into $\mathbf{H}^{-1/2}(\Omega)$ and thus compact from $\mathbf{H}^1(\Omega)$ into $\mathbf{H}^{-1}(\Omega)$. Thus, $\hat{F} = D_1 \mathbf{F}(\hat{\mathbf{u}}, \hat{p}, \hat{\mathbf{g}})$ is a Fredholm operator. Since \mathbf{Z} is now known to be closed and with finite codimension M (being the dimension of the space of solutions of (2.6)), we can write

$$\mathbf{Y} = \mathbf{Z} \oplus \mathbf{E}.$$

Property C expresses a condition of complete regularity (assumption (e) in Theorem 2); to see this, note that, under the assumption that property C holds, if $y \in \mathbf{Y}$, then there exist $(\mathbf{w}_1, q_1) \in \mathbf{X}$, $\mathbf{g} \in \mathcal{U}$, $\lambda \geq 0$ such that

$$(2.11) \quad y = \hat{F}(\mathbf{w}_1, q_1) + \lambda(\hat{\mathbf{v}}, \hat{p}, \mathbf{g}).$$

Let $Q : \mathbf{Y} \rightarrow \mathbf{Y}/\mathbf{Z} \cong \mathbf{E}$ be the canonical mapping. If (2.11) does not hold, then taking into account the finite dimensionality of \mathbf{E} and the convexity of $\mathbf{F}(\mathcal{U})$, we can find $y \in \mathbf{Y}$ such that

$$Qy \cdot Q\mathbf{F}(\hat{\mathbf{v}}, \hat{p}, \mathbf{g}) \leq 0, \quad \forall \mathbf{g} \in \mathcal{U}.$$

Define $\lambda = -Qy/|Qy|$ and $\Lambda = Q^*\lambda$, then clearly, $\Lambda \in \mathbf{Z}^\perp$ and $\langle \Lambda, \mathbf{F}(\mathcal{U}) \rangle \geq 0$, i.e., property C does not hold. Thus, we can find a finite number of $\mathbf{g}_i \in \mathcal{U}$, $1 \leq i \leq N$, such that $\sum \mathbf{F}(\hat{\mathbf{v}}, \hat{p}, \mathbf{g}_i) = \hat{\mathbf{F}}\mathbf{W}'$ for some $\mathbf{W}' = (\mathbf{w}', q') \in \mathbf{X}$, and so that the mapping

$$(\mathbf{w}, q, \lambda_1, \dots, \lambda_n) \mapsto \hat{\mathbf{F}}(\mathbf{w}, q) + \sum \lambda_i \mathbf{F}(\hat{\mathbf{v}}, \hat{p}, \mathbf{g}_i)$$

defined on $\mathbf{X} \times R_+^N$ is onto \mathbf{Y} . Let ϵ be given and let $(\mathbf{w}_0, q_0, \mathbf{g}_0)$ be such that

$$(2.12) \quad \hat{\mathbf{F}}(\mathbf{w}_0, q_0) + \mathbf{F}(\hat{\mathbf{v}}, \hat{p}, \mathbf{g}_0) = 0.$$

Then the mapping

$$\begin{aligned} G_\epsilon(\mathbf{v}, p, \mathbf{a}) = & (1 - a_0 - \epsilon \sum a_i) \mathbf{F}(\hat{\mathbf{v}} + \mathbf{v}, \hat{p} + p, \hat{\mathbf{g}}) \\ & + a_0 \mathbf{F}(\hat{\mathbf{v}} + \mathbf{v}, \hat{p} + p, \mathbf{g}_0) + \epsilon \sum a_i \mathbf{F}(\hat{\mathbf{v}} + \mathbf{v}, \hat{p} + p, \mathbf{g}_i), \end{aligned}$$

defined on $\mathbf{X} \times R_+^{N+1}$, is smooth at the origin and $DG(0, 0, 0)$ is surjective. We may now continue with the proof of Theorem 2 given in [5, p. 87] or [13, p. 51] to construct a $\hat{\mathbf{Z}}$ that satisfies (2.8) and (2.10).

The stationarity condition (2.8) gives

$$\begin{aligned} 0 = & a(\hat{\mathbf{v}}, \mathbf{w}) + a(\mathbf{w}, \hat{\boldsymbol{\xi}}) + c(\hat{\mathbf{v}}, \mathbf{w}, \hat{\boldsymbol{\xi}}) + c(\mathbf{w}, \hat{\mathbf{v}}, \hat{\boldsymbol{\xi}}) + \\ & b(\hat{\boldsymbol{\xi}}, q) + b(\mathbf{w}, \sigma) + \langle \boldsymbol{\zeta}_1, \gamma_e \mathbf{w} \rangle + \langle \boldsymbol{\zeta}_2, \gamma_c \mathbf{w} \rangle. \end{aligned}$$

The minimum principle (2.10), reduces in our case to the variational inequality

$$\langle \boldsymbol{\zeta}_2, \hat{\mathbf{g}} - \mathbf{g} \rangle \geq 0 \quad \forall \mathbf{g} \in \mathcal{U}.$$

To get a (formal) expression for the multiplier $\boldsymbol{\zeta}_2$, we integrate by parts to obtain the system of equations for the adjoint variables

$$\begin{aligned} -\nu \Delta \hat{\xi}_i + \hat{\xi}_j \frac{\partial \hat{v}_j}{\partial x_i} - \hat{v}_j \frac{\partial \hat{\xi}_i}{\partial x_j} + \frac{\partial \hat{\sigma}}{\partial x_i} &= -\nu \Delta \hat{v}_i \\ \nabla \cdot \hat{\boldsymbol{\xi}} &= 0 \\ \hat{\boldsymbol{\xi}}|_\Gamma &= 0 \\ \hat{\boldsymbol{\zeta}}_1 &= -(\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\hat{\boldsymbol{\xi}}))|_{\Gamma_e} \cdot \mathbf{n} \\ \hat{\boldsymbol{\zeta}}_2 &= -(\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\hat{\boldsymbol{\xi}}))|_{\Gamma_c} \cdot \mathbf{n}. \end{aligned}$$

Thus, the minimum principle reduces to

$$(2.13) \quad \int_{\Gamma_c} [\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\hat{\boldsymbol{\xi}})] \cdot \mathbf{n} \cdot (\mathbf{g} - \hat{\mathbf{g}}) d\Gamma \geq 0, \quad \forall \mathbf{g} \in \mathcal{U}.$$

Note that this condition is equivalent to:

choose $\hat{\mathbf{g}} \in \mathcal{U}$ that solves

$$\max_{\hat{\mathbf{g}} \in \mathcal{U}} \min_{\mathbf{g} \in \mathcal{U}} \int_{\Gamma} [\mathbf{T}(\mathbf{v}) + \mathbf{T}(\boldsymbol{\xi})] \cdot \mathbf{n} \cdot (\mathbf{g} - \hat{\mathbf{g}}) d\Gamma.$$

In the case where property C does not hold it follows immediately that there exists

$$\begin{aligned} \mathbb{Z} = (\boldsymbol{\xi}, \boldsymbol{\sigma}, \boldsymbol{\zeta}_e, \boldsymbol{\zeta}_c) &\in [\mathbf{H}^{-1}(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{1/2}(\Gamma) \times \mathbf{H}^{1/2}(\Gamma)]' \\ &= \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma) \times \mathbf{H}^{-1/2}(\Gamma) \\ (\text{or } &= \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega) \times (\mathbf{H}_0^{1/2}(\Gamma_{(1)}))' \times (\mathbf{H}_0^{1/2}(\Gamma_c))') \end{aligned}$$

that satisfies the system of equations (2.9), i.e.,

$$\begin{aligned} -\nu \Delta \hat{\xi}_i + \hat{\xi}_j \frac{\partial \hat{v}_j}{\partial x_i} - \hat{v}_j \frac{\partial \hat{\xi}_i}{\partial x_j} + \frac{\partial \hat{\sigma}}{\partial x_i} &= 0 \\ \nabla \cdot \hat{\boldsymbol{\xi}} &= 0 \\ \hat{\boldsymbol{\xi}}|_{\Gamma} &= 0 \\ \hat{\boldsymbol{\zeta}}_2 &= -\mathbf{T}(\hat{\boldsymbol{\xi}})|_{\Gamma_c} \cdot \mathbf{n} \end{aligned}$$

and

$$\int_{\Gamma_c} \mathbf{T}(\hat{\boldsymbol{\xi}}) \cdot \mathbf{n} \cdot (\mathbf{g} - \hat{\mathbf{g}}) d\Gamma \geq 0, \quad \forall \mathbf{g} \in \mathcal{U};$$

thus inequality (2.10) is seen to hold in all cases. \square

Let us see what Theorem 1 gives us in the case where \mathcal{U} is given more structure. Suppose that \mathcal{U} is given by

$$\mathcal{U} = \{\mathbf{g} \in \mathbf{H}^{1/2} : \mathbf{g} \in \mathbf{A}(\mathbf{s}), \quad \text{for almost all } \mathbf{s} \in \Gamma_c\}$$

where $\mathbf{A}(\mathbf{s})$ is a compact, convex subset of R^n for all \mathbf{s} . If we consider the sets

$$\mathcal{G}_{s_0, \epsilon} = \{\mathbf{g} \in \mathcal{U} \ni \mathbf{g} = \hat{\mathbf{g}} \text{ on } \Gamma_{s_0, \epsilon} = \Gamma - \Gamma \cap B(\mathbf{s}_0, \epsilon)\},$$

then our condition reduces to

$$\int_{\Gamma_{s_0, \epsilon}} [\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\hat{\boldsymbol{\xi}})] \cdot \mathbf{n} \cdot (\mathbf{g} - \hat{\mathbf{g}}) d\Gamma \geq 0, \quad \forall \mathbf{g} \in \mathcal{G}_{s_0, \epsilon}, \quad \forall \mathbf{s}_0 \in \Gamma_c, \quad \forall \epsilon > 0.$$

But since $\mathbf{s}_0 \in \Gamma_c, \epsilon > 0$ are arbitrary, we find that the pointwise condition

$$[\mathbf{T}(\hat{\mathbf{v}})(\mathbf{s}) + \mathbf{T}(\hat{\boldsymbol{\xi}})(\mathbf{s})] \cdot \mathbf{n} \cdot (\mathbf{g} - \hat{\mathbf{g}}) \geq 0, \quad \forall \mathbf{g}(\mathbf{s}) \in \mathbf{A}(\mathbf{s}),$$

holds for almost all $\mathbf{s} \in \Gamma_c$.

3. Finite-dimensional control. Suppose that \mathcal{U} is a compact convex subset of T , an m -dimensional subspace of $\mathbf{H}^{1/2}(\Gamma)$ spanned by the m functions $\{\boldsymbol{\phi}^k\}_1^m$. For the sake of unity of presentation we will assume that property C holds, although everything is true mutatis mutandis in any case and the final recipe is the same. Let the set of

vectors $\{\mathbf{w}^k\}$, $1 \leq k \leq m$, be a basis for R^m , which we identify with the set $\{\phi^k\}$, so that T can be thought of as either $R^m = \text{span}\{\mathbf{w}_k\}$ or as $\text{span}\{\phi^k\} \subset \mathbf{H}^{1/2}(\Gamma_c)$. Thus any control vector $\mathbf{g} \in \mathcal{U}$ has a representation of the form

$$\mathbf{g}(\mathbf{s}) = \sum g_k \phi^k \quad \text{or} \quad \mathbf{g} = \sum g_k \mathbf{w}^k$$

in T .

Let $\Pi : \mathbf{H}^{1/2} \rightarrow T$ be the projection. Let $j : T \rightarrow \mathbf{H}^{1/2}$ be the canonical injection. Then we can write the components, $\{\Pi \mathbf{g}\}_k$, as

$$\{\Pi \mathbf{g}\}_k = \langle \langle \mathbf{g}, \phi^k \rangle \rangle_T .$$

Here we use the $\mathbf{H}^{1/2}$ inner product.

Recall the minimum principle (2.13). The integral on the left in that inequality is the duality relation $\mathbf{H}^{-1/2} \times \mathbf{H}^{1/2}$, which can be written

$$\langle (T(\mathbf{v}) + T(\hat{\xi})) \cdot \mathbf{n}, j\Pi(\mathbf{g} - \hat{\mathbf{g}}) \rangle$$

for $\mathbf{g} \in T$. This equals

$$\langle j'(\mathbf{T} + \mathbf{T}), \Pi(\mathbf{g} - \hat{\mathbf{g}}) \rangle$$

which is the duality pairing of $T' \times T$. Thus the minimum principle is

$$\langle j'(\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\hat{\xi})) \cdot \mathbf{n}, (\mathbf{g} - \hat{\mathbf{g}}) \rangle \geq 0, \quad \forall \mathbf{g} \in \mathcal{U} .$$

(This is duality pairing in $T' \times T$.) Let us give T' the dual basis:

$$\text{either } \{\omega_k\}, \quad \text{or} \quad \{\psi^k\}$$

where

$$\langle \omega_k, \mathbf{w}_j \rangle = \delta_{kj}, \quad \langle \psi^k, \phi^j \rangle = \delta_{kj} .$$

The operator dual to j , $j' : \mathbf{H}^{-1/2} \rightarrow T'$ is a projection since T is closed. Thus we can define components

$$\eta^k = \langle \langle j'(\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\hat{\xi})), \psi^k \rangle \rangle_{-1/2}$$

so that the minimum principle (2.13) now becomes

$$\sum_k \eta^k (g - \hat{g})_k \geq 0, \quad \forall \mathbf{g} = \{g_k\} \in \mathcal{U} .$$

Let us look at the special case where \mathcal{U} is a parallelepiped

$$\{a_k \leq g_k \leq b_k\} ;$$

then the minimum principle is seen to resolve itself as m independent inequations

$$\eta^k (h - \hat{g}_k) \geq 0, \quad \forall h \in [a_k, b_k]$$

and thus we have the following prescription for the optimal control:

$$(3.1) \quad \begin{aligned} &\text{if } \eta^k > 0 \text{ then } \hat{g}_k = a_k \\ &\text{if } \eta^k < 0 \text{ then } \hat{g}_k = b_k . \end{aligned}$$

If $\eta^k = 0$, then the Lagrange necessary condition gives no information about \hat{g}_k .

We see that in this procedure, the η_k would seem to have to be computed in the $\mathbf{H}^{-1/2}$ inner product, which may pose computational difficulties. It turns out that by choosing the $\{\phi^k\}$ properly we can avoid this situation. In particular, suppose that the $\{\phi^k\}$ form an orthonormal set in $\mathbf{H}^{1/2}$. Let $\Lambda : \mathbf{H}^{1/2} \rightarrow \mathbf{H}^{-1/2}$ be the canonical isomorphism; then

$$\langle \Lambda \phi^k, \phi^j \rangle = \delta_{kj}$$

where this is duality. This means that we can choose the sequence $\{\psi^k\} = \{\Lambda \phi^k\}$, and

$$\begin{aligned} \eta_k &= \langle \mathbf{T}(\mathbf{v}) + \mathbf{T}(\boldsymbol{\xi}), \psi^k \rangle_{-1/2} = \langle \mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\boldsymbol{\xi}), \Lambda \phi^k \rangle_{-1/2} \\ &= \langle \mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\boldsymbol{\xi}), \phi^k \rangle; \end{aligned}$$

in other words,

$$(3.2) \quad \eta^k = \int_{\Gamma_c} [\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\hat{\boldsymbol{\xi}})] \cdot \mathbf{n} \cdot \phi^k d\Gamma.$$

In the degenerate case, the prescription (3.1) continues to hold, although in that case, we have

$$\eta^k = \int_{\Gamma_c} \mathbf{T}(\hat{\boldsymbol{\xi}}) \cdot \mathbf{n} \cdot \phi^k d\Gamma.$$

4. Application to drag reduction via discrete blow holes. Let us consider the situation where there are m subregions of Γ_c , say the set $\{\Gamma_k\}$, such that

$$\Gamma_c - \cup \Gamma_k \neq \emptyset, \quad \overline{\Gamma_k \cup \Gamma_j} = \emptyset \quad k \neq j.$$

Consider a set of vector-valued functions, $\{\phi^k\}$ in $\mathbf{H}^{1/2}(\Gamma_c)$ such that

$$\text{supp } \phi^k \subset \Gamma_k, \quad \forall k,$$

so, clearly, these functions are orthogonal; we also want them normalized in the $\mathbf{H}^{1/2}$ norm.

We will define our admissibility set for the control as

$$\mathcal{U} = \{ \mathbf{g} \in \mathbf{H}^{1/2}(\Gamma_c) : \mathbf{g} = \sum \gamma_k \phi^k, a_k \leq \gamma_k \leq b_k, a_k, b_k \in R, \quad \forall k \}.$$

Now we can apply the framework of the last section. Let T be identified with Euclidean m -space, with the usual basis; i.e.,

$$\{\mathbf{e}_1, \dots, \mathbf{e}_m\}.$$

The minimum principle is

$$\sum_k \int_{\Gamma_k} [\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\boldsymbol{\xi})] \cdot \mathbf{n} \cdot (\mathbf{g} - \hat{\mathbf{g}}) d\Gamma \geq 0, \quad \forall \mathbf{g} \in \mathcal{U},$$

which reduces to

$$\sum_k \eta^k (g - \hat{g})_k \geq 0, \quad \forall \mathbf{g} = \{g_k\} \in \mathcal{U},$$

where

$$\eta^k = \int_{\Gamma_k} [\mathbf{T}(\hat{\mathbf{v}}) + \mathbf{T}(\hat{\boldsymbol{\xi}})] \cdot \mathbf{n} \cdot \boldsymbol{\phi}^k d\Gamma.$$

Note that an *apparent* difficulty in implementation is the normalization of the basis vectors in the $\frac{1}{2}$ norm. Suppose that, instead,

$$\int_{\Gamma} [(\phi_1^k)^2 + \dots + (\phi_n^k)^2] d\Gamma = 1, \quad \forall k.$$

so that they are actually an orthonormal set in $\mathbf{L}^2(\Gamma)$. But this is also the duality pairing, thus we can choose the $\boldsymbol{\psi}$'s to be the $\boldsymbol{\phi}$'s. But in this case,

$$\eta_k = \langle \mathbf{T}, \boldsymbol{\phi}^k \rangle_{-1/2} = \langle \mathbf{T}, \Lambda^{-1} \boldsymbol{\phi}^k \rangle$$

which means that the η 's would be difficult to compute. In any case, the question of computing the η^k is moot, unless we know whether or not property C is to hold. The question of efficiently computing the optimum is far from satisfactorily settled. The formula (3.1) gives us the structure of the optimal solution, but it may be prohibitively expensive to have to visit each vertex of the m -cube. Note that the $\frac{1}{2}$ norm of the basis functions is not necessarily difficult to calculate. A reasonable choice of basis functions, at least for a_k and b_k small, are the piecewise linear functions, i.e., hat functions over the holes. These $\mathbf{H}^{1/2}$ -norms can be computed. For example, if $n = 2$, and $\Gamma_1 = [0, b]$, and

$$\phi_1^1 = \begin{cases} (2h/b)x & \text{if } x \leq b/2 \\ 2h(1 - x/b) & \text{if } x > b/2 \end{cases}$$

then,

$$\|\phi_1^1\|_{1/2}^2 = h^2[b/6 + 16/b^2 + 8(\ln(2) - 1/4)].$$

Remark 1. Note that the vector (η^1, \dots, η^m) is matrix representation for a Jacobian of $J'(\hat{\mathbf{g}})$. Thus, if $\eta^j = 0$ then $\hat{g}^j \in [a_k, b_k]$ is arbitrary, and we have a one-parameter family of extremals, parametrized by $[a_j, b_j]$. In the application at hand, this means that the j th control hole could be removed without effect on the functional. It would be interesting to know whether this kind of degeneracy affects the convergence of the approximation.

Remark 2. Care must be taken to make the problem well-posed, not only in the sense of existence and regularity, but also with respect to the control. Degeneracies can arise in several ways: if property C does not hold then it is seen that the necessary conditions do not involve the cost functional; this means that the constraint set does not have the structure that we want; it is not a manifold, or solutions of the constraint equations are so sparse that a variational approach is not useful. On the other hand, if $\mathbf{g} \in \mathcal{U}$ supplies an unconstrained minimum (for example, if $\mathbf{v}_\infty = 0$ and $\mathbf{g} = 0$, then $J'(\hat{\mathbf{v}}) \equiv 0$, and the constraint is superfluous; in which case a result such as (3.1) would be useless. Note that we do not have to explicitly rule out this case, for then, as can be deduced from the previous remark, $\eta_k = 0$, for all k .

5. A simple computational example. Recall that the problem to be discretized is given by

$$\begin{aligned} a(\mathbf{v}, \mathbf{w}) + c(\mathbf{v}, \mathbf{v}, \mathbf{w}) + b(\mathbf{w}, p) &= 0, & \forall \mathbf{w} \in \mathbf{H}_0^1(\Omega) \\ b(\mathbf{v}, q) &= 0, & \forall q \in L_0^2(\Omega) \\ \mathbf{v}|_{\Gamma_k} &= \mathbf{g}_k \\ \mathbf{v}|_{\Gamma - (\cup \Gamma_k) \cup \Gamma_{(1)}} &= \mathbf{w}_0 \\ \mathbf{T}(\mathbf{v}) \cdot \mathbf{n}|_{\Gamma_{(2)}} &= 0, \end{aligned}$$

where \mathbf{w}_0 is a prescribed function. For the simple example given below we did not use the adjoint system in the updating procedure, only the theoretical fact that the optimal solution is bang-bang i.e., given by (3.1) and (3.2). The discretization is effected using a standard finite element algorithm (cf. [7]). Thus, we choose finite element subspaces

$$\mathbf{V}^h \subset \mathbf{H}^1(\Omega)$$

and

$$S^h \subset L_0^2(\Omega)$$

and require that $\mathbf{v}^h \in \mathbf{V}^h$ and $p^h \in S^h$ satisfy

$$\begin{aligned} a(\mathbf{v}^h, \mathbf{w}^h) + c(\mathbf{v}^h, \mathbf{v}^h, \mathbf{w}^h) + b(\mathbf{w}^h, p^h) &= 0, & \forall \mathbf{w}^h \in \mathbf{V}^h \\ b(\mathbf{v}^h, q^h) &= 0, & \forall q^h \in S^h \\ \mathbf{v}^h|_{\Gamma_k} &= \mathbf{g}_k^h, \\ \mathbf{v}^h|_{\Gamma - (\cup \Gamma_k) \cup \Gamma_{(1)}} &= \mathbf{w}_0^h, \end{aligned}$$

where \mathbf{g}_k^h and \mathbf{w}_0^h are suitable approximations to \mathbf{g}_k and \mathbf{w}_0 , respectively. (See the discussion above.)

The particular computational problem we consider here is described in Fig. 1.

Fig. 1. Geometry and hole placement for flow over a forward facing step.

Here, Γ_k , $k = 1, 2, 3, 4$, are the regions indicated and \mathbf{w}_0 is zero on the top and bottom portions of $\Gamma - \cup_k \Gamma_k$ and nonzero on the inflow and outflow portions. This problem is of use in viscous drag reduction studies. The step represents a protuberance on a wing, e.g., due to struts, rivets, etc. These obstacles can trip separation or accelerate transition to turbulence. Our studies examine how the injection or suction of fluid can ameliorate the negative influence of the step. We use the Taylor-Hood element pair as amended by [12]. Continuous piecewise quadratic polynomials with respect to a triangulation of the flow domain are employed for the velocity components. For the pressure approximation, we use continuous piecewise linear polynomials with respect

to the same triangulation, augmented by a piecewise constant in each triangle. This locally mass conserving element pair is known to provide the error estimate (see [12])

$$\|\mathbf{v} - \mathbf{v}^h\|_0 + h(\|\mathbf{v} - \mathbf{v}^h\|_1 + \|p - p^h\|_0) \leq Ch^{s+1}(\|\mathbf{v}\|_{s+1} + \|p\|_s),$$

whenever

$$\mathbf{v} \in \mathbf{H}^{s+1}(\Omega), \quad p \in H^s(\Omega), \quad 1 \leq s \leq 2,$$

where h is a measure of the size of the finite element grid, and whenever \mathbf{g}_k^h and \mathbf{w}_0^h are accurate enough approximations. For example, the above estimate holds if we merely take \mathbf{g}_k^h and \mathbf{w}_0^h to be the interpolant, in \mathbf{V}^h restricted to the appropriate segment of Γ , of \mathbf{g}_k and \mathbf{w}_0 respectively.

For the computation we choose the velocity profile at the hole to satisfy

$$\mathbf{g}_k \cdot \mathbf{n} = \alpha_k p_{2k}, \quad \alpha_k \in [a_k, b_k] \quad \text{and} \quad \mathbf{g} \times \mathbf{n} = 0,$$

where p_{2k} is a quadratic polynomial vanishing at the edge of the hole. Then, our control set is determined by the appropriate parameters. From the theory presented above, we know that, for the optimal solution, α_k must be either a_k or b_k . Thus, to determine the optimal solution, we need to solve our finite element problem with \mathbf{g}_k given, following the above prescription. One may then compute $J(\mathbf{v})$ for each of these cases (16 in this example), and thus determine the minimum.

We choose the a_k, b_k so that the maximum mass flow in or out of any hole is 1/12 of the mass flow at the inflow. We compute the dissipation function with each hole blowing, sucking, or turned off. If only blowing is allowed, i.e., $a_k = 0$, it is found that the dissipation function is minimized if only the second hole is active. If only suction is allowed, i.e., $b_k = 0$, it is found that allowing only the third hole to be active is best. If both blowing and suction are allowed, i.e., $a_k = -b_k$, then having suction through the third hole and injection through the second hole is best.

THE DISCRETE TIME H_∞ CONTROL PROBLEM WITH MEASUREMENT FEEDBACK*

A. A. STOORVOGEL†

Abstract. This paper is concerned with the discrete time H_∞ control problem with measurement feedback. It follows that, as in the continuous time case, the existence of an internally stabilizing controller that makes the H_∞ norm strictly less than 1 is related to the existence of stabilizing solutions to two algebraic Riccati equations. However, in the discrete time case, the solutions of these algebraic Riccati equations must satisfy extra conditions.

Key words. H_∞ control, discrete time, algebraic Riccati equation, measurement feedback.

AMS(MOS) subject classifications. 93C05, 93C35, 93C45, 93C55, 49B99, 49C05

1. Introduction. The H_∞ control problem with measurement feedback has been thoroughly investigated (see, e.g., [5], [6], [7], [13], [14], [21], [22], [24], [28]). However, all of these papers discuss the continuous time case. In this paper, in contrast with the above papers, we discuss the discrete time case.

In practical applications, most people are mainly concerned with discrete time systems. One major reason is that to control a continuous time system we often apply a digital computer on which we can only implement a discrete time controller. One possible approach is to derive a continuous time H_∞ controller and then to discretize the controller so that a computer may be used.

Discretizing the system first and then using H_∞ control designed for discrete time systems might be a more useful approach. This comparison can, only be made, however, after the discrete time H_∞ control problem has been solved. Taking the effects of discretization into account is another possibility, see [3], [4].

Also, certain systems are in themselves inherently discrete, and certainly for these systems it is useful to have results available for H_∞ control problems.

One approach is to apply a transformation in the frequency-domain that transforms discrete time systems to continuous time systems. The transformation we have in mind is discussed, for instance, in [8, App. 1]. With this transformation, discrete time H_∞ functions are mapped isometrically onto continuous time H_∞ functions. We can then use the results available for continuous time systems and afterward apply the inverse transformation on the controller thus obtained.

This transformation, however, is not always attractive. It maps systems with a pole in 1 into nonproper systems. Also this transformation is such that it clouds the understanding of specific features of discrete time H_∞ control because of this complex transformation. If it is possible to derive results for discrete time systems, why not apply these results directly instead of performing this unnatural transformation?

In the papers on H_∞ control with continuous time, several methods were used to solve the H_∞ control problem. Recently, a paper solving the discrete time H_∞ control problem using frequency domain techniques has appeared (see [12]). Also the polynomial approach has been applied to discrete time systems (see [11]). Derivation of the results for the discrete time H_∞ control problem could probably also be based on the work of [26]. In addition, several papers have appeared using a time-domain approach

(see [1], [16], [27]). However, [16] does not contain any proof of the results obtained, and [1], [27] make a number of extra assumptions on the system under consideration. In [1], [16], [27] the authors first investigate the finite horizon problem and then derive a solution of the infinite horizon problem by considering it as a kind of limiting case as the endpoint tends to infinity.

In contrast, this paper directly investigates the infinite horizon case. We use time-domain techniques that have many familiarities with those used in [22], [24], which deal with the continuous time case. The method used in this paper was derived independently from [1], [16], [27]. The current paper is an extension of [23], which deals with the full-information case. However, contrary to the latter paper, here we give detailed proofs of all our results.

We assume that two particular transfer matrices are left- and right-invertible, respectively. The only other assumption we must make is that two subsystems have no invariant zeros on the unit circle. Our assumptions are exactly the discrete time analogues of the assumptions in [9]. The assumptions we make are weaker than the assumptions in [12], [27], and the same as the ones made in [16].

As in the continuous time case, the necessary and sufficient conditions for the existence of suitable controllers involve positive semidefinite stabilizing solutions of two algebraic Riccati equations. As in the continuous time case, the quadratic term in these algebraic Riccati equations is indefinite. However, compared to the continuous time case, the solutions of these equations must satisfy another assumption: matrices depending on these solutions should be positive definite.

The outline of this paper is as follows. In §2 we will formulate the problem and give our main results. In §3 we will derive the existence of a stabilizing solution of the first algebraic Riccati equation starting from the assumption that there exists an internally stabilizing feedback that makes the H_∞ norm of the closed loop system less than 1. In §4 we will show the existence of a stabilizing solution of the second algebraic Riccati equation and complete the proof that our conditions are necessary. This is done by transforming the original system into a new system with the property that a controller “works” for the new system if and only if it “works” for the original system. In §5 it is shown that our conditions are also sufficient. It follows that the system transformation of §4 repeated in a dual form exactly gives the desired results. We will end with some concluding remarks in §6.

2. Problem formulation and main results. By \mathcal{N} and \mathcal{R} we denote the natural numbers and the real numbers, respectively. Moreover, by σ we denote the shift $(\sigma x)(k) := x(k+1)$ for all $k \in \mathcal{N}$. At a certain stage, we also need a backward difference equation of the form $\sigma^{-1}x = Ax + Bu$. We define the solution x to be a mapping from $\mathcal{N} \cup \{-1\}$ to \mathcal{R}^n given by

$$\begin{cases} x|_{\mathcal{N}} = \sigma A(x|_{\mathcal{N}}) + \sigma Bu, \\ x(-1) = Ax(0) + Bu(0). \end{cases}$$

It will follow that extending this function from \mathcal{N} to $\mathcal{N} \cup \{-1\}$ is a useful definition.

We consider the following time-invariant system:

$$(2.1) \quad \Sigma : \begin{cases} \sigma x = Ax + Bu + Ew, \\ y = C_1x + \quad \quad + D_{12}w, \\ z = C_2x + D_{21}u + D_{22}w, \end{cases}$$

where for all $k \in \mathcal{N}$, $x(k) \in \mathcal{R}^n$ is the state, $u(k) \in \mathcal{R}^m$ is the control input, $y(k) \in \mathcal{R}^l$ is the measurement, $w(k) \in \mathcal{R}^9$ is the unknown disturbance, and $z(k) \in \mathcal{R}^p$ is the

output to be controlled. $A, B, E, C_1, C_2, D_{12}, D_{21}$, and D_{22} are matrices of appropriate dimension.

If we apply a dynamic feedback law $u = Fy$ to Σ , then the closed loop system with zero initial conditions defines a convolution operator $\Sigma_{cl,F}$ from w to y . We seek a feedback law $u = Fy$ that is internally stabilizing and that minimizes the ℓ_2 -induced operator norm of $\Sigma_{cl,F}$ over all internally stabilizing feedback laws. We will investigate dynamic feedback laws of the form

$$(2.2) \quad \Sigma_F : \begin{cases} \sigma p = Kp + Ly, \\ u = Mp + Ny. \end{cases}$$

We will say that the dynamic compensator Σ_F , given by (2.2), is internally stabilizing when applied to the system Σ , described by (2.1), if the following matrix is asymptotically stable:

$$(2.3) \quad \begin{pmatrix} A + BNC_1 & BM \\ LC_1 & K \end{pmatrix};$$

i.e., all its eigenvalues lie in the open unit disc. Denote by G_F the closed loop transfer matrix. The ℓ_2 -induced operator norm of the convolution operator $\Sigma_{cl,F}$ is equal to the H_∞ norm of the transfer matrix G_F and is given by

$$\begin{aligned} \|G_F\|_\infty &:= \sup_{\theta \in [0, 2\pi]} \|G_F(e^{i\theta})\| \\ &= \sup_w \left\{ \frac{\|z\|_2}{\|w\|_2} \mid w \in \ell_2^l, w \neq 0 \right\}, \end{aligned}$$

where the ℓ_2 -norm is given by

$$\|p\|_2 := \left(\sum_{k=0}^{\infty} p^T(k)p(k) \right)^{1/2}$$

and where $\|\cdot\|$ denotes the largest singular value. We refer to this norm as the H_∞ norm of the closed loop system.

In this paper we will derive necessary and sufficient conditions for the existence of a dynamic compensator Σ_F that is internally stabilizing and which is such that the closed loop transfer matrix G_F satisfies $\|G_F\|_\infty < 1$. Furthermore, if a stabilizing Σ_F exists, which makes the H_∞ norm of the closed loop system less than 1, then we derive an explicit formula for one particular Σ_F satisfying these requirements.

By scaling the plant, we can thus, in principle, find the infimum of the H_∞ norm of the closed loop system over all stabilizing controllers. This will involve a search procedure.

In the formulation of our main result we will need the concept of invariant zero: z_0 is called an *invariant zero* of the system (A, B, C, D) if

$$\text{rank}_{\mathcal{R}} \begin{pmatrix} z_0 I - A & -B \\ C & D \end{pmatrix} < \text{rank}_{\mathcal{R}(z)} \begin{pmatrix} zI - A & -B \\ C & D \end{pmatrix},$$

where $\text{rank}_{\mathcal{K}}$ denotes the rank as a matrix with entries in the field \mathcal{K} . By $\mathcal{R}(z)$ we denote the field of real rational functions. The system (A, B, C, D) is called *left- (right-) invertible* if the transfer matrix $C(zI - A)^{-1}B + D$ is left- (right-) invertible

as a matrix with entries in the field of real rational functions. We can now formulate our main result.

THEOREM 2.1. *Consider system (2.1). Assume that the system (A, B, C_2, D_{21}) has no invariant zeros on the unit circle and is left-invertible. Moreover, assume that the system (A, E, C_1, D_{12}) has no invariant zeros on the unit circle and is right invertible. The following statements are equivalent:*

- (i) *There exists a dynamic compensator Σ_F of the form (2.2) such that the resulting closed loop transfer matrix G_F satisfies $\|G_F\|_\infty < 1$ and the closed loop system is internally stable.*
- (ii) *There exist symmetric matrices $P \geq 0$ and $Y \geq 0$ such that*
 - (a) *We have*

$$(2.4) \quad V > 0, \quad R > 0,$$

where

$$\begin{aligned} V &:= B^T P B + D_{21}^T D_{21}, \\ R &:= I - D_{22}^T D_{22} - E^T P E \\ &\quad + (E^T P B + D_{22}^T D_{21}) V^{-1} (B^T P E + D_{21}^T D_{22}). \end{aligned}$$

This implies that the matrix $G(P)$ is invertible, where

$$(2.5) \quad G(P) := \begin{pmatrix} D_{21}^T D_{21} & D_{21}^T D_{22} \\ D_{22}^T D_{21} & D_{22}^T D_{22} - I \end{pmatrix} + \begin{pmatrix} B^T \\ E^T \end{pmatrix} P \begin{pmatrix} B & E \end{pmatrix}.$$

- (b) *P satisfies the discrete algebraic Riccati equation*

$$(2.6) \quad P = A^T P A + C_2^T C_2 - \begin{pmatrix} B^T P A + D_{21}^T C_2 \\ E^T P A + D_{22}^T C_2 \end{pmatrix}^T G(P)^{-1} \begin{pmatrix} B^T P A + D_{21}^T C_2 \\ E^T P A + D_{22}^T C_2 \end{pmatrix}.$$

- (c) *The matrix $A_{cl,P}$ is asymptotically stable, where*

$$(2.7) \quad A_{cl,P} := A - \begin{pmatrix} B & E \end{pmatrix} G(P)^{-1} \begin{pmatrix} B^T P A + D_{21}^T C_2 \\ E^T P A + D_{22}^T C_2 \end{pmatrix}.$$

Moreover, if, given the matrix P satisfying (a)–(c), we define the following matrices:

$$\begin{aligned} H &:= E^T P A + D_{22}^T C_2 - [E^T P B + D_{22}^T D_{21}] V^{-1} [B^T P A + D_{21}^T C_2], \\ A_P &:= A + E R^{-1} H, \\ E_P &:= E R^{-1/2}, \\ C_{1,P} &:= C_1 + D_{12} R^{-1} H, \\ C_{2,P} &:= V^{-1/2} (B^T P A + D_{21}^T C_2) + V^{-1/2} [B^T P E + D_{21}^T D_{22}] R^{-1} H, \\ D_{12,P} &:= D_{12} R^{-1/2}, \\ D_{21,P} &:= V^{1/2}, \\ D_{22,P} &:= V^{-1/2} (B^T P E + D_{21}^T D_{22}) R^{-1/2}, \end{aligned}$$

then the matrix Y should satisfy

(d) *We have*

$$(2.8) \quad W > 0, \quad S > 0,$$

where

$$\begin{aligned} W &:= D_{12,P} D_{12,P}^T + C_{1,P} Y C_{1,P}^T, \\ S &:= I - D_{22,P} D_{22,P}^T - C_{2,P} Y C_{2,P}^T \\ &\quad + (C_{2,P} Y C_{1,P}^T + D_{22,P} D_{12,P}^T) W^{-1} (C_{1,P} Y C_{2,P}^T + D_{12,P} D_{22,P}^T). \end{aligned}$$

This implies that the matrix $H_P(Y)$ is invertible, where

$$(2.9) \quad H_P(Y) := \begin{pmatrix} D_{12,P} D_{12,P}^T & D_{12,P} D_{22,P}^T \\ D_{22,P} D_{12,P}^T & D_{22,P} D_{22,P}^T - I \end{pmatrix} + \begin{pmatrix} C_{1,P} \\ C_{2,P} \end{pmatrix} Y \begin{pmatrix} C_{1,P} \\ C_{2,P} \end{pmatrix}^T.$$

(e) *Y satisfies the following discrete algebraic Riccati equation:*

$$(2.10) \quad Y = A_P Y A_P^T + E_P E_P^T - \begin{pmatrix} C_{1,P} Y A_P^T + D_{12,P} E_P^T \\ C_{2,P} Y A_P^T + D_{22,P} E_P^T \end{pmatrix}^T H_P(Y)^{-1} \begin{pmatrix} C_{1,P} Y A_P^T + D_{12,P} E_P^T \\ C_{2,P} Y A_P^T + D_{22,P} E_P^T \end{pmatrix}.$$

(f) *The matrix $A_{cl,P,Y}$ is asymptotically stable, where*

$$(2.11) \quad A_{cl,P,Y} := A_P - \begin{pmatrix} C_{1,P} Y A_P^T + D_{12,P} E_P^T \\ C_{2,P} Y A_P^T + D_{22,P} E_P^T \end{pmatrix}^T H_P(Y)^{-1} \begin{pmatrix} C_{1,P} \\ C_{2,P} \end{pmatrix}.$$

In the case where there exist $P \geq 0$ and $Y \geq 0$ satisfying (ii), then a controller of the form (2.2) satisfying the requirements in (i) is given by

$$\begin{aligned} N &:= -D_{21,P}^{-1} (C_{2,P} Y C_{1,P}^T + D_{22,P} D_{12,P}^T) W^{-1}, \\ M &:= -(D_{21,P}^{-1} C_{2,P} + N C_{1,P}), \\ L &:= B N + (A_P Y C_{1,P}^T + E_P D_{12,P}^T) W^{-1}, \\ K &:= A_{cl,P} - L C_{1,P}. \end{aligned}$$

Remarks.

(i) Necessary and sufficient conditions for the existence of an internally stabilizing feedback compensator, which makes the H_∞ norm of the closed loop system less than some, a priori given, upper bound $\gamma > 0$, can be easily derived from Theorem 2.1 by scaling.

(ii) If we compare these conditions with the conditions for the continuous time case (see [6], [22]) we note that conditions (2.4) and (2.8) are this time depending on the solutions of the two Riccati equations. A simple example showing that the assumption $G(P)$ invertible is not sufficient is given by the system

$$\begin{cases} \sigma x &= u + 2w, \\ y &= \begin{pmatrix} 1 \\ 0 \end{pmatrix} x + \begin{pmatrix} 0 \\ 1 \end{pmatrix} w, \\ z &= \begin{pmatrix} 1 \\ 0 \end{pmatrix} x + \begin{pmatrix} 0 \\ 1 \end{pmatrix} u. \end{cases}$$

There does not exist a dynamic compensator satisfying the requirements of part (i) of Theorem 2.1, but there does exist a positive semidefinite matrix P satisfying (2.6) such that matrix (2.7) is asymptotically stable, namely $P = 1$. However, for this P we have $R = -1$. Therefore matrices like E_p are ill-defined and we cannot even look for a matrix Y satisfying (2.8)–(2.11).

(iii) Since our starting point of the proof of (i) \Rightarrow (ii) will not be part (i) of theorem 2.1 but Condition 3.2, it can be shown that we cannot make the H_∞ norm less by allowing more general, possibly even nonlinear, causal feedbacks.

The proof of the existence of a stabilizing solution of the Riccati equation will be reminiscent of the proof given in [24] for the continuous time case. However due to our weaker assumptions and conditions (2.4) and (2.8), there are quite a number of extra intricacies. The remainder of the proof is based on [22].

Another interesting case was discussed in [23]. However, the latter reference only gives the general outline of the proof. In contrast, the present paper will give much more detail. Reference [23] discusses the so-called full-information case, shown below.

Full information case. $C_1 = \begin{pmatrix} I \\ 0 \end{pmatrix}$, $D_{12} = \begin{pmatrix} 0 \\ I \end{pmatrix}$.

In this case, we have $y_1 = x$ and $y_2 = w$; i.e., we know both the state and the disturbance of the system at time k . However, we cannot apply Theorem 2.1 to this case since system (A, E, C_1, D_{12}) is not right-invertible. Nevertheless, following the proof for this special case, it can be shown that there exists a feedback satisfying part (i) of Theorem 2.1 if and only if there exists a symmetric matrix $P \geq 0$ satisfying conditions (a)–(c) of part (ii) of Theorem 2.1. Moreover, in that case we can find static output feedbacks $u = F_1 x + F_2 w$ with the desired properties. One particular choice for $F = (F_1, F_2)$ is given by

$$(2.12) \quad F_1 := -(D_{21}^T D_{21} + B^T P B)^{-1} (B^T P A + D_{21}^T C_2),$$

$$(2.13) \quad F_2 := -(D_{21}^T D_{21} + B^T P B)^{-1} (B^T P E + D_{21}^T D_{22}).$$

3. Existence of stabilizing solutions of the Riccati equations. In this section we assume that part (i) of Theorem 2.1 is satisfied. We will show that the existence of P satisfying conditions parts (a)–(c) in (ii) is necessary.

Consider system (2.1). For given disturbance w and control input u let $x_{u,w,\xi}$ and $z_{u,w,\xi}$ denote, respectively, the resulting state and output for initial state $x(0) = \xi$. If $\xi = 0$ we will simply write $x_{u,w}$ and $z_{u,w}$. We first give a definition.

DEFINITION 3.1. An operator $f : \ell_2 \rightarrow \ell_2$, $w \rightarrow f(w)$ is called causal if for any $w_1, w_2 \in \ell_2$, and $k \in \mathcal{N}$:

$$w_1|_{[0,k]} = w_2|_{[0,k]} \Rightarrow f(w_1)|_{[0,k]} = f(w_2)|_{[0,k]}.$$

f is called strictly causal if for any $w_1, w_2 \in \ell_2$, and $k \in \mathcal{N}$ we have

$$w_1|_{[0,k-1]} = w_2|_{[0,k-1]} \Rightarrow f(w_1)|_{[0,k]} = f(w_2)|_{[0,k]}.$$

A controller of the form (2.2) always defines a causal operator. In the case where $N = 0$, this operator is strictly causal. We will label the following condition.

CONDITION 3.2. (A, B) stabilizable and for system (2.1) there exists causal $f : \ell_2^l \rightarrow \ell_2^n$ and $\delta < 1$ such that for all $w \in \ell_2^l$ with $u = f(w)$ we have $x_{u,w} \in \ell_2^n$ and $\|z_{u,w}\|_2 \leq \delta \|w\|_2$.

If there exists a dynamic compensator Σ_F such that $\|G_F\|_\infty < 1$ and such that the closed loop system is internally stable, then Condition 3.2 is satisfied. Hence if the

requirements of part (i) of Theorem 2.1 are satisfied, then Condition 3.2 holds. Note that Condition 3.2 is equivalent to the requirement that there exists a causal operator f such that the feedback $u = f(x, w)$ satisfies Condition 3.2. This follows from the fact that, after applying the feedback, there exists a causal operator g mapping w to x and, therefore, we could have started with the causal operator $u = f(g(w), w)$ in the first place. Conversely, if we have the feedback $u = f(w)$, then we define $f_1(x, w) := f(w)$, which then satisfies the requirements of the reformulated Condition 3.2.

Finally, we would like to remark that besides the obvious condition that (A, B) should be stabilizable, there is a more implicit extra condition $x_{u,w} \in \ell_2^n$, which is also related to stability. Intuitively, these two conditions imply that we cannot only find a controller that is input-output stabilizing (i.e., the closed loop transfer matrix is in H_∞) and that makes the H_∞ of the closed loop system less than 1, but even an internally stabilizing controller with the same property. This is only true for the full-information case (see [23]). For the more general measurement-feedback case, we need extra stability conditions related to detectability.

We will show that the existence of such causal f and $\delta < 1$ satisfying Condition 3.2 already implies that there exists a positive semidefinite solution of the discrete algebraic Riccati equation (2.6) such that (2.7) is asymptotically stable and (2.4) is satisfied. *We will assume for the time being that*

$$(3.1) \quad D_{21}^T [C_2 \quad D_{22}] = 0,$$

and we will derive the more general statement later. To prove the existence of the desired P , we will investigate the following sup-inf problem:

$$(3.2) \quad \mathcal{C}^*(\xi) := \sup_{w \in \ell_2^n} \inf_u \{ \|z_{u,w,\xi}\|_2^2 - \|w\|_2^2 \mid u \in \ell_2^m \text{ such that } x_{u,w,\xi} \in \ell_2^n \}$$

for arbitrary initial state ξ . We will prove that Condition 3.2 implies that $\mathcal{C}^*(\xi)$ is finite for every ξ . Moreover, it will be shown that there exists a $P \geq 0$ such that $\mathcal{C}^*(\xi) = \xi^T P \xi$. At the end of this section, we then prove that this P exactly satisfies conditions (a)–(c) of Theorem 2.1. We first infimize, for given $w \in \ell_2$ and $\xi \in \mathcal{R}^n$, the function $\|z_{u,w,\xi}\|_2^2 - \|w\|_2^2$ over all $u \in \ell_2$ for which $x_{u,w,\xi} \in \ell_2$. After that, we maximize over $w \in \ell_2$.

Our proof is based on Pontryagin's maximum principle. This only gives necessary conditions for optimality. However, in [15] a sufficient condition for optimality is derived over a finite horizon. We will use the ideas from [15], together with our stability requirement, $x_{u,w,\xi} \in \ell_2$, to adapt the proof to the infinite horizon case.

We start by constructing a solution of the adjoint Hamilton–Jacobi equation, which is a natural starting point if we use Pontryagin's maximum principle.

Let L be such that $D_{21}^T D_{21} + B^T L B$ is invertible and such that L is the positive semidefinite solution of the following discrete algebraic Riccati equation:

$$(3.3) \quad L = A^T L A + C_2^T C_2 - A^T L B (D_{21}^T D_{21} + B^T L B)^{-1} B^T L A$$

for which

$$(3.4) \quad A_L := A - B (D_{21}^T D_{21} + B^T L B)^{-1} B^T L A$$

is asymptotically stable. The existence of such L is guaranteed under the assumption that (A, B, C_2, D_{21}) has no invariant zeros on the unit circle and is left-invertible and,

moreover, that (A, B) is stabilizable (see [20]). We define

$$(3.5) \quad r(k) := - \sum_{i=k}^{\infty} [X_1 A^T]^{i-k} X_1 (LEw(i) + C_2^T D_{22}w(i+1)),$$

where

$$(3.6) \quad X_1 := I - LB(D_{21}^T D_{21} + B^T LB)^{-1} B^T.$$

Note that r is well defined since the matrix $A_L = X_1^T A$ is asymptotically stable, which implies that $X_1 A^T$ is asymptotically stable. Next, we define the functions y, \tilde{x} , and η by

$$(3.7) \quad y := M^{-1} B^T [A^T \sigma r - LEw - C_2^T D_{22} \sigma w],$$

$$(3.8) \quad \sigma \tilde{x} = A_L \tilde{x} + By + Ew, \quad \tilde{x}(0) = \xi,$$

$$(3.9) \quad \eta := -X_1 LA \tilde{x} + r,$$

where $M := D_{21}^T D_{21} + B^T LB$. Since $X_1 A^T$ is asymptotically stable, it can be checked straightforwardly that, given $\xi \in \mathcal{R}^n$ and $w \in \ell_2^l$, we have $r, \tilde{x}, \eta \in \ell_2$.

After some standard calculations, we find the following lemma.

LEMMA 3.3. *Let $\xi \in \mathcal{R}^n$ and $w \in \ell_2^l$ be given. The function $\eta \in \ell_2^n$ is a solution of the following backward difference equation:*

$$(3.10) \quad \sigma^{-1} \eta = A^T \eta - C_2^T C_2 \tilde{x} - C_2^T D_{22} w, \quad \lim_{k \rightarrow \infty} \eta(k) = 0.$$

Here η is extended to a function from $\mathcal{N} \cup \{-1\}$ to \mathcal{R}^n by choosing $\eta(-1)$ such that (3.10) is satisfied.

In the statement of Pontryagin's maximum principle, this equation is the so-called "adjoint Hamilton-Jacobi equation," and η is called the "adjoint state variable." We have constructed a solution to this equation and we show that this η indeed yields a minimizing u . Note the difference with the continuous time case (see [24]), where we could derive a differential equation forward in time, while in discrete time we can only derive a difference equation forward in time when A is invertible. To prevent these kinds of difficulties, it is assumed in [12] that A is invertible. The following lemma states that η yields a minimizing u .

LEMMA 3.4. *Let system (2.1) be given. Moreover, let w and ξ be fixed. Then*

$$\begin{aligned} \tilde{u} &:= -(D_{21}^T D_{21} + B^T LB)^{-1} B^T LA \tilde{x} + y \\ &= \arg \inf_u \{ \|z_{u,w,\xi}\|_2 \mid u \in \ell_2^m \text{ such that } x_{u,w,\xi} \in \ell_2^n \}. \end{aligned}$$

Proof. It can be easily checked that $\tilde{x} = x_{\tilde{u},w,\xi}$. Define

$$\mathcal{J}_T(u) := \sum_{i=0}^T \|C_2 x_{u,w,\xi}(i) + D_{21} u(i) + D_{22} w(i)\|^2.$$

Let $u \in \ell_2^m$ be an arbitrary control input such that $x_{u,w,\xi} \in \ell_2^n$. We find that

$$\begin{aligned} &\mathcal{J}_T(u) - \mathcal{J}_{T-1}(u) - 2\eta^T(T)x(T+1) + 2\eta^T(T-1)x(T) \\ &\quad \|C_2 x(T)\|^2 + [D_{21}^T D_{21} u(T) - 2B^T \eta(T)]^T u(T) - 2\eta^T(T)Ew(T) - 2x^T(T)C_2^T C_2 \tilde{x}(T). \end{aligned}$$

We also find that

$$\begin{aligned} \mathcal{J}_T(\tilde{u}) - \mathcal{J}_{T-1}(\tilde{u}) - 2\eta^T(T)\tilde{x}(T+1) + 2\eta^T(T-1)\tilde{x}(T) \\ = -\|C_2\tilde{x}(T)\|^2 + [D_{21}^T D_{21}\tilde{u}(T) - 2B^T\eta(T)]^T \tilde{u}(T) - 2\eta^T(T)Ew(T). \end{aligned}$$

Hence if we sum the last two equations from zero to infinity and subtract from each other we find that

$$\begin{aligned} \|z_{\tilde{u},w,\xi}\|_2^2 - \|z_{u,w,\xi}\|_2^2 &= \sum_{i=0}^{\infty} -\|C_2(x(i) - \tilde{x}(i))\|^2 \\ &+ \sum_{i=0}^{\infty} [D_{21}^T D_{21}\tilde{u}(i) - 2B^T\eta(i)]^T \tilde{u}(i) - [D_{21}^T D_{21}u(i) - 2B^T\eta(i)]^T u(i). \end{aligned}$$

It can easily be checked that $B^T\eta(i) = D_{21}^T D_{21}\tilde{u}(i)$ for all i . Therefore, for every i we have

$$[D_{21}^T D_{21}\tilde{u}(i) - 2B^T\eta(i)]^T \tilde{u}(i) = \inf_u [D_{21}^T D_{21}u - 2B^T\eta(i)]^T u.$$

Together, the last two equations imply that $\|z_{\tilde{u},w,\xi}\|_2 \leq \|z_{u,w,\xi}\|_2$, which is exactly what we had to prove. Since (A, B, C_2, D_{21}) is left-invertible, it can easily be shown that the minimizing u is unique. \square

We now maximize over $w \in \ell_2^l$. This will then yield $\mathcal{C}^*(\xi)$. Define $\mathcal{F}(\xi, w) := (\tilde{x}, \tilde{u}, \eta)$ and $\mathcal{G}(\xi, w) := z_{\tilde{u},w,\xi} = C_2\tilde{x} + D_{21}\tilde{u} + D_{22}w$. It is clear from the previous lemma that \mathcal{F} and \mathcal{G} are bounded linear operators. Define

$$\begin{aligned} \mathcal{C}(\xi, w) &:= \|\mathcal{G}(\xi, w)\|_2^2 - \|w\|_2^2, \\ \|w\|_C &:= (-\mathcal{C}(0, w))^{1/2}. \end{aligned}$$

It can be easily shown that $\|\cdot\|_C$ defines a norm on ℓ_2^l . Using Condition 3.2, it can be shown straightforwardly that

$$(3.11) \quad \|w\|_2 \geq \|w\|_C \geq \rho\|w\|_2,$$

where $\rho > 0$ is such that $\rho^2 = 1 - \delta^2$ and δ is such that Condition 3.2 is satisfied. Hence $\|\cdot\|_C$ and $\|\cdot\|_2$ are equivalent norms.

Note that Lemma 3.4 still holds if Condition 3.2 does not hold. However, the result that $\|\cdot\|_C$ is a norm and that even $\|\cdot\|_C$ and $\|\cdot\|_2$ are equivalent norms is the essential property, which is implied by Condition 3.2 and which is the key to our derivation.

We have

$$(3.12) \quad \mathcal{C}^*(\xi) = \sup_{w \in \ell_2^l} \mathcal{C}(\xi, w).$$

We can derive the following properties of \mathcal{C}^* .

LEMMA 3.5.

(i) For all $\xi \in \mathcal{R}^n$ we have

$$(3.13) \quad 0 \leq \xi^T L \xi \leq \mathcal{C}^*(\xi) \leq \frac{\xi^T L \xi}{1 - \delta^2},$$

where δ is such that Condition 3.2 is satisfied.

(ii) For all $\xi \in \mathcal{R}^n$ there exists a unique $w_* \in \ell_2^l$ such that $\mathcal{C}^*(\xi) = \mathcal{C}(\xi, w_*)$.

Proof. Part (i). It is well known that L , as the stabilizing solution of the discrete time algebraic Riccati equation (3.3), is the cost of the discrete time, linear quadratic problem with internal stability (see [20]). Hence $\|\mathcal{G}(\xi, 0)\|_2^2 = \mathcal{C}(\xi, 0) = \xi^T L \xi$. Therefore we have $0 \leq \xi^T L \xi \leq \mathcal{C}^*(\xi)$. Moreover,

$$\begin{aligned} \mathcal{C}(\xi, w) &= \|\mathcal{G}(\xi, w)\|_2^2 - \|w\|_2^2 \\ &\leq (\|\mathcal{G}(\xi, 0)\|_2 + \|\mathcal{G}(0, w)\|_2)^2 - \|w\|_2^2 \\ &\leq \left(\sqrt{\xi^T L \xi} + \delta \|w\|_2 \right)^2 - \|w\|_2^2 \\ &\leq \frac{\xi^T L \xi}{1 - \delta^2}. \end{aligned}$$

Part (ii) can be proved in the same way as in [24]. First, show that $\|\cdot\|_C$ satisfies

$$(3.14) \quad -\|w_\alpha - w_\beta\|_C^2 = 2\mathcal{C}(\xi, w_\alpha) + 2\mathcal{C}(\xi, w_\beta) - 4\mathcal{C}\left(\xi, \frac{1}{2}(w_\alpha + w_\beta)\right)$$

for arbitrary $\xi \in \mathcal{R}^n$. Then it can be shown that a maximizing sequence of $\mathcal{C}(\xi, w)$ is a Cauchy sequence with respect to the $\|\cdot\|_C$ -norm and hence, since $\|\cdot\|_C$ and $\|\cdot\|_2$ are equivalent norms, there exists a maximizing ℓ_2 function w_* . It is easy to show uniqueness using (3.14). \square

Define $\mathcal{H} : \mathcal{R}^n \rightarrow \ell_2^l$, $\xi \rightarrow w_*$. Unlike the explicit expression for \tilde{u} we can only derive an implicit formula for w_* . However, we show with the following lemma that w_* is the unique solution of a linear equation.

LEMMA 3.6. *Let $\xi \in \mathcal{R}^n$ be given. Then $w_* = \mathcal{H}\xi$ is the unique ℓ_2 -function w satisfying:*

$$(3.15) \quad (I - D_{22}^T D_{22})w = -E^T \eta + D_{22}^T C_2 x,$$

where $(x, u, \eta) = \mathcal{F}(\xi, w)$.

Proof. Define $(x_*, u_*, \eta_*) = \mathcal{F}(\xi, w_*)$. Moreover, define $w_0 := -E^T \eta(w_*) + D_{22}^T D_{22} w_* + D_{22}^T C_2 x_*$ and $(x_0, u_0, \eta_0) := \mathcal{F}(\xi, w_0)$. We find that

$$(3.16) \quad \begin{aligned} &\|z_{u_0, w_0, \xi}(T)\|^2 - \|w_0(T)\|^2 - 2\eta_*^T(T)x_0(T+1) + 2\eta_*^T(T-1)x_0(T) \\ &= \|z_{u_*, w_*, \xi}(T) - z_{u_0, w_0, \xi}(T)\|^2 - \|z_{u_*, w_*, \xi}(T)\|^2 + \|w_0(T)\|^2 \end{aligned}$$

Here we use the fact that $D_{21}^T D_{21} u_*(i) = B^T \eta_*(i)$ for all i . We also find that

$$(3.17) \quad \begin{aligned} &\|z_{u_*, w_*, \xi}(T)\|^2 - \|w_*(T)\|^2 - 2\eta_*^T(T)x_*(T+1) + 2\eta_*^T(T-1)x_*(T) \\ &= 2w_0^T(T)w_*(T) - \|z_{u_*, w_*, \xi}(T)\|^2 - \|w_*(T)\|^2 \end{aligned}$$

Summing (3.16) and (3.17) from zero to infinity and subtracting from each other gives us

$$(3.18) \quad \mathcal{C}(\xi, w_*) = \mathcal{C}(\xi, w_0) - \|w_0 - w_*\|_2^2 - \|z_{u_0, w_0, \xi} - z_{u_*, w_*, \xi}\|_2^2.$$

Since w_* maximizes $\mathcal{C}(\xi, w)$ over all w , this implies $w_0 = w_*$.

That w_* is the unique solution of the equation (3.15) can be shown in a similar way. Assume that, apart from w_* , w_1 also satisfies (3.15). Let $(x_1, u_1, \eta_1) := \mathcal{F}(\xi, w_1)$. We find from (3.17) that

$$(3.19) \quad \begin{aligned} &\|z_{u_*, w_*, \xi}(T)\|^2 - \|w_*(T)\|^2 - 2\eta_*^T(T)x_*(T+1) + 2\eta_*^T(T-1)x_*(T) \\ &= \|w_*(T)\|^2 - \|z_{u_*, w_*, \xi}(T)\|^2 \end{aligned}$$

We also find that

$$(3.20) \quad \begin{aligned} & \|z_{u_1, w_1, \xi}(T)\|^2 - \|w_1(T)\|^2 - 2\eta_*^\top(T)x_1(T+1) + 2\eta_*^\top(T-1)x_1(T) \\ &= \|z_{u_1, w_1, \xi}(T)\|^2 - \|w_1(T)\|^2 + 2w_*^\top(T)w_1(T) - 2z_{u_*, w_*, \xi}^\top(T)z_{u_1, w_1, \xi}(T). \end{aligned}$$

Summing (3.19) and (3.20) from 0 to ∞ and subtracting from each other gives us

$$(3.21) \quad \mathcal{C}(\xi, w_*) = \mathcal{C}(\xi, w_1) - \|w_* - w_1\|_C^2.$$

Since w_* was maximizing, we find that $\|w_* - w_1\|_C = 0$ and hence $w_* = w_1$. \square

Next, we show that $\mathcal{C}^*(\xi) = \xi^\top P \xi$ for some matrix P . To do that we first show that u_* , η_* , and w_* are linear functions of x_* in the result below.

LEMMA 3.7. *There exist constant matrices K_1 , K_2 , and K_3 such that*

$$(3.22) \quad u_* = K_1 x_*,$$

$$(3.23) \quad \eta_* = K_2 x_*,$$

$$(3.24) \quad w_* = K_3 x_*.$$

Proof. First we look at time 0. By Lemma 3.6 it is easily seen that $\mathcal{H} : \xi \rightarrow w_*$ is linear. Hence the mapping from ξ to $w_*(0)$ is also linear. This implies the existence of a matrix K_3 such that $w_*(0) = K_3 \xi$. From (3.10) and Lemma 3.4, it is easily seen that u_* and η_* are linear functions of ξ and w_* . This implies, since w_* is a linear function of ξ , that $u_*(0)$ and $\eta_*(0)$ are linear functions of ξ , and hence there exist K_1 and K_2 such that $u_*(0) = K_1 \xi$ and $\eta_*(0) = K_2 \xi$.

We now look at time t . The sup-inf problem starting at time t with initial value $x(t)$ can now be solved. Due to time invariance, we see that w_* restricted to $[t, \infty)$ satisfies (3.15), and hence for this problem the optimal x and η are x_* and η_* . However, since t is the initial time for this optimization problem, which is exactly equal to the original optimization problem, we find (3.22)–(3.24) at time t with the same matrices K_1 , K_2 , and K_3 as at time 0. Since t was arbitrary this completes the proof. \square

LEMMA 3.8. *There exists a matrix P such that $\sigma^{-1}\eta_* = -Px_*$. Moreover, for this P we find that*

$$(3.25) \quad \mathcal{C}^*(\xi) = \xi^\top P \xi.$$

Proof. We have

$$\begin{aligned} \sigma^{-1}\eta_* &= [A^\top \eta_* - C_2^\top C_2 x_* - C_2^\top D_{22} w_*] \\ &= (A^\top K_2 - C_2^\top C_2 - C_2^\top D_{22} K_3) x_*. \end{aligned}$$

We define $P := -(A^\top K_2 - C_2^\top C_2 - C_2^\top D_{22} K_3)$ using the matrices defined in lemma 3.7. We prove that this P satisfies (3.25). We can derive the following equation:

$$\begin{aligned} & \|z_{u_*, w_*, \xi}(T)\|^2 - \|w_*(T)\|^2 - 2\eta_*^\top(T)x_*(T+1) + 2\eta_*^\top(T-1)x_*(T) \\ &= \|w_*(T)\|^2 - \|z_{u_*, w_*, \xi}(T)\|^2 \end{aligned}$$

We sum this equation from zero to infinity. Since $\lim_{T \rightarrow \infty} \eta_*(T) = 0$ and $\lim_{T \rightarrow \infty} x_*(T) = 0$, we find that

$$\mathcal{C}(\xi, w_*) + 2\eta_*^\top(-1)x_*(0) = -\mathcal{C}(\xi, w_*).$$

Since $\mathcal{C}(\xi, w_*) = \mathcal{C}^*(\xi)$ and $\eta_*(-1) = -P\xi$, we find (3.25). \square

Next, we show that this matrix P satisfies conditions (a)–(c) of theorem 2.1. We first show part (a). Since we do not yet know if P is symmetric, we must be careful. This essential step in our derivation is new compared to the method for the continuous time as used in [24].

LEMMA 3.9. *Let P be given by Lemma 3.8. The matrices V and R as defined in part (ii) of theorem 2.1, condition (a), satisfy $V + V^T > 0$, $R + R^T > 0$.*

Proof. By Lemmas 3.5 and 3.8, we know that $(P + P^T)/2 \geq L$, and therefore we find that $(V + V^T)/2 \geq D_{21}^T D_{21} + B^T L B$. The latter matrix is positive definite, and hence $(V + V^T)/2$ is positive definite, i.e., $V + V^T > 0$.

We now look at the following “sup-inf-sup-inf” problem for initial condition 0:

$$(3.26) \quad \mathcal{J}(0) := \sup_{w(0)} \inf_{u(0)} \sup_{w^+} \inf_{u^+} \|z_{u,w}\|_2^2 - \|w\|_2^2,$$

where $w^+ := w|_{[1,\infty)}$ and $u^+ := u|_{[1,\infty)}$. We will always add the constraint that u^+ is such that the resulting state x is in ℓ_2 .

We know that there exists a causal operator f satisfying Condition 3.2, and hence this function makes the ℓ_2 -induced operator norm strictly less than 1 under the constraint $x \in \ell_2^n$. In (3.26) we set $u = f(w)$. This is possible since by causality we know that $u(0)$ only depends on $w(0)$ and u^+ depends on the whole function w . Thus we get

$$(3.27) \quad \begin{aligned} \mathcal{J}(0) &= \sup_{w(0)} \inf_{u(0)} \sup_{w^+} \inf_{u^+} \|z_{u,w}\|_2^2 - \|w\|_2^2 \\ &\leq \sup_w \|z_{f(w),w}\|_2^2 - \|w\|_2^2 \\ &\leq 0. \end{aligned}$$

Since, by Lemma 3.8, we have

$$(3.28) \quad \sup_{w^+} \inf_{u^+} \|z_{u^+,w^+,x(1)}\|_2^2 - \|w^+\|_2^2 = x^T(1) P x(1),$$

we can reduce (3.26) to the following “sup-inf” problem:

$$\sup_{w(0)} \inf_{u(0)} \begin{pmatrix} u(0) \\ w(0) \end{pmatrix}^T \begin{pmatrix} V & B^T P E + D_{21}^T D_{22} \\ E^T P B + D_{22}^T D_{21} & E^T P E + D_{22}^T D_{22} - I \end{pmatrix} \begin{pmatrix} u(0) \\ w(0) \end{pmatrix}.$$

When we define

$$\tilde{u}(0) = u(0) - (E^T P B + D_{22}^T D_{21}) V^{-1} w(0),$$

we get

$$(3.29) \quad \mathcal{J}(0) = \sup_{w(0)} \inf_{\tilde{u}(0)} \begin{pmatrix} \tilde{u}(0) \\ w(0) \end{pmatrix}^T \begin{pmatrix} V & 0 \\ 0 & -R \end{pmatrix} \begin{pmatrix} \tilde{u}(0) \\ w(0) \end{pmatrix}.$$

Since, by (3.27), $\mathcal{J}(0)$ is finite we immediately find that a necessary condition is $R + R^T \geq 0$.

Assume that $R + R^T$ is not invertible. Then there exists a $v \neq 0$ such that $v^T R v = 0$. Let $w^+(u(0))$ be the ℓ_2 -function that attains the optimum in the optimization (3.28) with initial state $x(1) = B u(0) + E v$. We define the function w by

$$(3.30) \quad [w(u(0))](t) := \begin{cases} v & \text{if } t = 0, \\ w^+(u(0))(t) & \text{otherwise.} \end{cases}$$

Assume that δ and f are such that Condition 3.2 is satisfied. Define u by

$$(3.31) \quad u = f[w(u(0))].$$

Since the map from u to w defined by (3.30) is strictly causal and since f is causal, u is uniquely defined by (3.31). To prove this, note that $u(0)$ only depends on $w(u(0))(0) = v$, and hence w^+ as a function of $u(0)$ is uniquely defined, which in turn yields u . Denote u and w obtained in this way by u_1 and w_1 . By (3.27) and (3.29), we find that, for this particular choice of w_1 and u_1 , we have

$$(3.32) \quad \|z_{u_1, w_1}\|_2^2 - \|w_1\|_2^2 \geq 0.$$

On the other hand, using Condition 3.2 we find that

$$\|z_{u_1, w_1}\|_2^2 - \|w_1\|_2^2 < (\delta^2 - 1) \|w_1\|_2^2 < 0$$

since $w_1(0) = v \neq 0$. Therefore we have a contradiction, and hence our assumption that $R + R^T$ is not invertible was incorrect. Together with $R + R^T \geq 0$, this yields $R + R^T > 0$. \square

LEMMA 3.10. *Assume that (A, B, C_2, D_{21}) has no invariant zeros on the unit circle and is left-invertible. Moreover, assume that $D_{21}^T[C_2 \ D_{22}] = 0$. If the condition in part (i) of Theorem 2.1 is satisfied, then there exists a symmetric matrix $P \geq 0$ satisfying (a)–(c) of part (ii) of Theorem 2.1.*

Proof. We define the matrices

$$\begin{aligned} M &:= D_{21}^T D_{21} + B^T L B > 0, \\ Z &:= I - D_{22}^T D_{22} - E^T X_1 L E. \end{aligned}$$

We know that $-(R + R^T)/2$ is the Schur complement of $(V + V^T)/2$ in $G((P + P^T)/2)$. By Lemma 3.9, we know that $R + R^T > 0$ and $V + V^T > 0$. Therefore $G((P + P^T)/2)$ has m eigenvalues on the positive real axis and l eigenvalues on the negative real axis. We know that $G((P + P^T)/2) - G(L) \geq 0$ since $(P + P^T)/2 \geq L$. An easy consequence of the theorem of Courant–Fischer (see [2]) then tells us that $G(L)$ has at least l eigenvalues on the negative real axis. Since $-Z$ is the Schur complement of $M > 0$ in $G(L)$, this implies that $Z > 0$.

By Lemma 3.8, we have $\eta_* = -\sigma P x_*$. By combining Lemmas 3.4 and 3.6 and rewriting the equations, we find that u_* and w_* satisfy the following equations:

$$\begin{aligned} w_* &= Z^{-1} \{E^T X_1 (P - L) \sigma x_* + (D_{22}^T C_2 + E^T X_1 L A) x_*\}, \\ u_* &= -M^{-1} B^T \{(P - L) \sigma x_* + L A x_* + L E w_*\}. \end{aligned}$$

Thus we get

$$(3.33) \quad \begin{aligned} &\{I + [B M^{-1} B^T - X_1^T E Z^{-1} E^T X_1] (P - L)\} x_*(k+1) \\ &= X_1^T \{A + E Z^{-1} E^T X_1 L A + E Z^{-1} D_{22}^T C_2\} x_*(k) \end{aligned}$$

Since, by Lemma 3.9, R as defined in Theorem 2.1 is invertible, it can be shown that the matrix on the left is invertible, and hence (3.33) uniquely defines $x_*(k+1)$ as a function of $x_*(k)$. It follows that (3.33) can be rewritten in the form $\sigma x_* = A_{cl} x_*$, with A_{cl} as defined by (2.7). Since $x_* \in \ell_2^n$ for every initial state ξ , we know that A_{cl} is asymptotically stable. Next, we show that P satisfies the discrete algebraic

Riccati equation (2.6). From the backward difference equation in (3.10) combined with Lemma 3.8 and the formula given above for w_* , we find that

$$P = A^T P A_{cl} + C_2^T C_2 + C_2^T D_{22} Z^{-1} \{E^T X_1 (P - L) A_{cl} + D_{22}^T C_2 + E^T X_1 L A\}$$

By some extensive calculations this equation turns out to be equivalent to the discrete algebraic Riccati equation (2.6). Next we show that P is symmetric. Note that both P and P^T satisfy the discrete algebraic Riccati equation. Using this we find that $(P - P^T) = A_{cl}^T (P - P^T) A_{cl}$. Since A_{cl} is asymptotically stable, this implies that $P = P^T$. P can be shown to be positive semidefinite by combining Lemma 3.5 and (3.25). It remains to be shown that P satisfies (2.4). Since P is symmetric, we know that V and R are symmetric. Equation (2.4) is then an immediate consequence of lemma 3.9. \square

We extend this result in the following corollary to systems that do not satisfy (3.1).

COROLLARY 3.11. *Assume that (A, B, C_2, D_{21}) has no invariant zeros on the unit circle and is left invertible. If part (i) of Theorem 2.1 is satisfied, then there exists a symmetric matrix $P \geq 0$ satisfying (a)–(c) of part (ii) of Theorem 2.1.*

Proof. We first apply a preliminary feedback $u = \tilde{F}_1 x + \tilde{F}_2 w + v$ such that $D_{21}^T (C_2 + D_{21} \tilde{F}_1) = 0$ and $D_{21}^T (D_{22} + D_{21} \tilde{F}_2) = 0$. Denote the new A , C_2 , D_{22} , and E by \tilde{A} , \tilde{C}_2 , \tilde{D}_{22} , and \tilde{E} . For this new system, Condition 3.2 is satisfied. We also know that by applying a preliminary state feedback, the invariant zeros of a system do not change. Therefore the new subsystem $(\tilde{A}, B, \tilde{C}_2, D_{21})$ does not have invariant zeros on the imaginary axis. Hence, since for this new system $D_{21}^T [\tilde{C}_2 \quad \tilde{D}_{22}] = 0$, we find conditions in terms of the new parameters by applying Lemma 3.10. Rewriting in terms of the original parameters gives the desired conditions (a)–(c) as given in part (ii) of Theorem 2.1. \square

4. A first system transformation. To proceed with the proof of Theorem 2.1, (i) \Rightarrow (ii), in this section we will transform our original system (2.1) into a new system. The problem of finding an internally stabilizing feedback that makes the H_∞ norm of the closed loop system less than 1 for the original system is equivalent to the problem of finding an internally stabilizing feedback that makes the H_∞ norm of the closed loop system less than 1 for the new transformed system. However, this new system has some very desirable properties, which makes working with it much easier. In particular, for this new system the disturbance decoupling problem with measurement feedback is solvable. We will perform the transformation in two steps.

First we will perform a transformation related to the full-information H_∞ problem, and next a transformation related to the filtering problem.

We assume that we have a positive semidefinite matrix P satisfying conditions (a)–(c) of Theorem 2.1. By the results of the previous section, this matrix exists in the case where part (i) of Theorem 2.1 is satisfied. We define the following system:

$$(4.1) \quad \Sigma_P : \begin{cases} \sigma x_P = A_P x_P + B u_P + E_P w_P, \\ y_P = C_{1,P} x_P + \quad \quad \quad + D_{12,P} w_P, \\ z_P = C_{2,P} x_P + D_{21,P} u_P + D_{22,P} w_P, \end{cases}$$

where the matrices are as defined in the statement of Theorem 2.1. Furthermore, we define the following system:

$$(4.2) \quad \Sigma_U : \begin{cases} \sigma x_U = A_U x_U + B_U u_U + E_U w, \\ y_U = C_{1,U} x_U + \quad \quad \quad + D_{12,U} w, \\ z_U = C_{2,U} x_U + D_{21,U} u_U + D_{22,U} w, \end{cases}$$

where

$$\begin{aligned}
A_U &:= A - BV^{-1}(B^T P A + D_{21}^T C_2), \\
B_U &:= BV^{-1/2}, \\
E_U &:= E - BV^{-1}(B^T P E + D_{21}^T D_{22}), \\
C_{1,U} &:= -R^{-1/2} H, \\
C_{2,U} &:= C_2 - D_{21} V^{-1}(B^T P A + D_{21}^T C_2), \\
D_{12,U} &:= R^{1/2}, \\
D_{21,U} &:= D_{21} V^{-1/2}, \\
D_{22,U} &:= D_{22} - D_{21} V^{-1}(B^T P E + D_{21}^T D_{22}),
\end{aligned}$$

and V , R , and H are as defined in Theorem 2.1. We will show that Σ_U has a very nice property. To do this, we will first give a definition and some results we will need in the sequel. A system is called *inner* if the system is internally stable, square (i.e., the number of inputs is equal to the number of outputs) and the transfer matrix of the system, denoted by G , satisfies

$$(4.3) \quad G(z)G^T(z^{-1}) = I$$

We will now formulate a generalization of [12, Lemma 5] to the case where $G(z)$ may have poles in zero. The proof is slightly more complicated than the one given in [12], since if G has a pole in zero then $G^T(z^{-1})$ is no longer proper. Nevertheless, a proof can be given by simply writing out (4.3).

LEMMA 4.1. *Assume that we have a square system*

$$(4.4) \quad \Sigma_{st} : \begin{cases} \sigma x = Ax + Bu, \\ z = Cx + Du. \end{cases}$$

Assume that A is asymptotically stable. The system Σ_{st} is inner if there exists a matrix X satisfying

1. $X = A^T X A + C^T C$,
2. $D^T C + B^T X A = 0$,
3. $D^T D + B^T X B = I$.

Remarks.

(i) If (A, B) is controllable, the reverse of the above implication is also true. However, in general, the reverse does not hold. A simple counterexample is given by $\Sigma_{st} := (0.5, 0, 1, 1)$, which is inner but for which (ii) does not hold for any choice of X .

(ii) Note that if a matrix X satisfies part (1) of Lemma 4.1, then it is equal to the observability gramian of (C, A) . We know, for instance, that $X > 0$ if and only if (C, A) is observable. In general, we only have $X \geq 0$.

We have the following important property of inner systems (see [17], [22]).

LEMMA 4.2. *Suppose that we have the following interconnection of two systems Σ_1 and Σ_2 , both described by some state-space representation:*

(4.5)

Assume that Σ_1 is inner. Denote its transfer matrix from (w, u) to (z, y) by L . Moreover, assume that if we decompose L compatible with the sizes of w, u, z , and y :

$$(4.6) \quad L \begin{pmatrix} w \\ u \end{pmatrix} =: \begin{pmatrix} L_{11} & L_{12} \\ L_{21} & L_{22} \end{pmatrix} \begin{pmatrix} w \\ u \end{pmatrix} = \begin{pmatrix} z \\ y \end{pmatrix},$$

we have $L_{21}^{-1} \in H_\infty$, and L_{22} is strictly proper. Then the following two statements are equivalent:

(i) The closed loop system (4.5) is internally stable and its closed loop transfer matrix has H_∞ norm less than 1.

(ii) The system Σ_2 is internally stable and its transfer matrix has H_∞ norm less than 1.

LEMMA 4.3. The system Σ_U as defined by (4.2) is inner. Denote the transfer matrix of Σ_U by U . We decompose U compatible with the sizes of w, u_U, z_U , and y_U :

$$U \begin{pmatrix} w \\ u_U \end{pmatrix} =: \begin{pmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{pmatrix} \begin{pmatrix} w \\ u_U \end{pmatrix} = \begin{pmatrix} z_U \\ y_U \end{pmatrix}.$$

Then U_{21} is invertible and its inverse is in H_∞ . Moreover, U_{22} is strictly proper.

Proof. It can be easily checked that P as defined by Theorem 2.1 (a)–(c) satisfies conditions (i)–(iii) of Lemma 4.1. Part (i) of Lemma 4.1 turns out to be equal to the discrete algebraic Riccati equation (2.6). Parts (ii) and (iii) follow by simply writing out the equations in terms of the original system parameters of system (2.1).

Next, we show that A_U is asymptotically stable. We know $P \geq 0$ and

$$(4.7) \quad P = A_U^T P A_U + \begin{pmatrix} C_{1,U}^T & C_{2,U}^T \end{pmatrix} \begin{pmatrix} C_{1,U} \\ C_{2,U} \end{pmatrix}.$$

It can be easily checked that $x \neq 0$, $A_U x = \lambda x$, $C_{1,U} x = 0$, and $C_{2,U} x = 0$ imply that $A_{cl,P} x = \lambda x$, where $A_{cl,P}$ is defined by (2.7). Since $A_{cl,P}$ is asymptotically stable, we have $\text{Re } \lambda < 0$. Hence the realization (4.2) is detectable. By standard Lyapunov theory, the existence of a positive semidefinite solution of (4.7), together with detectability, guarantees asymptotic stability of A_U .

We can immediately write down the following realization for U_{21}^{-1} :

$$\Sigma_{U_{21}^{-1}} : \begin{cases} \sigma x_U = (A_U - E_U D_{12,U}^{-1} C_{1,U}) x_U + E_U D_{12,U}^{-1} w, \\ y_U = -D_{12,U}^{-1} C_{1,U} x_U + D_{12,U}^{-1} w. \end{cases}$$

Since $A_{cl,P} = A_U - E_U D_{12,U}^{-1} C_{1,U}$ we know that U_{21}^{-1} is an H_∞ function.

Finally, the claim that U_{22} is strictly proper is trivial to check. This completes the proof. \square

We will now formulate our key lemma, below.

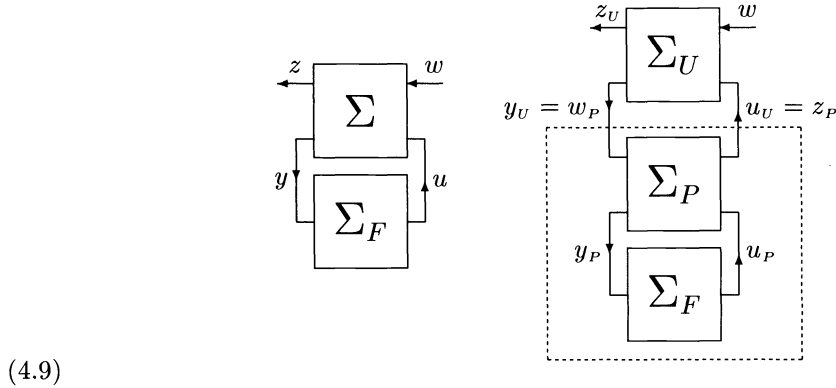

LEMMA 4.4. *Let P satisfy Theorem 2.1 part (ii), (a)–(c). Moreover, let Σ_F be an arbitrary linear time-invariant finite-dimensional compensator in the form (2.2). Consider the following two systems, where the system on the left is the interconnection of (2.1) and (2.2), and the system on the right is the interconnection of (4.1) and (2.2):*

Then the following statements are equivalent

- (i) The system on the left is internally stable and its transfer matrix from w to z has H_∞ norm less than 1.
- (ii) The system on the right is internally stable and its transfer matrix from w_P to z_P has H_∞ norm less than 1.

Proof. We investigate the following systems:

The system on the left is the same as the system on the left in (4.8), and the system on the right is described by system (4.2) interconnected with the system on the right in (4.8). A realization for the system on the right is given by

$$\sigma \begin{pmatrix} x_U - x_{1,P} \\ x_P \\ p \end{pmatrix} = \begin{pmatrix} A_{cl,P} & 0 & 0 \\ * & A + BNC_1 & BM \\ * & LC_1 & K \end{pmatrix} \begin{pmatrix} x_U - x_{1,P} \\ x_P \\ p \end{pmatrix} + \begin{pmatrix} 0 \\ E + BND_{12} \\ LD_{12} \end{pmatrix} w,$$

$$z_U = \begin{pmatrix} * & C_2 + D_{21}NC_1 & D_{21}M \end{pmatrix} \begin{pmatrix} x_U - x_{1,P} \\ x_P \\ p \end{pmatrix} + (D_{22} + D_{21}ND_{12}) w$$

where $A_{cl,P}$ is defined by (2.7). The $*$'s denote matrices that are unimportant for this argument. The system on the right is internally stable if and only if the system

described by the above set of equations is internally stable. If we also derive the system equations for the system on the left in (4.9), we immediately see that, since $A_{cl,P}$ is asymptotically stable, the system on the left is internally stable if and only if the system on the right is internally stable. Moreover, if we take zero initial conditions and both systems have the same input w then we have $z = z_U$; i.e., the input-output behaviour of both systems are equivalent. Hence the system on the left has H_∞ norm less than 1 if and only if the system on the right has H_∞ norm less than 1.

By Lemma 4.3, we may apply Lemma 4.2 to the system on the right in (4.9), and hence we find that the closed loop system is internally stable and has H_∞ norm less than 1 if and only if the dashed system is internally stable and has H_∞ norm less than 1.

Since the dashed system is exactly the system on the right in (4.8) and the system on the left in (4.9) is exactly equal to the system on the left in (4.8), we have completed the proof. \square

Using the previous lemma, we know that we only have to investigate the system Σ_P . This new system has some very nice properties, which we will use. First, we will look at the Riccati equation for the system Σ_P . It can be checked immediately that $X = 0$ satisfies (a)–(c) of Theorem 2.1 for the system Σ_P .

We now dualize Σ_P . We know that (A, E, C_1, D_{12}) is right-invertible and has no invariant zeros on the unit circle. It can be easily checked that this implies that $(A_P, E, C_{1,P}, D_{12})$ is right-invertible and has no invariant zeros on the unit circle. Hence for the dual of Σ_P we know that $(A_P^T, C_{1,P}^T, E^T, D_{21}^T)$ is left-invertible and has no invariant zeros on the unit circle. If there exists an internally stabilizing feedback for the system Σ , which makes the H_∞ norm of the closed loop system less than 1, then the same feedback is internally stabilizing and makes the H_∞ norm of the closed loop system less than 1 for the system Σ_P . If we dualize this feedback and apply it to the dual of Σ_P , then it is again internally stabilizing and again it makes the H_∞ norm of the closed loop system less than 1. We can now apply the dual version of Corollary 3.11, which exactly guarantees the existence of a matrix Y satisfying conditions (d)–(f) of Theorem 2.1. Thus we derived the following lemma, which gives the necessity part of Theorem 2.1.

LEMMA 4.5. *Let system (2.1) be given with zero initial state. Assume that (A, B, C_2, D_{21}) has no invariant zeros on the unit circle and is left-invertible. Moreover, assume that (A, E, C_1, D_{12}) has no invariant zeros on the unit circle and is right invertible. If part (i) of theorem 2.1 is satisfied, then there exist matrices P and Y satisfying (a)–(f) of part (ii) of Theorem 2.1.*

This completes the proof (i) \Rightarrow (ii). In the next section we will prove the reverse implication. Moreover, in the case where the desired feedback exists, we will derive an explicit formula for one choice for Σ_F that satisfies all requirements.

5. The transformation into a disturbance decoupling problem with measurement feedback. In this section we will assume that there exist matrices P and Y satisfying part (ii) of Theorem 2.1 for system (2.1). We will transform our original system Σ into another system $\Sigma_{P,Y}$. We will show that a compensator is internally stabilizing and makes the H_∞ norm of the closed loop system less than 1 for the system Σ if and only if the same compensator is internally stabilizing and makes the H_∞ norm of the closed loop system less than 1 for our transformed system $\Sigma_{P,Y}$. After that, we will show that $\Sigma_{P,Y}$ has the following very special property (see [19]):

There exists an internally stabilizing compensator that makes the closed loop transfer matrix equal to zero; i.e., w does not have any effect on the output of the system z . This property of $\Sigma_{P,Y}$ has a special name: “the disturbance decoupling problem with measurement feedback and internal stability (DDPMS).”

We first define $\Sigma_{P,Y}$. We start by transforming Σ into Σ_P . Then we apply the dual transformation on Σ_P to obtain $\Sigma_{P,Y}$:

$$(5.1) \quad \Sigma_{P,Y} : \begin{cases} \sigma x_{P,Y} = A_{P,Y} x_{P,Y} + B_{P,Y} u_{P,Y} + E_{P,Y} w_{P,Y}, \\ y_{P,Y} = C_{1,P} x_{P,Y} + D_{12,P} w_{P,Y}, \\ z_{P,Y} = C_{2,P} x_{P,Y} + D_{21,P} u_{P,Y} + D_{22,P} w_{P,Y}, \end{cases}$$

where

$$\begin{aligned} \tilde{H} &:= A_P Y C_{2,P}^T + E_P D_{22,P}^T - (A_P Y C_{1,P}^T + E_P D_{12,P}^T) W^{-1} \times \\ &\quad (C_{1,P} Y C_{2,P}^T + D_{12,P} D_{22,P}^T), \\ A_{P,Y} &:= A_P + \tilde{H} S^{-1} C_{2,P}, \\ C_{2,P,Y} &:= S^{-1/2} C_{2,P}, \\ B_{P,Y} &:= B + \tilde{H} S^{-1} D_{21,P}, \\ E_{P,Y} &:= (A_P Y C_{1,P}^T + E_P D_{12,P}^T) W^{-1/2} + \tilde{H} S^{-1} (C_{2,P} Y C_{1,P}^T + D_{22,P} D_{12,P}^T) W^{-1/2}, \\ D_{12,P,Y} &:= W^{1/2}, \\ D_{21,P,Y} &:= S^{-1/2} D_{21,P}, \\ D_{22,P,Y} &:= S^{-1/2} (C_{2,P} Y C_{1,P}^T + D_{22,P} D_{12,P}^T) W^{-1/2}. \end{aligned}$$

When we first apply Lemma 4.4 on the transformation from Σ to Σ_P and then the dual of Lemma 4.4 on the transformation from Σ_P to $\Sigma_{P,Y}$, we find the following result.

LEMMA 5.1. *Let P satisfy Theorem 2.1, part (ii) (a)–(c). Moreover, let an arbitrary linear time-invariant finite-dimensional compensator Σ_F be given, described by (2.2). Consider the following two systems, where the system on the left is the interconnection of (2.1) and (2.2), and the system on the right is the interconnection of (5.1) and (2.2):*

Then the following statements are equivalent:

(i) *The system on the left is internally stable and its transfer matrix from w to z has H_∞ norm less than 1.*

(ii) *The system on the right is internally stable and its transfer matrix from $w_{P,Y}$ to $z_{P,Y}$ has H_∞ norm less than 1.*

It remains to be shown that for $\Sigma_{P,Y}$ the DDPMS is solvable.

LEMMA 5.2. Let Σ_F be given by

$$(5.2) \quad \Sigma_F : \begin{cases} \sigma p &= K_{P,Y} p + L_{P,Y} y_{P,Y}, \\ u_{P,Y} &= M_{P,Y} p + N_{P,Y} y_{P,Y}, \end{cases}$$

where

$$\begin{aligned} N_{P,Y} &:= -D_{21,P,Y}^{-1} D_{22,P,Y} D_{12,P,Y}^{-1}, \\ M_{P,Y} &:= -(D_{21,P,Y}^{-1} C_{2,P,Y} + N_{P,Y} C_{1,P}), \\ L_{P,Y} &:= B_{P,Y} N_{P,Y} + E_{P,Y} D_{12,P,Y}^{-1}, \\ K_{P,Y} &:= A_{P,Y} + B_{P,Y} M_{P,Y} - E_{P,Y} D_{12,P,Y}^{-1} C_{1,P}. \end{aligned}$$

The interconnection of Σ_F and $\Sigma_{P,Y}$ is internally stable, and the closed loop transfer matrix from $w_{P,Y}$ to $z_{P,Y}$ is zero.

Proof. We can write out the formulas for a state-space representation of the interconnection of $\Sigma_{P,Y}$ and Σ_F . We then apply the following basis transformation:

$$\begin{pmatrix} x_{P,Y} - p \\ p \end{pmatrix} = \begin{pmatrix} I & -I \\ 0 & I \end{pmatrix} \begin{pmatrix} x_{P,Y} \\ p \end{pmatrix}.$$

After this transformation we immediately see that the closed loop transfer matrix from $w_{P,Y}$ to $z_{P,Y}$ is zero. Moreover, the system matrix (2.3) after this transformation is given by:

$$\begin{pmatrix} A_{cl,P,Y} & 0 \\ L_{P,Y} C_{1,P} & A_{cl,P} \end{pmatrix}$$

Since $A_{cl,P,Y}$ and $A_{cl,P}$ are asymptotically stable matrices, this implies that, indeed, Σ_F is internally stabilizing. \square

This controller is the same as the one described in the statement of Theorem 2.1. We know that Σ_F is internally stabilizing, and the resulting closed loop system has H_∞ norm less than 1 for the system $\Sigma_{P,Y}$. Hence, by applying Lemma 5.1, we find that Σ_F satisfies part (i) of Theorem 2.1. This completes the proof of (ii) \Rightarrow (i) of Theorem 2.1. We have already shown the reverse implication and hence the proof of Theorem 2.1 is complete.

6. Conclusions. In this paper we have solved the discrete time H_∞ problem with measurement feedback. It is shown that the techniques for the continuous time case can be applied to the discrete time case. Unfortunately, the formulas are much more complex, but it is still possible to give an explicit formula for one controller satisfying all requirements. It would, however, be interesting to generalize this work and find a characterization of all controllers satisfying the requirements. Another interesting open problem is to derive recursive formulas to calculate the solutions to these algebraic Riccati equations. It would also be interesting to find two dual Riccati equations and a coupling condition, as in [9]. Nevertheless, the results presented in this paper show that it is very possible to solve discrete time H_∞ problems directly, instead of transforming them to continuous time. The assumption of left-invertibility is not very restrictive. It implies that there are several inputs that have the same effect on the output and this nonuniqueness can be factored out (see [18] for a continuous time treatment). The assumption of right-invertibility can be removed by dualizing this reasoning. However, at this moment it is unclear as to how to remove the assumptions concerning zeros on the unit circle.

NEW RESULTS IN POLE ASSIGNMENT BY REAL OUTPUT FEEDBACK*

JOACHIM ROSENTHAL†

Abstract. This paper considers the problem of tuning natural frequencies of a linear system by a memoryless controller. Using algebro-geometric methods it is shown how it is possible to improve current sufficiency conditions.

The main result is an exact combinatorial characterization of the nilpotency index of the mod 2 cohomology ring of the real Grassmannian. Using this characterization, new sufficiency results for generic pole assignment for the linear system with m -inputs, p -outputs, and McMillan degree n are given. Among other results it is shown that

$$2.25 \cdot \max(m, p) + \min(m, p) - 3 \geq n$$

is a sufficient condition for generic real pole placement, provided $\min(m, p) \geq 4$.

Key words. output feedback, pole placement, intersection theory, symmetric functions.

AMS(MOS) subject classifications. 93, 55M30, 05A

1. Introduction. Consider a linear time invariant system Σ with m -inputs, p -outputs and McMillan degree n . In the time domain Σ can be modelled by the following system of differential equations:

$$(1.1) \quad \Sigma : \begin{cases} \dot{x} &= Ax + Bu \\ y &= Cx \end{cases} \quad x \in \mathbf{R}^n, y \in \mathbf{R}^p, u \in \mathbf{R}^m.$$

The problem of output pole assignment with a static compensator is the problem of finding a feedback law $u = Fy$ in such a way that the closed loop system

$$(1.2) \quad \Sigma_F : \begin{cases} \dot{x} &= (A + BFC)x \\ y &= Cx \end{cases}$$

is assigned a desired set of eigenvalues. The stability of equilibria or periodic motions of the closed loop system depends on the eigenvalues of the matrix $A + BFC$. In particular the closed loop system is asymptotically stable, if the eigenvalues of $A + BFC$ have negative real parts. In this paper we are interested in under which conditions it is possible to assign a set of real eigenvalues, in particular when it is possible to stabilize a generic system. Because the eigenvalues correspond to the poles of the transfer function under Laplace transform one often refers to this type of problem as the pole placement problem. This question has already been considered by many authors (e.g. [1], [2], [10], [16], [20], [21]), and interesting links to topological questions and Schubert calculus were made. An excellent survey article can be found in [3], where a larger bibliography is also given.

Kimura [10], motivated by the problem of stabilizing and controlling a mechanical system, studied this inverse eigenvalue problem in a systematic way. Typically such systems have m -inputs m -outputs and the dimension of the state is $2m$. More generally, one would hope that $m + p \geq n$ would imply pole assignability, and hence

* Received by the editors May 29, 1990; accepted for publication (in revised form) January 10, 1991.

† Department of Mathematics, University of Notre Dame, Notre Dame, Indiana 46556. This research, which constitutes a part of the author's Ph.D. dissertation at Arizona State University, was done during the author's stay at the Department of Systems Science and Mathematics, Washington University, St. Louis, Missouri 63130.

stabilizability for the generic $p \times m$ n -dimensional system. In 1975, Kimura proved a result, which came “within one degree of freedom” of the desired result.

THEOREM 1.1 (KIMURA [10]). *If (A, B) is controllable and (A, C) is observable and if $m + p - 1 \geq n$, an almost arbitrary set of distinct real or complex conjugate poles is assignable by real gain output feedback.*

In 1978, Willems and Hesselink [21] showed that in the case of $m = p = 2$, at most 3 real poles can be assigned arbitrarily for the generic system, so that Theorem 1.1 also gives a necessary condition for this case.

Quite surprisingly, as shown in this paper, the case studied by Willems and Hesselink is the only nontrivial case ($\min(m, p) \geq 2$) where $m + p \geq n$ is not a sufficient condition. This result will follow from a new combinatorial criterion, which will be formulated in the next section. In fact more will be shown. Using an identification of the mod 2 cohomology ring of the real Grassmannian with a quotient of the space of symmetric functions it will be possible to characterize the maximum number of nontrivial terms in a nonzero product of $H^*(\text{Grass}(p, m + p), \mathbb{Z}_2)$, sometimes called the cup length of this ring, in a combinatorial way. In the next section the combinatorial criterion is formulated and the main results stated.

2. A new combinatorial criterion. Consider a $m \times p$ array A , where m can be seen as the number of inputs and p as the number of outputs. Let $\mu = (\mu_1, \dots, \mu_s)$ be a partition of mp . This means $\mu_1 \geq \mu_2 \geq \dots \geq \mu_s > 0$ and $\sum \mu_i = mp$. Denote with K_μ the number of possibilities to insert μ_i integers i into the array A under the condition that the rows are increasing and the columns are strictly increasing.

DEFINITION 2.1. $c(m, p) := \max\{s \mid K_{(\mu_1, \dots, \mu_s)} \text{ is odd}\}$.

THEOREM 2.2. *The cup length of the mod 2 cohomology ring of the real Grassmannian $\text{Grass}(p, m + p)$ is $c(m, p)$.*

This cup length has an important topological meaning. As was shown by Eilenberg [4], this number gives a lower estimate for the Ljusternik Snirelmann category of a topological space.

In the innovative paper [1], Brockett and Byrnes explained the pole placement problem with static compensators as an intersection problem in some Grassmann variety. Moreover Byrnes [2] showed that the Ljusternik Snirelmann category of the real Grassmannian gives a lower bound for the number of real poles which can be generically assigned. Using Theorem 2.2 therefore, one has immediately the following result.

THEOREM 2.3. *$c(m, p) \geq n$ is a sufficient condition for generic pole placement of a generic, strictly proper linear system Σ_n with m inputs and p outputs and McMillan degree n .*

Clearly not every $m \times p$ system Σ of order n can be pole assigned by output feedback; in particular one needs controllability and observability of the system. The results we present in this paper are stated for a generic system (see, e.g., [21]). Recall that a subset of a variety is called generic if it contains a nonempty Zariski open subset. Before giving the proof of Theorem 2.3, it will be illustrated how it is possible to obtain new sufficiency conditions for generic real pole placement. The following examples were given in [15].

3. Examples and corollaries.

Example 3.1. Two inputs, two outputs or $m = p = 2$. To apply Theorem 2.3, compute K_μ for different partitions of 4:

$K_{(1,1,1,1)} = 2$ (\rightarrow even) given by the two possibilities:

1	2
3	4

1	3
2	4

$K_{(2,1,1)} = 1$ ($\rightarrow odd$) given by the only possibility:

1	1
2	3

Because $K_{(2,1,1)}$ is odd, $c(2,2) = 3$, consistent with the result of Kimura [10] and Willems and Hesselink [21].

Example 3.2. Two inputs, three outputs, or $m = 2$ and $p = 3$. In this case, one immediately computes $K_{(1^6)} = 5$ ($\rightarrow odd$) given by the possibilities:

1	2	3
4	5	6

1	2	4
3	5	6

1	2	5
3	4	6

1	3	4
2	5	6

1	3	5
2	4	6

In other words $c(2,3)=6$ and up to 6 poles can be placed generically. This result is somewhat surprising, although it was already established in the paper of Brockett and Byrnes [1].

Example 3.3. The following table shows $c(m,p)$ for $\max(m,p) \leq 5$.

(3.1)

$m \backslash p$	1	2	3	4	5
1	1	2	3	4	5
2	2	3	6	7	8
3	3	6	8	9	11
4	4	7	9	10	17
5	5	8	11	17	19

LEMMA 3.4. $m + p - 1 \geq n$ is a sufficient condition for generic real pole assignment.

Proof: Consider the partition $\mu = (p^{m-1}, 1^p)$. As one immediately verifies, $K_\mu = 1$ corresponding to the only possibility:

$$\left(\begin{array}{ccccc} 1 & 1 & \dots & \dots & 1 \\ 2 & 2 & \dots & \dots & 2 \\ \vdots & & & & \vdots \\ m-1 & m-1 & \dots & \dots & m-1 \\ m & m+1 & \dots & \dots & m+p-1 \end{array} \right).$$

THEOREM 3.5. The following conditions imply generic real pole assignability. (By duality assume $m \leq p$) :

- (3.2)

$m = 2$ and $1.5p \geq n$
- (3.3)

$m = 3$ and $2p + 1 \geq n$
- (3.4)

$m \geq 4$ and $2.25p + m - 3 \geq n$.

The proof of this theorem and Theorem 2.3 is based on an interesting identification of the mod 2 cohomology ring of the real Grassmannian and the space of symmetric functions $\mathcal{Z}_2[x_1, \dots, x_p]^{\mathcal{S}_p}$. A good description of the topology of the real Grassmann manifold can be found for example in [14]. The important properties about the ring structure of $H^*(Grass(p, m+p), \mathcal{Z}_2)$ are given in the next section. Several properties about the ring of symmetric functions $\mathcal{Z}_2[x_1, \dots, x_p]^{\mathcal{S}_p}$ are summarized in an Appendix, where further references are given.

4. The cohomology ring of the real Grassmannian. The collection of m -planes in \mathbf{R}^{m+p} is called the Grassmann manifold and will be denoted by $Grass(p, m+p)$. The Grassmannian $Grass(p, m+p)$ is a smooth, compact manifold of dimension mp . Additively, the cohomology ring $H^*(Grass(p, m+p), \mathcal{Z}_2)$ can be described as a free \mathcal{Z}_2 -module over the set of Schubert cocycles $[a_1, \dots, a_p]$ where $m \geq a_1 \geq \dots \geq a_p \geq 0$. This notation coincides with the notation adopted in Griffith and Harris [6] and is “reverse” to the notation used by Hiller [7], [8].

Denote with $\xi_{p,m+p}$ the canonical p -bundle over $Grass(p, m+p)$. The total space of $\xi_{p,m+p}$ is defined by

$$(4.1) \quad E(\xi_{p,m+p}) = \{(V, x) \in Grass(p, m+p) \times \mathbf{R}^{m+p} \mid x \in V\}$$

and the corresponding bundle map is a projection on the first factor. The orthogonal bundle of $\xi_{p,m+p}$ is an m -plane bundle and will be denoted with $\bar{\xi}_{p,p+m}$. Finally denote with w_k the k th Stiefel Whitney class of $\xi_{p,p+m}$ and with σ_j the j th Stiefel Whitney class of $\bar{\xi}_{p,p+m}$. In terms of Schubert cocycles those Stiefel Whitney classes are described by

$$(4.2) \quad w_k = \underbrace{[1, 1, \dots, 1, 0, \dots, 0]}_k, \quad k = 1, \dots, p$$

$$(4.3) \quad \sigma_j = [j, 0, \dots, 0], \quad j = 1, \dots, m.$$

The multiplicative structure of $H^*(Grass(p, n), \mathcal{Z}_2)$ is described by the classical formulas of Pieri and Giambelli. Giambelli’s formula expresses a general Schubert cocycle as a polynomial in the special Schubert cocycle σ_j and Pieri’s formula explains how a Schubert cocycle is multiplied with a special Schubert cocycle.

Pieri’s formula:

$$(4.4) \quad [a_1, \dots, a_p] \cdot \sigma_j = \sum_{\substack{a_{i-1} \geq b_i \geq a_i \\ \sum_{i=1}^p b_i = (\sum_{i=1}^p a_i) + j}} [b_1, \dots, b_p]$$

Giambelli’s formula:

$$(4.5) \quad [a_1, \dots, a_p] = \det(\sigma_{a_i+j-i}) = \det \begin{pmatrix} \sigma_{a_1} & \sigma_{a_1+1} & \dots & \sigma_{a_1+p-1} \\ \sigma_{a_2-1} & \sigma_{a_2} & & \vdots \\ \vdots & & \ddots & \vdots \\ \sigma_{a_p-p+1} & & \dots & \sigma_{a_p} \end{pmatrix}.$$

From Giambelli’s formula it follows in particular that the Stiefel Whitney classes of the orthogonal bundle $\bar{\xi}_{p,p+m}$ generate $H^*(Grass(p, m+p), \mathcal{Z}_2)$. As shown by Hiller [8, p. 530] the same is true for the Stiefel Whitney classes of the canonical bundle $\xi_{p,p+m}$. In fact we will show that a general Schubert cocycle can be expressed in terms of the Stiefel-Whitney classes $\{w_1, \dots, w_p\}$ using a well-known classical formula.

In order to achieve our results the relation between the cohomology ring of the real Grassmannian and the space of symmetric functions will be studied. It will be shown that the cohomology ring $H^*(Grass(p, m+p), \mathcal{Z}_2)$ is isomorphic to a quotient of the space of symmetric functions $\mathcal{Z}_2[x_1, \dots, x_p]^{S_p}$. Using this identification it is possible to characterize the cup-length of $H^*(Grass(p, m+p), \mathcal{Z}_2)$ in a combinatorial way.

In the case of a complex Grassmannian a connection between the space of symmetric functions $\mathcal{Z}[x_1, \dots, x_p]^{S_p}$ and the cohomology ring $H^*(Grass(p, m+p), \mathcal{Z})$ is well known. According to Stanley [17], Lesieur [12] was the first who recognized a formal similarity between (4.5) and the classical identity of Jacobi and Trudi (see the Appendix). Horrocks [9] showed that this relationship is more than formal and can be explained geometrically.

In this section we work out a similar relationship for the real Grassmannian. From a geometric point of view, this relation can be understood in the following way.

Consider the space $Flag(\mathbf{R}^{m+p})$ of mutually orthogonal and ordered $(m+p)$ -tuples of lines (l_1, \dots, l_{m+p}) . Over $Flag(\mathbf{R}^{m+p})$ are line bundles ξ_i with total space $E(\xi_i)$, where

$$(4.6) \quad E(\xi_i) := \{((l_1, \dots, l_{m+p}); y) \in Flag(\mathbf{R}^{m+p}) \times \mathbf{R}^{m+p} \mid y \in l_i\}.$$

One has a projection

$$(4.7) \quad \begin{aligned} \pi : Flag(\mathbf{R}^{m+p}) &\longrightarrow Grass(p, m+p) \\ (l_1, \dots, l_{m+p}) &\longmapsto \text{span}(l_1, \dots, l_p) \end{aligned}$$

This projection induces an embedding (compare Hiller [8] or Stong [19])

$$(4.8) \quad \begin{aligned} \pi^* : H^*(Grass(p, m+p), \mathcal{Z}_2) &\longrightarrow H^*(Flag(\mathbf{R}^{m+p})) \\ &\cong \mathcal{Z}_2[x_1, \dots, x_{m+p}] / I_{mp}, \end{aligned}$$

where I_{mp} is the ideal generated by the relations

$$(4.9) \quad \prod_{i=1}^{m+p} (1 + x_i) = 1,$$

expressing the triviality of the bundle

$$\xi_1 \oplus \dots \oplus \xi_{m+p}.$$

The projection π can be covered by a bundle map. Indeed, consider the p -bundle $\xi_1 \times \dots \times \xi_p$ over $Flag(\mathbf{R}^{m+p})$. It is immediate that $\pi^*(w(\xi_{p, m+p})) = w(\xi_1 \times \dots \times \xi_p) = \prod_{i=1}^p (1 + x_i)$. Under π^* , the k th Stiefel Whitney class w_k of the canonical p -bundle $\xi_{p, p+m}$ of $Grass(p, p+m)$ is therefore mapped onto the k th elementary symmetric function $e_k = \sum x_{i_1} \dots x_{i_k}$ of $\mathcal{Z}_2[x_1, \dots, x_p]$.

Because the Schubert cocycles $\{w_1, \dots, w_p\}$ generate $H^*(Grass(p, m+p), \mathcal{Z}_2)$ as a ring, $H^*(Grass(p, m+p), \mathcal{Z}_2)$ can be embedded into $\mathcal{Z}_2[x_1, \dots, x_p]^{S_p} / \tilde{I}_{mp}$, where $\tilde{I}_{mp} = I_{mp} \cap \mathcal{Z}_2[x_1, \dots, x_p]^{S_p}$. Because the elementary symmetric functions generate $\mathcal{Z}_2[x_1, \dots, x_p]^{S_p}$, this last embedding is even an isomorphism.

In the following we will represent the ideal \tilde{I}_{mp} as the kernel of a ring homomorphism. For this denote with h_k the k th complete homogenous symmetric function in

p variables (see the Appendix for details). The set $B := \{h_1, \dots, h_p\}$ is algebraically independent and forms a multiplicative basis of $\mathcal{Z}_2[x_1, \dots, x_p]^{\mathcal{S}_p}$ (compare [13]). Any map defined on B extends therefore in a unique way to a ring homomorphism. Consider now the following ring homomorphism:

$$(4.10) \quad \begin{aligned} \psi : \mathcal{Z}_2[x_1, \dots, x_p]^{\mathcal{S}_p} &\longrightarrow H^*(Grass(p, m+p), \mathcal{Z}_2) \\ h_j &\longmapsto \sigma_j. \end{aligned}$$

Here we assume that the j th Stiefel Whitney class σ_j of the orthogonal bundle $\bar{\xi}_{p,p+m}$ is zero for $j > m$. Using the equivalence of (4.5) and the Jacobi–Trudi identity (6.10), it is immediate that a general Schur function s_λ is mapped onto the Schubert cocycle $[\lambda_1, \dots, \lambda_p]$. From Theorem 6.3 it follows that the k th elementary symmetric function e_k is equal to the Schur function $s_{(1^k, 0, \dots, 0)}$, and this element is mapped onto the Stiefel Whitney class w_k . Again from (4.5) it follows that the kernel of the map ψ has an additive basis of Schur functions s_λ with $\lambda_1 > m$. Finally the Nagelbasch–Kostka identity (6.11) gives a formula expressing a general Schubert cocycle as a polynomial in the Stiefel Whitney classes $\{w_1, \dots, w_p\}$.

5. Proof of the theorems. In the following denote by c the cup length of $H^*(Grass(p, m+p), \mathcal{Z}_2)$ and assume that $g = g_1 \cdots g_c$ is a maximal nonzero product. Our first goal will be to show that $g \in H^{mp}$, in other words, $g = [m^p]$. If not, expand g in terms of Schubert cocycles $g = \sum_{i \in I} [\lambda]^i$ and define $d := \max\{b \mid b = m - \lambda_p\}_{i \in I}$. From (4.4) it follows that $g \cdot \sigma_d \neq 0$ contradicting the maximality of the length of the product. It is therefore immediate that $d = 0$ and $g = [m^p]$.

Using the Nagelbasch–Kostka identity (6.11) one can express each factor g_i as a polynomial in the classes $\{w_1, \dots, w_p\}$. In this way, g becomes a polynomial $g = v(w_1, \dots, w_p)$. Because H^{mp} is one-dimensional, v is just a monom, in other words $g = w_\mu = w_{\mu_1} \cdots w_{\mu_k}$. During the substitution process, the number of factors can only increase, in other words $k \geq c$. On the other hand c is equal to the cup length, which shows $k = c$.

In $\mathcal{Z}_2[x_1, \dots, x_p]^{\mathcal{S}_p}$, this product corresponds to a product of elementary symmetric functions $e_\mu = e_{\mu_1} \cdots e_{\mu_c}$. To say w_μ is nonzero is therefore equivalent to the condition that $e_\mu \notin \ker(\psi)$. Using Theorem 6.3, one can expand e_μ in terms of Schur functions:

$$(5.1) \quad e_\mu = \sum_{|\lambda|=mp} K_{\bar{\lambda}\mu} s_\lambda.$$

Because $|\lambda| = |\mu| = mp$, there is exactly one Schur function s_λ not lying in the ideal $\tilde{I}_{mp} = \ker(\psi)$, namely, $s_\lambda = s_{(m^p)}$.

In summary, w_μ is nonzero if and only if the Kostka number $K_{(p^m)\mu}$ is odd. But this number is equal to the number K_μ introduced in §2. This proves Theorem 2.2 and therefore also Theorem 2.3. \square

In fact, one can show a little more. Using (4.5) and the same argument as above one finds a description of g in terms of the special Schubert cocycle σ_j , i.e., $g = \sigma_\nu = \sigma_{\nu_1} \cdots \sigma_{\nu_c}$. In $\mathcal{Z}_2[x_1, \dots, x_p]^{\mathcal{S}_p}$. This product can be written as:

$$(5.2) \quad h_\nu = h_{\nu_1} \cdots h_{\nu_c} = \sum_{|\lambda|=mp} K_{\lambda\nu} s_\lambda.$$

To say that σ_ν is nonzero is therefore equivalent to the condition that the Kostka number $K_{(m^p)\nu}$ is odd. In this way we have proved Lemma 5.1.

LEMMA 5.1. $c(m, p) = c(p, m)$.

The proof of Theorem 3.5 is partially based on results obtained by Stong [19]. In this paper Stong calculates explicitly maximal nonzero cup products $w_\mu = w_{\mu_1} \cdots w_{\mu_c}$. In this way he calculates the numbers $c(m, p)$ for $m = 2, 3, 4$.

Putting his results in a little more convenient form one obtains

$$(5.3) \quad c(2, p) = k_2(p) \cdot p \quad \text{where} \quad 1.5 \leq k_2(p) \leq 2,$$

$$(5.4) \quad c(3, p) = k_3(p) \cdot p + 1 \quad \text{where} \quad 2 \leq k_3(p) \leq 2.5,$$

$$(5.5) \quad c(4, p) = k_4(p) \cdot p + 1 \quad \text{where} \quad 2.25 \leq k_4(p) \leq 3.$$

To get a lower bound for $c(m, p)$ in general ($m > 4$), Theorem 2.2 will be used. Consider a partition μ of the number $4p$ of length $c(4, p)$ in such a way that the Kostka number $K_{(p^4)(\mu)}$ is odd. But then it is immediate that the Kostka number $K_{(p^m)(p^{m-4}, \mu)}$ is odd as well. In this way one sees that $c(m, p) \geq c(4, p) + m - 4$, which completes the proof of Theorem 3.5. \square

6. Appendix: Symmetric functions. Let $\mu = (\mu_1, \dots, \mu_s)$ be a partition of n of length s . This means $\mu_1 \geq \mu_2 \geq \dots \geq \mu_s > 0$ and $\sum \mu_i = n$. If the integer μ_i is repeated r_i times in the partition μ , the abbreviated notation $\mu = (\mu_1^{r_1}, \dots, \mu_t^{r_t})$ will be used.

A partition μ defines a diagram D_μ , which can be considered as a left-justified array of boxes with μ_i boxes in the i th row.

Example 6.1. Two partitions with corresponding diagrams are illustrated:

The number $|\mu| = \sum \mu_i$ is sometimes called the *weight* of the partition μ and the numbers μ_i are called the *parts* of the partition. The dual partition $\bar{\mu} = (\bar{\mu}_1, \dots, \bar{\mu}_t)$ of a partition μ of n is obtained by taking the “transpose” of D_μ . In other words $\bar{\mu}_i$ is defined as the number of boxes in the column i of D_μ . Assume in addition that there is given a set $S \subseteq \mathcal{N}$.

DEFINITION 6.2. A standard Young tableau of shape μ is a diagram D_μ , where each box in D_μ contains a number from S under the constraint that the rows are increasing and the columns are strictly increasing.

Consider now $R = \mathcal{Z}_2[x_1, \dots, x_p]^{S_p}$, the ring of symmetric functions in p variables. R is in a natural way a graded ring:

$$(6.1) \quad R = A_0 + A_1 + \dots + A_n + \dots, \quad A_i A_j \subseteq A_{i+j}.$$

The homogenous component A_n can be described by different classical bases, where each basis is usually parametrized by the set of all partitions μ with weight n . In particular the dimension of A_n is equal to $p(n)$, the partition number of n .

Products of elementary symmetric functions:

$$(6.2) \quad e_\mu := e_{\mu_1} \cdots e_{\mu_s},$$

where $e_k = \sum x_{i_1} \cdots x_{i_k}$ is the k th elementary symmetric function.

Monomial symmetric functions:

$$(6.3) \quad m_\mu := \sum x_1^{\mu_1} \cdots x_p^{\mu_p},$$

where the summation has to be taken over all distinct monomials with exponents μ_1, \dots, μ_p .

Complete homogenous symmetric functions:

$$(6.4) \quad h_\mu := h_{\mu_1} \cdots h_{\mu_s},$$

where $h_k = \sum_{|\lambda|=k} m_\lambda$ is the k th complete symmetric function.

Schur functions: Classically, Schur functions were introduced by Jacobi (~1835) as the quotient of two alternating functions giving a symmetric function:

$$(6.5) \quad s_\mu = \frac{\det[x_i^{\mu_j + p - j}]}{\det[x_i^{p-j}]}, \quad i, j = 1, \dots, p.$$

The denominator of this expression is nothing else than the Vandermonde determinant and the numerator is a generalization of this type of determinant. The importance of those functions became apparent when Schur, a student of Frobenius, developed the character theory of the symmetric group (~1900).

The change of basis between the different bases of A_n is described by a linear transformation. In 1907, Kostka [11] published matrices describing the change of basis and showed that the different transformations are closely related. The following theorem, which is due to Kostka, is proven in [18].

THEOREM 6.3.

$$(6.6) \quad h_\mu = \sum_{|\lambda|=n} K_{\lambda\mu} s_\lambda,$$

$$(6.7) \quad s_\mu = \sum_{|\lambda|=n} K_{\mu\lambda} m_\lambda,$$

$$(6.8) \quad e_\mu = \sum_{|\lambda|=n} K_{\bar{\lambda}\mu} s_\lambda.$$

The coefficients $\{K_{\lambda\mu}\}$ are called the *Kostka coefficients*. The number $K_{\lambda\mu}$ can be described in a combinatorial way as the number of standard Young tableaux with shape λ and content μ . This means the number of ways of filling in μ_i integers i into the diagram D_λ under the condition that the rows are increasing and the columns are strictly increasing (see [18]).

Only in very special cases are formulas for the numbers $K_{\lambda\mu}$ known. For example if $\mu = (1, 1, \dots, 1)$, the number $K_{\lambda\mu}$ can be described by the famous hook formula of Frame, Robinson, and Thrall [5]. If in addition $\lambda = (p^m)$, the number $K_{\lambda\mu}$ is described by the following formula:

$$(6.9) \quad K_{(p^m)(1^mp)} = \frac{1! \cdots (p-1)! \cdot (mp)!}{m! \cdots (m+p-1)!}.$$

Finally, the following two classical formulas give a polynomial expression of a Schur function in terms of complete symmetric respective elementary symmetric functions.

Jacobi–Trudi identity:

$$(6.10) \quad s_\lambda = \det(h_{\lambda_i+j-i}), \quad i, j = 1, \dots, p.$$

Nagelbasch–Kostka identity:

$$(6.11) \quad s_\lambda = \det(e_{\bar{\lambda}_i+j-i}), \quad i, j = 1, \dots, \lambda_1.$$

More details about these identities are given in [13, p. 25] and in [18].

Acknowledgments. I would like to thank my thesis adviser and teacher Chris Byrnes for introducing me to the pole placement problem and for his constant encouragement during my graduate studies. For helpful comments I thank Stephan Stolz and the anonymous referees.

INFORMATION AND STRATEGIES IN DYNAMIC GAMES*

P. BERNHARD†

Abstract. This paper extends to the setting of stochastic dynamic games with incomplete information a theorem of Kuhn and uses it to prove the existence of a saddle point in a suitable class of strategies. It then particularizes this result to the situation where one of the players has full information to show existence of a saddle point in another class of strategies exhibiting a constant dimension sufficient statistic. A dynamic programming-like algorithm is naturally associated with this class of strategies and was proposed in a previous paper in a sufficient condition setting. For this same class of games, an example of another use of the main theorem is given, leading to a different dynamic programming-like algorithm.

Key words. games, saddle point, mixed strategies, dynamic programming

AMS(MOS) subject classifications. 90D20

1. Introduction. In an historical paper in 1953 [5], Kuhn introduced the modern concept of game in extensive form, extending and simplifying the concept introduced by von Neuman and Morgenstern [11]. In the same paper, he proved that all such games *with complete memory* have a saddle point in behavioral strategies.

We shall consider the equivalent property in the setting of dynamic, and more specifically, multistage games. When all variables range over finite sets, the latter are a special case of games in extensive form. However, our approach allows us to deal with the case where the decision variables range over infinite sets (we shall restrict them to compact sets for technical reasons) and with noisy information. Notice also that the property of *perfect memory*, which was somewhat technical in Kuhn's setup, becomes extremely natural and simple in the setup of dynamical systems.

For the sake of simplicity, we restrict our attention to two-player zero-sum games. It is clear that our form of Kuhn's theorem, as well as the original one, extends to many-person games. (The simplest way to see that is, following Aumann [1], to lump into "player two" the actions of all the other players.) Again for simplicity, we shall first derive it for deterministic games and extend it to stochastic games after. Of course, as in refs [8], [9] discussed below, we also could assume compacity of the control space of one player only and use the nonsymmetric version of Sion's theorem.

In his paper [1], Aumann proposed an extension of Kuhn's theorem to infinite games. He states (p. 628), "A mixed strategy can be thought of as a probability distribution, i.e., a measure, on the set of all pure strategies." This is exactly what we do here. He prefers not to place a measurable structure on the set of pure strategies. (We use Radon measures, with various topologies.) As a result, he has to use a rather restrictive class of mixed strategies, which are not really the direct generalization of Kuhn's mixed strategies but some superset of our, and his, behavioral strategies. But the difference between mixed and behavioral then appears somewhat artificial, since his definition of behavioral is that, in our notations, for $i > j$, the random variables u_i and u_j should be independent. However, the probability law of u_i is

*Received by the editors August 14, 1989; accepted for publication (in revised form) January 25, 1991.

†Institut National de Recherche en Informatique et en Automatique, Sophia Antipolis, Valbonne, France.

$p_i = \varphi_i(u^{t-1}, y^t)$, explicitly depending on the realization u_j . (In the notations of [1], our u_i is $y_i = b_i(x_i, \omega)$, where x_i plays the role of our r_i , and encodes, through the function u_i^j , the information on $y_j = u_i^j(x_i)$.)

In the past few years, several papers have dealt with this type of game, see, e.g., [8] and [9]. These two references and the related literature use a similar set up to ours, and their strategies are our behavioral strategies. The link with what we call mixed strategies is not made there. They do not consider either deterministic games (which are topologically more difficult to handle), nor, more importantly, partial or noisy state information. They deal with infinite time games. The main obstacle to doing so here is that the second part of the paper would not carry over in a simple way.

Starting with §7, we examine in more detail the case where one of the players has full (causal) information, where it is known that the second guessing problem simplifies. See [2] and the bibliography therein. A dynamic programming approach lets us achieve two things. On the one hand, it allows us to show that there exists a saddle point in the class of strategies used in [2], using finite dimensional sufficient statistics, which turns the sufficient condition of that paper into a necessary and sufficient condition. On the other hand, it may be more effective for short duration games to stay with the space of behavioral strategies, and we shall derive a different dynamic programming-like algorithm for the particular case of the rabbit and hunter game.

NOTATION. We shall study only *discrete time* games, so that we shall have to deal with finite sequences of objects. We shall adopt the following conventions. Let $a = \{a_1, a_2, \dots, a_T\}$ be a finite sequence, where $a_t \in A_t$. A subscript will refer to a particular element of the sequence, while a superscript will refer to the restriction of the sequence to its first elements: $a^t = \{a_1, a_2, \dots, a_t\} \in A_1 \times A_2 \times \dots \times A_t = A^t$. The notation A^t will therefore mean the cartesian power of A *only if* $A_1 = A_2 = \dots = A_t = A$. Likewise, if α is a function ranging over A^T , α_t will be its component in A_t , and α^t its first t components. Finally, if $a \in A^t$ and $b \in A_{t+1}$, then $a \cdot b$ stands for the element of A^{t+1} obtained by concatenating a and b .

Let us also agree that for a topological space A , we shall call $\pi(A)$ the set of all (Radon) probability measures over A .

2. Multistage game. A deterministic two-player zero-sum multistage game is given by

- An integer T called the *horizon* of the game. Let $\mathbf{T} = \{1, 2, \dots, T\}$ and $t \in \mathbf{T}$ is called the time.
- A sequence of *state spaces* X_t . We shall use $x_t \in X_t$, the *state at time* t .
- An *initial state* $x_1 \in X_1$, which is assumed to be part of the common knowledge of both players.
- Two sequences of *output spaces* Y_t and Z_t . $y_t \in Y_t$ and $z_t \in Z_t$ are the *measurements* of player 1 and 2 at time t .
- Two *control sets* \mathcal{U} and \mathcal{V} and two point to set maps *admissible controls* $y_t \mapsto U(y_t) \subset \mathcal{U}$ and $z_t \mapsto V(z_t) \subset \mathcal{V}$. We shall oftentimes write U_t and V_t instead of $U(x_t)$ and $V(x_t)$ when what is meant is clear. $u_t \in U_t$ and $v_t \in V_t$ are the *controls* of player 1 and 2 respectively at time t .
- A sequence of functions *dynamics* $f_t : X_t \times U_t \times V_t \rightarrow X_{t+1}$.

$$(1) \quad x_{t+1} = f_t(x_t, u_t, v_t).$$

- Two sequences of *output functions* $h_t : X_t \rightarrow Y_t$ and $k_t : X_t \rightarrow Z_t$, defining

$$(2a) \quad y_t = h_t(x_t),$$

$$(2b) \quad z_t = k_t(x_t),$$

(Actually, h_t and k_t need only be defined for $t \geq 2$)

- A *Capture set* $C \subset X^T \times \mathbf{T}$ defining the *final time* t_1 through

$$(3) \quad t_1 = \begin{cases} \min\{t \mid (x_t, t) \in C\} & \text{if capture happens,} \\ T & \text{otherwise.} \end{cases}$$

- A *criterion* (or *cost function*) G that player **1**, choosing the control, $u_t \in U_t$ strives to minimize, and **2**, choosing the controls $v_t \in V_t$ to maximize. G is defined via two sequences of functions: $L_t : X_t \times \mathcal{U} \times \mathcal{V} \rightarrow \mathbf{R}$ and $K_t : X_t \rightarrow \mathbf{R}$ by

$$(4) \quad G = \sum_{t=1}^{t_1-1} L_t(x_t, u_t, v_t) + K_{t_1}(x_{t_1}).$$

Remark. The above setup is that of dynamical systems and is by now classical. The important point for us is that it defines functions

$$(5a) \quad y_t = \tilde{h}_t(u^{t-1}, v^{t-1}),$$

$$(5b) \quad z_t = \tilde{k}_t(u^{t-1}, v^{t-1}).$$

We shall also make use of

$$(6a) \quad y^t = h^t(x^t) = \tilde{h}^t(u^{t-1}, v^{t-1}),$$

$$(6b) \quad z^t = k^t(x^t) = \tilde{k}^t(u^{t-1}, v^{t-1}),$$

and also

$$(7) \quad G = \tilde{G}_{t_1}(u^{t_1-1}, v^{t_1-1}).$$

Let us introduce a last notation. We shall be interested in games with complete memory. By this we mean that the *information* available to the players to make up their choice of control values at each instant of time is the whole sequence of their own past controls and their past and present measurements. We shall therefore write:

$$(8a) \quad r^t = (u^{t-1}, y^t) \quad \text{player 1's information,}$$

and

$$(8b) \quad s^t = (v^{t-1}, z^t) \quad \text{player 2's information.}$$

We shall also use the following definition

DEFINITION. If the sets \mathcal{U} and \mathcal{V} , (and for stochastic games, \mathcal{W}), are all finite, the game shall be called *finite*.

Note that for a finite game, the sets X_t , Y_t , and Z_t may, with no loss of generality be restricted to finite sets.

For infinite games, we shall use the following *topological hypothesis*.

HYPOTHESIS. The sets U_t , V_t , X_t , Y_t , and Z_t are all topological spaces, the first two *compact*. The functions f_t , h_t , k_t , L_t , and K_t are all continuous, (making G in (4) a continuous function of (x^T, u^{T-1}, v^{T-1}) , or \tilde{G} in (7) a continuous function of (u^{T-1}, v^{T-1})).

3. Strategies. To make precise the definition of the game, we must now specify the strategy sets and what are the quantities to be minimized or maximized.

DEFINITION. We call *pure strategy* of player **1** a *non anticipatory* measurable map

$$(9a) \quad \alpha : Y^{T-1} \rightarrow U^{T-1} : (y_1, \dots, y_{T-1}) \mapsto (u_1, \dots, u_{T-1})$$

and we call A the set of all such nonanticipatory maps, i.e., such that, for a and b in Y^{T-1}

$$a^t = b^t \implies \alpha_t(a) = \alpha_t(b).$$

Likewise, pure strategies of the second player are nonanticipatory measurable maps

$$(9b) \quad \beta \in B, \quad \beta : Z^{T-1} \rightarrow V^{T-1} : (z_1, \dots, z_{T-1}) \mapsto (v_1, \dots, v_{T-1}).$$

Any pair of pure strategies $(\alpha, \beta) \in A \times B$ generates a well defined game history by (1), (2), and

$$(10a) \quad u_t = \alpha_t(y_1, \dots, y_t, \eta),$$

$$(10b) \quad v_t = \beta_t(z_1, \dots, z_t, \zeta),$$

where η and ζ are arbitrary sequences that do not affect the resulting values of u_t and v_t , by the hypothesis of nonanticipativity. As a consequence, we shall omit them in the future. There corresponds to it a well-defined cost

$$G = \hat{G}(\alpha, \beta).$$

We can state the following fact.

LEMMA. *Under the topological hypothesis, the sets A and B of pure strategies are compact in the topology of pointwise convergence.*

Proof. The set of all functions from Y^{T-1} into U^{T-1} is isomorphic to the power set

$$(U^{T-1})^{Y^{T-1}}.$$

Since the U_t are all assumed compact, by Tychonov's theorem so is U^{T-1} , and therefore also the above power set, in the product topology, which coincides with the topology of pointwise convergence. Now, the property of nonanticipativity is clearly preserved in the pointwise limit, so that the sets of pure strategies are closed subsets of compact sets in that topology. \square

In the case where \hat{G} has no saddle point over $A \times B$, it is natural to introduce mixed strategies. Assuming we have chosen a topology on A and B , we may give the following definition.

DEFINITION. We call *mixed strategies* probability measures λ and μ over A and B respectively:

$$(11a) \quad \lambda \in \pi(A),$$

$$(11b) \quad \mu \in \pi(B).$$

We then wish to take as a new criterion

$$(12) \quad J(\lambda, \mu) = E(G) = \int_{A \times B} \hat{G}(\alpha, \beta) d\lambda(\alpha) d\mu(\beta).$$

The existence of the above integral is not guaranteed a priori, since \hat{G} is in general not continuous in α and β , and there is no guarantee that it be measurable. Three alternate sets of hypotheses are provided here as examples of setups where this integral exists and that preserve the compactness of the set of allowed pure strategies. The first set is rather trivial.

HYPOTHESIS 1. The game is finite.

Then the integral in (12) is merely a finite sum. The game is just a matrix game, (possibly with a very large matrix!), and we are in the classical setting of von Neuman and Morgenstern.

The second set allows us to avoid any finiteness hypothesis, but imposes rather strong restrictions on the allowed pure strategies.

HYPOTHESIS 2. The sets U_t , V_t , Y_t , and Z_t , are metric compact spaces, the pure strategies are restricted to be Lipschitz continuous with a prescribed Lipschitz modulus.

We then have the following fact.

LEMMA. *Under Hypothesis 2, the sets A and B are compact in the topology of uniform convergence, and the sequences u^{T-1} , v^{T-1} , and x^T depend continuously on (α, β) .*

Proof. The first claim is a direct consequence of the Arzela Ascoli theorem. The second claim derives from the fact that the x_t 's are then continuous functions of the strategies, as is easily seen by induction on t . \square

Finally, it is also possible to avoid regularity assumptions on the pure strategies, still keeping infinite control sets, by assuming finite observation sets. Notice that it follows from the standing topological hypothesis that the reachable game space is bounded, so that any quantization of the measurement with a finite mesh will produce a finite measurement set. This type of hypothesis was first proposed by Levine [6].

HYPOTHESIS 3. The sets Y_t and Z_t are finite. The functions h_t and k_t can therefore not be continuous. Assume that the sets $h^{-1}(y_k) \cap k^{-1}(z_l)$ have nonvoid interiors, the union of their boundaries is made of the finite union of sets on which h and k are constant, that satisfy the same hypothesis in the relative topology of this boundary, and so on recursively, the whole construction defining a finite partition of X^T .

LEMMA. *Under Hypothesis 3, the set $A \times B$ can be partitioned in a finite union of Borel sets (in the topology of pointwise convergence), the state trajectory x^T depending continuously on (α, β) over each of them, and thus also the control sequences u^{T-1} , v^{T-1} .*

Proof. Let, for simplicity, $A \times B = C$, $(\alpha, \beta) = \gamma$, and, for this proof, y stand for (y, z) . Let also $P_k, k = 1, \dots, K$ be the interior of the sets in X such that $y = \text{const}$, $P = \cup P_k$, and

$$C_t = \{\gamma \mid x_s \in P, \forall s \leq t\}.$$

It is easy to see by induction on t that C_t is open in C . As a matter of fact, let $\gamma^{(n)}$ be a sequence of strategies converging to $\gamma \in C_t$. Since y_1 is fixed, $u_1^{(n)} = \gamma_1^{(n)}(y_1) \rightarrow u_1$. By continuity of f_1 , $x_2^{(n)} \rightarrow x_2$. Since x_2 is interior to $h_2^{-1}(y_2)$, for n large enough, $y_2^{(n)} = y_2$. Therefore, we can use the convergence of $\gamma_2^{(n)}$ and the continuity of f_2 to

conclude that $x_3^{(n)} \rightarrow x_3$, and so on. Therefore $x_t^{(n)} \rightarrow x_t$, and for n large enough, $x_t^{(n)}$ is also in the interior of its set P_k , thus $\gamma^{(n)}$ is in C_t .

Therefore, the complement D_t of C_t in C_{t-1} is also a Borel set. This is the set of strategies γ such that $x_s \in P$, for $s = 1, \dots, t-1$, $x_t \in \partial P$. Now, assume again that $x_t \in Q_i$, where Q_i is the relative interior of one of the subsets of constant y in ∂P . The same type of argument will show that the subset E_l of D_t such that the next x_s , up to $s = l$, are in P is again open in D_t .

We finally have a finite number of subsets of C , depending on the subsets of the partition of X in which each of the x_t lie. All are Borel sets. And since we have shown the convergence of the $x_t^{(n)}$ in each case, \hat{G} is continuous in the relative interior of all of them. This proves the lemma. \square

As a consequence, \hat{G} is measurable, and J in (12) is well defined.

So we now have at least three cases where the following *existence hypothesis* is satisfied.

HYPOTHESIS. For a suitable topology on A and B , these sets are compact, and the state trajectory x^T , as well as the control histories u^{T-1} , v^{T-1} , are measurable functions of the pure strategies α and β .

As a consequence of this hypothesis, we have the following two facts.

PROPOSITION 0. *J in (12) is well defined, since G as defined in (4) is a continuous function of (x^T, u^{T-1}, v^{T-1}) .*

THEOREM 0. *Under the existence hypothesis, and if furthermore, \hat{G} is continuous, the game has a saddle point in mixed strategies.*

Proof. See Ekeland [4, p. 25] The proof makes use of Sion's theorem (see [10]) together with the vague topology on the set of measures.

The idea behind mixed strategies is that the players choose a pure strategy at random, according to the probability laws λ and μ respectively, once for all at the beginning of the game and for its whole duration. The spaces of mixed strategies are very large and complicated sets, and this type of behavior may not appear very natural. We shall therefore introduce another concept of strategies. But we first need a preliminary definition.

DEFINITION. We call *mixed control* of the first player at time t a probability law p_t over U_t , and likewise for the second player.

Let thus

$$(13a) \quad p_t \in P_t = \pi(U_t),$$

$$(13b) \quad q_t \in Q_t = \pi(V_t).$$

We now define the new class of strategies.

DEFINITION. We call *behavioral strategy* of the first player a sequence of measurable maps

$$(14a) \quad \varphi_t \in \Phi_t, \quad \varphi_t : U^{t-1} \times Y^t \rightarrow P_t : (u^{t-1}, y^t) \mapsto p_t = \varphi_t(u^{t-1}, y^t) = \varphi_t(r^t),$$

and similarly for the second player:

$$(14b) \quad \psi_t \in \Psi_t, \quad \psi_t : V^{t-1} \times Z^t \rightarrow Q_t : (v^{t-1}, z^t) \mapsto q_t = \psi_t(v^{t-1}, z^t) = \psi_t(s^t).$$

The game is then extended by considering $\{x_t\}$, $\{u_t\}$, $\{v_t\}$, $\{y_t\}$, and $\{z_t\}$ as stochastic processes, generated by (1) and (2), u_t and v_t being stochastic variables

with probability distributions p_t and q_t respectively, given by (14). Then the sequences u^{T-1} and v^{T-1} are stochastic variables, and we define the payoff of the game as

$$(15) \quad J = E(G) = E\left(\tilde{G}(u^{T-1}, v^{T-1})\right).$$

This is well defined, since \tilde{G} is continuous, and (14) clearly defines a Radon probability over $U^{T-1} \times V^{T-1}$. (By a finite, elementary, version of the Ionescu Tulcea theorem.)

The idea behind behavioral strategies is that at each instant of time, the players choose their controls at random, according to a probability distribution function of their information.

One might believe that this new set of strategies is richer than the previous mixed strategies, since it involves many random choices instead of a single one. A very simple example will teach us that this is not so.

4. Example. The following example is the smallest possible version of the Hunter and Rabbit game. Let $T = 4$ (i.e., the game has three time steps.) The state is $x = (y, w, z) \in \{1, 2\} \times \{0, 1, 2\}^2$ and $U = V = \{1, 2\}$. The dynamics are

$$\begin{aligned} y_{t+1} &= u_t, & y_1 &= 1, \\ w_{t+1} &= v_t, & w_1 &= 0, \\ z_{t+1} &= w_t, & z_1 &= 0. \end{aligned}$$

Player 1 has no other information than the sequence u^{t-1} at time t . Player 2 knows the whole state in addition to the past controls. The capture set is $y_t - z_t = 0$. The payoff to player 2 is 1 if $y_{t_1} = z_{t_1}$, i.e., if *capture* has occurred, and 0 otherwise. Hence, $J = E(G)$ is the capture probability. Recall that we always assume that the initial state is part of the rule of the game, and is therefore common knowledge.

Player 1 actually plays open loop, and therefore chooses among $2^3 = 8$ pure strategies.

Let us look at the possible strategies of player 2. The pure strategies are specified by the decision rules at time 1 and 2, since actions taken at time 3 have no effect on the outcome of the game. At time 1, no information is available beyond the rules of the game. The only two possibilities are either $v_1 = 1$ or $v_1 = 2$. At time 2, a measurement $y_2 = u_1$ is available, which can be equal to 1 or 2. Since v_2 can also be chosen as either 1 or 2, there are 4 possible decision rules for $\beta_2(y_2)$, i.e., $v_2 = 1 \forall y$, that we denote by **1**, or, with the same convention, **2**, or $v_2 = y_2$, or finally $v_2 = 3 - y_2$. We thus have the following list of 8 possible pure strategies:

strategy	1	2	3	4	5	6	7	8
time								
$t = 1$	1	1	1	1	2	2	2	2
$t = 2$	1	2	y_2	$3 - y_2$	1	2	y_2	$3 - y_2$

The mixed strategies are therefore given by 8 probabilities (μ_1, \dots, μ_8) whose sum is one, thus seven degrees of freedom.

Let us now look at the behavioral strategies, still for player 2. They are defined by the probability ψ_1 of playing $v_1 = 1$, (and $1 - \psi_1$ of playing $v_1 = 2$), and for time $t = 2$ the four probabilities $\psi_2(s^2)$ of playing $v_2 = 1$ according to the four possible values of $s^2 = (v_1, y_2)$. Thus, these strategies are defined by five independent probabilities.

We also see on this example that one can make a mixed strategy correspond to a unique behavioral strategy, its *behavior*, by seeing the latter as a conditional marginal probability. Here, for instance, assuming that the pure strategies are numbered according to the above table, we have

$$\begin{aligned}\psi_1 &= \Pr(v_1 = 1) = \mu_1 + \mu_2 + \mu_3 + \mu_4, \\ \psi_2(1, 1) &= \Pr(v_2 = 1 | v_1 = 1, y_2 = 1) = \frac{\mu_1 + \mu_3}{\mu_1 + \mu_2 + \mu_3 + \mu_4} \\ \psi_2(1, 2) &= \Pr(v_2 = 1 | v_1 = 1, y_2 = 2) = \frac{\mu_1 + \mu_4}{\mu_1 + \mu_2 + \mu_3 + \mu_4}\end{aligned}$$

Likewise, the conditioning on $v_1 = 2$ would lead to a denominator $\mu_5 + \mu_6 + \mu_7 + \mu_8$, and so on. It is easy to verify that this map is onto, but cannot be one-to-one. An infinity of different mixed strategies lead to the same behavioral strategy.

The aim of the next section of this paper is to show that it is enough to consider behavioral strategies, for the outcome of the game only depends on the behavior of the strategies used, as rigorously defined hereafter.

Let us remark before we close this example that the solution of this game is almost obvious: each player should play either 1 or 2 with probability $\frac{1}{2}$.

5. Kuhn's theorem. We must first make precise the relationship between a mixed strategy and its associated behavioral strategy.

DEFINITION. We define the map *behavior* γ from the set $\pi(A)$ of mixed strategies to the set Φ of behavioral strategies in the following way:

$\varphi_t(u^{t-1}, y^t)$ is the marginal law on $\alpha_t(y^t)$ knowing $\alpha^{t-1}(y^{t-1}) = u^{t-1}$.

In the finite case, for instance, this can be made explicit in the following way. Let y^t and u^{t-1} be fixed. Let

$$\begin{aligned}A_1 &= \{\alpha \in A | \alpha^{t-1}(y^{t-1}) = u^{t-1}\}, \\ A_2 &= \{\alpha \in A | \alpha^t(y^t) = u^{t-1} \cdot \bar{u}\} \subset A_1.\end{aligned}$$

Then, $\gamma(\lambda) = \varphi$ with, if $A_1 \neq \emptyset$

$$\varphi_t[u^{t-1}, y^t](\bar{u}) = \left(\sum_{\alpha \in A_2} \lambda(\alpha) \right) \left(\sum_{\alpha \in A_1} \lambda(\alpha) \right)^{-1}.$$

If $A_1 = \emptyset$, $\varphi_t[u^{t-1}, y^t]$ may be arbitrarily specified, and we shall always assume that $\varphi = \gamma(\alpha)$ has been so extended to all values of its arguments.

We shall also call γ the behavior map of the second player, from $\pi(B)$ into Ψ .

We now state the main theorem, which is an extension of Kuhn [5]:

THEOREM 1. *There exists a function \bar{J} from $\Phi \times \Psi$ into \mathbf{R} such that,*

$$\forall(\lambda, \mu) \in \pi(A) \times \pi(B), \quad J(\lambda, \mu) = \bar{J}(\gamma(\lambda), \gamma(\mu))$$

i.e., the criterion $J(\lambda, \mu)$ of the game only depends on the behaviors $\gamma(\lambda)$ and $\gamma(\mu)$.

Proof. Under the existence hypothesis, (u^{T-1}, v^{T-1}) is a measurable function of (α, β) . Thus a pair of mixed strategies (λ, μ) generates a probability distribution Π^{T-1} over the set $U^{T-1} \times V^{T-1}$, and one has

$$J(\lambda, \mu) = \int_{U^{T-1} \times V^{T-1}} \tilde{G}(u^{T-1}, v^{T-1}) d\Pi^{T-1}(u^{T-1}, v^{T-1}),$$

or, in the discrete case

$$J(\lambda, \mu) = \sum_{u^{T-1}, v^{T-1}} \tilde{G}(u^{T-1}, v^{T-1}) \Pi^{T-1}(u^{T-1}, v^{T-1}).$$

Therefore, J only depends on the probability law Π^{T-1} . Notice that, for fixed $\bar{u}^{T-1}, \bar{v}^{T-1}$, the event $(u^{T-1}, v^{T-1}) = (\bar{u}^{T-1}, \bar{v}^{T-1})$ can be written

$$(u^{T-2}, v^{T-2}) = (\bar{u}^{T-2}, \bar{v}^{T-2}) \quad \text{and} \quad (u_{T-1}, v_{T-1}) = (\bar{u}_{T-1}, \bar{v}_{T-1}).$$

Furthermore, it follows from the definition (12) that the strategies λ and μ are chosen independently by the two players, so that, for $u^{T-2} = \bar{u}^{T-2}$ and $v^{T-2} = \bar{v}^{T-2}$ fixed, the random variables u_{T-1} and v_{T-1} are independent.

Let therefore λ and μ be fixed, $\varphi = \gamma(\lambda)$ and $\psi = \gamma(\mu)$ their behaviors,

$$\begin{aligned} \tilde{h}^{T-1}(\bar{u}^{T-2}, \bar{v}^{T-2}) &= \bar{y}^{T-1}, & \tilde{k}^{T-1}(\bar{u}^{T-2}, \bar{v}^{T-2}) &= \bar{z}^{T-1}, \\ \varphi_{T-1}(\bar{u}^{T-2}, \bar{y}^{T-1}) &= \bar{p}_{T-1}, & \psi_{T-1}(\bar{v}^{T-2}, \bar{z}^{T-1}) &= \bar{q}_{T-1}. \end{aligned}$$

One has the equality

$$d\Pi^{T-1}(\bar{u}^{T-1}, \bar{v}^{T-1}) = d\Pi^{T-2}(\bar{u}^{T-2}, \bar{v}^{T-2}) d\bar{p}_{T-1}(\bar{u}^{T-1}) d\bar{q}_{T-1}(\bar{v}^{T-1}).$$

(See, for instance, the second part of proposition V.1.1 in [7].)

Or in the discrete case,

$$\Pi^{T-1}(\bar{u}^{T-1}, \bar{v}^{T-1}) = \Pi^{T-2}(\bar{u}^{T-2}, \bar{v}^{T-2}) \bar{p}_{T-1}(\bar{u}_{T-1}) \bar{q}_{T-1}(\bar{v}_{T-1}),$$

by Bayes rule.

One then iterates this process to write Π^{T-2} in terms of Π^{T-3} and of φ_{T-2} and ψ_{T-2} , and so on. This proves the theorem. \square

This allows us to carry over results obtained by topological means on games in normal form, such as Theorem 0 above, to dynamic games in behavioral strategies. We thus have, for instance, the following obvious fact.

COROLLARY 1. *Under the existence hypothesis, and if furthermore \hat{G} is continuous, a dynamic game with perfect memory admits a saddle point in behavioral strategies over the sets $\Phi = \gamma(A)$, $\Psi = \gamma(B)$.*

The difficult task, however, is to characterize the sets $\gamma(A)$ and $\gamma(B)$. This is trivial for finite games, where all behavioral strategies will be included. We shall see that the question is easy for nondegenerate stochastic games. For deterministic continuous games, let us look, for instance, at the setup defined by Hypothesis 2 of §3. A is the set of causal functions from Y^{T-1} into the compact U^{T-1} , Lipschitz continuous with Lipschitz modulus ℓ .

PROPOSITION. The behavioral strategies of $\gamma(A)$ have the following property : let $\tau : U_t \rightarrow \mathbf{R}$ be a function with Lipschitz modulus m , then

$$E^{r^t} \tau = \int_{U_t} \tau(u) d\varphi_t(r^t)(u)$$

is a Lipschitz continuous function of y^t with Lipschitz modulus ℓm .

The proof is elementary. This includes the obvious fact that if the pure strategies are restricted to open loop controls, so are the corresponding behavioral strategies,

since this is the case $\ell = 0$. We conjecture that this is a complete characterization of the set $\gamma(A)$, but this is not sure. We did not investigate this point in detail, since we do not need it in the sequel.

6. Stochastic games. Up to here, we have dealt with games with deterministic dynamics and measurements. The information available to the players is incomplete, but not noisy. We now extend all the previous theory to the case of stochastic games.

A stochastic multistage game is defined as in §2, except that (1) and (2) involve an extra stochastic process $\{w_t\}$, with values in sets \mathcal{W}_t , usually multidimensional. It will always be assumed to be white, with probability distributions W_t known to both players. Thus (1) and (2) are replaced respectively by

$$(17) \quad x_{t+1} = f_t(x_t, u_t, v_t, w_t),$$

$$(18a) \quad y_t = h_t(x_t, w_{t-1}),$$

$$(18b) \quad z_t = k_t(x_t, w_{t-1}).$$

The one time step shift in the argument w of h_t and k_t makes sense, since x_1 being known to both players, the first relevant measurement is y_2, z_2 . Moreover, with that convention, \tilde{h}_t and \tilde{k}_t , as well as r^t and s^t , all depend on u^{t-1}, v^{t-1} , and w^{t-1} , greatly simplifying the sequel. Of course, the hypothesis that w is a white process makes this much more than a pure notational trick. One case where this is not restrictive, and equivalent to the more classical approach, is when w enters in the dynamics and the measurements through distinct independent components.

In this setup, the sequences x, u, v , become stochastic processes, even with pure strategies, and (4) is replaced with a mathematical expectation:

$$(19) \quad G = E \left[\sum_t L_t(x_t, u_t, v_t) + K_{t_1}(x_{t_1}) \right].$$

For simplicity, we shall assume that the sets U_t and V_t do not depend on the current state.

The definitions of the strategies are unchanged. Note that the three sets of hypotheses that have been proposed as alternate setups that ensure satisfaction of the existence hypothesis still stand here. Hypothesis 1 leads to a standard matrix game the entries of which are the expected cost incurred. Hypothesis 2 needs no modification either. Convergence of the trajectories is ensured for each value of w^{T-1} , and thus the expected values converge. Hypothesis 3 must be extended to hold on the $X \times W$ space. It is just a bit cumbersome to state and deal with. A simple case is when $w = (\xi, \eta)$ is made of two independent components, ξ entering in the dynamics, and $h_t(x, w) = \hat{h}_t(x + \eta)$, and likewise for k_t . However, everything becomes much simpler if we assume that for all x_t, u_t, v_t , the transition probability induced by f_t is absolutely continuous with respect to the Lebesgue measure. (The so called *nondegenerate* case). Then, the existence hypothesis and continuity of \tilde{G} for pointwise convergence of the strategies is just a consequence of the Ionescu Tulcea theorem.

Theorem 1 is still valid in this context; its proof is slightly modified as follows.

Proof. (Theorem 1 for stochastic games.) As previously, let Π^{T-1} be the distribution law of the random variable $(u^{T-1}, v^{T-1}, w^{T-1})$ generated by a given pair of mixed strategies (λ, μ) . One has

$$J(\lambda, \mu) = \int_{U^{T-1} \times V^{T-1} \times W^{T-1}} \tilde{G}(u^{T-1}, v^{T-1}, w^{T-1}) d\Pi^{T-1}(u^{T-1}, v^{T-1}, w^{T-1}).$$

Moreover, as previously

$$d\Pi^{T-1}(u^{T-1}, v^{T-1}, w^{T-1}) = d\Pi^{T-2}(u^{T-2}, v^{T-2}, w^{T-2}) d\Pi^c(u_{T-1}, v_{T-1}, w_{T-1}),$$

where Π^c is the conditional law of $(u_{T-1}, v_{T-1}, w_{T-1})$ knowing $(u^{T-2}, v^{T-2}, w^{T-2})$. Using the notation

$$\begin{aligned} p_{T-1} &= \varphi_{T-1}(u^{T-2}, \tilde{h}^{T-1}(u^{T-2}, v^{T-2}, w^{T-2})) \\ q_{T-1} &= \psi_{T-1}(v^{T-2}, \tilde{k}^{T-1}(u^{T-2}, v^{T-2}, w^{T-2})) \end{aligned}$$

for the behaviors, which are, by definition, the conditional laws of u_{T-1}, v_{T-1} for a given r^{T-2} and s^{T-2} , and remembering that w_{T-1} is by hypothesis independent of the past, we derive, still as previously

$$\begin{aligned} d\Pi^{T-1}(u^{T-1}, v^{T-1}, w^{T-1}) = \\ d\Pi^{T-2}(u^{T-2}, v^{T-2}, w^{T-2}) dp_{T-1}(u_{T-1}) dq_{T-1}(v_{T-1}) dR_{T-1}(w_{T-1}). \end{aligned}$$

We may anew iterate the process, to conclude the proof. \square

7. Semicomplete information in finite games. One of the superiorities of behavioral strategies over mixed strategies is that, due to their sequential nature, they lend themselves to dynamic programming. We shall exploit this fact in the case of *finite games with semicomplete information*.

By this we mean that one of the players, say **2**, has full knowledge of the relevant variables of the game at each instant of time. More specifically, we shall assume that at time t , **2** knows x_t, y_t , and also u_{t-1} . This is not beyond the scope of our previous theory, since we may always augment the state with the variables η_t and ξ_t , with $\eta_{t+1} = w_t$, and $\xi_{t+1} = u_t$, so that knowing the full state also yields $y_t = h_t(x_t, \eta_t)$, and $u_{t-1} = \xi_t$. Of course the players are still assumed to have perfect memory, so that they also remember past values of their measurements.

Let ν_t be a probability distribution over $X^t \times V^{t-1}$. We think of ν_t as being player **1**'s conditional probability on (x^t, v^{t-1}) . Assume u^t given, as well as a behavioral strategy ψ^t of the second player. Then, using the dynamics (17), we can propagate ν_t into a probability $\bar{\nu}_{t+1}$ over $X^{t+1} \times V^t$, in the following way. Let $a \in X^{t+1}$ and $b \in V^t$,

$$\bar{\nu}_{t+1}(a, b) = \nu_t(a^t, b^{t-1}) \psi_t[a^t, u^{t-1}, b^{t-1}](b_t) \sum_w \delta(a_{t+1} - f_t(a_t, u_t, b_t, w)) W_t(w).$$

Then, when the measurement y_{t+1} comes in, one may compute the new conditional probability ν_{t+1} on (x^{t+1}, v^t) . We shall give explicit formulas only for the simple example of the next section. Anyhow, this defines a filter of the form

$$(20) \quad \nu_{t+1} = F_t(\nu_t, u^t, y_{t+1}, \psi_t),$$

and also a function

$$(21) \quad \nu_t = N_t(u^{t-1}, y^t, \psi^{t-1}) = N_t(r^t, \psi^{t-1}).$$

By summation over the component subspaces, we can project ν_t on X^t alone, let ρ^t be that law on x^t . We can further project on the component X_t , yielding a law

$$(22) \quad \rho_t = R_t(r^t, \psi^{t-1}).$$

We can now state a theorem of dynamic programming.

THEOREM 2. *Let a stochastic dynamic game be given by (17) to (19), and (φ^*, ψ^*) be a saddle point in behavioral strategies (which exists according to Corollary 1). There exists a sequence of functions V_t from $X^t \times U^{t-1} \times V^{t-1}$ to \mathbf{R} such that for all (x^t, u^{t-1}, v^{t-1}) reached with a non zero probability while playing according to (φ^*, ψ^*) , one has*

$$\begin{aligned}
 (23) \quad & V_t(x^t, u^{t-1}, v^{t-1}) \\
 &= \max_{v \in V_t} \sum_{w \in \mathcal{W}^t} \sum_{u \in U_t} [V_{t+1}(x^t \cdot f_t(x_t, u, v, w_t), u^{t-1} \cdot u, v^{t-1} \cdot v) + L_t(x_t, u, v)] p_t^*(u) W^t(w) \\
 &= \sum_{v \in V_t} \sum_{w \in \mathcal{W}^t} \sum_{u \in U_t} [V_{t+1} + L_t] p_t^*(u) W^t(w) q_t^*(v).
 \end{aligned}$$

(the arguments in V_{t+1} and L_t in the third term are of course the same as in the second) and

$$\begin{aligned}
 (24) \quad & \sum_{x^t, v^{t-1}} V_t(x^t, u^{t-1}, v^{t-1}) \nu_t^*(x^t, v^{t-1}) \\
 &= \min_{u \in U_t} \sum_{w \in \mathcal{W}^t} \sum_{v \in V_t} \sum_{x^t, v^{t-1}} [V_{t+1}(x^t \cdot f_t(x_t, u, v, w_t), u^{t-1} \cdot u, v^{t-1} \cdot v) \\
 &\quad + L_t(x_t, u, v)] \nu_t^*(x^t, v^{t-1}) q_t^*(v) W^t(w) \\
 &= \sum_{u \in U_t} \sum_{w \in \mathcal{W}^t} \sum_{v \in V_t} \sum_{x^t, v^{t-1}} [V_{t+1} + L_t] \nu_t^*(x^t, v^{t-1}) q_t^*(v) W^t(w) p_t^*(u),
 \end{aligned}$$

where p_t^* and q_t^* stand for $\varphi_t^*[r^t]$ and $\psi_t^*[x^t, u^{t-1}, v^{t-1}]$, respectively, ν_t^* for $N_t(r^t, \psi^*)$, and y^t in r^t for $h^t(x^t, w^{t-1})$, and

$$(25) \quad \forall(x, \tau) : (x_\tau, \tau) \in C, \forall(u, v), V_\tau(x^\tau, u^{\tau-1}, v^{\tau-1}) = K_\tau(x_\tau),$$

Conversely, if a sequence of functions V_t together with a pair of behavioral strategies φ^*, ψ^* satisfy equations (23) to (25), these strategies constitute a saddle point of the game, and the value of the game is $V_1(x_1)$.

Proof. The sufficiency part of the claim is a direct adaptation of the theorem in [2] and shall not be repeated in detail. The proof amounts to using (23)–(25) to show that, for an arbitrary sequence v^T , one has $G(\varphi^*, v^T) \leq V_1(x_1)$, and using (24) and (25) to derive the other inequality of the saddle point. This second part uses the fact that when calculating $G(u^T, \psi^*)$, since $\mathbf{2}$ plays ψ^* , $N_t(r^t, \psi^*)$ is actually a conditional probability. This fact is not true, but not needed either, in the first calculation.

Let us now look at necessity.

Notice first that the second equalities in (23) and (24) amount to the fact that q^* has its support contained in the set of v 's that provide the maximum in (23), and likewise for p^* with the minimum in (24).

Let (x^t, u^{t-1}, v^{t-1}) be a state of the game reached with a nonzero probability while playing (φ^*, ψ^*) . For each w^{t-1} , there corresponds a y^{t-1} , and we can describe the game history from there on under the strategies φ^*, ψ^* . Let

$$V_t(x^t, u^{t-1}, v^{t-1}) = \mathbf{E} \left[\sum_{i=t}^{t_1-1} L_i(x_i, u_i, v_i) + K(x_{t_1}) \right].$$

It is clear that V_t thus defined satisfies the second equality of (23), and thus of (24) by summing both sides of (23). Assume now that there exists $\hat{v} \in V_t$ that gives to the second term of (23) a value larger than V_t . Consider the strategy $\hat{\psi}$ that coincides with ψ^* everywhere, except at (x^t, u^{t-1}, v^{t-1}) where it is a dirac distribution at \hat{v} . Let, for simplicity, $L_{t_1} = K(x_{t_1})$, and write

$$\mathbf{E}\tilde{G}(u^{t_1-1}, v^{t_1-1}) = \mathbf{E} \sum_{i=1}^{t-1} L_i + \mathbf{E} \sum_{i=t}^{t_1} L_i.$$

Using the fact that the information algebra is increasing, write the second expectation above as

$$\mathbf{E} \sum_{i=t}^{t_1} L_i = \mathbf{E} \left[\mathbf{E} \left(\sum_{i=t}^{t_1} L_i \mid x^t, u^{t-1}, v^{t-1} \right) \right].$$

The inner expectation is larger for $(\varphi^*, \hat{\psi})$ than for (φ^*, ψ^*) by hypothesis. From all other possible states at time t , this expectation coincides for the two strategy pairs, since ψ^* and $\hat{\psi}$ coincide. However, this particular state is reached by hypothesis with a nonzero probability. Therefore the outer expectation is larger with the strategy $\hat{\psi}$, which contradicts the definition of the saddle point.

We do likewise with φ and (24), noticing as in the sufficiency proof that, when player 2 does play ψ^* , the quantity minimized in (24) actually is the expectation of V_t for player 1. We thus contradict the other inequality of the saddle point. The theorem is proved. \square

Note that, as in [2], this may be viewed as a fixed point theorem: multiply equation (23) by $\nu_t^*(x^t, v^{t-1})$ on both sides, and sum over all (x^t, v^{t-1}) . Then (23) and (24) together express the fact that φ_t^*, ψ_t^* provide a saddle point (over a product of simplices for ψ_t^*) of the matrix made up of the blocks $[V_{t+1} + L_t]$ weighted by $\nu_t^* = N_t(r^t, \psi^{t-1})$. So the problem is to find a ψ^* that gives rise to a ν^* for which this ψ^* is an argument of this sequence of saddle points.

In itself, this theorem is of little use. We shall see in the next section a case where it simplifies to the point where it can be used to compute the saddle point of the game. At this time, we show a theoretical consequence of interest.

COROLLARY 2. *Let $\rho_t^* = R_t(r^t, \psi^*)$. The game admits a saddle point in behavioral strategies of the form $\varphi_t^*[r^t] = \hat{\varphi}_t[\rho_t^*]$, $\psi_t^*[x^t, u^{t-1}, v^{t-1}] = \hat{\psi}_t[x_t, \rho_t^*]$. We can define a filter $\rho_{t+1} = g_t(\rho_t, u_t, y_{t+1}, \psi_t)$, and there exists a sequence of functions $V_t(x_t, \rho_t)$ such that for all (x_t, ρ_t) that are reached with a nonzero probability while playing optimally,*

$$\begin{aligned} (26) \quad & V_t(x_t, \rho_t) \\ &= \max_{v \in V_t} \sum_{w \in \mathcal{W}_t} \sum_{u \in U_t} [V_{t+1}(f_t(x_t, u, v, w), g_t(\rho_t, u, y_{t+1}, \hat{q}_t)) + L_t(x_t, u, v)] \hat{p}_t(u) W_t(w) \\ &= \sum_{v \in V_t} \sum_{w \in \mathcal{W}_t} \sum_{u \in U_t} [V_{t+1} + L_t] \hat{p}_t(u) W_t(w) \hat{q}_t(v) \end{aligned}$$

and

$$(27) \quad \sum_{x_t \in X_t} V_t(x_t, \rho_t) \rho_t(x) =$$

$$\begin{aligned} \min_{u \in U_t} \sum_{x_t} \sum_{w \in W_t} \sum_{v \in V_t} [V_{t+1}(f_t(x_t, u, v, w), g_t(\rho_t, u, y_{t+1}, \hat{q}_t)) + L_t(x_t, u, v)] \hat{q}_t(v) W_t(w) \rho_t(x_t) \\ = \sum_{u \in U_t} \sum_{x_t} \sum_{w \in W_t} \sum_{v \in V_t} [V_{t+1} + L_t] \hat{q}_t(v) W_t(w) \rho_t(x_t) \hat{p}(u). \end{aligned}$$

where \hat{p}_t stands for $\hat{\varphi}_t[\rho_t]$, \hat{q}_t for $\hat{\psi}_t[x_t, \rho_t]$, and y_{t+1} for $h_{t+1}(f_t(x_t, u, v, w), w)$, and

$$(28) \quad \forall(x_\tau, \tau) \in C, \forall \rho, V_\tau(x_\tau, \rho) = K_\tau(x_\tau).$$

Conversely, if a sequence of functions $\hat{\varphi}_t$, $\hat{\psi}_t$, and V_t satisfy these equations, they provide a saddle point of the game.

Proof. The fact that with strategies of this form there exists such a filter and the sufficiency part of the proof is exactly the main theorem of [2]. Let us look at the necessity.

Notice that, for each value of (x^t, v^{t-1}) in $X^t \times V^{t-1}$, we may multiply all terms of equation (23) by $\nu_t^*(x^t, v^{t-1})$, which is nonnegative, and sum over all such terms still preserving the inequalities. Conversely, writing the resulting summed inequality (implicit in the max operation) is *equivalent* to the separate inequalities, provided it is specified that q^* is allowed to depend on (x^t, v^{t-1}) . (Therefore the combined maximizing variable ranges over a product of simplices.)

Therefore, the mean value $\bar{V}(r^t) = \sum V_t \nu_t^*$ appears as the saddle point of the kernel $\sum_w \sum_{(x^t, v^{t-1})} [V_{t+1} + L_t] \nu_t^*(x^t, v^{t-1}) W^t(w)$, over a simplex for the minimizing variable, and a product of simplices for the maximizing variable. Now look at this definition for $t = T - 1$. Then, $V_{t+1} = K_T(x_T)$, and the kernel depends on past values of the various variables only through ν_{T-1}^* . Moreover, since the variables x^{T-2} , v^{T-2} , and w^{T-2} do not appear in V_T and L_{T-1} , we may first sum over these variables, ending up with the kernel $\sum_w \sum_x [V_T + L_{T-1}] \rho_{T-1}(x) W_{T-1}(w)$. Therefore, the value of the saddle point depends only on ρ_{T-1} . And using the sufficiency argument, we can replace φ_{T-1}^* and ψ_{T-1}^* by strategies of the form proposed for $\hat{\varphi}$ and $\hat{\psi}$. So V_{T-1} also depends only on x_{T-1} and ρ_{T-1} .

Finally, using the propagation of ρ_t as stated in the theorem, we can iterate this process for time $T - 2$, and so on down to 1. This proves the theorem. \square

This theorem shows that (x_t, ρ_t) constitutes a *sufficient statistic* of constant dimension for the decision problem at hand. The dynamic programming algorithm that one would like to derive from this theory remains quite cumbersome for two reasons. On the one hand, one must work in a space with a *continuous* component, while the game is discrete, and even finite. On the other hand, as was pointed out in [2], each step involves the solution of a difficult fixed point problem, since $(\hat{\varphi}_t, \hat{\psi}_t)$ must be the saddle point of a kernel that itself depends on $\hat{\psi}_t$ through its appearance in g_t . The above theory proves that this fixed point exists, a result which could not be obtained through the classical topological techniques, since the dependence of the kernel on $\hat{\psi}$ is not continuous. But computing it may remain a formidable task.

So we turn now to an example where one may prefer to stick with the full behavioral strategies.

8. Rabbit and Hunter game. This game is an extension of the example of §4. A hunter tries to shoot a rabbit that moves in a finite space made of N positions, assumed for this example to lie on a straight line. The game is specified by six integers:

- T , the horizon of the game. As usual, $\mathbf{T} = \{1, \dots, T\}$.
- N , the number of possible positions of rabbit. The game space is therefore $\mathbf{N} = \{1, \dots, N\}$.

- a , the amplitude of rabbit's jumps, (or a^- , a^+ , the left and right amplitudes).
- b , the number of bullets available to hunter,
- c , the capture radius (or lethal radius) of a bullet,
- d , the delay or time taken by the bullets to fly from hunter to rabbit.

The state x_t is composed of the following scalar variables:

- $y_t \in \mathbf{N}$, the position of rabbit.
- $w_t^k \in \mathbf{N} \cup \{0\}$, $k = 1, \dots, d-1$, the position the bullet shot k time steps earlier is flying to.
- $z_t \in \mathbf{N} \cup \{0\}$, the position where the bullet shot d time steps earlier is arriving. (It will be convenient to use this notation rather than w^d .)
- κ_t , the counter of expended bullets.

The players controls are

- $u_t \in U_t = [y_t - a, y_t + a] \cap \mathbf{N}$, (or $U_t = [y_t - a^-, y_t + a^+] \cap \mathbf{N}$), the next position of rabbit.
- $v_t \in V_t$, the position hunter aims at. $v_t = 0$ means that he does not shoot, since 0 is not a possible position of rabbit. To take into account the budget constraint, we set

$$V_t = \begin{cases} \mathbf{N} \cup \{0\} & \text{if } \kappa_t < b, \\ \{0\} & \text{if } \kappa_t = b. \end{cases}$$

The dynamics are

$$\begin{aligned} y_{t+1} &= u_t, & y_1 & \text{ given,} \\ w_{t+1}^1 &= v_t, & w_1^1 &= 0, \\ w_{t+1}^{k+1} &= w_t^k & w_1^k &= 0, \\ z_{t+1} &= w_t^{d-1} & z_1 &= 0, \\ \kappa_{t+1} &= \kappa_t + 1 - \delta(v_t), & \kappa_1 &= 0. \end{aligned}$$

Having included the budget constraint into V_t , we may take for the capture set $\{|z_t - y_t| \leq c\}$, pretending that the game goes on, even if hunter cannot shoot anymore.

In fact, to simplify the calculations below, we shall from now on assume that

$$b \leq N,$$

so that hunter shoots at all time steps, and we may ignore κ .

We shall need the following notations:

$$C(w) = \{u \mid |u - w^{d-1}| \leq c\}$$

and

$$\chi_w(u) = \begin{cases} 1 & \text{if } u \in C(w), \\ 0 & \text{otherwise.} \end{cases}$$

Furthermore, with a slight abuse of notations, we shall write either $u \in C(w)$ or $w \in C(u)$, meaning $(u, w) \in C$.

Introduce finally the following shift operator operating on the vector w :

$$\sigma(v) \cdot w = \begin{pmatrix} v \\ w^1 \\ \vdots \\ w^{d-2} \end{pmatrix}.$$

In the sequel, let

$$\begin{aligned} p_t^* &= \varphi_t^*[y^t], \\ q_t^* &= \psi_t^*[x^t]. \end{aligned}$$

The filter must take into account that the rabbit computes ρ_{t+1} only if it is alive, which gives extra information on the past. We get (see [3])

$$(29) \quad \rho_{t+1}(w) = \sum_{\omega \notin C(y_{t+1})} \delta(w - \sigma(w^1) \cdot \omega) q_t^*(w^1) \rho_t(\omega) \left[\sum_{\omega \notin C(y_{t+1})} \rho_t(\omega) \right]^{-1}.$$

The dynamic programming equations (23) and (25) now read

$$V_t(y^t, w^t, z^t) = \max_{v \in V_t} \sum_{u \in U_t} V_{t+1}(y^t \cdot u, w^t \cdot \sigma(v) \cdot w, z^t \cdot w^{d-1}) p_t^*(u)$$

if $y_t \notin C(z_t)$, i.e., $(y_t, z_t) \notin C$,

$$V_t(y^t, w^t, z^t) = 1 \quad \text{if } (y_t, z_t) \in C.$$

We may simplify this expression, and more importantly reduce the size of the space to be scanned, in the following manner. Introduce a function $W_t(y^t, w_t)$, which will be related to the function V_t according to the following definition:

$$(30) \quad V_t(y^t, w^t, z^t) = \begin{cases} W_t(y^t, w_t) & \text{if } (y_t, z_t) \notin C, \\ 1 & \text{if } (y_t, z_t) \in C. \end{cases}$$

This function satisfies the following dynamic programming equations, which show that it only depends on the indicated variables, exactly in the same way as we proved Corollary 2 above:

$$W_t(y^t, w_t) = \max_{v \in V_t} \sum_{u \in U_t} [\chi_{w_t}(u) + (1 - \chi_{w_t}(u)) W_{t+1}(y^t \cdot u, \sigma(v) \cdot w_t)] p_t^*(u),$$

or equivalently

$$(31) \quad W_t(y^t, w_t) = \max_{v \in V_t} \left[\sum_{u \in C(w_t)} p_t^*(u) + \sum_{u \notin C(w_t)} W_{t+1}(y^t \cdot u, \sigma(v) \cdot w_t) p_t^*(u) \right].$$

The second dynamic programming equation, (24), becomes now

$$(32) \quad \sum_w W_t(y^t, w) \rho_t(w) = \min_{u \in U_t} \sum_w [\chi_w(u) + (1 - \chi_w(u)) \sum_v W_{t+1}(y^t \cdot u, \sigma(v) \cdot w) q_t^*(v)] \rho_t(w).$$

Equations (31) and (32) may be used as the basis for a numerical algorithm, provided that the horizon T be short enough, (and a and N small enough) so that the state space remain of a tractable size. The algorithm again involves a fixed point search: for a given set of ρ_t 's at each point of the space, compute $\hat{\varphi}$ and $\hat{\psi}$ rearwards in time, then solve for the fixed point $N_t(y^t, \hat{\psi}) = \rho_t$. This can be done, for instance, via a successive approximation scheme, using subrelaxation as necessary. No convergence proof is available at this time, however.

Notice finally that, as in [3], the mean value

$$\sum_w W_t(y^t, w) \rho_t(w) = \bar{W}_t(y^t)$$

can be computed in a faster way, avoiding the separate computations according to the values of w . Taking ρ_{t+1} in (29), and for a fixed $y_{t+1} = u$, we have

$$\sum_w W_{t+1}(y^t \cdot u, \omega) \rho_{t+1}(\omega) = [1 - \rho_t(C_t(u))]^{-1} \sum_w \sum_{w \notin C(u)} \sum_v W_{t+1}(y^t \cdot u, \omega) \delta(\omega - \sigma(v) \cdot w) q_t^*(v) \rho_t(w).$$

Take the summation in ω inside the other two, and use the fact that then, the δ selects the only value $\omega = \sigma(v) \cdot w$, to get

$$\bar{W}_{t+1}(y^t \cdot u) = [1 - \rho_t(C_t(u))]^{-1} \sum_{w \notin C(u)} \sum_v W_{t+1}(y^t \cdot u, \sigma(v) \cdot w) q_t^*(v) \rho_t(w),$$

or equivalently

$$[1 - \rho_t(C_t(u))] \bar{W}_{t+1}(y^t \cdot u) = \sum_w (1 - \chi_w(u)) \sum_v W_{t+1}(y^t \cdot u, \sigma(v) \cdot w) q_t^*(v) \rho_t(w).$$

We recognize the right-hand side here as being the second term in the right-hand side of (32) above. Substituting into it we get a recurrent equation for \bar{W}_t :

$$\bar{W}_t(y^t) = \min_u [\rho_t(C(u)) + [1 - \rho_t(C_t(u))] \bar{W}_{t+1}(y^t \cdot u)].$$

Acknowledgment. This work owes much to fruitful discussions with Tamer Başar, of the University of Illinois, then on leave at INRIA Sophia Antipolis, who, among other things, suggested the example of §4 which led to the understanding of the nature of mixed versus behavioral strategies in dynamic games.

ON THE MODELLING AND EXACT CONTROLLABILITY OF NETWORKS OF VIBRATING STRINGS*

E. J. P. GEORG SCHMIDT†

Abstract. Using Hamilton's principle a nonlinear system of partial differential equations describing the dynamics of a network of vibrating strings is derived. An equilibrium is linearized to obtain a linear system of "wave equations." The equations are complemented by "coupling conditions" at the "multiple nodes" where several elements meet and by "boundary conditions" at the "simple nodes." Existence of solutions to the linear system is proved. Finally, multiplier techniques are used to prove exact controllability for certain specific networks.

Key words. boundary control, hyperbolic systems, vibrating networks

AMS(MOS) subject classifications. 36B37, 36L55, 49E15, 93C20, 73K03

1. Introduction. Our purpose is to describe the dynamics, and then to control exactly connected networks of vibrating strings in configurations such as those in Fig. 1.

FIG. 1

Our interest in this problem was stimulated by Chen, Delfour, Krall, and Payre [3], who dealt with the stabilization of "serial" beam configurations. We wanted to treat more complicated networks and have done so, in the technically somewhat simpler context of vibrating strings. We have focussed on exact controllability; results on stabilizability could surely be obtained using similar methods. A preliminary version

*Received by the editors December 11, 1989; accepted for publication (in revised form) November 30, 1990. This work was supported by Natural Sciences and Engineering Research Council grant A727, as well as by the Deutsche Forschungsgemeinschaft (Schwerpunktsprogramm: Anwendungsbezogene Optimierung und Steuerung).

†Department of Mathematics and Statistics, McGill University, 805 Sherbrooke Street West, Montreal, Quebec, Canada, H3A 2K6.

of this paper has appeared in a technical report [9]. Networks of beams are now the subject of a joint work with G. Leugering; some results on beam networks have appeared in [5].

The endpoints of the component strings will be referred to as *nodes*; the nodes where two or more strings meet will be called *multiple*, while the nodes corresponding to only one string will be called *simple*. In this paper the simple nodes will be fixed or subject to control, while the multiple nodes will be allowed to oscillate freely. We consider small perturbations of equilibrium configurations and linearize a certain system of nonlinear equations to obtain a hyperbolic system of linear equations that govern the evolution of the displacements from the equilibrium. It is that linear system that we shall deal with in detail. Here we deal with planar vibrations of planar networks—the generalisation to three dimensions involves no essential difficulties.

2. Modelling networks of vibrating strings. We begin by considering planar vibrations of a single elastic string segment. If the “natural” length of that string is ℓ , it is reasonable to consider the string as parametrised by the rest arc length σ with σ in $[0, \ell]$. The position at time t of that point corresponding to the rest position σ is to be denoted by the vector $\mathbf{R}(\sigma, t)$. If ρ is the density of the string, and if the string is assumed to satisfy Hooke’s law with constant h , the kinetic and potential energies of the string are given by

$$\frac{1}{2} \int_0^\ell \rho |\mathbf{R}_t(\sigma, t)|^2 d\sigma \quad \text{and} \quad \frac{1}{2} \int_0^\ell h [|\mathbf{R}_\sigma(\sigma, t)| - 1]^2 d\sigma,$$

respectively; here the subscripts indicate partial differentiation with respect to the indicated variables, and $|\cdot|$ denotes the Euclidean norm. The total energy is then

$$(1) \quad E(t) = \frac{1}{2} \int_0^\ell [\rho |\mathbf{R}_t(\sigma, t)|^2 + h [|\mathbf{R}_\sigma(\sigma, t)| - 1]^2] d\sigma.$$

Applying Hamilton’s principle to the Lagrangian

$$\mathcal{L}(\mathbf{R}(\sigma, t)) = \frac{1}{2} \int_0^T \int_0^\ell [\rho |\mathbf{R}_t(\sigma, t)|^2 - h [|\mathbf{R}_\sigma(\sigma, t)| - 1]^2] d\sigma dt,$$

we obtain the nonlinear system of partial differential equations

$$(2) \quad \rho \mathbf{R}_{tt} = h [(|\mathbf{R}_\sigma| - 1) \mathbf{R}_\sigma / |\mathbf{R}_\sigma|]_\sigma.$$

This needs to be complemented by suitable boundary conditions at $\sigma = 0$ and $\sigma = \ell$, as well as by initial conditions on $\mathbf{R}(\sigma, 0)$ and $\mathbf{R}_t(\sigma, 0)$. For time independent Dirichlet or Neumann boundary conditions, it is easy to check that energy is conserved when the equations are satisfied.

Remarks.

- (a) The system is of second order in both t and σ .
- (b) The assumption that Hooke’s law holds is certainly only reasonable for a limited range of extension (corresponding to $|\mathbf{R}_\sigma| > 1$) or contraction (corresponding to $|\mathbf{R}_\sigma| < 1$). Hooke’s law can be replaced by using other potential energy functions of the form $U(|\mathbf{R}_\sigma| - 1)$; this leads to a variety of interesting nonlinear systems.
- (c) For related nonlinear string models derived in alternate ways, see Carrier [2] and Antman [1].

A network consists of many string segments, each of which is parametrized and described as above. These strings may have different physical characteristics and therefore be associated with different constants ℓ_i , ρ_i , and h_i . Let the spatial displacement of the i th string be $\mathbf{R}^i(\sigma, t)$. Then the total energy of a network consisting of n strings is

$$(3) \quad E(t) = \frac{1}{2} \sum_{i=1}^n \int_0^{\ell_i} [\rho_i |\mathbf{R}_t^i(\sigma, t)|^2 + h_i [|\mathbf{R}_\sigma^i(\sigma, t)| - 1]^2] d\sigma,$$

and the corresponding Lagrangian is

$$(4) \quad \mathcal{L}(\{\mathbf{R}^i(\sigma, t)\}) = \frac{1}{2} \sum_{i=1}^n \int_0^T \int_0^{\ell_i} [\rho_i |\mathbf{R}_t^i(\sigma, t)|^2 - h_i [|\mathbf{R}_\sigma^i(\sigma, t)| - 1]^2] d\sigma.$$

We introduce the notation $\mathcal{E}(\mathbf{N}) = \{i : \text{the } i\text{th string meets } \mathbf{N}\}$, where $\mathbf{R}^i(\mathbf{N}, t)$ is equal to either $\mathbf{R}^i(\ell_i, t)$ or $\mathbf{R}^i(0, t)$ depending on the parameter value 0 or ℓ_i corresponding to \mathbf{N} . For the networks under consideration, the displacements $\mathbf{R}^i(\sigma, t)$ should clearly satisfy the following “geometric node condition” at each multiple node \mathbf{N} :

$$(5) \quad \text{the } \mathbf{R}^i(\mathbf{N}, t) \text{ are equal for all } i \in \mathcal{E}(\mathbf{N}).$$

Applying Hamilton’s principle to the Lagrangian (4) with the “variations” satisfying (5), we obtain the partial differential equations

$$(6) \quad \rho_i \mathbf{R}_{tt}^i = h_i [(|\mathbf{R}_\sigma^i| - 1) \mathbf{R}_\sigma^i / |\mathbf{R}_\sigma^i|]_\sigma, \quad i = 1 \text{ to } n,$$

as well as the following “dynamic” condition at multiple nodes \mathbf{N} :

$$(7) \quad \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) h_i [(|\mathbf{R}_\sigma^i(\mathbf{N}, t)| - 1) \mathbf{R}_\sigma^i(\mathbf{N}, t) / |\mathbf{R}_\sigma^i(\mathbf{N}, t)|] = 0,$$

where $\epsilon_i(\mathbf{N}) = -1$ or $+1$ depending on whether \mathbf{N} equals $\mathbf{R}^i(0, t)$ or $\mathbf{R}^i(\ell_i, t)$ (in which case $\epsilon_i(\mathbf{N}) \mathbf{R}_\sigma^i(\mathbf{N}, t)$ becomes the “outward pointing” derivative of \mathbf{R}).

Furthermore, the simple nodes can either be held fixed or controlled; this corresponds to imposing a Dirichlet condition at each simple node with Dirichlet data that is either fixed in time, or time dependent and subject to choice. Initial “states” $(\mathbf{R}^i(\sigma, 0), \mathbf{R}_t^i(\sigma, 0))$ also must be prescribed for each string segment. If the Dirichlet data are all taken as time independent, then it is easy to verify, at least formally, that the total energy of the network is conserved. Letting $E^i(t)$ denote the energy of the i th string we check that

$$\frac{d}{dt} E^i(t) = h_i [\mathbf{R}_t^i(\sigma, t) \cdot (|\mathbf{R}_\sigma^i(\sigma, t)| - 1) \mathbf{R}_\sigma^i(\sigma, t) / |\mathbf{R}_\sigma^i(\sigma, t)|]_{\sigma=0}^{\sigma=\ell_i}.$$

Now note that $\mathbf{R}_t^i(\sigma, t) = 0$ at the simple nodes, and add the contributions at each multiple node; using (5) and (7) we get that the sum of all these endpoint terms is zero.

For an equilibrium configuration of the network, each $\mathbf{R}^i(\sigma, t)$ will have the time independent form

$$(8) \quad \mathbf{R}^i(\sigma, t) = \mathbf{R}_0^i + \sigma s_i \mathbf{v}^i,$$

where \mathbf{v}^i is the unit direction pointing along the i th string segment and s_i is a constant measuring the amount of uniform stretching of that segment. We assume that $s_i > 1$, so that the string is under tension. Time independent boundary conditions, as well as the compatibility conditions at multiple nodes, need to be satisfied. We wish to linearize about such an equilibrium configuration.

To carry out the linearization, it is enough to consider a single string segment and assume that

$$(9) \quad \mathbf{R}(\sigma, t) = \mathbf{R}_0 + \sigma s \mathbf{v} + \mathbf{r},$$

where $\mathbf{r}(\sigma, \mathbf{t}) = (\mathbf{x}(\sigma, \mathbf{t}), \mathbf{y}(\sigma, \mathbf{t}))$. Then $\mathbf{R}_{tt}(\sigma, t) = \mathbf{r}_{tt}(\sigma, t) = (x_{tt}(\sigma, t), y_{tt}(\sigma, t))$. The right-hand side of (2) can either be linearized directly using a Taylor expansion in x and y of

$$|\mathbf{r}_\sigma| = [\mathbf{r}_\sigma \cdot \mathbf{r}_\sigma]^{1/2} = [s^2 + 2s\mathbf{v} \cdot (x, y) + x^2 + y^2]^{1/2}$$

about $(0,0)$, or, alternatively, we can similarly expand the potential energy up to quadratic terms in x_σ and y_σ to obtain

$$h[|\mathbf{R}_\sigma| - 1]^2 = \frac{k}{2}[(s-1)^2 + 2(s-1)\mathbf{v} \cdot (x_\sigma, y_\sigma) + (1 - \frac{1}{s})(x_\sigma^2 + y_\sigma^2) + \frac{1}{s}(\mathbf{v} \cdot (x_\sigma, y_\sigma))^2] + \dots$$

Either way, we obtain the system

$$\begin{aligned} \rho x_{tt} &= \frac{k}{s}(s-1+a^2)x_{\sigma\sigma} + \frac{k}{s}aby_{\sigma\sigma'}, \\ \rho y_{tt} &= \frac{k}{s}abx_{\sigma\sigma} + \frac{k}{s}(s-1+b^2)y_{\sigma\sigma'}, \end{aligned}$$

where $\mathbf{v} = (a, b)$. This linear system can be rewritten as

$$(10) \quad \rho \mathbf{r}_{tt} = H \mathbf{r}_{\sigma\sigma} \quad \text{with} \quad H = \begin{bmatrix} s-1+a^2 & ab \\ ab & s-1+b^2 \end{bmatrix}.$$

We note that H is a symmetric matrix with eigenvalues h and $h(1-s^{-1})$ (both positive since $s > 1$) corresponding respectively to eigenvectors \mathbf{v} and \mathbf{v}^\perp (a vector perpendicular to \mathbf{v}). This means that for a particular vibrating string segment the vibration can be uncoupled into transverse and longitudinal vibrations. For the potential energy of such a linearized string segment we keep only the quadratic term and, hence, the total energy of that segment is

$$(11) \quad E(t) = \frac{1}{2} \int_0^\ell [\rho |\mathbf{r}_t(\sigma, t)|^2 + H \mathbf{r}_\sigma(\sigma, t) \cdot \mathbf{r}_\sigma(\sigma, t)] d\sigma.$$

The linear equations governing the network near equilibrium now become

$$(12) \quad \rho_i \mathbf{r}_{tt}^i = H^i \mathbf{r}_{\sigma\sigma}^i \quad \text{for } i = 1 \text{ to } n.$$

It is notationally convenient to suppose that the simple nodes are $\mathbf{r}^i(\ell_i, t)$ with $i = 1$ to m , and that controls are applied at these points for $i = 1$ to p . The *boundary conditions* at the simple nodes then take the form

$$(13) \quad \mathbf{r}^i(\ell_i, t) = \begin{cases} \mathbf{u}^i(t) & \text{for } i = 1 \text{ to } p, \\ 0 & \text{for } i = p+1 \text{ to } m. \end{cases}$$

At the multiple nodes we require two *coupling conditions*: (5) rewritten as

$$(14) \quad \text{the } \mathbf{r}^i(\mathbf{N}, t) \text{ are equal for all } i \in \mathcal{E}(\mathbf{N});$$

and the linearization of (7), namely

$$(15) \quad \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) H^i \mathbf{r}_\sigma^i(\mathbf{N}, t) = 0.$$

The *initial conditions* accompanying (12) are

$$(16) \quad (\mathbf{r}^i(\sigma, 0), \mathbf{r}_t^i(\sigma, 0)) = (\mathbf{r}^{i,0}(\sigma), \mathbf{r}^{i,1}(\sigma)) \quad \text{for } i = 1 \text{ to } n.$$

We note that under the above conditions, with $\mathbf{u}^i(t) = \mathbf{c}^i$, where \mathbf{c}^i are given constant vectors, energy is conserved much as before.

3. Existence of solutions to the linearized system. We need an existence theory for the linear system described by (12)–(16). We begin by introducing the spaces in which solutions should lie.

Let $L_2(0, \ell_i)$ and $W^1(0, \ell_i)$ be the familiar Lebesgue and Sobolev spaces, with the understanding that in our context they consist of 2-vector valued functions. We then introduce the space \mathcal{H}_E as the set of all data $\{(\mathbf{r}^{i,0}(\sigma), \mathbf{r}^{i,1}(\sigma))\}$ (where $\{\cdots\}$ will denote n-tuples $\{\cdots\}_{i=1}^n$) belonging to the product of the n data spaces $W^1(0, \ell^i) \times L_2(0, \ell_i)$ for the separate segments satisfying the first coupling condition (14) at all multiple nodes. On this space we can define the “energy scalar product”

$$(17) \quad \begin{aligned} & \langle \{(\mathbf{r}^{i,0}(\sigma), \mathbf{r}^{i,1}(\sigma))\}, \{(\bar{\mathbf{r}}^{i,0}(\sigma), \bar{\mathbf{r}}^{i,1}(\sigma))\} \rangle_E \\ &= \frac{1}{2} \sum_{i=1}^n \int_0^{\ell_i} [\rho_i \mathbf{r}_t^i(\sigma, t) \cdot \bar{\mathbf{r}}_t^i(\sigma, t) + H^i \mathbf{r}_\sigma^i(\sigma, t) \cdot \bar{\mathbf{r}}_\sigma^i(\sigma, t)] d\sigma. \end{aligned}$$

This fails to be an inner product on \mathcal{H}_E because the associated norm vanishes for the “constant” data $\{(\mathbf{c}, \mathbf{0})\}$, which corresponds physically to a uniform displacement of the whole network by \mathbf{c} . It is convenient to identify $\{(\mathbf{r}^{i,0}(\sigma), \mathbf{r}^{i,1}(\sigma))\}$ with $\{\mathbf{r}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\}$. We require the second factor in this product to belong to the space \mathcal{H}_1 defined as the product space of the spaces $L_2(0, \ell^i)$ with inner product

$$\langle \{\mathbf{r}^i(\sigma)\}, \{\bar{\mathbf{r}}^i(\sigma)\} \rangle_1 = \frac{1}{2} \sum_{i=1}^n \int_0^{\ell_i} [\rho_i \mathbf{r}^i(\sigma) \cdot \bar{\mathbf{r}}^i(\sigma)] d\sigma.$$

The first factor is required to belong to a space that is consistent with the boundary condition (13), as well as the coupling condition (14). Let \mathcal{H}_0 denote the product space of the spaces $W^1(0, \ell_i)$ consisting of functions satisfying condition (14) at multiple nodes. If $p < m$ let \mathcal{H}_0^p be the subspace of \mathcal{H}_0 consisting of data satisfying $\mathbf{r}^i(\ell_i) = \mathbf{0}$ for $i = p+1$ to m) (i.e., at the fixed simple nodes). Otherwise, when $p = m$ and none of the simple nodes is fixed, we define \mathcal{H}_0^m to be the quotient space of \mathcal{H}_0 and the subspace of constant data $\{\mathbf{c}\}$; for notational simplicity we denote elements of this space by representatives of the corresponding equivalence class. In either case, we can introduce as the inner product

$$\langle \{\mathbf{r}^i(\sigma)\}, \{\bar{\mathbf{r}}^i(\sigma)\} \rangle_0 = \frac{1}{2} \sum_{i=1}^n \int_0^{\ell_i} [H^i \mathbf{r}_\sigma^i(\sigma) \cdot \bar{\mathbf{r}}_\sigma^i(\sigma)] d\sigma;$$

this inner product yields a norm equivalent to the standard inner product norm by a variant of the Poincaré lemma, which can be proved in the usual way (for example, by adapting the arguments of Necas [7, pp. 18–21]). Then (17) defines the “energy inner product” on the space $\mathcal{H}_E^p = \mathcal{H}_0^p \times \mathcal{H}_1$.

We pursue an analogy with the wave equation in a domain where the simple nodes of a network correspond to the boundary of the domain. We expect solutions to homogeneous boundary value problems to be given in terms of a unitary semigroup acting on initial data. We can rewrite (12) as

$$\frac{d}{dt} \begin{bmatrix} \mathbf{r}^i(\sigma, t) \\ \mathbf{r}_t^i(\sigma, t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ \frac{1}{\rho_i} H^i \partial_\sigma^2 & 0 \end{bmatrix} \begin{bmatrix} \mathbf{r}^i(\sigma, t) \\ \mathbf{r}_t^i(\sigma, t) \end{bmatrix}, \quad \text{for } i = 1 \text{ to } n,$$

where ∂_σ is the operation of partial differentiation with respect to σ . Alternatively, this system can be written as

$$(18) \quad \frac{d}{dt} \begin{bmatrix} \{\mathbf{r}^i(\sigma, t)\} \\ \{\mathbf{r}_t^i(\sigma, t)\} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ \mathcal{A} & 0 \end{bmatrix} \begin{bmatrix} \{\mathbf{r}^i(\sigma, t)\} \\ \{\mathbf{r}_t^i(\sigma, t)\} \end{bmatrix},$$

where \mathcal{A} is the linear map defined by

$$\mathcal{A}(\{\mathbf{r}^i(\sigma)\}) = \left\{ \frac{1}{\rho_i} H^i \partial_\sigma^2 \mathbf{r}^i(\sigma) \right\}$$

on a suitable domain to be specified below, with the understanding that 0 and 1 are to be understood as null and identity operators. This suggests the form that the skew adjoint generator of the appropriate semigroup should have. We now need to study the operator \mathcal{A} , which plays a role in networks analogous to that of the Laplacian for Euclidean domains.

Given $\{\mathbf{f}^i(\sigma)\}$ in \mathcal{H}_1 and constants \mathbf{c}^1 to \mathbf{c}^m , we say that $\{\mathbf{r}^i(\sigma)\}$ is a weak solution of the problem

$$(19) \quad \mathcal{A}\{\mathbf{r}^i(\sigma)\} = \{\mathbf{f}^i(\sigma)\}, \quad \mathbf{r}^i(\ell_i) = \mathbf{c}^i \text{ for } i = 1 \text{ to } m$$

subject to the node conditions (14) and (15), if and only if $\{\mathbf{r}^i(\sigma)\}$ belongs to \mathcal{H}_0 , satisfies the boundary conditions $\mathbf{r}^i(\ell_i) = \mathbf{c}^i$ for $i = 1$ to m as well as the weak identity

$$\langle \{\mathbf{r}^i(\sigma)\}, \{\phi^i(\sigma)\} \rangle_0 = -\langle \{\mathbf{f}^i(\sigma)\}, \{\phi^i(\sigma)\} \rangle_1, \quad \text{for all } \{\phi^i(\sigma)\} \text{ in } \mathcal{H}_0^0.$$

The assertions of the following theorem are proved in exactly the same way as the corresponding results on the Dirichlet problem for the Laplacian in a bounded domain; the principal tools are the Riesz representation theorem as well as Rellich’s compactness theorem.

THEOREM 3.1. *Given $\{\mathbf{f}^i(\sigma)\}$ in \mathcal{H}_1 and constants \mathbf{c}^1 to \mathbf{c}^m problem (19) has a unique weak solution. If each $\mathbf{c}^i = 0$, the solution $\{\mathbf{r}^i\}$ belongs to \mathcal{H}_0^0 and satisfies*

$$\|\{\mathbf{r}^i(\sigma)\}\|_0 \leq C \|\{\mathbf{f}^i(\sigma)\}\|_1,$$

where C is a suitable constant. Since $\mathcal{H}_0^0 \subset \mathcal{H}_1$ we can define a linear transformation $S : \mathcal{H}_1 \rightarrow \mathcal{H}_1$, which maps the data $\{\mathbf{f}^i(\sigma)\}$ to the solution $\{\mathbf{r}^i(\sigma)\}$. S is self-adjoint, positive, injective and compact with dense image. Let \mathcal{A}^0 be defined as the inverse of S ; it is a self-adjoint operator densely defined in \mathcal{H}_1 with positive point spectrum

accumulating at ∞ . If $\{\mathbf{r}^i(\sigma)\}$ belongs to the domain of \mathcal{A}^0 , each $\mathbf{r}^i(\sigma)$ belongs to $W^2(0, \ell_i)$.

Now, motivated by (18), we define an unbounded operator \mathcal{B}^0 in \mathcal{H}_E^0 by

$$\text{dom}(\mathcal{B}^0) = \text{dom}(\mathcal{A}^0) \times \mathcal{H}_0 \quad \text{and} \quad \mathcal{B}^0 \begin{bmatrix} \{\mathbf{r}^{1,0}(\sigma)\} \\ \{\mathbf{r}^{i,1}(\sigma)\} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ \mathcal{A}^0 & 0 \end{bmatrix} \begin{bmatrix} \{\mathbf{r}^{1,0}(\sigma)\} \\ \{\mathbf{r}^{i,1}(\sigma)\} \end{bmatrix}.$$

It turns out that \mathcal{B}^0 is skew-adjoint, so it generates a strongly continuous group $[U_t^0]_{t \in \mathbb{R}}$ of unitary operators on \mathcal{H}_E^0 . This allows us to obtain the solution $\{\mathbf{r}^i(\sigma, t)\}$ of (12), (13) (with $p = 0$), (14), (15), and (16) by taking the \mathcal{H}_0^0 - component of $U_t^0 \{\mathbf{r}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\}$.

Next we need to treat the equations with inhomogeneous boundary conditions. When controls are imposed at the first p simple nodes while the remaining simple nodes are kept fixed, we expect the solutions to remain in the space \mathcal{H}_E^p . As a first step to solving the inhomogeneous boundary value problem, we extend the semigroup to \mathcal{H}_E from \mathcal{H}_E^0 . This involves identifying the orthogonal complement of \mathcal{H}_E^0 in \mathcal{H}_E with respect to an appropriately chosen inner product for the latter space. It turns out that this complement consists of stationary solutions of our linear system so that we can define the group $[U_t]_{t \in \mathbb{R}}$ of operators on \mathcal{H}_E by setting U_t equal to U_t^0 on \mathcal{H}_E^0 and equal to the identity on the orthogonal complement.

We note that on \mathcal{H}_0 (and, indeed, on the spaces \mathcal{H}_0^p with $p < m$), the inner product

$$(20) \quad \langle \{\mathbf{r}^i(\sigma)\}, \{\bar{\mathbf{r}}^i(\sigma)\} \rangle_0 + \sum_{i=1}^m \mathbf{r}^i(\ell_i) \cdot \bar{\mathbf{r}}^i(\ell_i),$$

where \cdot denotes the dot product of vectors, is equivalent to the standard inner product. Evidently, the orthogonal complement of the subspace \mathcal{H}_0^0 in \mathcal{H}_0 with respect to the latter inner product consists of all weak solutions of equations of the form (19) with $\{\mathbf{f}^i\} = \{0\}$; we denote that complement by \mathcal{S}_0 . We endow $\mathcal{H}_E = \mathcal{H}_0 \times \mathcal{H}_1$ with the corresponding “modified energy inner product.” This yields the desired orthogonal decomposition $\mathcal{H}_E = \mathcal{H}_E^0 \oplus \mathcal{S}_E$, where

$$\mathcal{S}_E = \{ \{\mathbf{r}^i(\sigma)\} \times \{0\} \mid \{\mathbf{r}^i(\sigma)\} \in \mathcal{S}_0 \}.$$

The orthogonal decomposition of data is performed as follows:

$$\{\mathbf{r}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\} = \{\mathbf{r}^{i,0}(\sigma) - \bar{\mathbf{r}}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\} \oplus \{\bar{\mathbf{r}}^{i,0}(\sigma)\} \times \{0\},$$

where $\mathcal{A}\{\bar{\mathbf{r}}^{i,0}(\sigma)\} = \{0\}$ and $\bar{\mathbf{r}}^{i,0}(\ell_i) = \mathbf{r}^{i,0}(\ell_i)$ for $i = 1$ to m . We easily check that the data in \mathcal{S}_E is stationary corresponding to nonhomogeneous, time independent boundary conditions at the simple nodes. It is therefore natural to define

$$U_t \{\mathbf{r}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\} = U_t^0 \{\mathbf{r}^{i,0}(\sigma) - \bar{\mathbf{r}}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\} \oplus \{\bar{\mathbf{r}}^i(\sigma)\} \times \{0\};$$

we thus obtain a group of unitary operators on \mathcal{H}_E . For initial data $\{\mathbf{r}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\}$ in \mathcal{H}_E , we are allowed to solve the linear system with boundary conditions

$$\mathbf{r}^i(\ell_i, t) = \mathbf{r}^{i,0}(\ell_i) \text{ for } i = 1 \text{ to } m$$

by setting $\{\mathbf{r}^i(\sigma, t)\} \times \{\mathbf{r}^i(\sigma, t)\} = U_t \{\mathbf{r}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\}$. We can also define unitary groups $[U_t^p]_{t \in \mathbb{R}}$ on \mathcal{H}_E^p by restriction (if $p < m$), or by taking quotients (if $p = m$).

We note that the generator \mathcal{B} of $[U_t]_{t \in R}$ is the direct sum $0 \oplus \mathcal{B}^0$ with domain $\mathcal{S}_E \oplus \text{dom}(\mathcal{B}^0)$. The generator \mathcal{B}^p of $[U_t^p]_{t \in R}$ is obtained from \mathcal{B} by restriction (if $p < m$) or by taking quotients (if $p = m$). If the initial data lies in the domain of \mathcal{B} for the solution obtained above we have that, for each i , $\mathbf{r}^i(\cdot, t)$ belongs to the spaces $C([0, T]; W^2(0, \ell_i))$, $C^1([0, T]; W^1(0, \ell_i))$ and $C^2([0, T]; L_2(0, \ell_i))$.

Now we consider the general initial boundary value problem (12)–(16), assuming that the initial data belongs to \mathcal{H}_E and that the following compatibility condition is satisfied:

$$(21) \quad \mathbf{r}^{i,0}(\ell_i) = \begin{cases} \mathbf{u}^i(0) & \text{for } i = 1 \text{ to } p, \\ 0 & \text{for } i = p + 1 \text{ to } m. \end{cases}$$

First, let $p = m$. We then obtain the solution as the sum of $U_t\{\mathbf{r}^{i,0}\} \times \{\mathbf{r}^{i,1}\}$ and the solution to the problem with homogeneous initial conditions and boundary conditions

$$\mathbf{r}^i(\ell_i, t) = \mathbf{u}^i(t) - \mathbf{u}^i(0) \text{ for } i = 1 \text{ to } m.$$

The approach to these inhomogeneous boundary conditions is standard: we move the inhomogeneity into the equation itself and then use the fact that when $\{\mathbf{f}^{i,0}(\sigma, t)\} \times \{\mathbf{f}^{i,1}(\sigma, t)\}$ is a continuous map of $[0, T]$ into $\mathcal{H}_E^0 = \mathcal{H}_0^0 \times \mathcal{H}_1$ the solution of

$$(22) \quad \frac{d}{dt} \begin{bmatrix} \{\mathbf{r}^i(\sigma, t)\} \\ \{\mathbf{r}_t^i(\sigma, t)\} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ \mathcal{A} & 0 \end{bmatrix} \begin{bmatrix} \{\mathbf{r}^i(\sigma, t)\} \\ \{\mathbf{r}_t^i(\sigma, t)\} \end{bmatrix} + \begin{bmatrix} \{\mathbf{f}^{i,0}(\sigma, t)\} \\ \{\mathbf{f}^{i,1}(\sigma, t)\} \end{bmatrix},$$

subject to homogeneous boundary and initial conditions together with the coupling conditions, is given by

$$(23) \quad \{\mathbf{r}^i(\sigma, t)\} \times \{\mathbf{r}_t^i(\sigma, t)\} = \int_0^t U_{t-s}^0 \{\mathbf{f}^{i,0}(\sigma, s)\} \times \{\mathbf{f}^{i,1}(\sigma, s)\} ds,$$

which is again a continuous map of $[0, T]$ into $\mathcal{H}_E^0 = \mathcal{H}_0^0 \times \mathcal{H}_1$.

To transfer the inhomogeneity from the boundary condition into the equation, we begin by considering controls $\mathbf{u}^i(t) \in C_0^\infty((0, T])$. These functions vanish for $t = 0$ but not necessarily for $t = T$. For i between 1 and m , we then introduce functions $\phi^i(\sigma, t) \in C_0^\infty((0, \ell_i] \times (0, T])$ with $\phi^i(\ell_i, t) = \mathbf{u}^i(t)$; for $i > m$ it is convenient to set $\phi^i \equiv 0$. We now seek a solution to the inhomogeneous boundary value problem (with vanishing initial condition) in the form $\{\mathbf{r}^i(\sigma, t)\} = \{\phi^i(\sigma, t)\} + \{\bar{\mathbf{r}}^i(\sigma, t)\}$. Then $\{\bar{\mathbf{r}}^i(\sigma, t)\}$ will have to satisfy homogeneous boundary and initial conditions, the coupling conditions, as well as the equations

$$(24) \quad \rho_i \bar{\mathbf{r}}_{tt}^i = H^i \bar{\mathbf{r}}_{\sigma\sigma}^i + [H^i \phi_{\sigma\sigma}^i - \rho_i \phi_{t,t}^i] \text{ for } i = 1 \text{ to } n.$$

These equations can be written in the form (22) with $\mathbf{f}^{i,0}(\sigma, t)$ set equal to 0 and $\mathbf{f}^{i,1}(\sigma, t)$ equal to $H^i \phi_{\sigma\sigma}^i - \rho_i \phi_{t,t}^i$; this is then solved for $\{\bar{\mathbf{r}}^i(\sigma, t)\}$ using (23).

Applying results on the regularity of “mild solutions” to be found in Pazy [8] (in particular, Corollary 2.5 on p. 107), we can deduce that $\{\bar{\mathbf{r}}^i(\sigma, t)\} \times \{\bar{\mathbf{r}}_t^i(\sigma, t)\}$ is continuously differentiable with respect to t when regarded as a map from $[0, T]$ into \mathcal{H}_E^0 , and that this function and its t -derivatives take their values in $\text{dom}(\mathcal{B}^0)$. Consequently, each $\bar{\mathbf{r}}^i(\cdot, t)$ belongs to the spaces $C([0, T]; W^2(0, \ell_i))$, $C^1([0, T]; W^1(0, \ell_i))$ and $C^2([0, T]; L_2(0, \ell_i))$. That regularity is then inherited by $\{\mathbf{r}^i(\sigma, t)\}$.

System (12)–(16) can now also be solved for initial data in \mathcal{H}_E^p (with $p < m$) subject to the compatibility condition (21); the resulting trajectory remains in \mathcal{H}_E^p . Moreover, taking quotients, we can also solve the system in the space \mathcal{H}_E^m .

We have proved the following theorem.

THEOREM 3.2. *Given initial data $\{\mathbf{r}^{i,0}(\sigma)\} \times \{\mathbf{r}^{i,1}(\sigma)\}$ belonging to the space \mathcal{H}_E^p and boundary data $\mathbf{u}^1(t), \mathbf{u}^2(t), \dots, \mathbf{u}^p(t)$ belonging to $C^\infty([0, T])$ and satisfying the compatibility condition (21), the initial boundary value problem (12)–(16) has a solution such that $\{\mathbf{r}^i(\cdot, t)\} \times \{\mathbf{r}_t^i(\cdot, t)\}$ is a continuous trajectory in \mathcal{H}_E^p . Letting $[C_0^\infty((0, T))]^p$ denote the p -fold product of $C_0^\infty((0, T))$ we can define, for each $t \leq T$, a transformation $C_t^p : [C_0^\infty((0, T))]^p \rightarrow \mathcal{H}_E^p$ by assigning to the “control functions” $(\mathbf{u}^1, \mathbf{u}^2, \dots, \mathbf{u}^p)$ the solution at time t , namely $\{\mathbf{r}^i(\sigma, t)\} \times \{\mathbf{r}_t^i(\sigma, t)\}$, of the boundary value problem with zero initial values; in the case where $p = m$, this must be interpreted in terms of equivalence classes. The solution to the general initial boundary value problem is then given by*

$$(25) \quad \begin{aligned} \{\mathbf{r}^i(\cdot, t)\} \times \{\mathbf{r}_t^i(\cdot, t)\} &= U_t^p \{\mathbf{r}^{i,0}\} \times \{\mathbf{r}^{i,1}\} \\ &+ C_t^p(\mathbf{u}^1(\cdot) - \mathbf{u}^1(0), \mathbf{u}^2(\cdot) - \mathbf{u}^2(0), \dots, \mathbf{u}^p(\cdot) - \mathbf{u}^p(0)). \end{aligned}$$

If the initial data belongs to $\text{dom}(\mathcal{B})$, we have that each $\mathbf{r}^i(\cdot, t)$ belongs to the spaces $C([0, T]; W^2(0, \ell_i))$, $C^1([0, T]; W^1(0, \ell_i))$ and $C^2([0, T]; L_2(0, \ell_i))$.

Because of estimates in the next section, it will, in fact, be possible to extend the domain of the operators C_T^p from $[C_0^\infty((0, T))]^p$ to

$$\mathcal{U}^p = \{(\mathbf{u}^1, \mathbf{u}^2, \dots, \mathbf{u}^p) \in [W^1(0, T)]^p \mid \mathbf{u}^i(0) = 0 \text{ for } i = 1 \text{ to } p\}.$$

This latter space is the completion of $[C_0^\infty((0, T))]^p$ with respect to the norm associated with the inner product

$$(26) \quad \langle (\mathbf{v}^1, \mathbf{v}^2, \dots, \mathbf{v}^p), (\mathbf{u}^1, \mathbf{u}^2, \dots, \mathbf{u}^p) \rangle_{\mathcal{U}^p} = \frac{1}{2} \sum_{i=1}^p \int_0^T \mathbf{v}_t^i(t) \cdot \mathbf{u}_t^i(t) dt.$$

The operator C_T^p is studied thoroughly in the next section.

4. A priori estimates and the exact controllability of the linearized system. We are interested in the question of exact controllability for the control system (12)–(16). This involves establishing conditions on the network and on the time T , which ensure that the operator C_T^p becomes surjective, in which case any initial state in \mathcal{H}_E^p can be steered by suitable choice of the controls to any desired target state in the same space. First, we must specify the domain of C_T^p . Initially, we can regard C_T^p as a map from \mathcal{U}^p to \mathcal{H}_E^p having domain $[C_0^\infty((0, T))]^p$. Since the domain of C_T^p is dense, we can introduce the Hermitian adjoint $C_T^{p*} : \mathcal{H}_E^p \rightarrow \mathcal{U}^p$, which is identified in the next result involving “dual data” \mathbf{l}^i corresponding to a “dual problem.”

THEOREM 4.1. *Given $\{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}$ in \mathcal{H}_E^p , let $\{\mathbf{l}^i(\sigma, t)\}$ be a solution of the system (12) subject to the boundary conditions $\mathbf{l}^i(\ell_i, t) = \mathbf{l}^{i,0}(\ell_i)$ for $i = 1$ to m , the coupling conditions at the multiple nodes and the endpoint condition*

$$\{\mathbf{l}^i(\sigma, T)\} \times \{\mathbf{l}_T^i(\sigma, T)\} = \{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}.$$

Then, for each i from 1 to m , $\mathbf{l}_\sigma^i(\ell_i, t)$ is a well-defined function of t and there exists a constant K such that

$$(27) \quad \sum_{i=1}^m \int_0^T |H^i \mathbf{l}_\sigma^i(\ell_i, t)|^2 dt \leq K \| \{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\} \|_E^2.$$

Moreover, $C_T^{p*} \{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}$ can be identified with $\{\mathbf{l}_\sigma^i(\ell_i, t) \frac{\partial}{\partial t}\}$, which acts on the controls as follows:

$$(28) \quad \begin{aligned} & \langle C_T^{p*} \{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}, (\mathbf{u}^1, \mathbf{u}^2, \dots, \mathbf{u}^p) \rangle_{\mathcal{U}^p} \\ &= \frac{1}{2} \sum_{i=1}^p \int_0^T H^i \mathbf{l}_\sigma^i(\ell_i, t) \cdot \mathbf{u}_t^i(t) dt. \end{aligned}$$

The proof of this theorem will be given later. First, we deduce some corollaries. We note that the right-hand side of (28) can be rewritten as

$$\begin{aligned} \frac{1}{2} \sum_{i=1}^p \int_0^T \left[\int_0^t H^i \mathbf{l}_\sigma^i(\ell^i, s) ds \right]_t \cdot \mathbf{u}_t^i(t) dt &= \left(\int_0^t H^1 \mathbf{l}_\sigma^1(\ell^1, s) ds, \int_0^t H^2 \mathbf{l}_\sigma^2(\ell^2, s) ds, \dots, \right. \\ &\quad \left. \int_0^t H^p \mathbf{l}_\sigma^p(\ell^p, s) ds \right), (\mathbf{u}^1, \mathbf{u}^2, \dots, \mathbf{u}^p) \rangle_{\mathcal{U}^p}. \end{aligned}$$

From the form of the inner product (26), we therefore get

$$(29) \quad \|C_T^{p*} \{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}\|_{\mathcal{U}^p}^2 = \sum_{i=1}^p \int_0^T |H^i \mathbf{l}_\sigma^i(\ell_i, t)|^2 dt.$$

This, together with (27), yields the following corollary.

COROLLARY 4.2. *The operator C_T^{p*} is bounded and, therefore, C_T^p can be extended to a bounded operator defined on the entire space \mathcal{U}^p .*

Now, by a general result on closed linear transformations, the surjectivity of $C_T^p : \mathcal{U}^p \rightarrow \mathcal{H}_E^p$ is equivalent to the estimate

$$\|C_T^{p*} \{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}\|_{\mathcal{U}^p} > k \|\{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}\|_{\mathcal{H}}$$

for some suitable positive constant k . In view of (29), we therefore obtain Corollary 4.3.

COROLLARY 4.3. *System (12)–(16) is exactly controllable in time T (i.e., $\text{im}(C_T^p) = \mathcal{H}_E^p$) if and only if the following a priori estimate is valid for some constant k :*

$$(30) \quad \sum_{i=1}^p \int_0^T |H^i \mathbf{l}_\sigma^i(\ell_i, t)|^2 dt \geq k \|\{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}\|_E^2.$$

Before proving Theorem 4.1, we derive a multiplier identity from which the estimates (27) and (30) can be deduced by the appropriate choice of multipliers. This approach to obtaining a priori estimate goes back to at least Rellich, and has recently proved very powerful in the control of partial differential equations; many applications can be found in Lions [6]. The following lemma applies to a generic string element, where the superscript has been dropped.

LEMMA 4.4. *Let $\mathbf{l}(\sigma, t)$ belong to $C([0, T]; W^2(0, \ell))$, $C^1([0, T]; W^1(0, \ell))$, and $C^2([0, T]; L_2(0, \ell))$ and be a solution of*

$$\rho \mathbf{l}_{tt}(\sigma, t) = H \mathbf{l}_{\sigma\sigma}(\sigma, t), \text{ for } (\sigma, t) \in [0, \ell] \times [0, T].$$

Let $M(\sigma)$ be a smooth, symmetric matrix-valued function that commutes with H for each σ . Then

$$(31) \quad \begin{aligned} \frac{1}{2} \int_0^T \left[H \mathbf{l}_\sigma \cdot M \mathbf{l}_\sigma \right]_{\sigma=0}^{\sigma=\ell} dt &= \frac{1}{2} \int_0^T \int_0^\ell [\rho \mathbf{l}_t \cdot M_\sigma \mathbf{l}_t + H \mathbf{l}_\sigma \cdot M_\sigma \mathbf{l}_\sigma] d\sigma dt \\ &+ \left[\int_0^\ell \rho \mathbf{l}_t \cdot M \mathbf{l}_\sigma d\sigma \right]_{t=0}^{t=T} - \frac{1}{2} \int_0^T \left[\rho \mathbf{l}_t \cdot M \mathbf{l}_t \right]_{\sigma=0}^{\sigma=\ell} dt. \end{aligned}$$

Proof. The proof is obtained by rewriting the following obvious identity:

$$\int_0^T \int_0^\ell [\rho \mathbf{l}_{tt} - H \mathbf{l}_{\sigma\sigma}] \cdot M \mathbf{l}_\sigma d\sigma dt = 0.$$

We have that

$$\begin{aligned} \int_0^T \int_0^\ell \rho \mathbf{l}_{tt} \cdot M \mathbf{l}_\sigma d\sigma dt &= \left[\int_0^\ell \rho \mathbf{l}_t \cdot M \mathbf{l}_\sigma d\sigma \right]_{t=0}^{t=T} - \int_0^\ell \int_0^T \rho \mathbf{l}_t \cdot M \mathbf{l}_{\sigma t} dt d\sigma \\ &= \left[\int_0^\ell \rho \mathbf{l}_t \cdot M \mathbf{l}_\sigma d\sigma \right]_{t=0}^{t=T} - \frac{1}{2} \int_0^T \left[\rho \mathbf{l}_t \cdot M \mathbf{l}_t \right]_{\sigma=0}^{\sigma=\ell} dt \\ &+ \frac{1}{2} \int_0^T \int_0^\ell \rho \mathbf{l}_t \cdot M_\sigma \mathbf{l}_t d\sigma dt; \end{aligned}$$

and

$$\begin{aligned} - \int_0^T \int_0^\ell H \mathbf{l}_{\sigma\sigma} \cdot M \mathbf{l}_\sigma d\sigma dt &= - \int_0^T \left[H \mathbf{l}_\sigma \cdot M \mathbf{l}_\sigma \right]_{\sigma=0}^{\sigma=\ell} dt \\ &+ \int_0^T \int_0^\ell [H \mathbf{l}_\sigma \cdot M \mathbf{l}_{\sigma\sigma} + H \mathbf{l}_\sigma \cdot M_\sigma \mathbf{l}_\sigma] d\sigma dt \\ &= - \frac{1}{2} \int_0^T \left[H \mathbf{l}_\sigma \cdot M \mathbf{l}_\sigma \right]_{\sigma=0}^{\sigma=\ell} dt + \int_0^T \int_0^\ell H \mathbf{l}_\sigma \cdot M_\sigma \mathbf{l}_\sigma d\sigma dt; \end{aligned}$$

here we have used $HM = MH$ and the symmetry of H and M to write

$$H \mathbf{l}_\sigma \cdot M \mathbf{l}_{\sigma\sigma} = \frac{1}{2} [H \mathbf{l}_\sigma \cdot M \mathbf{l}_\sigma]_\sigma - \frac{1}{2} H \mathbf{l}_\sigma \cdot M_\sigma \mathbf{l}_\sigma.$$

By adding and rearranging the last identities, we get (31).

Proof of Theorem 4.1. We prove estimate (27) for terminal data $\{\mathbf{l}^{i,0}\} \times \{\mathbf{l}^{i,1}\}$ belonging to the domain of \mathcal{B} (and to \mathcal{H}_E^p in the case where $p < m$) so that the regularity needed for Lemma 4.4 is assured; the general result follows by continuity. We then choose the multiplier $M(\sigma) = [-1 + (2/\ell)\sigma]I$ (with I the identity matrix). This satisfies $M(0) = -I$, $M(\ell) = I$ and $M_\sigma = 2\ell^{-1}I$; thus, discarding redundant terms of known sign, we easily get from (31)

$$\frac{1}{2} \int_0^T H \mathbf{l}_\sigma(\ell, t) \cdot \mathbf{l}_\sigma(\ell, t) \leq \frac{1}{2} \int_0^T \int_0^\ell [\rho \mathbf{l}_t \cdot \mathbf{l}_t + H \mathbf{l}_\sigma \cdot \mathbf{l}_\sigma] d\sigma dt + \left[\int_0^\ell \rho \mathbf{l}_t \cdot M \mathbf{l}_\sigma d\sigma \right]_{t=0}^{t=T}.$$

It easily follows that

$$\begin{aligned} \int_0^T |H\mathbf{l}_\sigma(\ell, t)|^2 dt &\leq A \int_0^T \int_0^\ell [\rho \mathbf{l}_t \cdot \mathbf{l}_t + H\mathbf{l}_\sigma \cdot \mathbf{l}_\sigma] d\sigma dt \\ &+ B \left[\int_0^\ell [\rho \mathbf{l}_t \cdot \mathbf{l}_t + H\mathbf{l}_\sigma \cdot \mathbf{l}_\sigma](\sigma, T) d\sigma + \int_0^\ell [\rho \mathbf{l}_t \cdot \mathbf{l}_t + H\mathbf{l}_\sigma \cdot \mathbf{l}_\sigma](\sigma, 0) d\sigma \right], \end{aligned}$$

where A and B are suitable constants. We can then write down this inequality for each string segment and sum these inequalities to obtain

$$\begin{aligned} \sum_{i=1}^n \int_0^T |H^i \mathbf{l}_\sigma^i(\ell_i, t)|^2 dt &\leq A \int_0^T \|\{\mathbf{l}^i(\sigma, t)\} \times \{\mathbf{l}_t^i(\sigma, t)\}\|_E^2 dt \\ &+ B [\|\{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}\|_E^2 + \|\{\mathbf{l}^i(\sigma, 0)\} \times \{\mathbf{l}_t^i(\sigma, 0)\}\|_E^2], \end{aligned}$$

where A and B have been suitably redefined. By using conservation of energy, we have that $\|\{\mathbf{l}^i(\sigma, t)\} \times \{\mathbf{l}_t^i(\sigma, t)\}\|_E^2 = \|\{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}\|_E^2$ for all t so that (27) holds with $K = AT + B$. These constants can be estimated explicitly in terms of the various physical parameters. We note that, had we not discarded so many terms, we would have obtained the following generalisation of (27):

$$(32) \quad \sum_{i=10}^n \int_0^T [H^i \mathbf{l}_\sigma^i(\ell_i, t)|^2 + |H^i \mathbf{l}_\sigma^i(0, t)|^2 + |\mathbf{l}_t^i(\ell_i, t)|^2 + |\mathbf{l}_t^i(0, t)|^2] dt \leq K \|\{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}\|_E^2.$$

To prove (28) it is enough to establish
(33)

$$\langle \{\mathbf{l}^{i,0}(\sigma)\} \times \{\mathbf{l}^{i,1}(\sigma)\}, C_T^p(\mathbf{u}^1, \mathbf{u}^2, \dots, \mathbf{u}^p) \rangle_{\mathcal{U}^p} = \frac{1}{2} \sum_{i=1}^p \int_0^T H^i \mathbf{l}_\sigma^i(\ell_i, t) \cdot \frac{\partial}{\partial t} \mathbf{u}^i(t) dt.$$

Let $\{\mathbf{r}^i(\sigma, t)\}$ be the solution of (12) involved in the definition of C_T^p and $\{\mathbf{l}^i(\sigma, t)\}$ be as above. Then

$$\begin{aligned} 2 \frac{d}{dt} \langle \{\mathbf{r}^i(\sigma, t)\} \times \{\mathbf{r}_t^i(\sigma, t)\}, \{\mathbf{l}^i(\sigma, t)\} \times \{\mathbf{l}_t^i(\sigma, t)\} \rangle_E \\ = \sum_{i=1}^n \int_0^{\ell_i} [\rho_i \mathbf{r}_{tt}^i \cdot \mathbf{l}_t^i + \rho_i \mathbf{r}_t^i \cdot \mathbf{l}_{tt}^i + H^i \mathbf{r}_{\sigma t}^i \cdot \mathbf{l}_\sigma^i + H^i \mathbf{r}_\sigma^i \cdot \mathbf{l}_{\sigma t}^i] d\sigma \\ = \sum_{i=1}^n \left[H^i \mathbf{r}_t^i \cdot \mathbf{l}_\sigma^i + H^i \mathbf{r}_\sigma^i \cdot \mathbf{l}_t^i \right]_{\sigma=0}^{\sigma=\ell_i}. \end{aligned}$$

By integrating from 0 to T and using the initial boundary and coupling conditions (which involves extensive regrouping of the boundary terms corresponding to multiple nodes), we obtain (33), and this completes the proof of Theorem 4.1.

Finally, we return to the question of exact controllability. By Corollary 4.3 we need to establish the estimate (30); for this the configuration of the network plays an important role. Again, we can assume that the terminal data belongs to the domain of \mathcal{B}^p and obtain the general estimate by continuity. We now use multipliers of the

form $M^i(\sigma) = (\alpha_i\sigma + \beta_i)I$ (with β_i positive) so that $M_\sigma^i = \alpha_i I$ and $M^i(0) = \beta_i I$. Adding the identities (31) over all string elements we get on rearrangement

$$\begin{aligned}
 & \frac{1}{2} \sum_{i=1}^p \int_0^T [H^i \mathbf{l}_\sigma^i \cdot M^i \mathbf{l}_\sigma^i](\ell_i, t) dt \\
 &= \sum_{i=1}^n \beta_i \frac{1}{2} \int_0^T \int_0^{\ell_i} [\rho_i \mathbf{l}_t^i \cdot \mathbf{l}_t^i + H^i \mathbf{l}_\sigma^i \cdot \mathbf{l}_\sigma^i] d\sigma dt \\
 &+ \sum_{i=1}^n \left[\int_0^\ell \rho_i \mathbf{l}_t^i \cdot M^i \mathbf{l}_\sigma^i d\sigma \right]_{t=0}^{t=T} - \frac{1}{2} \sum_{i=p+1}^m \int_0^T [H^i \mathbf{l}_\sigma^i \cdot M^i \mathbf{l}_\sigma^i](\ell_i, t) dt \\
 &- \frac{1}{2} \sum_{\mathbf{N} \in \mathcal{N}_m} \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) \int_0^T [H^i \mathbf{l}_\sigma^i \cdot M^i \mathbf{l}_\sigma^i](\mathbf{N}, t) dt \\
 (34) \quad &- \frac{1}{2} \sum_{\mathbf{N} \in \mathcal{N}_m} \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) \int_0^T [\rho_i \mathbf{l}_t^i \cdot M^i \mathbf{l}_t^i](\mathbf{N}, t) dt,
 \end{aligned}$$

where \mathcal{N}_m is the set of multiple nodes, and we have used the fact that $\mathbf{l}_t^i(\ell_i, t)$ vanishes for $i = 1$ to m . By conservation of energy and Schwarz's inequality,

$$(35) \quad \sum_{i=1}^n \frac{1}{2} \int_0^T \int_0^{\ell_i} [\rho_i \mathbf{l}_t^i \cdot \mathbf{l}_t^i + H^i \mathbf{l}_\sigma^i \cdot \mathbf{l}_\sigma^i] d\sigma dt = T \| \{ \mathbf{l}^{i,0}(\sigma) \} \times \{ \mathbf{l}^{i,1}(\sigma) \} \|_E^2$$

and

$$(36) \quad \sum_{i=1}^n \left[\int_0^\ell \rho_i \mathbf{l}_t^i \cdot M^i \mathbf{l}_\sigma^i d\sigma \right]_{t=0}^{t=T} \geq \delta \| \{ \mathbf{l}^{i,0}(\sigma) \} \times \{ \mathbf{l}^{i,1}(\sigma) \} \|_E^2,$$

where δ is a positive constant. If

$$(37) \quad M^i(\ell_i) > 0 \quad \text{for } i = 1 \text{ to } p,$$

then we readily obtain from (34), using (35) and (36), that

$$\begin{aligned}
 & \gamma \sum_{i=1}^p \int_0^T |H^i \mathbf{l}_\sigma^i(\ell_i, t)|^2 dt \geq \alpha(T - T_0) \| \{ \mathbf{l}^{i,0}(\sigma) \} \times \{ \mathbf{l}^{i,1}(\sigma) \} \|_E^2 \\
 &- \frac{1}{2} \sum_{i=p+1}^m \int_0^T [H^i \mathbf{l}_\sigma^i \cdot M^i \mathbf{l}_\sigma^i](\ell_i, t) dt - \frac{1}{2} \sum_{\mathbf{N} \in \mathcal{N}_m} \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) \\
 &\cdot \int_0^T [H^i \mathbf{l}_\sigma^i \cdot M^i \mathbf{l}_\sigma^i](\mathbf{N}, t) dt - \frac{1}{2} \sum_{\mathbf{N} \in \mathcal{N}_m} \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) \int_0^T [\rho_i \mathbf{l}_t^i \cdot M^i \mathbf{l}_t^i](\mathbf{N}, t) dt,
 \end{aligned}$$

with α the minimum of the α_i 's, $T_0 = \delta/\alpha$, and γ a positive number such that $\gamma H^i \leq M^i(\ell_i)$ for $i = 1$ to p . We finally obtain (30) with $k = \alpha/\gamma(T - T_0)$ if the configuration is such that the multipliers can be chosen to satisfy (37) along with

$$(38) \quad M^i(\ell_i) \leq 0 \quad \text{for } i = p+1 \text{ to } m;$$

$$(39) \quad \sum_{\mathbf{N} \in \mathcal{N}_m} \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) [H^i \mathbf{l}_\sigma^i \cdot M^i \mathbf{l}_\sigma^i](\mathbf{N}, t) \leq 0;$$

and

$$(40) \quad \sum_{\mathbf{N} \in \mathcal{N}_m} \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) [\rho_i \mathbf{l}_t^i \cdot M^i \mathbf{l}_t^i](\mathbf{N}, t) \leq 0.$$

By the first of the coupling conditions, $\mathbf{l}_t^i(\mathbf{N}, t)$ is the same for each $i \in \mathcal{E}(\mathbf{N})$ and so (40) can be replaced by the condition

$$(41) \quad \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) \rho_i M^i(\mathbf{N}) \quad \text{is negative definite for each } \mathbf{N} \in \mathcal{N}_m.$$

The second coupling condition can also be used to rewrite (39) as

$$(42) \quad \sum_{i \in \mathcal{E}(\mathbf{N})} \mathbf{w}^i = 0 \quad \text{implies} \quad \sum_{i \in \mathcal{E}(\mathbf{N})} \epsilon_i(\mathbf{N}) M^i(\mathbf{N}) H^{i-1} \mathbf{w}^i \cdot \mathbf{w}^i \leq 0.$$

It is convenient to introduce $\overline{M}^i(\mathbf{N}) = \epsilon_i(\mathbf{N}) M^i(\mathbf{N})$, which at the simple nodes coincides with $M^i(\mathbf{N})$. Condition (41) is then satisfied if at every multiple node at least one $\overline{M}^i(\mathbf{N})$ is sufficiently negative to dominate the positive contributions at that node. It is an exercise in linear algebra to see that the subtler condition (42) will be satisfied if at each internal node at most one $\overline{M}^i(\mathbf{N})$ is positive and if each negative contribution is sufficiently small to dominate the positive contribution.

For a given network we try to define appropriate multipliers satisfying the above conditions. As a first step, we proceed “graphically” as follows. String segments will be denoted by

$$\bullet - \pm - \pm - \bullet,$$

where the signs indicate the signs of $\overline{M}^i(\mathbf{N})$ at the adjacent node. We note that because $M^i(\sigma)$ is monotone increasing the only possible sign allocations are

$$(43) \quad \bullet - + - + - \bullet, \quad \bullet - + - - - \bullet, \quad \text{and} \quad \bullet - - - + - \bullet;$$

the assignment $\bullet - - - - \bullet$ is impossible. Subject to this “constraint” we try to satisfy the following *sign rules*, which are necessary for our approach to yield exact controllability:

- (a) At the simple nodes we must assign positive values where controls are to be applied and negative values where the node is to be held fixed;
- (b) At each multiple node we must assign positive or negative values in such a way that at most one is positive.

If such a sign allocation is possible, we proceed to check whether the magnitudes of $\overline{M}^i(\mathbf{N})$ at both ends of each element can be adjusted to give the required dominance of the negative terms over the positive terms needed to ensure that (41) and (42) hold.

In the networks illustrated on the next page, the simple nodes at which controls are applied are marked by “ \mathbf{u}^i ”, while those that are kept fixed are marked by “0.”

FIG. 2

Nodes where the “sign rule” is violated are indicated by “!!,” and, in the cases of violation, we cannot remedy the situation by a different sign allocation. With these remarks, the diagrams should be self explanatory. When we try to adjust the values of $\overline{M}^i(\mathbf{N})$ for the networks in which the sign rules can be satisfied, we see that this is easily done when there are no “closed circuits.” Consequently, we have established the following theorem.

THEOREM 4.5. *The networks (a), (c) and (e) illustrated below in Fig. 2 can all be exactly controlled by controls at the indicated simple nodes.*

Remarks

- In the networks (b) and (d) where our sign rules cannot be satisfied, we are unable to make any general assertions; in the example given below, exact controllability of the network depends on the rationality or irrationality of a certain parameter. It appears that in some situations there is no interaction between certain oscillations occurring in part of the network and the oscillations on the rest of the network excited by control functions at some set of simple nodes.
- In the case of the network (f) with its closed circuit, we can easily convince ourselves that we cannot ensure that condition (42) is satisfied at all multiple nodes. This problem persists in more complicated networks involving closed circuits.

Whether such circuits are exactly controllable remains open.

- (c) We can easily generate exactly controllable networks that are much more complicated than those that we have treated.

Example. We consider network (b) with boundary conditions

$$\mathbf{r}^1(\ell_1, t) = \mathbf{u}(t), \quad \mathbf{r}^2(\ell_2, t) = \mathbf{0}, \quad \mathbf{r}^3(\ell_3, t) = \mathbf{0}.$$

We suppose for simplicity that the second and third strings are identical, perpendicular to each other, and lie symmetrically with respect to the third string. Moreover, we set $\rho_i = h_i = 1$ for $i = 2, 3$ and note that in this case $s_2 = s_3 = s$, say. We introduce the parameter μ by $\mu^{-2} = 1 - s^{-1}$. If μ is rational we can find two nontrivial real functions f and g defined on the real line that are both 2 and 2μ periodic and satisfy $f(t) = -g(-t)$. It follows easily that

$$f(\mu + t) + g(\mu - t) = 0 \quad \text{and} \quad f(1 + t) + g(1 - t) = 0.$$

Now let \mathbf{v} be the direction vector of the second string and set

$$\begin{aligned} \mathbf{l}^1(\sigma, t) &= \mathbf{0}, \\ \mathbf{l}^2(\sigma, t) &= [f(\sigma + t) + g(\sigma - t)]\mathbf{v}, \\ \mathbf{l}^3(\sigma, t) &= -\mu[f(\mu\sigma + t) + g(\mu\sigma - t)]\mathbf{v}. \end{aligned}$$

This gives a solution $\{\mathbf{l}^i(\sigma, t)\}$ to system (12) satisfying homogeneous boundary conditions as well as the two coupling conditions (14) and (15). Moreover, in this situation $C_T^{p*} \{\mathbf{l}^i(\sigma, T)\} \times \{\mathbf{l}_t^i(\sigma, T)\} = 0$, so that C_T^{p*} has a nontrivial nullspace, which implies that C_T^p is not surjective, and hence the system is not exactly controllable.

With an additional argument, we can show that when μ is irrational, C_T^{p*} is injective for T sufficiently large, in which case C_T^p has dense image. At this point we do not know whether the image is necessarily closed. Questions raised by the above example could be the topic of a future publication.

ON THE EXISTENCE OF OPTIMAL RELAXED CONTROLS OF STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS*

XUN YU ZHOU†

Abstract. This paper is concerned with control problem of systems governed by stochastic partial differential equations, the drift and diffusion terms of which are second- and first-order differential operators, respectively. The existence of an optimal relaxed control is studied in both cases where the systems are degenerate and nondegenerate. It is shown that the higher regularity conditions on the initial state, as required in the existing results, can be dispensed with if the Wiener process is one-dimensional. Some special cases of multidimensional Wiener process are also discussed, which in particular leads to an improvement of a recent result of Bensoussan and Nisio. The method is based on an analysis of the group generated by the first-order differential operator. As an application, an existence theorem of the optimal relaxed control is proved for partially observed diffusions with correlation between the controlled states and the observation noises.

Key words. stochastic partial differential equation (SPDE), optimal relaxed control, partially observed diffusion, group of operators

1. Introduction. In this paper we consider an optimal control problem of the following kind of stochastic partial differential equations (SPDE):

$$\begin{aligned}
 dq(t, x) = & [\partial_i(a^{ij}(x, u(t))\partial_j q(t, x)) + b^i(x, u(t))\partial_i q(t, x) \\
 & + c(x, u(t))q(t, x) + f(x, u(t))] dt \\
 & + [\sigma^i(x)\partial_i q(t, x) + h(x)q(t, x) + g(x)] dW(t), \\
 & x \in R^d, \quad t \in [0, T], \\
 q(0, x) = & q_0(x), \quad x \in R^d,
 \end{aligned}
 \tag{1.1}$$

where W is a one-dimensional Wiener process with $W(0) = 0$, $\{u(t): 0 \leq t \leq T\}$ is an admissible control (in the usual sense), and $\partial_i := \partial/\partial x_i$, $i = 1, 2, \dots, d$. Note that here and in the following we always use the conventional repeated indices for summation.

The optimal control problem is to minimize a given cost functional over the totality of admissible controls. SPDE (1.1) occurs in many areas of science, especially in physics (see [8]–[10] and [13] and the references therein). From the mathematical point of view, the most important example is perhaps the filtering problem. More precisely, the control problem of partially observed diffusions can be reduced to the control problem of SPDE (1.1) (Zakaï's equation), with the σ^i in (1.1) corresponding to the correlation between the controlled state and the observation noises ([12], [13], and [15]).

The existence of an optimal control in the usual sense seems to be a very difficult problem and remains open in general. Many authors turned to studying the relaxed control problem ([1], [4], [6] and [13]). For system (1.1), when $\sigma^i = 0$, Bensoussan and Nisio [1] have proved the existence of an optimal relaxed control, assuming (a^{ij}) is uniformly positive definite and $q_0 \in H^2(R^d)$ ($H^k(R^d) :=$ Sobolev space $W_2^k(R^d)$). When $\sigma^i \neq 0$, the situation is much more complicated. For this case, the recent delicate

† Department of Mathematics, Faculty of Science, Kobe University, Rokko, Kobe 657, Japan.

work of Nagase and Nisio [13] shows that the existence theorem still holds when $(a^{ij} - 3/2\sigma^i\sigma^j)$ is nonnegative definite and $q_0 \in H^3(R^d)$. Both [1] and [13] have applied a similar method to that of Nagase [12], the key point of which is to employ a compact embedding lemma, see [12, Remark 3.1]. These results, however, require the higher regularity on the initial point q_0 .

The purpose of the present paper is to establish the existence of an optimal relaxed control of SPDE (1.1), with some natural regularity conditions on the initial state q_0 . Different from that of [1], [12], and [13], our method depends on an analysis of the group generated by the first-order differential operator, inspired by Da Prato, Iannelli, and Tubaro [3]. This frees us from the set-up of [1], [12], and [13], allowing us to eliminate the higher regularity restriction on q_0 . The main results of this paper, roughly speaking, are as follows: Either

- (i) $(a^{ij} - 1/2\sigma^i\sigma^j)$ is nonnegative definite and $q_0 \in H^1(R^d)$, or
- (ii) $(a^{ij} - 1/2\sigma^i\sigma^j)$ is uniformly positive definite and $q_0 \in H^0(R^d) (= L^2(R^d))$

will ensure the existence of an optimal relaxed control.

An apparent defect of our method, however, is that the Wiener process W is required to be one-dimensional. For multidimensional cases, the method applies only to some special cases. In particular, we will show that our method is effective to the setting of Bensoussan and Nisio [1]; therefore, their result may be considerably improved.

It is also worth noting that this work benefits so much by the delicate and deep results of Krylov and Rozovskii [8]–[10] concerning the SPDE theory, and in particular, the a priori estimate of differential operators (Lemma 3.1 below).

The paper is organized as follows: In § 2, we will give a precise definition of the relaxed system of (1.1) as well as some basic notation and facts. Sections 3 and 4 are the main parts of the paper, in which the existence theorems are proved for degenerate case (i.e., $(a^{ij} - 1/2\sigma^i\sigma^j)$ is nonnegative definite) and nondegenerate case (i.e., $(a^{ij} - 1/2\sigma^i\sigma^j)$ is uniformly positive definite), respectively. In § 5, we discuss the cases when the Wiener process is multidimensional, as well as the application of the main results to the partially observed diffusions.

2. Preliminaries. We define a family of second-order differential operators $\{A(u): u \in \Gamma \subset R^m\}$ and a first-order differential operator M by

$$(2.1) \quad A(u)\phi(x) := \partial_i(a^{ij}(x, u)\partial_j\phi(x)) + b^i(x, u)\partial_i\phi(x) + c(x, u)\phi(x),$$

$$(2.2) \quad M\phi(x) := \sigma^i(x)\partial_i\phi(x) + h(x)\phi(x), \quad \text{for } x \in R^d,$$

where a^{ij} , b^i , c , σ^i , and h are real-valued functions for $i, j = 1, 2, \dots, d$.

Let H^k be the Sobolev space $W_2^k(R^d)$ with the norm $\|\cdot\|_k$ ($k = 0, \pm 1, \pm 2, \dots$). $\langle \cdot, \cdot \rangle_k$ denotes the duality pairing between H^{k-1} and H^{k+1} under $(H^k)^* = H^k$, and $(\cdot, \cdot)_k$ is the inner product in H^k . For $r \geq 0$, define

$$L_r^2 := \{\phi: \phi \text{ is a real-valued Borel function on } R^d,$$

$$\text{and } (1 + |\cdot|^2)^{r/2}\phi(\cdot) \in H^0\},$$

with the norm $\|\phi\|_{0,r} := (\int_{R^d} |(1 + |x|^2)^{r/2}\phi(x)|^2 dx)^{1/2}$.

Let H_r^k be the subspace of L_r^2 consisting of functions whose generalized derivatives up to the order k belong to L_r^2 . It becomes a Hilbert space with the norm

$$\|\phi\|_{k,r} := \left(\sum_{|\alpha| \leq k} \frac{|\alpha|!}{\alpha^1! \cdots \alpha^d!} \|D^\alpha \phi\|_{0,r}^2 \right)^{1/2},$$

see [10, § 2].

For any second-order differential operator L , when we write $\langle L\phi, \psi \rangle_k$, then L is understood to be an operator from H^{k+1} to H^{k-1} by formally using Green's formula. For example, for the operators $A(u)$ defined by (2.1), we have

$$(2.3) \quad \begin{aligned} \langle A(u)\phi, \psi \rangle_k &:= -(a^{ij}(\cdot, u)\partial_j\phi, \partial_i\psi)_k + (b^i(\cdot, u)\partial_i\phi, \psi)_k \\ &\quad + (c(\cdot, u)\phi, \psi)_k \quad \text{for } \phi, \psi \in H^{k+1}. \end{aligned}$$

Now we recall the definition of relaxed controls, according to [1], [4], and [13]. By Λ we denote the set of all measures λ on $[0, T] \times \Gamma$ such that

$$(2.4) \quad \lambda([0, s] \times \Gamma) = s, \quad \text{for } s \leq T.$$

If Γ is a compact set, then Λ is compact when endowed with the weak convergence topology ([1] and [13]).

Set $\sigma_t(\Lambda) :=$ the σ -field generated by $\{\lambda: \lambda([0, s] \times A) \in \mathcal{B}(R^+), s \leq t, A \in \mathcal{B}(\Gamma)\}$ and $\sigma(\Lambda) := \sigma_T(\Lambda)$. Let $\mathcal{P} := \mathcal{P}(\Lambda)$ be the space of probabilities on $(\Lambda, \sigma(\Lambda))$, then Prohorov's theorem yields that \mathcal{P} is a compact metric space when endowed with the weak convergence topology.

By (2.4), λ is represented by $\lambda(dt, du) = \lambda'(t, du) dt$, where $\lambda'(t, \cdot)$ is a probability on Γ for almost all t and determined uniquely except t -null set. For any bounded and uniformly continuous function ρ on $R^d \times \Gamma$, set $\tilde{\rho}(t, x, \lambda) := \int_{\Gamma} \rho(x, u) \lambda'(t, du)$. Define a family of operators $\{\tilde{A}(t, \lambda): t \in [0, T], \lambda \in \Lambda\}$:

$$(2.5) \quad \begin{aligned} \tilde{A}(t, \lambda)\phi(x) &:= \partial_i(\tilde{a}^{ij}(t, x, \lambda)\partial_j\phi(x)) + \tilde{b}^i(t, x, \lambda)\partial_i\phi(x) \\ &\quad + \tilde{c}(t, x, \lambda)\phi(x), \quad \text{for } x \in R^d. \end{aligned}$$

Now we introduce the relaxed system.

DEFINITION 2.1. $\mathcal{R} = (\Omega, \mathcal{F}, P, \mathcal{F}_t, W, \mu)$ is called a relaxed system if

$$(2.6) \quad (\Omega, \mathcal{F}, P, \mathcal{F}_t) \text{ is a standard probability space with filtration } \{\mathcal{F}_t: 0 \leq t \leq T\};$$

$$(2.7) \quad W \text{ is an } \mathcal{F}_t\text{-adapted one-dimensional Wiener process with } W(0) = 0;$$

$$(2.8) \quad \mu \text{ is an } \mathcal{F}_t\text{-adapted } \Lambda\text{-valued random variable } (\Lambda\text{-r.v.}), \text{ i.e., } \mu(B_1 \times B_2) \text{ is } \mathcal{F}_t\text{-measurable whenever } B_1 \in \mathcal{B}([0, t]) \text{ and } B_2 \in \mathcal{B}(\Gamma).$$

For simplicity, we put $\mathcal{R} = (W, \mu)$ if no confusion arises, and sometimes we simply call μ a relaxed control.

\mathcal{R} denotes the totality of relaxed controls. For $\mathcal{R} = (W, \mu)$, $\pi(\mathcal{R})$ denotes the image measure of (W, μ) on $C(0, T; R^1) \times \Lambda$. Again, by endowing the space $\Pi := \{\pi(\mathcal{R}): \mathcal{R} \in \mathcal{R}\}$ with the weak convergence topology, we have the following proposition [1], [13].

PROPOSITION 2.1. Π is a compact metric space.

DEFINITION 2.2. We say \mathcal{R}_n converges to \mathcal{R} , writing $\mathcal{R}_n \rightarrow \mathcal{R}$, if $\pi(\mathcal{R}_n) \rightarrow \pi(\mathcal{R})$ weakly.

Given $\mathcal{R} = (\Omega, \mathcal{F}, P, \mathcal{F}_t, W, \mu)$, consider the following SPDE:

$$(2.9) \quad \begin{aligned} dq(t) &= (\tilde{A}(t, \mu)q(t) + \tilde{f}(t, \mu)) dt + (Mq(t) + g) dW(t), \\ q(0) &= q_0. \end{aligned}$$

An H^1 -valued \mathcal{F}_t -adapted process $q = q^{\mathcal{R}}(\cdot, q_0)$ is called a solution of (2.9) or a response for the relaxed control \mathcal{R} if

$$(2.10) \quad E \int_0^T \|q(t)\|_1^2 dt < +\infty,$$

and for any $\eta \in C_0^\infty(R^d)$ (smooth function on R^d with compact support) and almost

all $(t, \omega) \in [0, T] \times \Omega$,

$$(2.11) \quad \begin{aligned} (q(t), \eta)_0 &= (q_0, \eta)_0 + \int_0^t \langle \tilde{A}(s, \mu)q(s), \eta \rangle_0 ds + \int_0^t (\tilde{f}(s, \mu), \eta)_0 ds \\ &\quad + \int_0^t (Mq(s) + g, \eta)_0 dW(s). \end{aligned}$$

For each initial q_0 , we are given a cost functional

$$(2.12) \quad J(q_0, \mathcal{R}) := E\{F(q^{\mathcal{R}}(\cdot, q_0)) + G(q^{\mathcal{R}}(T, q_0))\}, \quad \mathcal{R} \in \mathbf{R}.$$

The optimal relaxed control problem is to minimize $J(q_0, \cdot)$ over \mathbf{R} , for each q_0 .

Remark 2.1. Since we will mainly consider the relaxed control in the following, we will simply write $A(t, \mu) = \tilde{A}(t, \mu)$, etc., if no confusion arises.

3. Degenerate case. Let us fix a positive constant K . We introduce the following conditions on the functions appearing in (1.1):

- (A1) $a^{ij}, b^i, c: R^d \times \Gamma \rightarrow R^1, \sigma^i, h: R^d \rightarrow R^1$ are continuous functions; these functions and their derivatives in x up to second order do not exceed K in absolute value;
- (A2) $a^{ij} = a^{ji}, i, j = 1, 2, \dots, d$, and $(a^{ij} - \frac{1}{2}\sigma^i\sigma^j)_{ij}$ is a nonnegative definite matrix;
- (A3) $f(\cdot, u) \in H^1, g \in H^2$; the absolute values of f, g together with the H^1 -norm of $f(\cdot, u)$ and the H^2 -norm of g do not exceed K ;
- (A3)_r For some $r > 0, f(\cdot, u) \in L_r^2, g \in H_r^1$, the absolute values of f, g together with the L_r^2 -norm of $f(\cdot, u)$ and the H_r^1 -norm of g do not exceed K .

The following lemma of a prior estimate is a special case of [9, Lemma 2.1].

LEMMA 3.1. *Let \hat{A} and \hat{M} be any second-order and first-order differential operators that have the forms of (2.1) and (2.2), respectively, and whose coefficients satisfy (A1) and (A2). Then there exists a constant N depending only on K in (A1) such that*

$$(3.1) \quad 2\{\langle \hat{A}\phi, \phi \rangle_k + \langle \hat{M}\phi, \phi \rangle_k\} + \|\hat{M}\phi + \hat{g}\|_k^2 \leq N(\|\phi\|_k^2 + \|\hat{f}\|_k^2 + \|\hat{g}\|_{k+1}^2),$$

for any $\phi \in H^{k+1}, \hat{f} \in H^k, \hat{g} \in H^{k+1}; k = 0, 1$.

COROLLARY 3.1. *Let \hat{M} be a first-order differential operator that has the form of (2.2) and whose coefficients satisfy (A1). Then there exists a constant N depending only on K such that*

$$(3.2) \quad |\langle \hat{M}\phi + \hat{g}, \phi \rangle_k| \leq N(\|\phi\|_k^2 + \|\hat{g}\|_k^2), \quad \text{for any } \phi \in H^{k+1}, \hat{g} \in H^k; k = 0, 1.$$

The following result concerning the solution of SPDE is known from Krylov and Rozovskii [9] and [10].

PROPOSITION 3.1. *Assume (A1)–(A3) and $q_0 \in H^1$; then for any $\mathcal{R} \in \mathbf{R}$, (2.9) has a unique solution $q^{\mathcal{R}}(\cdot, q_0) \in L^2([0, T] \times \Omega; H^1) \cap L^2(\Omega; C(0, T; H^0))$ and there exists a constant C , depending only on K and T , such that*

$$(3.3) \quad \sup_{0 \leq t \leq T} E\|q^{\mathcal{R}}(t, q_0)\|_k^2 \leq CE \left\{ \|q_0\|_k^2 + \int_0^T [\|f(s, \mu)\|_k^2 + \|g\|_{k+1}^2] ds \right\}, \quad k = 0, 1.$$

Moreover, for any $p \geq 2$, there exists a constant $C(p)$ such that

$$(3.4) \quad \sup_{0 \leq t \leq T} E\|q^{\mathcal{R}}(t, q_0)\|_k^p \leq C(p)E \left\{ \|q_0\|_k^p + \int_0^T [\|f(s, \mu)\|_k^p + \|g\|_{k+1}^p] ds \right\},$$

$k = 0, 1$.

The main idea of the present paper is based on the fact that the first-order differential operator M generates a strongly continuous group on H^0 . The following proposition states the detailed properties of M , with the proof provided in the Appendix.

PROPOSITION 3.2. *On the Hilbert space H^0 , define an operator M by (2.2) with the domain $D(M) := H^1$, then*

(i) *M can be extended to a closed operator (still denoted by M) that generates a strongly continuous group $\{e^{Mt} : -\infty < t < +\infty\}$ on H^0 . Moreover, H^1 is an invariant subspace of e^{Mt} for each t , and there exists a constant N (the same as the constant in (3.2)), such that*

$$(3.5) \quad \|e^{Mt}\|_{L(H^0 \rightarrow H^0)} \leq e^{N|t|},$$

$$(3.6) \quad \|e^{Mt}\|_{L(H^1 \rightarrow H^1)} \leq e^{N|t|}, \quad \text{for any } t \in (-\infty, +\infty);$$

(ii) *Denote by M^* the adjoint operator of M on H^0 , then $H^1 \subset D(M^*)$ and M^* also generates a strongly continuous group $\{e^{M^*t} = (e^{Mt})^* : -\infty < t < +\infty\}$ on H^0 . Moreover, H^1 is an invariant subspace of e^{M^*t} for each t , and with the same constant N , we have*

$$(3.7) \quad \|e^{M^*t}\|_{L(H^0 \rightarrow H^0)} \leq e^{N|t|},$$

$$(3.8) \quad \|e^{M^*t}\|_{L(H^1 \rightarrow H^1)} \leq e^{N|t|}, \quad \text{for any } t \in (-\infty, +\infty);$$

(iii) *Define two operators M^2, M^{*2} from H^1 to H^{-1} by the following formula:*

$$(3.9) \quad \langle M^2 \phi, \psi \rangle_0 = \langle M\phi, M^* \psi \rangle_0 = \langle \phi, M^{*2} \psi \rangle_0, \quad \text{for } \phi, \psi \in H^1,$$

*then M^2 and M^{*2} are bounded linear operators from H^1 to H^{-1} .*

From now on, when we write M, M^*, M^2 , and M^{*2} , it is always understood to be in the sense of that in Proposition 3.2.

The following lemma will play an essential role in this paper.

LEMMA 3.2. *Let D be a set in R^d such that*

$$(3.10) \quad D \text{ is bounded, open, and with smooth boundary.}$$

Define $W_D[0, T] := \{\phi : \phi \in L^2(0, T; H^1(D)), d\phi/dt \in L^2(0, T; H^{-1}(D))\}$ with the norm

$$(3.11) \quad \|\phi\|_{W_D[0, T]} := \left(\int_0^T \|\phi(t)\|_{1,D}^2 dt + \int_0^T \|d\phi(t)/dt\|_{-1,D}^2 dt \right)^{1/2},$$

where $H^k(D)$ is the Sobolev space $W_2^k(D)$ with the Sobolev norm $\|\cdot\|_{k,D}$. Then the embedding $W_D[0, T] \rightarrow L^2(0, T; H^0(D))$ is compact.

Proof. Since the embedding $H^1(D) \rightarrow H^0(D)$ is compact, the result follows from [11, Thm. 5.1, p. 58]. \square

PROPOSITION 3.3. *Assume (A1)–(A3), $q_0 \in H^1$, and $\mathcal{R} \in \mathbb{R}$. Let $q(\cdot) = q^{\mathcal{R}}(\cdot, q_0)$ be the solution of (2.9). Set $p(t) := e^{-MW(t)} q(t)$, then p satisfies*

$$(3.12) \quad \begin{aligned} d(p(t), \phi)_0 &= \{ \langle (A(t, \mu) - \frac{1}{2}M^2)q(t), e^{-M^*W(t)} \phi \rangle_0 \\ &\quad + (e^{-MW(t)}(f(t, \mu) - Mg), \phi)_0 \} dt + (e^{-MW(t)}g, \phi)_0 dW(t), \end{aligned}$$

for any $\phi \in H^1$.

Proof. Take $\phi, \psi \in H^1$. Define $\rho(t) := (e^{-M^*t} \phi, \psi)_0$. By Proposition 3.2,

$$d\rho(t)/dt = -(M^* e^{-M^*t} \phi, \psi)_0 = -(e^{-M^*t} \phi, M\psi)_0,$$

$$d^2\rho(t)/dt^2 = (M^* e^{-M^*t} \phi, M\psi)_0 = \langle M^{*2} e^{-M^*t} \phi, \psi \rangle_0.$$

Hence by Itô's formula, we have

$$(3.13) \quad d\rho(W(t)) = \frac{1}{2} \langle M^{*2} e^{-M^*W(t)} \phi, \psi \rangle_0 dt - \langle M^* e^{-M^*W(t)} \phi, \psi \rangle_0 dW(t);$$

namely, we have the following formula in the space H^{-1} :

$$(3.14) \quad d(e^{-M^*W(t)} \phi) = \frac{1}{2} M^{*2} e^{-M^*W(t)} \phi dt - M^* e^{-M^*W(t)} \phi dW(t).$$

Therefore, again by Itô's formula,

$$\begin{aligned}
 d(p(t), \phi)_0 &= d(q(t), e^{-M^* W(t)} \phi)_0 \\
 &= \langle A(t, \mu)q(t) + f(t, \mu), e^{-M^* W(t)} \phi \rangle_0 dt \\
 &\quad + \langle Mq(t) + g, e^{-M^* W(t)} \phi \rangle_0 dW(t) \\
 &\quad + \langle q(t), \frac{1}{2} M^{*2} e^{-M^* W(t)} \phi \rangle_0 dt - \langle q(t), M^* e^{-M^* W(t)} \phi \rangle_0 dW(t) \\
 &\quad - \langle Mq(t) + g, M^* e^{-M^* W(t)} \phi \rangle_0 dt \\
 &= \{ \langle (A(t, \mu) - \frac{1}{2} M^2)q(t), e^{-M^* W(t)} \phi \rangle_0 \\
 &\quad + \langle e^{-M^* W(t)} (f(t, \mu) - Mg), \phi \rangle_0 \} dt \\
 &\quad + \langle e^{-M^* W(t)} g, \phi \rangle_0 dW(t).
 \end{aligned}
 \tag{3.15}$$

This proves (3.12). \square

We need an additional lemma for technical reasons.

LEMMA 3.3. *For some $r > 0$, we assume (A1)–(A3), (A3)_r, and $q_0 \in H^1 \cap L_r^2$. For $\mathcal{R} \in \mathcal{R}$, let $q(t, x) = q^{\mathcal{R}}(t, x, q_0)$ be the solution of (2.9), then there exists a constant C , independent of \mathcal{R} , such that*

$$E \int_{|x| > \rho} |q(t, x)|^2 dx \leq C/(1 + \rho^2)^r, \quad \text{for any } \rho > 0.
 \tag{3.16}$$

Proof. By Krylov and Rozovskii [10], we have a constant C' such that

$$\sup_{0 \leq t \leq T} E \|q(t)\|_{0,r}^2 \leq C' E \left\{ \|q_0\|_{0,r}^2 + \int_0^T (\|f(t, \mu)\|_{0,r}^2 + \|g\|_{1,r}^2) dr \right\} \leq C;$$

hence

$$E \int_{|x| > \rho} |q(t, x)|^2 dx \leq E \|q(t)\|_{0,r}^2 / (1 + \rho^2)^r \leq C/(1 + \rho^2)^r. \quad \square$$

THEOREM 3.1. *Assume (A1)–(A3), (A3)_r, and $q_0 \in H^1 \cap L_r^2$ for some $r > 0$. Denote by $q^{\mathcal{R}}(\cdot, q_0)$ the solution of (2.9) for $\mathcal{R} \in \mathcal{R}$. If $\mathcal{R}_n \rightarrow \mathcal{R}$, then*

$$q^{\mathcal{R}_n}(\cdot, q_0) \rightarrow q^{\mathcal{R}}(\cdot, q_0) \text{ in law, as } L^2(0, T; H^0)\text{-}r.v.;
 \tag{3.17}$$

$$q^{\mathcal{R}_n}(T, q_0) \rightarrow q^{\mathcal{R}}(T, q_0) \text{ in law, as } H^0\text{-}r.v.
 \tag{3.18}$$

Proof. Suppose $\mathcal{R}_n = (W_n, \mu_n)$ and $\mathcal{R} = (W, \mu)$. We write $q_n(\cdot) := q^{\mathcal{R}_n}(\cdot, q_0)$ for simplicity. Define $p_n(t) := e^{-M^* W_n(t)} q_n(t)$, $p_{n,1}(t) := \int_0^t e^{-M^* W_n(s)} g dW_n(s)$, and $p_{n,2}(t) := p_n(t) - p_{n,1}(t)$. Then, by Propositions 3.1 and 3.2, we have

$$\begin{aligned}
 E \int_0^T \|p_n(t)\|_1^2 dt &\leq E \int_0^T e^{2N|W_n(t)|} \|q_n(t)\|_1^2 dt \\
 &\leq E \left(\sup_{0 \leq t \leq T} e^{2N|W_n(t)|} \int_0^T \|q_n(t)\|_1^2 dt \right) \\
 &\leq \left(E \sup_{0 \leq t \leq T} e^{4N|W_n(t)|} \right)^{1/2} \left(E \int_0^T \|q_n(t)\|_1^4 dt \right)^{1/2} \cdot T^{1/2}.
 \end{aligned}
 \tag{3.19}$$

It is known from Fernique's lemma [5] that $\sup_n (E \sup_{0 \leq t \leq T} e^{4N|W_n(t)|}) < +\infty$; hence (3.19) yields

$$\sup_n E \int_0^T \|p_n(t)\|_1^2 dt < +\infty.
 \tag{3.20}$$

Similarly, we have

$$(3.21) \quad \sup_n E \int_0^T \|p_{n,1}(t)\|_1^2 dt \leq \sup_n E \int_0^T \int_0^t e^{2N|W_n(s)|} \|g\|_1^2 ds dt < +\infty.$$

Combining (3.20) and (3.21) gives

$$(3.22) \quad \sup_n E \int_0^T \|p_{n,2}(t)\|_1^2 dt < +\infty.$$

On the other hand, by virtue of Proposition 3.3,

$$(3.23) \quad \begin{aligned} d(p_{n,2}(t), \phi)_0 &= \{ \langle (A(t, \mu_n) - \frac{1}{2}M^2)q_n(t), e^{-M^*W_n(t)}\phi \rangle_0 \\ &\quad + \langle e^{-M^*W_n(t)}(f(t, \mu_n) - Mg), \phi \rangle_0 \} dt, \end{aligned}$$

for any $\phi \in H^1$.

Hence

$$\begin{aligned} |\langle dp_{n,2}(t)/dt, \phi \rangle_0| &\leq \| (A(t, \mu_n) - \frac{1}{2}M^2)q_n(t) \|_{-1} \| e^{-M^*W_n(t)}\phi \|_1 \\ &\quad + e^{N|W_n(t)|} \| f(t, \mu_n) - Mg \|_0 \| \phi \|_0 \\ &\leq \text{const } e^{N|W_n(t)|} (\|q_n(t)\|_1 + 1) \| \phi \|_1, \end{aligned}$$

for any $\phi \in H^1$.

This yields

$$(3.24) \quad \begin{aligned} \sup_n E \int_0^T \|dp_{n,2}(t)/dt\|_{-1}^2 dt \\ \leq \text{const } \sup_n E \int_0^T e^{2N|W_n(t)|} (\|q_n(t)\|_1^2 + 1) dt \\ < +\infty. \end{aligned}$$

Equations (3.22) and (3.24) imply that there exists a constant C_1 that is independent of n such that, for any $D \subset R^d$ with the property (3.10),

$$(3.25) \quad E \|p_{n,2}\|_{W_D[0,T]}^2 \leq C_1.$$

Let $D_k := \{x \in R^d : |x| < k\}$ for $k = 1, 2, \dots$. Define a metric \bar{d} on $L^2(0, T; H^0)$ by

$$(3.26) \quad \bar{d}(\phi, \psi) := \sum_{k=1}^{\infty} \frac{1}{2^k} \min \left\{ 1, \left(\int_0^T \|\phi(t) - \psi(t)\|_{0,D_k}^2 dt \right)^{1/2} \right\}.$$

We denote by $\bar{L}^2(0, T; H^0)$ the completion of $L^2(0, T; H^0)$ by \bar{d} . For $\lambda > 0$,

$$B_\lambda := \{ \phi \in \bar{L}^2(0, T; H^0) : \|\phi\|_{W_{D_k}[0,T]} \leq (2^k \lambda)^{1/2}, \quad k = 1, 2, \dots \}$$

is compact in $\bar{L}^2(0, T; H^0)$ due to Lemma 3.2. Now (3.25) yields

$$(3.27) \quad P(p_{n,2} \in B_\lambda) \leq \sum_{k=1}^{\infty} \frac{1}{2^k \lambda} C_1 \leq C_1 / \lambda, \quad \text{for any } \lambda > 0;$$

hence, $\{p_{n,2}\}$ is tight as $\bar{L}^2(0, T; H^0)$ -r.v. (cf. [7, Def. 2.2, p. 7]). Noting the compactness of Λ , $\{(W_n, \mu_n, p_{n,2})\}$ is tight as $C(0, T; R^1) \times \Lambda \times \bar{L}^2(0, T; H^0)$ -r.v. Hence by Skorohod's theorem, we can choose a subsequence $\{n'\}$ and have $(\hat{W}_{n'}, \hat{\mu}_{n'}, \hat{p}_{n',2})$, $(\hat{W}, \hat{\mu}, \hat{p}_2)$ on a suitable probability space $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$, such that

$$(3.28) \quad \text{law of } (\hat{W}_{n'}, \hat{\mu}_{n'}, \hat{p}_{n',2}) = \text{law of } (W_{n'}, \mu_{n'}, p_{n',2}),$$

and \hat{P} -almost surely

$$(3.29) \quad \hat{W}_{n'} \rightarrow \hat{W} \quad \text{uniformly on } [0, T],$$

$$(3.30) \quad \hat{\mu}_{n'} \rightarrow \hat{\mu} \quad \text{weakly on } \Lambda,$$

$$(3.31) \quad \hat{p}_{n',2} \rightarrow \hat{p}_2 \quad \text{in } \bar{L}^2(0, T; H^0), \text{ as } n' \rightarrow +\infty.$$

Define

$$\hat{p}_{n',1}(t) := \int_0^t e^{-M\hat{W}_{n'}(s)} g d\hat{W}_{n'}(s), \quad \hat{p}_1(t) := \int_0^t e^{-M\hat{W}(s)} g d\hat{W}(s).$$

By virtue of (3.29) and the strong continuity of the group $\{e^{Mt}\}$, we have for fixed $(s, \hat{\omega})$, $\|e^{-M\hat{W}_{n'}(s)} g - e^{-M\hat{W}(s)} g\|_0^2 \rightarrow 0$ as $n' \rightarrow \infty$. By Fernique's lemma, it is easy to check that

$$\sup_{n'} \hat{E} \int_0^T \|e^{-M\hat{W}_{n'}(s)} g - e^{-M\hat{W}(s)} g\|_0^4 ds < +\infty,$$

which means that $\{\|e^{-M\hat{W}_{n'}(s)} g - e^{-M\hat{W}(s)} g\|_0^2\}$ is uniformly integrable on $[0, T] \times \hat{\Omega}$; hence

$$(3.32) \quad e^{-M\hat{W}_{n'}(s)} g \rightarrow e^{-M\hat{W}(s)} g \quad \text{in } L^2([0, T] \times \hat{\Omega}; H^0), \text{ as } n' \rightarrow \infty.$$

Combining (3.32) with (3.29), by a similar argument to that in [12, Lemma 3.3], we get

$$(3.33) \quad \hat{E} \int_0^T \|\hat{p}_{n',1}(t) - \hat{p}_1(t)\|_0^2 dt \rightarrow 0, \quad \text{as } n' \rightarrow \infty.$$

Define

$$\hat{p}_{n'}(t) := \hat{p}_{n',1}(t) + \hat{p}_{n',2}(t), \quad \hat{p}(t) := \hat{p}_1(t) + \hat{p}_2(t);$$

then (3.31) and (3.33) yields and there exists a subsequence of $\{n'\}$ (still denoted by $\{n'\}$) such that

$$(3.34) \quad \hat{p}_{n'} \rightarrow \hat{p} \quad \text{in } \bar{L}^2(0, T; H^0), \quad \text{as } n' \rightarrow \infty, \quad \hat{P}\text{-a.s.}$$

Define

$$\hat{q}_{n'}(t) := e^{M\hat{W}_{n'}(t)} \hat{p}_{n'}(t), \quad \hat{q}(t) := e^{M\hat{W}(t)} \hat{p}(t).$$

Observing (3.28), we have

$$(3.35) \quad \text{law of } (\hat{W}_{n'}, \hat{\mu}_{n'}, \hat{q}_{n'}) = \text{law of } (W_{n'}, \mu_{n'}, q_{n'}).$$

Now we want to show

$$(3.36) \quad \hat{E} \int_0^T \|\hat{q}_{n'}(t) - \hat{q}(t)\|_0^2 dt \rightarrow 0, \quad \text{as } n' \rightarrow +\infty.$$

Indeed, for any $D \subset R^d$ that satisfies (3.10), we have

$$\begin{aligned} & \hat{E} \int_0^T \|\hat{q}_{n'}(t) - \hat{q}(t)\|_{0,D}^2 dt \\ &= \hat{E} \int_0^T \|e^{M\hat{W}_{n'}(t)} \hat{p}_{n'}(t) - e^{M\hat{W}(t)} \hat{p}(t)\|_{0,D}^2 dt \\ &\leq 2\hat{E} \int_0^T \|e^{M\hat{W}_{n'}(t)} (\hat{p}_{n'}(t) - \hat{p}(t))\|_{0,D}^2 dt \\ &\quad + 2\hat{E} \int_0^T \|(e^{M\hat{W}_{n'}(t)} - e^{M\hat{W}(t)}) \hat{p}(t)\|_{0,D}^2 dt = I_3 + I_4, \quad \text{say,} \end{aligned} \quad (3.37)$$

$$\begin{aligned}
I_3 &\leq 2\hat{E} \int_0^T e^{2N|\hat{W}_{n'}(t)|} \|\hat{p}_{n'}(t) - \hat{p}(t)\|_{0,D}^2 dt \\
&\leq 2\hat{E} \left(\sup_{0 \leq t \leq T} e^{2N|\hat{W}_{n'}(t)|} \int_0^T \|\hat{p}_{n'}(t) - \hat{p}(t)\|_{0,D}^2 dt \right) \\
&\leq \text{const} \left\{ \hat{E} \left(\int_0^T \|\hat{p}_{n'}(t) - \hat{p}(t)\|_{0,D}^2 dt \right)^2 \right\}^{1/2}.
\end{aligned}$$

By (3.4), it is easy to see that $\{(\int_0^T \|\hat{p}_{n'}(t) - \hat{p}(t)\|_{0,D}^2 dt)^2\}$ is uniformly integrable on $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$. Thus (3.34) derives $I_3 \rightarrow 0$ as $n' \rightarrow \infty$. Moreover, since for fixed $(t, \hat{\omega})$, $\|(e^{M\hat{W}_{n'}(t)} - e^{M\hat{W}(t)})\hat{p}(t)\|_{0,D}^2 \rightarrow 0$ as $n' \rightarrow \infty$, so by the uniformly integrability of $\{(e^{M\hat{W}_{n'}(t)} - e^{M\hat{W}(t)})\hat{p}(t)\|_{0,D}^2\}$ on $[0, T] \times \hat{\Omega}$, we have $I_4 \rightarrow 0$, as $n' \rightarrow +\infty$. Now we arrive at

$$(3.38) \quad \hat{E} \|\hat{q}_{n'} - \hat{q}\|_{L^2(0,T;H^0)} \rightarrow 0, \quad \text{as } n' \rightarrow +\infty.$$

By (3.38) and (3.16), we can write

$$\begin{aligned}
(3.39) \quad \hat{E} \int_0^T \int_{|x|>\rho} |\hat{q}(t, x)|^2 dx dt &= \lim_{k \rightarrow \infty} \lim_{n' \rightarrow \infty} \hat{E} \int_0^T \int_{\rho < |x| < k} |\hat{q}_{n'}(t, x)|^2 dx dt \\
&\leq CT/(1+\rho^2)^r \rightarrow 0, \quad \text{as } \rho \rightarrow +\infty.
\end{aligned}$$

Hence $\hat{q} \in L^2([0, T] \times \hat{\Omega}; H^0)$, and (3.36) follows from (3.38), (3.39), and (3.16).

By virtue of (3.38), we can prove that \hat{q} is just the response for $\hat{\mathcal{R}} := (\hat{W}, \hat{\mu})$ by a standard argument (cf. [1], [12], and [13]). Noting (3.28)–(3.36), we have proved (3.17). For (3.18), we can apply entirely the same argument, observing the compactness of the embedding: $H^1(D) \rightarrow H^0(D)$. The proof is now complete. \square

Remark 3.1. Condition (A3)_r and $q_0 \in L_r^2$ are required to ensure (3.36) from (3.38). If we drop these conditions, (3.38) still holds, and therefore \hat{q} is still the response of $\hat{\mathcal{R}}$ by the above proof. Thus we have the following corollary.

COROLLARY 3.2. *If we only assume (A1)–(A3) and $q_0 \in H^1$, then whenever $\mathcal{R}_n \rightarrow \mathcal{R}$, we have*

$$(3.40) \quad q^{\mathcal{R}_n}(\cdot, q_0) \rightarrow q^{\mathcal{R}}(\cdot, q_0) \text{ in law, as } w - L^2(0, T; H^1)\text{-r.v.};$$

$$(3.41) \quad q^{\mathcal{R}_n}(T, q_0) \rightarrow q^{\mathcal{R}}(T, q_0) \text{ in law, as } w - H^1\text{-r.v.,}$$

where “ $w - X$ ” denotes the space X endowed with the weak topology.

Now we are in the position to prove the existence of optimal relaxed control for system (2.9) with the cost functional (2.12).

THEOREM 3.2. *In addition to the same assumptions as in Theorem 3.1, we assume*

$$(3.42) \quad F, G \text{ are continuous mappings from } L^2(0, T; H^0) \text{ and } H^0 \text{ to } R^1, \text{ respectively, and there exists } K > 0, \text{ such that}$$

$$|F(\phi)| \leq K(1 + \|\phi\|_{L^2(0,T;H^0)}); \quad |G(\psi)| \leq K(1 + \|\psi\|_0).$$

Then there exists an optimal relaxed control for the system (2.9) with the cost functional (2.12).

Proof. By Theorem 3.1, $J(q_0, \cdot)$ is continuous. However, Π is a compact metric space, which yields the existence of an optimal relaxed control. \square

COROLLARY 3.3. *In addition to the assumptions of Corollary 3.2, we assume*

$$(3.43) \quad F, G \text{ are weakly continuous mappings from } L^2(0, T; H^1) \text{ and } H^1 \text{ to } R^1, \text{ respectively, and satisfy linear growth conditions as in (3.42).}$$

Then there exists an optimal relaxed control.

Proof. The result is a direct consequence of Corollary 3.2. \square

4. Nondegenerate case. In this section we consider the optimal relaxed control problem (2.9) and (2.12) under the assumption that $(a^{ij} - \frac{1}{2}\sigma^i\sigma^j)_{ij}$ is uniformly positive definite. It will be proved that the existence of an optimal relaxed control still holds even when $q_0 \in H^0$.

The following assumptions remain in force throughout this section:

(B1) Same as (A1) in § 3;

(B2) $a^{ij} = a^{ji}$, $i, j = 1, 2, \dots, d$, and there exists $\alpha > 0$ such that

$$(a^{ij}(x, u) - \frac{1}{2}\sigma^i(x)\sigma^j(x))\xi_i\xi_j \geq \alpha|\xi|^2, \quad \text{for any } (x, u, \xi) \in R^d \times \Gamma \times R^d;$$

(B3) $f(\cdot, u) \in H^{-1}$, $g \in H^0$; the absolute values of f, g together with the H^{-1} -norm of $f(\cdot, u)$ and the H^0 -norm of g do not exceed K .

The following proposition is an easy variant of the results in Krylov and Rozovskii [8] and Pardoux [14].

PROPOSITION 4.1. *Suppose $q_0 \in H^0$, then for any $\mathcal{R} \in \mathcal{R}$, (2.9) has a unique solution $q^{\mathcal{R}}(\cdot, q_0) \in L^2([0, T] \times \Omega; H^1) \cap L^2(\Omega; C(0, T; H^0))$ and there exists a constant C , depending only on K, T , and α , such that*

$$(4.1) \quad \sup_{0 \leq t \leq T} E \|q^{\mathcal{R}}(t, q_0)\|_0^2 \leq CE \left\{ \|q_0\|_0^2 + \int_0^T [\|f(s, \mu)\|_{-1}^2 + \|g\|_0^2] ds \right\},$$

$$(4.2) \quad E \left(\int_0^T \|q^{\mathcal{R}}(t, q_0)\|_1^2 dt \right)^2 \leq CE \left\{ \|q_0\|_0^4 + \int_0^T [\|f(s, \mu)\|_{-1}^4 + \|g\|_0^4] ds \right\}.$$

Moreover, for any $p \geq 2$, there exists a constant $C(p)$ such that

$$(4.3) \quad \sup_{0 \leq t \leq T} E \|q^{\mathcal{R}}(t, q_0)\|_0^p \leq C(p)E \left\{ \|q_0\|_0^p + \int_0^T [\|f(s, \mu)\|_{-1}^p + \|g\|_0^p] ds \right\}.$$

THEOREM 4.1. *Assume $q_0 \in H^0$. Denote by $q^{\mathcal{R}}(\cdot, q_0)$ the response for $\mathcal{R} = (W, \mu)$ of the system. Then whenever $\mathcal{R}_n \rightarrow \mathcal{R}$, we have*

$$(4.4) \quad q^{\mathcal{R}_n}(\cdot, q_0) \rightarrow q^{\mathcal{R}}(\cdot, q_0) \text{ in law, as } w - L^2(0, T; H^1)\text{-r.v.};$$

$$(4.5) \quad q^{\mathcal{R}_n}(T, q_0) \rightarrow q^{\mathcal{R}}(T, q_0) \text{ in law, as } w - H^0\text{-r.v.}$$

Proof. For simplicity, we denote $q_n(\cdot) := q^{\mathcal{R}_n}(\cdot, q_0)$, $q(\cdot) := q^{\mathcal{R}}(\cdot, q_0)$, for $\mathcal{R}_n = (W_n, \mu_n)$, $\mathcal{R} = (W, \mu)$.

Define $p_n(t) := e^{-MW_n(t)} q_n(t)$, then

$$\begin{aligned} E \int_0^T \|p_n(t)\|_1^2 dt &\leq E \int_0^T e^{2N|W_n(t)|} \|q_n(t)\|_1^2 dt \\ (4.6) \quad &\leq E \left(\sup_{0 \leq t \leq T} e^{2N|W_n(t)|} \int_0^T \|q_n(t)\|_1^2 dt \right) \\ &\leq \left(E \sup_{0 \leq t \leq T} e^{4N|W_n(t)|} \right)^{1/2} \left\{ E \left(\int_0^T \|q_n(t)\|_1^2 dt \right)^2 \right\}^{1/2}. \end{aligned}$$

So by (4.2), $\sup_n E \int_0^T \|p_n(t)\|_1^2 dt < +\infty$. Now by applying entirely the same argument as that in the proof of Theorem 3.1 and Corollary 3.2, we obtain (4.4). Noting (4.1), we also get (4.5). (But we no longer have $q_n(T) \rightarrow q(T)$ as $w - H^1$ -random variable.) The proof is complete. \square

Now we establish the existence of an optimal relaxed control for the system (2.9) with the cost functional (2.12).

THEOREM 4.2. *Suppose $q_0 \in H^0$ and F, G are weakly continuous mappings from $L^2(0, T; H^1)$ and H^0 , respectively, to R^1 , and they satisfy linear growth conditions. Then there exists an optimal relaxed control.*

5. Discussions and applications.

5.1. Multidimensional Wiener process cases. The method employed in the previous sections is somewhat similar to the *time change* technique in stochastic analysis. This method, however, fails to be effective in general for the system as follows:

$$(5.1) \quad \begin{aligned} dq(t) &= (A(t, \mu)q(t) + f(t, \mu)) dt + \sum_{k=1}^{d'} (M_k q(t) + g_k) dW^k(t), \\ q(0) &= q_0, \end{aligned}$$

where $W := (W^1, \dots, W^{d'})$ is a d' -dimensional Wiener process, and A, M_k have the same forms as (2.1) and (2.2).

However, in some special cases, we can still treat (5.1) by a similar argument to the one-dimensional Wiener process cases.

THEOREM 5.1. *Assume the coefficients of A, M_k ($k = 1, 2, \dots, d'$) satisfy (A1) and (A2) of § 3 (respectively, (B1) and (B2) of § 4). Assume further that*

$$(5.2) \quad M_k M_j = M_j M_k, \quad \text{for } k \neq j,$$

then Theorem 3.2 and Corollary 3.3 (respectively, Theorem 4.2) hold for the system (5.1).

Proof. We will show this for $d' = 2$ for simplicity. By the proofs in the previous sections, it suffices to prove that we can construct a transformation $q \rightarrow p$, such that p satisfies an SPDE whose diffusion term is independent of the state (refer to Proposition 3.3). To this end, define $p_1(t) := e^{-M_1 W^1(t)} q(t)$, then a similar calculation to that of Proposition 3.3 gives that p_1 satisfies the following differential formula in H^{-1} space:

$$(5.3) \quad \begin{aligned} dp_1(t) &= e^{-M_1 W^1(t)} \{ (A(t, \mu) - \tfrac{1}{2} M_1^2) q(t) + f(t, \mu) - M_1 g_1 \} dt \\ &\quad + e^{-M_1 W^1(t)} g_1 dW^1(t) + \{ e^{-M_1(t) W^1(t)} (M_2 q(t) + g_2) \} dW^2(t). \end{aligned}$$

Put $p(t) := e^{-M_2 W^2(t)} p_1(t)$, then, for any $\phi \in H^1$,

$$(5.4) \quad \begin{aligned} d(p(t), \phi)_0 &= d(p_1(t), e^{-M_2^* W^2(t)} \phi)_0 \\ &= \langle e^{-M_1 W^1(t)} \{ (A(t, \mu) - \tfrac{1}{2} M_1^2) q(t) + f(t, \mu) - M_1 g_1 \}, e^{-M_2^* W^2(t)} \phi \rangle_0 dt \\ &\quad + (e^{-M_1 W^1(t)} g_1, e^{-M_2^* W^2(t)} \phi)_0 dW^1(t) \\ &\quad + (e^{-M_1 W^1(t)} (M_2 q(t) + g_2), e^{-M_2^* W^2(t)} \phi)_0 dW^2(t) \\ &\quad + (p_1(t), \tfrac{1}{2} M_2^{*2} e^{-M_2^* W^2(t)} \phi)_0 dt - (p_1(t), M_2^* e^{-M_2^* W^2(t)} \phi)_0 dW^2(t) \\ &\quad + (e^{-M_1 W^1(t)} (M_2 q(t) + g_2), -M_2^* e^{-M_2^* W^2(t)} \phi)_0 dt \\ &= \langle (A(t, \mu) - \tfrac{1}{2} M_1^2 - \tfrac{1}{2} M_2^2) q(t), e^{-M_1 W^1(t)} e^{-M_2^* W^2(t)} \phi \rangle_0 dt \\ &\quad + (e^{-M_2 W^2(t)} e^{-M_1 W^1(t)} (f(t, \mu) - M_1 g_1 - M_2 g_2), \phi)_0 dt \\ &\quad + (e^{-M_2 W^2(t)} e^{-M_1 W^1(t)} g_1, \phi)_0 dW^1(t) \\ &\quad + (e^{-M_2 W^2(t)} e^{-M_1 W^1(t)} g_2, \phi)_0 dW^2(t). \end{aligned}$$

Note that in the above calculation, we have repeatedly employed the fact that $e^{M_1 t'} M_2|_{H^1} = M_2 e^{M_1 t'}|_{H^1}$, which is an easy consequence of the fact that $M_1 M_2 = M_2 M_1$. Now (5.4) has a similar form to (3.12), which allows us to apply the same argument as those in §§ 3 and 4 to obtain the desired results. \square

Remark 5.1. Equation (5.2) holds when the coefficients of $\{M_k\}$ are constants or satisfy some linear dependence conditions.

Remark 5.2. In particular, (5.2) holds for the following kind of systems:

$$(5.5) \quad \begin{aligned} dq(t) &= (A(t, \mu)q(t) + f(t, \mu)) dt + \sum_{k=1}^{d'} (h_k q(t) + g_k) dW^k(t), \\ q(0) &= q_0, \end{aligned}$$

where $h_k: R^d \rightarrow R^1$. The above system has been studied by Bensoussan and Nisio [1] (with $f = g_k = 0$). Their result is [1, Thm. 5.2]: if (a^{ij}) is uniformly positive definite and $q_0 \in H^2(R^d)$, then there exists an optimal relaxed control. Now we know the condition “ $q_0 \in H^2(R^d)$ ” can be weakened to “ $q_0 \in L^2(R^d)$ ”; on the other hand, if we assume $q_0 \in H^1(R^d)$, then the result is valid even if (a^{ij}) is degenerate.

5.2. Stochastic control with partial observation. First, let us remark that the results in §§ 3 and 4 are easily extended to the following kind of system:

$$(5.6) \quad \begin{aligned} dq(t) &= (\tilde{A}(t, W(t), \mu)q(t) + \tilde{f}(t, W(t), \mu)) dt + (Mq(t) + g(W(t))) dW(t), \\ q(0) &= q_0, \end{aligned}$$

where

$$\begin{aligned} \tilde{A}(t, w, \mu)\phi(x) &:= \partial_i(\tilde{a}^{ij}(t, x, w, \mu)\partial_j\phi(x)) + \tilde{b}^i(t, x, w, \mu)\partial_i\phi(x) \\ &\quad + \tilde{c}(t, x, w, \mu)\phi(x), \\ M\phi(x) &:= \sigma^i(x)\partial_i\phi(x) + h(x)\phi(x), \\ \tilde{a}^{ij}(t, x, w, \mu) &:= \int_{\Gamma} a^{ij}(x, w, u)\mu'(t, du), \quad \text{etc.} \end{aligned}$$

Let B and \hat{B} be independent Wiener processes on a probability space (Ω, \mathcal{F}, P) , with values in R^1 and R^d , respectively. Consider the following SPDE in R^d :

$$(5.7) \quad \begin{aligned} dX(t) &= \gamma(X(t), Y(t), U(t)) dt + \alpha(X(t), Y(t), U(t)) d\hat{B}(t) + \sigma(X(t)) dB(t), \\ X(0) &= \xi, \end{aligned}$$

with the observation

$$(5.8) \quad dY(t) = \kappa(X(t)) dt + dB(t), \quad Y(0) = 0,$$

where U is an admissible control. Note that σ is the correlation between the state and the observation.

Let Ξ and $L: R^d \times R^1 \rightarrow R^1$. The problem is to minimize the cost functional defined by

$$(5.9) \quad J(U) := E \left\{ \int_0^T \Xi(X(t), Y(t)) dt + L(X(t), Y(t)) \right\},$$

over the totality of admissible controls.

By the well-known relationship between the control problem for partially observed diffusions and that for SPDEs (cf. [12]–[15]), we may interpret the problem (5.7)–(5.9) to the one we have treated in the previous sections. Thus we have the following theorem, appealing to Corollary 3.3 and Theorem 4.2.

THEOREM 5.2. *We make the following assumptions:*

- (C1) $\alpha: R^d \times R^1 \times \Gamma \rightarrow R^{d \times d}$, $\sigma: R^d \rightarrow R^d$, $\gamma: R^d \times R^1 \times \Gamma \rightarrow R^d$, $\kappa: R^d \rightarrow R^1$ are continuous functions. α , σ and their derivatives in x up to fourth order do not exceed a constant K in absolute value; γ , κ , and their derivatives in x up to third order do not exceed K in absolute value;

(C2) $\Xi, L: R^d \times R^1 \rightarrow R^1$ are Lipschitz continuous and bounded by K .

Then there exists an optimal relaxed control of the problem (5.7)–(5.9), if we assume, in addition, either of the following two conditions:

- (i) ξ has a density $q_0 \in H^1$;
- (ii) ξ has a density $q_0 \in H^0$, and $\alpha\alpha^*(x, y, u)$ is uniformly positive definite.

Remark 5.3. In [12] and [13], in addition to the higher regularity condition on q_0 , it is required that $(\alpha\alpha^* - 2\sigma\sigma^*)$ be nonnegative definite, which means the correlation cannot be “too large.” In this paper, this restriction is removed.

Let us conclude the paper by two remarks.

Remark 5.4. The relaxed controls turn out to be (usual) admissible controls when assuming some convex conditions (Roxin’s conditions) on the coefficients a^{ij} , etc. The reader may refer to [1], [13] for details.

Remark 5.5. The aim of this paper is to reduce the regularity on the initial state. In the viewpoint of filtering problems, it is more natural to consider the Dirac initial state, although it seems to be a rather difficult problem since the SPDE theory itself with the Dirac initial condition has not been well established.

Appendix. In this appendix, we prove Proposition 3.2.

On the space H^0 , consider the following densely defined operator:

$$(A.1) \quad M: \begin{cases} D(M) & (= \text{the domain of } M) := H^1 \\ M\phi(x) := \sigma^i(x)\partial_i\phi(x) + h(x)\phi(x), & \text{for } \phi \in H^1, \quad x \in R^d. \end{cases}$$

M thus defined is not a closed operator, but it is clearly closable. Denote by \bar{M} the closed extension of M (i.e., the graph of \bar{M} is the closure of the graph of M). On the other hand, M^* , the adjoint operator of M on H^0 , is given by

$$(A.2) \quad M^*: \begin{cases} D(M^*) = \{\phi \in H^0: -\partial_i(\sigma^i\phi) + h\phi \in H^0\}, \\ M^*\phi(x) = -\partial_i(\sigma^i(x)\phi(x)) + h(x)\phi(x), & \text{for } \phi \in D(M^*), \quad x \in R^d. \end{cases}$$

Since H^0 is reflexive, so $\bar{M} \equiv M^{**}$, which is given by

$$(A.3) \quad \bar{M}: \begin{cases} D(\bar{M}) = \{\phi \in H^0: \sigma^i\partial_i\phi + h\phi \in H^0\}, \\ \bar{M}\phi(x) = \sigma^i(x)\partial_i\phi(x) + h(x)\phi(x), & \text{for } \phi \in D(\bar{M}), \quad x \in R^d. \end{cases}$$

Moreover, $\bar{M}^* = M^{***} = M^*$.

LEMMA A.1. There exists a constant N , which is given in Corollary 3.1, such that

$$(A.4) \quad |(\bar{M}\phi, \phi)_0| \leq N \|\phi\|_0^2, \quad \text{for } \phi \in D(\bar{M});$$

$$(A.5) \quad |(\bar{M}^*\phi, \phi)_0| \leq N \|\phi\|_0^2, \quad \text{for } \phi \in D(\bar{M}^*).$$

Proof. Since \bar{M} is the closed extension of M , for $\phi \in D(\bar{M})$, there exist $\{\phi_n\} \subset H^1$, such that $\phi_n \xrightarrow{H^0} \phi$, $M\phi_n \xrightarrow{H^0} \bar{M}\phi$. Hence (A.4) follows from Corollary 3.1. On the other hand, \bar{M}^* is the closed extension of $K\phi := -\partial_i(\sigma^i\phi) + h\phi$ with $D(K) := H^1$, so (A.5) is proved by a similar argument. \square

Proof of Proposition 3.2. Let $\lambda \in R^1$ such that $|\lambda| > N$. For $\phi \in D(\bar{M})$, set $\psi := (\lambda I - \bar{M})\phi$, then

$$(A.6) \quad |(\psi, \phi)_0| \geq |\lambda| \|\phi\|_0^2 - |(\bar{M}\phi, \phi)_0| \geq (|\lambda| - N) \|\phi\|_0^2,$$

which yields $\lambda I - \bar{M}$ is one-to-one, and $\text{Range}(\lambda I - \bar{M})$ is a closed set in H^0 . However, by virtue of (A.5), $\lambda I - \bar{M}^*$ is also one-to-one; thus $\text{Range}(\lambda I - \bar{M}) = \text{Ker}(\lambda I - \bar{M}^*)^\perp = H^0$. Then, by (A.6), λ is in the resolvent set of \bar{M} , and

$$(A.7) \quad \|(\lambda I - \bar{M})^{-1}\|_{L(H^0 \rightarrow H^0)} \leq (|\lambda| - N)^{-1}.$$

By [2, Cor. 17, p. 628], \bar{M} generates a strongly continuous group $\{e^{\bar{M}t}; -\infty < t < +\infty\}$ on H^0 and (3.5) holds.

On the space H^1 , consider the following densely defined operator M_1 :

$$(A.8) \quad M_1: \begin{cases} D(M_1) := H^2, \\ M_1\phi(x) := \sigma^i(x)\partial_i\phi(x) + h(x)\phi(x), \quad \phi \in H^2, \quad x \in R^d. \end{cases}$$

There is also a closed extension \bar{M}_1 of M_1 . By virtue of Corollary 3.1,

$$|(\bar{M}_1\phi, \phi)_1| \leq N\|\phi\|_1^2, \quad \text{for } \phi \in D(\bar{M}_1).$$

So by a similar argument as above, \bar{M}_1 generates a strongly continuous group $\{e^{\bar{M}_1 t}; -\infty < t < +\infty\}$ on H^1 , and

$$(A.9) \quad \|e^{\bar{M}_1 t}\|_{L(H^1 \rightarrow H^1)} \leq e^{N|t|}, \quad \text{for } t \in (-\infty, +\infty).$$

For $\phi \in H^2 \subset D(\bar{M}_1)$, since obviously $\bar{M} \equiv \bar{M}_1$ on $D(\bar{M}_1)$,

$$(A.10) \quad d(e^{\bar{M}_1 t}\phi)/dt = \bar{M}_1 e^{\bar{M}_1 t}\phi = \bar{M}e^{\bar{M}_1 t}\phi,$$

where “ d/dt ” is in H^1 -topology. Consequently, (A.10) holds on H^0 , which means $e^{\bar{M}_1 t}\phi = e^{\bar{M}t}\phi$ for any $\phi \in H^2$. However, H^2 is dense in H^1 , so $e^{\bar{M}_1 t}|_{H^1} \equiv e^{\bar{M}t}$. Now (3.6) follows from (A.9). This proves (i) of Proposition 3.2.

Note \bar{M}^* is also a closed extension of a first-order differential operator K , so (ii) of Proposition 3.2 is proved in a completely analogous way to (i). Moreover, since H^0 is reflexive, $e^{\bar{M}^* t} \equiv (e^{\bar{M}t})^*$.

Finally, (iii) of Proposition 3.2 is clear. \square

Acknowledgments. The author expresses his sincere thanks to Professor M. Nisio for bringing the author's interest to the present subject, and for her encouragement and discussion during the course of this research. Thanks are also due to the referees for many helpful criticism and comments.

A GAME THEORETIC APPROACH TO \mathcal{H}^∞ CONTROL FOR TIME-VARYING SYSTEMS*

DAVID J. N. LIMEBEER†, BRIAN D. O. ANDERSON‡, PRAMOD P. KHARGONEKAR§,
AND MICHAEL GREEN†

Abstract. A representation formula for all controllers that satisfy an \mathcal{L}^∞ -type constraint is derived for time-varying systems. It is now known that a formula based on two indefinite algebraic Riccati equations may be found for time-invariant systems over an infinite time support (see [J. C. Doyle et al., *IEEE Trans. Automat. Control*, AC-34 (1989), pp. 831–847]; [K. Glover and J. C. Doyle, *Systems Control Lett.*, 11 (1988), pp. 167–172]; [K. Glover et al., *SIAM J. Control Optim.*, 29 (1991), pp. 283–324]; [M. Green et al., *SIAM J. Control Optim.*, 28 (1990), pp. 1350–1371]; [D. J. N. Limebeer et al., in *Proc. IEEE conf. on Decision and Control*, Austin, TX, 1988]; [G. Tadmor, *Math. Control Systems Signal Processing*, 3 (1990), pp. 301–324]). In the time-varying case, two indefinite Riccati differential equations are required. A solution to the design problem exists if these equations have a solution on the optimization interval. The derivation of the representation formula illustrated in this paper makes explicit use of linear quadratic differential game theory and extends the work in [J. C. Doyle et al., *IEEE Trans. Automat. Control*, AC-34 (1989), pp. 831–847] and [G. Tadmor, *Math. Control Systems Signal Processing*, 3 (1990), pp. 301–324]. The game theoretic approach is particularly simple, in that the background mathematics required for the sufficient conditions is little more than standard arguments based on “completing the square.”

Key words. \mathcal{H}^∞ -optimal control, game theory, indefinite Riccati equations, four-block general distance problems, worst-case design

1. Introduction. Since the early 1980s, numerous techniques have been developed for solving \mathcal{H}^∞ -control problems. In addition to their individual interest, further insights have been gained by studying the interplay between these various methodologies, and researchers have now acquired a good understanding of several aspects of the theory. Over the last two years, there has been a flurry of activity that has had a significant impact on both the accessibility of the theoretical ideas and the ease of computation. Once an \mathcal{H}^∞ -norm bound has been decided, and provided that a solution exists, the computational burden associated with finding all \mathcal{H}^∞ controllers is essentially the same as that required in solving a linear quadratic Gaussian regulator problem [9], [10], [11], [13], [20], [21], [27]. \mathcal{H}^∞ problems in which perfect information is assumed may be solved using a single Riccati equation with dimension equal to that of the problem [18], [19], [23], while the output-feedback problem requires the solution of two Riccati equations.

The “two Riccati equation” formula for all stabilizing controllers satisfying a closed loop \mathcal{H}^∞ -norm constraint has been derived in a number of ways. A state-space solution via the “four-block” problem is reported in [11], [21], while an alternative approach reminiscent of classical linear quadratic theory may be found in [9]. A solution based on J -spectral factorization theory is given in [2], [13], while the related notion of conjugation is used in [20]. An interesting by-product of this activity has

been the discovery of a number of new interconnections. In [19], [28], the authors note a connection between \mathcal{H}^∞ -control and game theory. The interplay between indefinite factorization and game theory, probably first noted by Banker [3], has been rediscovered in the more general setting of \mathcal{H}^∞ control [10], [13], [22]. The connection between risk-sensitive optimal control [10], [30] and game theory, originally discovered by Jacobson in the perfect-information case [17], has also received renewed interest in the wider setting of \mathcal{H}^∞ control [7], [10]. More recently still, Tadmor [27] has given results on the finite-horizon time-varying case using the maximum principle.

The aim of the present paper, which builds on the work given in [9] and [27], is to give a solution to the finite-horizon time-varying \mathcal{H}^∞ -control problems, which makes explicit use of the existing theory of linear quadratic games. This approach offers the advantage of introducing game theoretic intuition to the solution path, and also gives a game theoretic interpretation to the change of variable introduced in [9]. We also show that the main infrastructure of a time-varying \mathcal{H}^∞ -control theory may be developed using classical arguments based on completing the square. This simple solution is possible because of the linear quadratic (LQ) nature of the problem, and, as a final comment, we mention that we have been able to remove all the removable assumptions in [27].

In this paper we will consider the finite-dimensional linear time-varying plant

$$(1.1a) \quad \begin{bmatrix} z \\ y \end{bmatrix} = \begin{bmatrix} \mathfrak{P}_{11} & \mathfrak{P}_{12} \\ \mathfrak{P}_{21} & \mathfrak{P}_{22} \end{bmatrix} \begin{bmatrix} w \\ u \end{bmatrix},$$

which has a time-varying state-space realization

$$(1.1b) \quad \begin{matrix} n \\ p \\ q \end{matrix} \begin{bmatrix} \hat{x} \\ z \\ y \end{bmatrix} (t) = \begin{bmatrix} \overset{n}{A} & \overset{l}{B_1} & \overset{m}{B_2} \\ C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{22} \end{bmatrix} (t) \begin{bmatrix} x \\ w \\ u \end{bmatrix} (t), \quad x(0) = 0.$$

The class of controls of interest is given by $u = \mathfrak{R}y$, where \mathfrak{R} is a linear time-varying (LTV) controller. Eliminating u and y gives rise to the closed loop operator $z = \mathfrak{R}w$, where $\mathfrak{R} = \mathfrak{P}_{11} + \mathfrak{P}_{12}\mathfrak{R}(I - \mathfrak{P}_{22}\mathfrak{R})^{-1}\mathfrak{P}_{21}$. Our goals are (1) to give necessary and sufficient conditions for the existence of LTV controllers such that $\|z\|_2 < \gamma\|w\|_2$ for all $w \neq 0$ and a given γ ($\|\cdot\|_2$ denotes the norm on $\mathcal{L}^2[0, T]$), and (2) to characterize all such controllers when they exist. We assume that the matrices in (1.1) have entries that are continuous functions of time, that D_{12} has full column rank m for all $t \in [0, T]$, and that D_{21} has full row rank q for all $t \in [0, T]$. The game theoretic nature of the problem is immediate: Roughly speaking, the w -player tries to maximize the energy in z , while the controller or u -player simultaneously seeks to minimize it.

Section 2 has a large tutorial component and deals with the time-varying problem in which perfect information is assumed. Section 2.1 establishes the necessary conditions for the existence of a solution to the \mathcal{H}^∞ -control problem via a conjugate point argument. We then show that \mathcal{H}^∞ -control problems with perfect information may be solved if and only if a solution to the Riccati differential equation (RDE) exists on $[0, T]$. Section 2.2 presents a representation formula for all solutions to the time-varying \mathcal{H}^∞ -control problem in the perfect-information case. A brief review of some pertinent properties of adjoint systems is given in § 2.3. Section 2.4 partially reconciles the more familiar time-invariant infinite-horizon \mathcal{H}^∞ -control problem with the time-varying finite-horizon case. This reconciliation calls for a connection between the limiting solution of the RDE and its algebraic counterpart.

Section 3 contains the main results of the paper. We begin with an analysis of problems in which both D_{12} and D_{21} are assumed to be square. A solution is found by calculating a plant inverse, and does not require the solution of any Riccati equations. It is interesting that the plant inverse has an observer structure that is indicative of the solution in the general case. Following that, we treat problems in which either D_{12} or D_{21} is square. Every problem of this type requires the solution of a single RDE. Finally, we treat the case in which neither D_{12} nor D_{21} is square, and we show that in these cases two RDEs are required. We give necessary and sufficient conditions for the existence of solutions and characterize all solutions (when they exist).

2. \mathcal{H}^∞ control and linear quadratic differential games. Numerous variants of the linear quadratic differential game have been studied over the last twenty years. As an example of the extensive literature on the subject, we refer the interested reader to Basar and Olsder [4] and the references therein. The purpose of this section is to review those aspects of the existing game theory literature that are relevant to the solution of the time-varying \mathcal{H}^∞ -control problem, and to study the connections between the two. We begin by considering a system with input vectors $u(t)$ and $w(t)$, dynamical description

$$(2.1) \quad \dot{x}(t) = A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \quad x(0) = 0,$$

and output,

$$(2.2) \quad z(t) = \begin{bmatrix} C(t)x(t) \\ D(t)u(t) \end{bmatrix}.$$

We will assume that $D(t)$ has full column rank, and that it has been scaled so that

$$(2.3) \quad D'(t)D(t) = I.$$

Each of the matrices in (2.1) and (2.2) is assumed to have entries that are continuous functions of time. In the interests of notational compactness, this time dependence will not always be shown from now on.

With (2.1)–(2.3) given, the \mathcal{H}^∞ -control problem is to find a linear causal control $u(t) = K(x(s), w(s), t)$, $0 \leq s \leq t$, such that $\|\mathcal{T}_{zw}\| = \sup_w \{\|\mathcal{T}_{zw}w\|_2 : w \in \mathcal{L}^2[0, T], \|w\|_2 \leq 1\} < \gamma$ for some given $\gamma > 0$. The operator \mathcal{T}_{zw} maps w to z when the control $u(t) = K(\cdot, \cdot, \cdot)$ is in place. If $z = \mathcal{T}_{zw}w$, then $\|\mathcal{T}_{zw}\| < \gamma$ if and only if

$$(2.4) \quad J(K, w) = \int_0^T (z'z - \gamma^2 w'w) dt \leq -\varepsilon \|w\|_2^2$$

for all $w \in \mathcal{L}^2[0, T]$ and some positive ε .

In the language of game theory, the \mathcal{H}^∞ -control problem is a leader-follower game and requires the control system designer to make the first move and select an admissible $u(t) = K(\cdot, \cdot, \cdot)$ that minimizes $J(K, w)$. A control functional $K(\cdot, \cdot, \cdot)$ is admissible if (1) $u(t) \in \mathcal{L}^2[0, T]$ for every $w(t) \in \mathcal{L}^2[0, T]$, and (2) $x(0) = 0$ and $w(t) \equiv 0 \Rightarrow u(t) \equiv 0$; we denote the set of admissible control functionals \mathcal{C} . After the designer's choice of control strategy has been made public, we assume that nature is malicious and selects that $w(t) \in \mathcal{L}^2[0, T]$, which maximizes (2.4). The \mathcal{H}^∞ -control problem therefore has a solution if and only if

$$(2.5) \quad \min_{K \in \mathcal{C}} \max_{w \in \mathcal{L}^2[0, T]} \{J(K, w)\} \leq -\varepsilon \|w\|_2^2$$

is satisfied. In the notation of (2.5), the w -player maximizes $J(K, w)$ over all $w \in \mathcal{L}^2[0, T]$ after the u -player has announced a choice of $K \in \mathcal{C}$.

Before studying the minimax problem (2.5) in detail, it is interesting to reconcile it with the classical linear quadratic optimal regulator. If we allow γ to increase without bound, then it is necessarily the case that the energy in $w(t)$ decreases to zero, rendering the w -player impotent. The game thus degenerates to the optimal regulator [1] as γ is increased without bound.

Our first result is based on a standard completion of squares argument [4, p. 290], and shows that the \mathcal{H}^∞ -control problem has a solution if a particular RDE has a solution on the time interval $[0, T]$.

THEOREM 2.1. *Suppose that the RDE*

$$(2.6) \quad -\dot{P} = PA + A'P - P(B_2B_2' - \gamma^{-2}B_1B_1')P + C'C, \quad P(T) = 0$$

has a solution on $[0, T]$. Then

$$(2.7) \quad u^* = -B_2'Px,$$

$$(2.8) \quad w^* = \gamma^{-2}B_1'Px$$

result in

$$(2.9) \quad \|z\|_2^2 - \gamma^2\|w\|_2^2 = \|u - u^*\|_2^2 - \gamma^2\|w - w^*\|_2^2$$

for any u (either open or closed loop) and $w \in \mathcal{L}^2[0, T]$ in (2.1), noting that $x(0) = 0$. With $u = u^$, we have*

$$(2.10) \quad \|\mathcal{J}_{zw}\| < \gamma.$$

Proof. Since (2.6) is assumed to have a solution on $[0, T]$ with $P(T) = 0$, we have, for any u and w , and $x(0) = 0$,

$$\begin{aligned} J(u, w) &= \int_0^T \left\{ z'z - \gamma^2 w'w + \frac{d}{dt}(x'Px) \right\} dt \\ &= \int_0^T \{ x'C'Cx + u'u - \gamma^2 w'w + (x'A' + w'B_1' + u'B_2')Px \\ &\quad + x'\dot{P}x + x'P(Ax + B_1w + B_2u) \} dt. \end{aligned}$$

Substituting from (2.6) gives us

$$\begin{aligned} J(u, w) &= \int_0^T \left\{ x'P(B_2B_2' - \gamma^{-2}B_1B_1')Px + u'u - \gamma^2 w'w \right. \\ &\quad \left. + [w' \quad u'] \begin{bmatrix} B_1' \\ B_2' \end{bmatrix} Px + x'P \begin{bmatrix} B_1 & B_2 \end{bmatrix} \begin{bmatrix} w \\ u \end{bmatrix} \right\} dt \\ (2.11) \quad &= \int_0^T [u' + x'PB_2][u + B_2'Px] dt \\ &\quad - \int_0^T [w' - x'\gamma^{-2}PB_1]\gamma^2[w - \gamma^{-2}B_1'Px] dt \\ &= \|u - u^*\|_2^2 - \gamma^2\|w - w^*\|_2^2 \end{aligned}$$

with w^*, u^* as in (2.7) and (2.8), which establishes (2.9). Suppose that \mathcal{L} is the operator with realization

$$\dot{x} = (A + B_2K)x + B_1w, \quad (w - w^*) = -\gamma^{-2}B_1'Px + w,$$

which maps w to $(w - w^*)$. Since \mathcal{L}^{-1} exists (and is given by $\hat{x} = (A + B_2K + \gamma^{-2}B_1B_1'P)x + B_1(w - w^*)$, $w = \gamma^{-2}B_1'Px + (w - w^*)$), we can write

$$\|\mathcal{T}_{zw}w\|_2^2 - \gamma^2\|w\|_2^2 = -\gamma^2\|w - w^*\|_2^2 = -\gamma^2\|\mathcal{L}w\|_2^2 \leq -\kappa\|w\|_2^2$$

for some positive κ . Thus $\|\mathcal{T}_{zw}\| < \gamma$, as required. \square

Remark 2.1 (Positive semidefiniteness of $P(t)$). It is not hard to show that if (2.6) with $P(T) = 0$ has a solution on $[0, T]$, then $P(t) \geq 0$ for all $t \in [0, T]$. Consider system (2.1) with $0 \leq t_o \leq t \leq T$, and with $x(t_o) = x_o$. If

$$(2.12) \quad J_{t_o}(u, w) := \int_{t_o}^T (z'z - \gamma^2 w'w) dt,$$

then we may complete the square as above to yield

$$J_{t_o}(u, w) - x_o'P(t_o)x_o = \|u - u^*\|_2^2 - \gamma^2\|w - w^*\|_2^2,$$

in which x_o is regarded as an arbitrary initial condition for the running period $[t_o, T] \subseteq [0, T]$. Consequently,

$$(2.13) \quad J_{t_o}(u^*, 0) + \gamma^2\|w^*\|_2^2 = x_o'P(t_o)x_o$$

for every x_o . Since $J_{t_o}(u^*, 0) \geq 0$ for any x_o , it follows that $P(t) \geq 0$ for all $t \in [0, T]$.

Note that the game Riccati equation (2.6) and the corresponding linear quadratic regulator Riccati equation “approach each other” as γ increases. Since the linear quadratic regulator Riccati equation always has a solution, we expect (2.6) to have a solution if γ is large enough. In the next section, we show that the existence of an admissible controller satisfying (2.5) is a necessary condition for (2.6) to have a solution on $[0, T]$.

2.1. The necessary conditions. The aim of this section is to show that if an admissible feedback control exists that solves the \mathcal{H}^∞ -control problem, then (2.6) has a solution on $[0, T]$. Our proof uses conjugate point arguments that are reminiscent of those found in [25], [26]. To begin, we introduce the two-point boundary value problem

$$(2.14) \quad \begin{bmatrix} \dot{x} \\ \dot{p} \end{bmatrix} = \begin{bmatrix} A & -(B_2B_2' - \gamma^{-2}B_1B_1') \\ -C'C & -A' \end{bmatrix} \begin{bmatrix} x \\ p \end{bmatrix}, \quad \begin{bmatrix} x(0) \\ p(T) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

and its associated transition matrix, which is generated by the linear differential equation

$$(2.15) \quad \begin{bmatrix} \Phi_{11} & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{bmatrix}(t, T) = \begin{bmatrix} A & -(B_2B_2' - \gamma^{-2}B_1B_1') \\ -C'C & -A' \end{bmatrix} \begin{bmatrix} \Phi_{11} & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{bmatrix}(t, T),$$

with $\Phi(T, T) = I$. Next, we note that

$$\begin{aligned} -\frac{d}{dt}(\Phi_{21}\Phi_{11}^{-1}) &= -\dot{\Phi}_{21}\Phi_{11}^{-1} + \Phi_{21}\Phi_{11}^{-1}\dot{\Phi}_{11}\Phi_{11}^{-1} \\ &= A'(\Phi_{21}\Phi_{11}^{-1}) + (\Phi_{21}\Phi_{11}^{-1})A - (\Phi_{21}\Phi_{11}^{-1})(B_2B_2' - \gamma^{-2}B_1B_1')(\Phi_{21}\Phi_{11}^{-1}) \\ &\quad + C'C. \end{aligned}$$

Thus, if $\Phi_{11}^{-1}(t, T)$ exists on $t \in [0, T]$, the RDE (2.6) has a solution on $[0, T]$ given by $P(t) = \Phi_{21}(t, T)\Phi_{11}^{-1}(t, T)$.

The existence of $\Phi_{11}^{-1}(t, T)$ is equivalent to a conjugate point condition, and this observation forms the basis of the necessity proof.

DEFINITION 2.1. Suppose that $t_o < t_f$. Then t_o and t_f are *conjugate points* if it is possible to find a *nontrivial* solution to (2.14) such that $x(t_o) = p(t_f) = 0$. We note also that $p(t_o) \neq 0$ and $x(t_f) \neq 0$, since otherwise (2.14) would only have the trivial solution $[x' \ p'](t) \equiv 0$.

LEMMA 2.2. The matrix $\Phi_{11}(t_o, t_f)$ defined by (2.15) is singular if and only if t_o and t_f are conjugate points.

Proof. Suppose that t_o and t_f are conjugate points. Since

$$\begin{bmatrix} x(t_o) \\ p(t_o) \end{bmatrix} = \begin{bmatrix} \Phi_{11} & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{bmatrix} (t_o, t_f) \begin{bmatrix} x(t_f) \\ p(t_f) \end{bmatrix},$$

and since t_o and t_f are conjugate points, we obtain

$$(2.16) \quad 0 = \Phi_{11}(t_o, t_f)x(t_f).$$

Hence $\Phi_{11}(t_o, t_f)$ is singular, as $x(t_f)$ is nonzero.

If, on the other hand, $\Phi_{11}(t_o, t_f)$ is singular, there exists a vector $g \neq 0$ such that $\Phi_{11}(t_o, t_f)g = 0$. By considering the final value problem with $x(t_f) = g$ and $p(t_f) = 0$, we see that $x(t_o) = 0$, which establishes that t_o and t_f are conjugate. \square

THEOREM 2.3. Consider the linear system (2.1). If there exists a closed loop control $\bar{K} \in \mathcal{C}$ such that

$$(2.17) \quad \|\mathcal{T}_{zw}\| < \gamma,$$

then $\Phi_{11}(t, T)$ is nonsingular for all $t \in [0, T]$. Consequently, the RDE (2.6), with boundary condition $P(T) = 0$, has a solution on $[0, T]$.

Proof. We suppose for contradiction that $t^* \in [0, T]$ is the largest time such that $\Phi_{11}(t^*, T)$ is singular. Since $\Phi_{11}(T, T) = I$, $t^* < T$ by continuity. It follows from Lemma 2.2 that t^* and T are conjugate points, giving $x(t^*) = p(T) = 0$. Next, we suppose that

$$\bar{w}(t) = \begin{cases} \gamma^{-2} B_1' p(t), & t^* \leq t \leq T, \\ 0, & 0 \leq t < t^*. \end{cases}$$

Since (2.14) has a nontrivial solution, $p(t) \neq 0$ $t \in [t^*, T]$. Furthermore, if $B_1' p(t) \equiv 0$, then (under this assumption) (2.14) becomes the two-point boundary problem for the LQ regulator; this can have no conjugate points [1]. Thus $\bar{w}(t) \neq 0$. Next, we see that $J(\bar{K}, \bar{w}) \geq J_{t^*}(\bar{K}, \bar{w})$, since $\bar{w}(t) = 0$ for $t < t^*$. Let $\tilde{u}(t)$ be the function generated by $x(t^*) = 0$, \bar{K} and $\bar{w}(t)$. Then it follows that

$$(2.18a) \quad J_{t^*}(\bar{K}, \bar{w}) = J_{t^*}(\tilde{u}, \bar{w}) \geq \min_{u(t)} \int_{t^*}^T \{ \tilde{x}' C' C \tilde{x} + u' u - \gamma^2 \bar{w}' \bar{w} \} dt,$$

subject to

$$(2.18b) \quad \dot{\tilde{x}} = A \tilde{x} + B_1 \bar{w} + B_2 u, \quad \tilde{x}(t^*) = 0.$$

The tilde is used to distinguish the state trajectory associated with (2.14) from that associated with the minimization problem in (2.18). The initial condition $\tilde{x}(t^*) = 0$ is a consequence of (i) $x(0) = 0$, (ii) $\bar{w} \equiv 0$ for all $t \in [0, t^*)$, and (iii) $K \in \mathcal{C}$. The minimization on the right-hand side of (2.18a) subject to (2.18b), with $u(\cdot)$ being sought in *open-loop* form is almost a standard LQ control problem and is solved as follows: Form

$$H(t, \tilde{x}, \lambda, u) = \frac{1}{2} (\tilde{x}' C' C \tilde{x} + u' u - \gamma^2 \bar{w}' \bar{w}) + \lambda (A \tilde{x} + B_1 \bar{w} + B_2 u).$$

Then

$$\frac{\partial H}{\partial u} = 0 \Rightarrow u_{\min} = -B_2' \lambda$$

and

$$-\dot{\lambda} = \frac{\partial H}{\partial x} \Rightarrow -\dot{\lambda} = C' C \tilde{x} + A' \lambda, \quad \lambda(T) = 0,$$

giving

$$(2.19) \quad \begin{bmatrix} \dot{\tilde{x}} \\ \dot{\lambda} \end{bmatrix} = \begin{bmatrix} A & -B_2 B_2' \\ -C' C & -A' \end{bmatrix} \begin{bmatrix} \tilde{x} \\ \lambda \end{bmatrix} + \begin{bmatrix} B_1 \bar{w} \\ 0 \end{bmatrix}, \quad \begin{bmatrix} \tilde{x}(t^*) \\ \lambda(T) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

Using $\bar{w} = \gamma^{-2} B_1' p$, and subtracting (2.19) from (2.14), gives us

$$(2.20) \quad \begin{bmatrix} \dot{\tilde{x}} - \dot{\hat{x}} \\ \dot{\lambda} - \dot{\hat{p}} \end{bmatrix} = \begin{bmatrix} A & -B_2 B_2' \\ -C' C & -A' \end{bmatrix} \begin{bmatrix} \tilde{x} - \hat{x} \\ \lambda - \hat{p} \end{bmatrix}, \quad \begin{bmatrix} (\tilde{x} - \hat{x})(t^*) \\ (\lambda - \hat{p})(T) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

Since there are no conjugate points associated with the LQ boundary problem in (2.20), $\tilde{x}(t) \equiv x(t)$ and $\lambda(t) \equiv p(t)$ for all $t \in [t^*, T]$. Consequently,

$$\begin{aligned} \min_{u(t)} \int_{t^*}^T \{ \tilde{x}' C' C \tilde{x} + u' u - \gamma^2 \bar{w}' \bar{w} \} dt &= \int_{t^*}^T \{ \tilde{x}' C' C \tilde{x} + \lambda' B_2 B_2' \lambda - \gamma^{-2} p' B_1 B_1' p \} dt \\ &= \int_{t^*}^T \{ x' C' C x + p' B_2 B_2' p - \gamma^{-2} p' B_1 B_1' p \} dt \\ &= - \int_{t^*}^T \{ x' (\dot{\hat{p}} + A' p) + p' (\dot{\hat{x}} - A x) \} dt \text{ by (2.14)} \\ &= - \int_{t^*}^T \frac{d}{dt} \{ x' p \} dt = 0, \end{aligned}$$

which contradicts (2.17). \square

Remark 2.2. In our later work, we will need to consider problems in which the output is given by

$$(2.21) \quad z(t) = C(t)x(t) + D(t)u(t),$$

rather than (2.2). This change in output has the effect of introducing a cross-coupling term between u and x in the functional $J(K, w)$. This may be removed by the change of variable $u = \hat{u} - D' C x$. In the case of an output given by (2.21), the Riccati equation (2.6) becomes

$$\begin{aligned} -\dot{P} &= P(A - B_2 D' C) + (A - B_2 D' C)P - P(B_2 B_2' - \gamma^{-2} B_1 B_1')P \\ &\quad + C(I - DD')C, \quad P(T) = 0, \end{aligned}$$

and the corresponding minimizing feedback control is given by $u^*(t) = -(D' C + B_2' P)(t)x(t)$, rather than (2.7).

2.2. A representation formula for all solutions. In Theorem 2.1 we found one feedback control that solves the time-varying \mathcal{H}^∞ -control problem. In the infinite-horizon case, it is well known that there are usually many feedback controls that result in $\|\mathcal{T}_{zw}\| < \gamma$. The aim of this section is to show how to construct all linear full-information (access to w and x) feedback controls such that $\|\mathcal{T}_{zw}\| < \gamma$. Our analysis is based on the output equation (2.21), rather than (2.2).

THEOREM 2.4. *Suppose that*

$$(2.22a) \quad \dot{\hat{x}}(t) = A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \quad x(0) = 0,$$

$$(2.22b) \quad z(t) = C(t)x(t) + D(t)u(t)$$

is given. Then there exists a control $\bar{K} \in \mathcal{C}$ such that $\|\mathcal{T}_{zw}\| < \gamma$ if and only if

$$(2.23) \quad -\dot{P} = (A - B_2 D' C)' P + P(A - B_2 D' C) - P(B_2 B_2' - \gamma^{-2} B_1 B_1') P + C'(I - DD')C$$

has a solution on $[0, T]$ with $P(T) = 0$. In this case, all closed-loop systems \mathcal{T}_{zw} generated by controls of the form

$$(2.24) \quad u(t) = -(\mathfrak{L}_1 x + \mathfrak{L}_2 w)(t),$$

where \mathfrak{L}_1 and \mathfrak{L}_2 are arbitrary causal linear operators such that

$$\|\mathcal{T}_{zw}\| < \gamma$$

are also generated by

$$(2.26) \quad u(t) = u^*(t) + (\mathfrak{U}(w - w^*))(t),$$

where

$$(2.27a) \quad u^*(t) = -F_\infty x = -(D' C + B_2' P)x,$$

$$(2.27b) \quad w^*(t) = \gamma^{-2} B_1' P x,$$

and $\gamma^{-1} \mathfrak{U}$ is an arbitrary linear causal strictly contractive operator on $\mathcal{L}^2[0, T]$ (i.e., $\|\mathfrak{U}\| < \gamma$).

Equivalently, every \mathfrak{L}_1 and \mathfrak{L}_2 may be parametrized by

$$(2.28a) \quad \mathfrak{L}_1 = F_\infty + \gamma^{-2} \mathfrak{U} B_1' P,$$

$$(2.28b) \quad \mathfrak{L}_2 = -\mathfrak{U}.$$

Equations (2.22), (2.26), and (2.27) may be represented diagrammatically, as in Fig. 1.

Proof. The first part, that the existence of a controller such that $\|\mathcal{T}_{zw}\| < \gamma$ is necessary and sufficient for the existence of $P(t)$ is just Theorems 2.1 and 2.3 for the cross-coupled game.

Now suppose that the RDE (2.23) with $P(T) = 0$ has a solution on $[0, T]$. We need to show (1) that there exists a causal \mathfrak{U} in (2.26) corresponding to every control of the form given in (2.24), and (2) that $\|\mathcal{T}_{zw}\| < \gamma$ if and only if $\gamma^{-1} \mathfrak{U}$ is strictly contractive.

Substituting (2.24) and (2.27b) into the dynamical equation (2.22a) gives us

$$\dot{x} = (A + \gamma^{-2} B_1 B_1' P - B_2(\mathfrak{L}_1 + \gamma^{-2} \mathfrak{L}_2 B_1' P))x + (B_1 - B_2 \mathfrak{L}_2)(w - w^*), \quad x(0) = 0,$$

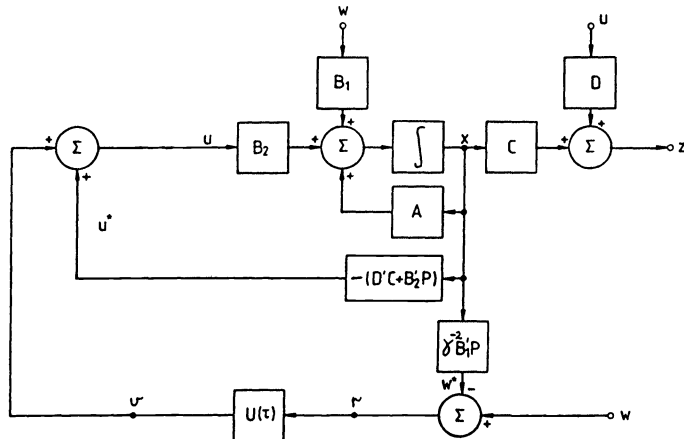

FIG. 1. All solutions to the \mathcal{H}^∞ -control problem with perfect information.

which shows that x depends causally on $(w - w^*)$, and so $x(t) = \mathfrak{L}_3(w - w^*)$, in which \mathfrak{L}_3 is a linear causal operator. Substituting (2.27) into (2.24) gives us

$$\begin{aligned} u - u^* &= -(\mathfrak{L}_1 - F_\infty - \gamma^{-2}\mathfrak{L}_2 B_1' P)x - \mathfrak{L}_2(w - w^*) \\ &= [-(\mathfrak{L}_1 - F_\infty - \gamma^{-2}\mathfrak{L}_2 B_1' P)\mathfrak{L}_3 - \mathfrak{L}_2](w - w^*) \\ &= \mathfrak{U}(w - w^*) \end{aligned}$$

for some linear causal \mathfrak{U} . This establishes the existence of the causal mapping in (2.26). The proof is completed by noting that $\gamma^{-1}\mathfrak{U}$ is strictly contractive as follows:

$$\begin{aligned} \|z\|_2^2 - \gamma^2\|w\|_2^2 &= \|u - u^*\|_2^2 - \gamma^2\|w - w^*\|_2^2 \\ &= \|\mathfrak{U}(w - w^*)\|_2^2 - \gamma^2\|w - w^*\|_2^2 \\ &= \|\mathfrak{U}\mathcal{L}w\|_2^2 - \gamma^2\|\mathcal{L}w\|_2^2 \\ &< 0 \text{ for all } w \neq 0 \in \mathcal{L}^2[0, T] \Leftrightarrow \gamma^{-1}\mathfrak{U} \text{ is strictly contractive.} \end{aligned}$$

In the above, \mathcal{L} is the causal and causally invertible operator linking w and $(w - w^*)$. The invertibility of \mathcal{L} was established in the proof of Theorem 2.1. \square

At this point it is interesting to reexamine Fig. 1. By reviewing (2.26), we see that $r = (w - w^*)$, and that $u = (v + u^*)$ drives B_2 with $v = \mathfrak{U}r$. If $w = w^*$, there is no signal into the \mathfrak{U} parameter, and the corresponding control is given by u^* (irrespective of \mathfrak{U}). If $w \neq w^*$, we do not have to use the control u^* . Thus for the purpose of solving the \mathcal{H}^∞ -control problem, the u -player only has to play well enough to ensure that $J(K, w) < 0$ for a given $w \neq 0 \in \mathcal{L}^2[0, T]$.

2.3. Adjoint systems. In § 3, where we derive a representation formula for all solutions to the time-varying \mathcal{H}^∞ problem with output feedback, we will require an elementary property of adjoint systems [8], [14].

Let $\mathfrak{L}: X \rightarrow Y$ be a linear operator between two Hilbert spaces X and Y . Then $\mathfrak{L}^*: Y \rightarrow X$, the adjoint of \mathfrak{L} , is the unique linear operator such that, for all $z \in Y$ and $w \in X$, $\langle z, \mathfrak{L}w \rangle = \langle \mathfrak{L}^*z, w \rangle$ [14, Thm. 2, p. 39]. Note also that $\|\mathfrak{L}\| = \|\mathfrak{L}^*\|$. Now suppose that \mathfrak{L} is described by the state-space equations

$$(2.29a) \quad \dot{x}(t) = A(t)x(t) + B(t)w(t), \quad x(0) = 0,$$

$$(2.29b) \quad y(t) = C(t)x(t) + D(t)w(t),$$

or, equivalently,

$$(2.30) \quad \begin{bmatrix} \frac{d}{dt} I - A(t) & -B(t) \\ C(t) & D(t) \end{bmatrix} \begin{bmatrix} x(t) \\ w(t) \end{bmatrix} = \begin{bmatrix} 0 \\ y(t) \end{bmatrix}, \quad x(0) = 0.$$

Thus

$$\begin{aligned} \langle z, \mathfrak{L}w \rangle &= \left\langle \begin{bmatrix} p \\ z \end{bmatrix}, \begin{bmatrix} \frac{d}{dt} I - A & -B \\ C & D \end{bmatrix} \begin{bmatrix} x \\ w \end{bmatrix} \right\rangle \\ &= \int_0^T \left(p' \frac{dx}{dt} \right) dt - \int_0^T p'(Ax + Bw) dt + \int_0^T z'(Cx + Dw) dt. \end{aligned}$$

Integrating the first term by parts gives us

$$\begin{aligned}
 &= p'(t_1)x(t_1) - \int_0^T \left(\frac{dp'}{dt} \right) x dt - \int_0^T p'(Ax + Bw) dt \\
 &\quad + \int_0^T z'(Cx + Dw) dt \\
 &= \left\langle \begin{bmatrix} -\left(\frac{d}{dt} I + A' \right) & C' \\ -B' & D' \end{bmatrix} \begin{bmatrix} p \\ z \end{bmatrix}, \begin{bmatrix} x \\ w \end{bmatrix} \right\rangle + p'(T)x(T) \\
 &= \langle \mathfrak{L}^* z, w \rangle,
 \end{aligned}$$

where the adjoint \mathfrak{L}^* is a linear system with realization

$$(2.31a) \quad -\dot{p}(t) = A'(t)p(t) + C'(t)z(t), \quad p(T) = 0,$$

$$(2.31b) \quad q(t) = B'(t)p(t) + D'(t)z(t).$$

In the following, we will require the solution of a dual LQ game system, which is obtained by applying Theorem 2.4 to its associated adjoint system.

2.4. The asymptotic properties of the game equation. This section represents a digression from the main stream of the time-varying finite-horizon \mathcal{H}^∞ -control problem, and its purpose is to make some connections with the more familiar time-invariant, infinite interval results [9]. In particular, we show that in the limit as $T \rightarrow \infty$, the solution of (2.6) approaches the smallest nonnegative solution of an algebraic Riccati equation (if such a solution exists). We also show that this smallest nonnegative solution is stabilizing in the sense alluded to in [9]. We begin by connecting the properties of the solution of the RDE (2.6) as $T \rightarrow \infty$ (when the various coefficient matrices are assumed to be constant) to the solution of the algebraic Riccati equation

$$(2.32) \quad 0 = PA + A'P - P(B_2B_2' - \gamma^{-2}B_1B_1')P + C'C.$$

In doing this, we will suppose that each of the matrices in (2.1) and (2.2) is time-invariant and that (A, B_2, C) is stabilizable and observable (it is not hard to remove the observability assumption, but we will not address this issue here).

If (2.6) is solved backward from the terminal condition $P(T) = Q$, then we will refer to the solution as $P(t, T, Q)$. If a limiting solution to (2.6) exists, we will call it $\bar{P}(t) = \lim_{T \uparrow \infty} P(t, T, Q)$. The first result of this section is standard and shows that $P(t)$ is nonincreasing if $P(T) = 0$.

LEMMA 2.5. *If (2.6) has a solution on $[0, T]$ with $P(T) = 0$, then $P(t)$ is nonincreasing (in the sense of semidefinite matrices).*

Proof. Differentiating (2.6) gives us

$$-\dot{\bar{P}} = \dot{\bar{P}}(A - (B_2B_2' - \gamma^{-2}B_1B_1')P) + (A - (B_2B_2' - \gamma^{-2}B_1B_1')P)' \dot{\bar{P}}, \quad \dot{\bar{P}}(T) = -C'C,$$

which has solution [8, Thm. 1, p. 59] $\dot{\bar{P}}(t) = -\Phi(t, T)'C'C\Phi(t, T)$, where $\Phi(t, T)$ is the transition matrix associated with $(A - (B_2B_2' - \gamma^{-2}B_1B_1')P)'$. It is evident that $\dot{\bar{P}}(t) \leq 0$ for all t , so $P(t)$ is nonincreasing. \square

If (2.32) has at least one nonnegative solution, then we will show that the smallest of these solutions, Y say, is an upper bound for $P(t)$ provided that $Y \geq P(T)$.

LEMMA 2.6. *Suppose that $P(t, T, Q)$ exists $[0, T]$ and that $Y = Y' \geq 0$ satisfies (2.32) with $Y \geq Q$. Then $Y \geq P(t)$ for all $t \in [0, T]$.*

Proof. Completing the square using (2.32) gives us

$$J_t(u, w) = \int_t^T [(u + B_2' Yx)'(u + B_2' Yx) - \gamma^2(w - \gamma^{-2} B_1' Yx)'(w - \gamma^{-2} B_1' Yx)] d\tau \\ + x'(t) Yx(t) - x'(T) Yx(T)$$

for any u and w . In the same way,

$$J_t(u, w) = \int_t^T [(u + B_2' Px)'(u + B_2' Px) - \gamma^2(w - \gamma^{-2} B_1' Px)'(w - \gamma^{-2} B_1' Px)] d\tau \\ + x'(t) P(t)x(t) - x'(T) P(T)x(T)$$

by invoking (2.6). Subtracting and setting $\tilde{u} := -B_2' Yx$ and $\tilde{w} := \gamma^{-2} B_1' Px$ yields

$$x'(t)[Y - P(t)]x(t) = x'(T)[Y - P(T)]x(T) + \gamma^2 \int_t^T (\tilde{w} - \gamma^{-2} B_1' Yx)'(\tilde{w} - \gamma^{-2} B_1' Yx) d\tau \\ + \int_t^T (\tilde{u} + B_2' Px)'(\tilde{u} + B_2' Px) d\tau \geq 0$$

for all $x(t)$. \square

We remark that a variation on the above argument, in conjunction with Lemma 2.5, will establish the following result.

COROLLARY 2.7. *Assume that $Y = Y' \geq 0$ satisfies (2.32) with $Y \geq Q \geq 0$. Then $P(t, T, Q)$ exists for all $t \leq T$ and $Y \geq P(t, T, Q) \geq P(t, T, 0) \geq 0$.*

If $\bar{P}(t)$ exists for some Q , it is easy to argue that it satisfies (2.6). Suppose that $t \leq T_1 \leq T$. Then $P(t, T, Q) = P(t, T_1, P(T_1, T, Q))$, and thus

$$\bar{P}(t) = \lim_{T \uparrow \infty} P(t, T, Q) = \lim_{T \uparrow \infty} P(t, T_1, P(T_1, T, Q)).$$

For any fixed T_1 , the solution $P(t, T_1, \tilde{Q})$ depends continuously on \tilde{Q} and therefore

$$(2.33) \quad \bar{P}(t) = P(t, T_1, \lim_{T \uparrow \infty} P(T_1, T, Q)) = P(t, T_1, \bar{P}(T_1)),$$

which shows that $\bar{P}(t)$ is a solution to (2.6) for all t . Since the system and output matrices have been assumed to be time-invariant, the value of the game $J_t(K^*, w^*) = x'(t)P(t)x(t)$ is invariant under time translations. Consequently, $\bar{P}(t) = \bar{P}$ is constant and therefore satisfies the algebraic equation (2.32).

If a nonnegative stabilizing (i.e., $(A - (B_2 B_2' - \gamma^{-2} B_1 B_1')P)$ asymptotically stable) solution to (2.32) exists, it is the smallest of the nonnegative solutions.

THEOREM 2.8. *Suppose that $[A, C]$ is observable and that $X \geq 0$ and $Y \geq 0$ satisfy*

$$(2.34) \quad A'P + PA - PDP + C'C = 0,$$

with $A - DX$ asymptotically stable. Then $Y \geq X$.

Proof. Due to the observability of $[A, C]$, every solution to (2.32) is nonsingular. We can therefore write $X(A - DX)X^{-1} = -(A' + C'CX^{-1})$, which shows that $A' + C'CX^{-1}$ is completely unstable. Now

$$AX^{-1} + X^{-1}A' - D + X^{-1}C'CX^{-1} = 0 \quad \text{and} \quad AY^{-1} + Y^{-1}A' - D + Y^{-1}C'CY^{-1} = 0.$$

Subtracting gives us

$$A(X^{-1} - Y^{-1}) + (X^{-1} - Y^{-1})A' + X^{-1}C'CX^{-1} - Y^{-1}C'CY^{-1} = 0 \\ \Rightarrow (A + X^{-1}C'C)(X^{-1} - Y^{-1}) + (X^{-1}Y^{-1})(A + X^{-1}C'C)' \\ = (X^{-1} - Y^{-1})C'C(X^{-1} - Y^{-1}).$$

Since $(A + X^{-1}C'C)$ is completely unstable, we must have $(X^{-1} - Y^{-1}) \geq 0$ and so $X \leq Y$. \square

Remark 2.3. Theorem 2.8 remains valid when the observability assumption on $[A, C]$ is weakened to one of detectability. Suppose that

$$A = \begin{bmatrix} A_{11} & 0 \\ A_{21} & A_{22} \end{bmatrix}, \quad C = [C_1 \ 0],$$

with $[A_{11}, C_1]$ observable, then argue as before on the smaller system $[A_{11}, C_1]$.

3. Solution to the time-varying \mathcal{H}^∞ -control problem: Main results. Now that the background game theory is in place, we are in a position to solve the general time-varying \mathcal{H}^∞ -control problem. As mentioned in the Introduction, the plant is described by

$$(3.1a) \quad \dot{x}(t) = A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \quad x(0) = 0,$$

$$(3.1b) \quad z(t) = C_1(t)x(t) + D_{12}(t)u(t),$$

$$(3.1c) \quad y(t) = C_2(t)x(t) + D_{21}(t)w(t),$$

in which we assume that all the matrices have entries that are continuous functions of time, and that D_{12} and D_{21} have full column and row rank, respectively, for all $t \in [0, T]$. Under this assumption, we may scale the problem so that $D'_{12}D_{12} = I$ and $D_{21}D'_{21} = I$. By a corollary of Doležal's theorem [29, Cor. 3, p. 70], we know that there exist continuous extensions D_\perp and \tilde{D}_\perp to D_{12} and D_{21} , respectively, such that $[D_{12} \ D_\perp]$ and $[D_{21}^* \ \tilde{D}_\perp^*]$ are orthogonal for all $t \in [0, T]$. Note that by generalizing the loop-shifting transformations in [11], [24] to the time-varying case, there is no loss of generality in the assumption that D_{11} and D_{22} are zero. Details of the scaling and loop-shifting transformations required in the time-varying case may be found in the Appendix.

3.1. Problems of the first kind. We begin with a preliminary result in which we assume that D_{12} and D_{21} are square; we call such problems problems of the first kind. Under this assumption, scaling arguments allow us to assume, without loss of generality, that $D_{12} = I$ and $D_{21} = I$. As we will now show, finite-horizon \mathcal{H}^∞ problems of the first kind may be solved by inverting the plant, and the resulting controllers have a remarkably simple observer structure.

THEOREM 3.1. *Consider the generalized plant described by*

$$(3.2a) \quad \dot{x}(t) = A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \quad x(0) = 0,$$

$$(3.2b) \quad z(t) = C_1(t)x(t) + u(t),$$

$$(3.2c) \quad y(t) = C_2(t)x(t) + w(t).$$

Then (i) the set of all linear causal output-feedback control laws such that $\|\mathcal{F}_{zw}\| < \gamma$ is parametrized by

$$(3.3a) \quad \dot{\hat{x}}(t) = (A - B_1C_2 - B_2C_1)(t)\hat{x}(t) + B_1(t)y(t) + B_2(t)v(t), \quad \hat{x}(0) = 0,$$

$$(3.3b) \quad u(t) = v(t) - C_1(t)\hat{x}(t),$$

$$(3.3c) \quad r(t) = y(t) - C_2(t)\hat{x}(t),$$

$$(3.3d) \quad v(t) = (\mathbb{U}r)(t),$$

in which \mathbb{U} is a causal strictly contractive operator on $\mathcal{L}^2[0, T]$, and (ii) there exists a linear causal controller such that the closed-loop mapping from w to z is identically zero.

Proof. Eliminating $y(t)$ and $u(t)$ from (3.2) and (3.3) gives us

$$\begin{bmatrix} \dot{\hat{x}} \\ \dot{\hat{x}} \end{bmatrix} = \begin{bmatrix} A - B_1 C_2 - B_2 C_1 & B_1 C_2 \\ -B_2 C_1 & A \end{bmatrix} \begin{bmatrix} \hat{x} \\ x \end{bmatrix} + \begin{bmatrix} B_1 & B_2 \\ B_1 & B_2 \end{bmatrix} \begin{bmatrix} w \\ v \end{bmatrix}$$

and

$$\begin{bmatrix} z \\ r \end{bmatrix} = \begin{bmatrix} -C_1 & C_1 \\ -C_2 & C_2 \end{bmatrix} \begin{bmatrix} \hat{x} \\ x \end{bmatrix} + \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} \begin{bmatrix} w \\ v \end{bmatrix}.$$

Consequently,

$$(3.4) \quad \begin{bmatrix} \dot{\hat{x}} \\ \dot{\hat{x}} - \dot{\hat{x}} \end{bmatrix} = \begin{bmatrix} A - B_2 C_1 & B_1 C_2 \\ 0 & A - B_1 C_2 \end{bmatrix} \begin{bmatrix} \hat{x} \\ x - \hat{x} \end{bmatrix} + \begin{bmatrix} B_1 & B_2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} w \\ v \end{bmatrix}$$

and

$$\begin{bmatrix} z \\ r \end{bmatrix} = \begin{bmatrix} 0 & C_1 \\ 0 & C_2 \end{bmatrix} \begin{bmatrix} \hat{x} \\ x - \hat{x} \end{bmatrix} + \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} \begin{bmatrix} w \\ v \end{bmatrix}.$$

The second row of (3.4) implies that the observations error $e(t) = (x - \hat{x})(t)$ is identically zero, thereby establishing the observer property.¹ In addition, it is clear that $\begin{bmatrix} z \\ r \end{bmatrix}(t) = \begin{bmatrix} v \\ w \end{bmatrix}(t)$ for all $t \in [0, T]$, which shows that the controller is plant inverting.

For the first part, we note that if \mathcal{R} is any strictly contractive mapping from $w(t)$ to $z(t)$, then \mathcal{R} will be generated by setting $\mathfrak{U} = \mathcal{R}$ in (3.3d). Setting $\mathfrak{U} = 0$ proves the second part. \square

The controller given in Theorem 3.1 is presented diagrammatically in Fig. 2, and is seen to have an observer structure with observer gain matrix $-B_1$ and state estimate feedback C_1 .

3.2. Problems of the second kind. In this section we show that all problems in which either D_{12} or D_{21} is square, which we will refer to as problems of the second kind, have controllers that may be characterized by the solution of a single RDE. Simple plant inversion is no longer possible, since this requires that both D_{12} and D_{21} be square. Nevertheless, a solution is still possible and involves the game theory of § 2. If D_{21} is assumed to be square, we can replace (3.1c) with

$$(3.1d) \quad y(t) = C_2(t)x(t) + w(t)$$

by an appropriate scaling operation.

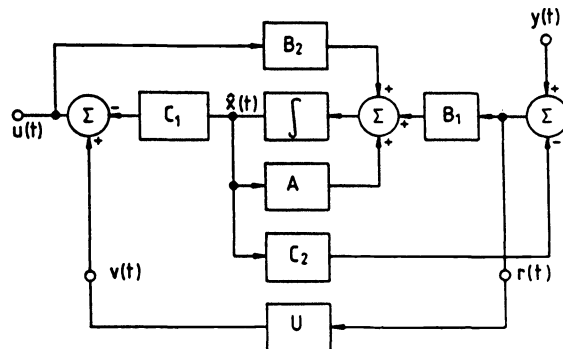

FIG. 2. The plant inverse as an observer.

¹ Since we are dealing with a finite time problem, the question of stability does not arise.

We now consider the possibility of obtaining a controller via a combination of an observer for x , and a linear feedback law as computed in § 2. Since the controllers that we are considering do not have access to w , the observer can only be driven by u and y . Suppose that

$$(3.5) \quad \dot{\hat{x}} = A\hat{x} + B_2u + K(C_2\hat{x} - y), \quad \hat{x}(0) = 0.$$

Subtracting (3.1) from (3.5) and substituting (3.1d) gives us

$$(3.6) \quad (\dot{\hat{x}} - \dot{x}) = A(\hat{x} - x) + K(C_2\hat{x} - C_2x - w) - B_1w = (A + KC_2)(\hat{x} - x) - (K + B_1)w.$$

Setting $K = -B_1$ as before, and $e := \hat{x} - x$ gives us

$$(3.7) \quad \dot{e} = (A - B_1C_2)e, \quad e(0) = 0$$

$\Rightarrow e(t) \equiv 0$ and so $\hat{x}(t) \equiv x(t)$. Again, the stability of $A - B_1C_2$ is not an issue for finite terminal times.

With the required observer property established, we may now find all linear closed-loop controls $K \in \mathcal{C}$ such that $\|\mathcal{T}_{zw}\| < \gamma$ as if full state information were available. As before,

$$(3.8) \quad J(u, w) = \int_0^T (z'z - \gamma^2 w'w) dt.$$

Using the results of § 2, we introduce the Riccati equation

$$(3.9) \quad \begin{aligned} -\dot{X}_\infty &= (A - B_2D'_{12}C_1)'X_\infty + X_\infty(A - B_2D'_{12}C_1) - X_\infty(B_2B'_2 - \gamma^{-2}B_1B'_1)X_\infty \\ &\quad + C'_1D_\perp D'_\perp C_1 \end{aligned}$$

with terminal condition $X_\infty(T) = 0$, and define

$$(3.10) \quad u^* = -(D'_{12}C_1 + B'_2X_\infty)x = -F_\infty x,$$

$$(3.11) \quad w^* = \gamma^{-2}B'_1X_\infty x,$$

which gives us

$$(3.12) \quad J(-F_\infty x, w) \leq -\varepsilon \|w\|_2^2$$

for some $\varepsilon > 0$.

By combining the observer given in (3.5) with $K = -B_1$, the equilibrium strategies (3.10), (3.11), and the characterization of all solutions in § 2.2, we obtain the controller configuration illustrated in Fig. 3 and the main result of this section.

THEOREM 3.2. *Given*

$$(3.13a) \quad \dot{x}(t) = A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \quad x(0) = 0,$$

$$(3.13b) \quad z(t) = C_1(t)x(t) + D_{12}(t)u(t),$$

$$(3.13c) \quad y(t) = C_2(t)x(t) + w(t),$$

then (i) an output-feedback controller exists such that $\|\mathcal{T}_{zw}\| < \gamma$ if and only if the RDE (3.9) has a solution on $[0, T]$ with terminal condition $X_\infty(T) = 0$, and (ii) every closed-loop operator \mathcal{T}_{zw} with $\|\mathcal{T}_{zw}\| < \gamma$, corresponding to an output feedback control $u = \mathcal{R}y$, is generated by

$$(3.14a) \quad \dot{\hat{x}}(t) = (A - B_1C_2 - B_2F_\infty)(t)\hat{x}(t) + B_1(t)y(t) + B_2(t)v(t), \quad \hat{x}(0) = 0,$$

$$(3.14b) \quad u(t) = v(t) - F_\infty(t)\hat{x}(t),$$

$$(3.14c) \quad r(t) = y(t) - (C_2 + \gamma^{-2}B'_1X_\infty)(t)\hat{x}(t),$$

$$(3.14d) \quad v(t) = (\mathbb{U}r)(t),$$

in which $\gamma^{-1}\mathbb{U}$ is a causal, strictly contractive operator on $\mathcal{L}^2[0, T]$.

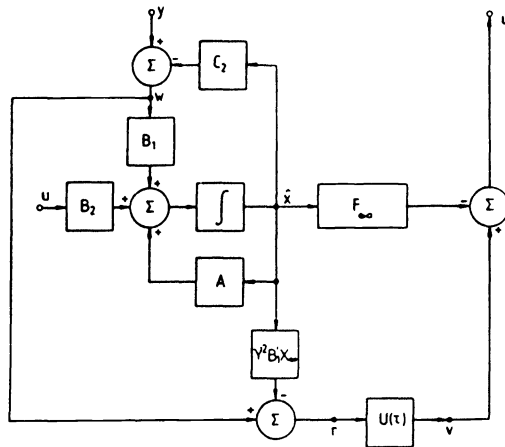

FIG. 3. All controllers for problems of the second kind.

Proof. (i) Suppose that a control of the form $u = \Re y$ exists such that $\|\mathcal{T}_{zw}\| < \gamma$. Then setting $u = \Re[C_2 \quad I][\begin{smallmatrix} x \\ w \end{smallmatrix}]$ in Theorem 2.3 proves the “only if” part. To prove the “if” part, we suppose that a solution to (3.9) exists. We then invoke the observer property developed in (3.5) to (3.7) and the completing-the-square argument given in Theorem 2.1.

Part (ii) is a consequence of Theorem 2.4 on substituting $\hat{x}(t)$ for $x(t)$. \square

A solution for problems of the second kind in which D_{12} , rather than D_{21} , is square is now given without proof. This particular result is needed in the next section in solutions to problems of the third kind and is solved via the dual game associated with the operator $[\mathfrak{P}_{11}^* \quad \mathfrak{P}_{21}^*]$ (see (1.1) for a definition).

THEOREM 3.3. *Given*

$$(3.15a) \quad \dot{x}(t) = A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \quad x(0) = 0,$$

$$(3.15b) \quad z(t) = C_1(t)x(t) + u(t),$$

$$(3.15c) \quad y(t) = C_2(t)x(t) + D_{21}w(t);$$

then (i) a feedback controller exists such that $\|\mathcal{T}_{zw}\| < \gamma$ if and only if the RDE

$$(3.16) \quad \begin{aligned} \dot{Y}_\infty = & (A - B_1 D_{21}' C_2) Y_\infty + Y_\infty (A - B_1 D_{21}' C_2)' - Y_\infty (C_2' C_2 - \gamma^{-2} C_1' C_1) Y_\infty \\ & + B_1 \tilde{D}_\perp' \tilde{D}_\perp B_1' \end{aligned}$$

has a solution on $[0, T]$ with $Y_\infty(0) = 0$, and (ii) every closed-loop operator \mathcal{T}_{zw} with $\|\mathcal{T}_{zw}\| < \gamma$, corresponding to an output feedback control $u = \Re y$, is generated by

$$(3.17a) \quad \dot{\hat{x}}(t) = (A - B_2 C_1 - H_\infty' C_2)(t) \hat{x}(t) - H_\infty'(t) y(t) - (B_2 + \gamma^{-2} Y_\infty C_1')(t) v(t),$$

$$(3.17b) \quad u(t) = C_1(t) \hat{x}(t) + v(t),$$

$$(3.17c) \quad r(t) = C_2(t) \hat{x}(t) + y(t),$$

$$(3.17d) \quad v(t) = (\mathbb{U}r)(t),$$

in which $\gamma^{-1} \mathbb{U}$ is a causal, strictly contractive operator on $\mathcal{L}^2[0, T]$ and $H_\infty = D_{21} B_1' + C_2 Y_\infty$.

Proof. Apply Theorem 3.2 to the adjoint system associated with (3.15). \square

3.3. Problems of the third kind. In this section we treat the case in which neither D_{21} nor D_{12} is square. We call such problems problems of the third kind. In the case where D_{21} has fewer rows than columns, the observer analysis in § 3.2 breaks down because the equation $\Re D_{21}(t) = -B_1(t)$ need not be soluble for \Re . What is required is a norm-preserving transformation to a new problem for which state reconstruction is possible. The desired transformation, which was first suggested in [9] in the time-invariant case, is immediate from identity (2.9). Suppose that

$$(3.18) \quad r = w - \gamma^{-2} B_1' X_\infty x,$$

$$(3.19) \quad v = u + F_\infty x.$$

Then (3.18), (3.19), and the completion-of-squares argument resulting in (2.9) gives us

$$(3.20) \quad \int_0^T (z'z - \gamma^2 w'w) dt = \int_0^T (v'v - \gamma^2 r'r) dt,$$

or, what is the same,

$$(3.21) \quad \|z\|_2^2 - \gamma^2 \|w\|_2^2 = \|v\|_2^2 - \gamma^2 \|r\|_2^2$$

for any r and v . Substituting (3.18) and (3.19) into (3.1) yields

$$(3.22a) \quad \dot{x} = (A + \gamma^{-2} B_1 B_1' X_\infty)x + B_1 r + B_2 u, \quad x(0) = 0,$$

$$(3.22b) \quad v = F_\infty x + Iu,$$

$$(3.22c) \quad y = (C_2 + \gamma^{-2} D_{21} B_1' X_\infty)x + D_{21} r.$$

LEMMA 3.4. *Suppose that the RDE (3.9) with $X_\infty(T) = 0$ has a solution on $[0, T]$. Suppose also that \Re is any controller, and that the control law $u = \Re y$ is applied to the systems given in (3.1) and (3.22)². Then $\|\mathcal{T}_{zw}\| < \gamma$ if and only if $\|\mathcal{T}_{vr}\| < \gamma$.*

Proof. First, note that the relationship between r and w in (3.18) is causally invertible. The result now follows directly from (3.21). \square

Lemma 3.4 shows that the tasks of designing controllers for the systems in (3.1) and (3.22) are interchangeable. The key feature of (3.22) is that D_{12} is square, and thus this system description is a problem of the second kind, which makes state reconstruction possible along the lines of § 3.2. If we define

$$(3.23) \quad F\left(\begin{bmatrix} \mathfrak{P}_{11} & \mathfrak{P}_{12} \\ \mathfrak{P}_{21} & \mathfrak{P}_{22} \end{bmatrix}, \Re\right) := \mathfrak{P}_{11} + \mathfrak{P}_{12} \Re (I - \mathfrak{P}_{22} \Re)^{-1} \mathfrak{P}_{21},$$

then it is immediate that

$$(3.24) \quad \left\{ F\left(\begin{bmatrix} \mathfrak{P}_{11} & \mathfrak{P}_{12} \\ \mathfrak{P}_{21} & \mathfrak{P}_{22} \end{bmatrix}, \Re\right) \right\}^* = F\left(\begin{bmatrix} \mathfrak{P}_{11}^* & \mathfrak{P}_{21}^* \\ \mathfrak{P}_{12}^* & \mathfrak{P}_{22}^* \end{bmatrix}, \Re^*\right)$$

and that

$$(3.25) \quad \left\| F\left(\begin{bmatrix} \mathfrak{P}_{11} & \mathfrak{P}_{12} \\ \mathfrak{P}_{21} & \mathfrak{P}_{22} \end{bmatrix}, \Re\right) \right\|_\infty = \left\| F\left(\begin{bmatrix} \mathfrak{P}_{11}^* & \mathfrak{P}_{21}^* \\ \mathfrak{P}_{12}^* & \mathfrak{P}_{22}^* \end{bmatrix}, \Re^*\right) \right\|_\infty.$$

A direct application of the results of § 2.3 (see (2.31)) shows that a state-space model for the adjoint operator associated with (3.22) is given by

$$(3.26a) \quad -\dot{p} = (A + \gamma^{-2} B_1 B_1' X_\infty)' p + F_\infty' u_1 + (C_2 + \gamma^{-2} D_{21} B_1' X_\infty)' u_2, \quad p(T) = 0,$$

$$(3.26b) \quad y_1 = B_1' p + D_{21}' u_2,$$

$$(3.26c) \quad y_2 = B_2' p + u_1.$$

² For the purposes of this result, \Re need not be linear.

If we now substitute (3.26) into (3.14), using (3.9) to (3.11), we obtain a representation formula for \mathfrak{R}^* and thus also for \mathfrak{R} . This calculation forms the basis of the next result.

THEOREM 3.5. *Given*

$$(3.27a) \quad \dot{x}(t) = A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \quad x(0) = 0,$$

$$(3.27b) \quad z(t) = C_1(t)x(t) + D_{12}(t)u(t),$$

$$(3.27c) \quad y(t) = C_2(t)x(t) + D_{21}(t)w(t),$$

then (i) a causal output-feedback control of the form $u = \mathfrak{R}y$ exists such that $\|\mathcal{T}_{zw}\| < \gamma$ if and only if the RDEs (3.9) and (3.30a) (given below) have solutions on $[0, T]$, and (ii) every closed-loop operator \mathcal{T}_{zw} with $\|\mathcal{T}_{zw}\| < \gamma$, corresponding to an output feedback control $u = \mathfrak{R}y$, is generated by

$$(3.28a) \quad \dot{x}_k(t) = A_k(t)x_k(t) + B_{k1}(t)y(t) + B_{k2}(t)v(t), \quad x_k(0) = 0,$$

$$(3.28b) \quad u(t) = C_{k1}(t)x_k(t) + v(t),$$

$$(3.28c) \quad r(t) = C_{k2}(t)x_k(t) + y(t),$$

$$(3.28d) \quad v(t) = (\mathbb{I}r)(t),$$

in which $\gamma^{-1}\mathbb{I}$ is a causal, strictly contractive operator on $\mathcal{L}^2[0, T]$ and

$$(3.29a) \quad A_k := A + \gamma^{-2}B_1B_1'X_\infty - B_2F_\infty - (B_1D_{21}' + Z_\infty(C_2' + \gamma^{-2}X_\infty B_1D_{21}')) \\ (C_2 + \gamma^{-2}D_{21}B_1'X_\infty),$$

$$(3.29b) \quad \begin{bmatrix} C_{k1} \\ C_{k2} \end{bmatrix} := \begin{bmatrix} F_\infty \\ C_2 + \gamma^{-2}D_{21}B_1'X_\infty \end{bmatrix},$$

$$(3.29c) \quad [B_{k1} \quad B_{k2}] := [-B_1D_{21}' - Z_\infty(C_2' + \gamma^{-2}D_{21}B_1'X_\infty)'] - B_2 - \gamma^{-2}Z_\infty F_\infty',$$

with

$$(3.30a) \quad \dot{Z}_\infty = A_z Z_\infty + Z_\infty A_z' - Z_\infty(C_{k2}'C_{k2} - \gamma^{-2}C_{k1}'C_{k1})Z_\infty + B_1\tilde{D}_\perp'\tilde{D}_\perp B_1', \\ Z_\infty(0) = 0,$$

in which

$$(3.30b) \quad A_z = A - B_1D_{21}'C_2 + \gamma^{-2}B_1\tilde{D}_\perp'\tilde{D}_\perp B_1'X_\infty.$$

Proof. (i) Suppose that a control given by $u = \mathfrak{R}y$ exists such that $\|\mathcal{T}_{zw}\| < \gamma$. Then $u = \mathfrak{R}[C_2 \quad D_{21}]\begin{bmatrix} x \\ w \end{bmatrix}$ together with Theorem 2.3 implies that (3.9) has a solution on $[0, T]$. Since $X_\infty(t)$ exists on $[0, T]$, we may apply the control $u_2 = \mathfrak{R}^*y_2$ to (3.26) to obtain $\|y_1\|_2 < \gamma\|u_1\|_2$ for all $u_1 \neq 0$ by Lemma 3.4 and (3.26). We may now use $u_2 = \mathfrak{R}^*[B_2' \quad I]\begin{bmatrix} p \\ u_1 \end{bmatrix}$ together with the “only if” part of Theorem 3.3 to establish the existence of $Z_\infty(t)$ on $[0, T]$. Sufficiency is immediate from Lemma 3.4 and Theorem 3.3.

(ii) The set of all closed-loop operators corresponding to (3.27) and $u = \mathfrak{R}y$ is the same as the set of all closed-loop operators corresponding to (3.26) and $u_2 = \mathfrak{R}^*y_2$ by Lemma 3.4. Since (3.26) is a problem of the second kind, we may invoke Theorem 3.3 to complete the proof. \square

In the last part of this section, we replace Z_∞ with Y_∞ , which is the solution to the RDE introduced in Theorem 3.3. As we will show, Y_∞ is the dual of X_∞ , and there is a close connection between X_∞ , Y_∞ , and Z_∞ . Before supplying this connection, we give a more general version of the connection between a Riccati equation and the Hamiltonian matrix associated with the two-point boundary value problem.

LEMMA 3.6. *The RDE*

$$(3.31) \quad \dot{P} = A'P + PA - PDP + Q, \quad P(0) = M$$

has a solution on $[0, T]$ if and only if there exists an X such that the boundary value problem

$$(3.32) \quad \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} X - \begin{bmatrix} A & -D \\ -Q & -A' \end{bmatrix} \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} = \frac{d}{dt} \begin{bmatrix} P_1 \\ P_2 \end{bmatrix}$$

has a solution on $[0, T]$ with $P_1(t)$ nonsingular for all $t \in [0, T]$ and $P_2(0)P_1(0)^{-1} = M$. In this case, $P(t) = P_2(t)P_1(t)^{-1}$ is a solution to (3.31) and

$$(3.33) \quad \begin{bmatrix} I \\ P \end{bmatrix} (A - DP) - \begin{bmatrix} A & -D \\ -Q & -A' \end{bmatrix} \begin{bmatrix} I \\ P \end{bmatrix} = \begin{bmatrix} 0 \\ \dot{P} \end{bmatrix}.$$

Proof. Suppose that the RDE has a solution $P(t)$. Then (3.33) is immediate, and the result follows.

Conversely, with $P = P_2P_1^{-1}$ we have from (3.32),

$$\begin{aligned} [P \quad -I] \begin{bmatrix} A & -D \\ -Q & -A' \end{bmatrix} \begin{bmatrix} I \\ P \end{bmatrix} &= [P \quad -I] \left\{ \begin{bmatrix} I \\ P \end{bmatrix} P_1 X - \frac{d}{dt} \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} \right\} P_1^{-1} \\ &= \dot{P}_2 P_1^{-1} - P_2 P_1^{-1} \dot{P}_1 P_1^{-1} = \dot{P}. \quad \square \end{aligned}$$

THEOREM 3.7. *Suppose that (3.9) has a solution $X_\infty(t)$ on $[0, T]$. Then (3.30) has a solution $Z_\infty(t)$ on $[0, T]$ if and only if (3.16) has a solution $Y_\infty(t)$ on $[0, T]$ and $\rho(X_\infty Y_\infty)(t) < \gamma^2$ for all $t \in [0, T]$. Furthermore, $Z_\infty(t) = Y_\infty(I - \gamma^{-2}X_\infty Y_\infty)^{-1}(t)$.*

Proof. A straightforward calculation using (3.9) shows that

$$(3.34) \quad \begin{bmatrix} I & -\gamma^{-2}X_\infty \\ 0 & I \end{bmatrix} H_Y \begin{bmatrix} I & \gamma^{-2}X_\infty \\ 0 & I \end{bmatrix} = H_Z + \begin{bmatrix} 0 & \gamma^{-2}\dot{X}_\infty \\ 0 & 0 \end{bmatrix},$$

where H_Y and H_Z are the Hamiltonian matrices from the boundary value problems associated with the RDEs for Y_∞ and Z_∞ , respectively.

Suppose that Z_∞ exists. Since $X_\infty, Z_\infty \geq 0$, it follows that $(I + \gamma^{-2}X_\infty Z_\infty)(t)$ is nonsingular for all $t \in [0, T]$. Also, $Z_\infty(I + \gamma^{-2}X_\infty Z_\infty)^{-1}(0) = 0$. Using (3.30a) and (3.34), we see that

$$(3.35) \quad H_Y \begin{bmatrix} I + \gamma^{-2}X_\infty Z_\infty \\ Z_\infty \end{bmatrix} = \begin{bmatrix} I + \gamma^{-2}X_\infty Z_\infty \\ Z_\infty \end{bmatrix} (A_z - Z_\infty(C'_{k2}C_{k2} - \gamma^{-2}C'_{k1}C_{k1}))' - \frac{d}{dt} \begin{bmatrix} I + \gamma^{-2}X_\infty Z_\infty \\ Z_\infty \end{bmatrix}.$$

So $Y_\infty = Z_\infty(I + \gamma^{-2}X_\infty Z_\infty)^{-1}$ is a solution to (3.16) by Lemma 3.6. Furthermore,

$$(3.36) \quad \rho[X_\infty Y_\infty] = \rho[X_\infty Z_\infty(I + \gamma^{-2}X_\infty Z_\infty)^{-1}] = \gamma^2 \frac{\rho(X_\infty Z_\infty)}{\gamma^2 + \rho(X_\infty Z_\infty)} < \gamma^2.$$

Conversely, if Y_∞ exists and $\rho(X_\infty Y_\infty) < \gamma^2$, then $I - \gamma^{-2}X_\infty Y_\infty$ is nonsingular on $[0, T]$, $Y_\infty(I - \gamma^{-2}X_\infty Y_\infty)^{-1}(0) = 0$, and from (3.16) we have that

$$\begin{aligned} H_Z \begin{bmatrix} I - \gamma^{-2}X_\infty Y_\infty \\ Y_\infty \end{bmatrix} &= \begin{bmatrix} I - \gamma^{-2}X_\infty Y_\infty \\ Y_\infty \end{bmatrix} (A - B_1 D'_{21} C_2 - Y_\infty(C'_2 C_2 - \gamma^{-2}C'_1 C_1))' \\ &\quad - \frac{d}{dt} \begin{bmatrix} I - \gamma^{-2}X_\infty Y_\infty \\ Y_\infty \end{bmatrix}. \end{aligned}$$

Thus $Z_\infty = Y_\infty(I - \gamma^{-2}X_\infty Y_\infty)^{-1}$ is a solution to (3.30a). \square

Substituting $Z_\infty = Y_\infty(I - \gamma^{-2}X_\infty Y_\infty)^{-1} = (I - \gamma^{-2}Y_\infty X_\infty)^{-1}Y_\infty$ into Theorem 3.5 gives our final result.

THEOREM 3.8. *Given*

$$(3.37a) \quad \dot{x}(t) = A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \quad x(0) = 0,$$

$$(3.37b) \quad z(t) = C_1(t)x(t) + D_{12}(t)u(t),$$

$$(3.37c) \quad y(t) = C_2(t)x(t) + D_{21}(t)w(t),$$

then (i) an output feedback $u = \Re y$ exists such that $\|\mathcal{T}_{zw}\| < \gamma$ if and only if (a) the Riccati equation (3.9) has a solution X_∞ on $[0, T]$, (b) the Riccati equation (3.16) has a solution Y_∞ on $[0, T]$, and (c) $\rho(X_\infty Y_\infty) < \gamma^2$ for all $t \in [0, T]$; and (ii) every closed-loop operator \mathcal{T}_{zw} with $\|\mathcal{T}_{zw}\| < \gamma$, corresponding to an output feedback control $u = \Re y$, is generated by

$$(3.38a) \quad \dot{x}_k(t) = A_k(t)x_k(t) + B_{k1}(t)y(t) + B_{k2}(t)v(t), \quad x_k(0) = 0,$$

$$(3.38b) \quad u(t) = C_{k1}(t)x_k(t) + v(t),$$

$$(3.38c) \quad r(t) = C_{k2}(t)x_k(t) + y(t),$$

$$(3.38d) \quad v(t) = (\mathbb{U}r)(t),$$

in which $\gamma^{-1}\mathbb{U}$ is a causal, strictly contractive operator on $\mathcal{L}^2[0, T]$ and

$$(3.39a) \quad \begin{bmatrix} C_{k1} \\ C_{k2} \end{bmatrix} := \begin{bmatrix} F_\infty \\ C_2 + \gamma^{-2}D_{21}B_1'X_\infty \end{bmatrix},$$

$$(3.39b) \quad [B_{k1} \ B_{k2}] := -(I - \gamma^{-2}Y_\infty X_\infty)^{-1}[H_\infty' | B_2 + \gamma^{-2}Y_\infty C_1' D_{12}],$$

$$(3.39c) \quad A_k := A + \gamma^{-2}B_1B_1'X_\infty - B_2F_\infty + B_{k1}C_{k2}.$$

Proof. This follows from Theorems 3.5 and 3.7. \square

As a check, we note that (3.38) and (3.39) reduce to those in [9], [11], [13], and [21] in the time-invariant case. In the infinite-horizon case, we must establish an internal stability property; this has already been done in the case of time-invariant problems [9], [11], [13], [21].

Appendix. Suppose that the design problem is described by the equation

$$(A.1) \quad \begin{matrix} n \\ p \\ q \end{matrix} \begin{bmatrix} \dot{x} \\ z \\ y \end{bmatrix} = \begin{bmatrix} A & B_1 & B_2 \\ C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{22} \end{bmatrix} \begin{bmatrix} x \\ w \\ u \end{bmatrix},$$

in which each of the matrices has entries that are continuous functions of time. We will also assume that D_{12} and D_{21} have, respectively, full column and row rank for all $t \in [0, T]$. The controller measures y and generates the control u via $u = \Re y$ and has the task of minimizing the worst-case energy gain between z and w .

It is the aim of this appendix to establish that, without loss of generality, we may assume that

$$(A.2) \quad (i) \quad D_{12}'D_{12} = I_m,$$

$$(A.3) \quad (ii) \quad D_{21}D_{21}' = I_q,$$

$$(A.4) \quad (iii) \quad D_{11} = 0,$$

$$(A.5) \quad (iv) \quad D_{22} = 0.$$

If one prefers, it is possible to have (i) and (ii) replaced by

$$(A.2)' \quad (i)' \quad D'_{12} = [I_m \quad 0_{p-m}],$$

$$(A.3)' \quad (ii)' \quad D_{21} = [I_q \quad 0_{i-q}],$$

which are clearly special cases of (i) and (ii).

To begin, we consider the closed-loop configuration in Fig. A.1, which contains the direct feedthrough matrix from (A.1), the controller, and four scaling matrices. S_1 and S_2 will be chosen to enforce (A.2) and (A.3), while S_3 and S_4 ensure that (A.2)' and (A.3)' are satisfied (should we wish to include them).

Suppose that

$$(A.6) \quad D'_{12} D_{12} = N' N$$

and

$$(A.7) \quad D_{21} D'_{21} = M M'$$

are the Cholesky factorizations. Then the entries of M and N are continuous, since they are expressible in terms of the entries of D_{12} and D_{21} [12, p. 88]. It is easy to check that $S_1 = M^{-1}$ and $S_2 = N^{-1}$ will achieve the desired orthogonalization of D_{21} and D_{12} , and that these scaling matrices will not destroy the continuity properties assumed for the original problem. It is evident from Fig. A.1 that we would design the controller \tilde{K} for the scaled problem, and then back substitute through S_1 and S_2 for K . Next, we introduce the orthogonal extensions D_\perp and \tilde{D}_\perp such that $[D_{12} \quad D_\perp]$ and $[D'_{21} \quad \tilde{D}'_\perp]$ are orthogonal. It is a consequence of Doležal's theorem that the extensions D_\perp and \tilde{D}_\perp exist and are continuous [29, Cor. 3, p. 70]. Setting

$$(A.8) \quad S'_3 = [D_{12} \quad D_\perp], \quad S'_4 = [D'_{21} \quad \tilde{D}'_\perp]$$

in Fig. A.1 leads to a direct feedthrough matrix of the form

$$(A.9) \quad \begin{bmatrix} D_{1111} & D_{1112} & I_m \\ D_{1121} & D_{1122} & 0_{p-m} \\ I_q & 0_{l-q} & D_{22} \end{bmatrix}.$$

The partitioning of D_{11} into D_{11ij} $i, j = 1, 2$ is induced by (A.2)' and (A.3)'. Since S_3 and S_4 are orthogonal and thus norm preserving, these scale factors do not change the set of admissible controllers and therefore the controller representation formula.

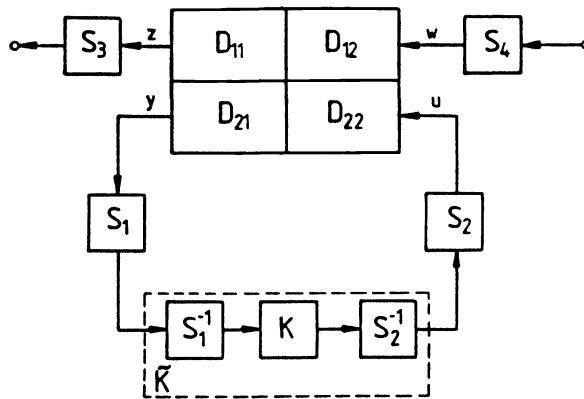

FIG. A.1. Scaling the D -matrix.

We are now in a position to invoke a loop-shifting argument that eliminates both D_{11} and D_{22} , and leads to a significant simplification in the main analysis [11], [24]. Defining

$$(A.10) \quad \gamma_p = \max \left(\sup_{t \in [0, T]} \|D_{1121} \quad D_{1122}\|_2, \sup_{t \in [0, T]} \|D'_{1112} \quad D'_{1122}\|_2 \right),$$

$$(A.11) \quad Q_\infty = -(D_{1111} + D_{1112}(\gamma_p^2 I - D'_{1122}D_{1122})^{-1}D'_{1122}D_{1121}),$$

$$(A.12) \quad F_\infty = (I + Q_\infty D_{22})^{-1}Q_\infty,$$

allows us to mimic the arguments in [11], [24], which remove D_{11} and D_{22} . In conclusion, we mention that the Cholesky factors in the Julia operator of [11] always exist and have continuous entries. \square

Addendum. After the completion of the first version of this paper, we became aware of [5] and [28]. Reference [28] discusses the connections between \mathcal{H}^∞ control and game theory, while [5] applies discrete game theory to the state-feedback \mathcal{H}^∞ -control problem.

STOCHASTIC HAMILTON–JACOBI–BELLMAN EQUATIONS*

SHIGE PENG†

Abstract. This paper studies the following form of nonlinear stochastic partial differential equation:

$$-d\Phi_t = \inf_{v \in U} \left\{ \frac{1}{2} \sum_{i,j} [\sigma\sigma^*]_{ij}(x, v, t) \partial_{x_i x_j} \Phi_t(x) + \sum_i b_i(x, v, t) \partial_{x_i} \Phi_t(x) + L(x, v, t) \right. \\ \left. + \sum_{i,j} \sigma_{ij}(x, v, t) \partial_{x_i} \Psi_{j,t}(x) \right\} dt - \Psi_t(x) dW_t, \quad \Phi_T(x) = h(x),$$

where the coefficients σ_{ij} , b_i , L , and the final datum h may be random. The problem is to find an adapted pair $(\Phi, \Psi)(x, t)$ uniquely solving the equation. The classical Hamilton–Jacobi–Bellman (HJB) equation can be regarded as a special case of the above problem. An existence and uniqueness theorem is obtained for the case where σ does not contain the control variable v . An optimal control interpretation is given. The linear quadratic case is discussed as well.

Key words. stochastic control, dynamic programming, Riccati equation, backward stochastic differential equation, stochastic partial differential equation

AMS(MOS) subject classifications. 93E, 60H, 35K

1. Introduction. In this paper, we study a class of backward stochastic partial differential equations which can be derived from certain stochastic optimal control problems where the coefficients may be random variables. We call these kinds of equations stochastic Hamilton–Jacobi–Bellman equations, or HJB equations.

It is well known that the classical HJB equation is the following form of (deterministic) second-order, nonlinear, partial differential equation of parabolic type:

$$(1.1) \quad \begin{aligned} -\partial_t \Phi &= H_1(D^2\Phi, D\Phi, x, t), \\ \Phi(x, T) &= h(x), \end{aligned}$$

where $H_1: \mathbb{R}^{n \times n} \times \mathbb{R}^n \times \mathbb{R}^n \times [0, T] \rightarrow \mathbb{R}$ is given by

$$H_1(A, p, x, v, t) = \inf_{v \in U} \left\{ \frac{1}{2} \text{tr} [\sigma\sigma^*(x, v, t)A] + (b(x, v, t), v) + L(x, v, t) \right\}$$

with

$$\begin{aligned} U &\subset \mathbb{R}^k, \\ \sigma(x, v, t) &: \mathbb{R}^n \times U \times [0, T] \rightarrow \mathbb{R}^n, \\ b(x, v, t) &: \mathbb{R}^n \times U \times [0, T] \rightarrow \mathbb{R}^n, \\ L(x, v, t) &: \mathbb{R}^n \times U \times [0, T] \rightarrow \mathbb{R}, \\ h(x) &: \mathbb{R}^n \rightarrow \mathbb{R}. \end{aligned}$$

This equation has a stochastic control interpretation: Let $\{W_t, t \geq 0\}$ be, for example, a one-dimensional standard Wiener process. For any given initial data $(x, t) \in \mathbb{R}^n \times [0, T]$, consider the following stochastic control system:

$$(1.2) \quad \begin{aligned} dz_s &= b(z_s, v_s, s) ds + \sigma(z_s, v_s, s) dW_s, \quad t \leq s \leq T, \\ z_t &= x, \end{aligned}$$

where v_s , $0 \leq s \leq T$ is a U -valued adapted stochastic process called admissible control. The optimal control problem is to minimize the following functional:

$$(1.3) \quad J_{x,t}(v) = E \left\{ \int_t^T L(z_s, v_s, s) ds + h(z_T) \right\}$$

over admissible controls. We can define the following value function:

$$\Phi(x, t) = \inf_v J_{x,t}(v),$$

which is defined on $\mathbb{R}^n \times [0, T]$ with values in \mathbb{R} . It can be proved that, under some reasonable assumptions, the value function is the unique solution to (1.1). We refer to Fleming and Rishel [6], Bensoussan and Lions [3], Krylov [11], [12], and Lions [14] for details.

In (1.1), the functions $\sigma(x, v, t)$, $b(x, v, t)$, $L(x, v, t)$, and $h(x)$ are all deterministic. The objective of this paper is to study the case when σ, b, L, h are possibly randomly perturbed. A typical case is when $h = h(x, \omega)$ is \mathcal{F}_T measurable. Here \mathcal{F}_t is the filtration generated by the Brownian motion W_t . In this case, the corresponding value function becomes random. In fact, it is a solution of the following type of backward stochastic partial differential equation:

$$(1.4) \quad \begin{aligned} -d\Phi_t &= H(D^2\Phi, D\Phi, D\Psi, x, t) dt - \Psi dW_t, \\ \Phi(x, T) &= h(x), \end{aligned}$$

with

$$(1.5) \quad H(A, p, x, B, t) = \inf_{v \in U} \{ \frac{1}{2} \text{tr}[\sigma \sigma^*(x, v, t) A] + (b(x, v, t), v) + (\sigma(x, v, t), B) + L(x, v, t) \}.$$

Here for any fixed $x \in \mathbb{R}^n$, $\Phi_t(x, \omega)$ and $\Psi_t(x, \omega)$ are \mathcal{F}_t -adapted processes. We call this equation a stochastic HJB equation.

The main result in this paper asserts the existence and uniqueness of an adapted pair (Φ, Ψ) with values in $H^1(\mathbb{R}^n) \times L^2(\mathbb{R}^n)$ satisfying (1.4). Due to the limitations of our approach, we can only deal with the case where σ does not contain the control variable v . Some nondegeneracy assumption is also needed.

The uniqueness part follows by an application of the backward Itô rule, while the existence is obtained by solving the equation iteratively and applying Itô's rule to estimate the errors between successive estimates.

The unusual feature here is the fact that Ψ is uniquely determined although no time derivative is specified. For understanding this point, let us recall the finite-dimensional situation (see Theorem 2.1 below) in which (1.4) is replaced by

$$(1.6) \quad X = x_t + \int_t^T b(x_s, m_s, s) ds + \int_t^T [\sigma(x_s) + m_s] dW_s, \quad 0 \leq t \leq T,$$

where the terminal value X is \mathcal{F}_T -measurable. Applying Itô's rule to the difference of two solutions $\rho_t = E(|x_t - x'_t|^2)$ yields

$$\begin{aligned} \rho_t + E \int_t^T |\sigma(x) - \sigma(x') + m - m'|^2 ds \\ = 2E \int_t^T \langle b(x, m) - b(x', m'), x - x' \rangle ds, \end{aligned}$$

$$0 \leq t \leq T.$$

Simple estimation then yields

$$\rho_t + \frac{1}{2}E \int_t^T |m - m'|^2 \leq C \int_t^T \rho_s ds.$$

Now ignoring the m -term and using Gronwall's inequality yields $x = x'$, and hence $m = m'$. The same method is used to establish convergence of Picard iteration of solution (x, m) . With more work the same idea lies at the basis of the existence and uniqueness problem for (1.4).

In the paper, a connection of (1.4) with an optimal control problem is described. This connection is similar to that of (1.1) with the optimal control problems (1.2) and (1.3). It should be pointed out that the function H given in (1.5) is itself allowed to be an adapted process.

As an important special case, we study the linear quadratic optimal control problem with random coefficients. A kind of matrix-valued backward stochastic differential equation, called a stochastic Riccati equation, is investigated, and a result of Bismut [4] is nontrivially generalized.

The attention to such kind of backward stochastic differential equations (SDEs) determined by a pair of unknown adapted processes was originated in the study of the stochastic maximum principle for optimal control systems, where the adjoint processes are a pair of adapted processes. This adapted pair can be characterized by a linear backward stochastic differential equation called an adjoint equation (see Bensoussan [1], Bismut [5], Haussmann [7], Kushner [13], and Peng [17], for the finite-dimensional case, and Bensoussan [2] and Hu and Peng [9] for the infinite-dimensional case). The study of forward stochastic partial differential equations can be found in Pardoux [15]. Recently, Pardoux and Peng [16] obtained an existence and uniqueness result for nonlinear backward stochastic differential equations. The infinite-dimensional case (for semi linear evolution systems) can be found in Hu and Peng [8]. The last two results have been applied in this paper. Some results of this paper were briefly announced in Peng [18].

This paper is organized as follows. In the next section, we recall some preliminary results, mainly concerning existence and uniqueness theorems for the backward stochastic differential equations. Section 3 is devoted to the stochastic control interpretation of the stochastic HJB equations and a related verification theorem. The existence and uniqueness result is discussed in § 4. In § 5, we consider linear quadratic optimal control problems with random coefficients.

2. Preliminaries. We first recall some results concerning adapted backward stochastic differential equations and a generalized Itô formula that will be used in the following.

2.1. Finite-dimensional case. Let (Ω, \mathcal{F}, P) be a probability space equipped with filtration \mathcal{F}_t^* . Let $\{W_t, t \geq 0\}$ be a d -dimensional standard Wiener process defined on it. We denote

$$\mathcal{F}_t = \sigma\{W_s; 0 \leq s \leq t\}.$$

For any given Hilbert (or Euclidean) space H , we will denote by $\mathcal{M}^2(H)$ the space of all \mathcal{F}_t -adapted processes with values in H , such that

$$E \int_0^T |x_t|_H^2 dt < \infty, \quad \forall x \in \mathcal{M}^2(H).$$

Obviously, $\mathcal{M}^2(H)$ is a Hilbert space. We denote by (\cdot, \cdot) (respectively, $|\cdot|$), the scalar product (respectively, norm) of a Euclidean space. Note that the space $\mathcal{L}(H; \mathbb{R}^n)$ is also a Hilbert (respectively, Euclidean) space under the scalar product

$$(m_1, m_2) = \text{tr}(m_1^* m_2), \quad \forall m_1, m_2 \in \mathcal{L}(\mathbb{R}^n; H),$$

where we denote by $\text{tr}(A)$, the trace of an $n \times n$ matrix A . Let the following functions be given:

$$\begin{aligned} f(x, m, t, \omega) &: \mathbb{R}^n \times \mathcal{L}(\mathbb{R}^d; \mathbb{R}^n) \times [0, T] \times \Omega \rightarrow \mathbb{R}^n, \\ \sigma(x, m, t, \omega) &: \mathbb{R}^n \times \mathcal{L}(\mathbb{R}^d; \mathbb{R}^n) \times [0, T] \times \Omega \rightarrow \mathcal{L}(\mathbb{R}^d; \mathbb{R}^n), \\ X(\omega) &: \Omega \rightarrow \mathbb{R}^n. \end{aligned}$$

We assume

- (i) for each $(x, m) \in \mathbb{R}^n \times \mathcal{L}(\mathbb{R}^d; \mathbb{R}^n)$, $f(x, m, \cdot) \in \mathcal{M}^2(\mathbb{R}^n)$
 $\sigma(x, m, \cdot) \in \mathcal{M}^2(\mathcal{L}(\mathbb{R}^d; \mathbb{R}^n))$;
- (2.1) (ii) for each $(t, \omega) \in [0, T] \times \Omega$, $f(x, m, t, \omega)$, $\sigma(x, m, t, \omega)$ are differentiable with respect to (x, m) , and the derivatives are all bounded;
- (iii) $X(\omega)$ is \mathcal{F}_T -measurable, and $E|X|^2 < \infty$.

Consider the following backward stochastic differential equation:

$$(2.2) \quad X = x_t + \int_t^T f(x_s, m_s, s) ds + \int_t^T [\sigma(x_s) + m_s] dW_s.$$

Our problem is to find a pair of adapted $\mathbb{R}^n \times \mathcal{L}(\mathbb{R}^d; \mathbb{R}^n)$ -valued processes (x_s, m_s) , which solves equation (2.2). We have the following result.

THEOREM 2.1. *Assume (2.1) holds. Then, there exists a unique pair (x_s, m_s) in $\mathcal{M}^2(\mathbb{R}^n) \times \mathcal{M}^2(\mathcal{L}(\mathbb{R}^d; \mathbb{R}^n))$, which solves (2.2). We have*

$$(2.3) \quad E \sup_{t \in [0, T]} |x_t|^2 < \infty.$$

Moreover, if

$$(2.4) \quad K = \sup_{\omega} \left\{ |X|^2 + \int_0^T |f(0, 0, s)|^2 ds + \int_0^T |\sigma\sigma^*(0, s)|^2 ds \right\} < \infty,$$

then

$$(2.5) \quad |x_t|^2 \leq K e^{C(T-t)},$$

where C is a positive constant depending only on the bound of $|f_x|, |\sigma_x|$.

Proof. The proof of existence and uniqueness for (2.2) and (2.3) can be found in [16]. We only prove (2.5). Applying Itô's formula to (2.2), we have, for $0 \leq r \leq t \leq T$,

$$(2.6) \quad E^{\mathcal{F}_r} |x_t|^2 + E^{\mathcal{F}_r} \int_t^T |(\sigma(x_s, s) + m_s)|^2 ds = E^{\mathcal{F}_r} |X|^2 - 2E^{\mathcal{F}_r} \int_t^T (x_s, f(x_s, m_s, s)) ds.$$

Thus

$$\begin{aligned} E^{\mathcal{F}_r} |x_t|^2 + \frac{1}{2} E^{\mathcal{F}_r} \int_t^T |m_s|^2 ds &\leq E^{\mathcal{F}_r} |X|^2 + E^{\mathcal{F}_r} \int_t^T |\sigma(x_s, s)|^2 ds \\ &\quad + 2E^{\mathcal{F}_r} \int_t^T |x_s| |f(x_s, m_s, s)| ds. \end{aligned}$$

Since the derivatives of f, σ with respect to (x, m) are bounded,

$$\begin{aligned} 2|x||f(x, m, s)| &\leq 2|x||f(0, 0, s)| + 2C_1|x|(|x| + |m|) \\ &\leq |f(0, 0, s)|^2 + (4C_1^2 + 2C_1 + 1)|x|^2 + \frac{1}{4}|m|^2, \\ |\sigma(x, s)|^2 &\leq |\sigma(0, s)|^2 + C_1|x|^2. \end{aligned}$$

It follows that

$$\begin{aligned} E^{\mathcal{F}_r}|x_t|^2 + \frac{1}{4}E^{\mathcal{F}_r} \int_t^T |m_s|^2 ds \\ \leq E^{\mathcal{F}_r}|X|^2 + E^{\mathcal{F}_r} \int_t^T (|f(0, 0, s)|^2 + |\sigma(0, s)|^2 + (4C_1^2 + 3C_1 + 1)|x|^2) ds \\ \leq K + \int_t^T (4C_1^2 + 3C_1 + 1)E^{\mathcal{F}_r}|x|^2 ds. \end{aligned}$$

Applying Gronwall's inequality, we obtain finally

$$E^{\mathcal{F}_r}|x_t|^2 \leq K e^{C(T-t)}, \quad \forall 0 \leq r \leq t \leq T,$$

with $C = 4C_1^2 + 3C_1 + 1$. This implies (2.5). \square

2.2. Infinite-dimensional case. Let V, H be two separable Hilbert spaces such that V is densely embedded in H . We identify H with its dual space, and denote by V' the dual of V . We have then

$$V \subset H \subset V'.$$

We will denote by $\|\cdot\|, |\cdot|, \|\cdot\|_*$ the norms of V, H , and V' , respectively; by $\langle \cdot, \cdot \rangle$ the duality product between V and V' , and by (\cdot, \cdot) the scalar product in H . For any $\varphi \in \mathcal{M}^2(\mathcal{L}(\mathbb{R}^n; H))$, we can define an H -valued random variable, called stochastic integral $\int_0^t \varphi_s dW_s$ by (see [15])

$$\left(h, \int_0^t \varphi_s dW_s \right) = \int_0^t (\varphi_s^* h) dW_s, \quad \forall h \in H.$$

Let the following functions be given:

$$\begin{aligned} A(t, \omega) &: [0, T] \times \Omega \rightarrow \mathcal{L}(V; V'), \\ f(y, t, \omega) &: H \times [0, T] \times \Omega \rightarrow V', \\ g(y, z, t, \omega) &: V \times \mathcal{L}(\mathbb{R}^d; H) \times [0, T] \times \Omega \rightarrow H, \\ \eta(y, t, \omega) &: H \times [0, T] \times \Omega \rightarrow \mathcal{L}(\mathbb{R}^d; H), \\ Y(\omega) &: \Omega \rightarrow H. \end{aligned}$$

We assume the following:

$$\begin{aligned} (2.7) \quad &\text{For each } (y, z), A(t), f(y, t), g(y, z, t), \eta(y, t) \text{ are } \mathcal{F}_t\text{-adapted,} \\ &\text{such that, } f(0, t) \in \mathcal{M}^2(V'), \eta(0, t) \in \mathcal{M}^2(\mathcal{L}(\mathbb{R}^d; H)), \\ &g(0, 0, t) \in \mathcal{M}^2(H), A(t) \in \mathcal{M}^2(\mathcal{L}(V, V')), \\ &\sup_{t, \omega} \|A(t, \omega)\|_{\mathcal{L}(V, V')} \leq C; \end{aligned}$$

$$\begin{aligned} (2.8) \quad &\exists \alpha > 0 \text{ and } \lambda, \text{ such that, } \forall y \in V, \\ &\langle A(t)y, y \rangle + \lambda|y|^2 \geq \alpha\|y\|^2, \quad \forall t; \end{aligned}$$

$$\begin{aligned}
& |g(y_1, z_1, t) - g(y_2, z_2, t)| \leq C(\|y_1 - y_2\| + |z_1 - z_2|), \\
& \mathbf{V}(y_1, z_1), (y_2, z_2) \in (V \times \mathcal{L}(\mathbb{R}^d; H)), \\
(2.9) \quad & |\eta(y_1, t) - \eta(y_2, t)| \leq C|y_1 - y_2|, \quad \mathbf{V}y_1, y_2 \in H, \\
& |\langle f(y_1, t) - f(y_2, t), y \rangle| \leq C|y_1 - y_2| \cdot \|y\|, \quad \mathbf{V}(y_1, y_2) \in H, \quad y \in V.
\end{aligned}$$

Consider the following semilinear backward stochastic equation:

$$(2.10) \quad Y = y_t + \int_t^T (A(s)y_s + f(y_s, s) + g(y_s, z_s, s)) ds + \int_t^T (\eta(y_s, s) + z_s) dW_s.$$

The problem is to find a pair of adapted processes (y, z) satisfying the above equation. We have the following theorem (see [8] for proof).

THEOREM 2.2. *We assume (2.7)–(2.9). Then there exists a unique pair $(y, z) \in \mathcal{M}^2(V) \times \mathcal{M}^2(\mathcal{L}(\mathbb{R}^d; H))$, satisfying the backward evolution equation (2.10).*

Remark. We can also obtain an estimate similar to (2.5).

We need also the following generalized Itô's formula due to Kunita [10].

THEOREM 2.3. *Let $F_t(x)$, $(x, t) \in \mathbb{R}^n \times [0, T]$ be a random field which is continuous in (x, t) almost surely, satisfying*

- (i) *For each t , $F_t(\cdot)$ is a C^2 -map from \mathbb{R}^n into R almost surely;*
- (ii) *For each x , $F_t(x)$ is a continuous semimartingale and it satisfies*

$$F_t(x) = F_0(x) + \sum_{j=1}^m \int_0^t f_s^j(x) dY_s^j, \quad \mathbf{V}x \in \mathbb{R}^n,$$

almost surely, where Y_s^j , $j = 1, \dots, d$ are continuous semimartingales, $f_s^j(x)$, $x \in \mathbb{R}^n$, $s \in [0, T]$, are random fields that are continuous in (x, s) and satisfy

- (a) *for each s , $f_s^j(x)$ is a C^2 -map from \mathbb{R}^n to R ,*
- (b) *for each x , $f_s^j(x)$ is an adapted process.*

Let $X_t = (X_t^1, \dots, X_t^n)$ be continuous semimartingales. Then we have

$$\begin{aligned}
(2.11) \quad F_t(X_t) &= F_0(X_0) + \sum_{j=1}^m \int_0^t f_s^j(X_s) dY_s^j + \sum_{i=1}^n \int_0^t \partial_{x_i} F_s(X_s) dX_s^i \\
&\quad + \sum_{j=1}^m \sum_{i=1}^n \int_0^t \partial_{x_i} f_s^j(X_s) d\langle Y^j, X^i \rangle_s \\
&\quad + \sum_{i,j=1}^n \int_0^t \partial_{x_i x_j} F_s(X_s) d\langle X^i, X^j \rangle_s,
\end{aligned}$$

where $\langle \cdot, \cdot \rangle_s$ stands for the quadratic variation of semimartingales.

3. Optimal control formulation of the stochastic HJB equation. We begin by considering a stochastic optimal control system in which all coefficients may be also stochastic processes. This can lead us to formulate what we call stochastic HJB equations. We present a general form of such equations. The discussion is formal because, in general, we have no sufficient regularity properties of the value function. We will also discuss the so-called “verification theorem” approach in which the rigorous proof can be easily given.

3.1. Optimal control system. Let $\{W_t^1; t \geq 0\}$ be a p -dimensional standard Wiener process in (Ω, \mathcal{F}, P) which is independent of $\{W_t; t \geq 0\}$. Without loss of generality, we consider only the case where W_t is a one-dimensional Brownian motion, i.e., $d = 1$. We assume

$$\mathcal{F}_t^* = \sigma\{W_s, W_s^1; 0 \leq s \leq t\}.$$

Consider the following stochastic control system parametrized by the initial data $(x, t) \in \mathbb{R}^n \times [0, T]$:

$$(3.1) \quad dy_s = b(y_s, v_s, s) ds + \sigma(y_s, v_s, s) dW_s + \pi(y_s, v_s, s) dW_s^1, \quad t \leq s \leq T, \quad y_t = x,$$

where

$$\begin{aligned} b(x, v, t) &: \mathbb{R}^n \times \mathbb{R}^k \times [0, T] \rightarrow \mathbb{R}^n, \\ \sigma(x, v, t) &: \mathbb{R}^n \times \mathbb{R}^k \times [0, T] \rightarrow \mathbb{R}^n, \\ \pi(x, v, t) &: \mathbb{R}^n \times \mathbb{R}^k \times [0, T] \rightarrow \mathcal{L}(\mathbb{R}^p; \mathbb{R}^n). \end{aligned}$$

An admissible control is an \mathcal{F}_t^* -adapted process v_t with values in U , such that

$$E \int_0^T |v_t|^2 dt < \infty.$$

We denote the set of admissible controls by \mathcal{U} . By analogy with the classical optimal control problem, our problem is, for a given initial data $y_0 = x_0$ in (3.1), to find an admissible control v_t which minimizes the following cost function:

$$(3.2) \quad E \left\{ \int_0^T L(y_s, v_s, s) ds + h(y_T) \right\},$$

where we denote

$$(3.3) \quad \begin{aligned} L(x, v, t) &: \mathbb{R}^n \times \mathbb{R}^k \times [0, T] \rightarrow \mathbb{R}, \\ h(x, \omega) &: \mathbb{R}^n \times \Omega \rightarrow \mathbb{R}. \end{aligned}$$

The main difference between the classical optimal control problem and the above one is that h is a random variable. We assume that $h(x)$ is \mathcal{F}_T -measurable.

Remark. We can also treat the case where σ, π, b , and L are \mathcal{F}_t -adapted random processes. The approach and the conclusion are the same.

Following the idea of dynamic programming, for any fixed initial data (x, t) in (3.1), we minimize the following cost function over admissible controls:

$$(3.4) \quad J_{x,t}(v) = E^{\mathcal{F}_t} \int_t^T L(y_s, v_s, s) ds + h(y_T).$$

The value function is defined as follows:

$$\Phi_t(x) = \inf_{v \in \mathcal{U}} J_{x,t}(v).$$

Observe that, for any fixed x , Φ_t is an \mathcal{F}_t -adapted process with values in \mathbb{R} . In general, Φ_t is not a bounded variation function with respect to t . In fact, we can only expect that Φ_t is a semimartingale

$$(3.5) \quad \Phi_t(x) = \int_t^T \Gamma_s(x) ds - \int_t^T \Psi_s(x) dW_s, \quad x \in \mathbb{R}^n, \quad 0 \leq t \leq T,$$

where, for each $x \in \mathbb{R}^n$ and $\Gamma_s(x), \Psi_s(x)$ are \mathcal{F}_s -adapted real processes.

If $\Phi_t(x)$ can be expressed in the form (3.5), and if $\Phi_t(x), \Gamma_t(x), \Psi_t(x)$ are almost surely continuous in (x, t) and are smooth enough with respect to x , then we can prove that the pair $(\Phi_t(x), \Psi_t(x))$ satisfies the following stochastic partial differential equation:

$$(3.6) \quad -d\Phi_t = H(D^2\Phi, D\Phi, D\Psi, x, t) dt - \Psi dW_t, \quad \Phi(x, T) = h(x),$$

or

$$(3.7) \quad \Phi_t = h(x) + \int_t^T H(D^2\Phi, D\Phi, D\Psi, x, s) ds - \int_t^T \Psi dW_s,$$

with

$$H(A, p, x, B, t) = \inf_{v \in U} \{ \text{tr}[a(x, v, t)A] + (b(x, v, t), p) + (\sigma(x, v, t), B) + L(x, v, t) \},$$

$$A \in \mathbb{R}^{n \times n}, \quad B \in \mathbb{R}^n,$$

where $D\Phi$ is the gradient of Φ , $D^2\Phi$ is the Hessian of Φ , and

$$a(x, v, t) = \frac{1}{2}[\sigma\sigma^*(x, v, t) + \pi\pi^*(x, v, t)].$$

Equation (3.6) or (3.7) is called a stochastic HJB equation. Comparing (3.6) with the classical HJB equation, which is a deterministic partial differential equation, an interesting feature of this equation is that its solution consists of a pair (Φ_t, Ψ_t) .

The following procedure can verify that (Φ_t, Ψ_t) as in (3.5) satisfies (3.7). First, similar to the classical case, we introduce Bellman's optimality principle

$$(3.8) \quad \begin{aligned} \Phi_t(x) &= \inf_{v \in \mathcal{U}} E^{\mathcal{F}_t} \left\{ \int_t^{t+r} L(y_s, v_s, s) ds + E^{\mathcal{F}_{t+r}} \left(\int_{t+r}^T L(y_s, v_s, s) ds + h(y_T) \right) \right\} \\ &= \inf_{v \in \mathcal{U}} E^{\mathcal{F}_t} \left\{ \int_t^{t+r} L(y_s, v_s, s) ds + \Phi_{t+r}(y_{t+r}) \right\}. \end{aligned}$$

Then, applying Itô-Kunita's formula (2.11) to the process $\Phi_s(y_s)$ yields

$$\begin{aligned} \Phi_{t+r}(y_{t+r}) &= \Phi_t(x) + E^{\mathcal{F}_t} \int_t^{t+r} [\text{tr}(a(y_s, v_s, s)D^2\Phi_s(y_s)) + (b(y_s, v_s, s), D\Phi_s(y_s)) \\ &\quad + \text{tr}(\sigma(y_s, v_s, s)D\Psi_s(y_s)) + \Gamma_s(y_s)] ds. \end{aligned}$$

This with (3.8) implies

$$\begin{aligned} r^{-1} \inf_{v \in \mathcal{U}} E^{\mathcal{F}_t} \int_t^{t+r} [L(y_s, v_s, s) + \text{tr}(a(y_s, v_s, s)D^2\Phi_s(y_s)) + (b(y_s, v_s, s), D\Phi_s(y_s)) \\ + (\sigma(y_s, v_s, s), D\Psi_s(y_s)) + \Gamma_s(y_s)] ds = 0. \end{aligned}$$

Passing limit as $r \rightarrow 0$, we have

$$\Gamma_t(x) = -H(D^2\Phi_t(x), D\Phi_t(x), D\Psi_t(x), x, t).$$

Substituting it into (3.5) yields (3.7).

Unfortunately, as in the classical case, even when the coefficients b, σ, π, L, h are sufficiently regular with respect to (x, v) , it is still difficult to verify the regularities of $(\Phi_t(x), \Psi_t(x))$.

3.2. Verification theorem approach. We now show that a sufficiently smooth solution of (3.7) coincides with the value function. In the classical case, this approach is called the verification theorem approach (see [6]).

Indeed, let a sufficiently smooth pair $(\varphi_t(x), \psi_t(x))$ be a solution of (3.7). Assume

- (i) For each t , $(\varphi_t(x), \psi_t(x))$ is a C^2 -map from \mathbb{R}^n into $\mathbb{R}^1 \times \mathbb{R}^d$.
- (ii) For each x , $(\varphi_t(x), \psi_t(x))$, $(D\varphi_t(x), D^2\varphi_t(x), D\psi_t(x))$ are continuous \mathcal{F}_t -adapted processes.

Without loss of generality, let $u_t(x)$ be a random field that is $\mathcal{F}_1 \times \mathcal{B}(\mathbb{R}^n)/\mathcal{B}(\mathbb{R}^k)$ -measurable with values in \mathcal{U} , such that

$$\begin{aligned} & \text{tr}[a(x, u_t, t)D^2\varphi_t] + (b(x, u_t, t), D\varphi_t) + (\sigma(x, u_t, t), D\psi_t) + L(x, u_t, t) \\ & = H(D^2\varphi_t(x), D\varphi_t(x), D\psi_t(x), x, t). \end{aligned}$$

Furthermore, suppose that $u_t(x)$ is regular enough such that the “feedback” control system

$$\begin{aligned} dy_s &= b(y_s, u_s(y_s), s) ds + \sigma(y_s, u_s(y_s), s) dW_s + \pi(y_s, u_s(y_s), s) dW_s^1, \\ t &\leq s \leq T, \quad y_t = x, \end{aligned}$$

is well posed. Finally, suppose that $H(D^2\varphi_t(x), D\varphi_t(x), D\psi_t(x), x, t)$ is smooth with respect to (x, t) . Then $(\varphi_t(x), \psi_t(x))$ coincides with $(\Phi_t(x), \Psi_t(x))$. Furthermore, for any initial data $(x_0, 0)$, $u_s^* = u_s(y_s)$ minimize the cost function (3.2).

Indeed, let v_s be an admissible control, and let z_s be the corresponding solution

$$dz_s = b(z_s, v_s, s) ds + \sigma(z_s, v_s, s) dW_s + \pi(z_s, v_s, s) dW_s^1, \quad t \leq s \leq T, \quad z_t = x.$$

From Itô–Kunita’s formula,

$$\begin{aligned} E^{\mathcal{F}_t}\varphi_T(z_T) &= \varphi_t(x) + E^{\mathcal{F}_t} \int_t^T [\text{tr}(a(z_s, v_s, s)D^2\varphi_s(z_s)) + (b(z_s, v_s, s), D\varphi_s(z_s)) \\ &\quad + (\sigma(z_s, v_s, s), D\psi_s(z_s)) - H(D^2\varphi_s(z_s), D\varphi_s(z_s), D\psi_s(z_s), z_s, s)] ds. \end{aligned}$$

This yields

$$\begin{aligned} (3.9) \quad \varphi_t(x) &\leq E^{\mathcal{F}_t} \left\{ \int_t^T L(z_s, v_s, s) ds + h(z_T) \right\} \\ &= J_{x,t}(v). \end{aligned}$$

On the other hand, if we take the above $u_s^* = u_s(y_s)$ as a control, then, again from Itô–Kunita’s formula,

$$\begin{aligned} E^{\mathcal{F}_t}\varphi_T(y_T) &= \varphi_t(x) + E^{\mathcal{F}_t} \int_t^T [\text{tr}(a(y_s, u_s^*, s)D^2\varphi_s(y_s)) + (b(y_s, u_s^*, s), D\varphi_s(y_s)) \\ &\quad + (\sigma(y_s, u_s^*, s), D\psi_s(y_s)) - H(D^2\varphi_s(y_s), D\varphi_s(y_s), D\psi_s(y_s), y_s, s)] ds. \end{aligned}$$

It follows from the definition of u_s^* that

$$\begin{aligned} \varphi_t(x) &= E^{\mathcal{F}_t} \left\{ \int_t^T L(y_s, u_s^*, s) ds + h(y_T) \right\} \\ &= J_{x,t}(u^*). \end{aligned}$$

This with (3.9) implies

$$\varphi_t(x) = \inf_{v \in \mathcal{U}} J_{x,t}(v) = \Phi_t(x).$$

Consequently, $\psi_t(x) = \Psi_t(x)$. The last assertion is easy to see since

$$E \left\{ \int_0^T L(y_s, v_s, s) ds + h(y_T) \right\} = EE^{\mathcal{F}_0} \left\{ \int_0^T L(y_s, v_s, s) ds + h(y_T) \right\}.$$

4. Existence and uniqueness. An existence and uniqueness theorem for the stochastic HJB equation (3.7), in terms of Sobolev space technique, is given in this section. We can only treat the case where no control variable appears in the diffusion coefficients σ and π . We also need a nondegeneracy assumption. The corresponding control system (3.1) becomes

$$(4.1) \quad dy_s = b(y_s, v_s, s) ds + \sigma(y_s, s) dW_s + \pi(y_s, s) dW_s^1, \quad t \leq s \leq T, \quad y_t = x,$$

with the following cost function to be minimized:

$$(4.2) \quad J_{x,t}(v) = E^{\mathcal{F}_t} \left\{ \int_t^T L(y_s, v_s, s) ds + h(y_T) \right\}.$$

We assume that

- (i) For each t , $b(x, v, t)$, $\sigma(x, t)$, $\pi(x, t)$, $L(x, v, t)$, $h(x)$ are continuous in (x, v) ;
- (4.3) (ii) For each (v, t) , they are continuously differentiable in x ;
- (iii) They and all their derivatives in x are bounded;
- (iv) For each (x, v) , they are continuous in t .

We also need the following nondegeneracy assumption on π :

$$(4.4) \quad \pi\pi^*(x, t) \geq 2\alpha I, \quad \forall (x, t),$$

where α is a positive constant.

Remark. Technically, the above nondegeneracy assumption will be used to satisfy (2.8). In general, if we have no such kind of condition, some kind of notion like “viscosity solution” seems necessary. A typical case is when h is deterministic and $\sigma = \pi = 0$. In this case the most suitable notation is the viscosity solution (see [14]).

Our problem is to find a unique pair $(\Phi_t(x), \Psi_t(x))$ satisfying (3.7), where the function H becomes

$$\begin{aligned} a(x, t) &= \frac{1}{2}(\sigma\sigma^*(x, t) + \pi\pi^*(x, t)), \\ H(A, p, B, x, t) &= \text{tr}(a(x, t)A) + (\sigma(x, t), B) + \inf_{v \in U} \{(b(x, v, t), p) + L(x, v, t)\} \\ &\quad \forall x \in \mathbb{R}^n, \quad t \in [0, T], \quad A \in S^n, \quad B \in \mathbb{R}^n. \end{aligned}$$

We introduce the following Sobolev space:

$$H^1(\mathbb{R}^n) = \{u \in L^2(\mathbb{R}^n): Du \in L^2(\mathbb{R}^n)\}.$$

We identify $L^2(\mathbb{R}^n)$ with its dual space, and denote the dual space of $H^1(\mathbb{R}^n)$ by $H^{-1}(\mathbb{R}^n)$. This gives us a triple as in § 2.2

$$(H^1(\mathbb{R}^n), L^2(\mathbb{R}^n), H^{-1}(\mathbb{R}^n)) = (V, H, V').$$

We can make the following assertion.

THEOREM 4.1. *Assume that (4.3) and (4.4) hold. Then there exists a unique pair $(\Phi_t(x), \Psi_t(x))$ in $(\mathcal{M}^2(V), \mathcal{M}^2(H))$ satisfying the stochastic HJB equation (3.7).*

To prove this theorem, we need a lemma that generalizes Theorem 2.2. Let $g(y, z, t)$, Y , $A(t)$ be as in Theorem 2.2. Let

$$\begin{aligned} A_1(t, \omega) &: [0, T] \times \Omega \rightarrow \mathcal{L}(V; V'), \\ f(y, z, t, \omega) &: H \times H \times [0, T] \times \Omega \rightarrow V'. \end{aligned}$$

We assume that the following are true:

(4.5) For each (y, z) , $A_1(t)$ and $f(y, z, t)$ are \mathcal{F}_t -adapted, $f(0, 0, t) \in \mathcal{M}^2(V)$;

(4.6) $\sup_{t, \omega} \|A_1(t, \omega)\|_{\mathcal{L}(V, V)} \leq C, \quad \langle A_1(t)y, y \rangle \geq 0, \quad \forall y \in V;$

(4.7) $|\langle f(y_1, z_1, t) - f(y_2, z_2, t), y \rangle| \leq C|y_1 - y_2|_H|y|_V + |z_1 - z_2|_H \langle 2A_1(t)y, y \rangle^{1/2},$
for each $(y_1, z_1), (y_2, z_2) \in H \times H$, for each $y \in V$.

Consider the following semilinear backward stochastic equation:

$$(4.8) \quad Y = y_t + \int_t^T (A(s)y_s + A_1(s)y_s + f(y_s, z_s, s) + g(y_s, z_s, s)) ds + \int_t^T z_s dW_s.$$

We have the following lemma.

LEMMA 4.2. Let $g(y, z, t)$, Y , $A(t)$ satisfy the assumptions of Theorem 2.2. Let (4.5)–(4.7) hold. Then, there exists a unique pair $(y, z) \in \mathcal{M}^2(V) \times \mathcal{M}^2(H)$, satisfying the backward evolution equation (4.8).

Proof. (i). *Uniqueness.* Let $(y_s^1, z_s^1), (y_s^2, z_s^2)$ be two solutions of (4.8). From Itô's formula, we can derive

$$\begin{aligned} E|y_t^1 - y_t^2|^2 + 2E \int_t^T \langle (A(s) + A_1(s))(y_s^1 - y_s^2), y_s^1 - y_s^2 \rangle + E \int_t^T |z_s^1 - z_s^2|^2 ds \\ = -2E \int_t^T (g(y_s^1, z_s^1, s) - g(y_s^2, z_s^2, s), y_s^1 - y_s^2) ds \\ - 2E \int_t^T \langle f(y_s^1, z_s^1, s) - f(y_s^2, z_s^2, s), y_s^1 - y_s^2 \rangle ds. \end{aligned}$$

Thus, by (2.8), (2.9), and (4.7), we obtain

$$\begin{aligned} E|y_t^1 - y_t^2|^2 + 2E \int_t^T \langle (A_1(s))(y_s^1 - y_s^2), y_s^1 - y_s^2 \rangle ds + 2\alpha E \int_t^T \|y_s^1 - y_s^2\|^2 ds \\ + E \int_t^T |z_s^1 - z_s^2|^2 ds \\ \leq 2\lambda E \int_t^T |y_s^1 - y_s^2|^2 ds + 2CE \int_t^T (|y_s^1 - y_s^2|^2 + |y_s^1 - y_s^2||z_s^1 - z_s^2|) ds \\ + 2E \int_t^T [C|y_s^1 - y_s^2| \|y_s^1 - y_s^2\| + |z_s^1 - z_s^2| \langle (2A_1(s))(y_s^1 - y_s^2), y_s^1 - y_s^2 \rangle^{1/2}] ds. \end{aligned}$$

Since $\|A_1(s)\|_{\mathcal{L}(V, V)} \leq C$, we can choose a small constant δ with $1 > 2\delta > 0$ such that

$$\frac{\delta}{1 - 2\delta} \langle 2A_1(s)y, y \rangle \leq \frac{\alpha}{2} \|y\|^2, \quad \forall y \in V.$$

Also, we have

$$2C|y^1 - y^2| \|y^1 - y^2\| < \frac{\alpha}{2} \|y^1 - y^2\|^2 + \frac{2}{\alpha} C^2 |y^1 - y^2|^2$$

and

$$\begin{aligned} & 2|z^1 - z^2| \langle 2A_1(s)(y^1 - y^2), y^1 - y^2 \rangle^{1/2} \\ & \leq (1 - 2\delta)|z^1 - z^2|^2 + \frac{1}{1 - 2\delta} \langle 2A_1(s)(y^1 - y^2), y^1 - y^2 \rangle, \\ & 2C|y^1 - y^2||z^1 - z^2| \leq C\delta^{-1}|y^1 - y^2|^2 + \delta|z^1 - z^2|^2. \end{aligned}$$

It follows that

$$\begin{aligned} & E|y_t^1 - y_t^2|^2 + \frac{\alpha}{2} E \int_t^T \|y_s^1 - y_s^2\|^2 ds + \delta E \int_t^T |z_s^1 - z_s^2|^2 ds \\ & \leq C_1 E \int_t^T |y_s^1 - y_s^2|^2 ds, \quad \forall t \in [0, T], \end{aligned}$$

with $C_1 = 2\lambda + 2C + 4\alpha^{-1}C^2 + \delta^{-1}C^2$. Thus we can apply Gronwall's inequality to obtain $y^1 = y^2, z^1 = z^2$.

(ii) *Existence.* Set $z_t^0 = 0$. According to Theorem 2.2, we can alternatively solve the following equation:

$$\begin{aligned} (4.9) \quad Y &= y_t^j + \int_t^T (A(s)y_s^j + A_1(s)y_s^j + f(y_s^j, z_s^{j-1}, s) + g(y_s^j, z_s^j, s)) ds \\ &+ \int_t^T z_s^j dW_s, \quad j = 1, 2, \dots \end{aligned}$$

By Itô's formula, we have

$$\begin{aligned} & E|y_t^{j+1} - y_t^j|^2 + 2E \int_t^T \langle (A(s) + A_1(s))(y_s^{j+1} - y_s^j), y_s^{j+1} - y_s^j \rangle \\ & \quad + E \int_t^T |z_s^{j+1} - z_s^j|^2 ds \\ &= -2E \int_t^T (g(y_s^{j+1}, z_s^{j+1}, s) - g(y_s^j, z_s^j, s), y_s^{j+1} - y_s^j) ds \\ & \quad - 2E \int_t^T \langle f(y_s^{j+1}, z_s^j, s) - f(y_s^j, z_s^{j-1}, s), y_s^{j+1} - y_s^j \rangle ds. \end{aligned}$$

Again, from (2.8), (2.9), and (4.7), we have

$$\begin{aligned} & E|y_t^{j+1} - y_t^j|^2 + 2E \int_t^T \langle A_1(s)(y_s^{j+1} - y_s^j), y_s^{j+1} - y_s^j \rangle ds \\ & \quad + 2\alpha E \int_t^T \|y_t^{j+1} - y_t^j\|^2 dt + E \int_t^T |z_s^{j+1} - z_s^j|^2 ds \\ & \leq CE \int_t^T (2\|y_t^{j+1} - y_t^j\| + |z_s^{j+1} - z_s^j|) |y_s^{j+1} - y_s^j| ds \\ & \quad + (2\lambda + 2C)E \int_t^T |y_s^{j+1} - y_s^j|^2 ds \\ & \quad + 2E \int_t^T |z_s^j - z_s^{j-1}| \langle 2A_1(s)(y_s^{j+1} - y_s^j), y_s^{j+1} - y_s^j \rangle^{1/2} ds. \end{aligned}$$

Taking δ as in the proof of the uniqueness and using the similar technique yield

$$(4.10) \quad \begin{aligned} & E|y_t^{j+1} - y_t^j|^2 + \frac{\alpha}{2} E \int_t^T \|y_s^{j+1} - y_s^j\|^2 dt + (1-\delta) E \int_t^T |z_s^{j+1} - z_s^j|^2 ds \\ & \leq C_2 E \int_t^T |y_s^{j+1} - y_s^j|^2 ds + (1-2\delta) E \int_t^T |z_s^j - z_s^{j-1}|^2 ds, \end{aligned}$$

where the constant C_2 is the same as in the proof of the uniqueness. Define

$$\begin{aligned} Y_s^j &= E \int_t^T |y_s^{j+1} - y_s^j|^2 ds, \quad j = 1, 2, \dots, \\ Z_s^j &= E \int_t^T |z_s^{j+1} - z_s^j|^2 ds, \quad j = 0, 1, 2, \dots. \end{aligned}$$

It follows from (4.10) that

$$(4.11) \quad -\frac{d}{dt} Y_t^j + (1-\delta) Z_t^j \leq C_2 Y_t^j + (1-2\delta) Z_t^{j-1} \quad Y_0^j = 0, \quad j = 1, 2, \dots,$$

or

$$-\frac{d}{dt} (Y_t^j e^{C_2 t}) + (1-\delta) e^{C_2 t} Z_t^j \leq (1-2\delta) e^{C_2 t} Z_t^{j-1} \quad Y_0^j = 0, \quad j = 1, 2, \dots.$$

Integrating from t to T yields

$$(4.12) \quad Y_t^j + (1-\delta) \int_t^T e^{C_2(s-t)} Z_s^j ds \leq (1-2\delta) \int_t^T e^{C_2(s-t)} Z_s^{j-1} ds.$$

It follows, in particular, that

$$\int_0^T e^{C_2 s} Z_s^j ds \leq \left(\frac{1-2\delta}{1-\delta} \right)^j K, \quad j = 1, 2, \dots,$$

with $K = E \int_0^T |z_s^1|^2 ds$; also then

$$(4.13) \quad Y_t^j \leq Y_0^j \leq \left(\frac{1-2\delta}{1-\delta} \right)^j K, \quad j = 1, 2, \dots.$$

From (4.11) and the fact that $dY_t^j dt \leq 0$, we derive that

$$Z_0^j \leq K_1 \left(\frac{1-2\delta}{1-\delta} \right)^j + \frac{(1-2\delta)}{(1-\delta)} Z_0^{j-1}, \quad j = 1, 2, \dots,$$

with $K_1 = C_2 K (1-\delta)^{-1}$. This implies

$$Z_0^j = E \int_0^T |z_s^{j+1} - z_s^j|^2 ds \leq \left(\frac{1-2\delta}{1-\delta} \right)^j (jK_1 + Z_0^0), \quad j = 1, 2, \dots.$$

It turns out that $\{(y^j, z^j)\}$ is a Cauchy sequence in $\mathcal{M}^2(H) \times \mathcal{M}^2(H)$. From (4.10), $\{y^j\}$ is also a Cauchy sequence in $\mathcal{M}^2(V)$ and $L^2(\Omega, C(0, T; H))$. Passing limit in (4.9) as $j \rightarrow \infty$, we obtain that the pair (y_t, z_t) defined by

$$\begin{aligned} y &= \lim_{j \rightarrow \infty} y^j \text{ in } \mathcal{M}^2(V), \\ z &= \lim_{j \rightarrow \infty} z^j \text{ in } \mathcal{M}^2(H) \end{aligned}$$

solves (4.8). \square

We now proceed to the proof of Theorem 4.1.

Proof of Theorem 4.1. Set

$$\begin{aligned}
 \langle A_1(t)\varphi_1, \varphi \rangle &= \frac{1}{2} \int_{R^n} (\sigma\sigma^*(x, t) D\varphi_1, D\varphi) dx, \quad \forall \varphi_1, \varphi \in V, \\
 \langle A(t)\varphi_1, \varphi \rangle &= \frac{1}{2} \int_{R^n} (\pi\pi^*(x, t) D\varphi_1, D\varphi) dx, \quad \forall \varphi_1, \varphi \in V, \\
 \langle f(\psi, t), \varphi \rangle &= \int_{R^n} (\psi(x), \sigma(x, t) D\varphi) dx, \quad \forall \psi \in H, \varphi \in V, \\
 g(\varphi, \psi, t) &= \frac{1}{2} \sum_{i,j=1}^n \partial_{x_i}(\sigma\sigma^*)_{ij} \partial_{x_j} \varphi \\
 &\quad + \frac{1}{2} \sum_{i,j=1}^n \partial_{x_i}(\pi\pi^*)_{ij} \partial_{x_j} \varphi - \psi \sum_{i=1}^n \partial_{x_i} \sigma_i(x, t) \\
 &\quad + \inf_{v \in U} \{(b(x, v, t), D\varphi(x)) + L(x, v, t)\}, \quad \forall \varphi \in V, \\
 \eta &= 0, \quad Y(\omega) = h(x, \omega).
 \end{aligned}$$

It is easy to see that

$$\begin{aligned}
 A_1(t), A_2(t) &: [0, T] \rightarrow \mathcal{L}(V; V'), \\
 f(\psi, t) &: H \times [0, T] \rightarrow V', \\
 g(\varphi, \psi, t) &: V \times H \times [0, T] \rightarrow H, \\
 Y(\omega) &: \Omega \rightarrow H.
 \end{aligned}$$

Thus, for each $w, \varphi \in V, \psi \in H$, we have that

$$\langle (A(s) + A_1(s))\varphi + f(\psi, s) + g(\varphi, \psi, s), w \rangle = \int_{R^n} H(D^2\varphi, D\varphi, D\psi, x, t) w(x) dx.$$

With the above notations, we can write the stochastic HJB equation (3.7) in the form of (4.8).

It remains to check that the conditions of Lemma 4.2 are satisfied. We will only verify (4.6) and (4.7) because the other conditions are easy to check. First, for (4.6), we need to verify

$$\begin{aligned}
 (4.14) \quad & \int_{R^n} \left| \inf_{v \in U} \{(b(x, v), D\varphi_1(x)) + L(x, v)\} \right. \\
 & \left. - \inf_{v \in U} \{(b(x, v), D\varphi_2(x)) + L(x, v)\} \right|^2 dx \leq C \|\varphi_2 - \varphi_1\|_V^2.
 \end{aligned}$$

For any $\varepsilon > 0$ and $\varphi_1, \varphi_2 \in V$, we can choose two measurable functions $v_l^\varepsilon(x): \mathbb{R}^n \rightarrow U$, $l = 1, 2$, such that

$$\begin{aligned}
 & \int_{R^n} |(b(x, v_l^\varepsilon, t), D\varphi_l(x)) + L(x, v_l^\varepsilon, t) - \inf_{v \in U} \{(b(x, v, t), D\varphi_l(x)) + L(x, v, t)\}|^2 \\
 & = \int_{R^n} |\delta_l^\varepsilon(x)|^2 dx \leq \varepsilon, \quad l = 1, 2.
 \end{aligned}$$

For each $x \in \mathbb{R}^n$, we have

$$\begin{aligned} & \inf_{v \in U} \{(b(x, v, t), D\varphi_1(x)) + L(x, v, t)\} - \inf_{v \in U} \{(b(x, v, t), D\varphi_2(x)) + L(x, v, t)\} \\ & \quad \cong (b(x, v_1^\varepsilon, t), D\varphi_1(x)) + L(x, v_1^\varepsilon, t) - (b(x, v_1^\varepsilon, t), D\varphi_2(x)) - L(x, v_1^\varepsilon, t) - |\delta_1^\varepsilon(x)| \\ & \quad \cong -C|D\varphi_1(x) - D\varphi_2(x)| - |\delta_1^\varepsilon(x)|. \end{aligned}$$

Similarly,

$$\begin{aligned} & \inf_{v \in U} \{(b(x, v, t), D\varphi_2(x)) + L(x, v, t)\} - \inf_{v \in U} \{(b(x, v, t), D\varphi_1(x)) + L(x, v, t)\} \\ & \quad \cong -C|D\varphi_1(x) - D\varphi_2(x)| - |\delta_2^\varepsilon(x)|. \end{aligned}$$

The above two inequalities imply

$$\begin{aligned} & \int_{\mathbb{R}^n} \left| \inf_{v \in U} \{(b(x, v, t), D\varphi_1(x)) + L(x, v, t)\} - \inf_{v \in U} \{(b(x, v, t), D\varphi_2(x)) + L(x, v, t)\} \right|^2 dx \\ & \quad \leq C \|\varphi_1 - \varphi_2\|_V^2 + |\delta_1^\varepsilon|_H^2 + |\delta_2^\varepsilon|_H^2 \\ & \quad \leq C \|\varphi_1 - \varphi_2\|_V^2 + 2\varepsilon. \end{aligned}$$

Let $\varepsilon \rightarrow 0$, we obtain (4.14).

Finally, the last Lipschitz condition in (2.9) can be derived as follows. For any $\psi_1, \psi_2 \in H$, $\varphi \in V$, $t \in [0, T]$, we have

$$\begin{aligned} |\langle f(\psi_1, t) - f(\psi_2, t), \varphi \rangle| &= \left| \int_{\mathbb{R}^n} (\psi_1 - \psi_2, \sigma^*(x, t) D\varphi) dx \right| \\ &\leq |\psi_1 - \psi_2|_H |\sigma^* D\varphi|_H \\ &= |\psi_1 - \psi_2|_H \left[\int_{\mathbb{R}^n} (\sigma \sigma^*(x, t) D\varphi, D\varphi) dx \right]^{1/2} \\ &= |\psi_1 - \psi_2|_H \langle A_1(t) \varphi, \varphi \rangle^{1/2}. \end{aligned} \quad \square$$

5. Linear quadratic case: Stochastic Riccati equation.

5.1. Problem formulation. As a particular but important case, we consider a linear stochastic control system with quadratic cost function and random coefficients. For simplicity, we assume that σ, π, b, L are all time-invariant. We assume also that W_t^1 is a one-dimensional Brownian motion ($p=1$). In this case all data in (3.1), (3.2) can be written as follows:

$$\begin{aligned} b(x, v) &= Ax + Bv, \\ \sigma(x, v) &= Cx + Dv, \\ \pi(x, v) &= Gx + Hv, \\ L(x, v) &= (Rx, x) + (Nv, v), \\ h(x, \omega) &= (Q(\omega)x, x), \end{aligned}$$

where A, C , and G are $n \times n$ matrices; B, D , and H are $n \times k$ matrices; $R \in S^n$; $N \in S^k$; $Q(\omega): \Omega \rightarrow S^n$. Here S^n (respectively, S^k) denotes the space of all $n \times n$ (respectively, $k \times k$ symmetric matrices), with scalar product $\langle Q_1, Q_2 \rangle = \text{tr}(Q_1, Q_2)$.

We assume

$$(5.1) \quad \begin{aligned} Q(\omega) &\text{ is } \mathcal{F}_T\text{-measurable, bounded, and nonnegative,} \\ R &\text{ is nonnegative, } N \text{ is positive.} \end{aligned}$$

The admissible controls now are valued in \mathbb{R}^k . Equation (2.1) now becomes

$$(5.2) \quad \begin{aligned} dy_s &= (Ay_s + Bv_s) ds + (Cy_s + Dv_s) dW_s + (Gy_s + Hv_s) dW_s^1, \\ 0 \leq s \leq t \leq T, \quad y_t &= x, \end{aligned}$$

and the value function is

$$(5.2) \quad \Phi_t(x) = \inf_{v \in \mathcal{M}^2(\mathbb{R}^k)} E^{\mathcal{F}_t} \left\{ \int_t^T [(Ry_s, y_s) + (Ny_s, y_s)] ds + (Qy_T, y_T) \right\}.$$

By classical methods, we can prove that $\Phi_t(x)$ is of the quadratic form

$$(5.3) \quad \Phi_t(x) = (K_t x, x), \quad \forall (x, t),$$

where K_t is an S^n -valued \mathcal{F}_t -adapted process. From § 3, we know that $\Phi_t(x)$ can be formally written as

$$(5.4) \quad \Phi_t(x) = (Qx, x) + \int_t^T \Gamma_s(x) ds - \int_t^T \Psi_s(x) dW_s,$$

where Γ_t and Ψ_t are \mathcal{F}_t -adapted real processes. Formally, we have

$$(5.5) \quad \Psi_t(x) = (M_t x, x),$$

where M_t is an \mathcal{F}_t -adapted process valued in S^n . If such (K_t, M_t) is bounded, we can use the dynamic programming principle to verify that the pair $(\Phi_t(x), \Psi_t(x))$ is a solution of the stochastic HJB equation (3.7).

We can formally derive the equation that characterizes (K_t, M_t) . Substituting (5.4), (5.5), and all linear or quadratic data b, σ, π, L, h into (3.7), from Itô's formula we can obtain

$$(5.6) \quad \begin{aligned} -dK_t &= [A^* K_t + K_t A + C^* K_t C + G^* K_t G + M_t C + C^* M_t \\ &\quad - \hat{B}(K_t, M_t) \hat{N}^{-1}(K_t) \hat{B}^*(K_t, M_t)] dt - M_t dW_t, \\ K_T &= Q, \end{aligned}$$

where for each $K, M \in S^n$, we denote

$$(5.7) \quad \begin{aligned} \hat{B} &= \hat{B}(K, M) = KB + MD + C^* KD + G^* KH, \\ \hat{N} &= \hat{N}(K) = N + D^* KD + H^* KH. \end{aligned}$$

Since $\hat{B} \hat{N}^{-1} \hat{B}$ are nonlinear with respect to K and M , (5.6) is a nonlinear backward stochastic equation. Equation (5.6) is called a stochastic matrix Riccati equation. When Q is deterministic, it becomes an ordinary (deterministic) Riccati equation.

5.2. Existence and uniqueness result. We can regard (5.6) as a nonlinear backward stochastic equation in the form (2.2), defined in the Euclidean space S^n . Theorem 2.1 cannot be applied directly, however, because $\hat{B} \hat{N}^{-1} \hat{B}$ does not satisfy the global Lipschitz condition. This kind of equation was first investigated by Bismut [4]. He obtained an existence theorem for the case where $C = 0, D = 0$ by a method based on the fixed point theorem. We will treat the case where only $D = 0$. In this case the

bounded variation part of K_t contains M_t . We must use a different method to overcome this difficulty. The case where D is nonzero is still an open problem.

When $D=0$, \hat{B} and \hat{N} become

$$(5.8) \quad \begin{aligned} \hat{B}(K, t) &= KB + G^*KH, \\ \hat{N}(K, t) &= N + H^*KH. \end{aligned}$$

We assert the following.

THEOREM 5.1. *We assume (5.1) and $D=0$. Then there exists a pair (K_t, M_t) in $(\mathcal{M}^2(S^n))^2$ satisfying the stochastic Riccati equation (5.6) such that K_t is nonnegative and bounded.*

To prove this theorem, the following lemma is in order.

LEMMA 5.2. *Let $\hat{A}_t, \hat{C}_t, \hat{G}_t$ be $\mathbb{R}^{n \times n}$ -valued, and \hat{R}_t be S^n -valued, \mathcal{F}_t -adapted processes. Assume that they are all bounded. Let \hat{Q} be a bounded \mathcal{F}_T -measurable random variable with values in S^n . Then there exists a pair (\hat{K}_t, \hat{M}_t) in $(\mathcal{M}^2(S^n))^2$ satisfying the following linear equation:*

$$(5.9) \quad \begin{aligned} -d\hat{K}_t &= [\hat{A}_t^* \hat{K}_t + \hat{K}_t \hat{A}_t + C_t^* \hat{K}_t C_t + \hat{G}_t^* \hat{K}_t \hat{G}_t \\ &\quad + (\hat{M}_t \hat{C}_t + \hat{C}_t^* \hat{M}_t) + \hat{R}_t], \end{aligned}$$

$$dt - \hat{M}_t dW_t, \quad \hat{K}_T = \hat{Q}.$$

Moreover,

$$(5.10) \quad \sup_{t, \omega} |\hat{K}_t(\omega)|^2 \leq k_0,$$

where the constant k_0 only depends on

$$\sup_{t, \omega} (|\hat{A}_t| + |\hat{C}_t| + |\hat{G}_t|),$$

and

$$\sup_{\omega} \left(|\hat{Q}|^2 + \int_0^T |\hat{R}_t|^2 \right) (\omega).$$

If \hat{R}_t, \hat{Q} are nonnegative, almost surely, then \hat{K}_t is also nonnegative, almost surely.

Proof. The above SDE can be regarded as an ordinary backward SDE in the Euclidean space S^n . According to Theorem 2.1, the existence and uniqueness as well as (5.10) hold. It remains to prove the nonnegativity of \hat{K} . For given (x, t) let y_s be the solution of

$$\begin{aligned} dy_s &= \hat{A}_s y_s ds + \hat{C}_s y_s dW_s + \hat{G}_s y_s dW_s^1, \\ y_t &= x, \quad t \leq s \leq T. \end{aligned}$$

Then, we can apply Itô's formula

$$d(\hat{K}_s y_s, y_s) = -(\hat{R}_s y_s, y_s) ds + (\hat{M}_s y_s, y_s) dW_s + 2(\hat{K}_s y_s, \hat{C}_s y_s dW_s + \hat{G}_s y_s dW_s^1).$$

Thus

$$(\hat{K}_t x, x) = E^{\mathcal{F}_t} \left[\int_t^T (\hat{R}_s y_s, y_s) ds + (\hat{Q} y_T, y_T) \right].$$

It follows that K_t is nonnegative whenever \hat{R}_s, \hat{Q}_s are nonnegative. \square

We now proceed to prove Theorem 5.1.

Proof of Theorem 5.1. (i) *Existence.* We define $F(K, M, U): S^n \times S^n \times \mathcal{L}(\mathbb{R}^n; \mathbb{R}^k) \rightarrow S^n$ by

$$\begin{aligned} F(K, M, U) &= (A + BU)^* K + K(A + BU) + C^* K C \\ &\quad + (G + HU)^* K (G + HU) + (MC + C^* M^*). \end{aligned}$$

We also define $\hat{U}(K): (S^n)^+ \rightarrow \mathcal{L}(\mathbb{R}^n; \mathbb{R}^k)$ by

$$\hat{U}(K) = -\hat{N}^{-1}(K)\hat{B}(K),$$

where $(S^n)^+$ is the set of nonnegative elements of S^n . With these notations, we can rewrite (5.6) as

$$(5.11) \quad \begin{aligned} -dK_t &= [F(K_t, M_t, \hat{U}(K_t)) + \hat{U}^*(K_t)N\hat{U}(K_t)] dt - M_t dW_t, \\ K_T &= Q. \end{aligned}$$

It is seen that

$$(5.12) \quad F(K, M, \hat{U}(K)) + \hat{U}^*(K)N\hat{U}(K) \leq F(K, M, U) + U^*NU, \quad \forall U \in \mathcal{L}(\mathbb{R}^n; \mathbb{R}^k).$$

We now iteratively construct a sequence of approximating solutions. First, we define (K_1, M_1) by solving the following linear backward SDE:

$$\begin{aligned} -dK_{1,t} &= F(K_{1,t}, M_{1,t}, 0) dt - M_{1,t} dW_t, \\ K_{1,T} &= Q. \end{aligned}$$

By Lemma 5.2, we can easily check that the above solution exists, and that $K_{1,t}$ is bounded and nonnegative. Thus $\hat{U}(K_{1,t})$ has meaning and is bounded. Then, we define (K_2, M_2) by solving

$$\begin{aligned} -dK_{2,t} &= [F(K_{2,t}, M_{2,t}, \hat{U}(K_{1,t})) + \hat{U}^*(K_{1,t})N\hat{U}(K_{1,t})] dt - M_{2,t} dW_t, \\ K_{2,T} &= Q. \end{aligned}$$

Again from Lemma 5.2, there is a unique solution (K_2, M_2) , which is bounded and nonnegative. Thus $\hat{U}(K_{2,t})$ is well defined and bounded. Inductively, we can define (K_{j+1}, M_{j+1}) , which is the unique bounded and nonnegative solution of

$$(5.13) \quad \begin{aligned} -dK_{j+1,t} &= F(K_{j+1,t}, M_{j+1,t}, \hat{U}(K_{j,t})) dt + \hat{U}^*(K_{j,t})N\hat{U}(K_{j,t}) dt - M_{j+1,t} dW_t, \\ K_{j+1,T} &= Q, \quad j = 1, 2, \dots \end{aligned}$$

We claim that the sequence $\{K_{j,t}\}$ is nonincreasing. Indeed, we have

$$\begin{aligned} -d(K_{j,t} - K_{j+1,t}) &= [F(K_{j,t}, M_{j,t}, \hat{U}(K_{j,t})) - F(K_{j+1,t}, M_{j+1,t}, \hat{U}(K_{j,t}))] dt \\ &\quad + [F(K_{j,t}, M_{j,t}, \hat{U}(K_{j-1,t})) + \hat{U}^*(K_{j-1,t})N\hat{U}(K_{j-1,t}) \\ &\quad - F(K_{j,t}, M_{j,t}, \hat{U}(K_{j,t})) - \hat{U}^*(K_{j,t})N\hat{U}(K_{j,t})] dt \\ &\quad - (M_{j,t} - M_{j+1,t}) dW_t \\ &= F(K_{j,t} - K_{j+1,t}, M_{j,t} - M_{j+1,t}, \hat{U}(K_{j,t})) dt \\ &\quad + R_{j,t} dt - (M_{j,t} - M_{j+1,t}) dW_t, \\ K_{j,T} - K_{j+1,T} &= 0, \end{aligned}$$

with

$$\begin{aligned} R_{j,t} &= F(K_{j,t}, M_{j,t}, \hat{U}(K_{j-1,t})) + \hat{U}^*(K_{j-1,t})N\hat{U}(K_{j-1,t}) \\ &\quad - F(K_{j,t}, M_{j,t}, \hat{U}(K_{j,t})) - \hat{U}^*(K_{j,t})N\hat{U}(K_{j,t}). \end{aligned}$$

From (5.12), R_j is nonnegative. Thus, according to Lemma 5.2, $K_{j,t} - K_{j+1,t}$ is also nonnegative. This implies that $\{K_{j,t}\}$ is the nonincreasing sequence

$$CI \geq K_{1,t} \geq K_{2,t} \geq \dots \geq K_{j,t} \geq \dots \geq 0.$$

It follows that $\{K_{j,t}\}$ converges almost surely to a nonnegative, S^n -valued process K_t . According to Lebesgue's convergence theorem, we have

$$E \int_0^T |K_{j,t} - K_t|^q \rightarrow 0, \quad \text{as } j \rightarrow \infty, \quad \forall q > 0.$$

Thus $\{K_{j,t}\}$, and also then $\{U(K_{j,t})\}$ is a Cauchy sequence in the above sense. We have also almost everywhere

$$E|K_{j,t} - K_t|^q \rightarrow 0, \quad \text{as } j \rightarrow \infty, \quad \forall q > 0.$$

By definition (5.13), we can apply Itô's formula to $|K_{k,t} - K_{j,t}|^2$,

$$\begin{aligned} & E|K_{k,0} - K_{j,0}|^2 + E \int_0^T |M_{k,t} - M_{j,t}|^2 dt \\ &= 2E \int_0^T \text{tr}[(K_{k,t} - K_{j,t})((M_{k,t} - M_{j,t})C + C^*(M_{k,t} - M_{j,t}))] dt + R(j, k), \\ &\leq \frac{1}{2} E \int_0^T |M_{k,t} - M_{j,t}|^2 dt + CE \int_0^T |K_{k,t} - K_{j,t}|^2 dt + R(j, k), \end{aligned}$$

where $R(j, k) \rightarrow 0$ as $\min(j, k) \rightarrow \infty$. Thus $\{M_{j,t}\}$ is a Cauchy sequence in $\mathcal{M}^2(\mathcal{L}(\mathbb{R}^d; S^n))$. Passing to the limit in (5.13), we obtain that (K_t, M_t) is a solution of (5.6), with

$$M_t = \lim_{j \rightarrow \infty} M_{j,t} \quad \text{in } \mathcal{M}^2(S^n).$$

(ii) *Uniqueness.* Let (K_t, M_t) and (K'_t, M'_t) be two pairs in $\mathcal{M}^2(S^n) \times \mathcal{M}^2(S^n)$ satisfying (5.6) (or (5.11)), such that K_t, K'_t are nonnegative and bounded. Then $\hat{U}(K_t)$ and $\hat{U}(K'_t)$ are well defined and bounded. We have

$$\begin{aligned} -d(K_t - K'_t) &= F(K_t - K'_t, M_t - M'_t, \hat{U}(K_t)) dt \\ &\quad + [F(K'_t, M'_t, \hat{U}(K_t)) + \hat{U}^*(K_t)N\hat{U}(K_t) \\ &\quad - F(K'_t, M'_t, \hat{U}(K'_t)) + \hat{U}^*(K'_t)N\hat{U}(K'_t)] dt - M_t dW_t, \\ K_T - K'_T &= 0, \end{aligned}$$

or

$$\begin{aligned} -d(K_t - K'_t) &= F(K_t - K'_t, M_t - M'_t, \hat{U}(K_t)) dt \\ &\quad + R' dt + (M_t - M'_t) dW_t, \\ K_T - K'_T &= 0, \end{aligned}$$

with

$$R' = F(K'_t, M'_t, \hat{U}(K_t)) + \hat{U}^*(K_t)N\hat{U}(K_t) - F(K'_t, M'_t, \hat{U}(K'_t)) + \hat{U}^*(K'_t)N\hat{U}(K'_t).$$

By (5.12), R' is nonnegative. It follows from Lemma 5.2 that $K_t - K'_t$ is nonnegative. Similarly, we can obtain that $K'_t - K_t$ is nonnegative. This implies $K_t = K'_t$. Consequently (from the uniqueness part of Lemma 5.2), $M_t = M'_t$. \square

As we mentioned in § 2 (verification theorem), once we obtain the solution of (5.6), which is regular enough, then the value function can be obtained by $\Phi_t = (K_t x, x)$. Moreover, the optimal feedback control can also be given. Specifically, we have the following corollary.

COROLLARY 5.3. *Let the assumptions of Theorem 5.1 hold. Then the value function is equal to $(K_t x, x)$. The optimal feedback control is*

$$u_t(x) = \hat{U}(K_t)x.$$

Proof. Since K_t is bounded and positive, $\hat{U}(K_t)$ is well posed and bounded. Let (x_0, t_0) be any given initial data. We want to minimize

$$J_{x_0, t_0}(v) = E \int_{t_0}^T [(Rx_t, x_t) + (N_t v_t, v_t)] ds + E(Qx_T, x_T)$$

subject to

$$dx_t = (Ax_t + Bv_t) dt + Cx_t dW_t + (Gx_t + Hv_t) dW_t^1, \quad x_{t_0} = x_0.$$

For any given admissible control v_t , we can apply Itô's formula to $(K_t x_t, x_t)$, and thus verify that

$$(K_{t_0} x_{t_0}, x_{t_0}) \leq E^{\mathcal{F}_{t_0}} \left\{ \left[(Qx_T, x_T) + \int_{t_0}^T (Rx_t, x_t) + (N_t v_t, v_t) \right] ds \right\}.$$

On the other hand, let y_t be a solution of

$$dy_t = (A + B\hat{U}(K_t))y_t dt + Cy_t dW_t + (G + H\hat{U}(K_t))y_t dW_t^1, \quad y_{t_0} = x_0.$$

We can again apply Itô's formula to $(K_t y_t, y_t)$,

$$(K_{t_0} x_{t_0}, x_{t_0}) = E^{\mathcal{F}_{t_0}} \left\{ \left[(Qy_T, y_T) + \int_{t_0}^T (Ry_t, y_t) + (N_t \hat{U}(K_t)y_t, \hat{U}(K_t)y_t) \right] ds \right\}.$$

It follows that, for almost surely (x_0, t_0) $(K_{t_0} x_0, x_0)$ is equal to the value function. Furthermore, if we set $u_t = \hat{U}(K_t)y_t$,

$$\begin{aligned} J_{x_0, t_0}(v) &= E \int_{t_0}^T [(Rx_t, x_t) + (N_t v_t, v_t)] ds + E(Qx_T, x_T) \\ &= EE^{\mathcal{F}_{t_0}} \left[\int_{t_0}^T [(Rx_t, x_t) + (N_t v_t, v_t)] ds + (Qx_T, x_T) \right] \\ &\geq EE^{\mathcal{F}_{t_0}} \left[\int_{t_0}^T [(Ry_t, y_t) + (N_t u_t, u_t)] ds + (Qy_T, y_T) \right] \\ &= J_{x_0, t_0}(u) \end{aligned}$$

It follows that u_t is the optimal control and so $U(K_t)x$ is the optimal feedback. \square

Acknowledgments. The author thanks the referees and the editors for their helpful suggestions, which made the revised version of this paper more readable.

A PENALIZATION METHOD FOR OPTIMAL CONTROL OF ELLIPTIC PROBLEMS WITH STATE CONSTRAINTS*

MAÏTINE BERGOUNIOUX†

Abstract. In this paper boundary or distributed stationary control problems are studied in relation to an elliptic operator and state and control constraints. Different kinds of conditions are formulated to prove the existence of a decoupled optimality system and Lagrange multipliers.

Key words. optimal control, optimality conditions, state constraints, Lagrange multipliers, elliptic operators

AMS(MOS) subject classification. 49B22

1. Introduction. In this paper we study state-constrained control problems for elliptic systems. Usually, the state constraints are pointwise constraints, but we do not need to specify them. We prove (for “classical” cases) the existence of a decoupled optimality system and Lagrange multipliers. The method and results are presented by simple examples of distributed or boundary control. It may be applied to many other systems (we must then choose a suitable functional frame). This question has been studied by many authors and, especially for distributed control systems, by Bonnans and Casas [7]–[10], [12], [13]. Their results concern the choice of a “good” functional space. Assuming the Slater qualification constraint, they obtain a first-order optimality system. Lasiecka [16], Barbu [4], and Mackenroth [20], [21] have studied parabolic problems (with a dual approach), White [23] hyperbolic problems, Abergel [1] ill-posed problems, and, with Temam [2], nonqualified problems.

Most of these methods consist in the “relaxation” of the convex (i.e., the state) constraints and use classical results of convex analysis. More precisely, let X, Y be two Banach spaces, $T: X \rightarrow Y$ a continuous linear map, $h: X \rightarrow \bar{\mathbb{R}}$, and $g: Y \rightarrow \bar{\mathbb{R}}$ lower semicontinuous (l.s.c.) convex function. We know [14], [22] that a solution (if it exists) \bar{x} of

$$(1.1) \quad \min h(x) + g(Tx), \quad x \in X,$$

also satisfies

$$(1.2) \quad \partial h(\bar{x}) + T^* \partial g(T\bar{x}) \ni 0$$

(that is, the first-order optimality system) if the following qualification condition is ensured:

$$(1.3) \quad \exists y \text{ in the range of } T; \quad g \text{ is continuous at } y.$$

In the cases we consider, (1.3) is realized as soon as the following condition is satisfied:

$$(1.4) \quad \text{Int}_Y [T(\text{dom}(f)) - \text{dom}(g)] \ni 0.$$

We do not use such methods; we keep the state constraints and penalize the relation linking the state y to the control v via the partial differential equations (and, if necessary, via the boundary condition). The method is classical (Lions [17]) and is generally used for the study of singular systems (especially for multistate systems [18]). We prove the existence of a decoupled optimality system, assuming, of course, a

† Département de Mathématiques, Université d'Orléans, B.P. 6759, 45046 Orléans Cédex 2, France.

qualification hypothesis. We retrieve already-known results and then try to weaken them by changing the topology of the test function spaces (see [6]).

2. Formulation of the problem. Let Ω be an open bounded subset of \mathbb{R}^n with C^∞ boundary Γ . Let us consider the following system:

$$(2.1) \quad \mathbf{P}(u, v) \begin{cases} Ay = u & \text{in } \Omega, \\ By = v & \text{on } \Gamma, \end{cases}$$

where

- (i) $u \in \mathbb{L}^2(\Omega)$, $v \in \mathbb{L}^2(\Gamma)$;
- (ii) A is a differential elliptic operator defined by

$$(2.2) \quad \begin{aligned} Ay &= - \sum_{i,j=1}^n \partial_{x_i} (a_{ij}(x) \partial_{x_j} y) + a_o(x)y \quad \text{with} \\ a_{ij}, a_o &\in \mathcal{C}^2(\bar{\Omega}) \text{ for } i, j = 1, \dots, n, \quad \inf_{x \in \bar{\Omega}} a_o(x) > 0, \end{aligned}$$

$$\sum_{ij=1}^n a_{ij}(x) \xi_i \xi_j \geq c \sum_{i=1}^n \xi_i^2 \quad \forall x \in \bar{\Omega}, \quad \forall \xi \in \mathbb{R}^n, c > 0;$$

- (iii) B is a boundary operator

$$(2.3) \quad \begin{aligned} By &= y|_{\Gamma} && \text{Dirichlet boundary conditions,} \\ By &= \frac{\partial y}{\partial \nu_A} && \text{Neumann boundary conditions,} \end{aligned}$$

where $\partial y / (\partial \nu_A)$ is the usual normal derivative (associated with A).

More precisely, we study the following two cases:

1. The control is *distributed*, so that $\mathbf{P}(u, v)$ becomes

$$\mathbf{P}(v) \begin{cases} Ay = f + v & \text{in } \Omega, \\ By = 0 & \text{on } \Gamma; \end{cases}$$

in this case, the control space X is $\mathbb{L}^2(\Omega)$ ($f \in \mathbb{L}^2(\Omega)$);

2. The control is a *boundary* one, so that $\mathbf{P}(u, v)$ becomes

$$\mathbf{P}(v) \begin{cases} Ay = f & \text{in } \Omega, \\ By = v & \text{on } \Gamma; \end{cases}$$

in this case, the control space X is $\mathbb{L}^2(\Gamma)$ ($f \in \mathbb{L}^2(\Omega)$).

We call T the affine application from X to $\mathbb{L}^2(\Omega)$ such that $y = T(v)$ is the unique solution of $\mathbf{P}(v)$ (in all the cases we consider, $\mathbf{P}(v)$ has a unique solution).

Let $J: \mathbb{L}^2(\Omega) \times X \rightarrow \mathbb{R}^+$ be a strictly convex, Gâteaux-differentiable functional (cost functional). We may choose, for example,

$$(2.4) \quad J(y, v) = \frac{1}{2} \|y - z_d\|_{\Omega}^2 + \frac{1}{2} \|v\|_X^2,$$

where $z_d \in \mathbb{L}^2(\Omega)$, N is a nonnegative real, $\|\cdot\|_X$ is the X -norm, and $\|\cdot\|_{\Omega}$ is the $\mathbb{L}^2(\Omega)$ -norm.

Let K be a nonempty closed convex subset of $\mathbb{L}^2(\Omega)$, and let U_{ad} be a nonempty closed convex subset of X .

Remark 1. K may be a priori any convex set, but we are essentially interested in *pointwise constraints*. So we must be able to define $y(x)$ everywhere on Ω . Let us consider, for example, the following distributed case: if the dimension n is less than

or equal to 3, it is (generally) sufficient to choose the control (and f) in $\mathbb{L}^2(\Omega)$ because most of the time the state y belongs to $\mathbb{H}^2(\Omega) \subseteq \mathcal{C}(\bar{\Omega})$ (due to Sobolev embeddings). For any dimension n , we should take \mathbb{L}^p as the control space, with $p > n/2$, so that $y(\in W^{2,p})$ still belongs to $\mathcal{C}(\bar{\Omega})$ (see [3]). Then a suitable choice of J may be, for example, $J(y, v) = \frac{1}{2}\|y - z_d\|_{\Omega}^2 + N/p\|v\|_X^p$. Anyway, the method can be developed in the same way without any difficulties.

We consider the following optimal control problem:

$$\begin{aligned} (\Pi) \quad & \text{Min } J(y, v), \\ & y = T(v), \\ & y \in K, v \in U_{\text{ad}}. \end{aligned}$$

Remark 2. When $f=0$, this problem may be considered as a particular case of (1.1) with X as the control space, $Y \subseteq \mathbb{L}^2(\Omega)$, $h = J \circ \mathcal{T}$, and $g = \mathbf{1}_K$. ($\mathcal{T}(v) = (T(v), v)$ for each v in X and $\mathbf{1}_K$ is the indicatrix of the state constraints set.) Then (1.4) is implied by the classical Slater condition [7], [13]

$$(\mathcal{S}) \quad \exists v_o \in U_{\text{ad}} \text{ such that } T(v_o) \in \text{Int}_Y(K).$$

We must suppose that the feasible domain \mathcal{D} of (II) is nonempty, i.e.,

$$(2.5) \quad \exists v_o \in U_{\text{ad}} \text{ such that } y_o = T(v_o) \in K$$

$$(\mathcal{D} = \{(y, v) \in K \times U_{\text{ad}} \mid y = T(v)\}).$$

$K \times U_{\text{ad}}$ is convex, closed, and the application from X to $\mathbb{L}^2(\Omega)$, $v \mapsto T(v)$ is affine. So \mathcal{D} is nonempty, closed, and convex; moreover, J is strictly convex, so (II) has a unique solution (\bar{y}, \bar{v}) .

Let us differentiate J as follows:

$$\forall v \in U_{\text{ad}} \text{ such that } T(v) \in K: J'(\bar{y}, \bar{v})(T(v) - T(\bar{v}), v - \bar{v}) \geq 0.$$

For example, when J is given by (2.4), and $X = \mathbb{L}^2(\Omega)$, this optimality condition can be written as follows:

$$(2.6) \quad \begin{aligned} & \forall v \in U_{\text{ad}}, \\ & \forall y \in K \text{ s.t. } y = T(v) \quad \int_{\Omega} (\bar{y} - z_d)(y - \bar{y}) \, dx + N \int_{\Omega} \bar{v}(v - \bar{v}) \, dx \geq 0. \end{aligned}$$

Thus it is easy to obtain a coupled optimality condition (even with state constraints). “Coupled” means that the test functions y and v are linked with the relation $y = T(v)$. The optimal solution of (II) is obtained by projection on the convex \mathcal{D} , quite difficult to “describe” (especially for numerical tests). The problem now is to obtain a decoupled system where the test functions v and y may be chosen in U_{ad} and K , independently of each other.

3. Case I. Distributed control.

3.1. Dirichlet boundary conditions.

3.1.1. Penalization of the problem (II). Let us consider the following *Dirichlet* problem:

$$(3.1) \quad \mathbf{P}(v) \begin{cases} Ay = f + v & \text{in } \Omega, \\ y = 0 & \text{on } \Gamma, \end{cases}$$

where $v \in \mathbb{L}^2(\Omega)$ and $f \in \mathbb{L}^2(\Omega)$. It is well known that $\mathbf{P}(v)$ has a unique solution $y(v)$

in $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$ (cf. [17], [18]) and T is affine and continuous from $\mathbb{L}^2(\Omega)$ to $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$. (If $f=0$, T is an isomorphism.)

In this case,

$$J(y, v) = \frac{1}{2} \int_{\Omega} (y - z_d)^2 dx + \frac{1}{2} \int_{\Omega} v^2 dx,$$

and K (respectively, U_{ad}) is a nonempty, closed, convex subset of $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$ (respectively, $\mathbb{L}^2(\Omega)$).

We are going to penalize (Π) (cf. [18]). Let us choose $\varepsilon > 0$ and define J_ε on $[\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)] \times \mathbb{L}^2(\Omega)$ by

$$(3.2) \quad J_\varepsilon(y, v) = J(y, v) + \frac{1}{2\varepsilon} \int_{\Omega} (Ay - v - f)^2 dx.$$

Let (Π_ε) be the penalized problem

$$(\Pi_\varepsilon) \quad \begin{aligned} &\text{Min } J_\varepsilon(y, v), \\ &y \in K, v \in U_{ad}. \end{aligned}$$

PROPOSITION 3.1. *Let $\varepsilon > 0$. There is a unique couple $(y_\varepsilon, v_\varepsilon)$ in $K \times U_{ad}$ optimal solution of (Π_ε) and for all $(y, v) \in K \times U_{ad}$, $J'_\varepsilon(y_\varepsilon, v_\varepsilon)(y - y_\varepsilon, v - v_\varepsilon) \geq 0$.*

Proof. J_ε is a coercive, strictly convex functional minimized on a nonempty closed, convex domain, so we get the existence of $(y_\varepsilon, v_\varepsilon)$. Moreover, J is differentiable, and we have the wanted inequality. \square

This means that

$$\begin{aligned} &\int_{\Omega} (y_\varepsilon - z_d)(y - y_\varepsilon) dx + N \int_{\Omega} v_\varepsilon(v - v_\varepsilon) dx + \frac{1}{\varepsilon} \int_{\Omega} (Ay_\varepsilon - v_\varepsilon - f)[A(y - y_\varepsilon)] dx \\ &\quad - \frac{1}{\varepsilon} \int_{\Omega} (Ay_\varepsilon - v_\varepsilon - f)(v - v_\varepsilon) dx \geq 0. \end{aligned}$$

As y and v are independent variables, this optimality condition can be decoupled to obtain the following system:

$$(3.3) \quad \forall y \in K \quad \int_{\Omega} (y_\varepsilon - z_d)(y - y_\varepsilon) dx + \frac{1}{\varepsilon} \int_{\Omega} [Ay_\varepsilon - v_\varepsilon - f][A(y - y_\varepsilon)] dx \geq 0,$$

$$(3.4) \quad \forall v \in U_{ad} \quad \int_{\Omega} \left[Nv_\varepsilon - \frac{1}{\varepsilon} (Ay_\varepsilon - v_\varepsilon - f) \right] (v - v_\varepsilon) dx \geq 0.$$

Let us call

$$(3.5) \quad q_\varepsilon = \frac{Ay_\varepsilon - v_\varepsilon - f}{\varepsilon} \in \mathbb{L}^2(\Omega),$$

and let $p_\varepsilon \in \mathbb{H}_o^1(\Omega) \cap \mathbb{H}^2(\Omega)$ be the adjoint state solution of

$$(3.6) \quad \begin{aligned} A^*p_\varepsilon &= y_\varepsilon - z_d && \text{in } \Omega, \\ p_\varepsilon &= 0 && \text{on } \Gamma, \end{aligned}$$

where A^* is the adjoint of A .

Remark 3. If A is given by (2.2), A^* is an isomorphism from $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$ onto $\mathbb{L}^2(\Omega)$.

Let us recall Green's formula (cf. [18]). For all $(y, z) \in \mathbb{H}^2(\Omega) \times \mathbb{H}^2(\Omega)$,

$$(3.7) \quad \int_{\Omega} (Ay)z \, dx = \int_{\Omega} y(A^*z) \, dx - \int_{\Gamma} \frac{\partial y}{\partial \nu_A} z \, d\Gamma + \int_{\Gamma} \frac{\partial z}{\partial \nu_{A^*}} y \, d\Gamma.$$

As (3.3) is equivalent to

$$\int_{\Omega} (A^*p_{\varepsilon})(y - y_{\varepsilon}) \, dx + \int_{\Omega} q_{\varepsilon}[A(y - y_{\varepsilon})] \, dx \geq 0, \quad \forall y \in K,$$

we obtain the following result.

PROPOSITION 3.2. *Let $(y_{\varepsilon}, v_{\varepsilon})$ be the solution of (Π_{ε}) ,*

$$(3.8) \quad \forall y \in K \quad \int_{\Omega} (q_{\varepsilon} + p_{\varepsilon})[A(y - y_{\varepsilon})] \, dx \geq 0,$$

$$(3.9) \quad \forall v \in U_{\text{ad}} \quad \int_{\Omega} (Nv_{\varepsilon} - q_{\varepsilon})(v - v_{\varepsilon}) \, dx \geq 0.$$

Now we must study the asymptotic behaviour of these relations. First, we can describe the behaviour of y_{ε} , v_{ε} , and p_{ε} as ε tends to zero.

THEOREM 3.3. *Let (\bar{y}, \bar{v}) be the solution of (2). v_{ε} converges to \bar{v} strongly in $\mathbb{L}^2(\Omega)$, and y_{ε} converges to \bar{y} strongly in $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$, as ε tends to zero.*

Proof. The proof is nearly the same as the one given by Lions [17] for a similar penalization problem.

Let us give $\varepsilon > 0$. We have

$$0 \leq J_{\varepsilon}(y_{\varepsilon}, v_{\varepsilon}) \leq J_{\varepsilon}(\bar{y}, \bar{v}) = J(\bar{y}, \bar{v}) = j < +\infty.$$

Therefore there exists $k_o \geq 0$ such that

$$\sup_{\varepsilon > 0} \|y_{\varepsilon}\|_{\Omega} \leq k_o \quad \text{and} \quad \sup_{\varepsilon > 0} \|v_{\varepsilon}\|_{\Omega} \leq k_o.$$

So (extracting subsequences) v_{ε} converges to v_o weakly in $\mathbb{L}^2(\Omega)$, and y_{ε} converges to y_o weakly in $\mathbb{L}^2(\Omega)$. It is easy to see that $y_o = T(v_o)$, $y_o \in K$, and $v_o \in U_{\text{ad}}$. Moreover,

$$J(\bar{y}, \bar{v}) \geq \liminf_{\varepsilon \rightarrow 0} J_{\varepsilon}(y_{\varepsilon}, v_{\varepsilon}) \geq \liminf_{\varepsilon \rightarrow 0} J(y_{\varepsilon}, v_{\varepsilon}) \geq J(y_o, v_o)$$

and

$$J(y_{\varepsilon}, v_{\varepsilon}) \leq J(\bar{y}, \bar{v}) \Rightarrow \liminf_{\varepsilon \rightarrow 0} J(y_{\varepsilon}, v_{\varepsilon}) = J(y_o, v_o) \leq J(\bar{y}, \bar{v}).$$

Therefore, $J(y_o, v_o) = J(\bar{y}, \bar{v})$ and $y_o = \bar{y}$, $v_o = \bar{v}$ (because the optimal solution of (Π) is unique). So we have just proved the weak convergence of y_{ε} to \bar{y} in $\mathbb{L}^2(\Omega)$, and v_{ε} to \bar{v} in $\mathbb{L}^2(\Omega)$.

Let us show the strong convergence; $\lim_{\varepsilon \rightarrow 0} J_{\varepsilon}(y_{\varepsilon}, v_{\varepsilon}) = J(\bar{y}, \bar{v})$ implies that

$$\lim_{\varepsilon \rightarrow 0} \|y_{\varepsilon} - \bar{y}\|_{\Omega}^2 + \|v_{\varepsilon} - \bar{v}\|_{\Omega}^2 = \|\bar{y} - \bar{y}\|_{\Omega}^2 + \|\bar{v} - \bar{v}\|_{\Omega}^2.$$

$\mathbb{L}^2(\Omega) \times \mathbb{L}^2(\Omega)$ is a Hilbert space, and so it is uniformly reflexive [11]. As we already have the weak convergence and the convergence of the norms, we then know that the convergence of v_{ε} to \bar{v} and y_{ε} to \bar{y} is strong in $\mathbb{L}^2(\Omega)$. Moreover, Ay_{ε} converges to $A\bar{y}$ strongly in $\mathbb{L}^2(\Omega)$, and A is an isomorphism; y_{ε} converges strongly to \bar{y} in $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$. \square

COROLLARY 3.4. *As ε tends to zero, p_ε converges to \bar{p} strongly in $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$, where \bar{p} is solution of*

$$(3.10) \quad \begin{aligned} A^* \bar{p} &= \bar{y} - z_d && \text{in } \Omega, \\ \bar{p} &= 0 && \text{on } \Gamma. \end{aligned}$$

COROLLARY 3.5. *There exists $\varepsilon_o > 0$, $k_o \geq 0$, such that*

$$\begin{aligned} \sup_{0 < \varepsilon \leq \varepsilon_o} \|y_\varepsilon\|_{\mathbb{H}^2(\Omega)} &\leq k_o; & \sup_{0 < \varepsilon \leq \varepsilon_o} \|v_\varepsilon\|_{\mathbb{L}^2(\Omega)} &\leq k_o, \\ \sup_{0 < \varepsilon \leq \varepsilon_o} \|\sqrt{\varepsilon} q_\varepsilon\|_{\mathbb{L}^2(\Omega)} &\leq k_o; & \sup_{0 < \varepsilon \leq \varepsilon_o} \|p_\varepsilon\|_{\mathbb{H}^2(\Omega)} &\leq k_o. \end{aligned}$$

3.1.2. Estimation of the multiplier q_ε . We must now estimate the multiplier q_ε to pass to the limit in the penalized optimality system (3.8), (3.9). So we must state an assumption stronger than (2.5) that allows us to obtain such an estimation.

The assumption we set shows that the interior of the convex \mathcal{D} must be nonempty (as does the Slater condition). We cannot avoid this kind of assumption, but we see that we may weaken it as far as possible if we consider the interior of \mathcal{D} for a stronger topology than the one of the state space Y .

Let \mathcal{E} be a dense subset of the control space $\mathbb{L}^2(\Omega)$ such that the injection is continuous. Let $\mathcal{B}(\mathcal{E})$ be the unit ball of \mathcal{E} : $\mathcal{B}(\mathcal{E}) = \{\kappa \in \mathcal{E} \mid \|\kappa\|_{\mathcal{E}} \leq 1\}$ ($\|\cdot\|_{\mathcal{E}}$ is the norm of \mathcal{E}).

We state the following assumption:

$$(3.11) \quad \begin{aligned} &\exists v_o \in U_{\text{ad}}, \quad \exists \rho > 0, \quad \exists R > 0 \text{ such that} \\ &\forall \kappa \in \mathcal{B}(\mathcal{E}), \quad \exists v_\kappa \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}}, \quad y_\kappa = T(f + v_\kappa - \rho\kappa) \in K. \end{aligned}$$

Remark 4. The condition $v_\kappa \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}}$ is not useful, of course, if U_{ad} is bounded (and may be replaced by $v_\kappa \in U_{\text{ad}}$). If U_{ad} is not bounded, we may suppose that v_o is given with (2.5) or $v_o = \bar{v}$. ($\mathcal{B}^2(v_o, R)$ is the \mathbb{L}^2 -ball, centered in v_o , of radius R .)

This assumption allows us to get an estimation of q_ε . We detail in the forthcoming section the optimality conditions to which different choices of \mathcal{E} lead.

PROPOSITION 3.6. *Let us assume (3.11). Then there exists $C \geq 0$, $\varepsilon_o > 0$ such that*

$$\sup_{0 < \varepsilon \leq \varepsilon_o} \|q_\varepsilon\|_{\mathcal{E}'} \leq k_o$$

(q_ε is bounded in the dual space of \mathcal{E} : \mathcal{E}').

Proof. Let κ belong to $\mathcal{B}(\mathcal{E})$. Let us add (3.8) and (3.9) applied to the couple (y_κ, v_κ) of $K \times U_{\text{ad}}$ defined by (3.11), as follows:

$$\begin{aligned} &\int_{\Omega} [q_\varepsilon + p_\varepsilon][A(y_\kappa - y_\varepsilon)] dx + \int_{\Omega} (Nv_\varepsilon - q_\varepsilon)(v_\kappa - v_\varepsilon) dx \geq 0, \\ &\int_{\Omega} p_\varepsilon(Ay_\kappa - f - v_\varepsilon) dx - \int_{\Omega} p_\varepsilon(Ay_\varepsilon - f - v_\varepsilon) dx + \int_{\Omega} q_\varepsilon(Ay_\kappa - v_\kappa - Ay_\varepsilon + v_\varepsilon) dx \\ &\quad + \int_{\Omega} Nv_\varepsilon(v_\kappa - v_\varepsilon) dx \geq 0, \\ &\int_{\Omega} p_\varepsilon(v_\kappa - v_\varepsilon - \rho\kappa) dx - \int_{\Omega} \varepsilon p_\varepsilon q_\varepsilon dx + \int_{\Omega} q_\varepsilon(\rho\kappa - \varepsilon q_\varepsilon) dx + \int_{\Omega} Nv_\varepsilon(v_\kappa - v_\varepsilon) dx \geq 0, \\ &\int_{\Omega} \rho q_\varepsilon \kappa dx \leq -\|\sqrt{\varepsilon} q_\varepsilon\|_{\Omega}^2 + \|Nv_\varepsilon\|_{\Omega} \|v_\kappa - v_\varepsilon\|_{\Omega} + \sqrt{\varepsilon} \|p_\varepsilon\|_{\Omega} \|\sqrt{\varepsilon} q_\varepsilon\|_{\Omega} \\ &\quad + \|p_\varepsilon\|_{\Omega} (\|v_\kappa - v_\varepsilon\|_{\Omega} + \rho \|\kappa\|_{\Omega}). \end{aligned}$$

Using Corollary 3.5, we have, for all $\varepsilon \in]0, \varepsilon_o]$,

$$\int_{\Omega} \rho q_{\varepsilon} \kappa \, dx \leq N k_o (\|v_{\kappa}\|_{\Omega} + k_o) + \sqrt{\varepsilon} k_o^2 + k_o (\|v_{\kappa}\|_{\Omega} + k_o + \rho \|\kappa\|_{\Omega}).$$

Moreover, the injection of \mathcal{E} in $\mathbb{L}^2(\Omega)$ is continuous so that

$$\forall \kappa \in \mathcal{B}(\mathcal{E}) \quad \|\kappa\|_{\Omega} \leq k_1 \|\kappa\|_{\mathcal{E}} = k_1.$$

Finally, as v_o does not depend on ε , and $\|v_{\kappa}\|_{\Omega} \leq (\|v_o\|_{\Omega} + R)$, we get

$$(3.12) \quad \exists C \geq 0, \quad \forall \varepsilon \in]0, \varepsilon_o], \quad \forall \kappa \in \mathcal{B}(\mathcal{E}) \quad \int_{\Omega} q_{\varepsilon} \kappa \, dx \leq C.$$

So q_{ε} is bounded in \mathcal{E}' . \square

We now specify what happens when we choose two different norms in \mathcal{E} .

3.1.3. A “strong” condition. Let \mathcal{E} be $\mathbb{L}^2(\Omega)$. Equation (3.11) then becomes

$$(3.13) \quad \begin{aligned} &\exists v_o \in U_{\text{ad}}, \quad \exists \rho > 0, \quad \exists R > 0 \quad \text{such that} \\ &\forall \kappa \in \mathcal{B}^2(\Omega), \quad \exists v_{\kappa} \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}}, \quad y_{\kappa} = T(f + v_{\kappa} - \rho \kappa) \in K, \end{aligned}$$

where $\mathcal{B}^2(\Omega)$ is the unit ball of $\mathbb{L}^2(\Omega)$.

We obtain the following result.

THEOREM 3.7. *Let us assume (3.13). Let (\bar{y}, \bar{v}) belong to \mathcal{D} , and \bar{p} be defined by (3.10). (\bar{y}, \bar{v}) is the optimal solution of (II) if and only if there exists $\bar{q} \in \mathbb{L}^2(\Omega)$ such that*

$$(3.13) \quad \forall y \in K \quad \int_{\Omega} (\bar{q} + \bar{p}) [A(y - \bar{y})] \, dx \geq 0,$$

$$(3.14) \quad \forall v \in U_{\text{ad}} \quad \int_{\Omega} (N\bar{v} - \bar{q})(v - \bar{v}) \, dx \geq 0.$$

Proof. Let us assume (3.13). Proposition 3.6 shows that q_{ε} is bounded in $\mathbb{L}^2(\Omega)$ (for $\mathbb{L}^2(\Omega)$ is its own dual).

Let (\bar{y}, \bar{v}) be the optimal solution of (II). q_{ε} is uniformly bounded (for the \mathbb{L}^2 -norm). We may then extract a subsequence that converges weakly to \bar{q} in $\mathbb{L}^2(\Omega)$. So, when ε tends to zero, the weak convergence in (3.8) and (3.9) gives us (3.13) and (3.14).

Conversely, let us choose $(y, v) \in \mathcal{D}$ and sum (3.13) and (3.14). As $Ay = f + v$ in Ω and $A\bar{y} = f + \bar{v}$ in Ω , we have

$$\int_{\Omega} (\bar{p} + N\bar{v})(v - \bar{v}) \, dx = \int_{\Omega} \bar{p} [A(y - \bar{y})] \, dx + \int_{\Omega} N\bar{v}(v - \bar{v}) \, dx \geq 0,$$

i.e.,

$$\forall (y, v) \in \mathcal{D}, \quad J'(\bar{y}, \bar{v})(y - \bar{y}, v - \bar{v}) \geq 0.$$

Thus (\bar{y}, \bar{v}) is the (unique) optimal solution of (II). \square

Remark 5. We have chosen $\mathcal{E} = \mathbb{L}^2(\Omega)$, but the proof is the same for any dense subset of $\mathbb{L}^2(\Omega)$. We may also choose very regular perturbations of the control setting, for instance, $\mathcal{E} = \mathcal{C}_o^{\infty}(\Omega)$ (the \mathcal{C}^{∞} -functions on Ω equal zero on Γ).

Remark 6. When $\mathcal{E} = \mathbb{L}^2(\Omega)$, (3.11) is equivalent to

$$\exists v_o \in U_{\text{ad}} \text{ such that } y_o = T(v_o) \in \text{Int}_{\mathbb{H}^2(\Omega)}(K)$$

($\text{Int}_X(K)$ is the interior of K in the sense of X -norm).

If $n \leq 3$, $\mathbb{H}^2(\Omega) \subset \mathcal{C}(\bar{\Omega})$, and (3.11) is equivalent to the Slater condition,

$$(3.15) \quad \exists u \in U_{\text{ad}}, \quad T(u) \in \text{Int}_{\mathbb{L}^{\infty}}(K).$$

So (according to Bonnans and Casas) if we choose U_{ad} such that $0 \in U_{\text{ad}}$ and $K = \{y \in \mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega) \mid |y(x)| \leq 1 \text{ in } \Omega\}$, (\mathcal{H}) is satisfied and Theorem 3.7 gives the optimality conditions.

Now let us consider another example. Let K and U_{ad} be the following sets ($n \leq 3$):

$$(3.15) \quad K = \{y \in \mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega) \mid \varphi(x) \leq y(x) \leq \psi(x) \text{ a.e. on } \Omega\},$$

$$(3.16) \quad U_{\text{ad}} = \{v \in \mathbb{L}^2(\Omega) \mid \alpha(x) \leq v(x) \leq \beta(x)\} \text{ in } \Omega.$$

If $\varphi|_{\Gamma} = \psi|_{\Gamma}$, the Slater condition (i.e., (\mathcal{H})) cannot be satisfied because the \mathbb{L}^∞ -interior of K is empty. So we would like now to weaken assumption (3.11) to extend the results of Theorem 3.7. Of course, under weaker assumptions we obtain a “weaker” optimality system. That will be done by changing the space \mathcal{E} and, more precisely, the topology of \mathcal{E} .

3.1.4. A “weak” condition. Let \mathcal{E} be $\mathcal{C}_o(\Omega)$ with the \mathbb{L}^∞ -norm. ($\mathcal{C}_o(\Omega)$ is the set of continuous functions equal to zero on Γ .) Equation (3.11) then becomes

$$(\mathcal{H}^*) \quad \begin{aligned} &\exists v_o \in U_{\text{ad}}, \quad \exists \rho > 0, \quad \exists R > 0 \quad \text{such that} \\ &\forall \kappa \in \mathcal{B}^\infty(\mathcal{C}_o(\Omega)), \quad \exists v_\kappa \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}}, \quad y_\kappa = T(f + v_\kappa - \rho \kappa) \in K, \end{aligned}$$

($\mathcal{B}^\infty(\mathcal{C}_o(\Omega)) = \{\kappa \in \mathcal{C}_o(\Omega) \mid \|\kappa\|_{\mathbb{L}^\infty} \leq 1\}$ is the unit ball of $\mathcal{C}_o(\Omega)$).

Remark 7. Let us consider K and U_{ad} defined with (3.15) and (3.16), and assume that we can find

1. $e \in \mathcal{C}_o^1(\Omega)$ such that $e > 0$ in Ω , $\partial e / \partial n < 0$, and $\varphi + e \leq \psi - e$ a.e. in Ω ;
2. $v_o \in U_{\text{ad}}$ such that $y_o = T(v_o) \in [\varphi + e, \psi - e]$;

then (\mathcal{H}^*) is satisfied.

We first note that it is sufficient to find $\rho > 0$ such that for all $\kappa \in \mathcal{B}^\infty(\mathcal{C}_o(\Omega))$, $x \in \Omega$,

$$(i) \quad |z(x)| - \frac{e(x)}{\rho} \leq 0,$$

where $z = T(\kappa)$.

Let κ be in $\mathcal{B}^\infty(\mathcal{C}_o(\Omega))$. $z = T(\kappa) \in \mathcal{C}_o^2(\Omega)$ and $\|\nabla z\|_\infty \leq M$, $\|z\|_\infty \leq M$, where M is independent of κ . Moreover, as $e \in \mathcal{C}_o^1(\Omega)$, we can find $m > 0$ such that for all $x \in \Gamma$, $(\partial e / \partial n)(x) \leq -m < 0$.

We first show that (i) is true (with $\rho \geq m/(2M)$) on an open subset \mathcal{V} of Ω , such that $\Gamma \subset \bar{\mathcal{V}}$.

Let x belong to Γ , and ν_x the exterior normal to Γ at x . We can see that (i) is satisfied on $I_x =]x, x - \alpha_x \nu_x[$, where α_x is small enough and nonnegative. (We use the Taylor formula applied to the restriction of e to I_x .) Then we set $\mathcal{V} = \bigcup \{I(x) \mid x \in \Gamma\}$. (We use the regularity properties of Ω and Γ , and the fact that Ω is locally on the same side of Γ .)

Then we may find a compact subset C of Ω such that $C \cap \Gamma = \emptyset$. As the function e is continuous on C and strictly positive, we can find $\tilde{m} > 0$ such that $e(x) \geq \tilde{m}$ for each x of C . So (i) is satisfied on C if we choose $\rho \geq \tilde{m}/M$.

Remark 8. We may note that (\mathcal{S}) (defined with Remark 6) implies (\mathcal{H}^*) , but is not equivalent because T is no longer an isomorphism from $\mathbb{L}^\infty(\Omega)$ to $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$.

Proposition 3.6 ensures that q_e is bounded in the dual space of \mathcal{E} , i.e., in the space of Radon measures on Ω : $\mathcal{M}(\Omega)$. As before, we would like to pass to the limit in the penalized optimality system. The main difficulty is that we must choose test functions

smooth enough to take the limit, in the dual sense $\langle \mathcal{M}(\Omega), \mathcal{C}_o(\Omega) \rangle$. So we define

$$(3.17) \quad \mathcal{F}(\bar{y}) = \{y \in \mathbb{H}^2(\Omega) \mid \exists \varphi \in \mathcal{C}_o(\Omega), Ay = A\bar{y} + \varphi \text{ a.e. on } \Omega\},$$

$$(3.18) \quad \mathcal{G}(\bar{v}) = \bar{v} + \mathcal{C}_o(\Omega).$$

(We note that $\bar{y} \in \mathcal{F}(\bar{y})$ and $\bar{v} \in \mathcal{G}(\bar{v})$).

We obtain the following result.

THEOREM 3.8. *Let us assume (\mathcal{H}^*) and let (\bar{y}, \bar{v}) be the solution of (II). Then there exists $\bar{q} \in \mathcal{M}(\Omega)$ such that*

$$(3.19) \quad \forall y \in K \cap \mathcal{F}(\bar{y}) \quad \int_{\Omega} (\bar{q} + \bar{p})[A(y - \bar{y})] dx \geq 0,$$

$$(3.20) \quad \forall v \in U_{\text{ad}} \cap \mathcal{G}(\bar{v}) \quad \int_{\Omega} (N\bar{v} - \bar{q})(v - \bar{v}) dx \geq 0.$$

Proof. We know (Proposition 3.6) that q_ε is uniformly bounded in $\mathcal{M}(\Omega)$, and we can then extract a subsequence that converges to \bar{q} in $\mathcal{M}(\Omega)$ (with weak star topology).

We cannot pass to the limit immediately in the penalized optimality system because Ay_ε does not converge to $A\bar{y}$ in $\mathcal{C}_o(\Omega)$. (We do not even know if Ay_ε belongs to $\mathcal{C}_o(\Omega)$ or if $A\bar{y}$ is in $\mathcal{C}_o(\Omega)$.) Nevertheless, we may write (3.8) and (3.9) as the following:

$$\forall y \in K \quad \int_{\Omega} p_\varepsilon A(y - y_\varepsilon) dx + \int_{\Omega} q_\varepsilon [A(y - \bar{y}) + (A\bar{y} - f) - (Ay_\varepsilon - f)] dx \geq 0,$$

$$\forall v \in U_{\text{ad}} \quad \int_{\Omega} Nv_\varepsilon(v - v_\varepsilon) dx - \int_{\Omega} q_\varepsilon [(v - \bar{v}) + (\bar{v} - v_\varepsilon)] dx \geq 0,$$

i.e.,

$$\forall y \in K \quad \int_{\Omega} p_\varepsilon A(y - y_\varepsilon) dx + \int_{\Omega} q_\varepsilon A(y - \bar{y}) dx + \int_{\Omega} q_\varepsilon (\bar{v} - v_\varepsilon) dx - \varepsilon \|q_\varepsilon\|_{\Omega}^2 \geq 0,$$

$$\forall v \in U_{\text{ad}} \quad \int_{\Omega} Nv_\varepsilon(v - v_\varepsilon) dx - \int_{\Omega} q_\varepsilon (v - \bar{v}) dx - \int_{\Omega} q_\varepsilon (\bar{v} - v_\varepsilon) dx \geq 0.$$

Adding these two inequalities, we obtain for all $y \in K$, $v \in U_{\text{ad}}$,

$$\int_{\Omega} p_\varepsilon A(y - y_\varepsilon) dx + \int_{\Omega} q_\varepsilon A(y - \bar{y}) dx + \int_{\Omega} Nv_\varepsilon(v - v_\varepsilon) dx - \int_{\Omega} q_\varepsilon (v - \bar{v}) dx \geq 0.$$

We know (without needing (\mathcal{H}^*)) that for all $y \in \mathbb{H}^2(\Omega)$, $v \in \mathbb{L}^2(\Omega)$,

$$\int_{\Omega} p_\varepsilon A(y - y_\varepsilon) dx \rightarrow \int_{\Omega} \bar{p} A(y - \bar{y}) dx \quad \text{and} \quad \int_{\Omega} Nv_\varepsilon(v - v_\varepsilon) dx \rightarrow \int_{\Omega} N\bar{v}(v - \bar{v}) dx.$$

Now we can pass to the limit in $\int_{\Omega} q_\varepsilon A(y - \bar{y}) dx$ and $\int_{\Omega} q_\varepsilon (v - \bar{v}) dx$ if and only if $A(y - \bar{y})$ and $(v - \bar{v})$ are “smooth enough,” i.e., $y \in \mathcal{F}(\bar{y})$ and $v \in \mathcal{G}(\bar{v})$. Thus we get for all $y \in K \cap \mathcal{F}(\bar{y})$, $v \in U_{\text{ad}} \cap \mathcal{G}(\bar{v})$,

$$\int_{\Omega} [\bar{p} + \bar{q}][A(y - \bar{y})] dx + \int_{\Omega} [N\bar{v} - \bar{q}][v - \bar{v}] dx \geq 0.$$

Then, decoupling again (with the successive choices of $y = \bar{y}$ and $v = \bar{v}$), we obtain (3.19) and (3.20). \square

Remark 9. As the test functions must be smooth we lose, of course, the fact that the optimality system is sufficient to ensure that (\bar{y}, \bar{v}) is the optimal solution. Moreover, the difficulty still remaining is to be sure that the test functions spaces $K \cap \mathcal{F}(\bar{y})$ and $U_{\text{ad}} \cap \mathcal{G}(\bar{v})$ are large enough to allow good numerical experimentation. It is the case, for example, if \bar{v} and f belongs to $\mathbb{H}^r(\Omega)$ with $r > n/2$: $\bar{v} \in \mathcal{C}^o(\bar{\Omega})$ and $\bar{y} \in \mathbb{H}^{r+2}(\Omega) \subseteq \mathcal{C}^2(\bar{\Omega})$.

Remark 10. Let us consider the particular case where $A = -\Delta + \text{Id}$, $f = 0$, $U_{\text{ad}} = \mathbb{L}^2(\Omega)$, and $K = \{y \in \mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega) \mid |y| \leq \alpha\}$. This problem is not qualified and has been studied by Abergel and Temam [2], who have proved the existence of an adjoint state (or multiplier) in $BL_o(\Omega)$, where $BL_o(\Omega) = \{q \in \mathbb{L}^2(\Omega) \mid -\Delta q + q \in \mathcal{M}(\Omega), q = 0 \text{ on } \Gamma\}$ ($\mathcal{M}(\Omega)$ bounded measures on Ω), and established sufficient and necessary optimality conditions for \bar{y} to be an optimal solution. Let us apply the penalization to the following problem. Proposition 3.2 gives

$$(a) \quad \forall y \in K \quad \int_{\Omega} [p_{\varepsilon} + q_{\varepsilon}] [-\Delta(y - y_{\varepsilon}) + (y - y_{\varepsilon})] dx \geq 0,$$

$$(b) \quad \forall v \in \mathbb{L}^2(\Omega) \quad \int_{\Omega} (Nv_{\varepsilon} - q_{\varepsilon})(v - v_{\varepsilon}) dx \geq 0.$$

Part (b) means that $q_{\varepsilon} = Nv_{\varepsilon}$ and so q_{ε} converges strongly in $\mathbb{L}^2(\Omega)$ to $\bar{q} = N\bar{v}$. We may pass to the limit in (a) without any qualification hypothesis, and we get

$$(c) \quad \forall y \in K \quad \int_{\Omega} [\bar{p} + \bar{q}] [-\Delta(y - \bar{y}) + (y - \bar{y})] dx \geq 0.$$

So if $\bar{q} \in BL_o(\Omega)$, we may define the measure $\bar{r} = -\Delta\bar{q} + \bar{q}$ according to [2], and

$$\forall y \in \mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega) \quad \int_{\Omega} (-\Delta\bar{q} + \bar{q})y = \int_{\Omega} \bar{q}(-\Delta y + y) dx.$$

Finally, \bar{y} is an optimal solution of (II) if and only if there exists, in $BL_o(\Omega)$, a multiplier (or adjoint state) \bar{q} such that

$$(d) \quad \forall y \in K \quad \int_{\Omega} [\bar{y} - z_d - \Delta\bar{q} + \bar{q}][y - \bar{y}] \geq 0, \\ \bar{q} = N(-\Delta\bar{y} + \bar{y}).$$

Let us note that

$$(d) \Leftrightarrow \int_{\Omega} (-z_d - \Delta\bar{q} + \bar{q})\bar{y} + \int_{\Omega} \bar{y}^2 dx = \inf_{y \in K} \left\{ \int_{\Omega} (\bar{y} - z_d - \Delta\bar{q} + \bar{q})(y) \right\}.$$

So we obtain an optimality system similar to the one of Temam and Abergel. Nevertheless, we are not able to prove that \bar{q} belongs to $BL_o(\Omega)$ with a proof different from the one of the above authors.

Remark 11. The weak optimality system ensures the existence of Lagrange multipliers (as measures) without the Slater condition. We may then use, for instance, Lagrangian methods to compute the solution. These methods are min-max methods dealing with the Lagrangian of the problem, which is well defined because the multiplier exists (cf. [15]).

3.2. Neumann boundary conditions.

3.2.1. Penalization. The method is the same as in § 3.1, so we just give results without detailed proofs (for more details, see [5]).

We now consider the following Neumann problem:

$$(3.21) \quad \mathbf{P}(v) \begin{cases} Ay = f + v & \text{sur } \Omega, \\ \frac{\partial y}{\partial v_A} = 0 & \text{sur } \Gamma, \end{cases}$$

where $v \in \mathbb{L}^2(\Omega)$, $f \in \mathbb{L}^2(\Omega)$.

$\mathbf{P}(v)$ has a unique solution $T(v)$ in $\mathbb{H}^2(\Omega)$ (cf. [19]) and $T: v \mapsto y = T(v)$ is affine. Let K be a nonempty, convex, closed subset of $\mathbb{H}^2(\Omega)$,

$$\left(y \in \mathbb{H}^2(\Omega) \Rightarrow \frac{\partial y}{\partial v_A} \in \mathbb{H}^{1/2}(\Gamma) \subseteq \mathbb{L}^2(\Gamma) \right).$$

Let U_{ad} be a nonempty, closed, convex subset of $\mathbb{L}^2(\Omega)$. For $\varepsilon > 0$, let us define J_ε on $\mathbb{V} \times \mathbb{L}^2(\Omega)$ by

$$(3.22) \quad J_\varepsilon(y, v) = J(y, v) + \frac{1}{2\varepsilon} \int_{\Omega} (Ay - f - v)^2 dx + \frac{1}{2\varepsilon} \int_{\Gamma} \left(\frac{\partial y}{\partial v} \right)_A^2 d\Gamma.$$

PROPOSITION 3.9. (Π_ε) has a unique solution $(y_\varepsilon, v_\varepsilon)$ in $K \times U_{\text{ad}}$ and

$$\forall (y, v) \in K \times U_{\text{ad}}, \quad J'_\varepsilon(y_\varepsilon, v_\varepsilon)(y - y_\varepsilon, v - v_\varepsilon) \geq 0.$$

So we call

$$(3.23) \quad \left[\begin{array}{l} q_\varepsilon = \frac{Ay_\varepsilon - f - v_\varepsilon}{\varepsilon} \in \mathbb{L}^2(\Omega), \\ r_\varepsilon = \frac{1}{\varepsilon} \frac{\partial y_\varepsilon}{\partial v_A} \in \mathbb{L}^2(\Gamma), \\ \text{and let } p_\varepsilon \in \mathbb{H}^2(\Omega) \text{ be the adjoint state solution of} \\ A^* p_\varepsilon = y_\varepsilon - z_d \quad \text{in } \Omega, \\ \frac{\partial p_\varepsilon}{\partial v_A} = 0 \quad \text{on } \Gamma. \end{array} \right.$$

The penalized optimality system is given by the following result.

PROPOSITION 3.10. Let $(y_\varepsilon, v_\varepsilon)$ be the optimal solution of (Π_ε) . Then

$$(3.24) \quad \forall y \in K \quad \int_{\Gamma} (r_\varepsilon + p_\varepsilon) \frac{\partial(y - y_\varepsilon)}{\partial v_A} d\Gamma + \int_{\Omega} [q_\varepsilon + p_\varepsilon][A(y - y_\varepsilon)] dx \geq 0,$$

$$(3.25) \quad \forall v \in U_{\text{ad}} \quad \int_{\Omega} (Nv_\varepsilon - q_\varepsilon)(v - v_\varepsilon) dx \geq 0.$$

The following theorem describes the asymptotic behaviour of y_ε , v_ε , and p_ε .

THEOREM 3.11. When ε tends to 0,

- (i) v_ε converges to \bar{v} strongly in $\mathbb{L}^2(\Omega)$;
- (ii) y_ε converges to \bar{y} strongly in $\mathbb{H}^2(\Omega)$, where (\bar{y}, \bar{v}) is the solution of (Π) ;
- (iii) p_ε converges to \bar{p} strongly in $\mathbb{H}^2(\Omega)$, where \bar{p} is the solution of

$$(3.26) \quad \begin{cases} A^* \bar{p} = \bar{y} - z_d & \text{in } \Omega, \\ \frac{\partial \bar{p}}{\partial v_A} = 0 & \text{on } \Gamma; \end{cases}$$

- (iv) $\partial y_\varepsilon / \partial v_A$ converges to $\partial \bar{y} / \partial v_A = 0$ (strongly in $\mathbb{L}^2(\Gamma)$).

Now we must estimate the two multipliers, q_ε and r_ε . So let \mathcal{E}_Ω and \mathcal{E}_Γ be two dense subsets of, respectively, $\mathbb{L}^2(\Omega)$ and $\mathbb{L}^2(\Gamma)$ such that the injections are continuous. We state the following assumption:

$$(3.27) \quad \begin{aligned} & \exists \rho > 0, \quad \exists v_o \in U_{\text{ad}}, \quad \exists R > 0 \quad \text{such that} \\ & \forall \eta = (\kappa, \xi) \in \mathcal{B}(\mathcal{E}_\Omega) \times \mathcal{B}(\mathcal{E}_\Gamma), \quad \exists v_\eta \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}} \quad \text{such that } y_\eta \in K, \end{aligned}$$

where y_η is the solution of

$$(P_\eta) \quad \begin{aligned} & Ay_\eta = f + v_\eta - \rho \kappa \quad \text{in } \Omega, \\ & \frac{\partial y_\eta}{\partial v_A} = -\rho \xi \quad \text{on } \Gamma. \end{aligned}$$

We may then ensure that r_ε and q_ε are uniformly bounded in the dual spaces of \mathcal{E}_Ω and \mathcal{E}_Γ .

PROPOSITION 3.12. *Assuming (3.27), there exists $C > 0$, $\varepsilon_o > 0$ such that*

$$\forall \varepsilon \in]0, \varepsilon_o], \quad \forall \kappa \in \mathcal{B}(\mathcal{E}_\Omega), \quad \forall \xi \in \mathcal{B}(\mathcal{E}_\Gamma) \quad \int_{\Omega} q_\varepsilon \kappa \, dx + \int_{\Gamma} r_\varepsilon \xi \, d\Gamma \leq C.$$

Then we still have two different optimality systems more or less “strong.”

3.2.2. The “strong” optimality system. Let us choose (as before) $\mathcal{E}_\Omega = \mathbb{L}^2(\Omega)$ and $\mathcal{E}_\Gamma = \mathbb{L}^2(\Gamma)$.

THEOREM 3.13. *Let (\bar{y}, \bar{v}) belong to \mathcal{D} and let us assume*

$$(H) \quad \begin{aligned} & \exists \rho > 0, \quad \exists v_o \in U_{\text{ad}}, \quad \exists R > 0 \quad \text{such that} \\ & \forall \eta = (\kappa, \xi) \in \mathcal{B}^2(\Omega) \times \mathcal{B}^2(\Gamma), \quad \exists v_\eta \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}}, \\ & \text{such that the solution } y_\eta \text{ of } (P_\eta) \text{ belongs to } K. \end{aligned}$$

(\bar{y}, \bar{v}) is the optimal solution of (Π) if and only if there exists $\bar{q} \in \mathbb{L}^2(\Omega)$, $\bar{r} \in \mathbb{L}^2(\Gamma)$ such that

$$(3.28) \quad \forall y \in K \quad \int_{\Gamma} (\bar{r} + \bar{p}) \frac{\partial(y - \bar{y})}{\partial v_A} \, d\Gamma + \int_{\Omega} [\bar{q} + \bar{p}][A(y - \bar{y})] \, dx \geq 0,$$

$$(3.29) \quad \forall v \in U_{\text{ad}} \quad \int_{\Omega} (N\bar{v} - \bar{q})(v - \bar{v}) \, dx \geq 0,$$

where \bar{p} is the adjoint state given by (3.26).

Proof. The proof is exactly the same as that of Theorem 3.7. \square

3.2.3. The “weak” optimality system. It holds that $\mathcal{E}_\Omega = \mathcal{C}_o(\Omega)$ and $\mathcal{E}_\Gamma = \mathcal{C}_o(\Gamma)$ (with the \mathbb{L}^∞ -norm).

As before, the test functions must be smooth enough to get the convergence in the dual sense. So we set

$$\mathcal{F}(\bar{y}) = \left\{ y \in \mathbb{V} \mid \exists (\varphi, \psi) \in \mathcal{C}_o(\Omega) \times \mathcal{C}_o(\Gamma), \quad Ay = A\bar{y} + \varphi \text{ on } \Omega, \quad \frac{\partial y}{\partial v_A} = \frac{\partial \bar{y}}{\partial v_A} + \psi \text{ on } \Gamma \right\},$$

$$\mathcal{G}(\bar{v}) = \bar{v} + \mathcal{C}_o(\Omega),$$

and we obtain a “weak” optimality system, which is no more sufficient.

THEOREM 3.14. *Let (\bar{y}, \bar{v}) be the optimal solution of (π) and assume that*

$$(H^*) \quad \begin{aligned} & \exists \rho > 0, \quad \exists v_o \in U_{\text{ad}}, \quad \exists R > 0 \quad \text{such that} \\ & \forall \eta = (\kappa, \xi) \in \mathcal{B}^\infty(\mathcal{C}_o(\Omega)) \times \mathcal{B}^\infty(\mathcal{C}_o(\Gamma)), \quad \exists v_\eta \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}}, \\ & \text{such that the solution } y_\eta \text{ of } (P_\eta) \text{ belongs to } K. \end{aligned}$$

Then there exists $\bar{q} \in \mathcal{M}(\Omega)$, $\bar{r} \in \mathcal{M}(\Gamma)$ such that

$$(3.30) \quad \forall y \in K \cap \mathcal{F}(\bar{y}) \quad \int_{\Gamma} (\bar{r} + \bar{p}) \frac{\partial(y - \bar{y})}{\partial v_A} d\Gamma + \int_{\Omega} [\bar{q} + \bar{p}][A(y - \bar{y})] dx \geq 0,$$

$$(3.31) \quad \forall v \in U_{ad} \cap \mathcal{G}(N\bar{v}) \quad \int_{\Omega} (N\bar{v} - \bar{q})(v - \bar{v}) dx \geq 0,$$

where \bar{p} is the adjoint state given by (3.26).

4. Case II: Boundary control problems.

4.1. Dirichlet boundary conditions.

4.1.1. Penalization. Let us consider the following *Dirichlet* problem:

$$(4.1) \quad \mathbf{P}(v) \begin{cases} Ay = f & \text{in } \Omega, \\ y = v & \text{on } \Gamma, \end{cases}$$

where $f \in \mathbb{L}^2(\Omega)$ and $v \in \mathbb{L}^2(\Gamma) (\subseteq \mathbb{H}^{-1/2}(\Gamma))$.

$\mathbf{P}(v)$ has a unique solution $y = T(v) \in \mathbb{W} = \{y \in \mathbb{L}^2(\Omega) \mid Ay \in \mathbb{L}^2(\Omega)\}$ (with the norm $\|y\|_{\mathbb{W}} = \|y\|_{\Omega} + \|Ay\|_{\Omega}$), and T is affine (linear if $f=0$). K (respectively, U_{ad}) is a nonempty, closed, convex subset of \mathbb{W} (respectively, $\mathbb{L}^2(\Gamma)$).

Remark 12. If we consider pointwise constraints, we must be able to define $y(x)$ everywhere in $\bar{\Omega}$. If $n \leq 3$, it is sufficient (cf. [19]) to take $U_{ad} \subseteq \mathbb{H}^{3/2}(\Gamma)$ so that $y \in \mathbb{H}^2(\Omega) (\subseteq \mathcal{C}(\bar{\Omega}))$.

We consider, for example, the “cost” functional defined on $\mathbb{L}^2(\Omega) \times \mathbb{L}^2(\Gamma)$

$$J(y, v) = \frac{1}{2} \int_{\Omega} (y - z_d)^2 dx + \frac{N}{2} \int_{\Gamma} v^2 dx.$$

We always consider the control problem (Π) (cf. § 2) and assume that (2.5) is satisfied. $\varepsilon > 0$ being given, let us define J_{ε} on $\mathbb{W} \times \mathbb{L}^2(\Gamma)$ with

$$(4.2) \quad J_{\varepsilon}(y, v) = \begin{cases} J(y, v) + \frac{1}{2\varepsilon} \int_{\Gamma} (y - v)^2 d\Gamma + \frac{1}{2\varepsilon} \int_{\Omega} (Ay + f)^2 dx, & \text{if } y|_{\Gamma} \in \mathbb{L}^2(\Gamma), \\ +\infty & \text{else.} \end{cases}$$

Remark 13. The second penalization term does not come from a relation between the state y and the control v . Anyway, it is more interesting to introduce it to simplify the convex where the test functions y are to be chosen. (If we omit it, we must take y in $\mathcal{H} = \{y \in K \mid Ay = f \text{ in } \Omega\}$.) Moreover, if y belongs to \mathbb{W} we do not know whether the trace of y on Γ belongs to $\mathbb{L}^2(\Gamma)$. We know that this trace can be defined in $\mathbb{H}^{-1/2}(\Gamma)$. So we define K^* as $K^* = \{y \in K \mid y|_{\Gamma} \in \mathbb{L}^2(\Gamma)\}$.

PROPOSITION 4.1. (Π_{ε}) has a unique solution $(y_{\varepsilon}, v_{\varepsilon})$ and

$$\forall (y, v) \in K^* \times U_{ad}, \quad J'_{\varepsilon}(y_{\varepsilon}, v_{\varepsilon})(y - y_{\varepsilon}, v - v_{\varepsilon}) \geq 0.$$

So we get

$$\begin{aligned} \forall y \in K^* \quad \int_{\Omega} (y_{\varepsilon} - z_d)(y - y_{\varepsilon}) dx + \frac{1}{\varepsilon} \int_{\Omega} [Ay_{\varepsilon} - f][A(y - y_{\varepsilon})] dx \\ + \frac{1}{\varepsilon} \int_{\Gamma} (y_{\varepsilon} - v_{\varepsilon})(y - y_{\varepsilon}) d\Gamma \geq 0, \end{aligned}$$

$$\forall v \in U_{ad} \quad \int_{\Gamma} \left[Nv_{\varepsilon} - \frac{1}{\varepsilon} (y_{\varepsilon} - v_{\varepsilon}) \right] [v - v_{\varepsilon}] d\Gamma \geq 0.$$

Let us define

$$(4.3) \quad \begin{aligned} q_\varepsilon &= \frac{y_\varepsilon - v_\varepsilon}{\varepsilon} \in \mathbb{L}^2(\Gamma), \\ s_\varepsilon &= \frac{Ay_\varepsilon - f}{\varepsilon} \in \mathbb{L}^2(\Omega). \end{aligned}$$

Let $p_\varepsilon \in (\mathbb{H}_o^1(\Omega) \cap \mathbb{H}^2(\Omega))$ be the solution of the dual problem

$$(4.4) \quad \begin{aligned} A^*p_\varepsilon &= y_\varepsilon - z_d \quad \text{in } \Omega, \\ p_\varepsilon &= 0 \quad \text{on } \Gamma. \end{aligned}$$

Using a henceforth classical calculus, we obtain the following penalized optimality system.

PROPOSITION 4.2. *Let $(y_\varepsilon, v_\varepsilon)$ be the solution of (Π_ε) ; then*

$$(4.5) \quad \forall y \in K \quad \int_\Gamma \left(-\frac{\partial p_\varepsilon}{\partial v_{A^*}} + q_\varepsilon \right) (y - y_\varepsilon) d\Gamma + \int_\Omega [s_\varepsilon + p_\varepsilon][A(y - y_\varepsilon)] dx \geq 0,$$

$$(4.6) \quad \forall v \in U_{\text{ad}} \quad \int_\Gamma (Nv_\varepsilon - q_\varepsilon)(v - v_\varepsilon) d\Gamma \geq 0.$$

The first result about the asymptotic behaviour of ε -quantities is given by the theorem below.

THEOREM 4.3. *When ε tends to 0,*

- (i) v_ε converges to \bar{v} strongly in $\mathbb{L}^2(\Gamma)$;
- (ii) y_ε converges to \bar{y} strongly in \mathbb{W} ((\bar{y}, \bar{v}) is the solution of (Π));
- (iii) p_ε converges to \bar{p} strongly in $\mathbb{H}^2(\Omega) \cap \mathbb{H}_o^1(\Omega)$, where \bar{p} is the adjoint state solution of

$$(4.7) \quad \begin{aligned} A^*\bar{p} &= \bar{y} - z_d \quad \text{in } \Omega, \\ \bar{p} &= 0 \quad \text{on } \Gamma; \end{aligned}$$

- (iv) $\lim_{\varepsilon \rightarrow 0} \partial p_\varepsilon / \partial v_{A^*} = \partial \bar{p} / \partial v_{A^*}$ strongly in $\mathbb{H}^{1/2}(\Gamma)$.

As we must now estimate q_ε and s_ε , we assume once again that

$$(4.8) \quad \begin{aligned} &\exists \rho > 0, \quad \exists v_o \in U_{\text{ad}}, \quad \exists R > 0 \quad \text{such that} \\ &\forall \eta = (\kappa, \xi) \in \mathcal{B}(\mathcal{E}_\Omega) \times \mathcal{B}(\mathcal{E}_\Gamma), \quad \exists v_\eta \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}} \quad \text{such that } y_\eta \in K, \end{aligned}$$

where y_η is the solution of

$$(\mathbf{P}_\eta) \begin{cases} Ay_\eta = f - \rho\kappa & \text{in } \Omega, \\ y_\eta = v_\eta - \rho\xi & \text{on } \Gamma, \end{cases}$$

where \mathcal{E}_Ω and \mathcal{E}_Γ are dense subsets of, respectively, $\mathbb{L}^2(\Omega)$ and $\mathbb{L}^2(\Gamma)$, such that the injections are continuous and $\mathcal{B}(\mathcal{E})$ is the unit ball of \mathcal{E} (for the \mathcal{E} -norm).

Then q_ε (respectively, s_ε) is bounded in the dual space of \mathcal{E}_Γ (respectively, \mathcal{E}_Ω).

PROPOSITION 4.4. *Assuming (4.8), there exists $C > 0$, $\varepsilon_o > 0$ such that*

$$\forall \varepsilon \in]0, \varepsilon_o], \quad \forall (\kappa, \xi) \in \mathcal{B}(\mathcal{E}_\Omega) \times \mathcal{B}(\mathcal{E}_\Gamma) \quad \int_\Gamma q_\varepsilon \xi d\Gamma + \int_\Omega s_\varepsilon \kappa dx \leq C.$$

Proof. The proof is the same as that of Proposition 3.6, but we are going to detail it somewhat.

Let (κ, ξ) belong to $\mathcal{B}(\mathcal{E}_\Omega) \times \mathcal{B}(\mathcal{E}_\Gamma)$. Let us sum (4.5) and (4.6) applied to the couple (y_η, v_η) of $K^* \times U_{\text{ad}}$ given by (4.8). We obtain

$$\begin{aligned} & \int_{\Gamma} \left(-\frac{\partial p_\varepsilon}{\partial v_{A^*}} + q_\varepsilon \right) (y_\eta - y_\varepsilon) d\Gamma + \int_{\Omega} [s_\varepsilon + p_\varepsilon][A(y_\eta - y_\varepsilon)] dx \\ & \quad + \int_{\Gamma} (Nv_\varepsilon - q_\varepsilon)(v_\eta - v_\varepsilon) d\Gamma \geq 0, \\ & \int_{\Gamma} \left(-\frac{\partial p_\varepsilon}{\partial v_{A^*}} + q_\varepsilon \right) (v_\eta - v_\varepsilon - p\xi - \varepsilon q_\varepsilon) d\Gamma + \int_{\Omega} [s_\varepsilon + p_\varepsilon][-\rho\kappa - \varepsilon s_\varepsilon] dx \\ & \quad + \int_{\Gamma} (Nv_\varepsilon - q_\varepsilon)(v_\eta - v_\varepsilon) d\Gamma \geq 0, \\ & \int_{\Omega} \rho(s_\varepsilon\kappa + q_\varepsilon\xi) dx \leq \int_{\Gamma} \left(Nv_\varepsilon - \frac{\partial p_\varepsilon}{\partial v_{A^*}} \right) (v_\eta - v_\varepsilon) d\Gamma + \int_{\Omega} p_\varepsilon(-\rho\kappa - \varepsilon s_\varepsilon) dx \\ & \quad + \int_{\Gamma} \left(-\frac{\partial p_\varepsilon}{\partial v_{A^*}} \right) (-\rho\xi - \varepsilon q_\varepsilon) d\Gamma - \varepsilon \int_{\Gamma} (q_\varepsilon^2 + s_\varepsilon^2) d\Gamma. \end{aligned}$$

As before, all the quantities of the right side are bounded, and we have the wanted inequality. \square

4.1.2. The optimality system. As before, we make two different choices for the norm of \mathcal{E} . First, we choose $\mathcal{E}_\Omega = \mathbb{L}^2(\Omega)$ and $\mathcal{E}_\Gamma = \mathbb{L}^2(\Gamma)$, so that (4.8) becomes

$$\exists \rho > 0, \quad \exists v_o \in U_{\text{ad}}, \quad \exists R > 0 \quad \text{such that}$$

$$(\mathcal{H}) \quad \forall \eta = (\kappa, \xi) \in \mathcal{B}^2(\Omega) \times \mathcal{B}^2(\Gamma), \quad \exists v_\eta \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}} \quad \text{such that}$$

the solution y_η of (P_η) belongs to K .

We obtain a “strong” optimality system, shown by the following result.

THEOREM 4.5. *Let us assume (\mathcal{H}) ; let (\bar{y}, \bar{v}) be in \mathcal{D} and \bar{p} be defined with (4.7). (\bar{y}, \bar{v}) is the optimal solution of (Π) if and only if there exists $\bar{q} \in \mathbb{L}^2(\Gamma)$, $\bar{s} \in \mathbb{L}^2(\Omega)$ such that*

$$(4.9) \quad \forall y \in K^* \quad \int_{\Gamma} \left(-\frac{\partial \bar{p}}{\partial v_{A^*}} + \bar{q} \right) (y - \bar{y}) d\Gamma + \int_{\Omega} [\bar{s} + \bar{p}][A(y - \bar{y})] dx \geq 0,$$

$$(4.10) \quad \forall v \in U_{\text{ad}} \quad \int_{\Gamma} (N\bar{v} - \bar{q})(v - \bar{v}) d\Gamma \geq 0.$$

Proof. As in § 3, q_ε and s_ε are bounded in \mathbb{L}^2 . So we are allowed to pass to the (weak) limit in the penalized optimality system. The rest of the proof is exactly the same. \square

Remark 14. Let us compare the condition (\mathcal{H}) to the Slater condition (\mathcal{S}) for the boundary case and assume for simplicity $f = 0$. It holds that

$$\mathbf{P}(v) \begin{cases} Ay = 0 & \text{in } \Omega, \\ y = v & \text{on } \Gamma, \end{cases}$$

has a unique solution $y = T(v)$, in \mathbb{W} for any v in $\mathbb{H}^{-1/2}(\Gamma)$.

The Slater condition, $0 \in \text{Int}_W(T(U_{\text{ad}}) - K)$, is equivalent to

$$(\mathcal{S}) \quad \exists \rho > 0, \quad \forall \varphi \text{ s.t. } \|\varphi\|_W \leq 1, \quad \exists v_\varphi \in U_{\text{ad}}, \quad \exists y_\varphi \in K, \quad y_\varphi = T(v_\varphi) - \rho\varphi,$$

and (\mathcal{H}) is

$$\begin{aligned} \exists R > 0, \quad \exists \rho > 0, \quad \exists v_o \in U_{\text{ad}}, \\ \forall \psi = (\kappa, \xi) \in \mathcal{B}^2(\Omega) \times \mathcal{B}^2(\Gamma), \quad \exists v_\psi \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}}, \\ \exists y_\psi \in K \text{ such that} \\ Ay_\psi = 0 \quad \text{in } \Omega, \\ y_\psi = v \quad \text{on } \Gamma. \end{aligned}$$

If U_{ad} is not bounded, (\mathcal{H}) is more restrictive than (\mathcal{S}) because we impose v_ψ in $\mathcal{B}^2(v_o, R)$. If U_{ad} is bounded, $(\mathcal{H}) \Leftrightarrow (\mathcal{S})$.

Proof. $(\mathcal{S}) \Rightarrow (\mathcal{H})$.

Let $\psi = (\kappa, \xi)$ be in $\mathcal{B}^2(\Omega) \times \mathcal{B}^2(\Gamma)$. $\exists! \varphi \in \mathbb{W}$ such that $A\varphi = \kappa$ in Ω and $\varphi = \xi$ on Γ . Moreover, $\|\varphi\|_W \leq C$ (because T is an isomorphism). So there exists $(v_\varphi, y_\varphi) \in U_{\text{ad}} \times K$ such that $y_\varphi = T(v_\varphi) - (\rho/C)\varphi$, and (\mathcal{H}) is satisfied (with ρ/C instead of ρ).

$(\mathcal{H}) \Rightarrow (\mathcal{S})$. Let $\varphi \in \mathbb{W}$ such that $\|\varphi\|_W \leq 1$, $A\varphi \in \mathbb{L}^2(\Omega)$, and $\|A\varphi\|_\Omega \leq 1$. So there exists $(v^*, y^*) \in U_{\text{ad}} \times K$ such that $Ay^* = -\rho A\varphi$ in Ω and $y^* = v^*$ on Γ . Then (\mathcal{S}) is satisfied with $y_\varphi = T(v^*) - \rho\varphi$. \square

Now we may weaken this result as we did in the previous section; we choose $\mathcal{E}_\Omega = \mathcal{C}_o(\Omega)$ and $\mathcal{E}_\Gamma = \mathcal{C}_o(\Gamma)$ (with the L^∞ -norm), so that (4.8) becomes (\mathcal{H}^*) ,

$$\begin{aligned} \exists \rho > 0, \quad \exists v_o \in U_{\text{ad}}, \quad \exists R > 0 \quad \text{such that} \\ \forall \eta = (\kappa, \xi) \in \mathcal{B}^\infty(\mathcal{C}_o(\Omega)) \times \mathcal{B}^\infty(\mathcal{C}_o(\Gamma)), \quad \exists v_\eta \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}} \quad \text{such that} \\ \text{the solution } y_\eta \text{ of } (P_\eta) \text{ belongs to } K; \\ (\mathcal{B}^\infty(\mathcal{C}_o(\Omega)) = \{\kappa \in \mathcal{C}_o(\Omega) \mid \|\kappa\|_{L^\infty(\Omega)} \leq 1\}). \end{aligned}$$

The difficulties we met in the distributed case still remain, of course. We may bound the multipliers in a measure space and pass to the limit in the dual sense $\langle \text{measures}, \mathcal{C}_o \text{ functions} \rangle$. So we must consider, once again, test functions that are smooth enough. Let us define

$$\begin{aligned} \mathcal{F}(\bar{y}) &= \{y \in \mathbb{W} \mid \exists (\varphi, \psi) \in \mathcal{C}_o(\Omega) \times \mathcal{C}_o(\Gamma), Ay = A\bar{y} + \varphi \text{ on } \Omega, y = \bar{y} + \psi \text{ on } \Gamma\}, \\ \mathcal{G}(\bar{v}) &= \bar{v} + \mathcal{C}_o(\Gamma). \end{aligned}$$

We then have the following theorem.

THEOREM 4.6. *Let (\bar{y}, \bar{v}) be the optimal solution of (Π) and assume (\mathcal{H}^*) . Then there exists $\bar{q} \in \mathcal{M}(\Gamma)$, $\bar{s} \in \mathcal{M}(\Omega)$ such that*

$$(4.11) \quad \forall y \in K^* \cap \mathcal{F}(\bar{y}) \quad \int_\Gamma \left(-\frac{\partial \bar{p}}{\partial \nu_{A^*}} + \bar{q} \right) (y - \bar{y}) \, d\Gamma + \int_\Omega [\bar{s} + \bar{p}][A(y - \bar{y})] \, dx \geq 0,$$

$$(4.12) \quad \forall v \in U_{\text{ad}} \cap \mathcal{G}(\bar{v}) \quad \int_\Gamma (N\bar{v} - \bar{q})(v - \bar{v}) \, d\Gamma \geq 0,$$

where $\mathcal{M}(\Omega)$ (respectively, $\mathcal{M}(\Gamma)$) is the set of bounded Radon measures on Ω (respectively, on Γ).

Remark 15. (\mathcal{H}^*) is weaker than (\mathcal{S}) . Indeed, if we take φ in \mathbb{W} such that $\|\varphi\|_W \leq 1$, we cannot always find v_φ in U_{ad} and y_φ in K (with the assumption (\mathcal{H}^*)) such that $Ay_\varphi = -\rho A\varphi$ in Ω because, generally, $A\varphi$ does not belong to $\mathbb{L}^\infty(\Omega)$. Anyway, the distinction between (\mathcal{H}) (i.e., (\mathcal{S})) and (\mathcal{H}^*) does not seem to be useful (at least in the case of pointwise state constraints) because it is essentially a distinction on interior perturbations, and we have a boundary problem.

Now let us end this remark with the following example:

$$K = \{y \in \mathbb{W} \mid \varphi \leq y \leq \psi \text{ a.e. in } \Omega\}$$

and

$$U_{\text{ad}} = \{v \in \mathbb{L}^2(\Gamma) \mid \alpha \leq v \leq \beta \text{ a.e. on } \Gamma\}$$

(with $\alpha \leq \varphi|_{\Gamma}$ and $\beta \geq \psi|_{\Gamma}$). If we can find $e \in \mathcal{C}^0(\bar{\Omega})$, $e > 0$, such that $\varphi + e \leq \psi - e$, then (\mathcal{H}) is satisfied (with $y_o \in [\varphi + e, \psi - e]$ and $v_o = y_o|_{\Gamma}$).

4.2. Neumann boundary conditions. We now consider the following *Neumann* problem:

$$(4.13) \quad \mathbf{P}(v) \begin{cases} Ay = f & \text{in } \Omega, \\ \frac{\partial y}{\partial v_A} = v & \text{on } \Gamma, \end{cases}$$

where $f \in \mathbb{L}^2(\Omega)$ and $v \in \mathbb{L}^2(\Gamma)$.

The unique solution $y = T(v)$ of $\mathbf{P}(v)$ is in $\mathbb{V} = \{y \in \mathbb{H}^1(\Omega) \mid Ay \in \mathbb{L}^2(\Omega)\}$. K and U_{ad} are nonempty, closed, convex, subsets of, respectively, \mathbb{V} and $\mathbb{L}^2(\Gamma)$. If y belongs to \mathbb{V} , then $(\partial y / \partial v_A)$ belongs to $\mathbb{H}^{-1/2}(\Gamma)$, but not necessarily to $\mathbb{L}^2(\Gamma)$. So we define, as before, the convex subset $K^* = \{y \in K \mid (\partial y) / (\partial v_A) \in \mathbb{L}^2(\Gamma)\}$.

Remark 16. If $U_{\text{ad}} \subseteq \mathbb{H}^{1/2}(\Gamma)$, then $T(v) \in \mathbb{H}^2(\Omega)$ and $K^* = K$.

Let us give $\varepsilon > 0$ and define J_ε on $\mathbb{V} \times \mathbb{L}^2(\Gamma)$ with

$$(4.14) \quad J_\varepsilon(y, v) = \begin{cases} J(y, v) + \frac{1}{2\varepsilon} \int_{\Omega} (Ay - f)^2 dx + \frac{1}{2\varepsilon} \int_{\Gamma} \left(\frac{\partial y}{\partial v_A} - v \right)^2 d\Gamma, & \text{if } \frac{\partial y}{\partial v_A} \in \mathbb{L}^2(\Gamma), \\ +\infty & \text{if not.} \end{cases}$$

PROPOSITION 4.7. *The penalized problem (Π_ε) has a unique optimal solution $(y_\varepsilon, v_\varepsilon)$ and for all $(y, v) \in K^* \times U_{\text{ad}}$ $J'_\varepsilon(y_\varepsilon, v_\varepsilon)(y - y_\varepsilon, v - v_\varepsilon) \geq 0$.*

We define (as usual)

$$(4.15) \quad \left[\begin{array}{l} s_\varepsilon = \frac{Ay_\varepsilon - f}{\varepsilon} \in \mathbb{L}^2(\Omega), \\ q_\varepsilon = \frac{1}{\varepsilon} \left(\frac{\partial y_\varepsilon}{\partial v_A} - v_\varepsilon \right) \in \mathbb{L}^2(\Gamma), \\ \text{and } p_\varepsilon \in \mathbb{H}^2(\Omega) \text{ (adjoint state), solution of} \\ A^* p_\varepsilon = y_\varepsilon - z_d \text{ in } \Omega, \\ \frac{\partial p_\varepsilon}{\partial v_{A^*}} = 0 \text{ on } \Gamma, \end{array} \right.$$

and we still obtain results similar to previous ones.

PROPOSITION 4.8. *Let $(y_\varepsilon, v_\varepsilon)$ be the optimal solution of (Π_ε) :*

$$(4.16) \quad \forall y \in K^* \quad \int_{\Gamma} (p_\varepsilon + q) \frac{\partial(y - y_\varepsilon)}{\partial v_A} d\Gamma + \int_{\Omega} [s_\varepsilon + p_\varepsilon][A(y - y_\varepsilon)] dx \geq 0,$$

$$(4.17) \quad \forall v \in U_{\text{ad}} \quad \int_{\Gamma} (Nv_\varepsilon - q_\varepsilon)(v - v_\varepsilon) d\Gamma \geq 0.$$

THEOREM 4.9. As ε tends to 0,

- (i) v_ε converges to \bar{v} strongly in $\mathbb{L}^2(\Gamma)$;
- (ii) y_ε to \bar{y} strongly in \mathbb{V} (where (\bar{y}, \bar{v}) is the solution of (Π));
- (iii) p_ε converges to \bar{p} strongly in $\mathbb{H}^2(\Omega)$, where \bar{p} is solution of

$$(4.18) \quad \begin{aligned} A^* \bar{p} &= \bar{y} - z_d \quad \text{in } \Omega, \\ \frac{\partial \bar{p}}{\partial v_{A^*}} &= 0 \quad \text{on } \Gamma. \end{aligned}$$

Once again, we must estimate q_ε and s_ε , and we assume that

$$(4.19) \quad \begin{aligned} &\exists \rho > 0, \quad \exists v_o \in U_{\text{ad}}, \quad \exists R > 0 \quad \text{such that} \\ &\forall \eta = (\kappa, \xi) \in \mathcal{B}(\mathcal{E}_\Omega) \times \mathcal{B}(\mathcal{E}_\Gamma), \quad \exists v_\eta \in \mathcal{B}^2(v_o, R) \cap U_{\text{ad}} \quad \text{such that } y_\eta \in K, \end{aligned}$$

where y_η is the solution of

$$(P_\eta) \quad \begin{cases} Ay_\eta = f - \rho\kappa & \text{in } \Omega, \\ \frac{\partial y_\eta}{\partial v_A} = v_\eta - \rho\xi & \text{on } \Gamma. \end{cases}$$

4.2.1. The “strong” optimality system.

THEOREM 4.9. Let us assume (4.19) with $\mathcal{E}_\Omega = \mathbb{L}^2(\Omega)$ and $\mathcal{E}_\Gamma = \mathbb{L}^2(\Gamma)$ and let (\bar{y}, \bar{v}) be in \mathcal{D} . (\bar{y}, \bar{v}) is the optimal solution of (Π) if and only if there exists $\bar{q} \in \mathbb{L}^2(\Gamma)$, $\bar{s} \in \mathbb{L}^2(\Omega)$ such that

$$(4.20) \quad \forall y \in K^* \quad \int_\Gamma (\bar{p} + \bar{q}) \frac{\partial(y - \bar{y})}{\partial v_A} d\Gamma + \int_\Omega (\bar{s} + \bar{p})[A(y - \bar{y})] dx \geq 0,$$

$$(4.21) \quad \forall v \in U_{\text{ad}} \quad \int_\Gamma (N\bar{v} - \bar{q})(v - \bar{v}) d\Gamma \geq 0,$$

where \bar{p} is the adjoint state defined by (4.18).

4.2.2. The “weak” optimality system. In this case, $\mathcal{F}(\bar{y})$ and $\mathcal{G}(\bar{v})$ are defined as follows:

$$\mathcal{F}(\bar{y}) = \left\{ y \in \mathbb{V} \mid \exists (\varphi, \psi) \in \mathcal{C}_o(\Omega) \times \mathcal{C}_o(\Gamma), Ay = A\bar{y} + \varphi \text{ on } \Omega, \frac{\partial y}{\partial v_A} = \frac{\partial \bar{y}}{\partial v_A} + \psi \text{ on } \Gamma \right\},$$

$$\mathcal{G}(\bar{v}) = \bar{v} + \mathcal{C}_o(\Gamma).$$

THEOREM 4.10. Let us assume (4.19) with $\mathcal{E}_\Omega = \mathcal{C}_o(\Omega)$ and $\mathcal{E}_\Gamma = \mathcal{C}_o(\Gamma)$ (with the \mathbb{L}^∞ -norm, so that $\mathcal{B}(\mathcal{E}) = \{\kappa \in \mathcal{C}_o \mid \|\kappa\|_{\mathbb{L}^\infty} \leq 1\}$). Let (\bar{y}, \bar{v}) be the optimal solution of (Π) ; then there exists $\bar{q} \in \mathcal{M}(\Gamma)$, $\bar{s} \in \mathcal{M}(\Omega)$ such that

$$(4.22) \quad \forall y \in K^* \cap \mathcal{F}(\bar{y}) \quad \int_\Gamma (\bar{p} + \bar{q}) \frac{\partial(y - \bar{y})}{\partial v_A} d\Gamma + \int_\Omega (\bar{s} + \bar{p})[A(y - \bar{y})] dx \geq 0,$$

$$(4.23) \quad \forall v \in U_{\text{ad}} \cap \mathcal{G}(\bar{v}) \quad \int_\Gamma (N\bar{v} - \bar{q})(v - \bar{v}) d\Gamma \geq 0,$$

where \bar{p} is the adjoint state defined by (4.18).

5. Conclusion. For every “classical” case we sought, we retrieve already-known results (i.e., the existence of an optimality system, assuming the Slater condition). In the case where the control is distributed, we have proved the existence of multipliers that are measures (if the Slater condition is not satisfied). The main problem then is to “estimate” the sets $\mathcal{F}(\bar{y})$ and $\mathcal{G}(\bar{v})$ defined for the “weak” system: are they “large

enough" to allow good numerical experimentation? The answer is not obvious; we must study how Lagrangian methods (for example) work and the regularity of the solution (\bar{y}, \bar{v}) .

This penalization method may be applied to any problem of control with state constraints (especially to nonlinear problems) and provides decoupled optimality systems that may be solved with classical multipliers methods. Moreover, the penalization itself may lead to algorithms that allow us to compute the solution and the multiplier simultaneously. Once again, the regularity of the multiplier is one of the main difficulties we are meeting, and the optimality system may answer this kind of question (see [13] and [2], for instance).

DIFFERENTIAL INCLUSIONS AND TARGET PROBLEMS*

MARC QUINCAMPOIX†

Abstract. Where and how solutions associated to a differential inclusion can or cannot enter a given target is studied. For this purpose, partitions of the target boundary are associated with the dynamic of the system. The behaviour of these solutions is qualitatively described in terms of viability and invariance kernels of sets. These kernels determine points such that there exist (respectively, all) solutions starting at these points remain in a given set of constraints. The sets that are reached in finite time by viable solutions to the system are also studied. Finally, some applications to control systems with one target are provided, and the concept of semipermeable barriers will be generalized.

Résumé. Il s'agit de savoir où et comment les solutions d'une inclusion différentielle peuvent ou non franchir le bord d'une cible donnée. On établit pour cela une partition de la frontière de la cible en fonction de la dynamique du système. Ceci sera utilisé pour décrire le comportement qualitatif des trajectoires par rapport aux noyaux de viabilité et d'invariance de plusieurs ensembles. Ces noyaux décrivent les conditions initiales à partir desquelles il existe des solutions de l'inclusion différentielle avec contraintes. Nous définirons aussi des ensembles qui sont atteints en temps fini par des solutions de l'inclusion différentielle avec contraintes. Cet article se termine par une application aux systèmes contrôlés à une cible et par une généralisation de la notion de barrière semi perméable.

Key words. viability, invariance, semipermeable barriers, differential inclusions

AMS(MOS) subject classification. 49A50

1. Introduction. We consider an open set C and a system whose evolution is described by the following differential inclusion:¹

$$x'(t) \in F(x(t)),$$

where F is a set-valued map and $x(t) \in X := \mathbb{R}^n$. We assume throughout this paper, that the set valued map F has nonempty values.²

A first question is: On what part of the boundary can the state of the system reach the target C ?

For that purpose, we prove a new result about the tangent cone to an intersection. Thanks to this, we define the three sets C^e , C^b , C^i of the boundary of C that form a partition of ∂C . Then we prove that solutions crossing the three areas C^e , C^b , C^i of ∂C have the following qualitative properties:

- If a solution crosses C^i , then it enters C ,
- If a solution crosses C^e , then it goes outside C ,
- If a solution crosses the interior³ of C^b , then it remains (locally) in ∂C .

In answering the above question, we prove a new result about the tangent cone to an intersection. Thanks to this, the three sets C^e , C^b , C^i form a partition of the boundary of C .

¹ This allows us to incorporate a lack of exact knowledge of dynamics or to represent a control system with state-dependent control map $U(x)$:

$$\begin{aligned} x'(t) &= f(x(t), u(t)), \\ u(t) &\in U(x(t)) \end{aligned}$$

through a differential inclusion, by setting: $F(x) := f(x, U(x))$.

² If it is not the case, we can study the differential inclusion in the interior of the domain of F .

³ In the relative topology of ∂C .

Another question is: From what initial conditions can the system reach C ?
Let us consider a differential inclusion with constraints

$$(1) \quad x'(t) \in F(x(t)), \quad x(t) \in K,$$

where K is a given closed set (we shall use $K := X \setminus C$).

We need some definitions and properties concerning differential inclusions with constraints (see [5], [6]).

We shall say that a solution $x(\cdot)$ of the differential inclusion (1) is *viable* in K if and only if

$$\forall t \geq 0, \quad x(t) \in K.$$

The solution $x(\cdot)$ is *locally viable* in K if and only if

$$\exists T > 0, \quad \text{such that } \forall t \leq T, \quad x(t) \in K.$$

A set K has the *viability property* if and only if, for any point x_0 of K , there exists at least one solution to (1) starting at this point that is viable in K .

A set K has the *invariance property* if and only if for any point x_0 of K , all solutions to (1) starting at this point are viable in K .

In the literature, the above properties appeared in different contexts under many names (when F is single-valued the both reduce to invariance of dynamical systems). For general control systems introduced by Roxin, these two properties have different names. “Viability property” is called “weak invariance,” and “invariance property” is called “strong invariance” (see [26], [27]). They also have been called “controlled invariance” by other authors (Wonham, Byrnes, Isidori, Morse, and others).

A closed set K is a *viability domain* if and only if

$$\forall x \in K, \quad F(x) \cap T_K(x) \neq \emptyset.$$

The set K is an *invariance domain* if and only if

$$\forall x \in K, \quad F(x) \subset T_K(x),$$

where $T_K(x)$ denotes the contingent cone⁴ to K at x .

If K is closed, if F is an upper semicontinuous⁵ set-valued map with nonempty closed convex compact values and linear growth,⁶ then, thanks to Haddad’s viability theorem (see [17], [5]), K is a viability domain if and only if the viability property holds for K .

When K is not a viability domain, the question arises as to how to find closed subsets in which it is possible to solve (1) in K . With these assumptions it is possible to define the *viability kernel*.

DEFINITION 1.1. The viability kernel of a closed set K is the largest closed viability domain contained in K .

We have some examples of computation of viability kernels in [7] and [14].

⁴ Recall that $T_K(x) := \{v \in X \mid \liminf_{h \rightarrow 0^+} d(x + hv, K)/h = 0\}$.

⁵ Let us recall that a set-valued map F is upper semicontinuous at x_0 if and only if

$$\forall \varepsilon > 0, \exists \alpha > 0, \quad F(x_0 + \alpha B) \subset F(x_0) + \varepsilon B.$$

⁶ We say that a map F has a linear growth if there exists $c > 0$ such that

$$\forall x \in X, \quad F(x) \subset c(1 + \|x\|)B.$$

In a similar way, thanks to the invariance theorem (see [5]), if K is closed and if F is Lipschitzian⁷ with compact convex values and linear growth, then K is an invariance domain if and only if the invariance property holds for K .

Under these assumptions it is possible to define (see [5]) the *invariance kernel*.

DEFINITION 1.2. The invariance kernel of a closed set K is the largest closed invariance domain contained in K .

In this paper, we prove some properties of the boundaries of viability and invariance kernels. In fact, under adequate assumptions, the boundaries of $\text{Viab}_F(K)$ and $\text{Inv}_F(K)$ are viability domains.

We shall also try to answer another question: Is it possible to find a solution to the differential inclusion with constraints that reaches a given point? To investigate this question, we shall introduce and study kernels for $-F$ that yields backward trajectories.

In the last section, results concerning the boundaries of the kernels of a differential inclusion will be used to study the following control system with a target C :

$$x'(t) = f(x(t), u(t)) \quad u(t) \in U(x(t)).$$

We shall generalize the concept of *semipermeable barrier* (introduced by Isaacs in [18] for differential games). Recall that a barrier allows us to separate the areas from which it is possible to reach C and the areas from which it is not possible (see also [10], [9], [11]). Recall that a C^1 -surface is semipermeable when it satisfies an equation such that $\max_u f(x, u) \cdot n \leq 0$ or $\min_u f(x, u) \cdot n \geq 0$ (where n is the normal vector of the surface). It means that the solutions of § 5.1, (5) are able to cross the surface in “only one direction.” In fact, we prove that the solutions of a control system can cross the boundaries of viability and invariance kernels only from the exterior of the kernel to the interior of the kernel. *In this sense* the boundaries of invariance and viability kernels are semipermeable.

2. The target boundary and the dynamics. We study a system whose dynamics are described by the differential inclusion:

$$(2) \quad x'(t) \in F(x(t)),$$

where F is the set-valued map whose values are nonempty convex and compact from a finite-dimensional vector space X into itself. We also consider a set C (the target) that is open nonempty and different from X .

Let us define two closed sets $K := X \setminus C$ and $\hat{K} := \overline{X \setminus K} = \bar{C}$. The Haddad viability theorem [17] provides conditions such that the state never reaches C . Here we study how it is possible to reach C .

We first state our results; their proofs will be given in § 2.4.

2.1. A geometrical result. We need a result concerning the contingent cone to an intersection of two closed sets.

DEFINITION 2.1. Let K be a closed set. The Dubovitsky–Milliutin tangent cone is defined by

$$D_K(x) := \{v \in X \mid \exists \alpha > 0, x +]0, \alpha][v + \alpha B) \subset K\}$$

or, equivalently, $D_K(x) = X \setminus T_{\overline{X \setminus K}}(x)$.

⁷ Let us recall (see [5], [6]) that a set-valued F is Lipschitzian if and only if there exists a positive real k such that

$$\forall (x, y) \in X \times X, \quad F(x) \subset F(y) + k\|x - y\|B.$$

THEOREM 2.2. *Let K_1 and K_2 be two closed sets of a normed vector space X . Then, for any x ,*

$$T_{K_1}(x) \cap T_{K_2}(x) \cap D_{K_1 \cup K_2}(x) \subset T_{K_1 \cap K_2}(x).$$

This result allows us to characterize the intersection of contingent cones, without assumptions on the regularity of these cones.⁸

COROLLARY 2.3. *Let K_1 and K_2 be two closed subsets of X .*

If $x \in K_1 \cap K_2 \cap \text{Int}(K_1 \cup K_2)$, then

$$T_{K_1}(x) \cap T_{K_2}(x) = T_{K_1 \cap K_2}(x).$$

We recall that the same conclusion can be obtained when we assume the following transversality condition:

$$(3) \quad C_{K_1}(x) - C_{K_2}(x) = X,$$

where $C_K(x)$ denotes the Clarke's cone⁹ to K at x .

Remark. These two results allow us to express the contingent cone to an intersection in different cases.

In \mathbb{R}^2 , we can compute the tangent cone at $(0, 0)$ to the intersection of

$$K_1 := \{(x, y) \mid x \leq 0\} \text{ and } K_2 := \{(x, y) \mid x \geq 0\}$$

thanks to Corollary 2.3, but not from the transversality condition (3). In the case of

$$K_1 := \{(x, y) \mid x = y\} \text{ and } K_2 := \{(x, y) \mid x = -y\},$$

it is possible to compute the intersection thanks to (3), but we cannot use Corollary 2.3.

We can deduce the very useful Corollary 2.4.

COROLLARY 2.4. *Let x belong to X . It holds that*

$$T_K(x) \cap T_{\hat{K}}(x) = T_{\partial K}(x)$$

and

$$D_K(x) = T_K(x) \setminus T_{\partial K}(x).$$

This corollary can be used in the study of the qualitative behaviour of replicator systems in the simplex (see [12]), or to study the fluctuations of solutions around the boundary of a given set (see [19]). Corollary 2.3 can be generalized to compute the contingent cone to an intersection of a finite number of closed sets as follows.

COROLLARY 2.5. *Let K_1, K_2, \dots, K_p be p closed subsets of a metric vector space X and let x belong to $\bigcap_{i=1}^p K_i$. If there exists an open set \mathcal{O} that contains x such that*

$$\forall j \leq p, \quad \mathcal{O} \subset K_j \cup \left(\bigcap_{i=1}^{j-1} K_i \right),$$

then

$$T_{\bigcap_{i=1}^p K_i}(x) = \bigcap_{i=1}^p T_{K_i}(x).$$

⁸ It is a pleasure for me to thank Halina Frankowska who suggested improving Corollary 2.3 into Theorem 2.2 by using Dubovitsky-Millutin tangent cones.

⁹ Recall the definition of the Clarke's tangent cone (see, for instance, [6, Chap. 4]), $C_K(x) = \{v \mid \liminf_{h \rightarrow 0^+, y \rightarrow x, y \in K} d(y \geq hv, K)/h = 0\}$.

2.2. First partition of the target boundary. Let us introduce three subsets of the boundary that are dependent on the dynamic of the system

$$\begin{aligned} K^i &:= \{x \in \partial K / F(x) \subset D_K(x)\}, \\ K^e &:= \{x \in \partial K / F(x) \subset X \setminus T_K(x)\}, \\ K^b &:= \{x \in \partial K / F(x) \cap T_{\partial K}(x) \neq \emptyset\}. \end{aligned}$$

PROPOSITION 2.6. *If $F: X \rightarrow X$ is an upper semicontinuous set-valued map with nonempty convex compact values, if K is closed nonempty, then (K^e, K^i, K^b) form a partition of the boundary ∂K (in the sense that $\partial K = K^i \cup K^b \cup K^e$ and these three sets are disjoint).*

If x_0 belongs to K^i , then all solutions starting at x_0 enter $\text{Int}(K)$ and stay in the interior on time interval $]0, T[$ (with $T > 0$).

If x_0 belongs to K^e , then all solutions starting at x_0 enter $\text{Int}(X \setminus K)$ and stay outside K on $]0, T[$ (with $T > 0$).

If x_0 belongs¹⁰ to $\text{Int}_{\partial K} K^b$, then there exists a solution starting at x_0 that stays on the boundary ∂K on $]0, T[$ (with $T > 0$).

Remark. We can note that, when ∂K is a C^1 surface, the subset $K^b \cup K^i$ is often called the *boundary usable part* and K^e the *boundary nonusable part*.

For a set A , we set $\hat{A} := \overline{X \setminus A}$ and we denote by $\text{Int}(A)$ its interior. We can introduce the same type of partition for the closed set $\bar{C} = \hat{K}$, i.e., the three sets $\bar{C}^i = \hat{K}^i$, $\bar{C}^b = \hat{K}^b$, $\bar{C}^e = \hat{K}^e$, which form a partition of $\partial \hat{K}$. A natural question arises: How can we compare \hat{K}^i , \hat{K}^b , \hat{K}^e and (K^e, K^i, K^b) ?

PROPOSITION 2.7. *Let K be a closed set and F a set-valued map with nonempty convex values.*

$$K^i = \hat{K}^e, K^e \subset \hat{K}^i, K^b \subset \hat{K}^b.$$

Equalities hold true if and only if $\overline{\text{Int}(\bar{K})} = K$.

The first statement and the inclusions are obvious. If the equalities $K^e = \hat{K}^i$, $K^b = \hat{K}^b$ hold, then necessarily $\partial K = \partial \hat{K}$, i.e., $\overline{\text{Int}(\bar{K})} = K$. It is easy to show that this condition is sufficient (in this case $\hat{K} = K$).

We can improve this partition to have a more precise one.

2.3. Second partition of the target boundary. Let us consider the following differential inclusion:

$$(4) \quad y'(t) \in -F(y(t)).$$

We can regard the solutions of (4) as solutions of (1) but in the reverse direction (i.e., if $x(\cdot)$ is a solution of (1) on $[0, T]$, then $y(t) := x(T - t)$ is solution of (4) on $[0, T]$). In this way, we get the backward trajectories of (1).

We introduce the subsets

$$\begin{aligned} K^{i-} &:= \{x \in \partial K / -F(x) \subset D_K(x)\}, \\ K^{e-} &:= \{x \in \partial K / -F(x) \subset X \setminus T_K(x)\}, \\ K^{b-} &:= \{x \in \partial K / -F(x) \cap T_{\partial K}(x) \neq \emptyset\}. \end{aligned}$$

These three sets also form a partition of ∂K . Consequently, these two partitions yield a new partition of the boundary made of nine subsets.

¹⁰ Here, we denote by $\text{Int}_{\partial K} K^b$ the interior of K^b in the space ∂K .

We can describe the qualitative behaviour of solution, as in the previous section, in the following proposition in which we shall denote by $\text{Int}(K^b)$ the interior of K^b in the space ∂K .

PROPOSITION 2.8. *Let K be a closed nonempty set.*

x_0 is an element of	Properties of solutions that start at x_0
$K^i \cap K^{i-}$	All solutions enter K at x_0 .
$K^i \cap K^{e-}$	No solutions come from the exterior of K . All solutions enter K at x_0 .
$K^i \cap \text{Int}(K^{b-})$	No solutions come from the interior of K . All solutions enter K at x_0 .
$K^e \cap K^{e-}$	There exists at least one trajectory locally viable on the boundary that comes into $\text{Int}(K)$ at x_0 . All solutions go outside K .
$K^e \cap K^{i-}$	No solutions come from the interior of K . All solutions go outside K .
$K^e \cap \text{Int}(K^{b-})$	No solutions come from the exterior of K . All solutions go outside K .
$\text{Int}(K^b) \cap \text{Int}(K^{b-})$	There exists at least one solution locally viable on the boundary that comes into $\text{Int}(K)$ at x_0 . There exists a solution passing through x_0 (i.e., $\exists \tau > 0$, $x(\tau) = x_0$) and locally viable (for F and $-F$) on the boundary.
$\text{Int}(K^b) \cap K^{i-}$	No solutions come from the exterior of K .
$\text{Int}(K^b) \cap K^{e-}$	There exists a solution locally viable on ∂K that comes from the interior of K . No solutions come from the interior of K . There exists a solution locally viable on ∂K that comes from the exterior of K .

2.4. Proofs.

Proof of Theorem 2.2. Let v be in $T_{K_1}(x) \cap T_{K_2}(x) \cap D_{K_1 \cup K_2}(x)$. According to the definitions of these sets, there exist sequences h_n^1, h_n^2 of nonnegative reals converging to 0, sequences v_n^1, v_n^2 converging to v , and a real α such that

$$\forall n \quad x + h_n^1 v_n^1 \in K_1, \quad x + h_n^2 v_n^2 \in K_2, \\ x +]0, \alpha](v + \alpha B) \subset K_1 \cup K_2.$$

Clearly, there exists N such that

$$\forall n > N, \quad x + h_n^i v_n^i \in x + [0, \alpha](v + \alpha B) \quad \text{for } i = 1, 2.$$

Since for all $n > N$, the two points $x + h_n^1 v_n^1$ and $x + h_n^2 v_n^2$ belong to the convex set $x + [0, \alpha](x + \alpha B)$

$$[x + h_n^1 v_n^1, x + h_n^2 v_n^2] \subset x + [0, \alpha](x + \alpha B) \subset K_1 \cup K_2.$$

On the other hand,

$$([x + h_n^1 v_n^1, x + h_n^2 v_n^2] \cap K_1) \cup ([x + h_n^1 v_n^1, x + h_n^2 v_n^2] \cap K_2) = [x + h_n^1 v_n^1, x + h_n^2 v_n^2].$$

We cannot form a partition of a connected set made of two nonempty closed sets. Hence the intersection of the two closed sets in the left-hand side of the above equality is nonempty. Consequently, there exists λ_n in $[0, 1]$ such that

$$\lambda_n(x + h_n^1 v_n^1) + (1 - \lambda_n)(x + h_n^2 v_n^2) \in K_1 \cap K_2$$

(if one of these sets is empty, we obtain the same conclusion by setting $\lambda_n := 0$ or 1).

By setting

$$\begin{aligned} h_n &:= \lambda_n h_n^1 + (1 - \lambda_n) h_n^2, \\ v_n &:= (\lambda_n h_n^1 v_n^1 + (1 - \lambda_n) h_n^2 v_n^2) / h_n, \end{aligned}$$

we see that $v_n \rightarrow v$, $h_n \rightarrow 0$ and $x_n + h_n v_n \in K_1 \cap K_2$. The proof is completed. \square

Corollaries 2.3 and 2.4 are obvious consequences of Theorem 2.2 if we note that

- $D_{K_1 \cup K_2}(x) = X$ by assumption of Corollary 2.3,
- $T_{K_1 \cap K_2}(x) \subset T_{K_1}(x) \cap T_{K_2}(x)$,
- $D_{K \cup \hat{K}}(x) = X$ trivially.

Proof of Corollary 2.5. Thanks to Corollary 2.3, we have

$$T_{K_p}(x) \cap T_{\bigcap_{i=1}^{p-1} K_i}(x) = T_{\bigcap_{i=1}^p K_i}(x).$$

But we have (with the assumption in the case where $j = p - 1$)

$$\emptyset \subset (K_{p-1}) \cup \left(\bigcap_{i=1}^{i=p-2} K_i \right).$$

Hence, according to Corollary 2.3,

$$T_{K_{p-1}}(x) \cap T_{\bigcap_{i=1}^{i=p-2} K_i}(x) = T_{\bigcap_{i=1}^{p-1} K_i}(x).$$

An obvious induction argument allows us to complete the proof. \square

Proof of Proposition 2.6. Thanks to Corollary 2.4, we can divide the space X into three sets: $D_K(x)$, $T_{\partial K}(x)$, $X \setminus T_K(x)$. That provides the partition of the boundary. In fact, we observe that $K^i \cap K^e = \emptyset$ and if $F(x) \cap T_K(x) \neq \emptyset$ and $F(x) \cap T_{\hat{K}}(x) \neq \emptyset$, then using that values of F are connected, we deduce that $x \in K^b$. Now, it is easy to characterize each area (see [5]). \square

3. Boundaries of invariant and viability kernels. In this section, X denotes a finite-dimensional vector space. Our purpose is to describe the boundary of the set of initial conditions of (1) from which it is possible to reach the target C . This set is the complement of the viability kernel of $K = X \setminus C$ associated with (1). We shall now characterize the boundary of these two kernels.

THEOREM 3.1. *Let $F: X \rightarrow X$ be a Lipchitzean set-valued map with nonempty convex compact values and with linear growth, and K be a closed nonempty set.*

If x_0 belongs to $\partial \text{Viab}_F(K) \setminus \partial K$, then there exists a solution viable in K , starting at x_0 that stays in the boundary of $\text{Viab}_F(K)$ as long as it does not cross ∂K . Furthermore, every viable solution starting at x_0 has the same behaviour.

Proof. We prove that there exists a viable solution starting at x_0 that stays on the boundary of the viability kernel until it reaches ∂K .

In fact, let $x(\cdot)$ be a viable solution starting at x_0 that enters the interior of $\text{Viab}_F(K)$ (i.e., there exists $T > 0$ such that $x(T) \in \text{Int}(\text{Viab}_F(K))$ and $x([0, T]) \subset \text{Int}(K) \cap \text{Viab}_F(K)$). According to Filippov's theorem,¹¹ there exists $l > 0$ such that, for all y in K , there exists a solution $y(\cdot)$ starting at y_0 such that

$$\forall t \leq T, \quad y(t) \in x(t) + l \|y_0 - x_0\| B.$$

Hence, it is possible to find $\alpha > 0$ such that, for all y_0 in $(x_0 + \alpha B) \setminus \text{Viab}_F(K)$, we have $y([0, T]) \subset K$ and $y(T) \in \text{Viab}_F(K)$. But there exists a viable solution $\tilde{y}(\cdot)$ starting at $y(T)$ ($\in \text{Viab}_F(K)$).

Let us define the new trajectory $\bar{y}(\cdot)$

$$\bar{y}(s) := \begin{cases} y(s) & \text{if } s \leq T, \\ \tilde{y}(s) & \text{if } s \geq T. \end{cases}$$

¹¹ If F is Lipchitzean with nonempty values, $y(\cdot) \in S_T(y_0)$ (set of solutions of (1) starting at y_0). There exists $l > 0$ such that $d_{W^{1,1}(0,T)}(y, S_T(x_0)) \leq l \|x_0 - y_0\|$ (see [6, Chap. 10]).

Then $\bar{y}(\cdot)$ is a solution to (1) viable in K . We have shown that $\text{Viab}_F(K) \cup \{\bar{y}(t), t \geq 0\}$ (which contains strictly $\text{Viab}_F(K)$) is a viability domain; this is a contradiction. \square

COROLLARY 3.2. *If assumptions of Theorem 3.1 hold true and if $\text{Viab}_F(K) \subset \text{Int}(K)$, then $\partial \text{Viab}_F(K)$ is a viability domain and the set $\overline{X \setminus \text{Viab}_F(K)}$ is an invariance domain.*

Proof. If we note that $\partial \text{Viab}_F(K) \cap \partial K = \emptyset$ then, thanks to Theorem 3.1, $\partial \text{Viab}_F(K)$ is a viability domain. Let us consider a solution $x(\cdot)$ starting at $x_0 \in \overline{X \setminus \text{Viab}_F(K)}$. If a solution reaches $\partial \text{Viab}_F(K)$, thanks to Theorem 3.1, it cannot enter in the interior of the viability kernel. \square

Remark and example. If $\text{Viab}_F(K) \subset \text{Int}(K)$, the sets $\partial \text{Viab}_F(K)$ and $\partial \text{Inv}_F(K)$ are viability and domains, but, generally, they are not invariance domains. We can see that in the following simple examples in the two-dimensional space \mathbb{R}^2 .

We consider a constant set-valued map and two closed sets

$$\begin{aligned} F &:= \{1\} \times [0, 1], \\ K_1 &:= \{(x, y) \in \mathbb{R}^2 \mid x > 0, y \leq 1/x\} \cup \mathbb{R}^- \times \mathbb{R}, \\ K_2 &:= \{(x, y) \in \mathbb{R}^2 \mid x > 0, y \geq -1/x\} \cup \mathbb{R}^- \times \mathbb{R}. \end{aligned}$$

Then, it is easy to check that

$$\text{Viab}_F(K_1) = \mathbb{R} \times \mathbb{R}^- \quad \text{Inv}_F(K_1) = \emptyset,$$

$$\text{Inv}_F(K_2) = \mathbb{R} \times \mathbb{R}^+,$$

$$\text{Viab}_F(K_2) = \{(x, y) \in \mathbb{R}^2 \mid x \geq 1, y \geq -1/x\} \cup \{(x, y) \in \mathbb{R}^2 \mid x \leq 1, y \geq x - 2\}.$$

Here, the boundaries of $\text{Viab}_F(K_1)$ and $\text{Inv}_F(K_2)$ are viability domains, but they are not invariance domains. We can see that all solutions starting at a point of $\{(x, y) \mid x \leq 1, y = x - 2\}$ stay in this set until they reach the boundary of $\text{Viab}_F(K_2)$ (at $(+1, -1)$). \square

We now prove a dual result.

PROPOSITION 3.3. *Let F be a Lipchitzian set-valued map with nonempty convex compact values, and K a closed compact nonempty set.*

If $\text{Inv}_F(K) \subset \text{Int}(K)$, then the boundary $\partial \text{Inv}_F(K)$ is a viability domain.

Proof of Proposition 3.3. We shall show a more precise result: $\overline{X \setminus \text{Inv}_F(K)}$ is a viability domain (so that, if $x_0 \in \partial \text{Inv}_F(K)$ there will exist a solution viable in $\overline{X \setminus \text{Inv}_F(K)}$ that necessarily is also viable $\text{Inv}_F(K)$; hence it is viable in the boundary). In doing this, it is sufficient to show that there exists a solution starting at any point of $\overline{X \setminus \text{Inv}_F(K)}$ that never crosses $\text{Inv}_F(K)$, so that $\overline{X \setminus \text{Inv}_F(K)} \subset \text{Viab}_F(\overline{X \setminus \text{Inv}_F(K)})$.

Since K is a compact set, there exists a nonnegative number α such that $\text{Inv}_F(K) + 2\alpha B \subset \text{Int}(K)$. We shall need the following lemma.

LEMMA 3.4. *Under the assumptions of Proposition 3.3, let $x(\cdot)$ be a solution to (1) and $\alpha > 0$. Then there exists $\tau > 0$ such that, for all $t \geq t' \geq 0$,*

$$x[t', t] \subset K, \quad \|x(t) - x(t')\| \geq \alpha \Rightarrow t - t' \geq \tau.$$

Proof of Lemma 3.4. Let us define $M := \sup_{x \in K} \|F(x)\|$ and $\tau := \alpha/M$. As K is compact and F Lipschitzian with compact values, M is different from infinity.¹² Since

¹² This is even true if we assume that F is upper semicontinuous with compact values.

$x(\cdot)$ is absolutely continuous, we have

$$\alpha \leq \|x(t) - x(t')\| = \left\| \int_{t'}^t x'(s) ds \right\| \leq M|t - t'|.$$

Hence $|t - t'| \geq \tau$. The proof of the lemma is completed. \square

Let $x \in K \setminus \text{Inv}_F(K)$; let us build a solution starting at x viable in $\overline{K \setminus \text{Inv}_F(K)}$. We know that there exists at least one solution $x(\cdot)$ that goes outside K (i.e., there exists $\tau_1 > 0$, $x(\tau_1) \in X \setminus K$). If this solution stays outside $\text{Inv}_F(K)$ then the proof is achieved. Otherwise, there exists a time $T_1 > \tau_1$ such that $x(T_1) \in (\text{Inv}_F(K) + \alpha B) \setminus \text{Inv}_F(K)$. According to Lemma 3.4, because $\|x(T_1) - x(\tau_1)\| \geq \alpha$, we have $|T_1 - \tau_1| \geq \tau$. But starting at $x(T_1)$ there exists a solution $\tilde{x}(\cdot)$ that goes outside K (there exists τ_2 , $\tilde{x}(\tau_2) \notin K$). Similar to the proof of Theorem 3.1, we obtain a solution to (1) starting at x_0 (again denoted $x(\cdot)$) such that $\tilde{x}(\tau_2) = x(T_1 + \tau_2)$. If this solution stays outside $\text{Inv}_F(K)$, then the proof is achieved, otherwise

$$\exists T_2 > T_1, x(T_2) \in (\text{Inv}_F(K) + \alpha B) \setminus \text{Inv}_F(K) \text{ with } T_2 - T_1 \geq \alpha.$$

If there is a finite number of T_i the proof is clearly achieved. If there is an infinite number of T_i this sequence converges to ∞ because $T_{n+1} - T_n \geq \alpha$. We have obtained a solution of (1) viable in $\overline{X \setminus \text{Inv}_F(K)}$. \square

When K is not compact but only closed, it is possible to prove a similar result.

PROPOSITION 3.5. *Let K be a closed set, and F a set-valued map satisfying the assumptions of Proposition 3.3.*

If $\text{Viab}_F(K) \subset \text{Int}(K)$, then $\overline{X \setminus \text{Inv}_F(K)}$ and $\partial \text{Inv}_F(K)$ are viability domains.

We then deduce a result that follows from Theorem 3.1 and Proposition 3.3.

COROLLARY 3.6. *Let F be a Lipschitzian set-valued map with nonempty convex compact values, and K a closed compact nonempty set. If $x_0 \in \partial \text{Inv}_F(K) \cap \partial \text{Viab}_F(K)$, then all solutions starting at x_0 stay on the boundary of $\text{Viab}_F(K)$, as long as they do not cross ∂K .*

Furthermore, if $\partial \text{Inv}_F(K) \cap \partial \text{Viab}_F(K) \subset \text{Int}(K)$, it is an invariance domain.

4. Backward trajectories for a differential inclusion. In previous sections, we were interested in studying solutions starting at a given point; now, we shall study solutions reaching a given point.

We compare in this section kernels associated to (1) and kernels associated to (4).

Roughly, the concatenation of solutions of (1) and (4) gives us a solution of the differential inclusion on $]-\infty, +\infty[$.

Let $\text{Viab}_{-F}(K)$ (respectively, $\text{Inv}_{-F}(K)$) denote the viability kernel of (4) (respectively, the invariance kernel) of K for the set-valued map $-F$. Of course, all results concerning boundaries of these sets are still available.

PROPOSITION 4.1. *Let F be a Lipschitzian set-valued map with nonempty convex compact values and linear growth, and K a closed set. Then*

- *The set $\text{Inv}_F(K) \cap \text{Viab}_{-F}(K)$ is an invariance domain for F .*
- *The set $\text{Inv}_{-F}(K) \cap \text{Viab}_F(K)$ is an invariance domain for $-F$.*
- *The set $\text{Viab}_F(K) \cap \text{Viab}_{-F}(K)$ is a viability domain for F and $-F$.*
- *The set $\text{Inv}_F(K) \cap \text{Inv}_{-F}(K)$ is a viability domain for F and $-F$.*

Proof. To prove this, we use a technique similar¹³ to the proof of Theorem 3.1. Let us prove, for instance, the first result.

Let x_0 belong to $\text{Inv}_F(K) \cap \text{Viab}_{-F}(K)$ and $x(\cdot)$ be a solution to (1). Fix $T > 0$. By setting $y(t) := x(T - t)$ ($t \in [0, T]$), we obtain a solution to (4) such that $y(T) = x_0 \in$

¹³ Let us recall $\text{Inv}_F(K) \subset \text{Viab}_F(K)$ and $\text{Inv}_{-F}(K) \subset \text{Viab}_{-F}(K)$.

$\text{Viab}_{-F}(K)$. Hence, there exists $\tilde{y}(\cdot)$ a solution to (4) starting at x_0 and viable in K with respect to $-F$. The concatenation of $y([0, T])$ and $\tilde{y}([T, \infty[)$ provides a solution starting at $x(T)$ viable in K (with respect to $-F$). Hence $x(T) \in \text{Viab}_{-F}(K)$; since T is arbitrary, the proof follows. \square

PROPOSITION 4.2. *If assumptions of Proposition 4.1 hold true, then*

- (i) $\text{Viab}_F(K) \subset \text{Int}(K) \Rightarrow \text{Viab}_F(K) \subset \text{Inv}_{-F}(K)$
- (ii) $\text{Viab}_{-F}(K) \subset \text{Int}(K) \Rightarrow \text{Viab}_{-F}(K) \subset \text{Inv}_F(K)$.

It follows by exactly the same arguments as in the previous proof.

Remark. We can now “mix” all these subsets and kernels to prove results of the type

$$\begin{aligned}\text{Viab}_F(K) \cap \text{Viab}_F(\hat{K}) &\subset K^b, \\ \text{Viab}_F(K) \cap \text{Inv}_{-F}(\hat{K}) &\subset K^b \cap \hat{K}^{i-},\end{aligned}$$

and so on. \square

5. An application to control systems with one target: Semipermeable barriers. A question naturally arises: Why is it useful to study the boundary of viability or invariance kernels? We give an example of controlled system with one target.

5.1. Certain and possible victory and defeat domains. We can model the controlled system¹⁴

$$(5) \quad x'(t) = f(x(t), u(t)), \quad u(t) \in U(x(t))$$

through the differential inclusion (1) by setting $F(x) := f(x, U(x))$. We shall assume that F is Lipschitzian with convex compact nonempty values.¹⁵

Our problem is to drive in finite time the state x inside a given open set C starting at a point outside of C . This has a precise mathematical sense by using the viability and invariance kernels of $K := X \setminus \overline{C}$. Let us introduce some definition of victory and defeat domains (see [3]).

DEFINITION 5.1. We define

- the domain of *certain defeat* by the set $\text{Inv}_F(X \setminus C)$,
- the domain of *possible defeat* by the set $\text{Viab}_F(X \setminus C)$,
- the domain of *certain victory* by the set $\overline{K \setminus \text{Viab}_F(X \setminus C)}$,
- the domain of *possible victory* by the set $\overline{K \setminus \text{Inv}_F(X \setminus C)}$.

Let us make more precise the qualitative behaviour of solutions in these domains.

PROPOSITION 5.2. *If $x_0 \in \text{Inv}_F(X \setminus C)$, then no solution to (5), starting at x_0 , can reach C (certain defeat).*

If $x_0 \in \text{Viab}_F(X \setminus C)$, there exist solutions of (5), starting at x_0 , that never reach C (possible defeat).

If $x_0 \in X \setminus \text{Viab}_F(X \setminus C)$, then all solutions of (5), starting at x_0 , reach C in finite time (certain victory).

If $x_0 \in K \setminus \text{Inv}_F(X \setminus C)$, there exist solutions to (5), starting at x_0 , that reach C in finite time (possible victory).

Proof. It is the obvious consequence of Definitions 1.2 and 1.1. \square

5.2. Semipermeable barrier. We shall define some subsets of the boundaries of these victory and defeat domains.

DEFINITION 5.3. The *barrier* is the set

$$\partial \text{Inv}_F(X \setminus C) \setminus \partial C.$$

¹⁴ Results of this paper can be easily extended to the nonautonomous case, i.e., $x'(t) = f(t, x(t), u(t))$, $u(t) \in U(t, x(t))$ (see [25]).

¹⁵ In particular, it is satisfied if f is Lipschitzian affine with respect to the control and U is a Lipschitzian set-valued map with nonempty convex compact values.

The *strict barrier* is the set

$$\partial \text{Viab}_F(X \setminus C) \setminus \partial C.$$

We can note that the barrier is contained in the intersection of the certain defeat domain and the possible victory domain. The strict barrier is contained in the intersection of the possible defeat domain and the certain victory domain. We can translate the results of § 3, and so we have a qualitative description of the behaviour of solution on the barriers.

PROPOSITION 5.4. *The strict barrier is a local viability domain.¹⁶ Furthermore, all solutions starting at any state x_0 of the strict barrier that are viable in $X \setminus C$ remain in this set until it reaches \bar{C} (and there exists such solution).*

The barrier is a viability domain¹⁷ as soon as

$$\bar{C} \cap \text{Viab}_F(X \setminus C) = \emptyset.$$

Proof. The first result is a consequence of Theorem 3.1, and the second one is a consequence of Proposition 3.5. \square

This generalizes the concept of semipermeable barriers (see [9], [10]). Recall that a C^1 -surface is semipermeable when it satisfies an equation such that $\max_u f(x, u) \cdot n \leq 0$ or $\min_u f(x, u) \cdot n \geq 0$ (where n is the normal vector of the surface). It means that the solutions of (5) are able to cross the surface in *only one direction*. Let us make this idea more precise by using the partition of § 2.

DEFINITION 5.5. Let A be a closed set. A subset B of ∂A is semipermeable for A if and only if, for any point x_0 of B , any solution $x(\cdot)$ starting at x_0 is locally viable in A .

Remark. Let us note that an obvious consequence of this definition is $B \cap A^e = \emptyset$.

Thanks to Proposition 5.4, we can state the following proposition.

PROPOSITION 5.6. *The strict barrier is semipermeable for $\text{Viab}_F(X \setminus C)$.*

In fact, thanks to Proposition 5.4, we know that a solution of (5) cannot cross the strict barrier if it comes from the exterior of the viability kernel $\text{Viab}_F(X \setminus C)$, but the converse is possible (i.e., there could exist solutions coming from the interior of the kernel that cross the strict barrier).

We can note that, thanks to Corollary 3.6, the intersection of the strict barrier and the barrier is a *local invariance domain*¹⁸ (if it is nonempty).

Acknowledgment. I am indebted to Halina Frankowska for her help and advice.

DYNAMIC DISTURBANCE DECOUPLING FOR NONLINEAR SYSTEMS*

H. J. C. HUIJBERTS[†], H. NIJMEIJER[†], AND L. L. M. VAN DER WEGEN[‡]

Abstract. In analogy with the dynamic input-output decoupling problem the dynamic disturbance decoupling problem for nonlinear systems is introduced. A local solution of this problem is obtained in the case that the system under consideration is invertible. The solution is given in algebraic as well as in geometric terms. The theory is illustrated by means of two examples: a mathematical one and an example of a voltage frequency controlled induction motor.

Key words. nonlinear control systems, dynamic disturbance decoupling, invertibility, dynamic precompensation

AMS(MOS) subject classifications. 93C10, 93B50, 93C35

1. Introduction. Consider a nonlinear multi-input-multi-output control system Σ of the form

$$(1) \quad \Sigma \begin{cases} \dot{x} = f(x) + g(x)u + p(x)q \\ y = h(x), \end{cases}$$

where $x \in \mathcal{X}$, an open subset of \mathbb{R}^n , the inputs $u \in \mathbb{R}^m$, the outputs $y \in \mathbb{R}^p$, the disturbances $q \in \mathbb{R}^r$, f and h are vector-valued analytic functions, and g and p are matrix-valued analytic functions, all of appropriate dimensions. In the disturbance decoupling problem (DDP) for (1), we search for a regular static state feedback

$$(2) \quad u = \alpha(x) + \beta(x)v,$$

with v a new m -dimensional control and $\beta(x)$ a nonsingular $m \times m$ matrix for all x , so that in the feedback modified dynamics

$$(3) \quad \dot{x} = f(x) + g(x)\alpha(x) + g(x)\beta(x)v + p(x)q,$$

the disturbances q do not affect the outputs y . A local solution of the DDP using differential geometric tools was initiated in [13] and [9] and has led to a more or less complete understanding of this problem; see, e.g., [12], [18]. The nonlinear DDP forms a direct generalization of the linear DDP, and the theory about the nonlinear DDP typically extends the well-known linear geometric theory (cf. [23]) to a nonlinear context.

The purpose of this paper is to study a dynamic version of the DDP for the nonlinear system (1). That is, instead of a static feedback law (2) we allow for a *regular* dynamic state feedback

$$(4) \quad \begin{aligned} \dot{z} &= \alpha(x, z) + \beta(x, z)v, \\ u &= \gamma(x, z) + \delta(x, z)v, \end{aligned}$$

with z the μ -dimensional compensator state and v an m -dimensional new control, and the regularity of (4) means that the system (4) with inputs v and outputs u is invertible for all z and constant x . Note that a somewhat different definition of regular

dynamic state feedback was given in [15]. In the dynamic disturbance decoupling problem (DDDP), we require that in the modified dynamics

$$(5) \quad \begin{aligned} \dot{x} &= f(x) + g(x)\gamma(x, z) + g(x)\delta(x, z)v + p(x)q, \\ \dot{z} &= \alpha(x, z) + \beta(x, z)v \end{aligned}$$

the disturbances q do not influence the outputs y . Clearly, the static DDP forms a special case of the DDDP by assuming that $\mu = 0$. As noted before, the theory for solving the nonlinear DDP is very much based on a proper extension of the solution of the linear DDP. We are therefore led to think that similarly a solution of the nonlinear DDDP naturally extends the DDDP for linear systems. However, a very simple argument shows that for linear systems the DDDP is solvable if and only if the static DDP is solvable (see, e.g., [1], [2]). Although an analogous result is also true for single-output nonlinear systems, i.e., when $p = 1$, this conclusion no longer holds true for multi-output nonlinear systems. In other words, when $p > 1$ it may happen that the nonlinear DDDP is (locally) solvable, whereas the nonlinear DDP is not.

Our goal is to establish necessary and sufficient conditions for the solvability of the DDDP, thereby discussing various different algebraic and geometric aspects of this problem for the case that the system (1) with $q \equiv 0$ is square and invertible.

The organization of the paper is as follows. In § 2 we introduce the dynamic disturbance decoupling problem with disturbance measurements (DDDPdm) and the dynamic disturbance decoupling problem (DDDP), and we show that both problems are locally solvable if and only if they are solvable by means of a compensator that is obtained from Singh's algorithm. In §§ 3 and 4 we translate the conditions for solvability of the DDDPdm obtained in § 2 into intrinsic and algorithm-independent conditions, using differential algebraic and geometric tools, respectively. In § 5 the theory of the foregoing sections will be applied to an example of a voltage frequency controlled induction motor as was described in [3]. Section 6 contains the conclusions of the paper.

2. The dynamic disturbance decoupling problem (DDDP). In this section we formulate and solve two kinds of DDDPs. These problems are dynamic extensions of the well-known static state feedback DDP, respectively, the static state feedback DDP with disturbance measurements.

DEFINITION 2.1. Consider the analytic system Σ and let a point $x_0 \in \mathcal{X}$ be given.

1. The DDDP is said to be locally solvable around x_0 if there exist an analytic dynamic state feedback for Σ of the form (4), to be denoted as R , with $z \in \mathbb{R}^\mu$, a neighborhood $U \subset \mathcal{X}$ of x_0 , and an open subset $\mathcal{Z} \subset \mathbb{R}^\mu$ such that R , with inputs v and outputs u , is invertible for all constants $x \in U$ and $z \in \mathcal{Z}$ and the outputs of the composite system $\Sigma \circ R$ restricted to $U \times \mathcal{Z}$ are independent of the disturbances.

2. The dynamic disturbance decoupling problem with disturbance measurements (DDDPdm) is said to be locally solvable around x_0 if there exist a dynamic state feedback for Σ of the form

$$(6) \quad Q \begin{cases} \dot{z} = \alpha(x, q, z) + \beta(x, q, z)v \\ u = \gamma(x, q, z) + \delta(x, q, z)v, \end{cases}$$

with $z \in \mathbb{R}^\mu$, a neighborhood $U \subset \mathcal{X}$ of x_0 , and an open subset $\mathcal{Z} \subset \mathbb{R}^\mu$, such that (6) with inputs v and outputs u is invertible for all constant $x \in U$ and all $q \in \mathbb{R}^r$ and $z \in \mathcal{Z}$, and the outputs of the composite system $\Sigma \circ Q$ restricted to $U \times \mathcal{Z}$ are independent of the disturbances.

If we furthermore require the compensators Q and R to be static state feedback compensators (i.e., $\mu = 0$), the problem will be referred to by DDPdm and DDP, respectively.

Recall that the DDP is locally solvable if and only if $\mathcal{P} \subset \Delta^*$ and that the DDPdm is locally solvable if and only if $\mathcal{P} \subset \Delta^* + \mathcal{G}$, where $\mathcal{G} = \text{span}\{g_1, \dots, g_m\}$, $\mathcal{P} = \text{span}\{p_1, \dots, p_r\}$, and Δ^* is the maximal locally controlled invariant distribution contained in $\ker dh$ (cf. [13]). It is well known (see, e.g., [1], [2]) that for linear systems the DDDP is solvable if and only if the DDP is solvable. That this is not the case for nonlinear systems can be seen from the following example.

Example 2.2. Consider the nonlinear system

$$\begin{aligned}
 \dot{x}_1 &= x_2 u_1, & y_1 &= x_1, \\
 \dot{x}_2 &= x_5, & y_2 &= x_3, \\
 \dot{x}_3 &= x_2 + x_4 + x_4 u_1, \\
 \dot{x}_4 &= u_2, \\
 \dot{x}_5 &= x_1 u_1 + q.
 \end{aligned}
 \tag{7}$$

For this system we have $\Delta^* = \{0\}$. Hence the DDP is not locally solvable. However, if we apply the compensator

$$\begin{aligned}
 \dot{z} &= v_1, \\
 u_1 &= z, \\
 u_2 &= v_2,
 \end{aligned}
 \tag{8}$$

where v_1, v_2 are the new inputs, we find for the compensated system (7), (8) that

$$\Delta_e^* = \text{span} \left\{ \frac{\partial}{\partial x_5}, x_2(1+z) \frac{\partial}{\partial x_2} + (x_2 - zx_4) \frac{\partial}{\partial x_4} - z(1+z) \frac{\partial}{\partial z} \right\},$$

where Δ_e^* is the maximal locally controlled invariant distribution contained in $\ker dh$ for (7), (8). Hence it is clear that the DDP for (7), (8) is solvable and thus the DDDP is solvable for (7).

In the following, we make the standing assumption, below.

(A1). The system Σ is square, i.e., $p = m$.

Instrumental in the solution of the DDDPdm is what we like to call a Singh compensator, which can be obtained via the so-called Singh algorithm. Singh's algorithm has been introduced in [19] for calculation of a left inverse of a nonlinear system. It is a generalization of the algorithm from [8], which was only applicable under some restrictive assumptions. Let Σ_0 denote the system Σ with $q \equiv 0$. We briefly repeat Singh's algorithm for the system Σ_0 , following [5].

ALGORITHM 2.3. Consider the analytic nonlinear system Σ_0 , satisfying (A1). Let a point $x_0 \in \mathcal{X}$ be given.

Step 1.

Calculate

$$\dot{y} = \frac{\partial h}{\partial x} [f(x) + g(x)u] =: a_1(x) + b_1(x)u
 \tag{9}$$

and assume that $b_1(x)$ has full rank ρ_1 on a neighborhood of x_0 . Define $s_1 := \rho_1$. Permute, if necessary, the components of the output, so that the first ρ_1 rows of $b_1(x)$ are linearly independent. Decompose y according to

$$(10) \quad \dot{y} = \begin{pmatrix} \dot{\hat{y}}_1 \\ \dot{\hat{y}}_1 \end{pmatrix},$$

where $\dot{\hat{y}}_1$ consists of the first ρ_1 rows of \dot{y} . Since the last rows of $b_1(x)$ are linearly dependent on the first ρ_1 rows, we can write

$$(11) \quad \dot{\hat{y}}_1 = \tilde{a}_1(x) + \tilde{b}_1(x)u, \quad \dot{\hat{y}}_1 = \hat{y}_1(x, \dot{\hat{y}}_1),$$

where the last equation is affine in $\dot{\hat{y}}_1$. Finally, set $\tilde{B}_1(x) := \tilde{b}_1(x)$.

Step $k+1$.

Suppose that in Steps 1 through k , $\dot{\hat{y}}_1, \dots, \tilde{y}_k^{(k)}, \hat{y}_k^{(k)}$ have been defined so that

$$(12) \quad \begin{aligned} \dot{\hat{y}}_1 &= \tilde{a}_1(x) + \tilde{b}_1(x)u, \\ &\vdots \\ \tilde{y}_k^{(k)} &= \tilde{a}_k(x, \{\tilde{y}_i^{(j)} \mid 1 \leq i \leq k-1, i \leq j \leq k\}) \\ &\quad + \tilde{b}_k(x, \{\tilde{y}_i^{(j)} \mid 1 \leq i \leq k-1, i \leq j \leq k-1\})u, \\ \hat{y}_k^{(k)} &= \hat{y}_k^{(k)}(x, \{\tilde{y}_i^{(j)} \mid 1 \leq i \leq k, i \leq j \leq k\}). \end{aligned}$$

Suppose also that there exist $\tilde{y}_{i0}^{(j)}$ ($1 \leq i \leq k-1, i \leq j \leq k-1$) such that the matrix $\tilde{B}_k := [\tilde{b}_1^T, \dots, \tilde{b}_k^T]^T$ has full rank ρ_k on a neighborhood of $(x_0, \{\tilde{y}_{i0}^{(j)} \mid 1 \leq i \leq k-1, i \leq j \leq k-1\})$. Then calculate

$$(13) \quad \hat{y}_k^{(k+1)} = \frac{\partial}{\partial x} \hat{y}_k^{(k)}[f(x) + g(x)u] + \sum_{i=1}^k \sum_{j=i}^k \frac{\partial \hat{y}_k^{(k)}}{\partial \tilde{y}_i^{(j)}} \tilde{y}_i^{(j+1)}$$

and write it as

$$(14) \quad \begin{aligned} \hat{y}_k^{(k+1)} &= a_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leq i \leq k, i \leq j \leq k+1\}) \\ &\quad + b_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leq i \leq k, i \leq j \leq k\})u. \end{aligned}$$

Define $B_{k+1} := [\tilde{B}_k^T, b_{k+1}^T]^T$, and suppose that there exist $\tilde{y}_{i0}^{(j)}$ ($1 \leq i \leq k, i \leq j \leq k$) such that B_{k+1} has constant rank ρ_{k+1} on a neighborhood of $(x_0, \{\tilde{y}_{i0}^{(j)} \mid 1 \leq i \leq k, i \leq j \leq k\})$. Permute, if necessary, the components of $\hat{y}_k^{(k+1)}$ so that on this neighborhood the first ρ_{k+1} rows of B_{k+1} are linearly independent. Decompose $\hat{y}_k^{(k+1)}$ as

$$\hat{y}_k^{(k+1)} = (\hat{y}_{k+1}^{(k+1)T} \quad \hat{y}_{k+1}^{(k+1)T})^T,$$

where $\hat{y}_{k+1}^{(k+1)}$ consists of the first $s_{k+1} := (\rho_{k+1} - \rho_k)$ rows. Since the last rows of B_{k+1} are linearly dependent on the first ρ_{k+1} rows, we can write

$$(15) \quad \begin{aligned} \dot{\hat{y}}_1 &= \tilde{a}_1(x) + \tilde{b}_1(x)u, \\ &\vdots \\ \tilde{y}_{k+1}^{(k+1)} &= \tilde{a}_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leq i \leq k, i \leq j \leq k+1\}) \\ &\quad + \tilde{b}_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leq i \leq k, i \leq j \leq k\})u, \\ \hat{y}_{k+1}^{(k+1)} &= \hat{y}_{k+1}^{(k+1)}(x, \{\tilde{y}_i^{(j)} \mid 1 \leq i \leq k+1, i \leq j \leq k+1\}). \end{aligned}$$

Finally, set $\tilde{B}_{k+1} := [\tilde{B}_k^T, \tilde{b}_{k+1}^T]^T$.

It should be noted that the integers $\rho_1, \dots, \rho_k, \dots$, defined above, do not depend on the particular permutation of the rows of $\hat{y}_k^{(k+1)}$ we employ, cf. [5]. So, using the

algorithm we obtain a uniquely defined sequence of integers $0 \leq \rho_1 \leq \dots \leq \rho_k \leq \dots \leq m$. The integer $\rho^* := \rho_n$ is called the *rank* of the system (1), cf. [18], [5]. We associate a notion of regularity with Singh's algorithm in the following way. (See [4] for a slightly different notion of regularity.)

DEFINITION 2.4. Let a point $x_0 \in \chi$ be given. We call x_0 a *strongly regular point* for Σ if, for each application of Singh's algorithm to Σ_0 , the constant rank assumptions of the algorithm are satisfied.

Besides (A1), we also introduce the following assumption.

(A2). The system Σ_0 is invertible, i.e., $\rho^* = m$.

Consider a system Σ satisfying (A1), (A2). Then we define a Singh compensator for Σ as follows (see also [20]). Let x_0 be a strongly regular point for Σ and apply Singh's algorithm for Σ_0 . This yields at the n th step

$$(16) \quad \begin{aligned} \dot{\tilde{y}}_n &= \tilde{A}_n(x, \{\tilde{y}_i^{(j)} | 1 \leq i \leq n-1, i \leq j \leq n\}) \\ &\quad + \tilde{B}_n(x, \{\tilde{y}_i^{(j)} | 1 \leq i \leq n-1, i \leq j \leq n-1\})u, \end{aligned}$$

where $\tilde{Y}_n = (\tilde{y}_1^T, \dots, \tilde{y}_n^{(n-1)T})$ and where \tilde{B}_n is invertible on a neighborhood of $(x_0, \{\tilde{y}_{i0}^{(j)} | 1 \leq i \leq n-1, i \leq j \leq n-1\})$ for some $\tilde{y}_{i0}^{(j)} (1 \leq i \leq n, i \leq j \leq n)$. Then (16) yields on this neighborhood

$$(17) \quad u = \tilde{B}_n^{-1}[\dot{\tilde{Y}}_n - \tilde{A}_n].$$

For $i = 1, \dots, m$, let γ_i be the lowest time-derivative and δ_i be the highest time-derivative of y_i appearing in (17). Then we rewrite (17) as

$$(18) \quad \begin{aligned} u &= \phi_1(x, \{y_i^{(j)} | 1 \leq i \leq m, \gamma_i \leq j \leq \delta_i - 1\}) \\ &\quad + \sum_{i=1}^m \phi_{2i}(x, \{y_i^{(j)} | 1 \leq i \leq m, \gamma_i \leq j \leq \delta_i - 1\})y_i^{(\delta_i)} \end{aligned}$$

for certain locally analytic vector-valued functions $\phi_1, \phi_{2i} (i = 1, \dots, m)$.

Let $z_i (i = 1, \dots, m)$ be a vector of dimension $\delta_i - \gamma_i$ and consider the system

$$(19) \quad \begin{aligned} \dot{z}_i &= A_i z_i + B_i v_i (i = 1, \dots, m), \\ u &= \phi_1(x, z_1, \dots, z_m) + \sum_{i=1}^m \phi_{2i}(x, z_1, \dots, z_m)v_i, \end{aligned}$$

with inputs v_1, \dots, v_m , outputs u , (A_i, B_i) in Brunovsky canonical form, and $z_{i0} = (y_{i0}^{(\gamma_i)}, \dots, y_{i0}^{(\delta_i-1)})^T (i = 1, \dots, m)$. Then (19) is called a *Singh compensator* for Σ around x_0 . Note that the Singh compensator (19) is an inverse of the system Σ_0 around x_0 .

Remark 2.5. The Singh compensator, constructed above, has dimension $\sigma = \sum_{i=1}^m (\delta_i - \gamma_i)$. It can be shown (see [11]) that every Singh compensator has dimension σ . Moreover, the numbers $\delta_i (i = 1, \dots, m)$ are equal to the essential orders (cf. [7]) of Σ (see also [11]).

We obtain a Singh compensator with disturbance feedthrough for Σ around x_0 by extending (19) in the following way. Define in the above notation

$$(20) \quad \phi_3(x, \{y_i^{(j)} | 1 \leq i \leq m, \gamma_i \leq j \leq \delta_i - 1\}) := -\tilde{B}_n^{-1} \frac{\partial \tilde{Y}_n}{\partial x} p(x)$$

and consider the following extension of (19):

$$(21) \quad \begin{aligned} \dot{z}_i &= A_i z_i + B_i v_i (i = 1, \dots, m), \\ u &= \phi_1(x, z_1, \dots, z_m) + \sum_{i=1}^m \phi_{2i}(x, z_1, \dots, z_m)v_i + \phi_3(x, z_1, \dots, z_m)q. \end{aligned}$$

Then (21) is called a *Singh compensator with disturbance feedthrough* for Σ around x_0 . It can be shown that the Singh compensator as well as the Singh compensator with disturbance feedthrough constitute a regular dynamic state feedback (cf. [10]).

We will now state our main result. In this statement we employ the following notation. If we apply Singh's algorithm to Σ_0 , the $\hat{y}_k^{(k)} (k=0, \dots, n; \hat{y}_0 := y)$ can be viewed as functions on $\mathcal{X}_e := \mathcal{X} \times \mathbb{R}^{nm}$. By the same token, $\ker d\hat{y}_k^{(k)} (k=0, \dots, n)$ defines a distribution on \mathcal{X}_e . Define the distributions $\mathcal{G}_e, \mathcal{P}_e$ on \mathcal{X}_e by $\mathcal{G}_e := \mathcal{G} \times \{0\}, \mathcal{P}_e := \mathcal{P} \times \{0\}$.

THEOREM 2.6. *Consider the analytic system Σ . Assume that it satisfies (A1), (A2) and that x_0 is a strongly regular point for Σ .*

1. (a) *The DDDP is locally solvable around x_0 if and only if it is solvable via a Singh compensator for Σ around x_0 .*

(b) *The above condition is equivalent to the condition that for each application of Singh's algorithm to Σ_0 we have for $k=0, \dots, n-1$:*

$$(22) \quad \mathcal{P}_e \subset \ker d\hat{y}_k^{(k)}.$$

2. (a) *The DDDPdm is locally solvable around x_0 if and only if it is solvable via a Singh compensator with disturbance feedthrough for Σ around x_0 .*

(b) *the above condition is equivalent to the condition that for each application of Singh's algorithm to Σ_0 we have, for $k=0, \dots, n-1$,*

$$(23) \quad \mathcal{P}_e \subset \ker d\hat{y}_k^{(k)} + \mathcal{G}_e.$$

Proof. We will prove only part 2. The proof of part 1 is analogous.

Sufficiency. Consider Σ and assume that it satisfies (A1), (A2), and let x_0 be a strongly regular point for Σ . Assume that for each application of Singh's algorithm to Σ_0 (23) holds for $k=0, \dots, n-1$. Apply Singh's algorithm to Σ_0 around x_0 , yielding a reordering $\tilde{y}_1, \dots, \tilde{y}_n$ of the outputs. Note that, without loss of generality, we may assume that for $k=1, \dots, n$: $\hat{y}_k = (\tilde{y}_{k+1}^T, \dots, \tilde{y}_n^T)^T$. The first step of Singh's algorithm applied to Σ_0 around x_0 yields

$$(24) \quad \begin{aligned} \dot{\tilde{y}}_1 &= \tilde{a}_1(x) + \tilde{b}_1(x)u, \\ \dot{\hat{y}}_1 &= \hat{a}_1(x) + \hat{b}_1(x)u, \end{aligned}$$

where $\tilde{b}_1(x)$ has full row rank ρ_1 on a neighborhood U of x_0 in \mathcal{X} . Let $\tilde{b}_1^+(x)$ be a right inverse of $\tilde{b}_1(x)$ on U . Then on U , \hat{y}_1 takes the form

$$(25) \quad \hat{y}_1 = \hat{a}_1(x) + \hat{b}_1(x)\hat{b}_1^+(x)(\dot{\tilde{y}}_1 - \tilde{a}_1(x)).$$

Note that, since on U each of the rows of $\hat{b}_1(x)$ is linearly dependent on the rows of $\tilde{b}_1(x)$, the form of \hat{y}_1 is independent of the choice of $\tilde{b}_1^+(x)$. For Σ we have

$$(26) \quad \begin{aligned} \dot{\tilde{y}}_1 &= \frac{\partial \tilde{y}_1}{\partial x} [f(x) + g(x)u + p(x)q] =: \tilde{a}_1(x) + \tilde{b}_1(x)u + \tilde{c}_1(x)q, \\ \dot{\hat{y}}_1 &= \frac{\partial \hat{y}_1}{\partial x} [f(x) + g(x)u + p(x)q] =: \hat{a}_1(x) + \hat{b}_1(x)u + \hat{c}_1(x)q, \end{aligned}$$

with $\tilde{a}_1(x), \tilde{b}_1(x), \hat{a}_1(x), \hat{b}_1(x)$ as in (24). It can easily be checked that the fact that (23) holds for $k=0$ is equivalent to the existence of a $\sigma_1(x)$ such that

$$(27) \quad \tilde{b}_1(x)\sigma_1(x) = \tilde{c}_1(x), \hat{b}_1(x)\sigma_1(x) = \hat{c}_1(x).$$

Then (26) and (27) yield

$$(28) \quad \dot{\hat{y}}_1 = \hat{a}_1(x) + \hat{b}_1(x)\tilde{b}_1^+(x)(\dot{\tilde{y}}_1 - \tilde{a}_1(x)).$$

Hence for Σ , \hat{y}_1 is given by the same expression as for Σ_0 . Applying the above arguments repeatedly, we can show that for Σ $\hat{y}_k^{(k)}$ ($k=1, \dots, n$) has the same form as for Σ_0 , and that for Σ , \hat{Y}_n takes the form (see also (16))

$$(29) \quad \dot{\hat{Y}}_n = \tilde{A}_n \hat{Y}_n + \tilde{B}_n u + \frac{\partial \hat{Y}_n}{\partial x} p(x) q.$$

This implies that if we apply the Singh compensator with disturbance feedthrough to Σ , the outputs of the resulting system satisfy

$$(30) \quad \begin{aligned} \frac{\partial y_i^{(j)}}{\partial q} &= 0 \quad (1 \leq i \leq m, 0 \leq j \leq \delta_i - 1), \\ y_i^{(\delta_i)} &= v_i. \end{aligned}$$

Hence the Singh compensator with disturbance feedthrough locally solves the DDDPdm for Σ around x_0 .

Necessity. Assume that the DDDPdm is locally solvable around x_0 by means of a compensator Q of the form (6). Apply Singh's algorithm to Σ_0 around x_0 , yielding a reordering $\tilde{y}_1, \dots, \tilde{y}_n$ of the outputs. Then with the notation of the necessity part of this proof, we have in particular for Σ

$$(31) \quad \begin{aligned} \dot{\hat{y}}_1 &= \tilde{a}_1(x) + \tilde{b}_1(x)u + \tilde{c}_1(x)q, \\ \dot{\hat{y}}_1 &= \hat{a}_1(x) + \hat{b}_1(x)\tilde{b}_1^+(x)(\dot{\hat{y}}_1 - \tilde{a}_1(x)) + (\hat{c}_1(x) - \hat{b}_1(x)\tilde{b}_1^+(x)\tilde{c}_1(x))q. \end{aligned}$$

Assume that (23) does not hold for $k=0$. This implies that $d_1(x) := \hat{c}_1(x) - \hat{b}_1(x)\tilde{b}_1^+(x)\tilde{c}_1(x) \neq 0$. Since Q solves the DDDPdm for Σ , the q -dependence in (31) should disappear if we plug the output of Q in (31). From the form of (31), it is clear that this is only possible if Q imposes the constraint $d_1(x)=0$ on the system $\Sigma \circ Q$. However, this would imply that the DDDPdm is at most solvable on a neighborhood of x_0 in $\{x \mid d_1(x)=0\}$ and not on a neighborhood of x_0 in \mathcal{X} . Hence we must necessarily have that (23) holds for $k=0$. Next assume that (23) does not hold for $k=1$. Then by the same arguments as above we will have for Σ that $\hat{y}_2^{(2)}$ explicitly depends on q via a function $d_2(x, \hat{y}_1)$ and that this q -dependence can only disappear if Q imposes the constraint $d_2(x, \hat{y}_1)=0$ on the system. However, by Lemma 1 of [14], this would imply that the rank of $\Sigma \circ Q$ is smaller than the rank of Σ , which would contradict the invertibility of Q . Therefore (23) must hold for $k=1$. Applying this argument repeatedly, we show that (23) holds for $k=0, \dots, n-1$, which establishes our claim. By the sufficiency part of this proof, this also immediately implies that we can solve the DDDPdm around x_0 via a Singh compensator with disturbance feedthrough. \square

Example 2.2 (continued). The Singh compensator

$$(32) \quad \begin{aligned} \dot{z} &= v_1, \\ u_1 &= \frac{z}{x_2}, \\ u_2 &= \frac{x_5(x_4 z - x_2)}{x_2 + z} - \frac{x_4}{x_2 + z} v_1 + \frac{x_2}{x_2 + z} v_2, \end{aligned}$$

solves the DDDP for system (7) of the earlier part of Example 2.2.

Remark 2.7. It is easily seen that if the input-output decoupling problem for Σ is locally solvable by means of a static state feedback, then the DDDPdm is locally

solvable if and only if the DDDPdm is. This implies in particular that if the output of Σ is one-dimensional, then the DDDPdm is locally solvable if and only if the DDPdm is.

3. Algebraic conditions. In this section we translate the conditions for solvability of the DDDPdm and the DDDP obtained in § 2 into intrinsic and algorithm-independent conditions. It will turn out that the conditions can be stated in terms of a certain structure at infinity.

For nonlinear systems there are several different definitions of the structure at infinity; see, e.g., [17], [14]. We call the structure at infinity that was defined in [17] the *geometric* structure at infinity. This structure at infinity has proved its importance in, e.g., the solution of the static state feedback input-output decoupling problem (cf. [17]) and in obtaining (sufficient) conditions for solvability of the nonlinear model matching problem (cf. [6]). Here we will use the algebraic definition of [14], which in general yields a different structure at infinity than the geometric one. This structure at infinity has already proved its importance in the dynamic state feedback input-output decoupling problem and in obtaining sufficient conditions for solvability of the nonlinear model matching problem (cf. [16]) that are weaker than the conditions obtained in [6]. To repeat this algebraic definition, we consider Singh's algorithm as described in § 2 and define the following integers:

$$(33) \quad \begin{aligned} \pi_1 &:= \rho^*, \\ \pi_k &:= \rho^* - \rho_{k-1}, \quad k \geq 2, \end{aligned}$$

$$\nu_i := \text{the number of } \pi_k \text{'s that are greater than or equal to } i, \quad i \geq 1.$$

DEFINITION 3.1 (see [14]). The *algebraic* structure at infinity of the system Σ_0 consists of the set $\{\nu_i\}$ of orders of the zeros at infinity, together with the set $\{\pi_k\}$ of numbers of zeros at infinity whose order is greater than or equal to k .

Essentially, the sets $\{\nu_i\}$, $\{\pi_k\}$, and $\{\rho_k\}$ contain the same information about the algebraic structure at infinity. In the following, we restrict ourselves to considering the set $\{\rho_k\}$.

Let Σ_q denote the system Σ where the disturbances are considered to be an extra set of inputs. For Σ_0 and Σ_q , the sets defining their algebraic structure at infinity are denoted by $\{\rho_{0k}\}$, $\{\rho_{qk}\}$, respectively.

THEOREM 3.2. Consider the analytic system Σ and assume that it satisfies (A1), (A2). Let x_0 be a strongly regular point for Σ . Then the DDDPdm is locally solvable around x_0 if and only if Σ_q and Σ_0 have the same algebraic structure at infinity.

Proof. Consider the first step of Singh's algorithm applied to Σ_0 and Σ_q around x_0 and employ the notation of the sufficiency part of the proof of Theorem 2.6. As was shown in this proof, condition (23) is satisfied for $k=0$ if and only if there exists a $\sigma_1(x)$ such that (27) holds. Hence the fact that (23) holds for $k=0$ is equivalent to

$$(34) \quad \rho_{q1} = \text{rank} \begin{pmatrix} \tilde{b}_1 & \tilde{c}_1 \\ \hat{b}_1 & \hat{c}_1 \end{pmatrix} = \text{rank} \begin{pmatrix} \tilde{b}_1 & \tilde{b}_1 \sigma_1 \\ \hat{b}_1 & \hat{b}_1 \sigma_1 \end{pmatrix} = \text{rank} \begin{pmatrix} \tilde{b}_1 \\ \hat{b}_1 \end{pmatrix} = \rho_{01}.$$

Applying the above arguments repeatedly, we show that (23) holds for $k=0, \dots, n-1$ if and only if $\rho_{qk} = \rho_{0k}$ for $k=1, \dots, n$, which establishes our claim. \square

Remark 3.3. Recall that for linear systems the geometric and algebraic structure at infinity are the same (cf. [14]). Moreover, recall from, e.g., [22] that for linear systems the DDPdm is solvable if and only if Σ_0 and Σ_q have the same structure at infinity.

We will now use the result of Theorem 3.2 to give conditions for the local solvability of the DDDP for Σ , using an idea from [22]. To do this we introduce an auxiliary system Σ_a , which is defined as

$$(35) \quad \Sigma_a \begin{cases} \dot{x} = f(x) + g(x)w + p(x)q \\ \dot{w} = v \\ y = h(x), \end{cases}$$

where v denotes the inputs of Σ_a . Let Σ_{a0} denote the system Σ_a with $q \equiv 0$ and let Σ_{aq} denote the system Σ_a where the disturbances are considered to be an extra set of inputs.

THEOREM 3.4. *Consider the analytic system Σ and assume that it satisfies (A1), (A2). Let x_0 be a strongly regular point for Σ . Then the DDDP is locally solvable around x_0 if and only if Σ_{aq} and Σ_{a0} have the same algebraic structure at infinity.*

Proof. Necessity. Assume that the DDDP is locally solvable around x_0 by means of a compensator

$$(36) \quad R \begin{cases} \dot{z} = \alpha(x, z) + \beta(x, z)\tilde{u} \\ u = \gamma(x, z) + \delta(x, z)\tilde{u}. \end{cases}$$

Consider the following compensator for Σ_a :

$$(37) \quad R_a \begin{cases} \dot{z}_1 = \alpha(x, z_1) + \beta(x, z_1)z_2 \\ \dot{z}_2 = \hat{u} \\ v = \sigma(x, w, z_1, z_2, q), \end{cases}$$

with

$$\begin{aligned} \sigma(x, w, z_1, z_2, q) = & \left[\frac{\partial \gamma}{\partial x}(x, z_1) + \frac{\partial \delta}{\partial x}(x, z_1)z_2 \right] [f(x) + g(x)w + p(x)q] \\ & + \left[\frac{\partial \gamma}{\partial z_1}(x, z_1) + \frac{\partial \delta}{\partial z_1}(x, z_1)z_2 \right] [\alpha(x, z_1) + \beta(x, z_1)z_2] + \delta(x, z_1)\hat{u} \end{aligned}$$

and \hat{u} denoting the new inputs. Then we find that

$$w = \int v \, dt = \gamma(x, z_1) + \delta(x, z_1)z_2,$$

and thus R_a locally solves the DDDPdm for Σ_a , since R solves the DDDP for Σ . Furthermore, we have as an (almost) immediate consequence of the fact that R is invertible, that R_a is also invertible. Thus, the DDDPdm is locally solvable for Σ_a and hence by Theorem 3.2, Σ_{aq} and Σ_{a0} have the same algebraic structure at infinity.

Sufficiency. Assume that Σ_{aq} and Σ_{a0} have the same algebraic structure at infinity; i.e., the DDDPdm is locally solvable for Σ_a , say, by means of a compensator

$$(38) \quad Q_a \begin{cases} \dot{z} = \alpha(x, w, z, q) + \beta(x, w, z, q)s \\ v = \gamma(x, w, z, q) + \delta(x, w, z, q)s, \end{cases}$$

with s denoting the new inputs. Then it is obvious that the compensator

$$(39) \quad Q \begin{cases} \dot{z}_1 = \gamma(x, z_1, z_2, q) + \delta(x, z_1, z_2, q)s \\ \dot{z}_2 = \alpha(x, z_1, z_2, q) + \beta(x, z_1, z_2, q)s \\ u = z_1 \end{cases}$$

locally solves the DDDPdm for Σ . Now apply Singh's algorithm to Σ_0 , yielding a reordering $\tilde{y}_1, \dots, \tilde{y}_n$ of the outputs. Employ the notation of the proof of Theorem 2.6. Then for Σ we have in particular that

$$(40) \quad \begin{aligned} \dot{\tilde{y}}_1 &= \tilde{a}_1(x) + \tilde{b}_1(x)u + \tilde{c}_1(x)q, \\ \dot{\hat{y}}_1 &= \hat{a}_1(x) + \hat{b}_1(x)u + \hat{c}_1(x)q. \end{aligned}$$

Since Q locally solves the DDDPdm for Σ , the q -dependence in (40) must have vanished if we put u in (40) equal to the output of Q . This implies that actually $\tilde{c}_1 \equiv 0$, $\hat{c}_1 \equiv 0$, since the output of Q does not depend on q . It can be checked that this implies that (22) holds for $k=0$. Applying the above arguments repeatedly, we can show that (22) holds for $k=0, \dots, n-1$. By Theorem 2.6 this implies that the DDDP is solvable around x_0 . \square

Remark 3.5. At this point it is useful to compare our (algebraic) results on the DDDP with the results of [16] on the so-called nonlinear model matching problem (MMP). In fact, as was already shown in [6], the nonlinear MMP can be related to some kind of DDPdm. However, in contrast with the situation we consider in this paper, it turns out that the corresponding state feedback solving this DDPdm need *not* be regular. Clearly, the existence of a regular solution is, of course, a sufficient condition for solvability of the nonlinear MMP. Hence by Theorem 3.2 the coincidence of certain algebraic structures at infinity is a sufficient condition for solvability of the nonlinear MMP. This is exactly the result of [16]. As the equality of the algebraic structures at infinity is only a sufficient condition for the solvability of the MMP, and *not* a necessary condition (see [16] for a counterexample), it is clear that our solution of the DDDPdm by means of *regular* dynamic state feedback cannot be cast in the results described in the aforementioned paper.

4. Geometric conditions. In this section we give intrinsic geometric conditions for local solvability of the DDDP and the DDDPdm by translating the results of § 3. We mainly restrict our attention to the DDDP. The reasoning for the DDDPdm follows the same lines.

Consider again system Σ and assume that it satisfies (A1), (A2). Let x_0 be a strongly regular point for Σ . Furthermore, assume that the DDDP for Σ is locally solvable around x_0 . Then according to Theorem 2.6 the DDDP is locally solvable by applying a Singh compensator. This compensator applied to Σ yields $y_i^{(\delta_i)} = v_i$, $i=1, \dots, m$. Obviously, the decoupling matrix (see [12], [18]) is equal to the $m \times m$ identity matrix. Hence the decoupling matrix of the composite system is of full rank. Then it is well known that the maximal locally controlled invariant distribution in $\ker dh$ for the composite system, denoted by Δ_e^* , is given by

$$(41) \quad \Delta_e^* = \bigcap_{i=1}^m \bigcap_{k=0}^{\delta_i-1} \ker dy_i^{(k)}.$$

Obviously, Δ_e^* depends on the choice of the $\tilde{y}_k^{(k)}$'s in Singh's algorithm, so Δ_e^* is by no means uniquely defined. However, the solvability of the DDDP does not depend on the way in which Singh's algorithm is performed (see Theorem 2.6). Hence, for any distribution Δ of the form (41) generated by applying Singh's algorithm to Σ_0 , we have $\mathcal{P} \times \{0\} \subset \Delta$. Consequently, the distribution $\mathcal{P} \times \{0\}$ spanned by the extended disturbance vector fields is always contained in Δ_e^* . Note that by construction Δ_e^* is contained in $T\mathcal{X} \times \{0\} \subset T\mathcal{X} \times T\mathcal{Z}$ (with abuse of notation). However, the vector fields that span Δ_e^* may very well depend on z . Since the disturbance vector fields p only depend on

x , they are contained in the (not necessarily controlled invariant) maximal subdistribution $\tilde{\Delta}_e^*$ of Δ_e^* that contains the vector fields in Δ_e^* that only depend on x . This distribution $\tilde{\Delta}_e^*$ can be found by means of the following algorithm.

ALGORITHM 4.1.

Step 1.

$$\Delta_0 := \Delta_e^*.$$

Step k .

$$\Delta_k := \left\{ \tau \in \Delta_{k-1} \left| \left[\tau, \frac{\partial}{\partial z} \right] \in \Delta_{k-1} + \text{span} \left\{ \frac{\partial}{\partial z} \right\} \right. \right\}.$$

Here $[\tau, \partial/\partial z]$ is shorthand notation for the Lie-brackets $[\tau, \partial/\partial z_i]$ for $i = 1, \dots, \sigma$.

LEMMA 4.2. Assume that the distributions Δ_k obtained in Algorithm 4.1 have constant dimension. Then for all k , $\dim \Delta_k \leq \dim \Delta_{k-1}$ and if $\Delta_{k^*} = \Delta_{k^*-1}$, then $\Delta_k = \Delta_{k^*}$ for all $k \geq k^*$.

Proof. See [12].

Assume now that Algorithm 4.1 converges to Δ_{k^*} . Then Δ_{k^*} fulfills the condition

$$(42) \quad \left[\Delta_{k^*}, \frac{\partial}{\partial z} \right] \subset \Delta_{k^*} + \text{span} \left\{ \frac{\partial}{\partial z} \right\}.$$

As can be seen in [21], it follows from (42) that the first n components of any vector field in Δ_{k^*} do not depend on z , and since $\Delta_{k^*} \subset \Delta_e^*$ (so the last σ components of vector fields in Δ_{k^*} equal zero) the vector fields in Δ_{k^*} do not depend on z at all. Moreover, by construction, Δ_{k^*} is the largest subdistribution of Δ_e^* having this property. Hence $\Delta_{k^*} = \tilde{\Delta}_e^*$.

LEMMA 4.3. $\tilde{\Delta}_e^*$ obtained in the way described above is independent of the way we apply Singh's algorithm.

Proof. Assume we have applied Singh's algorithm in two different ways, yielding Δ_{e1}^* and Δ_{e2}^* . Assume furthermore that by applying Algorithm 4.1 to these two distributions we obtain the distributions $\tilde{\Delta}_{e1}^*$ and $\tilde{\Delta}_{e2}^*$ with $\tilde{\Delta}_{e1}^* \neq \tilde{\Delta}_{e2}^*$. This implies that there are disturbance vector fields for which the DDDP is solvable by applying Singh's algorithm in one way, but not solvable by applying Singh's algorithm in the other way. This contradicts Theorem 2.6. Hence $\tilde{\Delta}_{e1}^*$ equals $\tilde{\Delta}_{e2}^*$. \square

Let $\tilde{\Delta}^*$ be defined as the projection of the distribution $\tilde{\Delta}_e^*$ on the $T\mathcal{X}$ -space. Note that, since (42) holds, $\tilde{\Delta}^*$ is a well-defined distribution on \mathcal{X} (cf. [21]). Then $\tilde{\Delta}^*$ contains all possible vector fields that can be decoupled from the outputs by dynamic state feedback.

For the DDDPdm the reasoning is slightly different, although it follows the same lines. Here, we apply Algorithm 4.1 starting from the (not necessarily involutive) distribution $\Delta_0 = \Delta_{e\mathcal{G}}^* := \Delta_e^* + \mathcal{G} \times \{0\}$, resulting in the distribution $\tilde{\Delta}_{e\mathcal{G}}^* := \Delta_{k^*}$. Analogously to Lemma 4.3, it is then possible to prove Lemma 4.4.

LEMMA 4.4. $\tilde{\Delta}_{e\mathcal{G}}^*$ obtained in the way described above is independent of the way we apply Singh's algorithm.

Now let $\tilde{\Delta}_{\mathcal{G}}^*$ be defined as the projection of the distribution $\tilde{\Delta}_{e\mathcal{G}}^*$ on the $T\mathcal{X}$ -space. Again, this is a well-defined distribution on \mathcal{X} (cf. [21]). It is easy to see that $\tilde{\Delta}_{\mathcal{G}}^*$ contains all possible vector fields that can be decoupled from the outputs by dynamic state feedback with disturbance measurements. Note that in particular $\mathcal{G} \subset \tilde{\Delta}_{\mathcal{G}}^*$. Summarizing, we have the following theorem.

THEOREM 4.5. *Consider the system Σ and assume that it satisfies (A1), (A2). Let x_0 be a strongly regular point for Σ . Then*

1. *The DDDPdm is locally solvable around x_0 if and only if*

$$(43) \quad \mathcal{P} \subset \tilde{\Delta}_{\mathcal{G}}^*.$$

2. *The DDDP is locally solvable around x_0 if and only if*

$$(44) \quad \mathcal{P} \subset \tilde{\Delta}^*.$$

In the theorem above, we have given geometric conditions under which the DDDPdm is locally solvable. Now, of course, the question arises as to when the problem is solvable by means of a static state feedback. For this we will have to calculate Δ^* , the maximal locally controlled invariant distribution for Σ contained in $\ker dh$. Obviously, Δ^* is contained in $\tilde{\Delta}^*$, because Δ^* consists of the set of disturbance vector fields that can be decoupled by static state feedback. Observing that also $\tilde{\Delta}^*$ is contained in $\ker dh$, it is easily seen that Δ^* is the maximally locally controlled invariant distribution contained in $\tilde{\Delta}^*$. Hence Δ^* can be calculated by applying the Controlled Invariant Distribution Algorithm (cf. [12]) starting from $\tilde{\Delta}^*$.

Remark 4.6. Note that if the dimension of Δ^* equals the dimension of the zero dynamics manifold, then the DDDP is solvable if and only if the DDP is solvable.

Theorem 4.5 applied to the example of § 2 yields the following result.

Example 4.7. Consider again the system of Example 2.2. Choose $\tilde{y}_1 = y_1$. Then

$$(45) \quad \Delta_e^* = \text{span} \left\{ \frac{\partial}{\partial x_5}, x_2(x_2 + z) \frac{\partial}{\partial x_2} - (x_2^2 - x_4 z) \frac{\partial}{\partial x_4} \right\}$$

and

$$(46) \quad \tilde{\Delta}^* = \text{span} \left\{ \frac{\partial}{\partial x_5} \right\}.$$

5. Example. Consider the voltage frequency controlled induction motor that was described in [3]. As state variables we take the projections of the stator current and flux vectors on a reference frame (α, β) , which is fixed to the stator windings, and the angular position of the voltage input vector. As inputs we take the amplitude of the voltage input vector and the voltage supply frequency. The parameters R_s and R_r are the stator and rotor resistances, L_s and L_r are the stator and rotor self-inductances, and M is the mutual inductance. The speed ω can be considered as a slowly varying parameter, due to the large separation of timescales between the mechanical and the electromagnetic dynamics. In the following, we will assume it to be constant.

We define $\bar{x} = (x_1, \dots, x_4)$ and $x = (\bar{x}, x_5)$, and we assume that a one-dimensional disturbance q influences the dynamics through the disturbance vector field $p(x) = (x_3 \ x_4 \ 0 \ 0 \ 0)^T$. Then the state equations are written as

$$(47) \quad \dot{x} = \begin{pmatrix} A\bar{x} \\ 0 \end{pmatrix} + \begin{pmatrix} g_1(x_5) & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + p(x)q,$$

where

$$(48) \quad A = \begin{pmatrix} -(\alpha + \beta) & -\omega & \beta/L_s & \omega/\sigma L_s \\ \omega & -(\alpha + \beta) & -\omega/\sigma L_s & \beta/L_s \\ -\alpha\sigma L_s & 0 & 0 & 0 \\ 0 & -\alpha\sigma L_s & 0 & 0 \end{pmatrix}, \quad g_1(x_5) = \begin{pmatrix} \cos x_5/\sigma L_s \\ \sin x_5/\sigma L_s \\ \cos x_5 \\ \sin x_5 \end{pmatrix},$$

and $\alpha = R_s/\sigma L_s$, $\beta = R_r/\sigma L_r$, $\sigma = 1 - (M^2/L_s L_r)$.

Suitable outputs for the system are defined in terms of the stator flux and the torque. Hence, the following nonlinear output functions will be used:

$$(49) \quad \begin{aligned} h_1(x) &= \Phi_s^2 = x_3^2 + x_4^2, \\ h_2(x) &= T_m = x_2x_3 - x_1x_4. \end{aligned}$$

Applying the Controlled Invariant Distribution Algorithm (cf. [12]), using REDUCE, we find that $\Delta^* = \{0\}$. Hence neither DDPm nor DDP is solvable for (47), (49). However, by applying Singh's algorithm to (47), (49), we find that we can solve the DDDPm by applying the following Singh compensator with disturbance feedthrough:

$$(50) \quad \begin{aligned} \dot{z} &= v_1, \\ u_1 &= \phi_1(x, z), \\ u_2 &= \phi_2(x, z, q, v_1, v_2), \end{aligned}$$

where

$$(51) \quad \phi_1(x, z) = \frac{2\alpha\sigma L_s(x_1x_3 + x_2x_4) + z}{2(x_3 \cos x_5 + x_4 \sin x_5)},$$

and where $\phi_2(x, z, q, v_1, v_2)$ can be calculated from

$$(52) \quad \begin{aligned} \phi_2(x, z, q, v_1, v_2) &= \frac{1}{\mathcal{L}_{g_2}\mathcal{L}_f y_2 + \phi_1 \mathcal{L}_{g_2}\mathcal{L}_{g_1} y_2} \left[v_2 - \frac{\partial \phi_1}{\partial z} \mathcal{L}_{g_1} y_2 \cdot v_1 \right. \\ &\quad - (\mathcal{L}_{f+\phi_1 g_1} \mathcal{L}_f y_2 + \mathcal{L}_{g_1} y_2 \mathcal{L}_{f+\phi_1 g_1} \phi_1 + \phi_1 \mathcal{L}_{f+\phi_1 g_1} \mathcal{L}_{g_1} y_2) \\ &\quad \left. - q(\mathcal{L}_p \mathcal{L}_f y_2 + \mathcal{L}_{g_1} y_2 \mathcal{L}_p \phi_1 + \phi_1 \mathcal{L}_p \mathcal{L}_{g_1} y_2) \right]. \end{aligned}$$

6. Conclusions. In this paper we have introduced the dynamic disturbance decoupling problem (DDDP) for nonlinear systems, and a local solution is obtained in the case where the system under consideration is invertible. The solution is given in both an algebraic and a (differential) geometric way. This clearly exhibits that the DDDP forms a proper extension of the standard (static) DDP (cf. [13]). As stated our solution is obtained for invertible (square) nonlinear systems. An extension of the results in this paper to nonsquare, noninvertible systems can be found in [10].

Acknowledgments. The authors would like to thank A. J. van der Schaft for some very useful discussions and suggestions. The second author gratefully acknowledges some very useful preliminary discussions with Prof. U. Kotta on the topic of this paper. Finally, we have learned that very recently W. Respondek (Warsaw) has obtained similar results on the DDDP using a different type of dynamic compensator than ours.

A NONREGULAR SOLUTION OF THE NONLINEAR DYNAMIC DISTURBANCE DECOUPLING PROBLEM WITH AN APPLICATION TO A COMPLETE SOLUTION OF THE NONLINEAR MODEL MATCHING PROBLEM*

H. J. C. HUIJBERTS†

Abstract. The nonregular dynamic disturbance decoupling problem for nonlinear control systems is introduced. A local solution is given by means of a constructive algorithm that is based on Singh's algorithm and the clamped dynamics algorithm. Further studied is the nonlinear model matching problem that is defined as follows: given a nonlinear control system, to be referred to as the plant, and another nonlinear control system, to be referred to as the model, can a compensator for the plant be found in such a way that the input-output behavior of the compensated plant matches that of the model? By proving that the solvability of the nonlinear model matching problem is equivalent to the solvability of an associated nonregular dynamic disturbance decoupling problem, a complete local solution of this problem can be established.

AMS(MOS) subject classifications. 93C10, 93B50, 93C35

1. Introduction. Consider a nonlinear multi-input multi-output control system with disturbances, of the form

$$(1) \quad \begin{aligned} \dot{x} &= f(x) + g(x)u + p(x)q, \\ y &= h(x), \end{aligned}$$

where $x \in \mathcal{X}$, an open subset of \mathbb{R}^n , the inputs $u \in \mathbb{R}^m$, the outputs $y \in \mathbb{R}^p$, the disturbances $q \in \mathbb{R}^r$, f and h are vector-valued analytic functions, and g and p are matrix-valued analytic functions, all of appropriate dimensions. In the disturbance decoupling problem (DDP) for the system (1) we search for a regular static state feedback

$$(2) \quad u = \alpha(x) + \beta(x)v,$$

with v a new m -dimensional control and $\beta(x)$ a nonsingular $m \times m$ matrix for all x , so that in the feedback-modified dynamics

$$(3) \quad \dot{x} = f(x) + g(x)\alpha(x) + g(x)\beta(x)v + p(x)q$$

the disturbances q do not affect the outputs y . A local solution of the DDP using differential geometric tools was initiated in [21] and [14] and has led to a more or less complete understanding of this problem; see, e.g., [20], [33]. The nonlinear DDP forms a direct generalization of the linear DDP and the theory about the nonlinear DDP typically extends the well-known linear geometric theory (see [36]) to a nonlinear context.

The purpose of this paper is to study, as in [17], a dynamic version of the DDP for the nonlinear system (1). That is, instead of a static feedback law (2) we allow for a dynamic state feedback

$$(4) \quad \begin{aligned} \dot{z} &= \alpha(x, z) + \beta(x, z)v, \\ u &= \gamma(x, z) + \delta(x, z)v, \end{aligned}$$

with z the μ -dimensional compensator state, and v an m -dimensional new control. In the dynamic version of the dynamic disturbance decoupling problem we require that in the modified dynamics

$$(5) \quad \begin{aligned} \dot{x} &= f(x) + g(x)\gamma(x, z) + g(x)\delta(x, z)v + p(x)q, \\ \dot{z} &= \alpha(x, z) + \beta(x, z)v \end{aligned}$$

the disturbances q do not influence the outputs y . In [17] a *regular* version of this problem was studied, where regularity means that we demand the system (4) with inputs v and outputs u to be invertible for all x . We refer to this problem as the dynamic disturbance decoupling problem (DDDP). In this paper we solve a version of the DDDP where we drop the requirement of regularity of the compensator (4). This problem will be referred to as the nonregular dynamic disturbance decoupling problem (nDDDP). The reason for studying this problem is that if the DDDP is not solvable, we may still be able to solve the nDDDP, albeit at the expense of some of the effective controls. The solution is given by means of an algorithm based on the clamped dynamics algorithm (cf. [22], [35]) and Singh's algorithm (cf. [34], [9]). Basically, the method used in this paper to solve the nDDDP is an extension of the method given in [17] to solve the DDDP. Here the basic tool was Singh's algorithm. One special feature of the algorithm is that it is constructive. A drawback is that it does not give a compensator of minimal order. Therefore we cannot make any statement about the solvability of the nonregular disturbance decoupling problem by means of static state feedback.

The solution of the nDDDP presented in this paper also turns out to be of use for solving another synthesis problem: the nonlinear model matching problem (MMP). This problem can be formulated as follows: Given an affine nonlinear control system, to be referred to as the plant P , and another affine nonlinear control system, to be referred to as the model M , can we find a compensator for P such that the input-output behavior of the precompensated plant matches that of M ?

For linear systems this problem is completely solved (see, e.g., [11], [27], [30]–[32]). For nonlinear systems until now only partial solutions have appeared (see, e.g., [6], [7], [10], [15], [18], [19], [29]). It will be shown in this paper that the nonlinear MMP can be formulated as an nDDDP with disturbance measurements. This observation was already made for linear systems in [32], [11]. In [10] sufficient conditions for solvability of the nonlinear MMP were given by solving an associated DDP with disturbance measurements by means of regular static state feedback. Furthermore, the sufficient conditions for solvability of the nonlinear MMP that were given in [29] can be viewed as following from the solution of an associated DDDP with disturbance measurements by means of regular dynamic state feedback as was also studied in [17]. It is important to note that the partial solutions to the MMP mentioned above are all given in terms of structural invariants of the system under consideration, whereas the complete solution given in this paper is in terms of an algorithm.

The paper is organized as follows. In § 2 we give the clamped dynamics algorithm. This algorithm allows us to determine the clamped dynamics of a nonlinear control system, i.e., the internal dynamics that are compatible with the constraint that the output is zero for all times. Furthermore, we give an important proposition that gives a connection between the clamped dynamics of a nonlinear control system and the clamped dynamics of the same system precompensated by a dynamic state feedback. In § 3 we introduce the nonregular dynamic disturbance decoupling problem with disturbance measurements (nDDDPdm) and the nDDDP, and we present an algorithm for solving both problems. In § 4 we formulate the nonlinear MMP and give a complete

local solution to this problem by associating an nDDDPdm with it. In § 5, finally, some conclusions will be drawn.

2. The clamped dynamics algorithm. In this section we introduce the notion of *clamped dynamics* and an algorithm to compute these, following [35]. Consider a nonlinear control system of the form

$$(6) \quad \begin{aligned} \dot{x} &= f(x) + g(x)u, \\ y &= h(x), \end{aligned}$$

where $x \in \mathcal{X}$, an open subset of \mathbb{R}^n , the inputs $u \in \mathbb{R}^m$, the outputs $y \in \mathbb{R}^p$, f and h are vector-valued analytic functions, and g is a matrix-valued analytic function, all of appropriate dimensions. The *clamped dynamics* of (6) are defined as the internal dynamics of (6) that are compatible with the constraint that the output is zero for all times. The notion of clamped dynamics was first identified, in the single-input single-output case, in [4], [28] (note, however, that in these references the notion was called zero dynamics). For the multi-input multi-output case it was further elaborated in [5], [22], [35]. In [22], a general algorithm to calculate the clamped dynamics was proposed. This algorithm was based on a modified version of Hirschorn's structure algorithm (see [13]). A different (but equivalent) algorithm was proposed in [35] and is based upon a modified version of Krener's algorithm (see [25]). In this paper we follow [35].

DEFINITION 2.1. A submanifold $N \subset \mathcal{X}$ is *controlled invariant* for (6) if there exists an analytic feedback $u = \alpha(x)$ such that the vector field $f(x) + g(x)\alpha(x)$ is tangent to N .

Remark 2.2. If $\dim(TN + \mathcal{G}) = \text{constant}$, where \mathcal{G} is the distribution spanned by the columns of g , this definition is equivalent to the following characterization: N is controlled invariant if for any $x_0 \in N$ there exists an admissible control $\bar{u}(t)$ such that the solution of $\dot{x}(t) = f(x) + g(x)\bar{u}(t)$, $x(0) = x_0$ remains in N (see [33]).

DEFINITION 2.3. $N \subset \mathcal{X}$ is an *output-nulling* controlled invariant submanifold for (6) if there exists a feedback $u = \alpha(x)$, such that $f(x) + g(x)\alpha(x)$ is tangent to N and $h(x)$ is zero on N .

To determine the dynamics compatible with the constraints $y(t) = 0$ for all t , we need to compute the maximal output-nulling controlled invariant submanifold, provided it exists. This can be done by means of the following algorithm that is based on the algorithm from [35].

ALGORITHM 2.4. Clamped dynamics algorithm. Consider the system (6). Let $x_0 \in \mathcal{X}$ be such that $h(x_0) = 0$ and assume that $h = (h_1, \dots, h_p)$ has constant rank p in a neighborhood of x_0 in $h^{-1}(x_0)$.

- Step 0

Locally around x_0 the set $N_0 = h^{-1}(0)$ is an $(n - p_0)$ -dimensional submanifold, where $p_0 := p$. Denote $\phi_0 := h$.

- Step k

Let N_{k-1} be a smooth $(n - p_{k-1})$ -dimensional manifold through x_0 , given as $N_{k-1} = \{x \mid \phi_{k-1}(x) = 0\}$. Calculate

$$(7) \quad \dot{\phi}_{k-1} = \frac{\partial \phi_{k-1}}{\partial x} [f(x) + g(x)u] =: A_k(x) + B_k(x)u.$$

Assume that $B_k(x)$ has constant rank r_k in a neighborhood of x_0 in N_{k-1} . After a possible permutation of the entries of ϕ_{k-1} we may assume that the first r_k

rows of B_k are linearly independent. Accordingly, we write (7) as

$$(8) \quad \begin{pmatrix} \dot{\phi}_{\bar{k}} \\ \dot{\phi}_{\bar{\ell}} \end{pmatrix} = \begin{pmatrix} \tilde{A}_k(x) + \tilde{B}_k(x)u \\ \hat{A}_k(x) + \hat{B}_k(x)u \end{pmatrix},$$

where $\tilde{B}_k(x)$ has full row rank r_k in a neighborhood of x_0 in N_{k-1} . Let $\tilde{B}_k^+(x)$ be a right inverse of $\tilde{B}_k(x)$. Letting $u = -\tilde{B}_k^+(x)\tilde{A}_k(x)$, we find from (8) that

$$(9) \quad \begin{pmatrix} \dot{\phi}_{\bar{k}} \\ \dot{\phi}_{\bar{\ell}} \end{pmatrix} = \begin{pmatrix} 0 \\ \hat{A}_k(x) - \hat{B}_k(x)\tilde{B}_k^+(x)\tilde{A}_k(x) \end{pmatrix} = \begin{pmatrix} 0 \\ \bar{\phi}_k(x) \end{pmatrix}.$$

Note that, since each row of $\hat{B}_k(x)$ is linearly dependent on the rows of $\tilde{B}_k(x)$, $\bar{\phi}_k(x)$ is independent of the choice of $\tilde{B}_k^+(x)$. Assume that $\bar{\phi}_k(x_0) = 0$ and that $\bar{\phi}_k(x)$ has constant rank s_k in a neighborhood of x_0 in N_{k-1} . Then locally around x_0 , $N_k := \{x \in N_{k-1} \mid \bar{\phi}_k(x) = 0\}$ is an $(n - p_k)$ -dimensional submanifold, with $p_k := p_{k-1} + s_k$. Permute the entries of $\bar{\phi}_k$ such that the first s_k entries are independent on N_k , and denote $\phi_k := (\phi_{k-1}, \phi_{k1}, \dots, \phi_{ks_k})$.

If, at every step of the algorithm, the two constant rank assumptions are satisfied and $\bar{\phi}_k(x_0) = 0$, then we call x_0 a *regular point* for the algorithm. If x_0 is a regular point for the clamped dynamics algorithm, then it easily follows that the algorithm terminates after $k^* < n$ iterations, where k^* is the least integer such that $N_{k^*-1} = N_{k^*}$, or equivalently k^* is the least integer for which $\bar{\phi}_k \equiv 0$ on N_{k-1} . We will call the maximal connected component of N_{k^*} containing x_0 the *clamped dynamics manifold* of (6) and we denote it by N^* . A control that renders the dynamics on N^* invariant is given by $u = -\tilde{B}_{k^*}^+(x)\tilde{A}_{k^*}(x)$.

In what follows we will control nonlinear systems of the form (6) by means of a compensator R of the form

$$(10) \quad R \begin{cases} \dot{z} = \alpha(x, z) + \beta(x, z)v \\ u = \gamma(x, z) + \delta(x, z)v \end{cases}$$

with $z \in \mathbb{R}^\mu$, v denoting the new inputs and real analytic $\alpha, \beta, \gamma, \delta$. A question that arises is: what is the connection between the clamped dynamics manifold of (6) and the clamped dynamics manifold of (6), (10)? The following proposition gives an answer to this question.

PROPOSITION 2.5. *Let the clamped dynamics manifold of (6) be given by $N^* = \{x \mid \phi_{k^*}(x) = 0\}$. Then the clamped dynamics manifold of (6), (10) is given by $M^* = \{(x, z) \mid \phi_{k^*}(x) = 0, \psi(x, z) = 0\}$ for some vector of functions $\psi(x, z)$.*

The proof appears in the Appendix.

3. The nonregular dynamic disturbance decoupling problem (nDDDP). In this section we formulate two kinds of nDDDPs and give a local solution for both problems.

Let Σ be a nonlinear multi-input multi-output control system with disturbances of the form

$$(11) \quad \Sigma \begin{cases} \dot{x} = f(x) + g(x)u + p(x)q \\ y = h(x), \end{cases}$$

where $x \in \mathcal{X}$, an open subset of \mathbb{R}^n , the inputs $u \in \mathbb{R}^m$, the outputs $y \in \mathbb{R}^p$, the disturbances $q \in \mathbb{R}^r$, f and h are vector-valued analytic functions, and g and p are matrix-valued analytic functions, all of appropriate dimensions. Analogously to [17] we define the following problems for Σ .

DEFINITION 3.6. Consider the system Σ and let a point $x_0 \in \mathcal{X}$ be given.

1. The local nDDDP with disturbance measurements (nDDDPdm) consists in finding (if possible) a compensator Q of the form

$$(12) \quad Q \begin{cases} \dot{z} = \alpha(x, q, z) + \beta(x, q, z)v \\ u = \gamma(x, q, z) + \delta(x, q, z)v \end{cases}$$

with $z \in \mathbb{R}^\mu$, a neighborhood U of x_0 in \mathcal{X} , an open subset V of \mathbb{R}^μ , and a map $F: U \rightarrow V$ with the property that $y^{\Sigma \circ Q}(\bar{x}, F(\bar{x}), t)$ is independent of q for all $\bar{x} \in U$. Here $y^{\Sigma \circ Q}(\bar{x}, F(\bar{x}), t)$ denotes the output of the precompensated system $\Sigma \circ Q$ initialized at $(\bar{x}, F(\bar{x}))$, at time t .

2. The local nDDDP consists in finding (if possible) a compensator R of the form

$$(13) \quad R \begin{cases} \dot{z} = \alpha(x, z) + \beta(x, z)v \\ u = \gamma(x, z) + \delta(x, z)v \end{cases}$$

with $z \in \mathbb{R}^\mu$, a neighborhood U of x_0 in \mathcal{X} , an open subset V of \mathbb{R}^μ , and a map $F: U \rightarrow V$ with the property that $y^{\Sigma \circ Q}(\bar{x}, F(\bar{x}), t)$ is independent of q for all $\bar{x} \in U$.

If we require the compensators Q and R to be invertible, the above problems will be referred to by DDDPdm and DDDP, respectively.

A solution of the DDDP and the DDDPdm can be found in [17]. Recall that for linear systems the conditions for solvability of nDDDPdm, DDPdm, nDDDPdm, and DDDPdm are all equivalent (see, e.g., [1], [2]). From Example 3.2 in [17] it has become clear that for nonlinear systems solvability of the DDP is not equivalent to the solvability of the DDDP. The following example illustrates that for nonlinear systems solvability of the nDDDP is not equivalent to solvability of the DDP nor the DDDP.

Example 3.7. Consider the nonlinear system

$$(14) \quad \begin{aligned} \dot{x}_1 &= x_2 u, \\ \dot{x}_2 &= x_3 + q, \\ \dot{x}_3 &= x_1 u, \\ y_1 &= x_1, \\ y_2 &= x_3. \end{aligned}$$

It is easy to see that we can solve the nDDDP for this system by putting $u = 0$, while using the theory developed in [17] it can be shown that the DDDP is not solvable for (14), which also implies that the DDP is not solvable for (14).

In what follows we will give a constructive algorithm to solve the nDDDPdm. In order to get a better insight into how the algorithm works, we first discuss the ideas behind the algorithm. So, consider a system Σ with disturbances, of the form (11). Choose a point $x_0 \in \mathcal{X}$. First assume that we want to solve the nDDDPdm around x_0 . Clearly, a compensator Q solves the nDDDPdm for Σ around x_0 if and only if for $\Sigma \circ Q$ the $y_i^{(j)}(t)$ do not depend on q for all t . We now apply the first steps of Singh's algorithm (cf. [34], [9]) to Σ . Thus, for Σ we determine

$$(15) \quad \dot{y} = \frac{\partial h}{\partial x}(x)[f(x) + g(x)u + p(x)q] =: a_1(x) + b_1(x)u + c_1(x)q.$$

Assume that $b_1(x)$ has constant rank ρ_1 in a neighborhood of x_0 . After a possible permutation of the entries of y , we may assume that the first ρ_1 rows of $b_1(x)$ are linearly independent. Accordingly, we write (15) as

$$(16) \quad \begin{pmatrix} \dot{\hat{y}}_1 \\ \hat{y}_1 \end{pmatrix} = \begin{pmatrix} \tilde{a}_1(x) + \tilde{c}_1(x)q \\ \hat{a}_1(x) + \hat{c}_1(x)q \end{pmatrix} + \begin{pmatrix} \tilde{b}_1(x) \\ \hat{b}_1(x) \end{pmatrix} u,$$

where $\tilde{b}_1(x)$ has full row rank ρ_1 in a neighborhood of x_0 . Let $\tilde{b}_1^+(x)$ be a right inverse of $\tilde{b}_1(x)$. Then from the upper part of (16) it follows that

$$(17) \quad u = \tilde{b}_1^+(x)(\dot{\hat{y}}_1 - \tilde{a}_1(x) - \tilde{c}_1(x)q).$$

Combining (16) and (17) we obtain

$$(18) \quad \dot{\hat{y}}_1 = \hat{a}_1(x) + \hat{b}_1(x)\tilde{b}_1^+(x)(\dot{\hat{y}}_1 - \tilde{a}_1(x) - \tilde{c}_1(x)q) + (\hat{c}_1(x) - \hat{b}_1(x)\tilde{b}_1^+(x)\tilde{c}_1(x))q =: \psi_1(x, q, \dot{\hat{y}}_1).$$

Note that ψ_1 is affine in q and $\dot{\hat{y}}_1$. Define the matrix-valued function

$$(19) \quad D_1(x) := \frac{\partial \psi_1(x, q, \dot{\hat{y}}_1)}{\partial q}.$$

Assume that $D_1 \neq 0$. This implies that $\dot{\hat{y}}_1$ explicitly depends on q . Furthermore, this dependence is intrinsic, meaning that with another partition (\tilde{y}_1, \hat{y}_1) of y also a q -dependence would occur via a matrix-valued function $\tilde{D}_1(x)$ with the property that $\tilde{D}_1(x) = T_1(x)D_1(x)$, where $T_1(x)$ is invertible (cf. [9]). Using similar arguments as in the proof of Proposition 2.5, we can show that this q -dependence can only be resolved by means of dynamic compensation if we can choose the compensator and its initial conditions in such a way that $D_1(x(t)) = 0$ for all t . However, this would imply that the nDDDPdm is not solvable in a neighborhood of x_0 in \mathcal{X} , but at most in a neighborhood of x_0 in $\{x \mid D_1(x) = 0\}$. Thus we must necessarily have that $D_1 \equiv 0$ if we want to solve the nDDDPdm. Assuming that $D_1 \equiv 0$ we proceed by determining

$$(20) \quad \begin{aligned} \hat{y}_1^{(2)} &= \frac{\partial \psi_1}{\partial x}(x, \dot{\hat{y}}_1)[f(x) + g(x)u + p(x)q] + \frac{\partial \psi_1}{\partial \dot{\hat{y}}_1}(x, \dot{\hat{y}}_1)\dot{\hat{y}}_1^{(2)} \\ &=: a_2(x, \dot{\hat{y}}_1, \tilde{y}_1^{(2)}) + b_2(x, \dot{\hat{y}}_1)u + c_2(x, \dot{\hat{y}}_1)q. \end{aligned}$$

Define $B_2 := (\tilde{b}_1^T b_2^T)^T$ and assume that $B_2(x, \dot{\hat{y}}_1)$ has constant rank ρ_2 in a neighborhood of x_0 . Then, after a possible permutation of the entries of \hat{y}_1 , we may assume that the first $\rho_2 - \rho_1$ rows of $b_2(x, \dot{\hat{y}}_1)$ are linearly independent. Accordingly, we write (20) and the upper part of (16) as

$$(21) \quad \begin{pmatrix} \dot{\hat{y}}_1 \\ \hat{y}_1^{(2)} \\ \hat{y}_2^{(2)} \end{pmatrix} = \begin{pmatrix} \tilde{a}_1(x) + \tilde{c}_1(x)q \\ \tilde{a}_2(x, \dot{\hat{y}}_1, \tilde{y}_1^{(2)}) + \tilde{c}_2(x, \dot{\hat{y}}_1)q \\ \hat{a}_2(x, \dot{\hat{y}}_1, \tilde{y}_1^{(2)}) + \hat{c}_2(x, \dot{\hat{y}}_1)q \end{pmatrix} + \begin{pmatrix} \tilde{b}_1(x) \\ \tilde{b}_2(x, \dot{\hat{y}}_1) \\ \hat{b}_2(x, \dot{\hat{y}}_1) \end{pmatrix} u,$$

where $\tilde{B}_2(x, \dot{\hat{y}}_1) := (\tilde{b}_1^T(x)\tilde{b}_2^T(x, \dot{\hat{y}}_1))^T$ has full row rank ρ_2 . Let $\tilde{B}_2^+(x, \dot{\hat{y}}_1)$ be a right inverse of $\tilde{B}_2(x, \dot{\hat{y}}_1)$ and define $\tilde{Y}_2 := (\dot{\hat{y}}_1^T \hat{y}_2^{(2)T})^T$, $\tilde{A}_2(x, \dot{\hat{y}}_1, \tilde{y}_1^{(2)}) := (\tilde{a}_1^T(x)\tilde{a}_2^T(x, \dot{\hat{y}}_1, \tilde{y}_1^{(2)}))^T$, $\tilde{C}_2(x, \dot{\hat{y}}_1) := (\tilde{c}_1^T(x)\tilde{c}_2^T(x, \dot{\hat{y}}_1))^T$. Then again we can rewrite $\hat{y}_2^{(2)}$ as

$$(22) \quad \begin{aligned} \hat{y}_2^{(2)} &= \hat{a}_2(x, \dot{\hat{y}}_1, \tilde{y}_1^{(2)}) - \hat{b}_2(x, \dot{\hat{y}}_1)\tilde{B}_2^+(x, \dot{\hat{y}}_1)(\tilde{A}_2(x, \dot{\hat{y}}_1, \tilde{y}_1^{(2)}) - \tilde{Y}_2) \\ &\quad + (\hat{c}_2(x, \dot{\hat{y}}_1) - \hat{b}_2(x, \dot{\hat{y}}_1)\tilde{B}_2^+(x, \dot{\hat{y}}_1)\tilde{C}_2(x, \dot{\hat{y}}_1))q =: \psi_2(x, q, \tilde{Y}_2). \end{aligned}$$

Define as before the matrix-valued function

$$(23) \quad D_2(x, \dot{y}_1) := \frac{\partial \psi_2(x, q, \tilde{Y}_2)}{\partial q}.$$

First assume that $D_2 \neq 0$. Then $\hat{y}_2^{(2)}$ explicitly depends on q . Again, this dependence is intrinsic in a similar sense as described above, and it can only be resolved by means of dynamic compensation if we can choose the compensator and its initial conditions in such a way that $D_2(x(t), \dot{y}_1(t)) = 0$ for all t . Now note that D_2 is a function of x and \dot{y}_1 . Thus it may be possible to find a neighborhood U of x_0 in \mathcal{X} such that for all $x \in U$ there is a $\dot{y}_1 \in \mathbb{R}^{p_1}$ such that $D_2(x, \dot{y}_1) = 0$. By the implicit function theorem, this is the case if and only if

$$(24) \quad \text{rank} \frac{\partial \hat{D}_2}{\partial \dot{y}_1} = \text{rank} \left(\frac{\partial \hat{D}_2}{\partial x} \frac{\partial \hat{D}_2}{\partial \dot{y}_1} \right),$$

where $\hat{D}_2(x, \dot{y}_1)$ is the vector of functions consisting of the nonzero entries of D_2 . If (24) holds, we can locally treat x as a “free variable,” i.e., there is a partition $(\dot{y}_{11}, \dot{y}_{12})$ of \dot{y}_1 and a function $\bar{D}_2(x, \dot{y}_{12})$ such that locally

$$(25) \quad \hat{D}_2(x, \dot{y}_1) = 0 \Leftrightarrow \dot{y}_{11} = \bar{D}_2(x, \dot{y}_{12}).$$

We now proceed by repeating the above procedure under the constraint that D_2 and its time derivatives are zero. If again an explicit q -dependence of the type described above or an explicit q -dependence of a time derivative of D_2 occurs, we add the function characterizing the dependence to the set of constraint functions and start all over again with the new set of constraint functions.

If, on the other hand, we have that $D_2 \equiv 0$, we continue with subsequent steps of Singh's algorithm until an intrinsic q -dependence occurs and then go through the whole procedure as described above. While going through the procedure, we should apply two intermediate checks. First, it may occur at a certain step that the submanifold on which the constraints are satisfied is empty. In this case the nDDDPdm is not solvable, and we can stop the procedure. Second, assume that at a certain step the set of constraint functions is given by $\Psi_k(x, \tilde{Y}_k)$. Then, to guarantee solvability of the nDDDPdm on a neighborhood of x_0 in \mathcal{X} , we must necessarily have that there is a neighborhood U of x_0 in \mathcal{X} such that for every $x \in U$ there is a \tilde{Y}_k satisfying $\Psi_k(x, \tilde{Y}_k) = 0$. By the implicit function theorem, this is the case if and only if

$$(26) \quad \text{rank} \frac{\partial \Psi_k}{\partial \tilde{Y}_k} = \text{rank} \left(\frac{\partial \Psi_k}{\partial x} \frac{\partial \Psi_k}{\partial \tilde{Y}_k} \right),$$

so that again, locally, x can be treated as a free variable. Thus, if (26) does not hold, the nDDDPdm is not solvable, and we can stop the procedure.

If we want to solve the nDDDP instead of the nDDDPdm, the procedure described above follows the same lines, with a few minor differences. Namely, while solving the nDDDPdm, at every step k we may resolve the intrinsic dependence of $\tilde{y}_1, \dots, \tilde{y}_k$ on q by choosing an appropriate input u depending on x, q and $\tilde{y}_1, \dots, \tilde{y}_k$ and its time derivatives (see (16), (17), (21)). However, if we want to solve the nDDDP, we can only resolve the intrinsic q -dependence of $\tilde{y}_1, \dots, \tilde{y}_k$ if the functions characterizing the dependence are constrained to be zero for all t , since u is not allowed to depend on q . For the procedure this means that, while solving the nDDDP, we should define $D_1(x) = (\partial \hat{y} / \partial q)(x)$, $D_2(x, \dot{y}_1) = \partial \hat{y}_1 / \partial q$, etc.

Summarizing, the algorithm we are going to present will consist of applying steps of Singh's algorithm and the clamped dynamics algorithm to Σ , together with some intermediate checks. The use of Singh's algorithm can be circumvented by observing that applying Singh's algorithm to Σ is equivalent to applying the clamped dynamics algorithm to the augmented system (cf. [35])

$$(27) \quad \Sigma_{a0} \begin{cases} \dot{x} = f(x) + g(x)u + p(x)q \\ \dot{w}_{i1} = w_{i2} \\ \dot{w}_{i2} = w_{i3} \\ \vdots \\ \dot{w}_{i\nu_0} = v_i \\ y_{0i} = h_i(x) - w_{i1} \end{cases} \quad (i = 1, \dots, p)$$

with $\nu_0 := n$. Thus we only have to use the clamped dynamics algorithm.

This leads to the following algorithm.

ALGORITHM 3.8.

• Step 0

Define the system Σ_{a0} as in (27).

• Step $k+1$

Let $\Sigma_{a0}, \dots, \Sigma_{ak}$ and ν_0, \dots, ν_k be defined. If we apply the clamped dynamics algorithm to Σ_{ak} , where we consider q as a parameter, we obtain (vectors of) functions $\phi_1^k(x, q, w), \dots, \phi_{\pi_k}^k(x, q, w)$, where π_k denotes the final step of the clamped dynamics algorithm applied to Σ_{ak} . While solving the nDDDPm, let τ_k be the smallest integer for which

$$(28) \quad 0 \neq D_{\tau_k}^k(x, w) := \frac{\partial \phi_{\tau_k+1}^k}{\partial q}.$$

While solving the nDDDP, let τ_k be the smallest integer for which

$$(29) \quad 0 \neq D_{\tau_k}^k(x, w) := \frac{\partial \dot{\phi}_{\tau_k}^k}{\partial q}.$$

If it turns out that $\tau_k \geq \pi_k$, we set $\tau_k := \pi_k$. Now distinguish the following cases (which should be checked sequentially):

1. $N_{\tau_k}^k := \{(x, w) \mid \phi_1^k(x, w) = \dots = \phi_{\tau_k}^k(x, w) = 0\} = \emptyset$. In this case we stop.
2. $\text{rank}(\partial \phi_{\tau_k}^k / \partial w) < \text{rank}((\partial \phi_{\tau_k}^k / \partial x)(\partial \phi_{\tau_k}^k / \partial w))$. In this case we stop.
3. $\pi_k = \tau_k$. In this case we stop, defining $N^* := N_{\pi_k}^k$.
4. If none of the cases 1, 2, or 3 hold, we define $\nu_{k+1} := \nu_k + \tau_k$ and $\hat{D}_{\tau_k}^k$ a vector of functions consisting of a maximal number of independent entries of $D_{\tau_k}^k$.

Then define the system

$$(30) \quad \Sigma_{ak+1} \begin{cases} \dot{x} = f(x) + g(x)u + p(x)q \\ \dot{w}_{i1} = w_{i2} \\ \dot{w}_{i2} = w_{i3} \\ \vdots \\ \dot{w}_{i\nu_{k+1}} = v_i \\ y_{k+1} = \begin{pmatrix} \phi_{\tau_k}^k \\ \hat{D}_{\tau_k}^k \end{pmatrix} \end{cases} \quad (i = 1, \dots, p).$$

Note that at every step k of Algorithm 3.8 we must apply only τ_k steps of the clamped dynamics algorithm to Σ_{ak-1} . If for a given x_0 at every step k there is a w_0^k

such that (x_0, w_0^k) is a regular point for the first τ_k steps of the clamped dynamics algorithm applied to Σ_{ak-1} , we call x_0 a *regular* point for Algorithm 3.8. If x_0 is a regular point, the algorithm terminates in a finite number, say k^* , of steps. Now we have the following theorem.

THEOREM 3.9. *Consider the system Σ . Let x_0 be a regular point for Algorithm 3.8 applied to Σ . Then*

1. *The (regular) DDDPdm is locally solvable around x_0 if and only if $k^* = 1$. Moreover, if $k^* = 1$, the algorithm terminates because of case 3.*

2. *If $k^* > 1$, the nDDDPdm is locally solvable around x_0 if and only if the algorithm terminates because of case 3.*

Proof. 1. See [17].

2. We only give the proof for the nDDDP. The proof for the nDDDPdm is analogous, with a few differences concerning the q -dependence of the compensator.

Sufficiency. Assume that the algorithm terminates because of case 3. For brevity of notation, we denote

$$(31) \quad \Phi(x, w) := \phi_{\pi_{k^*-1}}^{k^*-1}(x, w).$$

Thus, $N^* = \{(x, w) | \Phi(x, w) = 0\}$ and N^* is a controlled invariant submanifold for Σ_{ak^*-1} . Since case 2 does not apply for Φ , by the implicit function theorem we can find a partition (w_1, w_2) of w and a function $\Psi(x, w_2)$ such that locally N^* can be expressed as $\{(x, w) | w_1 = \Psi(x, w_2)\}$. Let $U \subset \mathcal{X}$ be a neighborhood of x_0 on which this parametrization of N^* holds. Now let $u = \alpha^*(x, w)$ be a control that renders N^* invariant for Σ_{ak^*-1} . Then it is obvious that if we apply this control to Σ_{ak^*-1} and we choose our initial conditions on N^* , we will have $y_i^{(j)}(t) = w_{ij}(t)$ for all t and thus $y(t), \dots, y^{(n)}(t)$ are independent of q for all t . Now let z_i ($i = 1, \dots, p$) be a vector of dimension ν_{k^*-1} and consider the compensator

$$(32) \quad Q \begin{cases} \dot{z}_i = Az_i + bv_i & (i = 1, \dots, p) \\ u = \alpha^*(x, z) \end{cases}$$

with (A, b) in Brunovsky form, initialized at $(\bar{x}, \Psi(\bar{x}, z^2), z^2)$ for an $\bar{x} \in U$. Then from the above it is clear that this compensator locally solves the nDDDP for Σ .

Necessity. Let x_0 be a regular point for Algorithm 3.8 applied to Σ . Assume that the nDDDP is locally solvable around x_0 by means of a compensator

$$(33) \quad Q \begin{cases} \dot{z} = \alpha(x, z) \\ u = \gamma(x, z). \end{cases}$$

Consider the system

$$(34) \quad \bar{\Sigma}_{a0} \begin{cases} \dot{x} = f(x) + g(x)u + p(x)q \\ \dot{w}_{i1} = w_{i2} \\ \dot{w}_{i2} = w_{i3} \\ \vdots \\ \dot{w}_{i\nu_{k^*-1}} = v_i \\ \bar{y}_{0i} = h_i(x) - w_{i1} \end{cases} \quad (i = 1, \dots, p).$$

Note that $\bar{\Sigma}_{a0}$ only differs from Σ_{a0} in the the number of w_{ij} 's for $\bar{\Sigma}_{a0}$ is larger. Since Q solves the nDDDP for Σ , it also solves the nDDDP for $\bar{\Sigma}_{a0}$. Thus, the clamped dynamics manifold of $\bar{\Sigma}_{a0} \circ Q$ is given by $M = \{(x, w, z) | \Phi(x, z) - w = 0\}$ for some

vector of functions $\Phi(x, z)$. Denote the clamped dynamics manifold of $\Sigma_{ak} \circ Q$ ($k = 0, \dots, k^* - 1$) by N^k . By Proposition 2.5, the functions determining the clamped dynamics manifold of Σ_{ak} are zero on N^k . This implies in particular that the functions determining the clamped dynamics manifold of Σ_{a0} are zero on M . Since $k^* > 1$, $\tau_0 < \pi_0$. Moreover, since $\partial \dot{\phi}_{\tau_0}^0 / \partial q \neq 0$ and

$$(35) \quad \dot{\phi}_{\tau_0}^0 = \frac{\partial \phi_{\tau_0}^0}{\partial x} [f(x) + g(x)u + p(x)q] + \frac{\partial \phi_{\tau_0}^0}{\partial w} \dot{w}$$

for $\bar{\Sigma}_{a0}$, it is easily seen that at least one of the functions determining M explicitly depends on q , and/or γ depends on q , unless $\hat{D}_{\tau_0}^0(x, w)$ and all of its time derivatives are zero on M . Since the former would be in contradiction with the form of M and/or the form of Q , the latter is the case. Now let the systems $\bar{\Sigma}_{ak}$ ($k = 1, \dots, k^* - 1$) be obtained from $\bar{\Sigma}_{ak-1}$ by augmenting the outputs according to

$$(36) \quad \bar{y}_k = \begin{pmatrix} \phi_{\tau_{k-1}}^{k-1} \\ \hat{D}_{\tau_{k-1}}^{k-1} \end{pmatrix}.$$

Again, note that $\bar{\Sigma}_{ak}$ only differs from Σ_{ak} in that the number of w_{ij} 's for $\bar{\Sigma}_{ak}$ is larger. Then, using the above and an induction argument, we can prove that the clamped dynamics manifold of $\bar{\Sigma}_{ak} \circ Q$ ($k = 0, \dots, k^* - 1$) is equal to M . If we compare the form of Σ_{ak} and $\bar{\Sigma}_{ak}$, we see that this implies that also N^k ($k = 0, \dots, k^* - 1$) is of the form $N^k = \{(x, w, z) \mid \Phi_k(x, z) - w = 0\}$ for some vector of functions $\Phi_k(x, z)$. Consider the sets $\tilde{N}^k := \{(x, w) \mid \text{there exists } z \text{ such that } (x, w, z) \in N^k\}$. By the form of N^k it is clear that $\tilde{N}^k \neq \emptyset$. Now, by Proposition 2.5, N^k can alternatively be written as $N^k = \{(x, w, z) \mid \phi_{\tau_k}^k(x, w) = 0, \psi_k(x, w, z) = 0\}$ for some vector of functions $\psi_k(x, w, z)$. Thus any element $(x, w) \in \tilde{N}^k$ must satisfy $\phi_{\tau_k}^k(x, w) = 0$, which implies that $\tilde{N}^k \subset N_{\tau_k}^k$. Hence $N_{\tau_k}^k \neq \emptyset$ and thus the algorithm cannot terminate because of case 1. Now assume that the algorithm terminates because of case 2. This implies that we cannot find a partition (w_1, w_2) of w and a vector of functions $\Psi_{k^*-1}(x, w_2)$ such that $N_{\tau_{k^*-1}}^{k^*-1} = \{(x, w) \mid w_1 = \Psi_{k^*-1}(x, w_2)\}$, i.e., x cannot be a "free variable" on $N_{\tau_{k^*-1}}^{k^*-1}$. By Proposition 2.5 this implies that x cannot be a free variable on N^{k^*-1} either, which gives a contradiction with the form of N^{k^*-1} . Hence the algorithm can only terminate because of case 3. \square

Remark 3.10. It is easy to see that while solving the nDDDPdm we can take the function $\alpha^*(x, q, w)$, which renders N^* as an invariant manifold for Σ_{ak^*-1} to be affine in q , i.e., we can take α^* of the form $\alpha^*(x, q, z) = \alpha_1^*(x, z) + \alpha_2^*(x, z)q$.

We chose the above form of the algorithm and construction of the compensator to make the algorithm and the proof of Theorem 3.9 as transparent as possible. However, the bookkeeping while applying the algorithm can become quite troublesome, and the order of the compensator can become unnecessarily high. For (relatively) simple examples, much can be improved by using ad hoc arguments in the vein of the algorithm, as will be illustrated by the following example.

Example 3.11. Consider the system

$$(37) \quad \begin{aligned} \dot{x}_1 &= x_2 u_1 + x_4, & y_1 &= x_1, \\ \dot{x}_2 &= x_3 + q_1, & y_2 &= x_3, \\ \dot{x}_3 &= x_1 u_1 + x_4, & y_3 &= x_5, \\ \dot{x}_4 &= x_5, & y_4 &= x_7, \end{aligned}$$

$$\begin{aligned}
\dot{x}_5 &= u_2 + x_9, \\
\dot{x}_6 &= x_8 u_3, \\
\dot{x}_7 &= x_6 u_2 + x_8 + x_9 + x_6 x_9, \\
\dot{x}_8 &= u_3, \\
\dot{x}_9 &= x_{10}, \\
\dot{x}_{10} &= q_2
\end{aligned}$$

((37) cont.)

for which we want to solve the nDDDP around points in the set $\{x \in \mathbb{R}^{10} \mid x_2 \neq 0, x_1 \neq 0, x_6 \neq 0, x_8 \neq 0\}$. Let us first restrict our attention to y_1 and y_2 . We find

$$\begin{aligned}
\dot{y}_1 &= x_2 u_1 + x_4 \Rightarrow u_1 = \frac{1}{x_2} (\dot{y}_1 - x_4), \\
\dot{y}_2 &= x_1 u_1 + x_4 = \frac{x_1}{x_2} (\dot{y}_1 - x_4) + x_4, \\
\ddot{y}_2 &= \frac{\dot{y}_1}{x_2} (\dot{y}_1 - x_4) - \frac{x_1(x_3 + q_1)}{x_2^2} (\dot{y}_1 - x_4) + \frac{x_1}{x_2} (\ddot{y}_1 - \dot{x}_5) + \dot{x}_5.
\end{aligned}$$

Thus \ddot{y}_2 intrinsically depends on q_1 . Hence we should have

$$(38) \quad \frac{x_1}{x_2^2} (\dot{y}_1 - x_4) = 0.$$

Since we are working in a neighborhood of point for which $x_1 \neq 0$, $x_2 \neq 0$, this implies that $(1/x_2)(\dot{y}_1 - x_4) = u_1 = 0$.

Having chosen $u_1 = 0$, we see from the structure of the system y_1 and y_2 can be made independent of q_2 if and only if y_3 and y_4 can be made independent of q_2 . Restricting our attention to y_3 and y_4 , we find

$$\begin{aligned}
\dot{y}_3 &= u_2 + x_0 \Rightarrow u_2 = \dot{y}_3 - x_9, \\
\dot{y}_4 &= x_6 u_2 + x_8 + x_9 + x_6 x_9 = x_6 \dot{y}_3 + x_8 + x_9, \\
\ddot{y}_4 &= x_8 \dot{y}_3 u_3 + x_6 \ddot{y}_3 + \dot{u}_3 + \dot{x}_{10} \Rightarrow u_3 = \frac{1}{x_8 \dot{y}_3 + 1} (\ddot{y}_4 - x_6 \ddot{y}_3 - \dot{x}_{10}).
\end{aligned}$$

(39)

Thus we can solve the nDDDPdm by choosing a compensator

$$\begin{aligned}
\dot{z} &= v_1, \\
u_1 &= 0, \\
u_2 &= z - x_9, \\
u_3 &= \frac{1}{x_8 z + 1} (v_2 - x_6 v_1 - x_{10}),
\end{aligned}$$

(40)

with $z(0) \neq -(1/x_8(0))$ and v_1, v_2 denoting the new inputs.

4. The nonlinear model matching problem. In this section we will use the results of the previous section to give a complete local solution of the nonlinear model matching problem. For linear systems, the idea that we can obtain a solution of the nonlinear model matching problem by associating it with a disturbance decoupling problem was elaborated in [32], [11]. It was first extended to nonlinear systems in [10].

First, we give a formulation of the problem. Consider a nonlinear plant P , described by equations of the form

$$(41) \quad P \begin{cases} \dot{x} = f(x) + g(x)u \\ y = h(x), \end{cases}$$

where $x \in \mathcal{X}$, an open subset of \mathbb{R}^n , the inputs $u \in \mathbb{R}^m$, the outputs $y \in \mathbb{R}^p$, f and h are vector-valued analytic functions, and g is a matrix-valued analytic function, all of appropriate dimensions.

Furthermore, let a nonlinear model M be given, which is described by the equations

$$(42) \quad M \begin{cases} \dot{x}^M = f^M(x^M) + g^M(x^M)u^M \\ y^M = h^M(x^M), \end{cases}$$

where $x^M \in \mathcal{X}^M$, an open subset of \mathbb{R}^{n_M} , the inputs $u^M \in \mathbb{R}^{m_M}$, the outputs $y^M \in \mathbb{R}^{p_M}$, f^M and h^M are vector-valued analytic functions, and g^M is a matrix-valued analytic function, all of appropriate dimensions.

The compensator Q used to control P is a nonlinear system described by equations of the form

$$(43) \quad Q \begin{cases} \dot{z} = a(x, z) + b(x, z)u^M \\ u = c(x, z) + d(x, z)u^M \end{cases}$$

with state $z \in \mathbb{R}^v$ and real analytic a, b, c, d .

The usual definition of the nonlinear model matching problem is given below (see [6], [10]).

DEFINITION 4.12 (Nonlinear model matching problem (MMP)). Given a plant $P = (f, g, h)$, a model $M = (f^M, g^M, h^M)$, and a point $(x_0, x_0^M) \in \mathcal{X} \times \mathcal{X}^M \subset \mathbb{R}^n \times \mathbb{R}^{n_M}$, find neighborhoods U of x_0 and U^M of x_0^M , an integer v , an open subset V of \mathbb{R}^v , a compensator $Q = (a, b, c, d)$ with a, b, c, d real analytic functions defined on $V \times U$, and a map $F: U \times U^M \mapsto V$, with the property that

$$(44) \quad y^{P \circ Q}(x, F(x, x^M), t) - y^M(x^M, t)$$

is independent of u^M for all t and for all $(x, x^M) \in U \times U^M$.

Given M and P we define an *extended system* E :

$$(45) \quad E \begin{cases} \dot{x}^E = f^E(x^E) + g^E(x^E)u^E + p^E(x^E)q^E \\ y^E = h^E(x^E) \end{cases}$$

with

$$x^E = \begin{pmatrix} x \\ x^M \end{pmatrix}, \quad f^E(x^E) = \begin{pmatrix} f(x) \\ f^M(x^M) \end{pmatrix}, \quad g^E(x^E) = \begin{pmatrix} g(x) \\ 0 \end{pmatrix},$$

$$p^E(x^E) = \begin{pmatrix} 0 \\ g^M(x^M) \end{pmatrix}, \quad h^E(x^E) = h(x) - h^M(x^M).$$

THEOREM 4.13. *The MMP is solvable for (M, P) if and only if the nDDDPdm is solvable for E .*

Proof. Necessity. Assume that the MMP is solvable for (M, P) by means of a compensator Q of the form (43). Then from the definition of the MMP it is obvious that the compensator

$$(46) \quad Q_E \begin{cases} \dot{z} = \alpha(x^E, q^E, z) \\ u = \gamma(x^E, q^E, z) \end{cases}$$

with $\alpha(x^E, q^E, z) = a(x, z) + b(x, z)q^E$, $\gamma(x^E, q^E, z) = c(x, z) + d(x, z)q^E$ solves the nDDDPdm for E .

Sufficiency (see also [10]). Assume that the nDDDPm is solvable for E by means of a compensator

$$(47) \quad Q_E \begin{cases} \dot{z} = \alpha_1(x^E, z) + \alpha_2(x^E, z)q^E \\ u = \gamma_1(x^E, z) + \gamma_2(x^E, z)q^E. \end{cases}$$

Note that we can indeed take the compensator to be affine in q (see Remark 3.10). Consider the following compensator for P :

$$(48) \quad Q \begin{cases} \dot{z}_1 = f^M(z_1) + g^M(z_1)u^M \\ \dot{z}_2 = \alpha_1(x, z_1, z_2) + \alpha_2(x, z_1, z_2)u^M \\ u = \gamma_1(x, z_1, z_2) + \gamma_2(x, z_1, z_2)u^M. \end{cases}$$

Then it is easy to see that Q solves the MMP for (M, P) . \square

Thus, using the results from Theorem 3.9, we can check if the MMP is solvable for given (M, P) and we can construct a compensator that solves the MMP. We will illustrate this by means of an example.

Example 4.14. Consider the plant

$$(49) \quad P \begin{cases} \dot{x}_1 = x_2 + x_2 u_2 & y_1 = x_1 \\ \dot{x}_2 = u_1 & y_2 = x_3 \\ \dot{x}_3 = u_2 & y_3 = x_3 \end{cases}$$

and the model

$$(50) \quad M \begin{cases} \dot{x}_1^M = x_2^M & y_1^M = x_1^M \\ \dot{x}_2^M = x_3^M + u_1^M & y_2^M = x_2^M \\ \dot{x}_3^M = u_2^M & y_3^M = x_4^M \\ \dot{x}_4^M = -x_4^M & \end{cases}$$

Then

$$\begin{aligned} \dot{y}_1 - \dot{y}_1^M &= x_2 + x_2 u_2 = x_2(1 + \dot{y}_3 - \dot{y}_3^M - x_4^M) - x_2^M, \\ \dot{y}_2 - \dot{y}_2^M &= u_1 - x_3^M - u_1^M \Rightarrow u_1 = \dot{y}_2 - \dot{y}_2^M + x_3^M + u_1^M, \\ \dot{y}_3 - \dot{y}_3^M &= u_2 + x_4^M \Rightarrow u_2 = \dot{y}_3 - \dot{y}_3^M - x_4^M, \\ \ddot{y}_1 - \ddot{y}_1^M &= (\dot{y}_2 - \dot{y}_2^M + x_3^M + u_1^M)(1 + \dot{y}_3 - \dot{y}_3^M - x_4^M) + x_2(\ddot{y}_3 - \ddot{y}_3^M - x_4^M) - x_3^M - u_1^M. \end{aligned}$$

Thus, $\ddot{y}_1 - \ddot{y}_1^M$ intrinsically depends on u_1^M (the disturbances). Hence to solve the MMP we must have

$$(51) \quad \dot{y}_3 - \dot{y}_3^M - x_4^M = u_2 = 0.$$

Then it is easy to see that we can solve the MMP by means of the nonregular compensator

$$(52) \quad Q \begin{cases} \dot{z}_1 = z_2 \\ \dot{z}_2 = z_3 + u_1^M \\ \dot{z}_3 = u_2^M \\ \dot{z}_4 = -z_4 \\ u_1 = z_3 + u_1^M \\ u_2 = 0 \end{cases}$$

with $z(0) = x^M(0)$.

5. Conclusions and remarks. In this paper we formulated and solved the local nDDDP. The solution was given by means of a constructive algorithm. A drawback

of the algorithm presented in this paper is that it does not give a compensator of minimal order solving the nDDDPm. Therefore we cannot make any statement about the solvability of the DDP by means of nonregular static state feedback. This remains a problem for future research. Another topic for future research is the generalization of the theory developed in this paper to general nonlinear systems of the form

$$(53) \quad \begin{cases} \dot{x} = f(x, q, u) \\ y = h(x, u). \end{cases}$$

Using the algorithm given in this paper we can immediately give sufficient conditions for the solvability of the nDDDPm for (53). Namely, consider the following extended system obtained from (53):

$$(54) \quad \begin{cases} \dot{x} = f(x, q, u) \\ \dot{u} = v \\ y = h(x, u). \end{cases}$$

Then any solution to the nDDDPm for (53) gives rise to a solution of the problem for (54). The converse is easily seen to be false. However, since for the system (53) versions of Singh's algorithm and the clamped dynamics algorithm are also available (see [26], [23], [24] for Singh's algorithm and [35] for the clamped dynamics algorithm), it seems that the method of this paper can be straightforwardly extended to systems of the form (53).

By proving that the solvability of the nonlinear MMP is equivalent to the solvability of an associated nDDDP with disturbance measurements, we also established a complete local solution of this problem. A problem that remains unsolved is the problem of internal stability of the compensated plant after we have solved the nonlinear MMP. Until now this problem has only been addressed in [3] in the case where the plant is a single-input, single-output system and in [15] in the case where the plant is decouplable by static state feedback. The problem consists in the fact that, even if we start from an internally stable plant and an internally stable model, we may very well introduce unstable unobservable modes in the closed loop. To solve this problem, further investigation of the structure of a model matching configuration is needed, especially concerning the "fixed" and "free" modes of such a configuration. For linear systems this investigation has already been performed in [31]. For nonlinear systems this is undoubtedly much more difficult to answer. So far, only results about "fixed" modes in the solution of the input-output decoupling problem have been obtained in [12]. It is not clear if a similar analysis is applicable for the nonlinear MMP considered here. We leave this open for future research.

Appendix.

Proof of Proposition 2.5. Denote the submanifolds obtained while applying the clamped dynamics algorithm to (6) and (6), (10) by $N_k = \{x \mid \phi_k(x) = 0\}$, M_k , respectively. We will prove by induction that we can find vectors of functions $\psi_k(x, z)$ such that $M_k = \{(x, z) \mid \xi_k(x, z) = 0\}$, with

$$\xi_k(x, z) = \begin{pmatrix} \phi_k(x) \\ \psi_k(x, z) \end{pmatrix}.$$

Obviously, we have $N_0 = \{x \mid \phi_0(x) = 0\}$, $M_0 = \{(x, z) \mid \xi_0(x, z) = 0\}$, with $\phi_0(x) = \xi_0(x, z) = h(x)$. Hence our claim holds for $k = 0$. Now apply the first step of the clamped

dynamics algorithm to (6), yielding matrices $A_1(x)$, $B_1(x)$, a vector of functions $\phi_1(x)$, and $N_1 = \{x \mid \phi_1(x) = 0\}$. Applying the first step of the clamped dynamics algorithm to (6), (10) yields

$$(55) \quad \begin{aligned} \dot{\xi}_0(x, z) &= \frac{\partial \phi_0}{\partial x}(x)[f(x) + g(x)(\gamma(x, z) + \delta(x, z)v)] \\ &= A_1(x) + B_1(x)\gamma(x, z) + B_1(x)\delta(x, z)v. \end{aligned}$$

Since (x_0, z_0) is a regular point for the clamped dynamics algorithm applied to (6), (10), $B_1(x)\delta(x, z)$ has full rank \tilde{r}_1 in a neighborhood of (x_0, z_0) in M_0 . It is clear that $\tilde{r}_1 < r_1 = \text{rank } B_1(x)$. Moreover, the rows of $\tilde{B}_1(x)\delta(x, z)$ are linearly dependent on the rows of $\tilde{B}_1(x)\delta(x, z)$, since the rows of $\tilde{B}_1(x)$ are linearly dependent on the rows of $\tilde{B}_1(x)$. Thus we can permute the entries of $\xi_0(x, z)$ in such a way that the first \tilde{r}_1 rows of $B_1(x)\delta(x, z)$ are linearly independent and the last $(p_0 - r_1)$ entries of $\xi_0(x, z)$ consist of $\dot{\phi}_0(x)$, i.e., we can write (55) as

$$(56) \quad \begin{pmatrix} \dot{\sigma}_0(x, z) \\ \dot{\sigma}_0(x, z) \\ \dot{\phi}_0(x, z) \end{pmatrix} = \begin{pmatrix} \tilde{A}_{\sigma_1}(x) + \tilde{B}_{\sigma_1}(x)\gamma(x, z) \\ \hat{A}_{\sigma_1}(x) + \hat{B}_{\sigma_1}(x)\gamma(x, z) \\ \hat{A}_1(x) + \hat{B}_1(x)\gamma(x, z) \end{pmatrix} + \begin{pmatrix} \tilde{B}_{\sigma_1}(x)\delta(x, z) \\ \hat{B}_{\sigma_1}(x)\delta(x, z) \\ \hat{B}_1(x)\delta(x, z) \end{pmatrix} v,$$

where $(\tilde{\sigma}_0^T, \hat{\sigma}_0^T)^T$ consists of the entries of $\tilde{\sigma}_0$ and $\tilde{B}_{\sigma_1}(x)\delta(x, z)$ has full row rank \tilde{r}_1 in a neighborhood of (x_0, z_0) in M_0 . Observe that

$$\begin{pmatrix} \tilde{B}_{\sigma_1}(x) \\ \hat{B}_{\sigma_1}(x) \end{pmatrix}$$

has full row rank r_1 in a neighborhood of (x_0, z_0) in M_0 . Thus, we can rewrite $\dot{\phi}_0(x, z)$ in (56) as

$$(57) \quad \dot{\phi}_0(x, z) = \hat{A}_1(x) + \hat{B}_1(x) \begin{pmatrix} \tilde{B}_{\sigma_1}(x) \\ \hat{B}_{\sigma_1}(x) \end{pmatrix}^+ \left[\begin{pmatrix} \dot{\sigma}_0(x, z) \\ \dot{\sigma}_0(x, z) \end{pmatrix} - \begin{pmatrix} \tilde{A}_{\sigma_1}(x) \\ \hat{A}_{\sigma_1}(x) \end{pmatrix} \right],$$

where

$$\begin{pmatrix} \tilde{B}_{\sigma_1} \\ \hat{B}_{\sigma_1} \end{pmatrix}^+ \text{ is a right inverse of } \begin{pmatrix} \tilde{B}_{\sigma_1} \\ \hat{B}_{\sigma_1} \end{pmatrix}.$$

Let $(\tilde{B}_{\sigma_1}(x)\delta(x, z))^+$ be a right inverse of $\tilde{B}_{\sigma_1}(x)\delta(x, z)$. Letting $v = -(\tilde{B}_{\sigma_1}(x)\delta(x, z))^+ \tilde{A}_{\sigma_1}(x)$ we find from (56)

$$(58) \quad \begin{pmatrix} \dot{\sigma}_0(x, z) \\ \dot{\sigma}_0(x, z) \end{pmatrix} = \begin{pmatrix} 0 \\ \hat{A}_{\sigma_1}(x) - \hat{B}_{\sigma_1}(x)(\tilde{B}_{\sigma_1}(x)\delta(x, z))^+ \tilde{A}_{\sigma_1}(x) \end{pmatrix} =: \begin{pmatrix} 0 \\ \bar{\sigma}_1(x, z) \end{pmatrix}.$$

Then M_1 is given as $M_1 = \{(x, z) \mid \phi_0(x) = 0, \dot{\phi}_0(x, z) = 0, \bar{\sigma}_1(x, z) = 0\}$. Since $\dot{\sigma}_0(x, z) = 0$ on M_1 and (obviously)

$$\begin{pmatrix} \tilde{B}_{\sigma_1}(x) \\ \hat{B}_{\sigma_1}(x) \end{pmatrix}^+ \begin{pmatrix} \tilde{A}_{\sigma_1}(x) \\ \hat{A}_{\sigma_1}(x) \end{pmatrix} = \tilde{B}_1^+(x) \tilde{A}_1(x),$$

we find from (57) that on M_1

$$(59) \quad \dot{\phi}_0(x, z) = \hat{A}_1(x) - \hat{B}_1(x) \tilde{B}_1^+(x) \tilde{A}_1(x) = \hat{\phi}_1(x).$$

Thus, $M_1 = \{(x, z) \mid \phi_0(x) = 0, \bar{\phi}_1(x) = 0, \bar{\sigma}_1(x, z) = 0\}$. Assume that $(\bar{\phi}_1^T(x), \bar{\sigma}_1^T(x, z))^T$ has constant rank \tilde{s}_1 in a neighborhood of (x_0, z_0) in M_1 . Obviously, $\tilde{s}_1 > s_1$. Since $\bar{\phi}_1(x)$ has constant rank s_1 in a neighborhood of (x_0, z_0) in M_1 , we can permute the entries of $\bar{\phi}_1(x)$ and $\bar{\sigma}_1(x, z)$ such that $(\bar{\phi}_{11}(x), \dots, \bar{\phi}_{1s_1}(x), \bar{\sigma}_{11}(x, z), \dots, \bar{\sigma}_{1\tilde{s}_1-s_1}(x, z))$

are independent on M_1 . Defining $\phi_1(x) = (\phi_0^T(x), \bar{\phi}_{11}(x), \dots, \bar{\phi}_{1s_1}(x))^T$, $\psi_1(x, z) = (\bar{\sigma}_{11}(x, z), \dots, \bar{\sigma}_{1s_1-s_1}(x, z))^T$ we find $M_1 = \{(x, z) | \phi_1(x) = 0, \psi_1(x, z) = 0\}$. Hence our claim also holds for $k = 1$. Using similar arguments as above, we can prove that our claim holds for $k = 0, \dots, k^*$, which completes the proof. \square

Acknowledgments. I would like to thank Henk Nijmeijer and Arjan van der Schaft for the many useful discussions we have had on the contents and organization of this paper.

ON THE EXTENSION OF NEWTON'S METHOD TO SEMI-INFINITE MINIMAX PROBLEMS*

E. POLAK†, D. Q. MAYNE‡, AND J. E. HIGGINS†

Abstract. This paper introduces two new techniques for the analysis and construction of semi-infinite optimization algorithms. The first is a very simple technique for establishing the superlinear rate of convergence of semi-infinite optimization algorithms. The second technique enables specification of discretization rules that preserve the superlinear convergence of *conceptual* superlinearly converging semi-infinite optimization algorithms.

Natural extensions of Newton's method to semi-infinite optimization are used as a vehicle for presenting the techniques. In particular, it is shown that both local and global versions of the conceptual extension of Newton's method converge Q -superlinearly, with rate at least $3/2$, and that their implementations, based on the discretization rules, retain this rate of convergence.

Key words. Newton's method, minimax problems, nondifferentiable optimization, superlinear convergence

AMS(MOS) subject classifications. 49K35, 49M15, 49M39

1. Introduction. This is a dual-purpose paper. The first purpose of this paper is to introduce a novel technique for establishing the superlinear convergence of a class of semi-infinite optimization algorithms; the second is to demonstrate the degree to which various discretization effects, associated with semi-infinite optimization problems, can be taken into account. In particular, this paper introduces discretization rules that preserve the superlinear convergence of *conceptual* superlinearly converging semi-infinite optimization algorithms.

In his pioneering paper [29] dealing with perturbed Kuhn–Tucker points, Robinson showed that by applying the implicit function theorem to the first-order optimality conditions of a finitely constrained optimization problem and then relating the result to the search direction finding problem of a particular algorithm, we can sometimes establish the superlinear convergence of this algorithm. The same technique can also be used for establishing the superlinear convergence of finite minimax algorithms; see, e.g., [26].

Unfortunately, Robinson's technique cannot be used in conjunction with semi-infinite optimization algorithms because the assumptions of the implicit function theorem are not usually satisfied in the semi-infinite case. The technique in this paper is based on function approximations and is therefore not restricted by the linear independence requirements associated with techniques based on the implicit function theorem.

To illustrate both our new technique for establishing the superlinear convergence of a semi-infinite optimization algorithm and the manner in which discretization effects can be taken into account, we chose an extension of Newton's method for the solution of semi-infinite optimization problems. Our choice was motivated partly by the fact

that Newton's method is the simplest method in the class that can be considered, and partly because Newton's method is one of the best understood, most studied, variously modified, adapted, and approximated algorithms in the literature (see, e.g., [6], [19], [9], [16], [17], [20], [25], [29], [30]).

In the area of nonlinear programming, Newton's method was at first used as a *local* method for unconstrained optimization of twice locally Lipschitz continuously differentiable, strongly convex functions on \mathbb{R}^n . Then, it was shown by Goldstein [8] that, for such functions, the local Newton method can be globally stabilized; i.e., it can be made globally convergent by the addition of the Armijo–Goldstein step-size rule [1], [8]. Since this step-size rule returns a stepsize of unity near a solution (see [8]), the Goldstein version of the globally stabilized Newton method converges quadratically. Finally, referring to [21], we see that it is possible to construct globally stabilized versions of Newton's method that converge quadratically in minimizing twice locally Lipschitz continuously differentiable, but not necessarily convex, functions on \mathbb{R}^n , whose local minimizers satisfy second-order sufficiency conditions. Such globally converging methods are obtained by using the Goldstein method if certain conditions are satisfied, and reverting to the Armijo gradient method [1] otherwise (see, e.g., [18]).

The extension of Newton's method (largely in the form of sequential quadratic programming) to semi-infinite optimization problems appears to have been confined to constrained problems that can be converted to ordinary nonlinear programming problems by means of the implicit function theorem (see, e.g., [11], [24], [5]). For example, a problem of the form

$$(1.1a) \quad \min \{f(x) \mid \phi(x, t) \leq 0, \forall t \in [0, 1]\}$$

can be converted to the standard nonlinear programming form

$$(1.1b) \quad \min \{f(x) \mid \phi(x, t^j(x)) \leq 0, j = 1, 2, \dots, q\},$$

when it is known that for all x near a local solution x^* , $\phi(x, \cdot)$ has exactly q local maximizers, and that $\phi_{tt}(x, t^j(x)) < 0$ for each j . It should be noted that some of these extensions are *conceptual algorithms* because in their analysis it was not considered that the local maximizers $t^j(x)$ cannot be computed exactly.

We can convert an unconstrained minimax problem of the form

$$(1.2a) \quad \min_{x \in \mathbb{R}^n} \max_{t \in [0, t]} \phi(x, t)$$

into a constrained problem of the form

$$(1.2b) \quad \min \{w \mid \phi(x, t) \leq w, \forall t \in [0, t]\},$$

and, assuming that the required assumptions are satisfied, apply one of the above-mentioned algorithms (i.e., [11], [24], [5]). Such an approach suffers from both aesthetic and practical drawbacks. First, it is displeasing to convert an unconstrained optimization problem into a constrained one. Second, to avoid the Maratos effect [15], we must use a curvilinear step-size rule or other modifications, such as the use of the modified Lagrangian merit function of Shittkowski and Powell, which are more complex than the simple Armijo–Goldstein rule mentioned earlier. Third, unlike Newton's method, the methods in [11], [24], [5] do not exhibit invariance under linear transformations. Last, we have observed that constrained semi-infinite optimization algorithms (such as Algorithm 5.7 in [22]) do not perform on (1.2b) as well as semi-infinite minimax algorithms (such as the version of Algorithm 5.2, based on (5.52) in [22]) do on (1.2a).

In this paper, we present natural extensions of both the local version of Newton's method and of the Goldstein globally stabilized version of Newton's method, for the solution of a class of convex semi-infinite minimax problems. The notable aspects of our work are (i) we do not impose the above-mentioned restrictive assumption that all the local maximizers of $\phi(x, \cdot)$ are strict and that their number is finite, (ii) we consider the most obvious approximations required to produce implementable algorithms, and (iii) we use a new and very simple technique for establishing superlinear convergence of our extensions of Newton's method. Since our technique is not based on the implicit function theorem (as in [29], [25]), it does not require the imposition of a strict complementarity condition.¹ In § 2 we show that a *conceptual* local Newton's method for semi-infinite minimax problems converges superlinearly with Q -rate $3/2$, under assumptions analogous to those needed in the minimization of twice locally Lipschitz continuously differentiable, strongly convex functions on \mathbb{R}^n . In § 3 we present a *conceptual* globally stabilized Newton method and show that it retains the Q -rate of $3/2$. In § 4 we present two *implementable* versions of the local Newton method for semi-infinite minimax problems and show that they converge locally with Q -rate $3/2$; a superlinearly converging (with Q -rate $3/2$) *implementable* version of our globally stabilized Newton method is presented in § 5. We present numerical results in § 6 and our concluding comments and final observations in § 7.

2. The local Newton method. We will consider the problem

$$(2.1a) \quad \mathbf{P}: \min_{x \in \mathbb{R}^n} \psi(x),$$

where

$$(2.1b) \quad \psi(x) = \max_{j \in \mathbf{q}} \max_{t \in [0,1]} \phi^j(x, t),$$

where $\mathbf{q} \triangleq \{1, 2, \dots, q\}$.

In keeping with standard assumptions for Newton's method (see [8]), we make the following hypotheses.

Assumption 2.1. (i) For all $j \in \mathbf{q}$, the functions $\phi^j: \mathbb{R}^n \times [0, 1]$ are twice Lipschitz continuously differentiable in the first argument (uniformly in the second).

(ii) For all $j \in \mathbf{q}$, $\phi^j(\cdot, \cdot)$, $\nabla_x \phi(\cdot, \cdot)$, and $\phi_{xx}^j(\cdot, \cdot)$ are all continuous.

(iii) There exist constants $0 < m \leq M$ such that for all $x \in \mathbb{R}^n$,

$$(2.2) \quad m \|h\|^2 \leq \langle h, \phi_{xx}^j(x, t)h \rangle \leq M \|h\|^2, \quad \forall h \in \mathbb{R}^n, \quad \forall t \in [0, 1], \quad \forall j \in \mathbf{q}.$$

Semi-infinite constrained optimization problems of the form $\min \{f(x) \mid \phi^j(x, t) \leq 0, \text{ for all } j \in \mathbf{q}, \text{ for all } t \in [0, 1]\}$ may be expressed in the form of \mathbf{P} by means of an appropriate exact penalty function. If $f(\cdot)$ is strictly convex and $\phi^j(\cdot, t)$ is convex for all $j \in \mathbf{q}$, and all $t \in [0, 1]$, then the resulting problem \mathbf{P} satisfies Assumption 2.1 (iii). Consequently, Assumption 2.1 is satisfied by many problems, particularly in the areas of optimal control and optimization-based design of linear multivariable control systems. For example, convex optimal control problems, such as the one described in § 6, when expressed in the form of \mathbf{P} satisfy Assumption 2.1 (iii). Also, some algorithms for the solution of more general state-constrained optimal control problems require an efficient subprocedure for solving convex optimal control problems that satisfy

¹ Referring to problem (1.2a), we note that an assumption of strict complementary slackness is highly restrictive for semi-infinite minimax problems because it implies that, at a solution x^* , the active gradients $\nabla_x \phi(x^*, t)$ are affinely independent which, in turn, implies that $\phi(x^*, \cdot)$ has at most $n+1$ maximizers. However, $\phi(x^*, \cdot)$ may well have a *continuum* of maximizers.

Assumption 2.1 (iii); see, for example, [28]. Another important class of optimization problems satisfying Assumption 2.1 (iii) arises in the design of linear multivariable control systems with control and state constraints when “ Q -parameterization” is employed; see [3].

PROPOSITION 2.1. *Suppose that Assumption 2.1 holds and that x^* is the minimizer of $\psi(\cdot)$. Then for all $x \in \mathbb{R}^n$,*

$$(2.3a) \quad \psi(x) - \psi(x^*) \geq \frac{m}{2} \|x - x^*\|^2.$$

Proof. For any $x \in \mathbb{R}^n$, and for any $j \in \mathbf{q}$, let

$$(2.3b) \quad \mathbf{q}^*(x) \triangleq \{j \in \mathbf{q} \mid \psi(x) = \max_{t \in [0,1]} \phi^j(x, t)\},$$

$$(2.3c) \quad T^{*j}(x) \triangleq \{t \in [0,1] \mid \phi^j(x, t) = \psi(x)\}.$$

Then, making use of the second-order expansion formula [7, p. 185] and of (2.2), we obtain that

$$\begin{aligned} \psi(x) - \psi(x^*) &\geq \max_{j \in \mathbf{q}} \max_{t \in [0,1]} \phi^j(x^*, t) - \psi(x^*) + \langle \nabla_x \phi^j(x^*, t), x - x^* \rangle + \frac{m}{2} \|x - x^*\|^2 \\ (2.3d) \quad &\geq \max_{j \in \mathbf{q}^*(x^*)} \max_{t \in T^{*j}(x^*)} \phi^j(x^*, t) - \psi(x^*) + \langle \nabla_x \phi^j(x^*, t), x - x^* \rangle + \frac{m}{2} \|x - x^*\|^2 \\ &= d\psi(x^*, x - x^*) + \frac{m}{2} \|x - x^*\|^2, \end{aligned}$$

where $d\psi(x^*, x - x^*)$ denotes the directional derivative of $\psi(\cdot)$ at x^* , in the direction $(x - x^*)$. Since x^* is the minimizer of $\psi(\cdot)$, $d\psi(x^*, x - x^*) \geq 0$, and (2.3a) follows. \square

By analogy with Newton's method for differentiable functions, we define a quadratic approximation $\hat{\psi}(\cdot | y)$ to $\psi(\cdot)$, around the point y , by

$$(2.4a) \quad \hat{\psi}(x | y) \triangleq \max_{j \in \mathbf{q}} \max_{t \in [0,1]} \phi^j(y, t) + \langle \nabla_x \phi^j(y, t), x - y \rangle + \frac{1}{2} \langle (x - y), \phi_{xx}^j(y, t)(x - y) \rangle.$$

Algorithm 2.1 (Local Newton Method).

Data: $x_0 \in \mathbb{R}^n$.

Step 0. Set $i = 0$.

Step 1. Compute

$$(2.4b) \quad x_{i+1} = \arg \min_{x \in \mathbb{R}^n} \hat{\psi}(x | x_i).$$

Step 2. Replace i by $i + 1$ and go to Step 1.

Proceeding as in the proof of Proposition 2.1, it can be shown that $\hat{\psi}(x | x_i) - \hat{\psi}(x_{i+1} | x_i) \geq \frac{1}{2} m \|x - x_{i+1}\|^2$. Hence we conclude that x_{i+1} is uniquely defined by (2.4b).

To establish the local convergence and rate of convergence of the above algorithm, we need the following lemmas.

LEMMA 2.1. *Suppose that Assumption 2.1 holds. Then there exists a $\hat{K} < \infty$ such that for any $x, y \in \mathbb{R}^n$,*

$$(2.5) \quad |\psi(x) - \hat{\psi}(x | y)| \leq \hat{K} \|x - y\|^3.$$

Proof. Let $L < \infty$ be a common Lipschitz constant for the Hessians $\phi_{xx}^j(\cdot, \cdot)$. Then, making use of second-order expansions, we obtain that

$$\begin{aligned}
 \psi(x) &= \max_{j \in q} \max_{t \in [0,1]} \phi^j(y, t) + \langle \nabla_x \phi^j(y, t)x, x - y \rangle + \frac{1}{2} \langle (x - y), \phi_{xx}^j(y, t)(x - y) \rangle \\
 (2.6) \quad &+ \int_{s \in [0,1]} (1 - s) \langle (x - y), [\phi_{xx}^j(y + s(x - y), t) - \phi_{xx}^j(y, t)](x - y) \rangle ds \\
 &\leq \hat{\psi}(x|y) + \frac{L}{6} \|x - y\|^3.
 \end{aligned}$$

The other half of the inequality in (2.5) follows similarly (with $\hat{K} = L/6$). \square

LEMMA 2.2. Suppose that Assumption 2.1 is satisfied. Let $h: \mathbb{R}^n \rightarrow \mathbb{R}^n$ and $\theta: \mathbb{R}^n \rightarrow \mathbb{R}$ be defined by

$$(2.7a) \quad h(x) \triangleq \arg \min_{h \in \mathbb{R}^n} \hat{\psi}(x + h|x),$$

$$(2.7b) \quad \theta(x) \triangleq \min_{h \in \mathbb{R}^n} \hat{\psi}(x + h|x) - \psi(x).$$

Then (a) both $h(\cdot)$ and $\theta(\cdot)$ are continuous; (b) for all $x \in \mathbb{R}^n$, $d\psi(x, h(x)) \leq \theta(x)$; (c) if x^* is a solution of (2.1a), then both $h(x^*) = 0$ and $\theta(x^*) = 0$; (d) for all $x \neq x^*$, $\theta(x) < 0$.

Proof. (a) Continuity of $\theta(\cdot)$ and $h(\cdot)$ follows from the maximum theorem in [2], strengthened by Assumption 2.1 (iii). The continuity of $h(\cdot)$ again follows from the maximum theorem in [2], which states that it is an upper-semicontinuous set-valued map, and the fact that $h(x)$ is always a singleton.

(b) Clearly, with $q^*(x)$, $T^{*j}(x)$ defined as in (2.3b), (2.3c), we must have that

$$(2.7c) \quad \theta(x) \geq \max_{j \in q^*(x)} \max_{t \in T^{*j}(x)} \phi^j(x, t) - \psi(x) + \langle \nabla_x \phi^j(x, t), h(x) \rangle = d\psi(x, h(x)).$$

Hence $d\psi(x, h(x)) \leq \theta(x)$.

(c) Since $0 \leq d\psi(x^*, h(x^*)) \leq \theta(x^*) \leq 0$, must hold, it follows that both $h(x^*) = 0$ and $\theta(x^*) = 0$.

(d) In view of Assumption 2.1 (iii), x^* is the only point satisfying the first-order necessary and sufficient condition $0 \in \partial\psi(x^*)$, where $\partial\psi(x)$ denotes the Clarke-generalized gradient of $\psi(\cdot)$ at x (for a definition, see [4, p. 27]). Hence this part is a simple generalization of Proposition 5.5 in [22], from which we see that $\theta(x) \leq 0$ for all $x \in \mathbb{R}^n$ and that $\theta(x) = 0$ if and only if $0 \in \partial\psi(x)$. \square

LEMMA 2.3. Suppose that $K \in (0, \infty)$, and that $t, s \geq 0$ are such that

$$(2.8a) \quad t^2 \leq K[(s + t)^3 + s^3],$$

$$(2.8b) \quad 0 \leq t \leq \frac{1}{9K}, \quad 0 \leq s \leq \frac{1}{9K}.$$

Then $t \leq s$ and

$$(2.8c) \quad t \leq 3\sqrt{K} s^{3/2}.$$

Furthermore, if $s \leq \gamma/9K$, with $\gamma \in (0, 1)$, then

$$(2.8d) \quad t \leq \sqrt{\gamma} s.$$

Proof. Let $\lambda \triangleq 1/9K$. Then, from (2.8a), (2.8b),

$$\begin{aligned}
 (2.9a) \quad t^2 &\leq K[2s^3 + 3s^2t + 3st^2 + t^3] \\
 &\leq K[2\lambda s^2 + 3\lambda s^2 + 3\lambda t^2 + \lambda t^2].
 \end{aligned}$$

Hence

$$(2.9b) \quad (1 - 4\lambda K)t^2 \leq 5K\lambda s^2.$$

Since $(1 - 4\lambda K) = 5K\lambda = 5/9$, it follows that $t \leq s$. Hence, replacing t by s in (2.8a), we obtain (2.8c).

Now, if $s \leq \gamma/9K$, then $\sqrt{s} \leq \sqrt{\gamma}/3\sqrt{K}$. Substituting for \sqrt{s} in (2.8c), we obtain (2.8d), which completes our proof. \square

COROLLARY 2.1. *Suppose that $K \in (0, \infty)$, $\gamma \in (0, 1)$, and that $\{\alpha_i\}_{i=0}^\infty$ is a real sequence such that*

$$(2.10a) \quad \alpha_{i+1}^2 \leq K[(\alpha_i + \alpha_{i+1})^3 + \alpha_i^3],$$

$$(2.10b) \quad 0 \leq \alpha_i \leq \frac{\gamma}{9K}, \quad \forall i \in \mathbb{N}.$$

Then $\alpha_i \rightarrow 0$ as $i \rightarrow \infty$ superlinearly, with Q -rate $3/2$.

Proof. It follows from Lemma 2.3 that $\alpha_{i+1} \leq \sqrt{\gamma} \alpha_i$, for all $i \in \mathbb{N}$. Hence $\alpha_i \rightarrow 0$ as $i \rightarrow \infty$. The $3/2$ Q -rate follows from (2.8c). \square

We are finally ready to establish the convergence properties of Algorithm 2.1.

THEOREM 2.1. *There exists a $\rho > 0$ such that if $\|x_0 - x^*\| \leq \rho$, where x^* is the solution of (2.1a), and $\{x_i\}_{i=0}^\infty$ is a sequence constructed by Algorithm 2.1, then, $x_i \rightarrow x^*$, as $i \rightarrow \infty$, Q -superlinearly, with rate at least $3/2$.*

Proof. Let $\alpha = m/2$, then, making use of (2.3a) and (2.4b), we obtain, for $i = 0, 1, 2, \dots$, that

$$(2.11a) \quad \begin{aligned} \alpha \|x_{i+1} - x^*\|^2 &\leq \psi(x_{i+1}) - \psi(x^*) \\ &\leq \psi(x_{i+1}) - \hat{\psi}(x_{i+1} | x_i) + \hat{\psi}(x_{i+1} | x_i) - \psi(x^*) \\ &\leq \psi(x_{i+1}) - \hat{\psi}(x_{i+1} | x_i) + \hat{\psi}(x^* | x_i) - \psi(x^*) \end{aligned}$$

because $\hat{\psi}(x_{i+1} | x_i) \leq \hat{\psi}(x^* | x_i)$, by construction of x_{i+1} . It now follows from (2.11a) and Lemma 2.1 that

$$(2.11b) \quad \begin{aligned} \|x_{i+1} - x^*\|^2 &\leq K[\|x_{i+1} - x_i\|^3 + \|x_i - x^*\|^3] \\ &\leq K[\|(x_{i+1} - x^*) - (x_i - x^*)\|^3 + \|x_i - x^*\|^3] \\ &\leq K[(\|x_{i+1} - x^*\| + \|x_i - x^*\|)^3 + \|x_i - x^*\|^3], \end{aligned}$$

where $K = \hat{K}/\alpha$ and \hat{K} is as in Lemma 2.1.

Next, since by Lemma 2.2, $h(\cdot)$ is continuous and $h(x^*) = 0$, it follows that given $\gamma^* \in (0, 1)$, there exists a $\bar{\rho} > 0$ such that if $\|x_i - x^*\| \leq \bar{\rho}$, then $\|h(x_i)\| = \|x_{i+1} - x_i\| \leq \gamma^*/18K$. Let $\rho^* = \min\{\bar{\rho}, \gamma^*/18K\}$. Then, if $\|x_i - x^*\| \leq \rho^*$, we must have that

$$(2.12) \quad \|x_{i+1} - x^*\| \leq \|x_{i+1} - x_i\| + \|x_i - x^*\| \leq \frac{\gamma^*}{18K} + \rho^* \leq \frac{\gamma^*}{9K}.$$

Letting $t \triangleq \|x_{i+1} - x^*\|$ and $s \triangleq \|x_i - x^*\|$, and making use of Lemma 2.3 (see (2.8b)), we obtain that

$$(2.13) \quad \|x_{i+1} - x^*\| \leq \sqrt{\gamma^*} \|x_i - x^*\|.$$

Hence, if $\|x_0 - x^*\| \leq \rho^*$, then $\|x_i - x^*\| \leq \rho^*$ for all $i = 1, 2, 3, \dots$, and therefore, by (2.13), $\|x_i - x^*\| \rightarrow 0$ as $i \rightarrow \infty$. It now follows from (2.11b) and Corollary 2.1 (via (2.8c)) that

$$(2.14) \quad \|x_{i+1} - x^*\| \leq 3\sqrt{K} \|x_i - x^*\|^{3/2}, \quad \forall i \in \mathbb{N},$$

which completes our proof. \square

3. The global Newton method. We will now present an extension of the globally stabilized Newton method, proposed by Goldstein in [7] (see also [23, p. 33]). Stabilization is achieved by adding an Armijo-type step-size rule to the local Newton method. The rate of convergence of the local Newton method is preserved because, as we will show, near the solution of (2.1a) under Assumption 2.1, the stepsize becomes unity; i.e., the global Newton method reverts to the local Newton method.

Algorithm 3.1 (Global Newton Method).

Data: $x_0 \in \mathbb{R}^n$, $\alpha, \beta \in (0, 1)$, $S \triangleq \{1, \beta, \beta^2, \dots\}$.

Step 0. Set $i = 0$.

Step 1. Compute $\theta(x_i)$, and $h_i = h(x_i)$, according to (2.7b), (2.7a). Stop if $\theta(x_i) = 0$.

Step 2. Compute the stepsize $\lambda_i \triangleq \max \{\lambda \in S \mid \psi(x_i + \lambda h_i) - \psi(x_i) \leq \lambda \alpha \theta(x_i)\}$.

Step 3. Set $x_{i+1} = x_i + \lambda_i h_i$. Replace i by $i + 1$ and go to Step 1.

First, we show that Algorithm 3.1 is globally convergent.

THEOREM 3.1. *Suppose that Assumption 2.1 holds and that x^* is the solution of (2.1a). Then any sequence $\{x_i\}_{i=0}^\infty$, constructed by Algorithm 3.1, converges to x^* .*

Proof. First, because of Assumption 2.1 (iii), the level sets of $\psi(\cdot)$ are bounded and, by construction in Step 2, $\psi(x_{i+1}) < \psi(x_i)$. Hence any sequence $\{x_i\}_{i=0}^\infty$, constructed by Algorithm 3.1, must have accumulation points. For the sake of contradiction, suppose that the sequence $\{x_i\}_{i=0}^\infty$ does not converge to x^* . Then it must have an accumulation point $x^{**} \neq x^*$. By Lemma 2.2, we then have that $\theta(x^{**}) < 0$ and $h(x^{**}) \neq 0$. Since by Lemma 2.2, the directional derivative $d\psi(x^{**}, h(x^{**})) \leq \theta(x^{**}) < 0$, it follows that there is an $s^{**} \in S$ such that

$$(3.1a) \quad \psi(x^{**} + s^{**}h(x^{**})) - \psi(x^{**}) < s^{**}\alpha\theta(x^{**}).$$

Hence, making use of the continuity of $\theta(\cdot)$ and $h(\cdot)$, for all x_i sufficiently near x^{**} , the stepsize $\lambda_i \geq s^{**}$ and $\theta(x_i) < \theta(x^{**})/2$. Therefore, for all such x_i ,

$$(3.1b) \quad \psi(x_i + \lambda_i h(x_i)) - \psi(x_i) \leq \lambda_i \alpha \theta(x_i) \leq s^{**} \alpha \theta(x^{**})/2.$$

Since the sequence $\{\psi(x_i)\}_{i=0}^\infty$ is monotone decreasing, (3.1b) implies that $\psi(x_i) \rightarrow -\infty$ as $i \rightarrow \infty$, which is a contradiction. Hence the theorem must be true. \square

Next, we establish superlinear convergence.

THEOREM 3.2. *Suppose that Assumption 2.1 holds and that x^* is the solution of problem (2.1a). Then any sequence $\{x_i\}_{i=0}^\infty$, constructed by Algorithm 3.1, converges to x^* , superlinearly, with Q -rate at least $3/2$.*

Proof. Since $\{x_i\}_{i=0}^\infty$ converges to x^* by Theorem 3.1, we only need to show that there exists an i_0 such that $\lambda_i = 1$ for all $i \geq i_0$, so that Algorithm 3.1 reduces to Algorithm 2.1, and invoke Theorem 2.1.

Now, it follows from (2.5) that

$$(3.2a) \quad \begin{aligned} \theta(x_i) &= \hat{\psi}(x_i + h(x_i) \mid x_i) - \psi(x_i + h(x_i)) + \psi(x_i + h(x_i)) - \psi(x_i) \\ &\geq \psi(x_i + h(x_i)) - \psi(x_i) - \hat{K} \|h(x_i)\|^3. \end{aligned}$$

Hence

$$(3.2b) \quad \psi(x_i + h(x_i)) - \psi(x_i) \leq \alpha \theta(x_i) + [(1 - \alpha)\theta(x_i) + \hat{K} \|h(x_i)\|^3].$$

Next, we establish a relationship between $\theta(x)$ and $\|h(x)\|$. Since $x + h(x)$ is the minimizer of $\hat{\psi}(\cdot \mid x)$, it follows that it satisfies the first-order condition

$$(3.3a) \quad 0 \in \partial \hat{\psi}(x + h(x) \mid x).$$

For any integer $p \geq 1$, let $\Sigma_p \triangleq \{\mu \in \mathbb{R}^p \mid \sum_{j=1}^p \mu^j = 1, \mu^j \geq 0, \text{ for all } j \in \mathbf{q}\}$. Then it follows from (3.3a), the definition of the generalized gradient $\partial \hat{\psi}(x + h(x) \mid x)$ (see [4]), and the Carathéodory theorem [31], that there exists a multiplier $\mu \in \Sigma_q$, multipliers $\nu_j \in \Sigma_{n+1}$, and $t_j^k \in [0, 1]$, with $j \in \mathbf{q}$ and $k \in \mathbf{n} + \mathbf{1}$, such that

$$(3.3b) \quad 0 = \sum_{j=1}^q \mu^j \sum_{k=1}^{n+1} \nu_j^k [\nabla_x \phi^j(x, t_j^k) + \phi_{xx}^j(x, t_j^k) h(x)],$$

which implies that²

$$(3.3c) \quad h(x) = - \left[\sum_{j=1}^q \mu^j \sum_{k=1}^{n+1} \nu_j^k \phi_{xx}^j(x, t_j^k) \right]^{-1} \sum_{j=1}^q \mu^j \sum_{k=1}^{n+1} \nu_j^k \nabla_x \phi^j(x, t_j^k).$$

Furthermore, the following complementary slackness condition (see (5.12a), (5.12b) in [22]) is satisfied:

$$(3.3d) \quad \begin{aligned} \theta(x) = & \sum_{j=1}^q \mu^j \sum_{k=1}^{n+1} \nu_j^k \left\{ [\phi^j(x, t_j^k) - \psi(x)] + \langle \nabla_x \phi^j(x, t_j^k), h(x) \rangle \right. \\ & \left. + \frac{1}{2} \langle h(x), \phi_{xx}^j(x, t_j^k) h(x) \rangle \right\}. \end{aligned}$$

Substituting for $h(x)$ from (3.3c) into (3.3d), we obtain, in view of Assumption 2.1 (iii), that

$$(3.4) \quad \begin{aligned} \theta(x) = & \sum_{j=1}^q \mu^j \sum_{k=1}^{n+1} \nu_j^k [\phi^j(x, t_j^k) - \psi(x)] \\ & - \frac{1}{2} \left\langle h(x), \left[\sum_{j=1}^q \mu^j \sum_{k=1}^{n+1} \nu_j^k \phi_{xx}^j(x, t_j^k) \right] h(x) \right\rangle \\ \leq & -\frac{m}{2} \|h(x)\|^2, \end{aligned}$$

with the last line following from the fact that $\phi^j(x, t_j^k) - \psi(x) \leq 0$ for all t_j^k .

Substituting for $\theta(x)$ from (3.4) into (3.2b), we obtain

$$(3.5a) \quad \psi(x_i + h(x_i)) - \psi(x_i) \leq \alpha \theta(x_i) - [m(1 - \alpha)/2 - \hat{K} \|h(x_i)\|] \|h(x_i)\|^2.$$

Since $h(x_i) \rightarrow 0$ as $i \rightarrow \infty$, it follows that there exists an i_0 such that for all $i \geq i_0$,

$$(3.5b) \quad \psi(x_i + h(x_i)) - \psi(x_i) \leq \alpha \theta(x_i),$$

i.e., that $\lambda_i = 1$. This completes our proof. \square

4. Implementations of the local algorithm. Note that numerical evaluations of $\psi(x)$ and $\theta(x)$, and hence of $h(x)$, are only approximate for $\psi(x)$ because intervals must be discretized, and for $\theta(x)$ and $h(x)$, because they are defined by a convex optimization problem that can only be solved approximately. Hence both the local and the global Newton methods that we have presented (Algorithms 2.1 and 3.1, respectively) must be viewed as *conceptual*. This brings us to the question of whether it is possible to construct *implementable* algorithms, using some form of discretization of the interval

² Since the $\mu^j \geq 0$ and the $\nu_j^k \geq 0$ in (3.3c), it follows from (2.2) that the matrix

$$\left[\sum_{j=1}^q \mu^j \sum_{k=1}^{n+1} \nu_j^k \phi_{xx}^j(x, t_j^k) \right]$$

is invertible.

$[0, 1]$, appearing in (2.1b), as well as some truncation rule for the algorithm used in computing approximations to $\theta(x)$, which retain the basic properties of Algorithms 2.1 and 3.1.

We need to strengthen Assumption 2.1 by adding the following hypothesis.

Assumption 4.1. There exists a Lipschitz constant $L < \infty$,³ such that for all $x \in \mathbb{R}^n$,

$$(4.1a) \quad |\phi^j(x, t) - \phi^j(x, t')| \leq L|t - t'|, \quad \forall t, t' \in [0, 1], \quad \forall j \in \mathbf{q}.$$

$$(4.1b) \quad \|\nabla_x \phi^j(x, t) - \nabla_x \phi^j(x, t')\| \leq L|t - t'|, \quad \forall t, t' \in [0, 1], \quad \forall j \in \mathbf{q}.$$

$$(4.1c) \quad \|\phi_{xx}^j(x, t) - \phi_{xx}^j(x, t')\| \leq L|t - t'|, \quad \forall t, t' \in [0, 1], \quad \forall j \in \mathbf{q}.$$

We begin with the following observations. For any integer $N > 0$, let⁴

$$(4.2a) \quad T_N \triangleq \{t \mid t = \frac{k}{N}, k = 0, 1, 2, \dots, N\},$$

$$(4.2b) \quad \psi_N(x) \triangleq \max_{j \in \mathbf{q}} \max_{t \in T_N} \phi^j(x, t),$$

$$(4.2c) \quad \hat{\psi}_N(x|y) \triangleq \max_{j \in \mathbf{q}} \max_{t \in T_N} \phi^j(y, t) + \langle \nabla_x \phi^j(y, t), x - y \rangle + \frac{1}{2} \langle (x - y), \phi_{xx}^j(y)(x - y) \rangle,$$

$$(4.2d) \quad h_N(x) \triangleq \arg \min_{h \in \mathbb{R}^n} \hat{\psi}_N(x + h|x),$$

$$(4.2e) \quad \theta_N(x) \triangleq \min_{h \in \mathbb{R}^n} \hat{\psi}_N(x + h|x) - \psi_N(x).$$

The relationships between the quantities associated with the original problem P in (2.1a) and the approximating problems

$$(4.3) \quad P_N : \min_{x \in \mathbb{R}^n} \psi_N(x),$$

are shown in the following result.

PROPOSITION 4.1. Suppose that Assumptions 2.1 and 4.1 hold. Let x^* denote the solution of (2.1), and, for any positive integer N , let x_N^* denote the solution of the discretized problem P_N . Then

$$(4.4a) \quad |\psi(x^*) - \psi_N(x_N^*)| \leq \frac{L}{2N},$$

$$(4.4b) \quad \|x^* - x_N^*\|^2 \leq \frac{2L}{mN},$$

and, for every bounded set $B \subset \mathbb{R}^n$, there exists an $L' < \infty$ such that

$$(4.4c) \quad |\theta(x) - \theta_N(x)| \leq \frac{L'}{2N}, \quad \forall x \in B,$$

$$(4.4d) \quad \|h(x) - h_N(x)\|^2 \leq \frac{L'}{mN}, \quad \forall x \in B.$$

Proof. First, let $x \in \mathbb{R}^n$ be arbitrary. Then, because $T_N \subset [0, 1]$,

$$(4.5a) \quad \frac{-L}{2N} < 0 \leq \psi(x) - \psi_N(x).$$

³ At the expense of some complication, it is possible to carry out the following analysis using local, rather than global, Lipschitz constants.

⁴ Note that there is nothing special about the discretization (4.2a). Any family of discrete sets $T_N \subset T$, where $T \triangleq [0, 1]$ can be used provided that (i) $d(T_N, T) \rightarrow 0$ as $N \rightarrow \infty$, and (ii) for any sequence of integers $\{N_i\}_{i=0}^\infty$, such that $N_{i+1} \geq 2N_i$, $\sum d(T_{N_i}, T) < \infty$, where $d(\cdot, \cdot)$ denotes the Hausdorff distance.

Next, let $\hat{t} \in [0, 1]$ and $\hat{j} \in \mathbf{q}$ be such that $\psi(x) = \phi^{\hat{j}}(x, \hat{t})$. Then there exist points $t' \in T_N$, such that $|t' - \hat{t}| \leq 1/(2N)$ and hence, making use of (4.1),

$$(4.5b) \quad \psi_N(x) \geq \phi^{\hat{j}}(x, t') \geq \phi^{\hat{j}}(x, \hat{t}) - \frac{L}{2N} = \psi(x) - \frac{L}{2N}.$$

Thus we have shown that

$$(4.5c) \quad |\psi(x) - \psi_N(x)| \leq \frac{L}{2N}.$$

As a result, we have

$$(4.5d) \quad \psi(x^*) \leq \psi(x_N^*) \leq \psi_N(x_N^*) + \frac{L}{2N}$$

and

$$(4.5e) \quad \psi_N(x_N^*) \leq \psi_N(x^*) \leq \psi(x^*),$$

which gives us (4.4a).

Next, making use of (2.3a) and (4.5c), we obtain that

$$(4.6a) \quad \frac{m}{2} \|x_N^* - x^*\|^2 \leq \psi(x_N^*) - \psi(x^*) \leq \psi_N(x_N^*) + \frac{L}{2N} - \psi(x^*) \leq \frac{L}{2N} < \frac{L}{N},$$

which establishes (4.4b).

Now suppose $B \subset \mathbb{R}^n$ is bounded, and let $x \in B$. Let the functions $\eta_x^j: \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}$, $j \in \mathbf{q}$, be defined by

$$(4.6b) \quad \eta_x^j(h, t) \triangleq \phi^j(x, t) + \langle \nabla_x \phi^j(x, t), h \rangle + \frac{1}{2} \langle h, \phi_{xx}^j(x, t) h \rangle.$$

Let $G \triangleq \max_{x \in B} \max_{j \in \mathbf{q}} \max_{t \in [0, 1]} \|\nabla_x \phi^j(x, t)\|$. Then it follows from the inequality

$$(4.6c) \quad \begin{aligned} \max_{j \in \mathbf{q}} \max_{t \in [0, 1]} \eta_x^j(h, t) &\geq \max_{j \in \mathbf{q}} \max_{t \in [0, 1]} \phi^j(x, t) - G \|h\| + \frac{m}{2} \|h\|^2 \\ &= \psi(x) - G \|h\| + \frac{m}{2} \|h\|^2 \end{aligned}$$

that if $\|h\| > 2G/m$, then the left-hand side of (4.6c) is greater than $\psi(x)$. Since $\theta(x) \leq 0$, we must have $\|h(x)\| \leq 2G/m$. A similar analysis shows that $\|h_N(x)\| \leq 2G/m$, also. Now suppose that $\|h\| \leq 2G/m$, and let $L_B \triangleq L(1 + 2G/m + 2G^2/m^2)$. Then

$$(4.6d) \quad |\eta_x^j(h, t) - \eta_x^j(h, t')| \leq L_B |t - t'|, \quad \forall t, t' \in [0, 1], \quad \forall j \in \mathbf{q}.$$

It now follows from (2.7b), (4.2e), and (4.5c), and an argument similar to that used to establish (4.4a), (4.4b) that (4.4c), (4.4d) hold, with $L' \triangleq L_B + L$. \square

Comment 4.1. Note that it follows from duality theory [14] that because (4.2e) is a convex problem, the dual of (4.2e) is given by

$$(4.7a) \quad \theta_N(x) = \max_{\mu \in \Sigma_N} J_d(\mu), \quad \Sigma_N \triangleq \left\{ \mu \in \mathbb{R}^q \times \mathbb{R}^{N+1} \left| \sum_{\substack{j \in \mathbf{q} \\ t \in T_N}} \mu^{j,t} = 1, \mu^{j,t} \geq 0 \right. \right\},$$

where

$$(4.7b) \quad J_{d,N}(\mu) \triangleq - \sum_{\substack{j \in \mathbf{q} \\ t \in T_N}} \mu^{j,t} [\psi_N(x) - \phi^j(x, t)] \\ - \frac{1}{2} \left\langle \sum_{\substack{j \in \mathbf{q} \\ t \in T_N}} \mu^{j,t} \nabla_x \phi^j(x, t), \left(\sum_{\substack{j \in \mathbf{q} \\ t \in T_N}} \mu^{j,t} \phi_{xx}^j(x, t) \right)^{-1} \sum_{\substack{j \in \mathbf{q} \\ t \in T_N}} \mu^{j,t} \nabla_x \phi^j(x, t) \right\rangle.$$

Hence, given any set of admissible multipliers $\mu^{j,t}$, we have that $\theta_N(x) \geq J_{d,N}(\mu)$.

Now an algorithm such as the barrier function method in [27], applied to (4.2e), produces not only approximations \hat{h} to $h_N(x)$, but also associated multipliers $\mu^{j,t}$, while an algorithm such as the Levitin–Polyak method [13], applied to (4.7a) produces multipliers $\mu^{j,t}$ that, via (3.3c) can be used to obtain an approximation \hat{h} to $h_N(x)$. Either way, we have that

$$(4.7c) \quad J_{p,N}(\hat{h}) \triangleq \hat{\psi}_N(x + \hat{h}) - \psi_N(x) \geq \theta_N(x) \geq J_{d,N}(\mu).$$

Therefore, given any $\varepsilon > 0$, to determine when such an algorithm has constructed an approximation $h_{N,\varepsilon}(x)$ such that

$$(4.7d) \quad 0 \leq \hat{\psi}_N(x + h_{N,\varepsilon}(x) | x) - \psi_N(x) - \theta_N(x) \leq \varepsilon,$$

we only need to check whether $J_{p,N}(h_{N,\varepsilon}(x)) - J_{d,N}(\mu) \leq \varepsilon$. Hence we see that the construction of such $h_{N,\varepsilon}(x)$ is a finite process. Furthermore, it follows from Proposition 2.1, applied to the function $h \mapsto \hat{\psi}_N(x + h | x)$ and (4.7d), that

$$(4.7e) \quad \varepsilon \geq \hat{\psi}_N(x + h_{N,\varepsilon}(x) | x) - \hat{\psi}_N(x + h_N(x) | x) \geq \frac{m}{2} \|h_{N,\varepsilon}(x) - h_N(x)\|^2.$$

We can now follow one of two alternatives. The first is to decide on an acceptable level of error and then to use (4.4a) or (4.4b) to determine the required level of discretization, i.e., the parameter N . In that case, we propose to solve P_N and we only need to invent a scheme for truncating the computation of $h_N(x)$. Such a scheme is incorporated in the following implementation of the local Newton method for solving problems P_N . The second alternative involves increasing the discretization mesh progressively, rather than using a fixed discretization.. This second alternative will be discussed subsequently.

Algorithm 4.1 (Implementable Finite Minimax Local Newton Method for P_N).

Data: $x_0 \in \mathbb{R}^n$, $\hat{\varepsilon} \in (0, 1)$.

Step 0: Set $i = 0$.

Step 1. Set $\varepsilon = \hat{\varepsilon}$.

Step 2. Compute a vector $h_{N,\varepsilon}(x_i) \in \mathbb{R}^n$ such that⁵

$$(4.8a) \quad 0 \leq \hat{\psi}_N(x_i + h_{N,\varepsilon}(x_i) | x_i) - \psi_N(x_i) - \theta_N(x_i) \leq \varepsilon.$$

Step 3. If

$$(4.8b) \quad \hat{\psi}_N(x_i + h_{N,\varepsilon}(x_i) | x_i) - \psi_N(x_i) \leq -2\varepsilon$$

and

$$(4.8c) \quad \varepsilon \leq \|h_{N,\varepsilon}(x_i)\|^3,$$

set $x_{i+1} = x_i + h_{N,\varepsilon}(x_i)$, $\varepsilon_i = \varepsilon$,⁶ and go to Step 4. Else replace ε by $\varepsilon/2$ and go to Step 2.

Step 4. Replace i by $i + 1$ and go to Step 1.

⁵ Note that $\theta_N(x_i)$ is *not* evaluated. See the paragraph preceding (4.7d).

⁶ Note that the computation of ε_i need not always begin with $\hat{\varepsilon}$. Rather, it is more efficient to start with ε_{i-1} .

Comment 4.2. The structure of the tests (4.8a)–(4.8c) is dictated by the proofs to follow, which establish the $3/2$ rate of convergence of the algorithm. Note that (4.8b) ensures that

$$(4.8d) \quad \varepsilon_i \leq \frac{-\theta_N(x_i)}{2}.$$

Hence, since $\theta_N(x_i) \rightarrow 0$ as $x_i \rightarrow x_N^*$, it follows that Algorithm 4.1 computes approximates $h_N(x_i)$ more accurately as the solution of P_N is approached. Also, if Algorithm 4.1 is initialized with $x_0 = x^*$, it cycles indefinitely up in the loop defined by Steps 2 and 3, reducing ε to zero.

THEOREM 4.1. *There exists a $\rho > 0$ such that if $\|x_0 - x_N^*\| \leq \rho$, where x_N^* is the solution of (4.3), and $\{x_i\}_{i=0}^\infty$ is a sequence constructed by Algorithm 4.1, then, $x_i \rightarrow x_N^*$, as $i \rightarrow \infty$, Q -superlinearly, with rate at least $3/2$.*

Proof. First, we note that (2.5) holds with $\psi(\cdot)$, $\hat{\psi}(\cdot|\cdot)$ replaced by $\psi_N(\cdot)$, $\hat{\psi}_N(\cdot|\cdot)$, respectively, that we may assume that $K \geq 1$ in (2.5), and that Theorem 2.1 equally applies to the obvious simplification of the local Newton method for problem P_N .

Next, for any i , let $x'_{i+1} \triangleq x_i + h_N(x_i)$. Then, by (2.11b),

$$(4.9a) \quad \|x'_{i+1} - x_N^*\|^2 \leq K[\|x'_{i+1} - x_i\|^3 + \|x_i - x_N^*\|^3].$$

Since by (4.7e) and (4.8c), we have that

$$(4.9b) \quad \begin{aligned} \|x_{i+1} - x'_{i+1}\|^2 &= \|h_{N,\varepsilon_i}(x_i) - h_N(x_i)\|^2 \\ &\leq \frac{2\varepsilon_i}{m} \leq \frac{2}{m} \|h_{N,\varepsilon_i}(x_i)\|^3 = \frac{2}{m} \|x_{i+1} - x_i\|^3, \end{aligned}$$

we obtain, using (4.9a) and the fact that $\|x + y\|^p \leq 2^{p-1}[\|x\|^p + \|y\|^p]$, $p = 2, 3$, that, with $K \geq 1$,

$$(4.9c) \quad \begin{aligned} \|x_{i+1} - x_N^*\|^2 &\leq 2[\|x'_{i+1} - x_N^*\|^2 + \|x_{i+1} - x'_{i+1}\|^2] \\ &\leq 2K[\|x'_{i+1} - x_i\|^3 + \|x_i - x_N^*\|^3 + \|x_{i+1} - x'_{i+1}\|^2] \\ &\leq 8K[\|x_{i+1} - x_i\|^3 + \|x_{i+1} - x'_{i+1}\|^3 + \|x_i - x_N^*\|^3 + \|x_{i+1} - x'_{i+1}\|^2]. \end{aligned}$$

Assuming that $x_i - x_N^*$ is sufficiently small, we must have, in view of the fact that by Lemma 2.1 $\theta_N(x_i) \rightarrow 0$ as $x_i \rightarrow x_N^*$ and, by (4.8d), that $2\varepsilon_i/m < 1$ and hence, by (4.9b), that $\|x_{i+1} - x'_{i+1}\| < 1$. Therefore, making use of (4.9b), (4.9c) leads to the conclusion that there exists a $K' \in [16K, \infty)$, depending on m , such that (4.9c) reduces to

$$(4.10a) \quad \begin{aligned} \|x_{i+1} - x_N^*\|^2 &\leq 16K[\|x_{i+1} - x_i\|^3 + \|x_i - x_N^*\|^3 + \|x_{i+1} - x'_{i+1}\|^2] \\ &\leq K'[\|x_{i+1} - x_i\|^3 + \|x_i - x_N^*\|^3]. \end{aligned}$$

The proof can now be completed by using arguments similar to those following (2.11b) in the proof of Theorem 2.1. This requires that we show that given any $\delta > 0$, there exists a $\rho > 0$ such that if $\|x_i - x_N^*\| \leq \rho$, then $\|x_{i+1} - x_i\| \leq \delta$. Making use of the triangle inequality, (4.7d) and (4.8d), we obtain that

$$(4.10b) \quad \begin{aligned} \|x_{i+1} - x_i\| &= \|h_{N,\varepsilon_i}(x_i)\| \\ &\leq \|h_{N,\varepsilon_i}(x_i) - h_N(x_i)\| + \|h_N(x_i)\| \\ &\leq \sqrt{\frac{-2\theta_N(x_i)}{m}} + \|h_N(x_i)\|. \end{aligned}$$

The desired continuity result now follows from Lemma 2.2, and we can now proceed as in the proof of Theorem 2.1, following (2.11b), to complete this proof. \square

There is evidence in the literature (see, e.g., [12], [10]) that we can reduce computing times considerably by increasing the discretization meshsize progressively, rather than using the finest mesh from the very start. This idea is incorporated in the following implementation of the local Newton method, which adjusts both the precision with which successive iterates are computed, as well as the meshsize.

Algorithm 4.2 (Implementable Finite Minimax Local Newton Method for P).

Data. $x_0 \in \mathbb{R}^n$, $\hat{\varepsilon} \in (0, 1)$, $K, \hat{\tau} \ll 1$, $N_0 \in \mathbb{N}$.

Step 0. Set $i = 0$.

Step 1. Set $\varepsilon = \hat{\varepsilon}$, $\tau = \hat{\tau}$, $N = N_i$.⁷

Step 2. Compute a vector $h_{N,\varepsilon}(x_i) \in \mathbb{R}^n$ such that (see Comment 4.1)

$$(4.11a) \quad 0 \leq \hat{\psi}_N(x_i + h_{N,\varepsilon}(x_i) | x_i) - \psi_N(x_i) - \theta_N(x_i) \leq \varepsilon.$$

Step 3. If

$$(4.11b) \quad \hat{\psi}_N(x_i + h_{N,\varepsilon}(x_i) | x_i) - \psi_N(x_i) \leq -2\varepsilon$$

and

$$(4.11c) \quad \varepsilon \leq \|h_{N,\varepsilon}(x_i)\|^3,$$

set $x'_{i+1} = x_i + h_{N,\varepsilon}(x_i)$ and go to Step 4.

Else,

if $\varepsilon \geq \tau$, replace ε by $\varepsilon/2$ and go to Step 2,

else, replace τ by $\tau/2$, N by $2N$, and go to Step 2.

Step 4. If

$$(4.11d) \quad \frac{K}{N} \leq \|x'_{i+1} - x_i\|^3,$$

set $x_{i+1} = x_{i+1}$, $\varepsilon_i = \varepsilon$, $N_i = N$, and go to Step 5. Else, replace N by $2N$ and go to Step 2.

Step 5. Replace i by $i+1$ and go to Step 2.

Comment 4.3. (a) The function of the coefficient K in (4.11d) is to limit the growth of the discretization parameter N . Thus suppose that we are willing to accept a solution corresponding to N^* discretization points, and that our stopping criterion is $\|h_{N^*}(x_i)\| \leq \omega$, with $\omega \ll 1$. Then we would set $K \leq N^* \omega$.

(b) It is possible that Algorithm 4.2 may cycle indefinitely in the loop defined by Step 2–Step 3 or Step 2–Step 4. If this happens, however, then $x_i = x^*$. To see this, note that if this cycling occurs, then one of the tests (4.11b)–(4.11d) must fail infinitely often and as a consequence, $N \rightarrow \infty$ and $\varepsilon \rightarrow 0$. Combining (4.4d) and (4.7e), we have $h_{N,\varepsilon}(x_i) \rightarrow h(x_i)$. Now suppose that the test (4.11b) fails infinitely often. The inequalities (4.4c), (4.5c), and (4.7e) imply that $\hat{\psi}(x_i + h(x_i) | x_i) - \psi(x_i) = 0$, and it follows from Lemma 2.2 that $x_i = x^*$. If either of the other two inequalities (4.11c)–(4.11d) fails infinitely often, it follows immediately that $h_{N,\varepsilon}(x_i) \rightarrow 0$, and so $h(x_i) = 0$, from which the desired conclusion follows.

THEOREM 4.2. *There exists a $\rho > 0$ and an integer $N_0 < \infty$, such that if $\|x_0 - x^*\| \leq \rho$, where x^* is the solution of (2.1a), and $\{x_i\}_{i=0}^\infty$ is a sequence constructed by Algorithm 4.2, then $x_i \rightarrow x^*$ as $i \rightarrow \infty$, Q -superlinearly, with rate at least $3/2$.*

⁷ Although it is reasonable to key ε_i , which controls the precision with which $\theta_{N_i}(x_i)$ is approximated, to the actual value of $\theta_{N_i}(x_i)$, so that ε_i may or may not decrease monotonically, it makes better sense to increase the discretization parameter N_i monotonically.

Proof. First, assuming that $\|x_i - x_{N_i}^*\| \leq 1$, it follows from (4.10) that for some $K' < \infty$, independent of N_i ,

$$(4.12a) \quad \|x_{i+1} - x_{N_i}^*\|^2 \leq K'[\|x_{i+1} - x_i\|^3 + \|x_i - x_{N_i}^*\|^3].$$

Hence, assuming, without loss of generality, that $K' \geq 1$ and that N_0 is sufficiently large to ensure that for all $N_i \geq N_0$, $\|x_{N_i}^* - x^*\| \leq 1$, we get

$$(4.12b) \quad \begin{aligned} \|x_{i+1} - x^*\|^2 &\leq 2[\|x_{i+1} - x_{N_i}^*\|^2 + \|x_{N_i}^* - x^*\|^2] \\ &\leq 2K'[\|x_{i+1} - x_i\|^3 + \|x_i - x_{N_i}^*\|^3 + \|x_{N_i}^* - x^*\|^2] \\ &\leq 8K'[\|x_{i+1} - x_i\|^3 + \|x_i - x^*\|^3 + \|x_{N_i}^* - x^*\|^3 + \|x_{N_i}^* - x^*\|^2] \\ &\leq 16K'[\|x_{i+1} - x_i\|^3 + \|x_i - x^*\|^3 + \|x_{N_i}^* - x^*\|^2]. \end{aligned}$$

Now, it follows from (4.4b) and (4.11d) that

$$(4.12c) \quad \|x_{N_i}^* - x^*\|^2 \leq \frac{2L}{mN_i} \leq \frac{2L}{m} \|x_{i+1} - x_i\|^3.$$

Substituting into (4.12b), we obtain that there exists a $K'' < \infty$, independent of N_i , such that

$$(4.12d) \quad \|x_{i+1} - x^*\|^2 \leq K''[\|x_{i+1} - x_i\|^3 + \|x_i - x^*\|^3].$$

To continue, let $B \triangleq \{x \in \mathbb{R}^n \mid \|x - x^*\| \leq 1\}$. It follows from Proposition 4.1 that there exists a $L' < \infty$ such that (4.4c), (4.4d) hold. As in the proof of Theorem 4.1, we will show that if N_0 is sufficiently large, then given any $\delta > 0$ there exists a $\rho > 0$ (where $\rho \leq 1$ without loss of generality) such that for all $N_i \geq N_0$ and $\|x_i - x^*\| \leq \rho$, $\|x_{i+1} - x_i\| \leq \delta$. Using the triangle inequality, (4.7d) and (4.4d), we obtain that

$$(4.13a) \quad \begin{aligned} \|x_{i+1} - x_i\| &= \|h_{N_i, e_i}(x_i)\| \\ &\leq \|h_{N_i, e_i}(x_i) - h_{N_i}(x_i)\| + \|h_{N_i}(x_i) - h(x_i)\| + \|h(x_i)\| \\ &\leq \sqrt{\frac{2\varepsilon_i}{m}} + \sqrt{\frac{4L'}{mN_i}} + \|h(x_i)\|. \end{aligned}$$

Furthermore, analogously to (4.8d), we have that

$$(4.13b) \quad \|x_{i+1} - x_i\| \leq \sqrt{\frac{|\theta_{N_i}(x_i)|}{m}} + \sqrt{\frac{4L'}{mN_i}} + \|h(x_i)\|.$$

Applying the triangle inequality once more and utilizing (4.4c), we obtain that

$$(4.13c) \quad \begin{aligned} \|x_{i+1} - x_i\| &\leq \sqrt{\frac{[|\theta(x_i)| + |\theta(x_i) - \theta_{N_i}(x_i)|]}{m}} + \sqrt{\frac{4L'}{mN_i}} + \|h(x_i)\| \\ &\leq \sqrt{\frac{[|\theta(x_i)| + L'/N_i]}{m}} + \sqrt{\frac{4L'}{mN_i}} + \|h(x_i)\|. \end{aligned}$$

It now follows from the continuity of $\theta(\cdot)$ and $h(\cdot)$ and the fact that $\theta(x^*) = 0$, $h(x^*) = 0$, that if N_0 is chosen sufficiently large and ρ sufficiently small, then the desired continuity result holds. We can now proceed as in the proof of Theorem 2.1, following (2.11b), to complete the proof. \square

5. Implementation of the global algorithm. To produce an implementation of Algorithm 3.1 (the global Newton method), we propose to use two mechanisms for controlling the precision of the approximations used. The first one will be taken from

Algorithm 4.2, and will ensure superlinear rate of convergence, while the second one, which we will allow to dominate the first one, will be an extension of the mechanism described in Appendix A of [23]. For our case, this extension can be described abstractly as follows. Suppose that for every integer $N \geq N_0 > 0$, $A_N : \mathbb{R}^n \rightarrow 2^{\mathbb{R}^n \times \mathbb{N}}$ (the set of all subsets of \mathbb{R}^n) is a (possibly) set-valued iteration map. The reason for introducing a second integer N' is that given an integer N , the algorithm may be required to increase it to a new value $N' \geq N$ before it can satisfy all the internal tests. Now consider the following algorithm model form solving the problem P in (2.1a).

Algorithm Model 5.1.

Data. $x_0 \in \mathbb{R}^n$, $N_0 \in \mathbb{N}$.

Step 0. Set $i = 0$.

Step 1. Set $N = N_i$.

Step 2. Compute a pair

$$(5.1a) \quad (y, N') \in A_N(x_i).$$

Step 3. If

$$(5.1b) \quad \psi_{N'}(y) - \psi_{N'}(x_i) \leq -\frac{1}{N'},$$

go to Step 4; else, replace N by $2N'$ and go to Step 2.

Step 4. Set $x_{i+1} = y$, $N_{i+1} = N$.

Step 5. Replace i by $i + 1$ and go to Step 1.

Our proof of convergence requires the following technical result.

LEMMA 5.1. *Suppose that the sequences of real numbers $\{\beta_i\}_{i=0}^\infty$ and $\{\eta_i\}_{i=0}^\infty$ satisfy the following conditions: (i) $\eta_i \geq 0$ for all $i \in \mathbb{N}$, (ii) $\sum_{i=0}^\infty \eta_i < \infty$, and (iii) $\beta_{i+1} \leq \beta_i + \eta_i$ for all $i \in \mathbb{N}$. Then either the sequence $\{\beta_i\}_{i=0}^\infty$ converges or $\beta_i \rightarrow -\infty$ as $i \rightarrow \infty$.*

Proof. It is clear from the assumptions that the following holds:

$$(5.2a) \quad \beta_n - \beta_0 = \sum_{i=0}^{n-1} (\beta_{i+1} - \beta_i) \leq \sum_{i=0}^\infty \eta_i.$$

Hence, β_i is bounded from above, and therefore $\hat{\beta} \triangleq \overline{\lim}_{i \rightarrow \infty} \beta_i < \infty$. Obviously, if $\hat{\beta} = -\infty$, then $\beta_i \rightarrow -\infty$ as $i \rightarrow \infty$.

Now suppose that $\hat{\beta} > -\infty$. To prove convergence of the sequence $\{\beta_i\}_{i=0}^\infty$, we will show by contradiction that $\lim_{i \rightarrow \infty} \beta_i = \hat{\beta}$. Thus let $\varepsilon > 0$ be arbitrary and suppose that there is no i_0 such that $\beta_i > \hat{\beta} - \varepsilon$ for all $i > i_0$. Clearly, there exists an i_1 such that $\sum_{k=i}^\infty \eta_k < \varepsilon/2$ for all $i \geq i_1$. It follows from our hypothesis that there exists an $i_2 \geq i_1$ such that $\beta_{i_2} \leq \hat{\beta} - \varepsilon$. It follows from (5.2a) that, for $i > i_2$,

$$(5.2b) \quad \beta_i - \beta_{i_2} = \sum_{k=i_2}^{i-1} (\beta_{k+1} - \beta_k) \leq \sum_{k=i_2}^\infty \eta_k \leq \frac{\varepsilon}{2}.$$

Hence $\beta_i \leq \hat{\beta} - \varepsilon/2$ for all i sufficiently large, which contradicts the definition of $\hat{\beta}$. It follows that $\lim_{i \rightarrow \infty} \beta_i = \hat{\beta}$. \square

THEOREM 5.1. *Suppose that Assumptions 2.1 and 4.1 hold, so that (4.4a) is valid, and that for every $x \in \mathbb{R}^n$ such that $0 \notin \partial\psi(x)$ there exist a $\rho_x > 0$, a $\delta_x > 0$, and an integer $N_x > 0$ such that*

$$(5.3) \quad \psi_{N'}(y') - \psi_{N'}(x') \leq -\delta_x$$

for all $N \geq N_x$, and all $x', y' \in \mathbb{R}^n$ such that $\|x' - x\| \leq \rho_x$, $(y', N') \in A_N(x')$.

Under these assumptions, if $\{x_i\}_{i=0}^\infty, \{N_i\}_{i=0}^\infty$ are a pair of sequences constructed by Algorithm Model 5.1, then $x_i \rightarrow x^*$ and $N_i \rightarrow \infty$ as $i \rightarrow \infty$, where x^* is the solution of (2.1a).

Proof. First, we use Lemma 5.1 to show that the sequence $\{\psi_{N_i}(x_i)\}_{i=0}^\infty$ converges. Let $I \triangleq \{i \in \mathbb{N} \mid N_{i+1} \neq N_i\}$, and let the sequence $\{\eta_i\}_{i=0}^\infty$ be defined by

$$(5.4a) \quad \eta_i \triangleq \begin{cases} L/N_i, & i \in I, \\ 0, & \text{otherwise,} \end{cases}$$

where L is the Lipschitz constant in Assumption 2.1(i). Now suppose that $i \in I$, and let $i_+ \triangleq \min \{j \in I \mid j > i\}$. Since by construction we have that $N_{i_+} \geq 2N_i$, it follows that

$$(5.4b) \quad \sum_{i=0}^\infty \eta_i = \sum_{i \in I} \eta_i \leq \sum_{k=0}^\infty \frac{L}{2^k N_0} < \infty.$$

Hence the sequence $\{\eta_i\}_{i=0}^\infty$ is summable. From (4.5c), we have that for all $i \in I$

$$(5.4c) \quad |\psi_{N_{i+1}}(x_i) - \psi_{N_i}(x_i)| \leq |\psi_{N_{i+1}}(x_i) - \psi(x_i)| + |\psi(x_i) - \psi_{N_i}(x_i)| \leq \frac{L}{2N_{i+1}} + \frac{L}{2N_i} \leq \frac{L}{N_i}.$$

Clearly, for all $i \in \mathbb{N} \setminus I$, i.e., such that $N_{i+1} = N_i$, $|\psi_{N_{i+1}}(x_i) - \psi_{N_i}(x_i)| = 0$. Hence for all $i \in \mathbb{N}$,

$$|\psi_{N_{i+1}}(x_i) - \psi_{N_i}(x_i)| \leq |\psi_{N_{i+1}}(x_i) - \psi(x_i)| + |\psi(x_i) - \psi_{N_i}(x_i)| \leq \frac{L}{2N_{i+1}} + \frac{L}{2N_i} \leq \frac{L}{N_i}.$$

Consequently, using (5.1b), we obtain that

$$(5.4d) \quad \begin{aligned} \psi_{N_{i+1}}(x_{i+1}) - \psi_{N_i}(x_i) &\leq \psi_{N_{i+1}}(x_{i+1}) - \psi_{N_{i+1}}(x_i) + \psi_{N_{i+1}}(x_i) - \psi_{N_i}(x_i) \\ &\leq -\frac{1}{N_{i+1}} + \eta_i \leq \eta_i. \end{aligned}$$

Furthermore, it follows from Proposition 2.1, (4.5c), and the fact that $N_{i+1} \geq N_i$ that

$$(5.4e) \quad \psi_{N_i}(x) \geq \psi(x^*) + \frac{m}{2} \|x - x^*\|^2 - \frac{L}{2N_0}.$$

Hence the sequence $\{\psi_{N_i}(x_i)\}_{i=0}^\infty$ satisfies the hypotheses of Lemma 5.1 and, in addition, it is bounded below. We therefore conclude that it converges.

Next, we show that $N_i \rightarrow \infty$. If this is not true, then since $N_{i+1} \geq N_i$ we must have $N_i = N^*$ for i sufficiently large. For such i , (5.1b) implies that

$$(5.4f) \quad \psi_{N^*}(x_{i+1}) - \psi_{N^*}(x_i) \leq -\frac{1}{N^*},$$

which contradicts the fact that the sequence $\{\psi_{N_i}(x_i)\}_{i=0}^\infty$ converges.

As a consequence of (5.4e), the sequence $\{x_i\}_{i=0}^\infty$ is bounded, and hence it must have accumulation points. For the sake of contradiction, suppose that the sequence $\{x_i\}_{i=0}^\infty$ does not converge to x^* . Then it must have an accumulation point $x^{**} \neq x^*$. Let $K \subset \mathbb{N}$ be the set of indices of the subsequence converging to x^{**} .

Since $x^{**} \neq x^*$, we have $0 \notin \partial\psi(x^{**})$, from which it follows by assumption that there exists a $\delta > 0$ such that for $i \in K$ sufficiently large,

$$(5.4g) \quad \psi_{N_{i+1}}(x_{i+1}) - \psi_{N_{i+1}}(x_i) \leq -\delta.$$

Referring to (5.4d), we see that for $i \in K$ sufficiently large,

$$(5.4h) \quad \psi_{N_{i+1}}(x_{i+1}) - \psi_{N_i}(x_i) \leq \psi_{N_{i+1}}(x_{i+1}) - \psi_{N_{i+1}}(x_i) + \psi_{N_{i+1}}(x_i) - \psi_{N_i}(x_i) \leq -\delta + \eta_i.$$

However, since $\eta_i \rightarrow 0$, (5.4h) contradicts the fact that the sequence $\{\psi_{N_i}(x_i)\}_{i=0}^\infty$ converges. Hence $0 \in \partial\psi(x^*)$. \square

The above algorithm model and our desire to retain the superlinear rate of convergence of the implementation of the local Newton method, Algorithm 4.2, leads us to the following algorithm.

Algorithm 5.2 (Implementable Global Newton Method for P).

Data. $x_0 \in \mathbb{R}^n$, $N_0 \in \mathbb{N}$, $\alpha, \beta \in (0, 1)$, $\varepsilon_0 > 0$, $K, \hat{\tau} \ll 1$, $S \triangleq \{1, \beta, \beta^2, \dots\}$.

Step 0. Set $i = 0$.

Step 1. Set $N = N_i$.

Step 2. Set $\varepsilon = \varepsilon_0$, $\tau = \hat{\tau}$.

Step 3. Compute a vector $h_{N,\varepsilon}(x_i) \in \mathbb{R}^n$ such that (see Comment 4.1)

$$(5.3a) \quad 0 \leq \hat{\psi}_N(x_i + h_{N,\varepsilon}(x_i) | x_i) - \psi_N(x_i) - \theta_N(x_i) \leq \varepsilon.$$

Step 4. If

$$(5.3b) \quad \hat{\psi}_N(x_i + h_{N,\varepsilon}(x_i)) - \psi_N(x_i) \leq -2\varepsilon$$

and

$$(5.3c) \quad \varepsilon \leq \|h_{N,\varepsilon}(x_i)\|^3,$$

go to Step 5.

Else,

if $\varepsilon \geq \tau$, replace ε by $\varepsilon/2$ and go to Step 3,

else, replace τ by $\tau/2$, N by $2N$, and go to Step 3.

Step 5. If

$$(5.3d) \quad \frac{K}{N} \leq \|h_{N,\varepsilon}(x_i)\|^3,$$

set $h_i = h_{N,\varepsilon}(x_i)$, and go to Step 6. Else, replace N by $2N$ and go to Step 3.

Step 6. Compute the stepsize

$$(5.3e) \quad \lambda_i \triangleq \max \{ \lambda \in S / \psi_N(x_i + \lambda h_i) - \psi_N(x_i) \leq \lambda \alpha [\hat{\psi}_N(x_i + h_i | x_i) - \psi_N(x_i)] \}.$$

Step 7. If

$$(5.3f) \quad \psi_N(x_i + \lambda h_i) - \psi_N(x_i) \leq -\frac{1}{N},$$

set $x_{i+1} = x_i + \lambda_i h_i$, $N_{i+1} = N$, and go to Step 8; else, replace N by $2N$ and go to Step 3.

Step 8. Replace i by $i+1$ and go to Step 1.

Theorem 5.1 can now be used to show that sequences constructed by Algorithm 5.2 converge to the solution x^* , while Theorem 4.2 leads to the conclusion that these sequences converge superlinearly.

THEOREM 5.2. *Suppose that Assumptions 2.1 and 4.1 hold and that x^* is the solution of problem (2.1a). Then any sequence $\{x_i\}_{i=0}^\infty$, constructed by Algorithm 5.2, converges to x^* superlinearly, with Q -rate at least $3/2$.*

Proof. The proof consists of two parts. The first part shows that the algorithm map $A_N(\cdot)$ satisfies the hypotheses of Theorem 5.1, from which we conclude that $x_i \rightarrow x^*$ as $i \rightarrow \infty$. The second part shows that for i sufficiently large, the stepsize λ_i is 1. In this case, Algorithm 5.2 reduces to the local Algorithm 4.2, and we may apply Theorem 4.2 (along with the fact that $N_i \rightarrow \infty$) to conclude that the iterates converge superlinearly.

(a) To show that $A_N(\cdot)$ satisfies the hypotheses of Theorem 5.1, suppose that $x \in \mathbb{R}^n$ is such that $0 \notin \psi(x)$. Then Lemma 2.2(d) implies that $\theta(x) < 0$. By continuity, there exist $\rho > 0$, $\delta > 0$ such that for all $x' \in B(x, \rho) \triangleq \{x' \in \mathbb{R}^n \mid \|x' - x\| \leq \rho\}$, $\theta(x') \leq -\delta < 0$. Furthermore, since $B(x, \rho)$ is bounded, (4.4c) implies that there exists an $\bar{N} \in \mathbb{N}$ such that for all $N \geq \bar{N}$ and $x' \in B(x, \rho)$ $\theta_N(x') \leq -\delta/2$.

Suppose that $x' \in B(x, \rho)$ and that the algorithm map $A_N(\cdot)$ produces a pair $(y', N') \in A_N(x')$ (with $N' \geq N$), and an ε satisfying the tests in Steps 3 and 4. Then from (5.3b) we have

$$(5.5) \quad \theta_{N'}(x') \leq \hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x') \leq -2\varepsilon,$$

which yields $-\theta_{N'}(x')/2 \geq \varepsilon$. Furthermore, using (5.3a), we obtain that

$$(5.6) \quad \hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x') \leq \varepsilon + \theta_{N'}(x') \leq \frac{\theta_{N'}(x')}{2}.$$

It follows from the convexity of the function $\lambda \mapsto \hat{\psi}_{N'}(x' + \lambda h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x')$ that for all $\lambda \in [0, 1]$,

$$(5.7) \quad \hat{\psi}_{N'}(x' + \lambda h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x') \leq \lambda [\hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x')].$$

By Lemma 2.1, applied to the functions $\psi_{N'}$, $\hat{\psi}_{N'}$, we have the estimate

$$(5.8) \quad |\hat{\psi}_{N'}(x' + \lambda h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x' + \lambda h_{N',\varepsilon}(x'))| \leq \hat{K} \lambda^3 \|h_{N',\varepsilon}(x')\|^3.$$

Combining (5.7) and (5.8) yields

$$(5.9) \quad \begin{aligned} & \psi_{N'}(x' + \lambda h_{N',\varepsilon}(x')) - \psi_{N'}(x') \\ & \leq \hat{K} \lambda^3 \|h_{N',\varepsilon}(x')\|^3 + \lambda [\hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x')]. \end{aligned}$$

Using (5.6) and (5.9), we obtain that for all $\lambda \in [0, 1]$,

$$(5.10) \quad \begin{aligned} & \psi_{N'}(x' + \lambda h_{N',\varepsilon}(x')) - \psi_{N'}(x') - \alpha \lambda [\hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x')] \\ & \leq \hat{K} \lambda^3 \|h_{N',\varepsilon}(x')\|^3 + (1 - \alpha) \lambda [\hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x')] \\ & = \lambda ((1 - \alpha) [\hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x')] + \hat{K} \lambda^2 \|h_{N',\varepsilon}(x')\|^3) \\ & \leq \lambda \left((1 - \alpha) \frac{\theta_{N'}(x')}{2} + \hat{K} \lambda^2 \|h_{N',\varepsilon}(x')\|^3 \right) \\ & \leq \lambda \left(-(1 - \alpha) \frac{\delta}{4} + \hat{K} \lambda^2 \|h_{N',\varepsilon}(x')\|^3 \right). \end{aligned}$$

Combining the facts that $h(\cdot)$ is continuous and $B(x, \rho)$ is bounded with (4.4d) and (4.7d), we conclude that there exists a constant $\Delta < \infty$ such that for all $x' \in B(x, \rho)$ and all $N' \geq N$, $\|h_{N',\varepsilon}(x')\| \leq \Delta$. Thus (5.10) yields

$$(5.11) \quad \begin{aligned} & \psi_{N'}(x' + \lambda h_{N',\varepsilon}(x')) - \psi_{N'}(x') - \alpha \lambda [\hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x')] \\ & \leq \lambda \left(-(1 - \alpha) \frac{\delta}{4} + \hat{K} \lambda^2 \Delta^3 \right), \end{aligned}$$

from which we conclude that there exists a $0 < \lambda_0 < 1$ such that for all $x' \in B(x, \rho)$, the stepsize λ' produced by Step 6 satisfies $\lambda' \geq \lambda_0$. Consequently, using (5.3e), (5.6), and the fact that $\theta_N(x') \leq -\delta/2$, we obtain that for all $x' \in B(x, \rho)$ and all $N' \geq N \geq \bar{N}$,

$$(5.12) \quad \begin{aligned} & \psi_{N'}(x' + \lambda' h_{N',\varepsilon}(x')) - \psi_{N'}(x') \leq \alpha \lambda_0 [\hat{\psi}_{N'}(x' + h_{N',\varepsilon}(x') \mid x') - \psi_{N'}(x')] \\ & \leq -\frac{\alpha \lambda_0 \delta}{4}. \end{aligned}$$

If we let $N_x = \bar{N}$, $\rho_x = \rho$, and $\delta_x = \alpha\lambda_0\delta/4$, we see that the map $A_N(\cdot)$ satisfies the conditions of Theorem 5.1. Hence $x_i \rightarrow x^*$, and as a consequence of Step 7, we see that $N_i \rightarrow \infty$.

(b) To complete the proof, we must show that for i sufficiently large, the stepsize λ_i is 1. If we set $\lambda = 1$ in the second to last line of (5.10) we obtain that

$$(5.13) \quad \begin{aligned} & \psi_{N_{i+1}}(x_i + h_i) - \psi_{N_{i+1}}(x_i) - \alpha[\hat{\psi}_{N_{i+1}}(x_i + h_i | x_i) - \psi_{N_{i+1}}(x_i)] \\ & \leq \left((1 - \alpha) \frac{\theta_{N_{i+1}}(x_i)}{2} + \hat{K} \|h_i\|^3 \right), \end{aligned}$$

where h_i is as defined in Step 5 of Algorithm 5.2. Using a result similar to (3.4) we obtain that $\theta_{N_{i+1}}(x_i) \leq -(m/2)\|h_{N_{i+1}}(x_i)\|^2$. Using (4.7d), (5.3c), and the fact that $\|x\|^2 \geq \frac{1}{2}\|y\|^2 - \|x - y\|^2$, we obtain that

$$(5.14) \quad \|h_{N_{i+1}}(x_i)\|^2 \geq \frac{1}{2}\|h_i\|^2 - \|h_i - h_{N_{i+1}}(x_i)\|^2 \geq \frac{1}{2}\|h_i\|^2 - \frac{2\varepsilon_i}{m} \geq \frac{1}{2}\|h_i\|^2 - \frac{2}{m}\|h_i\|^3.$$

Hence we obtain the bound

$$(5.15) \quad \theta_{N_{i+1}}(x_i) \leq \frac{-m}{4}\|h_i\|^2 + \|h_i\|^3.$$

Substituting this bound into (5.13), we obtain that

$$(5.16) \quad \begin{aligned} & \psi_{N_{i+1}}(x_i + h_i) - \psi_{N_{i+1}}(x_i) - \alpha[\hat{\psi}_{N_{i+1}}(x_i + h_i | x_i) - \psi_{N_{i+1}}(x_i)] \\ & \leq \frac{(1 - \alpha)}{2} \left(\frac{-m}{4}\|h_i\|^2 + \|h_i\|^3 \right) + \hat{K}\|h_i\|^3. \end{aligned}$$

From (4.13b) we note that $h_i \rightarrow 0$ as $i \rightarrow \infty$, and hence the right-hand side of (5.16) is negative for i sufficiently large. Hence $\lambda_i = 1$ for i sufficiently large. This completes the proof. \square

6. A numerical example. We will present the solution of a semi-infinite minimax problem that was constructed by converting an optimal control problem with control and state-space constraints, by means of an exact penalty function, into an unconstrained minimax problem.

The original optimal control problem is as follows:

$$(6.1) \quad \min_{x \in \mathbb{R}^{21}} \left\{ \frac{1}{2}(\|z(x, 1)\|^2 + 10^{-6}\|x\|^2) \mid z^2(x, t) - 0.15 \leq 0, \forall t \in [0, 20], x_j^2 - 1 \leq 0, \forall j \in \mathbf{p} \right\},$$

where $\mathbf{p} \triangleq \{0, \dots, 20\}$, and $z: \mathbb{R}^{21} \times [0, 20] \rightarrow \mathbb{R}^2$ solves the differential equation

$$(6.2) \quad \frac{d}{dt} z(x, t) = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} z(x, t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(x, t),$$

where $x(z, 0) = (-2.5, 0)^T$, and the control $u: \mathbb{R}^{21} \times [0, 20] \rightarrow \mathbb{R}$ is defined by the 21-dimensional parameter vector x , through linear interpolation, as follows: for any $j = 0, 1, \dots, 19$, and $t = \lambda j + (1 - \lambda)(j + 1)$, $u(x, j) = \lambda x_j + (1 - \lambda)x_{j+1}$. Note that the dynamics in (6.1) are so simple that we can integrate them exactly for the resulting piecewise linear control.

To convert the above optimal control problem into unconstrained form, we use a parameter of 100 in the exact penalty function, and obtain a problem of the form (2.1a), (2.1b), with $q = 23$, and the functions $\phi^j(\cdot, \cdot)$, $j \in \mathbf{q}$ defined by

$$(6.3a) \quad \phi^1(x, t) \triangleq \frac{1}{2}(\|z(x, 1)\|^2 + 10^{-6}\|x\|^2),$$

$$(6.3b) \quad \phi^2(x, t) \triangleq \phi^1(x, t) + 100(x_2(x, t/20) - 0.15),$$

$$(6.3c) \quad \phi^j(x, t) \triangleq \phi^1(x, t) + 100(x_{j-2}^2 - 1), \quad \forall j \in \{3, \dots, 23\},$$

with $t \in [0, 1]$. The algorithm was started from the initial point $x_0 = (1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1)$.

Figures 1 and 2 present our computational results. Figure 1 presents plots of the control sequence x^i versus i , while Fig. 2 presents phase-plane plots, i.e., plots of $x^1(t)$ versus $x^2(t)$, traditional in the control literature. We see from these plots that problem (6.1) is solved in two iterations, at the end of which the original semi-infinite constraint, $z^2(u, t) - 0.15 \leq 0$ for all $t \in [0, 20]$ has been satisfied. The initial value of the cost was $\psi_5(x_0) = 3.12501$, the final value of the cost was $\psi_{28}(2) = 2.09003 \times 10^{-7}$; the final value of the optimality function was $\theta_{28}(x_2) = -2.01827 \times 10^{-7}$. To limit the growth of the discretization index, we set $K = 10^{-20}$ in (5.3d) so as to be able to satisfy (5.3d) with $N = 100$ when $\|h_{N,\varepsilon}\| 10^{-10}$. We set $N_0 = 5$, and the algorithm set $N_1, N_2 = 28$.

FIG. 1. Plots of control sequence at iterations 0, 1, 2.

FIG. 2. Phase-plane plots at iterations 0, 1, 2.

To reduce the looping in the computation of the discretization parameter N , instead of simply doubling it whenever the test (5.3d) failed to be satisfied, we set the next value to the integer part of $\max \{6.4 \times 10^{-19} / \|h_{N,\epsilon}\|^3, 1.1N\}$.

We compute the search direction $h_{N,\epsilon}(x)$, satisfying (5.3a), by applying to the dual of problem (4.2e) the rapidly converging Levitin–Polyak constrained Newton method [13].

To illustrate how inequality (5.3a) is solved, consider the primal problem (4.2e). When expanded, it assumes the form

$$(6.4a) \quad \theta \triangleq \min_{h \in \mathbb{R}^n} \max_{j \in \mathbf{q}} f^j + \langle g_j, h \rangle + \frac{1}{2} \langle h, H^j h \rangle.$$

The dual of this problem is

$$(6.4b) \quad \theta = -\min_{\mu \in \Sigma} J_d(\mu),$$

where $J_d(\mu) \triangleq -\sum_{j=1}^q \mu^j f^j + \frac{1}{2} \langle \sum_{j=1}^q \mu^j g_j, (\sum_{j=1}^q \mu^j H^j)^{-1} \sum_{j=1}^q \mu^j g_j \rangle$, and Σ is the unit simplex in \mathbb{R}^n . The formula for the second derivative matrix of the dual cost function, required by the Levitin–Polyak method, is given in an appendix in [26].

When applied to the dual problem, the Levitin–Polyak method computes a sequence $\{\mu_i\}_{i=0}^\infty$, which converges quadratically to \hat{h} , a solution of the dual problem (6.4b). Furthermore, if we define $h: \Sigma \rightarrow \mathbb{R}^n$ by

$$(6.5) \quad h(\mu) \triangleq \left(\sum_{j=1}^q \mu^j H^j \right)^{-1} \sum_{j=1}^q \mu^j g_j,$$

it is easy to show that the corresponding sequence $\{h(\mu_i)\}_{i=0}^\infty$ converges to \hat{h} , the unique solution of the primal problem (6.4a). Noting that the iterations of the Levitin–Polyak algorithm generate both upper and lower bounds on θ , as given by

$$(6.6a) \quad J_p(\mu_i) \geq \theta \geq -J_d(\mu_i),$$

where

$$(6.6b) \quad J_p(\mu_i) \triangleq \max_{j \in \mathbf{q}} f^j + \langle g_j, h(\mu_i) \rangle + \frac{1}{2} \langle h(\mu_i), H^j h(\mu_i) \rangle,$$

and making use of the fact that $J_p(\mu_i) - J_d(\mu_i) \rightarrow 0$, we see that a point $h(\mu_i)$ satisfying (5.3a) can be computed in a finite number of iterations of the Levitin–Polyak method.

7. Conclusion. We have used a new and very simple proof technique to show that natural *conceptual* extensions of Newton's method converge superlinearly on a class of semi-infinite minimax problems. This technique has also enabled us to construct rate-preserving *implementations* of these extensions. Our implementations are interesting for two reasons: first, they account for all the significant approximations involved, and second, they do not require the knowledge of the Lipschitz constants or eigenvalue bounds associated with the problem functions and their first- and second-order derivatives.

Apart from the intrinsic interest that a theoretical extension of Newton's method to semi-infinite optimization possesses, our numerical results show that it is a viable procedure for the solution of such classical problems as state- and control-constrained optimal control problems with linear dynamics.

Acknowledgments. We thank the referees for their most helpful comments.

A PROBLEM DECOMPOSITION TECHNIQUE WITH APPLICATION TO THE OPTIMAL DISTRIBUTION OF ENZYMES*

DAVID E. STEWART†

Abstract. A model for enzyme-driven reactions in steady state is given which involves the enzyme concentrations linearly and the reactant concentrations nonlinearly. From this model an optimization problem is set up for the enzyme distributions, which involves only nonnegativity and integral constraints. Using some earlier theoretical work of Holm aker and Stewart [*SIAM J. Control Optim.* 25 (1987), pp. 1032–1052], a problem decomposition principle is proven. Results for a single enzyme-driven reaction is then used to produce a dynamic programming technique for trees and chains of enzyme driven reactions. This is extended to give a technique for determining the optimal amount of each enzyme subject to an overall cost limit. Numerical results are given for a test problem of the author's devising.

Key words. enzyme kinetics, optimal control, decomposition techniques

1. Introduction. In this paper we consider a class of optimisation problems related to enzyme-driven reactions in one-dimensional continuous flow reactors. This model seems to be appropriate for modelling reactions in liver tubules [2] and for “packed bed” reactors, where a solution containing reactants flows past enzymes (which are held fixed) that act on the reactants. Assuming that the system has negligible diffusion *along* the liver tubule or packed bed compared to convection, and diffusion dominates *across* the tubule or packed bed, which is in a steady state, then each reactant concentration satisfies a first-order *ODE*. It is assumed that the enzyme concentrations appear linearly in the ODEs, but that each reactant concentration may appear nonlinearly. The enzyme concentrations are considered to be the control functions and are subject only to nonnegativity and integral constraints. That is, negative concentrations are not allowed, and a fixed amount of each enzyme is available. If a variable amount is available, then there is usually a cost for the enzyme, and by analysing first the case where the amount of enzyme is fixed, the case where the amount of enzyme available is variable can be analysed as is done in §7. The crucial point is that there is no *a priori* bound on the concentrations of enzymes or on the mixtures of enzymes allowed.

The first such problem to appear in the literature to the author's knowledge is due to Bass, Bracken, and Vyborny[2], which deals with a problem involving two enzymes and is of interest in relation to enzyme distribution in the liver. In [2], the following model for the liver's elimination of a drug Phenacitin was used. Justification for this model can be found in [1]. Diagrammatically, the elimination proceeded in two steps $P \rightarrow M \rightarrow \hat{M}$, where P represents Phenacitin, M a metabolite, and \hat{M} a “conjugated” metabolite which could be safely eliminated from the body. We also use $P(x)$ to denote the *concentration* of Phenacitin at a point at distance x along a liver tubule. Similarly for $M(x)$ and $\hat{M}(x)$. If we let $f(x)$, $g(x)$ denote the concentrations of the first and second enzymes and $\alpha(P(x))$ denote the reaction rate of the first reaction step per

*Received by the editors April 25, 1990; accepted for publication (in revised form) February 18, 1991.

† University of Queensland, Department of Mathematics, St. Lucia, Queensland 4072, Australia.

unit enzyme, and $\beta(M(x))$ denote the reaction rate of the second reaction step per unit enzyme, then the differential equations for this system are:

$$\begin{aligned} P' &= dP/dx = -f(x)\alpha(P(x)), & P(0) &= P_0 \\ M' &= dM/dx = +f(x)\alpha(P(x)) - g(x)\beta(M(x)), & M(0) &= 0 \\ \hat{M}' &= d\hat{M}/dx = & +g(x)\beta(M(x)), & \hat{M}(0) = 0. \end{aligned}$$

The issue in [2] was that the metabolite M is toxic to the body, and therefore the output from the liver should contain as little of it as possible, while still maintaining the overall ability of the body to eliminate Phenacitin. This essentially means that the amount of conjugated metabolite \hat{M} in the output should be maximized, given the amount of each enzyme to be used.

The question of whether the this optimization is actually performed in nature is a matter for experimental verification, although it is not uncommon in theoretical biology to assume that over time nature finds "solutions" that are nearly optimal for the problems that organisms face. Of course, if the system under study (e.g., a packed bed reactor) is designed by humans, then it is the duty of the relevant engineer(s) to ensure that it operates as close to optimal as is possible.

Bass, Bracken, and Vyborny [2] used an integral equation approach to obtain results for certain cases. Fink [5] used a similar approach to obtain more complete results, while Holm aker [6] also obtained further results, but used Pontryagin's maximum principle instead. Holm aker and Stewart [7] used an invariance result to reduce a much larger class of such problems to a problem with (pointwise) bounded controls; they then used this approach to solve a problem involving three enzymes. The class of optimal control problems considered in [7] is to realize

$$(1.1a) \quad \min_{y,u} C(y,u) \quad \text{where } C(y,u) = g(y(L)) + \int_0^L d(y(x))^T u(x) dx$$

subject to

$$(1.1b) \quad \begin{aligned} y' &= dy/dx = A(y)u, & y(0) &\in K; & K &\text{compact} \\ u(x) &\geq 0 \quad \text{for all } x \in [0, L], & \int_0^T u(x) dx &= a \geq 0 \end{aligned}$$

where $y \in C([0, L], \mathbf{R}^n)$ and $u \in L^1([0, L], \mathbf{R}^m)$. Here $u_j(x)$ is to be interpreted to be the concentration of enzyme j , and $y_i(x)$ is the concentration of reactant i , at distance x from the point of inflow of material into the reactor or liver.

In this paper we wish to extend the invariance result of Holm aker and Stewart [7], and to show how this extension can be used to decompose (and thus solve) a class of large-scale optimal enzyme distribution problems. The key to decomposing such problems is to split the system into two parts, the first of which is independent of the second, and the second depends on the first only through a single scalar function of a suitable form. If the optimization criterion only directly involves the second subsystem, then the connection between the two subsystems can be reduced to a single number, which is the integral of the input to the second subsystem. In relation to enzyme driven reactions, this means that the problem of optimizing (say) the chain of reactions $P \rightarrow M \rightarrow \hat{M}$ can be reduced to that of maximizing the output of $P \rightarrow M$, and then maximizing the output of $\theta \rightarrow M \rightarrow \hat{M}$ where the θ is the source of M ; it is the *total* input from θ that is important, not how it is done.

More precisely, we assume that the optimal control problem has the following structure. Realize

$$(1.2a) \quad \min_{y_1, y_2, u_1, u_2} C(y_2, u_2) \quad \text{where } C(y_2, u_2) = g(y_2(L)) + \int_0^L d(y_2(x))^T u_2(x) dx$$

subject to

$$(1.2b) \quad \begin{aligned} S_1: y_1' &= A_1(y_1) u_1, & y_1(0) &\in K_1 \subset \mathbf{R}^{n_1} \\ u_1(x) &\geq 0, & \int_0^L u_1(x) dx &= a_1 \geq 0 \in \mathbf{R}^{m_1} \\ S_2: y_2' &= A_2(y_2) u_2 + c(y_1)^T u_1 \cdot b(y_2), & y_2(0) &\in K_2 \subset \mathbf{R}^{n_2} \\ u_2(x) &\geq 0, & \int_0^L u_2(x) dx &= a_2 \geq 0 \in \mathbf{R}^{m_2} \end{aligned}$$

where K_1, K_2 are compact and $c(y_1) \geq 0$ for all $y_1 \in \mathbf{R}^{n_1}$. The single scalar function that is treated as input to the second subsystem is $\theta(x) = c(y_1(x))^T u_1(x)$ which we assume to be nonnegative. Even if only $\lambda = \int_0^L \theta(x) dx$ is known, the infimum of $C(y_2, u_2)$ can be computed. Thus the optimization problems for the two subsystems can then (almost) be treated in isolation, and the results can be recombined by means of an extension of the invariance result in [7].

If the system of enzyme-driven reactions forms a chain or a tree, then the above decomposition techniques can be applied repeatedly until we only consider one-enzyme systems, possibly with an external input. The biologically important case of an enzyme-driven *cycle* is not decomposable by this scheme. The analytical results for one-enzymes systems that are known (see [2], [5], [7]) are extended and used to develop numerical methods for solving the optimal distribution problem for trees of reactions by means of dynamic programming. These results and methods can be extended to deal with the problem of finding the optimal *amount* of each enzyme, as well as the optimal distribution, according to some total enzyme cost criterion. These numerical methods have been implemented, and the numerical results obtained for a test problem are presented.

2. Previous theoretical results. In this section we wish to review the theoretical results of Holm aker and Stewart [7] that are of relevance here. Holm aker and Stewart [7] consider optimal control problems of the form

$$(2.1a) \quad \min_{y, u} C(y, u) \quad \text{where } C(y, u) = g(y(L)) + \int_0^L d(y(x))^T u(x) dx$$

subject to

$$(2.1b) \quad \begin{aligned} y' &= dy/dx = A(y) u, & y(0) &\in K; & K &\text{compact} \\ u(x) &\geq 0 \quad \text{for all } x \in [0, L], & \int_0^T u(x) dx &= a \geq 0 \end{aligned}$$

where $y \in C([0, L], \mathbf{R}^n)$ and $u \in L^1([0, L], \mathbf{R}^m)$. We make the following assumptions throughout the remainder of the paper:

- (1) $A: \mathbf{R}^n \rightarrow \mathbf{R}^{n \times m}$ is Lipschitz continuous.
- (2) K is compact and path connected.
- (3) g and d are continuous functions.

In [7], assumption (1) was weakened to simply requiring that A be continuous and satisfy a boundedness condition of the form

$$y^T A(y) u \leq C_0(1 + \|y\|^2) \|u\| \quad \text{for all } y \in \mathbf{R}^n \text{ and } u \in (\mathbf{R}_+)^m.$$

Assumption (2) can also be weakened to only requiring that K is compact and has only finitely many path-connected components. Then each path-connected component can be handled separately.

A major difficulty in applying the standard qualitative optimal control theory to (2.1) is that for each x the set of admissible control values $u(x)$ is not compact. To get around this difficulty, Holm aker and Stewart [7] showed that (2.1) is essentially invariant under the following transformation, which is called a *time transform* in [7].

DEFINITION 2.1. For $u, v \geq 0$, $u, v \in L^1(0, L)^m$ and absolutely continuous functions y, z on $[0, L]$, (v, z) is said to be an x -transform of (u, y) if there is an absolutely continuous (AC) nondecreasing surjective function $\phi: [0, L] \rightarrow [0, L]$ such that

$$(2.3a) \quad v(x) = u(\phi(x)) \cdot \phi'(x) \quad \text{for a.a. } x \in [0, L]$$

$$(2.3b) \quad z(x) = y(\phi(x)) \quad \text{for all } x \in [0, L].$$

Furthermore, we say that v is an x -transform of u if (2.3a) holds.

The following results were then proven in [7]:

LEMMA 2.2. If (v, z) is an x -transform of (u, y) and (u, y) satisfies (2.1b) then so does (v, z) , and further, $C(u, y) = C(v, z)$.

Proof. See [7, Lem. 2.1]. \square

The next result shows that we do not need to look at controls that are outside a weakly compact set.

LEMMA 2.3. If (v, z) satisfies (2.1b) then (v, z) is a time transform of some (u, y) that satisfies (2.1b) and

$$(2.4) \quad \sum_{i=1}^m u_i(x) = L^{-1} \sum_{i=1}^m a_i \quad \text{for all } x.$$

Proof. See [7, Lem. 2.2]. \square

Combining these results gives Theorem 2.4.

THEOREM 2.4. Solutions exist for problem (2.1).

Proof. A detailed proof is given in [6, Thm. 2.1]. The basic idea is sketched here.

By Lemma 2.3 and Lemma 2.2 it is sufficient to restrict attention to the set defined by (2.4) and $u(x) \geq 0$, which is closed and bounded in $L^1[0, L]$. By Alaoglu's theorem, this set is weak* compact in $L^1[0, L]$. As the functional defined by (2.1) is weak* continuous, it follows that there must be a minimum. \square

3. Problems with input. Consider the problem of realizing

$$(1.2a) \quad \min_{y_1, y_2, u_1, u_2} C(y_2, u_2) \quad \text{where } C(y_2, u_2) = g(y_2(L)) + \int_0^L d(y_2(x))^T u_2(x) dx$$

subject to

$$(1.2b) \quad \begin{aligned} S_1: y_1' &= A_1(y_1) u_1, & y_1(0) &\in K_1 \subset \mathbf{R}^{n_1} \\ u_1(x) &\geq 0, & \int_0^L u_1(x) dx &= a_1 \geq 0 \in \mathbf{R}^{m_1} \\ S_2: y_2' &= A_2(y_2) u_2 + c(y_1)^T u_1 \cdot b(y_2), & y_2(0) &\in K_2 \subset \mathbf{R}^{n_2} \\ u_2(x) &\geq 0, & \int_0^L u_2(x) dx &= a_2 \geq 0 \in \mathbf{R}^{m_2} \end{aligned}$$

where K_1, K_2 are compact and $c(y_1) \geq 0$ for all $y_1 \in \mathbf{R}^{n_1}$. This system can be split into two parts, S_1 and S_2 , and here we concentrate on S_2 . Let $\theta(x) = c(y_1(x))^T u_1(x)$,

so that under the assumption that $c(y_1) \geq 0$ for all $y_1 \in \mathbf{R}^{n_1}$, $\theta(x) \geq 0$ for all $x \in [0, L]$ and $\theta \in L^1[0, L]$. Then given optimal y_1 and u_1 , (1.2) is equivalent to the problem of realizing

$$(3.1a) \quad \min_{y_2, u_2} C(u_2, y_2)$$

subject to

$$(3.1b) \quad \begin{aligned} y_2' &= A_2(y_2) u_2 + b(y_2) \theta(x), & y_2(0) &\in K_2 \\ u_2(x) &\geq 0, & \int_0^L u_2(x) dx &= a_2 \geq 0. \end{aligned}$$

The subscripts will be dropped for the remainder of this section as it will be understood that we are working with subsystem S_2 . As θ is fixed (by subsystem S_1), the results of the previous section are not applicable and the minimum may not be attainable. However, replacing the minimum by an infimum does give a well-posed problem. Let

$$C^*(\theta) = \inf \{ C(u, y) \mid (u, y) \text{ satisfy (3.1)} \}.$$

THEOREM 3.1. *$C^*(\theta)$ is finite. Further, there is a function F^* such that for every $\theta \geq 0$ in L^1 , $C^*(\theta) = F^*(\lambda)$ where $\lambda = \int_0^L \theta(x) dx$.*

Proof. The proof of this result involves showing that $C^*(\theta)$ is equal to

$$(3.2a) \quad \min_{u, \phi, y} C(u, y)$$

subject to

$$(3.2b) \quad \begin{aligned} y' &= \bar{A}(y) \bar{u}(x) = \begin{bmatrix} A(y) & b(y) \end{bmatrix} \begin{bmatrix} u(x) \\ \phi(x) \end{bmatrix}, & y(0) &\in K \\ \begin{bmatrix} u(x) \\ \phi(x) \end{bmatrix} &\geq 0, & \int_0^L \begin{bmatrix} u(x) \\ \phi(x) \end{bmatrix} dx &= \begin{bmatrix} a \\ \lambda \end{bmatrix} \geq 0. \end{aligned}$$

Once this is done, the quantity $C^*(\theta)$ depends only on the parameters on which the optimisation problem (3.2) depends; in particular, it does not depend on the form of the function θ , but only on $\lambda = \int_0^L \theta(x) dx$.

First, by Theorem 2.4 the minimum for (3.2) can be obtained at some (u^*, ϕ^*, y^*) . But as any triple (u, θ, y) that satisfies (3.1) also satisfies (3.2), it follows that $C(u^*, y^*) \leq C(u, y)$ and so $C(u^*, y^*) \leq C^*(\theta)$. The infimum therefore is finite.

We now show that $C^*(\theta) = C(u^*, y^*)$. Define $F^*(\lambda)$ to be the optimal value of (3.1) for given $\lambda \geq 0$.

To show this equality holds for $C^*(\theta)$ it suffices to show that there is a sequence (u_ϵ, y_ϵ) as $\epsilon \downarrow 0$ such that $(u_\epsilon, \theta, y_\epsilon)$ satisfies (3.1b) and $C(u_\epsilon, y_\epsilon) \rightarrow C(u^*, y^*)$. This will be done using x -transforms.

Note that if $\lambda = 0$ then $\theta = \phi^* = 0$ almost everywhere, and hence $C(u^*, y^*) = C^*(\theta)$ and there is nothing left to prove. We therefore consider the case that $\lambda > 0$.

Firstly, define

$$\phi_\epsilon^*(x) = \max(\phi^*(x), \epsilon) - \eta(\epsilon)$$

where $\eta(\epsilon)$ is chosen so that

$$\int_0^L \phi_\epsilon^*(x) dx = \int_0^L \theta(x) dx = \lambda.$$

Now $\phi^* > 0$ on a set of positive measure, so $\max(\phi^*, \epsilon) < \phi^* + \epsilon$ on a set of positive measure. Thus

$$\begin{aligned}\lambda &= \int_0^L \phi_\epsilon^*(x) dx = \int_0^L \max(\phi^*(x), \epsilon) dx - \eta(\epsilon)L \\ &< \int_0^L \phi^*(x) dx + (\epsilon - \eta(\epsilon))L \\ &= \lambda + (\epsilon - \eta(\epsilon))L.\end{aligned}$$

Hence $\epsilon > \eta(\epsilon)$ and so $\phi_\epsilon^*(x) \geq \epsilon - \eta(\epsilon) > 0$ for all x . Define

$$\psi_\epsilon(x) = \int_0^x \phi_\epsilon^*(\xi) d\xi, \quad \psi(x) = \int_0^x \theta(\xi) d\xi.$$

Now both ψ and ψ_ϵ are nondecreasing AC functions with

$$\psi'_\epsilon = \phi_\epsilon^* \geq \epsilon - \eta(\epsilon) > 0 \quad \text{a.e.}$$

Thus ψ_ϵ is invertible and ψ_ϵ^{-1} is Lipschitz with constant $1/(\epsilon - \eta(\epsilon))$. Now consider the transformation

$$\tilde{\psi}_\epsilon = \psi_\epsilon^{-1} \circ \psi: [0, L] \rightarrow [0, L].$$

This is well defined as the range of ψ is $[0, \lambda]$, which is the domain of ψ_ϵ^{-1} . Furthermore, ψ_ϵ is AC and nondecreasing as both ψ_ϵ^{-1} and ψ are both nondecreasing and AC [8, Ex. 6, p. 333]. Finally, noting that $\tilde{\psi}_\epsilon(0) = 0$ and $\tilde{\psi}_\epsilon(L) = L$, we see that $\tilde{\psi}_\epsilon$ is also surjective.

We can now set

$$\begin{aligned}u_\epsilon(x) &= u^*(\tilde{\psi}_\epsilon(x)) \cdot \tilde{\psi}'_\epsilon(x) \quad \text{for a.a. } x \in [0, L] \\ \theta_\epsilon(x) &= \phi_\epsilon^*(\tilde{\psi}_\epsilon(x)) \cdot \tilde{\psi}'_\epsilon(x) \quad \text{for a.a. } x \in [0, L] \\ y_\epsilon(x) &= y_\epsilon^*(\tilde{\psi}_\epsilon(x)) \quad \text{for all } x \in [0, L]\end{aligned}$$

where y_ϵ^* is defined through the differential equation

$$y_\epsilon^{*'} = A(y_\epsilon^*) u^*(x) + b(y_\epsilon^*) \phi_\epsilon^*(x), \quad y_\epsilon^*(0) = y^*(0).$$

Thus $(u_\epsilon, \theta_\epsilon, y_\epsilon)$ is an x -transform of $(u^*, \phi_\epsilon^*, y_\epsilon^*)$, and so by Lemma 2.2, $C(u_\epsilon, y_\epsilon) = C(u^*, y_\epsilon^*)$ and $(u_\epsilon, \theta_\epsilon, y_\epsilon)$ satisfies (3.1b).

We now show that $\theta_\epsilon = \theta$ almost everywhere. To do this we apply the chain rule for AC functions [8, Thm. 6.95, p. 325] to $\tilde{\psi}_\epsilon = \psi_\epsilon^{-1} \circ \psi$. This gives $\tilde{\psi}'_\epsilon(x) = \theta(x)/\phi_\epsilon^*(\tilde{\psi}_\epsilon(x))$ for almost all x . Substituting this into the above formula for θ_ϵ then shows that $\theta = \theta_\epsilon$ almost everywhere.

To complete the proof, we now note that $\phi_\epsilon^* \rightarrow \phi^*$ uniformly, and so $y_\epsilon^* \rightarrow y^*$ uniformly, as $\epsilon \downarrow 0$. Hence

$$\lim_{\epsilon \downarrow 0} C(u_\epsilon, y_\epsilon) = \lim_{\epsilon \downarrow 0} C(u_\epsilon^*, y_\epsilon^*) = C(u^*, y^*)$$

as is required. \square

It should also be noted that F^* is, in fact, a continuous function. This follows from the more general result below.

THEOREM 3.2. *In (2.1) the minimum value of $C(u, y)$ is a continuous function of $a \in (\mathbf{R}_+)^m$.*

Proof. We reformulate (2.1) by setting $D = \text{diag}(a_1, \dots, a_m)$ and $u = D\eta$. Then (2.1) becomes the problem of realising

$$(3.3a) \quad \min_{\eta, y} C(\eta, y, a) \quad \text{where } C(\eta, y, a) = g(y(L)) + \int_0^L d(y(x))^T D \eta(x) dx$$

subject to

$$(3.3b) \quad \begin{aligned} y' &= A(y)D\eta, & y(0) &\in K \\ \eta(x) &\geq 0, & \int_0^L \eta(x) dx &= 1 \quad \text{for } i = 1, \dots, m \\ \sum_{i=1}^m \eta_i(x) &= m/L & \text{for all } x &\in [0, L]. \end{aligned}$$

The last equality can be included by Lemma 2.2 and Lemma 2.3.

We now need to show that the minimum value for (3.3) is a continuous function of $a \in (\mathbf{R}_+)^m$. This follows from a standard argument using the compactness of the set of admissible (η, y) pairs and continuity of C .

Firstly, the set of admissible (η, y) is compact, where η is in L^1 with the weak* topology, and y is in $C[0, L]$ with the usual strong topology. Further, $C(\eta, y, a)$ is continuous in $L^1[0, L] \times C[0, L] \times \mathbf{R}^m$ with these topologies. Thus $\min\{C(\eta, y, a) \mid (\eta, y) \text{ satisfy (3.3b)}\}$ depends continuously on a . \square

4. Properties of x -transforms and x -equivalences. Consider again a decomposable system (1.2) where we can compute the $F^*(\cdot)$ function. Suppose further that we know the optimal λ that maximizes $F^*(\lambda)$ and a pair (u_1, y_1) that achieves $\lambda = \int_0^L c(y_1(x))^T u_1(x) dx$. Put $\theta_1 = c(y_1)^T u_1$ and let (u_2, θ_2, y_2) be the optimal solution of the system with input (3.1). If θ_1 and θ_2 are not equal, then the results obtained so far allow us to compute the optimal value for (1.2), but not the controls that achieve it. We need some way of “matching” θ_1 and θ_2 . To do this “matching” step we need to extend the relation of “ x -transforms” to an equivalence relation, which we call “ x -equivalence.”

DEFINITION 4.1. A pair (u, y) is said to be x -equivalent to (v, z) if they have an x -transform in common. That is, there are AC nondecreasing surjective functions $\phi_1, \phi_2: [0, L] \rightarrow [0, L]$ such that

$$\begin{aligned} u(\phi_1(x)) \cdot \phi_1'(x) &= v(\phi_2(x)) \cdot \phi_2'(x) & \text{for a.a. } x \in [0, L] \\ y(\phi_1(x)) &= z(\phi_2(x)) & \text{for all } x \in [0, L]. \end{aligned}$$

Similarly, u and v are said to be x -equivalent if only the former equality holds.

We will show that θ_1 and θ_2 are, in fact, x -equivalent since they are both non-negative and have the same integral on $[0, L]$. Then by applying the appropriate x -transforms to (u_1, y_1) and (u_2, θ_2, y_2) respectively we can obtain a “matched” pair of systems and controls so that the complete system (1.2) can be solved. But to prove the x -equivalence of θ_1 and θ_2 we need the following result.

THEOREM 4.2. *If $\phi, \psi: [0, L] \rightarrow [0, a]$ are two continuous nondecreasing surjective functions then there are nondecreasing surjective Lipschitz functions $\rho, \sigma: [0, L] \rightarrow [0, L]$ such that*

$$\phi \circ \rho = \psi \circ \sigma.$$

Proof. We construct a sequence of pairs of functions $\rho_n, \sigma_n: [0, L] \rightarrow [0, L]$ that are Lipschitz with constant 2. Let $h_n = L/2^n$. We now construct $\rho_n(k h_n)$ and $\sigma_n(k h_n)$ for $k = 0, 1, \dots, 2^n$ by induction, and the value of ρ_n and σ_n on the remainder of $[0, L]$ is defined by linear interpolation on these values. We will prove the following, for our construction, by induction on k :

- (1) $\phi(\rho_n(k h_n)) = \psi(\sigma_n(k h_n))$.
- (2) $|\rho_n((k+1)h_n) - \rho_n(k h_n)| \leq 2 h_n$ and $|\sigma_n((k+1)h_n) - \sigma_n(k h_n)| \leq 2 h_n$.
- (3) $\rho_n((k+1)h_n) \geq \rho_n(k h_n)$ and $\sigma_n((k+1)h_n) \geq \sigma_n(k h_n)$.

For $k = 0$ we set $\rho_n(0) = \sigma_n(0) = 0$. Then (1) holds for $k = 0$ as $\phi(0) = \psi(0) = 0$.

Now suppose that $\rho_n(k h_n)$ and $\sigma_n(k h_n)$ have been constructed. We construct $\rho_n((k+1)h_n)$ and $\sigma_n((k+1)h_n)$ according to the following cases:

Case 1. If $\rho_n(k h_n) + 2h_n, \sigma_n(k h_n) + 2h_n \geq L$ then put $\rho_n((k+1)h_n) = \sigma_n((k+1)h_n) = L$. Then (1) holds as $\phi(L) = \psi(L) = a$. Items (2) and (3) hold by inspection.

Case 2a. If $\rho_n(k h_n) + 2h_n < L$ but $\sigma_n(k h_n) + 2h_n \geq L$ then put

$$\rho_n((k+1)h_n) = \rho_n(k h_n) + 2h_n$$

$$\sigma_n((k+1)h_n) = \min\{s \mid \psi(s) = \phi(\rho_n((k+1)h_n)) \text{ and } s \geq \sigma_n(k h_n)\}.$$

As $\psi(L) = \phi(L) \geq \phi(\rho_n((k+1)h_n))$ and $\psi(\sigma_n(k h_n)) = \phi(\rho_n(k h_n)) \leq \phi(\rho_n((k+1)h_n))$, a minimising $s \leq L$ must exist, and (2) holds. Item (1) follows directly from the definition of $\sigma_n((k+1)h_n)$ and (3) is apparent on inspection.

Case 2b. If $\sigma_n(k h_n) + 2h_n < L$ but $\rho_n(k h_n) + 2h_n \geq L$ then apply Case 2a, but with the roles of ρ_n, σ_n and ϕ, ψ reversed.

Case 3. Assume that $\rho_n(k h_n) + 2h_n, \sigma_n(k h_n) + 2h_n < L$, and assume without loss of generality that

$$\phi(\rho_n(k h_n) + 2h_n) \leq \psi(\sigma_n(k h_n) + 2h_n).$$

(Otherwise reverse the roles of ρ_n, σ_n and ϕ, ψ .) Then put

$$\rho_n((k+1)h_n) = \rho_n(k h_n) + 2h_n$$

$$\sigma_n((k+1)h_n) = \min\{s \mid \psi(s) = \phi(\rho_n((k+1)h_n)) \text{ and } s \geq \sigma_n(k h_n)\}.$$

By the same reasoning as in Case 2 there must be a minimising s where $\sigma_n(k h_n) \leq s \leq \sigma_n(k h_n) + 2h_n$, so (2) holds. Items (1) and (3) hold as in Case 2.

We now show that $\rho_n(k h_n) + \sigma_n(k h_n) \geq 2h_n$ by induction. Note that from this it follows that $\rho_n(L) + \sigma_n(L) = 2L$, and so $\rho_n(L) = \sigma_n(L) = L$.

For $k = 0$ the result is true since $\rho_n(0) = \sigma_n(0) = 0$.

Suppose true for k ; we now show the assertion holds for $k+1$. In Case 1, $\rho_n((k+1)h_n) + \sigma_n((k+1)h_n) = L + L \geq (k+1)h_n$. In Cases 2 and 3 either

$$\rho_n((k+1)h_n) = \rho_n(k h_n) + 2h_n \quad \text{or} \quad \sigma_n((k+1)h_n) = \sigma_n(k h_n) + 2h_n.$$

Since both ρ_n and σ_n are nondecreasing, the desired result follows.

Noting that $\rho_n, \sigma_n: [0, L] \rightarrow [0, L]$ are nondecreasing, surjective functions with Lipschitz constant 2, by the Arzelà–Ascoli theorem there must be a convergent subsequence with a limit (ρ, σ) . By the properties of uniform convergence, both ρ and σ are nondecreasing, surjective functions $[0, L] \rightarrow [0, L]$.

To show that $\phi \circ \rho = \psi \circ \sigma$, let $t = kL/2^n$ for some $k = 0, \dots, 2^n$. Then for $m \geq n$, $\phi(\rho_m(t)) = \psi(\sigma_m(t))$ and taking $m \rightarrow \infty$ in the above subsequence gives

$$\phi(\rho(t)) = \psi(\sigma(t)).$$

By continuity of ϕ, ψ, ρ and σ and that $\{kL/2^n \mid k = 0, \dots, 2^n, n \geq 0\}$ is dense in $[0, L]$ it follows that $\phi \circ \rho = \psi \circ \sigma$ everywhere. \square

COROLLARY 4.3. If $\theta, \eta: [0, L] \rightarrow \mathbf{R}_+$ are in $L^1[0, L]$ and

$$\int_0^L \theta(x) dx = \int_0^L \eta(x) dx$$

then θ and η are x -equivalent.

Proof. Let

$$\phi(x) = \int_0^x \theta(\xi) d\xi, \quad \psi(x) = \int_0^x \eta(\xi) d\xi.$$

Then by Theorem 4.2, there are nondecreasing, surjective Lipschitz functions $\rho, \sigma: [0, L] \rightarrow [0, L]$ such that

$$\phi \circ \rho = \psi \circ \sigma.$$

These composite functions are AC, since ρ and σ are both AC and nondecreasing. Differentiating this equation by the chain rule gives

$$\phi'(\rho(x)) \cdot \rho'(x) = \psi'(\sigma(x)) \cdot \sigma'(x) \quad \text{for a.a. } x$$

which is the desired x -equivalence. \square

Thus, θ_1 and θ_2 are x -equivalent as we wished to show. The following result is of independent interest.

COROLLARY 4.4. The relation “ x -equivalence” is an equivalence relation.

Proof. From the definition of “ x -equivalence” it is clear that it is both reflexive ((u, y) is always x -equivalent to (u, y)) and symmetric ((u, y) is x -equivalent to (v, z) implies the reverse x -equivalence). To complete the proof it suffices to show that “ x -equivalence” is a transitive relation.

Let (u_1, y_1) and (u_2, y_2) be x -equivalent; (u_2, y_2) and (u_3, y_3) be x -equivalent. We show that (u_1, y_1) and (u_3, y_3) are x -equivalent. By definition of x -equivalence there exist AC nondecreasing, surjective functions $\rho_1, \rho_2, \sigma_1, \sigma_2: [0, L] \rightarrow [0, L]$ such that

$$\begin{aligned} y_1(\rho_1(x)) &= y_2(\sigma_1(x)) & y_2(\rho_2(x)) &= y_3(\sigma_2(x)) \\ u_1(\rho_1(x))\rho_1'(x) &= u_2(\sigma_1(x))\sigma_1'(x) & u_2(\rho_2(x))\rho_2'(x) &= u_3(\sigma_2(x))\sigma_2'(x) \end{aligned}$$

for almost all $x \in [0, L]$. By Theorem 4.2 there are AC nondecreasing surjective functions $\omega_1, \omega_2: [0, L] \rightarrow [0, L]$ where $\sigma_1 \circ \omega_1 = \rho_2 \circ \omega_2$. Then if $\phi_1 = \rho_1 \circ \omega_1$ and $\phi_2 = \sigma_2 \circ \omega_2$ we find that

$$\begin{aligned} y_1(\phi_1(x)) &= y_1(\rho_1(\omega_1(x))) \\ &= y_2(\sigma_1(\omega_1(x))) = y_2(\rho_2(\omega_2(x))) \\ &= y_3(\sigma_2(\omega_2(x))) = y_3(\phi_2(x)). \end{aligned}$$

Similar arguments will show that $u_1(\phi_1(x))\phi_1'(x) = u_3(\phi_2(x))\phi_2'(x)$ by means of the chain rule for AC functions. \square

We can now return to the problem of how analysis of the two subsystems can be combined to provide a complete solution for the entire system (1.2). Note first, that whatever u_1 and y_1 are chosen satisfying (1.2b), the infimum of $C(u_2, y_2)$ over (u_2, y_2) satisfying (1.2b) depends only on $\lambda = \int_0^L \theta(x) dx = \int_0^L c(y_1(x))^T u_1(x) dx$. What, then, is the set of attainable values of λ ? By continuous dependence arguments it is easy to see that λ is a continuous function of (u_1, y_1) , weakly in u_1 . Further, by the results of §2 the set of admissible (u_1, y_1) is compact in $L^1[0, L] \times C[0, L]$, with $L^1[0, L]$ having the weak* topology. Also, as K_1 is connected, so is the set of admissible pairs (u_1, y_1) . Thus the set of attainable values of λ is a compact connected set; that is, this

set is a finite closed interval $[\lambda_{\min}, \lambda_{\max}]$. The extreme values λ_{\min} and λ_{\max} can be determined by solving the appropriate optimisation problems for subsystem S_1 :

$$\max / \min \int_0^L c(y_1(x))^T u_1(x) dx$$

subject to

$$\begin{aligned} y_1' &= A_1(y_1) u_1, & y_1(0) &\in K_1 \\ u_1(x) &\geq 0, & \int_0^L u_1(x) dx &= a_1. \end{aligned}$$

These problems are of the form of (2.1), and so by (3.2) solutions exist.

Now, for any value of λ , the infimum of $C(u_2, y_2)$ over (u_2, y_2) satisfying (1.2b) is given by $F^*(\lambda)$. We have shown that F^* is a continuous function, and as λ ranges over a compact set $[\lambda_{\min}, \lambda_{\max}]$ this function must have a minimum value $F^*(\lambda^*)$. By using the pathwise connectedness of the set of admissible (u_1, y_1) we can construct a pair (\bar{u}_1, \bar{y}_1) that satisfies (1.2b) and $\int_0^L c(\bar{y}_1(x))^T \bar{u}_1(x) dx = \lambda^*$. We also have a triple $(\bar{u}_2, \theta_2, \bar{y}_2)$ that solves (3.1) with $\lambda = \lambda^*$.

As

$$\int_0^L \theta_1(x) dx = \int_0^L \theta_2(x) dx = \lambda^*$$

θ_1 and θ_2 are x -equivalent; let $\phi_1, \phi_2: [0, L] \rightarrow [0, L]$ be two AC nondecreasing, surjective functions such that

$$(\theta_1 \circ \phi_1) \cdot \phi_1' = (\theta_2 \circ \phi_2) \cdot \phi_2' \quad \text{a.e.}$$

Then setting

$$\begin{aligned} y_1^*(x) &= \bar{y}_1(\phi_1(x)) & y_2^*(x) &= \bar{y}_2(\phi_2(x)) \\ u_1^*(x) &= \bar{u}_1(\phi_1(x))\phi_1'(x) & u_2^*(x) &= \bar{u}_2(\phi_2(x))\phi_2'(x) \end{aligned}$$

gives a solution to (1.2); $(u_1^*, u_2^*, y_1^*, y_2^*)$ satisfies (1.2b) and $C(u_2^*, y_2^*) = F^*(\lambda^*)$ is the required minimum.

5. Results for one-enzyme systems. Under the assumptions described in the introduction for a liver tubule or a packed-bed reactor, where diffusion along the flow is negligible, a one-enzyme subsystem is described by a pair of *ODEs*, one describing the concentration of the reactant R , and another for the product P , which are assumed to have reached steady state. The enzyme concentration at a distance x from the entrance to the reactor is $f(x)$; the reaction rate per unit enzyme is given by $\alpha(R)$; and we allow an "input" (possibly zero) of reactant denoted $\theta(x)$ per unit length. The *ODEs* are then

$$\begin{aligned} (5.1) \quad dR/dx &= \theta(x) - f(x)\alpha(R) \\ dP/dx &= f(x)\alpha(R). \end{aligned}$$

It is assumed that α satisfies the following properties:

$$\begin{aligned} \alpha(0) &= 0 \\ R > 0 &\implies \alpha(R) > 0 \\ \alpha &\text{ is a Lipschitz } C^1 \text{ function.} \end{aligned}$$

Also, f is assumed to satisfy

$$f(x) \geq 0 \quad \text{for all } x \in [0, L]$$

$$f \in L^1[0, L], \quad \int_0^L f(x) dx = q \geq 0.$$

This “input” θ may be the product of some other reaction or reactions.

Here we consider the problem of realising

$$(5.2a) \quad \max_{f, \theta} P(L)$$

subject to (5.1) and

$$(5.2b) \quad \begin{aligned} R(0) &= R_0, & P(0) &= P_0 \\ f(x) &\geq 0, & \theta(x) &\geq 0 \quad \text{for all } x \in [0, L], \\ \int_0^L f(x) dx &= q, & \int_0^L \theta(x) dx &= \lambda. \end{aligned}$$

Since $P(L) + R(L) = P(0) + R(0) + \lambda$, maximising $P(L)$ is equivalent to minimising $R(L)$.

The work of this section uses the ideas and analysis of Holm aker and Stewart[6] rather heavily, although [6] did not deal with problems where $R_0 > 0$. Consequently, some additional results are proven to complete the application.

Let

$$G^*(\lambda, q) = \min_{f, \theta} R(L) \quad \text{subject to (5.2b)}$$

$$F^*(\lambda, q) = \max_{f, \theta} P(L) \quad \text{subject to (5.2b)}.$$

In this section we show that

$$F^*(\lambda, q) = \max_{0 \leq \rho \leq \lambda + R_0} F(\rho, \lambda, q)$$

$$G^*(\lambda, q) = \min_{0 \leq \rho \leq \lambda + R_0} G(\rho, \lambda, q)$$

$$\text{where } F(\rho, \lambda, q) = \lambda + P_0 + R_0 - G(\rho, \lambda, q)$$

and $G(\rho, \lambda, q)$ is given by Table 5.1.

TABLE 5.1

Case	Conditions		$G(\rho, \lambda, q)$
1	$R_0 \leq \rho$	$\rho \geq \lambda + R_0$	$\int_G^{R_0 + \lambda} dr/\alpha(r) = q$
2	$R_0 \leq \rho$	$\rho + q\alpha(\rho) \geq \lambda + R_0 \geq \rho$	$\int_G^\rho dr/\alpha(r) = q - (\lambda + R_0 - \rho)/\alpha(\rho)$
3	$R_0 \leq \rho$	$\lambda + R_0 \geq \rho + q\alpha(\rho)$	$\lambda + R_0 - q\alpha(\rho)$
4	$R_0 \geq \rho$	$q \geq \lambda/\alpha(\rho) + \int_\rho^{R_0} dr/\alpha(r)$	$\int_G^{R_0} dr/\alpha(r) = q - \lambda/\alpha(\rho)$
5	$R_0 \geq \rho$	$\lambda/\alpha(\rho) + \int_\rho^{R_0} dr/\alpha(r) \geq q \geq \int_\rho^{R_0} dr/\alpha(r)$	$\lambda + \rho - \alpha(\rho) \left[q - \int_\rho^{R_0} dr/\alpha(r) \right]$
6	$R_0 \geq \rho$	$\rho \leq \rho_{\min}$	$\lambda + \rho_{\min}$

Here ρ_{\min} is defined by

$$\int_{\rho_{\min}}^{R_0} \frac{dr}{\alpha(r)} = q.$$

By inspection it is clear that $G(\rho, \lambda, q)$ is well defined for $\rho, \lambda, q \geq 0$.

First it should be noted that the values given for $G(\rho, \lambda, q)$ are attainable for each $\rho \in \mathbf{R}_+$. To demonstrate this, the following list that shows how to construct θ, f given (ρ, λ, q) so that the corresponding solution $R_\rho(x)$ satisfies $R_\rho(L) = G(\rho, \lambda, q)$. For the construction to proceed we need $0 < \xi_1 < \xi_2 < L$ and the intervals $I_1 = [0, \xi_1]$, $I_2 = [\xi_1, \xi_2]$ and $I_3 = [\xi_2, L]$.

Case 1. Put $\theta \geq 0$ and $f = 0$ on I_1 , and $\theta = 0$ and $f \geq 0$ on $I_2 \cup I_3$ so that $\int_{I_1} \theta = \lambda$ and $\int_{I_2 \cup I_3} f = q$.

Case 2. Put $\theta \geq 0$ and $f = 0$ on I_1 , with $\theta = \alpha(\rho)f \geq 0$ on I_2 and $\theta = 0$, $f \geq 0$ on I_3 so that $\int_{I_1} \theta = \rho$, $\int_{I_2} f = (\lambda + R_0 - \rho)/\alpha(\rho) \leq q$ and (consequently) $\int_{I_3} f = q - (\lambda + R_0 - \rho)/\alpha(\rho)$.

Case 3. Put $\theta \geq 0$ and $f = 0$ on $I_1 \cup I_3$ and $\theta = \alpha(\rho)f \geq 0$ on I_2 so that $\int_{I_1} \theta = \rho$, $\int_{I_2} f = q$ and $\int_{I_3} \theta = \lambda - \rho$.

Case 4. Put $\theta = 0$ and $f \geq 0$ on $I_1 \cup I_3$, $\theta = \alpha(\rho)f \geq 0$ on I_2 so that $\int_{I_1} f = \int_{\rho}^{R_0} dr/\alpha(r)$, $\int_{I_2} \theta = \lambda$ and $\int_{I_3} f = q - \lambda/\alpha(\rho) - \int_{\rho}^{R_0} dr/\alpha(r)$.

Case 5. Put $\theta = 0$ and $f \geq 0$ on I_1 , $\theta = \alpha(\rho)f \geq 0$ on I_2 , and $\theta \geq 0$ and $f = 0$ on I_3 so that $\int_{I_1} f = \int_{\rho}^{R_0} dr/\alpha(r)$, $\int_{I_2} f = q - \int_{\rho}^{R_0} dr/\alpha(r)$ and $\int_{I_3} \theta = \lambda - \alpha(\rho)(q - \int_{\rho}^{R_0} dr/\alpha(r))$.

Case 6. Put $\theta = 0$ and $f \geq 0$ on I_1 and $\theta \geq 0$, $f = 0$ on $I_2 \cup I_3$ so that $\int_{I_1} f = q$ and $\int_{I_2 \cup I_3} \theta = \lambda$.

That $R_\rho(L) = G(\rho, \lambda, q)$, and that admissible f and θ can be constructed according to the above rules, can be shown by inspection. As noted above, Cases 1–3 are proven in Holm aker and Stewart [7].

The problem now is to show that *any* solution $R(x)$ of (5.2.b) for admissible f and θ satisfies $R(L) \geq R_\rho(L)$ for some $\rho \in [0, \lambda]$. This is the substance of the following theorem.

THEOREM 5.1. *Let $G(\rho, \lambda, q)$ be defined as in Table 5.1 for $\rho, \lambda, q \geq 0$ and $F(\rho, \lambda, q) = \lambda + P_0 + R_0 - G(\rho, \lambda, q)$. Then the optimal values for $P(L)$ and $R(L)$ are given by*

$$\begin{aligned} F^*(\lambda, q) &= \max_{0 \leq \rho \leq \lambda + R_0} F(\rho, \lambda, q), \\ G^*(\lambda, q) &= \min_{0 \leq \rho \leq \lambda + R_0} G(\rho, \lambda, q), \quad \text{respectively.} \end{aligned}$$

Proof. We have already noted that $P(L) + R(L) = P_0 + R_0 + \lambda$, so that maximising $P(L)$ corresponds to minimising $R(L)$. Now $\min_{f, \theta} R(L) \leq G^*(\lambda, q)$ since we can construct a solution to (5.2.b) $R_{\rho^*}(x)$ that achieves $R_{\rho^*}(L) = G(\rho^*, \lambda, q) = G^*(\lambda, q)$.

We now show that the reverse inequality for $\min_{f, \theta} R(L)$ holds. Let $\alpha^* = \max\{\alpha(R(x)) \mid x \in [0, L]\}$ and $\xi = \max\{x \mid \alpha(R(x)) = \alpha^*\}$. Put $\rho = R(\xi)$. First, we note that if $\lambda > 0$ then $\rho > 0$, as otherwise $R(x) = 0$ for all x , so $\theta = 0$ almost everywhere, and $\lambda = 0$. In the case $\lambda = 0$ it is clear that $R(L)$ is independent of the particular admissible control f chosen.

The proofs for Cases 1–3 now follows Holm aker and Stewart [7, Thm. 5.1], with λ replaced by $\lambda + R_0$. We now consider in detail Cases 4–6; that is, $R_0 \geq \rho$ and so $R(x) > 0$ for all x .

Case 4. Here $R_\rho(L)$ is given by

$$\int_{R_\rho(L)}^{R_0} \frac{dr}{\alpha(r)} = q - \frac{\lambda}{\alpha(\rho)}.$$

However, for R ,

$$(5.3) \quad \frac{1}{\alpha(R(x))} \frac{dR}{dx} = \frac{\theta(x)}{\alpha(R(x))} - f(x).$$

Integrating this last equation from 0 to L gives

$$\begin{aligned} - \int_{R(L)}^{R_0} \frac{dr}{\alpha(r)} &= \int_0^L \frac{\theta(x) dx}{\alpha(R(x))} - \int_0^L f(x) dx \\ &\geq \frac{\lambda}{\alpha(\rho)} - q = - \int_{R_\rho(L)}^{R_0} \frac{dr}{\alpha(r)} \end{aligned}$$

so that $R_\rho(L) \leq R(L)$.

Case 5. Integrating (5.3) from 0 to ξ gives

$$(5.4) \quad \begin{aligned} - \int_\rho^{R_0} \frac{dr}{\alpha(r)} &= \int_0^\xi \frac{\theta(x) dx}{\alpha(R(x))} - \int_0^L f(x) dx \\ &\geq \frac{1}{\alpha(\rho)} \int_0^\xi \theta(x) dx - \int_0^L f(x) dx. \end{aligned}$$

Let $q' = q - \int_\rho^{R_0} dr/\alpha(r)$. Then integrating the ODE for R in (5.2.b) from ξ to L we find that

$$\begin{aligned} R(L) - \rho &= \int_\xi^L \theta(x) dx - \int_\xi^L \alpha(R(x)) f(x) dx \\ &\geq \int_\xi^L \theta(x) dx - \alpha(\rho) \int_\xi^L f(x) dx \\ &\geq \int_0^L \theta(x) dx - \alpha(\rho) q' \quad \text{by (5.4)} \\ &= \lambda - \alpha(\rho) q' \end{aligned}$$

so that $R(L) \geq \lambda + \rho - \alpha(\rho) q' = R_\rho(L)$ as required.

Case 6. Noting that integrating (5.3) from 0 to ξ gives the result that

$$(5.5) \quad \int_\rho^{R_0} \frac{dr}{\alpha(r)} \leq q.$$

Thus Case 6 can only occur if (5.5) is an equality, so that Case 5 may be applied. Noting that for $\rho < \rho_{\min}$ implies that $G(\rho, \lambda, q) = G(\rho_{\min}, \lambda, q)$, we see that this possibility does not affect the minimisation. \square

A stronger characterisation of the optimising value of ρ for $F(\rho, \lambda, q)$ can be obtained; this will allow the optimal value ρ^* to be computed almost directly.

THEOREM 5.2. *There is a minimizer $\rho^* \in [\rho_{\min}, \lambda + R_0]$ of $G(\cdot, \lambda, q)$ such that*

$$\alpha(\rho^*) = \max\{\alpha(\rho) \mid \rho \text{ lies between } R_0 \text{ and } \rho^*\}.$$

If, in addition, $\alpha \in C^1$ and $\rho^ \neq \lambda + R_0$, ρ_{\min} , then $\alpha'(\rho^*) = 0$.*

Proof. We prove the first part of the theorem. Let $G(\hat{\rho}, \lambda, q) = G^*(\lambda, q)$. Let $R_{\hat{\rho}}$ be defined as a solution of (5.2.b) with f and θ constructed as described above. Let $\rho^* = R_{\hat{\rho}}(\xi)$ where

$$\alpha(R_{\hat{\rho}}(\xi)) = \max\{\alpha(R_{\hat{\rho}}(x)) \mid x \in [0, L]\}.$$

Note that $R_{\hat{\rho}}(x) \in [\rho_{\min}, \lambda + R_0]$ for all x , so ρ^* lies in the required interval.

By the arguments used in Theorem 5.1 with ρ replaced by ρ^* and R replaced by $R_{\hat{\rho}}$, we find that $R_{\rho^*}(L) \leq R_{\hat{\rho}}(L)$. However, as $\hat{\rho}$ minimizes $G(\cdot, \lambda, q)$, it follows that $R_{\rho^*}(L) = R_{\hat{\rho}}(L)$ and ρ^* is another minimizer of G . Now $R_{\hat{\rho}}$ attains both R_0 and ρ^* , so that by definition of ρ^*

$$\alpha(\rho^*) \geq \max\{\alpha(\rho) \mid \rho \text{ lies between } R_0 \text{ and } \rho^*\}.$$

Setting $\rho = \rho^*$ in the maximisation makes it clear that the above is actually an equality.

We now show the second part of the theorem. Suppose that $\alpha \in C^1$ and $\rho^* \neq \lambda + R_0, \rho_{\min}$; we now show that $\alpha'(\rho^*) = 0$. To do this we note that the derivatives of $G(\rho, \lambda, q)$ with respect to ρ are as in Table 5.2.

TABLE 5.2

Case	$\partial G / \partial \rho(\rho, \lambda, q)$
1	0
2	$-(\lambda + R_0 - \rho)\alpha(G)\alpha'(\rho)/\alpha(\rho)^2$
3	$-q\alpha'(\rho)$
4	$-\lambda\alpha(G)\alpha'(\rho)/\alpha(\rho)^2$
5	$-\alpha'(\rho)\left[q - \int_{\rho}^{R_0} dr/\alpha(r)\right]$
6	0

By inspection of Table 5.2 and 5.1 $\partial G / \partial \rho$ is continuous except at $\rho = \lambda + R_0, \rho_{\min}$. Thus, as $\rho = \rho^*$ minimizes $G(\rho, \lambda, q)$ it follows that $\partial G / \partial \rho(\rho^*, \lambda, q) = 0$. Hence, by Table 5.2, $\alpha'(\rho^*) = 0$ as required. \square

The above formulae in 5.1 provide a fairly easy way of computing $G^*(\lambda, q)$ and $F^*(\lambda, q)$. However, F^* and G^* have some monotonicity properties that will be exploited later.

THEOREM 5.3. *Both $F^*(\lambda, q)$ and $G^*(\lambda, q)$ are monotonic increasing in λ with G^* being strictly increasing in λ . Furthermore, $F^*(\lambda, q)$ is strictly increasing in q and $G^*(\lambda, q)$ is strictly decreasing in q .*

Proof. Let $0 \leq \lambda_1 < \lambda_2$ and suppose that (θ, f) achieves $P(L) = F^*(\lambda_1, q)$ where P and R satisfy (5.1). We then define

$$\bar{\theta}(x) = \begin{cases} 2\theta(2x) & \text{for } 0 \leq x \leq L/2 \\ 2(\lambda_2 - \lambda_1)/L & \text{otherwise,} \end{cases}$$

$$\bar{f}(x) = \begin{cases} 2f(2x) & \text{for } 0 \leq x \leq L/2 \\ 0 & \text{otherwise,} \end{cases}$$

and let \bar{P} and \bar{R} satisfy (5.1) with (θ, f) replaced by $(\bar{\theta}, \bar{f})$. Then $\bar{P}(L) = P(L) = F^*(\lambda_1, q)$, so the maximum value of $P(L)$ over (θ, f) with $\int_0^L \theta(x) dx = \lambda_2$ must be at least as large as $F^*(\lambda_1, q)$; that is, $F^*(\lambda_2, q) \geq F^*(\lambda_1, q)$ as required.

On the other hand, suppose now that (θ, f) achieves $R(L) = G^*(\lambda_2, q)$. Then there is a $\xi \in (0, L)$ such that $\int_0^{\xi} \theta(x) dx = \lambda_1$. If $R_0 = 0$ and $\lambda_1 = 0$ the result follows trivially as then $R(L) = 0$ and thus $G^*(\lambda_1, q) = 0 < G^*(\lambda_2, q)$. We now assume that either R_0 or λ_1 is strictly positive; in this case $R(x) > 0$ for all $x \in [\xi, L]$. We define

$$\bar{\theta}(x) = \begin{cases} \theta(x) & \text{for } 0 \leq x \leq \xi \\ 0 & \text{otherwise.} \end{cases}$$

If \bar{P} and \bar{R} then satisfy (5.1) with θ replaced by $\bar{\theta}$ we find that

$$\begin{aligned}\int_{R(L)}^{R(\xi)} \frac{dr}{\alpha(r)} &= \int_{\xi}^L \frac{\theta(x) dx}{\alpha(R(x))} - \int_{\xi}^L f(x) dx \\ &> - \int_{\xi}^L f(x) dx = \int_{R(L)}^{\bar{R}(\xi)} \frac{dr}{\alpha(r)}\end{aligned}$$

so that $\bar{R}(L) < R(L) = G^*(\lambda_2, q)$. Thus $G^*(\lambda_1, q) < G^*(\lambda_2, q)$ as required.

We now consider the effect of varying q ; let $0 \leq q_1 < q_2$ and suppose (θ, f) achieves $P(L) = F^*(\lambda, q_1)$ and $R(L) = G^*(\lambda, q_1)$. We then define

$$\begin{aligned}\bar{\theta}(x) &= \begin{cases} 2\theta(2x) & \text{for } 0 \leq x \leq L/2 \\ 0 & \text{otherwise,} \end{cases} \\ \bar{f}(x) &= \begin{cases} 2f(2x) & \text{for } 0 \leq x \leq L/2 \\ 2(q_2 - q_1)/L & \text{otherwise.} \end{cases}\end{aligned}$$

Then clearly $\bar{P}(L) > P(L) = F^*(\lambda, q_1)$ and $\bar{R}(L) < G^*(\lambda, q_1)$ so that $F^*(\lambda, q_2) > F^*(\lambda, q_1)$ and $G^*(\lambda, q_2) < G^*(\lambda, q_1)$ as required. \square

These monotonicity results considerably simplify the application of the results of §§2–4 to networks of enzymatic reactions.

6. Solving complete networks. In this section we combine the results of §§4 and 5 to obtain a method for maximising the output of a large tree of enzymatic reactions by a dynamic programming approach. (Note that this includes problems where there is a *chain* of reactions, or independent reaction paths.) This method has been implemented numerically to obtain optimal values, and extended to also compute optimal *amounts* of each enzyme subject to a “total cost” limit. Currently the implementation provides only qualitative information about the optimal controls (enzyme distributions) themselves, though this alone is often sufficient to determine optimal distributions (e.g., “... the first enzyme is followed by the second enzyme which is followed by the thirrd ...”).

We consider firstly the problem of maximising output where the quantity of each enzyme is given and the set of reactions forms a tree directed towards a single product: the “output.” If the product is the product of more than one reaction, then the tree can be split into different parts—one for each reaction producing the product—which are entirely independent. Thus we can assume that there is only one reaction producing the final product. This means that the tree of reactions can be split into the form

$$T = T' \Rightarrow R \rightarrow P$$

where “ \Rightarrow ” means that R may be the product of more than one reaction. Now the first subsystem S_1 is the subtree $T' \Rightarrow R$, and the second, S_2 , is the one-enzyme reaction with input: $\theta \rightarrow R \rightarrow P$. (Here θ is the sum of the production rates of R over all reactions that produce R .) The maximum value of $P(L)$ over all θ, f satisfying the nonnegativity and the integral constraints

$$\int_0^L \theta(x) dx = \lambda, \quad \int_0^L f(x) dx = q$$

can be computed as $F^*(\lambda, q)$ by means of the results of the previous section. Noting that $F^*(\lambda, q)$ is monotonic increasing in λ , we see that if the set of attainable λ is

$[\lambda_{\min}, \lambda_{\max}]$, then the optimum value of λ is $\lambda^* = \lambda_{\max}$. But λ_{\max} in this case is simply the maximum output of subsystem S_1 :

$$T' \Rightarrow R.$$

This subsystem can then be analysed in terms of its own subsystems, which in turn can be analysed in the same manner, at least until we are dealing with single enzyme systems with no input, which are essentially trivial: any enzyme distribution satisfying the nonnegativity and integral conditions will achieve the maximum.

The optimal enzyme distributions themselves can be generated with the above recursive process; at each stage, once the optimal λ^* and associated output from the S_1 subsystem θ_1 has been determined, then the optimal input θ_2 can be determined by the results for one enzyme systems. Then the optimal distributions and trajectories for the two subsystems can be “matched” by means of the x -equivalence described at the end of §4.

We now briefly consider a particular case of a chain of enzymes where the reaction rate functions, the α 's, are C^1 and $\alpha'(\rho) > 0$ for every $\rho > 0$. Here we use the notation of the previous section and consider a one enzyme subsystem. By Theorem 5.2 we can pick an optimum ρ^* such that

$$\alpha(\rho^*) = \max\{\alpha(\rho) \mid \rho \text{ lies between } R_0 \text{ and } \rho^*\}.$$

Thus $\rho^* \geq R_0$. As $\alpha'(\rho^*) \neq 0$, we see that $\rho^* = \lambda$ or $\rho^* = \rho_{\min}$. But $\rho_{\min} < R_0$ for $R_0 > 0$, and $\rho_{\min} = 0$ if $R_0 = 0$, it follows that $\rho^* = \lambda$ and we can apply Case 1. We then subdivide the interval $[0, L]$ into two pieces $I_1 \cup I_2 = [0, \xi] \cup [\xi, L]$ and set $f = 0$ on I_1 and $\theta = 0$ on I_2 . That is, we put all of the current enzyme downstream of the enzymes that come earlier in the chain of reactions. Thus, in this case, the naive approach of putting the enzymes in order is actually optimal. For the more general case, we need to resort to numerical methods to determine the optimal distribution of enzymes, which are described below.

This technique can also be extended to give a dynamic programming method for obtaining the optimum *amount* of each enzyme as well as the optimum distribution of a given amount of each enzyme, subject to a limit on a “total enzyme cost” given as a weighted sum of the amounts of the various enzymes. For each reaction subsystem (i.e., subtree) a table of amounts of product for a given total enzyme cost for the subsystem is computed. To do this we have basically two cases to consider. The first is where a product P is produced from a reactant R , which in turn is the product of some system of reactions. The problem here is to decide how to split the total enzyme cost between the reaction $R \rightarrow P$ and the system of reactions that produces R . This is just a one-dimensional optimisation problem.

The second case is where the product P is the product of two independent systems of reactions. Then the problem to be solved is that of determining how to split this total enzyme cost between the two subsystems of reactions. This, again, is a one-dimensional optimisation problem that can be solved directly from the tables of product amounts for the two subsystems.

7. Numerical implementation and results. This decomposition algorithm has been implemented numerically in the C programming language to run on the Mathematics Dept. Pyramid 9810 computer. The method used to compute $G(\rho, \lambda, q)$ involves a one-dimensional root-finding routine based on that of Brent [3, pp. 58–59], and the integrals were computed by a 24-point Gauss–Legendre quadrature rule. Finally, the reaction rate functions α were stored in a form so that their critical points

could be computed directly. Then $F^*(\lambda, q)$ is given directly as the maximum of the $F(\rho, \lambda, q)$ as ρ ranges over the set of critical points of α in the interval $[\rho_{\min}, \lambda + R_0]$ together with $\rho = \lambda + R_0$ and $\rho = \rho_{\min}$.

The optimal amounts of product were computed for fixed amounts of enzymes, and for variable amounts of enzymes, for a problem devised by the author to test the algorithm, which is given in Fig. 7.1.

FIG. 1

The reaction rate functions are given in Table 7.1.

TABLE 7.1

Edge	Reaction rate	Amount	Critical points	$R_i(0)$
1	$\alpha_1(r) = 8r/(r^2 + 4)$	2	not used	3
2	$\alpha_2(r) = (r^2 + r)/(r^2 + r + 2)$	2	not used	3
3	$\alpha_3(r) = 6re^{-r}$	2	$\alpha_3(1) = 2.207 \dots$	0
4	$\alpha_4(r) = 4(e^{-r/5} - e^{-2r/5})$	3	$\alpha_4(3.465 \dots) = 1$	0

Note that edge i is the outgoing edge of node R_i .

For determining the optimal amount of each enzyme it was assumed that the total amount of enzyme was the same as for the case where the amount of each enzyme is given. The smallest change in the amount of an enzyme that was allowed by the numerical implementation was set to 0.2.

For making meaningful statements about the efficacy of the algorithm and the optimal amounts and distributions of enzymes, comparisons were made with two heuristics:

- (1) Uniform enzyme concentration.
- (2) Enzymes occur in the sequence determined by the reaction sequence.

The results are given in Table 7.2. The optimal enzyme amounts computed were

TABLE 7.2

Edge	1	2	3	4
Amount	1.6	1.4	1.8	4.2

The amounts of product produced under the different conditions were computed to be as in Table 7.3.

TABLE 7.3

Amounts	Heuristic 1	Heuristic 2	Optimal distribution
Given	1.796	2.283	2.802
Optimal	1.955	2.540	3.166

There is clearly significant advantage in using the computed optimal distributions and amounts.

ON THE LINEAR CONVERGENCE OF DESCENT METHODS FOR CONVEX ESSENTIALLY SMOOTH MINIMIZATION*

ZHI-QUAN LUO[†] AND PAUL TSENG[‡]

*Dedicated to those courageous people who, on June 4, 1989, sacrificed their lives in
Tiananmen Square, Beijing.*

Abstract. Consider the problem of minimizing, over a polyhedral set, the composition of an affine mapping with a strictly convex essentially smooth function. A general result on the linear convergence of descent methods for solving this problem is presented. By applying this result, the linear convergence of both the gradient projection algorithm of Goldstein and Levitin and Polyak, and a matrix splitting algorithm using regular splitting, is established. The results do not require that the cost function be strongly convex or that the optimal solution set be bounded. The key to the analysis lies in a new error bound for estimating the distance from a feasible point to the optimal solution set.

Key words. linear convergence, differentiable minimization, gradient projection, matrix splitting, coordinate descent

AMS(MOS) subject classifications. 49, 90

1. Introduction. Consider the problem of minimizing a strictly convex essentially smooth function subject to linear constraints. This problem contains a number of important optimization problems as special cases, including (strictly) convex quadratic programs, “ $x \ln(x)$ ” entropy minimization problems [Fri75], [Her80], [Jay82], [JoS84], [LaS81], [Pow88], and “ $-\ln(x)$ ” minimization problems [FiM68], [GMSTW86], [JoS84], [Son88]. A popular approach to solving this problem is to dualize the linear constraints to obtain a dual problem of minimizing, over a box, the composition of a strictly convex essentially smooth function with an affine mapping; then to apply a feasible descent method to solve the dual problem (see [Cen88], [CeL87], [CoP82], [Cry71], [Hil57], [Kru37], [LaS81], [LiP87], [MaD87], [MaD88a], [Tse90], [TsB87a], [TsB87b] and references therein). Popular choices for the descent method include a gradient projection algorithm of Goldstein [Gol64] and Levitin and Polyak [LeP65], the coordinate descent algorithm, and a matrix splitting algorithm using regular splitting [Kel65], [Man77], [OrR70], [Pan82].

An outstanding theoretical question concerns the *rate* of convergence of the iterates generated by the above solution approach. Most of the existing rate of convergence results require restrictive assumptions on the problem, such as that the cost function be strongly convex, which unfortunately do not hold in many practical situations. In fact, owing to the possible unboundedness of the optimal solution set, even the convergence of the iterates has been very difficult to establish (see [Che84], [LuT89a]). Nonetheless, by exploiting the special structure of the problem, it has been possible to

show *linear* convergence for two of the aforementioned algorithms: the gradient projection algorithm using small stepsizes (and under an additional Lipschitz assumption on the gradient) [BeG82] and the coordinate descent algorithm [LuT89b]. (Here and throughout, we mean by “linear convergence” the R -linear convergence in the sense of Ortega and Rheinboldt [OrR70].) In fact, the results for the gradient projection algorithm extend to variational inequality problems [BeG82].

In this paper, we extend the proof ideas and the results of [LuT89b] to a general class of feasible descent methods, including the aforementioned algorithms. In particular, we consider an extension of the above dual problem in which the constraint set is any polyhedral set, not just a box; we give general conditions for a feasible descent method to be linearly convergent when applied to solving this problem; and we show that the aforementioned algorithms (gradient projection, matrix splitting, etc.) satisfy these conditions and hence are linearly convergent when applied to solving this problem. The key to our analysis lies in a new bound for estimating the distance from a feasible point to the optimal solution set which, unlike many existing bounds, holds without requiring the cost function to be strongly convex.

We formally state our problem below. Let $f : \mathbb{R}^n \mapsto (-\infty, \infty]$ be a function of the form

$$(1.1) \quad f(x) = g(Ex) + \langle q, x \rangle, \quad \forall x,$$

where $g : \mathbb{R}^m \mapsto (-\infty, \infty]$ is some function, E is some $m \times n$ matrix (possibly with zero columns), and q is some vector in \mathbb{R}^n , the n -dimensional Euclidean space. In our notation, all vectors are column vectors and $\langle \cdot, \cdot \rangle$ denotes the usual Euclidean inner product. Notice that if q is in the row span of E , then f depends on x through Ex only. In general, however, this need not be the case.

We make the following standing assumptions regarding the function g .

ASSUMPTION 1.1. (a) The effective domain of g , denoted by C_g , is nonempty and open.

(b) g is strictly convex twice continuously differentiable on C_g .

(c) $g(t) \rightarrow \infty$ as t approaches any boundary point of C_g .

Assumption 1.1 implies that g is, in the terminology of Rockafellar [Roc70], a strictly convex *essentially smooth* function. Such a function has a number of interesting theoretical properties. For example, its conjugate function is also strictly convex essentially smooth (see [Roc70, Chap. 26]).

Let X be a polyhedral set in \mathbb{R}^n . Consider the following convex program associated with f and X :

$$(1.2) \quad \begin{array}{ll} \text{minimize} & f(x) \\ \text{subject to} & x \in X. \end{array}$$

We make the following standing assumptions regarding f and X .

ASSUMPTION 1.2. (a) The set of optimal solutions for (1.2), denoted by X^* , is nonempty.

(b) $\nabla^2 g(Ex^*)$ is positive definite for every $x^* \in X^*$.

Part (a) of Assumption 1.2 implies that the effective domain of f , denoted by C_f , makes a nonempty intersection with X and, moreover, f is bounded from below on X . It then follows from the special form of f (cf. (1.1)) and Assumption 1.1 that C_f is open, f is convex twice continuously differentiable on C_f , and $f(x) \rightarrow \infty$ as

x approaches any boundary point of C_f . Hence, f is convex essentially smooth but, unlike g , not necessarily strictly convex, since E may lack full column rank.

Part (b) of Assumption 1.2 states that g has a positive curvature on the image of X^* under the affine transformation $x \mapsto Ex$. This condition is guaranteed to hold if g has a positive curvature everywhere on C_g . (There are many important functions that satisfy this latter condition (in addition to Assumption 1.1), the most notable of which are the quadratic function, the exponential function, and the negative of the logarithm function.) Of course, if g is strongly convex and twice differentiable everywhere, then Assumptions 1.1 and 1.2 (b) hold automatically. We remark that the twice differentiability of g is not necessary for our results to hold, but it makes for a simpler statement of the assumptions. In general it suffices that g be differentiable on C_g and that ∇g be “locally” strongly monotone and Lipschitz continuous around Ex^* for all $x^* \in X^*$.

The problem (1.2) contains a number of important problems as special cases. For example, if E is the null matrix, then (1.2) reduces to a linear program. If g is a strictly convex quadratic function, then (1.2) reduces to the symmetric monotone linear complementarity problem [Man77], [LiP87] (also see §5). If g is the function given by $g(t) = -\sum_j \ln(t_j)$ for all $t \in (0, \infty)^m$ and $g(t) = \infty$ otherwise, where $\ln(\cdot)$ denotes the natural logarithm, and X is the nonnegative orthant in \mathbb{R}^n , then (1.2) reduces to the Lagrangian dual of a certain linearly constrained logarithmic penalty problem (see, e.g., [CeL87]).

For any $x \in \mathbb{R}^n$, let $[x]^+$ denote the orthogonal projection of x onto X , i.e.,

$$[x]^+ = \arg \min_{y \in X} \|x - y\|,$$

where $\|\cdot\|$ denotes the usual Euclidean norm (i.e., $\|x\| = \sqrt{\langle x, x \rangle}$ for all x). (Our notation for the projection operator is somewhat unconventional, but it has the advantage of simplicity.) Since C_f is nonempty, and f is differentiable on C_f , it is easily seen from the Kuhn–Tucker conditions for (1.2) that X^* comprises all $x \in X \cap C_f$ for which the orthogonal projection of $x - \nabla f(x)$ onto X is x itself, i.e.,

$$(1.3) \quad X^* = \{ x \in \mathbb{R}^n \mid x = [x - \nabla f(x)]^+ \}.$$

Note that since both f and X are closed and convex, then so is X^* (in fact, X^* is a polyhedral set as we show in Corollary 2.1). However, X^* may be unbounded.

This paper proceeds as follows. In §2 we prove a new bound on the distance to X^* from a feasible point near X^* . In §3 we use this bound to establish general conditions under which a sequence of feasible points converge at least linearly to an element of X^* . In §§4 and 5 we show that the sequence of iterates generated by either the gradient projection algorithm or the matrix splitting algorithm using regular splitting satisfy the convergence conditions outlined in §3. In §6 we give our conclusion and discuss possible extensions.

We adopt the following notation throughout. For any $k \times l$ matrix A , we denote by A^T the transpose of A , by $\|A\|$ the matrix norm of A induced by the vector norm $\|\cdot\|$ (i.e., $\|A\| = \max_{\|x\|=1} \|Ax\|$), by A_i the i th row of A and, for any nonempty $I \subseteq \{1, \dots, k\}$, by A_I the submatrix of A obtained by removing all rows $i \notin I$ of A . Analogously, for any vector $x \in \mathbb{R}^k$, we denote by x_i the i th coordinate of x , and, for any nonempty subset $I \subseteq \{1, \dots, k\}$, by x_I the vector with components x_i , $i \in I$ (with the x_i ’s arranged in the same order as in x).

2. A new error bound. In this section we prove a key result that, for all $x \in X \cap C_f$ sufficiently close to the optimal solution set X^* , the distance from x to X^* is of the order $\|x - [x - \nabla f(x)]\|$. This result will be used in the rate of convergence analysis of §3.

We first need the following lemma which says that the affine mapping $x \mapsto Ex$ is invariant over X^* . This lemma is a simple consequence of the strict convexity of g .

LEMMA 2.1. *There exists a $t^* \in \mathbb{R}^m$ such that*

$$Ex^* = t^*, \quad \forall x^* \in X^*.$$

Proof. For any $x^* \in X^*$ and $y^* \in X^*$, we have by the convexity of X^* that $(x^* + y^*)/2 \in X^*$. Then, $f(x^*) = f(y^*) = f((x^* + y^*)/2)$, so (1.1) yields $g((Ex^* + Ey^*)/2) = (g(Ex^*) + g(Ey^*))/2$. Since both $g(Ex^*)$ and $g(Ey^*)$ are finite, so that $Ex^* \in C_g$ and $Ey^* \in C_g$, this together with the strict convexity of g on C_g implies $Ex^* = Ey^*$. \square

As an immediate corollary of Lemma 2.1, we have the following interesting characterization of X^* .

COROLLARY 2.1. *X^* is a polyhedral set.*

Proof. Fix any $x^* \in X^*$ and consider the polyhedral set

$$\bar{X} = \{ x \in X \mid Ex = t^*, \langle q, x - x^* \rangle = 0 \}.$$

By using (1.1) and Lemma 2.1, we see that x is an element of \bar{X} if and only if $x \in X$ and $f(x) = f(x^*)$. Thus, $\bar{X} = X^*$. \square

By using the observation (cf. (1.1))

$$(2.1) \quad \nabla f(x) = E^T \nabla g(Ex) + q, \quad \forall x \in C_f,$$

we have that ∇f is invariant over X^* . In fact, it is easily seen from Lemma 2.1 that

$$(2.2) \quad \nabla f(x^*) = d^*, \quad \forall x^* \in X^*,$$

where we denote

$$(2.3) \quad d^* = E^T \nabla g(t^*) + q.$$

The above invariant property of ∇f on X^* is quite well known (see, e.g., [Man88]) and in fact holds for more general convex programs.

Since $\nabla^2 g(t^*)$ is positive definite (cf. Assumption 1.2 (b) and Lemma 2.1), it follows from the continuity property of $\nabla^2 g$ (Assumption 1.1 (b)) that $\nabla^2 g$ is positive definite in some open neighborhood of t^* . This in turn implies that g is strongly convex near t^* , i.e., there exist a positive scalar $\sigma > 0$ and a closed ball $\mathcal{U}^* \subseteq C_g$ containing t^* such that

$$(2.4) \quad g(z) - g(y) - \langle \nabla g(y), z - y \rangle \geq \sigma \|z - y\|^2, \quad \forall z \in \mathcal{U}^*, \forall y \in \mathcal{U}^*.$$

By interchanging the role of y with that of z in (2.4) and adding the resulting relation to (2.4), we also obtain

$$(2.5) \quad \langle \nabla g(z) - \nabla g(y), z - y \rangle \geq 2\sigma \|z - y\|^2, \quad \forall z \in \mathcal{U}^*, \forall y \in \mathcal{U}^*.$$

Since $\nabla^2 g$ is continuous on \mathcal{U}^* (cf. Assumption 1.1 (b)), so it is bounded there, then ∇g is Lipschitz continuous on \mathcal{U}^* , i.e., there exists a scalar $\rho > 0$ such that

$$(2.6) \quad \|\nabla g(z) - \nabla g(y)\| \leq \rho \|z - y\|, \quad \forall z \in \mathcal{U}^*, \forall y \in \mathcal{U}^*.$$

We next state a lemma on the Lipschitz continuity of the solution set of a linear system as a multifunction of the right-hand side. This lemma, originally due to [Hof52] (also see [Rob73], [MaS87]), will be used in the proof of Lemmas 2.4, 2.6, and 3.1.

LEMMA 2.2. *Let B be a $k \times l$ matrix, let C be an $h \times l$ matrix, and let d be a vector in \mathbb{R}^h . There exists a scalar $\theta > 0$ depending on B and C only such that, for any \bar{x} satisfying $C\bar{x} \geq d$ and any $e \in \mathbb{R}^k$ such that the linear system $By = e$, $Cy \geq d$ is consistent, there is a point \bar{y} satisfying $B\bar{y} = e$, $C\bar{y} \geq d$ and $\|\bar{x} - \bar{y}\| \leq \theta \|B\bar{x} - e\|$.*

By using Lemma 2.2 and Assumption 1.1, we can show the following technical fact.

LEMMA 2.3. *For any $\zeta \in \mathbb{R}$, the set $\{Ex \mid x \in X, f(x) \leq \zeta\}$ is a compact subset of C_g .*

Proof. For the proof see [Tse89, Lem. 9.1].

Since X is a polyhedral set, we can for convenience express it as $X = \{x \in \mathbb{R}^n \mid Ax \geq b\}$, for some $k \times n$ matrix A and some $b \in \mathbb{R}^k$. Then, for any $x \in X \cap C_f$, the vector $[x - \nabla f(x)]^+$ is the unique vector z which, together with some multiplier vector $\lambda \in \mathbb{R}^k$, satisfies the Kuhn–Tucker conditions

$$(2.7) \quad z - x + \nabla f(x) - A^T \lambda = 0, \quad Az \geq b, \quad \lambda \geq 0,$$

$$(2.8) \quad \lambda_i = 0, \quad \forall i \notin I(x), \quad A_i z = b_i, \quad \forall i \in I(x),$$

where we denote

$$I(x) = \{i \in \{1, \dots, k\} \mid A_i[x - \nabla f(x)]^+ = b_i\}.$$

We say that an $I \subseteq \{1, \dots, k\}$ is *active* at a vector $x \in X \cap C_f$ if $z = [x - \nabla f(x)]^+$ together with some $\lambda \in \mathbb{R}^k$ satisfies (2.7) and

$$(2.9) \quad \lambda_i = 0, \quad \forall i \notin I, \quad A_i z = b_i, \quad \forall i \in I.$$

(By (2.8), $I(x)$ is active at x for all $x \in X \cap C_f$).

We next have the following lemma, which roughly says that if $x \in X$ is sufficiently close to X^* , then those constraint indices that are active at x are also active at some element of X^* .

LEMMA 2.4. *For any $\zeta \in \mathbb{R}$, there exists an $\epsilon > 0$ such that, for any $x \in X$ with $f(x) \leq \zeta$ and $\|x - [x - \nabla f(x)]^+\| \leq \epsilon$, $I(x)$ is active at some $x^* \in X^*$.*

Proof. We argue by contradiction. If the claim does not hold, then for some $\zeta \in \mathbb{R}$, there would exist an $I \subseteq \{1, \dots, k\}$ and a sequence of vectors $\{x^r\}$ in X satisfying $f(x^r) \leq \zeta$ for all r , $x^r - z^r \rightarrow 0$, where we let $z^r = [x^r - \nabla f(x^r)]^+$ for all r , and $I(x^r) = I$ for all r , and yet there is no $x^* \in X^*$ for which I is active at x^* .

Since $\{f(x^r)\}$ is bounded, it follows from Lemma 2.3 that $\{Ex^r\}$ lies in a compact subset of C_g . Let t^∞ be any such cluster point of $\{Ex^r\}$ (so $t^\infty \in C_g$) and let \mathcal{R} be a subsequence of $\{0, 1, \dots\}$ such that

$$(2.10) \quad \{Ex^r\}_{\mathcal{R}} \rightarrow t^\infty.$$

We show below that t^∞ is equal to t^* .

Since $t^\infty \in C_g$ so ∇g is continuous in an open set around t^∞ , we obtain from (2.10) (and using the fact $\nabla f(x^r) = E^T \nabla g(Ex^r) + q$ for all r) that

$$(2.11) \quad \{\nabla f(x^r)\}_{\mathcal{R}} \rightarrow E^T \nabla g(t^\infty) + q.$$

For each $r \in \mathcal{R}$, consider the following linear system in x , z , and λ :

$$\begin{aligned} x - z + A^T \lambda &= \nabla f(x^r), & Ex &= Ex^r, & x - z &= x^r - z^r, \\ Az &\geq b, & \lambda &\geq 0, & A_i z &= b_i, \quad \forall i \in I, & \lambda_i &= 0, \quad \forall i \notin I. \end{aligned}$$

The above system is consistent since, by $I(x^r) = I$ and (2.7)–(2.8), (x^r, z^r) together with some $\lambda^r \in \mathbb{R}^k$ is a solution of it. Then, by Lemma 2.2, it has a solution $(\hat{x}^r, \hat{z}^r, \hat{\lambda}^r)$ whose size is bounded by some constant (depending on A and E only) times the size of the right-hand side. Since the right-hand side of the above system, by $z^r - x^r \rightarrow 0$ and (2.10)–(2.11), is bounded as $r \rightarrow \infty$, $r \in \mathcal{R}$, then $\{(\hat{x}^r, \hat{z}^r, \hat{\lambda}^r)\}_{\mathcal{R}}$ is bounded. Moreover, every one of its cluster points, say $(x^\infty, z^\infty, \lambda^\infty)$, satisfies

$$\begin{aligned} x^\infty - z^\infty + A^T \lambda^\infty &= E^T \nabla g(t^\infty) + q, & Ex^\infty &= t^\infty, & x^\infty - z^\infty &= 0, \\ Az^\infty &\geq b, & \lambda^\infty &\geq 0, & A_i z^\infty &= b_i, \quad \forall i \in I, & \lambda_i^\infty &= 0, \quad \forall i \notin I. \end{aligned}$$

This shows $x^\infty = [x^\infty - \nabla f(x^\infty)]^+$ (cf. (2.7), (2.8), and $\nabla f(x^\infty) = E^T \nabla g(Ex^\infty) + q$), so $x^\infty \in X^*$ (cf. (1.3)) and, by Lemma 2.1, $t^\infty = t^*$. Moreover, I is active at x^∞ (cf. (2.7) and (2.9)), so a contradiction is established. \square

Also, the proof of Lemma 2.4 shows the following lemma.

LEMMA 2.5. *For any $\zeta \in \mathbb{R}$ and any $\eta > 0$, there exists an $\epsilon' > 0$ such that $\|Ex - t^*\| \leq \eta$ for all $x \in X$ with $f(x) \leq \zeta$ and $\|x - [x - \nabla f(x)]^+\| \leq \epsilon'$.*

By using Lemmas 2.2, 2.4, and 2.5, we can prove the following intermediate lemma.

LEMMA 2.6. *For any $\zeta \in \mathbb{R}$, there exist scalars $\delta > 0$ and $\omega > 0$ such that, for any $x \in X$ with $f(x) \leq \zeta$ and $\|x - [x - \nabla f(x)]^+\| \leq \delta$, the following hold:*

- (a) $Ex \in \mathcal{U}^*$.
- (b) *There exists a $\lambda \in [0, \infty)^k$ satisfying*

$$(A_I)^T \lambda_I = z - x + \nabla f(x),$$

and an $x^ \in X^*$ and a $\lambda^* \in [0, \infty)^k$ satisfying*

$$(A_I)^T \lambda_I^* = \nabla f(x^*), \quad A_I x^* = b_I,$$

$$\|(x, \lambda) - (x^*, \lambda^*)\| \leq \omega (\|Ex - t^*\| + \|x - z\|),$$

where we let $I = I(x)$ and $z = [x - \nabla f(x)]^+$.

Proof. Fix any $\zeta \in \mathbb{R}$. By Lemma 2.5, there exists some $\epsilon' > 0$ such that $Ex \in \mathcal{U}^*$ for all $x \in X$ satisfying $f(x) \leq \zeta$ and $\|x - [x - \nabla f(x)]^+\| \leq \epsilon'$. Choose δ to be the minimum of this ϵ' and the ϵ given in Lemma 2.4.

Consider any $x \in X$ satisfying the hypothesis of the lemma (with the above choice of δ), and let $z = [x - \nabla f(x)]^+$. Then, by (2.7) and (2.8), there exists some $\lambda \in \mathbb{R}^k$ satisfying, together with x and z ,

$$A^T \lambda = z - x + \nabla f(x),$$

$$Az \geq b, \quad \lambda \geq 0, \quad \lambda_i = 0, \quad \forall i \notin I(x), \quad A_i z = b_i, \quad \forall i \in I(x).$$

By Lemma 2.4, there exists an $x^* \in X^*$ such that $I(x)$ is active at x^* , so, by Lemma 2.1 and (2.2), the following linear system in (x^*, z^*, λ^*) :

$$A^T \lambda^* = d^*, \quad Ex^* = t^*, \quad x^* - z^* = 0,$$

$$Az^* \geq b, \quad \lambda^* \geq 0, \quad \lambda_i^* = 0, \quad \forall i \notin I(x), \quad A_i z^* = b_i, \quad \forall i \in I(x),$$

is consistent. Moreover, every solution (x^*, z^*, λ^*) of this linear system satisfies $x^* \in X^*$. Upon comparing the above two systems, we see that, by Lemma 2.2, there exists a solution (x^*, z^*, λ^*) to the second system such that

$$\|(x^*, z^*, \lambda^*) - (x, z, \lambda)\| \leq \theta(\|z - x + \nabla f(x) - d^*\| + \|Ex - t^*\| + \|x - z\|),$$

where θ is some scalar depending on A and E only. Since our choice of δ also implies that $Ex \in \mathcal{U}^*$, (2.1)–(2.3) and the Lipschitz condition (2.6) yield $\|\nabla f(x) - d^*\| = \|E^T \nabla g(Ex) - E^T \nabla g(t^*)\| \leq \rho \|E^T\| \|Ex - t^*\|$. Hence the above relation implies

$$\|(x^*, z^*, \lambda^*) - (x, z, \lambda)\| \leq \theta(2\|x - z\| + (\rho\|E^T\| + 1)\|Ex - t^*\|). \quad \square$$

For any $x \in \mathbb{R}^n$, let $\phi(x)$ denote the Euclidean distance from x to X^* , i.e.,

$$\phi(x) = \min_{x^* \in X^*} \|x - x^*\|.$$

By using Lemmas 2.1 and 2.6, we can establish the main result of this section, which roughly says that, for all $x \in X \cap C_f$ sufficiently close to X^* , $\phi(x)$ can be bounded from above by the norm of the residual $x - [x - \nabla f(x)]^+$.

THEOREM 2.1. *For any $\zeta \in \mathbb{R}$, there exist scalars $\tau > 0$ and $\delta > 0$ such that*

$$(2.12) \quad \phi(x) \leq \tau \|x - [x - \nabla f(x)]^+\|,$$

for all $x \in X$ with $f(x) \leq \zeta$ and $\|x - [x - \nabla f(x)]^+\| \leq \delta$.

Proof. Fix any $\zeta \in \mathbb{R}$ and let δ and ω be the corresponding scalars given in Lemma 2.6.

Consider any $x \in X$ satisfying the hypothesis of the theorem (with the above choice of δ), and let $z = [x - \nabla f(x)]^+$, $I = I(x)$. Then,

$$(2.13) \quad A_I z = b_I,$$

and, by Lemma 2.6, $Ex \in \mathcal{U}^*$ and there exists a $\lambda \in [0, \infty)^k$ satisfying

$$(2.14) \quad (A_I)^T \lambda_I = z - x + \nabla f(x),$$

and an $x^* \in X^*$ and a $\lambda^* \in [0, \infty)^k$ satisfying

$$(2.15) \quad (A_I)^T \lambda_I^* = \nabla f(x^*), \quad A_I x^* = b_I,$$

$$(2.16) \quad \|(x, \lambda) - (x^*, \lambda^*)\| \leq \omega(\|Ex - t^*\| + \|x - z\|).$$

Also, since $Ex \in \mathcal{U}^*$ and $t^* \in \mathcal{U}^*$, we have from (2.5) that

$$(2.17) \quad 2\sigma \|Ex - t^*\|^2 \leq \langle Ex - t^*, \nabla g(Ex) - \nabla g(t^*) \rangle.$$

We claim that (2.13)–(2.17) are sufficient to establish (2.12). To see this, note that $Ex^* = t^*$ (cf. Lemma 2.1) and $\nabla f(x) - \nabla f(x^*) = E^T \nabla g(Ex) - E^T \nabla g(Ex^*)$ (cf. (2.1)), so (2.17) and (2.13)–(2.15) yield

$$\begin{aligned} 2\sigma \|Ex - t^*\|^2 &\leq \langle Ex - t^*, \nabla g(Ex) - \nabla g(t^*) \rangle \\ &= \langle x - x^*, \nabla f(x) - \nabla f(x^*) \rangle \\ &= \langle x - x^*, (A_I)^T \lambda_I - z + x - (A_I)^T \lambda_I^* \rangle \\ &= \langle A_I(x - x^*), \lambda_I - \lambda_I^* \rangle + \langle x - x^*, x - z \rangle \\ &= \langle A_I(x - z), \lambda_I - \lambda_I^* \rangle + \langle x - x^*, x - z \rangle \\ &= O(\|x - z\|(\|\lambda - \lambda^*\| + \|x - x^*\|)), \end{aligned}$$

where for convenience we use the notation $\alpha = O(\beta)$ to indicate that $\alpha \leq \kappa\beta$ for some scalar $\kappa > 0$ depending on ζ and the problem data only. Combining the above relation with (2.16) then gives

$$\begin{aligned} \|x - x^*\|^2 &\leq \omega^2 (\|Ex - t^*\| + \|x - z\|)^2 \\ &\leq 2\omega^2 (\|Ex - t^*\|^2 + \|x - z\|^2) \\ &= O(\|x - z\|(\|\lambda - \lambda^*\| + \|x - x^*\|) + \|x - z\|^2) \\ &= O(\|x - z\|(\|Ex - t^*\| + \|x - z\|)), \end{aligned}$$

where the last step follows from using (2.16). Hence $\|Ex - t^*\|^2$, which is clearly $O(\|x - x^*\|^2)$, must be $O(\|x - z\|(\|Ex - t^*\| + \|x - z\|))$, i.e., there exists a scalar $\kappa > 0$ (depending on ζ and the problem data only) such that

$$\|Ex - t^*\|^2 \leq \kappa (\|x - z\| \|Ex - t^*\| + \|x - z\|^2).$$

This is a quadratic inequality of the form $a^2 \leq \kappa(ab + b^2)$, which implies $a \leq (\kappa + \sqrt{\kappa^2 + 4\kappa})b/2$. Hence we obtain that

$$\|Ex - t^*\| \leq (\kappa + \sqrt{\kappa^2 + 4\kappa})\|x - z\|/2,$$

which when combined with (2.16) shows $\|x - x^*\| = O(\|x - z\|)$. Since $x^* \in X^*$ so clearly $\phi(x) \leq \|x - x^*\|$, this then completes our proof. \square

We remark that computable error bounds like the one given in Theorem 2.1 have been quite well studied. In fact, a bound identical to that given in Theorem 2.1 was proposed by Pang for the special case where f is strongly convex [Pan87]. Alternative bounds have also been proposed for strongly convex programs [MaD88b] and for monotone linear complementarity problems [MaS86]. However, it is unclear whether these alternative bounds are useful for analyzing the rate of convergence of algorithms. On the other hand, note that the bound in Theorem 2.1 holds only locally, and it would be interesting to see whether this bound can be extended to hold globally on $X \cap C_f$.

3. A general linear convergence result. In this section we give general conditions for a sequence of points in $X \cap C_f$ to converge at least linearly to an optimal

solution of (1.2) or, equivalently, to an element of X^* . This result, based in large part on the error bound developed in §2, will be used in §§4 and 5 to establish the linear convergence of a gradient projection algorithm and a matrix splitting algorithm.

We first state the following simple lemma.

LEMMA 3.1. *Let $\{x^r\}$ be a sequence of vectors in $X \cap C_f$ satisfying*

$$(3.1) \quad \|x^r - x^{r+1}\|^2 \leq \kappa_1(f(x^r) - f(x^{r+1})), \quad \forall r \geq r_0,$$

for some scalar $\kappa_1 > 0$. If $f(x^r)$ converges linearly, then $\{x^r\}$ also converges linearly.

(Recall that here “linear convergence” means R -linear convergence in the sense of Ortega and Rheinboldt [OrR70].)

The general linear convergence result is the following theorem.

THEOREM 3.1. *Let v^* denote the optimal value of (1.2). Let $\{x^r\}$ be a sequence of vectors in $X \cap C_f$ satisfying the following two conditions:*

$$(3.2) \quad f(x^r) - v^* \leq \kappa_2 \phi(x^r)^2, \quad \forall r \geq r_0,$$

$$(3.3) \quad \|x^r - [x^r - \nabla f(x^r)]^+\|^2 \leq \kappa_3(f(x^r) - f(x^{r+1})), \quad \forall r \geq r_0,$$

where κ_2, κ_3 and r_0 are some positive scalars. Then, $\{f(x^r)\}$ converges at least linearly to v^* . If, in addition, (3.1) holds, then $\{x^r\}$ converges at least linearly to an element of X^* .

Proof. By (3.3), $\{f(x^r)\}$ is monotonically decreasing. Since f is also bounded from below on X (cf. Assumption 1.2 (a)), then $f(x^r) - f(x^{r+1}) \rightarrow 0$, so (3.3) yields $\|x^r - [x^r - \nabla f(x^r)]^+\| \rightarrow 0$. Hence, by Theorem 2.1, there exist scalars $\tau > 0$ and $r_1 \geq r_0$ such that

$$(3.4) \quad \phi(x^r) \leq \tau \|x^r - [x^r - \nabla f(x^r)]^+\|, \quad \forall r \geq r_1.$$

By combining (3.2), (3.3), and (3.4), we obtain that, for each $r \geq r_1$, there holds

$$(3.5) \quad \begin{aligned} f(x^r) - v^* &\leq \kappa_2 \phi(x^r)^2 \\ &\leq \kappa_2 \tau^2 \|x^r - [x^r - \nabla f(x^r)]^+\|^2 \\ &\leq \kappa_2 \kappa_3 \tau^2 (f(x^r) - f(x^{r+1})). \end{aligned}$$

Upon rearranging terms in (3.5), we then obtain

$$f(x^{r+1}) - v^* \leq \left(1 - \frac{1}{\kappa_2 \kappa_3 \tau^2}\right) (f(x^r) - v^*),$$

so $\{f(x^r)\}$ converges at least linearly to v^* . If (3.1) holds, then it follows from Lemma 3.1 that $\{x^r\}$ converges at least linearly. Let x^∞ denote the limit point of $\{x^r\}$. Then, $x^\infty \in X$ (since X is closed) and, by the lower semicontinuity of f , $f(x^\infty) \leq v^*$. Therefore $x^\infty \in X^*$. \square

(Roughly speaking, (3.2) says that the difference in cost between an iterate and its nearest optimal solution should grow *at most* quadratically in the distance between them; and (3.3) says that the decrease in the cost at each iteration should grow *at least* quadratically in the “residual” at the current iterate.)

It turns out that, for our applications (see §§4 and 5), (3.1) and (3.3) are relatively easy to verify. The difficulty lies in verifying that (3.2) holds. To help us with this

endeavor, we develop below, by using Lemmas 2.2, 2.3, and 2.5, a sufficient condition for (3.2) to hold. This condition, although more restrictive than (3.2), is much easier to verify for the algorithms considered in this paper.

LEMMA 3.2.. *Suppose that $\{x^r\}$ satisfies (3.1) and (3.3) for some scalars κ_1, κ_3 , and r_0 , and*

$$(3.6) \quad x^{r+1} = [x^r - \alpha^r \nabla f(x^r) + e^r]^+, \quad \forall r \geq r_1,$$

for some index r_1 , some bounded sequence of scalars $\{\alpha^r\}$ bounded away from zero and some sequence of n -vectors $e^r \rightarrow 0$. Then $\{x^r\}$ satisfies (3.2) for some scalar κ_2 (possibly with a different value for r_0).

Proof. Since f is bounded from below on X (cf. Assumption 1.2 (a)) and (3.1) and (3.3) hold, then

$$(3.7) \quad x^r - x^{r-1} \rightarrow 0,$$

$$(3.8) \quad x^r - [x^r - \nabla f(x^r)]^+ \rightarrow 0.$$

We claim that there exists an index $r_2 \geq r_1$ such that

$$(3.9) \quad \langle \nabla f(x^*), x^r - x^* \rangle = 0, \quad \forall x^* \in X^*,$$

for all $r \geq r_2$. To see this, let X be expressed as $X = \{x \in \mathbb{R}^n \mid Ax \geq b\}$, for some $k \times n$ matrix A and some k -vector b , and, for every $r \geq r_1$, let I^r denote the set of indices $i \in \{1, \dots, k\}$ such that $A_i x^r = b_i$. For any $I \subseteq \{1, \dots, k\}$, define the index set $\mathcal{R}_I = \{r \in \{1, 2, \dots\} \mid I^r = I\}$. It suffices to show that, for any I with \mathcal{R}_I infinite, (3.9) holds for all $r \in \mathcal{R}_I$ sufficiently large. We show this below.

Fix any I for which \mathcal{R}_I is infinite. Our argument will follow closely the proof of Lemma 2.4. Since $\{f(x^r)\}$ is monotonically decreasing (cf. (3.1)), then it is bounded. Hence, by Lemma 2.3, $\{Ex^r\}$ lies in a compact subset of C_g . Let t^∞ be any cluster point of $\{Ex^{r-1}\}_{\mathcal{R}_I}$ (so $t^\infty \in C_g$) and let \mathcal{R}' be any subsequence of \mathcal{R}_I such that

$$(3.10) \quad \{Ex^{r-1}\}_{\mathcal{R}'} \rightarrow t^\infty.$$

Let $d^\infty = E^T \nabla g(t^\infty) + q$. Then, since $t^\infty \in C_g$ so ∇g is continuous in an open set around t^∞ , we obtain from (3.10) (and using the fact $\nabla f(x^r) = E^T \nabla g(Ex^r) + q$ for all r) that

$$(3.11) \quad \{\nabla f(x^{r-1})\}_{\mathcal{R}'} \rightarrow d^\infty.$$

For each $r \in \mathcal{R}'$, consider the following linear system in x, z , and λ :

$$\begin{aligned} x - z + A^T \lambda &= \alpha^{r-1} \nabla f(x^{r-1}) - e^{r-1}, & Ex &= Ex^{r-1}, & x - z &= x^{r-1} - x^r, \\ Az &\geq b, & \lambda &\geq 0, & A_i z &= b_i, \quad \forall i \in I, & \lambda_i &= 0, \quad \forall i \notin I. \end{aligned}$$

The above system is consistent since, by $I^r = I$ and (3.6), it is satisfied by $x = x^{r-1}$, $z = x^r$, and some λ in \mathbb{R}^k (cf. (2.7)–(2.8)). Then, by Lemma 2.2, it has a solution $(\hat{x}^r, \hat{z}^r, \hat{\lambda}^r)$ whose size is bounded by some constant (depending on A and E only) times the size of the right-hand side. Since the right-hand side of the above system

is bounded as $r \rightarrow \infty$, $r \in \mathcal{R}'$ (cf. (3.7), (3.10)–(3.11), $e^r \rightarrow 0$ and the boundedness of $\{\alpha^r\}$), we have that $\{(\hat{x}^r, \hat{z}^r, \hat{\lambda}^r)\}_{\mathcal{R}'}$ is also bounded. Moreover, every one of its cluster points, say $(x^\infty, z^\infty, \lambda^\infty)$, satisfies together with some $\alpha^\infty > 0$ the following conditions (cf. (3.7), (3.10)–(3.11), $e^r \rightarrow 0$, and the boundedness hypothesis on $\{\alpha^r\}$)

$$(3.12) \quad x^\infty - z^\infty + A^T \lambda^\infty = \alpha^\infty d^\infty, \quad E x^\infty = t^\infty, \quad x^\infty - z^\infty = 0,$$

$$(3.13) \quad A z^\infty \geq b, \quad \lambda^\infty \geq 0, \quad A_i z^\infty = b_i, \quad \forall i \in I, \quad \lambda_i^\infty = 0, \quad \forall i \notin I.$$

This shows $x^\infty = [x^\infty - \alpha^\infty \nabla f(x^\infty)]^+$ (cf. (2.7)–(2.8), $\nabla f(x^\infty) = E^T \nabla g(E x^\infty) + q$ and the definition of d^∞) so, by (1.3), $x^\infty \in X^*$. Fix any $r \in \mathcal{R}_I$. From (3.12)–(3.13) we also have that $A_I x^\infty = b_I$ and $\alpha^\infty \nabla f(x^\infty) = (A_I)^T \lambda_I^\infty$. Since $A_I x^r = b_I$ (cf. $I = I^r$), we thus obtain

$$(3.14) \quad \langle \nabla f(x^\infty), x^r - x^\infty \rangle = \frac{1}{\alpha^\infty} \langle \lambda_I^\infty, A_I(x^r - x^\infty) \rangle = 0.$$

Since x^∞ belongs to the convex set X^* and f is constant on X^* , then we must also have

$$\langle \nabla f(x^\infty), x^* - x^\infty \rangle = 0, \quad \forall x^* \in X^*,$$

which together with (3.14) and the invariance of ∇f on X^* (cf. (2.2)) proves (3.9).

Since $f(x^r) \leq f(x^0)$ for all r (cf. (3.3)) and (3.8) holds, then Lemma 2.5 implies $E x^r \rightarrow t^*$, so there exists an index $r_3 \geq r_2$ such that $E x^r \in \mathcal{U}^*$ for all $r \geq r_3$. Fix any $r \geq r_3$ and let x^* be an element of X^* with $\|x^r - x^*\| = \phi(x^r)$. By the Mean Value Theorem, there exists a ξ lying on the line segment joining x^r with $x^* \in X^*$ such that $f(x^r) - f(x^*) = \langle \nabla f(\xi), x^r - x^* \rangle$. This combined with (3.9) then yields

$$\begin{aligned} f(x^r) - f(x^*) &= \langle \nabla f(\xi), x^r - x^* \rangle \\ &= \langle \nabla f(\xi) - \nabla f(x^*), x^r - x^* \rangle + \langle \nabla f(x^*), x^r - x^* \rangle \\ &= \langle \nabla g(E\xi) - \nabla g(E x^*), E x^r - E x^* \rangle + \langle \nabla f(x^*), x^r - x^* \rangle \\ &\leq \rho \|E\|^2 \|x^r - x^*\|^2 + \langle \nabla f(x^*), x^r - x^* \rangle \\ &= \rho \|E\|^2 \|x^r - x^*\|^2, \end{aligned}$$

where the third equality follows from (2.1) and the inequality follows from the Lipschitz condition (2.6) (recall that $E x^r \in \mathcal{U}^*$ and $E x^* = t^* \in \mathcal{U}^*$). Since $\|x^r - x^*\| = \phi(x^r)$, this shows that (3.2) holds (with κ_2 and r_0 set to, respectively, $\rho \|E\|^2$ and r_3). \square

A few remarks about (3.6) are in order. Condition (3.6) roughly says that the iterates $\{x^r\}$ should eventually identify those constraints representing X that are active at some optimal solution. To see why this helps us to show (3.2), consider the case where X is simply a box (i.e., bound constraints). In this case, (3.6) translates to say that, for all r sufficiently large, those coordinates x_i^r of x^r for which $d_i^* > 0$ (respectively, $d_i^* < 0$) become fixed at the upper (respectively, lower) bound of x_i , which is also the bound that is active for any optimal solution. Then, it follows that, for each such r , there holds $\langle d^*, x^r - x^* \rangle = 0$, for all $x^* \in X^*$ (compare with (3.9)) from which (3.2) readily follows. The scalars $\{\alpha^r\}$ can be thought of as stepsizes and are introduced to model algorithms which incorporate stepsizes into their iterations (such as the gradient projection algorithm and algorithms that employ line search steps). The vectors $\{e^r\}$ carry no meaning in themselves and are introduced mainly

as a convenient tool to simplify the analysis. However, that e^r appears *inside* the projection operator $[\cdot]^+$ is crucial, for otherwise the above constraint identification property would not hold. As we shall see, (3.6) can be used to model a fairly diverse class of algorithms by suitably choosing $\{\alpha^r\}$ and $\{e^r\}$.

By using Lemma 3.2, we immediately obtain the following useful corollary of Theorem 3.1.

COROLLARY 3.1. *Suppose that $\{x^r\}$ satisfies (3.1), (3.3), and (3.6) for some scalars $\kappa_1, \kappa_3, r_0, r_1$, some bounded sequence of scalars $\{\alpha^r\}$ bounded away from zero and some sequence of n -vectors $e^r \rightarrow 0$. Then $\{f(x^r)\}$ converges at least linearly to the optimal value of (1.2) and $\{x^r\}$ converges at least linearly to an element of X^* .*

4. Linear convergence of a gradient projection algorithm. In this section, we make (in addition to Assumptions 1.1 and 1.2) the following assumptions on f .

ASSUMPTION 4.1. (a) $C_f = \mathbb{R}^n$.

(b) ∇f is Lipschitz continuous on \mathbb{R}^n , that is,

$$\|\nabla f(y) - \nabla f(x)\| \leq L\|y - x\|, \quad \forall x, \forall y,$$

where L is the Lipschitz constant.

Consider the following algorithm of Goldstein [Gol64] and of Levitin and Polyak [LeP65] applied to solve this special case of (1.2).

GRADIENT PROJECTION ALGORITHM.

Let $\sigma \in (0, 1)$, $\underline{\alpha} \in (0, 2(1 - \sigma)/L)$ and $\bar{\alpha} \geq \underline{\alpha}$ be given scalars. At the r th iteration, we are given an $x^r \in X$ (with x^0 chosen arbitrarily) and we compute a new iterate x^{r+1} in X according to

$$(4.1) \quad x^{r+1} = [x^r - \alpha^r \nabla f(x^r)]^+,$$

where α^r is any scalar in the interval $[\underline{\alpha}, \bar{\alpha}]$ such that x^{r+1} given by (4.1) satisfies

$$(4.2) \quad f(x^r) - f(x^{r+1}) \geq \frac{\sigma}{\alpha^r} \|x^r - x^{r+1}\|^2.$$

We remark that the restriction (4.2) is fairly mild and is satisfied by a number of well-known stepsize rules for the gradient projection algorithm, including (i) the rule given by [Gol64] and [LeP65]:

$$\epsilon \leq \alpha^r \leq 2/L - \epsilon,$$

with $\epsilon \in (0, 1/L)$ a given scalar; (ii) the Armijo-like rule given by [Ber76] (also see [Dun81]) in which α^r is the *largest* nonnegative power of a given scalar $\beta \in (0, 1)$, multiplied by another given positive scalar, such that x^{r+1} given by (4.1) satisfies

$$f(x^r) - f(x^{r+1}) \geq \kappa \langle \nabla f(x^r), x^r - x^{r+1} \rangle,$$

for some other given scalar $\kappa \in (0, 1)$; and (iii) the Goldstein rule (see [Gol74] for details).

The above gradient projection algorithm has been studied very extensively (see, e.g., [Ber76], [BeG82], [CaM87], [Che84], [Dun81], [Dun87], [GaB82], [GaB84], [Gol64],

[Gol74], [LeP65], [McT72]). Typically, a rate of convergence result for this algorithm requires some type of strong convexity assumption on f (see [Dun81], [Dun87], [LeP65]). An exception to this is a result of Bertsekas and Gafni [BeG82] which establishes linear convergence of the iterates under problem assumptions very similar to ours. On the other hand, their result applies only when the stepsizes are small, whereas the linear convergence result below applies for the general stepsize rule (4.2). This is an important distinction since, in general, it is impractical to use small stepsizes. To prove the latter, we show that the iterates satisfy the convergence conditions given in Corollary 3.1.

THEOREM 4.1. *Let $\{x^r\}$ be a sequence generated by the gradient projection algorithm (4.1)–(4.2). Then, $\{x^r\}$ satisfies the hypothesis of Corollary 3.1 and hence converges at least linearly to an element of X^* .*

Proof. From (4.2) and $\alpha^r \leq \bar{\alpha}$ for all r we see that

$$f(x^r) - f(x^{r+1}) \geq \frac{\sigma}{\bar{\alpha}} \|x^r - x^{r+1}\|^2, \quad \forall r,$$

so (3.1) holds with $\kappa_1 = \bar{\alpha}/\sigma$ and $r_0 = 0$.

Next, we show that (3.3) holds. It is known that, for any $x \in X$ and any $d \in \mathbb{R}^n$, the quantity $\|x - [x - \alpha d]^+\|$ is monotonically increasing with $\alpha > 0$ and the quantity $\|x - [x - \alpha d]^+\|/\alpha$ is monotonically decreasing with $\alpha > 0$ (see [Lem. 1, GaB84] or [Lem. 2.2, CaM87]), so that

$$\|x - [x - \alpha d]^+\| \geq \min\{1, \alpha\} \|x - [x - d]^+\|, \quad \forall \alpha > 0.$$

Applying the above bound with $x = x^r$, $d = \nabla f(x^r)$, and then using (4.1) yields

$$\|x^r - x^{r+1}\| = \|x^r - [x^r - \alpha^r \nabla f(x^r)]^+\| \geq \min\{1, \alpha^r\} \|x^r - [x^r - \nabla f(x^r)]^+\|, \quad \forall r.$$

Since $\alpha^r \geq \underline{\alpha}$ for all r , this together with (3.1) implies that (3.3) holds with $\kappa_3 = \kappa_1/\min\{1, \bar{\alpha}^2\}$ and $r_0 = 0$.

Finally, it is easily seen from (4.1) that (3.6) holds with α^r as given and with $e^r = 0$ for all r and $r_1 = 0$. \square

5. Linear convergence of a matrix splitting algorithm. In this section we make (in addition to Assumptions 1.1 and 1.2) the following assumption on f .

ASSUMPTION 5.1. f is a convex quadratic function, i.e.,

$$(5.1) \quad f(x) = \frac{1}{2} \langle x, Mx \rangle + \langle q, x \rangle, \quad \forall x \in \mathbb{R}^n,$$

where M is some $n \times n$ symmetric positive semidefinite matrix, and q is some n -vector.

(Such f is of the form (1.1) because any symmetric positive semidefinite matrix can be expressed as $E^T E$ for some matrix E .) If in addition X is the nonnegative orthant in \mathbb{R}^n , then (1.2) reduces to the well-known symmetric monotone linear complementarity problem.

Let (B, C) be a *regular splitting* of M (see, e.g., [Kel65], [LiP87], [OrR70]), i.e.,

$$(5.2) \quad M = B + C, \quad B - C \text{ is positive definite},$$

and consider the following algorithm for solving this special case of (1.2).

MATRIX SPLITTING ALGORITHM. At the r th iteration we are given an $x^r \in X$ (x^0 is chosen arbitrarily), and we compute a new iterate x^{r+1} in X satisfying

$$(5.3) \quad x^{r+1} = [x^{r+1} - Bx^{r+1} - Cx^r - q + h^r]^+,$$

where h^r is some n -vector. (One simple choice for (B, C) is $B = \mu I$ and $C = M - \mu I$, where μ is a fixed scalar greater than $\|M\|/2$.)

The problem of finding an x^{r+1} satisfying (5.3) may be viewed as an affine variational inequality problem, whereby x^{r+1} is the vector $y \in X$ which satisfies the variational inequality

$$(5.4) \quad \langle z - y, By + Cx^r + q - h^r \rangle \geq 0, \quad \forall z \in X.$$

Because B is positive definite ($2B$ is the sum of a positive definite matrix $B - C$ and a positive semidefinite matrix M), the above variational inequality problem always admits a unique solution (see, e.g., [BeT89], [KiS80]). Thus, the iterates $\{x^r\}$ are well defined.

The vector x^{r+1} may be viewed as an inexact solution of the affine variational inequality problem

$$(5.5) \quad y = [y - By - Cx^r - q]^+,$$

with h^r as the associated “error” vector (so $h^r = 0$ corresponds to an exact solution). The idea of introducing the error vector h^r in this manner is adopted from Mangasarian [Man90]. We remark that in some special cases, such as when X is a box and B is lower triangular, (5.5) can be solved exactly (see [LiP87]), but in general this is not possible. Let γ denote the smallest eigenvalue of the symmetric part of $B - C$ (which by hypothesis is positive) and let ϵ be a fixed scalar in $(0, \gamma/2]$. We will consider the following restriction on h^r governing how fast h^r tends to zero:

$$(5.6) \quad \|h^r\| \leq (\gamma/2 - \epsilon)\|x^r - x^{r+1}\|, \quad \forall r.$$

It can be verified, by using the linear convergence property of $\{x^r\}$ shown below (see Theorem 5.1), that (5.6) is a special case of the criteria introduced by Mangasarian for the case of a symmetric splitting (see [Man90, Alg. 2.1]). This criterion can be met, for example, by appropriately terminating any iterative method used to solve (5.5). To illustrate, fix r and suppose that we have a sequence of points converging to the solution of (5.5). (Methods for generating such a sequence are described in, for example, [BeT89].) Suppose that the limit is not x^r (otherwise x^r is already in X^*) and let $F : \mathbb{R}^n \mapsto \mathbb{R}^n$ be the continuous function given by $F(y) = [y - By - Cx^r - q]^+$. Then, for all points y sufficiently far along in this sequence we have

$$\|(I - B)(y - F(y))\| \leq (\gamma/2 - \epsilon)\|x^r - F(y)\|.$$

(This is because the limit, say \bar{y} , is not equal to x^r and satisfies $\bar{y} = F(\bar{y})$.) Take any such point y and set

$$h^r = (I - B)(y - F(y)), \quad x^{r+1} = F(y).$$

Then, h^r and x^{r+1} satisfy (5.3) and (5.6).

In the special case where X is a box, the above matrix splitting algorithm has been very well studied (see [Man77], [Pan82], [Pan84], [Pan86], [LuT89a]). But, even in this case, very little is known about its rate of convergence. Only very recently was it shown that the iterates generated by this algorithm indeed converge (see [LuT89a]). If the matrix splitting corresponds to an SOR iteration, then it is known that the sequence $\{Mx^r\}$ converges at least linearly (see [IuD90]). Below we improve on the above results by showing that the iterates converge at least linearly. Moreover, our result holds for the general case where X is any polyhedral set, not just a box. We remark that, from a theoretical standpoint, the general polyhedral case is no harder to treat (using our analysis) than the box case. However, from a practical standpoint, the box case is typically easier to work with.

THEOREM 5.1. *Let $\{x^r\}$ be the sequence generated by the matrix splitting algorithm (5.2)–(5.3), (5.6). Then $\{x^r\}$ satisfies the hypothesis of Corollary 3.1 and hence converges at least linearly to an element of X^* .*

Proof. We first verify that (3.1) holds. Fix any r . Since x^{r+1} satisfies the variational inequality (5.4), then, by plugging in x^r for z and x^{r+1} for y in (5.4), we obtain

$$\langle x^{r+1} - x^r, Bx^{r+1} + Cx^r + q - h^r \rangle \leq 0.$$

Also, from $M = B + C$ (cf. (5.2)) and our choice of f (cf. (5.1)) we have that

$$f(x^{r+1}) - f(x^r) = \langle x^{r+1} - x^r, Bx^{r+1} + Cx^r + q \rangle + \langle x^{r+1} - x^r, (C - B)(x^{r+1} - x^r) \rangle / 2.$$

Combining the above two relations then gives

$$\begin{aligned} f(x^{r+1}) - f(x^r) &\leq \langle x^{r+1} - x^r, h^r \rangle + \langle x^{r+1} - x^r, (C - B)(x^{r+1} - x^r) \rangle / 2 \\ &\leq \|x^{r+1} - x^r\| \|h^r\| - \gamma \|x^{r+1} - x^r\|^2 / 2 \\ &\leq -\epsilon \|x^{r+1} - x^r\|^2, \end{aligned}$$

where the last inequality follows from (5.6). Hence (3.1) holds with $\kappa_1 = 1/\epsilon$ and $r_0 = 0$.

We now show that (3.3) holds. From (5.3) we have that

$$\begin{aligned} \|x^r - [x^r - \nabla f(x^r)]^+\| &= \|x^r - [x^r - Mx^r - q]^+\| \\ &= \|x^r - [x^r - Mx^r - q]^+ - x^{r+1}\| \\ &\quad + \|x^{r+1} - Bx^{r+1} - Cx^r - q + h^r\|^+ \\ &\leq \|x^r - x^{r+1}\| + \|[x^r - Mx^r - q]^+ \\ &\quad - [x^{r+1} - Bx^{r+1} - Cx^r - q + h^r]^+\| \\ &\leq 2\|x^r - x^{r+1}\| + \|Mx^r - Bx^{r+1} - Cx^r + h^r\| \\ &\leq 2\|x^r - x^{r+1}\| + \|B(x^r - x^{r+1})\| + \|h^r\| \\ &\leq (2 + \|B\| + \gamma/2)\|x^r - x^{r+1}\|, \end{aligned}$$

where the second inequality follows from the nonexpansive property of the projection operator $[\cdot]^+$, the third inequality follows from $M = B + C$, and the last inequality follows from (5.6). This together with (3.1) shows that (3.3) holds with $\kappa_3 = (2 + \|B\| + \gamma/2)^2 \kappa_1$ and $r_0 = 0$.

Finally, we show that (3.6) holds with $\alpha^r = 1$ for all r and some sequence of n -vectors $e^r \rightarrow 0$. From (5.3), $\nabla f(x^r) = Mx^r + q$ (cf. (5.1)) and $M = B + C$ (cf. (5.2)) we have

$$x^{r+1} = [x^r - \nabla f(x^r) + B(x^r - x^{r+1}) + h^r]^+, \quad \forall r,$$

so (3.6) holds with $\alpha^r = 1$ and $e^r = B(x^r - x^{r+1}) + h^r$ for all r . Since f is bounded from below on X (cf. Assumption 1.2 (a)), then (3.1) implies $x^r - x^{r+1} \rightarrow 0$. Hence $h^r \rightarrow 0$ (cf. (5.6)) and therefore $e^r \rightarrow 0$. \square

Note that we can allow the matrix splitting (B, C) to vary from iteration to iteration, provided that the eigenvalues of the symmetric part of $B - C$ are bounded from above and are bounded away from zero.

6. Conclusion and extensions. In this paper we have presented a general framework for establishing the linear convergence of descent methods for solving (1.2) and have applied it to two well-known algorithms: the gradient projection algorithm of Goldstein and Levitin and Polyak, and the matrix splitting algorithm using regular splitting. The key to this framework lies in a new bound for estimating the distance from a feasible point to the optimal solution set.

There are a number of directions in which our results can be extended. For example, the bound of Theorem 2.1 can be shown to hold locally for any quadratic (possibly nonconvex) function f , which enables us to extend the results of §5 to symmetric non-monotone linear complementarity problems. In fact, the same bound can be shown to hold locally for nonsymmetric linear complementarity problems as well. (An example given by Mangasarian and Shiau [MaS86, Ex. 2.10] shows that this bound does not hold globally for nonsymmetric problems.) We hope to report on these extensions in the future. Finally, it would be worthwhile to find descent methods, other than those treated here, to which our linear convergence framework can be fruitfully applied. In fact, we have been able to apply this framework to the coordinate descent algorithm to obtain a proof of its linear convergence simpler than that given in [LuT89b].

Acknowledgment. We gratefully acknowledge the comments of the referees which led to significant improvements in the presentation of this paper.

ON THE OPTIMAL TRACKING PROBLEM*

OFER ZEITOUNI ^{†‡} AND MOSHE ZAKAI ^{†§}

Abstract. The problem of optimally tracking a stochastic process based on noisy measurements through a window is being considered. Such a problem arises in a variety of applications where the field of view of the measuring device is limited (e.g., the “aiming” problem). With the objective to minimize the probability to lose track, the problem is formulated as an optimal control problem with partial observations. The existence of an optimal control is proven for both cases of discrete and continuous time (diffusion) signal process observed in white noise. The low observation noise asymptotics are then considered: for a one-dimensional problem, a proposed suboptimal tracker is shown to be asymptotically logarithmically optimal.

Key words. stochastic control, nonlinear filtering, tracking

AMS(MOS) subject classifications. 93E20, 93E11

1. Introduction. Consider a typical tracking system as described in Fig. 1. Here, x_t denotes the (angular) location of a target. A telescope is “attempting” to track the target by changing its boresight angle u_t . Due to the (unknown) motion of the target, and possibly that of the platform on which the telescope is located, the angular position of the target is assumed to be random. The information available for tracking is the image of the target on a light-sensitive screen, whose output depends on the angle between the boresight and target directions. A typical error sensitivity curve $h(x - u)$ is shown in Fig. 1. This signal is then used to rotate the telescope towards the target. Due to the limited field of view of the telescope, information is lost if the pointing error $|x_t - u_t|$ exceeds a level c . The input available to the controller is a noisy version \dot{y}_t of the error signal, namely $\dot{y}_t = h(x_t - u_t) + \dot{v}_t$ where \dot{v}_t is the observation noise, which is generated by the photocell and is independent of the x_t process.

We can model the above problem as follows. Let $x_t \in R^k$ satisfy the stochastic Ito differential equation

$$(1.1) \quad dx_t = m(x_t) dt + \sigma(x_t) dw_t, \quad x_0 = x.$$

The observation $y_t \in R$ satisfies

$$(1.2) \quad dy_t = h(x_t - u_t) dt + \epsilon dv_t, \quad y_0 = 0,$$

where w , v are independent standard Brownian motions, and $\epsilon > 0$ is a constant. The control u_t has to be a functional of t and of the path $\{y_\theta, 0 \leq \theta \leq t\}$, which will

FIG. 1

be denoted y_o^t , namely $u_t = u(t, y_o^t)$. A slightly more general control strategy will be considered later on.

The control functional $u(t, y_o^t)$ has to be chosen so as to achieve the following goals:

1. To keep the target in the field of view for as long as possible.
2. To supply a reliable estimate \hat{x}_t of the target's position x_t .
3. To detect a loss of lock.

In this paper we only deal with the first goal, addressing it as an optimization problem. However, the results in §3 indicate that, in the case of high signal-to-noise ratios (ϵ small), an asymptotically optimal control for goal 1 above becomes (under appropriate assumptions) an asymptotically optimal control for goal 2.

We note that in the model of (1.1), (1.2), we have not taken into account any dynamics limitations on the control u . Such limitations appear, for example, when the inertia of the tracking antenna is taken into account. These limitations, while tractable, complicate the analysis and will not be considered in this paper. We observe, however, that in the case of a phase or delay locked loop, such physical limitations do not appear.

The tracking model described above is related not only to the optical tracker of Fig. 1 but also to other systems of technical significance, such as automatic range and angle trackers in radar systems, phase locked and delay locked loops in communication systems, etc. For a guide to applications of tracking systems, c.f. [1].

The design of systems of the type discussed in this paper is usually based on a linearization of $h(x)$ for all x and the application of extended Kalman filtering or Linear Quadratic Gaussian (LQG) techniques. This approach yields, no doubt, very good trackers. However, in general, the linearization approach does not seem to minimize the probability to lose track. In this paper, we focus on this latter minimization. Other tracking models have been analyzed in the literature quite extensively (cf. [1]), however it seems that this optimization framework has not been previously considered. Some recent papers deal with the related (though different) problem of controlling the escape probability of dynamical systems ([6], [11], [12] for the linear case). These

papers deal with the asymptotic ($\epsilon \rightarrow 0$) problem of controlling the system

$$dx^{u,\epsilon} = f(x^{u,\epsilon}, u)dt + \epsilon \sigma(x^{u,\epsilon})dw_t$$

so as to keep $x^{u,\epsilon}$ in a given set G for as long as possible. The tracking problem, even in its asymptotics, differs fundamentally from this model in that the process noise is not assumed to be small.

The existence of an optimal stochastic control for the model of (1.1), (1.2) seems at first sight to be a direct consequence of known results for the partially observed control problem. However, due to the presence of a control in the observation, the model does not conform with known results unless appropriate modifications are introduced. These are carried out in §2, where the optimal control aspects of the tracking problem are discussed. Following Fleming and Pardoux [9], we define the notion of weak sense controllers. We then modify the results of [9] and [4] to show the existence of an optimal weak controller in the case where $h(\cdot)$ is a linear function in the interior of its support. The Appendix discusses the optimal stochastic control problem defined by a discrete time model analogous to the one described above. Existence of solutions, the characterization of the optimizer, as well as some suboptimal controllers are presented.

In §3, which contains the main results of this paper, we derive upper and lower bounds on the performance for the continuous time case. In the particular case where

$$h(\theta) = \begin{cases} h_o \cdot \theta, & |\theta| \leq c, \\ 0, & \text{otherwise,} \end{cases}$$

the upper and lower bounds are asymptotically ($\epsilon \rightarrow 0$) logarithmically tight, leading to explicit asymptotically optimal controls. These bounds are based on appropriately defined discrete time versions of the continuous time models, on bounds on the nonlinear filtering problem, and on large deviations arguments. It is clear that an analogous version of the results could be derived using the same methods for the discrete time case.

Section 3 can be understood without following the proofs in §2.

2. The optimal control aspects of the tracking problem. We assume throughout that the coefficients in (1.1), (1.2) $m(\cdot)$, $\sigma(\cdot)$ are C_b^2 functions of appropriate dimensions, w_t , v_t are standard independent \mathcal{F}_t Brownian motions of dimensions $k, 1$, respectively, $h(\cdot)$ is a continuously differentiable function of compact support $2c$ (i.e., $h(z) \equiv 0$ for $|z| > c$), and $u \in U$, a convex set in \mathbb{R}^k that needs not necessarily be compact. The performance criterion that we want to maximize is

$$(2.1) \quad J_T^u = E(1_{\|x-u\|_T \leq c}).$$

Following [9], we adopt the following formulation: Let $\Omega_1 = C[[0, T]; \mathbb{R}^k]$, $\Omega_2 = C_o[[0, T]; \mathbb{R}]$, and $\Omega_3 = L^\infty([0, T]; \mathbb{R}^k)$. We endow $\Omega_1 \times \Omega_2$ with the supremum norm topology and Ω_3 with the weak topology, and denote $\Omega = \Omega_1 \times \Omega_2 \times \Omega_3$. The canonical element of Ω is denoted (x_t, y_t, u_t) .

Under our assumptions, there exists a strong solution to (1.1), and for each pair of paths $y \in \Omega_2$, $u \in \Omega_3$, there exists a regular conditional probability distribution (rcpd) $P_x^{y,u}$ over $(\Omega_1, \mathcal{B}(\Omega_1))$. Finally, define $\tilde{v}_t = \int_0^t u_s ds$ and let

$$\mathcal{F}_t^1 = \mathcal{F}_t(w), \quad \mathcal{F}_t^2 = \mathcal{F}_t(y) \times \mathcal{F}_t(\tilde{v}).$$

DEFINITION. An admissible wide sense control π is a probability measure on $(\Omega_2 \times \Omega_3, \mathcal{F}_T^2)$ which makes y into an \mathcal{F}_t^2 Brownian motion. The set of admissible controls is denoted Π . The resulting measure on Ω is denoted $\overset{\circ}{P}_\pi(x, y, u)$.

Next define

$$(2.2) \quad z_t = \exp \left(\int_0^t h(x_s - u_s) dy_s - \frac{1}{2} \int_0^t h^2(x_s - u_s) ds \right).$$

Since h is bounded, z_t is an L^1 martingale, and therefore, one may define a new probability measure P_π by

$$(2.3) \quad \frac{dP_\pi(x, y, u)}{d\overset{\circ}{P}_\pi(x, y, u)} = z_T.$$

Note that if $d\pi(y, u) = d\pi(y)\delta(u - g(y))$, where $g(y)$ is a progressively measurable functional on $C[[0, T]; \mathbb{R}]$, then (x, y, u) solves, under P_π , (1.1)–(1.2). In such cases, we will say that u is a *strict sense control*, and the set of such π' is denoted Π^s . Finally, the criterion J^u can be written alternatively as

$$(2.4) \quad J_\pi = E_\pi(1_{\|x-u\|_T \leq c}) = \overset{\circ}{E}_\pi(z_T 1_{\|x-u\|_T \leq c}),$$

where the optimization goal on hand is to compute

$$J^u \triangleq \sup_{\pi \in \Pi} J_\pi.$$

We note that, by an adaptation of the results of [5],

$$(2.5) \quad J^u = \sup_{\pi \in \Pi} J_\pi = \sup_{\pi \in \Pi^s} J_\pi,$$

and moreover, a “separation principle” [9] holds. However, the model (1.1)–(1.2) does not conform directly with the standard partially observed control literature [9], [4], [2], due to the existence of controls in the observation (1.2). To obtain results on the existence of optimal controls, we will restrict the observation function, as follows. Assume that

$$(2.6) \quad h(x) = \begin{cases} h^T x, & \|x\| \leq c, \\ 0, & \|x\| > c \end{cases}$$

The restriction to truncated linear observation functions as in (2.6) will be discussed in the remark following corollary 2.1. We now prove Lemma 2.1.

LEMMA 2.1. *The maximization problem (2.5) is equivalent to the problem of maximizing*

$$\tilde{J}^u = \sup_{\pi \in \Pi} \tilde{J}_\pi$$

where

$$(2.7) \quad \tilde{J}_\pi = \overset{\circ}{E}_\pi(\tilde{z}_T 1_{\|x-u\|_T \leq c})$$

and

$$(2.8) \quad \tilde{z}_t = \exp \left(\int_0^t h^T x_s dy_s - \frac{1}{2} \int_0^t |h^T x_s|^2 ds \right).$$

Proof. Let π^n be a maximizing sequence for (2.5). Define a new sequence of measures by the change of variables $y \rightarrow y + \int_0^\cdot u_s ds$, i.e.,

$$d\tilde{\pi}_n(y, u) = d\pi_n(y + v, u).$$

Clearly, $\tilde{J}_{\pi^n} = J_{\pi^n}$, and therefore $J^u \leq \tilde{J}^u$. The converse is obtained similarly and the lemma is established. \square

Remark. The same lemma holds for strict sense controls, i.e.,

$$\sup_{\pi \in \Pi^s} J_\pi = \sup_{\pi \in \Pi^s} \tilde{J}_\pi = J^u.$$

Lemma 2.1 enables us to apply the results of [4] to obtain Theorem 2.1.

THEOREM 2.1. *Assume U is compact. Then an optimal wide sense control π exists.*

Proof. In light of [4, Thm. 2.11] and of Lemma 2.1, we have only to check that $1_{\|x-u\|>c}$ is, for each $x_t \in \Omega_1$, lower semicontinuous with respect to the weak topology on L_∞ . However, $u_n \xrightarrow{w} u$ implies that $\liminf \|x - u_n\| \geq \|x - u\|$ and therefore $\liminf 1_{\|x-u_n\|>c} \geq 1_{\|x-u\|>c}$, and the conclusion follows. \square

We obtain the following corollary as well.

COROLLARY 2.1. *Theorem 2.1 continues to hold when $U = \mathbb{R}^k$.*

Proof. It suffices to show that the set of probability measures

$$\pi^* = \{\pi \mid J_\pi^u \leq J^u + 1\}$$

is tight. This follows from the fact that

$$P_x(\|x\| > n) \xrightarrow{n \rightarrow \infty} 0 \text{ and } P_v(\|v\| > n) \xrightarrow{n \rightarrow \infty} 0. \quad \square$$

Remark. We comment here on the particular choice of $h(\cdot)$ in (2.6). To simplify matters, consider the case $k = 1$. The proof of the lower semicontinuity of Theorem 3.1 in [9], [2], [4] relied heavily on the “pathwise transformation”

$$\int_0^t h(x_s) dy_s = y_t h(x_t) - \int_0^t y_s h'(x_s) dx_s - \frac{1}{2} \int_0^t y_s h''(x_s) \sigma^2(x_s) ds,$$

which had been used to obtain continuity results of the conditional density. In general, due to the u_t term in z_T , one cannot use this transformation without structural restrictions on u_t , which we prefer not to assume in this stage. Moreover, under the weak topology on u , the convergence of $u_n \xrightarrow{w} u$ does not imply convergence of $\int_0^t h(x_t - u_n(t)) dt$ to $\int_0^t h(x_t - u_t) dt$ or even semicontinuity in any direction. This leads to the (practically important) case (2.6). Note that under more stringent assumptions on u , e.g., $u \in C^1[0, T]$, one may relax that assumption. However, one loses then the compactness properties and consequently the existence theorem.

We conclude this section by pointing out that, for sufficiently smooth controls (and in particular C^1 controls), a separated control solution of the problem can be constructed. The interested reader is referred to [20].

3. High signal-to-noise ratio (SNR) asymptotics. In this section we consider the one-dimensional ($k = 1$) version of the problem (1.1), (1.2) with $\sigma(\cdot) \equiv 1$ and a truncated linear observation function. For the high SNR case, i.e., $\epsilon \rightarrow 0$, we propose a suboptimal filter that is based on the approximation to the conditional mean and show, by bounding techniques, that its performance in a suitable logarithmic sense, is asymptotically optimal. Specifically, we show that, for *any* admissible control rule u and any $T > 0$,

$$(3.1) \quad \liminf_{\epsilon \rightarrow 0} \epsilon \log \inf P^u(\|x - u\|_T > c) \geq -\frac{c^2 h}{2},$$

whereas, using the suboptimal filter \hat{u} described below,

$$(3.2) \quad \lim_{\epsilon \rightarrow 0} \epsilon \log P^{\hat{u}}(\|x - \hat{u}\|_T > c) = -\frac{c^2 h}{2},$$

from which the asymptotic log optimality of \hat{u} follows. Moreover, letting τ^ϵ denote the first exit time $\tau^\epsilon \triangleq \{\inf t : |x_t - u_t| > c\}$, it holds that for any admissible control law,

$$(3.1a) \quad \lim_{\epsilon \rightarrow 0} \epsilon \log E\tau^\epsilon \leq \frac{c^2 h}{2},$$

and for the particular control \hat{u} ,

$$(3.2a) \quad \lim_{\epsilon \rightarrow 0} \epsilon \log E\tau^\epsilon = \frac{c^2 h}{2}.$$

In the sequel, we rewrite the model and prove the asymptotic results. A discussion of the significance of various parameters in the design follows.

Consider the state equation where $\sigma(\cdot) \equiv 1$ and $m(\cdot)$ is a C_b^3 function,

$$(3.3) \quad dx_t = m(x_t) dt + dw_t, \quad x_t \in \mathbb{R}^1,$$

and the observation

$$(3.4) \quad dy_t = h \cdot (x_t - u_t) dt + \epsilon dv_t, \quad y_0 = 0.$$

Note that $h(\cdot)$ is a linear gain throughout this section. We have the following two lemmas.

LEMMA 3.1. *Let $u \in \Pi$. Then (3.1) and (3.1a) hold. Moreover, a nonasymptotic lower bound on the performance is given by (3.13).*

LEMMA 3.2. *Let \hat{u}_t satisfy*

$$d\hat{u}_t = m(\hat{u}_t) dt + \frac{1}{\epsilon} dy_t.$$

Then (3.2) and (3.2a) hold.

Proof of Lemma 3.1. Let $n(\epsilon)$ be a given integer, to be determined below, and define $\Delta t(\epsilon) = T/n(\epsilon)$. (In fact, we will prove more than needed; the less patient reader may assume $n(\epsilon) = 1$ throughout the proof.) Let $\tau_i \triangleq i \cdot \Delta t(\epsilon)$, $i = 0, 1, \dots, n(\epsilon)$. Clearly, for any $u \in \Pi$,

$$E(1_{\|x-u\|_T < c}) \leq P\left(\bigcap_i \{|x_{\tau_i} - u_{\tau_i}| < c\}\right).$$

Therefore (note that the classes of controls on both sides of (3.5) below are identical),

$$(3.5) \quad J_\pi = \sup_{u \in \Pi} E(1_{\|x-u\|_T < c}) \leq \sup_{u \in \Pi} P\left(\bigcap_i \{|x_{\tau_i} - u_{\tau_i}| < c\}\right).$$

Let Π^{dt} denote the controls u , which are adapted to

$$\sigma(y_0^t) \vee \mathcal{F}_{t-\Delta t(\epsilon)}^* \quad \text{where } \mathcal{F}_{t-\Delta t(\epsilon)}^* = \sigma(x_s, \quad 0 \leq s \leq t - \Delta t(\epsilon)),$$

namely, the controller “knows” not only y_0^t but also $x_0^{t-\Delta t(\epsilon)}$. From (3.5) and the definition of Π^{dt} , we have

$$(3.6) \quad \begin{aligned} J_\pi &\leq \sup_{u \in \Pi^{dt}} P\left(\bigcap_i \{|x_{\tau_i} - u_{\tau_i}| < c\}\right) \\ &\leq \prod_{i=0}^{n(\epsilon)} \sup_{u_i \in \sigma(y_{\tau_{i-1}}^{\tau_i}) \vee \mathcal{F}_{\tau_{i-1}}^*} P(|x_{\tau_i} - u_{\tau_i}| < c | x_{\tau_{i-1}}) \\ &= \prod_{i=0}^{n(\epsilon)} E\left\{ \sup_{u_i \in \sigma(y_{\tau_{i-1}}^{\tau_i}) \vee \mathcal{F}_{\tau_{i-1}}^*} P(|x_{\tau_i} - u_{\tau_i}| < c | y_{\tau_{i-1}}^{\tau_i}, x_{\tau_{i-1}}) \right\}, \end{aligned}$$

where we have used in (3.6) the Markov structure of (3.3) and that of $\sigma(y_{\tau_{i-1}}^{\tau_i}) \vee \sigma(x_{\tau_{i-1}})$. Since the right-hand side of (3.6) involves only a one step predictor, and the maximization is unaffected by normalization constants, its optimal solution is easily seen to be

$$(3.7) \quad u_i = \arg \max_u \int_{u-c}^{u+c} \rho_{x, \tau_i}^i(z) dz,$$

where $\rho_{x,t}^i(z)$ satisfies the equation ([17]):

$$(3.8) \quad \begin{aligned} d\rho_{x,t}^i(z) &= \frac{1}{2} \frac{\partial^2}{\partial z^2} \rho_{x,t}^i(z) dt - \frac{\partial(m(z)\rho_{x,t}^i(z))}{\partial z} + \frac{1}{\epsilon^2} h z \rho_{x,t}^i(z) dy_t \\ \rho_{x, \tau_{i-1}}^i(z) &= \delta_{x_{\tau_{i-1}}}(z). \end{aligned}$$

By [18, Thms. 1–3], it holds under our assumptions that

$$(3.9) \quad k_1(t) \mathcal{N}(\tilde{x}_i^L(t), \tilde{\sigma}_i^L(t)) \leq \rho_{x,t}^i(z) \leq k_2(t) \mathcal{N}(\tilde{x}_i^U(t), \tilde{\sigma}_i^U(t)),$$

where $\mathcal{N}(a, b)$ denotes a normal distribution, mean a , variance b , $\tilde{x}_i^L(t)$, $\tilde{x}_i^U(t)$ are the output of $y_{\tau_{i-1}}^{\tau_i}$ driven filters such that $|\tilde{x}_i^L(t) - \tilde{x}_i^U(t)|/(\sigma_i^L(t))^{1/2} \rightarrow 0$ as $\epsilon \rightarrow 0$, $\tilde{\sigma}_i^L(t)$, $\tilde{\sigma}_i^U(t)$, deterministic variances, are of the form

$$(3.10) \quad \tilde{\sigma}_i^{U,L}(t) = \frac{\epsilon}{h} \operatorname{tgh}\left(\frac{ht}{\epsilon}\right) + o(\epsilon),$$

(cf. [18, (3.3a)]), and k_1, k_2 satisfy appropriate stochastic equations such that for all $t > 0$, $k_1(t)/k_2(t) \xrightarrow{\epsilon \rightarrow 0} k(t)$, almost surely and in $L^2(\Omega)$, with $k(t) \neq 0$. Note that the results in [18] require a specific initial density parameterized by a variance γ . However, by the same derivation, these results hold for $\gamma = 0$ with the obvious modifications (i.e., using instead of (2.13a) in [18] the equation $d\Lambda_{it}/dt = I - (P_{it} + g^2 N_0^{-1})\Lambda_{it}^2$). Hence, they hold true for the case of Dirac initial condition, which is the case considered in (3.8). Substituting in the above $t = \tau_i$, we conclude that

$$(3.11) \quad \frac{k_2}{k_1} \mathcal{N}(\tilde{x}_i^U, \tilde{\sigma}_i^U) \geq p(x_t | x_{\tau_{i-1}}, y_{\tau_{i-1}}^{\tau_i}) \geq \frac{k_1}{k_2} \mathcal{N}(\tilde{x}_i^L, \tilde{\sigma}_i^L).$$

Therefore, using (3.11), we have

$$\begin{aligned} & E_{u_i \in \sigma(y_{\tau_{i-1}}^{\tau_i}) \vee \mathcal{F}_{\tau_{i-1}}^*} \inf P(|x_{\tau_i} - u_{\tau_i}| \geq c | y_{\tau_{i-1}}^{\tau_i}) \\ & \geq \frac{k_1}{k_2} E_{u_i \in \sigma(y_{\tau_{i-1}}^{\tau_i}) \vee \mathcal{F}_{\tau_{i-1}}^*} \int_{|x - u_{\tau_i}| > c} \mathcal{N}_x(\tilde{x}_i^L, \tilde{\sigma}_i^L) dx \\ & \geq \frac{k_1}{k_2} \int_{|x| > c} \mathcal{N}_x(0, \tilde{\sigma}_i^L) dx, \end{aligned}$$

which implies, by a direct computation using (3.11), that

$$\begin{aligned} (3.12) \quad & E_{u_i \in \sigma(y_{\tau_{i-1}}^{\tau_i}) \vee \mathcal{F}_{\tau_{i-1}}^*} \inf P(|x_{\tau_i} - u_{\tau_i}| \geq c | y_{\tau_{i-1}}^{\tau_i}, x_{\tau_{i-1}}) \\ & \geq \mu \exp\left(\frac{-c^2 h}{2\epsilon \tanh(h\Delta t/\epsilon)}\right) \geq \tilde{\mu} e^{-c^2 h/2\epsilon}, \end{aligned}$$

where $\mu, \tilde{\mu}$ are deterministic constants independent of Δt and ϵ . Therefore, substituting in (3.6), we have that

$$(3.13) \quad J_\pi \leq \left(1 - \mu \exp\left(-\frac{c^2 h}{2\epsilon \tanh(h\Delta t/\epsilon)}\right)\right)^{n(\epsilon)}.$$

We may optimize $n(\epsilon)$ to get the best possible bound in (3.13) as a function of ϵ . For our needs, it suffices to take $n(\epsilon) = 1$ and conclude that

$$\lim_{\epsilon \rightarrow 0} \epsilon \log \inf_{u \in \Pi} P^u(\|x - u\|_T > c) \geq -\frac{c^2 h}{2},$$

and (3.1) is proven. To see (3.1a), take $\Delta t = 1$ and note that as above the performance is bounded by the performance of the best controller with the additional information $x_{\tau_{i-1}}$. Due to the Markov structure and the uniform bound on the escape probability over an interval of length 1 (here, we use the fact that the escape probabilities are not only bounded below as in the proof above but are actually also bounded above with the same exponent, again due to (3.11)), we have that

$$E(\tau) \leq E \sum_{t=1}^{\infty} t P(|x_{\tau_t} - u_{\tau_t}| > c | x_{\tau_{t-1}}) \prod_{s=1}^{t-1} P(|x_{\tau_s} - u_{\tau_s}| \leq c | x_{\tau_{s-1}})$$

$$\leq k e^{-c^2 h/2\epsilon} \sum_{t=1}^{\infty} t(1 - k e^{-c^2 h/2\epsilon})^{t-1} \leq \tilde{k} e^{c^2 h/2\epsilon},$$

where k, \tilde{k} are ϵ independent constants, and (3.1a) follows. \square

Proof of Lemma 3.2. Define $\mu_t \triangleq u_t - x_t$, we have that

$$(3.14) \quad d\mu_t = (m(\hat{u}_t) - m(x_t)) dt - \frac{h}{\epsilon} \mu_t dt + \sqrt{2} d\tilde{w}_t,$$

where $\tilde{w}_t \triangleq (v_t - w_t)/\sqrt{2}$ is a standard Brownian motion. Consider now the equation

$$(3.15) \quad d\tilde{\mu}_t = -\frac{h}{\epsilon} \tilde{\mu}_t dt + \sqrt{2} d\tilde{w}_t,$$

with the same initial conditions as (3.14), i.e., $\tilde{\mu}_0 = \mu_0 = 0$. Setting $\rho_t = \mu_t - \tilde{\mu}_t$ and $\alpha_t = m(\hat{u}_t) - m(x_t)$, we have

$$\frac{d\rho_t}{dt} = \alpha_t - \frac{h}{\epsilon} \rho_t, \quad \rho_0 = 0$$

which yields

$$\rho_t = \int_0^t \alpha_s \exp\left(\frac{h}{\epsilon}(s-t)\right) ds.$$

Since $m(\cdot)$ was assumed bounded, $\alpha(\cdot)$ is bounded and therefore

$$(3.16) \quad \|\rho\|_t \leq \frac{M\epsilon}{h}$$

for all $0 \leq t \leq \infty$. Therefore, for any time interval, the large deviations behavior of (3.14) is the same as that of (3.15). Note that $\tilde{\mu}_t$ is a Gaussian process, and $\tilde{\mu}_t = \sqrt{2} \int_0^t \exp((h/\epsilon)(s-t)) d\tilde{w}_s$. Therefore,

$$E\tilde{\mu}_{t_1}\tilde{\mu}_{t_2} = \frac{\epsilon}{h} \left[\exp\left(-\frac{h}{\epsilon}|t_1 - t_2|\right) - \exp\left(-\frac{h}{\epsilon}(t_1 + t_2)\right) \right].$$

By known results for the extrema of Gaussian processes, cf. [15],

$$(3.17) \quad \lim_{\epsilon \rightarrow 0} \frac{P(\|\tilde{\mu}\|_T > c)}{(h/\sqrt{2\pi\epsilon}) \int_c^\infty \exp(-(hx^2/2\epsilon)) dx} = 1,$$

which is more than sufficient to show (3.2). Since $\tilde{\mu}_t$ is a Markov process, by (3.17) we obtain (3.2a) by following the derivation of [16, Chap. 6]. \square

Lemmas 3.1 and 3.2 jointly demonstrate that the filter \hat{u}_t is asymptotically logarithmically optimal. Following are some related issues and generalizations.

First, note that the performance is monotoneous in the value of ϵ . To see that, adjunct to y_t a new additional observation $d\tilde{y}_t = \tilde{\epsilon} d\tilde{v}_t$ where \tilde{v}_t is independent of all other Brownian motions in the model. Clearly, the optimal control does not change, and the optimal value is not worse than when observing the projection

$$\begin{aligned} \hat{y}_t = y_t + \tilde{y}_t &= \int_0^t h(x_t - u_t) dt + \epsilon v_t + \tilde{\epsilon} \tilde{v}_t \\ &= \int_0^t h(x_t - u_t) dt + \sqrt{\epsilon^2 + \tilde{\epsilon}^2} v_t, \end{aligned}$$

where $\stackrel{d}{=}$ denotes equality in distribution, which proves the monotonicity in ϵ . On the other hand, the problem of successfully designing an $h(x - u)$ that is optimal under a specific constraint on h (e.g. $|h|_{\max}$ or $\int_{-c}^c h(\theta)d\theta$) remains open.

Next, we comment on generalizations of the results in this section: A version of the upper bound on the performance (Lemma 3.2) is still valid under a general model ($\sigma(x)$, multidimensional x , nonlinear h) since it can be based on general large deviation estimates instead of the Gaussian estimates we have used. However, the lower bound (3.1) is much harder to compute: for x multidimensional, $h(\cdot)$ linear in the interior of its support, of rank k , $\sigma(x) \equiv \sigma$ and rank $\sigma \sigma^T = k$, one may still apply the results of [18, §4], and obtain the analog of Lemma 3.1. In general, however, Lemma 3.1 depends on obtaining good large deviation bounds on the conditional distribution. For σ or h nonlinear, no such results are available even in the one-dimensional case, and the best one has is [19] or [14], which is not good enough, for it does not provide an exponential rate of decay with ϵ for the unnormalized density. The general multidimensional case (rank $h < k$) is even more difficult since then the conditional density might not converge (as $\epsilon \rightarrow 0$) weakly to a Dirac measure as it does in the one-dimensional case.

Appendix. The discrete time case. In this appendix, we consider the discrete time stochastic control problem associated with the tracking problem.

Let Σ be the state space $\Sigma = \mathbb{R}^k$ or $\Sigma = \{1, 2, \dots, k\}$. Throughout, the norm on Σ is denoted $|\cdot|$. Let x_n be a discrete time Markov chain taking values in Σ with transition probability $P_{x_{n+1}}(\cdot | x_n)$. Let $h: \Sigma \rightarrow \mathbb{R}^1$ be a measurable function of compact support, and define the observation $y_n \in \mathbb{R}^1$ as

$$(A.1) \quad y_{n+1} = y_n + h(x_{n+1} - u_{n+1}) + \epsilon v_{n+1}, \quad y_0 = 0,$$

where $\epsilon > 0$, $\{v_n\}$ is a sequence of independent and identically distributed standard Normal random variables, and $u_{n+1} \in \Sigma$ is an admissible control, i.e., a measurable map $u_{n+1}: \{y_0, y_1, \dots, y_n\} \rightarrow \Sigma$. To simplify matters, the following restrictive assumption is made throughout this appendix:

(A) u_n takes values in a compact convex set $U \subset \Sigma$.

Dispensing of (A) is standard via tightness arguments and will therefore not be considered here. The class of admissible controls will be denoted Π in the sequel. The optimal control problem considered here is to find a policy $\{u_n\}$ that minimizes the cost

$$(A.2) \quad J^u \triangleq \text{Prob}(\|x - u\|_N > c),$$

where c is a given constant > 0 and $\|a\|_n = \sup_{0 \leq t \leq n} |a_t|$.

Remark. In general, we should allow for randomized controls u . However, using the results of [3], we can show that the infimum of J^u over randomized controls is the same as the infimum of J^u over strict sense controls. Since we will show below that the infimum over strict sense controls is indeed achieved, it is enough to consider strict sense controls only. That is in contrast with the continuous time case.

We now transfer this problem to the standard partially observed framework. First, enlarge the state space Σ to

$$\tilde{\Sigma} = \Sigma \times \{0, 1\}.$$

Next, define a *controlled Markov* chain on $\tilde{\Sigma}$ by considering pairs $\mu_n^u = \{x_n, z_n\}$, where x_n is as before and $z_1 = 0$, $z_n = 1_{\|x - u\|_n \geq c}$. Note that z_n has at most one transition

from zero to one. Furthermore, μ_n^u has a transition kernel of the form

$$\begin{aligned}
 (A.3) \quad & P_{\mu_{n+1}^u}((A, 0) \mid \mu_n^u = (x_n, 0)) = \int_A dP_{x_{n+1}}(\theta \mid x_n) 1_{|\theta - u_{n+1}| \leq c}, \\
 & P_{\mu_{n+1}^u}((A, 1) \mid \mu_n^u = (x_n, 0)) = \int_A dP_{x_{n+1}}(\theta \mid x_n) 1_{|\theta - u_{n+1}| > c}, \\
 & P_{\mu_{n+1}^u}((A, 0) \mid \mu_n^u = (x_n, 1)) = 0, \\
 & P_{\mu_{n+1}^u}((A, 1) \mid \mu_n^u = (x_n, 1)) = \int_A dP_{x_{n+1}}(\theta \mid x_n).
 \end{aligned}$$

Let $M_1(\tilde{\Sigma})$ denote the space of probability measures on $\tilde{\Sigma}$. $M_1(\tilde{\Sigma})$ is a Polish space, with the Levy-Prohorov metric, which is compatible with weak convergence [8, Chap. 3, Thm. 1.7]. We take $M_1(\tilde{\Sigma})$ to be our new state space, and on $M_1(\tilde{\Sigma})$ we will consider the process of conditional measures of μ_n^u conditioned on $y_o^n = \{y_o, y_1, \dots, y_n\}$,

$$Q_{\mu_n}^u(\cdot) \triangleq P_{\mu_n^u}(\cdot \mid y_o^n).$$

Note that for all Borel sets $A \subset B(\tilde{\Sigma})$,

$$\begin{aligned}
 (A.4) \quad & Q_{\mu_{n+1}}^u(A) = \sum_{\theta=0}^1 \int_{\eta \in \Sigma} dQ_{\mu_n}^u(\eta, \theta) P_{\mu_{n+1}^u}(A \mid \mu_n = \{\eta, \theta\}) \\
 & \frac{1}{\sqrt{2\pi\epsilon}} e^{-(y_{n+1} - y_n - h(\eta - u_{n+1}))^2 / 2\epsilon^2}.
 \end{aligned}$$

$Q_{\mu_{n+1}}^u \in M_1(\tilde{\Sigma})$ will be our new state. By the innovation decomposition,

$$(A.5) \quad y_{n+1} - y_n = \sum_{\theta=0}^1 \int_{\eta \in \Sigma} dQ_{\mu_n}^u(\eta, \theta) h(\eta - u_{n+1}) + \epsilon \hat{v}_{n+1},$$

where $\{\hat{v}\}_n$ is an independent and identically distributed standard Normal sequence such that \hat{v}_n is independent of $(Q_{\mu_1}^u, \dots, Q_{\mu_n}^u)$. Consequently, combining (A.4) and (A.5), one sees that the conditional measures form a controlled Markov chain in the sense of [3]. Moreover, note that

$$J^u = E(1_{\|x-u\|_N > c}) = \int_{\Sigma} dP_{\mu_N}(\theta, 1) = E \int_{\Sigma} dQ_{\mu_N}^u(\theta, 1),$$

where the last expectation is with respect to the sequence $\{\hat{v}_i\}$, $i = 1, \dots, N$. Therefore, the original problem transforms into a control problem in the variables $Q_{\mu_n}^u$ with terminal cost.

As a last general remark, note that

$$J^u = 1 - E \int_{\Sigma} dQ_{\mu_N}^u(\theta, 0).$$

Moreover, as far as the optimization problem is concerned, modifying $h(x_n - u_n)$ to $\tilde{h}(x_n - u_n, z_n)$ with $\tilde{h}(x_n - u_n, 0) = h(x_n - u_n)$ and $\tilde{h}(x_n - u_n, 1) = 0$ will not change the value function for any y measurable control. Indeed, let

$$\tilde{y}_{n+1} = \tilde{y}_n + \tilde{h}(x_{n+1} - u_{n+1}, z_{n+1}) + \epsilon v_n.$$

Let $u_n(\cdot)$ be an admissible control. Up to $\tau = \inf\{t \mid z_t = 1\}$, $y_n = \tilde{y}_n$, and therefore, $J_N^u = J_N$. Further,

$$(A.6) \quad \tilde{y}_{n+1} - \tilde{y}_n = \int_{\eta \in \Sigma} dQ_{\mu_n}^u(\eta, 0) h(\eta - u_{n+1}) + \epsilon \hat{v}_n.$$

As a result of the above, and using (A.4)–(A.6), we may rewrite the optimization problem in terms of $\tilde{Q}_{x_n}(A) \triangleq Q_{x_n}(A, 0)$ as follows.

(P) PROBLEM DEFINITION.

Maximize $E \int_{\Sigma} d\tilde{Q}_{x_n}(\theta)$ subject to the state equations (in $M_1(\Sigma)$):

$$(A.7) \quad \tilde{Q}_{x_{n+1}}(A) = \int_{\eta \in \Sigma \cap \{|x - u_{n+1}| \leq c\}} d\tilde{Q}_{x_n}(\eta) P_{x_{n+1}}(A | x_n = \eta) \\ \cdot \frac{1}{\sqrt{2\pi\epsilon}} \exp \left(- \left(\int_{\Sigma \cap \{|\theta - u_{n+1}| \leq c\}} d\tilde{Q}_{x_n}(\theta) h(\theta - u_{n+1}) - h(\eta - u_{n+1}) + \epsilon \hat{v}_n \right)^2 / 2\epsilon^2 \right),$$

where u_{n+1} is a measurable map of $\{\tilde{Q}_{x_n}\}$.

To discuss existence and structural results, we distinguish between the following two cases:

(a) $\Sigma = \mathbb{R}^k$, U is a closed compact set in \mathbb{R}^k .

(b) $U = \Sigma = \{1, 2, \dots, k\}$, and we take the discrete topology on both.

(a) THE CONTINUOUS CASE. We make the following assumption on the transition probability $P_{x_{n+1}}(A | x_n)$:

(A-C) $P_{x_{n+1}}(A | x_n)$ possesses a continuous density with respect to Lebesgue measure, which we denote by $P_{x_{n+1}}(\theta | x_n)$.

Using an induction argument, we have immediately the following Lemma.

LEMMA A.1. Assume (A-C). Then $\tilde{Q}_{x_{n+1}}^u(A)$ possesses a density with respect to Lebesgue measure and is a continuous function of u_1, u_2, \dots, u_n .

Equipped with Lemma A.1, we may apply a version of [3, Prop. 8.6] to show Theorem A.1.

THEOREM A.1. An optimal Markovian, nonrandomized control for the problem (P) exists, and is given by the solution to the dynamic programming equation:

$$V(m, \tilde{Q}) = \sup_u E^u(V(m+1, \tilde{Q}^*))$$

with the terminal condition

$$V(N, \tilde{Q}) = \int_{\Sigma} d\tilde{Q}(\theta)$$

where E^u is with respect to the transition kernel given by (A.7), i.e., expectation with respect to the Gaussian random variable \hat{v} in the formula

$$\tilde{Q}^*(A) = \frac{1}{\sqrt{2\pi\epsilon}} \int_{\eta \in \Sigma \cap \{|x-u| \leq c\}} d\tilde{Q}(\eta) P(A|\eta) \exp \left(- \left(\int_{\Sigma \cap \{|\theta-u| \leq c\}} d\tilde{Q}(\theta) h(\theta-u) - h(\eta-u) + \epsilon \hat{v} \right)^2 / 2\epsilon^2 \right).$$

Remark. The results of this section can be extended to the case where U is not compact, by noting that $P(\|x\| > K) \xrightarrow{K \rightarrow \infty} 0$, $P(\|\theta\| > K) \xrightarrow{K \rightarrow \infty} 0$ and by using the tightness of P_x , P_y , which follows from those relations.

(b) THE DISCRETE CASE. In this case, $\Sigma \in \{1, \dots, k\}$ and we take $u = \{1, \dots, k\}$. Note that the conditional density $P^u(x_i|y_o^i)$ is now a vector in \mathbb{R}^k . The problem (P) is now identical to the one solved in [7, §8.2]. The results of [7, §8.2] imply that the dynamic programming equation for the problem (P) yields an optimal measurable control, with the dynamic programming equation taking the form

$$(A.8a) \quad V(n, \tilde{Q}) = \sup_u E^u(V(n+1, \tilde{Q}^*))$$

$$(A.8b) \quad V(N, \tilde{Q}) = \sum_{i=1}^k \tilde{Q}(i)$$

where

$$\tilde{Q}^*(j) = \sum_{\ell \in \{1, \dots, k\} \cap \{|\ell-u| \leq c\}} \tilde{Q}(\ell)$$

We conclude this section by noting that solving (P) is equivalent to the following iterative five-step procedure:

- (a) Compute $P_{x_n}(A|y_o^{n+1}, \|x-u\|_n < c)$.
- (b) Propagate $P_{x_n}(A|y_o^{n+1}, \|x-u\|_{n+1} < c)$ according to the dynamics of x_n , i.e., form

$$P_{x_{n+1}}(A|y_o^{n+1}, \|x-u\|_n < c) = \int P_{x_n}(d\eta|y_o^{n+1}, \|x-u\|_n < c) P_{x_{n+1}}(A|\eta).$$

- (c) Choose a u_{n+1} according to an (optimal or suboptimal) strategy.

- (d) Compute $P_{x_{n+1}}(A|y_o^{n+1}, \|x-u\|_{n+1} < c)$.

- (e) Observe y_{n+2} and compute $P_{x_{n+1}}(A|y_o^{n+2}, \|x-u\|_{n+1} < c)$.

Intuitive candidates for suboptimal rules in step c above would be to pick up u_{n+1} as one of the followings:

- (R1) The conditional mean of $P_{x_{n+1}}(\cdot|y_o^{n+1}, \|x-u\|_n < c)$.
- (R2) The maximizer of the density $P_{x_{n+1}}(\cdot|y_o^{n+1}, \|x-u\|_n < c)$ (if such density and maximizer exist).
- (R3) The one-step best predictor, i.e.,

$$\tilde{u}_{n+1} = \arg \max_u \int_{|\eta-u| \leq c} dP_{x_{n+1}}(\eta|y_o^{n+1}, \|x-u\|_n < c)$$

The fact that the different rules may generally lead to very different controls is obvious. When $\epsilon \rightarrow 0$, i.e., the observation noise is small, as seen in §3, (R1) is asymptotically optimal (for the continuous model, although the results are similar in the discrete case), moreover (R2) and (R3) yield the same asymptotic performance as (R1).

A MONTE CARLO METHOD FOR SENSITIVITY ANALYSIS AND PARAMETRIC OPTIMIZATION OF NONLINEAR STOCHASTIC SYSTEMS: THE ERGODIC CASE.*

HAROLD J. KUSHNER^{†‡} AND JICHUAN YANG^{†§}

Abstract. For high-dimensional or nonlinear problems there are serious limitations on the power of available computational methods for the optimization or parametric optimization of stochastic systems of diffusion type. The paper develops an effective Monte Carlo method for obtaining good estimators of systems sensitivities with respect to system parameters, when the system is of interest over a long period of time. The value of the method is borne out by numerical experiments, and the computational requirements are favorable with respect to competing methods when the dimension is high or the nonlinearities “severe.” The method is a type of “derivative of likelihood ratio” method. For a wide class of problems, the cost function or dynamics need not be smooth in the state variables; for example, where the cost is the probability of an event or “sign” functions appear in the dynamics. Under appropriate conditions, it is shown that the invariant measures are differentiable with respect to the parameters. Since the basic diffusion (or other) model cannot be simulated exactly, simulatable approximations are discussed in detail, and estimators of the derivatives of the cost functions for these approximations are obtained and analyzed. It is shown that these estimators and their expectations converge to those for the original problem. Thus, we prove a robustness result for the sensitivity estimators, namely that the derivatives of the ergodic cost functions (and their estimators) for the simulatable approximations converge to those for the approximated process. Such results are essential if a simulation based method is to be used with confidence.

Key words. Monte Carlo method for diffusions, parametric optimization of stochastic systems, sensitivity analysis, optimization of stochastic systems, nonlinear stochastic systems, high-dimensional stochastic systems, parametric optimization of diffusion processes, likelihood ratio method for sensitivity analysis, parametric derivatives of invariant measures, ergodic control

AMS(MOS) subject classifications. 62E25, 93E20, 93E25

1. Introduction. This paper is concerned with a key question in the use of recursive Monte Carlo methods for system optimization, when the system operation and cost are of interest for a long period of time. For many control systems, the control is given a priori in a parametrized form, and for the use of Monte Carlo methods for the optimization of the parameter, we need good estimators of the derivatives of the cost function with respect to the parameter.

Reference [1] develops a very useful method for doing this when the system is of the diffusion or related type and the control interval of concern is finite. Numerical approximations to the unbiased estimators were developed and analyzed, and simulations showed that the method can be superior to competing methods if the system dimension is large or if the system is nonlinear. In this paper, the results of [1] are extended to the ergodic cost problem. New difficulties arise, since we essentially need to deal with derivatives of the invariant measures with respect to the control parameters and with the convergence of suitable computable approximations. Owing to these “ergodic” problems, the assumptions are stronger here than in [1].

Let $x(\cdot)$ be defined by the diffusion

$$(1.1) \quad dx = b(x, \alpha)dt + \sigma(x)dw, \quad x \in R^r,$$

where $a(x) = \sigma(x)\sigma'(x)$ is nondegenerate and α is a control parameter to be chosen. For each α of interest, let $x(\cdot)$ have a unique invariant measure $\mu(\alpha)$. Precise conditions will be given below. For “smooth cost rate” $k(\cdot, \alpha)$, define the “ergodic cost”

$$(1.2) \quad \langle \mu(\alpha), k(\alpha) \rangle \equiv \int \mu(dx, \alpha)k(x, \alpha) \equiv \bar{k}(\alpha).$$

We wish to get an unbiased estimator of $\partial \bar{k}(\alpha)/\partial \alpha$ (as well as reasonable “numerical” approximations from sample simulations) at selected values of α . Such estimators are necessary if we wish to minimize $\bar{k}(\alpha)$ over α by some recursive Monte Carlo (stochastic approximation) method.

Control problems are frequently of this type; i.e., the control is given in a parametric form. Often, a full optimal feedback control is not desired since it might be very difficult to implement, and all the state variables are not available. A good class of parametrized controls might be known, however. See [1] for some examples and further motivation, as well as a discussion of alternative approaches.

Generally, we cannot easily evaluate $\bar{k}(\alpha)$ or its derivatives. Then we might seek a method for getting good estimators that can be used in a recursive Monte Carlo optimization method. The ease of getting the estimates and their quality are key issues in such an approach. The estimators are to be obtained by simulations of (1.1) or of approximations to (1.1), since the solution of (1.1) cannot be known exactly.

Reference [1] developed a general “likelihood ratio derivative”-based method for getting such estimators, under conditions that are much broader than those used in this paper, but for a “finite time” problem. The numerical data in [1], and that obtained subsequently, show that the method can be quite superior to its competitors for nonlinear and high-dimensional systems. The quality of the estimator is judged by the “variance per CPU time required in the simulations.” The reader is referred to [1] for more motivation and examples. The ergodic cost problem is more difficult and requires stronger (hence, the nondegeneracy) conditions. Actually, the method has been successfully tested on many degenerate problems of the type used in [1], so that the conditions that our analysis requires can undoubtedly be weakened. There are ready extensions to the jump-diffusion, reflection, and other standard models. To introduce the idea, we give a brief informal review of one idea in [1], but we use slightly different terminology and stronger conditions than those used in [1].

For given $T < \infty$, define the “finite time” costs

$$C(x, \alpha) = \int_0^T k(x(s), \alpha)ds + k_0(x(T), \alpha), \quad \bar{C}(x, \alpha) = E_x^\alpha C(x, \alpha),$$

where E_x^α denotes the expectation with parameter α and $x(0) = x$. We always use α_0 to denote the point at which the derivative is to be taken. With no loss of generality, α will be a real number, since for the vector case we can estimate the derivative for each component separately. Let $P_x^\alpha(T)$ denote the measure induced by the solution to (1.1) with the initial condition $x(0) = x$, on $C^r[0, T]$, the space of R^r -valued continuous functions on $[0, T]$, with the sup norm. Let $b(x, \alpha)$, $k(x, \alpha)$, and $k_0(x, \alpha)$ be α -differentiable, and define $\alpha = \alpha_0 + \delta\alpha$ and $\delta b(x, \alpha_0, \delta\alpha) = b(x, \alpha_0 + \delta\alpha) - b(x, \alpha_0)$.

Define

$$\begin{aligned}\xi(0, T; \alpha_0, \delta\alpha) &= \int_0^T [\sigma^{-1}(x(s))\delta b(x(s), \alpha_0, \delta\alpha)]' dw(s) \\ &\quad - \frac{1}{2} \int_0^T |\sigma^{-1}(x(s))\delta b(x(s), \alpha_0, \delta\alpha)|^2 ds,\end{aligned}$$

and the Radon–Nikodym derivative

$$(1.3) \quad \frac{dP_x^{\alpha_0 + \delta\alpha}(T)}{dP_x^{\alpha_0}(T)} = \exp \xi(0, T; \alpha_0, \delta\alpha).$$

Define $Z(\cdot, \alpha_0)$ by

$$\begin{aligned}(1.4) \quad Z(T, \alpha_0) &= \int_0^T [\sigma^{-1}(x(s))b_\alpha(x(s), \alpha_0)]' dw(s) \\ &= \int_0^T [b'_\alpha(x(s), \alpha_0)a^{-1}(x(s))][dx(s) - b(x(s), \alpha_0)ds].\end{aligned}$$

We use the subscripted $b_\alpha(x, \alpha_0)$ and others to denote the α -derivatives at α_0 . Then the quantities

$$\begin{aligned}(1.5) \quad Q(\alpha_0) &= \int_0^T [k(x(s), \alpha_0)Z(s, \alpha_0) + k_\alpha(x(s), \alpha_0)]ds \\ &\quad + k_0(x(T), \alpha_0)Z(T, \alpha_0) + k_{0,\alpha}(x(T), \alpha_0),\end{aligned}$$

$$\begin{aligned}(1.5') \quad \hat{Q}(\alpha_0) &= \int_0^T [(k(x(s), \alpha_0) - \bar{k}(x(s), \alpha_0))Z(s, \alpha_0) + k_\alpha(x(s), \alpha_0)]ds \\ &\quad + (k_0(x(T), \alpha_0) - \bar{k}_0(x(T), \alpha_0))Z(T, \alpha_0) + k_{0,\alpha}(x(T), \alpha_0),\end{aligned}$$

where we use $\bar{k}(x(s), \alpha_0) = E_x^{\alpha_0} k(x(s), \alpha_0)$, are unbiased estimators of $\bar{C}_\alpha(x, \alpha_0)$. Thus, if a path of $x(\cdot)$ is available, one can calculate or approximate (1.5) or (1.5').

To avoid the very time-consuming task of evaluating (from the simulations) $\bar{k}(x(s), \alpha_0)$ for each $s \leq T$, in (1.5'), we usually use $\bar{k}(x(T), \alpha_0)$ in place of $\bar{k}(x(s), \alpha_0)$, and with good results.

Generally, paths of the true model $x(\cdot)$ are not available, and we can only approximate via a numerical method (say, a discrete time approximation). Reference [1] discusses two basic classes of such approximations and proves that the estimators obtained from them are good. Getting good estimators is more difficult for the ergodic problem, since we also need to truncate the infinite time interval and approximate (at least implicitly) derivatives of invariant measures, a nontrivial problem.

The proofs use a representation of the invariant measure of the diffusion process in terms of that of an imbedded Markov chain, defined by the random return times to a “recurrence set,” as well as certain Girsanov transformations defined on these “return intervals.” To be sure that these transformations are well defined, a bound on an exponential moment of the return time is needed. This is provided by the stability result in §2. Section 3 is concerned with ergodic properties of the diffusion

model. The imbedded Markov chain is defined, the invariant measure of the diffusion is defined in terms of this Markov chain, and the needed recurrence (ϕ -recurrence) properties of the chains are stated. Section 4 is concerned with the existence of the derivative of the invariant measure of the diffusion with respect to the parameter. The differentiability is first shown for the invariant measure of the imbedded chain, and this is then used to obtain the result for the diffusion. The differentiability is in two senses: setwise convergence and weak convergence. Some preliminary results concerning equicontinuity of certain sets of functions and invertibility of the operator $I - \tilde{P}(\alpha_0)$ (defined in the section) are first proved. It is also shown that the derivative of the invariant measure can be well approximated by the derivative of the transition function for large enough time.

Since the diffusion model is an "ideal" model and the paths can at best be approximated in some statistical sense, we need to know that the natural approximations can be used with confidence in any implementation. Reference [1] deals with two types of approximations, a discrete time model and a Markov chain approximation. Either can be used here, but we restrict our attention to the first approximation. The model is introduced in §5, and some preliminary sensitivity results are stated there. Some needed stability estimates (analogous to the estimates of §2), uniform in the approximation parameter, are obtained in §6. The main theoretical results for the approximations are in §7, where, after getting some preliminary results concerning the rate of convergence of certain quantities to their "invariant means," it is shown that the invariant measure of the discrete time approximation is differentiable with respect to the control parameter and that the derivatives converge to the derivative of the invariant measure of the diffusion. Results concerning finite time approximations are also shown. The results imply an important robustness of the derivatives with respect to the model. This is new and very useful from the point of view of applications, since otherwise general results concerning the existence of the derivatives for the ideal model would not have much practical relevance.

Numerical data is given in §8. The basic method of implementation requires the use of a discrete parameter approximation, over a finite time period. The period needs to be large enough to capture the "ergodic effects." Two methods are compared; a finite difference method, which has been altered to be fairly efficient, and several forms of our method. The comparison depends on the problem, but it is clear that for a large class of nonlinear problems, our method is preferable. We note that reasonable examples can be constructed so that any chosen method works best, keeping an open mind in any application.

The analysis is restricted to nondegenerate diffusion models, but a similar analysis can be carried out with various related process, provided only that ergodic results analogous to those of §3 are available.

2. Stability of $x(\cdot)$. To develop the ergodic results and use a Girsanov measure transformation method on random unbounded intervals, suitable stability properties of $x(\cdot)$ must be proved. We will use the following assumptions. The parameter α will be confined to a compact interval A_0 with α_0 in its interior. The symbol $'$ denotes transpose.

Assumption 2.1. $b(\cdot, \cdot)$ and $\sigma(\cdot)$ are continuous, $\sigma(\cdot)$ is bounded, and $\sigma(x)\sigma'(x) = a(x) \geq \varepsilon_0 I$ for some $\varepsilon_0 > 0$. For some $K < \infty$, $|b(x, \alpha)| \leq K|x| + K$.

Assumption 2.2. Equation (1.1) has a unique weak sense solution for each $x(0) = x$ and $\alpha \in A_0$.

Assumption 2.3. There is a twice continuously differentiable Lyapunov function $0 \leq V(x) \rightarrow \infty$ as $|x| \rightarrow \infty$ and $\varepsilon_1 > 0$ such that

- (a) $V_{xx}(x)$ is bounded and continuous,
- (b) $V'_x(x)b(x, \alpha) \leq -\varepsilon_1 < 0$ for large $|x|$, $\alpha \in A_0$,
- (c) $\lim_{|x| \rightarrow \infty} \sup_{\alpha \in A_0} |V_x(x)|^2 / |V'_x(x)b(x, \alpha)| < \infty$,
- (d) $\lim_{|x| \rightarrow \infty} \sup_{\alpha \in A_0} |V_{xx}(x) \cdot a(x)| / |V'_x(x)b(x, \alpha)| < 2$.

Assumption 2.4. When $b(x, \alpha) \equiv 0$, (1.1) has a unique weak sense solution for each $x = x(0)$.

Assumption 2.5. There is a bounded continuous function $b_\alpha(\cdot, \alpha_0)$ such that as $\delta\alpha \rightarrow 0$,

$$\delta b(x, \alpha_0, \delta\alpha) / \delta\alpha \rightarrow b_\alpha(x, \alpha_0)$$

boundedly and uniformly on each compact x -set.

Remark on Assumption 2.3. The condition does not seem to be very restrictive. It holds, in particular, for the linear case $b(x, \alpha) = A(\alpha)x$, where $A(\alpha)$ is “uniformly stable” for $\alpha \in A_0$.

The conditions in Assumption 2.3 can be satisfied when we start with a stable system that satisfies these conditions and then modifies the system by a Girsanov measure transformation. There are existence theorems for stochastic Lyapunov functions. The proofs in [7] can be extended to show the existence of the required $V(\cdot)$ under appropriate conditions.

Remark on Assumption 2.2. Assumption 2.4 and the stability Theorem 2.1 imply Assumption 2.2, but it is useful to isolate it as a separate condition.

THEOREM 2.1. *Suppose that Assumptions 2.1–2.3 hold. There is a compact set Q , which is the closure of its interior such that for each compact $Q_1 \supset Q$ and τ_1 defined by $\tau_1 = \min\{t: x(t) \in Q\}$, we have for small $\rho > 0$*

$$(2.1) \quad \sup_{\alpha \in A_0} \sup_{x \in Q_1 - Q} E_x^\alpha \exp \rho \tau_1 < \infty.$$

Proof. Let \mathcal{L} denote the differential generator of $x(\cdot)$: $\mathcal{L}f(x) = f'_x(x)b(x, \alpha) + \frac{1}{2}\text{trace } f_{xx}(x) \cdot a(x)$. Then

$$\begin{aligned} \mathcal{L}e^{\rho V(x)} &= \rho e^{\rho V(x)} [V'_x(x)b(x, \alpha) \\ &\quad + \rho \text{trace}(V_x(x)V'_x(x)) \cdot a(x)/2 + \text{trace } V_{xx}(x) \cdot a(x)/2]. \end{aligned}$$

Let Q be large enough and ρ small enough such that for $x \notin Q$ (use Assumption 2.3) and some $\lambda > 0$,

$$(2.2) \quad \mathcal{L}e^{\rho V(x)} \leq -\rho\lambda e^{\rho V(x)}.$$

It then follows that for small ρ and $x \notin Q$

$$(2.3) \quad \mathcal{L}[e^{\lambda\rho t} e^{\rho V(x)}] \leq 0.$$

From (2.3), Itô's lemma, and a stopping time argument, it follows that

$$(2.4) \quad E_x^\alpha e^{\lambda\rho\tau_1} \leq E_x^\alpha e^{\lambda\rho\tau_1} e^{\rho V(x(\tau_1))} \leq e^{\rho V(x)}$$

for small ρ and $x = x(0) \notin Q$, which yields the result. \square

COROLLARY. Suppose that Assumptions 2.1–2.3 hold. Let Q and Q_1 be as in the theorem. Define τ to be the first return time of $x(\cdot)$ to Q after hitting ∂Q_1 . Then, for small $\rho > 0$

$$(2.5) \quad \sup_{\alpha \in A_0} \sup_{x \in \partial Q} E_x^\alpha e^{\rho\tau} < \infty.$$

The proof follows from Theorem 2.1 and the nondegeneracy, and is omitted.

3. Ergodic properties of (1.1). By Assumptions 2.1–2.3 and Theorem 2.1, for each $\alpha \in A_0$, $x(\cdot)$ is a recurrent strong Feller process. Let $P(x, t, A \mid \alpha)$ denote the transition function. By [2] and [3], there is a unique invariant measure $\mu(\alpha)$ with $\mu(R^r, \alpha) = 1$ and $P(x, t, A \mid \alpha) \xrightarrow{t} \mu(A, \alpha)$ as $t \rightarrow \infty$, for each Borel A . For $t > 0$, $P(x, t, \cdot \mid \alpha)$ has a bounded and nowhere zero density with respect to Lebesgue measure, and so does $\mu(\alpha)$.

We next state a representation of $\mu(\alpha)$ first used by Khazminskii [2], which is very useful for analysis, largely because it is difficult to work with ergodic problems and to deal with questions concerning convergence to invariant measures when the state space is unbounded.

Let $G_1 \supset G$ be compact sets, each of which is connected and is the closure of its interior. Denote the boundaries by Γ_1 and Γ , respectively, and let G be strictly interior to G_1 . Let Γ and Γ_1 be differentiable. For any $x(0)$, define the following stopping times:

$$\begin{aligned} \tau' &= \inf\{t: x(t) \in \Gamma_1\}, \\ \tau_1 &= \inf\{t: x(t) \in \Gamma\}, \\ \tau'_1 &= \inf\{t > \tau_1: x(t) \in \Gamma_1\}. \end{aligned}$$

For $n > 1$,

$$\tau_n = \inf\{t > \tau'_{n-1}: x(t) \in \Gamma\}, \quad \tau'_n = \inf\{t > \tau_n: x(t) \in \Gamma_1\}.$$

For $x = x(0) \in \Gamma$, we use τ to denote $\tau_2 - \tau_1 = \tau_2$, the canonical “return” time to Γ , after hitting Γ_1 .

By Theorem 2.1, for small $\rho > 0$,

$$(3.1) \quad \sup_{x \in \Gamma, \alpha \in A_0} E_x^\alpha \tau < \infty, \quad \sup_{x \in \Gamma, \alpha \in A_0} E_x^\alpha e^{\rho\tau} < \infty.$$

Let $\alpha \in A_0$. Define the process $\tilde{X}_n = x(\tau_n)$. By [2] and Assumptions 2.1–2.3, $\{\tilde{X}_n\}$ is a recurrent homogeneous Markov chain on Γ . Let $\tilde{P}(x, n, \cdot \mid \alpha)$ denote its transition probability. It has a unique invariant measure $\tilde{\mu}(\alpha)$.

The chain is also defined for initial condition $x = \tilde{X}_0 \in G$. Even though $\tilde{X}_n \in \Gamma$, for $n \geq 1$, it will be useful to use G as the state space in §6 and afterwards, to unify the notation with that for the approximations. The results up to §5 hold with this change.

Define $\tau(A) = \int_0^\tau I_A(x(s))ds$ for Borel sets A . Then we can write ([2], [3])

$$(3.2) \quad \mu(A, \alpha) = \bar{\mu}(A, \alpha) / \bar{\mu}(R^r, \alpha),$$

where

$$\bar{\mu}(A, \alpha) = \int_\Gamma \tilde{\mu}(dx, \alpha) E_x^\alpha \tau(A).$$

Hence, for bounded measurable $f(\cdot)$, we have the representation

$$(3.3) \quad \langle \mu(\alpha), f \rangle = \frac{\int_{\Gamma} \tilde{\mu}(dx, \alpha) E_x^{\alpha} \int_0^{\tau} f(x(s)) ds}{\int_{\Gamma} \tilde{\mu}(dx, \alpha) E_x^{\alpha} \tau}.$$

Equation (3.3) and various approximations to it will be widely used in the following.

Properties of $\{\tilde{X}_n\}$. The chain $\{\tilde{X}_n\}$ on state space Γ is said to be uniformly ϕ -recurrent (for a given measure ϕ on the Borel sets of Γ) if for each Borel $B \subset \Gamma$ with $\phi(B) > 0$

$$P_x^{\alpha} \{\tilde{X}_i \in B, \text{ some } i \leq m\} \rightarrow 1 \text{ as } m \rightarrow \infty;$$

uniformly in $x \in \Gamma$. A sufficient condition [4, p. 29] is that if $\phi(B) > 0$, there exists $n < \infty$, $\varepsilon > 0$ (which can be B -dependent) such that

$$(3.4) \quad P_x^{\alpha} \{\tilde{X}_i \in B, \text{ some } i \leq n\} \geq \varepsilon, \quad \text{for all } x \in \Gamma.$$

If the chain is ϕ -recurrent and a -periodic then there exists $C < \infty$, $\gamma < 1$ such that for Borel sets B

$$(3.5) \quad |P_x^{\alpha} \{\tilde{X}_n \in B\} - \tilde{\mu}(B, \alpha)| \leq C\gamma^n,$$

and for bounded measurable $f(\cdot)$,

$$(3.6) \quad |E_x^{\alpha} f(\tilde{X}_n) - \tilde{f}^{\alpha}| \leq 2C\gamma^n \|f - \tilde{f}^{\alpha}\|,$$

where $\|f\| = \sup_x |f(x)|$ and $\tilde{f}^{\alpha} = \langle \tilde{\mu}(\alpha), f \rangle$.

The next theorem follows from [3, p. 339, proof of Theorem 5.1]. The model in the reference does not explicitly include a parameter α , but it is easily seen from the proof of the cited theorem that the nondegeneracy and the fact that the moment bounds in Theorem 2.1 do not depend on $\alpha \in A_0$ imply that (3.4) is uniform in $\alpha \in A_0$ for some $\varepsilon > 0$. In fact, we can use $n = 1$. Actually, we will only need the result for $\alpha = \alpha_0$.

THEOREM 3.1. *Suppose that Assumptions 2.1–2.3 hold. $\{\tilde{X}_n\}$ is ϕ -recurrent, where ϕ is Lebesgue measure on Γ . The recurrence is uniform in $\alpha \in A_0$ in the sense that the mean recurrence times are bounded uniformly for $\alpha \in A_0$. There are $C < \infty$, $\gamma < 1$ (not depending on $\alpha \in A_0$) such that (3.5) and (3.6) hold.*

It will be seen below (Lemma 4.1) that $\tilde{P}(x, n, B | \alpha)$ is continuous in x , uniformly in α, B . (The continuity is proved in [3], but we give a different proof, since the details to be used will be needed elsewhere in the paper.)

4. The α -derivative of $\tilde{\mu}(\alpha)$ (setwise sense). Let $C(\Gamma)$ denote the set of bounded and continuous functions on Γ , and $C_c(\Gamma)$ the centered functions: $f_1 \in C_c(\Gamma)$ if $f_1 = f - \tilde{f}$ for $f \in C(\Gamma)$, where $\tilde{f} = \langle \tilde{\mu}(\alpha_0), f \rangle$. To prove the differentiability of $\mu(\alpha)$ at α_0 , we first prove that of $\tilde{\mu}(\alpha)$, and then use (3.3).

DEFINITION. $\tilde{\mu}(\alpha)$ is said to be *differentiable at α_0 in the setwise (or weak) sense* if there is a finite signed measure v such that for each Borel set B

$$v(B) = \lim_{\delta\alpha \rightarrow 0} [\tilde{\mu}(B, \alpha_0 + \delta\alpha) - \tilde{\mu}(B, \alpha_0)] / \delta\alpha.$$

$\tilde{\mu}(\alpha)$ is said to be *differentiable at α_0 in the sense of weak convergence (or weak* sense)* if there is a finite signed measure v such that for each $f \in C(\Gamma)$,

$$\langle v, f \rangle = \lim_{\delta\alpha \rightarrow 0} \langle \tilde{\mu}(\alpha_0 + \delta\alpha) - \tilde{\mu}(\alpha_0), f \rangle / \delta\alpha.$$

DEFINITION. Let $L^\infty(\Gamma)$ denote the bounded Borel measurable functions on Γ . For any Borel set H , let $\mathcal{B}(H)$ denote the Borel subsets of H . Define the operator $\tilde{P}(\alpha)$ on $L^\infty(\Gamma)$ by $\tilde{P}(\alpha)f(x) = E_x^\alpha f(\tilde{X}_1)$.

LEMMA 4.1. Suppose that Assumptions 2.1–2.4 hold. Then the set $\{\tilde{P}(\alpha)L^\infty(\Gamma), \alpha \in A\}$ (restricted to functions with $\|f\| \leq 1$) is equicontinuous.

Proof. Define the process $y(\cdot)$ by $y(0) = x$ and

$$(4.1) \quad dy = \sigma(y)dw.$$

Define

$$\xi_0^\alpha(u, v) = \int_u^v [\sigma^{-1}(y(s))b(y(s), \alpha)]' dw(s) - \frac{1}{2} \int_u^v |\sigma^{-1}(y(s))b(y(s), \alpha)|^2 ds.$$

Given $\varepsilon > 0$, there are $T_2 > T_1 > T_0 > 0$ such that for all $\alpha \in A_0$ and $x \in \Gamma$,

$$(4.2) \quad P_x^\alpha\{\tau \geq T_2\} \leq \varepsilon, \quad P_x^\alpha\{\tau \leq T_1\} \leq \varepsilon,$$

$$(4.3) \quad E_x^\alpha \exp \xi_0^\alpha(T_0, T_1) = 1,$$

$$(4.4) \quad \sup_{x \in \Gamma, \alpha \in A_0} E_x^\alpha \exp 2\xi_0^\alpha(0, T_1) \leq K_1^2 < \infty,$$

$$(4.5) \quad (E|\exp \xi_0^\alpha(0, T_0) - 1|^2)^{1/2} \leq \varepsilon.$$

Let $\tau_{12} = (\tau \wedge T_2) \vee T_1$. By (4.2), we have

$$|E_x^\alpha f(\tilde{X}_1) - E_x^\alpha f(x(\tau_{12}))| \leq 4\varepsilon\|f\|.$$

Write

$$E_x^\alpha f(x(\tau_{12})) = E_x^\alpha E_{x(T_1)}^\alpha f(x(\tau_{12})) = E_x^\alpha f_1(x(T_1)),$$

where f_1 is defined in the obvious way and $\|f_1\| \leq \|f\|$. By use of a Girsanov measure transformation, (4.4), (4.5), and Schwarz's inequality, we can write

$$\begin{aligned} E_x^\alpha f_1(x(T_1)) &= E_x^\alpha f_1(y(T_1)) \exp \xi_0^\alpha(0, T_1) \\ &= E_x^\alpha E_{y(T_0)}^\alpha f_1(y(T_1)) \exp \xi_0^\alpha(T_0, T_1) + \varepsilon' \\ &= E_x^\alpha f_2(y(T_0)) + \varepsilon', \end{aligned}$$

where $\|\varepsilon'\| \leq \varepsilon K_1 \|f\|$, f_2 is defined in the obvious way, and $\|f_2\| \leq \|f\|$. Note that f_2 depends on α , but $y(T_0)$ does not.

By the above estimates and arbitrariness of ε , we need only show the equicontinuity of the set $\{E_x^\alpha f_2(y(T_0)) : \|f_2\| \leq 1, \alpha \in A_0, f_2 \in L^\infty(\Gamma)\}$. Since $y(T_0)$ has a bounded density with respect to Lebesgue measure, using characteristic functions, we can write

$$E_x^\alpha f_2(y(T_0)) = \frac{1}{(2\pi)^r} \int f_2(y) dy \left\{ \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} (\exp -iu'y) E_x^\alpha \exp iu'y(T_0) du \right\}.$$

We have

$$|E_x^\alpha \exp iu'y(T_0)| \leq \exp -O(|u|^2),$$

where $O(\cdot)$ can be chosen independently of $x \in \Gamma$ and $\alpha \in A_0$. Also, the bracketed term is the density (modulo a proportionality factor $(1/(2\pi)^r)$) of $y(T_0)$ and is bounded by $\exp -O(|y|^2)$, where $O(\cdot)$ can be chosen independently of $x \in \Gamma$ and $\alpha \in A_0$. Thus, we need only prove that $E_x^\alpha \exp iu'y(T_0)$ is x -continuous on each bounded u -set. This follows from the Feller property of $y(\cdot)$. \square

COROLLARY. *Suppose that Assumptions 2.1–2.4 hold. Then the transition function $\tilde{P}(x, n, B | \alpha) \equiv E_x^\alpha I_B(\tilde{X}_n)$ is continuous in x , uniformly in B , n , and $\alpha \in A_0$. Also $\tilde{\mu}(B, \alpha_0 + \delta\alpha) \rightarrow \tilde{\mu}(B, \alpha_0)$, uniformly in $B \in \mathcal{B}(\Gamma)$.*

Proof. The first assertion is a direct consequence of the lemma. Let $g \in L^\infty(\Gamma)$, $\|g\| \leq 1$. Then, by the invariance of $\tilde{\mu}(\alpha)$,

$$\langle \tilde{\mu}(\alpha_0 + \delta\alpha), g \rangle = \int_{\Gamma} \tilde{\mu}(dx, \alpha_0 + \delta\alpha) E_x^{\alpha_0 + \delta\alpha} g(\tilde{X}_1).$$

A measure transformation argument and the continuity of $b(\cdot)$ can be used to show that, as $\delta\alpha \rightarrow 0$, $E_x^{\alpha_0 + \delta\alpha} g(\tilde{X}_1)$ converges to $E_x^{\alpha_0} g(\tilde{X}_1)$, uniformly in $x \in \Gamma$. The latter function is continuous on Γ by Lemma 4.1. In fact, the continuity and the convergence is uniform in g . From this, the invariance of $\tilde{\mu}(\alpha_0)$ and the weak convergence $\tilde{\mu}(\alpha_0 + \delta\alpha) \Rightarrow \tilde{\mu}(\alpha_0)$ (see Lemma 4.3 below), we have

$$\begin{aligned} \lim_{\delta\alpha \rightarrow 0} \langle \tilde{\mu}(\alpha_0 + \delta\alpha), g \rangle &= \int_{\Gamma} \tilde{\mu}(dx, \alpha_0) E_x^{\alpha_0} g(\tilde{X}_1) \\ &= \int_{\Gamma} \tilde{\mu}(dx, \alpha_0) g(x), \end{aligned}$$

where the convergence is uniform in g : $\|g\| \leq 1$. \square

The next lemma will be used to get the differentiability of $\mu(\alpha)$ at α_0 from that of $\tilde{\mu}(\alpha)$, via (3.3).

LEMMA 4.2. *Suppose that Assumptions 2.1–2.5 hold. Then for $f \in L^\infty(\Gamma)$, as $\delta\alpha \rightarrow 0$,*

$$[\tilde{P}(\alpha_0 + \delta\alpha) - \tilde{P}(\alpha_0)]f/\delta\alpha$$

converges (uniformly in x) to the function with values $E_x^{\alpha_0} f(\tilde{X}_1)Z(\tau, \alpha_0)$. The limit is continuous and the convergence is uniform for f : $\|f\| \leq 1$. The set

$$\{E_x^{\alpha_0} Z(\tau, \alpha_0) f(\tilde{X}_1), \|f\| \leq 1, f \in L^\infty(\Gamma), \alpha \in A_0\}$$

is equicontinuous. The same result holds for the convergence

$$\begin{aligned} &\frac{1}{\delta\alpha} \left[E_x^{\alpha_0 + \delta\alpha} \int_0^\tau f(x(s)) ds - E_x^{\alpha_0} \int_0^\tau f(x(s)) ds \right] \\ &\rightarrow E_x^{\alpha_0} \int_0^\tau f(x(s)) ds Z(\tau, \alpha_0) = E_x^{\alpha_0} \int_0^\tau f(x(s)) Z(s, \alpha_0) ds. \end{aligned}$$

Proof. The proof of the last assertion is very similar to that of the prior assertions and will be omitted. By an argument analogous to that of Lemma 4.1, we can prove the equicontinuity of the cited set of functions. We will prove only the first assertion of the lemma. For $T < \infty$, via a Girsanov measure transformation,

$$\begin{aligned} \frac{E_x^{\alpha_0 + \delta\alpha} f(x(\tau \wedge T)) - E_x^{\alpha_0} f(x(\tau \wedge T))}{\delta\alpha} &= E_x^{\alpha_0} f(x(\tau \wedge T)) [\exp \xi(0, T; \alpha_0, \delta\alpha) - 1] / \delta\alpha \\ (4.6) \qquad \qquad \qquad &= E_x^{\alpha_0} f(x(\tau \wedge T)) [\exp \xi(0, \tau \wedge T; \alpha_0, \delta\alpha) - 1] / \delta\alpha. \end{aligned}$$

We have, by Assumption 2.5 and Theorem 2.1,

$$\lim_{\delta\alpha \rightarrow 0} \lim_{T \rightarrow \infty} E_x^{\alpha_0} \left[\frac{\exp \xi(0, \tau \wedge T; \alpha_0, \delta\alpha) - 1}{\delta\alpha} - Z(\tau, \alpha_0) \right]^2 = 0,$$

where the limit is attained uniformly in $x \in \Gamma$. The first assertion of the lemma follows from this and (4.6). \square

The next corollary shows that the setwise derivative of $\tilde{\mu}(\alpha)$ at α_0 is absolutely continuous with respect to $\tilde{\mu}(\alpha_0)$.

COROLLARY. *Suppose that Assumptions 2.1–2.4 hold. Define the set function \tilde{v} by*

$$\tilde{v}(B) = \lim_{\delta\alpha \rightarrow 0} \frac{1}{\delta\alpha} \int_{\Gamma} \tilde{\mu}(dx, \alpha_0) [\tilde{P}(x, 1, B \mid \alpha_0 + \delta\alpha) - \tilde{P}(x, 1, B \mid \alpha_0)].$$

Then there is $G \in L^1(\tilde{\mu}(\alpha_0))$ such that $\langle \tilde{\mu}(\alpha_0), G \rangle = 0$ and

$$\tilde{v}(B) = \int_B \tilde{\mu}(dx, \alpha_0) G(x).$$

The limit is uniform in B .

Proof. By the lemma, the limit is

$$\int_{\Gamma} \tilde{\mu}(dx, \alpha_0) E_x^{\alpha_0} Z(\tau, \alpha_0) I_B(\tilde{X}_1),$$

and the limit is taken on uniformly in B . (In fact, $E_x^{\alpha_0} Z(\tau, \alpha_0) I_B(\tilde{X}_1)$ is continuous, uniformly in B .) Both $\tilde{\mu}(\alpha_0)$ and the measure defined by the limit are mutually absolutely continuous with respect to Lebesgue measure, since the transition probability $\tilde{P}(x, 1, \cdot \mid \alpha_0)$ is. Let G denote the Radon–Nikodym derivative of \tilde{v} with respect to $\tilde{\mu}(\alpha_0)$. Since $E_x^{\alpha_0} Z(\tau, \alpha_0) I_{R^r}(\tilde{X}_1) = 0$, we have $\langle \tilde{\mu}(\alpha_0), G \rangle = 0$. \square

LEMMA 4.3. *Suppose that Assumptions 2.1–2.4 hold. Then $\tilde{\mu}(\alpha_0 + \delta\alpha) \Rightarrow \tilde{\mu}(\alpha_0)$.*

Proof. The proof follows from the uniqueness of $\tilde{\mu}(\alpha_0)$ and the convergence $\tilde{P}(x, 1, B \mid \alpha_0 + \delta\alpha) \rightarrow \tilde{P}(x, 1, B \mid \alpha_0)$, uniformly for $x \in \Gamma$ (Lemma 4.1), and the details are omitted. \square

DEFINITION. Let $L_c^\infty(\Gamma) \subset L^\infty(\Gamma)$ be the “centered” subset for which $\langle \tilde{\mu}(\alpha_0), f \rangle = 0$. We identify functions in $L_c^\infty(\Gamma)$ that are equal almost everywhere (Lebesgue measure).

The following lemma is a key result for proving the differentiability of $\tilde{\mu}(\alpha)$ at α_0 . The representations that are used occur throughout the following.

LEMMA 4.4. *Suppose that Assumptions 2.1–2.4 hold. Then $(I - \tilde{P}(\alpha_0)): L_c^\infty(\Gamma) \rightarrow L_c^\infty(\Gamma)$ is invertible.*

Proof. The fact that $\tilde{P}(\alpha_0)$ maps $L_c^\infty(\Gamma)$ into $L_c^\infty(\Gamma)$ follows from the fact that $\tilde{\mu}(\alpha_0)$ is an invariant measure for the transition function $\tilde{P}(x, n, \cdot \mid \alpha_0)$. We prove the invertability by simply exhibiting the inverse. Let $f \in L_c^\infty(\Gamma)$. Then it is easily seen from (3.6) and the definition of $(I - \tilde{P}(\alpha_0))$ that the “inverse” defined by

$$(4.7) \quad (I - \tilde{P}(\alpha_0))^{-1} f(x) \equiv \sum_{n=0}^{\infty} \tilde{P}^n(\alpha_0) f(x) = \sum_{n=0}^{\infty} E_x^{\alpha_0} f(\tilde{X}_n)$$

satisfies our needs. \square

COROLLARY. Suppose that Assumptions 2.1–2.4 hold. Then $(I - \tilde{P}(\alpha_0)): C_c(\Gamma) \rightarrow C_c(\Gamma)$ is invertible.

Proof. By Lemma 4.1, $\tilde{P}(\alpha_0)C_c(\Gamma) \subset C_c(\Gamma)$. The rest of the proof is as for the lemma. \square

THEOREM 4.1. Suppose that Assumptions 2.1–2.5 hold. Then $\tilde{\mu}_\alpha(\alpha_0)$ exists in the sense of setwise convergence and satisfies, for $f \in L^\infty(\Gamma)$ and all n ,

$$(4.8) \quad \langle \tilde{\mu}_\alpha(\alpha_0), f \rangle = \langle \tilde{\mu}(\alpha_0), \tilde{P}_\alpha^n(\alpha_0)f \rangle + \langle \tilde{\mu}_\alpha(\alpha_0), \tilde{P}^n(\alpha_0)f \rangle,$$

where

$$\tilde{P}_\alpha^n(\alpha_0)f(x) = \frac{d}{d\alpha} E_x^\alpha f(\tilde{X}_n) \Big|_{\alpha_0}.$$

Proof. For $f \in L_c^\infty(\Gamma)$, we have

$$(4.9) \quad \begin{aligned} \langle \tilde{\mu}(\alpha) - \tilde{\mu}(\alpha_0), f \rangle &= \langle \tilde{\mu}(\alpha), \tilde{P}(\alpha)f \rangle - \langle \tilde{\mu}(\alpha_0), \tilde{P}(\alpha_0)f \rangle \\ &= \langle \tilde{\mu}(\alpha) - \tilde{\mu}(\alpha_0), \tilde{P}(\alpha_0)f \rangle + \langle \tilde{\mu}(\alpha_0), (\tilde{P}(\alpha) - \tilde{P}(\alpha_0))f \rangle \\ &\quad + \langle \tilde{\mu}(\alpha) - \tilde{\mu}(\alpha_0), (\tilde{P}(\alpha) - \tilde{P}(\alpha_0))f \rangle. \end{aligned}$$

Write $\delta\tilde{\mu}(\alpha) = \tilde{\mu}(\alpha) - \tilde{\mu}(\alpha_0)$ and $\delta\tilde{P}(\alpha) = \tilde{P}(\alpha) - \tilde{P}(\alpha_0)$. Then (4.9) yields

$$(4.10) \quad \langle \delta\tilde{\mu}(\alpha)/\delta\alpha, (I - \tilde{P}(\alpha_0))f \rangle = \langle \tilde{\mu}(\alpha_0), \frac{\delta\tilde{P}(\alpha)}{\delta\alpha}f \rangle + \langle \delta\tilde{\mu}(\alpha), \frac{\delta\tilde{P}(\alpha)}{\delta\alpha}f \rangle.$$

By Lemma 4.2 and either Lemma 4.3 or the corollary to Lemma 4.1, the second right-hand term in (4.10) goes to zero as $\delta\alpha \rightarrow 0$ (uniformly in $f: \|f\| \leq 1$).

For $g \in L_c^\infty(\Gamma)$, define (use Lemma 4.4), $f = (I - \tilde{P}(\alpha_0))^{-1}g$. By Lemmas 4.2 and 4.4,

$$\frac{\delta\tilde{P}(\alpha)}{\delta\alpha} (I - \tilde{P}(\alpha_0))^{-1}g$$

converges (uniformly in x) to the function with values

$$E_x^{\alpha_0} f(\tilde{X}_1)Z(\tau, \alpha_0) = E_x^{\alpha_0} [Z(\tau, \alpha_0) \sum_{n=0}^{\infty} E_y^{\alpha_0} g(\tilde{X}_n) \Big|_{y=\tilde{X}_1}] \equiv \tilde{g}(x),$$

which is in $C_c(\Gamma)$. Hence

$$(4.11) \quad \lim_{\delta\alpha \rightarrow 0} \langle \delta\tilde{\mu}(\alpha)/\delta\alpha, g \rangle = \langle \tilde{\mu}(\alpha_0), \tilde{g} \rangle.$$

Since $g \in L_c^\infty(\Gamma)$, and $L_c^\infty(\Gamma) = L^\infty(\Gamma)$ modulo constant functions, (4.11) gives the desired setwise convergence.

The formula (4.8) follows in a similar way. \square

COROLLARY. Suppose that Assumptions 2.1–2.5 hold. Then $\tilde{\mu}_\alpha(\alpha_0)$ exists in the sense of weak convergence.

Remark. The corollary is obviously a special case of the theorem. It can be proved directly via the method of proof of the theorem, simply by replacing all $L_c^\infty(\Gamma)$ by $C_c(\Gamma)$. This remark will be useful when working with the approximations in §7, since there we work with weak convergence only.

Since the existence of $\tilde{\mu}_\alpha(\alpha_0)$ is now established, we can turn our attention to $\mu_\alpha(\alpha_0)$.

THEOREM 4.2. *Suppose that Assumptions 2.1–2.5 hold. Then $\mu_\alpha(\alpha_0)$ exists in the sense of setwise convergence, and for $f \in L^\infty(R^r)$,*

$$\begin{aligned}
 \langle \mu_\alpha(\alpha_0), f \rangle &= \frac{1}{\tilde{\mu}(R^r, \alpha_0)} \left[\int_{\Gamma} \tilde{\mu}(dx, \alpha_0) E_x^{\alpha_0} \int_0^\tau f(x(s)) Z(s, \alpha_0) ds \right. \\
 &\quad \left. + \int_{\Gamma} \tilde{\mu}_\alpha(dx, \alpha_0) E_x^{\alpha_0} \int_0^\tau f(x(s)) ds \right] \\
 &\quad - \frac{\langle \tilde{\mu}(\alpha_0), f \rangle}{(\tilde{\mu}(R^r, \alpha_0))^2} \left[\int_{\Gamma} \tilde{\mu}(dx, \alpha_0) E_x^{\alpha_0} \int_0^\tau Z(s, \alpha_0) ds + \int_{\Gamma} \tilde{\mu}_\alpha(dx, \alpha_0) E_0^\alpha \tau \right] \\
 (4.12) \quad &= \frac{d}{d\alpha} \left[\frac{\int_{\Gamma} \tilde{\mu}(dx, \alpha) E_x^\alpha \int_0^\tau f(x(s)) ds}{\int_{\Gamma} \tilde{\mu}(dx, \alpha) E_x^\alpha \tau} \right]_{\alpha_0}.
 \end{aligned}$$

Also, $\mu_\alpha(\alpha_0)$ is absolutely continuous with respect to Lebesgue measure and has finite variation.

Proof. Let $f \in L^\infty(R^r)$. Define $\delta\mu(\alpha) = \mu(\alpha_0 + \delta\alpha) - \mu(\alpha_0)$ and define $\delta\tilde{\mu}(\alpha)$ analogously. Define the operator $\hat{P}(\alpha)$ on $L^\infty(R^r)$ by $\hat{P}(\alpha)f = E_x^\alpha \int_0^\tau f(x(s)) ds$. Let \mathbf{e} denote the function that is identically unity. We need to show the differentiability of

$$\langle \tilde{\mu}(\alpha), \tilde{P}(\alpha)f \rangle / \langle \tilde{\mu}(\alpha), \tilde{P}(\alpha)\mathbf{e} \rangle = \langle \mu(\alpha), f \rangle.$$

It will be sufficient to show the differentiability of the numerator only. This will be the first bracketed term in (4.12). We can write

$$\begin{aligned}
 &\frac{1}{\delta\alpha} [\langle \tilde{\mu}(\alpha_0 + \delta\alpha), \hat{P}(\alpha_0 + \delta\alpha)f \rangle - \langle \tilde{\mu}(\alpha_0), \hat{P}(\alpha_0)f \rangle] \\
 &= \left\langle \frac{\delta\tilde{\mu}(\alpha)}{\delta\alpha}, \hat{P}(\alpha_0)f \right\rangle + \left\langle \tilde{\mu}(\alpha_0), \frac{(\hat{P}(\alpha_0 + \delta\alpha) - \hat{P}(\alpha_0))}{\delta\alpha} f \right\rangle \\
 &\quad + \left\langle \delta\tilde{\mu}(\alpha_0), \frac{(\hat{P}(\alpha_0 + \delta\alpha) - \hat{P}(\alpha_0))}{\delta\alpha} f \right\rangle.
 \end{aligned}$$

By Lemma 4.2, the second term on the right converges to the first term in the first bracket on the right-hand side of (4.12). The first term on the right converges to the second term in the first bracket on the right-hand side of (4.12) by Theorem 4.1 and the fact that $\hat{P}(\alpha_0)f \in C(\Gamma)$. Similarly, the last term on the right goes to zero. Representation (4.12) implies the absolute continuity assertion since it equals zero if $f = 0$ almost everywhere (Lebesgue measure). It also implies the finite variation. \square

Theorem 4.3 essentially says that the α -derivative of $E_x^\alpha f(x(t))$ equals that of $\langle \mu(\alpha), f \rangle$ for large t .

THEOREM 4.3. *Suppose that Assumptions 2.1–2.5 hold. Then for $f \in L^\infty(R^r)$,*

$$\begin{aligned}
 (4.13) \quad &\lim_{t \rightarrow \infty} \frac{d}{d\alpha} \int \mu(dx, \alpha) E_x^\alpha f(x(t)) \Big|_{\alpha=\alpha_0} = \frac{d}{d\alpha} \langle \mu(\alpha), f \rangle \Big|_{\alpha=\alpha_0} \\
 &= \lim_{t \rightarrow \infty} \int \mu(dx, \alpha_0) (E_x^{\alpha_0} f(x(t)))_\alpha,
 \end{aligned}$$

$$\begin{aligned}
 (4.14) \quad & \lim_{t \rightarrow \infty} \frac{d}{d\alpha} \int \mu(dx, \alpha) E_x^\alpha \frac{1}{t} \int_0^t f(x(s)) ds \Big|_{\alpha=\alpha_0} \\
 &= \lim_{t \rightarrow \infty} \int \mu(dx, \alpha_0) (E_x^{\alpha_0} f(x(t)))_\alpha,
 \end{aligned}$$

and the limits exist.

Proof. By the differentiability proved in Theorem 4.2 we can write

$$\begin{aligned}
 (4.15) \quad & \frac{d}{d\alpha} \int \mu(dx, \alpha) f(x) = \frac{d}{d\alpha} \int \mu(dx, \alpha) E_x^\alpha f(x(t)) \Big|_{\alpha=\alpha_0} \\
 &= \int \mu_\alpha(dx, \alpha_0) E_x^{\alpha_0} f(x(t)) + \int \mu(dx, \alpha_0) (E_x^{\alpha_0} f(x(t)))_\alpha.
 \end{aligned}$$

As $t \rightarrow \infty$, $E_x^{\alpha_0} f(x(t)) \rightarrow \langle \mu(\alpha_0), f \rangle$ for $\mu(\alpha_0)$ -almost all x . Since $\mu_\alpha(\alpha_0)$ is absolutely continuous with respect to Lebesgue measure (Theorem 4.2), and $\mu(\alpha_0)$ and Lebesgue measure are mutually absolutely continuous, we have that $\mu_\alpha(\alpha_0)$ is absolutely continuous with respect to $\mu(\alpha_0)$. Also $\langle \mu_\alpha(\alpha_0), \text{constant function} \rangle = 0$. These facts imply that the first term on the right-hand side of (4.15) goes to zero as $t \rightarrow \infty$, which yields the assertion concerning (4.13). Expression (4.14) is proved in the same way. \square

5. A discrete time approximation. Since the paths of $x(\cdot)$ and $w(\cdot)$ are not physically available, we cannot evaluate (1.5) or use Theorem 4.2 or 4.3 as stated to get estimates of the derivatives $\langle \mu(\alpha_0), f \rangle_\alpha$ via the use of paths of $x(\cdot)$ or $w(\cdot)$. We must work with computable approximations to $x(\cdot)$ and $w(\cdot)$. In [1], two types of approximations were used for the finite time problem: the first was a discrete time approximation and the second, a Markov chain approximation. Each one has its own advantages, but simulation studies indicate that their overall numerical properties are similar. We will work with the discrete time approximation here. In this section, the approximation is defined. Some necessary stability results are proved in the next section. Among other things to be shown, the robustness properties of approximations to derivatives of invariant measures and ergodic costs will be clear.

For $\Delta > 0$ and $\delta w(n\Delta) = w(n\Delta + \Delta) - w(n\Delta)$, define $\{X_n^\Delta\}$ by $X_0^\Delta = x$ and

$$(5.1) \quad X_{n+1}^\Delta = X_n^\Delta + \Delta b(X_n^\Delta, \alpha_0) + \sigma(X_n^\Delta) \delta w(n\Delta).$$

Define the interpolation $x^\Delta(\cdot)$ to be the piecewise constant (on intervals $[n\Delta, n\Delta + \Delta)$) process with $x^\Delta(n\Delta) = X_n^\Delta$. Define $Z^\Delta(\cdot, \alpha_0)$ to be the piecewise constant (on intervals $[n\Delta, n\Delta + \Delta)$) process with value at $n\Delta$:

$$\begin{aligned}
 Z^\Delta(n\Delta, \alpha_0) &= \sum_{i=0}^{n-1} [\sigma^{-1}(X_i^\Delta, \alpha_0) b_\alpha(X_i^\Delta, \alpha_0)]' \delta w(i\Delta) \\
 &= \sum_{i=0}^{n-1} [b'_\alpha(X_i^\Delta, \alpha_0) a^{-1}(X_i^\Delta)] [\delta X_i^\Delta - \Delta b(X_i^\Delta, \alpha_0)],
 \end{aligned}$$

where $\delta X_i^\Delta \equiv X_{i+1}^\Delta - X_i^\Delta$. For $T = N/\Delta$, [1, §4] shows that

$$\begin{aligned}
 Q^\Delta(\alpha_0) &= \sum_{n=0}^{N-1} \Delta [k(X_n^\Delta, \alpha_0) Z^\Delta(n\Delta, \alpha_0) + k_\alpha(X_n^\Delta, \alpha_0)] \\
 &\quad + k_{0,\alpha}(X_N^\Delta, \alpha_0) + k_0(X_N^\Delta, \alpha_0) Z^\Delta(N\Delta, \alpha_0)
 \end{aligned}$$

or the centered form

$$\begin{aligned}\hat{Q}^\Delta(\alpha_0) = & \sum_{n=0}^{N-1} \Delta[(k(X_{n,\alpha_0}^\Delta) - E_x^{\alpha_0} k(X_n^\Delta, \alpha_0))Z^\Delta(n\Delta, \alpha_0) + k_\alpha(X_n^\Delta, \alpha_0)] \\ & + k_{0,\alpha}(X_N^\Delta, \alpha_0) + (k_0(X_N^\Delta, \alpha_0) - \bar{k}_0^{\Delta, \alpha_0})Z^\Delta(N\Delta, \alpha_0)\end{aligned}$$

are appropriate approximations to (1.5). The $\hat{Q}^\Delta(\alpha_0)$ will have the smaller variance.

In fact, we have

$$E_x^{\alpha_0} \hat{Q}^\Delta(\alpha_0) = E_x^{\alpha_0} Q^\Delta(\alpha_0) = \frac{d}{d\alpha} \left[E_x^\alpha \int_0^T k(x^\Delta(s), \alpha) ds + k_0(x^\Delta(T), \alpha) \right]_{\alpha=\alpha_0},$$

and we have the weak convergence

$$(Z^\Delta(\cdot, \alpha_0), Q^\Delta(\alpha_0), \hat{Q}^\Delta(\alpha_0), x^\Delta(\cdot)) \Rightarrow (Z(\cdot, \alpha_0), Q(\alpha_0), Q(\alpha_0), x(\cdot)).$$

We will obtain various “infinite time” extensions of this result in §7.

Analogous to the comment below (1.5'), to reduce computation while exploiting the (variance reduction) advantages of the centering, in the simulations we replace $E_x^{\alpha_0} k(X_n^\Delta, \alpha_0)$ by $E_x^{\alpha_0} k(X_N^\Delta, \alpha_0)$, with good results in general.

A remark on using the derivative estimators in recursive Monte Carlo optimization. Suppose that a sequence α_n^Δ is generated by a stochastic approximation scheme and converges to a minimizing $\bar{\alpha}^\Delta$. Then, via weak convergence methods, it can be shown that the limit of any convergent subsequence of $\bar{\alpha}^\Delta$ is optimal for the original problem, under appropriate regularity conditions.

6. Stability of the approximation. An analogue of Theorem 2.1 is needed for the $\{X_n^\Delta\}$ process. We will require the following additional condition.

Assumption 6.1.

(a) $V'_x(x)b(x, \alpha) \rightarrow -\infty$ as $|x| \rightarrow \infty$, uniformly for $\alpha \in A_0$.

(b) $\liminf_{|x| \rightarrow \infty} \inf_{\alpha \in A_0} \frac{|V'_x(x)b(x, \alpha)|}{|b(x, \alpha)|^2} > 0$.

THEOREM 6.1. *Suppose that Assumptions 2.1–2.3 and 6.1 hold. There is a compact set Q such that for each compact $Q_1 \supset Q$, we have for small $\rho > 0$, $\delta > 0$, and $\Delta < \delta$,*

$$(6.1) \quad \sup_{\alpha \in A_0} \sup_{x \in Q_1 - Q} E_x^\alpha \exp \rho \tau^\Delta < \infty,$$

where $\tau^\Delta = \min\{t: x^\Delta(t) \in Q\}$.

Proof. Let $X_0^\Delta = x$. For some $K_0 < \infty$, we have

$$\begin{aligned}A & \equiv E_x^\alpha \exp \rho[V(X_1^\Delta) - V(x)] \\ & \leq E_x^\alpha \exp \rho[V'_x(x)(b(x, \alpha)\Delta + \sigma(x)\delta w) + K_0(|\delta w|^2 + |b(x, \alpha)|^2\Delta^2)].\end{aligned}$$

Note that for $2rk\Delta < 1$,

$$E_x^\alpha \exp k|\delta w|^2 \leq 1/(1 - 2rk\Delta).$$

Thus, for small ρ , Δ , and $k_i > 0$, $1/k_1 + 1/k_2 = 1$, Hölder's inequality yields

$$\begin{aligned}& E_x^\alpha \exp \rho[V'_x(x)\sigma(x)\delta w + K_0|\delta w|^2] \\ & \leq [\exp k_1^2 \rho^2 \Delta V'_x(x)a(x)V_x(x)/2]^{1/k_1} \cdot \frac{1}{(1 - 2r\rho k_2 K_0 \Delta)^{1/k_2}}.\end{aligned}$$

Thus, for small ρ , Δ , and k_1 fixed near unity,

$$A \leq \exp \rho [V'_x(x)b(x, \alpha)\Delta + K_0|b(x, \alpha)|^2\Delta^2 \\ + \frac{k_1}{2}\rho\Delta V'_x(x)a(x)V_x(x) + 4rK_0\Delta].$$

Thus, there is a compact set Q and $\varepsilon_1 > 0$ such that for small ρ and for $x \notin Q$, $A \leq \exp -2\rho\varepsilon_1\Delta$. Thus for small ρ and $x \notin Q$,

$$E_x^\alpha \exp \rho\Delta\varepsilon_1 \cdot \exp \rho V(X_1^\Delta) \leq \exp \rho V(x).$$

Hence

$$E_x^\alpha \exp \rho\varepsilon_1\tau^\Delta \cdot \exp \rho V(x^\Delta(\tau^\Delta)) \leq \exp \rho V(x),$$

which yields the result, as in Theorem 2.1. \square

7. Ergodic properties of $\{X_n^\Delta\}$. We now set up the machinery so that results analogous to those in §§4 and 5 and the limits as $\Delta \rightarrow 0$ can be obtained. Define Γ , G , Γ_1 , and G_1 as in §3. Define the following stopping times:

$$\begin{aligned} \tau^{\Delta'} &= \inf\{t: x^\Delta(t) \notin G_1 - \Gamma_1\}, \\ \tau_1^\Delta &= \inf\{t: x^\Delta(t) \in G\}, \\ \tau_1^{\Delta'} &= \inf\{t > \tau_1^\Delta: x^\Delta(t) \notin G_1 - \Gamma_1\}. \end{aligned}$$

For $n > 1$,

$$\tau_n^\Delta = \inf\{t > \tau_{n-1}^{\Delta'}: x^\Delta(t) \in G\}, \quad \tau_n^{\Delta'} = \inf\{t > \tau_n^\Delta: x^\Delta(t) \notin G_1 - \Gamma_1\}.$$

For $x = x^\Delta(0) \in G$, we use τ^Δ to denote $\tau_2^\Delta - \tau_1^\Delta = \tau_2^\Delta$, the canonical return time to G .

By Theorem 6.1, there are G, G_1 such that (e.g., let G equal the set Q of Theorem 6.1)

$$(7.1) \quad \sup_{x \in G, \alpha \in A_0} E_x^\alpha \tau^\Delta < \infty, \quad \sup_{x \in G, \alpha \in A_0} E_x^\alpha \exp \rho \tau^\Delta < \infty,$$

for small ρ . Define $\tilde{X}_n^\Delta = x^\Delta(\tau_n^\Delta)$. For $\alpha \in A_0$, the process $\{\tilde{X}_n^\Delta, n \geq 0\}$ is a homogeneous, positive recurrent Markov chain with state space G . Let $\tilde{P}^\Delta(x, n, \cdot | \alpha)$ denote the transition function. There is a unique invariant measure $\tilde{\mu}^\Delta(\alpha)$. Analogously to the situation in §3, define the following:

$$\begin{aligned} \tau^\Delta(A) &= \int_0^{\tau^\Delta} I_A(x^\Delta(s))ds, \quad A = \text{Borel set in } R^r, \\ \bar{\mu}^\Delta(A, \alpha) &= \int_G \tilde{\mu}^\Delta(dx, \alpha) E_x^\alpha \tau^\Delta(A), \\ \mu^\Delta(A, \alpha) &= \bar{\mu}^\Delta(A, \alpha) / \bar{\mu}^\Delta(R^r, \alpha). \end{aligned}$$

The same argument used to show that $\mu(\alpha)$ is invariant for $x(\cdot)$ [2, p. 183] can be used to show that $\mu^\Delta(\alpha)$ is invariant for $\{X_n^\Delta\}$, under parameter α . We can now write for bounded measurable f :

$$(7.2) \quad \langle \mu^\Delta(\alpha), f \rangle = \frac{\int_G \tilde{\mu}^\Delta(dx, \alpha) E_x^\alpha \int_0^{\tau^\Delta} f(x^\Delta(s))ds}{\int_G \tilde{\mu}^\Delta(dx, \alpha) E_x^\alpha \tau^\Delta}.$$

Let $L^\infty(G)$ denote the set of bounded Borel measurable functions on G . Define the operator $\tilde{P}^\Delta(\alpha)$ on $L^\infty(G)$ by $\tilde{P}^\Delta(\alpha)f(x) = E_x^\alpha f(\tilde{X}_1^\Delta)$, $x \in G$.

LEMMA 7.1. *Suppose that Assumptions 2.1–2.4 and 6.1 hold. Then the set $\{\tilde{P}^\Delta(\alpha)L^\infty(G)$ (restricted to $\|f\| \leq 1$), $\Delta > 0$, $\alpha \in A_0\}$ is equicontinuous.*

Remark on the proof. Define the process $\bar{y}^\Delta(\cdot)$ to be the piecewise constant interpolation (intervals $[n\Delta, n\Delta + \Delta)$) of the process defined by $\bar{Y}_0^\Delta = x$, $\bar{Y}_{n+1}^\Delta = \bar{Y}_n^\Delta + \sigma(\bar{Y}_n^\Delta)\delta w(n\Delta)$. Then $\bar{y}^\Delta(\cdot) \Rightarrow y(\cdot)$, defined in Lemma 4.1. Define the Radon–Nikodym derivative $\exp \xi_0^{\alpha, \Delta}(0, T)$, where

$$\begin{aligned} \xi_0^{\alpha, \Delta}(0, T) &= \sum_{n=0}^{T/\Delta-1} [\sigma^{-1}(\bar{Y}_n^\Delta)b(\bar{Y}_n^\Delta, \alpha)]' \delta w(n\Delta) \\ &\quad - \frac{1}{2} \sum_{n=0}^{T/\Delta-1} |\sigma^{-1}(\bar{Y}_n^\Delta)b(\bar{Y}_n^\Delta, \alpha)|^2 \Delta. \end{aligned}$$

From this point on, the proof is nearly identical to that of Lemma 4.1 and is omitted.

THEOREM 7.1. *Suppose that Assumptions 2.1–2.4 and 6.1 hold, and let $\alpha = \alpha_0$. Then $\tilde{X}_k^\Delta \Rightarrow \tilde{X}_k$ if $\tilde{X}_0^\Delta \Rightarrow \tilde{X}_0$, and $\tilde{\mu}^\Delta(\alpha_0) \Rightarrow \tilde{\mu}(\alpha_0)$. In addition, $E_x^{\alpha_0} f(\tilde{X}_k^\Delta) \xrightarrow{\Delta} E_x^{\alpha_0} f(\tilde{X}_k)$ uniformly in $x \in G$ and in f in any equicontinuous set with $\|f\| \leq 1$. Also, $\tilde{\mu}^\Delta(\alpha_0 + \delta\alpha) \Rightarrow \tilde{\mu}^\Delta(\alpha_0)$ as $\delta\alpha \rightarrow 0$ and $\mu^\Delta(\alpha_0) \Rightarrow \mu(\alpha_0)$. Finally,*

$$\bar{f}^{\Delta, \alpha_0} \equiv \langle \mu^\Delta(\alpha_0), f \rangle \rightarrow \langle \mu(\alpha_0), f \rangle \equiv \bar{f}^{\alpha_0},$$

uniformly for f in any equicontinuous set with $\|f\| \leq 1$.

Proof. Note that $(x^\Delta(\cdot), \tau^\Delta) \rightarrow (x(\cdot), \tau)$ uniformly in $x \in G$ in the sense that $E_x^{\alpha_0} F(x^\Delta(\cdot), \tau^\Delta) \rightarrow E_x^{\alpha_0} F(x(\cdot), \tau)$ uniformly in $x \in G$, for any bounded and continuous real valued $F(\cdot)$. The weak convergence $\tilde{X}_k^\Delta \Rightarrow \tilde{X}_k$ (if $\tilde{X}_0^\Delta \Rightarrow \tilde{X}_0$) follows from the uniform integrability of $\{\tau^\Delta, \Delta > 0, \alpha \in A_0\}$ and the (uniform) weak convergence of $x^\Delta(\cdot)$ to $x(\cdot)$. The asserted weak convergence can be proved by a standard martingale method [5], [6] (and using the nondegeneracy of $a(\cdot)$ and the smoothness of Γ, Γ_1 to get the weak convergence of τ^Δ). In fact, a standard weak convergence method can be used to get $\tilde{P}^\Delta(\alpha_0)f \rightarrow \tilde{P}(\alpha_0)f$, uniformly in f in any equicontinuous set in $C(G)$.

Now, for $f \in C(G)$, by the invariance of $\mu^\Delta(\alpha_0)$, we can write

$$\langle \tilde{\mu}^\Delta(\alpha_0), f \rangle = \langle \tilde{\mu}^\Delta(\alpha_0), \tilde{P}^\Delta(\alpha_0)f \rangle \equiv \bar{f}^{\Delta, \alpha_0}.$$

$\{\tilde{\mu}^\Delta(\alpha_0), \Delta > 0\}$ is obviously tight since G is compact. If $\hat{\mu}(\alpha_0)$ is the limit of a weakly convergent subsequence, then by the last expression, we have

$$\langle \hat{\mu}(\alpha_0), f \rangle = \langle \hat{\mu}(\alpha_0), \tilde{P}(\alpha_0)f \rangle, \quad f \in C(G),$$

which yields $\hat{\mu}(\alpha_0) = \tilde{\mu}(\alpha_0)$.

Now use (7.2), the weak convergence $\{\tau^\Delta, x^\Delta(\cdot)\} \Rightarrow \{\tau, x(\cdot)\}$, and the uniform integrability of $\{\tau^\Delta\}$ (Theorem 6.1) and $\tilde{\mu}^\Delta(\alpha_0) \Rightarrow \tilde{\mu}(\alpha_0)$ to get $\mu^\Delta(\alpha_0) \Rightarrow \mu(\alpha_0)$. The last assertion of the theorem is also proved by an argument by contradiction, and the proof is omitted. \square

An analogue of (3.6). The following lemma is needed to get an analogue of Lemma 4.4.

LEMMA 7.2. *Suppose that Assumptions 2.1–2.3 and 6.1 hold. Let k be such that $C\gamma^k \equiv \lambda < 1$ (see (3.5)). Let $C'(G) \subset C(G)$ be an equicontinuous set. Then*

$$(7.3) \quad \overline{\lim}_{\Delta \rightarrow 0} \sup_{f \in C'(G)} \frac{|E_x^{\alpha_0} f(\tilde{X}_k^\Delta) - \bar{f}^{\Delta, \alpha_0}|}{\|f - \bar{f}^{\Delta, \alpha_0}\|} \leq \lambda.$$

Equivalently, there are $\psi_1 < 1$, $C_1 < \infty$, such that for small $\Delta > 0$,

$$(7.4) \quad \|\tilde{P}^\Delta(\alpha_0)^n f - \tilde{f}^{\Delta, \alpha_0}\| \leq C_1 \psi_1^n \|f - \tilde{f}^{\Delta, \alpha_0}\|.$$

Proof. Suppose that (7.3) is false. Then there is $x_n \rightarrow x \in G$, $\Delta_n \rightarrow 0$, $\lambda_n \geq \lambda_0 > \lambda$, $f_n \in C'(G)$, $f_n \rightarrow f \in C'(G)$, such that

$$\frac{|E_{x_n}^{\alpha_0} f_n(\tilde{X}_k^{\Delta_n}) - \tilde{f}_n^{\Delta_n, \alpha_0}|}{\|f_n - \tilde{f}_n^{\Delta_n, \alpha_0}\|} \geq \lambda_n.$$

Without loss of generality, we can suppose that the infima of the denominators are positive. Then we can write

$$(7.5) \quad \frac{|E_x^{\alpha_0} f(\tilde{X}_k) - \tilde{f}^{\alpha_0}|}{\|f - \tilde{f}^{\Delta_n, \alpha_0}\|} \geq \frac{|E_{x_n}^{\alpha_0} f_n(\tilde{X}_k^{\Delta_n}) - \tilde{f}_n^{\Delta_n, \alpha_0}|}{\|f_n - \tilde{f}_n^{\Delta_n, \alpha_0}\|} \frac{\|f - \tilde{f}_n^{\Delta_n, \alpha_0}\|}{\|f_n - \tilde{f}_n^{\Delta_n, \alpha_0}\|}.$$

The last two terms on the right go to zero by the weak convergence $\tilde{X}_k^{\Delta_n} \Rightarrow \tilde{X}_k$ (initial conditions $\tilde{X}_0^\Delta = x_n$, $\tilde{X}_0 = x$, respectively), $\tilde{\mu}^{\Delta_n}(\alpha_0) \Rightarrow \tilde{\mu}(\alpha_0)$, and the convergence $f_n \rightarrow f$. The left side of (7.5) goes to $|E_x^{\alpha_0} f(\tilde{X}_k) - f^{\alpha_0}|/\|f - \tilde{f}^{\alpha_0}\| \leq C\psi^k = \lambda$, and we have a contradiction.

Inequality (7.4) follows from (7.3) by letting $\psi_1^k = (\lambda + \delta\lambda)$ for small $\delta\lambda > 0$, and iterating. \square

LEMMA 7.3. *Suppose that Assumptions 2.1–2.5 and 6.1 hold. Then for $f \in L^\infty(G)$,*

$$\frac{[\tilde{P}^\Delta(\alpha_0 + \delta\alpha) - \tilde{P}^\Delta(\alpha_0)]f}{\delta\alpha}$$

converges (as $\delta\alpha \rightarrow 0$) to the function $\tilde{P}_\alpha^\Delta(\alpha_0)f$ with values

$$E_x^{\alpha_0} Z^\Delta(\tau^\Delta, \alpha_0) f(\tilde{X}_1^\Delta) = \frac{d}{d\alpha} E_x^\alpha f(\tilde{X}_1^\Delta) \Big|_{\alpha=\alpha_0}.$$

The limit is continuous and the convergence is uniform in Δ , $x \in G$, and in $f \in C(G)$ for $\|f\| \leq 1$. The set $\{E_x^{\alpha_0} Z^\Delta(\tau^\Delta, \alpha_0) f(\tilde{X}_1^\Delta), \Delta > 0, f \in C(G), \|f\| \leq 1\}$ is equicontinuous.

The same result holds for the convergence

$$\begin{aligned} & \frac{1}{\delta\alpha} \left[E_x^{\alpha_0 + \delta\alpha} \int_0^{\tau^\Delta} f(x^\Delta(s)) ds - E_x^{\alpha_0} \int_0^{\tau^\Delta} f(x^\Delta(s)) ds \right] \\ & \rightarrow E_x^{\alpha_0} \int_0^{\tau^\Delta} f(x^\Delta(s)) Z^\Delta(s, \alpha_0) ds. \end{aligned}$$

The proof is analogous to that of Lemma 4.2 but uses the Radon–Nikodym derivative introduced in the remark under Lemma 7.1, and is omitted.

THEOREM 7.2. *Suppose that Assumptions 2.1–2.5 and 6.1 hold. Then $\tilde{\mu}_\alpha^\Delta(\alpha_0)$ and $\mu_\alpha^\Delta(\alpha_0)$ exist in the sense of weak convergence.*

Proof. Let $C_c^\Delta(G)$ be the subset of $C(G)$ for which $\langle f, \tilde{\mu}^\Delta(\alpha_0) \rangle = 0$. Following the proof of Lemma 4.4 and its corollary, we first show the invertability of $(I - \tilde{P}^\Delta(\alpha_0))$ on $C_c(G)$, on which we identify functions that are equal almost everywhere ($\tilde{\mu}^\Delta(\alpha_0)$). By Lemma 7.1 and the fact that $\tilde{\mu}^\Delta(\alpha_0)$ is an invariant measure for the transition function that defines $\tilde{P}^\Delta(\alpha_0)$, for $f \in C_c^\Delta(G)$ the sum below converges, and we have $(I - \tilde{P}^\Delta(\alpha_0))C_c^\Delta(G) \subset C_c^\Delta(G)$. By Lemma 7.2, we obviously have

$$(I - \tilde{P}^\Delta(\alpha_0)) \sum_{n=0}^{\infty} (\tilde{P}^\Delta(\alpha_0))^n f = \sum_{n=0}^{\infty} (\tilde{P}^\Delta(\alpha_0))^n (I - \tilde{P}^\Delta(\alpha_0)) f = f.$$

These facts yield that the inverse is

$$(7.6) \quad g^\Delta = (I - \tilde{P}^\Delta(\alpha_0))^{-1} f = \sum_{n=0}^{\infty} (\tilde{P}^\Delta(\alpha_0))^n f.$$

By Lemmas 7.1 and 7.2, the sum on the right side converges uniformly in Δ , and it is equicontinuous for $f \in C_c^\Delta(G)$, $\|f\| \leq 1$, $\Delta > 0$.

We can now use a proof analogous to that of Theorem 4.1 (but using weak rather than setwise convergence) together with Lemma 7.3 and the weak convergence $\tilde{\mu}^\Delta(\alpha_0 + \delta\alpha) \Rightarrow \tilde{\mu}^\Delta(\alpha_0)$ to get the existence of $\tilde{\mu}_\alpha^\Delta(\alpha_0)$ in the sense of weak convergence, and the few details are omitted. To get the existence of $\mu_\alpha^\Delta(\alpha_0)$ in the sense of weak convergence, use representation (7.2) and the α -differentiability of $\tilde{\mu}^\Delta(\alpha)$, $E_x^\alpha \int_0^{\tau^\Delta} f(x^\Delta(s)) ds$ at $\alpha = \alpha_0$, and $E_{x_0}^\alpha \tau^\Delta > 0$. The details are like those of Theorem 4.2, but the proof uses the equicontinuity of $\{E_x^\alpha \int_0^{\tau^\Delta} f(x^\Delta(s)) ds\}$ (in $f \in C(G)$, $\Delta > 0$, $\|f\| \leq 1$, $\alpha \in A_0$), the weak convergence, and the uniform integrability of $\{\tau^\Delta, \text{small } \Delta > 0, \alpha \in A_0\}$. \square

COROLLARY. *Assume the conditions of Theorem 7.2 hold. Then $\tilde{\mu}_\alpha^\Delta(\alpha_0)$ exists in the sense of setwise convergence. Also, $\{\tilde{\mu}_\alpha^\Delta(\alpha_0), \text{small } \Delta > 0\}$ is of bounded variation. For $g \in L^\infty(G)$, there is a unique $f \in L^\infty(G)$ such that*

$$(I - \tilde{P}^\Delta(\alpha_0))f = g - \tilde{g}^{\Delta, \alpha_0}$$

and $\tilde{f}^{\Delta, \alpha_0} = 0$.

Proof. Let $f \in L^\infty(G)$. Analogous to (4.9), write $\delta\tilde{P}(\alpha) = \tilde{P}^\Delta(\alpha_0 + \delta\alpha) - \tilde{P}^\Delta(\alpha_0)$, $\delta\tilde{\mu}^\Delta(\alpha) = \tilde{\mu}^\Delta(\alpha_0 + \delta\alpha) - \tilde{\mu}^\Delta(\alpha_0)$, and

$$(7.7) \quad \begin{aligned} \left\langle \frac{\delta\tilde{\mu}^\Delta(\alpha)}{\delta\alpha}, f \right\rangle &= \left\langle \frac{\delta\tilde{\mu}^\Delta(\alpha)}{\delta\alpha}, \tilde{P}^\Delta(\alpha_0)f \right\rangle \\ &+ \left\langle \tilde{\mu}^\Delta(\alpha_0), \frac{\delta\tilde{P}^\Delta(\alpha)}{\delta\alpha} f \right\rangle + \left\langle \delta\tilde{\mu}^\Delta(\alpha), \frac{\delta\tilde{P}^\Delta(\alpha_0)}{\delta\alpha} f \right\rangle \end{aligned}$$

By Lemma 7.3, $(\delta\tilde{P}^\Delta(\alpha)/\delta\alpha)f$ converges to a continuous function, uniformly in $x \in G$. This and $\delta\tilde{\mu}^\Delta(\alpha) \Rightarrow$ zero measure imply that the last term on the right of (7.7) tends to zero, as $\delta\alpha \rightarrow 0$. Furthermore, since $\tilde{\mu}_\alpha^\Delta(\alpha_0)$ exists in the sense of weak convergence by the theorem. The second term on the right of (7.7) tends to $\langle \tilde{\mu}^\Delta(\alpha_0), \tilde{P}_\alpha^\Delta(\alpha_0)f \rangle$.

Since $\tilde{P}^\Delta(\alpha_0)f$ is continuous (Lemma 7.1), and $\tilde{\mu}_\alpha^\Delta(\alpha_0)$ exists in the sense of weak convergence, the first term on the right tends to $\langle \tilde{\mu}_\alpha^\Delta(\alpha_0), \tilde{P}^\Delta(\alpha_0)f \rangle$. Thus the limit

of the left side of (7.7) exists. Now, the form of the limit of the right side implies that $\tilde{\mu}_\alpha^\Delta(\alpha_0)$ exists in the sense of setwise convergence.

Rewrite (7.7) as

$$\left\langle \tilde{\mu}_\alpha^\Delta(\alpha_0), (I - \tilde{P}^\Delta(\alpha_0))f \right\rangle = \left\langle \tilde{\mu}^\Delta(\alpha_0), \tilde{P}^\Delta(\alpha_0)f \right\rangle.$$

For $g \in L^\infty(G)$, set $\tilde{g} = g - \tilde{g}^{\Delta, \alpha_0}$ and define

$$(7.8) \quad \begin{aligned} f^\Delta &= \sum_{n=0}^{\infty} (\tilde{P}^\Delta(\alpha_0))^n \tilde{g} \\ &= \tilde{g} + \sum_{n=0}^{\infty} (\tilde{P}^\Delta(\alpha_0))^n (\tilde{P}^\Delta(\alpha_0)\tilde{g}). \end{aligned}$$

The sum converges uniformly in g, Δ , for $\|g\| \leq 1$, since $\{\tilde{P}^\Delta(\alpha_0)g, \Delta > 0, g \in L^\infty(G), \|g\| \leq 1\}$ is equicontinuous by Lemma 7.1. The uniqueness assertion follows.

Thus $(I - \tilde{P}^\Delta(\alpha_0))f^\Delta = \tilde{g}$ and

$$\langle \tilde{\mu}_\alpha^\Delta(\alpha_0), \tilde{g} \rangle = \langle \tilde{\mu}_\alpha^\Delta(\alpha_0), g \rangle = \langle \tilde{\mu}^\Delta(\alpha_0), \tilde{P}^\Delta(\alpha_0)f^\Delta \rangle.$$

The bounded variation assertion follows from this representation. \square

The following is the convergence theorem for the discretizations.

THEOREM 7.3. *Suppose that Assumptions 2.1–2.5 and 6.1 hold. Then $\tilde{\mu}_\alpha^\Delta(\alpha_0)$ converges setwise to $\tilde{\mu}_\alpha(\alpha_0)$ and $\mu_\alpha^\Delta(\alpha_0)$ converges setwise to $\mu_\alpha(\alpha_0)$.*

Proof. Let $f \in L^\infty(G)$. Let g^Δ and g , respectively, be the unique solutions in $L^\infty(G)$ (Theorem 7.2, Lemma 4.4) to

$$(I - \tilde{P}^\Delta(\alpha_0))g^\Delta = f - \tilde{f}^{\Delta, \alpha_0}, \quad (I - \tilde{P}(\alpha_0))g = f - \tilde{f}^{\alpha_0}.$$

Note that

$$\begin{aligned} \frac{d}{d\alpha} \langle \tilde{\mu}^\Delta(\alpha), g^\Delta \rangle|_{\alpha=\alpha_0} &= \langle \tilde{\mu}_\alpha^\Delta(\alpha_0), g^\Delta \rangle \\ &= \langle \tilde{\mu}_\alpha^\Delta(\alpha_0), \tilde{P}^\Delta(\alpha_0)g^\Delta \rangle + \langle \tilde{\mu}^\Delta(\alpha_0), \tilde{P}_\alpha^\Delta(\alpha_0)g^\Delta \rangle. \end{aligned}$$

Then we can write

$$(7.9) \quad \begin{aligned} \langle \tilde{\mu}_\alpha^\Delta(\alpha_0), f \rangle &= \langle \tilde{\mu}_\alpha^\Delta(\alpha_0), f - \tilde{f}^{\Delta, \alpha_0} \rangle \\ &= \langle \tilde{\mu}_\alpha^\Delta(\alpha_0), (I - \tilde{P}^\Delta(\alpha_0))g^\Delta \rangle \\ &= \int \tilde{\mu}^\Delta(dx, \alpha_0) \frac{d}{d\alpha} E_x^\alpha g^\Delta(\tilde{X}_1^\Delta)|_{\alpha=\alpha_0}. \end{aligned}$$

We have

$$\frac{d}{d\alpha} E_x^\alpha g^\Delta(\tilde{X}_1^\Delta)|_{\alpha=\alpha_0} = E_x^{\alpha_0} g^\Delta(\tilde{X}_1^\Delta) Z^\Delta(\tau^\Delta, \alpha_0).$$

Now, note that the sum in (7.6) converges uniformly in Δ (Lemma 7.2); hence $g^\Delta \rightarrow g$, since $\tilde{P}^\Delta(\alpha_0)^n f \rightarrow \tilde{P}(\alpha_0)^n f$. Using this, the weak convergence of $\{\tilde{X}_1^\Delta, Z^\Delta(\tau^\Delta, \alpha_0)\}$, the uniform integrability of $\{Z^\Delta(\tau^\Delta, \alpha_0), \Delta > 0\}$, the fact that the functions on the right side of (7.9) converge uniformly in $x \in G$ to the continuous limit, and the fact that $\tilde{\mu}^\Delta(\alpha_0) \Rightarrow \tilde{\mu}(\alpha_0)$ yields that the limit as $\Delta \rightarrow 0$ of the right side of (7.9) is

$$\int \tilde{\mu}(dx, \alpha_0) E_x^{\alpha_0} g(\tilde{X}_1) Z(\tau, \alpha_0) = \int \tilde{\mu}(dx, \alpha_0) \frac{d}{d\alpha} E_x^\alpha g(\tilde{X}_1)|_{\alpha=\alpha_0}$$

$$= \langle \tilde{\mu}_\alpha(\alpha_0), (I - \tilde{P}(\alpha_0))g \rangle = \langle \tilde{\mu}_\alpha(\alpha_0), f - \tilde{f}^{\alpha_0} \rangle = \langle \tilde{\mu}_\alpha(\alpha_0), f \rangle.$$

Thus $\langle \tilde{\mu}_\alpha^\Delta(\alpha_0), f \rangle \rightarrow \langle \tilde{\mu}_\alpha(\alpha_0), f \rangle$, which yields the setwise convergence of $\tilde{\mu}_\alpha^\Delta(\alpha_0)$ to $\tilde{\mu}_\alpha(\alpha_0)$. The setwise convergence of $\mu^\Delta(\alpha_0)$ to $\mu(\alpha_0)$ follows from representation (7.2). For example, to get the limit of the derivative of the denominator of (7.2), note that the derivative of the denominator is

$$\int_G \tilde{\mu}_\alpha^\Delta(dx, \alpha_0) E_x^{\alpha_0} \tau^\Delta + \int_G \tilde{\mu}_\alpha^\Delta(dx, \alpha_0) \frac{d}{d\alpha} E_x^\alpha \tau^\Delta \Big|_{\alpha=\alpha_0}.$$

Then use the representation

$$\frac{d}{d\alpha} E_x^\alpha \tau^\Delta \Big|_{\alpha=\alpha_0} = E_x^{\alpha_0} \tau^\Delta Z^\Delta(\tau^\Delta, \alpha_0),$$

and the proved convergence and uniform integrability (where appropriate) results for $\tilde{\mu}_\alpha^\Delta(\alpha_0)$, $X^\Delta(\cdot)$, τ^Δ , $Z^\Delta(\tau^\Delta, \alpha_0)$. \square

Below is a finite time approximation theorem, which shows that the derivative $\langle \mu_\alpha(\alpha_0), f \rangle$ of the ergodic cost can be arbitrarily well approximated by

$$\frac{d}{d\alpha} E_x^\alpha f(x^\Delta(t)) \Big|_{\alpha=\alpha_0}$$

for large t and small Δ . It is such approximations that are actually used in the applications. It is important to note that for large enough t , the quality of the approximation is uniformly good in (small) Δ .

THEOREM 7.4. *Suppose that Assumptions 2.1–2.5 and 6.1 hold. Then for $f \in L^\infty(R^r)$,*

$$\begin{aligned} (7.10) \quad \langle \mu_\alpha(\alpha_0), f \rangle &= \lim_{\Delta \rightarrow 0} \langle \mu_\alpha^\Delta(\alpha_0), f \rangle \\ &= \lim_{\substack{\Delta \rightarrow 0 \\ t \rightarrow \infty}} \int \mu^\Delta(dx, \alpha_0) \frac{d}{d\alpha} E_x^\alpha f(x^\Delta(t)) \Big|_{\alpha=\alpha_0}, \end{aligned}$$

where the limits as $\Delta \rightarrow 0$, $t \rightarrow \infty$ can be taken in any way at all.

Proof. Write, by the invariance of $\mu^\Delta(\alpha)$ and the differentiability

$$\begin{aligned} (7.11) \quad \frac{d}{d\alpha} \langle \mu^\Delta(\alpha), f \rangle_{\alpha=\alpha_0} &= \langle \mu_\alpha^\Delta(\alpha_0), P^\Delta(\alpha_0, t)f \rangle \\ &\quad + \langle \mu^\Delta(\alpha_0), P_\alpha^\Delta(\alpha_0, t)f \rangle, \end{aligned}$$

where $P^\Delta(\alpha_0, t)f(x) = E_x^{\alpha_0} f(x^\Delta(t))$ and $t > 0$. We have $P^\Delta(\alpha_0, t)f \rightarrow \tilde{f}^{\alpha_0} = \langle \mu(\alpha_0), f \rangle$ as $\Delta \rightarrow 0$, $t \rightarrow \infty$. Also, $\{\mu_\alpha^\Delta(\alpha_0), \Delta > 0\}$ is of bounded variation by the corollary to Theorem 7.2. Thus $\langle \mu_\alpha^\Delta(\alpha_0), P^\Delta(\alpha_0, t)f \rangle \rightarrow 0$ as $\Delta \rightarrow 0$ and $t \rightarrow \infty$, which yields the theorem. \square

A pathwise result. With the approximation of Theorem 7.4, we can give the pathwise result. Since we only have one long realization and cannot explicitly calculate the derivatives of the expectations, we need to show that a long simulation of $\{X_n^\Delta, n < \infty\}$ can yield a good approximation to the right side of (7.10) for fixed Δ . Typically, the t_0 in Theorem 7.5 is as large as can be, consistent with a modest sample variance.

THEOREM 7.5. *Suppose that Assumptions 2.1–2.5 and 6.1 hold. Fix $t = n\Delta$. Let $f(\cdot)$ be bounded and continuous. Then as $T \rightarrow \infty$ (or with centered f used as discussed in §5)*

$$(7.12) \quad \begin{aligned} & \frac{1}{T} \int_0^T [Z^\Delta(t_0 + s, \alpha_0) - Z^\Delta(s, \alpha_0)] f(x^\Delta(t_0 + s)) ds \\ & \xrightarrow{P} \int \mu^\Delta(dx, \alpha_0) E_{x^\Delta}^{\alpha_0} Z^\Delta(t_0, \alpha_0) f(x^\Delta(t_0)) \\ & = \left\langle \mu^\Delta(\alpha_0), \frac{d}{d\alpha} E^\alpha f(x^\Delta(t_0)) \Big|_{\alpha=\alpha_0} \right\rangle. \end{aligned}$$

Proof. Fix t_0 . Define $\delta Z^\Delta(t_0, s) = Z^\Delta(t_0 + s, \alpha_0) - Z^\Delta(s, \alpha_0)$ and $Y^\Delta(t_0, s) = \delta Z^\Delta(t_0, s) f(x^\Delta(t_0 + s))$. Then the process (parameter T) defined by

$$M^\Delta(T) = \int_0^T [Y^\Delta(t_0, s) - E_{x^\Delta(s)}^{\alpha_0} Y^\Delta(t_0, s)] ds$$

is a zero mean martingale whose variance is $O(T)$. Thus Kronecker's lemma implies that $M^\Delta(T)/T \rightarrow 0$ with probability one. This implies that for the purpose of evaluating the limit of the left side of (7.12), we can replace it by

$$(7.13) \quad \frac{1}{T} \int_0^T q(x^\Delta(s)) ds,$$

where we define

$$q(x^\Delta(s)) = E_{x^\Delta(s)}^{\alpha_0} Y^\Delta(t_0, s) = \frac{d}{d\alpha} E_{x^\Delta(s)}^\alpha f(x^\Delta(t_0 + s)) \Big|_{\alpha=\alpha_0}.$$

The function $q(\cdot)$ is continuous and bounded. Then, the ergodic properties of $\{X_n^\Delta, n < \infty\}$ imply that (as $T \rightarrow \infty$) (7.13) converges with probability one to its mean value $\langle \mu^\Delta(\alpha_0), q \rangle$, which is just the center term of (7.12). \square

8. Numerical comparisons. The approximation method of §7 has been simulated and compared with alternative methods on a variety of problems of dimension up to seven. Here, we comment on some comparisons with a finite difference method. The alternative methods are all described and discussed in [1], and we will repeat only a few of the comments made there.

The basic method used for all methods takes one long simulation, over an interval T_1 . A basic estimation interval T_0 is given, and the approximate model $X^\Delta(\cdot)$ is simulated. $N = T_1/T_0$ estimates of the derivative are made in the long simulation interval, each using T_0 units of time. Let X_n^Δ denote the state of the system at the start of the n th subinterval. Then X_n^Δ is the initial condition for the estimate on the $(n+1)$ st subinterval. The detailed results reported here are for a two-dimensional problem, with the parameter α being a scalar. We comment on larger problems later. For the finite difference estimate, a pair of simulations must be taken, with a parameter set at $\alpha_0 \pm \delta\alpha$, for some small $\delta\alpha$. The samples of the δw in (5.1) for the second member of the pair was the same as that of the first member of the pair, with the samples being independent from pair to pair. This reduced the variance over what would have been the case if all the samples of the δw random variables had been mutually independent, as in [1]. The reduction was particularly large if the system

TABLE 8.1

was linear, and the cost function smooth, although there was a noticeable reduction in the variance in all cases tested.

The two-dimensional problem was the noise-driven Van der Pol equation

$$dx_1 = x_2 dt, \quad dx_2 = [10x_2(1 - x_1^2) - \alpha x_1]dt + dw,$$

where $\alpha_0 = 2$. Note that this system is degenerate. Nevertheless, the method works well. The cost function of interest was $\int_0^S k(x(s))ds/S$ for large S , where

$$k(x) = I_{\{|x_2| \geq 0.3\}}.$$

The simplest estimator is

$$(8.1) \quad \frac{1}{N} \sum_{n=1}^N \frac{1}{T_0} \int_{nT_0}^{nT_0+T_0} [Z^\Delta(s, \alpha_0) - Z^\Delta(nT_0, \alpha_0)] k(X^\Delta(s)) ds.$$

An “antithetic” variable method was always used, since it gives a reduced variance: Let N be an even number, and let the δw samples used for the $2n$ th estimate be the negative of that used for the $(2n-1)$ th ($n = 1, 2, \dots$) estimate, with the δw used for the $(2n-1)$ th estimates ($n = 1, 2, \dots, N/2$) being mutually independent.

The centered form, where $k(X^\Delta(s))$ is replaced by the centered $k(X^\Delta(s)) - \bar{k}(nT_0 + T_0)$, where the centering is a sample estimate of the value of the cost at the cited time, actually gave better results. This method is referred to as the AC-method in the tables below (antithetic variable, centered). The centering is zero mean, but helps reduce the variance. As $n \rightarrow \infty$, (8.1) converges to

$$\frac{d}{d\alpha} \int \mu(dx, \alpha_0) E_x^{\alpha_0} k(X^\Delta(T_0)).$$

$\lambda = .5$.157	.106
$\lambda = 1$.150	.07
CPU Time		68.3

For large enough T_0 , this is a good estimate of the desired derivative. A better procedure would be to divide the interval $[0, T_0]$ into a reasonable number of subintervals to get a better approximation to the first centered form discussed in §5. We must keep in mind, however, that the CPU time required for a large number of subdivisions might be better used for taking more samples.

A third method, called the weighted AC-method, often (but not always) was advantageous. As $s \rightarrow \infty$, the variance of $[Z^\Delta(s, \alpha_0) - Z^\Delta(nT_0, \alpha_0)]$ goes to ∞ . If the system has a “short” memory, then the “earlier” part of the $Z^\Delta(\cdot)$ process contributes little to the estimate in the following sense: Let $nT_0 + T_0 > s > s_0 > nT_0$, and write

$$\begin{aligned}
 & [Z^\Delta(s, \alpha_0) - Z^\Delta(nT_0, \alpha_0)]k(X^\Delta(s)) \\
 &= [Z^\Delta(s, \alpha_0) - Z^\Delta(s_0, \alpha_0)]k(X^\Delta(s)) \\
 & \quad + [Z^\Delta(s_0, \alpha_0) - Z^\Delta(nT_0, \alpha_0)]k(X^\Delta(s)).
 \end{aligned}$$

Then the mean value of the second term goes to zero as $s - s_0 \rightarrow \infty$. If we reduce the sample interval, however, then a bias is added. To balance the opposing effects, we use a weighted substitute \tilde{Z}^Δ for Z^Δ , constructed as follows, where $\lambda \in (0, 1)$ is a weighing factor or exponential discount of the past (notation for the nondegenerate case):

$$\tilde{Z}^\Delta((n+1)\Delta) = [\sigma^{-1}(X_i^\Delta, \alpha_0)b_\alpha(X_i^\Delta, \alpha_0)]' \delta w(i\Delta) - \lambda \tilde{Z}^\Delta(n\Delta).$$

For the problem reported on here, this method gave excellent results. In other cases, where the “approach to ergodicity” is slower, a substantial bias could be introduced into the estimates.

Refer to Tables 8.1–8.3, where the sample means of the derivative estimates, their sample standard deviations, and the required CPU time are given. For the finite

difference estimates, $N=2500$ was used, and $N=5000$ otherwise. This is because two system simulations per finite difference estimate are needed, and only one for our method. The important quantity, however, is the sample standard deviation per CPU time unit. Note that the sample standard deviation for the weighted AC-method decreases as T_0 increases, while that for the AC-method increases. We can readily see the advantages of the methods introduced here. For linear systems, the finite difference method seems to work better owing to the 'smoothness' of the dependence of the estimates on the noise, and the value of the difference interval was not too important (did not seriously affect the sample variance), as long as it was small enough to control the bias.

There are important dimensionality advantages to our methods. Suppose that the dimension of the parameter is m . Then, to get a single estimate of a gradient, a finite difference method needs to simulate the system either $(m + 1)$ or $2m$ times, depending on the finite difference method used (one-sided or central). Our method requires the simulation of only one sample path per estimate, and the calculation of one Z -variable per component of the parameter. The calculation of the Z -variable, however, is usually much simpler than doing a simulation of the system. This is particularly true if the system is of high dimension, or if the dynamical terms are hard to compute. Thus, our methods require much less computer time than does the finite difference method, particularly for high-dimensional and nonlinear problems. Alternative methods, such as the finite difference method, can compensate for this only by having a better quality estimate, i.e., one with smaller bias or sample variance.

We emphasize that no general rule has been found that can tell us which method would be preferable for any particular class of problems. For many problems, the alternative methods are preferable. All methods must be taken as serious candidates, and techniques sought for their realization so that they perform as well as possible.

CONVEX DUALITY AND GENERALIZED SOLUTIONS IN OPTIMAL CONTROL PROBLEM FOR STOPPED PROCESSES: THE DETERMINISTIC MODEL*

HANG ZHU†

Abstract. The approach consists of imbedding the original control problem tightly in a convex mathematical programming problem on the space of measures and then solving the latter problem by duality in convex analysis. The dual to the control problem is to find the supremum of all smooth subsolutions to the Bellman equation. Because of the effect of stops at the boundary of the domain, a different formulation of strong and weak problems will be adopted to make use of the convex duality method. The results about the decomposition of weak measures provide a clear interpretation for such a effect in the weak formulation of our control problem.

Key words. optimal control, stopped processes, smooth subsolution, convex duality, strong and weak problems

AMS(MOS) subject classifications. 49J27, 49N15

1. Introduction. Recently, a new method has been developed in the study of optimal control problems. The method, which originated in Young's concept of generalized curves, took the approach from a point of view of convex analysis, and, in particular, use of duality between spaces of continuous functions and spaces of measures. This so-called "convex duality" method was first introduced by Vinter and Lewis [9], [10] in their study, which concerns deterministic control problems. They established the equivalence between the control problem and a related "weak" problem. This weak problem is actually a convex mathematical programming problem, and the objects in the weak problem are called the "generalized solutions." Upon establishing the equivalence of two problems, the new optimality conditions could then be obtained by setting up the Fenchel dual of the weak problem. It turns out that the dual problem is actually to find the supremum among all smooth subsolutions of the Bellman equation. Later on, this method was greatly simplified by Fleming and Vermes and applied in their studies of optimal control problems of (piecewise) deterministic processes [2], [8] as well as diffusion processes [3], [4]. The results in those papers were proved for the fixed finite time horizon and the infinite time horizon discounted cost problems.

In this paper, we consider a deterministic optimal control problem for stopped processes and address the role that the boundary will play in the duality formulation of Fleming–Vermes approach. By the "stopped process," we mean that the state process X_s under the control will be stopped at the first time it hits the boundary of a given domain $\Omega \subset \mathbb{R}^N$. Our objective is to minimize the cost functional that has a nonnegative integral cost up to the stopping time. Because of the effect of stops at the boundary of the domain, the correct weak problems are defined by coupling both the "interior" measure and "boundary" measure together in our formulation so that the standard Fenchel duality of convex analysis (see the Appendix in the end of paper) can still be set up appropriately to assert that the dual of our control problem is again to find the supremum among all smooth subsolutions of the Bellman equation.

*Received by the editors January 24, 1990; accepted for publication (in revised form) February 21, 1991.

†Division of Applied Mathematics, Brown University, Providence, Rhode Island 02912.

The equivalence between strong and weak formulations is obtained in §3 where we have presented a simple new proof for our main equivalence theorem. The proof is based on two important results, called the “canonical extension” and the “canonical extraction,” respectively. These two results give us an intuitive portrait about the structural content of weak measures in terms of the “stopping” effect in our control problems.

Related problems could be found in Soner [7] and Vermes [8]. In [7], where the author studies the control problem with state constraints, the processes are pushed back continuously from the boundary of the domain, and the value function there is characterized in terms of the notion of constrained viscosity solution. In [8], the processes can jump back from the boundary into the interior of the domain, and the author proved a disintegration theorem for general occupation measures and obtained, by the same convex duality method, a characterization of the value function as the supremum of all smooth subsolutions to the Bellman equation. The assumptions in both papers assure that all processes have a uniformly nonvanishing lateral speed in the boundary region, which is basically equivalent to our assumption (H3). The present paper differs from [7], [8] in the sense that the processes under control will simply stop when they come to the boundary region. The major achievement of this paper is that it establishes a two-way link between weak measures generated by processes stopped at the boundary and measures generated by continuing processes in the closed domain.

2. The stopped processes problem and its strong/weak formulations.

Consider the following deterministic control system,

$$(2.1) \quad \begin{aligned} \dot{X}_s &= f(s, X_s, u_s) \\ X_t &= x, \quad 0 \leq t \leq s \leq T, \end{aligned}$$

where the control u_s is Borel measurable, taking values in the control space U , and f is an R^N -valued function defined on $[0, T] \times R^N \times U$.

We want to restrict the state process of (2.1) to stay inside some given bounded domain Ω in R^N , and will stop the process X_s whenever it first hits the boundary $\partial\Omega$. The objective is to minimize

$$(2.2) \quad \mathcal{J}^u(t, x) = \int_t^\tau l_0(s, X_s, u_s) ds + L_0(\tau, X_\tau),$$

where the running cost l_0 and the terminal cost L_0 are the functions defined on $[t, T] \times R^N \times U$ and $[t, T] \times R^N$, respectively, and τ is the stopping time defined as

$$\tau = \begin{cases} \inf\{s \geq t : X_s \notin \Omega\} \\ T, & \text{if } X_s \in \Omega, \quad \forall t \leq s \leq T. \end{cases}$$

Note that both X_s and τ depend on the initial condition (t, x) and the control u_s being applied. In the rest of our paper, we will work with this cost functional (2.2) except in Theorem 3.4 (the main equivalence result), where $l_0 \geq 0$ and $L_0 \equiv 0$ are assumed.

Then the value function is given by

$$(2.3) \quad \psi(t, x) = \inf_{u \in \mathcal{U}} \mathcal{J}^u(t, x),$$

for $(t, x) \in \Sigma = [0, T] \times \bar{\Omega}$. Here $\mathcal{U} = \mathcal{U}(t)$ denotes the class of all Borel measurable, U -valued functions u_s on $[t, T]$. The Bellman equation takes the form

$$(2.4) \quad \inf_{u \in \mathcal{U}} \{ \partial_t \psi + f \cdot \nabla_x \psi + l_0 \} = 0, \quad \text{in } [t, T] \times \Omega \times U$$

with the terminal-boundary condition $\psi(t, x) = L_0(t, x)$ on $\Sigma_\partial = [0, T] \times \partial\Omega \cup \{T\} \times \bar{\Omega}$. This equation is understood in the viscosity solution sense of Lions [5].

It is convenient to summarize here the following notation and assumptions:

$$\Sigma = [0, T] \times \bar{\Omega}, \quad S = \Sigma \times U, \quad \Sigma_\partial = [0, T] \times \partial\Omega \cup \{T\} \times \bar{\Omega}.$$

$C(\Sigma), C(S), C(\Sigma_\partial)$ = the spaces of real-valued continuous functions on $\Sigma, S, \Sigma_\partial$, respectively.

$$C^{1,1}(\Sigma) = \{ \phi \in C(\Sigma) : \phi_t, \phi_{x_i} \in C(\Sigma), 1 \leq i \leq N \}.$$

(H1) The bounded domain $\Omega \subset \mathbb{R}^N$ has a C^1 -smooth boundary $\partial\Omega$. The control space U is a compact subset in \mathbb{R}^M .

(H2) The running cost function $l_0 \in C(S)$, $l_0 \geq 0$ and the terminal cost function $L_0 \in C(\Sigma_\partial)$. The system function $f \in C(S)$ satisfies the uniform x -Lipschitz condition

$$|f(t, x_1, u) - f(t, x_2, u)| \leq K|x_1 - x_2|, \quad \forall x_1, x_2 \in \bar{\Omega},$$

where K is some constant independent of (t, u) .

(H3) The system (2.1) assumes the following “boundary controllability” condition:

$$(2.5) \quad 0 \in \text{int}\{f(t, x, U)\}, \quad \forall (t, x) \in [0, T] \times \partial\Omega.$$

Here $\text{int}\{f(t, x, U)\}$ stands for the interior of the set $f(t, x, U) = \{f(t, x, u) : u \in U\}$.

Let us now start our formulation of strong and weak problems.

We introduce a more elaborate state space \tilde{S} , which is composed of the “interior” space S and the “boundary” space Σ_∂ as two separate components. Then every function $\tilde{l} \in C(\tilde{S})$ is denoted as a pair (l, L) with $l \in C(S)$ and $L \in C(\Sigma_\partial)$. The dual space $\mathcal{M}(\tilde{S})$ will consist of all pairs of measures $\tilde{M} = (M, N)$ with $M \in \mathcal{M}(S)$ and $N \in \mathcal{M}(\Sigma_\partial)$, where $\mathcal{M}(S), \mathcal{M}(\Sigma_\partial)$ are spaces of finite, signed measures on S, Σ_∂ , respectively.

Given the initial condition (t, x) , each control $u \in \mathcal{U}$ defines a measure $\tilde{M}^u \in \mathcal{M}(\tilde{S})$ as follows:

$$(2.6) \quad \begin{aligned} \langle \tilde{l}, \tilde{M}^u \rangle &= \langle l, M^u \rangle + \langle L, N^u \rangle \\ &= \int_t^\tau l(s, X_s^u, u_s) ds + L(\tau, X_\tau), \quad \forall \tilde{l} = (l, L) \in C(\tilde{S}). \end{aligned}$$

The measure $\tilde{M}^u = (M^u, N^u)$ clearly has the following disintegration:

$$\begin{aligned} M^u(ds, dx, du) &= I_{[t, \tau)} \lambda(ds) \times \delta_{X_s}(dx) \times \delta_{u_s}(du) \\ N^u(ds, dx) &= \delta_{(\tau, X_\tau)}(ds, dx), \end{aligned}$$

where X_s^u is the state process of (2.1) when the control u is applied, τ is the stopping time of this X_s^u . Here λ is the Lebesgue measure on $[0, T]$, $\delta_{(\tau, X)}$ is the Dirac measure at (τ, X) , and $I_{[t, \tau)}$ is an indicator function. The measures M^u and N^u are called,

respectively, the “interior” measure and the “boundary” measure generated by the underlying process.

By the above identification of u with $\tilde{M}^u = (M^u, N^u)$, our control problem can then be reformulated as a linear minimization problem:

$$(2.7) \quad \text{Minimize} \quad \langle \tilde{l}_0, \tilde{M} \rangle = \int_{\tilde{S}} \tilde{l}_0 d\tilde{M}$$

over $\mathcal{M}^s(t, x) = \{\tilde{M}^u = (M^u, N^u) : u \in \mathcal{U}\}$. This is called the *strong problem*.

For each $\tilde{M}^u = (M^u, N^u)$, we can calculate the norms

$$\begin{aligned} \|M^u\| &= \langle 1, M^u \rangle = \tau - t \leq T - t \\ \langle L, N^u \rangle &= L(\tau, X_\tau) \leq \|L\| \Rightarrow \|N^u\| \leq 1, \quad \forall u \in \mathcal{U}. \end{aligned}$$

It follows from the fundamental theorem of calculus that for any $\phi \in C^{1,1}(\Sigma)$

$$(2.8) \quad \phi(\tau, X_\tau) - \phi(t, x) = \int_t^\tau A\phi(s, X_s, u_s) ds, \quad \forall u \in \mathcal{U},$$

where $A\phi(t, x, u) = \partial_t \phi(t, x) + f(t, x, u) \cdot \nabla_x \phi(t, x)$. If we define the operator

$$\tilde{A} : C^{1,1}(\Sigma) \rightarrow C(\tilde{S})$$

by

$$\tilde{A}\phi(\tilde{x}) = \begin{cases} A\phi(t, x, u), & \text{if } \tilde{x} = (t, x, u) \in S \\ -\phi(t, x), & \text{if } \tilde{x} = (t, x) \in \Sigma_\partial, \end{cases}$$

then the above formula can be rewritten in terms of (2.6)

$$\begin{aligned} \phi(t, x) &= -\langle A\phi, M^u \rangle + \langle \phi, N^u \rangle \\ &= -\langle \tilde{A}\phi, \tilde{M}^u \rangle, \quad \forall \phi \in C^{1,1} \text{ and } u \in \mathcal{U}. \end{aligned}$$

Given the initial data (t, x) , let us introduce the space

$$(2.9) \quad \mathcal{M}^w(t, x) = \left(\tilde{M} = (M, N) \in \mathcal{M}(\tilde{S}) : \begin{array}{l} 1) M, N \geq 0 \text{ and } \|M\| \leq T - t, \|N\| \leq 1 \\ 2) \phi(t, x) = -\langle \tilde{A}\phi, \tilde{M} \rangle, \forall \phi \in C^{1,1}(\Sigma) \end{array} \right).$$

Note that this set is both convex and w^* -compact in $\mathcal{M}(\tilde{S})$.

The *weak problem* is therefore formulated as: Given the initial condition (t, x) and $\tilde{l}_0 \in C(\tilde{S})$,

$$(2.10) \quad \text{Minimize} \quad \langle \tilde{l}_0, \tilde{M} \rangle = \int_{\tilde{S}} \tilde{l}_0 d\tilde{M}$$

over $\mathcal{M}^w(t, x)$.

Throughout this paper, we use the following notation:

$$\psi^s(t, x) = \inf_{\mathcal{M}^s(t, x)} \langle \tilde{l}_0, \tilde{M} \rangle, \quad \psi^w(t, x) = \inf_{\mathcal{M}^w(t, x)} \langle \tilde{l}_0, \tilde{M} \rangle.$$

The weak formulation is reduced to the Fenchel's problem in convex analysis. By solving its dual, a maximization problem in the space $C(\tilde{S})$, it turns out that the

dual of minimization (2.10) is to find the supremum of all smooth subsolutions to the Bellman equation (2.4). This is the standard duality result in [4] and its modification will be demonstrated in the Appendix.

3. Decomposition of the weak measures and the main equivalence theorem. We establish two results in this section. The first is the canonical extension theorem, which constructs the weak measure of a continuing process from a stopped one. The second result is that from every weak measure, a minimal, stopped part can be extracted. As a consequence of these results, we give a short proof for the main equivalence theorem.

To present our results, we need to consider the corresponding deterministic control problem with state constraints. Let \bar{S} be the state space, which consists of the “interior” space S and the “terminal” space $\Sigma_T = \{T\} \times \bar{\Omega}$, as two separate components. The formulation of strong and weak problems for the state-constraint problem can then be defined in a similar way to those in §2.

We denote the strong space

$$(3.1) \quad \mathcal{M}^s(t, x) = \{(M_c^u, N_c^u) : X_s^u \in \bar{\Omega}, \forall s \in [t, T]\},$$

where each $\bar{M}_c^u = (M_c^u, N_c^u)$ is associated to a control u , which keeps the state process X_s^u inside $\bar{\Omega}$ for the entire period $[t, T]$, by the formula

$$\langle \bar{l}, \bar{M}_c^u \rangle = \int_t^T l(s, X_s^u, u_s) ds + L(T, X_T), \quad \forall \bar{l} = (l, L) \in C(\bar{S}).$$

If the process X_s^u hits the boundary $\partial\Omega$ at first time $\tau < T$, we have a stopped process that corresponds to a measure $\tilde{M}^u = (M^u, N^u) \in \mathcal{M}^s(t, x)$, and it is associated to the same control u by the (2.6)

$$\langle \tilde{l}, \tilde{M}^u \rangle = \int_t^\tau l(s, X_s^u, u_s) ds + L(\tau, X_\tau), \quad \forall \tilde{l} = (l, L) \in C(\tilde{S}).$$

Note that N_c^u , as a measure on Σ_T , can be identified with a measure on Σ_∂ by a trivial extension since $\Sigma_T \subset \Sigma_\partial$. By such an identification, we have that $\bar{M}_c^u \in \mathcal{M}^w(t, x)$ but not necessarily in $\mathcal{M}^s(t, x)$.

Compared to the original formulation in §2, we have the fundamental theorem of calculus:

$$\phi(T, X_T) - \phi(t, x) = \int_t^T A\phi(s, X_s, u_s) ds, \quad \forall \phi \in C^{1,1}(\Sigma).$$

By introducing the operator $\bar{A} : C^{1,1}(\Sigma) \rightarrow C(\bar{S})$ as

$$\bar{A}\phi(\bar{x}) = \begin{cases} A\phi(t, x, u), & \text{if } \bar{x} = (t, x, u) \in S \\ -\phi(t, x), & \text{if } \bar{x} = (t, x) \in \Sigma_T \end{cases}$$

we then define the weak space for the state-constraint problem:

$$(3.2) \quad \mathcal{M}_c^w(t, x) = \left(\begin{array}{l} \bar{M}_c = (M_c, N_c) \in \mathcal{M}(\bar{S}) : \\ 1) M_c, N_c \geq 0 \text{ and } \|M_c\| = T - t, \|N_c\| = 1 \\ 2) \phi(t, x) = -\langle \bar{A}\phi, \bar{M}_c \rangle, \forall \phi \in C^{1,1}(\Sigma) \end{array} \right).$$

Clearly, $\mathcal{M}_c^w(t, x) \subset \mathcal{M}^w(t, x)$ in the above-mentioned sense. This is expected since the “terminal” space Σ_T is contained in the boundary space $\Sigma_\partial = [0, T] \times \partial\Omega \cup \Sigma_T$.

Let us now illustrate how the measures in $\mathcal{M}^s(t, x)$ are related to the measures in $\mathcal{M}_c^s(t, x)$. For each measure $\tilde{M} = (M, N) \in \mathcal{M}^s(t, x)$, there exists a control u_s such that with $L \equiv 0$, (2.6) becomes

$$\langle l, M \rangle = \int_t^\tau l(s, X_s^u, u_s) ds, \quad \forall l \in C(S),$$

where X_s^u is the state process under the control u_s and τ is the stopping time of this X_s^u .

If $\tau < T$, the measure M corresponds to a stopped process X_s^u . In this case, a “canonical” extension M_c of M can be defined as

$$(3.3) \quad \langle l, M_c \rangle = \langle l, M \rangle + \int_\tau^T l(s, \xi, \bar{u}_s) ds,$$

where the control \bar{u}_s is chosen by the following lemma to keep the stopped process X_s^u at the place $\xi = X_\tau^u \in \partial\Omega$ until the terminal time T . That is, $X_s^{\bar{u}} = \xi$ for $\tau \leq s \leq T$.

LEMMA 3.1. *For each $(\tau, \xi) \in [t, T] \times \partial\Omega$, there is a control \bar{u}_s such that the corresponding state process $\bar{X}_s = X_s^{\bar{u}}$ satisfies*

$$\bar{X}_s = \xi, \quad \forall \tau \leq s \leq T.$$

Furthermore, this \bar{u}_s can be chosen to depend Borel-measurably on (τ, ξ) .

Proof. We consider the constant process $\bar{X}_s = X_s(\tau, \xi) \equiv \xi$, for $\tau \leq s \leq T$. By assumption (H3), this \bar{X}_s satisfies

$$\dot{X}_s(\tau, \xi) \equiv 0 \in f(s, X_s(\tau, \xi), U), \quad \forall \tau \leq s \leq T.$$

Now invoking the Filippov lemma (see the generalized version in McShane and Warfield [6]), a Borel-measurable function $\bar{u}_s = u_s(\tau, \xi) \in U$ can be chosen such that it also depends on (τ, ξ) Borel-measurably, and it holds

$$\dot{X}_s(\tau, \xi) \equiv 0 = f(s, X_s(\tau, \xi), u_s), \quad \forall \tau \leq s \leq T.$$

Therefore, we have $\bar{X}_s = X_s^{\bar{u}}$ and certainly $\bar{X}_s = \xi$ for $\tau \leq s \leq T$. \square

Motivated by our illustration before Lemma 3.1, let us prove the first result, which constructs a “canonical” extension for each weak measure.

PROPOSITION 3.2 (Canonical extension). *Every $\tilde{M} = (M, N) \in \mathcal{M}^w(t, x)$ has an extension $\bar{M}_c = (M_c, N_c) \in \mathcal{M}_c^w(t, x)$.*

Proof. For each $(\tau, \xi) \in [t, T] \times \partial\Omega$, we define $(M_{\tau, \xi}, N_{\tau, \xi}) \in \mathcal{M}_c^s(t, x)$ as follows:

$$\begin{aligned} \langle l, M_{\tau, \xi} \rangle &= \int_\tau^T l(s, \xi, \bar{u}_s) ds, \quad \forall l \in C([0, T] \times \partial\Omega \times U) \\ \langle L, N_{\tau, \xi} \rangle &= L(T, \xi), \quad \forall L \in C(\Sigma_T). \end{aligned}$$

By Lemma 3.1, the control \bar{u}_s is chosen to depend Borel-measurably on (τ, ξ) , then $M_{\tau, \xi}, N_{\tau, \xi}$ depends on (τ, ξ) Borel-measurably, too. We can therefore define the measures

$$(3.4) \quad \begin{aligned} M_\partial &= \int_{[t, T] \times \partial\Omega} M_{\tau, \xi} N(d\tau, d\xi) \\ N_\partial &= \int_{[t, T] \times \partial\Omega} N_{\tau, \xi} N(d\tau, d\xi) \end{aligned}$$

and take

$$M_c = M + M_\partial, \quad N_c = N|_{\Sigma_T} + N_\partial.$$

Note that each $M_{\tau,\xi}$ acts only on the boundary space $[t, T] \times \partial\Omega \times U$, then so does M_∂ .

Clearly, $M_c, N_c \geq 0$ and $M_c \in \mathcal{M}(S), N_c \in \mathcal{M}(\Sigma_T)$.

Let us compute that for any $\phi \in C^{1,1}$,

$$\begin{aligned} \langle A\phi, M_\partial \rangle &= \int_{[t,T] \times \partial\Omega} \langle A\phi, M_{\tau,\xi} \rangle N(d\tau, d\xi) \\ &= \int_{[t,T] \times \partial\Omega} \langle \phi, N_{\tau,\xi} \rangle N(d\tau, d\xi) - \langle \phi, N \rangle + \int_{\Sigma_T} \phi dN \\ &= \langle \phi, N_c \rangle - \langle \phi, N \rangle \end{aligned}$$

and then

$$\begin{aligned} \phi(t, x) &= -\langle A\phi, M \rangle + \langle \phi, N \rangle \\ &= -\langle A\phi, M_c \rangle + \langle A\phi, M_\partial \rangle + \langle \phi, N \rangle \\ &= -\langle A\phi, M_c \rangle + \langle \phi, N_c \rangle = -\langle \bar{A}\phi, \bar{M}_c \rangle \end{aligned}$$

Next by setting $\phi \equiv 1$ in the formula $\phi(t, x) = -\langle \bar{A}\phi, \bar{M}_c \rangle$, we get

$$1 = \langle 1, N_c \rangle \Rightarrow \|N_c\| = 1,$$

and by setting $\phi(t, x) = T - t$ in the same formula and noting that $\langle \phi, N_c \rangle = T - T = 0$, we have

$$T - t = \langle 1, M_c \rangle \Rightarrow \|M_c\| = T - t.$$

Hence $\bar{M}_c = (M_c, N_c) \in \mathcal{M}_c^w(t, x)$, and it is called in our terminology the “canonical” extension of $\bar{M} = (M, N)$. \square

Let “cl” denote the closure in the w^* -topology of $\mathcal{M}(\bar{S})$, consider also the space of relaxed measures in the state-constraint problem

$$\mathcal{M}_c^g(t, x) = cl\mathcal{M}_c^s(t, x),$$

and denote $\mathcal{M}_0^g(t, x) = \{M_c : (M_c, N_c) \in \mathcal{M}_c^g(t, x)\}$. Clearly, this is a w^* -closed set in $\mathcal{M}(\bar{S})$. We observe that for each $\mu \in \mathcal{M}_0^g(t, x)$, there exists a relaxed control ν_s such that $\mu = M^\nu$ has the disintegration

$$\mu(dr, dx, du) = \lambda(dr) \times \delta_{X_r^\nu}(dx) \times \nu_r(du).$$

The notion of relaxed control was introduced in Fleming [1], it is a Borel-measurable, $\mathcal{P}(U)$ -valued process. Here $\mathcal{P}(U)$ = the space of all probability measures on U . Correspondingly the state process X_s^ν is required to satisfy, instead of (2.1), that

$$(3.5) \quad \dot{X}_s = \int_U f(s, X_s, u) \nu_s(du).$$

In the following arguments, we will associate each μ to a state process X_s^μ , which is the solution of the above relaxed system under the relaxed control ν_s . In terms of $\mu \in \mathcal{M}_0^g(t, x)$, we can rewrite (3.5) as follows:

$$X_s^\mu = x + \int_t^s \int_U \int_{\bar{\Omega}} f(r, x, u) \mu(dr, dx, du), \quad \text{for } t \leq s \leq T.$$

Then it is clear that X_s^μ depends continuously on μ with respect to the w^* -topology of $\mathcal{M}_0^g(t, x)$.

We now prove the second result, which extracts a minimal, stopped part from each weak measure.

PROPOSITION 3.3 (Canonical extraction). *For each $\tilde{M} = (M, N) \in \mathcal{M}^w(t, x)$, there exists a measure $\tilde{M}^0 = (M^0, N^0) \in \mathcal{M}^w(t, x)$ such that $M^0([t, T] \times \partial\Omega \times U) = 0$ and $M^0 \leq M$.*

Remark. This M^0 is called the “stopped” part of M . It is generated by the processes stopped at the boundary of the domain.

Proof. We have shown in Proposition 3.2 that $\tilde{M} = (M, N) \in \mathcal{M}^w(t, x)$ has a “canonical” extension $\tilde{M}_c = (M_c, N_c) \in \mathcal{M}_c^w(t, x)$. By the formula below (3.8) in Fleming [2], this M_c has an integral representation:

$$M_c = \int_{\mathcal{M}_0^g(t, x)} \mu \alpha(d\mu)$$

for some probability measure α on $\mathcal{M}_0^g(t, x)$.

For each $\mu = M^\nu \in \mathcal{M}_0^g(t, x)$, we define the measure μ^0 by

$$\langle l, \mu^0 \rangle = \int_t^\tau \int_U l(s, X_s^\mu, u) \nu_s(du) ds, \quad \forall l \in C(S),$$

where τ is the stopping time of X_s^μ . In short, $d\mu^0 = I_{[t, \tau)} d\mu$.

Since X^μ depends continuously in μ , the stopping time $\tau^\mu = \inf\{s \geq t : X_s^\mu \notin \Omega\}$ is then lower semicontinuous with respect to μ in the w^* -topology. Let $\mu_n = M^{\nu_n} \in \mathcal{M}_0^g(t, x)$ such that $\mu_n \xrightarrow{w^*} \mu$, and $\mu^0(\mu_n)$ satisfies

$$\begin{aligned} \langle l, \mu^0(\mu_n) \rangle &= \int_t^{\tau^n} \int_U l(s, X_s^n, u) \nu_s^n(du) ds \\ (3.6) \quad &= \int_t^{\tau^n} \int_U \int_\Omega l(s, x, u) \mu^n(ds, dx, du), \quad \forall l \in C(S), \end{aligned}$$

where X_s^n is the state process associated to μ^n and τ^n is the stopping time of X_s^n . By the fact $\tau \leq \liminf_{n \rightarrow \infty} \tau^n$, we pass the limit in (3.6) to get

$$\langle l, \mu^0(\mu) \rangle \leq \liminf_{n \rightarrow \infty} \langle l, \mu^0(\mu_n) \rangle, \quad \text{for } l \geq 0.$$

However, any $l \in C(S)$ can be written as $l = l^+ - l^-$, then $\langle l, \mu^0(\cdot) \rangle = \langle l^+, \mu^0(\cdot) \rangle - \langle l^-, \mu^0(\cdot) \rangle$ is the difference of two lower semicontinuous functions and therefore Borel-measurable as a function of μ , for any $l \in C(S)$. Equivalently, $\mu^0(\cdot)$ is Borel-measurable in μ with respect to the w^* -topology of $\mathcal{M}_0^g(t, x)$.

We are then allowed to define

$$(3.7) \quad M^0 = \int_{\mathcal{M}_0^g(t, x)} \mu^0 \alpha(d\mu).$$

Because each μ^0 has the properties that $\mu^0 \leq \mu$ and $\mu^0([t, T] \times \partial\Omega \times U) = 0$, hence $M^0 \leq M_c$ and $M^0([t, T] \times \partial\Omega \times U) = 0$, too. That is, M^0 vanishes on the boundary space $[t, T] \times \partial\Omega \times U$.

Next, we compute that for any $\phi \in C^{1,1}$,

$$\begin{aligned}
 \langle A\phi, M^0 \rangle &= \int_{\mathcal{M}_0^g(t,x)} [\phi(\tau, X_\tau^\mu) - \phi(t, x)] \alpha(d\mu) \\
 (3.8) \quad &= \int_{\mathcal{M}_0^g(t,x)} \phi(\tau, X_\tau^\mu) \alpha(d\mu) - \phi(t, x) = \langle \phi, N^0 \rangle - \phi(t, x),
 \end{aligned}$$

where the boundary measure N^0 is defined by

$$(3.9) \quad \langle L, N^0 \rangle = \int_{\mathcal{M}_0^g(t,x)} L(\tau, X_\tau^\mu) \alpha(d\mu), \quad \forall L \in C(\Sigma_\partial).$$

This is well defined since both τ and X_τ^μ depend on $\mu \in \mathcal{M}_0^g(t, x)$ Borel-measurably.

Clearly, $M^0, N^0 \geq 0$, and $\|M^0\| \leq T - t, \|N^0\| \leq 1$. Together with (3.8), it implies that $\tilde{M}^0 = (M^0, N^0) \in \mathcal{M}^w(t, x)$ by its definition.

Finally, to show that $M^0 \leq M$, we note that $M^0 \leq M_c$ and $M|_{[t,T) \times \Omega \times U} = M_c|_{[t,T) \times \Omega \times U}$, since $M_c = M + M_\partial$, and M_∂ acts only on the boundary space Σ_∂ . Then, we have

$$\begin{aligned}
 \langle l, M^0 \rangle &= \int_{[t,T) \times \Omega \times U} l dM^0 \leq \int_{[t,T) \times \Omega \times U} l dM_c \\
 &= \int_{[t,T) \times \Omega \times U} l dM \leq \langle l, M \rangle
 \end{aligned}$$

for any $l \geq 0$ in $C(S)$. \square

The next result is entitled the Equivalence Principle in the convex duality approach for the optimal control problems. Owing to the results established above, we are able to give a simple proof here without directly employing the convolution argument in Fleming and Vermes [2], [3], [4].

THEOREM 3.4. *Assume that $l_0 \geq 0, L_0 \equiv 0$, then $\psi^w(t, x) = \psi^s(t, x)$. That is, the strong formulation (2.7) is equivalent to the weak formulation (2.10) in our stopped processes problem. Moreover, the minimum ψ is attained by a “stopped” measure.*

As a consequence of this equivalence theorem and Theorem A.3 in the Appendix, we conclude that

$$\psi(t, x) = \sup\{\phi(t, x) : \phi \text{ is a smooth subsolution}\}.$$

Proof. First, $\psi^w(t, x) \leq \psi^s(t, x)$ holds trivially since $\mathcal{M}^w(t, x) \supset \mathcal{M}^s(t, x)$.

To prove the opposite inequality, let us take any $\tilde{M} = (M, N) \in \mathcal{M}^w(t, x)$. By Proposition 3.3, there is a $\tilde{M}^0 = (M^0, N^0) \in \mathcal{M}^w(t, x)$ such that M^0 is a minimal, stopped part of M in terms of the boundary $\partial\Omega$.

Since $l_0 \geq 0$ and $L_0 \equiv 0$, it follows from the integral representation (3.7) that

$$\begin{aligned}
 \langle \tilde{l}_0, \tilde{M} \rangle &= \langle l_0, M \rangle \geq \langle l_0, M^0 \rangle \\
 &= \int_{\mathcal{M}_0^g(t,x)} \langle l_0, \mu^0 \rangle \alpha(d\mu) \\
 &\geq \int_{\mathcal{M}_0^g(t,x)} \psi^s \alpha(d\mu) = \psi^s(t, x).
 \end{aligned}$$

Therefore, we have $\psi^w(t, x) \geq \psi^s(t, x)$. \square

The proof also implies that the minimum ψ must be attained by some “stopped” measure. Otherwise, by employing the argument in Proposition 3.3, the “stopped” part can always be extracted so that it will yield a smaller cost. \square

Remark. (1) It is indicated in [2] that $\mathcal{M}_c^w(t, x)$ = the w^* -convex closure of $\mathcal{M}_c^s(t, x)$. We conjecture that in our stopped processes problem

$$(3.10) \quad \mathcal{M}^w(t, x) = \text{the } w^* - \text{convex closure of } \mathcal{M}^s(t, x)$$

holds true, although we have not obtained a rigorous proof for this assertion.

(2) The weak space $\mathcal{M}^w(t, x)$ in our stopped processes problem has measures generated by the stopped processes as well as measures generated by the continuing processes. Compared to the weak space $\mathcal{M}_c^w(t, x)$ in the state-constraint problem, this is a larger space and therefore yields a smaller minimum (i.e., the value function), which is expected in our problem since we have a nonnegative penalty cost.

Appendix. Convex duality and smooth subsolutions of the Bellman equation. The results in this section, which exhibits the approach from a viewpoint of convex analysis, are very similar to §5 of Vermes [8] and §4 of Fleming and Vermes [4]. Most arguments are the duplicates of those in [4], [8], therefore we will only state the results and indicate the differences in our proofs.

Let us bring the weak problem (2.10) into the Fenchel normal form.

Define the function

$$\tilde{h}(\tilde{M}) = \begin{cases} \langle \tilde{l}_0, \tilde{M} \rangle, & \tilde{M} \in \mathcal{M}^w(t, x) \\ +\infty, & \tilde{M} \in \mathcal{M}(\tilde{S}) \setminus \mathcal{M}^w(t, x) \end{cases}$$

for $\tilde{l}_0 = (l_0, L_0) \in C(\tilde{S})$. Clearly, this extended real-valued function \tilde{h} is convex and lower semicontinuous, and its dual \tilde{h}^* is defined by the Legendre–Fenchel transformation

$$\tilde{h}^*(\tilde{l}) = \sup_{\tilde{M} \in \mathcal{M}(\tilde{S})} \{ \langle \tilde{l}, \tilde{M} \rangle - \tilde{h}(\tilde{M}) \}, \quad \forall \tilde{l} \in C(\tilde{S}).$$

Rather than attempting to find \tilde{h}^* , we write $\tilde{h} = \tilde{h}_1 - \tilde{h}_2$ in such a way that the duals $\tilde{h}_1^*, \tilde{h}_2^*$ can be found explicitly.

Introduce the following pair of spaces:

$$\mathcal{M}_1(t, x) = \{ \tilde{M} = (M, N) \in \mathcal{M}(\tilde{S}) : 1) \text{ holds in (2.9)} \}$$

$$\mathcal{M}_2(t, x) = \{ \tilde{M} = (M, N) \in \mathcal{M}(\tilde{S}) : 2) \text{ holds in (2.9)} \}$$

and define

$$\tilde{h}_1(\tilde{M}) = \begin{cases} \langle \tilde{l}_0, \tilde{M} \rangle, & \tilde{M} \in \mathcal{M}_1(t, x) \\ +\infty, & \tilde{M} \in \mathcal{M}(\tilde{S}) \setminus \mathcal{M}_1(t, x), \end{cases}$$

$$\tilde{h}_2(\tilde{M}) = \begin{cases} 0, & \tilde{M} \in \mathcal{M}_2(t, x) \\ -\infty, & \tilde{M} \in \mathcal{M}(\tilde{S}) \setminus \mathcal{M}_2(t, x). \end{cases}$$

Both \tilde{h}_1 and $-\tilde{h}_2$ are clearly convex and lower semicontinuous, since $\mathcal{M}_1(t, x)$ and $\mathcal{M}_2(t, x)$ are both convex and closed. Then, it is immediate that the weak problem is equivalent to the Fenchel problem:

Minimize $\tilde{h}_1(\tilde{M}) - \tilde{h}_2(\tilde{M})$ over $\tilde{M} \in \mathcal{M}(\tilde{S})$. In other words,

$$\min_{\mathcal{M}^w(t, x)} \{ \langle \tilde{l}_0, \tilde{M} \rangle \} = \min_{\mathcal{M}(\tilde{S})} \{ \tilde{h}_1(\tilde{M}) - \tilde{h}_2(\tilde{M}) \}.$$

The Legendre–Fenchel transforms of \tilde{h}_1, \tilde{h}_2 are computed in the following lemma.
LEMMA A.1.

$$\begin{aligned} (1) \quad \tilde{h}_1^*(\tilde{l}) &= (T-t)\|(l-l_0)^+\| + \|(L-L_0)^+\|, \quad \forall \tilde{l} = (l, L) \in C(\tilde{S}) \\ (2) \quad \tilde{h}_2^*(\tilde{l}) &= \begin{cases} -\lim \phi_n(t, x), & \text{if } \tilde{l} = \lim_{n \nearrow \infty} \tilde{A}\phi_n \text{ with } \phi_n \in C^{1,1}(\Sigma) \\ -\infty, & \text{otherwise} \end{cases} \end{aligned}$$

The proof of this lemma will follow exactly the same line as that in Fleming and Vermes [4], [8].

We recall the Bellman equation (2.4):

$$\inf_{u \in U} \{ \partial_t \psi + f \cdot \nabla_x \psi + l_0 \} = 0$$

with the terminal and boundary conditions $\psi(t, x) = L_0(t, x)$ on Σ_∂ .

DEFINITION A.2. The function ϕ is called a smooth subsolution to the Bellman's equation (2.4) if $\phi \in C^{1,1}(\Sigma)$ satisfies

$$A^u \phi + l_0 \geq 0, \quad \text{in } [0, T) \times \Omega \times U$$

and $\phi(t, x) \leq L_0(t, x)$ on Σ_∂ .

The next theorem is the main result of this convex duality approach. Roughly it states that seeking maximal solution of the Bellman equation is the dual to the weak problem formulated in the §2. Under the current weak assumptions, no classical solutions to the Bellman equation need to exist.

THEOREM A.3. For any $\tilde{l}_0 = (l_0, L_0)$ in $C(\tilde{S})$, we have

$$\begin{aligned} \psi^w(t, x) &\stackrel{\text{def}}{=} \min \{ \langle \tilde{l}_0, \tilde{M} \rangle : \tilde{M} \in \mathcal{M}^w(t, x) \} \\ &= \sup \{ \phi(t, x) : \phi \text{ is a smooth subsolution} \}. \end{aligned}$$

That is, the value function (i.e., the minimum) of the weak problem is the upper envelope (i.e., supremum) of the smooth subsolutions to the Bellman equation.

Proof. As in Fleming and Vermes [4], [8], substitute \tilde{h}_1^* and \tilde{h}_2^* of Lemma A.1 in the Rockafellar duality formula and use the fact that $\{\tilde{A}\phi : \phi \in C^{1,1}\}$ is dense in set $\{\tilde{l} : \tilde{h}_2^*(\tilde{l}) > -\infty\}$. We obtain

$$\begin{aligned} \psi^w(t, x) &= \min \{ \tilde{h}_1(\tilde{M}) - \tilde{h}_2(\tilde{M}) : \tilde{M} \in \mathcal{M}(\tilde{S}) \} \\ &= \sup \{ \tilde{h}_2^*(\tilde{l}) - \tilde{h}_1^*(\tilde{l}) : \tilde{l} \in C(\tilde{S}) \} \\ &= \sup \{ \phi(t, x) - (T-t)\|(A\phi + l_0)^-\| - \|(\phi - L_0)^+\| : \phi \in C^{1,1} \}. \end{aligned}$$

Let $\Phi(t, x) = \phi(t, x) - (T-t)\|(A\phi + l_0)^-\| - \|(\phi - L_0)^+\|$. Clearly $\Phi \in C^{1,1}(\Sigma)$ and it satisfies

$$\begin{aligned} A\Phi + l_0 &= (A\phi + l_0) + \|(A\phi + l_0)^-\| \geq 0, \quad \text{in } [0, T) \times \Omega \times U, \\ \Phi(t, x) &\leq \phi - \|(\phi - L_0)^+\| \leq L_0(t, x), \quad \text{on } \Sigma_\partial. \end{aligned}$$

By Definition A.2, Φ is indeed a smooth subsolution to the Bellman equation (2.4) and we conclude the result of theorem. \square

Acknowledgment. The author would like to give his sincere thanks to Professor Wendell H. Fleming for suggesting the problem, his good advice, and his careful

reading of this manuscript, which brought a substantial change of the early version. The author also would like to thank the referees for many very helpful comments.

MESH INDEPENDENCE OF THE GRADIENT PROJECTION METHOD FOR OPTIMAL CONTROL PROBLEMS*

C. T. KELLEY[†] AND E. W. SACHS[‡]

Abstract. The gradient projection method and its application to optimal control have been analyzed with regard to the rate of convergence quite extensively. Here another aspect of this method is considered. In finite dimension the set of active indices is identified after finitely many iterations under mild nondegeneracy assumptions. However, it is clear that this property is restricted to the finite-dimensional case. In this paper, for example, a sequence of discretized optimal control problems is considered, and it is observed that the number of steps to identify all active indices increases with the refinement of the discretization. A result analogous to the finite-dimensional result is valid in this situation if identification of active indices is understood in the correct light. This paper shows that if a different termination criterion is imposed, then the number of necessary steps for termination is indeed mesh-independent. Numerical observations illustrating this result are reported for various examples from optimal control.

1. Introduction. Consider the constrained optimization problem,

$$(1.1) \quad \min F(u) \text{ such that } u \in U,$$

where H is a Hilbert space, $U \subset H$ is a bounded, closed, and convex set, and $F : H \rightarrow \mathbb{R}$ is the objective function. A popular method for solving (1.1) numerically is the gradient projection method. This algorithm requires an inexpensive way to compute the projection onto U , $P : H \rightarrow U$, where

$$(1.2) \quad P(h) \text{ solves } \min_{u \in U} \|u - h\|.$$

The sequence of iterates is defined by

$$(1.3) \quad u_{k+1} = P(u_k - \alpha_k \nabla F(u_k)),$$

where $\alpha_k > 0$ is a stepsize parameter that is determined by some stepsize rule. We will consider the Armijo stepsize rule, shown below.

For fixed $\tilde{\alpha} > 0, \beta, \delta \in (0, 1)$ set $\alpha_k = \tilde{\alpha}$ if

$$F(u_k) - F(P(u_k - \tilde{\alpha} \nabla F(u_k))) \geq \delta \langle \nabla F(u_k), u_k - P(u_k - \tilde{\alpha} \nabla F(u_k)) \rangle.$$

Otherwise, choose α_k such that $\alpha_k = \beta^{m_k} \tilde{\alpha}$, where m_k is the smallest integer $m \in \mathbb{N}$ with

$$(1.4) \quad F(u_k) - F(P(u_k - \beta^m \tilde{\alpha} \nabla F(u_k))) \geq \delta \langle \nabla F(u_k), u_k - P(u_k - \beta^m \tilde{\alpha} \nabla F(u_k)) \rangle.$$

In Hilbert space this algorithm has been considered in [7], [10], and [14] with application to control problems. In recent years the gradient projection method has again become the focus of various researchers for problems with simple constraints, called bound constraints or box constraints. In the finite-dimensional case, $H = \mathbb{R}^D$; this means that

$$(1.5) \quad U = \{u \in \mathbb{R}^D : a_i^- \leq u_i \leq a_i^+, i = 1, \dots, D\},$$

with fixed vectors $a^-, a^+ \in \mathbb{R}^D$ such that $a_i^- < a_i^+, i = 1, \dots, D$. This type of structure occurs, in particular, for the discrete formulations of optimal control problems with constraints on the magnitude of controls: Let $x(t) \in \mathbb{R}$ and $u(t) \in \mathbb{R}$ denote the state and control, respectively. The state $x(t)$ depends on the control through the differential equation

$$(1.6) \quad \dot{x}(t) = f(t, x(t), u(t)), \quad x(0) = x_0 \in \mathbb{R},$$

where $f \in C^1(\mathbb{R}^3)$. The feasible set of controls U is defined as

$$U = \{u \in L_\infty[0, T] : a^-(t) \leq u(t) \leq a^+(t) \text{ a.e. on } [0, T]\},$$

where $a^-, a^+ \in L_\infty[0, T]$ are fixed functions such that $a^-(t) < a^+(t)$ almost everywhere $[0, T]$.

The function that is to be minimized is given by

$$(1.7) \quad \int_0^T L(t, x(t), u(t)) dt,$$

with $L \in C^1(\mathbb{R}^3)$.

In discretized form, the optimal control problem can be written as

$$(1.8) \quad \min \sum_{i=1}^D L_i(x_i, u_i),$$

where x depends on u through a discretization of (1.6) such as

$$(1.9) \quad x_{i+1} = x_i + f_i(x_i, u_i), \quad i = 0, 1, \dots, D$$

and

$$(1.10) \quad L_i, f_i \in C^1(\mathbb{R}^2), \quad i = 0, 1, \dots, D$$

are functions arising from the discretization process. Our analysis does not require one-step schemes such as (1.9), and the discretization of the differential equation could also be realized through a finite element approach.

The results in this paper will require that the solutions to the discrete problems be in the same space as those of the continuous problem. This can be done for the discrete optimal control problems discussed above by regarding the control, state, and adjoint vectors as step functions. Full details of this correspondence are given in §4.

An index of a constraint is considered active when the inequality is an equality. Bertsekas [2] pointed out that an advantage of the gradient projection method is that it allows us to add or to drop several active indices in one iteration. This is especially important for problems with many active constraints at the solution. Furthermore,

Bertsekas showed that under certain nondegeneracy and second-order sufficiency assumptions, the set of active indices is identified after finitely many iterations.

Nondegeneracy assumption. Let the gradients of the constraints corresponding to the active indices at a point u_* , satisfying the necessary optimality conditions, be linearly independent and let the Lagrange multipliers corresponding to active indices be positive.

THEOREM 1.1 (Bertsekas [2]). *If u_k is a sequence produced by the gradient projection method with the Armijo step-size rule that converges to a solution u_* , where the nondegeneracy assumption holds, then there exists an index k_0 such that the set of active indices of u_k remains unchanged for k larger than k_0 .*

In a series of papers, the convergence analysis for the gradient projection method has been investigated. Dunn [7] related the convergence rate to a condition on the growth of the objective function or its first-order approximation as we move away from the optimal point. For some $a > 0$ and $\nu \geq 1$, let

$$(1.11) \quad \gamma(\sigma) \geq a\sigma^\nu \quad \text{for } \sigma > 0$$

hold where

$$(1.12) \quad \gamma(\sigma) := \inf_{u \in U, \|u - u_*\| \geq \sigma} F(u) - F(u_*), \quad \sigma > 0.$$

Note that the growth of γ could come from F or the feasible set U . A special case of Theorem 4.3 in [7] is the following result.

THEOREM 1.2. *Let U be a closed convex bounded subset of H and let F be convex and bounded with a continuous Fréchet derivative. If with γ in (1.12) $\gamma(\sigma) > 0$ for $\sigma > 0$, then for $r_k = F(u_k) - F(u_*)$ we have $r_k = o(1/k)$. In particular,*

$$r_k \leq r_0 \left(1 + \frac{4r_0\delta\alpha}{D^2}k \right)^{-1}$$

for $k \in \mathbb{N}$ with $\alpha_k \geq \alpha > 0$ and $D = \max\{\|u - v\| : u, v \in U\}$. If for some $a > 0$ (1.11) holds, then for $\nu = 2$ there exists $\hat{\alpha} \in (0, 1)$ with

$$\frac{r_{k+1}}{r_k} \leq \hat{\alpha} \text{ for } k \in \mathbb{N}$$

and, for $\nu > 2$,

$$r_k = O\left(\frac{1}{k^{\nu(\nu-2)}}\right).$$

The boundedness away from 0 for the stepsizes is a common requirement in this context, and we refer to Lemma 3.4. Papers [2], [3], [8], and [9] considered Newton-type variations of the gradient projection method to improve the convergence behavior. In [4] the notion of the projected gradient was used to improve and extend the result on finite identification of active constraints. In all papers, the choice of the stepsize rule plays a quite important role. References [5], [15], and [16] deal with a trust-region approach for the gradient projection method as a globalization strategy. Also in these publications, the finite identification of active constraints is a major issue in the proofs.

In the numerical results of [2] it is mentioned that for discretized optimal control problems the number of iterates required to identify the set of active constraints

TABLE 1.1
Finite identification of active indices

D_N	k_{act} for Ex. 1	k_{act} for Ex. 2	k_{act} for Ex. 3
4	163	56	6
8	779	53	7
16	5032	76	14
32	36472	127	24
64	277582	231	56

increases as the discretization is refined. This can lead to a prohibitively large number of iterates until the minimum is achieved. We illustrate this for some examples, which we use later in the section on numerical results (§4). We choose

$$L(t, x, u) = \frac{1}{2}x^2, \quad f(t, x, u) = bu, \quad x_0 = 1, \quad T = 1, \quad a^+(\cdot) = -a^-(\cdot) = 0.5$$

and three choices for b :

Example 1.1. $b(t) = (t - 0.5)^3$;

Example 1.2. $b(t) = (t - 0.5)^3 + 0.03$;

Example 1.3. $b(t) = \cos(3t)$.

We discretize this optimal control problem with (1.8) and (1.9):

$$D = D_N, \quad L_i(x, u) = \frac{1}{2D_N}x^2, \quad f_i(x, u) = b(i/D_N)u.$$

The set of active indices is defined as

$$I(u) = \{i : u_i = a_i^- \text{ or } u_i = a_i^+\}.$$

It can be shown that all the active indices are identified after finitely many steps. However, as we can see from Table 1.1, this statement can become irrelevant in the sense that the number of active indices and the number of steps required for their identification increases without bound as the discretization is refined. The number of steps needed to identify $D_N - 1$ active indices

$$k_{\text{act}} = \min\{k \in \mathbb{N} : |I(u_k)| = D_N - 1\}$$

is shown in Table 1.1.

The first example does not satisfy the quadratic growth condition, (1.11) with $\nu = 2$, but the second, which is a slightly perturbed example does satisfy the quadratic growth condition, albeit with a small σ . Table 1.1 clearly shows that the influence of an infinite-dimensional ill posed problem affects the algorithmic behavior of the finite-dimensional discretized problem. As a well-posed example, we use Example 1.3, where (1.11) is satisfied.

All three examples in Table 1.1 show that the number of steps required to identify the active indices is dependent on the dimension of the problem. It is evident (see, e.g., [16]) that for optimization problems with infinitely many constraints the active set will not be identified in finitely many steps. For discretizations of such problems, more iterations are necessary to identify the active set as the discretization is refined. This is an unsatisfactory situation because the computational effort does not only become larger because of the increasing dimension but also because of the higher number of iterations required for active constraint identification. Moreover, in the context of control, much of this work resolves the solution of the discrete problem to an accuracy beyond that of the discretization of the differential equation, and is

wasted. In this paper we will give measures of constraint identification that limit the number of iterations in a way that is independent of the dimension.

We seek mesh-independence results of several kinds for the identification of the active set of indices. One of the concepts of mesh independence that we use here was first defined in [1] and [12] in the context of nonlinear equations. In those papers, iteration schemes for solution of $F(u) = 0$ in a Hilbert space H were compared with those for an approximate equation $F_N(u) = 0$ on a space H_N . The number of iterates required to drive the norm of F or F_N to a given size were compared. Define $F_\infty = F$, $H_\infty = H$, and

$$l_N(\varepsilon) = \min\{k : \|F_N(u_k^N)\|_{H_N} < \varepsilon\}, \quad l_\infty(\varepsilon) = \min\{k : \|F(u_k)\|_H < \varepsilon\},$$

where u_k^N and u_k are the k th iterate for the iteration scheme on H_N and H , respectively. The results in [1] and [12] required only mild assumptions on the methods and the types of approximate problems and stated that for every $\varepsilon > \delta > 0$ sufficiently small there was $N_{\varepsilon,\delta}$ such that if $N > N_{\varepsilon,\delta}$, then

$$l_\infty(\varepsilon + \delta) \leq l_N(\varepsilon) \leq l_\infty(\varepsilon).$$

Our goal in this paper is to formulate and prove results of this type in the context of approximations to (1.1) in the specific case of optimal control with constraints on the magnitude of controls.

Section 2 contains the definition of the set J_ε , which is a subset of the set of active indices. This set is identified after finitely many steps, even for a problem in function space. For example, if the gradient satisfies a condition that plays an important role in the convergence rate analysis, then the set J_ε converges also at a certain rate to the set of active indices. Section 3 is devoted to approximate problems and the statements and proofs of the mesh-independence results. Under certain conditions on the convergence of the gradients, we can prove that the number of steps necessary to identify the set J_ε is independent of the meshsize, as is the number of iterates needed to drive the norm of the projected gradient to below ε . These statements illustrate the type of mesh independence that we seek.

An important assumption is that the stepsizes are uniformly bounded away from zero. We verify this assumption for an Armijo-type stepsize rule. In §4 we consider two examples from optimal control. For a problem with ordinary differential equations, we give numerical results that justify the claim that the number of iterations needed to identify all active constraints can be excessively high. The results indicate that the number of iterations remains almost constant under a mesh refinement if other termination criteria are used. The second example from the optimal control of the heat equation through boundary input gives similar results. It is noted that these observations are important in particular when the optimization problems are illposed.

2. Identification of active indices. In this section we consider statements about the finite identification of active indices for the infinite-dimensional problem (1.2) in function space. For simplicity, we choose in the definition of the feasible set U the functions a^- , a^+ to be 1 and -1:

$$(2.1) \quad U = \{u \in L_\infty[0, T] : |u(t)| \leq 1 \text{ a.e. on } [0, T]\}.$$

Since the projection in a Hilbert space is essential in the framework of the algorithm, the analysis for the convergence is usually carried with respect to the L_2 norm. The Fréchet differentiability in this norm has to be checked for the specific examples

because it is a much stronger requirement than differentiability with respect to the L_∞ norm. We denote the gradient $\nabla F(u_k)$ by s_k . In the context of the optimal control problems (1.6), (1.7) the gradient can be computed, if it exists, by

$$s_k(t) = L_u(t, x_k(t), u_k(t)) + p_k(t)f_u(t, x_k(t), u_k(t)),$$

where p_k solves

$$-\dot{p}_k = L_x(x_k, u_k) + p_k f_x(x_k, u_k), \quad p_k(T) = 0.$$

To formulate a result on finite identification of active indices in function space, we reconsider the bang-bang principle. Since at the optimal control u_*

$$\int_0^T s_*(t)(u(t) - u_*(t)) dt \geq 0 \quad \text{for all } u \in U,$$

where s_* is defined analogously to s_k , we deduce that

$$u_*(t) = -\operatorname{sgn} s_*(t) \quad \text{for a.a. } t \in [0, T], \quad \text{where } |s_*(t)| > 0.$$

Obviously, in a numerical scheme, the positivity of $s_*(t)$ will be considered satisfied if for an appropriate small value $\varepsilon > 0$, the inequality

$$(2.2) \quad |s_*(t)| \geq \varepsilon$$

holds. We will show in the following lemma that for all t where (2.2) is true, the values of u_* are identified after a fixed iteration index. This allows us to prove a result on finite identification of indices t , which satisfy (2.2), and to refine this statement later to mesh-independence results for the discretized problems.

LEMMA 2.1. *Let $s_k, s_*, u_k, u_* \in L_\infty[0, T]$, and $\alpha_k \in \mathbb{R}$ be given with some $\alpha > 0$ such that*

$$(2.3) \quad \alpha_k \geq \alpha > 0 \quad \text{for all } k \in \mathbb{N}$$

and

$$(2.4) \quad u_{k+1}(t) = \operatorname{sat}(u_k(t) - \alpha_k s_k(t)) \quad \text{a.e. on } [0, T].$$

In (2.4) the function sat is defined in the usual way as

$$(2.5) \quad \operatorname{sat}(u) = \begin{cases} 1 & \text{if } u > 1, \\ u & \text{if } u \in [-1, 1], \\ -1 & \text{if } u < -1. \end{cases}$$

Suppose that

$$\lim_{k \rightarrow \infty} \|s_k - s_*\|_{L_\infty[0, T]} = 0,$$

and, for all $\varepsilon > 0$,

$$(2.6) \quad |u_*(t)| = 1 \quad \text{a.e. on } J_\varepsilon = \{t \in [0, T] : |s_*(t)| \geq \varepsilon\}.$$

Then, for all $\varepsilon > 0$, there exists $k_\varepsilon \in \mathbb{N}$ with

$$(2.7) \quad u_k(t) = u_*(t) \quad \text{for all } k \geq k_\varepsilon, \quad t \in J_\varepsilon.$$

Proof. Choose $k_1(\varepsilon) \in \mathbb{N}$ such that, for all $k \geq k_1(\varepsilon)$,

$$\|s_k - s_*\|_{L_\infty[0,T]} \leq \frac{\varepsilon}{2}.$$

We introduce the sets

$$(2.8) \quad J_\varepsilon^+ = \{t \in J_\varepsilon : s_*(t) \geq \varepsilon\} \quad \text{and} \quad J_\varepsilon^- = \{t \in J_\varepsilon : s_*(t) \leq -\varepsilon\}.$$

Then

$$(2.9) \quad s_k(t) \geq \frac{\varepsilon}{2} \quad \text{for all } k \geq k_1(\varepsilon) \text{ and a.e. on } J_\varepsilon^+.$$

Hence for $l(\varepsilon) \in \mathbb{N}$ with $l(\varepsilon) \geq 4/(\alpha\varepsilon)$ we have with (2.3)

$$(2.10) \quad \sum_{k=k_1(\varepsilon)}^{l(\varepsilon)+k_1(\varepsilon)} \alpha_k s_k(t) \geq l(\varepsilon) \alpha \frac{\varepsilon}{2} \geq 2 \quad \text{a.e. on } J_\varepsilon^+,$$

and hence, according to iteration rule (2.4) of the gradient projection method,

$$(2.11) \quad u_k(t) = -1 \quad \text{for } k \geq l(\varepsilon) + k_1(\varepsilon) + 1 \text{ a.e. on } J_\varepsilon^+$$

Similarly, we obtain

$$(2.12) \quad u_k(t) = +1 \quad \text{for } k \geq l(\varepsilon) + k_1(\varepsilon) + 1 \text{ a.e. on } J_\varepsilon^-;$$

i.e., (2.7) holds with $k_\varepsilon = k_1(\varepsilon) + l(\varepsilon) + 1$. \square

It is evident that the size of the interval J_ε where finite identification occurs depends on the shape of the graph of s_* . If s_* has only finitely many zeros in $[0, T]$, then the length $m(J_\varepsilon)$ of J_ε converges to T , $\lim_{\varepsilon \rightarrow 0} m(J_\varepsilon) = T$, but this convergence can be arbitrarily slow. The following lemma gives conditions that relate the rate at which $m(J_\varepsilon)$ increases to properties of s^* . We define the set of zeros of s_* by $\mathcal{Z} = \{t \mid s_*(t) = 0\}$ and the complement by

$$(2.13) \quad \mathcal{A} = \{t \mid s_*(t) \neq 0\}.$$

We use the following condition

$$(2.14) \quad \begin{aligned} &\mathcal{Z} \text{ is a finite union of intervals } [c_i, d_i], i = 1, \dots, N_Z, \\ &\text{and there is } \hat{\sigma} > 0 \text{ and } \mu \geq 1 \text{ such that} \end{aligned}$$

$$|s_*(t)| \geq \hat{\sigma} \text{dist}(t, \mathcal{Z})^\mu.$$

LEMMA 2.2. *If (2.14) holds, then*

$$(2.15) \quad m(\mathcal{A} - J_\varepsilon) \leq c \varepsilon^{1/\mu}$$

holds for all $\varepsilon > 0$ sufficiently small and some fixed $c > 0$.

Proof. If $t \in \mathcal{A} - J_\varepsilon$, then

$$\varepsilon > |s_*(t)| > \hat{\sigma} \text{dist}(t, \mathcal{Z})^\mu.$$

Hence, if

$$\overline{\mathcal{Z}} = \bigcup_{1 \leq i \leq N_Z} [c_i, d_i],$$

then, if $\delta = (\varepsilon/\hat{\sigma})^{1/\mu}$,

$$t \in \bigcup_{1 \leq i \leq N_Z} ((c_i - \delta, c_i] \cup [d_i, d_i + \delta)).$$

This completes the proof with $c = 2N_Z\hat{\sigma}^{-1/\mu}$. \square

3. Approximate problems and mesh independence. In this section we approximate the problem of minimizing F on a subset U of H by the minimization of some $F_N : H_N \rightarrow \mathbb{R}$ on a set $U_N \subset H_N$. The issue in this section is how measures of progress toward identification of the set of active constraints \mathcal{A} vary with the level of approximation. Such questions come under the category of mesh-independence results.

We consider three notions of mesh independence. The first is the assertion in Theorem 3.1. This says that the iterate k after which the active interval has been identified up to ε is independent of N . This can be seen in the numerical results in Table 4.2.

We show that the set J_ε of indices is identified after a number of steps that is independent of the discretization level N in the following sense. In this theorem it is assumed that s_k^N converges uniformly in L_∞ to s_* , which is checked in §4 for the examples under consideration. This assumption also holds if the uniform rate estimate on the function values in Theorem 1.2 is applied to the following estimates. Conditions on f and L that yield the convergence of u_*^N, x_*^N, s_*^N to u_*, x_*, s_* like linearity of f and convexity of L , (cf. [6, p. 116]) imply that, for some $c > 0$,

$$c\|u_k^N - u_*^N\|_{L_2} \leq F_N(u_k^N) - F_N(u_*^N).$$

Hence u_k^N converges uniformly to u_* and, therefore, also to the corresponding switching functions.

THEOREM 3.1. *Let $s_k^N, s_* \in L_\infty[0, T]$, $k, N \in \mathbb{N}$ be such that*

$$(3.1) \quad \lim_{N, k \rightarrow \infty} \|s_k^N - s_*\|_{L_\infty[0, T]} = 0$$

holds and that there is α such that

$$(3.2) \quad \alpha_k^N \geq \alpha > 0.$$

Then for all $\varepsilon > 0$ such that (2.6) is true, there exist $k_\varepsilon, N_\varepsilon \in \mathbb{N}$ with

$$(3.3) \quad u_k^N(t) = u_*(t) \quad \text{for all } k \geq k_\varepsilon, N \geq N_\varepsilon, \text{ and } t \in J_\varepsilon.$$

Proof. Choose $k_1(\varepsilon), N_\varepsilon \in \mathbb{N}$ such that for all $k \geq k_1(\varepsilon)$, $N \geq N_\varepsilon$,

$$\|s_k^N - s_*\|_{L_\infty[0, T]} \leq \varepsilon/2.$$

Define $J_\varepsilon^+, J_\varepsilon^-$ as in (2.8). If we consider s_k^N with indices $k \geq k_1(\varepsilon)$, $N \geq N_\varepsilon$ we can follow through (2.9)–(2.12) to obtain (3.3) with $k_\varepsilon = k_1(\varepsilon) + l(\varepsilon) + 1$. \square

A traditional notion of mesh independence, described in [1] and [12], is that the iterate k after which the size of the projected gradient is less than ε is independent of N . To state a result of this type, we consider the difference between consecutive steps. This is feasible because the stepsizes α_k are assumed (see (2.3)) to be bounded from above and also uniformly from below away from zero. It holds that

$$k_N(\varepsilon) = \min\{k : \|u_k^N - u_{k-1}^N\|_H < \varepsilon\}, \quad k(\varepsilon) = \min\{k : \|u_k - u_{k-1}\|_H < \varepsilon\}.$$

The following mesh-independence result of the second type explains the results reported in Table 4.1.

THEOREM 3.2. *Assume that $u_k^N \rightarrow u_k$ in H for all $k \in \mathbb{N}$. Then for all $\varepsilon, \rho > 0$ there is $N_{\varepsilon, \rho}$ such that if $N \geq N_{\varepsilon, \rho}$, then*

$$k(\varepsilon + \rho) \leq k_N(\varepsilon) \leq k(\varepsilon).$$

Proof. By definition of $k(\varepsilon)$,

$$\nu(\varepsilon) := \varepsilon - \|u_{k(\varepsilon)} - u_{k(\varepsilon)-1}\|_H > 0.$$

The assumption of the theorem yields that for each $\mu > 0$ there are $N(\mu, k) \in \mathbb{N}$ such that

$$\|u_k^N - u_k\| < \mu \quad \text{for all } N \geq N(\mu, k).$$

In particular, we have that for

$$N > N_\varepsilon^1 := \max \{N(\nu(\varepsilon)/2, k(\varepsilon)), N(\nu(\varepsilon)/2, k(\varepsilon) - 1)\},$$

$$\begin{aligned} \|u_{k(\varepsilon)}^N - u_{k(\varepsilon)-1}^N\|_H &\leq \|u_{k(\varepsilon)} - u_{k(\varepsilon)-1}\|_H \\ &\quad + \|u_{k(\varepsilon)}^N - u_{k(\varepsilon)}\|_H + \|u_{k(\varepsilon)-1}^N - u_{k(\varepsilon)-1}\|_H \\ &< \varepsilon - \nu(\varepsilon) + \frac{1}{2}(\nu(\varepsilon) + \nu(\varepsilon)) \\ &= \varepsilon. \end{aligned}$$

Hence $k_N(\varepsilon) \leq k(\varepsilon)$.

On the other hand, for given $\varepsilon, \rho > 0$, we have

$$\|u_k - u_{k-1}\| \geq \varepsilon + \rho \quad \text{for all } k < k(\varepsilon + \rho).$$

Choose

$$N_{\varepsilon, \rho}^2 = \max \{N(\rho/2, k) : k = 1, \dots, k(\varepsilon + \rho)\}.$$

Then for all $N \geq N_{\varepsilon, \rho}^2$ and $k < k(\varepsilon + \rho)$

$$\begin{aligned} \|u_{k(\varepsilon)}^N - u_{k(\varepsilon)-1}^N\|_H &\geq \|u_{k(\varepsilon)} - u_{k(\varepsilon)-1}\|_H \\ &\quad - \|u_{k(\varepsilon)}^N - u_{k(\varepsilon)}\|_H - \|u_{k(\varepsilon)-1}^N - u_{k(\varepsilon)-1}\|_H \\ &\geq \varepsilon + \rho - \frac{1}{2}(\rho + \rho) \\ &= \varepsilon. \end{aligned}$$

Hence $k_N(\varepsilon) \geq k(\varepsilon + \rho)$ for all $N \geq N_{\varepsilon, \rho}^2$, and the statement follows with $N_{\varepsilon, \rho} = \max \{N_{\varepsilon}^1, N_{\varepsilon, \rho}^2\}$. \square

The third type of mesh-independence result considers the number of constraints that are changed in the transition from u_*^N to u_*^{N+1} . We will discuss this in the specific context of first-order differencing for the state and adjoint equations as described in §1. In this case,

$$(3.4) \quad \|s_*^N - s_*\|_\infty \leq \varepsilon_N.$$

In the case of an implicit Euler solution, $\varepsilon_N = ch_N$, where h_N is the stepsize at level N and the number of grid points is $1 + h_N^{-1}$. We accept $J^N = \{t \mid |s_*^N(t)| \geq \varepsilon_N\}$ as the active set at level n . Define $\Delta^N = J^N \Delta_{\mathcal{A}} J^{N+1}$. Here the A-symmetric difference of sets is

$$A \Delta_{\mathcal{A}} B = (A^c \cap B) \cup (B^c \cap A),$$

with $A^c = \mathcal{A} - (A \cap \mathcal{A})$ denoting the complement of A in \mathcal{A} . We state a set theoretic mesh-independence result.

THEOREM 3.3. *Let the assumptions of Theorem 3.1 hold. Assume that (2.14) and (3.4) hold and that $\varepsilon_N = \rho \varepsilon_{N-1}$ for some $\rho < 1$. Then there is \hat{c} independent of N , such that*

$$m(\Delta^N) \leq \hat{c} \varepsilon_N^{1/\mu}$$

for all N .

Proof. If $t \in (J^N)^c \cap J^{N+1}$, then

$$|s^*(t)| \leq |s_*^N(t)| + \varepsilon_N < 2\varepsilon_N$$

and, therefore, $t \in \mathcal{A} - J_{2\varepsilon_N}$. If $t \in (J^{N+1})^c \cap J^N$, then

$$|s^*(t)| \leq |s_*^{N+1}(t)| + \varepsilon_{N+1} \leq 2\varepsilon_{N+1} = 2\rho\varepsilon_N < 2\varepsilon_N.$$

Therefore $\Delta^N \subset \mathcal{A} - J_{2\varepsilon_N}$, which completes the proof by Lemma 2.2 with $\hat{c} = 2c$, where c is the constant in (2.15). \square

In the special case where \mathcal{Z} is a finite set, $\varepsilon_N = h_N = 2h_{N-1}$, and $\mu = 1$, the above result asserts that the number of grid points at level $N + 1$ for which

$$|s_*^N(t)| \geq \varepsilon_N, \quad (\text{approximately active at level } N)$$

but

$$|s_*^{N+1}(t)| < \varepsilon_{N+1}, \quad (\text{undetermined at level } N)$$

or vice versa, is bounded by a constant independent of N . To see this, note that the number of grid points in a set of size $\hat{c}h_N$ should be roughly \hat{c} . Hence only a finite number of constraint changes must be done if the initial iterate for level $N + 1$ is a converged result at level N .

If $\mu > 1$, however, the number of additional approximately active constraints that must be considered at each level will increase with N . The number of grid points in Δ_N will be approximately

$$m(\Delta_N)/\varepsilon_N = O(\varepsilon_N^{(1-\mu)/\mu}).$$

This estimate indicates that the number of changes for the number of approximately active constraints at each level is constant with $\mu = 1$ and increases for μ larger than 1.

To conclude this section, we show that the assumption on the uniform boundedness on α_k^N is satisfied for Armijo's rule under a uniform bound on the Lipschitz constant of F_N . The arguments are the same as for F and can be found in [2]. For completeness we include a proof.

LEMMA 3.4. *Let $u_k^N \in U_N$ be a sequence of points generated by the gradient projection algorithm with Armijo's stepsize rule (1.4). Assume that the constants $\tilde{\alpha}_N$ and δ_N specified for each N in (1.4) satisfy*

$$\tilde{\alpha}_N \geq \tilde{\alpha} > 0, \quad \delta_N \geq \delta > 0.$$

Suppose that there is $L > 0$ such that

$$\|\nabla F_N(u) - \nabla F_N(w)\| \leq L\|u - w\| \quad \text{for all } u, w \in U_N, \quad N \in \mathbb{N}.$$

Then there exists $\alpha \geq 0$ such that for all $k, N \in \mathbb{N}$,

$$\alpha_k^N \geq \alpha > 0$$

holds.

Proof. The definition of the projection implies that for all $u \in U_N$ and $\alpha > 0$

$$(3.5) \quad \langle \nabla F_N(u), u - P_N(u - \alpha \nabla F_N(u)) \rangle \geq \frac{1}{\alpha} \|u - P_N(u - \alpha \nabla F_N(u))\|^2$$

is true; see, e.g., [7, (2.6)]. The Lipschitz continuity yields for all $u, v \in D_N$ and all $N \in \mathbb{N}$

$$(3.6) \quad |F_N(u) - F_N(v) - \langle \nabla F_N(u), u - v \rangle| \leq \frac{1}{2}L\|u - v\|^2.$$

The Armijo stepsize rule implies that either $\alpha_k^N = \tilde{\alpha}_N$ or that with (3.5) and (3.6) the following inequalities hold:

$$\begin{aligned} & -\frac{L}{2} \|u_k^N - P_N(u_k^N - \frac{\alpha_N}{\beta_N} \nabla F_N(u_k^N))\|^2 \\ & \leq F_N(u_k^N) - F(P_N(u_k^N - \frac{\alpha_N}{\beta_N} \nabla F_N(u_k^N))) \\ & \quad - \langle \nabla F_N(u_k^N), u_k^N - P_N(u_k^N - \frac{\alpha_N}{\beta_N} \nabla F_N(u_k^N)) \rangle > \\ & \leq (\delta_N - 1) \langle \nabla F_N(u_k^N), u_k^N - P_N(u_k^N - \frac{\alpha_N}{\beta_N} \nabla F_N(u_k^N)) \rangle > \\ & \leq \frac{\delta_N - 1}{\alpha_N} \|u_k^N - P_N(u_k^N - \frac{\alpha_N}{\beta_N} \nabla F_N(u_k^N))\|^2, \end{aligned}$$

and therefore

$$2 \frac{1 - \delta}{L} \leq 2 \frac{1 - \delta_N}{L} \leq \alpha_k^N.$$

Hence we obtain

$$\alpha_k^N \geq \min\{\tilde{\alpha}, 2 \frac{1 - \delta}{L}\} > 0.$$

□

4. Numerical results. In this section we illustrate some of the theoretical results of the previous sections. Let us consider first a rather simple, but nevertheless illuminating, example from optimal control. The problem consists of minimizing

$$\frac{1}{2} \int_0^1 x(t)^2 dt,$$

subject to

$$\dot{x}(t) = b(t)u(t), \quad x(0) = 1, \quad t \in [0, 1]$$

and

$$u \in U = \{u \in L_2[0, 1] : |u(t)| \leq 0.5 \text{ a.e. in } [0, 1]\}.$$

Let us consider the following examples

Example 4.1. $b(t) = (t - 0.5)^3$;

Example 4.2. $b(t) = (t - 0.5)^3 + 0.03$;

Example 4.3. $b(t) = \cos(3t)$;

Example 4.4. $b(t) = (t - 0.5)|t - 0.5|$.

The first example does not satisfy the growth condition (1.11) for $\nu = 2$, but the second, which is a slightly perturbed example, does. As a more well-posed example, we use Example 4.3 where (1.11) is also satisfied.

The optimal control satisfies the following bang-bang-principle:

$$u_*(t) = -0.5 \operatorname{sgn} p_*(t)b(t) \quad \text{a.e. in } [0, 1],$$

where p_* solves the adjoint equation

$$-\dot{p}(t) = x_*(t), \quad p(1) = 0, \quad t \in [0, 1].$$

Since p is positive on $[0, 1)$ for all our choices of b , the function b determines the type of growth for the switching function

$$(4.1) \quad s_* = \frac{bp_*}{2}.$$

For the discrete case, we replace the feasible set U by

$$U_N = \{u \in L_2[0, 1] : u = \sum_{i=0}^{D_N-1} u_i \chi_i, |u_i| \leq 0.5 \ i = 0, \dots, D_N - 1\},$$

χ_i denoting the characteristic function on the interval $[i/(D_N), (i+1)/(D_N)]$, and the objective function F denoted by

$$(4.2) \quad F_N(u_N) = \frac{1}{2} \int_0^1 \left(\sum_{i=0}^{D_N-1} x_i \chi_i \right)^2 dt,$$

where x_i is the Euler approximation to the solution of the differential equation

$$x_{i+1} = x_i + \frac{1}{D_N} b_i u_i, \quad i = 0, \dots, D_N - 1, \quad x_0 = 1.$$

Here we set

$$b_i = b\left(\frac{i}{D_N}\right), \quad i = 0, \dots, D_N - 1.$$

The gradient of F_N can be computed by $s_N = \sum_{i=0}^{D_N-1} s_i \chi_i$, where

$$(4.3) \quad s_i = 0.5b_i p_i, \quad i = 0, \dots, D_N - 1.$$

Here p_i is the Lagrange multiplier that satisfies the discretized version of the adjoint differential equation by Euler's scheme.

To check the assumptions for Theorem 3.1, we note that all F_N and F are convex and continuously differentiable. Furthermore, the quadratic form of (4.2) implies under the use of the necessary optimality condition that

$$F_N(u^N) - F_N(u_*^N) \geq F_N(u^N - u_*^N) > 0$$

for all $u^N \in U_N$ with $u^N \neq u_*^N$. By invoking Theorem 1.2, we obtain uniform convergence of $F_N(u_k^N)$ to $F_N(u_*^N)$. More specifically, there is a constant $q \in \mathbb{R}$ with

$$(4.4) \quad \|x_k^N - x_*^N\|_{L_2} = F_N(u_k^N - u_*^N) \leq F_N(u_k^N) - F_N(u_*^N) \leq \frac{q}{k}$$

for all $k, N \in \mathbb{N}$. Since we know by inspection of the discretized problem that for sufficiently large N the optimal control u_*^N is bang-bang except for two subintervals, we have

$$\|u_* - u_*^N\|_{L_2} \rightarrow 0 \quad \text{and} \quad \|x_* - x_*^N\|_{L_\infty} \rightarrow 0.$$

From (4.1) and (4.3) we see that the convergence of the switching functions is determined by the corresponding adjoint states, which takes place in the L_∞ -norm because of the smoothing property of the adjoint differential and difference equation. Hence

$$\lim_{N, k \rightarrow \infty} \|s_k^N - s_*\|_{L_\infty} \leq \lim_{N, k \rightarrow \infty} \|s_k^N - s_*^N\|_{L_\infty} + \lim_{N \rightarrow \infty} \|s_*^N - s_*\|_{L_\infty} = 0.$$

Therefore, Theorem 3.1 is applicable to our examples, and we can expect mesh independence in the sense of the results in §3.

In Table 4.1 we do not terminate the algorithm on the identification of the active indices but rather when we reach a certain tolerance for the discrete L_2 -norm of the steps, i.e., the projected gradient:

$$k_N(10^{-4}) = \min\{k \in \mathbb{N} : \|u_k^N - u_{k-1}^N\| \leq 10^{-4}\}.$$

The table shows clearly that in all cases the number of iterations to reach this goal is independent on the dimension, which is in line with the results proved in Theorem 3.2.

We now discuss the condition $u_k^N \rightarrow u_k$ in H for all $k \in \mathbb{N}$, which occurs as an assumption in statement of Theorem 3.2. The iteration scheme (1.3) is given by

$$u_{k+1}^N = P(u_k^N - \alpha_k^N \nabla F_N(u_k^N)).$$

Our verification will be by induction and will be valid for almost every choice of the parameter ρ in the Armijo rule. This technical restriction on ρ is a consequence of the

discrete nature of the decision to accept or reject a step and was explained in detail in [11]. We refer the reader to that paper for a discussion of this point and will only note the issue below. Clearly, $u_0^N \rightarrow u_0$ uniformly. To complete the verification, we assume that $u_k^N \rightarrow u_k$ in L_2 then show that $u_{k+1}^N \rightarrow u_{k+1}$ in L_2 . Since $\nabla F_N(u_k^N) = s_k^N$, we can use similar arguments as above to check $s_k^N \rightarrow s_k$. The projection is continuous, and therefore $\alpha_k^N \rightarrow \alpha_k$ remains to be shown. This is true for almost every choice of ρ , as was the case in [11].

As a termination criterion in Table 4.2, we use the size of the interval where the indices are active. Termination occurs when the length of the interval corresponding to all active indices is a certain fixed percentage of the length of the total interval. Suppose we want to stop if p percent of the interval length is a bang-bang control; i.e., the corresponding indices are active. Then we define

$$k^p = \min\{k \in \mathbb{N} : |I(u_k)|/D_N \geq \frac{p}{100}\}$$

This termination criterion is related to Theorem 3.1 for an appropriate choice of ε . The results for this termination criterion are listed in Table 4.2 and show also the independence of the dimension of the problem. Example 4.1 is notably ill posed, so we also list the results for a less stringent termination criterion.

In Table 4.3 we illustrate the estimate in Theorem 3.3 on how the measure of set of almost active indices changes as the discretization is refined. Here the influence of the growth condition (2.14) can be documented for our examples. The values for ε_N in this table are $\varepsilon_N = .02h_N$ for Example 4.1, $\varepsilon_N = 10h_N$ for Example 4.3, and $\varepsilon = .1h_N$ for Example 4.4. According to the statement of Theorem 3.3 and the growth

condition for our examples, we should expect an estimate for the ratios

$$m(\Delta^N)/m(\Delta^{N-1})$$

of the following type: It should be 0.79 for Example 4.1, 0.50 for Example 4.3, and 0.71 for Example 4.4. For high discretizations, these estimates can be verified in the given examples.

As a second example, we look at an optimal control problem with partial differential equations. For further references see, e.g., [13]. Let $y(t, x)$ denote the temperature at time $t \in [0, T]$ and at location $x \in [0, 1]$. Heat conduction problems with memory can be modeled with pseudoparabolic differential equations. The boundary problem is given by

$$\begin{aligned} y_t(t, x) &= y_{xx}(t, x) + \varepsilon y_{xtx}(t, x), & x \in (0, 1), \quad t \in (0, T), \\ y(0, x) &= 0, & x \in (0, 1), \\ y_x(t, 1) &= 0, & t \in (0, T), \\ -y_x(t, 0) - \varepsilon y_{xt}(t, 0) &= u(t), & t \in (0, T]. \end{aligned}$$

The function u denotes the input or control function. The variable ε represents a material constant. The objective function is given by

$$F(u) = \int_0^1 \phi(y(T, x) - z(x)) dx + \frac{\alpha}{2} \int_0^T u(t)^2 dt,$$

where $\phi: \mathbb{R} \rightarrow \mathbb{R}$ is a given continuously differentiable function and $\alpha \geq 0$ a given constant. The set of feasible controls is given by

$$U = \{u \in L_2[0, T] : |u(t)| \leq 1 \text{ a.e. in } [0, T]\}.$$

We define for $u \in L_2[0, T]$ the solution $y(T, \cdot)$, which enters the objective function as follows:

$$Su(x) := y(T, x) = \sum_{j=0}^{\infty} a_j^2 b_j c_j(x) \int_0^T e^{-\lambda_j(T-s)} u(s) ds$$

with the following abbreviations for $j = 0, 1, 2, \dots$:

$$\begin{aligned} c_j(x) &= \cos j\pi x, & x \in [0, 1] \\ \mu_k &= j^2 \pi^2 \\ b_j &= \frac{1}{(1+\varepsilon \mu_j)}, \\ \lambda_j &= \frac{\mu_j}{(1+\varepsilon \mu_j)}, \\ a_j &= \sqrt{2}, \quad k > 0 \quad a_0 = 1. \end{aligned}$$

TABLE 4.4
Pseudoparabolic Control Problem

D_N	$ I(u_{\text{iter}}) $	l_{act}	r_{act}	iter
10	9 (90%)	0.2000	0.2500	32
25	21 (84%)	0.2000	0.2800	31
50	44 (88%)	0.2100	0.2700	28
75	65 (87%)	0.2067	0.2733	29
100	86 (86%)	0.2050	0.2750	30
150	130 (87%)	0.2067	0.2733	29
200	173 (87%)	0.2050	0.2725	29

If we use the adjoint operator S^* of $S : L_2[0, T] \rightarrow C[0, 1]$, we can show that the optimal control u_* satisfies the following necessary optimality condition:

$$u_*(t) = -\text{sgn}(S^*(\phi'(Su(\cdot) - z(\cdot)))(t) + \alpha u_*(t)), t \in [0, T].$$

or, equivalently,

$$u_*(t) = -\text{sat}\left(\frac{1}{\alpha} S^*(\phi'(Su(\cdot) - z(\cdot)))(t)\right),$$

where the function sat is defined by (2.5).

We approximate the problem by truncating the infinite series representation of S by

$$S_N u(x) = \sum_{j=0}^{j_N} a_j^2 b_j c_j(x) \int_0^T e^{-\lambda_j(T-s)} u(s) ds;$$

we replace the set U by piecewise constant functions U_N on a fixed grid with values in $[-1, 1]$ as in control problem above. The integration, along the space variable x from 0 to 1, is replaced by a quadrature rule. Hence the function F_N is determined by

$$F_N(v) = \frac{1}{l_N + 1} \sum_{l=0}^{l_N} \phi\left(S_N\left(\sum_{i=0}^{D_N-1} v_i \chi_i\right)(x_l) - z(x_l)\right) + \frac{1}{N} \sum_{i=0}^{D_N-1} v_i^2.$$

We set

$$T = 0.5, \quad \varepsilon = 10^{-4}, \quad \alpha = 0.1, \quad j_N = 50, \quad l_N = 100, \quad \phi(y) = y^4, \quad z(x) = 3(x-0.5).$$

The termination criterion is set to be

$$\|u_{k+1}^N - u_k^N\| \leq 10^{-6}.$$

This is a reasonable termination criterion because the description of the optimal control u^* tells us that it is not a bang-bang control and has a singular arc. We tabulate in Table 4.4 the number of iterations iter needed to reach the termination criterion, the number of active indices $|I(u_{\text{iter}})|$, and the interval $[l_{\text{act}}, r_{\text{act}}]$, which was identified as singular; i.e., the control has values inside the interval $(-1, 1)$.

Acknowledgments. The authors thank the referees for helpful comments and remarks on the paper.

CONTRÔLE OPTIMAL DANS LES ÉQUATIONS ELLIPTIQUES*

R. TAHRAOUI†

Abstract. The goal of this work is to study problems of control when the state is governed by an elliptic partial differential equation. The control dependency is nonconvex. These kinds of problems arise in such applications as domain control or hydrodynamics. Examples are provided.

Key words. contrôle optimal, équations elliptiques

1. Introduction et notation. On se propose, dans ce travail, de traiter quelques questions d'existence de contrôle optimal dans un cadre non convexe, et où l'état du système est défini par des équations uniformément elliptiques.

Il existe de nombreux travaux traitant de ce sujet. Les premiers résultats semblent remonter à 1955 avec le travail de Krein [17] qui, motivé par l'étude des zones de stabilité de l'équation

$$y'' + \lambda p(x)y = 0$$

où $x \in]-\infty, +\infty[$ et p est une fonction période, s'était intéressé aux deux problèmes suivants:

$$\inf \{ \lambda_n(v) / v \in \mathcal{U} \},$$

$$\max \{ \lambda_n(v) / v \in \mathcal{U} \},$$

où $\lambda_n = \lambda_n(v)$ est la n ième valeur propre de

$$y'' + \lambda_n \cdot v \cdot y = 0,$$

$$y(0) = y(1) = 0;$$

le contrôle v appartient à l'ensemble \mathcal{U} donné par

$$\mathcal{U} = \left\{ v \in L^\infty(0, 1) / h \leq v \leq H, \int_0^1 v \, dx = M \right\},$$

h, H, M étant des constantes positives données. Les résultats obtenus sont très précis (cf. [17]: la dimension d'espace $n = 1$ en est une des raisons). Motivé par l'étude des vibrations d'une barre Banks [18] aborda les deux questions précédentes pour l'opérateur du quatrième ordre suivant:

$$y^{(4)} - \lambda \cdot v y = 0, \quad y(0) = y(1) = y''(0) = y''(1) = 0,$$

le contrôle v appartenant à \mathcal{U} . Nous pouvons remarquer que, aussi bien dans [17] que dans [18], le problème de l'existence ne se pose pas: la dépendance du problème en fonction du contrôle est convexe.

† Centre de Recherches de Mathématiques de la Décision, Université de Paris-Dauphine, Place de Maréchal de Lattre Tassigny, 75775 Paris Cedex 16, France.

Dans un cadre plus général que dans [17] et [18], Zérah [19] donne des résultats d'existence, pour des situations non convexes, en utilisant diverses techniques, notamment l'homogénéisation et les réarrangements, pour certains problèmes de la forme suivante:

$$\begin{aligned}
 & -(a(v)y')' = \lambda_1 \cdot b(v) \cdot y \\
 (\mathcal{P}_1) \quad & J(v) = \lambda_1(v), \text{ qui est non convexe} \\
 & \sup \{J(v)\},
 \end{aligned}$$

sous différentes conditions aux limites, le contrôle v appartenant à un ensemble de type \mathcal{U} . De plus, Zérah donne plusieurs motivations mécaniques du problème (\mathcal{P}_1) dans la recherche des formes optimales:

- (i) recherche de la colonne la plus résistante,
- (ii) recherche de la colonne la plus haute, à volume donné (Tour Eiffel),
- (iii) vibrations transversales d'une poutre,
- (iv) minimisation de la déviation d d'une poutre dont le poids est donné i.e. minimiser:

$$J(a) = - \int_0^1 \sin \theta(s) ds$$

sous les contraintes:

$$\begin{aligned}
 & \frac{d}{ds} \left(a^2 \frac{d\theta}{ds} \right) = \cos \theta \\
 & \theta(0) = \theta'(1) = 0, \quad \int_0^1 a(s) ds = 1.
 \end{aligned}$$

On remarquera que J n'est pas convexe.

Signalons également que dans [26] on trouvera d'autres problèmes de contrôle non convexe comme, par exemple, le problème suivant: (anisotropie optimale d'une barre en torsion) il s'agit de maximiser la fonctionnelle

$$K(\alpha) = 2 \int_{\Omega} \varphi(x, y) dx dy,$$

où φ désigne l'état solution de l'équation suivante:

$$\begin{aligned}
 & -\operatorname{div} (A(\alpha) \cdot \nabla \varphi) = 2 \quad \text{dans } \Omega; \\
 & \varphi/\Gamma = 0, \quad \text{où } \Gamma = \partial\Omega
 \end{aligned}$$

dans laquelle α est une fonction contrôle décrivant l'orientation; la dépendance en α de $A(\cdot)$ est non convexe. Les motivations précédentes constituent une première justification de ce travail. Enfin signalons un résultat très significatif de [19]: (\mathcal{P}_1) possède au moins une solution si la fonction $v \rightarrow a(v) \cdot b(v)$ est strictement monotone. Ce résultat intéressant semble lié à la dimension d'espace $n = 1$.

En effet en dimension d'espace $n \geq 2$, d'une manière générale, si on se place dans une situation où la dépendance du contrôle est non convexe, l'existence d'une solution pour des problèmes du type (\mathcal{P}_1) n'est pas toujours assurée. Il est connu (cf. [28]) que le problème de contrôle de domaine suivant:

$$\begin{aligned}
 & -\operatorname{div} (v \cdot \nabla \omega) = 1 \\
 (\mathcal{P}_2) \quad & \omega/\Gamma = 0 \\
 & \inf (J(v), / v \in \mathcal{U}_1\}, \quad J(v) = \int_{\Omega} \omega dx = \int_{\Omega} v \cdot |\nabla \omega|^2 dx
 \end{aligned}$$

n'a pas de solutions si l'on prend

$$\mathcal{U}_1 = \{v \in L^\infty(\Omega) / v(x) \in \{\alpha, \beta\}, \text{mes}(v^{-1}(\alpha)) = \theta_1, \text{mes}(v^{-1}(\beta)) = \theta_2, \theta_1 + \theta_2 = \text{mes}(\Omega)\}.$$

Il se produit un phénomène d'homogénéisation: la solution optimale $\bar{\omega}$ exige un mélange de matériaux, i.e., le contrôle optimal \bar{u} vérifie

$$\alpha \leq \bar{u}(x) \leq \beta \quad \text{p.p. } x \in \Omega$$

avec

$$\int_{\Omega} \bar{u} \, dx = \text{mes}(\Omega), \quad \text{mes}(\{x \in \Omega / \alpha < \bar{u}(x) < \beta\}) > 0.$$

Dans notre travail le contrôle intervient dans les termes d'ordre zéro de l'opérateur. Il s'agit, par exemple, de maximiser l'énergie

$$J(v) = \int_{\Omega} |\nabla \omega|^2 \, dx,$$

où ω vérifie l'équation d'état:

$$(\mathcal{P}_3) \quad -\Delta \omega = v, \quad \omega / \Gamma = 0,$$

v étant le contrôle admissible qui appartient à l'ensemble

$$\mathcal{U}_2 = \{v \in L^\infty(\Omega) / \alpha \leq v \leq \beta, v_* = u_0\}^1,$$

où v_* est le réarrangement croissant unidimensionnel de v ; il est clair que \mathcal{U}_2 est non convexe et est une généralisation de \mathcal{U}_1 : il s'agit de mélange à un nombre, éventuellement, infini de matériaux.

Deux types d'applications importantes sont modélisés par (\mathcal{P}_3) .

(1) *Contrôle de domaine.* Dans ce cas $u_0(x) \in \{\alpha, \beta\}$ p.p. $x \in \Omega$; l'idée est de relaxer le problème au sens suivant, i.e., résoudre

$$(\mathcal{PP}_3) \quad \inf \{J(v) / v \in \mathcal{U}_3\},$$

quand l'ensemble des contrôles admissibles est

$$\mathcal{U}_3 = \left\{ v \in L^\infty(\Omega) / \alpha \leq v \leq \beta, \int_{\Omega} v \, dx = \gamma \right\}.$$

Ce problème relaxé admet une solution optimale $(\bar{u}, \bar{\omega})$. On conclut que le problème initial admet une solution en montrant que le contrôle \bar{u} est bang-bang. Cette dernière propriété importante sera, pour cette raison, étudiée dans un cadre assez général. Cette formulation englobe une classe assez large de problèmes d'optimisation de forme, i.e., de contrôle par le domaine tels que le problème de la rigidité à la torsion d'une barre de section droite de forme quelconque ou le problème de la capacité: [30].

(2) *Problème d'hydrodynamique.* Dans ce cas u_0 est une fonction croissante à valeurs dans \mathbb{R}^+ (signalons au passage le cas intéressant où cardinal de $(\text{Im } u_0)$ est fini); le problème (\mathcal{P}_3) modélise, entre autres, un problème d'hydrodynamique où ω représente le potentiel des vitesses $(\partial \omega / \partial x_2, -\partial \omega / \partial x_1)$, $J(v) = \int_{\Omega} |\nabla \omega|^2 \, dx$ représente l'énergie cinétique du fluide et $-\Delta \omega$ la vorticit  dont la fonction de distribution est fix e. Pour la formulation de ce probl me nous renvoy r   [36], [29], et [31].

¹ Ce type de contrainte se rencontre dans [12] dont nous avons re u le preprint en d cembre 1985 au moment o  la r daction de ce travail  tait achev e.

Tous ces problèmes entrent dans une formulation générale pour laquelle nous donnerons, dans un premier temps, des résultats d'existence sous des hypothèses assez simples; et en deuxième lieu nous fournirons, autant que possible, des informations qualitatives sur les solutions optimales. L'unicité sera également abordée. Enfin signalons que ce travail a été annoncé dans [15] et une première version en a été donnée dans [16].

Etant donné un ouvert borné régulier de R^n , on considère l'ensemble des contrôles admissibles

$$(1.1) \quad \mathcal{U}(\alpha, \beta, \gamma) = \mathcal{U} = \left\{ v \in L^\infty(\Omega), 0 < \alpha(x) \leq v(x) \leq \beta(x) \text{ p.p. } x, \int_{\Omega} v \, dx = \gamma \right\},$$

où α et β sont des fonctions de $L^\infty(\Omega)$ satisfaisant

$$0 < \alpha(x) < \beta(x) \quad \text{p.p. } x \in \Omega.$$

On suppose \mathcal{U} non vide, i.e., que γ vérifie

$$\int_{\Omega} \alpha \, dx \leq \gamma \leq \int_{\Omega} \beta \, dx.$$

Pour tout v dans \mathcal{U} , l'équation d'état du système est

$$(1.2) \quad \begin{aligned} -\Delta \omega &= a(x, v, \omega) \quad \text{dans } \Omega, \\ \omega/\Gamma &= 0, \end{aligned}$$

dans laquelle la fonction a de $\Omega \times \mathbb{R}^+ \times \mathbb{R}$ dans \mathbb{R} , supposée de Carathéodory satisfait la condition

$$(1.3) \quad a(x, s, t) \geq a_0 \quad \text{p.p. } x \in \Omega, \quad \forall (s, t) \in \mathbb{R}^+ \times \mathbb{R}.$$

Suivant les besoins du contexte, nous noterons la fonction état du système par ω , $\omega(v)$, $\omega(a)$, ou $\omega(a, v)$ si aucune ambiguïté n'est à craindre; et à (1.2) on associe la fonction coût

$$(1.4) \quad J(v) = \int_{\Omega} l(v) \cdot b(x, \omega) \, dx + \int_{\Omega} c(x, \omega) \, dx,$$

pour laquelle les fonctions b, c sont de caratheodory, l une fonction continue et ω une solution de (1.2), associée au contrôle v .

DÉFINITION 1.1. Le problème $P = P(a, b, c, l)$ consiste à trouver u dans \mathcal{U} tel que

$$J(u) = \inf \{J(v), v \in \mathcal{U}\}.$$

2. Resultats preliminaires. Nous avons besoin des hypothèses suivantes:

$$(2.1) \quad v \rightarrow a(x, v, t) \quad \text{est convexe, p.p. } x \in \Omega, \quad \forall t \in \mathbb{R}$$

et satisfait

$$(2.2) \quad \begin{aligned} |a(x, s, t)| &\leq r_1 |t| + r_2(x) \\ \text{p.p. } x \in \Omega, \quad \forall t \in \mathbb{R}, \quad \forall s \in [\inf \alpha, \sup \beta], \end{aligned}$$

où r_1 est une constante positive satisfaisant $r_1 < c(\Omega)$ constante de Poincaré; r_2 est une

fonction de $L^2(\Omega)$.

$$(2.3) \quad b(x, t) \geq 0 \quad \text{p.p. } x \in \Omega, \quad \forall t \in \mathbb{R}$$

$$(2.4) \quad b(x, t) \text{ croissante en } t, \text{ p.p. } x \in \Omega$$

$$(2.5) \quad c(x, t) \text{ croissante en } t, \quad \text{p.p. } x \in \Omega$$

$$(2.6) \quad l(t) \text{ est convexe, positive.}$$

$$(2.7) \quad a(x, s, t) \text{ est croissante en } t, \quad \text{p.p. } x, \quad \forall s.$$

Remarque 2.1. L'hypothèse (2.2) est faite pour simplifier la présentation et éviter de poser le problème de l'existence d'une solution de (1.2) qui n'est pas dans le but que nous nous sommes fixé ici.

Nous avons le résultat suivant.

THÉORÈME 2.1. *Sous les hypothèses (1.3) et (2.1) à (2.6) le problème $P(a, b, c, l)$ admet au moins une solution optimale $(\bar{u}, \bar{\omega} = \omega(\bar{u}))$.*

Démonstration. L'idée de la preuve, basée essentiellement sur le principe du maximum, a déjà servi pour un énoncé voisin mais pour une équation linéaire [8]. Sous (2.2), pour tout v dans \mathcal{U} , l'existence d'une solution de (1.2) est classique. Soit v_n une suite minimisante de $J(\cdot)$; on a

$$(2.8) \quad \begin{aligned} -\Delta \omega_n &= a(x, v_n, \omega_n) \quad \text{dans } \Omega, \\ \omega_n / \Gamma &= 0, \end{aligned}$$

et

$$J(v_n) \rightarrow \inf \{J(v), v \in \mathcal{U}\} \quad \text{quand } n \rightarrow +\infty;$$

la fonction ω_n étant borné dans $H_0^1(\Omega)$, il existe une sous-suite notée encore ω_n telle que

$$\begin{aligned} v_n &\rightarrow \bar{u} \quad \text{dans } L^\infty(\Omega) \text{ faible}^* \\ \omega_n &\rightarrow \tilde{\omega} \quad \text{dans } H_0^1(\Omega) \text{ faible} \\ \omega_n &\rightarrow \tilde{\omega} \quad \text{dans } L^2(\Omega) \text{ fort et p.p. } x \in \Omega. \end{aligned}$$

Et nous avons

$$(2.9) \quad \inf J(v) = \lim J(v_n) \geq \int_{\Omega} l(\bar{u}) b(x, \tilde{\omega}) dx + \int_{\Omega} c(x, \tilde{\omega}) dx.$$

Il s'agit de montrer que

$$J(\bar{u}) = \inf \{J(v), v \in \mathcal{U}\};$$

pour cela il suffit de montrer qu'il existe $z = \omega(\bar{u})$ solution de (1.2) tel que $\tilde{\omega} > z$. Un passage à la limite dans (2.8) donne, à une sous-suite près

$$\begin{aligned} -\Delta \tilde{\omega} &= \tilde{g}(x) \quad \text{dans } \Omega \\ \tilde{\omega} / \Gamma &= 0, \end{aligned}$$

où \tilde{g} est la limite faible dans $L^2(\Omega)$ de $\tilde{g}_n(x) = a(x, v_n(x), \omega_n(x))$, et qui vérifie:

$$\tilde{g}(x) \geq g(x) = a(x, \bar{u}(x), \tilde{\omega}(x)).$$

Nous allons définir une suite z_n de fonctions de $H_0^1(\Omega)$ dont la limite, à une sous-suite près, sera un état optimal z associé au contrôle \bar{u} . Pour cela considérons les équations récurrentes suivantes:

$$\begin{aligned} z_0 &= \tilde{\omega} \\ -\Delta z_n &= a(x, \bar{u}, z_{n-1}) \quad \text{dans } \Omega, \quad n \geq 1 \\ z_{n/\Gamma} &= 0. \end{aligned}$$

Le principe du maximum [13], la croissance de $a(x, s, \cdot)$ et (1.3) nous permettent d'affirmer que l'on a

$$(2.10) \quad z_1 \geq z_2 \geq \dots \geq z_n \geq y_0 \quad \text{dans } \Omega,$$

où y_0 est solution de: $-\Delta y_0 = a_0$, $y_{0/\partial\Omega} = 0$; ces inégalités (2.10) permettent d'établir que z_n est borné dans $H_0^1(\Omega)$; par conséquent, à une sous-suite près, z_n converge vers z dans $H_0^1(\Omega)$ faible et presque partout; z vérifie l'équation

$$(2.11) \quad -\Delta z = a(x, \bar{u}(x), z(x)), \quad z_{/\Gamma} = 0$$

et l'inégalité

$$(2.12) \quad \tilde{\omega}(x) \geq z(x) \quad \text{dans } \Omega.$$

Enfin la croissance de b et c donnent

$$\int_{\Omega} l(\bar{u})b(x, \tilde{\omega}) \, dx + \int_{\Omega} c(x, \tilde{\omega}) \, dx \geq \int_{\Omega} l(\bar{u})b(z, x) \, dx + \int_{\Omega} c(x, z) \, dx = J(\bar{u});$$

et cette inégalité jointe à (2.9) entraîne

$$\inf J(v) \geq J(\bar{u});$$

i.e.,

$$\inf J(v) = J(\bar{u});$$

par conséquent $(\bar{u}, z = \omega(\bar{u}))$ est solution optimale du problème. \square

Abordons maintenant l'unicité de la solution. Nous avons le théorème suivant.

THÉOREME 2.2. *On suppose que les fonctions $a(x, s, t)$ et $c(x, t)$ sont strictement croissantes par rapport à t et $a(x, s, t)$ strictement convexe en s . Alors sous les hypothèses du Théorème 2.1, nous avons les résultats suivants:*

(i) *si (u_1, ω_1) et (u_2, ω_2) désignent deux solutions optimales, alors on a $\omega_1 \leq \omega_2$ dans Ω ;*

(ii) *il y a unicité de la solution optimale si $b \equiv 0$.*

Démonstration.

Première étape. Soit deux solutions (u_1, ω_1) , (u_2, ω_2) de $P(a, b, c, l)$. Nous allons montrer que l'on ne peut avoir

$$|\{x \in \Omega / \omega_1(x) < \omega_2(x)\}| > 0 \quad \text{et} \quad |\{x \in \Omega / \omega_2(x) < \omega_1(x)\}| > 0.$$

En effet, dans le cas contraire, posons $z_0 = \inf(\omega_1, \omega_2)$ et considérons la fonction z_n solution de

$$-\Delta z_n = a(x, u_1, r_{n-1}), \quad z_{n/\partial\Omega} = 0,$$

où

$$r_0 = z_0, \quad r_n = \inf(z_n, z_{n-1}).$$

La croissance stricte de $a(x, s, \cdot)$ et le principe du maximum fort entraînent que

$$\omega_1 > z_1 \geq z_2 \geq \cdots \geq z_n \geq y_0 \quad \text{dans } \Omega$$

(la première inégalité s'entend pour au moins une composante connexe de Ω). A une sous-suite près, z_n et r_n convergent, dans $H_0^1(\Omega)$ fort, vers z solution de

$$-\Delta z = a(x, u_1, z)$$

$$z/\partial\Omega = 0,$$

et satisfaisant $z < \omega_1$. Ceci entraîne la contradiction suivante:

$$\int_{\Omega} l(u_1)b(x, z) \, dx + \int_{\Omega} c(x, z) \, dx < \inf \{J(v), v \in \mathcal{U}\};$$

ainsi $\omega_1 \leq \omega_2$ dans Ω .

Deuxième étape. Supposons $b(x, t) \equiv 0$; d'après la première étape nous avons $\omega_1(x) \leq \omega_2(x)$ pour tout x . De plus, si l'ensemble $\{x \in \Omega / \omega_1(x) < \omega_2(x)\}$ est de mesure non nulle, nous aurons

$$J(u_1) = \int_{\Omega} c(x, \omega_1) \, dx < \int_{\Omega} c(x, \omega_2) \, dx = J(u_2)$$

grâce à la stricte croissance de $c(x, \cdot)$. Ce qui contredit le fait que u_2 est optimal. Donc nous avons bien $\omega_1 = \omega_2$. Enfin, montrons que $u_1 = u_2$. Pour cela supposons $E = \{x / u_1(x) \neq u_2(x)\}$ de mesure > 0 . Par la stricte convexité de $a(x, \cdot, t)$ et l'égalité $\omega_1 = \omega_2$, nous avons

$$\begin{aligned} -\Delta \omega_1 &= \frac{1}{2} a(x, u_1, \omega_1) + \frac{1}{2} a(x, u_2, \omega_1) \\ &> a\left(x, \frac{u_1 + u_2}{2}, \omega_1\right) \quad \text{p.p. } x \in E. \end{aligned}$$

Considérons alors la suite \tilde{y}_n de fonctions, solution de l'équation

$$-\Delta \tilde{y}_n = a(x, \tilde{u}, \tilde{y}_{n-1}), \quad y_{n/\partial\Omega} = 0,$$

où

$$\tilde{u} = \frac{u_1 + u_2}{2}, \quad \tilde{y}_0 = \omega_1.$$

Par le principe du maximum fort cette suite vérifie

$$\omega_1 > \tilde{y}_1 \geq \tilde{y}_2 \geq \cdots \geq \tilde{y}_n \geq y_0 \quad \text{dans } \Omega.$$

A une sous-suite près, $\tilde{y}_n \rightarrow \tilde{y} = \tilde{y}(\tilde{u})$ solution de (1.2) avec $v = \tilde{u}$. On montre, grâce à la stricte croissance de $c(x, \cdot)$, que

$$J(\tilde{u}) = \int_{\Omega} c(x, \tilde{y}) \, dx < \inf \{J(v), v \in \mathcal{U}\} = J(u_1);$$

ce qui constitue une contradiction. Donc $u_1 = u_2$.

Remarque 2.2. (1) La stricte croissance de $c(x, \cdot)$ au voisinage de $t = 0$ suffit.

(2) Pour simplifier, nous supposons dans toute la suite α et β constants.

3. Dependance non convexe du contrôle. La situation la plus générale consiste à envisager le cas où ni l ni h ne sont convexes. Cependant pour simplifier la présentation de la démonstration, il nous a paru utile d'envisager séparément les trois cas suivants:

- (i) l est affine;
- (ii) h est affine;
- (iii) la situation générale.

3.1. On suppose que l est affine positive croissante sur $[\alpha, \beta]$, i.e.,

$$(3.1) \quad l(t) = l_0 \cdot t + s_0 \geq 0 \quad \forall t \in [\alpha, \beta], \quad l_0 > 0;$$

on désigne par $x = (x_1, x_2, \dots, x_n)$ un élément générique de Ω ; et pour tout i dans $\{1, 2, \dots, n\}$ on note $x = (x_i^v, x_i)$ où $x_i^v = (x_i, \dots, x_{i-1}, x_{i+1}, x_n)$. Nous supposons $c(x, t)$ régulière, $b(x, t)$ régulière telle que

(3.2) pour tout i dans $\{1, 2, \dots, n\}$ l'application $(x_i, t) \rightarrow b(x_i^v, x_i, t)$ est concave, et la fonction a de la forme

$$(3.3) \quad a(x, s, t) = f(x) + h(s)$$

avec h une fonction définie sur $[\alpha, \beta]$ régulière et f une fonction de $L^\infty(\Omega)$. Posons

$$K(h) = K = \{s \in \mathbb{R}^+ / h^{**}(s) < h(s)\};$$

on a

$$K = \bigcup_{i \in I} K_i, \quad K_i = K_i(h),$$

où I est un ensemble au plus dénombrable et K_i est un intervalle de \mathbb{R}^+ pour tout i . Il existe deux constantes μ_i et ν_i telles que

$$h^{**}(s) = \mu_i \cdot s + \nu_i \quad \forall s \in K_i.$$

Enfin on fait l'hypothèse suivante

$$(3.4) \quad \frac{\partial b}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} [l(s) \cdot (f(x) + h^{**}(s))] + \frac{\partial c}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} (f(x) + h^{**}(s)) > 0$$

p.p. $x \in \Omega$, $\forall s \in K(h)$, $\forall t \in \mathbb{R}$.

Remarque 3.1. Si $a(x, s, t) \geq 0$, on peut supposer, grâce au principe du maximum, (3.4) vrai seulement pour $t \in \mathbb{R}^+$. Ceci est également valable pour toute la suite.

Nous avons le résultat suivant.

THÉORÈME 3.1. *Sous les hypothèses (2.3) à (2.5), (3.1) à (3.4), le problème $P(a, b, c, l)$ admet au moins une solution optimale $(\bar{u}, \bar{\omega} = \omega(\bar{u}))$.*

Démonstration. On relaxe le problème (P) , i.e., on remplace, dans l'équation d'état, $a(x, s, t)$ par $f(x) + h^{**}(s)$ sa convexifiée en s ; on note le problème ainsi obtenu par (P^{**}) : $P^{**} = P(a^{**}, b, c, l)$. D'après le Théorème 2.1., (P^{**}) admet au moins une solution optimale $(\bar{u}, \bar{\omega} = \omega(\bar{u}))$. On se propose alors de démontrer que

$$h^{**}(\bar{u}(x)) = h(\bar{u}(x)) \quad \text{p.p. } x \in \Omega \text{ (étape 1),}$$

ensuite que $(\bar{u}, \bar{\omega})$ est aussi solution de (P) (étape 2).

Etape 1. Elle repose sur la relation d'extrémalité suivante dont la preuve est classique

$$(3.5) \quad \int_{\Omega} l'(\bar{u}) b(x, \bar{\omega}) \delta v \cdot dx + \int_{\Omega} \left[l(\bar{u}) \frac{\partial b}{\partial t}(x, \bar{\omega}) + \frac{\partial c}{\partial t}(x, \bar{\omega}) \right] \delta \omega \cdot dx \geq 0$$

pour tout δv accroissement admissible du contrôle, avec la fonction $\delta\omega$ solution de

$$(3.6) \quad -\Delta(\delta\omega) = \frac{dh^{**}}{ds}(\bar{u}) \cdot \delta v, \quad \delta\omega/\Gamma = 0.$$

Pour éliminer $\delta\omega$ dans (3.5) on introduit l'état adjoint

$$(3.7) \quad -\Delta\bar{p} = l(\bar{u}) \frac{\partial b}{\partial t}(x, \bar{\omega}) + \frac{\partial c}{\partial t}(x, \bar{\omega}), \quad \bar{p}/\Gamma = 0.$$

On multiplie (3.6) par \bar{p} et (3.7) par $\delta\omega$; on intègre par parties, ensuite on retranche membre à membre les deux équations obtenues; le résultat obtenu injecté dans (3.5) donne

$$(3.8) \quad \int_{\Omega} [l'(\bar{u})b(x, \bar{\omega}) + h^{**'}(\bar{u}) \cdot \bar{p}] \delta v \cdot dx \geq 0$$

pour tout δv accroissement admissible du contrôle.

PROPOSITION 3.1. *Sous l'hypothèse (3.2) vérifiée par $b(x, t)$, la fonction $b(x, \bar{\omega})$ appartient à $H_{\text{loc}}^2(\Omega)$ et satisfait*

$$(3.9) \quad -\Delta(b(x, \bar{\omega})) \geq \frac{\partial b}{\partial t}(x, \bar{\omega}) \cdot (f(x) + h^{**}(\bar{u})) \text{ dans } \Omega.$$

Démonstration. La fonction $b(x, \bar{\omega})$ appartient à $H^1(\Omega) \cap H_{\text{loc}}^2(\Omega)$: soit une suite $\omega_k \in H_0^1$, régulière convergeant vers $\bar{\omega}$ dans $H_0^1(\Omega) \cap W^{2,4}(\Omega) \cap C(\bar{\Omega})$; nous avons

$$(3.10) \quad -\Delta(b(x, \omega_k)) = - \sum_{i=1}^n E_i(x, \omega_k) - \frac{\partial b}{\partial t}(x, \omega_k) \cdot \Delta\omega_k,$$

où la fonction E_i a pour expression

$$E_i(x, \omega_k) = \frac{\partial^2 b}{\partial t^2}(x, \omega_k) \cdot \left(\frac{\partial \omega_k}{\partial x_i} \right)^2 + 2 \frac{\partial^2 b}{\partial x_i \partial t}(x, \omega_k) \cdot \frac{\partial \omega_k}{\partial x_i} + \frac{\partial^2 b}{\partial x_i^2}(x, \omega_k);$$

par l'hypothèse (3.2) $E_i(x, \omega_k)$ est négative; de plus elle est bornée dans $L^2(\Omega)$. A une sous-suite près, on passe à la limite dans (3.10)

$$-\Delta b(x, \bar{\omega}) = - \frac{\partial b}{\partial t}(x, \bar{\omega}) \cdot \Delta\bar{\omega} + \xi \quad \text{p.p. } x \in \Omega$$

où la fonction ξ est la limite dans $L^2(\Omega)$ faible de $-\sum_{i=1}^n E_i(x, \bar{\omega}_k)$; i.e., en utilisant l'équation d'état de (P^{**})

$$(3.11) \quad -\Delta b(x, \bar{\omega}) = \frac{\partial b}{\partial t}(x, \bar{\omega}) \cdot (f(x) + h^{**}(\bar{u})) + \xi;$$

ce qui entraîne que $b(x, \bar{\omega})$ appartient à $H_{\text{loc}}^2(\Omega)$ et

$$-\Delta b(x, \bar{\omega}) \geq \frac{\partial b}{\partial t}(x, \bar{\omega}) \cdot (f(x) + h^{**}(\bar{u})) \quad \text{dans } \Omega,$$

puisque ξ est positive par l'hypothèse (3.2). \square

Nous sommes maintenant en mesure de démontrer le résultat annoncé pour cette étape.

PROPOSITION 3.2. *On a*

$$h^{**}(\bar{u}(x)) = h(\bar{u}(x)) \quad p.p. \ x \in \Omega.$$

Démonstration. Il suffit de montrer que l'ensemble

$$F = \{x \in \Omega / h^{**}(\bar{u}(x)) < h(\bar{u}(x))\}$$

est de mesure nulle. Si l'on pose

$$F_i = \{x \in F / u(x) \in K_i\}$$

on a

$$F = \bigcup_{i \in I} F_i.$$

Supposons alors qu'il existe $i_0 \in I$ tel que $\text{mes}(F_{i_0}) > 0$; et considérons la fonction

$$S(x) = l_0 \cdot b(x, \bar{\omega}) + \mu_{i_0} \cdot \bar{p}(x) \quad \text{dans } \Omega;$$

elle appartient à $H_{\text{loc}}^2(\Omega)$ d'après (3.7) et la Proposition 3.1.; de plus elle satisfait $-\Delta S > 0$ dans F_{i_0} par (3.4). Ainsi S n'a pas de palier sur F_{i_0} ; ceci entraîne que

$$(3.12a) \quad \text{mes}(\{x \in F_{i_0} / S(x) = t\}) = 0 \quad \forall t \in \mathbb{R}.$$

A l'aide de cette propriété de S , nous allons montrer que $\text{mes}(F_{i_0}) > 0$ est en contradiction avec la condition nécessaire d'optimalité (3.8); pour cela on se donne v dans

$$\mathcal{U}_{i_0} = \left\{ v \in L^\infty(F_{i_0}) / \alpha \leq v \leq \beta, \int_{F_{i_0}} v \, dx = \int_{F_{i_0}} \bar{u} \, dx \right\};$$

le contrôle admissible

$$\tilde{v} = \begin{cases} \bar{u} & \text{sur } \Omega \setminus F_{i_0} \\ v & \text{sur } F_{i_0}, \end{cases}$$

porté dans (3.8) permet d'avoir:

$$(3.12b) \quad \int_{F_{i_0}} S(x)(v - \bar{u}) \, dx \geq 0 \quad \forall v \in \mathcal{U}_{i_0}.$$

On peut supposer par exemple $F_{i_0}^+ = \{x \in F_{i_0} / S(x) \geq 0\}$ de mesure non nulle et connexe, quitte à travailler sur une composante connexe de mesure non nulle; posons

$$G(t) = \{x \in F_{i_0}^+ / S(x) \geq t\} \quad \text{pour } t \geq 0$$

et définissons

$$R(t) = \text{mes}(G(t)) \quad \forall t \geq 0;$$

c'est une fonction continue par (3.12a). Il existe donc $t_0 > 0$ tel que

$$R(t_0) = \text{mes}(G(t_0)) = \frac{k_1 \text{mes}(F_{i_0}^+) - \int_{F_{i_0}^+} u \, dx}{k_1 - k_0},$$

où k_1 et k_0 , ($k_1 > k_0$), représentent les extrémités de K_{i_0} .

Dans le premier membre de (3.12b) prenons le "contrôle admissible" suivant

$$v_0 = \begin{cases} \bar{u} & \text{sur } F_{i_0}^- = F_{i_0} \setminus F_{i_0}^+ \\ k_0 & \text{sur } G(t_0) \\ k_1 & \text{sur } F_{i_0}^+ \setminus G(t_0); \end{cases}$$

et majorons cette intégrale; nous obtenons

$$\int_{F_{i_0}} S(x)(v_0 - \bar{u}) \, dx < t_0 \int_{G(t_0)} (k_0 - \bar{u}) \, dx + t_0 \int_{F_{i_0 \setminus G(t_0)}^+} (k_1 - \bar{u}) \, dx = 0;$$

ceci contredit (3.12b). Donc mes $(F_{i_0}^+) = 0$; de même $F_{i_0}^- = \{x \in F_{i_0} / S(x) < 0\}$ est de mesure nulle; et ainsi s'achève la preuve de la Proposition 3.2 et donc fin de l'étape 1. \square

Etape 2. $(\bar{u}, \bar{\omega})$ est aussi solution de $P(a, b, c, l)$. En effet, la solution $(\bar{u}, \bar{\omega})$ de (P^{**}) satisfait l'équation d'état de (P) :

$$-\Delta \bar{\omega} = f(x) + h(\bar{u}), \quad \bar{\omega}|_{\Gamma} = 0$$

puisque $h(\bar{u}) = h^{**}(\bar{u})$; si l'on note par $\omega_{**} = \omega_{**}(v)$ la solution de l'équation d'état de (P^{**}) correspondant à v , on a

$$J(\bar{u}) \leq \int_{\Omega} l(v)b(x, \omega_{**}) \, dx + \int_{\Omega} c(x, \omega_{**}) \, dx;$$

comme par le principe du maximum $\omega(v) \geq \omega_{**}$, il s'en suit grâce à la croissance de b et c

$$J(\bar{u}) \leq J(v) \quad \forall v \in \mathcal{U}. \quad \square$$

3.2. Enfin pour les deux cas qui restent nous supposons, à la place de (3.1) l'hypothèse

(3.1a) l^{**} est positive et croissante sur $K(l)$.

De plus, nous supposons dans le cas (ii)

(3.13) h est affine.

$$(3.14) \quad \frac{\partial b}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} [l^{**}(s) \cdot (f(x) + h(s))] + \frac{\partial c}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} (f(x) + h(s)) > 0$$

p.p. $x \in \Omega$, $\forall t \in \mathbb{R}$, $\forall s \in K(l)$;

dans le cas (iii)

$$(3.15) \quad K(h) \equiv K(l)$$

$$(3.16) \quad \frac{\partial b}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} [l^{**}(s) \cdot (f(x) + h^{**}(s))] + \frac{\partial c}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} (f(x) + h^{**}(s)) > 0$$

p.p. $x \in \Omega$, $\forall t \in \mathbb{R}$, $\forall s \in K(h) = K(l)$.

Nous avons alors le corollaire suivant.

COROLLAIRE 3.1. *On fait les hypothèses (2.3) à (2.5), (3.2), (3.3) et (3.1a). Alors le problème $P(a, b, c, l)$ admet au moins une solution dans les deux situations suivantes:*

(1) (3.13) et (3.14) ont lieu;

(2) (3.15) et (3.16) ont lieu.

La preuve de ce résultat est identique, dans ses grandes lignes, à celle du Théorème 3.1: si $(\bar{u}, \bar{\omega})$ désigne une solution du problème relâché $P(a^{**}, b, c, l^{**})$ alors la fonction $S = l^{**}(\bar{u}) \cdot b(x, \bar{\omega}) + h^{**}(\bar{u}) \cdot \bar{p}$ est ici également sans palier sur l'ensemble $F = \{x \in \Omega / \bar{u}(x) \in K(l)\}$. La suite de la démonstration demeure inchangée par rapport à celle du Théorème 3.1.

FIG. 1

Exemple 3.1.

$$\begin{aligned}
 b(x, t) &= t, \quad c(x, t) \equiv 0, \quad f(x) \equiv 0, \\
 K(h) &= K(l) =]k_1, k_2[\\
 -\Delta \omega &= h(v) \quad \text{dans } \Omega, \quad h(v) \geq 0 \quad \text{sur } [\alpha, \beta], \\
 \omega/\Gamma &= 0, \\
 J(v) &= \int_{\Omega} l(v) \cdot \omega \, dx;
 \end{aligned}$$

(cf. Fig. 1). La condition de positivité (3.16) devient:

$$\frac{d}{ds} (l^{**}(s) \cdot h^{**}(s)) > 0 \quad \text{sur }]k_1, k_2[.$$

Et si par exemple $h = l > 0$, la condition ci-dessus se réduit à $dl^{**}/ds(s) > 0$ sur $]k_1, k_2[$.

Remarque 3.2. Le Théorème 3.1 demeure valide si l'on suppose (3.4) < 0 a condition de modifier convenablement les autres hypothèses pour avoir $-\Delta S < 0$, i.e., S sans palier.

4. Contrôle bang-bang. Dans cette partie on suppose toujours α et β constants; et on fait les hypothèses suivantes:

$$\begin{aligned}
 (4.1) \quad h(v) &\geq H(v) = \theta_1 \cdot v + \delta_1, \quad \forall v \in [\alpha, \beta] \\
 h(\alpha) &= H(\alpha), \quad h(\beta) = H(\beta),
 \end{aligned}$$

$$\begin{aligned}
 (4.2) \quad l(v) &\geq L(v) = \theta_2 \cdot v + \delta_2, \quad \forall v \in [\alpha, \beta] \\
 l(\alpha) &= L(\alpha), \quad l(\beta) = L(\beta), \quad \theta_2 > 0
 \end{aligned}$$

$$\begin{aligned}
 (4.3) \quad \frac{\partial b}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} [L(s) \cdot (f(x) + H(s))] &+ \frac{\partial c}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} (f(x) + H(s)) > 0 \\
 \text{p.p. } x \in \Omega, \quad \forall t \in \mathbb{R}, \quad \forall s \in [\alpha, \beta].
 \end{aligned}$$

Nous avons le résultat suivant.

THÉORÈME 4.1. *On suppose les hypothèses (4.1)–(4.3), (2.3)–(2.5), (3.2), et (3.3). Alors le problème $P(a, b, c, l)$ possède au moins une solution optimale $(\bar{u}, \bar{\omega} = \omega(\bar{u}))$. De plus cette solution possède la propriété bang-bang; de façon plus précise si l'on pose*

$$S(x) = \theta_2 \cdot b(x, \bar{\omega}) + \theta_1 \cdot \bar{p}(x) \quad \forall x \in \Omega,$$

\bar{p} étant l'état adjoint associé à $\bar{\omega}$, il existe $t > 0$ tel que le contrôle optimal \bar{u} s'écrit

$$(4.3a) \quad \bar{u} = \begin{cases} \alpha & \text{sur } \Omega_\alpha \\ \beta & \text{sur } \Omega_\beta = \Omega \setminus \Omega_\alpha \end{cases}$$

où

$$\Omega_\alpha = \{x \in \Omega / S(x) \geq t\}.$$

Démonstration. Le problème relaxé $P(a^{**}, b, c, l^{**})$ possède au moins une solution optimale $(\bar{u}, \bar{\omega} = \omega(\bar{u}))$. Comme dans la preuve du Théorème 3.1 on montre que la fonction $S = \theta_2 \cdot b(x, \bar{\omega}) + \theta_1 \cdot \bar{p}$ est sans palier sur tout Ω ; ce qui entraîne que \bar{u} est de la forme (4.3a) en vertu de la condition d'optimalité

$$\int_{\Omega} S(x)(v - \bar{u}) \, dx \geq 0 \quad \forall v \in \mathcal{U}.$$

La propriété bang-bang de \bar{u} et les hypothèses (4.1) et (4.2) entraînent que $(\bar{u}, \bar{\omega})$ est solution optimale de $P(a, b, c, l)$ en vertu du principe du maximum et de la croissance de b et c .

Remarque 4.1. Le résultat précédent reste valable si l'on remplace \mathcal{U} donné en (1.1) par l'ensemble non convexe

$$\mathcal{U}' = \left\{ v \in L^\infty(\Omega) / \alpha \leq v \leq \beta, \int_{\Omega} g(v) \, dx = \gamma \right\}$$

où g est, par exemple, une fonction convexe, pour simplifier, strictement monotone, après quelques modifications naturelles en (4.3).

Pour illustrer cette remarque donnons un exemple.

Exemple 4.1.

$$-\Delta \omega = v$$

$$\omega|_{\partial\Omega} = 0 \quad \text{dans } \Omega, \quad J(v) = \int_{\Omega} v \cdot \omega \, dx$$

où v appartient

$$\mathcal{U} = \left\{ v \in L^\infty(\Omega) / v(x) \in \{\alpha, \beta\} \text{ p.p. } x \in \Omega \text{ et } \int_{\Omega} k(v) \, dx = \gamma \right\}$$

qu'on suppose non vide; k est une fonction strictement croissante de $[\alpha, \beta]$ dans \mathbb{R}^+ telle que son graphe soit en-dessous de la corde joignant les deux points $(\alpha, k(\alpha))$ et $(\beta, k(\beta))$. On fait un changement de fonction contrôle $V = k(v)$. Le problème devient:

$$-\Delta \omega = k^{-1}(V) \quad \text{dans } \Omega,$$

$$\omega|_{\partial\Omega} = 0, \quad J(V) = \int_{\Omega} k^{-1}(V) \cdot \omega \, dx,$$

$$\mathcal{U}' = \left\{ V \in L^\infty(\Omega) / V(x) \in \{k(\alpha), k(\beta)\} \text{ p.p. } x \in \Omega, \text{ et } \int_{\Omega} V \, dx = \gamma \right\}.$$

Il est alors aisé de vérifier que les conditions du Théorème 4.1 sont réunies.

Le résultat du Théorème 4.1 nous amène à la question naturelle: les hypothèses (4.1) et (4.2) sont-elles nécessaires pour que $P(a, b, c, l)$ admette un contrôle optimal bang-bang?

La réponse sera positive si l'on modifie quelque peu la condition de positivité (3.16): on la suppose vraie pour tout $s \in [\alpha, \beta]$, i.e.,

$$(4.4a) \quad \frac{\partial b}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} [l^{**}(s) \cdot (f(x) + h^{**}(s))] + \frac{\partial c}{\partial t}(x, t) \cdot \frac{\partial}{\partial s} (f(x) + h^{**}(s)) > 0 \\ \text{p.p. } x \in \Omega, \quad \forall t \in \mathbb{R}, \quad \forall s \in [\alpha, \beta];$$

si aucune des deux fonctions l et h n'est affine, on suppose que l'on a de plus

$$(4.4b) \quad K(h) \equiv K(l).$$

THÉORÈME 4.2. *On suppose que la fonction b est strictement positive et on fait les hypothèses (2.4), (2.5), (3.2), (3.3), et (4.4). Alors, (4.1) et (4.2) forment une condition nécessaire et suffisante d'existence d'un contrôle optimal bang-bang.*

Démonstration. (i) la condition suffisante résulte du Théorème 4.1.

(ii) Pour montrer que (4.1) et (4.2) sont nécessaires, nous raisonnerons par l'absurde. D'après le Corollaire (3.1) le problème $P(a, b, c, l)$ admet au moins une solution $(\bar{u}, \bar{\omega})$; supposons, par exemple, que (4.2) ne soit pas vrai, i.e.,

$$(4.5) \quad l^{**'}(\alpha) < l^{**'}(\beta)$$

et que \bar{u} soit bang-bang; $(\bar{u}, \bar{\omega})$ satisfait la condition d'optimalité

$$\int_{\Omega} S(x)(v - \bar{u}) dx \geq 0 \quad \forall v \in \mathcal{U},$$

où

$$S = l^{**'}(\bar{u}) \cdot b(x, \bar{\omega}) + h^{**'}(\bar{u}) \cdot \bar{p}.$$

Cette condition peut aussi s'écrire

$$(4.6) \quad S(x) \cdot v + \mu v \geq S(x)\bar{u}(x) + \mu \cdot \bar{u}(x) \\ \text{p.p. } x \in \Omega, \quad \forall v \in [\alpha, \beta]$$

où μ est un multiplicateur de Lagrange. Mais puisque $S(x)$ est sans palier par (4.4), on peut montrer qu'il existe t_0 tel que

$$\bar{u}(x) = \begin{cases} \alpha & \text{sur } \Omega_{\alpha} \\ \beta & \text{sur } \Omega_{\beta} \end{cases}$$

où

$$\Omega_{\alpha} = \{x \in \Omega / S(x) > t_0\}$$

$$\Omega_{\beta} = \{x \in \Omega / S(x) \leq t_0\}$$

et par conséquent (4.6) entraîne les deux inégalités

$$(4.7) \quad l^{**'}(\alpha)b(x, \bar{\omega}(x)) + \theta \bar{p}(x) + \mu \geq 0 \quad \text{p.p. } x \in \Omega_{\alpha},$$

$$(4.8) \quad l^{**'}(\beta)b(x, \bar{\omega}(x)) + \theta \bar{p}(x) + \mu \leq 0 \quad \text{p.p. } x \in \Omega_{\beta} = \Omega \setminus \Omega_{\alpha}$$

où $\theta = h^{**'}(\alpha) = h^{**'}(\beta)$. A l'aide de (4.5) majorons l'inégalité (4.7) et minorons (4.8), en utilisant la stricte positivité de b :

$$\forall \delta \in [l^{**'}(\alpha), l^{**'}(\beta)], \quad \delta \cdot b(x, \bar{\omega}(x)) + \theta \cdot \bar{p}(x) + \mu \geq 0 \quad \text{dans } \Omega_{\alpha}$$

$$\forall \delta \in [l^{**'}(\alpha), l^{**'}(\beta)], \quad \delta \cdot b(x, \bar{\omega}(x)) + \theta \cdot \bar{p}(x) + \mu \leq 0 \quad \text{dans } \Omega_{\beta}.$$

Ceci entraîne que l'une des deux fonctions $\bar{\omega}$ et \bar{p} n'est pas continue; d'où la contradiction. Si (4.1) n'a pas lieu ou si (4.1) et (4.2) n'ont pas lieu le raisonnement demeure inchangé. \square

Exemple 4.2.

$$-\Delta\omega = v \quad \text{dans } \Omega,$$

$$\omega|_{\partial\Omega} = 0, \quad J(v) = \int_{\Omega} l(v) \cdot \omega \, dx + \int_{\Omega} \omega^2 \, dx,$$

où $l(v)$ est une fonction convexe positive strictement croissante sur $[\alpha, \beta]$. Il est clair que dans ce cas la condition de positivité (4.4.a) est satisfaite. L'ensemble admissible \mathcal{U} étant toujours donné par (1.1), on suppose γ tel que

$$\int_{\Omega} \alpha \, dx < \gamma < \int_{\Omega} \beta \, dx.$$

D'après le théorème (3.1) il existe \bar{u} appartenant à \mathcal{U} tel que

$$J(\bar{u}) \leq J(v) \quad \forall v \in \mathcal{U}.$$

Le Théorème 4.2 entraîne que

$$|\{x \in \Omega / \alpha < \bar{u}(x) < \beta\}| > 0;$$

i.e., que la solution \bar{u} n'est pas bang-bang.

Par contre si l'on supprime, dans \mathcal{U} , la condition sur la masse $\int_{\Omega} v \, dx = \gamma$, le problème

$$\inf [J(v) / v \in L^{\infty}(\Omega), v(x) \in [\alpha, \beta] \text{ p.p.}]$$

admet l'unique solution $u_0 = \alpha$; et ce problème est identique au suivant

$$\inf [J(v) / v(x) \in \{\alpha, \beta\} \text{ p.p.}].$$

Cet exemple montre que la condition de masse fixée $\int_{\Omega} v \, dx = \gamma$, absente dans [3], joue ici un rôle important dans l'existence (cf. Théorème 3.1) ou la non existence d'un contrôle optimal bang-bang. C'est sa présence qui nécessite les différentes conditions de positivité de type (3.4), (4.4), etc. Dans [3] si l'on introduit la condition de masse, les résultats obtenus ne semblent pas s'adapter (tout au moins de façon immédiate).

5. Un ensemble de contrôle plus général. Dans ce paragraphe on choisit α et β constants, $a(x, s, t) = f(x) + h(s)$ qu'on suppose positive pour simplifier, et h et l affines. Pour la commodité du lecteur rappelons, pour toute fonction k positive mesurable de Ω dans \mathbb{R} , les définitions classiques suivantes [9], [10].

DÉFINITIONS 5.1. (1) Pour tout mesurable E de Ω , $|E|$ désigne la mesure de Lebesgue de E .

(2) La fonction de distribution de k est la fonction δ_k de \mathbb{R} dans $[0, |\Omega|]$, définie par

$$\delta_k(t) = |\{x \in \Omega / k(x) < t\}|.$$

(3) Le réarrangement croissant (unidimensionnel) de k est la fonction notée k_* de $[0, |\Omega|]$ dans \mathbb{R} telle que

$$(5.1) \quad \begin{aligned} k_*(s) &= \inf \{t \in \mathbb{R} / \delta_k(t) > s\} \text{ si } s \in [0, |\Omega|[, \\ k_*(|\Omega|) &= \sup_{\Omega} \text{ess } k. \end{aligned}$$

(4) Le réarrangement décroissant (unidimensionnel) de k est défini par

$$(5.2) \quad k^*(s) = k_*(|\Omega| - s) \text{ p.p. } s.$$

(5) On appelle ensemble de niveau ou ensemble équipotentiel de k tout sous-ensemble de Ω du type

$$E_1(t) = \{x \in \Omega / k(x) > t\}, \quad t \in \mathbb{R}$$

ou

$$E_2(t) = \{x \in \Omega / k(x) < t\}, \quad t \in \mathbb{R}$$

avec éventuellement des inégalités au sens large. Et nous désignerons par “courbes ou lignes de niveau” de k les ensembles tels que

$$E_3(t) = \{x \in \Omega / k(x) = t\}, \quad t \in \mathbb{R}.$$

(6) k est dit sans palier si $|\{x \in \Omega / k(x) = t\}| = 0 \quad \forall t \in \mathbb{R}$. Etant donnée une fonction croissante u_0 définie sur $[0, |\Omega|]$, telle que

$$0 < \alpha \leq u_0(s) \leq \beta \quad \text{p.p. } s \in [0, |\Omega|],$$

on introduit, à la place de (1.1), l'ensemble des contrôles admissibles suivant:

$$(5.3) \quad \mathcal{U} = \{v \in L^\infty(\Omega) / \alpha \leq v \leq \beta, v_* = u_0\}.$$

Et on se propose de résoudre le problème $P(a, b, c, l)$ qui, rappelons-le, consiste à trouver \bar{u} dans \mathcal{U} satisfaisant

$$J(\bar{u}) = \inf \{J(v), v \in \mathcal{U}\},$$

où

$$J(v) = \int_{\Omega} l(v)b(x, \omega) dx + \int_{\Omega} c(x, \omega) dx$$

et ω la fonction état solution de

$$-\Delta \omega = f(x) + h(v), \quad \omega / \partial \Omega = 0.$$

Nous avons le résultat suivant.

THÉORÈME 5.1. *On suppose réalisées les conditions suivantes: (2.3), (3.2), (4.4a) et (5.3), h affine croissante et l affine croissante positive. Alors le problème $P(a, b, c, l)$ possède une solution optimale $(\bar{u}, \bar{\omega} = \omega(\bar{u}))$. De plus cette solution possède les propriétés suivantes:*

(1) $\bar{\omega}$ et \bar{u} ont “les mêmes ensembles équipotentiels” au sens suivant: tout $t > 0$ il existe $s = s(t)$ tel que

$$\{x \in \Omega / \bar{u}(x) < s\} \subseteq \{x \in \Omega / l'(\bar{u})b(x, \bar{\omega}) + h'(\bar{u})\bar{p} \geq t\} \subseteq \{x \in \Omega / \bar{u}(x) \leq s\},$$

où \bar{p} désigne l'état adjoint associé à $\bar{\omega}$.

(2) \bar{u} est fonction décroissante de $l'(\bar{u})b(x, \bar{\omega}) + h'(\bar{u})\bar{p}$; de façon plus précise \bar{u} satisfait la relation

$$\bar{u} = \phi(l'(\bar{u})b(x, \bar{\omega}) + h'(\bar{u})\bar{p})$$

où

$$\phi(t) = u_0([l'(\bar{u})b(x, \bar{\omega}) + h'(\bar{u})\bar{p}]^*)^{-1}(t).$$

Démonstration. L'ensemble \mathcal{U} n'étant pas convexe, on se propose de relaxer le problème (P) en remplaçant \mathcal{U} par

$$\begin{aligned} \tilde{\mathcal{U}} = \left\{ v \in L^\infty(\Omega) / \alpha \leq v \leq \beta, \int_0^t v_*(s) ds \geq \int_0^t u_0(s) ds, \right. \\ \left. \forall t \in [0, |\Omega|], \text{ et } \int_0^{|\Omega|} v_*(s) ds = \int_0^{|\Omega|} u_0(s) ds \right\}; \end{aligned}$$

cet ensemble est convexe puisqu'il s'écrit:

$$\tilde{\mathcal{U}} = \left\{ v \in L^\infty(\Omega) / \alpha \leq v \leq \beta, \int_E v(x) dx \geq \int_0^{|E|} u_0(s) ds, \right. \\ \left. \forall \text{ mesurable } E \subseteq \Omega, \text{ et } \int_\Omega v(x) dx = \int_0^{|\Omega|} u_0(s) ds \right\}.$$

Le problème ainsi obtenu sera noté (\tilde{P}) . D'après le résultat de Migliaccio [11],² $\tilde{\mathcal{U}}$ est la fermeture de \mathcal{U} pour la topologie $\sigma(L^\infty, L^1)$. Donc (\tilde{P}) possède une solution $(\bar{u}, \bar{\omega})$; et on se propose de montrer que $(\bar{u}, \bar{\omega})$ est aussi solution de (P) , i.e., que \bar{u} appartient à \mathcal{U} .

Pour cela, nous partons de la relation d'extrémalité

$$(5.4) \quad \int_\Omega [l'(\bar{u})b(x, \bar{\omega}) + h'(\bar{u})\bar{p}](v - \bar{u}) dx \geq 0, \quad \forall v \in \tilde{\mathcal{U}},$$

où \bar{p} , défini par (3.7), représente l'état adjoint associé à $\bar{\omega}$; et on applique l'inégalité de Hardy-Littlewood:

$$(5.5) \quad \int_\Omega S(x)v(x) dx \geq \int_\Omega S(x)\bar{u}(x) dx \geq \int_0^{|\Omega|} S^*(s) \cdot \bar{u}_*(s) ds,$$

où, pour alléger les notations, nous avons posé

$$S = l'(\bar{u})b(x, \bar{\omega}) + h'(\bar{u})\bar{p}.$$

L'inégalité

$$A(t) = \int_0^t \bar{u}_*(s) ds \geq \int_0^t u_0(s) ds = A_0(t)$$

nous permet de minorer le dernier membre de (5.5) en effectuant deux intégrations par parties:

$$\int_0^{|\Omega|} S^*(s) \cdot \bar{u}_*(s) ds = S^*(|\Omega|) \cdot A(|\Omega|) - \int_0^{|\Omega|} \frac{dS^*(s)}{ds} A(s) ds \\ \geq S^*(|\Omega|) \cdot A_0(|\Omega|) - \int_0^{|\Omega|} \frac{dS^*(s)}{ds} A_0(s) ds$$

puisque $A(|\Omega|) = A_0(|\Omega|)$; d'où, après la deuxième intégration par parties:

$$(5.6) \quad \int_0^{|\Omega|} S^*(s) \cdot \bar{u}_*(s) ds \geq \int_0^{|\Omega|} S^*(s) \cdot u_0(s) ds.$$

D'après la proposition (3.1) et la condition de positivité (4.4a), la fonction $S(x)$ est continue sans palier; ce qui permet d'introduire

$$\phi(t) = u_0((S^*)^{-1})(t), \quad \psi(t) = t \cdot \phi(t);$$

cette définition de ϕ et l'équimesurabilité de $\psi(S(x))$ et $\psi(S^*(s))$ permettent de transformer (5.6) en

$$(5.7) \quad \int_0^{|\Omega|} S^*(s) \cdot \bar{u}_*(s) ds \geq \int_0^{|\Omega|} S^*(s) \cdot u_0(s) ds = \int_0^{|\Omega|} \psi(S^*(s)) ds \\ = \int_\Omega \psi(S(x)) dx.$$

² On peut également se reporter à [12].

Et on compare (5.7) avec les inégalités (5.5) dans lesquelles on remplace v par le contrôle admissible $\phi(S(x))$; on obtient la série d'égalités:

$$\begin{aligned} \int_{\Omega} S(x) \cdot \phi(S(x)) \, dx &= \int_{\Omega} S(x) \cdot \bar{u}(x) \, dx = \int_0^{|\Omega|} S^*(s) \cdot \bar{u}_*(s) \, ds \\ &= \int_0^{|\Omega|} S^*(s) \cdot u_0(s) \, ds. \end{aligned}$$

La dernière inégalité entraîne que $\bar{u}_* = u_0$ et la deuxième que S et \bar{u} ont les "mêmes ensembles équipotentiels," i.e., pour tout $t > 0$ il existe $s = s(t)$ tel que

$$\{x \in \Omega / \bar{u}(x) < s\} \subseteq \{x \in \Omega / S(x) \geq t\} \subseteq \{x \in \Omega / \bar{u}(x) \leq s\}.$$

Et enfin il est clair que $\bar{u}(x) = \phi(S(x))$ avec ϕ décroissante. \square

Abordons maintenant la question de l'unicité. Signalons tout d'abord qu'elle reste posée dans le cas général; et que nous ne disposons que d'une réponse très partielle donnée par le théorème suivant.

THÉORÈME 5.2. *On suppose les hypothèses du Théorème 5.1. Alors si l'ensemble des contrôles optimaux de (\tilde{P}) est convexe, (P) admet une solution unique.*

Démonstration. Une conséquence de la preuve du Théorème 5.1 est que toute solution de (P) est aussi solution de (\tilde{P}) , i.e., que les deux problèmes sont identiques; soit u_1 et u_2 deux contrôles optimaux de (\tilde{P}) ; par hypothèse $\theta u_1 + (1 - \theta)u_2$ est aussi contrôle optimal de (\tilde{P}) pour tout $\theta \in]0, 1[$; donc $\theta u_1 + (1 - \theta)u_2$ appartenant à \mathcal{U} pour tout θ , i.e.,

$$(\theta u_1 + (1 - \theta)u_2)_* = u_0.$$

Ceci entraîne $u_1 = u_2$. En effet, soit k une fonction régulière strictement convexe; on a par équimesurabilité

$$\int_{\Omega} k(\theta u_1 + (1 - \theta)u_2) \, dx = \int_0^{|\Omega|} k(u_0) \, ds \quad \forall \theta \in]0, 1[;$$

d'où

$$\frac{d}{d\theta} \int_{\Omega} k(\theta u_1 + (1 - \theta)u_2) \, dx = 0;$$

ce qui donne

$$\int_{\Omega} (k'(u_1) - k'(u_2))(u_1 - u_2) \, dx = 0,$$

i.e., $u_1 = u_2$. \square

Exemple 5.1 (Unicité). $f = 0$, $h(v) = v$, $b(x, t) = 0$, et $c(x, t)$ strictement croissante et convexe en t à x fixé:

$$-\Delta \omega = v, \quad \omega|_{\partial\Omega} = 0,$$

$$J(v) = \int_{\Omega} c(x, \omega) \, dx.$$

Exemple 5.2 (Contrôle de domaine). Etant données trois constantes $0 < \alpha = \alpha_1 < \alpha_2 < \alpha_3 = \beta$, on considère l'ensemble des contrôles admissibles suivant:

$$U = \left\{ D = (D_1, D_2, D_3), \text{ mesurable } \subset \Omega^3 / |D_i| = \gamma_i, D_i \cap D_j = \emptyset \text{ si } i \neq j, \bigcup_{i=1,3} D_i = \Omega \right\};$$

et on se pose le problème

$$(\pi) \quad \begin{aligned} -\Delta \omega_D &= v_D, & \omega_{D/\partial\Omega} &= 0, \\ \inf \{J(D), D \in U\}, \end{aligned}$$

où

$$v_D(x) = \alpha_i \quad \text{si } x \in D_i \quad i = 1, 2, 3,$$

et

$$J(D) = \int_{\Omega} v_D \cdot \omega_D dx.$$

Ce problème est équivalent à (P) puisque pour tout $D \in U$, $(v_D)_* = u_0$ qui est défini par

$$u_0(s) = \begin{cases} \alpha_1 & \text{si } 0 \leq s < \gamma_1, \\ \alpha_2 & \text{si } \gamma_1 \leq s < \gamma_1 + \gamma_2, \\ \alpha_3 & \text{si } \gamma_1 + \gamma_2 \leq s < \gamma_1 + \gamma_2 + \gamma_3 = |\Omega|. \end{cases}$$

Par conséquent, il existe $t_1 > 0$ et $t_2 > 0$ tels que (π) admet une solution $D^0 = (D_1^0, D_2^0, D_3^0)$ caractérisé par

$$D_1^0 = \{x \in \Omega / \omega_{D^0}(x) > t_1\},$$

$$D_2^0 = \{x \in \Omega / t_1 \leq \omega_{D^0}(x) > t_2\},$$

$$D_3^0 = \{x \in \Omega / t_2 \leq \omega_{D^0}(x)\}.$$

6. Applications.

6.1. Rigidité maximale à la torsion. On considère une poutre P creuse. (Cf. Fig. 2) Le creux est représenté par Ω_0 un ouvert fixé. L'aire de la section droite Σ de P étant fixée égale à β , il s'agit de trouver un contour déterminant Σ pour que la rigidité de P soit maximale si elle était soumise à des forces de torsion. Il s'agit là d'un problème typique d'optimisation de forme. Nous allons montrer que l'on peut appliquer

FIG. 2

les idées du § 4 que nous avons mises en oeuvre dans un cadre général. Ce problème a été considéré par divers auteurs; citons par exemple [26], [21], [20]. Et très récemment une étude en est faite avec une approche différente de la nôtre dans [20].

Nous supposons que la section droite du matériau occupe l'ouvert Σ et que le matériau est homogène, isotrope. Nous renvoyons à ([23], [26]) pour la présentation du modèle mécanique. La fonction contrainte u satisfait les équations suivantes:

$$(6.1) \quad \begin{aligned} -\Delta u &= 2 \quad \text{dans } \Sigma, \\ u/\partial\Sigma &= 0, \quad u/\Gamma_0 = c, \\ -\int_{\Gamma_0} \frac{\partial u}{\partial n} d\sigma &= 2\beta_0 \end{aligned}$$

où c est une constante inconnue, $\beta_0 = |\Omega_0|$ l'aire du trou et $|\Sigma| = \beta$ l'aire de la section du matériau.

La rigidité de torsion de P de section Σ a pour expression:

$$(6.2) \quad K(R, \Sigma) = \int_{\Sigma} |\nabla u|^2 dx = 2 \int_{\Sigma} u dx + 2cA_0$$

que nous noterons $K(\Sigma)$ sauf mention du contraire; la fonction $u = u_{\Sigma}$ est la solution de (6.1). Il s'agit de trouver un ouvert Σ tel que

$$(P) \quad K(\Sigma) \geq K(\Sigma')$$

pour tout Σ' ayant les caractéristiques énoncées précédemment. Ce problème entre dans notre cadre d'étude. En effet on plonge Ω_0 dans un "grand ouvert" $\tilde{\Omega} - (|\tilde{\Omega}| \gg A)$ — par exemple une boule $B(O, R) = B$ (Cf. Fig. 3), et on considère le problème de contrôle suivant:

(i) ensemble des contrôles admissibles:

$$(6.3) \quad \mathcal{U} = \left\{ v \in L^{\infty}(\Omega) / 0 \leq v \leq 1, \int_{\Omega} v dx = A \right\}.$$

On prolonge les éléments de \mathcal{U} à Ω_0 par la valeur 1.

FIG. 3

(ii) La fonction coût:

$$(6.4) \quad J(v) = \int_{\Omega} v \cdot \omega_v dx + 2c_v \cdot A_0$$

où $\omega = \omega_v$ désigne l'état du système, solution de l'équation d'état suivante:

(iii) équation d'état:

$$(6.5) \quad -\Delta \omega = 2v \quad \text{dans } B \setminus \Omega_0 = \Omega$$

$$(6.5) \quad \omega / \Gamma_0 = c, \quad c = \text{constante inconnue}$$

$$\omega / \partial B = 0, \quad \int_{\Gamma_0} \frac{\partial \omega}{\partial \eta} d\sigma = 2 \int_{\Omega_0} v dx = 2\beta_0.$$

Notre problème se formule alors comme suit: trouver $(\bar{v}, \bar{\omega} = \omega_{\bar{v}})$ tel que

$$(6.6) \quad J(\bar{v}) \leq J(v) \quad \forall v \in \mathcal{U}.$$

Remarque. L'unique solution de (6.5) est caractérisée par

$$(6.7) \quad \frac{1}{2} \int_B |\nabla \omega_v|^2 dx - 2 \int_B v \omega_v dx \leq \frac{1}{2} \int_B |\nabla \omega|^2 dx - 2 \int_B v \omega dx$$

pour tout ω dans V où V est l'espace suivant:

$$(6.8) \quad V = \{\omega \in H_0^1(B(0, R)) / \omega = \text{constante sur } \Omega_0\}.$$

Pour l'existence de ce problème on pourra consulter [23].

Pour éviter de se répéter et alourdir notre rédaction, nous ne présenterons pas le détail du résultat d'existence: le lecteur vérifiera que les résultats énoncés dans le cas général sont applicables ici. Il existe une solution optimale $(\bar{v}, \bar{\omega} = \omega_{\bar{v}})$ dont le contrôle \bar{v} est caractérisé par la condition d'optimalité suivante:

$$(6.9) \quad \int_{\Omega} \bar{\omega} \cdot (v - \bar{v}) dx \leq 0 \quad \forall v \in \mathcal{U},$$

condition qui entraîne que \bar{v} possède la propriété bang-bang, propriété qui a été abordée dans un cadre général au § 4. De plus il existe un réel \bar{t} tel que l'ensemble

$$(6.10) \quad \Sigma = \Sigma_{\bar{t}} = \{x \in B(0, R) / \bar{\omega}(x) > \bar{t}\}$$

et le contrôle \bar{v} vérifient:

$$(6.11) \quad \bar{v} = \begin{cases} 1 & \text{sur } \Sigma, \\ 0 & \text{sur } B(0, R) \setminus \bar{\Sigma}; \end{cases}$$

l'optimalité de $(\bar{\omega}, \bar{v})$ entraîne:

$$(6.12) \quad J(\bar{v}) = \frac{1}{2} \int_B |\nabla \bar{\omega}|^2 dx - 2 \int_B \bar{v} \cdot \bar{\omega} \leq \frac{1}{2} \int_B |\nabla \omega|^2 dx - 2 \int_B v \cdot \omega \quad \forall v \in \mathcal{U}, \forall \omega \in V.$$

La question importante qui se pose alors est la suivante: Comment retrouver la formulation initiale de notre problème, autrement dit a-t-on résolu le problème initial?

Nous avons le résultat suivant.

THÉORÈME 6.1. *Si l'on suppose que β est assez petit, alors il existe $\Sigma = \Sigma_R$ ouvert entourant Ω_0 , et une fonction ω_R satisfaisant (6.1) et tels que*

$$K_R = K(\Sigma_R) = \int_{\Sigma_R} |\nabla \omega_R|^2 dx \geq K(\Sigma')$$

pour tout ouvert Σ' satisfaisant $|\Sigma'| = A$, $\Sigma' \subset B(0, R) \setminus \Omega_0$.

Remarque. Nous montrons dans [30] que $c_{\bar{v}} \geq t$; ce qui entraîne que Σ_R entoure Ω_0 . Egalement nous montrons que Σ_R est une couronne simplement connexe.

Démonstration. Il s'agit de construire une fonction état et un contrôle tests utilisables dans le problème de contrôle classique. Considérons les deux problèmes suivants

$$\begin{aligned} -\Delta \omega' &= 2 & \text{dans } \theta = \Omega' \setminus \bar{\Omega}_0, \\ \omega' / \Gamma_0 &= c', & - \int_{\Gamma_0} \frac{\partial \omega'}{\partial \eta} d\sigma = 2\beta_0, \\ \omega' / \partial_1 \theta &= 0; \end{aligned}$$

et

$$\begin{aligned} -\Delta \hat{\omega} &= 0 & \text{dans } B \setminus \bar{\Omega}' \\ \hat{\omega} / \partial_1 \theta &= t', & \hat{\omega} / \partial B = 0 \end{aligned}$$

où t' est un réel qui sera précisé ultérieurement (Cf. Fig. 4).

Et définissons le couple admissible suivant (v_1, ω_1) :

$$\begin{aligned} \omega_1 &= \begin{cases} c' + t' & \text{sur } \Omega_0, \\ \omega' + t' & \text{sur } \theta, \\ \hat{\omega} & \text{sur } B \setminus \bar{\Omega}'; \end{cases} \\ v_1 &= \begin{cases} 1 & \text{sur } \Omega' \\ 0 & \text{sur } B \setminus \bar{\Omega}'. \end{cases} \end{aligned}$$

On utilise ce couple (v_1, w_1) comme fonction test dans (6.12). Après quelques calculs élémentaires on obtient

$$\begin{aligned} (6.13) \quad & \frac{1}{2} \int_{\Sigma} |\nabla(\bar{\omega} - \bar{t})|^2 dx - 2 \int_{\Sigma} (\bar{\omega} - \bar{t}) dx - 2(\bar{c} - \bar{t})\beta_0 - \Delta(t') \\ & \cong \int_{\theta} |\nabla \omega'|^2 dx - 2 \int_{\theta} \omega' dx - 2c'\beta_0 \end{aligned}$$

pour tout $t' > 0$, où

$$\Delta(t') = \frac{1}{2} \int_{B \setminus \bar{\Sigma}} |\nabla \bar{\omega}|^2 - 2\bar{t}(\beta + \beta_0) - \frac{1}{2} \int_{B \setminus \bar{\Omega}'} |\nabla \hat{\omega}|^2 dx + 2t'(\beta + \beta_0).$$

Remarquons que si l'on suppose qu'il existe t' tel que l'on ait

$$(6.14) \quad \Delta(t') \geq 0,$$

FIG. 4

alors Σ est le domaine optimal cherché, i.e., que (6.13) devient:

$$K(\Sigma) = \int_{\Sigma} |\nabla(\bar{\omega} - \bar{t})|^2 dx \cong \int_{\theta} |\nabla \omega'|^2 dx = K(\Omega')$$

prouvant ainsi que $(\bar{\omega} - \bar{t}, \Sigma)$ est la solution cherchée.

Si l'on suppose, par exemple, que β est assez petit et que les oscillations éventuelles de toute suite de domaines optimisants sont locales, i.e., ne partent pas à l'infini, alors on montre dans [30] que le résultat (6.14) a lieu.

Remarque. Des résultats qualitatifs concernant ce problème seront donnés dans [30].

6.2. Fluide parfait incompressible. On considère un fluide parfait incompressible non soumis à des forces extérieures, occupant un ouvert connexe Ω du plan R^2 (cf. Fig. 5).

Nous nous intéressons aux solutions de l'équation d'Euler stationnaire. Désignons par u la vitesse d'une particule du fluide dans la position (x, y) ; l'incompressibilité se traduit par

$$\operatorname{div} u = 0 \text{ (conservation de la masse).}$$

Il existe des principes variationnels relatifs aux équations d'Euler stationnaires ([27]) (cf. également [29], [31]): les solutions des équations

$$(6.15) \quad \begin{aligned} -u_1 \frac{\partial u_1}{\partial x} - u_2 \frac{\partial u_1}{\partial y} &= \frac{\partial p}{\partial x} \\ -u_1 \frac{\partial u_2}{\partial x} - u_2 \frac{\partial u_2}{\partial y} &= \frac{\partial p}{\partial y} \end{aligned}$$

$$\vec{u} \cdot \vec{n} / \Gamma = 0 \text{ condition de glissement}$$

où p désigne la pression, sont des éléments qui maximisent ou minimisent l'énergie cinétique: [27], [36]

$$E = E(u) = \frac{1}{2} \int_{\Omega} |u|^2 dx.$$

Il faut alors préciser la classe de fonctions sur laquelle on cherche à minimiser ou maximiser E . Pour cela on fait la remarque suivante: ([36], [31]) dans le cas instationnaire entre deux instants t_1 et t_2 la vorticit  du fluide

$$\omega = \operatorname{rot} u$$

FIG. 5

a un réarrangement fixé. Ce qui définit la nouvelle contrainte:

$$\min \{E(u)/\operatorname{div} u = 0, \text{réarrangement } \omega = v_0: \text{fixé}\}.$$

Transformons quelque peu ce problème: dans \mathbf{R}^2 la condition de conservation de la masse permet d'introduire une fonction courant φ définie à une constante près par

$$\frac{\partial \varphi}{\partial y} = u_1, \quad -\frac{\partial \varphi}{\partial x} = u_2.$$

Nous avons

$$\begin{aligned} \omega &= -\Delta \varphi \\ E &= \frac{1}{2} \int_{\Omega} |\nabla \varphi|^2 dx; \end{aligned}$$

et notre problème s'écrit: il s'agit de maximiser, par exemple, l'énergie

$$\frac{1}{2} \int_{\Omega} |\nabla \varphi|^2 dx$$

sous les contraintes suivantes:

(i)

$$\begin{aligned} -\Delta \varphi &= v \quad (\text{équation d'état}) \\ \varphi/\Gamma &= 0 \end{aligned}$$

(ii)

$$v \in \mathcal{U} = \{v \in L^\infty(\Omega)/\alpha \leq v \leq \beta/v_* = v_0\} \text{ (ensemble des contrôles).}$$

Cet ensemble n'est pas convexe.

Remarque. On peut considérer l'ensemble

$$\mathcal{U} = \{v \in L^p(\Omega)/v_* = v_0\}; \quad p > 1;$$

les résultats démontrés dans les chapitres précédents s'adaptent.

Il existe une solution optimale $(\bar{\varphi}, \bar{v})$ du problème du contrôle ci-dessus; de plus $\bar{v} = f(\bar{\varphi})$ où $f(t) = v_0((\bar{\varphi}^*)^{-1})(t)$ est une fonction décroissante. Vérifions enfin (cela est classique [37]) que \bar{u} défini par

$$\bar{u}_1 = \frac{\partial \bar{\varphi}}{\partial y}, \quad \bar{u}_2 = -\frac{\partial \bar{\varphi}}{\partial x}$$

est solution de (6.15).

Nous avons, formellement

$$\begin{aligned} p_1 &= u_1 \frac{\partial u_1}{\partial x} + u_2 \frac{\partial u_1}{\partial y} \\ &= \frac{\partial \varphi}{\partial y} \frac{\partial^2 \varphi}{\partial x \partial y} - \frac{\partial \varphi}{\partial x} \frac{\partial^2 \varphi}{\partial y^2} \\ &= \frac{\partial \varphi}{\partial y} \frac{\partial^2 \varphi}{\partial x \partial y} + \frac{\partial \varphi}{\partial x} \frac{\partial^2 \varphi}{\partial x^2} - \frac{\partial \varphi}{\partial x} \Delta \varphi \\ &= \frac{1}{2} \frac{\partial}{\partial x} [|\nabla \varphi|^2] + \frac{\partial \varphi}{\partial x} f(\varphi) \\ &= \frac{1}{2} \frac{\partial}{\partial x} [|\nabla \varphi|^2] + \frac{\partial}{\partial x} [F(\varphi)], \end{aligned}$$

où $F(t) = \int_0^t f(s) ds$. De même nous avons

$$\begin{aligned} p_2 &= u_1 \frac{\partial u_2}{\partial x} + u_2 \frac{\partial u_2}{\partial y} \\ &= \frac{1}{2} \frac{\partial}{\partial y} [|\nabla \varphi|^2] + \frac{\partial}{\partial y} [F(\varphi)], \end{aligned}$$

Nous voyons aisément que (p_1, p_2) est un gradient. Et de plus la pression cherchée p a pour expression:

$$-p(x, y) = \frac{1}{2} |\nabla \varphi|^2 + F(\varphi)$$

Remarque. La fonction φ possède la régularité $C^{1,\alpha}(\bar{\Omega}) \cap H^2(\Omega)$, $0 < \alpha < 1$. Ceci permet de justifier les calculs précédents.

Il nous reste à vérifier la condition aux limites

$$u \cdot n = 0 \quad \text{sur } \Gamma.$$

Par (1), pour ψ régulière nous avons $-(u \in (H^1(\Omega))^2) -$:

$$\begin{aligned} \int_{\Omega} [u \cdot \nabla \psi + \psi \operatorname{div} u] dx &= \int_{\Gamma} u \cdot n \psi d\sigma \\ &= \int_{\Omega} \left(\frac{\partial \varphi}{\partial y} \frac{\partial \psi}{\partial x} - \frac{\partial \varphi}{\partial x} \frac{\partial \psi}{\partial y} \right) dx = \int_{\Omega} \left[\frac{\partial}{\partial y} \left(\varphi \frac{\partial \psi}{\partial x} \right) - \frac{\partial}{\partial x} \left(\varphi \frac{\partial \psi}{\partial y} \right) \right] dx \\ &= - \int_{\Gamma} \varphi \left[\frac{\partial \psi}{\partial x} n_2 - \frac{\partial \psi}{\partial y} n_1 \right] d\sigma, \text{ par la formule de Green} \\ &= 0 \text{ puisque } \varphi/\Gamma = 0, \end{aligned}$$

i.e. $\int_{\Gamma} u \cdot n \cdot \psi d\sigma = 0$ pour tout ψ régulière et donc $u \cdot n/\Gamma = 0$ par densité.

Remarque. Dans le cas où le contrôle $v \notin L^\infty(\Omega)$ la régularité précédente n'a pas lieu; mais la preuve de $u \cdot n/\Gamma = 0$ peut encore être justifiée: si $u \in L^2(\Omega)$ est tel que $\operatorname{div} u \in L^2(\Omega)$, on peut encore définir la trace normale $u \cdot n/\Gamma$ [35] (cf. également [29]). \square

Remarque. Des problèmes voisins sont abordés dans [37] et [33] par des méthodes différentes.

ADDITIF:

D'après [12], Auchmuty et Benjamin, motivés par la mécanique des fluides, ont abordé, dans un travail en préparation, la question suivante:

$$\begin{aligned} -\Delta \omega &= v \quad \text{dans } \Omega \\ \omega/\partial\Omega &= 0, \\ \sup \left\{ \int_{\Omega} v \cdot \omega dx / v \cdot t \cdot q \cdot v_* = u_0 \text{ donné} \right\}, \end{aligned}$$

i.e., on prend, dans notre travail du § 5

$$l(v) = v, \quad b(x, \omega) = \omega, \quad c(x, \omega) \equiv 0.$$

Serre [29], avec des motivations voisines de celles de Auchmuty et Benjamin a également abordé un problème assez proche dans le cas où u_0 est une fonction à

valeurs discrètes. Enfin dans [12] on trouve d'autres types de problèmes d'optimisation à réarrangement fixé.

\mathcal{H}_∞ CONTROLLER SYNTHESIS BY J -LOSSLESS COPRIME FACTORIZATION*

MICHAEL GREEN†

Abstract. This paper develops a coprime factorization approach to the synthesis of internally stabilizing controllers for a given system such that the \mathcal{H}_∞ norm of the closed loop is strictly less than a given bound.

By the use of coprime factorizations, it is shown that the \mathcal{H}_∞ control problem is fundamentally related to the so-called analytic systems considered by Helton et al. [*Regional Conference Series in Mathematics* 68, 1987]. Such problems admit a solution if and only if a certain J -lossless factorization exists. Interpreted in the \mathcal{H}_∞ control context, this means that for a controller of the requisite type to exist the plant must admit a certain J -lossless coprime factorization. The full \mathcal{H}_∞ synthesis problem requires that two nested J -lossless factorizations exist. The results are independent of whether discrete time or continuous time systems are being considered.

It is then shown that J -lossless factorization is equivalent to the existence of a nonnegative, stabilizing solution to an algebraic Riccati equation, allowing a simple state-space formula for a generator of all controllers to be calculated.

Key words. \mathcal{H}_∞ control, coprime factorization, J -spectral factorization, J -contractive matrices, J -lossless matrices

1.1. Introduction. This paper concerns the problem of obtaining all stabilizing feedback controllers for a linear time invariant system such that the closed loop transfer function satisfies a prespecified infinity norm bound.

The basic paradigm [8], [11], [12] for solving this problem was to eliminate the internal stability constraint using a doubly coprime factorization and the parametrization of all stabilizing controllers. This leaves a model matching problem which can in turn be reduced to the so-called four block distance problem. Several spectral factorizations enable the four block distance problem to be turned into a Nehari problem, for which solution techniques are known [1], [5], [10], [11], [14]. A variation on this theme involves solving the model matching problem as a bitangential Nevanlinna-Pick interpolation problem [23], [26], [36].

This paradigm is unsatisfactory because the cumbersome chain of reductions, substitutions, factorizations, etc., necessary for the theory is both aesthetically unappealing and leads to computer software that is slow, subject to serious state dimension inflation, and plagued by numerical difficulties, although, in all but the most general case, it was known that controllers of the same degree as the plant exist [26], [29].

Recently the situation has improved dramatically. An elegant solution to the four block distance problem, based on all-pass embedding, has been developed and involves the solution of two algebraic Riccati equations [16], [17], [30]. These equations can also be seen to arise from J -factorizations [16], which have long been associated with the Nehari problem, and form the basis of a solution to the model matching problem [2], [18]. Other new approaches based on the model matching problem have also recently been developed [20], [24].

Separate from this school of thought, consideration was being given to polynomial matrix methods for \mathcal{H}_∞ control [25] and to the attainment of infinity norm objectives by state feedback, where a suitable control is obtained from the solution of a single

† Department of Electrical Engineering, Imperial College, London SW7 2BT, United Kingdom.

algebraic Riccati equation [7], [21], [22], [32], [37]. The full output feedback problem was tackled, although under certain assumptions, in [9], and the solution involved an observer, a state feedback and two Riccati equations.

Connections with other areas of control, such as risk sensitive optimal control [16] and linear quadratic differential games [9], [27], [28], have been established as well as generalizations to time-varying systems [27], [28], [33].

The new observer/state feedback approach of [9] differs fundamentally from the basic paradigm in that it by-passes the parametrization of all stabilizing controllers. Also of interest is that [9] describes, by means of state-space realizations, special problems that are relatively easy to solve, called full information, full control, output estimation, and disturbance feedforward, in terms of which the (restricted) general problem can also be solved. The assumptions made in [9], however, reduce the question of internal stability to input/output stability. So, despite the claim that these assumptions lead to “the simplest special case which captures all the essential features of the general problem,” the role played by internal stability is marginalized.

To fully understand the structure developed in [9], it is essential to find transfer matrix characterizations of the special problems of [9] and to analyze how this impacts upon the internal stability of such systems. This examination leads to the result that the special \mathcal{H}_∞ control problems of [9] are precisely the analytic system problems of Helton et al. [19] in a different form. The connection is revealed by coprime factorization and internal stability. In the general case, the \mathcal{H}_∞ control problem is seen to consist of two nested analytic system problems.

The so-called analytic system problem, for the stable case relevant to \mathcal{H}_∞ control, is the following: Given $G \in \mathcal{H}_\infty$, find all $Q_1, Q_2 \in \mathcal{H}_\infty$ such that

$$\begin{bmatrix} R \\ I \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix}, \quad \|R\|_\infty < \gamma.$$

The AS problem can be solved by a number of techniques, ranging from Ball-Helton theory, J -spectral factorization, and interpolation to the state-space approach of [9]. Since the main purpose of this paper is to elucidate the connection via coprime factorization between \mathcal{H}_∞ control and analytic systems, our approach to the AS problem is to show how it relates to model matching and to invoke the results of [18]. This shows that the AS problem has a solution if and only if there exists an outer matrix W such that GW^{-1} is J -lossless. In other words, G has a J -inner outer factorization $G = (GW^{-1})W$.

It follows that the disturbance feedforward \mathcal{H}_∞ problem admits solutions if and only if a right coprime factorization for the plant exists and has a certain J -lossless property. The general \mathcal{H}_∞ synthesis problem is then solved by two nested coprime factorizations, which have J -lossless properties. Since the results are in terms of the properties of transfer matrices, or operators, they apply to both continuous and discrete time systems.

The existence of a J -lossless factorization is shown to be equivalent to the existence of a stabilizing, nonnegative solution to an algebraic Riccati equation with indefinite quadratic term. This allows an explicit state-space formula to be given for a generator of all solutions to the \mathcal{H}_∞ synthesis problem. The state-space results will be proved for the continuous time case and given without detailed proof for discrete time.

1.2. Notation and preliminaries. Vector and matrix notation is standard. $\mathcal{R}^{p \times q}$ denotes the space of proper (bounded at ∞) $p \times q$ rational matrix functions of a complex variable. Let $\mathbb{C}_+ = \{s \in \mathbb{C} : s + \bar{s} \geq 0\} \cup \infty$ and $j\mathbb{R} = \{s \in \mathbb{C} : s + \bar{s} = 0\} \cup \infty$. Let $\mathbb{D}_+ = \{z \in \mathbb{C} : |z| \geq 1\} \cup \infty$ and $\mathbb{T} = \{z \in \mathbb{C} : |z| = 1\}$. Furthermore, let Δ_+ designate either \mathbb{C}_+ or

\mathbb{D}_+ with ∂ denoting either $j\mathbb{R}$ or \mathbb{T} . Denote by $\mathcal{RL}_\infty^{p \times q}(\Delta_+)$ and $\mathcal{RH}_\infty^{p \times q}(\Delta_+)$ the subspaces of $\mathcal{R}^{p \times q}$ without poles in ∂ and Δ_+ , respectively, with $\|\cdot\|_\infty$ the usual associated infinity norm. Denote by $\mathcal{GH}_\infty^p(\Delta_+)$ the group of units of $\mathcal{RH}_\infty^{p \times p}(\Delta_+)$ ($M \in \mathcal{GH}_\infty^p(\Delta_+) \Leftrightarrow M, M^{-1} \in \mathcal{RH}_\infty^{p \times p}$) and let $\gamma\mathcal{BH}_\infty^{p \times q}(\Delta_+) = \{M \in \mathcal{RH}_\infty^{p \times q}(\Delta_+): \|M\|_\infty \leq \gamma\}$. For $\Delta_+ = \mathbb{C}_+$, $\tilde{M}(s) = [M(-\bar{s})]^*$, while, for $\Delta_+ = \mathbb{D}_+$, $\tilde{M}(z) = [M(\bar{z}^{-1})]^*$. $M^*(z) = [M(z)]^*$. To avoid clutter, we will frequently make no explicit reference to Δ_+ or to dimensions of matrices, and speak of \mathcal{R} , \mathcal{RH}_∞ , etc., except where necessary in the interest of clarity or where the result applies only to $\mathcal{RH}_\infty(\mathbb{C}_+)$ or $\mathcal{RH}_\infty(\mathbb{D}_+)$. A matrix $A \in \mathbb{C}^{n \times n}$ is Δ_+ asymptotically stable if none of its eigenvalues lie in Δ_+ .

For $\gamma \neq 0$, define $J_{pq}(\gamma)$ by

$$J_{pq}(\gamma) = \begin{bmatrix} I_p & 0 \\ 0 & -\gamma^2 I_q \end{bmatrix}.$$

We will often abbreviate $J_{pq}(\gamma)$ to J .

A partitioned matrix $M \in \mathcal{R}^{(l+m) \times (q+m)}$ will be called *J-lossless* if $M^* J_{lm}(\gamma) M \leq J_{qm}(\gamma)$ in Δ_+ , with equality holding in ∂ . Also, M is *conjugate J-lossless* if M^* is *J-lossless* (i.e., $MJM^* \leq J$).

As defined, a *J-lossless* matrix need not be square, unlike the situation in [10], [13] (to which several “tricks” in this paper can be traced). Note, however, that if M is *J-lossless*, then $M^* JM$ is invertible on ∂ , so a *J-lossless* matrix is “tall,” i.e., $l \geq q$. Also, note that a *J-lossless* matrix is always assumed to be partitioned, so that the 2,2 corner is square.

Associated with $M \in \mathcal{R}^{p \times q}$ is a state-space realization

$$M(s) = D + C(sI - A)^{-1}B \stackrel{s}{=} \begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathbb{C}^{(n+p) \times (n+q)}.$$

Any $M \in \mathcal{R}^{p \times q}$ has right and left coprime factorizations (see [35])

$$M = ND^{-1} = \hat{D}^{-1}\hat{N}, \quad N, D, \hat{N}, \hat{D} \in \mathcal{RH}_\infty, \quad D(\infty), \hat{D}(\infty) \text{ nonsingular}.$$

As in [35], we will abbreviate right coprime as r.c. and right coprime factorization as r.c.f., and similarly for left coprime (l.c.) and left coprime factorization (l.c.f.)

If $P \in \mathcal{R}^{(l+m) \times (p+q)}$ and $K \in \mathcal{R}^{q \times m}$, then the linear fractional map $\mathcal{F}(P, K)$ is defined by

$$\mathcal{F}(P, K) = P_{11} + P_{12}K(I - P_{22}K)^{-1}P_{21}.$$

Note that $\mathcal{F}(P, K)$ is the transfer matrix from w to z in Fig. 1, and that

$$\|\mathcal{F}(P, K)\|_\infty = \sup_{w \neq 0} \frac{\|z\|_2}{\|w\|_2}.$$

FIG. 1

Thus, $\|\mathcal{F}(P, K)\|_\infty^2$ is the worst case energy gain of the closed loop system. The \mathcal{H}_∞ controller synthesis problem is to establish necessary and sufficient conditions for the existence of stabilizing controllers K satisfying $\|\mathcal{F}(P, K)\|_\infty < \gamma$ and, when these conditions hold, to parametrize all such controllers.

If P_{21} is invertible in \mathcal{R} and G is defined by

$$G = \begin{bmatrix} P_{11} & P_{12} \\ I & 0 \end{bmatrix} \begin{bmatrix} 0 & I \\ P_{21} & P_{22} \end{bmatrix}^{-1} = \begin{bmatrix} I & -P_{11} \\ 0 & P_{21} \end{bmatrix}^{-1} \begin{bmatrix} P_{12} & 0 \\ -P_{22} & I \end{bmatrix},$$

equivalently, G_{22} is invertible in \mathcal{R} and P is defined by

$$(1.1) \quad P = \begin{bmatrix} G_{11} & G_{12} \\ 0 & I \end{bmatrix} \begin{bmatrix} G_{21} & G_{22} \\ I & 0 \end{bmatrix}^{-1} = \begin{bmatrix} I & -G_{12} \\ 0 & G_{22} \end{bmatrix}^{-1} \begin{bmatrix} 0 & G_{11} \\ I & -G_{21} \end{bmatrix},$$

then

$$(1.2) \quad \mathcal{F}(P, K) = (G_{11}K + G_{12})(G_{21}K + G_{22})^{-1}.$$

Remark. Equations (1.1) and (1.2) give the basics of the connection between analytic systems, coprime factorization, and \mathcal{H}_∞ control. For if there exists a $G \in \mathcal{RH}_\infty$ such that P has the form (1.1)—which is to say P has a certain coprime factorization over \mathcal{RH}_∞ —we immediately see that

$$\mathcal{F}(P, K) = R_1 R_2^{-1}, \quad \begin{bmatrix} R_1 \\ R_2 \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} \begin{bmatrix} \bar{K}_1 \\ \bar{K}_2 \end{bmatrix},$$

where $\bar{K}_1 \bar{K}_2^{-1}$ is a r.c.f. of K . Internal stability amounts to $R_2 \in \mathcal{GH}_\infty$, so we can write the \mathcal{H}_∞ control problem as the analytic system problem

$$\begin{bmatrix} \mathcal{F}(P, K) \\ I \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} \begin{bmatrix} K_1 \\ K_2 \end{bmatrix}.$$

2. Stabilization theory. In § 2 we review the stabilization theory of the generalized regulator shown in Fig. 1.

The treatment is based on coprime factorizations over \mathcal{RH}_∞ (see, e.g., [35]).

2.1. The basic stabilization theorem. In this section we give conditions, in terms of coprime factorizations, for a controller to stabilize the generalized regulator. These conditions are given in [11, Chap. 4], but the proof given here is believed to be simpler.

DEFINITION. Let $P \in \mathcal{R}^{(l+m) \times (p+q)}$, $K \in \mathcal{R}^{q \times m}$ and suppose that

$$(2.1) \quad \begin{bmatrix} z \\ y \end{bmatrix} = P \begin{bmatrix} w \\ u \end{bmatrix} + \begin{bmatrix} 0 \\ v_1 \end{bmatrix}, \quad u = Ky + v_2.$$

System (2.1) is well defined if the nine transfer matrices from w, v_1, v_2 to z, y, u exist and are proper (i.e., $\in \mathcal{R}$). The system is *internally stable* if these nine transfer matrices are stable ($\in \mathcal{RH}_\infty$). In this case we say K is a *stabilizing controller* for P , or K *stabilizes* P . We say P is *stabilizable* if there exists a stabilizing controller for P .

THEOREM 2.1. Suppose that $P \in \mathcal{R}^{(l+m) \times (p+q)}$ and let $P = ND^{-1} = \hat{D}^{-1} \hat{N}$ be an r.c.f. and an l.c.f. of P . The following are equivalent:

(i) K stabilizes P ;

$$(2.2) \quad \text{(ii) } K = K_1 K_2^{-1}, \quad \text{with } \begin{bmatrix} D_{11} & D_{12} & 0 \\ D_{21} & D_{22} & K_1 \\ N_{21} & N_{22} & K_2 \end{bmatrix} \in \mathcal{GH}_\infty, K_2(\infty) \text{ nonsingular};$$

$$(2.3) \quad \text{(iii) } K = \hat{K}_2^{-1} \hat{K}_1, \quad \text{with } \begin{bmatrix} \hat{D}_{11} & \hat{D}_{12} & \hat{N}_{12} \\ \hat{D}_{21} & \hat{D}_{22} & \hat{N}_{22} \\ 0 & \hat{K}_1 & \hat{K}_2 \end{bmatrix} \in \mathcal{GH}_\infty, \hat{K}_2(\infty) \text{ nonsingular}.$$

Proof. (i) \Rightarrow (iii). Suppose that K stabilizes P , let K have an l.c.f. $\hat{K}_2^{-1}\hat{K}_1$, and let \hat{X} be the matrix in (2.3). Rewrite (2.1) as

$$(2.4) \quad \hat{X} \begin{bmatrix} z \\ y \\ -u \end{bmatrix} = \hat{Y} \begin{bmatrix} w \\ v_1 \\ -v_2 \end{bmatrix}, \quad \hat{Y} = \begin{bmatrix} \hat{N}_{11} & \hat{D}_{12} & 0 \\ \hat{N}_{21} & \hat{D}_{22} & 0 \\ 0 & 0 & \hat{K}_2 \end{bmatrix}.$$

Since \hat{D} , \hat{N} and \hat{K}_2 , \hat{K}_1 are l.c., it follows that \hat{X} and \hat{Y} are l.c. Thus, by coprimeness, $\hat{X}^{-1}\hat{Y} \in \mathcal{RH}_\infty \Rightarrow \hat{X} \in \mathcal{GH}_\infty$.

(iii) \Rightarrow (i). If (2.3) holds, then it follows from (2.4) that K is a stabilizing controller for P .

(iii) \Rightarrow (ii). Suppose that (2.3) holds. Now let $K = K_1K_2^{-1}$ be an r.c.f. of K . Define

$$X = \begin{bmatrix} -D_{11} & -D_{12} & 0 \\ N_{21} & N_{22} & K_2 \\ D_{21} & D_{22} & K_1 \end{bmatrix}, \quad Y = \begin{bmatrix} -N_{11} & -N_{12} & 0 \\ 0 & 0 & K_2 \\ D_{21} & D_{22} & 0 \end{bmatrix}.$$

Note that X , Y are r.c. and $\hat{X}Y = \hat{Y}X$. Therefore there exist \hat{U} , \hat{V} , U , $V \in \mathcal{RH}_\infty$ such that $\begin{bmatrix} \hat{V} & \hat{U} \\ -\hat{Y} & \hat{X} \end{bmatrix} \begin{bmatrix} X & -U \\ Y & -V \end{bmatrix} = I$. It follows that $X \in \mathcal{GH}_\infty (X^{-1} = \hat{V} + \hat{U}\hat{X}^{-1}\hat{Y})$.

(ii) \Rightarrow (iii). Use a similar argument to that above. \square

2.2. Stabilizability. We now consider necessary conditions on P for a stabilizing controller to exist; we see that P is stabilizable only if P has coprime factorizations in which the denominator matrix has a particular triangular form.

COROLLARY 2.2. *If $P \in \mathcal{R}^{(l+m) \times (p+q)}$ is stabilizable, then*

$$(2.5) \quad (i) \ P \text{ has an r.c.f. } P = ND^{-1}, \text{ with } D = \begin{bmatrix} I_p & 0 \\ D_{21} & D_{22} \end{bmatrix} \text{ and } N_{22}, D_{22} \text{ r.c.};$$

$$(2.6) \quad (ii) \ P \text{ has an l.c.f. } P = \hat{D}^{-1}\hat{N}, \text{ with } \hat{D} = \begin{bmatrix} I_l & \hat{D}_{12} \\ 0 & \hat{D}_{22} \end{bmatrix} \text{ and } \hat{D}_{22}, \hat{N}_{22} \text{ l.c.}$$

Note. Using these factorizations and Theorem 2.1, it is straightforward to show that K stabilizes P if and only if K stabilizes $P_{22} = N_{22}D_{22}^{-1} = \hat{D}_{22}^{-1}\hat{N}_{22}$.

Proof. We prove only that P stabilizable \Rightarrow (i), with (ii) following by similar reasoning.

Suppose that P is stabilizable and let K stabilize P . Let YX^{-1} be an r.c.f. of P , and $K_1K_2^{-1}$ an r.c.f. of K . From Theorem 2.1—see (2.2)—it follows that $[X_{11} \ X_{12}]$ is right invertible in \mathcal{RH}_∞ . Therefore there exist \bar{X}_{21} and \bar{X}_{22} such that $\bar{X} = \begin{bmatrix} X_{11} & X_{12} \\ \bar{X}_{21} & \bar{X}_{22} \end{bmatrix} \in \mathcal{GH}_\infty$. Define $N = Y\bar{X}^{-1}$, $D = X\bar{X}^{-1}$. \square

Remark. The converse to the above corollary is almost true. If P has an r.c.f. $P = ND^{-1}$ as in (2.5), then, since N_{22} , D_{22} are r.c., there exist K_1 , $K_2 \in \mathcal{RH}_\infty$ such that $\begin{bmatrix} D_{22} & K_1 \\ N_{22} & K_2 \end{bmatrix} \in \mathcal{GH}_\infty$. That $K = K_1K_2^{-1}$ stabilizes P follows from Theorem 2.1, provided $K_2(\infty)$ is nonsingular (this is assured if, for example, P_{22} is strictly proper, implying $N_{22}(\infty) = 0$). \square

2.3. Characterization of stabilizing controllers.

COROLLARY 2.3. *Suppose that $P \in \mathcal{R}^{(l+m) \times (p+q)}$ has an r.c.f. $P = ND^{-1}$, $D = \begin{bmatrix} I_p & 0 \\ D_{21} & D_{22} \end{bmatrix}$. Then K stabilizes P if and only if $K = \hat{K}_2^{-1}\hat{K}_1$, where \hat{K}_1 , \hat{K}_2 satisfy*

$$(2.7) \quad \begin{bmatrix} \hat{K}_1 & \hat{K}_2 \end{bmatrix} \begin{bmatrix} N_{21} & -N_{22} \\ -D_{21} & D_{22} \end{bmatrix} = \begin{bmatrix} Q & I_q \end{bmatrix}, \quad \hat{K}_1, \hat{K}_2 \in \mathcal{RH}_\infty, \quad \hat{K}_2(\infty) \text{ nonsingular}.$$

In this case,

$$(2.8) \quad \begin{bmatrix} \mathcal{F}(P, K) \\ I_p \end{bmatrix} = \begin{bmatrix} N_{11} & N_{12} \\ I_p & 0 \end{bmatrix} \begin{bmatrix} I_p \\ Q \end{bmatrix}.$$

Note. The important condition in (2.7) is the second block column; Q is just whatever comes out of the first column once the second is satisfied.

Proof. Suppose that K is a stabilizing controller for P with r.c.f. $K = K_1 K_2^{-1}$. Define

$$\begin{bmatrix} I & 0 & 0 \\ Q & \hat{K}_2 & -\hat{K}_1 \\ \hat{N}_{22} D_{21} - \hat{D}_{22} N_{21} & -\hat{N}_{22} & \hat{D}_{22} \end{bmatrix} = \begin{bmatrix} I & 0 & 0 \\ D_{21} & D_{22} & K_1 \\ N_{21} & N_{22} & K_2 \end{bmatrix}^{-1}.$$

Note that $\hat{K}_2(\infty)$ is nonsingular, since $\hat{K}_2^{-1} = D_{22} - K N_{22}$, and that $K = \hat{K}_2^{-1} \hat{K}_1$. Equation (2.7) follows.

Conversely, suppose that (2.7) holds. Hence \hat{K}_1, \hat{K}_2 are l.c. and N_{22}, D_{22} are r.c., so there exist $\hat{N}_{22}, \hat{D}_{22}, K_1, K_2 \in \mathcal{H}_\infty$ such that

$$\begin{bmatrix} \hat{K}_2 & -\hat{K}_1 \\ -\hat{N}_{22} & \hat{D}_{22} \end{bmatrix} \begin{bmatrix} D_{22} & K_1 \\ N_{22} & K_2 \end{bmatrix} = I.$$

It follows that $K_2(\infty)$ is nonsingular ($K_2^{-1} = \hat{D}_{22} - \hat{N}_{22} \hat{K}_1 \hat{K}_2^{-1}$) and by Theorem 2.1, $K = K_1 K_2^{-1} = \hat{K}_2^{-1} \hat{K}_1$ stabilizes P .

If \hat{K}_2, \hat{K}_1, Q satisfy (2.7), we have

$$\begin{aligned} \mathcal{F}(P, K) &= P_{11} + P_{12}(I - K P_{22})^{-1} K P_{21} \\ &= P_{11} + P_{12} D_{21} + P_{12} D_{22} (\hat{K}_2 D_{22} - \hat{K}_1 N_{22})^{-1} \\ &\quad \times [\hat{K}_1 P_{21} - (\hat{K}_2 D_{22} - \hat{K}_1 N_{22}) D_{22}^{-1} D_{21}] \\ &= P_{11} + P_{12} D_{21} + P_{12} D_{22} [\hat{K}_1 (P_{21} + N_{22} D_{22}^{-1} D_{21}) - \hat{K}_2 D_{21}] \\ &= N_{11} + N_{12} (\hat{K}_1 N_{21} - \hat{K}_2 D_{21}) \\ &= N_{11} + N_{12} Q. \end{aligned}$$

□

Remark. This characterization of all internally stabilizing controllers is implicit, in contrast to the explicit Youla parametrization (see [35]). The advantages for \mathcal{H}_∞ controller synthesis are (1) the parametrization $N_{11} + N_{12} Q$ of the closed loop is “one-sided,” and (2) N_{11} and N_{12} have the same order as P . The Youla parametrization leaves a “two-sided” problem with twice the order of P . Of course, Q in (2.8) is not a free parameter, being constrained by (2.7). The \mathcal{H}_∞ controller synthesis problem is therefore exposed as a two stage procedure, with each stage involving the solution of an analytic systems problem. In stage 1 we find all Q such that $\|N_{11} + N_{12} Q\|_\infty < \gamma$. All such Q 's are given in terms of a free stable matrix U with $\|U\|_\infty < \gamma$. It remains to establish which of these Q 's can be obtained from K via (2.7). Since the map connecting U and Q is invertible, we consider in stage 2 which U 's can be obtained from K by considering the map from K to U , which proves to be of the form in (2.7), that is, another AS problem.

Thus the constraint of internal stability exposes the structure of the general \mathcal{H}_∞ synthesis problem as two nested AS problems—(2.7) a left-handed AS problem, and (2.8) a right-handed AS problem. □

COROLLARY 2.4. Suppose that $P \in \mathcal{R}^{(l+m) \times (p+q)}$ has an l.c.f. $P = \hat{D}^{-1} \hat{N}$, $\hat{D} = \begin{bmatrix} I_l & \hat{D}_{12} \\ 0 & \hat{D}_{22} \end{bmatrix}$. Then K stabilizes P if and only if $K = K_1 K_2^{-1}$, where K_1, K_2 satisfy

$$(2.9) \quad \begin{bmatrix} \hat{Q} \\ I_m \end{bmatrix} = \begin{bmatrix} \hat{N}_{12} & -\hat{D}_{12} \\ -\hat{N}_{22} & \hat{D}_{22} \end{bmatrix} \begin{bmatrix} K_1 \\ K_2 \end{bmatrix} \quad K_1, K_2 \in \mathcal{H}_\infty, \quad K_2(\infty) \text{ nonsingular.}$$

In this case,

$$(2.10) \quad [\mathcal{F}(P, K) \quad I_l] = [I_l \quad \hat{Q}] \begin{bmatrix} \hat{N}_{11} & I_l \\ \hat{N}_{21} & 0 \end{bmatrix} \quad \square$$

2.4. \mathcal{H}_∞ control and analytic systems. Equation (2.10) shows that we can generate the closed loop $\mathcal{F}(P, K)$ from \hat{Q} , with \hat{Q} generated by the system of equations (2.9). Consider now the special case when \hat{N} has the form

$$(2.11) \quad \hat{N} = \begin{bmatrix} 0 & \hat{N}_{12} \\ I_m & \hat{N}_{22} \end{bmatrix}.$$

From (2.10), it follows that $\mathcal{F}(P, K) = \hat{Q}$. We have the following corollary.

COROLLARY 2.5. Suppose that $P \in \mathcal{R}^{(l+m) \times (m+q)}$ has an l.c.f. of the form

$$(2.12) \quad P = \begin{bmatrix} I_l & \hat{D}_{12} \\ 0 & \hat{D}_{22} \end{bmatrix}^{-1} \begin{bmatrix} 0 & \hat{N}_{12} \\ I_m & \hat{N}_{22} \end{bmatrix}.$$

Then K stabilizes P and $\|\mathcal{F}(P, K)\|_\infty \leq \gamma$ if and only if $K = K_1 K_2^{-1}$, where K_1, K_2 satisfy

$$\begin{bmatrix} \hat{Q} \\ I_m \end{bmatrix} = \begin{bmatrix} \hat{N}_{12} & -\hat{D}_{12} \\ -\hat{N}_{22} & \hat{D}_{22} \end{bmatrix} \begin{bmatrix} K_1 \\ K_2 \end{bmatrix} \quad K_1, K_2 \in \mathcal{RH}_\infty, \quad K_2(\infty) \text{ nonsingular}$$

with $\|\hat{Q}\|_\infty \leq \gamma$.

Note. It holds that $\mathcal{F}(P, K) = \hat{Q}$.

Proof. The result follows directly from Corollary 2.4, observing that $\hat{N}_{11} = 0$ and $\hat{N}_{21} = I$. \square

The above result shows that, for certain special systems, characterized by having a coprime factorization of a particular form, there is an exact correspondence between the \mathcal{H}_∞ control problem and the analytic system problem. Naturally, a “left-handed” dual version of Corollary 2.5 is obtained by considering systems with r.c.f. ND^{-1} as in Corollary 2.3 for which $N_{11} = 0$ and $N_{12} = I$.

2.5. Disturbance feedforward and output estimation. Sections 4.3 and 4.4 of [9] concern two special \mathcal{H}_∞ control problems, called disturbance feedforward and output estimation.

For disturbance feedforward, it is assumed that P has a state-space realization

$$(2.13) \quad P \stackrel{s}{=} \begin{bmatrix} A & B_1 & B_2 \\ C_1 & 0 & D_{12} \\ C_2 & I & 0 \end{bmatrix}$$

with $A - B_1 C_2$ asymptotically stable. This gives an l.c.f. as follows:

$$P = \hat{D}^{-1} \hat{N}, \quad \hat{N} \stackrel{s}{=} \begin{bmatrix} A - B_1 C_2 & 0 & B_2 \\ C_1 & 0 & D_{12} \\ C_2 & I & 0 \end{bmatrix}, \quad \hat{D} \stackrel{s}{=} \begin{bmatrix} A - B_1 C_2 & 0 & -B_1 \\ C_1 & I & 0 \\ C_2 & 0 & I \end{bmatrix}.$$

Noting that the states are uncontrollable through the first input, we see that this l.c.f. is of the form in Corollary 2.5.

The output estimation problem is similarly seen to be of the form in Corollary 2.3 with $N_{11} = 0$ and $N_{12} = I$.

The disturbance feedforward problem and the output estimation problem can be completely solved as analytic systems problems. We will see in § 3 that such problems require a single J -spectral factorization, and hence a single Riccati equation for their solution as is already established in [9].

The full information and full control problems of [9] do not appear to arise in a natural way within the framework considered here, since (as is remarked in [9]) they do not satisfy the assumptions that are in force for the general case. Nevertheless, their role in [9] is played by the “model matching” part of the problem—see (2.8) and (2.10). The relationship between disturbance feedforward and full information would seem to be bound up with the reduction of a general analytic system problem to a model-matching type problem. We will see how this is done in § 3.2.

3. Analytic systems. We will now discuss the theory of analytic systems of which those described so far are but a special case. They are stable analytic systems, and the sufficiency theory for such systems can be developed entirely from a consideration of J -lossless matrices. The necessity theory requires a deep theorem, such as the Nehari/AAK, Nevanlinna–Pick, or Ball–Helton theorems, somewhere along the line. To be as concrete as possible, the approach adopted here is to show how the AS problem relates to model matching and to invoke the results of [18]. More sophisticated approaches are possible, and results similar to those presented here can be found in the work of Ball and Helton, especially [4], [19]. Indeed [4] contains many interesting connections between notions of passivity, J -losslessness, analytic systems of various types, the geometry of shift invariant subspaces, and reproducing kernels.

3.1. The analytic system problem. (See [19, p. 57].) Given $G_{11}, G_{12} \in \mathcal{RL}_\infty$, $G_{21}, G_{22} \in \mathcal{RH}_\infty$, an integer $l \geq 0$, and a real number $\gamma > 0$, find the set of all R_1, R_2 such that R_2 is inner and of degree $\leq l$, $\|R_1\|_\infty < \gamma$ and such that there exist $Q_1, Q_2 \in \mathcal{RH}_\infty$ with

$$(3.1) \quad \begin{bmatrix} R_1 \\ R_2 \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix}.$$

By suitably choosing the matrix G in (3.1), many problems from operator and analytic function theory—such as Nevanlinna–Pick interpolation, Toeplitz Corona theory and the Nehari model matching and model reduction problems such as are of interest in \mathcal{H}_∞ control—can be posed as AS problems.

Setting $G_{21} = 0$ and $G_{22} = I$, for example, we see that we have the following model matching problem over $\mathcal{RH}_\infty(l)$:

$$(3.2) \quad \begin{bmatrix} R_1 \\ R_2 \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ 0 & I \end{bmatrix} \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix}.$$

Since $R_2 = Q_2$ is inner, it is invertible, and we see that (3.2) is the model matching problem of finding $Q (= Q_1 Q_2^{-1}) \in \mathcal{RH}_\infty(l)$ such that $\|G_{11}Q + G_{12}\|_\infty < \gamma$.

Specializing a little further, setting $G_{11} = I$, we have the Hankel norm model reduction problem, or when $l = 0$, the Nehari problem.

3.2. The case where $l = 0$. With $l = 0$, R_2 is required to be a constant, unitary matrix so, without loss of generality, we will require R_2 to be the identity. Equation (3.1) therefore becomes

$$(3.3) \quad \begin{bmatrix} R \\ I \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix}.$$

From the second row of (3.3), it follows that there exist \bar{G}_{11} , \bar{G}_{12} , \bar{Q}_1 , and \bar{Q}_2 such that

$$(3.4) \quad \bar{G} = \begin{bmatrix} \bar{G}_{11} & \bar{G}_{12} \\ G_{21} & G_{22} \end{bmatrix} = \begin{bmatrix} \bar{Q}_1 & Q_1 \\ \bar{Q}_2 & Q_2 \end{bmatrix}^{-1} \in \mathcal{GH}_\infty.$$

This gives

$$(3.5) \quad G = G\bar{G}^{-1}\bar{G} = \begin{bmatrix} \hat{G}_{11} & \hat{G}_{12} \\ 0 & I \end{bmatrix} \bar{G},$$

and, since $\bar{G} \in \mathcal{GH}_\infty$, the analytic system (3.3) is equivalent to the analytic system

$$(3.6) \quad \begin{bmatrix} R \\ I \end{bmatrix} = \begin{bmatrix} \hat{G}_{11} & \hat{G}_{12} \\ 0 & I \end{bmatrix} \begin{bmatrix} \hat{Q}_1 \\ I \end{bmatrix} \quad \text{with} \quad \begin{bmatrix} \hat{Q}_1 \\ I \end{bmatrix} = \bar{G} \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix}.$$

Thus all $l=0$ AS problems are model matching problems.

THEOREM 3.1 (See [18]). *Suppose that $\hat{G} = \begin{bmatrix} \hat{G}_{11} & \hat{G}_{12} \\ 0 & I_m \end{bmatrix} \in \mathcal{RL}_\infty^{(1+m) \times (q+m)}$ is left invertible in \mathcal{RL}_∞ . There exists a $\hat{Q} \in \mathcal{RH}_\infty$ such that*

$$(3.7) \quad \|\hat{G}_{11}\hat{Q} + \hat{G}_{12}\|_\infty < \gamma$$

if and only if there exists a \hat{W} such that

$$(3.8) \quad \hat{G}^* J_{lm}(\gamma) \hat{G} = \hat{W}^* J_{qm}(\gamma) \hat{W}, \quad \hat{W} \in \mathcal{GH}_\infty^{q+m}, \quad \text{and} \quad \hat{W}_{11} \in \mathcal{GH}_\infty^q.$$

In this case, all $\hat{Q} \in \mathcal{RH}_\infty$ satisfying $\|\hat{G}_{11}\hat{Q} + \hat{G}_{12}\|_\infty \leq \gamma$ are generated by

$$(3.9) \quad \hat{Q} = \hat{Q}_1 \hat{Q}_2^{-1}, \quad \begin{bmatrix} \hat{Q}_1 \\ \hat{Q}_2 \end{bmatrix} = \hat{W}^{-1} \begin{bmatrix} U \\ I_m \end{bmatrix}, \quad U \in \gamma \mathcal{BH}_\infty^{q \times m},$$

where \hat{W} is any solution to (3.8).

Furthermore, for any \hat{W} satisfying (3.8), the following hold:

- (a) *For all $U \in \gamma \mathcal{BH}_\infty^{q \times m}$, \hat{Q}_2 in (3.9) $\in \mathcal{GH}_\infty^m$;*
- (b) *For all $\hat{Q} \in \mathcal{RH}_\infty^{q \times m}$ satisfying $\|\hat{G}_{11}\hat{Q} + \hat{G}_{12}\|_\infty \leq \gamma$, $[0 \ I_m] \hat{W} \begin{bmatrix} \hat{Q} \\ I_m \end{bmatrix} \in \mathcal{GH}_\infty^m$.*

Proof. Variations of this result appear in a number of places; see, for example, [2], [3], [4], [19], or [18], from which the continuous time ($\Delta_+ = \mathbb{C}_+$) version of the above statement derives. The discrete time result follows by bilinear transformation. The Nehari case is treated in [5], [10], [11]. \square

COROLLARY 3.2. *Suppose that $G \in \mathcal{RL}_\infty^{(1+m) \times (q+m)}$ is left invertible in \mathcal{RL}_∞ , $[0 \ I_m]G \in \mathcal{RH}_\infty^{m \times (q+m)}$. There exist $Q_1, Q_2 \in \mathcal{RH}_\infty$ and an R with $\|R\|_\infty < \gamma$ satisfying the analytic system (3.3) if and only if there exists a W such that*

$$(3.10) \quad \hat{G}^* J_{lm}(\gamma) G = W^* J_{qm}(\gamma) W, \quad W \in \mathcal{GH}_\infty^{q+m}, \quad \text{and} \quad (GW^{-1})_{22} \in \mathcal{GH}_\infty^m.$$

In this case, all solutions R to the analytic system (3.3) are generated by

$$(3.11) \quad R = R_1 R_2^{-1}, \quad \begin{bmatrix} R_1 \\ R_2 \end{bmatrix} = GW^{-1} \begin{bmatrix} U \\ I_m \end{bmatrix}, \quad U \in \gamma \mathcal{BH}_\infty^m$$

with W any solution to (3.10).

Proof. First note that if a solution to the AS exists or a W satisfying (3.10) exists, then $[G_{21} \ G_{22}]$ is right invertible in \mathcal{RH}_∞ . The result follows from (3.4)-(3.6) and Theorem 3.1. Note that $\hat{W}_{11} \in \mathcal{GH}_\infty \Leftrightarrow (\hat{W}^{-1})_{22} \in \mathcal{GH}_\infty$ and that $(GW^{-1})_{22} = (\hat{W}^{-1})_{22}$. \square

3.3. J -lossless matrices and stable analytic systems. If $G \in \mathcal{RH}_\infty$, the conditions of Corollary 3.2 can be given an attractive, alternative form using J -lossless matrices via the following lemma.

LEMMA 3.3. Suppose that $X \in \mathcal{RH}_\infty^{(l+m) \times (q+m)}$. Then $X_{22} \in \mathcal{GH}_\infty^m$ and $X^* J_{lm}(\gamma) X = J_{qm(\gamma)}$ if and only if X is J -lossless.

Proof. Suppose that X is J -lossless. Then $X_{12}^* X_{12} - \gamma^2 X_{22}^* X_{22} \leq -\gamma^2 I$ in Δ_+ , so X_{22} is nonsingular in Δ_+ , i.e., $X_{22} \in \mathcal{GH}_\infty$. By J -losslessness, we have that $X^* JX = J$ on ∂ . Therefore, since X is rational, so $X^* JX$ is rational, we have that $X^* JX = J$.

Conversely, suppose that $X_{22} \in \mathcal{GH}_\infty$ and $X^* JX = J$. Let

$$X_1 = \begin{bmatrix} X_{11} & X_{12} \\ 0 & \gamma I \end{bmatrix}, \quad X_2 = \begin{bmatrix} I & 0 \\ \gamma X_{21} & \gamma X_{22} \end{bmatrix}.$$

Note that $X_2 \in \mathcal{GH}_\infty$ and $Y = X_1 X_2^{-1} \in \mathcal{RH}_\infty$. Now observe that

$$(3.12) \quad X' JX - J = X_2' \{ Y' Y - I \} X_2,$$

where X' denotes either X^* or X^* . With X' denoting X^* , we see that Y is all-pass. Since Y is stable, we have, by the maximum modulus principle, that Y is lossless ($Y^* Y \leq I$ in Δ_+). Therefore, from (3.12) with X' denoting X^* , X is J -lossless. \square

Before interpreting Theorem 3.2 in terms of J -lossless factorizations, we have the following generalization of Lemma 3.3, which is proved using Theorem 3.1. It can be proved independently, giving a sufficiently theory for stable analytic systems, but since we also need necessity, it is more efficient to use previously established results.

LEMMA 3.4. Let $X \in \mathcal{RH}_\infty^{(l+m) \times (q+m)}$ be J -lossless and define G and W by

$$W = \begin{bmatrix} I_q & 0 \\ X_{21} & X_{22} \end{bmatrix}^{-1}, \quad G = XW = \begin{bmatrix} G_{11} & G_{12} \\ 0 & I_m \end{bmatrix}.$$

(1) If $U \in \gamma \mathcal{BH}_\infty$, then $X_{21}U + X_{22} \in \mathcal{GH}_\infty$ and $(X_{11}U + X_{12})(X_{21}U + X_{22})^{-1} \in \gamma \mathcal{BH}_\infty$.

(2) If $Q \in \mathcal{RH}_\infty$ is such that $\|G_{11}Q + G_{12}\|_\infty \leq \gamma$, then $I - X_{21}Q \in \mathcal{GH}_\infty$ and $Q(I - X_{21}Q)^{-1}X_{22} = (I - QX_{21})^{-1}QX_{22} \in \gamma \mathcal{BH}_\infty$.

Proof. Since X is J -lossless, $G^* JG = W^* JW$ and $W \in \mathcal{GH}_\infty$, by Lemma 3.3. Clearly, $W_{11} \in \mathcal{GH}_\infty$. The result follows from Theorem 3.1—see (a) and (b). \square

THEOREM 3.5. Suppose that $G \in \mathcal{RH}_\infty^{(l+m) \times (q+m)}$ is left invertible in \mathcal{RL}_∞ . Then there exist $Q_1, Q_2 \in \mathcal{RH}_\infty$ and an R with $\|R\|_\infty < \gamma$ satisfying the analytic system (3.3) if and only if there exists a W such that

$$(3.13) \quad W \in \mathcal{GH}_\infty^{q+m} \text{ and } GW^{-1} \text{ is } J\text{-lossless}^1.$$

In this case, all solutions R to the analytic system (3.3) with $\|R\|_\infty \leq \gamma$ are generated by

$$R = R_1 R_2^{-1}, \quad \begin{bmatrix} R_1 \\ R_2 \end{bmatrix} = GW^{-1} \begin{bmatrix} U \\ I_m \end{bmatrix}, \quad U \in \gamma \mathcal{BH}_\infty^{q+m},$$

where W is any solution to (3.13). All Q_1, Q_2 are generated by

$$\begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} R_2 = W^{-1} \begin{bmatrix} U \\ I_m \end{bmatrix}, \quad U \in \gamma \mathcal{BH}_\infty^{q+m}.$$

¹ The theorem is stated with G assumed to be partitioned so that the 2,2 corner is square. We also need to consider the case when the 2,1 is square, i.e., $G \in \mathcal{RH}_\infty^{(l+m) \times (m+q)}$. One is converted to the other by swapping columns, and the off-diagonal blocks of W are then square, instead of the diagonal blocks.

Proof. The proof follows from Corollary 3.2 and Lemma 3.3. Note also that by Lemma 3.4, $R_2 \in \mathcal{GH}_\infty$. \square

3.4. Some comments concerning infinity. In the application of the theory of analytic systems to \mathcal{H}_∞ control, $K = K_1 K_2^{-1}$ is a stabilizing controller for a problem of disturbance feedforward type if and only if $\begin{bmatrix} K_1 \\ K_2 \end{bmatrix}$ satisfy an analytic system and $K_2(\infty)$ is nonsingular, or else K is not proper. That is, infinity is a special point because we allow the controller to have poles anywhere in \mathbb{C} but not at infinity.

The following lemma allows us to say that if $Q_2(\infty)$ is nonsingular in Theorem 3.5 for some strict contraction $U(\infty)$,² then we can assume $(W^{-1})_{22}(\infty)$ is nonsingular. This will mean that $Q_2(\infty)$ will be nonsingular for any U with $U(\infty) = 0$.

LEMMA 3.6. *Let $\bar{\Omega} \in \mathbb{C}^{(q+m) \times (q+m)}$ be nonsingular. There exists a constant matrix $U \in \mathbb{C}^{q \times m}$ such that $U^* U < \gamma^2 I$ and $\begin{bmatrix} 0 & I_m \end{bmatrix} \bar{\Omega} \begin{bmatrix} U \\ I_m \end{bmatrix}$ is nonsingular if and only if there exists a nonsingular matrix $\Omega \in \mathbb{C}^{(q+m) \times (q+m)}$ such that $\Omega J^{-1} \Omega^* = \bar{\Omega} J^{-1} \bar{\Omega}^*$, with $\Omega_{22} \in \mathbb{C}^{q \times q}$ nonsingular.*

Proof. If Ω exists, then $\Omega = \bar{\Omega} \Theta$, where $\Theta J^{-1} \Theta^* = J^{-1}$. This implies $\Theta_{12}^* \Theta_{12} - \gamma^{-2} \Theta_{22}^* \Theta_{22} = -\gamma^{-2} I$, so Θ_{22} is nonsingular and $U = \gamma^2 \Theta_{12} \Theta_{22}^{-1}$ satisfies $U^* U < \gamma^2 I$. We then have $\begin{bmatrix} 0 & I_m \end{bmatrix} \bar{\Omega} \begin{bmatrix} U \\ I_m \end{bmatrix} = \gamma^2 \Omega_{22} \Theta_{22}^{-1}$, which is nonsingular.

Conversely, if U exists, set $\Omega = \bar{\Omega} \mathcal{J}(U)$, where

$$\mathcal{J}(U) = \begin{bmatrix} (\gamma^2 I - UU^*)^{-1/2} & 0 \\ 0 & (\gamma^2 I - U^* U)^{-1/2} \end{bmatrix} \begin{bmatrix} \gamma I & \gamma U \\ \gamma^{-1} U^* & \gamma \end{bmatrix}.$$

We then have $\mathcal{J}(U) J^{-1} \mathcal{J}(U)^* = J^{-1}$ and that $\begin{bmatrix} 0 & I \end{bmatrix} \Omega^{-1} \begin{bmatrix} 0 \\ I \end{bmatrix} = \begin{bmatrix} 0 & I \end{bmatrix} \bar{\Omega}^{-1} \begin{bmatrix} U \\ I \end{bmatrix} \gamma (\gamma^2 I - U^* U)^{-1/2}$. \square

A further result we need for similar reasons is the following lemma.

LEMMA 3.7. *Suppose that $G \in \mathcal{RH}_\infty^{(l+m) \times (q+m)}$ with G_{21} strictly proper³ (or $G \in \mathcal{RH}^{(l+m) \times (m+q)}$ with G_{22} strictly proper) and there exists a \hat{W} satisfying (3.13). Then there exists a W satisfying (3.13) with W_{21} (respectively, W_{22}) strictly proper.*

Note. $W(\infty)$ nonsingular and $W_{21}(\infty) = 0$ (respectively, $W_{22}(\infty) = 0$) implies that $W_{11}(\infty)$ and $W_{22}(\infty)$ (respectively, $W_{21}(\infty)$ and $W_{12}(\infty)$) are nonsingular.

Proof. Consider the $G_{21}(\infty) = 0$ case.

For $\Delta_+ = \mathbb{C}_+$, since $\infty \in \partial$, we have $[\hat{W}^* J \hat{W}](\infty) = [G^* J G](\infty)$. Since $\hat{W}(\infty)$ is nonsingular, $[G^* J G](\infty)$ is nonsingular and it follows that $\{[G^* J G](\infty)\}_{11} > 0$. Now by taking the Schur complement, $W(\infty)$ with the desired $W_{21}(\infty) = 0$ property exists. Define $W = W(\infty) \hat{W}(\infty)^{-1} \hat{W}$.

For $\Delta_+ = \mathbb{D}_+$, since $\infty \in \mathbb{D}_+$, we have $[\hat{W}^* J \hat{W}](\infty) \geq [G^* J G](\infty)$. Let Λ be such that $[\hat{W}^* J \hat{W}](\infty) = [G^* J G](\infty) + \Lambda^* \Lambda = [\hat{G}^* \hat{J} \hat{G}](\infty)$, where $\hat{G}^*(\infty) = [\Lambda^* G^*(\infty)]$ and $\hat{J} = I \oplus J$. Now apply the same construction as for the \mathbb{C}_+ case. \square

3.5. Solution to \mathcal{H}_∞ control problems of analytic system type. Theorem 3.5 can now be used to solve the special \mathcal{H}_∞ control problems, which are of stable analytic system type described in § 2.4.

For disturbance feedforward problems, we have the following theorem.

THEOREM 3.8. *Let $P \in \mathcal{R}^{(l+m) \times (m+q)}$ have l.c.f.*

$$P = \begin{bmatrix} I_l & \hat{D}_{12} \\ 0 & \hat{D}_{22} \end{bmatrix}^{-1} \begin{bmatrix} 0 & \hat{N}_{12} \\ I_m & \hat{N}_{22} \end{bmatrix} \quad \text{with} \quad G = \begin{bmatrix} \hat{N}_{12} & -\hat{D}_{12} \\ -\hat{N}_{22} & \hat{D}_{22} \end{bmatrix}$$

left invertible in \mathcal{RL}_∞ .

² Since $\infty \in \Delta_+$, $U(\infty)$ is a strict contraction provided U is a strict contraction on Δ_+ .

³ G_{21} strictly proper means $G_{21}(\infty) = 0$.

There exists an internally stabilizing controller K such that $\|\mathcal{F}(P, K)\|_\infty < \gamma$ if and only if P has an r.c.f.

$$(3.14) \quad P = ND^{-1}, \quad \text{with} \quad \begin{bmatrix} N_{11} & N_{12} \\ D_{11} & D_{12} \end{bmatrix} J\text{-lossless and } N_{22}(\infty) \text{ nonsingular.}^4$$

In this case, all stabilizing controllers K such that $\|\mathcal{F}(P, K)\|_\infty \leq \gamma$ are given by $K = K_1 K_2^{-1}$, where K_1, K_2 are such

$$(3.15) \quad \begin{bmatrix} K_1 \\ K_2 \end{bmatrix} = \begin{bmatrix} D_{21} & D_{22} \\ N_{21} & N_{22} \end{bmatrix} \begin{bmatrix} U \\ I_m \end{bmatrix}, \quad U \in \gamma \mathcal{B}\mathcal{H}_\infty^{q \times m}, \quad K_2(\infty) \text{ nonsingular.}$$

Note. Since $N_{22}(\infty)$ is nonsingular, $K_2(\infty)$ in (3.15) is nonsingular for all strictly proper U ($U(\infty) = 0$).

Proof. First observe the following relationships: Rewrite the l.c.f. $\hat{D}^{-1}\hat{N}$ as the r.c.f. YX^{-1}

$$P = YX^{-1}, \quad Y = \begin{bmatrix} \hat{N}_{12} & -\hat{D}_{12} \\ 0 & I \end{bmatrix}, \quad X = \begin{bmatrix} -\hat{N}_{22} & \hat{D}_{22} \\ I & 0 \end{bmatrix}.$$

Now

$$P = ND^{-1} \text{ is a r.c.f. with } N_{22}(\infty) \text{ nonsingular}$$

$$\Leftrightarrow \exists W \in \mathcal{GH}_\infty \text{ with } YW^{-1} = N \text{ and } XW^{-1} = D, \quad (W^{-1})_{22}(\infty) \text{ nonsingular.}$$

Observing the structure of Y and X , we see that such a W exists if and only if

$$(3.16) \quad W^{-1} = \begin{bmatrix} D_{21} & D_{22} \\ N_{21} & N_{22} \end{bmatrix} \in \mathcal{GH}_\infty, \quad N_{22}(\infty) \text{ nonsingular}$$

and

$$(3.17) \quad G = \begin{bmatrix} \hat{N}_{12} & -\hat{D}_{12} \\ -\hat{N}_{22} & \hat{D}_{22} \end{bmatrix} = \begin{bmatrix} N_{11} & N_{12} \\ D_{11} & D_{12} \end{bmatrix} W.$$

Obviously, GW^{-1} J -lossless $\Leftrightarrow \begin{bmatrix} N_{11} & N_{12} \\ D_{11} & D_{12} \end{bmatrix}$ J -lossless.

Suppose that there exists a stabilizing controller K for P with $\|\mathcal{F}(P, K)\|_\infty < \gamma$. Then, by Corollary 2.5 and Theorem 3.5, there exists a $W \in \mathcal{GH}_\infty$ such that GW^{-1} is J -lossless, with G as in the first equality in (3.17). Also $K = K_1 K_2^{-1}$, with K_1, K_2 given by

$$\begin{bmatrix} K_1 \\ K_2 \end{bmatrix} = W^{-1} \begin{bmatrix} U \\ I \end{bmatrix}, \quad \text{some } U \in \mathcal{RH}_\infty, \quad \|U\|_\infty < \gamma.$$

Since K is proper, $K_2(\infty)$ is nonsingular. By Lemma 3.6 we can therefore assume $(W^{-1})_{22}(\infty)$ is nonsingular. Define $N = YW^{-1}$, $D = DW^{-1}$.

Conversely, suppose that P has an r.c.f. as in (3.14). Define W and G as in (3.16), (3.17). By Theorem 3.5 the analytic system defined by G has a solution, and we obtain a suitable controller for P by picking a U in (3.17) with $\|U\|_\infty < \gamma$. Note that, since $N_{22}(\infty)$ is nonsingular, $K_2(\infty)$ is nonsingular for any U with $U(\infty) = 0$.

By Corollary 2.5 and Theorem 3.5, all solutions are generated by (3.15). \square

⁴ $N \in \mathcal{RH}_\infty^{(l+m) \times (q+m)}$, $D \in \mathcal{RH}_\infty^{(m+q) \times (q+m)}$. That is, D_{12} and D_{21} are square, instead of the more usual situation where D_{11} and D_{22} are square. Some ‘‘swapping’’ inevitably occurs; we either do it here, or in Corollaries 2.3, 2.4, 2.5, etc. One reason for doing it this way is the more natural connection with the state-space notation.

For output estimation problems, we have the following theorem.

THEOREM 3.9. *Let $P \in \mathcal{R}^{(q+m) \times (p+q)}$ have r.c.f.*

$$P = \begin{bmatrix} 0 & I_q \\ N_{21} & N_{22} \end{bmatrix} \begin{bmatrix} I_p & 0 \\ D_{21} & D_{22} \end{bmatrix}^{-1}$$

with $G = \begin{bmatrix} N_{21} & -N_{22} \\ -D_{21} & D_{22} \end{bmatrix}$ right invertible in \mathcal{RL}_∞ .

There exists a stabilizing controller K such that $\|\mathcal{F}(P, K)\|_\infty < \gamma$ if and only if P has an l.c.f.

$$(3.18) \quad P = \hat{D}^{-1} \hat{N}, \quad \text{with} \quad \begin{bmatrix} \hat{N}_{11} & \hat{D}_{11} \\ \hat{N}_{21} & \hat{D}_{21} \end{bmatrix} \text{ conjugate } J\text{-lossless and } \hat{N}_{22}(\infty) \text{ nonsingular.}^5$$

In this case, all internally stabilizing controllers such that $\|\mathcal{F}(P, K)\|_\infty \leq \gamma$ are given by

$$(3.19) \quad K = \hat{K}_2^{-1} \hat{K}_1,$$

where \hat{K}_2, \hat{K}_1 are such that

$$(3.20) \quad [\hat{K}_1 \quad \hat{K}_2] = [U \quad I_q] \begin{bmatrix} \hat{D}_{12} & \hat{N}_{12} \\ \hat{D}_{22} & \hat{N}_{22} \end{bmatrix}, \quad U \in \gamma \mathcal{BH}_\infty^{q \times m}, \quad \hat{K}_2(\infty) \text{ nonsingular.}$$

4. \mathcal{H}_∞ control. Although certain \mathcal{H}_∞ control problems, as discussed in § 3.5, can be solved directly as analytic system problems, not all problems are of this type. In this section we treat the general case by observing that a necessary condition for a solution to exist can be used to turn the general problem into an equivalent AS type problem (of output estimation type), which can be solved using Theorem 3.9.

4.1. A necessary condition. By hypothesizing the existence of a stabilizing controller K such that $\|\mathcal{F}(P, K)\|_\infty < \gamma$, we see that a certain analytic system of the model matching type must have a solution. This implies that a certain J -lossless factorization exists. This is used to show that a certain right coprime factorization of P exists.

LEMMA 4.1. *Suppose that $P \in \mathcal{R}^{(l+m) \times (p+q)}$ has an r.c.f. $P = YX^{-1}$ such that $X = \begin{bmatrix} I_p & 0 \\ X_{21} & X_{22} \end{bmatrix}$, Y_{22}, X_{22} are r.c., and Y_{12} is left invertible in \mathcal{RL}_∞ .*

If there exists a stabilizing controller K for P such that $\|\mathcal{F}(P, K)\|_\infty < \gamma$, then P has an r.c.f.

$$(4.1) \quad P = ND^{-1}, \quad \text{with} \quad \begin{bmatrix} N_{11} & N_{12} \\ D_{11} & D_{12} \end{bmatrix} J\text{-lossless and } D_{21}(\infty) \text{ nonsingular.}^6$$

Proof. By Corollary 2.3 there exists a $Q \in \mathcal{RH}_\infty$ such that

$$\begin{bmatrix} \mathcal{F}(P, K) \\ I \end{bmatrix} = \begin{bmatrix} Y_{11} & Y_{12} \\ I & 0 \end{bmatrix} \begin{bmatrix} I \\ Q \end{bmatrix} = G \begin{bmatrix} I \\ Q \end{bmatrix}.$$

By Theorem 3.5 there exists a $W \in \mathcal{GH}_\infty$ such that GW^{-1} is J -lossless. Define $N = YW^{-1}$, $D = XW^{-1}$. By Lemma 3.7 we can take $W_{22}(\infty) = 0$, and it follows that $D_{21}(\infty) = X_{22}(\infty)W_{12}(\infty)^{-1}$. \square

Remarks. If a stabilizing controller exists, then P has a factorization YX^{-1} , with X lower triangular as in the lemma. The condition that Y_{12} have a left inverse in \mathcal{RL}_∞ is, however, an additional assumption.

It is easy to see that if $YX^{-1} = \hat{Y}\hat{X}^{-1}$ are two lower triangular r.c. factorizations, then Y_{12} has a left inverse in \mathcal{RL}_∞ if and only if \hat{Y}_{12} has a left inverse in \mathcal{RL}_∞ . ($\hat{Y}_{12} = Y_{12}X_{22}^{-1}\hat{X}_{22}$. Since $Y_{22}X_{22}^{-1} = \hat{Y}_{22}\hat{X}_{22}^{-1}$ are r.c.f.'s of P_{22} , $X_{22}^{-1}\hat{X}_{22} \in \mathcal{GH}_\infty$.)

⁵ $\hat{N} \in \mathcal{RH}_\infty^{(m+q) \times (p+q)}$, $\hat{D} \in \mathcal{RH}_\infty^{(m+q) \times (q+m)}$.

⁶ $N \in \mathcal{R}^{(l+m) \times (q+p)}$, $D \in \mathcal{R}^{(p+q) \times (q+p)}$, so the off-diagonal blocks of D are square.

Note also that, for Y_{12} to have a left inverse in \mathcal{RL}_∞ , it is necessary, but not sufficient, that P_{12} have a left inverse in \mathcal{RL}_∞ . (It is sufficient if $[Y_{12}]_{X_{22}}^{Y_{12}}$ has full column rank on ∂ : $P_{12} = Y_{12}X_{22}^{-1}$, so for $\lambda \in \partial$, $Y_{12}(\lambda)x = 0 \Rightarrow X_{22}(\lambda)x = y \neq 0$, so $P_{12}(\lambda)y = Y_{12}(\lambda)x = 0$.)

Remark. The best control, the worst disturbance, and the equilibrium equation of [9], [27] are easily seen from the factorization $P = ND^{-1}$ as follows:

$$\begin{bmatrix} u - u_{\text{opt}} \\ w - w_{\text{worst}} \end{bmatrix} = D^{-1} \begin{bmatrix} w \\ u \end{bmatrix} \Rightarrow \begin{bmatrix} z \\ w \end{bmatrix} = \begin{bmatrix} N_{11} & N_{12} \\ D_{11} & D_{12} \end{bmatrix} \begin{bmatrix} u - u_{\text{opt}} \\ w - w_{\text{worst}} \end{bmatrix}.$$

By J -losslessness, we have

$$\|z\|_2^2 - \gamma^2 \|w\|_2^2 = \|u - u_{\text{opt}}\|_2^2 - \gamma^2 \|w - w_{\text{worst}}\|_2^2.$$

The control u_{opt} is optimal in the entropy sense [15]. To obtain an explicit formula for u_{opt} , set $u = u_{\text{opt}}$ above:

$$\begin{bmatrix} w \\ u_{\text{opt}} \end{bmatrix} = D \begin{bmatrix} 0 \\ w - w_{\text{worst}} \end{bmatrix}$$

Thus

$$u_{\text{opt}} = D_{22}(w - w_{\text{worst}}) = D_{22}D_{12}^{-1}w = -(D^{-1})_{12}^{-1}(D^{-1})_{11}w.$$

Note. D_{12} is nonsingular, since it is the 2,2 block of a J -lossless matrix.

By using a left coprime factorization of P , we have the dual of Lemma 4.1, below.

LEMMA 4.2. Suppose that $P \in \mathcal{R}^{(l+m) \times (p+q)}$ has an l.c.f. $P = \hat{X}^{-1}\hat{Y}$ such that $\hat{X} = \begin{bmatrix} I_l & \hat{X}_{12} \\ 0 & \hat{X}_{22} \end{bmatrix}$, \hat{Y}_{22} , \hat{X}_{22} are l.c., and \hat{Y}_{21} is right invertible in \mathcal{RL}_∞ .

If there exists a stabilizing controller K such that $\|\mathcal{F}(P, K)\|_\infty < \gamma$, then P has an l.c.f.

$$(4.2) \quad P = \hat{D}^{-1}\hat{N}, \quad \text{with} \quad \begin{bmatrix} \hat{N}_{11} & \hat{D}_{11} \\ \hat{N}_{21} & \hat{D}_{21} \end{bmatrix} \text{ conjugate } J\text{-lossless and } \hat{D}_{12}(\infty) \text{ nonsingular.}^7$$

4.2. An equivalent problem. Using the special coprime factorization $P = ND^{-1}$ of Lemma 4.1, we show that K is a stabilizing controller for P with $\|\mathcal{F}(P, K)\|_\infty < \gamma$ if and only if K is a stabilizing controller for P_t with $\|\mathcal{F}(P_t, K)\|_\infty < \gamma$ and where P_t is of left-handed stable analytic system type (i.e., an output estimation type problem).

THEOREM 4.3. Suppose that the conditions of Lemma 4.1 hold and $P = ND^{-1}$ is a right coprime factorization as in Lemma 4.1. The following are equivalent:

(1) K is a stabilizing controller for P such that $\|\mathcal{F}(P, K)\|_\infty \leq \gamma$;

(2) K is a stabilizing controller for $P_t \in \mathcal{R}^{(q+m) \times (p+q)}$ such that $\|\mathcal{F}(P_t, K)\|_\infty \leq \gamma$,

where P_t is given by

$$(4.3) \quad P_t = \begin{bmatrix} I_q & 0 \\ N_{21} & N_{22} \end{bmatrix} \begin{bmatrix} 0 & I_p \\ D_{21} & D_{22} \end{bmatrix}^{-1} = \begin{bmatrix} 0 & I_q \\ N_{22} & N_{21} \end{bmatrix} \begin{bmatrix} I_p & 0 \\ D_{22} & D_{21} \end{bmatrix}^{-1}.$$

Proof. Since $\begin{bmatrix} N_{11} & N_{12} \\ D_{11} & D_{12} \end{bmatrix}$ is J -lossless, $D_{12} \in \mathcal{GH}_\infty$ (Lemma 3.3). Now consider the following new factorization of P :

$$(4.4) \quad \begin{bmatrix} \bar{N} \\ \bar{D} \end{bmatrix} = \begin{bmatrix} N \\ D \end{bmatrix} \begin{bmatrix} D_{11} & D_{12} \\ I & 0 \end{bmatrix}^{-1}.$$

⁷ $\hat{N} \in \mathcal{R}^{(m+l) \times (p+q)}$, $\hat{D} \in \mathcal{R}^{(m+l) \times (l+m)}$, so the off-diagonal blocks of \hat{D} are square.

Note that $\bar{D} = \begin{bmatrix} I & 0 \\ \bar{D}_{21} & \bar{D}_{22} \end{bmatrix}$. Hence, by Corollary 2.3, K stabilizes P if and only if $K = \bar{K}_2^{-1} \bar{K}_1$, where

$$(4.5) \quad [\bar{K}_1 \quad \bar{K}_2] \begin{bmatrix} \bar{N}_{21} & -\bar{N}_{22} \\ -\bar{D}_{21} & \bar{D}_{22} \end{bmatrix} = [Q \quad I], \quad \bar{K}_1, \bar{K}_2 \in \mathcal{RH}_\infty, \quad \bar{K}_2(\infty) \text{ nonsingular}$$

and that, in this case,

$$(4.6) \quad \begin{bmatrix} \mathcal{F}(P, K) \\ I \end{bmatrix} = \begin{bmatrix} \bar{N}_{11} & \bar{N}_{12} \\ I & 0 \end{bmatrix} \begin{bmatrix} I \\ Q \end{bmatrix}.$$

Suppose that 1 holds. Let $K = \bar{K}_2^{-1} \bar{K}_1$ be such that \bar{K}_1, \bar{K}_2 satisfy (4.5), with $\mathcal{F}(P, K) \in \gamma\mathcal{BH}_\infty$. Using Lemma 3.4, (4.4), and (4.6), it follows that $I - D_{11}Q \in \mathcal{GH}_\infty$ (equivalently, $I - QD_{11} \in \mathcal{GH}_\infty$) and that $R = (I - QD_{11})^{-1}QD_{12} \in \gamma\mathcal{BH}_\infty$. Now use (4.4) and (4.5) to get

$$(4.7) \quad [K_1 \quad K_2] \begin{bmatrix} N_{22} & -N_{21} \\ -D_{22} & D_{21} \end{bmatrix} = [R \quad I], \quad K_1, K_2 \in \mathcal{RH}_\infty, \quad K_2(\infty) \text{ nonsingular}$$

and

$$(4.8) \quad R \in \gamma\mathcal{BH}_\infty,$$

where

$$[K_1 \quad K_2] = (I - QD_{11})^{-1}[\bar{K}_1 \quad \bar{K}_2].$$

It follows from Corollary 2.3 that $K_2^{-1}K_1 = \bar{K}_2^{-1}\bar{K}_1 = K$ stabilizes P_t , and $\mathcal{F}(P_t, K) = R \in \gamma\mathcal{BH}_\infty$.

Suppose that 2 holds. By Corollary 2.3, let $K = K_2^{-1}K_1$ be such that (4.7) and (4.8) hold ($R = \mathcal{F}(P_t, K)$). Then, by Lemma 3.4, it follows that $D_{11}R + D_{12} \in \mathcal{GH}_\infty$ (equivalently, $I + D_{12}^{-1}D_{11}R \in \mathcal{GH}_\infty$, or $I + RD_{12}^{-1}D_{11} \in \mathcal{GH}_\infty$) and that $(N_{11}R + N_{12}) \times (D_{11}R + D_{12})^{-1} \in \gamma\mathcal{BH}_\infty$. Define

$$\begin{aligned} [\bar{K}_1 \quad \bar{K}_2] &= (I + RD_{12}^{-1}D_{11})^{-1}[K_1 \quad K_2], \\ Q &= (I + RD_{12}^{-1}D_{11})^{-1}RD_{12} = R(D_{11}R + D_{12})^{-1}. \end{aligned}$$

It is easily verified that (4.5) and (4.6) hold, with $\mathcal{F}(P, K) = (N_{11}R + N_{12})(D_{11}R + D_{12})^{-1}$. \square

4.3. The general solution. The necessary condition of Lemma 4.1 reduces the general suboptimal \mathcal{H}_∞ control problem to another suboptimal \mathcal{H}_∞ control problem of left-handed analytic system type (i.e., of output estimation type), by Theorem 4.3. This problem can be solved directly using the theory of § 3.

THEOREM 4.4. $P \in \mathcal{R}^{(l+m) \times (p+q)}$ has an r.c.f. $P = YX^{-1}$ and an l.c.f. $P = \hat{X}^{-1}\hat{Y}$ such that

- (1) $X = \begin{bmatrix} I_p & 0 \\ \hat{X}_{21} & \hat{X}_{22} \end{bmatrix}$, Y_{22}, X_{22} are r.c. and Y_{12} is left invertible in \mathcal{L}_∞ ;
- (2) $\hat{X} = \begin{bmatrix} I_l & \hat{X}_{12} \\ 0 & \hat{X}_{22} \end{bmatrix}$, $\hat{X}_{22}, \hat{Y}_{22}$ are l.c. and \hat{Y}_{21} is right invertible in \mathcal{L}_∞ .

There exists a stabilizing controller K for P such that $\|\mathcal{F}(P, K)\|_\infty < \gamma$ if and only if the following two conditions hold:

$$(4.9) \quad (a) \quad P \text{ has an r.c.f. } P = ND^{-1}, \text{ with } \begin{bmatrix} N_{11} & N_{12} \\ D_{11} & D_{12} \end{bmatrix} \text{ is } J\text{-lossless and } D_{21}(\infty)$$

nonsingular;

(b) P_t has a l.c.f.

$$(4.10) \quad P_t = \hat{D}^{-1} \hat{N}, \quad \text{with} \quad \begin{bmatrix} \hat{N}_{11} & \hat{D}_{11} \\ \hat{N}_{21} & \hat{D}_{21} \end{bmatrix} \text{ conjugate } J\text{-lossless and } \hat{N}_{22}(\infty) \text{ nonsingular},^8$$

where

$$(4.11) \quad P_t = \begin{bmatrix} I_q & 0 \\ N_{21} & N_{22} \end{bmatrix} \begin{bmatrix} 0 & I_p \\ D_{21} & D_{22} \end{bmatrix}^{-1} \in \mathcal{R}^{(q+m) \times (p+q)}.$$

In this case, K is a stabilizing controller for P such that $\|\mathcal{F}(P, K)\|_\infty \leq \gamma$ if and only if $K = \hat{K}_2^{-1} \hat{K}_1$, where

$$(4.12) \quad [\hat{K}_1 \quad \hat{K}_2] = [U \quad I_q] \begin{bmatrix} \hat{D}_{12} & \hat{N}_{12} \\ \hat{D}_{22} & \hat{N}_{22} \end{bmatrix}, \quad U \in \gamma \mathcal{B}\mathcal{H}_\infty^{q \times m}, \quad \hat{K}_2(\infty) \text{ nonsingular}.$$

Equivalently,

$$(4.13) \quad K = \mathcal{F}(K_a, U),$$

$$(4.14) \quad K_a = \begin{bmatrix} \hat{N}_{12} & I_m \\ \hat{N}_{22} & 0 \end{bmatrix}^{-1} \begin{bmatrix} \hat{D}_{12} & 0 \\ \hat{D}_{22} & I_q \end{bmatrix}.$$

Note. $\hat{N}_{22}(\infty)$ nonsingular ensures $\hat{K}_2(\infty)$ is nonsingular for any strictly proper U . It also ensures K_a is proper.

Proof. The result follows from Lemma 4.1, Theorem 4.3, and Theorem 3.9, provided G_t has a right inverse in \mathcal{RL}_∞ . ($G_t = \begin{bmatrix} N_{22} & -N_{21} \\ -D_{22} & D_{21} \end{bmatrix}$). We therefore must show that this is the case, provided P has l.c.f. satisfying 2. This we do as follows.

Since $ND^{-1} = \hat{X}^{-1} \hat{Y}$ are an r.c.f and an l.c.f of P , there exist $U, V, \hat{U}, \hat{V} \in \mathcal{RH}_\infty$ such that

$$(4.15) \quad \begin{bmatrix} D & -U \\ N & V \end{bmatrix} \begin{bmatrix} \hat{V} & \hat{U} \\ -\hat{Y} & \hat{X} \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}.$$

Suppose, to obtain a contradiction, that G_t does not have full row rank on ∂ . Then there exist $\lambda \in \partial$ and x_1, x_2 , not both zero, such that

$$\begin{aligned} [x_2 \quad -x_1] G_t(\lambda) &= [0 \quad 0] \\ \Leftrightarrow [0 \quad x_1 \quad 0 \quad x_2] \begin{bmatrix} D & -U \\ N & V \end{bmatrix}(\lambda) &= [0 \quad 0 \quad y_1 \quad y_2] \\ \Leftrightarrow [0 \quad x_1 \quad 0 \quad x_2] &= [0 \quad 0 \quad y_1 \quad y_2] \begin{bmatrix} \hat{V} & \hat{U} \\ -\hat{Y} & \hat{X} \end{bmatrix}(\lambda) \\ \Leftrightarrow y_1 &= 0 \text{ (by the structure of } \hat{X} \text{) and } y_2 [\hat{Y}_{21} \hat{Y}_{22} \hat{X}_{22}](\lambda) = [0 \quad x_1 \quad x_2]. \end{aligned}$$

So G_t has a right inverse in $\mathcal{RL}_\infty \Leftrightarrow \hat{Y}_{21}$ has a right inverse in \mathcal{RL}_∞ . \square

Remark. Suppose that $P(s) = D + C(sI - A)^{-1}B$. Then the factorizations with the requisite triangular structure exist provided (A, B_2, C_2) is stabilizable and detectable. In this case, Y_{12} and \hat{Y}_{21} are, respectively, left invertible and right invertible in \mathcal{RL}_∞ if and only if the matrices

$$\begin{bmatrix} A - \lambda I & B_2 \\ C_1 & D_{12} \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} A - \lambda I & B_1 \\ C_2 & D_{21} \end{bmatrix}$$

have full column and row rank, respectively, for all $\lambda \in \partial$. These conditions are also required in other approaches to the \mathcal{H}_∞ synthesis problem [9], [16]–[18], [28].

⁸ $\hat{N} \in \mathcal{R}^{(m+q) \times (p+q)}$, $\hat{D} \in \mathcal{R}^{(m+q) \times (q+m)}$.

Remark. Theorem 4.4 solves the \mathcal{H}_∞ controller synthesis problem in the sense that if and only if we can find the J -lossless coprime factorizations (4.9) and (4.10), the problem has solutions. This is only meaningful if we can actually say something about when we can find these factorizations. In the remainder of the paper, we will develop a state-space answer to the question of when these factorizations exist. However, one advantage of the transfer matrix statement of the result is that *any* method by which J -lossless factorizations can be calculated will be a method by which \mathcal{H}_∞ controllers can be calculated. An alternative to a state-space approach to the calculation of the J -lossless coprime factorizations is a polynomial matrix type approach.

Remark. The necessary condition of Lemma 4.2 plays no apparent role in the necessary and sufficient condition of Theorem 4.4. A number of questions therefore arise. How does the factorization (4.10) imply the existence of the factorization (4.2)? Is it equivalent to (4.2)? If not (and it is not), what additional condition is involved in (4.10)?

A further interesting point is that a dual necessary and sufficient condition, and a dual generator of all \mathcal{H}_∞ controllers, can be given based on Lemma 4.2 as the starting point instead of Lemma 4.1 (this particular route, where the observer is constructed first and the full information feedback second, was taken in [18]). Obviously, since both approaches are necessary and sufficient conditions for the solution of the same problem, they are equivalent. Do they give the same controller generator, however? How precisely are the four J -lossless factorizations involved in the two approaches connected? Some progress has been made toward answering these questions, but a complete answer is yet to emerge. It is true that the generators of all \mathcal{H}_∞ controllers obtained via the two dual approaches are exactly the same. A state space proof of this for the “uncoupled” case of [9] is very straightforward, but the calculations become very involved in the general case. A transfer matrix proof is possible, and will be reported elsewhere.

5. J -spectral and J -lossless factorizations.

5.1. J -spectral factorization.

DEFINITION. A matrix $H \in \mathbb{C}^{2n \times 2n}$ is a Hamiltonian matrix if $\hat{J}H = H^* \hat{J}^*$, $\hat{J} = \begin{bmatrix} 0 & I_n \\ I_n & 0 \end{bmatrix}$ (i.e., $H_{22} = -H_{11}^*$, $H_{12}^* = H_{12}$ and $H_{21}^* = H_{21}$).

If H is Hamiltonian, we say $H \in \text{dom}(\text{Ric})$ if there exists an $n \times n$ matrix Q such that

$$(5.1) \quad H \begin{bmatrix} I \\ Q \end{bmatrix} = \begin{bmatrix} I \\ Q \end{bmatrix} \Lambda, \quad \text{with } \Lambda \mathbb{C}_+ \text{ asymptotically stable.}$$

($\Lambda \mathbb{C}_+$ asymptotically stable means all eigenvalues of Λ have strictly negative real part.) If $H \in \text{dom}(\text{Ric})$, then $Q = \text{Ric}(H)$ has the properties

$$\begin{aligned} Q &= Q^*, \\ (H_{11} + H_{12}Q) &= \Lambda = (-H_{22} + QH_{12})^* \text{ is } \mathbb{C}_+ \text{ asymptotically stable,} \\ QH_{11} + H_{11}^*Q + QH_{12}Q - H_{21} &= 0. \end{aligned}$$

Thus Q is a stabilizing solution to an algebraic Riccati equation.

The equivalence between J -spectral factorization and the solution of indefinite Riccati equations is as follows.

THEOREM 5.1 (see [18]). Suppose that $G \in \mathcal{RH}_\infty^{(l+m) \times (q+m)}(\mathbb{C}_+)$ is given by the realization $G(s) = D + C(sI - A)^{-1}B$, with $A \in \mathbb{C}^{n \times n}$ asymptotically stable.⁹ There exists

⁹ We will also need $G \in \mathcal{RH}_\infty^{(l+m) \times (m+q)}$. The off-diagonal blocks of W are then the square ones instead of the diagonal ones.

a W such that

$$(5.2) \quad \tilde{G}^* J_{lm}(\gamma) G = \tilde{W}^* J_{qm}(\gamma) W \quad \text{with } W \in \mathcal{GH}_\infty^{q+m}(\mathbb{C}_+)$$

if and only if

(1) There exists a nonsingular constant matrix W_∞^{q+m} such that

$$(5.3) \quad D^* J_{lm}(\gamma) D = W_\infty^* J_{qm}(\gamma) W_\infty$$

and

(2) $H \in \text{dom}(\text{Ric})$, where, with $J = J_{lm}(\gamma)$,

$$(5.4) \quad H = \begin{bmatrix} A & 0 \\ -C^* J C & -A^* \end{bmatrix} - \begin{bmatrix} B \\ -C^* J D \end{bmatrix} (D^* J D)^{-1} [D^* J C \quad B^*].$$

In this case, $W \in \mathcal{GH}_\infty(\mathbb{C}_+)$ satisfies (5.2) if and only if, for some solution W_∞ of (5.3), W is given by

$$(5.5a) \quad W(s) = W_\infty + L(sI - A)^{-1} B,$$

where

$$(5.5b) \quad L = J^{-1} W_\infty^{-*} (D^* J C + B^* Q), \quad \text{with } Q = \text{Ric}(H).$$

Proof. For the proof, see [18]. \square

Remark. An alternative statement of the theorem is: If A is asymptotically stable, then there exists a $W \in \mathcal{GH}_\infty(\mathbb{C}_+)$ such that $\tilde{G}^* J G = \tilde{W}^* J W$, $G = D + C(sI - A)^{-1} B$ if and only if there exist $Q = Q^*$, L , W_∞ satisfying the linear matrix equality

$$(5.6) \quad \begin{bmatrix} QA + A^* Q + C^* J C & QB + C^* J D \\ D^* J C + B^* Q & D^* J D \end{bmatrix} = \begin{bmatrix} L^* \\ W_\infty^* \end{bmatrix} J \begin{bmatrix} I & W_\infty \end{bmatrix}$$

and such that

$$(5.7) \quad W_\infty \text{ is nonsingular and } A - BW_\infty^{-1}L \text{ is asymptotically stable.}$$

For discrete time, replace (5.6) with

$$(5.8) \quad \begin{bmatrix} A & B \\ C & D \end{bmatrix}^* \begin{bmatrix} Q & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} I & O \\ L & W_\infty \end{bmatrix}^* \begin{bmatrix} Q & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} I & 0 \\ L & W_\infty \end{bmatrix}.$$

This can be proved either directly or from the continuous time result via bilinear transformation of the realizations—see, e.g., [14, § 2.2]. Note that, if A is \mathbb{D}_+ asymptotically stable, then $(A - I)$ is nonsingular, which is required to transform the realization.

To calculate Q , L , W_∞ we must obtain the stable eigenspace of the Hamiltonian matrix (for continuous time). For discrete time, an analogous algorithm involving a symplectic matrix is appropriate [31].

Note also that more conventional-looking forms of the Riccati equations may be obtained from (5.6) and (5.8) by substituting for L and W_∞ from the (2,1) and (2,2) blocks into the (1,1) block. (Equivalently, take Schur complements with respect to the (2,2) block.) \square

The following lemma is useful in state-space calculations, especially in § 6.

LEMMA 5.2. Suppose that D_2 is a nonsingular matrix. Let

$$G_1 \stackrel{s}{=} \begin{bmatrix} A & B \\ C_1 & D_1 \end{bmatrix}$$

and

$$G_2 \stackrel{s}{=} \begin{bmatrix} A - BD_2^{-1}C_2 & BD_2^{-1} \\ C_1 - D_1D_2^{-1}C_2 & D_1D_2^{-1} \end{bmatrix} = \begin{bmatrix} A & B \\ C_1 & D_1 \end{bmatrix} \begin{bmatrix} I & 0 \\ C_2 & D_2 \end{bmatrix}^{-1}.$$

The Hamiltonian matrices H_1 and H_2 associated via (5.4) with the realizations above are identical. Furthermore, in obvious notation,

$$\begin{bmatrix} L_2 & W_2 \end{bmatrix} = \begin{bmatrix} L_1 & W_1 \end{bmatrix} \begin{bmatrix} I & 0 \\ C_2 & D_2 \end{bmatrix}^{-1}.$$

Proof. The proof is obtained by direct calculation. This is also easily seen from (5.6) (or (5.8) for the discrete time analogue). \square

5.2. J -lossless factorization. We now consider when the factorization $\tilde{G}^* J G = \tilde{W}^* J W$ is such that $G W^{-1}$ is J -lossless. We will show that this is the case if and only if the stabilizing solution to the algebraic Riccati equation is positive semidefinite.

THEOREM 5.3. *Let $G(s) = D + C(sI - A)^{-1}B \in \mathcal{RH}_\infty^{(l+m) \times (q+m)}(\mathbb{C}_+)$, with $A \in \mathbb{C}_+$ asymptotically stable. Then there exists a $W \in \mathcal{GH}_\infty^{q+m}(\mathbb{C}_+)$ such that $G W^{-1}$ is J -lossless if and only if*

(1) *There exists a nonsingular $W_\infty \in \mathbb{C}^{(q+m) \times (q+m)}$ such that $W_\infty^* J_{qm}(\gamma) W_\infty = D^* J_{lm}(\gamma) D$;*

(2) *$H \in \text{dom}(\text{Ric})$, with H as in (5.4);*

(3) *$\text{Ric}(H) \geq 0$.*

Proof. Conditions 1 and 2 are necessary and sufficient for the existence of a $W \in \mathcal{GH}_\infty$ such that $(G W^{-1})^* J (G W^{-1}) = J$ on $j\mathbb{R}$. Using (5.5), obtain a realization of $X = G W^{-1}$;

$$(5.9) \quad X = G W^{-1} \stackrel{s}{=} \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} I & 0 \\ L & W_\infty \end{bmatrix}^{-1} = \begin{bmatrix} \bar{A} & \bar{B} \\ \bar{C} & \bar{D} \end{bmatrix}.$$

Let $Q = \text{Ric}(H)$. Using Lemma 5.2, it follows from (5.9) and (5.6) that

$$(5.10) \quad \bar{D}^* J \bar{D} = (D W_\infty^{-1})^* J (D W_\infty^{-1}) = J,$$

$$(5.11) \quad \bar{D}^* J \bar{C} + \bar{B}^* Q = 0,$$

$$(5.12) \quad Q \bar{A} + \bar{A}^* Q + \bar{C}^* J \bar{C} = 0.$$

Since \bar{A} is asymptotically stable, $X \in \mathcal{RH}_\infty$. By Lemma 3.3, X is J -lossless $\Leftrightarrow X_{22} \in \mathcal{GH}_\infty$. Partition \bar{C} , \bar{B} , \bar{D} appropriately. By the asymptotic stability of \bar{A} , $X_{22} \in \mathcal{GH}_\infty \Leftrightarrow \bar{A} - \bar{B}_2 \bar{D}_{22}^{-1} \bar{C}_2$ is asymptotically stable. We now show this is the case if and only if $Q \geq 0$.

From the (2,2) block of (5.10), we have $\bar{D}_{12}^* \bar{D}_{12} - \gamma^2 \bar{D}_{22}^* \bar{D}_{22} = -\gamma^2 I$, so

$$(5.13) \quad \bar{D}_{22} \text{ is nonsingular, and } \|\bar{D}_{12} \bar{D}_{22}^{-1}\| < \gamma.$$

Also, from the (2,1) block of (5.11), we have that

$$(5.14) \quad \bar{D}_{12}^* \bar{C}_1 - \gamma^2 \bar{D}_{22}^* \bar{C}_2 + \bar{B}_2^* Q = 0.$$

Hence

$$\begin{aligned} & Q(\bar{A} - \bar{B}_2 \bar{D}_{22}^{-1} \bar{C}_2) + (\bar{A} - \bar{B}_2 \bar{D}_{22}^{-1} \bar{C}_2)^* Q \\ &= -\bar{C}_1^* \bar{C}_1 + \gamma^2 \bar{C}_2^* \bar{C}_2 + \bar{C}_2^* \bar{D}_{22}^{-*} [\bar{D}_{12}^* \bar{C}_1 - \gamma^2 \bar{D}_{22}^* \bar{C}_2] \\ & \quad + [\bar{D}_{12}^* \bar{C}_1 - \gamma^2 \bar{D}_{22}^* \bar{C}_2]^* \bar{D}_{22}^{-1} \bar{C}_2, \text{ using (5.14) and (5.12)} \\ &= -[\bar{C}_1^* \bar{C}_2^*] \begin{bmatrix} I & -\bar{D}_{12} \bar{D}_{22}^{-1} \\ -\bar{D}_{22}^* \bar{D}_{12}^* & \gamma^2 I \end{bmatrix} \begin{bmatrix} \bar{C}_1 \\ \bar{C}_2 \end{bmatrix} = -\bar{C}^* R \bar{C}. \end{aligned}$$

Since $\|\bar{D}_{12}\bar{D}_{22}^{-1}\| < \gamma$, $R > 0$ and since \bar{A} is asymptotically stable, $(R^{1/2}\bar{C}, \bar{A} - \bar{B}_2\bar{D}_{22}^{-1}\bar{C}_2)$ is detectable. Therefore $\bar{A} - \bar{B}_2\bar{D}_{22}^{-1}\bar{C}_2$ is asymptotically stable if and only if $Q \geq 0$ [34]. \square

Remark. For discrete time, the result is the following.

Let $G(z) = D + C(zI - A)^{-1}B \in \mathcal{RH}_\infty^{(l+m) \times (q+m)}(\mathbb{D}_+)$, with A asymptotically stable. There exists a $W \in \mathcal{GH}_\infty^{q+m}(\mathbb{D}_+)$ such that GW^{-1} is J -lossless if and only if there exists $Q \geq 0$, L , W_∞ satisfying (5.7) and (5.8).

The sufficiency proof is easy: By direct calculation, $(GW^{-1})^*J(GW^{-1}) = J + (1 - |z|^2)\bar{B}(\bar{z}I - \bar{A}^*)^{-1}Q(zI - \bar{A})^{-1}\bar{B}$.

For necessity, note that $GW^{-1} \in \mathcal{RH}_\infty$ J -lossless $\Rightarrow (GW^{-1})_{22} \in \mathcal{GH}_\infty \Rightarrow \bar{D}_{22} = (DW_\infty^{-1})_{22}(\infty)$ is nonsingular. The proof then goes similarly to the continuous case and can be compactly formulated as follows.

First, note that

$$(5.15) \quad \begin{bmatrix} \bar{A} & \bar{B} \\ \bar{C} & \bar{D} \end{bmatrix}^* \begin{bmatrix} Q & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} \bar{A} & \bar{B} \\ \bar{C} & \bar{D} \end{bmatrix} = \begin{bmatrix} Q & 0 \\ 0 & J \end{bmatrix}.$$

Partition \bar{B} , \bar{C} , \bar{D} and consider $(X^{-1})^*(5.15)X^{-1}$, with

$$X = \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ \bar{C}_2 & \bar{D}_{21} & \bar{D}_{22} \end{bmatrix}.$$

Examining the (1, 1) block, we obtain a Lyapunov equation for $\bar{A} - \bar{B}_2\bar{D}_{22}^{-1}\bar{C}_2$. \square

6. State-space formulae. We now calculate the controller generator of Theorem 4.4 by applying Theorem 5.3 twice. To avoid clutter, we will not specify the dimensions of matrices¹⁰. We will also use J instead of $J_{pq}(\gamma)$, etc. The disadvantage of this is that the symbol J is used within the same equation to mean different matrices. No confusion should however occur: a J that multiplies a B , C , or D matrix is different (of larger dimension) from one that multiplies a W , L , or M matrix.

The results will be stated for the continuous case, with remarks giving the changes for discrete time—the actual formula for the generator of all controllers is exactly the same, with the obvious replacement of continuous time L 's and W_∞ 's, etc., with their discrete time counterparts (see also [28]).

6.1. J -lossless coprime factorizations. The following lemma facilitates calculations involving matrix fractions.

LEMMA 6.1. Suppose that D_2 and D_3 are nonsingular matrices, and

$$\begin{bmatrix} N \\ D \end{bmatrix} \stackrel{s}{=} \begin{bmatrix} A & B \\ C_1 & D_1 \\ C_2 & D_2 \end{bmatrix} \begin{bmatrix} I & 0 \\ F & D_3 \end{bmatrix}^{-1}.$$

Then

$$ND^{-1} \stackrel{s}{=} \begin{bmatrix} A & B \\ C_1 & D_1 \end{bmatrix} \begin{bmatrix} I & 0 \\ C_2 & D_2 \end{bmatrix}^{-1}.$$

Proof. The proof is obtained by direct calculation. \square

THEOREM 6.2. Let P have state-space realization $D + C(sI - A)^{-1}B$, with (A, B) stabilizable and (C, A) detectable. Define \bar{C} and \bar{D} to be the matrices

$$(6.1) \quad \bar{D} = \begin{bmatrix} D_{11} & D_{12} \\ I & 0 \end{bmatrix}, \quad \bar{C} = \begin{bmatrix} C_1 \\ 0 \end{bmatrix}.$$

¹⁰ See the theorem statements in § 4 to get explicit dimensions.

Then P has an r.c.f. such that

$$(6.2) \quad P = ND^{-1}, \quad N, D, \text{ r.c., and } \begin{bmatrix} N_{11} & N_{12} \\ D_{11} & D_{12} \end{bmatrix} \text{ } J\text{-lossless and } D_{21}(\infty) \text{ nonsingular}$$

if and only if

(1) There exists a nonsingular matrix W_∞ such that

$$(6.3) \quad W_\infty^* J W_\infty = \bar{D}^* J \bar{D},$$

equivalently,

$$(6.4) \quad D_{12}^* D_{12} > 0 \quad \text{and} \quad \Phi = D_{11}^* [I - D_{12} (D_{12}^* D_{12})^{-1} D_{12}^*] D_{11} < \gamma^2 I;$$

(2) $H_X \in \text{dom}(\text{Ric})$, where

$$(6.5) \quad H_X = \begin{bmatrix} A & 0 \\ -\bar{C}^* J \bar{C} & -A^* \end{bmatrix} - \begin{bmatrix} B \\ -\bar{C}^* J \bar{D} \end{bmatrix} (\bar{D}^* J \bar{D})^{-1} [\bar{D}^* J \bar{C} \quad B^*];$$

(3) $X_\infty = \text{Ric}(H_X) \geq 0$.

In this case, N and D are given by the realizations

$$(6.6) \quad \begin{bmatrix} N \\ D \end{bmatrix} \stackrel{s}{=} \begin{bmatrix} A & B \\ C & D \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ L & W_\infty \end{bmatrix}^{-1},$$

where W_∞ is any solution to (6.3) and

$$(6.7) \quad W_\infty^* J L = \bar{D}^* J \bar{C} + B^* X_\infty.$$

One solution to (6.3) is given by

$$(6.8) \quad W_\infty = \begin{bmatrix} (D_{12}^* D_{12})^{-1/2} D_{12}^* D_{11} & (D_{12}^* D_{12})^{1/2} \\ \gamma^{-1} (\gamma^2 I - \Phi)^{1/2} & 0 \end{bmatrix}.$$

Proof. Let F be any matrix such that $A - BF$ is asymptotically stable and define Y and X by

$$(6.9) \quad \begin{bmatrix} Y \\ X \end{bmatrix} \stackrel{s}{=} \begin{bmatrix} A & B \\ C & D \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ F & I \end{bmatrix}^{-1}.$$

Note that Y, X are r.c. since (C, A) is detectable. Define G by

$$(6.10) \quad G = \begin{bmatrix} Y_{11} & Y_{12} \\ X_{11} & X_{12} \end{bmatrix} \stackrel{s}{=} \begin{bmatrix} A & B \\ \bar{C} & \bar{D} \end{bmatrix} \begin{bmatrix} I & 0 \\ F & I \end{bmatrix}^{-1}.$$

The coprime factorization in (6.2) exists if and only if there exists a $W \in \mathcal{GH}_\infty$ such that $N = YW^{-1}$, $D = XW^{-1}$, and GW^{-1} is J -lossless. The result now follows from Theorem 5.3, using Lemma 5.2.

That (6.8) is a solution to (6.3) follows by direct calculation. \square

Remark. For discrete time, X_∞, L, W_∞ must satisfy

$$\begin{bmatrix} A & B \\ \bar{C} & \bar{D} \end{bmatrix}^* \begin{bmatrix} X_\infty & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} A & B \\ \bar{C} & \bar{D} \end{bmatrix} = \begin{bmatrix} I & 0 \\ L & W_\infty \end{bmatrix}^* \begin{bmatrix} X_\infty & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} I & 0 \\ L & W_\infty \end{bmatrix},$$

W_∞ nonsingular, $A - BW_\infty^{-1}L$ asymptotically stable, and $X_\infty \geq 0$.

Note that conditions analogous to (6.4) and a formula for W_∞ of the form (6.8) can be simply obtained for the discrete case by considering

$$\tilde{D}_{11} = \begin{bmatrix} X_\infty^{1/2} B_1 \\ D_{11} \end{bmatrix}, \quad \tilde{D}_{12} = \begin{bmatrix} X_\infty^{1/2} B_2 \\ D_{12} \end{bmatrix}.$$

Remark. The Riccati equations obtained from Theorem 6.2 are associated with the full information or state feedback \mathcal{H}_∞ synthesis problem [9], [27]. They also arise in the theory of linear quadratic differential games, which can be used as the basis for a solution to the \mathcal{H}_∞ synthesis problem [27], [28].

Remark. In § 4.1, we saw that

$$\begin{bmatrix} 0 \\ w - w_{\text{worst}} \end{bmatrix} = D^{-1} \begin{bmatrix} w \\ u_{\text{opt}} \end{bmatrix}.$$

From (6.6), $D^{-1} \stackrel{s}{=} \begin{bmatrix} A & B \\ L & w_\infty \end{bmatrix}$. Hence

$$0 = L_1 x + W_{11} w + W_{12} u_{\text{opt}},$$

giving

$$u_{\text{opt}} = -W_{12}^{-1}(L_1 x + W_{11} w).$$

Note that u_{opt} is *not* a pure state feedback in general, which is the reason for the term “full information” introduced in [9]. The condition for pure state feedback is $W_{11} = 0$, which can be mapped back to original data from (6.8): $D_{12}^* D_{11} = 0$ in continuous time, and $B_2^* X_\infty B_1 + D_{12}^* D_{11} = 0$ in discrete time. That is, the contributions of the disturbance w and the control u to the controlled variable z are independent. In this case, the second condition in (6.4) becomes $D_{11}^* D_{11} < \gamma^2 I$ in continuous time and $D_{11}^* D_{11} + B_1^* X_\infty B_1 < \gamma^2 I$ in discrete time.

Similarly, from

$$\begin{bmatrix} u - u_{\text{opt}} \\ 0 \end{bmatrix} = D^{-1} \begin{bmatrix} w_{\text{worst}} \\ u \end{bmatrix},$$

we have

$$0 = L_2 x + W_{21} w_{\text{worst}},$$

so

$$w_{\text{worst}} = -W_{21}^{-1} L_2 x.$$

Note that these formulae are valid for both continuous time and discrete time systems—we just need to use the appropriate L ’s and W ’s.

THEOREM 6.3. *Let P have state-space realization $D + C(sI - A)^{-1}B$, with (A, B) stabilizable and (C, A) detectable. Define \bar{B} and \bar{D} to be the matrices*

$$(6.11) \quad \bar{D} = \begin{bmatrix} D_{11} & I \\ D_{21} & 0 \end{bmatrix}, \quad \bar{B} = \begin{bmatrix} B_1 & 0 \end{bmatrix}.$$

Then P has an l.c.f. such that

$$(6.12) \quad P = \hat{D}^{-1} \hat{N}, \quad \hat{D}, \hat{N} \text{ l.c. and } \begin{bmatrix} \hat{N}_{11} & \hat{D}_{11} \\ \hat{N}_{21} & \hat{D}_{21} \end{bmatrix} \text{ conjugate } J\text{-lossless and } \hat{D}_{12}(\infty) \text{ nonsingular}$$

if and only if

(1) *There exists a nonsingular matrix W_∞ such that*

$$(6.13) \quad \hat{W}_\infty J \hat{W}_\infty^* = \bar{D} J \bar{D}^*,$$

equivalently,

$$(6.14) \quad D_{21} D_{21}^* > 0 \quad \text{and} \quad \hat{\Phi} = D_{11} [I - D_{21}^* (D_{21} D_{21}^*)^{-1} D_{21}] D_{11}^* < \gamma^2 I;$$

(2) $H_Y \in \text{dom}(\text{Ric})$, where

$$(6.15) \quad H_Y = \begin{bmatrix} A^* & 0 \\ -\bar{B} J \bar{B}^* & -A \end{bmatrix} - \begin{bmatrix} C^* \\ -\bar{B} J \bar{D}^* \end{bmatrix} (\bar{D} J \bar{D}^*)^{-1} [\bar{D} J \bar{B}^* \quad C];$$

(3) $Y_\infty = \text{Ric}(H) \geq 0$.

In this case, \hat{N} and \hat{D} are given by the realizations

$$(6.16) \quad [\hat{N} \quad \hat{D}] \stackrel{s}{=} \begin{bmatrix} I & M \\ 0 & \hat{W}_\infty \end{bmatrix}^{-1} \begin{bmatrix} A & B & 0 \\ C & D & I \end{bmatrix},$$

where \hat{W}_∞ is any solution to (6.13) and

$$(6.17) \quad MJ\hat{W}_\infty^* = \bar{B}J\bar{D}^* + Y_\infty C^*.$$

One solution to (6.13) is given by

$$(6.18) \quad \hat{W}_\infty = \begin{bmatrix} D_{11}D_{21}^*(D_{21}D_{21}^*)^{-1/2} & \gamma^{-1}(\gamma^2 I - \hat{\Phi})^{1/2} \\ (D_{21}D_{21}^*)^{1/2} & 0 \end{bmatrix}.$$

Remark. For discrete time, Y_∞ , M , \hat{W}_∞ must satisfy

$$\begin{bmatrix} A & \bar{B} \\ C & \bar{D} \end{bmatrix} \begin{bmatrix} Y_\infty & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} A & \bar{B} \\ C & \bar{D} \end{bmatrix}^* = \begin{bmatrix} I & M \\ 0 & \hat{W}_\infty \end{bmatrix} \begin{bmatrix} Y_\infty & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} I & M \\ 0 & \hat{W}_\infty \end{bmatrix}^*,$$

\hat{W}_∞ nonsingular, $A - M\hat{W}_\infty^{-1}C$ asymptotically stable, and $Y_\infty \geq 0$.

6.2. Calculation of P_t .

LEMMA 6.4 (Hypotheses as for Theorem 6.2). Suppose also that 1, 2, 3 of Theorem 6.2 hold, and that W_∞ is given by (6.8). For convenience, write

$$(6.19) \quad W_\infty = \begin{bmatrix} W_{11} & W_{12} \\ W_{21} & 0 \end{bmatrix}.$$

Then

$$(6.20) \quad P_t = \begin{bmatrix} I & 0 \\ N_{21} & N_{22} \end{bmatrix} \begin{bmatrix} 0 & I \\ D_{21} & D_{22} \end{bmatrix}^{-1}$$

is given by the realization

$$(6.21) \quad P_t \stackrel{s}{=} \begin{bmatrix} A_t & B_t \\ C_t & D_t \end{bmatrix} = \begin{bmatrix} A & B_1 & B_2 \\ L_1 & W_{11} & W_{12} \\ C_2 & D_{21} & D_{22} \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ L_2 & W_{21} & 0 \\ 0 & 0 & I \end{bmatrix}^{-1}.$$

Proof. The proof follows from the realization (6.6) for N , D , and Lemma 6.1, noting that

$$\begin{array}{ccc|ccc} I & 0 & & A & B_1 & B_2 \\ N_{21} & N_{22} & & L_1 & W_{11} & W_{12} \\ & & & C_2 & D_{21} & D_{22} \\ 0 & I & \stackrel{s}{=} & L_2 & W_{21} & 0 \\ D_{21} & D_{22} & & 0 & 0 & I \end{array} \begin{bmatrix} I & 0 \\ L & W_\infty \end{bmatrix}^{-1}.$$

□

6.3. Factorization of P_t and the controller generator.

THEOREM 6.5 (Hypotheses and notation as for Lemma 6.4). Define \bar{B}_t and \bar{D}_t to be the matrices

$$(6.33) \quad \begin{bmatrix} \bar{B}_t \\ \bar{D}_t \end{bmatrix} = \begin{bmatrix} B_1 & 0 \\ W_{11} & I \\ D_{21} & 0 \end{bmatrix} \begin{bmatrix} W_{21} & 0 \\ 0 & I \end{bmatrix}^{-1}.$$

Then P_t has an l.c.f. such that

$$(6.24) \quad P = \hat{D}^{-1} \hat{N}, \hat{D}, \hat{N} \text{ l.c. and } \begin{bmatrix} \hat{N}_{11} & \hat{D}_{11} \\ \hat{N}_{21} & \hat{D}_{21} \end{bmatrix} \text{ conjugate } J\text{-lossless}$$

if and only if

(1) There exists a nonsingular matrix \tilde{W}_∞ such that

$$(6.25) \quad \tilde{W}_\infty J \tilde{W}_\infty^* = \bar{D}_t J \bar{D}_t^*;$$

(2) $H_Z \in \text{dom}(\text{Ric})$, where

$$(6.26) \quad H_Z = \begin{bmatrix} A_t^* & 0 \\ -\bar{B}_t J \bar{B}_t^* & -A_t \end{bmatrix} - \begin{bmatrix} C_t^* \\ -\bar{B}_t J \bar{D}_t^* \end{bmatrix} (\bar{D}_t J \bar{D}_t^*)^{-1} [\bar{D}_t J \bar{B}_t^* \quad C_t];$$

(3) $Z_\infty = \text{Ric}(H) \geq 0$.

In this case, \hat{N} and \hat{D} are given by the realizations

$$(6.27) \quad [\hat{N} \quad \hat{D}] \stackrel{s}{=} \begin{bmatrix} I & \tilde{M} \\ 0 & \tilde{W}_\infty \end{bmatrix}^{-1} \begin{bmatrix} A_t & B_t & 0 \\ C_t & D_t & I \end{bmatrix},$$

where \tilde{W}_∞ is any solution to (6.25) and

$$(6.28) \quad \tilde{M} J \tilde{W}_\infty^* = \bar{B}_t J \bar{D}_t^* + Z_\infty C_t^*.$$

Also, the controller generator K_a (see (4.14)) is given by

$$(6.29) \quad K_a = \begin{bmatrix} \hat{N}_{12} & I \\ \hat{N}_{22} & 0 \end{bmatrix}^{-1} \begin{bmatrix} \hat{D}_{12} & 0 \\ \hat{D}_{22} & I \end{bmatrix}$$

$$(6.30) \quad \stackrel{s}{=} \begin{bmatrix} I & B_2 & \tilde{M}_1 \\ 0 & W_{12} & \tilde{W}_{11} \\ 0 & D_{22} & \tilde{W}_{21} \end{bmatrix}^{-1} \begin{bmatrix} A_t & 0 & \tilde{M}_2 \\ C_{t1} & 0 & \tilde{W}_{12} \\ C_{t2} & I & \tilde{W}_{22} \end{bmatrix}.$$

Proof. The proof follows from the realization (6.21) for P_t and Theorem 6.3. Formula (6.30) for K_a is obtained from (6.27) by using the dual of Lemma 6.1. \square

Remark. Theorem 4.4 requires us to ensure that $\tilde{N}_{22}(\infty)$ is nonsingular, which is equivalent to $\begin{bmatrix} W_{12} & \tilde{W}_{11} \\ D_{22} & \tilde{W}_{21} \end{bmatrix}$ nonsingular. This is always true if $D_{22} = 0$.

Remark. For discrete time, Z_∞ , \tilde{M} , \tilde{W}_∞ must satisfy

$$\begin{bmatrix} A_t & \bar{B}_t \\ C_t & \bar{D}_t \end{bmatrix} \begin{bmatrix} Z_\infty & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} A_t & \bar{B}_t \\ C_t & \bar{D}_t \end{bmatrix}^* = \begin{bmatrix} I & \tilde{M} \\ 0 & \tilde{W}_\infty \end{bmatrix} \begin{bmatrix} Z_\infty & 0 \\ 0 & J \end{bmatrix} \begin{bmatrix} I & \tilde{M} \\ 0 & \tilde{W}_\infty \end{bmatrix}^*,$$

\tilde{W}_∞ nonsingular, $A_t - \tilde{M} \tilde{W}_\infty^{-1} C_t$ asymptotically stable, and $Z_\infty \geq 0$.

In [28] these formulae are derived using a state-space approach to the discrete time problem based on game theoretic methods.

Remark. It is an interesting exercise to carry out the calculations in this section for the special case considered in [9]—set $D_{11} = 0$, $D_{22} = 0$, $D_{12}^* [C_1 \quad D_{12}] = [0 \quad I]$, and $D_{21} [B_1^* \quad D_{21}^*] = [0 \quad I]$.

Remark. For (6.30) to be a generator of all \mathcal{H}_∞ controllers for P , the assumptions of Theorem 4.4 must be satisfied. The state-space versions of these assumptions, namely that (A, B_2, C_2) is stabilizable and detectable and $\begin{bmatrix} A - \lambda I & B_2 \\ C_1 & D_{12} \end{bmatrix}$ and $\begin{bmatrix} A - \lambda I & B_1 \\ C_2 & D_{21} \end{bmatrix}$ have full column and row rank, respectively, on ∂ , are necessary conditions for X_∞ , Y_∞ , Z_∞ of Theorems 6.2, 6.3, and 6.5 to exist. The (A, B_2, C_2) stabilizable/detectable condition is a necessary condition for the existence of an internally stabilizing controller, but the full rank on the boundary conditions are not necessary for the existence of an \mathcal{H}_∞ controller. If these conditions do not hold, the results say nothing about whether a controller exists and certainly cannot calculate one.

Remark. It is known (see [9], [17], [18], [27]) that the Riccati equation solutions involved in the factorizations of Theorems 6.2, 6.3, and 6.5 are related by $Z_\infty = Y_\infty(I - \gamma^{-1}X_\infty Y_\infty)^{-1}$. Although this suggests an elegant transfer matrix level connection between these factorizations, none has emerged so far. \square

7. Conclusion. In this paper the fundamental relationship between \mathcal{H}_∞ controller synthesis via the technique pioneered in [9] and analytic systems has been elucidated. This both clarifies the structure recognized in [9], exposing the role played by internal stability, and enables transfer function, or operator theoretic, methods to be employed. The result is that the solutions to the (suboptimal) \mathcal{H}_∞ control problem exists if and only if two coupled J -lossless coprime factorizations exist. The second coprime factorization provides a linear fractional representation for all solutions.

Thus, except for the final state-space calculations, the results are independent of whether continuous time or discrete time systems are considered. The state-space formulae can be developed in a few pages, and their structure is exactly the same, whether in continuous or discrete time.

The approach would not, however, appear to offer an easy extension to the optimal case, where more general factorizations need to be considered. Direct state-space methods using descriptor systems seem to offer the easiest approach to the optimal case [17], [30].

Acknowledgment. It is my pleasure to acknowledge the contribution made by David Limebeer to the development of the work in this paper. In particular, we have worked on several approaches to the discrete-time problem, and I am grateful for his permission to include material here resulting from collaborative efforts.

RATE-PRESERVING DISCRETIZATION STRATEGIES FOR SEMI-INFINITE PROGRAMMING AND OPTIMAL CONTROL*

ELIJAH POLAK† AND LIMIN HE†

Abstract. Neither semi-infinite programming nor optimal control problems can be solved without discretization, i.e., decomposition of the original problems into an infinite sequence of finite-dimensional, finitely described optimization problems. Three sets of discretization refinement rules are presented: (i) for unconstrained semi-infinite minimax problems, (ii) for constrained semi-infinite problems, and (iii) for unconstrained optimal control problems. These rules are built into a master algorithm that calls certain linearly converging algorithms for finite-dimensional, finitely described optimization problems. The discretization refinement rules ensure that the sequences constructed by the overall scheme converge to a solution of the original problem linearly, with the estimated rate constant equal to the estimated rate constant of the algorithms used to solve the finite-dimensional, finitely described approximations. Hence the resulting scheme has the potential to be more efficient than fixed discretization, a fact supported by numerical results.

Key words. approximation theory, minimax, semi-infinite programming, optimal control, rate of convergence

1. Introduction. The numerical solution of a semi-infinite optimization or optimal control problem always involves some form of discretization. There is considerable empirical evidence to suggest that the computationally most efficient approach is to increase discretization gradually. The heuristic explanation of the success of this approach is that far from a solution, coarse discretization does not appear to interfere with progress toward a solution, while resulting in considerable computational savings per iteration over fine discretization.

There are two basic, but not altogether disjoint, approaches to the construction of discretization refinements tests. The first is based on the concept of *diagonalization* (see, e.g., [4]–[6]), which can be used under minimal consistency conditions. Diagonalization decomposes the original optimization problem \mathbf{P} into an infinite sequence of *finite-dimensional, finitely described* optimization problems \mathbf{P}_q , $q = q_0, q_0 + 1, q_0 + 2, q_0 + 3, \dots$, which approximate \mathbf{P} more and more closely and which are therefore of increasing computational complexity¹. The problem \mathbf{P}_q is solved until a certain test is satisfied, and then the last iterate is used to initialize the solution of \mathbf{P}_{q+1} . For example, suppose that there is a family of continuous, negative-valued functions $\{\theta_q(\cdot)\}_{q=q_0}^\infty$ such that if \hat{x}_q is optimal for \mathbf{P}_q , then $\theta_q(\hat{x}_q) = 0$, and suppose that there is a continuous function $\theta(\cdot)$ such that (i) $\theta_q(x) \rightarrow \theta(x)$ as $q \rightarrow \infty$, uniformly in x (in a bounded set), and (ii) if \hat{x} is a solution to \mathbf{P} , then $\theta(\hat{x}) = 0$. Then an example of diagonalization scheme would consist of computing points x_q such that $\theta_q(x_q) \geq -1/q$. The main disadvantage of such a diagonalization approach is that all the convergence statements are in terms of the points x_q only (discarding the intermediate points constructed on the way to x_q); e.g., “all the accumulation points of the sequence

¹ By this we mean that one iteration of a particular algorithm on problem \mathbf{P}_{q+1} is more costly than one iteration of the same algorithm on problem \mathbf{P}_q .

$\{x_q\}_{q=q_0}^\infty$ are stationary points for the problem \mathbf{P} .” The second approach is more subtle: it starts with a *conceptual* algorithm for solving \mathbf{P} (see [7], [10]) and uses progressively more precise numerical evaluations of the cost and constraint functions, as well as of the conceptual iteration map as an *implementation* of the conceptual algorithm. Implementation requires stronger consistency conditions than diagonalization; these, fortunately, are frequently satisfied in practice. In return, it yields the considerable advantage that all the convergence statements are in terms of the *entire* sequence constructed by the algorithm; e.g., “all the accumulation points of the entire sequence $\{x_i\}_{i=0}^\infty$ constructed by the implementation are stationary points for the problem \mathbf{P} .” In [7], [10] we find an abstract theory for the construction of *implementable* algorithms. As a particular application, we find in [7] an implementation of the method of steepest descent for solving continuous optimal control problems. Interesting recent examples of work dealing either with diagonalization or implementation of conceptual algorithms for optimal control and Banach space problems can be found in [5], [18], [19]. The results in [5], [18], [19] relate convergence rates for grid refinement schemes to the convergence rates of an associated gradient-method-related algorithm for some underlying limiting problem. In this sense, this work goes beyond the results in [7] and can be viewed as a precursor of the work presented in this paper.

The reason diagonalization and implementation schemes are not totally disjoint, is that when suitable tests of precision augmentation are used, diagonalization schemes also become implementation schemes. Such diagonalization/implementation schemes appear to be computationally more efficient than pure implementation schemes. The reason for this is suggested by the following example. Suppose that we wish to solve an unconstrained optimal control problem of the form $\min f(u)$ using the Armijo version of the steepest descent algorithm. A pure implementation of this algorithm may use unrelated numerical integration methods for computing approximations $\phi(u)$, $g(u)$ to $f(u)$, $\nabla f(u)$, and hence $g(u) \neq \nabla \phi(u)$. At low to medium precision of integration, this causes the implementable algorithm to slow down quite considerably, as compared to a diagonalization/implementation scheme that always ensures that $g(u) = \nabla \phi(u)$.

The discretization adjustment tests described in [7], [10] are very basic: they make no use of optimality functions or rate of convergence properties of the conceptual algorithm. In this paper, we present three diagonalization/implementation schemes in the form of master discretization algorithms that differ from those based on the theory in [7], [10] in two respects: (i) they use tests, based on optimality functions and a measure of the accuracy with which the discretized problems approximate the original problem, for increasing discretization, and (ii) unlike master algorithms based on the theory in [7], [10], under suitable assumptions, they preserve the estimates of convergence rate constants of the conceptual algorithms that they implement. The reason for their superiority is as follows. First-order algorithms are characterized by an estimate of the *rate constant* $\eta \in (0, 1)$, which appears in formulas of the form $e_{i+1} \leq \eta e_i$. The estimates of the rate constant of a first-order algorithm, applicable to discretized problems \mathbf{P}_q , depend on basic constants such as bounds on second-order derivatives and the Fritz John multiplier associated with the cost function. An examination of particular examples of discretized problems \mathbf{P}_q shows that the entire family $\{\mathbf{P}_q\}$ shares the *same* values of these constants that are inherited from the original problem \mathbf{P} (see, e.g., [5], [12]). Hence the estimate of the linear rate constant for a particular first-order algorithm is the *same* for *every* member of the family $\{\mathbf{P}_q\}$. Now suppose that a master discretization algorithm (say \mathbf{M}), which calls a particular first-order algorithm (say \mathbf{A}) as a subroutine, is linearly converging on \mathbf{P} , with the *same* rate constant that \mathbf{A} has

on the problems \mathbf{P}_q . Then, given an initial point x_0 , k iterations of \mathbf{M} on \mathbf{P} yield an endpoint $x_k^{\mathbf{M}}$ and discretization parameter q_k , while k iterations of \mathbf{A} on the problem $\mathbf{P}_{q_k}^{\mathbf{A}}$ yield an endpoint $x_k^{\mathbf{A}}$. Because of the same rate of convergence, we can expect that $x_k^{\mathbf{M}}$ and $x_k^{\mathbf{A}}$ are equally good approximations to a solution of \mathbf{P} . If we ignore the overhead imposed by the discretization tests, the total computing time used to produce $x_k^{\mathbf{M}}$ must be less because the early iterations of \mathbf{A} , as called by \mathbf{M} , face coarser discretizations than those encountered by \mathbf{A} in solving \mathbf{P}_{q_k} directly. Our experimental results indicate that the computing cost due to the discretization tests is not significant enough to affect our qualitative conclusion that the master discretization algorithm is more efficient than a fixed discretization scheme.

In § 2 we present a master discretization algorithm, to be used in conjunction with the Pshenichnyi–Pironneau–Polak (PPP) minimax algorithm [9], [12], [15] for solving unconstrained semi-infinite minimax problems. Its estimated rate-of-convergence constant is shown to be the same as that of the PPP algorithm, established in [9], [12]. In § 3 we present a master discretization algorithm, to be used in conjunction with the Polak–He unified steerable phase I–phase II method of feasible directions (USFD)² [13], for solving constrained semi-infinite optimization problems. Its estimated rate-of-convergence constant is shown to be the same as that of USFD. In § 4 we present a master discretization algorithm, to be used in conjunction with the Armijo gradient method [1], for solving unconstrained optimal control problems. Its estimated rate-of-convergence constant is shown to be the same as that of the Armijo method on composite function problems, established in [14].³ Finally, in § 5 we present some numerical results that support our qualitative conclusions as to the superiority of the new discretization schemes over fixed discretization approaches.

We use standard notation; thus $L_\infty^m[0, T]$ denotes the space of equivalence classes of essentially bounded, measurable functions from $[0, T]$ into \mathbb{R}^m , $L_2^m[0, T]$ denotes the space of equivalence classes of square integrable functions from $[0, T]$ into \mathbb{R}^m , and $\|\cdot\|$, $\langle \cdot, \cdot \rangle$ denote the Euclidean norm and scalar product, respectively, in \mathbb{R}^n . For $A \in \mathbb{R}^{m \times n}$, $\|A\| \triangleq \max_{\|x\|=1} \|Ax\|$, for $u, v \in L_2^m[0, T]$, $\|u\|_2^2 \triangleq \int_0^T \|u(t)\|^2 dt$, $\langle u, v \rangle_2 \triangleq \int_0^T \langle u(t), v(t) \rangle dt$, for $u \in L_\infty^m[0, T]$, $\|u\|_\infty \triangleq \text{ess sup}_{t \in [0, T]} \|u(t)\|$, and for $U \in L_\infty^{m \times n}[0, T]$, $\|U\|_\infty \triangleq \text{ess sup}_{t \in [0, T]} \|U(t)\|$.

2. Minimax problems. We begin with minimax problems of the form

$$(2.1a) \quad \text{MMP: } \min_{x \in \mathbb{R}^n} \psi(x),$$

where

$$(2.1b) \quad \psi(x) \triangleq \max_{j \in \mathbf{I}} \max_{y_j \in \mathbf{Y}_j} \phi^j(x, y_j),$$

where $\mathbf{I} \triangleq \{1, 2, \dots, l\}$, $\phi^j: \mathbb{R}^n \times \mathbb{R}^{p_j} \rightarrow \mathbb{R}$ and \mathbf{Y}_j is a compact subset of \mathbb{R}^{p_j} . We will assume that the functions $\phi^j(\cdot, \cdot)$ and their gradients $\nabla_x \phi^j(\cdot, \cdot)$ are Lipschitz continuous. Since the exact calculation of the global maxima of $\phi^j(\cdot, \cdot)$ over the compact

² This algorithm is the only phase I–phase II method of feasible directions that we were able to implement in such a way that once a feasible point for a problem P_{q_0} was found, terminating phase I on P_{q_0} , the algorithm remained in phase II for this and all the following problems P_q .

³ Discrete optimal control problems have cost functions of the form $f(u) = g(x(N, u, x_0))$, and the Hessian of $f(\cdot)$ is positive-semi-definite, at best. Hence “standard” rate of convergence theory (see [8], [10]) leads to the conclusion that the Armijo method converges on these problems sublinearly. The results for linear dynamics, in [14], to be extended in this paper, show that this is not so.

set Y_j is not a numerically implementable operation, numerical methods for solving problem (2.1a) must discretize the compact sets Y_j . Hence we introduce a family of approximating problems, parametrized by the discretization parameter $q \in \mathbb{N}$:

$$(2.2a) \quad \mathbf{MMP}_q : \min_{x \in \mathbb{R}^n} \psi_q(x),$$

where

$$(2.2b) \quad \psi_q(x) \triangleq \max_{j \in I} \max_{y_j \in Y_j} \phi_q^j(x, y_j),$$

and the functions $\phi_q^j(\cdot, \cdot)$ are constructed by linear interpolation of the $\phi^j(\cdot, \cdot)$ over a “triangulated” (uniform) grid in the sets Y_j . Thus, for example, when $Y_j = [0, 1] \subset \mathbb{R}$, we divide this interval into q subintervals, and then we define $\phi_q^j(x, y)$ to be linear on each interval, so that

$$\begin{aligned} \phi_q^j(x, y) &= \lambda \phi^j(x, i/q) + (1 - \lambda) \phi^j(x, (i+1)/q) \\ \text{for } y &= \lambda i/q + (1 - \lambda)(i+1)/q, \quad \lambda \in [0, 1], \quad i = 0, 1, 2, \dots, q-1 \end{aligned}$$

When $Y_j = [0, 1] \times [0, 1] \subset \mathbb{R}^2$, we first break up the plane into small squares, with sides of length $1/q$, and each square is then divided into two triangles, using parallel diagonals. The function $\phi_q^j(x, y)$ is then defined as a continuous linear interpolation of $\phi^j(x, y)$ on this triangulated grid. We note that when defined in this manner, the evaluation of $\psi_q(x)$ is a finite process.

The master adaptive discretization algorithm that we will shortly introduce, calls the PPP minimax algorithm [9], [11], [15] as a subroutine. This algorithm computes search directions by evaluating an optimality function. Hence, proceeding as in [11], we define $\theta(x)$, $\theta_q(x)$ to be the *optimality functions* for problems **MMP** and problem **MMP**_q, respectively, as follows:

$$(2.3a) \quad \theta(x) \triangleq \min_{h \in \mathbb{R}^n} \max_{j \in I} \max_{y_j \in Y_j} \{ \phi^j(x, y_j) + \langle \nabla_x \phi^j(x, y_j), h \rangle + \tfrac{1}{2} \|h\|^2 - \psi(x) \},$$

$$(2.3b) \quad \theta_q(x) \triangleq \min_{h \in \mathbb{R}^n} \max_{j \in I} \max_{y_j \in Y_j} \{ \phi_q^j(x, y_j) + \langle \nabla_x \phi_q^j(x, y_j), h \rangle + \tfrac{1}{2} \|h\|^2 - \psi_q(x) \}.$$

When the functions $\phi_q^j(\cdot, \cdot)$ are defined by linear interpolation on a triangulated grid, (2.3b) is an ordinary quadratic programming problem that can be solved finitely using standard quadratic programming subroutines.

Let $h, h_q : \mathbb{R}^n \rightarrow \mathbb{R}$ be *search direction functions* defined by

$$(2.3c) \quad h(x) \triangleq \arg \min_{h \in \mathbb{R}^n} \max_{j \in I} \max_{y_j \in Y_j} \{ \phi^j(x, y_j) + \langle \nabla_x \phi^j(x, y_j), h \rangle + \tfrac{1}{2} \|h\|^2 - \psi(x) \},$$

$$(2.3d) \quad h_q(x) \triangleq \arg \min_{h \in \mathbb{R}^n} \max_{j \in I} \max_{y_j \in Y_j} \{ \phi_q^j(x, y_j) + \langle \nabla_x \phi_q^j(x, y_j), h \rangle + \tfrac{1}{2} \|h\|^2 - \psi_q(x) \}.$$

The PPP minimax algorithms for solving **MMP** and **MMP**_q use one of the above search direction functions (as appropriate) and an Armijo-type stepsize rule, which requires two parameters $\alpha, \beta \in (0, 1)$. Thus the *conceptual* PPP algorithm for solving **MMP**, described in [11], constructs iterates according to the rule

$$(2.3e) \quad x_{i+1} = x_i + \lambda_i h(x_i),$$

where

$$(2.3f) \quad \lambda_i = \max \{ \beta^k \mid k \in \mathbb{N}, \psi(x_i + \beta^k h(x_i)) - \psi(x_i) \leq \alpha \beta^k \theta(x_i) \},$$

while the *implementable* PPP algorithm for solving \mathbf{MMP}_q , described in [9], [11], [15], constructs iterates according to (2.3e), (2.3f), with $h(\cdot)$, $\psi(\cdot)$, and $\theta(\cdot)$ replaced by $h_q(\cdot)$, $\psi_q(\cdot)$, and $\theta_q(\cdot)$, respectively.

No matter how the approximating functions $\phi_q^j(\cdot, \cdot)$ are constructed, we will require that the functions $\phi_q^j(\cdot, \cdot)$, together with the functions $\phi^j(\cdot, \cdot)$, satisfy the following assumption.⁴

ASSUMPTION 2.1. (i) There exist constants $0 < K < \infty$ and $\tau > 0$ such that for all $x \in \mathbb{R}^n$ and all $q \in \mathbb{N}$,

$$(2.4a) \quad |\psi(x) - \psi_q(x)| \leq K/q^\tau.$$

(ii) For any $x \in \mathbb{R}^n$, $y_j \in \mathbf{Y}_j$, and $j \in \mathbf{I}$,

$$(2.4b) \quad \lim_{\substack{x' \rightarrow x \\ q \rightarrow \infty}} \phi_q^j(x', y_j) = \phi^j(x, y_j), \quad \lim_{\substack{x' \rightarrow x \\ q \rightarrow \infty}} \nabla_x \phi_q^j(x', y_j) = \nabla_x \phi^j(x, y_j).$$

LEMMA 2.1. (i) For any $x \in \mathbb{R}^n$,

$$(2.5a) \quad \theta(x) = -\min \{ \xi^0 + \frac{1}{2} \|\xi\|^2 \mid (\xi^0, \xi)^T \in G(x) \},$$

$$(2.5b) \quad \theta_q(x) = -\min \{ \xi^0 + \frac{1}{2} \|\xi\|^2 \mid (\xi^0, \xi)^T \in G_q(x) \},$$

where

$$(2.5c) \quad G(x) \triangleq \text{co} \left\{ \bigcup_{j \in \mathbf{I}} \bigcup_{y_j \in \mathbf{Y}_j} \begin{pmatrix} \psi(x) - \phi^j(x, y_j) \\ \nabla_x \phi^j(x, y_j) \end{pmatrix} \right\},$$

$$(2.5d) \quad G_q(x) \triangleq \text{co} \left\{ \bigcup_{j \in \mathbf{I}} \bigcup_{y_j \in \mathbf{Y}_j} \begin{pmatrix} \psi_q(x) - \phi_q^j(x, y_j) \\ \nabla_x \phi_q^j(x, y_j) \end{pmatrix} \right\}.$$

(ii) For any $x \in \mathbb{R}^n$, $\theta(x) = 0$ if and only if $0 \in \partial \psi(x)$,⁵ and $\theta_q(x) = 0$ if and only if $0 \in \partial \psi_q(x)$; i.e., the zeros of these functions are the stationary points of the corresponding problems.

(iii) Suppose that Assumption 2.1 holds. Then, for any $x \in \mathbb{R}^n$,

$$(2.6) \quad \lim_{\substack{x' \rightarrow x \\ q \rightarrow \infty}} \theta_q(x') = \theta(x).$$

Proof. Both (i) and (ii) are established in [11].

(iii) Since the sets \mathbf{Y}_j are compact, it follows from Assumption 2.1(ii) and (2.5c), (2.5d) that

$$(2.7) \quad \lim_{\substack{x' \rightarrow x \\ q \rightarrow \infty}} G_q(x') = G(x).$$

Hence (2.6) follows from (2.7) and the definitions (2.5a), (2.5b). \square

We can now state a master adaptive discretization algorithm that calls the PPP minimax algorithm as a subroutine, for solving the problem \mathbf{MMP} .

⁴ This assumption is satisfied, with $\tau = 1$, by the two examples we gave using a *uniform* discretization grid, when the functions $\phi^j(x, \cdot)$ are at least Lipschitz continuous. When the functions $\nabla_x \phi^j(x, \cdot)$ are Lipschitz continuous, then our assumption is satisfied with $\tau = 2$.

⁵ We denote the Clarke-generalized gradient [3] of a locally Lipschitz function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ at $x \in \mathbb{R}^n$ by $\partial f(x)$.

Adaptive Discretization Algorithm 2.1 (for MMP):

Data: $x_0 \in \mathbb{R}^n$, $q_{-1} \in \mathbb{N}$, $\alpha \in (0, 1)$, $\beta \in (0, 1)$, $D > 0$, and $\sigma > 1$.

Step 0: Set $i = 0$.

Step 1: Compute $q_i \in \mathbb{N}$, $\theta_{q_i}(x_i)$, and, simultaneously, $h_{q_i}(x_i)$ such that $q_i \geq q_{i-1}$ and

$$(2.8) \quad D/q_i^\sigma \leq [-\theta_{q_i}(x_i)]^\sigma.$$

Step 2: Set $\theta_i = \theta_{q_i}(x_i)$, $h_i = h_{q_i}(x_i)$ and compute the stepsize λ_i :

$$(2.9) \quad \lambda_i = \max \{\beta^k \mid k \in \mathbb{N}, \psi_{q_i}(x_i + \beta^k h_i) - \psi_{q_i}(x_i) \leq \alpha \beta^k \theta_i\}.$$

Step 3: Set $x_{i+1} = x_i + \lambda_i h_i$, replace i by $i + 1$, and go to Step 1.

Remark 2.1. (a) The discretization rule (2.8) is chosen to ensure both convergence and preservation of rate of convergence. As can be seen from [7], mere convergence can be ensured by other tests as well.

(b) It follows from Lemma 2.1(iii) that whenever $\theta(x_i) \neq 0$, Step 1 of Algorithm 2.1 yields a finite discretization parameter q_i . For simplicity, in the rest of this section we assume that Algorithm 2.1 does not produce an iterate x_i such that $\theta(x_i) = 0$, so that the resulting value of q_i in Step 1 is finite.

LEMMA 2.2. *Suppose that $\psi(\cdot)$ is bounded from below and that the sequence of iterates $\{x_i\}_{i=0}^\infty$ and corresponding sequence of discretization parameters $\{q_i\}_{i=0}^\infty$ were constructed by Algorithm 2.1. Then $q_i \rightarrow \infty$ as $i \rightarrow \infty$.*

Proof. For $i \in \mathbb{N}$, let q_i , θ_i , h_i , and λ_i be defined as in Algorithm 2.1, and suppose that $q_i \rightarrow \infty$ as $i \rightarrow \infty$ does not hold. Then, since $\{q_i\}_{i=0}^\infty$ is a nondecreasing sequence of integers, it follows that there exist i_0 , $\hat{q} \in \mathbb{N}$, such that for all $i \geq i_0$, $q_i = \hat{q}$, and hence, in conjunction with (2.8), that there exists an $\varepsilon > 0$, such that $\theta_i \leq -\varepsilon$ for all $i \geq i_0$. Making use of (2.9) and the assumption that $\psi(\cdot)$ is bounded from below, we conclude that $\psi_{\hat{q}}(\cdot)$ is also bounded from below. Hence we obtain that

$$-\infty < \sum_{i=i_0}^{\infty} [\psi_{\hat{q}}(x_{i+1}) - \psi_{\hat{q}}(x_i)] \leq \sum_{i=i_0}^{\infty} \alpha \lambda_i \theta_i.$$

Referring to (2.5b), we see that if

$$(\xi_i^0, \xi_i) = \arg \min \{ \xi_i^0 + \frac{1}{2} \|\xi\|^2 \mid (\xi_i^0, \xi) \in G_{q_i}(x_i) \},$$

then $h_i = -\xi_i$. Hence $\|h_i\|^2 \leq -2\theta_i$ and $-\theta_i \geq \varepsilon$ for $i \geq i_0$, we deduce that $\|h_i\|^2 \leq 2\theta_i^2/\varepsilon$ for all $i \geq i_0$. Hence, for any $j > i \geq i_0$,

$$(2.10) \quad \|x_j - x_i\| \leq \sum_{k=i}^{j-1} \|x_{k+1} - x_k\| \leq \sum_{k=i}^{j-1} \lambda_k \|h_k\| \leq \sum_{k=i}^{\infty} (2/\varepsilon)^{1/2} \lambda_k (-\theta_k).$$

Therefore $\{x_i\}_{i=0}^\infty$ is a Cauchy sequence in \mathbb{R}^n , and hence it follows from Theorem 5.2(b) and Corollary 5.1 in [11] (which show that any accumulation point x^* of $\{x_i\}_{i=0}^\infty$, constructed by the PPP algorithm, satisfies $\theta_{\hat{q}}(x^*) = 0$) that $\theta_{\hat{q}}(x_i) \rightarrow 0$, contradicting the construction in (2.8). \square

THEOREM 2.1. *Suppose that Assumption 2.1 holds, that $\psi(\cdot)$ is bounded from below, that the second derivatives $\partial^2 \phi_q^j(x, y_j)/\partial x^2$ exist for all $q \in \mathbb{N}$, and that there exists an $M \in [1, \infty)$ such that for all $x \in \mathbb{R}^n$, $z \in \mathbb{R}^n$, $j \in \mathbb{I}$, and $q \in \mathbb{N}$,*

$$(2.11) \quad \left\langle z, \frac{\partial^2 \phi_q^j(x, y_j)}{\partial x^2} z \right\rangle \leq M \|z\|^2, \quad \forall y_j \in \mathbf{Y}_j.$$

Then any accumulation point \hat{x} of the sequence of iterates $\{x_i\}_{i=0}^\infty$, generated by Algorithm 2.1, satisfies $\theta(\hat{x}) = 0$.

Proof. First, we obtain a bound on the decrease in $\psi(\cdot)$ at the i th iteration. Using (2.11), we obtain that

$$\begin{aligned}
 \psi_{q_i}(x_i + \lambda h_i) - \psi_{q_i}(x_i) &= \max_{j \in \mathbf{I}} \max_{y_j \in \mathbf{Y}_j} \{ \phi_{q_i}^j(x_i + \lambda h_i, y_j) - \psi_{q_i}(x_i) \} \\
 (2.12) \quad &\leq \max_{j \in \mathbf{I}} \max_{y_j \in \mathbf{Y}_j} \{ \phi_{q_i}^j(x_i, y_j) - \psi_{q_i}(x_i) + \langle \nabla_x \phi_{q_i}^j(x_i, y_j), \lambda h_i \rangle \\
 &\quad + \tfrac{1}{2} M \| \lambda h_i \|^2 \}.
 \end{aligned}$$

In view of (2.3b) and the fact that $\phi_{q_i}^j(x_i, y_j) - \psi_{q_i}(x_i) \leq 0$ and that $M \geq 1$, we find that for all $\lambda \in [0, 1/M]$,

$$(2.13) \quad \psi_{q_i}(x_i + \lambda h_i) - \psi_{q_i}(x_i) \leq \lambda \theta_{q_i}(x_i).$$

Therefore (2.9) is satisfied with $\lambda_i \geq \beta/M$, and thus

$$(2.14) \quad \psi_{q_i}(x_{i+1}) - \psi_{q_i}(x_i) \leq \alpha \lambda_i \theta_i \leq \alpha \beta \theta_i / M.$$

Hence it follows from Assumption 2.1(i) that

$$(2.15) \quad \psi(x_{i+1}) - \psi(x_i) \leq \alpha \beta \theta_i / M + 2K/q_i^\tau.$$

Next, since $\theta_i \leq -D^{1/\sigma}/(q_i^\tau)^{1/\sigma}$, we have that

$$(2.16) \quad \psi(x_{i+1}) - \psi(x_i) \leq -\frac{\alpha \beta D^{1/\sigma}}{M(q_i^\tau)^{1/\sigma}} \left[1 - \frac{2KM}{\alpha \beta D^{1/\sigma}(q_i^\tau)^{(\alpha-1)/\sigma}} \right].$$

Since $\sigma > 1$ and since by Lemma 2.2, $q_i \rightarrow \infty$ as $i \rightarrow \infty$, there exists an $i_0 \in \mathbb{N}$ such that for all $i \geq i_0$,

$$(2.17) \quad \psi(x_{i+1}) - \psi(x_i) \leq -\frac{\alpha \beta D^{1/\sigma}}{2M(q_i^\tau)^{1/\sigma}}.$$

Hence,

$$(2.18) \quad \psi(x_{i+1}) - \psi(x_{i_0}) \leq -\sum_{k=i_0}^i \frac{\alpha \beta D^{1/\sigma}}{2m(q_k^\tau)^{1/\sigma}}.$$

Because $\psi(\cdot)$ is bounded from below, the left-hand side of the above inequality is bounded from below, which leads to the conclusion that $\sum_{k=0}^{\infty} 1/(q_k^\tau)^{1/\sigma} < \infty$. Consequently, $\sum_{k=0}^{\infty} 1/(q_k^\tau) < \infty$. Next, returning to (2.15), we conclude that

$$(2.19) \quad \psi(x_{i+1}) - \psi(x_0) \leq -\sum_{k=0}^i \alpha \beta (-\theta_k) / M + \sum_{k=0}^i 2K/q_k^\tau.$$

Since both $\psi(x_{i+1}) - \psi(x_0)$ and $\sum_{k=0}^i 2K/q_k^\tau$ are bounded, it follows that $\sum_{k=0}^{\infty} (-\theta_k) < \infty$. The desired result now follows from Lemma 2.1(iii). \square

THEOREM 2.2. *Suppose that Assumption 2.1 holds, that the second derivatives $\partial^2 \phi^j(x, y_j)/\partial x^2$, $\partial^2 \phi_q^j(x, y_j)/\partial x^2$ exist for all $q \in \mathbb{N}$, and that there exist constants $0 < m < 1 < M < \infty$, such that for all $x \in \mathbb{R}^n$, $z \in \mathbb{R}^n$, and $j \in \mathbf{I}$,*

$$(2.20a) \quad m \|z\|^2 \leq \left\langle z, \frac{\partial^2 \phi_q^j(x, y_j)}{\partial x^2} z \right\rangle \leq M \|z\|^2 \quad \text{for all } y_j \in \mathbf{Y}_j, \quad q \in \mathbb{N},$$

$$(2.20b) \quad m \|z\|^2 \leq \left\langle z, \frac{\partial^2 \phi^j(x, y_j)}{\partial x^2} z \right\rangle \leq M \|z\|^2 \quad \text{for all } y_j \in \mathbf{Y}_j.$$

Then any sequence $\{x_i\}_{i=0}^\infty$, generated by Algorithm 2.1, converges to the unique solution \hat{x} of problem **MMP**, and

$$(2.21) \quad \lim_{i \rightarrow \infty} \frac{\psi(x_{i+1}) - \psi(\hat{x})}{\psi(x_i) - \psi(\hat{x})} \leq 1 - \alpha\beta m / M.$$

Proof. It follows from (2.20a), (2.20b) that the functions $\psi_q(\cdot)$ $q \in \mathbb{N}$, $\psi(\cdot)$ are strongly convex, and hence that they have unique minimizers. For any $q \in \mathbb{N}$, let \hat{x}_q be the unique solution of the problem **MMP** _{q} . First, we deduce from Assumption 2.1(i) that

$$(2.22) \quad |\psi_q(\hat{x}_q) - \psi(\hat{x})| \leq K / q^\tau.$$

Next, referring to [12], [14], we see that for all $x \in \mathbb{R}^n$ and $q \in \mathbb{N}$,

$$(2.23) \quad m[\psi_q(x) - \psi_q(\hat{x}_q)] \leq -\theta_q(x) \leq M[\psi_q(x) - \psi_q(\hat{x}_q)].$$

Combining (2.14) and (2.23), we get

$$(2.24) \quad \psi_{q_i}(x_{i+1}) - \psi_{q_i}(x_i) \leq \frac{\alpha\beta m}{M} [\psi_{q_i}(\hat{x}_{q_i}) - \psi_{q_i}(x_i)].$$

Adding $\psi_{q_i}(\hat{x}_{q_i})$ to both sides in (2.24) and rearranging terms, we obtain that

$$(2.25) \quad \psi_{q_i}(x_{i+1}) - \psi_{q_i}(\hat{x}_{q_i}) \leq [1 - \alpha\beta m / M][\psi_{q_i}(x_i) - \psi_{q_i}(\hat{x}_{q_i})].$$

It now follows from (2.22) and Assumption 2.1(i) that

$$(2.26) \quad \psi(x_{i+1}) - \psi(\hat{x}) \leq [1 - \alpha\beta m / M][\psi(x_i) - \psi(\hat{x})] + 4K / q_i^\tau.$$

Next, making use of Assumption 2.1(i), (2.22), (2.23), and the fact that $-\theta_i \geq D^{1/\sigma} / (q_i^\tau)^{1/\sigma}$, we obtain that

$$(2.27) \quad \begin{aligned} M[\psi(x_i) - \psi(\hat{x})] &\geq M[\psi_{q_i}(x_i) - \psi(\hat{x}_{q_i})] - 2MK / q_i^\tau \\ &\geq -\theta_i - 2MK / q_i^\tau \\ &\geq D^{1/\sigma} / (q_i^\tau)^{1/\sigma} - 2MK / q_i^\tau. \end{aligned}$$

Since $\sigma > 1$ and since by Lemma 2.2, $q_i \rightarrow \infty$ as $i \rightarrow \infty$, we conclude that there exists i_0 such that for all $i \geq i_0$,

$$(2.28) \quad M[\psi(x_i) - \psi(\hat{x})] \geq D^{1/\sigma} / [2(q_i^\tau)^{1/\sigma}].$$

It now follows from (2.26) and (2.28) that

$$(2.29) \quad \psi(x_{i+1}) - \psi(\hat{x}) \leq \left[1 - \frac{\alpha\beta m}{M} + \frac{8KM}{D^{1/\sigma}(q_i^\tau)^{(\sigma-1)/\sigma}} \right] [\psi(x_i) - \psi(\hat{x})] \quad \text{for } i \geq i_0.$$

Therefore (2.21) follows from (2.29) and the fact that by Theorem 2.1, $q_i \rightarrow \infty$ as $i \rightarrow \infty$. Since $\psi(x_i) \rightarrow \psi(\hat{x})$ and \hat{x} is the unique minimizer of $\psi(\cdot)$, $\{x_i\}_{i=0}^\infty$ must converge to \hat{x} . \square

For comparison, referring to [12], we find the following result for the *conceptual* PPP minimax algorithm.

THEOREM 2.3.⁶ Suppose that the second derivatives $\partial^2 \phi^j(x, y_j) / \partial x^2$ exist and that there exist constants $0 < m < 1 < M < \infty$, such that for all $x \in \mathbb{R}^n$, $z \in \mathbb{R}^n$, and $j \in \mathbf{1}$, (2.20b) is satisfied. Then any sequence $\{x_i\}_{i=0}^\infty$, generated by the PPP minimax algorithm defined by (2.3e), (2.3f), converges to the unique solution \hat{x} of problem **MMP**, and (2.21) holds.

⁶ It should be obvious that, under analogous assumptions, the conclusions of Theorem 2.3 remain valid for the implementable PPP minimax algorithm, which can be used to solve **MMP** _{q} .

We thus see that our Adaptive Discretization Algorithm 2.1 converges with exactly the same linear rate constant as the PPP minimax algorithm, whether applied to **MMP** or to any **MMP**_q. This leads us to the following observation as to the relative efficiency of our Adaptive Discretization Algorithm 2.1, under the assumptions in Theorem 2.3. Suppose that we are given an initial point x_0 (sufficiently close to \hat{x} , the solution of **MMP**), and that we perform k iterations, ending with a point x_k and discretization parameter q_k . If, instead, we perform k iterations on the problem **MMP**_{q_k}, ending at a point x'_k , we cannot expect to have $\psi(x'_k) < \psi(x_k)$. However, the total computing time used on solving **MMP**_{q_k} must be longer because the early iterations of Algorithm 2.1 use a coarser discretization. Hence Algorithm 2.1 has the potential for being more efficient than a fixed discretization scheme.

3. Constrained semi-infinite optimization problems. We will now consider constrained semi-infinite optimization problems of the form

$$(3.1a) \quad \text{CSP: } \min \{ \psi^0(x) \mid \psi^j(x) \leq 0, j \in \mathbf{I}, x \in \mathbb{R}^n \},$$

where $\mathbf{I} \triangleq \{1, 2, \dots, l\}$, and, with $\mathbf{L} \triangleq \{0, 1, 2, \dots, l\}$,

$$(3.1b) \quad \psi^j(x) = \max_{y_j \in \mathbf{Y}_j} \phi^j(x, y_j), \quad \forall j \in \mathbf{L},$$

where $\phi^j: \mathbb{R}^n \times \mathbb{R}^{p_j} \rightarrow \mathbb{R}$ and \mathbf{Y}_j is a compact set in \mathbb{R}^{p_j} . We will assume that the functions $\phi^j(\cdot, \cdot)$ and their gradients $\nabla_x \phi^j(\cdot, \cdot)$ are Lipschitz continuous.

Using the interpolation techniques mentioned in the preceding section, we can construct a family of approximating problems, parametrized by the discretization parameter $q \in \mathbb{N}$:

$$(3.2a) \quad \text{CSP}_q: \min \{ \psi_q^0(x) \mid \psi_q^j(x) \leq 0, j \in \mathbf{I}, x \in \mathbb{R}^n \},$$

where

$$(3.2b) \quad \psi_q^j(x) = \max_{y_j \in \mathbf{Y}_j} \phi_q^j(x, y_j), \quad \forall j \in \mathbf{L}.$$

In [13] we find a unified steerable phase I-phase II method of feasible directions, which uses a *steering parameter* $\gamma > 0$. We will refer to this algorithm as the USFD algorithm. The steering parameter controls the speed with which infeasible iterates approach the feasible set. When this parameter is greater than a certain value, the algorithm in [13] constructs a feasible point in a finite number of iterations. We will call this algorithm as a subroutine from the master adaptive discretization algorithm that we will describe shortly. For the original problem **CSP**, the algorithm in [13] requires the following functions:

$$(3.3a) \quad \psi(x) \triangleq \max_{j \in \mathbf{I}} \psi^j(x),$$

$$(3.3b) \quad \psi_+(x) \triangleq \max \{0, \psi(x)\},$$

$$(3.3c) \quad F_z(x) \triangleq \max \{ \psi^0(x) - \psi^0(z) - \gamma \psi_+(z), \psi(x) - \psi_+(z) \},$$

$$(3.3d) \quad \theta(x) \triangleq \min_{h \in \mathbb{R}^n} \max \left\{ \max_{y_0 \in \mathbf{Y}_0} \{ \phi^0(x, y_0) + \langle \nabla_x \phi^0(x, y_0), h \rangle + \tfrac{1}{2} \|h\|^2 - \psi^0(x) - \gamma \psi_+(x) \}, \right. \\ \left. \cdot \max_{j \in \mathbf{I}} \max_{y_j \in \mathbf{Y}_j} \{ \phi^j(x, y_j) + \langle \nabla_x \phi^j(x, y_j), h \rangle + \tfrac{1}{2} \|h\|^2 - \psi_+(x) \} \right\},$$

$$(3.3e) \quad h(x) \triangleq \arg \min_{h \in \mathbb{R}^n} \max \left\{ \max_{y_0 \in \mathbf{Y}_0} \{ \phi^0(x, y_0) + \langle \nabla_x \phi^0(x, y_0), h \rangle + \frac{1}{2} \|h\|^2 - \psi^0(x) - \gamma \psi_+(x) \} \right. \\ \left. \cdot \max_{j \in \mathbf{I}} \max_{y_j \in \mathbf{Y}_j} \{ \phi^j(x, y_j) + \langle \nabla_x \phi^j(x, y_j), h \rangle + \frac{1}{2} \|h\|^2 - \psi_+(x) \} \right\}.$$

For the problems \mathbf{CSP}_q , the algorithm in [13] uses corresponding quantities $\psi_q(\cdot)$, $\psi_{q+}(\cdot)$, $F_{z,q}(x)$, $\theta_q(x)$, and $h_q(x)$, resulting from the replacement of $\phi^j(\cdot, \cdot)$, $\nabla_x \phi^j(\cdot, \cdot)$, $\psi^j(\cdot)$, $\psi(\cdot)$, and $\psi_+(\cdot)$ by $\phi_q^j(\cdot, \cdot)$, $\nabla_x \phi_q^j(\cdot, \cdot)$, $\psi_q^j(\cdot)$, $\psi_q(\cdot)$, and $\psi_{q+}(x)$ in (3.3a)–(3.3e), respectively.

In addition to the steering parameter γ , the USFD algorithm in [13] uses two Armijo stepsize parameters: $\alpha, \beta \in (0, 1)$. In solving \mathbf{CSP} , this algorithm constructs iterates according to the rule

$$(3.3f) \quad x_{i+1} = x_i + \lambda_i h(x_i),$$

where

$$(3.3g) \quad \lambda_i = \max \{ \beta^k \mid k \in \mathbb{N}, F_{x_i}(x_i + \beta^k h(x_i)) - F_{x_i}(x_i) \leq \alpha \beta^k \theta(x_i) \}.$$

For solving \mathbf{CSP}_q , we make the obvious substitutions in the above rule.

We will assume that the following relationship between the functions defining the problems \mathbf{CSP}_q and problem \mathbf{CSP} .

Assumption 3.1. (i) There exist constants $0 < k < \infty$ and $\tau > 0$ such that for all $x \in \mathbb{R}^n$ and all $q \in \mathbb{N}$,

$$(3.4a) \quad |\psi^0(x) - \psi_q^0(x)| \leq K/q^\tau,$$

$$(3.4b) \quad |\psi(x) - \psi_q(x)| \leq K/q^\tau.$$

(ii) For any $x \in \mathbb{R}^n$, $y_j \in \mathbf{Y}_j$, and $j \in \mathbf{L}$,

$$(3.4c) \quad \lim_{\substack{x' \rightarrow x \\ q \rightarrow \infty}} \phi_q^j(x', y_j) = \phi^j(x, y_j), \quad \lim_{\substack{x' \rightarrow x \\ q \rightarrow \infty}} \nabla_x \phi_q^j(x', y_j) = \nabla_x \phi^j(x, y_j).$$

LEMMA 3.1. (i) For any $x \in \mathbb{R}^n$,

$$(3.5a) \quad \theta(x) = -\min \{ \xi^0 + \frac{1}{2} \|\xi\|^2 \mid (\xi^0, \xi)^T \in G(x) \},$$

$$(3.5b) \quad \theta_q(x) = -\min \{ \xi^0 + \frac{1}{2} \|\xi\|^2 \mid (\xi^0, \xi)^T \in G_q(x) \},$$

where

$$(3.5c) \quad G(x) \triangleq \text{co} \left\{ \bigcup_{y_0 \in \mathbf{Y}_0} \begin{pmatrix} \psi^0(x) - \phi^0(x, y_0) + \gamma \psi_+(x) \\ \nabla_x \phi^0(x, y_0) \end{pmatrix}, \right. \\ \left. \cdot \bigcup_{j \in \mathbf{I}} \bigcup_{y_j \in \mathbf{Y}_j} \begin{pmatrix} \psi(x) - \phi^j(x, y_j) \\ \nabla_x \phi^j(x, y_j) \end{pmatrix} \right\},$$

$$(3.5d) \quad G_q(x) \triangleq \text{co} \left\{ \bigcup_{y_0 \in \mathbf{Y}_0} \begin{pmatrix} \psi_q^0(x) - \phi_q^0(x, y_0) + \gamma \psi_{q+}(x) \\ \nabla_x \phi_q^0(x, y_0) \end{pmatrix}, \right. \\ \left. \cdot \bigcup_{j \in \mathbf{I}} \bigcup_{y_j \in \mathbf{Y}_j} \begin{pmatrix} \psi_q(x) - \phi_q^j(x, y_j) \\ \nabla_x \phi_q^j(x, y_j) \end{pmatrix} \right\}.$$

(ii) For any $x \in \mathbb{R}^n$, $\theta(x) = 0$ if and only if either $\psi(x) \leq 0$ and $0 \in \partial F_x(x)$ (i.e., x satisfies the first-order optimality condition for problem (3.1a)), or $\psi(x) > 0$ and $0 \in \partial \psi(x)$, (i.e., x satisfies the first-order optimality condition for the problem $\min_{x \in \mathbb{R}^n} \psi(x)$).

(iii) Suppose that Assumption 3.1 holds. Then, for any $x \in \mathbb{R}^n$,

$$(3.6) \quad \lim_{\substack{x' \rightarrow x \\ q \rightarrow \infty}} \theta_q(x') = \theta(x).$$

Proof. (i) Relations (3.5a), (3.5b) were established in [13] using von Neuman's minimax theorem.

(ii) This part can be deduced from Propositions 5.4 and 5.5 in [11].

(iii) Since \mathbf{Y}_j are compact sets, it follows from Assumption 3.1(ii) and (3.5c), (3.5d) that

$$(3.7) \quad \lim_{\substack{x' \rightarrow x \\ q \rightarrow \infty}} G_q(x') = G(x).$$

Hence (3.6) follows from (3.7) and (3.5a), (3.5b). \square

We are now ready to state an adaptive discretization scheme, based on the USFD algorithm in [13], for solving the problem CSP.

Adaptive Discretization Algorithm 3.1 (for CSP):

Data: $x_0 \in \mathbb{R}^n$, $q_{-1} \in \mathbb{N}$, $\alpha \in (0, 1)$, $\beta \in (0, 1)$, $\gamma > 0$, $D > 0$, and $\sigma > 1$.

Step 0: Set $i = 0$.

Step 1: Compute $q_i \in \mathbb{N}$, $\theta_{q_i}(x_i)$, and, simultaneously, $h_{q_i}(x_i)$, such that $q_i \geq q_{i-1}$ and

$$(3.8) \quad D/q_i^\gamma \leq [-\theta_{q_i}(x_i)]^\sigma$$

Step 2: Set $\theta_i = \theta_{q_i}(x_i)$, $h_i = h_{q_i}(x_i)$, and compute the stepsize λ_i :

$$(3.9) \quad \lambda_i = \max \{\beta^k \mid k \in \mathbb{N}, F_{x_i, q_i}(x_i + \beta^k h_i) - F_{x_i, q_i}(x_i) \leq \alpha \beta^k \theta_i\}.$$

Step 3: Set $x_{i+1} = x_i + \lambda_i h_i$, replace i by $i + 1$, and go to Step 1.

Remark 3.1. It follows from Lemma 3.1(ii)–(iii) that whenever $\theta(x_i) \neq 0$, Step 1 of Algorithm 3.1 yields a finite discretization parameter q_i . For simplicity, in the rest of this section we assume that Algorithm 3.1 does not produce an iterate x_i such that $\theta(x_i) = 0$, so that the resulting value of q_i in Step 1 is finite.

LEMMA 3.2. Suppose that $\psi^0(\cdot)$ is bounded from below and that the sequence of iterates $\{x_i\}_{i=0}^\infty$ and the corresponding sequence of discretization parameters $\{q_i\}_{i=0}^\infty$ were constructed by Algorithm 3.1. Then $q_i \rightarrow \infty$ as $i \rightarrow \infty$.

Proof. Suppose that $q_i \rightarrow \infty$ as $i \rightarrow \infty$ does not hold. Then, since $\{q_i\}_{i=0}^\infty$ is a nondecreasing sequence of integers, it follows that there exists an i_0 , $\hat{q} \in \mathbb{N}$, such that for all $i \geq i_0$, $q_i = \hat{q}$; hence, in view of (3.8), suppose there exists an $\varepsilon > 0$ such that $\theta_i \leq -\varepsilon$ for all $i \geq i_0$. It now follows from the properties of the algorithm defined by (3.3f), (3.3g) (see [13]), that there are two possibilities: either $\psi_{\hat{q}}(x_i) > 0$ for all $i \geq i_0$, or there exists an $i_1 \geq i_0$ such that $\psi_{\hat{q}}(x_i) \leq 0$ for all $i \geq i_1$. In the former case, $\psi_{\hat{q}}(x_{i+1}) - \psi_{\hat{q}}(x_i) \leq \alpha \lambda_i \theta_i$ for all $i \geq i_0$. In the latter case, $\psi_{\hat{q}}^0(x_{i+1}) - \psi_{\hat{q}}^0(x_i) \leq \alpha \lambda_i \theta_i$. Making use of (3.4a) and the assumption that $\psi^0(\cdot)$ is bounded from below, we conclude that $\psi_{\hat{q}}^0(\cdot)$ is also bounded from below. Hence we obtain that either

$$-\infty < \sum_{i=i_0}^{\infty} [\psi_{\hat{q}}(x_{i+1}) - \psi_{\hat{q}}(x_i)] \leq \sum_{i=i_0}^{\infty} \alpha \lambda_i \theta_i,$$

or that

$$-\infty < \sum_{i=i_0}^{\infty} [\psi_{\hat{q}}^0(x_{i+1}) - \psi_{\hat{q}}^0(x_i)] \leq \sum_{i=i_0}^{\infty} \alpha \lambda_i \theta_i.$$

In either event, we are led to the conclusion that $\sum_{i=i_0}^{\infty} \alpha \lambda_i \theta_i > -\infty$. Since $\|h_i\|^2 \leq 2(-\theta_i)$, we conclude, applying the reasoning used in proving Lemma 2.2, that $\{x_i\}_{i=0}^{\infty}$ is a Cauchy sequence in \mathbb{R}^n . Since by Lemma 3.2 in [13] (for algorithm (3.3f), (3.3g)), any accumulation point x^* of $\{x_i\}_{i=0}^{\infty}$ satisfies $\theta_{\hat{q}}(x^*) = 0$, it follows that $\theta_{\hat{q}}(x_i) \rightarrow 0$, which contradicts our assumption. Therefore $\lim_{i \rightarrow \infty} \theta_i = 0$. It now follows from (3.8) and the fact that $q_i \geq q_{i-1}$ that $q_i \rightarrow \infty$ as $i \rightarrow \infty$. \square

THEOREM 3.1. *Suppose that Assumption 3.1 holds, that $\psi^0(\cdot)$ is bounded from below, and that there exists a constant $M \in [1, \infty)$ such that for all $x \in \mathbb{R}^n$, $z \in \mathbb{R}^n$, $j \in \mathbf{L}$, and $q \in \mathbb{N}$,*

$$(3.10) \quad \left\langle z, \frac{\partial^2 \phi_q^j(x, y_j)}{\partial x^2} z \right\rangle \leq M \|z\|^2 \quad \text{for } y_j \in \mathbf{Y}_j.$$

Then any accumulation point \hat{x} of the sequence of iterates $\{x_i\}_{i=0}^{\infty}$ generated by Algorithm 3.1 satisfies $\theta(\hat{x}) = 0$.

Proof. It follows from the definitions of $F_{z,q}(\cdot)$ and $F_z(\cdot)$, and Assumption 3.1(i) that

$$(3.11) \quad |F_{z,q}(x) - F_z(x)| \leq (2 + \gamma)K/q^\tau \quad \text{for all } x \in \mathbb{R}^n, \quad z \in \mathbb{R}^n, \quad q \in \mathbb{N}.$$

Next, we observe the i th iteration of Algorithm 3.1 consists of one iteration of the PPP minimax algorithm on the problem $\min_{x \in \mathbb{R}^n} F_{x_i, q_i}(x)$ starting with x_i . Hence, replacing $\psi_{q_i}(\cdot)$, $\psi(\cdot)$ by $F_{x_i, q_i}(\cdot)$, $F_{x_i}(\cdot)$, we conclude from the proof of Theorem 2.1 that there exists an i_0 such that for all $i \geq i_0$,

$$(3.12) \quad F_{x_i}(x_{i+1}) - F_{x_i}(x_i) \leq \alpha \beta \theta_i / M + 2(2 + \gamma)K/q_i^\tau \leq -\frac{\alpha \beta D^{1/\sigma}}{2M(q_i^\tau)^{1/\sigma}}.$$

It now follows from the definition of $F_{x_i}(\cdot)$, (3.3c), that for all $i \geq i_0$,

$$(3.13a) \quad \psi^0(x_{i+1}) - \psi^0(x_i) - \gamma \psi_+(x_i) \leq -\alpha \beta \theta_i / M + (4 + 2\gamma)K/q_i^\tau \leq -\frac{\alpha \beta D^{1/\sigma}}{2M(q_i^\tau)^{1/\sigma}} < 0,$$

$$(3.13b) \quad \psi(x_{i+1}) - \psi_+(x_i) \leq \alpha \beta \theta_i / M + (4 + 2\gamma)K/q_i^\tau \leq -\frac{\alpha \beta D^{1/\sigma}}{2M(q_i^\tau)^{1/\sigma}} < 0.$$

We must consider two cases.

Case (i). There exists an integer $i_1 > i_0$ such that $\psi(x_{i_1}) \leq 0$. It then follows from (3.13b) that $\psi(x_i) \leq 0$ for all $i \geq i_1$ and from (3.13a) that

$$(3.14) \quad \psi^0(x_{i+1}) - \psi^0(x_i) \leq -\alpha \beta \theta_i / M + (4 + 2\gamma)K/q_i^\tau \leq -\frac{\alpha \beta D^{1/\sigma}}{2M(q_i^\tau)^{1/\sigma}} \quad \text{for all } i \geq i_1.$$

Hence, by the same reasoning used in the proof of Theorem 2.1, we conclude that $\sum_{k=i_1}^{\infty} \theta_k > -\infty$, which leads to the desired result.

Case (ii). $\psi(x_i) > 0$ for all $i > i_0$. It then follows from (3.13b) that for all $i > i_0$,

$$(3.15) \quad \psi(x_{i+1}) - \psi(x_i) \leq -\alpha \beta \theta_i / M + (4 + 2\gamma)K/q_i^\tau \leq -\frac{\alpha \beta D^{1/\sigma}}{2M(q_i^\tau)^{1/\sigma}}.$$

Since $\psi(x_i) > 0$ of all $i \geq i_0$, the reasoning used in the proof of Theorem 2.1 leads to the conclusion that $\sum_{k=i_0}^{\infty} \theta_k > -\infty$. Hence the desired result follows from Lemma 3.1(iii). \square

To establish the linear convergence of Algorithm 3.1, we need the following assumption and results, which we borrow from [13].

Assumption 3.2. (i) There exist $0 < m \leq 1 \leq M < \infty$ such that for all $x \in \mathbb{R}^n$, $z \in \mathbb{R}^n$, and $j \in \mathbf{L}$,

$$(3.16a) \quad m \|z\|^2 \leq \left\langle z, \frac{\partial^2 \phi_q^j(x, y_j)}{\partial x^2} z \right\rangle \leq M \|z\|^2 \quad \text{for all } y_j \in \mathbf{Y}_j, \quad q \in \mathbb{N},$$

$$(3.16b) \quad m \|z\|^2 \leq \left\langle z, \frac{\partial^2 \phi^j(x, y_j)}{\partial x^2} z \right\rangle \leq M \|z\|^2 \quad \text{for all } y_j \in \mathbf{Y}_j.$$

(ii) The set $\{x | \psi(x) < 0\}$ is not empty.

LEMMA 3.3 (Lemma 4.2, Lemma 4.3 in [13]). *Suppose that Assumption 3.2 holds.*

Then

- (i) *Problem (3.1a) has a unique solution \hat{x} ,*
- (ii) *\hat{x} is the unique zero of $\theta(\cdot)$.*
- (iii) *Let $\underline{\mu}^0 \triangleq \min \{\mu^0 | \mu \in L(\hat{x})\}$ and $\bar{\mu}^0 \triangleq \max \{\mu^0 | \mu \in L(\hat{x})\}$, where*

$$(3.17a) \quad L(\hat{x}) \triangleq \left\{ \mu = (\mu^0, \mu^1, \dots, \mu^l) \mid 0 \in \sum_{j=0}^l \mu^j \partial \psi^j(\hat{x}), \right. \\ \left. \sum_{j=1}^l \mu^j \psi^j(\hat{x}) = 0, \sum_{j=0}^l \mu^j = 1, \mu^j \geq 0 \right\}.$$

Then $0 < \underline{\mu}^0 \leq \bar{\mu}^0 \leq 1$.

(iv) *For all $x \in \mathbb{R}^n$,*

$$(3.17b) \quad \bar{\mu}^0 [\psi^0(\hat{x}) - \psi^0(x)] \leq (1 - \bar{\mu}^0) \psi_+(x).$$

THEOREM 3.2. *Suppose that Assumptions 3.1 and 3.2 hold. Then any sequence of iterates $\{x_i\}_{i=0}^\infty$ generated by Algorithm 3.1 converges to \hat{x} , and there exists an interger i_0 such that either*

(i) *$\psi(x_i) \leq 0$ for all $i \geq i_0$ and*

$$(3.18a) \quad \lim_{i \rightarrow \infty} \frac{\psi^0(x_{i+1}) - \psi^0(\hat{x})}{\psi^0(x_i) - \psi^0(\hat{x})} \leq 1 - \underline{\mu}^0 \alpha \beta m / M, \quad \text{or}$$

(ii) *$\psi(x_i) > 0$ for all $i \geq i_0$ and*

$$(3.18b) \quad \lim_{i \rightarrow \infty} \frac{\psi(x_{i+1})}{\psi(x_i)} \leq 1 - \gamma \underline{\mu}^0 \alpha \beta m / M,$$

where $\underline{\mu}^0$ is defined in Lemma 3.3 (iii).

Proof. Let $\hat{x}_{x,q}$, \hat{x}_x be the unique solutions of $\min_{x' \in \mathbb{R}^n} F_{x,q}(x')$ and $\min_{x' \in \mathbb{R}^n} F_x(x')$, respectively. First, we show that both $\{x_i\}_{i=0}^\infty$ and $\{\hat{x}_{x_i}\}_{i=0}^\infty$ converge to \hat{x} . It follows from (3.13b) that $\psi_+(x_{i+1}) \leq \psi_+(x_i)$ when i is sufficiently large. Since $\psi(\cdot)$ has bounded level sets, the sequence $\{x_i\}_{i=0}^\infty$ constructed by Algorithm 3.1 is bounded. It therefore follows from Lemma 3.3(i)-(ii) and Theorem 3.1 that $x_i \rightarrow \hat{x}$ as $i \rightarrow \infty$. Hence, making use of the fact that $F_{x_i}(\hat{x}_{x_i}) \leq F_{x_i}(x_i) = 0$, we deduce that $\{\hat{x}_{x_i}\}_{i=0}^\infty$ is bounded, and that because $F_x(x')$ is continuous in (x, x') any accumulation point \tilde{x} of $\{\hat{x}_{x_i}\}_{i=0}^\infty$, must satisfy $F_{\tilde{x}}(\tilde{x}) \leq 0$, which implies that $\tilde{x} = \hat{x}$. Therefore, $\hat{x}_{x_i} \rightarrow \hat{x}$ as $i \rightarrow \infty$.

Now the i th iteration of Algorithm 3.1 consists of one iteration of the PPP minimax algorithm on $\min_{x \in \mathbb{R}^n} F_{x_i, q_i}(x)$, starting with x_i . Therefore, replacing $\psi_{q_i}(\cdot)$, $\psi(\cdot)$, \hat{x}_{q_i} , and \hat{x} by $F_{x_i, q_i}(\cdot)$, $F_{x_i}(\cdot)$, \hat{x}_{x_i, q_i} , and \hat{x}_{x_i} , respectively, in the proof of Theorem 2.1, we conclude that there exists an integer i_1 such that for all $i \geq i_1$,

$$(3.19a) \quad F_{x_i}(x_{i+1}) - F_{x_i}(\hat{x}_{x_i}) \leq [1 - \nu_i][F_{x_i}(x_i) - F_{x_i}(\hat{x}_{x_i})],$$

where

$$(3.19b) \quad \nu_i \triangleq \frac{\alpha\beta m}{M} - \frac{8(2+\gamma)KM}{D^{1/\sigma}(q_i^\tau)^{(\sigma-1)/\sigma}} > 0.$$

Since $F_{x_i}(x_i) = 0$, we get

$$(3.20) \quad F_{x_i}(x_{i+1}) \leq \nu_i F_{x_i}(\hat{x}_{x_i}).$$

Now, since \hat{x}_i is the minimizer of $F_{x_i}(\cdot)$, there exists a multiplier $\hat{\mu}_i = (\hat{\mu}_i^0, \hat{\mu}_i^1, \dots, \hat{\mu}_i^l)$ such that

$$(3.21a) \quad 0 \in \sum_{j=0}^l \hat{\mu}_i^j \partial \psi^j(\hat{x}_{x_i}),$$

$$(3.21b) \quad \hat{\mu}_i^0 [\psi^0(\hat{x}_{x_i}) - \psi^0(x_i) - \gamma \psi_+(x_i)] + \sum_{j=1}^l \hat{\mu}_i^j [\psi^j(\hat{x}_{x_i}) - \psi_+(x_i)] = F_{x_i}(\hat{x}_{x_i}),$$

$$(3.21c) \quad \sum_{j=0}^l \hat{\mu}_i^j = 1, \quad \hat{\mu}_i^j \geq 0 \quad \text{for } j \in L.$$

Since both sequences $\{x_i\}_{i=0}^\infty$ and $\{\hat{x}_{x_i}\}_{i=0}^\infty$ converge to \hat{x} , any accumulation point of $\{\hat{\mu}_i\}_{i=0}^\infty$ is in $L(\hat{x})$. Hence

$$(3.22) \quad \underline{\mu}^0 \leq \liminf_{i \rightarrow \infty} \hat{\mu}_i^0 \leq \overline{\lim}_{i \rightarrow \infty} \hat{\mu}_i^0 \leq \bar{\mu}^0.$$

Let $\tilde{F}_i(\cdot)$ be defined by

$$(3.33) \quad \tilde{F}_i(x) = \hat{\mu}_i^0 [(\psi^0(x) - \psi^0(x_i) - \gamma \psi_+(x_i))] + \sum_{j=1}^l \hat{\mu}_i^j [\psi^j(x) - \psi_+(x_i)].$$

It follows from (3.21a)–(3.21c) that $0 \in \partial \tilde{F}_i(\hat{x}_{x_i})$. Since $\tilde{F}_i(\cdot)$ is strictly convex, \hat{x}_{x_i} must be its unique minimizer. Hence, making use of (3.21c) and the fact that $\tilde{F}_i(\hat{x}_{x_i}) = F_{x_i}(\hat{x}_{x_i})$ and that $\psi(\hat{x}) \leq 0$, we obtain that

$$(3.24) \quad F_{x_i}(\hat{x}_{x_i}) \leq \tilde{F}_i(\hat{x}) \leq \hat{\mu}_i^0 [(\psi^0(\hat{x}) - \psi^0(x_i))] - [1 + (\gamma - 1)\hat{\mu}_i^0] \psi_+(x_i).$$

Combining (3.20) and (3.24) and rearranging terms, we get

$$(3.25a) \quad \psi^0(x_{i+1}) - \psi^0(\hat{x}) \leq (1 - \hat{\mu}_i^0 \nu_i) [\psi^0(x_i) - \psi^0(\hat{x})] + [\gamma - (1 + (\gamma - 1)\hat{\mu}_i^0) \nu_i] \psi_+(x_i),$$

$$(3.25b) \quad \psi(x_{i+1}) \leq \hat{\mu}_i^0 \nu_i [\psi^0(\hat{x}) - \psi^0(x_i)] + (1 - (1 + (\gamma - 1)\hat{\mu}_i^0) \nu_i) \psi_+(x_i).$$

By Lemma 3.3, $q_i \rightarrow \infty$ as $i \rightarrow \infty$. Hence we deduce from (3.19b) that

$$(3.26) \quad \lim_{i \rightarrow \infty} \nu_i = \frac{\alpha\beta m}{M}.$$

Now, it was shown in the proof of Theorem 3.1 that there exists an integer $i_0 > i_1$ such that either (i) $\psi(x_i) \leq 0$ for all $i \geq i_0$, or (ii) $\psi(x_i) > 0$ for all $i \geq i_0$. In the former case, (3.18a) follows from (3.22), (3.25a), (3.26), and the fact that $\psi_+(x_i) = 0$ for $i \geq i_0$. In the latter case, we obtain from (3.25b) and (3.17b) that

$$(3.27) \quad \begin{aligned} \psi(x_{i+1}) &\leq [\hat{\mu}_i^0 \nu_i (1 - \bar{\mu}^0) / \bar{\mu}^0 + 1 - (1 + (\gamma - 1)\hat{\mu}_i^0) \nu_i] \psi_+(x_i) \\ &= [1 + (\hat{\mu}_i^0 / \bar{\mu}^0 - 1 - \gamma \hat{\mu}_i^0) \nu_i] \psi(x_i). \end{aligned}$$

Hence (3.18b) follows from (3.22), (3.26), and (3.27). \square

For comparison, we reproduce the rate-of-convergence theorem for the USFD algorithm described in [13].

THEOREM 3.3. *Suppose that the relevant part of Assumption 3.2 holds. Then any sequence of iterates $\{x_i\}_{i=0}^\infty$ generated by the USFD algorithm, defined by (3.3e)–(3.3g), converges to \hat{x} , and there exists an integer i_0 such that either (i) $\psi(x_i) \leq 0$ for all $i \geq i_0$ and*

$$(3.28a) \quad \lim_{i \rightarrow \infty} \frac{\psi^0(x_{i+1}) - \psi^0(\hat{x})}{\psi^0(x_i) - \psi^0(\hat{x})} \leq 1 - \underline{\mu}^0 \alpha \beta m / M,$$

or (ii) $\psi(x_i) > 0$ for all $i \geq i_0$ and

$$(3.28b) \quad \lim_{i \rightarrow \infty} \frac{\psi(x_{i+1})}{\psi(x_i)} \leq 1 - \gamma \underline{\mu}^0 \alpha \beta m / M,$$

where $\underline{\mu}^0$ is defined in Lemma 3.3(iii).

Thus we see that Algorithm 3.1 has the same rate of convergence as the USFD algorithm, and hence, by the same arguments used at the end of § 2, we conclude that using adaptive discretization in the form of Algorithm 3.1 should result in savings in computing time over the use of the USFD algorithm on a single high-precision approximation to the original problem.

4. Optimal control problems. Finally, we turn to unconstrained optimal control problems. The most natural space for establishing the differentiability of solutions of differential equations with respect to controls is L_∞ . However, this is not a natural space for extending finite-dimensional algorithms, defined on the Hilbert space \mathbb{R}^n , to optimal control problems. The natural space for this purpose is L_2 , but in L_2 , solutions of differential equations are Fréchet differentiable with respect to controls in L_2 only under a *growth condition* [2], [20]. Fortunately, since in the solution of optimal control problems, control sequences remain bounded in the L_∞ -norm, imposition of a growth condition, as we will shortly describe, amounts to only a technical artifice.

We will consider unconstrained optimal control problems of the form

$$(4.1a) \quad \text{OCP: } \min_{u \in G} c(u) = g(\bar{x}(u)),$$

where $g: \mathbb{R}^n \rightarrow \mathbb{R}$, $G \triangleq L_2^m[0, T]$, T is a given time period, and $\bar{x}: G \rightarrow \mathbb{R}^n$ is defined by $\bar{x}(u) \triangleq x(T, u, x_0)$, with $x(\cdot, u, x_0)$ the solution of the differential equation

$$(4.1b) \quad \dot{x}(t) = f(x(t), u(t), t), \quad t \in [0, T], \quad x(0) = x_0,$$

where x_0 is a given vector in \mathbb{R}^n .

In Assumption 4.1 below, we postulate local Lipschitz continuity conditions that are independent of bounds on the control. We justify this assumption as follows. We may assume that there exists a compact set $U \subset \mathbb{R}^m$, such that the control sequences $\{u_i(\cdot)\}_{i=0}^\infty$, constructed by our algorithm, take values in U . Hence there exists a bound $b < \infty$ such that for all $u \in U$, $|u^i| \leq b$, $i = 1, 2, \dots, m$. Consequently, we may assume without loss of generality that the function f has the form $f(x, u, t) = \tilde{f}(x, \text{SAT}(u), t)$, where $\text{SAT}: \mathbb{R}^m \rightarrow \mathbb{R}^m$ is such that

$$\text{SAT}(u) = (\text{sat}(u^1), \text{sat}(u^2), \dots, \text{sat}(u^m))$$

and for all $z \in \mathbb{R}$, $\text{sat}(z) = z$ if $|z| \leq 2b$ and $\text{sat}(z) = 2b \operatorname{sgn}(z)(1 - e^{-(|z|-2b)})$ otherwise, and $\tilde{f}(\cdot, \cdot, \cdot)$ satisfies standard assumptions. It is easy to see that Assumption 4.1 is satisfied under such a *growth condition* on the right-hand side of (4.1b).

We will assume that functions $g: \mathbb{R}^n \rightarrow \mathbb{R}$ and $f: \mathbb{R}^n \times \mathbb{R}^m \times [0, T] \rightarrow \mathbb{R}^n$ have the following properties.

Assumption 4.1. (i) The function $g(\cdot)$ and its gradient $\nabla g(\cdot)$ are locally Lipschitz continuous.

(ii) The function $f(\cdot, \cdot, \cdot)$ and its partial derivatives $\partial f(\cdot, \cdot, \cdot)/\partial x$ and $\partial f(\cdot, \cdot, \cdot)/\partial u$ are locally Lipschitz continuous, with the Lipschitz constant independent of the magnitude of the control u .

(iii) There exists a constant K_1 such that for all $x \in \mathbb{R}^n$, $u \in L_2^m[0, T]$, and $t \in [0, T]$,

$$(4.2a) \quad \|f(x, u, t)\| \leq K_1[\|x\| + 1],$$

$$(4.2b) \quad \left\| \frac{\partial f(x, u, t)}{\partial x} \right\| \leq K_1[\|x\| + 1],$$

$$(4.2c) \quad \left\| \frac{\partial f(x, u, t)}{\partial u} \right\| \leq K_1[\|x\| + 1].$$

The following result can be obtained using the implicit function theorem in Banach spaces, as shown in [2], [20].

LEMMA 4.1. *Suppose that Assumption 4.1 is satisfied. Then*

(i) *The differential equation (4.1b) has a unique solution for every $u \in G$.*

(ii) *The functions $\bar{x}(\cdot)$ and $c(\cdot)$ are continuously Fréchet differentiable on G .*

Since the functions $\bar{x}(\cdot)$ and $c(\cdot)$ are continuously Fréchet differentiable on G , there exist continuous functions, a “Jacobian” $(n \times m)$ -matrix-valued function $(\partial \bar{x}/\partial u)(t)$, $t \in [0, t]$, and a “gradient” $\nabla c: G \rightarrow G$, such that

$$(4.3a) \quad \lim_{\substack{\delta u \in G \\ \|\delta u\|_2 \rightarrow 0}} \frac{\left\| \bar{x}(u + \delta u) - \bar{x}(u) - \int_0^T \frac{\partial \bar{x}(u)}{\partial u}(t) \delta u(t) dt \right\|}{\|\delta u\|_2} = 0,$$

$$(4.3b) \quad \lim_{\substack{\delta u \in G \\ \|\delta u\|_2 \rightarrow 0}} \frac{\left| c(u + \delta u) - c(u) - \int_0^T \langle \nabla c(u)(t), \delta u(t) \rangle dt \right|}{\|\delta u\|_2} = 0.$$

The following result can be deduced from basic differential equation theory (see [2], [20]) and Lemma 4.1.

LEMMA 4.2. *Suppose that Assumption 4.1 is satisfied. Then (i) For every $u \in G$ and $t \in [0, T]$,*

$$(4.4a) \quad \frac{\partial \bar{x}(u)}{\partial u}(t) = \Phi_u(T, t) \frac{\partial f(x(u, t), u(t), t)}{\partial u},$$

$$(4.4b) \quad \nabla c(u)(t) = \left[\frac{\partial \bar{x}(u)}{\partial u}(t) \right]^T \nabla g(\bar{x}(u)),$$

where $\Phi_u(t, \tau)$ is the state transition matrix for the linear differential equation

$$(4.4c) \quad \dot{y}(t) = \frac{\partial f(x(t, u), u(t), t)}{\partial x} y(t) \text{ on } t \in [0, T];$$

(ii) *There exists a K_2 such that for all $u, \delta u \in G$,*

$$(4.4d) \quad \|\bar{x}(u)\| \leq K_2, \quad \left\| \frac{\partial \bar{x}(u)}{\partial u} \right\|_\infty \leq K_2, \quad \|\nabla c(u)\|_\infty \leq K_2,$$

$$(4.4e) \quad \|\bar{x}(u + \delta u) - \bar{x}(u)\| \leq K_2 \|\delta u\|_2,$$

$$(4.4f) \quad \left\| \bar{x}(u + \delta u) - \bar{x}(u) - \int_0^T \left[\frac{\partial \bar{x}(u)}{\partial u}(t) \right] \delta u(t) dt \right\| \leq K_2 \|\delta u\|_2^2.$$

As a first step toward the numerical solution of the infinite-dimensional problem **OCP**, we define a sequence of finite-dimensional subspaces G_q of G , $q \in \mathbb{N}$. Thus, for any $q \in \mathbb{N}$, let $\Delta_q \triangleq T/2^q$, and let

$$G_q \triangleq G \cap \{u \mid u(t) = u^j \in \mathbb{R}^m, \quad t \in [j\Delta_q, (j+1)\Delta_q), j = 0, 1, \dots, 2^q - 1\}.$$

Next, for any $q \in \mathbb{N}$, and any $u \in G_q$, let $\bar{x}_q(u)$ be an approximation to $\bar{x}(u)$, obtained by solving the differential equation (4.1b) by means of a numerical method, such as the Euler–Cauchy method, the modified Euler method, the Runge–Kutta method, and others. We can now define a family of finite-dimensional approximating problems, parametrized by the discretization parameter $q \in \mathbb{N}$

$$(4.5) \quad \mathbf{OCP}_q : \min_{u \in G_q} c_q(u),$$

where $c_q(u) \triangleq g(\bar{x}_q(u))$. We will assume that $\bar{x}_q(\cdot)$ approximates $\bar{x}(u)$ in the following sense.

Assumption 4.2. (i) There exists a $\tau \in (0, \infty)$ such that there exist constants K_3 , such that for any $q \in \mathbb{N}$,

$$(4.6a) \quad |x(u) - \bar{x}_q(u)| \leq K_3/(2^q)^\tau \quad \text{for all } u \in G_q,$$

(ii) $\bar{x}_q(\cdot)$ is continuously Fréchet differentiable on G_q . We will denote its “Jacobian” by $(\partial \bar{x}_q(u)/\partial u)(t)$.

(iii) For any $\varepsilon \in (0, \infty)$, there exists a $\hat{q} \in \mathbb{N}$ such that for all $q \geq \hat{q}$ and $u \in G_q$,

$$(4.6b) \quad \left\| \frac{\partial \bar{x}_q(u)}{\partial u} - \frac{\partial \bar{x}(u)}{\partial u} \right\|_\infty \leq \varepsilon;$$

(iv) There exists $K_4 \in (0, \infty)$ such that for all $q \in \mathbb{N}$ and all $u, \delta u \in G_q$,

$$(4.6c) \quad \|\bar{x}_q(u + \delta u) - \bar{x}_q(u)\| \leq K_4 \|\delta u\|_2,$$

$$(4.6d) \quad \left\| \bar{x}_q(u + \delta u) - \bar{x}_q(u) - \int_0^T \left[\frac{\partial \bar{x}_q(u)}{\partial u}(t) \right] \delta u(t) dt \right\| \leq K_4 \|\delta u\|_2^2. \quad \square$$

Remark 4.1. Referring to [7], we see that when the Euler–Cauchy method is used to define $\bar{x}_q(u)$, Assumption 4.2 is satisfied with $\tau = 1$. It is easy to show that when the modified Euler method or Runge–Kutta method are used to define $\bar{x}_q(u)$, Assumption 4.2 is satisfied with $\tau = 3$ and $\tau = 5$, respectively.

LEMMA 4.3. Suppose that Assumptions 4.1 and 4.2 are satisfied. Then (i) The function $c_q(\cdot)$ is continuously Fréchet differentiable on G_q , and for any $u \in G_q$ and $t \in [0, T]$,

$$(4.7a) \quad \nabla c_q(u)(t) = \left[\frac{\partial \bar{x}_q(u)}{\partial u}(t) \right]^T \nabla g(\bar{x}_q(u));$$

(ii) There exists a $K_5 \in (0, \infty)$ such that for $q \in \mathbb{N}$ and all $u \in G_q$,

$$(4.7b) \quad |c(u) - c_q(u)| \leq K_5/(2^q)^\tau.$$

Proof. Part (i) follows from the Assumption 4.2(ii), (4.6c), and the local Lipschitz continuity of $\nabla g(\cdot)$. Inequality (4.7b) follows from Assumption 4.2(i), (4.4d), and the local Lipschitz continuity of $g(\cdot)$. \square

Since G_q is isomorphic to \mathbb{R}^{2^q} , each problem **OCP**_q defined by (4.5) can be solved by the Armijo gradient method [1], which uses two parameters $\alpha, \beta \in (0, 1)$ and which for **OCP**_q constructs iterates according to the rule

$$(4.8a) \quad u_{i+1} = u_i - \lambda_i \nabla c_q(u_i),$$

with

$$(4.8b) \quad \lambda_i = \max \{ \beta^k \mid k \in \mathbb{N}, c_q(u_i - \beta^k \nabla c_q(u_i)) - c_q(u_i) \leq -\alpha \beta^k \|\nabla c_q(u_i)\|_2^2 \}.$$

We can now state an adaptive discretization scheme, based on the Armijo gradient method (4.8a), (4.8b), for solving the problem **OCP**.

Adaptive Discretization Algorithm 4.1 (for OCP):

Data: $u_0 \in G_{q_{-1}}$, $q_{-1} \in \mathbb{N}$, $\alpha \in (0, 1)$, $\beta \in (0, 1)$, $D > 0$, and $\sigma > 1$.

Step 0: Set $i = 0$.

Step 1: Compute $q_i \in \mathbb{N}$ and $\nabla c_{q_i}(u_i)$ such that $q_i \geq q_{i-1}$ and

$$(4.9a) \quad D / (2^{q_i})^\tau \leq [\|\nabla c_{q_i}(u_i)\|_2^2]^\sigma.$$

Step 2: Set $h_i = -\nabla c_{q_i}(u_i)$, $\theta_i = -\|\nabla c_{q_i}(u_i)\|_2^2$ and compute the stepsize λ_i :

$$(4.9b) \quad \lambda_i = \max \{ \beta^k \mid k \in \mathbb{N}, c_{q_i}(u_i + \beta^k h_i) - c_{q_i}(u_i) \leq \alpha \beta^k \theta_i \}.$$

Step 3: Set $u_{i+1} = u_i + \lambda_i h_i$, replace i by $i + 1$, and go to Step 1.

Remark 4.2. It follows from Assumptions 4.2(i) and 4.2(iii), (4.4b), and (4.7a), that whenever $\nabla c(u_i) \neq 0$ (i.e., u_i does not satisfy a first-order optimality condition for the problem **OCP**), Step 1 of Algorithm 4.1 yields a finite q_i . For simplicity, in the rest of this section we will assume that Algorithm 4.1 does not construct a u_i such that $\nabla c(u_i) = 0$, for any finite i .

LEMMA 4.4. Suppose that Assumption 4.1 is satisfied, that $g(\cdot)$ is bounded from below, and that the sequence of controls $\{u_i\}_{i=0}^\infty$ and the corresponding sequence of discretization parameters $\{q_i\}_{i=0}^\infty$ are constructed by Algorithm 4.1. Then $q_i \rightarrow \infty$ as $i \rightarrow \infty$.

Proof. Suppose that $q_i \rightarrow \infty$ as $i \rightarrow \infty$ does not hold. Then, using the same reasoning as in the proof of Lemma 2.2 and the fact that $\|h_i\|_2^2 = -\theta_i$, we conclude that there exist i_0 and $\hat{q} \in \mathbb{N}$ such that $q_i = \hat{q}$ for all $i \geq i_0$, and that $\{u_i\}_{i=0}^\infty$ is a Cauchy sequence in $G_{\hat{q}}$. Since for any accumulation point \hat{u} , of a sequence $\{u_i\}_{i=0}^\infty$ constructed by the Armijo gradient method (4.8a), (4.8b) in the finite-dimensional space, $G_{\hat{q}}$, $\nabla c_{\hat{q}}(\hat{u}) = 0$ (see [1]), $\theta_{\hat{q}}(u_i) = -\|\nabla c_{\hat{q}}(u_i)\|_2^2 \rightarrow 0$, which contradicts the test (4.9a). Thus we must have that $q_i \rightarrow \infty$ as $i \rightarrow \infty$. \square

THEOREM 4.1. Suppose that Assumptions 4.1 and 4.2 are satisfied, that $g(\cdot)$ is twice continuously differentiable and bounded from below, and that there exists a constant $M_g \in (0, \infty)$ such that for all $x \in \mathbb{R}^n$, $z \in \mathbb{R}^n$,

$$(4.10) \quad \left\langle z, \frac{\partial^2 g(x)}{\partial x^2} z \right\rangle \leq M_g \|z\|^2.$$

Then any accumulation point $\hat{u} \in G$ of a sequence of controls $\{u_i\}_{i=0}^\infty$ generated by Algorithm 4.1 satisfies $\nabla c(\hat{u}) = 0$.

Proof. Making use of (4.10), (4.7a), (4.6c), (4.6d), and the fact that $h_i = -\nabla c_{q_i}(u_i)$ and that $\theta_i = -\|h_i\|_2^2$, we obtain that for all $\lambda \in [0, 1]$,

$$\begin{aligned} c_q(u_i + \lambda h_i) - c_q(u_i) &= g(\bar{x}_{q_i}(u_i + \lambda h_i)) - g(\bar{x}_{q_i}(u_i)) \\ &\leq \langle \nabla g(\bar{x}_{q_i}(u_i)), (\bar{x}_{q_i}(u_i + \lambda h_i) - \bar{x}_{q_i}(u_i)) \rangle \\ &\quad + \frac{M_g}{2} \|\bar{x}_{q_i}(u_i + \lambda h_i) - \bar{x}_{q_i}(u_i)\|^2 \\ (4.11) \quad &\leq \left\langle \nabla g(\bar{x}_{q_i}(u_i)), \int_0^T \frac{\partial \bar{x}_{q_i}(u_i)}{\partial u}(t) \lambda h_i(t) dt \right\rangle \\ &\quad + K_4 \|\nabla g(\bar{x}_{q_i}(u_i))\| \|\lambda h_i\|_2^2 + \frac{M_g}{2} (K_4 \|\lambda h_i\|_2)^2 \\ &= \lambda \theta_i - \lambda^2 [K_4 \|\nabla g(\bar{x}_{q_i}(u_i))\| + M_g K_4^2 / 2] \theta_i. \end{aligned}$$

Since $\bar{x}_{q_i}(u_i)$ is bounded and $\nabla g(\cdot)$ is continuous, there exists a $K_6 \in (1, \infty)$ such that

$$(4.12) \quad c_q(u_i + \lambda h_i) - c_q(u_i) \leq (\lambda - \lambda^2 K_6) \theta_i = \alpha \lambda \theta_i + \lambda(1 - \alpha - K_6 \lambda) \theta_i, \\ \forall i \in \mathbb{N} \quad \forall \lambda \in [0, 1].$$

Hence (4.9b) is satisfied with

$$(4.13) \quad \lambda_i \leq (1 - \alpha) \beta / K_6,$$

and thus

$$(4.14) \quad c_{q_i}(u_{i+1}) - c_{q_i}(u_i) \leq \alpha \lambda_i \theta_i \leq \alpha(1 - \alpha) \beta \theta_i / K_6.$$

It therefore follows from (4.7b) that

$$(4.15) \quad c(u_{i+1}) - c(u_i) \leq \alpha(1 - \alpha) \beta \theta_i / K_6 + 2K_5 / (2^{q_i})^\tau.$$

Resorting to the reasoning used in the proof of Theorem 2.1, with $\psi(\cdot)$, x_i , q_i , M , and K replaced by $c(\cdot)$, u_i , 2^{q_i} , $K_6/(1 - \alpha)$, and K_5 , we can show that $\sum_{k=0}^{\infty} \theta_k > -\infty$. Hence $\theta_i \rightarrow 0$ as $i \rightarrow \infty$. Now, for all $i \in \mathbb{N}$,

$$(4.16) \quad \|\nabla c(\hat{u})\|_2 \leq \|\nabla c(\hat{u}) - \nabla c(u_i)\|_2 + \|\nabla c(u_i) - \nabla c_{q_i}(u_i)\|_2 + \|\nabla c_{q_i}(u_i)\|_2 \\ \leq \|\nabla c(\hat{u}) - \nabla c(u_i)\|_2 + T^{1/2} \|\nabla c(u_i) - \nabla c_{q_i}(u_i)\|_\infty + (-\theta_i)^{1/2}.$$

Consequently, the desired result follows from the continuity of $\nabla c(\cdot)$, (4.6b), Assumptions 4.1 and 4.2, Lemma 4.3 (specifically, (4.7a)), and the facts that $\theta_i \rightarrow 0$ and $q_i \rightarrow \infty$ as $i \rightarrow \infty$. \square

LEMMA 4.5. *Suppose that Assumptions 4.1 and 4.2 hold and that there exist $0 < m_g < M_g < \infty$ and $0 < m_c < M_c < \infty$ such that for all $x \in \mathbb{R}^n$, $z \in \mathbb{R}^n$, and $u \in G$,*

$$(4.17a) \quad m_g \|z\|^2 \leq \left\langle z, \frac{\partial^2 g(x)}{\partial x^2} z \right\rangle \leq M_g \|z\|^2,$$

$$(4.17b) \quad m_c \|z\|^2 \leq \left\langle z, \left\{ \int_0^T \left[\frac{\partial \bar{x}(u)}{\partial u}(t) \right] \left[\frac{\partial \bar{x}(u)}{\partial u}(t) \right]^T dt \right\} z \right\rangle \leq M_c \|z\|^2.$$

Then, for any $\varepsilon \in (0, m_c)$, there exists a \hat{q} such that, for any $q \geq \hat{q}$ and $u \in G_q$,

$$(4.18a) \quad (m_c - \varepsilon) \|z\|^2 \leq \left\langle z, \left\{ \int_0^T \left[\frac{\partial \bar{x}_q(u)}{\partial u}(t) \right] \left[\frac{\partial \bar{x}_q(u)}{\partial u}(t) \right]^T dt \right\} z \right\rangle \leq (M_c + \varepsilon) \|z\|^2,$$

$$(4.18b) \quad (m_c - \varepsilon) \|\nabla g(\bar{x}_q(u))\|^2 \leq \|\nabla c_q(u)\|_2^2 \leq (M_c + \varepsilon) \|\nabla g(\bar{x}_q(u))\|^2,$$

$$(4.18c) \quad \frac{1}{2M_g(M_c + \varepsilon)} \|\nabla c_q(u)\|_2^2 \leq c_q(u) - g(\hat{x}) \leq \frac{1}{2m_g(m_c - \varepsilon)} \|\nabla c_q(u)\|_2^2,$$

where \hat{x} is the unique minimizer of $g(\cdot)$.

Proof. Inequality (4.18a) follows directly from (4.4d), (4.17b), and Assumption 4.2 (iii), while (4.18b) follows from (4.7a) and (4.18a). Making use of (4.18b) and the fact that for all $x \in \mathbb{R}^n$,

$$(4.19) \quad \frac{1}{2M_g} \|\nabla g(x)\|^2 \leq g(x) - g(\hat{x}) \leq \frac{1}{2m_g} \|\nabla g(x)\|^2,$$

we get (4.18c). \square

Remark 4.3. The matrix

$$\int_0^T \left[\frac{\partial \bar{x}(u)}{\partial u}(t) \right] \left[\frac{\partial \bar{x}(u)}{\partial u}(t) \right]^T dt$$

is the controllability Grammian of the linearization of system (4.1b). When the dynamical system (4.1b) is linear, inequality (4.17b) holds if and only if (4.1b) is completely controllable on $[0, T]$. When the dynamical system (4.1b) is nonlinear, condition (4.17b) is a sufficient condition for the complete controllability of system (4.1b) on $[0, T]$ (see [16]).

THEOREM 4.2. *Suppose that Assumptions 4.1 and 4.2 are satisfied and that there exist $0 < m_g < M_g < \infty$ and $0 < m_c < M_c < \infty$ such that $M_g M_c \geq 2$ and (4.17a), (4.17b) hold. Let \hat{x} be the unique minimizer of $g(\cdot)$. If $\{u_i\}_{i=0}^\infty$ is a sequence of controls generated by Algorithm 4.1, then*

$$(4.20a) \quad (i) \quad \lim_{i \rightarrow \infty} \nabla g(\bar{x}_{q_i}(u_i)) = 0,$$

$$(4.20b) \quad (ii) \quad \lim_{i \rightarrow \infty} c(u_i) = g(\hat{x}),$$

$$(4.20c) \quad (iii) \quad \overline{\lim}_{i \rightarrow \infty} \frac{c(u_{i+1}) - g(\hat{x})}{c(u_i) - g(\hat{x})} \leq 1 - \frac{4(1-\alpha)\alpha\beta m_g m_c}{M_g M_c},$$

$$(iv) \quad \text{The sequence } \{\bar{x}_{q_i}(u_i)\}_{i=0}^\infty \text{ converges } R\text{-linearly to } \hat{x},$$

$$(v) \quad \text{There exists a } \hat{u} \in G \text{ such that } \nabla c(\hat{u}) = 0 \text{ and the sequence } \{\|u_i - \hat{u}\|_\infty\}_{i=0}^\infty \text{ converges } R\text{-linearly to } 0.$$

Proof. Making use of Lemmas 4.4 and 4.5, we conclude that for every $\varepsilon \in (0, m_c)$, there exists an i_ε such that for all $i \geq i_\varepsilon$, (4.18a)–(4.18c) hold for $q = q_i$ and all $u \in G_{q_i}$.

(i) By Theorem 4.1, $\|\nabla c_{q_i}(u_i)\|_2 \rightarrow 0$ as $i \rightarrow \infty$. Hence it follows from (4.18b) that $\nabla g(\bar{x}_{q_i}(u_i)) \rightarrow 0$ as $i \rightarrow \infty$.

(ii) Equation (4.20) follows from (4.7b), (4.18c), and the fact that $\|\nabla c_{q_i}(u_i)\|_2 \rightarrow 0$ and $q_i \rightarrow \infty$ as $i \rightarrow \infty$.

(iii) First, we will obtain a bound on the stepsize λ_i . Making use of (4.6d), (4.18a), and the fact that

$$h_i(t) = - \left[\frac{\partial \bar{x}_{q_i}(u_i)}{\partial u}(t) \right]^T \nabla g(\bar{x}_{q_i}(u_i))$$

and that $\langle v, A^2 v \rangle \leq \|A\| \langle v, Av \rangle$ for all symmetric, positive definite matrices A and vectors v , we obtain that for all $i \geq i_\varepsilon$ and $\lambda \in [0, 1]$,

$$\begin{aligned} \|\bar{x}_{q_i}(u_i + \lambda h_i) - \bar{x}_{q_i}(u_i)\| &\leq \left\| \int_0^T \left[\frac{\partial \bar{x}_{q_i}(u_i)}{\partial u}(t) \right] \lambda h_i(t) dt \right\| + K_4 \|\lambda h_i\|_2^2 \\ &= \lambda \left[\left\langle \nabla g(\bar{x}_{q_i}(u_i)), \left(\int_0^T \left[\frac{\partial \bar{x}_{q_i}(u_i)}{\partial u}(t) \right] \right. \right. \right. \\ &\quad \cdot \left. \left. \left[\frac{\partial \bar{x}_{q_i}(u_i)}{\partial u}(t) \right]^T dt \right)^T \nabla g(\bar{x}_{q_i}(u_i)) \right\rangle \right]^{1/2} + \lambda^2 K_4 \|h_i\|_2^2 \\ (4.21) \quad &\leq \lambda \left[(M_c + \varepsilon) \left\langle \nabla g(\bar{x}_{q_i}(u_i)), \left(\int_0^T \left[\frac{\partial \bar{x}_{q_i}(u_i)}{\partial u}(t) \right] \right. \right. \right. \\ &\quad \cdot \left. \left. \left[\frac{\partial \bar{x}_{q_i}(u_i)}{\partial u}(t) \right]^T dt \right)^T \nabla g(\bar{x}_{q_i}(u_i)) \right\rangle \right]^{1/2} + \lambda^2 K_4 \|h_i\|_2^2 \\ &\leq [(M_c + \varepsilon)^{1/2} + \lambda K_4 \|h_i\|_2] \lambda \|h_i\|_2. \end{aligned}$$

Next, we deduce from (4.17a), (4.6d), (4.7a), (4.21), and the fact that $h_i = -\nabla c_{q_i}(u_i)$, that for all $\lambda \in [0, 1]$,

$$\begin{aligned}
 c_q(u_i + \lambda h_i) - c_q(u_i) &= g(\bar{x}_{q_i}(u_i + \lambda h_i)) - g(\bar{x}_{q_i}(u_i)) \\
 &\leq \langle \nabla g(\bar{x}_{q_i}(u_i)), (\bar{x}_{q_i}(u_i + \lambda h_i) - \bar{x}_{q_i}(u_i)) \rangle \\
 &\quad + \frac{M_g}{2} \|\bar{x}_{q_i}(u_i + \lambda h_i) - \bar{x}_{q_i}(u_i)\|^2 \\
 &\leq -\lambda \|h_i\|_2^2 + \lambda^2 K_4 \|\nabla g(\bar{x}_{q_i}(u_i))\| \|h_i\|_2^2 \\
 &\quad + \frac{M_g}{2} \lambda^2 ((M_c + \varepsilon)^{1/2} + \lambda K_4 \|h_i\|_2)^2 \|h_i\|_2^2.
 \end{aligned}
 \tag{4.22}$$

Since $\|h_i\|_2 \rightarrow 0$ and $\|\nabla g(\bar{x}_{q_i}(u_i))\| \rightarrow 0$ as $i \rightarrow \infty$, it follows from (4.22) that there exists $i'_\varepsilon \geq i_\varepsilon$ such that for $i \geq i'_\varepsilon$ and $\lambda \in [0, 1]$,

$$\begin{aligned}
 c_{q_i}(u_i + \lambda h_i) - c_{q_i}(u_i) &\leq -\lambda \|h_i\|_2^2 + M_g(M_c + 2\varepsilon)\lambda^2 \|h_i\|_2^2/2 \\
 &= \lambda \theta_i - M_g(M_c + 2\varepsilon)\lambda^2 \theta_i/2.
 \end{aligned}
 \tag{4.23}$$

Hence (4.9b) is satisfied with $\lambda_i \geq 2(1 - \alpha)\beta/[M_g(M_c + 2\varepsilon)]$ for all $i \geq i'_\varepsilon$, and thus

$$c_{q_i}(u_{i+1}) - c_{q_i}(u_i) \leq \alpha \lambda_i \theta_i \leq 2\alpha(1 - \alpha)\beta \theta_i/[M_g(M_c + 2\varepsilon)], \quad \forall i \geq i'_\varepsilon.
 \tag{4.24}$$

Combining (4.24) and (4.18c) and rearranging terms, we obtain that for all $i \geq i'_\varepsilon$

$$c_{q_i}(u_{i+1}) - g(\hat{x}) \leq \left[1 - \frac{4(1 - \alpha)\alpha\beta m_g(m_c - \varepsilon)}{M_g(M_c + 2\varepsilon)} \right] [c_{q_i}(u_i) - g(\hat{x})].
 \tag{4.25}$$

Hence it follows from (4.7b) that for $i \geq i'_\varepsilon$,

$$c(u_{i+1}) - g(\hat{x}) \leq \left[1 - \frac{4(1 - \alpha)\alpha\beta m_g(m_c - \varepsilon)}{M_g(M_c + 2\varepsilon)} \right] [c(u_i) - g(\hat{x})] + 2K_5/(2^{q_i})^\tau.
 \tag{4.26}$$

Finally, making use of (4.7b), (4.18c), and the fact that $-\theta_i \geq D^{1/\sigma}/((2^{q_i})^\tau)^{1/\sigma}$, we obtain that for $i \geq i'_\varepsilon$,

$$\begin{aligned}
 2M_g(M_c + \varepsilon)[c(u_i) - g(\hat{x})] &\geq 2M_g(M_c + \varepsilon)[c_{q_i}(u_i) - g(\hat{x})] - 2M_g(M_c + \varepsilon)K_5/(2^{q_i})^\tau \\
 &\geq -\theta_i - 2M_g(M_c + \varepsilon)K_5/(2^{q_i})^\tau \\
 &\geq D^{1/\sigma}/((2^{q_i})^\tau)^{1/\sigma} - 2M_g(M_c + \varepsilon)K_5/(2^{q_i})^\tau.
 \end{aligned}
 \tag{4.27}$$

Since $\sigma > 1$ and by Lemma 4.3 $q_i \rightarrow \infty$ as $i \rightarrow \infty$, we claim that there exists $i''_\varepsilon \geq i'_\varepsilon$ such that for $i \geq i''_\varepsilon$

$$4M_g M_c [c(u_i) - g(\hat{x})] \geq \frac{1}{2} D^{1/\sigma}/((2^{q_i})^\tau)^{1/\sigma}.
 \tag{4.28}$$

Thus (4.20c) follows from (4.26), (4.28), and the arbitrary choice of ε in $(0, m_c)$.

(iv) Note that

$$\| \bar{x}_{q_i}(u_i) - \hat{x} \|^2 \leq \frac{2}{m_g} [g(\bar{x}_{q_i}(u_i)) - g(\hat{x})] = \frac{2}{m_g} [c_{q_i}(u_i) - g(\hat{x})].
 \tag{4.29}$$

This, together with (4.25), leads to the desired result.

(v) Since $\|u_i\|_\infty$ is bounded and, by Lemma 4.4, $q_i \rightarrow \infty$ as $i \rightarrow \infty$, it follows from Assumptions 4.1(iii) and 4.2(ii) and Lemma 4.2(ii) that there exists an $\omega > 0$ such that

for all $i \geq 0$, $\|(\partial \bar{x}_{q_i}(u_i))/\partial u\|_\infty \leq \omega$. Making use of this fact, of (4.19), (4.25), and of the fact that $\lambda_i \leq 1$, we obtain that for $i \geq i'_\varepsilon$,

$$\begin{aligned}
 \|u_{i+1} - u_i\|_\infty &\leq \lambda_i \|h_i\|_\infty \\
 &\leq \lambda_i \left\| \frac{\partial \bar{x}_{q_i}(u_i)}{\partial u} \right\|_\infty \|\nabla g(\bar{x}_{q_i}(u_i))\| \\
 (4.30) \quad &\leq \omega [2M_g[g(\bar{x}_{q_i}(u_i)) - g(\hat{x})]]^{1/2} \\
 &\leq \omega \left[2M_g \left[c_{q_{i'_\varepsilon}}(u_{i'_\varepsilon}) - g(\hat{x}) \right] \left[1 - \frac{4(1-\alpha)\alpha\beta m_g(m_c - \varepsilon)}{M_q(M_c + 2\varepsilon)} \right] \right]^{(1-i'_\varepsilon)/2}.
 \end{aligned}$$

Let

$$\eta \triangleq \left[1 - \frac{4(1-\alpha)\alpha\beta m_g(m_c - \varepsilon)}{M_q(M_c + 2\varepsilon)} \right]^{1/2}.$$

Then, for all $j > 1 \geq i'_\varepsilon$,

$$\begin{aligned}
 \|u_j - u_i\|_\infty &\leq \sum_{k=i}^{j-1} \|u_{k+1} - u_k\|_\infty \\
 (4.31) \quad &\leq \omega [2M_g[c_{q_{i'_\varepsilon}}(u_{i'_\varepsilon}) - g(\hat{x})]]^{1/2} \sum_{k=i}^{\infty} \eta^{k-i'_\varepsilon} \\
 &\leq \omega [2M_g[c_{q_{i'_\varepsilon}}(u_{i'_\varepsilon}) - g(\hat{x})]]^{1/2} \eta^{i-i'_\varepsilon} / (1-\eta).
 \end{aligned}$$

Therefore $\{u_i\}_{i=0}^\infty$ is a Cauchy sequence in $L_\infty^m[0, T]$. Since $L_\infty^m[0, T]$ is a complete space in the L_∞ -norm, there exists a $\hat{u} \in L_\infty^m[0, T]$ such that $u_i \rightarrow \hat{u}$ as $i \rightarrow \infty$ in L_∞ -norm. Let j go to ∞ in (4.31), then for all $i \geq i'_\varepsilon$,

$$(4.32) \quad \|\hat{u} - u_i\|_\infty \leq \omega [2M_g[c_{q_{i'_\varepsilon}}(u_{i'_\varepsilon}) - g(\hat{x})]]^{1/2} \eta^{i-i'_\varepsilon} / (1-\eta).$$

Thus, $\{\|\hat{u} - u_i\|_\infty\}_{i=0}^\infty$ converges to zero R -linearly. Finally, by Theorem 4.1, $\nabla c(\hat{u}) = 0$. \square

For comparison, we present a rate-of-convergence result for the Armijo algorithm (4.8a), (4.8b), as applied to composite functions. The proof of this theorem follows by generalization of the Armijo algorithm rate-of-convergence theorem for affine-composite functions presented in [14].

THEOREM 4.3. *Consider the problem*

$$(4.33a) \quad \min_{u \in \mathbb{R}^N} c(u),$$

where $c(u) \triangleq g(\bar{x}(u))$, with $g: \mathbb{R}^n \rightarrow \mathbb{R}$ twice continuously differentiable function satisfying (4.17a), with $0 < m_g \leq M_g < \infty$, and $\bar{x}: \mathbb{R}^N \rightarrow \mathbb{R}^n$ is a Lipschitz continuously differentiable function such that for some $0 < m_c \leq M_c < \infty$

$$(4.33b) \quad m_c \|z\|^2 \leq \left\langle z, \left(\frac{\partial \bar{x}(u)}{\partial u} \right) \left(\frac{\partial \bar{x}(u)}{\partial u} \right)^T z \right\rangle \leq M_c \|z\|^2, \quad \forall z \in \mathbb{R}^n, \quad u \in \mathbb{R}^N.$$

Suppose that $M_c M_g \geq 2$, that \hat{x} is the unique minimizer of $g(\cdot)$, and that $\{u_i\}_{i=0}^\infty$ is a sequence constructed by the Armijo method in solving problem (4.33a). Then

$$(4.34a) \quad (i) \quad \lim_{i \rightarrow \infty} \nabla g(\bar{x}(u_i)) = 0,$$

$$(4.34b) \quad (ii) \quad \lim_{i \rightarrow \infty} c(u_i) = g(\hat{x}),$$

$$(4.34c) \quad (iii) \quad \overline{\lim}_{i \rightarrow \infty} \frac{c(u_{i+1}) - g(\hat{x})}{c(u_i) - g(\hat{x})} \leq 1 - \frac{4(1-\alpha)\alpha\beta m_g m_c}{M_g M_c},$$

- (iv) The sequence $\{\bar{x}(u_i)\}_{i=0}^{\infty}$ converges R -linearly to \hat{x} ,
- (v) There exists a $\hat{u} \in \mathbb{R}^N$ such that $\nabla c(\hat{u}) = 0$ and the sequence $\{\|u_i - \hat{u}\|\}_{i=0}^{\infty}$ converges R -linearly to 0.

Again we see that the use of adaptive discretization is preferable to fixed discretization.

5. Numerical results. Our Adaptive Discretization Algorithm 2.1 and the corresponding version using fixed discretization were coded in C and both were executed on a SUN Sparc Workstation. In the experiments below, the algorithm parameters common to both versions, were set as follows: $\alpha = 0.9$, $\beta = 0.9$.

For Algorithm 2.1, we set $q_{-1} = 6$, $\tau = 1.0$, $\sigma = 1.25$, and $D = (10.0^{-6})^{\sigma}(q_{\text{Fix}})^{\tau}$, with $q_{\text{Fix}} = 200$.

The number of discretization points used in the fixed discretization version was $q_{\text{Fix}} = 200$.

To construct a meaningful common stopping criterion for both algorithms, for each test problem we determined a threshold value of the cost that was close to the optimum value, and stopped the fixed discretization version of the algorithm when final function value $\psi_{q_{\text{Fix}}}(x_{\text{final}}) \leq \psi_{\text{threshold}}$. We adopted a more stringent stopping criterion for the Adaptive Discretization Algorithm 2.1, which was stopped when the final function value $\psi_{q_{\text{final}}}(x_{\text{final}}) \leq \psi_{\text{threshold}}$ and $q_{\text{final}} \geq q_{\text{Fix}}$.

The following three test problems were selected from [17].

Problem 1 (see [17]). The following holds:

$$(5.1) \quad \begin{aligned} \psi(x) = & (x_1)^2 + (x_2)^2 + (x_3)^2 \\ & + \max \left\{ \max_{y \in [0,1]} (x_1 + x_2 \exp(x_3 y) + \exp(2y) - 2 \sin(4y)), 0 \right\}; \end{aligned}$$

initial point $x_0 = (1.0, 1.0, 1.0)$, $\psi_{200}(x_0) = 15.6209$, $\psi_{\text{threshold}} = 5.3347$.

Problem 2 (see [17]). The following holds:

$$(5.2) \quad \psi(x) = x_1 + x_2/2 + x_3/3 + \max \left\{ \max_{y \in [0,1]} (\tan(y) - x_1 - x_2 y - x_3 y^2), 0 \right\};$$

initial point $x_0 = (0.0, 0.0, 0.0)$, $\psi_{200}(x_0) = 1.5574$, $\psi_{\text{threshold}} = 0.6491$.

Problem 3 (see [17]). The following holds:

$$(5.3) \quad \begin{aligned} \psi(x) = & x_1 + x_2/2 + x_3/3 + x_4/4 + x_5/5 + x_6/6 \\ & + \max \left\{ \max_{y \in [0,1]} (\tan(y) - x_1 - x_2 y - x_3 y^2 - x_4 y^3 - x_5 y^4 - x_6 y^5), 0 \right\}; \end{aligned}$$

initial point $x_0 = (0.0, 0.0, 0.0, 0.0, 0.0, 0.0)$, $\psi_{200}(x_0) = 1.5574$, $\psi_{\text{threshold}} = 0.61682$.

Table 1 summarizes the performance of the two discretization schemes on the above three test problems. We report the performance of the two discretization schemes in terms of the composite number NT , which is the sum of the total number of function evaluations NF and the total number of gradient evaluations NG multiplied by the number of variables, i.e., $NT = NF + nNG$. It is clear from Table 1 that Adaptive Discretization Algorithm 2.1 outperformed the fixed discretization versions by a factor ranging from about 1.5 to 4, in terms of the measure NT .

6. Conclusion. There is an accumulation of empirical evidence to support the claim that, in skillful hands, adaptive discretization schemes can produce considerable computational savings in the solution of optimization problems that must be discretized.

TABLE 1
Summary of numerical results.

Problems	Algorithm 2.1			Fixed Discretization Algorithm		
	NT	q_{final}	$\psi_{q_{\text{final}}}(x_{\text{final}})$	NT	q_{Fix}	$\psi_{q_{\text{Fix}}}(x_{\text{final}})$
1	8,860	301	5.334687	39,600	200	5.334689
2	11,844	200	0.6490467	26,000	200	0.6490803
3	59,063	301	0.6168118	78,600	200	0.6168186

However, prior to the work presented in this paper, there was no automatic discretization scheme for first-order algorithms, whose computational savings could be predicted on the basis of analysis and whose overall rate of convergence could be established. We expect that the discretization techniques presented in this paper will prove to be of practical importance in engineering design and optimal control.

Acknowledgments. We thank the referees for their most helpful comments.

ON ROBUST PI-CONTROL OF INFINITE-DIMENSIONAL SYSTEMS*

HARTMUT LOGEMANN† AND HANS ZWART‡

Abstract. A PI-controller is applied to a class of linear multivariable infinite-dimensional minimum-phase systems satisfying a generalized “relative-degree one” condition. It is shown that the closed-loop system is stable and tracks asymptotically constant reference signals in the presence of asymptotically constant disturbances, provided that the controller gains are sufficiently large. It turns out that the closed-loop system has nice robustness properties under high-gain conditions. In particular, robustness criteria for external and internal stability are given if the closed-loop system is subjected to perturbations induced by nonlinearities in the feedback loop. The analysis is based on frequency-domain as well as state-space methods.

Key words. infinite-dimensional systems, PI-controllers, high-gain feedback control, robust stability, robust tracking, measurement nonlinearities, input-output stability, internal stability

1. Introduction. The concepts of classical control theory such as root locus plots, Nyquist diagrams, and PI- and PID-controllers are still very popular among control engineers because of their simplicity and their applicability to a great variety of practical problems. Designs based on classical frequency-domain methods lead to low-dimensional controllers, which are easy to implement. Although it was developed mainly for finite-dimensional systems, classical control theory has been applied by engineers to infinite-dimensional systems for many years, despite the fact that few precise theoretical results were available. Since the late 1970s, there has been a renewed theoretical interest in the use of methods from classical control theory for designing control laws for (multivariable) infinite-dimensional systems; see, e.g., Pohjolainen [33], Banks and Abbasi-Ghelnansarai [1], and Byrnes and Gilliam [3] for root-locus techniques; Boyd and Desoer [2] and Freudenberg and Looze [9] for a priori performance bounds on feedback systems such as Bode-type integral relationships; Desoer and Wang [7], Harris and Valenca [11], and Logemann [18], [19], [21] for Nyquist-type stability criteria; Pohjolainen [34], Jussila and Koivo [15], Kobayashi [17], and Logemann and Owens [24] for low-gain PI-control; and Logemann and Owens [22], [23] for high-gain PI-control.

In this paper we continue the work on high-gain PI-control of infinite-dimensional systems started by Logemann and Owens [22], [23]. We investigate stability, tracking, disturbance rejection, and robustness properties achieved by a high-gain PI-controller applied to an infinite-dimensional minimum-phase system satisfying a generalized “relative-degree one” condition. In particular, we study the robustness of closed-loop stability with respect to various classes of measurement nonlinearities. Our analysis is based on time-domain input-output methods, frequency-domain methods, as well as state-space methods. To relate frequency-domain results, on one hand, and state-space results, on the other hand, we express frequency-domain conditions in state-space terms, and vice versa (cf. § 4). Moreover, recent results on the relationship between input-output stability and internal stability of linear infinite-dimensional systems (see Jacobson [13], Jacobson and Nett [14], and Curtain [5]) will play an important role in § 5.

The content of the paper is as follows. Section 2 contains some preliminaries and introduces the notation used in the sequel. In § 3 we consider systems described by (not necessarily rational) transfer matrices G of the form

$$(1.1) \quad G(s) = \left(I + \frac{1}{s} D^{-1} H(s) \right)^{-1} \frac{1}{s} D^{-1},$$

where H is a “stable” transfer matrix (see § 3 for a precise definition) and D is a nonsingular constant matrix. We derive a necessary and sufficient condition for a transfer matrix to be of the form (1.1) in terms of its zeros and its behaviour as $|s| \rightarrow \infty$ in the right half-plane. A PI-controller is given that achieves input-output stability and tracking of asymptotically constant reference signals in the presence of asymptotically constant disturbances, provided that the controller gains are sufficiently large. It turns out that the transient performance of the closed-loop system improves as the controller gains increase and that it is perfect for infinitely large gains. Moreover, we investigate the robustness of closed-loop stability with respect to (possibly time-varying) finite-gain stable nonlinearities in the feedback loop. Static, as well as dynamic, nonlinearities are considered, and sufficient conditions for input-output stability of the nonlinear closed-loop system are given. We emphasize that wellposedness questions (i.e., the problem of existence and uniqueness of solutions) are carefully treated. Sections 4 and 5 are devoted to the special situation when the plant transfer matrix G can be realized by an abstract infinite-dimensional state-space system with bounded control and observation operators. In § 4 we prove that the zeros of an infinite-dimensional state-space system (as defined, e.g., in Zwart [40]) coincide with the zeros of its transfer matrix (as defined in § 2), provided that the system is exponentially stabilizable and exponentially detectable. Furthermore, we derive various sufficient conditions in state-space terms for (1.1) to be satisfied. In § 5 we deal with the problem of *internal* stability of the closed-loop system perturbed by nonlinearities in the feedback loop. Assuming that the realizations of the plant and the controller are both exponentially stabilizable and exponentially detectable, we show that the criterion for input-output stability given in § 3 also ensures global exponential stability of the nonlinear feedback scheme if the nonlinearities in the loop are static. In the case of dynamical nonlinearities, we can prove that the origin of the closed-loop system is globally attractive. The proofs of some of the results in §§ 3–5 are relegated to Appendices 1 and 2. For the convenience of the reader, we have included some recent material on exponential stabilizability and exponential detectability of infinite-dimensional systems in Appendix 3.

2. Notation and preliminaries.

- $\mathbb{C}_\alpha := \{s \in \mathbb{C} \mid \operatorname{Re}(s) > \alpha\}$, $\alpha \in \mathbb{R}$.
- Let $U \subset \mathbb{C}$ be open, then $\mathcal{H}(U)$ and $\mathcal{M}(U)$ denote the holomorphic and meromorphic functions on U , respectively.
- $H_\alpha^\infty := \{f: \mathbb{C}_\alpha \rightarrow \mathbb{C} \mid f \text{ bounded and holomorphic}\}$.
- $H_-^\infty := \bigcup_{\alpha < 0} H_\alpha^\infty$.
- Consider distributions of the form

$$(2.1) \quad f = f_a + \sum_{j=0}^{\infty} f_j \delta_{t_j},$$

where $f_a: \mathbb{R}_+ \rightarrow \mathbb{C}$ is measurable, $f_j \in \mathbb{C}$, $t_0 = 0$, $t_j > 0$ for $j \geq 1$, and δ_{t_j} denotes the Dirac distribution with support in $\{t_j\}$. Let \mathcal{A} be the set of all distributions f of the form (2.1) such that

$$(2.2) \quad \|f\|_{\mathcal{A}} := \int_0^\infty |f_a(t)| dt + \sum_{j=0}^\infty |f_j| < \infty.$$

\mathcal{A} is a convolution algebra and, provided with the norm given by (2.2), it becomes a Banach algebra (cf. Hille and Phillips [12, p. 141]).

- $\mathcal{A}_- := \{f \in \mathcal{A} \mid \text{there exists } \varepsilon > 0: fe^{\varepsilon \cdot} \in \mathcal{A}\}$.
- $\hat{\mathcal{A}}, \hat{\mathcal{A}}_-$ is the set consisting of the Laplace transformed elements of $\mathcal{A}, \mathcal{A}_-$, respectively. Realize that $\hat{\mathcal{A}} \subset H_0^\infty$ and $\hat{\mathcal{A}}_- \subset H_-^\infty$.
- \check{f} denotes the inverse Laplace transform of f .
- θ denotes the unit step.
- Let $M = (m_{ij}) \in \mathbb{C}^{p \times p}$, then $\|M\| := \max_{1 \leq i \leq p} \sum_{j=1}^p |m_{ij}|$ unless stated otherwise, $\bar{\sigma}(M) :=$ largest singular value of M , $W(M) :=$ numerical range of M (cf. Halmos [10]).
- Let X be a Banach space and $A: D(A) \subset X \rightarrow X$ a linear operator, then $\sigma(A) :=$ spectrum of A , $\sigma_p(A) :=$ point spectrum of A , and $\rho(A) :=$ resolvent set of A .
- For $F = (f_{ij}) \in (L^1(\mathbb{R}_+))^{p \times p}$ define $\|F\|_1 := \max_{1 \leq i \leq p} \sum_{j=1}^p \|f_{ij}\|_1$.
- Let $F = (f_{ij}) \in \mathcal{A}^{p \times p}$, then $\|F\|_{\mathcal{A}} := \max_{1 \leq i \leq p} \sum_{j=1}^p \|f_{ij}\|_{\mathcal{A}}$.
- If $f = (f_1, \dots, f_p)^t \in (L^q(\mathbb{R}_+))^p$, then $\|f\|_q := \max_{1 \leq j \leq p} \|f_j\|_q$.
- For $F \in (H_0^\infty)^{p \times p}$ define $\|F\|_\infty := \sup_{s \in \mathbb{C}_0} \bar{\sigma}(F(s))$.
- Let f be a function defined on an interval $[a, b)$, $a < b \leq \infty$; then we define, for $t \geq a$,

$$(\pi_t f)(\tau) := \begin{cases} f(\tau), & a \leq \tau \leq t, \\ 0, & \tau > t. \end{cases}$$

- Define the space $LL^q(\mathbb{R}_+)$ by $LL^q(\mathbb{R}_+) := \{f: \mathbb{R}_+ \rightarrow \mathbb{C} \mid f \text{ measurable and } \pi_t f \in L^q(\mathbb{R}_+) \text{ for all } t \geq 0\}$, i.e., $f \in LL^q(\mathbb{R}_+)$, if and only if $|f|^q$ is locally integrable.

We need three additional concepts:

H_-^∞ -stability. Let $G \in \mathcal{M}(\mathbb{C}_\alpha)^{p \times p}$ and $K \in \mathcal{M}(\mathbb{C}_\alpha)^{q \times p}$ for some $\alpha < 0$; then it is convenient to denote the feedback system shown in Fig. 1 by $\mathcal{F}[G, K]$, and we say that $\mathcal{F}[G, K]$ is H_-^∞ -stable if

$$\begin{pmatrix} (I + KG)^{-1}K & -(I + KG)^{-1}KG \\ (I + GK)^{-1}GK & (I + GK)^{-1}G \end{pmatrix}$$

is in $(H_-^\infty)^{(p+q) \times (p+q)}$.

Zeros of a square meromorphic matrix. Let $M \in \mathcal{M}(U)^{p \times p}$. Since it is well known that $\mathcal{M}(U)$ is the quotient field of $\mathcal{H}(U)$ and $\mathcal{H}(U)$ is a Bezout domain¹ (see, e.g., Rudin [35]), it follows that M admits a right coprime factorization over $\mathcal{H}(U)$, i.e., there exist matrices $N, D, X, Y \in \mathcal{H}(U)^{p \times p}$ such that $\det(D) \neq 0$, $M = ND^{-1}$, and $XD + YN = I$. Right coprime factorizations are unique up to multiplication from the right by units of $\mathcal{H}(U)^{p \times p}$ (see, for example, Vidyasagar, Schneider, and Francis [37]). The zeros of M are, by definition, the zeros of $\det(N)$.

FIG. 1

¹ An integral domain is called Bezout domain if every finitely generated ideal is principal.

Asymptotically constant signals. A function $f: \mathbb{R}_+ \rightarrow \mathbb{C}^p$ is called asymptotically constant if there exists $c \in \mathbb{C}^p$ such that $\lim_{t \rightarrow \infty} f(t) = c$.

3. Robust PI-control of infinite-dimensional systems: Results on input-output stability. Let G be a meromorphic transfer function of size $p \times p$ such that on \mathbb{C}_α (for some $\alpha < 0$)

$$(3.1) \quad G^{-1}(s) = sD + H(s), \quad \text{where } D \in \mathbb{C}^{p \times p}, \quad \det(D) \neq 0, \quad \text{and } H \in (H_-^\infty)^{p \times p}.$$

Of course, (3.1) is equivalent to

$$(3.2) \quad G(s) = \left(I + \frac{1}{s} D^{-1} H(s) \right)^{-1} \frac{1}{s} D^{-1}.$$

Hence (3.1) means that G can be decomposed, as shown in Fig. 2. The following proposition gives a necessary and sufficient condition for G to be of the form (3.2).

FIG. 2

PROPOSITION 3.1. Let G be a transfer matrix of size $p \times p$, which is meromorphic in \mathbb{C}_α for some $\alpha < 0$. Then G^{-1} is of the form (3.1) if and only if there exist a number β with $\alpha < \beta < 0$ and an invertible matrix $D \in \mathbb{C}^{p \times p}$ such that G has no zeros in $\bar{\mathbb{C}}_\beta$ and $sG(s) - D^{-1} = O(1/s)$ as $|s| \rightarrow \infty$ in \mathbb{C}_β .

As a consequence, we have the following corollary.

COROLLARY 3.2. Suppose that $A \in (H_-^\infty)^{n \times n}$, $B \in \mathbb{C}^{n \times p}$, and $C \in \mathbb{C}^{p \times n}$, and define

$$G(s) := C(sI - A(s))^{-1}B \quad \text{and} \quad \chi(s) := \det \begin{pmatrix} sI - A(s) & -B \\ C & 0 \end{pmatrix}.$$

If $\det(CB) \neq 0$ and if χ has no zeros in $\bar{\mathbb{C}}_0$, then G^{-1} is of the form (3.1) with $D = (CB)^{-1}$.

The proof of the proposition and the corollary can be found in Appendix 1.

We give two classes of infinite-dimensional systems whose transfer matrices satisfy (3.1).

Example 3.3 (Retarded systems). Consider the retarded system

$$\dot{x}(t) = \int_{-h}^0 dA(\tau)x(t+\tau) + Bu(t), \quad y(t) = Cx(t),$$

where $h > 0$ is the length of the delay, the function $A: [-h, 0] \rightarrow \mathbb{R}^{n \times n}$ is of bounded variation, $B \in \mathbb{R}^{n \times p}$, and $C \in \mathbb{R}^{p \times n}$. It is straightforward to show that $\hat{A}(s) := \int_{-h}^0 dA(\tau) e^{s\tau} d\tau$ is holomorphic and bounded on \mathbb{C}_α for any $\alpha \in \mathbb{R}$. In particular, we

have $\hat{A} \in (H_-^\infty)^{n \times n}$. The transfer matrix of the above retarded system is given by $G(s) = C(sI - \hat{A}(s))^{-1}B$. It follows from Corollary 3.2 that G^{-1} is of the form (3.1), provided the conditions $\det(CB) \neq 0$ and

$$\det \begin{pmatrix} sI - \hat{A}(s) & -B \\ C & 0 \end{pmatrix} \neq 0 \quad \text{for all } s \in \bar{\mathbb{C}}_0$$

are satisfied.

Example 3.4 (Volterra integrodifferential systems). Consider the system

$$\dot{x}(t) = A_0 x(t) + \int_0^t A_1(t-\tau)x(\tau) d\tau + Bu(t), \quad y(t) = Cx(t),$$

where $A_0 \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times p}$, $C \in \mathbb{R}^{p \times n}$, and $e^{\varepsilon \cdot} A_1(\cdot) \in L^1(\mathbb{R}_+)$ for some $\varepsilon > 0$. Noting that the Laplace transform \hat{A}_1 of A_1 is in $(H_-^\infty)^{n \times n}$, it follows from Corollary 3.2 that the transfer matrix $G(s) = C(sI - A_0 - \hat{A}_1(s))^{-1}B$ will satisfy (3.1) if $\det(CB) \neq 0$ and

$$\det \begin{pmatrix} sI - A_0 - \hat{A}_1(s) & -B \\ C & 0 \end{pmatrix} \neq 0 \quad \text{for all } s \in \bar{\mathbb{C}}_0.$$

It is fairly obvious that Examples 3.3 and 3.4 can be extended to certain classes of retarded systems with infinite delay and Volterra-Stieltjes integrodifferential systems.

Consider the PI-controller

$$(3.3) \quad K_k(s) := \Gamma \operatorname{diag}_{1 \leq j \leq p} \left(k_j + c_j + \frac{k_j c_j}{s} \right),$$

where $\Gamma \in \mathbb{C}^{p \times p}$, $\det(\Gamma) \neq 0$, $k = (k_1, \dots, k_p)'$, $k_j > 0$, $c_j > 0$ for all $j = 1, 2, \dots, p$. Sometimes it will be useful to emphasize the dependence of the controller (3.3) on the “gain vector” k , since we will be interested in the high-gain situation, where $k_j \rightarrow \infty$, $j = 1, \dots, p$. That is why we introduced the subscript k in (3.3).

The above controller was investigated in Owens and Chotai [31] when applied to finite-dimensional systems. The infinite-dimensional case is studied in Logemann and Owens [22], [23].

The following theorem gives sufficient conditions for robust stability when the controller (3.3) is applied to a system satisfying (3.1).

THEOREM 3.5. *Let G be a transfer matrix such that (3.1) is satisfied. Then (i) the feedback system $\mathcal{F}[G, K_k]$ is H_-^∞ -stable for all sufficiently large k_j , $j = 1, \dots, p$, if*

$$(3.4) \quad \|\Gamma^{-1}(\Gamma - D)\| < 1,$$

where $\|\cdot\|$ is any submultiplicative norm on $\mathbb{C}^{p \times p}$ with the additional property that $\|\operatorname{diag}(a_j)\| \leq \max_j |a_j|$ for arbitrary $a_1, \dots, a_p \in \mathbb{C}$; and (ii) under the additional assumption that $k_j = \gamma_j \kappa$ with $\gamma_j > 0$ fixed ($j = 1, \dots, p$) the feedback scheme $\mathcal{F}[G, K_k]$ is H_-^∞ -stable for a sufficiently large κ if

$$(3.5) \quad \sigma \left(\operatorname{diag}_j(\gamma_j) \Gamma^{-1} D \right) \subset \mathbb{C}_0$$

or

$$(3.6) \quad W(\Gamma^{-1} D) \subset \mathbb{C}_0.$$

Proof. See Logemann and Owens [22].

Remark 3.6. (i) Note that K_k does not depend on H . Trivially, (3.4)–(3.6) are satisfied if $\Gamma = D$. Obviously, $\Gamma = D$ would be a natural choice in (3.3). However, D might not be exactly known to the designer.

(ii) Further applications of the concept of numerical range to control problems can be found in Mees [25].

To study the tracking and output disturbance rejection properties of $\mathcal{F}[G, K_k]$ (cf. Fig. 3), define $L_k := (I + GK_k)^{-1}GK_k$ and $H_k := (I + GK_k)^{-1}$.

PROPOSITION 3.7. *Let G be a square meromorphic transfer matrix such that G^{-1} is of the form (3.1). If $\mathcal{F}[G, K_k]$ is H^∞ -stable, then the closed-loop system tracks asymptotically constant reference signals in the presence of asymptotically constant output disturbances, i.e., for $r: \mathbb{R}_+ \rightarrow \mathbb{C}^p$ and $d: \mathbb{R}_+ \rightarrow \mathbb{C}^p$ such that $\lim_{t \rightarrow \infty} r(t) = r_\infty$ and $\lim_{t \rightarrow \infty} d(t) = d_\infty$, we have*

$$\lim_{t \rightarrow \infty} (\check{L}_k * r)(t) = r_\infty \quad \text{and} \quad \lim_{t \rightarrow \infty} (\check{H}_k * d)(t) = 0.$$

Proof. It follows from the stability of $\mathcal{F}[G, K_k]$ that $L_k, H_k \in (H^\infty)^{p \times p}$. Now it is easy to see that $sL_k(s)$ and $s(H_k(s) - I)$ are bounded on \mathbb{C}_β for some $\beta < 0$, and hence we obtain, using a result in Mossaheb [27] (cf. also Logemann [18]), that $e^{\alpha \cdot} \check{L}_k \in (L^1(\mathbb{R}_+))^{p \times p}$ and $e^{\alpha \cdot} \check{H}_k \in (\mathbb{R}\delta_0 + L^1(\mathbb{R}_1))^{p \times p}$ for all $\alpha \in (0, -\beta)$, and thus L_k and $H_k \in (\hat{\mathcal{A}}_-)^{p \times p}$. By the final value theorem for transfer functions in $\hat{\mathcal{A}}_-$ (cf. Callier and Winkin [4]), it is sufficient to show that $L_k(0) = I$ and $H_k(0) = 0$.

An elementary calculation gives

$$\begin{aligned} L_k(s) &= ((G(s)K_k(s))^{-1} + I)^{-1} \\ &= \left\{ \text{diag} \left(\frac{s}{s(k_j + e_j) + k_j c_j} \right) \Gamma^{-1}(sD + H(s)) + I \right\}^{-1}. \end{aligned}$$

Since $k_j, c_j > 0$, $j = 1, \dots, p$, it follows that $L_k(0) = I$. Since $H_k = I - L_k$, we obtain $H_k(0) = 0$. \square

To investigate the transient performance of $\mathcal{F}[G, K_k]$ and the robustness of closed-loop stability with respect to measurement nonlinearities, the following lemma is useful.

LEMMA 3.8. *Let G be a square meromorphic transfer matrix such that G^{-1} is of the form (3.1), define K_k as in (3.3), and set*

$$G^*(s) := \frac{1}{s} \Gamma^{-1} \quad \text{and} \quad L_k^*(s) := (I + G^* K_k)^{-1} G^* K_k.$$

Then the following hold: (i) If $\Gamma = D$, we have

$$(3.7) \quad \lim_{k \rightarrow \infty} \|\check{L}_k^* - \check{L}_k\|_1 = 0$$

(by $k \rightarrow \infty$, we mean $\min_{1 \leq j \leq p} (k_j) \rightarrow \infty$);

(ii) If $\|\Gamma^{-1}(\Gamma - D)\| =: \varepsilon < \frac{1}{2}$, then

$$(3.8) \quad \limsup_{k \rightarrow \infty} \|\check{L}_k^* - \check{L}_k\|_1 \leq \frac{2\varepsilon}{1 - 2\varepsilon}.$$

FIG. 3

The proof of Lemma 3.8 can be found in Appendix 2. Part (i) was proved in Logemann and Owens [22] under the extra assumption that H in (3.1) belongs to $\hat{\mathcal{A}}_-^{p \times p}$. It should be noted that it is, in general, considerably more difficult to check if a given transfer function is in $\hat{\mathcal{A}}_-$ than to verify that it belongs to H_-^∞ .

Remark 3.9. (i) Define $\theta_j := e_j \theta$, where $e_j = (0, \dots, 1, \dots, 0)^t \in \mathbb{R}^p$. We consider the transient performance of the feedback system $\mathcal{F}[G^*, K_k]$. It is easy to see that the transfer matrix L_k^* is given by

$$L_k^*(s) = \text{diag} \left(\frac{(k_j + c_j)s + k_j c_j}{(s + k_j)(s + c_j)} \right)_{1 \leq j \leq p}.$$

Since we are interested in high-gain feedback, we may assume without loss of generality that $k_j > c_j$, $j = 1, \dots, p$. A routine calculation gives the following estimates for the overshoot O_j , the rise time T_j^r , and the settling time T_j^s in the j th loop (see, e.g., Franklin, Powell, and Emami-Naeini [8] for the notions of overshoot, rise time, and so forth).

We have $O_j \leq c_j / (k_j - c_j)$, $T_j^r \leq \frac{1}{2} \tau_j$, and $T_j^s \leq \max(\frac{1}{2} \tau_j, -1/c_j \ln((k_j - c_j)/100 c_j))$, where $\tau_j = (2(\ln(k_j) - \ln(c_j)) / (k_j - c_j))$ is the time when the maximal overshoot occurs. The settling time T_j^s is defined here as the time required for the signal $(L_k^* * \theta_j)_j(t)$ to stay within the interval $[0.99, 1.01]$.

The estimates show that the transient performance of the feedback system $\mathcal{F}[G^*, K_k]$ improves as the gains k_j , $j = 1, \dots, p$, increase.

(ii) Suppose that $\Gamma = D$. In this case, part (i) of this remark and (3.7) show that the transient performance of the feedback system $\mathcal{F}[G, K_k]$ improves as the gains k_j , $j = 1, \dots, p$ increase. If $\Gamma \neq D$, then (3.8) gives a bound on the performance degradation, provided that the condition of Lemma 3.8 (ii) is satisfied.

In the following, we investigate the effect of measurement nonlinearities on the stability of $\mathcal{F}[G, K_k]$. First, we will concentrate on memoryless nonlinearities. We consider functions $\varphi: \mathbb{R}_+ \times \mathbb{C}^p \rightarrow \mathbb{C}^p$, which satisfy the following conditions:

- (N1) $\varphi(t, x)$ is continuous in t and locally Lipschitz continuous in x , uniformly in t on bounded intervals;
- (N2) φ is unbiased, i.e., $\varphi(t, 0) = 0$, for all $t \geq 0$;
- (N3) $\varphi = \text{id}_{\mathbb{C}^p} + \varphi_1 + \varphi_2$, where φ_1 and φ_2 satisfy

$$\text{and } \left. \begin{array}{l} |\varphi_1(t, x)| \leq \lambda_1 |x| \\ |\varphi_2(t, x)| \leq \lambda_2 \end{array} \right\} \text{ for all } t \geq 0, x \in \mathbb{C}^p, \text{ and some constants } \lambda_1, \lambda_2 \geq 0.$$

Furthermore, for a function $\varphi: \mathbb{R}_+ \times \mathbb{C}_p \rightarrow \mathbb{C}^p$, let N_φ denote the operator induced by φ , i.e., $(N_\varphi u)(t) = \varphi(t, u(t))$ for any function $u: \mathbb{R}_+ \rightarrow \mathbb{C}^p$.

The following result gives a sufficient condition for the stability of the feedback system shown in Fig. 4.

THEOREM 3.10. *Let G be a square transfer matrix such that G^{-1} is of the form (3.1). Let the controller K_k be given by (3.3), suppose that $\varphi: \mathbb{R}_+ \times \mathbb{C}^p \rightarrow \mathbb{C}^p$ satisfies*

FIG. 4

(N1)–(N3), and assume that the reference signal r is bounded on bounded intervals. Then, if $\lambda_1 < 1$ and

$$(3.9) \quad \|\Gamma^{-1}(\Gamma - D)\| < \frac{1}{2}(1 - \lambda_1),$$

there exists $k^* > 0$ such that for all $k_j > k^*$ ($j = 1, \dots, p$) the nonlinear feedback system given by

$$(3.10) \quad y = \check{G} * e, \quad e = \check{K}_k * (r - N_\varphi(y))$$

is well posed (i.e., there exists a unique globally defined solution of (3.10)) and L^∞ -stable in the sense that there exist nonnegative constants m_1 and m_2 such that

$$(3.11) \quad \|y\|_\infty \leq m_1 + m_2 \|r\|_\infty$$

for all $r \in (L^\infty(\mathbb{R}_+))^p$.

Proof. First, realize that for all sufficiently large k_j ($j = 1, \dots, p$)

$$(3.12) \quad \|\check{L}_k\|_1 \lambda_1 < 1.$$

This follows from (3.9), Lemma 3.8(ii), and the fact that $\lim_{k \rightarrow \infty} \|\check{L}_k^*\|_1 = 1$ (cf. Logemann and Owens [22]), where \check{L}_k^* is defined as in Lemma 3.8. Equation (3.10) can be written in the form

$$(3.13) \quad y = \check{L}_k * r - \check{L}_k * (N_{\varphi_1}(y) + N_{\varphi_2}(y)),$$

which is a nonlinear Volterra integral equation in y . It follows from Theorem 1.2 and Corollary 2.7, in Miller [26] that (3.13) has a unique (continuous) solution that can be extended to the right as long as it remains bounded. Now pick $t > 0$ such that the solution of (3.13) exists on $[0, t]$. Application of the truncation operator π_t to (3.13) gives

$$(3.14) \quad \begin{aligned} \|\pi_t(y - y_l)\|_\infty &\leq \|\pi_t \check{L}_k * (\pi_t(N_{\varphi_1}(y) + N_{\varphi_2}(y)))\|_\infty \\ &\leq \|\check{L}_k\|_1 (\|\pi_t(N_{\varphi_1}(y))\|_\infty + \lambda_2) \\ &\leq \|\check{L}_k\|_1 (\lambda_1 \|\pi_t y\|_\infty + \lambda_2), \end{aligned}$$

where $y_l := \check{L}_k * r$ is the output of the linear feedback system $\mathcal{F}[G, K_k]$. Setting $\lambda := \|\check{L}_k\|_1$, we obtain

$$(1 - \lambda \lambda_1) \|\pi_t(y - y_l)\|_\infty \leq \lambda (\lambda_1 \|\pi_t y\|_\infty + \lambda_2),$$

and hence ($\lambda \lambda_1 < 1$ by (3.12))

$$(3.15) \quad \|\pi_t(y - y_l)\|_\infty \leq \frac{\lambda}{1 - \lambda \lambda_1} (\lambda_1 \|\pi_t y\|_\infty + \lambda_2).$$

Inequality (3.15) shows that the solution of (3.13) exists on \mathbb{R}_+ , since $\|\pi_t y_l\|_\infty$ is finite for all $t \in \mathbb{R}_+$. Moreover, it follows that (3.11) holds with $m_1 = \lambda \lambda_2 (1 - \lambda \lambda_1)^{-1}$ and $m_2 = \lambda (1 - \lambda \lambda_1)^{-1}$. \square

Remark 3.11. (i) The proof shows that Theorem 3.10 remains true if we replace ∞ by $q = 1, 2, 3, \dots$, provided that $\varphi_2 \equiv 0$.

(ii) Equation (3.15) yields an upper bound on the difference of the output signals of the linear and nonlinear feedback system corresponding to the same input signal r .

We now turn our attention to a certain class of dynamical measurement nonlinearities. We consider operators Φ from $(LL^q(\mathbb{R}_+))^p$ onto itself, which satisfy the following assumptions:

- (N4) Φ is causal, i.e., $\pi_t \Phi = \pi_t \Phi \pi_t$ for all $t \geq 0$ (cf. Willems [38]);
- (N5) Φ is locally Lipschitz continuous, i.e., for all $t \geq 0$ there exists $l_t \geq 0$ such that $\|\pi_t(\Phi u - \Phi v)\|_q \leq l_t \|\pi_t(u - v)\|_q$ for all $u, v \in (LL^q(\mathbb{R}_+))^p$ (cf. Willems [38]);
- (N6) Φ is unbiased, i.e., $\Phi(0) = 0$;
- (N7) $\Phi = \text{id} + \Psi$, where Ψ satisfies $\|\Psi u\|_q \leq \lambda_1 \|u\|_q + \lambda_2$ for all $u \in (L^q(\mathbb{R}_+))^p$ and some nonnegative constants λ_1 and λ_2 .

Remark 3.12. Consider the nonlinearity N_φ induced by the function $\varphi: \mathbb{R}_+ \times \mathbb{C}^p \rightarrow \mathbb{C}^p$. Then, in general, N_φ will not fulfill (N5) unless φ satisfies a global Lipschitz condition.

THEOREM 3.13. *Let G be a square transfer matrix such that G^{-1} is of the form (3.1), let the controller K_k be given by (3.3), suppose that $\Phi: (LL^q(\mathbb{R}_+))^p \rightarrow (LL^q(\mathbb{R}_+))^p$ satisfies (N4)–(N7), and assume that $r \in (LL^q(\mathbb{R}_+))^p$. Then we have (i) the nonlinear feedback system given by*

$$(3.16) \quad y = \check{G} * e, \quad e = \check{K}_k * (r - \Phi(y))$$

is well posed in the sense that there exists a unique (globally defined) solution $y \in (LL^q(\mathbb{R}_+))^p$; and (ii) suppose that $\lambda_1 < 1$ and

$$(3.17) \quad \|\Gamma^{-1}(\Gamma - D)\| < \frac{1}{2}(1 - \lambda_1);$$

then for all sufficiently large k_j ($j = 1, \dots, p$), the feedback system (3.16) is L^q -stable in the sense that there exist nonnegative constants m_1 and m_2 such that $\|y\|_q \leq m_1 + m_2 \|r\|_q$, for all $r \in (L^q(\mathbb{R}_+))^p$.

Proof. Equation (3.16) can be written in the form

$$(3.18) \quad y = \check{L}_k * r - \check{L}_k * \Psi(y).$$

It follows from Corollary 4.1.2 in Willems [38] that (3.18) admits a unique solution in $(LL^q(\mathbb{R}_+))^p$. The stability result can be shown, as in the proof of Theorem 3.10. \square

4. Conditions in state-space terms for (3.1) to be satisfied. In this section we will give sufficient conditions for a system in state-space form to satisfy the decomposition (3.1). Our state-space system is given by

$$(4.1a) \quad \dot{x} = Ax + Bu; \quad x(0) = x_0,$$

$$(4.1b) \quad y = Cx,$$

where (i) $A: D(A) \subset X \rightarrow X$, X is a Banach space, generates a strongly continuous semigroup, denoted by $T(t)$; (ii) $B: \mathbb{R}^p \mapsto X$; $(u_1, \dots, u_p)' \mapsto \sum_{i=1}^p b_i u_i$, where $b_i \in X$, $i = 1, \dots, p$; and (iii) $C: X \mapsto \mathbb{R}^p$, $x \mapsto (\langle x, c_1 \rangle, \dots, \langle x, c_p \rangle)'$, where $c_i \in X^*$; $i = 1, \dots, p$.

In § 3 we have seen that the zeros of the system play an essential role in determining if it has a decomposition (3.1). The next definition gives an equivalent definition for zeros of a state-space system.

DEFINITION 4.1. Let $z \in \mathbb{C}$; then z is a zero of system (4.1) if the kernel of the operator $\begin{bmatrix} zI - A & B \\ C & 0 \end{bmatrix}: D(A) \oplus \mathbb{C}^p \mapsto X \oplus \mathbb{C}^p$ is nonzero.

LEMMA 4.2. *If system (4.1) is α -exponentially stabilizable and α -exponentially detectable, then the zeros in \mathbb{C}_α of (4.1) are the same as the zeros of $G(s) := C(sI - A)^{-1}B$ as defined in § 2.*

For the definitions of α -exponentially stabilizability and detectability, see Appendix 3.

Proof. Since the state-space system is α -exponentially stabilizable, there exists a bounded linear operator $F: X \rightarrow \mathbb{R}^p$ such that the semigroup generated by $A + BF$, $T_{BF}(t)$, satisfies $\|T_{BF}(t)\| \leq M e^{\beta t}$, $\beta < \alpha$. With this feedback, we can construct the following right coprime factorization of $G(s)$ over $\mathcal{H}(\mathbb{C}_\alpha)$ (see Jacobson [13] and Nett, Jacobson, and Balas [30]):

$$G = NM^{-1}, \quad \text{where } N(s) = C(sI - A - BF)^{-1}B, \quad M(s) = I + F(sI - A - BF)^{-1}B.$$

Let $u \in \mathbb{C}^p$, $u \neq 0$, satisfy $C(s_0I - A - BF)^{-1}Bu = 0$ for some $s_0 \in \mathbb{C}_\alpha$. Then, by the coprimeness of N and M , $u + F(s_0I - A - BF)^{-1}Bu \neq 0$, and

$$(4.2) \quad \begin{bmatrix} s_0I - A & B \\ C & 0 \end{bmatrix} \begin{bmatrix} (s_0I - A - BF)^{-1}Bu \\ -u - F(s_0I - A - BF)^{-1}Bu \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

On the other hand, if

$$(4.3) \quad \begin{bmatrix} s_0I - A & B \\ C & 0 \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

for some $(x, u) \neq (0, 0) \in D(A) \oplus \mathbb{C}^p$, then

$$(4.4) \quad (s_0I - A - BF)x + B(u + Fx) = 0.$$

Premultiplying (4.4) with $C(s_0I - A - BF)^{-1}$ gives

$$0 = Cx + C(s_0I - A - BF)^{-1}B(u + Fx) = 0 + C(s_0I - A - BF)^{-1}B(u + Fx).$$

So, if $(u + Fx) \neq 0$, then s_0 is a zero of the transfer matrix G . If $u + Fx = 0$, then (4.4) with the invertibility of $(s_0I - A - BF)$ would imply that $x = 0$. Hence also $u = 0$, since $u = u + Fx - Fx$. This is in contradiction with $(x, u) \neq (0, 0)$. \square

For the system under consideration, we will prove that under certain conditions the transfer function can be decomposed in a similar way as in (3.1).

LEMMA 4.3. *Suppose that (A, B) is α -exponentially stabilizable. Assume further that $\det(CB) \neq 0$ and let $\gamma \in \mathbb{C}$. Then*

$$(4.5) \quad G^{-1}(s) = s[CB]^{-1} + (\gamma - s)[CB]^{-1}CA(sI - A - BF)^{-1}B[CB]^{-1}$$

holds on $\mathbb{C}_\alpha \cap \rho(A) \cap \rho(A + BF)$, where $G(s) = C(sI - A)^{-1}B$ and

$$(4.6) \quad F := [CB]^{-1}\{-CA + \gamma C\}.$$

Proof. The feedback F defined by (4.6) is an A -degenerate operator (Kato [16, Chap. IV, § 6]). Since (A, B) is α -exponentially stabilizable, the spectrum of A in \mathbb{C}_α is pure point spectrum with finite multiplicity (see Jacobson and Nett [14] or Appendix 3). Together with the fact that A generates a C_0 -semigroup, this implies that $A + BF$ has pure point spectrum with finite multiplicity in \mathbb{C}_α (see Kato [16, Chap. IV, § 6]). So, with the exception of countably many points, we may calculate $(sI - A - BF)^{-1}$ for $s \in \mathbb{C}_2$. Let $s \in \rho(A + BF) \cap \rho(A)$; then

$$\begin{aligned} CA(sI - A - BF)^{-1}B &= CA(sI - A)^{-1}B + CA(sI - A - BF)^{-1}BF(sI - A)^{-1}B \\ &= CA(sI - A)^{-1}B \\ &\quad + CA(sI - A - BF)^{-1}B[CB]^{-1}(-1)CA(sI - A)^{-1}B \\ &\quad + CA(sI - A - BF)^{-1}B[CB]^{-1}\gamma C(sI - A)^{-1}B \\ &= \left\{ I - \left(1 - \frac{\gamma}{s} \right) CA(sI - A - BF)^{-1}B[CB]^{-1} \right\} CA(sI - A)^{-1}B \\ &\quad + \frac{\gamma}{s} CA(sI - A - BF)^{-1}B, \end{aligned}$$

where in the last equality we have used that $C(sI - A)^{-1}B = 1/s\{CB + CA(sI - A)^{-1}B\}$. So

$$\begin{aligned} \left(1 - \frac{\gamma}{s}\right) CA(sI - A - BF)^{-1}B &= \left\{I - \left(1 - \frac{\gamma}{s}\right) CA(sI - A - BF)^{-1}B[CB]^{-1}\right\} \\ &\quad \times CA(sI - A)^{-1}B \\ \Rightarrow CA(sI - A)^{-1}B[CB]^{-1} &= \left\{I - \left(1 - \frac{\gamma}{s}\right) CA(sI - A - BF)^{-1}B[CB]^{-1}\right\}^{-1} \\ &\quad \times \left(1 - \frac{\gamma}{s}\right) CA(sI - A - BF)^{-1}B[CB]^{-1}. \end{aligned}$$

Using the equality $[I - Q(s)]^{-1}Q(s) = [I - Q(s)]^{-1} - I$ gives

$$CA(sI - A)^{-1}B[CB]^{-1} = \left\{I - \left(1 - \frac{\gamma}{s}\right) CA(sI - A - BF)^{-1}B[CB]^{-1}\right\}^{-1} - I.$$

So

$$\begin{aligned} sG(s) &= sC(sI - A)^{-1}B = CB + CA(sI - A)^{-1}B \\ &= \left\{I - \left(1 - \frac{\gamma}{s}\right) CA(sI - A - BF)^{-1}B[CB]^{-1}\right\}^{-1} [CB]. \end{aligned}$$

Thus

$$G^{-1}(s) = s[CB]^{-1} + (\gamma - s)[CB]^{-1}CA(sI - A - BF)^{-1}B[CB]^{-1}. \quad \square$$

So, the above lemma gives a decomposition similar to (3.1), but we do not know if $H(s) = (\gamma - s)[CB]^{-1}CA(sI - A - BF)^{-1}B[CB]^{-1} \in H_-^{\infty(p \times p)}$. This result will be given in Theorem 4.5. First, we will prove that, with the feedback F defined by (4.3), $(sI - A - BF)$ is invertible in \mathbb{C}_α , provided that $G(\cdot)$ has no zeros there.

LEMMA 4.4. *Suppose that (A, B) is α -exponentially stabilizable and (C, A) is α -exponentially detectable. If system (4.1) has no zeros in \mathbb{C}_α , and $\gamma < \alpha$, then $(sI - A - BF)$ is invertible on \mathbb{C}_α , where F is defined by (4.6).*

Proof. From the proof of Lemma 4.3 we know that $A + BF$ has only point spectrum on \mathbb{C}_α . Let λ be an eigenvalue of $(A + BF)$ in \mathbb{C}_α . Then there exists an $x \in X$, $x \neq 0$ such that

$$(\lambda I - A - BF)x = 0 \Leftrightarrow (\lambda I - A + B[CB]^{-1}CA)x - \gamma B[CB]^{-1}Cx = 0.$$

Premultiplying with C gives $\lambda Cx - CAx + CAx - \gamma Cx = 0$. Hence $\lambda = \gamma$ or $Cx = 0$. The first possibility is excluded by assumption, so suppose that $Cx = 0$. Then we have that

$$\begin{pmatrix} \lambda I - A & B \\ C & 0 \end{pmatrix} \begin{pmatrix} x \\ [CB]^{-1}CAx \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

Thus λ is a zero, but this is also excluded. So $\sigma(A + BF) \cap \mathbb{C}_\alpha = \emptyset$. \square

So, if the zeros of the system are in $\mathbb{C} \setminus \mathbb{C}_\alpha$, then $G^{-1}(s)$ exists everywhere on \mathbb{C}_α . We may always write $G^{-1}(s)$ as $G^{-1}(s) = sD + H(s)$, where $H(s)$ has no poles in \mathbb{C}_α . However, this is not enough to ensure that $H \in (H_-^\infty)^{p \times p}$. The next theorem will give sufficient conditions for this to hold.

THEOREM 4.5. *Suppose that (A, B) is exponentially stabilizable, (C, A) is exponentially detectable, system (4.1) has no zeros in \mathbb{C}_α for some $\alpha < 0$, and $\det(CB) \neq 0$. Then*

the transfer matrix $G(s) = C(sI - A)^{-1}B$ has the property that $G^{-1}(s) = s[CB]^{-1} + H(s)$ with $H \in (H_-^\infty)^{p \times p}$, provided that either

- (i) $c_i \in D(A^{*2})$; $i = 1, \dots, p$, or
- (ii) $b_i \in D(A)$, $c_i \in D(A^*)$; $i = 1, \dots, p$, or
- (iii) $b_i \in D(A^2)$; $i = 1, \dots, p$, or
- (iv) A generates an analytic semigroup and $b_i \in D(A)$, $i = 1, \dots, p$, or
- (v) A generates an analytic semigroup and $c_i \in D(A^*)$, $i = 1, \dots, p$.

Furthermore,

$$(4.7) \quad H(s) = (\gamma - s)[CB]^{-1}CA(sI - A - BF)^{-1}B[CB]^{-1}$$

with

$$(4.8) \quad F = [CB]^{-1}\{-CA + \gamma C\},$$

where $\gamma < 0$.

Proof. Note that if (A, B, C) is exponentially stabilizable and detectable, then it is also β -exponentially stabilizable and detectable for some $\beta < 0$. So, without loss of generality, we may assume that the system is α -exponentially stabilizable and detectable and that it has no zeros in \mathbb{C}_α for some negative α . Moreover, let $\gamma < \alpha$. These conditions ensure that on \mathbb{C}_α we have by Lemmas 4.3 and 4.4 that

$$G^{-1}(s) = s[CB]^{-1} + (\gamma - s)[CB]^{-1}CA(sI - A - BF)^{-1}B[CB]^{-1}.$$

So we must show that $H(s) := (\gamma - s)[CB]^{-1}CA(sI - A - BF)^{-1}B[CB]^{-1}$ is analytic and bounded on \mathbb{C}_α .

Assume first that $c_i \in D(A^*)$; $i = 1, \dots, p$. So CA is a bounded operator from X to \mathbb{R}^p , and thus F is bounded. Since (A, B) is exponentially stabilizable and since $A + BF$ has no eigenvalues in \mathbb{C}_α (Lemma 4.4), we have that $T_{BF}(t)$ is exponentially stable (see Appendix 3, Theorem A.6), and hence $\gamma[CB]^{-1}CA(s - A - BF)^{-1}B[CB]^{-1}$ is in $(H_-^\infty)^{p \times p}$. This is, in general, not sufficient to ensure that $H \in (H_-^\infty)^{p \times p}$. We can rewrite the operator $sCA(sI - A - BF)^{-1}B$ as

$$\begin{aligned} & CA(sI - A - BF)^{-1}B \\ &= CA(sI - A - BF)(sI - A - BF)^{-1}B + CA(A + BF)(sI - A - BF)^{-1}B \\ (4.9) \quad &= CAB + CA(A + BF)(s - A - BF)^{-1}B \end{aligned}$$

$$(4.10) \quad = CAB + CA(sI - A - BF)^{-1}(A + BF)B.$$

From (4.9) we see that $H \in (H_-^\infty)^{p \times p}$ if $c_i \in D(A^{*2})$; $i = 1, \dots, p$, and from (4.10) we see that $H \in (H_-^\infty)^{p \times p}$ if $c_i \in D(A^*)$ and $b_i \in D(A)$, $i = 1, \dots, p$. So we have proved that conditions (i) and (ii) imply the desired property. Now we will prove that condition (iii) does the same.

If $b_i \in D(A^2)$, $i = 1, \dots, p$, then let us consider a new realization (A_n, B_n, C_n) of $G(s)$, namely $A_n = A$, $B_n = AB$, and $C_n = CA^{-1}$, where we have assumed that $0 \in \rho(A)$, but this is not essential. If (A, B, C) is exponentially stabilizable and exponentially detectable, then (A_n, B_n, C_n) is, also. This follows easily from Theorem A.5 in Appendix 3, the “dual” version of Theorem A.5, and the definitions of A_n , B_n , and C_n . Since $\text{Im } B_n \subset D(A_n)$ and $\text{Im } C_n^* \subset D(A_n^*)$, we have by part (ii) that

$$(4.11) \quad H_n(s) = (\gamma - s)[C_n B_n]^{-1}C_n A_n(sI - A_n - B_n F_n)^{-1}B_n[C_n B_n]^{-1}$$

is an element of $(H_-^\infty)^{p \times p}$, where $F_n := [C_n B_n]^{-1}\{-C_n A_n + \gamma C_n\}$. It is clear that $F_n = FA^{-1}$, with F given by (4.8), and hence $H = H_n$. So it remains to show that condition (iv) or (v) is sufficient, also.

The feedback law F , as defined in (4.8), is an A -degenerate operator. From Zabczyk [39] it is known that if A generates an analytic semigroup, so does $A + BF$, for an A -degenerate feedback F . So, since any analytic semigroup satisfies the spectrum determined growth condition, and $\sigma(A + BF) \cap \mathbb{C}_\alpha = \emptyset$, there exists $M > 0$ such that

$$\|(sI - A - BF)^{-1}\| \leq \frac{M}{|s - \alpha|}; \quad s \in \mathbb{C}_\alpha.$$

Thus, if $c_i \in D(A^*)$; $i = 1, \dots, p$, then

$$\|H(s)\| \leq \frac{|\gamma - s|}{|s - \alpha|} \|CA\| \|[CB]^{-1}\|^2 \|B\| M; \quad s \in \mathbb{C}_\alpha.$$

On the other hand, if $b_i \in D(A)$, then we can rewrite $H(s)$ as

$$H(s) = (\gamma - s)[CB]^{-1}C(sI - A - ABFA^{-1})^{-1}AB[CB]^{-1}; \quad s \in \mathbb{C}_\alpha,$$

and we have that

$$\|H(s)\| \leq \frac{|\gamma - s|}{|s - \alpha|} \|C\| \|AB\| \|[CB]^{-1}\|^2 \tilde{M}; \quad s \in \mathbb{C}_\alpha$$

for some suitable constant $\tilde{M} > 0$. Thus in both cases $H \in (H_-^\infty)^{p \times p}$. \square

Remark 4.6. Since $G(s)$ and $s[CB]^{-1}$ are independent of γ , we must have that $H(\cdot)$ is independent of γ . In fact, for $\gamma > \alpha$ the zero at γ introduced by the term $s - \gamma$ is cancelled by the pole at γ of $(s - A - BF)^{-1}$ (see the proof of Lemma 4.4).

Remark 4.7. Retarded systems do not satisfy any of the smoothness conditions (i)–(v) in Theorem 4.5. However, by Example 3.3, there is a whole class of retarded systems whose transfer matrices admit a decomposition of the form (3.1). This shows that the conditions of Theorem 4.5 are sufficient but not necessary for (3.1) to be satisfied.

5. Internal stability. The stability results in § 3 are formulated in input-output terms. Suppose that the transfer matrix G of a state-space system of the form (4.1) satisfies condition (3.1) (Theorem 4.5 gives conditions in state-space terms for this to be true). If we apply Theorem 3.10 or Theorem 3.13 to G , can we expect internal stability of the closed-loop system? In the *linear* case (i.e., N_φ in Theorem 3.10 and Φ in Theorem 3.10 are equal to the identity) the answer is yes, provided that the state-space realizations of the plant and the controller are both exponentially stabilizable and exponentially detectable. This follows from recent results on the equivalence of input-output and internal stability for infinite-dimensional systems (cf. Jacobson and Nett [14] and Curtain [5]). In this section we investigate the internal asymptotic behaviour of the *nonlinear* feedback systems considered in § 3.

LEMMA 5.1. *Let $T(t)$ be an exponentially stable, strongly continuous semigroup on the Banach space X , denote the generator of $T(t)$ by A , let $B: \mathbb{R}^p \rightarrow X$ and $C: X \rightarrow \mathbb{R}^p$ be bounded linear operators, and suppose that $f: \mathbb{R}_+ \times \mathbb{R}^p$ satisfies (N1) and $|f(t, x)| \leq \lambda|x|$ for all $t \geq 0$, $x \in \mathbb{R}^p$ for some $\lambda > 0$. Moreover, set $R(t) = CT(t)B$ and for $t_0 \geq 0$ and $x_0 \in X$ let $x(t; t_0, x_0)$ denote the mild solution of*

$$(5.1) \quad \begin{aligned} \dot{x}(t) &= Ax + Bf(t, Cx(t)), & t \geq t_0, \\ x(t_0) &= x_0. \end{aligned}$$

If $\|R\|, \lambda < 1$, then (5.1) has a unique, globally defined mild solution and there exist positive constants M and ε such that $\|x(t; t_0, x_0)\| \leq M e^{-\varepsilon(t-t_0)} \|x_0\|$ for all $x_0 \in X$ and $t \geq t_0 \geq 0$.

Remark 5.2. The assumptions made in Lemma 5.1 ensure that (5.1) admits a unique mild solution that can be continued to the right as long as it remains bounded (see Pazy [32]).

The proof of Lemma 5.1 is similar to the proof of Theorem 3.2 in Logemann [21] and is therefore omitted.

Now let us turn our attention to dynamical nonlinearities.

LEMMA 5.3. *Let X , $T(t)$, A , B , C , and $R(t)$ be as in Lemma 5.1. Suppose that $F: (LL^q(\mathbb{R}_+))^p \rightarrow (LL^q(\mathbb{R}_+))^p$ ($q = 1, 2, 3, \dots$; $q \neq \infty$) is causal, unbiased, and locally Lipschitz continuous. Then the following statements hold. (i) The equation*

$$(5.2) \quad x(t) = T(t)x_0 + \int_0^t T(t-\tau)BF(Cx(\cdot))(\tau) d\tau$$

admits for all $x_0 \in X$ a unique globally defined continuous solution $x(\cdot, x_0): [0, \infty) \rightarrow X$, which will be called the mild solution of

$$(5.3) \quad \dot{x}(t) = Ax(t) + BF(Cx(\cdot))(t), \quad x(0) = x_0;$$

and (ii) suppose that F additionally satisfies the condition

$$\|F(u)\|_q \leq \lambda_1 \|u\|_q + \lambda_2$$

for all $u \in (L^q(\mathbb{R}_+))^p$, where λ_1 and λ_2 are nonnegative constants; then the origin will be globally attractive (i.e., $\lim_{t \rightarrow \infty} x(t; x_0) = 0$ for all $x_0 \in X$) if

$$(5.4) \quad \|R\|_1 \lambda_1 < 1.$$

Proof. (i) It is clear that the mapping $u(\cdot) \mapsto F(Cu(\cdot))$ is causal, unbiased, and locally Lipschitz continuous. Hence it follows from Corollary 4.1.2 in Willems [38] that (5.2) has a unique solution x in $LL^q(\mathbb{R}_+, X)$. Since the right-hand side of (5.2) is continuous in t , we see that $x(t)$ is continuous as well.

(ii) Consider the equation

$$(5.5) \quad \begin{aligned} y(t) &= CT(t)x_0 + C \int_0^t T(t-\tau)BF(y(\cdot))(\tau) d\tau \\ &= CT(t)x_0 + \int_0^t R(t-\tau)F(y(\cdot))(\tau) d\tau. \end{aligned}$$

If $x(t) := x(t; x_0)$ is the solution of (5.2), then it is clear that $Cx(t)$ is a solution of (5.5). Using (5.4) and the fact that $CT(\cdot)x_0 \in (L^q(\mathbb{R}_+))^p$, it follows from the small-gain theorem that $Cx(\cdot) \in (L^q(\mathbb{R}_+))^p$ and hence $z(\cdot) := BF(Cx(\cdot)) \in L^q(\mathbb{R}_+, X)$. It remains to show that $w(t) := \int_0^t T(t-\tau)z(\tau) d\tau$ tends to zero as $t \rightarrow \infty$. By the exponential stability of $T(t)$, there exist positive constants N and γ such that $\|T(t)\| \leq N e^{-\gamma t}$ for all $t \geq 0$.

Suppose for a moment that $q \neq 1$, and define q' by $1/q' + 1/q = 1$:

$$\begin{aligned} \|w(t)\| &\leq N \left\{ \int_0^{t/2} e^{-\gamma(t-\tau)} \|z(\tau)\| d\tau + \int_{t/2}^t e^{-\gamma(t-\tau)} \|z(\tau)\| d\tau \right\} \\ &= N \left\{ \int_{t/2}^t e^{-\gamma\tau} \|z(t-\tau)\| d\tau + \int_{t/2}^t e^{-\gamma(t-\tau)} \|z(\tau)\| d\tau \right\} \\ &\leq N \left\{ \left(\int_{t/2}^t e^{-q'\gamma\tau} d\tau \right)^{1/q'} \left(\int_{t/2}^t \|z(t-\tau)\|^q d\tau \right)^{1/q} \right. \\ &\quad \left. + \int_{t/2}^t e^{-q'\gamma(t-\tau)} d\tau \right)^{1/q'} \left(\int_{t/2}^t \|z(\tau)\|^q d\tau \right)^{1/q} \Big\}. \end{aligned}$$

We obtain

$$\|w(t)\| \leq N \left\{ \left(\int_{t/2}^{\infty} e^{-q'\gamma\tau} d\tau \right)^{1/q'} \|z\|_q + \|e^{-\gamma}\|_{q'} \left(\int_{t/2}^{\infty} \|z(\tau)\|^q d\tau \right)^{1/q} \right\}.$$

Now $\lim_{t \rightarrow \infty} \int_{t/2}^{\infty} e^{-q'\gamma\tau} d\tau = 0$ and $\lim_{t \rightarrow \infty} \int_{t/2}^{\infty} \|z(\tau)\|^q d\tau = 0$ and thus $\lim_{t \rightarrow \infty} \|w(t)\| = 0$. A similar argument holds for the case where $q = 1$. \square

Remark 5.4. If in Lemma 5.3 (ii) $\lambda_2 = 0$, then it is not difficult to see that the origin of (5.2) is globally asymptotically stable; i.e., $\lim_{t \rightarrow \infty} x(t; x_0) = 0$ for all $x_0 \in X$, and for all $\varepsilon > 0$ there exists $\delta > 0$ such that $\|x_0\| \leq \delta$ implies $\|x(t; x_0)\| \leq \varepsilon$ for all $t \geq 0$.

In the following, let the plant be given by

$$(5.6) \quad \dot{x}(t) = Ax(t) + Bu(t), \quad x(t_0) = x_0, \quad y(t) = Cx(t),$$

where the linear operator A generates a strongly continuous semigroup $T(t)$ on a Banach space X , $B: \mathbb{R}^p \rightarrow X$, $C: X \rightarrow \mathbb{R}^p$ are bounded linear operators, (A, B) is exponentially stabilizable, and (C, A) is exponentially detectable. A minimal realization of the controller K_k defined in (3.3) is given by

$$(5.7) \quad \dot{z}(t) = \text{diag}_{1 \leq j \leq p} (k_j c_j) v(t), \quad z(t_0) = z_0, \quad w(t) = \Gamma z(t) + \Gamma \text{diag}_{1 \leq j \leq p} (k_j + c_j) v(t).$$

Let Φ be an operator mapping $(LL^q(\mathbb{R}_+))^p$ into itself. We will interpret Φ as a measurement nonlinearity in the feedback interconnection of (5.6) and (5.7) as follows:

$$(5.8) \quad u = w, \quad v = -\Phi(y).$$

THEOREM 5.5. *Suppose that $G(s) := C(sI - A)^{-1}B$ satisfies condition (3.1) (cf. Theorem 4.5), and define $x_c(t) := (x(t), z(t))'$. The following statements hold. (i) If Φ in (5.8) is given by N_φ , where φ satisfies (N1)–(N3), $\lambda_1 < 1$, $\lambda_2 = 0$, and $\|\Gamma^{-1}(\Gamma - D)\| < \frac{1}{2}(1 - \lambda_1)$ then for all sufficiently large gains k_j , $j = 1, \dots, p$, there exist positive constants M and ε (dependent on k) such that $\|x_c(t)\| \leq M e^{-\varepsilon(t-t_0)} \|x_c(t_0)\|$ for all $x_c(t_0) \in X \times \mathbb{R}^p$, $t \geq t_0 \geq 0$, i.e., the nonlinear feedback system given by (5.6)–(5.8) is globally exponentially stable; and (ii) if Φ in (5.8) satisfies (N4)–(N7), $q < \infty$, $\lambda_1 < 1$, and $\|\Gamma^{-1}(\Gamma - D)\| < \frac{1}{2}(1 - \lambda_1)$, then for all sufficiently large k_j , $j = 1, \dots, p$, the feedback system (5.6)–(5.8) is internally stable in the sense that the origin is globally attractive; i.e., $\lim_{t \rightarrow \infty} x_c(t) = 0$ for all $x_c(0) \in X \times \mathbb{R}^p$.*

Proof. (i) Set $B_k := \text{diag}_{1 \leq j \leq p} (k_j c_j)$ and $D_k := \Gamma \text{diag}_{1 \leq j \leq p} (k_j + c_j)$. A routine calculation then shows that

$$(5.9) \quad \dot{x}_c(t) = A_c x_c(t) - B_c \varphi_1(t, C_c x_c(t)),$$

where

$$A_c = A_c(k) := \begin{pmatrix} A - BD_k C & B\Gamma \\ -B_k C & 0 \end{pmatrix}, \quad B_c = B_c(k) := \begin{pmatrix} BD_k \\ B_k \end{pmatrix}, \quad C_c := (C \ 0).$$

We know from Theorem 3.5(i) that $\mathcal{F}[G, K_k]$ is H^∞ -stable for all sufficiently large k_j , $j = 1, \dots, p$, and thus, by a result of Jacobson and Nett [14] (cf. also Curtain [5]), $A_c(k)$ generates an exponentially stable semigroup $T_{c,k}(t)$ on $X \times \mathbb{R}^p$ for all large enough k_j , $j = 1, \dots, p$. It follows from the condition $\|\Gamma^{-1}(\Gamma - D)\| < \frac{1}{2}(1 - \lambda_1)$ and Lemma 3.8(ii) that for all sufficiently large k_j ($j = 1, \dots, p$) $\|\check{L}_k\|_{\lambda_1} < 1$. (Here we have used that $\lim_{k \rightarrow \infty} \|\check{L}_k^*\|_1 = 1$; cf. Logemann and Owens [22].) Finally, realize that $\check{L}_k(t) = C_c T_{c,k}(t) B_c(k)$, and apply Lemma 5.1 to (5.9).

(ii) Using the same arguments as in (i) and applying Lemma 5.3 instead of Lemma 5.1, we can prove the second claim. \square

Remark 5.6. It is well known that the retarded system of Example 3.3 admits an abstract state-space realization of the form (5.6), where the state space X is given by $M^2(-h, 0; \mathbb{R}^n) := \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n)$. Using the notation of Example 3.3, let us assume that

$$(5.10) \quad \det \begin{pmatrix} sI - \hat{A}(s) & -B \\ C & 0 \end{pmatrix} \neq 0 \quad \text{for all } s \in \bar{\mathbb{C}}_0.$$

In particular, it follows from (5.10) that

$$\text{rk}(sI - \hat{A}(s) \ B) = n \quad \text{for all } s \in \bar{\mathbb{C}}_0$$

and

$$\text{rk} \begin{pmatrix} sI - \hat{A}(s) \\ C \end{pmatrix} = n \quad \text{for all } s \in \bar{\mathbb{C}}_0.$$

Hence the abstract state-space realization of the retarded system is exponentially stabilizable and exponentially detectable (see, e.g., Salamon [36]), and using Example 3.3 we see that under the extra assumption $\det(CB) \neq 0$, Theorem 5.5 applies to retarded systems.

Appendix 1.

Proof of Proposition 3.1. “Only if” Since G^{-1} admits a decomposition of form (3.1) with $H \in (H_\gamma^\infty)^{p \times p}$ for some $\gamma < 0$ we obtain

$$\begin{aligned} s(sG(s) - D^{-1}) &= s \left(\left(D + \frac{1}{s} H(s) \right)^{-1} - D^{-1} \right) \\ &= \left(D + \frac{1}{s} H(s) \right)^{-1} s \left(I - \left(D + \frac{1}{s} H(s) \right) D^{-1} \right) \\ &= - \left(D + \frac{1}{s} H(s) \right)^{-1} H(s) D^{-1}, \end{aligned}$$

which shows that $sG(s) - D^{-1} = O(1/s)$ as $|s| \rightarrow \infty$ in $\bar{\mathbb{C}}_\beta$, where $\beta \in (\gamma, 0)$ is arbitrary. To show that G has no zeros in $\bar{\mathbb{C}}_\beta$, pick holomorphic matrices $N, D \in \mathcal{H}(\mathbb{C}_\gamma)^{p \times p}$ such that N and D are right coprime and $G = ND^{-1}$. Then, trivially, $G^{-1} = DN^{-1}$ and by the right coprimeness of D and N it follows from the analyticity of G^{-1} in \mathbb{C}_γ that $\det(N)$ has no zeros in $\mathbb{C}_\gamma \cup \bar{\mathbb{C}}_\beta$.

“If” Setting $F(s) := (s + \gamma)G(s)$, $\gamma > |\beta|$, it follows from the assumption that

$$(A.1) \quad F(s) - D^{-1} = O(s^{-1}) \quad \text{as } |s| \rightarrow \infty \text{ in } \mathbb{C}_\beta$$

and, in particular,

$$(A.2) \quad \lim_{\substack{|s| \rightarrow \infty \\ s \in \mathbb{C}_\beta}} F(s) = D^{-1}.$$

Hence there exists $\rho > 0$ such that $F^{-1}(s)$ is bounded on $|s| > \rho$, $s \in \mathbb{C}_\beta$. Moreover, $F^{-1}(s) = (1/(s + \gamma))G^{-1}(s)$ and since G has no zeros in $\bar{\mathbb{C}}_\beta$, it follows that $F^{-1}(s)$ is bounded on $|s| \leq \rho$, $s \in \mathbb{C}_\beta$. Therefore F^{-1} is a bounded holomorphic function on \mathbb{C}_β , i.e., $F^{-1} \in (H_\beta^\infty)^{p \times p}$. Now realize that

$$(A.3) \quad \tilde{H}(s) := (s + \gamma)(F^{-1}(s) - D)$$

$$(A.4) \quad = (s + \gamma)F^{-1}(s)(D^{-1} - F(s))D.$$

It follows from (A.3) that \tilde{H} is holomorphic on \mathbb{C}_β and, furthermore, we obtain from (A.1), (A.2), and (A.4), using the boundedness of F^{-1} on \mathbb{C}_β , that \tilde{H} is bounded on \mathbb{C}_β ; hence $\tilde{H} \in (H_\beta^\infty)^{p \times p}$. Finally, we obtain

$$G^{-1}(s) = (s + \gamma)F^{-1}(s) = (s + \gamma)D + \tilde{H}(s) = sD + H(s),$$

where $H(s) := \gamma D + \tilde{H}(s)$. \square

Proof of Corollary 3.2. Since $A(s)$ is bounded on \mathbb{C}_γ for some $\gamma < 0$ there exists $\rho > 0$ such that

$$G(s) = \frac{1}{s} C \left(\sum_{j=0}^{\infty} \left(\frac{1}{s} A(s) \right)^j \right) B = \frac{1}{s} CB + \frac{1}{s} C \left(\sum_{j=1}^{\infty} \left(\frac{1}{s} A(s) \right)^j \right) B$$

for all $s \in \mathbb{C}_\gamma$ such that $|s| \geq \rho$. Hence

$$(A.5) \quad sG(s) - CB = O\left(\frac{1}{s}\right) \quad \text{as } |s| \rightarrow \infty \text{ in } \mathbb{C}_\gamma.$$

Moreover, since $\det(CB) \neq 0$, there exists an invertible matrix $Q \in \mathbb{C}^{n \times n}$ such that

$$Q^{-1}B = \begin{pmatrix} CB \\ 0 \end{pmatrix}, \quad CQ = (I_p \ 0).$$

Partition the matrix $Q^{-1}A(\cdot)Q$ as follows:

$$Q^{-1}A(\cdot)Q = \begin{pmatrix} A_{11}(\cdot) & A_{12}(\cdot) \\ A_{21}(\cdot) & A_{22}(\cdot) \end{pmatrix},$$

where $A_{11}(\cdot)$, $A_{12}(\cdot)$, $A_{21}(\cdot)$, and $A_{22}(\cdot)$ are matrices with entries in H_-^∞ of size $p \times p$, $p \times (n-p)$, $(n-p) \times p$, $(n-p) \times (n-p)$, respectively. As in Logemann [20], it follows that

$$(A.6) \quad \chi(s) = (-1)^p \det(CB) \det(sI - A_{22}(s)).$$

Now A_{22} is holomorphic and bounded on \mathbb{C}_α for some $\alpha < 0$, and therefore $\det(sI - A_{22}(s))$ has at most finitely many zeros in $\bar{\mathbb{C}}_\mu$ for any $\mu > \alpha$. Since, by assumption $\chi(s) \neq 0$ for all $s \in \bar{\mathbb{C}}_0$, we obtain, using (A.6),

$$(A.7) \quad \chi(s) \neq 0 \quad \text{for all } s \in \bar{\mathbb{C}}_\beta$$

for a negative β of sufficiently small modulus (without loss of generality, we may assume that $\gamma < \beta$). Let $G = ND^{-1}$ be a right coprime factorization over $\mathcal{H}(\mathbb{C}_\gamma)$ and use a well-known formula for the determinant of a four-block matrix to obtain

$$(A.8) \quad \begin{aligned} \chi(s) &= \det(sI - A(s)) \det(G(s)) \\ &= \frac{\det(sI - A(s))}{\det(D(s))} \det(N(s)). \end{aligned}$$

It is known that $\det(D(s))$ divides $\det(sI - A(s))$ (in $\mathcal{H}(\mathbb{C}_\gamma)$) (cf. Logemann [18]), and hence, by (A.8), we have that $\det(N)$ divides χ (in $\mathcal{H}(\mathbb{C}_\gamma)$). Thus, by (A.7),

$$(A.9) \quad \det(N(s)) \neq 0 \quad \text{for all } s \in \bar{\mathbb{C}}_\beta.$$

The claim now follows from (A.5), (A.9), and Proposition 3.1. \square

Appendix 2.

Proof of Lemma 3.8. An elementary computation shows that

$$(A.10) \quad L_k - L_k^* = \{[I - J_k(I - \Gamma^{-1}D) + P_k]^{-1} - I\}L_k^*,$$

where

$$J_k(s) := \text{diag}_{1 \leq j \leq p} \left(\frac{s}{s + k_j} \right)$$

and

$$P_k(s) := \text{diag}_{1 \leq j \leq p} \left(\frac{s}{(s + k_j)(s + c_j)} \right) \left\{ \Gamma^{-1} H(s) + \text{diag}_{1 \leq j \leq p} (c_j) (I - \Gamma^{-1} D) \right\}.$$

Note that we can factorize P_k as $P_k = J_k Q$, where

$$Q(s) := \text{diag}_{j=1, \dots, p} \left(\frac{1}{s + c_j} \right) \{ \Gamma^{-1} H(s) + \text{diag} (c_j) (I - \Gamma^{-1} D) \}.$$

Using a result by Mossaheb [27] (cf. also Logemann [18]), we see that $\check{Q} e^{\varepsilon \cdot} \in (L^1(\mathbb{R}_+))^{p \times p}$ for all sufficiently small $\varepsilon > 0$. Moreover, we have

$$(A.11) \quad \lim_{k \rightarrow \infty} \|\check{P}_k\|_1 = \lim_{k \rightarrow \infty} \|\check{J}_k * \check{Q}\|_1 = 0,$$

which can be derived using the equation $\check{J}_k = \delta_0 I - \text{diag}_{1 \leq j \leq p} (k_j e^{-k_j \cdot})$ and Lemma A.1. In the case where $\Gamma = D$, we obtain from (A.10), by taking inverse Laplace transforms,

$$(A.12) \quad \check{L}_k - \check{L}_k^* = \{(\delta_0 I + \check{P}_k)^{-1} - \delta_0 I\} * \check{L}_k^*.$$

It follows from (A.11) that the inverse of $\delta_0 I + \check{P}_k$ exists (in the Banach algebra $\mathcal{A}^{p \times p}$) if $\min_{1 \leq j \leq p} (k_j)$ is sufficiently large. Hence (A.12) makes sense for large $k_j, j = 1, \dots, p$. Part (i) of the lemma now follows from (A.12), (A.11), and the fact that

$$(A.13) \quad \lim_{k \rightarrow \infty} \|\check{L}_k^*\|_1 = 1$$

(cf. Logemann and Owens [22] for (A.13)).

To prove part (ii), set $M_k := J_k(I - \Gamma^{-1} D)$ and realize that $\|\check{M}_k\|_{\mathcal{A}} \leq \|\check{J}_k\|_{\mathcal{A}} \|I - \Gamma^{-1} D\| \leq 2\varepsilon < 1$. Taking inverse Laplace transforms, using (A.11), and employing the fact that $\mathcal{A}^{p \times p}$ is a Banach algebra, it follows from (A.10) that

$$\check{L}_k - \check{L}_k^* = \{[\delta_0 I - (\check{M}_k - \check{P}_k)]^{-1} - \delta_0 I\} * \check{L}_k^* = \left(\sum_{n=1}^{\infty} (\check{M}_k - \check{P}_k)^n \right) * \check{L}_k^*$$

for all sufficiently large $k_j, j = 1, \dots, p$. Moreover,

$$\|\check{L}_k - \check{L}_k^*\|_1 \leq \left(\sum_{n=1}^{\infty} (2\varepsilon + \|\check{P}_k\|_1)^n \right) \|\check{L}_k^*\|_1 = \frac{2\varepsilon + \|\check{P}_k\|_1}{1 - (2\varepsilon + \|\check{P}_k\|_1)} \|\check{L}_k^*\|_1$$

for all sufficiently large $k_j, j = 1, \dots, p$. We obtain, by using (A.13) and (A.11),

$$\limsup_{k \rightarrow \infty} \|\check{L}_k - \check{L}_k^*\|_1 \leq \frac{2\varepsilon}{1 - 2\varepsilon},$$

which is (ii). \square

LEMMA A.1. Set $e_k(t) := k e^{-kt} \theta(t)$, $t \geq 0$, $k \geq 0$. Then $\lim_{k \rightarrow \infty} \|e_k * f - f\|_1 = 0$ for all $f \in L^1(\mathbb{R}_+)$.

Remark A.2. Note that e_k is not a so-called approximate identity or Dirac sequence, because the support of e_k does not shrink to $\{0\}$ as $k \rightarrow \infty$.

Proof of Lemma A.1. In the following set $f(t) := 0$ for all $t < 0$

$$\begin{aligned}
 \|e_k * f - f\|_1 &= \int_0^\infty \left| \int_0^t e_k(t-s)f(s) ds - f(t) \right| dt \\
 (A.14) \qquad &= \int_0^\infty \left| \int_0^\infty e_k(\tau)(f(t-\tau) - f(t)) d\tau \right| dt \\
 &\leq \int_0^\infty e_k(\tau) \left\{ \int_0^\infty |f(t-\tau) - f(t)| dt \right\} d\tau.
 \end{aligned}$$

It is well known that for a given $\varepsilon > 0$ there exists $\delta > 0$ such that $\int_0^\infty |f(t-\tau) - f(t)| dt \leq \varepsilon$ for all $\tau \in [0, \delta]$. Hence it follows from (A.14) that

$$\begin{aligned}
 \|e_k * f - f\|_1 &\leq \int_0^\delta e_k(\tau) \left\{ \int_0^\infty |f(t-\tau) - f(t)| dt \right\} d\tau + 2\|f\|_1 \int_\delta^\infty e_k(\tau) d\tau \\
 &\leq \varepsilon + 2\|f\|_1 e^{-k\delta} \leq 2\varepsilon
 \end{aligned}$$

for all sufficiently large k .

Appendix 3. In this appendix we will present the most important results on stabilizability of infinite-dimensional systems. We use the same notation as in § 4.

DEFINITION A.3. System (A, B) is α -exponentially stabilizable if there exists a bounded linear operator $F \in L(X, \mathbb{R}^p)$ such that the semigroup $T_{BF}(t)$ generated by $A + BF$ satisfies $\|T_{BF}(t)\| \leq M e^{\beta t}$ for some $M \geq 1$ and $\beta < \alpha$. System (A, B) is exponentially stabilizable if it is 0-exponentially stabilizable. System (C, A) is α -exponentially detectable if there exists a bounded linear operator $K \in L(\mathbb{R}^p, X)$ such that the semigroup $T_{KC}(t)$ generated by $A + KC$ satisfies $\|T_{KC}(t)\| \leq M e^{\beta t}$ for some $M \geq 1$ and $\beta < \alpha$. System (C, A) is exponentially detectable if it is 0-exponentially detectable.

LEMMA A.4. Suppose that the underlying space X is reflexive. Then system (A, B) is α -exponentially stabilizable if and only if (B^*, A^*) is α -exponentially detectable.

We now have the following important theorem.

THEOREM A.5. The following conditions are equivalent. (i) System (A, B) is α -exponentially stabilizable; and (ii) the state space can be decomposed in two semigroup-invariant subspaces $X = X_s \oplus X_u$, where X_s and X_u satisfy

$$\|T(t)|_{X_s}\| \leq M e^{\beta t}; \quad M \geq 1, \quad \beta < \alpha,$$

$$\dim(X_u) < \infty,$$

$$\sigma(A|_{X_u}) = \sigma(A) \cap \bar{C}_\alpha = \sigma_p(A) \cap \bar{C}_\alpha,$$

—The finite-dimensional system $(A|_{X_u}, P_{X_u}B)$ is controllable, where P_{X_u} is the projection on X_u along X_s .

For the proof, see Desch and Schappacher [6], Nefedov and Sholokhovitch [29], Jacobson and Nett [14], or Curtain [5].

It is easy to show that X_u is the span of all unstable (generalized) eigenvectors of A .

The following theorem is used frequently in § 4.

THEOREM A.6. Assume that (A, B) is α -exponentially stabilizable and let $Q \in L(X)$ be compact. Then $A + Q$ generates an α -exponentially stable semigroup if and only if $\sigma_p(A + Q) \cap \bar{C}_\alpha = \emptyset$.

Proof. It follows from Theorem A.5 that the essential exponential growth bound $\omega_e(T(\cdot))$ of $T(t)$ (cf., e.g., Nagel [28]) satisfies $\omega_e(T(\cdot)) < \alpha$. Since Q is compact, we have that $\omega_e(T_Q(\cdot)) = \omega_e(T(\cdot)) < \alpha$. Let $\omega(T_Q(\cdot))$ denote the exponential growth

bound of the semigroup $T_Q(t)$. We must prove that $\omega(T_Q(\cdot)) < \alpha$. Let us assume the contrary. Then $\omega(T_Q(\cdot)) > \omega_e(T_Q(\cdot))$ and we can show, as in [28, p. 74], that there exists $\lambda \in \sigma_p(A+Q)$ satisfying $\operatorname{Re}(\lambda) = \omega(T_Q(\cdot)) \geq \alpha$. This leads to a contradiction because $\sigma_p(A+Q) \cap \bar{\mathbb{C}}_\alpha = \emptyset$ by assumption.

STOCHASTIC DISCRETE OPTIMIZATION*

DI YAN† AND H. MUKAI†

Abstract. In this paper a stochastic search method is proposed for finding a global solution to the stochastic discrete optimization problem in which the objective function must be estimated by Monte Carlo simulation. Although there are many practical problems of this type in the fields of manufacturing engineering, operations research, and management science, there have not been any nonheuristic methods proposed for such discrete problems with stochastic infrastructure. The proposed method is very simple, yet it finds a global optimum solution. The method exploits the randomness of Monte Carlo simulation and generates a sequence of solution estimates. This generated sequence turns out to be a nonstationary Markov chain, and it is shown under mild conditions that the Markov chain is strongly ergodic and that the probability that the current solution estimate is global optimum converges to one. Furthermore, the speed of convergence is also analyzed.

Key words. stochastic optimization, discrete parameters, Monte Carlo simulation, global optimization, Markov chain

1. Introduction. In the fields of manufacturing engineering, operations research, and management science, we often find a discrete optimization problem in which an objective function g is minimized over a nonempty discrete finite feasible set S :

$$(1.1) \quad \min \{g(s) | s \in S\},$$

where $g: S \rightarrow \mathbb{R}$ and $S = \{s_1, s_2, \dots, s_k\}$. In such a problem, the discreteness of the feasible set is the most salient characteristic, while the finiteness of the feasible set is mere convenience in theory without imposing any serious limitations in practice since the size can be made larger as needed.

In examining many practical problems of the form (1.1), we note that the objective function $g(s)$ is often the expectation of the performance of a system that is subject to stochastic phenomena. Hence we give $g(s)$ the following stochastic infrastructure:

$$(1.2) \quad g(s) = E[h(s, Y(s))],$$

where E denotes the expectation, h is a function of s and y , and $Y(s)$ is a random vector dependent on s . Hence $h(s, y)$ may represent the performance of the system when the parameter is set to s and the sample of random vector $Y(s)$ is y . In such problems, a closed-form formula is often not available for the objective function $g(s)$, and one is forced to estimate $g(s)$ by Monte Carlo-type simulation. For this purpose, we write a computer program for simulating the system and drive it by random number generators. Here the simulation program represents $h(s, y)$ and the random number generators represent $Y(s)$.

As an example, consider a queueing network consisting of stations with buffers. Such a network may represent an assembly line in the manufacturing industry, a network of processors for a parallel computer, or a communication network for message packets. Suppose that the optimal sizes of buffers are sought. Hence vector s represents buffer sizes at different stations. Random vector Y may represent the lengths of service time at different stations and the lengths of transfer time from station to station. The function $h(s, y)$ is often set to the amortized cost of buffers minus the revenues due

* Received by the editors June 5, 1989; accepted for publication (in revised form) April 4, 1991. This research was supported in part by United States Air Force grant AFOSR-89-0518.

† Department of Systems Science and Mathematics, Washington University, St. Louis, Missouri 63130.

to the processing speed. Therefore one tries to minimize $g(s) = E[h(s, Y)]$. In this case it is relatively easy to write a simulation program for $h(s, y)$ and to drive y by random number generators representing Y , but it is very time consuming to write an explicit formula for $h(s, y)$ in closed form. Furthermore when a multistation multiserver queueing network is subject to some recycling and a complex priority system, it would be impossible [3, p. 455] to model the network analytically and to obtain an explicit formula for $h(s, y)$.

As another example, consider a telephone installation problem in which several types of telephones are installed at an airport. One type of telephone may accept coins only, another may accept credit cards only, and yet another may accept both. Here vector s represents the numbers of telephones in different categories, and random vector $Y(s)$ may represent the length of time period between customer arrivals, and the length of time a customer spends at a telephone. We note that the latter depends on the type of telephone since credit card calls tend to take extra time for dialing the card number and for verification by a computer. Here the performance $h(s, y)$ may represent the average waiting time for a customer and the amortized cost of telephones.

In the past, a paper [5] considered a specific problem of buffer size selection in a serial production line and proposed a very heuristic method without any convergence analysis.

In the absence of any computational methods with theoretical underpinnings that are specifically designed to solve the discrete optimization problem with stochastic infrastructure, one might naively combine Monte Carlo simulation and a discrete optimization technique developed for the case in which the objective function is readily deterministically computable. The most straightforward approach would be to replace the objective function $g(s)$ by its estimate $\hat{g}_\ell(s)$ based on ℓ simulation experiments. For example, $\hat{g}_\ell(s)$ may be defined as $\hat{g}_\ell(s) = (1/\ell) \sum_{i=1}^{\ell} h(s, y_i(s))$, where $y_1(s), \dots, y_\ell(s)$ denote ℓ samples of $Y(s)$. In this case, it is not obvious how large the sample size ℓ should be to guarantee the convergence of the optimization technique.

In this paper, we take a different approach and propose a new method for solving the discrete optimization problem with stochastic infrastructure. In the above naive approaches, stochastic elements are suppressed by taking large sample sizes ℓ . Here we treat stochastic elements as they are in our proposed method. Moreover, we exploit the stochastic property of simulation in finding global optimal solution. In the proposed method, the new solution candidate is compared with an absolute scale. Given a practical situation, one can often guess an approximate range (a, b) for the stochastic objective function $h(s, Y(s))$ from experience. When such experience is not available, we can always run simulation experiments for different values of s and obtain an approximate range (a, b) for the stochastic objective function $h(s, Y(s))$. Then we may define a random variable $\Theta(a, b)$, which is uniformly distributed over the interval (a, b) , and we use this as a scale against which $h(s, Y(s))$ is measured. Thus we convert the original minimization problem (1.1) into the following probability maximization problem:

$$\max \{ \text{Prob} [h(s, Y(s)) \leq \Theta(a, b)] \mid s \in S \}.$$

Hence our strategy is to solve this maximization problem in place of the original problem (1.1). Here we must note that the probability being maximized is not numerically computable. Rather the probability is implicitly represented in the probabilistic simulation, and we exploit that implicit representation in designing a method for solving this maximization problem. In § 2, we exactly state the discrete optimization problem with stochastic infrastructure. Then, in § 3, we translate the original minimization problem into the probability maximization problem and discuss the relationship

between the two problems. In § 4, we list assumptions and describe our proposed method, which depends on a sequence $\{M_k\}$ of parameters for generating a sequence $\{X_k\}$ of solution estimates. Then, in § 5, we freeze the parameter M_k to a constant M , analyze the resulting stationary Markov chain, and obtain its stationary probability distribution $\pi(M)$ as a function of M . In § 6, we study the behavior of the stationary probability distribution $\pi(M)$ as M goes to infinity. Then, in § 7, we study the proposed method when the sequence $\{M_k\}$ of parameters monotonically increases to infinity, analyze the resulting nonstationary Markov chain, establish that the chain is strongly ergodic, and show that the probability that the solution estimate X_k is in the global optimum set goes to one as the iteration k goes to infinity. Furthermore, in § 8, we investigate the rate of convergence of the proposed method. Then the paper ends with some conclusions in § 9. In the interest of readability, all the proofs are relegated to the Appendix.

2. Problem structure and assumptions. Consider problem (1.1). Instead of local solutions, we seek global solutions to this problem. We denote the (global) optimum set by

$$(2.1) \quad S^* = \{s \in S \mid g(s) \leq g(s'), \forall s' \in S\}.$$

The objective function is now assumed to have the structure of (1.2), where $h(s, y)$ is a measurable function of s and y , and $Y(s)$ is a random vector defined on probability space (Ω_s, F_s, P_s) for each $s \in S$. We observe that the random variable $H(s)$ defined by

$$(2.2) \quad H(s) = h(s, Y(s))$$

is well defined on (Ω_s, F_s, P_s) for each $s \in S$. We further note that the probability distribution for $Y(s)$ is often known a priori and simple (e.g., the exponential distribution and the Gaussian distribution), but that the probability distribution for $H(s)$ is not generally known a priori and complex.

We shall assume throughout the paper that the variance of $H(s)$ is finite for each $s \in S$.

ASSUMPTION A0. We have that

$$(2.3) \quad E[H(s)^2] < \infty, \forall s \in S.$$

We would like to point out that this finite variance property is the only property that we demand of the problem.

3. Translation to a maximization problem. Consider the problem defined in the preceding sections. Given an $s \in S$, we can only obtain samples $\{h_i(s)\}$ of random variable $H(s)$ via simulation. Hence, given two elements, s and s' , from S , we cannot decide which element is better than the other based on a finite number of samples $\{h_i(s)\}$ and $\{h_i(s')\}$. However, these samples do contain some information about their underlying stochastic structures, and we need to extract it. To accomplish this, we propose to measure $H(s)$ against a stochastic ruler—another random variable. With this idea, we will be able to translate the original minimization problem into a maximization problem of a certain probability. As a stochastic ruler, we have selected a uniformly distributed random variable in this paper, but other choices are possible.

Let $\Theta(a, b)$ denote the random variable uniformly distributed between a and b provided $a < b$. Here a and b , respectively, represent in a loose sense a lower and an upper bound for $\{H(s) \mid s \in S\}$. For example, if it is known that $a' \leq H(s) \leq b'$ for all $s \in S$, then a and b may be, respectively, set to a' and b' .

Now we compare $H(s)$ with $\Theta(a, b)$ and let

$$(3.1) \quad P(s, a, b) = P[H(s) \leq \Theta(a, b)].$$

Here the random variable $H(s)$ representing the objective value is compared with a stochastic ruler $\Theta(a, b)$. We can intuitively see that minimizing $g(s) = E[H(s)]$ is equivalent to maximizing the probability $P(s, a, b)$ provided the interval (a, b) is sufficiently wide. Hence we consider the following maximization problem:

$$(3.2) \quad \max \{P(s, a, b) \mid s \in S\}.$$

The global optimum solution set for this maximization problem is

$$(3.3) \quad S^*(a, b) = \{s \in S \mid P(s, a, b) \geq P(s', a, b) \forall s' \in S\}.$$

The following theorem rigorously delineates the relationship between the original minimization problem (1.1) and the above maximization problem (3.2).

THEOREM 3.1. *There exist real numbers \bar{a} and \bar{b} such that $\bar{a} < \bar{b}$ and for any $a < \bar{a}$ and any $b > \bar{b}$, the following conclusions hold:*

- (1) *If $g(s) < g(s')$ then $P(s, a, b) > P(s', a, b)$,*
- (2) *$0 < P(s, a, b) < 1$, for all $s \in S$,*
- (3) *$S^*(a, b) \subset S^*$ and $S^*(a, b) \neq \emptyset$.*

Theorem 3.1 states that maximization problem (3.2) has at least one solution and that any solution of that problem is a solution of the original minimization problem (1.1) provided the interval (a, b) is sufficiently large. The natural question now is: Does the converse hold? We partly answer that question in the next theorem.

THEOREM 3.2. *Suppose there exist reals $a(s)$ and $b(s)$ such that*

$$(3.4) \quad a(s) \leq H(s) \leq b(s) \quad \text{w.p.1.}$$

If $a < \min \{a(s) \mid s \in S\}$ and $b > \max \{b(s) \mid s \in S\}$, then $S^(a, b) = S^*$.*

In closing this section, we note that assumption (3.4) of Theorem 3.2 is not necessary for the method proposed in the next section, which solves the maximization problem (3.2). Indeed, conclusion (3) of Theorem 3.1 guarantees that a solution exists for the latter problem (3.2) and that its solution is also a solution for the original problem (1.1).

Furthermore we note that probability (3.1) is not explicitly available. Hence it is not possible to apply any conventional discrete optimization techniques to (3.2) in a straightforward manner. However, probability (3.1) is implicitly available in the simulation of $H(s)$ and $\Theta(a, b)$, and we exploit this fact to construct a method for solving (3.2) in the next section.

4. Computational method. In this section we present a stochastic algorithm for solving the discrete optimization problem discussed in §§ 1 and 2. The basic idea of our approach is to make use of probabilistic simulation in constructing a nonstationary Markov chain that converges to a global solution to the problem. Our approach is related to, but different from, the technique of simulated annealing.

First, while the objective value in simulated annealing is assumed to be exactly computable, our method accepts samples of the objective value generated by probabilistic simulation. Second, while the objective value at a new solution candidate is compared with that of the current solution candidate in simulated annealing, the objective value at a new solution candidate is compared against a probabilistic ruler in our method.

In the following, we list definitions and assumptions we will make use of in the rest of this paper. First, to structure our search for an optimal solution in the feasible set S , we introduce the concept of neighbors in S .

DEFINITION 4.1. For each $s \in S$, there exists a subset $N(s)$ of $S - \{s\}$, which is called *the set of neighbors* of s .

Our search is organized in such a way that the next solution candidate is found among the neighbors of the present candidate. Hence, to ensure that our search will eventually cover all the elements of S , we make the following assumption about the system N of neighbors.

ASSUMPTION A1. For any pair (s, s') in $S \times S$, s' is *reachable* from s ; i.e., there exists a finite sequence, $\{n_i\}_{i=0}^\ell$ for some ℓ , such that

$$s_{n_0} = s, \quad s_{n_\ell} = s', \quad s_{n_{i+1}} \in N(s_{n_i}), \quad i = 0, 1, 2, \dots, \ell - 1.$$

Now we impose a stochastic structure to the selection of a candidate among the neighbors by the following function R . Given an $s \in S$, a candidate is selected among $N(s)$ such that the probability of selecting a neighbor $s' \in N(s)$ is equal to $R(s, s')$.

DEFINITION 4.2. A function $R: S \times S \rightarrow [0, 1]$ is said to be a *transition probability* for S and N if

- (1) $R(s, s') > 0 \Leftrightarrow s' \in N(s)$ and
- (2) $\sum_{s' \in S} R(s, s') = 1$.

Statement (1) says that every neighbor and only neighbors alone are given positive probability to be selected as a candidate. Statement (2) says the probabilities of selecting all the neighbors must add up to one. The simplest way to define $R(s, s')$ is perhaps to distribute the probability uniformly over $N(s)$, i.e., $R(s, s') = 1/|N(s)|$ for $s' \in N(s)$, and $R(s, s') = 0$ for $s' \notin N(s)$, where $|N(s)|$ denotes the number of elements in $N(s)$. However, given a particular problem, it may be more advantageous to skew the distribution.

Now we introduce the following simplification.

ASSUMPTION A2. The neighbor system N and the transition probability R for S are *symmetric*, i.e.,

- (1) $s' \in N(s) \Leftrightarrow s \in N(s')$ and
- (2) $R(s, s') = R(s', s)$.

In the algorithm, we make use of a sequence of positive integers tending to infinity.

ASSUMPTION A3. A sequence $\{M_k\}$ of positive integers satisfies $M_k \rightarrow \infty$ as $k \rightarrow \infty$.

Aside from N , R , and $\{M_k\}$ defined above, the proposed stochastic algorithm requires parameters, a and b , and an initial guess $s_0 \in S$ for the optimal solution.

THE STOCHASTIC ALGORITHM.

Data: $N, R, \{M_k\}, a, b, s_0 \in S$.

Step 0: Set $X_0 = s_0$ and $k = 0$.

Step 1: Given $X_k = s$, choose a candidate Z_k from $N(s)$ with probability distribution

$$P[Z_k = s' / X_k = s] = R(s, s'), \quad s' \in N(s).$$

Step 2: Given $Z_k = s'$, set

$$X_{k+1} = \begin{cases} Z_k, & \text{with probability } p_k, \\ X_k, & \text{with probability } (1 - p_k), \end{cases}$$

where

$$p_k = \{P[H(s') \leq \Theta(a, b)]\}^{M_k} = \{P(s', a, b)\}^{M_k}.$$

Remark. Since we are interested in cases in which the probability $P(s', a, b)$ given above in Step 2 is not explicitly computable, we suggest a subalgorithm for implementing Step 2 immediately following the algorithm.

Step 3: Set $k = k + 1$ and go to Step 1.

The implementation of Step 2 of the above algorithm may be accomplished by the following subalgorithm where $P(s', a, b)$ need not be computed.

SUBALGORITHM FOR STEP 2.

Given $Z_k = s'$, draw a sample $h(s')$ from $H(s')$, or equivalently draw a sample $y(s')$ from $Y(s')$ using random number generators and then compute $h(s', y(s'))$ by running one simulation experiment. Next draw a sample θ from $\Theta(a, b)$. If $h(s') = h(s', y(s')) > \theta$ then set $X_{k+1} = X_k$; otherwise draw another sample $h(s')$ from $H(s')$ (or equivalently draw another sample $y(s')$ and compute $h(s', y(s'))$ by running another experiment), and compare this against another sample θ from $\Theta(a, b)$. If $h(s') = h(s', y(s')) > \theta$, then set $X_{k+1} = X_k$; otherwise continue to draw and compare. If all M_k tests, $h(s') = h(s', y(s')) > \theta$, fail, then we accept the candidate Z_k and set $X_{k+1} = Z_k = s'$.

The random process $\{X_k\}$ produced by the Stochastic Algorithm is a discrete-time Markov chain defined over states S , and its state transition probabilities are given by

$$(4.1) \quad \begin{aligned} P_{ss'}(M_k) &= P[X_{k+1} = s' / X_k = s] \\ &= \begin{cases} R(s, s') \{P(s', a, b)\}^{M_k}, & \text{if } s' \in N(s); \\ 1 - \sum_{s'' \in N(s)} R(s, s'') \{P(s'', a, b)\}^{M_k}, & \text{if } s' = s; \\ 0, & \text{otherwise.} \end{cases} \end{aligned}$$

We make use of the state transition probability matrix, which is a matrix consisting of the above probabilities:

$$(4.2) \quad P(M_k) = (P_{ss'}(M_k)).$$

We also note that $P(M_k)$ is a stochastic matrix [6].

5. Analysis for the stationary process. In this section, we suspend Assumption A3 and set M_k to a positive constant integer M to investigate the stationary behavior of the algorithm in § 4. Indeed, the Markov chain then becomes stationary since the state transition probability (4.1) becomes independent of k .

For each $s \in S$, define

$$(5.1) \quad \pi_s(M) = \frac{\{P[H(s) \leq \Theta(a, b)]\}^M}{\sum_{s' \in S} \{P[H(s') \leq \Theta(a, b)]\}^M} = \frac{\{P(s, a, b)\}^M}{\sum_{s' \in S} \{P(s', a, b)\}^M}.$$

We will show in the next theorem that $\{\pi_s(M) | s \in S\}$ is the stationary probability distribution for the stationary Markov chain X_k generated by the algorithm with M_k set to M .

We now assume for the rest of the paper that parameters a and b are selected so as to satisfy the conditions in Theorem 3.1.

THEOREM 5.1. *The vector $\pi(M)$ consisting of $\pi_s(M)$ in (5.1) represents the stationary probability distribution for the Markov chain $\{X_k\}$ defined by (4.1) with $M_k = M$. Furthermore, this vector is the left eigenvector with eigenvalue one for the state transition probability matrix $P(M)$ defined in (4.2), i.e.,*

$$(5.2) \quad \pi(M)P(M) = \pi(M).$$

6. The limiting behavior of the stationary distribution. In this section, we investigate the behavior of the stationary probability distribution $\{\pi_s(M) | s \in S\}$ found in the preceding section as M goes to infinity.

DEFINITION 6.1. Given a finite set S , the set $\Pi(S)$ of positive unit vectors is called the set of probability vectors for S , below:

$$\Pi(S) = \{\pi \in [0, 1]^\kappa \mid \pi_s \geq 0, \|\pi\| = \sum_{s \in S} \pi_s = 1\},$$

where $\kappa = |S|$ represents the cardinality of S .

DEFINITION 6.2. A probability vector π^* for S is called *optimal* if $\pi_s^* = 0$ for any $s \notin S^*$.

Observe that if the probability vector is optimal, then the associated state s is in the optimal set S^* with probability one. Furthermore, if $\pi_s^* = 0$ for any $s \notin S^*(a, b)$ then π^* is optimal and the associated state s is again in the optimal set S^* with probability one provided $S^*(a, b) \subset S^*$.

THEOREM 6.1. The probability vector $\pi(M)$ defined in (5.1) converges, as M goes to infinity, to an optimal probability vector π^* . Furthermore

$$\pi_s^* = \begin{cases} 1/|S^*(a, b)|, & \text{if } s \in S^*(a, b), \\ 0, & \text{otherwise,} \end{cases}$$

where $|S^*(a, b)|$ represents the cardinality of $S^*(a, b)$.

The conclusions of the above theorem follow from (5.1) and conclusion (2) of Theorem 3.1. In the next proposition, we establish the monotone property of $\pi_s(M)$ as a function of M .

PROPOSITION 6.1. The following hold:

- (1) For each $s \in S^*(a, b)$, if $M < M'$ then $\pi_s(M) \leq \pi_s(M')$.
- (2) For each $s \notin S^*(a, b)$ there exists an integer M_s such that if $M_s \leq M < M'$ then $\pi_s(M) \geq \pi_s(M')$.

7. Convergence: Analysis for the nonstationary process. In this section we reinstate Assumption A3 and investigate the behavior of the Stochastic Algorithm described in § 4. Because the parameter M_k now varies from iteration to iteration, the algorithm produces a nonstationary Markov chain.

Consider a nonstationary Markov chain with a sequence $\{P(k)\}_{k=1}^\infty$ of state transition probability matrices. We denote by $P(\ell, k)$ the associated state transition probability matrix from iteration ℓ to iteration k where $k \geq \ell \geq 0$. Then

$$(7.1) \quad P(\ell, k) = \begin{cases} \prod_{i=\ell}^{k-1} P(i) & \text{if } k > \ell, \\ I & \text{if } k = \ell. \end{cases}$$

Furthermore, we denote by $x(\ell, k)$ the probability vector of the Markov chain at iteration k when the chain is started at iteration ℓ from the initial probability vector x_0 . Then

$$(7.2) \quad x(\ell, k) = x_0 P(\ell, k), \quad k \geq \ell.$$

Recall that a square matrix $P = (P_{ij})$ is called stochastic if all the entries are positive or zero, $P_{ij} \geq 0$, and the sum of all the entries in each row is one, $\sum_j P_{ij} = 1$.

DEFINITION 7.1. Given a stochastic matrix P , the coefficient of ergodicity is defined to be

$$(7.3) \quad \alpha(P) = \min_{ij} \sum_k \min(P_{ik}, P_{jk}),$$

and the delta coefficient of P is defined to be

$$(7.4) \quad \delta(P) = \frac{1}{2} \max_{ij} \sum_k |P_{ik} - P_{jk}|.$$

It is easy to show [6, p. 143] that

$$(7.5) \quad \alpha(P) = 1 - \delta(P).$$

We are now ready to show that the Markov chain $\{X_k\}$ generated by the Stochastic Algorithm proposed in § 4 is strongly ergodic under certain conditions. Before showing this, we need to obtain a bound on the number of transitions that the Markov chain needs to make before the probability transition matrix has all the elements in at least one column different from zero. For this we first represent the neighborhood system N as a graph by regarding each state $s \in S$ as a node and each neighbor relation $s' \in N(s)$ (hence $s \in N(s')$) as an edge. The length of a path from node s to another node s' is defined to be the number of edges in the path. Then the distance $d(s, s')$ between two nodes s and s' is defined to be the length of a minimum-length path from s to s' . Then the radius of the graph is given by

$$(7.6) \quad r = \min_{s \in S} \max_{s' \in S} d(s, s').$$

Let \hat{s} denote a node at which the above minimum is attained. Then it is called a center of the graph. Furthermore, the radius r represents an upper bound on the number of transitions Markov chain needs to make before the probability transition matrix has all the elements in at least one column, namely the column corresponding to \hat{s} , different from zero.

Now we find the smallest nonzero $R(s, s')$ and the smallest $P(s, a, b)$, as follows:

$$(7.7) \quad \rho = \min_{s \in S} \min_{s' \in N(s)} R(s, s'),$$

$$(7.8) \quad \mu(a, b) = \min_{s \in S} P(s, a, b).$$

It follows from the finiteness of set S and conclusion (2) of Theorem 3.1 that $\rho > 0$ and $0 < \mu(a, b) < 1$.

THEOREM 7.1. *Let a real $c > 0$ satisfy $c \leq 1/r$. Let a real $\sigma > 0$ satisfy $\sigma \geq 1/\mu(a, b)$. Let an integer k_0 satisfy $1 \leq c \log_\sigma(k_0 + 1)$. Let*

$$(7.9) \quad M_k = \text{trunc}[c \log_\sigma(k + k_0 + 1)]$$

for $k = 0, 1, 2, \dots$, where $\text{trunc}[\xi]$ denotes the greatest integer smaller or equal to ξ . Then the Markov chain $\{X_k\}$ generated by the Stochastic Algorithm in § 4 using these M_k is weakly ergodic.

Before showing that the Markov chain $\{X_k\}$ is strongly ergodic, we need to establish the following lemma.

LEMMA 7.1. *The probability vector $\pi(M)$ defined in (5.1) satisfies*

$$\sum_{k=0}^{\infty} \|\pi(M_{k+1}) - \pi(M_k)\| < \infty.$$

THEOREM 7.2. *Let $\{M_k\}$ be as defined in Theorem 7.1. Then the Markov chain $\{X_k\}$ generated by the Stochastic Algorithm in § 4 is strongly ergodic. Furthermore,*

$$(1) \lim_{k \rightarrow \infty} \sup_{x_0} \|x(\ell, k) - \pi^*\| = 0,$$

$$(2) \lim_{k \rightarrow \infty} P[X_k \in S^*(a, b)] = 1,$$

where $x(\ell, k) = x_0 P(\ell, k) = x_0 \prod_{i=\ell}^{k-1} P(M_i)$ and π^* is as defined in Theorem 6.1.

Conclusion (1) in the above theorem states that the probability vector $x(\ell, k)$ for the Markov chain $\{X_k\}$ generated by the Stochastic Algorithm in § 4 converges to π^* as the iteration k goes to infinity. Conclusion (2) states that the probability that the solution estimate X_k is in the optimum set $S^*(a, b)$ for the maximization problem (3.2) converges to one as the iteration k goes to infinity.

In view of Theorem 3.1, $S^*(a, b)$ is contained in the optimum set S^* for the original minimization problem (1.1) under mild conditions. Hence conclusion (2) implies that the probability that the solution estimate X_k is optimum for the original problem converges to one as the iteration k goes to infinity.

8. Rate of convergence. In this section we will show that the probability distribution $x(k)$ of the Markov chain $\{X_k\}$ generated by the Stochastic Algorithm of § 4 converges to the final distribution π^* at a certain speed.

Consider the Markov chain $\{X_k\}$ generated by the Stochastic Algorithm of § 4. The probability distribution $x(k)$ for X_k is expressed below in terms of the transition probability matrix $P(\ell, k)$ from iteration ℓ to k :

$$(8.1) \quad x(k) = x(0)P(0, k),$$

where $x(0)$ represents the initial probability distribution. The final distribution π^* is defined in Theorem 6.1. Hence

$$(8.2) \quad \begin{aligned} \|x(k) - \pi^*\| &= \sum_{s' \in S} \left| \sum_{s \in S} x_s(0) [P_{ss'}(0, k) - \pi_s^*] \right| \\ &\leq \sum_{s \in S} x_s(0) \sum_{s' \in S} |P_{ss'}(0, k) - \pi_s^*|. \end{aligned}$$

Now we develop a bound for the right side of (8.2) in the next lemma. The summation over integers from ℓ to k is to be interpreted as zero when $\ell > k$.

LEMMA 8.1. *For any $s \in S$ and for any integers $\ell \geq 0$ and $k \geq \ell$,*

$$(8.3) \quad \begin{aligned} \sum_{s' \in S} |P_{ss'}(0, k) - \pi_s^*| &\leq 4\delta(P(\ell, k)) \\ &+ \sum_{i=\ell}^{k-1} \|\pi(M_i) - \pi(M_{i+1})\| + \|\pi^* - \pi(M_\ell)\| + \|\pi(M_k) - \pi^*\|. \end{aligned}$$

Observing that the right-hand side of (8.3) is independent of s , we conclude from (8.2) and (8.3) that for any integer $\ell \leq k$,

$$(8.4) \quad \begin{aligned} \|x(k) - \pi^*\| &\leq 4\delta(P(\ell, k)) + \|\pi^* - \pi(M_\ell)\| \\ &+ \sum_{i=\ell}^{k-1} \|\pi(M_i) - \pi(M_{i+1})\| + \|\pi(M_k) - \pi^*\|. \end{aligned}$$

Now we will find a bound on the right-hand side of (8.4). Below, we denote by $P_{\max}(a, b)$ the maximum value for problem (3.2):

$$(8.5) \quad P_{\max}(a, b) = \max \{P(s, a, b) \mid s \in S\}.$$

If the associated optimum set $S^*(a, b)$ were equal to the feasible set S , then the original optimum set S^* would be the same as the feasible set S and both the original and above problems would be trivial. Hence we suppose that $S^*(a, b)$ is not the same as S . Then the second best value

$$(8.6) \quad P_{\text{sec}}(a, b) = \max \{P(s, a, b) \mid s \in S - S^*(a, b)\}$$

is well defined and is less than $P_{\max}(a, b)$.

PROPOSITION 8.1. Suppose that reals c and σ , integer k_0 and a sequence $\{M_k\}$ of positive integers are selected as in Theorem 7.1. Then there exists an integer k^* such that for any integers, $\ell \geq k^*$ and $k \geq \ell$,

$$(8.7) \quad \begin{aligned} & \|\pi^* - \pi(M_\ell)\| + \sum_{i=\ell}^{k-1} \|\pi(M_i) - \pi(M_{i+1})\| + \|\pi(M_k) - \pi^*\| \\ & \leq 4 \frac{|S - S^*(a, b)|}{|S^*(a, b)|} \sigma^\eta (\ell + k_0 + 1)^{-\eta c} \end{aligned}$$

where $\eta = \log_\sigma [P_{\max}(a, b)/P_{\sec}(a, b)] > 0$.

PROPOSITION 8.2. Assume the hypotheses of Proposition 8.1. Then there exists an integer m^* such that for any $m \geq m^*$,

$$(8.8) \quad \delta(P(\ell, mr)) \leq O(1/m^{\hat{t}}),$$

where $\ell = \text{trunc}[\sqrt{m}]r - r$, $\hat{t} = (\rho/r^c)^r/2$, and r and ρ are respectively defined in (7.6) and (7.7).

PROPOSITION 8.3. Assume the hypotheses for Proposition 8.1. Then there exists an integer m^* such that for any $m \geq m^*$,

$$\|\pi^* - \pi(M_\ell)\| + \sum_{i=\ell}^{k-1} \|\pi(M_i) - \pi(M_{i+1})\| + \|\pi(M_k) - \pi^*\| \leq O(1/m^{\bar{t}}),$$

where $k = mr$, $\ell = \text{trunc}[\sqrt{m}]r - r$, and $\bar{t} = \eta c/2$.

THEOREM 8.1. Suppose that reals c and r , integer k_0 , and a sequence $\{M_k\}$ are selected as in Theorem 7.1. Then for a sufficiently large integer m ,

$$\|x(mr) - \pi^*\| \leq O(1/m^t),$$

where $t = \min\{\hat{t}, \bar{t}\} = \min\{(\rho/r^c)^r/2, \eta c/2\} > 0$.

The conclusion for the last theorem follows from (8.4) and Propositions 8.2 and 8.3.

9. Conclusions. In this paper we have proposed a computation method for finding a global solution to the discrete optimization problem in which the objective function needs to be estimated by probabilistic simulation.

The proposed method has a remarkable degree of freedom in the scheme for selecting a candidate Z_k for the next solution estimate X_{k+1} given the current estimate X_k . Indeed some very mild conditions (Assumptions A1–A3) must be satisfied by the neighbor relationship N and the transition probability R for the feasible set S . Hence there is plenty of room for incorporating heuristic ideas in the method, thus making the method very practical and efficient yet theoretically robust, since its theoretical underpinnings are provided by the analysis in this paper.

When designing a practical method based on the algorithm proposed in this paper, one needs to set up a criterion for stopping the infinite process of the proposed method. Ideally, we would like to find some criteria that guarantee that the current estimate X_k is a global optimal solution with α percent confidence. However, such criteria appear to be difficult to find. Therefore, for the moment, we suggest the usual criteria: stop the method when the parameter M_k , the iteration counter k , the number of simulations, or the number of objective value samples exceeds a preselected fixed number.

The proposed algorithm is related to, but different from, the simulated annealing algorithm. While the objective value in simulated annealing is assumed to be exactly computable, the proposed algorithm accepts samples of the objective value generated by probabilistic simulation. The two algorithms are not equivalent even when the

parameter M_k goes to infinity, because the proposed algorithm does not rely on the sample mean to estimate the objective value.

Appendix.

Proof of Theorem 3.1. It follows from the finiteness of S that there exist reals c_1 and c_2 such that

$$(A1) \quad g(s) = E[H(s)] \in [c_1, c_2], \quad \forall s \in S.$$

It also follows that

$$(A2) \quad \varepsilon \triangleq \min \{|g(s) - g(s')| \mid (s, s') \in G\} > 0,$$

where $G = \{(s, s') \in S \times S \mid g(s) \neq g(s')\}$.

Let $D_s: \mathbb{R}^2 \rightarrow \mathbb{R}$ be defined by

$$D_s(a, b) = \int_{h < a}^{h > b} h F_{H(s)}(dh).$$

Not it follows from (2.3) that there exist reals c_3 and c_4 such that if $a \leq c_3$ and $b \geq c_4$ then

$$(A3) \quad |D_s(a, b)| \leq \varepsilon/4, \quad \forall s \in S.$$

Let

$$(A4) \quad V_{\max} = \max \{E[H(s)^2] \mid s \in S\}.$$

Let $c_5 = 8V_{\max}/\varepsilon$. Let $\bar{a} = \min\{c_1, c_3, -c_5\}$ and $\bar{b} = \max\{c_2, c_4, c_5\}$. Then $\bar{a} \leq -c_5 < 0 < c_5 \leq \bar{b}$.

Suppose that $a < \bar{a}$, $\bar{b} < b$ and $s \in S$. Then

$$\begin{aligned} P(s, a, b) &= P\{[H(s) \leq \Theta(a, b)] \cap [a \leq H(s) \leq b]\} \\ &\quad + P\{[H(s) \leq \Theta(a, b)] \cap [H(s) < a]\} \\ &\quad + P\{[H(s) \leq \Theta(a, b)] \cap [H(s) > b]\} \\ &= \int_a^b \int_h^b F_{\Theta}(d\theta) F_{H(s)}(dh) + P[H(s) < a] \\ &= \int_a^b \frac{b-h}{b-a} F_{H(s)}(dh) + P[H(s) < a] \\ &= \frac{b}{b-a} \int_a^b F_{H(s)}(dh) - \frac{1}{b-a} \int_a^b h F_{H(s)}(dh) + P[H(s) < a] \\ &= \frac{b}{b-a} \{1 - P[H(s) > b] - P[H(s) < a]\} \\ &\quad - \frac{1}{b-a} \{E[H(s)] - D_s(a, b)\} + P[H(s) < a] \\ &= \frac{1}{b-a} \{[b - g(s)] - bP[H(s) > b] - aP[H(s) < a] + D_s(a, b)\}. \end{aligned}$$

Hence, recalling $a < 0 < b$, we obtain

$$\begin{aligned}
 & P(s, a, b) - P(s', a, b) \\
 &= \frac{1}{b-a} [\{g(s') - g(s)\} + b\{P[H(s') > b] - P[H(s) > b]\} \\
 &\quad + a\{P[H(s') < a] - P[H(s) < a]\} + \{D_s(a, b) - D_{s'}(a, b)\}] \\
 &\geq \frac{1}{b-a} \{g(s') - g(s) - bP[H(s) > b] + aP[H(s') < a] \\
 (A5) \quad &\quad + D_s(a, b) - D_{s'}(a, b)\} \\
 &\geq \frac{1}{b-a} \{g(s') - g(s) - bP[|H(s)| \geq b] + aP[|H(s')| \geq |a|] \\
 &\quad - |D_s(a, b)| - |D_{s'}(a, b)|\} \\
 &\geq \frac{1}{b-a} \{g(s') - g(s) - \frac{1}{b} E[H(s)^2] + \frac{1}{a} E[H(s')^2] \\
 &\quad - |D_s(a, b)| - |D_{s'}(a, b)|\},
 \end{aligned}$$

where the last inequality follows from the Markov inequality

$$P[|H(s)| \geq c] \leq E[H(s)^2]/c^2.$$

If $g(s) < g(s')$, then it follows from (A2)-(A5) that

$$\begin{aligned}
 P(s, a, b) - P(s', a, b) &\geq \frac{1}{b-a} \left\{ \varepsilon - \frac{1}{b} V_{\max} + \frac{1}{a} V_{\max} - \varepsilon/2 \right\} \\
 &\geq \varepsilon/4(b-a) > 0.
 \end{aligned}$$

This establishes conclusion (1).

It now follows from (A1) that $g(s) = E[H(s)] \in (a, b)$, for all $s \in S$. Hence $P[H(s) \leq g(s)] > 0$ and $P[g(s) \leq \Theta(a, b)] > 0$. Noting

$$\{H(s) \leq g(s)\} \cap \{g(s) \leq \Theta(a, b)\} \subset \{H(s) \leq \Theta(a, b)\},$$

we conclude

$$P[H(s) \leq \Theta(a, b)] \geq P[H(s) \leq g(s)]P[g(s) \leq \Theta(a, b)] > 0.$$

Similarly, we conclude

$$P[H(s) > \Theta(a, b)] \geq P[H(s) \geq g(s)]P[g(s) > \Theta(a, b)] > 0.$$

Hence $P[H(s) \leq \Theta(a, b)] = 1 - P[H(s) > \Theta(a, b)] < 1$. These inequalities imply conclusion (2).

Consider the maximization problem (3.2). Since S is finite, the maximum exists and $S^*(a, b) \neq \emptyset$. Let $s \in S^*(a, b)$. Then $P(s, a, b) \geq P(s', a, b)$ for any $s' \in S$. It now follows from conclusion (1) that $g(s) \leq g(s')$ for any $s' \in S$. Hence $s \in S^*$. In other words, $S^*(a, b) \subset S^*$. \square

Proof of Theorem 3.2. Let $\bar{a} = \min \{a(s) | s \in S\}$ and $\bar{b} = \max \{b(s) | s \in S\}$. Let $a < \bar{a}$ and $b > \bar{b}$. Now for each $s \in S$,

$$\begin{aligned}
 P(s, a, b) &= P[H(s) \leq \Theta(a, b)] \\
 &= \int_{a(s)}^{b(s)} \int_h^b F_\theta(d\theta) F_{H(s)}(dh) \\
 &= \int_{a(s)}^{b(s)} \frac{(b-h)}{b-a} F_{H(s)}(dh)
 \end{aligned}$$

$$\begin{aligned}
&= \frac{b}{b-a} \int_{a(s)}^{b(s)} F_{H(s)}(dh) - \frac{1}{b-a} \int_{a(s)}^{b(s)} h F_{H(s)}(dh) \\
&= \frac{1}{b-a} \{b - E[H(s)]\} = \frac{1}{b-a} \{b - g(s)\}.
\end{aligned}$$

Hence

$$P(s, a, b) - P(s', a, b) = \frac{1}{b-a} \{g(s') - g(s)\}.$$

Therefore $g(s) \leq g(s')$ if and only if $P(s, a, b) \geq P(s', a, b)$. Hence $S^*(a, b) = S^*$. \square

The following proposition is needed in the proof of Theorem 5.1.

PROPOSITION A.1. *The stationary Markov chain $\{X_k\}$ defined by (4.1) with $M_k = M$ is irreducible and aperiodic.*

Proof. The irreducibility follows from Assumption A1, Definition 4.2, (4.1), and conclusion (2) in Theorem 3.1. The aperiodicity follows from (4.1) and conclusion (2) in Theorem 3.1. \square

Proof of Theorem 5.1. It follows from Theorem 3.1 and (5.1) that $\pi_s(M) > 0$ for each $s \in S$, and that

$$(A6) \quad \|\pi(M)\| = \sum_{s \in S} \pi_s(M) = 1$$

where $\|\cdot\|$ denotes the ℓ_1 -norm.

It follows from Assumption A2, (5.1), and (4.1) that for every pair (s, s') of neighbors, $s' \in N(s)$,

$$\frac{\pi_s(M)}{\pi_{s'}(M)} = \frac{\{P(s, a, b)\}^M}{\{P(s', a, b)\}^M} = \frac{R(s', s)\{P(s, a, b)\}^M}{R(s, s')\{P(s', a, b)\}^M} = \frac{P_{s's}(M)}{P_{ss'}(M)}$$

and that

$$(A7) \quad \pi_s(M) P_{ss'}(M) = \pi_{s'}(M) P_{s's}(M).$$

Observe that this equation trivially holds when $s = s'$ and even when s and s' are not neighbors to each other, in which case $P_{ss'}(M) = P_{s's}(M) = 0$. In other words, (A7) is valid for any s and s' in S . It now follows from (A7) that

$$(A8) \quad \pi_{s'}(M) = \sum_{s \in S} \pi_s(M) P_{s's}(M) = \sum_{s \in S} \pi_s(M) P_{ss'}(M).$$

By virtue of [6, Thms. III.2.2 and III.2.1], we conclude from (A6) and (A8) that $\{\pi_s(M) | s \in S\}$ is indeed the stationary probability distribution. \square

Proof of Proposition 6.1. Consider $\pi_s(M)$ as a function of a real variable M . Then π_s is differentiable with respect to M . Noting $d\alpha^M/dM = \alpha^M \ln \alpha$ and working out the details, we arrive at

$$\frac{d\pi_s(M)}{dM} = \left\{ \sum_{s' \in S} \left[\frac{P(s', a, b)}{P(s, a, b)} \right]^M \ln \left[\frac{P(s, a, b)}{P(s', a, b)} \right] \right\} \{\pi_s(M)\}^2$$

Suppose that $s \in S^*(a, b)$. Then $\ln [P(s, a, b)/P(s', a, b)] = 0$ for all $s' \in S^*(a, b)$ so that

$$\frac{d\pi_s(M)}{dM} = \left\{ \sum_{s' \in S - S^*(a, b)} \left[\frac{P(s', a, b)}{P(s, a, b)} \right]^M \ln \left[\frac{P(s, a, b)}{P(s', a, b)} \right] \right\} \{\pi_s(M)\}^2.$$

Furthermore, for any $s' \in S - S^*(a, b)$, $\ln [P(s, a, b)/P(s', a, b)] > 0$, so that $d\pi_s(M)/dM > 0$ for any $M > 0$. This implies conclusion (1).

Suppose that $s \notin S^*(a, b)$. Then

$$\begin{aligned} \frac{d\pi_s(M)}{dM} = & \left\{ \sum_{P(s,a,b) > P(s',a,b)} \left[\frac{P(s', a, b)}{P(s, a, b)} \right]^M \ln \left[\frac{P(s, a, b)}{P(s', a, b)} \right] \right. \\ & \left. - \sum_{P(s,a,b) < P(s',a,b)} \left[\frac{P(s', a, b)}{P(s, a, b)} \right]^M \ln \left[\frac{P(s', a, b)}{P(s, a, b)} \right] \right\} \{\pi_s(M)\}^2. \end{aligned}$$

Observe that the first term monotonically decreases to zero while the second term monotonically increases to infinity in magnitude as M goes to infinity. Hence $d\pi_s(M)/dM$ monotonically decreases to negative infinity. In other words, there exists a real M_s such that $d\pi_s(M)/dM < 0$ for any $M \geq M_s$. This implies conclusion (2). \square

Proof of Theorem 7.1. Let c, σ, k_0 be chosen as above. Then $\mu(a, b) \geq 1/\sigma$. Now if s and s' are neighbors to each other in S , then it follows from (4.1), (7.7), and (7.8) that

$$P_{ss'}(M_k) \geq \rho \left(\frac{1}{\sigma} \right)^{M_k}.$$

It also follows from (4.1) that $P_{ss}(M_k)$ monotonically increases as k increases for each $s \in S$. Since $(1/\sigma)^{M_k}$ monotonically decreases as k increases, there exists an integer k^* such that

$$P_{ss}(M_k) \geq \rho \left(\frac{1}{\sigma} \right)^{M_k}, \quad \forall k \geq k^*, \quad \forall s \in S.$$

Let $P(\ell, k)$ denote the transition probability matrix from iteration ℓ to iteration $k > \ell$. Then

$$P(\ell, k) = \prod_{i=\ell}^{k-1} P(M_i).$$

Recalling that after r iterations there is at least one path in the graph from the center \hat{s} to any $s \in S$, we observe that the entries in the column of $P(\ell, k)$ corresponding to the center \hat{s} satisfy for any $k \geq k^* + r$

$$(A9) \quad P_{s\hat{s}}(k-r, k) \geq \prod_{i=k-r}^{k-1} \left\{ \rho \left(\frac{1}{\sigma} \right)^{M_i} \right\} \geq \rho^r \left(\frac{1}{\sigma} \right)^{rM_{k-1}}, \quad \forall s \in S.$$

Let k be a multiple of r , i.e., $k = mr$. Then it follows from (7.3) and (A9) that the coefficient of ergodicity for $P(mr-r, mr)$ satisfies

$$\begin{aligned} \alpha(P(mr-r, mr)) &= \min_{s, s'} \sum_{s'' \in S} \min \{P_{ss''}(mr-r, mr), P_{s's''}(mr-r, mr)\} \\ &\geq \min_{s, s'} \min \{P_{s\hat{s}}(mr-r, mr), P_{s'\hat{s}}(mr-r, mr)\} \\ &\geq \rho^r \left(\frac{1}{\sigma} \right)^{rM_{mr-1}}, \quad \forall m \geq \frac{1}{r}(k^* + r). \end{aligned}$$

Let m^* be the smallest integer satisfying $m^* \geq (1/r)(k^* + r)$. It now follows from (7.9)

that $M_k \leq c \log_\sigma(k + k_0 + 1)$ and

$$\left(\frac{1}{\sigma}\right)^{M_k} \geq \frac{1}{(k + k_0 + 1)^c}$$

so that

$$\left(\frac{1}{\sigma}\right)^{rM_{mr-1}} \geq \frac{1}{(mr + k_0)^{cr}}.$$

Therefore

$$\sum_{m=m^*}^{\infty} \alpha(P(mr - r, mr)) \geq \sum_{m=m^*}^{\infty} \rho^r \frac{1}{(mr + k_0)^{cr}}.$$

The right-hand side goes to infinity since $0 < cr \leq 1$. It now follows from [6, Thm. V.3.2] that the Markov chain $\{X_k\}$ is weakly ergodic. \square

Proof of Lemma 7.1. It follows from Proposition 6.1 that there exists an integer k^* such that for any $k \geq k^*$,

$$\begin{aligned} \pi_s(M_{k+1}) &\geq \pi_s(M_k), \quad \forall s \in S^*(a, b), \\ \pi_s(M_{k+1}) &\leq \pi_s(M_k), \quad \forall s \notin S^*(a, b). \end{aligned}$$

Hence, for any $k \geq k^*$,

$$\|\pi(M_{k+1}) - \pi(M_k)\| = \sum_{s \in S^*(a, b)} [\pi_s(M_{k+1}) - \pi_s(M_k)] - \sum_{s \notin S^*(a, b)} [\pi_s(M_{k+1}) - \pi_s(M_k)].$$

Noting

$$\sum_{s \in S^*(a, b)} \pi_s(M_k) + \sum_{s \notin S^*(a, b)} \pi_s(M_k) = \|\pi(M_k)\| = 1,$$

we conclude that for any $k \geq k^*$

$$\|\pi(M_{k+1}) - \pi(M_k)\| = 2 \sum_{s \in S^*(a, b)} [\pi_s(M_{k+1}) - \pi_s(M_k)].$$

Hence, for any $\ell \geq k^*$,

$$\begin{aligned} \sum_{k=k^*}^{\ell} \|\pi(M_{k+1}) - \pi(M_k)\| &= 2 \sum_{s \in S^*(a, b)} [\pi_s(M_{\ell+1}) - \pi_s(M_{k^*})] \\ &\leq 2 \sum_{s \in S^*(a, b)} \pi_s(M_{\ell+1}) \leq 2. \end{aligned} \quad \square$$

Proof of Theorem 7.2. It follows from Theorem 7.1 that the Markov chain is weakly ergodic. It now follows from (5.1), Theorem 5.1, Lemma 7.1, Theorem 6.1, and [6, Thm. V.4.3] that the Markov chain is strongly ergodic and that conclusions (1) and (2) hold. \square

Proof of Lemma 8.1. Let $s \in S$ and $0 \leq \ell \leq k$ be fixed

$$\begin{aligned} &\sum_{s' \in S} |P_{ss'}(0, k) - \pi_{s'}^*| \\ &= \sum_{s' \in S} \left| \sum_{\bar{s} \in S} P_{s\bar{s}}(0, \ell) P_{\bar{s}s'}(\ell, k) - \pi_{s'}^* \right| \\ (A10) \quad &= \sum_{s' \in S} \left| \sum_{\bar{s} \in S} [P_{s\bar{s}}(0, \ell) - \pi_{\bar{s}}^*] P_{\bar{s}s'}(\ell, k) + \sum_{\bar{s} \in S} \pi_{\bar{s}}^* P_{\bar{s}s'}(\ell, k) - \pi_{s'}^* \right| \\ &\leq \sum_{s' \in S} \left| \sum_{\bar{s} \in S} [P_{s\bar{s}}(0, \ell) - \pi_{\bar{s}}^*] P_{\bar{s}s'}(\ell, k) \right| + \sum_{s' \in S} \left| \sum_{\bar{s} \in S} \pi_{\bar{s}}^* P_{\bar{s}s'}(\ell, k) - \pi_{s'}^* \right|. \end{aligned}$$

Consider the first term of the last expression of (A10).

$$\begin{aligned}
 \sum_{\bar{s} \in S} [P_{s\bar{s}}(0, \ell) - \pi_{\bar{s}}^*] &= \sum_{\bar{s} \in S} P_{s\bar{s}}(0, \ell) - \sum_{\bar{s} \in S} \pi_{\bar{s}}^* = 1 - 1 = 0, \\
 \sum_{s' \in S} \left| \sum_{\bar{s} \in S} [P_{s\bar{s}}(0, \ell) - \pi_{\bar{s}}^*] P_{\bar{s}s'}(\ell, k) \right| \\
 &= \max_{s'' \in S} \sum_{s' \in S} \left| \sum_{\bar{s} \in S} [P_{s\bar{s}}(0, \ell) - \pi_{\bar{s}}^*] [P_{s''s'}(\ell, k) - P_{\bar{s}s'}(\ell, k)] \right| \\
 &\leq \sum_{\bar{s} \in S} \left| P_{s\bar{s}}(0, \ell) - \pi_{\bar{s}}^* \right| \max_{s'' \in S} \sum_{s' \in S} |P_{s''s'}(\ell, k) - P_{\bar{s}s'}(\ell, k)| \\
 &\leq \sum_{\bar{s} \in S} |P_{s\bar{s}}(0, \ell) - \pi_{\bar{s}}^*| \max_{\bar{s}, s'' \in S} \sum_{s' \in S} |P_{s''s'}(\ell, k) - P_{\bar{s}s'}(\ell, k)| \\
 &\leq 4\delta(P(\ell, k)),
 \end{aligned}
 \tag{A11}$$

where the last inequality follows from (7.4) and

$$\sum_{\bar{s} \in S} |P_{s\bar{s}}(0, l) - \pi_{\bar{s}}^*| \leq 2.$$

Now consider the second term of the last expression of (A10). To find a bound on that term, we take advantage of the matrix norm induced by the vector ℓ_1 -norm $\| \cdot \|$ as follows:

$$\|A\| = \max_i \sum_j |a_{ij}|,$$

where $A = (a_{ij})$. Observe that $\|xA\| \leq \|x\| \|A\|$.

Let Q be the $\kappa \times \kappa$ matrix whose rows are all π^* . Let Q_k be the $\kappa \times \kappa$ matrix whose rows are all $\pi(M_k)$ for $k = 0, 1, 2, \dots$. Then

$$\begin{aligned}
 \sum_{s' \in S} \left| \sum_{\bar{s} \in S} \pi_{\bar{s}}^* P_{\bar{s}s'}(\ell, k) - \pi_{s'}^* \right| \\
 &= \|QP(\ell, k) - Q\| \\
 &\leq \|QP(\ell, k) - Q_\ell P(\ell, k)\| + \|Q_\ell P(\ell, k) - Q_k\| + \|Q_k - Q\|.
 \end{aligned}
 \tag{A12}$$

Since $\|P(\ell, k)\| = 1$, we find

$$\|QP(\ell, k) - Q_\ell P(\ell, k)\| = \|Q - Q_\ell\| \|P(\ell, k)\| = \|Q - Q_\ell\|.$$

It follows from (5.2) that

$$\pi(M_i)P(M_i) = \pi(M_i), \quad \forall i, \tag{A14}$$

$$Q_i P(i, i+1) = Q_i P(M_i) = Q_i, \quad \forall i. \tag{A15}$$

Suppose $k > \ell$. Then it follows from (A15) that

$$\begin{aligned}
 Q_\ell P(\ell, k) &= Q_\ell P(\ell, \ell+1)P(\ell+1, k) = Q_\ell P(\ell+1, k) \\
 &= (Q_\ell - Q_{\ell+1})P(\ell+1, k) + Q_{\ell+1}P(\ell+1, k).
 \end{aligned}$$

We may continue this process and obtain

$$Q_\ell P(\ell, k) = \sum_{i=\ell}^{k-1} (Q_i - Q_{i+1})P(i+1, k) + Q_k.$$

Observe that this equality holds even when $k = \ell$. It now follows that

$$\|Q_\ell P(\ell, k) - Q_k\| = \left\| \sum_{i=\ell}^{k-1} (Q_i - Q_{i+1})P(i+1, k) \right\| \leq \sum_{i=\ell}^{k-1} \|Q_i - Q_{i+1}\|. \tag{A16}$$

Collecting (A12), (A13), and (A16), we arrive at

$$\begin{aligned}
 (A17) \quad & \sum_{s' \in S} \left| \sum_{\bar{s} \in S} \pi_{\bar{s}}^* P_{\bar{s}s'}(\ell, k) - \pi_{s'}^* \right| \\
 & \leq \|Q - Q_\ell\| + \sum_{i=\ell}^{k-1} \|Q_i - Q_{i+1}\| + \|Q_k - Q\| \\
 & = \|\pi^* - \pi(M_\ell)\| + \sum_{i=\ell}^{k-1} \|\pi(M_i) - \pi(M_{i+1})\| + \|\pi(M_k) - \pi^*\|.
 \end{aligned}$$

Now (8.3) follows from (A10), (A11), and (A17). \square

Proof of Proposition 8.1. It follows from Proposition 6.1 that there exists an integer \hat{k} such that for any $k \geq \hat{k}$,

$$\pi_s(M_{k+1}) \geq \pi_s(M_k), \quad \forall s \in S^*(a, b),$$

$$\pi_s(M_{k+1}) \leq \pi_s(M_k), \quad \forall s \notin S^*(a, b).$$

Hence, recalling $\pi^* = \lim_{k \rightarrow \infty} \pi_s(M_k)$, we obtain for any integers $\ell \geq \hat{k}$ and $k \geq \ell$.

$$\begin{aligned}
 & \|\pi^* - \pi(M_\ell)\| + \sum_{i=\ell}^{k-1} \|\pi(M_i) - \pi(M_{i+1})\| + \|\pi(M_k) - \pi^*\| \\
 &= \sum_{s \in S^*(a, b)} \left\{ |\pi_s^* - \pi_s(M_\ell)| + \sum_{i=\ell}^{k-1} |\pi_s(M_{i+1}) - \pi_s(M_i)| + |\pi_s^* - \pi_s(M_k)| \right\} \\
 & \quad + \sum_{s \notin S^*(a, b)} \left\{ |\pi_s(M_\ell) - \pi_s^*| + \sum_{i=\ell}^{k-1} |\pi_s(M_i) - \pi_s(M_{i+1})| + |\pi_s(M_k) - \pi_s^*| \right\} \\
 &= 2 \left\{ \sum_{s \in S^*(a, b)} [\pi_s^* - \pi_s(M_\ell)] + \sum_{s \notin S^*(a, b)} [\pi_s(M_\ell) - \pi_s^*] \right\} \\
 &\leq 2 \left\{ 1 - \sum_{s \in S^*(a, b)} \pi_s(M_\ell) + \sum_{s \notin S^*(a, b)} \pi_s(M_\ell) \right\} \\
 &= 4 \left\{ 1 - \sum_{s \in S^*(a, b)} \pi_s(M_\ell) \right\}.
 \end{aligned}$$

Now it follows from (5.1) that

$$\begin{aligned}
 & 1 - \sum_{s \in S^*(a, b)} \pi_s(M_\ell) \\
 &= 1 - \sum_{s \in S^*(a, b)} \frac{\{P(s, a, b)\}^{M_\ell}}{\sum_{s' \in S} \{P(s', a, b)\}^{M_\ell}} \\
 &= \frac{\sum_{s \notin S^*(a, b)} \{P(s, a, b)\}^{M_\ell}}{\sum_{s \in S^*(a, b)} \{P(s, a, b)\}^{M_\ell} + \sum_{s \notin S^*(a, b)} \{P(s, a, b)\}^{M_\ell}} \\
 &\leq \frac{\sum_{s \notin S^*(a, b)} \{P(s, a, b)\}^{M_\ell}}{\sum_{s \in S^*(a, b)} \{P(s, a, b)\}^{M_\ell}} \\
 &= \frac{\sum_{s \notin S^*(a, b)} \{P(s, a, b)\}^{M_\ell}}{|S^*(a, b)| \{P_{\max}(a, b)\}^{M_\ell}}
 \end{aligned}$$

$$\begin{aligned}
&\leq \frac{1}{|S^*(a, b)|} \sum_{s \notin S^*(a, b)} \left\{ \frac{P_{\text{sec}}(a, b)}{P_{\text{max}}(a, b)} \right\}^{M_\ell} \\
&= \frac{|S - S^*(a, b)|}{|S^*(a, b)|} \left(\frac{1}{\sigma} \right)^{\eta M_\ell}.
\end{aligned}$$

It now follows from the selection (7.9) for M_ℓ that

$$\left(\frac{1}{\sigma} \right)^{M_\ell} \leq \frac{\sigma}{(\ell + k_0 + 1)^c}.$$

Hence we arrive at (8.7). \square

Proof of Proposition 8.2. According to the proof of Theorem 7.1, there exists an m^* such that for any $m \geq m^*$,

$$\alpha(P((m-1)r, mr)) = 1 - \delta(P((m-1)r, mr)) \leq \rho^r / (mr + k_0)^{cr}.$$

Suppose that k is an integer multiple of integer r , i.e., $k = mr$, so that $\text{trunc}[\sqrt{m}] \geq m^*$. Let $\ell = \text{trunc}[\sqrt{m}]r - r$ and $\bar{m} = \text{trunc}[\sqrt{m}]$. Then it follows from [6, Lemma V.2.3, p. 145] that

$$\begin{aligned}
\delta(P(\ell, k)) &= \delta(P(\text{trunc}[\sqrt{m}]r - r, mr)) \leq \prod_{i=\bar{m}}^m \delta(P((i-1)r, ir)) \\
&\leq \prod_{i=\bar{m}}^m \left\{ 1 - \frac{\rho^r}{(ir + k_0)^{cr}} \right\} \\
&= \prod_{i=\bar{m}}^m \left\{ 1 - \frac{(\rho/r^c)^r}{[i + (k_0/r)]^{rc}} \right\} \\
&\leq \prod_{i=\bar{m}}^m \exp \left\{ -\frac{2\hat{t}}{[i + (k_0/r)]^{rc}} \right\},
\end{aligned}$$

where the last inequality is derived from $1 + y \leq e^y$. Since $rc \leq 1$, we obtain

$$\delta(P(\ell, k)) \leq \exp \left\{ -2\hat{t} \sum_{i=\bar{m}}^m \frac{1}{[i + (k_0/r)]} \right\} \leq \left\{ \frac{\sqrt{m} + (k_0/r)}{m + k_0/r} \right\}^{2\hat{t}},$$

where the last inequality follows from the fact that

$$\sum_{i=n_1}^{n_2} \frac{1}{i} \geq \int_{n_1}^{n_2} \frac{1}{x} dx = \ln \left(\frac{n_2}{n_1} \right)$$

for any positive integers n_1 and $n_2 \geq n_1$.

The conclusion now follows from the above inequality. \square

Proof of Proposition 8.3. Suppose $k = mr$ and $\ell = \text{trunc}[\sqrt{m}]r - r$ are sufficiently large so that (8.7) holds. Then

$$\begin{aligned}
&\|\pi^* - \pi(M_\ell)\| + \sum_{i=\ell}^{k-1} \|\pi(M_i) - \pi(M_{i+1})\| + \|\pi(M_k) - \pi^*\| \\
&\leq 4 \frac{|S - S^*(a, b)|}{|S^*(a, b)|} \sigma^\eta \frac{1}{(\ell + k_0 + 1)^{\eta c}} \\
&\leq 4 \frac{|S - S^*(a, b)|}{|S^*(a, b)|} \sigma^\eta \frac{(1/r)^{\eta c}}{\left(\sqrt{m} + \frac{k_0 + 1}{r} - 1 \right)^{\eta c}} = O(1/m^{\bar{t}})
\end{aligned}$$

for a large m . \square

INVESTMENT-CONSUMPTION MODELS WITH TRANSACTION FEES AND MARKOV-CHAIN PARAMETERS*

THALEIA ZARIPHOUPOULOU†

Abstract. This paper considers an infinite horizon investment-consumption model in which a single agent consumes and distributes his wealth in two assets, a bond and a stock. The problem of maximization of the total utility from consumption is treated. State (amount allocated in assets) and control (consumption, rates of trading) constraints are present. It is shown that the value function is the unique viscosity solution of a system of variational inequalities with gradient constraints.

Key words. viscosity solutions, state constraints, variational inequalities, singular controls

AMS(MOS) subject classification. 90A35

Introduction. In this paper we examine a general investment and consumption decision problem for a single agent. The investor consumes at a nonnegative rate and he distributes his current wealth between two assets continuously in time. One asset is a bond, i.e., a riskless security with instantaneous rate of return r . The other asset is a stock, whose rate of return z_t is a continuous time Markov chain. In our version of the model the investor *cannot borrow* money to finance his investment in bond and he *cannot short-sell* the stock. In other words, the amount of money allocated in bond and stock must stay nonnegative.

When the investor makes a transaction, he pays transaction fees which are assumed to be proportional to the amount transacted. More specifically, let x_t and y_t be the investor's holdings in the riskless and the risky security prior to a transaction at time t . If the investor increases (or decreases) the amount invested in the risky asset to $y_t + h_t$ (or $y_t - h_t$), the holding of the riskless asset decreases (increases) to $x_t - h_t - \lambda h_t$ (or $x_t + h_t - \mu h_t$). The numbers λ and μ are assumed to be nonnegative and one of them must always be positive. The control objective is to maximize, in an infinite horizon, the expected discounted utility which comes only from consumption. Due to the presence of the transaction fees, this is a singular control problem.

The paper is organized as follows. Section 1 is devoted to the description of the model and its history; the two main theorems are also stated here. Section 2 contains preliminaries about the value function. In § 3 we approximate the problem by using absolutely continuous controls. Finally, in § 4 we show that the value function is the unique constrained viscosity solution of a system of Variational Inequalities with gradient constraints.

1. We consider a market with two assets: a *bond* and a *stock*. The price P_t^0 of the bond is given by

$$(1.1) \quad \begin{aligned} dP_t^0 &= rP_t^0 dt, \\ P_0^0 &= p_0, \end{aligned}$$

where $r > 0$. The price P_t of the stock satisfies

$$(1.2) \quad \begin{aligned} dP_t &= z(t)P_t dt, \\ P_0 &= p. \end{aligned}$$

† Department of Mathematical Sciences, Worcester Polytechnic Institute, Worcester, Massachusetts 01609. This work was partially supported by National Science Foundation Research planning grant 530177.

The rate of return z is a *finite state continuous time Markov chain*, defined on some underlying probability space (Ω, F, P) with jumping rate $q_{zz'}$ from state z to state z' . The state space is denoted by Z . The associated generator \mathcal{L} of the Markov chain has the form

$$\mathcal{L}v(z) = \sum_{z' \neq z} q_{zz'}[v(z') - v(z)].$$

Let $K = \max_{z \in Z} z$. A natural assumption is $K \geq r$. The amount of wealth x_t and y_t , invested at time t in bond and stock respectively, are the state variables and they evolve (see [17]) according to the equations

$$\begin{aligned} dx_t &= (rx_t - C_t) dt - (1 + \lambda) dM_t + (1 - \mu) dN_t, \\ dy_t &= z(t)y_t dt + dM_t - dN_t, \\ x_0 &= x, y_0 = y, z(0) = z. \end{aligned} \quad (1.3)$$

For simplicity we assume here that all financial charges are paid from the holdings in bond. The investor cannot borrow money or short-sell the stock. The control processes are the *consumption rate* C_t and the processes M_t and N_t which represent the *cumulative purchases* and *sales of stock* respectively. The controls (C_t, M_t, N_t) are *admissible* if

(i) C_t is F_t -measurable, where $F_t = \sigma(z_s : 0 \leq s \leq t)$, $C_t \geq 0$ almost everywhere for all $t \geq 0$, and $E \int_0^\infty e^{-rs} C_s ds < +\infty$.

(ii) M_t, N_t are F_t -measurable, right continuous, and nondecreasing processes.

(iii) $x_t \geq 0, y_t \geq 0$ almost everywhere for all $t \geq 0$, where x_t, y_t are the trajectories given by the state equation (1.3) using the controls (C_t, M_t, N_t) . We denote by A the set of admissible controls.

The total expected discounted utility J coming from consumption is given by

$$J(x, y, z, C, M, N) = E \int_0^{+\infty} e^{-\beta t} U(C_t) dt$$

with $(C, M, N) \in A$ and $z(0) = z$, where the utility function $U : [0, +\infty) \rightarrow [0, +\infty)$ is assumed to have the following properties:

U is strictly increasing, bounded, concave, C^1 function,

and

$$U(0) = 0, \lim_{c \rightarrow 0} U'(c) = +\infty, \lim_{c \rightarrow \infty} U'(c) = 0.$$

The discount factor $\beta > 0$ weights consumption now versus consumption later, large β denoting instant gratification. Note that the controls M and N are acting implicitly through the constraint (iii).

The value function u is given by

$$u(x, y, z) = \sup_A E \int_0^{+\infty} e^{-\beta t} U(C_t) dt.$$

Our goal is to derive the Bellman equation associated with this singular control problem and to characterize u as its unique solution. It turns out that the Bellman equation here is a system of variational inequalities.

We now state one of the main results. (For the definition of constrained viscosity solution, see Definition 3.1.)

THEOREM. *The value function u is the unique constrained viscosity solution of*

$$(1.4) \quad \begin{aligned} & \min [(1+\lambda)u_x - u_y, -(1-\mu)u_x + u_y, \\ & \beta u - rxu_x - zuu_y - \max_{c \geq 0} [-cu_x + U(c)] - \mathcal{L}u(z)] = 0 \\ & \forall (x, y, z) \in (0, +\infty) \times (0, +\infty) \times Z \end{aligned}$$

with

$$u(0, 0, z) = 0, \quad \forall z \in Z,$$

in the class of bounded and uniformly continuous functions.

We continue with a discussion about the history of the model.

Transaction costs are an essential feature of some economic theories, and many times are incorporated in the two-asset portfolio selection model. In [3] Constantinides assumes that the transaction costs deplete only the riskless asset and that the stock price is a logarithmic Brownian motion. He shows that if an optimal policy exists, it has to be *simple*. An investment policy is defined as simple if it is characterized by two reflecting barriers $\bar{\lambda}, \bar{\lambda}$ with $\bar{\lambda} \leq \bar{\lambda}$, such that the investor does not trade as long as the ratio y_t/x_t lies in $[\bar{\lambda}, \bar{\lambda}]$, and transacts to the closest boundary of the region of no transactions $[\bar{\lambda}, \bar{\lambda}]$ whenever this ratio lies outside this interval. He also shows that proportional transaction costs have only a second-order effect on equilibrium asset returns: the investors accommodate large transaction costs by drastically reducing the frequency and the volume of trade. Finally, he proves that the investor's expected utility of consumption is insensitive to deviations of the asset proportions from those proportions that are optimal in the absence of transaction costs. In a discrete-time version of the model, Constantinides [2], [3] proves that an optimal investment policy exists and it is simple.

In the continuous time framework, Taksar, Klass, and Assaf [16] assume that the investor does not consume but maximizes the long term expected rate of growth of wealth. In the same framework, but with more general assumptions, Fleming et al. [6] study the finite horizon problem, the average cost per unit time problem, and the growth problem and their relation.

Davis and Norman [5] relax the assumption that the transaction costs are charged only to the nonrisky asset. They consider a particular class of utility functions of the form $U(c) = c^p$ ($0 < p < 1$), and they prove that the optimal strategy confines the investor's portfolio to a certain wedge-shaped region in the portfolio plane.

Finally, there are several directions in which the two-asset problem with transaction costs can be extended. First, more than one risky asset can be allowed. Although this extension is straightforward, the computational requirements are enormous. Second, fixed transaction costs can be introduced. Some single-period models with fixed transaction costs are discussed in [1], [8], [11]–[14]. In multiperiod extensions of these models the optimal investment policy is complex, because the derived value function $u(x, y)$ is no longer homogeneous in x and y . Kandel and Ross [10] introduce quasifixed transaction costs. They use some aspects of fixed transaction costs and prove the homogeneity of the derived value function.

2. We examine some of the properties of the value function. Throughout the paper we assume

$$(2.1) \quad \beta > 2K + 1.$$

PROPOSITION 2.1. *For each $z \in Z$, u is jointly concave in x and y , strictly increasing in x , and increasing in y .*

Proof. Consider two points (x_1, y_1, z) , (x_2, y_2, z) . Let $\varepsilon > 0$ and $(C_1^\varepsilon, M_1^\varepsilon, N_1^\varepsilon)$, $(C_2^\varepsilon, M_2^\varepsilon, N_2^\varepsilon)$ be ε -optimal controls for these points respectively. Then

$$u(x_1, y_1, z) \leq E \int_0^{+\infty} e^{-\beta t} U(C_1^\varepsilon) dt + \varepsilon$$

and

$$u(x_2, y_2, z) \leq E \int_0^{+\infty} e^{-\beta t} U(C_2^\varepsilon) dt + \varepsilon.$$

Moreover, the policy $(\alpha C_1^\varepsilon + (1-\alpha)C_2^\varepsilon, \alpha M_1^\varepsilon + (1-\alpha)M_2^\varepsilon, \alpha N_1^\varepsilon + (1-\alpha)N_2^\varepsilon)$ is admissible for the point $(\alpha x_1 + (1-\alpha)x_2, \alpha y_1 + (1-\alpha)y_2, z)$. Therefore $u(\alpha x_1 + (1-\alpha)x_2, \alpha y_1 + (1-\alpha)y_2, z) \leq E \int_0^{+\infty} e^{-\beta t} U(\alpha C_1^\varepsilon + (1-\alpha)C_2^\varepsilon) dt$. Using the concavity of U , the inequalities above and sending $\varepsilon \rightarrow 0$ we conclude.

We now show that $u(\cdot, \cdot, z)$ is increasing. Consider the points (x_1, y_1, z) and (x_2, y_2, z) with $x_1 \leq x_2$, $y_1 \leq y_2$. Let $\varepsilon > 0$ and $(C^\varepsilon, M^\varepsilon, N^\varepsilon)$ be an ε -optimal policy for (x_1, y_1, z) . Since the policy $(C^\varepsilon, M^\varepsilon, N^\varepsilon)$ is admissible for the point (x_2, y_2, z) , we have

$$u(x_1, y_1, z) \leq u(x_2, y_2, z) + \varepsilon.$$

Sending $\varepsilon \rightarrow 0$ yields that $u(x_1, y_1, z) \leq u(x_2, y_2, z)$.

Finally, we show that $u(\cdot, y, z)$ is strictly increasing. To this end, let us suppose that there exist two points (x_1, y, z) and (x_2, y, z) such that $x_1 < x_2$ and $u(x_1, y, z) = u(x_2, y, z)$. Then $u(x, y, z) = u(x_1, y, z)$, for all $x \in [x_1, x_2]$. Since u is concave and nondecreasing, the interval $[x_1, x_2]$ cannot be finite. Therefore there exists a point $x_0 \geq 0$ such that $u(x, y, z) = u(x_0, y, z)$, for all $x \geq x_0$. Let $(C^\varepsilon, M^\varepsilon, N^\varepsilon)$ be an ε -optimal policy for (x_0, y, z) . Then

$$u(x_0, y, z) \leq E \int_0^{+\infty} e^{-\beta t} U(C_t^\varepsilon) dt + \varepsilon.$$

However, if $x_1 > \max(x_0, (U^{-1}[\beta(E \int_0^{+\infty} e^{-\beta t} U(C_t^\varepsilon) dt + \varepsilon)]/r)$, the policy $(rx_1, 0, 0)$ is admissible for (x_1, y, z) . Therefore

$$u(x_0, y, z) < \frac{1}{\beta} U(rx_1) = E \int_0^{+\infty} e^{-\beta t} U(rx_1) dt \leq u(x_1, y, z),$$

which contradicts our assumption. \square

PROPOSITION 2.2. *The value function u is uniformly continuous on $\bar{\Omega} = \{(x, y): x \geq 0, y \geq 0\}$.*

Proof. We first show that u is continuous on $\bar{\Omega}$. The value function is continuous in Ω , because it is concave. As a matter of fact, u is Lipschitz continuous in Ω with Lipschitz constant of order $\beta^{-1} \|U\|_\infty |(x, y)|^{-1}$.

We next show that u is continuous on the boundary. We start with the point $(0, 0)$. Since $u(0, 0, z) = 0$ (this is an immediate consequence of the assumptions in the model), we argue by contradiction.

Let us assume that for some fixed $z_0 \in Z$ there exists a positive constant M such that $\lim_{(x,y) \rightarrow (0,0)} u(x, y, z_0) = M$. Then there exists a sequence $(x_n, y_n) \rightarrow 0$ such that $u(x_n, y_n, z_0) > M/2$, for all $n \in N$. If (C^n, M^n, N^n) is an ε -optimal policy for the point (x_n, y_n, z_0) and (x_t^n, y_t^n) is the corresponding trajectory, let $w_t^n = x_t^n + (1-\mu)y_t^n$ and $w^n = x_n + (1-\mu)y_n$. Since the process M_t^n is nondecreasing we get

$$dw_t^n \leq (r + K)w_t^n dt - C_t^n dt$$

and

$$E \int_0^t e^{-\beta s} C_s^n ds \leq w^n - E[e^{\beta t} w_t^n] \leq w^n,$$

where we used (2.1) and $w_t^n \geq 0$, almost everywhere for all $t \geq 0$. From Jensen's inequality we have

$$u(x_n, y_n, z_0) - \varepsilon \leq E \int_0^{+\infty} e^{-\beta t} U(C_t^n) dt \leq \frac{1}{\beta} U(\beta w^n).$$

Sending $n \rightarrow \infty$ and using that $U(0) = 0$, we get

$$0 < \frac{M}{2} < \varepsilon.$$

Sending $\varepsilon \rightarrow 0$ we get a contradiction.

We now show that $\lim_{(x,y) \rightarrow (x_0,0)} u(x, y, z) = u(x_0, 0, z)$, for all $z \in Z$. As a matter of fact, it will be an immediate consequence of the proof that $\lim_{y \rightarrow 0} u(x, y, z) = u(x, 0, z)$ uniformly with respect to x . Consider a point $(x_0, 0, z)$ with $x_0 > 0$ fixed and a sequence (x^n, y^n, z) such that $x^n, y^n > 0$ and $\lim_{n \rightarrow \infty} (x^n, y^n) = (x_0, 0)$. Since u is locally Lipschitz it suffices to show that $\lim_{n \rightarrow \infty} |u(x_0, y^n, z) - u(x_0, 0, z)| = 0$. Finally, since u is increasing, we only need to show that $u(x_0, y^n, z) \leq u(x_0, 0, z) + \varepsilon$ for any $\varepsilon > 0$ and n sufficiently large.

Let (C^n, M^n, N^n) be an ε -optimal policy at (x_0, y^n, z) . Then

$$u(x_0, y^n, z) \leq E \int_0^{+\infty} e^{-\beta t} U(C_t^n) dt + \varepsilon.$$

Moreover, the control (C^n, \bar{M}^n, N^n) , where $d\bar{M}_t^n = dM_t^n + y^n \delta_0(t)$, is admissible for $(x_0 + (1 + \lambda)y^n, 0, z)$. Therefore

$$E \int_0^{+\infty} e^{-\beta t} U(C_t^n) dt \leq u(x_0 + (1 + \lambda)y^n, 0, z).$$

Combining the last two inequalities, we conclude. Note that all the above arguments were uniform with respect to x_0 .

We next show that $\lim_{(x,y) \rightarrow (0,y_0)} u(x, y, z) = u(0, y_0, z)$, $\forall z \in Z$. Moreover, it will be an immediate consequence of the proof that $\lim_{(x,y) \rightarrow (0,y_0)} u(x, y, z) = u(0, y_0, z)$, uniformly with respect to y .

Let $(0, y_0, z)$ with $y_0 > 0$ fixed. Arguing as before, we simply have to show that if $\varepsilon > 0$ and $x^n \rightarrow 0$ then $u(x^n, y_0, z) \leq u(0, y_0, z) + \varepsilon$.

Let (C^n, M^n, N^n) be an ε -optimal policy for (x^n, y_0, z) . Then

$$u(x^n, y_0, z) \leq E \int_0^{+\infty} e^{-\beta t} U(C_t^n) dt + \varepsilon.$$

Moreover, the policy (C^n, M^n, \bar{N}^n) is admissible for the point $(0, y_0 + (x^n/1 - \mu), z)$, where \bar{N}^n is given by $d\bar{N}_t^n = dN_t^n + (x^n/1 - \mu) \delta_0(t)$. Therefore

$$E \int_0^{+\infty} e^{-\beta t} U(C_t^n) dt \leq u\left(0, y_0 + \frac{x^n}{1 - \mu}, z\right).$$

Combining the last two inequalities, we conclude.

We now show that u is uniformly continuous on $\bar{\Omega}$.

We argue by contradiction. If u is not uniformly continuous, then there exist sequences (X_n) and (\bar{X}_n) , $X_n, \bar{X}_n \in \bar{\Omega}$, such that, as $n \rightarrow \infty$, $|X_n - \bar{X}_n| \rightarrow 0$ and

$$(2.2) \quad |u(X_n, z_0) - u(\bar{X}_n, z_0)| \geq \varepsilon$$

for some $\varepsilon > 0$ and $z_0 \in Z$.

In view of the first part of the proof, u is uniformly continuous on compact sets. Hence either (X_n) or (\bar{X}_n) , and therefore by assumption both must be unbounded. Let $X_n = (x_n, y_n)$ and $\bar{X}_n = (\bar{x}_n, \bar{y}_n)$. If $\lim_{n \rightarrow \infty} x_n > 0$ and $\lim_{n \rightarrow \infty} y_n > 0$, then the same holds for (\bar{x}_n, \bar{y}_n) . Since u is concave, locally Lipschitz with Lipschitz constant of order $|X|^{-1}$, (2.2) cannot hold.

We finally need to check what happens when either $\lim_{n \rightarrow \infty} x_n \rightarrow 0$ or $\lim_{n \rightarrow \infty} y_n = 0$. Here we only study the first case, since the other is similar. Without any loss of generality, we may assume that $\lim_{n \rightarrow \infty} x_n = 0$ and $\lim_{n \rightarrow \infty} y_n = +\infty$, otherwise we work along an appropriate subsequence. Then $\lim_{n \rightarrow \infty} \bar{x}_n = 0$ and $\lim_{n \rightarrow \infty} \bar{y}_n = +\infty$. On the other hand,

$$\begin{aligned} |u(x_n, y_n) - u(\bar{x}_n, \bar{y}_n)| &\leq |u(x_n, y_n) - u(x_n, \bar{y}_n)| + |u(x_n, \bar{y}_n) - u(\bar{x}_n, \bar{y}_n)| \\ &\leq |u(x_n, y_n) - u(x_n, \bar{y}_n)| + |u(x_n, \bar{y}_n) - u(0, \bar{y}_n)| \\ &\quad + |u(0, \bar{y}_n) - u(\bar{x}_n, \bar{y}_n)|. \end{aligned}$$

Letting $n \rightarrow \infty$ above and using the fact that u is Lipschitz continuous with respect to y uniformly with respect to x (the Lipschitz constant being of order y^{-1}) and that $\lim_{x \rightarrow \infty} u(x, y) = u(0, y)$ uniformly with respect to y , we conclude. \square

We now consider a similar control problem in which the controls, which represent the rates of trading, are assumed to be absolutely continuous processes. More precisely, we fix a positive constant L and we consider a market which offers a bond and a stock with prices evolving according to (1.1) and (1.2), respectively. The state variables x_t and y_t , which are the amount of money invested in bond and stock, obey the state equations

$$\begin{aligned} dx_t &= (rx_t - C_t) dt - (1 + \lambda)m_t dt + (1 - \mu)n_t dt, \\ dy_t &= z(t)y_t dt + m_t dt - n_t dt, \\ x_0 &= x, y_0 = y, z(0) = z. \end{aligned} \quad (2.3)$$

The controls of the investor are the *consumption rate* C_t and the *rates of trading* m_t and n_t , which are assumed to be almost everywhere bounded by L . The set of admissible controls A_L consists of controls (C, m, n) such that

- (i) C_t is F_t -measurable where $F_t = \sigma(z_s : 0 \leq s \leq t)$, $C_t \geq 0$ almost everywhere for all $t \geq 0$ and $E \int_0^{+\infty} e^{-rs} C_s ds < +\infty$.
- (ii) m_t, n_t are F_t -measurable right continuous and nonnegative processes.
- (iii) $0 \leq m_t, n_t \leq L$ almost everywhere $t \geq 0$.
- (iv) $x_t \geq 0, y_t \geq 0$ almost everywhere $t \geq 0$, where x_t, y_t are the solutions of (2.3) using the controls (C, m, n) .

The assumption that $E \int_0^{+\infty} e^{-rs} C_s ds < \infty$ is redundant here. Indeed, one can easily show that it follows from (iii) and (iv).

The control objective is to maximize the expected discounted utility from consumption over the set of admissible controls. For each fixed $L > 0$, the value function is

given by

$$u^L(x, y, z) = \sup_{A_L} E \int_0^{+\infty} e^{-\beta t} U(C_t) dt,$$

where U is the usual utility function and $\beta > 0$ is the discount factor.

PROPOSITION 2.3. *The value function u^L is jointly concave in x and y , strictly increasing in x , and increasing in y .*

Proof. The proof follows along the lines of Proposition 2.1. \square

PROPOSITION 2.4. *The value function u^L is uniformly continuous on $\bar{\Omega}$ uniformly in L .*

Proof. u^L is concave and therefore locally Lipschitz in Ω . Moreover, the Lipschitz constant is independent of L , since u^L is uniformly bounded by $\|U\|_\infty/\beta$. Therefore u^L is continuous in Ω uniformly in L . Working as in Proposition 2.2, we can prove that u^L is continuous at the point $(0, 0)$ independently of L .

We now show that u^L is continuous in $\Omega_1 = \{(x, y): x > 0, y = 0\}$. We argue by contradiction. Since u^L is locally Lipschitz in Ω_1 and nondecreasing, it suffices to assume that there exist $z_0 \in Z$ and $x_0 > 0$ such that $u^L(x_0, 0, z_0) < \lim_{y_n \rightarrow 0} u^L(x_0, y_n, z_0)$. This is equivalent to assuming that there exist $\theta > 0$ and $N_0 > 0$ such that

$$u^L(x_0, 0, z_0) + \theta \leq u^L(x_0, y_n, z_0), \quad \forall n \geq N_0.$$

On the other hand, the principle of dynamic programming gives

$$u^L(x_0, 0, z_0) \geq E \left[\int_0^\tau e^{-\beta s} U(C_s) ds + e^{-\beta \tau} u^L(x_\tau, y_\tau, z_\tau) \right]$$

for any random time τ .

Let $C_t = 0$, $m_t = 1$ and $n_t = 0$, for all $t \geq 0$, $t_n > 0$ and $\tau_n = t_n \wedge \tau_1$, where τ_1 is the first jump time of the process z_t . Then (2.3) gives

$$x_{\tau_n} = x_0 e^{r\tau_n} - \frac{1+\lambda}{r} (\exp(r\tau_n) - 1)$$

and

$$y_{\tau_n} = \frac{\exp(z_0 \tau_n) - 1}{z_0}.$$

Therefore

$$u^L(x_0, 0, z_0) \geq E \left[\exp(-\beta \tau_n) u^L \left(x_0 \exp(r\tau_n) - \frac{1+\lambda}{r} (\exp(r\tau_n) - 1), \frac{\exp(z_0 \tau_n) - 1}{z_0}, z_{\tau_n} \right) \right],$$

and, since u^L is nondecreasing

$$u^L(x_0, 0, z_0) \geq \exp(-\beta t_n) u^L \left(x_0 - \frac{1+\lambda}{r} (\exp(r t_n) - 1), \frac{\exp(z_0 t_n) - 1}{z_0}, z_0 \right) P(z_{\tau_n} = z_0).$$

We now choose t_n such that $(\exp(z_0 t_n) - 1)/z_0 = y_n$. Using that u^L is Lipschitz continuous in Ω (with the Lipschitz constant $k = k(x_0)$ independent of L), we obtain that

$$u^L(x_0, 0, z_0) \geq \exp(-\beta t_n) P(z_{\tau_n} = z_0) \left[u^L(x_0, y_n, z_0) - k \frac{1+\lambda}{r} (\exp(r t_n) - 1) \right].$$

Combining the above yields

$$u^L(x_0, 0, z_0) \geq \exp(-\beta t_n) P(z_{\tau_n} = z_0) \left[u^L(x_0, 0, z_0) + \theta - k \frac{1+\lambda}{r} (\exp(rt_n) - 1) \right].$$

We now send $y_n \rightarrow 0$. Then $\lim_{n \rightarrow \infty} t_n = 0$ and $\lim_{n \rightarrow \infty} P(z_{\tau_n} = z_0) = 1$ and $\theta \leq 0$, which is a contradiction. Therefore u^L is continuous in Ω_1 . It is also easily seen that the continuity was proved uniformly in L . Working similarly we can show that u^L is continuous in $\Omega_2 = \{(x, y): x = 0, y > 0\}$ uniformly in L . The proof that u^L is uniformly continuous on $\bar{\Omega}$ is similar to the one of Proposition 2.2 and therefore we omit it. \square

3. In this section we characterize the value functions u^L and u . We show that u^L is the unique viscosity solution of the corresponding Hamilton–Jacobi equation. We also show that the limit of u^L as $L \rightarrow \infty$ coincides with u , which is a unique viscosity solution of a system of variational inequalities. We first give the definition of viscosity solution, which was introduced by Crandall and Lions [4].

We consider a nonlinear partial differential equation of the form

$$(3.1) \quad F(X, z, u(X, z), Du(X, z)) = 0$$

where $z \in Z$, $X = (x, y)$ with $(x, y) \in \bar{\Omega}$, $Du(X, z) = (\partial u(X, z)/\partial x, \partial u(X, z)/\partial y)$ and $F: \bar{\Omega} \times Z \times \mathbb{R} \times \mathbb{R}^2 \rightarrow \mathbb{R}$ is continuous, for each $z \in Z$.

DEFINITION 3.1. A continuous function $u: \bar{\Omega} \times Z \rightarrow \mathbb{R}$ is a *constrained viscosity solution* of (3.1) if

(i) u is a *viscosity subsolution* of (3.1) on $\bar{\Omega}$, i.e., if for each $z \in Z$

$$(3.2) \quad F(X, z, u(X, z), r) \leq 0, \quad \forall X = (x, y) \in \bar{\Omega} \text{ and } r \in D_{(x,y)}^+ u(X, z),$$

where

$$D_{(x,y)}^+ u(X, z) = \left\{ r \in \mathbb{R}^2: \limsup_{h \rightarrow 0} \frac{u(X+h, z) - u(X, z) - r \cdot h}{|h|} \leq 0 \right\};$$

(ii) u is a *viscosity supersolution* of (3.1) in Ω , i.e., if for each $z \in Z$

$$(3.3) \quad F(X, z, u(X, z), r) \geq 0, \quad \forall X = (x, y) \in \Omega \text{ and } r \in D_{(x,y)}^- u(X, z),$$

where

$$D_{(x,y)}^- u(X, z) = \left\{ r \in \mathbb{R}^2: \liminf_{h \rightarrow 0} \frac{u(X+h, z) - u(X, z) - r \cdot h}{|h|} \geq 0 \right\}.$$

We now give an equivalent definition.

LEMMA 3.1. The above definition is equivalent to the following:

A continuous function $u: \bar{\Omega} \times Z \rightarrow \mathbb{R}$ is a *constrained viscosity solution* of (3.1) if

(i) u is a *viscosity subsolution* of (3.1) on $\bar{\Omega}$, i.e., if for all $\phi \in C^1(\bar{\Omega})$ at any local maximum point $X_0 \in \bar{\Omega}$ of $u - \phi$ the following holds:

$$F(X_0, z, u(X_0, z), D\phi(X_0, z)) \leq 0,$$

for each $z \in Z$.

(ii) u is a *viscosity supersolution* of (3.1) in Ω , i.e., if for all $\phi \in C^1(\Omega)$ at any local minimum point $X_0 \in \Omega$ of $u - \phi$ the following holds:

$$F(X_0, z, u(X_0, z), D\phi(X_0, z)) \geq 0$$

for each $z \in Z$.

For the proof see [4]. \square

We next show that u^L is the unique constrained viscosity solution of

$$(3.4) \quad \begin{aligned} & \beta u^L = rxu_x^L + zyu_y^L + \max_{c \geq 0} [-cu_x^L + U(c)] + \mathcal{L}u^L(z) \\ & + \max_{0 \leq m \leq L} [-(1+\lambda)u_x^L + u_y^L]m + \max_{0 \leq n \leq L} [(1-\mu)u_x^L - u_y^L]n, \\ & u^L(0, 0, z) = 0, \quad \forall z \in Z. \end{aligned}$$

This fact follows along the results of Fleming, Sethi, and Soner [7] and Soner [15], appropriately modified to deal with the generator of the process.

THEOREM 3.1. (i) u^L is a viscosity subsolution of (3.4) on $\bar{\Omega} \times Z$.

(ii) u^L is a viscosity supersolution of (3.4) in $\Omega \times Z$.

Proof. We first approximate u^L by a sequence of functions $\{u^{L,N}\}$ defined by

$$u^{L,N} = \sup_{A_{L,N}} E \int_0^{+\infty} e^{-\beta t} U(C_t) dt,$$

where

$$A_{L,N} = \{(C, m, n) \in A_L : 0 \leq C_t \leq N \text{ a.e. } \forall t \geq 0\}.$$

Working exactly as in Propositions 2.3 and 2.4, we can prove that $u^{L,N}$ is concave in (x, y) and continuous on $\bar{\Omega} \times Z$. The corresponding Hamilton–Jacobi equation is

$$(3.5) \quad \begin{aligned} & \beta u^{L,N} = rxu_x^{L,N} + zyu_y^{L,N} + \max_{N \geq c \geq 0} [-cu_x^{L,N} + U(c)] + \mathcal{L}u^{L,N}(z) \\ & + \max_{0 \leq m \leq L} [-(1+\lambda)u_x^{L,N} + u_y^{L,N}]m + \max_{0 \leq n \leq L} [(1-\mu)u_x^{L,N} - u_y^{L,N}]n. \end{aligned}$$

We first prove that $u^{L,N}$ is a viscosity subsolution of (3.5) on $\bar{\Omega}$. We will need the following lemma.

LEMMA 3.2. Let $v \in C_b(\bar{\mathcal{O}})$ be concave, where \mathcal{O} is an open subset of \mathbb{R}^n . Then

(i) $D^+v(X) \neq \emptyset, \forall X \in \mathcal{O}$

and

(ii) if $p \in D^+v(X_0)$ and $\lambda(X - X_0) + X_0 \in \bar{\mathcal{O}}, \forall X \in \bar{\mathcal{O}}$ and $\lambda \in [0, 1]$, then $v(X) \leq v(X_0) + p(X - X_0)$.

Proof. (i) Let $X_0 \in \mathcal{O}$ be fixed and consider the functions $v^\varepsilon = v * \rho_\varepsilon$, where $\varepsilon > 0$, ρ_ε is a standard mollifier and $*$ denotes convolution. Since $v^\varepsilon \rightarrow v$ as $\varepsilon \rightarrow 0$ in $B(\bar{X}_0, r) \subset \mathcal{O}$, for some $r > 0$, the functions v^ε are bounded in $B(X_0, r)$ uniformly in ε . Since the v^ε 's are also concave (recall that v is concave), the v^ε 's are also Lipschitz continuous in $B(X_0, r)$ and the Lipschitz constant is dependent of ε . By Taylor's theorem and concavity, we get

$$v^\varepsilon(X) \leq v^\varepsilon(X_0) + Dv^\varepsilon(X_0)(X - X_0), \quad \forall X \in B(X_0, r).$$

Since $|Dv^\varepsilon(X_0)| \leq C$, along subsequences $\varepsilon_n \rightarrow 0$ we have $Dv_{\varepsilon_n}(X_0) \rightarrow p$ with $p \in \mathbb{R}^N$. Letting $\varepsilon_n \rightarrow 0$ above, we get

$$v(X) \leq v(X_0) + p(X - X_0), \quad \forall X \in B(X_0, r),$$

which in turn yields that $p \in D^+v(X_0)$.

(ii) Let $p \in D^+v(X_0)$. Then

$$v(X) \leq v(X_0) + p(X - X_0) + o(|X - X_0|), \quad \forall X \in \bar{\mathcal{O}}.$$

Fix $X \in \bar{\mathcal{O}}$. Since $\lambda(X - X_0) + X_0 \in \bar{\mathcal{O}}$, for all $\lambda \in [0, 1]$, the concavity of v yields

$$v(\lambda(X - X_0) + X_0) \geq \lambda v(X) + (1 - \lambda)v(X_0).$$

Combining the last two inequalities, we get

$$\lambda v(X) + (1 - \lambda)v(X_0) \leq v(X_0) + \lambda p(X - X_0) + o(|\lambda(X - X_0)|).$$

Therefore

$$\lambda v(X) \leq \lambda v(X_0) + \lambda p(X - X_0) + o(|\lambda(X - X_0)|).$$

Dividing first by λ and then sending $\lambda \rightarrow 0$, we conclude. \square

We continue now with the proof of Theorem 3.1.

Proof. (i) In view of the definition of the constrained viscosity solution, we need to show that, if $(x_0, y_0, z) \in \bar{\Omega} \times Z$ is such that $D^+ u^{L,N}(x_0, y_0, z) \neq \emptyset$, then

$$\begin{aligned} \beta u^{L,N}(x_0, y_0, z) &\leq rx_0 p_z + zy_0 q_z + \max_{c \geq 0} [-cp_z + U(c)] + \max_{0 \leq m \leq L} [-(1 + \lambda)p_z + q_z]m \\ &\quad + \max_{0 \leq n \leq L} [(1 - \mu)p_z - q_z]n + \mathcal{L}u^{L,N}(x_0, y_0, z) \end{aligned}$$

for every $(p_z, q_z) \in D^+ u^{L,N}(x_0, y_0, z)$. To this end, assume that (x_0, y_0, z) and (p_z, q_z) are such that $(p_z, q_z) \in D^+ u^{L,N}(x_0, y_0, z)$, $z \in Z$, and define $\Phi: \mathfrak{H} \times \mathfrak{H} \times Z \rightarrow \mathfrak{H}$ by

$$\Phi(x, y, z) = u^{L,N}(x_0, y_0, z) + p_z(x - x_0) + q_z(y - y_0).$$

Lemma 3.2 yields

$$u^{L,N}(x, y, z) \leq \Phi(x, y, z), \text{ for all } (x, y, z) \in \bar{\Omega} \times Z.$$

On the other hand, the dynamic programming principle implies that for any stopping time $\tau > 0$,

$$u^{L,N}(x_0, y_0, z_0) = \sup_{A_{L,N}} E \left[\int_0^\tau e^{-\beta s} U(C_s) ds + e^{-\beta \tau} u^{L,N}(x_\tau, y_\tau, z(\tau)) \right].$$

Since $u^{L,N} \leq \Phi$, the above equality yields

$$\Phi(x_0, y_0, z_0) \leq \sup_{A_{L,N}} E \left[\int_0^\tau e^{-\beta s} U(C_s) ds + e^{-\beta \tau} \Phi(x_\tau, y_\tau, z(\tau)) \right].$$

Let θ be a positive constant and τ_1 be the first jump time of the process $z(t)$. Using Dynkin's formula and the fact that $\Phi_x(x_0, y_0, z_0) = p_{z_0}$ and $\Phi_y(x_0, y_0, z_0) = q_{z_0}$ we obtain

$$\begin{aligned} &E[e^{-\beta(\theta \wedge \tau_1)} \Phi(x_{\theta \wedge \tau_1}, y_{\theta \wedge \tau_1}, z(\theta \wedge \tau_1)) - \Phi(x_0, y_0, z_0)] \\ &= E \left[\int_0^{\theta \wedge \tau_1} e^{-\beta s} (-\beta \Phi(x_s, y_s, z_0) + rp_{z_0}x_s + z_0 q_{z_0}y_s + \mathcal{L}\Phi(x_s, y_s, z_0) \right. \\ &\quad \left. - p_{z_0}C_s + [-(1 + \lambda)p_{z_0} + q_{z_0}]m_s + [(1 - \mu)p_{z_0} - q_{z_0}]n_s) ds \right]. \end{aligned}$$

Let $\theta = 1/\ell$ and $(C^\ell, m^\ell, n^\ell) \in A_{L,N}$ be an $1/\ell^2$ -optimal policy. Then, combining the above inequalities, we get

$$\begin{aligned} -\frac{1}{\ell^2} &\leq E \int_0^{(1/\ell) \wedge \tau_1} e^{-\beta s} [U(C_s^\ell) + rp_{z_0}x_s + z_0 q_{z_0}y_s + \mathcal{L}\Phi(x_s, y_s, z_0) - p_{z_0}C_s^\ell \\ &\quad - \beta \Phi(x_s, y_s, z_0) + [-(1 + \lambda)p_{z_0} + q_{z_0}]m_s^\ell + [(1 - \mu)p_{z_0} - q_{z_0}]n_s^\ell] ds. \end{aligned}$$

On the other hand, the state equations together with the constraint $0 \leq m_t, n_t \leq L$ for almost every $t \geq 0$ give

$$|x_t^\ell - x_0| \leq (e^{rt} - 1) \left[x_0 + \frac{1 - \mu}{r} L \right],$$

$$|y_t^\ell - y_0| \leq (e^{Kt} - 1) \left[y_0 + \frac{L}{K} \right].$$

Using the above and the form of Φ , we can find a constant C_1 such that

$$\begin{aligned} -\frac{1}{\ell^2} &\leq E \int_0^{(1/\ell) \wedge \tau_1} e^{-\beta s} [rp_{z_0}x_0 + z_0q_{z_0}y_0 + \mathcal{L}\Phi(x_0, y_0, z_0) - \beta\Phi(x_0, y_0, z_0)] ds \\ &+ E \int_0^{(1/\ell) \wedge \tau_1} e^{-\beta s} [U(C_s^\ell) - p_{z_0}C_s^\ell + (-(1+\lambda)p_{z_0} + q_{z_0})m_s^\ell + ((1-\mu)p_{z_0} - q_{z_0})n_s^\ell] ds \\ &+ C_1 E \int_0^{(1/\ell) \wedge \tau_1} e^{-\beta s} \left[(e^{rs} - 1) \left(x_0 + \frac{1-\mu}{r} L \right) + (e^{Ks} - 1) \left(y_0 + \frac{L}{K} \right) \right] ds. \end{aligned}$$

Taking into account that the controls and the utility function are bounded and that $\Phi(x_0, y_0, z_0) \leq \|U\|_\infty / \beta$, we can also find a constant C_2 such that

$$\begin{aligned} -\frac{1}{\ell^2} &\leq C_2 E \int_0^{(1/\ell) \wedge \tau_1} (1 - e^{-\beta s}) ds \\ &+ C_1 E \int_0^{(1/\ell) \wedge \tau_1} e^{-\beta s} \left[(e^{rs} - 1) \left(x_0 + \frac{1-\mu}{r} L \right) + (e^{Ks} - 1) \left(y_0 + \frac{L}{K} \right) \right] ds \\ &+ E \int_0^{(1/\ell) \wedge \tau_1} [rp_{z_0}x_0 + z_0q_{z_0}y_0 + \mathcal{L}\Phi(x_0, y_0, z_0) - \beta\Phi(x_0, y_0, z_0)] ds \\ &+ E \int_0^{(1/\ell) \wedge \tau_1} U(C_s^\ell) ds - E \int_0^{(1/\ell) \wedge \tau_1} p_{z_0}C_s^\ell ds \\ &+ E \int_0^{(1/\ell) \wedge \tau_1} (-(1+\lambda)p_{z_0} + q_{z_0})m_s^\ell ds + E \int_0^{(1/\ell) \wedge \tau_1} ((1-\mu)p_{z_0} - q_{z_0})n_s^\ell ds. \end{aligned}$$

We now divide both sides by $E[(1/\ell) \wedge \tau_1]$ and we pass to the limit as $\ell \rightarrow \infty$. The first two terms will go to zero. Let

$$\begin{aligned} A_1^\ell &= \frac{1}{E((1/\ell) \wedge \tau_1)} E \int_0^{(1/\ell) \wedge \tau_1} U(C_s^\ell) ds \\ A_2^\ell &= -\frac{1}{E((1/\ell) \wedge \tau_1)} E \int_0^{(1/\ell) \wedge \tau_1} C_s^\ell ds \\ A_3^\ell &= \frac{1}{E((1/\ell) \wedge \tau_1)} E \int_0^{(1/\ell) \wedge \tau_1} (-(1+\lambda)p_{z_0} + q_{z_0})m_s^\ell ds \\ A_4^\ell &= \frac{1}{E((1/\ell) \wedge \tau_1)} E \int_0^{(1/\ell) \wedge \tau_1} ((1-\mu)p_{z_0} - q_{z_0})n_s^\ell ds. \end{aligned}$$

Let $\Gamma_{L,N} = \{U(C), C, m, n\}$ for $0 \leq C \leq N, 0 \leq m, n \leq L$. Then $(A_1^\ell, A_2^\ell, A_3^\ell, A_4^\ell) \in \overline{co}\Gamma_N$. Since the latter is a compact set, there is an element (A_1, A_2, A_3, A_4) to which $(A_1^\ell, A_2^\ell, A_3^\ell, A_4^\ell)$ converges along a subsequence. We conclude easily that

$$\begin{aligned} \beta\Phi(x_0, y_0, z_0) &\leq rx_0p_{z_0} + z_0y_0q_{z_0} + \max_{c \geq 0} [-cp_{z_0} + U(c)] + \max_{0 \leq m \leq L} [-(1+\lambda)p_{z_0} + q_{z_0}]m \\ &+ \max_{0 \leq n \leq L} [(1-\mu)p_{z_0} - q_{z_0}]n + \mathcal{L}\Phi(x_0, y_0, z_0). \end{aligned}$$

Using that $\Phi = u^{L,N}$ at (x_0, y_0, z_0) , we get (3.2).

We will next show that $\lim_{N \rightarrow \infty} u^{L,N} = u^L$ uniformly on compact subsets of $\bar{\Omega} \times Z$. We will need the following lemma.

LEMMA 3.3. Let $(C, m, n) \in A_L$ and $N > 0$. Then $(C \wedge N, m, n) \in A_{L,N}$ and

$$\lim_{N \rightarrow \infty} E \int_0^\infty e^{-\beta s} U(C_s \wedge N) ds = E \int_0^\infty e^{-\beta s} U(C_s) ds.$$

We first prove the above claim and then we present the proof of Lemma 3.3. To this end, fix $(x_0, y_0, z_0) \in \bar{\Omega} \times Z$ and let $(C^\varepsilon, m^\varepsilon, n^\varepsilon) \in A_L$ be an ε -optimal policy. Then

$$u^L(x_0, y_0, z_0) \leq E \int_0^{+\infty} e^{-\beta s} U(C_s^\varepsilon) ds + \varepsilon.$$

On the other hand, Lemma 3.3 yields that, for each $N > 0$, $(C^\varepsilon \wedge N, m^\varepsilon, n^\varepsilon) \in A_{L,N}$ and

$$E \int_0^{+\infty} e^{-\beta s} U(C_s^\varepsilon) ds \leq E \int_0^{+\infty} e^{-\beta s} U(C_s^\varepsilon \wedge N) ds + \varepsilon \text{ for } N \geq N(\varepsilon).$$

Combining the last two inequalities yields

$$u^L(x_0, y_0, z_0) \leq E \int_0^{+\infty} e^{-\beta s} U(C_s^\varepsilon \wedge N) ds + 2\varepsilon \leq u^{L,N}(x_0, y_0, z_0) + 2\varepsilon \text{ for } N \geq N(\varepsilon);$$

hence $u^{L,N}(x_0, y_0, z_0)$ is a nondecreasing sequence that converges to $u^L(x_0, y_0, z_0)$. Since both $u^{L,N}$ and u^L are continuous functions, Dini's theorem implies that $u^{L,N} \rightarrow u^L$ locally uniformly.

Proof of Lemma 3.3. The fact that $(C \wedge N, m, n) \in A_{L,N}$ follows immediately from the definitions of A_L and $A_{L,N}$.

On the other hand, since U is increasing, bounded and $U(0) = 0$,

$$0 \leq E \int_0^\infty e^{-\beta s} U(C_s) ds - E \int_0^\infty e^{-\beta s} U(C_s \wedge N) ds \leq \|U\|_\infty E \left[\int_{\{C_s \geq N\}} e^{-\beta s} ds \right].$$

To conclude we need to show that

$$\lim_{N \rightarrow \infty} E \left[\int_{\{C_s \geq N\}} e^{-\beta s} ds \right] = 0.$$

However,

$$NE \left[\int_{\{C_s \geq N\}} e^{-\beta s} ds \right] \leq E \left[\int_{\{C_s \geq N\}} e^{-\beta s} C_s ds \right] \leq E \int_0^\infty e^{-\beta s} C_s ds < \infty,$$

where the last inequality follows from the facts that $(C, m, n) \in A_L$ and $\beta > r$. Hence

$$E \left[\int_{\{C_s \geq N\}} e^{-\beta s} ds \right] \leq \frac{1}{N} E \int_0^\infty e^{-\beta s} C_s ds.$$

Letting $N \rightarrow \infty$, we conclude. \square

Finally, we show that u^L is a viscosity subsolution of (3.4) on $\bar{\Omega}$. Let $(p_{z_0}, q_{z_0}) \in D_{(x,y)}^+ u^L(x_0, y_0, z_0)$. Then there exists (cf. [4]) a smooth function $\phi: \mathfrak{R} \times \mathfrak{R} \times Z \rightarrow \mathfrak{R}$ such that $\phi_x(x_0, y_0, z_0) = p_{z_0}$, $\phi_y(x_0, y_0, z_0) = q_{z_0}$, and $u^L - \phi$ has a strict local maximum at (x_0, y_0, z_0) . Then $(u^{L,N} - \phi)(\cdot, \cdot, z_0)$ has a local maximum at (x_N, y_N, z_0) and $(x_N, y_N, z_0) \rightarrow (x_0, y_0, z_0)$. Moreover,

$$\begin{aligned} \beta u^{L,N}(x_N, y_N, z_0) &\leq rx_N p_{z_0} + z_0 y_N q_{z_0} + \max_{c \geq 0} [-cp_{z_0} + U(c)] + \max_{0 \leq m \leq L} [-(1+\lambda)p_{z_0} + q_{z_0}]m \\ &\quad + \max_{0 \leq n \leq L} [(1-\mu)p_{z_0} - q_{z_0}]n + \mathcal{L}u^{L,N}(x_N, y_N, z_0). \end{aligned}$$

Sending $N \rightarrow \infty$, we get that u^L is a viscosity subsolution of (3.4).

(ii) We now prove that $u^{L,N}$ is a supersolution of (3.4) in Ω . Let $(x_0, y_0, z_0) \in \Omega$ and $(p_{z_0}, q_{z_0}) \in D_{(x,y)}^- u^{L,N}(x_0, y_0, z_0)$. Since, by Lemma 3.2(i), $D^+ u^{L,N}(x_0, y_0, z) \neq \emptyset$,

the properties of D^+ and D^- yield that $u^{L,N}$ is differentiable in the X -direction at the point (x_0, y_0, z_0) (cf. [4]). Let Φ be defined as in (i). There exists a continuous function h with $h(0) = 0$ such that

$$u^{L,N}(x, y, z_0) \geq \Phi(x, y, z_0) + |X - X_0| h(|X - X_0|).$$

Using again the dynamic programming principle, we get

$$(3.6) \quad \Phi(x_0, y_0, z_0) \geq \sup_{A_{L,N}} E \left[\int_0^\theta e^{-\beta s} U(C_s) ds + e^{-\beta\theta} \Phi(x_\theta, y_\theta, z_\theta) + e^{-\beta\theta} |X_\theta - X_0| h(|X_\theta - x_0|) \right].$$

Let $(C, m, n) \in A_{L,N}$ with $C_t = C_0$, $m_t = m_0$, $n_t = n_0$, $\forall t \geq 0$ and $\tau = \theta \wedge \tau_1$ where $\theta = T \wedge \inf\{\tau > 0: x_\tau^0 = 0\} \wedge \inf\{\tau > 0: y_\tau^0 = 0\}$ and x_τ^0, y_τ^0 are the corresponding trajectories. Using Dynkin's formula and (3.6), we get

$$\begin{aligned} 0 &\geq C_1 E \int_0^{\theta \wedge \tau_1} e^{-\beta s} \left[(e^{rs} - 1) \left(x_0 + \frac{1-\mu}{r} L \right) + (e^{Ks} - 1) \left(y_0 + \frac{L}{K} \right) \right] ds \\ &\quad + C_2 E \int_0^{\theta \wedge \tau_1} (1 - e^{-\beta s}) ds \\ &\quad + E \int_0^{\theta \wedge \tau_1} [U(C_0) - p_{z_0} C_0 + r x_0 p_{z_0} + z_0 y_0 q_{z_0} + [-(1+\lambda)p_{z_0} + q_{z_0}] m_0 \\ &\quad + [(1-\mu)p_{z_0} - q_{z_0}] n_0 + \mathcal{L}\Phi(x_0, y_0, z_0) - \beta\Phi(x_0, y_0, z_0)] ds \end{aligned}$$

for some constants C_1 and C_2 . Dividing by $E[\theta \wedge \tau_1]$, sending $T \rightarrow 0$ and using that $u^{L,N}(x_0, y_0, z_0) = \Phi(x_0, y_0, z_0)$ we obtain (3.3). Finally, working similarly as in (i) we can show that u^L is a viscosity supersolution of (3.4) in $\bar{\Omega}$. \square

THEOREM 3.2. *Let u and v be bounded, uniformly continuous such that u is a viscosity subsolution of (3.4) on $\bar{\Omega}$ and v is a viscosity supersolution of (3.4) in Ω . Then $u \leq v$ on $\bar{\Omega}$.*

Proof. Let $X = (x, y) \in \bar{\Omega}$, $P = (p, q) \in R \times R$ and $H: \bar{\Omega} \times Z \times R^2 \rightarrow R$ be given by

$$H(X, z, P) = rxp + zyq + F(p) + \max_{0 \leq m \leq L} [(1+\lambda)p - q]m + \max_{0 \leq n \leq L} [-(1-\mu)p + q]n,$$

where $F(p) = \max_{c \geq 0} [-cp + U(c)]$, $p > 0$.

We argue by contradiction; i.e., we assume that

$$(3.7) \quad \max_{z \in Z} \sup_{X \in \bar{\Omega}} [u(X, z) - v(X, z)] > 0.$$

Then for sufficiently small $\theta > 0$

$$(3.8) \quad \max_{z \in Z} \sup_{X \in \bar{\Omega}} [u(X, z) - v(X, z) - \theta|X|^2] > 0.$$

Indeed, if not, there would be a sequence $\theta_n \downarrow 0$ such that $\max_{z \in Z} \sup_{X \in \bar{\Omega}} [u(X, z) - v(X, z) - \theta_n|X|^2] \leq 0$, which in turn yields $\max_{z \in Z} \sup_{X \in \bar{\Omega}} [u(X, z) - v(X, z)] \leq 0$, contradicting (3.7).

Since the process z takes a finite number of values and u and v are bounded, we can find points $z_0 \in Z$ and $\bar{X} \in \bar{\Omega}$ such that

$$(3.9) \quad u(\bar{X}, z_0) - v(\bar{X}, z_0) - \theta|\bar{X}|^2 = \max_{z \in Z} \sup_{X \in \bar{\Omega}} [u(X, z) - v(X, z) - \theta|X|^2].$$

In what follows we omit z_0 .

Next, for $\varepsilon > 0$ we define $\psi: \bar{\Omega} \times \bar{\Omega} \rightarrow \mathbb{R}$ by

$$\psi(X, Y) = u(X) - v(Y) - \left| \frac{Y - X}{\varepsilon} - 4(1, 1) \right|^2 - \theta|X|^2,$$

and we claim that ψ attains its maximum at a point, say (X_0, Y_0) , such that for ε small and some $\ell > 0$

$$(3.10) \quad |Y_0 - X_0| \leq \ell\varepsilon.$$

Indeed, observe that ψ is bounded. Let (X_n, Y_n) be a maximizing sequence. Then

$$\lim_{n \rightarrow \infty} \left[u(X_n) - v(Y_n) - \left| \frac{Y_n - X_n}{\varepsilon} - 4(1, 1) \right|^2 - \theta|X_n|^2 \right] = \sup_{\bar{\Omega} \times \bar{\Omega}} \psi(X, Y) < +\infty.$$

However,

$$(3.11) \quad \sup_{\bar{\Omega} \times \bar{\Omega}} \psi(X, Y) \geq \psi(\bar{X}, \bar{X} + 4\varepsilon(1, 1)) \geq u(\bar{X}) - v(\bar{X}) - \theta|\bar{X}|^2 - \omega_v(k\varepsilon),$$

where ω_v is the modulus of continuity of v and $k > 0$. Using (3.8) and (3.9), we see that for ε sufficiently small

$$(3.12) \quad \sup_{\bar{\Omega} \times \bar{\Omega}} \psi(X, Y) > 0.$$

We also observe that if

$$u(X_n) - v(Y_n) - \left| \frac{Y_n - X_n}{\varepsilon} - 4(1, 1) \right|^2 \leq 0$$

as $n \rightarrow \infty$ we contradict (3.12). Therefore

$$u(X_n) - v(Y_n) \geq \left| \frac{Y_n - X_n}{\varepsilon} - 4(1, 1) \right|^2,$$

which implies (3.10). On the other hand, the choice of (X_n, Y_n) and (3.12) yield that the sequence (X_n) , and, in view of the above observation, (Y_n) are bounded as $n \rightarrow \infty$. Hence, along subsequences, (X_n, Y_n) converge to a maximum point of ψ , which we denote by (X_0, Y_0) .

Moreover, (3.10) and (3.11) give

$$(3.13) \quad \left| \frac{Y_0 - X_0}{\varepsilon} - 4(1, 1) \right|^2 \leq \omega_n(k\varepsilon) + \omega_v(\ell\varepsilon).$$

We can choose ε small such that $\omega_n(k\varepsilon) + \omega_v(\ell\varepsilon) \leq 1$. Then there is a vector e with $|e| \leq 1$ such that $Y_0 = X_0 + 4\varepsilon(1, 1) + \varepsilon e$, which implies that $Y_0 \in \Omega$.

We now consider the functions

$$\begin{aligned} \phi(Y) &= u(X_0) - \left| \frac{Y - X_0}{\varepsilon} - 4(1, 1) \right|^2 - \theta|X_0|^2, \\ \bar{\phi}(X) &= v(Y_0) + \left| \frac{Y_0 - X}{\varepsilon} - 4(1, 1) \right|^2 + \theta|X|^2. \end{aligned}$$

Since $u - \bar{\phi}$ has a maximum at $X_0 \in \bar{\Omega}$ and $v - \phi$ has a minimum at $Y_0 \in \Omega$, applying the definition of viscosity solution as in Lemma 3.1, we get

$$\beta u(X_0, z_0) \leq H(X_0, z_0, P_\varepsilon + 2\theta X_0) + \sum_{z_0 \neq z'} q_{z_0 z'} [u(X_0, z) - u(X_0, z_0)]$$

and

$$\beta v(Y_0, z_0) \geq H(Y_0, z_0, P_\varepsilon) + \sum_{z_0 \neq z'} q_{z_0 z'} [v(Y_0, z) - v(Y_0, z_0)],$$

where

$$P_\varepsilon = -\frac{2}{\varepsilon} \left(\frac{Y_0 - X_0}{\varepsilon} - 4(1, 1) \right).$$

Combining the above inequalities yields

$$\begin{aligned} \beta[u(X_0, z_0) - v(Y_0, z_0)] &\leq [H(X_0, z_0, P_\varepsilon + 2\theta X_0) - H(Y_0, z_0, P_\varepsilon)] \\ (3.14) \quad &+ \sum_{z_0 \neq z'} q_{z_0 z'} [u(X_0, z) - u(X_0, z_0) - v(Y_0, z) + v(Y_0, z_0)]. \end{aligned}$$

On the other hand, from the definition of H , we have that

$$\begin{aligned} (3.15) \quad &|H(X_0, z_0, P_\varepsilon + 2\theta X_0) - H(Y_0, z_0, P_\varepsilon)| \\ &\leq |H(X_0, z_0, P_\varepsilon + 2\theta X_0) - H(X_0, z_0, P_\varepsilon)| + K|X_0 - Y_0||P_\varepsilon| \end{aligned}$$

for some $K > 0$. Let $X_0 = (x_0, y_0)$ and $P_\varepsilon = (p_\varepsilon, q_\varepsilon)$. Then

$$\begin{aligned} &H(x_0, y_0, z_0, 2\theta x_0 + p_\varepsilon, 2\theta y_0 + q_\varepsilon) - H(x_0, y_0, z_0, p_\varepsilon, q_\varepsilon) \leq 2\theta[rx_0^2 + zy_0^2] \\ &+ \left[\max_{0 \leq m \leq L} [(1+\lambda)(2\theta x_0 + p_\varepsilon) - (2\theta y_0 + q_\varepsilon)]m - [(1+\lambda)p_\varepsilon - q_\varepsilon]L \right] \\ &+ \left[\max_{0 \leq n \leq L} [-(1-\mu)(2\theta x_0 + p_\varepsilon) + (2\theta y_0 + q_\varepsilon)]n - [-(1-\mu)p_\varepsilon + q_\varepsilon]L \right] \\ &\leq C\theta L|X_0| + 2\theta[rx_0^2 + zy_0^2] \leq \theta|X_0|^2 + \theta C^2 L^2 + 2\theta[rx_0^2 + zy_0^2] \\ &\leq \beta\theta|X_0|^2 + C^2 L^2 \theta, \end{aligned}$$

for some $C > 0$, where we used that $K \geq r$, (2.1), and that F is a decreasing function. Using the above inequality and (3.10), (3.13), and (3.15), we get

$$\begin{aligned} (3.16) \quad &|H(X_0, z_0, P_\varepsilon + 2\theta X_0) - H(Y_0, z_0, P_\varepsilon)| \\ &\leq 2K\ell[\omega_v(\ell\varepsilon) + \omega_v(k\varepsilon)]^{1/2} + \beta\theta|X_0|^2 + C^2 L^2 \theta. \end{aligned}$$

Moreover, from (3.10) we have

$$u(X_0, z) - v(X_0, z) \leq u(X_0, z_0) - v(Y_0, z_0) + \omega_v(k\varepsilon),$$

which combined with (3.11) gives

$$[u(X_0, z) - u(X_0, z_0)] - [v(Y_0, z) - v(Y_0, z_0)] \leq \omega_v(k\varepsilon) + \omega_v(\ell\varepsilon).$$

Finally, using that $0 \leq q_{zz'} \leq 1$ and $\sum_{z' \in Z} q_{zz'} = 1$, we get

$$(3.17) \quad \mathcal{L}u(X_0, z_0) - \mathcal{L}v(Y_0, z_0) \leq \omega_v(k\varepsilon) + \omega_v(\ell\varepsilon).$$

Using now (3.14), (3.16), and (3.17), we have

$$\begin{aligned} \beta[u(X_0, z_0) - v(Y_0, z_0) - \theta|X_0|^2] &\leq 2K\ell[\omega_v(\ell\varepsilon) + \omega_v(k\varepsilon)]^{1/2} \\ &+ C^2 L^2 \theta + \omega_v(k\varepsilon) + \omega_v(\ell\varepsilon), \end{aligned}$$

and, using the definition of (X_0, Y_0) ,

$$\max_{\Omega \times \Omega} \psi(X, Y) \leq \frac{1}{\beta} \left[2K\ell[\omega_v(\ell\varepsilon) + \omega_v(k\varepsilon)]^{1/2} + \omega_v(k\varepsilon) + \omega_v(\ell\varepsilon) \right] + \frac{C^2 L^2 \theta}{\beta}.$$

Then, however, (3.9) and (3.11) yield

$$\begin{aligned} & \max_{z \in Z} \sup_{X \in \bar{\Omega}} [u(X, z) - v(X, z) - \theta |X|^2] \\ & \leq \omega_v(k\varepsilon) + \frac{1}{\beta} [2K\ell[\omega_v(\ell\varepsilon) + \omega_v(k\varepsilon)]^{1/2} + \omega_v(k\varepsilon) + \omega_v(\ell\varepsilon)] + \frac{C^2 L^2}{\beta} \theta, \end{aligned}$$

which, in turn, implies that

$$u(X, z) - v(X, z) - \theta |X|^2 \leq \frac{C^2 L^2}{\beta} \theta \quad \forall X \in \bar{\Omega} \text{ and } \forall z \in Z.$$

Letting $\theta \rightarrow 0$ contradicts (3.7). \square

Remark 3.1. Although it was not necessary for the above proof, but it will be used later on, we show that

$$(3.18) \quad \lim_{\theta \downarrow 0} \lim_{\varepsilon \downarrow 0} \theta |X_0(\theta, \varepsilon)|^2 = 0.$$

Indeed, from (3.11) we have

$$\psi(X_0, X_0) + \omega_v(k\varepsilon) \geq u(\bar{X}) - v(\bar{X}) - \theta |\bar{X}|^2 - \omega_v(k\varepsilon),$$

which yields

$$(3.19) \quad u(X_0, z_0) - v(X_0, z_0) - \theta |X_0|^2 \geq [u(\bar{X}, z_0) - v(\bar{X}, z_0) - \theta |\bar{X}|^2] - 2\omega_v(k\varepsilon),$$

and, in turn $\sup_{\varepsilon > 0} |X_0(\theta, \varepsilon)| < \infty$.

Therefore there exists $\hat{X}_0(\theta)$ such that $\lim_{\varepsilon \rightarrow 0} |X_0(\theta, \varepsilon)|^2 = \hat{X}_0(\theta)$, otherwise we contradict (3.19). The limit here is taken along subsequences, which to simplify notation we denote the same way as the whole family. By sending $\varepsilon \downarrow 0$, (3.19) combined with (3.9) implies

$$(3.20) \quad u(\hat{X}_0, z_0) - v(\hat{X}_0, z_0) - \theta |\hat{X}_0|^2 \geq u(X, z) - v(X, z) - \theta |X|^2 \quad \forall X \in \bar{\Omega}, \forall z \in Z.$$

We now send $\theta \rightarrow 0$. If $\lim_{\theta \downarrow 0} \theta |\hat{X}_0|^2 = \alpha \neq 0$, again along subsequences, (3.20) yields

$$\max_{z \in Z} \sup_{\bar{\Omega}} [u(X, z) - v(X, z)] - \alpha \geq \max_{z \in Z} \sup_{\bar{\Omega}} [u(X, z) - v(X, z)].$$

Therefore $\max_{z \in Z} \sup_{\bar{\Omega}} [u(X, z) - v(X, z)] < 0$, which contradicts (3.7).

PROPOSITION 3.1. As $L \rightarrow \infty$, $u^L \rightarrow w \in C(\bar{\Omega})$.

Proof. Fix $(x_0, y_0) \in \bar{\Omega}$. The sequence $u^L(x_0, y_0)$ is increasing as $L \rightarrow \infty$, therefore $\lim_{L \rightarrow \infty} u^L(x_0, y_0) = w(x_0, y_0)$ exists. Moreover, since the functions u^L are continuous at (x_0, y_0) uniformly in L , w is continuous on $\bar{\Omega}$. \square

4. In this section we prove that w coincides with the value function $u \in C(\bar{\Omega})$. We first show that u is a constrained viscosity solution of a certain variational inequality and second that this variational inequality has a unique constrained viscosity solution.

THEOREM 4.1. The value function u is a constrained viscosity solution of

$$(4.1) \quad \begin{aligned} & \min [(1 + \lambda)u_x - u_y, -(1 - \mu)u_x + u_y, \beta u - rxu_x - zy u_y - F(u_x) - \mathcal{L}u(z)] = 0 \\ & \forall (x, y, z) \in (0, +\infty) \times (0, +\infty) \times Z \text{ with } u(0, 0, z) = 0, \forall z \in Z. \end{aligned}$$

Proof. We first show that u is viscosity subsolution of (4.1) on $\bar{\Omega}$. To this end, let (x_0, y_0, z_0) be fixed with $(x_0, y_0) \in \bar{\Omega}$, consider $(p_{z_0}, q_{z_0}) \in D_{x,y}^+ u(x_0, y_0, z_0)$ and define $\Phi: \Re \times \Re \times Z \rightarrow \Re$ by

$$\Phi(x, y, z) = u(x_0, y_0, z) + p_z(x - x_0) + q_z(y - y_0),$$

where $(p_z, q_z) \in D_{(x,y)}^+ u(x_0, y_0, z)$. Lemma 3.2 yields

$$(4.2) \quad u(x, y, z) \leq \Phi(x, y, z).$$

We are going to show that

$$(4.3) \quad \min [(1+\lambda)p_{z_0} - q_{z_0}, -(1-\mu)p_{z_0} + q_{z_0}, \beta u - rx_0p_{z_0} - z_0y_0q_{z_0} - F(p_{z_0}) - \mathcal{L}u(z_0)] \leq 0$$

where $F(p) = \max_{c \geq 0} [-cp + U(c)]$.

If $(1+\lambda)p_{z_0} - q_{z_0} \leq 0$ or $-(1-\mu)p_{z_0} + q_{z_0} \leq 0$, the above inequality is obvious. So let us assume that

$$(4.4) \quad (1+\lambda)p_{z_0} - q_{z_0} > 0 \text{ and } -(1-\mu)p_{z_0} + q_{z_0} > 0.$$

In the following, we are first going to assume that the control C is such that $0 \leq C_t \leq N$ for almost every $t \geq 0$, and then we will remove the upper bound. Since the arguments are similar to the ones used in Theorem 3.1, we proceed as if there is no bound on C . Later, we will mention when we use this upper bound.

Applying the dynamic programming principle at the point (x_0, y_0, z_0) with stopping time $\theta = (1/\ell) \wedge \tau_1 = \min\{1/\ell, \tau_1\}$, where τ_1 is the first jump time of z_t , we obtain

$$(4.5) \quad u(x_0, y_0, z_0) \leq E \left[\int_0^\theta e^{-\beta s} U(C_s^\ell) ds + e^{-\beta\theta} u \left(e^{r\theta} \left(x_0 - \int_0^\theta e^{-rs} C_s^\ell ds - (1+\lambda)m_\theta^\ell + (1-\mu)n_\theta^\ell \right), e^{z_0\theta} (y_0 + \hat{m}_\theta^\ell - \hat{n}_\theta^\ell), z_\theta \right) \right] + \frac{1}{\ell^2},$$

where (C^ℓ, M^ℓ, N^ℓ) is an $1/\ell^2$ -optimal policy and

$$m_\theta^\ell = \int_0^\theta e^{-rs} dM_s^\ell, \quad \hat{m}_\theta^\ell = \int_0^\theta \exp(-z_0 s) dM_s^\ell$$

and

$$n_\theta^\ell = \int_0^\theta e^{-rs} dN_s^\ell, \quad \hat{n}_\theta^\ell = \int_0^\theta \exp(-z_0 s) dN_s^\ell.$$

Let $r \geq z_0$ (the case $r < z_0$ is treated similarly). Then

$$(4.6) \quad m_\theta^\ell \leq \hat{m}_\theta^\ell \text{ and } n_\theta^\ell \leq \hat{n}_\theta^\ell.$$

Since the control (C^ℓ, M^ℓ, N^ℓ) is admissible, we also have

$$(4.7) \quad x_0 - \int_0^\theta e^{-rs} C_s^\ell ds \geq (1+\lambda)m_\theta^\ell - (1-\mu)n_\theta^\ell$$

and

$$(4.8) \quad y_0 \geq -\hat{m}_\theta^\ell + \hat{n}_\theta^\ell.$$

Moreover,

$$(4.9) \quad \hat{m}_\theta^\ell \leq (\exp(r - z_0)\theta) \int_0^\theta e^{-rs} dM_s^\ell \leq \left(\exp\left(\frac{r - z_0}{\ell}\right) \right) m_\theta^\ell$$

and, similarly,

$$(4.10) \quad \hat{n}_\theta^\ell \leq \left(\exp\left(\frac{r - z_0}{\ell}\right) \right) n_\theta^\ell.$$

From (4.7)–(4.10) we get

$$(4.11) \quad m_\theta^\ell \leq \frac{x_0 + (1-\mu)y_0}{c},$$

where $c > 0$ is such that $(1 + \lambda) - (1 - \mu) \exp((r - z_0)/\ell) \geq c$ for ℓ sufficiently large. Similarly,

$$(4.12) \quad n_\theta^\ell \leq \frac{\exp((r - z_0)/\ell)x_0 + (1 + \lambda)y_0}{c} \leq \frac{2x_0 + (1 + \lambda)y_0}{c}$$

for ℓ sufficiently large.

Moreover, since

$$m_\theta^\ell = \int_0^\theta e^{-rs} dM_s^\ell \geq \exp(-r/\ell)(M_\theta^\ell - M_0^\ell),$$

using (4.11) we obtain

$$(4.13) \quad M_\theta^\ell - M_0^\ell \leq \exp(r/\ell) \frac{x_0 + (1 - \mu)y_0}{c} \leq k_1$$

for some $k_1 > 0$, and, similarly

$$(4.14) \quad N_\theta^\ell - N_0^\ell \leq k_2$$

for some $k_2 > 0$.

Therefore there exist constants \bar{C} , K_1 and K_2 such that

$$(4.15) \quad \hat{m}_\theta^\ell - m_\theta^\ell \leq E \int_0^\theta \bar{C}s dM_s^\ell \leq \frac{K_1}{\ell}$$

and

$$(4.16) \quad \hat{n}_\theta^\ell - n_\theta^\ell \leq \frac{K_2}{\ell}.$$

Using that u is a nondecreasing function, $r \geq z_0$, (4.5), and (4.15), we have

$$(4.17) \quad \begin{aligned} u(x_0, y_0, z_0) &\leq \|U\|_\infty E(\theta) + E[e^{-\beta\theta} u(e^{r\theta}(x_0 + \bar{X}_\theta), e^{r\theta}(y_0 + \bar{Y}_\theta), z_\theta) \\ &\quad - e^{-\beta\theta} u(x_0 + \bar{X}_\theta, y_0 + \bar{Y}_\theta, z_0)] \\ &\quad + E[e^{-\beta\theta} u(x_0 + \bar{X}_\theta, y_0 + \bar{Y}_\theta, z_0)], \end{aligned}$$

where

$$\bar{X}_\theta = -(1 + \lambda)\hat{m}_\theta^\ell + \frac{(1 + \lambda)K_1}{\ell} + (1 - \mu)\hat{n}_\theta^\ell$$

and

$$\bar{Y}_\theta = \hat{m}_\theta^\ell - \hat{n}_\theta^\ell.$$

Let ω be the modulus of continuity of u . Then

$$(4.18) \quad \begin{aligned} &E[e^{-\beta\theta} u(e^{r\theta}(x_0 + \bar{X}_\theta), e^{r\theta}(y_0 + \bar{Y}_\theta), z_\theta) - e^{-\beta\theta} u(x_0 + \bar{X}_\theta, y_0 + \bar{Y}_\theta, z_0)] \\ &\leq K_3[\|u\|_\infty P(z_\theta \neq z_0) + \omega(e^{r\theta} - 1)] \end{aligned}$$

for some positive constant K_3 .

Moreover, (4.2), (4.17), and (4.18) yield

$$\begin{aligned} u(x_0, y_0, z_0) &\leq \|U\|_\infty E(\theta) + K_3[\|u\|_\infty P(z_\theta \neq z_0) + \omega(e^{r\theta} - 1)] \\ &\quad + E e^{-\beta\theta} [u(x_0, y_0, z_0) + p_{z_0} \bar{X}_\theta + q_{z_0} \bar{Y}_\theta]. \end{aligned}$$

Since $P[z_\theta \neq z_0] = 0(\theta)$, we get

$$\begin{aligned} & E[(1+\lambda)p_{z_0} - q_{z_0}]\hat{m}_\theta^\ell + (-(1-\mu)p_{z_0} + q_{z_0})\hat{n}_\theta^\ell \\ & \leq K_3[\|u\|_\infty E(\theta) + \omega(e^{r\theta} - 1)] + \|U\|_\infty E(\theta) + \frac{(1+\lambda)K_1}{\ell}. \end{aligned}$$

Finally, in view of (4.4), we can find positive constants M_1 and M_2 such that

$$E(\hat{m}_\theta^\ell) \leq M_1 \left[E(\theta) + \omega\left(\frac{1}{\ell}\right) + \frac{1}{\ell} \right]$$

and

$$E(\hat{n}_\theta^\ell) \leq M_2 \left[E(\theta) + \omega\left(\frac{1}{\ell}\right) + \frac{1}{\ell} \right].$$

From (4.2) and (4.5) we get

$$u(x_0, y_0, z_0) \leq E \int_0^\theta e^{-\beta s} U(C_s^\ell) ds + E[e^{-\beta\theta} \Phi(x_\theta^\ell, y_\theta^\ell, z_\theta)] + \frac{1}{\ell^2},$$

where $x_\theta^\ell, y_\theta^\ell$ are given by (1.3) with control (C^ℓ, M^ℓ, N^ℓ) . Using Dynkin's formula, we have

$$\begin{aligned} u(x_0, y_0, z_0) & \leq E \int_0^\theta e^{-\beta s} U(C_s^\ell) ds + u(x_0, y_0, z_0) \\ & \quad + E \int_0^\theta e^{-\beta s} [-\beta \Phi(x_s^\ell, y_s^\ell, z_0) + rx_s^\ell p_{z_0} + z_0 y_s^\ell q_{z_0} - C_s^\ell p_{z_0} \\ & \quad + \mathcal{L}\Phi(x_s^\ell, y_s^\ell, z_0)] ds + E \int_0^\theta e^{-\beta s} [-(1+\lambda)p_{z_0} + q_{z_0}] dM_s^\ell \\ & \quad + E \int_0^\theta e^{-\beta s} [(1-\mu)p_{z_0} - q_{z_0}] dN_s^\ell + \frac{1}{\ell^2}. \end{aligned}$$

Since M_t and N_t are nondecreasing processes, using (4.4), we get

$$\begin{aligned} 0 & \leq E \int_0^\theta e^{-\beta s} U(C_s^\ell) ds + E \int_0^\theta [rp_{z_0}(x_s^\ell - x_0) + z_0 q_{z_0}(y_s^\ell - y_0)] ds \\ & \quad + E \int_0^\theta e^{-\beta s} [-\beta u(x_0, y_0, z_0) + rp_{z_0} x_0 \\ & \quad + z_0 q_{z_0} y_0 - p_{z_0} C_s^\ell + \mathcal{L}\Phi(x_s^\ell, y_s^\ell, z_0)] ds + \frac{1}{\ell^2}. \end{aligned}$$

Let

$$A(\theta) = E \int_0^\theta [rp_{z_0}(x_s^\ell - x_0) + z_0 q_{z_0}(y_s^\ell - y_0)] ds$$

and

$$B(\theta) = E \int_0^\theta e^{-\beta s} [-\beta u(x_0, y_0, z_0) + rx_0 p_{z_0} + z_0 y_0 q_{z_0} - p_{z_0} C_s^\ell + \mathcal{L}\Phi(x_s^\ell, y_s^\ell, z_0)] ds.$$

Then

$$A(\theta) = E \int_0^\theta (rp_{z_0}[(e^{rs} - 1)x_0 - (1 + \lambda)e^{rs}m_s^\ell + (1 - \mu)e^{rs}n_s^\ell] \\ + z_0q_{z_0}[(\exp(z_0s) - 1)y_0 + (\exp(z_0s))\hat{m}_s^\ell - (\exp(z_0s))\hat{n}_s^\ell]) ds.$$

Since $E \int_0^\theta e^{hs}k_s^\ell ds \leq (1/\ell)e^{h/\ell}E(k_\theta^\ell) \leq (K/\ell)e^{h/\ell}[E(\theta) + \omega(1/\ell) + 1/\ell]$, where h is r or z_0 and k_s^ℓ is m_s^ℓ , \hat{m}_s^ℓ , n_s^ℓ , or \hat{n}_s^ℓ , we have

$$(4.19) \quad \lim_{\ell \rightarrow \infty} \frac{1}{E(\theta)} E \int_0^\theta e^{hs}k_s^\ell ds = 0.$$

Therefore $\lim_{\ell \rightarrow \infty} A(\theta)/E(\theta) = 0$.

Relations (4.7), (4.12), and $\beta > r$ give

$$(4.20) \quad \int_0^\theta e^{-\beta s} C_s^\ell ds \leq x_0 + \frac{(1 - \mu)[2x_0 + (1 + \lambda)y_0]}{c}.$$

On the other hand,

$$\begin{aligned} \mathcal{L}\Phi(x_s^\ell, y_s^\ell, z_0) &= \sum_{z' \neq z} q_{z'z} [\Phi(x_s^\ell, y_s^\ell, z') - \Phi(x_s^\ell, y_s^\ell, z_0)] \\ &= \sum_{z' \neq z} q_{z'z} [u(x_0, y_0, z') + p_{z'}(x_s^\ell - x_0) + q_{z'}(y_s^\ell - y_0) \\ &\quad - u(x_0, y_0, z_0) - p_{z_0}(x_s^\ell - x_0) - q_{z_0}(y_s^\ell - y_0)]. \end{aligned}$$

Using that Z is a finite set and (4.19), we get

$$(4.21) \quad \lim_{\ell \rightarrow \infty} \frac{E \int_0^\theta e^{-\beta s} \mathcal{L}\Phi(x_s^\ell, y_s^\ell, z_0) ds}{E(\theta)} = \mathcal{L}u(x_0, y_0, z_0).$$

Finally, from (4.19)–(4.21) we conclude that

$$\beta u(x_0, y_0, z_0) \leq rx_0p_{z_0} + z_0y_0q_{z_0} + \mathcal{L}u(x_0, y_0, z_0) + F(p_{z_0}).$$

This last conclusion follows along the lines of the analogous argument in the proof of Theorem 3.1. To complete the proof, we need to remove the bound on C_t , which can be done again as in Theorem 3.1.

We finally show that u is a supersolution of (4.1) in Ω . To this end, fix $(x_0, y_0, z_0) \in \Omega \times Z$ and consider $(p_{z_0}, q_{z_0}) \in D_{(x,y)}^- u(x_0, y_0, z_0)$. Then there exists a smooth function $\psi: \mathbb{R} \times \mathbb{R} \times Z \rightarrow \mathbb{R}$ such that $u - \psi$ has a strict minimum at (x_0, y_0, z_0) , $u(x_0, y_0, z_0) = \psi(x_0, y_0, z_0)$ and $p_{z_0} = \psi_x(x_0, y_0, z_0)$, $q_{z_0} = \psi_y(x_0, y_0, z_0)$. Then

$$(4.22) \quad \psi(x_0, y_0, z_0) \geq \sup_A E \left[\int_0^\theta e^{-\beta s} U(C_s) ds + e^{-\beta\theta} \psi(x_\theta, y_\theta, z_\theta) \right].$$

In particular, if we use a control (C, M, N) such that $C_t = 0$, for all $t \geq 0$, $M_0 = M$, $N_0 = N$ and $M_t = N_t = 0$, for all $t > 0$ in (4.22), we get

$$\psi(x_0, y_0, z_0) \geq \psi(x_0 - (1 + \lambda)M + (1 - \mu)N, y_0 + M - N, z_0).$$

This yields

$$(4.23) \quad \min [(1 + \lambda)\psi_x(x_0, y_0, z_0) - \psi_y(x_0, y_0, z_0), -(1 - \mu)\psi_x(x_0, y_0, z_0) \\ + \psi_y(x_0, y_0, z_0)] \geq 0.$$

Now if we use a constant control $(C_0, 0, 0)$ in (4.22), we obtain

$$\psi(x_0, y_0, z_0) \geq E \left[\int_0^\theta e^{-\beta s} U(C_s) ds + e^{-\beta \theta} \psi(x_\theta, y_\theta, z_\theta) \right],$$

where $\theta = (1/\ell) \wedge \inf \{\tau: x_\tau^0 = 0\}$, where $\ell > 0$ and x_τ^0 is the corresponding trajectory. We proceed as in Theorem 3.1 and we obtain

$$(4.24) \quad \beta u(x_0, y_0, z_0) \geq rx_0 p_{z_0} + z_0 y_0 q_{z_0} + F(p_{z_0}) + \mathcal{L}u(x_0, y_0, z_0).$$

Combining (4.23) and (4.24), we get

$$\begin{aligned} \min [(1+\lambda)p_{z_0} - q_{z_0}, -(1-\mu)p_{z_0} - q_{z_0}, \beta u - rx_0 p_{z_0} - z_0 y_0 q_{z_0} \\ - F(p_{z_0}) - \mathcal{L}u(x_0, y_0, z_0)] \geq 0. \end{aligned} \quad \square$$

THEOREM 4.2. *The variational inequality (4.1) has a unique constrained viscosity solution in the class of bounded uniformly continuous functions.*

Proof. We are going to show that if v and u are respectively a supersolution in Ω and a subsolution on $\bar{\Omega}$ of (4.1) then $v \geq u$ on $\bar{\Omega}$. To end this, we follow the strategy of Ishii [9]. Let $\phi: \bar{\Omega} \rightarrow \Re$ be defined by $\phi(x, y) = C_1 x + C_2 y + k$, where C_1, C_2, k are positive constants satisfying

$$(1-\mu)C_1 < C_2 < (1+\lambda)C_1$$

and

$$\beta k > rC_1 + KC_2 + F(C_1).$$

Let $X = (x, y) \in \bar{\Omega}$, $P = (p, q) \in \Re \times \Re$ and $H: \bar{\Omega} \times Z \times \Re \times \Re^2 \rightarrow \Re$ given by

$$H(X, z, v, P) = \min [(1+\lambda)p - q, -(1-\mu)p + q, \beta v - rxp - z y q - F(p) - \mathcal{L}v].$$

An easy calculation shows that there exists a positive constant M such that

$$(4.25) \quad H(X, z, \phi, \nabla \phi) \geq M > 0, \quad \forall X \in \bar{\Omega} \setminus \{0, 0\}, z \in Z.$$

Let $\theta \in (0, 1)$ and define $v_\theta = \theta v + (1-\theta)\phi$ on $\bar{\Omega} \times Z$. The functions v_θ are bounded and uniformly continuous. Moreover, since the map $(v, P) \rightarrow H(X, z, v, P)$ is concave, ϕ satisfies (4.25) and v is a supersolution in Ω , we have that

$$(4.26) \quad \begin{aligned} H(X, z, v_\theta, \nabla v_\theta) &\geq \theta H(X, z, v, \nabla v) + (1-\theta)H(X, z, \phi, \nabla \phi) \\ &\geq M(1-\theta) > 0, \quad \forall (X, z) \in \Omega \times Z \end{aligned}$$

holds in the viscosity sense. Therefore v_θ is a supersolution of $H(X, z, v_\theta, \nabla v_\theta) = M(1-\theta)$ in Ω . We now need the following lemma.

LEMMA 4.1. *Let $w, v: \bar{\Omega} \times Z \rightarrow \Re$ be uniformly continuous and nondecreasing with respect to x . If w is a subsolution of $H(X, z, w, \nabla w) = 0$ on $\bar{\Omega}$ and v is a supersolution of $H(X, z, v, \nabla v) = c$ in Ω for some $c > 0$, v is bounded from below and w is bounded, then $v \geq w$ on $\bar{\Omega}$.*

Proof. Since the proof is similar to the one of Theorem 3.2, we only show the main steps. We assume that

$$(4.27) \quad \max_{z \in Z} \sup_{X \in \bar{\Omega}} [w(X, z) - v(X, z)] > 0.$$

This implies that for sufficiently small $\theta > 0$

$$(4.28) \quad \max_{z \in Z} \sup_{X \in \bar{\Omega}} [w(X, z) - v(X, z) - \theta |X|^2] > 0.$$

We can find points $z_0 \in Z$ and $\bar{X} \in \bar{\Omega}$ such that

$$(4.29) \quad w(\bar{X}, z_0) - v(\bar{X}, z_0) - \theta|\bar{X}|^2 = \max_{z \in Z} \sup_{X \in \bar{\Omega}} [w(X, z) - v(X, z) - \theta|X|^2].$$

Next, we consider the function $\psi: \bar{\Omega} \times \bar{\Omega} \rightarrow \mathbb{R}$ with

$$\psi(X, Y) = w(X, z_0) - v(Y, z_0) - \left| \frac{Y - X}{\varepsilon} - 4(1, 1) \right|^2 - \theta|X|^2$$

for $\varepsilon > 0$ and we look at its maximum denoted by (X_0, Y_0) . Working as in Theorem 3.2 we can show that $Y_0 \in \Omega$. Moreover, from Remark 3.1 we have that

$$(4.30) \quad \lim_{\theta \downarrow 0} \lim_{\varepsilon \downarrow 0} \theta|X_0|^2 = 0.$$

We now consider the functions

$$\begin{aligned} \phi(Y) &= w(X_0) - \left| \frac{Y - X_0}{\varepsilon} - 4(1, 1) \right|^2 - \theta|X_0|^2, \\ \bar{\phi}(X) &= v(Y_0) + \left| \frac{Y_0 - X}{\varepsilon} - 4(1, 1) \right|^2 + \theta|X|^2. \end{aligned}$$

Since $w - \bar{\phi}$ has a maximum at X_0 and $v - \phi$ has a minimum at Y_0 , from Lemma 3.1 we have

$$H(X_0, z_0, w(X_0, z_0), P_\varepsilon + 2\theta X_0) \leq 0$$

and

$$H(Y_0, z_0, v(Y_0, z_0), P_\varepsilon) \geq c,$$

where

$$P_\varepsilon = -\frac{2}{\varepsilon} \left(\frac{Y_0 - X_0}{\varepsilon} - 4(1, 1) \right).$$

Combining the above inequalities yields

$$(4.31) \quad H(X_0, z_0, w(X_0, z_0), P_\varepsilon + 2\theta X_0) - H(Y_0, z_0, v(Y_0, z_0), P_\varepsilon) \leq -c.$$

Let $X_0 = (x_0, y_0)$, $Y_0 = (\bar{x}_0, \bar{y}_0)$ and $P_\varepsilon = (p_\varepsilon, q_\varepsilon)$. Using the form of H , (4.31) becomes

$$\begin{aligned} (4.32) \quad & \min [(1 + \lambda)(p_\varepsilon + 2\theta x_0) - (q_\varepsilon + 2\theta y_0), -(1 - \mu)(p_\varepsilon + 2\theta x_0) + (q_\varepsilon + 2\theta y_0), \\ & \beta w - r x_0(p_\varepsilon + 2\theta x_0) - z_0 y_0(q_\varepsilon + 2\theta y_0) - F(p_\varepsilon + 2\theta x_0) - \mathcal{L}w(X_0, z_0)] \\ & - \min [(1 + \lambda)p_\varepsilon - q_\varepsilon, -(1 - \mu)p_\varepsilon + q_\varepsilon, \beta v - r \bar{x}_0 p_\varepsilon - z_0 \bar{y}_0 q_\varepsilon \\ & - F(p_\varepsilon) - \mathcal{L}v(Y_0, z_0)] \leq -c. \end{aligned}$$

We now look at the following cases.

Case (i). $H(X_0, z_0, w(X_0, z_0), P_\varepsilon + 2\theta X_0) = (1 + \lambda)(p_\varepsilon + 2\theta x_0) - (q_\varepsilon + 2\theta y_0)$. Then (4.32) yields

$$(1 + \lambda)2\theta x_0 - 2\theta y_0 \leq -c.$$

Using (4.30), we get a contradiction.

Case (ii). $H(X_0, z_0, x(X_0, z_0), P_\varepsilon + 2\theta X_0) = -(1 - \mu)(p_\varepsilon + 2\theta x_0) + (q_\varepsilon + 2\theta y_0)$.
In this case, (4.32) yields

$$2\theta[-(1 - \mu)x_0 + y_0] \leq -c,$$

which contradicts (4.30).

Case (iii).

$$\begin{aligned} H(X_0, z_0, w(X_0, z_0), P_\varepsilon + 2\theta X_0) &= \beta w - rx_0(p_\varepsilon + 2\theta x_0) - z_0 y_0(q_\varepsilon + 2\theta y_0) \\ &\quad - F(p_\varepsilon + 2\theta x_0) - \mathcal{L}w(X_0, z_0). \end{aligned}$$

Then (4.32) yields

$$\begin{aligned} \beta[w(X_0, z_0) - v(Y_0, z_0)] + c &\leq r(x_0 - \bar{x}_0)p_\varepsilon + z_0(y_0 - \bar{y}_0)q_\varepsilon + F(p_\varepsilon + 2\theta x_0) \\ &\quad - F(p_\varepsilon) + \mathcal{L}w(X_0, z_0) - \mathcal{L}v(Y_0, z_0). \end{aligned}$$

Working similarly as in the proof of Theorem 3.2, we get

$$\beta[w(X_0, z_0) - v(Y_0, z_0)] + c \leq \theta |X_0|^2 + 2K\ell[\omega_v(\ell\varepsilon) + \omega_v(k\varepsilon)]^{1/2} + \omega_v(k\varepsilon) + \omega_v(\ell\varepsilon).$$

Again working as in the proof of Theorem 3.2, sending first $\varepsilon \rightarrow 0$, then $\theta \rightarrow 0$, and using (4.30), we contradict (4.27). \square

Acknowledgment. This work is part of the author's Ph.D. dissertation under the direction of Professor W. H. Fleming, whom I thank for his suggestions and advice.

ESTIMATION OF UNKNOWN VARIABLE PARAMETERS IN MOVING BOUNDARY PROBLEMS*

K. A. MURPHY†

Abstract. The problem of estimating unknown variable parameters appearing in moving boundary problems is considered; these are specifically nonlinear diffusion equations defined on a moving spatial domain. A spline-based approximation method that results in a sequence of computationally tractable approximate parameter estimation problems has been developed. A convergence result is proved for a certain class of these moving boundary problems. The paper is concluded with a set of representative numerical examples.

Key words. parameter estimation, moving boundary problems, spline approximation

AMS(MOS) subject classifications. 65, 69

1. Introduction. Moving boundary problems model phenomena in diverse areas. Many examples can be found in the papers collected in [7], [10], [12], and [29] (this represents just a sample). We consider explicit one-dimensional moving boundary problems; this type consists of a parabolic partial differential equation defined on a moving domain (of one spatial dimension), coupled to an ordinary differential equation describing the movement of the boundary. Within this type of moving boundary problem, we consider fairly general model equations. The coefficients we propose to estimate can be functions of time, space, or the state variables. We do not require a priori parametrizations of nonconstant parameters.

Moving boundary problems present interesting theoretical questions, as can be seen from surveying the many papers and books devoted to theoretical aspects (again, we give just a small sample of the available literature: [7], [12]–[14], [29]). Similarly, much attention has been paid to the development of numerical algorithms for the forward problem: Given fixed parameters, find a numerical approximation to the solution of the moving boundary problem (see, for example, [1], [11], [20], [22]).

Our concern here is the development of computational and theoretical ideas for the solution of the parameter estimation problem: Given observations of a process that we assume can be modelled by a moving boundary problem, we would like to estimate unknown variable parameters within the model equations. For the Stefan problem, specifically, several methods (see, e.g., [15], [17]) have been proposed for parameter estimation and control problems (both are often referred to as “inverse Stefan problems”); for a survey, see [16] and the references therein. Here, we develop both a theoretical framework and a corresponding computational algorithm, applicable to a general type of model equation (we note that the Stefan problem is not included in this theoretical framework; however, our numerical algorithm has been successfully applied to a test Stefan problem).

Our approach to the parameter estimation problem is similar in spirit to that of [2]–[6]. For a given set of model equations containing unknown parameters, we pose the problem as one of minimizing a least squares fit-to-data. As the evaluation of the

† Department of Mathematics, University of North Carolina, Chapel Hill, North Carolina 27599.

objective function requires solution of an infinite-dimensional problem (in that the states are the solution of the coupled partial and ordinary differential equations, and the parameters are, in general, functions), we replace the original problem with a sequence of approximating problems. It is then necessary to prove that the parameters we estimate with the computationally tractable, finite-dimensional approximate problems converge in some sense to best-fit parameters for the original model of interest.

This paper is structured as follows. We describe our model equations in § 2, defining there the class of problems to which our theoretical results apply. In § 3 we discuss several motivating example problems. These model equations arise from various biological and engineering applications. Three of our example problems belong to the class for which we have demonstrated both theoretical and numerical results; for two examples, we present only numerical results (although we do have some preliminary theoretical results for the Stefan problem; this is in preparation).

In § 4 we restate our equations in variational form (see, e.g., [2], [6]), and formulate our approximations. We precisely state all of our hypotheses, both on solutions of the original model equations as well as on our approximations. Our main convergence results are then stated in § 5 (with the proofs presented in the Appendix).

We turn to numerical considerations in §§ 6 and 7. The numerical implementation is described in § 6, and the results of numerical test examples are presented in § 7.

We use the following notation throughout the paper: $|\cdot|$ denotes absolute value, $|\cdot|_\infty$ designates the $L^\infty(\Omega)$ norm (where the domain Ω should be clear from the context), and $\langle \cdot, \cdot \rangle$, $\|\cdot\|$ represent the inner product and norm in $L^2(0, 1)$.

2. The parameter estimation problem. We consider general model equations of the following form:

$$\begin{aligned}
 (2.1) \quad & \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left(D \frac{\partial u}{\partial x} + Vu \right) + \rho(u) + f(t, x), \quad 0 < x < s(t), \quad 0 < t \leq T; \\
 & \alpha_{11} \left(D \frac{\partial u}{\partial x} + V_1 u \right) \Big|_{x=0} - \alpha_{12} u(t, 0) = g(t); \\
 & \alpha_{21} \left(D \frac{\partial u}{\partial x} + V_1 u \right) \Big|_{x=s(t)} + \alpha_{22} u(t, s(t)) = h(t), \quad 0 < t \leq T; \\
 & u(0, x) = u_0(x), \quad 0 \leq x \leq s_0; \\
 & \frac{ds}{dt} = \mathcal{F}(s(t), u(t, \cdot); \gamma), \quad 0 \leq t \leq T; \\
 & s(0) = s_0.
 \end{aligned}$$

Parameter spaces will be defined more precisely below; generally, the diffusion term is assumed to be a function of both t and x . The convective term V is assumed to have two components: $V \equiv V_1(t, x) + V_2(\dot{s})$ (this is motivated by one of the applications examples to be discussed in the next section). We allow the boundary terms α_{ij} to be time dependent (in fact, we let α_{22} depend on \dot{s} in one special case), satisfying $\alpha_{ij} \geq 0$ for i and $j = 1, 2$; we require that α_{i1} ($i = 1, 2$) is either identically zero or nonzero for all $t \in [0, T]$, and that $\alpha_{i1}^2 + \alpha_{i2}^2 \neq 0$. The functional \mathcal{F} , describing the dynamics of the

moving boundary, will, in general, depend on the states of the system (s and u), as well as an additional parameter(s) designated by γ ; this parameter might be a function of time, location, and/or the states. We classify moving boundary problems according to \mathcal{F} ; we discuss this in more detail below.

There are many papers in the literature that address the existence and regularity of solutions of moving boundary problems, primarily those of Stefan type (see, e.g., [13], [14], [29]); however, there is as yet no general theory that can be applied to a class of problems. Our interest here is in the parameter estimation problem and, in particular, the question of convergence of our approximation scheme. For a given model equation, we assume that a weak solution exists, and that by appropriately restricting the parameter sets, the solution will possess sufficient smoothness for our convergence theory (this is precisely stated in § 4). We prove that weak solutions are unique, thereby ensuring that our least squares fit-to-data functional is well defined.

Suppose that we have data corresponding to measurements of u and/or s . The data could represent various quantities, depending on the experiment, but we assume that they correspond to the following type of observations:

$$\hat{u}_i \sim \int_0^{s(t_i)} u(t_i, x) dx \quad \text{and} \quad \hat{s}_i \sim s(t_i), \text{ (or } \hat{s}_i \sim s(t_i) - s_0), \quad \text{for } i = 1, \dots, m,$$

where (u, s) is a solution of the above model equations. This is the form of data to which our theory, developed in § 5, can be directly applied. Another likely form of measurement is $u(t_i, 0)$ or $u(t_i, s(t_i))$, (or, perhaps less natural, we might have a set of observations of u distributed throughout the spatial domain, i.e., $u(t_i, x_j)$). Given data of this form (i.e., discrete spatial measurements) we would need a stronger convergence statement than that obtained in § 5 to make our theory complete. We do include some numerical test examples using such forms of data, and observe that our method is still successful. This suggests that our methods may be useful for a broader set of circumstances than that covered by our theory.

In addition to the data, we assume that f and some subset of the remaining parameters are known. The method we discuss in this paper can be used to estimate any of D , V_1 , V_2 , ρ , α_{ij} , g , h , γ , u_0 , and s_0 . Clearly, in practice, we could not hope to simultaneously estimate all of the parameters listed from one set of data; for the purpose of discussion, however, and to show the full capabilities of the method, we proceed as though all parameters are unknown. We expect the data to be noisy and, moreover, the model equations cannot be considered exact. Therefore, we pose the estimation problem as one of minimizing a least squares fit-to-data criterion.

The inverse problem suffers, as do all inverse problems, from certain theoretical and numerical difficulties. Of particular worry is the lack of uniqueness of solutions and the lack of continuous dependence of the parameters on the data. Such issues, while of obvious import, are not the focus of the investigations reported here. They are discussed in [9] and [18], for example. As described in [2], the use of compactness constraints on the admissible parameter sets can mitigate these difficulties (both theoretical and numerical). By imposing compactness assumptions on our parameter sets, we are able to prove a theorem regarding convergence of our approximations, as well as ensuring that the “method stability” defined in [2] holds.

It will be convenient to have the model equations defined on a fixed spatial domain, so we make the change of variables (see, e.g., [10, p. 187]) $y = x/(s(t))$, and define the new state $U(t, y) = u(t, x(y))$, the forcing function $F(t, y) = f(t, x(y))$, and the parameters $\mathcal{D}(t, y) = D(t, x(y))$, $\mathcal{V}_1(t, y) = V_1(t, x(y))$, $\mathcal{V}_2(\dot{s}) = V_2(\dot{s})$ (no change of variable is required; however, we keep our notation consistent), $U_0(y) = u_0(x(y))$,

$\Gamma(t, y, s, U) = \gamma(t, x(y), s, u(t, x(y)))$, and $\tilde{\mathcal{F}}(s, U; \Gamma) = \mathcal{F}(s, u; \gamma)$, thereby obtaining

$$\frac{\partial U}{\partial t} = \frac{1}{s^2} \frac{\partial}{\partial y} \left(\mathcal{D} \frac{\partial U}{\partial y} \right) + \frac{1}{s} \frac{\partial}{\partial y} (\mathcal{V}_1 U) + \frac{1}{s} \mathcal{V}_2 \frac{\partial U}{\partial y} + \frac{\dot{s}}{s} y \frac{\partial U}{\partial y} + \rho(U) + F(t, y), \quad 0 < y < 1,$$

$$0 < t \leq T;$$

$$\begin{aligned} & \alpha_{11} \left(\frac{\mathcal{D}}{s} \frac{\partial U}{\partial y} + \mathcal{V}_1 U \right) \Big|_{y=0} - \alpha_{12} U(t, 0) = g(t); \\ (2.2) \quad & \alpha_{21} \left(\frac{\mathcal{D}}{s} \frac{\partial U}{\partial y} + \mathcal{V}_1 U \right) \Big|_{y=1} + \alpha_{22} U(t, 1) = h(t), \quad 0 < t \leq T; \\ & U(0, y) = U_0(y), \quad 0 \leq y \leq 1; \\ & \frac{ds}{dt} = \tilde{\mathcal{F}}(s, U; \Gamma), \quad 0 \leq t \leq T; \\ & s(0) = s_0. \end{aligned}$$

We defer the discussion of the compactness assumptions required for the parameter sets to § 4; there we define the set \mathcal{Q}_c , a compact subset of the underlying space \mathcal{X}_q . Let $q = (\mathcal{D}, \mathcal{V}_1, \mathcal{V}_2, \rho, \alpha_{11}, \alpha_{12}, \alpha_{21}, \alpha_{22}, g, h, \Gamma, V_0, s_0)$ designate the vector of all parameters. Let $\Omega \equiv [0, T] \times [0, 1]$ and, given any space \mathbb{X} , let $(\mathbb{X})^m$ represent the product of m copies of \mathbb{X} . While the specific form of the functional $\tilde{\mathcal{F}}: \mathbb{R} \times L^\infty(0, 1) \times \mathcal{G} \rightarrow \mathbb{R}$ and the definition of the set \mathcal{G} are problem dependent, we always assume that \mathcal{G} is a subset of some normed space \mathcal{X}_γ (we consider three examples in § 3). Given the positive constants K_s and \bar{u} , we define the space \mathcal{X}_q as

$$\mathcal{X}_q \equiv (C(\Omega))^2 \times C[-K_s, K_s] \times C[0, \bar{u}] \times (C[0, T])^6 \times \mathcal{X}_\gamma \times C(0, 1) \times \mathbb{R}.$$

We then write $\mathcal{Q} = \mathcal{D} \times \mathcal{B}_1 \times \mathcal{B}_2 \times \mathcal{P} \times \mathbb{I}_{11} \times \mathbb{I}_{12} \times \mathbb{I}_{21} \times \mathbb{I}_{22} \times \mathcal{G} \times \mathcal{S} \times \mathcal{G} \times \mathcal{I}_v \times \mathcal{I}_s$, where we assume that $\mathcal{Q} \subset \mathcal{X}_q$ is a bounded subset of \mathcal{X}_q . Given the positive constants D_L , ρ^{Lip} , and $\mathcal{V}_2^{\text{Lip}}$, we further assume that

$$\begin{aligned} \mathcal{D} & \subset \{\mathcal{D} \in C(\Omega) \mid \mathcal{D}(t, y) \geq D_L\}, \\ \mathcal{B}_2 & \subset \{\mathcal{V}_2 \in C[-K_s, K_s] \mid |\mathcal{V}_2(\theta_1) - \mathcal{V}_2(\theta_2)| \leq \mathcal{V}_2^{\text{Lip}} |\theta_1 - \theta_2|\}, \\ \mathcal{P} & \subset \{\rho \in C[0, \bar{u}] \mid |\rho(\theta_1) - \rho(\theta_2)| \leq \rho^{\text{Lip}} |\theta_1 - \theta_2|\}, \\ \mathbb{I}_{ij} & \subset \{\alpha \in C[0, T] \mid \alpha(t) \geq 0\} \quad \text{for each } i, j = 1, 2. \end{aligned}$$

We make the following general assumptions about $\tilde{\mathcal{F}}$:

(H \mathcal{F}) $\tilde{\mathcal{F}}: \mathbb{R} \times L^\infty(0, 1) \times \mathcal{G} \rightarrow \mathbb{R}$ is continuous in all arguments, and for each

$\Gamma \in \mathcal{G}$, $\tilde{\mathcal{F}}$ satisfies

$$|\tilde{\mathcal{F}}(s, U_1; \Gamma) - \tilde{\mathcal{F}}(s, U_2; \Gamma)| \leq \lambda(|s|, \Gamma) |U_1 - U_2|_\infty,$$

$$|\tilde{\mathcal{F}}(s_1, U; \Gamma) - \tilde{\mathcal{F}}(s_2, U; \Gamma)| \leq \mu(|U|_\infty, \Gamma) |s_1 - s_2|,$$

where λ and μ are continuous in both arguments.

Assumption (H \mathcal{F}) is the means by which we classify moving boundary problems. It is for such model equations that we prove a convergence theorem for approximations of the parameter estimation problem. In the next section, we give several examples that fall into this class. We note that this class excludes some well-known moving boundary problems, such as the Stefan problem and the oxygen diffusion problem

(see, e.g., [10], [21]); our numerical scheme, however, has nevertheless proved successful for these problems (see § 7).

3. Motivating examples. In this section we describe three models arising from a variety of applications areas, each of which can be seen to belong to the class of moving boundary problems defined above. We also describe two models that do not fit into our theoretical framework, but for which we have had success with preliminary numerical test examples.

3.1. Biofilm on activated carbon particles. In [8] a model is derived to describe the process by which contaminants diffuse through a liquid and bind to activated carbon particles. As described in [8] (we refer the interested reader to this paper and the references cited there for a full discussion), a biofilm layer, containing bacteria, forms in a thin layer around the carbon particles. The contaminant must therefore diffuse through this layer to attach to the carbon. The contaminant is a source of nutrient for the bacteria, and as the bacteria utilize the contaminant, the biofilm layer grows. Simultaneously, the biofilm layer may decrease in thickness due to shear loss. The full model developed in [8] consists of a coupled system of partial and ordinary differential equations describing the dynamics in the surrounding bulk liquid, the biofilm layer, and in the carbon particles.

We have simplified this model, in a way that extracts the moving boundary dynamics; this simplified version has been briefly discussed in [24]. Essentially, we uncouple the biofilm dynamics from the rest of the problem by assuming that certain boundary parameters are known functions of time. Here in our notation is the simplified model, where $u(t, x)$ represents the concentration of contaminant in the biofilm layer, $s(t)$ represents the width of the layer with $x = 0$ corresponding to the carbon-biofilm interface, and $x = s$ corresponds to the biofilm-liquid interface:

$$\begin{aligned}
 (3.1) \quad & \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left(D \frac{\partial u}{\partial x} \right) - \rho(u), \quad t \in (0, T], \quad x \in (0, s(t)); \\
 & \left(D \frac{\partial u}{\partial x} \right) \Big|_{x=0} = g(t); \\
 & \left(D \frac{\partial u}{\partial x} \right) \Big|_{x=s(t)} + \alpha u(t, s(t)) = h(t), \quad t \in (0, T]; \\
 & u(0, x) = u_0(x), \quad x \in [0, s_0]; \\
 & \frac{ds}{dt} = \int_0^{s(t)} (\gamma_1(u(t, x)) - \gamma_2(t)) \, dx, \quad t \in [0, T]; \\
 & s(0) = s_0.
 \end{aligned}$$

In [8] the nonlinear terms ρ and γ_1 have been parametrized, with $\gamma_1(u) = Yku/(K + u)$ and $\rho = (1/Y)\gamma_1$. We can estimate these terms without any such a priori assumptions, but we do assume that they exhibit similar behavior; for example, we assume that there exist constants K_γ and γ_1^{Lip} such that γ_1 satisfies $|\gamma_1| \leq K_\gamma$ and $|\gamma_1(u_1) - \gamma_1(u_2)| \leq \gamma_1^{\text{Lip}}|u_1 - u_2|$. We also assume that $\gamma_2 \in C[0, T]$. Making the change of variables to fixed domain, we find that $\tilde{\mathcal{F}}(s, U; \Gamma) \equiv s \int_0^1 (\gamma_1(U(t, y)) - \gamma_2(t)) \, dy$. It is easily verified that $\tilde{\mathcal{F}}$ satisfies assumption (H $\tilde{\mathcal{F}}$) of the previous section, with

$$\lambda(|s|, \Gamma) = |s| \gamma_1^{\text{Lip}} \quad \text{and} \quad \mu(|U|_\infty, \Gamma) = \left(K_\gamma + \sup_{t \in [0, T]} |\gamma_2| \right).$$

For this example, given the constant \bar{u} , we let $\mathcal{X}_\gamma = C[0, \bar{u}] \times C[0, T]$ and suppose that \mathcal{G} is a bounded subset of \mathcal{X}_γ satisfying $\mathcal{G} \subset \{(\gamma_1, \gamma_2) \in \mathcal{X}_\gamma \mid |\gamma_1| \leq K_\gamma \text{ and } |\gamma_1(u_1) - \gamma_1(u_2)| \leq \gamma_1^{\text{Lip}}|u_1 - u_2|\}$.

3.2. Acrosomal elongation. We consider a model derived by Perelson and Coutsias [26], specifically (15)–(20). For a detailed description of the model, we refer the interested reader to [26]; we will describe it briefly here. In the process of fertilizing an egg, the sperm must extend a long tube called the acrosomal process. It is still not completely understood how this structure is created on the timescale necessary. Perelson and Coutsias present a moving boundary model that describes one possible mechanism. By analyzing their model, as they have presented it, they conclude the proposed mechanism does not adequately model the observed phenomenon.

Nevertheless, we feel that this moving boundary model can provide a beginning for study, with parameter estimation techniques providing a valuable tool. We let $u(t, x)$ represent the concentration of unbound monomer and $s(t)$ represent the length of the acrosomal process at any time t . The model equations are

$$\begin{aligned} \frac{\partial u}{\partial t} &= D \frac{\partial^2 u}{\partial x^2} - s \frac{\partial u}{\partial x}, & t \in (0, T], \quad x \in (0, s(t)); \\ u(t, 0) &= u_0; \\ (3.2) \quad D \frac{\partial u}{\partial x}(t, s(t)) &+ k_1 \alpha(t) u(t, s(t)) = k_{-1} \alpha(t), & t \in (0, T]; \\ u(0, x) &= u_0, & x \in [0, s_0]; \\ \frac{ds}{dt} &= \gamma_1 u(t, s(t)) - \gamma_2, & t \in [0, T]; \\ s(0) &= s_0. \end{aligned}$$

While our notation is different, we have essentially reproduced the equations of Perelson and Coutsias, except that we allow our boundary coefficient α to be time varying. While Perelson and Coutsias acknowledge that this parameter should realistically be nonconstant, it is unknown whether this change is enough to make the model realistic.

The parameters γ_1 and γ_2 are assumed to be constants. After the change of variables, we obtain $\tilde{\mathcal{F}}(s, U; \Gamma) \equiv \gamma_1 U(t, 1) - \gamma_2$, and it is trivial to verify that assumption (H $\tilde{\mathcal{F}}$) holds with $\lambda(|s|, \Gamma) = |\gamma_1|$, and $\mu(|U|_\infty, \Gamma) \equiv 0$. For this example, \mathcal{G} is assumed to be a bounded subset of $\mathcal{X}_\gamma = \mathbb{R}^2$.

3.3. Glassy polymers. This model problem comes from [13]. The equations derived there describe the morphological change caused by the presence of a solvent in a polymer, when that solvent exists at a sufficiently high concentration. For the details of the model derivation, we refer the interested reader to [13] and the references therein. In brief, the solvent diffuses through the polymer, which initially has a glassy quality. When the solvent reaches a sufficiently high concentration, the polymer instantly assumes a gel-like quality.

This model of Fasano and Ricci has been discussed in some detail in the context of parameter estimation in [25]. There, the original model equations of [13] are changed slightly (we retain the diffusion constant explicitly in the model equations and shift time by an arbitrarily small amount to obtain nonzero initial conditions). In our notation, u represents the concentration of the solvent in the glassy region, and s

represents the location of discontinuity between the two regions. Our model equations are

$$\begin{aligned}
 (3.3) \quad & \frac{\partial u}{\partial t} = D \frac{\partial^2 u}{\partial x^2}, \quad t \in (0, T], \quad x \in (0, s(t)); \\
 & u(t, 0) = 1; \\
 & D \frac{\partial u}{\partial x}(t, s(t)) + \dot{s}(t)u(t, s(t)) = -\dot{s}(t)\sigma(t), \quad t \in (0, T]; \\
 & u(0, x) = u_0(x), \quad x \in [0, s_0]; \\
 & \frac{ds}{dt} = \gamma(u(t, s(t))), \quad t \in [0, T]; \\
 & s(0) = s_0.
 \end{aligned}$$

We direct the reader's attention to the boundary condition at $x = s(t)$; this is nonlinear and requires a redefinition of the set \mathbb{U}_{12} and \mathfrak{S} , since the parameters α_{12} and h depend on \dot{s} . In fact, this nonlinearity makes the convergence arguments of § 5 delicate, requiring more than just the redefinition of parameter sets; we pursue this in § 5.

We obtain $\tilde{\mathcal{F}}(s, U; \Gamma) \equiv \gamma(U(t, 1))$ after the change of variables; if we assume that γ satisfies $\gamma \in C[0, \bar{u}]$ and $|\gamma(u_1) - \gamma(u_2)| \leq \gamma^{\text{Lip}}|u_1 - u_2|$, then it is easy to show that $\tilde{\mathcal{F}}$ satisfies $(H\tilde{\mathcal{F}})$, with $\lambda(|s|, \Gamma) = \gamma^{\text{Lip}}$ and $\mu(|U|_\infty, \Gamma) \equiv 0$. Given the constant \bar{u} , we define $\mathcal{X}_\gamma = C[0, \bar{u}]$; our admissible set \mathcal{G} for this example is assumed to be a bounded subset of \mathcal{X}_γ , additionally satisfying

$$\mathcal{G} \subset \{\gamma \in \mathcal{X}_\gamma \mid \gamma(0) = 0, \gamma \text{ is nondecreasing, and } |\gamma(u_1) - \gamma(u_2)| \leq \gamma^{\text{Lip}}|u_1 - u_2|\}.$$

The assumptions we impose on γ are slightly weaker than those in [13].

3.A.1. Stefan problem. The Stefan problem (see, e.g., [10]) was originally formulated as a model for the melting of ice, although it is now used to model many phenomena (see, e.g., [10], [12], [29]). We consider the simplest one-dimensional one-phase model here. Let u represent the temperature of the water in the liquid phase and s represent the location of the ice-water interface. The units are such that the temperature in the ice phase is 0. The model equations can be written as

$$\begin{aligned}
 (3.4) \quad & \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left(D \frac{\partial u}{\partial x} \right), \quad t \in (0, T], \quad x \in (0, s(t)); \\
 & \left. \frac{\partial u}{\partial x} \right|_{x=0} = g(t); \\
 & u(t, s(t)) = 0, \quad t \in (0, T]; \\
 & u(0, x) = u_0(x), \quad x \in [0, s_0]; \\
 & \frac{ds}{dt} = -\gamma D \frac{\partial u}{\partial x}(t, s(t)), \quad t \in [0, T]; \\
 & s(0) = s_0.
 \end{aligned}$$

Due to the pointwise evaluation of the flux, this $\tilde{\mathcal{F}}$ does not satisfy $(H\tilde{\mathcal{F}})$.

Our numerical method is essentially a Galerkin method, based on a weak formulation of the partial differential model equations. As can be seen in the proof of uniqueness (§ 4), for example, a natural measure for the solution $u(t, \cdot)$ of a parabolic equation

in weak form is given by the $H^1(0, 1)$ norm; thus the Stefan condition, involving $u_x(t, s(t))$, is too strong. After the change of variables to fixed domain, such a condition must be measured in the $W^{1,\infty}(0, 1)$ or $H^2(0, 1)$ topology (for almost every t). The majority of numerical methods for the Stefan problem, especially those accompanied by rigorous error analysis, are based on weaker formulations of the model equations—the enthalpy or variational formulations, for example. A survey of such methods can be found in [10].

3.A.2. Oxygen diffusion. We consider the second stage of the model presented in [21] for the diffusion of oxygen through tissue. As a precursor to radiation treatment for cancer, cells are saturated with oxygen. In the first stage of this procedure, oxygen is pumped into the cancerous tissue. In the second stage, the tissue is sealed and the treatment is applied. During the procedure, the oxygen diffuses, and the point of furthest penetration into the tissue recedes (hence the moving boundary). The procedure and the development of the simple model equations, which we present below, are discussed in [21]. Let u represent the concentration of oxygen in the tissue (after sealing) and s represent the furthestmost point of penetration. Our equations are

$$\begin{aligned}
 (3.5) \quad & \frac{\partial u}{\partial t} = D \frac{\partial^2 u}{\partial x^2} - \rho, \quad t \in (0, T], \quad x \in (0, s(t)); \\
 & \left. \frac{\partial u}{\partial x} \right|_{x=0} = 0; \\
 & u(t, s(t)) = 0, \quad t \in (0, T]; \\
 & u(0, x) = u_0(x), \quad x \in [0, s_0]; \\
 & \frac{\partial u}{\partial x}(t, s(t)) = 0, \quad t \in [0, T]; \\
 & s(0) = s_0.
 \end{aligned}$$

Here it is assumed that D and ρ are constants. Following Liapis, Lipscomb, and Crosser [21], we take the special form for the initial conditions

$$u_0(x) = \frac{\rho}{2D} (x - s_0)^2, \quad s_0 = \sqrt{\frac{2Du_i}{\rho}},$$

where, for convenience, we take $u_i = 1$. This particular example differs from all others presented here in that it is an “implicit” rather than an “explicit” moving boundary problem; i.e., rather than an equation for s or \dot{s} , we are given another condition on the state u at $x = s$. We have converted this (see [10, p. 166]) to the explicit condition

$$\frac{ds}{dt} = -\frac{D^2}{\rho} \frac{\partial^3 u}{\partial x^3}(t, s(t)).$$

Clearly, we require more smoothness on the state u than previously. Here, again, this form of $\tilde{\mathcal{F}}$ does not fit into our framework.
